The ansatz (77) [or (96)] is not suitable for generalizing beyond $q>1$. This is one of our reasons for starting with (7). The general formulation of linear pairs[16] can thus be applied specifically[1,4] to (quasi)periodic fields for constructing higher q solutions. Details can be found in those papers. Here we just indicate where iterations can be implemented.

For $q=2$, one starts with *two* functions

$$g_1=\Pi_{j=1}^{n}\left(\frac{a_j+e^{-k_j(R+it)}}{\overline{a}_j+e^{k_j(R+it)}}\right),$$
$$g_2=\Pi_{j=1}^{n}\left(\frac{b_j+e^{-k_j(\overline{R}+it)}}{\overline{b}_j+e^{k_j(\overline{R}+it)}}\right), \tag{99}$$

where, with real c,

$$R=(r^2-c^2-i2cr\cos\theta)^{1/2},$$
$$\overline{R}=(r^2-c^2+i2cr\cos\theta)^{1/2},$$

implying an *imaginary* translation (ic) parallel to the z axis. For the solutions to be regular the parameters (c,a_j,b_j) have to satisfy constraints.[1,4] More generally one starts with q functions g for charge q. Iterations can be implemented for these functions. But one must then verify carefully the regularity constraints afterwards. That, presumably, would be difficult.

C. Gauge group SU(N)

Self-dual, (quasi)periodic solutions for arbitrary N were presented in Ref. 5. Again we only indicate, in the simplest case for $N>2$, namely, SU(3), how the g functions (which can be iterated) appear in the class of solutions obtained. The details of the generalized ansatz[5] will not be reproduced here.

For SU(3) we just note that, instead of one function e^{ζ}, as in (5), (6), and (7), one needs two,

$$e^{-b_1}=d_1P^{-1}(r^2(\partial_r^2+\partial_t^2)(g\overline{g}))^{-1}((p_3-p_2)(g\overline{g})^{p_1}+\text{cyclic}),$$
$$e^{-b_2}=d_2P^{-1}(r^2(\partial_r^2+\partial_t^2)(g\overline{g}))^{-1}((p_3-p_2)(g\overline{g})^{2-p_1}+\text{cyclic}), \tag{100}$$

where d_1,d_2 are constants (given in Ref. 5),

$$P=(p_2-p_1)(p_3-p_1)(p_3-p_2)$$

and (p_1,p_2,p_3) are rational numbers satisfying

$$p_1<p_2<p_3,\quad p_1+p_2+p_3=3.$$

To avoid certain problems concerning branch points (explained in Ref. 5) we set

$$g=\left(\prod_{j=1}^{n}\left(\frac{a_j+e^{-k_j(r+it)}}{\overline{a}_j+e^{k_j(r+it)}}\right)\right)^{Q}$$

such that Qp_i $(i=1,2,3)$ are integers.

Iterations can be introduced separately for the factors of g or for g as a whole. One can also use g of (76) as a starting point.

For higher values of N a set of $N-1$ independent parameters p enters into the solutions.[5] For $N>2$ a single magnetic winding number is no longer sufficient for characterizing the asymptotic configurations in R^3. This is one reason for an increasing number of parameters.

D. Use of hyperbolic coordinates

The uses of the coordinate transformation

$$(r+it)=\tanh \tfrac{1}{2}(\rho+i\tau)$$

in the construction of instantons or the so-called hyperbolic monopoles were studied in a series of papers. (Apart from Ref. 17 they are all summarized in Ref. 18—a review article.) The metric is

$$\begin{aligned} ds^2 &= dt^2+dr^2+r^2(d\theta^2+(\sin\theta)^2 d\phi^2) \\ &= (\cosh\rho+\cos\tau)^{-2}(d\tau^2+d\rho^2+(\sinh\rho)^2(d\theta^2+(\sin\theta)^2 d\phi^2)). \end{aligned} \tag{101}$$

In Refs. 17 and 18 τ-static solutions [depending on (r,t) through ρ] were considered. In Refs. 2 and 4 we indicated the passage from the t-periodic to the τ-periodic solutions. One can replace in (6) the subscripts (r,t) by (ρ,τ), respectively, and set

$$e^{\zeta}=\frac{\sinh\rho}{(1-g\bar{g})}((\partial_\rho^2+\partial_\tau^2)(g\bar{g}))^{1/2} \tag{102}$$

and, for example,

$$g=\prod_{j=1}^{n}\left(\frac{a_j+e^{-k_j(\rho+i\tau)}}{\bar{a}_j+e^{k_j(\rho+i\tau)}}\right). \tag{103}$$

The action is evaluated in Ref. 2. To avoid irregularities at

$$\rho=0, \quad \tau=\pm\pi$$

the k's in (103) have to be integers. [The role of the conformal factor in (101) is crucial concerning this point.[18]] This is a restriction. But the formalism is more general in the following sense. A simple rescaling

$$\rho=\lambda r', \quad \tau=\lambda t', \quad A_\tau=\lambda^{-1}A_{\tau'}, \quad A_\rho=\lambda^{-1}A_{\tau'}$$

gives back the previous formalism, in the limit $\lambda\to 0$, with

$$ds'^2=4\lambda^{-2}\,ds^2=dt'^2+dr'^2+r'^2(d\theta^2+(\sin\theta)^2 d\phi^2).$$

The restriction on the k's can be lifted after the scaling limit is taken.

But let us consider the situation without any such rescaling. As it stands, g in (103) has already a quite special type of (r,t) dependence via (ρ,τ). After several iterations one can have a very complex (r,t) dependence, say for the action density. But the situation can still be studied relatively simply using (ρ,τ).

The coordinate transformation introduced maps the (r,t) half-plane on the strip

$$0\leqslant\rho<\infty, \quad -\pi\leqslant\tau\leqslant\pi.$$

More generally one can consider our solutions in the context of three noncompact and one compact dimension, all with the same signature. If T is the period associated with the last one then the condition concerning integer values, say n_j of k_j, is to be generalized to $k_j=(2\pi n_j)/T$ assuring single-valued solutions. One can also consider the possibility of embedding our solutions into such subspaces of higher dimensional spaces.

VII. REMARKS

Chaos in gauge theories is a popular topic. Many authors have studied various aspects of this domain. A convenient reference is,[19] a book devoted to this field with a long bibliography. Among more recent papers one may note Ref. 20, again citing many sources. Compared to most of the above-mentioned studies, ours is more modest in one respect but more ambitious in another.

We have shown (the Appendix) that our iterative map, though simple, is a chaotic one. But its implementation up to any given order does not automatically render our field configurations fully chaotic. The precise way in which the implemented iterations influence the time evolution of the gauge field has been pointed out in Sec. I. When the configuration is strictly periodic it comes back, by definition, to its initial state after each period T. But the sensitive time dependence discussed in Sec. I implies that any quantity (such as the action density at a given point or within a small volume) can fluctuate, within a single period, more and more with higher number of iterations and in a more complex fashion. It can wander far and waywardly before coming back. When the configuration is quasiperiodic it does not return repeatedly to an initial state (Sec. III), though arbitrarily close approaches are possible. How should one precisely characterize such fields with increasingly sensitive time dependence generated by iterations? We have not adequately explored the implications, the consequences of the two most striking features of our solutions, namely sensitive time dependence and jumps in rotation numbers. We have exhibited their existence. A more thorough exploration can probably indicate a satisfactory characterization. At this stage, after a ''large'' number of iterations, ''at the edge of chaos'' might be a convenient description (though precaution is necessary due to broad, fashionable uses of this terminology). Sufficiently accurate numerical studies can help in understanding. But that is beyond the competence of the present author.

Having noted the limitations, one may now note the positive qualities of our approach. In order to be able to apply techniques developed for one-dimensional dynamical systems authors frequently consider gauge fields depending, effectively, on one coordinate only. Thus, for example, one studies time evolutions of fields homogeneous in space (Refs. 21, 20, and a number of papers cited in Ref. 19). In Ref. 22 the static problem is reduced to the one-dimensional Duffing equation and then time dependence is introduced as a perturbation. It is known that, considered in full generality, Yang–Mills fields are nonintegrable (Ref. 19 and sources cited therein). The fully chaotic aspects are then related to this nonintegrability.

Our approach, one may say, is antithetic to the preceding one. The intriguing features we exhibit via the mapping arise in fully integrable (explicitly solved) self-dual configurations. We start with solutions, found in our previous papers, which have a whole range of remarkable properties, quite apart from those revealed in the present study. They combine topological aspects of standard instantons and monopoles and are characterized by two topological numbers (both integers for periodic solutions). Instead of considering solitonic and chaotic aspects to be entirely incompatible (and leaving it at that) we have tried to explore, using our mapping, how close and with what possible limitations, they can be brought together. This has revealed probably hitherto unsuspected possibilities.

Quark confinement has been studied using approaches as different as that of a dual superconductor and that of random fields (see Chap. 11 of Ref. 19). Our spinors (except for one subclass) provide explicit solutions damped exponentially away from the origin. This is not confinement but is worth noting. It should also be noted that this damping *increases* with the temperature (with some typical frequency K, inverse of the period), while confinement is usually supposed to break down at a sufficiently high temperature. Spinors in backgrounds with several incommensurable frequencies should be further explored for a better understanding. Rather than being fully, dully chaotic they might provide a terrain favorable to genesis of rewardingly complex patterns and structures.

Periodic instantons have been considered from the beginning[23–25] to be of particular interest in the study of gauge fields at finite temperatures. Our more general solutions (as noted in Sec. I) show very clearly that strict periodicity involves extremely fine tuning of a set of parameters (the k's). Irrationals being dense on the real line, infinitesimal shifts in one or more k's can make a periodic solution quasiperiodic and vice versa. Since such solutions exist it would be quite artificial to consider periodic solutions exclusively. Numerically, as is well known, it is a delicate task to distinguish between commensurable and incommensurable cases. But since their mathematical properties are strikingly different, can one understand better the significance of the role of quasiperiodicity in the context of finite temperature? In a realistic situation the temperature cannot be absolutely steady. A suitably chosen interval covering small fluctuations of a roughly steady temperature would cover a continuum of frequencies. Slowly varying temperatures would again need different considerations. Though such aspects might be worth considering, we have no simple adequate answer concerning the role of quasiperiodicity in the context of finite temperatures. We have studied quasiperiodicity for the light they shed on topological aspects and the possibilities formally engendered by the presence of several incommensurable periods in the background.

We have obtained the propagators for (quasi)periodic backgrounds in particularly convenient forms, where one can implement an arbitrary number of our iterations. One can next try to compute the fluctuation determinants. Then one can start to carry over the consequences of the chaotic features of our mapping into quantum domains through semiclassical developments. It would be interesting to see in what fashion and to what extent such features can thus seep through.

Our spinor solutions are limited to zero mass and to the gauge group SU(2). But they, along with the propagator for spinor fields (Sec. V), can provide a starting point, exploiting the full range of our self-dual solutions, for the study of quarks in a finite temperature gluon background.

In the context of ADHMN[26–29] and Nahm's formalism[30] for calorons (periodic instantons) recently solutions have been obtained with nontrivial holonomy and Polyakov loop.[31–34] The explicit solution has zero total magnetic charge. A limiting static form with magnetic charge has also been obtained.[35] We have exhibited the role of nonzero magnetic charge in periodic instantons concerning index theorems and linear modes with implied consequences of the ''magnetic defect'' for the moduli space.

ACKNOWLEDGMENT

I thank Pierre Collet for discussions concerning iterative maps.

APPENDIX: ITERATIVE MAP

An iterative map of the unit disk is presented and some of its properties are studied. In Sec. I we indicate how this mapping is implemented in the construction of (quasi)periodic gauge fields and with what consequences. See also the remarks in Sec. VII.

1. The map

Let Z_p be a point in the unit disk, centered at the origin, in the complex plane. Consider the map, with $0<|a_p|<1$,

$$Z_{p+1}=\frac{a_p+Z_p}{\bar{a}_p+Z_p^{-1}}=Z_p\frac{a_p+Z_p}{1+\bar{a}_pZ_p}. \tag{A1}$$

For $0\leqslant|Z_p|\leqslant 1$ one obtains $0\leqslant|Z_{p+1}|\leqslant 1$.

The inverse power in the denominator (Z_p^{-1}) leads to properties quit different from those of the standard Möbius-type maps. The most evident difference is that here zero is a fixed point. But there are other profound differences. To take just one example, the Schwarzian derivative (identically zero for Möbius maps) makes an interesting contribution in the action density near the spatial origin (Sec. II). One may set

$$a_p=a_{p-1}=\cdots=a_0=a.$$

A more general possibility is

$$a_p = f(a_{p-1}) \tag{A2}$$

with f so chosen as to guarantee $0<|a_p|<1$ for $0<|a_0|<1$. An interesting example of f will be given below. But the explicit form of f will usually be unspecified, leaving room for eventual different convenient choices.

The crucial role of a suitable (r,t) parametrization is emphasized in Sec. I. For the choice (2), ψ_0 being the phase of Z_0,

$$Z_0 = |Z_0| e^{-i\psi_0} = e^{-k(r+it)} \quad (k>0, r\geqslant 0, -\infty<t<\infty). \tag{A3}$$

For the gauge fields we are finally interested in the space–time dependence. *But in the Appendix (r,t) should be considered as convenient notations defining*

$$\ln|Z_0| = -kr, \quad \psi_0 = kt. \tag{A4}$$

If (3) is chosen for Z_0, some different notation, say $(\widehat{kr}, \widehat{kt})$, would be more appropriate. We will, however, continue to use in the Appendix (r,t) as in (A4), hoping that no confusion can arise. Moreover some of our comments will refer specifically to (2) or (A3).

Define

$$Z_p = |Z_p| e^{-i\psi_p}, \quad a_p = |a_p| e^{-i\alpha_p}, \quad \chi_p = \psi_p - \alpha_p .$$

Then from (A1),

$$|Z_{p+1}| e^{-i(\psi_{p+1} - 2\alpha_p)} = |Z_p| e^{-i\chi_p} \frac{|a_p| + |Z_p| e^{-i\chi_p}}{1 + |a_p||Z_p| e^{-i\chi_p}}. \tag{A5}$$

2. Moduli

One has

$$|Z_{p+1}|^2 = |Z_p|^2 \frac{|a_p|^2 + |Z_p|^2 + 2|a_p||Z_p|\cos\chi_p}{1 + |a_p|^2|Z_p|^2 + 2|a_p||Z_p|\cos\chi_p} \equiv |Z_p|^2 |\tilde{Z}_p|^2, \tag{A6}$$

where

$$(1 - |\tilde{Z}_p|^2) = \frac{(1-|a_p|^2)(1-|Z_p|^2)}{1 + |a_p|^2|Z_p|^2 + 2|a_p||Z_p|\cos\chi_p} \geqslant 0. \tag{A7}$$

Thus for

$$|Z_p| = 0, 1, <1, \quad |Z_{p+1}| = 0, 1, <|Z_p|,$$

respectively.

Hence not only is zero a fixed point, but the circumference of the disk ($|Z_0|=1$ or $r=0$) is stable as a whole leading to circle maps to be studied in detail soon. For the inverse map, both the roots of the quadratic

$$Z_P^2 + (a_p - \bar{a}_p Z_{p+1}) Z_p = Z_{p+1} \tag{A8}$$

must correspond to $0<|Z_p|<1$ for $0<|Z_{p+1}|<1$. (For $|Z_p|\geqslant 1, |\tilde{Z}_p|\geqslant 1$, and hence $|Z_{p+1}|\geqslant 1$.) These roots coincide for

$$Z_{p+1} = -\left(\frac{a_p}{\bar{a}_p}\right)\left(\frac{1-\sqrt{1-|a_p|^2}}{1+\sqrt{1-|a_p|^2}}\right) \tag{A9}$$

to

$$Z_p=-\left(\frac{a_p}{1+\sqrt{1-|a_p|^2}}\right). \tag{A10}$$

Thus starting with $|Z_0|<1$ (or $r>0$), $|Z|$ moves away under iterations toward the attractive fixed point ($Z=0$). Generically two values of Z_p (which may coincide) are mapped on a Z_{p+1} with a lesser modulus. But instead of a stepwise migration toward the fixed point zero, the latter might be reached abruptly due to the following feature.

3. Zeros

One has $Z_{p+1}=0$ for

$$Z_p=0$$

and for

$$Z_p=-a_p.$$

The second possibility is worth further study. As will be seen later, the more general condition $|Z_p|=|a_p|$ provides crucial domains of discontinuities of rotation numbers associated to the phases. Moreover

$$Z_p=Z_{p-1}\frac{a_{p-1}+Z_{p-1}}{1+\bar{a}_{p-1}Z_{p-1}}=-a_p$$

furnishes an interesting context for exploring the consequences of different choices for f in $a_p=f(a_{p-1})$. One has

$$\left(\frac{Z_{p-1}}{\sqrt{a_p}}\right)^2+2\lambda_p\left(\frac{Z_{p-1}}{\sqrt{a_p}}\right)+1=0, \tag{A11}$$

where

$$\lambda_p=(2\sqrt{a_p})^{-1}(a_{p-1}+a_p\bar{a}_{p-1}).$$

Hence

$$Z_{p-1}=\sqrt{a_p}(-\lambda_p\pm\sqrt{\lambda_p^2-1}).$$

The two roots coincide to $Z_{p-1}=\mp\sqrt{a_p}$ for $\lambda_p=\pm 1$ or

$$\sqrt{a_p}=\pm(\bar{a}_{p-1})^{-1}(1-\sqrt{1-|a_{p-1}|^2}). \tag{A12}$$

Denoting, with real μ_p,

$$a_p=(\tanh\mu_p)e^{-i\alpha_p}, \tag{A13}$$

(A12) gives

$$\tanh\mu_p=(\tanh\tfrac{1}{2}\mu_{p-1})^2,\quad \alpha_p=2\alpha_{p-1}.$$

This is an example of the choice of f assuring special properties (here double zeros). For comparison note that choosing, for all p,

$$a_p=\overline{a}_p=a \quad (0<a<1)$$
$$\lambda_p=\tfrac{1}{2}\sqrt{a}(1+a)=\cos\zeta \tag{A14}$$

say, ζ being real. Now (A11) gives

$$Z_{p-1}=-\sqrt{a}e^{\mp i\zeta}. \tag{A15}$$

4. Circle map on the circumference (chaotic aspects)

For $|Z_0|=1$, (i.e., $r=0$), for all p,

$$|Z_p|=1.$$

For the phases ψ_p, using the notations of (A5), one has the circle map

$$e^{-i\psi_{p+1}}=\frac{a_p+e^{-i\psi_p}}{\overline{a}_p+e^{i\psi_p}}=e^{-i2\alpha_p}\frac{|a_p|+e^{-i\chi_p}}{|a_p|+e^{i\chi_p}}. \tag{A16}$$

Hence

$$\frac{d\psi_{p+1}}{d\psi_p}=2\left(\frac{1+|a_p|\cos\chi_p}{1+|a_p|^2+2|a_p|\cos\chi_p}\right)=1+\frac{(1-|a_p|^2)}{(1-|a_p|)^2+4|a_p|(\cos(\chi_p/2))^2}>1. \tag{A17}$$

Thus ψ_{p+1} is *monotonic* (increasing) in ψ_p and

$$e^{-i(\psi_{p+1}-2\alpha_p)}=1 \quad \text{for } \chi_p=0,\pi,2\pi$$
$$=-1 \quad \text{for } \cos\chi_p=-|a_p|, \quad \sin\chi_p=\pm\sqrt{1-|a_p|^2}. \tag{A18}$$

Hence as

$$\psi_p\to\psi_p+2\pi, \quad \psi_{p+1}\to\psi_{p+1}+4\pi. \tag{A19}$$

[This result also follows from an approach analogous to the one leading to (A52) for $|Z_0|>|a_0|$, since here $|Z_p|=1>|a_p|$. But the foregoing instructive one follows the rotations in more detail.] The result (A19) is fundamental in computing the actions of the gauge fields after iterations (Sec. II). But here we concentrate on another aspect.

It is well-known (Ref. 9, p. 50 and also p. 18) that the apparently very simple circle map

$$\theta_{p+1}=2\theta_p, \quad \frac{d\theta_{p+1}}{d\theta_p}=2 \tag{A20}$$

is *chaotic*. It satisfies all the requisite conditions, the most important one being a strong sensitivity to initial conditions (here in the form of expansiveness with index $\ln 2$). Our example (A16) will be seen to satisfy the same conditions, but in a more subtle fashion. In fact, our case contains (A20) as a particularly simple limit ($a_p=0$). ''On average'' ψ_{p+1} turns twice as fast as ψ_p. But the rate is less than twice in one domain and just sufficiently more than twice in the complementary one to compensate.

For

$$\cos\chi_p=\pm 1, \quad v_p\equiv\frac{d\psi_{p+1}}{d\psi_p}=\frac{2}{1\pm|a_p|} \tag{A21}$$

and for

$$\cos\chi_p = -|a_p|, \quad v_p = 2.$$

The complementary domains are

$$1 \geqslant \cos\chi_p > -|a_p|, \quad (v_p < 2),$$

$$-1 \leqslant \cos\chi_p < -|a_p| \quad (v_p > 2).$$

As $|a_p| \to 1$ the first domain increases, but so does v_p in the other to compensate (becoming very high near $\cos\chi_p = -1$).

After p iterations (with $\psi_0 = kt$)

$$\frac{d\psi_p}{d\psi_0} = \frac{1}{k}\frac{d\psi_p}{dt} = \prod_{j=0}^{p-1} v_j = \prod_{j=0}^{p-1} \left(\frac{2(1+|a_j|\cos\chi_j)}{1+|a_j|^2+2|a_j|\cos\chi_j} \right) \tag{A22}$$

and

$$\frac{d^2\psi_p}{d\psi_0^2} = \frac{1}{k^2}\frac{d^2\psi_p}{dt^2} = \frac{d\psi_p}{d\psi_0}\left(\sum_{j=0}^{p-1} V_j\left(\frac{d\psi_j}{d\psi_0} \right) \right), \tag{A23}$$

where

$$V_j = \frac{(1-|a_j|^2)|a_j|\sin\chi_j}{(1+|a_j|\cos\chi_j)(1+|a_j|^2+2|a_j|\cos\chi_j)}.$$

In (A22) each factor $v_j > 1$. But due to the factor $\sin\chi_j$ in V_j the terms in (A23) can change sign.

The sensitive dependence on initial data should be evident from the preceding analysis. But let us formulate it more precisely in terms of a *characteristic index*. For (A20) the index is evidently $\ln 2$.[9] This is recovered in our case in the limit of each $a_j = 0$. For (A16) it depends on the sequence $(a_0, a_1, \ldots)$. *But it has a positive lower bound.* In (A22) replacing each v_j by its upper and lower bound, respectively,

$$\prod_{j=0}^{N-1} \left(\frac{2}{1-|a_j|} \right) \geqslant \frac{d\psi_N}{d\psi_0} \geqslant \prod_{j=0}^{N-1} \left(\frac{2}{1+|a_j|} \right) > 1. \tag{A24}$$

Setting for simplicity all $|a_j| = |a|$, the characteristic index λ satisfies

$$\ln\left(\frac{2}{1-|a|} \right) \geqslant \lambda \geqslant \ln\left(\frac{2}{1+|a|} \right) > 0. \tag{A25}$$

More generally $(2/1 \pm |a|)$ should be considered as the geometric means of the corresponding products in (A24).

For a map to be chaotic it must have a dense set of periodic points.[9] For (A20) the periodic points are given by[9]

$$\theta_n = 2^n\theta = \theta + 2k\pi \quad \text{or} \quad \theta = \frac{2k\pi}{2^n-1}, \tag{A26}$$

where k is an integer and

$$0 \leqslant k \leqslant 2^n - 1.$$

This is the situation for all a's zero in (A16). But for (A16) one cannot obtain as simply a general formula. One can, however, proceed stepwise to show how the periodic points remain dense but are shifted as the parameters a increase from zero. For simplicity consider all a_p's equal and real. Then

$$e^{-i\psi_{p+1}}=\frac{a+e^{-i\psi_p}}{a+e^{i\psi_p}}$$

gives

$$\psi_{p+1}=2\psi_p-2(a\sin\psi_p-\tfrac{1}{2}a^2\sin 2\psi_p+\cdots). \tag{A27}$$

Thus

$$\psi_n=2^n\psi_0-a\left(\sum_{l=1}^{n}2^l\sin 2^{n-l}\psi_0\right)+O(a^2). \tag{A28}$$

Hence up to $O(a)$ the periodic points are given by

$$\psi=\frac{2k\pi}{2^n-1}+aS_1, \tag{A29}$$

where

$$S_1=\left(\frac{2^n}{2^n-1}\right)\left(\sum_{l=1}^{n}2^{-n+l}\sin 2^{n-l}\left(\frac{2k\pi}{2^n-1}\right)\right)<\left(\frac{2^n}{2^n-1}\right)\left(\sum_{l=1}^{n}2^{-n+l}\right)=2.$$

Thus the dense set (A26) is shifted as shown above. One may now iterate to higher powers of a and find an analogous situation. We cannot produce a general solution for (A16) in a closed form, but the smooth continuity with (A26) is clear enough.

A third criterion for chaoticity[9] is topological transitivity. This is satisfied by (A16) as obviously as by (A20). Our preceding analysis of rotations makes it evident that their effects cannot remain confined in one particular segment of a circle.

Thus all three criteria for being chaotic are satisfied by our map.

5. Series expansion near the circumference (small *r*)

For the gauge field configurations principally considered in this paper the time dependence is exponentially damped as r increases. So the (quasi)periodic time evolution is best studied for small r. For our mapping this corresponds to a domain near the circumference at a distance $(1-e^{-kr})$.

Let ψ_p *continue* to denote the value of the phase for $r=0$ and let

$$Z_p=e^{-i\psi_p}(1+C_p^{(1)}r+C_p^{(2)}r^2+\cdots), \tag{A30}$$

where the C's can be *complex* since the r dependence of the total phase is included in them. The expansion (A30) is general, but particularly useful for small r due to evident reasons. (In this subsection only, ψ_p denotes not the total phase but a part. The notation $\psi_p^{(0)}$ would have been more consistent. But this simplification, leaving room for other indices to come, should not cause confusion.)

Supressing the index p temporarily and using the holomorphy condition

$$(\partial_r+i\partial_t)Z=0 \tag{A31}$$

one obtains

$$C^{(1)}+2C^{(2)}r+3C^{(3)}r^2+\cdots=-\frac{d\psi}{dt}(1+C^{(1)}r+C^{(2)}r^2+\cdots)-i\left(\frac{dC^{(1)}}{dt}r+\frac{dC^{(2)}}{dt}r^2+\cdots\right). \tag{A32}$$

Thus

$$C^{(1)}=-\frac{d\psi}{dt}$$

and, for $l>1$,

$$lC^{(l)}=C^{(1)}C^{(l-1)}-i\frac{dC^{(l-1)}}{dt}. \tag{A33}$$

The general solution is

$$C^{(l)}=\frac{e^{i\psi}}{l!}\left(-i\frac{d}{dt}\right)^l(e^{-i\psi}). \tag{A34}$$

This expansion displays precisely how the chaotic properties of the circle map for the phase are carried over through ψ and its derivatives in the coefficients.

The result (A34) is compact and elegant. But separate explicit expressions for the total phase and the amplitude of Z are useful for the gauge fields. We give the first few terms of the r expansion for both. The coefficients $(\psi^{(l)},B_l)$ will now all be real. One obtains, keeping terms up to $O(r^4)$,

$$Z=e^{-i\psi}(1+C_1r+C_2r^2+C_3r^3+C_4r^4)=e^{-i(\psi^{(0)}+\psi^{(2)}r^2+\psi^{(4)}r^4)}(1+B_1r+B_2r^2+B_3r^3+B_4r^4). \tag{A35}$$

The coefficients $\psi^{(1)}$ and $\psi^{(3)}$ turn out to be zero and one obtains, in terms of the C's given before,

$$\begin{aligned}\psi^{(2)}&=\frac{i}{2}(C^{(2)}-\overline{C}^{(2)}),\\ \psi^{(4)}&=\frac{i}{2}\left((C^{(4)}-\overline{C}^{(4)})-\frac{1}{2}((C^{(2)})^2-(\overline{C}^{(2)})^2)\right),\end{aligned} \tag{A36}$$

and

$$\begin{aligned}B_1&=C^{(1)},\\ B_2&=\tfrac{1}{2}(C^{(2)}+\overline{C}^{(2)}),\\ B_3&=\tfrac{1}{2}(C^{(3)}+\overline{C}^{(3)}),\\ B_4&=\tfrac{1}{2}(C^{(4)}+\overline{C}^{(4)})-\tfrac{1}{8}((C^{(2)})^2+(\overline{C}^{(2)})^2).\end{aligned} \tag{A37}$$

One may also note that

$$Z\overline{Z}=1+D_1r+D_2r^2+D_3r^3+D_4r^4+O(r^5), \tag{A38}$$

where

$$D_1=2C^{(1)},$$

$$D_2=2(C^{(1)})^2,$$
$$D_3=\frac{4}{3}(C^{(1)})^3-\frac{1}{3}\frac{d^2}{dt^2}C^{(1)}, \tag{A39}$$
$$D_4=\frac{2}{3}\left((C^{(1)})^4-C^{(1)}\frac{d^2}{dt^2}C^{(1)}\right).$$

Higher order terms can be evaluated stepwise. These results hold, of course, for any p. If the product of several factors $(Z_p Z'_{p'}\cdots)$ is considered, one has the same expansion with

$$C^{(1)}=-\frac{d}{dt}(\psi_p+\psi'_{p'}+\cdots). \tag{A40}$$

Consistency with this constraint is a useful check on the numerical coefficients obtained above. The notation indicates that for each factor the sequence of the parameters a, the periods involved, and also the order of iterations can be different. The results (A39) yield the leading term in the action density near the spatial origin (Sec. II).

6. Annular maps and rotation numbers

We have studied some interesting properties of our map on the circumference of the unit disk and nearby $(r=0,\ r\ll 1)$. One can continue an analogous study away from the edge. But we now concentrate on a different class of remarkable features associated to specific values of r as it increases.

For $|Z|=1$ the iterations affect only the phase giving a circle map. For $|Z|<1$ the amplitude also changes. It diminishes and becomes a function of the phases of the previous steps. The domain of variation of Z (as a function of these phases) becomes an annulus, which can, crucially, become a disk. To emphasize this aspect we use the term ''annular map.'' The rotation numbers to be defined will be associated to the phases. We are fundamentally interested in variations of functions of the phase of Z_0 as the latter moves on a circle of radius e^{-kr}. This provides, most directly through (2), the link with the time evolution of gauge fields.

From (A5) and (A6), with the notations defined there $(\chi_p=\psi_p-\alpha_p,\ldots)$

$$|Z_{p+1}|^2=|Z_p|^2\frac{|a_p|^2+|Z_p|^2+2|a_p||Z_p|\cos\chi_p}{1+|a_p|^2|Z_p|^2+2|a_p||Z_p|\cos\chi_p} \tag{A41}$$

and

$$\psi_{p+1}=\psi_p+\frac{i}{2}(\ln f_1+\ln f_2)+2\alpha_p, \tag{A42}$$

where

$$f_1=\left(\frac{|a_p|+|Z_p|e^{-i\chi_p}}{|a_p|+|Z_p|e^{i\chi_p}}\right),\quad f_2=\left(\frac{1+|a_p||Z_p|e^{i\chi_p}}{1+|a_p||Z_p|e^{-i\chi_p}}\right).$$

In particular, for $p=0$ with $Z_0=e^{-k(r+it)}$,

$$|Z_1|^2=e^{-2kr}\frac{|a_0|^2+e^{-2kr}+2|a_0|e^{-kr}\cos\chi_0}{1+|a_0|^2e^{-2kr}+2|a_0|e^{-kr}\cos\chi_0}. \tag{A43}$$

For fixed r, this can be shown to be a monotonic increasing function of $\cos\chi_0$. One obtains

$$|Z_1|_{\max}=|Z_0|\left(\frac{|a_0|+|Z_0|}{1+|a_0||Z_0|}\right), \tag{A44}$$

$$|Z_1|_{\min}=|Z_0|\left(\frac{|a_0|-|Z_0|}{1-|a_0||Z_0|}\right). \tag{A45}$$

The width of the annulus is

$$W_1=|Z_1|_{\max}-|Z_1|_{\min}.$$

For $|Z_0|>|a_0|$,

$$W_1=2|a_0||Z_0|\left(\frac{1-|Z_0|^2}{1-(|a_0||Z_0|)^2}\right). \tag{A46}$$

For $|Z_0|<|a_0|$,

$$W_1=2|Z_0|^2\left(\frac{1-|a_0|^2}{1-(|a_0||Z_0|)^2}\right). \tag{A47}$$

For $|Z_0|=|a_0|$, *the annulus becomes a disk* with

$$|Z_1|_{\min}=0$$

and

$$W_1=\frac{2|a_0|^2}{1+|a_0|^2}. \tag{A48}$$

As $|Z_1|$ touches zero the phase of Z_1 becomes undefined with crucial consequences. We will study them now.

Our aim is to compare the rates of rotation of ψ_0 and ψ_1 for the following domains of $|Z_0| = e^{-kr}$:

$$|Z_0|>|a_0|, \quad |Z_0|=|a_0|,$$

and

$$|Z_0|<|a_0|.$$

For $|Z_p|=1(>|a_p|)$ we have already seen [(A16)–(A21)] that on the average ψ_{p+1} turns twice as fast as ψ_p. In particular, ψ_1 turns twice as fast as ψ_0. This result will be seen to hold more generally for $|Z_0|>|a_0|$. But discontinuities appear as $|Z_0|$ comes down to $|a_0|$ and crosses over. We will demonstrate this now.

Let us examine (A42) for $p=0$ and in particular the term $\ln f_1$. For $|Z_0|>|a_0|$ the real part of $(|a_0|+|Z_0|e^{-i\chi_0})$ can vanish and change sign. *This feature is absent in* f_2 *since always* $|a_p||Z_p|<1$. So the term $\ln f_1$ has to be treated carefully to keep track of additive contributions as ψ_0 rotates (t increases). It is convenient to proceed as follows. For

$$|Z_0|>|a_0|,$$
$$f_1=e^{-i2\chi_0}\left(\frac{1+\dfrac{|a_0|}{|Z_0|}e^{i\chi_0}}{1+\dfrac{|a_0|}{|Z_0|}e^{-i\chi_0}}\right). \tag{A49}$$

For

$$|Z_0| = |a_0|, \quad f_1 = e^{-i\chi_0}. \tag{A50}$$

For

$$|Z_0| < |a_0|,$$
$$f_1 = \left(\frac{1 + \frac{|Z_0|}{|a_0|} e^{-i\chi_0}}{1 + \frac{|Z_0|}{|a_0|} e^{i\chi_0}} \right). \tag{A51}$$

Hence for the three domains, respectively,

$$\psi_1 = 2\psi_0 + \Lambda_{(+)}, \quad \psi_1 = \tfrac{3}{2}\psi_0 + \Lambda_{(0)}, \quad \psi_1 = \psi_0 + \Lambda_{(-)}, \tag{A52}$$

where one can now safely consider that

$$\Lambda_\delta(\psi_0 + 2\pi) = \Lambda_\delta(\psi_0) \quad (\delta = +,0,-). \tag{A53}$$

Hence for $\psi_0 \to \psi_0 + 2n\pi$ there are no cumulative, additive contributions from Λ_δ giving a supplementary term proportional to n (as does the first term proportional to ψ_0). The discontinuity involved for ψ_1 at $|Z_0| = |a_0|$ is now explicit.

In view of the crucial role of this result we present an alternative approach, closely following the argument for the circle map [(A18)–(A21)] but generalizing it for all $|Z_0| > |a_0|$. (This also generalizes the arguments for chaoticity on the circumference for the interior of the disk.)

It is sufficient to consider one single term (f_1) as follows. Define

$$e^{-i\beta} = \frac{|a_0| + |Z_0| e^{-i\chi_0}}{|a_0| + |Z_0| e^{i\chi_0}} \tag{A54}$$

when

$$\frac{d\beta}{d\psi_0} = \frac{2|Z_0|(|Z_0| + |a_0|\cos\chi_0)}{(|a_0|^2 + |Z_0|^2 + 2|a_0||Z_0|\cos\chi_0)}.$$

Hence for $|Z_0| > |a_0|$ one has strict monotonicity with

$$\frac{d\beta}{d\psi_0} > 0 \tag{A55}$$

but *not* for $|Z_0| < |a_0|$. For the exceptional value $|Z_0| = |a_0|$ one has simply

$$e^{-i\beta} = e^{-i\chi_0}. \tag{A56}$$

For $|Z_0| > |a_0|$ along with strict monotonicity one has

$$e^{-i\beta} = -1 \quad \text{for} \ \cos\chi_0 = -\frac{|a_0|}{|Z_0|}, \sin\chi_0 = \pm\sqrt{1 - \frac{|a_0|^2}{|Z_0|^2}}, \tag{A57}$$

$$e^{-i\beta}=1 \quad \text{for } \cos\chi_0=0,\pi,2\pi.$$

Hence, as for the circle map, ''on the average'' β turns twice as fast as ψ_0. This corresponds to the factor 2 in the first equation of (A52), namely,

$$\psi_1=2\psi_0+\Lambda_{(+)}.$$

Now suppose we consider the Poincaré sections for

$$t_n=t+nT \quad (n=0,1,2,...)$$

with some suitably chosen period *T*. The ''rotation number'' for $\psi_0(=kt)$ is defined in terms of

$$\psi_0^{(n)}=kt_n$$

as

$$\Omega_0=(n^{-1}(\psi_0^{(n)}-\psi_0))_{n\to\infty}=kT. \tag{A58}$$

(We reserve the term ''winding number'' for the magnetic charge q of the gauge fields.) Here, of course, it would have been natural to set

$$T=2\pi k^{-1}$$

or, rescaling, obtain an integer (say, unit) value for Ω_0. But we keep T unspecified here since for the gauge fields there will be the simultaneous presence of different periodic building blocks each with its own period, which may even be mutually incommensurable. (See Sec. III.) Now, similarly defining the rotation number Ω_1 for ψ_1, one obtains from (A52) and (A53)

$$\Omega_1=2\Omega_0 \quad \text{for } e^{-kr}>|a_0|, \quad \Omega_1=\tfrac{3}{2}\Omega_0 \quad \text{for } e^{-kr}=|a_0|, \quad \Omega_1=\Omega_0 \quad \text{for } e^{-kr}<|a_0|. \tag{A59}$$

Hence there is a step discontinuity at $r=-k^{-1}\ln|a_0|$. Let us further examine how this implies *sensitive dependence on small differences in the value of a parameter*. Let $\psi_1^{(\pm)}$ and $\hat{\psi}_1$ denote the values of ψ_1, respectively, for

$$|Z_0|=|a_0|(1\pm\epsilon), \quad |a_0|.$$

Here $\epsilon\ll 1$. From (A42) with $p=0$, up to $O(\epsilon)$, one obtains

$$\psi_1^{(\pm)}=\hat{\psi}_1\pm\epsilon\left(\frac{1}{2}\tan\frac{\chi_0}{2}-\frac{|a_0|^2\sin\chi_0}{1+|a_0|^4+2|a_0|^2\sin\chi_0}\right). \tag{A60}$$

But such a development is valid if not only $\epsilon\ll 1$ but *also* $\epsilon\tan(\chi_0/2)\ll 1$. Even if one starts with a suitably small value of the latter, the constraint will be violated as χ_0 approaches the values $(2N+1)\pi$. Near such values one may proceed as follows. The contribution to $-i2(\psi_1^{(+)}-\psi_1^{(-)})$ from the term $\ln f_1$ in (A42) is

$$\ln\left(\left(\frac{1+e^{i\chi_0}+\epsilon}{1+e^{-i\chi_0}+\epsilon}\right)\left(\frac{1+e^{-i\chi_0}-\epsilon}{1+e^{i\chi_0}-\epsilon}\right)\right)=\ln\left(\frac{\cos(\chi_0/2)-i(\epsilon/2)\sin(\chi_0/2)}{\cos(\chi_0/2)+i(\epsilon/2)\sin(\chi_0/2)}\right). \tag{A61}$$

For $\chi_0=(2N+1)\pi$ this is no longer proportional to ϵ but becomes $\ln(-1)$. The additive contribution at each turn gives a difference $(\psi_1^{(+)}-\psi_1^{(-)})$ consistent with (A59).

So far we have analyzed the effect of the passage $Z_0 \to Z_1$. For the next step, write

$$Z_2 = \left(\frac{a_1 + Z_1}{\overline{a_1} + Z_1^{-1}} \right) = Z_0^{-2} \left(\frac{a_0 + Z_0}{\overline{a_0} + Z_0^{-1}} \right) \left(\frac{\mu_+ + Z_0}{\overline{\mu_+} + Z_0^{-1}} \right) \left(\frac{\mu_- + Z_0}{\overline{\mu_-} + Z_0^{-1}} \right), \tag{A62}$$

where [compare (A11) and the discussion that follows]

$$\mu_\pm = \sqrt{a_1} (\lambda_0 \pm \sqrt{\lambda_0^2 - 1}) \tag{A63}$$

with

$$\lambda_0 = \frac{a_0 + \overline{a_0} a_1}{2 \sqrt{a_1}}.$$

One sees that for studying Ω_2 (the rotation number associated to the phase ψ_2 of Z_2) one should extend the previous considerations to *three* spherical shells

$$|Z_0| = |a_0|, \quad |\mu_+|, \quad |\mu_-|, \tag{A64}$$

where

$$|\mu_+||\mu_-| = |a_1|.$$

One may get special features corresponding to a possible double zero when $|\mu_+|$ and $|\mu_-|$ coincide to $\sqrt{|a_1|}$. The number of possibilities continue to increase with each iteration. Generically the process is systematic, but roots can coincide leading to special features. The cumulative effects of the jumps give more and more elaborate staircaselike patterns (Sec. II).

Considering $(|Z_p|, \psi_p)$ as independent variables one may carry out a similar analysis for the step $Z_p \to Z_{p+1}$ (for $p > 0$). One then obtains formally, like (A52) with the Λ's satisfying the criterion (A53),

$$\begin{aligned} \psi_{p+1} &= 2\psi_p + \Lambda_{(+)}^{(p)}, \\ \psi_{p+1} &= \tfrac{3}{2}\psi_p + \Lambda_{(0)}^{(p)}, \\ \psi_{p+1} &= \psi_p + \Lambda_{(-)}^{(p)}, \end{aligned} \tag{A65}$$

respectively, for

$$|Z_p| > |a_p|, \quad |Z_p| = |a_p|, \quad |Z_p| < |a_p|.$$

But it should be clearly noted that for $p \geqslant 1$ all $|Z_p|$'s are time dependent even for the choice (2) for Z_0. For the choice (3) even $|Z_0|$ is time dependent. The formal steps of the iterations and their consequences in the context of the mapping do not depend on the parametrization of Z_0 (provided it satisfies $Z_0 < 1$). But when the time evolution is studied in the context of the gauge fields much depends evidently on the initial choice.

(Received 2 February 1998; accepted for publication 23 October 1998)

The osp(1,2)-covariant Lagrangian quantization of general gauge theories is formulated which applies also to massive fields. The formalism generalizes the Sp(2)-covariant Batalin–Lavrov–Tyŭtin (BLT) approach and guarantees symplectic invariance of the quantized action. The dependence of the generating functional of Green's functions on the choice of gauge in the massive case disappears in the limit $m \rightarrow 0$. Ward identities related to osp(1,2) symmetry are derived. Massive gauge theories with closed algebra are studied as an example. © *1999 American Institute of Physics.* [S0022-2488(99)01802-2]

I. INTRODUCTION

Recently, a general method for quantizing gauge theories in the Lagrangian formalism has been proposed[1–3] which is based on extended Becchi–Rouet–Stora–Tyutin (BRST) symmetry, i.e., simultaneous invariance under both BRST and antiBRST transformations. It is characterized by a quantum action functional $S = S(\phi^A, \phi^*_{Aa}, \bar{\phi}_A)$ depending on, besides the dynamical fields $\phi^A = (A^i, B^{\alpha_0}, C^{\alpha_0 a_0})$, also on related antifields (or external sources) $\phi^*_{Aa}, \bar{\phi}_A$, where A^i, B^{α_0} and $C^{\alpha_0 a_0}$ are the gauge, the auxiliary and the (anti)ghost fields, respectively, and both a and a_0 indicate members of Sp(2) doublets. To guarantee their (anti)BRST symmetry the action S (and the related gauge fixed extended action $S_{\rm ext}$) is required to satisfy two master equations which are generated by two nilpotent, anticommuting differential operators, $\bar{\Delta}^a$. The method applies to irreducible as well as reducible, complete gauge theories with either open or closed gauge algebra. (The condition of irreducibility requires the generators of the gauge transformations to be linearly independent at the stationary point of the classical action, and the condition of completeness requires the degeneracy of the Hessian of the classical action $S_{\rm cl}(A)$ to be solely due to its gauge invariance.[4,5])

Although this formalism is seemingly manifest Sp(2)-covariant among the solutions of the master equations, there are both Sp(2)-symmetric and Sp(2)-nonsymmetric ones. The symmetric solutions may be singled out by the explicit requirement of invariance under Sp(2) transformations by additional master equations whose generating differential operators $\bar{\Delta}_\alpha$ ($\alpha = 0, +, -$) are related to the generators of the symplectic group Sp(2). The algebra of these operators may be chosen to obey the orthosymplectic (super)algebra osp(1,2). (Actually, its even part is the algebra sl(2) generating the special linear transformations, but due to their isomorphism to the algebra sp(2) we will speak about symplectic transformations.) Moreover, if also massive fields should be considered to circumvent possible infrared singularities occurring in the process of subtracting ultraviolet divergences, without breaking the extended BRST symmetry, then this algebra appears

[a)]Electronic mail: geyer@rz.uni-leipzig.de necessarily. Let us also mention that the osp(1,2) superalgebra occurs in many problems where $N=1$ superconformal symmetry is involved; e.g., in the minimal $N=1$ superconformal models this symmetry appears in the light-cone approach to two-dimensional supergravity.[6] It is also of interest in this respect that topological osp(1,2)/osp(1,2) coset theories can be used to describe the noncritical Ramond–Neveu–Schwarz superstrings.[7]

The goal of the present paper will be to generalize the BLT quantization procedure to another one being osp(1,2)-covariant. For the sake of simplicity we restrict ourselves to the case of irreducible (or zero-stage) complete gauge theories and thereby we follow very closely the exposition of Ref. 1. (The extension to L-stage reducible theories will be dealt with in a succeeding paper.[19]) We also used the condensed notation introduced by DeWitt[8] and conventions adopted in Ref. 1; if not otherwise specified, derivatives with respect to the antifields are the (usual) left ones and that with respect to the fields are right ones. Left derivatives with respect to the fields are labeled by the subscript L, for example, $\delta_L/\delta\phi^A$ denotes the left derivative with respect to the fields ϕ^A.

The paper is organized as follows. In Sec. II we shortly review the standard Sp(2)-covariant approach and point out how it will be generalized to the osp(1,2)-covariant quantization procedure. As a consequence of the enlarged algebra a canonical definition of the ghost number (Faddeev–Popov charge) is obtained. Furthermore, to be able to express this algebra through operator identities and to get nontrivial solutions of the generating equations it is necessary to enlarge the set of antifields. In Sec. III the explicit construction of generating differential operators fulfilling the osp(1,2) algebra is outlined, starting with the approximation of the action S_m at lowest order in $\hbar$ which is assumed to be linear with respect to the antifields. In Sec. IV the gauge dependence of the generating functional of Green's functions is studied and corresponding Ward identities are derived. It is shown that the mass terms destroy gauge independence of the S-matrix. In Sec. V we consider massive theories with closed gauge algebra, thereby extending the solution given in Ref. 1.

II. GENERAL STRUCTURE OF osp(1,2)-COVARIANT QUANTIZATION OF IRREDUCIBLE GAUGE THEORIES

Let us consider a set of gauge (as well as matter) fields A^i with Grassmann parity $\epsilon(A^i)=\epsilon_i$ for which the classical action $S_{\mathrm{cl}}(A)$ is assumed to be invariant under the gauge transformations

$$\delta A^i = R^i_{\alpha_0}\xi^{\alpha_0}, \quad S_{\mathrm{cl},i}R^i_{\alpha_0}=0, \tag{1}$$

where ξ^{α_0} are the parameters of these transformations and $R^i_{\alpha_0}(A)$ are the gauge generators having Grassmann parity $\epsilon(\xi^{\alpha_0})=\epsilon_{\alpha_0}$ and $\epsilon(R^i_{\alpha_0})=\epsilon_i+\epsilon_{\alpha_0}$, respectively; by definition $X_{,j}=\delta X/\delta A^j$. (In the following an additional label 0 is put on the indices α_0 and a_0 to prepare the notation for later generalizations to reducible gauge theories.) We assume the set of generators $R^i_{\alpha_0}$ to be linearly independent and complete. The (open) algebra of generators has the general form[1]

$$R^i_{\alpha_0,j}R^j_{\beta_0}-(-1)^{\epsilon_{\alpha_0}\epsilon_{\beta_0}}R^i_{\beta_0,j}R^j_{\alpha_0}=-R^i_{\gamma_0}F^{\gamma_0}_{\alpha_0\beta_0}-M^{ij}_{\alpha_0\beta_0}S_{\mathrm{cl},j}, \tag{2}$$

where $F^{\gamma_0}_{\alpha_0\beta_0}(A)$, in general, are field-dependent structure functions and $M^{ij}_{\alpha_0\beta_0}(A)$ obeys the graded antisymmetry conditions

$$M^{ij}_{\alpha_0\beta_0}=-(-1)^{\epsilon_i\epsilon_j}M^{ji}_{\alpha_0\beta_0}=-(-1)^{\epsilon_{\alpha_0}\epsilon_{\beta_0}}M^{ij}_{\beta_0\alpha_0}. \tag{3}$$

Theories whose generators satisfy Eqs. (2) and (3) are called general gauge theories. In the case $M^{ij}_{\alpha_0\beta_0}=0$ the algebra is closed.

The total configuration space of fields ϕ^A and their Grassmann parities are

$$\phi^A=(A^i,B^{\alpha_0},C^{\alpha_0 a_0}),\quad \delta(\phi^A)\equiv\epsilon_A=(\epsilon_i,\epsilon_{\alpha_0},\epsilon_{\alpha_0}+1);$$

here, the auxiliary fields B^{α_0} are Sp(2)-scalar whereas the (anti)ghosts $C^{\alpha_0 a_0}$ transform as a Sp(2)-doublet. Moreover, for each field ϕ^A one introduces two sets of antifields, a Sp(2)-doublet and a Sp(2)-singlet (with respect to a):

$$\phi^*_{Aa}=(A^*_{ia},B^*_{\alpha_0 a},C^*_{\alpha_0 a a_0}),\quad \epsilon(\phi^*_{Aa})=\epsilon_A+1,\quad \overline{\phi}_A=(\overline{A}_i,\overline{B}_{\alpha_0},\overline{C}_{\alpha_0 a_0}),\quad \epsilon(\overline{\phi}_A)=\epsilon_A .$$

Raising and lowering of Sp(2)-indices is obtained by the invariant tensor of the group,

$$\epsilon^{ab}=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix},\quad \epsilon^{ac}\epsilon_{cb}=\delta^a_b .$$

Let us point to the fact that in the Sp(2)-approach the internal Sp(2) index a_0 of the third component is a dummy one, i.e., it is not affected by operations being introduced by the present approach.

Let us now shortly review the Sp(2)-covariant quantization scheme. The basic object is the bosonic action $S=S(\phi^A,\phi^*_{Aa},\overline{\phi}_A)$ satisfying the extended quantum master equations (i.e., the generating equations with respect to the extended BRST symmetry)

$$\overline{\Delta}^a\exp\{(i/\hbar)S\}=0,\quad \overline{\Delta}^a=\Delta^a+(i/\hbar)V^a, \tag{4}$$

where the odd (second-order) differential operators $\overline{\Delta}^a$ possess the important properties of nilpotency and (relative) anticommutativity:

$$\{\overline{\Delta}^a,\overline{\Delta}^b\}=0. \tag{5}$$

The solution of (4) is sought as a power series in Planck's constant $\hbar$:

$$S=\sum_{n=0}^{\infty}\hbar^n S_{(n)},$$

with the boundary condition $S|_{\phi^*_a=\overline{\phi}=\hbar=0}=S_{\rm cl}(A)$.

To remove the degeneracy of the action S a gauge has to be introduced with the following properties: First, it should lift the degeneracy in ϕ^A and, second, it should retain Eqs. (4), thereby providing the extended BRST symmetry also for the gauge fixed action denoted by $S_{\rm ext}=S_{\rm ext}(\phi^A,\phi^*_{Aa},\overline{\phi}_A)$. Introducing the gauge-fixing Sp(2)-invariant bosonic functional $F=F(\phi^A)$ the action $S_{\rm ext}$ is defined by

$$\exp\{(i/\hbar)S_{\rm ext}\}=\hat{U}(F)\exp\{(i/\hbar)S\},$$

where the operator $\hat{U}(F)$ has the general form

$$\hat{U}(F)=\exp\{(\hbar/i)\hat{T}(F)\},\quad \hat{T}(F)=\tfrac{1}{2}\epsilon_{ab}\{\overline{\Delta}^b,[\overline{\Delta}^a,F]\}.$$

Here, $\hat{T}(F)$ has been chosen such that, by virtue of (5), it commutes with $\overline{\Delta}^a$,

$$[\overline{\Delta}^a,\hat{T}(F)]=0;$$

hence $S_{\rm ext}$ obeys also Eqs. (4):

$$\overline{\Delta}^a\exp\{(i/\hbar)S_{\rm ext}\}=0.$$

Let us now briefly state the essential modifications of the Sp(2)-formalism to obtain the osp(1,2)-covariant quantization of an irreducible complete theory of massive fields whose action S_m depends on the mass m as a further parameter. First, in addition to the m-extended generalized quantum master equations

$$\overline{\Delta}_m^a \exp\{(i/\hbar)S_m\}=0, \quad \overline{\Delta}_m^a=\Delta^a+(i/\hbar)V_m^a, \tag{6}$$

which ensure (anti)BRST invariance, the action S_m is required to satisfy the generating equation of Sp(2)-invariance, too:

$$\overline{\Delta}_\alpha \exp\{(i/\hbar)S_m\}=0, \quad \overline{\Delta}_\alpha=\Delta_\alpha+(i/\hbar)V_\alpha, \tag{7}$$

where $\overline{\Delta}_m^a$ and $\overline{\Delta}_\alpha$ are odd and even (second-order) differential operators, respectively (for explicit expressions see Sec. III below).

As long as $m\neq 0$ the operators $\overline{\Delta}_m^a$ are neither nilpotent nor do they anticommute among themselves; instead, together with the operators $\overline{\Delta}_\alpha$ they generate a superalgebra isomorphic to osp(1,2) (see Appendix A):

$$[\overline{\Delta}_\alpha,\overline{\Delta}_\beta]=(i/\hbar)\epsilon_{\alpha\beta}{}^{\gamma}\overline{\Delta}_\gamma, \tag{8}$$

$$[\overline{\Delta}_\alpha,\overline{\Delta}_m^a]=(i/\hbar)\overline{\Delta}_m^b(\sigma_\alpha)_b{}^a, \tag{9}$$

$$\{\overline{\Delta}_m^a,\overline{\Delta}_m^b\}=(i/\hbar)m^2(\sigma^\alpha)^{ab}\overline{\Delta}_a, \tag{10}$$

where the Sp(2)-indices are raised or lowered corresponding to

$$(\sigma_\alpha)^{ab}=\epsilon^{ac}(\sigma_\alpha)_c{}^b=(\sigma_\alpha)^a{}_c\epsilon^{cb}=\epsilon^{ac}(\sigma_\alpha)_{cd}\epsilon^{ab}, \quad (\sigma_\alpha)_a{}^b=-(\sigma_\alpha)^b{}_a\,.$$

Here, the matrices σ_α $(\alpha=0,+,-)$ generate the group of special linear transformations:

$$\sigma_\alpha\sigma_\beta=g_{\alpha\beta}+\frac{1}{2}\epsilon_{\alpha\beta\gamma}\sigma^\gamma, \quad \sigma^\alpha=g^{\alpha\beta}\sigma_\beta, \quad \mathrm{Tr}(\sigma_\alpha\sigma_\beta)=2g_{\alpha\beta}, \quad g^{\alpha\beta}=\begin{pmatrix}1&0&0\\0&0&2\\0&2&0\end{pmatrix}, \quad g^{\alpha\gamma}g_{\gamma\beta}=\delta^\alpha_\beta,$$

$\epsilon_{\alpha\beta\gamma}$ being the antisymmetric tensor, $\epsilon_{0+-}=1$ [all relations containing the matrices σ_α hold for any representation written below Eqs. (8)–(10)]. Notice that sl$(2,R)$, the even part of osp(1,2), is isomorphic to sp$(2,R)$. From (10) it is obvious that, if and only if the action S_m is Sp(2)-invariant, it can be (anti)BRST-invariant as well. For the generators σ_α we may choose the representation

$$\sigma_0=\tau_3, \quad \sigma_\pm=-\tau_\pm=-\tfrac{1}{2}(\tau_1\pm i\tau_2), \tag{11}$$

where τ_α $(\alpha=1,2,3)$ are the Pauli matrices.

In order that the (anti)commutation relations (8)–(10) are consistent, the structure constants $\epsilon_{\alpha\beta}{}^\gamma$, $(\sigma_\alpha)_b{}^a$ and $(\sigma^\alpha)^{ab}$ on the right-hand side of these relations must and, in fact, will obey certain conditions which follow from the (graded) Jacobi identities. The requirement that the set of these identities, namely

$$[\overline{\Delta}_\alpha,[\overline{\Delta}_\beta,\overline{\Delta}_\gamma]]+[\overline{\Delta}_\beta,[\overline{\Delta}_\gamma,\overline{\Delta}_\alpha]]+[\overline{\Delta}_\gamma,[\overline{\Delta}_\alpha,\overline{\Delta}_\beta]]=0,$$

$$[\overline{\Delta}_\alpha,[\overline{\Delta}_\beta,\overline{\Delta}_m^a]]-[\overline{\Delta}_\beta,[\overline{\Delta}_\alpha,\overline{\Delta}_m^a]]-[[\overline{\Delta}_\alpha,\overline{\Delta}_\beta],\overline{\Delta}_m^a]=0,$$

$$\{\overline{\Delta}_m^a,[\overline{\Delta}_\alpha,\overline{\Delta}_m^b]\}+\{\overline{\Delta}_m^b,[\overline{\Delta}_\alpha,\overline{\Delta}_m^a]\}+[\{\overline{\Delta}_m^a,\overline{\Delta}_m^b\},\overline{\Delta}_\alpha]=0,$$

$$[\overline{\Delta}_m^a,\{\overline{\Delta}_m^b,\overline{\Delta}_m^c\}]+[\overline{\Delta}_m^b,\{\overline{\Delta}_m^c,\overline{\Delta}_m^a\}]+[\overline{\Delta}_m^c,\{\overline{\Delta}_m^a,\overline{\Delta}_m^b\}]=0,$$

be fulfilled is equivalent to the demand that in the adjoint representation of $\overline{\Delta}_\alpha$ and $\overline{\Delta}_m^a$,

$$\overline{\Delta}_\alpha=\begin{pmatrix} R_\alpha & 0 \\ 0 & S_\alpha \end{pmatrix}, \quad \overline{\Delta}_m^a=m\begin{pmatrix} 0 & U^a \\ T^a & 0 \end{pmatrix},$$

the matrices R_α and S_α should form a representation of the (even) subalgebra sl(2) of osp(1,2). The elements of these matrices are

$$(R_\alpha)_\beta{}^\gamma=\epsilon_{\beta\alpha}{}^\gamma, \quad (S_\alpha)_a{}^b=(\sigma_\alpha)_a{}^b, \quad (T^a)_b{}^\alpha=i(\sigma^\alpha)_b{}^a, \quad (U^a)_\alpha{}^b=-i(\sigma_\alpha)^{ab}.$$

Therefore, we have the following conditions: (I) the matrices R_α form the adjoint representation of sl(2) and (II) the matrices S_α form the fundamental representation of this algebra; (III) the matrix elements $(T^a)_b{}^\alpha$ and $(U^a)_\alpha{}^b$ [which do not form a representation of sl(2) because of the different indices] are numerical invariants under sl(2),

$$(T^a)_b{}^\gamma\epsilon_{\gamma\alpha}{}^\beta=(\sigma_\alpha)_b{}^c(T^a)_c{}^\beta-(T^c)_b{}^\beta(\sigma_\alpha)_c{}^a, \quad \epsilon_{\alpha\beta}{}^\gamma(U^a)_\gamma{}^b=(\sigma_\alpha)^a{}_c(U^c)_\beta{}^b-(U^a)_\beta{}^c(\sigma_\alpha)_c{}^b;$$

and (IV) there holds the cyclic identity,

$$(\sigma^\alpha)^{ab}(\sigma_\alpha)^c{}_d+\text{cyclic perm}(a,b,c)=0,$$

which restricts the possible representations $\overline{\Delta}_m^a$ of the algebra sl(2) spanned by $\overline{\Delta}_\alpha$ (in general, not every ordinary Lie algebra can be extended to a superalgebra).

Let us notice that by invoking osp(1,2)-symmetry the notion of ghost number will be a natural property of the superalgebra (8)–(10). Indeed, from (8) and (9) we observe the relations

$$(\hbar/i)[\overline{\Delta}_0,\overline{\Delta}_\pm]=\pm 2\overline{\Delta}_\pm, \quad (\hbar/i)[\overline{\Delta}_0,\overline{\Delta}_m^a]=\overline{\Delta}_m^b(\sigma_0)_b{}^a,$$

showing that $(\hbar/i)\overline{\Delta}_0=\Delta_{gh}$ is the Faddeev–Popov operator whose eigenvalues $gh(X)$ define the ghost numbers of the corresponding quantities X of the theory in question, i.e., $([\Delta_{gh},X]-gh(X)X)\exp\{(i/\hbar)S_m\}=0$.

However, insisting on osp(1,2)-symmetry this approach brings in a fundamentally new aspect. Namely, in order to express the superalgebra (8)–(10) by operator identities and to get nontrivial solutions of the generating equations (6) and (7) one is forced to enlarge the set of antifields. More precisely, because the (anti)ghost fields $C^{\alpha_0 a_0}$ as well as their related antifields transform under Sp(2) in a nontrivial way one has to introduce additional sources,

$$\eta_A=(D_i,E_{\alpha_0},F_{\alpha_0 a_0}), \quad \epsilon(\eta_A)=\epsilon_A.$$

Let us remark that D_i always could be set equal to zero (here also E_{α_0} has been introduced only for the sake of completeness and formal analogy to other fields—it could be chosen equal to zero, too). For irreducible theories $F_{\alpha_0 a_0}$ is necessary in order to close the extended BRST algebra. [For L-stage reducible theories both sources $F_{\alpha_s|a_0\cdots a_s}$ and $E_{\alpha_s|a_0\cdots a_s}$ $(s=0,...,L)$ are necessary in order to close the extended BRST algebra with respect to the more general space of auxiliary and (anti)ghost fields $B^*_{\alpha_s a|a_1\cdots a_s}$, $C^*_{\alpha_s a|a_0\cdots a_s}$, $\overline{B}_{\alpha_s|a_1\cdots a_s}$, $\overline{C}_{\alpha_s|a_0\cdots a_s}$.]

In order to set up the gauge fixing, the new generalized gauge fixed quantum action $S_{m,\text{ext}}=S_{m,\text{ext}}(\phi^A,\phi^*_{Aa},\overline{\phi}_A,\eta_A)$ will be introduced according to

$$\exp\{(i/\hbar)S_{m,\text{ext}}\}=\hat{U}_m(F)\exp\{(i/\hbar)S_m\}, \tag{12}$$

where the operator $\hat{U}_m(F)$ has to be chosen as

$$\hat{U}_m(F)=\exp\{(\hbar/i)\hat{T}_m(F)\}, \quad \overline{T}_m(F)=\tfrac{1}{2}\epsilon_{ab}\{\overline{\Delta}_m^b,[\overline{\Delta}_m^a,F]\}+(i/\hbar)^2m^2F, \tag{13}$$

$F=F(\phi^A)$ being the gauge fixing functional. Then, by virtue of (9) and (10), one establishes the relations

$$[\overline{\Delta}_m^a,\overline{T}_m(F)]=\tfrac{1}{2}(i/\hbar)m^2(\sigma_\alpha)^a{}_b[\overline{\Delta}_m^b,[\overline{\Delta}^\alpha,F]] \tag{14}$$

and

$$[\overline{\Delta}_\alpha,\hat{T}_m(F)]=\tfrac{1}{2}\epsilon_{ab}\{\overline{\Delta}_m^b,[\overline{\Delta}_m^a,[\overline{\Delta}_\alpha,F]]\}+(i/\hbar)^2m^2[\overline{\Delta}_\alpha,F]. \tag{15}$$

Restricting F to be a Sp(2) scalar by imposing

$$[\overline{\Delta}_\alpha,F]S_m=0, \tag{16}$$

it can be verified by using the explicit expressions of $\overline{\Delta}_m^a$ and $\overline{\Delta}_\alpha$ that the commutators $[\overline{\Delta}_m^a,\hat{U}_m(F)]\exp\{(i/\hbar)S_m\}=0$ and $[\overline{\Delta}_\alpha,\hat{U}_m(F)]\exp\{(i/\hbar)S_m\}=0$ vanish on the subspace of admissible actions S_m (the proof of this statement will be postponed to Sec. III). Hence, the gauge fixed action $S_{m,\mathrm{ext}}$ satisfies Eqs. (6) and (7) as well,

$$\overline{\Delta}_m^a\exp\{(i/\hbar)S_{m,\mathrm{ext}}\}=0, \quad \overline{\Delta}_\alpha\exp\{(i/\hbar)S_{m,\mathrm{ext}}\}=0. \tag{17}$$

Here, some remarks are in order. The operator $\overline{\Delta}_m^a$ is a nonlinear one; to be able to express the superalgebra (8)–(10) through operator identities the operator $\overline{\Delta}_\alpha$ must be a nonlinear operator, too. Therefore, it is not possible to impose the strong operator equation $[\overline{\Delta}_\alpha,F]=0$ except for the particular case $F=F(A^i)$ where $[\overline{\Delta}_\alpha,F]$ vanishes identically, rather it must be replaced by the weaker condition $[\overline{\Delta}_\alpha,F]S_m=0$. As a consequence, in order to prove that $S_{m,\mathrm{ext}}$ possesses the same symmetry properties as S_m one needs the explicit realization of the operators $\overline{\Delta}_m^a$ and $\overline{\Delta}_\alpha$.

In this way the Sp(2)-covariant approach is generalized to another one based on the superalgebra osp(1,2). Moreover, in this approach one can introduce a mass m (which is necessary at least intermediately in the process of BPHZL renormalization) without breaking the extended BRST symmetry.

III. EXPLICIT CONSTRUCTION OF THE OPERATORS OF osp(1,2)-ALGEBRA

After having stated the general structure of the osp(1,2) quantization procedure being an obvious extension of Sp(2) quantization we have to find an operational realization of the general operators just introduced. Thereby we proceed in such away that all formulas hold also for reducible gauge theories, except for the definition of the operator $(P_+)^{Ba}_{Ab}$ introduced below which has to be generalized. The explicit expressions for the operators $\overline{\Delta}_m^a$ and $\overline{\Delta}_\alpha$ in the generating equations (6) and (7) will be determined in two steps: First we construct a functional $\overline{S}_m$ (at lowest order of $\hbar$) which is linear with respect to the antifields and is invariant under both (anti)BRST- and Sp(2) transformations; later on we generalize to the case of nonlinear dependence. The corresponding (linear) symmetry operators being denoted by $\mathbf{s}_m^a$ and $\mathbf{d}_\alpha$ are required to fulfill the osp(1,2)-superalgebra:

$$[\mathbf{d}_\alpha,\mathbf{d}_\beta]=\epsilon_{\alpha\beta}{}^\gamma\mathbf{d}_\gamma, \quad [\mathbf{d}_\alpha,\mathbf{s}_m^a]=\mathbf{s}_m^b(\sigma_\alpha)_b{}^a, \quad \{\mathbf{s}_m^a,\mathbf{s}_m^b\}=-m^2(\sigma^\alpha)^{ab}\mathbf{d}_\alpha.$$

Let us make for $\overline{S}_m$ the following ansatz:

$$\overline{S}_m=S_{\mathrm{cl}}+W_X, \quad W_X=(\tfrac{1}{2}\epsilon_{ab}\mathbf{s}_m^b\mathbf{s}_m^a+m^2)X, \tag{18}$$

where X is assumed to be the following Sp(2)-scalar (in fact the only one we are able to build up linear in the antifields),

$$X=\overline{\phi}_A\phi^A, \quad \mathbf{d}_\alpha X=0.$$

Then, by virtue of

$$\mathbf{s}_m^c(\tfrac{1}{2}\epsilon_{ab}\mathbf{s}_m^b\mathbf{s}_m^a+m^2)=\tfrac{1}{2}m^2(\sigma^\alpha)^c{}_d s_m^d\mathbf{d}_\alpha, \quad [\mathbf{d}_\alpha,\tfrac{1}{2}\epsilon_{ab}\mathbf{s}_m^b\mathbf{s}_m^a+m^2]=0,$$

it follows that $\overline{S_m}$ is both (anti)BRST- and Sp(2)-invariant, $\mathbf{s}_m^a\overline{S_m}=0$ and $\mathbf{d}_\alpha\overline{S_m}=0$. Thereby, it is taken into account that due to gauge invariance (1) of $S_{\rm cl}(A)$ it holds $\mathbf{s}_m^a S_{\rm cl}(A)=0$ with $\mathbf{s}_m^a A^i=R^i_{\alpha_0}C^{\alpha_0 a}$ (here, the action of $\mathbf{s}_m^a$—and also of $\mathbf{d}_\alpha$—on the auxiliary and (anti)ghost fields is irrelevant and already left open).

The strategy to define the operators $\overline{\Delta}_m^a=\Delta^a+(i/\hbar)V_m^a$, $\overline{\Delta}_\alpha=\Delta_\alpha+(i/\hbar)V_\alpha$ is governed by a specific realization of the (anti)BRST- and Sp(2)-transformations of the antifields (extending the standard definitions of Ref. 1). Therefore, let us decompose $\mathbf{s}_m^a$ and $\mathbf{d}_\alpha$ into a component acting on the fields and another one acting on the antifields as follows:

$$\mathbf{s}_m^a=(\mathbf{s}_m^a\phi^A)\frac{\delta_L}{\delta\phi^A}+V_m^a, \quad \mathbf{d}_\alpha=(\mathbf{d}_\alpha\phi^A)\frac{\delta_L}{\delta\phi^A}+V_\alpha.$$

The action of V_m^a and V_α on $\overline{\phi}_A$, ϕ^*_{Aa} and η_A are uniquely defined by

$$V_m^a\overline{\phi}_A=\epsilon^{ab}\phi^*_{Ab}, \quad V_\alpha\overline{\phi}_A=\overline{\phi}_B(\sigma_\alpha)^B_A,$$

$$V_m^a\phi^*_{Ab}=m^2(P_+)^{Ba}_{Ab}\overline{\phi}_B-\delta^a_b\eta_A, \quad V_\alpha\phi^*_{Aa}=\phi^*_{Ab}(\sigma_\alpha)^b{}_a+\phi^*_{Ba}(\sigma_\alpha)^B{}_A, \tag{19}$$

$$V_m^a\eta_A=-m^2\epsilon^{ab}(P_-)^{Bc}_{Ab}\phi^*_{Bc}, \quad V_\alpha\eta_A=\eta_B(\sigma_\alpha)^B{}_A,$$

where the following abbreviations are used:

$$(P_-)^{Ba}_{Ab}\equiv(P_+)^{Ba}_{Ab}-(P_+)^B_A\delta^a_b+\delta^B_A\delta^a_b, \quad (P_+)^B_A\equiv\delta^b_a(P_+)^{Ba}_{Ab}, \quad (\sigma_\alpha)^{BA}\equiv(\sigma_\alpha)^b{}_a(P_+)^{Ba}_{Ab}.$$

Here, we introduced the matrix

$$(P_+)^{Ba}_{Ab}\equiv\begin{cases}\delta^i_j\delta^a_b & \text{for} \quad A=i,B=j,\\ \delta^{\beta_0}_{\alpha_0}\delta^a_b & \text{for} \quad A=\alpha_0,B=\beta_0,\\ 2\,\delta^{\beta_0}_{\alpha_0}S^{b_0a}_{a_0b} & \text{for} \quad A=\alpha_0a_0,B=\beta_0b_0,\\ 0 & \text{otherwise,}\end{cases}$$

where the symmetrizer $S^{b_0a}_{a_0b}$ is defined as

$$S^{b_0a}_{a_0b}\equiv\tfrac{1}{2}\frac{\partial}{\partial X^{a_0}}\frac{\partial}{\partial X^b}X^aX^{b_0}=\tfrac{1}{2}(\delta^a_b\delta^{a_0}_{b_0}+\delta^a_{a_0}\delta^{b_0}_b),$$

X^a being independent bosonic variables.

The matrices $(P_-)^B_A\equiv\delta^a_b(P_-)^{Ba}_{Ab}$ and $(\sigma_\alpha)^B{}_A$ act nontrivially on the components of the (anti) fields having an internal (dummy) Sp(2) index. For example,

$$(P_-)^B_A\overline{\phi}_B=(0,0,-\overline{C}_{\alpha_0a_0}), \quad \overline{\phi}_B(\sigma_\alpha)^B{}_A=(0,0,\overline{C}_{\alpha_0c}(\sigma_\alpha)^c{}_{a_0}).$$

Therefore, V_α acts only on the (anti)ghost part of the antifields, and V_m^a is partly of that kind. Of course, we could have used also a componentwise notation, however, then the equations would be less easy to survey [a componentwise notation of the transformations (19) is given in Appendix E].

In order to prove that the transformations (19) obey the osp(1,2)-superalgebra

$$[V_\alpha, V_\beta] = \epsilon_{\alpha\beta}{}^\gamma V_\gamma, \quad [V_\alpha, V_m^a] = V_m^b (\sigma_\alpha)_b{}^a, \quad \{V_m^a, V_m^b\} = -m^2 (\sigma^\alpha)^{ab} V_\alpha, \tag{20}$$

one needs the following two equalities:

$$\epsilon^{ad}(P_+)^{Bb}_{Ad} + \epsilon^{bd}(P_+)^{Ba}_{Ad} = -(\sigma^\alpha)^{ab}(\sigma_\alpha)^B{}_A,$$

$$\epsilon^{ad}(P_+)^{Bb}_{Ac} + \epsilon^{bd}(P_+)^{Ba}_{Ac} - (\sigma^\alpha)^{ab}(\sigma_\alpha)^e{}_c (P_-)^{Bd}_{Ae} = -(\sigma^\alpha)^{ab}((\sigma_\alpha)^d{}_c \delta^B_A + \delta^d_c (\sigma_\alpha)^B{}_A),$$

or, equivalently,

$$\epsilon^{ad}\delta^b_c + \epsilon^{bd}\delta^a_c = -(\sigma^\alpha)^{ab}(\sigma_\alpha)^d{}_c, \tag{21}$$

$$(\sigma^\alpha)^{ab}((\sigma_\alpha)^{b_0}{}_c \delta^d_{a_0} + \delta^{b_0}_c (\sigma_\alpha)^d{}_{a_0}) = (\sigma^\alpha)^{ab}((\sigma_\alpha)^d{}_c \delta^{b_0}_{a_0} + \delta^d_c (\sigma_\alpha)^{b_0}{}_{a_0}), \tag{22}$$

and the relation $(P_-)^{Ab}_{Cd}(P_+)^{Cd}_{Ba} = 0$.

Then from (18) one gets for $\overline{S}_m$ the expression

$$\overline{S}_m = S_{\rm cl} + (\eta_A - \tfrac{1}{2} m^2 (P_+)^B_A \bar{\phi}_B)\phi^A - (\mathbf{s}^a_m \phi^A)\phi^*_{Aa} + \bar{\phi}_A(\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m + m^2)\phi^A. \tag{23}$$

Now, the symmetry properties of $\overline{S}_m$ with respect to (anti)BRST- and Sp(2)-transformations may be expressed by the following set of equations:

$$\tfrac{1}{2}(\overline{S}_m, \overline{S}_m)^a + V_m^a \overline{S}_m = 0, \quad \tfrac{1}{2}\{\overline{S}_m, \overline{S}_m\}_\alpha + V_\alpha \overline{S}_m = 0; \tag{24}$$

here the extended antibrackets $(F,G)^a$, introduced for the first time in Ref. 1, define an odd-graded and $\{F,G\}_\alpha$ a new even-graded algebraic structure on the space of fields and antifields (see Appendix B):

$$(F,G)^a = \frac{\delta F}{\delta \phi^A}\frac{\delta G}{\delta \phi^*_{Aa}} - (-1)^{(\epsilon(F)+1)(\epsilon(G)+1)}\frac{\delta G}{\delta \phi^A}\frac{\delta F}{\delta \phi^*_{Aa}} \tag{25}$$

and

$$\{F,G\}_\alpha = (\sigma_\alpha)_B{}^A\left(\frac{\delta F}{\delta \phi^A}\frac{\delta G}{\delta \eta_B} + (-1)^{\epsilon(F)\epsilon(G)}\frac{\delta G}{\delta \phi^A}\frac{\delta F}{\delta \eta_B}\right), \tag{26}$$

and, in accordance with (19), the first-order differential operators V_m^a and V_α are given by

$$V_m^a = \epsilon^{ab}\phi^*_{Ab}\frac{\delta}{\delta \bar{\phi}_A} - \eta_A \frac{\delta}{\delta \phi^*_{Aa}} + m^2 (P_+)^{Ba}_{Ab}\bar{\phi}_B \frac{\delta}{\delta \phi^*_{Ab}} - m^2 \epsilon^{ab}(P_-)^{Bc}_{Ab}\phi^*_{Bc}\frac{\delta}{\delta \eta_A} \tag{27}$$

and

$$V_\alpha = \bar{\phi}_B (\sigma_\alpha)^B{}_A \frac{\delta}{\delta \bar{\phi}_A} + (\phi^*_{Ab}(\sigma_\alpha)^b{}_a + \phi^*_{Ba}(\sigma_\alpha)^B{}_A)\frac{\delta}{\delta \phi^*_{Aa}} + \eta_B (\sigma_\alpha)^B{}_A \frac{\delta}{\delta \eta_A}. \tag{28}$$

We also introduce the second-order differential operators Δ^a and Δ_α whose structure is extracted from (25) and (26):

$$\Delta^a=(-1)^{\epsilon_A}\frac{\delta_L}{\delta\phi^A}\frac{\delta}{\delta\phi^*_{Aa}},\quad \Delta_\alpha=(-1)^{\epsilon_A}(\sigma_\alpha)_B{}^A\frac{\delta_L}{\delta\phi^A}\frac{\delta}{\delta\eta_B}. \tag{29}$$

Let us now consider the general case where the action S_m is assumed to appear in the form of a series expansion in powers of $\hbar$ which may depend also nonlinear on the antifields. This action will be required to satisfy the following set of quantum master equations (see Appendix C):

$$\tfrac{1}{2}(S_m,S_m)^a+V^a_mS_m=i\hbar\Delta^aS_m,\quad \tfrac{1}{2}\{S_m,S_m\}_\alpha+V_\alpha S_m=i\hbar\Delta_\alpha S_m, \tag{30}$$

or, equivalently,

$$\overline{\Delta}{}^a_m\exp\{(i/\hbar)S_m\}=0,\quad \overline{\Delta}_\alpha\exp\{(i/\hbar)S_m\}=0. \tag{31}$$

Furthermore, by an explicit calculation it can be verified that $\overline{\Delta}{}^a_m=\Delta^a+(i/\hbar)V^a_m$ and $\overline{\Delta}_\alpha=\Delta_\alpha+(i/\hbar)V_\alpha$ obey the osp(1,2)-superalgebra (8)–(10).

In order to lift the degeneracy of S_m we follow the general gauge-fixing procedure suggested by (12) and (13). Let us introduce the gauge fixed action

$$\exp\{(i/\hbar)S_{m,\mathrm{ext}}\}=\hat{U}_m(F)\exp\{(i/\hbar)S_m\}, \tag{32}$$

where the operator $\hat{U}_m(F)=\exp\{(i/\hbar)\hat{T}_m(F)\}$ is defined according to the formula (13). If the gauge-fixing functional is assumed to depend only on the fields, $F=F(\phi^A)$, then one gets

$$\hat{U}_m(F)=\exp\left\{\frac{\delta F}{\delta\phi^A}\left(\frac{\delta}{\delta\overline{\phi}_A}-\frac{1}{2}m^2(P_-)^A_B\frac{\delta}{\delta\eta_B}\right)-(\hbar/i)\frac{1}{2}\epsilon_{ab}\frac{\delta}{\delta\phi^*_{Aa}}\frac{\delta^2F}{\delta\phi^A\delta\phi^B}\frac{\delta}{\delta\phi^*_{Bb}}+(i/\hbar)m^2F\right\}. \tag{33}$$

Let us prove that $S_{m,\mathrm{ext}}$ obeys the generating equations (30) and (31) as well. Clearly, since $\overline{\Delta}{}^a_m$, $\overline{\Delta}_\alpha$ and $\hat{U}_m(F)$ do not commute with each other, this proof will be more involved than in the Sp(2)-approach. This is due to the fact that, looking back at (14) and (15), neither

$$[\overline{\Delta}{}^a_m,\hat{T}_m(F)]=\tfrac{1}{2}(i/\hbar)m^2(\sigma^\alpha)^a{}_b[\overline{\Delta}{}^b_m,[\overline{\Delta}_\alpha,F]]$$

nor

$$[\overline{\Delta}_\alpha,\hat{T}_m(F)]=\tfrac{1}{2}\epsilon_{ab}\{\overline{\Delta}{}^b_m,[\overline{\Delta}{}^a_m,[\overline{\Delta}_\alpha,F]]\}+(i/\hbar)^2m^2[\overline{\Delta}_\alpha,F]$$

does vanish, since due to the nonlinearity of $\overline{\Delta}_\alpha$ one cannot require the strong condition $[\overline{\Delta}_\alpha,F]=0$. However, a direct verification shows that $\hat{T}_m(F)$ commutes with any term on the right-hand side of both previous relations, i.e., it holds

$$[\hat{T}_m(F),[\overline{\Delta}{}^a_m,\hat{T}_m(F)]]=0,\quad [\hat{T}_m(F),[\overline{\Delta}_\alpha,\hat{T}_m(F)]]=0.$$

Then, by the help of these relations one obtains

$$[\overline{\Delta}{}^a_m,\hat{U}_m(F)]=(\hbar/i)\hat{U}_m(F)[\overline{\Delta}{}^a_m,\hat{T}_m(F)],\quad [\overline{\Delta}_\alpha,\hat{U}_m(F)]=(\hbar/i)\hat{U}_m(F)[\overline{\Delta}_\alpha,\hat{T}_m(F)].$$

Let us require [see (16)]

$$[\overline{\Delta}_\alpha,F]S_m\equiv(\sigma_\alpha)_B{}^A\frac{\delta F}{\delta\phi^A}\frac{\delta S_m}{\delta\eta_B}=0,\quad (\sigma_\alpha)_B{}^A\frac{\delta F}{\delta\phi^A}\phi^B=0. \tag{34}$$

Then, taking into account that S_m solves the generating equations (31), it is easily seen that $[\overline{\Delta}_m^a, \hat{U}_m(F)]$ and $[\overline{\Delta}_\alpha, \hat{U}_m(F)]$ vanish after acting on $\exp\{(i/\hbar)S_m\}$:

$$[\overline{\Delta}_m^a, \hat{U}_m(F)]\exp\{(i/\hbar)S_m\}=0, \quad [\overline{\Delta}_\alpha, \hat{U}_m(F)]\exp\{(i/\hbar)S_m\}=0.$$

Summarizing, we have the results

$$\overline{\Delta}_m^a \exp\{(i/\hbar)S_{m,\mathrm{ext}}\}=0, \quad \overline{\Delta}_\alpha \exp\{(i/\hbar)S_{m,\mathrm{ext}}\}=0, \tag{35}$$

i.e., the gauge-fixed action $S_{m,\mathrm{ext}}$ satisfies the same generating equations (30) and (31) as S_m, which is indeed what we intended to prove.

Finally, let us return to the requirement (34) and discuss how it can be fulfilled. If we differentiate Eqs. (30) with respect to η_A, we get

$$Q_m^a\left(\frac{\delta S_m}{\delta \eta_A}-\phi^A\right)=0, \quad Q_\alpha\left(\frac{\delta S_m}{\delta \eta_A}-\phi^A\right)=0, \tag{36}$$

where the operators Q_m^a and Q_α are defined by the formulas

$$Q_m^a X \equiv (S_m, X)^a - i\hbar \overline{\Delta}_m^a X, \quad Q_\alpha X \equiv \{S_m, X\}_\alpha - i\hbar \overline{\Delta}_\alpha X, \tag{37}$$

with arbitrary functional X. These operators possess the properties

$$[Q_\alpha, Q_\beta]=\epsilon_{\alpha\beta}{}^\gamma Q_\gamma, \quad [Q_\alpha, Q_m^a]=Q_m^b(\sigma_\alpha)_b{}^a, \quad \{Q_m^a, Q_m^b\}=-m^2(\sigma^\alpha)^{ab}Q_\alpha. \tag{38}$$

The equations (36) suggest that the restriction on S_m to be linear in η_A seems to be the natural solution of the requirement (34), namely

$$\frac{\delta S_m}{\delta \eta_A}=\phi^A. \tag{39}$$

Then, the second equation in (30) simplifies into

$$(\sigma_\alpha)_B{}^A \frac{\delta S_m}{\delta \phi^A}\phi^B + V_\alpha S_m = 0,$$

since σ_α are traceless. Although the restriction (39) seems to be a particular but not the general case it should be preferred to all other solutions since, due to its linearity, it can be realized for any (renormalized) action S_m (see also Appendix D).

IV. WARD IDENTITIES, GENERATING FUNCTIONALS AND GAUGE (IN)DEPENDENCE

Next, we turn to the question of gauge independence of physical quantities, especially of the *S*-matrix. In discussing this question it is convenient to study first the symmetry properties of the vacuum functional,

$$Z_m(0)=\int d\phi^A \exp\{(i/\hbar)S_{m,\mathrm{eff}}\}, \tag{40}$$

where $S_{m,\mathrm{eff}}(\phi^A)=S_{m,\mathrm{ext}}(\phi^A, \phi^*_{Aa}, \overline{\phi}_A, \eta_A)|_{\phi^*_a=\overline{\phi}=\eta=0}$. It can be represented in the form

$$Z_m(0)=\int d\phi^A d\eta_A d\phi^*_{Aa} d\pi^{Aa} d\overline{\phi}_A d\lambda^A \delta(\eta_A)\exp\{(i/\hbar)(S_{m,\mathrm{ext}}-W_X)\} \tag{41}$$

with

$$W_X = (\eta_A - \tfrac{1}{2} m^2 (P_+)^B_A \overline{\phi}_B)\phi^A - \phi^*_{Aa}\pi^{Aa} - \overline{\phi}_A(\lambda^A - \tfrac{1}{2} m^2 (P_-)^A_B \phi^B), \tag{42}$$

where we have extended the space of variables by introducing the auxiliary fields π^{Aa} and λ^A. It is straightforward to check that W_X can be cast into the form (42). Indeed, performing in (41) first of all the integrations over λ^A and π^{Aa}, which yields the delta-functions $\delta(\overline{\phi}_A)$ and $\delta(\phi^*_{Aa})$, and, after that, carrying out the integrations over $\overline{\phi}_A$, ϕ^*_{Aa} and η_A one gets the expression (40).

Since η_A for $m \neq 0$ transforms nontrivially under osp(1,2) we express $\delta(\eta_A)$ by

$$\delta(\eta_A) = \int d\zeta^A \exp\{(i/\hbar)\eta_A \zeta^A\}$$

and change within (41) the integration variables ϕ^A and λ^A according to $\phi^A \to \phi^A + \zeta^A$ and $\lambda^A \to \lambda^A + (1/2)m^2((P_-)^A_B - (P_+)^A_B)\zeta^B$. Then, for $Z_m(0)$ this yields

$$Z_m(0) = \int d\phi^A d\eta_A d\zeta^A d\phi^*_{Aa} d\pi^{Aa} d\overline{\phi}_A d\lambda^A \exp\{(i/\hbar)(S^\zeta_{m,\mathrm{ext}} - W_X)\}, \tag{43}$$

where $S^\zeta_{m,\mathrm{ext}}$ is obtained from $S_{m,\mathrm{ext}}$ by performing the replacement $\phi^A \to \phi^A + \zeta^A$. At this stage we remark that $(\phi^A, \pi^{Aa}, \lambda^A)$ and $(\overline{\phi}_A, \phi^*_{Aa}, \eta_A)$ constitute the components of the superfield and superantifield, respectively, of the superfield quantization scheme;[9] here we changed the notation $J_A \to \eta_A$ relative to Ref. 9. Of course, the formalism introduced here may be written in that form also.

The term W_X may be cast into the osp(1,2)-invariant form

$$W_X = \tfrac{1}{2}\epsilon_{ab}(V^b_m(V^a_m X - X U^a_m) + (V^a_m X - X U^a_m)U^b_m) + m^2 X,$$

where

$$X = \overline{\phi}_A \phi^A, \quad V_\alpha X + X U_\alpha = 0,$$

with V^a_m and V_α, whose action on $\overline{\phi}_A$, ϕ^*_{Aa}, η_A are already defined in (19), satisfying the osp(1,2)-superalgebra (20), and the action of U^a_m and U_α on ϕ^A, π^{Aa}, λ^A and ζ^A being defined according to

$$\begin{aligned}
&\phi^A U^a_m = \pi^{Aa}, \quad \phi^A U_\alpha = \phi^B (\sigma_\alpha)_B{}^A, \\
&\pi^{Ab} U^a_m = \epsilon^{ab}\lambda^A + m^2 \epsilon^{ac}(P_+)^{Ab}_{Bc}\phi^B, \quad \pi^{Aa} U_\alpha = \pi^{Ab}(\sigma_\alpha)_b{}^a + \pi^{Ba}(\sigma_\alpha)_B{}^A, \\
&\lambda^A U^a_m = m^2 (P_-)^{Aa}_{Bb}\pi^{Bb}, \quad \lambda^A U_\alpha = \lambda^B (\sigma_\alpha)_B{}^A, \\
&\zeta^A U^a_m = 0, \quad \zeta^A U_\alpha = \zeta^B (\sigma_\alpha)_B{}^A.
\end{aligned} \tag{44}$$

Here, U^a_m and U_α are defined as right derivatives, in contrast to V^a_m and V_α, which was defined as left ones. In order to prove that the transformations (44) obey the osp(1,2)-superalgebra

$$[U_\alpha, U_\beta] = -\epsilon_{\alpha\beta}{}^\gamma U_\gamma, \quad [U_\alpha, U^a_m] = -U^b_m (\sigma_\alpha)_b{}^a, \quad \{U^a_m, U^b_m\} = m^2 (\sigma^\alpha)^{ab} U_\alpha, \tag{45}$$

one needs the following two equalities:

$$\epsilon^{ad}(P_+)^{Bb}_{Ad} + \epsilon^{bd}(P_+)^{Ba}_{Ad} = (\sigma^\alpha)^{ab}(\sigma_\alpha)_A{}^B,$$

$$\epsilon^{ad}(P_-)^{Bb}_{Ac} + \epsilon^{bd}(P_-)^{Ba}_{Ac} - (\sigma^\alpha)^{ab}(\sigma_\alpha)^e{}_c (P_+)^{Bd}_{Ae} = (\sigma^\alpha)^{ab}((\sigma_\alpha)_c{}^d \delta^B_A + \delta^d_c (\sigma_\alpha)_A{}^B),$$

and the relation $(P_-)^{Ab}_{Cd}(P_+)^{Cd}_{Ba}=0$. It is easily seen that both equalities are equivalent to (21) and (22), too.

Inserting into (43) the relations (32) and (33) and integrating by parts yields

$$Z_m(0)=\int d\phi^A d\eta_A d\zeta^A d\phi^*_{Aa} d\pi^{Aa} d\overline{\phi}_A d\lambda^A \exp\{(i/\hbar)(S^\zeta_m+W^\zeta_F-W_X)\} \tag{46}$$

with the following expression for W_F:

$$W_F=-\frac{\delta F}{\delta\phi^A}\left(\lambda^A+\frac{1}{2}m^2(P_+)^A_B\phi^B\right)-\frac{1}{2}\epsilon_{ab}\pi^{Aa}\frac{\delta^2 F}{\delta\phi^A\delta\phi^B}\pi^{Bb}+m^2F, \tag{47}$$

which may be recast into the osp(1,2)-invariant form

$$W_F=F(\tfrac{1}{2}\epsilon_{ab}U^b_mU^a_m+m^2),\quad FU_\alpha=0.$$

(Again, S^ζ_m and W^ζ_F are obtained from S_m and W_F, respectively, by carrying out the replacement $\phi^A\rightarrow\phi^A+\zeta^A$.)

Let us now introduce the combined (first-order) differential operators

$$L^a_mX\equiv V^a_mX-(-1)^{\epsilon(X)}XU^a_m,\quad L_\alpha X\equiv V_\alpha X+XU_\alpha,$$

X being an arbitrary functional, where U^a_m and U_α, in accordance with (44), are defined by

$$U^a_m=\frac{\delta}{\delta\phi^A}\pi^{Aa}+\frac{\delta}{\delta\pi^{Ab}}\epsilon^{ab}\lambda^A+\frac{\delta}{\delta\pi^{Ab}}m^2\epsilon^{ac}(P_+)^{Ab}_{Bc}\phi^B+\frac{\delta}{\delta\lambda^A}m^2(P_-)^{Aa}_{Bb}\pi^{Bb}$$

and

$$U_\alpha=\frac{\delta}{\delta\phi^A}\phi^B(\sigma_\alpha)_B{}^A+\frac{\delta}{\delta\lambda^A}\lambda^B(\sigma_\alpha)_B{}^A+\frac{\delta}{\delta\pi^{Aa}}(\pi^{Ab}(\sigma_\alpha)_b{}^a+\pi^{Ba}(\sigma_\alpha)_B{}^A)+\frac{\delta}{\delta\zeta^A}\zeta^B(\sigma_\alpha)_B{}^A;$$

here, the derivatives with respect to ϕ^A, π^{Ab}, λ^A and ζ^A are right ones [V^a_m and V_α are already defined in (27) and (28)]. Then, by virtue of (20) and (45), it follows that L^a_m and L_α satisfy the osp(1,2)-superalgebra

$$[L_\alpha,L_\beta]=\epsilon_{\alpha\beta}{}^\gamma L_\gamma,\quad [L_\alpha,L^a_m]=L^b_m(\sigma_\alpha)_b{}^a,\quad \{L^a_m,L^b_m\}=-m^2(\sigma^\alpha)^{ab}L_\alpha.$$

Hence, it holds

$$L^c_m(\tfrac{1}{2}\epsilon_{ab}L^b_mL^a_m+m^2)=\tfrac{1}{2}m^2(\sigma^\alpha)^c{}_dL^d_mL_\alpha,\quad [L_\alpha,\tfrac{1}{2}\epsilon_{ab}L^b_mL^a_m+m^2]=0. \tag{48}$$

We assert now that (46) is invariant under the following (global) transformations [thereby, one has to make use of the first equation in (30) and (48), respectively]:

$$\begin{gathered}\delta_m\phi^A=\phi^AU^a_m\mu_a,\quad \delta_m\zeta^A=0,\quad \delta_m\overline{\phi}_A=\mu_aV^a_m\overline{\phi}_A,\\ \delta_m\pi^{Ab}=\pi^{Ab}U^a_m\mu_a,\quad \delta_m\phi^*_{Ab}=\mu_aV^a_m\phi^*_{Ab}+\mu_a(S^\zeta_m,\phi^*_{Ab})^a,\\ \delta_m\lambda^A=\lambda^AU^a_m\mu_a,\quad \delta_m\eta_A=\mu_aV^a_m\eta_A,\end{gathered} \tag{49}$$

where μ_a, $\epsilon(\mu_a)=1$, is a Sp(2)-doublet of constant anticommuting parameters. The transformations (49) realize the m-extended BRST symmetry in the space of variables ϕ^A, $\overline{\phi}_A$, ϕ^*_{Aa}, η_A, π^{Aa}, λ^A and ζ^A.

Moreover, it is straightforward to check that (46) is also invariant under the following transformations [where one has to make use of the second equation in (30) and (48), respectively]:

$$\delta\phi^A = \phi^A U_\alpha \theta^\alpha, \quad \delta\zeta^A = \zeta^A U_\alpha \theta^\alpha, \quad \delta\overline{\phi}_A = \theta^\alpha V_\alpha \overline{\phi}_A,$$
$$\delta\pi^{Ab} = \pi^{Ab} U_\alpha \theta^\alpha, \quad \delta\phi^*_{Ab} = \theta^\alpha V_\alpha \phi^*_{Ab}, \tag{50}$$
$$\delta\lambda^A = \lambda^A U_\alpha \theta^\alpha, \quad \delta\eta_A = \theta^\alpha V_\alpha \eta_A + \theta^\alpha \{S^\zeta_m, \eta_A\}_\alpha,$$

where θ^α, $\epsilon(\theta^\alpha)=0$, are constant commuting parameters. The transformations (50) realize the Sp (2)-symmetry in the space of variables ϕ^A, $\overline{\phi}_A$, ϕ^*_{Aa}, η_A, π^{Aa}, λ^A and ζ^A.

In principle, for a general gauge functional F, μ_a may be assumed to depend on all these variables ϕ^A, $\overline{\phi}_A$, ϕ^*_{Aa}, η_A, π^{Aa}, λ^A and ζ^A. As long as F depends only on the fields it is sufficient for μ_a to depend on ϕ^A and π^{Aa} only. Then the symmetry of the vacuum functional $Z_m(0)$ with respect to the transformations (49) permits the study of the question whether the mass-dependent terms of the action violate the independence of the S-matrix on the choice of the gauge.

Indeed, let us change the gauge-fixing functional $F(\phi)\rightarrow F(\phi)+\delta F(\phi)$. Then the gauge-fixing term W_F changes according to

$$W_F \rightarrow W_{F+\delta F} = W_F + W_{\delta F}, \quad W_{\delta F} = \delta F(\phi)\left(\tfrac{1}{2}\epsilon_{ab} U^b_m U^a_m + m^2\right). \tag{51}$$

Now, performing in (46) the transformations (49), we choose

$$\mu_a = \mu_a(\phi,\pi) \equiv -(i/\hbar)\,\tfrac{1}{2}\epsilon_{ab}\delta F(\phi) U^b_m.$$

This induces the factor $\exp(\mu_a U^a_m)$ in the integration measure. Combining its exponent with W_F leads to

$$W_F \rightarrow W_F + (\hbar/i)\mu_a U^a_m = W_F - \tfrac{1}{2}\epsilon_{ab}\delta F(\phi) U^b_m U^a_m = W_F - W_{\delta F} + m^2 \delta F(\phi).$$

By comparison with (51) we see that the mass term $m^2 F$ in W_F violates the independence of the vacuum functional $Z_m(0)$ on the choice of the gauge. This result, together with the equivalence theorem,[10] is sufficient to prove that the same is true also for the S-matrix.

One may try to compensate this undesired term $m^2\delta F(\phi)$ by means of an additional change of variables. But this change should not destroy the form of the action arrived at in the previous stage. However, an additional change of variables leads to a Berezinian which is equal to one because σ_α are traceless. Therefore, the unwanted term could never be compensated.

Finally, we shall derive the Ward identities for the extended BRST-and the Sp(2)-symmetries. To begin with, let us introduce the generating functional of the Green's functions:

$$Z_m(J_A;\phi^*_{Aa},\overline{\phi}_A,\eta_A) = \int d\phi^A \exp\{(i/\hbar)(S_{m,\mathrm{ext}}(\phi^A,\phi^*_{Aa},\overline{\phi}_A,\eta_A) + J_A\phi^A)\}. \tag{52}$$

If we multiply Eqs. (35) from the left by $\exp\{(i/\hbar)J_A\phi^A\}$ and integrate over ϕ^A we get

$$\int d\phi^A \exp\{(i/\hbar)J_A\phi^A\}\overline{\Delta}^a_m \exp\{(i/\hbar)S_{m,\mathrm{ext}}(\phi^A,\phi^*_{Aa},\overline{\phi}_A,\eta_A)\} = 0,$$

$$\int d\phi^A \exp\{(i/\hbar)J_A\phi^A\}\overline{\Delta}_\alpha \exp\{(i/\hbar)S_{m,\mathrm{ext}}(\phi^A,\phi^*_{Aa},\overline{\phi}_A,\eta_A)\} = 0.$$

Now, integrating by parts and assuming the integrated expressions to vanish, we can rewrite the resulting equalities with the help of the definition (52) as

$$\left(J_A \frac{\delta}{\delta \phi^*_{Aa}} - V^a_m \right) Z_m = 0, \quad \left((\sigma_\alpha)_B{}^A J_A \frac{\delta}{\delta \eta_B} - V_\alpha \right) Z_m = 0,$$

which are the Ward identities for the generating functional of Green's functions.

Introducing as usual the generating functional of the vertex functions,

$$\Gamma_m(\phi^A; \phi^*_{Aa}, \bar{\phi}_A, \eta_A) = (\hbar/i) \ln Z_m(J_A; \phi^*_{Aa}, \bar{\phi}_A, \eta_A) - J_A \phi^A,$$

$$\phi^A = (\hbar/i) \frac{\delta \ln Z_m(J_A; \phi^*_{Aa}, \bar{\phi}_A, \eta_A)}{\delta J_A},$$

we obtain

$$\tfrac{1}{2}(\Gamma_m, \Gamma_m)^a + V^a_m \Gamma_m = 0, \quad \tfrac{1}{2}\{\Gamma_m, \Gamma_m\}_\alpha + V_\alpha \Gamma_m = 0. \tag{53}$$

For Yang–Mills theories the first identities in (53) are the Slavnov–Taylor identities of the extended BRST symmetries. Furthermore, choosing for σ_α the representation (11), the second identities in (53) express for $\alpha = 0$ the ghost number conservation and, in Yang–Mills theories, for $\alpha = (+,-)$ the Delduc–Sorella identities of the Sp(2)-symmetry.[11]

V. MASSIVE THEORIES WITH A CLOSED GAUGE ALGEBRA

To illustrate the formalism of the osp(1,2)-quantization developed here, we consider irreducible massive gauge theories with a closed algebra. Such theories are characterized by the fact, first, that, because of $M^{ij}_{\alpha_0 \beta_0} = 0$, the algebra of generators, Eq. (2), reduce to

$$R^i_{\alpha_0, j} R^j_{\beta_0} - R^i_{\beta_0, j} R^j_{\alpha_0} = -R^i_{\gamma_0} F^{\gamma_0}_{\alpha_0 \beta_0}; \tag{54}$$

for the sake of simplicity we assume throughout this and the succeeding section that the A^i are bosonic fields, and, second, that $R^i_{\alpha_0}$ has no zero modes (contrary to the case of reducible theories), i.e., any equation of the form $R^i_{\alpha_0} X^{\alpha_0} = 0$ has only the trivial solution $X^{\alpha_0} = 0$. Then, in the case of field-dependent structure functions, the Jacobi identity looks like

$$F^{\delta_0}_{\eta_0 \alpha_0} F^{\eta_0}_{\beta_0 \gamma_0} - R^i_{\alpha_0} F^{\delta_0}_{\beta_0 \gamma_0, i} + \text{cyclic perm}(\alpha_0, \beta_0, \gamma_0) = 0. \tag{55}$$

We shall restrict ourselves to consider only solutions of Eqs. (24) being linear in the antifields ϕ^*_{Aa}, $\bar{\phi}_A$ and η_A. Such solutions can be cast into the form [see Eq. (18)]

$$\bar{S}_m = S_{\text{cl}} + (\tfrac{1}{2} \epsilon_{ab} \mathbf{s}^b_m \mathbf{s}^a_m + m^2) X,$$

with $X = \bar{A}_i A^i + \bar{B}_{\alpha_0} B^{\alpha_0} + \bar{C}_{\alpha_0 c} C^{\alpha_0 c}$. A realization of the (anti)BRST- and the Sp(2)-transformations of the antifields already has been given (see Appendix E). Thus, we are left with the exercise to determine the corresponding transformations for the fields A^i, B^{α_0} and $C^{\alpha_0 c}$. Let us briefly look at the derivation of these transformations. Imposing the osp(1,2)-superalgebra

$$[\mathbf{d}_\alpha, \mathbf{d}_\beta] = \epsilon_{\alpha\beta}{}^\gamma \mathbf{d}_\gamma, \quad [\mathbf{d}_\alpha, \mathbf{s}^a_m] = \mathbf{s}^b_m (\sigma_\alpha)_b{}^a, \quad \{\mathbf{s}^a_m, \mathbf{s}^b_m\} = -m^2 (\sigma^\alpha)^{ab} \mathbf{d}_\alpha, \tag{56}$$

on the gauge fields A^i, due to $\mathbf{d}_\alpha A^i = 0$, this yields $\{\mathbf{s}^a_m, \mathbf{s}^b_m\} A^i = 0$. Then, with

$$\mathbf{s}^a_m A^i = R^i_{\alpha_0} C^{\alpha_0 a}, \tag{57}$$

by virtue of (54), we find

$$R^i_{\alpha_0}(\mathbf{s}^a_m C^{\alpha_0 b} + \mathbf{s}^b_m C^{\alpha_0 a} + F^{\alpha_0}_{\beta_0\gamma_0} C^{\beta_0 a} C^{\gamma_0 b}) = 0.$$

Because the $R^i_{\alpha_0}$ are irreducible the general solution of this equation is given by

$$\mathbf{s}^a_m C^{\alpha_0 b} = \epsilon^{ab} B^{\alpha_0} - \tfrac{1}{2} F^{\alpha_0}_{\beta_0\gamma_0} C^{\beta_0 a} C^{\gamma_0 b}. \tag{58}$$

Imposing the superalgebra (56) on the (anti)ghost fields $C^{\alpha_0 c}$ and taking into account $\mathbf{d}_\alpha C^{\alpha_0 b} = C^{\alpha_0 c}(\sigma_\alpha)_c{}^b$ it gives $\{\mathbf{s}^a_m, \mathbf{s}^b_m\} C^{\alpha_0 c} = -m^2 (\sigma^\alpha)^{ab} C^{\alpha_0 d}(\sigma_\alpha)_d{}^c$. The right-hand side of this restriction can be rewritten by means of the relations $(\sigma_\alpha)_d{}^c = \epsilon_{de}\epsilon^{fc}(\sigma_\alpha)^e{}_f$ and $(\sigma^\alpha)^{ab}(\sigma_\alpha)^e{}_f = -(\epsilon^{ae}\delta^b_f + \epsilon^{be}\delta^a_f)$ as $\{\mathbf{s}^a_m, \mathbf{s}^b_m\} C^{\alpha_0 c} = -m^2(\epsilon^{ac} C^{\alpha_0 b} + \epsilon^{bc} C^{\alpha_0 a})$. Then, with (58), by virtue of (55), we obtain

$$\begin{aligned}\{\epsilon^{bc}(\mathbf{s}^a_m B^{\alpha_0} + m^2 C^{\alpha_0 a} - \tfrac{1}{2} F^{\alpha_0}_{\beta_0\gamma_0} B^{\beta_0} C^{\gamma_0 a})\\ + \tfrac{1}{4}(F^{\alpha_0}_{\eta_0\beta_0} F^{\eta_0}_{\gamma_0\delta_0} + F^{\alpha_0}_{\eta_0\delta_0} F^{\eta_0}_{\beta_0\gamma_0} - 2R^i_{\beta_0} F^{\alpha_0}_{\gamma_0\delta_0,i}) C^{\beta_0 a} C^{\gamma_0 b} C^{\delta_0 c}\} + \mathrm{sym}(a \leftrightarrow b) = 0,\end{aligned}$$

where $\mathrm{sym}(a \leftrightarrow b)$ means symmetrization with respect to the indices a and b.

The general solution of this equation reads

$$\mathbf{s}^a_m B^{\alpha_0} = -m^2 C^{\alpha_0 a} + \tfrac{1}{2} F^{\alpha_0}_{\beta_0\gamma_0} B^{\beta_0} C^{\gamma_0 a} + \tfrac{1}{12}\epsilon_{cd}(F^{\alpha_0}_{\eta_0\beta_0} F^{\eta_0}_{\gamma_0\delta_0} + 2R^i_{\beta_0} F^{\alpha_0}_{\gamma_0\delta_0,i}) C^{\gamma_0 a} C^{\delta_0 c} C^{\beta_0 d}. \tag{59}$$

For the particular case $m=0$ the transformations (57)–(59) were already obtained earlier in Ref. 12.

Note that, due to (56), the only nonzero variation of A^i is of the form

$$\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m A^i = R^i_{\alpha_0} B^{\alpha_0} + \tfrac{1}{2}\epsilon_{ab} R^i_{\alpha_0,j} R^j_{\beta_0} C^{\beta_0 b} C^{\alpha_0 a}; \tag{60}$$

for the corresponding variations of $C^{\alpha_0 c}$ and B^{α_0} one gets

$$\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m C^{\alpha_0 c} = \tfrac{1}{2} m^2 C^{\alpha_0 c} - F^{\alpha_0}_{\beta_0\gamma_0} B^{\beta_0} C^{\gamma_0 c} - \tfrac{1}{6}\epsilon_{ab}(F^{\alpha_0}_{\eta_0\beta_0} F^{\eta_0}_{\gamma_0\delta_0} + 2R^i_{\beta_0} F^{\alpha_0}_{\gamma_0\delta_0,i}) C^{\gamma_0 c} C^{\delta_0 a} C^{\beta_0 b}, \tag{61}$$

$$\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m B^{\alpha_0} = -m^2 B^{\alpha_0}. \tag{62}$$

The relations (55)–(62) specify the transformations of the osp(1,2)-symmetry for gauge theories with a closed algebra. Substituting these expressions into

$$\begin{aligned}\overline{S}_m = S_{\mathrm{cl}} + A^*_{ia}(\mathbf{s}^a_m A^i) + B^*_{\alpha_0 a}(\mathbf{s}^a_m B^{\alpha_0}) - C^*_{\alpha_0 ac}(\mathbf{s}^a_m C^{\alpha_0 c}) + (F_{\alpha_0 c} - \tfrac{1}{2} m^2 \overline{C}_{\alpha_0 c}) C^{\alpha_0 c}\\ + \overline{A}_i(\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m A^i) + \overline{B}_{\alpha_0}(\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m B^{\alpha_0}) + \overline{C}_{\alpha_0 c}(\tfrac{1}{2}\epsilon_{ab}\mathbf{s}^b_m \mathbf{s}^a_m C^{\alpha_0 c}),\end{aligned} \tag{63}$$

$F_{\alpha_0 c}$ being the only nonvanishing component of η_A, a direct verification shows that the resulting action S_m satisfies Eqs. (24) identically.

Finally, let us determine the gauge-fixed action $S_{m,\mathrm{eff}}$ in (40) for the class of minimal gauges F depending only on A^i and $C^{\alpha_0 c}$. Inserting into (46) for S_m the action (63) and performing the integration over antifields and auxiliary fields we are led to the following expression for $S_{m,\mathrm{eff}}$ (at the lowest order of $\hbar$) in the vacuum functional:

$$Z_m(0) = \int dA^i dB^{\alpha_0} dC^{\alpha_0 c} \exp\{(i/\hbar) S_{m,\mathrm{eff}}\}, \quad S_{m,\mathrm{eff}} = S_{\mathrm{cl}} + W_F,$$

where W_F is given by

$$W_F = m^2 F + \frac{1}{2}\epsilon_{ab}\left(\frac{\delta F}{\delta A^i}\mathbf{s}_m^b \mathbf{s}_m^a A^i + \frac{1}{2}\epsilon_{ab}\frac{\delta F}{\delta C^{\alpha_0 c}}\mathbf{s}_m^b \mathbf{s}_m^a C^{\alpha_0 c}\right) - \frac{1}{2}\epsilon_{ab}\left(\mathbf{s}_m^a A^i \frac{\delta^2 F}{\delta A^i \delta A^j}\mathbf{s}_m^b A^j + \mathbf{s}_m^a C^{\alpha_0 c}\frac{\delta^2 F}{\delta C^{\alpha_0 c}\delta C^{\beta_0 d}}\mathbf{s}_m^b C^{\beta_0 d}\right).$$

Again, this gauge-fixing term W_F can be rewritten as

$$W_F = (\tfrac{1}{2}\epsilon_{ab}\mathbf{s}_m^b \mathbf{s}_m^a + m^2)F,$$

showing that the action $S_{m,\mathrm{eff}}$ is, in fact, osp(1,2)-invariant and that the method of gauge fixing proposed in Sec. III will actually lift the degeneracy of the classical gauge-invariant action. As has been shown recently,[13] in the particular case of Yang–Mills theories $S_{m,\mathrm{eff}}$ coincides with the gauge-fixed action in the massive Curci–Ferrari model[14] in the Delbourgo–Jarvis gauge.[15] The classical action S_{YM} is invariant under the non-Abelian gauge transformations

$$\delta A_\mu^\alpha = D_\mu^{\alpha\beta}\theta^\beta(x), \quad D_\mu^{\alpha\beta} \equiv \delta^{\alpha\beta}\partial_\mu - F^{\alpha\beta\gamma}A_\mu^\gamma,$$

where $F^{\alpha\beta\gamma}$ are the totally antisymmetric structure constants. As before, the osp(1,2)-invariance of the gauge-fixed action

$$S_{m,\mathrm{eff}} = S_{\mathrm{YM}} + (\tfrac{1}{2}\epsilon_{ab}\mathbf{s}_m^b \mathbf{s}_m^a + m^2)F, \quad F = \tfrac{1}{2}(A_\mu^\alpha A^{\mu\alpha} + \xi\epsilon_{cd}C^{\alpha c}C^{\alpha d}),$$

where ξ is the gauge parameter, is assured by construction. Using

$$\mathbf{s}_m^a A_\mu^\alpha = D_\mu^{\alpha\beta}C^{\beta a},$$

$$\mathbf{s}_m^a C^{\alpha b} = \epsilon^{ab}B^\alpha - \tfrac{1}{2}F^{\alpha\beta\gamma}C^{\beta a}C^{\gamma b},$$

$$\mathbf{s}_m^a B^\alpha = -m^2 C^{\alpha a} + \tfrac{1}{2}F^{\alpha\beta\gamma}B^\beta C^{\gamma a} + \tfrac{1}{12}\epsilon_{cd}F^{\alpha\eta\beta}F^{\eta\gamma\delta}C^{\gamma a}C^{\delta c}C^{\beta d},$$

for the gauge-fixing terms one gets

$$\tfrac{1}{4}\epsilon_{ab}\mathbf{s}_m^b \mathbf{s}_m^a (A_\mu^\alpha A^{\mu\alpha}) = A_\mu^\alpha \partial^\mu B^\alpha + \tfrac{1}{2}\epsilon_{ab}(\partial^\mu C^{\alpha b})D_\mu^{\alpha\beta}C^{\beta a},$$

$$\tfrac{1}{4}\epsilon_{ab}\epsilon_{cd}\mathbf{s}_m^b \mathbf{s}_m^a (C^{\alpha c}C^{\alpha d}) = \tfrac{1}{2}m^2\epsilon_{cd}C^{\alpha c}C^{\alpha d} + B^\alpha B^\alpha - \tfrac{1}{24}\epsilon_{ab}\epsilon_{cd}F^{\eta\alpha\beta}F^{\eta\gamma\delta}C^{\alpha a}C^{\beta c}C^{\gamma b}C^{\delta d}.$$

The elimination of B^α can be performed by Gaussian integration; it provides the gauge-fixing term $1/2\xi^{-1}(\partial^\mu A_\mu^\alpha)^2$ and, in addition, among other interactions quartic (anti)ghost terms. This shows that the degeneracy of the classical action is indeed removed.

Concluding, we shall emphasize that, up to now, we have ignored the important question whether the action (63) is the general solution of Eqs. (24), i.e., being stable against perturbations. Unfortunately, this is not the case, because the fields A^i, B^{α_0}, $C^{\alpha_0 c}$ and the antifields $\bar{A}_i$, $\bar{B}_{\alpha_0}$, $\bar{C}_{\alpha_0 c}$ have the same quantum numbers and hence mix under renormalization. Therefore, we are confronted with the complicated problem how the action (63) must be changed in order to ensure the required stability. To attack this problem one is forced to introduce within (63) the antifields in a nonlinear manner (see Ref. 13); however, then the corresponding altered action cannot be expressed in such simple form as in (63). The solution of that problem has been given for a particular case in Ref. 13; a general proof will be given in another paper.[16]

VI. CONCLUDING REMARKS

We have proved the possibility of a consistent generalization of the Sp(2) quantization scheme based on the orthosymplectic superalgebra osp(1,2). Introducing mass terms into the theory, which do not break the extended BRST symmetry, the quantum master equations of the Sp(2)-symmetry must be satisfied in order to fulfill the corresponding equations of the extended BRST symmetry. To ensure Sp(2)-invariance of the theory also in the massless case, then, besides of the requirement of extended BRST symmetry the action S must be subjected to the requirement of Sp(2)-symmetry explicitly. An open problem is the general proof, analogous to Refs. 1 and 3, of existence theorems, i.e., absence of anomalies of the theory.

Finally, let us give some remarks concerning the renormalization of the theory. In Ref. 3 this problem was discussed rather formally; thereby the standard hypothesis on the existence of a regularization respecting the Ward identities for the extended BRST symmetries had been accepted.

On the other hand, there is a well-established renormalization scheme, incidentally the most general one known until now, namely the Bogoliubov–Parasiŭk–Hepp–Zimmermann–Lowenstein (BPHZL) scheme,[17] which does not need any regularization. Moreover, the renormalized quantum action principles, which sum up all properties of the renormalized perturbation series, were first established using the BPHZL renormalization scheme (they were rederived in different other schemes confirming their character as general theorems in renormalization theory, independent of the renormalization scheme). These theorems are extremely powerful and suffice for discussing the most useful identities among renormalized Green's functions, such as Ward identities or their generalizations describing gauge invariance (e.g., the existence proofs for generating equations established in Refs. 1 and 2 could be proven also by means of the action principles without any reference to a given renormalization and regularization scheme). Furthermore, within the BPHZL scheme it is possible to perform renormalization when we are concerned with massless theories. If massless fields are involved, ultraviolet subtractions would generate drastic spurious infrared divergences. Lowenstein and Zimmermann introduced a more involved subtraction procedure which is free of spurious infrared divergences. In order to avoid these divergences one has to introduce a mass $m^2(s-1)^2$ with s being an additional infrared subtraction parameter. Then, the disease that ultraviolet subtractions lead to nonintegrable infrared singularities is cured by performing ultraviolet subtractions and extra infrared subtractions with respect to $(s-1)$. It had been proven rigorously that $s=1$ defines the renormalized massless theory; i.e., the introduction of the mass $m^2(1-s)^2$ does not lead to a contradictory massive theory. Of course, mass terms softly violate the gauge dependence of the S-matrix so that, after performing renormalization, one may take the massless limit $s=1$.

Of course, this renormalization scheme could be applied also in the Sp(2)-approach, but then the introduction of mass terms would violate the extended BRST symmetries. On the other hand, using the osp(1,2)-approach, it is possible to introduce mass terms (at the stage of gauge fixing) in such a way that the Ward identities of the extended BRST symmetries will not be violated, provided the Ward identity of the Sp(2)-symmetry is fulfilled to all orders of perturbation theory! Besides, we can use the quantum action principles to get rigorous statements without any reference to a given renormalization and regularization scheme.

Obviously, the osp(1,2)-covariant frame of quantization can be formulated within the superfield approach[9] without much effort. On the other hand, the generalization of the formalism to the case of L-stage reducible theories analogous to Ref. 2 will be more involved.

APPENDIX A: SUPERALGEBRA osp(1,2)

The (anti)commutation relations of the superalgebra osp(1,2) in the Cartan–Weyl basis read (see Ref. 18)

$$[L_0,L_\pm]=\pm L_\pm\,,\quad [L_+,L_-]=2L_0\,, \tag{A1}$$

$$[L_0,R_\pm]=\pm\tfrac{1}{2}R_\pm\,,\quad [L_\pm,R_\mp]=-R_\pm\,,\quad [L_\pm,R_\pm]=0, \tag{A2}$$

$$\{R_\pm,R_\pm\}=\pm\tfrac{1}{2}L_\pm\,,\quad \{R_+,R_-\}=\tfrac{1}{2}L_0\,, \tag{A3}$$

and for the fundamental representation these generators are given by

$$L_0=\begin{pmatrix}\frac{1}{2} & 0 & 0\\ 0 & -\frac{1}{2} & 0\\ 0 & 0 & 0\end{pmatrix},\quad L_+=\begin{pmatrix}0 & 1 & 0\\ 0 & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\quad L_-=\begin{pmatrix}0 & 0 & 0\\ 1 & 0 & 0\\ 0 & 0 & 0\end{pmatrix},$$

$$R_+=\begin{pmatrix}0 & 0 & \frac{1}{2}\\ 0 & 0 & 0\\ 0 & \frac{1}{2} & 0\end{pmatrix},\quad R_-=\begin{pmatrix}0 & 0 & 0\\ 0 & 0 & -\frac{1}{2}\\ \frac{1}{2} & 0 & 0\end{pmatrix}.$$

The superalgebra (8)–(10) is obtained by the following identifications:

$$(\hbar/i)\overline{\Delta}_0=2L_0\,,\quad (\hbar/i)\overline{\Delta}_\pm=L_\pm\,,\quad (\hbar/i)\overline{\Delta}_m^1=2mR_+\,,\quad (\hbar/i)\overline{\Delta}_m^2=2mR_-\,;$$

so the relations (A1)–(A3) may be written instead as follows ($\alpha=0,+,-$):

$$[\overline{\Delta}_\alpha,\overline{\Delta}_\beta]=(i/\hbar)\epsilon_{\alpha\beta}{}^{\gamma}\overline{\Delta}_\gamma\,, \tag{A4}$$

$$[\overline{\Delta}_\alpha,\overline{\Delta}_m^a]=(i/\hbar)\overline{\Delta}_m^b(\sigma_\alpha)_b{}^a, \tag{A5}$$

$$\{\overline{\Delta}_m^a,\overline{\Delta}_m^b\}=(i/\hbar)m^2(\sigma_\alpha)^{ab}\overline{\Delta}^\alpha, \tag{A6}$$

σ_α generating the group of special linear transformations with the sl(2) algebra:

$$\sigma_\alpha\sigma_\beta=g_{\alpha\beta}+\tfrac{1}{2}\epsilon_{\alpha\beta\beta}\sigma^\gamma,\quad \sigma^\alpha=g^{\alpha\beta}\sigma_\beta\,,\quad \mathrm{Tr}(\sigma_\alpha\sigma_{gb})=2g_{\alpha\beta}\,,$$

$$g^{\alpha\beta}=\begin{pmatrix}1 & 0 & 0\\ 0 & 0 & 2\\ 0 & 2 & 0\end{pmatrix},\quad g^{\alpha\gamma}g_{\gamma\beta}=\delta^\alpha_\beta\,,$$

$\epsilon_{\alpha\beta\gamma}$ being the antisymmetric tensor, $\epsilon_{0+-}=1$. Then, from (A5), the following realization of σ_α is obtained,

$$(\sigma_+)_a{}^b=\begin{pmatrix}0 & -1\\ 0 & 0\end{pmatrix},\quad (\sigma_-)_a{}^b=\begin{pmatrix}0 & 0\\ -1 & 0\end{pmatrix},\quad (\sigma_0)_a{}^b=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},$$

and by raising the first index according to $(\sigma_\alpha)^{ab}=\epsilon^{ac}(\sigma_\alpha)_c{}^b$ we get

$$(\sigma_+)^{ab}=\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},\quad (\sigma_-)^{ab}=\begin{pmatrix}-1 & 0\\ 0 & 0\end{pmatrix},\quad (\sigma_0)^{ab}=\begin{pmatrix}0 & -1\\ -1 & 0\end{pmatrix}.$$

The quadratic Casimir operator is given by $C_2 = 1/2\epsilon_{ab}\overline{\Delta}_m^b\overline{\Delta}_m^a + m^2\overline{\Delta}^\alpha\overline{\Delta}_\alpha$.

APPENDIX B: PROPERTIES OF THE BRACKETS

From the definitions (25), (26) and (29) it follows

$$\epsilon(\{F,G\}_\alpha) = \epsilon(F) + \epsilon(G), \quad \{F,G\}_\alpha = \{G,F\}_\alpha(-1)^{\epsilon(F)\epsilon(G)},$$

$$\epsilon((F,G)^a) = \epsilon(F) + \epsilon(G) + 1, \quad (F,G)^a = -(G,F)^a(-1)^{(\epsilon(F)+1)(\epsilon(G)+1)},$$

i.e., $\{F,G\}_\alpha((F,G)^a)$ defines an even (odd) graded bracket, and

$$\Delta_\alpha(FG) = (\Delta_\alpha F)G + F(\Delta_\alpha G) + \{F,G\}_\alpha, \tag{B1}$$

$$\Delta^a(FG) = (\Delta^a F)G + F(\Delta^a G)(-1)^{\epsilon(F)} + (F,G)^a(-1)^{\epsilon(F)}, \tag{B2}$$

where the last two relations may be understood as the definitions of the new brackets $\{F,G\}_\alpha$ and the extended antibrackets $(F,G)^a$ introduced in Ref. 1, respectively. Furthermore, it holds

$$\{F,GH\}_\alpha = \{F,G\}_\alpha H + G\{F,H\}_\alpha(-1)^{\epsilon(F)\epsilon(G)},$$

$$(F,GH)^a = (F,G)^a H + G(F,H)^a(-1)^{(\epsilon(F)+1)\epsilon(G)},$$

i.e., both brackets act on the algebra of functions under multiplications.

Let us now briefly state the properties of the new brackets $\{F,G\}_\alpha$ and $(F,G)^a$. Applying the following identities [their validity is verified by means of (29)]

$$[\Delta_\alpha,\Delta_\beta] = 0, \quad \{\Delta^a,\Delta^b\} = 0, \quad [\Delta_\alpha,\Delta^a] = 0 \tag{B3}$$

of the operators Δ^a and Δ_α to a product of two functions FG and making use of (B1) and (B2), one gets

$$\Delta_{[\alpha}\{F,G\}_{\beta]} = \{\Delta_{[\alpha}F,G\}_{\beta]} + \{F,\Delta_{[\alpha}G\}_{\beta]},$$

$$\Delta^{\{a}(F,G)^{b\}} = (\Delta^{\{a}F,G)^{b\}} + (F,\Delta^{\{a}G)^{b\}}(-1)^{\epsilon(F)+1},$$

$$\Delta_\alpha(F,G)^a - \Delta^a\{F,G\}_\alpha(-1)^{\epsilon(F)} = (\Delta_\alpha F,G)^a + (F,\Delta_\alpha G)^a - \{\Delta^a F,G\}_\alpha(-1)^{\epsilon(F)} - \{F,\Delta^a G\}_\alpha,$$

where the square (curly) bracket indicates antisymmetrization (symmetrization) in the indices α and β (a and b), respectively. Next, applying the relations (B3) to a product of three functions FGH by means of simple but cumbersome calculations, one arrives at the following Jacobi identities satisfied by the two brackets:

$$\{\{F,G\}_{[\alpha},H\}_{\beta]}(-1)^{\epsilon(F)\epsilon(H)} + \text{cyclic}(F,G,H) \equiv 0, \tag{B4}$$

$$((F,G)^{\{a},H)^{b\}}(-1)^{(\epsilon(F)+1)(\epsilon(H)+1)} + \text{cyclic}(F,G,H) \equiv 0, \tag{B5}$$

$$(\{(F,G)^a,H\}_\alpha - (\{F,G\}_\alpha,H)^a(-1)^{\epsilon(G)})(-1)^{\epsilon(F)(\epsilon(H)+1)} + \text{cyclic}(F,G,H) \equiv 0. \tag{B6}$$

Furthermore, one needs the operators V_α and V_m^a, Eqs. (27) and (28), to obey the osp(1,2)-superalgebra:

$$[V_\alpha,V_\beta] = \epsilon_{\alpha\beta}{}^\gamma V_\gamma, \quad \{V_m^a,V_m^b\} = -m^2(\sigma^\alpha)^{ab}V_\alpha, \quad [V_\alpha,V_m^a] = V_m^b(\sigma_\alpha)_b{}^a. \tag{B7}$$

Applying the identities [their validity is established by means of Eqs. (27)–(29)]

$$[\Delta_\alpha,V_\beta] + [V_\alpha,\Delta_\beta] = \epsilon_{\alpha\beta}{}^\gamma\Delta_\gamma,$$

$$\{\Delta^a,V_m^b\}+\{V_m^a,\Delta^b\}=-m^2(\sigma^\alpha)^{ab}\Delta_\alpha, \tag{B8}$$
$$[\Delta_\alpha,V_m^a]+[V_\alpha,\Delta^a]=\Delta^b(\sigma_\alpha)_b{}^a$$

to a product of two functions FG, one can establish the following relations which define the action of the operators V_α and V_m^a upon the brackets,

$$V_{[\alpha}\{F,G\}_{\beta]}=\epsilon_{\alpha\beta}{}^\gamma\{F,G\}_\gamma+\{V_{[\alpha}F,G\}_{\beta]}+\{F,V_{[\alpha}G\}_{\beta]},$$
$$V_m^{\{a}(F,G)^{b\}}=-m^2(\sigma^\alpha)^{ab}\{F,G\}_\alpha+(V_m^{\{a}F,G)^{b\}}+(F,V_m^{\{a}G)^{b\}}(-1)^{\epsilon(F)+1},$$
$$V_\alpha(F,G)^a-V_m^a\{F,G\}_\alpha(-1)^{\epsilon(F)}=(F,G)^b(\sigma_\alpha)_b{}^a+(V_\alpha F,G)^a+(F,V_\alpha G)^a$$
$$-\{V_m^aF,G\}_\alpha(-1)^{\epsilon(F)}-\{F,V_m^aG\}_\alpha,$$

where, as before, square (curly) bracket means antisymmetrization (symmetrization) in the indices α and β (a and b), respectively.

Note that the properties (B7) of V_m^a and V_α are inherited by the the operators $\overline{\Delta}_m^a=\Delta^a+(i/\hbar)V_m^a$ and $\overline{\Delta}_\alpha=\Delta_\alpha+(i/\hbar)V_\alpha$ [see Eqs. (8)–(10)], due to the properties (B3) and (B8).

Finally, let us specify $F=G=H\equiv S$ to be any bosonic functional S, $\epsilon(S)=0$. Then, the Jacobi identities simplify into

$$\{\{S,S\}_{[\alpha},S\}_{\beta]}\equiv 0,\quad ((S,S)^{\{a},S)^{b\}}\equiv 0,\quad \{(S,S)^a,S\}_\alpha-(\{S,S\}_\alpha,S)^a\equiv 0. \tag{B9}$$

For the action of the operators Δ_α, Δ^a and V_α, V_m^a upon the brackets $\{S,S\}_\alpha$ and $(S,S)^a$ one becomes

$$\tfrac{1}{2}\Delta_{[\alpha}\{S,S\}_{\beta]}=\{\Delta_{[\alpha}S,S\}_{\beta]},$$
$$\tfrac{1}{2}\Delta^{\{a}(S,S)^{b\}}=(\Delta^{\{a}S,S)^{b\}}, \tag{B10}$$
$$\tfrac{1}{2}(\Delta_\alpha(S,S)^a-\Delta^a\{S,S\}_\alpha)=(\Delta_\alpha S,S)^a-\{\Delta^aS,S\}_\alpha$$

and

$$\tfrac{1}{2}V_{[\alpha}\{S,S\}_{\beta]}=\{V_{[\alpha}S,S\}_{\beta]}+\tfrac{1}{2}\epsilon_{\alpha\beta}{}^\gamma\{S,S\}_\gamma,$$
$$\tfrac{1}{2}V_m^{\{a}(S,S)^{b\}}=(V_m^{\{a}S,S)^{b\}}-\tfrac{1}{2}m^2(\sigma^\alpha)^{ab}\{S,S\}_\alpha, \tag{B11}$$
$$\tfrac{1}{2}(V_\alpha(S,S)^a-V_m^a\{S,S\}_\alpha)=(V_\alpha S,S)^a-\{V_m^aS,S\}_\alpha+\tfrac{1}{2}(S,S)^b(\sigma_\alpha)_b{}^a.$$

APPENDIX C: COMPATIBILITY PROOF FOR GENERATING EQUATIONS

A solution $\overline{S}_m$ of the generating equations (24) at the lowest-order approximation has been constructed in (23):

$$\tfrac{1}{2}(\overline{S}_m,\overline{S}_m)^a+V_m^a\overline{S}_m=0,\quad \tfrac{1}{2}\{\overline{S}_m,\overline{S}_m\}_\alpha+V_\alpha\overline{S}_m=0. \tag{C1}$$

Let us prove that the generalization (30) of these equations at any order of $\hbar$, namely,

$$\tfrac{1}{2}(S_m,S_m)^a+V_m^aS_m+(\hbar/i)\Delta^aS_m=0,\quad \tfrac{1}{2}\{S_m,S_m\}_\alpha+V_\alpha S_m+(\hbar/i)\Delta_\alpha S_m=0, \tag{C2}$$

for the full quantum action

$$S_m = \overline{S_m} + \sum_{n=1}^{\infty} \hbar^n S_{m(n)},$$

is compatible with the algebraic properties of the brackets $(S_m, S_m)^a$ and $\{S_m, S_m\}_\alpha$ (see Appendix B).

Suppose that functionals $S_{m(k)}$, $k \leqslant n$, have been found obeying Eqs. (C2) up to and including the nth order in $\hbar$. Then for the $(n+1)$th order the following equations should be satisfied:

$$\overline{Q}^a_m S_{m(n+1)} = Y^a_{m(n+1)}, \quad \overline{Q}_\alpha S_{m(n+1)} = Y_{\alpha(n+1)}, \tag{C3}$$

where $\overline{Q}^a_m$ and $\overline{Q}_\alpha$ are the lowest-order approximations of the operators (37),

$$\overline{Q}^a_m X \equiv (\overline{S_m}, X)^a + V^a_m X, \quad \overline{Q}_\alpha X \equiv \{\overline{S_m}, X\}_\alpha + V_\alpha X, \tag{C4}$$

X being an arbitrary functional. By virtue of Eqs. (C1) the operators $\overline{Q}^a_m$ and $\overline{Q}_\alpha$ obey the osp(1,2)-superalgebra:

$$[\overline{Q}_\alpha, \overline{Q}_\beta] = \epsilon_{\alpha\beta}{}^\gamma \overline{Q}_\gamma, \quad [\overline{Q}_\alpha, \overline{Q}^a_m] = \overline{Q}^b_m (\sigma_\alpha)_b{}^a, \quad \{\overline{Q}^a_m, \overline{Q}^b_m\} = -m^2 (\sigma^\alpha)^{ab} \overline{Q}_\alpha. \tag{C5}$$

The functionals $Y^a_{m(n+1)}$ and $Y_{\alpha(n+1)}$ in Eqs. (C3) have the following form:

$$Y^a_{m(n+1)} = i\Delta^a S_{m(n)} - \frac{1}{2}\sum_{k=1}^{n} (S_{m(n+1-k)}, S_{m(k)})^a,$$

$$Y_{\alpha(n+1)} = i\Delta_\alpha S_{m(n)} - \frac{1}{2}\sum_{k=1}^{n} \{S_{m(n+1-k)}, S_{m(k)}\}_\alpha.$$

In order to ensure that Eqs. (C3) are compatible with the osp(1,2)-superalgebra (85), it is necessary that the following relations hold:

$$\begin{aligned} \overline{Q}_\alpha Y_{\beta(n+1)} - \overline{Q}_\beta Y_{\alpha(n+1)} &= \epsilon_{\alpha\beta}{}^\gamma Y_{\gamma(n+1)}, \\ \overline{Q}^a_m Y^b_{m(n+1)} + \overline{Q}^b_m Y^a_{m(n+1)} &= -m^2 (\sigma^\alpha)^{ab} Y_{\alpha(n+1)}, \\ \overline{Q}_\alpha Y^a_{m(n+1)} - \overline{Q}^a_m Y_{\alpha(n+1)} &= Y^b_{m(n+1)} (\sigma_\alpha)_b{}^a. \end{aligned} \tag{C6}$$

Let us show that the relations (C6) indeed are satisfied. To begin with, we consider the Jacobi identity $\{S_m, \{S_m, S_m\}_{[\alpha}\}_{\beta]} \equiv 0$, Eqs. (B9). By virtue of the algebraic properties (B10) and (B11) of $\{S_m, S_m\}_\alpha$, the left-hand side of this identity can be rewritten as

$$\begin{aligned} \{S_m, \tfrac{1}{2}\{S_m, S_m\}_{[\alpha}\}_{\beta]} &\equiv (S_m, \tfrac{1}{2}\{S_m, S_m\}_{[\alpha} + V_{[\alpha} S_m + (\hbar/i)\Delta_{[\alpha} S_m\}_{\beta]} - \{S_m, V_{[\alpha} S_m + (\hbar/i)\Delta_{[\alpha} S_m\}_{\beta]} \\ &= \{S_m, \tfrac{1}{2}\{S_m, S_m\}_{[\alpha} + V_{[\alpha} S_m + (\hbar/i)\Delta_{[\alpha} S_m\}_{\beta]} \\ &\quad - V_{[\alpha}(\tfrac{1}{2}\{S_m, S_m\}_{\beta]} + V_{\beta]} S_m + (\hbar/i)\Delta_{\beta]} S_m) - (\hbar/i)\Delta_{[\alpha}(\tfrac{1}{2}\{S_m, S_m\}_{\beta]} \\ &\quad + V_{\beta]} S_m + (\hbar/i)\Delta_{\beta]} S_m) + \epsilon_{\alpha\beta}{}^\gamma (\tfrac{1}{2}\{S_m, S_m\}_\gamma + V_\gamma S_m + (\hbar/i)\Delta_\gamma S_m). \end{aligned} \tag{C7}$$

Considering the generating equation (C2) in the $(n+1)$th order in $\hbar$,

$$\tfrac{1}{2}\{S_m, S_m\}_\alpha + V_\alpha S_m + (\hbar/i)\Delta_\alpha S_m = \hbar^{n+1}(\overline{Q}_\alpha S_{m(n+1)} - Y_{\alpha(n+1)}) + O(\hbar^{n+2}),$$

then for the equality (C7) in the $(n+1)$th order one gets

$$\overline{Q}_{[\beta}(\overline{Q}_{\alpha]}S_{m(n+1)}-Y_{\alpha](n+1)})+\epsilon_{\alpha\beta}{}^{\gamma}(\overline{Q}_{\gamma}S_{m(n+1)}-Y_{\gamma(n+1)})=0, \tag{C8}$$

where the definition (C4) of the operator $\overline{Q}_\alpha$ has been used. Taking into account the properties (C5) of $\overline{Q}_\alpha$ we conclude from (C8) that the first relation (C6) is fulfilled. In the same way, using the Jacobi identities $(S_m,(S_m,S_m)^{\{a})^{b\}}\equiv 0$ and $\{S_m,(S_m,S_m)^a\}_\alpha-(S_m,\{S_m,S_m\}_\alpha)^a\equiv 0$, Eqs. (B9), it can be verified that also the remaining relations (C6) are fulfilled, thus establishing the compatibility of Eqs. (C3). Obviously, by virtue of (C5), the equations (C6) are solved by

$$Y^a_{m(n+1)}=\overline{Q}^a_m X_{m(n+1)}, \quad Y_{\alpha(n+1)}=\overline{Q}_\alpha X_{m(n+1)}, \tag{C9}$$

with arbitrary functional $X_{m(n+1)}$. Here, we do not check that any solution of (C6) has the form (C9), which means that the theory is anomaly free; in order to check that, one can adopt the methods of Refs. 1 and 3. Choosing $S_{m(n+1)}=X_{m(n+1)}$ the generating equations (C2) are satisfied up to and including the $(n+1)$th order in $\hbar$ and we can proceed by induction.

APPENDIX D: NATURAL TRANSFORMATIONS OF SOLUTIONS OF THE GENERATING EQUATIONS

In this Appendix we study transformations that allow one to consider the characteristic arbitrariness of a solution of the generating equations. These transformations convert any local solution S_m of Eqs. (30) into another local solution $\tilde{S}_m$ of the same equations. For that reason let us introduce an interpolating functional $S_m(\zeta)$, $0\leqslant\zeta\leqslant 1$, where $S_m(1)\equiv\tilde{S}_m$ is the solution we are looking for and where $S_m(0)\equiv S_m$. This functional is required to satisfy the generating equations

$$\tfrac{1}{2}(S_m(\zeta),S_m(\zeta))^a-i\hbar\overline{\Delta}^a_m S_m(\zeta)=0, \quad \tfrac{1}{2}\{S_m(\zeta),S_m(\zeta)\}_\alpha-i\hbar\overline{\Delta}_\alpha S_m(\zeta)=0. \tag{D1}$$

Differentiating Eqs. (90) with respect to ζ for $\partial S_m(\zeta)/\partial\zeta$ one gets the conditions

$$Q^a_m(\zeta)\frac{\partial}{\partial\zeta}S_m(\zeta)=0, \quad Q_\alpha(\zeta)\frac{\partial}{\partial\zeta}S_m(\zeta)=0, \tag{D2}$$

where the operators $Q^a_m(\zeta)$ and $Q_\alpha(\zeta)$, analogous to (37), are defined by

$$Q^a_m(\zeta)X\equiv(S_m(\zeta),X)^a-i\hbar\overline{\Delta}_m X, \quad Q_\alpha(\zeta)X\equiv\{S_m(\zeta),X\}_\alpha-i\hbar\overline{\Delta}_\alpha X,$$

X being an arbitrary functional. Hence, analogous to (38), we have

$$[Q_\alpha(\zeta),Q_\beta(\zeta)]=\epsilon_{\alpha\beta}{}^{\gamma}Q_\gamma(\zeta),$$

$$[Q_\alpha(\zeta),Q^a_m(\zeta)]=Q^b_m(\zeta)(\sigma_\alpha)_b{}^a,$$

$$\{Q^a_m(\zeta),Q^b_m(\zeta)\}=-m^2(\sigma^\alpha)^{ab}Q_\alpha(\zeta).$$

Let us make for $\partial S_m(\zeta)/\partial\zeta$ the following ansatz:

$$\frac{\partial}{\partial\zeta}S_m(\zeta)=\hat{W}_m(\zeta)Y, \quad \hat{W}_m(\zeta)\equiv\frac{1}{2}\epsilon_{ab}Q^b_m(\zeta)Q^a_m(\zeta)+m^2, \tag{D3}$$

with $Y=Y(\phi^A,\overline{\phi}_A,\phi^*_{Aa},\eta_A)$ an arbitrary local Sp(2)-scalar. Then, by virtue of

$$Q^a_m(\zeta)\hat{W}_m(\zeta)=\tfrac{1}{2}m^2(\sigma_\alpha)^a{}_b Q^b_m(\zeta)Q^\alpha(\zeta), \quad Q_\alpha(\zeta)\hat{W}_m(\zeta)=\hat{W}_m(\zeta)Q_\alpha(\zeta),$$

the (consistency) conditions (D2) are fulfilled provided it holds that

$$Q_\alpha(\zeta)Y=0, \quad (\sigma_\alpha)_B{}^A \frac{\delta Y}{\delta\phi^A}\phi^B+V_\alpha Y=0. \tag{D4}$$

The equations

$$Q_m^a(\zeta)\left(\frac{\delta S_m(\zeta)}{\delta\eta_A}-\phi^A\right)=0, \quad Q_\alpha\left(\frac{\delta S_m(\zeta)}{\delta\eta_A}-\phi^A\right)=0,$$

which are obtained from (D1) after differentiating with respect to η_A, and

$$Q_\alpha(\zeta)Y=(\sigma_\alpha)_B{}^A\left(\frac{\delta S_m(\zeta)}{\delta\phi^A}\frac{\delta Y}{\delta\eta_B}+\frac{\delta Y}{\delta\phi^A}\left(\frac{\delta S_m(\zeta)}{\delta\eta_B}-\phi^B\right)-i\hbar\Delta_\alpha Y\right)=0$$

suggest that the natural solution of the requirement (D3) is [see (39)]

$$\frac{\delta S_m(\zeta)}{\delta\eta_A}=\phi^A, \quad \frac{\delta Y}{\delta\eta_A}=0, \tag{D5}$$

i.e., that $S_m(\zeta)$ is linear in η_A and that $Y=Y(\phi^A,\overline{\phi}_A,\phi^*_{Aa})$ must be independent of η_A. Then, as a consequence of the restrictions (D5), the second equation in (D1) becomes

$$(\sigma_\alpha)_B{}^A\frac{\delta S_m(\zeta)}{\delta\phi^A}\phi^B+V_\alpha S_m(\zeta)=0. \tag{D6}$$

The integration of Eq. (D3) leads to

$$\exp\{(i/\hbar)S_m(\zeta)\}=\hat{U}_m(\zeta Y)\exp\{(i/\hbar)S_m\},$$

$$\hat{U}_m(\zeta Y)=\exp\{(\hbar/i)\hat{T}_m(\zeta Y)\}, \quad \hat{T}_m(\zeta Y)=\tfrac{1}{2}\epsilon_{ab}\{\overline{\Delta}_m^b,[\overline{\Delta}_m^a,\zeta Y]\}+(i/\hbar)^2m^2\zeta Y.$$

From this transformation, by virtue of

$$\left[\overline{\Delta}_m^a,\frac{\delta}{\delta\eta_A}-\phi^A\right]=0, \quad \left[\overline{\Delta}_\alpha,\frac{\delta}{\delta\eta_A}-\phi^A\right]=0, \quad \left[Y,\frac{\delta}{\delta\eta_A}-\phi^A\right]=0,$$

it follows that imposing the conditions (D5) for $\zeta=0$ is sufficient to ensure their validity also for $0<\zeta\leqslant 1$, so that $S_m(\zeta)$ indeed solves the first equation in (D1) and Eq. (D6). Moreover, it is seen that the gauge (12) itself is introduced through the use of a special transformation of this kind, namely by choosing $Y=F(\phi^A)$ and $\zeta=1$.

For the iterative solution of Eq. (D3) in the form of a series expansion in powers of ζ one gets

$$S_m(\zeta)=\sum_{n=0}^{\infty}\zeta^n S_m^{(n)}, \quad S_m^{(0)}\equiv S_m,$$

$$(n+1)S_m^{(n+1)}=\frac{1}{2}\epsilon_{ab}\left\{\sum_{k=0}^{n}(S_m^{(k)},(S_m^{(n-k)},Y)^a)^b+(\hbar/i)(S_m^{(n)},\overline{\Delta}_m^a Y)^b+(\hbar/i)\overline{\Delta}_m^b(S_m^{(n)},Y)^a\right.$$
$$\left.+(\hbar/i)^2\delta_{n,0}\overline{\Delta}_m^b\overline{\Delta}_m^a Y\right\}+\delta_{n,0}m^2Y, \quad n\geqslant 0,$$

which shows that if both S_m and Y are local functions, then $S_m(\zeta)$ is a local function as well.

APPENDIX E: COMPONENTWISE NOTATION OF THE TRANSFORMATIONS (19)

In componentwise notation the extended BRST- and Sp(2)-transformations (19) of the antifields read as follows (D_i and E_{α_0} have been put equal to zero):

$$
\begin{aligned}
&V_m^a \bar{A}_i = \epsilon^{ab} A_{ib}^*, \qquad V_\alpha \bar{A}_i = 0,\\
&V_m^a A_{ib}^* = m^2 \delta_b^a \bar{A}_i, \quad V_\alpha A_{ib}^* = A_{id}^* (\sigma_\alpha)^d{}_b,\\
&V_m^a \bar{B}_{\alpha_0} = \epsilon^{ab} B_{\alpha_0 b}^*, \quad V_\alpha \bar{B}_{\alpha_0} = 0,\\
&V_m^a B_{\alpha_0 b}^* = m^2 \delta_b^a \bar{B}_{\alpha_0}, \quad V_\alpha B_{\alpha_0 b}^* = B_{\alpha_0 d}^* (\sigma_\alpha)^d{}_b,\\
&V_m^a \bar{C}_{\alpha_0 c} = \epsilon^{ab} C_{\alpha_0 bc}^*, \quad V_\alpha \bar{C}_{\alpha_0 c} = \bar{C}_{\alpha_0 d} (\sigma_\alpha)^d{}_c,\\
&V_m^a F_{\alpha_0 c} = m^2 \epsilon^{ab} (C_{\alpha_0 bc}^* - C_{\alpha_0 cb}^*), \quad V_{\alpha_0 c} = F_{\alpha_0 d} (\sigma_\alpha)^d{}_c,\\
&V_m^a C_{\alpha_0 bc}^* = m^2 (\delta_b^a \bar{C}_{\alpha_0 c} + \delta_c^a \bar{C}_{\alpha_0 b}) - \delta_b^a F_{\alpha_0 c}, \quad V_\alpha C_{\alpha_0 bc}^* = C_{\alpha_0 dc}^* (\sigma_\alpha)^d{}_b + C_{\alpha_0 bd}^* (\sigma_\alpha)^d{}_c,
\end{aligned}
\tag{D7}
$$

where the additional antifield $F_{\alpha_0 c}$ has to be introduced in order to obey the osp(1,2)-superalgebra (C7) (see Appendix B). Let us stress that expressing this algebra through operator identities is a stronger restriction than satisfying this algebra by the help of (anti)BRST transformations (D7), which could be also realized without introducing $F_{\alpha_0 c}$, namely by choosing $C_{\alpha_0 ab}^* = C_{\alpha_0 ba}^*$.

The componentwise notation of the operators V_m^a, V_α and Δ^a, Δ_α is given by [see (27)–(29)]

$$
\begin{aligned}
V_m^a =\; & \epsilon^{ab} A_{ib}^* \frac{\delta}{\delta \bar{A}_i} + m^2 \bar{A}_i \frac{\delta}{\delta A_{ia}^*} + \epsilon^{ab} B_{\alpha_0 b}^* \frac{\delta}{\delta \bar{B}^{\alpha_0}} + m^2 \bar{B}^{\alpha_0} \frac{\delta}{\delta B_{\alpha_0 a}^*} + \epsilon^{ab} C_{\alpha_0 bc}^* \frac{\delta}{\delta \bar{C}_{\alpha_0 c}}\\
& + m^2 \bar{C}_{\alpha_0 c} \left(\frac{\delta}{\delta C_{\alpha_0 ac}^*} + \frac{\delta}{\delta C_{\alpha_0 ca}^*} \right) - F_{\alpha_0 c} \frac{\delta}{\delta C_{\alpha_0 ac}^*} + m^2 \epsilon^{ab} (C_{\alpha_0 bc}^* - C_{\alpha_0 cb}^*) \frac{\delta}{\delta F_{\alpha_0 c}},
\end{aligned}
$$

$$
\begin{aligned}
V_\alpha =\; & A_{id}^* (\sigma_\alpha)^d{}_b \frac{\delta}{\delta A_{ib}^*} + B_{\alpha_0 d}^* (\sigma_\alpha)^d{}_b \frac{\delta}{\delta B_{\alpha_0 b}^*} + \bar{C}_{\alpha_0 d} (\sigma_\alpha)^d{}_c \frac{\delta}{\delta \bar{C}_{\alpha_0 c}}\\
& + (C_{\alpha_0 dc}^* (\sigma_\alpha)^d{}_b + C_{\alpha_0 bd}^* (\sigma_\alpha)^d{}_c) \frac{\delta}{\delta C_{\alpha_0 bc}^*} + F_{\alpha_0 d} (\sigma_\alpha)^d{}_c \frac{\delta}{\delta F_{\alpha_0 c}},
\end{aligned}
$$

and

$$
\Delta^a = (-1)^{\epsilon_i} \frac{\delta_L}{\delta A^i} \frac{\delta}{\delta A_{ia}^*} + (-1)^{\epsilon_{\alpha_0}} \frac{\delta_L}{\delta B^{\alpha_0}} \frac{\delta}{\delta B_{\alpha_0 a}^*} + (-1)^{\epsilon_{\alpha_0}+1} \frac{\delta_L}{\delta C^{\alpha_0 c}} \frac{\delta}{\delta C_{\alpha_0 ac}^*},
$$

$$
\Delta_\alpha = (-1)^{\epsilon_{\alpha_0}+1} (\sigma_\alpha)_d{}^c \frac{\delta_L}{\delta C^{\alpha_0 c}} \frac{\delta}{\delta F_{\alpha_0 d}}.
$$

Then, it can be verified that V_m^a, V_α and Δ^a, Δ_α fulfill the (anti)commutation relations (B3), (B7) and (B5) (see Appendix B).

Constructive inversion of energy trajectories in quantum mechanics

Richard L. Hall
Department of Mathematics and Statistics, Concordia University, 1455 de Maisonneuve Boulevard West, Montréal, Québec H3G 1M8, Canada

(Received 22 May 1998; accepted for publication 30 September 1998)

We suppose that the ground-state eigenvalue $E=F(v)$ of the Schrödinger Hamiltonian $H=-\Delta+vf(x)$ in one dimension is known for all values of the coupling $v>0$. The potential shape $f(x)$ is assumed to be symmetric, bounded below, and monotone increasing for $x>0$. A fast algorithm is devised which allows the potential shape $f(x)$ to be reconstructed from the energy trajectory $F(v)$. Three examples are discussed in detail: a shifted power-potential, the exponential potential, and the sech-squared potential are each reconstructed from their known exact energy trajectories. © *1999 American Institute of Physics.*

I. INTRODUCTION

This paper is concerned with what may be called ''geometric spectral inversion.'' We suppose that a discrete eigenvalue $E=F(v)$ of the Schrödinger Hamiltonian

$$H=-\Delta+vf(x) \tag{1.1}$$

is known for all sufficiently large values of the coupling parameter $v>0$ and we try to use this data to reconstruct the potential shape f. The usual ''forward'' problem would be: given the potential (shape) $f(x)$, find the energy trajectory $F(v)$; the problem we now consider is the inverse of this $F\rightarrow f$.

This problem must at once be distinguished from the ''inverse problem in the coupling constant'' discussed, for example, by Chadan and Sabatier.[1] In this latter problem, the discrete part of the ''input data'' is a set $\{v_i\}$ of values of the coupling constant that all yield the identical energy eigenvalue E. The index i might typically represent the number of nodes in the corresponding eigenfunction. In contrast, for the problem discussed in the present paper, i is kept fixed and the input data is the graph $(F(v),v)$, where the coupling parameter has any value $v>v_c$, and v_c is the critical value of v for the support of a discrete eigenvalue with i nodes. We shall mainly discuss the bottom of the spectrum $i=0$ in this paper. However, on the basis of results we have obtained for the inversion (IWKB) of the Wentzel–Kramers–Brillouin (WKB) approximation,[2] there is good reason to believe that constructive inversion may also be possible starting from any discrete eigenvalue trajectory $F_i(v)$, $i>0$. In fact, perhaps not surprisingly, IWKB yields better results starting from higher trajectories; moreover, they become asymptotically exact as the eigenvalue index is increased without limit.

By making suitable assumptions concerning the class of potential shapes, theoretical progress has already been made with this inversion problem.[3–5] The most important assumptions that we retain throughout the present paper are that $f(x)$ is symmetric, monotone increasing for $x>0$, and bounded below; consequently the minimum value is $f(0)$. We assume that our spectral data, the energy trajectory $F(v)$, derives from a potential shape $f(x)$ with these features. We have discussed[3] how two potential shapes f_1 and f_2 can cross over and still preserve spectral ordering $F_1<F_2$. It is known[4] that lowest point $f(0)$ of f is given by the limit

$$f(0)=\lim_{v\to\infty}\frac{F(v)}{v}. \tag{1.2}$$

We have proved[4] that a potential shape f has a finite flat portion $(f'(x)=0)$ in its graph starting at $x=0$ if and only if the mean kinetic energy is bounded. That is to say, $s=F(v)-vF'(v)<K$, for some positive number K. More specifically, the size b of this patch can be estimated from F by means of the inequality

$$s\leqslant K\Rightarrow f(x)=f(0),\quad |x|\leqslant b,\quad \text{and}\quad b=\frac{\pi}{2}K^{-1/2}. \tag{1.3}$$

The monotonicity of the potential, which allows us to prove results like this, also yields the

Concentration Lemma:[4]

$$q(v)=\int_{-a}^{a}\psi^2(x,v)dx>\frac{f(a)-F'(v)}{f(a)-f(0)}\to 1,\quad v\to\infty, \tag{1.4}$$

where $\psi(x,v)$ is the normalized eigenfunction satisfying $H\psi=F(v)\psi$. More importantly, perhaps, if $F(v)$ derives from a symmetric monotone potential shape f which is bounded below, then f is *uniquely* determined.[5] The significance of this result can be appreciated more clearly upon consideration of an example. Suppose the bottom of the spectrum of H is given by $F(v)=\sqrt{v}$, what is f? It is well known, of course, that $f(x)=x^2\to F_0(v)=\sqrt{v}$; but are there any others? Are scaling arguments reversible? A possible source of disquiet for anyone who ponders such questions is the uncountable number of (unsymmetric) perturbations[6] of the harmonic oscillator all of which have the identical spectrum to that of the unperturbed oscillator $f(x)=x^2$.

If, in addition to symmetry and monotonicity, we also assume that a potential shape $f_1(x)$ vanishes at infinity and that $f_1(x)$ has area, then a given trajectory function $F_1(v)$ corresponding to $f_1(x)$ can be ''scaled''[5] to a standard form in which the new function $F(v)=\alpha F_1(\beta v)$ corresponds to a potential shape $f(x)$ with area -2 and minimum value $f(0)=-1$. Thus square-well potentials, which of course are completely determined by depth and area, are immediately invertible; moreover it is known that, amongst all standard potentials, the square-well is ''extremal'' for it has the lowest possible energy trajectory. In Ref. 5 an approximate variational inversion method is developed; it is also demonstrated constructively that all separable potentials are invertible. However, these results and additional constraints are not used in the present paper. When a potential has area $2A$, we first assumed, during our early attempts at numerical inversion, that it would be very useful to determine A from $F(v)$ and then appropriately constrain the inversion process. However, the area constraint did not turn out to be useful. Thus the numerical method we have established for constructing $f(x)$ from $F(v)$ does not depend on the use of this constraint, and is therefore not limited to the reconstruction of potentials which vanish at infinity and have an area.

Much of numerical analysis assumes that errors arising from arithmetic computations or from the computation of elementary functions is negligibly small. The errors usually studied in depth are those that arise from the discrete representation of continuous objects such as functions, or from operations on them, such as derivatives or integrals. In this paper we shall take this separation of numerical problems to a higher level. We shall assume that we have a numerical method for solving the eigenvalue problem in the *forward* direction $f(x)\to F(v)$ that is reliable and may be considered for our purposes to be essentially error free. Our main emphasis will be on the design of an effective algorithm for the inverse problem *assuming* that the forward problem is numerically soluble. The forward problem is essential to our methods because we shall need to know not only the given exact energy trajectory $F(v)$ but also, at each stage of the reconstruction, what eigenvalue a partly reconstructed potential generates. This line of thought immediately indicates that we shall also need a way of temporarily extrapolating a partly reconstructed potential to all x.

Our constructive inversion algorithm hinges on the assumed symmetry and monotonicity of $f(x)$. This allows us to start the reconstruction of $f(x)$ at $x=0$, and sequentially increase *x*. In Sec. II it is shown how numerical estimates can be made for the shape of the potential near $x=0$, that is for $x<b$, where *b* is a parameter of the algorithm. In Sec. III we explore the implications of the potential's monotonicity for the ''tail'' of the wave function. In Sec. IV we establish a numerical representation for the form of the unknown potential for $x>b$ and construct our inversion algorithm. In Sec. V the algorithm is applied to three test problems.

II. THE RECONSTRUCTION OF $f(x)$ NEAR $x=0$

Since the energy trajectory $F(v)$ which we are given is assumed to arise from a symmetric monotone potential, and since the spectrum generated by the potential is invariant under shifts along the *x*-axis, we may assume without loss of generality that the minimum value of the potential occurs at $x=0$. We now investigate the behavior of $F(v)$, either analytically or numerically, for large values of v. The purpose is to establish a value for the starting point $x=b>0$ of our inversion algorithm and the shape of the potential in the interval $x\in[0,b]$. First of all, the minimum value $f(0)$ of the potential is provided by the limit (1.2). Now, if the mean kinetic energy $s=(\psi,-\Delta\psi)=F(v)-vF'(v)$ is found to be bounded above by a positive number *K*, then we know[4] that the potential shape $f(x)$ satisfies $f(x)=f(0)$, $x\in[0,b]$, where *b* is given by (1.3). In this case we have a value for *b* and also the shape $f(x)$ inside the interval $[0,b]$.

If the mean potential energy *s* is (or appears numerically to be) unbounded, then we adopt another strategy: we model $f(x)$ as a shifted power potential near $x=0$. Since we never know $f(x)$ *exactly*, we shall need another symbol for the approximation we are currently using for $f(x)$. We choose this to be $g(x)$ and we suppose that the bottom of the spectrum of $-\Delta+vg(x)$ is given by $G(v)$. The goal is to adjust $g(x)$ until $G(v)$ is close to the given $F(v)$. Thus we write

$$f(x)\approx g(x)=f(0)+Ax^q,\quad x\in[0,b]. \tag{2.1}$$

Therefore we have three positive parameters to determine, *b*, *A*, and *q*. We first suppose that $g(x)$ has the form (2.1) for *all* $x\geqslant 0$. We now choose a ''large'' value v_1 of v. This is related to the later choice of *b* by a bootstrap argument; the idea is that we choose v_1 so large that the turning point determined by

$$\psi_{xx}(x,v_1)/\psi(x,v_1)=v_1f(x)-F(v)=0 \tag{2.2}$$

is equal to *b*. The concentration lemma guarantees that this is possible. By scaling arguments we have

$$G(v)=f(0)v+E(q)(vA)^{2/(2+q)}, \tag{2.3}$$

where $E(q)$ is the bottom of the spectrum of the pure-power Hamiltonian $-\Delta+|x|^q$. We now ''fit'' $G(v)$ to $F(v)$ by the equations $G(v_1)=F(v_1)$ and $G(2v_1)=F(2v_1)$ which yield the estimate for *q* given by

$$\eta=\frac{2}{2+q}=\frac{\log(F(2v_1)-2v_1f(0))-\log(F(v_1)-v_1f(0))}{\log(2)}. \tag{2.4}$$

Thus *A* is given by

$$A=((F(v_1)-v_1f(0))/E(q))^{1/\eta}/v_1. \tag{2.5}$$

We choose *b* to be equal to the turning point corresponding to the model potential $g(x)$ with the smaller value of v, that is to say so that $f(0)+Ab^q=F(v_1)/v_1$, or

$$b=\left(\frac{F(v_1)-v_1f(0)}{Av_1}\right)^{1/q}. \tag{2.6}$$

Thus we have determined the three parameters which define the potential model $g(x)$ for $x\in[-b,b]$.

III. THE TAIL OF THE WAVE FUNCTION

Let us suppose that the ground-state wave function is $\psi(x,v)$. Thus the turning point $\psi_{xx}(x,v)=0$ occurs for a given v when

$$x=x_t(v)=f^{-1}(R(v)),\quad R(v)=\left(\frac{F(v)}{v}\right). \tag{3.1}$$

The concentration lemma (1.4) quantifies the tendency of the wave function to become, as the coupling v is increased, progressively more concentrated on the patch $[-c,c]$, where $x=c$ is the point (perhaps zero) where $f(x)$ first starts to increase. This allows us to think in terms of the wave function having a ''tail.'' We think of a symmetric potential as having been determined from $x=0$ up to the current point x. The question we now ask is: what value of v should we use to determine how $f(x)$, or, more particularly, our *approximation* $g(x)$ for $f(x)$, continues beyond the current point. We have found that a good choice is to choose v so that the turning point $x_t(v)=x/2$, or some other similar fixed fraction $\sigma<1$ of the current x value. The algorithm seems to be insensitive to this choice. Since $g(x)$ has been constructed up to the current point, and $F(v)$ is known, the value of v required follows by inverting (3.1). It has been proven[4] that $R(v)$ is monotone and therefore invertible. Hence we have the following general recipe for v:

$$v=R^{-1}(g(\sigma x)),\quad \sigma=\tfrac{1}{2}. \tag{3.2}$$

Since we can only determine Schrödinger eigenvalues of $H=-\Delta+vg(x)$ if the potential is defined for all x, we must have a policy about temporarily extending $g(x)$. We have tried many possibilities and found the simplest and most effective method is to extend $g(x)$ in a straight line, with the slope to be determined.

In Fig. 1 we illustrate the ideas just discussed for the case of the sech-squared potential. The inset graph shows the sech-squared potential perturbed from $x=x_a$ by five straight line extensions; meanwhile the main graph shows the corresponding set of five wave functions which agree for $0\leqslant x\leqslant x_a$ and then continue with different ''tails'' dictated by the corresponding potential extensions. The value of the coupling v is the value that makes the turning point of the wave function occur at $x=x_a/2$. This figure illustrates the sort of graphical study that has lead to the algorithm described in this paper.

IV. THE INVERSION ALGORITHM

We must first define the ''current'' approximation $g(x)$ for the potential $f(x)$ sought. For values of x less than b, $g(x)$ is defined either as the horizontal line $f(x)=f(0)$ or as the shifted power potential (2.1). For values of x greater than b, the x-axis is divided into steps of length h. Thus the ''current'' value of x would be of the form $x=x_k=b+kh$, where k is a positive integer. The idea is that $g(x_k)$ is determined sequentially and $g(x)$ is interpolated linearly between the x_k points. We suppose that $\{g(x_k)\}$ have already been determined up to k and we need to find $y=g(x_{k+1})$. For $x\geqslant x_k$ we let

$$g(x)=g(x_k)+(y-g(x_k))\frac{x-x_k}{h}. \tag{4.1}$$

If, from a study of $F(v)$, the underlying potential $f(x)$ has been shown[5] to be bounded above, it is convenient to rescale $F(v)$ so that it corresponds to a potential shape $f(x)$ which vanishes at

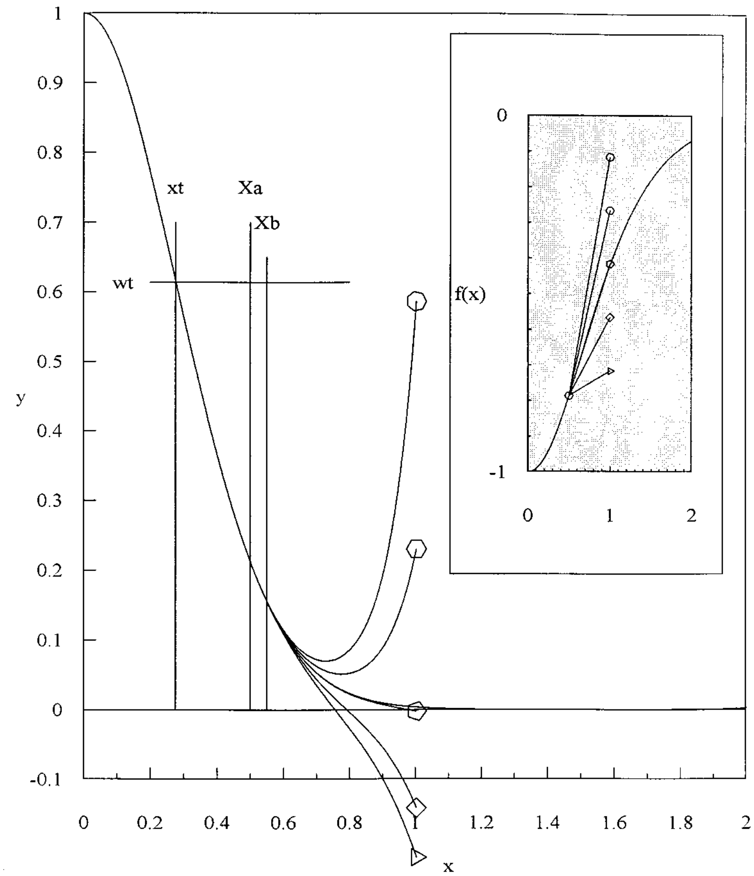

FIG. 1. The potential $f(x) = -\text{sech}^2(x)$ is perturbed from $x = x_a$ by straight-line segments. Each segment leads to a perturbation in the tail of the corresponding wave function. The coupling v is chosen so that $x_a = x_t/2$, where x_t is the turning point of the wave function.

infinity. In this case it is slightly more efficient to modify (4.1) so that for large x the straight-line extrapolation of $g(x)$ is ''cut'' to zero instead of becoming positive. In either case we now have for the current point x_k an approximate potential $g(x)$ parametrized by the ''next'' value $y = g(x_{k+1})$. The task of the inversion algorithm is simply to choose this value of y.

Let us suppose that, for given values of k and y, the bottom of the spectrum of $H = -\Delta + vg(x)$ is given by $G(v,k,y)$, then the inversion algorithm may be stated in the following succinct form in which $\sigma < 1$ is a fixed parameter. Find y such that

$$vg(\sigma x_k) = F(v) = G(v,k,y); \quad \text{then } g(x_{k+1}) = y. \tag{4.2}$$

The value of v is first chosen so that the turning point of the wave function generated by g occurs at σx_k; after this, the value of y is chosen so that G ''fits'' F for this value of v. The value of the parameter σ chosen for the examples discussed in Sec. V below is $\sigma = \frac{1}{2}$. The idea behind this choice can best be understood from a study of Fig. 1. The value of the coupling v must be such that the current value of x for which y is sought is in the ''tail'' of the corresponding wave function; that is to say, the turning point σx should be before x, but not too far away. Fortunately the inversion algorithm seems to be insensitive to the choice of σ.

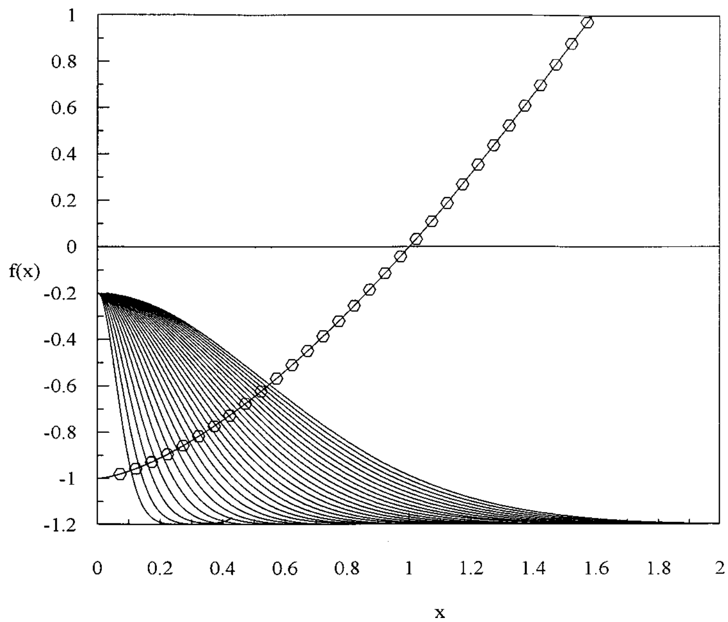

FIG. 2. Constructive inversion of the energy trajectory $F(v)$ for the shifted power potential $f(x)=-1+|x|^{3/2}$. For $x \leqslant b=0.072$, the algorithm correctly generates the model $f(x)$; for larger values of x, in steps of size $h=0.05$, the hexagons indicate the reconstructed values for the potential $f(x)$, shown exactly as a smooth curve. The unnormalized wave functions are also shown.

V. THREE EXAMPLES

The first example we consider is the unbounded potential whose shape $f(x)$ and corresponding exact energy trajectory $F(v)$ are given by the $\{f,F\}$ pair

$$f(x)=-1+|x|^{3/2} \leftrightarrow F(v)=-v+E(3/2)v^{4/7}, \tag{5.1}$$

where $E(3/2)$ is the bottom of the spectrum of $H=-\Delta+|x|^{3/2}$ and has the approximate value $E(3/2)\approx 1.001\,184$. Applying the inversion algorithm to $F(v)$ we obtain the reconstructed potential shown in Fig. 2. We first set $v_1=10^4$ and find that the initial shape is determined (as described in Sec. II) to be $-1+x^{1.5}$ for $x<b=0.072$. For larger values of x the step size is chosen to be $h=0.05$ and 40 iterations are performed by the inversion algorithm. The results are plotted as hexagons on top of the exact potential shape shown as a smooth curve. This entire computation takes less than 20 s with a program written in C++ running on a 200 MHz Pentium Pro.

The following two examples are bounded potentials both having a large-x limit zero, lowest point $f(0)=-1$, and area -2. The exponential potential[7,8] has the $\{f,F\}$ pair

$$f(x)=-e^{-|x|} \leftrightarrow J'_{2|E|^{1/2}}(2v^{1/2})=0 \equiv E=F(v), \tag{5.2}$$

where $J'_\nu(x)$ is the derivative of the Bessel function of the first kind of order ν. For the sech-squared potential[8] we have

$$f(x)=-\operatorname{sech}^2(x) \leftrightarrow F(v)=-[(v+\tfrac{1}{4})^{1/2}-\tfrac{1}{2}]^2. \tag{5.3}$$

In Fig. 3 the two energy trajectories are plotted. Since the two *potentials* have the lowest value -1 and area -2 it follows[5] that the corresponding trajectories both have the form $F(v)\approx -v^2$ for small v and they both satisfy the large-v limit $\lim_{v\to\infty}(F(v)/v)=-1$. Thus the differences between the potential shapes is somehow encoded in the fine differences between these two similar energy curves for intermediate values of v; It is the task of our inversion theory to decode this

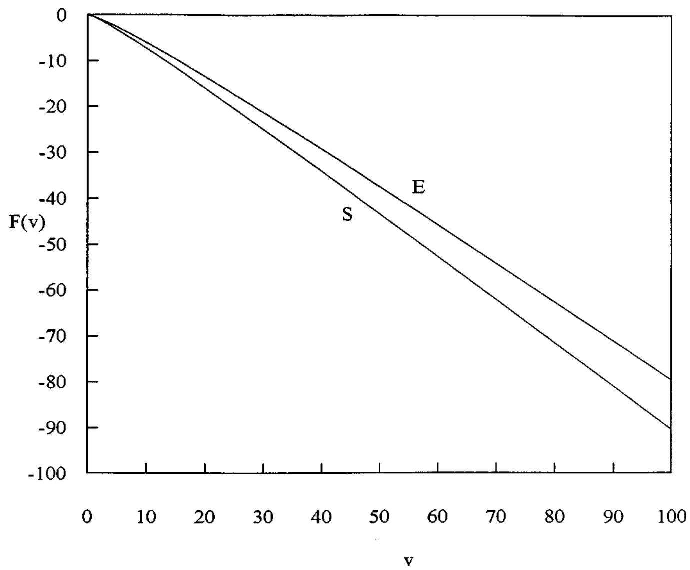

FIG. 3. The ground-state energy trajectories $F(v)$ for the exponential potential (E) and the sech-squared potential (S). For small v, $F(v) \approx -v^2$; for large v, $\lim_{v\to\infty}(F(v)/v) = -1$. The shapes of the underlying potentials are buried in the details of $F(v)$ for intermediate values of v.

information and reveal the underlying potential shape. If we apply the inversion algorithm to these two problems we obtain the results shown in Figs. 4 and 5. The parameters used are exactly the same as for the first problem described above. The time taken to perform the inversions is again less than 20 s if we discount, in the case of the exponential potential, the extra time taken to compute $F(v)$ itself.

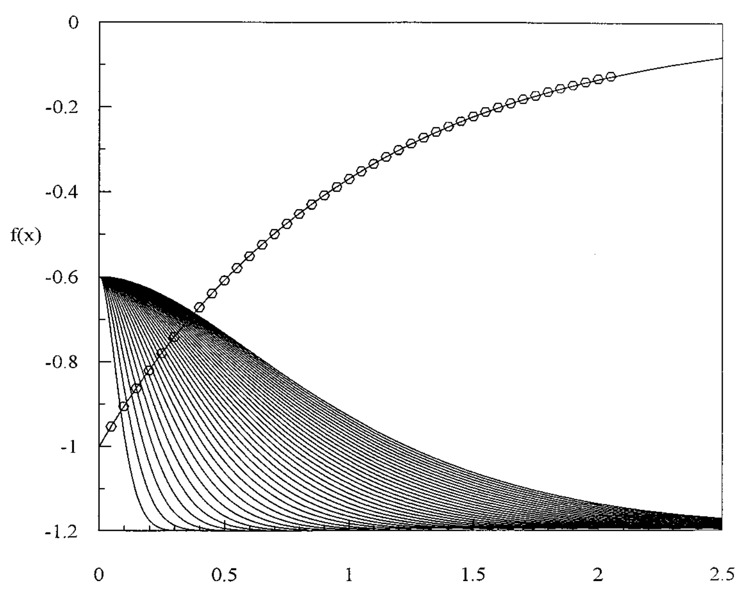

FIG. 4. Constructive inversion of the energy trajectory $F(v)$ for the exponential potential $f(x) = -\exp(x)$. For $x \leq b = 0.048$, the algorithm correctly generates the model $f(x) = -1 + |x|$; for larger values of x, in steps of size $h = 0.05$, the hexagons indicate the reconstructed values for the potential $f(x)$, shown exactly as a smooth curve. The unnormalized wave functions are also shown.

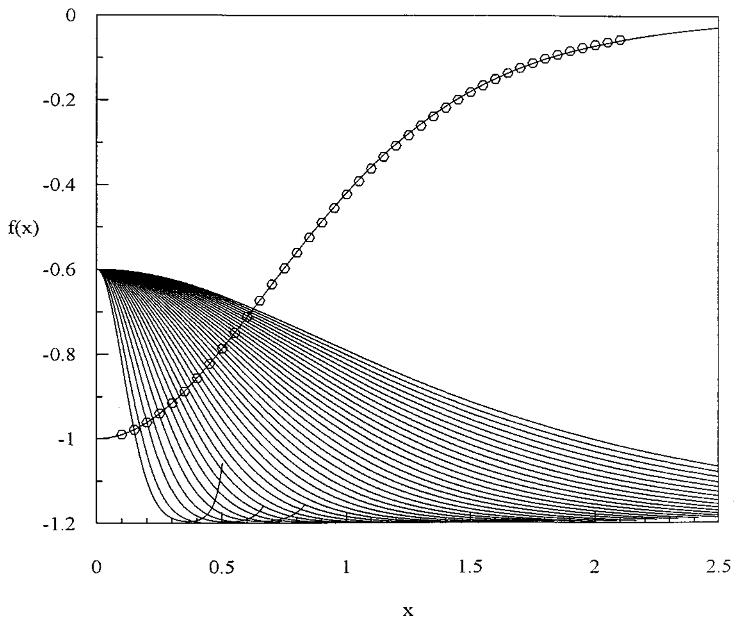

FIG. 5. Constructive inversion of the energy trajectory $F(v)$ for the sech-squared potential $f(x)=-\mathrm{sech}^2(x)$. For $x\leq b=0.1$, the algorithm correctly generates the model $f(x)=-1+x^2$; for larger values of x, in steps of size $h=0.05$, the hexagons indicate the reconstructed values for the potential $f(x)$, shown exactly as a smooth curve. The unnormalized wave functions are also shown.

VI. CONCLUSION

Once we suspect (or know) that an energy trajectory $F(v)$ is derived from a potential shape $f(x)$, it is certainly possible in principle to model the potential discretely as $g(x)$ and then find g approximately by a least-squares fit of $G(v)$ to $F(v)$. Such a ''brute force'' method would not be easy or fast, even for problems in one dimension. In terms of the reconstructions presented in this paper, one would have to consider minimizing a function of the form $\Sigma_{i=1}^{40}|G(v_i;\mathbf{Y})-F(v_i)|^2$, where the vector $\mathbf{Y}$ represents the 40 values of $g(x_k)$ to be determined. We have found that such a function of $\mathbf{Y}$ has very erratic behavior unless the starting point can be chosen quite close to the critical point.

The purpose of the approach discussed in this paper is however not so much to do with efficiency as with understanding. The method we have found is intimately linked to the basic properties of the problem; the implications of monotonicity, the relation between the position of the turning point of the wave function and the value of v, and the tail behavior. The effectiveness of the resulting algorithm stems from its systematic use of all this information. If a potential shape $f(x)$ is symmetric but *not* monotonic (on the half-axis), then for large values of the coupling v the problem will necessarily split into regimes that become more and more isolated as v increases. The situation could become arbitrarily complicated, perhaps involving resonances, and we have no idea at present whether reconstruction $F\rightarrow f$ would in principle be possible in the general case.

If the potential were unimodal and monotonic away from the minimum point, we do not at present know what might be the spectral inheritance of the additional property of the symmetry of $f(x)$. Is there nonuniqueness in this case? Could a symmetric potential be constructed that would have the same energy trajectory $F(v)$ as that of a given nonsymmetrical unimodal potential shape $f(x)$? Many interesting questions such as this which are simple to pose nevertheless appear at present to be very difficult to answer.

In our earlier papers on this topic we discussed some suggestions for applications of this form of spectral inversion. The situations that are most strongly suggestive are those such as the screened-Coulomb potentials used in atomic physics where the coupling varies with the atomic number. In such a case $F_n(v)$ or, more accurately, pair *differences* between such functions, would only be known at certain isolated points. Now that an effective form of constructive inversion is available, it will be possible to consider this more physically important type of application. Another approach which has not yet been applied to geometric spectral inversion is via control theory. Rabitz *et al.*[9,10] have successfully used ideas from control theory to reconstruct molecular potentials from sets of data that are directly measurable. This is the ultimate goal of the present work on geometric spectral inversion.

Potentials for which the corresponding Schrödinger equation is maximally superintegrable in three-dimensional Euclidean space are studied. The quadratic algebra which is associated with each of these potentials is constructed and the bound state wave functions are computed in the separable coordinates. © *1999 American Institute of Physics.* [S0022-2488(99)02602-X]

I. INTRODUCTION

The present paper continues our study of the systems with *hidden symmetry* or so-called *superintegrable* systems in spaces with constant curvature.

The best known systems of this kind in three-dimensional Euclidean space are the harmonic oscillator and Kepler–Coulomb problems, which have many special properties distinct from other spherically symmetric potentials. These include the phenomena of separation of variables for the Hamilton–Jacobi and Schrödinger equations in more than one orthogonal coordinate system and the existence of integrals of motion in addition to the total angular momentum $\mathbf{L}^2$. In particular for the isotropic oscillator there is the Demkov tensor $D_{ik}=p_ip_k+\omega^2 x_i x_k$,[1] and, in the case of the Kepler–Coulomb problem, the Pauli–Runge–Lenz vector $\mathbf{A}=1/2([\mathbf{L}\times\mathbf{p}]-[\mathbf{p}\times\mathbf{L}])-\mathbf{r}/|r|$. Both these systems possess five functionally independent integrals of motion.[2,3] The first systematic search for all potentials for which the Schrödinger equation admits separation of variables in two or more coordinate systems was begun by Smorodinsky and Winternitz with co-workers in Refs. 4–6 and continued by Evans in Refs. 3 and 7. They found all such systems in two- and three-dimensional flat space and introduced the notion of *superintegrability*. In general, a physical system in N dimensions is called *minimally* superintegrable if it has $2N-2$ integrals of motion, and *maximally* superintegrable if it has $2N-1$ integral of motions. There are five known maximally (and some minimally) superintegrable potentials listed in Refs. 3, 8, and 10 and investigated from different points of view in the last decade.[8–13] Note also that superintegrable potentials in spaces of constant curvature were introduced in Refs. 14–16.

In previous articles[17–19] we have looked at potentials in two-dimensional Euclidean space and the two-dimensional sphere and hyperboloid, for which the Schrödinger equation is maximally superintegrable. In this article we extend this study to the case of three-dimensional Euclidean space. As previously seen in the case of two dimensions, some of these potentials (see Table I) admit bound state or finite solutions and it is these to which we draw attention in this article.

The basic equation that we investigate is of course the Schrödinger equation ($\hbar=m=1$)

$$\mathcal{H}\Psi=-\frac{1}{2}\Delta\Psi+V(x,y,z)\Psi=-\frac{1}{2}\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}\right)\Psi+V(x,y,z)\Psi=E\Psi. \tag{1}$$

The idea is to find solutions of this equation via a separation of variables ansatz

TABLE I. The three-dimensional maximally superintegrable potentials.

Potential $V(x,y,z)$	Separating coordinates
$V_1=\frac{\omega^2}{2}(x^2+y^2+z^2)+\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}+\frac{k_3^2-\frac{1}{4}}{z^2}\right)$	Cartesian Spherical Cylindrical polar Cylindrical elliptic Sphero-conical Oblate spheroidal Prolate spheroidal Ellipsoidal
$V_2=\frac{\omega^2}{2}(x^2+y^2+4z^2)+\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right)$	Cartesian Cylindrical polar Cylindrical parabolic Cylindrical elliptic Parabolic
$V_3=-\frac{\alpha}{\sqrt{x^2+y^2+z^2}}+\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right)$	Spheroidal-conical Spherical Parabolic Prolate spheroidal II

$$\Psi=\prod_{j=1}^{3}\psi_j(u_j)$$

for some suitable orthogonal coordinates u_j (see Table II).

In Secs. II–IV we consider three maximally superintegrable potentials (see Table I) and use the Niven-type (or Bethe[20]) ansatz for constructing the solution of the Schrödinger equation in coordinates such as spheroidal, sphero-conical, and ellipsoidal (see Table II). In addition we discuss the extension to the quadratic algebras that were in evidence in the case of two dimensions and see what their implications may be.

Section V is devoted to the calculation of interbasis expansion coefficients for the V_3 potential between spherical and parabolic bases.

II. GENERALIZED ISOTROPIC OSCILLATOR

The first potential (see Table I) on our list of three is

$$V_1(x,y,z)=\frac{\omega^2}{2}(x^2+y^2+z^2)+\frac{1}{2}\left[\frac{(k_1^2-\frac{1}{4})}{x^2}+\frac{(k_2^2-\frac{1}{4})}{y^2}+\frac{(k_3^2-\frac{1}{4})}{z^2}\right], \tag{2}$$

where the constant $k_i\geqslant\frac{1}{2}$. For $k_i=\frac{1}{2}$ we have the ordinary isotropic oscillator potential. The corresponding Schrödinger equation admits solutions via a separation of variables in eight coordinate systems: Cartesian, spherical, sphero-conical, cylindrical polar, cylindrical elliptic, prolate and oblate spheroidal, and ellipsoidal. We summarize the bound state solutions in each case.

Before considering various coordinate systems we note that a basis for the symmetries of Schrödinger's equation with the potential (2) consists of the six operators:

TABLE II. Systems of coordinate in three-dimensional Euclidean space.

Coordinate system	Coordinates
I. Cartesian $x,y,z\in\mathbf{R}$	x,y,z
II. Cylindrical polar $\rho>0,\ \varphi\in[0,2\pi)$	$x=\rho\cos\varphi,\ y=\rho\sin\varphi,\ z$
III. Cylindrical elliptic $z\in\mathbf{R},\ e_1<\mu_1<e_2<\mu_2$	$x^2=\frac{(\mu_1-e_1)(\mu_2-e_1)}{(e_2-e_1)},\quad y^2=\frac{(\mu_1-e_2)(\mu_2-e_2)}{(e_1-e_2)},z$
IV. Cylindrical parabolic $\xi,x\in\mathbf{R},\ \eta\geqslant 0$	$x,y=\xi\eta,\ z=\frac{1}{2}(\xi^2-\eta^2)$
V. Spherical $r>0,\ \theta\in[0,\pi],\ \varphi\in[0,2\pi)$	$x=r\cos\theta\cos\varphi,\ y=r\sin\theta\sin\varphi,\ z=r\cos\theta$
VI. Prolate spheroidal $e_1<u_1<e_2<u_2,\ \varphi\in[0,2\pi)$	$x^2=\frac{(u_1-e_2)(u_2-e_2)}{(e_1-e_2)}\cos^2\varphi,$ $y^2=\frac{(u_1-e_2)(u_2-e_2)}{(e_1-e_2)}\sin^2\varphi,$ $z^2=\frac{(u_1-e_1)(u_2-e_1)}{(e_2-e_1)}$
VII. Oblate spheroidal $e_1<u_1<e_2<u_2,\ \varphi\in[0,2\pi)$	$x^2=\frac{(u_1-e_1)(u_2-e_1)}{(e_2-e_1)}\cos^2\varphi,$ $y^2=\frac{(u_1-e_1)(u_2-e_1)}{(e_2-e_1)}\sin^2\varphi,$ $z^2=\frac{(u_1-e_2)(u_2-e_2)}{(e_1-e_2)}$
VIII. Sphero-conical $r\geqslant 0,\ e_1<\rho_1<e_2<\rho_2<e_3$	$x^2=r^2\frac{(\rho_1-e_1)(\rho_2-e_1)}{(e_1-e_2)(e_1-e_3)},$ $y^2=r^2\frac{(\rho_1-e_2)(\rho_2-e_2)}{(e_2-e_1)(e_2-e_3)},$ $z^2=r^2\frac{(\rho_1-e_3)(\rho_2-e_3)}{(e_3-e_2)(e_3-e_1)}$
IX. Parabolic $\xi,\eta\geqslant 0,\ \varphi\in[0,2\pi)$	$x=\xi\eta\cos\varphi,\ y=\xi\eta\sin\varphi,\ z=\frac{1}{2}(\xi^2-\eta^2)$
X. Ellipsoidal $a_1<u_1<a_2<u_2<a_3<u_3$	$x^2=\frac{(u_1-a_1)(u_2-a_1)(u_3-a_1)}{(a_3-a_1)(a_2-a_1)},$ $y^2=\frac{(u_1-a_2)(u_2-a_2)(u_3-a_2)}{(a_1-a_2)(a_3-a_2)},$ $z^2=\frac{(u_1-a_3)(u_2-a_3)(u_3-a_3)}{(a_1-a_3)(a_2-a_3)}$
XI. Paraboloidal $0<\eta_1<a_2<\eta_2<a_3<\eta_3$	$x^2=\frac{(\eta_1-a_3)(\eta_2-a_3)(\eta_3-a_3)}{(a_3-a_2)},$ $y^2=\frac{(\eta_1-a_2)(\eta_2-a_2)(\eta_3-a_2)}{(a_2-a_3)},$ $z^2=\frac{1}{2}(\eta_1+\eta_2+\eta_3-a_2-a_3)$

$$M_i=-D_{ii}-\frac{k_i^2-\frac{1}{4}}{x_i^2},\quad -\mathcal{H}=M_1+M_2+M_3, \tag{3}$$

$$J_{ij}=L_{ij}^2-\left(k_i^2-\frac{1}{4}\right)\frac{x_j^2}{x_i^2}-\left(k_j^2-\frac{1}{4}\right)\frac{x_i^2}{x_j^2}-\frac{1}{2},\quad i,j=1,2,3, \tag{4}$$

where $L_{ij}=x_i\partial_{x_j}-x_j\partial_{x_i}$, $D_{ii}=-\partial_{x_i}^2+\omega^2x_i^2$ is a diagonal components of the Demkov tensor[1] and we have the notation $x_1=x,\ x_2=y,\ x_3=z$.

The commutators of the operators (3) and (4) can be closed to form a quadratic algebra as follows:

$$[M_i,M_j]=0,\quad [M_i,J_{jk}]=0,\quad [M_i,J_{ij}]=Q_{ij}=Q_{[ij]},\quad [J_{ij},J_{ik}]=R_{[ijk]}=R,$$

where Q_{ij} is totally antisymmetric and the totally antisymmetric quantity $R_{[ijk]}$ is denoted by R. Further commutators are calculated to be

$$[M_i,Q_{jk}]=0,\quad [M_i,Q_{ij}]=4\{M_i,M_j\}+16J_{ij},\quad [M_i,R]=4\{M_k,J_{ij}\}-4\{M_j,J_{ik}\},$$

$$[J_{ij},Q_{ij}]=4\{M_i,J_{ij}\}-4\{M_j,J_{ij}\}-8(k_j^2-1)M_i+8(k_i^2-1)M_j,$$

$$[J_{ij},Q_{ik}]=4\{M_i,J_{jk}\}-4\{M_j,J_{ik}\},$$

$$[J_{ij},R]=4\{J_{ij},J_{jk}\}-4\{J_{ij},J_{ik}\}-8(k_i^2-1)J_{jk}+8(k_j^2-1)J_{ik},$$

where $\{A,B\}=AB+BA$. The expression for the commutators of the Q and R are

$$[Q_{ij},Q_{ik}]=4\{M_i,Q_{jk}\},\quad [Q_{ij},R]=-4\{J_{ij},Q_{ik}\}-4\{J_{ij},Q_{jk}\}.$$

All the commutators of the operators M_i, J_{mn}, Q_{pq}, and R can be expressed in terms of quadratic symmetric products of themselves. The algebra, therefore, is closed quadratically. There are relations between the symmetric products of the generators of this algebra. The exhaustive list of these is as follows:

$$\begin{aligned}Q_{ij}^2={}&\tfrac{8}{3}\{J_{ij},M_i,M_j\}+\tfrac{64}{3}\{M_i,M_j\}+16\omega^2J_{ij}^2-16(1-k_j^2)M_i^2\\&-16(1-k_i^2)M_j^2-\tfrac{128}{3}\omega^2J_{ij}-64\omega^2(1-k_i^2)(1-k_j^2),\end{aligned}$$

$$\begin{aligned}\{Q_{ij},Q_{ik}\}={}&\tfrac{8}{3}\{J_{ij},M_i,M_k\}+\tfrac{8}{3}\{J_{ik},M_i,M_j\}-\tfrac{8}{3}\{J_{jk},M_i,M_i\}\\&+32\omega^2(1-k_i^2)\{J_{ij},J_{ik}\}-32(1-k_i^2)M_jM_k-64\omega^2(1-k_i^2)J_{jk},\end{aligned}$$

$$\begin{aligned}\{Q_{ij},R\}={}&\tfrac{8}{3}\{J_{ij},J_{ij},M_k\}-\tfrac{8}{3}\{J_{ij},J_{ik},M_j\}-\tfrac{8}{3}\{J_{ij},J_{jk},M_i\}-\tfrac{64}{3}\{J_{ij},M_k\}-\tfrac{64}{3}\{J_{ik},M_j\}\\&-\tfrac{64}{3}\{J_{jk},M_i\}+16(1-k_i^2)\{J_{jk},M_j\}+16(1-k_j^2)\{J_{ik},M_i\}-64(1-k_i^2)(1-k_j^2)M_k,\end{aligned}$$

$$\begin{aligned}R^2={}&-\tfrac{4}{3}\{J_{ij},J_{ik},J_{jk}\}+\tfrac{64}{3}\{J_{ij},J_{ik}\}+\tfrac{64}{3}\{J_{ij},J_{jk}\}+\tfrac{64}{3}\{J_{ik},J_{jk}\}-16(1-k_k^2)J_{ij}^2\\&-16(1-k_j^2)J_{ik}^2-16(1-k_i^2)J_{jk}^2+\tfrac{128}{3}(1-k_k^2)J_{ij}\\&+\tfrac{128}{3}(1-k_j^2)J_{ik}+\tfrac{128}{3}(1-k_i^2)J_{jk}+64(1-k_i^2)(1-k_j^2)(1-k_k^2),\end{aligned}$$

where $\{A,B,C\}=ABC+CAB+BCA$. Note that only five operators from (3) and (4) are functionally independent,[7] and for all the coordinate systems that provide separable solutions for the Schrödinger equation the operators characterizing the separation are always combinations of the M_i and J_{ij}.

In the limiting case $k_i=\frac{1}{2}$, we obtain a quadratic algebra, too. In this case

$$Q_{ij}=2(L_{ij}D_{ij}+D_{ij}L_{ij}),\quad R=\{L_{ik},\{L_{ij},L_{kj}\}\},$$

and instead of operators $\{M_i,J_{ij},Q_{ij},R\}$ we can consider as a basis for the symmetries the Demkov tensor D_{ij}, and the components of orbital momentum, L_{ij}. In this regard we arrive at the Lie algebra corresponding to the symmetries of the isotropic oscillator.[1]

Of all the coordinate systems for which separation is possible, in the case of this potential there are only five which are not essentially a Euclidean two-space coordinate system supplemented by an additional Cartesian coordinate z. Such coordinate systems we do not consider further here and the corresponding solutions of the Schrödinger equation and invariant algebra are given in our previous paper[17] (see also Refs. 3 and 8). For the remaining systems we now work out bound state solutions and their corresponding symmetry characterization.

A. Oblate spheroidal basis

Let us consider what we call oblate spheroidal coordinates (see Table II). If we write these coordinates in the form

$$x=x'\cos\varphi,\quad y=x'\sin\varphi,\quad z=y',\tag{5}$$

and put $\Psi=(x')^{-1/2}\Phi$, the Schrödinger equation (1) with potential (2) assumes the form

$$\frac{\partial^2\Phi}{\partial x'^2}+\frac{\partial^2\Phi}{\partial y'^2}+\left[2E-\omega^2(x'^2+y'^2)+\frac{1}{x'^2}\left(\frac{\partial^2}{\partial\varphi^2}-\frac{k_1^2-\frac{1}{4}}{\cos^2\varphi}-\frac{k_2^2-\frac{1}{4}}{\sin^2\varphi}\right)+\frac{1}{4x'^2}-\frac{k_2^3-\frac{1}{4}}{y'^2}\right]\Phi=0.$$

If we now write

$$\Phi=\Lambda(x',y')Y(\varphi),$$

the φ dependence can be extracted by requiring that

$$\left[\frac{\partial^2}{\partial\varphi^2}-\frac{k_1^2-\frac{1}{4}}{\cos^2\varphi}-\frac{k_2^2-\frac{1}{4}}{\sin^2\varphi}\right]Y(\varphi)=-M^2Y(\varphi).\tag{6}$$

The orthonormal solution of Eq. (6) for $\varphi\in[0,\pi/2]$ has the following form:

$$Y_m^{(k_1,k_2)}(\varphi)=\sqrt{\frac{2(2m+k_1+k_2+1)m!\Gamma(m+k_1+k_2+1)}{\Gamma(m+k_1+1)\Gamma(m+k_2+1)}}$$
$$\times(\cos\varphi)^{k_1+1/2}(\sin\varphi)^{k_2+1/2}P_m^{(k_1,k_2)}(\cos2\varphi),\tag{7}$$

where $P_n^{(\alpha,\beta)}(z)$ is a Jacobi polynomial and the separation constant quantizes as

$$M=2m+k_1+k_2+1,\quad m=0,1,2,\ldots.\tag{8}$$

The remaining equation for the function $\Lambda(x',y')$ is

$$\left\{\frac{\partial^2}{\partial x'^2}+\frac{\partial^2}{\partial y'^2}+\left[2E-\omega^2(x'^2+y'^2)-\frac{k_3^2-\frac{1}{4}}{y'^2}-\frac{M^2-\frac{1}{4}}{x'^2}\right]\right\}\Lambda(x',y')=0.$$

This is exactly the equation we have already found (see Ref. 17) in the case of two-dimensional Euclidean space in elliptic coordinates. In terms of the original Cartesian coordinates the bound state solutions have the form

$$\Lambda_{nm}^{k_3}(x,y,z)=e^{-(\omega/2)(x^2+y^2+z^2)}(x^2+y^2)^{m+(k_1+k_2+1)/2}z^{k_3+1/2}\prod_{i=1}^{n}\left(\frac{x^2+y^2}{\theta_i-e_1}+\frac{z^2}{\theta_i-e_2}-1\right), \quad (9)$$

where the θ_i satisfy of the system of n nonlinear equations

$$\frac{M+1}{\theta_i-e_1}+\frac{k_3+1}{\theta_i-e_2}+\sum_{j\neq i}^{n}\frac{2}{\theta_i-\theta_j}-\omega=0.$$

We note that this prescription does correctly give a separable solution by noting the identity

$$\frac{x^2+y^2}{\theta-e_1}+\frac{z^2}{\theta-e_2}-1=-\frac{(u_1-\theta)(u_2-\theta)}{(\theta-e_1)(\theta-e_2)}.$$

The energy E is quantized according to

$$E=\omega(2n+M+k_3+3)=\omega(2N+k_1+k_2+k_3+3), \quad (10)$$

where $N=n+m$ is the principal quantum number.

Consider the Schrödinger equation in the spheroidal separable coordinates (u_1,u_2,φ). After the substitution $\Psi=\psi_1(u_1)\psi_2(u_2)Y(\varphi)$, the separation equations are

$$\frac{d^2\psi(u)}{du^2}+\frac{1}{2}\left(\frac{2}{u-e_1}+\frac{1}{u-e_2}\right)\frac{d\psi(u)}{du}+\frac{1}{4}\left\{\frac{2Eu-\omega^2(u-e_1)(u-e_2)+\lambda}{(u-e_1)(u-e_2)}+\frac{(e_2-e_1)M^2}{(u-e_1)^2(u-e_2)}\right.$$
$$\left.+\frac{(e_1-e_2)(k_3^2-\frac{1}{4})}{(u-e_1)(u-e_2)^2}\right\}\psi(u)=0, \quad (11)$$

where $u=u_1,u_2$ and λ is the oblate spheroidal separation constant. The operator whose eigenvalue is λ is

$$\mathcal{L}_1=\frac{u_2(u_1-e_1)(u_1-e_2)}{u_1-u_2}\left\{\frac{\partial^2}{\partial u_1^2}+\frac{1}{2}\left[\frac{2}{u_1-e_1}+\frac{1}{u_1-e_2}\right]\frac{\partial}{\partial u_1}\right\}-\frac{u_1(u_2-e_1)(u_2-e_2)}{u_1-u_2}$$
$$\times\left\{\frac{\partial^2}{\partial u_2^2}+\frac{1}{2}\left[\frac{2}{u_2-e_1}+\frac{1}{u_2-e_2}\right]\frac{\partial}{\partial u_2}\right\}+\frac{1}{4}\left[\omega^2(e_2e_2-u_1u_2)+\frac{M^2(e_1-e_2)}{(u_1-e_1)(u_2-e_1)}\right.$$
$$\left.\times(u_1+u_2-e_1)+\frac{(k_3^2-\frac{1}{4})(e_2-e_1)}{(u_1-e_2)(u_2-e_2)}(u_1+u_2-e_2)\right]$$
$$=J_{13}+J_{23}+J_{12}+(e_1-e_2)M_3-e_2\mathcal{H}-(k_1^2+k_2^2+k_3^2)+\tfrac{3}{4} \quad (12)$$

with eigenvalues

$$\lambda=-4e_2\sum_i^n\frac{M+1}{\theta_i-e_1}-4e_1\sum_i^n\frac{k_3+1}{\theta_i-e_2}-2[(e_1+e_2)+(e_1k_3+e_2M)]\omega-(k_1^2+k_2^2+k_3^2)+\frac{3}{4}, \quad (13)$$

and the second operator which characterizes the separation of variables in these coordinates is

$$\mathcal{L}_2\Psi=(J_{12}-k_1^2-k_2^2+1)\Psi=-M^2\Psi. \quad (14)$$

To close this paragraph let us note that in the limit $(e_2-e_1)\to 0$ and $(e_2-e_1)\to\infty$ the oblate spheroidal coordinates are changed into spherical and cylindrical polar coordinates, respectively.[8] Correspondingly, the oblate spheroidal bases transform to spherical and cylindrical polar ones.

B. Prolate spheroidal basis

For prolate coordinates the description is almost exactly the same. All that is essentially involved is the interchange of e_1 and e_2.

C. Ellipsoidal basis

For ellipsoidal coordinates (see Table II) we proceed as follows. We consider the Schrödinger equation in Cartesian coordinates,

$$\left(\frac{\partial^2\Psi}{\partial x^2}+\frac{\partial^2\Psi}{\partial y^2}+\frac{\partial^2\Psi}{\partial z^2}\right)+\left[2E-\omega^2(x^2+y^2+z^2)-\frac{(k_1^2-\frac{1}{4})}{x^2}-\frac{(k_2^2-\frac{1}{4})}{y^2}+\frac{(k_3^2-\frac{1}{4})}{z^2}\right]\Psi=0.$$

If we now write

$$\Psi(x,y,z)=e^{-\omega(x^2+y^2+z^2)}x^{2k_1+1}y^{2k_2+1}z^{2k_3+1}\Phi(x,y,z),$$

the equation for Φ becomes

$$\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}+\frac{2k_1+1}{x}\frac{\partial}{\partial x}+\frac{2k_2+1}{y}\frac{\partial}{\partial y}+\frac{2k_3+1}{z}\partial_z-2\omega\left(x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}+z\frac{\partial}{\partial z}\right)\right.$$
$$\left.-2\omega(k_1+k_2+k_3+3)\right]\Psi=-2E\Psi.$$

To obtain the appropriate finite solutions we can make use of the identity

$$\frac{x^2}{\theta-e_1}+\frac{y^2}{\theta-e_2}+\frac{z^2}{\theta-e_3}-1=-\frac{(u_1-\theta)(u_2-\theta)(u_3-\theta)}{(\theta-e_1)(\theta-e_2)(\theta-e_3)}$$

and write

$$\Phi(x,y,z)=\prod_{j=1}^{N}\left(\frac{x^2}{\theta_j-e_1}+\frac{y^2}{\theta_j-e_2}+\frac{z^2}{\theta_j-e_3}-1\right), \tag{15}$$

where

$$\frac{k_1+1}{\theta_i-e_1}+\frac{k_2+1}{\theta_i-e_2}+\frac{k_3+1}{\theta_i-e_3}+\sum_{j\neq i}^{N}\frac{2}{\theta_i-\theta_j}-\omega=0$$

and the energy level E is given by Eq. (10).

Writing the Schrödinger equation in terms of the ellipsoidal coordinates u_i and using the identities

$$E\equiv\sum_{i=1}^{3}\frac{E_i^2}{\Pi_{i\neq j}(u_i-u_j)},\quad (x^2+y^2+z^2)\equiv\sum_{i=1}^{3}\frac{P(u_i)}{\Pi_{i\neq j}(u_i-u_j)},$$

$$\left[\frac{(k_1^2-\frac{1}{4})}{x^2}+\frac{(k_2^2-\frac{1}{4})}{y^2}+\frac{(k_3^2-\frac{1}{4})}{z^2}\right]\equiv\sum_{i=1}^{3}\frac{A(u_i)}{\Pi_{i\neq j}(u_i-u_j)},$$

where $P(u_i)=(u_i-a_1)(u_i-a_2)(u_i-a_3)$ and $[a_{ik}\equiv(a_i-a_k)]$ and

$$A(u)=a_{31}a_{21}\frac{(k_1^2-\frac{1}{4})}{u-a_1}+a_{12}a_{32}\frac{(k_2^2-\frac{1}{4})}{u-a_2}+a_{13}a_{23}\frac{(k_1^2-\frac{1}{4})}{u-a_3},$$

we arrive at the following equation:

$$\sum_{i=1}^{3}\frac{1}{\Pi_{i\neq j}(u_i-u_j)}\left\{4\sqrt{P(u_i)}\frac{\partial}{\partial u_i}\sqrt{P(u_i)}\frac{\partial}{\partial u_i}+2Eu_i^2-\omega^2P(u_i)-A(u_i)\right\}\Psi=0,$$

which, after the substitution $\Psi=\psi_1(u_1)\psi_2(u_2)\psi_3(u_3)$ and the introduction of the ellipsoidal constants λ_1 and λ_2, is divided into three identical differential equations

$$\sqrt{P(u)}\frac{d}{du}\sqrt{P(u)}\frac{d\psi}{du}+\frac{1}{4}\left[2Eu^2-\omega^2P(u)+\lambda_1u-\lambda_2-\frac{(k_1^2-\frac{1}{4})}{(u-a_1)}(a_3-a_1)(a_2-a_1)\right.$$
$$\left.-\frac{(k_2^2-\frac{1}{4})}{(u-a_2)}(a_1-a_2)(a_3-a_2)-\frac{(k_3^2-\frac{1}{4})}{(u-a_3)}(a_1-a_3)(a_2-a_3)\right]\psi=0,$$

where $u=u_1,u_2,u_3$. The operators that specify the eigenvalues λ_1 and λ_2 are

$$\Lambda_1=J_{12}+J_{23}+J_{23}+(a_2+a_3)M_1+(a_2+a_1)M_3+(a_1+a_3)M_2-(k_1^2+k_2^2+k_3^2)+\tfrac{3}{4}$$

and

$$\Lambda_2=a_3J_{12}+a_2J_{13}+a_1J_{23}+a_2a_3M_1+a_2a_1M_3+a_1a_3M_2$$
$$-k_1^2(a_3+a_2-a_1)-k_2^2(a_1+a_3-a_2)-k_3^2(a_1+a_2-a_3)+\tfrac{3}{4}(a_1+a_2+a_3),$$

respectively. In terms of the zeros θ_j the eigenvalues of these operators are

$$\lambda_1=-2[k_2(a_1+a_3)+k_1(a_2+a_3)+k_3(a_1+a_2)-4(a_1+a_2+a_3)]\omega-2(k_1+k_2+k_3)$$
$$\times(k_1+k_2+k_3+1)-\tfrac{9}{2}+4\left[\sum_{i=1}^{N}a_2\frac{(k_2+1)}{(\theta_i-a_2)}+\sum_{i=1}^{N}a_1\frac{(k_1+1)}{(\theta_i-a_1)}+\sum_{i=1}^{N}a_3\frac{(k_3+1)}{(\theta_i-a_3)}\right] \quad (16)$$

and

$$\lambda_2=-\tfrac{1}{2}(a_1+a_2+a_3)-2\omega[a_2a_3(k_1+1)+a_2a_1(k_3+1)+a_1a_3(k_2+1)]-a_1(k_2+k_3+1)^2$$
$$-a_2(k_1+k_3+1)^2-a_3(k_2+k_1+1)^2$$
$$-4\left[\sum_{i=1}^{N}a_3a_1\frac{(k_2+1)}{(\theta_i-a_2)}+\sum_{i=1}^{N}a_3a_2\frac{(k_1+1)}{(\theta_i-a_1)}+\sum_{i=1}^{N}a_2a_1\frac{(k_3+1)}{(\theta_i-a_3)}\right]. \quad (17)$$

D. Spherical and sphero-conical bases

For spherical-type coordinates there are two possibilities.

If we choose coordinates in Euclidean space accordingly,

$$x=rs_1,\quad y=rs_2,\quad z=rs_3, \quad (18)$$

where $s_1^2+s_2^2+s_3^2=1$, and put the wave function in the form

$$\Psi=R(r)S(\rho_1,\rho_2), \quad (19)$$

where ρ_1,ρ_2 are the spherical or sphero-conical coordinates, after separation of variables, we arrive at two equations,

$$\frac{d^2R}{dr^2}+\frac{2}{r}\frac{dR}{dr}+\left[2E-\omega^2r^2-\frac{J(J+1)}{r^2}\right]R=0, \tag{20}$$

$$\left\{L_{12}+L_{23}+L_{13}+\left[J(J+1)-\frac{(k_1^2-\frac{1}{4})}{s_1^2}-\frac{(k_2^2-\frac{1}{4})}{s_2^2}-\frac{(k_3^2-\frac{1}{4})}{s_3^2}\right]\right\}S=0, \tag{21}$$

where J is the spherical separation constant.

(1) In the spherical coordinates (see Table II) the wave function $S(\rho_1,\rho_2)$ has the separable form

$$S(\vartheta,\varphi)=Z(\vartheta)Y_m^{(k_1,k_2)}(\varphi),$$

where $Y_m^{(k_1,k_2)}(\varphi)$ is given by formula (7). This leads to the equation for Z:

$$\frac{1}{\sin\vartheta}\frac{d}{d\vartheta}\sin\vartheta\frac{dZ}{d\vartheta}+\left[J(J+1)-\frac{M^2}{\sin^2\vartheta}-\frac{k_3^2-\frac{1}{4}}{\cos^2\vartheta}\right]Z=0,\quad M=2m+k_1+k_2+1.$$

The solution of the above equation is (see Ref. 8)

$$Z(\theta)=\sqrt{\frac{2[2(m+l+1)+k_1+k_2+k_3]l!\,\Gamma(l+2m+k_1+k_2+k_3+2)}{\Gamma(l+k_3+1)\Gamma(l+2m+2+k_1+k_2)}}$$
$$\times(\cos\theta)^{1/2+k_3}(\sin\theta)^MP_l^{(M,k_3)}(\cos2\theta),\quad l\in\mathbf{N}, \tag{22}$$

and for a spherical separation constant we get

$$J=2l+M+k_3+\tfrac{1}{2}=2l+2m+k_1+k_2+k_3+\tfrac{3}{2}. \tag{23}$$

(2) If we choose the sphero-conical coordinates on the sphere (see Table II), the solution of the equation (21) has the form

$$S(\rho_1,\rho_2)=\prod_{\ell=1}^{3}s_\ell^{k_\ell+1/2}\prod_{j=1}^{n}\left(\frac{s_1^2}{\theta_j-e_1}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}\right), \tag{24}$$

and the spherical separation constant is quantized according to Eq. (23) where $n=l+m$. This achieves a separation of variables solution because of the identity

$$\frac{s_1^2}{\theta_j-e_1}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}=\frac{(\rho_1-\theta_j)(\rho_2-\theta_j)}{(\theta_j-e_1)(\theta_j-e_2)(\theta_j-e_3)}$$

and the Niven equations

$$\frac{k_1+1}{\theta_i-e_1}+\frac{k_2+1}{\theta_i-e_2}+\frac{k_3+1}{\theta_i-e_3}+\sum_{j\neq i}^{q}\frac{2}{\theta_i-\theta_j}=0.$$

The functions $S(\rho_1,\rho_2)$ have the separable form

$$S(\rho_1,\rho_2)=B_1(\rho_1)B_2(\rho_2), \tag{25}$$

and the separation equations are $[P(\rho)=(\rho-e_1)(\rho-e_2)(\rho-e_3)]$

$$\sqrt{P(\rho)}\frac{d}{d\rho}\sqrt{P(\rho)}\frac{dB}{d\rho}+\frac{1}{4}\left[\lambda-J(J+1)-\frac{(k_1^2-\frac{1}{4})}{(\rho-e_1)}(e_1-e_2)(e_1-e_3)-\frac{(k_2^2-\frac{1}{4})}{(\rho-e_2)}(e_2-e_1)(e_2-e_3)\right.$$
$$\left.-\frac{(k_3^2-\frac{1}{4})}{(\rho-e_3)}(e_3-e_2)(e_3-e_1)\right]B=0, \tag{26}$$

where $B=B_1,B_2$ according as $\rho=\rho_1,\rho_2$, respectively. The sphero-conical wave functions satisfy the eigenfunction equations

$$(J_{12}+J_{13}+J_{23})S=[(k_1^2+k_2^2+k_3^2)-(2q+2+k_1+k_2+k_3)^2-\tfrac{1}{2}]S \tag{27}$$

$$(e_1J_{23}+e_2J_{13}+e_3J_{12})S$$
$$=[k_1^2(e_2+e_3-e_1)+k_2^2(e_1+e_3-e_2)+k_3^2(e_1+e_2-e_3)-\tfrac{3}{4}(e_1+e_2+e_3)-\lambda]S, \tag{28}$$

where

$$\lambda=2[k_1(e_2+e_3)+k_2(e_1+e_3)+k_3(e_2+e_1)+e_3k_1k_2+e_2k_1k_3+e_1k_3k_2]+\tfrac{3}{2}(e_1+e_2+e_3)$$
$$-4\left[e_2e_3\sum_{i=1}^{n}\frac{k_1+1}{\theta_i-e_1}+e_1e_3\sum_{i=1}^{n}\frac{k_2+1}{\theta_i-e_2}+e_2e_1\sum_{i=1}^{n}\frac{k_3+1}{\theta_i-e_3}\right]. \tag{29}$$

Let us now go to the radial equation (20). This equation is very reminiscent of the radial equation for the three-dimensional harmonic oscillator except that the orbital quantum number l is replaced by $2l+2m+k_1+k_2+k_3+\frac{3}{2}$. The orthonormal solution of the radial equation (20), in terms of Laguerre polynomials $L_n^{\alpha}(x)$, is

$$R_{n_rJ}(r)=\sqrt{\frac{2\omega^{3/2}n_r!}{\Gamma(n_r+2l+2m+k_1+k_2+k_3+3)}}(\sqrt{\omega}r)^J\exp\left(-\frac{\omega}{2}r^2\right)L_{n_r}^{J+1/2}(\omega r^2), \tag{30}$$

and the energy spectrum is given by formula (10) where the $n_r=0,1,2,...$ is the radial quantum number and the principal quantum number now is $N=(n_r+n)=(n_r+l+m)$.

III. GENERALIZED ANISOTROPIC OSCILLATOR

The second potential (see Table I) is

$$V_2(x,y,z)=\frac{\omega^2}{2}(x^2+y^2+4z^2)+\frac{1}{2}\left[\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right]. \tag{31}$$

The corresponding Schrödinger equation has separable solutions in five coordinate systems: Cartesian coordinates, cylindrical polar coordinates, cylindrical elliptic coordinates, cylindrical parabolic coordinates, and parabolic coordinates. It is the last of these that gives interesting new solutions. The first four coordinate systems are of cylindrical type and can be deduced from what we already know for Euclidean two-dimensional space (see Refs. 8 and 17). Before considering the bound state solutions in the case of the parabolic coordinate system we consider the quadratic algebra of second-order symmetry operators which are associated with this potential. A basis for these operators is

$$M_1=\partial_x^2-\omega^2x^2+\frac{k_1^2-\frac{1}{4}}{x^2},\quad M_2=\partial_y^2-\omega^2y^2-\frac{k_2^2-\frac{1}{4}}{y^2},\quad P=\partial_z^2-4\omega^2z^2, \tag{32}$$

$$L=L_{12}^2-\left(k_1^2-\frac{1}{4}\right)\frac{y^2}{x^2}-\left(k_2^2-\frac{1}{4}\right)\frac{x^2}{y^2}-\frac{1}{2}, \tag{33}$$

$$S_1=-\frac{1}{2}(p_xL_{13}+L_{13}p_x)+z\left(\omega^2x^2-\frac{k_1^2-\frac{1}{4}}{x^2}\right),$$

$$S_2=-\frac{1}{2}(p_yL_{23}+L_{23}p_y)+z\left(\omega^2y^2-\frac{k_2^2-\frac{1}{4}}{x^2}\right), \tag{34}$$

where $p_{x,y}=\partial_{x,y}$.

The relations that define the quadratic algebra are obtained by exhaustive commutation. The nonzero commutators of the above basis are

$$[M_1,L]=[L,M_2]=Q,\quad [L,S_1]=[S_2,L]=B,\quad [M_i,S_i]=A_i,\quad [P,S_i]=-A_i.$$

Further nonzero commutators with Q are

$$[M_i,Q]=[Q,M_2]=4\{M_1,M_2\}+16\omega^2L,\quad [S_1,Q]=[Q,S_2]=4\{M_1,M_2\},$$

$$[L,Q]=4\{M_1,L\}-4\{M_2,L\}+16(1-k_1^2)M_1-16(1-k_2^2)M_2;$$

nonzero commutators with A_i are

$$[M_i,A_i]=16\omega^2S_i,\quad [L,A_1]=[A_2,L]=4\{M_1,S_2\}-4\{M_2,S_1\},\quad [P,A_i]=-16\omega^2S_i,$$

$$[S_i,A_i]=\{M_i,M_i\}-2\{M_i,P\}+8\omega^2(1-k_i^2),\quad [S_i,A_j]=\{M_i,M_j\}+4\omega^2L;$$

and nonzero commutators with B are

$$[M_1,B]=-4\{M_2,S_1\},\quad [M_2,B]=-4\{M_1,B\},\quad [P,B]=4\{M_2,S_1\}-4\{M_1,S_2\},$$

$$[L,B]=-4\{L,S_1\}+4\{L,S_2\}-16(1-k_2^2)S_1+16(1-k_1^2)S_2,$$

$$[S_1,B]=\{L,M_1\}-2\{L,P\}-4\{S_1,S_2\}-4(1-k_1^2)M_2,$$

$$[B,S_2]=\{L,M_2\}-2\{L,P\}-4\{S_1,S_2\}-4(1-k_2^2)M_1.$$

The remaining nonzero commutators are

$$[Q,A_i]=-4\{M_i,A_j\},\quad [Q,B]=-4\{L,A_1\}-4\{L,A_2\},\quad [A_1,A_2]=4\omega^2Q,$$

$$[A_1,B]=\{M_1,Q\}-4\{S_1,A_2\},\quad [B,A_2]=\{M_2,Q\}-4\{S_2,A_1\}.$$

There are also various relations among the generators of our quadratic algebra:

$$\{M_1,B\}=\{L,A_1\}-\{S_1,Q\}-4(1-k_1^2)A_2,$$

$$\{M_2,B\}=-\{L,A_2\}-\{S_2,Q\}+4(1-k_2^2)A_1,$$

$$\{P,Q\}=2\{S_1,A_2\}-2\{S_2,A_1\},\quad \{M_1,A_2\}-\{M_2,A_1\}-4\omega^2B=0,$$

$$Q^2=\tfrac{8}{3}\{L,M_1,M_2\}+8\omega^2\{L,L\}-16(1-k_1^2)M_1^2-16(1-k_2^2)M_2^2$$
$$+\tfrac{64}{3}\{M_1,M_2\}-\tfrac{128}{3}\omega^2L-128\omega^2(1-k_1^2)(1-k_2^2),$$

$$\{Q,A_1\}=\tfrac{8}{3}\{M_1,M_2,S_1\}-\tfrac{8}{3}\{M_1,M_1,S_2\}+16\omega^2\{L,S_1\}-64(1-k_1^2)S_2,$$

$$\{Q,A_2\}=-\tfrac{8}{3}\{M_1,M_2,S_2\}+\tfrac{8}{3}\{M_2,M_2,S_1\}-16\omega^2\{L,S_2\}+64(1-k_2^2)S_1,$$

$$\{Q,B\}=-\tfrac{8}{3}\{M_2,L,S_1\}-\tfrac{8}{3}\{M_1,L,S_2\}+16(1-k_1^2)\{M_2,S_2\}$$
$$+16(1-k_2^2)\{M_1,S_1\}-\tfrac{64}{3}\{M_1,S_2\}-\tfrac{64}{3}\{M_2,S_1\},$$

$$A_1^2=\tfrac{2}{3}\{M_1,M_1,P\}+8\omega^2\{S_1,S_1\}+16\omega^2(1-k_1^2)P-32\omega^2M_1,$$

$$\{A_1,A_2\}=\tfrac{4}{3}\{M_1,M_2,P\}+16\omega^2\{S_1,S_2\}+8\omega^2\{L,P\},$$

$$\{A_1,B\}=\tfrac{8}{3}\{M_1,S_1,S_2\}-\tfrac{8}{3}\{M_2,S_1,S_1\}+\tfrac{4}{3}\{M_1,L,P\}+\tfrac{32}{3}\{M_1,M_2\}-8(1-k_1^2)\{M_1,P\}-\tfrac{64}{3}\omega^2L,$$

$$\{A_2,B\}=-\tfrac{8}{3}\{M_2,S_2,S_1\}+\tfrac{8}{3}\{M_1,S_2,S_2\}-\tfrac{4}{3}\{M_2,L,P\}$$
$$-\tfrac{32}{3}\{M_1,M_2\}+8(1-k_2^2)\{M_2,P\}+\tfrac{64}{3}\omega^2L,$$

$$B^2=\tfrac{8}{3}\{L,S_1,S_2\}+\tfrac{2}{3}\{L,L,P\}+\tfrac{64}{3}\{S_1,S_2\}-16(1-k_1^2)S_2^2-16(1-k_2^2)S_1^2$$
$$+\tfrac{16}{3}\{L,M_1\}-\tfrac{16}{3}\{L,P\}+\tfrac{32}{3}(1-k_2^2)M_1+\tfrac{32}{3}(1-k_1^2)M_2-16(1-k_1^2)(1-k_2^2)P.$$

This completes the nonzero relations for the quadratic algebra and the associated relations among the generators. For the last coordinate system in our list we develop the bound state solutions.

Parabolic basis

The Schrödinger equation in Cartesian coordinates with this potential has the form

$$\left(\frac{\partial^2\Psi}{\partial x^2}+\frac{\partial^2\Psi}{\partial y^2}+\frac{\partial^2\Psi}{\partial z^2}\right)+\left[2E-\omega^2(x^2+y^2+4z^2)-\frac{(k_1^2-\frac{1}{4})}{x^2}+\frac{(k_2^2-\frac{1}{4})}{y^2}\right]\Psi=0.$$

If we choose the coordinates (x',y',φ) according formula (6) and the wave function Ψ in the form

$$\Psi(x',y',\varphi)=(x')^{-1/2}\Lambda(x',y')Y_m^{(k_1,k_2)}(\varphi),\quad m=0,1,...,$$

where $Y_m^{(k_1,k_2)}(\varphi)$ is given by (7), then the equation for the function $\Lambda(x',y')$ is

$$\left[\frac{\partial^2}{\partial x'^2}+\frac{\partial^2}{\partial y'^2}-\omega^2(x'^2+4y'^2)-\frac{(M^2-\frac{1}{4})}{x'^2}+2E\right]\Lambda(x',y')=0.$$

This just the problem whose solution has been found (see Ref. 1) in the case of two-dimensional Euclidean space. If now we write

$$\Lambda(x,y,z)=e^{-(\omega/2)(x^2+y^2)-\omega z^2}(x^2+y^2)^{(k_2/2+1/4)}P(x,y),$$

where

$$P(x,y)=\prod_{j=1}^{n}\left(\frac{x^2+y^2}{\theta_j^2}+2z-\theta_j^2\right),$$

then the λ_j satisfy

$$\frac{4(\lambda+1)}{\theta_\ell^2}+\sum_{i\neq l}^{n}\frac{4}{\theta_\ell^2-\theta_i^2}-2\omega\theta_\ell^2=0$$

and energy E quantizes according to

$$E=\omega(2n+M+2)=\omega(2N+k_1+k_2+3), \tag{35}$$

where the principal quantum number $N=n+m$. This method of solution is based on the identity

$$\frac{x^2+y^2}{\theta^2}+2z-\theta^2=\frac{(\xi^2-\theta^2)(\eta^2+\theta^2)}{\theta^2}.$$

In fact, the separation equations in ξ and η for solution of the Schrödinger equation

$$\Psi(\xi,\eta,\varphi)=X_1(\xi)X_2(\eta)Y_m^{(k_1,k_2)}(\varphi)$$

have the form

$$\left[\frac{d^2}{d\rho^2}+\frac{1}{\rho}\frac{d}{d\rho}+\left(2E\rho^2-\omega^2\rho^6-\frac{M^2}{\rho^2}+\epsilon\beta\right)\right]X(\rho)=0, \tag{36}$$

where $\epsilon=1$ if $\rho=\xi$ and -1 if $\rho=\eta$, and β is the parabolic separation constant. By eliminating the energy E from Eqs. (36) we produce the operator, the eigenvalues of which is β:

$$\mathcal{L}=\frac{1}{\xi^2+\eta^2}\left(\frac{\xi^2}{\eta}\frac{\partial}{\partial\eta}\eta\frac{\partial}{\partial\eta}-\frac{\eta^2}{\xi}\frac{\partial}{\partial\xi}\xi\frac{\partial}{\partial\xi}\right)+\omega^2\xi^2\eta^2(\xi^2-\eta^2)-\frac{\xi^2-\eta^2}{\xi^2\eta^2}\left(\frac{\partial^2}{\partial\varphi^2}-\frac{k_1^2-\frac{1}{4}}{\cos^2\varphi}-\frac{k_2^2-\frac{1}{4}}{\sin^2\varphi}\right). \tag{37}$$

In Cartesian coordinates the operator $\mathcal{L}$ can be written as

$$\mathcal{L}=z\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\omega^2(x^2+y^2)-\frac{k_1^2-\frac{1}{4}}{x^2}-\frac{k_2^2-\frac{1}{4}}{y^2}\right]-\frac{\partial}{\partial z}\left(x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}-1\right),$$

and thus the parabolic basis satisfies two eigenvalue equations

$$L\Psi=(k_1^2+k_2^2-M^2-1)\Psi,\quad \mathcal{L}\Psi=2(S_1+S_2)\Psi=\beta\Psi,$$

where operators L, $S_{1,2}$ are given by formulas (33) and (34) and the eigenvalue β is

$$\beta=-2(M-1)\prod_{j=1}^{n}\theta_j^2\left(\sum_{k=1}^{n}\theta_k^{-2}\right). \tag{38}$$

IV. GENERALIZED KEPLER–COULOMB SYSTEM

The third potential we consider is

$$V_3(x,y,z)=-\frac{\alpha}{\sqrt{x^2+y^2+z^2}}+\frac{1}{2}\left[\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right]. \tag{39}$$

The corresponding Schrödinger equation has the form

$$\left(\frac{\partial^2\Psi}{\partial x^2}+\frac{\partial^2\Psi}{\partial y^2}+\frac{\partial^2\Psi}{\partial z^2}\right)+\left[2E+\frac{2\alpha}{\sqrt{x^2+y^2+z^2}}-\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right)\right]\Psi=0.$$

This equation admits separable solutions in the four coordinate systems: spherical, spheroconical, prolate spheroidal, and parabolic.

The second-order symmetries of the corresponding Schrödinger equation are

$$J_{23}=L_{23}^2-\left(k_2^2-\frac{1}{4}\right)\frac{z^2}{y^2}-\frac{1}{2},\quad J_{13}=L_{13}^2-\left(k_1^2-\frac{1}{4}\right)\frac{z^2}{x^2}-\frac{1}{2},$$

$$J_{12}=L_{12}^2-\left(k_2^2-\frac{1}{4}\right)\frac{x^2}{y^2}-\left(k_1^2-\frac{1}{4}\right)\frac{y^2}{x^2}-\frac{1}{2},\tag{40}$$

$$L=-\frac{1}{2}[\{p_x,L_{13}\}+\{p_y,L_{23}\}]+\frac{\alpha z}{\sqrt{x^2+y^2+z^2}}-z\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right).\tag{41}$$

These symmetry operators do not appear to close under repeated commutation. One obvious subalgebra that is quadratically closed is that generated by the elements J_{12}, J_{13}, and J_{23}. The closure relations can be readily deduced from the algebra given for the first potential with the proviso that $k_3=\frac{1}{2}$.

A. Spherical and sphero-conical bases

If we use polar coordinates according to (18) and write the wave function Ψ in the separable form $\Psi=R(r)S(\rho_1,\rho_2)$, then the separable equations are

$$\frac{d^2R}{dr}+\frac{2}{r}\frac{dR}{dr}+\left[2E+\frac{2\alpha}{r}-\frac{J(J+1)}{r^2}\right]R=0,\tag{42}$$

$$\left\{L_{12}+L_{23}+L_{13}+\left[J(J+1)-\frac{(k_1^2-\frac{1}{4})}{s_1^2}-\frac{(k_2^2-\frac{1}{4})}{s_2^2}\right]\right\}S=0.\tag{43}$$

(1) In the spherical coordinates, choosing the wave function $S(\rho_1,\rho_2)$ according to

$$S(\vartheta,\varphi)=Z(\vartheta)Y_m^{(k_1,k_2)}(\varphi),\quad m=0,1,2,...,$$

where $Y_m^{(k_1,k_2)}(\varphi)$ is given by formula (7), we go to the equation for Z:

$$\frac{1}{\sin\vartheta}\frac{d}{d\vartheta}\sin\vartheta\frac{dZ}{d\vartheta}+\left[J(J+1)-\frac{M^2}{\sin^2\vartheta}\right]Z=0,\quad M=2m+k_1+k_2+1.$$

The orthonormal solution of the above equation for $\vartheta\in[0,\pi]$ is

$$Z(\vartheta)=\frac{2^M}{\sqrt{\pi}}\sqrt{\frac{(2l+2M+1)l!}{2\Gamma(l+2M+1)}}\Gamma\left(M+\frac{1}{2}\right)(\sin\vartheta)^M C_l^{M+1/2}(\cos\vartheta),\tag{44}$$

where $l\in\mathbf{N}$ and $C_n^\lambda(x)$ is a Gegenbauer polynomial.[21] The spherical separation constant is given by

$$J=l+M=l+2m+k_1+k_2+1.\tag{45}$$

(2) The solution of the Schrödinger equation (43) in sphero-conical coordinates follows from what we have done before in Sec. II D, part (2). If we write $S(\rho_1,\rho_2)$ as

$$S(\rho_1,\rho_2)=s_3^\epsilon\prod_{\ell=1}^{2}s_\ell^{k_\ell+1/2}\prod_{j=1}^{n}\left(\frac{s_1^2}{\theta_j-e_1}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}\right),$$

where $\epsilon=0,1$ then the zeros satisfy the Niven equations

$$\frac{k_1+1}{\theta_i-e_1}+\frac{k_2+1}{\theta_i-e_2}+\frac{\epsilon+\frac{1}{2}}{\theta_i-e_3}+\sum_{j\neq i}^{n}\frac{2}{\theta_i-\theta_j}=0.$$

The functions $S(\rho_1,\rho_2)$ satisfy the eigenfunction equations

$$(J_{12}+J_{13}+J_{23})S=[(k_1^2+k_2^2)-(2q+\tfrac{3}{2}+k_1+k_2+\epsilon)^2-\tfrac{7}{4}]S, \tag{46}$$

$$(e_1J_{23}+e_2J_{13}+e_3J_{12})S=[(e_2-e_1)(k_1^2-k_2^2)+e_3(k_1^2+k_2^2-1)-\tfrac{1}{2}(e_1+e_2)-\lambda]S, \tag{47}$$

where the sphero-conical separation constant λ is

$$\lambda=-2[k_1(e_2+e_3)+k_2(e_1+e_3)+(\epsilon-\tfrac{1}{2})(e_2+e_1)+e_3k_1k_2+(e_2k_1+e_1k_2)(\epsilon-\tfrac{1}{2})]$$
$$-\frac{3}{2}(e_1+e_2+e_3)-4\left[e_2e_3\sum_{i=1}^{n}\frac{k_1+1}{\theta_i-e_1}+e_1e_3\sum_{i=1}^{n}\frac{k_2+1}{\theta_i-e_2}+e_2e_1\sum_{i=1}^{n}\frac{\epsilon+\frac{1}{2}}{\theta_i-e_3}\right]. \tag{48}$$

Finally, let us consider the radial equation (42). The introduction of (45) into (42) leads to

$$\frac{d^2R}{dr}+\frac{2}{r}\frac{dR}{dr}+\left[2E+\frac{2\alpha}{r}-\frac{(l+2m+k_1+k_2+1)(l+2m+k_1+k_2+2)}{r^2}\right]R=0,$$

which is the radial equation for the Coulomb problem, except the orbital quantum number l is replaced here by $(l+2m+k_1+k_2+1)$. The bound state solution of Eq. (43) is

$$R_{NJ}(r)=\frac{2(\alpha)^{3/2}}{N^2}\sqrt{\frac{\Gamma(N+J+1)}{(N-J-1)!}}\left(\frac{2\alpha r}{N}\right)^J\frac{e^{-\alpha r/N}}{\Gamma(2J+1)}\,{}_1F_1\left(-N+J+1;2J+2;\frac{2\alpha r}{N}\right)$$

and the energy spectrum given by

$$E=-\frac{\alpha^2}{N^2},\quad N=n_r+J+1=2m+n_r+l+k_1+k_2+2,\quad n_r=0,1,2,\dots.$$

B. Parabolic and prolate spheroidal bases

The remaining solutions for which separation of variables is possible can be best observed by writing the Schrödinger equation in parabolic coordinates. If we do this and choose solutions of the form

$$\Psi=S(\xi,\eta)(\xi\eta)^{-1/2}Y_m^{(k_1,k_2)}(\varphi),\quad m=0,1,2,\dots, \tag{49}$$

where $Y_m^{(k_1,k_2)}(\varphi)$ is given by formula (7), we find that the Schrödinger equation has the reduced form

$$\frac{\partial^2S}{\partial\xi^2}+\frac{\partial^2S}{\partial\eta^2}+\left[2E(\xi^2+\eta^2)+\left(M^2-\frac{1}{4}\right)\left(\frac{1}{\xi^2}+\frac{1}{\eta^2}\right)+4\alpha\right]S=0.$$

This is clearly recognizable as solvable via separation of variables in parabolic coordinates ξ and η. The separable solution for the wave function $S(\xi,\eta)$ is

$$S(\xi,\eta)=\frac{\sqrt{2}(\alpha)^{3/2}}{N^2}(\xi\eta)^{-1/2}f_{n_1}^M(\xi)f_{n_2}^M(\eta),\quad n_{1,2}\in\mathbf{N},\quad M=2m+k_1+k_2+1, \tag{50}$$

where

$$f_n^M(x)=\sqrt{\frac{\Gamma(n_1+M+1)}{n_1!}\frac{e^{-(\alpha/2N)x^2}}{\Gamma(M+1)}}\left(\frac{\alpha x^2}{N}\right)^{M/2}{}_1F_1\left(-n_1;M+1;\frac{\alpha x^2}{N}\right) \tag{51}$$

and $N=n_1+n_2+M+1=n_1+n_2+2m+k_1+k_2+2$.

It is also interesting to observe that we could contemplate an E-dependent algebra of second-order symmetries acting on the functions $H(\xi,\eta)$. Indeed, a basis for such symmetries is

$$P_1=\partial_\xi^2+\left(M^2-\frac{1}{4}\right)\frac{1}{\xi^2}+2E\xi^2,\quad P_2=\partial_n^2+\left(M^2-\frac{1}{4}\right)\frac{1}{\eta^2}+2E\eta^2,$$

$$M=(\xi\partial_\eta-\eta\partial_\xi)^2-\left(M^2-\frac{1}{4}\right)\left(\frac{\xi^2}{\eta^2}+\frac{\eta^2}{\xi^2}\right)-\frac{1}{2}.$$

The corresponding closure relations can be deduced from those given for the first potential.

Apart from the symbols this has the same form as was dealt with in two dimensions. If we now regard ξ and η as Cartesian coordinates, separation is also possible in polar and elliptical coordinates. The case of polar coordinates has essentially been done above. The case of elliptic coordinates can be done by the standard prescription. This is achieved by looking for solutions of the form

$$S(\xi,\eta)=e^{-\sqrt{-2E(x^2+y^2+z^2)}}(x^2+y^2)^{(1/2)(M+1/2)}\prod_{j=1}^{s}\left(\frac{\sqrt{x^2+y^2+z^2}+z}{\theta_m-e_1}+\frac{\sqrt{x^2+y^2+z^2}-z}{\theta_m-e_1}-1\right),$$

where we have written the solutions in the coordinate representation. (Recall that $\xi^2=\sqrt{x^2+y^2+z^2}+z$ and $\eta^2=\sqrt{x^2+y^2+z^2}-z$.) With

$$\xi=\sqrt{\frac{(u_1-e_1)(u_2-e_1)}{(e_2-e_1)}},\quad \eta=\sqrt{\frac{(u_1-e_2)(u_2-e_2)}{(e_1-e_2)}},$$

where $e_1<u_1<e_2<u_2$, the choice of Cartesian coordinates that is appropriate in this case is

$$x=\frac{1}{e_2-e_1}\sqrt{\left[\left(\frac{e_2-e_1}{2}\right)^2-\left(u_1-\frac{e_2+e_1}{2}\right)^2\right]\left[\left(u_2-\frac{e_2+e_1}{2}\right)^2-\left(\frac{e_2-e_1}{2}\right)^2\right]}\cos\varphi,$$

$$y=\frac{1}{e_2-e_1}\sqrt{\left[\left(\frac{e_2-e_1}{2}\right)^2-\left(u_1-\frac{e_2+e_1}{2}\right)^2\right]\left[\left(u_2-\frac{e_2+e_1}{2}\right)^2-\left(\frac{e_2-e_1}{2}\right)^2\right]}\sin\varphi,$$

$$z=\frac{1}{e_2-e_1}\left[\left(u_1-\frac{e_2+e_1}{2}\right)\left(u_2-\frac{e_2+e_1}{2}\right)+\left(\frac{e_2-e_1}{2}\right)^2\right].$$

This corresponds to the choice of prolate spheroidal coordinates of type II.[22,8]

V. INTERBASIS EXPANSION

According to the principles of quantum mechanics the solutions of the same Schrödinger equation in the different separable coordinate systems for a given value of energy E are connected by unitary transformations or interbasis expansions. For example, we examine here the direct calculation of the interbasis expansion between the spherical and parabolic wave functions for potential V_3. We have

$$\Psi_{n_1,n_2,m}(\xi,\eta,\varphi)=\sum_{l=0}^{n_1+n_2} W^l_{n_1n_2m}(k_1,k_2)\Psi_{n_rlm}(r,\vartheta,\varphi). \tag{52}$$

where $n_r+l=n_1+n_2$. For calculation of the coefficients of interbasis expansion in (52) we may use the ''asymptotic method,''[18,22] which is the following. Writing the parabolic wave function on the left-hand side of (52) in spherical coordinates (r,ϑ,φ) accordingly,

$$\xi^2=r(1+\cos\vartheta),\quad \eta^2=r(1-\cos\vartheta),$$

eliminating the function $Y_m^{(k_1,k_2)}(\varphi)$ on both sides of (52), and using the formula

$${}_1F_1(-n;\alpha;x)\sim\frac{\Gamma(\alpha)}{\Gamma(\alpha+n)}(-x)^n$$

for x arbitrary large, we see that the expansion (52) yields an equation which depends only on the variable ϑ. Then, by using the orthogonality relations for the functions $Z_{lm}(\vartheta)$ in the quantum number l, we arrive at the following expression for interbasis expansions coefficients:

$$\begin{aligned}W^l_{n_1n_2m}(k_1,k_2)&=(-1)^l\frac{\Gamma(M+1/2)}{2^{n_1+n_2+1}\sqrt{\pi}}\\&\times\sqrt{\frac{(2l+2M+1)\Gamma(n_1+n_2+l+2M+2)(n_1+n_2-l)!l!}{\Gamma(l+2M+1)\Gamma(n_1+M+1)\Gamma(n_1+M+1)(n_1)!(n_2)!}}\\&\times\int_0^\pi(1+\cos\vartheta)^{n_1+M}(1-\cos\vartheta)^{n_2+M}C_l^{M+1/2}(\vartheta)\sin\vartheta\,d\vartheta,\\M&=2m+k_1+k_2+1.\end{aligned}\tag{53}$$

By using the Rodrigues formula for the Gegenbauer polynomials[21]

$$C_n^\lambda(x)=\frac{(-1)^l}{l!}\frac{\sqrt{\pi}\Gamma(l+2\lambda)}{2^{l+2\lambda-1}\Gamma(\lambda)\Gamma(l+\lambda+1/2)}(1-x^2)^{-\lambda+1/2}\frac{d^l}{dx^l}(1-x^2)^{l+\lambda-1/2}$$

and comparing (53) with the integral representation for the Clebsch–Gordan coefficients of the Lie group SU(2) (Ref. 23),

$$\begin{aligned}C^{c\gamma}_{a\alpha;b\beta}=\delta_{\alpha+\beta,\gamma}&\sqrt{\frac{(2c+1)(J+1)!(J-2c)!(c+\gamma)!}{(J-2a)!(J-2b)!(a-\alpha)!(a+\alpha)!(b-\beta)!(b+\beta)!(c-\gamma)!}}\frac{(-1)^{a-c+\beta}}{2^{J+1}}\\&\times\int_{-1}^1(1-x)^{a-\alpha}(1+x)^{b-\beta}\frac{d^{c-\gamma}}{dx^{c-\gamma}}[(1-x)^{J-2a}(1+x)^{J-2b}]dx\end{aligned}$$

with $J=a+b+c$, we obtain

$$\begin{gathered}W^l_{n_1n_2m}(k_1,k_2)=(-1)^{n_2}C^{c,\alpha+\beta}_{a\alpha;a\beta},\\a=\frac{n_1+n_2+2m+k_1+k_2+1}{2},\quad c=l+2m+k_1+k_2+1,\\\alpha=\frac{n_1-n_2+2m+k_1+k_2+1}{2},\quad \beta=\frac{n_2-n_1+2m+k_1+k_2+1}{2}.\end{gathered}\tag{54}$$

Since the parameters in (54) in general are not integers or half-integers, the coefficients of interbasis expansion (51) may be considered as analytic continuation, for real values of their arguments, of the SU(2) Clebsch–Gordan coefficients. Note also that the inverse expansion of (52) follows from the orthonormality of SU(2) Clebsch–Gordan coefficients.

A quantum algebra invariant integrable closed spin 1 chain is introduced and analyzed in detail. The Bethe ansatz equations as well as the energy eigenvalues of the model are obtained. The highest weight property of the Bethe vectors with respect to $U_q(sl(2))$ is proved. © *1999 American Institute of Physics.* [S0022-2488(98)01512-6]

I. INTRODUCTION

The quantum inverse scattering method (QISM) has proved to be a powerful procedure in the analysis of one-dimensional integrable quantum chains or two-dimensional lattice models of statistical mechanics (e.g., see Ref. 1). Central to this formalism is the Yang–Baxter equation whose solutions are sufficient to guarantee integrability of the associated model. The advent of quantum algebras[2,3] provided a systematic treatment for obtaining solutions of the Yang–Baxter equation. However, the most common approach to the QISM, which was to impose periodic boundary conditions, was quickly realized to be incompatible with the quantum algebra symmetry of the model. Several authors were able to overcome this problem by working with a model on an open chain.[4–8] This practice made the Bethe ansatz solutions of such models more difficult and in some instances only postulated solutions are available.[9]

More recently, it has been demonstrated that it is in fact possible to construct closed chain models with preservation of quantum algebra symmetry.[10–13] Significantly, the $U_q(sl(2))$ invariant closed spin $\frac{1}{2}$ XXZ model was shown to be connected with a lattice quantization of the Liouville model.[14] The algebraic Bethe ansatz solutions of such models showed that the closed chain quantum algebra invariant case was not fraught with the same difficulties that were faced in the instances of open chains. The existence of such symmetry makes available results such as the highest weight property of the Bethe states for the fundamental representation of $U_q(sl(n))$, and furthermore a characterization of ''good'' and ''bad'' states in terms of q-dimensions when q takes values of roots of unity.[15] Initially, just quantum algebra invariant closed chains of the Hecke algebra type were analyzed. It was subsequently shown[16] that a more general formulation existed.

Here we wish to expand on the knowledge of closed chain quantum algebra invariant models by undertaking a detailed study of the $U_q(sl(2))$ invariant spin 1 model. Integrable spin 1 models built from a $U_q(sl(2))$ invariant R-matrix have already been the subject of some analysis.[17,18] Our study of the closed chain $U_q(sl(2))$ invariant spin 1 model exposes new mathematical aspects not present in the previously studied models;[10–12] viz. the model is not of Hecke algebra type and it is an example of a higher spin system where the most natural approach to the Bethe ansatz solution is to use a transfer matrix defined on an auxiliary space different from the local quantum space. We then find the eigenvalues of the transfer matrix whose auxiliary space is isomorphic to the local quantum space following the method of Babujian and Tsvelick.[19] The need to use two transfer matrices defined on different auxiliary spaces means working with more than one solution

[a)]Electronic mail: jrl@maths.uq.oz.au

[c)]Electronic mail: karowski@physik.fu-berlin.de

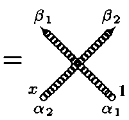
of the Yang–Baxter equation. Throughout we will follow the notation of[19,20] in distinguishing the spaces on which the various operators act. Specifically, we use the symbol σ to denote action on the spin $\frac{1}{2}$ space and s for action on the spin 1 space.

The paper is organized as follows. In Sec. II we define some basic quantities, e.g., R matrices, monodromy, and transfer matrices. A quantum algebra invariant closed spin-1 chain is introduced and its relation with one of the transfer matrices is presented. In Sec. III the system is analyzed through a combination of the techniques developed to handle with quantum algebra invariant closed chains[10] and higher-spin chains[18] and the Bethe ansatz equations as well as the energy eigenvalues of the model are obtained. In Sec. IV we show that the Bethe vectors are highest weight vectors with respect to $U_q(sl(2))$. We also argue that use of the $U_q(sl(2))$ generators allows use to generate a complete set of states for the model. A summary of our main results is presented in Sec. V.

II. THE MODEL

We begin by recalling the R-matrix for the spin-$\frac{1}{2}$ chain

$$ {}_{\sigma\sigma}R^{\beta_1\beta_2}_{\alpha_1\alpha_2}(x) = $$



$$ = \frac{1}{{}_{\sigma\sigma}a}\left(\begin{array}{cc|cc} {}_{\sigma\sigma}a & 0 & 0 & 0 \\ 0 & {}_{\sigma\sigma}b & {}_{\sigma\sigma}c_- & 0 \\ \hline 0 & {}_{\sigma\sigma}c_+ & {}_{\sigma\sigma}b & 0 \\ 0 & 0 & 0 & {}_{\sigma\sigma}a \end{array}\right), \tag{1} $$

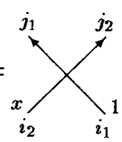
with

$$ {}_{\sigma\sigma}a = xq - \frac{1}{xq}, \quad {}_{\sigma\sigma}b = x - \frac{1}{x}, \quad {}_{\sigma\sigma}c_+ = x\left(q - \frac{1}{q}\right), \quad {}_{\sigma\sigma}c_- = \frac{1}{x}\left(q - \frac{1}{q}\right), \tag{2} $$

which acts in the tensor product of two two-dimensional auxiliary spaces $\mathbf{C}^2 \otimes \mathbf{C}^2$. Above α_1, α_2 (β_1 and β_2) are column (row) indices running from 1 to 2.

For the spin-1 chain the R-matrix is given by[21,22]

$$ {}_{ss}R^{j_1 j_2}_{i_1 i_2}(x) = $$



$$ = \frac{1}{{}_{ss}g}\left(\begin{array}{ccc|ccc|ccc} {}_{ss}g & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & {}_{ss}a & 0 & {}_{ss}c_- & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & {}_{ss}b & 0 & {}_{ss}d_- & 0 & {}_{ss}e_- & 0 & 0 \\ \hline 0 & {}_{ss}c_+ & 0 & {}_{ss}a & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & {}_{ss}d_+ & 0 & {}_{ss}f & 0 & {}_{ss}d_- & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & {}_{ss}a & 0 & {}_{ss}c_- & 0 \\ \hline 0 & 0 & {}_{ss}e_+ & 0 & {}_{ss}d_+ & 0 & {}_{ss}b & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & {}_{ss}c_+ & 0 & {}_{ss}a & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & {}_{ss}g \end{array}\right), \tag{3} $$

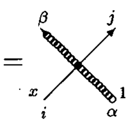
where

$$
\begin{aligned}
&{}_{ss}g=xq^2-\frac{1}{xq^2},\quad {}_{ss}a=x-\frac{1}{x},\quad {}_{ss}b=\left(x-\frac{1}{x}\right)\left(\frac{x^2-q^2}{x^2q^2-1}\right),\\
&{}_{ss}c_-=\frac{1}{x}\,{}_{ss}c,\quad {}_{ss}c_+=x\,{}_{ss}c,\quad {}_{ss}c,=\left(q^2-\frac{1}{q^2}\right),\quad {}_{ss}f={}_{ss}a+{}_{ss}e,\\
&{}_{ss}d_-=\frac{1}{x}\,{}_{ss}d,\quad {}_{ss}d_+=x\,{}_{ss}d,\quad {}_{ss}d=\left(\frac{xq}{x^2q^2-1}\right)\left(x-\frac{1}{x}\right)\left(q^2-\frac{1}{q^2}\right),\\
&{}_{ss}e_-=\frac{1}{x^2}\,{}_{ss}e,\quad {}_{ss}e+=x^2\,{}_{ss}e,\quad {}_{ss}e=\left(\frac{xq}{x^2q^2-1}\right)\left(q-\frac{1}{q}\right)\left(q^2-\frac{1}{q^2}\right),
\end{aligned}
\tag{4}
$$

and it acts in $\mathbf{C}^3\otimes\mathbf{C}^3$, with $\mathbf{C}^3$ a three-dimensional auxiliary space.

For later convenience we also introduce an R-matrix which acts on $\mathbf{C}^2\otimes\mathbf{C}^3$ (Ref. 22)

$${}_{\sigma s}R^{\beta j}_{\alpha i}(x)=$$



$$
=\frac{1}{{}_{\sigma s}a}\left(\begin{array}{ccc|ccc}
{}_{\sigma s}a & 0 & 0 & 0 & 0 & 0\\
0 & {}_{\sigma s}b & 0 & {}_{\sigma s}d_- & 0 & 0\\
0 & 0 & {}_{\sigma s}c & 0 & {}_{\sigma s}d_- & 0\\
\hline
0 & {}_{\sigma s}d_+ & 0 & {}_{\sigma s}c & 0 & 0\\
0 & 0 & {}_{\sigma s}d_+ & 0 & {}_{\sigma s}b & 0\\
0 & 0 & 0 & 0 & 0 & {}_{\sigma s}a
\end{array}\right),
\tag{5}
$$

where

$$
\begin{aligned}
&{}_{\sigma s}a=xq^{3/2}-\frac{1}{xq^{3/2}},\quad {}_{\sigma s}b=xq^{1/2}-\frac{1}{xq^{1/2}},\quad {}_{\sigma s}c=\frac{x}{q^{1/2}}-\frac{q^{1/2}}{x},\quad {}_{\sigma s}d_-=\frac{1}{x}\,{}_{\sigma s}d,\\
&{}_{\sigma s}d_+=x\,{}_{\sigma s}d,\quad {}_{\sigma s}d=\sqrt{\left(q-\frac{1}{q}\right)\left(q^2-\frac{1}{q^2}\right)}.
\end{aligned}
\tag{6}
$$

These R-matrices satisfy the following properties:

(i) Yang–Baxter equations

$$R^{\alpha''\beta''}_{\alpha'\beta'}(x/y)R^{\alpha'\gamma''}_{\alpha\gamma'}(x)R^{\beta'\gamma'}_{\beta\gamma}(y)=R^{\beta''\gamma''}_{\beta'\gamma'}(y)R^{\alpha''\gamma'}_{\alpha'\gamma}(x)R^{\alpha'\beta'}_{\alpha\beta}(x/y). \tag{7}$$

(ii) Generalized Cherednik reflection property[23]

$$R^{\alpha\beta}_{\alpha'\beta'}(x)(R^{-1})^{\alpha'\beta'}_{\gamma\delta}(y^{-1})=R^{\alpha\beta}_{\alpha'\beta'}(y)(R^{-1})^{\alpha'\beta'}_{\gamma\delta}(x^{-1}). \tag{8}$$

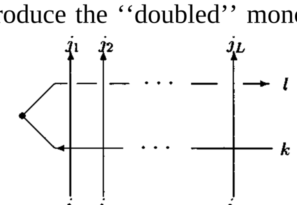
(iii) Crossing unitarity[24]

$$(R^{t_1})^{\alpha\beta}_{\alpha'\beta'}(x\eta)K^{\alpha'}_{\alpha''}((R^{-1})^{t_1})^{\alpha''\beta'}_{\gamma'\delta}(x)(K^{-1})^{\gamma'}_{\gamma}=\delta^{\alpha}_{\gamma}\delta^{\beta}_{\delta}, \tag{9}$$

where t_1 denotes matrix transposition in the first space, η is a crossing parameter and $K=K^t$ is the crossing matrix. Explicit forms for K are given below. We remark that Eq. (8) is the natural generalization of Cherednik's reflection property to the case where the R-matrix acts on two nonisomorphic spaces.

Let us now introduce the ''doubled'' monodromy matrix ${}_{ss}\mathcal{U}$

$${}_{ss}\mathcal{U}^{l\{j\}}_{k\{i\}}(x)=$$



$$={}_{ss}R_{-\,l'\,j_1'}^{\;\,l_2\,j_1}\;{}_{ss}R_{-\,l_2\,j_2'}^{\;\,l_3\,j_2}\cdots{}_{ss}R_{-\,l_L\,j_L'}^{\;\,l\,j_L}\;{}_{ss}R^{l'\,j_1'}_{k_2\,i_1}(1/x)\;{}_{ss}R^{k_2\,j_2'}_{k_3\,i_2}(1/x)\ldots{}_{ss}R^{k_L\,j_L'}_{k\,i_L}(1/x),$$

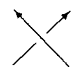
(10)

which acts in the tensor product of a three-dimensional auxiliary space and a quantum space $\mathbf{C}^3 \otimes \mathbf{C}^{3L}$ and can be regarded as a 3×3 matrix of matrices acting in the quantum space

$$
{}_{ss}\mathcal{U}^l_k(x) = \begin{pmatrix} {}_{ss}\mathcal{U}^1_1 & {}_{ss}\mathcal{U}^1_2 & {}_{ss}\mathcal{U}^1_3 \\ {}_{ss}\mathcal{U}^2_1 & {}_{ss}\mathcal{U}^2_2 & {}_{ss}\mathcal{U}^2_3 \\ {}_{ss}\mathcal{U}^3_1 & {}_{ss}\mathcal{U}^3_2 & {}_{ss}\mathcal{U}^3_3 \end{pmatrix}. \tag{11}
$$

Above the constant ${}_{ss}R$-matrix is defined as

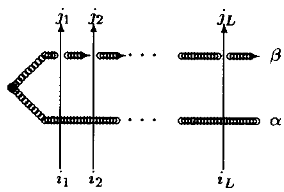
$$
{}_{ss}R_{-} = -\lim_{x\to 0}\ {}_{ss}R^{-1}(x) =
$$



, (12)

For later convenience we also define the auxiliary doubled monodromy matrix

$$
{}_{\sigma s}\mathcal{U}^{\beta\{j\}}_{\alpha\{i\}}(x) =
$$



$$
= {}_{\sigma s}R_{-}{}^{\beta_2 j_1}_{\alpha' j_1'}\ {}_{\sigma s}R_{-}{}^{\beta_3 j_2}_{\beta_2 j_2'} \cdots {}_{\sigma s}R_{-}{}^{\beta j_L}_{\beta_L j_L'}\ {}_{\sigma s}R^{\alpha' j_1'}_{\alpha_2 i_1}(1/x)\ {}_{\sigma s}R^{\alpha_2 j_2'}_{\alpha_3 i_2}(1/x) \ldots {}_{\sigma s}R^{\alpha_L j_L'}_{\alpha\, i_L}(1/x)\ , \tag{13}
$$

where ${}_{\sigma s}R_{-}$ corresponds to the leading term in the limit of the matrix ${}_{\sigma s}R^{-1}(x)$ for $x\to 0$, analogously to ${}_{ss}R_{-}$ [see Eq. (12)]. It acts on $\mathbf{C}^2\otimes\mathbf{C}^{3L}$ and can be represented as a 2×2 matrix in the auxiliary space whose entries are matrices acting in the quantum space

$$
{}_{\sigma s}\mathcal{U}^{\beta}_{\alpha}(x) = \begin{pmatrix} A & B \\ C & D \end{pmatrix}. \tag{14}
$$

Using Eqs. (7) and (8) we can prove that the following Yang–Baxter equations are fulfilled:

$$
\begin{aligned}
&{}_{\sigma\sigma}R^{\alpha\beta}_{\alpha'\beta'}(y/x)\ {}_{\sigma s}\mathcal{U}^{\beta'}_{\gamma'}(x)\ {}_{\sigma\sigma}R_{-}{}^{\alpha'\gamma'}_{\delta'\alpha}\ {}_{\sigma s}\mathcal{U}^{\delta'}_{\delta}(y) \\
&\quad = {}_{\sigma s}\mathcal{U}^{\alpha}_{\alpha'}(y)\ {}_{\sigma\sigma}R^{+}{}^{\alpha'\beta}_{\delta'\beta'}\ {}_{\sigma s}\mathcal{U}^{\beta'}_{\gamma'}(x)\ {}_{\sigma\sigma}(R^{-1})^{\delta'\gamma'}_{\delta\gamma}(x/y),
\end{aligned} \tag{15}
$$

$$
{}_{\sigma s}R^{\alpha i}_{\alpha' i'}(y/x)\ {}_{ss}\mathcal{U}^{i'}_{j'}(x)\ {}_{\sigma s}R_{-}{}^{\alpha' j'}_{\beta' j}\ {}_{\sigma s}\mathcal{U}^{\beta'}_{\beta}(y) = {}_{\sigma s}\mathcal{U}^{\alpha}_{\alpha'}(y)\ {}_{\sigma s}R^{+}{}^{\alpha' i}_{\beta' i'}\ {}_{ss}\mathcal{U}^{i'}_{j'}(x)\ {}_{\sigma s}(R^{-1})^{\beta' j'}_{\beta j}(x/y), \tag{16}
$$

$$
{}_{ss}R^{\alpha i}_{\alpha' i'}(y/x)\ {}_{ss}\mathcal{U}^{i'}_{j'}(x)\ {}_{ss}R_{-}{}^{\alpha' j'}_{\beta' j}\ {}_{ss}\mathcal{U}^{\beta'}_{\beta}(y) = {}_{ss}\mathcal{U}^{\alpha}_{\alpha'}(y)\ {}_{ss}R^{+}{}^{\alpha' i}_{\beta' i'}\ {}_{ss}\mathcal{U}^{i'}_{j'}(x)\ {}_{ss}(R^{-1})^{\beta' j'}_{\beta j}(x/y). \tag{17}
$$

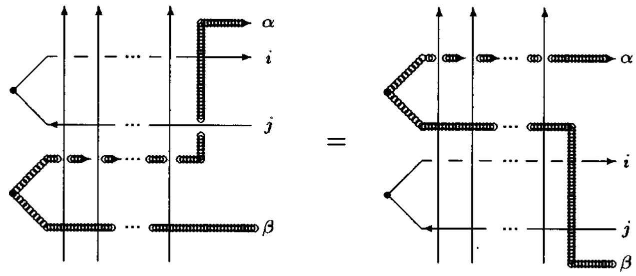
Above we have defined (for R-matrices acting on any two spaces)

$$
R^{+} = \lim_{x\to\infty} R(x).
$$

For later use we also define

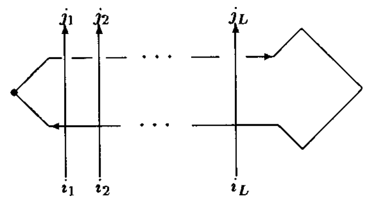
$$
R^{-} = \lim_{x\to 0} R(x).
$$

Equation (16) is depicted graphically below. Similar graphical representations apply for Eqs. (15) and (17) but will not be presented.



Finally, the spin-1 transfer matrix is constructed by taking the spin-1 Markov trace of the monodromy matrix (10) in the auxiliary space

$${}_{ss}\mathcal{T}^{\{j\}}_{\{i\}}(x)=\sum_{\alpha}\ {}_{s}K^{\alpha}_{\alpha}\ \ {}_{ss}\mathcal{U}^{\alpha\{j\}}_{\alpha\{i\}}\ \ = \tag{18}$$

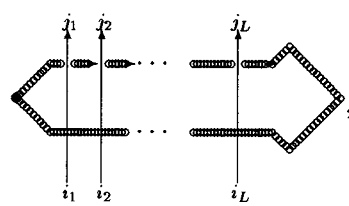


where

$${}_{s}K=\begin{pmatrix} q^{2} & & \\ & 1 & \\ & & q^{-2}\end{pmatrix}. \tag{19}$$

By using Eqs. (9) and (17) it can be shown that this transfer matrix forms a commuting family, i.e., it commutes for different spectral parameters. A quantum algebra invariant spin-1 *XXZ* Hamiltonian with closed boundary conditions will be obtained later from it. However, in order to diagonalize it, the usual algebraic Bethe ansatz scheme which applies to monodromy matrices whose auxiliary space is the fundamental representation cannot be adopted. As in other higher-spin chains[18,20,25–27] this problem can be solved by introducing an auxiliary spin-$\frac{1}{2}$ transfer matrix ${}_{\sigma s}\mathcal{T}$ which commutes with the spin-1 transfer matrix ${}_{ss}\mathcal{T}$. This spin-$\frac{1}{2}$ auxiliary transfer matrix is constructed using the auxiliary ${}_{\sigma s}R(x)$ (5) and doubled monodromy ${}_{\sigma s}\mathcal{U}(x)$ (13) matrices and is given by

$${}_{\sigma s}\mathcal{T}^{\{j\}}_{\{i\}}(x)=\sum_{\alpha}\ {}_{\sigma}K^{\alpha}_{\alpha}\ \ {}_{\sigma s}\mathcal{U}^{\alpha\{j\}}_{\alpha\{i\}}\ \ = \tag{20}$$



with

$${}_{\sigma}K=\begin{pmatrix} q & \\ & q^{-1}\end{pmatrix}. \tag{21}$$

Using Eqs. (9) and (16) we can also show that the above transfer matrices commute

$$[{}_{\sigma s}\mathcal{T}(x),{}_{ss}\mathcal{T}(y)]=0. \tag{22}$$

Therefore, we can simultaneously diagonalize ${}_{\sigma s}\mathcal{T}$ and ${}_{ss}\mathcal{T}$ which will be presented in the next section.

A quantum algebra invariant closed spin-1 Hamiltonian can be defined through

$$\mathcal{H}={}_{ss}\mathcal{T}'(x)\;{}_{ss}\mathcal{T}^{-1}(x)|_{x=1}, \tag{23}$$

where the prime indicates differentiation with respect to the variable x. This yields (see Ref. 16 for details about this general construction)

$$\mathcal{H}=\sum_{n=1}^{L-1} h_n+h_0, \tag{24}$$

where

$$\begin{aligned} h_n \propto \mathbf{J}_n.\mathbf{J}_{n+1}-(\mathbf{J}_n.\mathbf{J}_{n+1})^2+\frac{(q-q^{-1})^2}{2}[J_n^zJ_{n+1}^z+(J_n^z)^2+(J_{n+1}^z)^2-(J_n^zJ_{n+1}^z)^2] \\ -(q^{1/2}-q^{-1/2})^2[(J_n^xJ_{n+1}^x+J_n^yJ_{n+1}^y)J_n^zJ_{n+1}^z+J_n^zJ_{n+1}^z(J_n^xJ_{n+1}^x+J_n^yJ_{n+1}^y)], \end{aligned} \tag{25}$$

and $\mathbf{J}_n$ are spin-1 generators of $sl(2)$. The boundary term h_0 is given by

$$h_0=\underbrace{{}_{ss}\hat{R}_1^-\;{}_{ss}\hat{R}_2^-\cdots{}_{ss}\hat{R}_{L-1}^-}_{G}\,h_{L-1}\,\underbrace{{}_{ss}\hat{R}_{L-1}^+\cdots{}_{ss}\hat{R}_2^+\;{}_{ss}\hat{R}_1^+}_{G^{-1}}, \tag{26}$$

with

$${}_{ss}\hat{R}_{n\{\beta\}}^{\pm\{\gamma\}}=\mathbf{1}_{\beta_1}^{\gamma_1}\otimes\mathbf{1}_{\beta_2}^{\gamma_2}\otimes\cdots\otimes{}_{ss}R^{\pm\,\gamma_n\gamma_{n+1}}_{\;\;\beta_{n+1}\beta_n}\otimes\cdots\mathbf{1}_{\beta_L}^{\gamma_L},\quad n=1,2,...,L-1. \tag{27}$$

In Eq. (24) L is the number of lattice sites. The operators H, h_n and $\hat{R}_n^{\pm}$ $(n=1,2,...,L-1)$ act on the ''quantum space'' $\mathbf{C}^{3L}$ (for simplicity, we omit the quantum space indices and write them only whenever necessary). The model is periodic in the sense that the operator G^{-1} maps h_n into h_{n-1}

$$G^{-1}h_nG=h_{n-1},\quad n=2,...L-1, \tag{28}$$

and h_1 into h_0

$$G^{-1}h_1G=Gh_{L-1}G^{-1}. \tag{29}$$

The quantum algebra invariance of such a construction is discussed in Ref. 16.

III. BETHE ANSATZ METHOD

In this section we solve the eigenvalue problem of the transfer matrix

$${}_{ss}\mathcal{T}\Psi=(q^2\;{}_{ss}\mathcal{U}_1^1+{}_{ss}\mathcal{U}_2^2+q^{-2}\;{}_{ss}\mathcal{U}_3^3)\Psi={}_{ss}\Lambda\Psi, \tag{30}$$

[and consequently that of the Hamiltonian (24)] through a combination of the techniques developed to handle with quantum group invariant closed chains[10] and higher-spin chains.[18] First, from the fact that Eq. (22) is satisfied, ${}_{ss}\mathcal{T}$ and ${}_{\sigma s}\mathcal{T}$ have a common set of eigenvectors, which can be determined by applying the algebraic Bethe ansatz method to ${}_{\sigma s}\mathcal{T}$(20). Following Babujian,[20] the vector Ψ can be written as

$$\Psi=B(x_1)B(x_2)\cdots B(x_M)\Phi, \tag{31}$$

where Φ is the reference state defined by the equation

$$C\Phi=0,$$

whose solution is $\Phi=\otimes_{i=1}^{L}|1\rangle_i$. It is an eigenstate of A and D

$$A(x)\Phi=q^{3L/2}\Phi,$$

$$D(x)\Phi = q^{-L/2}\,\frac{{}_{\sigma s}c(1/x)^L}{{}_{\sigma s}a(1/x)^L}\,\Phi. \tag{32}$$

Next we apply $A(x)$ and $D(x)$ to Ψ (31), push them through all the $B's$ using the following commutation rules derived from the Yang–Baxter relation (15):

$$A(x)B(y) = \frac{1}{q}\,\frac{{}_{\sigma\sigma}a(x/y)}{{}_{\sigma\sigma}b(x/y)}\,B(y)A(x) - \frac{1}{q}\,\frac{{}_{\sigma\sigma}c_-(x/y)}{{}_{\sigma\sigma}b(x/y)}\,B(x)A(y) - \frac{q-1/q}{q}\,B(x)D(y),$$

$$D(x)B(y) = q\,\frac{{}_{\sigma\sigma}a(y/x)}{{}_{\sigma\sigma}b(y/x)}\,B(y)D(x) - q\,\frac{{}_{\sigma\sigma}c_-(y/x)}{{}_{\sigma\sigma}b(y/x)}\,B(x)D(y), \tag{33}$$

and apply them to the reference state Φ using Eq. (32). From the first terms of the r.h.s. of Eq. (32) we get the ''wanted'' contributions, while the other terms originate the ''unwanted'' terms, since they can never give a vector proportional to Ψ

$$A(x)\Psi = q^{3L/2-M}\prod_{i=1}^{M}\,\frac{{}_{\sigma\sigma}a(x/x_i)}{{}_{\sigma\sigma}b(x/x_i)}\,\Psi + \text{u.t.},$$

$$D(x)\Psi = q^{-L/2+M}\,\frac{{}_{\sigma s}c(1/x)^L}{{}_{\sigma s}a(1/x)^L}\prod_{i=1}^{M}\,\frac{{}_{\sigma\sigma}a(x_i/x)}{{}_{\sigma\sigma}b(x_i/x)}\,\Psi + \text{u.t.} \tag{34}$$

The cancellation of all unwanted terms ensure that Ψ, as given by (31) is an eigenstate of the transfer matrix ${}_{\sigma s}\mathcal{T}(x)$ (20) and this indeed happens if the Bethe ansatz equations (BAE) hold

$$q^{2(1+L-M)}\left(\frac{{}_{\sigma s}a(1/x_k)}{{}_{\sigma s}c(1/x_k)}\right)^L\prod_{i=1}^{M}\,\frac{{}_{\sigma\sigma}a(x_k/x_i)}{{}_{\sigma\sigma}b(x_k/x_i)}\,\frac{{}_{\sigma\sigma}b(x_i/x_k)}{{}_{\sigma\sigma}a(x_i/x_k)} = -1, \quad k=1,\dots,M. \tag{35}$$

Note that these equations are much simpler than those obtained for the quantum group invariant spin-1 chain with open boundary conditions (see Ref. 18). Also in the limit $q\to 1$ we recover the BAE for the usual periodic case.[20]

Let us now find the eigenvalues of ${}_{ss}\mathcal{T}(x)$ by acting with this transfer matrix on Ψ (31), according to (30). For this purpose we need the commutation relations between ${}_{ss}\mathcal{U}_1^1(x)$, ${}_{ss}\mathcal{U}_2^2(x)$, ${}_{ss}\mathcal{U}_3^3(x)$, and ${}_{ss}\mathcal{U}_2^1(y)$ and their action on the reference state Φ. Rewriting the Yang–Baxter equation (16) we can find the following relations:

$${}_{\sigma s}\mathcal{U}^{\alpha}_{\alpha'}(y)\ {}_{\sigma s}R^{+\alpha' i}_{\ \ \beta i'}\ {}_{ss}\mathcal{U}^{i'}_{j}(x) = {}_{\sigma s}R^{\alpha i}_{\alpha' i'}(y/x)\ {}_{ss}\mathcal{U}^{i'}_{j'}(x)\ {}_{\sigma s}R_{-\ \beta' j''}^{\ \alpha' j'}\ {}_{\sigma s}\mathcal{U}^{\beta'}_{\beta''}(y)\ {}_{\sigma s}R^{\beta'' j''}_{\beta j}(x/y), \tag{36}$$

which yield the commutation rules

$${}_{ss}\mathcal{U}_1^1(x)B(y) = \frac{1}{q^2}\,\frac{{}_{\sigma s}a(x/y)}{{}_{\sigma s}c(x/y)}\,B(y)\ {}_{ss}\mathcal{U}_1^1(x) - \frac{1}{q}\,\frac{{}_{\sigma s}d_-(x/y)}{{}_{\sigma s}c(x/y)}\ {}_{ss}\mathcal{U}_2^1(x)A(y)$$
$$- \frac{1}{q}\sqrt{\left(1-\frac{1}{q^2}\right)\left(q^2-\frac{1}{q^2}\right)}\left({}_{ss}\mathcal{U}_2^1(x)D(y) + \frac{{}_{\sigma s}d_-(x/y)}{{}_{\sigma s}c(x/y)}\ {}_{ss}\mathcal{U}_3^1(x)C(y)\right),$$

$${}_{ss}\mathcal{U}_2^2(x)B(y) = \frac{{}_{\sigma s}a(y/x)\ {}_{\sigma s}a(x/y)}{{}_{\sigma s}b(y/x)\ {}_{\sigma s}b(x/y)}\,B(y)\ {}_{ss}\mathcal{U}_2^2(x) - \frac{{}_{\sigma s}d_-(y/x)}{{}_{\sigma s}b(y/x)}\ {}_{ss}\mathcal{U}_2^1(x)D(y)$$
$$- \frac{{}_{\sigma s}d_-(x/y)}{{}_{\sigma s}b(x/y)}\left(\frac{1}{q}\ {}_{ss}\mathcal{U}_3^2(x)A(y) + q\,\frac{{}_{\sigma s}d_-(y/x)}{{}_{\sigma s}b(y/x)}\ {}_{ss}\mathcal{U}_3^1(x)C(y)\right)$$
$$- \sqrt{\left(1-\frac{1}{q^2}\right)\left(q^2-\frac{1}{q^2}\right)}\ {}_{ss}\mathcal{U}_3^2(x)D(y),$$

$$ {}_{ss}\mathcal{U}_3^3(x)B(y)=q^2\,\frac{{}_{\sigma s}a(y/x)}{{}_{\sigma s}c(y/x)}\,B(y)\,{}_{ss}\mathcal{U}_3^3(x)-q^2\,\frac{{}_{\sigma s}d_-(y/x)}{{}_{\sigma s}c(y/x)}\,{}_{ss}\mathcal{U}_3^2(x)D(y). \tag{37} $$

We also observe that

$$ {}_{ss}\mathcal{U}_1^1(x)\Phi=\Phi,\quad {}_{ss}\mathcal{U}_2^2(x)\Phi=q^{-2L}\,{}_{ss}a(1/x)^L\Phi,\quad {}_{ss}\mathcal{U}_3^3(x)\Phi=q^{-4L}\,{}_{ss}b(1/x)^L\Phi. \tag{38} $$

Then applying the transfer matrix ${}_{ss}\mathcal{T}$ on the vector Ψ (31) and using Eqs. (36) and (38) we get the eigenvalues of ${}_{ss}\mathcal{T}$

$$ {}_{ss}\Lambda(x)=q^{2-2M}\prod_{i=1}^{M}\frac{{}_{\sigma s}a(x/x_i)}{{}_{\sigma s}c(x/x_i)}+q^{-2L}\,{}_{ss}a(1/x)^L\prod_{i=1}^{M}\frac{{}_{\sigma s}a(x/x_i)\,{}_{\sigma s}a(x_i/x)}{{}_{\sigma s}b(x/x_i)\,{}_{\sigma s}b(x_i/x)} $$
$$ +q^{2(M-2L-1)}\,{}_{ss}b(1/x)^L\prod_{i=1}^{M}\frac{{}_{\sigma s}a(x_i/x)}{{}_{\sigma s}c(x_i/x)}. \tag{39} $$

We have obtained (39) by taking into account only the first terms on the r.h.s. of Eq. (36). All other terms generate unwanted contributions and the condition of their equality to zero yields the BAE (35). A simpler way to recover the BAE from (39) is by demanding that the eigenvalue ${}_{ss}\Lambda(x)$ (39) has no poles at $x=q^{\pm 1/2}x_i$, since ${}_{ss}\mathcal{T}$ is an analytic function in x. Finally, we obtain the eigenvalues of the Hamiltonian (24) from (23) and (39)

$$ E=\sum_{i=1}^{M}\frac{-2(q^2-q^{-2})}{(x_i^{-1}q^{-1/2}-x_iq^{1/2})(x_i^{-1}q^{3/2}-x_iq^{-3/2})}. \tag{40} $$

In the rational limit $q\to 1$, this expression reduces to that obtained by Babujian[20] for the usual periodic case (with appropriate rescaling).

IV. HIGHEST WEIGHT PROPERTY

In this section we show that the Bethe vectors are highest weight vectors with respect to $U_q(sl(2))$. We begin by writing

$$ {}_{\sigma s}R^+=\begin{pmatrix} q^{1/2h} & 0\\ q^{-1/2}(q-q^{-1})e & q^{-1/2h}\end{pmatrix}, $$
$$ {}_{\sigma s}R_-=\begin{pmatrix} q^{-1/2h} & -q^{1/2}(q-q^{-1})f\\ 0 & q^{1/2h}\end{pmatrix}, \tag{41} $$

where h, e, f are the $sl(2)$ generators in the spin-1 representation. Next, defining the constant auxiliary monodromy matrix as

$$ {}_{\sigma s}\mathcal{U}_\alpha^{-\beta}=\lim_{x\to 0}\,{}_{\sigma s}\mathcal{U}_\alpha^\beta(x)=({}_{\sigma s}R_-)^{\beta j}_{\alpha' j'}({}_{\sigma s}R^+)^{\alpha' j'}_{\alpha i}, \tag{42} $$

we have from (41)

$$ C^-=q^{-1/2}(q-q^{-1})q^{-1/2h}e. \tag{43} $$

The Bethe vectors (31) are highest weight vectors if

$$ C^-\Psi=0. \tag{44} $$

This can be proven by observing that from the Yang–Baxter algebra (15) we can obtain the following relation:

$$ C^-B(x)=B(x)C^-+(1-q^{-2})(A(x)D^--D^-D(x)), \tag{45} $$

which, using the fact that $C^{-}\Phi=0$, allows us to write

$$C^{-}\Psi=\sum_{i=1}^{M} Y_i W_i \Phi \tag{46}$$

where

$$W_i=B(x_1)B(x_2)\cdots B(x_{i-1})B(x_{i+1})\cdots B(x_M). \tag{47}$$

The Y_i can be computed using Eqs. (32) and (33) which yield

$$Y_i=(1-q^{-2})q^{3/2L}\ {}_{\sigma s}a(1/x_i)^L\prod_{j\neq i}^{M} q^{-1}\ \frac{{}_{\sigma\sigma}a(x_i/x_j)}{{}_{\sigma\sigma}b(x_i/x_j)}-(1-q^{-2})q^{-L/2}\ {}_{\sigma s}c(1/x_i)^L\prod_{j\neq i}^{M} q\ \frac{{}_{\sigma\sigma}a(x_j/x_i)}{{}_{\sigma\sigma}b(x_j/x_i)}. \tag{48}$$

Because of the BAE (35), each of the coefficients Y_i vanishes which implies

$$C^{-}\Psi=0.$$

It immediately follows that each of the Bethe states are highest weight states. By using the $U_q(sl(2))$ lowering operator f we obtain additional states which will also be eigenstates of the transfer matrix because of the quantum symmetry of the model.

For generic values of the deformation parameter q it is well known that the dimensions and weight spectrum of the finite dimensional irreducible representations of $U_q(sl(2))$ are in 1-1 correspondence with those of $sl(2)$. Since it is known[26,28] in the $q=1$ case that the Bethe states combined with the $sl(2)$ symmetry give a complete set of states for the model, it should be possible to prove, using methods developed in Ref. 29, that this is also true for the model described above.

V. CONCLUSIONS

We have solved a quantum algebra invariant integrable closed spin-1 chain by an algebraic Bethe ansatz approach. Particularly eigenstates of the model were constructed and their energy eigenvalues evaluated. A proof of the highest weight property of the Bethe vectors with respect to $U_q(sl(2))$ was also presented. A natural extension of this work would be to generalize the results of the spin-1 chain to corresponding chains of arbitrary spin s.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 2 FEBRUARY 1999

Deconstructing supersymmetry

N. S. Manton[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge CB3 9EW, England

(Received 15 June 1998; accepted for publication 9 November 1998)

Two supersymmetric classical mechanical systems are discussed. Concrete realizations are obtained by supposing that the dynamical variables take values in the Grassmann algebra B_2 with two generators. The equations of motion are explicitly solved, and the action of the supergroup on the space of solutions is elucidated. The Lie algebra of the supergroup is the even part of the tensor product $B_2 \otimes \mathcal{G}$, where $\mathcal{G}$ is the super Lie algebra of supersymmetries and time translations. For each system, the solutions with zero energy need to be constructed separately. For these Bogomolny-type solutions, the orbit of the supergroup is smaller than in the generic case. © *1999 American Institute of Physics.* [S0022-2488(99)03302-2]

I. INTRODUCTION

Supersymmetry is one of the most powerful ideas in theoretical physics, combining bosonic and fermionic fields into a unified framework. Most supersymmetric theories are defined by a Lagrangian, from which the classical field equations are derived. However the meaning of the fermionic fields in such equations is not always clear, because they need to be anticommuting. Moreover, there are usually sources for the bosonic fields which are bilinear in the fermionic fields, and such sources are not ordinary functions. So an interpretation of the bosonic fields as ordinary functions fails in supersymmetric theories. It is mathematically consistent to treat bosonic and fermionic fields as ordinary functions, as in classical QED or QCD, but such a treatment cannot be supersymmetric.

It might be thought that only the quantized versions of supersymmetric theories really make sense. This is not so. The formalism for making sense of classical supersymmetric theories is readily available, but perhaps not sufficiently appreciated by theoretical physicists. As emphasized by De Witt,[1] and also by Freund,[2] fields in a supersymmetric field theory must take their values in a Grassmann algebra B. B is the direct sum of an even part B_e and an odd part B_o. The bosonic fields are valued in B_e, and the fermionic fields in B_o. It is necessary to decide which algebra B to work with. B can have a finite number, n, of generators, or an infinite number, and the content of the classical theory will depend on the choice. With n generators, a scalar bosonic field is represented by 2^{n-1} ordinary functions, and by an infinite number if B is infinitely generated. This is rather daunting, and it is not clear what all these functions might mean physically. However, we shall choose $n=2$ in what follows, and the resulting equations are quite manageable. (The choice $n=1$ leads to trivial equations.) Choosing n to be as small as possible means that the theory, while including fermions, is as close as possible to the underlying classical, purely bosonic, theory. It is sometimes argued that choosing n to be finite leads to ambiguities or contradictions. The argument is connected with Green's functions and quantization. In a classical context there appear to be no problems—at least, we encounter no problems in the models discussed here, except one small matter which is dealt with in Sec. II.

Our aim is to present concrete examples of classical supersymmetric theories, and to solve the equations of motion. Rather than considering a genuine field theory, we shall simplify matters by considering supersymmetric mechanical models, whose dynamical variables depend only on time. Mechanical models, with bosonic and fermionic dynamical variables taking values in a Grassmann

[a)]Electronic mail: N.S.Manton@damtp.cam.ac.uk

algebra, were investigated by Casalbuoni[3] and by Berezin and Marinov,[4] although not solved except in very simple cases. Supersymmetry constrains the structure of such models. The dynamical variables, taken together, define a point in a supermanifold, which traces out a curve as time varies. The mathematically rigorous treatment of the geometry of dynamical systems in supermanifolds is tricky, and there is more than one point of view. For discussions of functions and their derivatives on a supermanifold, and of the topology and geometry of supermanifolds, the reader may turn to a number of papers, e.g. Refs. 5 and 6, as well as Ref. 1. We will not use supermanifold theory in any significant way here.

We analyze two supersymmetric mechanical models below. We present the Lagrangian and equations of motion, their symmetries, and the associated conserved quantities, and proceed to find the explicit form of the general solution of the equations of motion. We believe that this has not been done before. The possibility of constructing general solutions of the nonlinear coupled ordinary differential equations (ODEs) shows the power of the supersymmetry of these models. From the super Lie algebra of supersymmetries and time translations we construct, in a standard way, a genuine Lie algebra of infinitesimal symmetries, which generates a genuine Lie group of symmetries of the dynamics—the supergroup. Technically, if n is finite, the supergroup is the nth skeleton of the full supergroup. The solutions depend on a number of constants of integration, and we comment on the extent to which, when $n=2$, the supergroup relates solutions with different values of these constants.

For each of these models, the solutions with zero energy need to be constructed independently. Here, one of the bosonic equations of motion reduces to a first-order Bogomolny-type equation.[7] The solution space is still acted on by the supergroup, but the orbit is of lower dimension than in the generic case. This feature of Bogomolny equations is not unfamiliar, but the complete solution of the equations of motion, including the fermionic variables, is perhaps novel.

Section II discusses the $N=2$ supersymmetric mechanics of a particle moving in one dimension, subject to a potential. The model is a variant of the one whose quantized version was analyzed by Witten.[8] Section III is concerned with the zero energy, Bogomolny case. Section IV discusses the $N=1$ supersymmetric mechanics of a particle moving in one dimension. Again the model is a variant of the standard one, as the Lagrangian depends on a constant odd parameter. We conclude in Sec. V with some comments on the analysis, and on potential generalizations of this work.

II. $N=2$ SUPERSYMMETRIC MECHANICS

Consider the following $N=2$ supersymmetric Lagrangian (Refs. 8, 1—Sec. 5.7):

$$L=\tfrac{1}{2}\dot{x}^2+\tfrac{1}{2}U(x)^2+\tfrac{1}{2}\dot{\psi}_1\psi_1-\tfrac{1}{2}\dot{\psi}_2\psi_2+U'(x)\psi_1\psi_2, \tag{2.1}$$

where the dynamical variables x, ψ_1, and ψ_2 take values in an arbitrary Grassmann algebra B. This describes the supersymmetric mechanics of a particle moving in one dimension in a potential $-U^2$. $x(t)$ is bosonic (i.e., commuting) and $\psi_1(t)$ and $\psi_2(t)$ are fermionic (i.e., anticommuting) variables. Thus x is valued in B_e, whereas ψ_1 and ψ_2 are valued in B_o. Any function of x, e.g., $U(x)$, commutes with x. Such functions are defined as polynomials or power series with real coefficients. If $U(x)=x^p$, with p a positive integer, then $U'(x)=px^{p-1}$, with the obvious extension to polynomials and power series. An overdot denotes the derivative with respect to time t. $\dot{x}$ commutes with x, and similarly, $\dot{\psi}_1$ and $\dot{\psi}_2$ anticommute with both ψ_1 and ψ_2; hence the dynamics is classical, rather than quantized. Note that the terms $\dot{\psi}_1\psi_1$ and $\dot{\psi}_2\psi_2$ are not total time derivatives.

The Lagrangian L may be obtained by dimensional reduction of the $1+1$-dimensional $N=1$ supersymmetric field theory with Lagrangian density

$$\mathcal{L}=\frac{1}{2}\partial_+\Phi\partial_-\Phi-\frac{1}{2}U(\Phi)^2+\frac{i}{2}\psi_1\partial_-\psi_1+\frac{i}{2}\psi_2\partial_+\psi_2+i\frac{dU}{d\Phi}\psi_1\psi_2, \tag{2.2}$$

where ∂_+ and ∂_- are the standard light cone derivatives. By assuming that all fields are independent of the spatial coordinate, then absorbing certain factors of $\sqrt{i}$, etc., in the fields and potential, and finally writing Φ as x, we recover the expression (2.1). The density (2.2) is real in a certain sense,[1] but for our purposes the manifestly real expression (2.1) is a more convenient Lagrangian to discuss.

To obtain the equations of motion we calculate the formal variation ΔL due to variations Δx, $\Delta\psi_1$, and $\Delta\psi_2$. We combine $\Delta\dot{x}$, $\Delta\dot{\psi}_1$, and $\Delta\dot{\psi}_2$ into total time derivative terms, which are ignored, then move Δx, $\Delta\psi_1$, and $\Delta\psi_2$ to the left in each term. The result is

$$\Delta L=\Delta x(-\ddot{x}+UU'+U''\psi_1\psi_2)+\Delta\psi_1(-\dot{\psi}_1+U'\psi_2)+\Delta\psi_2(\dot{\psi}_2-U'\psi_1), \tag{2.3}$$

so the equations of motion are

$$\ddot{x}=UU'+U''\psi_1\psi_2, \tag{2.4a}$$

$$\dot{\psi}_1=U'\psi_2, \tag{2.4b}$$

$$\dot{\psi}_2=U'\psi_1. \tag{2.4c}$$

There is a possible ambiguity here. ΔL should be zero for all Δx in B_e and all $\Delta\psi_1$, $\Delta\psi_2$ in B_o. If B has an infinity of generators, this implies Eqs. (2.4). However, if B has n generators, then the coefficients of $\Delta\psi_1$ and $\Delta\psi_2$ need not be zero, but could be an element of highest degree in B, with arbitrary time dependence. This possibility can be excluded by careful definition of odd derivatives.[9] More trivially, below we shall assume that n is even $(n=2)$, and then this possibility is excluded because these coefficients are constrained to be odd.

There are two supersymmetry operators $\mathcal{Q}$ and $\tilde{\mathcal{Q}}$. Together with d/dt they are a basis for a super Lie algebra over the real numbers with nontrivial relations

$$\mathcal{Q}^2=\frac{d}{dt}, \quad \tilde{\mathcal{Q}}^2=-\frac{d}{dt}, \quad \mathcal{Q}\tilde{\mathcal{Q}}+\tilde{\mathcal{Q}}\mathcal{Q}=0. \tag{2.5}$$

Formally, the algebra has a representation on the dynamical variables

$$\mathcal{Q}x=\psi_1, \quad \mathcal{Q}\psi_1=\dot{x}, \quad \mathcal{Q}\psi_2=U, \tag{2.6a}$$

$$\tilde{\mathcal{Q}}x=\psi_2, \quad \tilde{\mathcal{Q}}\psi_2=-\dot{x}, \quad \tilde{\mathcal{Q}}\psi_1=-U, \tag{2.6b}$$

with d/dt acting in the obvious way. This ''on-shell'' representation requires that the equations $\dot{\psi}_1=U'\psi_2$ and $\dot{\psi}_2=U'\psi_1$ are satisfied, so that, e.g., $\mathcal{Q}^2\psi_2=\mathcal{Q}U=U'(\mathcal{Q}x)=U'\psi_1=\dot{\psi}_2$. $\mathcal{Q}$, $\tilde{\mathcal{Q}}$, and d/dt are all symmetries of the Lagrangian, provided $\mathcal{Q}$ and $\tilde{\mathcal{Q}}$ are treated as antiderivations [an extra minus sign in the Leibniz rule when $\mathcal{Q}$ or $\tilde{\mathcal{Q}}$ goes past a fermionic variable, e.g., $\mathcal{Q}(\psi_1\psi_2)=(\mathcal{Q}\psi_1)\psi_2-\psi_1\mathcal{Q}\psi_2=\dot{x}\psi_2-\psi_1 U$]. Now although the actions of $\mathcal{Q}$ and $\tilde{\mathcal{Q}}$ given by (2.6) make formal sense, they cannot be regarded as variations of the dynamical variables. A bosonic variable cannot be varied by a fermionic one. Moreover, the vague requirement that the coefficients of $\mathcal{Q}$ and $\tilde{\mathcal{Q}}$ should be anticommuting, common in the literature, is not sufficiently precise. However, genuine variations are obtained by taking the coefficients of $\mathcal{Q}$ and $\tilde{\mathcal{Q}}$ to be arbitrary infinitesimal elements of B_o, and the coefficient of d/dt to be an infinitesimal element of B_e.

The super Lie algebra over the real numbers becomes an ordinary Lie algebra if the coefficients lie in B, as above. This construction is, in fact, well known.[2,10] If one takes a super Lie algebra $\mathcal{G}$ and tensors it with a Grassmann algebra of coefficients B, and keeps just the even part

$$(B\otimes\mathcal{G})_e=(B_e\otimes\mathcal{G}_e)\oplus(B_o\otimes\mathcal{G}_o), \tag{2.7}$$

then this is an ordinary Lie algebra over the reals, if the bracket is defined by

$$[b_1 g_1, b_2 g_2] = b_1 b_2 [g_1, g_2](-1)^{|b_2||g_1|}, \tag{2.8}$$

where $|\ |$ denotes the grade (0 for even elements, 1 for odd), and $[g_1,\ g_2]$ is the bracket in the super Lie algebra. The Lie group generated by this Lie algebra is the supergroup, and is the concrete symmetry group of our mechanical system.

Thus, the variations of the dynamical quantities generated by the supersymmetry operator $\mathcal{Q}$ are

$$\delta x = \eta \psi_1, \quad \delta\psi_1 = \eta \dot{x}, \quad \delta\psi_2 = \eta U, \tag{2.9}$$

where η is an arbitrary infinitesimal constant in B_o. It is easily shown that the variation of the Lagrangian L is a total time-derivative

$$\delta L = \eta \frac{d}{dt}\left(\frac{1}{2}\dot{x}\psi_1 + \frac{1}{2}U\psi_2\right) \tag{2.10}$$

using $\dot{U} = U'\dot{x}$. The usual Noether method gives the conserved supersymmetry charge

$$Q = \dot{x}\psi_1 - U\psi_2. \tag{2.11}$$

The conservation of Q is easily verified using the equations of motion:

$$\dot{Q} = \ddot{x}\psi_1 + \dot{x}\dot{\psi}_1 - U'\dot{x}\psi_2 - U\dot{\psi}_2 = UU'\psi_1 + U''\psi_1\psi_2\psi_1 + \dot{x}U'\psi_2 - U'\dot{x}\psi_2 - UU'\psi_1 = 0 \tag{2.12}$$

since $\psi_1\psi_2\psi_1 = -\psi_1\psi_1\psi_2 = 0$. The variations generated by the second supersymmetry operator $\tilde{\mathcal{Q}}$ are

$$\tilde{\delta} x = \eta\psi_2, \quad \tilde{\delta}\psi_2 = -\eta\dot{x}, \quad \tilde{\delta}\psi_1 = -\eta U, \tag{2.13}$$

and lead to the conserved supersymmetry charge

$$\tilde{Q} = \dot{x}\psi_2 - U\psi_1. \tag{2.14}$$

The supersymmetries relate different solutions of the equations of motion. To see this, consider the linearized variations of Eqs. (2.4),

$$(\Delta \ddot{x}) = (UU')'\Delta x + U'''\Delta x\psi_1\psi_2 + U''\Delta\psi_1\psi_2 + U''\psi_1\Delta\psi_2, \tag{2.15a}$$

$$(\Delta\dot{\psi}_1) = U''\Delta x\psi_2 + U'\Delta\psi_2, \tag{2.15b}$$

$$(\Delta\dot{\psi}_2) = U''\Delta x\psi_1 + U'\Delta\psi_1, \tag{2.15c}$$

and assume that x, ψ_1, and ψ_2 satisfy (2.4). The linear equations (2.15) are satisfied by setting $\Delta = \delta$ or $\Delta = \tilde{\delta}$, and using the variations defined in (2.9) and (2.13). Later, we shall see more concretely, and not just in the linearized approximation, how supersymmetry relates different solutions.

Since the Lagrangian (2.1) does not depend explicitly on time, we expect a conserved energy, associated with time translation symmetry. This symmetry is defined by the infinitesimal variations

$$\Delta x = \eta\dot{x}, \quad \Delta\psi_1 = \eta\dot{\psi}_1, \quad \Delta\psi_2 = \eta\dot{\psi}_2, \tag{2.16}$$

where η is now an arbitrary infinitesimal element of B_e. The energy is

$$H=\tfrac{1}{2}\dot{x}^2-\tfrac{1}{2}U^2-U'\psi_1\psi_2, \tag{2.17}$$

and its conservation is easily checked using the equations of motion.

In simple cases, it is possible to solve the equations of motion for any choice of the Grassmann algebra B, and without explicit reference to B. An example is when $U(x)=\omega x$, with ω a real constant, so $U'=\omega$ and $U''=0$, and the equations simplify. This is the analog of the supersymmetric harmonic oscillator, discussed and solved by De Witt,[1] but in our case the potential is inverted. The solution can be expressed in terms of initial data as

$$x(t)=x(0)\cosh\omega t+\frac{1}{\omega}\dot{x}(0)\sinh\omega t, \tag{2.18a}$$

$$\psi_1(t)=\psi_1(0)\cosh\omega t+\psi_2(0)\sinh\omega t, \tag{2.18b}$$

$$\psi_2(t)=\psi_2(0)\cosh\omega t+\psi_1(0)\sinh\omega t. \tag{2.18c}$$

We have not been able to solve the equations of motion (2.4) for general $U(x)$ and an arbitrary choice of the Grassmann algebra B, and in particular for B having an infinity of generators. It would be interesting to do so. If B has just one generator, then the equations are rather trivial, because $\psi_1\psi_2$ vanishes. So the simplest nontrivial case, which we discuss from here on, is where B is generated by just two elements α,β satisfying

$$\alpha^2=0,\quad \beta^2=0,\quad \alpha\beta+\beta\alpha=0. \tag{2.19}$$

A basis for the algebra is $\{1,\alpha,\beta,\alpha\beta\}$, and it follows from (2.19) that $(\alpha\beta)^2=0$. There is a matrix realization of these relations, although we will not use it. Let $\{\gamma^\mu:1\leqslant\mu\leqslant 4\}$ denote Dirac matrices in four Euclidean dimensions, and set $\alpha=\gamma^1+i\gamma^2$, $\beta=\gamma^3+i\gamma^4$.

Let us write the dynamical variables in component form as

$$x(t)=x_0(t)+x_1(t)\alpha\beta, \tag{2.20a}$$

$$\psi_1(t)=a_1(t)\alpha+b_1(t)\beta, \tag{2.20b}$$

$$\psi_2(t)=a_2(t)\alpha+b_2(t)\beta, \tag{2.20c}$$

where x_0,x_1,a_1,b_1,a_2,b_2 are ordinary functions of time. The ''body,'' $x_0(t)$, can be regarded as classical, but its partner $x_1(t)$ is a less familiar quantity.

Any positive power of x now has the truncated expansion

$$x^n=x_0^n+nx_0^{n-1}x_1\alpha\beta, \tag{2.21}$$

which extends to an arbitrary function of x as

$$U(x)=U(x_0)+U'(x_0)x_1\alpha\beta, \tag{2.22}$$

where $U'(x_0)$ denotes the usual derivative of $U(x_0)$ with respect to x_0. Henceforth, if the argument of U and its derivatives is not shown, it is x_0, with x_0 itself a function of t. The Lagrangian is the even function $L=L_0+L_1\alpha\beta$, where

$$L_0=\tfrac{1}{2}\dot{x}_0^2+\tfrac{1}{2}U^2, \tag{2.23a}$$

$$L_1=\dot{x}_0\dot{x}_1+UU'x_1+\dot{a}_1b_1-\dot{a}_2b_2+U'(a_1b_2-a_2b_1). \tag{2.23b}$$

Substituting (2.20) into (2.4), we obtain the equations of motion for the components

$$\ddot{x}_0 = UU', \tag{2.24a}$$

$$\ddot{x}_1 = (UU')'x_1 + U''(a_1 b_2 - a_2 b_1), \tag{2.24b}$$

$$\dot{a}_1 = U' a_2, \tag{2.24c}$$

$$\dot{a}_2 = U' a_1, \tag{2.24d}$$

$$\dot{b}_1 = U' b_2, \tag{2.24e}$$

$$\dot{b}_2 = U' b_1. \tag{2.24f}$$

These equations can also be derived as the variational equations of L_0 and L_1. In fact, surprisingly, they can all be derived from L_1 alone, as the equation of motion for x_0, obtained from L_0, is the same as the equation obtained from L_1 by varying x_1.

There are a host of symmetries and conservation laws associated with the component form of the system. With B generated by α and β, the supergroup is six dimensional, its Lie algebra having basis elements

$$\mathcal{Q}_\alpha = \alpha \mathcal{Q}, \quad \mathcal{Q}_\beta = \beta \mathcal{Q}, \quad \tilde{\mathcal{Q}}_\alpha = \alpha \tilde{\mathcal{Q}}, \quad \tilde{\mathcal{Q}}_\beta = \beta \tilde{\mathcal{Q}}, \quad \frac{d}{dt}, \quad \frac{\tilde{d}}{dt} = \alpha\beta \frac{d}{dt}, \tag{2.25}$$

where d/dt is the usual time derivative and $\widetilde{d/dt}$ we call the mini-time-derivative. Almost all these generators commute, except that

$$[\mathcal{Q}_\alpha, \mathcal{Q}_\beta] = -2\frac{\tilde{d}}{dt}, \quad [\tilde{\mathcal{Q}}_\alpha, \tilde{\mathcal{Q}}_\beta] = 2\frac{\tilde{d}}{dt}. \tag{2.26}$$

Note that the signs in (2.26) are consistent with (2.8).

Following (2.9), we define two variations δ_α and δ_β, generated by $\mathcal{Q}_\alpha$ and $\mathcal{Q}_\beta$, by

$$\delta_\alpha x = \epsilon \alpha \psi_1, \quad \delta_\alpha \psi_1 = \epsilon \alpha \dot{x}, \quad \delta_\alpha \psi_2 = \epsilon \alpha U(x), \tag{2.27}$$

where ϵ is infinitesimal and real, and δ_β similarly by replacing α by β. In components, the first of these variations becomes

$$\delta_\alpha (x_0 + x_1 \alpha\beta) = \epsilon b_1 \alpha\beta \tag{2.28}$$

so $\delta_\alpha x_0 = 0$ and $\delta_\alpha x_1 = \epsilon b_1$. Similarly, by expanding out, we find the complete set of component variations

$$\delta_\alpha x_1 = \epsilon b_1, \quad \delta_\alpha a_1 = \epsilon \dot{x}_0, \quad \delta_\alpha a_2 = \epsilon U, \tag{2.29a}$$

$$\delta_\beta x_1 = -\epsilon a_1, \quad \delta_\beta b_1 = \epsilon \dot{x}_0, \quad \delta_\beta b_2 = \epsilon U, \tag{2.29b}$$

with all other variations, e.g., $\delta_\beta a_1$, vanishing. The generators $\tilde{Q}_\alpha$ and $\tilde{Q}_\beta$ lead similarly to the two independent sets of variations

$$\tilde{\delta}_\alpha x_1 = \epsilon b_2, \quad \tilde{\delta}_\alpha a_1 = -\epsilon U, \quad \tilde{\delta}_\alpha a_2 = -\epsilon \dot{x}_0, \tag{2.30a}$$

$$\tilde{\delta}_\beta x_1 = -\epsilon a_2, \quad \tilde{\delta}_\beta b_1 = -\epsilon U, \quad \tilde{\delta}_\beta b_2 = -\epsilon \dot{x}_0. \tag{2.30b}$$

x_0, and hence L_0, is unchanged by all these variations.

It is easy to verify that all four sets of variations δ_α, δ_β, $\tilde{\delta}_\alpha$, $\tilde{\delta}_\beta$ are Noether symmetries of the Lagrangian L_1, giving total time derivatives. For example,

$$\delta_\alpha L_1 = \epsilon(\dot{x}_0\dot{b}_1 + UU'b_1 + \ddot{x}_0 b_1 - U'\dot{x}_0 b_2 + U'(\dot{x}_0 b_2 - Ub_1)) = \epsilon\frac{d}{dt}(\dot{x}_0 b_1). \tag{2.31}$$

In the usual way, we obtain the conserved Noether charges

$$Q_\alpha = \dot{x}_0 b_1 - Ub_2, \tag{2.32a}$$

$$Q_\beta = -\dot{x}_0 a_1 + Ua_2, \tag{2.32b}$$

$$\tilde{Q}_\alpha = \dot{x}_0 b_2 - Ub_1, \tag{2.32c}$$

$$\tilde{Q}_\beta = -\dot{x}_0 a_2 + Ua_1, \tag{2.32d}$$

and may verify their conservation using the equations of motion (2.24). Of course, these charges are just the components of the supersymmetry charges we found earlier, although with labels switched, namely

$$Q = -Q_\beta\alpha + Q_\alpha\beta, \tag{2.33a}$$

$$\tilde{Q} = -\tilde{Q}_\beta\alpha + \tilde{Q}_\alpha\beta. \tag{2.33b}$$

Both L_0 and L_1 are invariant under ordinary time translations, leading to the conservation of two energies

$$H_0 = \tfrac{1}{2}\dot{x}_0^2 - \tfrac{1}{2}U^2, \tag{2.34a}$$

$$H_1 = \dot{x}_0\dot{x}_1 - UU'x_1 - U'(a_1 b_2 - a_2 b_1). \tag{2.34b}$$

The conserved energy we found earlier is $H = H_0 + H_1\alpha\beta$.

There is a further symmetry, the mini-time-translation symmetry. The variations generated by $\widetilde{d/dt}$ are

$$\Delta x = \epsilon\alpha\beta\dot{x}, \quad \Delta\psi_1 = \epsilon\alpha\beta\dot{\psi}_1, \quad \Delta\psi_2 = \epsilon\alpha\beta\dot{\psi}_2, \tag{2.35}$$

with ϵ real. Expanding out in components, we find a single nonzero variation

$$\Delta x_1 = \epsilon\dot{x}_0. \tag{2.36}$$

The associated variation of L_1 is the total time derivative

$$\Delta L_1 = \epsilon(\dot{x}_0\ddot{x}_0 + UU'\dot{x}_0) = \epsilon\frac{d}{dt}\left(\frac{1}{2}\dot{x}_0^2 + \frac{1}{2}U^2\right), \tag{2.37}$$

and the conserved quantity is

$$\tfrac{1}{2}\dot{x}_0^2 - \tfrac{1}{2}U^2, \tag{2.38}$$

which is H_0. So we see that the equations of motion and both conserved energies, and all four components of the supersymmetry charges, can be derived from L_1.

This exhausts the infinitesimal action of the supergroup, but there are yet more symmetries which mix the functions a_1, a_2, b_1, b_2. The combined variations

$$\Delta a_1 = \epsilon b_1, \quad \Delta a_2 = \epsilon b_2 \tag{2.39}$$

leave L_1 invariant, as do the variations

$$\Delta b_1 = \epsilon a_1, \quad \Delta b_2 = \epsilon a_2. \tag{2.40}$$

Finally, L_1 is invariant under

$$\Delta a_1 = \epsilon a_2, \quad \Delta a_2 = \epsilon a_1, \quad \Delta b_1 = \epsilon b_2, \quad \Delta b_2 = \epsilon b_1. \tag{2.41}$$

These symmetries imply that

$$R_a = b_1^2 - b_2^2, \tag{2.42a}$$

$$R_b = a_1^2 - a_2^2, \tag{2.42b}$$

$$R = a_1 b_2 - a_2 b_1 \tag{2.42c}$$

are all conserved. The conservation of R can also be understood from the symmetry of the original Lagrangian L under the infinitesimal variations

$$\Delta \psi_1 = \epsilon \psi_2, \quad \Delta \psi_2 = \epsilon \psi_1 \tag{2.43}$$

with ϵ real, which implies the conservation of $\psi_1 \psi_2$.

We turn now to the solution of the coupled equations (2.24). We start with the equation for x_0. This is the classical equation of the model without fermionic variables. It has the first integral

$$\dot{x}_0^2 - U^2 = 2E, \tag{2.44}$$

where $H_0 = E$ is the conserved energy, hence

$$\dot{x}_0 = (2E + U^2)^{1/2}. \tag{2.45}$$

The solution in integral form is

$$\int_{X_0}^{x_0} \frac{dx_0'}{(2E + U(x_0')^2)^{1/2}} = t, \tag{2.46}$$

where $x_0 = X_0$ at $t = 0$.

Given $x_0(t)$, and hence $U'(x_0(t))$, we can solve the linear equations for a_1, a_2, b_1, b_2. Of course, one solution is that these four functions all vanish. The supersymmetry variations (2.29) and (2.30) suggest the solution

$$a_1 = \lambda \dot{x}_0 + \mu U, \tag{2.47a}$$

$$a_2 = \lambda U + \mu \dot{x}_0, \tag{2.47b}$$

$$b_1 = \sigma \dot{x}_0 + \tau U, \tag{2.47c}$$

$$b_2 = \sigma U + \tau \dot{x}_0, \tag{2.47d}$$

where $\lambda, \mu, \sigma, \tau$ are arbitrary real constants, and U denotes $U(x_0(t))$. These functions do satisfy the equations of motion, e.g.,

$$\dot{a}_1 = \lambda \ddot{x}_0 + \mu U' \dot{x}_0 = \lambda U U' + \mu U' \dot{x}_0 = U' a_2, \tag{2.48}$$

and the presence of four constants implies that (2.47) is the general solution. The value of the conserved supersymmetry charge component Q_α is

$$Q_\alpha=\dot{x}_0 b_1-Ub_2=\sigma(\dot{x}_0^2-U^2)=2E\sigma, \tag{2.49}$$

and similarly $Q_\beta=-2E\lambda$, $\tilde{Q}_\alpha=2E\tau$, and $\tilde{Q}_\beta=-2E\mu$. The R charges take the values $R_a=2E(\sigma^2-\tau^2)$, $R_b=2E(\lambda^2-\mu^2)$, and $R=2E(\lambda\tau-\mu\sigma)$. There is a problem, however, if $E=0$, for then

$$\dot{x}_0=\pm U \tag{2.50}$$

and the expressions (2.47) depend on only two arbitrary constants. Equation (2.50) is the Bogomolny equation for this system. We postpone discussion of the general solution in this case to Sec. III.

The remaining equation for x_1 is the inhomogeneous linear equation

$$\ddot{x}_1=(UU')'x_1+2E(\lambda\tau-\mu\sigma)U'', \tag{2.51}$$

where we have substituted the conserved value of $R=a_1b_2-a_2b_1$. The supersymmetry transformations and the mini-time-translation suggest that solutions can be constructed from U and $\dot{x}_0$. It may be verified, using (2.24a) and (2.44), that a particular integral of (2.51) is

$$x_1=(\lambda\tau-\mu\sigma)U. \tag{2.52}$$

A solution of the homogeneous equation $\ddot{x}_1=(UU')'x_1$ is $x_1=\dot{x}_0=(2E+U^2)^{1/2}$, since $d^3x_0/dt^3=d(UU')/dt=(UU')'\dot{x}_0$. A second solution must satisfy $\dot{x}_1\dot{x}_0-x_1\ddot{x}_0=C$ for some constant (Wronskian) C. Write $x_1=f(t)\dot{x}_0$. Then f must satisfy $\dot{f}=C/\dot{x}_0^2$, so

$$\frac{df}{dx_0}=\frac{C}{\dot{x}_0^3}=\frac{C}{(2E+U^2)^{3/2}}, \tag{2.53}$$

and hence the second solution is

$$x_1=C(2E+U^2)^{1/2}\int_{X_0}^{x_0(t)}\frac{dx_0'}{(2E+U(x_0')^2)^{3/2}}. \tag{2.54}$$

The complete solution of (2.51) is therefore

$$x_1=(\lambda\tau-\mu\sigma)U+C_1(2E+U^2)^{1/2}+C_2(2E+U^2)^{1/2}\int_{X_0}^{x_0(t)}\frac{dx_0'}{(2E+U(x_0')^2)^{3/2}}. \tag{2.55}$$

The value of the energy constant H_1 is C_2.

We have therefore found the general solution of the equations of motion (2.24), in terms of eight constants of integration $X_0,E,\lambda,\mu,\sigma,\tau,C_1,C_2$. Although the potential $-U(x_0)^2$ is negative, the motion can be a bounded nonlinear oscillation if the minimum of the potential is finite and occurs at finite x_0, and if $2E$ is negative but greater than this minimum. The motion is unbounded if E is positive.

From the infinitesimal action of the supergroup on the dynamical variables, one can find its action on the constants of integration of the general solution. For example, a mini-time-translation changes C_1, and has no other effect. It is clear that the supergroup has six-dimensional orbits in the space of solutions. Only E and C_2 are invariant.

III. ZERO ENERGY SOLUTIONS

When the energy $E=0$, the method described above does not give the general solution of the equations of motion (2.24). For this value of E,

$$\dot{x}_0^2 - U^2 = 0, \tag{3.1}$$

so x_0 satisfies the first-order Bogomolny equation

$$\dot{x}_0 = \pm U. \tag{3.2}$$

For either choice of sign, $\dot{x}_0$ and U are no longer independent functions of time, so the expressions (2.47) depend effectively on only two arbitrary constants, and are no longer the general solution.

For simplicity, let us choose the upper sign in (3.2). The lower sign choice is essentially the same, and corresponds to a time reversal. Then the solution of (3.2) is

$$\int_{X_0}^{x_0} \frac{dx_0'}{U(x_0')} = t. \tag{3.3}$$

To find the general solution of the equations for a_1, a_2, b_1, b_2, it helps to consider the limit $E \to 0$ of the solution given earlier. Note that for small nonzero E,

$$\dot{x}_0 = (2E + U^2)^{1/2} = U + \frac{E}{U} + O(E^2). \tag{3.4}$$

A suitable linear combination of $\dot{x}_0$ and U is proportional to $1/U$ in the limit $E \to 0$. We therefore try

$$a_1 = \frac{\lambda}{U} + \mu U. \tag{3.5}$$

Then

$$\dot{a}_1 = -\frac{\lambda}{U^2} U' \dot{x}_0 + \mu U' \dot{x}_0 = U' \left(-\frac{\lambda}{U} + \mu U \right) \tag{3.6}$$

if $\dot{x}_0 = U$. Thus $a_2 = -\lambda/U + \mu U$ gives a solution of (2.24c), and it is easily checked that (2.24d) is also satisfied. Similarly we can solve Eqs. (2.24e) and (2.24f). So the general solution of Eqs. (2.24c)–(2.24f) is

$$\begin{aligned} a_1 &= \frac{\lambda}{U} + \mu U, \quad a_2 = -\frac{\lambda}{U} + \mu U, \\ b_1 &= \frac{\sigma}{U} + \tau U, \quad b_2 = -\frac{\sigma}{U} + \tau U, \end{aligned} \tag{3.7}$$

where $\lambda, \mu, \sigma, \tau$ are arbitrary constants.

The constants of the motion take the following values:

$$\begin{aligned} Q_\alpha = -\tilde{Q}_\alpha = 2\sigma, \quad -Q_\beta = \tilde{Q}_\beta = 2\lambda, \\ R_a = 2\sigma\tau, \quad R_b = 2\lambda\mu, \quad R = 2(\lambda\tau - \mu\sigma). \end{aligned} \tag{3.8}$$

These values are generally nonzero because of the careful way the limit $E \to 0$ was taken, even though previously these quantities were proportional to E.

The remaining equation for x_1 also needs special treatment. This equation is

$$\ddot{x}_1 = (UU')' x_1 + RU'', \tag{3.9}$$

where R is the constant given in (3.8). The previous solution had a particular integral proportional to U, and one homogeneous solution proportional to $\dot{x}_0$. When $E=0$, and $\dot{x}_0 = U$, one homogeneous solution is still U. But a new particular integral is required. Again the limiting procedure suggests that this should be proportional to $1/U$, and this is correct. Finding a second homogeneous solution is as before, but with $E=0$. The result is that the general solution of (3.9) is

$$x_1 = -\frac{R}{2U} + C_1 U + C_2 U \int_{X_0}^{x_0(t)} \frac{dx_0'}{U(x_0')^3}, \tag{3.10}$$

where C_1 and C_2 are arbitrary constants. $H_1 = C_2$, as before.

Note that in the zero energy, Bogomolny case, the orbits of the supergroup on the space of solutions are four dimensional, rather than six dimensional. Only the coefficients of U in (3.7) and (3.10) can be varied by the group action. This is consistent with the observation that the supersymmetry generator $\mathcal{Q} + \tilde{\mathcal{Q}}$ produces no variation at all when $\dot{x}_0 = U$ and a_1, a_2, b_1, b_2, x_1 all vanish.

A further observation is the following. Suppose the fermionic variables ψ_1 and ψ_2 take values obtained by acting with the supergroup, starting from zero. In other words $\lambda = \sigma = 0$, and the terms proportional to $1/U$ are absent. Then all the constants (3.8) are zero, and in particular there is no inhomogeneous term in the equation for x_1. So x_1 can be zero, although it need not be. In this kind of solution the fermions have no backreaction at all on the bosonic variables x_0 and x_1. It is perhaps rather generally true for Bogomolny-type solutions in supersymmetric theories that the fermions may have no backreaction on the bosons.

IV. *N*=1 SUPERSYMMETRIC MECHANICS

Another example of a solvable supersymmetric mechanical model is that of a particle moving in one dimension with $N=1$ supersymmetry (sometimes referred to as $N=\frac{1}{2}$ supersymmetry).[3,11] The supersymmetry algebra is simply

$$\mathcal{Q}^2 = \frac{d}{dt}. \tag{4.1}$$

The dynamical variables are a bosonic variable $x(t)$ and a single fermionic variable $\psi(t)$, taking values in B_e and B_o, respectively. The Lagrangian is

$$L = \tfrac{1}{2}\dot{x}^2 + \tfrac{1}{2}\dot{\psi}\psi + \alpha U(x)\psi. \tag{4.2}$$

α is an odd constant, an element of B_o. It is necessary for α to be odd, and L even, otherwise the equations of motion are inconsistent. This model is a variant of the usual nontrivial $N=1$ supersymmetric mechanical models. Normally, such a model has two or more fermionic variables.[12] Here, one of these is replaced by the odd constant α.

Taking the variation of L, ignoring total time derivatives, and shifting the variations to the left, gives

$$\Delta L = -\Delta x(\ddot{x} - \alpha U'\psi) - \Delta\psi(\dot{\psi} + \alpha U). \tag{4.3}$$

ΔL is required to vanish for any Δx in B_e and $\Delta\psi$ in B_o, so the equations of motion are

$$\ddot{x} = \alpha U'\psi, \tag{4.4a}$$

$$\dot{\psi} = -\alpha U. \tag{4.4b}$$

As before, there is no ambiguity, provided B has an even number or an infinite number of generators. Note that Eqs. (4.4) are consistent, because both sides of (4.4a) are in B_e, and both sides of (4.4b) in B_o.

The formal action of the supersymmetry operator $\mathcal{Q}$ on the dynamical variables is

$$\mathcal{Q}x = \psi, \quad \mathcal{Q}\psi = \dot{x}, \tag{4.5}$$

so (4.1) is satisfied. Genuine variations of the dynamical variables are

$$\delta x = \eta\psi, \quad \delta\psi = \eta\dot{x}, \tag{4.6}$$

where η is an arbitrary infinitesimal odd constant. The corresponding variation of L is

$$\delta L = \eta(\tfrac{1}{2}\dot{x}\dot{\psi} + \tfrac{1}{2}\ddot{x}\psi - \alpha U\dot{x}). \tag{4.7}$$

Let us introduce $V(x)$, satisfying $V' = U$. Then we can write δL as a total time derivative

$$\delta L = \eta \frac{d}{dt}\left(\frac{1}{2}\dot{x}\psi - \alpha V\right). \tag{4.8}$$

Hence L is supersymmetric, and the conserved supersymmetry charge is

$$Q = \dot{x}\psi + \alpha V. \tag{4.9}$$

Using standard arguments, we also obtain the energy

$$H = \tfrac{1}{2}\dot{x}^2 - \alpha U\psi. \tag{4.10}$$

Its conservation follows from the equations of motion, together with $\alpha^2 = 0$.

We may again obtain a concrete realization of this model by supposing that the Grassmann algebra B is B_2, with just two generators. Without loss of generality we may suppose that α is one of these generators, and that the other is β. The algebra is then identical to that in Sec. II. Note that if B had only one generator, then $\alpha\psi$ would be zero, and the model would become trivial.

We write the component expansion of the dynamical variables as

$$x(t) = x_0(t) + x_1(t)\alpha\beta, \tag{4.11a}$$

$$\psi(t) = a(t)\alpha + b(t)\beta, \tag{4.11b}$$

where x_0, x_1, a, b are ordinary functions. The Lagrangian has the expansion $L = L_0 + L_1\alpha\beta$, where

$$L_0 = \tfrac{1}{2}\dot{x}_0^2, \tag{4.12a}$$

$$L_1 = \dot{x}_0\dot{x}_1 + \tfrac{1}{2}\dot{a}b - \tfrac{1}{2}\dot{b}a + U(x_0)b. \tag{4.12b}$$

The equations of motion become

$$\ddot{x}_0 = 0, \tag{4.13a}$$

$$\ddot{x}_1 = U'(x_0)b, \tag{4.13b}$$

$$\dot{a} = -U(x_0), \tag{4.13c}$$

$$\dot{b}=0. \tag{4.13d}$$

These can be obtained as the components of Eqs. (4.4). They are also the variational equations obtained from L_1 and L_0, and, as before, L_0 is redundant.

Equations (4.13) imply the conservation of

$$Q_\alpha=\dot{x}_0 a+V(x_0), \tag{4.14a}$$

$$Q_\beta=\dot{x}_0 b, \tag{4.14b}$$

$$H_0=\tfrac{1}{2}\dot{x}_0^2, \tag{4.14c}$$

$$H_1=\dot{x}_0\dot{x}_1-U(x_0)b, \tag{4.14d}$$

and these are the components of Q and H.

It is straightforward to solve Eqs. (4.13), starting with

$$x_0=\lambda t+\mu, \quad b=\nu, \tag{4.15}$$

where λ,μ,ν are arbitrary constants. The energy H_0 is $\frac{1}{2}\lambda^2$. We now regard Q_α as a constant of integration, obtaining

$$a=\frac{Q_\alpha}{\lambda}-\frac{1}{\lambda}V(\lambda t+\mu) \tag{4.16}$$

as the solution of (4.13c). Finally, treating H_1 similarly, we have

$$\dot{x}_1=\frac{H_1}{\lambda}+\frac{\nu}{\lambda}U(\lambda t+\mu) \tag{4.17}$$

so

$$x_1=\frac{H_1}{\lambda}t+X_1+\frac{\nu}{\lambda^2}V(\lambda t+\mu), \tag{4.18}$$

where X_1 is a constant. The general solution of the model involves six arbitrary constants λ, μ, ν, Q_α, H_1, X_1.

Let us now clarify how the supergroup acts in this model. The Lie algebra of the supergroup is obtained from the supersymmetry and time translation operators by taking coefficients in B_o and B_e, respectively. It therefore has basis

$$\mathcal{Q}_\alpha=\alpha\mathcal{Q}, \quad \mathcal{Q}_\beta=\beta\mathcal{Q}, \quad \frac{d}{dt}, \quad \frac{\tilde{d}}{dt}=\alpha\beta\frac{d}{dt}. \tag{4.19}$$

The only nontrivial bracket is

$$[\mathcal{Q}_\alpha,\mathcal{Q}_\beta]=-2\frac{\tilde{d}}{dt}. \tag{4.20}$$

Acting with $\mathcal{Q}_\alpha$ and $\mathcal{Q}_\beta$, we obtain from (4.5) two independent supersymmetry variations

$$\delta_\alpha x=\epsilon\alpha\psi, \quad \delta_\alpha\psi=\epsilon\alpha\dot{x}, \tag{4.21a}$$

$$\delta_\beta x=\epsilon\beta\psi, \quad \delta_\beta\psi=\epsilon\beta\dot{x}, \tag{4.21b}$$

where ϵ is now infinitesimal and real. Writing x and ψ in terms of components, we find

$$\delta_\alpha x_1 = \epsilon b, \quad \delta_\alpha a = \epsilon \dot{x}_0, \tag{4.22a}$$

$$\delta_\beta x_1 = -\epsilon a, \quad \delta_\beta b = \epsilon \dot{x}_0, \tag{4.22b}$$

with all other variations vanishing. These are symmetries of L_1, and trivially of L_0. In addition there is symmetry under an infinitesimal time translation of all the dynamical quantities. Finally, there is symmetry under the mini-time-translation, with generator $\widetilde{d/dt}$. As before, an infinitesimal mini-time-translation is

$$\Delta x_1 = \epsilon \dot{x}_0 \tag{4.23}$$

with ϵ real.

By considering how the supergroup generators act on the solutions of this model, we see that with the supergroup we may independently vary μ, ν, Q_α, X_1, but not the constants defining the energy λ and H_1. The orbits of the supergroup are therefore four dimensional, in general.

The solution as we have presented it does not make sense if $\lambda = 0$. This is the zero energy, Bogomolny case. If $H_0 = 0$ then $\dot{x}_0 = 0$, so x_0 takes a constant value μ, hence U and U' take constant values $U(\mu)$ and $U'(\mu)$. The general solution is then easily found to be

$$x_0 = \mu, \quad b = \nu, \tag{4.24a}$$

$$a = -U(\mu)(t - t_0), \tag{4.24b}$$

$$x_1 = \tfrac{1}{2} U'(\mu) \nu t^2 + rt + X_1, \tag{4.24c}$$

where μ, ν, t_0, r, X_1 are constants of integration. The second energy constant is $H_1 = -U(\mu)\nu$. Supersymmetry transformations and time translations change the constants r, X_1, and t_0. However, unlike in the $H_0 \neq 0$ case, Eq. (4.22b) implies that the value of b cannot be changed, and the orbits of the supergroup are three dimensional rather than four dimensional.

V. CONCLUSIONS

We have presented two supersymmetric classical mechanical models. By supposing that the dynamical variables take values in the Grassmann algebra B_2 with two generators, we have deconstructed the models into component form and obtained equations of motion which can be explicitly solved. These equations are the variational equations of a Lagrangian L_1 of nonstandard form, and in each case, the ''body'' variable x_0 obeys a classical equation unaffected by the fermionic variables. The supergroup, which is a genuine Lie group, generated from the super Lie algebra of supersymmetries and time translations by tensoring with B_2, acts on the space of solutions.

One could ask how the solutions would look if the dynamical variables were reconstructed from their components, so as to be B_2 valued, or further combined into supermanifold dynamical variables. At first sight there is only a slight gain in elegance, but this needs more careful study. It is also of interest to know whether the equations remain solvable if B is a larger algebra.

The model discussed in Sec. IV involved an odd constant α. Possibly, Grassmann-valued constants are of use in other supersymmetric models. For example, it might be possible in certain ''brane'' models to have a nonreal cosmological constant.

One of the motivations for this work was to better understand the solitons that occur in many supersymmetric field theories. These are solutions of the classical field equations, with the fermionic fields set equal to zero. They usually also satisfy first-order Bogomolny equations. It would be much more satisfactory if they could be regarded as special cases of solutions where the fermionic fields are nonzero. Our mechanical models suggest that the ''body'' fields of the soliton will be unaffected by the fermionic fields. But the general solutions will involve nonzero fermionic fields coupled to the soliton, and in addition there can be nonzero bosonic fields with values in the even, nonreal part of the Grassmann algebra.

The connection between the classical models discussed here and their quantized versions is also worth exploring. The Heisenberg equations of the quantized theory may be formally the same as the equations that we have solved, but $x, \dot{x}$ and $\psi, \dot{\psi}$ need to obey canonical commutation and anticommutation relations, respectively. It would be interesting to know whether the general classical solution describes a suitable limit of a quantum state.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 2 FEBRUARY 1999

Stochastic quantum geometry within a (1+1) manifold: A basic construction

Steven D. Miller[a]
University of Strathclyde, Glasgow, Scotland, United Kingdom

(Received 13 April 1998; accepted for publication 3 September 1998)

A bounded, globally hyperbolic, space–time manifold $\mathscr{M}^2$ with topology $I(t) \otimes \mathbb{R}$ is presented as a simple classical, deterministic, geometry, with ADM (1+1) slicing via a lapse function and shift vectors. The Cauchy development is then equivalent to the evolution of a spatial Riemann 1-metric $\beta(x,0) \rightarrow \beta(x,t)$ for a bounded spatial interval $I(t)=[0,l]$ such that $x-x'<=l$ for all $x,x' \in (t)$ for all $t \in \mathbb{R}$. The 1-metric is considered a parametrized, stochastically fluctuating variable $\{\beta(x,t)\} \in Riemm(I)$ for some critical (microscopic) correlation scale l, where $Riemm(I)$ is the space of all 1-metrics on I. If the metric fluctuations are constrained by a scale-dependent probability kernel or density distribution on [0,1], then a Fokker–Planck equation can be developed for the Cauchy evolution of the kernel. The stationary (Cauchy invariant) equilibrium limit solution is obtained. The equilibrium limit correlations $\langle \beta(x,t)\beta(x',t)\rangle$ at second order derived from the stochastic model, can be directly identified with the general, well-known form of the metric two-point (equal time) correlations obtained from linearized general relativity treated as a quantum field theory. The metric diffusion coefficients of the stochastic model are then correctly identified. The uncertainty relation $l\delta\beta>=l_*$ for nonzero metric fluctuations $\delta\beta$, emerges from the solution and is a necessary condition for the kernel to be constrained on [0,1]. The 1-metric fluctuations are exponentially damped or amplified as the spatial interval $I=[0,l]$ is expanded or contracted with respect to the Planck length l_*.
[S0022-2488(99)01601-1]

I. INTRODUCTION

The essential idea behind stochastic quantization schemes is to reformulate quantum mechanics or quantum field theory as the thermal-equilibrium limits of a hypothetical stochastic process.[1–3] One might consider this as a third approach to quantization, in addition to the standard canonical and path integral methods. The purpose of this stochastic interpretation is to find the unknown physical origins of quantum fluctuations by replacing or reformulating quantum theories with theories based on classical stochastic dynamics. The *n*-point equal time correlation or Green's function of quantum field theory are identified with the thermal equilibrium correlations of the stochastic process. The stochastic interpretation has its roots in the formal similarity between the linear Schrödinger equation and the linear diffusion equation for Brownian particles. The Schrödinger equation is essentially a diffusion equation in imaginary time with $\mathscr{D}=\hbar/2m$ playing the role of a diffusion coefficient that vanishes for classical (large) m. Both Bohm and Nelson[4,5] formulated stochastic interpretations of quantum mechanics in real time. Bohm attempted to replace quantum mechanics with a classical stochastic dynamics via hidden variables. The theories of Bohm and Nelson remain interesting from the point of view of assigning a stochastic interpretation to quantum fluctuations. A major development in stochastic quantization is due to Parisi and Wu,[1–3] which gives quantum mechanics as a thermal equilibrium limit of a hypothetical stochastic

process. Unlike Nelson's approach in real time, the Parisi–Wu scheme is formulated with respect to a fictitious time variable rather than ordinary time. Both theories are based on a Markovian process of the Weiner type with Gaussian white noise. Here, a d-dimensional quantum system is equivalent to a $(d+1)$-dimensional classical system with random, stochastic fluctuations. The new time variable is treated as a computational convenience with no direct physical content. The usual formulations of quantum mechanics and quantum field theory have so far utilized imaginary time or Euclidean manifolds via Wick rotations in order to have better defined path integrals. The theories of Bohm and Nelson are formulated in ordinary real time and recently some authors have also formulated viable stochastic quantum mechanical approaches in terms of ordinary Minkowski space coordinates, keeping real time within the formalism.[6–8] These theories demonstrate that the use of imaginary time or Euclidean manifolds is not inevitable. Despite success in dealing with quantum fields and gauge theories and the emergence of results not obtainable via conventional methods, stochastic interpretations have not fully been applied to the problem of the quantization of gravity and geometry. It is possible that the stochastic method may also have the potential to extend the scope of quantum gravity and geometry.

The current approaches to quantum gravity and quantum geometry are (i) canonical quantum gravity and the developments involving loop space and Ashtekar variables;[9–12] (ii) the Euclidean path integral approaches;[13] and (iii) superstring theory and M(atrix) theory.[14–16] Despite progress, unresolved mathematical, technical, and conceptual difficulties remain. It is extremely difficult to construct any self-consistent interpretation of quantum gravity. A review of the current status and difficulties can be found in Ref. 17. Despite these ongoing problems, key physical concepts can be identified, which lie at the heart of quantized gravity and geometry. These are metric fluctuations and the existence of a lower length scale truncation of $l_* = (G\hbar/c^3)^{1/2} = 10^{-33}$ cm, the Planck length. Beyond this scale, the deterministic, geometrical structure of space–time is lost. This is a model-independent feature of quantum gravity and many different arguments give rise to this same conclusion.[18] In classical general relativity, the d-dimensional space–time manifold $\mathscr{M}^d$ is pseudo-Riemannian, generally globally hyperbolic,[10] and is assumed C^2 differentiable with a casual, Lorentzian metric structure $g_{uv}(x) = g_{uv}(x,t)$. The manifold is smooth and continuous down to zero length scales, with the existence of infinitesimal differential limits on space and time such that $\delta x^u \to 0$. However, as pointed out in Ref. 19, all known physical systems possess inherent noise at some critical length scale with the manifestation of fluctuation-correlation behavior. If a vacuum space–time manifold $\mathscr{M}^4$ with metric $g_{uv}(x)$, describing a static gravitational field is itself considered as a fundamental physical system, the solutions $g_{uv}(x)$ of the vacuum Einstein equations $(R_{uv} = 0)$ should exhibit ''geometric noise'' or a strong fluctuation-correlation behavior at a critical length scale or correlation length, of the order of the Planck scale.

Wheeler[20,21] originally introduced the concept of geometrodynamics or space–time quantum ''foam'' and demonstrated that geometry itself must fluctuate near the Planck length, as exhibited by quantum mechanical fluctuations in the metric tensor itself of order $\langle g \rangle \sim (l_*/l)$, where l is the spatial resolution. Clearly for $l > l_*$, the fluctuations $\langle g \rangle$ rapidly vanish and can be ignored since $\langle g \rangle \sim 10^{-20}$, even on the nuclear scale. This suggests that as $l \to l_*$, gravity exhibits a strongly coupled fluctuating phase (the foam) on which there are no correlations on a large scale. The length l_* seems to play a role in space–time geometry similar to the role played by c in relativistic mechanics.[18] One can get closer and closer to c but never reach it; there are no velocities beyond c. Similarly, for any geometric variation $\delta x = |\mathbf{x} - \mathbf{x}'|$, one can get arbitrarily close to l_*, but the uncertainty relation $\delta x >= l_*$ strictly holds; there are no distances below l_*.

I propose that stochastic analysis may be a viable mathematical framework within which to interpret and formulate descriptions of basic features of metric fluctuations, discretization, and foam structure in geometry and gravity. Rumpf[22] presented a basic stochastic treatment for the gravitational field using real time. Most recently, Moffat[19] has considered treating the gravitational field stochastically. For strong metric fluctuations, it is shown, via stochastic Raychaudhuri and Langevin equations, how caustic singularities in space–time structure can potentially be avoided for congruences of converging geodesics and collapsing stars. This illustrates the potential of the interpretation. In this paper, the emphasis is on the conceptual issues, and future potential rather than intricate technical subtleties, focusing on well-established key physical consequences of quantum geometry (metric fluctuations and Planck length truncation). It is felt, however, that the points addressed here are a necessary prerequisite toward mature stochastic models of quantum geometry.

II. VACUUM QUANTUM FLUCTUATIONS IN SCALAR FIELD THEORY AND LINEARIZED EINSTEIN GRAVITY

We briefly consider scalar quantum field theory on a flat manifold $(\mathscr{M}^4, \eta_{ab})$ and estimate the typical magnitude of a quantum fluctuation when a massless spin-0 scalar field $\varphi(x)$ is probed at a physical length scale l, on a local inertial frame. The result can then be extended to linearized Einstein gravity for massless spin-2 fields. These basic and heuristic aspects of quantum fields will be adequate in the form presented and useful later when we come to consider the equal time correlations. Scalar field theory is paradigmatic and well known, so for our purposes we will label only the key expressions. The Hamiltonian is $H=\frac{1}{2}\int d^3x[(d\varphi(\mathbf{x},t)/dt)^2+(\boldsymbol{\nabla}\varphi)^2]$. The free field equation is $\Box\varphi(x)=0$. Quantizing, the functional Schrödinger equation is[23] $i\hbar\,\partial_t\Psi(\varphi(\mathbf{x}),t)) =H\Psi(\varphi(\mathbf{x}),t))$. The quantum field theoretic state $\Psi[\varphi(\mathbf{x}),t]=\Psi[\varphi(\mathbf{x},t)]=\Psi[\varphi(x)]$ is a function of real time $t\in\mathbb{R}$, but a functional of the field $\varphi(\mathbf{x})$. By comparison and analogy with the ordinary quantum mechanical simple harmonic oscillator, the ground state or vacuum functional for the quantum field theory is immediately of the form

$$\Psi_0[\varphi(\mathbf{x},t]\sim\exp\left[-\frac{1}{2\hbar}\int d^3x\;\varphi(\mathbf{x})(-\nabla^2)^{1/2}\varphi(\mathbf{x})\right]\exp[-iE_0/\hbar]. \tag{2.1}$$

Here $(-\nabla^2)^{1/2}$ is the formal square root of $(-\nabla^2)$, and is interpreted as a pseudodifferential operator. If we take a Fourier transform $\mathcal{F}[\nabla^2]=-k^2$ then $\mathcal{F}[(-\nabla^2)^{1/2}]=\|\mathbf{k}\|$. The ground state energy $E=\frac{1}{2}\hbar\,\mathrm{tr}(-\nabla^2)^{1/2}$ is formally infinite. However, this is of no concern: the key feature is that the ground state wave functional is peaked at $\boldsymbol{\nabla}\varphi=0$.

Suppose now the scalar field $\varphi(\mathbf{x})$ is probed at a scale l. We define the correlation function or two-point function as $\langle\varphi(\mathbf{y})\varphi(\mathbf{x})\rangle=\langle\Psi_0|\varphi(\mathbf{y})\varphi(\mathbf{x})|\Psi_0\rangle$. We also define an object $[\Delta\varphi]_l$ as

$$[\Delta\varphi]_l=[\langle\varphi(\mathbf{x}')\varphi(\mathbf{x})\rangle]^{1/2}{}_{l=|\mathrm{x}-\mathrm{x}'|}. \tag{2.2}$$

This is the quantum fluctuation probed at distance $l=|\mathbf{x}-\mathbf{x}'|$. The correlator is $\langle\varphi(x')\varphi(x)\rangle -\langle\varphi(x')\rangle\langle\varphi(x)\rangle$, but at the lower-energy length scales, one can take the correlations to be weak so that $\langle\varphi(x')\varphi(x)\rangle-\langle\varphi(x)\rangle\langle\varphi(x')\rangle\sim\epsilon$ for infinitesimal (but nonzero) ϵ. Then (2.2) is justified. The best way to determine $[\Delta\varphi]_l$ is to move to momentum space $\varphi(\mathbf{k})$ so that

$$\varphi(\mathbf{x})=\int\frac{d^3k}{2\pi^3}\,\varphi(\mathbf{k})\exp(i\mathbf{k}\cdot\mathbf{x}). \tag{2.3}$$

Then the vacuum wave functional is $\Psi_0[\varphi(\mathbf{k})]$ is

$$\Psi_0[\varphi(\mathbf{k})]\sim\exp\left[-\frac{1}{2\hbar}\int\frac{d^3x}{2\pi^2}\,k\varphi(\mathbf{k})^2\right], \tag{2.4}$$

and the momentum two-point function is $\langle\varphi(\mathbf{k})\varphi(\mathbf{k})\rangle=[\hbar(2\pi)^3/k_1]\delta^3(\mathbf{k}_1-\mathbf{k}_2)$. The position two-point correlator then follows from the inverse Fourier transform:

$$\langle\varphi(\mathbf{x}')\varphi(\mathbf{x})\rangle=\int\frac{d^3k}{2\pi^3}\frac{\hbar}{k}\exp[i\mathbf{k}(\mathbf{x}-\mathbf{x}')]=\frac{2\hbar}{(2\pi)^3|\mathbf{x}-\mathbf{x}'|^2}. \tag{2.5}$$

Hence $[\Delta\varphi]_l=(2\hbar)^{1/2}/2\pi l\sim\sqrt{\hbar}/l$, where $l=|\mathbf{x}-\mathbf{x}'|$. Quantum fluctuations therefore only become significant on small physical scales l. The characteristic size of the quantum fluctuations $\Delta\varphi$ about the average field φ depend on the physical length scale l being probed. Vacuum fluctuations in the gravitational field can be estimated in a similar manner and we can make use of Eq. (2.5). The linearized Einstein–Hilbert action S_{LEH} for gravity coupled to matter follows from expanding the Ricci scalar to second order[24] with $g_{ab}(x)=\eta_{ab}(x)+\gamma_{ab}(x)$:

$$S_{\mathrm{LEH}}=-\frac{l}{32\pi l_*^2}\int d^4x\ \gamma^{ab}(x)\Box\gamma_{ab}(x)+\int d^4x\ \gamma^{ab}(x)\left[\Theta_{ab}-\frac{1}{2}\Theta\,\eta_{ab}\right]+O(\gamma^2). \quad (2.6)$$

The field equations are (gauge fixed) linear wave equations for a massless spin-2 field γ:

$$\Box\gamma_{ab}(x)=-\frac{16\pi l_*^2}{\hbar}\left[\Theta_{ab}-\frac{1}{2}\Theta\,\eta_{ab}\right]+O(\gamma^2) \quad (2.7)$$

or $\Box\gamma_{ab}(x)=0$ in vacuum. These equations have a simple retarded potential and plane wave solutions of the tensor form $\gamma_{ab}(x)=H_{ab}\exp(i\Sigma_\mu k_\mu x^\mu)$ for $\mu=1$–3, describing massless spin-2 gravitons with two polarization states. Since the linearized Einstein action is quadratic in γ, quantization proceeds in analogy with the scalar field. This leads to two-point correlation functions $\langle\gamma(x)\gamma(x')\rangle$, $\langle\gamma_{ab}(x)\gamma(x')\rangle$, and $\langle\gamma_{ab}(x)\gamma_{cd}(x')\rangle$. If we set $\Theta_{uv}=0$, we can calculate the trace–trace correlator $\langle\gamma(x)\gamma(x')\rangle$ using (2.6) from the scalar field case so that $\langle\gamma(x)\gamma(x')\rangle=(16\pi l_*^2/\hbar)\langle\varphi(x)\varphi(x')\rangle$. The scalar correlation contains the essential quantitative and qualitative features. Then, at equal times,

$$\langle\gamma(\mathbf{x}',t)\gamma(\mathbf{x},t)\rangle=\frac{16\pi l_*^2}{\hbar}\frac{2\hbar}{(2\pi)^2|\mathbf{x}-\mathbf{x}'|^2}=\left(\frac{8}{\pi}\right)\frac{l_*^2}{|\mathbf{x}-\mathbf{x}'|^2}. \quad (2.8)$$

When we probe geometry at a distance l, the vacuum quantum metric fluctuations $[\Delta\gamma]l$ are

$$[\Delta\gamma]_l=[\langle\gamma(\mathrm{x},t)\gamma(\mathrm{x}',t)\rangle]^{1/2}{}_{l=|\mathrm{x}-\mathrm{x}'|}\sim\langle\gamma(\mathrm{x},t)\rangle\sim(l_*/l), \quad (2.9)$$

or $[\Delta\gamma]l=(8/\pi)^{1/2}(l_*/l)$. These become significant only as we approach the Planck length $l\to l_*$ and rapidly damp out as l increases, even at the nuclear scale, where $l_*/l\sim10^{-20}$.

III. THE ADM (3+1) AND (1+1) SLICING OF SPACE–TIME

Let $(\mathscr{M}^d,g_{ab})$ be a generic, globally hyperbolic d-dimensional space–time; then $(\mathscr{M}^d,g_{uv})$ is stably casual and permits a foliation of $(d-1)$-dimensional space-like hypersurfaces $\{\Sigma\}$. A global time function $t\equiv\mathbb{R}$ can be chosen such that each $(d-1)$-geometry of constant $t\in\mathbb{R}$ is a space-like Cauchy surface Σ with parametrization $\Sigma(t)$. The (fixed) topology of the space–time is then $\mathscr{M}^d\sim\mathbb{R}\times\Sigma$. A point $p\in\mathscr{M}^4$ can be locally represented as $x=(\mathbf{x},t)$ where $\mathbf{x}\in\Sigma(t)$ and $\mathbf{x}=(x_1,x_2,\ldots,x_{d-1})$ and $t\in\mathbb{R}$. A crucial feature of global hyperbolicity is that it permits a well-defined initial value (Cauchy) problem for the Green's function or two-point propagators $\{G(x,x')\}$ or $\langle\varphi(x)\varphi(x')\rangle$ in classical and quantum field theory, such as in (2.6). Solutions of the massless wave equations for scalars, photons, and gravitons ($\Box\varphi=0$, $\Box A^a=0$, or $\Box\gamma_{ab}=0$) must vanish outside the forward light cone.[25]

Given $d=4$, for example, then explicitly, the ADM (3+1) decomposition of the 4-geometry $(\mathscr{M}^4,g_{uv}(\mathbf{x},t))$ consists of the following geometric data[26]

(i) The induced fundamental form or Riemmann 3-metric $h_{ij}(\mathbf{x},t)$ on each $\Sigma(t)$, for $i,j=1,2,3$ and $\mathbf{x}\in\Sigma(t)$ and $t\in\mathbb{R}$. This is the intrinsic geometry of the 3-space and h_{ij} is positive definite.

(ii) The manner in which each Σ is embedded in $(\mathscr{M}^4,g_{uv})$. This is ascertained once we are able to compute the spatial part of the covariant derivative of the normal n to $\Sigma(t)$. If $\boldsymbol{\nabla}$ is the four-dimensional connection of $(\mathscr{M}^4,g_{uv})$, one can define the extrinsic curvature tensor $K_{ij}\equiv-\boldsymbol{\nabla}_j n_i$, so that symmetric K_{ij} require symmetric $\boldsymbol{\nabla}$. Alternatively, $K_{ij}\equiv-\frac{1}{2}(\mathcal{L}_n h)_{ij}$, where $\mathcal{L}_n$ is the Lie derivative along the normal to $\Sigma(t)$.

(iii) The manner in which the coordinates are propagated. One defines the vector $(N,N^i) = (N,N^1,N^2,N^3)dt$ connecting $(x^i,t)=(\mathbf{x},t)$ with the point $(x^i,t+\delta t)=(\mathbf{x},t+\delta t)$.

Given the surface $x^0=t$ and surface $x^0=t+\delta t$, the quantity $N\ dt = d\tau$ defines a displacement normal to surface $x^0=t$. Here, N is the lapse function and N^i are the shift vectors. The $N^i\ dt$ yield the displacement from the point (t,x^i) to the base of the normal to $x^0=t$ through $(t+\delta t,x^i)$. The full metric can be expressed as

$$\begin{aligned} ds^2 &= g_{uv}\ dx^u\ dx^v \\ &= h_{ij}(dx^i+N^i\ dt)(dx^i+N^j\ dt)-N^2\ dt\ dt \\ &= -(N^2-N_iN^i)dt^2+N_i(dx^i\ dt+dt\ dx^i)+h_{ij}\ dx^i\ dx^j. \end{aligned} \tag{3.1}$$

Then $g_{00}=-(N^2-N_iN^i)$, $g_{i0}=g_{0i}=N^i$, $g_{ij}=h_{ij}$, and $K_{ij}=(-\partial_t h_{ij}+N_{i;j}+N_{j;i})$. The ''gauge choice'' $N^i=0$ eliminates the off-diagonal components, so that

$$ds^2=-N^2\ dt^2+h_{ij}\ dx^i\ dx^j. \tag{3.2}$$

The Cauchy evolution from $\Sigma(0)$ to $\Sigma(t)$ can be interpreted as the change of Riemmann 3-metric from $h_{ij}(\mathbf{x},0)$ to $h_{ij}(\mathbf{x},t)$ so that h_{ij} is the dynamical variable. This is the motivation for Hamiltonian general relativity and (pre-Ashtekhar) canonical quantum gravity. We are primarily interested in the induced Riemmann metric $h_{ij}(\mathbf{x},t)$ on $\Sigma(t)$ and set $N=$const. For the 3-geometry,

$$ds^2=h_{ij}(\mathrm{x},t)dx^i\ dx^j=h_{11}(x,y,z,t)dx^2+h_{22}(x,y,z,t)dy^2+h_{33}(x,y,z,t)dz^2. \tag{3.3}$$

Given Σ, one denotes[26] by *Riemm*(Σ) the space of Riemannian C^∞ metrics h_{ij} on Σ, and *Diff*(Σ), the group of diffeomorphisms on Σ. If $\phi\in Diff(\Sigma)$ then $\phi:\Sigma\to\Sigma$, and the group *Diff*(Σ) preserves the metric structure. If $h_{ij}\in Riemm(\Sigma)$ and $\phi\in Diff(\Sigma)$ then $\phi^*h(\phi(\mathbf{x}),t))=h(\mathbf{x},t)$ for $\mathbf{x}\in\Sigma$ and $t\in\mathbb{R}$, where ϕ^* is the pullback of ϕ. The group *Diff*(Σ) acts as a transformation group on *Riemm*(Σ). Its action maps (ϕ,h) to ϕ^*h for all $\beta\in Riemm(\Sigma)$ and $\phi\in Diff(\Sigma)$. Displacements ds^2 are preserved. The space of all orbits of *Diff*(Σ) is $\mathcal{S}(\Sigma)$:

$$\mathcal{S}(\Sigma)=Riemm(\Sigma)/Diff(\Sigma). \tag{3.4}$$

The space $\mathcal{S}(\Sigma)$ is (Wheeler's) superspace.[26] Hence, for all $h\in Riemm(\Sigma)$, one considers all metrics derived from h, by the group elements $\phi\in Diff(\Sigma)$. If two 3-metrics h and h' are on the same orbit, then there is ϕ of Σ such that $\phi^*h=h'$, so that h and h' are isometric. Superspace $\mathcal{S}(\Sigma)$ is then the set of geometries of Σ that are equivalence classes of isometric Riemannian metrics.

To make the analysis as clear and simple as possible, we can let $d=2$, giving a (1+1)-dimensional manifold with topology $\mathscr{M}^2=I(t)\times\mathbb{R}$, so that $I(t)$ for any $t\in\mathbb{R}$ is an interval and $x\in I(t)$. This still embodies the essential features we wish to elucidate. The (1+1) decomposition procedure of the metric $g_{ab}=(g_{00},\beta)$ is as before:

$$ds^2=\beta(x,t)dx^2-N^2\ dt^2, \tag{3.5}$$

so that along the one-dimensional spatial manifold $I(t)$, we have ${}^{(3)}ds^2=\beta(x,t)dx^2$. The $I(t)$ can be a closed interval or a circle S^1. For a bounded interval, $I(t)=[0,l]\supset\mathbb{R}$ so that for any $x,x'\in I(t)$; then $|x-x'|_{\max}=l$ or $|x-x'|<l$. The spatial metric β is then simply a scalar function $\beta(x,t)$ for any $x\in I(t)$ and $t\in\mathbb{R}$ and $\beta(x,t')=\beta(x,t)$ for all t', $t\in\mathbb{R}$. The group *Diff*(I) or *Diff*($I(t)$) is the group of diffeomorphisms on the interval $I(t)$ and *Riemm*(I) is the space of all metrics $\beta(x,t)$ on $I(t)$ for all $x\in I(t)$ and $t\in\mathbb{R}$, with $\phi\in Diff(I)$. As before, $\phi^*\beta(\phi(x),t)=\beta(x,t)$ and a ''superspace'' of 1-metrics $\mathscr{S}(I)=Riemm(I)/Diff(I)$.

All known physical systems possess noise at some critical length scale l with emergence of correlation–fluctuation behavior. For example, in Ref. 27, it is suggested that Einstein's equations are macroscopic ''state equations,'' arising from such a deeper microsubstructure of the classical geometry itself. In the same way, a homogeneous gas with macroscopic temperature and pressure is comprised of discrete atoms. Linearized Einstein gravity treated as a quantum field theory [see Eq. (2.10)], suggests that for $\mathbf{x},\mathbf{x}' \in I(t)$ with $|\mathbf{x}-\mathbf{x}'| <= l$ and $t \in \mathbb{R}$, $\langle \beta(\mathbf{x},t)\beta'(\mathbf{x}',t)\rangle \sim (l_*/l)^2$ at equal time. Correlations emerge as $l \to l_*$, so, depending on l, the 1-metric $\beta(x,t)$ can evolve from a fixed, deterministic variable β into a randomly fluctuating (stochastic) variable such that $\beta \to \langle \beta \rangle$. Essentially, a simple quantum $(1+1)$ space–time will be interpreted as a classical space–time subject to random stochastic fluctuations (in real time $t \in \mathbb{R}$). This first requires a reasonable metric fluctuation probability interpretation and measure on the bounded real interval $I(t)=[0,l]$.

IV. PARAMETRIZED STOCHASTIC FLUCTUATIONS OF THE RIEMANN 1-METRIC

The function $\beta(x,t)$ is redefined as a random, stochastic variable that appears or evolves to being deterministic under specific conditions. Following Refs. 27–29, we briefly address the general theory of random variables and then apply the formalism to the Riemmann 1-metric function $\beta(x,t)$ for the $(1+1)$ manifold $\mathscr{M}^2$ with $x \in I(t)$ and $t \in \mathbb{R}$. If Ω is a generic set then a σ-algebra $\mathcal{F}$ on Ω is a family $\mathcal{F}$ of subsets of Ω with the following properties: (i) $\emptyset \in \mathcal{F}$; (ii) if $A \in \mathcal{F}$ then $A^{\mathrm{com}} \in \mathcal{F}$, where $A^{\mathrm{com}} = \Omega/A$ is the complement of A in Ω; (iii) if $A_1, A_2, \ldots, \in \mathcal{F}$ then

$$A = \bigcup_{i=1}^{\infty} A_i \in \mathcal{F}. \tag{4.1}$$

The pair $(\Omega,\mathcal{F})$ is the measurable space. A probability measure $\mathcal{P}$ on $(\Omega,\mathcal{F})$ is a function $\mathcal{P}:\mathcal{F} \to [0,1]$ such that (a) $\mathcal{P}(\emptyset)=0$ and $\mathcal{P}(\Omega)=1$ (b) for $A_1, A_2, \ldots, \in \mathcal{F}$ and for $\{A_i\}_{i\to 1}$ disjoint (i.e., $A_i \cap A_j = \emptyset$ if $i \neq j$); then

$$\mathcal{P}(\bigcup_i A_i) = \sum_i \mathcal{P}(A_i). \tag{4.2}$$

The triplet $(\Omega,\mathcal{F},\mathcal{P})$ is the probability space. The subsets S of Ω that belong to $\mathcal{F}$ are $\mathcal{F}$-measurable sets. In the probability interpretation, these sets are called events, and we use the interpretation $\mathcal{P}(S)=$''probability that event S occurs.'' If $\mathcal{P}(S)=1$, then the probability is absolute or deterministic. A random variable Q is $Q:\Omega \to \mathbb{R}^n$. A generic, stochastic process in time $\{Q_t\}_{t} \in \mathbb{R}$ is a parametrized collection of random variables, defined on $(\Omega,\mathcal{F},\mathcal{P})$ and assuming values in $\mathbb{R}^n$. For example, the process may depend on two variables (t,ω) on $(\Omega \otimes \mathbb{R})$ so that $(t,\omega) \to Q(t,\omega)$ from $(\mathbb{R} \times \Omega)$ onto $\mathbb{R}^n$. As t evolves, then $Q(t,\omega)$ is a random Brownian path. For a random variable Q on $[0,\infty)$ or $\mathbb{R}$, the distribution function F of Q is $F(q)=\mathcal{P}[Q<=q]$, with $0<=F<=1$; $\lim_{q\to 0} F(q) \to 0$; $\lim_{q\to\infty} F(q)=1$. The variable Q has the density $p(q)$ if

$$F(q) = \int_0^q p(v)\,dv, \quad \forall q, \tag{4.3}$$

and the expectation $\mathscr{E}[q]$ is

$$\mathscr{E}[q] = \int_{\mathbb{R}} q p(q)\,dq. \tag{4.4}$$

If the stochastic process $\{Q(\omega,t)\}$ is identified with $\{\beta(x,t)\}$ for $\beta \in \mathit{Riemm}(I(t)) \subset \mathbb{R}$ and $x \in I(t)$ and $t \in \mathbb{R}$, then

$$\{\beta(x,t)\} = \{\beta_1(x_1,t_1), \beta_2(x_2,t_2), \ldots, \beta_k(x_k,t_k), \ldots\} \tag{4.5}$$

is the set of parametrized, random metric fluctuations or Brownian paths about an initial deterministic metric $\beta(x,t)$ with $x\in I(t)$, $t\in\mathbb{R}$, and $\{x_1,x_2,\ldots,x_k,\ldots\}\in I(t)=[0,l]$ and Cauchy development $t<t_1<t_2<\cdots<t_k<\cdots$. These metric fluctuations all lie on the same orbit $\mathcal{S}(I)=\mathit{Riemm}(I)/\mathit{Diff}(I)$. For the classical (1+1) manifold, $\beta(x,t)$ is deterministic so that $\beta(x,t)=\beta(x,t_1)=\beta(x,t_2)=\cdots$ is a deterministic sample path generated by the Cauchy development. The density for the fluctuating metric is a functional of $\beta(x,t)$, so that we identify $p(q)$ with $\mathsf{K}[\![\beta(x,t)]\!]$. The differential variation in $\beta(x,t)$ is then simply $d\beta(x,t)=\partial_k\partial_x\beta(x,t)\,\delta x+\partial_t\beta(x,t)\,\delta t$. For classical, determinstic geometry, the first term is zero so that $d\beta(x,t)=\partial_t\beta(x,t)\,\delta t$. The $\mathsf{K}[\![\beta(x,t)]\!]$ is a scalar on $[0,1]$ and normalized. Note the notation $[\![\cdots]\!]$, for functionals of $\beta(x,t)$. The density or kernel $\mathsf{K}[\![\beta(x,t)]\!]$ is normalized on $[0,1]$ as

$$\int_{\mathit{Riemm}(I)\supset\mathbb{R}}\mathsf{K}[\![\beta(x,t)]\!]d\beta(x,t)=1, \tag{4.6}$$

for all $x\in I(t)$ and $t\in\mathbb{R}$. The kernel $\mathsf{K}[\![\beta(x,t)]\!]$ and the normalization is invariant under $\phi\in\mathit{Diff}(I)$, in that $\phi^*\mathsf{K}[\![l:\beta(\phi(x),t)]\!]=\mathsf{K}[\![l:\beta(x,t)]\!]$. Since $I(t)=[0,l]$, we can include the dependence on l via the notation $\mathsf{K}[\![l:\beta(x,t)]\!]$ so that $\mathsf{K}\rightarrow 1$ and is deterministic for some $l\rightarrow l_c$. The normalization and expectations $\mathscr{E}[\beta(x,t)]\equiv\langle\beta(x,t)\rangle$ and $\mathscr{E}[\Psi[\![\beta(x,t)]\!]]\equiv\langle\Psi[\![\beta(x,t)]\!]\rangle$ for a functional $\Psi[\![\beta(x,t)]\!]$ are defined as (at a given $t\in\mathbb{R}$)

$$\int_{\mathit{Riemm}(I)}\mathsf{K}[\![l:\beta(x,t)]\!]d\beta(x,t)=1, \tag{4.7a}$$

$$\mathscr{E}[\beta(x,t)]=\int_{\mathit{Riemm}(I)}\beta(x,t)\mathsf{K}[\![l:\beta(x,t)]\!]d\beta(x,t), \tag{4.7b}$$

$$\mathscr{E}[\Psi[\![\beta(x,t)]\!]]=\int_{\mathit{Riemm}(I)}\Psi[\![\beta(x,t)]\!]\mathsf{K}[\![l:\beta(x,t)]\!]d\beta(x,t). \tag{4.7c}$$

The expectations are taken as invariant under the group action $\phi\in\mathit{Diff}(I)$. If the kernel $\mathsf{K}[\![l:\beta(x,t)]\!]$ is invariant under all time shifts or Cauchy development $I(t)\rightarrow I(t+\delta t)\rightarrow I(t+2\delta t)\rightarrow\cdots$, then K is stationary over the Cauchy evolution. If a fluctuating metric has value $\beta'(x,t)$ for $x'\in I(t')$ and $t'\in\mathbb{R}$ and value $\beta(x,t)$ for $x\in I(t)$ and $t\in\mathbb{R}$ with $t>t'$, then the transition kernel is $\mathsf{K}[\![l:\beta(x,t)|\beta'(x',t')]\!]$. Of course, $I(t')=I(t)=[0,l]$ and $|x-x'|<=l$. For the smooth, classical, deterministic (1+1) geometry, we always have $\mathsf{K}[\![l:\beta(x,t)|\beta'(x',t')]\!]=0$ and $\mathsf{K}[\![[l:\beta'(x',t)|\beta'(x',t')]\!]=1$. Given $\phi\in\mathit{Diff}(I)$, we take it to hold that K and expressions derived from K are invariant under the action of ϕ for all $x\in I(t)$ and $t\in\mathbb{R}$. At some microlength scale l, the transition kernal is defined on $[0,1]$ for the parametrized stochastic process $\{\beta(x,t)\}$ for all $x\in I(t)$ and $t\in\mathbb{R}$.

V. CAUCHY EVOLUTION OF THE KERNEL: DERIVATION OF A FOKKER–PLANCK EQUATION

The quantum fluctuations in $I(t)$ will be modeled as a stochastic Weiner–Markov process[30,31] in real time $t\in\mathbb{R}$ on the (1+1) Lorentzian manifold $\mathscr{M}^2$. Quantum fluctuations of conventional fields (scalars and gauge) are considered a Markov–Weiner process in Refs. 1–3 so this should be viable for the metric, at least within a linear or quadratic approximation. A Markov process has no memory of its past for a given present so that only the initial data is required for prediction of the future evolution. This fits in nicely with the notion of classical deterministic Cauchy development for a finite time into the future. For data on a general spacelike surface $\Sigma(0)$ at $t=0$, the state at $\Sigma(t)$ can be ascertained. For $\Sigma(t)=I(t)$ and for initial stochastic probability $\mathsf{K}[\![l:\beta(x,t)]\!]$ for $x\in I(t)$ and $t\in\mathbb{R}$, only the future probability can be deduced from an iterative Chapman–Kolmogorov integral. As $t\rightarrow\infty$, we are interested in the stationary or (thermal) equilibrium limit solution and its associated correlations.

Let $\beta'(x',t)$ be the scalar classical metric component at $x' \in I(t)$ and $t \in \mathbb{R}$, which fluctuates to $\beta(x) = \beta'(x',t) + \delta\beta = \beta(x',t+\delta t)$ at $t = t + \delta t$ for small Cauchy variation δt or $I(t) \to I(t + \delta t)$. At a length scale l, the transition probability kernel on $[0,1]$ would be denoted $\mathsf{K}[\![l:\beta(x,t + \delta t)|\beta'(x',t)]\!]$. The Cauchy evolution is also smooth since we take it that $\delta t > t_*$, the Planck time. Since the fluctuations are taken to be Markovian, then in the limit of infinitesimal Cauchy variation δt, the Kolmogorov integral is

$$\mathsf{K}[\![l:\beta(x,t+\delta t)]\!] = \int d\beta'(x')\mathsf{K}[\![l:\beta(x,t+\delta t)|\beta'(x',t)]\!]\mathsf{K}[\![l:\beta'(x',t)]\!]. \tag{5.1}$$

The integral is understood to be over the space of all metrics on I. Given that we have the initial data that the metric has the value $\beta'(x,t)$ with respect to $x' \in I(t)$, then we predict the future probability with respect to $I(t+\delta t)$, that the metric randomly fluctuates to some $\beta(x,t+\delta t)$; the past values with respect to $I(t-\delta t)$ are considered irrelevant to the future evolution. All Brownian sample paths or histories are equivalent. Classically, Eq. (4.1) reduces to $0=(0)\times(1)$, for a classical metric component $\beta'(x',t)$ that has no fluctuations. The purely deterministic Cauchy evolution or sample path is $\beta'(x',t) \to \beta'(x',t+\delta t) = \beta'(x',t)$, since the Cauchy development is built into the Riemann 1-metric $\beta(x,t)$. Of course, one cannot guarantee that both diffeomorphism invariance and the Markov assumption are not lost at the Planck length, however, it will be taken that they still hold very near the scale.

Given $\mathsf{K}[\![l:\beta(x,t+\delta t)]\!]$ in the limit of infinitesimal δt, one can define the σth-order (diffusion) functionals $\mathscr{D}_\sigma[\![l:\beta'(x',t)]\!]$. This is always possible[30,31] for a generic Weiner–Markov process $\{K\}$ on $[0,1]$ obeying (5.1):

$$\mathscr{D}_\sigma[\![l:\beta(x',t)]\!] = [\sigma(\sigma-1)(\sigma-2)\cdots]^{-1}(\delta t)^{-1}| \times \int \mathsf{K}[\![l:\beta(x,t+\delta t)|\beta'(x',t)]\!]\left(\prod_{j=1}^{\sigma} |\beta_j(x_j - \beta'(x')|\right) d\beta(x). \tag{5.2}$$

Let $G:\mathbb{R}\to\mathbb{R}$ or $G:Riemm(I)\to\mathbb{R}$, be a functional of $\beta(x,t)$ at some $t \in \mathbb{R}$ so that $G[\![\beta(x)]\!] = G[\![\beta(x,t)]\!]$. The parametrized, stochastic, random 1-metrics are $\beta_j(x_j,t)$, for all $x_j \in I(t)$ and $t \in \mathbb{R}$. The functional Taylor expansion of $G[\![\beta(x)]\!]$ with respect to $G[\![\beta'(x')]\!]$ is

$$G[\![\beta(x)]\!] = G[\![\beta'(x')]\!] + \sum_{\sigma=1}^{\infty} [\sigma!]^{-1}\left(\prod_{j}^{\sigma} |\beta_j(x_j) - \beta'(x')| \frac{\delta}{\delta\beta_j(x_j)}\right) G[\![\beta'(x')]\!]. \tag{5.3}$$

The functional derivatives on $I(t)$ for $x_j \in I(t)$ are defined as

$$\prod_{j=1}^{1} \frac{\delta}{\delta\beta_j(x_j)} = \frac{\delta}{\delta\beta_1(x_1)}, \tag{5.4a}$$

$$\prod_{j=1}^{2} \frac{\delta}{\delta\beta_j(x_j)} = \frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}, \tag{5.4b}$$

$$\prod_{j=1}^{3} \frac{\delta}{\delta\beta_j(x_j)} = \frac{\delta^3}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)\,\delta\beta_3(x_3)}. \tag{5.4c}$$

For example, second-order 3-metric functional derivatives $\partial^2/\partial h_{ij}\,\partial h_{kl}$ occur in the Wheeler–DeWitt equation for the wave function $\Psi[h,\phi]$ of the universe.[26,32] To second order, the expansion of $G[\![\beta(x)]\!]$ is

$$G[\![\beta(x)]\!]=G[\![\beta'(x')]\!]+(\beta_1(x_1)-\beta'(x'))\ \frac{\delta}{\delta\beta_1(x_1)}\ G[\![\beta'(x')]\!]$$
$$+\frac{1}{2}\left((\beta_1(x_1)-\beta'(x'))\right)\left((\beta_2(x_2)-\beta'(x'))\right)\ \frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\ G[\![\beta'(x')]\!]+\cdots\ . \tag{5.5}$$

We can derive a stochastic integrodifferential equation for the functional expectation $\langle G[\![\beta(x)]\!]\rangle$ to all orders in σ, and from this equation derive moment relations to any order. Multiply Eq. (5.1) by $G[\![\beta(x)]\!]$ and integrate over $d\beta(x)$. The $G[\![\beta(x)]\!]$ can be placed under the integral $\int d\beta'(x')$ and then replace by the right-hand side of the Taylor series expansion (5.3) for $G[\beta(x)]$:

$$\begin{aligned}\langle G[\![\beta(x)]\!]\rangle_{t+\delta t}&\equiv\langle G[\![\beta(x,t+\delta t)]\!]\rangle\\ &=\int d\beta(x)G[\![\beta\langle x)]\!]\mathsf{K}[\![l:\beta(x,t+\delta t)]\!]\\ &=\int\int\left[G[\![\beta'(x')]\!]+\sum_{\sigma=1}^{\infty}\left(\left(\prod_{j=1}^{\sigma}|\beta_j(x_j)-\beta'(x',t)|\right)\right.\right.\\ &\quad\left.\left.\times\left(\prod_{j=1}^{\sigma}\frac{\delta}{\delta\beta_j(x_j)}\right)G[\![\beta'(x')]\!]\right)\right]\\ &\quad\times\mathsf{K}[\![l:\beta(x,t+\delta t)|\beta'(x',t)]\!]\mathsf{K}[\![l:\beta'(x',t)]\!]d\beta(x)d\beta'(x').\end{aligned} \tag{5.6}$$

Using the normalization $\int \mathsf{K}[\![l:\beta(x,t+\delta t)|\beta'(x',t)]\!]d\beta'(x')=1$ and Eq. (5.2) for $\mathscr{D}_\sigma[\![l:\beta(x,t)]\!]$ gives a simpler expression:

$$\begin{aligned}\langle G[\![\beta(x)]\!]\rangle_{t+\delta t}=\langle G[\![\beta(x)]\!]\rangle_t+[\delta t]\sum_{\sigma=1}^{\infty}\left[\int d\beta'(x')\mathsf{K}[\![l:\beta'(x',t)]\!]\right.\\ \left.\times\left(\prod_{j=1}^{\sigma}\frac{\delta}{\delta\beta_j(x_j)}\left[G[\![\beta'(x')]\!]\mathscr{D}_j[\![l:\beta'(x',t)]\!]\right]\right)\right].\end{aligned} \tag{5.7}$$

Note that $\langle G[\![\beta(x)]\!]\rangle_t\equiv\langle G[\![\beta(x,t)]\!]\rangle$. Since $\langle G[\![\beta(x)]\!]\rangle_{t+\delta t}-\langle G[\![\beta(x)]\!]\rangle_t=\delta t\ \partial_t\langle G[\![\beta(x)]\!]\rangle$, the differential equation satisfied by the functional expectation $\langle G[\![\beta(x)]\!]\rangle$ to all orders in σ over the Cauchy evolution of $\beta(x,t)=\beta(x)$ is

$$\begin{aligned}\frac{\partial\langle G[\![\beta(x)]\!]\rangle}{\partial t}&=\sum_{\sigma=1}^{\infty}\left\langle\mathscr{D}_\sigma(l)\left(\prod_{j=1}^{\sigma}\frac{\delta}{\delta\beta_j(x_j)}\ G[\![\beta(x)]\!]\right)\right\rangle\\ &=\left\langle\mathscr{D}_1(l)\ \frac{\delta}{\delta\beta_1(x_1)}\ G[\![\beta(x)]\!]\right\rangle+\left\langle\mathscr{D}_2(l)\ \frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\ G[\![\beta(x)]\!]\right\rangle+\cdots.\end{aligned} \tag{5.8}$$

In the equilibrium limit $\partial_t\langle G[\![\beta(x)]\!]\rangle=0$. The functional $\mathscr{D}_\sigma[\![l:\beta(x,t)]\!]$ is taken as homogeneous over all $x\in I(t)$ and $t\in\mathbb{R}$. The fundamental nature of the fluctuations in geometry should be equivalent within any small region anywhere in the universe and for any time. Hence, $\mathscr{D}_\sigma(l)=\text{const}$ and $\mathscr{D}_\sigma(l)\to 0$ as l increases beyond the fluctuation–correlation length scale. The coefficients should depend only on the relative positions $l=x-x'$ or length scale of the fluctuations, and not on the location of the fluctuation itself.

Let $x_j=x_1,x_2,x_3\in I(t)$. If we set $G[\![\beta_1(x,t)]\!]=\beta_1(x_1,t)$ then $G[\![\beta(x,t)]\!]=\beta_1(x_1,t)\beta_2(x_2,t)$ and $G[\![\beta(x,t)]\!]=\beta_1(x_1,t)\beta_2(x_2,t)\beta_3(x_3,t)\cdots$ in Eq. (4.8) we obtain moment relations to any order σ:

$$\partial_t\langle\beta_1(x_1,t)\rangle=-\langle\mathscr{D}_1(l)\rangle=\mathscr{D}_1(l), \tag{5.9a}$$

$$\partial_t \langle \beta_1(x_1,t)\beta_2(x_2,t)\rangle = 2\langle \beta_2(x_2,t)\mathscr{D}_1(l)\rangle + \langle \mathscr{D}_2(l)\rangle, \tag{5.9b}$$

and so on. To second order, the coefficient $\mathscr{D}_1 = \mathscr{D}_1(l)$ is a "drift" while $\mathscr{D}_2(l)$ is a "diffusion."

It is now possible to derive differential equations to all orders for $\{\mathsf{K}[\![:l\beta(x,t)]\!]\}$ at length scale l, where $0<\mathsf{K}<1$, and deduce the functional dependence on l. If we take the expectation of the Dirac Δ functional $G[\beta(x_j)] = \Delta[\beta(x)-\beta_j(x_j)]$, then

$$\begin{aligned}\langle G[\![\beta_j(x_j)]\!]\rangle &= \langle \Delta[\beta(x)-\beta_j(x_j)]\rangle \\ &\equiv \langle \Delta[\beta_j(x_j)-\beta(x)]\rangle \\ &= \int G[\![\beta_j(x_j)]\!]\Delta[\beta(x)-\beta_j(x_j)]d\beta_j(x_j) = G[\![l:\beta(x,t)]\!].\end{aligned} \tag{5.10}$$

Note that we use the notation "$\Delta\,[\beta(x)-\beta_j(x_j)]$" here to denote the Dirac Δ function rather than the conventional "$\delta[\beta(x)-\beta_j(x_j)]$" in order to avoid potential confusion with differential metric variations $\delta\beta$. If this choice is inserted into Eq. (5.8),

$$\begin{aligned}&\frac{\partial}{\partial t}\langle[\Delta(\beta(x_j)-\beta(x))]\rangle \\ &\quad\equiv \partial_t \mathsf{K}[\![l:\beta(x,t)]\!] \\ &\quad= \sum_{\sigma=1}^{\infty}\left[\mathscr{D}_\sigma(l)\left(\prod_{j=1}^{\sigma}\int d\beta_j(x_j)\,\frac{\delta}{\delta\beta_j(x_j)}\,\Delta[\beta(x)-\beta_j(x_j)]\mathsf{K}[\![l:\beta(x,t)]\!]\right)\right] \\ &\quad= \int \mathscr{D}_1(l)\int d\beta_1(x_1)\,\frac{\delta}{\delta\beta_1(x_1)}\,\Delta[\beta(x)-\beta_1(x_1)]\mathsf{K}[\![l:\beta(x,t)] \\ &\qquad+\mathscr{D}_2(l)\int d\beta_1(x_1)\int d\beta_2(x_2)\,\frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)} \\ &\qquad\times\Delta[\beta(x)-\beta_1(x_1)]\Delta[\beta(x)-\beta_2(x_2)]\mathsf{K}[\![l:\beta(x,t)]\!]+\cdots\,.\end{aligned} \tag{5.11}$$

Integrating (by parts) and using the filter properties of $\Delta[\beta(x)-\beta_j(x_j)]$ gives a differential equation for $\mathsf{K}[\![l:\beta(x,t)]\!]$ to all perturbation orders in σ:

$$\frac{\partial}{\partial t}\mathsf{K}[\![l:\beta(x,t)]\!] = \sum_{\sigma=1}^{\infty}\mathscr{D}_\sigma(l)\left(\prod_{\sigma=1}^{\sigma}\frac{\delta}{\delta\beta_j(x_j)}\mathsf{K}[\![l:\beta(x,t)]\!]\right) = -f\mathsf{K}[\![l:\beta(x,t)]\!]. \tag{5.12}$$

The equation can be expressed as

$$\frac{\partial}{\partial t}\mathsf{K}[\![l:\beta(x,t)]\!] = f\mathsf{K}[\![l:\beta(x,t)]\!] = \sum_{\sigma=1}^{\infty} f_\sigma \mathsf{K}[\![l:\beta(x,t)]\!], \tag{5.13}$$

where the functional differential operator f is defined by the infinite expansion:

$$f = \sum_{\sigma=1}^{\infty}\mathscr{D}_\sigma(l)\left(\prod_{j=1}^{\sigma}\frac{\delta}{\delta\beta_j(x_j)}\right) = \sum_{\sigma=1}^{\infty} f_\sigma\,. \tag{5.14}$$

Expanding out Eq. (5.12) in powers of σ gives

$$\frac{\partial}{\partial t}\mathsf{K}[\![l:\beta(x,t)]\!]=\left(\sum_{\sigma=1}^{\infty}f_{\sigma}\right)\mathsf{K}[\![l:\beta(x,t)]\!]$$
$$=\mathscr{D}_1(l)\,\frac{\delta}{\delta\beta_1(x_1)}\,\mathsf{K}[\![:l:\beta(x,t)]\!]+\mathscr{D}_2(l)\,\frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\,\mathsf{K}[\![l:\beta(x,t)]\!]+\cdots\,. \tag{5.15}$$

If we truncate the expansion at order $\sigma=2$ in (5.15), we then obtain linear (Fokker–Planck) equations for kernels $\{\mathsf{K}[\![l:\beta(x,t)]\!]\}$.

VI. THE EQUILIBRIUM LIMIT SOLUTION AND ITS CORRELATIONS

Stationary or equilibrium solutions $\mathsf{K}_E[\![l:\beta(x)]\!]$ remain invariant under Cauchy development $I(t')\rightarrow I(t)$ for all $t>t'\in\mathbb{R}$ and $x\in I$. We also require that $(\partial_t\mathsf{K})=0$. One can also find the full time-dependent solution and take the limit $t\rightarrow\infty$ to obtain the equilibrium, stationary solution K_E as $\mathsf{K}[\![l:\beta(x,t)]\!]=\exp(ft)\mathsf{K}_E[\![l:\beta(x)]\!]$. The main idea behind stochastic quantization is to identify the (thermal) equilibrium or stationary correlations of a stochastic model with the equal time n-point Green's functions or correlations of the corresponding quantum theory. The stationary Fokker–Planck equation for the Cauchy-invariant fluctuation processes $\{\mathsf{K}\}$ in the geometry $I(t)$ for all $t\in\mathbb{R}$ is then

$$\left(\mathscr{D}_1(l)\,\frac{\delta}{\delta\beta_1(x_1)}\,\mathsf{K}_E[\![l:\beta(x)]\!]+\mathscr{D}_2(l)\,\frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\,\mathsf{K}_E[\![l:\beta(x)]\!]\right)=0. \tag{6.1}$$

In the equilibrium limit, any functional $G[\![\beta(x)]\!]$ satisfies Eq. (5.8), with $\partial_t G[\![\beta(x)]\!]=0$,

$$\left\langle\mathscr{D}_1(l)\,\frac{\delta}{\delta\beta_1(x_1)}\,G[\![l:\beta(x)]\!]\right\rangle+\left\langle\mathscr{D}_2(l)\,\frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\,G[\![l:\beta(x)]\!]\right\rangle=0. \tag{6.2}$$

Given a generic functional derivative $\delta/\delta q(x)$, there exists the trivial vanishing integral $\int dq(x)[\delta/\delta q(x)]=0$. It will be useful to express the stationary Fokker–Planck equation (6.1) in the equivalent form

$$\int d\beta_1(x_1)\mathscr{D}_1(l)\left(\frac{\delta}{\delta\beta_1(x_1)}\right)\mathsf{K}_E[\![l:\beta(x)]\!]+\int d\beta_1(x_1)\int d\beta_2(x_2)\mathscr{D}_2(l)$$
$$\times\left(\frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\right)\mathsf{K}_E[\![l:\beta(x)]\!]=0. \tag{6.3}$$

The equilibrium solution is easily found to be

$$\mathsf{K}_E[\![l:\beta(x)]\!]=\left(\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\right)\exp\left[-\left(\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\right)\beta(x)\right], \tag{6.4a}$$

$$\mathsf{K}_E[\![l:\delta\beta(x)]\!]=\left(\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\right)\exp\left[-\left(\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\right)\delta\beta(x)\right], \tag{6.4b}$$

where $\delta\beta(x)\equiv\beta(x)-\beta_j(x_j)$ for any $x\in I$ and $x_j\in I$ with $|x-x'|<=l$. As $\mathscr{D}_1(l)\rightarrow 0$ and $\mathscr{D}_2(l)\rightarrow 0$ by appropriately varying the resolution or interval boundary l since $I=[0,l]$, the fluctuation distribution vanishes, so there is zero probability of a fluctuation to any $\beta_j(x_j)$ away from the classical deterministic value $\beta(x)$. The fluctuations decay exponentially so the probability of large fluctuations should diminish rapidly, at a scale determined by the ratio $(\mathscr{D}_1(l)/\mathscr{D}_2(l))$. When the functional derivative of $\mathsf{K}_E[\![l:\beta(x)]\!]$ is taken with respect to $\delta/\delta\beta_1(x_1)$ or $\delta/\delta\beta_2(x_2)$ for $x,x_1,x_2\in I$, the exponent brings down delta functions, since

$$\left(\frac{\delta}{\delta\beta_1(x_1)}\right)\beta(x)=\Delta[\beta(x)-\beta_1(x_1)]=\Delta[\beta_1(x_1)-\beta(x)], \tag{6.5a}$$

$$\left(\frac{\delta}{\delta\beta_2(x_2)}\right)\beta(x)=\Delta[\beta(x)-\beta_2(x_2)]=\Delta[\beta_2(x_2)-\beta(x)], \tag{6.5b}$$

since the Dirac Δ function is symmetrical.

Hence,

$$\begin{aligned}\mathscr{D}_1(l)\,\frac{\delta}{\delta\beta_1(x_1)}\,\mathsf{K}_E[\![l:\beta(x,t)]\!]&=-\frac{[\mathscr{D}_1(l)]^3}{[\mathscr{D}_2(l)]^2}\left(\frac{\delta}{\delta\beta_1(x_1)}\right)\beta(x)\exp\left[-\frac{\mathscr{D}_1}{\mathscr{D}_2}\,\beta(x)\right]\\&=-\frac{[\mathscr{D}_1(l)]^3}{[\mathscr{D}_2(l)]^2}\,\Delta[\beta(x)-\beta_1(x_1)]\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta(x)\right].\end{aligned} \tag{6.6}$$

Similarly,

$$\begin{aligned}&\mathscr{D}_2(l)\left(\frac{\delta^2}{\delta\beta_1(x_1)\,\delta\beta_2(x_2)}\right)\mathsf{K}_E[\![l:\beta(x)]\!]\\&\quad=\frac{[\mathscr{D}_1(l)]^3}{[\mathscr{D}_2(l)]^2}\,\Delta[\beta(x)-\beta_1(x_1)]\Delta[\beta(x)-\beta_2(x_2)]\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta(x)\right].\end{aligned} \tag{6.7}$$

The equilibrium Fokker–Planck equation (6.3) then becomes

$$\begin{aligned}0=&\int d\beta_1(x_1)\Delta[\beta(x)-\beta_1(x_1)]\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta(x)\right]\\&+\int d\beta_1(x_1)\int d\beta_2(x_2)\Delta[\beta(x)-\beta_1(x_1)]\Delta[\beta(x)-\beta_2(x_2)]\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta(x)\right],\end{aligned} \tag{6.8}$$

which is satisfied since

$$\int d\beta_1(x_1)\Delta[\beta(x)-\beta_1(x_1)]=1, \tag{6.9a}$$

$$\int d\beta_1(x_2)\Delta[\beta(x)-\beta_2(x_2)]=1. \tag{6.9b}$$

This is compatible with Eq. (5.10). Using this Cauchy-invariant or equilibrium solution K_E, one can calculate the correlations $\langle\beta(x)\rangle$ and $\langle\beta_1(x_1)\beta_2(x_2)\rangle$ in order to deduce the drift and diffusion coefficients $\mathscr{D}_1(l)$ and $\mathscr{D}_2(l)$. A generic correlation $C_{12}=\langle\varphi_1\varphi_2\rangle$ in field theory or statistical mechanics, generally has a scale dependence and C_{12} falls off as a power law or exponential $C_{12}\sim x^{-v}\exp(-x/\xi)$ for distances large in comparison to the correlation length ξ. For linearized general relativity treated as a quantum field theory, Eq. (2.9) gives equal time correlations, $\sqrt{[\langle\beta(x_1)\beta(x_2)\rangle]}=(8/\pi)(l_*|x_2-x_1|^{-1})$ or $\langle\beta_1(x_1)\beta_2(x_2)\rangle\sim(l_*/l)^2$, where l_* is the Planck length. Using (6.4a), the expectations $\mathscr{E}[\beta(x)]\equiv\langle\beta(x)\rangle$ and $\mathscr{E}[\beta_1(x_1)\beta_2(x_2)]\equiv\langle\beta_1(x_1)\beta_2(x_2)\rangle$ are derived from the equilibrium solution

$$\langle\beta(x)\rangle=\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\int\beta(x)\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta(x)\right]d\beta(x), \tag{6.10a}$$

$$\langle\beta_1(x_1)\beta_2(x_2)\rangle=\frac{[\mathscr{D}_1(l)]^2}{[\mathscr{D}_2(l)]^2}\int\int\beta_1(x_1)\beta_2(x_2)\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta_1(x_1)\right]$$
$$\times\exp\left[-\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\,\beta_2(x_2)\right]d\beta_1(x_1)\,d\beta_2(x_2). \tag{6.10b}$$

The form of the integral is straightforward: $\int_D^\infty q(x)\exp[-aq(x)]dq(x)=(1/a^2)$ for fixed x, where $a=[\mathscr{D}_1(l)/\mathscr{D}_2(l)]$. Hence,

$$\langle\beta(x)\rangle=\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\left(\frac{\mathscr{D}_2(l)}{\mathscr{D}_1(l)}\right)^2=\left(\frac{\mathscr{D}_2(l)}{\mathscr{D}_1(l)}\right), \tag{6.11a}$$

$$\langle\beta_1(x_1)\beta_2(x_2)\rangle=\left(\frac{\mathscr{D}_1(l)}{\mathscr{D}_2(l)}\right)^2\left(\frac{\mathscr{D}_2(l)}{\mathscr{D}_1(l)}\right)^3=\left(\frac{\mathscr{D}_2(l)}{\mathscr{D}_1(l)}\right)^2. \tag{6.11b}$$

The correlations in the stationary, equilibrium limit of the stochastic model can be compared with the equal time correlations estimated from the linearized Einstein theory [see (2.8) and (2.9)] treated as a quantum field theory: $\langle\beta_1(x_1)\beta_2(x_2)\rangle\sim(l_*/l)^2$, where $l=x_1-x_2$. Both results are derived at second order, which in the stochastic model was tantamount to truncation at $\sigma=2$ to yield a Fokker–Planck equation. One has $(\mathscr{D}_2(l)/\mathscr{D}_1(l))^2=(l_*/l)^2$, which is satisfied if we have $\mathscr{D}_1(l)=(l_*/l)$ and $\mathscr{D}_2(l)=(l_*/l)^2$. The maximum allowed spatial fluctuations of order $|x-x'|=l$ within I diminish rapidly as the resolution l is increased and the corresponding diffusion coefficient $\mathscr{D}_2(l)\sim(l_*/l)^2$ vanishes along with the drift coefficent $\mathscr{D}_1(l)\sim(l^*/l)$. Note, even on the nuclear scale, that we have $(l_*/l)\sim10^{-20}$. The equilibrium kernel is

$$\mathsf{K}_E[\![l:\delta\beta(x)]\!]=\frac{l}{l_*}\exp\left[-\frac{l}{l_*}\,\delta\beta(x)\right]. \tag{6.12}$$

This rapidly damps to zero for $l\gg l_*$. For a real probability on [0,1] we require

$$0\leqslant\frac{l}{l_*}\exp\left[-\frac{l}{l_*}\,\delta\beta(x)\right]<1. \tag{6.13}$$

Clearly, $(l/l_*)>0$ is always satisfied and $\exp[-(l/l_*)\delta\beta(x)]<=(l_*/l)<=1$ if $l=l_*$ is a lower bound, such that $I\rightarrow I_*=[0,l_*]$. This gives the uncertainty relation $l\,\delta\beta(x)>=l_*$ or $\delta\beta(x)>=(l_*/l)$. The fluctuations rapidly vanish for $l\gg l_*$ and the kernel is defined on [0,1] only if $l>=l_*$. For $l\gg l_*$, the probabiity has a sharp peak at $\delta\beta=0$. The expansion or contraction of the spatial interval $[0,l]$ then damps or amplifies the fluctuations in the 1-metric. As l is reduced toward l_*, the smooth interval $I=[0,l]$ becomes increasingly ''fuzzy'' and the continuous, deterministic geometry is lost. Also, as l gets very near to l_*, higher-order correlations emerge between three $(x_1,x_2,x_3)\in I$ or more points $(\sigma>=2)$ within I, with $\mathscr{D}_\sigma(l)\sim(l_*/l)^\sigma$. Equation (5.8) is a linear approximation to order $\sigma=2$. This situation is somewhat analogous to the kinetic theory of a gas. As the density ρ increases, the probability for a larger number of molecules to collide at the same point increases. The expansion parameter is the density $\rho\sim(1/V)\sim(1/l^3)$ or $\rho\sim(1/l)$ for a one-dimensional gas. For the fluctuations in geometry, the expansion parameter is similarly $\mathscr{D}_\sigma(l)\sim(l_*/l)^\sigma$. However, in the classical limit as $l\gg1_p$ or $\hbar\rightarrow0$, then $l_*=(G\hbar)^{1/2}\rightarrow0$ and all $\mathscr{D}_\sigma(l)\rightarrow0$ and so $\mathsf{K}_E[\![\beta(x)]\!]\rightarrow0$. Correlations to all orders vanish and the geometry returns to being deterministic at all length scales.

Interestingly, a similar mathematical structure to (6.12) can be obtained for a fluctuation amplitude in standard Euclidean path integral quantum gravity. Padmanabhan[33,34] has deduced the existence of a minimum length within quantum gravity, where the conformal factor is quantized. Beginning with a conformally flat metric $g_{uv}=[1+\phi(x)^2]\eta_{uv}$, the Euclidean path integral over the conformal fluctuation ϕ is

$$\int \mathscr{D}\phi \exp\left(-\frac{i}{l_*^2}\int d^4x\ \eta_{uv}\ \nabla_u\phi\ \nabla_v\phi\right), \tag{6.14}$$

which can be evaluated in a closed form. The resulting amplitude for a measurement of the conformal fluctuation having value ϕ is

$$\mathcal{A}(\phi)=\left(\frac{l}{l_*}\right)^{1/4}\exp\left(-\left(\frac{l}{l_*}\right)^2\phi^2\right). \tag{6.15}$$

This amplitude behaves in a very similar way to the probability in (5.6) and damps out for $l \gg l_*$.

VII. CONCLUSIONS

A basic stochastic construction has been presented to describe Planck scale fluctuations in the geometry of a simple globally hyperbolic $(1+1)$ manifold. The emphasis has been on the conceptual issues and potential of such an approach rather than on technical subtleties, but the scheme is mathematically self-consistent and makes contact with basic physical features of metric fluctuations and quantum geometry. The second-order stationary equilibrium solution of the Fokker–Planck equation derived from the construction makes contact with the quantum field theoretic predictions for metric fluctuations and equal time correlations in linearized general relativity. It is predicted that probabilities for (linear) stochastic metric component fluctuations on the interval $[0,l]$ diminish exponentially with a scale dependence $l \gg l_*$. As l increases above l_*, the second-order solution illustrates that the spatial geometry evolves from being smooth and deterministic to stochastic or noisy, with a maxima at the Planck length. This is the so-called quantum ''foam'' structure. Away from the Planck length, the spatial geometry returns to a smooth and deterministic condition. Clearly, there are many highly nontrivial technical issues that arise in any approach to a quantum interpretation of space–time or gravitation. These include problems in defining general path measures and the potential for ill-defined expressions. However, the point of view presented is that a basic construction of this kind, with the emergence of a well-known and expected physical consequence of quantum gravity and geometry, is a necessary prerequisite to more detailed approaches, which may have the potential to extend the scope of quantum geometry.

On rotational coherent states in molecular quantum dynamics

Jorge A. Morales, Erik Deumens, and Yngve Öhrn
Quantum Theory Project, Departments of Chemistry and Physics, University of Florida, Gainesville, Florida 32611-8435

(Received 5 June 1998; accepted for publication 16 November 1998)

Coherent states suitable for the description of molecular rotations are developed and their connection to similar coherent states in the literature are explored. In particular their quasiclassical properties are developed. The use of such coherent states in time-dependent electron nuclear dynamics studies of molecular collision processes is discussed.
[S0022-2488(99)04602-2]

I. INTRODUCTION

Coherent states (CS) are a set of elements $\{|\mu\rangle\}$ of a Hilbert space $\mathcal{H}$. All CS share two properties in common:[1]
(1) continuity, i.e., the states $|\mu\rangle$ are continuous functions[1] of a parameter set μ,

$$\lim_{\mu\to\mu_0}|\mu\rangle=|\mu_0\rangle, \tag{1}$$

(2) resolution of the identity, i.e., there exists a positive measure $d\mu_+\geqslant 0$ for which

$$1=\int d\mu_+|\mu\rangle\langle\mu|. \tag{2}$$

There exists a weaker formulation of the second property which will allow a larger class of CS:[1]
$(2')$ The closed linear span of $\{|\mu\rangle\}$ is the Hilbert space $\mathcal{H}$. This means that any state vector in the Hilbert space may be represented as a (possibly infinite) linear sum of CS.[1] Such CS may satisfy a resolution of the identity with an indefinite measure $d\mu_\pm$,

$$1=\int d\mu_\pm|\mu\rangle\langle\mu|. \tag{3}$$

Both in the stronger and the weaker definitions, the CS form a nonorthogonal overcomplete set.

There are a great variety of CS known and used in various areas of physics. For problems in molecular physics and in chemistry the canonical CS[2,1] also referred to as Glauber states[3] are commonly used.[4] These states $\{|\alpha\rangle\}$ are associated with the harmonic oscillator Hamiltonian $H_{\mathrm{vib}}=\hbar\omega(a^\dagger a+\frac{1}{2})$, where ω is the angular frequency. The harmonic oscillator creation operators can be expressed as

$$a^\dagger=\frac{1}{\sqrt{2}}\left(\sqrt{\frac{m\omega}{\hbar}}\hat{x}-\frac{i}{\sqrt{m\hbar\omega}}\hat{p}\right) \tag{4}$$

in terms of the self-adjoint operators of position $\hat{x}$ and momentum $\hat{p}$, where m is the oscillator mass. The complex parameter α can be expressed in terms of the real parameters of average position $x_\alpha=\langle\alpha|\hat{x}|\alpha\rangle$ and average momentum $p_\alpha=\langle\alpha|\hat{p}|\alpha\rangle$ as

$$\alpha=\frac{1}{\sqrt{2}}\left(\sqrt{\frac{m\omega}{\hbar}}x_\alpha-\frac{i}{\sqrt{m\hbar\omega}}p_\alpha\right). \tag{5}$$

An expansion in terms of harmonic oscillator stationary states $\{|n\rangle, n=0,1,...\}$ exists,

$$|\alpha\rangle=\exp\left(-\frac{1}{2}|\alpha|^2\right)\sum_{n=0}^{\infty}\frac{\alpha^n}{\sqrt{n!}}|n\rangle=\exp\left(-\frac{1}{2}|\alpha|^2\right)\exp(\alpha a^\dagger)|0\rangle, \tag{6}$$

from which the resolution of the identity is readily proven with the positive measure

$$d\mu_+(\alpha)=\frac{1}{\pi}d\ \mathrm{Re}\ \alpha d\ \mathrm{Im}\ \alpha. \tag{7}$$

The spin coherent states $\{|\beta\rangle\}$, with a complex parameter β, constitute another example of CS used in molecular physics.[1] These states are associated with the total spin angular momentum $\vec{S}=(S_x S_y S_z)$ and an expansion in terms of spin eigenstates $\{|SM\rangle, S=0,1/2,1,...; M=S, S-1,...-S\}$ exists,

$$|\beta\rangle=\sum_{M=-S}^{S}\sqrt{\frac{(2S)!}{(S-M)!(S+M)!}}\left[\frac{\beta^{S+M}}{(1+|\beta|^2)^s}\right]|SM\rangle=\frac{1}{(1+|\beta|^2)^s}\exp(\beta S_+)|S\ -S\rangle, \tag{8}$$

where $S_\pm=S_x\pm iS_y$. The resolution of the identity exists with the positive measure

$$d\mu_+(\beta)=\frac{2S+2}{\pi(1+|\beta|^2)^2}d\ \mathrm{Re}\ \beta d\ \mathrm{Im}\ \beta. \tag{9}$$

It suffices here to mention as a third example the fermion CS,[1] also known as the Thouless determinant.[5,6] These CS are used, e.g., in the description of many-electron systems.[4] For N electrons in a basis of rank $K\geqslant N$ the normalized Thouless CS $\{|z\rangle\}$ can be expressed as

$$|z\rangle=\det(I+z^\dagger z)^{-1/2}\exp\left[\sum_{h=1}^{N}\sum_{p=N+1}^{K}z_{ph}b_p^\dagger b_h\right]|\Psi_0\rangle, \tag{10}$$

where z denotes the set of complex parameters $\{z_{ph}\}$, the $b_i^\dagger$ and b_i are the fermion creation and annihilation operators, respectively, and where

$$|\Psi_0\rangle=\prod_{i=1}^{N}b_i^\dagger|\mathrm{vac}\rangle. \tag{11}$$

The resolution of the identity exists with the positive measure

$$d\mu_+(z)=\eta\det(I+z^\dagger z)^{-K}d^2z, \tag{12}$$

where

$$d^2z=\frac{1}{\pi}\prod_{ph}d\ \mathrm{Re}\ z_{ph}d\ \mathrm{Im}\ z_{ph}, \tag{13}$$

and

$$\eta=\frac{1!2!\cdots K!}{1!2!\cdots(K-J)!1!2!\cdots J!}. \tag{14}$$

A set of coherent states may be related to a particular Lie group. Rasetti[7] and Solomon[8] have made seminal contributions to the theory of group-related CS. Perelomov[9] introduced a systematic procedure for the construction of such group-related CS. For instance, the canonical CS of the harmonic oscillator are related to the Weyl group, the spin CS to the special unitary group SU(2), and the Thouless CS to the unitary group U(K). There are, however, important CS that are not group related. The construction of coherent states requires a portion of mathematical intuition.

II. QUASICLASSICAL COHERENT STATES

A prominent property of many CS is their quasiclassical dynamics. A state $|\psi\rangle$ is said to be quasiclassical when the evolution of average position, momenta, and energy,

$$x_{\mathrm{qc}}=\langle\psi|\hat{x}|\psi\rangle,\quad p_{\mathrm{qc}}=\langle\psi|\hat{p}|\psi\rangle,\quad H_{\mathrm{qc}}=\langle\psi|\hat{H}|\psi\rangle, \tag{15}$$

satisfy classical Hamilton equations, i.e.,

$$\dot{x}_{\mathrm{qc}}=\frac{\partial H_{\mathrm{qc}}}{\partial x_{\mathrm{qc}}},\quad \dot{p}_{\mathrm{qc}}=-\frac{\partial H_{\mathrm{qc}}}{\partial p_{\mathrm{qc}}}. \tag{16}$$

In other words, the average position and momentum of the quasiclassical state evolve in time as the position and momentum of their classical analogs. One should note that the definition of a quasiclassical state does not demand the semiclassical limit $\hbar\to 0$ to be invoked. Neither is there *a priori* any guarantee that a quasiclassical state even exists for a given Hamiltonian. Ehrenfest's theorem[10] offers a means to investigate the quasiclassical property, i.e., the equations

$$\begin{aligned} i\hbar\frac{d}{dt}\langle\psi|\hat{x}|\psi\rangle&=\langle\psi|[\hat{x},\hat{H}]|\psi\rangle,\\ i\hbar\frac{d}{dt}\langle\psi|\hat{p}|\psi\rangle&=\langle\psi|[\hat{p},\hat{H}]|\psi\rangle \end{aligned} \tag{17}$$

should reduce to the classical ones of Eq. (16) for the state $|\psi\rangle$ to be quasiclassical.

In this manner it is straightforward to show that the canonical CS of Eq. (6) are quasiclassical. In particular,

$$\begin{aligned} \langle\alpha|\hat{x}|\alpha\rangle&=x_{\alpha}(t)=\sqrt{\frac{2\hbar}{m\omega}}\,\mathrm{Re}[\alpha\exp(-i\omega t)],\\ \langle\alpha|\hat{p}|\alpha\rangle&=p_{\alpha}(t)=\sqrt{2m\hbar\omega}\,\mathrm{Im}[\alpha\exp(-i\omega t)] \end{aligned} \tag{18}$$

and the total energy using the harmonic oscillator Hamiltonian is

$$E_{\alpha}\equiv H_{\mathrm{qc}}=\langle\alpha|H_{\mathrm{vib}}|\alpha\rangle=\hbar\omega|\alpha|^2+\frac{\hbar\omega}{2}=E_c^{\alpha}+\frac{\hbar\omega}{2}, \tag{19}$$

where

$$E_c^{\alpha}=\frac{1}{2m}p_{\alpha}^2+\frac{1}{2}m\omega^2x_{\alpha}^2 \tag{20}$$

is the classical energy of the harmonic oscillator. This particular set of CS satisfies the minimum uncertainty relation

$$\Delta x_{\alpha}(t)\Delta p_{\alpha}(t)=\hbar/2, \tag{21}$$

where the widths $\Delta x_\alpha(t)$ and $\Delta p_\alpha(t)$ are

$$\Delta x_\alpha(t)=\Delta x_\alpha=\sqrt{\frac{\hbar}{2m\omega}},\quad \Delta p_\alpha(t)=\Delta p_\alpha=\sqrt{\frac{m\hbar\omega}{2}}. \tag{22}$$

The coordinate representation of the canonical CS is

$$\psi_\alpha(x,t)=\langle x|\alpha(t)\rangle=\exp(i\theta_\alpha(t))\left(\frac{m\omega}{\pi\hbar}\right)^{1/4}\exp(-i\omega t)\exp\left(-\left(\frac{x-x_\alpha}{2\Delta x_\alpha}\right)^2\right)\exp\left(\frac{ip_\alpha(t)x}{\hbar}\right), \tag{23}$$

where $\theta_\alpha(t)$ is a global phase. The spin CS, Eq. (8), are quasiclassical with respect to a Hamiltonian describing the spin dynamics under a time-dependent magnetic field.[11,1] Minimum uncertainty conditions are also known for this CS.[11,1] There are CS that do not exhibit the quasiclassical property. The Thouless CS is not a quasiclassical state. However, it is possible to obtain classical-like equations for the Thouless parameters via the time-dependent variational principle (TDVP).[4,12]

III. ELECTRON NUCLEAR DYNAMICS AND COHERENT STATES

In this section, we make the connection between the CS and the electron nuclear dynamics (END) theory.[13,4,12] The END wave function[4] is

$$\Psi_{\mathrm{END}}(t)=\frac{1}{N_{\mathrm{nucl}}}F_{\mathrm{nucl}}[\mathbf{R}(t),\mathbf{P}(t)]f_{\mathrm{el}}[\mathbf{z}(t),\mathbf{R}(t)]\exp\left[\frac{i}{\hbar}\gamma_{\mathrm{END}}(t)\right], \tag{24}$$

where $\gamma_{\mathrm{END}}(t)$ is the total phase. At the simplest level of approximation the nuclear part F_{nucl} is the product of Gaussian wave packets of positions $\mathbf{R}(t)$ and momenta $\mathbf{P}(t)$,

$$F_{\mathrm{nucl}}(\mathbf{X};\mathbf{R},\mathbf{P})=\prod_{k=1}^{\mathrm{nucl}}\exp(-a_k[\mathbf{X_k}-\mathbf{R_k}(t)]^2+i\mathbf{P_k}(t)\cdot[\mathbf{X_k}-\mathbf{R_k}(t)]), \tag{25}$$

and the electronic part $f_{\mathrm{el}}[z_{ph}(t),\mathbf{R}(t),]=|z\rangle$ is the fermion (Thouless) CS shown above. The very role of the fermion CS is to provide a nonredundant and continuous parametrization of the single-determinant electronic wave function. It should be noted that the total system END wave function is given in the laboratory frame and includes translational and overall rotational motion. Using this approximate $\Psi_{\mathrm{END}}(t)$ and the TDVP a set of classical Hamilton-like equations are obtained for the Thouless parameters $\mathbf{z}(t)$ and $\mathbf{z}^*(t)$.[13,14,4,12] In order to obtain the proper END equations for this level of approximation the quantum mechanical Lagrangian is first obtained in the limit of zero width nuclear Gaussian wave packets. This approach leads to a classical treatment of the nuclei that retains the nonadiabatic electron–nuclear coupling terms. This approximation may be described as full, nonlinear time-dependent Hartree–Fock (TDHF) for electrons and narrow wave packet nuclei.

The time propagation of a molecular system undergoing a reaction may produce a set of product fragments. One important aim of molecular reaction dynamics is to predict the distribution of products over rovibrational states. The treatment of such a reactive process at the simplest END level of approximation leads to a fragment in some electronic state with its system of nuclei vibrating and rotating as a classical object. It has been demonstrated how the END representation of the nuclear part of such a fragment under very general conditions factors as

$$F_{\mathrm{nucl}}[\mathbf{X};\mathbf{R}(t),\mathbf{P}(t)]\approx F_0F_{\mathrm{vib}}F_{\mathrm{rot}}. \tag{26}$$

Viewing this wave function, even in the narrow wave packet limit, as an evolving state and representing this state in terms of suitable CS makes possible an *a posteriori* quantum state resolution of the nuclear dynamics. In this way we adopt the approximate labeling of product states in terms of vibrational (harmonic oscillator) quantum numbers and rotational (rigid rotor) quantum numbers. Obviously, more ambitious CS could be attempted, but this level of sophistication seems reasonable for low energy reactive collisions.

The *a posteriori* vibrational analysis in terms of harmonic oscillator CS has been outlined (see Ref. 12) and applied to obtain vibrationally resolved differential cross sections for proton collisions with hydrogen molecules at 30 eV,[15] in excellent agreement with experiment. A corresponding analysis for a quasiclassical treatment of the rotational dynamics is an interesting prospect and the necessary development is discussed in this paper.

IV. ROTATIONAL COHERENT STATES

The term rotational CS denotes those CS which are quasiclassical with a field-free rotor Hamiltonian. It is important to emphasize that the previously discussed spin CS is not a rotational CS by virtue of the preceding definition. Most of the rotational CS known in the literature stem in some way from the spin CS. Except for one case discussed below,[16] the majority of the rotational CS concerns the description of the linear rotor.

The first known rotational CS were derived by Atkins and Dobson.[17] The Atkins–Dobson CS are group generated by the Schwinger boson operators of the angular momentum,[18] have a positive measure, and can in principle be applied to linear rotors. An interesting and more useful contribution to the theory of rotational CS was made by Janssen,[16,1] who constructed rotational CS for the general asymmetric rotor. Janssen CS $\{|xyz\rangle\}$ can be expressed as

$$|xyz\rangle=\sum_{IMK} J_{IMK}(x,y,z)|IMK\rangle, \tag{27}$$

where $|IMK\rangle$; $I=0,\frac{1}{2},1,...$; M, $K=0,\pm\frac{1}{2},\dots\pm I$ are the integer (boson) and half-integer (fermion) rotational states associated with the asymmetric rotor Hamiltonian, x, y, and z the CS parameters, and $J_{IMK}(x,y,z)$ a set of coefficients. Janssen CS are not group generated and have an indefinite measure. These CS satisfy quasiclassical dynamical equations when evolved by the asymmetric rotor Hamiltonian in the Hilbert space spanned by the states $|IMK\rangle$. An interesting feature is that the Janssen CS are identical to the Atkins–Dobson CS in the limit of the linear rotor. The proof of that identity involves a proper reparametrization of Janssen CS. Both sets of CS have the property of mixing half-integer and integer quantum numbers. Therefore, they are not directly useful for the discussion of molecular rotational spectra for which a corresponding development in terms of only integer quantum numbers is necessary.

Similar developments were published by Bhaumik *et al.*, but again for the case of the linear rotor states $|IMK=0\rangle$. A review of some rotational CS for linear rotors was published by Fonda *et al.*[19] This study discusses the Atkins–Dobson CS among many others but misses those by Janssen and Bhaumik *et al.* More importantly, new CS generated by the $SO(3)\otimes R^5$ group are developed there to study diatomic molecules in the presence of an electromagnetic field.

In this section we introduce a new set of rotational CS following closely the definition of Janssen. Only integer quantum numbers are used for these CS and their quasiclassical behavior is analyzed.

A. Rotor Hamiltonian

The pure rotor Hamiltonian for a molecular system can be written as[20]

$$\hat{H}_{\rm rot}=\frac{\hat{L}_x^2}{2A_x}+\frac{\hat{L}_y^2}{2A_y}+\frac{\hat{L}_z^2}{2A_z}, \tag{28}$$

where A_i $(i=x,y,z)$ are the moments of inertia and $\hat{L}_i$ the body-fixed components of the orbital angular momentum. Please note that from here on $\hbar=1$. The analogous space-fixed components of orbital angular momentum are $\hat{J}_i$ and the following relations hold $(\hat{J}^2=\hat{L}^2)$:

$$[\hat{J}_i,\hat{J}_j]=i\epsilon_{ijl}\hat{J}_l, \quad [\hat{L}_i,\hat{L}_j]=-i\epsilon_{ijl}\hat{L}_l \tag{29}$$

and

$$[\hat{J}_i,\hat{L}_k]=[\hat{L}^2,\hat{L}_z]=[\hat{J}^2,\hat{J}_z]=0, \tag{30}$$

where ϵ_{ikl} are the components of the Levi–Civita tensor. Note the so-called anomalous commutation relationship[20] of the $\hat{L}_i$ components. As a result of these commutation relationships, there exists a complete set of rotor eigenstates $|IMK\rangle$ so that

$$\begin{aligned}
\hat{L}^2|IMK\rangle &= I(I+1)|IMK\rangle, \quad I=0,1,2,...,\\
\hat{L}_z|IMK\rangle &= K|IMK\rangle, \quad K=0,\pm 1,...,\pm I,\\
\hat{J}_z|IMK\rangle &= M|IMK\rangle, \quad M=0,\pm 1,...,\pm I.
\end{aligned} \tag{31}$$

These rotor eigenstates in angular representation are

$$\langle \phi,\theta,\chi|IMK\rangle=\left[\frac{2I+1}{8\pi^2}\right]^{1/2} D^{I*}_{MK}(\phi,\theta,\chi), \tag{32}$$

where $D^I_{MK}(\phi,\theta,\chi)$ are elements of a rotation matrix (Wigner D functions).[20]

It follows from the above commutator relations that the rotational Hamiltonian satisfies

$$[\hat{H}_{\mathrm{rot}},\hat{J}_i]=0, \quad [\hat{H}_{\mathrm{rot}},\hat{J}^2]=0. \tag{33}$$

The Hamiltonian eigenfunctions Ψ^α_{IM} must satisfy

$$\begin{aligned}
\hat{H}_{\mathrm{rot}}\Psi^\alpha_{IM} &= E^\alpha_{\mathrm{rot}}\Psi^\alpha_{IM},\\
\hat{J}^2\Psi^\alpha_{IM} &= I(I+1)\Psi^\alpha_{IM}, \quad I=0,1,2,...,\\
\hat{J}_z\Psi^\alpha_{IM} &= M\Psi^\alpha_{IM}, \quad M=0,\pm 1,...,\pm I,
\end{aligned} \tag{34}$$

where the superscript α is an additional label of a particular rotational eigenstate. Another set of relations implied by the above commutation relations is

$$[\hat{H}_{\mathrm{rot}},\hat{L}_i]=i\sum_j \frac{\epsilon_{ijk}}{2A_k}(\hat{L}_j\hat{L}_k+\hat{L}_k\hat{L}_j). \tag{35}$$

The Ψ^α_{IM} eigenfunctions are expressed in the symmetric rotor basis as

$$\Psi^\alpha_{IM}=\sum_K c^{IM\alpha}_K|IMK\rangle, \tag{36}$$

where the coefficients $c^{IM\alpha}_K$ are to be determined.

In the special case of a spherical rotor $A=A_x=A_y=A_z$ (e.g., CH_4 and SF_6), the eigenvalue problem simplifies to

$$\hat{H}_{\mathrm{rot}}=\frac{\hat{L}^2}{2A}=\frac{\hat{J}^2}{2A}, \quad \Psi^\alpha_{IM}=\Psi_{IM}=|IMK\rangle, \quad E^{IM\alpha}_{\mathrm{rot}}=E^I_{\mathrm{rot}}=\frac{I(I+1)}{2A}. \tag{37}$$

In the case of a prolate symmetric rotor, the moments of inertia satisfy $A_x \leqslant A_y = A_z$ (e.g., CH_3Cl and PCl_5). The eigenvalue problem then becomes

$$\hat{H}_{\mathrm{rot}} = \frac{\hat{L}^2}{2A_z} + \left(\frac{1}{2A_x} - \frac{1}{2A_z} \right) \hat{L}_z^2,$$

$$\Psi_{IM}^{\alpha} = \Psi_{IM} = |IMK\rangle, \tag{38}$$

$$E_{\mathrm{rot}}^{IM\alpha} = E_{\mathrm{rot}}^{IM} = \frac{I(I+1)}{2A_z} + \left(\frac{1}{2A_x} - \frac{1}{2A_z} \right) K^2.$$

The equivalent expressions for the case of an oblate symmetric rotor $A_x = A_y \leqslant A_z$ (e.g., $CHCl_3$ and C_6H_6) can be obtained by interchanging the A_x with the A_z in the last equations. The case of the linear rotor (e.g., all diatomics, CO_2, and C_2H_2) is obtained as the $A_x = 0$ limit of the prolate symmetric case. Then

$$\hat{H}_{\mathrm{rot}} = \frac{\hat{J}^2}{2A}, \quad \Psi_{IM}^{\alpha} = \Psi_{IM} = |IM0\rangle,$$

$$E_{\mathrm{rot}}^{IM\alpha} = E_{\mathrm{rot}}^{I} = \frac{I(I+1)}{2A}, \quad \langle \theta, \phi | IM0 \rangle = Y_{IM}(\theta, \phi), \tag{39}$$

where the $Y_{IM}(\theta,\phi)$ are the spherical harmonics.[20] Finally, in the case of an asymmetric rotor, with the moments of inertia satisfying $A_x \leqslant A_y \leqslant A_z$ (e.g., CH_2H_2), the eigenfunctions Ψ_{IM}^{α} keep their linear combination form, and the $c_K^{IM\alpha}$ coefficients must be specifically calculated.

B. Groups

Although the set of CS under construction is not group related in the Perelomov sense, it is, of course, connected to the rotation groups. Specifically, the states $|IMK\rangle$ span the irreducible representations of the semidirect product of SO(3)⊗SO(3) with an Abelian group. The generators of the first SO(3) group are the $\hat{L}_i$, referring to the molecule-fixed frame, while those of the second one are the $\hat{J}_i$ referring to the space-fixed frame. The generators of the Abelian group $R^{(2\lambda+1)^2}$ belong to a family of tensor operators $\hat{T}_{\mu\nu}^{\lambda}$ ($\lambda = 0, \frac{1}{2}, 1, \frac{3}{2}, \ldots;\ \mu, \nu = 0, \pm\frac{1}{2}, \ldots, \pm\lambda$). We select the tensors with $\lambda = 1$ in order to limit the CS to integer rotational quantum numbers. These tensor operators commute among themselves, i.e.,

$$[\hat{T}_{\mu\nu}^{\lambda}, \hat{T}_{\mu'\nu'}^{\lambda}] = 0 \tag{40}$$

and satisfy the relations

$$\hat{T}_{\mu\nu}^{\lambda\dagger} = (-1)^{\nu-\mu} \hat{T}_{-\mu-\nu}^{\lambda}, \tag{41}$$

and

$$\sum_{\mu} \hat{T}_{\mu\nu}^{\lambda\dagger} \hat{T}_{\mu\nu'}^{\lambda} = \delta_{\nu\nu'}, \quad \sum_{\nu} \hat{T}_{\mu\nu}^{\lambda\dagger} \hat{T}_{\mu'\nu}^{\lambda} = \delta_{\mu\mu'}. \tag{42}$$

In addition to the commutation relations among these tensor operators we need the ones with the SO(3) generators in Eq. (29) and the relations (30),

$$[\hat{L}_z, \hat{T}_{\mu\nu}^{\lambda}] = \nu \hat{T}_{\mu\nu}^{\lambda}, \quad [\hat{J}_z, \hat{T}_{\mu\nu}^{\lambda}] = \mu \hat{T}_{\mu\nu}^{\lambda}, \tag{43}$$

as well as

$$
\begin{aligned}
&[\hat{L}_{\pm},\hat{T}^{\lambda}_{\mu\nu}]=[\lambda(\lambda+1)-\nu(\nu\mp1)]^{1/2}\hat{T}^{\lambda}_{\mu\nu\mp\lambda},\\
&[\hat{J}_{\pm},\hat{T}^{\lambda}_{\mu\nu}]=[\lambda(\lambda+1)-\mu(\mu\pm1)]^{1/2}\hat{T}^{\lambda}_{\mu\pm\lambda\nu},
\end{aligned}
\tag{44}
$$

where

$$
\hat{L}_{\pm}=\hat{L}_x\mp i\hat{L}_y,\quad \hat{J}_{\pm}=\hat{J}_x\pm i\hat{J}_y. \tag{45}
$$

The rotation matrix elements $D^{\lambda}_{\mu\nu}(\alpha,\beta,\gamma)$, $(\lambda=0,\frac{1}{2},1,\frac{3}{2},\ldots;\ \mu,\nu=0,\pm\frac{1}{2},\ldots,\pm\lambda)$ are a realization of the $\hat{T}^{\lambda}_{\mu\nu}$ operators and define their action on the states $|IMK\rangle$. Here it suffices to know that

$$
\hat{T}^{1}_{-1-1}|I\ -I\ -I\rangle=\left(\frac{2I+1}{2I+3}\right)^{1/2}|I+1\ -I-1\ -I-1\rangle. \tag{46}
$$

C. Construction of coherent states

The straightforward application of Perelemov's prescription[9] would make the set of rotational coherent states be

$$
X(x,\psi)Z(z,\omega)Y(y^{1}_{\mu\nu})|000\rangle, \tag{47}
$$

where the $X(x,\psi)$ and $Z(z,\omega)$ operators are two parametrizations of the SO(3) group

$$
\begin{aligned}
&X(x,\psi)=N_X e^{xJ_+}e^{-x^*J_-}e^{-i\psi J_z},\\
&Z(z,\omega)=N_Z e^{zL_+}e^{-z^*L_-}e^{-i\omega L_z},
\end{aligned}
\tag{48}
$$

with the real parameters $0\leqslant\psi\leqslant2\pi$, $0\leqslant\omega\leqslant2\pi$, and the complex parameters x $(-\infty\leqslant\operatorname{Re}x\leqslant\infty$, $-\infty\leqslant\operatorname{Im}x\leqslant\infty)$ and z $(-\infty\leqslant\operatorname{Re}z\leqslant\infty$, $-\infty\leqslant\operatorname{Im}z\leqslant\infty)$, respectively. N_X and N_Z denote normalization constants. The unitary operator $Y(y^{1}_{\mu\nu})$ is a general element of the Abelian group R^9 generated by the tensor operators $T^{1}_{\mu\nu}$, i.e.,

$$
Y(y^{1}_{\mu\nu})=\exp\left(\sum_{\mu,\nu}y^{1}_{\mu\upsilon}T^{1}_{\mu\nu}\right) \tag{49}
$$

with the complex parameters $y^{1}_{\mu\nu}$ $(-\infty\leqslant\operatorname{Re}y^{1}_{\mu\nu}\leqslant\infty$, $-\infty\leqslant\operatorname{Im}y^{1}_{\mu\nu}\leqslant\infty)$ satisfying $y^{1}_{\mu\nu}=(-1)^{\mu-\upsilon+1}y^{1*}_{-\mu-\nu}$. This mode of construction combines two spin CS with CS belonging to the abelian group R^9. This produces a set of CS of some complexity, which will not be further analyzed.

Instead, in analogy with the Janssen's approach,[16] we propose the simpler construction

$$
|xyz\rangle=\exp[-\tfrac{1}{2}yy^*(1+xx^*)^2(1+zz^*)^2]e^{xJ_+}e^{zL_+}\exp[yf(\hat{I})T^{1}_{-1-1}]|000\rangle, \tag{50}
$$

where the parameter y relates to the above discussion such that $y=y^{1}_{-1-1}$. The function $f(\hat{I})$ is

$$
f(\hat{I})=\sqrt{(2\hat{I}^2+\hat{I})/(2\hat{I}-1)}, \tag{51}
$$

where the operator $\hat{I}$ is defined by (compare Ref. 16)

$$
\hat{I}|IMK\rangle=I|IMK\rangle. \tag{52}
$$

The effect of the $f(\hat{I})$ function is to generate a desired Poisson distribution by canceling some factors occurring in Eq. (46). The operator $\hat{I}$ can be expressed in terms of the Schwinger boson operators, but in the present context it can be seen as a purely formal construct that serves to simplify some expressions. Note the subtle differences in the normalization factor and in the right exponential operator in comparison to those in Ref. 16. It follows straightforwardly that

$$\exp(yf(\hat{I})\hat{T}^{1}_{-1-1})|000\rangle=\sum_{I=0,1,\ldots}^{\infty}\frac{(yf(\hat{I})\hat{T}^{1}_{-1-1})^{I}}{I!}|000\rangle=\sum_{I=0,1,\ldots}^{\infty}\frac{y^{I}}{\sqrt{I!}}|I\ -I\ -I\rangle \tag{53}$$

and that

$$\begin{aligned} e^{z\hat{L}_+}|I\ -I\ -I\rangle &=\sum_{n=0}^{\infty}\frac{z^n}{n!}\hat{L}_+^n|I\ -I\ -I\rangle \\ &=\sum_{n=0}^{2I}\frac{z^n}{n!}\{2I(2I-1)\cdots[2I-(n-1)]\}^{1/2}(n!)^{1/2}|I\ -I\ -I+n\rangle \\ &=\sum_{K=-I}^{I}\frac{z^{(I+K)}}{[(I+K)!]^{1/2}}\left[\frac{(2I)!}{(I-K)!}\right]^{1/2}|I-IK\rangle, \end{aligned} \tag{54}$$

where $n=I+K$ has been used from the second to the third line. By changing M to K, and $\hat{L}_+$ to $\hat{J}_+$, the analogous expansion of $e^{x\hat{J}_+}|I-I-I\rangle$ is obtained. These results make possible the following expression for the CS:

$$\begin{aligned} |xyz\rangle &=\exp[-\tfrac{1}{2}yy^*(1+xx^*)^2(1+zz^*)^2] \\ &\quad\times\sum_{IMK}\left\{\frac{[(2I)!]^2}{(I+M)!(I-M)!(I+K)!(I-K)!}\right\}^{1/2}\frac{x^{(I+M)}y^{I}z^{(I+K)}}{(I!)^{1/2}}|IMK\rangle. \end{aligned} \tag{55}$$

Each member in this set of CS is normalized to unity since

$$\begin{aligned} \langle xyz|xyz\rangle &=\exp[-yy^*(1+xx^*)^2(1+zz^*)^2] \\ &\quad\times\sum_{IMK}\frac{[(2I)!]^2}{(I+M)!(I-M)!(I+K)!(I-K)!}\frac{(xx^*)^{(I+M)}(yy^*)^{I}(zz^*)^{(I+K)}}{I!} \\ &=\exp[-yy^*(1+xx^*)^2(1+zz^*)^2]\sum_{I=0}^{\infty}\frac{(yy^*)^{I}}{I!} \\ &\quad\times\sum_{M=-I}^{I}\frac{(2I)!(xx^*)^{(I+M)}}{(I+M)!(I-M)!}\sum_{K=-I}^{I}\frac{(2I)!(zz^*)^{(I+K)}}{(I+K)!(I-K)!} \\ &=\exp[-yy^*(1+xx^*)^2(1+zz^*)^2]\sum_{I=0}^{\infty}\frac{[(yy^*)(1+xx^*)^2(1+zz^*)^2]^{I}}{I!}=1, \end{aligned} \tag{56}$$

where the power expansions, such as

$$(1+zz^*)^{2I}=\sum_{K=-I}^{I}\frac{(2I)!}{(I+K)!(I-K)!}(zz^*)^{I+K} \tag{57}$$

have been used. It is noteworthy that we now have a Poisson distribution in the variable $yy^*(1+xx^*)^2(1+zz^*)^2$. In addition, the overlap $\langle x'y'z'|xyz\rangle$ between two different members of the set of CS is

$$\langle x'y'z'|xyz\rangle = \exp[-\tfrac{1}{2}yy^*(1+xx^*)^2(1+zz^*)^2]\exp[-\tfrac{1}{2}y'y'^*(1+x'x'^*)^2(1+z'z'^*)^2] \times \exp[yy'^*(1+xx'^*)^2(1+zz'^*)^2], \tag{58}$$

which can be obtained in an analogous manner showing the general nonorthogonality of these CS.

Because of their construction, the $\{|xyz\rangle\}$ states satisfy the condition Eq. (1) for CS. In order to verify whether these CS satisfy the stronger or the weaker formulation of the second condition, we need to construct a proper measure $d\mu$. Using the measure of Ref. 16 as a guide we obtain

$$d\mu_{\pm}(x,y,z) = \frac{1}{\pi^3}\{4[(1+xx^*)(1+zz^*)]^4(yy^*)^2 - 8[(1+xx^*)(1+zz^*)]^2yy^* + 1\}dx\, dy\, dz, \tag{59}$$

where

$$dx = d\,\mathrm{Re}\, x\, d\,\mathrm{Im}\, x, \quad dy = d\,\mathrm{Re}\, y\, d\,\mathrm{Im}\, y, \quad dz = d\,\mathrm{Re}\, z\, d\,\mathrm{Im}\, z \tag{60}$$

so that

$$\int d\mu_{\pm}(x,y,z)|xyz\rangle\langle xyz| = \sum_{IMK} |IMK\rangle\langle IMK| = 1. \tag{61}$$

Then, it follows immediately [see Eq. (55)] that

$$|IMK\rangle = \int d\mu_{\pm}(x,y,z)\exp\left[-\frac{1}{2}yy^*(1+xx^*)^2(1+zz^*)^2\right]x^{*I+M}y^{*I}z^{*I+K} \times \left\{\frac{[(2I)!]^2}{I!(I+M)!(I-M)!(I+K)!(I-K)!}\right\}^{1/2}|xyz\rangle. \tag{62}$$

Note that both the CS from Ref. 16 and the present ones satisfy the weaker version of the second condition for CS, because the measure of neither is positive.

D. Coherent state operator averages

In order to develop the dynamics related to the rotational CS certain operator averages need to be determined. Evaluation of the necessary integrals involves using some properties of the binomial power expansion and the Poisson distribution. The final results are as follows:

$$\langle \hat{I}\rangle = yy^*(1+xx^*)^2(1+zz^*)^2 = \zeta, \tag{63}$$

$$\langle \hat{L}_x\rangle = \frac{z+z^*}{1+zz^*}\zeta, \quad \langle \hat{L}_y\rangle = \frac{i(z^*-z)}{1+zz^*}\zeta, \quad \langle \hat{L}_z\rangle = \frac{(zz^*-1)}{1+zz^*}\zeta, \tag{64}$$

$$\langle \hat{L}_i^2\rangle = \begin{cases} \dfrac{\zeta}{2} + \langle \hat{L}_i\rangle^2\left[1+\dfrac{1}{2\zeta}\right] & \text{if } \zeta>0, \\ 0 & \text{if } \zeta=0, \end{cases} \tag{65}$$

$$\langle \hat{L}_i\hat{L}_j + \hat{L}_j\hat{L}_i\rangle = \begin{cases} 2\langle \hat{L}_i\rangle\langle \hat{L}_j\rangle\left[1+\dfrac{1}{2\zeta}\right] & \text{if } \zeta>0, \\ 0 & \text{if } \zeta=0, \end{cases} \tag{66}$$

where $i \neq j$, and the notation $\langle \cdots \rangle = \langle xyz | \cdots | xyz \rangle$ is used. By changing $\hat{L}_i$ to $\hat{J}_i$, and z to x^* in the above expressions, the averages of the components of $\hat{J}$ are obtained. The integral $\langle xyz | \hat{I} | xyz \rangle$ turns out to be slightly different from that of Ref. 16. However, the functionality of the first-order averages with respect to that basic integral remains essentially the same and real differences appear in the second-order averages.

Uncertainty relationships for the CS can be derived by combining the well-known relationship[10]

$$(\Delta \hat{L}_i)^2 (\Delta \hat{L}_j)^2 \geq \tfrac{1}{4} |\langle \hat{L}_k \rangle|^2 \quad (i \neq j \neq k), \tag{67}$$

where

$$(\Delta \hat{L}_i)^2 = \langle \hat{L}_i^2 \rangle - \langle \hat{L}_i \rangle^2, \tag{68}$$

with Eqs. (64) and (65) to obtain

$$(\Delta L_i)^2 (\Delta L_j)^2 = \begin{cases} \dfrac{1}{4} \left[1 + \dfrac{\langle \hat{L}_i \rangle^2}{\zeta^2} \right] \left[1 + \dfrac{\langle \hat{L}_j \rangle^2}{\zeta^2} \right] \zeta^2 & \text{if } \zeta < 0 \\ 0 & \text{if } \zeta = 0. \end{cases} \tag{69}$$

Note that in the special case of $\langle \hat{L}_i \rangle = \langle \hat{L}_j \rangle = 0$, $\zeta > 0$ the uncertainty relationship is minimized for that pair of components, i.e., $(\Delta \hat{L}_i)^2 (\Delta \hat{L}_j)^2 = \frac{1}{4} |\langle \hat{L}_k \rangle|^2$, $(i \neq j \neq k)$.

E. Reparametrization

For the purpose of physical interpretation a new parametrization of the CS is introduced. The parameters related to the spin CS, i.e., x and z, are changed by adopting the stereographic projection onto a plane[18]

$$x = e^{-i\alpha} \cot \frac{\beta}{2}, \quad z = e^{+i\gamma} \cot \frac{\delta}{2}, \tag{70}$$

where $0 \leq \alpha, \gamma \leq 2\pi$, and $0 \leq \beta, \delta \leq \pi$. The remaining parameter y is expressed as

$$y = \zeta^{1/2} \sin^2 \frac{\beta}{2} \sin^2 \frac{\delta}{2} e^{i(\alpha - \gamma - \epsilon)}, \tag{71}$$

where $0 \leq \zeta \leq \infty$ and $0 \leq \epsilon \leq 2\pi$. In terms of these new parameters one finds

$$\begin{gathered} xx^* = \cot^2 \frac{\beta}{2}, \quad zz^* = \cot^2 \frac{\delta}{2}, \quad 1 + xx^* = \operatorname{cosec}^2 \frac{\beta}{2}, \\ 1 + zz^* = \operatorname{cosec}^2 \frac{\delta}{2}, \quad yy^* = \zeta \sin^4 \frac{\beta}{2} \sin^4 \frac{\delta}{2}, \quad yy^*(1 + xx^*)^2 (1 + zz^*)^2 = \zeta, \end{gathered} \tag{72}$$

and

$$
\begin{aligned}
|xyz\rangle &= |\alpha\beta\gamma\delta\epsilon\zeta\rangle \\
&= \exp\left(-\frac{\zeta}{2}\right)\sum_{IMK}\left\{\frac{[(2I)!]^2}{(I+K)!(I-K)!(I+M)!(I-M)!}\right\}^{1/2}\left[e^{-iM\alpha}\cos^{I+M}\left(\frac{\beta}{2}\right)\sin^{I-M}\left(\frac{\beta}{2}\right)\right] \\
&\quad\times\left[e^{+iK\gamma}\cos^{I+M}\left(\frac{\delta}{2}\right)\sin^{I-K}\left(\frac{\delta}{2}\right)e^{-iI\epsilon}\right]\frac{\zeta^{1/2}}{\sqrt{I!}}|IMK\rangle \\
&= \exp\left(-\frac{\zeta}{2}\right)\sum_{IMK} D^I_{MI}(\alpha,\beta,0)D^I_{KI}(-\gamma,\delta,\epsilon)\frac{\zeta^{1/2}}{\sqrt{I!}}|IMK\rangle,
\end{aligned}
\tag{73}
$$

where the definition of the rotational matrices D^I_{MK}[18,20] has been used.

We write

$$
\langle\alpha\beta\gamma\delta\epsilon\zeta|\hat{I}|\alpha\beta\gamma\delta\epsilon\zeta\rangle \equiv \langle\hat{I}\rangle = \zeta \tag{74}
$$

and similarly

$$
\begin{aligned}
\langle\hat{L}_x\rangle &= \zeta\cos\gamma\sin\delta, \quad \langle\hat{J}_x\rangle = \zeta\cos\alpha\sin\beta, \\
\langle\hat{L}_y\rangle &= \zeta\sin\gamma\sin\delta, \quad \langle\hat{J}_y\rangle = \zeta\sin\alpha\sin\beta, \\
\langle\hat{L}_z\rangle &= \zeta\cos\delta, \quad \langle\hat{J}_z\rangle = \zeta\cos\beta,
\end{aligned}
\tag{75}
$$

and

$$
\langle\hat{L}^2\rangle = \langle\hat{J}^2\rangle = \zeta(\zeta+2). \tag{76}
$$

From these expressions, it follows that the parameter ζ is the angular momentum modulus, the pairs of angles γ,δ, and α,β are the azimuthal and the polar angle of the $\langle\hat{\mathbf{L}}\rangle$ and $\langle\hat{\mathbf{J}}\rangle$ vectors in the body-fixed and the space-fixed frame, respectively. The angle ϵ is associated with the relative orientation of the body-fixed and the space-fixed frames. Finally, the probability $P_{IMK}(\zeta,\beta,\delta)$ to find the rotational state $|IMK\rangle$ in the CS is

$$
\begin{aligned}
P_{IMK}(\zeta,\beta,\delta) &= \left\{\frac{[(2I)!]^2}{(I+K)!(I-K)!(I+M)!(I-M)!}\right\}\left[\cos^{2(I+M)}\frac{\beta}{2}\sin^{2(I-M)}\frac{\beta}{2}\right] \\
&\quad\times\left[\cos^{2(I+K)}\frac{\delta}{2}\sin^{2(I-K)}\frac{\delta}{2}\right]\exp(-\zeta)\frac{\zeta^I}{I!} \\
&= \left\{\frac{[(2I)!]^2}{(I+K)!(I-K)!(I+M)!(I-M)!}\right\}p^{(I+M)}(1-p)^{(I-M)} \\
&\quad\times q^{(I+K)}(1-q)^{(I-M)}\exp(-\zeta)\frac{\zeta^I}{I!},
\end{aligned}
\tag{77}
$$

where $p=\cos^2\delta$ and $q=\cos^2\beta$. Note that $P_{IMK}(\zeta,\beta,\delta)$ combines binomial distributions in p and q, and a Poisson distribution in ζ. The result

$$
\sum_{I=0,1,\ldots,}^{\infty}\sum_{M=-I}^{I}\sum_{K=-I}^{I}P_{IMK}(\zeta,\beta,\delta)=1 \tag{78}
$$

is readily obtained. Alternatively, one can write

$$P_{IMK}(\zeta,\beta,\delta)=|D^{I}_{MI}(\alpha,\beta,0)|^2|D^{I}_{KI}(-\gamma,\delta,\epsilon)|^2\frac{\zeta^I}{I!}\exp(-\zeta)$$

$$=[d^{I}_{MI}(\beta)]^2[d^{I}_{KI}(\delta)]^2\frac{\zeta^I}{I!}\exp(-\zeta). \tag{79}$$

This probability exhibits more detail than is commonly needed and when used in the calculation of suitable *S*-matrix elements averaging procedures will wash out the excessive details.

F. Coherent state dynamics

Applying Ehrenfest's theorem to the operators $\hat{L}_i$ for $i=x,y,z$, i.e.,

$$\frac{d}{dt}\langle\hat{L}_i\rangle=-i\langle[\hat{H}_{\rm rot},\hat{L}_i]\rangle=\left\langle\sum_j \varepsilon_{ijk}\frac{1}{2A_k}(\hat{L}_j\hat{L}_k+\hat{L}_k\hat{L}_j)\right\rangle, \tag{80}$$

for $\zeta>0$ results in [see Eq. (66)]

$$\begin{aligned}\frac{d}{dt}\langle\hat{L}_x\rangle&=\langle\hat{L}_y\rangle\langle\hat{L}_z\rangle\left(1+\frac{1}{2\zeta}\right)\left(\frac{1}{A_z}-\frac{1}{A_y}\right),\\ \frac{d}{dt}\langle\hat{L}_y\rangle&=\langle\hat{L}_z\rangle\langle\hat{L}_x\rangle\left(1+\frac{1}{2\zeta}\right)\left(\frac{1}{A_z}-\frac{1}{A_x}\right),\\ \frac{d}{dt}\langle\hat{L}_z\rangle&=\langle\hat{L}_x\rangle\langle\hat{L}_y\rangle\left(1+\frac{1}{2\zeta}\right)\left(\frac{1}{A_x}-\frac{1}{A_y}\right),\end{aligned} \tag{81}$$

and for $\zeta=0$,

$$\frac{d}{dt}\langle\hat{L}_i\rangle=0,\quad i=x,y,z. \tag{82}$$

The quasiclassical rotation vector or angular velocity $\boldsymbol{\omega}$ is then defined with components

$$\omega_i=\begin{cases}\dfrac{1}{A_i}\dfrac{\zeta+\frac{1}{2}}{\zeta}\langle\hat{L}_i\rangle, & \zeta>0\\ 0, \quad \zeta=0.\end{cases} \tag{83}$$

The quasiclassical nature of this rotation vector is evident from

$$\begin{aligned}\dot{\omega}_x&=\frac{\omega_y\omega_z}{A_x}(A_y-A_z),\\ \dot{\omega}_y&=\frac{\omega_x\omega_z}{A_y}(A_x-A_z),\\ \dot{\omega}_z&=\frac{\omega_x\omega_y}{A_z}(A_x-A_y),\end{aligned} \tag{84}$$

which are the classical Euler equations for the motion of a rigid body without torque.[21] It follows that the rotation vector $\vec{\omega}$ behaves exactly as that of a classical rigid body with the same moment of inertia when the CS are propagated by the Schrödinger equation with the Hamiltonian of Eq. (28). This is analogous to the classical motion Eq. (18) of the harmonic oscillator CS Eq. (6).

However, the definition of the rotation vector $\boldsymbol{\omega}$ in Eq. (83) differs from the definition

$$\omega_i = \frac{1}{A_i} \langle \hat{L}_i \rangle \tag{85}$$

by Janssen,[16] which corresponds exactly to the classical definition[21]

$$\omega_i = \frac{1}{A_i} L_i . \tag{86}$$

This means that for the Janssen all-spin rotational CS the expectation values of the angular momenta $\hat{L}_i$ are quasiclassical variables, whereas they are not for our integer-only rotational CS. Inspection of Eq. (83) reveals that the variables

$$\Lambda_i = \begin{cases} \dfrac{\zeta + \frac{1}{2}}{\zeta} \langle \hat{L}_i \rangle, & \zeta > 0 \\ 0, & \zeta = 0, \end{cases} \tag{87}$$

are quasiclassical. This difference requires some explanation, which, as will be shown, is to be found in the Heisenberg uncertainty principle.

The proportionality factor $(\zeta + \frac{1}{2})/\zeta$ between the quasiclassical variables and the expectation values of $\hat{L}_i$ is a constant of the motion related to the total angular momentum. The limit of total angular momentum tending to zero is equivalent to $\zeta \to 0$ [Eq. (76)]. This means that for the Janssen all-spin CS

$$\omega^2 = \omega_x^2 + \omega_y^2 + \omega_z^2 \leqslant \frac{1}{A_x} (\langle \hat{L}_x \rangle^2 + \langle \hat{L}_y \rangle^2 + \langle \hat{L}_z \rangle^2) \leqslant \frac{\zeta^2}{A_x}, \tag{88}$$

where we have used the convention $A_z \geqslant A_y \geqslant A_x$. From this it follows that $\omega^2 \to 0$ when the angular momentum is decreased to zero and the CS are "spinning down." In contrast, the same calculation for the integer-only CS shows that

$$\frac{1}{A_x} \left(\zeta + \frac{1}{2} \right)^2 \geqslant \omega^2 \geqslant \frac{1}{A_z} \left(\zeta + \frac{1}{2} \right)^2 \tag{89}$$

and, thus, as the angular momentum decreases toward zero these CS keep "spinning" with an angular momentum of $\frac{1}{2}$ in units of $\hbar$, i.e., the zero angular momentum state cannot be reached by continuously decreasing the value of the angular momentum.

This result is related to the uncertainty principle. The orientation of the rigid body in terms of the Euler angles with decreasing angular momentum cannot be determined precisely, neither can the rotation vector being the time derivative of the orientation. As a result the integer-only CS, which are the appropriate ones to describe rotating bodies, yield a finite lower bound to the value of the angular velocity as the angular momentum decreases. Thus, since the angular velocity cannot decrease below a certain value, one cannot assume that the orientation can change by an arbitrarily small amount in a given time interval. It is noteworthy that apart from the lower bound Eq. (89) in the rotation vector length the motion is completely classical. The lower bound tends to zero for increasing moments of inertia indicating that this effect is not present for macroscopic bodies.

The remaining question is why the Janssen all-spin CS do not exhibit this finite lower bound on the angular velocity vector. The answer lies in the fact that half-integer spin systems have angular momenta that do not correspond to any position coordinate. As a result they always possess an uncertainty of $\frac{1}{2}\hbar$ in the orientation part of the total angular momentum even when its value tends to zero. For such CS the attempt to precisely define the angular momentum orientation does not introduce additional constraints allowing the angular velocity $\boldsymbol{\omega}$ to decrease to zero when the total angular momentum does.

V. APPLICATIONS

The rotational CS can with advantage be applied to spectroscopic analysis of molecular processes. For instance, the harmonic oscillator CS have been employed to successfully predict the distribution of reaction products over vibrational quantum states.[22] The role of the CS in this analysis was to allow a detailed *a posteriori* quantum level analysis of calculations on a reactive molecular system that only employed essentially classical trajectories. This procedure results in great savings of computer time and thus increases the range of studies to quite complex chemical reactions.

Because rotations and vibrations are intimately coupled in molecular systems, such analysis is most successful when both kinds of motion are treated on an equal footing. This is accomplished by combining the canonical CS and the integer-only rotational CS developed here. The theory can be applied without difficulties to general molecular fragments and it is straightforward to study a general asymmetric rotor. However, in order to avoid inessential technicalities we describe in this section how the theory applies to a diatomic molecule, which can be thought of as a linear rotor.

A. Linear rotor CS

By selecting the body-fixed z axis of a diatomic molecule $(A_x = A_y,\ A_z = 0)$ as that of the molecular bond, the component of the angular momentum vector $\hat{\mathbf{L}}$ in that direction vanishes at all times $(K=0)$. In that case, the rotational states $|IMK\rangle$ become the eigenstates of the linear rotor, i.e., the spherical harmonics $Y_{IM}(\theta,\varphi)$, see Eq. (39). Furthermore, inserting $\omega_z = 0$ into Eq. (84) makes the other two components of $\boldsymbol{\omega}$ in the body-fixed frame constant as well. This implies that the z parameter does not vary in time, its specific value being dependent on the orientation of the x and the y axes in the body-fixed frame. The CS of Eq. (55) then become

$$\langle \theta\varphi | xy \rangle_{\text{diat}} = \exp[-\tfrac{1}{2} yy^*(1+xx^*)^2] \sum_{IM} \left\{ \frac{(2I)!}{(I+M)!(I-M)!} \right\}^{1/2} \frac{x^{(I+M)} y^I}{\sqrt{I!}} Y_{IM}(\theta,\varphi), \quad (90)$$

where the superfluous terms in z^{I+K} have been omitted. Alternatively, these CS can be reparametrized so that

$$\begin{aligned} \langle \theta\varphi | xy \rangle_{\text{diat}} &= \langle \theta\varphi | \alpha\beta\zeta \rangle_{\text{diat}} \\ &= \exp\left(-\frac{\zeta}{2}\right) \sum_{IM} \left\{ \frac{(2I)!}{(I+M)!(I-M)!} \right\}^{1/2} \left[e^{-iM\alpha} \cos^{I+M}\frac{\beta}{2} \sin^{I-M}\frac{\beta}{2} \right] \frac{\zeta^{I/2}}{\sqrt{I!}} Y_{IM}(\theta,\varphi) \\ &= \exp\left(-\frac{\zeta}{2}\right) \sum_{IM} D^I_{MI}(\alpha,\beta,0) \frac{\zeta^{I/2}}{\sqrt{I!}} Y_{IM}(\theta,\varphi). \end{aligned} \quad (91)$$

When the CS are prepared with the vector $\langle \alpha\beta\zeta | \hat{\mathbf{J}} | \alpha\beta\zeta \rangle$ normal to the xy plane (i.e., with $\langle \alpha\beta\zeta | J_x | \alpha\beta\zeta \rangle = \langle \alpha\beta\zeta | J_y | \alpha\beta\zeta \rangle = 0$) it holds that the initial value of β is 0, or π. Consider the case $\beta = 0$. Then,

$$\langle \theta\varphi | 00\zeta \rangle_{\text{diat}} = \exp\left(-\frac{\zeta}{2}\right) \sum_I \frac{\zeta^{I/2}}{\sqrt{I!}} Y_{II}(\theta,\varphi), \quad (92)$$

where the angle α has been arbitrarily set to zero. The CS time evolution of $|0\beta(t)\zeta\rangle_{\text{diat}}$ from that initial condition, is

$$\begin{aligned}\langle\theta\varphi|0\beta(t)\zeta\rangle_{\text{diat}}&=\langle\theta\varphi|\exp(-i\hat{H}t)|00\zeta\rangle_{\text{diat}}\\&=\langle\theta\varphi|\exp\left(-\frac{\zeta}{2}\right)\sum_I\frac{\zeta^{I/2}}{\sqrt{I!}}\exp\left[-i\frac{I(I+1)}{2A}t\right]Y_{II}(\theta,\varphi),\\&=\exp\left(-\frac{\zeta}{2}\right)\sum_I\frac{\zeta^{I/2}}{\sqrt{I!}}Y_{II}(\theta,\varphi-\omega_I t),\end{aligned}\tag{93}$$

where $\hat{H}$ is the diatomic Hamiltonian, A the moment of inertia, and

$$\omega_I=\frac{(I+1)}{2A}.\tag{94}$$

In the last line of Eq. (93), the explicit form[23]

$$Y_{I\pm I}(\theta,\varphi)=(-1)^I\frac{1}{2^I I!}\left(\frac{(2I+1)!}{4\pi}\right)^{1/2}\sin^I\theta\exp(iI\varphi)\tag{95}$$

has been used. From Eqs. (93) and (95), it is easy to see that the rotational CS peak symmetrically around $\theta=\pi/2$ (i.e., the maximum lies in the xy plane) throughout the evolution. The shape of the rotational CS with respect to the angle φ is more difficult to describe analytically. For large ζ values, the superposition of the spherical harmonics given by Eq. (93) is sharply peaked around $I=I_{\max}\sim\zeta$. When this holds, the sum over I can be approximated by an integration. The evaluation of that integral by the stationary phase method[24] reveals that the CS peak around the value $\phi=\phi_{\max}$ where

$$\phi_{\max}(t)\sim\frac{(I_{\max}+\frac{1}{2})}{A}t\sim\frac{(\zeta+\frac{1}{2})}{A}t\sim\omega_z t.\tag{96}$$

This implies that when the total angular momentum is high the peak's center moves with the constant angular velocity ω_z along the equator of the θ,φ sphere. The general properties of the diatomic rotational CS can be easily derived form this example prepared with $\beta=0$. If the rotation $\hat{R}(\alpha,\beta,0)$ is applied to $|00\zeta\rangle_{\text{diat}}$ then the general diatomic rotational CS, Eq. (91), are recovered

$$\begin{aligned}\langle\theta\varphi|\alpha\beta\zeta\rangle_{\text{diat}}&=\langle\theta\varphi|\hat{R}(\alpha,\beta,0)|00\zeta\rangle_{\text{diat}}\\&=\exp\left(-\frac{\zeta}{2}\right)\sum_{IM}D^I_{MI}(\alpha,\beta,0)\frac{\zeta^{I/2}}{\sqrt{I!}}Y_{IM}(\theta,\varphi)\\&=\exp\left(-\frac{\zeta}{2}\right)\sum_I\frac{\zeta^{I/2}}{\sqrt{I!}}Y_{II}(\theta',\varphi'),\end{aligned}\tag{97}$$

where the properties of the spherical harmonics have been applied and where the angles θ' and φ' are given with respect to the rotated space-fixed frame. The rotation transforms the vector $\langle\alpha\beta\zeta|\hat{\mathbf{J}}|\alpha\beta\zeta\rangle$ from the z direction of the space-fixed frame to the (α,β) direction, in accordance with Eq. (75). The final expression in Eq. (97) is formally identical to the nonrotated CS in Eq. (92). The properties of $|\alpha\beta\zeta\rangle_{\text{diat}}$ are the same as those of $|00\zeta\rangle_{\text{diat}}$ but now referred to a plane normal to the vector $\langle\alpha\beta\zeta|\hat{\mathbf{J}}|\alpha\beta\zeta\rangle$.

No closed form expression is known for the rotational CS Eq. (55) or Eq. (90). However, in Sec. V B a wave function for a diatomic molecule is constructed that clarifies the CS and makes their structure more explicit.

B. The diatom END wave function

For purposes of interpretation in terms of CS we rewrite the END wave function in the center-of-mass (c.m.) frame. The actual END propagation is always done in the space-fixed laboratory frame, but the analysis of reagents (at the initial time) and products (at the final time) is better done in the c.m. frame of each fragment. The END wave function for each fragment in the narrow wave packet limit for the nuclei and with a Thouless determinant[5] for the electrons takes the form

$$\Psi_{\mathrm{END}}(\mathbf{X},\mathbf{x},t)=F_{\mathrm{nucl}}[\mathbf{X};\mathbf{R}(t),\mathbf{P}(t)]f_{\mathrm{el}}[\mathbf{x};\mathbf{z}(t),\mathbf{R}(t)]\exp[i\gamma_{\mathrm{END}}(t)], \tag{98}$$

when there no longer exist any overlaps or exchange terms between fragments. For the case of a diatomic fragment the nuclear part consists of two generalized frozen Gaussian wave packets,

$$F_{\mathrm{nucl}}(\mathbf{X};\mathbf{R},\mathbf{P})=\frac{1}{N_{\mathrm{nucl}}}\prod_{k=1}^{2}\exp\left\{-a_k[\mathbf{X_k}-\mathbf{R_k}(t)]^2+\frac{i}{\hbar}\mathbf{P_k}(t)\cdot[\mathbf{X_k}-\mathbf{R_k}(t)]\right\}. \tag{99}$$

The electronic part $f_{\mathrm{el}}[\mathbf{z}(t),\mathbf{R}(t)]$ is a Thouless single determinant wave function. The total phase $\gamma_{\mathrm{END}}(t)$ is the quantum mechanical action

$$\gamma_{\mathrm{END}}(t)=\int_0^t ds\, L[\mathbf{R}(s),\mathbf{P}(s),\mathbf{z}(s)], \tag{100}$$

in terms of the END quantum Lagrangian $L(\mathbf{R},\mathbf{P},\mathbf{z})$.

The Gaussian wave packets have finite width, $1/a_k$, explicitly defined as those of canonical CS [compare Eqs. (22) and (23)]. The SC limit of zero width then yields the simplest END approximation.

The transformation to the c.m. coordinates is using Jacobi coordinates, i.e.,

$$\mathbf{X_0}=\frac{1}{M}(m_1\mathbf{X_1}+m_2\mathbf{X_2}),\quad \mathbf{x}=\mathbf{X_2}-\mathbf{X_1}, \tag{101}$$

with a similar transformation of the average nuclear positions

$$\begin{aligned}\mathbf{R_0}(t)&=\frac{1}{M}[m_1\mathbf{R_1}(t)+m_2\mathbf{R_2}(t)],\\ \mathbf{r}(t)&=\mathbf{R_2}(t)-\mathbf{R_1}(t),\end{aligned} \tag{102}$$

and with $M=m_1+m_2$ the total mass. This transformation results in the product of two independent Gaussian wave packets:

$$F_{\mathrm{nucl}}(\mathbf{X};\mathbf{R},\mathbf{P})=F_0(\mathbf{X_0};\mathbf{R_0},\mathbf{P_0})F_{\mathrm{int}}(\mathbf{x};\mathbf{r},\mathbf{p}) \tag{103}$$

only if the condition: $\omega_1=\omega_2=\omega$ is imposed. Then it follows that

$$F_0(\mathbf{X_0};\mathbf{R_0},\mathbf{P_0})=\frac{1}{N_0}\exp\{-a_0[\mathbf{X_0}-\mathbf{R_0}(t)]^2+i\mathbf{P_0}(t)\cdot[\mathbf{X_0}-\mathbf{R_0}(t)]\}, \tag{104}$$

and

$$F_{\text{int}}(\mathbf{x};\mathbf{r},\mathbf{p})=\frac{1}{N_{\text{int}}}\exp\{-a_{\mu}[\mathbf{x}-\mathbf{r}(t)]^2+i\mathbf{p}(t)\cdot[\mathbf{x}-\mathbf{r}(t)]\}. \tag{105}$$

Here, the new momentum parameters are

$$\mathbf{P_0}(t)=\mathbf{P_1}(t)+\mathbf{P_2}(t) \tag{106}$$

and

$$\mathbf{p}(t)=\mu(\dot{\mathbf{R}}_2-\dot{\mathbf{R}}_1)=\mu\dot{\mathbf{r}}, \tag{107}$$

respectively, where μ is the reduced mass. The transformed exponents turn out to be

$$a_0=\frac{M\omega}{2} \tag{108}$$

and

$$a_{\mu}=\frac{\mu\omega}{2}, \tag{109}$$

in units of $1/\hbar$. The electronic part of the wave function, being a function of relative nuclear positions only, is not be affected by this transformation. A similar partition of the total phase means that

$$\gamma_{\text{END}}(t)=\gamma_0(t)+\gamma_{\text{int}}(t), \tag{110}$$

where $\gamma_0(t)$ contains only the nuclear c.m. variables and $\gamma_{\text{int}}(t)$ the internal nuclear variables along with the electronic parameters.

The c.m. part is a Gaussian with a trivial time evolution. This part together with its phase $\gamma_0(t)$ can be totally separated from the rest leaving the internal END wave function

$$\Psi_{\text{int}}^{\text{END}}(t)=F_{\text{int}}[\mathbf{r}(t),\mathbf{p}(t)]f_{\text{el}}[\mathbf{z}(t),\mathbf{r}(t)]\exp[i\gamma_{\text{int}}(t)]. \tag{111}$$

The internal wave function is now split into a vibrational and a rotational part. Because of the coupling of rotations and vibrations in molecules this separation must be approximate. Define $\mathbf{x}=x\mathbf{n}$ and $\mathbf{r}=r\mathbf{m}$, where $\mathbf{n}$ and $\mathbf{m}$ are unit vectors. For a vibrating molecule rotating with rotation vector $\boldsymbol{\omega}$ we write the momentum

$$\mathbf{p}=\mu\dot{\mathbf{r}}=p_v\mathbf{m}+\mu b\boldsymbol{\omega}\times\mathbf{m}, \tag{112}$$

with p_v the vibrational part of the momentum parallel to the axis of the molecule and b the equilibrium bond length. The END evolution of the molecule is described through the parameters $\mathbf{r}(t)$, $\mathbf{p}(t)$, and $\mathbf{z}(t)$ only. When the coupling of rotation and vibration is neglected the rotation vector is constant yielding the angular momentum

$$\mathbf{L}=A\boldsymbol{\omega}=\mu b^2\boldsymbol{\omega}. \tag{113}$$

The exponent of $F_{\text{int}}(\mathbf{x};\mathbf{r},\mathbf{p})$ in Eq. (105) becomes

$$\begin{aligned}-a_{\mu}[\mathbf{x}-\mathbf{r}]^2+i\mathbf{p}\cdot[\mathbf{x}-\mathbf{r}]=&-a_{\mu}(x-r)^2-2a_{\mu}r(x-r)\mathbf{n}\cdot(\mathbf{n}-\mathbf{m})\\&-a_{\mu}r^2(\mathbf{n}-\mathbf{m})^2+i(x-r)p_v\mathbf{m}\cdot\mathbf{n}+i\mu b(x-r)(\boldsymbol{\omega}\times\mathbf{m})\cdot\mathbf{n}\\&+irp_v\mathbf{m}(\mathbf{n}-\mathbf{m})+i\mu br(\boldsymbol{\omega}\times\mathbf{m})\cdot(\mathbf{n}-\mathbf{m}).\end{aligned} \tag{114}$$

Introducing the angles η between $\mathbf{n}$ and $\mathbf{m}$ and ξ between $\boldsymbol{\omega}\times\mathbf{m}$ and $\mathbf{n}$ yields

$$-a_\mu(x-r)^2-2a_\mu r(x-r)(1-\cos\eta)-2a_\mu r^2(1-\cos\eta),$$
$$i(x-r)p_v\cos\eta+i\mu b\omega(x-r)\cos\xi-irp_v(1-\cos\eta)+i\mu b\omega r\cos\xi. \tag{115}$$

Since **x** and **r** are close the angle η is small and so is $\pi/2-\xi$. Using these facts in an order analysis considering $x-r$ as small, omitting terms of third order or higher in the real part, and of second order or higher in the imaginary part, and leaving out the coupling term result in

$$-a_\mu(x-r)^2-2a_\mu r^2(1-\cos\eta),$$
$$+i(x-r)p_v+i\mu\omega br\cos\xi. \tag{116}$$

Replacing r in the angular part by the equilibrium bond distance b, using Eq. (109) for a_μ, and expressing η and ξ in terms of the polar coordinates θ,φ of **x** in the laboratory frame using obvious right spherical triangles produces a vibrational and a rotational factor

$$F_{\text{int}}(x,\theta,\varphi;r,0,0)\approx F_{\text{vib}}(x;r)F_{\text{rot}}(\theta,\varphi;0,0), \tag{117}$$

with

$$F_{\text{vib}}(x;r)=\frac{1}{N_{\text{vib}}}\exp\left[-\frac{\mu\omega}{2}(x-r)^2+ip_v(x-r)\right] \tag{118}$$

and

$$F_{\text{rot}}(\theta,\varphi)=\frac{1}{N_{\text{rot}}}\exp[-\mu\omega b^2(1-\sin\theta\cos\varphi)+i\mu\omega b^2\sin\theta\sin\varphi]$$
$$=\frac{1}{N_{\text{rot}}}\exp[-\mu\omega b^2(1-\sin\theta e^{i\varphi})]. \tag{119}$$

The general case is obtained by rotating $\boldsymbol{\omega}$ to the orientation α,β in the laboratory frame.

Identification of the CS parameter ζ can be accomplished by evaluation of the expectation values of $\hat{\mathbf{J}}$ and its square with respect to the END wave function Eq. (99),

$$F_{\text{nucl}}=F_0F_{\text{int}}=F_0F_{\text{vib}}F_{\text{rot}}. \tag{120}$$

One finds easily that

$$\langle\hat{J}_x\rangle=\mu\omega b^2\sin\beta\cos\alpha,$$
$$\langle\hat{J}_y\rangle=\mu\omega b^2\sin\beta\sin\alpha, \tag{121}$$
$$\langle\hat{J}_z\rangle=\mu\omega b^2\cos\beta,$$

and that

$$\langle\hat{J}_x^2\rangle=\langle\hat{J}_x\rangle^2+A_{xx}\omega,\quad \langle\hat{J}_y^2\rangle=\langle\hat{J}_y\rangle^2+A_{yy}\omega,\quad \langle\hat{J}_z^2\rangle=\langle\hat{J}_z\rangle^2+A_{zz}\omega. \tag{122}$$

Using the result

$$\text{Tr}(A)=2\mu b^2, \tag{123}$$

it follows that

$$\langle \hat{\mathbf{J}}^2 \rangle = \langle \hat{\mathbf{J}} \rangle^2 + 2\mu b^2 \omega = \mu \omega b^2 (\mu \omega b^2 + 2) = \zeta(\zeta + 2), \tag{124}$$

such that the CS parameter ζ may be identified with the total nuclear angular momentum $\mu \omega b^2$ of the diatomic molecule in units of $\hbar$.

The expansion of the rotational factor of the END wave function Eq. (119)

$$F_{\text{rot}}(\theta, \varphi; 0,0) = \frac{1}{N_{\text{rot}}} \exp(-\zeta) \sum_I \frac{(\zeta \sin \theta e^{i\varphi})^I}{I!} \tag{125}$$

should be compared to the CS Eq. (93) using Eq. (95)

$$\langle \theta\varphi | 00\zeta \rangle_{\text{diat}} = \exp(-\zeta/2) \sum_I \left(\frac{(2I+1)!!}{4\pi(2I)!!} \right)^{1/2} \frac{(-\zeta^{1/2} \sin \theta e^{i\varphi})^I}{\sqrt{I!}}. \tag{126}$$

The two series have the same structure for the arguments θ and φ, but consecutive terms in the CS series decrease less rapidly as functions of I.

Even though the two functions are not identical the rotational CS are useful for final state analysis. That the vibrational CS match the vibrational part of the END wave function is, of course, not surprising as the END wave function is built from Gaussians with the appropriate widths. The CS, because of their nature, retain shape during evolution. Thus, the choice of fixed a Gaussian shape for the END wave function ensures that also the shape of the rotational factor persists during evolution. Our analysis has shown that the average orientation and the width match those of the rotational CS. Furthermore, the END wave function by the TDVP construction is limited to the dynamics of average values, which are the internal vibrational coordinates and orientation of the body fixed frame. It then makes sense to replace the factors of the END wave function by their CS counterparts with the matching parameters, including the time evolution generated by the END wave function. This procedure is the recommended one to use for *a posteriori* quantum state analysis even when the END evolution has been done for the case of zero width Gaussians, i.e., classical nuclei. Thus, since it is now established that the END nuclear wave function for low excitations can to a good approximation be represented as a product of vibrational and rotational CS, the expressions in Eqs. (6) and (79) can be used to compute probabilities for vibrational and rotational eigenstates, and, thus, provide *a posteriori* quantum vibrational and rotational resolution of cross sections obtained from classical trajectory calculations.

VI. CONCLUSION

The canonical CS have countless applications. First derived by Schrödinger[2] and later analyzed by many[1] these CS display remarkable properties. One of the most useful properties in the context of molecular processes is the quasiclassical evolution. Janssen[16] constructed all-spin rotational CS that evolve quasiclassically. Involving both integer and half-integer spins these CS have not seen much application to physical systems. Our work establishes that integer-only rotational CS can be constructed that exhibit quasiclassical dynamics. A notable property of the integer-only rotational CS is the nonzero minimum angular velocity attained as the angular momentum decreases to zero. The Janssen construction does not follow Perelomov's prescription of constructing group-related CS. The metric of these CS for the resolution of the identity is nondefinite. The facts that the construction of Atkins and Dobson[17] employs Perelomov's prescription for the case of the symmetric rotor CS, that it coincides with the Janssen construction restricted to symmetric rotors, and that these have a positive definite measure, make it plausible that there exists CS from a suitable Perelomov construction with a positive measure for both the all-spin CS and the integer-only CS.

It is known that the canonical CS remain quasiclassical in the presence of a time-dependent linear external field. We have not investigated whether this holds true also for the rotational CS when subjected to some external torque.

In this paper we have concentrated on extracting probabilities for rotational quantum levels of molecules from nuclear trajectory calculations of molecular processes. This application is valid both for dynamics involving predetermined potential energy surfaces as well as for direct nonadiabatic approaches such as END.

(Received 17 November 1997; accepted for publication 30 September 1998)

We present a mathematical framework of gauge theories that is based upon a skew-adjoint Lie algebra and a generalized Dirac operator, both acting on a Hilbert space. © *1999 American Institute of Physics.* [S0022-2488(99)02201-X]

I. INTRODUCTION

In this article the author's previous article,[1] in which we proposed a mathematical calculus towards gauge field theories based upon graded differential Lie algebras is made more precise. Given a skew-adjoint Lie algebra $\mathfrak{g}$, a representation π of $\mathfrak{g}$ on a Hilbert space h_0 as well as an (unbounded) operator D and a grading operator Γ on h_0, we developed a scheme providing connection and curvature forms to build physical actions. The general part of our exposition was on a very formal level; we worked with unbounded operators (even the splitting of a bounded in two unbounded operators) without specification of the domain.

In the present article, we correct this shortcoming. The idea is to introduce a second Hilbert space h_1, which is the domain of the unbounded operator D. Now, D is a linear continuous operator from h_1 to h_0, and the just mentioned splitting involves continuous operators only. Moreover, the awkward connection theory in the previous paper is resolved in a strict algebraic description in terms of normalizers of graded Lie algebras. Finally, our construction of the universal graded differential Lie algebra is considerably simplified (thanks to a hint by Schmüdgen).

The scope of our framework is the construction of Yang–Mills–Higgs models in noncommutative geometry.[2] The standard procedure[3,4] starts from spectral triples with real structure[5,6] and is limited to the standard model.[7] The hope is[8] that the replacement of the unital associative $*$-algebra in the prior Connes–Lott prescription[9] by a skew-adjoint Lie algebra admits representations general enough to construct grand unified theories. For a realization of this strategy see Refs. 10–12. We discuss the relation to the axiomatic formulation[6] of noncommutative geometry in the last section.

II. THE ALGEBRAIC SETTING

Let $\mathfrak{g}$ be a skew-adjoint Lie algebra, $a^*=-a$ for all $a\in\mathfrak{g}$. Let h_0,h_1 be Hilbert spaces, where h_1 is dense in h_0. Denoting by $\mathcal{B}(h_0)$ and $\mathcal{B}(h_1)$ the algebras of linear continuous operators on h_0 and h_1, respectively, we define $\mathcal{B}:=\mathcal{B}(h_0)\cap\mathcal{B}(h_1)$. The vector space of linear continuous mappings from h_1 to h_0 is denoted by $\mathcal{L}$. Let π be a representation of $\mathfrak{g}$ in $\mathcal{B}$. Let $D\in\mathcal{L}$ be a generalized Dirac operator with respect to $\pi(\mathfrak{g})$. This means that D has an extension to a self-adjoint operator on h_0, that $[D,\pi(a)]\in\mathcal{L}$ even belongs to $\mathcal{B}$ for any $a\in\mathfrak{g}$ and that the resolvent of D is compact. Finally, let $\Gamma\in\mathcal{B}$ be a grading operator, i.e., Γ^2 is the identity on both h_0 and h_1, $[\Gamma,\pi(a)]=0$ on both h_0,h_1 for any $a\in\mathfrak{g}$ and $D\Gamma+\Gamma D=0$ on h_1 extends to 0 on h_0. This setting was called *L-cycle* in Ref. 1, referring to a *Lie*-algebraic version of a *K-cycle*, the former name[2,9] for spectral triple.[5,6]

The standard example of this setting $(\mathfrak{g},h_0,h_1,D,\pi,\Gamma)$ is

[a)]Present address: Centre de Physique Théorique, CNRS-Luminy, Case 907, F-13288 Marseille, France. Electronic mail: raimar@cpt.univ-mrs.fr or raimar.wulkenhaar@itp.uni-leipzig.de

$$\mathfrak{g} = C^\infty(X) \otimes \mathfrak{a}, \quad h_0 = L^2(\mathcal{S}) \otimes \mathbb{C}^F,$$
$$h_1 = W_1^2(\mathcal{S}) \otimes \mathbb{C}^F, \quad D = \mathrm{i}\partial\!\!\!/ \otimes 1_F + \boldsymbol{\gamma} \otimes \mathcal{M},$$
$$\pi = \mathrm{id} \otimes \hat{\pi}, \quad \Gamma = \boldsymbol{\gamma} \otimes \hat{\Gamma}.$$

Here, $C^\infty(X)$ denotes the algebra of real-valued smooth functions on a compact Riemannian spin manifold X, $\mathfrak{a}$ is a skew-adjoint matrix Lie algebra, $L^2(\mathcal{S})$ denotes the Hilbert space of square integrable sections of the spinor bundle $\mathcal{S}$ over X, $W_1^2(\mathcal{S})$ denotes the Sobolev space of square integrable sections of $\mathcal{S}$ with a generalized first derivative, $\mathrm{i}\partial\!\!\!/$ is the Dirac operator of the spin connection, $\boldsymbol{\gamma}$ is the grading operator on $L^2(\mathcal{S})$ anti-commuting with $\mathrm{i}\partial\!\!\!/$, $\hat{\pi}$ is a representation of $\mathfrak{a}$ in $M_F\mathbb{C}$ and $\hat{\Gamma}$ a grading operator on $M_F\mathbb{C}$ commuting with $\hat{\pi}(\mathfrak{a})$ and anti-commuting with $\mathcal{M} \in M_F\mathbb{C}$.

III. THE UNIVERSAL GRADED DIFFERENTIAL LIE ALGEBRA Ω

For $\mathfrak{g}$ being a real Lie algebra we consider the real vector space $\mathfrak{g}^2 = \mathfrak{g} \times \mathfrak{g}$, with the linear operations given by $\lambda_1(a_1,a_2) + \lambda_2(a_3,a_4) = (\lambda_1 a_1 + \lambda_2 a_3, \lambda_1 a_2 + \lambda_2 a_4)$, for $a_i \in \mathfrak{g}$ and $\lambda_i \in \mathbb{R}$. Let T be the tensor algebra of $\mathfrak{g}^2$, equipped with the $\mathbb{N}$–grading structure $\deg((a,0)) = 0$ and $\deg((0,a)) = 1$, and linear extension to higher degrees, $\deg(t_1 \otimes t_2) = \deg(t_1) + \deg(t_2)$, for $t_i \in T$. Defining $T^n = \{t \in T : \deg(t) = n\}$, we have $T = \oplus_{n\in\mathbb{N}} T^n$ and $T^k \otimes T^l \subset T^{k+l}$. We regard T as a graded Lie algebra with graded commutator given by $[t^k, t^l] := t^k \otimes t^l - (-1)^{kl} t^l \otimes t^k$, for $t^n \in T^n$.

Let $\tilde{\Omega} = \oplus_{n\in\mathbb{N}} \tilde{\Omega}^n = \Sigma\, [\mathfrak{g}^2,[\cdots[\mathfrak{g}^2,\mathfrak{g}^2]\cdots]]$ be the $\mathbb{N}$-graded Lie subalgebra of T (due to the graded Jacobi identity) given by the set of sums of repeated commutators of elements of $\mathfrak{g}^2$. Let I' be the vector subspace of $\tilde{\Omega}$ of sums of elements of the following type:

$$[(a,0),(b,0)] - ([a,b],0), \quad [(a,0),(0,b)] + [(0,a),(b,0)] - (0,[a,b]), \tag{2}$$

for $a,b \in \mathfrak{g}$. The first part extends the Lie algebra structure of $\mathfrak{g}$ to the first component of $\mathfrak{g}^2$ and the second part plays the rôle of a Leibniz rule, see below. Obviously, $I := I' + [\mathfrak{g}^2, I'] + [\mathfrak{g}^2,[\mathfrak{g}^2,I']] + \cdots$ is an $\mathbb{N}$-graded ideal of $\tilde{\Omega}$, so that $\Omega := \oplus_{n\in\mathbb{N}} \Omega^n$, $\Omega^n := \tilde{\Omega}^n/(I \cap \Omega^n)$ is an $\mathbb{N}$-graded Lie algebra.

On T we define recursively a graded differential as an $\mathbb{R}$-linear map $d: T^n \to T^{n+1}$ by

$$d(a,0) = (0,a), \quad d(0,a) = 0, \tag{3}$$

$$d((a,0)\otimes t) = d(a,0) \otimes t + (a,0) \otimes dt, \quad d((0,a)\otimes t) = -(0,a) \otimes dt,$$

for $a \in \mathfrak{g}$ and $t \in T$. One easily verifies $d^2 = 0$ on T and the graded Leibniz rule $d(t^k \otimes t^l) = dt^k \otimes t^l + (-1)^k t^k \otimes dt^l$, for $t^n \in T^n$. Thus, d defined by (3) is a graded differential of the tensor algebra T and of the graded Lie algebra T as well, $d[t^k,t^l] = [dt^k,t^l] + (-1)^k [t^k, dt^l]$.

Due to $d\mathfrak{g}^2 \subset \mathfrak{g}^2$ we conclude that d is also a graded differential of the graded Lie subalgebra $\tilde{\Omega} \subset T$. Moreover, one easily checks $dI' \subset I'$, giving $dI \subset I$. Therefore, $(\Omega, [,], d)$ is a graded differential Lie algebra, with the graded differential d given by $d(\varpi + I) := d\varpi + I$, for $\varpi \in \tilde{\Omega}$.

We extend the involution $*: a \mapsto -a$ on $\mathfrak{g}$ to an involution of T by $(a,0)^* = -(a,0)$, $(0,a)^* = -(0,a)$ and $(t_1 \otimes t_2)^* = t_2^* \otimes t_1^*$, giving $[t^k,t^l]^* = -(-1)^{kl}[t^{k*}, t^{l*}]$. Clearly, this involution extends to Ω. The identity $a = -a^*$ yields $\omega^{k*} = -(-1)^{k(k-1)/2}\omega^k$, for any $\omega^k \in \Omega^k$.

The graded differential Lie algebra Ω is universal in the following sense.

Proposition 1: Let $\Lambda = \oplus_{n\in\mathbb{N}} \Lambda^n$ *be an* $\mathbb{N}$*-graded Lie algebra with graded differential* d *such that*

(i) $\Lambda^0 = \pi(\mathfrak{g})$ *for a surjective homomorphism* π *of Lie algebras,*

(ii) Λ *is generated by* $\pi(\mathfrak{g})$ *and* $\mathrm{d}\pi(\mathfrak{g})$ *as the set of repeated commutators. Then there exists a differential ideal* $I_\Lambda \subset \Omega$ *fulfilling* $\Lambda \cong \Omega/I_\Lambda$.

Proof: Define a linear surjective mapping $p: \Omega \to \Lambda$ by

$$p((a,0))=\pi(a), \quad p(d\omega)=\mathrm{d}(p(\omega)), \quad p([\omega,\tilde{\omega}]):=[p(\omega),p(\tilde{\omega})],$$

for $a\in\mathfrak{g}$ and $\omega,\tilde{\omega}\in\Omega$. Because of $d\ker p\subset\ker p$, $I_\Lambda=\ker p$ is the desired differential ideal of Ω. □

IV. THE GRADED DIFFERENTIAL LIE ALGEBRA Ω_D

Using the grading operator Γ we define on $\mathcal{L}$ and $\mathcal{B}$ a $\mathbb{Z}_2$-grading structure, the even subspaces carry the subscript 0 and the odd subspaces the subscript 1. Then, the graded commutator $[\,.\,,\,.\,]_g:\mathcal{L}_i\times\mathcal{B}_j\to\mathcal{L}_{(i+j)\bmod 2}$ is defined by

$$[A_i,B_j]_g:=A_i\circ B_j-(-1)^{ij}B_j\circ A_i\equiv-(-1)^{ij}[B_j,A_i]_g, \tag{4}$$

where $B_j\in\mathcal{B}_j$ and $A_i\in\mathcal{L}_i$. If $A_i\in\mathcal{B}_i$ then $[\,.\,,\,.\,]_g$ maps h_1 to h_1 and h_0 to h_0.

Using the elements π and D of our setting we define a linear mapping $\pi:\Omega\to\mathcal{B}$ by

$$\begin{gathered}\pi((a,0)):=\pi(a), \quad \pi((0,a)):=[-\mathrm{i}D,\pi(a)]_g,\\ \pi([\omega^k,\omega^l]):=[\pi(\omega^k),\pi(\omega^l)]_g,\end{gathered} \tag{5}$$

for $a\in\mathfrak{g}$ and $\omega^n\in\Omega^n$. The self-adjointness of D on h_0 implies that π is involutive, $\pi(\omega^*)=(\pi(\omega))^*$.

Note that $\pi(\Omega)$ is not a graded *differential* Lie algebra. The standard procedure to construct such an object is to define $\mathcal{J}=\ker\pi+d\ker\pi\subset\Omega$. It is easy to show that $\mathcal{J}$ is a graded differential ideal of Ω, providing the graded differential Lie algebra,

$$\Omega_D=\bigoplus_{n\in\mathbb{N}}\Omega_D^n, \quad \Omega_D^n:=\Omega^n/\mathcal{J}^n\cong\pi(\Omega^n)/\pi(\mathcal{J}^n), \tag{6}$$

where $\mathcal{J}^n=\mathcal{J}\cap\Omega^n$. One has $\Omega_D^0\cong\pi(\Omega^0)\equiv\pi(\mathfrak{g})$ and $\Omega_D^1\cong\pi(\Omega^1)$. By construction, the differential d on Ω_D is given by $d(\pi(\omega^n)+\pi(\mathcal{J}^n)):=\pi(d\omega^n)+\pi(\mathcal{J}^{n+1})$, for $\omega^n\in\Omega^n$.

It is very useful to consider an extension of the second formula of (5), $\pi(d(a,0)):=[-\mathrm{i}D,\pi((a,0))]_g$, *to higher degrees:*

$$\pi(d\omega^n)=[-\mathrm{i}D,\pi(\omega^n)]_g+\sigma(\omega^n), \quad \omega^n\in\Omega^n. \tag{7}$$

It turns out[1] that $\sigma:\Omega\to\mathcal{L}$ is a linear mapping recursively given by

$$\begin{gathered}\sigma((a,0))=0, \quad \sigma((0,a))=[D,[D,\pi(a)]_g]_g,\\ \sigma([\omega^k,\omega^l])=[\sigma(\omega^k),\pi(\omega^l)]_g+(-1)^k[\pi(\omega^k),\sigma(\omega^l)]_g.\end{gathered} \tag{8}$$

Equation (7) has an important consequence: Putting $\omega^n\in\ker\pi$ we get

$$\pi(\mathcal{J}^{n+1})=\{\sigma(\omega^n):\omega^n\in\Omega^n\cap\ker\pi\}. \tag{9}$$

The point is that $\sigma(\Omega)$ can be computed from the last equation (8) once $\sigma(\Omega^1)$ is known. Then one can compute $\pi(\mathcal{J})$ and obtains with (7) an explicit formula for the differential on Ω_D.

V. CONNECTIONS

We define the graded normalizer $N_{\mathcal{L}}(\pi(\Omega))$ of $\pi(\Omega)$ in $\mathcal{L}$, its vector subspace $\mathcal{H}$ compatible with $\pi(\mathcal{J})$ and the graded centralizer $\mathcal{C}$ of $\pi(\Omega)$ in $\mathcal{L}$ by

$$
\begin{aligned}
N^k_{\mathcal{L}}(\pi(\Omega)) = \{ \eta^k \in \mathcal{L}_{k \bmod 2} :\ \eta^k \ \text{has} \left\{ {\text{self-adjoint} \atop \text{skew-adjoint}} \right\} \text{extension for } \tfrac{k(k-1)}{2} \left\{ {\text{odd} \atop \text{even}} \right\}, \\
[\eta^k, \pi(\omega^n)]_g \in \pi(\Omega^{k+n}) \forall \omega^n \in \Omega^n, \forall n \in \mathbb{N} \}, \\
\mathcal{H}^k = \{ \eta^k \in N^k_{\mathcal{L}}(\pi(\Omega)) : [\eta^k, \pi(j^n)]_g \in \pi(\mathcal{J}^{k+n}) \forall j^n \in \mathcal{J}^n \}, \\
\mathcal{C}^k = \{ c^k \in N^k_{\mathcal{L}}(\pi(\Omega)) : [c^k, \pi(\omega)]_g = 0 \forall \omega \in \Omega \}.
\end{aligned} \tag{10}
$$

Here, the linear continuous operator $[\eta^k, \pi(\omega^n)]_g : h_1 \to h_0$ must have its image even in the subspace $h_1 \subset h_0$ and must have an extension to a linear continuous operator on h_0. For each degree n we have the following system of inclusions:

$$
\begin{array}{ccccccc}
\mathcal{L} & \supset & \mathcal{H}^n & \supset & \pi(\Omega^n) & \supset & \pi(\mathcal{J}^n) \\
 & & \cup & & \cap & & \\
 & & \mathcal{C}^n & & \mathcal{B} & \subset & \mathcal{L}
\end{array} . \tag{11}
$$

The graded Jacobi identity and Leibniz rule define the structure of a graded differential Lie algebra on $\hat{\mathcal{H}} = \oplus_{n \in \mathbb{N}} \hat{\mathcal{H}}^n$, with $\hat{\mathcal{H}}^n = \mathcal{H}^n / (\mathcal{C}^n + \pi(\mathcal{J}^n))$:

$$
\begin{aligned}
& [[\eta^k + \mathcal{C}^k + \pi(\mathcal{J}^k),\ \eta^l + \mathcal{C}^l + \pi(\mathcal{J}^l)]_g,\ \pi(\omega^n) + \pi(\mathcal{J}^n)]_g \\
& \quad := [\eta^k, [\eta^l, \pi(\omega^n)]_g]_g - (-1)^{kl} [\eta^l, [\eta^k, \pi(\omega^n)]_g]_g + \pi(\mathcal{J}^{k+l+n}), \\
& [d(\eta^k + \mathcal{C}^k + \pi(\mathcal{J}^k)),\ \pi(\omega^n) + \pi(\mathcal{J}^n)]_g \\
& \quad := \pi \circ d \circ \pi^{-1}([\eta^k, \pi(\omega^n)]_g) - (-1)^k [\eta^k, \pi(d\omega^n)]_g + \pi(\mathcal{J}^{k+n+1}),
\end{aligned} \tag{12}
$$

for $\eta^n \in \mathcal{H}^n$ and $\omega^n \in \Omega^n$.

The lesson is that $\pi(\Omega)$ and its ideal $\pi(\mathcal{J})$ give rise not only to the graded differential Lie algebra Ω_D but also to $\hat{\mathcal{H}}$, both being natural. It turns out that it is the differential Lie algebra $\hat{\mathcal{H}}$ which occurs in our connection theory

Definition 2: Within our setting, a connection ∇ *and its associated covariant derivative* $\mathcal{D}$ *are defined by*
(i) $\mathcal{D} \in \mathcal{L}_1$ *with a self-adjoint extension,*
(ii) $\nabla : \Omega^n_D \to \Omega^{n+1}_D$ *is linear,*
(iii) $\nabla(\pi(\omega^n) + \pi(\mathcal{J}^n)) = [-\mathrm{i}\mathcal{D}, \pi(\omega^n)]_g + \sigma(\omega^n) + \pi(\mathcal{J}^{n+1}),\quad \omega^n \in \Omega^n.$
The operator $\nabla^2 : \Omega^n_D \to \Omega^{n+2}_D$ *is called the curvature of the connection.*

This definition states that the covariant derivative $\mathcal{D}$ generalizes the operator D of the setting and the connection ∇ generalizes the differential d. In particular, both $\mathcal{D}$ and ∇ are related via the same equation (iii) as D and d are according to (7).

Proposition 3: Any connection/covariant derivative has the form $\nabla = d + [\rho + \mathcal{C}^1, \cdot]_g$ *and* $\mathcal{D} = D + \mathrm{i}\rho$, *for* $\rho \in \mathcal{H}^1$. *The curvature is* $\nabla^2 = [\theta, \cdot]$, *with* $\theta = d\hat{\rho} + \frac{1}{2}[\hat{\rho}, \hat{\rho}]_g \in \hat{\mathcal{H}}^2$, *where* $\hat{\rho} = \rho + \mathcal{C}^1 \in \hat{\mathcal{H}}^1$.

Proof: There is a canonical pair of connection/covariant derivative given by $\nabla = d$ and $\mathcal{D} = D$. If $(\nabla^{(1)}, \mathcal{D}^{(1)})$ and $(\nabla^{(2)}, \mathcal{D}^{(2)})$ are two pairs of connections/covariant derivatives, we get from (iii),

$$
(\nabla^{(1)} - \nabla^{(2)})(\pi(\omega^n) + \pi(\mathcal{J}^n)) = [\nabla^{(1)}_h - \nabla^{(2)}_h, \pi(\omega^n)]_g + \pi(\mathcal{J}^{n+1}).
$$

This means that $\rho := \nabla^{(1)}_h - \nabla^{(2)}_h \in \mathcal{H}^1$ is a concrete representative and $\nabla^{(1)} - \nabla^{(2)} = [\hat{\rho}, \cdot]_g$, where $\hat{\rho} = \rho + \mathcal{C}^1 \in \hat{\mathcal{H}}^1$. The formula for θ is a direct consequence of (12). □

VI. GAUGE TRANSFORMATIONS

The exponential mapping defines a unitary group

$$\mathcal{U}:=\left\{\prod_{\alpha=1}^{N}\exp(v_\alpha):\ \exp(v_\alpha):=1_{\mathcal{B}}+\sum_{k=1}^{\infty}\frac{1}{k!}(v_\alpha)^k,\ \ v_\alpha\in\mathcal{H}^0\cap\mathcal{B},dv_\alpha-[-\mathrm{i}D,v_\alpha]\in\mathcal{C}^1\right\}. \qquad (13)$$

Due to $\exp(v)A\exp(-v)=A+\Sigma_{k=1}^{\infty}\frac{1}{k!}([v,[v,\ldots,[v,A]\cdots]])_k$, where $()_k$ contains k commutators of $A\in\mathcal{L}$ with v, we have a natural degree-preserving representation Ad of $\mathcal{U}$ on $\mathcal{H}$, $\mathrm{Ad}_u(\eta^n)=u\,\eta^n u^*\in\mathcal{H}^n$, for $\eta^n\in\mathcal{H}^n$ and $u\in\mathcal{U}$.

Definition 4: In our setting, the gauge group is the group $\mathcal{U}$ defined in (13). Gauge transformations of the connection and the covariant derivative are given by

$$\nabla\mapsto\nabla':=\mathrm{Ad}_u\nabla\mathrm{Ad}_{u^*},\qquad \mathcal{D}\mapsto\mathcal{D}':=u\,\mathcal{D}u^*,\qquad u\in\mathcal{U}.$$

Note that the consistency relation (iii) in Definition 2 reduces on the infinitesimal level to the condition $dv_\alpha-[-\mathrm{i}D,v_\alpha]\in\mathcal{C}^1$ in (13). The gauge transformation of the curvature form reads as $\theta\mapsto\theta'=\mathrm{Ad}_u\theta$.

VII. PHYSICAL ACTION

We borrow the integration calculus introduced by Connes to noncommutative geometry[2,5] and summarize the main results. Let E_n be the eigenvalues of the compact operator (compactness was assumed in the setting) $|D|^{-1}=(DD^*)^{-1/2}$ on h_0, arranged in decreasing order. Here, the finite dimensional kernel of D is not relevant so that $E_1<\infty$. The K-cycle (h_0,D) over the C^*-algebra $\mathcal{B}(h_0)$ is called d^+-summable if $\Sigma_{n=1}^{N}E_n=O(\Sigma_{n=1}^{N}n^{-1/\mathrm{d}})$. Equivalently, the partial sum of the first N eigenvalues of $|D|^{-\mathrm{d}}$ has (at most) a logarithmic divergence as $N\to\infty$ so that $|D|^{-\mathrm{d}}$ belongs to the (two-sided) Dixmier trace class ideal $\mathcal{L}^{(1,\infty)}(h_0)$. Therefore, $f|D|^{-\mathrm{d}}\in\mathcal{L}^{(1,\infty)}(h_0)$ for any $f\in\mathcal{B}(h_0)$, and the Dixmier trace provides for $f>0$ a linear functional $f\mapsto\mathrm{Tr}_\omega(f|D|^{-\mathrm{d}})=\mathrm{Lim}_\omega(1/\ln N)\Sigma_{n=1}^{N}\mu_n\in\mathbb{R}^+$. Here, μ_n are the eigenvalues of $f|D|^{-\mathrm{d}}$ and the limit Lim_ω involves an appropriate limiting procedure ω. The Dixmier trace fulfills $\mathrm{Tr}_\omega(f|D|^{-\mathrm{d}})=\mathrm{Tr}_\omega(ufu^*|D|^{-\mathrm{d}})$, for unitary $u\in\mathcal{B}(h_0)$.

Let $\theta_0^*:h_0\to h_1$ be the uniquely determined adjoint of a representative $\theta_0:h_1\to h_0$ of the curvature form $\theta\in\hat{\mathcal{H}}^2$. It follows that $\theta_0\theta_0^*\in\mathcal{B}(h_0)$ so that we propose the following definition for the physical action.

Definition 5: The bosonic action S_B and the fermionic action S_F of the connection ∇ and covariant derivative $\mathcal{D}$ are given by

$$S_B(\nabla):=\min_{\mathrm{j}^2\in\mathcal{C}^2+\pi(\mathcal{J}^2)}\mathrm{Tr}_\omega((\theta_0+\mathrm{j}^2)(\theta_0+\mathrm{j}^2)^*|D|^{-\mathrm{d}}),$$
$$S_F(\psi,\mathcal{D}):=\langle\psi,\mathcal{D}\psi\rangle_{h_0},\qquad \psi\in h_1, \qquad (14)$$

where $\langle,\rangle_{h_0}$ is the scalar product on h_0.

The bosonic action S_B is independent of the choice of the representative θ_0. Thus, we can take the canonical dependence of the gauge potential ρ,

$$\theta_0=\{-\mathrm{i}D,\rho\}+\tfrac{1}{2}\{\rho,\rho\}+\sigma\circ\pi^{-1}(\rho),$$

where $\sigma\circ\pi^{-1}$ is supposed to be extended from $\pi(\Omega^1)$ to $\mathcal{H}^1$. It is unique up to elements of $\mathcal{C}^2+\pi(\mathcal{J}^2)$. Since the Dixmier trace is positive, the element $\mathrm{j}_0^2\in\mathcal{C}^2+\pi(\mathcal{J}^2)$ at which the minimum in (14) is attained is the unique solution of the equation

$$\mathrm{Tr}_\omega((\theta_0+j_0^2)(j^2)^*|D|^{-\mathrm{d}})=0,\qquad \forall\, j^2\in\mathcal{C}^2+\pi(\mathcal{J}^2).$$

It is clear that the action (14) is invariant under gauge transformations,

$$\nabla \mapsto \mathrm{Ad}_u \nabla \mathrm{Ad}_{u*}, \quad \mathcal{D} \to u\mathcal{D}u^*, \quad \psi \mapsto u\psi, \quad u \in \mathcal{U}. \tag{15}$$

Note that our gauge group as defined in (13) is always connected, which means that we have no access to ''big'' gauge transformations. Note further that there exist Lie groups having the same Lie algebra. In that case there will exist fermion multiplets ψ which can be regarded as multiplets of different Lie groups. For the bosonic sector only the Lie algebra is important, so one can have the pathological situation of a model with identical particle contents and identical interactions, but different gauge groups. We consider such gauge theories as identical.

VIII. REMARKS ON THE STANDARD EXAMPLE

Recall (5) that the general form of an element $\tau^1 \in \pi(\Omega^1)$ is

$$\tau^1 = \sum_{\alpha, z \geq 0} [\pi(a_\alpha^z), [\cdots [\pi(a_\alpha^1), [-\mathrm{i}D, \pi(a_\alpha^0)]] \cdots]], \quad a_\alpha^i \in \mathfrak{g}. \tag{16}$$

For $a_\alpha^i = f_\alpha^i \otimes \hat{a}_\alpha^i \in C^\infty(X) \otimes \mathfrak{a}$ we get with (1),

$$\tau^1 = \sum_{\alpha, z \geq 0} (f_\alpha^z \cdots f_\alpha^1 \not{\partial}(f_\alpha^0) \otimes \hat{\pi}([\hat{a}_\alpha^z, [\cdots [\hat{a}_\alpha^1, \hat{a}_\alpha^0] \cdots]])$$

$$+ f_\alpha^z \cdots f_\alpha^1 f_\alpha^0 \boldsymbol{\gamma} \otimes [\hat{\pi}(\hat{a}_\alpha^z), [\cdots [\hat{\pi}(\hat{a}_\alpha^1), [-\mathrm{i}\mathcal{M}, \hat{\pi}(\hat{a}_\alpha^0)]] \cdots]]). \tag{17}$$

Let us first assume that $\mathfrak{a}$ is semisimple. In this case the two lines in (17) are independent. The first line belongs to $\Lambda^1 \otimes \hat{\pi}(\mathfrak{a})$, because the gamma matrices occurring in $\not{\partial}$ provide a 1-form basis. In physical terminology, these Lie algebra-valued 1-forms are Yang–Mills fields acting via the representation $\mathrm{id} \otimes \hat{\pi}$ on the fermions. In the second line of (17) we split $\mathcal{M}$ into generators of irreducible representations of $\mathfrak{a}$, tensorized by generation matrices. Obviously, these irreducible representations are spanned after taking the commutators with $\hat{\pi}(\hat{a}_\alpha^i)$. Thus, the second line of (17) contains sums of function-valued representations of the matrix Lie algebra (times $\boldsymbol{\gamma}$ and generation matrices), which are physically interpreted as Higgs fields. In other words, the prototype τ^1 of a connection form (=gauge potential) describes representations of both Yang–Mills and Higgs fields on the fermionic Hilbert space.

From a physical point of view, this is a more satisfactory picture than the usual noncommutative geometrical construction of Yang–Mills–Higgs models.[3,4] Namely, descending from Connes' noncommutative geometry[2,5,6] there is only a limited set of Higgs multiplets possible:[13] Admissible Higgs multiplets are tensor products $\mathbf{n} \otimes \mathbf{m}^*$ of fundamental representations (and their complex conjugate) $\mathbf{n}, \mathbf{m}$ of simple gauge groups, where the adjoint representation never occurs. This rules out[7] the construction of interesting physical models. In our framework there are no such restrictions and — depending on the choice of $\mathcal{M}$ and h — Higgs fields in any representation of a Lie group are possible. Thus, a much larger class of physical models can be constructed.

The treatment of Abelian factors $\mathfrak{a}'' \subset \mathfrak{a}$ in our approach is somewhat tricky. One remarks that in the first line of (17) only the $(z=0)$-component of $\mathfrak{a}''$ survives. The consequence is that linear independence of the two lines in (17) is not automatic. Thus, to avoid pathologies, we need a condition[1] between $\mathcal{M}$ and the representations of $\mathfrak{a}$ to assure independence. The $u(1)$-part of the standard model is admissible in this sense.

The second consequence of the missing $(z>0)$-components in the first line is that the space–time 1-form part of Abelian factors in τ^1 is a total differential $\not{\partial}(f_0^0) \in d\Lambda^0 \subset \Lambda^1$. This seems to be a disaster at first sight for the description of Abelian Yang–Mills fields. However, our gauge potential lives in the bigger space $\mathcal{H}^1 \supset \pi(\Omega^1)$. Always, if there is a part $d\Lambda^0 \otimes \pi(\mathfrak{a}'')$ in $\pi(\Omega^1)$ there is a part $\Lambda^1 \otimes \pi(\mathfrak{a}'')$ in $\mathcal{H}^1$. There can be even further contributions from $\mathcal{H}^1$ to the gauge potential, which are difficult to control, in general. Fortunately, it turns out[1] that after imposing a locality condition for the connection (which is equivalent to saying that ρ commutes with functions), possible additional $\mathcal{H}^1$-degrees of freedom are either of the Yang–Mills type or the Higgs type.

This framework of gauge field theories was successfully applied to formulate the standard model,[10] the flipped SU(5)×U(1)-grand unification[11] and SO(10)-grand unification.[12] It is not possible to describe pure electrodynamics. The reason is that in the Abelian case the curvature form $\theta\neq 0$ commutes with all elements of $\pi(\Omega)$. Hence, it belongs to the graded centralizer $\mathcal{C}^2$ and is projected away in the bosonic action (14).

IX. DO THE AXIOMS OF NONCOMMUTATIVE GEOMETRY EXTEND TO THE LIE ALGEBRAIC SETTING?

The present status of noncommutative geometry is that this theory is governed by seven axioms.[6] In the commutative case, these axioms provide the algebraic description of classical spin manifolds. The question now is whether or not our Lie algebraic version, which is in close analogy with the prior Connes–Lott formulation[9] of noncommutative geometry, can also be brought into contact with Connes' axioms. We list and discuss below the axioms in their form they would have in terms of Lie algebras.

(1) *Dimension: $|D|^{-1}$ is an infinitesimal of order 1/d, i.e., the eigenvalues E_n of $|D|^{-1}$ grow as $n^{-1/\mathrm{d}}$, where d is an even natural number.*

(3) *Smoothness: For any $a\in\mathfrak{g}$, both a and $[D,a]$ belong to the domain of δ^m, where $\delta(.)$ $:=[|D|,\cdot]$.*

The axioms (1) and (3) can be directly transferred to the Lie algebraic setting. We cannot treat the odd-dimensional case as the grading operator Γ is essential to detect the sign for the graded commutator.

(4) *Orientability:* Connes requires the $\mathbb{Z}_2$-grading operator Γ to be the image under π of a Hochschild d-cycle. We are not going to touch the extension of Hochschild homology to Lie algebras, but even a requirement such as $\Gamma\in\pi(\Omega^{\mathrm{d}})$ is problematic. For the standard example we have the decomposition $\Gamma=\boldsymbol{\gamma}\otimes\hat{\Gamma}$, and the comparison with the general form[1] of $\pi(\Omega^{\mathrm{d}})$ yields that $\hat{\Gamma}$ has to be the image under $\hat{\pi}$ of the non-Abelian part of $\mathfrak{a}$. In all models we have studied so far this is not the case. It seems to be impossible to maintain orientability in our framework. The grading operator Γ, which commutes with $\pi(\mathfrak{g})$ and anti-commutes with D, is an extra piece which has no relation with orientability.

(7) *Reality: There exists an antilinear isometry $J:h_i\to h_i$ such that $[\pi(a),J\pi(b)J^{-1}]=0$ for all $a,b\in\mathfrak{g}$, $J^2=\epsilon$, $JD=DJ$ and $J\Gamma=\epsilon'\Gamma J$, with $\epsilon=(-1)^{\mathrm{d(d+2)/8}}$ and $\epsilon'=(-1)^{\mathrm{d/2}}$.*

(2) *First order: $[[D,\pi(a)],J\pi(b)J^{-1}]=0$ for all $a,b\in\mathfrak{g}$.*

Both axioms (7) and (2) can be trivially fulfilled as soon as an antilinear involution $\mathcal{I}$ on h_i is available. It suffices to define

$$J:=\begin{pmatrix}0 & \epsilon\mathcal{I}^{-1}\\ \mathcal{I} & 0\end{pmatrix},\quad h_i\mapsto\begin{pmatrix}h_i\\ h_i\end{pmatrix},\quad D\mapsto\begin{pmatrix}D & 0\\ 0 & \mathcal{I}D\mathcal{I}^{-1}\end{pmatrix},$$

$$\pi(a)\mapsto\begin{pmatrix}\pi(a) & 0\\ 0 & 0\end{pmatrix},\qquad \Gamma\mapsto\begin{pmatrix}\Gamma & 0\\ 0 & \epsilon'\mathcal{I}\Gamma\mathcal{I}^{-1}\end{pmatrix}.$$

The question is whether there are nontrivial real structures which also satisfy the other axioms. The existence of the real structure J (Tomita's involution) is a central piece of Connes' theory. It has proved very useful in understanding the commuting electroweak and strong sectors of the standard model. The same idea could be applied to our formulation of the standard model.[10] For other gauge theories,[11,12] however, a nontrivial real structure J seems to be rather disturbing as it requires the fermions to sit in (generalized) adjoint representations. To achieve this one had to add auxiliary $u(1)$-factors, which is in contradiction to the grand unification philosophy.

(5) *Finiteness and absolute continuity:* Connes requires $h_\infty = \cap_m \text{domain}(D^m)$ to be a finite projective module. Thus, our task would be to define the notion of a finite projective module over a Lie algebra $\mathfrak{g}$ and the Lie analogs of the *K*-groups. We are not aware of these structures, but without them it is impossible to talk about generalizations of the index pairing of *D* with the *K*-groups and of the following.

(6) *Poincaré duality*.

In conclusion, our Lie algebraic version of noncommutative geometry is not a possible generalization of classical spin manifolds, or at least there is a lot to do to derive the Lie analogs of standard algebraic structures. Our approach provides a powerful tool to build gauge field theories with spontaneous symmetry breaking; the price for this achievement is the lost of any contact with spin manifolds.

A general model is proposed for constrained dynamical systems on a symplectic manifold which covers, among others, the description of Lagrangian and Hamiltonian systems with nonholonomic constraints and the canonical description of mechanical systems with a singular Lagrangian. The reduction properties of these systems in the presence of symmetry are investigated within this general framework. © *1999 American Institute of Physics.* [S0022-2488(99)00902-0]

I. INTRODUCTION

In this paper, we propose a general model for constrained Hamiltonian systems on a symplectic manifold, providing a unified setting for the description of various types of mechanical systems with constraints. Special attention is then paid to aspects concerning symmetry and reduction for the class of systems under consideration.

The constraints encountered in classical mechanics can be classified, roughly speaking, into two different categories, which may be labeled as ''internal constraints'' and''external constraints,'' respectively. Internal constraints are those that find their origin in the degeneracy of the Lagrangian describing a certain system, which prevents a straightforward transition to an equivalent Hamiltonian formulation. This type of constraint usually reflects the presence of ''gauge'' degrees of freedom, and is, in fact, more relevant to relativistic mechanics and field theory. The standard treatment of degenerate (or singular) Lagrangian systems is based on the Dirac–Bergmann constraint analysis (see, e.g., Ref. 1). An intrinsic geometric formulation and generalization of this theory is provided by the so-called presymplectic constraint algorithm, developed by Gotay and Nester.[2–4] A different approach to singular Lagrangian systems, advocated by Tulczyjew, consists in treating them as implicit dynamical systems (see, e.g., Ref. 5).

External constraints refer to those physical constraints which are imposed on a given system from outside. Here we can make a further distinction between (time-independent or time-dependent) holonomic and nonholonomic, one-sided and two-sided constraints. Holonomic constraints are restrictions on the admissible configurations (i.e., ''positions'') of the system under consideration, whereas nonholonomic constraints depend on the velocities in an essential way, i.e.,

they can not be integrated to relations depending on the position variables only. The prototype of nonholonomic constraints are the conditions for ''rolling without slipping.'' For the purpose of this paper, we restrict our attention to the case of systems with two-sided, time-independent nonholonomic constraints. (For a geometric approach to systems with one-sided constraints, which are analytically expressed by inequalities, we refer to Refs. 6, 7.) The classical approach to nonholonomic mechanical systems is based on the method of Lagrange multipliers (see, e.g., Ref. 8 for a comprehensive treatment). The fundamental work of Vershik and Faddeev[9,10] has marked the beginning of a period of intensive research on nonholonomic systems within the realm of geometric mechanics: see, for instance, Refs. 11–14 for a more detailed bibliography. In particular, the relevance of these studies for the further development of control theory has recently attracted a lot of attention (see, e.g., Refs. 15, 16, and references therein). We note, in passing, that nonholonomic systems have also been treated as implicit dynamical systems by Ibort *et al.*[11]

In spite of the difference in the ''physical'' nature of the constraints, it turns out that the geometrical models adopted for describing systems with either internal or external constraints, have many aspects in common. Indeed, in the canonical treatment of degenerate systems as well as in the Lagrangian and Hamiltonian treatment of nonholonomic systems, the search for consistent equations of motion eventually leads to a framework consisting of the following ingredients: a symplectic manifold (P,ω), a smooth function H on P, a submanifold M of P, and a distribution F along M (i.e., a subbundle of the restricted tangent bundle $TP_{|M}$). Depending on the case, P hereby represents the velocity phase space TQ or the momentum phase space T^*Q of the system under consideration, with underlying configuration space Q, and ω is either the Poincaré–Cartan 2-form on TQ, induced by a regular Lagrangian, or the canonical symplectic form on T^*Q. In the case of degenerate systems, M is the ''final constraint submanifold'' generated by the appropriate constraint algorithm, and F coincides either with TM or with the tangent bundle of a larger submanifold containing M (the primary constraint submanifold). H denotes the energy function or the (extended) Hamiltonian. In the case of a nonholonomic system, M simply denotes the constraint submanifold defined by the given external constraints, and the distribution F is characterized by the property that its annihilator is the co-distribution generated by the reaction forces, induced by the constraints. The problem then consists in finding a vector field on P, generated by H, which is tangent to M and compatible, in an appropriate sense, with the distribution F.

In the present paper we will take the above ingredients as building stones for constructing a general model for constrained dynamical systems in a symplectic setting. This model can be seen, in particular, as a unifying model for the description of degenerate systems as well as of mechanical systems with nonholonomic constraints. Our main goal then is to study the geometry of such systems in the presence of symmetry. Guided by various recent treatments of nonholonomic systems with symmetry (cf. Refs. 17, 15, 12, 18, 19), we will discuss in some detail the reduction problem for general constrained Hamiltonian systems with symmetry.

The scheme of this paper is as follows. In the next section we briefly recall some aspects of the geometrical approach to singular Lagrangian systems and to systems with nonholonomic constraints. In Sec. III we then propose a general model for constrained systems and investigate the existence and uniqueness conditions for the dynamics. In Sec. IV we deal with the problem of solving the dynamics. In Sec. V, we introduce symmetry into our model and present some general reduction results. After putting forward a classification of constrained systems with symmetry, inspired on the one introduced by Bloch *et al.*[15] for nonholonomic systems, we describe some further reduction results for each class separately in Sec. VI. Finally, in Sec. VII we illustrate the obtained results on some particular cases.

Throughout this paper, we work in the category of smooth (i.e., C^∞) objects. For convenience, we will usually not make a notational distinction between a (vector) bundle over a manifold and the ring of its smooth sections, i.e., if F denotes a vector bundle over a manifold N (for instance, a subbundle of TN), then $X \in F$ simply means that $X:N \rightarrow F$ is a section of F. The sole exception to this rule will be the occasional use of the notation $\mathfrak{X}(N)$ for the ring of smooth vector fields on N.

II. EQUATIONS OF MOTION OF CONSTRAINED LAGRANGIAN SYSTEMS

Consider a smooth, finite dimensional manifold Q, with local coordinates denoted by (q^A). As is well known, the tangent bundle TQ of Q, with canonical projection $\tau_Q : TQ \to Q$, is equipped with a dilation vector field Δ, i.e., the so-called Liouville vector field, and a canonical type (1,1) tensor field S, called the vertical endomorphism, which determines the almost tangent structure of TQ. In the natural bundle coordinates (q^A, v^A) of TQ these objects read as

$$\Delta = v^A \frac{\partial}{\partial v^A}, \quad S = \frac{\partial}{\partial v^A} \otimes dq^A.$$

Given a Lagrangian on TQ, i.e., a smooth function $L: TQ \to \mathbb{R}$, one can define the corresponding Poincaré–Cartan 1- and 2-forms θ_L and ω_L, respectively, and the energy function E_L, according to

$$\theta_L = S^*(dL), \quad \omega_L = -d\theta_L, \quad E_L = \Delta(L) - L,$$

with S^* denoting the action of S on 1-forms. In geometrical terms, the equations of motion for the Lagrangian system with Lagrangian L can then be expressed by

$$i_Z \omega_L = dE_L. \tag{1}$$

If L is regular, that is, if the Hessian matrix $(\partial^2 L / \partial v^A \partial v^B)$ is nondegenerate everywhere, then ω_L is a symplectic form. In that case (1) admits a unique solution for Z, which we will denote by Γ_L, and which is usually called the Euler–Lagrange vector field corresponding to L. In particular, Γ_L is a second order differential equation field (SODE, for short), that is, $S(\Gamma_L) = \Delta$. The base integral curves $q^A(t)$ of Γ_L (i.e., the projections of its integral curves onto Q) verify the Euler–Lagrange equations,

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^A}\right) - \frac{\partial L}{\partial q^A} = 0. \tag{2}$$

For later use, we recall that the symplectic form ω_L, corresponding to a regular Lagrangian, induces two bundle isomorphisms (''musical mappings'') $\flat_L : T(TQ) \to T^*(TQ)$ and $\sharp_L : T^*(TQ) \to T(TQ)$, where $\flat_L(X) = i_X \omega_L$ and $\sharp_L = \flat_L^{-1}$.

A. Singular Lagrangian systems

A Lagrangian (system) is called singular, or degenerate, if the Hessian matrix $(\partial^2 L / \partial v^A \partial v^B)$ is singular. In such a case, the equation of motion (1), in general, does not have a solution, and if a solution exists, it will not be unique. If the Poincaré–Cartan 2-form ω_L corresponding to a singular Lagrangian has constant rank and, hence, ω_L happens to be a presymplectic form, one can apply the so-called presymplectic constraint algorithm, developed by Gotay and Nester (see, e.g., Refs. 2, 3). This algorithm generates a descending sequence of constraint submanifolds which, under the appropriate conditions, converges to a closed immersed submanifold P_f of TQ (the ''final constraint submanifold'') on which there exist consistent equations of motion for the given system. More precisely, it follows by construction that the equation

$$(i_Z \omega_L - dE_L)_{|P_f} = 0 \tag{3}$$

admits at least one solution Z which is everywhere tangent to P_f. In addition, one can always find a submanifold of P_f on which there exists a unique solution Z which also verifies the SODE condition (cf. Ref. 4). For quantization purposes, however, it is more convenient to develop the analysis of a degenerate Lagrangian system on an ambient symplectic space. This can be achieved by passing to an appropriate Hamiltonian formulation.

Let us recall that, given a Lagrangian L, the Legendre map Leg:$TQ \to T^*Q$ is a fibered mapping over Q, which is locally written as

$$\mathrm{Leg}(q^A, v^A) = (q^A, p_A),$$

where $p_A = \partial L / \partial v^A$. If ω_Q denotes the canonical symplectic form on T^*Q, we have $\mathrm{Leg}^* \, \omega_Q = \omega_L$ (see, e.g., Ref. 20). Hence, L is regular if and only if Leg is a local diffeomorphism, and L is said to be hyperregular if Leg is a global diffeomorphism. For a singular Lagrangian system it is not possible, in general, to obtain a consistent Hamiltonian description. Let us assume, however, that L is almost-regular, i.e., $M_1 = \mathrm{Leg}(TQ)$ is a submanifold of T^*Q and Leg is a submersion onto M_1 with connected fibers. In that case, the energy function E_L projects onto a function $h_1 : M_1 \to \mathbb{R}$ which is uniquely determined by $h_1 \circ \mathrm{Leg}_1 = E_L$, where Leg_1 simply stands for the ''restriction'' of Leg, regarded as a mapping from TQ onto M_1. If we now denote by ω_1 the pull-back of ω_Q to M_1, then the equation

$$i_X \omega_1 = dh_1, \tag{4}$$

is precisely the Hamiltonian counterpart of Eq. (1).

Starting from (4), one can again apply the presymplectic constraint algorithm which, in case the given problem is consistent, leads to a nonempty final constraint submanifold M_f such that the equation

$$(i_X \omega_1 - dh_1)_{|M_f} = 0 \tag{5}$$

admits well-defined solutions. This approach yields a global version of the classical Dirac–Bergmann theory for constrained systems.[1] Let ''$\perp$'' denote the symplectic orthogonal with respect to the canonical symplectic form ω_Q. Then, if X is an arbitrary solution of (5), all other solutions will be of the form $X+Y$, with $Y \in TM_f \cap TM_1^{\perp}$.

A simple argument shows that, for almost regular Lagrangians, the Lagrangian and the Hamiltonian formulations are fully equivalent (see Refs. 2, 3). In particular, the final constraint submanifolds on both sides are connected via the Legendre transformation, in the sense that the latter induces a fibration $\mathrm{Leg}_f : P_f \to M_f$. Whenever Z is a projectable solution of (3), its projection onto M_f yields a solution of (5) and, conversely, given a solution X of (5), any vector field Z on P_f which projects onto X satisfies (3).

A geometric constraint algorithm, closely related to the Gotay–Nester approach, is the one developed by Hinds[21] (see also Ref. 2 for a brief discussion). Again starting from (4), this algorithm generates a descending sequence of constraint submanifolds. In the favorable case, the algorithm stabilizes at a final constraint submanifold which, for simplicity, we will denote again by M_f. It is important to point out that, in general, this M_f will be different from the final constraint submanifold obtained by the presymplectic constraint algorithm. In principle, both algorithms start to diverge from each other after the second step. This is due to the fact that in the Hinds algorithm, at each step, possibly new constraints are generated by imposing consistency conditions on the equations of motion induced on the previous constraint submanifold by a pull-back procedure. In the presymplectic constraint algorithm, on the other hand, the consistency conditions are imposed on the equations obtained by taking the restriction of (4) to the successive constraint submanifolds. The equations of motion obtained through Hinds' algorithm can be written as

$$i_X \omega_f = dh_f, \tag{6}$$

with ω_f and h_f denoting the pull-back to M_f of ω_1 and h_1, respectively. Given a solution X of this equation, it follows that $X+Y$ is also a solution for any $Y \in TM_f \cap TM_f^{\perp}$. Note that (6) is an equation induced on the final constraint submanifold, i.e., it expresses an equality of 1-forms on

M_f, whereas (5) represents an equality of 1-forms on M_1, restricted to points of the corresponding M_f. This indeed reflects the difference in spirit between both algorithms, as described above.

Following Dirac,[1] the constraints produced in the course of the constraint analysis can be classified in two different ways. On the one hand, depending on the order of appearance, there are primary, secondary, (tertiary, etc.,) constraints. On the other hand, there is the more significant distinction between first and second class constraints. In physics, it is customary to assume that all first class constraints (primary, secondary,...) are generators of gauge transformations, i.e., transformations that do not change the physical state of the system (see, e.g., Refs. 22, 23). This property is automatically verified when applying Hinds' algorithm. In the Gotay–Nester approach, all primary first class constraints generate gauge transformations but, in general, this need not be the case for all subsequent (secondary,...) first class constraints (see Ref. 2 for more details). From a physical point of view, therefore, it may be argued that (6) is in better agreement with the ''standard'' interpretation of gauge transformations than (5).

We will now recast the equations (5) and (6) into a form which better serves our purpose. Taking an arbitrary extension $H_1 : T^*Q \to \mathbb{R}$ of the Hamiltonian $h_1 : M_1 \to \mathbb{R}$, it follows that (5) is formally equivalent to

$$(i_X\omega_Q - dH_1)_{|M_f} \in (TM_1^o)_{|M_f}, \quad X_{|M_f} \in TM_f, \tag{7}$$

where TM_1^o is the annihilator of TM_1 in T^*T^*Q. Locally, these conditions precisely generate the equations of motion ensuing from the classical Dirac–Bergmann constraint analysis. Likewise, taking an arbitrary extension H_f of h_f to T^*Q, (6) can be rewritten in terms of the canonical symplectic form as follows:

$$(i_X\omega_Q - dH_f)_{|M_f} \in TM_f^o, \quad X_{|M_f} \in TM_f, \tag{8}$$

where it should be emphasized again that, for the same system, the constraint submanifolds M_f in (7) and (8), in general, need not be the same.

B. Nonholonomic Lagrangian systems

In this section, we start by considering a regular Lagrangian system with Lagrangian $L : TQ \to \mathbb{R}$, subjected to a set of nonholonomic constraints which are linear in the velocities, i.e., they can be (locally) represented by a set of independent functions of the form $\phi_i := \mu_{iA}(q)v^A$, for $1 \leqslant i \leqslant m$. We can describe this nonholonomic Lagrangian system in geometrical terms as follows. The constraint equations $\phi_i = 0$ define a $(n-m)$-dimensional distribution $\mathcal{D}$ on the n-dimensional configuration manifold Q. We denote its total space by D, which is a $(2n-m)$-dimensional submanifold of TQ: *the constraint submanifold*. For simplicity we always assume in the sequel that $\tau_Q(D) = Q$, i.e., the constraints are ''purely kinematical'' in the sense that they do not impose restrictions on the allowable positions. The motions of the system are forced to take place on D, and this requires the introduction of some (unknown) ''reaction forces.'' In de León *et al.*,[24] an intrinsic expression for the equations of motion was obtained, which we will describe below.

First of all, we define a distribution $\mathcal{D}^v$ on TQ by prescribing its annihilator as a subbundle of T^*TQ which, along the constraint submanifold D, represents the bundle of reaction forces. More precisely, given a set of independent 1-forms $\{\mu_i ; 1 \leqslant i \leqslant m\}$ on Q, which locally generate the annihilator $\mathcal{D}^o$ of $\mathcal{D}$, we put

$$(\mathcal{D}^v)^o = \langle \mu_i^v \rangle,$$

where μ_i^v denotes the vertical lift of the 1-form μ_i to TQ (see Ref. 20). A direct computation reveals that $\mathcal{D}^v$ is, in fact, globally defined. Note, in passing, that with $\mu_i = \mu_{iA}\, dq^A$, the given constraint functions ϕ_i are precisely the evaluation maps of these 1-forms.

Next, it can then be shown that the equations of motion for such a nonholonomic mechanical system are given by

$$(i_X\omega_L - dE_L)_{|D} \in (\mathcal{D}^v)^o, \quad X_{|D} \in TD. \tag{9}$$

It should be pointed out that each solution of (9) (if there exists one) is automatically a SODE along D. This implies that, in local coordinates, the integral curves of X on D are of the form $(q^A(t),\dot{q}^A(t))$, whereby the $q^A(t)$ are solutions of the system of differential equations

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^A}\right) - \frac{\partial L}{\partial q^A} = \lambda^i \mu_{iA}, \tag{10}$$

together with the constraint equations $\mu_{iA}(q)\dot{q}^A = 0$, and where the λ^i are Lagrange multipliers.

We will now describe a procedure which permits us to decide under what conditions (9) admits a solution and, if these conditions are fulfilled, to obtain a solution by projection of the Euler–Lagrange vector field of the corresponding unconstrained system.

Applying the isomorphism $\sharp_L$ to the co-distribution $(\mathcal{D}^v)^o$ we obtain the symplectic orthogonal complement (with respect to ω_L) of $\mathcal{D}^v$, i.e., $\sharp_L((\mathcal{D}^v)^o) = (\mathcal{D}^v)^\perp$. Obviously, $\dim(\mathcal{D}^v)^\perp$ is equal to the number of independent constraints. We will say that the given nonholonomic system satisfies the *compatibility condition* if $T_xD \cap (\mathcal{D}^v_x)^\perp = \{0\}$ at each point $x \in D$. In such a case, taking into account that $\dim(\mathcal{D}^v_x)^\perp = m$, we have a direct sum decomposition,

$$T_x(TQ) = T_xD \oplus (\mathcal{D}^v_x)^\perp, \quad x \in D,$$

which, in turn, gives rise to two complementary projectors, say

$$\mathcal{P}_x : T_x(TQ) \to T_xD, \quad \mathcal{Q}_x : T_x(TQ) \to (\mathcal{D}^v_x)^\perp.$$

A direct calculation shows that $\Gamma_{L,D} = \mathcal{P}(\Gamma_{L_{|D}})$ is a solution of (9). Moreover, one can easily show that this solution is necessarily unique.[24] The procedure just described is essentially equivalent to the classical one based on the use of Lagrange multipliers.

If the nonholonomic system does not verify the compatibility condition, that is, $T_xD \cap (\mathcal{D}^v_x)^\perp \neq \{0\}$ at some points $x \in D$, we can develop a constraint algorithm which is very similar to the one described above for singular Lagrangians (cf. Ref. 24). Under the appropriate conditions, this algorithm determines a final constraint submanifold D_f on which there exist consistent equations of motion for the given constrained problem. More precisely, the algorithm guarantees the existence of well-defined solutions X of the system

$$(i_X\omega_L - dE_L)_{|D_f} \in (\mathcal{D}^v)^o, \quad X_{|D_f} \in TD_f \tag{11}$$

(see Ref. 24 for details). Again, it turns out that a solution of (11) is a SODE along D_f.

The previous analysis of nonholonomic systems can be further extended to the case where, in addition, the Lagrangian happens to be singular (see Refs. 25, 26). To fix the ideas, let us assume that L is almost regular, and that $\ker(\mathrm{Leg})_* \subset \mathcal{D}^c$, where $\mathcal{D}^c$ denotes the tangent or complete lift of $\mathcal{D}$ to TQ, i.e., $\mathcal{D}^c$ is the distribution on TQ whose annihilator is given by $(\mathcal{D}^c)^o = \langle \mu_i^v, \mu_i^c \rangle$. The nonholonomic mechanical system (L,D) is then also said to be almost regular. Under these assumptions, the following is proved in Ref. 25 (using the notations of the previous subsection):

- $\overline{D} = \mathrm{Leg}(D)$ is a submanifold of $M_1 = \mathrm{Leg}(TQ)$, and the restriction $\mathrm{Leg}_{|D} : D \to \overline{D}$ is a surjective submersion whose fiber at a point $x \in \overline{D}$ is precisely given by $\mathrm{Leg}^{-1}(x)$.
- If $\{\mu_i\}$ is a basis of $\mathcal{D}^o$, then $(\overline{\mathcal{D}^v})^o = \langle \pi_Q^* \mu_i \rangle$ defines a distribution $\overline{\mathcal{D}^v}$ on T^*Q, where $\pi_Q : T^*Q \to Q$ is the canonical projection. By construction, the distributions $\mathcal{D}^v$ and $\overline{\mathcal{D}^v}$ are Leg-related.
- Let $\overline{\mathcal{D}_1^v}$ be the distribution on M_1, the annihilator of which is the co-distribution obtained by taking the pull-back to M_1 of the forms generating $(\overline{\mathcal{D}^v})^o$. The system

$$(i_Y\omega_1 - dh_1)_{|\overline{D}} \in (\overline{\mathcal{D}_1^v})^o, \quad Y_{|\overline{D}} \in T\overline{D}, \tag{12}$$

is then equivalent to the system

$$(i_X\omega_L - dE_L)_{|D} \in (\mathcal{D}^v)^o, \quad X_{|D} \in TD,$$

where h_1 is the projection of E_L onto M_1. Indeed, one can develop a constraint algorithm for both systems such that, at each stage, the respective constraint submanifolds D_k and $\overline{D}_k$ are Leg-related, that is, $\mathrm{Leg}(D_k) = \overline{D}_k$. Moreover, with D_f and $\overline{D}_f$ denoting the final constraint submanifolds, one can show that the Legendre map induces a surjective submersion $\mathrm{Leg}_f : D_f \to \overline{D}_f$ which projects solutions onto solutions.

In particular, when applying the constraint algorithm to (12) we end up with the dynamical equation,

$$(i_Y\omega_1 - dh_1)_{|\overline{D}_f} \in (\overline{\mathcal{D}_1^v})^o, \quad Y_{|\overline{D}_f} \in T\overline{D}_f, \tag{13}$$

which, by construction, admits well-defined solutions Y. Finally, as in the treatment of (free) singular Lagrangian systems, discussed in the previous subsection, one can prove the formal equivalence of (13) with

$$(i_Y\omega_Q - dH)_{|\overline{D}_f} \in (\overline{\mathcal{D}^v} \cap TM_1)^o, \quad Y_{|\overline{D}_f} \in T\overline{D}_f, \tag{14}$$

where $H: T^*Q \to \mathbb{R}$ is an arbitrary extension of h_1.

Remark II.1: In the previous discussion we have confined ourselves to the case of linear nonholonomic constraints. Much of the above, however, applies equally well to the case of affine or even nonlinear constraints. For instance, for a regular Lagrangian system, subjected to nonlinear, nonholonomic constraints, described by a submanifold M of the tangent bundle TQ, the equations of motion are again of the form (9), with the vector subbundle D being replaced by M and $(\mathcal{D}^v)^o$ by the co-distribution $S^*((TM)^o)$ (see, e.g., Refs. 27, 28).

III. A GENERAL FRAMEWORK FOR CONSTRAINED SYSTEMS

When looking at the systems (7), (8), (9), (11) and (14), we see that, in spite of the difference in (physical) origin and interpretation, they all have a similar geometrical structure. This prompts us to introduce the following general model for constrained dynamical systems within a symplectic setting.

Consider a symplectic manifold (P,ω), a smooth function $H: P \to \mathbb{R}$ (the Hamiltonian), an embedded submanifold M of P (the constraint submanifold) and a distribution F on P along M, i.e., F is a vector subbundle of $TP_{|M}$. We are then interested in the following problem: find a smooth section X of the restricted tangent bundle $TP_{|M} \to M$, such that

$$(i_X\omega - dH)_{|M} \in F^o, \quad X \in TM, \tag{15}$$

with F^o the annihilator of F in $T^*P_{|M}$. In particular, X then defines a vector field on M. It is clear that (7), (8), (9), (11) and (14) belong to the class of problems described by (15). (We thereby ignore the technicality that in the treatment of singular Lagrangian systems, the final constraint submanifold, in principle, may be an immersed rather than an embedded submanifold.)

In what follows we will denote by $\flat : TP \to T^*P, X \mapsto i_X\omega$ and $\sharp = \flat^{-1}: T^*P \to TP$, the bundle isomorphisms over P induced by the symplectic form ω.

We now first study the problem of the existence and uniqueness of solutions of the constrained system (15).

Proposition III.1: (i) (Existence) The system (15) admits a solution if and only if

$$dH(x) \in (F_x \cap T_x M^\perp)^o,$$

at each point $x \in M$.

(ii) (Uniqueness) If (15) has a solution, then it is unique if and only if

$$F^\perp \cap TM = 0.$$

Proof: (i) If X is a solution of (15) then, since $X(M) \subset TM$, we have $i_X \omega_{|M} \in (TM^\perp)^o$, from which it follows that

$$dH_{|M} \in F^o + (TM^\perp)^o = (F \cap TM^\perp)^o.$$

Conversely, assume that $dH_{|M} \in F^o + (TM^\perp)^o$. Then, $dH_{|M} - \beta \in (TM^\perp)^o$ for some $\beta \in F^o$. Since $\flat(TM) = (TM^\perp)^o$, we deduce that there exists a vector field X satisfying (15).

(ii) Now, let X and X' be two solutions of (15). Then

$$X - X' \in F^\perp \cap TM.$$

Hence, if a solution exists, it will be unique if and only if $F^\perp \cap TM = 0$. Q.E.D.

Note that the existence condition can be equivalently expressed as

$$X_{H|M} \in TM + F^\perp,$$

where X_H denotes the (unconstrained) Hamiltonian vector field on (P, ω) with Hamiltonian H. Hence, any solution X of (15) is of the form

$$X = X_{H|M} + Z, \tag{16}$$

for some $Z \in F^\perp$. An interesting special case occurs when rank $F = \dim M$ or, equivalently, $\dim F_x = \dim T_x M$ for all $x \in M$.

Corollary III.2: If rank $F = \dim M$, *then the condition* $F^\perp \cap TM = 0$ *implies both the existence and uniqueness of a solution of (15).*

Proof: A simple algebraic argument shows that, under the given assumptions, $TP_{|M} = F^\perp \oplus TM$. Taking the symplectic complements of both sides, we find that $0 = F \cap TM^\perp$ and, hence, $T^*P_{|M} = (F \cap TM^\perp)^o$. The result now readily follows from the previous Proposition. Q.E.D.

Under the conditions of the Corollary, (15) is a constrained Hamiltonian system in the sense of Marle,[19] who has studied such systems in the more general setting of Poisson manifolds.

Let us now check the existence and uniqueness conditions for the examples discussed in the previous section. For the nonholonomic system (9), with a regular Lagrangian, we have $(P, \omega) = (TQ, \omega_L)$, $M = D$ and $F = \mathcal{D}^v$. The compatibility condition introduced for such a system precisely coincides with the unicity condition from Proposition 3.1. Since a simple counting of dimensions shows that rank $\mathcal{D}^v = \dim D$, it follows from the above Corollary that a compatible nonholonomic system indeed admits a unique solution. For the other cases (7), (8), (11) and (14), we note that the equations of motion are obtained after applying a constraint algorithm. The latter is precisely conceived so as to guarantee the existence of a consistent solution, i.e., in these cases the existence condition of Proposition 3.1 holds by construction. The uniqueness condition, however, need not be satisfied: in general, there will be ''gauge degrees of freedom.''

Returning to the general model (15), it is important to point out that if the system admits a solution X, it need not be true, in general, that (the restriction of) H is a first integral of X. In classical mechanics, for instance, it is well known that imposing nonholonomic constraints on a conservative mechanical system may destroy the conservation of energy (see, e.g., Ref. 19). An additional assumption on the nature of the constraints therefore is needed to ensure the conservation of energy. For a Lagrangian system subject to general (i.e., not necessarily linear) nonholonomic constraints, a sufficient condition for the energy E_L to be conserved is that the constraints are ''homogeneous,'' which, in geometrical terms, means that the dilation vector field Δ should be tangent to the constraint submanifold (see Refs. 27, 28, where the less appropriate denomination ''ideal constraints'' was used instead of homogeneous constraints). In the case of linear constraints, this condition is always fulfilled.

Remark III.3: If (15) admits no solution, then it is possible to develop a constraint algorithm which, at least in case the given problem is consistent, will lead to a final constraint submanifold M_f on which there exist a well-defined dynamics. The system to be considered then reads as

$$(i_X\omega - dH)_{|M_f} \in F^o, \quad X_{|M_f} \in TM_f, \tag{17}$$

which is again of the same type as (15). By construction this system now has well-defined solutions. Therefore, without loss of generality, we will henceforth always assume that the existence condition of Proposition 3.1 is satisfied

IV. SOLVING THE DYNAMICS

Given a constrained system of the form (15) for which condition (i) of Proposition 3.1 holds, we will now indicate how one can explicitly construct a (local) solution for the dynamics.

Let X_H again denote the ''unconstrained'' Hamiltonian system on (P,ω), corresponding to the Hamiltonian H. Take a local basis $\{\mu_i; 1 \leqslant i \leqslant m\}$ of F^o, and let $\{\Phi_a; 1 \leqslant a \leqslant s\}$ be an independent set of constraint functions which locally define M. Denote by Z_i the symplectic gradient of μ_i, that is, $\flat(Z_i) = \mu_i$. Then, $F^\perp$ is locally generated by the vector fields Z_i and, according to (16), any solution X of (15) can be written as

$$X = X_H + \lambda^i Z_i,$$

where the λ^i are Lagrange multipliers which can be determined from the tangency condition:

$$0 = X(\Phi_a)_{|M} = X_H(\Phi_a)_{|M} + \lambda^i Z_i(\Phi_a)_{|M}, \quad \forall a.$$

Indeed, the existence condition for solutions of (15), in particular, implies that this system of equations can be solved for the λ^i, i.e., on M we have

$$\operatorname{rank}(Z_i(\Phi_a)) = \operatorname{rank}(Z_i(\Phi_a); -X_H(\Phi_a)).$$

Of course, the solution for the λ^i need not be unique.

Next, let us assume that both conditions of Proposition 3.1 are satisfied, so that the system admits a unique solution. Our goal now is to construct a projection operator which allows us to deduce the constrained dynamics from the unconstrained dynamics X_H.

From the assumption $F^\perp \cap TM = 0$ it readily follows that for each $x \in M$, $\dim F_x^\perp \leqslant \operatorname{codim} T_xM$, i.e., $m = \operatorname{corank} F \leqslant \operatorname{codim} M = s$. We can now distinguish the following two cases.

Assume $m = s$.

A simple dimensional argument shows that

$$TP_{|M} = TM \oplus F^\perp.$$

Therefore, there exist two complementary projectors $\mathcal{P}: TP_{|M} \to TM$ and $\mathcal{Q}: TP_{|M} \to F^\perp$ and it is straightforward to check that $\mathcal{P}(X_H)$ is a solution of (15). Using the above notations, a local expression for $\mathcal{P}$ is given by

$$\mathcal{P} = Id - \mathcal{C}^{ij} Z_i \otimes d\Phi_j,$$

where $(\mathcal{C}^{ij})$ is the inverse of the regular matrix $(\mathcal{C}_{ij})$, with $\mathcal{C}_{ij} = Z_j(\Phi_i)$. Hence we obtain

$$\mathcal{P}(X_H) = X_H - \mathcal{C}^{ij} X_H(\Phi_j) Z_i. \tag{18}$$

Assume $m<s$.

In this case, we have

$$TM\oplus F^{\perp}\subsetneq TP_{|M},$$

with two complementary projectors $\mathcal{P}:TM\oplus F^{\perp}\to TM$ and $\mathcal{Q}:TM\oplus F^{\perp}\to F^{\perp}$. From the existence condition it easily follows that $X_{H|M}\in TM\oplus F^{\perp}$. As above, the projection $\mathcal{P}(X_H)$ then provides the unique solution of the constrained dynamics.

The matrices $(Z_i(\Phi_a))$ and $(Z_i(\Phi_a);-X_H(\Phi_a))$, with $(1\leqslant i\leqslant m;1\leqslant a\leqslant s)$, both have maximal rank m. To obtain an explicit (local) description for $\mathcal{P}(X_H)$ we only need to select m independent rows from the matrix $(Z_i(\Phi_a))$. Without loss of generality, we may assume these to be the first m rows $(1\leqslant a\leqslant m)$, so that we recover (18).

Remark IV.1: Recently, various authors have pointed out that the dynamics of nonholonomic systems can be conveniently described in terms of a ''pseudo-Poisson'' bracket (see, e.g., Refs. 18, 29, 30). On the other hand, in Refs. 31, 25, a unified treatment of constrained systems has also been proposed in terms of Dirac brackets. The relation between these various bracket approaches has been discussed in Cantrijn *et al.*[32] It is rather straightforward to see that these bracket formulations of constrained dynamics can be extended to the general model for constrained systems considered in this paper, but we will not further enter into this matter here.

In the next three sections we wish to investigate the effect of symmetry on the dynamics of constrained systems of type (15). In particular, we will describe various reduction schemes for such systems. The subsequent analysis remains close in spirit to some related treatments of nonholonomic systems with symmetry (see, for instance, Refs. 33, 17, 15, 27, 34, 19, 35).

V. SYMMETRY AND REDUCTION

Consider a constrained system of the form (15) and let there be a given symplectic action $\Phi:G\times P\to P$ of a Lie group G on the symplectic manifold (P,ω), such that the submanifold M, the Hamiltonian function H and the vector subbundle F are G-invariant. For simplicity we will always assume that this action is free and proper. For each $g\in G$ and $x\in P$ we put $\Phi(g,x)=\Phi_g(x)=gx$. The infinitesimal generator (fundamental vector field) corresponding to $\xi\in\mathfrak{g}$, with $\mathfrak{g}$ the Lie algebra of G, will be denoted by ξ_P. By assumption we thus have for all $g\in G$,

- $\Phi_g^*(H)=H\circ\Phi_g=H$;
- $\Phi_g(M)\subseteq M$;
- $T\Phi_g(F_x)=F_{\Phi_g(x)}$, for all $x\in M$.

If (15) admits a solution X, it is routine to verify that Φ_g^*X will also be a solution for each $g\in G$. This still means that at each point $x\in M$, $\Phi_g^*X(x)-X(x)\in F_x^{\perp}\cap T_xM$. In particular, in case (15) has a unique solution, the latter will be G-invariant.

In discussing the reduction of a G-invariant solution of (15) we will proceed in two stages. First, we will show that the above assumptions already allow us to construct a Poisson reduction. Next, upon invoking an additional hypothesis, we will establish a kind of symplectic reduction, in the sense of the one derived by Bates and Śniatycki[17] for nonholonomic Hamiltonian systems.

(i) Poisson reduction. Since the action Φ is free and proper, the orbit space $\bar{P}=P/G$ is a differentiable manifold and $\rho:P\to\bar{P}$ is a principal bundle over $\bar{P}$ with structure group G, whereby ρ denotes the natural projection. Moreover, Φ being a symplectic action, it is, in particular, a Poisson action with respect to the natural Poisson structure induced by ω on P, i.e., it leaves the corresponding Poisson tensor field Λ on P invariant. It is known that the orbit space $\bar{P}$ then admits a unique Poisson structure such that the projection ρ becomes a Poisson map (see, e.g., Ref. 36). The corresponding Poisson tensor field $\bar{\Lambda}$ on $\bar{P}$ is unambiguously determined by

$$\bar{\Lambda}(d\bar{f},d\bar{g})(\bar{y})=\Lambda(\rho^*d\bar{f},\rho^*d\bar{g})(y),$$

for all $\overline{f},\overline{g} \in C^\infty(\overline{P})$ and $y \in \rho^{-1}(\overline{y})$. Let $\overline{\sharp}: T^*\overline{P} \to T\overline{P}$ be the linear bundle map induced by $\overline{\Lambda}$ according to

$$\langle \overline{\sharp}(\overline{\alpha}),\overline{\beta}\rangle = \overline{\Lambda}_{\overline{y}}(\overline{\alpha},\overline{\beta}),$$

for all $\overline{y} \in \overline{P}$ and $\overline{\alpha},\overline{\beta} \in T^*_{\overline{y}}\overline{P}$.

The Hamiltonian H being G-invariant, it induces a function $\overline{H}$ on $\overline{P}$. Moreover, M is also assumed to be G-invariant and, clearly, the G-action induced by Φ on M will still be free and proper. Thus, the quotient manifold $\overline{M} = M/G$ is a smooth submanifold of $\overline{P}$. Finally, we note that the G-invariance of F also implies the G-invariance of $F^\perp$. For each $\overline{x} \in \overline{M}$ we put $(\overline{F^\perp})_{\overline{x}} = T\rho(F_x^\perp)$ for some $x \in \rho^{-1}(\overline{x})(\subset M)$. This definition is independent of the choice of $x \in \rho^{-1}(\overline{x})$. We then put

$$\overline{F^\perp} = \cup_{\overline{x}\in\overline{M}}(\overline{F^\perp})_{\overline{x}},$$

which defines a generalized distribution on $\overline{P}$ along $\overline{M}$. In principle, the bundle $\overline{F^\perp}$ need not have constant rank. Assume now that there exists a G-invariant solution X of (15). As pointed out above, this will automatically be the case if the equation admits a unique solution. Then, X is projectable onto $\overline{M}$ and its projection $\overline{X}$ verifies

$$\overline{X} \in \overline{\sharp}(d\overline{H}) + \overline{F^\perp},$$

that is,

$$\overline{X} = X_{\overline{H}|\overline{M}} + \overline{Z},$$

for some $\overline{Z} \in \overline{F^\perp}$, with $X_{\overline{H}} = \overline{\sharp}(d\overline{H})$. Indeed, according to (16) we can always write X in the form $X = X_H + Z$, with $Z \in F^\perp$. The symmetry assumptions already guarantee the projectability of the Hamiltonian vector field X_H. Therefore, if X is G-invariant, Z is also G-invariant and its projection onto $\overline{M}$ is a section of $\overline{F^\perp}$.

Next, we will show that under an additional condition, the reduced dynamics $\overline{X}$ can be expressed in terms of a 2-form defined on a vector subbundle of $T\overline{P}_{|\overline{M}}$. The analysis closely follows the one developed in Ref. 17 (see also Ref. 34).

(ii) Bates–Śniatycki reduction. In what follows, we assume that there exists a G-invariant solution X of (15) such that $X \in F$. Recall that the latter assumption, in particular, implies that $X(H) = 0$.

Remark V.1: For the mechanical systems considered in Sec. II, the condition that the constrained dynamics should belong to the distribution F is not at all restrictive. Indeed, for (7) and (8) we have that every solution X automatically belongs to F since, in those cases, $TM \subset F$. In the case of (9) and (11), the property that $X \in F$ is a consequence of the fact that X is a SODE. Finally, for (14), the condition will be satisfied if the solution Y on $\overline{D}_f$ is the projection of a SODE along a submanifold of D_f. It is known that one can always find such a submanifold and such a solution.[25]

In the sequel, we will denote by $\mathcal{V}$ the subbundle of TP whose fibers are the tangent spaces to the G-orbits, i.e., $\mathcal{V}_x = T_x(Gx)$ or, equivalently, $\mathcal{V} = \ker T\rho$. Note that $\mathcal{V}_x \subset T_xM$ for all $x \in M$, i.e., $\mathcal{V}_{|M} \subset TM$. For simplicity, we will also usually write $\mathcal{V}$, instead of $\mathcal{V}_{|M}$, when referring to its restriction to M (the precise meaning should be clear from the context).

We now define a (generalized) vector subbundle U of $TP_{|M}$, whose fiber at $x \in M$ is given by

$$U_x = \{v \in F_x \cap T_xM / \omega(v,\tilde{\xi}) = 0, \quad \text{for all } \tilde{\xi} \in \mathcal{V}_x \cap F_x\}. \tag{19}$$

In general, this bundle need not be of constant rank, i.e., it determines a generalized distribution on P along M. In the sequel, however, we will always tacitly assume that U is a genuine vector bundle over M, although much of the analysis also holds in the more general situation. Note that $U=(F\cap TM)\cap(\mathcal{V}\cap F)^{\perp}$, where $(\mathcal{V}\cap F)^{\perp}$ is the ω-complement of $\mathcal{V}\cap F$ in $TP_{|M}$. It is readily seen that U is G-invariant and, hence, projects onto a subbundle $\bar{U}$ of $T\bar{P}_{|\bar{M}}$. Let us now denote by ω_U the restriction of ω to U. Clearly, ω_U is also G-invariant and since, moreover, $i_{\tilde{\xi}}\omega_U=0$ for all $\tilde{\xi}\in\mathcal{V}\cap U$, the 2-form ω_U pushes down to a 2-form $\omega_{\bar{U}}$ on $\bar{U}$ (i.e., $\omega_{\bar{U}}$ only acts on vectors belonging to $\bar{U}$). Similarly, the restriction of dH to U, denoted by d_UH, pushes down to a 1-form $d_{\bar{U}}\bar{H}$ on $\bar{U}$, which is simply the restriction of $d\bar{H}$ to $\bar{U}$. Note that neither $\omega_{\bar{U}}$ nor $d_{\bar{U}}\bar{H}$ are genuine differential forms on $\bar{M}$; they are exterior forms on a vector bundle over $\bar{M}$, with smooth dependence on the base point.

Proposition V.2: Let X be a G-invariant solution of (15) such that, in addition, X belongs to F. Then, the projection $\bar{X}$ of X onto $\bar{M}$ is a section of $\bar{U}$ satisfying the equation

$$i_{\bar{X}}\omega_{\bar{U}}=d_{\bar{U}}\bar{H}.$$

Proof: Essentially, all that remains to be checked is that X is a section of U. Along M, the given solution X verifies

$$i_X\omega=dH+\beta,$$

with $\beta\in F^o$. H being G-invariant, it follows that for any section $\tilde{\xi}$ of $\mathcal{V}\cap F$, $dH(\tilde{\xi})=0$. Since, obviously, we also have $\beta(\tilde{\xi})=0$, we may indeed conclude that $X\in U$. Consequently, the following relation holds along M:

$$i_X\omega_U=d_UH.$$

The remainder of the proof now readily follows from the symmetry assumptions and from the previous considerations. Q.E.D.

It is important to observe that, in general, the 2-form $\omega_{\bar{U}}$ may be degenerate. However, in the case of a mechanical system with linear nonholonomic constraints, for instance, one can prove that $\omega_{\bar{U}}$ is nondegenerate, such that $(\bar{U},\omega_{\bar{U}})$ becomes a symplectic vector bundle over $\bar{M}$ (see Ref. 17). The reduced dynamics is then uniquely determined by the equation mentioned in the previous Proposition.

In the next section, we will identify three distinguished classes of constrained systems with symmetry, which will be analyzed in some more detail.

VI. A CLASSIFICATION OF CONSTRAINED SYSTEMS WITH SYMMETRY

We again consider a constrained system (15) with symmetry, as described in the previous section. Recall that $\mathcal{V}=\ker T\rho$. For each infinitesimal generator ξ_P of the given group action on P, corresponding to some $\xi\in\mathfrak{g}$, the restriction to M is precisely the infinitesimal generator ξ_M of the induced action on M. If ξ_M is a section of $\mathcal{V}\cap F$, we will call it a **horizontal symmetry** of the given constrained system (see also Refs. 17, 15). The following classification, which is inspired on the one introduced by Bloch *et al.*[15] for mechanical systems with linear or affine nonholonomic constraints, reflects the various possible ways the subspaces $\mathcal{V}_x$ and F_x may intersect.

(i) *The purely kinematic case:* $\mathcal{V}_x\cap F_x=\{0\}$ and $T_xM=\mathcal{V}_x+(F_x\cap T_xM)$, for all $x\in M$.
(ii) *The case of horizontal symmetries:* $\mathcal{V}_x\cap F_x=\mathcal{V}_x$, for all $x\in M$, which is equivalent to $\mathcal{V}_x\subset F_x$, for all $x\in M$.
(iii) *The general case:* $\{0\}\subsetneq\mathcal{V}_x\cap F_x\subsetneq\mathcal{V}_x$, for all $x\in M$.

A. The purely kinematic case

Suppose that $\mathcal{V}_x \cap F_x = \{0\}$ and $T_x M = \mathcal{V}_x + (F_x \cap T_x M)$, for all $x \in M$. This implies that $T_x M = \mathcal{V}_x \oplus (F_x \cap T_x M)$. In other words, observing that in this case $U = F \cap TM$, we have $TM = \mathcal{V}_{|M} \oplus U$. Since U is G-invariant, this decomposition defines a principal connection Γ on the principal G-bundle $\rho_{|M}: M \to \overline{M}$, with horizontal subspace U_x at $x \in M$. Note, in passing, that U here represents a vector bundle of constant rank. In what follows we let X denote a fixed G-invariant solution of (15) which, moreover, belongs to F. In particular, this means that X is horizontal, i.e., $X \in U$.

Denote by $\mathbf{h}: TM \to U$ and $\mathbf{v}: TM \to \mathcal{V}$ the horizontal and vertical projectors associated with the decomposition $TM = \mathcal{V}_{|M} \oplus U$. The curvature of Γ is the tensor field of type (1,2) on M, given by

$$R = \tfrac{1}{2}[\mathbf{h}, \mathbf{h}],$$

where [,] denotes the Nijenhuis bracket of type (1,1) tensor fields. Taking into account that in the present case $\overline{U} = T\overline{M}$, and applying the method developed in Sec. V, we obtain on $\overline{M}$ a 2-form $\overline{\omega}$ (which is now a genuine differential form on $\overline{M}$) and a function $\overline{H}$ such that the projection $\overline{X}$ of X verifies

$$i_{\overline{X}} \overline{\omega} = d\overline{H}. \tag{20}$$

It should be pointed out that the reduced 2-form $\overline{\omega}$ in general need not be closed. We will show, however, that in case the given 2-form ω on P is exact, one can construct a reduced equation, equivalent to (20), but now in terms of a closed 2-form on $\overline{M}$.

Assume $\omega = d\theta$ for some 1-form θ on P. Denote by θ' the 1-form on M defined by $\theta' = j_M^* \theta$, where $j_M: M \hookrightarrow P$ is the canonical inclusion. By means of the given solution X of (15) we can construct a 1-form α_X on M as follows:

$$\alpha_X = i_X(\mathbf{h}^* d\theta' - d\mathbf{h}^* \theta'), \tag{21}$$

with the usual convention that, for an arbitrary p-form β, $\mathbf{h}^*\beta$ is the p-form defined by the prescription $\mathbf{h}^*\beta(X_1, \ldots, X_p) = \beta(\mathbf{h}(X_1), \ldots, \mathbf{h}(X_p))$.

Lemma VI.1: We have that

$$\alpha_X(Y) = \mathbf{v}(Y)(\theta'(X)) - \theta'(R(X,Y)) + \theta'(\mathbf{h}[X, \mathbf{v}(Y)]),$$

for all $Y \in \mathfrak{X}(M)$.

Proof: Indeed, for any $Y \in \mathfrak{X}(M)$ we easily find

$$\begin{aligned} \alpha_X(Y) &= i_X(\mathbf{h}^* d\theta' - d\mathbf{h}^*\theta')(Y) \\ &= \mathbf{h}X(\theta'(\mathbf{h}Y)) - \mathbf{h}Y(\theta'(\mathbf{h}X)) - \theta'[\mathbf{h}X, \mathbf{h}Y] - X(\theta'(\mathbf{h}Y)) + Y(\theta'(\mathbf{h}X)) + \theta'(\mathbf{h}[X,Y]) \\ &= \mathbf{v}Y(\theta'(X)) - \theta'(R(X,Y)) + \theta'(\mathbf{h}[X, \mathbf{v}Y]), \end{aligned}$$

taking into account that X is horizontal. Q.E.D.

Proposition VI.2: Assume, in addition, that the given action Φ *leaves* θ *invariant. Then, the 1-forms* $\mathbf{h}^*\theta'$ *and* α_X *are projectable. Moreover, the projection* $\overline{X}$ *of* X*, which is a solution of (20), also satisfies the equation*

$$i_{\overline{X}}\, d\overline{\theta'}_h = d\overline{H} - \overline{\alpha_X}, \tag{22}$$

where $\overline{\theta'}_h$ *and* $\overline{\alpha_X}$ *are the projections of the 1-forms* $\mathbf{h}^*\theta'$ *and* α_X*, respectively.*

Proof: We divide the proof in three parts: (i) the ρ-projectability of $\mathbf{h}^*\theta'$; (ii) the ρ-projectability of α_X; (iii) the derivation of the reduced equation of motion (22).

(i) Let ξ_M be the fundamental vector field on M induced by an arbitrary element $\xi \in \mathfrak{g}$. One can readily see that $i_{\xi_M}\mathbf{h}^*\theta' = 0$. We now show that also $i_{\xi_M}d(\mathbf{h}^*\theta') = 0$. Observe that for all $X' \in \mathfrak{X}(M)$ we have

$$i_{\xi_M}(d\mathbf{h}^*\theta')(X') = \xi_M(\theta'(\mathbf{h}X')) + \theta'(\mathbf{h}[\xi_M, X']).$$

Thus, for X' vertical, i.e., $X' \in \mathcal{V}$, we obtain $i_{\xi_M}(d\mathbf{h}^*\theta')(X') = 0$. Suppose now that X' is horizontal, i.e., $X' \in U$. Taking into account the G-invariance of θ' we deduce that

$$0 = \xi_M(\theta'(X')) - \theta'([\xi_M, X']).$$

Herewith we obtain

$$i_{\xi_M}(d\mathbf{h}^*\theta')(X') = \theta'([\xi_M, X'] - \mathbf{h}[\xi_M, X']) = \theta'(\mathbf{v}[\xi_M, X']) = 0,$$

since X' is horizontal.

Summarizing, we have shown that each fundamental vector field of the G-action on M is a characteristic vector field of $\mathbf{h}^*\theta'$ and, hence, the latter is a ρ-projectable 1-form.

(ii) To prove the projectability of α_X we first note that

$$i_{\xi_M}\alpha_X = i_{\xi_M} i_X(\mathbf{h}^*\, d\theta' - d\mathbf{h}^*\, \theta') = -i_{\xi_M} i_X(d\mathbf{h}^*\theta') = 0,$$

where the last equality follows by a similar argument as above, taking into account that the given X is horizontal.

Next, we prove that $i_{\xi_M} d\alpha_X = 0$. For this it suffices to show that $i_{\xi_M} d\alpha_X$ vanishes when acting on infinitesimal generators and on horizontal lifts of vector fields on $\bar{M}$. Using the previous property, i.e., $\alpha_X(\xi_M) = 0$, a straightforward calculation shows that for all $X' \in \mathfrak{X}(M)$:

$$(i_{\xi_M} d\alpha_X)(X') = \xi_M(\alpha_X(X')) - X'(\alpha_X(\xi_M)) - \alpha_X([\xi_M, X']) = \xi_M(\alpha_X(X')) - \alpha_X([\xi_M, X']).$$

From this we immediately deduce that if X' is a fundamental vector field of the group action, $i_{\xi_M}\, d\alpha_X(X') = 0$. On the other hand, if X' is the horizontal lift of a vector field Y on $\bar{M}$, i.e., $X' = Y^h$, we obtain, using Lemma VI.1 and the fact that the function $\theta'(R(X, Y^h))$ is G-invariant,

$$(i_{\xi_M}\, d\alpha_X)(Y^h) = \xi_M(\alpha_X(Y^h)) = -\xi_M(\theta'(R(X, Y^h))) = 0.$$

(iii) Recall that X satisfies an equation of the form $i_X\, d\theta = dH + \beta$, for some $\beta \in F^o$. Putting $H' = j_M^*(= H_{|M})$ and $\beta' = j_M^*\beta$, and taking into account that X is tangent to M, we can take the pull-back of this equation to M:

$$i_X\, d\theta' = dH' + \beta'.$$

Since X is horizontal, i.e., $\mathbf{h}X = X$, it follows that $\mathbf{h}^*(i_X\, d\theta') = i_X\mathbf{h}^* d\theta'$. Furthermore, H (and, hence H') being G-invariant, we have $\mathbf{h}^*\, dH' = dH'$ and, finally, it is also readily seen that $\mathbf{h}^*\beta' = 0$. The horizontal projection of the equation of motion on M therefore becomes

$$i_X\mathbf{h}^*\, d\theta' = dH'.$$

In view of the definition of the 1-form α_X, we then obtain

$$i_X\, d\mathbf{h}^*\theta' = i_X\mathbf{h}^*\, d\theta' - \alpha_X = dH' - \alpha_X.$$

All terms in this equation are projectable onto $\bar{M}$ and the reduced equation is indeed given by (22).

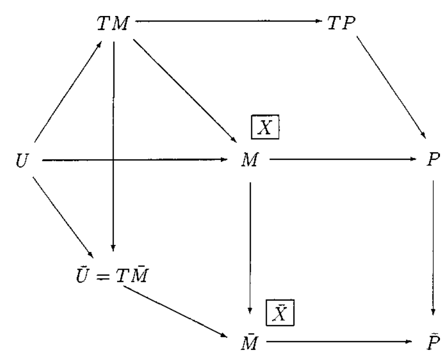
Q.E.D.

Proposition 6.2 describes a situation where a constrained Hamiltonian system (15) with symmetry, admits a reduction to an unconstrained system (22), but with an additional ''nonconservative force'' represented by $\overline{\alpha_X}$. It is interesting to observe that, by construction, the 1-form α_X satisfies

$$i_X \alpha_X = 0.$$

We now briefly comment on the problem of reconstructing the dynamics on M from the reduced dynamics on $\bar{M}$ in the case where (15) admits a unique solution X. Suppose the flow of the reduced system $\bar{X}$ is known. In order to recover flow of the constrained dynamics on M, one can first lift the integral curves of $\bar{X}$ to M by means of the horizontal lift operation associated with the principal connection Γ. The integral curves of X are then obtained by ''shifting'' these lifted curves along the fibres of $\rho_{|M}$. This second step can be implemented in the standard way.[37,38]

Finally, we can summarize the situation in the case of purely kinematic constraints in the following diagram:



B. The case of horizontal symmetries

The assumption now is that $\mathcal{V}_x \cap F_x = \mathcal{V}_x$, for all $x \in M$ or, equivalently, $\mathcal{V}_{|M} \subset F$. In particular, every infinitesimal generator of the given group action then yields a horizontal symmetry as defined at the beginning of this section. Note also that an unconstrained Hamiltonian system with symmetry can be regarded as a special subcase of this case, since we then have $M = P$, $F = TP$ and, obviously, $\mathcal{V} \subset TP$.

For the further analysis of this case we assume, in addition, that the given symplectic action Φ on P is a Hamiltonian action, in the sense that it admits an Ad*-equivariant momentum map $J: P \to \mathfrak{g}^*$, such that for all $\xi \in \mathfrak{g}$, $i_{\xi_P}\omega = d\langle J, \xi \rangle$. Let $\mu \in \mathfrak{g}^*$ be a regular value of J, and suppose that the isotropy group G_μ acts freely and properly on the level set $J^{-1}(\mu)$. It is known (see Refs. 37, 36) that under these conditions $(P_\mu = J^{-1}(\mu)/G_\mu, \omega_\mu)$ is a symplectic manifold, where ω_μ is the 2-form defined by

$$\pi_\mu^* \omega_\mu = j_\mu^* \omega,$$

with $\pi_\mu : J^{-1}(\mu) \to P_\mu$ the canonical projection and $j_\mu : J^{-1}(\mu) \hookrightarrow P$ the natural inclusion.

With ξ_P again denoting the infinitesimal generator of the group action on P, corresponding to an element $\xi \in \mathfrak{g}$, it follows from the definition of the momentum mapping that $\xi_P = X_{J_\xi}$, where $J_\xi(x) = J(x)(\xi)$ for all $x \in P$. Taking into account that, by assumption, $\mathcal{V}_{|M} \subset F$, we find that for any solution X of (15), along the constraint submanifold M,

$$X(J_\xi) = 0,$$

i.e., the components of the momentum mapping are conserved quantities for the constrained dynamics. This is a version of Noether's theorem for constrained systems. (For the case of mechanical systems with nonholonomic constraints, see in this respect also Refs. 15, 39, 35.)

Imposing a condition of clean intersection of M and $J^{-1}(\mu)$, we have that $M' = M \cap J^{-1}(\mu)$ is a submanifold of $J^{-1}(\mu)$ which is G_μ-invariant. Passing to the quotient we then obtain a submanifold $M_\mu = M'/G_\mu$ of P_μ. Next, we can define a distribution F' on P along M' by putting

$$F'_{x'} = T_{x'}(J^{-1}(\mu)) \cap F_{x'}, \quad \forall x' \in M',$$

and we now make the further simplifying assumption that F' has constant rank. It is obvious that F' is a G_μ-invariant subbundle of $TP_{|M'}$ and, hence, it projects onto a subbundle F_μ of TP_μ along M_μ. Finally, since the restriction of the Hamiltonian H to $J^{-1}(\mu)$ is also G_μ-invariant, it induces a function H_μ on P_μ.

Theorem VI.3: *Suppose that X is a G-invariant solution of (15). Then, X induces a vector field X_μ on M_μ, such that*

$$(i_{X_\mu}\omega_\mu - dH_\mu)_{|M_\mu} \in F^o_\mu, \quad X_\mu \in TM_\mu. \tag{23}$$

Proof: First of all, notice that $X' = X_{|M'}$ is everywhere tangent to M', since both $J^{-1}(\mu)$ and M are invariant submanifolds of X. Pulling back (15) to $J^{-1}(\mu)$, we find that X' satisfies an equation of the form

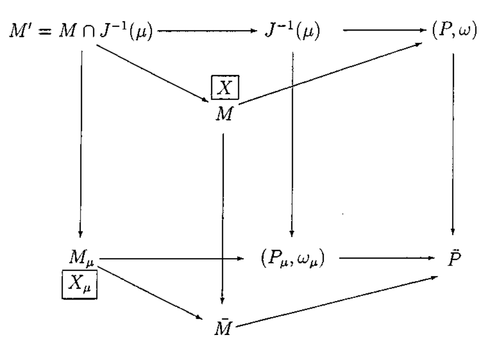
$$(i_{X'} j^*_\mu \omega - d(H \circ j_\mu))_{|M'} = \beta$$

for some section β of F'^o. Since X is G-invariant, and taking account the other symmetry assumptions, it follows that both X' and β are G_μ-equivariant sections of TM' and F'^o, respectively. Moreover, from the fact that we are dealing with horizontal symmetries we may deduce, in particular, that for all $\xi \in \mathfrak{g}_\mu$ (= the Lie algebra of G_μ), $(\xi_P)_{|M'}$ is a section of F'. Therefore, β projects onto a section of F^o_μ. Using a standard argument, it now readily follows that X' projects onto a vector field on M_μ for which (23) holds. Q.E.D.

In the case of horizontal symmetries we have thus proved that, under the appropriate assumptions, the given constrained problem on (P,ω) reduces to a constrained problem on (P_μ, ω_μ).

As far as the reconstruction of the original constrained dynamics from the reduced dynamics is concerned, we observe that, unlike in the purely kinematic case, we now first have to select an arbitrary connection on the principal G_μ-bundle $M' \to M_\mu$. This connection will enable us to subsequently lift the integral curves of the reduced system from M_μ to M'. The reconstruction of the flow of X then further proceeds as in the previous case.

The following diagram illustrates the situation in the case of horizontal symmetries. Note in passing that, modulo the appropriate embeddings, one may identify M_μ with $\bar{M} \cap P_\mu$ where, as before, $\bar{M} = M/G$.



C. The general case

We now consider the case where, at $x\in M$, $\{0\}\neq\mathcal{V}_x\cap F_x\neq\mathcal{V}_x$. Assuming again that the given action of G on P is Hamiltonian, with momentum map J, it is no longer true that J is a conserved quantity for the constrained dynamics. However, extending a procedure developed by Bloch *et al.*[15] for nonholonomic mechanical systems (see also Ref. 40), we will derive an equation which describes the evolution of some components of the momentum map along the integral curves of the constrained system.

For each $x\in M$, we put

$$\mathfrak{g}^x=\{\xi\in\mathfrak{g}\,|\,\xi_M(x)\in F_x\},$$

and

$$S^x=\{\xi_M(x)\,|\,\xi\in\mathfrak{g}^x\},$$

i.e., $S^x=\mathcal{V}_x\cap F_x$. Recall that ξ_M is just the restriction of ξ_P to the G-invariant submanifold M. We have that $\mathfrak{g}^x$ and S^x are vector subspaces of $\mathfrak{g}$ and T_xM $(\subset T_xP)$, respectively. Putting

$$\mathfrak{g}^F=\coprod_{x\in M}\mathfrak{g}^x,\quad S^F=\coprod_{x\in M}S^x,$$

where we use the symbol ''$\coprod$'' to denote the disjoint union of the respective vector spaces, we obtain two (''generalized'') vector bundles over M, with corresponding natural projections $\mathfrak{g}^F\to M:\xi\in\mathfrak{g}^x\mapsto x$ and $S^F\to M:\xi_M(x)\mapsto x$. In general, these bundles need not have constant rank. However, for the subsequent discussion we make the simplifying assumption that $\mathfrak{g}^F$ and S^F are genuine vector bundles over M, the fibers of which have constant dimension (independent of the base point). The given action being a free action, the mapping $\mathfrak{g}^F\to S^F:\xi\in\mathfrak{g}^x\mapsto\xi_M(x)$ then defines a smooth vector bundle isomorphism.

Suppose now that the symplectic form ω is exact, say $\omega=d\theta$, and that the G-action leaves θ invariant. In such a case there always exists a well-defined momentum mapping $J:P\to\mathfrak{g}^*$ such that

$$\langle J(x),\xi\rangle=-(\theta_x)(\xi_P(x)),\quad\forall x\in P,\quad\forall\xi\in\mathfrak{g}$$

(see, e.g., Ref. 37). Herewith we can define a smooth section $J^{(c)}:M\to(\mathfrak{g}^F)^*$ of the dual bundle $(\mathfrak{g}^F)^*$ as follows:

$$J^{(c)}(x):\mathfrak{g}^x\to\mathbb{R},\quad J^{(c)}(x)(\xi)=\langle J(x),\xi\rangle.$$

We may call $J^{(c)}$ the ''constrained momentum map.'' In Ref. 15, which deals with nonholonomic mechanical systems, this map was denoted by J^{nhc}. Given a smooth section $\overline{\xi}$ of the vector bundle $\mathfrak{g}^F$, we can then define a smooth function $J^{(c)}_{\overline{\xi}}$ on M according to

$$J^{(c)}_{\overline{\xi}}=\langle J^{(c)},\overline{\xi}\rangle.$$

In addition, we can construct a vector field Ξ on M by putting

$$\Xi(x)=(\overline{\xi}(x))_M(x),\quad\forall x\in M.$$

Denoting the Lie derivative operator with respect to Ξ as $\mathcal{L}_\Xi$, we have the following interesting result.

Theorem VI.4: *Let X be an arbitrary solution of (15). For any smooth section $\overline{\xi}$ of $\mathfrak{g}^F$ we then have*

$$X(J_{\xi}^{(c)}) = -(\mathcal{L}_{\Xi}\theta)(X). \tag{24}$$

Proof: Since Ξ takes values in F, it follows from (15) that, along M,

$$i_{\Xi} i_X \omega - i_{\Xi}\, dH = 0.$$

From the above definitions we further deduce that $J_{\xi}^{(c)} = -i_{\Xi}(j_M^* \theta)$, with $j_M : M \hookrightarrow P$ again denoting the inclusion map. A straightforward computation then gives

$$X(J_{\xi}^{(c)}) = -i_X\, d i_{\Xi}(j_M^*\theta) = -i_X \mathcal{L}_{\Xi}(j_M^*\theta) + i_X i_{\Xi}(j_M^*\omega) = -\mathcal{L}_{\Xi} i_X(j_M^*\theta) + i_{[\Xi,X]}(j_M^*\theta) - \Xi(H \circ j_M).$$

Since H is G-invariant, it follows from the definition of Ξ that $\Xi(H \circ j_M) = 0$. Herewith, the previous relation immediately reduces to (24) (with a slight abuse of notation). Q.E.D.

Note that for the above result we do not have to require X to be G-invariant. Equation (24) is called *the momentum equation* for the given constrained system. In the case of linear nonholonomic constraints we precisely recover the result established by Bloch *et al.*[15]

Suppose again that X is a solution of (15) and let $\overline{\xi}$ be a constant section of $\mathfrak{g}^F$, i.e., $\overline{\xi}(x) = \xi^0 \in \mathfrak{g}$ for all $x \in M$. We may then identify the corresponding vector field Ξ with the infinitesimal generator ξ_M^0 and, clearly, $J_{\xi}^{(c)} = (J_{\xi^0})_{|M}$. Moreover, by construction, ξ_M^0 is a horizontal symmetry. The momentum equation (24) then leads to

$$X(J_{\xi}^{(c)}) = X(J_{\xi^0})_{|M} = 0,$$

i.e., we have obtained a conserved quantity of X associated with the horizontal symmetry ξ_M^0. This is again a manifestation of Noether's theorem for constrained systems (cf. the previous subsection).

In the next section we will apply some of the previous results to the case of a singular Lagrangian system and to a Lagrangian system with linear nonholonomic constraints induced by a principal connection.

VII. APPLICATIONS

A. Singular Lagrangian systems

Consider a system described by a singular Lagrangian function $L: TQ \to \mathbb{R}$ such that ω_L is presymplectic. We assume that a Lie group G acts freely and properly on the configuration manifold Q and that L is invariant under the lifted action of G on TQ. It then easily follows that both ω_L and E_L are also G-invariant. In addition, we know that the lifted action of G on T^*Q leaves invariant the Liouville 1-form θ_Q and, hence, also the canonical symplectic form $\omega_Q = -d\theta_Q$ (see, e.g., Ref. 37). From all this, one can subsequently deduce that the Legendre mapping is G-equivariant and that the constraint submanifolds generated by the presymplectic constraint algorithm, both on the Lagrangian and on the Hamiltonian side, are G-invariant. In particular, the final constraint submanifold M_f in T^*Q is G-invariant.

Let us now consider the constrained equations of motion (7) where, for simplicity, we write H instead of H_1, i.e.,

$$(i_X \omega_Q - dH)_{|M_f} \in TM_1^o, \quad X_{|M_f} \in TM_f.$$

Since M_f is G-invariant, it follows that $\mathcal{V}_{|M_f} \subset TM_f \subseteq TM_1 = F$ and, hence, we are in the case of horizontal symmetries. Moreover, the lifted symplectic action of G on T^*Q admits an equivariant momentum map J and so we can apply the reduction procedure described in subsection IV B. Given a regular value μ of J, it is easy to check that the reduced system then becomes

$$(i_{X_\mu}\omega_\mu - dH_\mu)_{|(M_f)_\mu} \in (T(M_1)_\mu)^o, \quad X_\mu \in T(M_f)_\mu,$$

whereby we observe that

$$(T(M_1)_\mu)^o \subset (T(M_f)_\mu)^o.$$

Suppose, on the other hand, we would have started from the description of the given constrained system in terms of (8), again denoting the extended Hamiltonian by H, i.e.,

$$(i_X\omega_Q - dH)_{|M_f} \in TM_f^o, \quad X_{|M_f} \in TM_f. \tag{25}$$

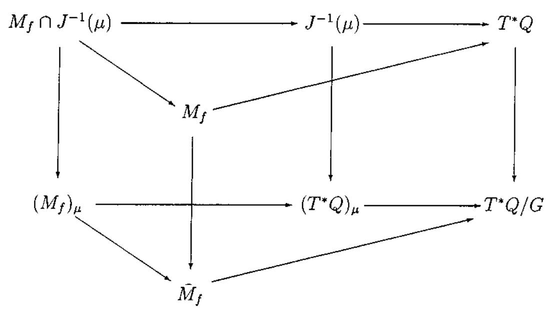
Under the given assumptions, the final constraint submanifold M_f, generated through Hinds' algorithm, will also be G-invariant such that $\mathcal{V}_{|M_f} \subset F = TM_f$, i.e., we are again in the case of horizontal symmetries. Given a regular value μ of the momentum map J, it is easy to check that we now have

$$(TM_f)_\mu^o = (T(M_f)_\mu)^o,$$

where, assuming clean intersection of M_f and $J^{-1}(\mu)$, $(M_f)_\mu = (M_f \cap J^{-1}(\mu))/G_\mu$ and $(TM_f)_\mu = (TJ^{-1}(\mu) \cap TM_f)/G_\mu$. If (25) admits a G-invariant solution X, it follows from Theorem 6.3 that the reduced dynamics will satisfy the constrained system

$$(i_{X_\mu}\omega_\mu - dH_\mu)_{|(M_f)_\mu} \in (T(M_f)_\mu)^o, \quad X_\mu \in T(M_f)_\mu. \tag{26}$$

We now have the following diagram:



Notice that, according to Proposition 3.1, the reduced system (26) admits a unique solution if and only if $T(M_f)_\mu^\perp \cap T(M_f)_\mu = 0$, which implies that $(M_f)_\mu$ is a symplectic submanifold of $(T^*Q)_\mu$. In that case we have the direct sum decomposition

$$T((T^*Q)_\mu)_{|(M_f)_\mu} = T(M_f)_\mu \oplus T(M_f)_\mu^\perp$$

and we can construct the unique solution of (26) in the following way. Let X_{H_μ} denote the Hamiltonian vector field on $((T^*Q)_\mu, \omega_\mu)$, corresponding to H_μ. The reduction X_μ of X is then obtained by first taking the restriction of X_{H_μ} to $(M_f)_\mu$, and then projecting it onto $T(M_f)_\mu$.

Example: Consider the singular Lagrangian function $L: T\mathbb{R}^6 \to \mathbb{R}$ given by

$$L = m_2(\dot{x}_2^2 + \dot{y}_2^2) + m_3(\dot{x}_3^2 + \dot{y}_3^2) + \dot{y}_2 x_2 - \dot{x}_2 y_2 + \dot{y}_3 x_3 - \dot{x}_3 y_3 - x_1^2 - y_1^2 - x_2^2 - y_2^2 - x_3^2 - y_3^2,$$

with coordinates $(x_1, y_1, x_2, y_2, x_3, y_3, \dot{x}_1, \dot{y}_1, \dot{x}_2, \dot{y}_2, \dot{x}_3, \dot{y}_3)$ on $T\mathbb{R}^6$. Here m_2 and m_3 are constants. The above Lagrangian is a particular case of those considered by Capri and Kobayashi[41,42] (see also Ref. 43). This type of Lagrangian occurs in some models of field theories coupled to external fields.

When passing to the Hamiltonian side, we obtain the following two primary constraints: $\phi_1 = p_{x_1} = 0$ and $\phi_2 = p_{y_1} = 0$ which determine the constraint submanifold M_1. The 2-form ω_1 is given in local coordinates $(x^1, y^1, x^2, y^2, x^3, y^3, p_{x_2}, p_{y_2}, p_{x_3}, p_{y_3})$ on M_1 by

$$\omega_1 = dx_2 \wedge dp_{x^2} + dy_2 \wedge dp_{y^2} + dx_3 \wedge dp_{x^3} + dy_3 \wedge dp_{y^3},$$

which is presymplectic, with

$$\ker \omega_1 = \left\langle \frac{\partial}{\partial x_1}, \frac{\partial}{\partial y_1} \right\rangle.$$

The energy function E_L projects onto the function h_1 on M_1 given by

$$h_1 = \frac{1}{4m_2}((p_{x_2}+y_2)^2 + (p_{y_2}-x_2)^2) + \frac{1}{4m_3}((p_{x_3}+y_3)^2 + (p_{y_3}-x_3)^2) + (x_1)^2 + (y_1)^2 + (x_2)^2 + (y_2)^2 + (x_3)^2 + (y_3)^2.$$

Consistency of the constraints ϕ_1 and ϕ_2 leads to the secondary constraints

$$\phi_3 = x_1 = 0, \quad \phi_4 = y_1 = 0,$$

and the constraint submanifold M_2 determined by the vanishing of the constraints ϕ_i, $1 \leqslant i \leqslant 4$, turns out to be the final constraint submanifold, i.e., $M_2 = M_f$. We note, in passing, that in this case the final constraint submanifolds generated by the Gotay–Nester algorithm and the Hinds algorithm, coincide.

Consider the function H on T^*Q with coordinate expression equal to that of h_1. (In fact, one might take any arbitrary extension of h_1 which coincides with the latter on M_f; for instance: $\tilde{H} = H + \lambda_1 \phi_1 + \lambda_2 \phi_2$ for some arbitrary functions λ_i). Note also that

$$TM_f^{\perp} = \left\langle \frac{\partial}{\partial x_1}, \frac{\partial}{\partial y_1}, \frac{\partial}{\partial p_{x_1}}, \frac{\partial}{\partial p_{y_1}} \right\rangle.$$

The constrained equations of motion (8), i.e.,

$$i_X \omega_Q - dH \in TM_f^o, \quad X \in TM_f, \tag{27}$$

admit a unique solution since $TM_f \cap TM_f^{\perp} = 0$.

The initial system admits nongauge symmetries which are rotations on the configuration space. The action

$$\Phi : \mathbb{T}^2 \times \mathbb{R}^6 \to \mathbb{R}^6,$$

where $\mathbb{T}^2$ is the two-dimensional torus, is given by

$$\Phi((\theta_2,\theta_3)\times(x^1,y^1,x^2,y^2,x^3,y^3)) = (x_1, y_1, x_2 \sin\theta_2 + y_2 \cos\theta_2, x_2 \cos\theta_2 - y_2 \sin\theta_2, x_3 \sin\theta_3 + y_3 \cos\theta_3, x_3 \cos\theta_3 - y_3 \sin\theta_3).$$

The infinitesimal generators of this action are

$$\left\langle x_i \frac{\partial}{\partial y_i} - y_i \frac{\partial}{\partial x_i} \right\rangle, \quad 2 \leqslant i \leqslant 3.$$

The infinitesimal generators of the lifted action to T^*Q are

$$\left\langle x_i \frac{\partial}{\partial y_i} - y_i \frac{\partial}{\partial x_i} + p_{x_i} \frac{\partial}{\partial p_{y_i}} - p_{y_i} \frac{\partial}{\partial p_{x_i}} \right\rangle, \quad 2 \leqslant i \leqslant 3.$$

This lifted action is symplectic and preserves the Hamiltonian H. Moreover, the manifold M_f is also $\mathbb{T}^2$-invariant.

According to our classification of constrained systems, we are in the case of horizontal symmetries, since at each point $x \in M_f$,

$$\mathcal{V}_x \cap (F_x \cap T_x M_f) = \mathcal{V}_x,$$

because $F = TM_f$.

Consider the equivariant momentum map $J: T^*Q \to \mathbb{R}^2$ given by

$$J(x_1, y_1, x_2, y_2, x_3, y_3; p_{x_1}, p_{y_1}, p_{x_2}, p_{y_2}, p_{x_3}, p_{y_3}) = (x_2 p_{y_2} - y_2 p_{x_2}, x_3 p_{y_3} - y_3 p_{x_3}).$$

For any regular value $\mu = (\mu_1, \mu_2)$, applying the cotangent bundle reduction, we have that $J^{-1}(\mu)/(\mathbb{T}^2)_\mu$ is a differentiable manifold equipped with a symplectic 2-form ω_μ. Denote by H_μ the projection of $H_{|J^{-1}(\mu)}$, and by $(M_f)_\mu$ the projection of $M_f \cap J^{-1}(\mu)$, with projection map $\pi_\mu : J^{-1}\mu \to J^{-1}(\mu)/(\mathbb{T}^2)_\mu$. Then, from Theorem 6.3 it follows that the solution of system (27) projects onto the solution of the system

$$(i_{X_\mu}\omega_\mu - dH_\mu)_{|(M_f)_\mu} \in (T(M_f)_\mu)^o, \quad X_\mu \in T(M_f)_\mu.$$

By taking polar coordinates on M_f, i.e., $(r_2, \varphi_2, r_3, \varphi_3; p_{r_2}, p_{\varphi_2}, p_{r_3}, p_{\varphi_3})$, we have that $J^{-1}(\mu) \cap M_f$ is the $(\mathbb{T}^2)_\mu$-invariant submanifold of M_f determined by

$$p_{\varphi_2} = \mu_1 \quad \text{and} \quad p_{\varphi_3} = \mu_2.$$

Passing to the quotient we find that $(M_f)_\mu$ is a four-dimensional submanifold of $J^{-1}(\mu)/(\mathbb{T}^2)_\mu$, with induced coordinates $(r_2, r_3; p_{r_2}, p_{r_3})$ and equipped with the symplectic form

$$(\omega_{M_f})_\mu = dr_2 \wedge dp_{r_2} + dr_3 \wedge dp_{r_3}.$$

B. Nonholonomic Lagrangian systems

We again consider an action of a Lie group G on a manifold Q, and let $L: TQ \to \mathbb{R}$ be a regular Lagrangian which is G-invariant. The lifted action of G on the symplectic manifold (TQ, ω_L) is then Hamiltonian. We assume that the Lagrangian system is subjected to some linear nonholonomic constraints, described by a distribution $\mathcal{D}$ on Q, such that the resulting nonholonomic system verifies the compatibility condition (cf. Sec. II B) and such that, in addition, the vector subbundle D of TQ, spanned by $\mathcal{D}$, is G-invariant. The constrained equations then read (cf. (9))

$$i_X \omega_L - dE_L \in (\mathcal{D}^v)^o, \quad X_{|D} \in TD. \tag{28}$$

We now consider an interesting special subcase of the purely kinematic case, namely, a (generalized) *Čaplygin system*. For a system of Čaplygin type, the configuration manifold Q is a principal G-bundle $\pi: Q \to Q/G$, and the constraints are given by the horizontal subspaces of a principal connection Γ on π (see Refs. 12, 24).

Under the above conditions, one can easily see that there exists a well-defined Lagrangian function $L^*: T(Q/G) \to \mathbb{R}$, given by

$$L^*(Y) = L((Y^h)_q),$$

for any $Y \in T_y(Q/G)$, where $q \in Q$ is an arbitrary point in the fiber over $y \in Q/G$ and Y^h denotes the horizontal lift of Y with respect to Γ.

A direct computation shows that, with the notations introduced in Sec. V, $\mathcal{V} \cap \mathcal{D}^v = 0$. Moreover, we have $U = \mathcal{D}^v \cap TD$, and U is symplectic with respect to ω_L. Therefore we deduce that

$$TD=\mathcal{V}\oplus U.$$

Thus, a Čaplygin system fits indeed very nice in the purely kinematic case. Moreover, one can prove that $\overline{D}=D/G\cong T(Q/G)$ and $\overline{E}_L=E_{L*}$.

We have seen that the compatibility condition,

$$(\mathcal{D}^v)^{\perp}\cap TD=0,$$

ensures the existence of a unique solution $X=\Gamma_{L,D}$ of (28) which, moreover, is a SODE. Notice that $\Gamma_{L,D}$ can be obtained by projecting the unconstrained Euler–Lagrange vector field Γ_L by means of the first projector associated with the decomposition,

$$T(TQ)_{|D}=TD\oplus(\mathcal{D}^v)^{\perp}.$$

Since $\omega_L=-d\theta_L$, the reduced equation becomes

$$i_{\overline{X}}\omega_{L*}=dE_{L*}-\overline{\alpha_{\Gamma_{L,D}}},$$

where $\overline{\alpha_{\Gamma_{L,D}}}$ is the projection of the 1-form $\alpha_{\Gamma_{L,D}}$, defined by (21). Observe that

$$i_{\overline{\Gamma}}\overline{\alpha_{\Gamma_{L,D}}}=0,$$

for any SODE $\overline{\Gamma}$ on $T(Q/G)$. This implies that $\overline{\alpha_{\Gamma_{L,D}}}$ is a 1-form of gyroscopic type.

Example VII.1: The vertical rolling disk. Consider a rolling disk of radius R constrained to remain vertical on a horizontal plane. The standard coordinates of the configuration space $\mathbb{R}\times S^1\times S^1$ are: the Cartesian coordinates x,y of the center of mass, the angle θ_1 between the tangent of the disk at the point of contact and the x-axis and the angle θ_2 determined by some diameter of the disk and the vertical.

The dynamics of this mechanical system is described by the following:

(i) the regular Lagrangian:

$$L=\tfrac{1}{2}(m\dot{x}^2+m\dot{y}^2+I_1\dot{\theta}_1^2+I_2\dot{\theta}_2^2),$$

where m is the mass, and I_1,I_2 are moments of inertia;

(ii) the nonholonomic constraints:

$$\phi_1=\dot{x}-(R\cos\theta_1)\dot{\theta}_2=0,\quad \phi_2=\dot{y}-(R\sin\theta_1)\dot{\theta}_2=0.$$

The Poincaré–Cartan 2-form of the Lagrangian L is

$$\omega_L=m\ dx\wedge d\dot{x}+m\ dy\wedge d\dot{y}+I_1\ d\theta_1\wedge d\dot{\theta}_1+I_2\ d\theta_2\wedge d\dot{\theta}_2,$$

so that the Euler–Lagrange vector field of the free (i.e., unconstrained system) is

$$\Gamma_L=\dot{x}\frac{\partial}{\partial x}+\dot{y}\frac{\partial}{\partial y}+\dot{\theta}_1\frac{\partial}{\partial\theta_1}+\dot{\theta}_2\frac{\partial}{\partial\theta_2}.$$

Consider the group $G=\mathbb{R}^2$ and its trivial action by translations on Q:

$$\Phi:G\times Q\to Q$$

$$(r,s)\times(x,y,\theta_1,\theta_2)\mapsto(x+r,y+s,\theta_1,\theta_2).$$

If we consider the lifted action Φ^1 of Φ to TQ, given by $(\Phi^1)_g=T\Phi_g$, then the infinitesimal generators of this action are

$$\mathcal{V} = \left\langle \frac{\partial}{\partial x}, \frac{\partial}{\partial y} \right\rangle.$$

One easily verifies that the constraint submanifold D, determined by ϕ_1, ϕ_2, is invariant with respect to Φ^1. Choose local coordinates $(x, y, \theta_1, \theta_2, \dot{\theta}_1, \dot{\theta}_2)$ on D. In these coordinates we find that the distribution U on D is generated by the vector fields:

$$U = \left\langle \frac{\partial}{\partial \theta_1}, \frac{\partial}{\partial \theta_2}, R \cos \theta_1 \frac{\partial}{\partial x} + R \sin \theta_1 \frac{\partial}{\partial y} + \frac{\partial}{\partial \dot{\theta}_2}, \frac{\partial}{\partial \dot{\theta}_1} \right\rangle,$$

and we readily have that $\mathcal{V}_{|D} \subset TD$ and $\mathcal{V}_{|D} \oplus U = TD$, i.e., we are in the purely kinematic case. In fact, noting that $\rho: Q \to S^1 \times S^1$ is a principal bundle, with structure group $G = \mathbb{R}^2$, and D is the horizontal subbundle of a principal connection, we see that the given system is a Čaplygin system. Following the above analysis we then obtain

$$L^* = \tfrac{1}{2}(I_1 \dot{\theta}_1^2 + (mR^2 + I_2)\dot{\theta}_2^2),$$

$$\omega_{L^*} = I_1 \, d\theta_1 \wedge d\dot{\theta}_1 + (mR^2 + I_2) d\theta_2 \wedge d\dot{\theta}_2.$$

In this particular case the gyroscopic 1-form $\overline{\alpha_{\Gamma_{L,D}}} = 0$ and then the 2-form ω_U^- is closed and

$$\omega_U^- = \omega_{L^*}.$$

Example VII.2: The two-wheeled carriage. The configuration space of the two-wheeled carriage is $Q = \mathbb{R}^2 \times S^1 \times \mathbb{T}^2$ with coordinates $(x, y, \varphi, \Psi_1, \Psi_2)$ (see, e.g., Ref. 24 for more details).

This system is determined by the following data:

(i) A regular Lagrangian L,

$$L = \tfrac{1}{2} m(\dot{x}^2 + \dot{y}^2) + m_0 l \dot{\varphi}(\dot{y} \cos \varphi - \dot{x} \sin \varphi) + \tfrac{1}{2} I \dot{\varphi}^2 + \tfrac{1}{2} C(\dot{\Psi}_1^2 + \dot{\Psi}_2^2);$$

(i) and the nonholonomic constraints,

$$\phi_1 = \dot{x} + \frac{a \cos \varphi}{2} \dot{\Psi}_1 + \frac{a \cos \varphi}{2} \dot{\Psi}_2,$$

$$\phi_2 = \dot{y} + \frac{a \sin \varphi}{2} \dot{\Psi}_1 + \frac{a \sin \varphi}{2} \dot{\Psi}_2,$$

$$\phi_3 = \dot{\varphi} + \frac{a}{2r} \dot{\Psi}_1 - \frac{a}{2r} \dot{\Psi}_2.$$

These constraints are linear in the velocities and determine a distribution $\mathcal{D}$ on Q whose annihilator is generated by the 1-forms,

$$\mu_1 = dx + \frac{a \cos \varphi}{2} d\Psi_1 + \frac{a \cos \varphi}{2} d\Psi_2,$$

$$\mu_2 = dy + \frac{a \sin \varphi}{2} d\Psi_1 + \frac{a \sin \varphi}{2} d\Psi_2,$$

$$\phi_3 = d\varphi + \frac{a}{2r} d\Psi_1 - \frac{a}{2r} d\Psi_2.$$

Consider the group of Euclidean motions in the plane, $G = \mathbb{R}^2 \times S^1$, with its standard action on Q:

$$\Phi : G \times Q \to Q,$$

$$(r,s,\theta)\times(x,y,\varphi,\Psi_1,\Psi_2)\mapsto(r+x\cos\theta-y\sin\theta, s+x\sin\theta+y\cos\theta, \theta+\varphi,\Psi_1,\Psi_2),$$

whose infinitesimal generators are

$$\left\langle \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, -y\frac{\partial}{\partial x}+x\frac{\partial}{\partial y}+\frac{\partial}{\partial\varphi}\right\rangle.$$

Observe that the distribution $\mathcal{D}$ is G-invariant and, hence, also the constraint submanifold D is preserved, that is, for all $x\in D$ and $g\in G$, $T\Phi_g(x)\in D$.

Taking $(x,y,\varphi,\Psi_1,\Psi_2,\dot\Psi_1,\dot\Psi_2)$ as coordinates on D, we have that the pull-back ω_D of the Poincaré–Cartan 2-form ω_L to D is

$$\begin{aligned}
\omega_D=&\left(-\frac{am\cos\varphi}{2}+\frac{am\sin\varphi}{2}\dot\Psi_1+\frac{am_0 l\sin\varphi}{2r}\right)dx\wedge d\dot\Psi_1\\
&+\left(-\frac{am\cos\varphi}{2}+\frac{am\sin\varphi}{2}\dot\Psi_2-\frac{am_0 l\sin\varphi}{2r}\right)dx\wedge d\dot\Psi_2\\
&+\left(-\frac{am\sin\varphi}{2}-\frac{am\cos\varphi}{2}\dot\Psi_2-\frac{am_0 l\cos\varphi}{2r}\right)dy\wedge d\dot\Psi_1\\
&+\left(-\frac{am\sin\varphi}{2}-\frac{am\cos\varphi}{2}\dot\Psi_2+\frac{am_0 l\cos\varphi}{2r}\right)dy\wedge d\dot\Psi_2\\
&+\frac{am_0 l\sin\varphi}{2r}(\dot\Psi_1-\dot\Psi_2)dy\wedge d\varphi+\frac{am_0 l\cos\varphi}{2r}(\dot\Psi_1-\dot\Psi_2)dx\wedge d\varphi\\
&-\frac{aI}{2r}d\varphi\wedge d\dot\Psi_1+\frac{aI}{2r}d\varphi\wedge d\dot\Psi_2+Cd\Psi_1\wedge d\dot\Psi_1+Cd\Psi_2\wedge d\dot\Psi_2.
\end{aligned}$$

A basis of $U=\mathcal{D}^v\cap TD$ is given by the vectors fields

$$\begin{aligned}
&\left\langle\frac{\partial}{\partial\dot\Psi_1},\frac{\partial}{\partial\dot\Psi_2},\frac{\partial}{\partial\Psi_1}-\frac{a}{2}\cos\varphi\frac{\partial}{\partial x}-\frac{a}{2}\sin\varphi\frac{\partial}{\partial y}-\frac{a}{2r}\frac{\partial}{\partial\varphi},\right.\\
&\left.\frac{\partial}{\partial\Psi_2}-\frac{a}{2}\cos\varphi\frac{\partial}{\partial x}-\frac{a}{2}\sin\varphi\frac{\partial}{\partial y}+\frac{a}{2r}\frac{\partial}{\partial\varphi}\right\rangle.
\end{aligned}$$

Observe again that D/G can be identified with the space $T(Q/G)$. The projected 2-form $\omega_{\bar U}$ is

$$\begin{aligned}
\omega_{\bar U}=&-\frac{a^3}{4r^2}m_0 l(\dot\Psi_1-\dot\Psi_2)d\Psi_1\wedge d\Psi_2+\left(\frac{ma^2}{4}+\frac{Ia^2}{4r^2}+C\right)d\Psi_1\wedge d\dot\Psi_1\\
&+\left(\frac{ma^2}{4}+\frac{Ia^2}{4r^2}+C\right)d\Psi_2\wedge d\dot\Psi_2+\left(\frac{ma^2}{4}-\frac{Ia^2}{4r^2}\right)d\Psi_1\wedge d\dot\Psi_2\\
&+\left(\frac{ma^2}{4}-\frac{Ia^2}{4r^2}\right)d\Psi_2\wedge d\dot\Psi_1.
\end{aligned}$$

This 2-form $\omega_{\bar U}$ is an almost symplectic form, that is, it is nondegenerate but not closed. The solution of the dynamics after the reduction procedure is given by

$$i_{\bar{X}}\omega_{\bar{U}} = dE_{L*},$$

where $L^*:T(\mathbb{T}^2)\rightarrow\mathbb{R}$ is defined by

$$L^*(\Psi_1,\Psi_2,\dot{\Psi}_1,\dot{\Psi}_2)=\frac{1}{8}ma^2(\dot{\Psi}_1+\dot{\Psi}_2)^2+\frac{Ia^2}{8r^2}(\dot{\Psi}_2-\dot{\Psi}_1)^2+\frac{1}{2}C(\dot{\Psi}_1^2+\dot{\Psi}_2^2).$$

Alternatively, it is possible to find an equation in terms of a symplectic 2-form, but with an additional gyroscopic type 1-form:

$$i_{\bar{X}}\omega_{L*} = dE_{L*} + \overline{\alpha_{\Gamma_{L,D}}},$$

where

$$\overline{\alpha_{\Gamma_{L,D}}}=\frac{m_0la^3}{4r^2}(\dot{\Psi}_2-\dot{\Psi}_1)\dot{\Psi}_2\, d\Psi_1-\frac{m_0la^3}{4r^2}(\dot{\Psi}_2-\dot{\Psi}_1)\dot{\Psi}_1\, d\Psi_2.$$

(Received 29 June 1998; accepted for publication 29 October 1998)

A classification of variationally trivial Lagrangians on T^*M which are invariant under the Lie algebra of infinitesimal gauge transformations of the principal bundle $\pi: M\times \mathrm{U}(1)\to M$, is given. A characterization of Lagrangian densities on T^*M which are invariant under the Lie algebra of all infinitesimal automorphisms of $M\times \mathrm{U}(1)$ is also obtained.
[S0022-2488(99)02202-1]

I. INTRODUCTION

In the theory of the electromagnetic field, the notion of gauge invariance plays an important role. Given a space–time M, a gauge potential is a differential one-form ω on the manifold M. Moreover, the cotangent bundle T^*M can be identified in a natural way with the bundle of connections of the space of phase factors $\pi: P=M\times \mathrm{U}(1)\to M$. The automorphisms of the bundle P inducing the identity over M are the gauge transformations. The infinitesimal gauge transformations (that is, the gauge algebra of P, denoted $\mathrm{gau}\,P$) are the π-vertical U(1)-invariant vector fields on P. The flow of a vector field in $\mathrm{gau}\,P$ induces a one-parameter family of automorphisms of P. Automorphisms act on connections by pulling back connection forms. Taking the derivative of this representation we thus obtain a Lie algebra representation $X\mapsto \tilde{X}$, from the gauge algebra of P into the vector fields of T^*M. It is a well-known fact that gauge invariance corresponds to invariance under this representation. More precisely, a Lagrangian density $\mathcal{L}v_n$, where v_n is a volume form on M and $\mathcal{L}$ is a differentiable function on $J^1(T^*M)$, is said to be gauge invariant if for every $X\in \mathrm{gau}\,P$ we have $L_{\tilde{X}^{(1)}}(\mathcal{L}v_n)=0$, where $\tilde{X}^{(1)}$ is the natural lifting of $\tilde{X}$ to the one-jet bundle. As $\tilde{X}^{(1)}$ is π-vertical the above condition simply says that $\tilde{X}^{(1)}(\mathcal{L})=0$. Gauge-invariant Lagrangians are classified by the so-called geometric formulation of Utiyama's theorem (see, e.g., Refs. 1–4).

In this paper we first classify Lagrangian densities which are not only gauge invariant but also invariant under the full Lie algebra of infinitesimal automorphisms of P (not necessarily π-vertical), which is denoted by $\mathrm{aut}\,P$. Note that $\mathrm{gau}\,P$ is an Abelian ideal in $\mathrm{aut}\,P$ and $\mathrm{aut}\,P/\mathrm{gau}\,P\cong\mathfrak{X}(M)$. Theorem 3 states that there is no $\mathrm{aut}\,P$-invariant Lagrangian density if $n=\dim M$ is odd, and each $\mathrm{aut}\,P$-invariant Lagrangian density is proportional to the Pfaffian if $n=\dim M$ is even. An immediate consequence is that every $\mathrm{aut}\,P$-invariant Lagrangian density is variationally trivial. Hence invariance under the full Lie algebra of infinitesimal automorphism is a too strong condition in order to be of variational interest. This poses the problem of determining all gauge-invariant Lagrangians which are also variationally trivial. This is achieved in the second part of the paper. These Lagrangians admit a natural geometric interpretation in terms of multivector fields on the ground manifold (Theorem 6). In this way we also obtain a criterion for two gauge-invariant Lagrangians $\mathcal{L},\mathcal{L}'$ to be variationally equivalent.

II. PRELIMINARIES

A. The bundle $M\times U(1)$

Given a C^∞ manifold M of dimension n, let us consider the trivial bundle $\pi:P=M\times U(1)\to M$. The bundle of connections of π can be identified with the cotangent bundle $p:T^*M\to M$. In fact, every connection form on $M\times U(1)$ can be uniquely written as $\omega_\Gamma=(d\theta+\pi^*\omega)\otimes A$, where ω is an arbitrary one-form on M, θ is the angle coordinate on U(1), and A stands for the standard basis of the Lie algebra $\mathfrak{u}(1)$; that is, A is the invariant vector field on U(1) corresponding to the homomorphism $\mathbb{R}\to U(1)$, $t\mapsto\exp(tA)$. Let $(U;q^1,\dots,q^n)$ be a coordinate open domain in M. A vector field X on P is U(1)-invariant if and only if it can be written as

$$X=f^i(q^1,\dots,q^n)\frac{\partial}{\partial q^i}+g(q^1,\dots,q^n)V,\quad f^i,g\in C^\infty(U), \tag{1}$$

where V is the fundamental vector field on P defined by A. Note that each U(1)-invariant vector field X on P is π-projectable and its projection is given by

$$\pi_*X=f^i(q^1,\dots,q^n)\frac{\partial}{\partial q^i}.$$

In particular, X is π-vertical (and hence it is a gauge vector field) if and only if $f^i=0$. We think of the Lie algebra of U(1)-invariant vector fields as being the infinitesimal automorphisms of the principal bundle P and we denote it by $\operatorname{aut}P$. Gauge vector fields are an Abelian ideal in $\operatorname{aut}P$, and we have an exact sequence of Lie algebras

$$0\to\operatorname{gau}P\to\operatorname{aut}P\xrightarrow{\pi_*}\mathfrak{X}(M)\to 0. \tag{2}$$

In fact, $\operatorname{aut}P$ is the semidirect sum of $\operatorname{gau}P$ and $\mathfrak{X}(M)$. We denote by $(p^{-1}(U);q^1,\dots,q^n,p_1,\dots,p_n)$ the coordinate system induced on the cotangent bundle. That is, $w=p_i(w)(dq^i)_x$, for every covector $w\in T_x^*M$.

B. The basic representation

Automorphisms of a principal bundle act on connections in a natural way (Ref. 5, Sec. II, Preposition 6.1). The induced representation of the Lie algebra $\operatorname{aut}P$ into the vector fields of the cotangent bundle is then given by (Ref. 2, Sec. III B)

$$\tilde{X}=f^i\frac{\partial}{\partial q^i}-\left(\frac{\partial g}{\partial q^i}+\frac{\partial f^h}{\partial q^i}p_h\right)\frac{\partial}{\partial p_i}, \tag{3}$$

where the local expression of $X\in\operatorname{aut}P$ is given by formula (1). In particular, for gauge vector fields we have

$$\tilde{X}=-\frac{\partial g}{\partial q^i}\frac{\partial}{\partial p_i},\quad X\in\operatorname{gau}P. \tag{4}$$

We remark that in this case $\tilde{X}$ is the Hamiltonian vector field associated with the function g with respect to the canonical symplectic form $dq^i\wedge dp_i$.

C. Jet prolongation

Let $p_1:J^1(T^*M)\to M$ be the first jet prolongation of the cotangent bundle. Each coordinate open domain $(U;q^1,\dots,q^n)$ in M induces a system of coordinates $(q^i,p_i;p_{i,j})$, $i,j=1,...,n$, in $p_1^{-1}(U)\subseteq J^1(T^*M)$, where $(p^{-1}(U);q^i,p_i)$ is the coordinate system induced on the cotangent bundle, which are defined by

$$p_{i,j}(j_x^1\omega)=\frac{\partial(p_i\circ\omega)}{\partial q^j}(x), \quad i,j=1,...,n.$$

From the general formulas for jet prolongation for every $X\in \operatorname{aut} P$ we obtain

$$\tilde{X}^{(1)}=f^i\frac{\partial}{\partial q^i}-\left(\frac{\partial g}{\partial q^i}+\frac{f^h}{\partial q^i}p_h\right)\frac{\partial}{\partial p_i}-\left(\frac{\partial^2 g}{\partial q^i\partial q^j}+\frac{f^h}{\partial q^i}p_{h,j}+\frac{\partial f^h}{\partial q^j}p_{i,h}+\frac{\partial^2 f^h}{\partial q^i\partial q^j}p_h\right)\frac{\partial}{\partial p_{i,j}}, \quad (5)$$

which is the jet prolongation of the algebra of infinitesimal automorphisms.

D. Lie derivative with respect to a multivector field

We recall (cf. Ref. 6; Ref. 7—p. 79) that a decomposable multivector field $\chi=X_1\wedge\ldots\wedge X_k \in\wedge^k\mathfrak{X}(M)$, induces a $C^\infty(M)$-linear graded endomorphism $i_\chi:\Omega^\cdot(M)\to\Omega^\cdot(M)$ of degree $-k$ by setting

$$i_\chi\omega_r=i_{X_1}\circ\ldots\circ i_{X_k}\omega_r\in\Omega^{r-k}(M), \quad \omega_r\in\Omega^r(M). \quad (6)$$

For an arbitrary multivector field χ we can define i_χ by extending the above formula by linearity. Then the Lie derivative $L_\chi:\Omega^\cdot(M)\to\Omega^\cdot(M)$ with respect to $\chi\in\wedge^k\mathfrak{X}(M)$ is given by the formula

$$L_\chi=i_\chi\circ d-(-1)^k d\circ i_\chi=[i_\chi,d]. \quad (7)$$

We remark that L_χ is a graded operator of degree $-k+1$.

III. INVARIANT LAGRANGIANS

A. Gauge invariance

A Lagrangian function $\mathcal{L}:J^1(T^*M)\to\mathbb{R}$ is said to be gauge invariant if

$$\tilde{X}^{(1)}(\mathcal{L})=0, \quad \forall X\in \operatorname{gau} P.$$

As the structure group is Abelian the Utiyama theorem states that a Lagrangian is gauge invariant if and only if it can be written as

$$\mathcal{L}=\bar{\mathcal{L}}\circ\Omega,$$

where $\Omega:J^1(T^*M)\to\wedge^2T^*M$ is the mapping given by $\Omega(j_x^1\omega)=(d\omega)_x$ and $\bar{\mathcal{L}}:\wedge^2T^*M\to\mathbb{R}$ is an arbitrary differentiable function (cf. Ref. 1). Let us introduce coordinates on the bundle $p_2:\wedge^2T^*M\to M$. For every two-covector $w_2\in\wedge^2T_x^*M$ we set

$$w_2=p_{ij}(w_2)(dq^i\wedge dq^j)_x, \quad i<j.$$

Then, (q^i,p_{ij}) is a coordinate system on $p_2^{-1}(U)$. We set $p_{ij}=-p_{ji}$ for $i\geqslant j$. With respect to these coordinates the equations of Ω are

$$p_{ij}\circ\Omega=p_{i,j}-p_{j,i}. \quad (8)$$

Hence gauge-invariant Lagrangians can be locally written as

$$\mathcal{L}=\bar{\mathcal{L}}(q^h,p_{i,j}-p_{j,i}).$$

B. aut P-invariance

Let us assume that M is oriented by a volume form v_n. A Lagrangian density $\mathcal{L}v_n$, $\mathcal{L}\in C^\infty(J^1(T^*M))$, is said to be invariant under the Lie algebra of all infinitesimal automorphisms of P (in short, aut P-invariant) if

$$L_{\tilde{X}^{(1)}}(\mathcal{L}v_n)=0, \quad \forall X\in \mathrm{aut}\,P.$$

As $L_{\tilde{X}^{(1)}}(\mathcal{L}v_n)=(\tilde{X}^{(1)}(\mathcal{L}))v_n+\mathcal{L}\,\mathrm{div}(\pi_* X)v_n=0$, where the divergence is taken with respect to v_n, the invariance condition is equivalent to the following:

$$\tilde{X}^{(1)}(\mathcal{L})+\mathcal{L}\,\mathrm{div}(\pi_* X)=0, \quad \forall X\in \mathrm{aut}\,P.$$

Remark: Unlike the case of gauge-invariant Lagrangians, there are no aut P-invariant Lagrangians except for constant functions. This is easily seen from formula (5). In fact, assume that the Lagrangian $\mathcal{L}$ is aut P-invariant; i.e., $\tilde{X}^{(1)}(\mathcal{L})=0$, $\forall X\in \mathrm{aut}\,P$. Taking $f^i=1$, $g=0$ in (1) we obtain $\partial\mathcal{L}/\partial q^i=0$; taking $f^i=0$, $g=q^i$, we obtain $\partial\mathcal{L}/\partial p_i=0$; finally, the choice $f^i=0$, $g=q^iq^j$ yields $\partial\mathcal{L}/\partial p_{i,j}=0$. In the next theorem we classify the aut P-invariant Lagrangian densities.

Lemma 1: Let N be a differentiable manifold. If $f\in C^\infty(\mathbb{R}^k\times N)$ satisfies $f=\Sigma_{i=1}^k x_i(\partial f/\partial x_i)$, then $\partial f/\partial x_i\in C^\infty(N)$, $1\leqslant i\leqslant k$.

Proof: From the property in the statement we obtain $f(tx,y)=tf(x,y)$, $\forall t\in\mathbb{R}$, $\forall x\in\mathbb{R}^n$, $\forall y\in N$. Hence $tf(x,y)=f(tx,y)=\Sigma_{i=1}^k tx_i(\partial f/\partial x_i)(tx,y)$ and then, $f(x,y)=\Sigma_{i=1}^k x_i(\partial f/\partial x_i)(tx,y)$. Letting $t=0$, we have $f(x,y)=\Sigma_{i=1}^k x_i(\partial f/\partial x_i)(0,y)$ and taking derivatives with respect to x_j, we conclude. □

Lemma 2: If $f\in C^\infty(\wedge^2T^*\mathbb{R}^n)$ satisfies

$$f=\sum_{j=1}^n p_{ij}(\partial f/\partial p_{ij}), \quad 1\leqslant i\leqslant n, \tag{9}$$

then,

(1) *If n is odd, then $f=0$.*
(2) *If n is even, then f is a polynomial of the form $\lambda^{i_1i_2\cdots i_{n-1}i_n}p_{i_1i_2}\cdots p_{i_{n-1}i_n}$, with $\{i_1,i_2,\ldots,i_{n-1},i_n\}=\{1,2,\ldots,n-1,n\}$, where $\lambda^{i_1i_2\cdots i_{n-1}i_n}\in C^\infty(\mathbb{R}^n)$.*

Proof: We proceed by induction on n. If $n=2$, then $f=p_{12}(\partial f/\partial p_{12})$. Hence f is proportional to p_{12}. If $n=3$, then for $i=1$, we have $f=p_{12}(\partial f/\partial p_{12})+p_{13}(\partial f/\partial p_{13})$ and for $i=2$ we also have $f=p_{21}(\partial f/\partial p_{21})+p_{23}(\partial f/\partial p_{23})$. By virtue of Lemma 1 the functions $\partial f/\partial p_{12}$, $\partial f/\partial p_{13}$ do not depend on p_{12}, p_{13} and $\partial f/\partial p_{21}=-\partial f/\partial p_{12}$, $\partial f/\partial p_{23}$ do not depend on p_{23}. Accordingly, $\partial f/\partial p_{12}$ is a constant. Similarly, $\partial f/\partial p_{13}$ is also a constant. By comparing the above two expressions of f we conclude that $\partial f/\partial p_{23}=0$ and the same occurs for the other variables.

Assume $n>3$. We set $f_i^j=\partial f/\partial p_{ij}$. For $i=1,\ldots,n$, we have $f=p_{ij}f_i^j$ and from Lemma 1 we can conclude $\partial f_i^j/\partial p_{ik}=0$. In particular, $\partial f_1^j/\partial p_{1k}=0$ and $\partial f_1^j/\partial p_{jk}=-\partial f_1^j/\partial p_{jk}=0$. In other words, f_1^j does not depend on p_{ik} for $i=1,j$, $1\leqslant k\leqslant n$. Next, we prove that f_1^j also satisfies (9) in $\wedge^2T^*\mathbb{R}^{n-2}$. In fact, for $i>1$, we have

$$f=p_{ik}\frac{\partial f}{\partial p_{ik}}=p_{ik}\frac{\partial}{\partial p_{ik}}(p_{1j}f_1^j)=-p_{i1}f_1^i+p_{ik}p_{1j}\frac{\partial f_1^j}{\partial p_{ik}},$$

and taking derivatives with respect to p_{1l}, with $l\neq i$, we obtain

$$f_1^l=\sum_{k=1}^n p_{ik}\frac{\partial f_1^l}{\partial p_{ik}}.$$

Consequently, we can apply the induction hypothesis thus concluding. □

Theorem 3: *We have*

(1) *If the dimension of M is even, say* $\dim M = 2m$, *then up to a multiplicative constant, the unique* aut P*-invariant Lagrangian density on* T^*M *is* $(Pf\circ\Omega)v_{2m}$, *where* $\mathrm{Pf}:\wedge^2 T^*M \to \mathbb{R}$ *is the Pfaffian function,* i.e.,

$$\mathrm{Pf}(w_2)v_{2m} = w_2 \wedge \overset{(m}{\ldots} \wedge w_2 .$$

(2) *If the dimension of M is odd, then zero is the unique* aut P*-invariant Lagrangian density*.

Proof: Let $(U;q^1,\ldots,q^n)$ be a coordinate open domain such that $v_n = dq^1\wedge\cdots\wedge dq^n$. Let us consider an aut P-invariant Lagrangian density $\mathcal{L}v_n$. In particular, $\mathcal{L}$ is gauge invariant. Hence from Utiyama's theorem we have $\mathcal{L}=\overline{\mathcal{L}}\circ\Omega$, where $\overline{\mathcal{L}}:\wedge^2 T^*M\to\mathbb{R}$ is an arbitrary differentiable function, or else $\mathcal{L}=\overline{\mathcal{L}}(q^h,p_{i,j}-p_{j,i})$, locally. Consequently we only need to impose invariance under the vector fields such that $g=0$. We have

$$0=\tilde{X}^{(1)}\mathcal{L}+\mathcal{L}\ \mathrm{div}(\pi_* X)=f^i\,\frac{\partial\mathcal{L}}{\partial q^i}-\left(\frac{\partial f^h}{\partial q^i}\,p_{h,j}+\frac{\partial f^h}{\partial q^j}\,p_{i,h}+\frac{\partial^2 f^h}{\partial q^i\partial q^j}\,p_h\right)\frac{\partial\mathcal{L}}{\partial p_{i,j}}+\mathcal{L}\,\frac{\partial f^i}{\partial q^i}.$$

Let us fix an index $b=1,\ldots,n$. If we take $f^a=\delta^{ab}$, $1\leqslant a\leqslant n$, then we obtain

$$\frac{\partial\mathcal{L}}{\partial q^i}=0,\quad 1\leqslant i\leqslant n. \tag{10}$$

If we take $f^a=\delta^{ab}q^b$, $1\leqslant a\leqslant n$, then we obtain

$$\mathcal{L}=p_{i,j}\,\frac{\partial\mathcal{L}}{\partial\partial p_{i,j}}+p_{j,i}\,\frac{\partial\mathcal{L}}{\partial p_{j,i}},\quad 1\leqslant i\leqslant n. \tag{11}$$

Finally, if we fix another index $c\neq b$, and take $f^a=\delta^{ab}q^c$, $1\leqslant a\leqslant n$, we obtain

$$p_{i,j}\,\frac{\partial\mathcal{L}}{\partial p_{k,j}}+p_{j,i}\,\frac{\partial\mathcal{L}}{\partial p_{j,k}}=0,\quad i,k=1,\ldots,n,\quad i\neq k. \tag{12}$$

Taking into account that

$$\frac{\partial\mathcal{L}}{\partial p_{i,j}}=\frac{\partial\overline{\mathcal{L}}}{\partial p_{ij}}\circ\Omega,$$

and that Ω is surjective, Eqs. (10)–(12) can be rewritten as

$$\frac{\partial\overline{\mathcal{L}}}{\partial q^i}=0,\quad 1\leqslant i\leqslant n. \tag{13}$$

$$\overline{\mathcal{L}}\delta^{hi}=p_{hj}\,\frac{\partial\overline{\mathcal{L}}}{\partial p_{ij}},\quad h,i=1,\ldots,n. \tag{14}$$

Letting $h=i$ in (14), from Lemma 2 we deduce that $\overline{\mathcal{L}}$ vanishes if n is odd and if n is even then $\overline{\mathcal{L}}$ is a polynomial,

$$\overline{\mathcal{L}}=\lambda^{i_1 i_2\cdots i_{n-1} i_n}p_{i_1 i_2}\cdots p_{i_{n-1} i_n}, \tag{15}$$

where $i_1,\ldots,i_n$ is a permutation of $1,\ldots,n$, and $\lambda^{i_1 i_2 \cdots i_{n-1} i_n}$ are constants due to (13). If we take $h \neq i$ in (14) we obtain

$$p_{hj}\,\frac{\partial \overline{\mathcal{L}}}{\partial p_{ij}}=0. \tag{16}$$

Taking derivatives with respect to p_{hk} in (16) we have

$$\frac{\partial \overline{\mathcal{L}}}{\partial p_{ij}}+p_{hj}\,\frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{hk}\partial p_{ij}}=0,$$

and taking derivatives with respect to p_{hl} in the above equation, we have

$$\frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{hl}\partial p_{ik}}+\frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{hk}\partial p_{il}}=0, \tag{17}$$

as the third partial derivative with respect to p_{hl}, p_{hk}, p_{il} vanishes by virtue of (15). Equation (17) tells us that $\lambda^{i_1,\ldots,k,\ldots,l,\ldots,i_n}+\lambda^{i_1,\ldots,l,\ldots,k,\ldots,i_n}=0$, and since the transpositions generate the group of permutations we obtain

$$\lambda^{\pi(1),\ldots,\pi(n)}=(\operatorname{sgn}\,\pi)\lambda^{1,\ldots,n},$$

for every permutation π of $1,\ldots,n$, and the result follows from the very definition of the Pfaffian [cf. Ref. 8 formula (4.12), p. 66; Ref. 5, Sec. XII]. □

Remark: Once the function $\mathcal{L}$ is known to be a polynomial of degree *m*, the above result can be also obtained from (Ref. 9, Theorem 2.6.2), taking into account the remark below.

Remark: Let $\pi: P \to M$ be an arbitrary principal U(1)-bundle and let us denote by $p:\mathcal{C}(P) \to M$ the bundle of connections of P (see, e.g., Ref. 10). As in the case of the trivial bundle, we can introduce coordinates (q^i, p_j) on the bundle $\mathcal{C}(P)$. Then, it is not difficult to see that the manifold $J^1(\mathcal{C}(P))$ is endowed with a canonical horizontal two-form locally given by $\eta=(p_{i,j}-p_{j,i})dq^i \wedge dq^j$. This form enjoys the following characteristic property. If $\sigma_\Gamma: M \to \mathcal{C}(P)$ is the section of p induced from a connection Γ on P, then $\pi^*(j^1\sigma_\Gamma)^*\eta=\Omega_\Gamma$, the curvature form of the given connection. Because of this, the form η can be called the universal Chern form of line bundles.

Taking into account the above observation, it is worth mentioning that the first item of Theorem 3 can be interpreted by saying that the only aut P-invariant Lagrangian densities for connections on P are constant multiples of the m-fold wedge product of the universal Chern form.

IV. VARIATIONALLY TRIVIAL LAGRANGIANS

A Lagrangian density $\mathcal{L}v_n$, $\mathcal{L}\in C^\infty(J^1(T^*M))$, is said to be variationally trivial if every differential one-form is a solution to the Euler–Lagrange equations of the given Lagrangian; that is, for every differential form ω defined on a neighborhood of a point $x \in M$ we have

$$\frac{\partial \mathcal{L}}{\partial p_i}\,(j_x^1\omega)-\frac{\partial}{\partial q^k}\left(\frac{\partial \mathcal{L}}{\partial p_{i,k}}\circ j^1\omega\right)(x)=0. \tag{18}$$

Proposition 4: A Lagrangian density $\mathcal{L}v_n$ on T^*M is variationally trivial if and only if the following partial differential equations hold true:

$$\frac{\partial^2 \mathcal{L}}{\partial p_{i,h}\partial p_{j,k}}+\frac{\partial^2 \mathcal{L}}{\partial p_{i,k}\partial p_{j,h}}=0, \quad \forall h,i,j,k=1,\ldots,n, \tag{19}$$

$$\frac{\partial \mathcal{L}}{\partial p_i} = \frac{\partial^2 \mathcal{L}}{\partial q^k \partial p_{i,k}} + \frac{\partial^2 \mathcal{L}}{\partial p_j \partial p_{i,k}} p_{j,k}, \quad \forall i = 1,...,n. \tag{20}$$

Proof: Expanding Eq. (18) we obtain

$$\frac{\partial \mathcal{L}}{\partial p_i}(j_x^1\omega) = \frac{\partial^2 \mathcal{L}}{\partial q^k \partial p_{i,k}}(j_x^1\omega) + \frac{\partial^2 \mathcal{L}}{\partial p_j \partial p_{i,k}}(j_x^1\omega)\frac{\partial f_j}{\partial q^k}(x) + \frac{\partial^2 \mathcal{L}}{\partial p_{j,h} \partial p_{i,k}}(j_x^1\omega)\frac{\partial^2 f_j}{\partial q^h \partial q^k}(x),$$

where $\omega = f_j dq^j$. Once the one-jet of ω at x has been fixed, the second partial derivatives $(\partial^2 f_j / \partial q^h \partial q^k)(x)$ can be arbitrarily taken. Hence Eq. (19) follows and also Eq. (20). □

Notation 5: Given a multivector field $\chi_k \in \Gamma(M, \wedge^{2k}TM)$ of even degree $2k$, we denote by $\overline{\chi_k} : \wedge^2 T^*M \to \mathbb{R}$ the function given by

$$\overline{\chi_k}(w_2) = i_{\chi_k}(w_2 \wedge \overset{(k}{\ldots} \wedge w_2), \quad w_2 \in \overset{2}{\wedge} T^*M,$$

where i_χ is the total insertion operator (cf. Sec. II D).

Theorem 6: *A gauge-invariant Lagrangian density $\mathcal{L}v_n$ on T^*M is variationally trivial if and only $\mathcal{L}$ can be written as follows:*

$$\mathcal{L} = \overline{\chi} \circ \Omega,$$

where $\Omega : J^1(T^*M) \to \wedge^2 T^*M$ is the curvature mapping (see Sec. III A) *and*

$$\overline{\chi} = \sum_{k=0}^{[n/2]} \overline{\chi_k},$$

χ_k being a multivector field of degree $2k$, such that $L_{\chi_k} v_n = 0$ (cf. Sec. II D).

Proof: As $\mathcal{L}v_n$ is gauge invariant according to Utiyama's theorem (Sec. III A) we have

$$\mathcal{L} = \overline{\mathcal{L}} \circ \Omega,$$

where $\overline{\mathcal{L}}$ is an arbitrary differentiable function on $\wedge^2 T^*M$. As $\mathcal{L}$ must also be variationally trivial, the above composition should satisfy Eqs. (19) and (20). Taking into account the equations of Ω [see formula (8)] we have

$$\frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{ih} p_{jk}} \circ \Omega + \frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{ik} \partial p_{jh}} \circ \Omega = 0, \quad \forall h,i,j,k = 1,...,n,$$

and

$$\frac{\partial^2 \overline{\mathcal{L}}}{\partial q^k \partial p_{ik}} \circ \Omega = 0, \quad \forall i = 1,...,n,$$

as $\partial \mathcal{L} / \partial p_i$, $\partial^2 \mathcal{L} / \partial p_j \partial p_{i,k}$ vanish for $\mathcal{L}$ does not depend on p_i. Since Ω is a surjective mapping we obtain the corresponding equations for $\overline{\mathcal{L}}$ on the bundle $\wedge^2 T^*M$, i.e.,

$$\frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{ih} \partial p_{jk}} + \frac{\partial^2 \overline{\mathcal{L}}}{\partial p_{ik} \partial p_{jh}} = 0, \quad \forall h,i,j,k = 1,...,n, \tag{21}$$

$$\frac{\partial^2 \overline{\mathcal{L}}}{\partial q^k \partial p_{ik}} = 0, \quad \forall i = 1,...,n. \tag{22}$$

From (21) we obtain $\partial^2 \overline{\mathcal{L}}/\partial p_{ih}^2 = 0$. Hence for each variable p_{ih} we have $\overline{\mathcal{L}} = a + b p_{ih}$, where a,b are differentiable functions depending on q^j and the rest of the variables p_{kl}. By recurrence we conclude that $\overline{\mathcal{L}}$ is a polynomial in the variables p_{ih} with coefficients in $C^\infty(M)$; that is,

$$\overline{\mathcal{L}} = \sum_k f^{i_1 \cdots i_{2k}} p_{i_1 i_2} \cdots p_{i_{2k-1} i_{2k}}, \quad f^{i_1 \cdots i_{2k}} \in C^\infty(M). \tag{23}$$

For $k = h$, from (21) we conclude that the functions $f^{i_1 \cdots i_{2k}}$ with a repeated index, must vanish. For arbitrary indices, Eq. (21) tells us that $f^{i_1, \dots, j, \dots, l, \dots, i_{2k}} + f^{i_1, \dots, l, \dots, j, \dots, i_{2k}} = 0$. Hence

$$f^{i_{\pi(1)}, \dots, i_{\pi(2k)}} = (\operatorname{sgn} \pi) f^{i_1, \dots, i_{2k}},$$

for every permutation π of $1,...,2k$, and therefore

$$\overline{\mathcal{L}} = \sum_{k=0}^{[n/2]} \sum_{i_1 < \cdots < i_{2k}} \sum_{\pi \in \mathfrak{S}_{2k}} (\operatorname{sgn} \pi) f^{i_1, \dots, i_{2k}} p_{i_{\pi(1)} i_{\pi(2)}} \cdots p_{i_{\pi(2k-1)} i_{\pi(2k)}}.$$

Hence $\overline{\mathcal{L}} = \overline{\chi} = \Sigma_{k=0}^{[n/2]} \overline{\chi}_k$, where

$$\chi_k = (-1)^{\binom{2k}{2}} 2^k \sum_{i_1 < \cdots < i_{2k}} f^{i_1, \dots, i_{2k}} \frac{\partial}{\partial q^{i_1}} \wedge \cdots \wedge \frac{\partial}{\partial q^{i_{2k}}}.$$

Let us check that Eq. (22) implies that each multivector field χ_k is divergence free. Let $(U; q^1, \dots, q^n)$ be a coordinate open domain such that $v_n = dq^1 \wedge \cdots \wedge dq^n$. By using the formula (7) in Sec. II D, we have

$$\begin{aligned} c_k(L_{\chi_k} v_n) &= (-1)^{k+1} \sum_{i_1 < \cdots < i_{2k}} d(f^{i_1, \dots, i_{2k}} i_{\partial/\partial q^{i_1} \wedge \cdots \wedge \partial/\partial q^{i_{2k}}} (dq^1 \wedge \cdots \wedge dq^n)) \\ &= - \sum_{i_1 < \cdots < i_{2k}} (-1)^{i_1 + \cdots + i_{2k}} d(f^{i_1, \dots, i_{2k}} dq^{j_1} \wedge \cdots \wedge dq^{j_{n-2k}}), \end{aligned}$$

where $c_k = (-1)\binom{2k}{2} 2^{-k}$ and $j_1 < \cdots < j_{n-2k}$ is the complementary subset of $i_1 < \cdots < i_{2k}$ in $\{1,...,n\}$. Hence

$$c_k(L_{\chi_k} v_n) = - \sum_{i_1 < \cdots < i_{2k}} (-1)^{i_1 + \cdots + i_{2k}} \sum_\alpha \frac{\partial f^{i_1, \dots, i_{2k}}}{\partial q^\alpha} dq^\alpha \wedge dq^{j_1} \wedge \cdots \wedge dq^{j_{n-2k}}.$$

If $j_0 < \cdots < j_{n-2k}$ is the complementary subset of $i_2 < \cdots < i_{2k}$ in $\{1,...,n\}$, then the coefficient of $dq^{j_0} \wedge dq^{j_1} \wedge \cdots \wedge dq^{i_{n-2k}}$ in the above formula is

$$(-1)^{i_2 + \cdots + i_{2k}} \sum_\alpha \frac{\partial f^{\alpha, i_2, \dots, i_{2k}}}{\partial q^\alpha},$$

where for (not necessarily increasing) pairwise different indices $i_1, \dots, i_{2k}$ we have set $f^{i_1, \dots, i_{2k}} = (\operatorname{sgn} \pi) f^{\pi(i_1), \dots, \pi(i_{2k})}$, π being the unique permutation of the set $\{i_1, \dots, i_{2k}\}$ such that $\pi(i_1) < \cdots < \pi(i_{2k})$. Accordingly, $L_{\chi_k} v_n = 0$ if and only if

$$\sum_\alpha \frac{\partial f^{\alpha, i_2, \dots, i_{2k}}}{\partial q^\alpha} = 0. \tag{24}$$

Moreover, from the formula (23) we have

$$\frac{\partial^2 \overline{\mathcal{L}}}{\partial q^\alpha \partial p_{j\alpha}} = \sum_{k=0}^{[n/2]} \frac{\partial f^{i_1,\ldots,i_{2k}}}{\partial q^\alpha} \frac{\partial p_{i_1 i_2} \cdots p_{i_{2k-1} i_{2k}}}{\partial p_{j\alpha}} = \sum_{k=0}^{[n/2]} k \frac{\partial f^{j,\alpha,i_3 \cdots i_{2k}}}{\partial q^\alpha} p_{i_3 i_4} \cdots p_{i_{2k-1} i_{2k}}.$$

Hence the formula (22) holds true if and only if

$$\sum_\alpha \frac{\partial f^{j,\alpha,i_3 \cdots i_{2k}}}{\partial q^\alpha} = 0,$$

which is equivalent to (24), thus finishing the proof of the theorem. □

Corollary 7: Every aut P*-invariant Lagrangian density on* T^*M *is variationally trivial.*

Proof: If dim M is odd, the result is trivial as in odd dimensions every aut P-invariant Lagrangian density vanishes by virtue of Theorem 3. Assume dim $M = n = 2m$. In this case, on a coordinate system such that $v_n = dq^1 \wedge \cdots \wedge dq^n$, as a simple calculation shows we have $Pf = \overline{\chi_m}$, where

$$\chi_m = (-1)^{\binom{n}{2}} \frac{\partial}{\partial q^1} \wedge \cdots \wedge \frac{\partial}{\partial q^n},$$

and $L_{\chi_m} v_n = 0$ obviously. □

On the geometric structure of thermodynamics

M. Chen
Vanier College, 821 Ste. Croix Avenue, St. Laurent, Quebec H4L 3X9, Canada

(Received 5 October 1998; accepted for publication 28 October 1998)

In this paper we consider symmetry transformations of the generalized entropy function that preserve the Gibbs one-form (Gibbs relation). We show that this symmetry consideration naturally leads to the geometric structure of thermodynamics in terms of contact geometry. We also construct an example based on the van der Waals' fluid to illustrate the method discussed in the paper. © *1999 American Institute of Physics.* [S0022-2488(99)03102-3]

I. INTRODUCTION

It is well known that Legendre transformations play an important role in equilibrium thermodynamics (ET).[1] In 1973 Hermann[2] suggested that ET might be reformulated in a geometric setting in terms of a contact manifold M. Since then several geometric theories of ET have been proposed in the past.[3] Recently Mrugala *et al.*[4] further investigated the applications of contact geometry to ET, where thermodynamic processes were considered as the flows of a vector field in TM, the tangent bundle of M. The work of Mrugala *et al.* was modified and extended to irreversible thermodynamics by Chen and Tseng.[5] In this paper we reexamine the symmetry property of the second law of thermodynamics and show that this symmetry consideration naturally gives rise to the intrinsic geometric structure of thermodynamics.

Consider a system of molecules in r components contained in a volume V, where no chemical reactions take place. Let E be the total internal energy of the system, N_i be the number of molecules of species i, P be the hydrostatic pressure, and μ_i be the chemical potential corresponding to N_i. In ET the work one-form dW is given by $dW=-P\,dV+\sum_i\mu_i\,dN_i$. In order to consider irreversible processes we enlarge the set of conserved variables (E,V,N_i) by including the nonconserved variables Φ_i^α, where Φ_i^α denotes the various generalized fluxes such as the mass flux, heat flux, etc.[6] Thus, $\{E,V,N_i,\Phi_i^\alpha;\ i=1,2,...,r;\ \alpha=1,2,...,k\}$ is the set of global thermodynamic variables. Note that the index α represents the different kinds of fluxes. For simplicity we denote $\{E,V,N_i,\Phi_i^\alpha\}$ by $(x^1,x^2,\ldots,x^n)=(x^1,\hat{x})$, where x^i is a differentiable function of time t. Let B_n be the thermodynamic space with coordinate cover x. The work one-form for a dissipative system can be written as

$$dW=-P\,dV+\sum_i \mu_i\,dN_i-\sum_{i,\alpha} X_i^\alpha\,d\Phi_i^\alpha, \tag{1}$$

where X_i^α is the generalized potential conjugate to the generalized fluxes Φ_i^α.[6] Hereafter we assume that P, μ_i, and X_i^α are functions of x of class C^1 on an open set of B_n with compact support. These functions are the constitutive relations based on phenomenological considerations.

The global formulation of the first law can be expressed as

$$\Delta E=\Delta W+\Delta Q+\Delta Q_d, \tag{2}$$

while the second law can be expressed as[7]

$$\Omega\wedge d\Omega=0, \tag{3a}$$

$$\Delta Q_d\geqslant 0. \tag{3b}$$

Here $\Omega = dE - dW$ and ΔQ represents the net amount of heat exchanged between the system and its surroundings, while ΔQ_d represents the change of dissipative energy associated with irreversible processes. We assume that ΔQ_d is semipositive definite and vanishes only at thermodynamic equilibrium. It should be noticed that ΔQ and ΔQ_d cannot be considered as one-forms in the vector space $\wedge(B_n)$ of differential forms in B_n, while $\Omega = dE - dW$ is a one-form in $\wedge^1(B_n)$.[8]

Let γ be a closed path in B_n. It can be proved that the second law formulated in (3a) and (3b) is equivalent to Clausius' inequality[9]

$$\int_\gamma T^{-1}\, dQ \leqslant 0,$$

as well as Kelvin's principle.[10]

Denote $\{-P, \mu_i, -X_i^\alpha;\ i=1,2,...,r;\ \alpha=1,2,...,k\}$ by $(w_2, w_3, \ldots, w_n)$. Then the work one-form dW can be rewritten as

$$dW = \sum_{j \geqslant 2} w_j(x)\, dx^j, \tag{4}$$

and the one-form $\Omega = dE - dW$ as

$$\Omega = dE - dW = dx^1 - \sum_{j \geqslant 2} w_j(x)\, dx^j. \tag{5}$$

It can be shown that the Caratheodory inaccessibility condition (3a) (or Frobenius integrability condition[11]) is equivalent to the Maxwell relations $\partial_j w_k = \partial_k w_j$ for $j,k \geqslant 2$.[7] Consequently, there exists a C^2 function H defined in B_n such that $w_j = -\partial_j H$, $j \geqslant 2$. The function H is closely related to the generalized Helmholtz potential function[5] which can be obtained by solving the Pfaffian equation $\Omega = 0$. Hence we consider the following equation;

$$dx^1 = \sum_{j \geqslant 2} w_j(x)\, dx^j, \quad x^1(0) = u, \tag{6}$$

where u is a real number. Fix $\hat{a} = (a^2, \ldots, a^n)$ and set $\hat{x} = \hat{a}t$. By assumption w_j is a C^1 function in an open subset of B_n with compact support. According to the theory of ordinary differential equations, (6) has a unique solution curve $x^1 = \hat{F}(t,u,\hat{a})$ such that $x^1(0) = u$. Since $x^1 = \hat{F}(\alpha t, u, \alpha^{-1} a)$ also satisfies (6),

$$x^1 = \hat{F}(t,u,\hat{a}) = \hat{F}(\alpha t, u, \alpha^{-1} a)$$

is the unique solution of (6). Set $\alpha t = 1$ and denote $\hat{F}(1,u,\hat{a}t) = F(u,\hat{a}t)$. Then

$$x^1 = F(u,\hat{a}t), \quad x^1(0) = F(u,0) = u.$$

The solution of (6) depends continuously on the initial value of u. In order to obtain the solution surface of the Pfaffian equation $\Omega = 0$, we consider u as well as $\hat{a}t$ as a new set of coordinate variables in a neighborhood (nbd) U of the origin ($u=0$, $\hat{a}t=0$). Without loss of generality we denote the new variables $\hat{a}t$ by $\hat{x}^*$. Let $(u,\hat{x}^*)$ be an arbitrary point in U and let D be an open subset of B_n. Define $G: U \to D$ by $G(u,\hat{x}^*) = (x^1, \hat{x})$ where $x^1 = F(u,\hat{x})$, $\hat{x} = \hat{x}^*$. Since the determinant of the Jacobian matrix of G does not vanish at the origin, by the inverse function theorem there exists an open subset $U_1 \subset U$ containing the origin, such that $G|U_1$ has an inverse which is a C^1 function defined on $V = G(U_1)$ containing $G(0) = 0 \in V$. This inverse function is given by

$$G^{-1}(x) = (f(x), \hat{x}) = (u, \hat{x}),$$

that is, $u=f(x)$ if and only if $x^1=F(u,\hat{x})$. We now identify $H=-F$ so that $w_j=\partial_j F$, $j\geqslant 2$. Therefore

$$\Omega=dx^1-\sum_{j\geqslant 2} w_j(x)\,dx^j=(\partial_u F)du+\sum_{j\geqslant 2}(\partial_j F-w_j)\,dx^j=(\partial_u F)\,du,$$

where $\partial_u F=\partial F/\partial u$. Since $(\partial_u F)(x)\neq 0$, we have $du=[(\partial_u F)(x)]^{-1}\Omega$. If we identify $(\partial_u F)\times(x)$ as the thermodynamic temperature T in absolute temperature scale, and $u=S=f(x)$ as the generalized entropy function, then

$$\Omega=TdS=dE+PdV-\sum_i \mu_i\,dN_i+\sum_{i,\alpha} X_i^\alpha\,d\Phi_i^\alpha \tag{7}$$

is the generalized Gibbs one-form (Gibbs relation).

In the next section we consider symmetry transformations of the generalized entropy surface $u=S=f(x)$ that preserve the contact condition specified by the Gibbs one-form (7).

II. INVARIANCE OF THE SECOND LAW

From a mathematical point of view it is evident that Caratheodory's inaccessibility condition (3a) is equivalent to the Gibbs one-form (7). Thus we consider the symmetry transformations of the generalized entropy surface that preserve the one-form (7). Let $(x,u)\in B_n\times R^1$ and consider the transformations

$$x^*=F(x,u),\quad u^*=G(x,u), \tag{8}$$

where G and $F=(F_1,\ldots,F_n)$ are differentiable functions. Furthermore, we assume that the transformation $(x,u)\to(x^*,u^*)$ is one-to-one. By (8) $u=f(x)$ becomes $u^*=f^*(x^*,u^*)$, where f^* is a C^1 function. Denote $y=(y_1,\ldots,y_n)$, $y^*=(y_1^*,\ldots,y_n^*)$, and $y_i=\partial_i f$, $y_i^*=\partial_i^* f^*$, where ∂_i, ∂_u, ∂^i, ∂_i^*, and ∂_u^* are partial differentiation operators with respect to the variables x^i, u, y_i, $(x^*)^i$, and u^*, respectively. Now (8) preserves the contact condition

$$du^*=\sum_i y_i^*\,d(x^*)^i=y_i^*\,d(x^*)^i,$$

if and only if

$$(D_i F)u_j^*=D_i G,\quad D_i=\partial_i+y_i\partial_u\,. \tag{9}$$

Here we have adopted the summation convention over repeated indices. Let

$$A=\begin{bmatrix} D_1F_1 & \cdots & D_1F_n\\ \vdots & & \vdots\\ D_nF_1 & \cdots & D_nF_n\end{bmatrix}$$

and assume that A is invertible. Then (9) can be rewritten as

$$\begin{bmatrix} y_1^*\\ \vdots\\ y_n^*\end{bmatrix}=A^{-1}\begin{bmatrix} D_1G\\ \vdots\\ D_nG\end{bmatrix}. \tag{10}$$

Thus (8) and (10) lead to the following extended transformation $(x,u,y)\to(x^*,u^*,y^*)$ given by

$$x^*=F(x,u),\quad u^*=G(x,u),\quad y^*=H(x,u,y). \tag{11}$$

Suppose the transformations in (11) define a one-parameter Lie group of transformations

$$(x^*)^i = F^i(x,u;\varepsilon), \quad u^* = G(x,u;\varepsilon), \quad y_i^* = H_i(x,u,y;\varepsilon). \tag{12}$$

Consider the infinitesimal transformations of (12):

$$\begin{aligned} (x^*)^i &= x^i + \xi^i(x,u)\varepsilon + O(\varepsilon^2), \\ u^* &= u + \eta(x,u)\varepsilon + O(\varepsilon^2), \\ y_i^* &= y_i + \eta_i(x,u,y)\varepsilon + O(\varepsilon^2). \end{aligned} \tag{13}$$

According to (10) and (13) the infinitesimal generator X of (13) can be obtained easily as[12]

$$X = \xi^i(x,u)\partial_i + \eta(x,u)\partial_u + \eta_i(x,u,y)\partial^i \tag{14}$$

with

$$\eta_i = D_i\eta - (D_i\xi^j)y_j = (\partial_i + y_i\partial_u)g, \tag{15}$$

where $g = \eta - y_j\xi^j$ is a C^1 function of (x,u,y). Hence (3a) is invariant under (13) if and only if (15) is satisfied. We conclude this section with a discussion on Legendre transformations in ET.[1] Let $u = f(x)$ and consider the following transformations:

$$x_i^* = F^i(x,u,y), \quad u^* = G(x,u,y), \quad y_i^* = H_i(x,u,y). \tag{16}$$

In order to preserve the one-form $du^* = y_i^* d(x^*)^i$, y_i^* must satisfy the conditions

$$D_kG = (D_kF^i)y_i^*, \quad \partial^kG = (\partial^kF^i)y_i^*. \tag{17}$$

Now let

$$\begin{aligned} u^* &= G(x,u,y) = -u + \sum_{i=1}^{m} y_i x^i, \quad m \leqslant n, \\ x^* &= F(x,u,y) = (y_1,\ldots,y_m, x^{m+1},\ldots,x^n), \quad m \leqslant n. \end{aligned} \tag{18}$$

By (17) we have

$$y_i^* = \begin{cases} x^i, & i = 1,2,\ldots,m, \\ -y_{m+i}, & i = 1,2,\ldots,n-m. \end{cases} \tag{19}$$

Define the transformation ρ: $R^{2n+1} \to R^{2n+1}$ by

$$\rho(x,u,y) = (x^*,u^*,y^*),$$

where x^*, u^* and y^* are given by (18) and (19). Let $\omega = du - y_i dx^i$ and $\omega^* = du^* - y_i^* d(x^*)^i$. Furthermore, let ρ^* be the pull back of ρ. Then $\rho^*\omega^* = -\omega$ and $\rho^2 = I$ (identity). Hence ρ is a partial Legendre involution. Define

$$L = \{(x,u,y) \in R^{2n+1} | u = f(x), y_i = \partial_i f\}$$

and

$$L^* = \{(x^*,u^*,y^*) \in R^{2n+1} | u^* = f^*(x^*), y_i^* = \partial_i^* f^*\}.$$

Then $L^* = \rho L$. Therefore (3a) is invariant under ρ. Notice that L represents the fundamental equation of state in ET.

The discussions presented in this section can be reformulated in a more geometric setting in terms of contact geometry. This will be discussed in the next section.

III. CONTACT GEOMETRY IN THERMODYNAMICS

In the previous section we considered the symmetry transformations of the generalized entropy surface that preserved the inaccessibility condition of Caratheodory. We also discussed the partial Legendre involutions in ET. These discussions naturally lead to the basic concept of contact geometry we now elucidate. Although some of our discussions in the following overlap somewhat with the work of Mrugala *et al.*,[4] our approach is different. It further clarifies and supplements the work presented in Ref. 4.

Let B_n be the thermodynamic space with coordinate cover $x = (E, V, N_i, \Phi_i^\alpha) = (x^1, x^2, \ldots, x^n)$, and let $G = R \times B_n$ with coordinate cover $(u,x) = (S,x)$, where $u = S = f(x)$ is the generalized entropy function of class C^1 on B_n. Denote the conjugate variables of x by $y = (T^{-1}, PT^{-1}, -\mu_i T^{-1}, X_i^\alpha T^{-1}) = (y_1, y_2, \ldots, y_n)$ so that $y_i = \partial f$. Consider $M = G \times B_n$ with coordinate cover (u,x,y) where u,x,y are independent variables. Define the one-form $\omega = du - y_i dx^i$ in M. For every $x \in B_n$ the vector space $\Delta_x = \{ v \in T_x M \,|\, \langle w(x), v(x) \rangle = w_i v^i = 0; w(x) = w_i(x) dx^i, v(x) = v^i(x) \partial_i \}$ is called the contact hyperplane to M at x. Since $\omega \wedge (d\omega)^n \neq 0$ and $\omega \wedge (d\omega)^{n+1} = 0$, the one-form ω defines a nondegenerate hyperplane distribution $x \rightarrow \Delta_x$, where Δ_x is the kernel of ω. This distribution of the hyperplanes (field of hyperplanes) is called the contact structure of M. If λ is a nowhere vanishing function on M, then $\lambda\omega$ defines the same contact structure of M. The differentiable manifold M equipped with such a one-form ω is called a contact manifold.[13] Thus M is a $(2n+1)$-dimensional manifold which can be identified as $M = T^*(B_n) \times R$, where $T^*(B_n)$ is the contangent bundle of B_n.

Notice that M can also be identified with the one-jet space $J^1(B_n, R)$ from B_n into R, which is a vector bundle with base B_n. The fiber at $x \in B_n$ is $R \times T^*(B_n)$. The jet $j_x^1 f$ is the pair $(f(x), df(x))$ and the canonical projection $\pi: M \rightarrow B_n$ is the mapping $j_x^1 f \rightarrow x$. A section of M is a mapping $\sigma: B_n \rightarrow M$ such that $\pi \circ \sigma(x) = x$ for every $x \in B_n$. Hence the mapping $j^1 f: x \rightarrow j_x^1 f = (f(x), df(x))$ defines a global section of M such that $(j^1 f)^* \omega = 0$. The image of B_n under $j^1 f$ is the one-graph space L given by

$$L = \{ (u,x,y) \in M \,|\, u = f(x), y_i = \partial_i f \}, \tag{20}$$

which is an n-dimensional Legendre submanifold of M. Therefore, the generalized entropy surface $u = f(x)$ can be used to define a Legendre submanifold with $y = (T^{-1}, PT^{-1}, -\mu_i T^{-1}, X_i^a T^{-1})$ as the conjugate variables of the thermodynamics variables x, and Gibbs one-form (7) can be utilized to define the contact one-form ω in M.

Next we consider the transformations in (13) as transformations in the contact manifold M. To this end we let $\eta - y_i \xi^i = g$. Then $\xi^i = -\partial^i g$. In view of (14) and (15) the infinitesimal generator X of (13) can be expressed as

$$\begin{aligned} X &= \xi^i(x,u)\partial_i + \eta(x,u)\partial_u + \eta_i(x,u,y)\partial^i \\ &= g\partial_u + \{ -(y_j \partial^j g)\partial_u + (y_i \partial_u g)\partial^i + [(\partial_i g)\partial^i - (\partial^i g)\partial_i] \} \\ &= X_v + X_H, \end{aligned} \tag{21}$$

with $X_v = g\partial_u$ and X_H given in the curly bracket.

Suppose $\hat{X} = v^i \partial_i$ and $\theta = \theta_i dx^i$. An inner multiplication between $\hat{X}$ and θ is defined by $\hat{X} \lrcorner \theta = i(\hat{X})\theta = v^i \theta_i$. Thus $\partial_i \lrcorner dx^j = \delta_i^j$. The following results can be easily verified:

$$i(X_v)\omega = g, \quad i(X_v)d\omega = 0, \tag{22a}$$

$$i(X_H)\omega=0, \quad i(X_H)d\omega=i(x)d\omega=-Dg, \tag{22b}$$

where $Dg=dg-[i(X_u)dg]\omega$, $X_u=\partial_u$. Thus $X_v\in\ker\omega$ and $X_H\in\ker d\omega$ where $\ker d\omega$ is a vector bundle generated by X_u. Therefore X is a vector field in the tangent bundle TM and the decomposition of X into a vertical component X_v and a horizontal component X_H is unique.

The infinitesimal generator X generates a one-parameter group of transformations $\rho_\tau=T(\tau)=e^{iX\tau}:M\to M$ in (12) with $\varepsilon=\tau$. Let $L(X)$ be the Lie derivative associated with X. Then

$$L(X)\omega=i(X)d\omega+di(X)\omega=(\partial_u g)\omega=\lambda\omega. \tag{23}$$

Hence the contact ideal generated by ω is invariant under ρ_τ. Since $(f,df)\to(f^*,df^*)$ under ρ_τ and the graph of j^1f is a Legendre submanifold of M, thus a Legendre submanifold L is carried into another Legendre submanifold L^* by ρ_τ. By assumption the dissipative energy ΔQ_d is semipositive definite for any irreversible process (independent of ρ_τ); the second law formulated in (3a) and (3b) is therefore invariant under the contact transformations generated by X.

It should be noticed that the construction of the vector field X in (21) depends on an arbitrary function $g(x,u,y)$ defined on M, such that, $\xi^i(x,u)=-\partial^i g$, $\eta(x,u)=g+y_i\xi^i(x,u)$ and $\eta_i=(\partial_i+y_i\partial_u)g$. In fact, there is a one-to-one correspondence between a C^1 function g defined on K with the properties specified above and the vector field $X\in TM$. This one-to-one correspondence gives rise to an isomorphism ψ from the Lie algebra of vector fields in TM onto the vector space of real-valued functions on M, whose Lie algebra structure is defined by the Jacobi bracket $[g_1,g_2]=i([X_{g_1},X_{g_2}])\omega$.

Once X is determined, the flows of X are governed by the following equations:

$$\frac{du}{d\tau}=\eta(x,u), \quad \frac{dx^i}{d\tau}=\xi^i(x,u), \quad \frac{dy_i}{d\tau}=\eta_i(x,u,y). \tag{24}$$

Consider the projection of the flow equations on L:

$$\left.\frac{du}{d\tau}\right|_L=\eta(x,f(x))=(\partial_i f)\left.\frac{dx^i}{d\tau}\right|_L=(\partial_i f)\xi^i(x,f(x)).$$

This implies that $g=\eta-y_i\xi^i$ vanishes on L. Conversely if $g|_L=0$, then the flows of X lie on L. Thus $X_L=\xi^i(x,u)\partial_i+\eta(x,u)\partial_u$ is the projection of X on L, while X is the lift of X_L from TL to TM.

For an illustration of this argument we conclude this paper with an example on the van der Waals fluid with constant heat capacity in ET. Let $x^1=E$, $x^2=V$, $y_1=\partial_1 f=T^{-1}$, $y_2=\partial_2 f=PT^{-1}$, $x=(x^1,x^2)$, and $y=(y_1,y_2)$, where the entropy function S is given by

$$u=S=f(x^1,x^2)=\frac{3}{2}R\ln\left(x^1+\frac{a}{x^2}\right)+R\ln(x^2-b)-\left[\frac{3}{2}R\ln c_v+R\ln R\right]. \tag{25}$$

Here R is the gas constant and c_v is the specific heat at constant volume.

A vector field X_L on the entropy surface can be written as

$$X_L=\eta(x,u)\partial_u+\xi^1(x,u)\partial_1+\xi^2(x,u)\partial_2$$

with $\eta(x,u)=R/(x^2-b)$, $\xi^1=a/(x^2)^2$, and $\xi^2=1$, where a, b are constants. This vector field is constructed such that $i(X_L)\theta=0$, $\theta=du-y_i dx^i$. Next we lift X_L to the contact manifold M with coordinate cover (x^1,x^2,u,y_1,y_2). Define the scalar-valued function g by

$$g(x^1,x^2,u,y_1,y_2)=\eta(x,u)-y_1\xi^1(x,u)-y_2\xi^2(x,u).$$

Then

$$\eta_1=(\partial_1+y_1\partial_u)g=0$$

and

$$\eta_2=(\partial_2+y_2\partial_u)g=-\frac{R}{(x^2-b)^2}+\frac{2ay_1}{(x^2)^3}.$$

Consequently, the vector field X can be written as

$$X=\eta\partial_u+\xi^i\partial_i+\eta_i\partial^i,$$

which yields the following flow equations:

$$\frac{dx^1}{d\tau}=\xi^1(x,u)=\frac{a}{(x^2)^2},\quad \frac{dx^2}{d\tau}=1,$$

$$\frac{dy_1}{d\tau}=\eta_1(x,u,y)=0,\quad \frac{dy_2}{d\tau}=\eta_2(x,u,y)=-\frac{R}{(x^2-b)^2}+\frac{2ay_1}{(x^2)^3},$$

$$\frac{du}{d\tau}=\eta(x,u)=\frac{R}{x^2-b}.$$

We now solve these flow equations. First, $dx^2/d\tau=1$. We set $x^2=\tau$. Then $dx^1=[a/(x^2)^2]dx^2$. So $x^1=-a/x^2+c_1$ or $x^1+a/x^2=c_1$. Next, $dy_1/d\tau=0$. Thus, $y_1=T^{-1}=\text{const}$. Let $c_1=3RT/2$. Then $y_1=\partial_1 f=T^{-1}=\frac{3}{2}R(x^1+a/x^2)^{-1}$, which yields the constitutive relation

$$x^1=E=\frac{3RT}{2}-\frac{a}{V}.$$

The equation for y_2 has the solution $y_2=R/(x^2-b)-ay_1/(x^2)^2+c_2$. If we set $c_2=0$, we immediately obtain the second constitutive relation

$$y_2=PT^{-1}=\partial_2 f=\frac{R}{x^2-b}-\frac{3R}{2}\left(x^1+\frac{a}{x^2}\right)^{-1}\frac{a}{(x^2)^2}$$

or

$$\left(P+\frac{a}{V^2}\right)(V-b)=RT.$$

The equation for u can be rewritten as

$$\begin{aligned}du&=\frac{R}{x^2-b}dx^2=(\partial_1 f)dx^1+(\partial_2 f)dx^2\\&=\frac{3R}{2}\left(x^1+\frac{a}{x^2}\right)^{-1}dx^1+\left[\frac{R}{x^2-b}-\frac{3R}{2}\left(x^1+\frac{a}{x^2}\right)^{-1}\frac{a}{(x^2)^2}\right]dx^2,\end{aligned}\tag{26}$$

which yields the solution given by (25). Furthermore, we can show that g vanishes on the entropy surface $u=S=f(x^1,x^2)$.[14]

This example shows that the flows of X give rise to the constitutive relations. We remark that this example is different from the one given in Ref. 4, which describes an unphysical system since the results there depend on an unbounded continuous parameter. Further, it is incomprehensible that the equation of states for an ideal gas can be transformed into those of a real gas through a sequence of contact transformations ρ_τ as stated in Ref. 4.

Finally, it is interesting to note that for some model equations describing irreversible processes, the dynamical equations of the thermodynamic variables can be embedded in the flows of the vector field X.[15]

Green's function of the Fokker–Planck equation: General formula of frequency expansion

Toru Miyazawa[a)]
Department of Physics, Gakushuin University, Tokyo 171-8588, Japan

(Received 28 April 1998; accepted for publication 12 November 1998)

The one-variable Fokker–Planck equation is studied in its general form by means of an algebraic method. An expression of the Green's function is derived as an expansion in powers of the square root of frequency. The expansion coefficient of arbitrary order is expressed as a functional of the potential in terms of integrals. © *1999 American Institute of Physics.* [S0022-2488(99)03402-7]

I. INTRODUCTION

In this paper we study the one-variable Fokker–Planck equation describing the Brownian motion of a particle in an external potential. It has the form[1]

$$\frac{\partial}{\partial t}P(x;t)=\frac{\partial^2}{\partial x^2}P(x;t)-2\frac{\partial}{\partial x}[f(x)P(x;t)], \tag{1.1}$$

$$f(x)=-\frac{1}{2}\frac{d}{dx}V(x), \tag{1.2}$$

where $P(x;t)$ denotes the probability density of the particle, and $V(x)$ is the external potential. This equation is a fundamental equation describing fluctuations in nonequilibrium phenomena, and it is of considerable importance in various fields of physics.

The Green's function plays the most important role in diffusion problems. We define the Green's function $G(x,x';t)$ as the solution of (1.1) satisfying the initial condition $P(x;t=0)=\delta(x-x')$. It can be interpreted as the transition probability, i.e., the probability density of finding the particle at position x at time t under the condition that it was initially at position x'. Let $G(x,x';\omega)$ denote the Fourier–Laplace transform of $G(x,x';t)$ with respect to time:

$$G(x,x';\omega)=\int_0^\infty e^{i\omega t}G(x,x';t)dt. \tag{1.3}$$

If the potential $V(x)$ is an x-independent constant, the Green's function has the well-known form

$$G(x,x';t)=\frac{1}{\sqrt{4\pi t}}e^{-(x-x')^2/(4t)}, \tag{1.4}$$

and, correspondingly,

$$G(x,x';\omega)=\frac{i}{2\kappa}e^{i\kappa|x-x'|}, \tag{1.5}$$

where κ is defined by

$$\kappa^2 = i\omega, \quad \operatorname{Im} \kappa \geqslant 0. \tag{1.6}$$

We are going to study $G(x,x';\omega)$ for general $V(x)$. For the time being, let us assume that both $V(+\infty) \equiv \lim_{x\to+\infty} V(x)$ and $V(-\infty) \equiv \lim_{x\to-\infty} V(x)$ are finite, and that $V(x)$ tends to these limits sufficiently fast. (We also discuss other cases later.) The Green's function can be expressed as a power series in terms of κ as

$$G(x,x';\omega) = \frac{i}{2\kappa} e^{-V(x)} [p_0 + i\kappa p_1 + (i\kappa)^2 p_2 + (i\kappa)^3 p_3 + \cdots]. \tag{1.7}$$

(The expansion coefficients p_i depend on x and x'. We have singled out the factor $e^{-V(x)}$ so as to make p_i more symmetric.) By Fourier transforming this expression, we can obtain a large-t expansion of $G(x,x';t)$. Thus, the power-series expression (1.7) is important for analyzing the long-time behavior. (See the Appendix for a more detailed description.) The main objective in this paper is to derive an expression of the expansion coefficient p_i for general order i. It is expressed as a functional of $V(x)$ in terms of integrals involving $V(x)$.

A method for calculating p_i was discussed in a previous work.[2] However, only an algorithm for calculation was given there, and, in practice, only the first few terms of expansion could be calculated by that method. In the present paper we use a different, more sophisticated method, and derive a more explicit formula for the expansion coefficient of arbitrary order.

It is well known that the Fokker–Planck equation (1.1) is equivalent to the Schrödinger equation with the potential $V_S(x) \equiv [f(x)]^2 + f'(x)$. It has been customary to study the Fokker–Planck equation by transforming it into the Schrödinger equation, for which various methods of solution are available. The method developed in this paper is different from any existing method for solving the Schrödinger equation. So we may apply this new method to problems described by the Schrödinger equation as well. The frequency expansion formula derived here provides a general and systematical method for the analysis of quantum-mechanical problems in the low-energy region.

We use as our starting point an algebraic expression of the Green's function, which was derived in a previous paper.[3] We review this expression in Sec. II. Sections III and IV are devoted to mathematical preliminaries. Section V contains the main result of the present paper. An expression for the coefficients of expansion is derived here. In Sec. VI we discuss some properties of these expansion coefficients. In Sec. VII the power series expansion is studied in relation to the behavior of the potential at infinity.

II. ALGEBRAIC EXPRESSION

Here we review the algebraic expression of the Green's function, which is the starting point for the analysis in the present paper. Only the result is shown here. The derivation is given in Ref. 3.

We consider a set of operators $J_\pm$, J_3, and $Q_\pm$ satisfying the following commutation relations:

$$[J_3, J_+] = J_+, \quad [J_3, J_-] = -J_-, \quad [J_+, J_-] = 2J_3, \tag{2.1a}$$

and

$$\begin{gathered} [J_3, Q_+] = \tfrac{1}{2} Q_+, \quad [J_+, Q_+] = 0, \quad [J_-, Q_+] = Q_-, \\ [J_3, Q_-] = -\tfrac{1}{2} Q_-, \quad [J_+, Q_-] = Q_+, \quad [J_-, Q_-] = 0, \\ \{Q_+, Q_+\} = -2J_+, \quad \{Q_-, Q_-\} = 2J_-, \quad \{Q_+, Q_-\} = 2J_3, \end{gathered} \tag{2.1b}$$

where $[A,B]=AB-BA$ and $\{A,B\}=AB+BA$. These operators constitute a Lie superalgebra[4] that is called OSp(1/2). (Note that this superalgebra has no relation to the well-known ''super-symmetiric'' structure[5] of the Fokker–Planck equation.) As can be seen from (2.1a), the operators J_3, J_+, and J_- are generators of SU(2) [or its complex form SL(2,**C**)]. As usual, we also use the notation

$$J_1=(J_+ + J_-)/2, \quad J_2=-i(J_+ - J_-)/2. \tag{2.2}$$

The operators $J_\pm$, J_3, and $Q_\pm$ act on vectors belonging to a certain representation space. We define an inner product in the representation space, which we denote by $(\cdots,\cdots)$. We require that it should have the following properties:

$$(\Phi,J_3\Psi)=(J_3\Phi,\Psi), \quad (\Phi,J_\pm\Psi)=-(J_\mp\Phi,\Psi), \quad (\Phi,Q_\pm\Psi)=(Q_\mp\Phi,\Psi), \tag{2.3}$$

where Ψ and Φ are arbitrary vectors. As an inner product, it should also satisfy

$$(\Psi,c_1\Phi_1+c_2\Phi_2)=c_1(\Psi,\Phi_1)+c_2(\Psi,\Phi_2), \quad (\Psi,\Phi)=(\Phi,\Psi)^*, \tag{2.4}$$

but the condition of positive definiteness is not necessary.

We let Ψ_0 denote the lowest state, which is the vector annihilated by Q_-:

$$Q_-\Psi_0=0. \tag{2.5}$$

We define the evolution operator $U(x,x')$ as the solution of

$$\frac{\partial}{\partial x}U(x,x')=[2i\kappa J_3-2f(x)J_1]U(x,x'), \tag{2.6}$$

with the initial condition $U(x=x')=1$ (identity operator). Here $f(x)$ is the function that appears in the Fokker–Planck equation (1.1), and κ is the complex number defined by (1.6). The operator $U(x,x')$ depends on κ, though we do not write it explicitly.

With these definitions, we can express the Green's function of the Fokker–Planck equation as

$$G(x,x';\omega)=\frac{g_0}{2}\frac{(\Psi_0,U(\infty,x)(Q_++Q_-)U(x,x')(Q_++Q_-)U(x',-\infty)\Psi_0)}{(\Psi_0,U(\infty,-\infty)J_3\Psi_0)}, \tag{2.7}$$

with

$$g_0\equiv\frac{i}{2\kappa}e^{-[V(x)-V(x')]/2}. \tag{2.8}$$

[In this paper we assume $x\geqslant x'$ without loss of generality. The expression for $x'\geqslant x$ is obtained by interchanging x and x' in (2.7).] Equation (2.7) holds in any representation as long as (2.1), (2.3), (2.5), and (2.6) are satisfied. We can obtain various expressions for the Green's function by writing (2.7) in specific representations.

III. REPRESENTATION OF SL(2,*C*)

Equation (2.7) is a purely algebraic expression; the operators J_3, $J_\pm$, and $Q_\pm$ in (2.6) and (2.7) can be any operators as long as the commutation relations (2.1) are satisfied. We can obtain a specific expression for the Green's function by choosing a specific form of these operators. We wish to obtain the power series expression (1.7) by writing (2.7) in an appropriate representation. Here and in the next section we make technical preparations for this purpose. (The method we use here is an extension of the techniques employed in Ref. 6 for studying the scattering coefficients.)

Let us first focus our attention on J_3 and $J_\pm$, leaving $Q_\pm$ aside for the time being. We consider a realization of the commutation relations (2.1a) in terms of differential operators of the form

$$J_3^{(\nu)}=\frac{\nu}{2}\cosh w+\sinh w\,\frac{\partial}{\partial w},$$
$$J_\pm^{(\nu)}=\mp\frac{\nu}{2}\sinh w+(1\mp\cosh w)\,\frac{\partial}{\partial w}, \tag{3.1}$$

where ν is a real parameter. These operators act on functions of w, which we assume to be a complex variable; namely, the representation space is the space of analytic functions of w. The background of (3.1), as well as the meaning of w, is explained in Ref. 6. However, for our present purpose it it not necessary to be concerned about the meaning of (3.1). Here it suffices to note only that the operators (3.1) with arbitrary ν indeed satisfy the commutation relations (2.1a). In terms of J_1 and J_2 these expressions read as

$$J_1^{(\nu)}=\frac{\partial}{\partial w},\quad J_2^{(\nu)}=i\,\frac{\nu}{2}\sinh w+i\cosh w\,\frac{\partial}{\partial w},\quad J_3^{(\nu)}=\frac{\nu}{2}\cosh w+\sinh w\,\frac{\partial}{\partial w}. \tag{3.2}$$

Also, let us remark that (3.1) can be rewritten as

$$J_3^{(\nu)}=2\left(\cosh\frac{w}{2}\sinh\frac{w}{2}\right)^{1-\nu/2}\frac{\partial}{\partial w}\left(\cosh\frac{w}{2}\sinh\frac{w}{2}\right)^{\nu/2}, \tag{3.3a}$$

$$J_+^{(\nu)}=-2\left(\sinh\frac{w}{2}\right)^{2-\nu}\frac{\partial}{\partial w}\left(\sinh\frac{w}{2}\right)^{\nu},\quad J_-^{(\nu)}=2\left(\cosh\frac{w}{2}\right)^{2-\nu}\frac{\partial}{\partial w}\left(\cosh\frac{w}{2}\right)^{\nu}. \tag{3.3b}$$

We define the function $u_0^{(\nu)}(w)$ as

$$u_0^{(\nu)}(w)\equiv\left(\cosh\frac{w}{2}\right)^{-\nu}. \tag{3.4}$$

From (3.3b) we find that $u_0^{(\nu)}$ is the lowest state in the representation space satisfying

$$J_-^{(\nu)}u_0^{(\nu)}=0. \tag{3.5}$$

Substituting (3.4) into (3.3a), we obtain

$$J_3^{(\nu)}u_0^{(\nu)}=\frac{\nu}{2}u_0^{(\nu)}. \tag{3.6}$$

This relation means that the quantity $-\nu/2$ corresponds to the spin. Thus, the number ν serves as a label of the representation. In this paper we deal with infinite-dimensional representations with $\nu\geqslant 0$.

We construct the basis $u_n^{(\nu)}$ ($n=0,1,2,...$) by repeatedly applying $J_+^{(\nu)}$ to the lowest state:

$$u_n^{(\nu)}(w)\equiv(-1)^n\frac{1}{n!}(J_+^{(\nu)})^n u_0^{(\nu)}(w)=\binom{\nu+n-1}{n}\left(\cosh\frac{w}{2}\right)^{-\nu}\left(\tanh\frac{w}{2}\right)^{n}, \tag{3.7}$$

where the binomial coefficient is defined as

$$\binom{\nu+n-1}{n}\equiv\frac{\nu(\nu+1)\cdots(\nu+n-1)}{n!}. \tag{3.8}$$

[For $n=0$ we have $\binom{\nu-1}{0}=1$.] We define the inner product between basis states as

$$(u_m^{(\nu)},u_n^{(\nu)})^{(\nu)}\equiv\binom{\nu+n-1}{n}\delta_{mn}. \tag{3.9}$$

[The meaning of the basis (3.7) and the inner product (3.9) is also explained in Ref. 6.] By rescaling the basis as

$$\psi_n^{(\nu)}\equiv\frac{1}{\sqrt{\binom{\nu+n-1}{n}}}u_n^{(\nu)}, \tag{3.10}$$

we can rewrite (3.9) as

$$(\psi_m^{(\nu)},\psi_n^{(\nu)})^{(\nu)}=\delta_{mn}. \tag{3.11}$$

The inner product of arbitrary two states is determined by (3.11) with the property of linearity (2.4).

We let $A^\dagger$ denote the adjoint of A, satisfying

$$(A^\dagger\phi_1,\phi_2)^{(\nu)}=(\phi_1,A\phi_2)^{(\nu)}, \tag{3.12}$$

for arbitrary ϕ_1 and ϕ_2. It is easy to show that the basis states satisfy

$$J_3^{(\nu)}\psi_n^{(\nu)}=\left(\frac{\nu}{2}+n\right)\psi_n^{(\nu)}, \tag{3.13a}$$

$$J_+^{(\nu)}\psi_n^{(\nu)}=-\sqrt{(\nu+n)(n+1)}\,\psi_{n+1}^{(\nu)},\quad J_-^{(\nu)}\psi_n^{(\nu)}=\sqrt{(\nu+n-1)n}\,\psi_{n-1}^{(\nu)}. \tag{3.13b}$$

From (3.13) and (3.11) it is obvious that

$$(J_3^{(\nu)})^\dagger=J_3^{(\nu)},\quad (J_\pm^{(\nu)})^\dagger=-J_\mp^{(\nu)}. \tag{3.14}$$

For an operator A we define its kernel A_K as

$$A_K(w_1,w_2^*)\equiv\sum_{n=0}^{\infty}[A\psi_n^{(\nu)}(w_1)][\psi_n^{(\nu)}(w_2)]^*. \tag{3.15}$$

[Strictly speaking, the expression $A\psi_n^{(\nu)}(w_1)$ should read as $(A\psi_n^{(\nu)})(w_1)$.] By using the completeness of the basis, we can rewrite (3.15) as

$$\begin{aligned}A_K(w_1,w_2^*)&=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\psi_m^{(\nu)}(w_1)(\psi_m^{(\nu)},A\psi_n^{(\nu)})^{(\nu)}[\psi_n^{(\nu)}(w_2)]^*\\&=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\psi_m^{(\nu)}(w_1)(A^\dagger\psi_m^{(\nu)},\psi_n^{(\nu)})^{(\nu)}[\psi_n^{(\nu)}(w_2)]^*\\&=\sum_{n=0}^{\infty}\psi_n^{(\nu)}(w_1)[A^\dagger\psi_n^{(\nu)}(w_2)]^*.\end{aligned} \tag{3.16}$$

The kernel of the identity operator is obtained as

$$I_K^{(\nu)}(w_1,w_2^*)=\sum_{n=0}^{\infty}\psi_n^{(\nu)}(w_1)[\psi_n^{(\nu)}(w_2)]^*=\left[\cosh\left(\frac{w_1-w_2^*}{2}\right)\right]^{-\nu}, \tag{3.17}$$

where we have used (3.10), (3.7), and the formula $\Sigma_n \binom{\nu+n-1}{n}x^n=(1-x)^{-\nu}$. We also define the operator $\overleftarrow{A}$, which operates to the left, as

$$\phi(w)\overleftarrow{A}\equiv(A^\dagger)^*\phi(w). \tag{3.18}$$

[Here the asterisk means that we take complex conjugate of scalars included in the operator. For example, from (3.2) we have $(J_2^{(\nu)})^*=-J_2^{(\nu)}$. Note that w is not replaced by w^*.]

For the convenience of notation, we shall hereafter write w and w' in place of w_1 and w_2^*. The kernel of identity is written as

$$I_K^{(\nu)}(w,w')=\left[\cosh\left(\frac{w-w'}{2}\right)\right]^{-\nu}. \tag{3.19}$$

From (3.15), (3.16), and (3.17) it follows that

$$A_K(w,w')=AI_K^{(\nu)}(w,w')=I_K^{(\nu)}(w,w')\overleftarrow{A}', \tag{3.20}$$

where A' is the operator obtained from A by replacing w with w'. Here we are assuming that the differential operator A acts on w and not on w'; similarly, $\overleftarrow{A}'$ acts on w' and not on w.

Matrix elements of an operator A can be easily obtained from its kernel A_K. In particular, since $\psi_0(0)=1$ and $\psi_n(0)=0$ $(n\neq 0)$, from the first line of (3.16) we find

$$(\psi_0^{(\nu)},A\psi_0^{(\nu)})^{(\nu)}=A_K(w=w'=0). \tag{3.21}$$

Corresponding to (2.6), we define the evolution operator restricted within SL(2,**C**) as the solution of

$$\frac{\partial}{\partial x}U^{(\nu)}(x,x')=[2i\kappa J_3^{(\nu)}-2f(x)J_1^{(\nu)}]U^{(\nu)}(x,x'),\quad U^{(\nu)}(x=x')=1, \tag{3.22}$$

with $J_1^{(\nu)}$ and $J_3^{(\nu)}$ given by (3.2). Just like $J_1^{(\nu)}$ and $J_3^{(\nu)}$, this $U^{(\nu)}(x,x')$ is a differential operator that acts on functions of w. [Note that the operator $U^{(\nu)}$ represents an element of the SL(2,**C**) Lie group.] Here we make a position-dependent shift of the variable,

$$w\rightarrow W\equiv w+V(x), \tag{3.23}$$

and express $U^{(\nu)}(x,x')$ in terms of W rather than w. Under (3.23) the partial derivatives change as

$$\frac{\partial}{\partial x}\rightarrow\frac{\partial}{\partial x}+\frac{dV}{dx}\frac{\partial}{\partial W}=\frac{\partial}{\partial x}-2f(x)\frac{\partial}{\partial W},\quad \frac{\partial}{\partial w}\rightarrow\frac{\partial}{\partial W}, \tag{3.24}$$

and so (3.22) becomes

$$\frac{\partial}{\partial x}U^{(\nu)}(x,x')=i\kappa[e^{-V(x)}\hat{J}_+^{(\nu)}+e^{V(x)}\hat{J}_-^{(\nu)}]U^{(\nu)}(x,x'),\quad U^{(\nu)}(x=x')=1, \tag{3.25}$$

where

$$\hat{J}_+^{(\nu)}\equiv e^{W}\left(\frac{\nu}{2}+\frac{\partial}{\partial W}\right),\quad \hat{J}_-^{(\nu)}\equiv e^{-W}\left(\frac{\nu}{2}-\frac{\partial}{\partial W}\right). \tag{3.26}$$

Let us remark that $\hat{J}_+$ and $\hat{J}_-$, together with $\hat{J}_3 \equiv \partial/\partial W$, satisfy the commutation relations (2.1a). Since $\hat{J}_\pm^{(\nu)} = e^{\pm V(x)}(J_3^{(\nu)} \mp iJ_2^{(\nu)})$, from (3.14) we find

$$(\hat{J}_\pm^{(\nu)})^\dagger = \hat{J}_\pm^{(\nu)}. \tag{3.27}$$

The solution of (3.25) is obtained as[6]

$$U^{(\nu)}(x,x') = \sum_{n=0}^{\infty} (i\kappa)^n \sum_{\{s_i=\pm 1\}} [s_1,\ldots,s_n]_{x'}^{x} \hat{J}_{-s_n}^{(\nu)} \cdots \hat{J}_{-s_1}^{(\nu)}, \tag{3.28}$$

where we have introduced the notation

$$[s_1,s_2,\ldots,s_n]_{x'}^{x} \equiv \int \cdots \int_{x' \leq y_1 \leq y_2 \leq \cdots \leq y_n \leq x} dy_1 \cdots dy_n \exp\left[\sum_{i=1}^{n} s_i V(y_i)\right] \quad (s_i = \pm 1). \tag{3.29}$$

The second summation in (3.28) is over $s_1 = \pm 1$, $s_2 = \pm 1$,...,$s_n = \pm 1$. Here $\hat{J}_{-s}^{(\nu)}$ stands for $\hat{J}_-^{(\nu)}$ and $\hat{J}_+^{(\nu)}$ for $s = +1$ and $s = -1$, respectively. (Note that $\hat{J}_{-s}^{(\nu)}$ with $s = -1$ is not $\hat{J}_1^{(\nu)}$.) The term of order $n = 0$ in (3.28) should be understood as the identity operator. The integrations in (3.29) are carried out in the interval (x',x) with the restriction $y_{i-1} \leq y_i \leq y_{i+1}$.

It is easy to check that the operator $U^{(\nu)}$ given by (3.28) indeed satisfies (3.25). The expression (3.28) is the expansion of the evolution operator in powers of κ. The coefficients of expansion are expressed in terms of integrals defined by (3.29). We shall see later that the expansion coefficients p_i of the Green's function [see Eq. (1.7)] can be expressed in terms of integrals of the form (3.29), too.

Let us consider the kernel of the evolution operator. According to (3.20) we may write

$$U_K^{(\nu)} = U^{(\nu)}(x,x') I_K^{(\nu)}(w,w') = U^{(\nu)}(x,x') \left[\cosh\left(\frac{w-w'}{2}\right)\right]^{-\nu}. \tag{3.30}$$

Since the expression (3.28) [with (3.26)] is written in terms of W, it is natural to express $U_K^{(\nu)}$ as a function of W rather than w. The evolution operator $U^{(\nu)}(x_2,x_1)$ transfers the position from x_1 to x_2; so the position-dependent shift (3.23) implies $W = w + V(x_1)$ before the operation of $U^{(\nu)}(x_2,x_1)$, and $W = w + V(x_2)$ after the operation. Therefore, the variable w in the expression $\cosh[(w-w')/2]$ in Eq. (3.30) is to be replaced by $W - V(x')$, since this w is a quantity before the operation of $U^{(\nu)}(x,x')$. If we define $W' \equiv w' + V(x')$, then (3.30) becomes

$$U_K^{(\nu)}(x,x';W,W') = U^{(\nu)}(x,x') \left[\cosh\left(\frac{W-W'}{2}\right)\right]^{-\nu}. \tag{3.31}$$

Substituting (3.28) into (3.31), we can express $U_K^{(\nu)}$ in terms of W and W', where

$$W = w + V(x), \quad W' = w' + V(x'). \tag{3.32}$$

Now we have $W = w + V(x)$ [not $W = w + V(x')$], since this W is a quantity obtained after the operation of $U^{(\nu)}(x,x')$. By using the last expression of (3.20), we can also write

$$U_K^{(\nu)}(x,x';W,W') = \left[\cosh\left(\frac{W-W'}{2}\right)\right]^{-\nu} \overleftarrow{U}'^{(\nu)}(x,x'), \tag{3.33}$$

where

$$\tilde{U}'^{(\nu)}(x,x')=\sum_{n=0}^{\infty}(i\kappa)^n\sum_{\{s_i=\pm 1\}}[s_1,\ldots,s_n]_{x'}^{x}\hat{\tilde{J}}'^{(\nu)}_{-s_n}\cdots\hat{\tilde{J}}'^{(\nu)}_{-s_1}. \tag{3.34}$$

From (3.27) and the definition (3.18), we can see that the operators $\hat{\tilde{J}}'^{(\nu)}_{\pm}$ act as

$$g(W')\hat{\tilde{J}}'^{(\nu)}_{\pm}=\hat{J}'^{(\nu)}_{\pm}g(W'), \tag{3.35}$$

for arbitrary $g(W')$.

Matrix elements of the evolution operator can be obtained from $U_K^{(\nu)}$. Since $U_K^{(\nu)}$ is now expressed as a function of W and W', Eq. (3.21) reads as

$$(\psi_0^{(\nu)},U^{(\nu)}(x,x')\psi_0^{(\nu)})^{(\nu)}=U_K^{(\nu)}(x,x';W=V(x),W'=V(x')). \tag{3.36}$$

IV. EXTENSION TO SUPERALGEBRA

Now let us extend the arguments of the previous section to the superalgebra, taking into account Q_+ and Q_- in addition to J_3 and $J_\pm$. The operators Q_+ and Q_- raises and lowers, respectively, the value of the spin by $\frac{1}{2}$. In the previous section we labeled the representation by a number ν, and, as explained below Eq. (3.6), the spin corresponds to $-\nu/2$. So $Q_\pm$ changes the value of ν by one. We can construct a representation of the superalgebra (2.1) by putting together two representations of the SL(2,**C**) algebra, with labels ν and $\nu+1$. The operators J_3, $J_\pm$, and $Q_\pm$ can be expressed in the form of 2×2 matrices as

$$\mathsf{J}_a^{(\nu,\nu+1)}=\begin{pmatrix} J_a^{(\nu)} & 0\\ 0 & J_a^{(\nu+1)}\end{pmatrix}\quad (a=1,2,3,\ \text{or}\ \pm), \tag{4.1a}$$

$$\mathsf{Q}_+^{(\nu,\nu+1)}=\begin{pmatrix} 0 & \nu^{1/2}\sinh(w/2)\\ -[\nu^{1/2}\sinh(w/2)]^{-1}J_+^{(\nu)} & 0\end{pmatrix}, \tag{4.1b}$$

$$\mathsf{Q}_-^{(\nu,\nu+1)}=\begin{pmatrix} 0 & \nu^{1/2}\cosh(w/2)\\ [\nu^{1/2}\cosh(w/2)]^{-1}J_-^{(\nu)} & 0\end{pmatrix}, \tag{4.1c}$$

where $J_a^{(\nu)}$ are the operators defined by (3.1). It is easy to check by direct calculation that the operators (4.1) satisfy the commutation relations (2.1). From now on we work with the representation given by (4.1). Although we shall hereafter drop the representation label $(\nu,\nu+1)$, it should not be forgotten that these expressions depend on ν. We write J and Q instead of J and Q in order to stress that they are 2×2 matrices of the form (4.1).

Now the representation space consists of two-component column vectors, where each component is an analytic function of w. The basis $\boldsymbol{\Psi}_n$ $(n=0,1,2,...)$ is given by

$$\boldsymbol{\Psi}_{2m}=\begin{pmatrix}\psi_m^{(\nu)}\\ 0\end{pmatrix},\quad \boldsymbol{\Psi}_{2m+1}=\begin{pmatrix}0\\ \psi_m^{(\nu+1)}\end{pmatrix}\quad (m=0,1,2,...), \tag{4.2}$$

with ψ_m defined by (3.10) and (3.7). From (3.5) it is obvious that $\boldsymbol{\Psi}_0$ is the lowest state satisfying $\mathsf{Q}_-\boldsymbol{\Psi}_0=0$.

We define the inner product between basis vectors as

$$(\boldsymbol{\Psi}_m,\boldsymbol{\Psi}_n)=\delta_{mn}. \tag{4.3}$$

Then it follows that the inner product of arbitrary two vectors $\boldsymbol{\Phi}_a=\binom{a_1}{a_2}$ and $\boldsymbol{\Phi}_b=\binom{b_1}{b_2}$ is

$$(\boldsymbol{\Phi}_a,\boldsymbol{\Phi}_b)=(a_1,b_1)^{(\nu)}+(a_2,b_2)^{(\nu+1)}, \tag{4.4}$$

with $(\cdots,\cdots)^{(\nu)}$ defined by (3.11). We let $\mathsf{A}^\dagger$ denote the adjoint of A, satisfying

$$(\mathsf{A}^\dagger \mathbf{\Phi}_a, \mathbf{\Phi}_b) = (\mathbf{\Phi}_a, \mathsf{A}\mathbf{\Phi}_b). \tag{4.5}$$

Since we have

$$\begin{aligned} &\mathsf{Q}_+ \mathbf{\Psi}_{2m} = \sqrt{\nu+m}\,\mathbf{\Psi}_{2m+1}, \quad \mathsf{Q}_+ \mathbf{\Psi}_{2m-1} = \sqrt{m}\,\mathbf{\Psi}_{2m}, \\ &\mathsf{Q}_- \mathbf{\Psi}_{2m+1} = \sqrt{\nu+m}\,\mathbf{\Psi}_{2m}, \quad \mathsf{Q}_- \mathbf{\Psi}_{2m} = \sqrt{m}\,\mathbf{\Psi}_{2m-1}, \\ &\mathsf{J}_3 \mathbf{\Psi}_{2m} = \left(\frac{\nu}{2}+m\right)\mathbf{\Psi}_{2m}, \quad \mathsf{J}_3 \mathbf{\Psi}_{2m+1} = \left(\frac{\nu+1}{2}+m\right)\mathbf{\Psi}_{2m+1}, \end{aligned} \tag{4.6}$$

it is obvious that

$$(\mathsf{J}_3)^\dagger = \mathsf{J}_3, \quad (\mathsf{J}_\pm)^\dagger = -\mathsf{J}_\mp, \quad (\mathsf{Q}_\pm)^\dagger = \mathsf{Q}_\mp, \tag{4.7}$$

where we have also used $(\mathsf{Q}_\pm)^2 = \mp \mathsf{J}_\pm$. Thus, the inner product defined by (4.3) satisfies the requirements (2.3).

Let us make some definitions parallel to the ones in the last section. The kernel of a 2×2 operator matrix A is defined as

$$\mathsf{A}_K(w_1, w_2^*) \equiv \sum_n [\mathsf{A}\mathbf{\Psi}_n(w_1)][\mathbf{\Psi}_n(w_2)]^{*T} = \sum_n \mathbf{\Psi}_n(w_1)[\mathsf{A}^\dagger \mathbf{\Psi}_n(w_2)]^{*T}. \tag{4.8}$$

Here T denotes transposition; $(\mathbf{\Psi}_n)^{*T}$ is a two-component row vector, and so A_K is a 2×2 matrix. As before, we shall write w and w' in place of w_1 and w_2^*. It is easy to see that the kernel of the identity operator is

$$\mathsf{I}_K(w,w') = \begin{pmatrix} I_K^{(\nu)}(w,w') & 0 \\ 0 & I_K^{(\nu+1)}(w,w') \end{pmatrix}, \tag{4.9}$$

with $I_K^{(\nu)}$ given by (3.19). We define $\overleftarrow{\mathsf{A}}$ by

$$\mathbf{\Phi}^T \overleftarrow{\mathsf{A}} \equiv [(\mathsf{A}^\dagger)^* \mathbf{\Phi}]^T. \tag{4.10}$$

[Note that $(\mathsf{A}^\dagger)^* \neq \mathsf{A}^T$, since the components of A are differential operators.] As an extension of (3.20), we have

$$\mathsf{A}_K(w,w') = \mathsf{A}\mathsf{I}_K(w,w') = \mathsf{I}_K(w,w')\overleftarrow{\mathsf{A}}', \tag{4.11}$$

where A' is the operator obtained from A by replacing w with w'. Once again, let us notice that the operator A acts on w and not on w', whereas $\overleftarrow{\mathsf{A}}'$ acts on w' and not on w. Corresponding to (3.21), we have

$$(\mathbf{\Psi}_0, \mathsf{A}\mathbf{\Psi}_0) = (\mathsf{A}_K)_{11}(w = w' = 0), \tag{4.12}$$

where $(\mathsf{A}_K)_{11}$ denotes the upper-left component of the 2×2 matrix A_K.

The evolution operator U, which is the solution of

$$\frac{\partial}{\partial x}\mathsf{U}(x,x') = [2i\kappa \mathsf{J}_3 - 2f(x)\mathsf{J}_1]\mathsf{U}(x,x'), \quad \mathsf{U}(x=x') = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{4.13}$$

is simply obtained as

$$\mathsf{U}=\begin{pmatrix} U^{(\nu)} & 0 \\ 0 & U^{(\nu+1)} \end{pmatrix}. \tag{4.14}$$

Now we are ready to write out the expression (2.7) in our representation given by (4.1).

V. POWER SERIES EXPRESSION

We define

$$\mathsf{S}(x,x';z,z')\equiv \mathsf{U}(z,x)(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{U}(x,x')(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{U}(x',z'), \tag{5.1}$$

where $\mathsf{Q}_\pm$ and U are the 2×2 operator matrices introduced in the last section. The relation (4.11) gives the kernel of S as

$$\mathsf{S}_K(x,x';z,z';w,w')=\mathsf{S}(x,x';z,z')\mathsf{I}_K(w,w'). \tag{5.2}$$

We let S_0 denote the upper-left component of the matrix S_K:

$$S_0\equiv(\mathsf{S}_K)_{11}. \tag{5.3}$$

Now let us write Eq. (2.7) in the representation (4.1). We can express it in terms of S as

$$G(x,x')=\frac{g_0}{2}\frac{(\mathbf{\Psi}_0,\mathsf{S}(x,x';\infty,-\infty)\mathbf{\Psi}_0)}{(\mathbf{\Psi}_0,\mathsf{U}(\infty,-\infty)\mathsf{J}_3\mathbf{\Psi}_0)}=\frac{g_0}{\nu}\frac{(\mathbf{\Psi}_0,\mathsf{S}(x,x';\infty,-\infty)\mathbf{\Psi}_0)}{(\mathbf{\Psi}_0,\mathsf{U}(\infty,-\infty)\mathbf{\Psi}_0)}, \tag{5.4}$$

where we have used $\mathbf{J}_3\mathbf{\Psi}_0=(\nu/2)\mathbf{\Psi}_0$. [Here and hereafter $G(x,x')$ stands for $G(x,x';\omega)$.] More precisely, Eq. (5.4) means

$$G(x,x')=\lim_{\substack{z\to\infty\\ z'\to-\infty}}\frac{g_0}{\nu}\frac{(\mathbf{\Psi}_0,\mathsf{S}(x,x';z,z')\mathbf{\Psi}_0)}{(\mathbf{\Psi}_0,\mathsf{U}(z,z')\mathbf{\Psi}_0)}. \tag{5.5}$$

From (4.14), (4.2), and (4.4) we have

$$(\mathbf{\Psi}_0,\mathsf{U}\mathbf{\Psi}_0)=(\psi_0^{(\nu)},U^{(\nu)}\psi_0^{(\nu)})^{(\nu)}. \tag{5.6}$$

It can be shown that[7]

$$(\psi_0^{(\nu)},U^{(\nu)}\psi_0^{(\nu)})^{(\nu)}=[(\psi_0^{(1)},U^{(1)}\psi_0^{(1)})^{(1)}]^{\nu}, \tag{5.7}$$

and hence

$$\lim_{\nu\to 0}(\mathbf{\Psi}_0,\mathsf{U}\mathbf{\Psi}_0)=\lim_{\nu\to 0}(\psi_0^{(\nu)},U^{(\nu)}\psi_0^{(\nu)})^{(\nu)}=1. \tag{5.8}$$

Since (5.5) holds for any ν, we may take the limit $\nu\to 0$ in (5.5). We obtain

$$G(x,x')=\lim_{\substack{z\to\infty\\ z'\to-\infty}}\lim_{\nu\to 0}\frac{g_0}{\nu}(\mathbf{\Psi}_0,\mathsf{S}(x,x';z,z')\mathbf{\Psi}_0)=\lim_{\substack{z\to\infty\\ z'\to-\infty}}\lim_{\nu\to 0}\frac{g_0}{\nu}S_0(x,x';z,z';w=w'=0), \tag{5.9}$$

where we have used (4.12) and (5.3). By using (4.11), we can write (5.2) as

$$\begin{aligned}\mathsf{S}_K&=\mathsf{U}(z,x)(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{U}(x,x')(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{U}(x',z')\mathsf{I}_K(w,w')\\ &=\mathsf{U}(z,x)(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{U}(x,x')(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{I}_K(w,w')\tilde{\mathsf{U}}'(x',z'),\end{aligned} \tag{5.10}$$

where

$$\overleftarrow{\mathsf{U}}' = \begin{pmatrix} \overleftarrow{U}'^{(\nu)} & 0 \\ 0 & \overleftarrow{U}'^{(\nu+1)} \end{pmatrix}. \tag{5.11}$$

Adding (4.1b) and (4.1c), we have

$$\mathsf{Q}_+ + \mathsf{Q}_- = \begin{pmatrix} 0 & \nu^{1/2} e^{w/2} \\ \nu^{-1/2} e^{w/2}\left(\nu + 2\dfrac{\partial}{\partial w}\right) & 0 \end{pmatrix}. \tag{5.12}$$

From (3.19), we can easily see that

$$\left(\nu + 2\frac{\partial}{\partial w}\right) I_K^{(\nu)} = \nu e^{(w'-w)/2} I_K^{(\nu+1)}. \tag{5.13}$$

Therefore, from (5.12) and (4.9) we find

$$(\mathsf{Q}_+ + \mathsf{Q}_-)\mathsf{I}_K = \begin{pmatrix} 0 & \nu^{1/2} e^{w/2} I_K^{(\nu+1)} \\ \nu^{1/2} e^{w'/2} I_K^{(\nu+1)} & 0 \end{pmatrix}. \tag{5.14}$$

Substituting (4.14), (5.11), (5.12), and (5.14) into the last expression of (5.10), we obtain the upper-left component of S_K as

$$S_0 = \nu U^{(\nu)}(z,x) e^{w/2} U^{(\nu+1)}(x,x') I_K^{(\nu+1)}(w,w') e^{w'/2} \overleftarrow{U}'^{(\nu)}(x',z'). \tag{5.15}$$

It is convenient to change the variables from (w,w') to (W,W'), as we did for U_K in Sec. III, and express everything in terms of W and W' rather than w and w'. Using (3.30) we can write (5.15) in the form

$$\begin{aligned} S_0 &= \nu U^{(\nu)}(z,x) e^{w/2} U_K^{(\nu+1)}(x,x';W,W') e^{w'/2} \overleftarrow{U}'^{(\nu)}(x',z') \\ &= \nu U^{(\nu)}(z,x) e^{[W-V(x)]/2} U_K^{(\nu+1)}(x,x';W,W') e^{[W'-V(x')]/2} \overleftarrow{U}'^{(\nu)}(x',z'). \end{aligned} \tag{5.16}$$

Substituting (3.31) and (3.33) gives

$$\begin{aligned} S_0 &= \nu e^{-[V(x)+V(x')]/2} U^{(\nu)}(z,x) e^{W/2} U^{(\nu+1)}(x,x') \left(\frac{1}{\cosh[(W-W')/2]}\right)^{\nu+1} e^{W'/2} \overleftarrow{U}'^{(\nu)}(x',z') \\ &= \nu e^{-[V(x)+V(x')]/2} U^{(\nu)}(z,x) e^{W/2} \left(\frac{1}{\cosh[(W-W')/2]}\right)^{\nu+1} \overleftarrow{U}'^{(\nu+1)}(x,x') e^{W'/2} \overleftarrow{U}'^{(\nu)}(x',z'). \end{aligned} \tag{5.17}$$

The operators U and $\overleftarrow{U}'$ are expressed in terms of W and W' as (3.28) and (3.34). Substituting them into (5.17), we obtain S_0 as a function of W and W'. As mentioned before, the operator $U^{(\nu)}(z,x)$ transfers the position from x to z. So we have $W = w + V(z)$ after the operation of $U^{(\nu)}(z,x)$. Similarly, we have $W' = w' + V(z')$ after the operation of $\overleftarrow{U}'^{(\nu)}(x',z')$. Therefore, in the final expression of $S_0(x,x';z,z')$, the relation between (W,W') and (w,w') is

$$W = w + V(z), \quad W' = w' + V(z'). \tag{5.18}$$

Now (5.9) reads as

$$G(x,x')=\lim_{\substack{z\to\infty\\ z'\to-\infty}}\lim_{\nu\to0}\frac{g_0}{\nu}S_0(x,x';z,z';W=V(z),W'=V(z')).\tag{5.19}$$

We define

$$\overline{G}(x,x';z,z';W,W')=\lim_{\nu\to0}\frac{g_0}{\nu}S_0(x,x';z,z';W,W').\tag{5.20}$$

This $\overline{G}$ can be interpreted as a generalized form of the Green's function $G(x,x')$, and hence we may deal with $\overline{G}$ instead of G. The original Green's function is recovered as

$$G(x,x')=\overline{G}(x,x';\infty,-\infty;V(\infty),V(-\infty)).\tag{5.21}$$

As a matter of fact, it can be shown that $\overline{G}(x,x',z,z';W,W')$ is the Green's function for the Fokker-Planck equation with the potential $V(x)$ replaced by

$$\overline{V}(x)=\begin{cases}W' & (x<z'),\\ V(x) & (z'<x<z),\\ W & (z<x).\end{cases}\tag{5.22}$$

For a detailed explanation on this interpretation, see Ref. 6.

We obtain $\overline{G}$ by substituting (5.17) into (5.20). The factor ν cancels out, and so we can set $\nu=0$ in the rest of the expression. As a result, we have

$$\begin{aligned}\overline{G}(x,x';z,z';W,W')&=\frac{i}{2\kappa}e^{-V(x)}U^{(0)}(z,x)e^{W/2}U^{(1)}(x,x')\frac{1}{\cosh[(W-W')/2]}e^{W'/2}\overleftarrow{U}'^{(0)}(x',z')\\ &=\frac{i}{2\kappa}e^{-V(x)}U^{(0)}(z,x)e^{W/2}\frac{1}{\cosh[(W-W')/2]}\overleftarrow{U}'^{(1)}(x,x')e^{W'/2}\overleftarrow{U}'^{(0)}(x',z').\end{aligned}\tag{5.23}$$

Substituting (3.28) and (3.34) into (5.23), we obtain

$$\begin{aligned}\overline{G}=\frac{i}{2\kappa}e^{-V(x)}&\sum_{n_1,n_2,n_3=0}^{\infty}\sum_{\{a_i,b_i,c_i=\pm1\}}(i\kappa)^{n_1+n_2+n_3}C(a_1,\dots,a_{n_1};b_1,\dots,b_{n_2};c_1,\dots,c_{n_3})\\ &\times[a_1,\dots,a_{n_1}]_{z'}^{x'}[b_1,\dots,b_{n_2}]_{x'}^{x}[c_1,\dots,c_{n_3}]_{x}^{z},\end{aligned}\tag{5.24}$$

where

$$\begin{aligned}&C(a_1,\dots,a_{n_1};b_1,\dots,b_{n_2};c_1,\dots,c_{n_3})\\ &=\hat{J}^{(0)}_{-c_{n_3}}\cdots\hat{J}^{(0)}_{-c_1}e^{W/2}\hat{J}^{(1)}_{-b_{n_2}}\cdots\hat{J}^{(1)}_{-b_1}\frac{1}{\cosh[(W-W')/2]}e^{W'/2}\overleftarrow{\hat{J}}'^{(0)}_{-a_{n_1}}\cdots\overleftarrow{\hat{J}}'^{(0)}_{-a_1}\\ &=\hat{J}^{(0)}_{-c_{n_3}}\cdots\hat{J}^{(0)}_{-c_1}e^{W/2}\frac{1}{\cosh[(W-W')/2]}\overleftarrow{\hat{J}}'^{(1)}_{-b_{n_2}}\cdots\overleftarrow{\hat{J}}'^{(1)}_{-b_1}e^{W'/2}\overleftarrow{\hat{J}}'^{(0)}_{-a_{n_1}}\cdots\overleftarrow{\hat{J}}'^{(0)}_{-a_1}.\end{aligned}\tag{5.25}$$

The second summation in (5.24) is over $a_1=\pm 1$, $a_2=\pm 1$,...,$a_{n_1}=\pm 1$, and so on. For $n_1=0$, the expression $[a_1,\ldots,a_{n_1}]_{z'}^{x'}$ in (5.24) is replaced by 1, and the corresponding product of operators in (5.25) is interpreted as the identity operator (and similarly for the cases $n_2=0$ and $n_3=0$). Using (3.35) we can rewrite (5.25) as

$$
\begin{aligned}
C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3})
&=\hat{J}^{(0)}_{-c_{n_3}}\cdots\hat{J}^{(0)}_{-c_1}e^{W/2}\hat{J}^{(1)}_{-b_{n_2}}\cdots\hat{J}^{(1)}_{-b_1}\hat{J}'^{(0)}_{-a_1}\cdots\hat{J}'^{(0)}_{-a_{n_1}}e^{W'/2}\frac{1}{\cosh[(W-W')/2]}\\
&=\hat{J}'^{(0)}_{-a_1}\cdots\hat{J}'^{(0)}_{-a_{n_1}}e^{W'/2}\hat{J}'^{(1)}_{-b_1}\cdots\hat{J}'^{(1)}_{-b_{n_2}}\hat{J}^{(0)}_{-c_{n_3}}\cdots\hat{J}^{(0)}_{-c_1}e^{W/2}\frac{1}{\cosh[(W-W')/2]},
\end{aligned}
\tag{5.26}
$$

although (5.25) is more transparent in structure. The expression (5.24) with (5.25) is the power series expansion of the Green's function in terms of κ; thus, we have achieved our main purpose.

It is also possible to express the coefficients C entirely in terms of $\hat{J}$, without $\overleftarrow{\hat{J}}'$ or $\hat{J}'$. Let us assume $n_1\neq 0$. It can be shown that[8]

$$
\begin{aligned}
&\hat{J}'^{(0)}_{-a_1}\hat{J}'^{(0)}_{-a_2}\cdots\hat{J}'^{(0)}_{-a_{n_1}}\tanh[(W-W')/2]\\
&\quad=\hat{J}^{(2)}_{-a_{n_1}}\cdots\hat{J}^{(2)}_{-a_2}\hat{J}^{(2)}_{-a_1}\tanh[(W-W')/2]+\hat{J}^{(2)}_{-a_{n_1}}\cdots\hat{J}^{(2)}_{-a_2}a_1e^{-a_1W}.
\end{aligned}
\tag{5.27}
$$

Since

$$
\hat{J}'^{(0)}_{\pm}\frac{e^{W'/2}}{\cosh[(W-W')/2]}=-e^{W/2}\hat{J}'^{(0)}_{\pm}\tanh[(W-W')/2],
\tag{5.28}
$$

from (5.26) and (5.27) we obtain

$$
\begin{aligned}
&C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3})\\
&\quad=\hat{J}^{(0)}_{-c_{n_3}}\cdots\hat{J}^{(0)}_{-c_1}e^{W/2}\hat{J}^{(1)}_{-b_{n_2}}\cdots\hat{J}^{(1)}_{-b_1}e^{W/2}\hat{J}^{(2)}_{-a_{n_1}}\cdots\hat{J}^{(2)}_{-a_2}\{-a_1e^{-a_1W}-\hat{J}^{(2)}_{-a_1}\tanh[(W-W')/2]\}.
\end{aligned}
\tag{5.29}
$$

For $n_1=0$ we have simply

$$
C(;b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3})=\hat{J}^{(0)}_{-c_{n_3}}\cdots\hat{J}^{(0)}_{-c_1}e^{W/2}\hat{J}^{(1)}_{-b_{n_2}}\cdots\hat{J}^{(1)}_{-b_1}e^{W'/2}\frac{1}{\cosh[(W-W')/2]}.
\tag{5.30}
$$

VI. PROPERTIES OF THE EXPANSION COEFFICIENTS

From (5.25), we can easily see that

$$
\begin{aligned}
C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3},+)&=-e^{-W}\frac{\partial}{\partial W}C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3}),\\
C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3},-)&=e^{W}\frac{\partial}{\partial W}C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3}),\\
C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2},+;)&=e^{-W}\left(1-\frac{\partial}{\partial W}\right)C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};),
\end{aligned}
\tag{6.1}
$$

$$C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2},-;)=e^W\frac{\partial}{\partial W}C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};),$$

where we have written "+" and "−" in place of "+1" and "−1" for simplicity. Here $C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};)$ denotes the coefficients for $n_3=0$. Similarly, we have

$$\begin{aligned}
C(+,\ldots;\ldots;\ldots)&=-e^{-W'}\frac{\partial}{\partial W'}C(\ldots;\ldots;\ldots),\\
C(-,\ldots;\ldots;\ldots)&=e^{W'}\frac{\partial}{\partial W'}C(\ldots;\ldots;\ldots),\\
C(;+,\ldots;\ldots)&=e^{-W'}\left(1-\frac{\partial}{\partial W'}\right)C(;\ldots;\ldots),\\
C(;-,\ldots;\ldots)&=e^{W'}\frac{\partial}{\partial W'}C(;\ldots;\ldots),
\end{aligned}\tag{6.2}$$

where $C(;\ldots;\ldots)$ stands for the coefficients with $n_1=0$. The coefficient for $n_1=n_2=n_3=0$ is

$$C(;;)=\frac{e^{(W+W')/2}}{\cosh[(W-W')/2]}=\frac{2}{e^{-W}+e^{-W'}}.\tag{6.3}$$

We can calculate the coefficients $C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3})$ by using the relations (6.1) and (6.2), starting from (6.3). It is evident that these coefficients have the left–right symmetry,

$$C(a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3};W,W')=C(c_{n_3},\ldots,c_1;b_{n_2},\ldots,b_1;a_{n_1},\ldots,a_1;W',W),\tag{6.4}$$

where we have written out the dependence on W and W' explicitly. It is also obvious that

$$C(\ldots;\ldots;\ldots,+)=-e^{-2W}C(\ldots;\ldots;\ldots,-)\tag{6.5a}$$

and

$$C(+,\ldots;\ldots;\ldots)=-e^{-2W'}C(-,\ldots;\ldots;\ldots).\tag{6.5b}$$

Finally, from (6.1) and (6.2) it follows that

$$C(\ldots,-;\ldots;\ldots)=C(\ldots;-,\ldots;\ldots),\quad C(\ldots;\ldots,-;\ldots)=C(\ldots;\ldots;-,\ldots).\tag{6.6}$$

Namely, a minus sign can pass through a semicolon. (This does not hold for a plus sign.)

Now let us write down the first few terms of the expansion (5.24) explicitly. We define the notation

$$[a_1,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3}]\equiv[a_1,\ldots,a_{n_1}]_{z'}^{x'}[b_1,\ldots,b_{n_2}]_{x'}^{x}[c_1,\ldots,c_{n_3}]_x^z.\tag{6.7}$$

If $n_1=0$, the quantity $[a_1,\ldots,a_{n_1}]_{z'}^{x'}$ on the right-hand side should be interpreted as unity, and similarly for $n_2=0$ or $n_3=0$; for example, $[+;;-]=[+]_{z'}^{x'}[-]_x^z$ and $[;+-;]=[+-]_{x'}^x$. Using this notation, we can write

$$\overline{G}(x,x';z,z';W,W')=\frac{i}{2\kappa}e^{-V(x)}[\overline{p_0}+i\kappa\overline{p_1}+(i\kappa)^2\overline{p_2}+(i\kappa)^3\overline{p_3}+\cdots],\tag{6.8}$$

with

$$\overline{p_0}=C(;;)=\frac{2}{e^{-W}+e^{-W'}}, \tag{6.9a}$$

$$\begin{aligned}\overline{p_1}&=C(-;;)[-;;]+C(;-;)[;-;]+C(;;-)[;;-]\\&\quad+C(+;;)[+;;]+C(;+;)[;+;]+C(;;+)[;;+]\\&=\frac{\overline{p_0}^2}{2}\{[-]_{z'}^{x'}+[-]_{x'}^{x}+[-]_{x}^{z}-e^{-2W'}[+]_{z'}^{x'}+e^{-W-W'}[+]_{x'}^{x}-e^{-2W}[+]_{x}^{z}\},\end{aligned} \tag{6.9b}$$

$$\begin{aligned}\overline{p_2}=\frac{\overline{p_0}^3}{2}\Bigg(&[--;;]+[-;-;]+[-;;-]+[;--;]+[;-;-]+[;;--]-e^{-2W'}\{[+-;;]\\&+[+;-;]+[+;;-]\}-e^{-2W}\{[;;-+]+[;-;+]+[-;;+]\}-\frac{e^{-W}-e^{-W'}}{2}e^{-W}\{[-;+;]\\&+[;-+;]\}+\frac{e^{-W}-e^{-W'}}{2}e^{-W'}\{[;+;-]+[;+-;]\}+e^{-W-W'}\{[-+;;]+[;;+-]\}\\&-e^{-W-3W'}[++;;]-e^{-W'-3W}[;;++]+\frac{e^{-W}-e^{-W'}}{2}e^{-W-2W'}[+;+;]\\&-\frac{e^{-W}-e^{-W'}}{2}e^{-W'-2W}[;+;+]+e^{-2W-2W'}\{[+;;+]+[;++;]\}\Bigg).\end{aligned} \tag{6.9c}$$

For example, the coefficient of $[;-+;]$ in (6.9c) has been calculated by using (6.1) as

$$\begin{aligned}C(;-+;)&=e^{-W}\left(1-\frac{\partial}{\partial W}\right)C(;-;)\\&=e^{-W}\left(1-\frac{\partial}{\partial W}\right)e^{W}\frac{\partial}{\partial W}C(;;)\\&=e^{-W}\left(1-\frac{\partial}{\partial W}\right)e^{W}\frac{\partial}{\partial W}\overline{p_0}=-\frac{1}{4}e^{-W}(e^{-W}-e^{-W'})\overline{p_0}^3.\end{aligned} \tag{6.10}$$

In such a calculation, it is convenient to use the property

$$\left(e^{W}\frac{\partial}{\partial W}\right)^{n}\overline{p_0}=\frac{n!}{2^n}\overline{p_0}^{n+1}, \tag{6.11}$$

which can be easily proved.

VII. THE LIMITING PROCESS

The original Green's function $G(x,x')$ is obtained from $\overline{G}(x,x';z,z';W,W')$ given by (5.24) by taking the limit $z\to\infty$, $z'\to-\infty$, $W\to V(\infty)$, and $W'\to V(-\infty)$. [We are assuming that both $V(\infty)$ and $V(-\infty)$ are finite.] Accordingly, the expansion coefficients p_0, p_1, $p_2,\ldots$ [Eq. (1.7)] are obtained from $\overline{p_0}$, $\overline{p_1}$, $\overline{p_2},\ldots$ [Eq. (6.8)] in this limit. This is not a trivial matter since the power series expansion is not necessarily commutable with the limiting process. We have to make sure that the coefficients $\overline{p_i}$ thus obtained are indeed finite.

Let us look at the coefficient $\overline{p_1}$ given by (6.9b). The integrals $[-]_{z'}^{x'}$, $[-]_x^z$, $[+]_{z'}^{x'}$, and $[+]_x^z$ all diverge in the limit $z'\to-\infty$, $z\to+\infty$. However, if we first set $W=V(\infty)$, $W'=V(-\infty)$ and then take the limit $z'\to-\infty$, $z\to+\infty$, the divergence is canceled. Indeed, we have

$$\lim_{z'\to-\infty}([-]_{z'}^{x'}-e^{-2V(-\infty)}[+]_{z'}^{x'})=2e^{-V(-\infty)}\int_{-\infty}^{x'}\sinh[V(-\infty)-V(y')]dy', \tag{7.1a}$$

$$\lim_{z\to+\infty}([-]_x^z-e^{-2V(\infty)}[+]_x^z)=2e^{-V(\infty)}\int_x^{\infty}\sinh[V(\infty)-V(y)]dy, \tag{7.1b}$$

and these integrals are finite as long as the potential $V(x)$ converges to $V(\infty)$ and $V(-\infty)$ sufficiently fast at $x\to\pm\infty$. This cancellation of divergence takes place at every order of expansion on account of the properties (6.5a) and (6.5b). We define

$$\begin{aligned}\langle -,a_2,a_3,\ldots,a_{n_1}]_{-\infty}^{x'}&\equiv[-,a_2,a_3,\ldots,a_{n_1}]_{-\infty}^{x'}-e^{-2V(-\infty)}[+,a_2,a_3\ldots,a_{n_1}]_{-\infty}^{x'}\\&=2e^{-V(-\infty)}\int\cdots\int_{-\infty\leq y_1\leq\cdots\leq y_{n_1}\leq x'}dy_1\cdots dy_{n_1}\\&\quad\times\sinh[V(-\infty)-V(y_1)]\exp\left(\sum_{i=2}^{n_1}a_iV(y_i)\right),\end{aligned} \tag{7.2}$$

and

$$\begin{aligned}[c_1,c_2,\ldots,c_{n_3-1},-\rangle_x^{\infty}&\equiv[c_1,c_2,\ldots,c_{n_3-1},-]_x^{\infty}-e^{-2V(\infty)}[c_1,c_2,\ldots,c_{n_3-1},+]_x^{\infty}\\&=2e^{-V(\infty)}\int\cdots\int_{x\leq y_1\leq\cdots\leq y_{n_3}\leq\infty}dy_1\cdots dy_{n_3}\\&\quad\times\sinh[V(\infty)-V(y_{n_3})]\exp\left(\sum_{i=1}^{n_3-1}c_iV(y_i)\right).\end{aligned} \tag{7.3}$$

[For $n_1=1$ and $n_3=1$, we let $\langle-]_{-\infty}^{x'}$ and $[-\rangle_x^{\infty}$ stand for the integrals (7.1a) and (7.1b), respectively.] We obtain the expansion coefficient p_n as

$$p_n(x,x')=\lim_{\substack{z\to+\infty\\z'\to-\infty}}\overline{p_n}(x,x';z,z';W=V(\infty),W'=V(-\infty)), \tag{7.4}$$

and p_n can be expressed in terms of finite integrals of the form (7.2) and (7.3). We can also write (7.4) as

$$p_n(x,x')=\lim_{\substack{z\to+\infty\\z'\to-\infty}}\overline{p_n}(x,x';z,z';W=V(z),W'=V(z')), \tag{7.5}$$

but we cannot let $z\to\infty$ and $z'\to-\infty$ before $W\to V(\infty)$ and $W'\to V(-\infty)$.

In the same way as (6.7), let us use the notation

$$\begin{aligned}&\langle -,a_2,\ldots,a_{n_1};b_1,\ldots,b_{n_2};c_1,\ldots,c_{n_3-1},-\rangle\\&\quad\equiv\langle -,a_2,\ldots,a_{n_1}]_{-\infty}^{x'}[b_1,\ldots,b_{n_2}]_{x'}^{x}[c_1,\ldots,c_{n_3-1},-\rangle_x^{\infty}.\end{aligned} \tag{7.6}$$

We also use this notation for $n_1=0$, where $\langle;\ldots;\ldots\rangle\equiv[\ldots]_{x'}^{x}[\ldots\rangle_x^{\infty}$, and similarly for $n_3=0$. For example, $\langle--;;\rangle=\langle--]_{-\infty}^{x'}$ and $\langle;+;-\rangle=[+]_{x'}^{x}[-\rangle_x^{\infty}$. With this notation, we can obtain p_0, p_1, $p_2,\ldots,$ from $\overline{p_0}$, $\overline{p_1}$, $\overline{p_2},\ldots,$ shown in (6.9) by replacing W and W' by $V(\infty)$ and $V(-\infty)$, removing the terms with $a_1=+1$ or $c_{n_3}=+1$, and replacing [...;...;...] by ⟨...;...;...⟩. Namely, we have

$$p_0=\frac{2}{e^{-V}+e^{-V'}},\tag{7.7a}$$

$$p_1=\frac{p_0^2}{2}\{\langle-;;\rangle+\langle;-;\rangle+\langle;;-\rangle+e^{-V-V'}\langle;+;\rangle\},\tag{7.7b}$$

$$\begin{aligned}p_2=\frac{p_0^3}{2}\Bigg(&\langle--;;\rangle+\langle-;-;\rangle+\langle-;;-\rangle+\langle;--;\rangle+\langle;-;-\rangle+\langle;;--\rangle\\&-\frac{e^{-V}-e^{-V'}}{2}e^{-V}\{\langle-;+;\rangle+\langle;-+;\rangle\}+\frac{e^{-V}-e^{-V'}}{2}e^{-V'}\{\langle;+;-\rangle+\langle;+-;\rangle\}\\&+e^{-V-V'}\{\langle-+;;\rangle+\langle;;+-\rangle\}+e^{-2V-2V'}\langle;++;\rangle\Bigg),\end{aligned}\tag{7.7c}$$

where $V\equiv V(\infty)$ and $V'\equiv V(-\infty)$.

Until now we have been assuming that both $V(+\infty)$ and $V(-\infty)$ are finite. However, this formalism is also applicable to some other cases. Let us first consider the case where $V(+\infty)$ is finite and $V(-\infty)=+\infty$. In this case we can also use (7.4) to obtain the coefficients p_i. Namely, we let $W'\to+\infty$ in $\overline{p_i}$ before taking the limit $z'\to-\infty$. Using the notation $[A;B;C\rangle\equiv[A]_{-\infty}^{x'}[B]_{x'}^{x}[C\rangle_x^{\infty}$, we can write

$$p_0=2e^{V(\infty)},\quad p_1=2e^{2V(\infty)}([-;;\rangle+[;-;\rangle+[;;-\rangle),\tag{7.8a}$$

$$\begin{aligned}p_2=&4e^{3V(\infty)}([--;;\rangle+[-;-;\rangle+[-;;-\rangle+[;--;\rangle+[;-;-\rangle+[;;--\rangle)\\&-2e^{V(\infty)}([-;+;\rangle+[;-+;\rangle).\end{aligned}\tag{7.8b}$$

The integrals in these expressions are finite if $V(x)$ diverges at $x\to-\infty$ faster than $\log|x|$. Similarly, if $V(+\infty)$ is finite and $V(-\infty)=-\infty$, we may first let $W'\to-\infty$ and then $z'\to-\infty$. We have

$$p_0=0,\quad p_1=-2[+;;\rangle,\tag{7.9a}$$

$$p_2=-4e^{-V(\infty)}[++;;\rangle-2e^{-V(\infty)}[+;+;\rangle.\tag{7.9b}$$

Expressions for the cases $V(+\infty)=\pm\infty$ with $V(-\infty)$ finite can be obtained in the same way.

The expressions become still simpler if $V(+\infty)=+\infty$ and $V(-\infty)=-\infty$. We can obtain p_i by taking the limit $W\to+\infty$, $W'\to-\infty$ in $\overline{p_i}$ and then letting $z\to\infty$, $z'\to-\infty$. It is easy to see that $p_n=0$ for n even. We have

$$p_1=-2[+;;],\tag{7.10a}$$

$$p_3=2[+;+;-]+2[+;+-;]+4[++;;-]+4[++;-;]+4[++-;;],\tag{7.10b}$$

and so on. [Here we are using the notation (6.7) with $z'=-\infty$ and $z=\infty$.] The case $V(+\infty)=-\infty$, $V(-\infty)=+\infty$ can be treated similarly.

TABLE I. Classification of the behavior of $V(x)$ at infinity.

	$V(+\infty)=$finite	$V(+\infty)=+\infty$	$V(+\infty)=-\infty$
$V(-\infty)=$finite	i	ii	iii
$V(-\infty)=+\infty$	ii′	iv	v
$V(-\infty)=-\infty$	iii′	v′	vi

The cases $V(+\infty)=+\infty$ with $V(-\infty)=+\infty$ and $V(+\infty)=-\infty$ with $V(-\infty)=-\infty$ need special care. The expansion coefficients p_i for these cases cannot be obtained simply by taking the limit of $\overline{p_i}$. In particular, for the case $V(+\infty)=+\infty$ with $V(-\infty)=+\infty$, the power series expansion of the Green's function begins with a term of order $1/\kappa^2$, not $1/\kappa$ as in (1.7). Extending the formalism of the present paper to such cases is an interesting problem, and it will be discussed elsewhere.

VIII. CONCLUSION

In this paper we derived an expression for the power series expansion of the Green's function. Our main result is (5.24) with (5.25). This is only a basic expression, and we may further study the structure of the expansion coefficients starting from (5.25). By doing so we can derive more practically useful expressions, and investigate various properties of the Green's function.

APPENDIX: LONG TIME BEHAVIOR OF THE GREEN'S FUNCTION

The small-ω behavior (and the long-time behavior) of the Green's function depends much on the behavior of the potential $V(x)$ at $x\to+\infty$ and $x\to-\infty$. We consider the following three cases for the behavior at $x\to+\infty$:

$$V(+\infty)=\text{finite},\quad V(+\infty)=+\infty,\quad V(+\infty)=-\infty,$$

where $V(+\infty)$ stands for $\lim_{x\to\infty}V(x)$. We assume that the potential either converges to a finite limit sufficiently fast or diverges sufficiently fast. (If the potential is a function that converges or diverges slowly, the Green's function may show a singular behavior.[9] However, here we do not discuss such cases.) Similarly, we consider the three cases for $x\to-\infty$:

$$V(-\infty)=\text{finite},\quad V(-\infty)=+\infty,\quad V(-\infty)=-\infty.$$

In all, there are nine cases, as shown in Table I. The Green's function behaves at small ω as[10]

$$G(x,x';\omega)=\frac{C_{-1}}{\kappa}+C_0+C_1\kappa+C_2\kappa^2+\cdots,\quad \text{cases (i), (ii), and (ii}'\text{)},\tag{A1}$$

$$=C_0+C_1\kappa+C_2\kappa^2+C_3\kappa^3+\cdots,\quad \text{cases (iii) and (iii}'\text{)},\tag{A2}$$

$$=\frac{C_{-2}}{\kappa^2}+C_0+C_2\kappa^2+C_4\kappa^4+\cdots,\quad \text{case (iv)},\tag{A3}$$

$$=C_0+C_2\kappa^2+C_4\kappa^4+C_6\kappa^6+\cdots,\quad \text{cases (v), (v}'\text{), and (vi)},\tag{A4}$$

where κ is defined by (1.6).

The long-time behavior is also classified according to (A1)–(A4) above. The expressions (A1) and (A2) correspond to the cases where the eigenvalue spectrum of the Fokker–Planck operator (or the ''energy'' spectrum) is continuous. By Fourier transforming (A1) or (A2), we obtain the

−rge-t expression of $G(x,x';t)$ as an expansion in powers of $1/t$. (The contribution comes only from odd powers of κ.) For (A1) the power series begins with the $t^{-1/2}$ term, and for (A2) it begins with $t^{-3/2}$. Thus, $G(x,x';t)$ shows a power-law decay for large t.

On the other hand, (A3) and (A4) correspond to the cases of a discrete spectrum (at least in the low-energy region). In these cases $G(x,x';\omega)$ does not include odd powers of κ, and hence $G(x,x';t)$ does not contain a part that falls off with a power law. The long-time behavior of the Green's function is determined by low-lying eigenvalues, and $G(x,x';t)$ decays exponentially for large t. The eigenvalues correspond to the poles of $G(x,x';\omega)$. (See Refs. 6 and 11 for a method for the calculation of the eigenvalues.)

The Camassa–Holm equation as a geodesic flow on the diffeomorphism group

Shinar Kouranbaeva[a)]
Department of Mathematics, University of California, Santa Cruz, California 95064

(Received 23 July 1998; accepted for publication 2 November 1998)

Misiolek [J. Geom. Phys. **24**, 203–208 (1998)] has shown that the Camassa–Holm equation is a geodesic flow on the Bott–Virasoro group. In this paper it is shown that the Camassa–Holm equation for the case $\kappa=0$ is the geodesic spray of the weak Riemannian metric on the diffeomorphism group of the line or the circle obtained by right translating the H^1 inner product over the entire group. This paper uses the right-trivialization technique to rigorously verify that the Euler–Poincaré theory for Lie groups can be applied to diffeomorphism groups. The observation made in this paper has led to physically meaningful generalizations of the CH-equation to higher dimensional manifolds. © *1999 American Institute of Physics.* [S0022-2488(99)02102-7]

I. INTRODUCTION

Camassa and Holm[1,2] derived a new completely integrable dispersive shallow water equation that is bi-Hamiltonian and thus possesses an infinite number of conservation laws in involution. The Camassa–Holm (CH) equation is obtained by using an asymptotic expansion directly in the Hamiltonian for Euler's equations in the shallow water regime. Camassa and Holm[1] also have the formal Lie–Poisson derivation of the equation. Below, another remarkable property of the CH-equation is shown. Namely, the CH-equation can be realized as a geodesic equation on a Riemannian manifold on which the methods of infinite-dimensional geometry can be applied. The geodesic nature of the CH-equation enables one to transfer the problem from the equation to a problem of finding geodesics on the diffeomorphism group. This idea was first rigorously carried out by Ebin and Marsden[3] for the Euler equations. They have shown that the Euler equations are geodesic equations for the right-invariant L^2 metric on the group of volume-preserving diffeomorphisms.

Section II illustrates the main result by formally applying the Euler–Poincaré theory for Lie groups to a continuum mechanical system. Section III verifies the legitimacy of the application. In addition, Sec. III contains independent results on the Riemannian geometry of a C^1-manifold which is also a topological group with C^1 right translation. Using the right-trivialization technique, a global Christoffel map is introduced, and formulas are derived for the spray and the Levi–Civita connection similar to the finite-dimensional case. The method is inspired by the theory of affine connections on parallelizable manifolds developed by Marsden, Ratiu and Raugel.[4] At the end of Sec. III, a version of the Euler–Poincaré theorem for a diffeomorphism group is verified. Section IV utilizes the results of Sec. III to demonstrate that the CH-equation is a geodesic flow of the right-invariant metric on the diffeomorphism group of **R** or of the circle. Section V addresses uniqueness and existence issues for solutions of the CH-equation. Observations made in this paper have n-dimensional generalizations to the volume-preserving diffeomorphism group of a Riemannian manifold which lead to a new class of models for mean hydrodynamic motion. See Ref. 5 for application of this to numerous fluids models, such as those in geophysics, and see Ref. 6 for the development of the geometry and curvature of volume-preserving diffeomorphism groups with right-invariant H^1 metric. For Riemannian manifolds with

[a)]Electronic mail: shinar@cats.ucsc.edu

boundary, new subgroups of the diffeomorphism group have been established which give rise to remarkable theorems on the limit of zero viscosity. See Ref. 7 for a detailed account.

II. FORMAL DERIVATION

In this section we illustrate the main result of the paper by *formally* applying the pure Euler–Poincaré theorem on the right-invariant Lagrangians on Lie groups (see Ref. 8, and references therein) to the case of the diffeomorphism group of a certain Sobolev class H^s, $s>\frac{3}{2}$. The diffeomorphism group is *not* a Lie group (left translation and inversion are not smooth, only continuous, whereas right translation is smooth), and the pure Euler–Poincaré theorem strictly does not apply. However, we will demonstrate in the following sections that the formal derivation given in this section can be rigorously justified using standard trivialization techniques.

Let M be the flat circle S^1 or the real line $\mathbf{R}$. $\mathrm{Diff}^s(M)\equiv\mathcal{D}^s$ denotes the diffeomorphism group of M of some given Sobolev class. The case $M=S^1$ corresponds to periodic boundary conditions. For the case $M=\mathbf{R}$, the chosen Sobolev space automatically imposes appropriate decay hypotheses at infinity. Under these boundary conditions, $\mathrm{Diff}^s(M)$ is a smooth infinite-dimensional manifold and a topological group relative to the induced manifold topology. $\boldsymbol{\mathcal{X}}(M)$ denotes the vector fields on M of the same differentiability class. Formally, this is the *right* Lie algebra of $\mathrm{Diff}^s(M)$, e.g., the standard left Lie algebra bracket is *minus* the usual Lie bracket for vector fields. For $u,v\in\boldsymbol{\mathcal{X}}(M)$ the adjoint action of the Lie algebra on itself is given by

$$\mathrm{ad}_u v=[u,v].$$

Consider the H^1 inner product on $\boldsymbol{\mathcal{X}}(M)$ and define a weak Riemannian metric on the whole group $\mathcal{D}^s$ by right-translation of the given inner product on the Lie algebra. The corresponding quadratic form defines a right-invariant Lagrangian on $\mathrm{Diff}^s(M)$ whose restriction to the Lie algebra $\boldsymbol{\mathcal{X}}(M)$ is equal to the square of the H^1 norm:

$$l(u)=\frac{1}{2}\int_M (u^2+u_x^2)\,dx. \tag{1}$$

Next, one defines ad_u^* the adjoint of ad_u with respect to the H^1 inner product, that is, for $u,v,w \in\boldsymbol{\mathcal{X}}(M)$

$$\langle \mathrm{ad}_u^*\, w,v\rangle_{H^1}=\langle w,[u,v]\rangle_{H^1}.$$

Also, for a function $l:\boldsymbol{\mathcal{X}}(M)\to\mathbf{R}$, define the functional derivative $\delta l/\delta u\in\boldsymbol{\mathcal{X}}(M)$ with respect to the given metric by

$$\left\langle \frac{\delta l}{\delta u},v\right\rangle_{H^1}=\delta l(u)\cdot v \quad \text{for } v\in\boldsymbol{\mathcal{X}}(M).$$

Assuming the existence of ad_u^* for each $u\in\boldsymbol{\mathcal{X}}(M)$, we can formally write the Euler–Poincaré equations

$$\frac{d}{dt}\frac{\delta l}{\delta u}=-\mathrm{ad}_u^*\frac{\delta l}{\delta u}.$$

After computing ad_u^* and $\delta l/\delta u$ (for the computations see Sec. IV) the Euler–Poincaré equations yield the Camassa–Holm equation

$$u_t-u_{xxt}=-3uu_x+2u_xu_{xx}+uu_{xxx}. \tag{2}$$

The above observation motivates one to develop a theory to perform the procedure.

III. RIEMANNIAN GEOMETRY OF PARTIAL LIE GROUPS

A. Review of definitions

In what follows, the general structure needed is that of a C^1-manifold G which is also a topological group in the induced manifold topology, and it is assumed that only the right translation is C^1. We call such a group G a partial Lie group. Below we review the notations used in the paper. The proofs for the stated formulas can be found in the standard texts such as Spivak.[9] Let G be a manifold equipped with a metric $\langle\cdot,\cdot\rangle$. Let $\pi_G:TG\to G$ and $\pi_{TG}:TTG\to TG$ be the tangent bundle projections and denote by $V=\ker T\pi_G$ the vertical subbundle of TTG. The *connector* $K:TTG\to TG$ is given by

$$K(TY\cdot X)=\nabla_X Y,$$

for $X,Y\in\mathcal{X}(G)$ the Lie algebra of vector fields and ∇ the Levi-Civita connection coming from a metric.

A vector $U\in TTG$ is called *horizontal* if $U\in\ker K$; $H=\ker K$ is a subbundle of TTG called the *horizontal subbundle* of the connection and we have the decomposition $TTG=H\oplus V$ over TG with the projection π_{TG}. Then the *horizontal lift* of $w\in T_gG$ to $T_v(TG)$, $v\in T_gG$, is defined as

$$\mathrm{hor}_v\, w=(T_v\pi_G|H_v)^{-1}(w).$$

The horizontal lift operator $\mathrm{hor}_v:T_gG\to H_v$ is an isomorphism for all $v\in TG$ and locally,

$$\mathrm{hor}_v\, w=b^i\frac{\partial}{\partial x^i}-\Gamma^i_{jk}b^ja^k\frac{\partial}{\partial v^i},$$

where $v=a^i\partial/\partial x^i$ and $w=b^i\partial/\partial x^i$.

The *spray* $S:TG\to TTG$ is by definition the Lagrangian vector field of the energy function $E(v)=L(v)=\frac{1}{2}\langle v,v\rangle$, i.e.,

$$\mathbf{i}_S\omega_L=\mathbf{d}E,$$

where ω_L is the symplectic form on TG, and $\mathbf{i}_S$ denotes the interior product (for more details refer to *Foundations of Mechanics*[10]). Locally,

$$S(v)=a^i\frac{\partial}{\partial x^i}-\Gamma^i_{jk}a^ja^k\frac{\partial}{\partial v^i},$$

where $v=a^i\partial/\partial x^i$, and notice that by definition, we have the useful identity

$$S(v)=\mathrm{hor}_v\, v. \tag{3}$$

Let $g(t)$ be a smooth curve in G and let $\dot g(t)$ be its tangent vector field. If Y is another vector field, define the *covariant derivative* of Y along $g(t)$ by

$$\frac{DY}{dt}=\nabla_{\dot g(t)}Y.$$

If the covariant derivative of Y is zero, Y is said to be parallel along $g(t)$. It follows from the definition of a connector that $TY(\dot g(t))\in H$ if and only if $DY/dt=0$. Locally for a given curve $g(t)$ this equation becomes a linear system of ordinary differential equations

$$\frac{dY^i(t)}{dt}+\Gamma^i_{jk}\dot g^j(t)Y^k(t)=0.$$

A curve $g(t)$ is called the *geodesic* of a connection ∇, if $\dot{g}(t)$ is parallel along $g(t)$, i.e., if

$$\nabla_{\dot{g}(t)}\dot{g}(t)=0.$$

Locally, this is a second-order differential equation

$$\ddot{g}^i(t)+\Gamma^i_{jk}\dot{g}^j(t)\dot{g}^k(t)=0.$$

B. The Levi–Civita connection and the spray for a right-invariant metric on *G*

Let G be a C^1-manifold which is a topological group with C^1 right translation. Assume that G admits a right-invariant metric. There is a vector bundle isomorphism called the right trivialization map

$$\rho: TG \to G\times\mathcal{G},$$

$$v \mapsto (g, T_g R_{g^{-1}}\cdot v).$$

Then $T\rho: TTG\to T(G\times\mathcal{G})$ maps TTG isomorphically onto $TG\times\mathcal{G}\times\mathcal{G}$. We can further trivialize via $\rho\times id$

$$TTG \overset{(\rho\times id)\circ T\rho}{\longrightarrow} G\times\mathcal{G}\times\mathcal{G}\times\mathcal{G}.$$

Note the isomorphic image of the vertical subbundle of TTG is equal to $G\times O\times\mathcal{G}\times\mathcal{G}$, the projection being onto the first and third factors. To keep the base points in the first two factors, we apply the involution map

$$\sigma: G\times\mathcal{G}\times\mathcal{G}\times\mathcal{G}\to G\times\mathcal{G}\times\mathcal{G}\times\mathcal{G},$$

$$(g,X,Y,Z)\mapsto(g,Y,X,Z).$$

Then the image of the vertical bundle V of TTG equals $G\times\mathcal{G}\times O\times\mathcal{G}$ with the projection being on the first two factors. Therefore, the isomorphism we are working with is

$$TTG \overset{\sigma\circ(\rho\times id)\circ T\rho}{\longrightarrow} G\times\mathcal{G}\times\mathcal{G}\times\mathcal{G}.$$

A given metric gives rise to the Levi–Civita connection which determines the horizontal bundle. We wish to express it in the trivialization ρ, which in turn helps us to find the spray. Define the continuous $\mathbf{R}$-bilinear map $\gamma_g:\mathcal{G}\times\mathcal{G}\to\mathcal{G}$ depending smoothly on g by

$$\rho((\nabla_X Y)(g))=(g, d\overline{Y}(g)\cdot X(g)+\gamma_g(\overline{X}(g),\overline{Y}(g))), \tag{4}$$

where

$$\rho(X(g))=(g,\overline{X}(g)),\quad X,Y\in\boldsymbol{\mathcal{X}}(G).$$

Recall that a connection in a finite-dimensional case in coordinates is given by

$$S(X)=X^i\frac{\partial}{\partial g^i}-\Gamma^i_{jk}X^jX^k\frac{\partial}{\partial\dot{g}^i},$$

and

$$(\nabla_X Y)^i=X^jY^i_{,j}+\Gamma^i_{jk}X^jX^k.$$

Define $\gamma = \Gamma^i_{jk} X^j X^k \partial/\partial \dot{g}^i$, then

$$(\nabla_X Y)^i = X^j Y^i_{,j} + \gamma^i. \tag{5}$$

Observe that formulas (4) and (5) are analogous.

Let $g(t)$ be a curve in G with $g(0)=g$, $\dot{g}(0)=w$, and $v \in T_g G$. There exists a curve $v(t) \in TG$ such that

$$v(0)=v, \quad \pi_G(v(t))=g(t), \quad \frac{Dv(t)}{dt}=0. \tag{6}$$

Therefore, $Tv(t)\cdot \dot{g}(t)$ is horizontal; i.e. the tangent vector field dv/dt of $v(t)$ is always horizontal. Therefore $\dot{v}(0)=\mathrm{hor}_v\, w$, the horizontal lift of $w=\dot{g}(0)\in T_g G$ to $T_v(TG)$. If

$$\rho(v(t)) = (g(t),\xi(t)), \quad \rho(v)=(g,\xi),$$

$$\rho(\dot{g}(t)) = (g(t),\zeta(t)), \quad \rho(w)=(g,\zeta),$$

then $v(0)=v$ in the trivialization reads $\xi(0)=\xi$, and the base projection condition is automatically satisfied. By the definition of a covariant derivative and the chain rule, we find that

$$\rho\left(\frac{Dv}{dt}\right) = (g(t), d\xi(t)\cdot \dot{g}(t) + \gamma_{g(t)}(\zeta(t),\xi(t))) = \left(g(t), \frac{d\xi}{dt} + \gamma_{g(t)}(\zeta(t),\xi(t))\right),$$

so that $(g(t),\xi(t))$ is parallel along $g(t)$ in $G\times\mathcal{G}$ relative to the push-forward connection by ρ *if and only if*

$$\frac{d\xi}{dt} + \gamma_{g(t)}(\zeta(t),\xi(t)) = 0, \quad \xi(0)=\xi. \tag{7}$$

Equation (7) enables us to compute the horizontal lift of (g,ζ) to $T_{(g,\xi)}(G\times\mathcal{G})$ and hence the spray using (3). Let us compute $\mathrm{hor}_v\, w = \dot{v}(0)$ in the trivialization given by ρ. We have that

$$\begin{aligned}(\sigma\circ(\rho\times id)\circ T\rho)(\dot{v}(0)) &= \sigma\circ(\rho\times id)\left(\left.\frac{d}{dt}\right|_{t=0} (\rho\circ v)(t)\right)\\ &= \sigma\circ(\rho\times id)\left(\dot{g}(0), \xi(0), \left.\frac{d\xi(t)}{dt}\right|_{t=0}\right)\\ &= \sigma(g(0),\zeta(0),\xi(0), -\gamma_{g(0)}(\zeta(0),\xi(0))) = (g,\xi,\zeta,-\gamma_g(\zeta,\xi)).\end{aligned}$$

Therefore,

$$\mathrm{hor}_{(g,\xi)}(g,\zeta) = (g,\xi,\zeta,-\gamma_g(\zeta,\xi))$$

and the spray of the Levi–Civita connection in its right trivialization is given by

$$\overline{S}(g,\xi) = \mathrm{hor}_{(g,\xi)}(g,\xi) = (g,\xi,\xi,-\gamma_g(\xi,\xi)). \tag{8}$$

Applying $(\rho^{-1}\times id)\circ\sigma^{-1}$ we can express the right trivialization of the spray as

$$\overline{S}(g,\xi) = (T_e R_g \cdot \xi, \xi, -\gamma_g(\xi,\xi)), \tag{9}$$

where $X(g) = T_e R_g\cdot\xi$ is the right-invariant vector field on G associated with a Lie algebra element ξ. It follows that

$$S(v)=T\rho^{-1}\circ\overline{S}\circ\rho(v). \tag{10}$$

Given a vector bundle E over G, we shall denote by $\mathcal{E}$ the collection of all smooth sections $\sigma:G\rightarrow E$ such that $\pi\circ\sigma=id_G$. Let $E=G\times\mathcal{G}$, then the condition $\pi\circ\sigma=id_G$ implies that

$$\mathcal{E}=\{\sigma:G\rightarrow\mathcal{G}\mid\sigma\ \text{is smooth}\}.$$

If $\rho(X(g))=(g,\overline{X}(g))$, define the map $\overline{\nabla}:\boldsymbol{\mathcal{X}}(\mathrm{G})\times\mathcal{E}\rightarrow\mathcal{E}$ via

$$(\overline{\nabla}_X\sigma)(g)=T_g\sigma\cdot X(g)+\gamma_g(\overline{X}(g),\sigma(g)).$$

It is straightforward to check that $\overline{\nabla}$ is a vector bundle connection. Therefore, a bilinear map γ_g defines the vector bundle connection $\overline{\nabla}:\boldsymbol{\mathcal{X}}(G)\times\mathcal{E}\rightarrow\mathcal{E}$. Moreover when γ_g is defined as in (4), the push-forward by ρ of the Levi–Civita connection is equal to

$$\rho(\nabla_X Y(g))=(g,\overline{\nabla}_X Y(g)),$$

and therefore,

$$\nabla_X Y(g)=T_e R_g(\overline{\nabla}_X\overline{Y}(g)).$$

Conclusion 1: If for a given connection ∇ *we think of the map* $\gamma_g:T_eG\times T_eG\rightarrow T_eG$ *as a generalized Christoffel map of the push-forward connection* $\overline{\nabla}$ *under the right trivialization map* ρ, *then we have the formula*

$$\nabla_X Y(g)=\rho^{-1}(d\overline{Y}(g)\cdot X(g)+\gamma_g(\overline{X}(g),\overline{Y}(g))).$$

If in addition we restrict ourselves to the Levi–Civita connection coming from a given metric on G, *we have the formula for the spray using the Christoffel map*

$$S(X(G))=T\rho^{-1}(X(g),\overline{X}(g),-\gamma_g(\overline{X}(g),\overline{Y}(g))).$$

The above two formulas are analogous to the finite-dimensional formulas and they are globally defined on G.

Notice we have not used the right-invariance condition, these conclusions are true for any metric on G. However, our results below will depend heavily on the right-invariance of the metric.

Proposition III.1: Let G be a C^1-manifold which is a topological group with C^1 right translation. Suppose that G admits a right-invariant metric. Then the spray of the corresponding Lagrangian $L(v)=\frac{1}{2}\langle v,v\rangle_g$ is given by

$$S(v)=T\rho^{-1}\circ\overline{S}\circ\rho(v),$$

where

$$\overline{S}(g,\xi)=(T_eR_g\cdot\xi,\xi,-B(\xi,\xi)) \tag{11}$$

and

$$B:T_eG\times T_eG\rightarrow T_eG$$

is defined implicitly by

$$\langle B(\zeta,\xi),\eta\rangle=\langle\zeta,[\xi,\eta]\rangle,\quad \xi,\eta,\zeta\in T_eG. \tag{12}$$

Remark: There is an assumption in the proposition that the operator B exists.

Remark: For the case of Lie groups, the proof of this result can be found in Ref. 10. The operator B was introduced by Arnold.[11] The above proposition is more general as it covers diffeomorphism groups which are of a great interest in hydrodynamics.

Proof: To verify (11) we need to calculate the Christoffel map $\gamma_g(\xi,\xi)$ in (9).

Since ρ is a diffeomorphism, we can push-forward the symplectic form ω_L on TG to define the symplectic form $\omega^s=\rho_*\omega_L$ (the superscript s stands for ''spatial'' because the right trivialization gives rise to spatial coordinates in applications). It can be checked that the push-forward of the spray S on TG is the Lagrangian vector field expressed in space coordinates and $\rho_*S=\overline{S}$; consequently,

$$\mathbf{i}_{\overline{S}}\omega^s=\mathbf{d}(\rho_*E). \tag{13}$$

To calculate the left-hand side recall the following formula (see Ref. 10):

$$\omega^s(g,\xi)((v,\zeta),(w,\eta))=-\langle\zeta,T_gR_{g^{-1}}(w)\rangle_e+\langle\eta,T_gR_{g^{-1}}(v)\rangle_e-\langle\xi,[T_gR_{g^{-1}}(v),T_gR_{g^{-1}}(w)]\rangle_e.$$

By this formula we have that

$$\omega^s(g,\xi)((T_eR_g\cdot\xi,-\gamma_g(\xi,\xi)),(w,\eta))=-\langle-\gamma_g(\xi,\xi),T_gR_{g^{-1}}(w)\rangle_e+\langle\eta,\xi\rangle_e \\ -\langle\xi,[\xi,T_gR_{g^{-1}}(w)]\rangle_e. \tag{14}$$

Since the metric is right-invariant, it follows that

$$E\circ\rho^{-1}(g,\xi)=\tfrac{1}{2}\langle T_eR_g\cdot\xi,T_eR_g\cdot\xi\rangle_g=\tfrac{1}{2}\langle\xi,\xi\rangle_e.$$

Therefore the right-hand side of (13) is equal to

$$\mathbf{d}(E\circ\rho^{-1})(g,\xi)\cdot(w,\eta)=\langle\xi,\eta\rangle_e. \tag{15}$$

From (13), (14), and (15) we may conclude that the value of $\gamma_g(\xi,\xi)$ does not depend on the base point g. Moreover, its value is defined by the following relationship:

$$\langle\gamma(\xi,\xi),\zeta\rangle_e=\langle\xi,[\xi,\zeta]\rangle_e\quad\text{for }\ \xi,\zeta\in T_eG.$$

From the definition (22) of the operator B it follows that $\gamma(\xi,\xi)=B(\xi,\xi)$, and hence (11) is true.

It is known that $-B(\xi,\xi)=(\nabla_{X_\xi}X_\xi)(e)$, where $X_\xi(g)=T_eR_g\cdot\xi$ (see Arnold,[11] Bao and Ratiu[12]). Thus, for right-invariant vector fields, we also have that

$$\overline{S}(g,\xi)=(X_\xi(g),\xi,(\nabla_{X_\xi}X_\xi)(e)).$$

Conclusion 2: Given a right-invariant metric on G, we can find its geodesic equations by finding the spray. The above formulas show that the spray is completely defined by either the operator B or the value of the Levi–Civita connection at the identity.

See the remark in Sec. V.

C. The Euler–Poincaré equations

The Euler–Poincaré equations are the fundamental result about geodesic flow on an arbitrary Lie group. See, for example, Theorem 13.8.3 in Marsden and Ratiu[8] or Appendix 2 in Arnold.[13] Herein, this result is proven for diffeomorphism groups, the configuration space for ideal fluid dynamics. The idea of studying geodesics on diffeomorphism groups in order to do hydrodynamics is due to Arnold.[11]

In order to establish our notation, let us recall some results from Refs. 3 and 14. For $s > n/2$ and M a compact manifold without boundary, we may define the Sobolev H^s maps from M into M. Let $\mathcal{D}^s(M) = \{\eta \in H^s(M,M) | \eta \text{ is bijective and } \eta^{-1} \in H^s(M,M)\}$. If $s > n/2+1$, then $\mathcal{D}^s(M)$ is open in $H^s(M,M)$ and hence is a manifold. Note that $\mathcal{D}^s$ is not a Lie group, but rather a topological group. However, like a Lie group, $\mathcal{D}^s$ has an exponential map which associates to every tangent vector at the identity a one-parameter subgroup of $\mathcal{D}^s$. Such a tangent vector is an H^s vector field on M and the one-parameter subgroup is its flow. If $\pi: TM \to M$ is the canonical projection, one forms the Hilbert space

$$T_\eta \mathcal{D}^s = \{V: M \to TM | V \text{ is } H^s \quad \text{and} \quad \pi \circ V = \eta\},$$

the tangent space at $\eta \in \mathcal{D}^s$. An element V of the tangent space at $\eta \in \mathcal{D}^s$ is called a vector space over η.

Theorem III.1: *Assume that $\mathcal{D}^s(M)$ is equipped with a metric $\langle \cdot , \cdot \rangle$ that is invariant under right translations. Also assume that there exists the operator $B: \boldsymbol{\mathcal{X}}(M) \times \boldsymbol{\mathcal{X}}(M) \to \boldsymbol{\mathcal{X}}(M)$ defined by the identity*

$$\langle B(w,u),v \rangle = \langle w,[u,v] \rangle \quad \text{for } u,v,w \in \boldsymbol{\mathcal{X}}(M).$$

Then a curve $t \to \eta(t)$ in $\mathcal{D}^s$ is a geodesic of this metric if and only $u(t) = T_{\eta(t)} R_{\eta(t)^{-1}} \dot{\eta}(t) = \dot{\eta}(t) \circ \eta^{-1}(t)$ satisfies

$$\frac{du}{dt} = -B(u,u). \tag{16}$$

Proof: By proposition (III.1) the spray S is given by

$$S(V) = T\rho^{-1}(V, V\circ \eta^{-1}, -B(V \circ \eta^{-1}, V\circ \eta^{-1})) \quad \text{for } V \in T_\eta \mathcal{D}^s. \tag{17}$$

In this case the group $G = \mathcal{D}^s$ and the algebra $\mathcal{G} = \boldsymbol{\mathcal{X}}(M)$. Let us compute $T\rho^{-1}$:

$$\rho^{-1}: G \times \mathcal{G} \to TG,$$

$$(\eta, u) \mapsto u \circ \eta,$$

$$T_{(\eta,u)}\rho^{-1}: T_\eta \mathcal{D}^s \times \mathcal{G} \to T_{u\circ\eta}(TG).$$

Let $(\eta(t), u(t))$ be a curve in $\mathcal{D}^s \times \boldsymbol{\mathcal{X}}(M)$ such that $(\eta(0), u(0)) = (\eta, u)$ and $(\dot{\eta}(0), \dot{u}(0)) = (V, w)$, then

$$T_{(\eta,u)}\rho^{-1} \cdot (V,w) = \left.\frac{d}{dt}\right|_{t=0} \rho^{-1}(\eta(t), u(t)) = \left.\frac{d}{dt}\right|_{t=0} u(t) \circ \eta(t) = w \circ \eta + Tu \circ V.$$

Therefore,

$$S(V) = -B(V\circ \eta^{-1}, V \circ \eta^{-1}) \circ \eta + T(V \circ \eta^{-1}) \circ V,$$

or

$$S(V)\circ\eta^{-1}=-B(V\circ\eta^{-1},V\circ\eta^{-1})+T(V\circ\eta^{-1})\circ(V\circ\eta^{-1}). \tag{18}$$

For an integral curve $V_t\in T_{\eta(t)}\mathcal{D}^s(M)$, its pullback $u_t=V_t\circ\eta_t^{-1}$ is a curve in $T_e\mathcal{D}^s(M)$ that consists of H^s-vector fields on M. Then the spray equation,

$$\frac{dV_t}{dt}=S(V_t), \tag{19}$$

is equivalent to

$$\frac{d}{dt}(u_t\circ\eta_t)=S(V_t),$$

or

$$\frac{du_t}{dt}=S(V_t)\circ\eta_t^{-1}-Tu_t\circ u_t=-B(u_t,u_t)+Tu_t\circ u_t-Tu_t\circ u_t=-B(u_t,u_t). \tag{20}$$

□

IV. CAMASSA–HOLM EQUATION AS A GEODESIC FLOW

Henceforth, the subscript t will denote the partial derivative with respect to t. We shall apply the general results obtained in Sec. III to the CH-equation (2). For periodic boundary conditions, the configuration space is $G=\mathcal{D}^s(S^1)$ with Lie algebra $\mathcal{G}=\boldsymbol{\mathcal{X}}(S^1)$ of the same differentiability class. One may also consider (2) on R with the appropriate decay conditions at infinity guaranteed by the Sobolev class H^s. Formal computations are identical in both cases and, hence, may be treated simultaneously. Consider the H^1 inner product on $\mathcal{G}$ given by

$$\langle u,v\rangle_1=\int (uv+u_xv_x)dx,$$

where the integral may either be taken over S^1 or R. Camassa and Holm[2] have shown that the Lagrangian for the CH-equation (2) is given by the square of the H^1 norm (1).

Given an inner product on a Lie algebra, we can define a metric on all $T\mathcal{D}^s$ by right translation so that for $V,W\in T_\eta\mathcal{D}^s$,

$$\begin{aligned}\langle V,W\rangle_\eta&=\langle T_\eta R_{\eta^{-1}}\cdot V,T_\eta R_{\eta^{-1}}\cdot W\rangle_{id}\\&=\langle V\circ\eta^{-1},W\circ\eta^{-1}\rangle_1\\&=\int [(V\circ\eta^{-1})(W\circ\eta^{-1})+(V\circ\eta^{-1})_x(W\circ\eta^{-1})_x]dx.\end{aligned} \tag{21}$$

This metric is right-invariant by definition and it defines the extended Lagrangian

$$L(V)=\tfrac{1}{2}\langle V,V\rangle_\eta.$$

The main result of this section is

Theorem IV.1: *Let $t\to\eta(t)$ be a curve in the diffeomorphism group $\mathcal{D}^s$ starting at the identity. Then $\eta(t)$ is a geodesic of the metric (21) if and only if the time-dependent vector field $u(t)=\dot\eta(t)\circ\eta^{-1}(t)$ satisfies the CH-equation (2).*

Proof: By the theorem (III.1), the geodesic equations for the metric (21) are equivalent to (16). From the definition of the operator B, we have that

$$\begin{aligned}\langle B(w,u),v\rangle=\langle w,[u,v]\rangle&=\int(-uv_x+u_xv)w+(-uv_x+u_xv)_xw_x\,dx\\&=\int(u_xw+(uw)_x)v-w_{xx}(-uv_x+u_xv)\,dx\\&=\int(2u_xw-2u_xw_{xx}+uw_x-uw_{xxx})\,v\,dx\\&=\int(2u_x(1-\partial_x^2)w+u(1-\partial^2)w_x)v\,dx.\end{aligned}$$

Furthermore,

$$\langle B(w,u),v\rangle=\int(B(w,u)v+B(w,u)_xv_x)\,dx=\int((1-\partial^2)B(w,u))v\,dx,$$

and hence the formula for the operator B is

$$B(w,u)=(1-\partial^2)^{-1}(2u_x(1-\partial^2)w+u(1-\partial^2)w_x). \tag{22}$$

Observe that the map $v\mapsto(1-\partial^2)v$ is a smooth map from H^s to H^{s-2}. The product (not the composition) of H^s functions is H^s again. Also $(1-\partial^2)^{-1}$ is an isomorphism from H^{s-2} to H^s. Therefore (22) explicitly shows that the operator $B:T\mathcal{D}^s\times T\mathcal{D}^s\to T\mathcal{D}^s$ has no derivative loss. Now we obtain the Euler–Poincaré equation:

$$\begin{aligned}\frac{\partial u}{\partial t}=-B(u,u)&=-(1-\partial^2)^{-1}(2u_xu+uu_x-2u_xu_{xx}-uu_{xxx})\\&=-(1-\partial^2)^{-1}(3uu_x-2u_xu_{xx}-uu_{xxx}).\end{aligned}$$

This completes the proof that the geodesic equations for the metric coming from the H^1 inner product on the Lie algebra of vector fields $\mathcal{G}$ are equivalent to the CH-equation (2).

Remark: The Lie-algebra bracket $[u,v]$ on $\mathfrak{X}(M)$ is minus the Jacobi–Lie bracket (for an explanation refer to Marsden and Ratiu,[8] Chap. 9). □

(a) *Alternative derivation.* Below, we begin to compute the geodesic equations for the metric (21) by calculating the spray of the corresponding Lagrangian. Camassa and Holm[2] have shown that the CH-equation can be expressed in the integral form

$$u_t+uu_x=-(1-\partial^2)^{-1}\partial(u^2+\tfrac{1}{2}u_x^2)=-\int e^{-|x-y|}\left(uu_y+\frac{1}{2}u_yu_{yy}\right)dy.$$

Equation (18) together with the fact that $Tu\circ u$ is simply uu_x in one dimension shows that the spray is equal to

$$S(V)=-(1-\partial^2)^{-1}\partial((V\circ\eta^{-1})^2+\tfrac{1}{2}(V\circ\eta^{-1})_x^2)\circ\eta. \tag{23}$$

Letting $u=V\circ\eta^{-1}$ verifies the claim.

Remark. Herein, we have established that the spray (23) does not have derivative loss, and hence is a continuous operator from H^s into H^s. In fact, the spray (23) is actually smooth and this fact follows from arguments in Theorem 3.3 in Shkoller[6] as well as Theorem 4.2 in Ref. 7. See the remark in Sec. V.

V. DISCUSSION

We would like to emphasize that we built a right invariant metric on $\mathcal{D}^s$ by taking the H^1 inner product on the tangent space at the identity and right-translating it over the whole space. This does not coincide with the *usual* H^1 metric on each fiber $T_\eta \mathcal{D}^s$; see the remark after Theorem 4.1 in Ref. 7. To illustrate the difference of two approaches let us compare the geodesics of the L^2 metric with the right-invariant L^2 metric in the one-dimensional case.

A curve $\eta(t) \in \mathcal{D}^s$ is a geodesic of the L^2-metric if and only if the corresponding spatial velocity field

$$u = V \circ \eta^{-1}$$

satisfies Burger's equation:

$$u_t + u u_x = 0. \tag{24}$$

The corresponding Euler–Lagrange equations for the material velocity $V = \dot{\eta}$ are given by

$$V_t = 0.$$

The spray of this metric is equal to zero and hence smooth; however, as the metric is not right invariant, the Euler–Poincaré theorem does not apply.

For the right-invariant L^2 metric the Euler–Poincaré equations are given by

$$u_t + 3 u u_x = 0. \tag{25}$$

The corresponding Euler–Lagrange equations are given by

$$\eta_X \dot{V} + 2 V V_X = 0,$$

where η_X is the Jacobian of η, and X denotes the material coordinate of the fluid particle. The spray in this case is given by

$$S(\eta, V) = -\frac{2}{\eta_X} V V_X. \tag{26}$$

Since there is a loss of derivatives, the spray is not smooth (cf. Remark 3.5 in Shkoller[6]).

As we see from the above calculations, the two equations in the spatial velocities differ only in a scalar coefficient multiplying the derivative term, however, the corresponding sprays are completely different.

Remark: We note that Eq. (23) for the geodesic spray of the right-invariant H^1 metric on either S^1 or R has no derivative loss and hence shows that the CH-equation is an ordinary differential equation on the group $\mathcal{D}^s$. Thus, existence and uniqueness of solutions to (2) may be obtained by standard Picard iteration argument in the event that S is locally Lipschitz.

Lemmas 3.1 and 3.2 of Shkoller[6] show that S is C^1, and hence the result follows. See Refs. 7 and 6 for the well-posedness of the geodesic flow of the diffeomorphism groups on n-dimensional Riemannian manifolds.

It would be interesting to study the Lagrangian stability of the CH-equation, and this requires analysis of the curvature operator. Misiolek[15] has computed the sectional curvature of $\mathcal{D}^s(S^1)$. Shkoller[6] has obtained an explicit form for the H^1 covariant derivative $\tilde{\nabla}^1$ on volume-preserving diffeomorphism groups and has proved that the weak curvature tensor of $\tilde{\nabla}^1$ is a bounded trilinear operator in the H^s topology. We would like to explore these type of estimates on the full diffeomorphism group of the circle, as well as investigate the role of generalized flows in peakon dynamics. Regarding peakon dynamics, there is the paper of Alber *et al.*[16]

ACKNOWLEDGMENTS

I am thankful to Darryl D. Holm and Tudor Ratiu for their kind guidance during the course of this work. Their helpful suggestions, patient discussions, and sincere interest in the subject helped me to build confidence in this work. I also would like to thank Jerrold E. Marsden and Steve Shkoller for their comments on the paper. Their comments helped to make the paper more clear and detailed.

Large smoke rings with concentrated vorticity

Carlo Marchioro[a)]
Dipartimento di Matematica, Università di Roma La Sapienza, Piazzale A. Moro 2, 00185 Roma, Italy

(Received 23 March 1998; accepted for publication 30 September 1998)

In this paper we study an incompressible inviscid fluid when the initial vorticity is sharply concentrated in N disjoint regions. This problem has been well studied when a planar symmetry is present, i.e., the fluid moves in R^2. In this case we know that, when the diameter σ of each region supporting the vorticity is very small, the time evolution of the fluid is quite well described by a dynamical system with finite degrees of freedom called the ''point vortex model.'' In particular the connection between this model and the Euler equation has been proved rigorously as $\sigma \to 0$. In the present paper we discuss the ''stability'' of the point vortex model with respect to a particular small perturbation of the planar symmetry. More precisely we consider a fluid moving in R^3 with a cylindrical symmetry without swirl in which each vortex is no longer a straight tube, but a vorticity ring. We prove that large annuli of radii $r \approx \sigma^{-\beta}$ for any $\beta > 0$ remain ''localized'' and hence we obtain the point vortex model as $\sigma \to 0$.
[S0022-2488(99)02701-2]

I. INTRODUCTION

In the present paper we study the time evolution of an incompressible inviscid fluid when the initial vorticity is concentrated in N small disjoint regions of space. This problem is well studied when a planar symmetry is present, i.e., the fluid moves in $\mathbb{R}^2$. In this case we can approximate the time evolution of the flow by using a model with finite degrees of freedom, called the ''point vortex system,'' which reads

$$\dot{\mathbf{x}}_i = -\frac{1}{2\pi} \sum_{j=1, j\neq i}^{N} a_j \nabla_i^{\perp} \ln|\mathbf{x}_i - \mathbf{x}_j|, \quad \mathbf{x}_i(0) = \mathbf{x}_i, \quad i = 1,...,N, \tag{1.1}$$

where

$$\nabla_i^{\perp} \equiv (\partial_{y_i}, -\partial_{x_i}), \quad \mathbf{x}_i \equiv (x_i, y_i) \in \mathbb{R}^2. \tag{1.2}$$

The N real constants a_i are called ''charges'' or ''intensities'' of the vortices.

This model was introduced in the 19th century[1–4] and widely studied in many papers.[5–12] One of the more interesting applications is related to the so-called ''vortex method,'' a mean field limit introduced by Chorin to investigate fluids with a weak viscosity[13] and generalized to an inviscid flow by many authors. (On the system (1.1), the vortex method and related topics there is a wide literature. We quote here some main papers[1–35] and we suggest for more detailed references to see, for instance, Ref. 33). This limit corresponds to N going to ∞ and each ''charge'' going to 0. Another possible connection exists; N and the ''charges'' remain fixed and the diameter of the region supporting the vorticity goes to zero. This limit has been rigorously studied in[27–35] and in particular the following result called ''localization''[33–35] has been proved. Let the initial vorticity be concentrated in N small disjoint regions $\Lambda_i(0)$ of diameter σ, then, for any fixed time, the time

[a)]Electronic mail: marchioro@axcasp.caspur.it

evolved vorticity remains concentrated in N small disjoint regions $\Lambda_i(t)$ of diameter d such that $d \to 0$ as $\sigma \to 0$. This property provides the main tool for proving the connection between the Euler flow and the point vortex model.

In the present paper we discuss the same problem in the presence of a small perturbation of the planar symmetry. It would be more interesting to deform each vortex tube independently. Asymptotic results have been obtained in this direction (see Ref. 36, and references quoted in), but the task to obtain rigorous results appears too hard. So we consider a common curvature perturbation. More precisely, we consider a fluid moving in $\mathbb{R}^3$ and with a cylindrical symmetry without swirl (see Sec. II). In this case the analog of the straight vortex tubes become rings of vorticity (the so-called ''smoke ring''). We consider N smoke rings of mean radius $r_i \approx r_0$, transversal section of diameter σ and nonzero intensity. When r_0 is bounded and $\sigma \to 0$, they move with an infinite speed proportional to ln σ. The case of one vortex ring of intensity proportional to $\ln^{-1} \sigma$ has been studied and it has been proven that as $\sigma \to 0$ the smoke ring moves with a constant speed.[37] (For more results on a single vortex ring see for instance Refs. 38–43, and the reference therein.) Heuristically in this limit many vortex rings do not interact. When r_0 grows the system can have some nontrivial limit. When $r_0 \approx |\ln \sigma|$ the fluid ''converges'' (formally) to a dynamical system studied in a recent paper.[44] When r_0 increases, it is reasonable to expect that with *some* dependence of r_0 on σ we obtain the point vortex model. The main result of the present paper is that this dependence is *very weak* in such a way that the two limits $(r_0 \to \infty, \sigma \to 0)$ are almost independent. In fact in the next section we prove that when $r_0 \approx \sigma^{-\beta}$ *for any* $\beta > 0$ the solutions of the Euler Equation remain ''localized'' and converge as a measure to the system (1.1). We remark that the validity of this result for any β means essentially that the point vortex model is ''stable'' with respect of such curvature perturbations.

It is interesting also to obtain the ''stability'' of the point vortex model with respect to a viscosity perturbation. This problem has been studied in the planar case Refs. 45,46.

In the next section we give the exact statement of the problem studied in the present paper. The proof is quite similar to the planar case, but it differs by an essential point: the interaction between the fluid particles differs from the one of the planar case because of a term in the Green function. This term is similar to an external field already studied in other papers but, unfortunately, it is *not Lipschitz,* while in the planar case the smoothness of the field was essential. So we need some improvements and for completeness we prefer to sketch here the whole proof.

II. STATEMENTS AND PROOFS

We consider an incompressible inviscid fluid of unitary density moving in $\mathbb{R}^3$. The Euler equation reads

$$\partial_t \mathbf{u} + (\mathbf{u} \cdot \boldsymbol{\nabla}) \mathbf{u} = -\boldsymbol{\nabla} p, \tag{2.1}$$

$$\boldsymbol{\nabla} \cdot \mathbf{u} = 0 \tag{2.2}$$

with the initial and the boundary conditions. Here $\mathbf{u} = \mathbf{u}(\mathbf{x},t)$ denotes the velocity field and $p = p(\mathbf{x},t)$ the pressure.

In the present paper we assume that the velocity $\mathbf{u}$ decays at infinity.

We introduce the vorticity $\boldsymbol{\omega}$ as

$$\boldsymbol{\omega} = \nabla \wedge \mathbf{u}. \tag{2.3}$$

We can reconstruct the velocity field by means on the vorticity $\boldsymbol{\omega}$ as

$$\mathbf{u}(\mathbf{x},t) = -\frac{1}{4\pi} \int_{R^3} d\mathbf{y} \, \frac{(\mathbf{x}-\mathbf{y}) \wedge \boldsymbol{\omega}(\mathbf{y},t)}{|\mathbf{x}-\mathbf{y}|^3}. \tag{2.4}$$

We introduce cylindrical coordinates (z, r, θ) and we suppose that the initial velocity field is axisymmetric without swirl, i.e.,

$$\mathbf{u}(\mathbf{x},t)=(u_z(z,r,t),u_r(z,r,t),0). \tag{2.5}$$

We observe that the time evolution conserves the symmetry and Eqs. (2.1), (2.2), (2.3) become

$$\boldsymbol{\omega}=\nabla\wedge\mathbf{u}=(0,0,\omega_\theta)=(0,0,\partial_z u_r-\partial_r u_z), \tag{2.6}$$

$$\partial_t\omega_\theta+(u_z\partial_z+u_r\partial_r)\alpha_\theta-\frac{u_r\omega_\theta}{r}=0, \tag{2.7}$$

$$\partial_z(ru_z)+\partial_r(ru_r)=0. \tag{2.8}$$

From now on we denote ω_θ by ω. We want to study the system when no strong property of regularity is assumed on the initial data, and so we consider a weak formulation of the Euler equation. A first one follows from the observation that Eq. (2.7) means the conservation during the motion of the quantity ω/r,

$$\frac{\omega(z(0),r(0),0)}{r(0)}=\frac{\omega(z(t),r(t),t)}{r(t)}, \tag{2.9}$$

where $z(t)$ and $r(t)$ are the time evolution of $r(0)$ and $r(0)$ according to the velocity field given by Eq. (2.4), i.e.,

$$\dot{z}=u_z,\quad \dot{r}=u_r. \tag{2.10}$$

Equations (2.4), (2.9), (2.10) give a weak formulation of the Euler equation. Another equivalent weak formulation is given by a (formal) integration by parts of (2.7),

$$\partial_t\omega_t[f]=\omega_t[u_z\partial_z f+u_r\partial_r f+\partial_t f], \tag{2.11}$$

where $f=f(z,r,t)$ is a bounded smooth test function and

$$\omega_t[f]=\int_{-\infty}^{\infty}dz\int_0^{\infty}dr\ f\omega. \tag{2.12}$$

From Eq. (2.4) we obtain

$$u_z(z,r,t)=-\frac{1}{2\pi}\int_{-\infty}^{\infty}dz'\int_0^{\infty}r'\ dr'\int_0^{\pi}d\theta\,\frac{\omega(z',r',t)(r\cos\theta-r')}{[(z-z')^2+(r-r')^2+2rr'(1-\cos\theta)]^{3/2}}, \tag{2.13}$$

$$u_r(z,r,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dz'\int_0^{\infty}r'\ dr'\int_0^{\pi}d\theta\,\frac{\omega(z',r',t)(z-z')\cos\theta}{[(z-z')^2+(r-r')^2+2rr'(1-\cos\theta)]^{3/2}}. \tag{2.14}$$

We now introduce a change of variables

$$z=x,\quad r=r_0+y;\quad \mathbf{x}=(x,y), \tag{2.15}$$

where r_0 will be precise in the sequel.

In the proofs discussed later on it is useful to outline the difference between the velocity fields given by Eqs. (2.13), (2.14) and the planar case in which

$$\mathbf{u}_0(\mathbf{x},t)=\int\mathbf{K}(\mathbf{x}-\mathbf{x}')\omega(\mathbf{x}',t)d\mathbf{x}', \tag{2.16}$$

where

$$\mathbf{K}(\mathbf{x})=\left(-\frac{1}{2\pi}\frac{y}{|\mathbf{x}|^2},\ \frac{1}{2\pi}\frac{x}{|\mathbf{x}|^2}\right). \tag{2.17}$$

We write the velocity field as

$$\mathbf{u}(\mathbf{x},t)=\int(\mathbf{K}(\mathbf{x}-\mathbf{x}')+\mathbf{D}(\mathbf{x},\mathbf{x}'))\omega(\mathbf{x}',t)d\mathbf{x}', \tag{2.18}$$

where the previous equation is a definition of **D**.

We consider initial data of the form

$$\omega_\sigma(\mathbf{x},0)=\sum_{i=1}^{N}\omega_{\sigma,i}(\mathbf{x},0), \tag{2.19}$$

where $\omega_{\sigma,i}(\mathbf{x},0)$ is a function with a definite sign supported in a region $\Lambda_{\sigma,i}$ such that

$$\Lambda_{\sigma,i}\equiv\text{supp }\omega_{\sigma,i}\subset\Sigma(\mathbf{x}_i|\sigma), \tag{2.20}$$

where

$$(x_i,y_i)\neq(x_j,y_j)\quad\text{if } i\neq j$$
$$\sigma<\tfrac{1}{2}\min_{i,j\ \ i\neq j}((x_i-x_j)^2+(y_i-y_j)^2)^{1/2} \tag{2.21}$$

and consequently

$$\Sigma(\mathbf{x}_i|\sigma)\cap\Sigma(\mathbf{x}_j|\sigma)=\emptyset\quad\text{if } i\neq j. \tag{2.22}$$

Here $\Sigma(\mathbf{x}|\sigma)$ denotes a disk of center ($\mathbf{x}$) and radius σ.

We assume that initially

$$|\omega_{\sigma,i}(\mathbf{x},0)|\leq M\sigma^{-\gamma},\ \ 0<M<\infty,\ \ 2\leq\gamma<\infty, \tag{2.23}$$

and

$$\int_{-\infty}^{\infty}dx\int_{-r_0}^{\infty}dy\ \ \omega_{\sigma,i}(\mathbf{x},0)=a_i, \tag{2.24}$$

where $a_i\in\mathbb{R}$, $i=1,...,N$, and a_i is called the "intensity of the i-annulus of vorticity."

We study now the time evolution of the Euler equation with the initial conditions (2.19) when σ becomes very small and r_0 becomes very large,

$$r_0=\text{const }\sigma^{-\beta}, \tag{2.25}$$

where from now on const denotes a constant independent of σ.

Depending on the size of β, we have different behavior of the solutions as $\sigma\to 0$: if $r_0=\text{const}$ the velocity field (2.13) and (2.14) is unbounded and so the problem has no meaning, if $r_0=\text{const}\ |\log\sigma|$ we obtain, in a formal way, a dynamical system widely studied in Ref. 44, if r_0 is given by Eq. (2.25) we obtain the point vortex model as we will see in this section.

Theorem 2.1: *Let assumption (2.25) hold and denote by $\omega_\sigma(\mathbf{x},t)$ the time evolution of $\omega_\sigma(\mathbf{x},0)$ according to the Euler equation. Then, for any fixed $T>0$ and for any $\alpha<\min(\frac{1}{3},\beta/3)$:*

(1) There exists $C(\alpha,T)$ such that for $0\leq t\leq T$

$$\text{supp }\omega_{\sigma,i}(\mathbf{x},t)\subset\Sigma(\mathbf{x}_i(t)|d), \tag{2.26}$$

where

$$d=C(\alpha,T)\sigma^{\alpha}, \tag{2.27}$$

and $\mathbf{x}_i(t)$ *is the solution of the ordinary system (1.1) provided that such a solution exists up to the time T.*

(2) For any continuous bounded function $f(\mathbf{x})$,

$$\int d\mathbf{x}\ \omega_{\sigma,i}(\mathbf{x},t)f(\mathbf{x})\rightarrow\sum_{i=1}^{N} a_i f(\mathbf{x}_i(t)) \quad\text{as}\quad \sigma\rightarrow 0. \tag{2.28}$$

Proposition (1) states that the blobs of vorticity remain concentrated until time T. Proposition (2) states that

$$\omega_{\sigma}(\mathbf{x},t)\rightarrow\sum_{i=1}^{N} a_i\delta(\mathbf{x}_i(t)) \quad\text{as}\quad \sigma\rightarrow 0 \tag{2.29}$$

weakly in the sense of the measures, where $\delta(\cdot)$ denotes the Dirac measure. This last statement gives a rigorous justication of the point vortex model as a limit of large annuli.

We remark that the singular nature of the right-hand side of Eq. (1.1), diverging when two vortices are close, does not guarantee the existence of the solution of Eq. (1.1) for every time. In many cases (for instance, for all $a_i>0$) collapses are forbidden by the first integrals of motion, but there are cases in which singularities happen. However it can be proved that the collapses are exceptional.[28] We can say that Theorem 2.1 holds up to the time T for which the solution of Eq. (1.1) exists.

Proof: The proof is similar to that studied in Refs. 32,34, but the nonregularity of the interaction in the cylindrical case imposes some improvements and hence, for completeness, we sketch it wholly.

Initially the blobs of vorticity are disjoint. We follow the evolution of one of them. Its center of vorticity moves under the action of the curvature of the annulus and of the other vortices. We simulate the influence of the other vortices by an external field and we study in details the time evolution of a single annulus of vorticity under a suitable external field. We will prove (in the next Theorem) that it remains concentrated. Finally it is easy to obtain from this result the proof of Theorem 2.1.

We consider a single blob of unitary vorticity moving in an external, divergence-free, uniformly bounded, time dependent vector field satisfying the Lipschitz condition velocity field $\mathbf{F}(\mathbf{x},t)$,

$$|\mathbf{F}(\mathbf{x},t)-\mathbf{F}(\mathbf{y},t)|\leq L|\mathbf{x}-\mathbf{y}|, \quad L>0. \tag{2.30}$$

Equation (2.10) becomes

$$\dot{\mathbf{x}}(t)=\mathbf{u}(\mathbf{x},t)+\mathbf{F}(\mathbf{x},t) \tag{2.31}$$

while Eqs. (2.9), (2.4) remain unchanged. The Euler equation in weak form reads also

$$\dot{\omega}[f]=\omega[(\mathbf{u}+\mathbf{F})\cdot\nabla f]+\omega[\partial_t f]. \tag{2.32}$$

We prove proposition (1) of Theorem 2.1 for this particular evolution. Define the center of vorticity of the blob as

$$\mathbf{B}_{\sigma}(t)=\int \mathbf{x}\omega_{\sigma}(\mathbf{x},t)d\mathbf{x}. \tag{2.33}$$

Theorem 2.2: *Suppose that*

$$\int \omega_\sigma(\mathbf{x},0)d\mathbf{x}=1, \tag{2.34}$$

$$\text{supp } \omega_\sigma(\mathbf{x},0)\subset\Sigma(\mathbf{x}^*|\sigma), \tag{2.35}$$

and

$$|\omega_\sigma(\mathbf{x},0)|\leq \text{const } \sigma^{-\gamma} \quad 2\leq\gamma<\infty. \tag{2.36}$$

Then, for any fixed $T>0$ and for any $\alpha<\min(\frac{1}{3},\beta/3)$

(1) there exists $C(\alpha,T)$ such that for $0\leq t\leq T$,

$$\text{supp } \omega_\sigma(\mathbf{x},t)\subset\Sigma(\mathbf{B}(t)|d), \tag{2.37}$$

where

$$d=C(\alpha,T)\sigma^\alpha \tag{2.38}$$

and $\mathbf{B}(t)$ is the solution of the ordinary system

$$\dot{\mathbf{B}}(t)=\mathbf{F}(\mathbf{B}(t),t) \quad \mathbf{B}(0)=\mathbf{x}^*. \tag{2.39}$$

Moreover,

$$|\mathbf{B}_\sigma(t)-\mathbf{B}(t)|\to 0 \text{ as } \sigma\to 0 \textit{ uniformly in } t\in[0,T], \textit{ at least as } \sigma^{\beta'} \tag{2.40}$$

for any $\beta'<\beta$.

Proof: The difficulty of the proof arises from the singularity of the kernel $\mathbf{K}+\mathbf{D}$ which forces a fluid particle to rotate with a very large velocity around the center of vorticity. To overcome this difficulty we study the motion of the center of vorticity, which turn out to be more regular than the motion of a given fluid particle. Moreover we control the spreading of the vorticity around the center of vorticity by using the moment of inertia, which is almost conserved during the motion. However, as we will see, this control is not enough and it must be improved to acheive the proof.

Theorem 2.2 states an asymptotic result as $\sigma\to 0$ and hence without lack of generality we can suppose that $\sigma\ll 1$.

The more difficult case arises for β small and so in the proof we suppose, without lack of generality, that $\beta<1$.

We start supposing they exist y_M, y_m, independent of σ such that $|y_M|<\infty$, $|y_m|<\infty$, and up to time t, $O\leq t\leq T$, the support of the vorticity remains bounded,

$$\text{supp } \omega(\mathbf{x}(t),t)\subset\{\mathbf{x}|y_m\leq y\leq y_M\}. \tag{2.41}$$

At the end of this section we shall prove that this hypothesis is fulfilled.

We remark that the vorticity remains constant during the motion,

$$\int \omega_\sigma(\mathbf{x}(t),t)d\mathbf{x}=\int \omega_\sigma(\mathbf{x}(0),0)d\mathbf{x}=1 \tag{2.42}$$

as we can see by using Eq. (2.11).

We introduce the moment of inertia $I_\sigma(t)$ with respect of $\mathbf{B}_\sigma(t)$,

$$I_\sigma(t)=\int \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))^2 d\mathbf{x} \tag{2.43}$$

and we study the growth in time of $\mathbf{B}_\sigma(t)$ and $I_\sigma(t)$. By using the Euler equation, we have

$$\dot{\mathbf{B}}_\sigma(t)=\int d\mathbf{x}[\mathbf{u}(\mathbf{x},t)+\mathbf{F}(\mathbf{x},t)]\omega_\sigma(\mathbf{x},t), \tag{2.44}$$

$$\begin{aligned}\dot{I}_\sigma(t)&=2\int d\mathbf{x}\{(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot(\mathbf{u}(\mathbf{x},t)+\mathbf{F}(\mathbf{x},t))-(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\dot{\mathbf{B}}_\sigma(t)\}\omega_\sigma(\mathbf{x},t)\\&=2\int d\mathbf{x}\ \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\left(\mathbf{u}(\mathbf{x},t)-\int d\mathbf{x}'\ \omega_\sigma(\mathbf{x}',t)\mathbf{u}(\mathbf{x}',t)\right)\\&\quad+2\int d\mathbf{x}\ \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\left(\mathbf{F}(\mathbf{x},t)-\int d\mathbf{x}'\ \omega_\sigma(\mathbf{x}',t)\mathbf{F}(\mathbf{x}',t)\right).\end{aligned} \tag{2.45}$$

We study in detail Eq. (2.45). The terms with $\mathbf{F}$ can be easily bounded by using the Lipschitz condition, the Cauchy–Schwarz inequality and the remark that

$$\int d\mathbf{x}\ \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot(\mathbf{F}(\mathbf{B}_\sigma(t),t)-\mathbf{F}(\mathbf{x}',t))=0. \tag{2.46}$$

We obtain

$$\begin{aligned}&\left|2\int d\mathbf{x}\ \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\left(\mathbf{F}(\mathbf{x},t)-\int d\mathbf{x}'\ \omega_\sigma(\mathbf{x}',t)\mathbf{F}(\mathbf{x}',t)\right)\right|\\&\quad=\left|2\int d\mathbf{x}\ \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\int d\mathbf{x}'\ \omega_\sigma(\mathbf{x}',t)[\mathbf{F}(\mathbf{x},t)-\mathbf{F}(\mathbf{x}',t)]\right|\leqslant 2LI_\sigma(t).\end{aligned} \tag{2.47}$$

To evaluate the terms in $\mathbf{u}$ we use the following two properties discussed in the Appendix:

$$\left|\int d\mathbf{x}\ \mathbf{u}(\mathbf{x},t)\omega_\sigma(\mathbf{x},t)\right|\leqslant\text{const }\sigma^\beta\ \ln|\sigma|\leqslant\text{const }\sigma^{\beta'}\quad\text{for any}\quad\beta'<\beta, \tag{2.48}$$

$$\left|\int d\mathbf{x}\ \omega_\sigma(\mathbf{x},t)(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\mathbf{u}(\mathbf{x},t)\right|\leqslant\text{const }\sigma^{\beta'}I_\sigma^{1/2}\quad\text{for any}\quad\beta'<\beta. \tag{2.49}$$

In conclusion,

$$|\dot{I}_\sigma(t)|\leqslant 2LI_\sigma(t)+\text{const }\sigma^{\beta'}I_\sigma^{1/2} \tag{2.50}$$

and then

$$I_\sigma(t)\leqslant\text{const }\sigma^{2\beta'}. \tag{2.51}$$

The next steps to obtain Eq. (2.40) are similar to that used in Ref. 32 to obtain Eq. (3.16) and we omit them.

We have obtained Eq. (2.51), which says that the main part of the vorticity is concentrated around the center of vorticity. *A priori* small filaments of vorticity could go far away. We want to prove that this not the case and the support of the vorticity remains concentrated around the center. For this purpose we study the radial part of the velocity field near the boundary of the support of the vorticity and we prove that the difference between this field and the velocity field acting on the center of the vortex vanishes as $\sigma\to 0$. So, the particle paths cannot go far apart from $\mathbf{B}_\sigma$. The radial field is essentially due to three terms; the velocity produced by the external field, the velocity produced by the particles near the center of the vortex and the velocity produced by the particle near the boundary. The first contribution is easily controlled by the Lipschitz condition, the second contribution vanishes as the vorticity is sharply concentrated, and the third contribution needs more care and vanishes after an iterative procedure, which is given in the sequel.

We study the growth in time of the distance of the particle in $\mathbf{x}\in \text{supp}\ \omega(\mathbf{x},t)$ farthest from $\mathbf{B}_\sigma$,

$$\left|(\mathbf{u}(\mathbf{x},t)+\mathbf{F}(\mathbf{x},t)-\dot{\mathbf{B}}_\sigma(t))\cdot \frac{\mathbf{x}-\mathbf{B}_\sigma(t)}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\right|$$
$$\leqslant\left|\mathbf{F}(\mathbf{x},t)-\int d\mathbf{y}\ \omega_\sigma(\mathbf{y},t)\mathbf{F}(\mathbf{y},t)\right|+\left|\left(\mathbf{u}(\mathbf{x},t)-\int d\mathbf{y}\ \omega_\sigma(\mathbf{y},t)\mathbf{u}(\mathbf{y},t)\right)\cdot \frac{\mathbf{x}-\mathbf{B}_\sigma(t)}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\right|$$
$$\leqslant\left|\int d\mathbf{y}\ \omega_\sigma(\mathbf{y},t)(\mathbf{F}(\mathbf{x},t)-\mathbf{F}(\mathbf{y},t))\right|+\left|\mathbf{u}(\mathbf{x},t)\cdot \frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\right|+\text{const}\ \sigma^{\beta'}. \tag{2.52}$$

The first contribution due to the external field can be controlled by using the Lipschitz condition,

$$\left|\int d\mathbf{y}\ \omega_\sigma(\mathbf{y},t)(\mathbf{F}(\mathbf{x},t)-\mathbf{F}(\mathbf{y},t)\right|\leqslant \text{const}\ R, \tag{2.53}$$

where

$$R\equiv|\mathbf{x}-\mathbf{B}_\sigma(t)|. \tag{2.54}$$

We study now the other terms,

$$\left|\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot\mathbf{u}(\mathbf{x},t)\right|=\left|\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot(\mathbf{u}_0(\mathbf{x},t)+(\mathbf{u}(\mathbf{x},t)-\mathbf{u}_0(\mathbf{x},t))\right|, \tag{2.55}$$

where $\mathbf{u}_0(\mathbf{x},t)$ is the planar velocity field defined in Eq. (2.16). The last term can be bounded by using the following equation:

$$|(\mathbf{u}(\mathbf{x},t)-\mathbf{u}_0(\mathbf{x},t))|\leqslant \text{const}\ \sigma^{\beta'}, \tag{2.56}$$

a consequence of the estimates of the Appendix.

We evaluate the term $|(\mathbf{x}-\mathbf{B}_\sigma(t))/|\mathbf{x}-\mathbf{B}_\sigma(t)|\cdot\mathbf{u}_0(\mathbf{x},t)|$. We divide the circle $\Sigma(\mathbf{B}_\sigma(t),R)$ into many different annuli,

$$\Sigma(\mathbf{B}_\sigma(t)|R)=\sum_{k=1}^{k*}[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]\cup[\Sigma(\mathbf{B}_\sigma(t)|R)-\Sigma(\mathbf{B}_\sigma(t)|a_{k*})], \tag{2.57}$$

where

$$a_0=0,\ \ a_1=\sigma^{\beta'},\ \ a_k=2a_{k-1}. \tag{2.58}$$

We choose $k*$ such that $a_{k*+1}\leqslant R$ and $a_{k*+2}>R$.

The radial velocity can be expressed by the sum of the contribution obtained when the particles are contained in each annulus,

$$\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot\int_{[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]}\mathbf{K}(\mathbf{x}-\mathbf{x}')\,\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'$$
$$=\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot\int_{[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]}\mathbf{K}(\mathbf{x}-\mathbf{B}_\sigma(t))\,\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'$$
$$+\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot\int_{[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]}(\mathbf{K}(\mathbf{x}-\mathbf{x}')-\mathbf{K}(\mathbf{x}-\mathbf{B}_\sigma(t)))\,\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'. \tag{2.59}$$

The first term in the right-hand side of Eq. (2.59) vanishes because of $\mathbf{x}\cdot\mathbf{K}(\mathbf{x})=0$. Moreover by the explicit form of $\mathbf{K}(\mathbf{x})$, we have

$$|\mathbf{K}(\mathbf{x}-\mathbf{x}')-\mathbf{K}(\mathbf{x})|<\text{const}\,\frac{\rho}{|\mathbf{x}|(|\mathbf{x}|-\rho)}\quad\text{if}\ \ |\mathbf{x}'|<\rho<|\mathbf{x}|. \tag{2.60}$$

Hence

$$\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot\int_{[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]}(\mathbf{K}(\mathbf{x}-\mathbf{x}')-\mathbf{K}(\mathbf{x}-\mathbf{B}_\sigma(t)))\,\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'$$
$$<\text{const}\,\frac{a_k}{R(R-a_k)}\int_{[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]}\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'. \tag{2.61}$$

The last integral can be bounded by $I_\sigma(t)$. In fact it is obvious that

$$I_\sigma(t)\geqslant r^2 m_t(r), \tag{2.62}$$

where

$$m_t(r)=\int_{R^2-\Sigma(\mathbf{B}_\sigma(t)|r)}\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'. \tag{2.63}$$

Equation (2.51) implies

$$m_t(r)\leqslant\text{const}\ \sigma^{2\beta'}r^{-2}. \tag{2.64}$$

Hence

$$\int_{[\Sigma(\mathbf{B}_\sigma(t)|a_k)-\Sigma(\mathbf{B}_\sigma(t)|a_{k-1})]}\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'<\text{const}\,\frac{\sigma^{2\beta'}}{a_{k-1}^2},\quad k>1. \tag{2.65}$$

We put Eq. (2.65) in Eq. (2.61) and we obtain

$$\frac{(\mathbf{x}-\mathbf{B}_\sigma(t))}{|\mathbf{x}-\mathbf{B}_\sigma(t)|}\cdot\int_{\Sigma(\mathbf{B}_\sigma(t)|a_{k*})}\mathbf{K}(\mathbf{x}-\mathbf{x}')\,\omega_\sigma(\mathbf{x}',t)\,d\mathbf{x}'<\text{const}\,\frac{\sigma^{2\beta'}}{R^2}. \tag{2.66}$$

Now we prove that the vorticity mass close to the boundary of the support is very small and so it can produce a very weak velocity field.

To control the vorticity flux we introduce for any $R>0$ the following non-negative function $G_R\in C^\infty(\mathbb{R}^2)$, $\mathbf{r}\rightarrow G_R(\mathbf{r})$ depending only on $|\mathbf{r}|$, defined as

$$G_R(\mathbf{r})=\begin{cases}1 & \text{if } |r|>2R\\ 0 & \text{if } |r|<R\end{cases}\tag{2.67}$$

such that for some $C_1>0$,

$$|\nabla G_R(\mathbf{r})|<\frac{C_1}{R}\tag{2.68}$$

$$|\nabla G_R(\mathbf{r})-\nabla G_R(\mathbf{r}')|<\frac{C_1}{R^2}\,|\mathbf{r}-\mathbf{r}'|.\tag{2.69}$$

We define the quantity

$$\mu_t(R)=\int G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\,\omega_\sigma(\mathbf{x},t)\,d\mathbf{x}.\tag{2.70}$$

We choose $\mu_t(R)$ as a measure of the localization of $\omega_\sigma(\mathbf{x},t)$ around $\mathbf{B}_\sigma(t)$. In fact if supp $\omega_\sigma(\mathbf{x},t)\subset\Sigma(\mathbf{B}_\sigma(t)|R)$, then $\mu_t(R)=0$. We evaluate its time derivative by using Eq. (2.11),

$$\begin{aligned}\dot{\mu}_t(R)&=\int d\mathbf{x}\;\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot(\mathbf{u}(\mathbf{x},t)+\mathbf{F}(\mathbf{x},t))-\dot{\mathbf{B}}_\sigma(t))\,\omega_\sigma(\mathbf{x},t)\\&=\int d\mathbf{x}\;\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\,\omega_\sigma(\mathbf{x},t)\cdot\int d\mathbf{x}'\;\mathbf{K}(\mathbf{x}-\mathbf{x}')\,\omega_\sigma(\mathbf{x}',t)\\&\quad+\int d\mathbf{x}\;\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\,\omega_\sigma(\mathbf{x},t)\cdot\int d\mathbf{x}'\;\mathbf{D}(\mathbf{x}-\mathbf{x}')\,\omega_\sigma(\mathbf{x}',t)\\&\quad-\int d\mathbf{x}\;\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\int d\mathbf{x}'\;\mathbf{u}(\mathbf{x}',t)\,\omega_\sigma(\mathbf{x}',t)\\&\quad+\int d\mathbf{x}\;\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\,\omega_\sigma(\mathbf{x},t)\cdot\left[\left(\mathbf{F}(\mathbf{x},t)-\int d\mathbf{x}'\;\mathbf{F}(\mathbf{x}',t)\right)\omega_\sigma(\mathbf{x}',t)\right].\end{aligned}\tag{2.71}$$

We estimate the first term in the right-hand side of Eq. (2.71). By the antisymmetry of **K**, it can be written as

$$\frac{1}{2}\int\int d\mathbf{x}\,d\mathbf{x}'(\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))-\nabla G_R(\mathbf{x}'-\mathbf{B}_\sigma(t))\cdot\mathbf{K}(\mathbf{x}-\mathbf{x}')\,\omega_\sigma(\mathbf{x},t)\,\omega_\sigma(\mathbf{x}',t).\tag{2.72}$$

To estimate this term for $R=\sigma^{\beta'}2^{n-1}$, we split the integration domain in the following sets:

$$T_h=\{(\mathbf{x},\mathbf{x}')|\mathbf{x}\notin\Sigma(\mathbf{B}_\sigma(t)|R),\;\;\mathbf{x}'\in(\Sigma(\mathbf{B}_\sigma(t)|a_h)-\Sigma(\mathbf{B}_\sigma(t)|a_{h-1}))\quad\text{if } h<n,\tag{2.73}$$

$$T_h=\{(\mathbf{x},\mathbf{x}')|\mathbf{x}\notin\Sigma(\mathbf{B}_\sigma(t)|R),\;\;\mathbf{x}'\notin\Sigma(\mathbf{B}_\sigma(t)|a_{h-1})\quad\text{if } h=n,\tag{2.74}$$

$$S_h=\{(\mathbf{x},\mathbf{x}')|\mathbf{x}'\notin\Sigma(\mathbf{B}_\sigma(t)|R),\;\;\mathbf{x}\in(\Sigma(\mathbf{B}_\sigma(t)|a_h)-\Sigma(\mathbf{B}_\sigma(t)|a_{h-1})\quad\text{if } h<n,\tag{2.75}$$

$$S_h=\{(\mathbf{x},\mathbf{x}')|\mathbf{x}'\notin\Sigma(\mathbf{B}_\sigma(t)|R),\;\;\mathbf{x}\notin\Sigma(\mathbf{B}_\sigma(t)|a_{h-1})\quad\text{if } h=n.\tag{2.76}$$

Remark that the integrand in Eq. (2.72) vanishes in the complement of $\cup_{h=1}^{n}(T_h\cup S_h)$.

Thanks to the identities $\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\cdot\mathbf{K}(\mathbf{x}-\mathbf{B}_\sigma(t))=0$ and $\nabla G_R(\mathbf{x}'-\mathbf{B}_\sigma(t))=0$ if $\mathbf{x}'\in(\Sigma(\mathbf{B}_\sigma(t)|a_h)-\Sigma(\mathbf{B}_\sigma(t)|a_{h-1})$, $h<n$, the contribution to the integral due to T_h, $h<n$ is bounded by

$$\left| \int d\mathbf{x} \int_{\Sigma(\mathbf{B}_\sigma(t)|a_h) - \Sigma(\mathbf{B}_\sigma(t)|a_{h-1})} d\mathbf{x}' \nabla G_R(\mathbf{x} - \mathbf{B}_\sigma(t)) \right.$$
$$\left. \cdot (\mathbf{K}(\mathbf{x}-\mathbf{x}') - \mathbf{K}(\mathbf{x} - \mathbf{B}_\sigma(t)))\, \omega_\sigma(\mathbf{x},t)\, \omega_\sigma(\mathbf{x}',t) \right|. \tag{2.77}$$

We now use Eq. (2.68), the fact that $\nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))=0 \quad \text{if } |\mathbf{x}-\mathbf{B}_\sigma(t)|<R$, and we obtain the bound

$$(2.72) < \text{const}\, \frac{m_t(R)}{R} \left(\text{const}\, \frac{\sigma^{2\beta'}}{R^2} + \sum_{h=2}^{n-1} \frac{a_h}{R(R-a_h)} \frac{\sigma^{2\beta'}}{a_{h-1}^2} \right) < \text{const}\, \frac{\sigma^{\beta'}}{R^3}\, m_t(R). \tag{2.78}$$

To estimate the contribution due to T_n, we use the obvious inequality $|\mathbf{K}(\mathbf{x})| \le |\mathbf{x}|^{-1}$, Eq. (2.69) and the bound

$$|(\nabla G_R(\mathbf{x}) - \nabla G_R(\mathbf{x}')) \cdot \mathbf{K}(\mathbf{x}-\mathbf{x}')| < \frac{\text{const}}{R^2}. \tag{2.79}$$

We obtain this contribution smaller than const $(\sigma^{2\beta'}/R^4)m_t(R)$. We can handle in the same way the term with S_h. We study now the second term in the right-hand side of Eq. (2.71) that is smaller than

$$\frac{\text{const}\ \sigma^{\beta'}}{R}\, m_t(R) \tag{2.80}$$

as a consequence of estimates of the Appendix.

By using Eq. (2.48) the third term is smaller than

$$\text{const}\, \frac{\sigma^{\beta'}}{R}\, m_t(R). \tag{2.81}$$

Finally we study the last term in Eq. (2.71). We consider two cases; either $|\mathbf{x}'-\mathbf{B}_\sigma(t)|>R$ or $|\mathbf{x}'-\mathbf{B}_\sigma(t)|\le R$. In the first case,

$$\left| \int d\mathbf{x}\ \nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\, \omega_\sigma(\mathbf{x},t) \int d\mathbf{x}' (\mathbf{F}(\mathbf{x},t) - \mathbf{F}(\mathbf{x}',t))\, \omega_\sigma(\mathbf{x}',t) \right| < \text{const} \|\mathbf{F}\|_\infty \frac{\sigma^{2\beta'}}{R^3}\, m_t(R). \tag{2.82}$$

In the second case, by using the Lipschitz condition,

$$\left| \int d\mathbf{x}\ \nabla G_R(\mathbf{x}-\mathbf{B}_\sigma(t))\, \omega_\sigma(\mathbf{x},t) \int d\mathbf{x}' (\mathbf{F}(\mathbf{x},t) - \mathbf{F}(\mathbf{x}',t))\, \omega_\sigma(\mathbf{x}',t) \right| < \text{const}\ m_t(R). \tag{2.83}$$

In conclusion, we have

$$\dot{\mu}_t(R) \le A(R)\, m_t(R), \tag{2.84}$$

where

$$A(R) = \text{const}\, \frac{\sigma^{\beta'}}{R^3} + \text{const}\, \frac{\sigma^{2\beta'}}{R^4} + \text{const}. \tag{2.85}$$

We observe now that

$$m_t(R) \leqslant \mu_t\left(\frac{R}{2}\right). \tag{2.86}$$

We put Eq. (2.86) in the integral form of Eq. (2.85) and we obtain

$$\mu_t(R) \leqslant \mu_0(R) + A(R) \int_0^t \mu_{t_1}\left(\frac{R}{2}\right) dt_1. \tag{2.87}$$

We start an iterative procedure

$$\begin{aligned} \mu_t(R) &\leqslant \mu_0(R) + A(R) \int_0^t \mu_{t_1}\left(\frac{R}{2}\right) dt_1 \\ &\leqslant \mu_0(R) + A(R)t + A(R)A(R/2) \int_0^t dt_1 \int_0^{t_1} \mu_{t_2}\left(\frac{R}{4}\right) dt_2 \end{aligned} \tag{2.88}$$

and so on.

We start from $R = \text{const } \sigma^{\alpha}$, where $\alpha < \min(\frac{1}{3}, \sigma^{\beta'}/3)$. We iterate Eq. (2.84) n times, where n is chosen such that $n \to \infty$ as $\sigma \to 0$ and in the same time $A(R2^{-k})$ is bounded for any positive integer $k \leqslant n$ and $\mu_0(R2^{-n}) = 0$. We choose

$$n = \text{Integer part of } \left[-\frac{1-3\alpha}{4} \log_2 \sigma^{\beta'} \right]. \tag{2.89}$$

Then

$$R2^{-n} = \text{const } \sigma^{[\beta'(1+\alpha)]/4} \tag{2.90}$$

and

$$A(R2^{-k}) \leqslant \text{const} \tag{2.91}$$

for any positive integer $k \leqslant n$. Hence after n iterations we have

$$m_t(R) \leqslant \frac{(\text{const})^n}{n!} \to 0 \text{ faster than any power in } \sigma. \tag{2.92}$$

In conclusion we have proven that the vorticity mass becomes very small near the boundary of the support. We bound the velocity field produced by it,

$$\begin{aligned} &\left| \int_{\Sigma(\mathbf{B}_\sigma(t)|R) - \Sigma(\mathbf{B}_\sigma(t)|a_{k^*})} d\mathbf{x}' (\mathbf{K}(\mathbf{x}-\mathbf{x}') + \mathbf{D}(\mathbf{x},\mathbf{x}')) \omega_\sigma(\mathbf{x}',t) \right| \\ &\qquad \leqslant \text{const} \left| \int_{\Sigma(\mathbf{B}_\sigma(t)|R) - \Sigma(\mathbf{B}_\sigma(t)|a_{k^*})} d\mathbf{x}' |\mathbf{x}-\mathbf{x}'|^{-1} \omega_\sigma(\mathbf{x}',t) \right|. \end{aligned} \tag{2.93}$$

The integrand is monotonically unbounded as $\mathbf{x} \to \mathbf{x}'$ and so the maximum of the integral is obtained when we rearrange the vorticity mass as closed as possible to the singularity,

$$\left| \int_{\Sigma(\mathbf{B}_\sigma(t)|R) - \Sigma(\mathbf{B}_\sigma(t)|a_{k^*})} d\mathbf{x}' |\mathbf{x}-\mathbf{x}'|^{-1} \omega_\sigma(\mathbf{x}',t) \right| \leqslant \text{const } \sigma^{-\gamma} \left| \int_{\Sigma(\mathbf{O}|\eta} d\mathbf{x}' |\mathbf{x}'|^{-1}, \tag{2.94}$$

where $\mathbf{O}$ denotes the origin and η is such that

$$M\sigma^{-\gamma}\pi\eta^2=m_t(a_{k*}). \tag{2.95}$$

By using Eq. (2.92) we have that

$$\left|\int_{\Sigma(\mathbf{B}_\sigma(t)|R)-\Sigma(\mathbf{B}_\sigma(t)|a_{k*})} d\mathbf{x}'|\mathbf{x}-\mathbf{x}'|^{-1}\omega_\sigma(\mathbf{x}',t)\right|\to 0 \text{ faster than any power.} \tag{2.96}$$

We are now able to bound the radial velocity of a particle at a distance R from $\mathbf{B}_\sigma(t)$. We sum the partial bounds we have obtained and we have

$$\dot{R}\leqslant \text{const } R+\text{const }\frac{\sigma^{\beta'}}{R^2}+\text{terms smaller than any power in } \sigma \text{ when } R>\text{const }\sigma^{\alpha}. \tag{2.97}$$

Hence for $R>\text{const }\sigma^\alpha$ the last two terms in the right-hand side of Eq. (2.97) are neglectable and this differential inequality gives bound (2.37) by using the Gronwall Lemma. □

We return to the proof of Theorem 2.1. It is similar to that of the planar case and we only sketch it. We denote R_m the minimal distance between point vortices evolving via Eq. (1.1) and we choose $\sigma\ll R_m$. Initially the vortices are separeted and we study one vortex. We simulate the influence of other vortices on it as an external fields. We observe that actually the other vortices produce a velocity field depending on σ but this dependence is very small. Moreover each vortex moves in a bounded region of the space and so assumption (2.41) is satisfied. Then, it is easy to prove the convergence stated in Theorem 2.1. □

ACKNOWLEDGMENT

APPENDIX

We will use the following two integrals I_1 and I_2:

$$I_1=\int_0^\pi d\theta\,\frac{\cos\,\theta}{[a^2+2(1-\cos\,\theta)]^{3/2}}=\int_0^\pi d\theta\,\frac{\cos\frac{\theta}{2}+\left(\cos\,\theta-\cos\frac{\theta}{2}\right)}{\left[a^2+4\left(\sin\frac{\theta}{2}\right)^2\right]^{3/2}}. \tag{A1}$$

The first term is easily computed,

$$\int_0^\pi d\theta\,\frac{\cos\frac{\theta}{2}}{\left[a^2+4\left(\sin\frac{\theta}{2}\right)^2\right]^{3/2}}=\frac{2}{a^2(a^2+4)^{1/2}}. \tag{A2}$$

The remaining terms are less divergent for small a (see the study of I_2) and so, for small a, $I_1\approx a^{-2}$,

$$I_2 = \int_0^\pi d\theta \, \frac{(1-\cos\,\theta)}{[a^2+2(1-\cos\,\theta)]^{3/2}}$$
$$= \int_0^\pi d\theta \, \frac{2\left(\sin\frac{\theta}{2}\right)^2 \cos\frac{\theta}{2} + \left[1-\cos\,\theta - 2\left(\sin\frac{\theta}{2}\right)^2 \cos\frac{\theta}{2}\right]}{\left[a^2+4\left(\sin\frac{\theta}{2}\right)^2\right]^{3/2}}. \tag{A3}$$

The first term is easily computed

$$\int_0^\pi d\theta \, \frac{2\left(\sin\frac{\theta}{2}\right)^2 \cos\frac{\theta}{2}}{\left[a^2+4\left(\sin\frac{\theta}{2}\right)^2\right]^{3/2}} = -\frac{1}{(a^2+4)^{1/2}} + \frac{1}{2}\ln[2+(a^2+4)^{1/2}] - \frac{1}{2}\ln a. \tag{A4}$$

The other terms for small a are bounded and so $I_2 \approx -\frac{1}{2}\ln a$.

We are now able to obtain the bound (2.48). We use definition (2.18) and we study separately terms with **K** and with **D**. The term with **K** vanishes as we can easily prove, writing explicitely Eq. (2.48), interchanging **x** and **x**′ and using the antisymmetry of **K**. We evaluate the term with **D**. We use the explicit form of **u**, we take the leading term in σ^{-1}, and we obtain by using the previous eximates on I_1 and I_2 a bound of the form,

$$(2.48) \leq \text{const } \sigma^\beta + \text{const } \sigma^\beta \int\int\int d\mathbf{x}\, d\mathbf{x}' \;\; \omega_\sigma(\mathbf{x},t)\,\omega_\sigma(\mathbf{x}',t)(\text{const } \sigma^\beta + |\ln|\mathbf{x}-\mathbf{x}'||). \tag{A5}$$

To give a bound to the last integral we use the assumption (2.36), we perform a symmetrical rearrangement on the vorticity around the point (x,y), that is we concentrate the vorticity in a disk centered in the singularity (x,y) having a radius η such that the total vorticity is preserved, i.e., $(M/\sigma^\gamma)\pi\eta^2 = 1$. We perform the integral in the polar coordinate and it is smaller than const ln $\sigma^{-\beta}$. We put this bound in Eq. (A5) and we obtain the bound (2.48) [and in the same time Eq. (2.56)].

Equation (2.49) is obtained in the same way. In addition, in this case in the last step we use the Cauchy-Schwarz inequality.

(Received 29 December 1997; accepted for publication 26 October 1998)

Three new exact periodic solutions of the complex Ginzburg–Landau equation are obtained in terms of the Weierstrass elliptic function $\wp$. Furthermore, the new periodic solutions and other shock solutions appear as their bounded limits (along the real axis) for particular relationships between the coefficients in the equation. In the general case, bounded limits are nothing but the already known pulse, hole, and shock solutions. It is also shown that the shapes of the solutions are quite different from the shape of the usual envelope wave solution. In particular, the spatial structure of the new bounded periodic solutions varies in time, while the pulse solution may exhibit breather-like behavior. © *1999 American Institute of Physics.* [S0022-2488(99)02302-6]

I. INTRODUCTION

Most of the mathematical work in the realm of nonlinear phenomena refers to integrable equations and their exact solutions, particularly periodic. Among the recently developed general methods, the algebro-geometrical approach may be used in an efficient way to find such solutions. Not only the numerical realization and graphical representation of the solution is provided by this method, but also multiphase quasiperiodic solutions as well as purely periodic ones may be represented using the algebrogeometrical approach, as illustrated in Ref. 1.

It is only recently that due to significant progress achieved in the study of patterns and waves in nonequilibrium, dissipative systems the need appeared of the study of equations nonintegrable by means of the Inverse Scattering Transform Method (ISTM). A paradigmatic case is the complex Ginzburg–Landau equation (CGLE).

$$\iota u_t + p u_{xx} + q|u|^2 u = \iota \gamma u, \tag{1}$$

where the constant coefficients are $p = p_r + \iota p_i$, $q = q_r + \iota q_i$, with p_j, $q_j \neq 0$, $(u,p,q) \in \mathbb{C}$, $\gamma \in \mathbb{R}$. The subscripts t and x denote temporal and spatial derivatives, respectively. This equation appears in the description of a large variety of physical phenomena,[2,3] (and references therein). Here we concentrate on obtaining *exact* solutions of (1). Moreover, we shall not study any *degeneracies* of CGLE, corresponding to vanishing of any of p_j, q_j, or γ, because these cases are already studied in the literature (see Refs. 4 and 5 and references therein). Exact solutions usually appear as a result of some balance between the significant terms in the equation. In particular, CGLE (1), besides nonlinear ($q_r|u|^2u$) and dispersive ($p_r u_{xx}$) terms, contains nonlinear saturation ($q_i|u|^2u$) and diffusion ($p_i u_{xx}$) terms, as well as the linear growth term (γu); thus solitary wave and shocks are possible solutions of (1). Exact solutions may describe not only the propagation of nonlinear waves but also spatially localized structures of permanent shape that may be of interest to experimenters.[6–8] Finally, the knowledge of particular exact solutions may be useful when numerically exploring unsteady processes governed by Eq. (1).

As the CGLE (1) is nonintegrable, only particular *exact* solutions may be obtained. To find such solutions various *direct* methods seem promising. Indeed, the pulse solution of (1) with *nonzero coefficients* was obtained in Ref. 9 using a special ansatz, while the shock-wave solution was found in Ref. 10 by direct integration. A modified Hirota bilinear method has been applied in Ref. 11, and three exact solutions, pulse, hole, and shock solution, respectively, were found. Further, the development of a movable critical points analysis or Painlevé analysis[12] led to direct methods based on the nature of the poles of the solution (see, e.g., Refs. 5, 13, and references therein). However, neither the application of the truncated Painlevé expansions[13] nor another extension of the Painlevé analysis proposed in Ref. 5, have led to new exact solutions of the CGLE. Moreover, no bounded periodic solutions of (1) have been found other than usual harmonic wave solution or the so-called phase winding solution.[14]

Particular periodic solutions of nonintegrable equations may be obtained using direct methods based either on the application of a suitable change of variables bringing equations under study to those possessing already known exact periodic solutions or by using an appropriate ansatz for the solution. In order to construct the ansatz, a clue may come from the Painlevé analysis, which is based, in particular, on looking for solutions whose movable critical points are poles only. Therefore the use of elliptic functions in the ansatz is rather natural because they are the most general functions having such singular points. However, complications appear due to the need of using in the ansatz *four* theta functions; see, e.g., Ref. 15, or *three* Jacobi elliptic functions; see, e.g., Ref. 16. The possibility exists to look for solutions using just *one* Weierstrass elliptic function $\wp$.[17,18]

The paper is organized as follows. In Sec. II a procedure is proposed to obtain exact solutions using the Weierstrass elliptic $\wp$ function. A transformation of CGLE (1) into two coupled equations for the amplitude and the phase parts of the solution is provided in Sec. III, and possibilities of their decoupling are found. In Sec. IV, the procedure introduced in Sec. II is applied to obtain exact solutions in terms of the Weierstrass elliptic function for the amplitude and the phase equations. Three new solutions are obtained. It is shown in Sec. V that their periodic and localized limits bounded along the real axis may be represented in terms of Jacobi elliptic functions and hyperbolic functions. The profiles of these bounded solutions are studied in Sec. VI in order to clarify the role of the phase part of the solution on its qualitative behavior. In Sec. VII we summarize our results.

II. WEIERSTRASS ELLIPTIC FUNCTION AS A TOOL FOR OBTAINING EXACT SOLUTIONS

According to its definition,[19] the Weierstrass function is analytical in the complex plane other than in points where it has double poles. It obeys the equation

$$\{\wp'(\zeta)\}^2=4\wp^3-g_2\wp-g_3, \tag{2}$$

where g_2 and g_3 are constants. Any derivative of the function $\wp$ can be written by means of itself. Further, any *elliptic function* f may be expressed using $\wp$ and its first derivative as

$$f=A(\wp)+B(\wp)\wp', \tag{3}$$

where A and B are rational functions with respect to $\wp$.[19] Depending on the ratio between g_2 and g_3, the Weierstrass function may be bounded or unbounded inside the domain under study. The bounded periodic solutions are more conveniently expressed by writing them in terms of the Jacobi elliptic functions cn, sn, and dn, which are bounded along the real axis. For this purpose the relationship between the Weierstrass function and the Jacobi functions is used as a special case of (3). Indeed, the familiar link is obtained in Ref. 19, but using the singular function sn^{-2},

$$\wp(\zeta,g_2,g_3)=e_3+(e_1-e_3)\mathrm{sn}^{-2}(\sqrt{e_1-e_3}\zeta,k). \tag{4}$$

However, following the method introduced in Ref. 19, one can check that

$$\wp(\zeta,g_2,g_3)=e_2-(e_2-e_3)\mathrm{cn}^2(\sqrt{e_1-e_3}\zeta,k), \tag{5}$$

connects the Weierstrass function with the Jacobi function cn, regular along the real axis. Here $k=\sqrt{(e_2-e_3)/(e_1-e_3)}$ is the modulus of the Jacobian elliptic function, while $\tau=e_m$ ($m=1,2,3,e_3\leqslant e_2\leqslant e_1$) are the real roots of the cubic equation,

$$4\tau^3-g_2\tau-g_3=0. \tag{6}$$

Expressing these results in terms of an appropriate choice of parameters, the *wave number* $\kappa=\sqrt{e_1-e_3}$ and the Jacobian elliptic modulus k, we have

$$\begin{gathered} e_1=\frac{2-k^2}{3}\kappa^2, \quad e_2=\frac{2k^2-1}{3}\kappa^2, \quad e_3=-\frac{1+k^2}{3}\kappa^2, \\ g_2=\tfrac{8}{3}\kappa^4(1-k^2+k^4), \quad g_3=\frac{4}{27}\kappa^6(k^2+1)(2-k^2)(1-2k^2). \end{gathered} \tag{7}$$

The localized solutions appear in the limit $k\to 1$ of the Jacobi elliptic functions.

Recently, the Weierstrass function was used for finding periodic solutions by applying the spectral theory for the Láme equation with elliptic potentials,[20] and some exact solutions have been obtained for the coupled nonlinear Schrödinger equations (CNLSEs) at high symmetry. This method can only be applied to integrable nonlinear equations admitting Lax pairs representation.

As the CGLE is known to exhibit chaotic behavior, it is not integrable. However, exact solutions may be found, even for nonintegrable equations using the Weierstrass elliptic function $\wp$. For instance, Samsonov[17,18] obtained some exact solutions of the Korteweg-de Vries–Burgers equation, the Gardner equation, the Hunter–Shroulle equation, and the FitzHugh–Nagumo equation. He provided the relevant set of transformations bringing a wide class of second-order nonlinear ordinary differential equations to just Eq. (2). Moreover, the use of (3) was proposed in Ref. 18 to construct the ansatz for direct substitution in the equation under study. Recently various new exact periodic solutions have been obtained in Ref. 21 for CNLSEs for *arbitrary* values of the coefficients, when CNLSEs are nonintegrable, and for two dissipative–dispersive equations, appearing in convective problems.[22,23] Comparing these results with others, based on the use of theta functions[15] or Jacobi functions,[16] we see that the algebra is drastically simplified when the ansatz for the solution demands only *one* Weierstrass function instead of *four* theta functions or *three* Jacobi elliptic functions. Only self-similar or traveling wave solutions may be found using this method.

The ansatz for the possible solution may be constructed using the information about the poles of the solution. The Painlevé analysis,[12,13] as well as the nature of the poles of the Weierstrass function, ought to be taken into account.[21–23] However, any poles may be modeled by means of various expressions in terms of the Weierstrass function, and the problem of selecting the most ''efficient'' expression is far from being solved.

An alternative is to try to transform the equation under study to the Weierstrass equation (2) or, more generally, to Painlevé-type equations. This procedure is far from simple, especially for dissipative nonlinear equations. As mentioned, earlier some progress has been achieved in this direction in Ref. 18. However, the transformations proposed in Ref. 18 look rather inconvenient when searching for a solution in closed form. Here we propose a different approach. We restrict consideration to second-order ordinary differential equations. Consider the equation

$$y''+y'^2Q_1(y)+y'Q_2(y)+Q_3(y)=0, \tag{8}$$

where Q_i are rational functions with respect to y. The standard reduction of this autonomous equation, $y' = \sqrt{F(y)}$, yields an ''irrational'' and nonautonomous equation for F. Therefore, obtaining a solution of Eq. (8) is unlikely. In order to overcome this problem we propose the following alternative transformation:

$$y = A_1 v + A_2 v'/v + A_3, \quad v' = \sqrt{F(v)}, \tag{9}$$

where A_i are constants. After substitution of (9) into the equation (8), we get

$$R_1(v,F) + \sqrt{F(v)} R_2(v,F) = 0, \tag{10}$$

where both R_1 and R_2 are polynomials in v and F and its first- and second-order derivatives. Equating to zero R_1 and R_2 separately, one can find for this overdetermined system the solution for F, polynomial in v. Then the solution for y (9) may be obtained by direct integration.

III. TRANSFORMATIONS OF THE CGLE

First, we decompose the solution $u(x,t)$ in its amplitude, y, and phase, θ, both real,

$$u = y(\zeta) e^{\iota\theta}, \tag{11}$$

where $\zeta = x - ct$, $\theta = \theta(\zeta,t)$. Substituting (11) into (1) and equating to zero the real and imaginary parts, we get for y and $z \equiv \theta_\zeta$,

$$p_r y_{\zeta\zeta} - p_i(2 y_\zeta z + y z_\zeta) - p_r y z^2 + c y z - \beta y + q_r y^3 = 0, \tag{12}$$

$$p_i y_{\zeta\zeta} + p_r(2 y_\zeta z + y z_\zeta) - p_i y z^2 - c y_\zeta - \gamma y + q_i y^3 = 0, \tag{13}$$

where $\theta_t \equiv \beta = \text{const}(t)$. A further simplification of Eqs. (12), (13) may be achieved if we assume that $\Phi = y^2$ and $\Psi = y^2 z$. Then (12), (13) become

$$2\Phi\Phi_{\zeta\zeta} - \Phi_\zeta^2 - a_1 \Phi\Phi_\zeta + a_2 \Phi\Psi - 4\Psi^2 - a_3\Phi^2 + a_4 \Phi^3 = 0, \tag{14}$$

$$\Psi_\zeta - b_1 \Phi_\zeta - b_2 \Psi + b_3 \Phi + b_4 \Phi^2 = 0, \tag{15}$$

with

$$a_1 = \frac{2 p_i c}{l_1}, \quad a_2 = \frac{4 p_r c}{l_1}, \quad a_3 = \frac{4(p_r\beta + p_i\gamma)}{l_1}, \quad a_4 = \frac{4 l_3}{l_1},$$

$$b_1 = \frac{a_2}{8}, \quad b_2 = \frac{a_1}{2}, \quad b_3 = \frac{p_i\beta - p_r\gamma}{l_1}, \quad b_4 = \frac{l_2}{l_1},$$

$$l_1 = p_r^2 + p_i^2, \quad l_2 = p_r q_i - p_i q_r, \quad l_3 = p_r q_r + p_i q_i.$$

Equation (14) is *quadratic algebraic* for Ψ, but substitution of the expression for Ψ into Eq. (15) results in a very complicated equation for Φ. On the other hand, the form of Eq. (15) provides conditions for Eqs. (14) and (15) to be solved separately. Indeed, in the nonlinear Schrödinger equation (NLSE) limit, $p_i = q_i = \gamma = 0$, Eq. (15) is integrated, giving $\Psi = b_1\Phi + C$, $C = \text{const}$. Two possibilities exist when (15) is solved for the function Ψ if the coefficients of the CGLE do not vanish; either

$$(\text{A.1}) \quad \Psi = C, \quad \text{if } c = 0, \quad l_2 = 0, \quad b_3 = 0;$$

or

$$(\text{A.2}) \quad \Psi = b_1 \Phi, \quad \text{if } l_2 = 0, \quad b_1 b_2 = b_3 .$$

Otherwise we have to deal with Eqs. (14) and (15) together.

Let us now use Painlevé analysis to the equations to learn about the poles of the solutions in the general case. Assume that possible solutions of the equations (14), (15) have a pole at $\zeta = \zeta_0$. Then solutions can be sought near that point as a Laurent series:

$$\Phi = \frac{r_k}{(\zeta - \zeta_0)^k} + \frac{r_{k-1}}{(\zeta - \zeta_0)^{k-1}} + \cdots, \quad \Psi = \frac{h_m}{(\zeta - \zeta_0)^m} + \frac{h_{m-1}}{(\zeta - \zeta_0)^{m-1}} + \cdots, \tag{16}$$

with both k and m real. The order of the pole may be found by substituting the series (16) into the equations (14), (15) and comparing the leading-order terms. When the leading-order nonlinear term and the leading-order derivative term are in balance, then from Eq. (15) we have the condition $m+1=k$, which used in Eq. (14) yields $k=2$, $m=3$. Then, for subsequent action we assume

$$(\text{B}) \quad \Psi = A \Phi_\zeta + B \Phi + S,$$

with A, B, and S parameters yet to be determined.

In cases (A.1), (A.2) we deal with only one equation (14) for just one unknown Φ, while in case (B) Eq. (15) is not satisfied for arbitrary Φ, and we need to solve an overdetermined system of two equations for only one unknown.

IV. EXACT SOLUTIONS OF THE EQUATIONS (14) AND (15) IN TERMS OF THE WEIERSTRASS ELLIPTIC FUNCTION

A. Case (A.1)

Consider case (A.1) with Eq. (15) satisfied identically for an arbitrary function Φ. Substituting $\Psi = C$ into Eq. (14), we get.

$$2\Phi\Phi_{\zeta\zeta} - \Phi_\zeta^2 - 4C^2 - \frac{4\beta}{p_r}\Phi^2 + \frac{4q_r}{p_r}\Phi^3 = 0, \tag{17}$$

where the conditions $c=0$ and $\beta = p_r \gamma / p_i$ have been used. Using the procedure introduced in Sec. II, one obtains from Eq. (10) that $R_2 \equiv 0$, and the solution of equation $R_1 = 0$ is written through the Weierstrass elliptic function $\wp(\zeta, g_2, g_3)$ as

$$\Phi = Q\wp + G, \tag{18}$$

with $Q = -2p_r/q_r$, and $G = 2\gamma/q_i$. The parameter g_2 is free, while C and g_3 obey the relationship

$$\frac{4C^2}{Q^2} = 4\left(\frac{G}{Q}\right)^3 - g_2\left(\frac{G}{Q}\right) + g_3 . \tag{19}$$

Depending on the relationship between g_2 and g_3, the solution (18) describes either bounded or unbounded periodic solutions.[19] Localized limits yield, respectively, either a solitary wave solution or a localized discontinuous solution.

B. Case (A.2)

Equation (15) is again satisfied identically. Substituting $\Psi = b_1 \Phi$ into Eq. (14), we obtain

$$2\Phi\Phi_{\zeta\zeta} - \Phi_\zeta^2 - a_1 \Phi \Phi_\zeta + (a_2 b_1 - 4b_1^2 - a_3)\Phi^2 + a_4 \Phi^3 = 0. \tag{20}$$

The equation (20) belongs to the class of (8). Then, replacing in (9) y with Φ and substituting the transformation into our equation, we obtain an equation of the form (10). Then the conditions $R_1=0$, $R_2=0$ allow us to assume the polynomial functional form for F, and finally yields

$$\Phi = A\wp + \frac{B\wp_\zeta}{\wp + C} + S, \tag{21}$$

with

$$A=-\frac{2p_r}{q_r},\quad B=\frac{p_i p_r c}{3q_r l_1},\quad C=-\frac{p_i^2 c^2}{108 l_1^2},\quad S=-\frac{5p_i^2 p_r c^2}{54 q_r l_1^2},\quad c^2=\frac{36\gamma l_1^2}{p_i(p_i^2-9l_1)},$$
$$g_2=12C^2,\quad 4C^3-g_2C+g_3=0. \tag{22}$$

It follows from (22) that the solution (21) bounded along the real axis corresponds only to the solitary wave solution. Other possibilities are either localized or periodic discontinuities.

C. Case (B)

We have an overdetermined system of two equations. Using the ansatz (B) from Sec. IV B, Eq. (15) reduces to

$$\Phi_{\zeta\zeta} + \alpha_0\Phi_\zeta + \alpha_1\Phi + \alpha_2\Phi^2 + \alpha_3 = 0, \tag{23}$$

with

$$\alpha_0=\frac{B-b_1-Ab_2}{A},\quad \alpha_1=\frac{b_3-Bb_2}{A},\quad \alpha_2=\frac{b_4}{A},\quad \alpha_3=-\frac{Sb_2}{A}.$$

Equation (23) is the ODE reduction of the Korteweg–de Vries–Burgers equation (KdVBE), which is the dynamical system underlying a Helmholtz–Thompson oscillator.[24–26] Its exact solution is[17]

$$\Phi = 6\alpha_0^2/(25\alpha_2)\exp(-2\alpha_0\zeta/5)\wp[\exp(-\alpha_0\zeta/5)+z_0,0,g_3],$$

where z_0 and g_3 are free parameters. Unfortunately, additional conditions are needed for the existence of this solution, such as $\alpha_3=0$ and $\alpha_1=6\alpha_0^2/25$.

Another solution can be obtained using the procedure from Sec. II. Thus, using (9), we get from the conditions $R_1=0$ and $R_2=0$ that again the solution for F is a third-order polynomial, hence

$$\Phi = M\wp + \frac{N\wp_\zeta}{\wp + C} + R, \tag{24}$$

with the parameters defined by either

$$(\text{B.1})\quad M=-6/\alpha_2,\quad N=-3\alpha_0/(5\alpha_2),\quad R=\alpha_0^2/(50\alpha_2)-\alpha_1/(2\alpha_2),\quad g_2=12C^2,$$
$$g_3=8C^3,\quad C=-\alpha_0^2/300,\quad \text{if}\ \ \alpha_3=\alpha_1^2/(4\alpha_2)-9\alpha_0^4/(625\alpha_2);$$

or

$$(\text{B.2})\quad M=-6/\alpha_2,\quad N=0,\quad R=-\alpha_1/(2\alpha_2),\quad g_2=\alpha_1^2/12-\alpha_2\alpha_3/3,\quad g_3\text{-free},\quad \text{if}\ \ \alpha_0=0.$$

Using the ansatz (B) and Eq. (23), Eq. (14) becomes

$$\Phi_\zeta^2+\beta_0\Phi\Phi_\zeta+\beta_1\Phi_\zeta+\beta_2+\beta_3\Phi+\beta_4\Phi^2+\beta_5\Phi^3=0, \tag{25}$$

with

$$\beta_0=\frac{16B-a_2}{8A},\quad \beta_1=\frac{8AS}{1+4A^2},\quad \beta_2=\frac{4S^2}{1+4A^2},\quad \beta_3=\frac{S(8AB-a_1-a_2A)}{A(1+4A^2)},$$

$$\beta_4=\frac{2b_3+a_3A-a_2AB-a_1B+4B^2}{A(1+4A^2)},\quad \beta_5=\frac{2b_4-a_4}{A(1+4A^2)}.$$

Substituting (24) into (25) for case (B.1), we get

$$A=(-3l_3\pm\sqrt{D})/(4l_2),\quad D=8l_2^2+9l_3^2,\quad B=c(3p_r-4Ap_i)/(6l_1),$$

with either

(B.1.a)

$$S=0,\quad c^2=-\frac{36\gamma l_1^2}{p_i(8l_1+p_r^2)},\quad \beta=\frac{p_r\gamma(p_r^2-10l_1)}{p_i(8l_1+p_r^2)}; \tag{26}$$

or

(B.1.b)

$$S=\frac{6cp_i(l_2-2Al_3)}{l_2[l_2(2p_i^2+9p_r^2+24Ap_ip_r)+3Al_3(4p_i^2-9p_r^2)]},$$

$$c^2=\frac{36l_1^2(2Al_3-l_2)\gamma}{p_i[l_2(2p_i^2+9p_r^2+24Ap_ip_r)+3Al_3(4p_i^2-9p_r^2)]},$$

$$\beta=\frac{p_r}{p_i}\gamma+\frac{2p_i+3Ap_r}{6Al_1}c^2. \tag{27}$$

The second possibility is realized when the coefficients of the CGLE satisfy either

$$9(1-l_2)l_3^2=2l_2(3-l_2),$$

or

$$3l_2l_3[l_3(135p_r^2-36p_i^2)-88l_2p_ip_r]+A[8l_2p_ip_r(26l_2+135l_3)$$
$$+135l_3^2(4p_i^2-9p_r^2)+2l_2^2l_3(56p_i^2-99p_r^2)]=0.$$

For case (B.2), we get

$$A=(-3l_3\pm\sqrt{D})/(4l_2),\quad D=8l_2^2+9l_3^2,\quad B=0,\quad S=0,\quad c=0,\quad \alpha_3=0,\quad g_3=\alpha_1^3/212,$$

with

$$\beta=\frac{(p_r-4Ap_i-4A^2p_r)\gamma}{p_i+4Ap_r-4A^2p_i}.$$

These results have been obtained using the MATHEMATICA package.[27] Again, for both cases (B.1) and (B.2) the relationships between g_2 and g_3 ensure the existence of only a localized (not periodic) limit of the solution (24) bounded along the real axis.

V. BOUNDED SOLUTIONS OF THE CGLE

Using solutions (18), (21), and (24), one can obtain solutions (11) of the CGLE (1) in terms of the Weierstrass function. Let us concentrate on solutions u (11) *bounded along the real axis*. A representation of these particular cases is better done in terms of Jacobi elliptic functions using the relationship (5). Further, we need to change the parameter set according to (7). Thus, from (19) and (6) we obtain for the case (A.1),

$$C^2=-Q^2(H_1-e_1)(H_1-e_2)(H_1-e_3), \tag{28}$$

with $H_1\equiv -G/Q$. For $C=0$ the possibilities are $G=-Qe_m$ $(m=1,2,3)$. More generally, H_1 may lie in either $I_1\equiv(-\infty,e_3]$ or $I_2\equiv(e_2,e_1)$, where the right-hand side of Eq. (28) is positive. Then for I_1, we get $H_1=c_3-\delta^2$, $\delta=\delta(C)$, and

$$u=\sqrt{-\frac{2q_r}{p_r}[k^2\kappa^2\,\mathrm{sn}^2(\kappa\zeta,k)+\delta^2]}\exp\iota\theta, \tag{29}$$

with

$$\theta=\frac{p_r\gamma}{p_i}t-\frac{p_rC\Pi[\varphi,n,k]}{2q_r\delta^2\kappa}-\theta_0,\quad \kappa^2=-\frac{3}{1+k^2}\left(\frac{\gamma}{3p_i}+\delta^2\right), \tag{30}$$

$\Pi[\varphi,n,k]$ is the elliptic integral of the third kind, $\sin\varphi=\mathrm{sn}(\kappa\zeta,k)$, and $n=-\kappa^2k^2/\delta^2$.

Similarly, for I_2 we assume that $H_1=e_1-\delta_1^2$, $0\leqslant\delta_1^2\leqslant\kappa_1^2(1-k^2)$, $\delta_1=\delta_1(C)$. The solution is

$$u=\sqrt{\frac{2q_r}{p_r}\{\kappa_1^2\,\mathrm{dn}^2(\kappa_1\zeta,k)-\delta_1^2\}}\exp\iota\theta, \tag{31}$$

with

$$\theta=\frac{p_r\gamma}{p_i}t+\frac{p_rC\Pi[\varphi,n_1,k]}{2q_r(\kappa_1^2-\delta_1^2)\kappa_1}-\theta_0,\quad \kappa_1^2=\frac{3}{2-k^2}\left(\frac{\gamma}{3p_i}+\delta_1^2\right),\quad n_1=\frac{k^2\kappa_1^2}{\kappa_1^2-\delta_1^2}. \tag{32}$$

The only bounded limit corresponds to the case (A.2), namely, a shock-type solution,

$$u=\sqrt{-\frac{2p_r}{q_r}}\,\kappa[1+\tanh(\kappa\zeta)]\exp\iota(\beta t+b_1\zeta-\theta_0), \tag{33}$$

with

$$\beta=\frac{p_r\gamma(p_i^2-10l_1)}{p_i(26l_1+p_r^2)},\quad \kappa=\frac{p_ic}{6l_1},\quad c\ \text{ is defined by (22).}$$

We get for both possibilities (B.1.a) and (B.1.b) the only bounded shock-type solution:

$$u=\sqrt{-\frac{6Al_1}{l_2}}\,\kappa[1-\tanh(\kappa\zeta)]\exp\iota\theta, \tag{34}$$

with $\kappa=\alpha_0/10$, while for θ we obtain

$$\theta=\beta t+B\zeta+2A\ln\left\{\sqrt{-\frac{6Al_1}{l_2}}\,\kappa[1-\tanh(\kappa\zeta)]\right\}$$
$$+S\left(\frac{1}{4[1-\tanh(\kappa\zeta)]^2}+\frac{1}{4[1-\tanh(\kappa\zeta)]}+\frac{1}{8}\ln\left|\frac{1+\tanh(\kappa\zeta)}{1-\tanh(\kappa\zeta)}\right|\right),$$

where the parameters S, c, and β are defined by either (26) or (27). A solution for the case (B.1) yields the shock solution obtained in Ref. 11.

In case (B.2) the bounded limit of our general solution (24) is either the *pulse* solution,

$$u=\sqrt{\frac{6Al_1}{l_2}}\,\kappa\cosh^{-1}(\kappa\zeta)\exp\iota\theta, \tag{35}$$

with

$$\kappa^2=-\frac{\gamma}{2(p_i+4Ap_r-4A^2p_i)},$$

or the *hole* solution,

$$u=\sqrt{-\frac{6Al_1}{l_2}}\,\kappa\tanh(\kappa\zeta)\exp\iota\theta, \tag{36}$$

with

$$\kappa^2=\frac{\gamma}{p_i+4Ap_r-4A^2p_i}$$

in agreement with the results found in Ref. 11.

VI. ANALYSIS OF WAVE PROFILES

Strictly speaking, only the solution (33) for the case (A.2) is a ''genuine'' envelope wave similar to the *bright* soliton of the NLSE. Other solutions have an amplitude-dependent phase, θ. Let us begin by considering the new periodic wave solutions (29) and (31). Because of their similar behavior we shall study in detail (31) only. The first derivative of its real part with respect to x, $v=(\mathrm{Re}\,u)_x$ is

$$v=\frac{Z}{y}\sin\left[\theta+\arcsin\left(\frac{y\,y_x}{Z}\right)\right], \tag{37}$$

with

$$y=\sqrt{\frac{2q_r}{p_r}[\kappa_1^2\,\mathrm{dn}^2(\kappa_1\zeta,k)-\delta_1^2]},\quad Z=\sqrt{y^2y_x^2+C^2}. \tag{38}$$

When $C=0$, the zeros of the first derivative (37) are defined by the zeros of the function y_x and correspond to the zeros of the Jacobi functions cn and sn. Their positions do not change in time, and for u we have harmonic temporal oscillations of the spatially periodic state defined by the amplitude parts of the solutions (31). However, the situation changes dramatically when $C\neq 0$. In this case Z never vanishes, and the zeros of the first derivative are defined by the zeros of

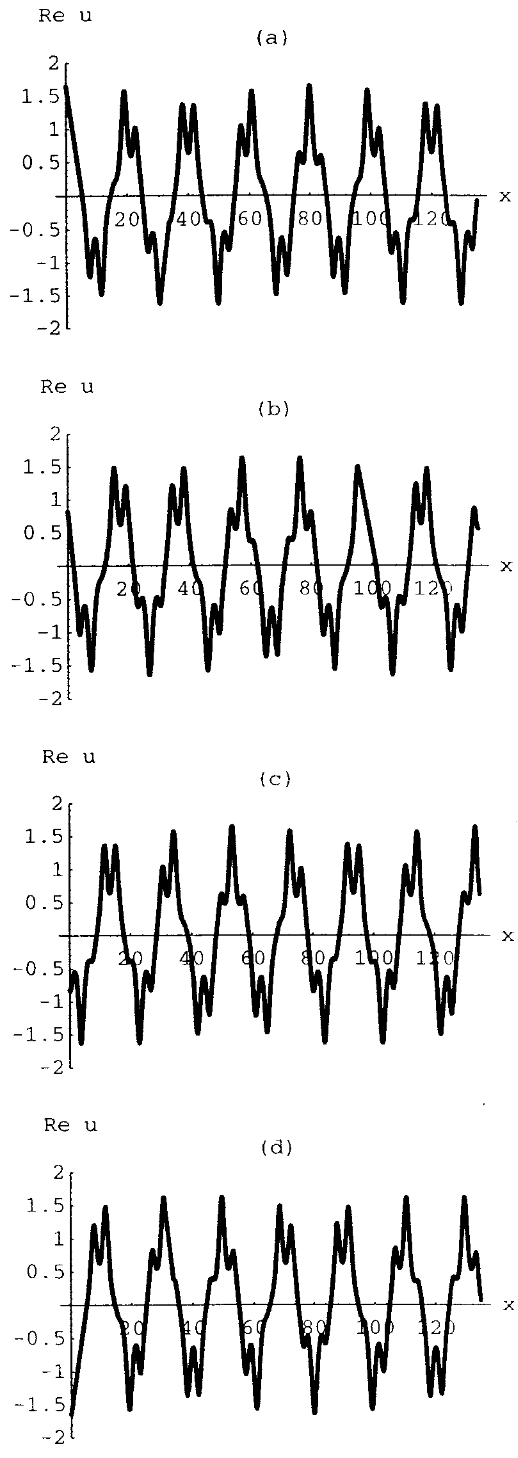

FIG. 1. Evolution of the periodic solution (31) Re u vs x for times $t=mp_i\pi/(3p_r\gamma)$, $0<m<3$ with $k=0.9$, $\delta_1=0.5$. (a) $m=0$, (b) $m=1$, (c) $m=2$, (d) $m=3$.

the sin function only, whose position varies in time. A typical situation is shown in Fig. 1. Figure 1(a) shows a structure with four spatially repeated parts. During half of the time period the shapes of these parts vary, and we get in Fig. 1(d) a profile that is practically the mirror image to Fig. 1(a). Qualitatively, this evolution does not depend upon the value of the modulus k of Jacobi functions.

Consider now the case (B.2) for pulse or hole solutions. In particular, the first derivative for the real part of (35) is

$$(\mathrm{Re}\, u)_x = \sqrt{\frac{6Al_1(1+4A^2)}{l_2}}\,\kappa^2 \cosh^{-1}(\kappa\zeta)\tanh(\kappa\zeta)\sin\left[\theta - \arctan\left(\frac{1}{2A}\right)\right]. \tag{39}$$

Thus, from (39) it follows that additional zeros of the first derivative may appear if

$$\kappa > \sqrt{\frac{l_2}{6Al_1}}\exp\left(\frac{\arctan[1/(2A)]}{2A}\right). \tag{40}$$

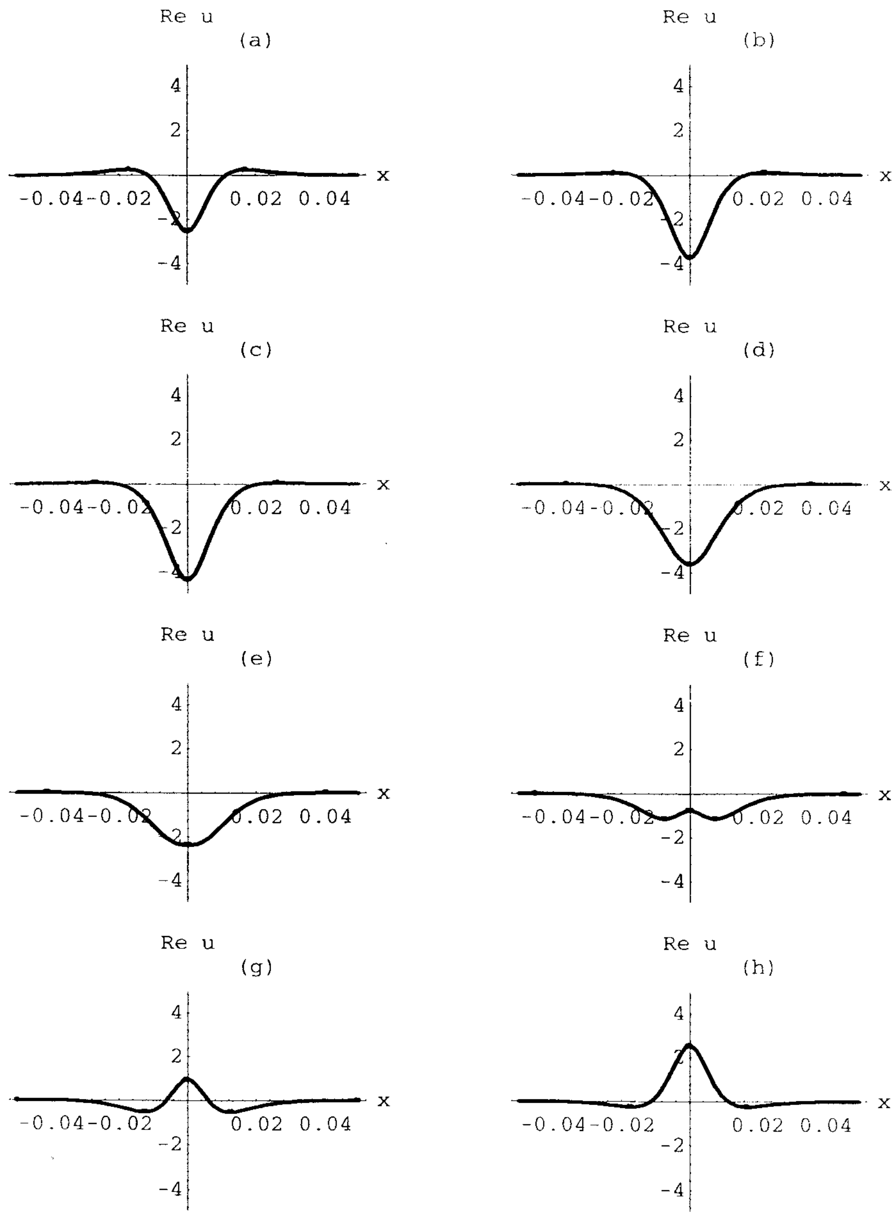

FIG. 2. Evolution of the pulse solution (35) Re u vs x for times $t = m\pi/\beta$, $0 < m < 8$. (a) $m=0$; (b) $m=1$, (c) $m=2$, (d) $m=4$, (e) $m=5$, (f) $m=6$, (g) $m=7$, (h) $m=8$.

The evolution of the real part of the solution (35) is illustrated in Fig. 2. Again, we see that two initial maxima in Fig. 2(a) disappear, Fig. 2(e); then an initial minimum at $\zeta=0$ is changed into a maximum, while two minima arise, Figs. 2(f)–2(h). Therefore, our solution is breather-like. If (40) is not satisfied, there is a pulse solution whose spatial behavior is determined by the function $\cosh^{-1}(\kappa\zeta)$, only with one extremum at $\zeta=0$. A similar situation occurs for the hole solution (36).

The evolution of the solution in case (B.1) depends upon the relationship between β, A, B, and S in the phase θ. However, due to the dependence upon the hyperbolic tangent function, any significant alterations can only occur in the narrow area, $|\kappa\zeta|\ll 1$. Thus, no qualitatively new solutions are found relative to the usual envelope wave.

VII. CONCLUSIONS

New exact general *periodic* solutions of the complex Ginzburg–Landau equation (1), (18), (21), and (24), are obtained in terms of the Weierstrass elliptic function. Among their special limits, we found new *exact periodic* solutions to the CGLE *bounded along the real axis*. Their existence requires additional but nontrivial restrictions on the coefficients of the equation. Accordingly, only a suitable balance between all significant terms in the CGLE is required in order to get a periodic solution. We also found a new shock solution (34), with parameters defined by (27). All bounded solutions early found in Ref. 11 by the modified Hirota method are found also as *particular* limits of the Weierstrass function solutions.

The role of the amplitude dependence in the phase of the solutions has been studied. The form of the solution may strongly differ from the usual envelope solution. In particular, a pulse solution exhibits breather-like behavior. Also, a temporal change in the spatial structure occurs for the bounded periodic solutions.

ACKNOWLEDGMENTS

The authors wish to thank Dr. P. Colinet for useful comments on the manuscript. They are also grateful to the anonymous referee for references and suggestions that helped improve the presentation of the results. This research was carried out while A.V.P. worked as a Visiting Scientist at Instituto Pluridisciplinar, UCM, supported by to the Spanish Ministry of Education and Science. This research has also been supported by DGICYT (Spain) under Grant No. PB 96-0599 and by the European Union under Network Grant No. FRB FM RX-CT96-10.

(Received 9 December 1997; accepted for publication 14 July 1998)

For a class of perfect fluids first considered by Wainwright [Int. J. Theor. Phys. **10**, 39 (1974)], a complete symmetry analysis of the field equations is performed. The results are used for a symmetry reduction of the field equations and the construction of (new) similarity solutions.
[S0022-2488(99)02501-3]

I. INTRODUCTION

In 1974, Wainwright[1] considered a special class of algebraically special perfect fluids for which the multiple null eigenvector **k** is geodesic, twist free, shear free, but expanding. They thus generalize the vacuum Robinson–Trautman solutions and contain them as a limiting case. He was able to reduce the field equations to one or two partial differential equations in three independent variables (given in Sec. II). Up to now only very few solutions of these differential equations have been found; one has been given by Wainwright[1] himself, two others are contained in Kramer[2] and Drauschke.[3]

Here we give a complete symmetry analysis of these equations (Sec. III). The Lie-point-symmetries turn out to show a richer structure than one might have guessed. We then use them to perform a one- or twofold similarity reduction of the field equations (Sec. IV); the resulting ordinary differential equations are listed in the Appendix. In Sec. V, we solve some of these equations and find several new classes of solutions. The results are discussed in Sec. VI.

II. THE METRICS AND DIFFERENTIAL EQUATIONS

The metrics and field equations as given by Wainwright[1] divide into two classes. The first metric and the associated field equations read

$$\begin{gathered} ds^2 = 2\epsilon(r^2-1)P^{-2}(\zeta,\overline{\zeta},u)d\zeta\, d\overline{\zeta} - 2du\, dr - 2H(\zeta,\overline{\zeta},r,u)du^2, \\ H = -r\partial_u \ln P + \epsilon K/2 - \epsilon(r^2-1)\left(b - 3m\int \frac{dr}{(r^2-1)^2}\right) - \epsilon c, \\ P^2\partial_\zeta\partial_{\overline{\zeta}}K + P^2\partial_u\partial_u(P^{-2}) + 6\epsilon m\partial_u \ln P + 2c(K-2c) = 0, \\ \text{with } K = 2P^2\partial_\zeta\partial_{\overline{\zeta}}\ln P, \quad cm=0, \quad c(c+2b)=0, \quad \epsilon=\pm 1 \end{gathered} \tag{1}$$

(ϵ has to be chosen such that the metric has the correct signature), where four-velocity u_i, pressure p and mass density μ are given by

$$u_i\, dx^i = [2\epsilon c(r^2-1) - 2H]^{-1/2}(-dr - \epsilon c(r^2-1)du),$$

[a)]Electronic mail: ste@tpi.uni-jena.de

$$p=\frac{2}{(r^2-1)^2}\left(r\partial_u \ln P+\epsilon c-\frac{\epsilon}{2}K\right)-\frac{2\epsilon b}{r^2-1}(3r^2-2)$$
$$-\frac{2\epsilon m}{r^2-1}\left[\frac{r}{r^2-1}+(3r^2-2)\int\frac{dr}{(r^2-1)^2}\right], \tag{2}$$
$$\mu-p=\frac{4\epsilon b}{r^2-1}(3r^2-1)+\frac{4\epsilon c}{r^2-1}+\frac{4\epsilon m}{r^2-1}\left[\frac{r}{r^2-1}+(3r^2-1)\int\frac{dr}{(r^2-1)^2}\right].$$

For $c=0$, the constant b appearing (via H) in the line element does not enter the main field equation (the fourth-order equation for P); the addition of a term $2b\epsilon(r^2-1)du^2$ to the metric is always possible. This transformation is a generalized Kerr–Schild transformation, i.e., a transformation of the form $\tilde{g}_{ab}=g_{ab}+2H^0k_ak_b$. This property is in fact an extra symmetry of Einstein's equations.

If one performs a coordinate transformation

$$r=\tilde{r}/\lambda,\quad P=\tilde{P}/\lambda,\quad u=\tilde{u}\lambda, \tag{3}$$

in metric (1), followed by the limit $\lambda\rightarrow 0$ (and $b=0$), one arrives at the Robinson–Trautman class of vacuum solutions. For larger r, so that $\epsilon=1$, and regular P and K, pressure and mass density approach $\mu=-p=6b$, i.e., vacuum for $b=0$. In general there will be singularities at $r^2=1$.

The second metric and the associated field equations are given by

$$ds^2=2\epsilon rP^{-2}(\zeta,\bar{\zeta},u)d\zeta\, d\bar{\zeta}-2du\, dr-2H(\zeta,\bar{\zeta},r,u)du^2,$$
$$H=-r\partial_u \ln P-\epsilon ra-\epsilon br\ln\epsilon r-H^0(\zeta,\bar{\zeta},u), \tag{4}$$
$$2P^2\partial_\zeta\partial_{\bar{\zeta}}\ln P-\epsilon\partial_u \ln P=b,\quad 2\partial_\zeta\partial_{\bar{\zeta}}H^0+\epsilon\partial_u(H^0P^{-2})=0,$$

with

$$u_u\, dx^i=-(-2H)^{-1/2}\, dr,$$
$$p=r^{-1}(\tfrac{1}{2}\partial_u \ln P-2\epsilon b-\tfrac{1}{2}\epsilon a)+\tfrac{1}{2}r^{-2}H^0-\tfrac{1}{2}\epsilon br^{-1}\ln\epsilon r, \tag{5}$$
$$\mu-p=2\epsilon r^{-1}(2b+a)+2\epsilon br^{-1}\ln\epsilon r.$$

The terms $H^0+\epsilon ra$ appearing (via H) in the line element do not enter the main field equation for P; they again represent a generalized Kerr–Schild transformation. From the two differential equations the (nonlinear) equation for P is the more difficult one, and we will concentrate on its symmetries; the (linear) equation for H^0 may or may not share these symmetries. The extra symmetry due to linearity of the field equation for H^0 offers the possibility of adding arbitrary solutions H^0, i.e., performing Kerr–Schild transformation. For large r (and regular P and K), these metrics approach vacuum ($\mu=p=0$). Note that the four-velocity is timelike only for $H<0$, but then the coordinate r is necessarily timelike, too.

For both metrics, dust solutions and solutions of Petrov type *III* or *N* are not possible.

III. THE SYMMETRIES AND SUBALGEBRAS

A. The symmetries

The result of the symmetry analysis is that the following generators $\mathbf{X}_a$ can occur as symmetries of the differential equation(s) for the function P [$h(\zeta)$ is an arbitrary function].

Case I: Metric (1) with $c=0=m$, metric (4) with $b=0$:

$$\begin{aligned} \mathbf{X}_1 &= h(\zeta)\partial_\zeta + \overline{h(\zeta)}\partial_{\bar\zeta} + \tfrac{1}{2}[h' + \overline{h'}]P\partial_P, \\ \mathbf{X}_2 &= \partial_u, \quad \mathbf{X}_3^1 = u\partial_u - \tfrac{1}{2}P\partial_P. \end{aligned} \tag{6}$$

Case II: Metric (1) with $c=0$, $m\neq 0$, $\alpha\equiv 3\epsilon m$, metric (4) with $b\neq 0$, $\alpha\equiv 2\epsilon b$:

$$\begin{aligned} \mathbf{X}_1 &= h(\zeta)\partial_\zeta + \overline{h(\zeta)}\partial_{\bar\zeta} + \tfrac{1}{2}[h' + \overline{h'}]P\partial_P, \\ \mathbf{X}_2 &= \partial_u, \quad \mathbf{X}_3^2 = e^{\alpha u}\partial_u - \tfrac{1}{2}\alpha e^{\alpha u}P\partial_P. \end{aligned} \tag{7}$$

Case III: Metric (1) with $c\neq 0$, $m=0$:

$$\mathbf{X}_1 = h(\zeta)\partial_\zeta + \overline{h(\zeta)}\partial_{\bar\zeta} + \tfrac{1}{2}[h' + \overline{h'}]P\partial_P, \quad \mathbf{X}_2 = \partial_u. \tag{8}$$

[$\mathbf{X}_3^1$ is the limit $\alpha\to 0$ of $(\mathbf{X}_3^2 - \mathbf{X}_2)/\alpha$.]

Since it is known that the only symmetries of Einstein's field equations are those corresponding to coordinate transformations and scalings, one would in general also expect that the specialized field equations given above will admit only these symmetries—from experience in other subcases of Einstein's equations one knows that additional symmetries are rare. The symmetries $\mathbf{X}_1$ and $\mathbf{X}_2$ fit into this picture: they correspond to the still existing coordinate freedom in the metrics and lead to Killing vectors. The occurrence of the symmetries $\mathbf{X}_3^1$ and $\mathbf{X}_3^2$ is a surprise. For (4) with $b=0$, $\mathbf{X}_3^1$ corresponds to a scaling combined with a Kerr–Schild transformation; in the other cases they are new symmetries. Their existence will lead to a richer structure than one may have guessed.

The finite transformations belonging to the generators listed above are

$$\begin{aligned} &\mathbf{X}_1: \ \tilde\zeta = h(\zeta), \quad \tilde u = u, \quad \tilde P = |h_{,\zeta}|P, \\ &\mathbf{X}_2: \ \tilde\zeta = \zeta, \quad \tilde u = u + \varepsilon, \quad \tilde P = P, \\ &\mathbf{X}_3^1: \ \tilde\zeta = \zeta, \quad \tilde u = u e^{\varepsilon}, \quad \tilde P = P e^{-\varepsilon/2}, \\ &\mathbf{X}_3^2: \ \tilde\zeta = \zeta, \quad \tilde u = -\frac{1}{\alpha}\ln(e^{-\alpha u} - \alpha\varepsilon), \quad \tilde P = (1 - \alpha\varepsilon e^{\alpha u})^{1/2}P, \end{aligned} \tag{9}$$

ε being the group parameter. These transformations can—and will—be used to simplify generators and metrics.

Obviously the cases I and II are the most interesting ones. Since the symmetry reduction mainly depends on the structure of the Lie algebra, we will discuss the different subalgebras and the corresponding similarity variables for these two cases in the next sections, and only then will we return to the field equations and their solutions.

B. The nonequivalent one-dimensional subalgebras and their similarity variables

By choosing suitable coordinates, one can always make $h(\zeta)=i$. With that choice the following one-dimensional algebras can occur:

Case	Symmetry	Similarity variables
I	$\mathbf{Y}_1 = i(\partial_\zeta - {}_{\bar\zeta})$	$P, u, x=\zeta+\bar\zeta$
	$\mathbf{Y}_2 = \partial_u$	$P, \zeta, \bar\zeta$
	$\mathbf{Y}_3 = u\partial_u - \tfrac{1}{2}P\partial_P$	$w = P\sqrt{u}, \zeta, \bar\zeta$
	$\mathbf{Y}_4 = i(\partial_\zeta - \partial_{\bar\zeta}) + \partial_u$	$P, z=u+i\zeta, \bar z$

	$\mathbf{Y}_5=i(\partial_\zeta-\partial_{\bar\zeta})+u\partial_u-\frac{1}{2}P\partial_P$	$w=P\sqrt{u},\ z=ue^{i\zeta},\ \bar z$
II	$\mathbf{Y}_1=i(\partial_\zeta-\partial_{\bar\zeta})$	$P,u,x=\zeta+\bar\zeta$
	$\mathbf{Y}_2=\partial_u$	$P,\zeta,\bar\zeta$
	$\mathbf{Y}_3=e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P)$	$w=Pe^{\alpha u/2},\zeta,\bar\zeta$
	$\mathbf{Y}_4=i(\partial_\zeta-\partial_{\bar\zeta})+\partial_u$	$P,z=u+i\zeta,\bar z$
	$\mathbf{Y}_5=i(\partial_\zeta-\partial_{\bar\zeta})+e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P)$	$w=Pe^{\alpha u/2},\ z=i\zeta-e^{-\alpha u}/\alpha$
III	$\mathbf{Y}_1=i(\partial_\zeta-\partial_{\bar\zeta})$	$P,u,x=\zeta+\bar\zeta$
	$\mathbf{Y}_2=\partial_u$	$P,\zeta,\bar\zeta$
	$\mathbf{Y}_4=i(\partial_\zeta-\partial_{\bar\zeta})+\partial_u$	$P,z=u+i\zeta,\bar z$

These generators are essentially different in that they cannot be transformed into each other by group transformations.

For the two metrics (with their subcases), a similarity reduction will thus lead to 23 partial differential equations in two independent variables.

C. The nonequivalent two-dimensional subalgebras and their similarity variables

In each case, one can start with one of the normal forms $[\mathbf{X}_1,\mathbf{X}_2]=\mathbf{X}_1$ or $[\mathbf{X}_1,\mathbf{X}_2]=0$ of a two-dimensional algebra, then take for $\mathbf{X}_1$ one of the five different normal forms $\mathbf{Y}_\alpha$ given in the tables and determine the possible different structures of $\mathbf{X}_2$. The results is the following lists.

Case	Symmmetries	Similarity variables
I.1	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}$	P,u
I.2	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}-2\partial_u$	$P,u+\zeta+\bar\zeta$
I.3	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}+u\partial_u-\frac{1}{2}P\partial_P$	$P\sqrt{u},\ ue^{-(\zeta+\bar\zeta)/2}$
I.4	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P$	$P/(\zeta+\bar\zeta),u$
I.5	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P+c_1(u\partial_u-\frac{1}{2}P\partial_P)$	$Pu^{(A-2)/2A},\ (\zeta+\bar\zeta)u^{-1/A}$
I.6	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_u+\zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P$	$Pe^{-u},\ (\zeta+\bar\zeta)e^{-u}$
I.7	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_u$	$P,\zeta+\bar\zeta$
I.8	$i(\partial_\zeta-\partial_{\bar\zeta}),\ u\partial_u-\frac{1}{2}P\partial_P$	$P\sqrt{u},\ \zeta+\bar\zeta$
I.9	$\partial_u,\ u\partial_u-\frac{1}{2}P\partial_P$	($\zeta,\bar\zeta$; no P !)
I.10	$\partial_u,\ i(\partial_\zeta-\partial_{\bar\zeta})+u\partial_u-\frac{1}{2}P\partial_P$	$Pe^{-i(\zeta-\bar\zeta)/4},\ \zeta+\bar\zeta$
I.11	$i(\partial_\zeta-\partial_{\bar\zeta})+\partial_u,\ \zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+\frac{1}{2}P\partial_P+u\partial_u$	$P/\sqrt{\zeta+\bar\zeta},\ \dfrac{2u+i(\zeta-\bar\zeta)}{\zeta+\bar\zeta}$

Case	Symmetries	Similarity variable
II.1	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}$	P,u
II.2	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}-2\partial_u$	$P,u+\zeta+\bar\zeta$
II.3	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}+e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P)$	$Pe^{\alpha u/2},\ \zeta+\bar\zeta+2e^{-\alpha u}/\alpha$
II.4	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P$	$P/(\zeta+\bar\zeta),u$
II.5	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P+e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P)$	$P\ \exp[\alpha u/2+e^{-\alpha u}/\alpha]$, $\alpha\ \ln(\zeta+\bar\zeta)+e^{-\alpha u}$
II.6	$i(\partial_\zeta-\partial_{\bar\zeta}),\ A\partial_u+\zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P$	$Pe^{-u/A},\ (\zeta+\bar\zeta)e^{-u/A}$

II.7	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_u$	$P,\zeta+\bar\zeta$
II.8	$i(\partial_\zeta-\partial_{\bar\zeta}),\ e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P)$	$Pe^{\alpha u/2},\ \zeta+\bar\zeta$
II.9	$\partial_u,\ e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P)$	$(\zeta,\bar\zeta;$ no P !)
II.10	$e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P),\ i(\partial_\zeta-\partial_{\bar\zeta})+\partial_u$ $i(\partial_\zeta-\partial_{\bar\zeta})+e^{\alpha u}(\partial_u-(\alpha/2)\ P\partial_P),$	$Pe^{\alpha[2u+i(\zeta-\bar\zeta)]/4},\ \zeta+\zeta$
II.11	$\zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P-(1/\alpha)\ \partial_u$	$\dfrac{Pe^{\alpha u/2}}{\sqrt{\zeta+\bar\zeta}},\ \dfrac{i(\zeta-\bar\zeta)-2e^{-\alpha u}/\alpha}{\zeta+\bar\zeta}$

Case	Symmetries	Similarity variables
III.1	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}$	P,u
III.2	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_\zeta+\partial_{\bar\zeta}-2\partial_u$	$P,u+\zeta+\bar\zeta$
III.3	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P$	$P/(\zeta+\bar\zeta),u$
III.4	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \zeta\partial_{\bar\zeta}+\bar\zeta\partial_\zeta+P\partial_P+A\partial_u$	$Pe^{-u/A},\ (\zeta+\bar\zeta)e^{-u/A}$
III.5	$i(\partial_\zeta-\partial_{\bar\zeta}),\ \partial_u$	$P,\zeta+\bar\zeta$

D. The nonequivalent three-dimensional subalgebras with a G_3 acting on V_2 (in the space of variables)

Due to the generators $\mathbf{X}=h(\zeta)\partial_\zeta+\overline{h(\zeta)}\partial_{\bar\zeta}+\frac{1}{2}h'+\overline{h'}]P\partial_P$ there are also two three-dimensional algebras with two-dimensional orbits, namely $[i(\partial_\zeta-\partial_{\bar\zeta}),\partial_\zeta+\partial_{\bar\zeta},i(\zeta\partial_\zeta-\bar\zeta\partial_{\bar\zeta})]$, with similarity variables P and u, and $[i(\partial_\zeta-\partial_{\bar\zeta}),\zeta\partial_\zeta+\bar\zeta\partial_{\bar\zeta}+P\partial_P,i(\zeta^2\partial_\zeta-\bar\zeta^2\partial_{\bar\zeta})+i(\zeta-\bar\zeta)P\partial_P]$, with similarity variables $P/(\zeta+\bar\zeta)$ and u. Both have two-dimensional subalgebras and are thus special cases of the types already considered. The algebra $[i(\partial_\zeta-\partial_{\bar\zeta}),\cos\zeta\partial_\zeta+\cos\bar\zeta\partial_{\bar\zeta},i(\sin\zeta\partial_\zeta-\sin\bar\zeta\partial_{\bar\zeta})]$ (two-dimensional representation of the rotation group) is *not* a symmetry of the field equations.

IV. THE REDUCED FIELD EQUATIONS

For each of the five subcases of the two field equations (1) and (4) one can perform the standard symmetry reduction, using the appropriate five (or three) nonequivalent symmetries of Cases I–III given in Section III A (one assumes a functional relationship between the three similarity variables exists in each case, e.g., of the form $P=e^{-\alpha u/2}f(\zeta,\bar\zeta)$ for Case I, $\mathbf{Y}_3$). We will not give a list of all the resulting 23 partial differential equations in two independent variables: they are relatively easy to obtain (see Rainer[4])—but of course nonlinear, and in most cases a solution can be found only when a *twofold* similarity reduction has been performed. Using the nonequivalent two-dimensional subalgebras given in Sec. III C, such a twofold reduction will lead to a set of 45 ordinary differential equations (not all of them are different). They are given in the Appendix.

V. SOLUTIONS AND METRICS

Of course, not all the differential equations given in the Appendix could be solved. Some could, but then one has to be aware that different solutions P may give rise to the same metrics (metrics of the same constant curvature K may appear in different disguises, etc.). Since in all cases two of the (at most) three symmetries are related to Killing vectors, a solution obtained by a twofold reduction will admit at least one Killing vector, and the following classes of metrics will occur:

(1) Space–times with a G_3 on V_2 (spherical, pseudospherical and plane symmetry).

(2) Space–times with one or two Killing vectors.
(3) Space–times without symmetries (e.g., solutions of (4) with $H^0 \neq 0$ which are related by a generalized Kerr–Schild transformation to a background with $H^0=0$ admitting symmetries), see the remarks following Eqs. (2) and (5).

For each of the two metrics, we will treat the first two of these three classes now in turn. We do not intend to discuss the linear differential equation for H^0, i.e., $2\partial_\zeta \partial_{\bar\zeta} H^0 + \epsilon \partial_u (H^0 P^{-2}) = 0$; for most of the functions P given below, many solutions H^0 of this linear equation could be found.

A. Space–times with a G_3 on V_2

As we will show, this high symmetry will occur if the ζ-$\bar\zeta$ space has constant curvature $K = K(u)$; space–time necessarily inherits this symmetry from the ζ-$\bar\zeta$ space. This subcase covers all field equations obtained by reductions using the algebras I.1, I.4, II.1, II.4, III.1 and III.3 for metrics (1), and I.7, I.10, II.7, II.8 and II.10 for the metric (4), and is contained as a special case in several of the other reductions. We will not start from any of these particular cases, but attack the field equations directly.

For constant curvature $K = K(u)$ it is known that the metric function P is of the form

$$P = \eta(u)\zeta\bar\zeta + \beta(u)\zeta + \bar\beta(u)\bar\zeta + \delta(u), \quad K = 2(\eta\delta - \beta\bar\beta), \tag{10}$$

see Kramer *et al.*[5]

In case of the metric (1), the field equation reads

$$P^2 \partial_u \partial_u (P^{-2}) + 6\epsilon m \partial_u \ln P + 2c(K - 2c) = 0, \quad cm = 0. \tag{11}$$

Inserting here the above representation of P and equating to zero the coefficients of the different powers of ζ and $\bar\zeta$, one obtains

$$\begin{aligned}
&\eta\eta'' - 3\eta'^2 - 3\epsilon m \eta\eta' = c(K-2c)\eta^2,\\
&\beta\beta'' - 3\beta'^2 - 3\epsilon m \beta\beta' = c(K-2c)\beta^2,\\
&\delta\delta'' - 3\delta'^2 - 3\epsilon m \delta\delta' = c(K-2c)\delta^2,\\
&\beta\eta'' + \beta''\eta - 6\eta'\beta' - 3\epsilon m(\beta\eta)' = 2c(K-2c)\eta\beta,\\
&\beta\delta'' + \beta''\delta - 6\delta'\beta' - 3\epsilon m(\beta\delta)' = 2c(K-2c)\delta\eta,\\
&\eta\delta'' + \eta''\delta + \beta\bar\beta'' + \beta''\bar\beta - 6(\eta'\delta' + \beta'\bar\beta')\\
&\quad - 3\epsilon m(\eta\delta + \beta\bar\beta)' = 2c(K-2c)(\delta\eta + \beta\bar\beta).
\end{aligned} \tag{12}$$

Eliminating the second derivatives in last three equations by means of the first three gives

$$(\ln \eta)' = (\ln \beta)' = (\ln \delta)', \tag{13}$$

i.e., the coefficients η, β and δ depend on u only by a common factor, and P has the form

$$P^2 = h^{-1}(u)(1 + k\zeta\bar\zeta/2)^2, \quad K(u) = k/h(u), \quad k = 0, \pm 1 \tag{14}$$

[note that for this choice of P other normal forms of the symmetry generators may apply, e.g., $i(\zeta\partial_\zeta - \bar\zeta\partial_{\bar\zeta})$ instead of $i(\partial_\zeta - \partial_{\bar\zeta})$]. With this result, the field equation (11) yields

$$h^{-1}\partial_u\partial_u(h) - 3\epsilon m h'/h + 2c(k/h - 2c) = 0. \tag{15}$$

Depending on the different possible values of m and c, we thus arrive at the metrics

$$ds^2=2\epsilon(r^2-1)\,\frac{h(u)d\zeta\,d\overline{\zeta}}{(1+k\zeta\overline{\zeta}/2)^2}-2du\,dr-2H(r,u)du^2,$$

$$H=\frac{1}{2}\,rh'/h-\frac{1}{2}\,\epsilon k/h-\epsilon(r^2-1)\left(b-3m\int\frac{dr}{(r^2-1)^2}\right)-\epsilon c, \tag{16}$$

$$\text{with}\quad \begin{aligned} &h(u)=Au+B \quad \text{for } m=0,\ c=0,\\ &h(u)=A+Be^{3\epsilon mu} \quad \text{for } m\neq 0,\ c=0,\\ &h(u)=A\,\sinh(2cu+B)+k/2c \quad \text{for } m=0,\ c=-2b. \end{aligned}$$

In case of the metric (4), $K=K(u)$ leads to

$$K(u)-\epsilon\partial_u\,\ln P=b, \tag{17}$$

which together with (10) again gives (14). The corresponding metrics are

$$ds^2=2\epsilon r\,\frac{h(u)d\zeta\,d\overline{\zeta}}{(1+k\zeta\overline{\zeta}/2)^2}-2du\,dr-2H(\zeta,\overline{\zeta},r,u)du^2,$$

$$H=\tfrac{1}{2}\,rh'/h-\epsilon ra-\epsilon br\,\ln\,\epsilon r-H^0(\zeta,\overline{\zeta},u), \tag{18}$$

$$2\partial_\zeta\partial_{\overline{\zeta}}H^0+\epsilon(1+k\zeta\overline{\zeta}/2)^{-2}\partial_u(hH^0)=0,$$

$$\text{with}\quad \begin{aligned} &h(u)=2\epsilon ku+A \quad \text{for } b=0\\ &h(u)=Ae^{2b\epsilon u}+k/b \quad \text{for } b\neq 0. \end{aligned}$$

The metrics (16) and (18) exhaust the space–times with $K=K(u)$; they admit a G_3 on V_2 [for metric (18): if H^0 is chosen appropriately]: they are spherically, or pseudospherically, or plane symmetric. Contained here is the solution $k=0=b$ found by Wainwright.[1]

B. Space–times with at most two Killing vectors I: The case $2P^2\partial_\zeta\partial_{\overline{\zeta}}K=0$, $K_{,\zeta}\neq 0$

The only explicitly known class of functions $P(\zeta,\overline{\zeta},u)$ which obey the condition $2P^2\partial_\zeta\partial_{\overline{\zeta}}K=0$, $K_{,\zeta}\neq 0$ is given by

$$P=[f(\zeta)_{,\zeta}\overline{f(\zeta)}_{,\overline{\zeta}}]^{-1/2}[f(\zeta,u)+\overline{f(\zeta,u)}]^{3/2},\quad K=-3(f+\overline{f}), \tag{19}$$

where $f(\zeta,u)$ is an arbitrary function; it has been found in the search for Robinson–Trautman *vacuum* solutions of the Petrov type III (see Kramer *et al.*,[5] Chap. 24). Since the field equations obtained by a reduction of the metric (1) using the algebras I.7, I.8, II.7 and II.8 satisfy $2P^2\partial_\zeta\partial_{\overline{\zeta}}K=0$, $K_{,\zeta}\neq 0$, their available (new) solutions contain subcases of (19). They read:

$$ds^2=2\epsilon(r^2-1)\,\frac{h(u)d\zeta\, d\bar{\zeta}}{(\zeta+\bar{\zeta})^3}-2du\; dr-2H\; du^2,$$

$$2H=r\,\frac{h'(u)}{h(u)}-\frac{3\epsilon(\zeta+\bar{\zeta})}{h(u)}+2\epsilon(r^2-1)\left[b-3m\int\frac{dr}{(r^2-1)^2}\right],\qquad (20)$$

$$h=Au+B\quad\text{for}\quad m=0,\quad h=Ae^{3\epsilon mu}+B\quad\text{for}\quad m\neq 0.$$

These solutions admit a Killing vector $i(\partial_\zeta-\partial_{\bar{\zeta}})$ and may thus be called axially symmetric.

C. Space–times with at most two Killing vectors II: The case $2P^2\partial_\zeta\partial_{\bar{\zeta}}K\neq 0$

Of course we tried to solve as many of the reduced field equations as possible in this most general case, but because of the shear amount of equations we did not attack all of them with some obstinacy. We could not find solutions in the cases I.3, I.5, I.6, I.10, I.11, II.5, II.6, II.11, III.2 and III.6 of Eq. (1), and in the cases I.3, I.6, I.11, II.5, II.6 and II.11 of Eq. (4). The following solutions have been obtained (or rediscovered).

Metric (1) with $2P^2\partial_\zeta\partial_{\bar{\zeta}}K\neq 0$:

$$ds^2=\frac{(1-r^2)}{2\epsilon c}\left[\frac{dw^2}{4w}+we^w\; d\varphi^2\right]-2du\; dr-\epsilon c(r^2+2w+3)du^2,$$

Case III.5: $P^{-2}(\zeta+\bar{\zeta})=-e^{w+2}w/2c,\quad w'=\sqrt{2}we^{1+w/2}.$ [Kramer (1984)[2]] (21)

$$ds^2=2\epsilon\,\frac{r^2-1}{P^2(z)}\,d\zeta\; d\bar{\zeta}-2du\; dr-2H\; du^2,$$

Case I.2: $P^2(z)=(e^{2Az}+2Be^{Az}+B^2-A^2)e^{-Az}/4A^2,$

$z=\zeta+\bar{\zeta}+u,\quad c=0=m$ [Drauschke (1997)[4]], (22)

Case II.2: $P^2(z)=e^{3\epsilon mu}(e^{2Az}+2Be^{Az}+B^2-A^2)e^{-Az}/4A^2,$

$$z=\zeta+\bar{\zeta}+2e^{-3\epsilon mu}/3\epsilon m,\quad c=0,\quad m\neq 0.$$

Metric (4) with $2P^2\partial_\zeta\partial_{\bar{\zeta}}K\neq 0$:

$$ds^2=2\epsilon rP^{-2}(z)d\zeta\; d\bar{\zeta}-2du\; dr-2H(\zeta,\bar{\zeta},r,u)du^2,$$

Case I.2: $P^2=\exp(Az)+\epsilon/2,\quad z=\zeta+\bar{\zeta}+u,\quad b=0,$

Case III.3: $P^2=e^{-2\epsilon bu}[\exp(Az)-1]/A;\quad z=\zeta+\bar{\zeta}+\epsilon e^{-2\epsilon bu}/b,\quad b\neq 0,$

$$\text{Case II.11:} \quad P^2 = \tfrac{1}{2}\,[Be^{-4\epsilon bu} - b(\zeta+\bar{\zeta})^2], \quad b \neq 0. \tag{23}$$

Except for the indicated rediscoveries, these solutions are new.

VI. CONCLUSIONS

When we started, we were aware of the few known solutions of the class under consideration, which all had at least one Killing vector. We set a goal of making a thorough search for solutions with symmetries, using the standard techniques of the symmetry analysis of differential equations, and hoped to find one or the other new solution. What we finally found was a surprise in some aspects (not all of them being positive).

First of all, it is known that the only Lie-point-symmetries admitted by Einstein's field equations correspond to coordinate transformations and scalings (leading to Killing or homothetic vectors in the similarity reduction). A restriction to a special class of solutions (here: algebraically special, etc.) may enlarge the group of admitted symmetries. But the experience from other special classes, e.g., from the algebraically special vacuum solutions, or axially symmetric stationary perfect fluids, showed that this rarely happens. So it was rather unexpected that in our case additional symmetries also showed up. This result should encourage people to always try a symmetry analysis when asking for solutions! As a side result we found that these metrics admit generalized Kerr–Schild transformations.

Connected with these additional symmetries was the huge number of different ordinary differential equations we obtained by the symmetry reduction (23 partial, or 45 ordinary differential equations, the latter ones being given in the Appendix). This made it practically impossible to make a detailed analysis of each of them. So we concentrated on a few simple classes.

The first class are the solutions where the curvature K of the ζ-$\bar{\zeta}$ space is a (possibly time-dependent) constant. The field equations then imply that the metrics admit a G_3 on V_2, i.e., they are of spherical, pseudospherical, or plane symmetry. The general solution for this case is given in (16) and (18). Many solutions with this symmetry are known from other approaches, but they were usually found and given in comoving (and non-null) coordinates. Since an inspection shows that our solutions have nonzero shear, they do not belong to the best-known class of solutions with vanishing shear and are probably new. As in most spherically (pseudospherically, plane) symmetric perfect fluids, a surface of vanishing pressure will exist, but the four-velocity will not be tangent to this surface so that it cannot serve as the outer boundary of a finite perfect fluid sphere. But since for large r pressure and mass density approach zero (if $b=0$), these solutions may be interpreted as approximate models for outer regions of an extended source. On the other hand, the interior regions ($r^2<1$) may serve as inhomogeneous cosmological models.

The second class (20) has been constructed by using the only known solution of the corresponding vacuum Robinson–Trautman class. The rest of the solutions, given in (21)–(23), could be found because of the simplicity of the reduced field equations for these cases. Except for the subcases due to Refs. 3 and 4, they are new.

Unfortunately, none of these last new solutions admits a convincing physical interpretation. Technically this is due to the fact that we did not start from any physical assumption as, e.g., an equation of state or special properties of the four velocity, but made a mathematical study of the field equations and tried to fill in the physics at a later stage. More specifically, we were not able to find examples where, e.g., there is a regular surface with vanishing pressure p which could serve as a model of an isolated source. So the hope of finding some interior solutions for the Robinson–Trautman vacuum solutions was not fulfilled.

APPENDIX: LISTS OF REDUCED FIELD EQUATIONS

We here give the lists of the ordinary differential equations which result from the field equations (1) and (4) after a twofold similarity reduction. In each of the five lists, we give the original field equation and then label the resulting equations using the tables of nonequivalent two-dimensional subalgebras.

1. Field equation (1), $c=0=m$: $\partial_\zeta\partial_{\bar\zeta}K+\partial_u\partial_u(P^{-2})=0$, $K\equiv 2P^2\partial_\zeta\partial_{\bar\zeta}\ln P$

Case	P	K	Field equation
I.1	$P(u)$	0	$(P^{-2})''=0$
I.2	$P(\zeta+\bar\zeta+u)$	$2P^2(\ln P)''$	$K''+(P^{-2})''=0$
I.3	$f(z)/\sqrt{u}$, $z\equiv ue^{-(\zeta+\bar\zeta)/2}$	$zf^2[z(\ln f)']'/2u$	$2u(zK')'+16(f^{-2})'+8z(f^{-2})''=0$
I.4	$(\zeta+\bar\zeta)f(u)$	$-2f^2$	$(f^{-2})''=0$
I.5	$u^{(2-A)/2A}f(z)$, $z\equiv(\zeta+\bar\zeta)u^{-1/A}$	$2f^2(\ln f)''/u$	$A^2uK''+z^2(f^{-2})''+(5-A)z(f^{-2})'+2(2-A)f^{-2}=0$
I.6	$e^uf(z)$, $z\equiv(\zeta+\bar\zeta)e^{-u}$	$2f^2(\ln f)''$	$K''z^2(f^{-2})''+5z(f^{-2})'+4f^{-2}=0$
I.7	$P(\zeta+\bar\zeta)$	$2P^2(\ln P)''$	$K''=0$
I.8	$f(\zeta+\bar\zeta)/\sqrt{u}$	$2f^2(\ln f)''/u$	$K''=0$
I.10	$e^{i(\zeta-\bar\zeta)/4}f(\zeta+\bar\zeta)$	$2e^{i(\zeta-\bar\zeta)/2}w$, $w\equiv f^2(\ln f)''$	$4w''+w=0$
I.11	$[(\zeta+\bar\zeta)f(z)]^{1/2}$, $z\equiv\frac{u+i(\zeta-\bar\zeta)/2}{\zeta+\zeta}$	$(\zeta+\bar\zeta)^{-1}w$, $w\equiv f[2z(\ln f)'-1+(z^2+\frac{1}{4})(\ln f)'']$	$[2+4z\partial_z+(z^2+\frac{1}{4})\partial_z\partial_z]w+(f^{-1})''=0$

2. Field equation (1), $c=0$, $m\neq 0$: $\alpha=3\epsilon m$: $P^2\partial_\zeta\partial_{\bar\zeta}K+P^2\partial_u\partial_u(P^{-2})+6\epsilon m\partial_u\ln P=0$

Case	P	K	Field equation
II.1	$P(u)$	0	$P^2(P^{-2})''+2\alpha(\ln P)'=0$
II.2	$P(\zeta+\bar\zeta+u)$	$2P^2(\ln P)''$	$P^2[K''+(P^{-2})'']+2\alpha(\ln P)'=0$
II.3	$e^{-(\alpha/2)u}f\left(\zeta+\bar\zeta+\frac{2}{\alpha}e^{-\alpha u}\right)$	$2e^{-\alpha u}f^2(\ln f)''$	$f^2(\ln f)''+2(f^{-2})''=0$
II.4	$(\zeta+\bar\zeta)f(u)$	$-2f^2$	$f^2(f^{-2})''+2\alpha(\ln f)'=0$
II.5	$\exp\left(-\frac{\alpha}{2}u-\frac{1}{\alpha}e^{-\alpha u}\right)f(z)$, $z\equiv(\zeta+\bar\zeta)\exp(e^{-\alpha u}/\alpha)$	$2e^{-\alpha u}f^2(\ln f)''$	$e^{\alpha u}f^2K''+z^2f^2(f^{-2})''-10z(\ln f)'+4=0$
II.6	$e^{u/A}f(z)$, $z\equiv(\zeta+\bar\zeta)e^{-u/A}$	$2f^2(\ln f)''$	$K''+[(z\partial_z)^2+(4+\alpha A)z\partial_z+4+2\alpha A]f^{-2}=0$
II.7	$P(\zeta+\bar\zeta)$	$2P^2(\ln P)''$	$K''=0$
II.8	$e^{-\alpha u/2}f(\zeta+\bar\zeta)$	$2e^{-\alpha u}f^2(\ln f)''$	$K''=0$

II.10	$\exp\{-(\alpha/2)[u+(i/2)(\zeta-\bar{\zeta})]\}f(\zeta+\bar{\zeta})$	$2\exp(-\alpha\{[u+\frac{1}{2}(\zeta-\bar{\zeta})]\})w$, $w\equiv f^2(\ln f)''$	$w''+\alpha^2 w/2=0$
II.11	$[(\zeta+\bar{\zeta})e^{-\alpha u}f(\zeta)]^{1/2}$, $z\equiv\dfrac{i(\zeta-\bar{\zeta})-2e^{-\alpha u}/\alpha}{\zeta+\bar{\zeta}}$	$(\zeta+\bar{\zeta})^{-1}e^{-\alpha u}w$, $w\equiv f[2z(\ln f)'+(z^2+1)(\ln f)''-1]$	$[(z^2+1)w]''+4(f^{-1})''=0$

3. Field equation (1), $c\neq 0$, $m=0$: $P^2\partial_\zeta\partial_{\bar{\zeta}}K+P^2\partial_u\partial_u(P^{-2})+2c(K-2c)=0$

Case	P	K	Field equation
III.1	$P(u)$	0	$P^2(P^{-2})''=0$
III.2	$P(\zeta+\bar{\zeta}+u)$	$2P^2(\ln P)''$	$P^2[K''+(P^{-2})'']+2c(K-2c)=0$
III.3	$(\zeta+\bar{\zeta})f(u)$	$-2f^2$	$f^2(f^{-2})''-4c(f^2+c)=0$
III.4	$e^{u/A}f(z)$, $z\equiv(\zeta+\bar{\zeta})e^{-1/A}$	$2f^2(\ln f)''$	$A^2f^2K''+z^2f^2(f^{-2})''+5zf^2(f^{-2})'+4+2A^2c(K-2c)=0$
III.5	$P(\zeta+\bar{\zeta})$	$2P^2(\ln P)''$	$P^2K''+4c(K-2c)=0$

4. Field equation (4), $b=0$: $2P^2\partial_\zeta\partial_{\bar{\zeta}}\ln P=\epsilon\partial_u\ln P$

Case	P	K	Field equation
I.1	$P(u)$	0	$(\ln P)'=0$
I.2	$P(\zeta+\bar{\zeta}+u)$	$2P^2(\ln P)''$	$K-\epsilon(\ln P)'=0$
I.3	$f(z)/\sqrt{u}$, $z\equiv ue^{-(\zeta+\bar{\zeta})/2}$	$zf^2[z(\ln f)']'/2u$	$2uK-2\epsilon z(\ln f)'+\epsilon=0$
I.4	$(\zeta+\bar{\zeta})f(u)$	$-2f^2$	$K=\epsilon(\ln f)'$
I.5	$u^{(2-A)/2A}f(z)$, $z\equiv(\zeta+\bar{\zeta})u^{-1/A}$	$2f^2(\ln f)''/u$	$4Af^2(\ln f)''+2\epsilon z(\ln f)' = (2-A)\epsilon$
II.6	$e^u f(z), z\equiv(\zeta+\bar{\zeta})e^{-u}$	$2f^2(\ln f)''$	$K+\epsilon z(\ln f)'=\epsilon$
I.7	$P(\zeta+\bar{\zeta})$	$2P^2(\ln P)''$	$K=0$
I.8	$f(\zeta+\bar{\zeta})/\sqrt{u}$	$2f^2(\ln f)''/u$	$2uK+\epsilon=0$
I.10	$e^{i(\zeta-\bar{\zeta})/4}f(\zeta+\bar{\zeta})$	$2e^{i(\zeta-\bar{\zeta})/2}f^2(\ln f)''$	$K=0$
I.11	$[(\zeta+\bar{\zeta})f(z)]^{1/2}$, $z\equiv\dfrac{u+i(\zeta-\bar{\zeta})/2}{\zeta+\bar{\zeta}}$	$w/(\zeta+\bar{\zeta})$, $w\equiv f[2z(\ln f)' + (z^2+\frac{1}{4})(\ln f)''-1)]$	$2K(\zeta+\bar{\zeta})=\epsilon(\ln f)'$

5. Field equation (4), $b\neq 0$, $\alpha=2\epsilon b$: $2P^2\partial_\zeta\partial_{\bar\zeta}\ln P-\epsilon\partial_u \ln P=b$

Case	P	K	Field equation
II.1	$P(u)$	0	$(\ln P)'=-\epsilon b$
II.2	$P(\zeta+\bar\zeta+u)$	$2P^2(\ln P)''$	$K-\epsilon(\ln P)'=b$
II.3	$e^{-(\alpha/2)u}f(\zeta+\bar\zeta+(2/\alpha)\,e^{-\alpha u})$	$2e^{-\alpha u}f^2(\ln f)''$	$f^2(\ln f)''+\epsilon(\ln f)'=0$
II.4	$(\zeta+\bar\zeta)f(u)$	$-2f^2$	$K-\epsilon(\ln f)'=b$
II.5	$\exp(-(\alpha/2)\,u-(1/\alpha)\,e^{-\alpha u})f(z)$, $z\equiv(\zeta+\bar\zeta)\exp(1/\alpha\, e^{-\alpha u})$	$2e^{-\alpha u}f^2(\ln f)''$	$2f^2(\ln f)''+\epsilon z(\ln f)'=\epsilon$
II.6	$e^{u/A}f(z)$, $z\equiv(\zeta+\bar\zeta)e^{-u/A}$	$2f^2(\ln f)''$	$AK+\epsilon z(\ln f)'=Ab+\epsilon$
II.7	$P(\zeta+\bar\zeta)$	$2P^2(\ln P)''$	$K=b$
II.8	$e^{-\alpha u/2}f(\zeta+\bar\zeta)$	$2e^{-\alpha u}f^2(\ln f)''$	$K=0$
II.10	$\exp\{-(\alpha/2)\,[u+(i/2)\,(\zeta-\bar\zeta)]\}f(\zeta+\bar\zeta)$	$2e\{-\alpha[u+\frac{1}{2}(\zeta-\bar\zeta)]\}w$, $w\equiv f^2(\ln f)'$	$K=0$
II.11	$[(\zeta+\bar\zeta)e^{-\alpha u}f(z)]^{1/2}$, $z\equiv\dfrac{i(\zeta-\bar\zeta)-2e^{-\alpha u}/\alpha}{\zeta+\bar\zeta}$	$(\zeta+\bar\zeta)^{-1}e^{-\alpha u}w$, $w\equiv f[2z(\ln f)'+(z^2+1)\times(\ln f)''-1]$	$f[2z(\ln f)'-\epsilon(\ln f)'+(z^2+1)(\ln f)''-1]=0$

(Received 2 October 1998; accepted for publication 21 October 1998)

We introduce a proposal to modify Einstein's equations by embedding them in a larger symmetric hyperbolic system. The additional dynamical variables of the modified system are essentially first integrals of the original constraints. The extended system of equations reproduces the usual dynamics on the constraint surface of general relativity, and therefore naturally includes the solutions to Einstein gravity. The main feature of this extended system is that, at least for a linearized version of it, the constraint surface is an attractor of the time evolution. This feature suggests that this system may be a useful alternative to Einstein's equations when obtaining numerical solutions to full, nonlinear gravity. © *1999 American Institute of Physics.* [S0022-2488(99)03002-9]

I. INTRODUCTION

Over the past decade, computer power has increased to the point that simulations of two- and even three-dimensional general relativity are now feasible. These simulations, which assume little or no symmetry of their generic field configurations, at first seemed to represent straightforward generalizations of simpler one-dimensional calculations. However, attempts to perform the higher dimensional simulations have revealed a variety of unexpected features which limit accurate simulations to a rather short time interval. One such feature, which is believed to be a major source of numerical error, is that numerical time evolution generates a rapidly growing violation of the constraint equations. In this paper, we propose a system of dynamical equations wherein the evolution naturally remains close to the constraint surface. Although the most obvious application of this approach is to numerical simulations, it may prove useful in other branches of general relativity as well.

As is well known analytically, the time evolution predicted by the exact Einstein equations is such that the constraint equations are satisfied on each time slice when they are satisfied by the initial data. Geometrically, the evolution vector field is tangential to the constraint submanifold, implying that solutions to the complete set of equations are insensitive to properties of the evolution field in the vicinity of the constraint surface. In discrete approximations, on the other hand,

[a)]Electronic mail: simo@mayu.physics.duq.edu

the notion of tangency is approximate, as is that of the constraint surface itself. As a consequence, the numerical evolution becomes sensitive to possible instabilities of the constraint submanifold and numerical solutions are, in general, carried away from it exponentially fast with time. Even in case one were able to construct a code whose discretized vector field were exactly tangent to a discretized version of the constraint submanifold, the same problem would be likely to arise, as numerical errors on the initial data would prevent a start of the time integration exactly on the constraint submanifold.

As demonstrated in Ref. 1, evolution schemes can be constructed in such a way that the violation of the constraints has the same convergence order as the scheme itself. This property, which is in the meantime a standard requirement for evolution schemes, implies that the choice of an appropriately fine grid is sufficient to satisfy the constraint equations at any given time with arbitrary accuracy. However, since the violation of the constraints grows very quickly with time, the utility of grid refinements to reduce constraint violations is very limited, especially in two- and three-dimensional calculations.

In the so-called constrained evolution schemes one attempts to solve this problem by isolating two sets of variables in Einstein's equations. One uses evolution equations to evolve one set and determines the variables of the other set by solving constraint equations on each time slice. This method has frequently been used in one-dimensional simulations where, on the one hand, it is easy to split the variables into dynamical and longitudinal ones, and where, on the other hand, the constraint equations are ordinary differential equations along a spacelike direction. However, in two- and three-dimensional simulations with spacelike hypersurfaces as time surfaces, the elliptic character of the constraint equations makes it expensive in computer time to solve the constraint equations on each time slice (not to mention the problems arising in the treatment of the grid boundaries). Furthermore, this approach does not guarantee that the complete set of Einstein's equations is solved. Since only a subset of the variables is determined by evolution equations, some of these equations remain unused. The problem is, therefore, shifted to the preservation of the unused evolution equations, which, as shown in Ref. 2, is a problem of similar nature.

In order to guarantee a good approximation to the complete set of field equations, it is, therefore, necessary to analyze the behavior of the evolution vector field in a whole neighborhood of the constraint submanifold. Away from the constraint submanifold the evolution field is not uniquely determined as field configurations violating the constraint equations are physically not relevant. Hence, the evolution vector field can be modified in an arbitrary way, as long as its values on the constraint submanifold remain unchanged, and as long as the modified field continues to be strongly hyperbolic, so that the Cauchy problem is well posed in a whole neighborhood of the constraint surface.

Of particular interest are modified equations for which the constraint submanifold is asymptotically stable, because for equations with this feature, sufficiently accurate codes are expected to generate solutions which remain close to the constraint surface, and which, therefore, would represent improved approximations to Einstein's equations.

Modifications of the evolution vector field have previously been studied. However, in general, these preserve the time reversal symmetry of Einstein's equations, which implies that modifications of this type cannot have the desired properties. Time reversal symmetry implies that if the evolution field is such that a solution to some initial data in a neighborhood of the constraint submanifold approaches the constraint submanifold during time evolution, then the solution to the time reversed initial data will asymptotically be carried away from this submanifold. Thus, without a modification of Einstein's equations which breaks the time reversal symmetry, the best one can expect to achieve is a set of equations for which the constraint submanifold is stable, but not asymptotically stable. However, stability of the undiscretized equations is not sufficient for numerical simulations, since spurious solutions to the discretized equations can grow very rapidly even for stable systems. To eliminate the impact of such solutions, it is, therefore, necessary that the constraint manifold is an attractor for the time evolution.

The above-mentioned modifications of Einstein's equations are, in general, obtained by including dynamical quantities which are proportional to the constraint expressions. An alternative argument showing that extensions of this type cannot lead to an asymptotically stable constraint surface is the following: Since the constraint equations are of the same order as the evolution equations, their inclusion affects mainly the principal part of the evolution equations, whence the freedom remaining after requiring that these terms do not destroy strong hyperbolicity is very limited. Thus, such extensions ensure that the problem is the well posed, but not the asymptotic stability. This can only be obtained either via modifications of the lower order terms or the addition of higher (second) order terms, that is, by including damping or diffusion terms.

In Sec. II, we propose a modification of Einstein's equations which includes new dynamical terms proportional to certain first integrals of the constraint expressions, rather than to the constraints themselves. The dissipation, that is, the time asymmetry, is not of the diffusive type, and is built into the definition of these integrals. (One could also introduce diffusive dissipation, but this would significantly reduce the allowed maximal time step in explicit discretization schemes.)

We show that the Cauchy problem for the resulting new system, which we call the λ-system, is locally well posed. (The name is a remnant of the way the system was originally guessed by Brodbeck and Hübner, namely by a formal application of Lagrangian multiplier techniques.) We also prove that if the constraints are initially satisfied, and if their first integrals initially vanish, then the λ-system provides solutions to Einstein's equations. Moreover, for initial data sets for the λ-system, which are sufficiently close to the constraint submanifold and sufficiently close to zero, respectively, we suspect that the solutions asymptotically tend to solutions to Einstein's equations.

In Sec. III, we give support to our expectation by proving that the linearized extended system is asymptotically stable, thus showing that in the linearized case, the constraint submanifold is indeed an attractor for the λ-system. In Sec. IV, we discuss further expectations in connection with our proposal.

II. THE λ-SYSTEM

In this section we spell out our proposal for a modification of Einstein's equations with an asymptotically stable constraint submanifold. For definiteness, we choose the symmetric hyperbolic system introduced by Frittelli and Reula in Ref. 3, which corresponds to the parameters $\alpha=\beta=-1$ in Ref. 4. Although the full equations (with the nonprincipal part terms added) are given in Ref. 5, we repeat them for completeness.

In the version of Einstein's vacuum equations chosen, the system is given by the following set of dynamical equations (where Latin indices run from 1 to 3):

$$\dot{h}^{ij}=N^n h^{ij}{}_{,n}+Q\sqrt{h}(2P^{ij}-Ph^{ij})-2h^{n(i}N^{j)}{}_{,n}, \tag{1}$$

$$\begin{aligned}\dot{M}^{ij}{}_k=&N^n M^{ij}{}_{k,n}+Q\sqrt{h}(P^{ij}{}_{,k}-2\delta_k{}^{(i}P^{j)n}{}_{,n})+Q\sqrt{h}(\tfrac{3}{2}P^{ij}M_k-PM^{ij}{}_k+Q^{-1}P^{ij}Q_{,k}\\&-2\delta_k{}^{(i}[h^{j)q}h_{mr}h_{ns}P^{mn}M^{rs}{}_q-2M^{j)p}{}_n P^{mn}h_{prn}+\tfrac{3}{2}P^{j)n}M_n-\tfrac{1}{2}h^{j)n}PM_n])\\&+h^{ij}N^n{}_{,nk}-h^{n(i}N^{j)}{}_{,nk}-2N^{(i}{}_{,n}M^{j)n}{}_k+N^m{}_{,k}M^{ij}{}_m,\end{aligned} \tag{2}$$

$$\begin{aligned}\dot{P}^{ij}=&N^n P^{ij}{}_{,n}+Q\sqrt{h}(h^{mn}M^{ij}{}_{m,n}-2h^{n(i}M^{j)k}{}_{k,n})+Q\sqrt{h}(4h_{np}h^{m(i}M^{j)n}{}_k M^{kp}{}_m\\&-h^{ik}h^{jn}h_{rp}h_{sq}M^{rs}{}_k M^{pq}{}_n+\tfrac{1}{2}h^{ik}h^{jn}M_k M_n+2M^{nk}{}_k M^{ij}{}_n-2M^{ik}{}_n M^{jn}{}_k-2h_{mn}h^{kp}M^{im}{}_k M^{jn}{}_p\\&-2h^{n(i}M^{j)k}{}_k M_n+M^{ij}{}_n h^{nk}M_k-Q^{-1}[h^{ik}h^{jn}Q_{,kn}+2M^{k(i}{}_n h^{j)n}Q_{,k}-M^{ij}{}_m h^{mk}Q_{,k}\\&-h^{ij}(h^{kn}Q_{,kn}+2M^{km}{}_m Q_{,k})]+2P^{ik}h_{kn}P^{nj}-\tfrac{3}{2}PP^{ij}+h^{ij}(\tfrac{1}{2}P^2-h_{mr}h_{ns}P^{mn}P^{rs}))\\&-2P^{k(i}N^{j)}{}_{,k}.\end{aligned} \tag{3}$$

Here, h^{ij} is the inverse intrinsic metric of the spacelike hypersurfaces Σ_t, $P^{ij}:=k^{ij}-h^{ij}k$ denotes a linear combination of the extrinsic curvature k^{ij} of the slice and its trace k, and $M^{ij}{}_k:=\tfrac{1}{2}(h^{ij}{}_{,k}$

$-h^{ij}h_{rs}h^{rs}{}_{,k}$) represents a linear combination of spatial derivatives of the inverse intrinsic metric. The functions P and M_k are abbreviations for $h_{ij}P^{ij}$ and $h_{ij}M^{ij}{}_k$, respectively, and Q and N^i are arbitrarily given functions fixing the gauge degrees of freedom.

This evolution system is symmetric hyperbolic with respect to the inner product

$$\langle h_1^{ij},P_1^{ij},M_1^{ij}{}_k|H_e|h_2^{ij},P_2^{ij},M_2^{ij}{}_k\rangle := \int_{\Sigma_t}\{e_{im}e_{jn}\overline{h_1^{ij}}h_2^{mn}+e_{im}e_{jn}\overline{P_1^{ij}}P_2^{mn}+e_{im}e_{jn}e^{kl}\overline{M_1^{ij}{}_k}M_2^{mn}{}_l\}d\Sigma, \tag{4}$$

where e_{ij} denotes an Euclidean flat metric on the hypersurface Σ_t. It is completed by the following set of constraints equations:

$$\mathcal{C}=0, \quad \mathcal{C}^i=0, \quad \mathcal{C}^{ij}{}_k=0, \tag{5}$$

where

$$\mathcal{C}\equiv -M^{kn}{}_{n,k}+h_{pq}M^{pk}{}_nM^{qn}{}_k-M^{kq}{}_qM_k+\tfrac{1}{4}h^{kn}M_kM_n-\tfrac{1}{2}h_{mn}h_{rs}h^{pq}M^{mr}{}_pM^{ns}{}_q$$
$$-\tfrac{1}{2}h_{mn}h_{rs}P^{mr}P^{ns}+\tfrac{1}{4}P^2, \tag{6}$$

$$\mathcal{C}^i\equiv P^{ik}{}_{,k}-2h_{mn}M^{im}{}_kP^{nk}-\tfrac{1}{2}h^{ik}PM_k+h_{mn}h_{pq}h^{ik}M^{mp}{}_kP^{nq}+\tfrac{3}{2}P^{ik}M_k, \tag{7}$$

$$\mathcal{C}^{ij}{}_k\equiv 2M^{ij}{}_k-h^{ij}h_{pq}M^{pq}{}_k-h^{ij}{}_{,k}. \tag{8}$$

The first two constraints are the scalar and the vector constraint of Einstein's equations, that is the time–time and time–space components of the Einstein tensor for a given 3+1 decomposition of space–time. The third is the statement that the tensor $M^{ij}{}_k$ is a linear combination of spatial derivatives of the three-metric.

To solve the initial value problem of general relativity in this approach, one prescribes an initial data set $(h_0^{ij},P_0^{ij},M_0^{ij}{}_k)$ at $t=0$ which satisfies the constraints' equations and subsequently solves the above evolution equations. Symmetric hyperbolicity of the evolution system implies that a unique local solution does exist.

By taking a time derivative of Eqs. (6)–(8) and using (1)–(3) to eliminate time derivatives in favor of spatial derivatives, the following evolution equations for the constraints are obtained:

$$\dot{\mathcal{C}}=N^n\mathcal{C}_{,n}+3Q\sqrt{h}\mathcal{C}^k{}_{,k}+\cdots, \tag{9}$$

$$\dot{\mathcal{C}}^i=N^n\mathcal{C}^i{}_{,n}+Q\sqrt{h}(h^{ik}\mathcal{C}_{,k}+h^{rs}\mathcal{C}^{ik}{}_{[r,k]s}+h^{is}h^{kl}h_{mn}\mathcal{C}^{mn}{}_{[s,k]l})+\cdots, \tag{10}$$

$$\dot{\mathcal{C}}^{ij}{}_k=N^n\mathcal{C}^{ij}{}_{k,n}-2Q\sqrt{h}(2\delta_k{}^{(i}\mathcal{C}^{j)}-h^{ij}h_{kl}\mathcal{C}^l)+\cdots, \tag{11}$$

where the ellipses ''$\cdots$'' represent undifferentiated terms which are linear in the constraint quantities and at least linear in the variables P^{ij} and $M^{ij}{}_k$.

Since Eq. (10) is of second order in spatial derivatives, we introduce a further constraint by[4]

$$\mathcal{C}^{ij}{}_{kl}:=2M^{ij}{}_{[k,l]}+2M^{ij}{}_{[k}M_{l]}. \tag{12}$$

(One could also consider the constraint $\mathcal{C}^i{}_j\equiv\mathcal{C}^{ik}{}_{jk}$, which still makes the constraint system symmetric hyperbolic and produces a smaller number of extra fields.) By taking a time derivative of (12), we obtain

$$\dot{\mathcal{C}}^{ij}{}_{kl}=N^n\mathcal{C}^{ij}{}_{kl,n}-2Q\sqrt{h}(\delta_k{}^{(i}\mathcal{C}^{j)}{}_{,l}-\delta_l{}^{(i}\mathcal{C}^{j)}{}_{,k})+\cdots, \tag{13}$$

and by plugging (12) into (10), we see that the evolution equation for $\mathcal{C}^i$ can be rewritten as

$$\dot{\mathcal{C}}^i = N^n \mathcal{C}^i{}_{,n} + Q\sqrt{h}(h^{ik}\mathcal{C}_{,k} + h^{rs}\mathcal{C}^{ik}{}_{rk,s}) + \cdots . \tag{14}$$

The constraint quantities $\mathcal{C}$, $\mathcal{C}^i$, $\mathcal{C}^{ij}{}_k$, and $\mathcal{C}^{ij}{}_{kl}$ thus propagate according to the first-order system of equations consisting of (9), (11), and (13)–(14), which is symmetric hyperbolic with respect to the following inner product:

$$\langle C_1, C_1^i, C_1^{ij}{}_k, C_1^{ij}{}_{kl} | H_C | C_2, C_2^i, C_2^{ij}{}_k, C_2^{ij}{}_{kl} \rangle := \int_{\Sigma_t} \left\{ \frac{1}{3}\overline{C}_1 C_2 + e_{ij}\overline{C}_1^i C_2^j + e_{ij}e_{kl}e^{rs}\overline{C}_1^{ik}{}_r C_2^{jl}{}_s + \frac{1}{4} e_{im}e_{jn}e^{kp}e^{lq}\overline{C}_1^{ij}{}_{kl} C_2^{mn}{}_{pq} \right\} d\Sigma. \tag{15}$$

The uniqueness of the solutions to this system implies that if the constraints are initially satisfied, then the exact evolution equations preserve them. When, as in numerical simulations, the constraint variables initially are not precisely zero, then the corresponding solution is, in general, carried away from the constraint surface during time evolution. However, since the evolution equations for the constraint variables are symmetric hyperbolic, the violation of the constraints becomes smaller when the constraints initially are satisfied with better accuracy.

In order to obtain a system with an asymptotically stable constraint submanifold, we propose a modification of Einstein's equations, which is inspired by the behavior of dissipative systems, where a transient eventually is dissipated away as the system settles down. We extend the set of dynamical variables by considering the following ''time integrals'' of the constraint variables:

$$\dot{\lambda} = \alpha_0 \mathcal{C} - \beta_0 \lambda, \tag{16}$$

$$\dot{\lambda}^i = \alpha_1 \mathcal{C}^i - \beta_1 \lambda^i, \tag{17}$$

$$\dot{\lambda}^{ij}{}_k = \alpha_3 \mathcal{C}^{ij}{}_k - \beta_3 \lambda^{ij}{}_k, \tag{18}$$

$$\dot{\lambda}^{ij}{}_{kl} = \alpha_4 \mathcal{C}^{ij}{}_{kl} - \beta_4 \lambda^{ij}{}_{kl}, \tag{19}$$

where the tensor-valued λ-variables are assumed to have the same symmetries as the corresponding C-variables, and where $\alpha_i \neq 0$ and $\beta_i > 0$ are constants.

Equations (16)–(19) represent evolution equations for the λ-variables which in terms of the fundamental variables $(h^{ij}, P^{ij}, M^{ij}{}_k)$ are given by

$$\dot{\lambda} = \alpha_0(-M^{kn}{}_{n,k} + h_{pq}M^{pk}{}_n M^{qn}{}_k - M^{kq}{}_q M_k + \tfrac{1}{4}h^{kn}M_k M_n) - \beta_0 \lambda, \tag{20}$$

$$\dot{\lambda}^i = \alpha_1(P^{ik}{}_{,k} - 2h_{mn}M^{im}{}_k P^{nk} - \tfrac{1}{2}h^{ik}PM_k) - \beta_1 \lambda^i, \tag{21}$$

$$\dot{\lambda}^{ij}{}_k = \alpha_3(2M^{ij}{}_k - h^{ij}h_{rs}M^{rs}{}_k - h^{ij}{}_{,k}) - \beta_3 \lambda^{ij}{}_k, \tag{22}$$

$$\dot{\lambda}^{ij}{}_{kl} = \alpha_4(2M^{ij}{}_{[k,l]} + 2M^{ij}{}_{[k}M_{l]}) - \beta_4 \lambda^{ij}{}_{kl}. \tag{23}$$

In the present form, the combined system (1)–(3), (20)–(23) is not symmetric hyperbolic, since Eqs. (20)–(23) involve spatial derivatives of the variables $(h^{ij}, P^{ij}, M^{ij}{}_k)$, whereas Eqs. (1)–(3) do not contain λ-variables at all. However, by adding terms containing first derivatives of the λ-variables it is possible to bring the system (1)–(3), (20)–(23) into a symmetric hyperbolic form,

$$\dot{h}^{ij} = \alpha_3 h^{mn}\lambda^{ij}{}_{m,n} + N^n h^{ij}{}_{,n} + \text{source terms}, \tag{24}$$

$$\dot{M}^{ij}{}_k = 2\alpha_4 h^{lm}\lambda^{ij}{}_{kl,m} - \alpha_0 \delta_k{}^{(i}h^{j)l}\lambda_{,l} + N^n M^{ij}{}_{k,n} + Q\sqrt{h}(P^{ij}{}_{,k} - 2\delta_k{}^{(i}P^{j)n}{}_{,n}) + \text{source terms}, \tag{25}$$

$$\dot{P}^{ij}=\alpha_2 h^{l(i}\lambda^{j)}{}_{,l}+N^n P^{ij}{}_{,n}+Q\sqrt{h}(h^{mn}M^{ij}{}_{m,n}-2h^{n(i}M^{j)k}{}_{k,n})+\text{source terms}. \tag{26}$$

By construction, the ''λ-system'' (20)–(26) is symmetric hyperbolic with respect to the inner product

$$\langle h_1^{ij},P_1^{ij},M_{1\,k}^{ij},\lambda_1,\lambda_1^i,\lambda_{1\,k}^{ij},\lambda_{1\,kl}^{ij}|H_E^\lambda|h_2^{ij},P_2^{ij},M_{2\,k}^{ij},\lambda_2,\lambda_2^i,\lambda_{2\,k}^{ij},\lambda_{2\,kl}^{ij}\rangle$$

$$:=\int_{\Sigma_t}\{e_{im}e_{jn}\overline{h_1^{ij}}h_2^{mn}+e_{im}e_{jn}\overline{P_1^{ij}}P_2^{mn}+e_{im}e_{jn}e^{kl}\overline{M_{1\,k}^{ij}}M_{2\,\,1}^{mn}+\overline{\lambda_1}\lambda_2+e_{ij}\overline{\lambda_1^i}\lambda_2^j$$

$$+e_{ip}e_{jq}e^{kr}\overline{\lambda_{1\,k}^{ij}}\lambda_{2\,r}^{pq}+e_{ip}e_{jq}e^{kr}e^{ls}\overline{\lambda_{1\,kl}^{ij}}\lambda_{2\,rs}^{pq}\}d\Sigma. \tag{27}$$

The initial data for this purely dynamical set of equations consists of arbitrary functions

$$(h_0^{ij},P_0^{ij},M_{0\,k}^{ij},\lambda_0,\lambda_0^i,\lambda_{0\,k}^{ij},\lambda_{0\,kl}^{ij}). \tag{28}$$

However, the dynamical degrees of freedom are extended by 40 λ-variables.

Clearly, for an arbitrary solution to Einstein's equations, $(h_E^{ij},P_E^{ij},M_{E\,k}^{ij})$, the embedded field configuration $(h^{ij},P^{ij},M^{ij}{}_k,\lambda,\lambda^i,\lambda^{ij}{}_k,\lambda^{ij}{}_{kl}):=(h_E^{ij},P_E^{ij},M_{E\,k}^{ij},0,0,0,0)$ is a solution to the λ-system. Conversely, every solution to the λ-system with vanishing λ-variables is also a solution to Einstein's equations. Due to this property, and since the solutions to the λ-system are unique, the λ-system naturally reproduces the dynamics on the constraint submanifold of general relativity.

Note that if the constraints are initially not satisfied, then, even when the λ-variables initially vanish, the λ-variables would pick up a nonzero value during time evolution. Hence, solutions to the λ-system corresponding to such initial data sets would not represent solutions to the complete set of Einstein's equations. In fact, they would not even solve the evolution equations of general relativity. However, for constraint- and λ-variables which initially are sufficiently close to zero, we suspect that the solutions asymptotically approach solutions to the Einstein equations. In Sec. III, we give analytical evidence that this conjecture could be true.

The system is by no means uniquely ''extended,'' since one could still add nonprincipal (undifferentiated) terms, as long as they vanish when $\lambda=\lambda^i=\lambda^{ij}{}_k=\lambda^{ij}{}_{kl}=0$. Such terms might be useful in order to treat the strongly nonlinear regime. Of particular interest might be to choose the coefficients α_i and β_i, which control the damping in the λ-equations, to be quadratic functions of the basic variables $(h^{ij},P^{ij},M^{ij}{}_k)$, so that the damping becomes stronger at points where the nonlinearities intensify.

It is fairly easy to implement similar schemes for alternative symmetric hyperbolic systems for the Einstein equations, as well as for symmetric hyperbolic systems for other theories with constraints, like, for instance, Yang–Mills theories. The strategy is the same: One writes equations with damping for first integrals of the constraints and modifies the evolution equations such that the extended system becomes symmetric hyperbolic. This can always be achieved, because the inclusion of the new equations modifies an off-diagonal sector of the principal symbol matrix.

III. ASYMPTOTIC STABILITY OF THE CONSTRAINT PROPAGATION

The inclusion of the λ-terms into (1)–(3) affects, in turn, the evolution of the constraint quantities $\mathcal{C}$, $\mathcal{C}^i$, $\mathcal{C}^{ij}{}_k$, and $\mathcal{C}^{ij}{}_{kl}$. Recalculating the time derivative of these, and using (24)–(26), yields the constraint evolution equations for the new system,

$$\dot{\mathcal{C}}=N^n\mathcal{C}_{,n}+3Q\sqrt{h}\mathcal{C}^k{}_{,k}-2\alpha_4 h^{mn}\lambda^{kl}{}_{km,nl}+2\alpha_0 h^{mn}\lambda_{,mn}+\cdots, \tag{29}$$

$$\dot{\mathcal{C}}^i=N^n\mathcal{C}^i{}_{,n}+Q\sqrt{h}(h^{ik}\mathcal{C}_{,k}+h^{rs}\mathcal{C}^{ik}{}_{rk,s})+\alpha_1 h^{m(n}\lambda^{i)}{}_{,mn}+\cdots, \tag{30}$$

$$\dot{\mathcal{C}}^{ij}{}_k = N^n \mathcal{C}^{ij}{}_{k,n} - 2Q\sqrt{h}(2\delta_k{}^{(i}\mathcal{C}^{j)} - h^{ij}h_{kl}C^l) + 2\alpha_3 h^{mn}\lambda^{ij}{}_{m,nk} + 2\alpha_4 h^{mn}(2\lambda^{ij}{}_{km,n} - h^{ij}h_{rs}\lambda^{rs}{}_{km,n}) - \alpha_0(2\delta^{(i}{}_k h^{j)l}\lambda_{,l} - h^{ij}\lambda_{,k}) + \cdots, \tag{31}$$

$$\dot{\mathcal{C}}^{ij}{}_{kl} = N^n \mathcal{C}^{ij}{}_{kl,n} - 2Q\sqrt{h}(\delta_k{}^{(i}\mathcal{C}^{j)}{}_{,l} - \delta_l{}^{(i}\mathcal{C}^{j)}{}_{,k}) + 2\alpha_4(h^{mn}\lambda^{ij}{}_{km,nl} - h^{mn}\lambda^{ij}{}_{lm,nk}) - \alpha_0(\delta_k{}^{(i}h^{j)m}\lambda_{,ml} + \delta_l{}^{(i}h^{j)m}\lambda_{,mk}) + \cdots. \tag{32}$$

Again the ellipses ''...'' represent undifferentiated terms that are linear in the constraint quantities and at least linear in $(P^{ij}, M^{ij}{}_k)$.

The propagation of the constraints is ruled by the system of equations consisting of (16)–(19) and (29)–(32), which determines whether or not the constraints asymptotically ''decay'' to zero. The crucial feature of this system is that the right-hand side also contains nonprincipal terms. Roughly speaking, the operator on the right-hand side amplifies constraint violations if the matrix representing its action on periodic functions has any eigenvalue with a positive real part. On the other hand, if all the eigenvalues have a negative real part, the operator induces an asymptotic decay of these violations.

Instead of attacking the full nonlinear problem as stated, which represents a problem well beyond the scope of present analytical techniques, we consider the linear regime of general relativity. That is, we restrict attention to three-metrics of the form $h^{ij} = e^{ij} + \epsilon\gamma^{ij}$ with $e^{ij} = \delta^{ij}$ and $\epsilon \ll 1$. This implies that the variables $(P^{ij}, M^{ij}{}_k)$ are of first order in ϵ, as are the constraint quantities $(\mathcal{C}, \mathcal{C}^i, \mathcal{C}^{ij}{}_k, \mathcal{C}^{ij}{}_{kl})$ and the variables $(\lambda, \lambda^i, \lambda^{ij}{}_k, \lambda^{ij}{}_{kl})$. Thus, the terms represented by the ellipses ''$\cdots$'' in Eqs. (29)–(32) are of second order in ϵ and shall be neglected. Without loss of generality, we restrict the following arguments to the case where the gauge source functions Q and N^i are constant. All arguments that follow refer to this linearized regime.

Although we lack a proof for the nonlinear case, the following considerations provide analytical evidence for the asymptotic stability of the constraint propagation, in particular since the full evolution equations are quasilinear.

For, as we believe, purely technical reasons, we adopt the following choice of coefficients: $\beta_0 = \beta_1 = \beta_3 = \beta_4 \equiv \beta > 0$ and $\alpha_4 = (\sqrt{3}/2)\alpha_0$.

Theorem 1: *With the above assumptions, the constraint submanifold of the linearized Einstein equations is an asymptotically stable submanifold for the solutions to the linearized, λ-extended Einstein equations.*

We partition the proof of this theorem in several lemmas: We first show that the initial value problem is well posed and that the solutions stay bounded with time. Thus, it is possible to apply Laplace transformation techniques, which reduce the problem to the study of the eigenfrequencies of the system. For these frequencies, we show that the real part is nonpositive, only approaches zero as the wave number goes to zero, and does so quadratically. Then stability follows from estimates in Ref. 6.

Without loss of generality, we expand the linearized dynamical fields in Fourier integrals of the the following form:

$$\lambda(x,t) = \int \hat{\lambda}(k,t)\exp(ik\cdot x)d^3k, \tag{33}$$

$$\lambda^i(x,t) = \int \hat{\lambda}^i(k,t)\exp(ik\cdot x)d^3k, \tag{34}$$

$$\vdots \tag{35}$$

$$C^{ij}{}_k(x,t) = \int \hat{C}^{ij}{}_k(k,t)\exp(ik\cdot x)d^3k, \tag{36}$$

$$C^{ij}{}_{kl}(x,t)=\int \hat{C}^{ij}{}_{kl}(k,t)\exp(ik\cdot x)d^3k, \tag{37}$$

where $k\cdot x:=k_i x^i$.

In terms of the Fourier transformed variables, Eqs. (29)–(32) and (16)–(19) reduce to the system of ordinary differential equations given by

$$\dot{\hat{\lambda}}=-\beta\hat{\lambda}+\alpha_0\hat{\mathcal{C}}, \tag{38}$$

$$\dot{\hat{\lambda}}{}^i=-\beta\hat{\lambda}^i+\alpha_1\hat{\mathcal{C}}^i, \tag{39}$$

$$\dot{\hat{\lambda}}{}^{ij}{}_{kl}=-\beta\hat{\lambda}^{ij}{}_{kl}+\frac{\sqrt{3}}{2}\alpha_0\hat{\mathcal{C}}^{ij}{}_{kl}, \tag{40}$$

$$\dot{\hat{\mathcal{C}}}=ik_nN^n\hat{\mathcal{C}}+3iQk_m\hat{\mathcal{C}}^m+\sqrt{3}\alpha_0\hat{\lambda}^{rl}{}_{rm}k^mk_l-2\alpha_0\hat{\lambda}k^nk_n, \tag{41}$$

$$\dot{\hat{\mathcal{C}}}{}^i=ik_nN^n\hat{\mathcal{C}}^i+iQ(k^i\hat{\mathcal{C}}+k^r\hat{\mathcal{C}}^{in}{}_{rn})-\tfrac{1}{2}\alpha_1(k^nk_n\hat{\lambda}^i+k^ik_n\hat{\lambda}^n), \tag{42}$$

$$\begin{aligned}\dot{\hat{\mathcal{C}}}{}^{ij}{}_{kl}=&ik_nN^n\hat{\mathcal{C}}^{ij}{}_{kl}-2iQ(\delta_k{}^{(i}\hat{\mathcal{C}}^{j)}k_l-\delta_l{}^{(i}\hat{\mathcal{C}}^{j)}k_k)-\sqrt{3}\alpha_0(\hat{\lambda}^{ij}{}_{kr}k^rk_l-\hat{\lambda}^{ij}{}_{lr}k^rk_k)\\&+\alpha_0\hat{\lambda}(\delta_k{}^{(i}k^{j)}k_l-\delta_l{}^{(i}k^{j)}k_k),\end{aligned} \tag{43}$$

and

$$\dot{\hat{\lambda}}{}^{ij}{}_k=-\beta\hat{\lambda}^{ij}{}_k+\alpha_3\hat{\mathcal{C}}^{ij}{}_k, \tag{44}$$

$$\dot{\hat{\mathcal{C}}}{}^{ij}{}_k=ik_nN^n\hat{\mathcal{C}}^{ij}{}_k-\alpha_3\hat{\lambda}^{ij}{}_mk^mk_k+\hat{S}^{ij}{}_k, \tag{45}$$

where

$$\hat{S}^{ij}{}_k:=-2Q(2\delta_k{}^{(i}\hat{\mathcal{C}}^{j)}-\delta^{ij}\hat{\mathcal{C}}_k)-\alpha_0(2\delta^{(i}{}_kk^{j)}-h^{ij}k_k)\hat{\lambda}+\sqrt{3}\alpha_0k^m(2\hat{\lambda}^{ij}{}_{km}-h^{ij}h_{rs}\hat{\lambda}^{rs}{}_{km}). \tag{46}$$

This system of equations naturally splits up in two subsystems, since Eqs. (38)–(42) couple to Eqs. (44) and (45) only via the ''source'' term in (45). In the following, we will first establish that the solutions to the subsystem (38)–(42), and hence the coupling term in (45), asymptotically decay to zero. In a second step, we consider this coupling as a given, decaying source, and discuss the asymptotic behavior of solutions to the subsystem (44)–(45).

Lemma 1: Let $\mathcal{H}$ be the space of the Fourier transformed $\hat{\lambda}^{ij}{}_{kl}\in L^2$, and let $\mathcal{D}\subset\mathcal{H}$ be the subspace defined by $\hat{\lambda}^{ij}{}_{ks}k^s=0$. Then $\mathcal{D}$ is invariant under time evolution, and the trivial solution $\hat{\lambda}^{ij}{}_{kl}=0$ is asymptotically stable for the evolution restricted to $\mathcal{D}$.

Proof: Multiplying Eq. (40) by k_m, antisymmetrizing, and using that $\hat{C}^{ij}{}_{[kl}k_{m]}=\hat{M}^{ij}{}_{[k}k_lk_{m]}=0$, we obtain

$$\dot{\hat{\lambda}}{}^{ij}{}_{[kl}k_{m]}=-\beta\hat{\lambda}^{ij}{}_{[kl}k_{m]}. \tag{47}$$

Next we note that for a function $\hat{\lambda}^{ij}{}_{kl}$ in $\mathcal{H}$, the component $(\hat{\lambda}^{ij}{}_{kl})^{\parallel}$ in $\mathcal{D}$ is given by $(\hat{\lambda}^{ij}{}_{kl})^{\parallel}=\hat{\alpha}^{ij}k^r\epsilon_{rkl}$, where $\hat{\alpha}^{ij}=\hat{\lambda}^{ij}{}_{[kl}k_{r]}\epsilon^{klr}/(6k^2)$. Equation (47) is, therefore, equivalent to

$$(\dot{\hat{\lambda}}{}^{ij}{}_{kl})^{\parallel}=-\beta(\hat{\lambda}^{ij}{}_{kl})^{\parallel}, \tag{48}$$

which proves lemma 1.

By direct inspection of the evolution equations, it follows that the equation for the component of $\hat{\lambda}^{ij}{}_{kl}$ in the subspace $\mathcal{D}$ decouples. It is, therefore, sufficient to concentrate on the evolution in the space $CF_\lambda \oplus CF_C$ which comprises those functions $(\hat{\lambda},\hat{\lambda}^i,\hat{\lambda}^{ij}{}_{kl},\hat{\mathcal{C}},\hat{\mathcal{C}}^i,\hat{\mathcal{C}}^{ij}{}_{kl}) \in L^2$ for which $\hat{\lambda}^{ij}{}_{kl} \in \mathcal{D}^\perp$. Here, $\mathcal{D}^\perp$ denotes the L^2 complement of $\mathcal{D}$ in $\mathcal{H}$, which, as easily seen, is spanned by the elements $\hat{\lambda}^{ij}{}_{kl} \in L^2$ satisfying $\hat{\lambda}^{ij}{}_{[kl}k_{m]}=0$. (For functions $\hat{\lambda}^{ij}{}_{kl}$ in $\mathcal{D}$ only the components along k^m are nontrivial, $\hat{\lambda}^{ij}{}_{kl}=-2k_{[l}\hat{\lambda}^{ij}{}_{k]m}k^m/k^2$. This can be seen by solving $\hat{\lambda}^{ij}{}_{[kl}k_{m]}=0$, and by using the antisymmetry in the lower indices of $\hat{\lambda}^{ij}{}_{kl}$.) Since for the constraint variable $\hat{C}^{ij}{}_{kl}$, the same property is fulfilled, $\hat{C}^{ij}{}_{[kl}k_{m]}=0$, this shows that the spaces CF_λ and CF_C are naturally isomorphic, $CF_\lambda \approx CF_C =: CF$.

To simplify the notation, and to display the structure of the evolution equations considered more transparently, let us introduce the following operator $\mathbf{E}$ acting on functions $\mathbf{v}\equiv(v,v^i,v^{ij}{}_{kl})$ in CF:

$$\mathbf{E}(\mathbf{v})\equiv(E(\mathbf{v}),E^i(\mathbf{v}),E^{ij}{}_{kl}(\mathbf{v})), \tag{49}$$

where

$$E(\mathbf{v})\equiv\sqrt{3}\,\alpha_0 v^{rl}{}_{rm}k^m k_l - 2\alpha_0 v k^n k_n\,, \tag{50}$$

$$E^i(\mathbf{v})\equiv -\tfrac{1}{2}\alpha_1(v^i k^n k_n + v^n k^i k_n), \tag{51}$$

$$E^{ij}{}_{kl}(\mathbf{v})\equiv -\sqrt{3}\,\alpha_0(v^{ij}{}_{kn}k^n k_l - v^{ij}{}_{ln}k^n k_k) + \alpha_0 v(\delta_k{}^{(i}k^{j)}k_l - \delta_l{}^{(i}k^{j)}k_k). \tag{52}$$

Taking advantage of these definitions, the evolution system (38)–(43) restricted to the subspace $CF\oplus CF$ can be rewritten as

$$\frac{d}{dt}\begin{pmatrix}\boldsymbol{\lambda}\\ \mathbf{C}\end{pmatrix} = \begin{pmatrix}-\mathbf{S} & \boldsymbol{\Gamma}\\ \mathbf{E} & i\mathbf{A}\end{pmatrix}\begin{pmatrix}\boldsymbol{\lambda}\\ \mathbf{C}\end{pmatrix} =: \mathbf{P}\begin{pmatrix}\boldsymbol{\lambda}\\ \mathbf{C}\end{pmatrix}, \tag{53}$$

where $\mathbf{S}$ and $\boldsymbol{\Gamma}$ are diagonal matrices determined by the parameters β and α_i, respectively, and where $\mathbf{A}$ is an operator of the form $\mathbf{A}^m k_m$.

In a next step, we show that the operator $e^{\mathbf{P}t}$ is bounded with respect to a suitably chosen norm. To this end, we first establish the following:

Lemma 2: The operator $H_\lambda := -\boldsymbol{\Gamma}^{-1}H_c\mathbf{E}$ considered as a matrix-valued field on the Fourier space $\mathbf{R}^3$ is symmetric and coercive with respect to the inner product $\langle\mathbf{u},\mathbf{v}\rangle := \bar{u}v + e_{ij}\bar{u}^i v^j + e_{ip}e_{jq}e^{kr}e^{ls}\bar{u}^{ij}{}_{kl}v^{pq}{}_{rs}$. That is, $\langle\mathbf{u},H_\lambda\mathbf{v}\rangle = \langle H_\lambda\mathbf{u},\mathbf{v}\rangle$ for all $\mathbf{u},\mathbf{v}\in CF$, and there exists a constant $c>0$ such that $\langle\mathbf{u},H_\lambda\mathbf{u}\rangle \geqslant ck^2(\mathbf{u},\mathbf{u})$ for all $\mathbf{u}\in CF$.

Proof: We have

$$\begin{aligned}
&\langle u,\boldsymbol{\Gamma}^{-1}H_c\mathbf{E}(\mathbf{v})\rangle - \langle\boldsymbol{\Gamma}^{-1}H_c\mathbf{E}(\mathbf{u}),\mathbf{v}\rangle\\
&= \frac{1}{3\alpha_0}\bar{u}(-2\alpha_0 v k_n k^n + \sqrt{3}\,\alpha_0 v^{kl}{}_{km}k^m k_l) + \frac{1}{\alpha_1}\bar{u}^i\left(-\frac{\alpha_1}{2}(v^j k_n k^n + k^j v^l k_l)\right)e_{ij}\\
&+ \frac{1}{2\sqrt{3}\,\alpha_0}e_{im}e_{jn}e^{kp}e^{lq}\bar{u}^{ij}{}_{kl}(-2\sqrt{3}\,\alpha_0 v^{mn}{}_{ps}k^s k_q + 2\alpha_0 v\,\delta^m{}_p k^n k_q)\\
&- \frac{1}{3\alpha_0}v(-2\alpha_0\bar{u}k_n k^n + \sqrt{3}\,\alpha_0\bar{u}^{kl}{}_{km}k^m k_l) - \frac{1}{\alpha_1}v^i\left(-\frac{\alpha_1}{2}(\bar{u}^j k_n k^n + k^j\bar{u}^l k_l)\right)e_{ij}
\end{aligned}$$

$$+\frac{1}{2\sqrt{3}\alpha_0} e_{im} e_{jn} e^{kp} e^{lq} v^{ij}{}_{kl}(-2\sqrt{3}\alpha_0 \overline{u}^{mn}{}_{ps} k^s k_q + 2\alpha_0 \overline{u} \delta^m{}_p k^n k_q) = 0.$$

The remaining part of the proof is given in Appendix A, where we show that H_λ is coercitive with constant $c = 1/4$.

With the help of lemma 2, it is now easy to prove

Lemma 3: The matrix-valued fields $\mathbf{P}_\pm$,

$$\mathbf{P}_+ := \begin{pmatrix} \mathbf{S} & 0 \\ 0 & 0 \end{pmatrix}, \quad \mathbf{P}_- := \begin{pmatrix} 0 & \mathbf{\Gamma} \\ \mathbf{E} & i\mathbf{A} \end{pmatrix}, \tag{54}$$

are Hermitian, respectively, anti-Hermitian with respect to the inner product

$$\langle (\boldsymbol{\lambda}_1, \mathbf{C}_1), H_T(\boldsymbol{\lambda}_2, \mathbf{C}_2)\rangle := \langle \boldsymbol{\lambda}_1, H_\lambda \boldsymbol{\lambda}_2\rangle + \langle \mathbf{C}_1, H_c \mathbf{C}_2\rangle. \tag{55}$$

Proof: Since $\mathbf{S} = \beta \mathbf{I}$, the statement for $\mathbf{P}_+$ is trivially true. The antisymmetry of $\mathbf{P}$ follows directly from lemma 2, and the symmetry of $\mathbf{A}$ with respect to H_c.

Taking advantage of lemma 3, we now obtain the following important estimate for the operator $\mathbf{P} = \mathbf{P}_+ + \mathbf{P}_-$:

$$H_T \mathbf{P} + \mathbf{P}^\dagger H_T = H_\lambda \mathbf{S} + \mathbf{S} H_\lambda = -2\beta H_\lambda \leqslant -2\beta \tfrac{1}{4} k_n k^n \leqslant 0, \tag{56}$$

where, for any Hermitian matrix $\mathbf{M}$, the inequality $\mathbf{M} \leqslant 0$ means $\langle \mathbf{v}, \mathbf{M}\mathbf{v}\rangle \leqslant 0$ for all $\mathbf{v}$. (Clearly, there are other possible choices of the operators $\mathbf{S}$ which lead to the same inequality. Here we have restricted ourselves to the simplest possibility, but for practical applications, alternative choices might be better suited.)

The symmetry and coercivity of the operator H_λ imply that H_λ can be used to define a scalar product on a (dense) subspace $\mathcal{D}(CF)$ of the Hilbert space CF,[7] which, in turn, shows that the operator $H_T = H_c + H_\lambda$ gives rises to a scalar product on $CF \oplus \mathcal{D}(CF)$. (In physical space, the relevant function space equipped with the norm corresponding to the above scalar product is very similar to the Sobolev space H_0^1.)

As is well known (see, for instance, Ref. 7), the estimate (56) implies that for all $t > 0$, the operator $e^{\mathbf{P}t}$ is bounded with respect to the norm defined by H_T. Hence, the initial value problem for the system considered is well posed. Moreover, all solutions with initial data which are bounded with respect to this norm remain bounded for all positive times. Thus Laplace transformation techniques can be applied,[7] and the relevant questions are the *sign* of the real part of the eigenvalues of $\mathbf{P}$, and how fast they approach zero as the wave number $k = \sqrt{k^i k_i}$ goes to zero. Hence, the proof is reduced to the eigenvalue problem for the operator $\mathbf{P}$,

$$\mathbf{P}\begin{pmatrix} \boldsymbol{\lambda}_s \\ \mathbf{C}_s \end{pmatrix} = s \begin{pmatrix} \boldsymbol{\lambda}_s \\ \mathbf{C}_s \end{pmatrix}. \tag{57}$$

Then we have the following:

Lemma 4: The eigenvalues of the above system have a nonpositive real part and furthermore there exist positive constants c_1 *and* w_1 *such that*

$$\Re(s) \leqslant -c_1 \frac{k^2}{w_1 + k^2} \tag{58}$$

for all wave vectors k_i.

Proof: From the $\boldsymbol{\lambda}$-rows of the eigenvalue equation, we get

$$\mathbf{C}_s = (s + \beta)\mathbf{\Gamma}^{-1} \boldsymbol{\lambda}_s. \tag{59}$$

Using this in the **C**-rows, we next obtain

$$(\mathbf{E}+(s+\beta)(-s\mathbf{I}+i\mathbf{A})\mathbf{\Gamma}^{-1})\boldsymbol{\lambda}_s=0. \tag{60}$$

Multiplying Eq. (60) by $-(\mathbf{\Gamma}^{-1})^\dagger\mathbf{H}_c$ from the left and subsequently contracting with $\boldsymbol{\lambda}_s$, we find the following second-order equation for the eigenvalue s:

$$\langle\boldsymbol{\lambda}_s,H_\lambda\boldsymbol{\lambda}_s\rangle+(s+\beta)(s\langle\boldsymbol{\lambda}_s,(\mathbf{\Gamma}^{-1})^\dagger H_c\mathbf{\Gamma}^{-1}\boldsymbol{\lambda}_s\rangle-i\langle\boldsymbol{\lambda}_s,(\mathbf{\Gamma}^{-1})^\dagger H_c\mathbf{A}\mathbf{\Gamma}^{-1}\boldsymbol{\lambda}_s\rangle)=0. \tag{61}$$

The established properties of the involved operators imply that

$$c(k_i^0)k^2:=\frac{\langle\boldsymbol{\lambda}_s,H_\lambda\boldsymbol{\lambda}_s\rangle}{\langle\boldsymbol{\lambda}_s,(\mathbf{\Gamma}^{-1})^\dagger H_c\mathbf{\Gamma}^{-1}\boldsymbol{\lambda}_s\rangle} \tag{62}$$

is positive for $k_i\neq 0$, and that

$$b(k_i^0)k:=\frac{\langle\boldsymbol{\lambda}_s,(\mathbf{\Gamma}^{-1})^\dagger H_c\mathbf{A}\mathbf{\Gamma}^{-1}\boldsymbol{\lambda}_s\rangle}{\langle\boldsymbol{\lambda}_s,(\mathbf{\Gamma}^{-1})^\dagger H_c\mathbf{\Gamma}^{-1}\boldsymbol{\lambda}_s\rangle} \tag{63}$$

is real, where k_i^0 denotes the unit vector in the direction of k_i, and k is the norm of k_i. Thus we have for each direction of k^i

$$(s+\beta)(s-ibk)+ck^2=0 \tag{64}$$

with β, b, c real and β, c positive. For this equation we prove in Appendix B that the real part of the roots satisfies the desired inequality, which establishes the result for each direction of the wave vector k_i. Using the maximal values of $-c_1k^2/(w_1+k^2)$ on the two-sphere of directions of k_i, we obtain the final inequality.

With this bound on the decay constants, it is now easy to prove asymptotic stability for the subsystem (38)–(43). Splitting the set of solutions into a part with frequencies with $k<1$, and another with $k\geqslant 1$, the above bound tells us that the solutions of the higher frequency part decay faster than $\exp(-c_1t/(w_1+1))$, while the decay of the solutions of the low frequency part can be estimated as in Ref. 6, lemma 1 and 2 of Sec. III].

We now turn our attention to the second set of equations, given by (44) and (45), and establish the following:

Lemma 5: Let $\mathcal{H}_3$ *be the space of the Fourier transformed* $(\hat{\lambda}^{ij}{}_k,\hat{C}^{ij}{}_k)\in L^2$. *Then* $\mathcal{H}_3$ *is invariant under time evolution, and the trivial solution* $(\hat{\lambda}^{ij}{}_k,\hat{C}^{ij}{}_k)=0$ *is asymptotically stable for the evolution restricted to* $\mathcal{H}_3$.

Proof: In a first step, we discuss the equation for the component of a solution in the subspace

$$\mathcal{D}_3:=\{(\hat{\lambda}^{ij}{}_k,\hat{C}^{ij}{}_k)\in L^2|\hat{\lambda}^{ij}{}_mk^m=\hat{C}^{ij}{}_mk^m=0\}. \tag{65}$$

Taking advantage of Eqs. (8), (12), and (44), we obtain

$$\dot{\hat{\lambda}}^{ij}{}_{[k}k_{l]}=-\beta\hat{\lambda}^{ij}{}_{[k}k_{l]}+\alpha_3\hat{C}^{ij}{}_{[k}k_{l]}, \tag{66}$$

$$i\hat{C}^{ij}{}_{[k}k_{l]}=\hat{C}^{ij}{}_{kl}-\tfrac{1}{2}\delta^{ij}\delta_{mn}\hat{C}^{mn}{}_{kl}, \tag{67}$$

which implies that the space $\mathcal{D}_3$ is invariant under time evolution. As already shown, the constraint variable $\hat{C}^{ij}{}_{kl}$ asymptotically decays to zero. The dynamics in $\mathcal{D}_3$ is, therefore, described by a system of ordinary differential equations of the form $\dot{u}=-u+f$, where f is a given source with $f\to 0$ as $t\to\infty$. Since any solution to this system satisfies $u\to 0$ as $t\to\infty$, it follows that solutions in $\mathcal{D}_3$ decay with time. [For a proof, choose T such that $f(t)<\epsilon/2$ for all $t>T$. Since the general solution to the above system is given by $u(t)=e^{-t}(u(0)+\int_0^t e^{\tilde{t}} f(\tilde{t})d\tilde{t})$, it follows that $u(t) \leq e^{-t}(u(0)+\int_0^T e^{\tilde{t}} f(\tilde{t})d\tilde{t}-\epsilon e^T/2)+\epsilon/2$. Hence, for a sufficiently large time $t_0>T$, the absolute value of the first term becomes smaller than $\epsilon/2$, which implies $|u(t)|<\epsilon$ for all $t>t_0$.]

It remains to discuss the complementary subspace $\mathcal{D}_3^\perp$,

$$\mathcal{D}_3^\perp=\{(\lambda^{ij}{}_k,\hat{C}^{ij}{}_k)\in L^2|\hat{\lambda}^{ij}{}_{[k}k_{l]}=\hat{C}^{ij}{}_{[k}k_{l]}=0\}. \tag{68}$$

For the component of a solution in this subspace, we find

$$\frac{d}{dt}\begin{pmatrix}\boldsymbol{\lambda}_3\\ \mathbf{C}_3\end{pmatrix}=\begin{pmatrix}-\beta & \alpha_3\\ -\alpha_3 k^2 & ik_m N^m\end{pmatrix}\begin{pmatrix}\boldsymbol{\lambda}_3\\ \mathbf{C}_3\end{pmatrix}-\begin{pmatrix}0\\ F^{ij}k_k\end{pmatrix}, \tag{69}$$

where $(\boldsymbol{\lambda}_3,\mathbf{C}_3):=(\hat{\lambda}^{ij}{}_k,\hat{C}^{ij}{}_k)^\perp\in\mathcal{D}_3^\perp$, and where $\hat{F}^{ij}k_k$ is a shorthand for the perpendicular component of the source term $\hat{S}^{ij}{}_k$, $\hat{F}^{ij}=\hat{S}^{ij}{}_m k^m/k^2$. Thus, as expected, the subspace $\mathcal{D}_3$ is invariant as well.

Since $\hat{P}^{ij}$ and consequently $\hat{C}^i/|k|=\hat{P}^{im}k_m/|k|$ are contained in L^2, Eq. (46) implies that the same is true for $\hat{F}^{ij}$, $\hat{F}^{ij}\in L^2$. Furthermore, the real part of the eigenvalues of the system (69) can, as in lemma 4, be estimated by the inequality (58), albeit for different constants. Adopting a similar reasoning as in the previous discussion, and applying lemmas 1 and 2 of Ref. 6 to this system, it follows that solutions in $\mathcal{D}_3^\perp$ also decay with time.

This completes the proof of lemma 5 and hence the proof of our main result.

IV. CONCLUSIONS

In the present paper we have shown that an arbitrary system of symmetric hyperbolic evolution equations with constraints admits extensions to symmetric hyperbolic systems which reproduce the original dynamics on the embedded constraint submanifold. We have given analytical evidence that the class of extensions proposed is sufficiently rich to contain systems for which the embedded constraint submanifold is an attractor of the time evolution. For the Einstein equations, we have constructed an extended evolution system for which, at least in the linearized case, this property is fulfilled.

It is natural to expect that, by making use of techniques developed in Ref. 6, the results proven for the linearized Einstein equations can be generalized to the regime of nonlinear general relativity describing space–times in the vicinity of Minkowski space. However, to establish similar results for more extended regions of the phase space of general relativity is well beyond the scope of present analytic techniques.

Numerical experiences with the Navier–Stokes equations for incompressible fluids show that asymptotic stability of the constraint submanifold is essential for accurate results.[8] For this system, techniques with a very similar effect have been used to include the incompressibility constraint into the evolution equations. On the basis of this observation, and the results established for linearized gravity, we suspect that the extensions of Einstein's equations constructed could be of interest when obtaining numerical solutions to general relativity. Numerical experiments testing aspects of this conjecture are in progress.

APPENDIX A: PROOF OF COERCIVITY

In this Appendix we show that

$$\langle \mathbf{u}, H_\lambda \mathbf{u} \rangle \geq \tfrac{1}{4} k_n k^n \tag{A1}$$

for unitary $\mathbf{u}$ satisfying $u^{ij}{}_{rs} = u^{(ij)}{}_{[rs]}$ and $u^{ij}{}_{[rs}k_{l]} = 0$, as needed for Lemma 2. We treat this as the problem of extremizing the quadratic function of $\mathbf{u}$ on the left-hand side of (A1) under the constraint condition $\langle \mathbf{u}, \mathbf{u} \rangle = 1$.

From (50)–(52), we obtain

$$\langle \mathbf{u}, H_\lambda \mathbf{u} \rangle + \tau k^n k_n (1 - \langle \mathbf{u}, \mathbf{u} \rangle) = \tfrac{2}{3} k^n k_n u \overline{u} + \tfrac{1}{2} k^n k_n u^i \overline{u_i} + \tfrac{1}{2} u^i k_i \overline{u_n} k^n + u^{ij}{}_{rs} k^s \overline{u_{ij}}{}^{rm} k_m - \frac{\sqrt{3}}{3} \overline{u} u^{ij}{}_{is} k^s k_j$$
$$- \frac{1}{\sqrt{3}} u \overline{u_{ij}}{}^{is} k_s k^j + \tau k^n k_n (1 - u\overline{u} - u^i \overline{u_i} - u^{ij}{}_{rs} \overline{u_{ij}}{}^{rs}), \tag{A2}$$

where τ is a Lagrange multiplier and where indices are raised and lowered with e_{ij}. To simplify the algebra, we choose a basis in which $k^n = (0,0,k)$. Then $u^{ij}{}_{rs} = 0$, except when $s = 3$. Hence,

$$F(\mathbf{u},\tau) \equiv \langle \mathbf{u}, H_\lambda \mathbf{u} \rangle + \tau k^n k_n (1 - \langle \mathbf{u}, \mathbf{u} \rangle)$$
$$= k^2 \left(\tfrac{2}{3} u \overline{u} + \tfrac{1}{2} u^i \overline{u_i} + \tfrac{1}{2} u^3 \overline{u_3} + u^{ij}{}_{r3} \overline{u_{ij}}{}^{r3} - \frac{1}{\sqrt{3}} \overline{u} u^{i3}{}_{i3} - \frac{1}{\sqrt{3}} u \overline{u_{i3}}{}^{i3} \right.$$
$$\left. + \tau (1 - u \overline{u} - u^i \overline{u_i} - u^{ij}{}_{rs} \overline{u_{ij}}{}^{rs}) \right). \tag{A3}$$

The function $F(\mathbf{u},\tau)$ is extremized at points $(\mathbf{u},\tau)$ where

$$\frac{\partial F}{\partial \mathbf{u}} + \frac{\partial F}{\partial \overline{\mathbf{u}}} = 0, \tag{A4}$$

$$\frac{\partial F}{\partial \mathbf{u}} - \frac{\partial F}{\partial \overline{\mathbf{u}}} = 0, \tag{A5}$$

$$\frac{\partial F}{\partial \tau} = 0. \tag{A6}$$

Equation (A6) is the requirement that $\mathbf{u}$ has unit length. Equations (A4) and (A5) constitute a homogeneous linear system of equations for the real and imaginary parts of $\mathbf{u}$. Since $\mathbf{u}$ cannot vanish, the determinant of the linear system has to vanish. Up to numerical factors, this is given by

$$(2\tau - 1)^{13} (\tau - 1)^2 (\tau - \tfrac{1}{6}). \tag{A7}$$

As easily verified, $\tau = 1$ yields the following minimal value of $F(\mathbf{u},\tau)$ [when evaluated at unit $\mathbf{u}$ such that (A4)–(A5) are satisfied]:

$$F(\mathbf{u}_{\min}, 1) = \tfrac{1}{4} k^2, \tag{A8}$$

from which (A1) follows. The other extreme values of $F(\mathbf{u},\tau)$ are $(5/3)k^2$ and $(1/2)k^2$ for $\tau = 1/6, 1/2$.

APPENDIX B: ON THE PROOF OF LEMMA 4

In this Appendix we prove that the roots $s_\pm$ of the polynomial

$$P(s)=s^2+s(\beta-ibk)+ck^2 \tag{B1}$$

are subject to the inequality

$$\Re(s_\pm)\leqslant -c_1\frac{k^2}{w_1+k^2}, \tag{B2}$$

where $c_1=\beta c/(b^2+4c)$ and $w_1=\beta^2/(b^2+4c)$. As in the body of the text, it is assumed that the parameters of P are real, and that β and c are strictly positive.

To begin with, let us rewrite the polynomial P, and the above estimate in terms of suitably rescaled parameter. Defining

$$\tilde{s}=s/\beta,\quad \tilde{k}=2k\sqrt{b^2+4c}/\beta,\quad \tilde{b}=b/\sqrt{b^2+4c}, \tag{B3}$$

and dropping tildes, we obtain for the polynomial

$$P/\beta^2=s^2+s(1-ibk)+(1-b^2)k^2/4. \tag{B4}$$

The estimate for the roots in terms of the scaled parameters assumes the form

$$\Re(s_\pm)\leqslant -\frac{\gamma^2}{4}\,\frac{k^2}{1+k^2}, \tag{B5}$$

where $\gamma^2:=1-b^2\in(0,1]$.

As easily verified, the roots of the scaled polynomial satisfy

$$\max\{\Re(2s_+),\Re(2s_-)\}=-1+|\Re\sqrt{1-k^2+2ibk}|. \tag{B6}$$

It is, therefore, sufficient to show that

$$|\Re\sqrt{1-k^2+2ibk}|\leqslant 1-\frac{\gamma^2}{2}\,\frac{k^2}{1+k^2}. \tag{B7}$$

To give a proof of this inequality, we first evaluate the identity

$$2|\Re\sqrt{z}|^2=|z|+\Re(z) \tag{B8}$$

for $z:=1-k^2+2ibk$,

$$2|\Re\sqrt{z}|^2=\sqrt{(1-k^2)^2+4b^2k^2}+(1-k^2)=\sqrt{(1+k^2)^2-4\gamma^2k^2}-(1+k^2)+2.$$

Hence,

$$|\Re\sqrt{z}|^2=1+(1+k^2)\{\sqrt{1-4\gamma^2k^2/(1+k^2)^2}-1\}/2\leqslant 1-\gamma^2\frac{k^2}{1+k^2}, \tag{B9}$$

where we have used the estimate $\sqrt{1-x}\leqslant 1-x/2$, which holds for $x\leqslant 1$. Taking advantage of the latter estimate once again, it follows that

$$|\Re\sqrt{z}|\leqslant 1-\frac{\gamma^2}{2}\,\frac{k^2}{1+k^2}, \tag{B10}$$

which completes the proof of our claim.

Gravitating brane systems: Some general theorems

K. A. Bronnikov[a)]
Centre for Gravitation and Fundamental Metrology,
VNIIMS, 3-1 M. Ulyanovoy St., Moscow 117313, Russia

(Received 4 August 1998; accepted for publication 9 September 1998)

Multidimensional gravity interacting with intersecting electric and magnetic *p*-branes is considered for fields depending on a single variable. Some general features of the system behavior are revealed without solving the field equations. Thus, essential asymptotic properties of isotropic cosmologies are indicated for different signs of spatial curvature; a no-hair-type theorem and a single-time theorem for black holes are proved (the latter makes sense in models with multiple time coordinates). The validity of the general observations is verified for a class of exact solutions known for the cases when certain vectors, built from the input parameters of the model, are either orthogonal in minisuperspace, or form mutually orthogonal subsystems. From the nonexistence of Lorentzian wormholes, a universal restriction is obtained, applicable to orthogonal or block-orthogonal subsystems of any *p*-brane system. © *1999 American Institute of Physics.* [S0022-2488(99)01402-4]

I. INTRODUCTION

In the weak field limits of the bosonic sectors of supergravities,[1] superstring and M-theory, their generalizations and modifications,[2–6] there naturally appear multiple self-gravitating scalar dilatonic fields and antisymmetric forms, associated with *p*-branes.

This paper continues the studies of such models on the basis of a general action, see (1), without fixing the total space-time dimension D or other input parameters,[7–16] thus to a large extent abstracting from the details of specific underlying models, but with a hope to predict some features of new models, unformulated by now. We will here deal with the one-variable sector of the model, where all fields depend on a single coordinate: time in cosmological models, a radial coordinate in spherically symmetric models, etc. In this case the model reduces to a Toda-type dynamical system in minisuperspace, see (15), (16).

Much work has been devoted to searches for exact solutions and their subsequent analysis. Thus, in Ref. 15 the most general one-variable solution was presented for the case when certain vectors Y_s in the target space, built from the input parameters of the model, form an orthogonal system (OS). This solution describes a set of intersecting electrically and magnetically charged *p*-branes and generalized many previously found ones, beginning with Schwarzschild and Reissner-Nordström and ending with dilatonic and some more special *p*-brane solutions (see Refs, 4, 16–19, and references therein). The OS solution was further generalized[20] to models where Y_s forms a block-orthogonal system (BOS). The OS solution is recovered when each block consists of a single vector. Other families of exact solutions have been found for cases when Y_s forms the bases of integrable Toda models, see Refs. 14, 19, 21, and references therein. Many solutions are known beyond the one-variable sector (see Ref. 22, and references therein).

The exact solutions have disclosed many features of interest of physically relevant configurations, such as cosmological models and black holes. The generality of these features remains, however, questionable, since the equations of motion can be solved exactly only for special (though numerous) choices of the input parameters. To have an idea of what can and what cannot be expected from yet unknown solutions, it makes sense to try to extract some information directly from the equations. Such an attempt is undertaken here.

a)Electronic mail: kb@rgs.mccme.ru

It appears possible to reveal some important properties of p-brane cosmologies, namely, the nature of asymptotics for different signs of spatial curvature. For spherically symmetric configurations, among other results, two theorems about black holes (BHs) are proved: a ''no-hair theorem,'' that a BH is incompatible with the so-called quasiscalar F-forms (see (5)), and a ''single-time theorem,'' that even in spaces with multiple times a black hole may only exist with its unique, one-dimensional (physical) time.

One more general observation is[20] the absence of spherically symmetric Lorentzian wormholes under the requirement that all the fields bear positive energy, just as in conventional general relativity. On the other hand, for the known families [OS and BOS (Ref. 20)] of exact solutions one can deduce necessary and sufficient conditions under which a specific solution describes a wormhole, no matter, Lorentzian or Euclidean. Combined, these results lead to a universal restriction upon the input parameters of the model, valid for any brane system which has an OS or BOS subsystem (Theorems 4 and 4a, already announced[20] in a slightly different form). Having been obtained on the basis of specific exact solutions, this restriction still applies to systems for which solutions are yet to be found.

The paper is organized as follows. The introductory Sec. II describes the model and a convenient Toda-type representation of its one-variable sector, in line with our previous papers. Section III is devoted to general properties of cosmological and spherically symmetric p-brane configurations. Section IV gives a brief description of the OS and BOS solutions, necessary for obtaining the above-mentioned universal restriction. The latter is formulated in Sec. V. Section VI contains some concluding remarks, in particular, on the use of different conformal frames.

II. THE MODEL: MINISUPERSPACE REPRESENTATION

The starting point is, as in Refs. 10–15, the model action for D-dimensional gravity with several scalar dilatonic fields φ^a and antisymmetric n_s-forms F_s:

$$S=\frac{1}{2\kappa^2}\int_{\mathcal{M}} d^D z\sqrt{|g|}\left\{R[g]-\delta_{ab}g^{MN}\partial_M\varphi^a\partial_N\varphi^b-\sum_{s\in\mathcal{S}}\frac{\eta_s}{n_s!}e^{2\lambda_{sa}\varphi^a}F_s^2\right\}, \tag{1}$$

in a (pseudo-)Riemannian manifold $\mathcal{M}=\mathbb{R}_u\times\mathcal{M}_0\times\cdots\times\mathcal{M}_n$ with the metric

$$ds^2=g_{MN}dz^M dz^N=we^{2\alpha(u)}du^2+\sum_{i=0}^{n} e^{2\beta^i(u)}ds_i^2, \quad w=\pm 1, \tag{2}$$

where u is a selected coordinate ranging in $\mathbb{R}_u\subseteq\mathbb{R}$; $g^i=ds_i^2$ are metrics on d_i-dimensional factor spaces $\mathcal{M}_i$ of arbitrary signatures $\varepsilon_i=\text{sign } g^i$; $|g|=|\det g_{MN}|$ and similarly for subspaces; $F_s^2 =F_{s,M_1\ldots M_{n_s}}F_s^{M_1\ldots M_{n_s}}$; λ_{sa} are coupling constants; $\eta_s=\pm 1$ (to be specified later); $s\in\mathcal{S}$, $a\in\mathcal{A}$, where $\mathcal{S}$ and $\mathcal{A}$ are some finite sets. All $\mathcal{M}_i, i>0$ are assumed to be Ricci-flat, while $\mathcal{M}_0$ is allowed to be a space of constant curvature $K_0=0, \pm 1$.

In the one-variable sector, $\varphi^a=\varphi^a(u)$. The set of indices $\mathcal{S}=\{s\}$ in (1) will be used to jointly describe essentially u-dependent electric (F_{eI}) and magnetic (F_{mI}) F-forms, to be associated with different subsets $I=\{i_1,\cdots,i_k\}$ $(i_1<\ldots<i_k)$ of the set of numbers labelling the factor spaces: $\{i\}=I_0=\{0,\ldots,n\}$. Thus one can write

$$\mathcal{S}=\{s\}=\{eI_s\}\cup\{mI_s\}. \tag{3}$$

A given F-form may have several essentially (nonpermutatively) different components, both electric and magnetic; such a situation is sometimes called ''composite p-branes.''[18,23]

For convenience, we will nevertheless treat essentially different components of the same F-form as individual (''elementary'') F-forms. A subsequent reformulation to the composite ansatz is straightforward.

So, by construction, nonzero components of F_{eI} carry coordinate indices of u and the subspaces $\mathcal{M}_i, i\in I$, those of F_{mI} — the indices of $\mathcal{M}_i, i\in \overline{I} \stackrel{\rm def}{=} I_0\backslash I$ since a magnetic form is built as a form dual to a possible electric one. Therefore

$$n_{eI}=\text{rank}F_{eI}=d(I)+1, \quad n_{mI}=\text{rank}F_{mI}=D-\text{rank}F_{eI}=d(\overline{I}), \tag{4}$$

where $d(I)=\Sigma_{i\in I}d_i$ are the dimensions of the subspaces $\mathcal{M}_I=\mathcal{M}_{i_1}\times\cdots\times\mathcal{M}_{i_k}$.

Several electric and/or magnetic forms (with maybe different coupling constants λ_{sa}) can be associated with the same I and are then labeled by different values of s. (The index s by I is, however, sometimes omitted when this cannot cause confusion.)

This problem setting covers various classes of models: isotropic and anisotropic cosmologies where u is a timelike coordinate and $w=-1$; static models with various spatial symmetries (spherical, planar, pseudospherical, cylindrical, toroidal), where u is a spatial coordinate, $w=+1$, and time is selected among $\mathcal{M}_i$; and Euclidean models with similar symmetries or models with a Euclidean ''external'' space-time, where also $w=+1$.

A simple analysis shows that a positive energy density $-T^t_t$ of the fields F_s is achieved in all Lorentzian models with the signature $(-++\cdots+)$ if one chooses in (1), as usual, $\eta_s=1$ for all s. In more general models, with arbitrary ε_i, the requirement $-T^t_t>0$ is fulfilled if

$$\eta_{eI}=-\varepsilon(I)\varepsilon_t(I), \quad \eta_{mI}=-\varepsilon(\overline{I})\varepsilon_t(\overline{I}) \tag{5}$$

$$\varepsilon(I)\stackrel{\rm def}{=}\prod_{i\in I}\varepsilon_i, \quad \varepsilon_t(I)=\begin{cases}1, & \mathbb{R}_t\subset\mathcal{M}_I,\\ -1 & \text{otherwise},\end{cases} \tag{6}$$

where $\mathbb{R}_t$ is the time axis. If $\varepsilon_t(I)=1$, we are dealing with a genuine electric or magnetic field, while otherwise the F-form behaves as an effective scalar or pseudoscalar in the physical subspace. The latter happens, in particular, in isotropic cosmologies and their Euclidean counterparts where the time coordinate is u and $\mathbb{R}_t=\mathbb{R}_u$, unrelated to any subset I. F-forms with $\varepsilon_t(I)=-1$ will be called *quasiscalar.*

Example: Consider a spherically symmetric configuration, with $D=6$, $\mathcal{M}=\mathbb{R}_0\times\mathbb{R}_1\times S^2\times\mathbb{R}_4\times\mathbb{R}_5$, where the coordinate indices 0, 1, 4, 5, refer to time, radius and two extra dimensions, 2 and 3 to the spherical angles, respectively; thus $\mathbb{R}_0=\mathbb{R}_t$ and $\mathbb{R}_1=\mathbb{R}_u$. Then, for rank $F=3$, the component F_{015} is electric, $I\mapsto(0,5)$; F_{234} is magnetic, $I\mapsto(0,5)$; F_{145} is electric quasiscalar, $I\mapsto(4,5)$; F_{023} is magnetic quasiscalar, $I\mapsto(4,5)$, where the figures in parentheses are coordinate indices of the respective subspaces $\mathcal{M}_I$.

Let us now, as in Ref. 24 and many later papers, choose the harmonic u coordinate $(\nabla^M\nabla_M u=0)$, such that

$$\alpha(u)=\sum_{i=0}^{n} d_i\beta^i\equiv d_0\beta^0+\sigma_1(u), \quad \sigma_1(u)\stackrel{\rm def}{=}\sum_{i=1}^{n} d_i\beta^i. \tag{7}$$

The Maxwell-type equations due to (1) for the F-forms are easily integrated, giving

$$F_{eI}^{uM_1\ldots M_{d(I)}}=Q_{eI}e^{-2\alpha-2\overline{\lambda}_{eI}\overline{\varphi}}\varepsilon^{M_1\ldots M_{d(I)}}/\sqrt{|g_I|}, \quad Q_{eI}=\text{const}, \tag{8}$$

$$F_{mI,M_1\ldots M_{d(\overline{I})}}=Q_{mI}\varepsilon_{M_1\ldots M_{d(\overline{I})}}\sqrt{|g_{\overline{I}}|}, \quad Q_{mI}=\text{const}, \tag{9}$$

where $|g_I|=\Pi_{i\in I}|g^i|$, Q_s are charges and overbars replace summing in a. In what follows we will restrict the set $\mathcal{S}=\{s\}$ to such s that the charges $Q_s\neq 0$.

Consequently, at the r.h.s. of the Einstein equations due to (1), $R^N_M-\frac{1}{2}\delta^N_M R=T^N_M$, the energy-momentum tensor (EMT) T^N_M takes the form

$$e^{2\alpha}T_M^N=-\frac{w}{2}\sum_s \epsilon_s Q_s^2 e^{2\sigma(I)-2\chi_s\overline{\lambda}_s\overline{\varphi}}\mathrm{diag}(+1,[1]_I,[-1]_{\overline{I}})+\frac{w}{2}(\dot{\varphi}^a)^2\mathrm{diag}(+1,[-1]_{I_0}), \quad (10)$$

where the first place on the diagonal belongs to u and the symbol $[f]_J$ means that the quantity f is repeated along the diagonal for all indices referring to $\mathcal{M}_j, j\in J$; $\sigma(I)\overset{\mathrm{def}}{=}\Sigma_{i\in I}d_i\beta^i$; the sign factors ϵ_s and χ_s are

$$\epsilon_{eI}=-\eta_{eI}\varepsilon(I), \quad \epsilon_{mI}=w\,\eta_{mI}\varepsilon(\overline{I}); \quad \chi_{eI}=+1, \quad \chi_{mI}=-1, \tag{11}$$

so that χ_s distinguishes electric and magnetic forms.

Let us suppose, as is usually (and reasonably) done in p-brane studies, that *neither of I_s such that $Q_s\neq 0$ contains the index 0*, that is, neither of the branes ''lives'' in the subspace $\mathcal{M}_0$, interpreted as the external space or its subspace. (This means that, e.g., in the spherically symmetric case there is no electric or magnetic field along a coordinate sphere $\mathcal{M}_0=S^{d_0}$.) Then each constituent EMT and hence the total EMT possess the property $T_u^u+T_z^z=0$ if z belongs to M_0. As a result, the corresponding combination of the Einstein equations has a Liouville form and is integrated:

$$\begin{gathered}\ddot{\alpha}-\ddot{\beta}^0=wK_0(d_0-1)^2e^{2\alpha-2\beta^0}=0,\\ e^{\beta^0-\alpha}=(d_0-1)S(wK_0,k,u),\end{gathered}\tag{12}$$

where k is an integration constant (IC) and we have introduced the notation

$$\begin{gathered}S(1,h,t)=\begin{cases}h^{-1}\sinh ht, & h>0,\\ t, & h=0,\\ h^{-1}\sin ht, & h<0;\end{cases}\\ S(-1,h,t)=h^{-1}\cosh ht, \quad h>0;\\ S(0,h,t)=e^{ht}, \quad h\in\mathbb{R}.\end{gathered}\tag{13}$$

Another IC is suppressed by properly choosing the origin of the u coordinate.

With (12) the D-dimensional line element may be written in the form ($\overline{d}\overset{\mathrm{def}}{=}d_0-1$)

$$ds^2=\frac{e^{-2\sigma_1/\overline{d}}}{[\overline{d}S(wK_0,k,u)]^{2/d}}\left[\frac{w\,du^2}{[\overline{d}S(wK_0,k,u)]^2}+ds_0^2\right]+\sum_{i=1}^n e^{2\beta^i}ds_i^2. \tag{14}$$

Let us treat the remaining set of unknowns $\beta^i(u),\varphi^a(u)$ as a real-valued vector function $x^A(u)$ (so that $\{A\}=\{1,\ldots,n\}\cup\mathcal{A}$) in an $(n+|\mathcal{A}|)$-dimensional vector space $\mathcal{V}$ (target space). The field equations for β^i and φ^a can be derived from the Toda-type Lagrangian

$$\begin{gathered}L=G_{AB}\dot{x}^A\dot{x}^B-V_Q(y)\equiv\sum_{i=1}^n(\dot{\beta}^i)^2+\frac{\dot{\sigma}_1^2}{d_0-1}+\delta_{ab}\dot{\varphi}^a\dot{\varphi}^b-V_Q(y),\\ V_Q(y)=-\sum_s \epsilon_s Q_s^2 e^{2y_s},\end{gathered}\tag{15}$$

with the ''energy'' constraint

TABLE I. Sign factors wK_0 and ϵ_s for different kinds of models.

		Cosmology $w=-1$	Static spaces $w=+1$	Euclidean $w=+1$
	wK_0	$-K_0$	K_0	K_0
	Electric	none	$+1$	none
ϵ_s	Magnetic	none	$+1$	none
	Electric quasiscalar	-1	-1	-1
	Magnetic quasiscalar	-1	-1	$+1$

$$E=G_{AB}\dot{x}^A\dot{x}^B+V_Q(y)=\frac{d_0}{d_0-1}K, \quad K=\begin{cases} k^2\text{sign } k, & wK_0=1; \\ k^2, & wK_0=0,-1, \end{cases} \tag{16}$$

where the IC k has appeared in (12). The nondegenerate symmetric matrix

$$(G_{AB})=\begin{pmatrix} d_i d_j/\bar{d}+d_i\delta_{ij} & 0 \\ 0 & \delta_{ab} \end{pmatrix} \tag{17}$$

defines a positive-definite metric in $\mathcal{V}$; the functions $y_s(u)$ are defined as scalar products:

$$y_s=\sigma(I_s)-\chi_s\overline{\lambda_s}\overline{\varphi}\equiv Y_{s,A}x^A, \quad (Y_{s,A})=(d_i\delta_{iI_s}, \quad -\chi_s\lambda_{sa}), \tag{18}$$

where $\delta_{iI}=1$ if $i\in I$ and $\delta_{iI}=0$ otherwise. The contravariant components and scalar products of the vectors $\mathbf{Y}_s$ are found using the matrix G^{AB} inverse to G_{AB}:

$$(G^{AB})=\begin{pmatrix} \delta^{ij}/d_i-1/\bar{D} & 0 \\ 0 & \delta^{ab} \end{pmatrix}, \quad (Y_s{}^A)=\left(\delta_{iI}-\frac{d(I)}{\bar{D}}, \quad -\chi_s\lambda_{sa}\right); \tag{19}$$

$$Y_{s,A}Y_{s'}{}^A\equiv\mathbf{Y}_s\mathbf{Y}_{s'}=d(I_s\cap I_{s'})-\frac{d(I_s)d(I_{s'})}{\bar{D}}+\chi_s\chi_{s'}\overline{\lambda_s}\overline{\lambda_{s'}}, \quad \bar{D}=D-2. \tag{20}$$

The equations of motion in terms of $\mathbf{Y}_s$ read

$$\ddot{x}^A=\sum_s q_s Y_s{}^A e^{2y_s}, \quad q_s\overset{\text{def}}{=}\epsilon_s Q_s^2. \tag{21}$$

III. GENERAL PROPERTIES OF THE BRANE SYSTEMS

The positive energy requirement (5) that fixes the input signs η_s, can be written as follows for Lorentzian models using the notations (11):

$$\epsilon_s=\varepsilon_t(I_s). \tag{22}$$

The corresponding requirement for Euclidean models is obtained by applying the conventional Wick rotation to Lorentzian cosmologies. This rotation of the time t changes w but preserves all η_s as well as $\varepsilon(I)$ since $\mathbb{R}_t\not\subset\mathcal{M}_I$, $\forall I$. Then by (11), ϵ_{eI} remain invariable while ϵ_{mI} change. This distinction between electric and magnetic forms is also connected with the property of the duality transformation to change the sign of the EMT in Euclidean models.[25,26]

Table I shows the sign factors wK_0 and $\epsilon_s=\text{sign } q_s$ for F-forms in different classes of models under the above positive energy requirement.

In what follows, we restrict ourselves to the model described in Sec. II with the sign factors specified in Table I, unless specially indicated.

One general statement, to be taken into account in the subsequent proofs, can be formulated as a lemma:

Lemma 1: At any regular point of the space-time, for all $a \in \mathcal{A}$ *and* $s \in \mathcal{S}$,

$$e^{-2\alpha}(\dot{\varphi}^a)^2 < \infty, \quad e^{-2\alpha + 2y_s} < \infty. \tag{23}$$

Indeed, regularity implies finite values of all curvature invariants, including R and $R_M^N R_N^M$; by virtue of the Einstein equations, one must have $T_M^N T_N^M < \infty$. Since T_M^N has a block-diagonal structure, the latter invariant can be written as a sum of squares, where each summand must thus be finite, including $(T_t^t)^2$. The component T_t^t is in turn, due to (22), a sum of negative-definite terms, corresponding to scalar fields φ^a and F-forms F_s. Therefore every such term must be finite, leading to (23).

A. Isotropic cosmology

Table I shows that in isotropic cosmologies, when u is a time coordinate and $\mathcal{M}_0$ is identified with the physical space (conventionally $d_0 = 3$), $\epsilon_s = -1$: there are only quasiscalar forms since a true electric or magnetic field would violate the spatial isotropy.

The logarithm of the extra-dimension volume factor, σ_1, by virtue of (21) obeys the equation

$$\ddot{\sigma}_1 = -\frac{d_0 - 1}{D-2} \sum_s d(I_s) Q_s^2 e^{2y_s}, \tag{24}$$

whence $\ddot{\sigma}_1 < 0$. So this volume factor cannot have a minimum and, moreover, if it tends to a finite value $e^{\sigma_{10}}$ as $u \to \pm\infty$, at other values of u it is smaller than $e^{\sigma_{10}}$. This feature is unfavorable for obtaining models with the so-called dynamical compactification, where the size of extra dimensions decreases to microscopic scales in the course of the evolution.

Next, due to $\epsilon_s = -1$, both terms in the expression (16) for E are positive-definite, so that nontrivial solutions correspond to $k > 0$. The range of u is $\mathbb{R}$ for $K_0 = 0, +1$ and (without loss of generality) $u > 0$ for $K_0 = -1$. By (13) and (14), the model asymptotics are characterized as follows.

For any K_0, at the asymptotic $u \to +\infty$ the total volume factor $e^{d_0\beta^0 + \sigma_1}$ (which, by (7), coincides with e^{α}) tends to zero. Although separately the physical scale factor $a(u) = e^{\beta_0}$ and the ''internal'' one, e^{σ_1}, may have various limits, the behavior of e^{α} indicates that this asymptotic is singular. Moreover, since asymptotically $\alpha \sim cu$, $c = \text{const} < 0$, the proper time $t = \int e^{\alpha} du < \infty$: the singularity occurs at a finite proper time.

For $K_0 = +1$ the other asymptotic $u \to -\infty$ is like the one just described, due to the symmetry of the function cosh ku in (13). Thus closed models evolve in a finite proper time interval between two singularities where the total volume of the Universe tends to zero.

For $K_0 = 0$, the asymptotic $u \to -\infty$ corresponds to an infinitely growing total volume factor e^{α} while the proper time t is also infinite. In the special case when $\sigma_1 \to \sigma_{10} = \text{const}$, the physical scale factor a obeys the law $a \sim |t|^{1/d_0}$.

For $K_0 = -1$ the second asymptotic is $u \to 0$, and this is a regular point of the equations of motion (21) determining x^A. So the metric behavior is (now in the general case) governed by the function $S(1,k,u) \approx u$ in (14), while all e^{β^i}, $i > 0$ and consequently σ_1 tend to finite limits. As $u \to 0$,

$$e^{\alpha} \sim u^{-1-1/\bar{d}}, \quad |t| \sim u^{-1/\bar{d}} \to \infty, \quad a(t) = e^{\beta^0} \sim |t|, \tag{25}$$

corresponding to linear expansion or contraction of the physical space.

Finally, Eq. (16) with $V_Q > 0$ implies that all $\dot{x}^A$ are bounded above, hence $x^A(u)$ are finite for all finite u and cannot create a singularity. Therefore the above description of the asymptotics is quite general and applies to all isotropic cosmologies in the field model under consideration.

It should be noted, however, that this discussion concerns the model behavior in the D-dimensional Einstein conformal frame, in which the action (1) was postulated. See further comments in Sec. VI. One can add that after reduction to $1+d_0$ physical dimensions, one obtains cosmology with a set of interacting massless scalar fields, so that the $(1+d_0)$-metric can be written explicitly: in the $(1+d_0)$-dimensional Einstein frame it corresponds to the well-known solutions with ultrastiff matter.

B. Static spherical symmetry: General observations

In static, spherically symmetric models, where u is a radial coordinate, $w=+1$, $\mathcal{M}_0=S^{d_0}$, $K_0=+1$, among other $\mathcal{M}_i$ there should be a one-dimensional subspace, say, $\mathcal{M}_1$, which may be identified with time: $\varepsilon_1=-1$. The sign factor wK_0 in (12) is $+1$, while ϵ_s is, due to (22), $+1$ for normal electric and magnetic forms F_I and -1 for quasiscalar ones.

By construction, see Eqs. (13), (14), spatial infinity corresponds to $u=0$ (where the usual ''area function'' $e^{\beta^0}\sim u^{1/\bar{d}}$) and, without loss of generality, the range of u is

$$0<u<u_{\max}, \tag{26}$$

where $u_{\max}$ is either $+\infty$, or the smallest value of u where the fields lose regularity.

The experience of dealing with particular models belonging to the class (1) indicates that a generic spherically symmetric solution exhibits a naked singularity. Possible exceptions can be (i) black holes (BHs), (ii) wormholes (WHs) or wormhole-like objects with a neck and a second nonsingular asymptotic, (iii) configurations with a regular center (a soliton-like object, which might be expected for an interacting field system) and, finally, (iv) a situation where the coordinate patch we use is incomplete, terminates at a regular sphere $u=u_{\max}$ (which may be even infinitely remote in our static frame of reference), and a possible continuation may reveal either a singularity, or one of the opportunities (i)–(iii).

One can show, however, that for our model only the BH opportunity is viable. Lorentzian WHs do not exist according to Ref. 20 (see also Sec. V), while variants (iii) and (iv) are ruled out by the following theorem:

Theorem 1: *The model specified in Sec. II does not admit solutions describing a static, spherically symmetric configuration (a) with a regular center or (b) where $u=u_{\max}$ corresponds to a regular surface such that $\mathcal{M}_0$ is a sphere of finite radius.*

Proof: (a) A regular center implies local flatness of the metric at some $u=u^*$, where $e^{\beta^0}=0$, while other β^i remain finite. One easily shows that with Ref. 14 it may happen only when $k=0$, $u^*=u_{\max}=\infty$ (otherwise the correct radius-to-circumference ratio for small circles around the center cannot be achieved).Then due to (7), since $|\sigma_1|<\infty$,

$$e^{\beta^0}\sim u^{1/(d_0-1)}, \quad e^{\alpha}\sim u^{-d_0/(d_0-1)} \quad \text{as} \quad u\to\infty. \tag{27}$$

On the other hand, the EMT regularity requirement[27] (see Lemma 1) leads to $|\varphi|<\infty$ as $u\to\infty$. Therefore at such a center the F-forms behave like free fields exhibiting (see (8)–(10)) a singularity, with infinite values of the EMT invariants. Item (a) is proved.

The assumption **(b)** means that both β_0 and σ_1 are finite at $u=u_{\max}$. This cannot happen at $u_{\max}<\infty$ since there would be no reason to stop at this value of u; and at $u_{\max}=\infty$ this means that $S(1,k,\infty)<\infty$, contrary to the definition (13).

C. Black holes: No-hair and single-time theorems

We see that the only positive-energy Lorentzian spherically symmetric configurations without naked singularities are BHs. BH solutions of various models belonging to the class (1) have been studied in numerous recent papers (see Refs. 3, 15, and 18, and references therein). However, exact solutions have been (and probably can be) only obtained for a small subset of the whole set of models (1), whereas some general properties of BH solutions may be discovered without solving the equations. Two such properties, having the form of restrictions generalizing the previously observed properties of specific solutions,[15,20] are proved here.

In what follows, we will call a *horizon* a nonsingular surface $u=u_*$ in $\mathcal{M}$ where some scale factors $e^{\beta^i}=0$ (corresponding to possibly multiple time coordinates), while other β^i remain finite. A *BH solution* is a static, spherically symmetric solution containing a horizon. These working definitions, though incomplete, are sufficient for our purposes.

An immediate observation is

Lemma 2: BH solutions can only exist for $k\geqslant 0$ *and the horizon is then at* $u=\infty$.

Indeed, at a horizon, the function σ_1 defined in (7) tends to $-\infty$ along with a part of its constituents, another part remaining finite. According to (14), to obtain a finite value of β^0, one has then to require that $S(1,k,u_*)=+\infty$, which by (13) is only possible when $k\geqslant 0$ and $u_*=\infty$.

Another result applies to BHs in manifolds $\mathcal{M}$ with several time coordinates, as suggested in some recent unification models (see Refs. 5, 28, and references therein). If there is another time coordinate, some branes can evolve with it. The following theorem shows, however, that in our framework, even in a space-time with multiple times, a BH can only exist with its unique preferred, physical time, while other times are not distinguished by the metric behavior from extra spatial coordinates.

Theorem 2 (Single-Time Theorem): *Any* BH *solution with* $k>0$ *contains precisely one coordinate* t *such that* $g_{tt}=0$ *at the horizon.*

Proof: Suppose that $u=\infty$ is a horizon where some $e^{\beta^i}\to 0$, $i\in I_t\subseteq(I_0\backslash 0)$. As follows from (7), at the asymptotic $u\to\infty$ one has $\alpha\to-\infty$ and, moreover, the finiteness of β^0 means (see (14)) that $\alpha\sim -ku$. On the other hand, the condition (24) holds only if for all F-forms, at most,

$$e^{2y_s}=O(e^{-2ku}). \tag{28}$$

The equations of motion (21) then show that, as $u\to\infty$,

$$\dot{x}^A=-c^A+o(1), \quad c^A=\text{const}, \tag{29}$$

where $c^i>0$ for $i\in I_t$ and $c^i=0$ for other A.

In the constraint (16), the potential $V_Q(u)\underset{u\to\infty}{\longrightarrow}0$ due to (29), therefore

$$G_{AB}c^Ac^B=\frac{d_0}{d_0-1}. \tag{30}$$

The asymptotic of α and the condition (7) show that, simultaneously,

$$\sum_{i\in I_t} d_ic^i=k, \tag{31}$$

so that $c_i\leqslant k$. From (30) with (31) and (17) it follows

$$\sum_{i\in I_t} d_ic^{i2}=k^2. \tag{32}$$

Combined, Eqs. (31) and (32) lead to

$$\sum_{i\in I_t} d_ic^i(k-c^i)=0, \tag{33}$$

which is compatible with (32) for $0\leqslant c^i\leqslant k$ only when the sum consists of one term, to be labeled $i=1$, such that $d_1=1$ and $c^1=k$. This proves the theorem.

One more theorem shows that BH solutions can contain only true electromagnetic F-forms rather than quasiscalar ones.

Theorem 3 (No-Hair Theorem): *All F-forms in a* BH *solution with $k>0$ possess the property $\delta_{1I_s}=1$, where the number $i=1$ refers to the time axis.*

The proof rests on Lemma 1, which, applied to F-forms, leads again to (28). Now, according to Theorem 2, at a horizon $(u\to\infty)$ only $\beta^1\to-\infty$, while other β^i are finite. As is directly verified, (28) holds in the case $\delta_{1I_s}=1$ (for true electromagnetic forms), while for quasiscalar ones one has finite limits for e^{y_s}, leading to infiniteness of the corresponding EMT constituent.

Remark 1: The regularity of the scalar fields, $x^A=\varphi^a$, at $u\to\infty$ was not required in the conditions of Theorems 2 and 3; for $k>0$ it follows from (23). Under the additional requirement $\varphi^a<\infty$ as $u\to\infty$, Theorem 3 is easily proved for $k=0$ as well.

Remark 2: For $k=0$ we have no Theorem 2; moreover, Theorem 3 is not proved for $k=0$ without assuming $\varphi^a<\infty$. Nevertheless, for BH solutions with $k=0$ obtainable as a limit of ones with $k>0$, the statements of both theorems remain valid. (For known exact BH solutions, $k=0$ corresponds to the extreme limit of minimal mass for given charges.) Meanwhile, the existence of exceptional BH solutions with $k=0$, nonzero quasiscalar forms and/or multi-time horizons is not ruled out by our study; such solutions may perhaps exist with infinite limits of scalar fields that balance the infinity of $e^{-\alpha}$ in the EMT of F-forms.

Remark 3: If there are BH solutions, there are also others, where the scale factor showing a zero value is associated, instead of physical time, with one of the extra coordinates (such solutions are obtained from BH ones by simple re-denoting). One thus finds the so-called T-holes, where crossing a horizon leads to changing the signature of the external, physical space from $(-+++\cdots)$ to $(--++\cdots)$. Possible properties of such objects are discussed in more detail elsewhere[17,29] within the frames of dilaton gravity, but the considerations thereof are valid as well for the more general model (1). Theorems 2 and 3 are valid for T-holes after proper reformulation.

IV. SOME EXACT SOLUTIONS

A. Orthogonal systems (OS)

The field equations are entirely integrated if all $\mathbf{Y}_s$ are mutually orthogonal in $\mathcal{V}$, that is,

$$\mathbf{Y}_s\mathbf{Y}_{s'}=\delta_{ss'}/N_s^2, \quad 1/N_s^2=d(I)[1-d(I)/\overline{D}]+\overline{\lambda_s^2}>0. \tag{34}$$

Then the functions $y_s(u)$ obey the decoupled Liouville equations $\ddot{y}_s=b_s e^{2y_s}$, with $b_s\overset{\text{def}}{=}\epsilon_s Q_s^2/N_s^2$, whence

$$e^{-y_s(u)}=\sqrt{|b_s|}S(\epsilon_s,h_s,u+u_s), \tag{35}$$

where h_s and u_s are ICs and the function $S(.,.,.)$ has been defined in (13). For the sought functions $x^A(u)=(\beta^i,\varphi^a)$ we then obtain:

$$x^A(u)=\sum_s N_s^2 Y_s{}^A y_s(u)+c^A u+\underline{c}^A, \tag{36}$$

where the vectors of ICs $\mathbf{c}$ and $\underline{\mathbf{c}}$ are orthogonal to all Y_s: $c^A Y_{s,A}=\underline{c}^A Y_{s,A}=0$, or

$$c^i d_i\delta_{iI_s}-c^a\chi_s\lambda_{sa}=0, \quad \underline{c}^i d_i\delta_{iI_s}-\underline{c}^a\chi_s\lambda_{sa}=0. \tag{37}$$

The solution is general for the properly chosen input parameters; the number of independent charges equals the number of F-forms.

B. Block-orthogonal systems (BOS)

Suppose now[20] that the set $\mathcal{S}$ splits into several nonintersecting nonempty subsets,

$$\mathcal{S}=\bigcup_{\omega}\mathcal{S}_\omega, \quad |\mathcal{S}_\omega|=m(\omega), \tag{38}$$

such that the vectors $\mathbf{Y}_{\mu(\omega)}$ $(\mu(\omega)\in S_\omega)$ form mutually orthogonal subspaces $\mathcal{V}_\omega$ in $\mathcal{V}$:

$$\mathbf{Y}_{\mu(\omega)}\mathbf{Y}_{\nu(\omega')}=0, \quad \omega\neq\omega'. \tag{39}$$

Suppose, further, that, for each fixed ω, all $\mathbf{Y}_\nu$ (where $\nu=\nu(\omega)$) are linearly independent and the charge factors $q_\nu=\epsilon_\nu Q_\nu^2\neq 0$ satisfy the set of linear algebraic equations

$$(\mathbf{Y}_\nu-\mathbf{Y}_{\nu'})\mathbf{Z}_\omega=0, \quad \mathbf{Z}_\omega\stackrel{\text{def}}{=}\sum_{\mu\in\mathcal{S}_\omega} q_\mu\mathbf{Y}_\mu, \tag{40}$$

for each pair (ν,ν'). Then the function $y_\omega(u)\stackrel{\text{def}}{=}Y_{\mu(\omega),A}x^A$ is the same for all $\mu\in\mathcal{S}_\omega$ and satisfies the Liouville equation $\ddot{y}_\omega=b_\omega e^{2y_\omega}$. As a result, we obtain a solution to the equations of motion, generalizing (35), (36):

$$e^{-y_\omega}=\sqrt{|b_\omega|}S(\text{sign } b_\omega, h_\omega, u+u_\omega), \tag{41}$$

$$x^A=\sum_\omega N_\omega^2 Y_\omega{}^A y_\omega(u)+c^A u+\underline{c}^A, \tag{42}$$

where h_ω and u_ω are ICs; the constants c^A and $\underline{c}^A$ satisfy the same orthogonality relations (38) as for OS, that is, the vectors $\mathbf{c}$ and $\underline{\mathbf{c}}$ are orthogonal to each individual $\mathbf{Y}_s$, even if it is a member of a BOS subsystem. We have used the notations

$$b_\omega=\mathbf{Y}_{\nu(\omega)}\mathbf{Z}_\omega; \quad \mathbf{Y}_\omega=\mathbf{Z}_\omega\hat{q}_\omega; \quad N_\omega^{-2}=\mathbf{Y}_\omega^2=\frac{b_\omega}{\hat{q}_\omega}; \quad \hat{q}_\omega=\sum_{\mu\in\mathcal{S}_\omega} q_\mu. \tag{43}$$

Here b_ω is nonzero and independent of $\nu(\omega)\in S_\omega$ due to (40); moreover, $\hat{q}_\omega\neq 0$ since $\hat{q}_\omega=\mathbf{Z}_\omega^2/b_\omega$ while the nonzero vector $\mathbf{Z}_\omega$ is determined up to extension by (40).

The linear independence of $\mathbf{Y}_{\mu(\omega)}$ thus guarantees that Eqs. (40) yield $q_{\mu(\omega)}$ for a given subsystem up to a common factor. Therefore, unlike the OS solution, the BOS one is special: the number of independent charges coincides with $|\{\omega\}|$, the number of subsystems; however, we thus gain exact solutions for more general sets of input parameters, e.g., a one-charge solution can be obtained for actually an arbitrary configuration of branes with linearly independent $\mathbf{Y}_\mu$ (except possible cases when the solution of (40) leads to at least one zero charge).

When $m=1$, we have a single vector $\mathbf{Y}_\omega=\mathbf{Y}_s$ orthogonal to all others, with the norm $N_\omega^{-2}=N_s^{-2}$, and the charge factor is $b_\omega=b_s$. Thus single branes and BOS subsystems are represented in a unified way, and the OS solution is a special case $(m(\omega)=1,\forall\omega)$ of the BOS one.

The metric has the form (14), where the function σ_1 is

$$\sigma_1=-\frac{d_0-1}{D-2}\sum_\omega N_\omega^2 y_\omega(u)\sum_{\mu\in\mathcal{S}_\omega}\frac{q_\mu}{\hat{q}_\omega}d(I_\mu)+u\sum_{i=1}^n c^i+\sum_{i=1}^n \underline{c}^i. \tag{44}$$

For OS $(\omega\mapsto s)$ the sum in μ reduces to $d(I_s)$. The "conserved energy" (16) is

$$E=\sum_\omega N_\omega^2 h_\omega^2 \text{sign } h_\omega+c_A c^A=\frac{d_0}{d_0-1}K. \tag{45}$$

In the special case $m=2$, $\mathbf{Y}_1^2=\mathbf{Y}_2^2$, one easily obtains $b_1=b_2$, as was shown in Ref. 13 for a single F-form. By definition of b_s that means not only $Q_1^2=Q_2^2$, but also a coincidence of the sign factors $\operatorname{sign} b_s=\epsilon_s$. For instance, in spherical symmetry, the F-fields must be either both true electric/magnetic ones ($\operatorname{sign} b_s=1$), or both quasiscalar ones ($\operatorname{sign} b_s=-1$).

C. On cosmological and black-hole solutions

There is a large number of exact cosmological solutions to special cases of the model (1), see Refs. 12, 21, 30, and references therein. It can be seen that the description of Sec. III A (which is certainly confirmed by exact solutions) actually exhausts all general features of the model, since other details, such as, e.g., the particular behavior of the physical scale factor $a(t)$, depend on the choice of integration constants.

BHs are obtained as special spherically symmetric solutions when $h_\omega>0$, $u_{\max}=\infty$. The functions β^i $(i=0,2,\ldots,n)$ and φ^a remain finite as $u\to\infty$ under the following constraints on the ICs:

$$h_\omega=k, \quad \forall\omega; \quad c^A=k\sum_\omega N_\omega^2 Y_\omega{}^A-k\delta^A_1, \tag{46}$$

where $A=1$ corresponds to $i=1$ (time), $d_1=1$ (according to Theorem 2). The constraint (45) then holds automatically.

The subfamily (46) exhausts all BH solutions under OS or BOS assumptions, except the extreme case $k=0$; extreme BHs are obtained by subsequently passing to the limit $k\to 0$. One can notice that exceptional extreme BH solutions, whose possibility was mentioned in Sec. III C, are not found in this way.

General explicit forms of the OS and BOS BH solutions have been presented in Refs. 15 and 20, respectively. The BH properties stated in Theorems 2 and 3 are confirmed for the OS and BOS solutions and, moreover, have been first observed[15,20] for these solutions.

V. WORMHOLES

A. Wormhole existence conditions

Wormhole-like configurations which can appear as special OS or BOS solutions, have an infinite ''external radius'' $e^{\beta^0(u)}$ at both ends $u_\pm$ of the u range and are regular between them; all $\beta^i(u_\pm)$ $(i>0)$ and $\varphi^a(u_\pm)$ are finite. This happens when $k<0$ and the solution behavior is governed by the function $\sin ku$ (so that $u_-=0$ and $u_+=\pi/|k|$) and is possible if the first positive zero of the function $\sin[|h_s|(u-u_s)]$ is greater than $\pi/|k|$ for any s such that $h_s<0$ (see Fig. 1).

In the cosmological setting, this behavior would correspond to nonsingular, bouncing models, which are, however, absent according to Sec. III A (due to $k>0$). The static and Euclidean cases are not *a priori* excluded.

As is evident from Fig. 1, any WH solution is characterized by $|k|>|h_\omega|$ for all h_ω which are negative. Due to (45), for $k<0$ at least some h_ω should be negative as well. Furthermore, for $k<0$ and $h_\omega<0$ it is necessary to have $wK_0=1$ and $b_\omega>0$, respectively.

Table I shows that WHs can exist in static or Euclidean models only with spherical rather than pseudospherical or planar symmetry. In cosmology we have no fields capable to give negative h_s or h_ω, which again confirms the absence of nonsingular ''bounced'' models. In static spherical symmetry the necessary F-forms are true electric and magnetic ones. In Euclidean models, magnetic quasiscalar forms are needed.

Suppose $k<0$. Since in (45) $\mathbf{c}^2\geqslant 0$, the requirement $|k|>|h_s|$ means that

$$\sum_{\{\omega:\, h_\omega<0\}} N_\omega^2>\frac{d_0}{d_0-1}. \tag{47}$$

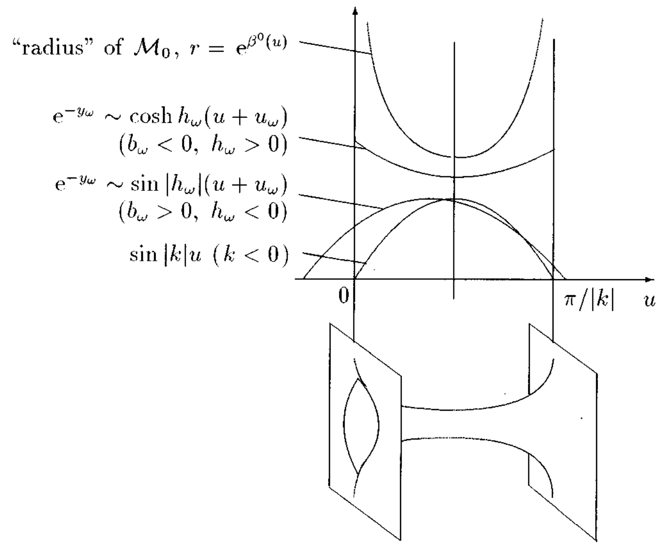

FIG. 1. A wormhole configuration; qualitative picture.

This inequality is not only *necessary*, but also *sufficient* for the existence of WHs with given input parameters: d_i and the vectors $\mathbf{Y}_s$. Indeed, put $c^A=0$ and turn to zero the charges $Q_{\mu(\omega)}$ in all subsystems with $\hat{q}_\omega<0$ (note that, by (43), sign $\hat{q}_\omega=\text{sign}b_\omega$.) Choose all h_ω to be negative and equal, then due to (47) $|h_\omega|<|k|$. It is now an easy matter to choose the ICs u_ω in such a way that $\sin[|h_\omega|(u+u_\omega)]>0$ on the whole segment $[0,\pi/|k|]$, and this results in a WH solution.

B. Lorentzian wormholes and a universal restriction for brane systems

In general relativity static[31] and even dynamic[32] traversable WHs are known to violate the null energy condition. It can be verified[20] that, under the present positive energy requirement, the model (1) after reduction to d_0+2 dimensions by integrating out all $\mathcal{M}_i, i>1$ and a transition to the Einstein conformal frame, reduces to general relativity with a set of material fields whose EMT satisfies the null energy condition, which rules out static WHs. On the other hand, given a static WH in D dimensions as described in the previous subsection, it would also appear as a static WH in (d_0+2)-dimensional Einstein frame since the relevant conformal factor (the volume factor of extra dimensions) is everywhere finite and nonzero. We have to conclude that static WHs are absent in our model.

This means in turn that the sufficient condition (47) must be violated, and a properly formulated opposite inequality must hold. We arrive at the following theorem for brane systems having an orthogonal subsystem:

Theorem 4: *Consider a vector space $\mathcal{V}$, with a scalar product defined by the metric* (17), *where $d_i\in\mathbb{N}$, $i=0,\ldots,n$, $d_0>1$, $d_1=1$, $\bar{D}=\Sigma_{i=0}^n d_i-1$, and a set of nonzero vectors $\mathbf{Y}_s, s\in\mathcal{S}$, defined in* (18) *($I_s\subseteq\{1,\ldots,n\}$, $\chi_s\lambda_{sa}\in\mathbb{R}$). Let there be a subset $\mathcal{S}_\perp\subset\mathcal{S}$ such that $\mathbf{Y}_s\mathbf{Y}_{s'}=0$ for $s\neq s'$, $s,s'\in\mathcal{S}_\perp$. Then the following inequality holds:*

$$\sum_{s\in\mathcal{S}_\perp}\delta_{1I_s}N_s^2\leqslant\frac{d_0}{d_0-1},\quad \textit{or for}\ \lambda_{sa}=0,$$
$$\sum_{s\in\mathcal{S}_\perp}\delta_{1I_s}\left[d(I_s)\left(1-\frac{d(I_s)}{D-2}\right)\right]^{-1}\leqslant\frac{d_0}{d_0-1}. \tag{48}$$

The factor δ_{1I_s} in (48) excludes quasiscalars. For $\mathcal{S}_\perp = \mathcal{S}$ the theorem has been already proved by the above reasoning. If there are $\mathbf{Y}_s \notin \mathcal{S}_\perp$, their influence can be ruled out by turning to zero the corresponding charges Q_s, and then, as before, assuming the contrary of (48), we immediately obtain a Lorentzian WH solution.

Comment: The formulation of Theorem 4 does not mention F-forms, time, or any other physical entities and is actually of purely geometric (or even combinatorial) nature. From the combinatorial viewpoint it is essential that in the set $I_0 = \{0, \ldots, n\}$ there is a distinguished number, in our case 1, with $d_1 = 1$, included in all subsets I_s entering into the sum. Our proof, however, rests on physically motivated analytical considerations.

A similar theorem for a brane system with a BOS subsystem is readily obtained:

Theorem 4a: *Consider the model described in Sec. II, under the conditions specified in the first sentence of Theorem 4. Let there be a subset* $\mathcal{S}' \subset \mathcal{S}$ *such that the vectors* $\mathbf{Y}_s, s \in \mathcal{S}'$ *form a block-orthogonal system with respect to the metric* (17). *Then the following inequality holds for* $s \in \mathcal{S}'$:

$$\sum_{\{\omega:\, \hat{q}_\omega > 0\}} N_\omega^2 \leqslant \frac{d_0}{d_0 - 1}, \tag{49}$$

where $\hat{q}_\omega$ *and* N_ω^2 *are defined in* (43) *and, for all* q_s *included in the sum,* $\epsilon_s = \operatorname{sign} q_s = -1 + 2\delta_{1I_s}$.

According to the latter condition, ϵ_s depends on the inclusion or noninclusion of the distinguished one-dimensional factor space $\mathcal{M}_1$ $(= \mathbb{R}_t$ in Lorentzian models) into the world volume of specific BOS members. Thus, unlike the OS case, the sum may include F-forms with different ϵ_s, but in such a way that the combined factor $\hat{q}_\omega = \Sigma_{\mu \in \omega} q_\mu$ be positive for each ω.

VI. CONCLUDING REMARKS

(1) Some general restrictions on the behavior of brane systems described by the action (1) have been obtained, independent of specific space-time symmetry and signature: cosmological asymptotics, some BH properties and a universal restriction on the parameters of possible orthogonal or block-orthogonal subsystems (Theorems 4 and 4a).

Throughout the paper, the D-dimensional Einstein (D-E) conformal frame was used, although in such a general setting of the problem there is no evident reason to prefer one frame or another. For any specific underlying theory that leads to (1) in a weak field limit, two conformal frames are physically distinguished: one where the theory is originally formulated and another, providing the validity of the weak equivalence principle (or geodesic motion) for ordinary matter in 4 dimensions; the latter depends on how fermions are introduced in the underlying theory.[17,33,34] The first one should be used when discussing such issues as singularities or topology of a model, etc. (*what happens as a matter of fact*), while the second one, the so-called atomic system of measurements, is necessary for formulating observational predictions (*what we see*). They are, generally speaking, different.

Among the present results, however, only cosmological ones are conformal frame-dependent if different frames are connected by exponentials of the internal scale factors β^i and dilatonic fields φ^a. Indeed, such factors, being regular everywhere including horizons and asymptotics, cannot change the BH or WH nature of a given metric. (The only exceptions are hypothetic exceptional extreme BH solutions mentioned in Remark 2.)

The conclusions of Sec. III A on cosmological asymptotics are directly applicable to theories formulated in the outset in the D-E frame, like the weak-field bosonic sector of $D = 11$ supergravity following from M-theory,[3] where the action (truncated by neglecting the Chern-Simons term) has the form (1) with a single antisymmetric 4-form and no scalar fields.

(2) Unlike Lorentzian ones, Euclidean WHs (EWHs) are not ruled out, and the reason is (taking, say, OS solutions as an example) that, when selecting the F-forms (branes) for WH

construction, in the Euclidean case we are no more restricted to I_s containing a distinguished number, connected with $\mathbb{R}_t$, while now $\mathbb{R}_t = \mathbb{R}_u$. So there is a wider choice of I_s able to give $h_s < 0$ and to fulfill the WH necessary and sufficient condition (47).

As seen from Table I, EWHs corresponding to (1), if any, may be built only with the aid of magnetic forms F_s, though the existence of electric forms in a WH solution is not excluded.

The situation is well exemplified for $D=11$ supergravity. Indeed, the orthogonality conditions (34) are satisfied by 2-branes, $d(I_s)=3$, and 5-branes, $d(I_s)=6$, if the intersection rules hold:

$$d(3\cap 3)=1, \quad d(3\cap 6)=2, \quad d(6\cap 6)=4. \tag{50}$$

(the notations are evident); for all F-forms $N_s^2 = 1/2$. In particular, with $d_0=2$ or $d_0=3$ and other $d_i=1$, there is a maximal OS of seven 2-branes,[12,15]

$$\begin{array}{ll} a:\ 123, & d:\ 345, \\ b:\ 147, & e:\ 246, \\ c:\ 156, & f:\ 257, \\ & g:\ 367, \end{array} \tag{51}$$

where the figures 1, . . . ,7 label one-dimensional factor spaces, and for static models ''1'' refers to the time axis $\mathbb{R}_t$. Only three of these I_s (a,b,c) have $\delta_{1I_s}=1$, i.e., describe true electric or magnetic fields in a static space-time. Lorentzian WHs are absent since (47) requires $\Sigma_s N_s^2 > 2$ for $d_0=2$ and $>3/2$ for $d_0=3$.

In the Euclidean case we can have as many as 7 magnetic 2-branes, each with $N_s^2=1/2$, and WHs are easily found. Though, the latter is true if one considers F_{mI} of rank 7. If one remains restricted, as usual, to F_s of rank 4,[3] then for magnetic forms $d(I)=6$, and EWHs cannot be obtained. In other words, OS and BOS solutions do not lead to EWHs in standard 11-dimensional supergravity. Examples of EWHs have been found[20] for $D=12$ theory.[6]

By construction, classical EWHs possess finite actions and are related to possible quantum tunneling processes. Explicit expressions for their action and throat radii in the case of symmetric WHs described by OS and BOS solutions, have been calculated[20] explicitly in a general form for WHs which are symmetric with respect to their throats.

(3) The present conclusions rest on the positive energy requirement that seems quite natural as long as we deal with classical fields. Thus, in particular, the well-known singularity theorems of general relativity actually work as well in multidimensional p-brane cosmology. Meanwhile, the low energy limit of the unification theories is believed to work at scales from Planckian to subatomic and in the early universe where quantum effects of both gravity and material fields must be of importance (e.g., the Casimir effect due to compactification of extra dimensions), and a classical treatment is only a tentative, though necessary, stage in studying such systems. One can mention some papers discussing the relevant quantum effects: the Wheeler-DeWitt equation for p-branes[14,21] and the Casimir effect in cosmology.[35] Some nonquantum effects able to prevent a cosmological singularity are discussed by Kaloper *et al.*[30] and Gasperini;[36] see also references therein. All such effects necessarily violate the usual energy requirements and can therefore create traversable Lorentzian wormholes.

ACKNOWLEDGMENTS

Nonlinear realizations of the diffeomorphism group in metric-affine gauge theory of gravity

Giovanni Giachetta
Department of Mathematics and Physics, University of Camerino, 63032 Camerino MC, Italy

(Received 25 February 1998; accepted for publication 27 October 1998)

The action of diffeomorphisms on coupled metric and spinor fields on a world manifold X is interpreted in terms of nonlinear realizations of the group $\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$, the universal twofold covering group of the general linear group $\mathrm{GL}^+(4,\mathbb{R})$, on the quotient manifold $(\widetilde{\mathrm{GL}}^+(4,\mathbb{R})\times V)/\mathrm{SL}(2,\mathbb{C})$, where $\mathrm{SL}(2,\mathbb{C})$ is the spin group and V is the spinor space. By using nonlinear realizations the connection of a metric-affine world manifold couples naturally to standard spinor fields. This enables us not to exceed the scope of usual spinor models as in the case in which infinite-dimensional representations of $\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$ are considered. As an application, by starting from the familiar Lagrangian for spin-1/2 models and using the nonlinear realization method, a Lagrangian density for spinor fields which has $\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$ as invariance group is constructed. The total Lagrangian density is obtained by adding the Lagrangian of the metric-affine gravity. The energy-momentum current associated with every vector field on the world manifold X is calculated explicitly. It turns out that spinor fields do not contribute to the corresponding superpotential, which takes a form similar to that obtained by Komar. © *1999 American Institute of Physics.* [S0022-2488(99)01902-7]

I. INTRODUCTION

As is well known,[1] the classical theory of general relativity, especially when the tetrad approach is used, can be reformulated in terms of nonlinear realizations[2] of the general linear group $\mathrm{GL}(4,\mathbb{R})$. This description is particularly well suited in gauge gravitation theory if one regards general covariance as a spontaneously violated symmetry because of the presence of spinor fields, the gravitational (metric) field being regarded as a Higgs field.[3]

More recently, a framework has been introduced to deal with dynamical gravitational fields in the presence of spinor fields.[4,5] For each gravitational field there is a distinct spinor bundle. Therefore the configuration space of coupled gravitational and spinor fields can be conveniently represented as the total space S of the composite fiber bundle

$$S\to\Sigma\to X, \tag{1}$$

where $\Sigma\to X$ is the configuration space of gravitational fields on the world manifold X and $S\to\Sigma$ is a vector bundle with structure group the spin group $\mathrm{SL}(2,\mathbb{C})$. Given a gravitational field $h:X\to\Sigma$, the restriction of $S\to\Sigma$ to $h(X)\subset\Sigma$ is exactly the space of spinors for h.

In this paper we show that this framework has the structure of a gauge theory with the structure group, the universal twofold covering group

$$\zeta:\widetilde{\mathrm{GL}}^+(4,\mathbb{R})\to\mathrm{GL}^+(4,\mathbb{R}) \tag{2}$$

of the general linear group $\mathrm{GL}^+(4,\mathbb{R})$, acting nonlinearly on the quotient

$$(\widetilde{\mathrm{GL}}^+(4,\mathbb{R})\times V)/\mathrm{SL}(2,\mathbb{C}). \tag{3}$$

Here V is the spinor space and the quotient is defined by choosing a spinor representation of $SL(2,\mathbb{C})$ in V. Note that (3) is the total space of the fiber bundle associated with the principal bundle

$$\widetilde{GL}^+(4,\mathbb{R})\to\widetilde{GL}^+(4,\mathbb{R})/SL(2,\mathbb{C}).$$

In particular, we prove that the composite fiber bundle (1) can be regarded as a fiber bundle associated with a $\widetilde{GL}^+(4,\mathbb{R})$-principal bundle, its typical fiber being exactly the quotient $(\widetilde{GL}^+(4,\mathbb{R})\times V)/SL(2,\mathbb{C})$ on which $\widetilde{GL}^+(4,\mathbb{R})$ acts nonlinearly on the left.

In the gauging of $\widetilde{GL}^+(4,\mathbb{R})$ by using nonlinear realizations, the connection of a metric-affine world manifold is naturally coupled to standard fermionic matter. Alternatively, one can consider spinor representations of $\widetilde{GL}^+(4,\mathbb{R})$[6,7] which, however, are infinite dimensional [the only finite-dimensional linear representations of $\widetilde{GL}^+(4,\mathbb{R})$ are those obtained from representations of $GL^+(4,\mathbb{R})$ via composition with the covering map (2)]. Elements of these representations are called world spinors and the corresponding field theory has been already developed (see Ref. 6 and references therein).

Under suitable topological conditions on X, every diffeomorphism $\varphi:X\to X$ can be lifted to a diffeomorphism $\varphi_S:S\to S$ which preserves the composite fiber bundle structure (1), but in general this action yields only a projective representation of the diffeomorphism group $D(X)$. Here we calculate explicitly the infinitesimal version of this action. More precisely, for every vector field $\tau:X\to TX$ on X we find the expression of its natural lift $\tau_S:S\to TS$ on S. This vector field projects onto a vector field τ_Σ on Σ and, of course, onto τ. Note that, since only the normal subgroup $D_0(X)$ of diffeomorphisms which are homotopic to the identity is involved at the infinitesimal level, the association $\tau\mapsto\tau_S$ yields a true representation, and not just a projective one.

As an application, starting with the familiar Lagrangian density for spin-1/2 models and using the nonlinear realization method, we construct a Lagrangian $\mathcal{L}_M$ which has $\widetilde{GL}^+(4,\mathbb{R})$ as invariance group and in which the spinor fields are coupled with the torsion of the linear connection on X. Then the total Lagrangian density $\mathcal{L}=\mathcal{L}_M+\mathcal{L}_{MAG}$, where $\mathcal{L}_{MAG}$ is the Lagrangian density of the metric-affine gravitation theory, is invariant under the action of the diffeomorphism group $D(X)$ on the total configuration space $C\times_X S$. Here $C\to X$ is the fiber bundle of linear connections on X. Hence, for every vector field τ on X, the Lie derivative of $\mathcal{L}$ with respect to the lift τ_{CS} of τ on $C\times_X S$ vanishes identically, and therefore the corresponding energy-momentum current is conserved. It turns out that spinor fields do not contribute at all to the energy-momentum superpotential, which takes the form of the generalized Komar superpotential in the metric-affine theory of gravity.[8]

The ideas and results are arranged as follows. In Sec. II we describe how the symmetry reduction scheme used in gauge gravitation theory can be extended to general gauge theories. This can be done by introducing fields (Higgs fields) transforming nonlinearly under the action of the gauge group. In Sec. III we set our notations and review the main concepts related to spin structures on a four-manifold. In Sec. IV we deal with the problems of constructing a configuration bundle of coupled metric and spinor fields and defining a covariant derivative of its sections. In Sec. V we concentrate on the action of the diffeomorphism group $D(X)$ on the coupled metric-spinor configuration space. Section VI is devoted to the example sketched above. An appendix is added to describe the general approach to differential conservation laws in Lagrangian field theory.

Throughout the paper manifolds are real, finite dimensional, Hausdorff, second countable (hence paracompact), and connected.

II. SPONTANEOUS SYMMETRY BREAKING

In this section we illustrate the general description of spontaneously broken symmetries in gauge theories where matter fields admit only exact symmetry transformations.[9,10]

In classical field theory the spontaneous symmetry breaking is described by classical Higgs fields. If the gauge theory is formulated on a principal bundle $P \to X$, the necessary condition for spontaneous symmetry breaking is the reduction of the structure group G (the group whose realizations are required) of this principal bundle to the closed subgroup H of exact symmetries. Higgs fields are then represented by global sections h of the fiber bundle

$$\Sigma = P/H \to X.$$

This is a P-associated bundle with the typical fiber G/H on which the structure group G acts naturally on the left.

As is well known (see Ref. 11, p. 57), the set of Higgs fields h is in one-to-one correspondence with the set of reduced H-principal subbundles P^h of P. Given such a subbundle P^h, let

$$Y^h = (P^h \times V)/H \to X \tag{4}$$

be an associated fiber bundle with a typical fiber V carrying a linear representation of the subgroup H. Its sections describe matter fields in the presence of the Higgs field h.

Let us now consider the composite fiber bundles

$$P \to \Sigma \to X \tag{5}$$

and

$$Y \to \Sigma \to X, \tag{6}$$

where

$$P \to \Sigma \tag{7}$$

is a principal bundle with the structure group H and

$$Y = (P \times V)/H \to \Sigma \tag{8}$$

is a fiber bundle associated with it. Given a Higgs field h and the corresponding fiber bundle (4), it is easily seen that this latter is canonically isomorphic with the subbundle of the composite fiber bundle (6) given by the restriction of $Y \to \Sigma$ to $h(X) \subset \Sigma$. It follows that there is one-to-one correspondence between pairs (h, ψ_h), formed by a matter field ψ_h in the presence of the Higgs field h, and sections $\psi : X \to Y$ of the composite fiber bundle (6).

We regard Y as the configuration space for coupled Higgs and matter fields in gauge theory with spontaneously broken symmetries.

Note that for different Higgs fields h and h' we have different bundles Y^h and $Y^{h'}$, and there is no natural way of identifying these bundles. In other words, the fiber bundle $Y \to \Sigma$ is not in general the fibered product of the configuration space of Higgs fields Σ and some typical matter bundle. Essentially, this is due to the fact that matter fields admit only exact symmetry transformations. More precisely, there is no representation of the group G in V that restricts to the given representation of H in V. In fact, the following result holds.

Proposition 1: Let the linear representation of H in V be the restriction of a representation of G in V. Then the fiber bundle (8) is canonically isomorphic with the pull-back bundle $\Sigma \times_X (P \times V)/G$.

Proof: It is readily verified that the map defined by

$$(p,v)H \mapsto (pH,(p,v)G), \quad \forall p \in P, \quad v \in V,$$

is an isomorphism of Y onto $\Sigma \times_X (P \times V)/G$, over Σ. □

Let us now specify the transformation laws for Higgs and matter fields. Every automorphism ϕ of the principal bundle $\pi : P \to X$ [a diffeomorphism $\phi : P \to P$ such that $\phi(pg) = \phi(p)g$ for every $p\in P$, $g\in G$] defines diffeomorphisms $\phi_\Sigma:\Sigma\to\Sigma$ and $\varphi:X\to X$ such that the following diagram commutes:

$$\begin{array}{ccc} P & \xrightarrow{\phi} & P \\ \downarrow & & \downarrow \\ \Sigma & \xrightarrow{\phi_\Sigma} & \Sigma \\ \downarrow & & \downarrow \\ X & \xrightarrow{\varphi} & X. \end{array}$$

Since ϕ is also an automorphism of the principal bundle $P\to\Sigma$, it defines an automorphism ϕ_Y of the associated bundle (8) according to the law

$$(p,v)H\mapsto(\phi(p),v)H, \quad \forall p\in P, \quad v\in V.$$

We have the following commutative diagram:

$$\begin{array}{ccc} Y & \xrightarrow{\phi_Y} & Y \\ \downarrow & & \downarrow \\ \Sigma & \xrightarrow{\phi_\Sigma} & \Sigma \\ \downarrow & & \downarrow \\ X & \xrightarrow{\varphi} & X. \end{array}$$

Remark 1: Given a pair (h,ψ_h) formed by a Higgs field h and a section ψ_h of the fiber bundle (4), the automorphism ϕ_Y defined above takes this pair into $(h',\psi_{h'})$, where $h'=\phi_\Sigma\circ h\circ\varphi^{-1}$ is the transformed Higgs field and $\psi_{h'}$ is the section of $Y^{h'}\to X$ uniquely determined by h' and the section $\psi'=\phi_Y\circ\psi\circ\varphi^{-1}$. Here $\psi:X\to Y$ is the section corresponding to (h,ψ_h) under the correspondence described above.

Having specified the transformation laws for the fields, we now have to define the covariant derivatives of field systems on composite fiber bundles. We assume that the Lie algebra $\mathfrak{g}$ of G is the direct sum

$$\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{m}$$

of the Lie algebra $\mathfrak{h}$ of the subgroup H and a subspace $\mathfrak{m}\subset\mathfrak{g}$ such that

$$\mathrm{ad}(H)(\mathfrak{m})\subset\mathfrak{m},$$

where ad is the adjoint representation.

Let $\omega:P\to\mathfrak{g}$ be a connection form on P. Then the $\mathfrak{h}$-component $\omega_\mathfrak{h}$ of ω is a connection form on the H-principal bundle $P\to\Sigma$, whereas the $\mathfrak{m}$-component $\omega_\mathfrak{m}$ is a tensorial form of type (ad,$\mathfrak{m}$) on $P\to\Sigma$.[11] For every Higgs field h, the pull-back of $\omega_\mathfrak{h}$ on P^h is a connection form on the reduced subbundle $P^h\to X$. Moreover, the pull-back of $\omega_\mathfrak{m}$ on P^h coincides with the covariant derivative of h with respect to ω. It gives the obstruction for ω to reduce to a connection on P^h.

The connection form $\omega_\mathfrak{h}$ induces a connection $A:Y\to J^1Y_\Sigma$ on the associated bundle (8). Here J^1Y_Σ denotes the first jet prolongation of this bundle. If the total space Y is provided with adapted coordinates (x^μ,σ^p,y^i), where (x^μ,σ^p) are bundle coordinates on the fiber bundle $\Sigma\to X$, then A reads locally

$$A = dx^\mu \otimes \left(\frac{\partial}{\partial x^\mu} + I(\mathbf{A}_\mu)^i{}_j y^j \frac{\partial}{\partial y^i} \right) + d\sigma^p \otimes \left(\frac{\partial}{\partial \sigma^p} + I(\mathbf{A}_p)^i{}_j y^j \frac{\partial}{\partial y^i} \right),$$

where $\mathbf{A}_\mu$ and $\mathbf{A}_p$ are the connection parameters of $\omega_{\mathfrak{h}}$ (which are opposite in sign to the gauge potentials) and $I(\cdot)^i{}_j$ are the Lie algebra representation matrices of the given representation of H.

Let us consider the jet manifolds $J^1\Sigma$ of $\Sigma \to X$, $J^1 Y_\Sigma$ of $Y \to \Sigma$ and $J^1 Y$ of $Y \to X$, with the corresponding coordinates

$$(x^\mu, \sigma^p, \sigma^p_\mu), \quad (x^\mu, \sigma^p, y^i, \widetilde{y}^i_\mu, y^i_p), \quad (x^\mu, \sigma^p, y^i, \sigma^p_\mu, y^i_\mu).$$

Then there exists the canonical morphism

$$\rho: J^1\Sigma \underset{\Sigma}{\times} J^1 Y_\Sigma \to J^1 Y,$$

$$\rho(j^1_x h, j^1_{h(x)} g) = j^1_x (g \circ h), \quad y^i_\mu \circ \rho = \widetilde{y}^i_\mu + y^i_p \sigma^p_\mu,$$

where g and h are sections of the fiber bundles $Y \to \Sigma$ and $\Sigma \to X$, respectively. Using the composition

$$\rho \circ A : J^1\Sigma \times_\Sigma Y \to J^1 Y,$$

$$y^i_\mu \circ \rho \circ A = I(\mathbf{A}_\mu + \mathbf{A}_p \sigma^p_\mu)^i{}_j y^j,$$

and the affine structure of the fiber bundle $J^1 Y \to Y$, one obtains the first-order differential operator

$$D: J^1 Y \to T^*X \otimes VY_\Sigma,$$
$$D = dx^\lambda \otimes [y^i_\mu - I(\mathbf{A}_\mu + \mathbf{A}_p \sigma^p_\mu)^i{}_j y^j] \frac{\partial}{\partial y^i}. \tag{9}$$

Here VY_Σ denotes the vertical tangent bundle of $Y \to \Sigma$.

The operator (9) has the following property. Given a Higgs field h, the restriction

$$D_h : J^1 Y^h \to T^*X \otimes VY^h,$$

$$D_h = dx^\mu \otimes [y^i_\mu - I(\mathbf{A}_\mu + \mathbf{A}_p \partial_\mu h^p)^i{}_j y^j] \frac{\partial}{\partial y^i},$$

of D to Y^h is the familiar covariant derivative relative to the principal connection

$$A_h = dx^\mu \otimes \left[\frac{\partial}{\partial x^\mu} + I(\mathbf{A}_\mu + \mathbf{A}_p \partial_\mu h^p)^i{}_j y^j \frac{\partial}{\partial y^i} \right]$$

on the fiber bundle (4).

One can use D in order to construct Lagrangians on the jet manifold $J^1 Y$ of the configuration space Y which are invariant under automorphisms of the G-principal bundle $P \to X$, starting from any Lagrangian which is invariant under the subgroup H. A G-invariant quadratic term in ω_m can be added if the Higgs fields have to propagate like the matter fields.

Let us now consider the H-principal bundle $G \to G/H$ and its associated bundle $(G \times V)/H \to G/H$. The group G acts on $(G \times V)/H$ on the left as follows. For every $a \in G$, the left translation L_a of G (sending $g \in G$ into $ag \in G$) is an automorphism of the principal bundle $G \to G/H$, over the diffeomorphism $\overline{L_a}$ of the quotient space G/H which takes a coset gH into the coset agH. Hence L_a induces the automorphism

$$\Lambda_a:(g,v)H\mapsto(ag,v)H$$

of the associated bundle $(G\times V)/H\to G/H$, over the diffeomorphism $\overline{L_a}$.

The group action of G on the quotient space $(G\times V)/H$ can be regarded as a nonlinear realization of G on the objects of physical interest, which are used as parameters or coordinates on the quotient G/H, and on all other (matter) fields. To see this, note that by using a (local) gauge s of the principal bundle $G\to G/H$, one can write

$$as(gH)=s(agH)h(gH,a), \quad \forall a,g\in G,$$

where $h(\cdot,a)$ is a function of G/H into the subgroup H. This relation defines implicitly the group action $\overline{L_a}$ on G/H by the formula

$$s(agH)=as(gH)h(gH,a)^{-1},$$

but it also defines the function h. This functions governs the behavior of the matter fields under the action of G by the law:

$$v\in V\mapsto h(gH,a)v\in V.$$

Going back to the framework based on composite fiber bundles and their automorphisms, the key remark which relates this framework to the nonlinear realization method is formulated in the following proposition.

Proposition 2: The composite fiber bundle (6) can be regarded as a fiber bundle with structure group G and typical fiber $(G\times V)/H$. In fact, $(P\times V)/H$ can be identified with the total space of the fiber bundle $(P\times(G\times V)/H)/G\to X$ associated with $P\to X$ [the group action of G on the typical fiber $(G\times V)/H$ being that described above] as follows. An element

$$(p,(g,v)H)G\in(P\times(G\times V)/H)/G, \quad p\in P, \;\; g\in G, \;\; v\in V,$$

is mapped into the element

$$(pg,v)H\in(P\times V)/H.$$

Note that in addition to the fiber bundle structure over X, $(P\times(G\times V)/H)/G$ is provided also with a natural structure of fibration over Σ. It is easily seen that this structure is preserved under the above identification with $(P\times V)/H$.

III. SPIN STRUCTURES

Hereafter, by a world manifold X we mean a noncompact, parallelizable four-dimensional manifold with a given orientation.

Remark 2: In classical field theory, if cosmological models are not considered, the world manifold X is assumed to satisfy accepted rules of causality.[12] A compact manifold does not have these properties because every Lorentz metric on it generates closed timelike curves. On the other hand, on a noncompact four-dimensional manifold X a Lorentz metric can always be chosen as to give no closed timelike curves (see Ref. 13, p. 168). Moreover, given such a Lorentz metric X admits a spin structure if and only if it is parallelizable.[14]

A Lorentz metric h on the world manifold X is a section of the fiber bundle

$$\Sigma=LX/\mathrm{SO}^0(1,3)\to X, \tag{10}$$

where $\pi:LX\to X$ is the $\mathrm{GL}^+(4,\mathbb{R})$-principal bundle of oriented linear coframes on X and $\mathrm{SO}^0(1,3)$ denotes the proper Lorentz group. As is well known, (10) is a LX-associated fiber bundle with the typical fiber $\mathrm{GL}^+(4,\mathbb{R})/\mathrm{SO}^0(1,3)$.

Given a chart (U,x^μ) on X, every element $\xi=\{\xi^a\}\in\pi^{-1}(U)\subset LX$ takes the form

$$\xi^a = \xi^a{}_\mu dx^\mu,$$

where the matrix $\xi^a{}_\mu$ belongs to $\mathrm{GL}^+(4,\mathbb{R})$. Hence the coframe bundle LX can be provided with bundle coordinates

$$(x^\mu, \xi_a{}^\mu),$$

where $\xi_a{}^\mu$ denotes the inverse matrix of $\xi^a{}_\mu$. In these coordinates, the canonical right action of the structure group $\mathrm{GL}^+(4,\mathbb{R})$ on LX reads

$$\xi_a{}^\mu \mapsto \xi_b{}^\mu g^b{}_a, \quad \forall g^b{}_a \in \mathrm{GL}^+(4,\mathbb{R}).$$

For subsequent purposes, we also introduce coordinates on LX adapted to the composite fibration

$$LX \to \Sigma \to X \tag{11}$$

as follows. Every element $\xi_a{}^\mu$ of $\mathrm{GL}^+(4,\mathbb{R})$ in some suitable neighborhood of the identity element may be written as

$$\xi_a{}^\mu = \langle \xi \rangle_b{}^\mu [\xi]^b{}_a,$$

where $[\xi]^b{}_a$ is an element of $\mathrm{SO}^0(1,3)$ and $\langle \xi \rangle_b{}^\mu$ is pseudo-symmetric, that is,

$$\langle \xi \rangle_a{}^\mu \eta_{\mu b} = \langle \xi \rangle_b{}^\mu \eta_{\mu a}.$$

It follows that the pseudo-symmetric matrices $\sigma_a{}^\mu$ form a local coordinate system on the quotient manifold $\mathrm{GL}^+(4,\mathbb{R})/\mathrm{SO}^0(1,3)$, and hence

$$(x^\mu, \sigma_a{}^\mu, \lambda^a{}_b),$$

where $\lambda^a{}_b$ are elements of the proper Lorentz group, are suitable bundle coordinates on LX adapted to the composite fibration (11).

By the way, note that the $\mathrm{SO}^0(1,3)$-principal fiber bundle $LX \to \Sigma$ admits the (local) gauge

$$\overline{\xi} \to \langle \xi \rangle^a{}_\mu dx^\mu, \tag{12}$$

where $\overline{\xi}$ denotes the coset of ξ.

Every metric field h determines the tetrad functions

$$h_a{}^\mu(x) = \sigma_a{}^\mu \circ h(x),$$

which are related to the metric functions $g^{\mu\nu}(x)$ by the well-known relation

$$g^{\mu\nu}(x) = h_a{}^\mu(x) h_b{}^\nu(x) \eta^{ab}. \tag{13}$$

Here

$$\eta_{ab} = \mathrm{diag}\ (1,-1,-1,-1)$$

is the Minkowski metric written with respect to an orthonormal basis $\{e_a\}$ of the Minkowski space M.

Coming to spinors, let us briefly introduce our notations (see Refs. 15 and 16 for a general description of the Clifford algebra techniques). Let $\mathbb{C}_{1,3}$ be the complex Clifford algebra generated by elements of M. The spinor space V is defined to be a minimal left ideal of $\mathbb{C}_{1,3}$ on which this algebra acts on the left. We denote by

$$\gamma : M \otimes V \to V, \quad \gamma(e_a) = \gamma_a \tag{14}$$

the representation of elements of the Minkowski space M by γ-matrices in V.

The Clifford group $G_{1,3}$ comprises all invertible elements $\tilde{\lambda}$ of the real Clifford algebra $\mathbb{R}_{1,3}$ such that the corresponding inner automorphisms induce Lorentz transformations of the Minkowski space M, that is,

$$\tilde{\lambda} e \tilde{\lambda}^{-1} = \lambda(e), \quad \forall e \in M, \tag{15}$$

with $\lambda \in \mathrm{O}(1,3)$. The representation (14) satisfies the following equivariance property:

$$\gamma(\lambda e \otimes \tilde{\lambda} v) = \tilde{\lambda} \gamma(e \otimes v), \quad \forall \tilde{\lambda} \in G_{1,3}, \quad e \in M, \ v \in V.$$

Since the action (15) of the Clifford group on the Minkowski space M is not effective, one usually considers the pin subgroup Pin (1,3) of $G_{1,3}$. The even part of Pin (1,3) is the spin group Spin (1,3). The restriction of the map (15) to the identity component

$$\mathrm{Spin}^0(1,3) \simeq \mathrm{SL}(2,\mathbb{C})$$

of Spin(1,3) yields the well-known twofold universal covering group

$$\zeta_0 : \mathrm{SL}(2,\mathbb{C}) \to \mathrm{SO}^0(1,3)$$

of the proper Lorentz group. The spin group $\mathrm{SL}(2,\mathbb{C})$ acts on the spinor space V by the generators

$$I_{ab} = \tfrac{1}{4}[\gamma_a, \gamma_b], \tag{16}$$

induced by the generators

$$L_{ab}{}^c{}_d = \delta^c_a \eta_{db} - \delta^c_b \eta_{da} \tag{17}$$

of the Lie algebra of $\mathrm{SO}^0(1,3)$.

Let $L^h X$ denote the $\mathrm{SO}^0(1,3)$-principal subbundle of the coframe bundle LX corresponding to the metric field $h : X \to \Sigma$. In order to define spinor fields in the presence of h, we have first to give a h-spin structure on X, i.e., an $\mathrm{SL}(2,\mathbb{C})$-principal bundle $\widetilde{L^h X} \to X$ and a principal bundle morphism

$$z_h : \widetilde{L^h X} \to L^h X \tag{18}$$

over X.[16] Spinor fields in the presence of the metric field h are sections of the vector bundle

$$S^h = (\widetilde{L^h X} \times V)/\mathrm{SL}(2,\mathbb{C}) \to X$$

associated with $\widetilde{L^h X}$ via the spinor representation of $\mathrm{SL}(2,\mathbb{C})$ in the spinor space V.

IV. CONFIGURATION MANIFOLDS

If one considers theories in which the Lorentz metrics are dynamical variables as well as the spinor fields, one has to take into account deformations of the spin structure as a consequence of deformations of the metric. This dependence on the metric can be taken into account by introducing a double cover of the coframe bundle (see also Refs. 4 and 5).

As is well known, the group $\mathrm{GL}^+(4,\mathbb{R})$ is not simply connected. Its first homotopy group is[17]

$$\pi_1(\mathrm{GL}(4,\mathbb{R})) = \pi_1(\mathrm{SO}(4)) = \mathbb{Z}_2.$$

Therefore $\mathrm{GL}^+(4,\mathbb{R})$ admits the universal twofold covering group (2) as to make commutative the diagram[18]

$$\begin{array}{ccc} \widetilde{\mathrm{GL}}^+(4,\mathbb{R}) & \xrightarrow{\zeta} & \mathrm{GL}^+(4,\mathbb{R}) \\ {\scriptstyle \tilde{i}}\uparrow & & \uparrow{\scriptstyle i} \\ \mathrm{SL}(2,\mathbb{C}) & \xrightarrow{\zeta_0} & \mathrm{SO}^0(1,3) \end{array}$$

Here $\tilde{i}$ and i are the inclusion morphisms.

In order to apply the procedure outlined in Sec. II, the first step is that of choosing the subgroup H to $G=\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$ from which the quotient G/H can be formed. We take H to be the spin group $\mathrm{SL}(2,\mathbb{C})$. The choice of this subgroup, along with its known representations, enable us to define group actions of $\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$ on half-integer as well as integer spinor fields. As a second step we take a prolongation $(\widetilde{LX},z)$ of LX to $\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$, i.e., a $\widetilde{\mathrm{GL}}^+(4,\mathbb{R})$-principal bundle $\widetilde{LX}\to X$ and a principal bundle morphism

$$z=\widetilde{LX}\to LX$$

over X.

Note that the quotient manifold $\widetilde{LX}/\mathrm{SL}(2,\mathbb{C})$ can be identified with $\Sigma=LX/\mathrm{SO}^0(1,3)$. This is a straightforward consequence of the diffeomorphism

$$\widetilde{\mathrm{GL}}^+(4,\mathbb{R})/\mathrm{SL}(2,\mathbb{C})\cong \mathrm{GL}^+(4,\mathbb{R})/\mathrm{SO}^0(1,3)$$

between their typical fibers. Therefore the following diagram commutes:

$$\begin{array}{ccc} \widetilde{LX} & \xrightarrow{z} & LX \\ & \searrow\swarrow & \\ & \Sigma & \end{array}$$

Let us consider the composite fiber bundle

$$\widetilde{LX}\to\Sigma\to X$$

and the composite spinor bundle

$$S\to\Sigma\to X, \tag{19}$$

where

$$S=(\widetilde{LX}\times V)/\mathrm{SL}(2,\mathbb{C})\to\Sigma$$

is the fiber bundle associated with the $\mathrm{SL}(2,\mathbb{C})$-principal bundle $\widetilde{LX}\to\Sigma$. In accordance with Sec. II, S can be regarded as the configuration space of coupled metric and spinor fields. Given a metric field h, the restriction of the spinor bundle $S\to\Sigma$ to $h(X)\subset\Sigma$ is canonically isomorphic with the spinor bundle S^h associated with the h-spin structure defined by the following commutative diagram:

$$\begin{array}{ccc} \widetilde{LX} & \xrightarrow{z} & LX \\ {\scriptstyle \tilde{i}}\uparrow & & \uparrow{\scriptstyle i} \\ \widetilde{L^hX} & \xrightarrow{z_h} & L^hX \end{array}$$

Remark 3: Given a metric field h, one can show[4] that the topological obstructions to the existence of a prolongation $(\widetilde{LX},z)$ are the same as the obstructions to the existence of a h-spin structure. Moreover, the set of equivalence classes of prolongations of LX is in one-to-one correspondence with the set of equivalence classes of h-spin structures.

Let us now define a covariant derivative on the configuration space S. To begin with, recall that there is one-to-one correspondence between principal connections on $\widetilde{LX}\to X$ and principal connections on the coframe bundle $LX\to X$ (linear connections on X). If $\omega:TLX\to\mathfrak{gl}(4,\mathbb{R})$ is a connection form on LX, the corresponding connection form $\tilde{\omega}:T\widetilde{LX}\to\tilde{\mathfrak{gl}}(4,\mathbb{R})$ on $\widetilde{LX}$ is defined by the composition

$$\tilde{\omega}=(\zeta')^{-1}\circ(z^*\omega),$$

where $\zeta':\tilde{\mathfrak{gl}}(4,\mathbb{R})\to\mathfrak{gl}(4,\mathbb{R})$ is the Lie algebra isomorphism induced by ζ.

As is readily seen, the Lie algebra of the general linear group $GL(4,\mathbb{R})$ is the direct sum

$$\mathfrak{gl}(4,\mathbb{R})=\mathfrak{so}^0(1,3)\oplus\mathfrak{m}$$

of the Lie algebra $\mathfrak{so}^0(1,3)$ of the Lorentz group and a subspace $\mathfrak{m}\subset\mathfrak{gl}(4,\mathbb{R})$ such that

$$\mathrm{ad}(SO^0(1,3))(\mathfrak{m})\subset\mathfrak{m},$$

where ad is the adjoint representation. Then (see Sec. II) the $\mathfrak{so}^0(1,3)$-component ω' of a connection form ω on LX is a principal connection on $\widetilde{LX}\to\Sigma$, whereas the $\mathfrak{m}$-component $\omega_{\mathfrak{m}}$ is a tensorial form of type $(\mathrm{ad},\mathfrak{m})$ on the same fiber bundle. The local expressions of ω, ω', and $\omega_{\mathfrak{m}}$ with respect to the bundle coordinates $(x^\mu,\xi_a{}^\mu)$ of LX are given respectively by

$$\omega^a{}_b=\xi^a{}_\mu(d\xi_b{}^\mu-K^\mu{}_{\nu\alpha}\xi_b{}^\nu dx^\alpha),$$

$$\omega^{[ab]}=\tfrac{1}{2}(\xi^a{}_\mu\eta^{bc}-\xi^b{}_\mu\eta^{ac})(d\xi_c{}^\mu-K^\mu{}_{\nu\alpha}\xi_c{}^\nu dx^\alpha),$$

$$\omega^{(ab)}=\tfrac{1}{2}(\xi^a{}_\mu\eta^{bc}+\xi^b{}_\mu\eta^{ac})(d\xi_c{}^\mu-K^\mu{}_{\nu\alpha}\xi_c{}^\nu dx^\alpha),$$

where the connection parameters $K^\mu{}_{\nu\alpha}$ are local functions on X.

The pull-back of ω' with respect to the gauge (12) yields the following expression for its connection parameters in the bundle coordinates $(x^\mu,\sigma_\alpha{}^\mu)$ on Σ:

$$A^{ab}{}_\alpha=\tfrac{1}{2}(\sigma^a{}_\mu\eta^{bc}-\sigma^b{}_\mu\eta^{ac})K^\mu{}_{\nu\alpha}\sigma_c{}^\nu,$$

$$A^{abc}{}_\mu=-\tfrac{1}{2}(\sigma^a{}_\mu\eta^{bc}-\sigma^b{}_\mu\eta^{ac}).$$

It follows that the differential operator (9) reads

$$D:J^1S\to T^*X\underset{\Sigma}{\otimes}S,$$

$$D=dx^\alpha\otimes\left[y^i_\alpha-\frac{1}{4}(\sigma^a{}_\nu\eta^{bc}-\sigma^b{}_\nu\eta^{ac})(K^\nu{}_{\mu\alpha}\sigma_c{}^\mu-\sigma_c{}^\nu{}_{,\alpha})I_{ab}{}^i{}_jy^j\right]\frac{\partial}{\partial y^i}, \tag{20}$$

where $(x^\mu,\sigma_a{}^\mu,y^i)$ denote bundle coordinates on S and $I_{ab}{}^i{}_j$ are the Lie algebra representation matrices (16) of the given representation of $SL(2,\mathbb{C})$.

Starting from any $SL(2,\mathbb{C})$-invariant Lagrangian and using the differential operator (20), one can construct Lagrangians which are invariant under automorphisms of the $\widetilde{GL}^+(4,\mathbb{R})$-principal bundle $\widetilde{LX}\to X$. For example, the familiar Dirac Lagrangian for spin-1/2 models leads to the following Lagrangian defined on the configuration space $C\times_XS$:

$$\mathcal{L}_M : C \underset{X}{\times} J^1 S \to \overset{4}{\wedge} T^*X, \quad \mathcal{L}_M = L_M d^4 x,$$

$$L_M = \frac{i}{2} \left\{ y_i^*(\gamma^0 \gamma^\alpha)^i{}_j \left[y^j_\alpha - \frac{1}{4} (\sigma^a{}_\nu \eta^{bc} - \sigma^b{}_\nu \eta^{ac})(k^\nu{}_{\mu\alpha} \sigma_c{}^\mu - \sigma_c{}^\nu{}_{,\alpha}) I_{ab}{}^j{}_k y^k \right] \right.$$
$$\left. - \left[y^*_{i\alpha} - \frac{1}{4} (\sigma^a{}_\nu \eta^{bc} - \sigma^b{}_\nu \eta^{ac})(k^\nu{}_{\mu\alpha} \sigma_c{}^\mu - \sigma_c{}^\nu{}_{,\alpha}) y^*_k I^*_{ab}{}^k{}_i \right] (\gamma^0 \gamma^\alpha)^i{}_j y^j \right\}$$
$$\times \det(\sigma^a{}_\mu) - m y_i^* (\gamma^0)^i{}_j y^j \det(\sigma^a{}_\mu). \tag{21}$$

Here $*$ denotes complex conjugation, $\gamma^\alpha = \gamma^a \sigma_a{}^\alpha$ and $C \to X$ is the fiber bundle of principal connections on LX. Its total space is the quotient[19]

$$C = J^1 LX / \mathrm{GL}^+(4,\mathbb{R}),$$

with bundle coordinates denoted by

$$(x^\mu, k^\mu{}_{\nu\alpha}). \tag{22}$$

It is easily verified that $\mathcal{L}_M$ satisfies the following relations:

$$\frac{\partial L_M}{\partial k^\alpha{}_{\beta\mu}} + \frac{\partial L_M}{\partial k^\alpha{}_{\mu\beta}} = 0, \tag{23}$$

$$\frac{\partial L_M}{\partial k^\alpha{}_{\nu\mu}} = \frac{\partial L_M}{\partial \sigma_a{}^\alpha{}_{,\nu}} \sigma_a{}^\mu. \tag{24}$$

Note that, by virtue of (23), the Lagrangian density (21) depends only on the torsion of the linear connection on X.

V. SPIN AND INFINITESIMAL DIFFEOMORPHISMS

In this section we define a morphism of the Lie algebra $\Xi(X)$ of vector fields on the world manifold X into the Lie algebra $\Xi(S)$ of vector fields on the configuration space S of coupled metric and spinor fields.

Every orientation-preserving diffeomorphism φ of the world manifold X lifts naturally to an automorphism $\hat{\varphi}$ of the coframe bundle LX defined by

$$\hat{\varphi}(\xi) = \{\xi^a \circ T\phi^{-1}\}, \quad \forall \xi \in LX. \tag{25}$$

We denote by φ_Σ the unique diffeomorphism of Σ such that the following diagram commutes:

$$\begin{array}{ccc} LX & \xrightarrow{\hat{\varphi}} & LX \\ \downarrow & & \downarrow \\ \Sigma & \xrightarrow{\varphi_\Sigma} & \Sigma \\ \downarrow & & \downarrow \\ X & \xrightarrow{\varphi} & X. \end{array}$$

It follows that, given a one-parameter group of orientation-preserving diffeomorphisms φ_t of X generated by a vector field $\tau : X \to TX$, the lift $\hat{\varphi}_t$ of φ_t to the coframe bundle generates a $\mathrm{GL}^+(4,\mathbb{R})$-invariant vector field $\hat{\tau}$ which is projectable onto a vector field τ_Σ on Σ and this, in turn, onto τ:

$$\begin{array}{ccc} LX & \xrightarrow{\hat{\tau}} & TLX \\ \downarrow & & \downarrow \\ \Sigma & \xrightarrow{\tau_\Sigma} & T\Sigma \\ \downarrow & & \downarrow \\ X & \xrightarrow{\tau} & TX. \end{array}$$

Since $z:\widetilde{LX}\to LX$ is a covering space, there exists a natural lift of $\hat{\varphi}_t$ to a one-parameter group of automorphisms $\widetilde{\varphi}_t$ of the principal bundle $\widetilde{LX}\to X$ and, hence, to a one-parameter group of automorphisms of the configuration space S of coupled metric and spinor fields given by

$$[\widetilde{\xi},v]\mapsto[\widetilde{\varphi}_t(\widetilde{\xi}),v], \quad \forall\widetilde{\xi}\in\widetilde{LX}, \ v\in V,$$

where $[\widetilde{\xi},v]$ is the coset of the element $(\widetilde{\xi},v)$. As a result, one obtains a vector field τ_S on S such that the following diagram commutes:

$$\begin{array}{ccc} S & \xrightarrow{\tau_S} & TS \\ \downarrow & & \downarrow \\ \Sigma & \xrightarrow{\tau_\Sigma} & T\Sigma \\ \downarrow & & \downarrow \\ X & \xrightarrow{\tau} & TX. \end{array}$$

Let us find the expression of the vector field τ_S in the bundle coordinates $(x^\mu,\sigma_a{}^\mu,y^i)$ of S. We start from the local expression of the automorphism (25) in the bundle chart $(x^\mu,\xi_a{}^\mu)$ of LX:

$$\hat{\varphi}:(x^\mu,\xi_a{}^\mu)\mapsto\left(\phi^\mu(x),\ \frac{\partial\phi^\mu}{\partial x^\nu}\ \xi_a{}^\nu\right).$$

Now, given a gauge $s:W\subset\Sigma\to LX$ of the principal bundle $LX\to\Sigma$, one can write

$$\hat{\varphi}\circ s(\overline{\xi})=(s\circ\varphi_\Sigma(\overline{\xi}))h(\overline{\xi}),$$

where $\overline{\xi}$ is the coset of ξ and h is a function of W into $\mathrm{SO}^0(1,3)$. In particular, if s is the gauge (12) the expression of $\hat{\varphi}$ reads

$$\hat{\varphi}:(x^\mu,\sigma_a{}^\mu,\lambda^a{}_b)\mapsto\left(\phi^\mu(x),\ \frac{\partial\phi^\mu}{\partial x^\nu}\ \sigma_b{}^\nu(h^{-1})^b{}_a,h^a{}_c\lambda^c{}_b\right). \tag{26}$$

Let $\tau=\tau^\mu\partial/\partial x^\mu$ be a vector field on X. Then, from (26), one finds the following expression for the vector field $\hat{\tau}$ on LX:

$$\hat{\tau}=\tau^\mu\ \frac{\partial}{\partial x^\mu}+\left(\frac{\partial\tau^\mu}{\partial x^\nu}\ \sigma_a{}^\nu-\sigma_b{}^\mu\tau^b{}_a\right)\ \frac{\partial}{\partial\sigma_a{}^\mu}+\frac{1}{2}\ \tau^{ab}\mathbf{e}_{ab}, \tag{27}$$

where $\tau^a{}_b(x^\mu,\sigma_a{}^\mu)$ is a function taking values into $\mathfrak{so}^0(1,3)$. Latin indices are lowered and raised with the Minkowski metric η_{ab} and $\mathbf{e}_{ab}=-\mathbf{e}_{ba}$ are the right invariant vector fields on $\mathrm{SO}^0(1,3)$ corresponding to the basis (17) of $\mathfrak{so}^0(1,3)$ given by

$$\mathbf{e}_{ab}=\frac{1}{2}\,(\delta^c_a\eta_{db}-\delta^c_b\eta_{da})\lambda^d{}_k\,\frac{\partial}{\partial\lambda^c{}_k}.$$

Consequently, the coordinate expression of the vector field τ_S on S reads

$$\tau_S=\tau^\mu\,\frac{\partial}{\partial x^\mu}+\left(\frac{\partial\tau^\mu}{\partial x^\nu}\,\sigma_a{}^\nu-\sigma_b{}^\mu\tau^b{}_a\right)\frac{\partial}{\partial\sigma_a{}^\mu}+\frac{1}{2}\,\tau^{ab}\left(I_{ab}{}^i{}_j y^j\,\frac{\partial}{\partial y^i}+y^*_j I^*_{ab}{}^j{}_i\,\frac{\partial}{\partial y^*_i}\right).$$

Given an orientation-preserving diffeomorphism φ of X, the equivariance of $\hat{\varphi}$ [with respect to the right action of $\mathrm{GL}^+(4,\mathbb{R})$ on LX] implies that the jet extension $j^1\hat{\varphi}:J^1LX\to J^1LX$ goes to the quotient $C=J^1LX/\mathrm{GL}^+(4,\mathbb{R})$, defining in this way an automorphism $\varphi_C:C\to C$ over φ. It follows that every vector field $\tau=\tau^\mu\partial_\mu$ on X can be naturally lifted to a vector field τ_C on C, whose expression with respect to the coordinates (22) is

$$\tau_C=\tau^\mu\partial_\mu+(\partial_{\beta\nu}\tau^\mu-k^\mu{}_{\beta\alpha}\partial_\nu\tau^\alpha-k^\mu{}_{\alpha\nu}\partial_\beta\tau^\alpha+k^\alpha{}_{\beta\nu}\partial_\alpha\tau^\mu)\,\frac{\partial}{\partial k^\mu{}_{\beta\nu}}$$

or, using the compact notation $y^A=k^\mu{}_{\beta\nu}$,

$$\tau_C=\tau^\mu\partial_\mu+(u^{A\beta\nu}_\mu\partial_{\beta\nu}\tau^\mu+u^{A\mu}_\beta\partial_\mu\tau^\beta)\,\frac{\partial}{\partial y^A}.$$

Later, we shall denote by

$$\tau_{CS}=\tau_C+\tau_S:C\underset{X}{\times}S\to T(C\underset{X}{\times}S)$$

the vector field on the configuration space $C\underset{X}{\times}S$ which is the sum of the vector fields τ_C and τ_S.

VI. APPLICATIONS

Let us consider the Lagrangian density

$$\mathcal{L}=\mathcal{L}_M+\mathcal{L}_{\mathrm{MAG}}:J^1(C\underset{X}{\times}S)\to\overset{4}{\wedge}T^*X,$$

where $\mathcal{L}_M$ is the Lagrangian density (21) and

$$\mathcal{L}_{\mathrm{MAG}}=L_{\mathrm{MAG}}d^4x,$$

$$L_{\mathrm{MAG}}=\sigma_a{}^\beta\sigma_b{}^\mu\eta^{ab}R^\alpha{}_{\beta\alpha\mu}\,\det(\sigma^a{}_\mu)$$

is the Lagrangian density of the metric-affine theory of gravity. Here

$$R^\alpha{}_{\beta\nu\mu}=k^\alpha{}_{\beta\nu,\mu}-k^\alpha{}_{\beta\mu,\nu}+k^\alpha{}_{\sigma\nu}k^\sigma{}_{\beta\mu}-k^\alpha{}_{\sigma\mu}k^\sigma{}_{\beta\nu}$$

is the curvature tensor. Note that

$$\partial L_{\mathrm{MAG}}/\partial k^\alpha{}_{\beta\mu,\nu}\equiv\pi_\alpha{}^{\beta\mu\nu}=-\pi_\alpha{}^{\beta\nu\mu},\tag{28}$$

$$\partial L_{\mathrm{MAG}}/\partial k^\alpha{}_{\beta\mu}=\pi_\sigma{}^{\beta\mu\nu}k^\sigma{}_{\alpha\nu}-\pi_\alpha{}^{\sigma\mu\nu}k^\beta{}_{\sigma\nu}.\tag{29}$$

By construction, the Lagrangian densities $\mathcal{L}_M$ and $\mathcal{L}_{\mathrm{MAG}}$ are invariant under the action of the diffeomorphism group $D(X)$. Hence they obey the relations

$$\mathbf{L}_{\tilde{\tau}_{CS}}\mathcal{L}_M=0, \quad \mathbf{L}_{\tilde{\tau}_{CS}}\mathcal{L}_{\mathrm{MAG}}=0, \quad \forall \tau \in \Xi(X), \tag{30}$$

which lead to conserved energy-momentum currents. Let us analyze these currents. For every vector field $\tau \in \Xi(X)$, one obtains the current (see the Appendix)

$$\begin{aligned} V^\mu(\mathcal{L},\tau)=&\frac{\partial L_{\mathrm{MAG}}}{\partial y^A_\mu}\,(u^{A\beta\gamma}_{\ \ \alpha}\partial_{\beta\gamma}\tau^\alpha+u^{A\alpha}_{\ \ \beta}\partial_\alpha\tau^\beta-y^A_\alpha\tau^\alpha)+\frac{\partial L_M}{\partial \sigma_c{}^\alpha{}_{,\mu}}\,(\sigma_c{}^\beta\partial_\beta\tau^\alpha-\sigma_a{}^\alpha\tau^a{}_c-\sigma_c{}^\alpha{}_{,\beta}\tau^\beta)\\ &+\frac{\partial L_M}{\partial y^i_\mu}\left(\frac{1}{2}\,\tau^{ab}I_{ab}{}^i{}_j y^j-y^i_\alpha\tau^\alpha\right)+\frac{\partial L_M}{\partial y^*_{i\mu}}\left(\frac{1}{2}\,\tau^{ab}y^*_j I^*{}_{ab}{}^j{}_i-y^*_{i\alpha}\tau^\alpha\right)+\tau^\mu(L_{\mathrm{MAG}}+L_M). \end{aligned} \tag{31}$$

By explicit calculation, one readily verifies that the term

$$-\frac{\partial L_M}{\partial \sigma_c{}^\alpha{}_{,\mu}}\,\sigma_a{}^\alpha\tau^a{}_c+\frac{1}{2}\,\frac{\partial L_M}{\partial y^i_\mu}\,\tau^{ab}I_{ab}{}^i{}_j y^j+\frac{1}{2}\,\frac{\partial L_M}{\partial y^*_{i\mu}}\,\tau^{ab}y^*_j I^*{}_{ab}{}^j{}_i\,,$$

corresponding to an ''internal'' transformation, vanishes identically. Therefore the current (31) reduces to

$$\begin{aligned} V^\mu(\mathcal{L},\tau)=&\frac{\partial L_{\mathrm{MAG}}}{\partial y^A_\mu}\,(u^{A\beta\gamma}_{\ \ \alpha}\partial_{\beta\gamma}\tau^\alpha+u^{A\alpha}_{\ \ \beta}\partial_\alpha\tau^\beta-y^A_\alpha\tau^\alpha)+\frac{\partial L_M}{\partial \sigma_c{}^\alpha{}_{,\mu}}\,(\sigma_c{}^\beta\partial_\beta\tau^\alpha-\sigma_c{}^\alpha{}_{,\beta}\tau^\beta)\\ &-\frac{\partial L_M}{\partial y^i_\mu}\,y^i_\alpha\tau^\alpha-\frac{\partial L_M}{\partial y^*_{i\mu}}\,y^*_{i\alpha}\tau^\alpha+\tau^\mu(L_{\mathrm{MAG}}+L_M). \end{aligned} \tag{32}$$

Due to the arbitrariness of the functions τ^α, the relations (30) imply the equalities

$$\delta^\alpha_\mu L_{\mathrm{MAG}}+\sigma_a{}^\alpha\,\frac{\partial L_{\mathrm{MAG}}}{\partial \sigma_a{}^\mu}+u^{A\alpha}_{\ \ \mu}\,\frac{\partial L_{\mathrm{MAG}}}{\partial y^A}+d_\beta u^{A\alpha}_{\ \ \mu}\,\frac{\partial L_{\mathrm{MAG}}}{\partial y^A_\beta}-y^A_\mu\,\frac{\partial L_{\mathrm{MAG}}}{\partial y^A_\alpha}=0, \tag{33}$$

and

$$\delta^\alpha_\mu L_M+\sigma_a{}^\alpha\,\frac{\partial L_M}{\partial \sigma_a{}^\mu}+\sigma_a{}^\alpha{}_{,\beta}\,\frac{\partial L_M}{\partial \sigma_a{}^\mu{}_{,\beta}}-\sigma_a{}^\beta{}_{,\mu}\,\frac{\partial L_M}{\partial \sigma_a{}^\beta{}_{,\alpha}}+u^{A\alpha}_{\ \ \mu}\,\frac{\partial L_M}{\partial y^A}-y^i_\mu\,\frac{\partial L_M}{\partial y^i_\alpha}-y^*_{i\mu}\,\frac{\partial L_M}{\partial y^*_{i\alpha}}=0. \tag{34}$$

Substituting the terms

$$\delta^\alpha_\mu L_{\mathrm{MAG}}-y^A_\mu\,\frac{\partial L_{\mathrm{MAG}}}{\partial y^A_\alpha}$$

and

$$\delta^\alpha_\mu L_M-\sigma_a{}^\beta{}_{,\mu}\,\frac{\partial L_M}{\partial \sigma_a{}^\beta{}_{,\alpha}}-y^i_\mu\,\frac{\partial L_M}{\partial y^i_\alpha}-y^*_{i\mu}\,\frac{\partial L_M}{\partial y^*_{i\alpha}}$$

from (33) and (34) into (32) and using the relations (23), (24), (28), and (29), the current $V^\mu(\mathcal{L},\tau)$ takes the superpotential form

$$V^\mu(\mathcal{L},\tau)\approx d_\beta U^{\beta\mu}(\mathcal{L},\tau),$$

where

$$U^{\beta\mu}(\mathcal{L},\tau)=\pi_\nu{}^{\kappa\beta\mu}(\nabla_\kappa\tau^\nu+T^\nu{}_{\alpha\kappa}\tau^\alpha). \tag{35}$$

Here ∇ is the covariant derivative with respect to the connection ω and T is its torsion.

Since

$$\pi_\nu{}^{\kappa\beta\mu}=(\sigma_a{}^\kappa\sigma_b{}^\mu\eta^{ab}\delta^\beta_\nu-\sigma_a{}^\kappa\sigma_b{}^\beta\eta^{ab}\delta^\mu_\nu)\ \det(\sigma^a{}_\mu),$$

(35) can be regarded as a generalized Komar superpotential, in the sense that if the connection ω has vanishing torsion and nonmetricity, then (35) coincides with the well-known Komar expression.[20]

APPENDIX: LAGRANGIAN CONSERVATION LAWS

In this Appendix, the basic features of Lagrangian field theory in jet bundle terms are briefly introduced.[21,22]

Classical fields are represented by sections of a fiber bundle $Y\to X$ and their dynamics is described by means of jet manifolds. The first jet prolongation of $Y\to X$ is denoted by J^1Y. Given bundle coordinates (x^μ,y^i) on Y $(1\leqslant\mu\leqslant m=\dim X,\ 1\leqslant i\leqslant n, m+n=\dim Y)$, the induced coordinates on J^1Y are denoted by (x^λ,y^i,y^i_μ) and the vector fields along these coordinate directions are written (in compact notation) as $(\partial_\mu,\partial_i,\partial^\mu_i)$.

A (projectable) vector field

$$u:Y\to TY,\quad u=u^\mu(x)\partial_\mu+u^i(x,y)\partial_i\,,$$

on Y (an infinitesimal transformation of both the field and the base manifold variables y^i and x^μ, respectively) can be lifted to a (projectable) vector field $\overline{u}$ on J^1Y:

$$\overline{u}:J^1Y\to TJ^1Y,\quad \overline{u}=u^\mu\partial_\mu+u^i\partial_i+u^i_\mu\partial^\mu_i\,,\quad u^i_\mu=d_\mu u^i-y^i_\nu\partial_\mu u^\nu. \tag{A1}$$

Here

$$d_\mu=\partial_\mu+y^j_\mu\partial_j+\cdots$$

is the total derivative with respect to x^μ.

Let

$$\mathcal{L}:J^1Y\to\overset{m}{\wedge}T^*X,$$

$$\mathcal{L}=L(x^\mu,y^i,y^i_\mu)d^mx,\quad d^mx=dx^1\wedge\cdots\wedge dx^m,$$

be a first-order Lagrangian density. Given a vector field $u:Y\to TY$, the corresponding current is defined to be

$$V(\mathcal{L},u):J^1Y\to\overset{m-1}{\wedge}T^*X,\quad V(\mathcal{L},u)=V^\mu(\mathcal{L},u)\partial_\mu\rfloor d^mx,$$

$$V^\mu(\mathcal{L},u)=\partial^\mu_iL(u^i-y^i_\nu u^\nu)+u^\mu L.$$

By computing the Lie derivative $\mathbf{L}_{\overline{u}}\mathcal{L}$ of the Lagrangian density $\mathcal{L}$ with respect to the vector field (A1), one finds the relation

$$\mathbf{L}_{\bar{u}}\mathcal{L} \approx d_\mu V^\mu(\mathcal{L},u) d^m x, \tag{A2}$$

where the symbol $\approx$ stands for an equality valid on solutions of the field equations.

It follows that if the vector field u is an infinitesimal symmetry transformation of the Lagrangian density $\mathcal{L}$, i.e.,

$$\mathbf{L}_{\bar{u}}\mathcal{L} = 0,$$

then (A2) yields the differential conservation law

$$d_\mu V^\mu(\mathcal{L},u) \approx 0.$$

(Received 4 May 1998; accepted for publication 26 October 1998)

We construct a general approach to the decomposition of the tangent bundle of pseudo-Riemannian manifolds into direct sums of subbundles, and the associated decomposition of geometric objects. An invariant structure $\mathcal{H}^r$ defined as a set of r projection operators is used to induce decomposition of the geometric objects into those of the corresponding subbundles. We define the main geometric objects characterizing decomposition. Invariant nonholonomic generalizations of the Gauss–Codazzi–Ricci's relations have been obtained. All the known types of decomposition (used in the theory of frames of reference, in the Hamiltonian formulation for gravity, in the Cauchy problem, in the theory of stationary spaces, and so on) follow from the present work as special cases when fixing a basis and dimensions of subbundles, and parametrization of a basis of decomposition. Various methods of decomposition have been applied here for the unified multidimensional Kaluza–Klein theory and for relativistic configurations of a perfect fluid. Discussing an invariant form of the equations of motion we have found the invariant equilibrium conditions and their 3+1 decomposed form. The formulation of the conservation law for the curl has been obtained in the invariant form. © *1999 American Institute of Physics.* [S0022-2488(99)01502-9]

I. INTRODUCTION

Most approaches and formalisms in General Relativity as well as in the multidimensional Unified Theories are connected with decomposition of spaces into direct sums of subspaces and the associated decomposition of geometrical objects. It means that in addition to the usual structures (differentiable structure, the metric structure, and so on) one should introduce a *split structure* which induces the decomposition of manifolds. This extra structure determines decomposition of all objects and structures defined on a manifold. Among the varieties of formalism of decomposition are the methods aimed to describe frames of reference and observable quantities in the theory of gravity. Similar methods have gained the wide acceptance in a great number of problems. Some of these problems are the canonical formalism for gravitational waves, the Cauchy problem in General Relativity, construction of the Unified Theory of interacting fields, quantization of the gravitational field, the tetradic formalism, the Newman–Penrose formalism, the theory of stationary and axisymmetric gravitational fields, the multidimensional and four-dimensional cosmologies.

Mathematicians and physicists developed methods of decomposition starting mainly from their intrinsic interests. It often took place independently and parallely, so that sometimes the same advances were overlooked and then refound.

The early stage of the development of mathematical technique for decomposition could be seen in the classical theory of hypersurfaces, and in the theory of n-dimensional surfaces imbedded in the n-dimensional Riemannian manifold.[1] Then, in the history of split methods, we can distinguish several ways. In mathematics, at the classical stage, there were constructed coordinate

[a]Electronic mail: gladush@ff.dsu.dp.ua

techniques for nonholonomic spaces and subspaces.[2,3] Owing to the use of the coordinate language such methods were rather cumbersome. In Physics split methods were induced by attempts to create the Unified Theory of fields, and, in particular, by appearance of the Kaluza–Klein theory.[4,5] This led to construction of a $4+1$ split method for a five-dimensional manifold and gave an impulse to study multidimensional Kaluza–Klein theories and multidimensional cosmologies[6–9] (see also references in Ref. 9).

Another physical branch of split methods was developed much more later than the original works on a $4+1$ split were. This branch has begun, apparently, with the work by Echart[10] and has been completed in the papers.[11–16] There have been constructed $(3+1)$, $(2+2)$, $(1+1+2)$ coordinate split methods and their special cases (see Ref. 17, and references therein).

The other independent direction to construct a split of spaces in General Relativity is connected with the questions of convenience of mathematical representation of the Einstein equations and with the study of these equations' structure. This branch is brought about by needs for construction of the canonical formalism,[18] of various projection formalisms in the theory of the stationary and axisymmetric gravitational fields[19–21] and for the positing of the Cauchy problem in General Relativity.[22]

Unfortunately, many of the works mentioned above, which have already become classical, use different and often inassociated approaches. Moreover a coordinate language applied there, especially in early works, makes it almost impossible to calculate the Einstein equations for some forms of the metric.

A new stage of development of split methods is based on modern differential geometry.[23,24] Its invariant language has become a working one in General Relativity.[25] It is not only a natural language for geometry in the whole, but also a convenient approach to calculations. Obtaining formulas is reduced, the formulas themselves become universal, and all the calculations can easily be made by computer.

The invariant split method was considered in Ref. 26 but without any connection with the previous works on a split. Objects introduced formally in this work have no clear geometrical meaning. One of us proposed the general invariant method of an $(n+m)$ split for pseudo-Riemannian manifolds.[27–30] Most of the approaches in this field were unified in the works,[27–30] and the objects introduced there have clear physical and geometrical meaning. For special cases of $(1+4)$, $(1+3)$, $(2+2)$, $(n+4)$ splits, in the coordinate representation, these objects reduce to known physical characteristics of a system.[8–16]

Multidimensional cosmologies and the Unified Theories imply that a manifold should be decomposed into more than two submanifolds. That is one reason why a split of a manifold requires the most general representation.

The theory of $(n_1+n_2+\cdots+n_r)$ decomposition of a pseudo-Riemannian manifold into the r nonholonomic orthogonal subbundles Σ_a of a dimension n_a $(a=1,2,\ldots,r)$ has been constructed in the present work $(n=n_1+n_2+\cdots+n_r$ is a dimension of a manifold). The $(n+m)$ and $(n+1)$ forms of invariant decomposition have been obtained as consequences. Choosing the projection operators and gauges of a basis of decomposition we construct various special cases. Some applications of this method are considered. Let us emphasize that we do not refer to problems of global geometry, but use its invariant formulations to construct decomposition of spaces into direct sums of subspaces.

Note, that the theory of structures mentioned above has found its further mathematical development, and now is widely known in differential geometry under the name ''almost product structure.''[26] The latter can be treated from a ''G-structure'' point of view[31] (see also Ref. 32, and references therein). We will follow a more natural approach and use the term ''a split structure,'' which is, in our opinion, more in the spirit of physical conceptions aroused in General Relativity when dealing with $(3+1)$, $(2+2)$, $(1+1+2)$ decomposition of space–time.

The plan of the paper is as follows. In Sec. II we introduce the necessary notations used in differential geometry, and the main definition of the theory, *a split structure* on a pseudo-Riemannian manifold. Then we introduce the metrics and connections induced on the corresponding subbundles as well as the main associated geometrical objects on the subbundles; the tensors of extrinsic curvature and of extrinsic torsion, analogies of the Ricci coefficients of rotation, and the curvature tensor. The invariant nonholonomic generalization of the Gauss–Codazzi–Ricci's relations has been found as various projections of the curvature tensor into every possible subbundle (see Appendix A).

In Sec. III the special case of the invariant split structure $r=2$ (when we deal with two subbundles only) is considered. In this case the generalized coefficients of rotation disappear from the curvature tensor, thereby the final formulas become much simpler. In Sec. IV the invariant formulas in the $(n+1)$ split form complete the scheme of the invariant split for a pseudo-Riemannian manifold. Further, for any concrete calculations, we must fix projection operators.

In Sec. V we, for illustration, briefly consider the $(n+m)$ and $(n+1)$ coordinate decomposition of the manifold with respect to the natural basis $\{\partial_\mu, dx^\nu\}$. In Sec. VI the method of $(n+m)$ decomposition is constructed with respect to an adopted basis. All the relations obtained in Sec. VI are basic ones for the other variants of decomposition in this paper. The final formulas (in Appendices B and C) can be used as an algorithm to compute the Ricci tensor, the Riemann tensor, the scalar curvature, and the corresponding Lagrangians.

In Sec. VII we define the canonical parametrization of a basis of decomposition. There have been obtained the main geometric objects with respect to this basis. Various well known special cases, which follow from this parametrization, are discussed in the section. Connections and relations among them are analyzed.

In Sec. VIII we obtain the decomposition induced by a given family of surfaces. In Sec. IX we consider the decomposition induced by a group of isometries. On the basis of this section's results we construct the Lagrangian of the unified multidimensional Kaluza–Klein theory (Sec. X). This decomposition, apart from everything else, serves as a methodical illustration of the possible use of the present method for physical theories.

Finally Sec. XI deals with the theory of configurations of a perfect fluid. Using the (3+1) canonical parametrization, one can define a one-form of the entalphy and a two-form of the curl. We have obtained the invariant equations of motion for a perfect fluid. The conservation law for the curl of an isentropic perfect fluid has been obtained in the invariant form. For this fluid, rotating in the stationary gravitational field, we have also deduced the equilibrium conditions and constructed its Lagrangian.

In this work we considered a torsion-free pseudo-Riemannian manifold only, nonetheless, our approach can be used without principal changes for theories of gravity with nonzero torsion. We see further development of the present theme in the possible expanding of the invariant decomposition to supergravity theories. We, mostly, used notations and definitions of the works.[23–25]

II. A SPLIT STRUCTURE ON A PSEUDO-RIEMANNIAN MANIFOLD

Let M be a pseudo-Riemannian manifold with the metric g; $T(M)=\cup_{p\in M}T_p$ and $T^*(M)=\cup_{p\in M}T_p^*$ are the tangent and cotangent bundles over M, where T_p and T_p^* are the corresponding fibers over a point p of M. The objects $X,Y,Z,\ldots\in T(M)$ and $\alpha,\beta,\omega,df\in T^*(M)$ denote contravariant and covariant vector fields (d is an exterior differential). We shall denote by $\omega(X)$ an inner product of a one-form ω and vector X. The scalar product of two vectors X,Y, and two forms α,β is determined by the metric g,

$$X\cdot\equiv(X,Y)\equiv g(X,Y);\ \ \langle\alpha,\beta\rangle\equiv g^{-1}(\alpha,\beta), \tag{2.1}$$

where g^{-1} is the inverse of the metric g.

We need to note that for each vector field $Y\in T(M)$ a dual one-form ω is determined uniquely by $\omega(X)=g(X,Y)$, $\forall X\in T(M)$. From now on we just will write $\omega=g(.,Y)$. Then the inverse of the metric g is given by

$$g^{-1}(\omega,\alpha)=g^{-1}(g(.,Y),\alpha)=\alpha(Y),\ \ \forall Y\in T(M),\ \ \forall\alpha\in T^*(M), \tag{2.2}$$

so that $Y=g^{-1}(.,w)$.

A linear operator L on $T(M)$ is a tensor of type (1,1) which acts according to the relation $L\cdot X \equiv L(X) \in T(M)$, $\forall X \in T(M)$. Then

$$(L^T\cdot\omega)(X)=(\omega\cdot L)(X)\equiv\omega(L(X)), \quad \forall X\in T(M), \tag{2.3}$$

where L^T is a transpose of an operator L.

The product of two linear operators $L\cdot H$ is defined by

$$(L\cdot H)\cdot X = L\cdot(H\cdot X)\in T(M), \quad \forall X\in T(M). \tag{2.4}$$

An operator H is called a symmetric one if

$$(H\cdot X,Y)=(X,H\cdot Y), \quad \forall X,Y\in T(M). \tag{2.5}$$

We have to introduce the new notation, *a split*, which denotes decomposition into direct sums. Therefore we shall say that *a split structure* $\mathcal{H}^r$ is introduced on M if the r linear symmetric operators H^a $(a=1,2,...,r)$ of a constant rank with the properties

$$H^a\cdot H^b=\delta^{ab}H^b; \quad \sum_{a=1}^{r} H^a = I, \tag{2.6}$$

where I is the unit operator ($I\cdot X=I$, $\forall X\in T(M)$), are defined on $T(M)$.

Now we introduce the notations

$$\Sigma_p^a \equiv \operatorname{Im} H_p^a; \ \ (\Sigma_a^*)_p\equiv \operatorname{Im}(H_p^a)^T; \ \ n_a=\dim\Sigma_p^a=\dim(\Sigma_a^*)_p\,, \tag{2.7}$$

where $\operatorname{Im} H_p^a$ is an image of an operator H^a at a point p of M, i.e., $\Sigma_p^a=\{X_p\in T_p | H^a\cdot X_p=X_p\}$. It is important that owing to constancy of a rank of the operator H^a, dimension n_a does not depend on a point p of M.

From the definitions presented here we can obtain the decomposition of the tangent and cotangent spaces,

$$T_p=\bigoplus_{a=1}^{r}\Sigma_p^a; \quad T_p^*=\bigoplus_{a=1}^{r}(\Sigma_a^*)_p; \quad \dim T_p=\dim T_p^*=\sum_{a=1}^{r} n_a\,, \tag{2.8}$$

where the sign $\oplus$ denotes the direct sum. Thus the tensors $\{H^a\}$ are the projection operators, which bring about decomposition of the fibers T_p, T_p^* into the r local subspaces Σ_p^a and $(\Sigma_a^*)_p$, respectively. By the same way, the bundles $T(M)$ and $T^*(M)$ are decomposed into the $(n_1+n_2+\cdots+n_r)$ subbundles Σ^a, Σ_a^*, so that

$$T(M)=\bigoplus_{a=1}^{r}\Sigma^a; \quad T^*(M)=\bigoplus_{a=1}^{r}\Sigma_a^*; \quad \Sigma^a=\bigcup_{p\in M}\Sigma_p^a; \quad \Sigma_a^*=\bigcup_{p\in M}(\Sigma_a^*)_p\,. \tag{2.9}$$

Then arbitrary vectors, covectors, and metrics are decomposed according to the scheme,

$$X=\sum_{a=1}^{r}X^a, \quad \alpha=\sum_{a=1}^{r}\alpha_a\,, \quad g=\sum_{a=1}^{r}g^a, \quad g^{-1}=\sum_{a=1}^{r}g_a^{-1}, \tag{2.10}$$

where

$$X^a=H^a\cdot X^a=H^a\cdot X; \quad H^b\cdot X^a=0; \quad X^a\cdot X^b=0; \quad (a\neq b), \tag{2.11}$$

$$\alpha_a=\alpha_a\cdot H^a=\alpha\cdot H^a; \quad \alpha_a\cdot H^b=0; \quad \alpha_a(X^b)=0 \quad (a\neq b),$$

$$g^a(X^a,Y^a)\equiv g(X^a,Y^a);\quad g_a^{-1}(\alpha_a,\beta_a)\equiv g^{-1}(\alpha_a,\beta_a),\tag{2.12}$$

$$\forall X^a,Y^a\in\Sigma^a,\quad \forall\alpha_a,\beta_a\in\Sigma_a^*.$$

In these relations $\{g^a\}$ are the metrics induced on the subbundles $\{\Sigma^a\}$ of the tangent bundle $T(M)$. Using this scheme we can obtain the decomposition of more complex tensors. We assume that all objects with indices $a,b,\dots$ are defined on the associated subbundles $\Sigma^a,\Sigma^b,\dots$.

Let ∇ be an affine (symmetric and compatible with g) connection such that

$$\nabla_X Y-\nabla_Y X=[X,Y],\quad X(Y\cdot Z)=Z\cdot\nabla_X Y+Y\cdot\nabla_X Z,\tag{2.13}$$

where $[X,Y]=XY-YX$ is the Lie bracket of two vector fields X and Y, $\nabla_X Y$ is the covariant derivative of Y in the direction X. A consequence of this is that

$$2Z\cdot\nabla_X Y=X(Y\cdot Z)+Y(Z\cdot X)-Z(X\cdot Y)+Z\cdot[X,Y]+Y\cdot[Z,X]-X\cdot[Y,Z].\tag{2.14}$$

Then the covariant derivative $\nabla_X T$ of a tensor T of type (s,r), where $s=0,1$ with respect to X is defined by

$$(\nabla_X T)(Y_1,\dots,Y_r)=\nabla_X(T(Y_1,\dots,Y_r))-\sum_{i=1}^{r}T(Y_1,\dots,Y_{i-1},\nabla_X Y_i,Y_{i+1},\dots,Y_r).\tag{2.15}$$

The Lie derivative $\mathcal{L}_X T$ of a tensor T with respect to a vector X and the exterior derivative of an r-form Ω are given by

$$(\mathcal{L}_X T)(Y_1,\dots,Y_r)=\mathcal{L}_X(T(Y_1,\dots,Y_r))-\sum_{i=1}^{r}T(Y_1,\dots,Y_{i-1},\mathcal{L}_X Y_i,Y_{i+1},\dots,Y_r),$$

$$(d\Omega)(Y_0,Y_1,\dots,Y_r)=\sum_{i=0}^{r}(-1)^i Y_i(\Omega(Y_0,\dots,\hat{Y}_i,\dots,Y_r))$$

$$+\sum_{0\le i<j\le r}(-1)^{i+j}\Omega([Y_i,Y_j],Y_0,\dots,\hat{Y}_i,\dots,\hat{Y}_j,\dots,Y_r),\tag{2.16}$$

where $\mathcal{L}_X Y=[X,Y]$, $\mathcal{L}_X\varphi=\nabla_X\varphi=(d\varphi)(X)=X\varphi$ for any scalar function φ; the symbol $\hat{}$ means that the associated term is omitted.

The curvature tensor is defined by the formula

$$R(X,Y)Z=(\nabla_X\nabla_Y-\nabla_Y\nabla_X-\nabla_{[X,Y]})Z.\tag{2.17}$$

Using a split structure $\mathcal{H}^r$, the decomposition of ∇ is easily set up,

$$\nabla_X Y=\sum_{a,b,c=1}^{r}\nabla^a_{X^b}Y^c,\quad \forall X,Y\in T(M).\tag{2.18}$$

In this sum we can distinguish the five different sorts of objects $\{\nabla^a_{X^a}Y^a,\ \nabla^a_{X^b}Y^b,\ \nabla^a_{X^a}Y^b,\ \nabla^a_{X^b}Y^a,\ \nabla^a_{X^b}Y^c\}$ $(a\neq b\neq c)$, which complete the whole of the projected connections. In particular, in this sum the objects

$$\nabla^a_{X^a}Y^a\equiv H^a\cdot\nabla_{X^a}Y^a,\quad \forall X^a,Y^a\in\Sigma^a\quad(a=1,2,...,r)\tag{2.19}$$

define connections $\{\nabla^a\}$ induced on the subbundles $\{\Sigma^a\}$. The object

$$\nabla^a_{X^b}Y^b\equiv H^a\cdot\nabla_{X^b}Y^b\equiv -B^a(X^b,Y^b),\quad \forall X^b,Y^b\in\Sigma^b\tag{2.20}$$

is the tensor of extrinsic nonholonomicity of the subbundle Σ^b. One can think that the objects

$$\nabla^a_{X^b} Y^c \equiv H^a \cdot \nabla_{X^b} Y^c \equiv -Q^a(X^b,Y^c) \equiv -Q^a_{bc}(X^b,Y^c), \quad \forall a \neq b \neq c \tag{2.21}$$

define the generalization of the Ricci's coefficients of rotation γ^a_{bc}.[34] In the general case they give the objects of rotation Q^a_{bc} of the subbundles Σ^b, Σ^c in the n_a-dimensional direction Σ^a. The other components can be expressed in terms of the introduced objects and the Lie derivative $\mathcal{L}_{X^b} Y^c$ projected into every possible subbundle Σ^a $(a \neq b \neq c)$. Thus, the components $\nabla^a_{X^a} Y^b \equiv H^a \cdot \nabla_{X^a} Y^b$ and $\nabla^a_{X^b} Y^a \equiv H^a \cdot \nabla_{X^b} Y^a$ satisfy the relations

$$Z^a \cdot \nabla^a_{X^a} Y^b = Y^b \cdot B^b(X^a,Z^a) \quad (a \neq b), \tag{2.22}$$

$$Z^a \cdot \nabla^a_{X^b} Y^a = Z^a \cdot \Lambda^a(X^b,Y^a) + X^b \cdot B^b(Y^a,Z^a), \tag{2.23}$$

where

$$\Lambda^a(X^b,Y^c) = [X^b,Y^c]^a \equiv H^a \cdot [X^b,Y^c] \equiv \mathcal{L}^a_{X^b} Y^c \quad (a \neq b \neq c). \tag{2.24}$$

Taking into account the relation (2.14) and the definition (2.21) we have

$$2Z^a \cdot Q^a(X^b,Y^c) = X^b \cdot \Lambda^b(Y^c,Z^a) - Z^a \cdot \Lambda^a(X^b,Y^c) - Y^c \cdot \Lambda^c(Z^a,X^b).$$

The tensor of extrinsic nonholonomicity can be expressed as the sum of symmetric and antisymmetric parts

$$B^a(X^b,Y^b) = S^a(X^b,Y^b) + A^a(X^b,Y^b), \tag{2.25}$$

where $S^a(X^b,Y^b)$ and $A^a(X^b,Y^b)$ define the tensors of extrinsic curvature and extrinsic torsion of subbundle Σ^b in the direction of the subbundle Σ^a. For these objects one can obtain the relations

$$2Z^a \cdot S^a(X^b,Y^b) = (\mathcal{L}_{Z^a} g^b)(X^b,Y^b), \tag{2.26}$$

$$2A^a(X^b,Y^b) = -[X^b,Y^b]^a \equiv -H^a \cdot [X^b,Y^b]. \tag{2.27}$$

It can easily be shown that a connection ∇^a induced on the subbundle Σ^a will be symmetric and compatible with the metric g^a. The projecting of the curvature tensor into the subbundles $\Sigma^a, \Sigma^b, \ldots$ gives us the nonholonomic generalizations of the Gauss–Codazzi–Ricci's equations. Using the definitions (2.10)–(2.12), (2.17)–(2.27) one can obtain all the necessary projections of the curvature tensor (for more details see Appendix A).

III. INVARIANT $n+m$ DECOMPOSITION OF A PSEUDO-REIMANNIAN MANIFOLD

If $r=2$, then there are only two subbundles Σ' and Σ'' of the tangent bundle $T(M)$ and the previous formulas become much simpler. Owing to the importance of this case it was deemed worthwhile to consider the split structure independently from Sec. II.[29,30]

Let H' be a linear idempotent symmetric operator of a constant rank with the property

$$H' \cdot H' = H'. \tag{3.1}$$

We shall say that H' defines *a* $(n+m)$ *split structure* on M if

$$\dim \operatorname{Im} H' = n; \quad \dim \operatorname{Ker} H' = m; \quad \dim M = n+m, \tag{3.2}$$

where $\operatorname{Ker} H'$ is a kernel of the operator H'. Since H' is defined, thereby we define the operator H'' such that

$$H''\cdot H''=H''; \quad H''\cdot H'=H'\cdot H''=0; \quad H'+H''=I. \tag{3.3}$$

Therefore H' and H'' are the projection operators which determine the split structure $\mathcal{H}^2$ on M due to the definition (2.6). We have

$$T(M)=\Sigma'\oplus\Sigma''; \quad \Sigma'=\bigcup_{p\in M}\Sigma'_p; \quad \Sigma'_p=\operatorname{Im}H'_p; \quad \Sigma''=\bigcup_{p\in M}\Sigma''_p; \quad \Sigma''_p=\operatorname{Ker}H'_p; \tag{3.4}$$

$$X=X'+X''; \quad g=g'+g''; \quad g^{-1}=(g')^{-1}+(g'')^{-1};$$

$$X'=H'\cdot X; \quad X''=H''\cdot X; \quad X'\cdot X''=0;$$

$$g'(X',Y')=g(X',Y'); \quad g''(X'',Y'')=g(X'',Y''). \tag{3.5}$$

A connection ∇ is decomposed into the following components: a connection on Σ', and the tensor of extrinsic nonholonomicity of the subbundle Σ', respectively,

$$\nabla'_{X'}Y'=H'\cdot\nabla_{X'}Y', \tag{3.6}$$

$$B''(X',Y')=-\nabla''_{X'}Y'=-H''\cdot\nabla_{X'}Y'. \tag{3.7}$$

Other components of ∇ can be expressed in terms of the components (3.6), (3.7) and the Lie derivatives of two vector fields

$$X'\cdot\nabla'_{Y'}Z''=Z''\cdot B''(Y',X'), \tag{3.8}$$

$$X'\cdot\nabla'_{Y''}Z'=X'\cdot\mathcal{L}_{Y''}Z'+Y''\cdot B''(Z',X'). \tag{3.9}$$

The rest of the components of ∇ $\{\nabla''_{X''}Y'', \nabla'_{X''}Y'', \nabla''_{X''}Y', \nabla''_{X'}Y''\}$ may be written out by substituting $X',Y',B',H',\ldots$ for $X'',Y'',B'',H'',\ldots$ and vice versa in formulas (3.6)–(3.9). This completes the set of all the eight possible projections of the connection.

The tensor B'' may be expressed as the sum of its symmetric and antisymmetric parts,

$$B''(X',Y')=S''(X',Y')+A''(X',Y'), \tag{3.10}$$

$$2Z''\cdot S''(X',Y')=(\mathcal{L}_{Z''}g')(X',Y'); \quad 2A''(X',Y')=-H''\cdot[X',Y'], \tag{3.11}$$

where S'' and A'' are the tensors of extrinsic curvature and torsion, respectively. If $A''=0$, the subbundle Σ' will be holonomic. It means that the subbundle Σ' is the union of the tangent bundles of an m-parameter family of n-dimensional surfaces $\{M^n(q)\subset M\}$, where $q=\{c^i\}\in D\subset R^m$ parametrizes the surfaces $M^n(q)$, and D is some range of parameters c^i $(i=1,2,...,m)$ in R^m, that is $\Sigma'=\cup_{q\in D}T(M^n(q))$. This implies that a covector basis of locally exact one-forms $\{dx^i\}$ exists on the dual subbundle $(\Sigma'')^*$, so that each of the surfaces of $\{M^n(q)\}$ is the intersection of hypersurfaces $x^i=c^i$ $(i=1,2,...,m)$ for some values of $c^i\in D$.

Using the definition of the curvature tensor (2.17) one can find every possible projection of the curvature tensor

$$\begin{aligned}R(X',Y')Z'\cdot V'={}&R'(X',Y')Z'\cdot V'+B''(X',Z')\cdot B''(Y',V')\\&-B''(Y',Z')\cdot B''(X',V')+2A''(X',Y')\cdot B''(Z',V');\end{aligned} \tag{3.12}$$

$$R(X',Y')Z'\cdot V''=V''\cdot\{(\nabla''_{Y'}B'')(X',Z')-(\nabla''_{X'}B'')(Y',Z')\}+2Z'\cdot B'(A''(X',Y'),V''); \tag{3.13}$$

$$R(X',Y'')Z'\cdot V''=(Z'\cdot(\nabla'_{X'}B')+\langle X'\cdot B',Z'\cdot B'\rangle)(Y'',V'')$$
$$+(V''\cdot(\nabla''_{Y''}B'')+\langle Y''\cdot B'',V''\cdot B''\rangle)(X',Z'); \tag{3.14}$$

R' is the curvature tensor of the subbundle Σ'

$$R'(X',Y')Z'\equiv\{\nabla'_{X'}\nabla'_{Y'}-\nabla'_{Y'}\nabla'_{X'}-\nabla'_{[X',Y']'}+2\mathcal{L}'_{A''(X',Y')}\}Z',\quad \forall X',Y',Z'\in\Sigma', \tag{3.15}$$

where $\mathcal{L}'$ is the Lie derivative projected into the subbundle Σ' $(\mathcal{L}'_X Y\equiv H'\cdot\mathcal{L}_X Y)$. This definition of the curvature tensor, introduced in the works,[28–30] is the invariant generalization of that introduced in coordinate form in Refs. 11–13 by analogy with Ref. 2. Note that the latter term in (3.15) is necessary in order that the differential curvature operator $R'(X',Y')$ on Σ' be a linear multiplicative one, or, in other words, R' be a tensor of type (1,3) on the nonholonomic subbundle Σ'. In a similar fashion this concerns the general case of $\mathcal{H}^r$ split structure [see Appendix A, (A6) for $R^a(X^a,Y^a)Z^a$].

The following expression, with the fixed vectors X',Z',Y'',V'',

$$(\langle Y''\cdot B'',V''\cdot B''\rangle)(X',Z')\equiv\langle Y''\cdot B''(X',.),V''\cdot B''(.,Z')\rangle$$

defines the scalar product of the two one-forms $\alpha\equiv Y''\cdot B''(X',.)$ and $\beta\equiv V''\cdot B''(.,Z')$ according to (2.1) by the metric $(g')^{-1}$. The covariant derivatives of the tensor B' are given by

$$(\nabla'_{X'}B')(Y'',Z'')=\nabla'_{X'}(B'(Y'',Z''))-B'(\nabla''_{X'}Y'',Z'')-B'(Y'',\nabla''_{X'}Z''), \tag{3.16}$$

$$(\nabla'_{X''}B')(Y'',Z'')=\nabla'_{X''}(B'(Y'',Z''))-B'(\nabla''_{X''}Y'',Z'')-B'(Y'',\nabla''_{X''}Z''). \tag{3.17}$$

The relations (3.12)–(3.14) are nonholonomic analogs of the well-known Gauss–Codazzi–Ricci's equations. Other nontrivial projections of the curvature tensor may be written out using the substitution "′" for "″" and vice versa.

In the special case of the coordinate representation of (3+1) and (2+2) decomposition, the objects introduced above give us the known tensors,[11–16] which have clear physical and geometrical meaning.

Let us note that the objects, presented in the work[26] may be expressed in terms of these tensors. For example, the torsion tensor introduced there as the Nijenhuis tensor[24] proved to be equal

$$S_{H'}(X,Y)\equiv[X,Y']'+[X',Y]'-[X',Y']-[X,Y]'=2A'(X'',Y'')+2A''(X',Y')$$

and the tensors T_XY and Q_XY of the work[26] are given by

$$T_XY\equiv\nabla''_{X'}Y'+\nabla'_{X'}Y''=-B''(X',Y')+g^{-1}(Y''\cdot B''(X',.),.),$$

$$Q_XY\equiv\nabla'_{X''}Y''+\nabla''_{X''}Y'=-B'(X'',Y'')+g^{-1}(Y'\cdot B'(X'',.),.).$$

They have not any simple interpretation even in the classical case of the hypersurfaces in M.

IV. AN INVARIANT $(n+1)$ SPLIT STRUCTURE ON A PSEUDO-RIEMANNIAN MANIFOLD

In this section we give the invariant generalization of $(n+1)$ decomposition of spaces (the monad method[13,15]) as a special case of $(n+m)$ decomposition when $m=1$.

Let u be a vector field (field of a monad) on M such that $u\cdot u=\epsilon=\pm 1$. It gives a one-form ω and projection operators uniquely by the formulas

$$\omega(X)=\epsilon u\cdot X,\quad \forall X\in T(M), \tag{4.1}$$

$$H''=u\otimes\omega;\quad H'=I-H''. \tag{4.2}$$

The operators satisfy all the necessary relations (3.1)–(3.3) when Σ'' is a one-dimensional subbundle $(m=1)$. The tensor product is denoted by ''$\otimes$.''

Thus, defining vector or covector fields, u or ω, respectively, we, thereby, induce an $(n+1)$ split structure on M. For any vector field X and metric g, this implies

$$X=X'+\omega(X)u,\quad g=g'+\epsilon\omega\otimes\omega,\quad g^{-1}=(g')^{-1}+\epsilon u\otimes u. \tag{4.3}$$

Hence it is apparent that $X''=\omega(X)u$ is collinear to u. The metrics $g''=\epsilon\omega\otimes\omega$, $(g'')^{-1}=\epsilon u\otimes u$ and g', $(g')^{-1}$ are the metrics on the subbundles $\Sigma'',\Sigma^{*}{}''$ and $\Sigma',\Sigma^{*}{}'$, correspondingly. A connection ∇ has the following components:

$$\nabla_{X'}Y'=\nabla'_{X'}Y'-B(X',Y')u;\quad \nabla_u u=\nabla'_u u=-B'(u,u)\equiv F, \tag{4.4}$$

where $B(X',Y')=\omega(B''(X',Y'))$. The latter equation in (4.4) follows from the formula $u\cdot u=\epsilon=\pm1$. If we consider a congruence of curves for which the vector u is the tangent vector, then F is the first curvature of this congruence. The tensor B of type (0,2) is the tensor of extrinsic nonholonomicity of the subbundle Σ' and can be written as the sum of its symmetric and antisymmetric parts,

$$B(X',Y')=-\omega(\nabla''_{X'}Y')=\epsilon S(X',Y')+A(X',Y'), \tag{4.5}$$

where $S(X',Y')=\epsilon\omega(S''(X',Y'))$, $A(X',Y')=\omega(A''(X',Y'))$, and

$$2S(X',Y')=(\mathcal{L}_u g')(X',Y');\quad 2A(X',Y')=(d\omega)(X',Y') \tag{4.6}$$

are the tensors of extrinsic curvature and extrinsic torsion of the subbundle Σ'.

The components of the curvature tensor in an $(n+1)$ decomposed form lead to the generalized Gauss–Codazzi–Ricci's equations,

$$R(X',Y')Z'\cdot V'=R'(X',Y')Z'\cdot V'+\epsilon[2A(X',Y')B(Z',V')+B(X',Z')B(Y',V')-B(Y',Z')(X',V')], \tag{4.7}$$

$$R(X',Y')Z'\cdot u=-2A(X',Y')F\cdot Z'+\epsilon[(\nabla_{Y'}B)(X',Z')-(\nabla_{X'}B)(Y',Z')], \tag{4.8}$$

$$R(X',u)Y'\cdot u=-Y'\cdot\nabla'_{X'}F+\epsilon(F\cdot X')(F\cdot Y')+(\epsilon\mathcal{L}_u B-\langle B,B^T\rangle)(X',Y'), \tag{4.9}$$

where the curvature tensor of the subbundle Σ' (see Ref. 27) is given by

$$R'(X',Y')Z'\equiv\{\nabla'_{X'}\nabla'_{Y'}-\nabla'_{Y'}\nabla'_{X'}-\nabla'_{[X',Y']'}+2A(X',Y')\mathcal{L}'_u\}Z'. \tag{4.10}$$

It is to be noted that for tensors of an arbitrary type the projection operators are constructed by the tensor product of the operators (4.2) and their transposes. If one does no more than $(n+1)$ decomposition of objects only from the Cartan algebra of exterior forms on M then the universal invariant construction of the projection operators is feasible (see, for example, Ref. 33 for the (3+1) decomposition).

V. $(n+m)$ DECOMPOSITION OF A PSEUDO-RIEMANNIAN MANIFOLD IN A COORDINATE FORM

In order to obtain a coordinate form of the invariant objects it is necessary to choose coordinate covector and vector bases $\{\partial_\mu=\partial/\partial x^\mu\}$, $\{dx^\mu\}$ in the domain U of some map x^μ $(\mu,\nu,\rho,\ldots=1,2,\ldots,n,n+1,\ldots,n+m)$. Then we can find all the relations given above with respect to this basis, i.e., in covariant form.

Thus in the case of an $(n+m)$ decomposition one has

$$H'=h'^{\nu}_{\mu}\partial_\nu\otimes dx^\mu=h'^{\nu}_{\mu}\partial'_\nu\otimes d'x^\mu;\quad \partial'_\mu\equiv h'^{\nu}_{\mu}\partial_\nu,\quad d'x^\mu\equiv h'^{\mu}_{\nu}dx^\nu,$$

$$H''=h''^{\nu}_{\mu}\partial_\nu\otimes dx^\mu=h''^{\nu}_{\mu}\partial''_\nu\otimes d''x^\mu;\quad \partial''_\mu\equiv h''^{\nu}_{\mu}\partial_\nu,\quad d''x^\mu\equiv h''^{\mu}_{\nu}dx^\nu,$$

$$h'^{\nu}_{\mu}h'^{\mu}_{\rho}=h'^{\nu}_{\rho};\quad h''^{\nu}_{\mu}h''^{\mu}_{\rho}=h''^{\nu}_{\rho};\quad h'^{\nu}_{\mu}h''^{\mu}_{\rho}=0;\quad h'^{\nu}_{\mu}+h''^{\nu}_{\mu}=\delta^\nu_\mu, \tag{5.1}$$

$$g=g'+g''=g'_{\mu\nu}d'x^\mu\otimes d'x^\nu+g''_{\mu\nu}d''x^\mu\otimes d''x^\nu,$$

$$g_{\mu\nu}\equiv\partial_\mu\cdot\partial_\nu=g'_{\mu\nu}+g''_{\mu\nu};\quad g'_{\mu\nu}=h'^{\rho}_{\mu}h'^{\sigma}_{\nu}g_{\rho\sigma}\quad g''_{\mu\nu}=h''^{\rho}_{\mu}h''^{\sigma}_{\nu}g_{\rho\sigma}. \tag{5.2}$$

Further, introducing the definitions

$$[\partial'_\mu,\partial'_\nu]'\equiv\lambda^{\rho'}_{\mu'\nu'}\partial'_\rho;\quad [\partial'_\mu,\partial''_\nu]'\equiv\lambda^{\rho'}_{\mu'\nu''}\partial'_\rho;\quad [\partial''_\mu,\partial''_\nu]'\equiv-2A^{\rho'}_{\mu''\nu''}\partial'_\rho, \tag{5.3}$$

$$\nabla'_{\partial'_\mu}\partial'_\nu\equiv L^{\rho'}_{\mu'\nu'}\partial'_\rho;\quad B'\equiv B^{\rho'}_{\mu''\nu''}\partial'_\rho\otimes d''x^\mu\otimes d''x^\nu; \tag{5.4}$$

one has

$$L^{\rho'}_{\mu'\nu'}=d'x^\rho(\nabla_{\partial'_\mu}\partial'_\nu);\quad B^{\rho'}_{\mu''\nu''}=dx'^{\rho}(\nabla_{\partial''_\mu}\partial''_\nu)=S^{\rho'}_{\mu''\nu''}+A^{\rho'}_{\mu''\nu''}, \tag{5.5}$$

$$2A^{\rho'}_{\mu''\nu''}=h''^{\omega}_{\mu}h''^{\gamma}_{\nu}(h'^{\rho}_{\gamma,\omega}-h'^{\rho}_{\omega,\gamma});\quad 2S_{\rho'\mu''\nu''}=\partial'_\rho g''_{\mu\nu}+g''_{\mu\sigma}\lambda^{\sigma''}_{\nu''\rho'}+g''_{\sigma\nu}\lambda^{\sigma''}_{\mu''\rho'}. \tag{5.6}$$

Here $h_\gamma\equiv\partial h/\partial x^\gamma$; $\mu',\nu',\rho',\ldots,\mu'',\nu'',\rho'',\ldots=1,2,...,n,n+1,...,n+m$. The indices "$'$" and "$''$" indicate that the corresponding objects are associated with the subbundles Σ' and Σ'', respectively. From the previous formulas it follows that there are the objects which are associated with both subbundles Σ' and Σ''. For instance, the tensor of extrinsic nonholonomicity $B^{\rho'}_{\mu''\nu''}$ is a contravariant vector on the subbundle Σ', and a covariant tensor of rank 2 on the subbundle Σ''.

The other necessary objects can be found by substituting "$'$" for "$''$" and vice versa. Using these formulas we can obtain the Gauss–Codazzi–Ricci's equations in terms of the introduced objects. If $n=m=2$, our treatment is reduced to the dyadic formalism (see Ref. 16).

In the case of an $(n+1)$ split structure (see Sec. IV), we have $u=u^\mu\partial_\mu$, $(\mu,\nu=1,2,...,n,n+1)$, and

$$u_\mu u^\mu=\epsilon=\pm1,\quad h''^{\nu}_{\mu}=\epsilon u_\mu u^\nu,\quad h'^{\nu}_{\mu}=\delta^\nu_\mu-\epsilon u_\mu u^\nu,$$

$$g_{\mu\nu}=\epsilon u_\mu u_\nu+g'_{\mu\nu};\quad g^{\mu\nu}=\epsilon u^\mu u^\nu+g'^{\mu\nu}, \tag{5.7}$$

$$g'_{\mu\nu}=h'^{\alpha}_{\mu}h'^{\beta}_{\nu}g_{\alpha\beta};\quad g'^{\mu\nu}=h'^{\mu}_{\alpha}h'^{\nu}_{\beta}g^{\alpha\beta}, \tag{5.8}$$

$$\partial'_\mu=h'^{\nu}_{\mu}\partial_\nu;\quad [\partial'_\mu,\partial'_\nu]=\epsilon A_{\mu\nu}u;\quad [\partial'_\mu,u]=-F_\mu u, \tag{5.9}$$

$$2A_{\mu\nu}=h'^{\rho}_{,\mu}h'^{\sigma}_{,\nu}(u_{\rho,\sigma}-u_{\sigma,\rho});\quad F_\mu=(u_{\mu,\nu}-u_{\nu,\mu})u^\nu;\quad 2S_{\mu\nu}=\mathcal{L}_u g'_{\mu\nu}. \tag{5.10}$$

Replacing all the objects in (4.7)–(4.9) by these relations we can find the components of the curvature tensor. Furthermore if we consider the $(3+1)$ decomposition of a relativistic space–time, our formalism is reduced to the monad method,[11–15] and to his special gauges. In this case abstract geometrical objects will have an explicit physical meaning. So, one can think of $A_{\mu\nu}$ as the local angular velocity tensor of the frame of reference. The first curvature vector of the congruence F_μ determines the acceleration of the reference body in a given point, and $S_{\mu\nu}$ is the rate of strain tensor.[17]

VI. $(n+m)$ DECOMPOSITION WITH RESPECT TO AN ADOPTED BASIS

To find all the relations considered above in an $(n+m)$ decomposed form for some fixed basis is a question of great significance for applications. The coordinate form of $(n+m)$ decomposition considered in Sec. V is rather cumbersome, and the objects themselves prove to be singular. One of the reasons of this is that the range of indices $\mu', \mu'', \dots$ is redundant. Therefore it is more convenient for applications to choose the adopted bases of $(n+m)$ decomposition which will eliminate such redundancy. One's choice of one basis or another is dictated by a physical situation, requirements of an interpretation of results, or just by the necessity to use the most comfortable way of calculation. We shall present here the invariant relations of Sec. III with respect to an adopted basis of decomposition. Note that in such a form the formulas will be quite feasible for any concrete basis of decomposition. All the known types of decomposition (for torsion free theories) can be obtained as special cases of the present formalism by choosing the corresponding bases. In an $(n+m)$ decomposed form our method is essentially useful for calculation of the Riemann tensor, the Ricci tensor, and the curvature scalar by computer.

We shall now consider two adopted dual bases of decomposition; a vector one $\{E_\mu\} = \{E_a, E_i\}$ on $T(M)$, and a covector basis $\{\theta^\mu\} = \{\theta^a, \theta^i\}$ on $T^*(M)$, where $E_b \in \Sigma' \equiv \Sigma^n$, $E_i \in \Sigma'' \equiv \Sigma^m$; $\theta^a \in \Sigma^{*\prime} \equiv \Sigma^{*n}$; $\theta^i \in \Sigma^{*\prime\prime} \equiv \Sigma^{*m}$. According to (3.4)–(3.5) we have

$$\theta^a(E_b) = \delta^a_b, \quad \theta^a(E_j) = 0; \quad \theta^i(E_b) = 0; \quad \theta^i(E_k) = \delta^i_k, \tag{6.1}$$

$$E_b \cdot E_k = 0, \quad \langle \theta^a, \theta^i \rangle = 0. \tag{6.2}$$

It should be emphasized that the indices $a, b, c, \dots$ and $i, j, k, \dots$ indicate the subbundles Σ^n, Σ^{*n} and Σ^m, Σ^{*m}, respectively. With respect to the basis $\{E_\mu\}$, $\{\theta^\mu\}$ one has

$$H' = E_a \otimes \theta^a; \quad H'' = E_i \otimes \theta^i; \quad g = g' + g'' = \gamma_{ab}\theta^a \otimes \theta^b + h_{ik}\theta^i \otimes \theta^k, \tag{6.3}$$

where $\gamma_{ab} = E_a \cdot E_b$ and $h_{ik} = E_i \cdot E_k$ are the components of the metrics g', g'' induced on the subbundles Σ^n and Σ^m.

Then we introduce the definitions

$$\begin{aligned} \nabla'_{E_a} E_b &= L^c_{ab} E_c; \quad \nabla''_{E_i} E_j = L^k_{ij} E_k; \\ B'(E_i, E_k) &= B^a_{ik} E_a; \quad B''(E_a, E_b) = B^i_{ab} E_i, \end{aligned} \tag{6.4}$$

$$\begin{aligned} [E_a, E_b]' &= \lambda^c_{ab} E_c; \quad [E_i, E_j]'' = \lambda^k_{ij} E_k; \\ [E_a, E_i]' &= \lambda^b_{ai} E_b; \quad [E_i, E_a]'' = \lambda^k_{ia} E_k, \end{aligned} \tag{6.5}$$

where L^c_{ab} and L^i_{jl} are the coefficients of connections ∇' induced on Σ^n and ∇'' induced on Σ^m. Similarly B^c_{ik} and B^i_{ab} are the coefficients of the tensors of extrinsic nonholonomicity of the subbundles Σ^m and Σ^n, respectively. Using the identity (2.14) one can find

$$\begin{aligned} L^c_{ab} &= \Delta^c_{ab} + \gamma^c_{ab}; \quad L^i_{jk} = \Delta^i_{jk} + \gamma^i_{jk}; \\ B^a_{ik} &= S^a_{ik} + A^a_{ik}; \quad B^i_{ab} = S^i_{ab} + A^i_{ab}, \end{aligned} \tag{6.6}$$

where

$$2\Delta_{cab} = E_a\gamma_{bc} + E_b\gamma_{ac} - E_c\gamma_{ab}; \quad 2\gamma_{cab} = \lambda_{cab} + \lambda_{bca} - \lambda_{abc}, \tag{6.7}$$

$$\begin{aligned} 2S_{aik} &= (\mathcal{L}_{E_a} g'')(E_i, E_k) = E_a h_{ik} + \lambda_{ika} + \lambda_{kia}; \\ 2A^a_{ik} &= (d\theta^a)(E_i, E_k); \quad 2A_{aik} = -E_a \cdot [E_i, E_k]. \end{aligned} \tag{6.8}$$

The coefficients $A_{iab}, S_{iab}, \gamma_{ijk}, \Delta_{ijk}$, unwritten here, can be obtained from (6.7)–(6.8) by the replacement $(a,b,c,\ldots \leftrightarrow i,j,k,\ldots)$. Adhering to this style here and below we shall write and discuss only those relations which can not be found by the change of indices. We should remind also that the indices $a,b,c,\ldots$ are raised and lowered by the metrics γ^{ab} and γ_{ab}. The curvature tensor and its contractions are presented in Appendix B.

In the special case of $(n+1)$ decomposition, i.e., when $m=1$ one has adopted bases $\{E_\mu\} = \{E_a, E\}$, $\{\theta^\mu\} = \{\theta^a, \theta\}$, $(a,b=1,2,...,n)$, so that

$$\begin{gathered}\theta^a(E_b) = \delta^b_a; \quad \theta_a(E) = 0 = \theta(E_a); \\ \theta(E) = 1; \quad E\cdot E_a = 0; \quad E\cdot E \equiv \epsilon N^2,\end{gathered} \tag{6.9}$$

where $\{E_a\} \in \Sigma^n$; $\theta^a \in \Sigma^{*n}$ and $E \in \Sigma^1$; $\theta \in \Sigma^{*1}$. In this case the projectors $H' = E_a \otimes \theta^a$ and $H'' = E \otimes \theta$ induce the decomposition of the metric

$$g = g' + g'' = \gamma_{ab}\theta^a \otimes \theta^b + \epsilon N^2 \theta \otimes \theta. \tag{6.10}$$

Then using the relations (6.4)–(6.8), (B1)–(B9), when $i=j=k=1$ or (4.4)–(5.1) when $u = N^{-1}E$, $\omega = N\theta$ we can find all the necessary relations in the $(n+1)$ decomposed form in an adopted basis. Thus, from (4.4) it follows that

$$F = N^{-2}(G - (E \log N)E); \quad G = \nabla_E E. \tag{6.11}$$

The tensor of extrinsic nonholonomicity of the subbundle Σ^n can be written in the form

$$B(E_a, E_b) = \epsilon S_{ab} + A_{ab} \equiv \epsilon N^{-1}\mathcal{B}_{ab}; \quad 2\mathcal{B}_{ab} = 2D_{ab} + F_{ab}, \tag{6.12}$$

where

$$\begin{gathered}S_{ab} = N^{-1}D_{ab}; \quad 2D_{ab} = (\mathcal{L}_E g')(E_a, E_b) = E\gamma_{ab} + E_a\cdot[E_b, E] + E_b\cdot[E_a, E]; \\ 2A_{ab} = \epsilon N^{-1}F_{ab}; \quad F_{ab} = \epsilon N^2 (d\theta)(E_a, E_b) = -E\cdot[E_a, E_b].\end{gathered} \tag{6.13}$$

Acting in the same way as in the previous sections we can find the generalized Gauss–Codazzi–Ricci's equations (see Appendix C).

VII. CANONICAL PARAMETRIZATION OF AN $(n+m)$ SPLIT STRUCTURE AND ITS SPECIAL CASES

The relations of Sec. VI are invariant under the transformation of adopted bases,

$$\theta^a = L^a_b e^b; \quad \theta^l = L^l_k e^k; \quad E_a = (L^{-1})^b_a e_b; \quad E_i = (L^{-1})^k_i e_k, \tag{7.1}$$

where $\{L^a_b\}$ and $\{L^k_i\}$ are $(n\times n)$ and $(m\times m)$ nonsingular matrices, and $\{(L^{-1})^b_a\}$ and $\{(L^{-1})^k_i\}$ are their inverse matrices. Using this property of invariance one can choose, without loss of generality, the simplest basis of decomposition which is useful for applications.

For this purpose we consider the expansion of the covector basis on Σ^{*m} in the domain U of definition of the map x^μ $(\mu = 1,2,...,n,n+1,...,n+m)$, i.e., $\theta^i = \theta^i_\mu dx^\mu$. Due to the fact that the rank of the $n\times(n+m)$ matrix $\{\theta^i_\mu\}$ is equal to n, there is an $(m\times m)$ nonsingular matrix $\{\theta^i_k\}$ as a box in $\{\theta^i_\mu\}$. Then the covectors θ^i can be written in the form, $\theta^i = \theta^i_k dx^k + \theta^i_a dx^a = L^i_k(dx^k + N^k_a dx^a) \equiv L^i_k e^k$, where $L^i_k = \theta^i_k$, $N^k_a = (L^{-1})^k_i \theta^i_a$. Thus the covector basis θ^i goes over into the new covector basis $e^k \in \Sigma^{*m}$. The vector basis on Σ^n can be written similarly as $E_a = E^\mu_a \partial_\mu$. From the condition of duality $e^k(E_a) = 0$ it follows that $E_a = (L^{-1})^b_a(\partial_b - N^k_b \partial_k) \equiv (L^{-1})^b_a e_b$, where $(L^{-1})^b_a = E^b_a$. Thereby we defined the new vector basis $e_b \in \Sigma^n$. The other vector and covector bases ($e^i \in \Sigma^m$ and $e^a \in \Sigma^{*n}$, respectively) are defined by the condition of duality up to $(n\cdot m)$ functions B^a_i. As a result one obtains the following parametrization of the basis of decomposition:

$$e^a = dx^a + B_i^a e^i \in \Sigma^{*n}; \quad e_a = \partial_a - N_a^i \partial_i \in \Sigma^n;$$
$$e^i = dx^i + N_a^i dx^a \in \Sigma^{*m}; \quad e_i = \partial_i - B_i^a e_a \in \Sigma^m. \tag{7.2}$$

We shall call this parametrization the canonical one.

If one follows similar procedure beginning with the covector basis $\theta^a \in \Sigma^{*n}$, one will obtain the other canonical parametrization of $(n+m)$ decomposition,

$$e^a = dx^a + A_i^a dx^i \in \Sigma^{*n}; \quad e_a = \partial_a - M_a^k e_k \in \Sigma^n;$$
$$e^i = dx^i + M_a^i e^a \in \Sigma^{*m}; \quad e_k = \partial_k - A_k^a \partial_a \in \Sigma^m. \tag{7.3}$$

When some metric g is fixed on M, the functions B_i^a (or M_a^i) can be found from the condition of orthogonality (6.2) in terms of $g_{\mu\nu}$ and N_a^i (or A_k^b). If, otherwise, we fix B_i^a (or M_a^i), then we can obtain the metric for both cases according to (6.3):

$$g = \gamma_{ab}(dx^a + B_i^a e^i) \otimes (dx^c + B_k^c e^k) + h_{ik} e^i \otimes e^k,$$
$$g = \gamma_{ab} e^a \otimes e^b + h_{ik}(e^i + M_a^i e^a) \otimes (e^k + M_b^k e^b). \tag{7.4}$$

With respect to the canonically parametrized basis (7.2), the objects (6.6)–(6.8) and the Lie bracket of the basic vector fields have the form

$$\lambda_{ab}^c = -2B_i^c A_{ab}^i; \quad \lambda_{ij}^k = (B_i^a e_j - B_j^a e_i) N_a^k;$$
$$\lambda_{ai}^c = -e_a B_i^c + 2A_{ab}^k B_i^b B_k^c + N_{a,i}^k B_k^c; \quad \lambda_{ia}^k = -2A_{ac}^k B_i^c - N_{a,i}^k,$$
$$2A_{ab}^i = e_b N_a^i - e_a N_b^i; \quad 2A_{ij}^a = e_i B_j^a - e_j B_i^a - \lambda_{ij}^k B_k^a, \tag{7.5}$$
$$2S_{aik} = (\mathcal{L}_{e_a} h)(e_i, e_k); \quad 2S_{iab} = (\mathcal{L}_{e_i} \gamma)(e_a, e_b),$$

where $\gamma = \gamma_{ab} e^a \otimes e^b$ and $h = h_{ik} e^i \otimes e^k$. Here all the geometrical characteristics are expressed in terms of the functions $h_{ij}, \gamma_{ab}, B_i^a, N_b^k$ and their derivatives. Substituting the objects (7.5) for those used in (B2)–(B8) we can obtain the Riemann tensor, the Ricci tensor and the scalar curvature in an $(n+m)$ decomposed form with respect to the canonically parametrized basis (7.2). All the relations for the parametrization (7.3) are found from (7.5) by the substitution $(a,b \leftrightarrow i,j;\ B_i^a \rightarrow M_a^i,\ N_a^i \rightarrow A_i^a)$.

In the case of $(n+1)$ decomposition both types of parametrizations should be considered independently. Thus for the (3+1) monad method there are two kinds of canonical parametrizations (with respect to local coordinates $\{x^\mu\} = \{t, x^i\}$) determined by

$$e_0 = \partial_t - N^i \partial_i = Nu; \quad e^0 = dt + B_i e^i = N^{-1}\omega;$$
$$e_i = \partial_i - B_i e_0; \quad e^i = dx^i + N^i dt, \tag{7.6}$$

and

$$e_0 = \partial_t - M^i e_i = Vu; \quad e^0 = dt + A_i dx^i = V^{-1}\omega;$$
$$e_i = \partial_i - A_i \partial_i; \quad e^k = dx^k + M^k e^0, \tag{7.7}$$

where u is a monad vector, ω is a one-form of time such that $\omega(u) = 1$.

The first set of bases (7.6) is the generalization of the well-known ADM parametrization.[18] In this case the metric has the form

$$ds^2 = N^2(dt + B_j e^j)^2 - h_{ik} e^i e^k, \quad (e^i = dx^i + N^i dt). \tag{7.8}$$

The second set of bases (7.7) implies that the metric is given by

$$ds^2 = V^2(e^0)^2 - h_{ik}(dx^i + M^i e^0)(dx^k + M^k e^0), \tag{7.9}$$

where $e^0 = dt + A_j dx^j$.

The latter parametrization is the generalization of those often used when describing stationary spaces. It is worth emphasizing that the redundant ''degrees of freedom'' of the metrics (7.8)–(7.9) may be used to fix a frame of reference or to simplify the Einstein equations. In the theory of stationary configurations, representation (7.9) is useful for examining of solutions, for which a flux of matter and the timelike Killing's vectors are noncollinear (so-called skew solutions[21]).

If B_j vanishes the metric (7.8) goes over into the standard ADM parametrization,

$$ds^2 = N^2 dt^2 - h_{ik}(dx^i + N^i dt)(dx^k + N^k dt). \tag{7.10}$$

When M^k vanishes, the metric (7.9) has the form

$$ds^2 = V^2(dt + A_j dx^j)^2 - h_{ik} dx^i dx^k. \tag{7.11}$$

This parametrization is often used when describing stationary spaces. If we take $N^i = 0$ or $A_j = 0$ for the metrics (7.10) and (7.11), respectively, then in both cases we have

$$ds^2 = g_{00} dt^2 - h_{ik} dx^i dx^k. \tag{7.12}$$

This kind of decomposition corresponds to a trivial case when Σ^3 is a family of hypersurfaces, where each of the hypersurfaces is orthogonal to the curves $x^i = \text{const}$. This decomposition is invariant under the transformations

$$t = t(t'), \quad x^i = x^i(x'^k). \tag{7.13}$$

The three-dimensional part of these transformations acts uniformly on all the hypersurfaces. Now we shall start, otherwise, from three-dimensional transformations (7.13) which can be extended to the gauge ones by supposing that they depend on time, i.e.,

$$t = t(t'), \quad x^i = x^i(t', x'^k). \tag{7.14}$$

These transformations, under which the hypersurfaces $t = \text{const}$ remain unchanged, have been called the kinemetric ones.[12] In order that the decomposition of the metric be invariant with respect to (7.14) we must ''make longer'' the time derivative $\partial_t \to \partial_t - N^i \partial_i$ (simultaneously we take $dx^i \to dx^i + N^i dt$) by using the gauge vector N^i. Thus it leads to the kinemetric method of decomposition,[12] which coincides with the ADM representation.[18]

Similarly extending the transformations of time we obtain the chronometric transformations[11]

$$t = t(t', x^{k\prime}), \quad x^i = x^i(x'^k). \tag{7.15}$$

It is obvious that the transformations (7.15) do not change the congruence of world lines $x^i = \text{const}$. According to Zelmanov[11] these transformations have been taken as a basis for the definition of the frame of reference. ''Making longer'' the time differential $dt \to dt + A_i dx^i$ (herewith $\partial_i \to \partial_i - A_i \partial_t$) we obtain the chronometric method of decomposition. The transformations (7.15) and (7.14) are the complements of one another and form together the general covariant transformations $x^\mu = x^\mu(x'^\nu)$.

Further generalizations of (7.10) and (7.11) lead to various parametrizations of the monad method. Thus, making longer dt, $dt \to dt + B_i e^i$ $(\partial_i \to \partial_i - B_i e_0)$ one has the canonical parametrization (7.6), (7.8). Making longer ∂_t, $\partial_t \to \partial_t - M^i e_i$ $(dx^k \to dx^k + M^k e_0)$ one obtains the other canonical parametrization (7.7), (7.9) of the monad method for M^4. ''Lengthening'' as referred to is connected with an extension of the admissible transformations, which are not coordinate but basic ones. The generalization (7.8) of the ADM parametrization is invariant under the transformations

$$\tilde{e}^k = \alpha_i^k e^i, \quad \tilde{h}_{ij} = \alpha_i^m \alpha_j^n h_{mn}, \quad \tilde{B}_j = \alpha_j^k B_k. \tag{7.16}$$

If we write the inverse of the metric (7.9),

$$(\partial_s)^2 = V^{-2}(\partial_t - M^i e_i)^2 - h^{ik} e_i e_k, \tag{7.17}$$

then it easily can be seen that the metric (7.9) is invariant under the transformations

$$\tilde{e}_i = \beta_i^k e_k, \quad \tilde{h}^{ij} = \beta_m^i \beta_n^j h^{mn}, \quad \tilde{M}^i = \beta_k^i M^k. \tag{7.18}$$

In (7.16), (7.18), $\{\alpha_k^i\}$ and $\{\beta_k^i\}$ are nonsingular matrices depending on a point p of M. From this we can clearly see the role of the parametrizations (7.8), (7.9) as such generalizations of the kinemetric and chronometric methods that the corresponding metrics admit nonholonomic transformations of spatial vector and covector bases (7.16) and (7.18), respectively.

VIII. DECOMPOSITION INDUCED BY A FAMILY OF SURFACES

Let $\{M^m \subset M\}$ be an n-parameter family of m-dimensional surfaces. One may think of these surfaces as intersections of the hypersurfaces $x^a = \text{const}$, i.e., $M^m = \cap_a \{x^a = \text{const}\}$. It is obvious that such a family induces $(n+m)$ decomposition of M. Indeed, there exists the vector basis $e_i = \partial_i$ on $T(M)$, $(i = n+1,...,n+m)$, because of holonomicity of the M^m itself. As a consequence of it, the covector basis on the dual to $T(M^m)$ subbundles Σ^{*n} is a set of one-forms $\{e^a = dx^a\}$. The corresponding dual bases to the bases $\{e_i\}$ and $\{e^a\}$ are determined up to $(n \cdot m)$ functions N_a^i such that

$$\begin{aligned} e^a &= dx^a \in \Sigma^{*n}, \quad e_a = \partial_a - N_a^i \partial_i \in \Sigma^n, \\ e^i &= dx^i + N_a^i dx^a \in \Sigma^{*m}, \quad e_i = \partial_i \in \Sigma^m. \end{aligned} \tag{8.1}$$

The functions N_a^i are expressed in terms of the components of the metric g by using the condition of orthogonality $e_a \cdot e_i = 0$. Thus the projection operators and the metric have the form

$$H' = (\partial_a - N_a^i \partial_i) \otimes dx^a, \quad H'' = \partial_k \otimes (dx^k + N_a^k dx^a), \tag{8.2}$$

$$g = \gamma_{ab} dx^a \otimes dx^b + h_{ik}(dx^i + N_c^i dx^c) \otimes (dx^k + N_d^k dx^d). \tag{8.3}$$

From the form of the metric (8.3) it can be seen that here we used the special case of canonical parametrization of $(n+m)$ decomposition (7.2) when B_i^a vanishes. In this case the formulas (7.5) become much simpler. Thus, one finds

$$\lambda_{ab}^c = 0; \quad \lambda_{ij}^k = 0; \quad \lambda_{ai}^c = 0; \quad \lambda_{ia}^k = -N_{a,i}^k; \quad A_{ij}^a = 0; \tag{8.4}$$

$$2S_{iab} = \gamma_{ab,i}; \quad 2A_{ab}^i = e_b N_a^i - e_a N_b^i, \tag{8.5}$$

$$2S_{aik} = h_{ik,a} - h_{ik,l} N_a^l - h_{lk} N_{a,i}^l - h_{il} N_{a,k}^l, \tag{8.6}$$

$$2L_{cab} = 2\Delta_{cab} = e_a \gamma_{bc} + e_b \gamma_{ca} + e_c \gamma_{ab}, \tag{8.7}$$

$$2L_{ijk} = 2\Delta_{ijk} = h_{ij,k} - h_{ik,j} - h_{jk,i}. \tag{8.8}$$

The partial derivatives with respect to coordinates x^i and x^a are denoted here by i and a, respectively. Then, according to (B2)–(B8), one can find the curvature tensor and its contractions.

IX. DECOMPOSITION INDUCED BY A GROUP OF ISOMETRIES

Let M assume to a nontransitive group of isometries G^n with the n linearly independent Killing's vectors $\{\xi_a\}$, which satisfy the relations

$$[\xi_a,\xi_b]=C^d_{ab}\xi_d \quad (a,b,d=1,2,...,n), \tag{9.1}$$

where the C^d_{ab} are the structure constants and obey the Jacobi identity $C^c_{[ab}C^f_{d]c}=0$ and the condition $C^c_{ab}+C^c_{ba}=0$. In addition, the metric g satisfies the Killing's equations,

$$(\mathcal{L}_{\xi_a}g)(X,Y)=\xi_a(X\cdot Y)-[\xi_a,X]\cdot Y-X\cdot[\xi_a,Y]=0, \quad \forall X,Y\in T(M). \tag{9.2}$$

The group G^n decomposes M into a family of m-codimensional surfaces $\{M^n\}\subset M$, on which G^n is simply transitive ($\{M^n\}$ are invariant manifolds). Thus, we can say that the group G^n induces $(n+m)$ decomposition of M into the m-parameter family of n-dimensional surfaces of transitivity. Then the subbundle $\Sigma^n=\cup T(M^n)$ is a union of the tangent bundles of the family $\{M^n\}$, and Σ^m is a union of all the m-dimensional directions, which are tangent to M and orthogonal to $T(M^n)$.

Now we shall start in the same way as in the previous section. Thus one may think of the surfaces M^n as an intersection of the invariant hypersurfaces $\{x^i=\text{const}\}$, i.e., $M^m=\cap_i\{x^i=\text{const}\}$, $(i=n+1,...,n+m)$. Moreover, one has $dx^i(\xi_a)=\xi_a x^i=0$. This is obvious that the invariant differential one-forms dx^i can be chosen as a covector basis on the subbundles Σ^{*m}. Then there exists the vector basis $\{\partial_a\}\in T(M^n)$, so that $dx^i(\partial_a)=0$ and $\xi_a=\xi^b_{(a)}\partial_b$. Having extended these bases to the "complete ones," $\{dx^i\}\rightarrow\{dx^\mu\}=\{dx^a,dx^i\}\in T^*(M)$ and $\{\partial_a\}\rightarrow\{\partial_\mu\}=\{\partial_a,\partial_i\}\in T(M)$, where $dx^\mu(\partial_\nu)=\delta^\mu_\nu$ and $[\xi_a,\partial_i]=0$, we can define one-forms ω^a such that

$$\omega^a(\xi_b)=\delta^a_b;\quad \omega^a(\partial_i)=0;\quad \mathcal{L}_{\partial_i}\omega^a=0, \tag{9.3}$$

$$\mathcal{L}_{\xi_a}\omega^b=-C^b_{ad}\omega^d;\quad 2d\omega^a=C^a_{bd}\omega^b\wedge\omega^d. \tag{9.4}$$

Let us now introduce an auxiliary definition. We shall say that a split structure $\mathcal{H}^2$ is compatible with a group of isometries if the conditions of invariance of $\mathcal{H}^2$ are satisfied, i.e., if

$$\mathcal{L}_{\xi_a}H'=0,\quad \mathcal{L}_{\xi_a}H''=0,\quad (a=1,2,...,n). \tag{9.5}$$

Using (6.3) and (9.1) one can easily verify that for the other vector and covector bases $\{E_k\}\in\Sigma^m$ and $\{\theta^a\}\in\Sigma^{*n}$ we have, respectively,

$$\mathcal{L}_{\xi_a}\theta^b=-C^b_{ad}\theta^d;\quad \mathcal{L}_{\xi_a}E_k=0. \tag{9.6}$$

To concretize the basis of decomposition we take $\theta^a=\theta^a_\mu dx^\mu$ and $E_i=E^\mu_i\partial_\mu$. Then the conditions of duality $\theta^a(\xi_b)=\delta^a_b$, $\theta^a(E_i)=0$, $dx^k(E_i)=\delta^k_i$ determine these bases up to $(n\cdot m)$ functions A^a_i. As a result the basis of $(n+m)$ decomposition has the form

$$\begin{gathered}\xi_a\in\Sigma^n;\quad e^a=\omega^a+A^a_i dx^i\in\Sigma^{*n},\\ e_i=\partial_i-A^a_i\xi_a\in\Sigma^m;\quad dx^k\in\Sigma^{*m},\quad [\xi_a,e_i]=0.\end{gathered} \tag{9.7}$$

The projection operators and the metric can be written as

$$H'=\xi_a\otimes(\omega^a+A^a_i dx^i);\quad H''=(\partial_i-A^a_i\xi_a)\otimes dx^i, \tag{9.8}$$

$$g=g'+g''=\gamma_{ab}(\omega^a+A_i^a dx^i)\otimes(\omega^b+A_j^b dx^j)+h_{kl}dx^k\otimes dx^l. \tag{9.9}$$

From the Killing's equations one finds

$$\xi_a\gamma_{bc}-C_{ab}^d\gamma_{dc}-C_{ac}^d\gamma_{bd}=0;\quad \xi_a A_i^b-C_{ad}^b A_i^d=0;\quad \xi_a h_{ik}=0. \tag{9.10}$$

Using these equations we obtain the main geometrical objects

$$\begin{gathered}A''(\xi_a,\xi_b)=0;\quad 2A'(e_i,e_k)\equiv F_{ik}^a\xi_a,\\ F_{ik}^a=A_{k,i}^a-A_{i,k}^a+C_{bd}^a A_k^b A_i^d,\\ S'(e_i,e_k)=0;\quad 2e_i\cdot S''(e_a,e_b)\equiv 2S_{iab}=e_i\gamma_{ab},\\ 2L_{abc}=C_{cab}+C_{bca}+C_{acb};\\ 2L_{ijk}=2\Delta_{ijk}=e_jh_{ik}+e_kh_{ij}-e_ih_{jk}.\end{gathered} \tag{9.11}$$

In the end, from relations (B2)–(B8) we can find the curvature tensor, the Ricci tensor, and scalar curvature (see Appendix D). When $m=0$ we come to the case of homogeneous spaces.

X. LAGRANGIANS OF THE UNIFIED MULTIDIMENSIONAL KALUZA–KLEIN THEORIES

The mathematical model we shall use for spaces of the unified theories is the totality of the following objects: (a) a connected $(4+n)$-dimensional pseudo-Riemannian C^∞ manifold M^{4+n} with a nonsingular metric g on it; (b) an n-parameter compact group of isometries G^n on M^{4+n} with linearly independent Killing's vectors $\xi_a\in T(M^{4+n})$ for which the structure constants C_{bd}^a satisfy the condition $C_{ad}^a=0$, $(a,b,d=4,5,...,n+3)$.

The physical space–time $V^4\equiv M^{4+n}/M^n$ is the quotient space M^{4+n} with respect to the invariant manifolds M^n of the group G^n. The V^4 is described by the components h_{ik} of the metric h, by the set of gauge fields A_i^b and by the multiplet $n(n+1)/2$ of scalar fields $\varphi_{ab}\equiv-\gamma_{ab}$. All these tensors are obtained under the $(4+n)$ decomposition of M^{4+n} (see Sec. IX). The true physical configuration is described not by a single set of fields $\{h_{ik},A_j^b,\varphi_{cd}\}$, but by a whole equivalence class of such sets; each of them corresponds to some point of the orbit G^n. The signature of the metric g is defined by two conditions; first, the metric h is a Lorentz one, and second, the energy density is positive for obtained Lagrangian of fields $\{A_j^b,\varphi_{cd}\}$. In addition, the metric g satisfies the $(4+n)$-dimensional variational Hilbert principle for the functional $S[g]$, i.e.,

$$\delta S[g]=\delta\left\{-\frac{1}{4\pi V}\int R^{(4+n)}\Omega^{(4+n)}\right\}=0, \tag{10.1}$$

where $R^{(4+n)}$ is the curvature scalar on $M^{(4+n)}$, the $(4+n)$-form $\Omega^{(4+n)}$ is the volume measure on M^{4+n}, and V is the n-dimensional invariant volume of M^n,

$$V=\int_{M^n}\omega^4\wedge\omega^4\wedge\cdots\wedge\omega^{4+n}\equiv\int_{M^n}\Omega^{(n)}. \tag{10.2}$$

The conditions $C_{ab}^a=0$ follow from the requirement that the volume measure $\Omega^{(n)}$ must be invariant. They are necessary for compatibility of the variational Hilbert principle and homogeneity of M^n with respect to the group of isometries G^n. This restricts the admissible variations of fields $\mathcal{L}_{\xi_a}\delta g=0$ in (10.1). (The similar situation may be found in the theory of homogeneous models of cosmology.[35,36])

Using the formulas of Sec. IX and Appendix D for the metric g in the $(n+4)$ decomposed form

$$g=h_{ik}dx^i\otimes dx^k-\varphi_{ab}(\omega^a+A^a_m dx^m)\otimes(\omega^b+A^b_n dx^n) \tag{10.3}$$

and omitting a divergence of some vector, we obtain

$$S^{(4+n)}[g]=S[\varphi_{ab},A^a_i,h_{jk}]=\int_{V^4}\sqrt{-h}L d^4x. \tag{10.4}$$

The Lagrangian density is

$$\sqrt{-h}L=-\frac{1}{4\pi}\sqrt{|h\varphi|}\left\{R^{(4)}+\frac{1}{4}\varphi_{ab}F^a_{ij}F^{bij}+(\varphi^{ab}\varphi^{cd}-\varphi^{ac}\varphi^{bd})h^{ik}D_i\varphi_{ab}D_k\varphi_{cd}+U(\varphi_{ab})\right\}, \tag{10.5}$$

where

$$U(\varphi_{ab})=\tfrac{1}{2}\varphi^{cd}C^a_{bc}(C^b_{ad}+\tfrac{1}{2}\varphi_{ap}\varphi^{bq}C^p_{qd}), \tag{10.6}$$

and

$$D_i\varphi_{ab}=\varphi_{ab,i}-T(A_i)^d_a\varphi_{db}-T(A_i)^d_b\varphi_{ad} \tag{10.7}$$

is the gauge-invariant derivative. The components $T(A)^a_b\equiv C^a_{bd}A^d$ of the matrix $T(A)$ realize the adjoint representation of the group G^n:$[T(A),T(B)]=T([A,B])$, $A=A^a\xi_a$, $B=B^a\xi_a$. The Lagrangian of this kind (but with the second derivatives of the fields φ_{ab}) has been obtained in Ref. 37.

When $n=1$ the Lagrangian (10.5) reduces to the Lagrangian of the five-dimensional Kaluza–Klein theory.[27] In the static case of spherical symmetry from $n=1$ it follows the Lagrangian of the simple dynamic system. Its equations can be integrated by the separation of variables of the corresponding Hamilton–Jacobi equation. In such a way the solution for the interacting scalar, electromagnetic, and gravitational fields was obtained in Ref. 38 within the framework of the united five-dimensional Kaluza–Klein theory.

XI. RELATIVISTIC CONFIGURATIONS OF A PERFECT FLUID

Let us consider space–time M^4 with the metric g in the $(3+1)$ decomposed form

$$g=V^2e^0\otimes e^0-h_{ik}e^i\otimes e^k,\quad g^{-1}=V^{-2}e_0\otimes e_0-h^{ik}e_i\otimes e_k, \tag{11.1}$$

where g^{-1} is the inverse of the metric g. For the time being, we require the basis of decomposition to be an adopted abstract one (i.e., not concretized). Let the source of the gravitational field described by the metric (11.1) be a perfect fluid with the field of 4-velocities $u=V^{-1}e_0=d/ds$ which is tangent to the flow lines $x^\mu=x^\mu(s)$. Herewith the mass density ρ obeys the conservation law,

$$\mathrm{div}(\rho u)\equiv(\nabla_{e_\mu}\rho u)(e_\mu)=V^{-1}h^{-1/2}\mathcal{L}''_{e_0}(\rho h^{1/2})=0, \tag{11.2}$$

where $\mathcal{L}''_{e_0}$ is the Lie derivative with respect to the basis $\{e_i\}$:$\mathcal{L}''_{e_0}\sqrt{h}=\frac{1}{2}\sqrt{h}h^{ik}(\mathcal{L}_{e_0}h)(e_i,e_k)$. The equation of motion for the fluid follows from the relation,

$$\mathrm{div}\, T\equiv(\nabla_{e_\mu}T)(e^\mu,.)=0. \tag{11.3}$$

The energy-momentum tensor T is

$$T=\mu V^{-2}e_0\otimes e_0+Ph^{ik}e_i\otimes e_k, \tag{11.4}$$

where μ is the energy density of the fluid, P is the pressure. Using the thermodynamic relations

$$d\mathcal{H}=Tds+\rho^{-1}dP,\quad \mathcal{H}=(\mu+P)\rho^{-1}, \tag{11.5}$$

one finds the equations of motion

$$(\operatorname{div} T)(e_0)=\rho TV^{-1}uS=-\rho V^{-1}dS/ds=0, \tag{11.6}$$

$$(\operatorname{div} T)(e_i)=h^{ik}(dP-\rho\mathcal{H}\mathcal{L}_u\omega)(e_k)=0. \tag{11.7}$$

Here we use the following notations: $\mathcal{H}$ is the enthalpy, S is the entropy, T is the temperature, and ω is the covector of the 4-velocity of the fluid ($\omega=Ve^0$, $\omega(u)=1$). We introduce ''the one-form of the enthalpy θ'' and ''the two-form of the curl Ω'' by

$$\theta=\mathcal{H}\omega=\mathcal{H}Ve^0,\quad \Omega=d\theta. \tag{11.8}$$

Then the equations of motion (11.6), (11.7) can be expressed as

$$\mathcal{L}_{e_0}\theta=d(\mathcal{H}V)-VTdS. \tag{11.9}$$

Using the formula $\mathcal{L}_{e_0}=i_{e_0}d+di_{e_0}$, where the operator i_{e_0} is defined by the relation $(i_{e_0}\Omega)(Y)=\Omega(e_0,Y)$, $\forall Y\in T(M^4)$, we obtain one more form of the equations of motion

$$i_{e_0}\Omega=-VTdS. \tag{11.10}$$

The condition of integrability of these relations leads to the equations of motion for the curl of a perfect fluid

$$\mathcal{L}_{e_0}\Omega=-d(TV)\wedge dS. \tag{11.11}$$

In the special case $S=\text{const}$ a perfect fluid is isentropic so that the equations for ''the one-form of the enthalpy'' (11.9) and ''the two-form of the curl'' (11.10), (11.11) are reduced to the relations

$$\mathcal{L}_{e_0}\theta=d(\mathcal{H}V), \tag{11.12}$$

$$i_{e_0}\Omega=0,\quad \mathcal{L}_{e_0}\Omega=0. \tag{11.13}$$

It is to be noted that the last equation in (11.13) is the condition of integrability of the equation (11.12). Moreover we may regard this condition as an invariant formulation of the theorem,[39] which states that the two-form of the curl Ω is constant along the world lines of particles of an isentropic perfect fluid. From the first relation in (11.13) it follows that Ω is singular, i.e., $\Omega(e_0,X)=0$, $\forall X\in T(M^4)$, and therefore ''completely spatial.'' This implies

$$\Omega=\sum_{i,j}\Omega_{ij}e^i\wedge e^j;\quad \Omega\wedge\Omega=d\theta\wedge d\theta=0. \tag{11.14}$$

Since in general case $\theta\wedge d\theta\neq 0$, then according to the theorem Darboux (see, for example, Ref. 23) it follows that there exists such functions ξ, η, ζ that $\theta=d\xi+\eta d\zeta$. This representation has been used in Ref. 40 to construct a number of families of solutions of the Einstein equations for an isentropic perfect fluid.

Now we shall consider the stationary spaces of General Relativity with a timelike Killing's vector ∂_t. Then the equations (11.6), (11.7), as well as their consequences (11.9)–(11.13), go over into the equilibrium conditions of a perfect fluid. For an isentropic stationary flow they admit completely three-dimensional formulation. Indeed, in this case one has

$$\mathcal{L}_{\partial_t}g=0,\quad \mathcal{L}_{\partial_t}e^\mu=0,\quad [\partial_t,e_\mu]=0. \tag{11.15}$$

Then using the parametrization of decomposition (7.7) we deduce that the functions V, A_i, M^k, h_{ik} as well as $\rho, \mu, P, \mathcal{H}$, do not depend on time. We define the vector $\mathbf{M}$ and covector A on the subbundles $\Sigma'' \equiv \Sigma^3$ by

$$\mathbf{M} = M^i \partial_i, \quad A = A_k dx^k. \tag{11.16}$$

In terms of $\mathbf{M}$ and A the conservation law for mass (11.2) is transformed into the three-dimensional equation of continuity of the flow lines

$$\mathrm{div}^{(3)}(\rho \mathbf{M}) \equiv (\nabla_{e_i} \rho \mathbf{M})(e^i) = h^{-1/2} \mathcal{L}_{\mathbf{M}}(\rho h^{1/2}) = 0. \tag{11.17}$$

When $S = \mathrm{const}$ the condition (11.9) may be rewritten in the three-dimensional form as well

$$i_{\mathbf{M}} dA = -d \log(\mathcal{H} V); \quad \mathbf{M}(\mathcal{H} V) = 0. \tag{11.18}$$

From now on the objects and operations are defined in the three-dimensional manifold $t = \mathrm{const}$ with respect to the bases $\{\partial_i\}$ and $\{dx^k\}$. For example, $dA = (1/2) \mathcal{F}_{ik} dx^i \wedge dx^k$, where $\mathcal{F}_{ik} = A_{k,i} - A_{i,k}$. The equilibrium condition (11.18) may be expressed in the form

$$\mathcal{L}_{\mathbf{M}} A = d\{A(\mathbf{M}) - \log(\mathcal{H} V)\} \tag{11.19}$$

showing that the one-form $\mathcal{L}_{\mathbf{M}} \mathbf{A}$ is exact. Hence, as the condition of integrability one obtains the conservation three-dimensional theorem for the curl dA along the three-dimensional flow lines, i.e.,

$$\mathcal{L}_{\mathbf{M}} dA = 0. \tag{11.20}$$

In the case of parametrization (7.6) for the stationary spaces the functions V, B_i, N^k, h_{jk} do not depend on time either. By analogy with (11.19) one has

$$\mathcal{L}_{\mathbf{N}} B = -d \log(\mathcal{H} V), \tag{11.21}$$

where

$$\mathbf{N} = N^i \partial_i, \quad B = B_k dx^k. \tag{11.22}$$

The condition of integrability gives the conservation theorem for the curl of B

$$\mathcal{L}_{\mathbf{N}} dB = 0. \tag{11.23}$$

If one of the two objects A and $\mathbf{M}$ in (11.19) (or $\mathbf{N}$ and B in (11.21)) vanishes then the equilibrium condition of an isentropic perfect fluid has the simple form

$$\mathcal{H} V = V(\mu + p)/\rho = k, \tag{11.24}$$

where k is the constant. Thus the Lagrangian of an isentropic perfect fluid in equilibrium is

$$L_m \equiv -V \sqrt{h} P = (k\rho - \mu V) \sqrt{h} = [k - (1+\epsilon) V] \rho \sqrt{h}, \tag{11.25}$$

where $\epsilon = \epsilon(\rho)$ is the internal energy of the fluid and $\mu = \rho(1+\epsilon)$.

As was noted above, the parametrizations (7.6), (7.7) have spurious degrees of freedom. It means that the vector $\mathbf{M}$ or covector A in (7.7) can be chosen arbitrarily, by using additional physical reasons. Therefore we have a right to introduce the potential of rotation Ψ_1 by the formula

$$\mathcal{L}_{\mathbf{M}} A = d(\log \Psi_1). \tag{11.26}$$

Then the equilibrium condition (11.19) is written as a relation for potentials

$$\Psi_1 HV = C_1 \exp(A_i M^i), \quad C_1 = \text{const} \tag{11.27}$$

and actually gives us the integral of motion. In another case of the parametrization the equilibrium condition (7.6) can be expressed in the form

$$\mathcal{L}_{\mathbf{N}} B = d(\log \Psi_2), \quad \Psi_2 HV = C_2 = \text{const}. \tag{11.28}$$

Thus the potentials Ψ_1 and Ψ_2 are different from each other by the exponential factor $\exp(A_i M^i)$.

ACKNOWLEDGMENTS

We would like to acknowledge M. Korkina and A. Sokolovsky for interesting and helpful discussions, and Yu. Vladimirov for encouragement and continual attention to the theme of this research. The authors wish also to thank M. Godina who was helpful in pointing out some inaccuracies and A. Boroviec for drawing our attention to several important works on the theory of ''almost-product structures.''

APPENDIX A: THE GENERALIZED GAUSS–CODAZZI–RICCI'S EQUATIONS

Replacing all the connections in the definition of the curvature tensor (2.17) by their ''split representatives'' (2.18)–(2.21) we have obtained the invariant nonholonomic generalizations of the Gauss–Codazzi–Ricci's equations,

$$R(X^a,Y^a)Z^a\cdot V^a = R^a(X^a,Y^a)Z^a\cdot V^a + \sum_{c\neq a}\{2A^c(X^a,Y^a)\cdot B^c(Z^a,V^a) + B^c(Y^a,V^a)\cdot B^c(X^a,Z^a) - B^c(X^a,V^a)\cdot B^c(Y^a,Z^a)\}, \tag{A1}$$

$$R(X^a,Y^a)Z^a\cdot V^b = V^b\cdot\{(\nabla^b_{Y^a}B^b)(X^a,Z^a) - (\nabla^b_{X^a}B^b)(Y^a,Z^a)\} + 2Z^a\cdot B^a(A^b(X^a,Y^a),V^b) + \sum_{c\neq a,b}\{2Z^a\cdot Q^a(A^c(X^a,Y^a),V^b) + B^c(X^a,Z^a)\cdot Q^c(Y^a,V^b) - B^c(Y^a,Z^a)\cdot Q^c(X^a,V^b)\}, \tag{A2}$$

$$R(X^a,Y^b)Z^a\cdot V^b = (Z^a\cdot(\nabla^a_{X^a}B^a) + \langle X^a\cdot B^a, Z^a\cdot B^a\rangle)(Y^b,V^b) + (V^b\cdot(\nabla^b_{Y^b}B^b) + \langle Y^b\cdot B^b, V^b\cdot B^b\rangle)(X^a,Z^a) + \sum_{c\neq a,b}\{B^c(X^a,Z^a)\cdot B^c(Y^b,V^b) - Q^c(X^a,V^b)\cdot Q^c(Y^b,Z^a) + V^b\cdot Q^b(\Lambda^c(X^a,Y^b),Z^a)\}, \tag{A3}$$

$$R(X^a,Y^b)Z^a\cdot V^d = V^d\cdot\{(\nabla^d_{Y^b}B^d)(X^a,Z^a) - (\nabla^d_{X^a}Q^d)(Y^b,Z^a) - B^d(Y^b,B^b(X^a_r,Z^a))\} + Z^a\cdot\{B^a(Y^b,Q^b(X^a,V^d)) - B^a(\Lambda^d(X^a,Y^b),V^d)\} + (\langle Y^b\cdot B^b, V^d\cdot B^d\rangle)(X^a,Z^a) - (\langle X^a, B^a, V^d\cdot Q^d\rangle)(Y^b,Z^a) - \sum_{c\neq a,b,d}\{Z^a\cdot Q^a(\Lambda^c(X^a,Y^b),V^d) - B^c(X^a,Z^a)\cdot Q^c(Y^b,V^d) + Q^c(X^a,V^d)\cdot Q^c(Y^b,Z^a)\}, \tag{A4}$$

$$\begin{aligned}R(X^a,Y^b)Z^c\cdot V^d=&V^d\cdot\{(\nabla^d_{Y^b}Q^d)(X^a,Z^c)-(\nabla^d_{X^a}Q^d)(Y^b,Z^c)\}\\&+B^d(X^a,Q^a(Y^b,Z^c))-B^d(Y^b,Q^b(X^a,Z^c))+B^d(\Lambda^c(X^a,Y^b),Z^c)\}\\&+Z^c\cdot\{B^c(Y^b,Q^b(X^a,V^d))-B^c(X^a,Q^a(Y^b,V^d))\\&-Q^c(\Lambda^c(X^a,Y^b),V^d)\}+(\langle Y^b\cdot B^b,V^d\cdot Q^d\rangle)(X^a,Z^c)\\&-(\langle X^a\cdot B^a,V^d\cdot Q^d\rangle)(Y^b,Z^c)+\sum_{f\neq a,b,c,d}\{Q^f(Y^b,V^d)\cdot Q^f(X^a,Z^c)\\&-Q^f(Y^b,Z^c)\cdot Q^f(X^a,V^d)+V^d\cdot Q^d(\Lambda^f(X^a,Y^b),Z^c)\}.\end{aligned}\tag{A5}$$

In the formula (A1) the curvature tensor R^a of the subbundle Σ^a, introduced in Ref. 30, is

$$R^a(X^a,Y^a)Z^a\equiv\left\{\nabla^a_{X^a}\nabla^a_{Y^a}-\nabla^a_{Y^a}\nabla^a_{X^a}-\nabla^a_{[X^a,Y^a]^a}+2\sum_{c\neq a}\mathcal{L}^a_{A^c(X^a,Y^a)}\right\}Z^a.\tag{A6}$$

The covariant derivatives of the values B^d and Q^d are given by

$$(\nabla^b_{X^a}B^b)(Y^a,Z^a)=\nabla^b_{X^a}(B^b(Y^a,Z^a))-B^b(\nabla^a_{X^a}Y^a,Z^a)-B^b(Y^a,\nabla^a_{X^a}Z^a),\tag{A7}$$

$$(\nabla^d_{X^b}B^b)(Y^a,Z^a)=\nabla^d_{X^b}(B^d(Y^a,Z^a))-B^d(\nabla^a_{X^b}Y^a,Z^a)-B^d(Y^a,\nabla^a_{X^b}Z^a),\tag{A8}$$

$$(\nabla^d_{X^a}Q^d)(Y^b,Z^c)=\nabla^d_{X^a}(Q^d(Y^b,Z^c))-Q^d(\nabla^b_{X^a}Y^b,Z^c)-Q^d(Y^b,\nabla^c_{X^a}Z^c).\tag{A9}$$

We also used the definition

$$(\langle Y^b\cdot B^b,V^d\cdot Q^d\rangle)(X^a,Z^c)\equiv\langle Y^b\cdot B^b(X^a,.),V^d\cdot Q^d(.,Z^c)\rangle.\tag{A10}$$

When fixing the vectors X^a, Y^b, V^d, Z^c, the definition (A10) gives us the scalar product $\langle\alpha^{ba},\beta^{dc}\rangle$ of one-forms

$$\alpha^{ba}\equiv Y^b\cdot B^b(X^a,.),\quad \beta^{dc}\equiv V^d\cdot Q^d(.,Z^c).$$

When $n_a=1$ $(a=1,2,...,r)$, i.e., when all the subbundles are one-dimensional, the relations obtained here reduce to the r-dimensional variant of the tetradic method's formulas.[34]

APPENDIX B: COMPONENTS OF THE CURVATURE TENSOR WITH RESPECT TO AN ADOPTED BASIS FOR $(n+m)$ DECOMPOSITION

Due to the definitions

$$\{E_\mu\}=\{E_a,E_i\};\quad R(E_\mu,E_\nu)E_\rho\cdot E_\sigma=R_{\sigma\rho\mu\nu};\quad R(E_\mu,E_\nu)E_\rho=R^\sigma_{\rho\mu\nu}E_\sigma,\tag{B1}$$

the generalized Gauss–Codazzi–Ricci's equations (3.12)–(3.15) have the form

$$R_{abcd}=R^{(n)}_{abcd}+2A^i_{.cd}B_{iba}+B^i_{.cb}B_{ida}+B^i_{.db}B_{ica},\tag{B2}$$

$$R_{ibcd}=B_{icb|d}-B_{idb|c}+2A^k_{.cd}B_{bki}+B^k_{.db}(B_{cik}-\lambda_{kic})-B^k_{.cb}(B_{dik}-\lambda_{kid}),\tag{B3}$$

$$R_{ibcj}=B_{bji|c}-B_{icb|j}-B_{bjk}B_{ci.}{}^k-B_{icd}B_{jb.}{}^d+B_{bki}\lambda^k_{.jc}+B_{bjk}\lambda^k_{.ic}+B_{idb}\lambda^d_{.cj}+B_{icd}\lambda^d_{.bj},\tag{B4}$$

where the curvature tensor of the subbundle Σ^n is defined by its components $R^{(n)}_{abcd}$ according to

$$R^{(n)a}{}_{bcd}=E_cL^a_{db}-E_dL^a_{cb}+L^f_{db}L^a_{cf}-L^f_{cb}L^a_{df}-\lambda^f_{cd}L^a_{fb}+2A^i_{.cd}\lambda^a_{bi}\tag{B5}$$

(and similarly for the replacement $n \to m$ and $a,b,c,\ldots \leftrightarrow i,j,k,\ldots$). Then the components of the Ricci tensor and the curvature scalar have the form

$$R_{bd} = R_{bd}^{(n)} - B_{db|i}^{i} - S_{b|d} + 2A_{ad}^{i} A_{ib.}{}^{a} + 2S_{iad} S^{ia}{}_{b} - S_{b}{}^{ij} S_{dij} + A_{bij} A_{d}{}^{ij} - S_{i} B_{.db}^{i} - B_{.da}^{i} \lambda_{.bi}^{a} - B_{.ab}^{i} \lambda_{.di}^{a}, \tag{B6}$$

$$R_{ia} = B_{ia.|b}^{b} + B_{ai.|k}^{k} - S_{i|a} - S_{a|i} - 2S_{ik}^{b} S_{ab}^{k} - 6A_{ik}^{b} A_{ab}^{k} + S^{k}(B_{aik} - \lambda_{kia}) + S^{b}(B_{iab} - \lambda_{bai}) + B_{ab}^{k} \lambda_{ki.}{}^{b} + B_{ik}^{b} \lambda_{ba.}{}^{k}, \tag{B7}$$

$$R = R^{(n)} = 2S^{i}{}_{|i} - S^{i} S_{i} - S_{ab}^{i} S_{i..}^{ab} - A_{ab}^{i} A_{i..}^{ab} + R^{(m)} - 2S_{|a}^{a} - S^{a} S_{a} - S_{ij}^{a} S_{a.}^{ij} - A_{ij}^{a} A_{a..}{}^{ij}, \tag{B8}$$

where $S^{i} = S_{ab}^{i} \gamma^{ab}$, $S^{a} = S_{ik}^{a} h^{ik}$. The signs ''$_{|i}$'' and ''$_{|a}$'' denote the covariant derivative with respect to the connections L_{mn}^{k} and L_{bc}^{a} in the directions of the vectors E_{i} and E_{a}, respectively. For example,

$$B_{icb|d} = E_{d} B_{icb} - B_{iab} L_{dc}^{a} - B_{ica} L_{db}^{a} \quad (a,b,c \leftrightarrow i,j,k). \tag{B9}$$

The other components of the Ricci tensor and the curvature tensor can be found from (B2)–(B7) by the formal substitution $a,b,c,\ldots$ for $i,j,k,\ldots$ and otherwise.

APPENDIX C: COMPONENTS OF THE CURVATURE TENSOR WITH RESPECT TO AN ADOPTED BASIS FOR $(n+1)$ DECOMPOSITION

The generalized Gauss–Codazzi–Ricci's equations for the metric (6.10) with respect to the basis (6.9) have the form,

$$R_{abcd} = R_{abcd}^{(n)} + \epsilon N^{-2} (\mathcal{B}_{cb} \mathcal{B}_{da} - \mathcal{B}_{db} \mathcal{B}_{ca} + F_{cd} \mathcal{B}_{ba}), \tag{C1}$$

$$R_{n+1,bcd} = N\{(N^{-1} \mathcal{B}_{cb})_{|d} - (N^{-1} \mathcal{B}_{db})_{|c}\} - \epsilon N^{-2} G_{b} F_{cd}, \tag{C2}$$

$$R_{n+1,bc,n+1} = N \mathcal{L}_{E} (N^{-1} \mathcal{B}_{cb}) - \mathcal{B}_{ca} \mathcal{B}_{b.}{}^{a} + \epsilon N^{-2} G_{b} G_{c} - N^{2} (N^{-2} G_{b})_{|c}, \tag{C3}$$

$$R_{bd} = R_{bd}^{(n)} - \epsilon N^{-2} [N \mathcal{L}_{E} (N^{-1} \mathcal{B}_{db}) + D \mathcal{B}_{db} + \tfrac{1}{2} F_{ba} F_{d.}{}^{a} - 2 D_{ba} D_{d.}{}^{a}] + \epsilon (N^{-2} G_{b})_{|d} - N^{-4} G_{b} G_{d}, \tag{C4}$$

$$R_{n+1,a} = N[(N^{-1} \mathcal{B}_{a.}{}^{b})_{|b} - E_{a}(N^{-1} D)] - \epsilon N^{-1} F_{ab} G^{b}, \tag{C5}$$

$$R_{n+1,n+1} = -N E(N^{-1} D) - D_{ab} D^{ab} + \tfrac{1}{4} F_{ab} F^{ab} + N^{2} (N^{-2} G^{a})_{|a} - \epsilon N^{-2} G_{a} G^{a}, \tag{C6}$$

$$R = R^{(n)} - 2\epsilon N^{-1} E(N^{-1} D) - \epsilon N^{-2} (D^{2} + D_{ab} D^{ab} + \tfrac{1}{4} F_{ab} F^{ab}) + 2\epsilon (N^{-2} G_{a})_{|a} - 2N^{-4} G_{a} G^{a}, \tag{C7}$$

$$R^{(n)a}{}_{bcd} = E_{c} L_{db}^{a} - E_{d} L_{cb}^{a} + L_{db}^{f} L_{cf}^{a} - L_{cb}^{f} L_{df}^{a} - \lambda_{cd}^{f} L_{fb}^{a} + \epsilon N^{-2} F_{cd} \lambda_{b}^{a}, \tag{C8}$$

where $\lambda_{b}^{a} = \theta^{a}([E_{b}, E])$ and $R^{(n)} = \gamma^{bd} R_{bd}^{(n)}$; $R_{bd}^{(n)} = R^{(n)a}{}_{bad}$.

APPENDIX D: COMPONENTS OF THE CURVATURE TENSOR FOR A DECOMPOSITION INDUCED BY A GROUP OF ISOMETRIES

The curvature tensor and its contractions with respect to the basis (9.7) for the metric (9.9) have the form,

$$R_{dcab}^{(m+n)} = R_{dcab}^{(n)} + S_{ic[a} S_{b]d}^{i}, \tag{D1}$$

$$R^{(m+n)}_{icab}=S^{k}_{c[a}F_{b]ki}+S_{icd}C^{d}_{.ba}+2S_{id[a}\gamma^{d}_{.b]c}\,, \tag{D2}$$

$$R^{(m+n)}_{ickb}=-S_{ibc;k}+S_{ibd}S_{kc.}{}^{d}+\tfrac{1}{4}F_{ckj}F_{bi.}{}^{j}-\tfrac{1}{2}\gamma^{d}_{.bc}F_{dki}\,, \tag{D3}$$

$$R^{(m+n)}_{ajkl}=F_{aj[l;k]}+F_{bj[k}S_{l]a}{}^{b}+F_{bkl}S^{b}_{ja}\,, \tag{D4}$$

$$R^{(m+n)}_{ijkl}=R^{(m)}_{ijkl}+\tfrac{1}{2}F_{ai[k}F^{a}_{.l]j}-\tfrac{1}{2}F_{aij}F^{a}_{kl}\,, \tag{D5}$$

$$R^{(m)i}_{jlk}=2e_{[k}\Delta^{i}_{l]j}+2\Delta^{m}_{j[l}\Delta^{i}_{k]m}\,,\quad R^{(n)d}_{.cab}=2\gamma^{d}_{q.[a}\gamma_{b]c.}{}^{q}-C^{qd}_{..c}\gamma_{aqb}\,, \tag{D6}$$

$$R^{(m+n)}_{ab}=R^{(n)}_{ab}-S^{i}_{ab;i}-S^{i}_{ab}S_{i}+2S^{i}{}_{ac}S^{\ c}_{ib}+\tfrac{1}{4}F_{aij}F_{b}{}^{ij}\,, \tag{D7}$$

$$R^{(m+n)}_{ai}=\tfrac{1}{2}F_{ai;k}{}^{k}+\tfrac{1}{2}F_{ail}S^{l}+C^{d}_{.ba}S^{b}_{id}-C^{b}_{bd}S^{d}_{ia}\,, \tag{D8}$$

$$R^{(m+n)}_{ik}=R^{(m)}_{ik}-S_{(i;k)}-S_{iab}S_{k}{}^{ab}+\tfrac{1}{2}F_{aij}F^{aj}_{..k}\,, \tag{D9}$$

$$R^{(m+n)}=R^{(n)}+R^{(m)}-2S^{i}_{;i}-S^{i}S_{i}-S^{iab}S_{iab}-\tfrac{1}{4}F^{a}_{ij}F_{a}{}^{ij}\,. \tag{D10}$$

Here $R^{(m)}=h^{ik}R^{(m)}_{ik}$; $R^{(m)}_{ik}=R^{(m)l}_{ilk}$, and $R^{(n)}=\gamma^{bd}R^{(n)}_{bd}$; $R^{(n)}_{bd}=R^{(n)a}_{bad}$. The covariant derivative in the direction of the vector e_k with respect to the connection Δ^{i}_{jk} is denoted by '';*k*.''

Computations of the strong field generation of gravitational waves by black hole processes produces waveforms that are dominated by quasinormal (QN) ringing, a damped oscillation characteristic of the black hole. We describe here the mathematical problem of quantifying the QN content of the waveforms generated. This is done in several steps: (i) We develop the mathematics of QN systems that are complete (in a sense to be defined) and show that there is a quantity, the ''excitation coefficient,'' that appears to have the properties needed to quantify QN content. (ii) We show that incomplete systems can (at least sometimes) be converted to physically equivalent complete systems. Most notably, we give a rigorous proof of completeness for a specific modified model problem. (iii) We evaluate the excitation coefficient for the model problem, and demonstrate that the excitation coefficient is of limited utility. We finish by discussing the general question of quantification of QN excitations, and offer a few speculations about unavoidable differences between normal mode and QNM systems. © *1999 American Institute of Physics.* [S0022-2488(99)03201-6]

I. INTRODUCTION AND OUTLINE

Essentially all computations of the generation of gravitational waves by strong field black hole processes produce a gravitational wave with the shape of a damped sinusoid.[1] The oscillation period and damping time depend only on the parameters of the black hole, and not on the manner of excitation. The meaning of the complex frequency of this damped oscillation is now well understood. A single frequency perturbation outside the hole can satisfy the natural radiative boundary conditions (radiation into the black hole and outward to infinity) only if the frequency is one of the discrete set of frequencies, called quasinormal (hereafter QN) frequencies. The least damped of these complex frequencies is what dominates the appearance of computed waveforms.

QN excitations are relevant, in principle, to most or all systems with radiative boundary conditions. Stellar models, for example, have short periods for nonradial oscillations driven by fluid pressures, and long damping times of these fluid oscillations due to the weak emission of gravitational waves. The motions of the stellar fluid can be studied with radiation damping omitted (e.g., with the use of Newtonian gravitation theory, or post-Newtonian theory) and the weak radiation can be added, after the fact. When the radiative coupling is ''turned off'' the problem of the oscillation of a perfect fluid stellar model can be analyzed in normal modes[2,3] and one can find the radiated energy coming from each separate oscillation frequency, and can decompose the radiative power into that fraction assigned to each frequency.

The situation is dramatically different for black holes, which have only a single time scale. (For a nonrotating hole this is $2GM/c^3$ where G is the universal gravitational constant, c is the speed of light, and M is the mass of the hole.) The period and damping time are therefore of the same order and there is no meaningful way of turning off the damping for black hole oscillations; there is no underlying normal mode system. This suggests that there may be no clear way of specifying ''how much QN ringing'' of some particular black hole QN frequency is contained in an emitted waveform. This suggestion is made plausible by the mathematical origins of normal modes and QN modes. The properties and usefulness of normal modes are closely related to the fact that they are eigensolutions to a self adjoint problem. QN modes, on the other hand, are eigensolutions of a problem that is not self adjoint. But the dominance of QN frequencies in computed waveforms is so robust that it seems that the strength of QN ringing *must* be quantifiable, or at least that mathematical sense must be made of the question.

In this paper we try to make mathematical sense of quantification. In attempting this we draw upon parallels with normal modes systems. By the ''excitation'' of a mode we mean, in parallel to excitation in normal modes systems, an index of the contribution that each mode makes to the overall waveform and to the energy. To develop a description of QN excitation we start with a viewpoint that a meaningful and rigorous quantification is very implausible unless the QN system is, in some sense, complete. We then follow a three step process. First, in Sec. II, we define and posit the existence of QN systems that are complete (in a sense to be defined). We then point out difficulties in quantifying excitation in a complete QN system. We construct a particular measure, the ''excitation coefficient,'' that overcomes these difficulties, and is closely related to the description of the excitation of normal modes.

Our next step is to prove the existence of complete QN systems and relate the mathematics of black hole processes to complete systems. This step, carried out in Sec. III, requires a rather lengthy discussion of ''induced completeness.'' Though this discussion is not directly related to the problem of QN excitation, it is a necessary step (and is interesting in its own right). The discussion in Sec. III shows that completeness can be induced. That is, an incomplete QN system can be changed with a modification that satisfies two criteria: (i) The effect of the modification can be made arbitrarily weak. More specifically, the modification can be made small enough so that the waveform that evolves from any initial conditions is arbitrarily close to the waveform evolving with no modification. (ii) No matter how weak the modification is, the modified QN system is complete. Our demonstration in Sec. III does not consist of a general theory for such modifications; a conjecture about the general conditions has been given by Young *et al.*[4] (though their definition of completeness is somewhat different from ours). Here we will sacrifice generality and direct astrophysical relevance for specificity and rigor. We present the details of a specific model. We will start with a model, the ''TDP,'' with only a single conjugate pair of QN frequencies, and modify it to the ''spiked TDP,'' a model with an infinite QN spectrum. In the Appendix we give a rigorous proof of completeness of the spiked TDP (i.e., that under specified circumstances the outgoing waveform is a convergent sum of components at quasinormal frequencies). Numerical results are shown in Sec. III to demonstrate the negligible effect of the modification, and to demonstrate the pattern of convergence of sums of single frequency excitations.

Having established that completeness can be induced (at least in one model problem), we return, in Sec. IV, to the question of measuring the excitation of QN modes and, in particular, to the excitation coefficient, introduced in Sec. II. We demonstrate, with a few examples, that this formal measure of excitation does not generally give a useful quantification. The failure of this measure is discussed along with a broader discussion of differences between QN and normal mode systems, and conjectures about mathematical properties of QN systems.

II. COMPLETE QN SYSTEMS

A. Definition of QN frequencies

For definiteness we will limit considerations to solutions of the equation,

$$\frac{\partial^2\Psi}{\partial x^2}-\frac{\partial^2\Psi}{\partial t^2}-V(x)\Psi=0. \tag{1}$$

Such an equation describes the dynamics of many mechanical systems, and the evolution of multipole perturbations (scalar, electromagnetic, or gravitational) of spherically symmetric

(Schwarzschild) black holes.[5–7] Perturbations of rotating (Kerr) holes,[7] on the other hand, cannot be reduced to radial-time equations. QN oscillations are single frequency solutions of the form $\Psi(t,r)=\psi(x)\exp(i\omega t)$ and hence are solutions of the equation

$$\frac{\partial^2\Psi}{\partial x^2}+[\omega^2-V(x)]\Psi=0. \tag{2}$$

We assume that the domain of x includes $x=\infty$, and that the nature of the potential $V(x)$ is such that a ''radiative boundary condition'' can be defined at $x\rightarrow\infty$. A clear example is a potential with support of $V(x)$ only for x less than some x_{max}. In this case the boundary condition is that $\psi(x)\propto\exp(-i\omega x)$ for $x>x_{max}$.

For potentials that do not vanish, but fall off sufficiently fast as $x\rightarrow\infty$, the more general radiative boundary condition for real frequencies will be that for large x, the solution for $\psi(x)$ have the form $\exp(-i\omega x)F(\omega,x)$, with $F\rightarrow$constant, as $x\rightarrow\infty$. This condition is not quite sufficient if ω has a positive imaginary part; see Ref. 8 for a complete discussion. In short, the solution satisfying a radiative boundary condition for complex ω can be regarded as an analytical continuation of a solution satisfying a radiative boundary condition for real ω.

The boundary condition at the other end of of the x domain may be a standard Sturm–Liouville boundary condition (e.g., $\Psi=0$ at $x=0$) or may be a radiative boundary condition at $x\rightarrow-\infty$. For spherically symmetric black holes, the range of x extends from $-\infty$ to ∞, with $-\infty$ representing the black hole horizon.[8,9] The potentials fall off exponentially in x as $x\rightarrow-\infty$ and as const/x^2, as $x\rightarrow\infty$. Radiative boundary conditions are imposed both at $x\rightarrow-\infty$ and $x\rightarrow\infty$, corresponding to radiation moving inward through the black hole horizon, and outward towards spatial infinity.

QN frequencies are the eigenvalues $\omega=\omega_{QN}$ to the problem defined by (2) for radiative boundary conditions of the type just discussed. Due to the boundary conditions, this problem is generally not of the Sturm–Liouville type and the usual features of eigenvalues of a Sturm–Liouville problem are absent. In particular, the QN frequencies ω_{QN} are generally not real. A positive imaginary part indicates an exponential decrease with time. A negative imaginary part would indicate an instability; no frequencies with negative imaginary parts have been found for black hole QN systems.

It is clear that QN frequencies must occur in conjugate pairs. If ω_{QN} is a solution to the eigenproblem corresponding to ψ_{QN}, then $-\omega_{QN}^*$ is also a solution corresponding to ψ_{QN}^*. We will use a tilde (~) to denote the conjugate relationship of QN frequencies. Thus the conjugate to QN frequeny ω_7 is $\omega_{\tilde{7}}$, that is $\omega_{\tilde{7}}=-\omega_7^*$.

B. Definition of completeness

We will choose to give a rather specific meaning to a complete system of QN modes. The Cauchy data for (1) consists of ψ_0 and $\dot{\psi}_0$, the initial value of Ψ and of its time derivative,

$$\psi_0(x)\equiv\Psi(t,x)|_{t=0}, \quad \dot{\psi}_0(x)\equiv\partial\Psi(t,x)/\partial t|_{t=0}. \tag{3}$$

We consider an interval $x_2<x<x_1$ in the domain of x and we consider Cauchy data at $t=0$ for (1) which has support only in this interval. We then consider the solutions Ψ to (1) for such data, and we focus attention on the value of this solution at $x_{\rm obs}$, a particular value of x satisfying $x_{\rm obs}>x_1$. This corresponds to the physical situation of an observer at $x_{\rm obs}$ detecting radiation resulting from an initial disturbance located at some distance from her. The ''observed waveform'' that we focus on is then

$$f(t)\equiv\Psi(x_{\rm obs},t). \tag{4}$$

As shown in Fig. 1, there will, in general, be a minimum value $t_{\rm min}$ of t, such that the point $x_{\rm obs},t$ is influenced by the evolved Cauchy data. That is, for $t<t_{\rm min}$, the area between the past directed

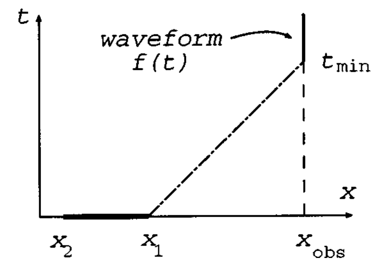

FIG. 1. Propagation of initial data to the observation location $x_{\rm obs}$ defining the waveform $f(t)$.

characteristics from $t,x_{\rm obs}$ intersects the $t=0$ hypersurface outside the support of the Cauchy data. We are interested in $f(t)$ only for $t\geqslant t_{\rm min}$. The physical interpretation of this is that we are considering only the waveform generated by the Cauchy data.

We take a complete QN system to be one which satisfies the following criteria.

- The solutions to the QN eigenvalue problem form a discrete spectrum and can be arranged in order of increasing $|\Re(\omega_n)|$.
- We consider only Cauchy data that
  –has support only within a compact region $[x_2,x_1]$,
  –belongs to a specific continuity class C^p, where p depends on the nature of the problem,
  –results in a waveform which is square integrable from $t=t_{\rm min}$ to ∞.
- For such Cauchy data, the waveform $f(t)$ that evolves from any such allowed Cauchy data can be written as

$$f(t)=\sum_n a^n e^{i\omega_n t}. \tag{5}$$

Here a^n is the nth coefficient in the sum over QN modes. Since $f(t)$ is a function of $x_{\rm obs}$, the a^n coefficients are also functions of $x_{\rm obs}$, but we shall not explicitly exhibit this dependence. The summation in (5) is in order of increasing $|\Re(\omega_n)|$, and the convergence is uniform for $t>t_{\rm min}$.

It is important to note that our view of completeness is rather different from other possible meanings of the term. In particular, our choice of the meaning of completeness has nothing directly to do with the x-dependence of the single frequency solutions and with the question of whether these solutions can be used to span acceptable Cauchy data. Our meaning of completeness, then, is rather different from that of Young *et al.*[4] It also differs from the concept of completeness used by Husain and Price[10] and by Beyer,[2] and Beyer and Schmidt,[3] but is closely related to the completeness used by Beyer[11] in his work on the Pöschl–Teller potential.[12]

C. Function space and inner product

In accordance with our definition of completeness, our vector space is the space of all functions $f(t)$, $t\geqslant t_{\rm min}$ that can evolve from acceptable Cauchy data. Our class of acceptable Cauchy data will always be chosen so that $f(t)$ is square integrable from $t=t_{\rm min}$ to ∞. On this space of functions we define an inner product to be

$$f\cdot g\equiv\int_{t_{\rm min}}^{\infty} f^*(t)g(t)dt. \tag{6}$$

We could, of course, include a weight function $W(t-t_{\rm min})$ in the integral defining the inner product, but the time translational symmetry of the background suggests that W should be constant. The choice in Eq. (6), furthermore, means that $f\cdot f$ is the time integral of the square of the wave function, a measure closely related to the energy content of a wave. (For black hole processes, the connection with gravitational wave power will be made explicit presently.) Our assumption of completeness above means that the functions $\exp(i\omega_{QN}t)$, while not elements of our function space themselves, span this function space in the sense of (5); we will therefore consider them a basis. For a function $f(t)$ in our space we can use the inner product to compute another set of coefficients a_n by

$$a_n \equiv (e^{i\omega_n t}) \cdot f(t) = \int_{t_{\min}}^{\infty} e^{-i\omega_n^* t} f(t) dt. \tag{7}$$

The following relations for the coefficients of conjugate modes are straightforward to verify:

$$a_{\tilde{k}} = (a_k)^*, \quad a^{\tilde{k}} = (a^k)^*. \tag{8}$$

Since the convergence is uniform by hypothesis, we can integrate term by term in the sum-of-modes expression for the norm of f to find

$$\int_{t_{\min}}^{\infty} |f(t)|^2 \, dt = \int_{t_{\min}}^{\infty} \left(\sum_n a^n e^{i\omega_n t} \right)^* f(t) dt = \sum_n (a^n)^* a_n . \tag{9}$$

The final sum in (9) is real, as it must be, since for any k, the sum $(a^k)^* a_k + (a^{\tilde{k}})^* a_{\tilde{k}}$ is real.

In most physical problems the radiated power is the square of the time derivative of the waveform. If at x_{obs} our wave function evolving from the initial data is $f(t) \equiv \psi(x_{\text{obs}}, t)$. If $f(t_{\min})$ vanishes (i.e., if the waveform starts continuously) then this type of energy can be evaluated as

$$\int_{t_{\min}}^{\infty} |f(\dot{t})|^2 \, dt = \sum_n (\omega_n^*)^2 (a^n)^* a_n . \tag{10}$$

As in (9) the reality of the sum is guaranteed by the relations of conjugate coefficients in (8).

Since we have an inner product, we have an equivalence between vectors and dual vectors in our function space and we can define a set of covariant basis functions $\phi^m(t)$ by the property $\phi^m(t) \cdot e^{i\omega_n t} = \delta_{nm}$. If follows from Eq. (7) that the a_n are the expansion coefficients for $f(t)$ with respect to the covariant basis functions ϕ^n. We shall henceforth refer to a^n and a_n, respectively, as the contravariant and covariant coefficients of $f(t)$. The components of the metric, in this function space, with respect to the QN basis, are

$$(e^{i\omega_n t}) \cdot (e^{i\omega_k t}) = \int_{t_{\min}}^{\infty} e^{it(\omega_k - \omega_n^*)} \, dt \equiv G_{nk} . \tag{11}$$

It should be noted that G is a Hermitian matrix, but it is not diagonal, i.e., the QN oscillations are not orthogonal. The metric coefficients can be used, in principle, to relate a^n and a_n. The expression for $f(t)$ in Eq. (5) can be substituted in Eq. (7). Since the convergence in Eq. (5) is uniform, we can integrate term by term and get

$$a_n = \sum_k G_{nk} a^k. \tag{12}$$

Since G_{nk} is not diagonal, the covariant basis vectors, i.e., the basis vectors dual to $e^{i\omega_n t}$, are mixtures of the $e^{i\omega_n t}$ functions (usually involving all of them). An indication of the unfamiliar problems this produces can be seen in the following rough argument. Let us suppose that we have a waveform that in some sense is ''almost pure'' (say) seventh mode. That is, suppose that $f(t) \approx a^7 e^{i\omega_7 t} + a^{\tilde{7}} e^{i\omega_{\tilde{7}} t}$. (We are supposing that this relationship is only approximate since it will, in general, be impossible to excite a truly pure single frequency mode with smooth, compact initial

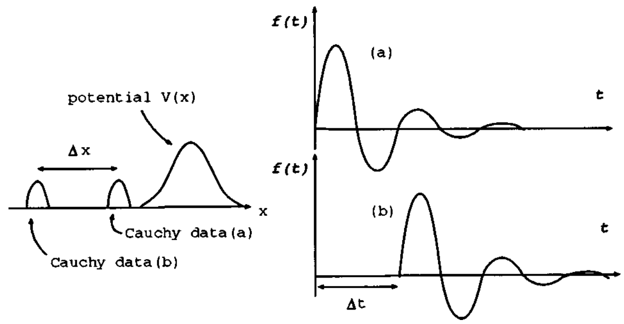

FIG. 2. Initial data shifted in location produces identical waveforms shifted in time.

data.) This waveform, for which (almost) the only contravariant coefficients are a^7 and $a^{\tilde{7}}$, will have contravariant coefficients a^n for all n. A waveform that is a pure (or almost pure) single mode excitation in one sense is therefore not a single mode excitation in another. This presages some of the problems in quantifying the excitation of a mode, and we will return to this point at the end of Sec. IV.

It is possible, of course, to use Gram–Schmidt orthogonalization to find basis functions which are orthogonal according to the inner product of (6). The resulting basis functions will not (except for one of them) correspond to single frequency excitations, and do not seem to be of interest.

D. Intuitive insights; the excitation coefficient

Some rough considerations of model problems suggest the intuitive basis for some of the mathematical difficulties to appear below, and point to a possible approach to quantifying excitation. The most obvious difficulty is the ''time shift'' problem. We imagine a configuration like that pictured in Fig. 2: A potential with compact support and two sets of Cauchy data (a) and (b). The two Cauchy data sets are localized and are identical except that set (b) is shifted to the left, to smaller x, by some finite displacement Δx. The support of neither Cauchy data set overlaps the support of the potential. In this case it is clear that the waveform generated from the two cases will be identical except that the waveform from (b) will be shifted to later times, relative to that for (a), by an amount $\Delta t = \Delta x$. Each contravariant coefficient will therefore be larger in the (b) waveform than in the (a) waveform. The conjugate pair of contravariant coefficients $\{a^7, a^{\tilde{7}}\}$ will, for example, be larger by $\exp[(\Im\omega_7)\Delta t]$ for (b) than for (a), though the excitation is physically identical. The analogous difficulty does not arise for normal modes; since they are not damped, the time delay only causes a phase shift. The trend is opposite for the covariant coefficients $\{a_7, a_{\tilde{7}}\}$. As defined in (7) $\{a_7, a_{\tilde{7}}\}$ will be smaller for (b), since $\exp(-i\omega_7^* t)$ (or $\exp(-i\omega_{\tilde{7}}^* t)$) are smaller by $\exp[(-\Im\omega_7)\Delta t]$ at the later times during which the (b) waveform has support. Therefore, neither the coefficients a^k nor a_k alone can provide a useful measure for the excitation of a QN mode.

Any useful measure of excitation *must* give the same result for the two waveforms in Fig. 2. We take advantage of the opposite tendencies of the contravariant and covariant coefficients under a time shift to define a quantity that is the same for both waveforms, the ''excitation coefficient'' A_k for the kth QN mode:

$$A_k \equiv (a_k)^* a^k + (a_{\tilde{k}})^* a^{\tilde{k}}. \tag{13}$$

We conjecture that these excitation coefficients, or quantities constructed from them (sums of excitation coefficients, functions of excitation coefficients, etc.), or quantities very closely related (see the energy excitation coefficient, below), are the only relevant mathematical objects in the vector space that are unaffected by the time shifts, and have the additional properties that we outline in the following.

In addition to the insensitivity of the excitation coefficient to time shifts of waveforms, the excitation coefficient has another important and relevant property [cf. Eq. (9)]:

$$\int_{t_{\min}}^{\infty}|f(t)|^2dt=\sum_k A_k, \tag{14}$$

where the sum is over conjugate pairs. The excitation coefficients of the complete set of QN modes sums to the norm of the waveform. We can define a quantity closely related to A_k:

$$E_k\equiv(\omega_k^*)^2(a_k)^*a^k+(\omega_k)^2(a_{\tilde{k}})^*a^{\tilde{k}}. \tag{15}$$

We shall refer to the E_k as the energy excitation coefficient. According to (10), the sum over conjugate pairs of these coefficients gives the norm of $\dot{f}$. The summation properties of the A_k and the E_k are important in clarifying what we mean by the ''excitation'' we are attempting to quantify. These coefficients appear to tell us the contribution made by each mode to a measure of the waveform. In the case of black hole perturbations it turns out that it is possible to make an even more direct connection. If $f(t)$ is a solution of the Zerilli equation[6] for even parity perturbations, then the integral on the left of (10) is proportional to the radiated energy and E_k has the appearance of the energy in the kth mode. If $f(t)$ is a solution of the Regge–Wheeler equation[5] for odd parity perturbations, then the integral in Eq. (9) is the energy and A_k has the appearance of the energy in the kth mode.

The possibility of quantification with the excitation coefficient (or energy excitation coefficient) will be a central focus, of Sec. IV, but before we begin specific computations, there are a few more possibly useful insights that can be found from intuitive considerations. For one thing, it is interesting that the two sets of coefficients can be related to two different aspects of an emitted wave. The contravariant coefficients, telling us how much of a certain mode must be added in order to get the waveform, can be considered a ''theoretical'' coefficient. For a given waveform, the projection operation on the waveform defined by (7) can be considered to give the ''experimental'' excitation coefficient.

Simple considerations can also produce insights into the nature of the metric matrix G_{nk} defined in (11). Consider the signal produced by some Cauchy data, and let the vector $\overline{a}$ denote the contravariant coefficients of the resulting waveform with respect to the QN mode basis. Let the vector of covariant coefficients be given by $\underline{a}$, so that $\underline{a}=G\overline{a}.$ Now consider the same Cauchy data, shifted to the left by Δx. The new contravariant and covariant coefficient vectors will be given by: $\tilde{\bar{a}}^k=\exp(-i\omega_k\Delta x)\overline{a}^k$ and $\tilde{\underline{a}}_k=\exp i\omega_k)\Delta x)\underline{a}_k$. Taking the standard linear algebra norm, we have $\|\tilde{\bar{a}}\|=\alpha\|\overline{a}\|$ and $\|\tilde{\underline{a}}\|=\beta\|\underline{a}\|$, where $\alpha>1$ and $\beta<1$.

The exact magnitude of α depends on the distribution of the contravariant coefficients and the shift Δx. In fact, we can always make the shift large enough so that $\alpha\gg1$. In the same way, we can ensure that $\beta\ll1$. Assuming that the metric matrix G has a minimum eigenvalue $e_{\min}$ and a maximum eigenvalue $e_{\max}$, we then find

$$e_{\min}\leqslant\frac{\|\tilde{\underline{a}}\|}{\|\tilde{\bar{a}}=\|}=\frac{\beta}{\alpha}\,\frac{\|\underline{a}\|}{\|\overline{a}\|}\ll\frac{\|\underline{a}\|}{\|\overline{a}\|}\leqslant e_{\max}. \tag{16}$$

Since G is an infinite dimensional matrix there need not be a maximum or a minimum eigenvalue. For the model problem introduced in Sec. III, we will give numerical evidence, in Sec. IV B, that the ratio of maximum and minimum eigenvalues diverges. The G matrix therefore is in some sense singular.

We now make the additional assumption that we have constructed Cauchy data such that the waveform consists almost exclusively of ringing in a single QN mode. (In the specific example discussed in the following sections, this will be possible for the fundamental mode using an arbitrarily short ''burst'' of initial data.) Let us modify the example of Fig. 2, by reducing the size of Cauchy data (b) by a factor $\exp(\Im\omega_1)\Delta x$, so that once the response to the (b) data starts it is

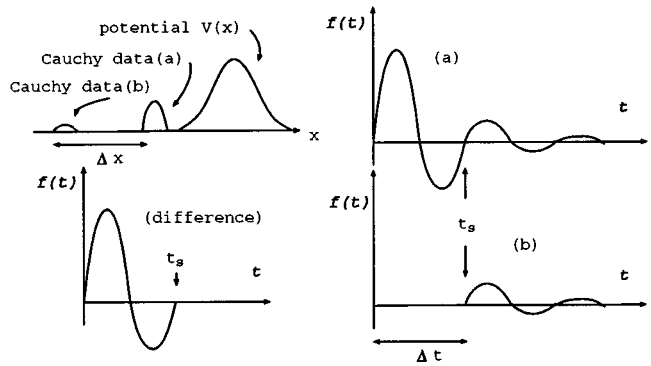

FIG. 3. Oscillations produced by shifting and scaling initial data.

identical to that of the (a) response at the same time. This situation is shown in Fig. 3 in which the response $f(t)$ is the same in both plots for $t \geqslant t_s = \Delta t$. Now let us suppose that the waveforms are dominated by ringing of the fundamental mode, and that $f(t)$ consists only of ringing of the fundamental mode. The difference between the two responses is a sum of QN modes which has the appearance of truncated fundamental mode ringing, but which has $a^1 = \tilde{a}^1 = 0$ in its mode sum. The time t_s can, in principle, be made arbitrarily long, so the truncation in the difference curve can be made arbitrarily late. We then have a sum of modes that looks arbitrarily close to fundamental mode ringing, but containing no fundamental mode. This suggests that the fundamental mode can ''almost'' be built as a superposition of the modes other than the fundamental mode, and that the modes are ''almost'' linearly dependent. We will discuss this further, based on numerical results, in Sec. IV C.

Again, this suggests that the infinite metric matrix G_{nk} is in some sense ''almost'' singular. A physical insight can be associated with this nature of the metric: Since G_{nk} is ''almost singular'' it is ''almost noninvertible.'' This means that there are difficulties in finding the contravariant coefficients from the covariant coefficients, since this requires the inverse of G_{nk}. The implication of this is possibly of pragmatic importance: the near singularity makes it difficult to find the ''theoretical'' coefficients from the ''experimental'' ones.

III. INDUCED COMPLETENESS

A. Small change

Our approach to quantification of excitation is based on the idea of complete QN systems. It is important to demonstrate that complete QN systems exist and to have an example of a system in which we can compute excitation coefficients. We must also deal with a more specific issue. The QN modes of potentials for black hole problems do not form a complete set; both the Regge–Wheeler potential, which describes perturbations of a Schwarzschild black hole, and the Pöschl–Teller potential,[12] which has been used as an approximation to the black hole potential,[13] have quasinormal mode sets which cannot completely describe the waveform resulting from an initial perturbation. An important question is what the relevance is to black hole processes, of any quantification based on an assumption of complete systems. The details of this section are somewhat disjoint from the main goal of the paper: quantification of QN excitation, but are a necessary step in developing our approach. (They are also rather interesting in their own right!)

The key idea in developing a demonstrably complete QN system, and in showing its relevance to black holes, is ''induced completeness.'' It has been argued[4] that for the problem defined by (2), the eigenmodes will be complete if there are two values of x at which $V(x)$ is not C^∞. If this is true, it appears that the black hole potentials can be modified in such a way that completeness of

QN oscillations is induced, while the effect on other aspects of the problem—in particular on the evolution of Cauchy data—is kept arbitrarily small. In this section we explore induced completeness.

It is not our purpose here to look into the generality of induced completeness. Rather, we want to have a specific example of a complete QN system with which to explore the question of quantifiability of QN excitations. We will therefore focus on a very specific model that contains most of the flavor of black hole potentials, but is simple enough to allow rather straightforward analysis and a proof of completeness.

We use the fact that (2) can be solved with elementary functions in the case that the potential has the form of a truncated centrifugal potential,

$$V_{\mathrm{TCP}}(x)=\begin{cases}0, & x<x_0,\\ l(l+1)/x^2, & x\geqslant x_0,\end{cases} \tag{17}$$

where l is an integer. It gives a good representation of the sharp cutoff of the black hole potential as $x\to-\infty$ and the approximate asymptotic form of the black hole potential at $x\to\infty$. It differs from the true black hole potential in the details of the $x\to\infty$ potential that give rise to the power-law late time tails of black hole waveforms. These tails almost certainly are an obstacle to an analysis of QN excitation, and a modification of the potential to eliminate these tails has already been made in work on QN excitation.

We will hereafter consider only the case $l=1$, to be called the ''truncated dipole potential'' (TDP). An example of the simplicity of the TDP problem is that it has only a single pair of QN frequencies: $\omega_1=(1+i)/2x_0$ and $\omega_{\tilde{1}}=(-1+i)/2x_0$ (see Sec. 1 of Appendix A). There are several ways in which we could try to induce completeness into this problem. We have studied both the addition of a small step (with discontinuities) to the TDP and the addition of a delta function. The delta function has the disadvantage of its distributional nature, but it offers the advantage of considerable simplicity as compared with the step. We have found no significant ''practical'' difference between the results (QN locations, convergence of QN sums) between the two examples, so we will describe here completeness induced with a delta function. The total potential in this case will be called the ''spiked truncated dipole potential'' (STDP) and is given by

$$V_{\mathrm{STDP}}(x)=V_{\mathrm{TDP}}(x)+V_\delta\delta(x-x_\delta), \tag{18}$$

where $V_{\mathrm{TDP}}(x)$ is the $l=1$ form of the potential in (17).

We first establish that the influence on the evolution of initial data can be made arbitrarily small. To do this we choose the Cauchy data, at $t=0$, to be given by

$$\psi_0=\sin\left(2\pi\frac{x-x_2}{x_1-x_2}\right)\quad(x_2\leqslant x'\leqslant x_1),$$
$$\dot{\psi}_0=-\partial\psi_0/\partial x, \tag{19}$$

with $x_1\leqslant x_0$, so that the initial data has the form of one full cycle of a sine wave, located to the left of the potential, traveling to the right. (This Cauchy data is chosen for convenience in demonstrating mathematical points; it has no justification as initial data for gravitational waves being produced in the neighborhood of a black hole.)

For the results to be shown here and in following sections, we choose $x_0=1$, $x_1=1$, $x_2=-5$, and $x_\delta=10$, and $x_{\mathrm{obs}}=120$. For this choice of x_1 and x_2, the sine has a wavelength, 6, that is roughly half that of the QN oscillation of the TDP. This allows us to see similar, but distinguishable signs in the evolved waveform of the propagation of the Cauchy data and of QN oscillation.

Figure 4 shows the time evolution of the Cauchy data for the original TDP and for the TDP with an added δ-function with different amplitudes ranging from $V_\delta=1$ to $V_\delta=10^{-6}$. The waveforms are followed out to times at which they have decreased in magnitude from the maximum by

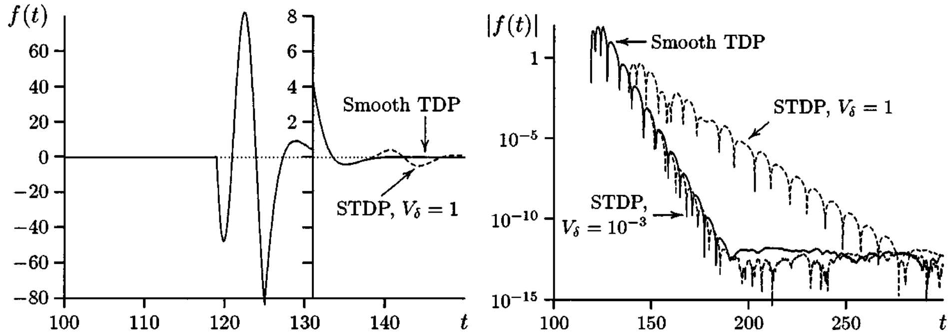

FIG. 4. Time evolution for initial data incident on the TDP and on the TDP with an added δ-function. Left: linear plot, right: logarithmic plot.

a factor of $\sim 10^{-15}$, at which point numerical error obscures the results. Even for the largest value of V_δ, the influence of the delta function on evolution is visible in the linear plot only after we change the scale for $f(t)$ at $t=131$. To see the effects more clearly we also plot the logarithm of $|f(t)|$ for a longer observation time, showing several interesting features. For all but the largest amplitude of the delta function ($V_\delta=1$) the waveform after the first few oscillations consists only of QN ringing, with the characteristic distance $\Delta t = |\Re\omega_7|\pi = 2\pi x_0 = 2\pi$ between zeros of $f(t)$. For $V_\delta=10^{-3}$, the effect of the delta function shows up only as a phase shift after the the first four, or so, full cycles of oscillation. The effect of the smallest delta function amplitude $V_\delta = 10^{-6}$ is smaller by two orders of magnitude than that for $V_\delta=10^{-3}$, and too small to be seen even in the logarithmic plot of Fig. 4.

These results make it clear that any reasonable measure of the influence of the delta function, such as the integral of the square deviation from the TDP waveform, is tiny and decreases with decreasing V_δ. We will accept these numerical results as a sufficient demonstration of this point, and will not attempt an analytic proof of this point.

B. QN spectra

Although the influence of a small delta function on the evolution of Cauchy data is negligible, the influence on the spectrum of QN frequencies is profound. The method of computing the QN frequencies for the STDP is outlined in Appendix A. The results of the computation are presented in Fig. 5 for the same potentials considered in Fig. 4.

The original TDP has only one pair of QN frequencies at $(\pm 1 + i)/2$. With an added δ-function, an entirely new set of modes appear. Note that the real parts of the additional frequen-

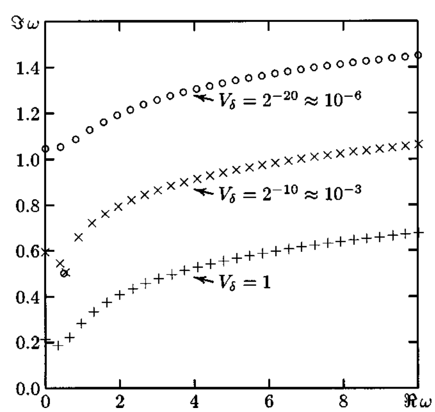

FIG. 5. Quasinormal frequencies for the TDP with an additional δ-function at $x_\delta = 10$.

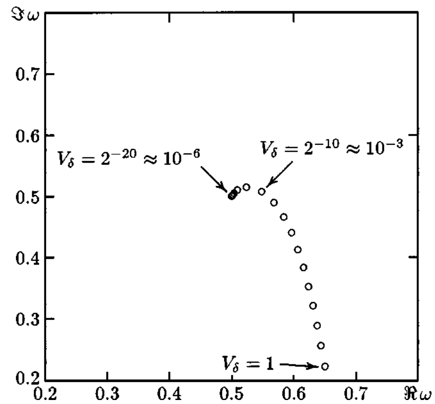

FIG. 6. ''Path'' of the original quasinormal frequency of the TDP as the amplitude of the additional δ-function is decreased.

cies seem to be unbounded. The asymptotic spacing $\Re(\omega_n) = 2\pi/10$ of the real parts of the frequencies is shown in Sec. 3 of Appendix A to correspond to the length of the ''cavity'' bounded by x_0 and the δ-function: $L \equiv x_\delta - x_0 = 10$. The imaginary parts are shown in Appendix A to increase as the logarithm of the real part.

When V_δ becomes sufficiently small, one of the QN frequencies approaches the value $(1 + i)/2x_0$ of the ''native'' QN frequency, that of the original, TDP. This can be seen more clearly in Fig. 6, which shows the ''path'' of this QN frequency in the complex plane for values of V_δ varying in steps of 1/2 from $V_\delta = 1$ to $V_\delta \sim 10^{-6}$. As V_δ decreases, the imaginary parts of the additional frequencies increase, moving them away from the native one, eventually leading to two very distinct subsets of QN frequencies.

It might seem that it is an obvious necessity for the QN spectrum to have a mode approximately at the location of the native mode, since the evolution of Cauchy data is only slightly affected. This turns out not to be true, however, for other ways of inducing apparent completeness.[14] Cutting off the TDP potential at some very large value of x, for example, has a negligible effect on the evolution of Cauchy data, and it also produces an unbounded set of additional QN frequencies. However, the spectrum of QN frequencies turns out to contain no frequency near the location of the native mode.

C. Complete sums

We now develop the connection between the Cauchy data ψ_0 and $\dot{\psi}_0$ and the coefficients of QN oscillations (i.e., the contravariant components a^n in the case of complete QN bases). Here we simply outline how coefficients associated with QN basis functions are computed in general. In Appendix B a proof of completeness of sums with these coefficients will be given for the case of the spiked TDP, and of Cauchy data meeting certain criteria. One of the criteria will be compact support for the Cauchy data, and we will assume from the outset that ψ_0 and $\dot{\psi}_0$ vanish outside the interval $x_2 < x < x_1$.

The QN coefficients are found by starting with a Laplace transform,

$$\hat{\psi}(s,x) = \int_0^\infty e^{-st} \Psi(t,x)\, dt. \tag{20}$$

(The connection between the Laplace variable s and the Fourier ω used in Appendix A and most of the paper is through the correspondence $s \leftrightarrow i\omega$.) The transformed wave equation reads as

$$\partial \hat{\psi}(s,x)/\partial x^2 - [s^2 + V(x)]\hat{\psi}(s,x) = J(s,x), \tag{21}$$

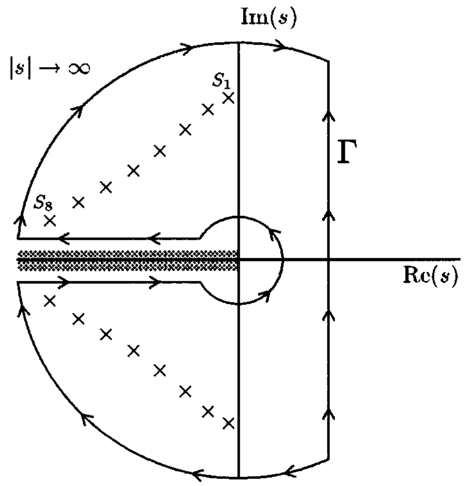

FIG. 7. Closing the contour for integration in the complex s plane. The curve Γ is the original contour of integration. It can be closed by the addition of an arc at infinity. If there is a branch point at the origin, as shown, then a branch cut can be drawn from $s=0$ to $s=-\infty$, and the contour shown can be drawn.

in which the source $J(s,x)$ is determined by the Cauchy data:

$$J(s,x)=-\dot{\psi}_0(x)-s\psi_0(x). \tag{22}$$

A solution can be found in the form

$$\hat{\psi}(s,x)=\int_{x_2}^{x_1}G(s,x,x')J(s,x')dx'. \tag{23}$$

Here the Green's function can be constructed from the homogeneous solutions $f_-(s,x)$ and $f_-(s,x)$ of the wave equation (21):

$$G(s,x,x')=\frac{1}{W(s)}\begin{cases} f_-(s,x')f_+(s,x) & (x'<x),\\ f_-(s,x)f_+(s,x') & (x'>x),\end{cases} \tag{24}$$

where $W(s)$, the Wronskian of f_- and f_+, is independent of x and x'.

We will assume that the potential falls off quickly enough at $x\to\pm\infty$ so that homogeneous solutions f_- and f_+ can be found with the property

$$f_-(s,x)\sim e^{sx}(1+\mathcal{O}(1/|x|)),\ \text{as}\ x\to-\infty \quad \text{and} \quad f_+(s,x)\sim e^{-sx}(1+\mathcal{O}(1/|x|)),\ \text{as}\ x\to\infty. \tag{25}$$

This condition is satisfied for black hole potentials and for the TDP.

Once we have found a solution of the Laplace transformed wave equation, we can reconstruct a solution of the time-dependent wave equation by applying the inverse Laplace transform:

$$\Psi(t,x)=\frac{1}{2\pi i}\int_\Gamma e^{st}\hat{\psi}(s,x)ds, \tag{26}$$

where Γ denotes the path of integration, which lies parallel to and just to the right of the imaginary axis.

Figure 7 illustrates features in the complex s plane. There may be poles and essential singularities, drawn as $\times$'s, and there may be a branch point, like that shown at $s=0$ in the figure. The contour Γ can be closed with the addition of a single arc to the left if $\hat{\psi}(s,x)$ is a single valued function of s to the left of Γ. If there are branch points then a path like that shown in Fig. 7 must be used. The Green's function for the Regge–Wheeler potential has a branch point at $s=0$, while the TDP and the STDP do not.

The integral for $\hat{\psi}$ may then be evaluated as

$$\Psi(t,x)=\sum \operatorname{Res}(e^{st}\hat{\psi}(s,x),s_j)+\frac{1}{2\pi i}\int_{\mathcal{C}} e^{st}\hat{\psi}(s,x)ds, \tag{27}$$

where the first term is the sum of residues at the singularities inside the completed contour. The second term represents contributions to the integral from arcs at ∞, and along branch cuts. In the case of the spiked TDP there is no branch cut, and the arc at ∞ makes no contributions, so we are left only with the first term, a sum of oscillations at discrete frequencies s_j that correspond to singularities of $\hat{\psi}(s,x)$. From (23) and (24) we see that singularities in $\hat{\psi}(s,x)$ must either be singularities of the homogeneous solutions f_+, f_- or zeros of the Wronskian. For any finite s we can find homogeneous solutions f_+ and f_- of (21); therefore, singularities in the Green's function can occur only at zeros of $W(s)$, and the residues in (27) must be taken at these zeros. But the vanishing of $W(s)$ at s_j means that $f_+ \propto f_-$ at s_j, and hence that s_j is a QN frequency.[8]

If, as in the case of the sTDP, the only contributions to (27) occur in the sum, then we are left with

$$\Psi(t,x)=\sum \operatorname{Res}(e^{st}\hat{\psi}(s,x),s_j), \tag{28}$$

where the sum is over QN frequencies.

We now assume that the zeros of $W(s)$ are all first order, so that

$$W(s)=\left.\frac{dW}{ds}\right|_{s=s_j}(s-s_j)+\mathcal{O}[(s-s_j)^2]. \tag{29}$$

For $x>x_1$ (i.e., for x to the right of the region in which the Cauchy data have support) we have, from (24), that

$$G(s,x,x')=\frac{f_-(s_j,x')f_+(s_j,x)}{dW/ds|_{s_j}(s-s_j)}+\mathcal{O}(s-s_j)^0, \tag{30}$$

and hence, from (23), the residues of $\hat{\psi}$ at s_j is

$$\operatorname{Res}\hat{\psi}(s,x)=\frac{e^{s_j t}f_+(s_j,x)}{dW/ds|_{s_j}}\int_{x_2}^{x_1} J(s_j,x')f_-(s_j,x')dx'. \tag{31}$$

Finally, the sum over the QN basis functions can be written as

$$\Psi(t,x)=\sum b^j u_j(t,x), \tag{32}$$

where

$$u_j(t,x)=f_+(s_j,x)e^{s_j t} \tag{33}$$

and

$$b^j=-\frac{1}{dW/ds|_{(s_j)}}\int (\dot{\psi}_0(x')+s_j\psi_0(x'))f_-(s_j,x')dx'. \tag{34}$$

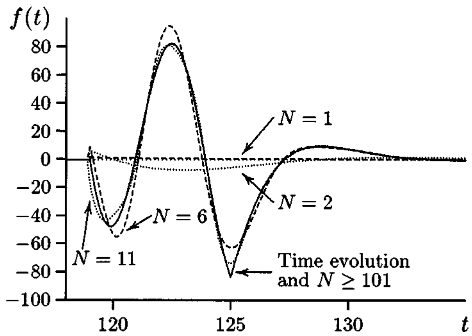

FIG. 8. Values of the mode sum for a different number of terms N, compared to the waveform resulting from integrating the time-dependent wave equation ($V_\delta = 1$).

The waveform at $x_{\text{obs}} > x_1$ is then given by (5) with

$$i\omega_j = s_j, \quad a^j = b^j f_+(s_j, x_{\text{obs}}). \tag{35}$$

This prescription has been applied to the spiked TDP, and the sine wave Cauchy data, with our standard choice of parameter values, $x_0 = 1$, $x_\delta = 10$. Notice that our choice $x_2 = -5$ in (19) satisfies the criterion in the convergence proof that the continuous, but nonsmooth, Cauchy data have support only for $x > x_0 - 2/3(x_\delta - x_0) = -5$. For this potential and these Cauchy data, the functions $\psi_0(x)$, $\dot{\psi}_0(x)$ and $f_-(s_j, x)$ are trigonometric or exponential functions, so the integral in (34) is elementary. Once the QN frequencies, ω_j, and the factors $dW/ds|_{\omega_j}$ have been computed (as described in Appendix A), the coefficients are easily evaluated. The figures below show the result of using these coefficients in sums of the form (5).

Figure 8 shows the computed result for time evolution of the Cauchy data in the case that $V_\delta = 1$. This is compared along with mode sums for an increasing number of terms, up to $N = 10\,001$ terms. Figure 9 shows the same plots in the case that $V_\delta = 10^{-6}$. In order to avoid cluttering the picture, we do not plot the values of the mode sums when they are far from having converged. These figures illustrate the fact that the mode sum converge faster for a larger δ-function. Also, for the smaller δ-function, the mode sum converges more rapidly at later times, with convergence ''sweeping down'' from late to early times.

For a better view of the differences between the mode sums and the time evolved wave functions, Fig. 10 shows the logarithmic difference (evolved waveform versus mode sum) for $V_\delta = 10^{-6}$.

Some of the systematics shown in these figures can be heuristically understood. The convergence in the $V_\delta = 1$ case is similar to that of a Fourier series (equally rapid at different times) since

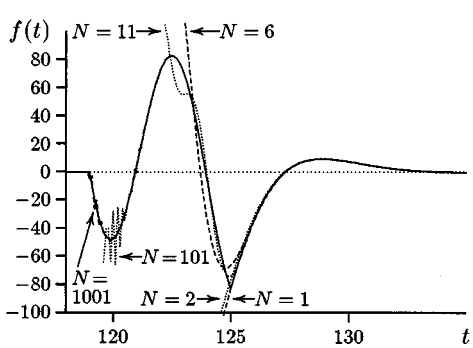

FIG. 9. Values of the mode sum for a different number of terms N, compared to the waveform resulting from integrating the time-dependent wave equation ($V_\delta = 10^{-6}$).

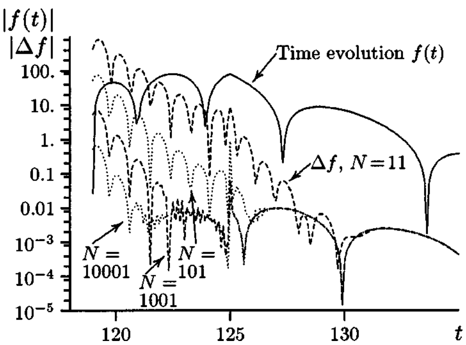

FIG. 10. Logarithmic difference Δf between the values of the mode sum for a different number of terms and the waveform resulting from integrating the time-dependent wave equation ($V_\delta = 10^{-6}$).

the QN frequencies, in this case, with small imaginary parts, are similar to the real frequencies of a Fourier series. On the other hand, for $V_\delta = 10^{-6}$, the damping of the additional (i.e., non-native) modes is much stronger and increases faster with N. Any error that originates from cutting off the mode sum after a finite number of terms can be regarded as being composed of modes with very strong damping; these modes are very large at early time.

We point out here an interesting technical feature of these results. The mode sums are so accurate at later times that the differences shown in Fig. 10 for $N = 10\,001$, is actually dominated, after $t \approx 122$, by the numerical truncation error in computing the evolved waveform. A smaller time step in numerical evolution can improve the numerical accuracy of the computed waveform, and can move to a slightly larger time the point at which the evolution versus sum difference is dominated by the numerical errors in the evolution.

IV. QUANTIFYING EXCITATION

A. The excitation coefficient

We now return to the question of how to quantify the excitation of QN oscillation. In Sec. II we defined the excitation coefficient A_k for a QN oscillation in a complete QN system. Due to the time shift problem, we argued that the excitation coefficient seems the only plausible indicator of the QN content of a waveform. In Sec. III we have seen that, at least in the particular example of the TDP, completeness can be induced in an incomplete system to create one that is ''physically equivalent,'' i.e., differs negligibly in the evolution of Cauchy data. We can now ask whether, at least for the model problem at hand, we can use the excitation coefficients of the completed system to quantify the QN oscillation in the original (''native'') system.

It is worth emphasizing that the TDP is a particularly simple starting point for these considerations, since it has only a single conjugate pair of native QN modes. The sine wave data we have used in the previous sections is also convenient since it produces a waveform (see Fig. 4) which clearly contains QN ringing, but contains significant oscillation at a different frequency ($\omega = 2\pi/6$).

The results of computations with this model are presented in Table I. Results are shown for the spiked TDP for different values of V_δ and for the standard Cauchy data, a right moving sine wave initially extending over the interval $[-5,1]$. For comparison, a shifted sine wave, initially at $[-8,-2]$, was also computed in the case $V_\delta = 10^{-6}$. Also included are results for the smooth TDP, and for the Zerilli equation with the Regge–Wheeler potential with initial data corresponding the the Close Limit technique for black hole collisions.[15]

The table presents values of excitation coefficients $A_1 \equiv a^1(a_1)^* + (a^1)^*(a_1)$ and the energy excitation coefficients $E_1 \equiv (\omega_1^*)^2 (a_1)^* a^1 + (\omega_1)^2 (\tilde{a_1})^* \tilde{a}^1$, introduced in (13) and (15). In each case the QN frequency ω_1 is taken to be that eigenfrequency which corresponds to the native mode in the limit $V_\delta \to 0$; that is, ω_1 always lies on the path in the complex plane shown in Fig.

6. For small values of V_δ this QN frequency is close to the native QN frequency $(\pm1+i)/2$. The waveform norm and the total energy are computed from waveforms obtained by explicit numerical integration of the wave equation (1). Also included are estimates for the numerical uncertainties of the results.

The norm and total energy can be computed from Eq. (9), or directly from the waveform. Similarly, the covariant coefficient may be computed from the contravariant ones, using Eq. (12), or from the waveform via Eq. (7). Even the contravariant coefficients can be obtained from the waveform itself, using an asymptotic fit as it approaches a pure QN oscillation at the least damped QN frequency, instead of the residues of the Green's function through Eqs. (34) and (35). The waveform itself, in turn, can be obtained by direct numerical integration of the wave equation, or by using the mode sum as in Eq. (5). We have checked these alternatives for obtaining the quantities listed in the table; they result in essentially the same values as the route we have taken here.

We first notice that the values for the excitation coefficients are identical, within the numerical errors, for the original initial data (sine wave over the interval $[-5,1]$) and the shifted initial data (over the interval $[-8,-2]$). This confirms our earlier argument that the excitation coefficients we have defined are independent of a translation of the initial data or, correspondingly, to a time shift of the evolved waveform.

It is important to realize that there are different ways to compute the quantities in the table, and several of them do not depend on the complete set of modes. The waveform and energy norm, of course, require only the waveform, but all coefficients can also be computed entirely from the waveform itself. The least damped QN frequency can be inferred from the asymptotic late time behavior, as can the contravariant coefficient for the least damped mode. [See (5).] Of the cases we study the least damped mode always corresponds to the native mode except for the $V_\delta=1$ model. (See Fig. 5.) Once the QN frequency is known the covariant coefficient can be computed directly from the integral in (7) and, with the contravariant coefficient known, the excitation and energy coefficients can then be found from (13) and (15). Since the quantities in the table can be computed from waveforms, we can compute them for the smooth TDP. In this case we do not have a complete set of modes, but that is irrelevant to the procedure for computation. (It turns out, in fact, that the simplicity of the smooth TDP and the sine wave data allows a closed form solution for the waveform, and for the norms and coefficients. This closed form solution has been used, and the values for the smooth TDP can be found for the table to an essentially arbitrary precision.)

The numbers in the table make it clear that the results for the smooth TDP are the $V_\delta\to0$ limit of the spiked TDP. This is obvious from a computational point of view, since all results can be computed from the waveform, and the $V_\delta\to0$ waveform approaches the smooth TDP waveform. From another point of view, however, this result is interesting and important. It means that we can compute the excitation coefficient independent of the method with which completeness is induced. Put another way, it means that we can compute the excitation coefficient for a small completeness-inducing change, independent of the nature of the change. This conclusion, in fact, is crucial to the possible importance of the excitation coefficient. We could not use the excitation coefficient to characterize an excitation of a physical system if the value of the coefficient depended on our choice of a modification of that physical system.

The table also gives a value for the excitation coefficient for the gravitational radiation produced, in the close limit approximation,[14] by the head on collision of two equal mass nonrotating holes. In this case the QN spectrum is infinite, but the QN oscillations are not complete. The excitation coefficient given is for the least damped of the QN oscillations, a frequency that appears to dominate the waveform produced.

Up to this point we have noted that computations with the model problem illustrate and confirm the features of the excitation coefficient that made it an attractive candidate for the quantification of the excitation of QN oscillations. Table I, however, also makes it unlikely that the excitation is a *useful* index of QN oscillation. For the small-δ spiked TDP the excitation coefficient is negative, and is larger (by a factor ~ 3) in magnitude than the norm. Note that we cannot ignore this ''wrong'' sign, and simply keep the large magnitude as an indication of a strong QN presence. Due to relation (9) we must conclude that the sum of all the other QN oscillations (those unrelated to the native QN mode) must be greater (by a factor ~ 4) than the norm. For the close limit waveform the excitation coefficient is roughly twice the size of the norm of f and hence the sum of excitation coefficients of all other QN oscillations (if the system were made complete somehow) would be negative.

As a possible alternative to the excitation coefficient we have also computed the energy excitation coefficient, as defined in (15). The results listed for E_1 and the norm of $\dot{f}$, however, do not make this any more attractive as a measure of QN excitation.

At this point, we also note that the excitation coefficient A_1 is not related to the norm of the QN mode contribution corresponding to the first pair of modes, i.e., of $b^1 u_1 + (b^1 u_1)^*$. Similarly, the energy excitation coefficient E_1 is no measure for the energy of this QN mode contribution.

It is, of course, impossible to prove that something like quantifying QN excitations cannot be done in a mathematically acceptable way. Despite this, and perhaps to provoke further work (by others!) we are tempted to offer the following very tentative conclusion: Consider the following three conditions, which allow a mathematically meaningful as well as a useful measure of excitation; they are all satisfied for normal mode systems.

- The measure of excitation is independent of a simple shift of the wave form (i.e., a shift in space of the initial data, corresponding to a shift in time for the time evolved waveform).
- Excitation strength can be quantified individually for any number of modes, with the individual excitations adding up to the total norm of the waveform.
- The measure of excitation is useful for quantifying the excitation in a comparative way; in particular, it always lies between 0% and 100%.

We conjecture: There is no quantification of QN oscillations of the waveform, based on the algebra of the function space of QN oscillations, which satisfies all three of these criteria.

The excitation coefficients we are defining in this paper satisfy the first two conditions, but not the third one. (In Table I we see that the excitation coefficient can be negative and can be greater than 100%.) One might regard these two conditions as related to mathematical properties of the QN mode system, while the third one is of a more practical significance. We are currently investigating another technique to quantify excitations, with a measure that satisfies the first and third criteria, but not the second one. This measure may turn out to be of some practical utility, but is not as closely related to the mathematics of the function space as are the present considerations. A description of this work will be published elsewhere.

Our conjecture is based specifically on the appearance of the excitation coefficient as the only quantity in that function space that solves the ''time shift'' problem, and on the observed failure of the excitation coefficient to be ''useful.'' It is also based, less specifically, on our belief that there are differences between normal mode and QN systems that cannot be bridged. For this

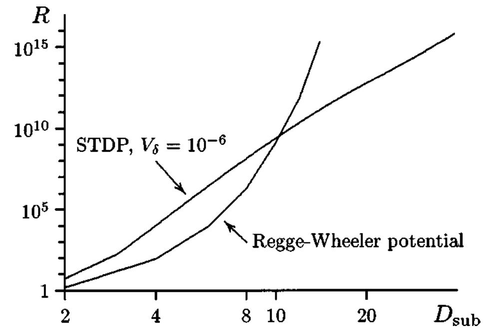

FIG. 11. The condition number R for the metric matrix for a truncated subspace of dimension $D_{\rm sub}$, spanned by the first $D_{\rm sub}$ QN basis functions. Results are shown for both the spiked TDP ($V_\delta = 10^{-6}$) and the Regge–Wheeler potential.

reason we speculate that inducing completeness, while it is mathematically interesting, is not likely to lead to useful tools for understanding the underlying native system. The reason is that the spectrum of added QN frequencies is unrelated to the native system and characterizes only the method used to induce the completeness. We, in fact, are willing to extrapolate in the direction of this speculation. We conjecture that in a complete QN spectrum which has a dense set of frequencies, and a small number of ''isolated'' frequencies, like the spectrum of the spiked TDPs in Fig. 5, it is useful to modify the system to *remove* completeness, in order to get a more useful understanding and a simplified method of analysis. The obvious example of this is removing the δ functions from the spiked TDP problem in order to get a physically equivalent, but simpler incomplete system.

A very similar point of view is that in a QN spectrum, not all frequencies are equally important. Some will actually be evident in waveforms produced in the evolution of generic Cauchy data; others will not. For the small-δ spectra of Fig. 5, the ''interesting'' QN frequencies are the isolated ones near $(1+i)/2$. In the $V_\delta = 1$ case, on the other hand, there is again the appearance of QN ringing in the waveform, but the spectrum contains no isolated frequency. A similar situation was found in a study where the Regge–Wheeler potential was replaced by a series of step potentials.[14] More generally, one should ask the following: If one has only the spectrum and the associated quantities (e.g., the metric matrix), is there a way of identifying which QN frequencies are ''important'' in the sense of really characterizing the evolution of Cauchy data? In this sense we are asking a question related to ''to what extent are (some) QN modes like normal modes?'' since normal modes *do* characterize the system in which they arise.

B. Condition number of the metric matrix

The metric matrix (11) would appear to be a likely place to find a way of characterizing a QN system without regard to specific waveforms produced by specific Cauchy data. We will now discuss some numerical results which confirm the intuitive insight we had gained by doing thought experiments on specific Cauchy data in Sec. II D. Studying the metric matrix directly, we do not need to refer to specific initial data any more, as we had to do before.

We first note the singular nature of the infinite metric matrix in two cases. To characterize this singular property we truncate the set of QN functions, keeping only the first D. We then compute the condition number R (ratio of maximum to minimum eigenvalue) for the D dimensional subspace. The condition number as a function of $D_{\rm sub}$ is plotted in Fig. 11 for two cases: the spiked TDP and the QN spectrum of Schwarzschild black holes (the QN modes of the Zerilli or Regge–Wheeler potentials). For the spiked TDP the approximately straight line in the log–log plot suggests that the condition number increases roughly as the twelfth power of the dimension $D_{\rm sub}$ of the subspace. For the black hole QN spectrum the increase is even more dramatic, suggesting perhaps a ''more singular'' metric for this incomplete QN spectrum.

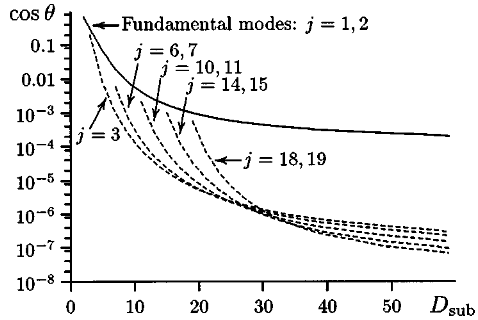

FIG. 12. Cosine of angles between several contravariant and covariant basis vectors, as a function of the dimension of a subspace spanned by $D_{\rm sub}$ QN modes of the spiked TDP with $V_\delta = 10^{-6}$.

C. Angles between basis functions

In Sec. II we introduced covariant basis functions $\phi^m(t)$ with the definition $\phi^m(t)\cdot e^{i\omega_n t} = \delta_{mn}$. If the basis functions $e^{i\omega_n t}$ were orthogonal we would have that $\phi^n(t)$ and $e^{i\omega_n t}$ are ''parallel,'' that is, $\phi^n(t) \propto e^{i\omega_n t}$. It is plausible that such statements as ''this wave is dominated by oscillation at the fundamental QN frequency'' are most meaningful if the covariant and contravariant basis vectors are nearly ''parallel.'' To measure the extent to which $\phi^j(t)$ and $e^{i\omega_j t}$ fail to be proportional we can introduce an angle α_j between them, defined by

$$\cos(\alpha_j) = \frac{\phi^j(t)\cdot e^{i\omega_j t}}{\|\phi^j(t)\|\ \|e^{i\omega_j t}\|} = \frac{1}{\sqrt{G_{jj}G^{jj}}}, \tag{36}$$

where G^{ij} is the matrix inverse of G_{ij}. The components of the infinite matrix G^{ij} cannot be computed, so again we truncate a subspace by keeping only the first $D_{\rm sub}$ vectors, and we compute the angles in that subspace with (36). Results are shown in Fig. 12 for the spiked TDP with $V_\delta = 10^{-6}$. The value of $\cos(\alpha_j)$ is shown for several QN modes as a function of $D_{\rm sub}$, the dimension at which the subspace is truncated. Figure 13 shows $\cos(\alpha_j)$ for the black hole QN spectrum. In Fig. 12, the decrease of $\cos(\alpha_1)$, corresponding to the native mode, is much slower than that of the additional modes. One might speculate that this is related to the fact that the native mode is more characteristic of the system than the additional ones. No such clear distinction can be seen in Fig. 13 for the case of the Regge–Wheeler potential. However, the angles increase much faster for the more highly damped modes as well, which might again indicate that the fundamental, least damped mode is more characteristic of the system than the more strongly damped ones.

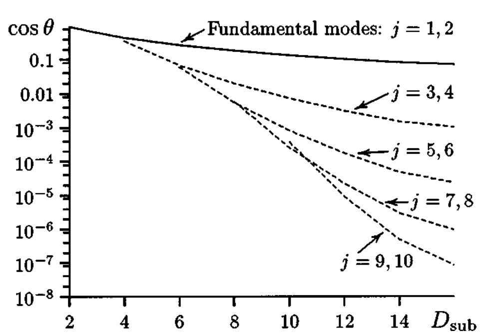

FIG. 13. Cosine of angles between several contravariant and covariant basis vectors, as a function of the dimension of a subspace spanned by $D_{\rm sub}$ QN modes of the Regge–Wheeler potential.

ACKNOWLEDGMENTS

We wish to thank Ted Newman for useful discussions and numerous helpful suggestions on the presentations of these results. We also thank Karel Kuchař, Wai-Mo Suen, and John Whelan for useful discussions during the development of this work. We thank the Deutsche Forschungsgemeinschaft for support through SFB 382 and NATO for support through Grant No. CRG.971092. One of us (R.H.P.) thanks the National Science Foundation for support under Grants No. PHY95-07719 and No. PHY97-34871.

APPENDIX A: FINDING QUASINORMAL FREQUENCIES OF THE TDP AND OF THE SPIKED TDP

1. The unmodified TDP

The TDP is defined as

$$V(x)=\begin{cases}0, & x<x_0,\\ l(l+1)/x^2, & x\geqslant x_0,\end{cases} \tag{A1}$$

where l is an integer. We look only at $l=1$, but the procedure can easily be extended for larger values of l. Also, we will generally let $x_0=1$.

The domain of the wave equation is naturally divided into two regions.

I. $x<x_0$. In this region, the potential vanishes, and therefore the wave equation has the two trivial solutions:

$$\psi_{\mathrm{I}1}(x)=e^{+i\omega x}, \tag{A2}$$

$$\psi_{\mathrm{I}2}(x)=e^{-i\omega x}. \tag{A3}$$

II. $x\geqslant x_0$. For integer values of l, the solutions are given by finite sums. For $l=1$, we have

$$\psi_{\mathrm{II}1}(x)=e^{+i\omega x}\left(1-\frac{1}{i\omega x}\right), \tag{A4}$$

$$\psi_{\mathrm{II}2}(x)=e^{-i\omega x}\left(1+\frac{1}{i\omega x}\right). \tag{A5}$$

Obviously, the solutions satisfying the required boundary conditions at negative and positive infinity are

$$\psi_-(x)=\psi_{\mathrm{I}1}(x)\quad (x<x_0), \tag{A6}$$

$$\psi_+(x)=\psi_{\mathrm{II}2}(x)\quad (x\geqslant x_0). \tag{A7}$$

In general, of course, $\psi_-(x)$ will be a linear combination of $\psi_{\mathrm{II}1}(x)$ and $\psi_{\mathrm{II}2}(x)$ for $x\geqslant x_0$, and $\psi_+(x)$ a combination of $\psi_{\mathrm{I}1}(x)$ and $\psi_{\mathrm{I}2}(x)$ for $x<x_0$. A quasinormal mode is a solution where both boundary conditions are satisfied simultaneously, i.e., $\psi_-(x)=\psi_+(x)$. The easiest way to find out if this is the case is to compare $\psi_-(x)$ and $\psi_+(x)$, as defined in (A6), at $x=x_0$. Strictly speaking, $\psi_-(x)$ is not defined at $x=x_0$. However, any solution of the wave equation will have to be continuous, and have a continuous first derivative, at $x=x_0$. It is therefore permissible to use the left limit of $\psi_-(x)$ and of $\psi'_-(x)$ as $x\to x_{0^-}$, and compare them with the values of $\psi_+(x)$ and $\psi'_+(x)$ at $x=x_0$.

The comparison is done using the Wronskian determinant of $\psi_-(x)$ and $\psi_+(x)$:

$$W[\psi_-,\psi_+](x_0)=\psi_-(x_0)\psi'_+(x_0)-\psi'_-(x_0)\psi_+(x_0)$$
$$=-2i\omega-\frac{2}{x_0}-\frac{1}{i\omega x_0^2}. \tag{A8}$$

Solving the equation $W[\psi_-,\psi_+](x_0)=0$ for ω yields the quasinormal frequencies

$$\omega=\frac{\pm 1+i}{2x_0}. \tag{A9}$$

Therefore, for $l=1$, there is only one pair of quasinormal frequencies.

2. QN frequencies of the spiked TDP

We define the ''spiked'' potential as

$$\overline{V}(x)=V(x)+V_\delta\delta(x-x_\delta). \tag{A10}$$

We now have to distinguish three areas.

I. $x<x_0$. This region is identical to region I for the unmodified potential, with the same set of two solutions.

IIa. $x_0\leqslant x\leqslant x_\delta$. Again, there are two linearly independent solutions:

$$\psi_{\mathrm{IIa1}}(x)=e^{+i\omega x}\left(1-\frac{1}{i\omega x}\right), \tag{A11}$$

$$\psi_{\mathrm{IIa2}}(x)=e^{-i\omega x}\left(1+\frac{1}{i\omega x}\right). \tag{A12}$$

IIb. $x>x_\delta$. The two linearly independent solutions are

$$\psi_{\mathrm{IIb1}}(x)=e^{+i\omega x}\left(1-\frac{1}{i\omega x}\right), \tag{A13}$$

$$\psi_{\mathrm{IIb2}}(x)=e^{-i\omega x}\left(1+\frac{1}{i\omega x}\right). \tag{A14}$$

In our notation the function $\psi_{\mathrm{IIb2}}(x)$, for example, refers to the solution in all regions that, in region IIb, has the functional form shown in Eq. (A14).

Due to the δ-function separating regions IIa and IIb, the solutions $\psi_{\mathrm{IIa2}}(x)$ and $\psi_{\mathrm{IIb2}}(x)$ are not the same. Rather, $\psi_{\mathrm{IIb2}}(x)$ will be a linear combination of $\psi_{\mathrm{IIa1}}(x)$ and $\psi_{\mathrm{IIa2}}(x)$ in region IIa:

$$\psi_{\mathrm{IIb2}}(x)=p_1\psi_{\mathrm{IIa1}}(x)+p_2\psi_{\mathrm{IIa2}}(x). \tag{A15}$$

Once again, the solutions

$$\psi_-(x)=\psi_{\mathrm{I1}}(x)\quad (x<x_0), \tag{A16}$$

$$\psi_+(x)=\psi_{\mathrm{IIb2}}(x)\quad (x\geqslant x_\delta), \tag{A17}$$

satisfy the boundary conditions at negative and positive infinity. However, in order to compare solutions at $x=x_0$, we now have to determine the representation of $\psi_{\mathrm{IIb2}}(x)$ in region IIa, i.e., we need to know the coefficients for the linear combination (A15).

These coefficients can be determined using the junction conditions for any solution $\psi(x)$ of the wave equation across the δ-function.

(1) $\psi(x)$ must be continuous at x_δ.
(2) The derivative $\psi'(x)$ must have a discontinuity given by

$$\psi'(x_\delta^+)-\psi'(x_\delta^-)=V_\delta\psi(x_\delta). \tag{A18}$$

The second condition is obtained by integrating the wave equation from $x=x_\delta-\epsilon$ to $x=x_\delta+\epsilon$, letting $\epsilon\rightarrow 0$, and using the first condition.

Using ψ_{IIb2} for $\psi'(x_\delta^+)$ and Eq. (A15) for $\psi'(x_\delta^-)$, we can solve these conditions for p_1 and p_2. We obtain

$$p_1=V_\delta\frac{[\psi_{\mathrm{IIa2}}(x_\delta)]^2}{W_{+12}}, \tag{A19}$$

$$p_2=1-V_\delta\frac{\psi_{\mathrm{IIa1}}(x_\delta)\,\psi_{\mathrm{IIa2}}(x_\delta)}{W_{+12}}, \tag{A20}$$

where $W_{+12}=W[\psi_{\mathrm{IIa1}},\psi_{\mathrm{IIa2}}]=-2i\omega$.

Therefore,

$$\begin{aligned}W[\psi_-,\psi_+](x_0)=W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIb2}}](x_0)&=p_1W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIa1}}](x_0)+p_2W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIa2}}](x_0)\\&=R_1+V_\delta(R_2+R_3e^{-2i\omega L}),\end{aligned} \tag{A21}$$

where $L=x_\delta-x_0$, and $W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIa1}}](x_0)=e^{2i\omega x_0}/(i\omega x_0^2)$, and thus

$$R_1=W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIa2}}](x_0)=-2i\omega-\frac{2}{x_0}-\frac{1}{i\omega x_0^2}, \tag{A22}$$

$$R_2=-\frac{\psi_{\mathrm{IIa1}}(x_\delta)\,\psi_{\mathrm{IIa2}}(x_\delta)}{W_{+12}}W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIa2}}](x_0)=-\left(1-\frac{1}{(i\omega x_\delta)^2}\right)\left(1+\frac{1}{i\omega x_0}+\frac{1}{2(i\omega x_0)^2}\right), \tag{A23}$$

$$R_3=e^{2i\omega L}\frac{\psi_{\mathrm{IIa2}}(x_\delta)^2}{W_{+12}}W[\psi_{\mathrm{I1}},\psi_{\mathrm{IIa1}}](x_0)=-\frac{1}{2(i\omega x_0)^2}\left(1+\frac{1}{i\omega x_\delta}\right)^2. \tag{A24}$$

The quasinormal frequencies of the spiked TDP can now be computed numerically by searching for roots of the equation

$$W[\psi_-,\psi_+](x_0)=0. \tag{A25}$$

3. Asymptotic approximation for the QN frequencies of the spiked TDP

It is possible to find an asymptotic formula for the QN frequencies under the assumption that the absolute value of the frequency becomes large. We start by assuming that in (A25), we have $|\omega x_0|\gg 1$ and $|\omega x_\delta|\gg 1$. The condition for QN frequencies can then be written as

$$2i\omega x_0+\mathcal{O}([\omega x)]^0)+V_\delta\left[1+\mathcal{O}([\omega x)]^{-1})+\frac{e^{-2i\omega L}}{2(i\omega x_0)^2}(1+\mathcal{O}([\omega x)]^{-1}))\right]=0, \tag{A26}$$

where x is the minimum of x_0 and x_δ. It is clear that for $|\omega x|\gg 1$ there can be solutions only if

$$2i\omega+V_\delta\frac{1}{2(i\omega x_0)^2}\,e^{-2i\omega L}\approx 0, \tag{A27}$$

and we use this approximation to find an iterative solution for the QN frequencies. We start by taking the cube root of

$$e^{-2i\omega L} = -\frac{4(i\omega)^3 x_0^2}{V_\delta} \tag{A28}$$

to write

$$e^{(-2/3)i\omega_R L} e^{(2/3)\omega_I L} e^{i\Delta} = -\left(\frac{4x_0^2}{V_\delta}\right)^{(1/3)} i\omega \equiv -Ai\omega, \tag{A29}$$

where $\Delta = j\frac{2}{3}\pi,\ j=0,1,2$.

Taking the absolute values on both sides gives

$$e^{(2/3)\omega_I L} = A|\omega|. \tag{A30}$$

With $\omega \equiv \omega_R + i\omega_I$ this last relation already shows that $\omega_I \ll |\omega| \approx \omega_R$ is required for a QN frequency.

Using (A30) to rewrite (A29) we find

$$\cos\left(\frac{2}{3}L\omega_R + \Delta\right) - i\,\sin\left(\frac{2}{3}L\omega_R + \Delta\right) = -i\frac{\omega}{|\omega|}. \tag{A31}$$

We now make the approximation $\omega_I \approx 0$, i.e., $\omega \approx \omega_R \approx |\omega|$, leading to

$$\cos\left(\frac{2}{3}L\omega_R + \Delta\right) = 0, \quad \sin\left(\frac{2}{3}L\omega_R + \Delta\right) = 1, \tag{A32}$$

$$\frac{2}{3}L\omega_R = \frac{\pi}{2} + 2N\pi - \frac{2}{3}j\pi, \quad N=0,1,\ldots;\ j=0,1,2, \tag{A33}$$

or, equivalently,

$$(\omega_R)_n = \frac{1}{L}\left(\frac{3\pi}{4} + n\pi\right), \quad n=0,1,\ldots. \tag{A34}$$

An approximation for ω_I is then obtained by using (A30):

$$(\omega_I)_n = \frac{3}{2}\frac{1}{L}(\ln A + \ln\,\omega_R). \tag{A35}$$

The approximate solutions of (A34) and (A35) can now be iteratively improved. We rewrite (A25) as

$$e^{-2i\omega L} = -\frac{R_1 + V_\delta R_2}{V_\delta R_3} =: R(\omega) = R(\omega_R, \omega_I), \tag{A36}$$

and take absolute values to get

$$e^{2\omega_I L} = |R|, \tag{A37}$$

$$\omega_I = \frac{\ln|R|}{2L}. \tag{A38}$$

With these inserted in (A36) we arrive at

$$\cos(2\omega_R L) = -\frac{\Re(R)}{|R|}, \quad \sin(2\omega_R L) = \frac{\Im(R)}{|R|}. \tag{A39}$$

This can be used as an iterative method to find the pth iteration from the $(p-1)$th approximation, as follows:

$$\cos(2(\omega_R)^p L) = -\frac{\Re(R((\omega_R)^{p-1},(\omega_I)^{p-1}))}{|R((\omega_R)^{p-1},(\omega_I)^{p-1})|}, \quad \sin(2(\omega_R)^p L) = \frac{\Im(R(\ldots))}{|R(\ldots)|}, \tag{A40}$$

and

$$(\omega_I)^p = \frac{\ln|R((\omega_R)^p,(\omega_I)^{p-1})|}{2L}. \tag{A41}$$

This iterative solution can be started with *any* value of n in the zeroth approximation of (A34) and (A35), and the iteration converges to the exact solution. The iteration cannot be used to find the native QN frequency of the smooth TDP since $V_\delta = 0$ in that case.

APPENDIX B: PROOF OF CONVERGENCE

A proof is given here of the convergence of the sum of quasinormal excitations for the spiked TDP under appropriate restrictions on the Cauchy data. To do this we start by defining the integral

$$\mathcal{I}(d_1) \equiv \int F(s)ds \equiv \frac{1}{2\pi i}\int \frac{s^2\phi(s)e^{s(d_1+d_2)}}{\Delta(s)}ds. \tag{B1}$$

Here $\Delta(s)$ is defined to be

$$\Delta(s) \equiv P_1(s) + e^{2sL}s^3 P_2(s), \tag{B2}$$

in which P_1 and P_2 are polynomials of finite order in $1/s$:

$$P_1(s) \equiv A_1 + B_1/s + \ldots, \quad P_2(s) \equiv A_2 + B_2/s + \ldots\ . \tag{B3}$$

The path of integration in the complex s plane is along the vertical axis, from $-i\infty$ to $+i\infty$. For $\Re(s) \leqslant 0$ the function $\phi(s)$ is required to have the property that for some real constants K_ϕ and p,

$$|\phi(s)| < \frac{K_\phi}{|s|^p}. \tag{B4}$$

(This condition will be related below to restrictions on acceptable Cauchy data.) The constants appearing in (B1) are taken to satisfy the following conditions: (i) The ratio A_1/A_2 is real and positive. (ii) L, d_1 and d_2 are real and nonnegative, and $2L > d_2$. (iii) The constant p appearing in (B4) must be large enough that

$$p + \frac{3d_2}{2L} - 2 > 0. \tag{B5}$$

The roots of Δ are denoted s_k. (They represent, of course, the QN frequencies according to the usual correspondence $s \leftrightarrow i\omega$.) Since they must occur in complex conjugate pairs it is convenient here to use the notation $s_1, s_{-1}, s_2, s_{-2}, \ldots$, with $s_{\pm k}$ indicating the corresponding roots with positive and negative imaginary parts.

What we will prove is that under the conditions stated above $\mathcal{I}(d_1)$ can be written as

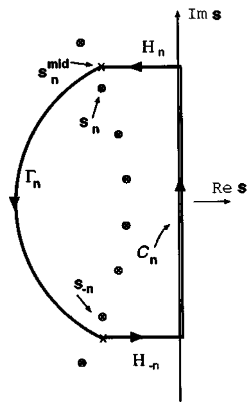

FIG. 14. Contour for proving convergence for the spiked TDP oscillations.

$$\mathcal{I}(d_1)=\sum_{k=-\infty}^{k=+\infty} a^{(k)}e^{s_k d_1}, \tag{B6}$$

where

$$a^{(k)}\equiv s_k^2\phi(s_k)e^{s_k d_2}/(d\Delta/ds)|_{s=s_k}. \tag{B7}$$

The convergence of the sum in (B6) is not uniform at $d_1\to 0$, but is uniform for any interval of d_1 bounded away from 0. We give the details of the relationship to the physical problem of Sec. III after we prove the main result above. The proof is organized with a set of lemmas.

Lemma 1: Let $s_n^{mid}=s_n+i\pi/2L$ and let H_n be the horizontal path (as shown in Fig. 14) in the s plane from the imaginary s axis to the point s_n^{mid}. Let

$$\mathcal{I}_{H_n}\equiv\int_{H_n}F(s)ds \tag{B8}$$

be the integral of $F(s)$ on this path, then N can be chosen so that, for $n>N$,

$$|\mathcal{I}_{H_n}|\leqslant \text{const}\times n^{2-p-(3d_2/2L)}. \tag{B9}$$

Proof: The discussion of the roots of the spiked TDP Wronskian in Appendix A can be applied to the roots of Δ. For large n, the n dependence of the roots takes the form

$$\Im(s_n)=n\pi/L+\text{const}+\ldots, \tag{B10}$$

$$\Re(s_n)=-(3/2L)\ln(n)+\text{const}+\ldots\ . \tag{B11}$$

It follows that a constant can be chosen so that $|s_n|>\text{const}\times n$, and hence $|\phi(s)|<2\pi K/n^p$, for some constant K independent of n. Since $\Re(s)\leqslant 0$ on H_n and d_1 is non-negative, we have that $|e^{sd_1}|\leqslant 1$. With $s=s_n+i\pi/2L+\sigma$ and with σ running from $-\Re(s_n)$ to 0 on the path H_n, the integral must satisfy

$$|\mathcal{I}_{H_n}|\leqslant\frac{K}{n^{p-2}}\left|\int_0^{-\Re(s_n)}\frac{d\sigma}{D(s)}\right|, \tag{B12}$$

where $D(s)\equiv e^{-sd_2}\Delta(s)$. On H_n we have that

$$e^{2Ls}=-e^{2Ls_n}e^{2L\sigma}, \tag{B13}$$

and $D(s)$ can be written as

$$D(s)=P_1(s_n)e^{-i\Im(s)d_2}[e^{-\Re(s)d_2}\mathcal{R}_1+e^{2L\sigma}e^{-\Re(s)d_2}\mathcal{R}_2], \tag{B14}$$

where

$$\mathcal{R}_1=\frac{P_1(s)}{P_1(s_n)}, \quad \mathcal{R}_2=\frac{s^3P_2(s)}{s_n^3P_2(s_n)}. \tag{B15}$$

For n larger than some N we can make both $\mathcal{R}_1$ and $\mathcal{R}_2$ arbitrarily close to unity. For $n>N$ it follows that the magnitude of the sum in square brackets in (B14) must be larger than the second term, and hence

$$|D(s)|>|P_1(s_n)|e^{2L\sigma}e^{-\Re(s)d_2}|\mathcal{R}_2|. \tag{B16}$$

By choosing N large enough we can make $|P_1(s_n)|$ and $|\mathcal{R}_2|$ larger than n-independent constants, so that

$$|D(s)|>\text{const}\times e^{2L\sigma}e^{-\Re(s)d_2}=\text{const}\times e^{2L\sigma}e^{-\Re(s_n)d_2}e^{-\sigma d_2}. \tag{B17}$$

We have then that

$$\begin{aligned}|\mathcal{I}_{H_n}|&\leqslant\frac{K'}{n^{p-2}}e^{\Re(s_n)d_2}\left|\int_0^{-\Re(s_n)}e^{\sigma(d_2-2L)}\,d\sigma\right|\\&<\frac{K'}{n^{p-2}}e^{\Re(s_n)d_2}\left|\frac{1}{2L-d_2}\right|.\end{aligned} \tag{B18}$$

It follows from (B10) that we can choose a constant so that $|e^{\Re(s_n)d_2}|<\text{const}/n^{(3d_2/2L)}$, and therefore that

$$|\mathcal{I}_{H_n}|\leqslant\frac{\text{const}}{n^{p+(3d_2/2L)-2}}, \tag{B19}$$

which was to be proven. A similar proof shows that the same result applies to $|\mathcal{I}_{H_{-n}}|$.

Lemma 2: On the arc Γ_n from s_n^{mid} to s_{-n}^{mid} with $|s|=|s_n^{mid}|$, the magnitude of $\Delta(s)$ is larger than some constant that is independent of n.

Proof: We write

$$\Delta(s)=P_1(s)[1+\Phi(s)], \tag{B20}$$

where

$$\Phi(s)\equiv e^{2sL}s^3P_2(s)/P_1(s). \tag{B21}$$

We must show that $|1+\Phi|$ is bounded from below by an n-independent constant. We recall that $s_n^{mid}=s_n+i\pi/2L$ and that $\Phi(s_n)=-1$, so that

$$\Phi(s_n^{mid})\equiv\left(\frac{s_n^{mid}}{s_n}\right)^3\frac{P_2(s_n^{mid})}{P_2(s_n)}\frac{P_1(s_n)}{P_1(s_n^{mid})}. \tag{B22}$$

For n larger than some $N_{\min}$ we have that $\Phi(s_n^{mid})$ is arbitrarily close to unity, so that

$$\Phi(s_n^{mid})=1+\lambda, \tag{B23}$$

and $N_{\min}$ can be chosen large enough to make $|\lambda|$ arbitrarily small.

On the arc Γ_n we write $\Phi(s)$ as

$$\Phi(s)=e^{2sL}s^3(A_2/A_1)[1+\rho(s)]. \tag{B24}$$

By choosing $N_{\min}$ sufficiently large, we can bound the magnitude of ρ to be less than an arbitrarily small n-independent constant. For s on the arc Γ_n, we now write s as

$$s=R_n ie^{i\theta}, \tag{B25}$$

where $R_n\equiv|s_n^{mid}|$ and θ is the counterclockwise angle from the positive imaginary s axis to the point s on Γ_n. We denote by θ_n the angle to s_n^{mid}, so that $s_n^{mid}\equiv R_n ie^{i\theta_n}$ and we write $\theta\equiv\theta_n+\delta\theta$. In terms of this notation we have

$$\Phi(s)=F_0F_1(\delta\theta)F_2(\delta\theta), \tag{B26}$$

where

$$F_0\equiv(1+\lambda)(1+\rho(s))/(1+\rho(s_n^{mid})), \tag{B27}$$

$$F_1\equiv e^{2iLR_n[\cos(\theta_n+\delta\theta)-\cos(\theta_n)]}e^{3i\delta\theta}, \tag{B28}$$

$$F_2\equiv e^{2LR_n[\sin(\theta_n)-\sin(\theta_n+\delta\theta)]}. \tag{B29}$$

The complex phase of $\Phi(s)$ is near zero at $s=s_n^{mid}$, and decreases as s moves counterclockwise along the arc Γ_n. We use the expressions above to find at what value $\delta\theta^*$ of $\delta\theta$ the phase of Φ first becomes $-\pi/2$. We note that $|F_1|=1$ and on the top half of the arc $F_2\leqslant 1$. The value of $\delta\theta^*$ is given by

$$2LR_n[\cos(\theta_n+\delta\theta^*)-\cos(\theta_n)]+3\delta\theta^*+\zeta(\theta_n+\delta\theta^*)=-\pi/2, \tag{B30}$$

where $\zeta(\theta)$ is the phase of F_0. We note that

$$|\cos(\theta_n+\delta\theta^*)-\cos(\theta_n)|>\sin(\theta_n)\delta\theta^*.$$

From (B10) we know that sin θ_n decreases with n as $\ln(n)/n$, and R_n increases as n. Thus, the first term in (B30) is larger than the second by a factor that increases as $\ln(n)$. The third term, the ζ term, decreases with increasing n, and we can bound it to be smaller than an arbitrarily small constant by choosing $N_{\min}$ sufficiently large. From these considerations it follows that we can choose $N_{\min}$ large enough that the magnitude of the first term in (B30) is larger than, say 2/3, of the magnitude of the left hand side, and hence $\delta\theta^*$ satisfies

$$2LR_n[\cos(\theta_n)-\cos(\theta_n+\delta\theta^*)]>\pi/3. \tag{B31}$$

Let us also take $N_{\min}$ large enough so that $\theta_n+\delta\theta^*<\pi/4$. In that case we have

$$\frac{\sin(\theta_n+\delta\theta^*)-\sin(\theta_n)}{\cos(\theta_n)-\cos(\theta_n+\delta\theta^*)}>1. \tag{B32}$$

From this it follows that $2LR_n[\sin(\theta_n+\delta\theta^*)-\sin(\theta_n)]>\pi/3$, and hence $F_2<e^{-\pi/3}$. Since the deviation of $|F_0|$ from unity is arbitrarily small, let us use $|F_0|<e^{\pi/12}$ and conclude that $|\Phi|<e^{-\pi/4}$ at the point along Γ_n at which Φ first becomes purely imaginary. As $\delta\theta$ increases, the magnitude of Φ continues to decrease. It follows that for every point along the top of the arc,

$$|1+\Phi|>1-e^{-\pi/4}. \tag{B33}$$

A similar analysis starting at s_{-n} shows that (B33) holds also for the bottom half of the arc.

Lemma 3: On the arc Γ_n from s_n^{mid} to s_{-n}^{mid} with $|s|=|s_n^{mid}|$, the integral,

$$\mathcal{I}_{\Gamma_n}(d_1)\equiv\frac{1}{2\pi i}\int\frac{s^2\phi(s)e^{s(d_1+d_2)}}{\Delta(s)}ds, \tag{B34}$$

satisfies

$$|\mathcal{I}_{\Gamma_n}(d_1)|<\frac{\text{const}}{n^{p+(3d_2/L)-2}}, \tag{B35}$$

where the constant is independent of n.

Proof: On Γ_n we have that $\Re(s)\leqslant\Re(s_n)$, so that

$$|e^{sd_2}|\leqslant|e^{\Re(s_n)d_2}|, \tag{B36}$$

and, for some constant, the right hand side of (B36) is less than const/$n^{(3d_2/2L)}$. We have seen that $|\Delta|$ is bounded from below on Γ_n. With the bound on $|\phi(s)|$ from (B4), we have then that

$$|\mathcal{I}_{\Gamma_n}(d_1)|<\frac{\text{const}}{n^{p+(3d_2/2L)-2}}\int_{\Gamma_n}e^{\Re(s)d_1}|ds|. \tag{B37}$$

Since the integrand is everywhere non-negative, we have that

$$\int_{\Gamma_n}e^{\Re(s)d_1}|ds|<\int_{\text{arc}}e^{\Re(s)d_1}|ds|, \tag{B38}$$

where the arc is the half circle with $|s|=|s_n^{mid}|=R_n$ in the left half plane. But, the integral along the half circle is

$$\int_{\text{arc}}e^{\Re(s)d_1}|ds|=R_n\int_0^{\pi}e^{-d_1R_n\sin\theta}d\theta=2R_n\int_0^{\pi/2}e^{-d_1R_n\sin\theta}d\theta$$
$$<R_n\int_0^{\pi/2}e^{-2d_1R_n\theta/\pi}d\theta=\frac{\pi}{d_1}(1-e^{-d_1R_n}). \tag{B39}$$

This completes the proof of the lemma.

Proof of main result: We define C_n as the integration path on the imaginary s axis from $i\Im(s_{-n})-i\pi/2L$ to $i\Im(s_n)+i\pi/2L$, and we define

$$\mathcal{I}_n(d_1)\equiv\int_{C_n}F(s)ds. \tag{B40}$$

We let $\mathcal{I}_{n,\text{closed}}(d_1)$ be the integral on the closed path consisting of C_n, of Γ_n, of H_n and of H_{-n} traced backwards. From the lemmas above we have

$$|\mathcal{I}_n(d_1)-\mathcal{I}_{n,\text{closed}}(d_1)|<|\mathcal{I}_{\Gamma_n}(d_1)|+|\mathcal{I}_{H_n}(d_1)|+|\mathcal{I}_{H_{-n}}(d_1)|<\frac{\text{const}}{n^{p+(3d_2/2L)-2}}. \tag{B41}$$

The integral on the closed path is $2i\pi$ times the sum of the residues inside the path,

$$\mathcal{I}_{n,\text{closed}}(d_1)=\sum_{-n}^{n}a^{(k)}e^{s_kd_1}, \tag{B42}$$

where $a^{(k)}$ is the residue of $s^2\phi(s)e^{sd_2}/\Delta$ at $s=s_k$. Since the only singularities of the integrand in the finite s plane are simple poles at the roots of $\Delta(s)$, these $a^{(k)}$ coefficients are those defined in (B7). We have then

$$\left|\mathcal{I}_n(d_1)-\sum_{-n}^{n} a^{(k)}e^{s_k d_1}\right|<\frac{\text{const}}{n^{p+(3d_2/2L)-2}}, \tag{B43}$$

and our main result follows from the fact that $\mathcal{I}(d_1)$ is the limit of $\mathcal{I}_n(d_1)$ as $n\to\infty$.

We now turn to the role played by the Cauchy data. In the Green's function solution for the waveform [see the discussion following (21)], a function of s appears representing the integral of the product of $f_-(s,x)$ and the combination $J(x,s)\equiv-\dot{\psi}_0(x)-s\psi_0(x)$. In the case of the TDP or spiked TDP, $f_-(s,x)=e^{sx}$. Let us suppose that the support of the Cauchy data is confined to the region $x_2<x<x_1$. The Cauchy data then enters the s integral through the function

$$\mathcal{J}(s)\equiv\int_{x_2}^{x_1}J(x,s)e^{sx}dx. \tag{B44}$$

If the initial waveform $\psi_0(x)$ satisfies

$$\left|\frac{d^{p+1}}{dx^{p+1}}\psi_0(x)\right|<b_0, \tag{B45}$$

then from integration by parts, we have

$$\int_{x_2}^{x_1}e^{sx}\psi_0(x)dx=-\frac{1}{s}\int_{x_2}^{x_1}e^{sx}\frac{d}{dx}[\psi_0(x)]dx \tag{B46}$$

$$=\ldots\pm\frac{1}{s^{p+1}}\int_{x_2}^{x_1}e^{sx}\frac{d^{p+1}}{dx^{p+1}}[\psi_0(x)]dx \tag{B47}$$

$$=\ldots\pm\frac{1}{s^{p+1}}e^{sx_2}\int_{x_2}^{x_1}e^{s(x-x_2)}\frac{d^{p+1}}{dx^{p+1}}[\psi_0(x)]dx. \tag{B48}$$

For $\Re(s)\leqslant 0$ the factor $e^{s(x-x_2)}$ in the last integral is $\leqslant 1$, so that

$$\left|e^{-sx_2}\int_{x_2}^{x_1}e^{sx}\psi_0(x)dx\right|<\frac{|b_0(x_1-x_2)|}{|s|^{p+1}}. \tag{B49}$$

If, in addition to the constraint in (B45) we have that the pth derivative of $\dot{\psi}_0(x)$ is bounded, then by a very similar argument we can show that $\phi(s)$, defined as $e^{-sx_2}\mathcal{J}(s)$, satisfies

$$|\phi(s)|<\frac{\text{const}}{|s|^p}. \tag{B50}$$

We can now apply the above mathematical results to the Green's function integral from Sec. III. The waveform is given by the following integral along the imaginary s axis:

$$\psi(t,x)=\frac{1}{2i\pi}\int\frac{e^{s(t-x)}\mathcal{J}(s)}{W(s)}ds, \tag{B51}$$

where $W(s)$ is given in (A21)–(A24) and has the form $W(s)=s^{-2}e^{-2sL}\Delta(s)$ in which $\Delta(s)$ is a special case of (B2) and (B3). We can therefore rewrite the solution as

$$\psi(t,x)=\frac{1}{2i\pi}\int\frac{s^2e^{s(t-x+x_2+2L)}\phi(s)}{\Delta(s)}ds. \tag{B52}$$

The above proof requires that p, d_1, d_2, and L satisfy the inequalities that follow (B4). The details of the proof show that the rate of convergence depends on these parameters. In particular, on the value of $\gamma\equiv p+(3d_2/2L)-2$. A small value of this parameter means slow convergence. We can now relate the details of the proof to the examples presented in Sec. III, and examine the interesting nature of the convergence of the series given there. We start by noting that a straightforward computation of $\phi(s)\equiv e^{-sx_2}\mathcal{J}(s)$, for the Cauchy data of (19), shows that $p=1$. Comparing (B1) and (B52) we see that

$$d_1+d_2=t-x+x_2+2L=t-x+x_1-x_1+x_2+2L. \tag{B53}$$

An ''obvious'' choice is to take $d_1=t-x+x_1$, the retarded time from the start of the reception of signals from the Cauchy data. At any x this is the equivalent of $t-t_{\min}$. With this choice we are left with $d_2=x_2-x_1+2L$. (Note that $2L-d_2=x_1-x_2$ is positive, as required in the proof.) The value of γ for this choice is given by

$$\gamma\equiv p+\frac{3d_2}{2L}-2=2-3\frac{x_1-x_2}{2L}. \tag{B54}$$

In our examples, we choose x_1-x_2, the range of support of the Cauchy data, to be 6 and we have $L=9$, so γ is unity. Suppose, though, that we had chosen $x_1=1$ (as in our standard sine wave data of Sec. III) but had decreased the value of x_2 below our standard choice, -5. The details of the proof show that convergence would require more terms for a given level of accuracy and that the series would fail to converge for $x_2\leqslant 11$. This limit can be extended if we use initial data with one or more continuous derivatives, i.e., if $p>1$. This rather unusual feature was, in fact, exactly what was observed in numerical experiments.

We point out next that Lemma 3 shows that convergence is not uniform in d_1. As d_1 gets smaller, more terms in the series are needed. With our choice of d_1 to be $t-t_{\min}$, this implies that the convergence of our QN series in (B6) is not uniform as $t-t_{\min}\to 0$, contradicting our claims of uniform convergence made following (5). But note that we can choose $d_1\equiv t-t_{\min}+1$, so that convergence *is* uniform for $t>t_{\min}$. In this case we have $\gamma=2-3(x_1-x_2+1)/2L$. For both our sine wave Cauchy data this γ has a numerical value of 5/6, and the series is convergent. It is clear that there is an interaction between the allowed range of the Cauchy data, and the range of t for which the QN series converges. By moving the left edge of the support of the Cauchy data to the left by some amount δ, we increase by $3\delta/(2L)$ the value of t at which the series first converges. It should also be noted that the dependence on d_1 explains why the QN series converge more quickly at early times than at late, a feature evident in Fig. 9.

(Received 18 May 1998; accepted for publication 8 July 1998)

An algorithm for the construction of O(n) Gel'fand–Zetlin states in an invariant vector space is developed. The states are calculated recursively using a new type of coefficient of fractional parentage. These coefficients are the eigenvectors of the Gel'fand invariants. It is shown that the calculation of the Gel'fand invariants' matrix elements can be reduced to the evaluation of a single generator at each step. This algorithm provides a new approach to the calculation of the Clebsh–Gordon coefficients and isoscalar factors for the orthogonal group and can be applied to construct a basis function with well-defined orthogonal symmetry for physical systems where separation between collective motions and intrinsic motions, associated with the group O(n), is of interest.
[S0022-2488(99)01702-8]

I. INTRODUCTION

A few years ago Novoselsky, Katriel, and Gilmore (NKG)[1] developed a new algorithm for the construction of irreducible representations (irreps) of the symmetric group. In their approach they used the canonical nature of the group subgroup chain of the symmetric groups, $S_n \supset S_{n-1} \supset \cdots \supset S_2 \supset S_1$, and formulated a recursive algorithm in which one starts with basis functions that belong to the irreps of S_1, then transforms this basis into new basis functions that belong to well-defined irreps of S_2. These basis functions are then symmetrized with respect to S_3, and so on. After $n-1$ recurrence steps one gets basis functions that belong to well-defined irreps of the symmetric group S_n and are characterized by the Yamanouchi symbols. Assuming that basis functions with well-defined S_{n-1} symmetry have already been constructed, NKG have shown that the eigenvalues of the transposition class-sum operator uniquely identify the irreps of symmetric group S_n, and, therefore, the eigenvectors are the new basis functions which belong to well defined irreps of S_n. The key point in this algorithm is that the calculation of the matrix elements of the transposition class-sum operator can be reduced to the calculation of the matrix elements of the transposition $(n,n-1)$. The algorithm has been successfully applied for a number of mathematical and physical problems, such as the calculation of coefficients of fractional parentage in the $L-S$ coupling scheme[1] and the evaluation of the inner product and the outer product isoscalar factors of the symmetric group.[2] It was also applied for constructing harmonic oscillator nonspurious states[3] and hyperspherical states[4] with definite permutational symmetry. In all these applications the *same* basic algorithm has been employed using the appropriate realization of the transposition $(n,n-1)$ and the invariant subspaces. Comparing it with other symmetrization methods the NKG algorithm was proven to be very suitable for numerical calculations.

In the current work we present a generalization of the NKG algorithm for a canonical chain of Lie groups. This paper is devoted to the orthogonal group O(n) because of its importance in physics.[5] However, the results may be applied with minor necessary changes to the unitary group as well.

The orthogonal group O(n) is the set of all linear transformations in the n-dimensional real

[a)]Electronic mail: barnea@ect.unitn.it

Euclidean space which conserve the quadratic form, i.e., the sum over all the squares of the coordinates. This group is actually the set of all $n\times n$ real orthogonal matrices with determinant ±1 [For the special case where the determinant of these matrices is only $+1$ we obtain the special orthogonal group SO(n).] The irreducible representations of this group are well known. The analog of the Yamanouchi symbol for O(n) is the Gel'fand–Zetlin (GZ) pattern[6,7] which provides an elegant way for labeling the states in a definite O(n) irrep in terms of the canonical group subgroup chain $\mathrm{O}(n)\supset\mathrm{O}(n-1)\supset\cdots\supset\mathrm{O}(3)\supset\mathrm{O}(2)$.

The orthogonal group and the GZ basis play already an important role in the theoretical microscopic approach to nuclear collective models[8,9]. A problem of $3n$ degrees of freedom of n nucleons can be described by 9 collective degrees of freedom and $3n-9$ internal degrees of freedom which may be associated with the manifold $\mathrm{O}(n-1)/\mathrm{O}(n-4)$. Looking for wave functions with a definite irrep of a dynamical group Sp($6n$), where $\mathrm{Sp}(6)\times\mathrm{O}(n-1)$ is one of its subgroups, Moshinsky[10] has noted that the collective effects can be introduced by the constraint that the n-body wave function is restricted to a given irrep of the orthogonal group $\mathrm{O}(n-1)$. Moshinsky and Quesene have shown in Ref. 11 that the irrep of the group $\mathrm{O}(n-1)$ determines that of the group $Sp(6)$ and thus these two groups are ''complementary.'' Therefore, some of the microscopic collective models of the nuclei are related to the $Sp(6)$ group and others to the $\mathrm{O}(n-1)$ group.

Another physical application for the GZ states and the O(n) group-subgroup chain, arises in a few body calculations where one tries to construct n-body basis functions with definite permutational symmetry. The symmetric group S_n is a subgroup of the orthogonal group $\mathrm{O}(n-1)$. Knowing that, Surkov[12] suggested many years ago to use the orthogonal group as an intermediate step in the construction of symmetric hyperspherical states. In his work, Surkov constructed, at first, four-body hyperspherical states, of power 4 or less, that belong to well defined irreps of O(3) and then reduced these states into irreps of the symmetric group S_4. The main difficulty in applying these ideas to physics is the problem of constructing basis functions which belong to a definite GZ state. This problem was a great obstacle in the development of the orthogonal group approach to the n-body problem[10,13,14] and in further development of Surkov's approach.

Recently Barnea and Novoselsky[5] have extended the NKG method for the calculation of hyperspherical states with definite $\mathrm{O}(n-1)$ GZ pattern. This states where later symmetrized using the original NKG method for the evaluation of the $\mathrm{O}(n-1)\downarrow S_n$ coefficients of fractional parentage. The new computational algorithm was applied for the construction of states with arbitrary permutational symmetry and found to be substantially more efficient than the original one. In that work,[5] we used the second-order Casimir operator to separate the O(n) irreps. However, unlike the transposition class-sum operator the eigenvalues of the second-order Casimir operator of O(n) are degenerate, i.e., they have different irreps with the same eigenvalue, for instance, the irreps (4,0) and (3,3) of O(4) have the same eigenvalue 24. The usual method to remove this degeneracy is to use higher-order Casimir operators, also known as the Gel'fand invariants. In the case of the orthogonal group one should use only the forth-, sixth-, ..., i.e., the even-order operators since the eigenvalues of the $(2k+1)$th-order operator can be written as a function of the eigenvalues of the second-, forth-, $\ldots,2k$-th order operators. However, the Gel'fand operators involve a sum over products of generators and their evaluation is an unpleasant task in practice. Therefore, we were forced to use the Gram–Schmidt procedure in order to remove the degeneracy.

In this paper we present a method which overcome this difficulty, and reduce the evaluation of the Gel'fand invariants to the evaluation of a single generator at each recurrence step. In order to overcome this difficulty we follow Edwards[15] who has shown that the mth order Gel'fand invariant can be related with the trace of the mth power of a suitably defined operator P. Using this idea, the calculation of the Gel'fand invariants is reduced to evaluation of the matrix elements of a single generator, namely $X_{k,k-1}$ at each step. Unlike Ref. 5, which was dedicated for the specific case of the hyperspherical basis function, in this work we present general derivation of the recursive algorithm for constructing O(n) Gel'fand–Zetlin states in terms of orthogonal parentage coefficients, opcs. This algorithm can be applied for the efficient construction of n-body states as well as for the calculation of the Clebsh–Gordon coefficients and the outer product isoscalar factors of the orthogonal group. Its application for the unitary group is straightforward. The only differences that come along with the application of the method to various problems are the identification of the invariant subspaces and the realization of the generators.

The algorithm proceeds as follows:

(i) After $(k-1)$ recurrence steps the $O(n)$ invariant space is reduced into $O(k)$ invariant subspaces, each correspond to a single $O(k)$ irrep. Every subspace is spanned by the appropriate GZ states.

(ii) The even-order Gel'fand invariants, i.e., the second-order Casimir operator, the forth-order Casimir operator, etc., of the group $O(k+1)$ are diagonalized in this basis. The operators are diagonalized one by one until all the irreps are uniquely identified.

(iii) After the diagonalization of the appropriate matrices:

(1) The eigenvalues identify the irrep of the relevant group to which the eigenvector belong, and
(2) the eigenvectors are the $O(k)\rightarrow O(k+1)$ transformation coefficients. These are the orthogonal parentage coefficients, opcs.

(iv) If $k+1$ is an even number, we diagonalize the generator $X_{k,k+1}$ in the highest weight $O(k)$ state, in order to distinguish the two $SO(k+1)$ irreps in $O(k+1)$.

We start this paper by reviewing the concept of parentage coefficients in view of its role in our algorithm; we also define the orthogonal parentage coefficients, opcs, and their properties. The Gel'fand invariants and Edwards method for their evaluation are then presented in Sec. III. In Sec. IV we derive the recurrence relation for the calculation of the P operator and then present in Sec. V the evaluation of the Gel'fand invariants in terms of the generator $X_{n,n-1}$. The $O(k+1)$ Gel'fand invariants do not mix states from different $O(k)$ irreps since they commute with all the generators of $O(k)$. Therefore, different $O(k)$ states enter into the $O(k+1)$ irrep with arbitrary phase. The procedure used to solve this problem is also discussed in Sec. V. A full and systematic presentation of the algorithm presented above is given in Sec. VI.

II. THE ORTHOGONAL PARENTAGE COEFFICIENTS

The rank, r, of the Lie algebra associated with the Lie group $O(k)$ is given by $r=[k/2]$. Therefore the irreducible representations (irreps) of the orthogonal group $O(k)$, $\boldsymbol{\lambda}_k$, are labeled by $\boldsymbol{\lambda}_k=(\lambda_{k,1},\lambda_{k,2},\ldots,\lambda_{k,r})$. The values of $\lambda_{k,j}$ are positive and either all integers or half-integers. In the case $k=2r$, the $O(k)$ representations $(\lambda_{k,1},\lambda_{k,2},\ldots,\lambda_{k,r})$ splits into the two $SO(k)$ irreps $(\lambda_{k,1},\lambda_{k,2},\ldots,\lambda_{k,r})$ and $(\lambda_{k,1},\lambda_{k,2},\ldots,-\lambda_{k,r})$ if $\lambda_{k,r}\neq 0$, while for $\lambda_{k,r}=0$ or odd k the irreps of $O(k)$ are irreducible under $SO(k)$. In what follows we shall be working with the group $SO(k)$, remembering the connection between its irreps and the irreps of $O(k)$. The basis vectors of an irrep $\boldsymbol{\lambda}_k$ are completely specified by the Gel'fand-Zetlin[5] states, $\boldsymbol{\Lambda}_k$. These states, $\boldsymbol{\Lambda}_k$, are labeled by the canonical chain of subgroups $SO(k)\supset SO(k-1)\supset\cdots\supset SO(3)\supset SO(2)$, or $\boldsymbol{\Lambda}_k=[\boldsymbol{\lambda}_k\boldsymbol{\lambda}_{k-1}\cdots\boldsymbol{\lambda}_2]$, and are restricted according to the following rules, given by Gel'fand and Zetlin,[6] $\lambda_{k,j}\geqslant\lambda_{k-1,j}\geqslant|\lambda_{k,j+1}|$ and $\lambda_{k,j}\geqslant|\lambda_{k-1,j}|$.

The purpose of this paper is to present a recursive method to transform a given basis, $\{|a\rangle,a=1,\ldots,dim(V_p)\}$, of an $O(n)$ invariant vector space V_p into the Gel'fand–Zetlin basis, i.e., we are looking for the transformation

$$|\boldsymbol{\Lambda}_k^p a_k\rangle=\sum_{a_1=1}^{\dim(V_p)} U^{(k)}_{\boldsymbol{\Lambda}_k^p a_k,a_1}|a_1\rangle. \tag{1}$$

Here a_k is the degeneracy of the $SO(k)$ irrep $\boldsymbol{\lambda}_k$ in V_p, $a_1=a$, $\mathbf{U}^{(k)}$ is an unitary matrix and the superscript p is used to denote the vectors in V_p, the primary space (we are going to introduce another, secondary vector space in the next section). The main idea in the recursive method is to present $\mathbf{U}^{(k)}$ as a product of a sequence of block diagonal matrices $\{\mathbf{C}^{(m)},m=2,\ldots,k\}$, where $\mathbf{C}^{(m)}$, the step transformation matrix, is used to transform the $O(m-1)$ GZ states into $O(m)$ states,

$$|\mathbf{\Lambda}_m^p a_m\rangle=\sum_{a_{m-1}} C^{(m)\mathbf{\Lambda}_{m-1}^p}_{\boldsymbol{\lambda}_m^p a_m,a_{m-1}}|\mathbf{\Lambda}_{m-1}^p a_{m-1}\rangle. \tag{2}$$

The step transformation matrix $\mathbf{C}^{(m)}$ is block diagonal since $\mathbf{\Lambda}_m^p=[\boldsymbol{\lambda}_m^p,\mathbf{\Lambda}_{m-1}^p]$ and it doesn't alter the value of $\mathbf{\Lambda}_{m-1}^p$. Therefore, we can see that

$$U^{(k)}_{\mathbf{\Lambda}_k^p a_k,a_1}=\sum_{a_{k-1},a_{k-2},\ldots,a_2} C^{(k)\mathbf{\Lambda}_{k-1}^p}_{\boldsymbol{\lambda}_k^p a_k,a_{k-1}} C^{(k-1)\mathbf{\Lambda}_{k-2}^p}_{\boldsymbol{\lambda}_{k-2}^p a_{k-1},a_{k-2}}\cdots C^{(2)}_{\boldsymbol{\lambda}_2^p a_2,a_1}. \tag{3}$$

The orthogonal parentage coefficients, opcs, are the matrix elements of the step transformation matrix $C^{(m)\mathbf{\Lambda}_{m-1}^p}_{\boldsymbol{\lambda}_m^p a_m,a_{m-1}}$. The opcs, defined in Eq. (2) satisfy, the orthogonality relation

$$\sum_{a_{m-1}} C^{(m)\mathbf{\Lambda}_{m-1}^p}_{\boldsymbol{\lambda}_m^p a_m,a_{m-1}}{}^{*}C^{(m)\mathbf{\Lambda}_{m-1}^p}_{\boldsymbol{\lambda}'^p_m a'_m,a_{m-1}}=\delta_{\boldsymbol{\lambda}'^p_m,\boldsymbol{\lambda}_m^p}\delta_{a'_m,a_m}, \tag{4}$$

which follows from the orthogonality of the mth step basis states. The opcs also satisfy the completeness relation

$$\sum_{\boldsymbol{\lambda}_m^p,a_m} C^{(m)\mathbf{\Lambda}_{m-1}^p}_{\boldsymbol{\lambda}_m^p a_m,a_{m-1}}{}^{*}C^{(m)\mathbf{\Lambda}_{m-1}^p}_{\boldsymbol{\lambda}_m^p a_m,a'_{m-1}}=\delta_{a'_{m-1},a_{m-1}}. \tag{5}$$

As an example, let V_p be the invariant subspace created by the outer product of two irreps of O(n), i.e., $V_p=\boldsymbol{\lambda}_n^1\otimes\boldsymbol{\lambda}_n^2$. In this case the matrix elements of the transformation matrix $\mathbf{U}^{(k)}$, which transforms the outer product subspace $\boldsymbol{\lambda}_n^1\otimes\boldsymbol{\lambda}_n^2$ into the GZ states $\boldsymbol{\lambda}_n^p$ are just the O(n) Clebsh–Gordon coefficients, and the opcs are the O(n) isoscalar factors.

III. THE O(n) GENERATORS AND THE P OPERATOR

Let X_{ij} be the generators of the group O(n) in the primary invariant vector space, V_p, satisfying the following commutation relations:

$$[X_{ij},X_{kl}]=-i(\delta_{jk}X_{il}+\delta_{il}X_{jk}-\delta_{ik}X_{jl}-\delta_{jl}X_{ik}). \tag{6}$$

The set of operators, namely the Gel'fand invariants for O(n), defined by

$$I_k(X_{ij})=\sum_{i_1,i_2,\ldots,i_k}^{n} X_{i_1i_2}X_{i_2i_3}\ldots X_{i_ki_1}, \tag{7}$$

are a set of Casimir operators for O(n), which commute with the algebra generators, i.e., $[I_k(X_{ij}),X_{i_1i_2}]=0$ for $i_1,i_2=1,\ldots,n$. The eigenvalue of $I_k(X_{ij})$ corresponding to a given irrep of O(n) or SO(n), presented by $\boldsymbol{\lambda}_n$, can be written in the following way:[15]

$$I_k|_{\boldsymbol{\lambda}_n}=\sum_{i=1}^{n}(q_i)^k\Pi_{j=1 j\neq i}^{n}\frac{q_j-q_i+1+\epsilon_{ji}}{q_j-q_i}, \tag{8}$$

where

$$\epsilon_{ji}=\begin{cases}-\delta_{j,n+1-i} & \text{for } n=2r,\\ \delta_{j,n+1-i}-\delta_{i,r+1} & \text{for } n=2r+1,\end{cases} \tag{9}$$

and the q_i's are given by the following expressions: for $i=1,\ldots,r=[(n/2)]$,

$$q_i=\lambda_{n,i}+n-i-1, \tag{10}$$

for $i=n-r+1,\dots,n$,

$$q_i=-\lambda_{n,n+1-i}+n-i, \tag{11}$$

and if n is an odd number, then

$$q_{(n+1)/2}=r. \tag{12}$$

The spectra of the Gel'fand invariants can be used to uniquely identify the irreps of $\mathrm{O}(n)$. It turns out[16] that the invariant operators $I_k(X_{ij})$ with odd k are not independent and can be expressed in terms of the $I_{2j}(X_{ij})$ operators with $2j<k$. However, the Gel'fand operators $I_k(X_{ij})$ with even k are invariant to reflection and therefore they can't be used to split an $\mathrm{O}(n)$ irrep into the proper $\mathrm{SO}(n)$ irreps. Following Edwards[15] we introduce a second invariant vector space, V_s, taken to be the carrier space of the fundamental representation $1_n=(1,0,\dots,0)$ and denote by E_{ij} the generators of $\mathrm{O}(n)$ on V_s. We may now define a representation on the tensor product carrier space $V=V_s\otimes V_p$ by the generators $G_{ij}=E_{ij}\otimes 1+1\otimes X_{ij}$. Consider now the operator P_n in $V_s\otimes V_p$, defined by

$$P_n=\frac{1}{2}\sum_{ij}^{n} E_{ij}\otimes X_{ij}. \tag{13}$$

We shall see that the kth-order Gel'fand invariant can be identified with the trace of $(P_n)^k$. P_n commutes with the generators G_{ij} as can be seen from the identity

$$I_2(G_{ij})=(E_{ij}\otimes 1+1\otimes X_{ij})(E_{ij}\otimes 1+1\otimes X_{ij})=I_2(E_{ij})\otimes 1+4P_n+1\otimes I_2(X_{ij}). \tag{14}$$

We may choose a basis for V_s such that the generators of $\mathrm{O}(n)$ have matrix elements:

$$\langle\alpha|E_{ij}|\beta\rangle=\delta_{i\alpha}\delta_{j\beta}-\delta_{j\alpha}\delta_{i\beta}. \tag{15}$$

If we denote by $|a\rangle$ the set of basis vectors of V_p, then by writing $|\alpha;a\rangle$ for $|\alpha\rangle\otimes|a\rangle$ we have

$$\langle\alpha;a|P_n|\beta;b\rangle=\langle a|X_{\alpha\beta}|b\rangle. \tag{16}$$

Then

$$\begin{aligned}\langle\alpha;a|(P_n)^k|\beta;b\rangle&=\sum_{a_1\dots a_{k-1}}\sum_{\alpha_1\dots\alpha_{k-1}}\langle\alpha;a|P_n|\alpha_1;a_1\rangle\\&\quad\times\langle\alpha_1;a_1|P_n|\alpha_2;a_2\rangle\dots\langle\alpha_{k-1};a_{k-1}|P_n|\beta;b\rangle\\&=\sum_{a_1\dots a_{k-1}}\sum_{\alpha_1\dots\alpha_{k-1}}\langle a|X_{\alpha\alpha_1}|a_1\rangle\langle a_1|X_{\alpha 1\alpha_2}|a_2\rangle\dots\langle a_{k-1}|X_{\alpha_{k-1}\beta}|b\rangle\\&=\sum_{\alpha_1\dots\alpha_{k-1}}\langle a|X_{\alpha\alpha_1}X_{\alpha 1\alpha_2}\dots X_{\alpha_{k-1}\beta}|b\rangle.\end{aligned} \tag{17}$$

Thus,

$$\sum_{\alpha}\langle\alpha;a|(P_n)^k|\alpha;b\rangle=\sum_{\alpha\alpha_1\dots\alpha_{k-1}}\langle a|X_{\alpha\alpha_1}X_{\alpha_1\alpha_2}\dots X_{\alpha_{k-1}\alpha}|b\rangle=\langle a|I_k(X_{ij})|b\rangle. \tag{18}$$

It should be noted that this result is independent of the choice of basis for V_s, as we use the trace operator in this space.

IV. THE RECURRENCE RELATIONS FOR P_n

In this section the general algorithm for the construction of the GZ states is given. First let us assume the existence of a complete set of basis vectors, $|\boldsymbol{\Lambda}_{n-1}^p a_{n-1}\rangle$, for the primary space, V_p. These states are characterized by the SO$(n-1)$ GZ states and by a_{n-1}, the degeneracy of the SO$(n-1)$ irrep $\boldsymbol{\lambda}_{n-1}^p$ in V_p. Our aim is to transform this basis vectors into basis vectors that belong to well-defined irreps of the group SO(n). The actual transformation will take place by diagonalization of the Gel'fand invariants, Eq. (7), one by one until all the O(n) irreps are completely determined. The procedure for reducing the O(n) irreps into the proper SO(n) irreps will be presented below. The common eigenvectors of $I_k, \{k=2,4,\ldots,n\}$ are simply the step transformation matrix $\mathbf{C}^{(n)}$ for SO$(n-1)\rightarrow$O(n), whose elements are the opcs. As we have seen in the previous section, the calculation of the matrix elements of the Gel'fand invariants is equivalent to the calculation of the matrix elements of the operator P_n in the tensor product space V. The operator P_n presented in Sec. III, Eq. (13), can be rewritten as

$$P_n = P_{n-1} + \sum_{i=1}^{n-1} E_{ni} \otimes X_{ni}. \tag{19}$$

Since P_n commutes with the generators of O(n) in the tensor product carrier space V, the set $P_2, P_3, \ldots, P_n$ forms a set of mutually commuting operators. More than that, P_n is a block diagonal and does not mix vectors that belong to different irreps of SO(k) for $k<n$. Denoting by $|\boldsymbol{\Lambda}_{n-1}^s\rangle$ the basis vectors of V_s, we can use the SO$(n-1)$ Clebsch–Gordan coefficients to construct basis vectors of irreducible representations in the tensor product space:

$$|(\boldsymbol{\lambda}_{n-1}^s;\boldsymbol{\lambda}_{n-1}^p a_{n-1})\boldsymbol{\Lambda}_{n-1}\rangle = \sum_{\boldsymbol{\Lambda}_{n-2}^s \boldsymbol{\Lambda}_{n-2}^p} \left(\begin{matrix} \boldsymbol{\lambda}_{n-1}^s & \boldsymbol{\lambda}_{n-1}^p \\ \boldsymbol{\Lambda}_{n-2}^s & \boldsymbol{\Lambda}_{n-2}^p \end{matrix} \middle| \begin{matrix} \boldsymbol{\lambda}_{n-1} \\ \boldsymbol{\Lambda}_{n-2} \end{matrix} \right) |\boldsymbol{\lambda}_{n-1}^s \boldsymbol{\Lambda}_{n-2}^s\rangle \otimes |\boldsymbol{\lambda}_{n-1}^p \boldsymbol{\Lambda}_{n-2}^p a_{n-1}\rangle. \tag{20}$$

In principle there might be multiplicity of the representation $\boldsymbol{\lambda}_{n-1}$ in the tensor product space $1_{n-1}\otimes\boldsymbol{\lambda}_{n-1}^p$. However, as can be seen in Appendix A, as far as we are concerned there is no such problem. These vectors, Eq. (20), are eigenvectors of the second-order Casimir operators in V_p, V_s and in V. Therefore, as a result of Eq. (14) they are eigenvectors of P_{n-1} as well,

$$\begin{aligned} &\langle(\boldsymbol{\lambda}_{n-1}^s;\boldsymbol{\lambda}_{n-1}^p)\boldsymbol{\Lambda}_{n-1}a_{n-1}|P_{n-1}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\Lambda}'_{n-1}a'_{n-1}\rangle \\ &\quad = \delta_{\boldsymbol{\Lambda}_{n-1}\boldsymbol{\Lambda}'_{n-1}} \delta_{\boldsymbol{\lambda}_{n-1}^s,\boldsymbol{\lambda}'^s_{n-1}} \delta_{\boldsymbol{\lambda}_{n-1}^p,\boldsymbol{\lambda}'^p_{n-1}} \delta_{a_{n-1},a'_{n-1}} \tfrac{1}{4}[I_2|(\boldsymbol{\lambda}_{n-1}) - I_2|(\boldsymbol{\lambda}_{n-1}^p) - I_2|(\boldsymbol{\lambda}_{n-1}^s)]. \end{aligned} \tag{21}$$

The second term on the right-hand side of Eq. (19) can be evaluated recalling the fact that an element $g_{i,n-1}$ always exists in SO$(n-1)$ such that $E_{n,i}\otimes X_{n,i} = g_{i,n-1}^{-1}(E_{n,n-1}\otimes X_{n,n-1})g_{i,n-1}$. Therefore the matrix element of the second term in (19) is

$$\begin{aligned} &\sum_{i=1}^{n-1} \langle(\boldsymbol{\lambda}_{n-1}^s;\boldsymbol{\lambda}_{n-1}^p)\boldsymbol{\Lambda}_{n-1}a_{n-1}|E_{n,i}\otimes X_{n,i}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\Lambda}'_{n-1}a'_{n-1}\rangle \\ &\quad = \delta_{\boldsymbol{\Lambda}_{n-1}\boldsymbol{\Lambda}'_{n-1}} \sum_{i=1}^{n-1} \langle(\boldsymbol{\lambda}_{n-1}^s;\boldsymbol{\lambda}_{n-1}^p)\boldsymbol{\Lambda}_{n-1}a_{n-1}|g_{i,n-1}^{-1}(E_{n,n-1} \\ &\qquad \otimes X_{n,n-1})g_{i,n-1}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\Lambda}_{n-1}a'_{n-1}\rangle. \end{aligned} \tag{22}$$

The $\delta_{\boldsymbol{\Lambda}_{n-1}\boldsymbol{\Lambda}'_{n-1}}$ term on the rhs of Eq. (22) results from the fact that P_n is a scalar operator with respect to O$(n-1)$ in V. Replacing the $g_{i,n-1}$ operators by their representation matrices $D^{(\boldsymbol{\lambda}_{n-1})}_{\boldsymbol{\Lambda}_{n-2},\boldsymbol{\Lambda}'_{n-2}}(g_{i,n-1})$ we obtain the following expression for the matrix element (22):

$$\sum_{i=1}^{n-1} \langle(\boldsymbol{\lambda}^s_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\Lambda}_{n-1}a_{n-1}|E_{n,i}\otimes X_{n,i}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\Lambda}'_{n-1}a'_{n-1}\rangle$$
$$=\delta_{\boldsymbol{\Lambda}_{n-1}\boldsymbol{\Lambda}'_{n-1}}\sum_{i=1}^{n-1}\sum_{\boldsymbol{\Lambda}''_{n-2}} D^{(\boldsymbol{\lambda}_{n-1})}_{\boldsymbol{\Lambda}_{n-2},\boldsymbol{\Lambda}''_{n-2}}(g^{-1}_{i,n-1})D^{(\boldsymbol{\lambda}_{n-1})}_{\boldsymbol{\Lambda}''_{n-2},\boldsymbol{\Lambda}_{n-2}}(g_{i,n-1})$$
$$\times\langle(\boldsymbol{\lambda}^s_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\lambda}_{n-1}\boldsymbol{\Lambda}''_{n-2}a_{n-1}|E_{n,n-1}\otimes X_{n,n-1}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\lambda}_{n-1}\boldsymbol{\Lambda}''_{n-2}a'_{n-1}\rangle. \quad (23)$$

Deriving Eq. (23) we used the fact that the operators $X_{n,n-1}$ and $E_{n,n-1}$ commute with the generators of $O(n-2)$ and therefore the matrix element on the right-hand side is diagonal with respect to the $O(n-2)$ GZ states $\boldsymbol{\Lambda}''_{n-2}$. Since the matrix element is independent of $\boldsymbol{\Lambda}_{n-2}$, we can equivalently sum Eq. (23) on $\boldsymbol{\Lambda}_{n-2}$ and divide by $|\boldsymbol{\lambda}_{n-1}|$, the dimension of the $SO(n-1)$ irrep $\boldsymbol{\lambda}_{n-1}$, to get

$$\sum_{i=1}^{n-1} \langle(\boldsymbol{\lambda}^s_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\Lambda}_{n-1}a_{n-1}|E_{n,i}\otimes X_{n,i}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\Lambda}'_{n-1}a'_{n-1}\rangle$$
$$=\delta_{\boldsymbol{\Lambda}_{n-1}\boldsymbol{\Lambda}'_{n-1}}\frac{n-1}{|\boldsymbol{\lambda}_{n-1}|}\sum_{\boldsymbol{\Lambda}''_{n-2}}\langle(\boldsymbol{\lambda}^s_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\lambda}_{n-1}\boldsymbol{\Lambda}''_{n-2}a_{n-1}|E_{n,n-1}$$
$$\otimes X_{n,n-1}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\lambda}_{n-1}\boldsymbol{\Lambda}''_{n-2}a'_{n-1}\rangle. \quad (24)$$

Using Eqs. (15) and (20) and noting that in the fundamental representation

$$|n\rangle=[\boldsymbol{\lambda}_n=1_n,\boldsymbol{\lambda}_{n-1}=0_{n-1},\boldsymbol{\Lambda}_{n-2}=[0_{n-2}]],$$
$$|n-1\rangle=[\boldsymbol{\lambda}_n=1_n,\boldsymbol{\lambda}_{n-1}=1_{n-1},\boldsymbol{\Lambda}_{n-2}=[0_{n-2}]] \quad (25)$$

[here 1_n stands for the fundamental representation of $O(n)$ and 0_n stands for the scalar representation], the matrix element on the rhs of Eq. (24) takes the following form:

$$\langle(\boldsymbol{\lambda}^s_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\lambda}_{n-1}\boldsymbol{\Lambda}''_{n-2}a_{n-1}|E_{n,n-1}\otimes X_{n,n-1}|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\lambda}_{n-1}\boldsymbol{\Lambda}''_{n-2}a'_{n-1}\rangle$$
$$=(\delta_{\boldsymbol{\lambda}^s_{n-1},0_{n-1}}\delta_{\boldsymbol{\lambda}'^s_{n-1},1_{n-1}}-\delta_{\boldsymbol{\lambda}^s_{n-1},1_{n-1}}\delta_{\boldsymbol{\lambda}'^s_{n-1},0_{n-1}})$$
$$\times\left(\begin{array}{cc|c}\boldsymbol{\lambda}^s_{n-1} & \boldsymbol{\lambda}^p_{n-1} & \boldsymbol{\lambda}_{n-1}\\ [0_{n-2}] & \boldsymbol{\Lambda}^p_{n-2} & \boldsymbol{\Lambda}''_{n-2}\end{array}\right)^*\left(\begin{array}{cc|c}\boldsymbol{\lambda}'^s_{n-1} & \boldsymbol{\lambda}'^p_{n-1} & \boldsymbol{\lambda}_{n-1}\\ [0_{n-2}] & \boldsymbol{\Lambda}^p_{n-2} & \boldsymbol{\Lambda}''_{n-2}\end{array}\right)$$
$$\times\langle\boldsymbol{\lambda}^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}a_{n-1}|X_{n,n-1}|\boldsymbol{\lambda}'^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}a'_{n-1}\rangle. \quad (26)$$

Summing up the results of Eqs. (19) and (26) we get the expression for the matrix elements of P_n,

$$\langle(\boldsymbol{\lambda}^s_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\Lambda}_{n-1}a_{n-1}|P_n|(\boldsymbol{\lambda}'^s_{n-1};\boldsymbol{\lambda}'^p_{n-1})\boldsymbol{\Lambda}'_{n-1}a'_{n-1}\rangle$$
$$=\delta_{\boldsymbol{\Lambda}_{n-1}\boldsymbol{\Lambda}'_{n-1}}\Bigg\{\frac{1}{4}[I_2(\boldsymbol{\lambda}_{n-1})-I_2(\boldsymbol{\lambda}^p_{n-1})-I_2(\boldsymbol{\lambda}^s_{n-1})]\delta_{\boldsymbol{\lambda}^s_{n-1},\boldsymbol{\lambda}'^s_{n-1}}\delta_{\boldsymbol{\lambda}^p_{n-1},\boldsymbol{\lambda}'^p_{n-1}}\delta_{a_{n-1},a'_{n-1}}$$
$$+\frac{n-1}{|\boldsymbol{\lambda}_{n-1}|}\sum_{\boldsymbol{\Lambda}''_{n-2}}\langle\boldsymbol{\lambda}^p_{n-1}\boldsymbol{\Lambda}''_{n-2}a_{n-1}|X_{n,n-1}|\boldsymbol{\lambda}'^p_{n-1}\boldsymbol{\Lambda}''_{n-2}a'_{n-1}\rangle$$
$$\times\left[\left(\begin{array}{cc|c}1_{n-1} & \boldsymbol{\lambda}'^p_{n-1} & \boldsymbol{\lambda}_{n-1}\\ [0_{n-2}] & \boldsymbol{\Lambda}''_{n-2} & \boldsymbol{\Lambda}''_{n-2}\end{array}\right)\delta_{\boldsymbol{\lambda}^p_{n-1},\boldsymbol{\lambda}_{n-1}}-\left(\begin{array}{cc|c}1_{n-1} & \boldsymbol{\lambda}^p_{n-1} & \boldsymbol{\lambda}_{n-1}\\ [0_{n-2}] & \boldsymbol{\Lambda}''_{n-2} & \boldsymbol{\Lambda}''_{n-2}\end{array}\right)^*\delta_{\boldsymbol{\lambda}'^p_{n-1},\boldsymbol{\lambda}_{n-1}}\right]\Bigg\}. \quad (27)$$

The SO(n) CG coefficients needed in Eq. (27) were explicitly evaluated by Pang and Hecht[17] and are given in the appendix. Therefore the calculation of P_n is reduced to the calculation of $X_{n,n-1}$ at each recurrence step. It is assumed that we know how to evaluate the matrix elements of the generator $X_{n,n-1}$ between bra and ket states that belong to the original basis, i.e., $\{|a_1\rangle, a_1 = 1,\ldots,\dim(V_p)\}$, of the primary invariant subspace V_p. Then using the transformation matrix $\mathbf{U}^{(n-1)}$ defined in Eq. (1), we get the following expression

$$\langle \boldsymbol{\lambda}^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}a_{n-1}|X_{n,n-1}|\boldsymbol{\lambda}'^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}a'_{n-1}\rangle = \sum_{a_1,a'_1=1}^{\dim(V_p)} U^{(n-1)*}_{[\boldsymbol{\lambda}^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}]a_{n-1},a_1} U^{(n-1)}_{[\boldsymbol{\lambda}'^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}]a'_{n-1},a'_1}\langle a_1|X_{n,n-1}|a'_1\rangle, \tag{28}$$

for the matrix element of $X_{n,n-1}$. While applying this algorithm to the construction of hyperspherical or harmonic oscillator GZ functions we know how to evaluate the matrix elements of this generator between bra and ket states that belong to the set of basis states obtained before the last recurrence step. If this is the case we can save a lot of computation time and computer memory, skip the calculation of the transformation matrix $\mathbf{U}^{(n-1)}$, and write

$$\langle \boldsymbol{\lambda}^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}a_{n-1}|X_{n,n-1}|\boldsymbol{\lambda}'^p_{n-1}\boldsymbol{\Lambda}^p_{n-2}a'_{n-1}\rangle = \sum_{a_{n-2},a'_{n-2}} C^{(n-1)\boldsymbol{\Lambda}^p_{n-2}*}_{\boldsymbol{\lambda}^p_{n-1}a_{n-1},a_1} C^{(n-1)\boldsymbol{\Lambda}^p_{n-2}}_{\boldsymbol{\lambda}'^p_{n-1}a'_{n-1},a'_1}\langle \boldsymbol{\Lambda}^p_{n-2}a_{n-2}|X_{n,n-1}|\boldsymbol{\Lambda}^p_{n-2}a'_{n-2}\rangle. \tag{29}$$

As an example, let V_p be again the invariant subspace created by the outer product of two irreps of O(n), i.e., $V_p = \boldsymbol{\lambda}^1_n \otimes \boldsymbol{\lambda}^2_n$. The basis states obtained after $n-2$ recurrence steps are labeled in this example by $|\boldsymbol{\lambda}^1_n\boldsymbol{\lambda}^2_n(\boldsymbol{\lambda}^1_{n-1};\boldsymbol{\lambda}^2_{n-1})\boldsymbol{\Lambda}_{n-1}\rangle$. Since the generator $X_{n,n-1} = 1\otimes X^1_{n,n-1} + X^2_{n,n-1}\otimes 1$ commutes with the generators of O$(n-2)$ its matrix elements are independent of the O$(n-3)$ GZ states.

V. THE CALCULATION OF THE OPCS

So far we have seen that the calculation of the Gel'fand invariants can be reduced to the calculation of the operator P_n and that of P_n can be reduced to the calculation of the generator $X_{n,n-1}$ in each recurrence step. By simultaneous diagonalization of the Gel'fand invariants we can construct states which belong to a well defined O(n) irreps. The eigenvectors of these invariants are just the opcs of the SO$(n-1)\uparrow$O(n) induced representation up to a phase factor. The matrix elements of the Gel'fand invariants can be easily evaluated using Eqs. (18) and (20):

$$\begin{aligned}\langle \boldsymbol{\Lambda}^p_{n-1}a_{n-1}|I_k|\boldsymbol{\Lambda}'^p_{n-1}a'_{n-1}\rangle &= \delta_{\boldsymbol{\Lambda}^p_{n-1}\boldsymbol{\Lambda}'^p_{n-1}}\Bigg\{\langle(0_{n-1};\boldsymbol{\lambda}^p_{n-1})\Lambda^p_{n-1}a_{n-1}|(P_n)^k|(0_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\Lambda}^p_{n-1}a'_{n-1}\rangle \\ &+ \sum_{\boldsymbol{\Lambda}^s_{n-2}}\sum_{\Lambda_{n-1}}\left(\begin{array}{cc|c} 1_{n-1} & \lambda^p_{n-1} & \lambda_{n-1} \\ \Lambda^s_{n-1} & \Lambda^p_{n-2} & \Lambda_{n-2}\end{array}\right)^*\left(\begin{array}{cc|c} 1_{n-1} & \lambda^p_{n-1} & \lambda_{n-1} \\ \Lambda^s_{n-1} & \Lambda^p_{n-2} & \Lambda_{n-2}\end{array}\right) \\ &\times\langle(1_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\Lambda}_{n-1}a_{n-1}|(P_n)^k|(1_{n-1};\boldsymbol{\lambda}^p_{n-1})\boldsymbol{\Lambda}_{n-1}a'_{n-1}\rangle\Bigg\}.\end{aligned} \tag{30}$$

In deriving Eqs (30) we have used the fact that the fundamental representation $\boldsymbol{\lambda}_n = 1_n$ contains only the O$(n-1)$ irreps 0_{n-1} and 1_{n-1}. Furthermore, the Clebsch–Gordan coefficient for 0_{n-1} is 1. Since I_k commutes with $X_{i,j}$ it is diagonal with respect to $\boldsymbol{\Lambda}^p_{n-1}$, and we can sum Eq. (30) on $\boldsymbol{\Lambda}^p_{n-2}$ and use the orthogonality properties of the Clebsch–Gordan coefficients to obtain

$$\langle \mathbf{\Lambda}^p_{n-1} a_{n-1} | I_k | \mathbf{\Lambda}^p_{n-1} a'_{n-1} \rangle = \langle (0_{n-1}; \boldsymbol{\lambda}^p_{n-1}) \mathbf{\Lambda}^p_{n-1} a_{n-1} | (P_n)^k | (0_{n-1}; \boldsymbol{\lambda}^p_{n-1}) \mathbf{\Lambda}^p_{n-1} a'_{n-1} \rangle + \frac{1}{|\boldsymbol{\lambda}^p_{n-1}|} \times \sum_{\mathbf{\Lambda}_{n-1}} \langle (1_{n-1}; \boldsymbol{\lambda}^p_{n-1}) \mathbf{\Lambda}_{n-1} a_{n-1} | (P_n)^k | (1_{n-1}; \boldsymbol{\lambda}^p_{n-1}) \mathbf{\Lambda}_{n-1} a'_{n-1} \rangle. \tag{31}$$

Thus, we can see that at each recurrence step, once we know the matrix elements of the generator $X_{n,n-1}$, we can calculate P_n and then take its kth power to get the matrix elements of the Gel'fand invariants. The calculation of $(P_n)^k$ can be done by simply inserting a complete set of states between each power of P_n. After the diagonalization of $I_k\{k=2,4,\ldots,n\}$, we get states that belong to well-defined irreps of O(n).

When n is even we would like to split the O(n) irreps into SO(n) irreps. For this purpose, for each O(n) irrep we discard all the opcs but those originated from the highest weight SO($n-1$) irrep, $\boldsymbol{\lambda}^p_{n-1} = (\lambda^p_{n,1}, \lambda^p_{n,2}, \ldots, \lambda^p_{n,h})$, $(h=[(n-1)/2])$. The generator $X_{n,n-1}$ is then diagonalized in the space of the highest weight SO($n-2$) irrep $\boldsymbol{\lambda}^p_{n-2} = (\lambda^p_{n,1}, \lambda^p_{n,2}, \ldots, \lambda^p_{n,h'})$, $(h'=[(n-2)/2])$. The possible eigenvalues of $X_{n,n-1}$ are $\pm \lambda^p_{n\frac{n}{2}}$. The rest of the opcs will be recalculated using the procedure presented below for ensuring consistent phase of the opcs.

When states with a given SO(n) irrep $\boldsymbol{\lambda}^p_n$ can be obtained from more then one SO($n-1$) irrep $\boldsymbol{\lambda}^p_{n-1}$, our procedure leaves the relative phases of these states undetermined, since the diagonalization is performed for each SO($n-1$) irrep separately and the states $|\boldsymbol{\lambda}^p_{n-1} \mathbf{\Lambda}^p_{n-2} a_{n-1}\rangle$ enter the calculation in pairs. However from the works of Gel'fand and Zetlin[6] or Pang and Hecht[17] such states should be related as

$$\langle \boldsymbol{\lambda}^p_n \mathbf{\Lambda}'^p_{n-1} a_n | X_{n,n-1} | \boldsymbol{\lambda}^p_n \mathbf{\Lambda}^p_{n-1} a_n \rangle = \delta_{\mathbf{\Lambda}'_{n-2}, \mathbf{\Lambda}_{n-2}} F_n(\boldsymbol{\lambda}^p_n, \boldsymbol{\lambda}'^p_{n-1}, \boldsymbol{\lambda}^p_{n-1}, \boldsymbol{\lambda}^p_{n-2}), \tag{32}$$

where F_n, given in Appendix B, is zero unless $\boldsymbol{\lambda}'_{n-1} = \boldsymbol{\lambda}_{n-1}$ or $\lambda'_{n-1,i} = \lambda_{n-1,i} \pm \delta_{i,j}$. By expanding both sides of Eq. (32) in terms of the opcs and using the orthogonality of the opcs, Eq. (4), we obtain

$$C^{(n)\boldsymbol{\lambda}'^p_{n-1} \mathbf{\Lambda}^p_{n-2}}_{\boldsymbol{\lambda}^p_n a_n, a'_{n-1}} = \frac{1}{F_n(\boldsymbol{\lambda}^p_n, \boldsymbol{\lambda}'^p_{n-1}, \boldsymbol{\lambda}^p_{n-1}, \boldsymbol{\lambda}^p_{n-2})} \times \sum_{a_{n-1}} \langle \boldsymbol{\lambda}'^p_{n-1} \mathbf{\Lambda}^p_{n-2} a'_{n-1} | X_{n,n-1} | \boldsymbol{\lambda}^p_{n-1} \mathbf{\Lambda}^p_{n-2} a_{n-1} \rangle C^{(n)\boldsymbol{\lambda}^p_{n-1} \mathbf{\Lambda}^p_{n-2}}_{\boldsymbol{\lambda}^p_n a_n, a_{n-1}}. \tag{33}$$

This relation yields the orthogonal parentage coefficients $\boldsymbol{\lambda}'^p_{n-1} \to \boldsymbol{\lambda}^p_n$ in terms of the $\boldsymbol{\lambda}^p_{n-1} \to \boldsymbol{\lambda}^p_n$ orthogonal parentage coefficients. In conclusion, whenever the SO(n) irrep $\boldsymbol{\lambda}^p_n$ originates from more than one SO($n-1$) irrep we keep after diagonalization only the set of orthogonal parentage coefficients that originate from one particular irrep $\boldsymbol{\lambda}^p_{n-1}$ of SO($n-1$). The orthogonal parentage coefficients that originate from other SO($n-1$) irreps are constructed from the relation (33).

VI. THE COMPUTATIONAL ALGORITHM

In the previous sections we described the recursive method for the construction of O(n) GZ states by diagonalization of the Casimir operators I_k. Starting from basis states that belong to well-defined irreps of SO($n-1$) we may adopt the following procedure to carry out our algorithm systematically:

(i) Pick an irrep $\tilde{\boldsymbol{\lambda}}^p_{n-1}$ of SO(n), consider all the possible irreps $\boldsymbol{\lambda}_{n-1}$ that can be obtained from $\tilde{\boldsymbol{\lambda}}^p_{n-1}$ by the outer product $1_{n-1}\otimes\tilde{\boldsymbol{\lambda}}^p_{n-1}$. The possible $\boldsymbol{\lambda}_{n-1}$ irreps are $\lambda_{n-1,j}=\lambda^p_{n-1,j}$ and the irreps given by $\lambda_{n-1,j}=\lambda^p_{n-1,j}\pm\delta_{ij}$ that obey the GZ restrictions $\lambda_{n-1,j}\geqslant|\lambda_{n-1,j+1}|$.

(ii) For every irrep $\boldsymbol{\lambda}_{n-1}$ construct all the states (20) with $\boldsymbol{\lambda}^s_{n-1}=1_{n-1}$ or 0_{n-1} and the appropriate irreps $\boldsymbol{\lambda}^p_{n-1}$ of $SO(n-1)$.

(iii) Use Eq. (27) to evaluate the matrix elements of the operator P_n for each invariant subspace defined by $\boldsymbol{\lambda}_{n-1}$.

(iv) Calculate the matrix elements of the Gel'fand invariants $I_k, k=2,4,\ldots,n$ by taking the kth power of P_n, using Eq. (31).

(v) Evaluate the $SO(n-1)\uparrow O(n)$ opcs by diagonalizing of the Gel'fand invariants, $I_k, k=2,4,\ldots$, one by one until all the $O(n)$ irreps are completely determined.

(vi) For each $O(n)$ irrep $\boldsymbol{\lambda}^p_n$ keep the opcs for the highest weight $SO(n-1)$ irrep in $\boldsymbol{\lambda}^p_n$, i.e., $\boldsymbol{\lambda}^p_{n-1}=(\lambda^p_{n,1},\lambda^p_{n,2},\ldots,\lambda^p_{n,h})$, $(h=[(n-1)/2])$, and discard all the rest.

(vii) If n is even, split each $O(n)$ irrep into the appropriate $SO(n)$ irreps: for each $O(n)$ irrep diagonalize the generator $X_{n,n-1}$ in the space of highest weight states, taking $\boldsymbol{\lambda}^p_{n-2}=(\lambda^p_{n,1},\lambda^p_{n,2},\ldots,\lambda^p_{n,h'})$, $(h'=[(n-2)/2])$.

(viii) Regenerate the discarded opcs, with consistent phases, using Eq. (33) successively.

(ix) Pick another $SO(n-1)$ irrep and repeat the process. Continue for all the $SO(n-1)$ irreps.

It should be noted that if the invariant subspace is not too large, it is much more efficient to store the calculated matrix elements of P_n instead of regenerating them for each irrep $\tilde{\boldsymbol{\lambda}}^p_{n-1}$ of $SO(n)$.

VII. CONCLUSIONS

A new method for the construction of $O(n)$ Gel'fand–Zetlin states has been developed. The states are evaluated in terms of the given basis functions using the orthogonal parentage coefficients, opcs. The orthogonal parentage coefficients are calculated by diagonalization of the Gel'fand invariants. A crucial point is that it is sufficient to evaluate the matrix elements of the generator $X_{n,n-1}$ at each step. The construction of $O(n)$ Gel'fand Zetlin states is important primarily for systems with approximate $O(n)$ symmetry such as the general many-body theory where collective states are restricted to definite irrep of $O(n)$, or in the construction of states with definite permutational symmetry as the symmetry group S_n is a subgroup of $O(n-1)$. The recursive method described in this paper for the orthogonal group is closely related to the method developed few years ago by Novoselsky, Katriel, and Gilmore[1,3,4] for the calculation of the symmetry group cfps. This method may be applied to the harmonic oscillator or hyperspherical harmonic bases as well as for the calculation of outer product isoscalar factors of the orthogonal group.

ACKNOWLEDGMENTS

I wish to thank Professor Victor Mandelzweig for his comments and to Dr. Akiva Novoselsky for many inspiring discussions during this work.

APPENDIX A: CLEBSCH GORDON COEFFICIENTS

The $O(n)$ CG coefficients needed in Eq. (27) are the generalized CG coefficients for the Kronecker product $|1_n[0_{n-1}]\rangle\otimes|\boldsymbol{\lambda}_n\boldsymbol{\Lambda}_{n-1}\rangle$. This coefficients where explicitly evaluated by Pang and Hecht.[17] It is evident that these coefficients do not depend on the value of $\boldsymbol{\Lambda}_{n-2}$, thus we can write:

$$\left(\begin{matrix} 1_n & \boldsymbol{\lambda}'_n & \boldsymbol{\lambda}_n \\ [0_{n-1}] & \boldsymbol{\Lambda}_{n-1} & \boldsymbol{\Lambda}_{n-1} \end{matrix}\right)=\left(\begin{matrix} 1_n & \boldsymbol{\lambda}'_n & \boldsymbol{\lambda}_n \\ [0_{n-1}] & \boldsymbol{\lambda}_{n-1} & \boldsymbol{\lambda}_{n-1} \end{matrix}\right). \tag{A1}$$

The nonzero CG coefficients are given below by

$$\begin{pmatrix} 1_n & (\lambda_{n,1},\ldots,\lambda_{n,j}+1,\ldots,\lambda_{n,h},\lambda_{n,h+1}) & (\lambda_{n,1},\ldots,\lambda_{n,j},\ldots,\lambda_{n,h},\lambda_{n,h+1}) \\ [0_{n-1}] & (\lambda_{n-1,1},\ldots,\lambda_{n-1,j},\ldots,\lambda_{n-1,h}) & (\lambda_{n-1,1},\ldots,\lambda_{n-1,j},\ldots,\lambda_{n-1,h}) \end{pmatrix}$$

$$=\left|\prod_{i=1}^{h}\frac{(\lambda_{n,j}-\lambda_{n-1,i}+i-j+1)(\lambda_{n,j}+\lambda_{n-1,i}+n-i-j)}{(\lambda_{n,j}-\lambda_{n,i}+i-j+1)(\lambda_{n,j}+\lambda_{n,i}+n-i-j)}\right|^{\frac{1}{2}}, \tag{A2}$$

$$\left(\begin{matrix} 1_n & (\lambda_{n,1},\ldots,\lambda_{n,j},\ldots,\lambda_{n,h}) \\ [0_{n-1}] & (\lambda_{n-1,1},\ldots,\lambda_{n-1,j},\ldots,\lambda_{n-1,h}) \end{matrix}\middle| \begin{matrix} (\lambda_{n,1},\ldots,\lambda_{n,j},\ldots,\lambda_{n,h}) \\ (\lambda_{n-1,1},\ldots,\lambda_{n-1,j},\ldots,\lambda_{n-1,h}) \end{matrix}\right)$$

$$=(2h+2-n)\prod_{i=1}^{h}\frac{(\lambda_{n-1,i}+h-i)}{(\lambda_{n,i}+h-i)}. \tag{A3}$$

Here $h=[(n-1)/2]$, and for odd n $(n=2h+1)$ $\lambda_{n,h+1}=0$ in Eq. (A2). The expression for the CG coefficients for $\lambda_{n,j}-1$ are the same, replacing $\lambda_{n,j}$ by $\lambda_{n,j}-1$ on the rhs of Eq. (A2).

APPENDIX B: MATRIX ELEMENTS OF $X_{n,n-1}$

The matrix elements of the generator $X_{n,n-1}$ between GZ states have been given at first by Gel'fand and Zetlin[6] and were rederived later by Pang and Hecht.[17] For the sake of brevity we will denote the matrix elements of $X_{n,n-1}$ by F_n:

$$\langle \boldsymbol{\lambda}_n \boldsymbol{\Lambda}'_{n-1}|X_{n,n-1}|\boldsymbol{\lambda}_n\boldsymbol{\Lambda}_{n-1}\rangle=\delta_{\boldsymbol{\Lambda}'_{n-2},\boldsymbol{\Lambda}_{n-2}}F_n(\boldsymbol{\lambda}_n,\boldsymbol{\lambda}'_{n-1},\boldsymbol{\lambda}_{n-1},\boldsymbol{\lambda}_{n-2}). \tag{B1}$$

Here F_n is zero unless $\boldsymbol{\lambda}'_{n-1}=\boldsymbol{\lambda}_{n-1}$ or $\lambda'_{n-1,i}=\lambda_{n-1,i}\pm\delta_{i,j}$. Following the notation of Pang and Hecht[17] we shall define $t_{n,i}=\lambda_{n,i}+[(n+1)/2]-i$ and obtain for odd n $(=2k+1)$ the following expressions:

$$F_n(\boldsymbol{\lambda}_n,\boldsymbol{\lambda}'_{n-1}+\delta_{i,j},\boldsymbol{\lambda}_{n-1},\boldsymbol{\lambda}_{n-2})$$
$$=\frac{1}{2}\left|\frac{\Pi_{\alpha=1}^{k-1}(t_{2k-1,\alpha}-t_{2k,j}-1)(t_{2k-1,\alpha}+t_{2k,j})\Pi_{\beta=1}^{k}(t_{2k+1,\beta}-t_{2k,j}-1)(t_{2k+1,\beta}+t_{2k,j})}{\Pi_{\alpha\neq j}^{k}(t_{2k,\alpha}^2-t_{2k,j}^2)(t_{2k,\alpha}^2-(t_{2k,j}+1)^2)}\right|^{1/2}. \tag{B2}$$

For even n $(=2k)$ the diagonal matrix element is given by

$$F_n(\boldsymbol{\lambda}_n,\boldsymbol{\lambda}_{n-1},\boldsymbol{\lambda}_{n-1},\boldsymbol{\lambda}_{n-2})=i\,\frac{\Pi_{\alpha=1}^{k-1}t_{2k-2,\alpha}\Pi_{\beta=1}^{k}t_{2k,\beta}}{\Pi_{\alpha=1}^{k-1}t_{2k-1,\alpha}(t_{2k-1,\alpha}-1)} \tag{B3}$$

and the nondiagonal matrix element is

$$F_n(\boldsymbol{\lambda}_n,\boldsymbol{\lambda}_{n-1}+\delta_{i,j},\boldsymbol{\lambda}_{n-1},\boldsymbol{\lambda}_{n-2})$$
$$=\left|\frac{\Pi_{\alpha=1}^{k-1}(t_{2k-2,\alpha}^2-t_{2k-1,j}^2)\Pi_{\beta=1}^{k}(t_{2k,\beta}^2-t_{2k-1,j}^2)}{t_{2k-1,j}^2(4t_{2k-1,j}^2-1)\Pi_{\alpha\neq j}^{k-1}(t_{2k-1,\alpha}^2-t_{2k-1,j}^2)[(t_{2k-1,\alpha}-1)^2-t_{2k-1,j}^2]}\right|^{1/2}. \tag{B4}$$

Note that for $k=1$ there are undefined products in Eqs. (B2)–(B4) (for example, $\Pi_{\alpha=1}^{k-1}$). These products are equal to 1 in this case.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 2 FEBRUARY 1999

Deformations of global symmetries in the extended antifield formalism

Friedemann Brandt[a)]
Institut für Theoretische Physik, Universität Hannover, Appelstraße 2, D-30167 Hannover, Germany

(Received 11 June 1998; accepted for publication 11 November 1998)

It is outlined how deformations of field theoretical rigid symmetries can be constructed and classified by cohomological means in the extended antifield formalism. Special attention is devoted to deformations referring only to a subset of the rigid symmetries of a given model and leading to a nontrivial extension of the graded Lie algebra associated with that subset. The method is illustrated for a $D=4$, $N=2$ supersymmetric model where the central extension of the supersymmetry algebra emerges via a deformation. Deformations of gauge fixed actions with a BRST symmetry are discussed too and illustrated by the Curci–Ferrari model. © *1999 American Institute of Physics.* [S0022-2488(99)02802-9]

I. INTRODUCTION

A problem often met in field theory is to what degree a given action functional can be nontrivially deformed while keeping some of its symmetries. A particularly interesting issue is whether the symmetry transformations themselves can be deformed in a nontrivial way, i.e., whether there are simultaneous deformations of the action and its symmetries.

Deformations of this sort can be studied systematically by cohomological methods in the spirit of Gerstenhaber's approach to deformation theory.[1] This was first described in Ref. 2 (see also Refs. 3 and 4) for gauge symmetries in the framework of the standard antifield formalism.[5–7] The inclusion of rigid (=global) symmetries was roughly sketched more recently in Ref. 8 within an extended antifield formalism. The aim of this work is to develop the latter approach more thoroughly, with special attention to deformations which are required to maintain only (a deformed version of) a *subset* of the rigid symmetries of a given model.

The restriction to a subset of the rigid symmetries is a typical situation, as often it is neither possible nor desirable to keep all the rigid symmetries when deforming a field theory because that may constrain the sought deformations too much. We shall thus base the deformation theory on an extended antifield formalism which involves only a ''closed'' subset of rigid symmetries. The ''closure'' of the subset requires that the graded commutator algebra of the rigid symmetries under study closes in the soft (field theoretical) sense, i.e., up to gauge transformations and on-shell trivial symmetries. (In order to set up the extended antifield formalism, it may be necessary to include also ''symmetries of higher order.''[8,9]) In other words, a closed subset of rigid symmetries forms a subalgebra (in the soft sense) of the graded commutator algebra of all the rigid symmetries.

When one applies the extended antifield formalism to study deformations of such a subset of rigid symmetries, one may encounter a ''subtlety.'' Namely, a deformation may turn a subset of rigid symmetries which is closed in the soft sense into an open one. That is, it can happen that the deformed commutator algebra involves symmetries which did not occur in the undeformed one. These additional symmetries are not ''new'' ones which are introduced through the deformation. Rather, they are present already in the original (undeformed) model. The subtlety is that usually it is not clear from the outset which additional symmetries of the original model can show up in the

[a)]Electronic mail: brandt@itp.uni-hannover.de

deformed commutator algebra. In particular, this may depend on the deformation itself.

Hence, the property of a subset of rigid symmetries to be a closed one is not necessarily preserved by deformations. This is actually an interesting phenomenon as it is related to extensions of the (graded) Lie algebra associated with the commutator algebra of the subset of rigid symmetries under study. Important examples are central extensions of extended supersymmetry algebras.[10] As an illustration, we shall discuss a simple four-dimensional $N=2$ supersymmetric model for a hypermultiplet[11,12] where the central extension of the supersymmetry algebra arises indeed via a deformation of the model.

The antifield formalism serves in this context as a tool that allows one to formulate the deformation theory conveniently in cohomological terms. Ghost fields are not dynamical in this approach (in particular, they are not paired with antighost fields), in contrast to their counterparts in the quantum field theoretical context. Nevertheless, the formalism applies also to gauge fixed action functionals which contain dynamical ghost and antighost fields. This application just requires a slight change of the point of view as compared to the one familiar from quantum field theory. Namely, the gauge fixed action simply takes the role of a classical action. Accordingly, the dynamical ghost and antighost fields occurring in the gauge fixed action are counted among the classical fields, and the Becchi–Rouet–Stora–Tyutin (BRST) symmetry of the gauge fixed action counts among the rigid symmetries. In particular this allows one to investigate deformations of the BRST symmetry after fixing the gauge. We shall discuss and illustrate this particular application in some detail in the Curci–Ferrari model.[13–15]

The paper has been organized as follows. Section II summarizes basic properties of global and local symmetries in Lagrangian field theory which are used later on. Then the extended antifield formalism and the construction and properties of the extended BRST differential are briefly reviewed in Secs. III and IV. The systematic approach to the deformation problem is described in Sec. V. Sections VI and VII contain the examples mentioned above, i.e., the hypermultiplet of $N=2$ supersymmetry and the Curci–Ferrari model. The paper is ended with some concluding remarks in Sec. VIII.

II. GLOBAL AND LOCAL SYMMETRIES

We shall first briefly summarize the definition and some properties of continuous rigid and gauge symmetries in Lagrangian field theories, following the presumably most popular approach based on the action (alternatively one can define rigid and gauge symmetries on the level of the field equations, via conserved currents and Noether identities respectively). We shall thus consider Lagrangian field theories which derive from an action functional for a set of fields $\phi^i(x)$,

$$S_{\text{class}}[\phi]=\int d^nxL(x,[\phi]), \tag{2.1}$$

where $L(x,[\phi])$ is a Lagrangian constructed of the fields and their partial derivatives. {Here and in the following, $[\phi]$ denotes collectively dependence on the fields and on their derivatives. In more precise mathematical terms, $\phi^i,\partial_\mu\phi^i,\partial_\mu\partial_\nu\phi^i,\ldots$ are to be understood as local coordinates of a jet space, and $\phi^i(x)$ as sections of the jet bundle over an n-dimensional base manifold (''space–time'') with local coordinates x^μ $(\mu=1,\ldots,n)$. The arguments of $L(x,[\phi])$ indicate that the Lagrangian may (but, of course, need not) depend explicitly on the x^μ.} The field equations (equations of motion) derive via the variational principle from S_{class}, i.e., they are the corresponding Euler–Lagrange equations.

A continuous rigid symmetry of an action (2.1) is generated by transformations of the fields with a constant infinitesimal parameter ε,

$$\phi^i\rightarrow\tilde{\phi}^i=\phi^i+\varepsilon\, G^i(x,[\phi]),\quad \varepsilon=\text{const}, \tag{2.2}$$

such that $L(x,[\tilde{\phi}])$ differs from $L(x,[\phi])$ to first order in ε at most by a total derivative,

$$L(x,[\tilde{\phi}])=L(x,[\phi])+\varepsilon\partial_\mu k^\mu(x,[\phi])+O(\varepsilon^2). \tag{2.3}$$

A gauge symmetry of an action (2.1) is defined similarly, with the important difference that it involves, instead of a constant parameter, an additional field $\lambda=\lambda(x)$ (i.e., a field which does not occur in the Lagrangian). It is generated by infinitesimal transformations of the form

$$\phi^i\to\tilde{\phi}^i=\phi^i+\sum_{k\geq 0} r^{i\mu_1\cdots\mu_k}(x,[\phi])\partial_{\mu_1}\cdots\partial_{\mu_k}\lambda \tag{2.4}$$

such that $L(x,[\tilde{\phi}])$ and $L(x,[\phi])$ differ to first order in λ at most by a total derivative,

$$L(x,[\tilde{\phi}])=L(x,[\phi])+\partial_\mu h^\mu(x,[\phi,\lambda])+O(\lambda^2). \tag{2.5}$$

This invariance condition must hold for an unconstrained field λ, i.e., it must neither impose a differential equation for λ, nor determine λ in terms of the fields ϕ^i and their derivatives [otherwise λ would turn into a function of the x^μ, ϕ^i and their derivatives and thus (2.4) would reduce to a rigid symmetry of the form (2.2)].

Now, the above standard definitions do not yet characterize symmetries satisfactorily for our purpose. An important ingredient, underplayed in many textbooks, is still missing: the distinction between trivial and nontrivial symmetries. For instance, consider transformations (2.2) and (2.4) with

$$G^i(x,[\phi])=E^{ij}(x,[\phi])\frac{\hat{\partial}L}{\hat{\partial}\phi^j}, \tag{2.6}$$

$$\sum_{k\geq 0} r^{i\mu_1\cdots\mu_k}(x,[\phi])\partial_{\mu_1}\cdots\partial_{\mu_k}\lambda=E^{ij}(x,[\phi,\lambda])\frac{\hat{\partial}L}{\hat{\partial}\phi^j}, \tag{2.7}$$

where $\hat{\partial}L/\hat{\partial}\phi^i$ is the Euler–Lagrange derivative of the Lagrangian with respect to ϕ^i,

$$\frac{\hat{\partial}L}{\hat{\partial}\phi^i}=\frac{\partial L}{\partial\phi^i}-\partial_\mu\frac{\partial L}{\partial(\partial_\mu\phi^i)}+\cdots, \tag{2.8}$$

and E^{ij} are any functions which are only required to be graded antisymmetric in their indices,

$$E^{ij}=(-)^{\epsilon_i\epsilon_j+1}E^{ji}, \tag{2.9}$$

where ϵ_i is the Grassmann parity of ϕ^i. It is easily verified that (2.6) and (2.7) give rigid and gauge symmetries, satisfying (2.3) and (2.5), respectively, for any choice of E^{ij} fulfilling (2.9). Such symmetries are examples of trivial symmetries which may be called ''on-shell trivial symmetries'' (the terminology reflects that the symmetry transformations vanish for every solution of the field equations, as the latter read $\hat{\partial}L/\hat{\partial}\phi^i=0$). More general trivial symmetries of this type are obtained from (2.6) and (2.7) when E^{ij} are differential operators of the form $E^{ij}=\sum e^{ij\,\mu_1\cdots\mu_k}\partial_{\mu_1}\cdots\partial_{\mu_k}$ with properties generalizing (2.9) appropriately.

In addition to on-shell trivial symmetries, there is a second type of trivial rigid symmetry whenever the action possesses a true gauge symmetry, i.e., a gauge symmetry which is not on-shell trivial. Indeed, in that case the action has automatically infinitely many further rigid symmetries which are to be considered as trivial too, even though they are not on-shell trivial. These additional trivial rigid symmetries arise from nontrivial gauge transformations (2.4) by replacing λ with $\varepsilon\, f(x,[\phi])$ there, where $f(x,[\phi])$ is any function of the fields and their derivatives. Indeed, as (2.5) holds for any λ, such a replacement results in a transformation (2.2) satisfying (2.3) with

$$G^i(x,[\phi])=\sum_{k\geqslant 0} r^{i\,\mu_1\cdots\mu_k}(x,[\phi])\,\partial_{\mu_1}\cdots\partial_{\mu_k}f(x,[\phi]). \tag{2.10}$$

Hence, every action has infinitely many trivial gauge and rigid symmetries. Gauge and rigid symmetries are therefore best defined as *equivalence classes* where two symmetries are called equivalent when they differ by a trivial symmetry (and by irrelevant redefinitions of the respective ε and λ, i.e., by multiplications of ε and λ with arbitrary constants and field dependent functions, respectively). [Clearly, two symmetries differing only through such redefinitions are to be identified, as (2.3) and (2.5) must hold for arbitrary constant parameters ε and unconstrained fields λ.] One can then introduce the concept of a basis of symmetries, containing one representative of each nontrivial equivalence class. We shall characterize such bases for the gauge and rigid symmetries through operations $\{\delta_\alpha\}$ and $\{\Delta_a\}$, respectively, which are related to symmetry transformations (2.2) and (2.4) according to

$$\delta_\alpha\phi^i=R^i_\alpha(x,[\phi])\equiv\sum_{k\geqslant 0} r_\alpha^{i\,\mu_1\cdots\mu_k}(x,[\phi])\,\partial_{\mu_1}\cdots\partial_{\mu_k}, \tag{2.11}$$

$$\Delta_a\phi^i=G^i_a(x,[\phi]). \tag{2.12}$$

As the graded commutator of two infinitesimal symmetry transformations is automatically again an infinitesimal symmetry transformation (due to the derivation property of infinitesimal transformations), there is always a graded commutator algebra associated with such bases. However, due to the presence of trivial symmetries, this graded commutator algebra is in general a quotient algebra because, in general, the graded commutator of two elements of the basis can be expressed in terms of elements of the same basis only up to trivial symmetries. In particular, the general form of the graded commutator of any two elements of a basis of infinitesimal rigid symmetry transformations is thus

$$[\Delta_a,\Delta_b]\phi^i=f_{ab}^c\Delta_c\phi^i+R^i_\alpha f^\alpha_{ab}(x,[\phi])+E^{ij}_{ab}(x,[\phi])\,\frac{\hat\partial L}{\hat\partial\phi^j}, \tag{2.13}$$

where the graded commutator of two objects A and B is defined by means of their Grassmann parities $\epsilon(A)$ and $\epsilon(B)$ through

$$[A,B]=AB-(-)^{\epsilon(A)\epsilon(B)}BA. \tag{2.14}$$

In (2.13), f_{ab}^c are constant coefficients which are the structure constants of a graded Lie algebra (as a consequence of $[[\Delta_a,\Delta_b],\Delta_c]+\text{cyclic}=0)$, while $f^\alpha_{ab}(x,[\phi])$ and $E^{ij}_{ab}(x,[\phi])$ are, in general, field-dependent functions and operators appearing in trivial rigid symmetries as described above, cf. (2.10) and (2.6).

III. EXTENDED ANTIFIELD FORMALISM

We shall now recall the basic features of the extended antifield formalism and fix our notation and conventions. For simplicity, we shall concentrate on the case that the gauge transformations (if any) are irreducible and that only ordinary rigid symmetries are present or needed, but no rigid symmetries of higher order in the terminology of Ref. 8. The general case is a straightforward extension of this one. As mentioned already, the extended antifield formalism can be established for any closed subset of rigid symmetries.[8] When higher-order rigid symmetries are absent, a closed subset is simply a subset $\{\Delta_{\underline{a}}\}$ of a basis $\{\Delta_a\}$ of nontrivial rigid symmetries such that, in the notation of the previous section,

$$\{\Delta_a\}=\{\Delta_{\underline{a}},\Delta_{\hat{a}}\},\quad f_{\underline{ab}}^{\hat{c}}=0\quad \forall \underline{a},\underline{b},\hat{c}. \tag{3.1}$$

Here $f_{\underline{ab}}^{\hat{c}}=0$ requires that the graded commutator algebra of the $\Delta_{\underline{a}}$ is a subalgebra of (2.13) in the "soft" sense, i.e., with respect to the quotient structure "modulo trivial rigid symmetries."

The fields and antifields of the standard antifield formalism are denoted by Φ^A and Φ_A^* where $\{\Phi^A\}$ contains the "classical" fields ϕ^i, i.e., the fields occurring in the "classical" action (2.1) under study, and the ghost fields C^α corresponding to the nontrivial gauge symmetries of this action. (As mentioned in the Introduction, the "classical" action may be actually a gauged fixed one. Ghost and antighost fields occurring in such an action count among the ϕ^i and must not be confused with the C^α. See Sec. VII for an example.) The extended antifield formalism, restricted to the subset $\{\Delta_{\underline{a}}\}$, contains in addition constant ("global") ghosts $\xi^{\underline{a}}$ for each $\Delta_{\underline{a}}$. These global ghosts have ghost number 1 and Grassmann parity opposite to the corresponding rigid symmetries. It is also very convenient (though not necessary in principle) to accompany each $\xi^{\underline{a}}$ with a constant antifield $\xi_{\underline{a}}^*$. The latter has ghost number (-2) and Grassmann parity opposite to $\xi^{\underline{a}}$. In particular, this allows one to set up the extended antifield formalism through an extended master equation of the form

$$(S,S)=0, \tag{3.2}$$

where $(\,,\,)$ is an extended antibracket defined by

$$(X,Y)=\frac{\partial^R X}{\partial \xi^{\underline{a}}}\frac{\partial^L Y}{\partial \xi_{\underline{a}}^*}-\frac{\partial^R X}{\partial \xi_{\underline{a}}^*}\frac{\partial^L Y}{\partial \xi^{\underline{a}}}+\int d^nx\left[\frac{\delta^R X}{\delta\Phi^A(x)}\frac{\delta^L Y}{\delta\Phi_A^*(x)}-\frac{\delta^R X}{\delta\Phi_A^*(x)}\frac{\delta^L Y}{\delta\Phi^A(x)}\right]. \tag{3.3}$$

Here superscripts R and L indicate right and left derivatives, respectively. The extended antibracket is defined in the space of local functionals of the form

$$\Gamma[\Phi,\Phi^*,\xi]+M^{\underline{a}}(\xi)\xi_{\underline{a}}^*, \tag{3.4}$$

where $\Gamma[\Phi,\Phi^*,\xi]$ is the space–time integral of a local function of the fields and antifields which may depend on the global ghosts but not on the global antifields, and $M^{\underline{a}}(\xi)$ is a polynomial in the global ghosts [note: $M^{\underline{a}}(\xi)\xi_{\underline{a}}^*$ does not involve a space–time integration]. The solution S of the extended master equation is a functional with ghost number 0 of the form (3.4). It contains the classical action, and encodes its gauge symmetries and the subset $\{\Delta_{\underline{a}}\}$ of its rigid symmetries, as well as the graded commutator algebra of these symmetries. In addition one often imposes that S be real. One then needs consistent conventions for complex conjugation. We denote complex conjugation by a bar, and use the convention (familiar from supersymmetry, see, e.g., Ref. 16) that complex conjugation of products involves a sign factor depending on the Grassmann parities,

$$\overline{(XY)}=(-)^{\epsilon_X\epsilon_Y}\overline{X}\,\overline{Y}. \tag{3.5}$$

The complex conjugate of an antifield Φ^* equals minus the antifield of the complex conjugate of Φ (independently of the Grassmann parity of Φ),

$$\overline{(\Phi^*)}=-(\overline{\Phi})^*\quad \forall \Phi\in\{\Phi^A,\xi^{\underline{a}}\}. \tag{3.6}$$

For instance, with these conventions, the antifield of a real field is purely imaginary.

To describe and compute S, it is useful to expand it in the antifield number (agh). The latter vanishes for the fields, and equals minus the ghost number for the antifields,

$$\begin{aligned}&\text{agh }\phi^i=\text{agh }C^\alpha=\text{agh }\xi^{\underline{a}}=0,\\ &\text{agh }\phi_i^*=1,\quad \text{agh }C_\alpha^*=\text{agh }\xi_{\underline{a}}^*=2.\end{aligned} \tag{3.7}$$

The expansion of S is denoted by

$$S=\sum_{k\geqslant 0} S_k, \quad \text{agh}\, S_k=k. \tag{3.8}$$

Here S_0 is the classical action,

$$S_0=S_{\text{class}}[\phi]. \tag{3.9}$$

S_1 encodes both the gauge transformations and the subset of the rigid symmetries under study,

$$S_1=-\int d^nx(R_\alpha^i C^\alpha+\xi^{\underline{a}}\Delta_{\underline{a}}\phi^i)\phi_i^*, \tag{3.10}$$

where we used the notation of the previous section. S_2 encodes the graded commutator algebra of the gauge symmetries and the subset of rigid symmetries under study, and thus, in particular, the subalgebra of (2.13) referring to $\{\Delta_{\underline{a}}\}$,

$$S_2=\frac{1}{2}\xi^{\underline{b}}\xi^{\underline{a}}\tilde{f}_{\underline{ab}}^{\underline{c}}\xi_{\underline{c}}^*+\int d^nx\, \xi^{\underline{b}}\xi^{\underline{a}}\left(\tfrac{1}{2}\tilde{f}_{\underline{ab}}^{\alpha}C_\alpha^*+\tfrac{1}{4}\phi_i^*\tilde{E}_{\underline{ab}}^{ij}\phi_j^*+\cdots\right), \tag{3.11}$$

where $\tilde{f}_{\underline{ab}}^{\underline{c}}$, $\tilde{f}_{\underline{ab}}^{\alpha}$, $\tilde{E}_{\underline{ab}}^{ij}$ coincide with $f_{\underline{ab}}^{\underline{c}}$, $f_{\underline{ab}}^{\alpha}$, $E_{\underline{ab}}^{ij}$ in (2.13) up to signs which follow from the formulas [e.g., $\tilde{f}_{\underline{ab}}^{\underline{c}}=(-)^{\epsilon_{\underline{b}}+1}f_{\underline{ab}}^{\underline{c}}$ where $\epsilon_{\underline{b}}$ is the Grassmann parity of $\Delta_{\underline{b}}$]. The nonwritten terms in (3.11) encode analogously the graded commutator algebra of the gauge symmetries, and of the gauge symmetries with the $\Delta_{\underline{a}}$. Higher terms S_k $(k>2)$ in the expansion of S reflect consistency relations following from the graded commutator algebra. The solution of the extended master equation encodes thus the complete algebraic structure of the gauge and rigid symmetries under study. In particular, the piece in $(S,S)=0$ which is linear in ξ^* yields

$$f_{[\underline{ab}}^{\underline{e}}f_{\underline{c}]\underline{e}}^{\underline{d}}=0, \tag{3.12}$$

where $[\cdots]$ indicates graded antisymmetrization. Equation (3.12) is the Jacobi identity for the structure constants of a graded Lie algebra and reflects again that the commutator algebra of the $\Delta_{\underline{a}}$ constitutes a subalgebra of (2.13) in the soft sense. Of course, in general this commutator algebra is not a true graded Lie algebra, but still a graded Lie algebra in the soft sense.

IV. EXTENDED BRST AND KOSZUL–TATE DIFFERENTIAL

The extended antifield formalism outlined in the previous section implies the existence of a nilpotent antiderivation which generalizes the standard BRST differential so as to incorporate rigid symmetries. We call this antiderivation extended BRST differential and denote it by s. It is defined in the space of local functionals of the form (3.4) via the extended antibracket through

$$sX=(S,X). \tag{4.1}$$

With this definition, s squares to zero (=is ‘‘nilpotent’’),

$$s(XY)=(sX)Y+(-)^{\epsilon_X}X(sY), \quad s^2=0. \tag{4.2}$$

Furthermore, s is a real differential if S is a real functional. As s is Grassmann odd, this means, due to (3.5),

$$\overline{(sX)} = (-)^{\epsilon_X} s\overline{X}. \tag{4.3}$$

It is useful to expand s in the antifield number. The structure of S implies that the expansion of s starts with a piece δ that has antifield number -1 (i.e., δ lowers the antifield number by one unit),

$$s = \delta + \gamma + \sum_{i \geqslant 1} s_i, \quad \text{agh}\,\delta = -1,, \quad \text{agh}\,\gamma = 0, \quad \text{agh}\,s_i = i. \tag{4.4}$$

The nilpotency of s implies anticommutation relations between the pieces in this decomposition,

$$\delta^2 = 0, \quad [\delta,\gamma] = 0, \quad \gamma^2 + [\delta, s_1] = 0, \ldots . \tag{4.5}$$

Here δ is the extension of the field theoretical Koszul–Tate differential.[6,17,18] It acts nontrivially only on the antifields, and coincides on Φ_A^* with the standard Koszul–Tate differential, while $\delta\xi_{\underline{a}}^*$ is an integrated local functional associated with the corresponding rigid symmetry,

$$\delta\Phi^A = \delta\xi^{\underline{a}} = 0, \quad \delta\phi_i^* = \frac{\hat{\partial}^R L}{\hat{\partial}\phi^i}$$
$$\delta C_\alpha^* = R_\alpha^{i\,\dagger}\phi_i^*, \quad \delta\xi_{\underline{a}}^* = (-)^{\epsilon_{\underline{a}}} \int d^n x (\Delta_{\underline{a}}\phi^i)\phi_i^*, \tag{4.6}$$

where $R_\alpha^{i\,\dagger}$ is the operator adjoint to R_α^i (its precise definition, which includes a sign depending on the Grassmann parity, follows from the formulas).

Here δ is a nilpotent antiderivation by (4.5). It therefore establishes the cohomological groups $H_k(\delta)$ at antifield number k in the space of local functionals (3.4). By construction, δ is acyclic at all positive antifield numbers $[H_k(\delta) \simeq 0 \ \ \forall k > 0]$ when S encodes *all* the gauge and rigid symmetries (of first and higher order).[8] In contrast, when only a subset of the rigid symmetries is included, $H_k(\delta)$ corresponds at positive antifield number k to the remaining rigid symmetries of order k and is represented by functionals that would be of the form $M^{\hat{a}}(\xi)\delta\xi_{\hat{a}}^*$ if all the rigid symmetries had been included. Hence, $H_1(\delta)$ is represented by functionals

$$M^{\hat{a}}(\xi) \int d^n x (\Delta_{\hat{a}}\phi^i)\phi_i^* . \tag{4.7}$$

V. DEFORMATION THEORY

The extended antifield formalism allows one to describe deformations of a given model and some of its symmetries as deformations of the solution of the extended master equation along the lines of Ref. 2. However, as anticipated in the Introduction, a deformation does not necessarily preserve the property that the selected subset of symmetries is a closed one. Therefore, the deformation itself may make it necessary to enlarge the subset of symmetries one has started with. In this section we describe how to cope with this phenomenon within a systematic approach to the deformation problem.

The starting point is a solution ${}^{(0)}S$ of the extended master equation which encodes the original (undeformed) classical action, its gauge symmetries and a closed subset $\{{}^{(0)}\Delta_{\underline{a}}\}$ of its rigid symmetries. The basic idea is to seek a continuous deformation of this solution of the form

$$S = \overset{(0)}{S} + g\overset{(1)}{S} + g^2\overset{(2)}{S} + \cdots , \tag{5.1}$$

where g is the deformation parameter. This problem is analyzed ‘‘perturbatively’’ by expanding $(S,S) = 0$ in g,

$$(\overset{(0)}{S},\overset{(0)}{S})=0, \tag{5.2}$$

$$(\overset{(0)}{S},\overset{(1)}{S})=0, \tag{5.3}$$

$$(\overset{(1)}{S},\overset{(1)}{S})+2(\overset{(0)}{S},\overset{(2)}{S})=0, \tag{5.4}$$

$$\vdots$$

Equation (5.2) is satisfied by assumption. In order to discuss the subsequent equations, one may now be tempted to adopt the arguments valid for deformations preserving only the gauge symmetries, as given in Ref. 2. One would then conclude from (5.3) that ${}^{(1)}S$ must be invariant under the undeformed extended BRST differential ${}^{(0)}s$, as the latter is generated by the antibracket with ${}^{(0)}S$ [see (4.1)]. Furthermore one can assume without loss of generality that ${}^{(1)}S$ is nontrivial in the cohomology of ${}^{(0)}s$, because otherwise it can be removed through local field redefinitions and/or redefinitions of the gauge and rigid symmetry transformations by adding trivial symmetries. This follows from standard arguments which parallel those for deformations of gauge symmetries (see, e.g., Ref. 3) and are not repeated here. In this way one would conclude that ${}^{(1)}S$ represents a nontrivial cohomology class of $H^0({}^{(0)}s)$, the cohomology of ${}^{(0)}s$ at ghost number 0 in the space of local functionals (3.4). However, this kind of reasoning overlooks that ${}^{(0)}s$ encodes only a subset of the rigid symmetries and may thus be extended, if necessary.

In order to discuss this possibility, we analyze (5.3) and the subsequent equations more carefully by expanding them in the antifield number. To this end we denote the decomposition of ${}^{(n)}S$ by

$$\overset{(n)}{S}=\sum_{k\geqslant 0}\overset{(n)}{S}_k,\quad \mathrm{agh}\,\overset{(n)}{S}_k=k. \tag{5.5}$$

The interpretation of the various terms in this expansion follows from the general discussion in Sec. III: ${}^{(n)}S_0$ is the deformation of the original classical action at order n in g, ${}^{(n)}S_1$ encodes the nth-order deformations of the symmetry transformations under study, ${}^{(n)}S_2$ yields the nth-order deformation of the graded commutator algebra of these symmetries, etc. Using the expansion of ${}^{(0)}s$ in the antifield number as in (4.4), Eq. (5.3) decomposes into

$$\overset{(0)}{\gamma}\overset{(1)}{S}_0+\overset{(0)}{\delta}\overset{(1)}{S}_1=0, \tag{5.6}$$

$$\overset{(0)}{s}_1\overset{(1)}{S}_0+\overset{(0)}{\gamma}\overset{(1)}{S}_1+\overset{(0)}{\delta}\overset{(1)}{S}_2=0, \tag{5.7}$$

$$\vdots$$

Equation (5.6) requires ${}^{(1)}S_0$ to be *invariant on-shell* under the undeformed gauge and rigid symmetries under study, where ''on-shell'' refers to the undeformed equations of motion. This is so because the undeformed symmetries under study and the original equations of motion are encoded in ${}^{(0)}\gamma$ and ${}^{(0)}\delta$, respectively. Let us assume we have found a solution to (5.6). The possible need for an enhancement of the subset of rigid symmetries under study arises for the first time in the next step, i.e., when seeking a solution of (5.7). To see this we act with ${}^{(0)}\gamma$ on (5.6). Using the anticommutation relations (4.5) for ${}^{(0)}s$, we infer that the functional W_1 defined by

$$W_1=\overset{(0)}{s}_1\overset{(1)}{S}_0+\overset{(0)}{\gamma}\overset{(1)}{S}_1 \tag{5.8}$$

is ${}^{(0)}\delta$-closed,

$$\overset{(0)}{\delta} W_1 = 0. \tag{5.9}$$

Now, (5.7) requires that W_1 be ${}^{(0)}\delta$-exact. Equation (5.9) is thus a necessary condition for the existence of a solution to (5.7). However, it is not sufficient in general when ${}^{(0)}s$ encodes only a subset of the rigid symmetries (see Sec. IV).

The question at this stage is therefore: can it happen that W_1 contains a rigid symmetry of the original action which is not contained in the closed subset of symmetries one has started with? The answer to this question is affirmative, as we shall illustrate explicitly in the next sections. Hence, as W_1 has antifield number 1, it may contain contributions of the form (4.7). Furthermore, W_1 has ghost number 1. Its general form is thus

$$W_1 = \frac{1}{2}(-)^{\epsilon_{\underline{a}}+\epsilon_{\hat{c}}} \overset{(1)}{f}{}_{\underline{ab}}^{\hat{c}} \xi^{\underline{b}} \xi^{\underline{a}} \int d^n x (\overset{(0)}{\Delta}_{\hat{c}} \phi^i) \phi_i^* - \overset{(0)}{\delta}(\cdots). \tag{5.10}$$

Recall that ${}^{(0)}\Delta_{\hat{c}}$ denotes a rigid symmetry of ${}^{(0)}S_0$ that is not contained in $\{{}^{(0)}\Delta_{\underline{a}}\}$. If such symmetries occur in W_1, i.e., if there are nonvanishing coefficients ${}^{(1)}f_{\underline{ab}}^{\hat{c}}$, the subset of rigid symmetries under study needs to be enlarged by including these symmetries in order to solve (5.7). Of course, this requires one first of all to construct a new solution ${}^{(0)}S$ of the extended master equation which incorporates the additional symmetries, too, and then to reexamine Eqs. (5.6) and (5.7) as ${}^{(0)}s$ gets extended.

Let us assume now that Eqs. (5.6) and (5.7) have been solved. Then there are no further obstructions to a solution of Eq. (5.3) if higher-order symmetries are absent, i.e., all the equations subsequent to (5.7) can be solved without further ado because then ${}^{(0)}\delta$ is acyclic at all antifield numbers exceeding 1. In contrast, if there are higher-order symmetries, it cannot be excluded in principle that some of them show up at a certain stage and must be included, too.

Once one has solved (5.3), one has to analyze (5.4) and the subsequent equations. Now, one has $({}^{(0)}S,({}^{(1)}S,{}^{(1)}S))=0$ as a consequence of (5.3), thanks to the Jacobi identity for the extended antibracket. $({}^{(1)}S,{}^{(1)}S)$ has ghost number 1 and is thus a cocycle in $H^1({}^{(0)}s)$. This is a necessary condition for the existence of a solution to (5.4) but, in general, it is not sufficient because (5.4) requires that $({}^{(1)}S,{}^{(1)}S)$ be ${}^{(0)}s$-exact. Therefore (5.4) may obstruct deformations through $H^1({}^{(0)}s)$. Note, however, that some of the cohomology classes in $H^1({}^{(0)}s)$ will originate from rigid symmetries that have not been included so far. These classes are represented by ${}^{(0)}s$-invariant extensions of functionals of the form (4.7) and their analogs for higher-order rigid symmetries (if any). Such classes can be removed by further extending the subset of rigid symmetries. We shall therefore refer to them as ''spurious anomalies,'' and call the other classes ''true anomalies.'' [The term ''anomaly'' is (ab)used here because these obstructions parallel those to the Slavnov–Taylor identity through gauge anomalies in quantum field theory. Indeed, the Slavnov–Taylor identity can be cast in the form of the master equation[19,20] and the gauge anomalies represent BRST cohomology classes at ghost number 1.[21]] These two kinds of anomalies show up at different antifield numbers. [I have not found an example where $({}^{(1)}S,{}^{(1)}S)$ contains spurious anomalies. On the other hand, I have neither found a general argument which excludes the occurrence of spurious anomalies. Hence, the question whether or not such anomalies can really occur in $({}^{(1)}S,{}^{(1)}S)$ is actually still open.] Using the expansion

$$(\overset{(1)}{S},\overset{(1)}{S}) = -2\sum_{k\geq 0} A_k, \quad \mathrm{agh}\, A_k = k, \tag{5.11}$$

(5.4) decomposes into

$$A_0 = \overset{(0)}{\gamma} \overset{(2)}{S}_0 + \overset{(0)}{\delta} \overset{(2)}{S}_1, \tag{5.12}$$

$$A_1 = \overset{(0)}{s}_1 \overset{(2)}{S}_0 + \overset{(0)}{\gamma} \overset{(2)}{S}_1 + \overset{(0)}{\delta} \overset{(2)}{S}_0, \tag{5.13}$$

$$\vdots$$

True anomalies can show up only in A_0 through contributions that are weakly (=on-shell) ${}^{(0)}\gamma$-closed but not weakly ${}^{(0)}\gamma$-exact. They can thus obstruct (5.12). In contrast, spurious anomalies would show up in the A_k with $k>0$, and thus in (5.13) and the equations subsequent to it. Thereby spurious anomalies stemming from rigid symmetries of order k would show up in A_k. In particular, when higher-order rigid symmetries are absent, actually only A_1 can give rise to spurious anomalies through terms of the form (4.7) with ghost number 1. Analogously one analyzes the equations subsequent to (5.4) and infers that they can obstruct the deformation in the same way through $H^1({}^{(0)}s)$.

To summarize, the extended antifield formalism permits a systematic analysis of deformations preserving certain rigid symmetries in addition to the gauge symmetries in a manner which is quite similar to the deformation theory[2] based on the standard antifield formalism. The main difference is that the deformation itself may force one to enlarge the subset of rigid symmetries one has started with. It should be clear from the above discussion that, in general, one cannot predict from the outset which symmetries need to be included in addition to those one has started with because that may depend on the solution to (5.6).

A deformation which requires the enlargement of an originally closed subset of symmetries results in a deformed symmetry algebra. For instance, (5.10) would yield

$$\overset{(1)}{S}_2 = \tfrac{1}{2}(-)^{\epsilon_{\underline{b}}+1} \xi^{\underline{b}} \xi^{\underline{a}} \overset{(1)}{f}{}_{\underline{ab}}^{\hat{c}} \xi^*_{\hat{c}} + \cdots . \tag{5.14}$$

This shows that the graded commutator algebra of the $\Delta_{\underline{a}}$ (i.e., of the deformed transformations) would not close anymore in the soft sense but involve the $\Delta_{\hat{c}}$. The ${}^{(1)}f_{\underline{ab}}^{\hat{c}}$ are the corresponding structure constants of the deformed graded Lie algebra to first order.

VI. CENTRAL CHARGE OF THE $N=2$ HYPERMULTIPLET

As an illustration, we shall now treat an $N=2$ supersymmetric model for a Fayet–Sohnius hypermultiplet[11,12] in flat four-dimensional spacetime. The multiplet contains two complex Lorentz-scalar fields φ^i ($i=1,2$) and two complex Weyl-spinor fields χ^α, ψ^α ($\alpha=1,2$). (We use conventions with a Minkowski metric $\eta_{\mu\nu}=\mathrm{diag}(+,-,-,-)$ as in Ref. 22 which differ only through signs from those in Ref. 16). As the basis of the classical fields we use these fields and their complex conjugates (equivalently we could have chosen, for instance, the real and imaginary parts of the fields),

$$\{\phi\} = \{\varphi^i, \overline{\varphi}_i, \chi^\alpha, \overline{\chi}^{\dot\alpha}, \psi^\alpha, \overline{\psi}^{\dot\alpha}\},$$

where $\overline{\varphi}_i$, $\overline{\chi}$ and $\overline{\psi}$ are complex conjugate to φ^i, χ and ψ, respectively,

$$\overline{\varphi}_i = \overline{\varphi^i}, \quad \overline{\chi}^{\dot\alpha} = \overline{\chi^\alpha}, \quad \overline{\psi}^{\dot\alpha} = \overline{\psi^\alpha}.$$

The position of the index of $\overline{\varphi}_i$ indicates that it transforms contragrediently to φ^i under the SU(2)-automorphism group of $N=2$ supersymmetry [i refers to the fundamental representation of this SU(2)]. Undotted and dotted spinor indices distinguish the (1/2,0) and (0,1/2) representations of the Lorentz group [resp., of its covering group SL(2,C)].

Our starting point is the action

$$\overset{(0)}{S}_0 = \int d^4x [\partial_\mu \varphi^i \partial^\mu \overline{\varphi}_i - \tfrac{1}{2}(\chi \partial\!\!\!/ \overline{\chi} + \overline{\chi} \partial\!\!\!/ \chi + \psi \partial\!\!\!/ \overline{\psi} + \overline{\psi} \partial\!\!\!/ \psi)], \tag{6.1}$$

where

$$\partial_{\alpha\dot\alpha}=\sigma^{\mu}_{\alpha\dot\alpha}\partial_{\mu}.$$

The action ${}^{(0)}S_0$ is among others invariant under rigid $N=2$ supersymmetry transformations ${}^{(0)}\Delta_{\alpha}{}^{i}$, ${}^{(0)}\Delta_{\dot\alpha i}$ given by

ϕ	φ^j	$\overline{\varphi_j}$	χ^β	$\overline{\chi}^{\dot\beta}$	ψ^β	$\overline{\psi}^{\dot\beta}$
$\overset{(0)}{\Delta}{}_{\alpha}{}^{i}\phi$	$\epsilon^{ij}\chi_\alpha$	$\delta^i_j\psi_\alpha$	0	$-\mathrm{i}\partial^{\dot\beta}_{\alpha}\overline{\varphi^i}$	0	$-\mathrm{i}\partial^{\dot\beta}_{\alpha}\varphi^i$
$\overset{(0)}{\Delta}{}_{\dot\alpha i}\phi$	$\delta^j_i\overline{\psi}_{\dot\alpha}$	$-\epsilon_{ij}\overline{\chi}_{\dot\alpha}$	$\mathrm{i}\partial^{\beta}_{\dot\alpha}\varphi_i$	0	$-\mathrm{i}\partial^{\beta}_{\dot\alpha}\overline{\varphi_i}$	0

(6.2)

where indices i are raised and lowered with the rules

$$X^i=\epsilon^{ij}X_j,\quad X_i=\epsilon_{ij}X^j,\quad \epsilon^{ij}=-\epsilon^{ji},\quad \epsilon_{ij}=-\epsilon_{ji},\quad \epsilon^{12}=\epsilon_{21}=1.$$

We consider the following subset of rigid symmetries, containing the supersymmetry transformations and the spacetime translations,

$$\{\overset{(0)}{\Delta}{}_{\underline{a}}\}\equiv\{\overset{(0)}{\Delta}{}_{\alpha}{}^{i},\overset{(0)}{\Delta}{}_{\dot\alpha i},\partial_\mu\}. \tag{6.3}$$

The graded commutator algebra of these symmetries reads

$$[\overset{(0)}{\Delta}{}_{\alpha}{}^{i},\overset{(0)}{\Delta}{}_{\dot\alpha j}]\approx-\mathrm{i}\delta^i_j\partial_{\alpha\dot\alpha},\quad [\overset{(0)}{\Delta}{}_{\underline{a}},\overset{(0)}{\Delta}{}_{\underline{b}}]\approx 0\quad \text{otherwise}, \tag{6.4}$$

where $\approx$ denotes equality up to on-shell trivial symmetries. Equation (6.4) is indeed the $N=2$ supersymmetry algebra without central charge (on-shell). The action has no gauge symmetries. Therefore, it has no higher-order symmetries either.[23] This implies the existence of a solution to the extended master equation which encodes only the symmetries (6.3) and their graded commutator algebra. This solution, which was computed first in Ref. 24, reads

$$\overset{(0)}{S}=\overset{(0)}{S}{}_0+\overset{(0)}{S}{}_1+\overset{(0)}{S}{}_2,$$

$$\overset{(0)}{S}{}_1=-\int d^4x\sum_{\phi}\,(\xi^\alpha_i\overset{(0)}{\Delta}{}_{\alpha}{}^{i}\phi+\overline{\xi}^{\dot\alpha i}\overset{(0)}{\Delta}{}_{\dot\alpha i}\phi+\xi^\mu\partial_\mu\phi)\phi^*, \tag{6.5}$$

$$\overset{(0)}{S}{}_2=-\mathrm{i}\xi_i\sigma^\mu\overline{\xi^i}\xi^*_\mu+\int d^4x[\overline{\chi}^*\overline{\xi^i}\xi_i\chi^*+\overline{\psi}^*\overline{\xi^i}\xi_i\psi^*+\tfrac{1}{2}\xi_i\xi^i\overline{\chi}^*\overline{\psi}^*+\tfrac{1}{2}\overline{\xi^i\xi_i}\psi^*\chi^*],$$

where

$$\{\phi^*\}=\{\varphi^*_i,\overline{\varphi}^{i*},\chi^*_\alpha,\overline{\chi}^*_{\dot\alpha},\psi^*_\alpha,\overline{\psi}^*_{\dot\alpha}\}.$$

The supersymmetry ghosts ξ^α_i and $\overline{\xi}^{\dot\alpha i}$ are Grassmann even and the translation ghosts ξ^μ are Grassmann odd. The ghosts and antifields have the reality properties

$$\overline{\xi}^{\dot\alpha i}=\overline{\xi^\alpha_i},\quad \xi^\mu=\overline{\xi^\mu},\quad \overline{\xi}^*_{\dot\alpha i}=-\overline{\xi^{i*}_\alpha},\quad \xi^*_\mu=-\overline{\xi^*_\mu},$$

$$\overline{\varphi}^{i*}=-\overline{\varphi^*_i},\quad \overline{\chi}^*_{\dot\alpha}=-\overline{\chi^*_\alpha},\quad \overline{\psi}^*_{\dot\alpha}=-\overline{\psi^*_\alpha}.$$

The first term in ${}^{(0)}S_2$ contains the structure constants of the supersymmetry algebra (6.4), while the contributions which are quadratic in the antifields reflect that the symmetry algebra closes only on-shell.

We now study deformations of the above model along the lines of the previous section. A solution to (5.6) which introduces mass terms for the fermions is easily found. Namely,

$$\overset{(1)}{S}_0=\int d^4x[m_1\chi\psi+\overline{m}_1\overline{\chi}\overline{\psi}+\tfrac{1}{2}(m_2\chi\chi+\overline{m}_2\overline{\chi\chi}+m_3\psi\psi+\overline{m}_3\overline{\psi\psi})] \tag{6.6}$$

is supersymmetric on-shell and translation invariant for any choice of complex mass parameters m_1, m_2 and m_3 and therefore yields a solution to (5.6). The corresponding functional ${}^{(1)}S_1$ is

$$\begin{aligned}\overset{(1)}{S}_1=\int d^4x[&m_1(\overline{\varphi_i}\overline{\chi}^*\overline{\xi^i}-\varphi_i\overline{\psi}^*\overline{\xi^i})-\overline{m}_1(\overline{\varphi}^i\xi_i\psi^*+\varphi^i\xi_i\chi^*)\\&-m_2\varphi_i\overline{\chi}^*\overline{\xi^i}-\overline{m}_2\overline{\varphi}^i\xi_i\chi^*+m_3\overline{\varphi_i}\overline{\psi}^*\overline{\xi^i}-\overline{m}_3\varphi^i\xi_i\psi^*].\end{aligned} \tag{6.7}$$

Next we calculate the functional W_1 in (5.8). The result is

$$\begin{aligned}\overset{(0)}{s}_1\overset{(1)}{S}_0+\overset{(0)(1)}{\gamma\, S}_1=\frac{1}{2}\overline{\xi^i}\overline{\xi_i}\int d^4x[&(-m_1\varphi^j+m_3\overline{\varphi}^j)\varphi_j^*+\overline{\varphi}^{j*}(m_1\overline{\varphi_j}-m_2\varphi_j)\\&-(m_1\chi+m_3\psi)\chi^*+\overline{\chi}^*(m_1\overline{\chi}-m_2\overline{\psi})\\&+(m_1\psi+m_2\chi)\psi^*+\overline{\psi}^*(-m_1\overline{\psi}+m_3\overline{\chi})]+\text{c.c.},\end{aligned} \tag{6.8}$$

where c.c. denotes complex conjugation. Equation (6.8) has the form of the first term in (5.10), i.e., it brings in an additional symmetry. This symmetry is part of a rigid SU(2)-invariance of the action (6.1). Indeed, as the functional (6.8) is ${}^{(0)}\delta$-invariant for any choice of m_1, m_2 and m_3, the parts in (6.8) involving m_1, m_2 and m_3, respectively, correspond to independent symmetries of the action (6.1). These symmetries form an SU(2) under which $(\varphi^1,\overline{\varphi}^1)$, $(\varphi^2,\overline{\varphi}^2)$, (χ,ψ) and $(\overline{\psi},\overline{\chi})$ transform as doublets (i.e., in the fundamental representation) and which commutes with the supersymmetry transformations (6.2). However, in contrast to the undeformed action, the first-order deformation (6.6) is not invariant under the full SU(2) but it is still invariant under a U(1) subgroup thereof generated by the transformations in (6.8). Hence, the deformation breaks the SU(2) but preserves this U(1) subgroup. (An analogous phenomenon was observed in Ref. 25 within the construction of supergravity couplings for hypermultiplets.)

We thus have to enlarge the subset of symmetries (6.3) by this U(1). It turns out that this suffices in order to construct a deformed solution of the extended master equation. We shall not further discuss the computation and spell out the solution only for the case $m_2=m_3=0$. Using $m=gm_1$ (g being the deformation parameter in the notation of the previous section), the deformed solution reads then

$$S=S_0+S_1+S_2, \tag{6.9}$$

$$S_0=\overset{(0)}{S}_0+\int d^4x(m\chi\psi+\overline{m\chi}\overline{\psi}-m\overline{m}\varphi^i\overline{\varphi_i}), \tag{6.10}$$

$$S_1=\int d^4x\Big[-\sum_{\phi}\,(\xi_i^{\alpha}\overset{(0)}{\Delta}{}_{\alpha}{}^{i}\phi+\overline{\xi}^{\dot\alpha i}\overset{(0)}{\Delta}{}_{\dot\alpha i}\phi+\xi^{\mu}\partial_{\mu}\phi)\phi^*$$
$$+\mathrm{i}\xi_{U(1)}(\varphi^i\varphi_i^*-\overline{\varphi}_i\overline{\varphi}^{i}{}^*+\chi\chi^*-\overline{\chi}^*\overline{\chi}-\psi\psi^*+\overline{\psi}^*\overline{\psi})$$
$$+m(\overline{\varphi}_i\overline{\chi}^*\overline{\xi}^i-\varphi_i\overline{\psi}^*\overline{\xi}^i)-\overline{m}(\overline{\varphi}^i\xi_i\psi^*+\varphi^i\xi_i\chi^*)\Big], \tag{6.11}$$

$$S_2=\overset{(0)}{S}{}_2+\frac{\mathrm{i}}{2}(m\overline{\xi^i\xi_i}+\overline{m}\xi_i\xi^i)\xi^*_{U(1)}, \tag{6.12}$$

with ${}^{(0)}S_2$ as in (6.5). Here $\xi_{U(1)}$ and $\xi^*_{U(1)}$ are the global ghost and antifield of the rigid U(1) symmetry obtained from (6.8) in the case $m_2=m_3=0$ ($\xi_{U(1)}$ is real and Grassmann odd, $\xi^*_{U(1)}$ is purely imaginary and Grassmann even).

Equation (6.10) is the deformed classical action. Apart from the original action (6.1) and its first-order deformation (6.6) (in the case $m_2=m_3=0$), it contains also a mass term for the Lorentz-scalar fields which arises at second order in the deformation parameter.

Equation (6.11) contains the deformed supersymmetry transformations, the rigid U(1) transformations, and the space–time translations. The deformed supersymmetry and the U(1) transformations are

ϕ	φ^j	$\overline{\varphi}_j$	χ^β	$\overline{\chi}^{\dot\beta}$	ψ^β	$\overline{\psi}^{\dot\beta}$
$\Delta_\alpha{}^i\phi$	$\epsilon^{ij}\chi_\alpha$	$\delta^i_j\psi_\alpha$	$\overline{m}\delta^\beta_\alpha\varphi^i$	$-\mathrm{i}\partial^{\dot\beta}_\alpha\overline{\varphi}^i$	$\overline{m}\delta^\beta_\alpha\overline{\varphi}^i$	$-\mathrm{i}\partial^{\dot\beta}_\alpha\varphi^i$
$\Delta_{\dot\alpha i}\phi$	$\delta^j_i\overline{\psi}_{\dot\alpha}$	$-\epsilon_{ij}\overline{\chi}_{\dot\alpha}$	$\mathrm{i}\partial^\beta_{\dot\alpha}\varphi_i$	$-m\delta^{\dot\beta}_{\dot\alpha}\overline{\varphi}_i$	$-\mathrm{i}\partial^\beta_{\dot\alpha}\overline{\varphi}_i$	$m\delta^{\dot\beta}_{\dot\alpha}\varphi_i$
$\Delta_{U(1)}\phi$	$-\mathrm{i}\varphi^j$	$\mathrm{i}\overline{\varphi}_j$	$-\mathrm{i}\chi^\beta$	$\mathrm{i}\overline{\chi}^{\dot\beta}$	$\mathrm{i}\psi^\beta$	$-\mathrm{i}\overline{\psi}^{\dot\beta}$

(6.13)

Equation (6.12) encodes the graded commutator algebra of the deformed symmetry transformations. The $N=2$ supersymmetry algebra has become extended by the U(1) through the deformation. The nonvanishing graded commutators are

$$[\Delta_\alpha{}^i,\Delta_{\dot\alpha j}]\approx-\mathrm{i}\,\delta^i_j\partial_{\alpha\dot\alpha},$$
$$[\Delta_\alpha{}^i,\quad\Delta_\beta{}^j]\approx\mathrm{i}\overline{m}\epsilon^{ij}\epsilon_{\alpha\beta}\Delta_{U(1)}, \tag{6.14}$$
$$[\Delta_{\dot\alpha i},\Delta_{\dot\beta j}]\approx-\mathrm{i}m\epsilon_{ij}\epsilon_{\dot\alpha\dot\beta}\Delta_{U(1)},$$

where $\approx$ now denotes equality up to transformations which are trivial on-shell in the deformed model (i.e., these transformations involve the deformed equations of motion).

Remark: The above results hold analogously in a formulation of the hypermultiplet with the standard auxiliary fields used already in Refs. 11 and 12. In that approach one sometimes introduces an ''off-shell central charge'' in order to close the commutator algebra of the supersymmetries, the central charge and the space–time translations off-shell. However, in the massless model that central charge is trivial on-shell and thus not to be accompanied by global ghosts. In contrast, the massive (deformed) model involves again a ''true'' central charge that does not vanish on-shell.

VII. CURCI–FERRARI MODEL

A particular case of a rigid symmetry is the BRST symmetry of a gauge fixed action constructed in the standard way from a solution to the usual master equation.[5–7] Deformations of a gauge fixed action may be obtained in two ways: (i) one constructs first consistent deformations of the underlying gauge theory along the lines of Ref. 2 and fixes the gauge afterwards, or (ii) one investigates directly deformations of the gauge fixed model and its BRST symmetry.

These two approaches are not equivalent in general. In particular, the first approach leads by construction to an on-shell nilpotent BRST symmetry of the standard type, whereas the second one may destroy the nilpotency property and is not physically acceptable in general. This is related to the different properties of the BRST cohomology before and after gauge fixing[26] (cf. also the remark at the end of this section), and is now to be discussed for the Curci–Ferrari model[13–15] in the framework of the extended antifield formalism. The loss of nilpotency emerges in this approach as a deformation of the BRST algebra along the lines of Sec. V. In the particular case of the Curci–Ferrari model, the deformed action has even the *same* BRST symmetry as the original one, but in the deformed model that symmetry does not square weakly to zero anymore (as the equations of motion change). Rather, it squares into a different nontrivial rigid symmetry.

We consider four-dimensional non-Abelian Yang–Mills theory with the following gauge fixed action,

$$\overset{(0)}{S}_0=\int d^4x\,\mathrm{Tr}\left[\frac{1}{4}F_{\mu\nu}F^{\mu\nu}+\frac{1}{2\alpha}(\partial_\mu A^\mu)^2-\frac{1}{2}B(\partial_\mu D^\mu+D_\mu\partial^\mu)C+\frac{\alpha e^2}{4}B^2C^2\right], \tag{7.1}$$

where α is the gauge fixing parameter, e is the gauge coupling constant, and $A_\mu=A^i_\mu t_i$, $F_{\mu\nu}=F^i_{\mu\nu}t_i$, $C=C^it_i$ and $B=B^it_i$ are the Lie algebra valued gauge fields, field strengths, ghost fields and antighost fields, respectively ($\{t_i\}$ denotes an appropriate matrix representation of the Lie algebra of the gauge group normalized such that $\mathrm{Tr}(t_it_j)=-\delta_{ij}$), and $D_\mu C$ is defined by

$$D_\mu C=\partial_\mu C+e(A_\mu C-CA_\mu). \tag{7.2}$$

{The gauge fixed action (7.1) arises in the standard manner from a ''minimal'' solution $S_{\min}$ of the usual master equation as follows. First one adds to $S_{\min}$ the ''nonminimal'' term $\int d^4x\,\mathrm{Tr}(-HB^*)$ where the H^i are Nakanishi–Lautrup auxiliary fields. Then one shifts the antifields by $\Phi^*_A\rightarrow\Phi^*_A+\delta^L\Psi/\delta\Phi^A$ where Ψ is the ''gauge fixing fermion'' $\Psi[\Phi]=\int d^4x\,\mathrm{Tr}[(\alpha/2)(BH+eB^2C)-B\partial_\mu A^\mu]$. Finally one eliminates the H^i by their algebraic equations of motion.} The action (7.1) is invariant under the rigid BRST transformations

$$\Delta_{\mathrm{brs}}A_\mu=D_\mu C,\quad \Delta_{\mathrm{brs}}C=-eC^2,\quad \Delta_{\mathrm{brs}}B=\frac{1}{\alpha}\partial_\mu A^\mu-\frac{e}{2}(BC+CB). \tag{7.3}$$

These transformations are nilpotent on-shell,

$$(\Delta_{\mathrm{brs}})^2=\tfrac{1}{2}[\Delta_{\mathrm{brs}},\Delta_{\mathrm{brs}}]\approx 0. \tag{7.4}$$

More precisely, Δ_{brs} is strictly nilpotent on A^i_μ and C^i, but squares into an on-shell trivial symmetry on B^i,

$$(\Delta_{\mathrm{brs}})^2A^i_\mu=(\Delta_{\mathrm{brs}})^2C^i=0,\quad (\Delta_{\mathrm{brs}})^2B^i=\frac{1}{\alpha}\delta^{ij}\frac{\delta^L\overset{(0)}{S}_0}{\delta B^j}. \tag{7.5}$$

We shall now apply the extended antifield formalism to the gauge fixed action (7.1) and the BRST symmetry (7.3). In this approach (7.1) plays the role of the classical action, i.e., the ghost and antighost fields C and B are viewed as Grassmann odd ''classical'' fields (C is real, B purely imaginary),

$$\{\phi\}=\{A^i_\mu,B^i,C^i\}.$$

Accordingly, we assign antifield number 1 to $A_i^{\mu *}$, B_i^* and C_i^*. Furthermore, we introduce a Grassmann even global ghost $\xi_{\rm brs}$ for the BRST symmetry (7.3).

That is, in this case we consider a subset of rigid symmetries containing only one element, namely $\Delta_{\rm brs}$:

$$\{\overset{(0)}{\Delta}_{\underline{a}}\}=\{\Delta_{\rm brs}\}. \tag{7.6}$$

The corresponding graded commutator algebra (2.13) is just (7.5). As the gauge fixed action (7.1) has no gauge symmetry and thus no higher-order rigid symmetry either, a corresponding solution of the extended master equation exists. This solution coincides, of course, with the gauge fixed solution of the master equation obtained in the standard antifield formalism, except that now the global ghost $\xi_{\rm brs}$ appears,

$$\overset{(0)}{S}=\overset{(0)}{S}_0+\overset{(0)}{S}_1+\overset{(0)}{S}_2,$$

$$\overset{(0)}{S}_1=\xi_{\rm brs}\int d^4x\,\mathrm{Tr}\left[A^{\mu *}D_\mu C+eC^2C^*-\left\{\frac{1}{\alpha}\partial_\mu A^\mu-\frac{e}{2}(BC+CB)\right\}B^*\right], \tag{7.7}$$

$$\overset{(0)}{S}_2=\frac{1}{2\alpha}\xi^2_{\rm brs}\int d^4x\,\mathrm{Tr}(B^*B^*),$$

where we have used $A^{\mu *}=-\delta^{ij}A_i^{\mu *}t_j$, etc. The presence of the term quadratic in B^* reflects that the algebra closes on B^i only on-shell [see (7.5)]. The ''extended'' BRST differential ${}^{(0)}s$, constructed from ${}^{(0)}S$ as in Eq. (4.1), coincides with the usual gauge fixed BRST operator for the action (7.1), except that now $\xi_{\rm brs}$ occurs. It is strictly nilpotent, in contrast to $\Delta_{\rm brs}$, and acts on the fields by

$$\overset{(0)}{s}A_\mu=\xi_{\rm brs}D_\mu C,\qquad \overset{(0)}{s}C=-\xi_{\rm brs}eC^2,$$
$$\overset{(0)}{s}B=\xi_{\rm brs}\left[\frac{1}{\alpha}\partial_\mu A^\mu-\frac{e}{2}(BC+CB)\right]-\frac{1}{\alpha}\xi^2_{\rm brs}B^*. \tag{7.8}$$

We shall now discuss the deformation of the action (7.1) through the Curci–Ferrari mass term

$$\overset{(1)}{S}_0=\int d^4x\,\mathrm{Tr}\left[\frac{1}{2}A_\mu A^\mu+\alpha BC\right]. \tag{7.9}$$

This term is off-shell invariant under the transformations (7.3) and thus yields a solution to Eq. (5.6) with

$$\overset{(1)}{S}_1=0. \tag{7.10}$$

The functional W_1 in Eq. (5.8) reads in this case

$$\overset{(0)}{s}_1\overset{(1)}{S}_0=-\xi^2_{\rm brs}\int d^4x\,\mathrm{Tr}(B^*C). \tag{7.11}$$

This has the form of the first term in Eq. (5.10) and contains an additional nontrivial rigid symmetry of the gauge fixed action (7.1), namely,

$$\Delta_{\mathrm{add}}B = C, \quad \Delta_{\mathrm{add}}A_\mu = \Delta_{\mathrm{add}}C = 0. \tag{7.12}$$

Hence, in order to construct a deformed solution of the extended master equation with ${}^{(1)}S_0$ as in (7.9), we *must* include this symmetry. It is straightforward to verify that this yields the following deformed solution of the extended master equation,

$$S = S_0 + S_1 + S_2, \quad S_0 = \overset{(0)}{S}{}_0 + g\,\overset{(1)}{S}{}_0,$$
$$S_1 = -\int d^4x \sum_\phi \,(\xi_{\mathrm{brs}}\Delta_{\mathrm{brs}}\phi + \xi_{\mathrm{add}}\Delta_{\mathrm{add}}\phi)\,\phi^*, \tag{7.13}$$
$$S_2 = \overset{(0)}{S}{}_2 + g\,\xi^2_{\mathrm{brs}}\xi^*_{\mathrm{add}}.$$

with ${}^{(0)}S_2$ as in (7.7). The last term reflects that the graded commutator algebra of Δ_{brs} and Δ_{add} reads in the deformed model

$$(\Delta_{\mathrm{brs}})^2 \approx g\Delta_{\mathrm{add}}, \quad [\Delta_{\mathrm{brs}}, \Delta_{\mathrm{add}}] = 0, \tag{7.14}$$

where $\approx$ now denotes on-shell equality in the deformed model, i.e., for the equations of motion following from ${}^{(0)}S_0 + g\,{}^{(1)}S_0$. Notice that Δ_{brs} is still a symmetry of the deformed model, without having been deformed. Nevertheless it is not nilpotent anymore on-shell because the equations of motion have changed.

Remarks: (a) In order to avoid possible confusion, we stress that the BRST cohomologies before and after gauge fixing are always isomorphic (provided all the antifields are kept). What changes, however, when the gauge fixed action is treated as a classical one, are the assignments of antifield numbers and the corresponding concept of weak (=on-shell) equality (as the ghost fields count now among the classical fields). As a consequence, it is *not* true that each local functional with vanishing antifield number which is on-shell Δ_{brs}-invariant can be extended to a cocycle of ${}^{(0)}s$ (this is just the phenomenon discussed in Ref. 26, but in the language used here). The Curci–Ferrari mass term (7.9) illustrates exactly this phenomenon: it *cannot* be extended so as to be ${}^{(0)}s$-closed, although it is Δ_{brs}-invariant. As a consequence, Δ_{brs} is not nilpotent anymore on-shell in the deformed model.

(b) The Curci–Ferrari model illustrates a general fact: a deformation of a gauge fixed action which destroys the on-shell nilpotency of Δ_{brs} (or a deformation thereof) *cannot* reflect a consistent deformation of the gauge symmetry in the sense of Ref. 2 because such consistent deformations result by their very construction in an on-shell nilpotent Δ_{brs} after gauge fixing.

(c) Of course, (7.13) yields via (4.1) a strictly nilpotent operator which incorporates both Δ_{brs} and Δ_{add}. However, this nilpotent operator cannot cure the unitarity problems of the Curci–Ferrari model discussed in Refs. 14 and 15 because Δ_{add} does not impose additional conditions that may select physical states. Indeed, as it is just the square of Δ_{brs} (on-shell), a state that is annihilated by Δ_{brs} (resp. by its quantum version) is automatically also annihilated by Δ_{add}. For the same reason, a state that is Δ_{add}-exact is also in the image of Δ_{brs}.

VIII. CONCLUSION

We have outlined how continuous deformations of an action functional, its gauge symmetries and a closed subset of its rigid symmetries can be analyzed systematically in the extended antifield formalism. The procedure is very similar to the study of continuous deformations of actions and their gauge symmetries described in Ref. 2. The main difference is that the deformation itself may make it necessary to enlarge the particular subset of rigid symmetries one has started with. This happens when the commutator algebra of the deformed version of the originally considered subset of symmetries does not close anymore in the soft sense (i.e., modulo gauge transformations and on-shell trivial symmetries) and thus results in a deformation of the symmetry algebra.

It is, however, not always clear from the outset which additional symmetries can occur in the deformed commutator algebra. This subtlety can be mastered when one proceeds as described in Sec. V, using an expansion in the antifield number. In this approach one first seeks functionals of the classical fields that are ''weakly'' (=on-shell) invariant under the symmetries under study. The method then provides automatically the additional symmetries which need to be included. This has been illustrated for the hypermultiplet of four-dimensional $N=2$ supersymmetry where the central extension of the $N=2$ supersymmetry algebra emerges via the deformation of a massless model to a massive one. The central extension turns out to be a surviving generator of an SU(2) symmetry of the massless action broken by the deformation. In this case it depends on the mass parameters, i.e., on the deformation itself, how the SU(2) is broken and which generator becomes the central extension.

We have also illustrated, for the Curci–Ferrari model, how deformations of a gauge fixed action and its BRST symmetry can be analyzed within this approach. The BRST symmetry is then treated in the same manner as other rigid symmetries, too, while the gauge fixed action is treated as a classical one. However, such deformations do not correspond necessarily to consistent deformations of the gauge symmetries in the sense of Ref. 2, and are therefore not always physically acceptable. In particular, it can happen that there are deformations of a gauge fixed action which are BRST invariant but nevertheless inconsistent because the BRST symmetry does not square to zero on-shell anymore in the deformed model. The Curci–Ferrari model illustrates exactly this phenomenon. Hence, a necessary condition for a deformation of a gauge fixed action to be a consistent one is the on-shell nilpotency of the BRST symmetry of the deformed action.

Finally, I remark that the procedure outlined in Sec. V can be extended analogously to the case that only a subset of the gauge symmetries is included. However, from the physical point of view this extension is mainly of academic interest and was therefore not discussed here.

(Received 20 July 1998; accepted for publication 6 October 1998)

In an arbitrary Lorentzian manifold we provide a description for the construction of null surfaces and their associated singularities, via solutions of the Eikonal equation. In particular, we study the singularities of the past light-cones from points on null infinity, the future light-cones from arbitrary interior points and the intersection of these with null infinity and unifying relationships between the different singularities. The starting point for this work is the assumption of a known family of solutions to the Eikonal equation. The work is based on the standard theory of singularities of smooth maps by Arnold and his colleagues. Though the work is intended to stand on its own, it can be thought of as being closely related to the recently developed null surface reformulation of GR. © *1999 American Institute of Physics.* [S0022-2488(99)01302-X]

I. INTRODUCTION

In a recent work[1] we studied properties of solutions of the flat-space–time Eikonal equation, namely,

$$\eta^{ab}\partial_a S\partial_b S=0,$$

whose level "surfaces" [$S=S(x^a)=\text{const.}$], are, by definition, null (or characteristic) three-surfaces. These level surfaces, called by Arnold[2,3] "big wave fronts," can have self-intersections and need not be smooth everywhere. In particular we were concerned with finding the analytic form (described parametrically) of the general solution to the equation, studying its level surfaces and the "small (two-dimensional) wave fronts," (i.e., the intersection of a three surface with a big wave front) and then analyzing some of the resulting structures; the caustics of the full solution (three-dimensional), the singularities of the big wave front (two-dimensional), and the singularities of the "small wave fronts" (one-dimensional). These singularities are defined, respectively, by the intersection of a big wave front and the small wave front with the caustic surface. A special application of these ideas was to the study of 2-parameter families of solutions to the Eikonal equation from which it was possible to see an alternative analytic treatment of the structure of the singularities. This latter point of view plays an important role in a recent reformulation of GR known as the null surface formulation.[4,5]

In the present paper, we extend the ideas from the Minkowski case to,[1] first to arbitrary Lorentzian space–times and then specialize them to asymptotically flat space–times. There are two main reasons for doing this: (1) We want to understand in detail the structure of light-cones in the large, i.e., globally, in arbitrary space–times which are of great relevance to the general theory of gravitational lensing and (2) a recent reformulation of GR in terms of families of characteristic surfaces requires a deeper understanding of the singularities of the big and small wave fronts.

In Sec. II, we will show how from any arbitrary, but given, two parameter family of solutions of the curved-space Eikonal equation, any arbitrary characteristic surface can be constructed.

This construction will, in Sec. III, be specialized to an asymptotically flat space–time where the two-parameter family is chosen in a special way; namely, they are the family of past light cones from all the points on null infinity, $\mathfrak{I}^+$. Directly in terms of this fiducial family we can express any characteristic surface and in particular, we can express the light-cone, $\mathfrak{C}_x$, of any interior point x^a. Of particular interest is the singularity structure of the cones, $\mathfrak{C}_x$, which can be analyzed in terms of the variables of the fiducial family.

In Sec. IV, we will study the particular class of small wave fronts (two-dimensional) defined by the intersection of the three-dimensional cones, $\mathfrak{C}_x$, with the null surface $\mathfrak{I}^+$, i.e., the so-called light-cone cuts $\mathfrak{c}(x^a)$ of $\mathfrak{I}^+$. In particular we will be interested in finding (via Arnold's theory of Lagrange and Legendre maps[2,3,6,7]) the appropriate tools and variables to describe the singularities of these light-cone cuts.

Finally in Sec. V, we return to an issue that we deliberately postponed. We took, in Sec. III, a fiducial family of solutions of the Eikonal and used them to study the singularities of other characteristic surfaces but we avoided any discussion of the singularities of the fiducial family itself. The reason for the postponement is that this discussion is more complicated and difficult than the earlier ones and uses, in addition, different techniques; namely the equations of geodesic deviation.

The present work is partially intended to fill in the details of an earlier brief work in the Twistor Newsletter (TN43, 1997), where we anticipated some of these results.

II. SOLUTIONS OF THE EIKONAL EQUATION IN CURVED SPACE

In this section we will treat the Eikonal equation in a general curved Lorentzian space–time, $(g,\mathfrak{M})$, i.e.,

$$g^{ab}(x^a)\partial_a S\partial_b S=0 \tag{1}$$

and show how, if a special class of solutions is known, *any* solution can be easily constructed. An important special case of this will be the construction of any single characteristic surface, i.e., a level surface of *some* S, ''a big wave front.''

The difficult task (and it is very difficult, where perturbation techniques must be relied on) is to produce this special class. Specifically, the special class will be a two-parameter family of solutions, $S_0=Z(x^a,\zeta,\overline{\zeta})$ where the parameters are the complex stereographic coordinates on the sphere, S^2, and the null covector, $p_a=\partial_a Z(x^a,\zeta,\overline{\zeta})$ ranges over the entire light-cone at each point x^a as $(\zeta,\overline{\zeta})$ ranges over S^2. Later, in asymptotically flat space–times, we will make a unique choice of this family.

Now assuming that an allowable $Z(x^a,\zeta,\overline{\zeta})$ is known we can produce an arbitrary solution in the following fashion:[8] first, we rescale Z with a constant β and add to Z an arbitrary function, at least once differentiable, of $(\beta,\zeta,\overline{\zeta})$ and then extremize it with respect to the $(\beta,\zeta,\overline{\zeta})$, i.e., we have

$$S=\beta Z(x^a,\zeta,\overline{\zeta})-h(\beta,\zeta,\overline{\zeta}) \tag{2}$$

with

$$\beta\partial_\zeta Z-\partial_\zeta h=0,\quad \beta\partial_{\overline{\zeta}}Z-\partial_{\overline{\zeta}}h=0,\quad Z-\partial_\beta h=0. \tag{3}$$

For the simplicity of the immediate discussion (though the issue is an important one), we assume that the latter three equations can be solved for the $(\beta,\zeta,\overline{\zeta})$ as functions of the x^a, i.e., with

$$(\beta,\zeta,\bar{\zeta})=(B(x^a),\Upsilon(x^a),\bar{\Upsilon}(x^a)), \tag{4}$$

then on substitution back into Eq. (2), the resulting function of x^a also satisfies the Eikonal equation. To see this we have, from (3) that

$$\partial_a S=\beta\partial_a Z+(Z-\partial_\beta h)\partial\beta/\partial x^a+(\beta\partial_\zeta Z-\partial_\zeta h)\partial\zeta/\partial x^a+(\beta\partial_{\bar{\zeta}} Z-\partial_{\bar{\zeta}} h)\partial\bar{\zeta}/\partial x^a=\beta\partial_a Z, \tag{5}$$

which satisfies the Eikonal equation, by the assumption on Z.

The important issue of how to deal with the case when Eq. (3) cannot be solved for $(\beta,\zeta,\bar{\zeta})$ is discussed later in this section.

Though we will not go into the proof one can show that given arbitrary Cauchy data, $S_C(x^i)$ for the Eikonal equation, i.e., a function of three arguments, then it determines the function $h(\beta,\zeta,\bar{\zeta})$. The construction, thus, allows for the general solution to the Eikonal equation.

Remark 1: Since the function $h(\beta,\zeta,\bar{\zeta})$ determines a single solution $S^*(x^a)$ of the Eikonal equation (i.e., a one parameter family of characteristic surfaces) by replacing the $h(\beta,\zeta,\bar{\zeta})$ by the function $h(\beta,\zeta,\bar{\zeta};\eta,\bar{\eta})$ the above construction then produces a two-parameter family of solution of the Eikonal equation, $S^*=Z^*(x^a,\eta,\bar{\eta})$. We thus have that from any special two-parameter family, Z we can construct any other two parameter family that could also be used as the ''special'' family.

We now specialize the construction so that we can obtain any single characteristic surface to be given by $S=u=\text{constant}$; Eqs. (2) and (3) are replaced by the specialization, $\beta=1$,

$$S=Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta})=u, \tag{6}$$

$$\partial_\zeta Z-\partial_\zeta h=0, \quad \partial_{\bar{\zeta}} Z-\partial_{\bar{\zeta}} h=0. \tag{7}$$

Assuming that Eq. (7) can be solved for

$$(\zeta,\bar{\zeta})=(\Upsilon(x^a),\bar{\Upsilon}(x^a)), \tag{8}$$

that any characteristic surface can be obtained by a judicious choice of $h(\zeta,\bar{\zeta})$ can be seen from the argument that if we begin with any spacelike two-surface, $\mathfrak{G}$, parametrized by the same $(\zeta,\bar{\zeta})$, i.e., given by

$$x^a=x_0^a(\zeta,\bar{\zeta}), \tag{9}$$

we can choose

$$h(\zeta,\bar{\zeta})=Z(x_0^a(\zeta,\bar{\zeta}),\zeta,\bar{\zeta}). \tag{10}$$

The resulting characteristic surface. $S=0$, is formed by the null normals to $\mathfrak{G}$ and since any characteristic surface is formed by the null normals to some two-surface we have proven our contention.

Actually, in general, there are lower dimensional regions where Eqs. (7) cannot be solved for the $(\zeta,\bar{\zeta})$ pair. These regions (three dimensional) define the caustics of the solution. The intersection of these caustic regions with any particular level surface of S (big wave front), i.e., with $u=S=\text{const}$ defines the ''big wave front'' singularities[7] of Arnold. The intersection of $u=S$ with a generic three-surface, (e.g., a constant time surface) defines a ''small wave front'' while the intersection of the ''small wave front'' with the caustic three-surface, defines the ''small wave front'' singularities. Though for precise usage we should only refer to the full three dimensional caustic region as the ''caustics,'' we, however, will take the liberty of referring to the singularities of either the big or small wave front as the ''caustics.''

These caustic regions (or on the big or small wave front singularities) which are characterized by the inability to solve for the $(\zeta,\bar{\zeta})$ are simply determined from the implicit function theorem, by the condition

$$\hat{D}\equiv\begin{vmatrix}\frac{\partial^2(Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta}))}{\partial\zeta^2} & \frac{\partial^2(Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta}))}{\partial\zeta\partial\bar{\zeta}} \\ \frac{\partial^2(Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta}))}{\partial\zeta\partial\bar{\zeta}} & \frac{\partial^2(Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta}))}{\partial\bar{\zeta}^2}\end{vmatrix}=0, \tag{11}$$

a condition that will later play a basic role.

To determine the solution S, there is an alternative to solving Eqs. (7) for the $(\zeta,\bar{\zeta})$ that is often more desirable and can be used even when $\hat{D}=0$. Equations (6) and (7) can be considered as defining families of three different 3-surfaces parametrized by the $(\zeta,\bar{\zeta})$ pair. Their intersection defines a family of curves (parametrized by the $(\zeta,\bar{\zeta})$) that are the null geodesics that rule the level surfaces of $u=S$. The equations can always be solved in the following manner: of the four x^a there will be a subset of three of them (say x^i) and the fourth one, say x^* such that

$$x^i=X^i(x^*,u,\zeta,\bar{\zeta}), \tag{12}$$

which are the null geodesics themselves. They define, parametrically, the level surfaces of $u=S$.

An alternative treatment of the null geodesics, Eq. (12), is to introduce a geodesic parameter (not in general an affine parameter) by

$$r=(1+\zeta\bar{\zeta})^2\frac{\partial^2}{\partial\zeta\partial\bar{\zeta}}(Z-h), \tag{13}$$

which, with Eqs. (6) and (7), can be solved for

$$x^a=X^a(r,u,\zeta,\bar{\zeta}) \tag{14}$$

yielding the parametric description of the null geodesics ruling the level surfaces of S. Unfortunately this description can break down at the caustics of S where r sometimes becomes infinite. It nevertheless is a means of treating the geodesics almost everywhere.

Remark 2: The description we have given here for the construction of solutions to the Eikonal equation involves the construction of envelopes of tangent lines to the original two-parameter family of solutions $Z(x^a,\zeta,\bar{\zeta})$ to form the $S(x^a)$. This description and the treatment of the caustics is an example of V. I. Arnold's theory of generating families.[2,7]

III. EIKONAL EQUATION IN ASYMPTOTICALLY FLAT SPACE–TIMES

Before the introduction of a special or fiducial family of null surfaces $S_0=Z(x^a,\zeta,\bar{\zeta})$, we begin with a brief discussion of asymptotically flat space–times. These space–times allow a conformal rescaling of the space–time metric bringing null infinity (the end points of all future-directed null geodesics) into a finite region thereby defining a (null boundary) for the space–time. Though we will not be using the conformal rescaling explicitly, we will however use the language of the conformal boundary. The boundary, referred to as $\mathfrak{I}^+$, can be attained by limiting procedures in the unrescaled space–time. The boundary, which is a null three surface with topology

$R\times S^2$ can be given coordinates $(u,\zeta,\bar{\zeta})$, with u on the R part and the complex stereographic coordinates $(\zeta,\bar{\zeta})$ on the S^2 which label the null generators (geodesics) of $\mathfrak{I}^+$. It is this structure that we will use to obtain the fiducial family of null surfaces.

For *each* generator of $\mathfrak{I}^+$, i.e., for $(\zeta,\bar{\zeta})=(\zeta_0,\bar{\zeta}_0)=\text{constant}$, we choose the one parameter family of *past null cones* having their apexes on that generator. This yields the special solution of the Eikonal equation, $u=Z(x^a,\zeta_0,\bar{\zeta}_0)$. Doing the same for each generator defines for us our unique fiducial family of solutions. $S_0\equiv u=Z(x^a,\zeta,\bar{\zeta})$, the past cones of each point of $\mathfrak{I}^+$. We emphasize that we are describing these null surfaces in the language of the conformal compactification—in the language of the physical space–time they describe the family of all asymptotic plane waves and in the case of flat space they *are* the family of *all* plane waves. As the concepts described here are conformally invariant, the choice of language is at our discretion.

Our special family of solutions

$$u=Z(x^a,\zeta,\bar{\zeta}) \tag{15}$$

has the two important dual meanings: (1) As we just mentioned for fixed point. $(u,\zeta,\bar{\zeta})$, on $\mathfrak{I}^+$, as x^a varies, it defines the past cone of the point and (2) for a fixed value of the x^a, as $(\zeta,\bar{\zeta})$ are varied over the S^2, $u=Z$ defines a two-surface on $\mathfrak{I}^+$, the end points of all the null geodesics leaving x^a. This two-surface is referred to as the *light-cone cut* of the point x^a and is denoted by $\mathfrak{c}(x^a)$. The function $Z(x^a,\zeta,\bar{\zeta})$ will be referred to as the *light-cone cut function*.

Both meanings to $u=Z(x^a,\zeta,\bar{\zeta})$ play a fundamental role in the remainder of this work. The actual determination of $u=Z(x^a,\zeta,\bar{\zeta})$ is quite difficult and up to the present, depends on perturbation arguments that have not yet been completed. We nevertheless will assume that the function $Z(x^a,\zeta,\bar{\zeta})$ is known; we then study several consequences of this knowledge.

Remark 3: Though we will not be concerned with it here, we mention that the $Z(x^a,\zeta,\bar{\zeta})$ codes all conformal information of the space–time metric[4,5,9] *and in fact determines a conformal metric. Furthermore $Z(x^a,\zeta,\bar{\zeta})$, with a scalar function $\Omega(x^a,\zeta,\bar{\zeta})$ that acts as a conformal factor, can be used as the basic variables, replacing the metric, in a reformulation of the Einstein equations.*[4,5,9]

Our goal here is somewhat simpler (though some of the calculations themselves are not simple); we want to study the structure of the singular regions of different surfaces. First, we will show how to construct from the $Z(x^a,\zeta,\bar{\zeta})$, using the techniques of the previous section, the entire light cone $\mathfrak{C}_{x_0}$ of an arbitrary interior point x_0^a and then study its singularities. The light-cone cut $\mathfrak{c}(x_0^a)$ is the intersection of $\mathfrak{C}_{x_0}$ with $\mathfrak{I}^+$, defining a small wave front; its singularities will then be studied. Finally we return to and study the singular regions of the fiducial family of null surfaces, defined by the light-cone cut function, $Z(x^a,\zeta,\bar{\zeta})$ itself.

We first define, in the case of asymptotically flat spaces, several variables that play an important later role. Instead of using the notation of ∂_ζ and $\partial_{\bar{\zeta}}$ for the $(\zeta,\bar{\zeta})$ derivatives, we make use of the *edth* notation, e.g., $\eth Z=(1+\zeta\bar{\zeta})\partial_\zeta Z$. $\eth\bar{\eth}Z=(1+\zeta\bar{\zeta})^2\partial_\zeta\partial_{\bar{\zeta}}Z$ or $\eth^2 Z=\partial_\zeta\{(1+\zeta\bar{\zeta})^2\partial_\zeta Z\}$, etc. We then have by direct calculation from the $Z(x^a,\zeta,\bar{\zeta})$,

$$(1)\quad \omega\equiv\eth Z,\quad \bar{\omega}\equiv\eth Z,\quad \text{the tangent directions to the light-cone cuts,}$$

$$(2)\quad \Lambda\equiv\eth^2 Z,\quad \bar{\Lambda}\equiv\bar{\eth}^2 Z,\quad \text{``accelerations'' along the } (\bar{\zeta},\zeta) \text{ constant curves,}$$

$$(3)\quad R\equiv\eth\bar{\eth}Z \quad \text{extrinsic curvature of the light-cone cuts.} \tag{16}$$

Using this notation, the determination of the caustics, i.e., the vanishing of the determinant $\hat{D}$ from Eq. (11) is equivalent, using Eq. (7), to

$$D \equiv \begin{vmatrix} \eth^2[Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta})] & \eth\bar{\eth}[Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta})] \\ \eth\bar{\eth}[Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta})] & \bar{\eth}^2[Z(x^a,\zeta,\bar{\zeta})-h(\zeta,\bar{\zeta})] \end{vmatrix} = 0. \tag{17}$$

IV. LIGHT-CONES AND THEIR SINGULARITIES

In this section we consider the future light-cone of a point x_0^a, namely, the set of all (future directed) null geodesics that pass through x_0^a. As a three-surface in the four-dimensional space–time, the light-cones in general have singularities that are caused by the focusing effect of the space–time curvature. These singularities are characterized by the vanishing of the geodesic deviation vector associated with neighboring geodesics on the light-cone and are what we have been referring to as the caustics of the null surface. It is our purpose here to first find these light-cones and then describe their singularities in terms of the light-cone cut function, $Z(x^a,\zeta,\bar{\zeta})$.

As we pointed out earlier (Sec. II), given a two-parameter family of solutions to the Eikonal equation, $Z(x^a,\zeta,\bar{\zeta})$, any characteristic surface can be constructed by adding a term that depends only on the parameters $(\zeta,\bar{\zeta})$; i.e.,

$$S(x^a,\zeta,\bar{\zeta}) = Z(x^a,\zeta,\bar{\zeta}) - h(\zeta,\bar{\zeta})$$

and extremizing with respect to the two parameters. If we choose

$$h(\zeta,\bar{\zeta}) = Z(x_0^a,\zeta,\bar{\zeta}) \equiv Z_0(\zeta,\bar{\zeta}), \tag{18}$$

then the level surface obtained from

$$S = 0 = Z(x^a,\zeta,\bar{\zeta}) - Z(x_0^a,\zeta,\bar{\zeta}) \tag{19}$$

with the extremal conditions

$$\begin{aligned} &\eth[Z(x^a,\zeta,\bar{\zeta}) - Z(x_0^a,\zeta,\bar{\zeta})] = 0, \\ &\bar{\eth}[Z(x^a,\zeta,\bar{\zeta}) - Z(x_0^a,\zeta,\bar{\zeta})] = 0, \end{aligned} \tag{20}$$

describes the light-cone from the point x_0^a. To see this, we first remember that this construction yields characteristic surfaces, then we see that the surface does go through the point $x^a = x_0^a$ and coincides on $\mathfrak{I}^+$, with the light-cone cut of x_0^a. Finally if we take its gradient, i.e.,

$$\partial_a S|_{x=x_0} = \partial_a[Z(x^a,\zeta,\bar{\zeta}) - Z(x_0^a,\zeta,\bar{\zeta})]|_{x=x_0} = \partial_a Z(x^a,\zeta,\bar{\zeta})|_{x=x_0} \equiv p_a(x_0^a,\zeta,\bar{\zeta}), \tag{21}$$

we see that it ranges over the entire light-cone at x_0^a.

A Caveat: We have assumed that the cut function, $u = Z(x^a,\zeta,\bar{\zeta})$, for fixed x^a is a single valued function on $\mathfrak{I}^+$. In fact, in general, this is not true; most often there will be regions on $\mathfrak{I}^+$ where it will be multivalued and it must be given as several different ''sheets'' in different $(\zeta,\bar{\zeta})$ patches. Though this does not present obstacles in principle, it does present technical difficulties in implementation. Then Eqs. (19) and (20) must be repeated on the different sheets. A way to avoid this difficulty is to describe the light-cone cut function and the light-cone cut itself parametrically, i.e., to write it as $u = U(x^a,\lambda,\bar{\lambda})$ and $\zeta = \Gamma(x^a,\lambda,\bar{\lambda})$ with single-valued functions. For simplicity of presentation we will, for the moment, continue to treat the cut function as if it were single valued.

If, to the set of Eqs. (19) and (20), we add, from Eq. (13), the equation

$$r = (1+\zeta\bar{\zeta})^2 \frac{\partial^2}{\partial\zeta\partial\bar{\zeta}}(Z - Z_0) \equiv \eth\bar{\eth}(Z(x^a,\zeta,\bar{\zeta}) - Z(x_0^a,\zeta,\bar{\zeta})), \tag{22}$$

they implicitly define all the null geodesics of the light-cone $\mathfrak{C}_{x_0}$, i.e., they determine

$$x^a = X^a(x_0^a, r, \zeta, \overline{\zeta}). \tag{23}$$

If the geodesic goes from x_0^a to $\mathfrak{I}^+$ without encountering a caustic then r goes from 0 to infinity along that geodesic; if however it does encounter a caustic before $\mathfrak{I}^+$, r then becomes infinite before $\mathfrak{I}^+$.

The location of the caustics of $\mathfrak{C}_{x_0}$ (or the conjugate points to x_0^a) is given by the vanishing of D from Eq. (17), with $h = Z(x_0^a, \zeta, \overline{\zeta})$;

$$D \equiv \begin{vmatrix} \eth^2[Z(x^a,\zeta,\overline{\zeta}) - Z(x_0^a,\zeta,\overline{\zeta})] & \eth\bar{\eth}[Z(x^a,\zeta,\overline{\zeta}) - Z(x_0^a,\zeta,\overline{\zeta})] \\ \eth\bar{\eth}[Z(x^a,\zeta,\overline{\zeta}) - Z(x_0^a,\zeta,\overline{\zeta})] & \bar{\eth}^2[Z(x^a,\zeta,\overline{\zeta}) - Z(x_0^a,\zeta,\overline{\zeta})] \end{vmatrix} = 0, \tag{24}$$

or, with definitions (16),

$$D = (\Lambda - \Lambda_0)(\overline{\Lambda} - \overline{\Lambda}_0) - (R - R_0)^2 = 0. \tag{25}$$

We have thus been able to express the location of the caustics of an arbitrary light-cone in terms of derivatives of the cut function $Z(x^a, \zeta, \overline{\zeta})$. Given a fixed point x_0^a and a particular null geodesic (labeled by $(\zeta, \overline{\zeta})$), the curvature and ''acceleration'' of its light-cone cut is given by $(R_0(x_0^a, \zeta, \overline{\zeta}), \Lambda_0(x_0^a, \zeta, \overline{\zeta}))$ while for an arbitrary point along that geodesic it would be $(R(x^a, \zeta, \overline{\zeta}), \Lambda(x^a, \zeta, \overline{\zeta}))$. D which begins as zero at $r = 0$, does not vanish any other place along a geodesic that does not encounter a caustic but does go to zero at the caustic. There are special geodesics $(\zeta, \overline{\zeta})_c$ which meet the caustic on $\mathfrak{I}^+$. For this limiting case, it is difficult to study the behavior of Eq. (25) since $\Lambda \Rightarrow 0$ and $R \Rightarrow \infty$, the flat-space limits, which applies here since the points x^a near $\mathfrak{I}^+$ are in the very weak field region and R_0 and Λ_0 are infinite (see next section). Other techniques for this study are needed. (See Fig. 1, the light-cone with the crossovers and cusps.)

V. THE LIGHT-CONE CUTS AND THEIR SINGULARITIES

As we saw earlier, the cut function, $u = Z(x^a, \zeta, \overline{\zeta})$ has the dual meaning of being the past light-cones of the points $(u, \zeta, \overline{\zeta})$ of $\mathfrak{I}^+$ and representing the light-cone cut of an interior point, x^a. Fixing the interior point $x^a = x_0^a$, we studied, in the last section, its light-cone and saw that we could locate its caustics but as the caustics approached $\mathfrak{I}^+$ difficulties developed. We wish to study the singularities of the light-cone cuts by an alternative method.

First of all, if we assume that *all* the null geodesics leaving x_0^a arrive at $\mathfrak{I}^+$ without encountering a caustic then the cut function, $u = Z(x^a, \zeta, \overline{\zeta})$, will describe a single-valued smooth 2-surface on $\mathfrak{I}^+$. If however some did encounter caustics then the cut-surface will only be piecewise smooth and will have, in general, self-intersections. The appropriate way to describe the cut is not through the cut function but instead via the mapping of the space of null directions at x_0^a, i.e., at $S^2(x_0^a)$, coordinatized by $(\lambda, \overline{\lambda})$, onto $\mathfrak{I}^+$. It would be given by the relations

$$(u, \zeta, \overline{\zeta}) = (U(x_0^a, \lambda, \overline{\lambda}), \Gamma(x_0^a, \lambda, \overline{\lambda}), \overline{\Gamma}(x_0^a, \lambda, \overline{\lambda})), \tag{26}$$

which are just the ''end-points'' or boundary points of the null geodesics originating at x_0^a in the $(\lambda, \overline{\lambda})$ directions. (If the $(\lambda, \overline{\lambda}) \Rightarrow (\zeta, \overline{\zeta})$ were invertible, then one would have the smooth case, $u = U(x_0^a, \lambda, \overline{\lambda}) = Z(x_0^a, \zeta, \overline{\zeta})$.)

To obtain a clearer picture the light-cone cut can, in some sense, be thought of as an infinitely late ''small wave front.'' The ''early'' wave fronts on the future lightcone of x_0^a are smooth deformations of spheres, but they may become singular at sufficiently late times, from the focusing

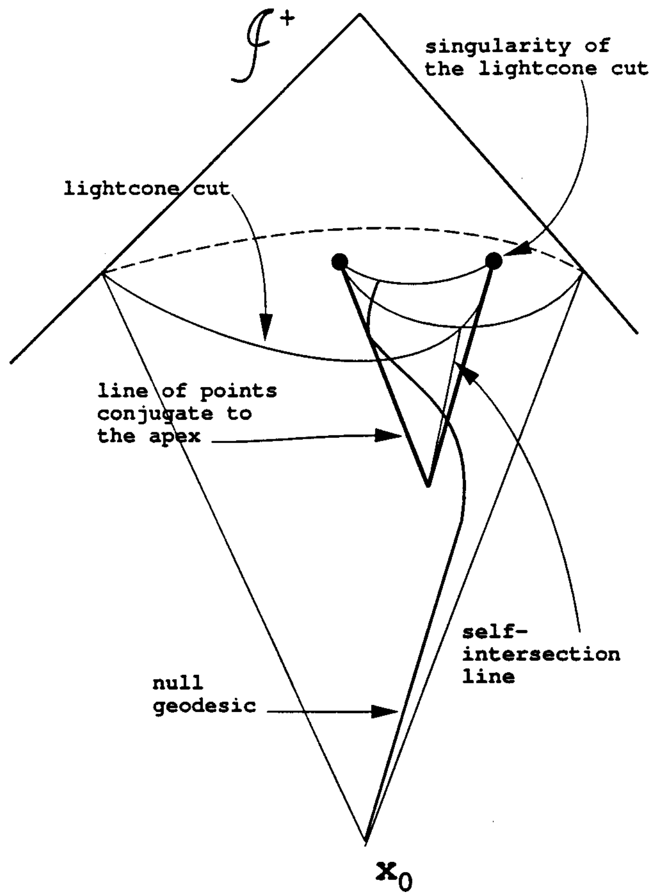

FIG. 1. The future light-cone and light-cone cut of a point x_0.

due to curvature. Therefore, light-cone cuts of (early) points in space–time are generically singular two-surfaces in three-dimensions, and they must exhibit the standard stable singularities, the cusp ridges, and swallowtails. In this view, for a fixed point x_0^a, a singularity in the light-cone cut would be a conjugate point to x_0^a. Generically, because singularities of two-surfaces lie on curves, the singularities of a light-cone cut would single out a one-parameter set $(\zeta(s),\overline{\zeta}(s))$ of null geodesics in the future light-cone for which the apex is a focal point.

Because Eq. (26) arises from the Hamiltonian evolutions (null geodesic flow) the map is a Legendre map and we can use the general theory of Legendre submanifolds and Legendre maps of Arnold and his colleagues in order to have a description of the location of the singularities of the light-cone cuts.[3,6] A two-dimensional surface in a three-manifold which is obtained by a Legendre map can always be represented as the projection of a smooth 2-surface (a Legendre submanifold) in a five-dimensional space, with the singularities located by the singularities of the projection. In other words, there exists a way to ''unfold'' a singular surface by adding two dimensions to the space where the surface lives. In this view, one of the three original dimensions (the u coordinate of $\mathfrak{I}^+$) is singled out from the remaining two-dimensional space; the two-dimensions, $(\zeta,\overline{\zeta})$, are to be considered as a configuration space. The two added dimensions consist of the two-dimensional cotangent space over the configuration space. Thus the enlarged five-dimensional space on which our surfaces ''unfold'' consists of points $(\zeta,\overline{\zeta},p_\zeta,p_{\overline{\zeta}},u)$, a contact bundle over the sphere. It is preferable to use *real* coordinates, and later translate the results in terms of our complex coordinates. Thus, in the following we assume that we have real coordinates (q^1,q^2) on the sphere, which can be taken to be the real and imaginary parts of ζ, and their corresponding momenta as (p_1,p_2).

A smooth ''unfolding'' is generically represented in terms of a smooth generating function $G(q^1,p_2)$. The points (q^1,q^2,p_1,p_2,u) that lie on such unfolding are given by

$$q^2=-\frac{\partial G(q^1,p_2)}{\partial p_2}, \tag{27a}$$

$$p_1=\frac{\partial G(q^1,p_2)}{\partial q^1}, \tag{27b}$$

$$u=G(q^1,p_2)+p_2q^2, \tag{27c}$$

and arbitrary values for q^1 and p_2. This is the expression of a two-dimensional surface within a five-dimensional space, parametrized by (q^1,p_2).

Remark 4: Note that from the general theory, there must be an invertible relationship between the parametrization (q^1,p_2) *of the Legendre submanifold and the directions* $(\lambda,\bar{\lambda})$.

A projection of this surface down to the space (q^1,q^2,u) is parametrically represented by a map $(q^1,p_2)\rightarrow(q^1,q^2(q^1,p_2),u(q^1,p_2))$ which breaks down at points where the Jacobian matrix

$$\left\|\begin{matrix} \dfrac{\partial q^1}{\partial q^1} & \dfrac{\partial q^1}{\partial p_2} \\ \dfrac{\partial q^2}{\partial q^1} & \dfrac{\partial q^2}{\partial p_2} \\ \dfrac{\partial u}{\partial q^1} & \dfrac{\partial u}{\partial p_2} \end{matrix}\right\| = \left\|\begin{matrix} 1 & 0 \\ -\dfrac{\partial^2 G}{\partial q^1\partial p_2} & -\dfrac{\partial^2 G}{\partial p_2^2} \\ \dfrac{\partial G}{\partial q^1}-p_2\dfrac{\partial^2 G}{\partial q^1\partial p_2} & -p_2\dfrac{\partial^2 G}{\partial p_2^2} \end{matrix}\right\| \tag{28}$$

drops rank, from 2 to 1 or 0. The drop in rank takes place where the three 2×2 determinants vanish, namely, where

$$\frac{\partial^2 G}{\partial p_2^2}=0, \tag{29}$$

$$p_2\frac{\partial^2 G}{\partial p_2^2}=0, \tag{30}$$

$$\frac{\partial G}{\partial q^1}\frac{\partial^2 G}{\partial p_2^2}=0. \tag{31}$$

Clearly all three equations can be satisfied if and only if

$$K(q^1,p_2)\equiv\frac{\partial^2 G(q^1,p_2)}{\partial p_2^2}=0. \tag{32}$$

Thus Eq. (32) locates the curve $K(q^1,p_2)=0$ in the (q^1,p_2) parameter space and hence, via Eqs. (27a) and (27c), it locates the singular points on the surface. Equation (32) also expresses the location of points where Eq. (27a) fails to be invertible; namely, if we think of Eq. (27a) as implicitly defining $p^2=h(q^1,q^2)$, then h fails to be differentiable there. (From the drop in rank, it is straightforward to see that $\partial h/\partial q^2$ blows up. See Eq. (39a) below.)

In order to translate this treatment into our complex notation, we pass from (q^1,q^2) to the complex coordinates $\zeta=\frac{1}{2}(q^1+iq^2)$ and reinterpret

$$u=G(x^a,q^1,h(q^1,q^2))+q^2h(q^1,q^2)$$

as our cut function $u=Z(x^a,\zeta,\overline{\zeta})$, where x^a are fixed parameters and play no role in the discussion of this section. We can then express Eq. (32) in terms of derivatives of Z in the following manner.

Beginning with the function $\Lambda\equiv\eth^2Z$, we express it parametrically in terms of (q^1,p_2),

$$\Lambda=2(1+\zeta\overline{\zeta})\overline{\zeta}\frac{\partial Z}{\partial\zeta}+(1+\zeta\overline{\zeta})^2\frac{\partial^2Z}{\partial\zeta^2}, \tag{33}$$

where

$$\frac{\partial}{\partial\zeta}=\left.\frac{\partial}{\partial q^1}\right|_{q^2}-i\left.\frac{\partial}{\partial q^2}\right|_{q^1}. \tag{34}$$

Carrying through the calculation, which involves several implicit differentiations, we first arrive at

$$\omega=(1+\zeta\overline{\zeta})\left(\frac{\partial G}{\partial q^1}-ip_2\right),\quad \overline{\omega}=(1+\zeta\overline{\zeta})\left(\frac{\partial G}{\partial q^1}+ip_2\right), \tag{35}$$

where

$$\zeta=\frac{1}{2}\left(q^1-i\frac{\partial G}{\partial p_2}\right),\quad \overline{\zeta}=\frac{1}{2}\left(q^1+i\frac{\partial G}{\partial p_2}\right). \tag{36}$$

Then

$$\Lambda=2\overline{\zeta}\omega+(1+\zeta\overline{\zeta})^2\left\{\frac{\partial^2G}{\partial(q^1)^2}-\left(\frac{\partial^2G}{\partial q^1\partial p_2}-i\right)^2\left(\frac{\partial^2G}{\partial p_2^2}\right)^{-1}\right\}. \tag{37}$$

Similarly, we obtain a parametric expression for $R\equiv\bar{\eth}\eth Z=(1+\zeta\overline{\zeta})^2(\partial^2Z/\partial\zeta\partial\overline{\zeta})$ in the form

$$R=(1+\zeta\overline{\zeta})^2\left\{\frac{\partial^2G}{\partial(q^1)^2}-\left(1+\left(\frac{\partial^2G}{\partial q^1\partial p_2}\right)^2\right)\left(\frac{\partial^2G}{\partial p_2^2}\right)^{-1}\right\}. \tag{38}$$

In deriving (37) and (38), the following were needed:

$$\frac{\partial h}{\partial q^1}=-\frac{\partial^2G}{\partial q^1\partial p_2}\left(\frac{\partial^2G}{\partial p_2^2}\right)^{-1},\quad \frac{\partial h}{\partial q^2}=-\left(\frac{\partial^2G}{\partial p_2^2}\right)^{-1}, \tag{39}$$

which are obtained by taking derivatives $\partial/\partial q^1|_{q^2}$ and $\partial/\partial q^2|_{q^1}$ of Eq. (27a).

From (37) and (38) we can see that both Λ and R diverge at points where Eq. (32) is satisfied, and only at those points, since G is assumed to be smooth. Therefore, we can locate the singular points (a curve), $(\zeta(s),\overline{\zeta}(s))$ of light-cone cuts by either of the conditions,

$$P(x_0^a,\zeta,\overline{\zeta})\equiv\frac{1}{\bar{\eth}\eth Z(x_0^a,\zeta,\overline{\zeta})}=0, \tag{40}$$

$$L(x_0^a,\zeta,\overline{\zeta})\equiv\frac{1}{\eth^2Z(x_0^a,\zeta,\overline{\zeta})}=0 \tag{41}$$

for given values of x_0^a.

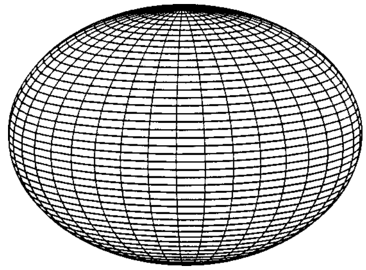

FIG. 2. A regular light-cone cut.

We interpret this result as follows. The light-cone cut represents a wave front that has progressed out to infinity, tracing the future light-cone of the point x_0^a. For a class of points x_0^a (at least sufficiently early), the wave front starts out spherical, but there is a time at which it becomes self-intersecting. Late wave fronts have singularities which represent the location of points conjugate to x_0^a. When the wave front reaches infinity, the points conjugate to the apex lie at infinity and form the singularities of the light-cone cut (See Fig. 2, for a smooth light-cone cut and Fig. 3, for a generic light-cone cut with cusp ridges and swallowtails.)

Finally note that the vanishing of $P(x_0^a,\zeta,\overline{\zeta})$ and $L(x_0^a,\zeta,\overline{\zeta})$ are not inconsistent with Eq. (25) of the previous section where as $\mathfrak{I}^+$ is approached. $\Lambda \to 0$. $R\to\infty$ and the $\Lambda_0\to\infty$ and $R_0\to\infty$.

VI. SINGULARITIES OF THE PAST LIGHT-CONES FROM $\mathfrak{I}^+$

Up to this point we have simply assumed that we had the three parameter family of null surfaces (or equivalently the two parameter family of solutions to the Eikonal equation) that we called the fiducial family or the light-cone cut function, namely, $u=Z(x^a,\zeta,\overline{\zeta})$, with $(u,\zeta,\overline{\zeta})$ constant. We never raised the issue of the location of their singularities until now. The reason was that, to locate them, requires a different technique, namely the use of pairs of geodesic deviation vectors (Jacobi fields) and their associated area element. It will be the vanishing of the area element (obtained from the Jacobi fields) along a geodesic that locates the singularities. We begin by returning to certain structures obtainable from the light-cone cut function $Z(x^a,\zeta,\overline{\zeta})$ that were defined earlier; namely,

$$u=Z(x^a,\zeta,\overline{\zeta}), \tag{42}$$

which represents the past light-cones from all points on $\mathfrak{I}^+$,

$$\omega=\eth Z(x^a,\zeta,\overline{\zeta}), \quad \overline{\omega}=\bar{\eth} Z(x^a,\zeta,\overline{\zeta}), \tag{43}$$

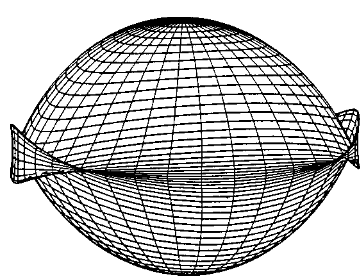

FIG. 3. A singular light-cone cut, showing cusp ridges and swallowtails.

which label the null geodesics leaving the point $(u,\zeta,\overline{\zeta})$ of $\mathfrak{I}^+$. From the compactified point of view they are the (stereographic) angles labeling the directions from the past light-cone while from the physical space point of view they are the ''distance'' between the asymptotic parallel geodesics,

$$R=\bar{\eth}\eth Z(x^a,\zeta,\overline{\zeta}), \tag{44}$$

which defines an ''optical distance'' or geodesic parameter (not affine) along the geodesics $(u,\omega,\overline{\omega})=\text{const}$. As we mentioned earlier, geometrically R is a curvature of the cut.

Using the notation

$$\theta^i=\theta^i(x^a,\zeta,\overline{\zeta})\equiv(u,\omega,\overline{\omega},R), \quad \text{with} \quad (i=0,+,-,1), \tag{45}$$

Eq. (45) can be interpreted either as a coordinate transformation, $\theta^i \Leftrightarrow x^a$, for every fixed value of the two parameters $(\zeta,\overline{\zeta})$ or simply as the introduction of four scalar functions parametrized by the $(\zeta,\overline{\zeta})$. We will make extensive use of the transformation interpretation though care must be taken in the regions where the Jacobian either vanishes or diverges. One might even expect that the troublesome region will be where the (big) wave front singularities develop.

In generic space–times, the presence of the curvature, Weyl or Ricci-type, has a *focusing effect* on parallel beams of light.[10] Thus, generically, two neighboring null geodesics in our asymptotically parallel congruences meet at some point, which means that our coordinate system breaks down by assigning two different labels to the same space–time point.

We will describe two alternative approaches to the region of breakdown.

(1) We can calculate the Jacobian of Eq. (45) most easily by returning to the description of the cut function Z by the generating function, $G(x^a,q^1,p_2)$ of the previous section, $Z=G+q^2p_2$. By a completely straightforward calculation (using MATHEMATICA to calculate the determinant) we find that

$$\left|\frac{\partial\theta^i}{\partial x^a}\right| \propto \left(\frac{\partial^2 G(x^a,q^1,p_2)}{\partial p_2^2}\right)^{-1}, \tag{46}$$

$$\left|\frac{\partial x^a}{\partial\theta^i}\right| \propto \left(\frac{\partial^2 G(x^a,q^1,p_2)}{p_2^2}\right) \tag{47}$$

so that the Jacobian breaks down precisely at the comparable point where the light-cone cut had its singularities.

Remark 5: In the previous section we saw that for fixed x^a, but varying the $(\zeta,\overline{\zeta})$, the functions $R(x^a,\zeta,\zeta)$ and $\Lambda(x^a,\zeta,\overline{\zeta})$ both diverged at the singularities of the light-cone cut. We can now see that for fixed $(\zeta,\overline{\zeta})$ but varying the point x^a along a null geodesic, the same functions diverge at the caustic of the past light-cone.

(2) In the second approach, we derive an explicit algebraic condition to locate these regions, by finding the points where a geodesic deviation vector vanishes. Our present derivation is in great measure a reinterpretation of an earlier derivation due to Kozameh and Newman,[11] reproduced here in current notation in order to maintain the unity of the present work.

By (in principle) inverting Eq. (45) we obtain

$$x^a=X^a(\theta^i,\zeta,\overline{\zeta})=X^a(u,\omega,\overline{\omega},R,\zeta,\overline{\zeta}), \tag{48}$$

which for fixed values of $(u,\zeta,\overline{\zeta})$ is the parametric form of the past cone of $\mathfrak{I}^+$ and for fixed values of $(u,\omega,\overline{\omega},\zeta,\overline{\zeta})$ it is the parametric form for the null geodesics on the cone each labeled by $(\omega,\overline{\omega})$.

Of prime importance to us are the connecting vectors to the null geodesics that are on the past null cone. Two connecting vectors (from which all others can be constructed) are given by

$$M^a = \frac{\partial X^a}{\partial \omega}, \quad \overline{M}^a = \frac{\partial X^a}{\partial \overline{\omega}}. \tag{49}$$

We are interested in the area A constructed from M^a and $\overline{M}^a$. Taking a pair of (complex) spacelike unit vectors m^a and $\overline{m}^a$ ($g_{ab}m^a m^b = 0$, $g_{ab}\overline{m}^a\overline{m}^b = 0$, $g_{ab}\overline{m}^a m^b = -1$), that are parallel transported along the null geodesics. M^a and $\overline{M}^a$ can be written as

$$M^a = \xi m^a + \overline{\eta m}^a, \quad \overline{M}^a = \overline{\xi}\overline{m}^a + \eta m^a, \tag{50}$$

so that the ''area'' form is

$$M^{[a}\overline{M}^{b]} = (\xi\overline{\xi} - \eta\overline{\eta}) m^{[a}\overline{m}^{b]} \equiv A m^{[a}\overline{m}^{b]}. \tag{51}$$

From this we see that

$$A^2 \equiv (g_{ab}M^a\overline{M}^b)^2 - (g_{ab}M^a M^b)(g_{ab}\overline{M}^a\overline{M}^b) \equiv (M\cdot\overline{M})^2 - (M\cdot M)(\overline{M}\cdot\overline{M}). \tag{52}$$

Our task (which requires a bit of preparation) is to express the $M\cdot\overline{M}$ and $M\cdot M$ in terms of $Z(x^a,\zeta,\overline{\zeta})$ and its derivatives. We choose the one-form basis

$$\theta^i_a \equiv \partial_a\theta^i = (\partial_a Z, \partial_a\omega, \partial_a\overline{\omega}, \partial_a R) \equiv (\theta^0_a, \theta^+_a, \theta^-_a, \theta^1_a) \tag{53}$$

and the dual vectors

$$\theta^a_i = (\theta^a_0, \theta^a_+, \theta^a_-, \theta^a_1) = (\partial X^a/\partial u, \partial X^a/\partial\omega, \partial X^a/\partial\overline{\omega}, \partial X^a/\partial R) \tag{54}$$

which satisfy

$$\theta^a_i\theta^j_a = \delta^j_i, \quad \theta^a_i\theta^i_c = \delta^a_c. \tag{55}$$

From the one-form basis θ^i_a, using the space–time metric, g^{ab}, one can express the dual basis set by

$$\theta^a_i = g^{ac}\theta^j_c\eta_{ji} \quad \text{or} \quad \theta^i_c = g_{ac}\theta^a_j\eta^{ij}, \tag{56}$$

where

$$\eta_{ij} = \theta^a_i\theta^c_j g_{ac}, \quad \eta^{ij} = \theta^i_a\theta^j_c g^{ac}. \tag{57}$$

Returning to the computation of the area, we have for the tangent vector to the geodesics,

$$\theta^a_1 \equiv L^a = \partial X^a/\partial R, \tag{58}$$

and from the geodesic deviation vectors, $M^a = \partial X^a/\partial\omega = \theta^a_+$ and $\overline{M}^a = \partial X^a/\partial\overline{\omega} = \theta^a_-$ that

$$M\cdot\overline{M} = \eta_{+-}, \quad M\cdot M = \eta_{++}, \quad \overline{M}\cdot\overline{M} = \eta_{--}. \tag{59}$$

Remark 6: Note that $l^a \equiv \Omega^2 L^a$ is the affine parametrized tangent vector to the geodesics. [See (Eq. (63) below for the definition of Ω.]

The calculation of the three η's though lengthy, is fairly straightforward; It is found from the inverse of η^{ij} [i.e., from the second version of Eq. (57)]. The components of η^{ij} are found by beginning with

$$\eta^{00}=\theta_a^0\theta_c^0 g^{ac}=g^{ac}\partial_a Z\partial_c Z=0 \tag{60}$$

which vanishes by definition. By applying the operators ð and $\bar{ð}$ several times to Eq. (60) one finds[4] for the relevant components of η^{ij} [see Eq. (16) for definitions]

$$\eta^{00}=0, \tag{61}$$

$$\eta^{0+}=0, \quad \eta^{0-}=0, \tag{62}$$

$$\eta^{01}\equiv\Omega^2=g^{ac}\partial_a Z ð\bar{ð}(\partial_c Z)=g^{ac}\partial_a Z\partial_c R, \tag{63}$$

$$\eta^{++}=-\Omega^2 L^a ð^2(\partial_a Z)=-\Omega^2 L^a\partial_a\Lambda=-\Omega^2\partial\Lambda/\partial R, \tag{64}$$

$$\eta^{--}=-\Omega^2 L^a \bar{ð}^2(\partial_a Z)=-\Omega^2 L^a\partial_a\overline{\Lambda}=-\Omega^2\partial\overline{\Lambda}/\partial R, \tag{65}$$

$$\eta^{-+}=-\Omega^2, \tag{66}$$

which in turn leads to

$$M\cdot M=\eta_{++}=-\frac{1}{\Omega^2\left(1-\frac{\partial\Lambda}{\partial R}\frac{\partial\overline{\Lambda}}{\partial R}\right)}, \tag{67}$$

$$M\cdot\overline{M}=\eta_{+-}=-\frac{\frac{\partial\overline{\Lambda}}{\partial R}}{\Omega^2\left(1-\frac{\partial\Lambda}{\partial R}\frac{\partial\overline{\Lambda}}{\partial R}\right)}. \tag{68}$$

The area then is

$$A^2=\frac{1}{\Omega^4\left(1-\frac{\partial\Lambda}{\partial R}\frac{\partial\overline{\Lambda}}{\partial R}\right)}. \tag{69}$$

This expression for A tells us several things; first of all to keep A real we must have the inequality

$$\left|\frac{\partial\Lambda}{\partial R}\right|\leqslant 1, \tag{70}$$

and we learn that Ω must diverge at the singularity given by $A=0$.

We have thus learned in this section that the singularities of the past light-cones from $\mathfrak{I}^+$ can be characterized by one of several methods:

(1) Using the generating function $G(x^a,q^1,p_2)$, the singularities are given by the vanishing of the Jacobian of the transformation (45), i.e., by

$$\frac{\partial^2 G(x^a,q^1,p_2)}{\partial p_2^2}=0. \tag{71}$$

(2) This, in turn, tells us (from the previous section) that both $R(x^a,\zeta,\overline{\zeta})$ and $\Lambda(x^a,\zeta,\overline{\zeta})$ diverge as the singularities are approached.

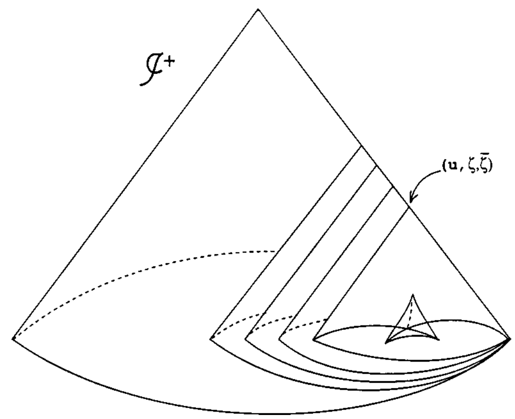

FIG. 4. The foliation of space–time by past light-cones from points at null infinity.

(3) From the geodesic deviation argument

$$\Omega \rightarrow \infty \tag{72}$$

as the singularity is approached.

(4) From Eqs. (69) and (70) we learn that $|\partial\Lambda/\partial R|$ must be bounded but we can not see what is its behavior is as the singularity is approached. However on the basis of several examples, e.g., Ref. 1, where $|\partial\Lambda/\partial R| \rightarrow 1$ it appears to be reasonable to expect that this result might be true in general. If so, then we would have that $[1-(\partial\Lambda/\partial R)(\partial\bar{\Lambda}/\partial R)] \rightarrow 0$ as the singularity is approached. In turn, from Eq. (69), we would gain some information about how fast both Ω and $[1-(\partial\Lambda/\partial R)(\partial\bar{\Lambda}/\partial R)]$ approach their limits. (See Fig. 4, a past light-cone from $\mathfrak{I}^+$.)

VII. SUMMARY AND CONCLUSIONS

In this work we have studied the kinematics or general structure of several different classes of surfaces (associated with surface forming null geodesic congruences) in asymptotically flat Lorentzian space–times, namely, the future light cones of interior points, $\mathfrak{C}_x$; the intersection of $\mathfrak{C}_x$ with $\mathfrak{I}^+$, i.e., the light-cone cuts, $\mathfrak{c}(x^a)$; and the past light-cones from points $(u,\zeta,\bar{\zeta})$ on $\mathfrak{I}^+$.

These surfaces, which in general have singularities, are closely related to each other; in particular there is a close association between their singularities. As was pointed out earlier, for the future light cones $\mathfrak{C}_{x_0}$ with an apex x_0^a that is sufficiently early in time, the small wave fronts begin spherical but as they evolve they become self-intersecting and develop singularities (the stable one being cusp ridges and swallowtails[6]) which represent the conjugate points to x_0^a. The limit, in the asymptotic future, of these small wave fronts is the light-cone cut $\mathfrak{c}(x_0^a)$; the singularities of $\mathfrak{c}(x_0^a)$ being the points conjugate to the apex. They are also the intersection of the singularities of $\mathfrak{C}_{x_0}$ with $\mathfrak{I}^+$ (see Figs. 1, 2, and 3.)

Alternatively (an example of the reciprocity theorem of Penrose and Sachs[11,12]), the singularities of light-cone cuts must be related to the singularities of the past light cones from points at infinity. The singularities of light-cone cuts are interpreted as singling out the null geodesics leaving $\mathfrak{I}^+$ which are conjugate to or focus at x_0^a. These null geodesic belong to two congruences of interest to us. First, they belong to the future light cone of the point x_0^a, and second, they belong to the past light cone of the point $(u,\zeta,\bar{\zeta})$ of $\mathfrak{I}^+$ reached by the first set. The light-cone cut function, with the vanishing of either $P(x^a,\zeta,\bar{\zeta})$ or $L(x^a,\zeta,\bar{\zeta})$, locate both the singularities of the light-cone cut and the interior points conjugate to points on $\mathfrak{I}^+$ (see Fig. 4).

Most of the kinematic issues raised here are, we believe, now reasonably well understood. {It still would be of considerable interest to determine the behavior of $[1-(\partial\Lambda/\partial R)(\partial\bar{\Lambda}/\partial R)]$, in the neighborhood of the caustics.} Our interest now is to apply these kinematic insights to the study of null surfaces (specifically, light-cones) in vacuum Einstein spaces. Though there is a formalism[4,5] in which the Einstein equations have been rewritten as differential equations for the cut function, $Z(x^a,\zeta,\overline{\zeta})$ and $\Omega(x^a,\zeta,\overline{\zeta})$ (aside from some very special cases), the equations have been difficult to deal with because of the difficulty of treating the caustics, which are ubiquitous. We feel that the situation has changed; we now know how to identify the presence of the caustics in terms of both R and Λ. {The reason for our interest in the term $[1-(\partial\Lambda/\partial R)(\partial\overline{\Lambda}/\partial R)]$ is that it arises frequently in denominators of the field equations and we would like to know if it always tends to zero at a caustic.} We have also realized that it probably will be very advantageous to use the representation of $Z(x^a,\zeta,\overline{\zeta})$ by

$$Z(x^a,\zeta,\overline{\zeta})=G(x^a,q^1,p_2)+q^2p_2 \tag{73}$$

with $q^2=-\partial G/\partial p_2$, $\zeta=1/2(q^1+iq^2)$ (see Secs. V and VI). Our immediate goals are first to find the behavior of $[1-(\partial\Lambda/\partial R)(\partial\overline{\Lambda}/\partial R)]$ near caustics and then rewrite the field equations in terms of the $G(x^a,q^1,p_2)$ rather than $Z(x^a,\zeta,\overline{\zeta})$.

(Received 28 April 1998; accepted for publication 15 October 1998)

By departing from the previous attempt [Phys. Rev. E **51**, 4114 (1995)] we give a detailed construction of conditional and perturbed Markov processes, under the assumption that the Cauchy law of probability replaces the Gaussian law (appropriate for the Wiener process) as the model of primordial noise. All considered processes are regarded as probabilistic solutions of the so-called Schrödinger interpolation problem, whose validity is thus extended to the jump-type processes and their step process approximants. © *1999 American Institute of Physics.* [S0022-2488(99)00302-3]

I. INTRODUCTION

Probabilistic solutions of the so-called Schrödinger boundary data problem[1,2] are known to yield a unique Markovian interpolation between any two strictly positive probability densities designed to form the input–output statistics data (possibly phenomenological) for a certain dynamical process, taking place in a finite-time interval. The key problem, if one attempts to reconstruct the *most likely* (Markovian) dynamics, is to select the jointly continuous in space variables positive and contractive semigroup kernel. That issue was analyzed before in a number of publications.[1–8]

In the framework of the Schrödinger problem the choice of the integral kernel is arbitrary, except for the strict positivity (cf., however, Ref. 8) and continuity demand. It is thus rather natural to ask for the most general stochastic interpolation, that is admitted under the above premises.

First of all, the concept of Gaussian noise, regarded as a stochastic analog of the mechanical ''state of rest'' and traditionally linked with a Wiener process, can be extended to all infinitely divisible probability laws via the Lévy–Khintchine formula. It expands our framework from continuous diffusion processes to jump-type or combined diffusion–jump propagation scenarios[5] as appropriate mathematical models of the primordial ''free noise'' (this particular viewpoint is a novelty in the physics literature, where the Gaussian approach is dominant).

The next natural step in the analysis is to account for typical perturbations of any given process, according to the pattern of the Feynman–Kac formula, hence in terms of perturbed semigroups, where an appropriate generator (replacing the Laplacian) is additively modified by a suitable potential.[9,10] The additive perturbation choice stems from the fact[3,6,7] that basic stochastic processes of the nonequilibrium statistical physics (like, e.g., the Smoluchowski diffusion processes) involve perturbed Feynman–Kac kernels as building blocks of transition probability densities. We expect that an analogous feature (which is an artefact of the implicit Girsanov–Cameron–Martin measure change formula), is valid for non-Gaussian stochastic processes, see, e.g., Ref. 5 for explicit quantum mechanical motivations.

By referring to a physical terminology, let us consider Hamiltonians (semigroup generators) of the form $H=F(\hat{p})$, where $\hat{p}=-i\nabla$ stands for the momentum operator and for $-\infty<k<+\infty$, $F=F(k)$ is a real valued, bounded from below, locally integrable function. Here, $\hbar=c$

$=1$. We simplify further discussion by considering processes in one spatial dimension (this limitation can be removed cf. the Remark closing Sec. III of the paper).

We easily learn that for times $t \geq 0$ there holds

$$[\exp(-tH)]f(x) = [\exp(-tF(p))\hat{f}(p)]^{\vee}(x), \tag{1}$$

where the superscript $\vee$ denotes the inverse Fourier transform and $\hat{f}$ stands for the Fourier transform of f.

Let us set $k_t = (1/\sqrt{2\pi})[\exp(-tF(p))]^{\vee}$, then the action of $\exp(-tH)$ can be given in terms of a convolution: $\exp(-tH)f = f * k_t$, where $(f*g)(x) := \int_R g(x-z)f(z)dz$.

We are interested in those $F(p)$ which give rise to positivity preserving semigroups: if $F(p)$ satisfies the Lévy–Khintchine formula, then k_t is a positive measure for all $t \geq 0$. Let us concentrate on the integral part of the Lévy–Khintchine formula, which is responsible for arbitrary stochastic jump features:

$$F(p) = -\int_{-\infty}^{+\infty} \left[\exp(ipy) - 1 - \frac{ipy}{1+y^2} \right] \nu(dy), \tag{2}$$

where $\nu(dy)$ stands for the so-called Lévy measure.

There are not many explicit examples (analytic formulas for probability densities) for processes governed by (2), except possibly for the so-called stable probability laws. Nowadays, their potential physical meaning gains recognition in various contexts ranging from deterministic (chaos) implementations of anomalous transport, anomalous diffusion studies in nonequilibrium statistical physics, through stochastic interpretation of nonlinear field equations and relativistic Hamiltonian problems in quantum theory, to investigations of the early evolution (inhomogeneity issue) of the Universe cf. Refs. 5, 11–20.

The best known example of the stable law is provided by the classic Cauchy density which will be our reference model below. Let us focus our attention on that selected choice for the characteristic exponent $F(p)$, namely: $F_0(p) = |p|$ which is the Cauchy process generator. The semigroup generator H_0 is a pseudodifferential operator. The associated kernel k_t in view of the ''free noise'' restriction (no potentials at the moment) is a transition density of the jump-type (Lévy) process, determined by the corresponding Lévy measure $\nu(dy) = (1/\pi)(dy/y^2)$. It is instructive to notice that a pseudodifferential analog of the Fokker–Planck equation holds true: $F_0(p) \Rightarrow \partial_t \overline{\rho}(x,t) = -|\nabla| \overline{\rho}(x,t)$. This evolution rule gives rise to the Cauchy process probability density $\rho(x,t) = (1/\pi)[t/(t^2+x^2)]$ and the corresponding space–time homogeneous transition density (e.g., the semigroup kernel in this free propagation case).

Our principal goal in the present paper is to generalize this observation to encompass the additive perturbations by physically motivated potentials and construct the related Markov processes. It is not *a priori* obvious that perturbed processes preserve the generic (jump-type) sample path properties of the unperturbed (the Cauchy ''free noise'') process. In addition, the physical intuition demands that an approximation of the jump-type process in terms of traditional jump processes should be generally possible which, is certainly not obvious. Those obstacles are overcome by giving a characterization of the affiliated Markovian jump-type processes in terms of approximating (convergent) families of *step* processes, that solve a suitable version of the Schrödinger interpolation problem. The construction is based on the Feynman–Kac formula for perturbed semigroups, with strictly positive and jointly continuous kernel functions.

Our demonstration explicitly pertains to the Cauchy process and its relatives, albeit the techniques and major statements may be extended to a broader class of Lévy processes and their perturbed versions cf. Refs. 5, 11–13, and 14–18 for related mathematical and physical connotations, including the numerical simulation issue, Ref. 20, with its inherent cutoffs (generic lower bound for the jump size).

II. THE CAUCHY PROCESS AND ITS CONDITIONAL RELATIVES

We consider Markovian propagation scenarios so remaining within the well established framework, where the input–output statistics data are provided in terms of two strictly positive boundary densities $\rho(x,0)$ and $\rho(x,T)$, $T>0$. In addition, a bivariate transition probability density is given in a specific factorized form: $m(x,y)=f(x)k(x,0,y,T)g(y)$, with marginals:

$$\int_R m(x,y)dy=\rho(x,0), \quad \int_R m(x,y)dx=\rho(y,T). \tag{3}$$

Here, $f(x)$, $g(y)$ are the *a priori* unknown functions, to come out as strictly positive solutions of the integral system of equations (3), provided that in addition to the density boundary data we have in hand *any* strictly positive, jointly continuous in space variables *function* $k(x,0,y,T)$. Additionally, we impose a restriction that $k(x,0,y,T)$ represents a certain strongly continuous dynamical semigroup kernel $k(y,s,x,t)$, $0\leqslant s\leqslant t<T$, while given at the time interval borders: It secures the Markov property of the sought for stochastic process.

Under those circumstances,[6] once we define functions

$$\theta(x,t)=\int dy\ k(x,t,y,T)g(y), \quad \theta_*(y,s)=\int dx\ k(x,0,y,s)f(x) \tag{4}$$

there exists a transition density

$$p(y,s,x,t)=k(y,s,x,t)\ \frac{\theta(x,t)}{\theta(y,s)}, \tag{5}$$

which implements a Markovian propagation of the probability density

$$\rho(x,t)=\theta(x,t)\,\theta_*(x,t), \qquad \rho(x,t)=\int p(y,s,x,t)\rho(y,s)dy \tag{6}$$

between the prescribed boundary data.

For a given semigroup which is characterized by its generator (Hamiltonian), the kernel $k(y,s,x,t)$ and the emerging transition probability density $p(y,s,x,t)$ are unique in view of the uniqueness of solutions $f(x)$, $g(y)$ (cf. Theorem 3.2 in Ref. 2). For Markov processes, the knowledge of the transition probability density $p(y,s,x,t)$ for all intermediate times $0\leqslant s<t\leqslant T$ suffices for the derivation of all other relevant characteristics.

At this point, let us make a definite choice of the kernel function, namely, that of the Cauchy kernel:

$$k(y,s,x,t)=\frac{1}{\pi}\,\frac{t-s}{(t-s)^2+(x-y)^2}. \tag{7}$$

We have:

Theorem 1:

(a) $p(y,s,x,t)$ defined by Eqs. (5) and (7) is a Markov transition kernel, that is (weak limit in below)

$$\int_R p(y,s,x,t)dx=1, \qquad \lim_{t\downarrow s}p(y,s,x,t)=\delta_y(x),$$

$$\int_R p(y,t_1,z,t_2)p(z,t_2,x,t_3)dz=p(y,t_1,x,t_3)$$

for all $0 \leq t_1 < t_2 < t_3 \leq T$, with δ_y standing for the Dirac delta.

(b) $\rho(x,t)$, Eq. (6), is a probability distribution interpolating between ρ_0 and ρ_T:

$$\int_R \rho(x,t)dx = 1, \qquad \rho(x,0) = \rho_0(x), \rho(x,T) = \rho_T(x).$$

(c) The process X_t having $p(y,s,x,t)$ as the transition kernel is a Markov interpolating process:

$$\int_R p(y,s,x,t)\rho(y,s)dy = \rho(x,t)$$

for all $0 \leq s < t \leq T$.

Proof: See, e.g., Refs. 5 and 6.

Let us notice that the process X_t is obtained from the Cauchy process X_t^C by means of a multiplicative transformation of transition function. Clearly, $\alpha_t^s = [\theta(X_t^C,t)/\theta(X_s^C,s)]$ is a multiplicative functional of X_t^C such that its average with respect to the Cauchy process reads $\int \alpha_t^s(\omega) P_x^C(d\omega) = 1$ for any $0 \leq s \leq t \leq T$ and any $x \in R$, see, e.g., Ref. 21. However α_t^s is not homogeneous and, even worse, not contracting (in fact, not even bounded). We cannot be *a priori* sure that the generic sample path properties of the Cauchy process can be attributed to X_t as well. In particular, an approximation of X_t in terms of jump processes with a finite number of jumps in a finite time interval is by no means obvious and needs a demonstration (to be given in below).

To this end, let us first notice that θ_* and θ satisfy the conjugate pseudodifferential equations:

$$\partial_t \theta_* = -|\nabla| \theta_*, \qquad \partial_t \theta = |\nabla| \theta, \tag{8}$$

where the operator $|\nabla|$ acts as follows:

$$|\nabla| f(x) = -\frac{1}{\pi} \int_R \left[f(x+y) - f(x) - \frac{y \nabla f(x)}{1+y^2} \right] \frac{dy}{y^2}. \tag{9}$$

Let us define a new operator $|\nabla|_\epsilon$ by

$$|\nabla|_\epsilon f(x) = -\frac{1}{\pi} \int_{|y|>\epsilon} [f(x+y) - f(x)] \frac{dy}{y^2} \tag{10}$$

and, accordingly,

$$\partial_t \theta_*^\epsilon = -|\nabla|_\epsilon \theta_*^\epsilon, \qquad \partial_t \theta^\epsilon = |\nabla|_\epsilon \theta^\epsilon, \tag{11}$$

with $\theta_*^\epsilon(x,0) = \theta_*(x,0)$, $\theta^\epsilon(x,T) = \theta(x,T)$ chosen to coincide with the respective initial and terminal data for solutions of Eq. (8).

Furthermore, let

$$q_\epsilon(x) = \frac{1}{\pi} \chi_{I_\epsilon^c}(x) \frac{1}{x^2}, \tag{12}$$

where $I_\epsilon^c = [-\epsilon, \epsilon]^c = \{x \in R : |x| > \epsilon\}$ and χ_A is an indicator function of a set A.

We have:

Theorem 2: Let us define the Poisson transition kernel corresponding to the measure $q_\epsilon(x)dx$:

$$k_\epsilon(x,t) = \left[\exp\left(-\frac{2t}{\epsilon\pi} \right) \right] \left[\delta_0(x) + t q_\epsilon(x) + \frac{t^2}{2!} (q_\epsilon * q_\epsilon)(x) + \cdots \right].$$

Then, functions,

$$\theta_*^\epsilon(x,t)=\int_R k_\epsilon(x-y,t)\,\theta_*(y,0)dy,$$

$$\theta^\epsilon(x,t)=\int_R k_\epsilon(x-y,T-t)\,\theta(y,T)dy,$$

solve Eq. (11).

Proof: The transition function in the above is called the Poisson transition kernel following the terminology of Ref. 21. We have $\theta_*^\epsilon(x,0)=\int_R \delta_0(x-y)\,\theta_*(y,0)dy=\theta_*(x,0)$ and

$$\partial_t\theta_*^\epsilon(x,t)=\int_R[\partial_t k_\epsilon(x-y,t)]\,\theta_*(y,0)dy,$$

where

$$\partial_t k_\epsilon(x,t)=-\frac{2}{\pi\epsilon}\,k_\epsilon(x,t)+\left[\exp\left(-\frac{2t}{\epsilon}\right)\right][q_\epsilon(x)+t(q_\epsilon*q_\epsilon)(x)+\cdots].$$

Consequently,

$$\begin{aligned}[\partial_t k_\epsilon(\cdot,t)*\theta_*(\cdot,0)](x)&=-\frac{2}{\pi\epsilon}\,\theta_*^\epsilon(x,t)+\left[\left[\exp\left(-\frac{2t}{\epsilon}\right)\right]q_\epsilon*\left(\delta_0+tq_\epsilon+\frac{t^2}{2!}\,q_\epsilon*q_\epsilon+\cdots\right)*\theta_*\right](x)\\&=-\frac{2}{\pi\epsilon}\,\theta_*^\epsilon(x,t)+[q_\epsilon*\theta_*^\epsilon(\cdot,t)](x)\\&=-\frac{2}{\pi\epsilon}\,\theta_*^\epsilon(x,t)+\int_R q_\epsilon(y)\,\theta_*^\epsilon(x-y,t)dy.\end{aligned}$$

But, there holds

$$\int_R q_\epsilon(y)\,\theta_*^\epsilon(x-y,t)dy=\frac{1}{\pi}\int_{|y|>\epsilon}\theta_*^\epsilon(x-y,t)\,\frac{dy}{y^2}=\frac{1}{\pi}\int_{|y|>\epsilon}\theta_*^\epsilon(x+y,t)\,\frac{dy}{y^2}$$

and, in view of the obvious identity

$$\frac{2}{\pi\epsilon}\,\theta_*^\epsilon(x,t)=\frac{1}{\pi}\int_{|y|>\epsilon}\theta_*^\epsilon(x,t)\,\frac{dy}{y^2},$$

we finally arrive at

$$\partial_t\theta_*^\epsilon(x,t)=\frac{1}{\pi}\int_{|y|>\epsilon}[\theta_*^\epsilon(x+y,t)-\theta_*^\epsilon(x,t)]\,\frac{dy}{y^2}=-|\nabla|_\epsilon\theta_*^\epsilon(x,t).$$

An analogous line of arguments follows with respect to $\theta^\epsilon(x,t)$, which completes the proof.

A random process with a Poisson transition function belongs to the class of so-called step processes,[21,22] that is jump processes with no accumulation points of jumps in a finite time interval: The number of jumps is finite on each finite time interval. We have:

Lemma 1: The Markov process Y_t^ϵ given by the transition function $k_\epsilon(x,t)$ is a step process with a characteristic function:

$$\Phi_\epsilon(p,t)=\exp(-t[\hat{q}_\epsilon(0)-\hat{q}_\epsilon(p)]),$$

where $\hat{q}_\epsilon(p)$ is the Fourier transform of $q_\epsilon(x)$.

Proof: We need to evaluate the characteristic function of the transition kernel, that is,

$$\Phi_\epsilon(p,t)=\exp\left(-\frac{2t}{\pi\epsilon}\right)\cdot\int_{-\infty}^{+\infty}[\exp(-ipx)]\left[\delta_0(x)+tq_\epsilon(x)+\frac{t^2}{2!}(q_\epsilon * q_\epsilon)(x)+\dots\right]dx$$

$$=\exp\left(-\frac{2t}{\pi\epsilon}\right)\cdot\left[1+t\hat{q}_\epsilon(p)+\frac{t^2}{2!}(\hat{q}(p))^2+\cdots\right]=\exp\left[-\frac{2t}{\pi\epsilon}+t\hat{q}_\epsilon(p)\right].$$

In view of $\hat{q}_\epsilon(0)=2/\pi\epsilon$, the Lemma holds true.

As a technical warm up we shall now prove that the Cauchy process is the limit (in distributions) of a one-parameter family of step processes Y_t^ϵ. We touch here an important issue of limits (convergence) of jump processes,[23–25] and there are many types of the pertinent convergence. For example, it is known that Y_t^ϵ tends to the Cauchy process in probability; Ref. 23, while major modern techniques refer to the weak convergence of probability measures, Ref. 25). Also, typical proofs refer only to processes with stationary independent increments, while we cannot respect this limitation in the presence of perturbations.

Lemma 2: There holds: $\lim_{\epsilon\to 0}\Phi_\epsilon(p,t)=\psi(p,t)$, where $\psi(p,t)$ is the Cauchy characteristic function $\psi(p,t)=\exp(-t|p|)$. Moreover, the limit is uniform for all $t\in[0,T]$.

Proof: Let us evaluate $\hat{q}_\epsilon(p)$:

$$\hat{q}_\epsilon(p)=\frac{1}{\pi}\int_{-\infty}^{+\infty}\exp(ipx)\cdot\hat{q}_\epsilon(x)dx=\frac{1}{\pi}\int_{|x|>\epsilon}\exp(ipx)\cdot\frac{dx}{x^2}=\frac{2}{\pi}\int_\epsilon^\infty\frac{\cos(px)-1}{x^2}dx+\frac{2}{\pi\epsilon}.$$

Consequently,

$$\Phi_\epsilon(p,t)=\exp\left[-\frac{2t}{\pi}\int_\epsilon^\infty\frac{1-\cos(px)}{x^2}dx\right].$$

In view of

$$\lim_{\epsilon\to 0}\int_\epsilon^\infty\frac{1-\cos(px)}{x^2}dx=\frac{|p|\pi}{2},$$

we arrive at

$$\lim_{\epsilon\to 0}\Phi_\epsilon(p,t)=\exp\left[-\frac{2t}{\pi}\cdot\frac{|p|\pi}{2}\right]=\exp(-t|p|).$$

The proof is completed.

Clearly, $|\nabla|_\epsilon$ is a well-defined semigroup generator for the step process Y_t^ϵ. Let us recall that sample paths of a step process have only a finite number of jumps in each finite time interval, and between jumps the sample path is constant.[22] The limiting Cauchy process belongs to the category of jump-type processes, where apart from the long jumps-tail (no fixed bound can be imposed on their length) that implies the nonexistence of moments of the probability measure, sample paths of the Cauchy process may have an infinite number of jumps of arbitrarily small size. By general arguments, pertaining to the space $D_E[0,\infty)$ of right continuous functions with left limits (cadlag), both in the finite and infinite time interval the number of jumps is at most countable.[23,26] It is also useful to recall that on a finite time interval there can be at most finitely many points $t\in[0,T]$ at which the jump size exceeds a given positive number. In view of that, $\sup_{t\in[0,T]}|Y_t^\epsilon|<\infty$. Obviously, there is no fixed upper bound for the size of jumps (except for being finite), since a stochastically continuous process with independent increments having, with probability 1, no jumps exceeding a certain constant C, would possess all moments.[22]

Now, we shall pass to a slightly more involved demonstration that a well-defined family of Markov processes X_t^ϵ (in fact, step ones) can be constructed, such that the process X_t of Theorem 1 can be approximated (in the sense of suitable convergence) to an arbitrary degree of accuracy.

Here, we are motivated by a heuristic analysis carried out in our earlier paper.[5] There, we found that after neglecting ''small jumps,'' the time evolution of the resultant probability density $\overline{\rho_\epsilon}=\theta^\epsilon\theta_*^\epsilon$ may be written as

$$\partial_t\overline{\rho_\epsilon}(A,t)=\int_R q_\epsilon(t,x,A)\overline{\rho_\epsilon}(x,t)dx+\langle v\rangle_A(t)\int_{|y|>\epsilon}\frac{y}{1+y^2}\,d\nu(y), \tag{13}$$

where $\langle v\rangle_A=\int_A\overline{\rho_\epsilon}(x,t)[\nabla\ \ln(\theta^\epsilon/\theta_*^\epsilon)(x,t)]dx$. The measure $d\nu$ is symmetric around the point $\{0\}$, hence the second term cancels, and we arrive at

$$\partial_t\overline{\rho_\epsilon}(A,t)=\int_R q_\epsilon(t,x,A)\overline{\rho_\epsilon}(x,t)dx, \tag{14}$$

where the so-called jump intensity reads

$$q_\epsilon(t,y,A)=\int_{|y|>\epsilon}\frac{\theta^\epsilon(y+x,t)}{\theta^\epsilon(y,t)}\,[\chi_A(x+y)-\chi_A(y)]d\nu(x) \tag{15}$$

and $\theta^\epsilon(x,t)$ comes out as a solution of the second pseudodifferential equation in the formula (11).

Let us define [cf. Eq. (12)]

$$h_\epsilon(t,y)=\int_{-\infty}^{+\infty}\frac{\theta^\epsilon(x+y,t)}{\theta^\epsilon(y,t)}\,q_\epsilon(x)dx \tag{16}$$

and

$$h_\epsilon(t,y,x)=\frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,t)}\,q_\epsilon(x-y). \tag{17}$$

Then, clearly the jump intensity (14) takes the form

$$q_\epsilon(t,y,A)=\int_A h_\epsilon(t,y,x)dx-h_\epsilon(t,y)\chi_A(y). \tag{18}$$

With those notations, we have:

Lemma 3: If the function $g(y)$ [cf. Eq. (4)] is uniformly bounded, then $h_\epsilon(t,y,x)$ is a density of a finite measure and $h_\epsilon(t,y)=\int_R h_\epsilon(t,y,x)dx$.

Proof: By our assumption, $g(y)\le M$ for all $y\in R$. Because of $\theta^\epsilon(x,t)=\int_R k_\epsilon(T-t,x-y)g(y)dy$, we have a bound

$$\theta^\epsilon(x,t)\le M\int_R k_\epsilon(T-t,x-y)dy=M.$$

Hence

$$\int_{-\infty}^{+\infty}h_\epsilon(t,y,x)dx=\int_{-\infty}^{+\infty}\frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,t)}\,q_\epsilon(x-y)dx=h_\epsilon(t,y)$$

and

$$h_\epsilon(t,y) \leqslant \frac{M}{\theta^\epsilon(y,t)} \frac{2}{\epsilon}.$$

It is also clear that $h_\epsilon(t,y,x) \geqslant 0$, which completes the proof.

Let us define $\overline{h}_\epsilon(t,y,A) = -h_\epsilon(t,y)\chi_A(y) + \int_A h_\epsilon(t,y,x)dx$. It is obvious that $\overline{h}_\epsilon$ is a charge (that is a real-valued measure with the property $\overline{h}_\epsilon(t,y,R)=0$).[22]

We shall show that there exists a *step* process corresponding to the charge $\overline{h}_\epsilon$.

To this end let us first prove:

Lemma 4: For any Borel set $A \subset R$, the function $t \rightarrow \int_A h_\epsilon(t,y,x)dx$ is continuous in t, uniformly in A.

Proof: We have the following estimate [cf. Eq. (18) and Lemma 3]:

$$\begin{aligned}
&\left| \int_A h_\epsilon(t,y,x)dx - \int_A h_\epsilon(t_0,y,x)dx \right| \\
&= \left| \int_A \frac{\theta^\epsilon(y+x,t)}{\theta^\epsilon(y,t)} q_\epsilon(x)dx - \int_A \frac{\theta^\epsilon(y+x,t_0)}{\theta^\epsilon(y,t_0)} q_\epsilon(x)dx \right| \\
&\leqslant \left| \int_{A\cap K^c} \left[\frac{\theta^\epsilon(y+x,t)}{\theta^\epsilon(y,t)} - \frac{\theta^\epsilon(y+x,t_0)}{\theta^\epsilon(y,t)} \right] q_\epsilon(x)dx \right| + \left| \int_{A\cap K} \left[\frac{\theta^\epsilon(y+x,t)}{\theta^\epsilon(y,t)} - \frac{\theta^\epsilon(y+x,t_0)}{\theta^\epsilon(y,t)} \right] q_\epsilon(x)dx \right| \\
&\quad + \left| \int_A \left[\frac{\theta^\epsilon(y+x,t_0)}{\theta^\epsilon(y,t)} - \frac{\theta^\epsilon(y+x,t_0)}{\theta^\epsilon(y,t_0)} \right] q_\epsilon(x)dx \right|,
\end{aligned}$$

where K is a compact set while K^c is its complement.

Let us denote the summands A_1, A_2, A_3, respectively. For the first summand we have

$$A_1 \leqslant \frac{1}{\theta^\epsilon(y,t)} \sup_{x\in R}(\theta^\epsilon(x,t) + \theta^\epsilon(x,t_0)) \int_{K^c} q_\epsilon(x)dx.$$

But

$$\sup_{x\in R}\theta^\epsilon(x,t) = \sup_{x\in R}\int_R k_\epsilon(T-t,x-y)g(y)dy \leqslant M \sup_{x\in R}\int_R k_\epsilon(T-t,x-y)dy = M.$$

By defining $N(y) = \sup_{t\in[t_0,t_0+1]}[1/\theta^\epsilon(y,t)]$ and adjusting the compact set K so that $\int_{K^c} q_\epsilon(x)dx \leqslant \delta/3MN(y)$, we arrive at $A_1 \leqslant \delta/3$.

With the second summand, A_2, we proceed as follows:

$$A_2 = \left| \int_{A\cap K} \left[\frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,t)} - \frac{\theta^\epsilon(x,t_0)}{\theta^\epsilon(y,t)} \right] q_\epsilon(y-x)dx \right| \leqslant N(y)\sup_{x\in K}|\theta^\epsilon(x,t) - \theta^\epsilon(x,t_0)| \frac{2}{\pi\epsilon}.$$

By choosing t so close to t_0 that $\sup_{x\in K}|\theta^\epsilon(x,t) - \theta^\epsilon(x,t_0)| \leqslant \pi\delta\epsilon/6N(y)$, we get $A_2 \leqslant \delta/3$. Analogously with A_3:

$$A_3 \leqslant \left| \frac{1}{\theta^\epsilon(y,t)} - \frac{1}{\theta^\epsilon(y,t_0)} \right| 2 \sup_{x\in R}\theta^\epsilon(x,t_0) \frac{2}{\pi\epsilon} \leqslant \frac{4}{\pi\epsilon} MN^2(y)|\theta^\epsilon(y,t_0) - \theta^\epsilon(y,t)|,$$

where by taking t such that $|\theta^\epsilon(y,t_0) - \theta^\epsilon(y,t)| \leqslant \pi\delta\epsilon/12MN^2(y)$ we shall get $A_3 \leqslant \delta/3$. The overall bound is thus δ, and the Lemma is proved.

As a byproduct of the above demonstration, we realize that the function $t \rightarrow h_\epsilon(t,x,A)$ is continuous in t uniformly on compact sets. As a consequence, see, e.g., Theorem 4 in Chap. 7, Sec. 7 of Ref. 22, there exists a stochastically continuous Markov process X_t^ϵ with continuous from the right sample paths. Moreover, for any $s \in [0,T]$, $y \in R$ and $A \subset R$, there holds

$$\lim_{t\downarrow s} \frac{p_\epsilon(y,s,A,t) - \chi_A(y)}{t-s} = \overline{h}_\epsilon(s,y,A), \tag{19}$$

where $p_\epsilon(y,s,A,t)$ is the transition kernel of the process X_t^ϵ.
There follows:

Theorem 3: The transition probability density of X_t^ϵ reads:

$$p_\epsilon(y,s,x,t) = k_\epsilon(t-s,x-y)\,\frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,s)}$$

and is a solution of the first Kolmogorov equation:

$$\partial_s p_\epsilon(y,s,x,t) = -\int_R p_\epsilon(z,s,x,t)\overline{h}_\epsilon(s,y,z)\,dz.$$

Proof: We must demonstrate that Eq. (19) is valid for the just introduced transition density (compare, e.g., also Theorem 1), i.e., there holds

$$\lim_{t\downarrow s} \frac{1}{t-s}\left[k_\epsilon(t-s,x-y)\,\frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,s)} - \delta_y(x)\right] = \overline{h}_\epsilon(s,y,x).$$

To this end, let us notice (adding and subtracting the same summand) that

$$\begin{aligned}\overline{h}_\epsilon(s,y,x) &= \frac{\theta^\epsilon(x,s)}{\theta^\epsilon(y,s)} \lim_{t\downarrow s} \frac{1}{t-s}\,[k_\epsilon(t-s,x-y) - \delta_y(x)]\\ &\quad + \frac{\delta_y(x)}{\theta^\epsilon(y,s)} \lim_{t\downarrow s} \frac{1}{t-s}\,[\theta^\epsilon(x,t) - \theta^\epsilon(y,s)]\\ &= \frac{\theta^\epsilon(x,s)}{\theta^\epsilon(y,s)}\left[q_\epsilon(x-y) - \frac{2}{\pi\epsilon}\,\delta_y(x)\right] + \frac{\delta_y(x)}{\theta^\epsilon(y,s)} \lim_{t\downarrow s} \frac{1}{t-s}\,[\theta^\epsilon(x,t) - \theta^\epsilon(y,s)].\end{aligned}$$

To evaluate the second term, let us take a continuous and bounded function $a(x)$ and consider

$$\begin{aligned}&\lim_{t\downarrow s} \int_R \frac{\delta_y(x)}{\theta_\epsilon(y,s)}\,\frac{1}{t-s}\,[\theta^\epsilon(x,t) - \theta^\epsilon(y,s)]a(x)\,dx\\ &\quad = \lim_{t\downarrow s} \frac{a(y)}{\theta^\epsilon(y,s)}\,\frac{1}{t-s}\,[\theta^\epsilon(y,t) - \theta^\epsilon(y,s)] = \frac{a(y)}{\theta^\epsilon(y,s)}\,\partial_s\theta^\epsilon(y,s).\end{aligned}$$

So, the second term converges weakly to

$$\frac{\delta_y(x)}{\theta^\epsilon(y,s)}\,\partial_s\theta^\epsilon(y,s).$$

We know that

$$\partial_s\theta^\epsilon(y,s) = |\nabla|_\epsilon\theta^\epsilon(y,s) = -\int_R [\theta^\epsilon(y+z,s) - \theta^\epsilon(y,s)]q_\epsilon(z)\,dz.$$

Consequently,

$$\frac{\partial_s \theta^\epsilon(y,s)}{\theta^\epsilon(y,s)} = -\int_R \frac{\partial^\epsilon(y+z,s)}{\theta^\epsilon(y,s)}\, q_\epsilon(z)dz + \frac{2}{\pi\epsilon} = \frac{2}{\pi\epsilon} - h_\epsilon(s,y)$$

and thus

$$\lim_{t\downarrow s} \frac{1}{t-s}\,[p_\epsilon(y,s,x,t) - \delta_y(x)] = \frac{\theta^\epsilon(x,s)}{\theta^\epsilon(y,s)}\, q_\epsilon(x-y) - \frac{2}{\pi\epsilon}\,\delta_y(x) + \frac{2}{\pi\epsilon}\,\delta_y(x) - h_\epsilon(s,y)\,\delta_y(x)$$
$$= h_\epsilon(s,y,x) - h_\epsilon(s,y)\,\delta_y(x)$$
$$= \overline{h}_\epsilon(s,y,x).$$

The first part of our Theorem is proved, and we can pass to its second part.

To check the validity of the Kolmogorov equation, we shall begin from

$$\partial_s p_\epsilon(y,s,x,t) = [\partial_s k_\epsilon(t-s,x-y)]\, \frac{\theta^\epsilon(x,t)}{\theta_\epsilon(y,s)} - p_\epsilon(y,s,x,t)\, \frac{\partial_s \theta^\epsilon(y,s)}{\theta^\epsilon(y,s)}.$$

But

$$\partial_s k_\epsilon(t-s,x-y) = -[q_\epsilon * k_\epsilon(t-s,\cdot)](x-y) + k_\epsilon(x-y)\, \frac{2}{\pi\epsilon}$$

and

$$\frac{\partial_s \theta^\epsilon(y,s)}{\theta_\epsilon(y,s)} = \frac{2}{\pi\epsilon} - h_\epsilon(s,y),$$

which leads to

$$\partial_s p(y,s,x,t) = -[q_\epsilon * k_\epsilon(t-s,\cdot)](x-y)\, \frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,s)} + \frac{2}{\pi\epsilon}\, p_\epsilon(y,s,x,t)$$
$$- \frac{2}{\pi\epsilon}\, p_\epsilon(y,s,x,t) + p_\epsilon(y,s,x,t) h_\epsilon(s,y)$$
$$= -\frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,s)} \int_R q_\epsilon(x-y-z) k_\epsilon(t-s,z)dz + p_\epsilon(y,s,x,t) \int_R \frac{\theta^\epsilon(x+y,s)}{\theta^\epsilon(y,s)}\, q_\epsilon(x)dx.$$

On the other hand,

$$-\int_R p_\epsilon(z,s,x,t)\overline{h}(s,y,z)dz = -\int_R k_\epsilon(t-s,x-z)\, \frac{\theta^\epsilon(x,t)}{\theta^\epsilon(z,s)} \left[\frac{\theta^\epsilon(z,s)}{\theta^\epsilon(y,s)}\, q_\epsilon(z-y) - \delta_y(z) h_\epsilon(s,y) \right] dz$$
$$= -\frac{\theta^\epsilon(x,t)}{\theta_\epsilon(y,s)} \int_R k_\epsilon(t-s,x-z) q_\epsilon(z-y)dz + p_\epsilon(y,s,x,t) h_\epsilon(s,y).$$

Since we know that $h_\epsilon(s,y) = \int_R [\theta^\epsilon(x+y,s)/\theta_\epsilon(y,s)] q_\epsilon(x)dx$, the assertion (e.g., the validity of the first Kolmogorov equation) follows.

Corollary 1: X_t^ϵ is a step process.

Proof: It suffices to check that $p_\epsilon(y,s,R,t) = 1$ (cf. Ref. 22). Since

$$p_\epsilon(y,s,R,t) = \int_R p_\epsilon(y,s,x,t)dx = \int_R k_\epsilon(t-s,x-y)\, \frac{\theta^\epsilon(x,t)}{\theta^\epsilon(y,s)}\, dx$$

and, by Theorem 2,

$$\int_R k_\epsilon(t-s,x-y)\,\theta^\epsilon(x,t)\,dx=\theta^\epsilon(y,s)$$

the Corollary holds true.

All previous considerations can be finally summarized by showing that the family X_l^ϵ of step processes consistently approximates (converges to) the process X_t. Indeed, we have:

Theorem 4: The limit

$$\lim_{\epsilon\downarrow 0}X_t^\epsilon=X_t$$

holds true in distributions and uniformly in $t\in[0,T]$. Moreover, the transition probability density p_ϵ converges pointwise to p when $\epsilon\downarrow 0$.

Proof: The probability density of the process X_t^ϵ equals $\rho_\epsilon(x,t)=\theta_*^\epsilon(x,t)\,\theta^\epsilon(x,t)$ and that of the process X_t is given by $\rho(x,t)=\theta_*(x,t)\,\theta(x,t)$. But, $\theta_*^\epsilon(x,t)=\int_R k_\epsilon(t,x-y)f(y)dy$ and $k_\epsilon(t,x-y)$ converges weakly to the Cauchy kernel $k(t,x-y)$, uniformly in t. Consequently $\lim_{\epsilon\downarrow 0}\ \theta_*^\epsilon(x,t)=\theta_*(x,t)$ also uniformly in $t\in[0,T]$. The same holds true for $\theta^\epsilon(x,t)$, and the first assertion follows.

The second statement follows from the fact that $k_\epsilon(t,x)$ tends to the Cauchy kernel $k(t,x)$ (see Lemma 2) when $\epsilon\downarrow 0$.

As stated before, considerations of the present section were mostly a preparation to the study of perturbed problems. However, it is useful to mention that the conditional Cauchy processes are covered by the developed scheme. In fact, we can here adjust to the Cauchy noise an observation previously utilized in the context of the Wiener noise.[2,6,5] The pertinent density can be given in the following form:

$$\rho(x,t)=\frac{k(y_0,t_0,x,t)k(x,t,z_T,T)}{k(y_0,t_0,z_T,T)} \tag{20}$$

with $y_0,z_T\in R$ and $0<t_0<t<T$. All previous considerations directly apply to the interpolating process supported by this density. See also a discussion of Lévy bridges (while specialized to the Cauchy context) in Ref. 27.

III. PERTURBATIONS OF THE CAUCHY NOISE

We are motivated by the strategy of Refs. 6 and 5 and the techniques developed in Sec. II. Let us address the problem analogous to that of Eq. (11), but now in reference to a perturbed semigroup:[11]

$$\partial_t\theta_*=-|\nabla|\,\theta_*-V\theta_*,\qquad \partial_t\theta=|\nabla|\,\theta+V\theta, \tag{21}$$

where V is a measurable function such that:

(a) for all $x\in R$, $V(x)\geqslant 0$,
(b) for each compact set $K\subset R$ there exists C_K such that for all $x\in K$, V is locally bounded $V(x)\leqslant C_K$.

Then V is locally integrable and for any compact K we have

$$\lim_{t\downarrow 0}\ \sup_{x\in R}\ E_x^C\left\{\int_0^t \chi_K(X_s^C)V(X_s^C)ds\right\}=0. \tag{22}$$

As a consequence, there holds

Lemma 5: If $1\leqslant r\leqslant p\leqslant\infty$ and $t>0$, then the operators T_t^V defined by

$$(T_t^V f)(x) = E_x^C\left\{ f(X_t^C)\exp\left[-\int_0^t V(X_s^C)ds\right]\right\}$$

are bounded from $L^r(R)$ into $L^p(R)$. Moreover, for each $r \in [1,\infty]$ and $f \in L^r(R)$, $T_t^V f$ is a bounded and continuous function.

Proof: See, e.g., Ref. 11, Proposition III.1.

Let us notice that for the ultimate construction of the (forward, see Refs. 3, 6, and 7) Markov process we utilize only the second equation (21) [cf. also Eq. (11)], although both equations (21) are indispensable for the Schrödinger problem solution.

We shall use another identity proved by Carmona,[11] namely:

Lemma 6: For any real-valued $f,g \in L^2(R)$ there holds

$$\int_R dx\, f(x)E_x^C\left\{ g(X_t^C)\exp\left[-\int_0^t V(X_s^C)ds\right]\right\} = \int_R dx\, g(x)E_x^C\left\{ f(X_t^C)\exp\left[-\int_0^t V(X_s^C)ds\right]\right\}.$$

Proof: See also Eq. (III.9) in Ref. 11.

We need to prove that T_t^V is an integral operator. To this end, a direct transfer of Simon's arguments, cf. Ref. 28, originally with respect to the Laplace differential operator, i.e., the usage of the Dunford–Pettis theorem (see pp. 450 in Ref. 28) and Lemma 5, gives rise to:

Lemma 7: For any $p \in [1,\infty]$ and $f \in L^p(R)$ there holds

$$(T_t^V f)(x) = \int_R k_t^V(x,y) f(y)dy,$$

where $k_t^V(x,y) \geqslant 0$ almost everywhere and, for q such that $1/q + 1/p = 1$, the kernel satisfies

$$\sup_{x\in R}\left[\int_R [k_t^V(x,y)]^q dy\right]^{1/q} < \infty.$$

Proof: See also Theorem A.1.1 and Corollary A.1.2 in Ref. 28.

Notice that by putting $p=1$ and thus $q=\infty$ we obtain that $k_t^V(x,y) \in L^\infty(R^2)$.

Our ultimate goal is to utilize $k_t^V(x,y)$ in the context of the Schrödinger boundary data and interpolation problem, Refs. 2 and 6, hence suitable properties of the kernel must be established. For our purposes, the joint continuity and positivity of the kernel is essential.

Lemma 8: $k_t^V(x,y)$ is jointly continuous in (x,y).

Proof: We begin from demonstrating that $k_t^V(x,y) = k_t^V(y,x)$ almost everywhere. By Lemma 6, we have

$$\int\int_{R^2} dx\, dy f(x) k_t^V(x,y) g(y) = \int\int_{R^2} dx\, dy g(x) k_t^V(x,y) f(y),$$

hence

$$\int\int_{R^2} dx\, dy f(x) g(y)[k_t^V(x,y) - k_t^V(y,x)] = 0$$

for all $f,g \in L^2(R)\cap L^1(R)$.

The same holds true for all finite combinations $\Sigma_{i,j}\, a_{ij} f_i(x) g_j(y)$. Therefore $\int\int_{R^2}[k_t^V(x,y) - k_t^V(y,x)]f(x,y)dx\, dy = 0$ for all $f(x,y)$ from a dense subset of $L^1(R^2)$. Because $L^\infty(R^2)$ is the dual space to $L^1(R^2)$, we conclude that $k_t^V(x,y) = k_t^V(y,x)$ almost everywhere.

Let us exploit the semigroup property of $k_t^V(x,y)$:

$$k_t^V(x,y)=\int_R k_{t/2}^V(x,w)k_{t/2}^V(w,y)dw.$$

For each y, $w\to k_{t/2}^V(w,y)\in L^\infty(R)$ so, by Lemma 5, $k_t^V(x,y)$ is continuous in x. By the symmetry, $k_t^V(x,y)$ is separately continuous in x and y.

Let us consider a sequence $(x_n,y_n)\to(x,y)$. Then:

$$\begin{aligned}|k_t^V(x_n,y_n)-k_t^V(x_0,y_0)|&\leqslant\left|\int\int_{R^2}dw\ dz[k_{t/3}^V(x_n,w)-k_{t/3}^V(x_0,w)]k_{t/3}^V(w,z)k_{t/3}^V(z,y_n)\right|\\&\quad+\left|\int\int_{R^2}dw\ dz k_{t/3}^V(x_0,w)k_{t/3}^V(w,z)[k_{t/3}^V(z,y_n)-k_{t/3}^V(x,y)]\right|\\&=\left|\int_R dw[k_{t/3}^V(x_n,w)-k_{t/3}^V(x_0,w)]k_{2t/3}^V(w,y_n)\right|\\&\quad+|k_t^V(x_0,y_n)-k_t^V(x_0,y_0)|.\end{aligned}$$

Because of

$$\|k_{2t/3}^V(\cdot,y_n)\|_{L^\infty}<C$$

for all y_n, knowing that $\sup_n k_{t/3}^V(x_n,w)$ exists and is integrable with respect to w, by the Lebesgue dominated convergence theorem the first summand tends to zero. Hence, $k_t^V(x,y)$ is jointly continuous in (x,y).

Lemma 9: $k_t^V(x,y)$ is strictly positive.

Proof: Because for the Cauchy process we have[20] (more general estimates of the growth of random walks and Lévy processes can be found in Ref. 29):

$$E_x^C\{\sup_{0\leqslant s\leqslant t}|X_s^C|>n\}\leqslant 3\ \sup_{0\leqslant s\leqslant t}E_x^C\left\{|X_s^C|>\frac{n}{3}\right\}$$

and

$$\sup_{0\leqslant s\leqslant t}E_x^C\left\{|X_s^C|>\frac{n}{3}\right\}=E_x^C\left\{|X_t^C|>\frac{n}{3}\right\}=1-\frac{2}{\pi}\ \arctan\left(\frac{n}{3t}\right)$$

there follows:

$$\lim_{n\to\infty}\ E_x^C\{\sup_{0\leqslant s\leqslant t}\ |X_s^C|>n\}=0.$$

This property will be used below.

Let $0<\delta<1$, then:

$$\int_{y-\delta}^{y+\delta}dy\ k_t^V(x,y)=E_x^C\left\{\chi_{[y-\delta,y+\delta]}(X_t^C)\exp\left[-\int_0^t V(X_s^C)ds\right]\right\}.$$

By the previously deduced property, for fixed x and y, we can choose a compact set $[-n,n]$ such that

$$E_x^C\{\Omega_{(t,[y-\delta,y+\delta])}^{(0,x)}(n)\}>\frac{1}{2}\int_{y-\delta}^{y+\delta}k_t(x,y)dy,$$

where

$$\Omega^{(0,x)}_{(t,[y-\delta,y+\delta])}(n)=\{\omega:\omega(0)=x,\omega(t)\in[y-\delta,y+\delta];s\in[0,t]\Rightarrow\omega(s)\in[-n,n]\}$$

and $k_t(x,y)$ is the Cauchy kernel. Hence

$$\int_{y-\delta}^{y+\delta}dy\ k_t^V(x,y)\geqslant\int_{\Omega(n)}\exp\left[-\int_0^t V(X_s^C)ds\right]dP_x^C(\omega)\geqslant\frac{1}{2}\exp(-c_nt)\cdot\int_{y-\delta}^{y+\delta}k_t(x,y)dy,$$

where $c_n=\sup_{x\in[-n,n]}V(x)$.

Because $k_t^V(x,y)$ is continuous and δ was arbitrary, we get

$$k_t^V(x,y)\geqslant\tfrac{1}{2}\exp(-c_nt)\cdot k_t(x,y).$$

The assertion of Lemma 9 is thus valid.

Lemmas 8 and 9 provide us with a strictly positive and jointly continuous in space variables kernel, which can be directly exploited for the analysis of the Schrödinger interpolation problem, as exemplified by Eqs. (3)–(6), see also Refs. 2, 3, and 6. Indeed, let $\rho_0(x)$ and $\rho_T(x)$ be strictly positive densities. Then, the Markov process X_t^V characterized by the transition probability density:

$$p^V(y,s,x,t)=k_{t-s}^V(x,y)\ \frac{\theta(x,t)}{\theta(y,s)} \tag{23}$$

and the density of distributions

$$\rho(x,t)=\theta_*(x,t)\,\theta(x,t),$$

where

$$\theta_*(x,t)=\int_R k_t^V(x,y)f(y)dy,\qquad \theta_*(y,t)=\int_R k_{T-t}^V(x,y)g(x)dx$$

is precisely that interpolating Markov process to which Theorem 1 extends its validity, when the perturbed semigroup kernel replaces the Cauchy kernel.

Clearly, for all $0\leqslant s\leqslant t\leqslant T$ we have

$$\theta_*(x,t)=\int_R k_{t-s}^V(x,y)\,\theta_*(y,s)dy,\qquad \theta(y,s)=\int_R k_{t-s}^V(x,y)\,\theta(x,t)dx \tag{24}$$

and that suffices for the Theorem 1 to hold true in the present case as well.

Following the strategy of Sec. II, we shall investigate an issue of approximating the perturbed Cauchy process (set by Lemmas 8 and 9 and Theorem 1) by means of step processes.

Let us first invoke the step process Y_t^ϵ of Lemma 1. It corresponds to the unperturbed generator $|\nabla|_\epsilon$. To account for a perturbation and the involved perturbed semigroup, let us consider a multiplicative, homogeneous, and contracting functional:

$$\alpha_t^s(\omega)=\exp\left[-\int_s^t V(Y_\tau^\epsilon(\omega))d\tau\right] \tag{25}$$

of the process Y_t^ϵ, for times $0\leqslant s\leqslant t\leqslant T$.

We recall that the process Y_t^ϵ is a step process obtained from the Cauchy process by neglecting ''small jumps'' (the ϵ cutoff).

We shall associate with the multiplicative functional (25) the process $Y_t^{\epsilon,V}$ and prove that under additional restrictions on the potential V, the pertinent perturbed process is also a step process.

Theorem 5: Let $0 \leqslant V(x) \leqslant M$ for all $x \in R$. The transition function:

$$p_{\epsilon,V}(t,x,\Gamma) = E_x^{\epsilon}\left\{ \chi_\Gamma(Y_t^{\epsilon}) \exp\left[-\int_0^t V(Y_s^{\epsilon}) ds \right] \right\}$$

determines the step process $Y_t^{\epsilon,V}$.

Proof: By Theorem 3.8 of Ref. 21 a sufficient condition for the existence of a Markovian step process $Y_t^{\epsilon,V}$ is that its transition function obeys

$$\lim_{t\downarrow 0} p_{\epsilon,V}(t,x,\{x\}) = 1$$

uniformly in $x \in R$.

Let us choose $t_1 > 0$ so that $1-\delta \leqslant \exp(-Mt_1)$ is secured. In view of

$$\exp(-Mt) \leqslant \exp\left[-\int_0^t V(Y_s^{\epsilon}(\omega)) ds \right] \leqslant 1$$

for all ω, we have for all $t < t_1$ the following estimate:

$$(1-\delta) p_{\epsilon}(t,x,\Gamma) \leqslant p_{\epsilon,V}(t,x,\Gamma) \leqslant p_{\epsilon}(t,x,\Gamma).$$

On the other hand, there exists t_2 such that for all $t < t_2$,

$$p_{\epsilon}(t,x,\{x\}) \geqslant 1-\delta$$

is valid for all $x \in R$.

Hence, for all $t < \min(t_1,t_2)$ we get

$$(1-\delta)^2 \leqslant p_{\epsilon,V}(t,x,\{x\}) \leqslant 1.$$

Because δ is arbitrary, after taking $\delta \to 0$, the assertion follows.

From the formula $p_{\epsilon,V}(t,x,\Gamma) \leqslant p_{\epsilon}(t,x,\Gamma)$ we conclude that the transition function $p_{\epsilon,V}(t,x,\Gamma)$ is absolutely continuous with respect to the Lebesgue measure, and hence posesses a density $k_{\epsilon,V}(t,x,y)$.

A new process $X_t^{\epsilon,V}$ can be defined by considering a multiplicative transformation of the process $Y_t^{\epsilon,V}$ by means of

$$\alpha_s^t = \frac{\theta^{\epsilon}(Y_t^{\epsilon,V},t)}{\theta^{\epsilon}(Y_s^{\epsilon,V},s)}, \tag{26}$$

where θ^{ϵ} is a positive solution of $\partial_t \theta^{\epsilon} = |\nabla|_{\epsilon} \theta^{\epsilon} + V\theta^{\epsilon}$.

The transition probability density of $X_t^{\epsilon,V}$ reads

$$p_{\epsilon,V}(s,y,t,x) = k_{\epsilon,V}(t-s,y,x) \frac{\theta^{\epsilon}(x,t)}{\theta^{\epsilon}(y,s)} \tag{27}$$

and by repeating arguments mimicking those of Sec. II, one can show that the perturbed step process $X_t^{\epsilon,V}$ converges in distribution to the perturbed Cauchy process X_t^V, when $\epsilon \to 0$, uniformly in $t \in [0,T]$.

A concise summary of all mathematical arguments of Secs. II and III, reads:

Corollary 2:

(a) The Schrödinger boundary-data and interpolation problem (3)–(6) admits a class of unique solutions in terms of Markov stochastic processes, for each concrete choice of the (Feynman–Kac) kernel function that is determined by the Cauchy generator plus a locally bounded, positive and measurable potential function.

(b) The pertinent processes are of the jump-type and arise as suitable limits of *step* processes. In particular, the uniform in time $t\in[0,T]$ convergence in distribution to the perturbed Cauchy process X_t^V is established, when the potential function is bounded.

Proof: To settle (a), the strictly positive and continuous Feynman–Kac kernel function is necessary. Theorem 1 refers to the Cauchy process, and its conditional relatives. Lemmas 8 and 9 refer to the perturbed Cauchy process.

The step-process approximations and their convergence to the corresponding jump-type processes are established in Theorems 2 through 4 in case of the Cauchy and conditional Cauchy processes. Theorem 5 together with Eqs. (26) and (27) are the key ingredients for the convergence-in-distribution argument.

Remark 1: The developed techniques can be used to investigate the existence issue (including that of the step process approximation) of more general jump-type processes, in particular those related to the quantum evolution with relativistic Hamiltonians.[5,30]

Remark 2: In the present paper, to simplify calculations and to make formulas more transparent, we have considered processes associated with the Cauchy generator (and thus with the α-stable symmetric process as a major tool) in space dimension 1. A glance at the construction of solutions of the Schrödinger problem makes clear that the previous limitations are inessential. In fact, we could consider any $\alpha\in(0,2)$-symmetric stable processes on R^n, for arbitrary $n\geqslant 1$, and secure the strict positivity and joint continuity in space variables of the corresponding transition density. Such properties for $n\geqslant 2$ and for potentials from the Kato class $K_{n,\alpha}$ were established in a very recent publication, Ref. 31, Theorems 3.3 and 3.5. However, an issue of sample path properties and of step-process approximations must be settled separately.

Howe duality for the quantum groups $\mathcal{U}_q\mathrm{u}(m,n)$, $\mathcal{U}_q\mathrm{u}(M)$

Gavin Green
Department of Mathematics, School of Mathematics and Statistics, University of Newcastle, Newcastle upon Tyne NE1 7RU, England

(Received 30 March 1998; accepted for publication 8 July 1998)

A dual pair is defined to be a pair of mutually centralizing subgroups of the real symplectic group. Let (G,G') be a dual pair of reductive groups in which G is also compact and consider the decomposition of the metaplectic representation of the symplectic group into GG'-irreducibles. Each such irreducible is a tensor product of an irreducible of G with one of G', and it turns out there is a bijective correspondence between them, a particular irreducible of G only occurring with a particular one of G' and vice versa. This so-called Howe duality is here generalized to the quantum group case $(\mathcal{U}_q\mathrm{u}(m,n),\mathcal{U}_q\mathrm{u}(M))$ for q not a root of unity. A metaplectic representation for this dual pair is given in terms of the q-oscillator algebra and a $\mathcal{U}_q\mathrm{u}(m,n)\times\mathcal{U}_q\mathrm{u}(M)$-covariant Heisenberg–Weyl algebra is also constructed and realized on Fock space. The heart of the proof lies in showing that $\mathcal{U}_q\mathrm{u}(m,n)$ and $\mathcal{U}_q\mathrm{u}(M)$ are essentially mutual commutants on Fock space. The duality follows using the compactness of $\mathcal{U}_q\mathrm{u}(M)$. The proof is independent of the classical theory. As a consequence, given any two unitary highest weight representations of a quantum pseudo-unitary group (which arise from the restriction of a metaplectic representation), the decomposition of their tensor product is the same as in the classical case. [S0022-2488(98)02511-0]

I. INTRODUCTION

The metaplectic or oscillator representation of the real symplectic group first arose in the quantum field theory work of Shale and Segal.[1] Let $\mathcal{W}(n)$ denote the real Heisenberg–Weyl algebra generated by creation and annihilation operators, a_i^+, a_j $(i,j=1,...,n)$, satisfying the standard canonical commutation relations with $\hbar=1$,

$$[a_i,a_j]=[a_i^+,a_j^+]=0, \quad [a_i,a_j^+]=\delta_{ij}$$

and with real form $(a_i)^*=a_i^+$, $(a_i^+)^*=a_i$.

The complex symplectic Lie algebra $\mathrm{sp}(2n,\mathbb{C})$ may be realized as the complex span of the symmetrized quadratic expressions

$$a_ia_j, \quad \tfrac{1}{2}(a_ia_j^+ + a_j^+a_i), \quad a_i^+a_j^+,$$

with the Lie bracket defined as the commutator. The real form of $\mathcal{W}(n)$ picks out the real symplectic algebra, $\mathrm{sp}(2n,\mathbb{R})$. The Fock space action of $\mathcal{W}(n)$ then gives a unitary, infinite dimensional representation of the real symplectic Lie algebra, the infinitesimal version of the metaplectic representation.

It turns out that this exponentiates to a projective representation of the real symplectic group $\mathrm{Sp}(2n,\mathbb{R})$, only becoming single valued on the twofold covering group, the metaplectic group. It is an exact analog of the spin representation of the orthogonal group. At the group level there exists a cleaner abstract definition of the metaplectic representation as the set of intertwining operators of equivalent (by Stone–von Neumann theorem) representations of the Heisenberg group. We shall resist the temptation to give any details (see Refs. 2, 3), since we shall deal with quantum groups at the enveloping algebra level where the infinitesimal version is more suitable.

Further investigation of the metaplectic representation, its restriction to subgroups and the tensor products of representations so obtained, subsequently appeared in the literature, for example (Ref. 4). In particular, since we may identify $\mathbb{R}^{2(m+n)}\simeq\mathbb{C}^{m+n}$ such that the symplectic form is the imaginary part of a pseudo-Hermitian form on the complex space, we see that $\mathrm{U}(m,n)\subset \mathrm{Sp}(2(m+n),\mathbb{R})$. The pseudo-unitary group therefore has a metaplectic representation given by restriction. The M-fold tensor product of this was decomposed in Ref. 5, where the irreducibles were all shown to be unitary with highest weight. It was also conjectured and subsequently proved in Ref. 6 that in fact all such representations appear in such a decomposition for some M. Such results were encompassed and extended by Roger Howe's theory of dual pairs.[7–9]

A dual pair, (G,G'), is a pair of subgroups of the real symplectic group which are mutual centralizers. In the case that both groups are reductive we speak of a reductive dual pair. Howe proved the following theorem.

Theorem 1: *Let (G,G') be a reductive dual pair with G compact and let their corresponding Lie algebras be $\mathfrak{g}$, $\mathfrak{g}'$ respectively. The invariants in $\mathcal{W}(n)$ under the adjoint action of G (and hence which commute with G) are generated by (the image of) $\mathfrak{g}'$.*

It follows that we have the decomposition of the metaplectic μ into GG' irreducibles,

$$\mu|_{GG'} = \bigoplus \rho_i \otimes \rho_i' , \tag{1}$$

where ρ_i and ρ_i' are irreducible representations of G and G' respectively. Furthermore, there is a bijective correspondence, ρ_i only occurring with ρ_i' and vice versa. ■

The construction of dual pairs is straightforward by decomposing the underlying real symplectic vector space. Many families of dual pairs exist, the reductive ones having been classified.[8–10] Indeed every classical group arises as the member of some dual pair (ignoring centers and connected components).

For example, let $V\simeq \mathbb{C}^{m+n}$ be a pseudo-Hermitian of type (m,n) and $W\simeq \mathbb{C}^{M}$ be Hermitian. Then $V\otimes W$ is pseudo-Hermitian with respect to the natural product form, and thus $\mathrm{U}(m,n)$, $\mathrm{U}(M)\subset \mathrm{U}(mM,nM)$. Since $\mathrm{U}(mM,nM)\subset \mathrm{Sp}(2(m+n)M,\mathbb{R})$, as we saw earlier, a dual pair is obtained

$$\mathrm{U}(m,n),\mathrm{U}(M)\subset \mathrm{Sp}(2(m+n)M,\mathbb{R}). \tag{2}$$

Furthermore, the restriction of the action of $\mathrm{Sp}(2(m+n)M,\mathbb{R})$ to the subgroup $\mathrm{U}(m,n)$ is just the M-fold tensor product of its own metaplectic, that is, coming from restriction of the metaplectic of $\mathrm{Sp}(2(m+n),\mathbb{R})$. The duality theory then allows one to study the decomposition of this tensor product representation, (as studied in Refs. 5 and 6), in terms of the dually paired groups $\mathrm{U}(M)$. The precise theorem is given in Ref. 8, Theorem 4.6.

It is an analog of Theorem 1 for the quantum groups $\mathcal{U}_q\mathrm{u}(m,n),\mathcal{U}_q\mathrm{u}(M)$ which we shall prove. As a consequence we shall also deduce an analog of Theorem 4.6 of Ref. 8, referred to above.

Our motivations are several. First, from a mathematical point of view it would be desirable to extend the scope of the duality as far as it will go; by giving more and more examples we may shed light on a deeper underlying theory. There have already been several examples of duality which go beyond the scope of Theorem 1; for nonreductive groups,[10] super cases,[7] and modular representations.[11] In Refs. 12 and 13 independent proofs of duality were given for the pair of quantum unitary groups $(\mathcal{U}_q\mathrm{u}(2),\mathcal{U}_q\mathrm{u}(3))$. Reference 14 extends these results to the family of compact quantum unitary groups, $(\mathcal{U}_q\mathrm{u}(m),\mathcal{U}_q\mathrm{u}(M))$.

For quantum groups with q a root of unity some genuinely new representation theory occurs which appears to have similarities to the modular representations in the classical case. The example of duality for modular representations,[11] suggests that some remnant of duality may exist. Our goals presently are more modest, however, only dealing with q a nonroot of unity.

After some preliminary definitions and conventions, we recall the metaplectic representation of the quantum symplectic group and construct a new representation of the quantum pseudo-unitary group in Sec. IV. Using the fact that the classical action of $\mathrm{U}(m,n)\subset \mathrm{Sp}(2(m+n)M,\mathbb{R})$ is the M-fold tensor action, we construct in Sec. V the dual pair of quantum groups $\mathcal{U}_q\mathrm{u}(m,n),\mathcal{U}_q\mathrm{u}(M)$ and their action on Fock space.

This action of the dual pair gives an adjoint action on the endomorphism algebra of Fock space, and thus on the Heisenberg–Weyl algebra. Section VI is concerned with the construction of a deformed Heisenberg–Weyl algebra which transforms nicely under this action; a so-called covariant algebra. The heart of the proof of duality is to show that the dual pair are essentially mutual commutants in this algebra, which we do using the q analog of the Schur–Weyl duality between the general linear and symmetric groups. The duality correspondence is then deduced from the compactness of $\mathcal{U}_q\mathrm{u}(M)$.

From the duality, as in the classical case, the Clebsch–Gordan theory for the unitary highest weight representations which occur in tensor products of the metaplectic of $\mathcal{U}_q\mathrm{u}(m,n)$ (classically this is all unitary highest weight representations) is controlled by the theory for $\mathcal{U}_q\mathrm{u}(M)$ as M varies. Since the finite dimensional representation theory for quantum groups is the same as in the classical case (generically) we can conclude, as we might expect, that the decomposition of tensor products of the unitary highest weight representations of $\mathcal{U}_q\mathrm{u}(m,n)$ (occurring in tensor products of the metaplectic) is basically the same as in the classical case. For example, we shall get a handle on the ladder representations of $\mathcal{U}_q\mathrm{su}(2,2)$ which can be thought of as a quantum version of the conformal group.

It is worth noting that although one might expect that there is a duality for other pairs of quantum groups, the constructions used in the given proof do not always work; for example, a covariant Heisenberg–Weyl algebra for the dual pair $(\mathcal{U}_q\mathrm{o}(m),\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R}))$ cannot be constructed in the same way.

The proof given is independent of the classical theory and thus may provide a model for a proof of some duality in the root of unity cases. Certainly some of the constructions can still be made.

II. QUANTUM GROUP CONVENTIONS

We shall assume throughout that q is a nonzero complex number which is not a root of unity. First some standard notation,

$$[n]_q=\frac{q^n-q^{-n}}{q-q^{-1}},\quad [n]_q!=[n]_q[n-1]_q\ldots[1]_q,\quad \begin{bmatrix} m \\ n \end{bmatrix}_q=\frac{[m]_q!}{[n]_q![m-n]_q!}.$$

Let a_{ij} be a symmetrizable Cartan matrix and put $q_i=q^{d_i}$, where d_i is the least positive integer such that d_ia_{ij} is symmetric.

$\mathcal{U}_q\mathfrak{g}$ is defined to be the unital, associative algebra over $\mathbb{C}$ generated by $\{e_{\pm i},k_i^{\pm 1/2}\}_{i=1}^{n-1}$ subject to

$$[k_i^{\pm 1},k_j^{\pm 1}]=[k_i^{\mp 1},k_j^{\mp 1}]=0,\quad k_ie_{\pm j}k_i^{-1}=q_i^{\pm a_{ij}}e_{\pm j},$$

$$[e_i,e_{-j}]=\delta_{ij}\,\frac{k_i-k_i^{-1}}{q_i-q_i^{-1}},$$

$$\sum_{k=0}^{1-a_{ij}}(-1)^k\begin{bmatrix} 1-a_{ij} \\ k \end{bmatrix}_q(e_{\pm i})^ke_{\pm j}(e_{\pm i})^{1-a_{ij}-k}=0,\quad i\neq j,$$

$$\Delta(e_{\pm i})=e_{\pm i}\otimes k_i^{(1/2)}+k_i^{-(1/2)}\otimes e_{\pm i},\quad \Delta(k_i^{\pm(1/2)})=k_i^{\pm(1/2)}\otimes k_i^{\pm(1/2)},$$

$$S(e_{\pm i})=-q_i^{\pm 1}e_{\pm i},\quad S(k_i^{\pm(1/2)})=k_i^{\mp(1/2)},$$

where S is the antipode and Δ the coproduct.

With the Cartan matrix of types A and C we obtain the quantum special linear and symplectic groups, respectively. For $q\in\mathbb{R}\backslash\{0,\pm 1\}$ the real forms (1) $\mathcal{U}_q\mathrm{su}(m,n)$ and (2) $\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R})$ may be defined by the $*$-structures: (1) $k_i^*=k_i$ for all $i=1,...,n-1$, $e_{\pm i}^*=e_{\mp i}$ for $i=1,...,m-1,m+1,...,m+n-1$ and $e_{\pm m}^*=-e_{\mp m}$ and (2) $k_i^*=k_i$ for all $i=1,...,n$, $e_{\pm i}^*=e_{\mp i}$ for $i=1,...,n-1$, and $e_{\pm n}^*=-e_{\mp n}$. The quantum general linear group may be defined by adjoining group-like, central elements $k_\epsilon^{\pm 1}$ to the special linear group. To define $\mathcal{U}_q\mathrm{u}(m,n)$ we put $(k_\epsilon^{\pm 1})^*=k_\epsilon^{\pm 1}$.

If $\mathcal{R}\in\mathcal{U}_q\mathfrak{g}\otimes\mathcal{U}_q\mathfrak{g}$ is the universal R-matrix of a QUE algebra with fundamental representation ρ, then we let $R=(\rho\otimes\rho)\mathcal{R}$. Denote the flip operator by P, set $\hat{R}=PR$, $\check{R}=RP$ and use $\hat{R}^{-1}$ and

$\check{R}^{-1}$ as shorthand for $(\hat{R})^{-1}$ and $(\check{R})^{-1}$, respectively. The standard notation $\hat{R}_{ij}$ denotes an operator on a tensor product space acting as $\hat{R}$ in the ith and jth factors, and the identity elsewhere.

In the particular case that $\mathfrak{g}=\mathrm{sl}(n,\mathbb{C})$ (or $\mathrm{u}(n)$)

$$R=\sum_{i\neq j} E^i{}_i\otimes E^j{}_j+q\sum_i E^i{}_i\otimes E^i{}_i+(q-q^{-1})\sum_{i<j} E^i{}_j\otimes E^j{}_i,$$

where $E^i{}_j$ are the standard matrices with 1 in the ijth place and zeros elsewhere. The matrix $\hat{R}$ satisfies

$$(\hat{R}-q)(\hat{R}+q^{-1})=0. \tag{3}$$

The Artin braid group, B^p, is generated by $\{\tau_i\}_{i=1}^{p-1}$ subject to

$$\tau_i\tau_{i+1}\tau_i=\tau_{i+1}\tau_i\tau_{i+1},\quad \tau_i\tau_j=\tau_j\tau_i,\quad |i-j|\leq 2,$$

and the Hecke algebra, H_q^p, is the quotient by

$$(\tau_i-q)(\tau_i+q^{-1})=0\quad i=1,...,p-1.$$

The following analog of the Schur–Weyl duality,[15–17] will be used later.

Theorem 2: *The matrices $\hat{R}_{i(i+1)}$ for $i=1,...,p-1$ provide a representation of the Hecke algebra H_q^p by $\tau_i\to\hat{R}_{i(i+1)}$ on the space $\otimes^pV$, where V is the space on which the fundamental representation of $\mathcal{U}_q\mathrm{u}(n)$ is realized. Furthermore, in $\mathrm{End}(\otimes^pV)$ the Hecke algebra and $\mathcal{U}_q\mathrm{u}(n)$ generate mutual commutants.* ■

III. *q*-OSCILLATOR ALGEBRA

Define the deformed or q-oscillator algebra, $\mathcal{W}_q(n)$,[18–20] to be the unital, associative algebra over $\mathbb{C}$ generated by A_i, A_i^+ and $\nu_i^{\pm 1}$ for $i=1,...,n$, subject to

$$A_iA_i^+-q^{\pm 1}A_i^+A_i=\nu_i^{\mp 2},\quad \nu_i^{\pm 1}A_i^+=q^{\pm 1/2}A_i^+\nu_i^{\pm 1},\quad \nu_i^{\pm 1}A_i=q^{\mp 1/2}A_i\nu_i^{\pm 1},$$

and with $\{A_i,A_i^+,\nu_i^{\pm 1}\}$ commuting with $\{A_j,A_j^+,\nu_j^{\pm 1}\}$ for $i\neq j$. The real form is given for $q\in\mathbb{R}\backslash\{0,\pm 1\}$ by the $*$-structure $A^*=A^+$, $(A^+)^*=A$, and $(\nu_i^{\pm 1})^*=\nu_i^{\pm 1}$. (In some definitions only one of the relations between A and A^+ is assumed but both hold in the following Fock representation anyway.)

Let Ω be a vacuum vector, $A_i\Omega=0$ for all $i=1,...,n$. Introduce the shorthand notation

$$A^+(\mathbf{s})=(A_i^+)^{s_1}\ldots(A_n^+)^{s_n},\quad \mathbf{z}(\mathbf{s})=A^+(\mathbf{s})\Omega.$$

Proposition 3: There is a unitary action of $\mathcal{W}_q(n)$ on Fock space given by

$$A_i^+\mathbf{z}(\mathbf{s})=\mathbf{z}(\mathbf{s}+\mathbf{e}_i),\quad A_i\mathbf{z}(\mathbf{s})=[s_i]_q\mathbf{z}(\mathbf{s}-\mathbf{e}_i),\quad \nu_i^{\pm 1}\mathbf{z}(\mathbf{s})=q^{\pm(s_i/2)}\mathbf{z}(\mathbf{s}),$$

with the inner product, unique up to normalization,

$$\langle\mathbf{z}(\mathbf{s}),\mathbf{z}(\mathbf{t})\rangle=\delta_{\mathbf{s},\mathbf{t}}[s_1]_q!\ldots[s_n]_q!.$$

■

IV. METAPLECTIC REPRESENTATIONS

An explicit infinitesimal metaplectic or oscillator representation for the quantum symplectic group was given in Ref. 20. (A more implicit version was also given in Ref. 21 which gave the generators L of Ref. 22 in terms of a covariant Heisenberg–Weyl algebra. However, as was pointed out there, the approach did not allow one to give explicit expressions for the full generators $L^{\pm 1}$.)

Proposition 4: For $q\in\mathbb{R}\backslash\{0,\pm 1\}$ there is an algebra $*$-homomorphism

$$\mu:\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R})\to\mathcal{W}_q(n),$$

determined for $i=1,...,n$ *by*

$$\mu(e_i)=\begin{cases}A_i^+A_{i+1}\\ \dfrac{-1}{q+q^{-1}}(A_n^+)^2\end{cases},\quad \mu(k_i^{1/2})=\begin{cases}\nu_i\nu_{i+1}^{-1} & i<n\\ q^{1/2}\nu_n^2 & i=n\end{cases}.$$

The Fock space representation of $\mathcal{W}_q(n)$ *therefore induces a unitary representation of* $\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R})$. ■

Since classically $\mathrm{U}(m,n)$ is a subgroup of $\mathrm{Sp}(2(m+n),\mathbb{R})$ it inherits a metaplectic representation. In the quantum case this is still true for the compact quantum unitary group which sits nicely as a Hopf $*$-subalgebra in the quantum symplectic group. It is not as obvious how a general quantum pseudo-unitary group will sit inside the symplectic group so we give an independent definition of the representation, but one which coincides with the restriction in the classical limit. The proof is straightforward.

Proposition 5: For $q\in\mathbb{R}\backslash\{0,\pm1\}$ *there is a* $*$*-homomorphism,*

$$\mu:\mathcal{U}_q\mathrm{u}(m,n)\to\mathcal{W}_q(m+n),$$

determined for $i=1,...,m+n-1$ *by*

$$\mu(e_i)=\begin{cases}A_i^+A_{i+1}\\ -A_m^+A_{m+1}^+,\\ -A_iA_{i+1}^+\end{cases}\quad \mu(k_i^{1/2})=\begin{cases}\nu_i\nu_{i+1}^{-1} & i<m\\ q^{1/2}\nu_m\nu_{m+1} & i=m,\\ \nu_{i+1}\nu_i^{-1} & i>m\end{cases}$$

and with $\mu(k_\epsilon^{\pm1})=(\nu_1^2\ldots\nu_m^2\nu_{m+1}^{-2}\ldots\nu_{m+n}^{-2})^{\pm1}$.

The Fock space representation of $\mathcal{W}_q(n)$ *therefore induces a unitary representation of* $\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R})$. ■

Note that the image of $\mathcal{U}_q\mathrm{u}(m,n)$ is still a $*$-subalgebra of the image of $\mathcal{U}_q\mathrm{sp}(2(m+n),\mathbb{R})$.

The dual representation μ^* is given by $\mu^*(h)=(\mu(S(h)))^*$ for all $h\in\mathcal{U}_q\mathrm{u}(m,n)$. In the case $n=0$ we normalize this to obtain the equivalent representation $\mu'\simeq\mu^*$ given by

$$\mu'(e_i)=A_iA_{i+1}^+,\quad \mu'(k_i^{1/2})=\nu_{i+1}\nu_i^{-1},\quad i=1,...,m-1.$$

V. DUAL PAIR $\mathcal{U}_q\mathrm{u}(m,n)$, $\mathcal{U}_q\mathrm{u}(M)$

For the construction of dual pairs in the classical case one can decompose the underlying symplectic vector space and so rely on the groups being defined by their fundamental representations. This is no longer true in the quantum case and there are considerable difficulties in trying to construct quantum dual pairs inside the quantum symplectic group (or alternatively starting with a deformed dual pair and trying to construct a deformed symplectic group around them). We shall not address these problems further here (see Refs. 12, 14), and so avoid giving a definition of a dual pair in the quantum case.

Instead we use the fact that the action of the pseudo-unitary group $\mathrm{U}(m,n)\subset\mathrm{Sp}(2(m+n)M,\mathbb{R})$ obtained by restriction of the metaplectic of $\mathrm{Sp}(2(m+n)M,\mathbb{R})$ is just the M-fold tensor action of its own metaplectic. The action of the dually paired $\mathrm{U}(M)\subset\mathrm{Sp}(2(m+n)M,\mathbb{R})$ is $\otimes^m\mu\otimes\otimes^n\mu^*$. We can therefore define the action of the dual pair without reference to the symplectic group at all. A slightly modified version of this works in the quantum case.

Denote the generators of $\mathcal{U}_q\mathrm{u}(m,n)$ by $\{e_{\pm i},k_i^{\pm(1/2)},k_\epsilon^{\pm1}\}_{i=1}^{m+n-1}$ and those of $\mathcal{U}_q\mathrm{u}(M)$ by $\{E_{\pm I},K_I^{\pm(1/2)},K_\epsilon^{\pm1}\}_{I=1}^{M-1}$.

Proposition 6: There exists a $*$*-algebra homomorphism,*

$$\mathcal{U}_q\mathrm{u}(m,n)\otimes\mathcal{U}_q\mathrm{u}(M)\to\mathcal{W}_q((m+n)M).$$

The unitary action of $\mathcal{W}_q((m+n)M)$ *on Fock space gives an action of the dual pair such that as* $q\to1$ *we obtain the classical metaplectic representation.*

Proof: Denote the metaplectic representations of $\mathcal{U}_q\mathrm{u}(m,n)$ and $\mathcal{U}_q\mathrm{u}(M)$ by $\mu_{(m,n)}$ and μ_M, respectively, so we have $*$-algebra homomorphisms into q-oscillator algebras

$$\mu_{(m,n)}:\mathcal{U}_q\mathrm{u}(m,n)\rightarrow\mathcal{W}_q(m+n),\quad \mu_M:\mathcal{U}_q\mathrm{u}(M)\rightarrow\mathcal{W}_q(M).$$

The tensor product representations $\otimes^M\mu_{(m,n)}$ and $\otimes^m\mu_M\otimes\otimes^n\mu'_M$ can be regarded as $*$-homomorphisms into $\mathcal{W}_q((m+n)M)$ by using the algebra isomorphisms

$$\mathcal{W}_q((m+n)M)\simeq\otimes^M\mathcal{W}_q(m+n)\simeq\otimes^{m+n}\mathcal{W}_q(M).$$

It remains to be proven that these actions of $\mathcal{U}_q\mathrm{u}(m,n)$ and $\mathcal{U}_q\mathrm{u}(M)$ commute. The relations between the Cartan subalgebra of $\mathcal{U}_q\mathrm{u}(m,n)$ (generated by the K's) with $\mathcal{U}_q\mathrm{u}(M)$ are trivial, and vice versa. The remaining relations can be proven directly for the generators. However, much work can be saved by noting that the actions of the maximal compact subgroups of each preserve the degree and are in fact subrepresentations of the tensor algebra of the fundamental representation. It is therefore sufficient to check that their actions commute on $V^{(m+n)}\otimes V^M$, the fundamental representation of the dual pair. Finally one may prove directly that

$$[e_m,E_{\pm I}]=[e_{-m},E_{\pm I}]=0,\quad I=1,...M-1.$$

■

Note that the image of the dual pair still forms a $*$-subalgebra of the image of $\mathcal{U}_q\mathrm{sp}(2(m+n)M,\mathbb{R})$. Also, the central $\mathcal{U}_q\mathrm{u}(1)$'s of each member are mapped to the same image; this is to be expected since in the classical case the central U(1) lies in the intersection of the dual pair inside the symplectic group.

VI. DUAL PAIR-COVARIANT HEISENBERG–WEYL ALGEBRAS

An algebra is said to be covariant with respect to the action of a Hopf algebra if the multiplication intertwines with this action. A deformation of the Heisenberg–Weyl algebra which is covariant with respect to the action of some quantum group will therefore be referred to as a covariant Heisenberg–Weyl algebra.

The most familiar examples are the $\mathcal{U}_q\mathrm{u}(n)$-covariance of Ref. 23 and $\mathcal{U}_q\mathrm{o}(n)$-covariance discussed in Ref. 24. In Ref. 14 the $\mathcal{U}_q\mathrm{u}(n)$-covariance is extended to the full $\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R})$-covariance. Using the braided theory as presented in Ref. 25 we can regard the Pusz–Woronowicz algebra as a $\mathcal{U}_q\mathrm{sp}(2n,\mathbb{R})$ braided vector space, and thus take braided tensor products of it. In this way we could construct a Heisenberg–Weyl algebra which is covariant with respect to the action of one member of the dual pair. (We should also be able to use a braided exponential to obtain Weyl-type relations, that is, exponentiated canonical commutation relations.)

However, we can actually do slightly better for this dual pair and consider a deformation of the Heisenberg–Weyl algebra which is covariant under the joint action of the pair $\mathcal{U}_q\mathrm{u}(m,n)$, $\mathcal{U}_q\mathrm{u}(M)$. This is a generalization of the $\mathcal{U}_q\mathrm{u}(m)\otimes\mathcal{U}_q\mathrm{u}(M)$-covariance considered in Refs. 26 and 27 and also Ref. 14.

Proposition 7: The algebra $\mathcal{W}_{AA}((m,n),M)$ *with generators* $\{v_{iI},u^{iI}\}$ *for* $i=1,...,m+n$ *and* $I=1,...,M$ *satisfying the relations*

$$\mathbf{v}_1\mathbf{v}_2(\hat{r}^{-1}\hat{R}-1)=0,\quad(\check{r}^{-1}\check{R}-1)\mathbf{v}^*{}_1\mathbf{v}^*{}_2=0,\tag{4}$$

$$\mathbf{v}^*{}_1\mathbf{v}_2-\mathbf{v}_2r_{21}R_{21}\mathbf{v}^*{}_1=I,\tag{5}$$

is $\mathcal{U}_q\mathrm{gl}(m+n,\mathbb{C})\otimes\mathcal{U}_q\mathrm{gl}(M,\mathbb{C})$*-covariant, has the same Poincaré series as the classical Heisenberg–Weyl algebra, and is a* $*$*-algebra with respect to*

$$v_{iI}^*=\begin{cases}v^{iI} & i=1,...,m\\ -v^{iI} & i=m+1,...,m+n\end{cases}.$$

Before giving the proof we explain the notation. The subscript *AA* refers to the Cartan-type of $\mathcal{U}_q\mathrm{gl}(m+n,\mathbb{C})\otimes\mathcal{U}_q\mathrm{gl}(M,\mathbb{C})$ (which defines the braided or quasitensor category within which we work). The R-matrices of $\mathcal{U}_q\mathrm{gl}(m+n,\mathbb{C})$ and $\mathcal{U}_q\mathrm{gl}(M,\mathbb{C})$ (or their corresponding real forms) will be denoted by r and R, respectively, and thus that of the product will be $r_{13}R_{24}$, though we shall generally suppress the subscripts.

$((m,n),M)$ is used to distinguish the real form of $\mathcal{W}_{AA}$ we are considering, for compatability with $\mathcal{U}_q\mathrm{u}(m,n)\otimes\mathcal{U}_q\mathrm{u}(M)$. In the future we shall simply use the notation $\mathcal{W}_{AA}$ since the real form shall be understood.

Let $V=V^{(m+n)}\otimes V^M$ denote the fundamental representation (space) of the dual pair, and V^* its dual. Then the q-analogs of the symmetric algebras will be denoted $S_{AA}(V)$ and $S_{AA}(V^*)$, respectively.

The coordinate free notation in the relations is standard, see, for example, Ref. 25. $\mathbf{v}$ is thought of as a row vector with entries v_{iI}, $\mathbf{v}^*$ a column vector with entries v^{iI}; $\mathbf{v}_1=\mathbf{v}\otimes 1$ and $\mathbf{v}_2=1\otimes\mathbf{v}$. The R-matrices r and R lie in a tensor product of matrix spaces and the coordinate free notation is simply matrix and vector notation.

Proof: Let $\{v_{iI}\}$ be a basis for V with respect to which the representing matrices take the standard form, and let $\{v^{iI}\}$ be the dual basis of V^*. We wish to consider covariant algebras generated by these. The construction of such algebras is discussed for example in Ref. 25.

By analogy with the classical case, we would like the v_{iI} to generate a deformation of the symmetric algebra. Consideration of the eigenvalues and eigenspaces of $\hat{r}\hat{R}$, $\hat{r}\hat{R}^{-1}$ and $\hat{r}^{-1}\hat{R}$, using (3), leads to the relations (4). One can similarly construct a symmetric algebra from the dual basis v^{iI}.

It also follows from

$$(\hat{r}\hat{R}+1)(\hat{r}\hat{R}^{-1}-1)=0$$

that this algebra is a braided vector space as defined in Ref. 25, with respect to the braid matrix $\hat{r}\hat{R}$. This allows us to define the cross-relations (5) by braided differentiation; see also (Refs. 28, 14).

It is straightforward to check (using Bergmann's diamond lemma as applied in Ref. 29) that the Poincaré series (graded dimensions) of $S_{AA}(V)$ and $S_{AA}(V^*)$ are the same as the classical symmetric algebras. It then follows from the Wick ordering property given in the next proposition that the Poincaré series of $\mathcal{W}_{AA}$ is the same as that of the classical Heisenberg–Weyl algebra. ■

In order to be able to define a Fock representation of $\mathcal{W}_{AA}$ we need to check that it is a Wick algebra;[28] in other words the relations must allow us to order any expression such that the annihilation operators lie to the right of any creation operators. With foresight we define

$$a^+_{iI}=\begin{cases} v_{iI} \\ q^{(i+I-1-m)}v^{iI}, \end{cases} \quad a_{iI}=\begin{cases} v^{iI} & i\leqslant m \\ -q^{(i+I-1-m)}v_{iI} & i>m \end{cases}, \tag{6}$$

so that $a^*_{iI}=a^+_{iI}$ for all (iI).

Proposition 8: $\mathcal{W}_{AA}$ is a Wick algebra.

Proof: We wish to prove that any expression can be reordered so that all the a's lie to the right of all the a^+'s. By induction it is sufficient to prove that all the expressions $a_{iI}a^+_{jJ}$ may be so ordered.

There are four cases to consider, depending on the values of i, and j. In cases $i,j\leqslant m$ or $i\leqslant m,j>m$ or $i>m,j\leqslant m$, the explicit relations obtained from (4) and (5) may be used directly to give the result.

In the final case $i,j>m$ we need to invert the last relation by multiplying by the matrix $(r^{t_2}_{21})^{-1}(R^{t_2}_{21})^{-1}$, where t_2 denotes transposition in the second factor, and we use $R^{t_2}_{21}$ to mean $(R_{21})^{t_2}$. Explicitly $(R^{t_2}_{21})^{-1}$ is given by

$$\sum_{i\neq j} E^i{}_i\otimes E^j{}_j+q^{-1}\sum_i E^i{}_i\otimes E^i{}_i+(q^{-1}-q)\sum_{i>j} q^{-2(i-j)}E^i{}_j\otimes E^i{}_j\,.$$

Some of the terms obtained by this inversion will still not be ordered, but may then be ordered as previously, and the result follows.

Note that our choice of factors in defining the creation and annihilation operators was such that in the expressions for reordering $a_{iI}a_{iI}^{+}$, the constant term which appears will simply be 1.■

Now we can construct a Fock representation in the usual way by considering the existence of a vacuum vector Ω which is killed by the annihilation operators, $a_{iI}\Omega=0$ for all (iI).

Define an ordering of the double indices by $(iI)<(jJ)$ if $i<j$ or $(i=j$ and $I<J)$. The Fock space may then be built on the vacuum by the creation operators; we shall use the shorthand notation

$$a^{+}(\mathbf{s})=(a_{11}^{+})^{s_{11}}\dots(a_{m+nM}^{+})^{s_{m+nM}},\quad a(\mathbf{s})=(a^{+}(\mathbf{s}))^{*},$$

where the ordering on the right-hand side of the first equation is as given above.

Lemma 9: Let $s_{jJ}=0$ for all $(jJ)\leqslant(iI)$. *Then*

$$a_{iI}a^{+}(\mathbf{s})\Omega=0,$$

$$(a(\mathbf{s}))a^{+}(\mathbf{s})\Omega=(s_{11})_{q^{-1}}!\dots(s_{mM})_{q^{-1}}!(s_{m+11})_{q}!\dots(s_{m+nM})_{q}!\Omega,$$

where the second q-integer is defined to be

$$(n)_q=\frac{1-q^{-2n}}{1-q^{-2}}.$$

Proof: The first is a direct consequence of the relations. The second may be proved by an induction on $\Sigma_{iI}s_{iI}$ using the first. ■

Proposition 10: There is up to normalization a unique inner product such that the Fock representation is a $*$*-representation; explicitly*

$$(a^{+}(\mathbf{s})|a^{+}(\mathbf{t}))=\delta_{\mathbf{s},\mathbf{t}}(s_{11})_{q^{-1}}!\dots(s_{mM})_{q^{-1}}!(s_{m+11})_{q}!\dots(s_{m+nM})_{q}!.$$

It is irreducible, faithful, and unitary for $q\in\mathbb{R}\backslash\{0,\pm1\}$ (*i.e., the inner product is positive definite*).

Proof: The inner product follows from the previous lemma.

To prove that the representation is irreducible assume that W is an invariant subspace and let $\Sigma_{\mathbf{r}}b_{\mathbf{r}}\mathbf{x}(\mathbf{r})$ be any nonzero vector in W. Define an ordering on $\mathbb{N}^{(m+n)M}$ by $\mathbf{s}>\mathbf{r}$ if for some iI, $s_{iI}>r_{iI}$ and for all $jJ<iI$ we have $s_{jJ}=r_{jJ}$. Define $\mathbf{s}$ to be the maximum element of $\{\mathbf{r}|b_{\mathbf{r}}\neq0\}$. Then

$$a(\mathbf{s})\sum_{\mathbf{r}}b_{\mathbf{r}}\mathbf{x}(\mathbf{r})=b_{\mathbf{s}}(s_{11})_{q^{-1}}!\dots(s_{mM})_{q^{-1}}!(s_{m+11})_{q}!\dots(s_{m+nM})_{q}!\Omega.$$

This is nonzero if q is a nonroot of unity. The result then follows from the fact that Ω is a generating vector for the module.

For the representation to be faithful we consider

$$\sum_{\mathbf{s},\mathbf{t}}\alpha_{\mathbf{s},\mathbf{t}}a^{+}(\mathbf{s})a(\mathbf{t})\mathbf{x}(\mathbf{r})=0,$$

for all $\mathbf{r}$. If we let $\mathbf{t}_0$ be the least $\mathbf{t}$ such that $\alpha_{\mathbf{s},\mathbf{t}}\neq0$ then we deduce that $\alpha_{s,\mathbf{t}_0}=0$ and by an inductive argument that all $\alpha_{\mathbf{s},\mathbf{t}}=0$, hence the result.

For unitarity it is sufficient to note that for $q\in\mathbb{R}\backslash\{0,\pm1\}$, $(n)_q>0$ for all $n\in\mathbb{N}$. ■

In summary, we have an abstract $*$-algebra, $\mathcal{W}_{AA}$, which is acted on covariantly by the dual pair such that the generators transform as the fundamental and dual representations. In addition, we have actions of both $\mathcal{W}_{AA}$ and the dual pair on Fock space. There is therefore a second action of the dual pair on $\mathcal{W}_{AA}$ using the adjoint representation. Recall that if $\mathcal{H}$ is a Hopf algebra acting on a vector space V, then there is an associated adjoint action of $\mathcal{H}$ on $\mathrm{End}(V)$ given by

$$h(a)=\sum_{(h)}h^{(1)}aS(h^{(2)}),\quad \text{for all}\quad h\in\mathcal{H},a\in\mathrm{End}(V),\tag{7}$$

where $\Delta(h)=\Sigma_{(h)}h^{(1)}\otimes h^{(2)}$, and where we suppress the representation V.

We would like these actions to coincide, as in the classical case.

Proposition 11: Let $\mathcal{U}_q\mathrm{u}(m,n)\otimes\mathcal{U}_q\mathrm{u}(M)$ *act on the image of* $\mathcal{W}_{AA}$ *on Fock space using the adjoint action. Then the images of* v_{iI} *and* v^{iI} *still transform as the basis of the fundamental and dual representations (or in other words form the components of tensor operators for the fundamental and dual representations).*

Proof: First, note that $v_{11}=a_{11}^{+}=A_{11}^{+}q^{(1/2)N_{11}}$ on Fock space. One can also easily check directly that it is a highest weight vector for the fundamental representation under the adjoint action of the dual pair. Similarly $v^{11}=a_{11}=q^{(1/2)N_{11}}A_{11}$ is a lowest weight vector for the dual representation. We can now set $\tilde{v}_{11}=v_{11}$, $\tilde{v}^{11}=v^{11}$ and from this starting point construct operators $\tilde{v}_{iI}$ and $\tilde{v}^{iI}$ by applying the generators of the dual pair in the adjoint action. Bases for the fundamental and dual are assured by considering the classical limit and the finite dimensional representation theory of quantum groups at nonroots of unity. We may then define $\tilde{a}_{iI}^{+}$ and $\tilde{a}_{iI}$ by the same formulas as before, (6), only with tildes on each element.

The operators $\tilde{v}_{iI}$ must satisfy the same relations as v_{iI} since they are constructed to transform in the same way. In addition, an easy induction shows that

$$\tilde{a}^{+}(\mathbf{s})\Omega=c(\mathbf{s})A^{+}(\mathbf{s})\Omega,$$

for some constant $c(\mathbf{s})$. It follows by a dimensional argument that in fact $\tilde{v}_{iI}$ cannot satisfy any extra relations to those of v_{iI}. By applying the $*$-structure this is true of $\tilde{v}^{iI}$ also.

The action of $\tilde{a}_{iI}^{+}$ and $\tilde{a}_{iI}$ on $\tilde{a}^{+}(\mathbf{s})\Omega$ will be the same (under the obvious identification) as a_{iI}^{+} and a_{iI} on $a^{+}(\mathbf{s})\Omega$ since their Fock actions are completely determined by the relations and the fact that the vacuum is killed by the annihilation operators. By identifying the bases $a^{+}(\mathbf{s})\Omega$, $\tilde{a}^{+}(\mathbf{s})\Omega$ and $c(\mathbf{s})A^{+}(\mathbf{s})\Omega$ we can finally conclude that

$$\tilde{a}_{iI}^{+}=a_{iI}^{+},\quad \tilde{a}_{iI}=a_{iI}.$$

■

VII. DUALITY FOR $(\mathcal{U}_q\mathrm{u}(m,n),\mathcal{U}_q\mathrm{u}(M))$

The essential point to show is that the algebra of elements in $\mathcal{W}_{AA}$ which commute with the action of $\mathcal{U}_q\mathrm{u}(M)$ on Fock space, are actually generated by the image of elements of $\mathcal{U}_q\mathrm{u}(m,n)$. The proof of duality follows easily from this result by using the compactness of $\mathcal{U}_q\mathrm{u}(M)$ and the density of $\mathcal{W}_{AA}$ on Fock space.

Recall that an invariant, a, of a general Hopf algebra, $\mathcal{H}$, with counit ϵ, is an object which transforms according to

$$h(a)=\epsilon(h)a,\quad \forall h\in\mathcal{H}. \tag{8}$$

With this definition, we may begin with the following theorem as proved in Ref. 30.

Theorem 12: Let a Hopf algebra $\mathcal{H}$ *and an algebra* $\mathcal{A}$ *act on some vector space* V, *then* $\mathcal{H}$ *acts on* $\mathcal{A}$ *in the adjoint action. The* $\mathcal{H}$ *invariants are just those elements of* $\mathcal{A}$ *which commute with* $\mathcal{H}$ *on* V. ■

The elements in $\mathcal{W}_{AA}$ with which $\mathcal{U}_q\mathrm{u}(M)$ commutes are therefore just the invariants under the q-adjoint action. Let V denote the fundamental representation of the dual pair, V^* its dual. Now, there exists a $\mathcal{U}_q\mathrm{u}(M)$-module isomorphism

$$\mathcal{W}_{AA}\simeq S_{AA}(V)\otimes S_{AA}(V^*)\subset T(V)\otimes T(V^*),$$

with the q-adjoint action on $\mathcal{W}_{AA}$ and the tensor action on the others. So now we need only look for invariants in $T(V)\otimes T(V^*)$ and restrict them to $\mathcal{W}_{AA}$ using the identification with $S_{AA}(V)\otimes S_{AA}(V^*)$. Since $\mathcal{U}_q\mathrm{u}(M)$ preserves the natural grading, a general invariant will be a sum of homogeneous invariants and furthermore, by considering the action of the central $\mathcal{U}_q\mathrm{u}(1)$ we may restrict our search to $\otimes^{p}V\otimes\otimes^{p}V^*$. Now this question is answered by the q-Schur–Weyl theorem, Theorem 2. It then remains to show that these invariants (restricted to the Weyl algebra) are generated by the quadratic ones and that the quadratic invariants lie in the image of $\mathcal{U}_q\mathrm{u}(m,n)$.

Theorem 13: The $\mathcal{U}_q\mathrm{u}(M)$-invariants in $\mathcal{W}_{AA}$ are generated by the quadratic invariants. Furthermore, these quadratic invariants lie inside the image of $\mathcal{U}_q\mathrm{u}(m,n)$.

Proof: As outlined above, we need only look for invariants in $\otimes^p V \otimes \otimes^p V^* \simeq \mathrm{End}(\otimes^p V)$ and applying Theorem 12 we see that the required invariants are those elements of $\mathrm{End}(\otimes^p V)$ which commute with the action of $\mathcal{U}_q\mathrm{u}(M)$. However, these are given by Theorem 2,

$$\sum_I \tau(v_{i_1 I_1} \otimes v_{i_2 I_2} \otimes \cdots \otimes v_{i_p I_p}) \otimes (v^{j_p I_p} \otimes \cdots \otimes v^{j_1 I_1}),$$

where τ is any element of the Hecke algebra, $\{v_{iI}\}$ and $\{v^{iI}\}$ are bases for V and V^*, respectively. The restriction of these to $S_{AA}(V) \otimes S_{AA}(V^*)$ may then be identified with the elements

$$\sum_I \tau(v_{i_1 I_1} v_{i_2 I_2} \cdots v_{i_p I_p})(v^{j_p I_p} \cdots v^{j_1 I_1}),$$

of $\mathcal{W}_{AA}$ (abusing notation). Now using the fact that the indices $i_1,\ldots,i_p$ and $j_1,\ldots,j_p$ are arbitrary and the relations of the v_{iI}, (4), we see in fact that all order $2p$ invariants can be written as linear combinations of

$$\sum_{\mathbf{I}} (v_{i_1 I_1} v_{i_2 I_2} \cdots v_{i_p I_p})(v^{j_p I_p} \cdots v^{j_1 I_1}).$$

We now wish to show that all such invariants are generated by the quadratic invariants, $\Sigma_I v_{iI} v^{jI}$, for which we use induction on the order of the invariant. Trivially the quadratic invariants themselves are quadratic, and for the induction hypothesis we assume that all invariants of order $2(p-1)$ or less are generated by quadratic ones. Now the general invariant above can be suggestively rewritten

$$\sum_I \left(v_{i_1 I_1} v_{i_2 I_2} \cdots v_{i_{p-1} I_{p-1}} \left(\sum_{I_p} v_{i_p I_p} v^{j_p I_p} \right) v^{j_{p-1} I_{p-1}} \cdots v^{j_1 I_1} \right),$$

so that if we can drag the quadratic term in the middle through to the right hand side to produce a sum of products of order 2 and order $2(p-1)$ invariants plus a sum of lower order invariants, then we are done. This boils down to the following lemma.

Lemma 14: There exist constants α^{jkv}_{iub} (which may be determined), such that

$$\left(\sum_I v_{iI} v^{jI} \right) v^{kK} = \sum_{u,v,b} \alpha^{jkv}_{iub} v^{uK} \left(\sum_I v_{vI} v^{bI} \right) - \sum_b \alpha^{jku}_{iub} v^{bK}.$$

Proof:

$$\left(\sum_I v_{iI} v^{jI} \right) v^{kK} = \sum_{I,a,b,A,B} v_{iI}((\check{r})^{-1}{}^{jk}_{ab} \check{R}^{IK}_{AB} v^{aA} v^{bB})$$

$$= \sum_{I,a,b,A,B} (\check{r})^{-1}{}^{jk}_{ab} \hat{R}^{IK}_{AB} \left(\sum_{u,v,U,V} (r^{t_2}_{21})^{-1}{}^{ai}_{uv} (R^{t_2}_{21})^{-1}{}^{AI}_{UV} (v^{uU} v_{vV} - \delta^u_v \delta^U_V) \right) v^{bB}$$

$$= \sum_{a,b,B,u,v} (\check{r})^{-1}{}^{jk}_{ab} (r^{t_2}_{21})^{-1}{}^{ai}_{uv} (v^{uK} v_{vB} v^{bB} - \delta^u_v) v^{bK},$$

where the first two lines come from the relations of the algebra, (4) and (5), and the third uses $(\check{R})^{IK}_{AB} = (R^{t_2}_{21})^{KB}_{AI}$. The result follows. ∎

For the last part, we note that from the defining relations and the action on the basis, one can prove that

$$\sum_I v_{1I}v^{1I}=\sum_I q^{2\Sigma_{J<I}N_{1J}}(N_{1I})_{q^{-1}}=\left(\sum_I N_{1I}\right)_{q^{-1}},$$

where N_{iI} is the number operator, $N_{iI}\mathbf{x}(\mathbf{s})=s_{iI}\mathbf{x}(\mathbf{s})$, and since $(\Sigma_I N_{1I})_{q^{-1}}$ is in the image of $\mathcal{U}_q\mathrm{u}(m,n)$, so is $\Sigma_I v_{1I}v^{1I}$. It now follows by simple induction that all quadratic invariants lie in the image of $\mathcal{U}_q\mathrm{u}(m,n)$ since we can construct them from $\Sigma_I v_{1I}v^{1I}$ using the adjoint action of $\mathcal{U}_q\mathrm{u}(m,n)$.

This completes the proof of the theorem. ■

To conclude the duality theory, we need a technical lemma which uses the Haar measure on the dual quantum group. For general reference see Ref. 17.

Define $(\mathcal{F}_q^1 G,*)$ to be the Hopf $*$-subalgebra of the Hopf dual of $\mathcal{U}_q\mathfrak{g}$ generated by the matrix elements of finite dimensional representations of type 1. (A finite dimensional representation is said to be of type 1 if the weight $\mathbf{w}$ has $w_i=q^{(\alpha_i,\lambda)}$ for $\lambda\in P^+$.) Let $\int$ denote the Haar measure of $(\mathcal{F}_q^1 G,*)$. Let the coaction of $(\mathcal{F}_q^1 G,*)$ on $\mathcal{W}_{AA}$ be denoted δ so that $\delta:\mathcal{W}_{AA}\to\mathcal{W}_{AA}\otimes\mathcal{F}_q^1 G$.

Lemma 15: Let $\mathcal{A}$ denote those operators in $\mathcal{W}_{AA}$ which commute with the action of $\mathcal{U}_q\mathrm{u}(M)$ on $S_{AA}(V)$.

There exists a unique projection $\pi:\mathcal{W}_{AA}\to\mathcal{A}$ of $\mathcal{W}_{AA}$ onto $\mathcal{A}$, which satisfies the conditional expectation property,

$$(AB^\pi)^\pi=A^\pi B^\pi,\quad \forall A,B\in\mathcal{W}_{AA},$$

and such that if U is a finite dimensional $\mathcal{U}_q\mathrm{u}(M)$-invariant subspace of Fock space and $A\in\mathcal{W}_{AA}$ leaves U invariant and commutes with $\mathcal{U}_q\mathrm{u}(M)$ on U, then

$$A^\pi|_U=A|_U.$$

Proof: Classically we would define $A^\pi=\int_G dg\ \mathrm{ad}(g)(A)$. Since we have quantum analogs of the adjoint action and the Haar measure we can make essentially the same definition.

Define

$$A^\pi=\left(1\otimes\int\right)\delta A,\quad A\in\mathcal{W}_{AA}.$$

It is clear that the projection is onto since if A is invariant, $A^\pi=A$,

$$A^\pi=\left(1\otimes\int\right)\delta A=\left(1\otimes\int\right)(A\otimes 1)=A.$$

We also have (suppressing the unit map)

$$\delta A^\pi=\delta\left(\left(1\otimes\int\right)\delta A\right)=\left(1\otimes 1\otimes\int\right)(\delta\otimes 1)\delta A=\left(1\otimes 1\otimes\int\right)(1\otimes\Delta)\delta A=\left(1\otimes\int\right)\delta A=A^\pi\otimes 1.$$

Therefore, A^π is invariant by definition and so commutes with the action of $\mathcal{U}_q\mathrm{u}(M)$ by Theorem 12.

We also have the conditional expectation,

$$(AB^\pi)^\pi=\left(1\otimes\int\right)\delta(AB^\pi)=\left(1\otimes\int\right)(\delta A)(B^\pi\otimes 1)=A^\pi B^\pi.$$

Finally, assume U is a finite dimensional $\mathcal{U}_q\mathrm{u}(M)$ and A-invariant subspace on which the two commute. For any $\mathrm{u}\in U$,

$$(\delta A)\mathrm{u}=A\mathrm{u}\otimes 1,$$

since this is just the dual of the statement that A is invariant under the $\mathcal{U}_q\mathrm{u}(M)$-action when restricted to U, using the nondegeneracy of the Hopf pairing. It follows that

$$A^{\pi}\mathrm{u}=\left[\left(1\otimes\int\right)(\delta A)\right]\mathrm{u}=\left(1\otimes\int\right)(A\mathrm{u}\otimes 1)=A\mathrm{u}.$$

■

Theorem 16: Let q be a nonroot of unity. The decomposition of the joint metaplectic action of $\mathcal{U}_q\mathrm{u}(M)$, $\mathcal{U}_q\mathrm{u}(m,n)$ *is of the form*

$$\mu\simeq\bigoplus_i \rho_i\otimes\rho_i',$$

where ρ_i *and* ρ_i' *are irreducible representations of* $\mathcal{U}_q\mathrm{u}(M)$ *and* $\mathcal{U}_q\mathrm{u}(m,n)$, *respectively. Furthermore, there is bijection between these representations such that* ρ_i *only occurs with* ρ_i' *and vice versa; this is the duality correspondence.*

Proof: Let P denote the polynomial subspace on which the dual pair act. With respect to the $\mathcal{U}_q\mathrm{u}(M)$ action there will be an isotypic decomposition

$$P\simeq\bigoplus_{i=0}^{\infty} I_i.$$

By irreducibility, $\mathcal{W}_{AA}$ is dense on the representation space, so the restriction to any finite dimensional subspace will be the full endomorphism algebra. The isotypic components I_i are a direct sum of $\mathcal{U}_q\mathrm{u}(M)$-invariant finite dimensional spaces. On any invariant finite dimensional subspace $U\subset I_i$, the full commutant of $\mathcal{U}_q\mathrm{u}(M)$ in End(U) will just be the restriction of $\mathcal{U}_q\mathrm{u}(m,n)$ to U by Lemma 15. Then the double commutant theorem says that U is an irreducible representation under the action of $\mathcal{U}_q\mathrm{u}(M)\otimes\mathcal{U}_q\mathrm{u}(m,n)$. Since U was arbitrarily large, however, this must also hold for I_i, and so $I_i=V_i\otimes V_i'$, where V_i and V_i' are the spaces on which ρ_i and ρ_i' act, where these are irreducible representations of $\mathcal{U}_q\mathrm{u}(M)$ and $\mathcal{U}_q\mathrm{u}(m,n)$, respectively. It also follows by the lemma that for any $i\neq j$ there exists an element $X\in\mathcal{U}_q\mathrm{u}(m,n)$ which is 0 on I_i but nonzero on I_j. Thus we obtain the duality correspondence. ■

As an immediate consequence of the duality, we see that certain aspects of the Clebsch–Gordon theory of $\mathcal{U}_q\mathrm{u}(m,n)$ can be addressed by looking at $\mathcal{U}_q\mathrm{u}(M)$. For example, we give the quantum analog of Theorem 4.6 of Ref. 8. Let ρ_1 and ρ_2 be irreducible representations of $\mathcal{U}_q\mathrm{u}(m,n)$ which arise in the decomposition of $\otimes^M\mu_{(m,n)}$ and $\otimes^N\mu_{(m,n)}$, respectively, where $\mu_{(m,n)}$ is the metaplectic representation of $\mathcal{U}_q\mathrm{u}(m,n)$. We wish to consider the decomposition of $\rho_1\otimes\rho_2$ into irreducibles.

Theorem 17: Let ρ_1,ρ_2 *be as above then the duality theory allows one to associate to them the representations* ρ_1' *and* ρ_2' *of* $\mathcal{U}_q\mathrm{u}(M)$ *and* $\mathcal{U}_q\mathrm{u}(N)$, *respectively. If* ρ_3 *is an irreducible representation of* $\mathcal{U}_q\mathrm{u}(m,n)$ *occurring in* $\rho_1\otimes\rho_2$, *then its multiplicity in that space is the same as the multiplicity of the irreducible* $\mathcal{U}_q\mathrm{u}(M)\otimes\mathcal{U}_q\mathrm{u}(N)$*-module occurring in* ρ_3', *where* ρ_3', *is the irreducible representation of* $\mathcal{U}_q\mathrm{u}(M+N)$ *associated to* ρ_3 *via duality.*

Proof: Note first that the representation space of $\otimes^M\mu_{(m,n)}$ is acted on by $\mathcal{U}_q\mathrm{u}(M)$ and that furthermore, $\mathcal{U}_q\mathrm{u}(m,n)$ and $\mathcal{U}_q\mathrm{u}(M)$ form a dual pair; similarly for $\mathcal{U}_q\mathrm{u}(N)$ and $\mathcal{U}_q\mathrm{u}(M+N)$.

The result follows by applying the duality theory for $\mathcal{U}_q\mathrm{u}(m,n)$ when paired with $\mathcal{U}_q\mathrm{u}(M)$, $\mathcal{U}_q\mathrm{u}(N)$, and $\mathcal{U}_q\mathrm{u}(M+N)$. ■

Singularities at the tip of a plane angular sector

Joseph B. Keller[a)]
Departments of Mathematics and Mechanical Engineering, Stanford University, Stanford, California 94305-2125

(Received 27 April 1998; accepted for publication 16 October 1998)

Solutions of the Helmholtz and Laplace equations in three dimensions which vanish, or have vanishing normal derivative on an angular sector of opening angle β, are considered. The solutions are required to be functions of distance from the tip of the sector multiplied by functions of the angular coordinates. The angular functions are eigenfunctions of the Laplace–Beltrami operator on the unit sphere, which vanish or have vanishing normal derivative, on a great circle arc of length β. It is shown that the Dirichlet eigenvalues are nondecreasing functions of β, and the Neumann eigenvalues are nonincreasing. Furthermore, each Dirichlet eigenvalue of a sector of angle β is a Neumann eigenvalue of a sector of angle $2\pi-\beta$ and conversely. The eigenvalues for $\beta=0$, π, and 2π are found explicitly. These results lead to a qualitative description of the eigenvalues as functions of β. The eigenvalues determine the singular behavior of the solutions at the tip. © *1999 American Institute of Physics.* [S0022-2488(99)02002-2]

I. INTRODUCTION

We consider two boundary value problems in R^3 for the Helmholtz equation:

$$(\Delta+k^2)u=0, \quad x\notin S_\beta, \quad u(x)=0, \quad x\in S_\beta, \tag{1.1D}$$

$$(\Delta+k^2)u=0, \quad x\notin S_{\beta_1}, \quad \partial_n u(x)=0, \quad x\in S_\beta. \tag{1.1N}$$

Here S_β is a plane angular sector of opening angle β, $0\leq\beta\leq 2\pi$, and k is a real constant. We call (1.1D) the Dirichlet problem and (1.1N) the Neumann problem, and we seek solutions of the product form

$$\begin{aligned} u(x)&=k^{-\nu}j_\nu(kr)U(\theta,\varphi), \quad k\neq 0,\\ u(x)&=r^\nu U(\theta,\varphi), \quad k=0. \end{aligned} \tag{1.2}$$

The spherical Bessel function $j_\nu(kr)$ tends to $(kr)^\nu$ as kr tends to zero, so both expressions in (1.2) behave like r^ν near $r=0$. Thus the exponent ν determines the behavior of u at the tip of the plane angular sector, so it is important in scattering from objects with such tips. Therefore, we shall study the values of ν and their dependence upon β.

Upon using (1.2) in (1.1) we find that ν is an eigenvalue and U is the corresponding eigenfunction of one of the following problems:

$$BU+\nu(\nu+1)U=0, \quad (\theta,\varphi)\notin C_\beta, \quad U=0, \quad (\theta,\varphi)\in C_\beta, \tag{1.3D}$$

$$BU+\nu(\nu+1)U=0, \quad (\theta,\varphi)\notin C_\beta, \quad \partial_n U=0, \quad (\theta,\varphi)\in C_\beta. \tag{1.3N}$$

In (1.3), B is the Laplace–Beltrami operator on the unit sphere and C_β is the great circle arc of length β in which the plane angular sector S_β intersects the unit sphere.

[a)]Electronic mail: keller@math.stanford.edu

To describe our results we write $\nu_j = D_j(\beta)$ and $\nu_j = N_j(\beta)$ for the jth Dirichlet and Neumann eigenvalue, respectively, $j = 1,2,...$. In Sec. II we shall prove the following theorems:

Theorem 1:

(a) $D_j(\beta)$ is a nondecreasing function of $\beta, j = 1,2,...$.
(b) $N_j(\beta)$ is a nonincreasing function of $\beta, j = 1,2,...$.

Theorem 2: Every Dirichlet eigenvalue $D_j(\beta)$ is equal to some Neumann eigenvalue $N_{j'}(2\pi - \beta)$, and conversely: $D_j(\beta) = N_{j'}(2\pi - \beta)$.

Note that Theorem 2 and either part of Theorem 1 implies the other part of Theorem 1. In Sec. III, Theorem 3, we give $D_j(\beta)$ and $N_j(\beta)$ for all j and $\beta = 0$, π, and 2π. In Theorem $2^\sharp$ of Sec. IV, we give the relation between the values of j and j' which appear in Theorem 2.

The preceding results enable us to determine the qualitative behavior of all the eigenvalues as functions of β, as we shall show in Figs. 1 and 2. Therefore they supplement the numerical results obtained for the first few eigenvalues by Kraus and Levine,[1] Blume and Kirchner,[2] Blume and Kahl,[3] De Smedt and Van Bladel,[4,5] Boersma,[6] and Abawi *et al.*[7] Kraus and Levine[1] reduced (1.3) to two problems for two Lamé ordinary differential equations by separation of variables in spheroconal coordinates. Boersma[6] proved the special case of Theorem 2 for $j = 1$ and $j' = 2$, and we make use of his idea to prove it in general. Abawi *et al.*[7] proved that for $0 < \beta < \pi$, $D_j(\beta)$ lies between an integer n and $n + 1/2$ when the eigenfunction is even and $N_j(\beta)$ lies between $m + 1/2$ and m when the eigenfunction is odd, where m is an integer. These results follow from our Theorems 1 and 3. They also derived large j asymptotic formulas for $D_j(\beta)$ and $N_j(\beta)$.

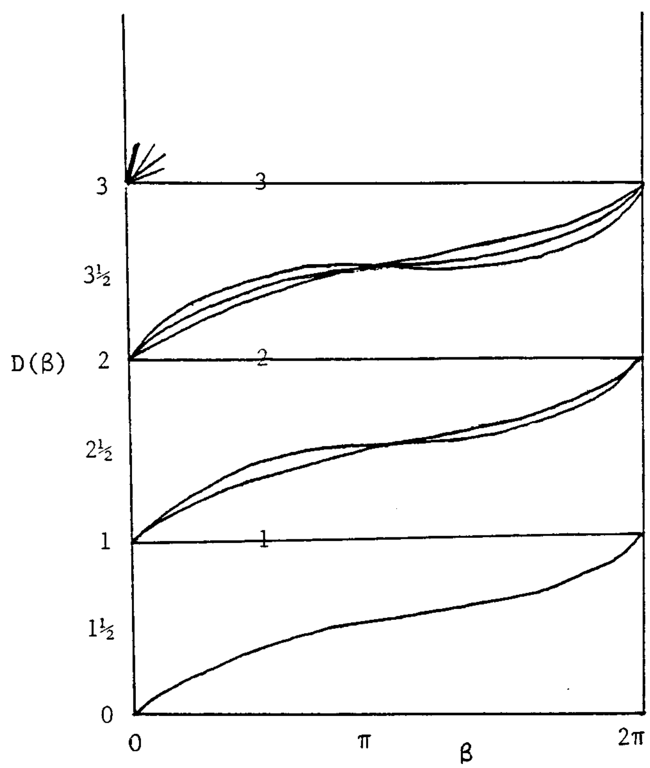

FIG. 1. Sketch of the Dirichlet eigenvalues $D_j(\beta)$ as functions of β. At $\beta = 0$, $D_j(0) = n$ with multiplicity $2n + 1$. Of them, n remain constant as β increases, and $n + 1$ increase. These $n + 1$ all equal $n + \frac{1}{2}$ at $\beta = \pi$ and all equal $n + 1$ at $\beta = 2\pi$.

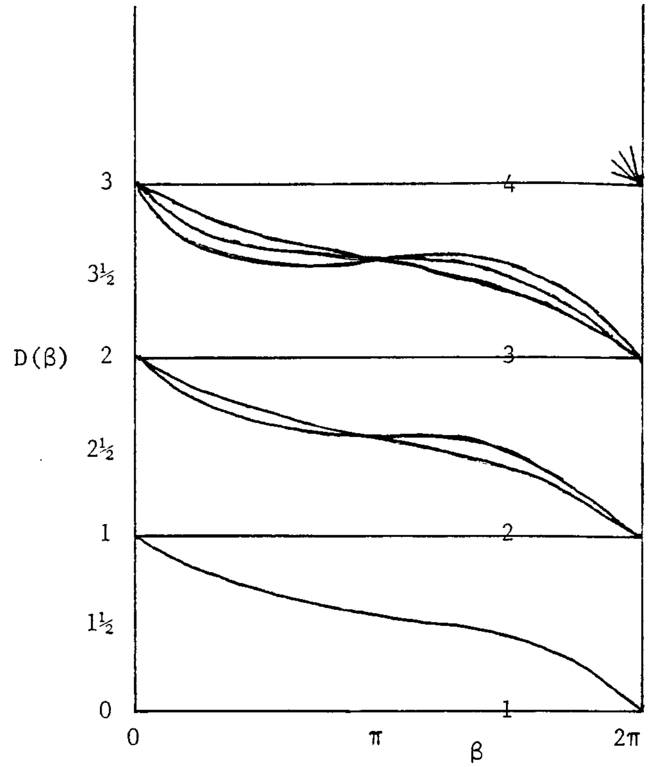

FIG. 2. Sketch of the Neumann eigenvalues $N_j(\beta)$ as functions of β. At $\beta=2\pi$, $N_j(2\pi)=n$ with multiplicity $2n+2$. Of them, $n+1$ remain constant and $n+1$ increase as β decreases. The increasing $n+1$ all equal $n+\frac{1}{2}$ at $\beta=\pi$ and all equal $n+1$ at $\beta=0$. There the multiplicity of $N_j(0)=n+1$ is $2(n+1)+1$. According to Theorem 2, Figs. 1 and 2 are mirror images of one another about the vertical line $\beta=\pi$. For each n, the numbers of constant eigenvalues differ by one.

II. PROOFS OF THEOREMS 1 AND 2

To prove Theorem 1 we recall that each eigenvalue is determined by the Courant minimax principle. For the Dirichlet problem, the admissible functions must vanish on the arc C_β. Since this arc increases with β, the class of admissible functions decreases as β increases. Therefore, the mimimax does not decrease as β increases, which proves part (a).

For the Neumann problem, the boundary condition is a natural condition, so it does not restrict the admissible functions. In fact, the admissible functions may be discontinuous across C_β, so as β increases, the class of admissible functions increases. Therefore, the minimax does not increase as β increases, which proves part (b), and completes the proof of Theorem 1.

To prove Theorem 2 we suppose that the plane angular sector lies in the plane $z=0$. The operator Δ in (1.1) is even in z. Therefore the even and odd parts of each solution u of (1.1) are also solutions of (1.1), so we can consider only even and odd solutions. Let $v_j^D(\beta)$ be an even eigenfunction of (1.1D) corresponding to the eigenvalue $D_j(\beta)$. Then the normal derivative of $v_j^D(\beta)$ vanishes in the complementary sector $S_{2\pi-\beta}$. Therefore the odd function $(\operatorname{sgn} z)v_j^D(\beta)$ has vanishing normal derivative on both sides of $S_{2\pi-\beta}$. Furthermore it is continuous across S_β because it vanishes there, and its normal derivative is continuous across S_β because $v_j^D(\beta)$ is even. Thus $(\operatorname{sgn} z)v_j^D(\beta)$ is a solution of (1.1N) with $S_{2\pi-\beta}$ instead of S_β and with the eigenvalue $\nu=D_j(\beta)$. Therefore $D_j(\beta)$ is also a Neumann eigenvalue of $S_{2\pi-\beta}$, say $N_{j'}(2\pi-\beta)$. Thus $D_j(\beta)=N_{j'}(2\pi-\beta)$. On the other hand, if $v_{j'}^N(2\pi-\beta)$ is an odd eigenfunction of (1.1N) with eigenvalue $N_{j'}(2\pi-\beta)$ then $(\operatorname{sgn} z)v_{j'}^N(2\pi-\beta)$ is a solution of (1.1D) with S_β instead of $S_{2\pi-\beta}$ and with eigenvalue $N_{j'}(2\pi-\beta)$. Therefore $N_{j'}(2\pi-\beta)$ is a Dirichlet eigenvalue of S_β, say $D_j(\beta)$, so $N_{j'}(2\pi-\beta)=D_j(\beta)$.

We have now shown that every Dirichlet eigenvalue $D_j(\beta)$ with an even eigenfunction is equal to some Neumann eigenvalue $N_j(2\pi-\beta)$ with an odd eigenfunction, and conversely. Next we consider a Dirichlet eigenvalue $D_j(\beta)$ with an odd eigenfunction. Such an eigenfunction must vanish on the entire plane $z=0$. Therefore it is a Dirichlet eigenfunction of S_β with eigenvalue $D_j(\beta)$ for every value of β in the interval $0\leqslant\beta\leqslant 2\pi$. In particular, $D_j(\beta)$ is a Dirichlet eigenvalue for $\beta=2\pi$. In Theorem 3, we shall show that every such eigenvalue is also a nonzero Neumann eigenvalue for $\beta=2\pi$, and also for every value of β in $0\leqslant\beta\leqslant 2\pi$, with the corresponding eigenfunction being even. In the same way we can show that every Neumann eigenvalue $N_{j'}(2\pi-\beta)$ with an even eigenfunction is also a Dirichlet eigenvalue $D_j(\beta)$ with an odd eigenfunction. This completes the proof of Theorem 2.

III. EIGENVALUES AND EIGENFUNCTIONS FOR $\beta=0,\pi,2\pi$

Now we shall determine the solutions of (1.3) explicitly by separation of variables in spherical polar coordinates for three special angles $\beta=0,\pi,2\pi$. For $\beta=0$, the boundary conditions are irrelevant, as can be shown by reformulating each problem in variational form. The consequence is that for both problems the eigenfunctions and eigenvalues are exactly those for the full sphere, which are just the spherical harmonics:

$$\begin{aligned} Y^e_{nm}(\theta,\varphi)&=P^m_n(\cos\theta)\cos m\varphi, \quad \nu=n, \quad m=0,1,...,n, \quad n=0,1,2,...,\\ Y^o_{nm}(\theta,\varphi)&=P^m_n(\cos\theta)\sin m\varphi, \quad \nu=n, \quad m=1,...,n, \quad n=1,2,... . \end{aligned} \tag{3.1}$$

Thus the multiplicity of the eigenvalue n is $2n+1$. To find the jth eigenvalues $D_j(0)$ and $N_j(0)$, we count the number of eigenvalues less than n with their multiplicities. This is just the sum of $2n'+1$ from $n'=0$ to $n'=n-1$, which is exactly n^2. Therefore we have

$$D_j(0)=N_j(0)=n, \quad j=n^2+m, \quad m=1,...,2n+1, \quad n=0,1,2,... . \tag{3.2}$$

To solve (1.3) for $\beta=2\pi$, we assume that the plane angular sector is the plane $z=0$ so that the great circle $C_{2\pi}$ is the circle $\theta=\pi/2$. The solutions of (1.3D) are those spherical harmonics (3.1) which vanish on $\theta=\pi/2$, and they are just the ones for which $P^m_n(\cos\theta)$ is an odd function of $\cos\theta$. Similarly the solutions of (1.3N) are those solutions (3.1) for which $P^m_n(\cos\theta)$ is an even function of $\cos\theta$. Since $P^m_n(-\cos\theta)=(-1)^{n+m}P^m_n(\cos\theta)$, the eigenfunction Y^e_{nm} or Y^o_{nm} is an odd or even function of $\cos\theta$ depending on whether $n+m$ is odd or even. It follows that n of the Y_{nm} are odd and $n+1$ are even. Therefore for (1.3D), $\nu=n$ with multiplicity n, while for (1.3N), $\nu=n$ with multiplicity $n+1$. Thus counting the eigenvalues less than n we find

$$D_j(2\pi)=n, \quad j=\frac{n^2-n}{2}+m, \quad m=1,2,...,n, \quad n=1,2,..., \tag{3.3}$$

$$N_j(2\pi)=n, \quad j=\frac{n^2+n}{2}+m, \quad m=1,...,n+1, \quad n=0,1,2,... . \tag{3.4}$$

When $\beta=\pi$ the plane angular sector is a half-plane that we choose to be the half-plane $\varphi=0$, which is also $\varphi=2\pi$. Then the Dirichlet eigenfunctions are spherical harmonics that vanish at $\varphi=0$ and $\varphi=2\pi$. They are

$$\left.\begin{aligned} \tilde{U}^o_{nm}(\theta,\varphi)&=P^{-m+1/2}_{n-1/2}(\cos\theta)\sin(m-\tfrac{1}{2})\varphi, \quad &\nu=n-\tfrac{1}{2}\\ U^o_{nm}(\theta,\varphi)&=P^m_n(\cos\theta)\sin m\varphi, \quad &\nu=n \end{aligned}\right\} \begin{aligned} &m=1,2,...,n,\\ &n=1,2,... . \end{aligned} \tag{3.5}$$

Thus each of the two eigenvalues $\nu=n$ and $\nu=n-\frac{1}{2}$ has multiplicity n for $n=1,2,...$. Upon counting the number of eigenvalues less than $n-\frac{1}{2}$ with their multiplicities, we get $n(n-1)$, while the number less than n is n^2. Thus we have

$$\left.\begin{array}{ll} D_j(\pi)=n-\tfrac{1}{2}, & j=n(n-1)+m \\ D_j(\pi)=n, & j=n^2+m, \end{array}\right\} \begin{array}{l} m=1,2,\ldots,n \\ n=1,2,\ldots . \end{array} \tag{3.6}$$

The Neumann eigenfunctions for $\beta=\pi$ are

$$\tilde{U}^e_{nm}(\theta,\varphi)=P^{-m+1/2}_{n-1/2}(\cos\theta)\cos(m-\tfrac{1}{2})\varphi, \quad \nu=n-\tfrac{1}{2}, \quad m=1,\ldots,n, \quad n=1,2,\ldots,$$

$$U^e_{nm}(\theta,\varphi)=P^m_n(\cos\theta)\cos m\varphi, \quad \nu=n, \quad m=0,1,\ldots,n, \quad n=0,1,\ldots . \tag{3.7}$$

For $n=0,1,2,\ldots$ there is an eigenvalue $\nu=n$ with multiplicity $n+1$, while for $n=1,2,\ldots$ there is an eigenvalue $\nu=n-\frac{1}{2}$ with multiplicity n. Counting leads to

$$N_j(\pi)=n-\tfrac{1}{2}, \quad j=n^2+m, \quad m=1,2,\ldots,n, \quad n=1,2,\ldots=n,$$

$$N_j(\pi)=n, \quad j=n(n+1)+m, \quad m=1,2,\ldots,n+1, \quad n=0,1,2,\ldots . \tag{3.8}$$

We shall summarize the preceding results as a theorem.

Theorem 3(a): The eigenvalues $D_j(0)$ and $N_j(0)$ are given by (3.2) and the corresponding eigenfunctions are given by (3.1).

(b): The eigenvalues $D_j(\pi)$ and $N_j(\pi)$ are given by (3.6) and (3.8), respectively, while the corresponding eigenfunctions are given by (3.5) and (3.7), respectively. The plane angular sector is the half-plane $\varphi=0$ and $\varphi=2\pi$.

(c): The eigenvalues $D_j(2\pi)$ and $N_j(2\pi)$ are given by (3.3) and (3.4), respectively, while the corresponding eigenfunctions are given by (3.1) with $n+m$ odd for $D_j(2\pi)$ and $n+m$ even for $N_j(2\pi)$. The plane angular sector is the plane $\theta=\pi/2$.

We note that the Dirichlet and Neumann eigenfunctions and eigenvalues for $\beta=2\pi$ are also eigenfunctions and eigenvalues for any value of β in $0\leqslant\beta\leqslant2\pi$. This is so because they vanish or have vanishing normal derivative on the whole plane $\theta=\pi/2$. Therefore they satisfy the differential equation and boundary conditions (1.3D) or (1.3N), respectively. Of course they are not all the eigenfunctions and eigenvalues. We shall state this as a corollary.

Corollary: Each eigenvalue $D_j(2\pi)=n$ with multiplicity n and $N_j(2\pi)=n$ with multiplicity $n+1$ is an eigenvalue with the same multiplicity, for every value of β in $0\leqslant\beta\leqslant2\pi$. It is not necessarily the jth one unless $\beta=2\pi$.

It is also possible to calculate the derivative with respect to β of each eigenvalue at $\beta=0,\pi$, and 2π. One way to do this is to use the Lamé ordinary differential equations obtained by Kraus and Levine,[1] which simplify at these values of β to the equations for Legendre functions and for trigonometric functions. Another way is to use the method of Ward and Keller,[8] which treats strong localized perturbations of eigenvalue problems, including perturbations of boundaries.

We have applied the latter method to calculate the derivative of the lowest Dirichlet eigenvalue at $\beta=\pi$, and we have obtained

$$D_1'(\pi)=\frac{1}{2\pi}. \tag{3.9}$$

This is just the slope of the straight line in the plane of β and $D_1(\beta)$ through the three points $[0,D_1(0)=0]$, $[\pi,D_1(\pi)=\frac{1}{2}]$, and $[2\pi,D_1(2\pi)=1]$.

We also find

$$D'_{m(n-1)+m}(\pi)\neq 0, \quad m=1$$

$$D'_{m(n-1)+m}(\pi)=0, \quad m=2,3,\ldots,n. \tag{3.10}$$

IV. CONCLUSION

Now we shall use our theorems and corollary to describe the overall behavior of the eigenvalues as functions of β. Let us begin with the Dirichlet eigenvalues $D_j(\beta)$ (See Fig. 1.) Theorem 3(a) shows via (3.2) that at $\beta=0$ each integer $n\geqslant 0$ is an eigenvalue with multiplicity $2n+1$. The corollary shows that of the $2n+1$ eigenvalues equal to n, n of them remain constant as β increases from 0 to 2π. The other $n+1$ are nondecreasing functions of β according to Theorem 1(a). At $\beta=\pi$ these $n+1$ eigenvalues have increased to the value $(n+1)-\frac{1}{2}=n+\frac{1}{2}$, as shown by Theorem 3(b) via (3.6) with n replaced by $n+1$. At $\beta=2\pi$ these $n+1$ eigenvalues have increased to the value $n+1$, as Theorem 3(c) shows, via (3.3) with n replaced by $n+1$.

Figure 2 displays the Neumann eigenvalues $N_j(\beta)$ as functions of β. Theorem 3(a) shows via (3.2) that at $\beta=0$ each integer $n\geqslant 0$ is an eigenvalue with multiplicity $2n+1$. The corollary shows that $n+1$ of them remain equal to n as β increases. Theorem 1(b) shows that the remaining n of them are nonincreasing functions of β. In Fig. 2, the $2n+1$ eigenvalues which equal $n+1$ at $\beta=0$ are shown. Of them, $n+2$ remain constant and $n+1$ decrease as β increases, reaching the value $n+\frac{1}{2}$ at $\beta=\pi$ and n at $\beta=2\pi$.

Theorem 2 implies that Figs. 1 and 2 are mirror images of one another about the vertical line $\beta=\pi$. The multiplicity of the constant eigenvalues, i.e., those independent of β, is greater by one in Fig. 2 than it is in Fig. 1. By using Figs. 1 and 2 we can determine the value of j' corresponding to j in Theorem 2. We can express the result as the following more precise form of Theorem 2:
Theorem 2#(a): For $n\geqslant 0$ and $s=1,2,...,n-1$,

$$D_{n^2+n+s}(\beta)=N_{(n+1)^2+s}(2\pi-\beta).$$

(b): For $n\geqslant 1$,

$$\begin{aligned} n&=D_{n^2+1}(\beta)=D_{n^2+2}(\beta)=\cdots=D_{n^2+n}(\beta)\\ &=N_{(n+1)^2-n}(2\pi-\beta)=\cdots=N_{(n+1)^2-1}(2\pi-\beta)\\ &=N_{(n+1)^2}(2\pi-\beta). \end{aligned}$$

Characteristic surface data for the eikonal equation

Ezra T. Newman and Alejandro Perez
Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260

(Received 14 September 1998; accepted for publication 24 September 1998)

A method of solving the eikonal equation, in either flat or curved space–times, with arbitrary Cauchy data, is extended to the case of data given on a characteristic surface. We find a beautiful relationship between the Cauchy and characteristic data for the same solution, namely they are related by a Legendre transformation. From the resulting solutions, we study and describe the wave-front singularities that are associated with their level surfaces (the characteristic surfaces or ''big wave fronts''). © *1999 American Institute of Physics.* [S0022-2488(99)03301-0]

I. INTRODUCTION

The high frequency limit of the wave equation is given by the eikonal equation, written in an arbitrary space–time as

$$g^{ab}(x^a)\partial_a S(x^a)\partial_b S(x^a)=0, \tag{1}$$

where the $x^a=(x^i,t)$ are any local coordinates, and $g^{ab}(x^a)$ is the metric of the given space–time. The level surfaces of a solution of Eq. (1), $S(x^a)=\text{const}$ (which need not be smooth every place and could have self-intersections), are three-dimensional characteristic surfaces (the ''big wave fronts'' in the terminology of Arnold[1]), and the sections $t=\text{constant}$ of these surfaces are the two-dimensional (''small'') wave fronts. The vector field $l^a=g^{ab}\partial_b S$ is tangent to the null geodesic that generate the characteristic surfaces.

In flat space–time the eikonal equation becomes

$$\eta^{ab}\partial_a S\partial_b S=(\partial_t S)^2-(\partial_x S)^2-(\partial_y S)^2-(\partial_z S)^2=0. \tag{2}$$

In Sec. II we review the method[2] to give a general solution of the eikonal equation in flat space–time adapted to appropriate Cauchy data given at $t=t_0$. In Sec. III we modify the method so that the eikonal equation is solved with arbitrary *characteristic* data given at null infinity. The relation between both methods is studied in Sec. IV where we find that the Cauchy and characteristic data are related by a Legendre transformation. The wave-front singularities of the level surfaces of the resulting solutions are described parametrically in Sec. V and finally the generalization of our results to asymptotically flat spaces–times is given in Sec. VI.

II. SOLUTIONS OF THE EIKONAL EQUATION

From the point of view of the theory of partial differential equation, the eikonal equation is a homogeneous first-order nonlinear partial differential equation; there exists a solution S^*, called the ''complete integral,'' depending on three arbitrary constants,[3] e.g., in flat space–time the function

$$S^*(x^i,t,\alpha_i)=x^i\alpha_i-t\sum\ (\alpha_i)^2 \tag{3}$$

is easily seen to satisfy (2).

Remark 1: The fact that the equation is homogeneous plays no role in this section, but will be crucial in the generalization to characteristic data.

Remark 2: From now on we will treat the problem of the eikonal in flat space; we leave the discussion of general space–times to the end.

It is possible to generate a ''general integral,'' i.e., a solution of the eikonal equation depending on an arbitrary function, by means of the following procedure: First, define the function $S^{**}(x^i,t,\alpha_i)$ of the coordinates and the free parameters α_i as

$$S^{**}(x^i,t,\alpha_i)\equiv S^*(x^i,t,\alpha_i)-H(\alpha_i), \tag{4}$$

where $H(\alpha_i)$ is any function of the α_i's.

Next, think of the α_i's as functions of the space–time points obtained from the following conditions:

$$\partial S^{**}/\partial\alpha_i=\partial S^*/\partial\alpha_i-\partial H/\partial\alpha_i=0. \tag{5}$$

Equation (5) determine the space–time dependence of the α_i's $[\alpha_i=A_i(x^i,t)]$ given that

$$\left|\frac{\partial^2 S^{**}(x^i,t,\alpha_i)}{\partial\alpha_i\partial\alpha_j}\right|\neq 0. \tag{6}$$

This condition can fail in lower dimensional regions called the caustics. This issue will be returned to in Sec. V.

Substituting $\alpha_i=A_i(x^i,t)$ into Eq. (4) we eliminate the α_i, and obtain

$$S^{**}(x^i,t)=S^*(x^i,t,A_i(x^i,t))-H(A_i(x^i,t)). \tag{7}$$

It is easy to verify that, because of the condition (5),

$$\partial_a S^{**}=\partial_a S^*, \tag{8}$$

which means that $S^{**}(x^i,t)$ is a new solution of the eikonal equation (1) determined by an arbitrary function H. We can determine the free function H so that the solution (7) satisfies initial Cauchy data at $t=t_0$. We denote the Cauchy data by $S_{\text{Cauchy}}(x^i)$. Conditions (5) imply that at $t=t_0$, $\alpha_i=\partial S_{\text{Cauchy}}/\partial x^i$. Inverting these relations we obtain $x^i=X^i(\alpha_i)$, and replacing them in (7) at $t=t_0$ we find the sought for relation:

$$H(\alpha_i)=S^*(X^i(\alpha_i),t_0,\alpha_i)-S_{\text{Cauchy}}(X^i(\alpha_i)). \tag{9}$$

This last equation relates the arbitrary function $H(\alpha_i)$ with the Cauchy data, $S_{\text{Cauchy}}(x^i)$, at $t=t_0$ and allows us to construct solutions of the eikonal equation in flat space–time for any initial data.

We now change the set of the α_i's for new parameters that are more appropriate to the study of asymptotically flat spaces and we rewrite our previous equations in terms of them. A complete integral of the eikonal equation, Eq. (1), can be written in terms of new parameters $(\beta,\zeta,\bar{\zeta})$ as

$$S^*(x^a,\beta,\zeta,\bar{\zeta})=\beta x^a l_a(\zeta,\bar{\zeta}), \tag{10}$$

where

$$l_a(\zeta,\bar{\zeta})=\frac{1}{\sqrt{2}(1+\zeta\bar{\zeta})}((1+\zeta\bar{\zeta}),(\zeta+\bar{\zeta}),-i(\zeta-\bar{\zeta}),(\zeta\bar{\zeta}-1)) \tag{11}$$

is the null covector pointing in the $(\zeta,\bar{\zeta})$ direction. The $(\zeta,\bar{\zeta})$ are the stereographic coordinates that parametrize the sphere of null directions.

From (10) and (11), we get the relations between the new parameters $(\beta,\zeta,\bar{\zeta})$, and the old α's:

$$\alpha_1 = \frac{\beta}{\sqrt{2}} \frac{\zeta + \bar{\zeta}}{1 + \zeta\bar{\zeta}}, \quad \alpha_2 = -i \frac{\beta}{\sqrt{2}} \frac{\zeta - \bar{\zeta}}{1 + \zeta\bar{\zeta}}, \quad \alpha_3 = \frac{\beta}{\sqrt{2}} \frac{\zeta\bar{\zeta} - 1}{1 + \zeta\bar{\zeta}^2}, \tag{12}$$

and

$$\beta = \sqrt{2 \sum \alpha_i^2}. \tag{13}$$

In terms of the new parameters Eq. (4) reads:

$$S^{**}(x^a, \beta, \zeta, \bar{\zeta}) = \beta x^a l_a(\zeta, \bar{\zeta}) - H(\beta, \zeta, \bar{\zeta}), \tag{14}$$

where $H(\beta,\zeta,\bar{\zeta})$ is an arbitrary function that will be determined by the initial conditions. Conditions (5) on $(\beta,\zeta,\bar{\zeta})$ become

$$x^a l_a(\zeta, \bar{\zeta}) - \frac{\partial H}{\partial \beta}(\beta, \zeta, \bar{\zeta})|_{\zeta,\bar{\zeta}} = 0, \tag{15}$$

$$\beta x^a m_a(\zeta, \bar{\zeta}) - \eth H(\beta, \zeta, \bar{\zeta})|_{\beta} = 0, \tag{16}$$

$$\beta x^a \bar{m}_a(\zeta, \bar{\zeta}) - \bar{\eth} H(\beta, \zeta, \bar{\zeta})|_{\beta} = 0. \tag{17}$$

Remark 3: We have replaced the derivatives with respect to ζ and $\bar{\zeta}$, respectively, by

$$\eth = (1 + \zeta\bar{\zeta}) \frac{\partial}{\partial \bar{\zeta}}, \quad \bar{\eth} = (1 + \zeta\bar{\zeta}) \frac{\partial}{\partial \zeta},$$

and used the fact that $\eth l_a(\zeta,\bar{\zeta}) = m_a$ and $\eth\bar{\eth} l_a = n_a - l_a$ where $(l_a, n_a, m_a, \bar{m}_a)$ form a null Minkowski space tetrad for each $(\zeta,\bar{\zeta})$.

The function $H(\beta,\zeta,\bar{\zeta})$ can be determined by means of the same procedure using the conditions $\alpha_i = \partial S_{\text{Cauchy}}/\partial x^i$ at $t = t_0$ and relations (12) to obtain the $x^i = X^i(\beta,\zeta,\bar{\zeta})$, and finally rewriting (9)

$$H(\beta,\zeta,\bar{\zeta}) = S^*(X^i(\beta,\zeta,\bar{\zeta}), t_0, \beta, \zeta, \bar{\zeta}) - S_{\text{Cauchy}}(X^i(\beta,\zeta,\bar{\zeta})).$$

III. CHARACTERISTIC DATA FOR THE EIKONAL EQUATION

The eikonal equation, being hyperbolic, admits a characteristic formulation. Even though the results of this section can be applied to any characteristic hypersurface in Minkowski, in flat space (as in any asymptotically simple space–time) there are two preferred characteristic surfaces, namely future and past null infinity, respectively. In the following we will formulate the characteristic problem in terms of data given at future null infinity, $\mathfrak{I}^+$. $\mathfrak{I}^+$ has the topology of $S^2 \times R$; we choose Bondi coordinates on it, namely $(\zeta,\bar{\zeta})$ on the S^2 and the retarded time u_B along R. In an analogous manner as for the Cauchy problem, the characteristic data at future null infinity will be defined by a function of $(u_B,\zeta,\bar{\zeta})$:

$$S_{\text{characteristic}} = L(u_B, \zeta, \bar{\zeta}). \tag{18}$$

The goal of this section is to develop a method to construct solutions of the eikonal equation geometrically adapted to the characteristic data, Eq. (18), at $\mathfrak{I}^+$.

Remark 4: In asymptotically flat space–times, in the neighborhood of future null infinity, $\mathfrak{I}^+$, there is a preferred class of coordinates referred to as Bondi coordinates. Given a Bondi system

$(u_B,\zeta,\bar\zeta)$ *at* $\mathfrak{I}^+$, *a new system*[4] $(u,\zeta,\bar\zeta)$ *can be defined by* $(u,\zeta,\bar\zeta)=(L(u_B,\zeta,\bar\zeta),\zeta,\bar\zeta)$. *The characteristic data, (18), can be thought of as being generated by this coordinate change representing a one parameter family of arbitrary* $u=\mathrm{const}$ *slices of* $\mathfrak{I}^+$.

In flat space–times we can define a two parameter family of null surfaces by

$$S^*=x^a l_a(\zeta,\bar\zeta). \tag{19}$$

As was pointed out in Ref. 2, Eq. (19) has a dual interpretation. For $(\zeta,\bar\zeta)$ kept constant, its level surfaces define null planes intersecting the time axis at a time equal the value of S^* and with its direction given by $(\zeta,\bar\zeta)$; on the other hand, for a fixed value of x^a it represents the light cone cut at $\mathfrak{I}^+$ of the space–time point x^a in the interior, i.e., it represents the intersection of the null cone from x^a with $\mathfrak{I}^+$.

We can think of the characteristic data (18) geometrically, as defining a one parameter family of cuts at $\mathfrak{I}^+$ in terms of $u=L(u_B,\zeta,\bar\zeta)=\mathrm{const}$. [It is assumed that this can be inverted so that the cuts are given by $u_B=L^{-1}(u=\mathrm{const},\zeta,\bar\zeta)$.] With this point of view, we construct a solution of the eikonal equation (1) [corresponding to the characteristic data $L(u_B,\zeta,\bar\zeta)$], such that the family of null surfaces in the interior are defined by the null geodesics normal to the family of cuts at infinity given by $L(u_B,\zeta,\bar\zeta)=\mathrm{const}$. In order to do so we will generalize the method of Sec. II.

Defining

$$S^{**}(x^a,\zeta,\bar\zeta)=L(S^*,\zeta,\bar\zeta)=L(x^a l_a(\zeta,\bar\zeta),\zeta,\bar\zeta), \tag{20}$$

we see immediately that it is a solution of the eikonal equation depending on two free parameters. [Note the duplication of notation which arises from the different meanings to the same object; $S^*=u_B=x^a l_a(\zeta,\bar\zeta)$.] By putting the requirement on ζ and $\bar\zeta$ that $\eth S^{**}=\bar\eth S^{**}=0$, i.e.,

$$\begin{aligned}\dot L(S^*,\zeta,\bar\zeta)x^a m_a(\zeta,\bar\zeta)+\eth L(S^*,\zeta,\bar\zeta)=0,\\ \dot L(S^*,\zeta,\bar\zeta)x^a \bar m_a(\zeta,\bar\zeta)+\bar\eth L(S^*,\zeta,\bar\zeta)=0,\end{aligned} \tag{21}$$

where $\dot L\equiv\partial_{S'}L$. we can solve for ζ and $\bar\zeta$ in terms of x^a, i.e., Eq. (21) gives us

$$\zeta=\Gamma(x^a) \tag{22}$$

and

$$\bar\zeta=\bar\Gamma(x^a), \tag{23}$$

except at the caustics when[5]

$$\begin{vmatrix}\eth^2 S^{**} & \eth\bar\eth S^{**}\\ \eth\bar\eth S^{**} & \bar\eth^2 S^{**}\end{vmatrix}=0. \tag{24}$$

This issue will be discussed in Sec. V.

Finally replacing $(\zeta,\bar\zeta)$ in (20) and differentiating we find

$$\partial_a S^{**}(x^a,\Gamma(x^a),\bar\Gamma(x^a))=\dot L l_a(\Gamma(x^a),\bar\Gamma(x^a)). \tag{25}$$

Therefore, the function

$$S^{**}(x^a,\Gamma(x^a),\bar\Gamma(x^a)) \tag{26}$$

satisfies the eikonal equation, and by construction (20) it is adapted to the characteristic data defined by the function $L(u_B,\zeta,\bar\zeta)$ at $\mathscr{I}^+$. The null normals to level surfaces

$$S^{**}(x^a,\Gamma(x^a),\overline{\Gamma}(x^a))=\text{const} \tag{27}$$

are normal to the cuts $L(u_B,\zeta,\overline{\zeta})=\text{const.}$ at $\mathscr{I}^+$. Note that the fact that $S^{**}(x^a)$ is a new solution of the eikonal equation is a consequence of property of the eikonal equation of being homogeneous in $\partial_a S$.

IV. RELATION BETWEEN THE CAUCHY AND CHARACTERISTIC CONSTRUCTIONS

In this section we give the connection between the two methods of construction. Earlier we showed how to relate the Cauchy data, $S_{\text{Cauchy}}(x^t)$, with the arbitrary function $H(\beta,\zeta,\overline{\zeta})$ of Sec. II, so that any solution of the eikonal equation can be cast in the form of Eq. (14). Therefore, there must be a relationship of the characteristic construction to the construction via Cauchy data and hence a relationship between the functions $L(x^a l_a(\zeta,\overline{\zeta}),\zeta,\overline{\zeta})$ and $H(\beta,\zeta,\overline{\zeta})$.

We first note that though in both methods there is an arbitrary function of three variables, in the characteristic method there appear only two parameters $(\zeta,\overline{\zeta})$ while in the Cauchy method there are the three $(\beta,\zeta,\overline{\zeta})$.

We can reduce the three to two by solving Eq. (15),

$$x^a l_a(\zeta,\overline{\zeta})-\frac{\partial H}{\partial\beta}(\beta,\zeta,\overline{\zeta})=0, \tag{28}$$

for $\beta=\beta(x^a l_a,\zeta,\overline{\zeta})$ or changing notation and using $u_B=x^a l_a$, we have $\beta=\beta(u_B,\zeta,\overline{\zeta})$. Now thinking of (28) as an implicit relation defining either $u_B=U(\beta,\zeta,\overline{\zeta})\equiv(\partial H/\partial\beta)(\beta,\zeta,\overline{\zeta})$ or $\beta=\beta(u_B,\zeta,\overline{\zeta})$. Note that if we treat H as a function of $(u_B,\zeta,\overline{\zeta})$, i.e., $H=H(\beta(u_B,\zeta,\overline{\zeta}),\zeta,\overline{\zeta})$ then

$$\dot{H}\equiv\partial_{u_B}H|_{\zeta,\overline{\zeta}}=\frac{\partial H}{\partial\beta}(\beta,\zeta,\overline{\zeta})\dot{\beta} \tag{29}$$

or

$$\dot{\beta}=\frac{\dot{H}}{\partial H/\partial\beta}. \tag{30}$$

We replace $\beta=\beta(u_B,\zeta,\overline{\zeta})$ into the two conditions, Eqs. (16) and (17), obtaining

$$\begin{aligned}\beta(u_B,\zeta,\overline{\zeta})x^a m_a(\zeta,\overline{\zeta})-\eth H(\beta(u_B,\zeta,\overline{\zeta}),\zeta,\overline{\zeta})|_\beta=0,\\ \beta(u_B,\zeta,\overline{\zeta})x^a \overline{m}_a(\zeta,\overline{\zeta})-\overline{\eth} H(\beta(u_B,\zeta,\overline{\zeta}),\zeta,\overline{\zeta})|_\beta=0,\end{aligned} \tag{31}$$

which appear similar to Eq. (21), namely:

$$\begin{aligned}\dot{L}(u_B,\zeta,\overline{\zeta})x^a m_a(\zeta,\overline{\zeta})+\eth L(u_B,\zeta,\overline{\zeta})|_{u_B}=0,\\ \dot{L}(u_B,\zeta,\overline{\zeta})x^a \overline{m}_a(\zeta,\overline{\zeta})+\overline{\eth} L(u_B,\zeta,\overline{\zeta})|_{u_B}=0.\end{aligned} \tag{32}$$

We explicitly write $|_\beta$ and $|_{u_B}$ in the ð operators to mean that the angular derivatives are taken keeping β or u_B constant, respectively; also $\dot{L}$ means $\partial_{u_B}L|_{\zeta,\overline{\zeta}}$ for any $L(u_B,\zeta,\overline{\zeta})$.

Remark 5: As we mentioned earlier, Eqs. (31) *or* (32) *implicitly define* $\zeta=\Gamma(x^a)$ *and* $\overline{\zeta}=\overline{\Gamma}(x^a)$ *everywhere except at the caustics. They can be approached in a limiting fashion.*

Given an arbitrary function $F(\beta,\zeta,\overline{\zeta})$ and $\beta(u_B,\zeta,\overline{\zeta})$ there is the following relation between differential operators,

$$\eth F(\beta,\zeta,\bar{\zeta})|_{\beta}=\eth F(\beta,\zeta,\bar{\zeta})|_{u_B}-(\partial F/\partial\beta)(\beta,\zeta,\bar{\zeta})\eth\beta|_{u_B},$$
$$\bar{\eth} F(\beta,\zeta,\bar{\zeta})|_{\beta}=\bar{\eth} F(\beta,\zeta,\bar{\zeta})|_{u_B}-(\partial F/\partial\beta)(\beta,\zeta,\bar{\zeta})\bar{\eth}\beta|_{u_B}. \tag{33}$$

Using these relations to replace the $\eth$ and $\bar{\eth}$ derivative operators at β constant by operators at u_B constant in (32) we obtain:

$$\beta x^a m_a(\zeta,\bar{\zeta})-\eth H(\beta,\zeta,\bar{\zeta})|_{u_B}+(\partial H/\partial\beta)(\beta,\zeta,\bar{\zeta})\eth\beta|_{u_B}=0,$$
$$\beta x^a \bar{m}_a(\zeta,\bar{\zeta})-\bar{\eth} H(\beta,\zeta,\bar{\zeta})|_{u_B}+(\partial H/\partial\beta)(\beta,\zeta,\bar{\zeta})\bar{\eth}\beta|_{u_B}=0. \tag{34}$$

Applying relations (33) to the function $F=u_B=x^a l_a(\zeta,\bar{\zeta})$, thought of as $u_B=U(\beta,\zeta,\bar{\zeta})$, via the following steps:

$$\eth F(\beta,\zeta,\bar{\zeta})|_{\beta}=\eth(x^a l_a)=x^a m_a\,, \tag{35}$$

$$\eth F(\beta,\zeta,\bar{\zeta})|_{u}=\eth u|_{u}=0, \tag{36}$$

$$(\partial F/\partial\beta)\eth\beta|_{u_B}=(\partial u/\partial\beta)\eth\beta|_{u_B}=\dot{\beta}^{-1}\eth\beta|_{u_B}, \tag{37}$$

we get the following important equation:

$$\dot{\beta}x^a m_a=-\eth\beta|_{u_B}. \tag{38}$$

Finally inserting this relation, with Eq. (30), into (34) we obtain

$$\beta x^a m_a(\zeta,\bar{\zeta})-\eth H(\beta,\zeta,\bar{\zeta})|_{u_B}-\dot{H}x^a m_a(\zeta,\bar{\zeta})=0,$$
$$\beta x^a \bar{m}_a(\zeta,\bar{\zeta})-\bar{\eth} H(\beta,\zeta,\bar{\zeta})|_{u_B}-\dot{H}x^a \bar{m}_a(\zeta,\bar{\zeta})=0, \tag{39}$$

which can be rewritten as

$$\eth(u_B\beta-H)|_{u_B}+\frac{\partial}{\partial u_B}(u_B\beta-H)x^a m_a(\zeta,\bar{\zeta})=0,$$
$$\bar{\eth}(u_B\beta-H)|_{u_B}+\frac{\partial}{\partial u_B}(u_B\beta-H)x^a \bar{m}_a(\zeta,\bar{\zeta})=0. \tag{40}$$

Comparing Eq. (40) with (32) we see that they are identical when we set

$$L(u_B,\zeta,\bar{\zeta})=u_B\beta(u_B,\zeta,\bar{\zeta})-H(\beta(u_B,\zeta,\bar{\zeta}),\zeta,\bar{\zeta}). \tag{41}$$

From Eq. (28) we also have that

$$u_B=\partial H/\partial\beta, \quad \beta=\partial L/\partial u_B\,. \tag{42}$$

We see that the two data functions $L(u_B,\zeta,\bar{\zeta})$ and $H(\beta,\zeta,\bar{\zeta})$ are related by the Legendre transformation, Eqs. (41) and (42). We have finally arrived at a very simple and beautiful relation between the two methods. An essential property of the eikonal equation for this relationship is that it is homogeneous in $\partial_a S$.

V. PARAMETRIC DESCRIPTION OF THE WAVE FRONTS

Using the methods described above we can construct a general solution of the eikonal equation either for the Cauchy or the (corresponding) characteristic data. In Sec. IV we showed that they are simply related by a Legendre transformation in the variables u_B and β. Once we have the solution of the eikonal equation we can study the geometry of its wave fronts. In particular we are interested in the description of the singularities developed by them, namely, its caustics.

A key step in both methods consists of expressing the free parameters, e.g., $(\beta,\zeta,\bar{\zeta})$, contained in the formalism as functions of the space–time points, x^a. In many cases the problem of inverting Eqs. (15)–(17) or Eq. (21) in order to get either $(\zeta,\bar{\zeta})$ or $(\beta,\zeta,\bar{\zeta})$ as functions of the space–time coordinates x^a, can be a formidable task and at times impossible. However, it is not absolutely necessary, since it is possible to give a parametric description of the null surfaces defined by Eq. (14) or Eq. (26), respectively. (We follow the path given in Ref. 2 for the case of the stationary eikonal equation).

In the Cauchy case we have three parameters $(\zeta,\bar{\zeta},\beta)$ in the initial data for the eikonal equation. See Eq. (14). We introduce the new parameter r together with $(\zeta,\bar{\zeta},\beta)$ by means of the following equation:

$$r=\beta^{-1}\eth\bar{\eth}S^{**}=x^a(n_a-l_a)-\beta^{-1}\eth\bar{\eth}H(\beta,\zeta,\bar{\zeta})|_{\beta} \tag{43}$$

and the previous equations;

$$x^a l_a(\zeta,\bar{\zeta})-\frac{\partial H}{\partial\beta}(\beta,\zeta,\bar{\zeta})|_{\zeta,\bar{\zeta}}=0,$$

$$\beta x^a m_a(\zeta,\bar{\zeta})-\eth H(\beta,\zeta,\bar{\zeta})=0,\quad \beta x^a \bar{m}_a(\zeta,\bar{\zeta})-\bar{\eth}H(\beta,\zeta,\bar{\zeta})=0. \tag{44}$$

The four equations (44) and (43) can be solved for the coordinates x^a in terms of $(\beta,r,\zeta,\bar{\zeta})$, using the orthonormality of the null tetrad:

$$x^a=\frac{\partial H}{\partial\beta}(l^a+n^a)-\left(r-\frac{\eth\bar{\eth}H}{\beta}\right)l^a-\frac{\bar{\eth}H}{\beta}m^a-\frac{\eth H}{\beta}\bar{m}^a. \tag{45}$$

Equation (45) is not very convenient for the analysis of the wave fronts because the parameter β does not have a simple geometric meaning related with the null surfaces. On the other hand, as we know, the level surfaces of $S^{**}=u=\text{const}$ in Eq. (14) define the null surfaces in which we are interested. Therefore, a sensible parametrization will be the one that replaces the β with the parameter u defined by

$$u=\beta x^a l_a-H(\beta,\zeta,\bar{\zeta})=L(x^a l_a,\zeta,\bar{\zeta}). \tag{46}$$

Constant values of u label the characteristic surfaces themselves and are different than $u_B=x^a l_a$. By changing the parameter β in favor of u we are switching to the characteristic description which provides a better framework to study the dynamics of the wave fronts.

Remark 6: Note that $r\equiv\beta^{-1}\eth\bar{\eth}S^{**}=\beta^{-1}\eth\bar{\eth}u$ *defines an affine parameter along the null geodesics that rule the characteristic surfaces* $u=\text{const}$.

Instead of performing the transformation from the "Cauchy parametrization" to the new set $(u,r,\zeta,\bar{\zeta})$ we take a shortcut, and start directly with the characteristic approach. Using the notation of the previous sections for the characteristic problem the new parameters are determined by the previous equations:

$$u=u(x^a)=L(x^a l_a,\zeta,\bar{\zeta}), \tag{47}$$

$$\begin{aligned}&\dot{L}(x^a l_a,\zeta,\bar{\zeta})x^a m_a(\zeta,\bar{\zeta})+\eth L(x^a l_a,\zeta,\bar{\zeta})=0\\&\dot{L}(x^a l_a,\zeta,\bar{\zeta})x^a \bar{m}_a(\zeta,\bar{\zeta})+\bar{\eth}L(x^a l_a,\zeta,\bar{\zeta})=0,\end{aligned} \tag{48}$$

and the new one defined by $r=\dot{L}^{-1}\eth\bar{\eth}S^{**}$ yielding

$$r=x^a(n_a-l_a)+\frac{\bar{\eth}\dot{L}}{\dot{L}}\,x^a m_a+\frac{\eth\dot{L}}{\dot{L}}\,x^a\bar{m}_a+\frac{\ddot{L}}{\dot{L}}\,x^a x^b m_a\bar{m}_b+\frac{\eth\bar{\eth}L}{\dot{L}}. \tag{49}$$

The coordinates x^a can be written in terms of the four parameters u, r, ζ, and $\bar{\zeta}$ as

$$x^a=u_B(l^a+n^a)+(r+\bar{\eth}\Phi+\bar{\Phi}\dot{\Phi})l^a-\bar{\Phi}m^a-\Phi\bar{m}^a, \tag{50}$$

where

$$\Phi\equiv-\eth L/\dot{L}, \tag{51}$$

and the function $u_B\equiv x^a l_a$ is written in terms of the parameters u, ζ, and $\bar{\zeta}$ implicitly by $u=L(x^a l_a,\zeta,\bar{\zeta})$, i.e., $x^a l_a=L^{-1}(u,\zeta,\bar{\zeta})$. ($L^{-1}$ denotes the inverse *function* of L.)

Treating Eq. (50) as a coordinate transformation between the natural coordinates associated with the solution, i.e., the $(u,\zeta,\bar{\zeta},r)$, and the standard space–time coordinates x^a, the transformation breaks down when its Jacobian vanishes. This is a three surface in the space–time; the caustic set associated with the solution.

After a lengthy calculation we find that this occurs when

$$J=\frac{\partial(t,x,y,z)}{\partial(u,r,\zeta,\bar{\zeta})}=r^2-\sigma^0\bar{\sigma}^0=0, \tag{52}$$

where

$$\sigma^0=\eth\Phi+\Phi\dot{\Phi}. \tag{53}$$

This is equivalent to Eq. (3.1) of Ref. 4.

There is a simple geometric interpretation of Eqs. (52) and (53); the shear function σ of the congruence of null geodesics that generate the surfaces $u=\text{constant}$, with the affine parameter r, is given by[6]

$$\sigma=\frac{\sigma^0}{r^2-\sigma^0\bar{\sigma}^0}.$$

Therefore, the vanishing of the Jacobian (52) implies that the shear of the congruence diverges. We regain the expression defining caustics from Ref. 2 in the stationary case, namely,

$$r^2-\eth^2L\bar{\eth}^2L=0, \tag{54}$$

since $\sigma^0=\eth^2L$.

The form of the metric tensor in the new coordinates is

$$\begin{aligned}ds^2&=\eta_{ab}\,dx^a\,dx^b\\&=2\,\frac{du}{\dot{L}}\left\{dr+du\left(\frac{1+\eth\overline{\dot{\Phi}}+\Phi\overline{\ddot{\Phi}}}{\dot{L}}\right)+d\bar{\zeta}\left(\frac{\eth\bar{\sigma}^0+\Phi\dot{\bar{\sigma}}^0-\dot{\Phi}\bar{\sigma}^0+\overline{\dot{\Phi}r}}{P}\right)\right.\\&\quad\left.+d\zeta\left(\frac{\bar{\eth}\sigma^0+\bar{\Phi}\dot{\sigma}^0-\overline{\dot{\Phi}}\sigma+\dot{\Phi}r}{P}\right)\right\}-\frac{2r}{P^2}\,(\sigma^0d\zeta^2+\bar{\sigma}^0d\bar{\zeta}^2)-2(r^2+\sigma^0\bar{\sigma}^0)\,\frac{d\zeta\,d\bar{\zeta}}{P^2},\end{aligned} \tag{55}$$

where $P=1+\zeta\bar{\zeta}$. This line element, corresponding to shearing nonstationary null coordinates, defined by Eq. (50) reduces to the one given in Ref. 2 in the stationary regime. As pointed out in this reference it might be of interest to use Eq. (55) as a background metric in linearized gravity for higher order pertubations in problems where gravitational radiation is important.

VI. THE EIKONAL EQUATION IN ASYMPTOTICALLY FLAT SPACE–TIMES

In a straightforward manner all our results can be generalized to the case of arbitrary curved space–times, and the proofs of all the relations above follow basically the same path. We will assume that there is given a system of local coordinates x^a in an arbitrary curved space–time and a two parameter family (sphere's worth) of solutions of the eikonal equation, i.e., $Z(x^a,\zeta,\bar{\zeta})$ such that

$$g^{ab}(x^a)\partial_a Z(x^a,\zeta,\bar{\zeta})\partial_b Z(x^a,\zeta,\bar{\zeta})=0, \tag{56}$$

such that its (null) gradient sweeps out the light cone at x^a as $(\zeta,\bar{\zeta})$ range over the sphere.

Such characteristic functions $S=Z(x^a,\zeta,\bar{\zeta})$ are one of the main variables of the null surface formulation of general relativity; they contain all the conformal information of the space–time. [7] In the special case of asymptotically flat space–times $Z(x^a,\zeta,\bar{\zeta})$ can be interpreted either as the light cone cut of $\mathscr{I}^+$ of the point with coordinates x^a, or as the past light cone of a point at $\mathscr{I}^+$ with coordinates $(u,\zeta,\bar{\zeta})$.[7]

We take the complete solution $\beta Z(x^a,\zeta,\bar{\zeta})$, and define, in an analogous manner to the flat–space construction,

$$u=S^{**}(x^a,\beta,\zeta,\bar{\zeta})=\beta Z(x^a,\zeta,\bar{\zeta})-H(\beta,\zeta,\bar{\zeta}). \tag{57}$$

On Eq. (57) we impose the conditions, equivalent to (15), (16), and (17), namely,

$$\frac{\partial S^{**}}{\partial\beta}=Z(x^a,\zeta,\bar{\zeta})-\frac{\partial H(\beta,\zeta,\bar{\zeta})}{\partial\beta}=0, \tag{58}$$

$$\eth S^{**}=\beta\eth Z(x^a,\zeta,\bar{\zeta})-\eth H(\beta,\zeta,\bar{\zeta})=0, \tag{59}$$

$$\bar{\eth} S^{**}=\beta\bar{\eth} Z(x^a,\zeta,\bar{\zeta})-\bar{\eth} H(\beta,\zeta,\bar{\zeta})=0, \tag{60}$$

and solve for $(\beta,\zeta,\bar{\zeta})$ [as noted earlier, this is always possible, aside from lower dimensional (caustic) regions which can be approached in a limiting fashion] in terms of the x^a.

When these are resubstituted into Eq. (57), S^{**} then becomes a new solution of the eikonal equation since

$$\partial_a S^{**}=\beta\partial_a Z. \tag{61}$$

As in the flat case, we can determine the arbitrary function $H(\beta,\zeta,\bar{\zeta})$ in terms of corresponding data given on a Cauchy surface Σ. Suppose that we are given a coordinate system (τ,x^i) such that $\tau=\tau_0$ corresponds to our Cauchy surface, together with suitable Cauchy data $S_{\text{Cauchy}}(x^i)$ on Σ. A needed generalization of the relationship $\alpha_i=\partial S_{\text{Cauchy}}/\partial x^i$ from Sec. II is

$$\frac{\partial S_{\text{Cauchy}}(x^i)}{\partial x^i}-\frac{\beta\partial Z(x^i,\tau_0,\zeta,\bar{\zeta})}{\partial x^i}=0, \tag{62}$$

which is to be considered as three equations for the determination of x^i in terms of $(\beta,\zeta,\bar{\zeta})$, i.e., $x^i=X^i(\beta,\zeta,\bar{\zeta})$. When these are inserted into Eq. (57) at $\tau=\tau_0$ we obtain

$$H(\beta,\zeta,\bar{\zeta})=\beta Z(X^i(\beta,\zeta,\bar{\zeta}),\tau_0,\zeta,\bar{\zeta})-S_{\text{Cauchy}}(X^i(\beta,\zeta,\bar{\zeta})),$$

in analogy to the results of Sec. II.

The characteristic formulation from Sec. III is even simpler. Starting with any function $L(u_B,\zeta,\bar{\zeta})$ defined on $\mathfrak{I}^+$, we obtain a solution to the eikonal equation with the characteristic data given by

$$u=S^{**}(x^a,\zeta,\bar{\zeta})=L(Z(x^a,\zeta,\bar{\zeta}),\zeta,\bar{\zeta}), \tag{63}$$

where $(\zeta,\bar{\zeta})$ are functions of the coordinates x^a such that the equivalent to Eq. (21) holds, i.e., when

$$\eth S^{**}=\dot{L}\eth Z(x^a,\zeta,\bar{\zeta})-\eth L(Z,\zeta,\bar{\zeta})=0, \tag{64}$$

$$\bar{\eth} S^{**}=\dot{L}\bar{\eth} Z(x^a,\zeta,\bar{\zeta})-\bar{\eth} L(Z,\zeta,\bar{\zeta})=0. \tag{65}$$

Again the relationship between $H(\beta,\zeta,\bar{\zeta})$ and $L(u,\zeta,\bar{\zeta})$ is given by the Legendre transformation

$$L(Z,\zeta,\bar{\zeta})=Z\beta(Z,\zeta,\bar{\zeta})-H(\beta(Z,\zeta,\bar{\zeta}),\zeta,\bar{\zeta}), \tag{66}$$

with

$$Z=\partial H/\partial\beta, \quad \beta=\partial L/\partial Z. \tag{67}$$

VII. CONCLUSION

We have generalized the results of Ref. 2 concerning solutions of the flat-space eikonal equation. We saw two different means of giving data and solving the eikonal equation: the Cauchy, and the characteristic formulation. Each one leads to different methods. The two methods are beautifully related by a Legendre transformation, Eqs. (41) and (42). Moreover, all our results can be generalized to the case of curved space–times. The characteristic formulation appears to be better for the study of the dynamics of the wave fronts. By means of a suitable parameterization we could describe the caustics in the wave fronts, and find a simple geometric interpretation in terms of the shear σ of the null congruence generating the wave fronts.

(Received 10 August 1998; accepted for publication 15 October 1998)

A formalism is developed for using geometric probability techniques to evaluate interaction energies arising from a general radial potential $V(r_{12})$, where $r_{12}=|\mathbf{r}_2-\mathbf{r}_1|$. The integrals that arise in calculating these energies can be separated into a radial piece that depends on r_{12} and a nonradial piece that describes the geometry of the system, including the density distribution. We show that all geometric information can be encoded into a ''radial density function'' $G(r_{12};\rho_1,\rho_2)$, which depends on r_{12} and the densities ρ_1 and ρ_2 of two interacting regions. $G(r_{12};\rho_1,\rho_2)$ is calculated explicitly for several geometries and is then used to evaluate interaction energies for several cases of interest. Our results find application in elementary particle, nuclear, and atomic physics. © *1999 American Institute of Physics.* [S0022-2488(99)00102-4]

I. INTRODUCTION

In many areas of physics, integrals of the form

$$U=\int d^3r_1\ d^3r_2\ \rho(\mathbf{r}_1)\rho(\mathbf{r}_2)V(|\mathbf{r}_1-\mathbf{r}_2|) \tag{1.1}$$

are encountered, which typically describe the self-energy of a system with density profile $\rho(\mathbf{r})$ in the presence of a two-body central potential $V(|\mathbf{r}_1-\mathbf{r}_2|)$. A familiar example of such an integral arises in the calculation of the electrostatic self-energy of a spherical charge distribution (e.g., a nucleus) due to the Coulomb potential $V_C(|\mathbf{r}_1-\mathbf{r}_2|)$,

$$V_C(|\mathbf{r}_1-\mathbf{r}_2|)=\frac{e_0^2}{|\mathbf{r}_1-\mathbf{r}_2|}, \tag{1.2}$$

where e_0 is the electric charge ($e_0^2\cong\frac{1}{137}$). For a simple potential such as $V_C(|\mathbf{r}_1-\mathbf{r}_2|)$, the integral in Eq. (1.1) can be evaluated directly, by expanding $1/|\mathbf{r}_1-\mathbf{r}_2|$ in terms of Legendre polynomials. However, for some types of potentials, evaluating U in this way can be extremely tedious. An example of current interest[1,2] is the self-energy of a nucleus or a neutron star arising from neutrino–antineutrino ($\nu-\overline{\nu}$) exchange. In this case the analog of V_C in Eq. (1.2) for the neutron–neutron ($n-n$) potential in a neutron star arising from $\nu-\overline{\nu}$ exchange is[3–5]

$$V_{\nu\nu}(|\mathbf{r}_1-\mathbf{r}_2|)=\frac{G_F^2a_n^2}{4\pi^3|\mathbf{r}_1-\mathbf{r}_2|^5}, \tag{1.3}$$

where G_F is the weak Fermi constant, and $a_n=-\frac{1}{2}$ the coupling constant describing the strength of the $\nu-n$ interaction. One of the difficulties that arises in evaluating U, starting from Eq. (1.3),

[b]Present address: Department of Natural Sciences, Longwood College, Farmville, Virginia 23909.

is that the integral is well defined only if the neutron–neutron hard core interaction is used to cut off the lower limit of integration when $|\mathbf{r}_1-\mathbf{r}_2|<r_c\cong 0.5\times 10^{-13}$ cm. However, since this constraint applies to $r_{21}=|\mathbf{r}_1-\mathbf{r}_2|=r_{12}$, and not to $r_1=|\mathbf{r}_1|$ or $r_2=|\mathbf{r}_2|$ separately, the integration region in Eq. (1.1) implied by this constraint is somewhat complicated. As we discuss in detail below, the evaluation of integrals involving potentials such as $V_{\nu\nu}(r_{12})$, and other potentials as well, can be greatly facilitated using geometric probability techniques. By use of these techniques the six-dimensional integral in Eq. (1.1) can be replaced by a one-dimensional integral in the variable r_{12}, which can be easily integrated in all cases of interest. The geometric probability techniques are especially useful when $\rho(\mathbf{r}_1)$ is radially varying ($\rho(\mathbf{r}_1)=\rho(|\mathbf{r}_1|)$).

It is helpful to introduce the formalism of geometric probability by first considering the electrostatic (Coulomb) energy of a uniform spherical charge distribution of radius R. Direct evaluation of the six-dimensional integral in Eq. (1.1) yields

$$U_{\mathrm{C}}=\frac{6}{5}\,\frac{e_0^2}{R}. \tag{1.4}$$

For a spherically symmetric distribution containing Z charges there are $Z(Z-1)/2$ possible pairs, and hence the total Coulomb energy W_{C} of such a distribution is

$$W_{\mathrm{C}}=\frac{Z(Z-1)}{2}\,U_{\mathrm{C}}=\frac{3}{5}\,Z(Z-1)\,\frac{e_0^2}{R}, \tag{1.5}$$

which is the standard result.[6,7]

In contrast to the preceding derivation, which begins with a six-dimensional integral, the formalism of integral geometry expresses U_{C} immediately as a one-dimensional integral. For any function $g(r_{12})$, its average value $\langle g\rangle$ taken over a uniform spherical volume of radius R is

$$\langle g\rangle=\int_0^{2R}dr_{12}\,\mathcal{P}_3(r_{12})g(r_{12}), \tag{1.6}$$

where

$$\int_0^{2R}dr_{12}\,\mathcal{P}_3(r_{12})=1. \tag{1.7}$$

The function $\mathcal{P}_3(r_{12})$ denotes the normalized probability density for finding two points randomly chosen in a uniform three-dimensional sphere to be a distance r_{12} apart. The functional form of $\mathcal{P}_3(r_{12})$ has been obtained previously by a number of authors,[8–13]

$$\mathcal{P}_3(r_{12})=\frac{3r_{12}^2}{R^3}\left[1-\frac{3}{2}\left(\frac{r_{12}}{2R}\right)+\frac{1}{2}\left(\frac{r_{12}}{2R}\right)^3\right]. \tag{1.8}$$

Using Eq. (1.8), U_{C} is given by

$$U_{\mathrm{C}}=\langle e_0^2/r_{12}\rangle=\int_0^{2R}dr_{12}\left(\frac{3r_{12}^2}{R^3}\right)\left[1-\frac{3}{2}\left(\frac{r_{12}}{2R}\right)+\frac{1}{2}\left(\frac{r_{12}}{2R}\right)^3\right]\left(\frac{e_0^2}{r_{12}}\right)=\frac{6}{5}\,\frac{e_0^2}{R}, \tag{1.9}$$

in agreement with Eq. (1.4). The utility of the geometric probability formalism becomes more evident when one attempts to evaluate $U_{\nu\nu}=\langle V_{\nu\nu}(r_{12})\rangle$ using Eq. (1.3),

$$U_{\nu\nu}=\frac{G_{\mathrm{F}}^2a_n^2}{4\pi^3}\int_{r_c}^{2R}dr_{12}[\,\eta(r_c,R)\mathcal{P}_3(r_{12})]\,\frac{1}{r_{12}^5}. \tag{1.10}$$

In Eq. (1.10) $\eta(r_c,R)$ is a constant that ensures that $\mathcal{P}_3(r_{12})$ is appropriately normalized in the interval $2R \geqslant r_{12} \geqslant r_c$, and is given by

$$\eta(r_c,R)=(1-8s_c^3+8s_c^4-2s_c^6)^{-1}, \tag{1.11}$$

where $s_c=r_c/2R$. It follows from Eq. (1.11) that $\eta(0,R)=1$, as expected. Combining Eqs. (1.10) and (1.11) then gives immediately,

$$U_{\nu\nu}=\frac{3}{8\pi^3}\frac{G_F^2 a_n^2}{\hbar c}\frac{1}{R^3 r_c^2}\left(1-\frac{r_c}{2R}\right)^3\eta(r_c,R). \tag{1.12}$$

For a sphere containing N particles, the total energy $W_{\nu\nu}$ is then given by

$$W_{\nu\nu}=\frac{N(N-1)}{2}U_{\nu\nu}=\frac{3}{16\pi^3}N(N-1)\frac{G_F^2 a_n^2}{\hbar c}\frac{1}{R^3 r_c^2}\left(1-\frac{r_c}{2R}\right)^3\eta(r_c,R). \tag{1.13}$$

To evaluate $\langle g\rangle$ in Eq. (1.6) for a particular geometry, one must first determine the functional form of $\mathcal{P}_3(r_{12})$ appropriate to that geometry. In practice, it would be of great value to know $\mathcal{P}(r)\equiv\mathcal{P}_3(r_{12})$ for different (nonconstant) density distributions, as well as for other geometries. In this paper we address the former problem, by developing a general framework for calculating $\mathcal{P}(r)$ for geometries with variable density. We illustrate this approach in Sec. II by first rederiving (in a much simpler way) the result for a sphere of constant density given in Eq. (1.8). We then obtain $\mathcal{P}(r)$ for a sphere with a Gaussian density distribution. In Sec. III we apply our formalism to geometries that can be used to calculate the interaction energy between microscopic objects due to a generalized two-body interaction potential. One example is the van der Waals interaction.

II. GENERAL FORMALISM

A. The radial density function

Returning to Eq. (1.1), we introduce the change of variables,

$$\begin{aligned}\mathbf{r}_{12}&=\mathbf{r}_2-\mathbf{r}_1,\\ d^3r_{12}&=d^3r_2,\end{aligned} \tag{2.1}$$

so that

$$\begin{aligned}U&=\int dr_{12}\left[r_{12}^2\int d\Omega_{12}\int d^3r_1\ \rho_1(\mathbf{r}_1)\rho_2(\mathbf{r}_{12}+\mathbf{r}_1)\right]V(r_{12}),\\ &\equiv\int dr_{12}\ G(r_{12};\rho_1,\rho_2)V(r_{12}),\end{aligned} \tag{2.2}$$

where $r_{12}=|\mathbf{r}_2-\mathbf{r}_1|$. The ''radial density function'' $G(r_{12};\rho_1,\rho_2)$ is the generalization of the probability function $\mathcal{P}_3(r_{12})$ in Eq. (1.8). $G(r_{12};\rho_1,\rho_2)$ incorporates all the geometric information about the densities $\rho_1(\mathbf{r}_1)$ and $\rho_2(\mathbf{r}_2)$ and the geometry, but is independent of $V(r_{12})$.

B. Geometry with spherical symmetry

The first case we consider is when both $\rho_1(\mathbf{r}_1)$ and $\rho_2(\mathbf{r}_2)$ exhibit spherical symmetry about a common origin, so that $\rho_1=\rho_1(|\mathbf{r}_1|)$ and $\rho_2=\rho_2(|\mathbf{r}_2|)$ about this origin. From Eq. (2.2) we can then write

$$G(r_{12};\rho_1,\rho_2)=r_{12}^2\int d^3r_1\int d\Omega_{12}\ \rho_1(r_1)\rho_2(|\mathbf{r}_{12}+\mathbf{r}_1|). \tag{2.3}$$

Since $\rho(r_1)$ and $\rho_2(|\mathbf{r}_{12}+\mathbf{r}_1|)=\rho(r_2)$ are independent of $d\Omega_1$ and $d\phi_{12}$, we can integrate over these variables immediately to give

$$G(r_{12};\rho_1,\rho_2)=r_{12}^2\int_0^\infty dr_1\, 4\pi r_1^2\rho_1(r_1)\int_0^\pi d\theta_{12}\, 2\pi\, \sin\, \theta_{12}\rho_2(|\mathbf{r}_{12}+\mathbf{r}_1|). \tag{2.4}$$

Note that the upper limit of integration for r_1 can always be taken to be infinite, even for a finite spherical mass distribution, since $\rho_1(r_1)$ can be defined to be zero for $r_1>R$. Using the law of cosines, we have

$$-\cos\, \theta_{12}=\frac{r_{12}^2+r_1^2-r_2^2}{2r_1r_{12}}. \tag{2.5}$$

Since r_{12} and r_1 are the independent variables of integration in Eq. (2.3), it follows that cos θ_{12} depends only on r_2 for fixed values of r_{12} and r_1. Thus,

$$\sin\, \theta_{12}\, d\theta_{12}=\frac{-r_2}{r_1r_{12}}\, dr_2. \tag{2.6}$$

Combining Eqs. (2.6) and (2.4) then gives

$$G(r_{12};\rho_1,\rho_2)=8\pi^2 r_{12}\int_0^\infty dr_1\, r_1\rho_1(r_1)\int_{|r_{12}-r_1|}^{r_{12}+r_1} dr_2\, r_2\rho_2(r_2). \tag{2.7}$$

As an application of Eq. (2.7) we recalculate the Coulomb energy of a sphere of radius R and constant density $1/V$, where the density is normalized so that its integral over the spherical volume is unity. Since the integral in Eq. (2.7) is symmetric in the interchange of r_1 and r_2, we can write

$$G_{\text{sphere}}(r_{12};\rho_1,\rho_2)=16\pi^2 r_{12}\int_{r_{12}/2}^\infty dr_1\, r_1\rho(r_1)\int_{|r_{12}-r_1|}^{r_1} dr_2\, r_2\rho(r_2). \tag{2.8}$$

The lower limit on the r_1 integration follows by noting that when $r_2=r_1$ the triangle formed by the vectors $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_{12}$ is isosceles, and hence by the triangle inequality $2r_1>r_{12}$. From Eq. (2.8) we have

$$G_{\text{sphere}}(r_{12};\rho_1,\rho_2)=\frac{16\pi^2 r_{12}}{V^2}\int_{r_{12}/2}^R dr_1\, r_1\int_{|r_{12}-r_1|}^{r_1} dr_2\, r_2=\frac{3r_{12}^2}{R^3}\left[1-\frac{3}{2}\left(\frac{r_{12}}{2R}\right)+\frac{1}{2}\left(\frac{r_{12}}{2R}\right)^3\right], \tag{2.9}$$

in agreement with the expression for $\mathcal{P}_3(r_{12})$ in Eq. (1.8). The expression for the Coulomb energy of a sphere of charge then follows immediately from Eq. (1.9). Having demonstrated that the present formalism correctly reproduces the classical results for a sphere of constant density, we turn in the next section to a problem that has not been considered previously in the literature, the distribution of points in a sphere with a Gaussian density variation.

III. RADIAL DENSITY FUNCTION FOR A GAUSSIAN DISTRIBUTION

We derive in this section the radial density function for a spherically symmetric distribution of matter centered at the origin, whose density varies as

$$\rho(r)=Ae^{-r^2/R_0^2}, \tag{3.1}$$

where A and R_0 are constants, and r is measured from the origin. If we normalize $\rho(r)$ so that its integral over all space is unity, then

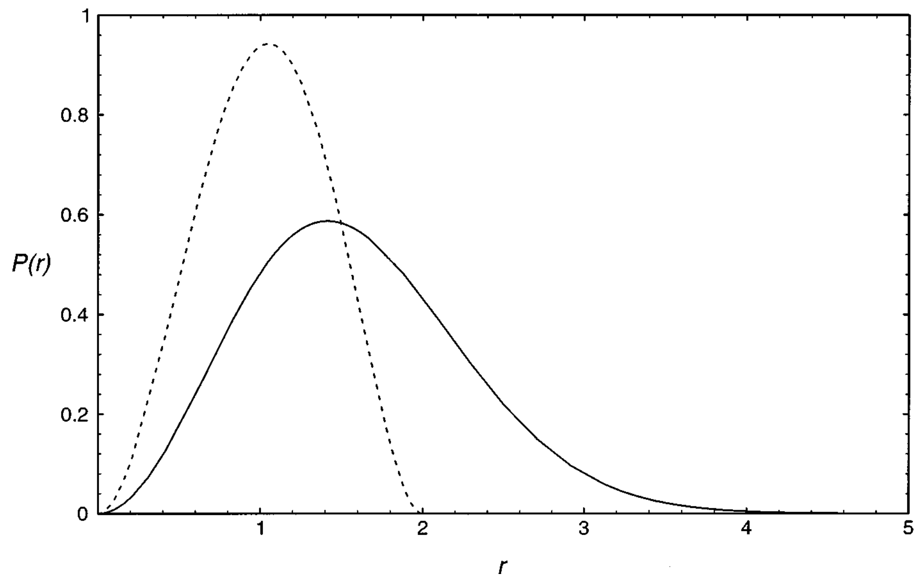

FIG. 1. The plot of $P(r)\equiv G(r;\rho)$ in Eq. (3.6) as a function of $r=r_{12}$ (solid line). For comparison the function $\mathcal{P}_3(r)$ in Eq. (1.8) is also shown (dashed line).

$$A=R_0^{-3}\pi^{-3/2}. \tag{3.2}$$

Combining Eqs. (3.1) and (2.8), we find

$$G(r_{12};\rho_1,\rho_2)\equiv G(r_{12};\rho)=8\pi^2A^2r_{12}\int_0^\infty dr_1r_1e^{-r_1^2/R_0^2}\int_{|r_{12}-r_1|}^{r_{12}+r_1}dr_2r_2e^{-r_2^2/R_0^2}. \tag{3.3}$$

Carrying out the integration with respect to r_2, we find

$$G(r_{12};\rho)=4\pi^2A^2R_0^2r_{12}e^{-r_{12}^2/R_0^2}\int_0^\infty dr_1r_1e^{-2r_1^2/R_0^2}[e^{-2r_{12}r_1/R_0^2}-e^{2r_{12}r_1/R_0^2}]. \tag{3.4}$$

The integration with respect to r_1 can then be performed by completing the square, which gives

$$G(r_{12};\rho)=4\pi^2A^2R_0^2r_{12}e^{-r_{12}^2/2R_0^2}\int_0^\infty dr_1\ r_1\{\exp[-2(r_1-r_{12}/2)^2/R_0^2]-\exp[-2(r_1+r_{12}/2)^2/R_0^2]\}$$

$$=4\pi^2A^2R_0^2r_{12}e^{-r_{12}/2R_0^2}\left[\frac{1}{2}\sqrt{\frac{\pi}{2}}\ r_{12}R_0\right]. \tag{3.5}$$

Combining Eqs. (3.2) and (3.5) yields the final result,

$$G(r_{12};\rho)=\sqrt{\frac{2}{\pi}}\frac{r_{12}^2}{R_0^3}\ e^{-r_{12}^2/2R_0^2}. \tag{3.6}$$

$G(r_{12};\rho)$ is shown in Fig. 1 and is normalized to unity over the interval $[0,\infty]$. When the lower limit of integration is replaced by r_c, $G(r_{12};\rho)$ must be divided by the constant $C(r_c,R_0)$ to be properly normalized, where

$$C(r_c,R_0)=\int_{r_c}^\infty dr_{12}\ G(r_{12};\rho)\cong 1-\sqrt{\frac{2}{\pi}}\frac{r_c^3}{3R_0^3}. \tag{3.7}$$

We note that for $r_{12}^2/R_0^2 \ll 1, G(r_{12};\rho)$ can be approximated by

$$G(r_{12};\rho) \cong \sqrt{\frac{2}{\pi}} \frac{r_{12}^2}{R_0^3}, \tag{3.8}$$

which agrees (up to an overall constant) with the results for a uniform sphere given in Eqs. (1.8) and (2.9). This agreement conforms to our intuition that when r_{12} is small compared to R_0, a spherically symmetric Gaussian distribution will look like that of a sphere with an approximately constant local density.

The result in Eq. (3.6) can be applied immediately to calculate both the Coulomb energy and the neutrino-exchange energy of a matter distribution with the Gaussian density profile given in Eq. (3.1). The Coulomb energy W_C is then given by

$$W_C = \frac{Z(Z-1)}{2} \left\langle \frac{e^2}{r_{12}} \right\rangle = \frac{Z(Z-1)}{2} \int_0^\infty dr_{12} \left(\frac{e^2}{r_{12}} \right) \times \frac{r_{12}^2}{R_0^3} \sqrt{\frac{2}{\pi}} e^{-r_{12}^2/2R_0^2} = \frac{1}{\sqrt{2\pi}} \frac{Z(Z-1)e^2}{R_0}. \tag{3.9}$$

As noted in the Introduction, geometric probability techniques are particularly useful when evaluating expressions where the nucleon–nucleon hard core radius r_c appears, as in the integral for $U_{\nu\nu}$ in Eq. (1.10). From Eq. (3.6) we have, for a Gaussian density distribution of N neutrons,

$$W_{\nu\nu} = \frac{N(N-1)}{2} \left\langle \frac{G_F^2 a_n^2}{4\pi^3 r_{12}^5} \right\rangle = \frac{N(N-1)}{2C(r_c, R_0)} \int_{r_c}^\infty dr_{12} \left(\frac{G_F^2 a_n^2}{4\pi^3 r_{12}^5} \right) \frac{r_{12}^2}{R_0^3} \sqrt{\frac{2}{\pi}} e^{-r_{12}^2/2R_0^2}. \tag{3.10}$$

Evaluation of the integral in Eq. (3.10) yields

$$W_{\nu\nu} = \frac{G_F^2 a_n^2}{8\pi^3} \frac{N(N-1)}{C(r_c, R_0)} \left\{ \frac{1}{\sqrt{2\pi}} \frac{e^{-r_c^2/R_0^2}}{r_c^2 R_0^3} + \frac{1}{2} \sqrt{\frac{\pi}{2}} \frac{1}{R_0^5} \left[-i + \frac{1}{\pi} Ei \left(\frac{-r_c^2}{2R_0^5} \right) \right] \right\}, \tag{3.11}$$

$$Ei(z) = P \int_{-z}^\infty \frac{(-1)}{te^t} dt,$$

where P denotes the principal value integration. We note that the quantity in square brackets in Eq. (3.11) is real, as hence $W_{\nu\nu}$ is real as well. As can be seen from Eq. (3.11), by using $G(r_{12};\rho)$ in Eq. (3.6) we obtain an exact closed-form expression for $W_{\nu\nu}$ for the case of a Gaussian density distribution. By way of contrast, the conventional approach would lead to an infinite series expression for $W_{\nu\nu}$. We complete this discussion by noting that for $r_c/R_0 \ll 1$ we can write

$$\int_{r_c}^\infty dr \frac{G(r;\rho)}{r^5} \cong \frac{2}{\sqrt{\pi}} \frac{1}{r_c^2 R_0^3}, \tag{3.12}$$

and, hence,

$$W_{\nu\nu} \cong \frac{G_F^2 a_n^2 N(N-1)}{8\sqrt{2}\pi^{7/2}} \frac{1}{r_c^2 R_0^3}. \tag{3.13}$$

As expected from Eq. (1.13), $W_{\nu\nu} \sim 1/r_c^2$ when $r_c/R_0 \ll 1$ for the Gaussian distribution, just as in the case of the uniform sphere.

IV. INTERACTION BETWEEN SOURCES

A. General formalism

In the previous section we have focused on calculating the radial density function $G(r_{12};\rho_1,\rho_2)$ needed to evaluate the self-energy of a spherically symmetric matter distribution. In this section we calculate the analogous expressions for $G(r_{12};\rho_1,\rho_2)$, which characterize the interaction of two different matter distributions in volumes ω_1 and ω_2, respectively. In particular, we generalize the calculations of Israelachvili[14] to allow any two-body radial potential. These results are of interest in the field of tribology, specifically in calculating interaction forces and energies due to van der Waals-type forces. This technique has been used to study the force of interaction between an Atomic Force Microscopy (AFM) probe tip and a flat sample.[15]

Returning to Eq. (2.3), we can rewrite the expression for $G(r_{12};\rho_1,\rho_2)$ in the form

$$G(r_{12};\rho_1,\rho_2)=r_{12}^2\int d\Omega_{12}\int d^3r_1\ \rho_1(\mathbf{r}_1)\rho_2(\mathbf{r}_{12}+\mathbf{r}_1)$$
$$=\int d^3r_1\ \rho_1(\mathbf{r}_1)\left\{r_{12}^2\int d\Omega_{12}\ \rho_2(\mathbf{r}_2)\right\}. \tag{4.1}$$

In Eq. (4.1) we have interchanged the order of the integrations, and have used Eq. (2.1) to replace $\mathbf{r}_{12}+\mathbf{r}_1$ by $\mathbf{r}_2$. In this section we deal with the situation in which $\rho_i(\mathbf{r}_i)$ are given by

$$\rho_i(\mathbf{r}_i)=\begin{cases}\rho_i, & \text{when } \mathbf{r}_i\in\omega_i,\\ 0, & \text{otherwise.}\end{cases} \tag{4.2}$$

For illustrative purposes we take ρ_1 and ρ_2 to be constants, so that

$$G(r_{12};\rho_1,\rho_2)=\rho_1\rho_2\int_{\omega_1}d^3r_1\left\{r_{12}^2\int_{4\pi}d\Omega_{12}\right\}\equiv\rho_1\rho_2\int_{\omega_1}d^3r_1\ S(r_{12},\mathbf{r}_1). \tag{4.3}$$

$S(r_{12},\mathbf{r}_1)$ can be viewed as the surface area formed by the intersection of a sphere centered at $\mathbf{r}_1=0$ (in the volume ω_1) and having radius r_{12}, with the second volume ω_2. Several examples will serve to clarify the application of Eq. (4.3).

B. Point to sphere

Here ω_1 is a point having an infinitesimal volume $d\tau$, so that Eq. (4.3) becomes

$$G(r_{12};\rho_1,\rho_2)=(\rho_1\ d\tau)\rho_2 S(r_{12},\mathbf{r}_1). \tag{4.4}$$

If ω_2 is a sphere of radius R, then, from Fig. 2,

$$R^2=r_{12}^2+r^2-2rr_{12}\cos\theta_0, \tag{4.5}$$

where r is the distance from the point to the center of the spherical distribution ω_2. It follows that

$$S(r_{12},\mathbf{r}_1)=2\pi r_{12}^2\int_0^{\theta_0}\sin\theta_{12}\,d\theta_{12}=\pi\frac{r_{12}}{r}[R^2-(r-r_{12})^2]. \tag{4.6}$$

Combining Eqs. (4.4) and (4.6) then gives

$$G(r_{12};\rho_1,\rho_2)=(\rho_1 d\tau)\rho_2\left\{\pi\frac{r_{12}}{r}[R^2-(r-r_{12})^2]\right\}. \tag{4.7}$$

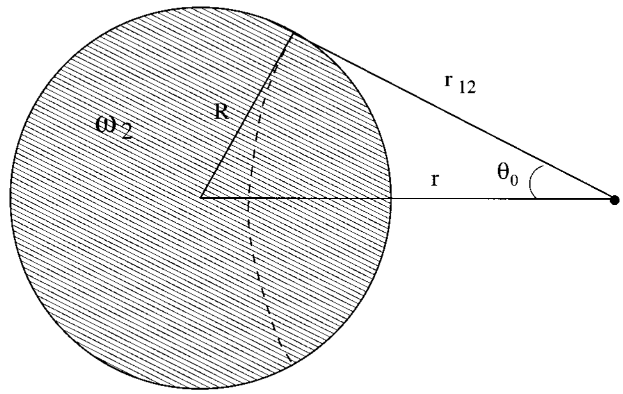

FIG. 2. The representation of the point-to-sphere geometry. R is the radius of the sphere, whose center is a distance r from the external point. $G(r_{12};\rho_1,\rho_2)$ is calculated as a function of the distance r_{12} between the external point and a point in the sphere.

Equation (4.7) can be checked by noting that when $r=R$, $G(r_{12};\rho_1,\rho_2)$ describes the distribution of distances between two points in a sphere, given that one of these points lies on the surface of the sphere. The latter distribution has been derived by Parry,[16] and it is straightforward to show that Eq. (4.7) agrees with this result when $r=R$. When combined with Eq. (2.3), Eq. (4.7) allows the interaction energy U to be calculated for an arbitrary two-body potential $V(r_{12})$ (e.g., Coulomb, Yukawa, van der Waals, etc.).

C. Point to half-space

This geometry is very similar to the point-to-sphere case, except that ω_2 is now an infinite half-space separated by a distance r from an external point. For this geometry, cos θ_0 is given by

$$\cos\ \theta_0=\frac{r}{r_{12}}, \tag{4.8}$$

and hence

$$S(r_{12},\mathbf{r}_1)=2\pi r_{12}^2(1-\cos\ \theta_0)=2\pi r_{12}(r_{12}-r). \tag{4.9}$$

Combining Eqs. (4.4) and (4.9), the radial density function is given by

$$G(r_{12};\rho_1,\rho_2)=(\rho_1\ d\tau)\rho_2\{2\pi r_{12}(r_{12}-r)\}. \tag{4.10}$$

As in the previous case, the expression in Eq. (4.10) can be checked by noting that when $r=0$, $G(r_{12};\rho_1,\rho_2)$ becomes proportional to r_{12}^2, which is the expected result for an infinite half-space.[16]

D. Arbitrary volume to half-space

We can apply the previous result to compute the radial density function for an arbitrary volume ω_1, in the presence of an infinite half-space. From Eq. (4.9) we see that $S(r_{12},\mathbf{r}_1)$ depends only on the distance x of a volume element from the boundary, and hence we need only specify the expression for the cross section $A(x)$ of ω_1 as a function of x. Then, from Eq. (4.10) we have

$$G(r_{12};\rho_1,\rho_2)=2\pi\rho_1\rho_2\int_0^{r_{12}}dx(r_{12}-x)A(x). \tag{4.11}$$

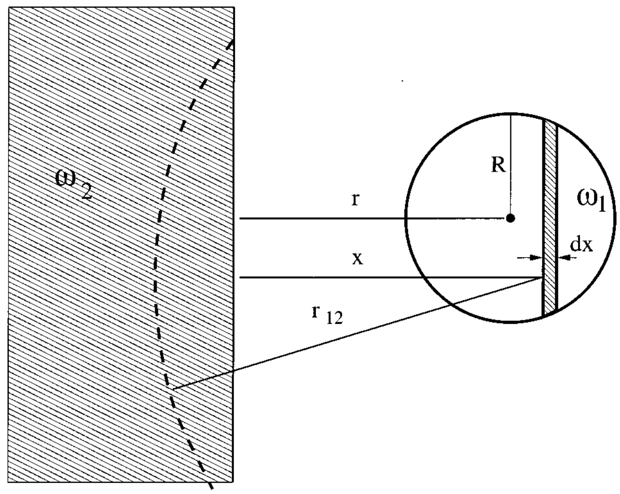

FIG. 3. Representation of the sphere-to-half-space geometry. See the text and the caption to Fig. 2 for details.

If ω_1 is a sphere of radius R whose center is a distance r from the boundary of the half-space, then, from Fig. 3,

$$A(x)=\begin{cases} 0, & x\leqslant r-R, \\ \pi[R^2-(r-x)^2], & r-R\leqslant x\leqslant r+R, \\ 0, & x\geqslant r+R. \end{cases} \tag{4.12}$$

Correspondingly, the density function is divided into three regions: $G(r_{12};\rho_1,\rho_2)=0$ if $r_{12}\leqslant(r-R)$, and

$$G(r_{12};\rho_1,\rho_2)=\begin{cases} \dfrac{\pi^2}{6}\,\rho_1\rho_2 r_{12}(r-R-r_{12})^3(r_{12}-r-3R), & r-R\leqslant r_{12}\leqslant r+R, \\ \dfrac{8\pi^2}{3}\,\rho_1\rho_2 r_{12}R^3(r_{12}-r), & r+R\leqslant r_{12}. \end{cases} \tag{4.13}$$

The results in Eq. (4.13) are useful in Atomic Force Microscopy since they can be used to analyze the interaction of a general AFM probe tip interacting with a flat sample.

V. CONCLUSIONS

The discussion in the Introduction illustrates the power of geometric probability techniques by demonstrating how a six-dimensional integral can be immediately reduced to a straightforward one-dimensional problem. In practice, this facilitates the evaluation of interaction energies such as $U_{\nu\nu}$ in Eq. (1.10), which would be extremely difficult to treat otherwise, due to the presence of r_c. We have extended the classical results of Refs. 8–13 to calculate for the first time the radial density functions for a Gaussian density profile, and for two regions of different shapes interacting with each other. These results can be applied to a wide variety of physical systems, as we will discuss elsewhere.

ACKNOWLEDGMENTS

One of the authors (E.F.) wishes to thank Albert Overhauser for introducing him to the subject of geometric probability, and for making available the unpublished results in Ref. 11. We also wish to thank Dennis Krause and Michael Yurko for helpful discussions. This work was supported in part by the U.S. Department of Energy under Contract No. DE-AC02-76ER01428.

[S0022-2488(99)00402-8]

We list a series of corrections to equations appearing in Ref. 1. None of the following affect the content of the article. Equation (m_I) in the set of Eqs. (1) is missing a factor $\frac{1}{2}$. The correct equation reads as

$$(m_I) \quad \eth\Omega = \tfrac{1}{2} W(\Lambda,_1)\Omega. \tag{1}$$

On p. 6399, the expression for Q given in between Eqs. (1) and (2) is incorrect by an overall minus sign. The correct expression reads as

$$Q \equiv \frac{1}{4q}\overline{\Lambda},_{11}\Lambda,_{11} + \frac{3}{8q^2}(q,_1)^2 - \frac{1}{4q}q,_{11}\,. \tag{2}$$

There is a typo in the first line of Eq. (71) for the Green function. The correct expression reads as

$$\begin{aligned}\overline{K}^{+}_{2,0} \overset{\text{def}}{=} & -\frac{1}{4\pi}\frac{(1+\overline{\zeta}\eta)^2(\overline{\eta}-\overline{\zeta})}{(1+\zeta\overline{\zeta})(1+\eta\overline{\eta})(\eta-\zeta)} \\ = & -\frac{1}{4\pi}\frac{m\cdot\widehat{\overline{m}}\; m\cdot\hat{l}\; l\cdot\hat{m}}{l\cdot\hat{l}\; l\cdot\hat{n}}.\end{aligned} \tag{3}$$

On p. 6404, the expressions for σ and $\overline{\sigma}$ given by Eqs. (32) are mismatched. The correct expressions are

$$\overline{\sigma} = \frac{\overline{\eta}^2}{A}D\left(\frac{\overline{\xi}}{\overline{\eta}}\right), \quad \sigma = \frac{\eta^2}{A}D\left(\frac{\xi}{\eta}\right). \tag{4}$$

On p. 6405, the expression for ρ given by (44) is incorrect. The correct expression reads as

$$\rho = \tfrac{1}{2}D\;\ln(\Omega^2\sqrt{q}). \tag{5}$$

[S0022-2488(99)00602-7]

We list a series of corrections to equations appearing in Ref. 1. None of the following affect the content of the article. Equations (14b) and (14d) have misprints. The correct equations read as

$$(1-\lambda_1\lambda_1^*)T_j^1=(\partial^*\lambda_j+\lambda_0\delta_j^-+\lambda_+\delta_j^1+\lambda_-\lambda_j^*)+\lambda_1(\partial\lambda_j^*+\lambda_0^*\delta_j^++\lambda_-^*\delta_j^1+\lambda_+^*\lambda_j), \tag{1}$$

$$(1-\lambda_1\lambda_1^*)T_j^{*1}=(\partial\lambda_j^*+\lambda_0^*\delta_j^++\lambda_-^*\delta_j^1+\lambda_+^*\lambda_j)+\lambda_1^*(\partial^*\lambda_j+\lambda_0\delta_j^-+\lambda_+\delta_j^1+\lambda_-\lambda_j^*). \tag{2}$$

Equations (24) have missing parentheses and misprints. The correct equations read as

$$\partial^* g^{0+}-\partial g^{0-}\equiv 0, \tag{3}$$

$$\partial^*(g^{++}+g^{01}\lambda_1)-\partial(g^{+-}+g^{01})\equiv 0, \quad \partial^*(g^{+-}+g^{01})-\partial(g^{--}+g^{01}\lambda_1^*)\equiv 0, \tag{4}$$

$$\partial^*(g^{1+}+g^{-i}\lambda_i)-\partial(g^{1-}+g^{+i}\lambda_i^*)\equiv 0. \tag{5}$$

Equations (26a) and (26b). A factor $\frac{1}{2}$ is missing from both. The correct equations read as

$$W(1-\tfrac{1}{4}\lambda_1\lambda_1^*)=-(\tfrac{1}{2}\partial^*\lambda_1-T_1^1-\tfrac{1}{2}\lambda_1\{\tfrac{1}{2}\partial\lambda_1^*-T_1^{*1}\}), \tag{6}$$

$$W^*(1-\tfrac{1}{4}\lambda_1\lambda_1^*)=-(\tfrac{1}{2}\partial\lambda_1^*-T_1^{*1}-\tfrac{1}{2}\lambda_1^*\{\tfrac{1}{2}\partial^*\lambda_1-T_1^1\}). \tag{7}$$

Equations (28). There are wrong signs and complex conjugations. The correct equations read as

$$g^{00}=0, \quad g^{01}=\Omega^2, \quad g^{0+}=g^{0-}=0, \tag{8}$$

$$g^{11}=\Omega^2(\partial^*(W-T_1^1)+W^*(W-T_1^1))-g^{+-}T_-^{*1}-g^{++}T_+^{*1}-g^{+1}T_1^{*1}, \tag{9}$$

$$g^{1+}=\Omega^2(W-T_1^1), \quad g^{1-}=\Omega^2(W^*-T_1^{*1}), \tag{10}$$

$$g^{++}=-\Omega^2\lambda_1, \quad g^{+-}=-\Omega^2, \quad g^{--}=-\Omega^2\lambda_1^*. \tag{11}$$

We list a series of corrections to equations appearing in Ref. 1. None of the following affect the content of the article. On p. 4991, the expression given for g^{11} in Eq. (2.22) contains two typos. The correct expression should read as

$$g^{11}=-2g^{01}+\bar{\eth}g^{1+}-g^{ab}\ \eth Z_{,a}\ \eth\bar{\Lambda}_{,b}. \tag{1}$$

On p. 4993, in the text of the *Remark*, one undisplayed equation is wrong. In the paper it reads as $\boldsymbol{\nabla}_b G=-4\kappa\boldsymbol{\nabla}_a(T^a{}_b-\frac{1}{4}\delta^a{}_b T)$. The correct equation should read as

$$\boldsymbol{\nabla}_b G=\kappa\ \boldsymbol{\nabla}_b T. \tag{2}$$

On p. 4996, there are incorrect signs in the expression of the vector ℓ_a. The correct expression should read as

$$\ell_a=\frac{1}{\sqrt{2}(1+\zeta\zeta)}((1+\zeta\bar{\zeta}),-(\zeta+\bar{\zeta}),i(\zeta-\bar{\zeta}),(1-\zeta\bar{\zeta})). \tag{3}$$

On p. 4998, the expression for the metric component g^{11} in Eqs. (A1) contains a typo. The correct expression reads as

$$g^{11}=-2-\tfrac{1}{2}\bar{\eth}^2\Lambda_{,1}+\eth\bar{\Lambda}_{,-}=-2-\tfrac{1}{2}\eth^2\bar{\Lambda}_{,1}+\bar{\eth}\Lambda_{,+}. \tag{4}$$

On p. 5000, the expression for Q given by (A8) is incorrect by an overall minus sign. The correct expression reads as

$$Q=\frac{1}{4q}D\bar{\Lambda}_1 D\Lambda_1+\frac{3}{8q^2}(Dq)^2-\frac{1}{4q}D^2 q. \tag{5}$$

In Appendix B, there is a typo on the T_1^i given by Eq. (B4). The correct expression for the T_i^1 reads as

$$qT_i^1=\{\Lambda_{,i}\bar{\Lambda}_{,+}+\eth\bar{\Lambda}_{,i}+\bar{\Lambda}_-\delta_i^1+\bar{\Lambda}_{,0}\delta_i^+-2\delta_i^-\}\Lambda_{,1}+\bar{\eth}\Lambda_{,i}+\Lambda_{,-}\bar{\Lambda}_{,i}+\Lambda_{,0}\delta_i^-+\Lambda_+\delta_i^1-2\delta_i^+. \tag{6}$$

[S0022-2488(99)00802-6]

We list a series of corrections to equations appearing in Ref. 1. None of the following affect the content of the article. On p. 5007 and 5018, Eq. (8) contains a sign mistake. The correct equation (8) should read as

$$\nu' = \nu + \tfrac{1}{4}\partial^a \xi_a . \tag{1}$$

On p. 5011, the expressions for the metric components f^{11} and f_{00} in Eqs. (24) and (25) contain a typo. The correct expressions read as

$$f^{11} = -\tfrac{1}{2}\bar{\eth}^2\Lambda_1 + \eth\overline{\Lambda_-} = -\tfrac{1}{2}\eth^2\overline{\Lambda_1} + \bar{\eth}\Lambda_+ , \tag{2}$$

$$f_{00} = -\tfrac{1}{2}\bar{\eth}^2\Lambda_1 + \eth\overline{\Lambda_-} = -\tfrac{1}{2}\eth^2\overline{\Lambda_1} + \bar{\eth}\Lambda_+ . \tag{3}$$

On p. 5015, in the text of the 18th line, one undisplayed expression is wrong. In the paper it reads as *Using (27) to eliminate* $\eth\Lambda_-$ *on the left* . . . . The correct expression should read as *Using (27) to eliminate* $\eth\Lambda_1$ *on the left* . . .

On p. 5016, a sequence of four displayed equations contain mistaken factors. The correct equation (48) should read as

$$-\frac{1}{4}\eth^3\overline{\Lambda_1} = \bar{\eth}\sigma,_0 + 3\bar{\eth}\int_\infty^R \partial_-\ \eth\nu\ d\tilde{R} - 3\eth\nu - \frac{3}{2}\,\eth^2\ \bar{\eth}\nu. \tag{4}$$

The displayed equation immediately below (48) should read as

$$\bar{\eth}^2\Lambda_0 = -\tfrac{1}{4}\,\bar{\eth}\ \eth^3\overline{\Lambda_1} - \tfrac{1}{4}\,\eth\bar{\eth}^3\Lambda_1 + 2\bar{\eth}\ \eth\nu + \eth\bar{\eth}\eth\ \bar{\eth}\nu. \tag{5}$$

The correct equation (49) should read as

$$\bar{\eth}^2\Lambda_0 = \bar{\eth}^2\sigma,_0 + \eth^2\overline{\sigma},_0 + 3\bar{\eth}^2\int_\infty^R \partial_-\ \eth\nu\ d\tilde{R} + 3\eth^2\int_\infty^R \partial_+\ \bar{\eth}\nu\ d\tilde{R} - 4\bar{\eth}\ \eth\nu - 2\bar{\eth}\eth^2\ \bar{\eth}\nu. \tag{6}$$

Finally, the correct lightcone cut equation (50) should read as

$$\bar{\eth}^2\ \eth^2 Z = \eth^2\sigma + \eth^2\overline{\sigma} + \int^u \left(3\bar{\eth}^2\int_\infty^R \partial_-\ \eth\nu\ d\tilde{R} + 3\eth^2\int_\infty^R \partial_+\bar{\eth}\nu\ d\tilde{R} - 4\bar{\eth}\eth\nu\ \ - 2\bar{\eth}\eth^2\ \bar{\eth}\nu \right) d\tilde{u}. \tag{7}$$

Analytical solution of the relativistic Coulomb problem with a hard core interaction for a one-dimensional spinless Salpeter equation

F. Brau[a)]
Université de Mons-Hainaut, Place du Parc 20, B-7000 Mons, Belgium

(Received 25 March 1998; accepted for publication 11 December 1998)

In this paper, we construct an analytical solution of the one-dimensional spinless Salpeter equation with a Coulomb potential supplemented by a hard core interaction, which keeps the particle in the x positive region. © *1999 American Institute of Physics.* [S0022-2488(99)02003-4]

I. INTRODUCTION

A simple relativistic version of the Schrödinger equation is the Spinless Salpeter Equation (SSE). For the one-dimensional case we have

$$\sqrt{-d_x^2+m^2}\Psi(x)=(E-V(x))\Psi(x), \tag{1}$$

where m is the mass of the particle, $V(x)$ is the potential interaction, E the eigenenergy of the stationary state $\Psi(x), d_x^2=d^2/dx^2=-p^2$ and p is the relative momentum of the particle ($\hbar=c=1$). p and x are conjugate variables. The differential operator of the Schrödinger equation is well defined because it is a second derivative. To solve a physical problem, we must just solve an ordinary eigenvalue differential equation. The situation is more complicated with the SSE because the associated differential operator is a nonlocal one. Its action cannot be calculated directly from its operator form. Indeed, its action on a function $f(x)$ is known only if $f(x)$ is an eigenfunction of the operator d_x^2. In this case we obtain

$$\sqrt{-d_x^2+m^2}f(x)=\sqrt{-\alpha+m^2}f(x), \tag{2}$$

where α is the corresponding eigenvalue of d_x^2. That is why we need first to rewrite the SSE into a form easier to handle. Since the operator is a nonlocal one, this form could be an integral equation. This have been done for the three-dimensional case in Refs. 1, 2. We present the one-dimensional corresponding form in the next section. With the method used to obtain this form, it is possible to rewrite the SSE as an integro-differential equation (see Ref. 2 for the three-dimensional case). But the kernel is really complicated and the resulting equation seems to be very difficult to treat. We will use, here, another method to obtain the solution of the equation.

To solve the relativistic Coulomb problem we do not solve any differential equation. We calculate the action of the square-root operator on the functions $x^n e^{-\beta x}$. Because the result is analytical and because the wave functions of the Coulomb problem with a hard core interaction are an exponential multiplied by a polynomial, which is also the form of the Schrödinger and Klein–Gordon wave functions, a complete solution of Eq. (1), with $V(x)\propto 1/x$ and $x>0$, can be found.

The paper is organized as follow. In Sec. II, we give some useful mathematical results concerning the square-root operator. In Sec. III, we solve the one-dimensional Coulomb problem

[a)]Electronic mail: fabian.brau@umh.ac.be

with a hard core interaction. In Sec. IV, we compare our results to those obtained with the Schrödinger equation[3–6] and with the Klein–Gordon equation.[7,8] At last, we give our conclusion in Sec. V.

II. MATHEMATICAL FRAMEWORK

In this section we give some results concerning the square-root operator which we use to solve the Coulomb problem supplemented by a hard core interaction.

A. Integral representation of the square-root operator

To obtain the integral representation of the square-root operator we use the Fourier transform of the one-dimensional delta function. We have

$$\sqrt{-d_x^2+m^2}\Psi(x)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}dp\,dq\,\sqrt{p^2+m^2}e^{-i(q-x)p}\Psi(q). \tag{3}$$

Extracting the operator $-d_x^2+m^2$ and integrating over the momentum p (see Ref. 1) we obtain

$$\begin{aligned}\sqrt{-d_x^2+m^2}\Psi(x)&=\frac{1}{\pi}(-d_x^2+m^2)\int_{-\infty}^{+\infty}dq\,K_0(m|q-x|)\Psi(q)\\&=\frac{1}{\pi}(-d_x^2+m^2)\int_0^{+\infty}dq\,K_0(mq)[\Psi(x+q)+\Psi(x-q)],\end{aligned} \tag{4}$$

where $K_0(x)$ is the modified Bessel function of order 0 (Ref. 9, p. 952).

B. Invariant space functions of the one-dimensional square-root operator

In this section we calculate the action of the square-root operator on the functions $x^n e^{-\beta x}$. We obtain that the result is equal to a polynomial of order n, $M_n(m,\beta,x)$, multiplied by the same exponential. Thus, the space of functions $P_n(x)e^{-\beta x}$ is the invariant space functions of this operator. Using formula (4) we have

$$\sqrt{-d_x^2+m^2}x^n e^{-\beta x}=\frac{1}{\pi}(-d_x^2+m^2)e^{-\beta x}\int_0^{+\infty}dq\,K_0(mq)[(x+q)^n e^{-\beta q}+(x-q)^n e^{\beta q}]. \tag{5}$$

This leads to (Ref. 9, p. 712)

$$\sqrt{-d_x^2+m^2}x^n e^{-\beta x}=\frac{1}{\sqrt{\pi}}(-d_x^2+m^2)e^{-\beta x}\sum_{k=0}^{n}\binom{n}{k}G_k(m,\beta)x^{n-k}. \tag{6}$$

The coefficients $G_k(m,\beta)$ are given by

$$G_k(m,\beta)=\frac{\Gamma(k+1)^2}{\Gamma(k+3/2)}\left(\frac{1}{(m+\beta)^{k+1}}F\left(k+1,1/2;k+3/2;-\frac{m-\beta}{m+\beta}\right)+(-)^k(\beta\to-\beta)\right), \tag{7}$$

where $F(\alpha,\beta;\gamma;x)$ is the hypergeometric function (Ref. 9, p. 1039). Performing the derivation in Eq. (6) and rearranging the obtained relation, we have

$$\begin{aligned}\sqrt{-d_x^2+m^2}x^n e^{-\beta x}=\frac{1}{\sqrt{\pi}}e^{-\beta x}\sum_{k=0}^{n}\binom{n}{k}\{&(m^2-\beta^2)G_k(m,\beta)\\&+2\beta k G_{k-1}(m,\beta)-k(k-1)G_{k-2}(m,\beta)\}x^{n-k}.\end{aligned} \tag{8}$$

It is possible to write the coefficients $G_k(m,\beta)$ into a more useful form. This form will allow us to find a recursion relation between the coefficients $G_k(m,\beta)$ and to simplify the expression (8). We will be able to construct the polynomial, $M_n(m,\beta,x)$, for each value of n. We have the relation (Ref. 10, p. 562)

$$F(a,1/2;a+1/2;-x)=\Gamma(a+1/2)\,\frac{x^{(1-2a)/4}}{\sqrt{1+x}}\,P_{-1/2}^{1/2-a}\left(\frac{1-x}{1+x}\right), \tag{9}$$

with $x>0$. The functions $P_\nu^\mu(x)$ are the associated Legendre functions for x real and $|x|<1$. With this relation, we find that

$$G_{k-1}(m,\beta)=\frac{\Gamma(k)^2}{\sqrt{2m}(m^2-\beta^2)^{(2k-1)/4}}[P_{-1/2}^{1/2-k}(\beta/m)+(-)^{k-1}P_{-1/2}^{1/2-k}(-\beta/m)]. \tag{10}$$

Now, using the recursion relation of the associated Legendre functions (Ref. 9, p. 1005),

$$P_\nu^{\mu+2}(x)=-2(\mu+1)\,\frac{x}{\sqrt{1-x^2}}\,P_\nu^{\mu+1}(x)+(\mu-\nu)(\mu+\nu+1)P_\nu^\mu(x), \tag{11}$$

and the explicit expression of $P_{-1/2}^{-1/2}(x)$ and $P_{-1/2}^{1/2}(x)$ (Ref. 9, p. 1008), we can write the following relations:

$$G_{k+2}(m,\beta)=\frac{1}{m^2-\beta^2}[(k+1)^2G_k(m,\beta)-(2k+3)\beta G_{k+1}(m,\beta)], \tag{12}$$

with

$$G_0(m,\beta)=\sqrt{\frac{\pi}{m^2-\beta^2}}, \tag{13}$$

$$G_1(m,\beta)=-\frac{\sqrt{\pi}\beta}{(m^2-\beta^2)^{3/2}}. \tag{14}$$

At last, one can find, using Eq. (12), that the general coefficient of the sum of Eq. (8) becomes

$$F_{k,n}(m,\beta)=\frac{1}{\sqrt{\pi}}\binom{n}{k}[\beta G_{k-1}(m,\beta)-(k-1)G_{k-2}(m,\beta)], \quad \text{with } k\geqslant 1. \tag{15}$$

And with this form, a recursion relation for $F_{k,n}(m,\beta)$ can be easily found. Thus, to conclude this section, we are able now to rewrite Eq. (8) into a simple form:

$$\sqrt{-d_x^2+m^2}x^n e^{-\beta x}=M_n(m,\beta,x)e^{-\beta x}=\left[\sum_{k=0}^{n}F_{k,n}(m,\beta)x^{n-k}\right]e^{-\beta x}, \tag{16}$$

$$F_{0,n}(m,\beta)=\sqrt{m^2-\beta^2}, \tag{17}$$

$$F_{1,n}(m,\beta)=\frac{n\beta}{\sqrt{m^2-\beta^2}}, \tag{18}$$

$$F_{k+2,n}(m,\beta)=\frac{n-k-1}{(k+2)(m^2-\beta^2)}[(k-1)(n-k)F_{k,n}(m,\beta)-(2k+1)\beta F_{k+1,n}(m,\beta)], \tag{19}$$

$$F_{k,n+1}=\frac{n+1}{n+1-k}F_{k,n}. \tag{20}$$

We can see that we obtain the expected relation [from Eq. (2)] for $n=0$. And thus we see that we must have $\beta<m$. With the relations (17)–(20) the polynomial $M_n(m,\beta,x)$ is completely defined and we can construct it for each value of n. This result will allow us to find, with few calculations, the solution of the one-dimensional relativistic Coulomb problem with a hard core interaction. We give below the polynomials, as an example, for $n=0\rightarrow 4$,

$$M_0(m,\beta,x)=S, \tag{21}$$

$$M_1(m,\beta,x)=Sx+\frac{\beta}{S}, \tag{22}$$

$$M_2(m,\beta,x)=Sx^2+\frac{2\beta}{S}x-\frac{m^2}{S^3}, \tag{23}$$

$$M_3(m,\beta,x)=Sx^3+\frac{3\beta}{S}x^2-\frac{3m^2}{S^3}x+\frac{3m^2\beta}{S^5}, \tag{24}$$

$$M_4(m,\beta,x)=Sx^4+\frac{4\beta}{S}x^3-\frac{6m^2}{S^3}x^2+\frac{12m^2\beta}{S^5}x-\frac{3m^2}{S^7}(m^2+4\beta^2), \tag{25}$$

with

$$S=\sqrt{m^2-\beta^2}. \tag{26}$$

Note that these last relations can be simply checked by acting the square-root operator on each side of Eq. (16). For $n=1$, we see that we have an identity if we use the relation for $n=0$. Now, knowing these two relations we see that the relation for $n=2$ is also an identity, and so on for each value of n.

III. THE ONE-DIMENSIONAL RELATIVISTIC COULOMB PROBLEM WITH A HARD CORE INTERACTION

The equation to solve is

$$\sqrt{-d_x^2+m^2}\Psi(x)=\left(E+\frac{\kappa}{x}\right)\Psi(x). \tag{27}$$

We just consider here the case $x>0$ (we will discuss after the extension to the whole x axis). Physically this means that we have a hard core interaction for $x\leqslant 0$. Then the wave functions will possess the following asymptotic behavior: $\Psi(x)=0$ for $x\leqslant 0$ and for $x=+\infty$. Suppose that the wave functions have the following form:

$$\begin{aligned}\Psi(x)&\propto\sum_{k=1}^{n}\gamma_{k,n}x^k e^{-\beta x}, \quad \text{for} \quad x>0 \quad \text{and} \quad n=1,2,...,\\ \Psi(x)&=0 \quad \text{for} \quad x\leqslant 0.\end{aligned} \tag{28}$$

We do not consider the normalization of the functions here. Thus, replacing Eq. (28) into Eq. (27) and using Eq. (16), we obtain

$$\sum_{k=1}^{n} \gamma_{k,n} \sum_{p=0}^{k} F_{p,k}(m,\beta) x^{k-p} = E \sum_{k=1}^{n} \gamma_{k,n} x^k + \kappa \sum_{k=1}^{n} \gamma_{k,n} x^{k-1}. \tag{29}$$

Now equaling order by order we will determine the solution. The term of order n gives

$$E = F_{0,n}(m,\beta) = \sqrt{m^2 - \beta^2}. \tag{30}$$

From the term of order $n-1$, we have

$$\kappa = F_{1,n}(m,\beta), \tag{31}$$

which leads to

$$\beta = \frac{\kappa m}{n\sqrt{1+(\kappa/n)^2}}. \tag{32}$$

We can remark that we have as well the necessary relation $\beta < m$. We are now already able to determine the energy spectrum. Using Eq. (30) and Eq. (32) we have

$$E = \frac{m}{\sqrt{1+(\kappa/n)^2}}. \tag{33}$$

To obtain a complete solution, we must now find all the $\gamma_{k,n}$, and prove that the system of equations which gives these quantities always has a solution. Obviously we can fix $\gamma_{n,n}=1$. We see that the term of order $n-j$ determines the coefficient $\gamma_{n-j+1,n}$ if the previous $\gamma_{k,n}$ are known. Beginning with the term of order $n-2$, we obtain directly $\gamma_{n-1,n}$. And now we can get $\gamma_{n-2,n}$ from the term of order $n-3$. The independent term will fix the last factor $\gamma_{1,n}$. Thus, we have a triangular system of $n-1$ algebraic equations with $n-1$ unknowns. This system will always possess a solution if the determinant of the coefficient matrix is non-null. As this is a triangular matrix, the determinant is the product of the diagonal elements. The expression of these elements is $\kappa - F_{1,n-j}(m,\beta)$ which is equal to $j\beta/S$. These quantities are always non-null since $j>0$. The general form of $\gamma_{k,n}$ is obtained from the term of order $n-j-1$. We have

$$\gamma_{n-j,n} = \frac{S}{j\beta} \sum_{k=0}^{j-1} \gamma_{n-k,n} F_{j-k+1,n-k}(m,\beta). \tag{34}$$

We can inverse the summation to finally obtain

$$\gamma_{n-j,n} = \sum_{p_1=0}^{j-1} \sum_{p_2=0}^{p_1-1} \cdots \sum_{p_j=0}^{p_{j-1}-1} \tilde{F}(n,p_1,j)\tilde{F}(n,p_2,p_1)\ldots\tilde{F}(n,p_j,p_{j-1}), \tag{35}$$

with

$$\tilde{F}(n,k,j) = \frac{S}{j\beta} F_{j-k+1,n-k}(m,\beta). \tag{36}$$

For the summation in Eq. (35), we must use the following rule: If in a summation over p_α, α being arbitrary, the bound $p_{\alpha-1}-1$ is negative, all the $\tilde{F}(n,k,j)$ containing the indices $p_{\beta \geqslant \alpha}$ are equal to 1. With the formula (35), we are able to construct the wave functions for the Coulomb problem with a hard core interaction. As an example we give the three first wave functions:

$$\Psi(x) \propto x Q_n(m,\kappa,x) e^{-\beta x}, \tag{37}$$

with β given by Eq. (32), and

$$Q_1(m,\kappa,x)=1, \tag{38}$$

$$Q_2(m,\kappa,x)=x-\frac{m^2}{S^2\beta}, \tag{39}$$

$$Q_3(m,\kappa,x)=x^2-\frac{3m^2}{S^2\beta}x+\frac{3m^2}{2\beta^2S^4}(\beta^2+m^2), \tag{40}$$

with S defined by Eq. (26). Again, we can perform a simple verification by putting these solutions into Eq. (27) and using Eq. (16).

Contrary to the Schrödinger or Klein–Gordon equation, the extension of the solution to the whole x axis is really more complicated. We can try to use $\exp(-\beta|x|)$ instead of $\exp(-\beta x)$ in our solution. But the situation is quite more difficult. Indeed, the construction of the solution was based on the fact that $\exp(-\beta x)$ was an eigenfunction of the square-root operator and that the invariant space functions of this operator was $P_n(x)\exp(-\beta x)$, where $P_n(x)$ is a polynomial of order n. But it is easy to show, with Eq. (4), that

$$\sqrt{-d_x^2+m^2}\exp(-m|x|)=\frac{2m}{\pi}K_0(m|x|). \tag{41}$$

This is non-null, as this is the case in the Eq. (16). Thus, $\exp(-\beta|x|)$ is not an eigenfunction of the square-root operator and $P_n(x)\exp(-\beta|x|)$ is not an invariant space function of this operator. So it seems that the pure Coulomb problem has quite different solutions for the wave functions and certainly for the spectrum.

IV. DISCUSSION

The one-dimensional Coulomb problem has been treated by many authors, both nonrelativistically[3–6] and relativistically.[7,8] But in these works the whole x axis is considered. As a consequence, the ground state gives some difficulties.

In the nonrelativistic case the solution is

$$\Psi(x)=x\exp(-\kappa m|x|/n)L_{n-1}^{(1)}(2\kappa m|x|/n), \tag{42}$$

$$E=m-\frac{m\kappa^2}{2n^2}, \quad \text{with } n=1,2,\ldots. \tag{43}$$

But we see that for $n=1$, the wave function has a node at the origin. So this is not the wave function for the ground state. In fact, it is found to be infinitely bounded and the wave function is a delta function.[3,8]

In the Klein–Gordon case the solution is

$$\Psi(x)=x^S\exp(-\beta|x|/2)L_{n-1}^{(\gamma)}(\beta|x|), \tag{44}$$

$$E=m\Big/\sqrt{1+\frac{\kappa^2}{(n-1+S)^2}}, \tag{45}$$

with

$$\beta=2m\kappa/\sqrt{(n-1+S)^2+\kappa^2}, \quad \text{with } n=1,2,\ldots, \tag{46}$$

and

$$S=\tfrac{1}{2}(1+\gamma)=\tfrac{1}{2}(1\pm\sqrt{1-4\kappa^2}). \tag{47}$$

Thus, we see that we have two distinct solutions according the sign for S. Actually, the spectrum with the minus sign for S is not acceptable. Indeed, a reason is that, for $n=1$, when we perform the limit $\kappa\to 0$, we obtain $E=0$. This means that the particle is still bounded when the interaction vanishes. Thus, the problem for the ground state persists (see Ref. 8 for a complete discussion).

In this paper we do not consider the whole x axis and we have no problem with the ground state. We consider a hard core interaction, for $x\leqslant 0$, which gives $\Psi(x)=0$ in this region. Thus, $x\exp(-\beta x)$ is the wave function for the ground state. Actually the purpose of these work was to solve a particular kind of differential equations with a difficult to handle nonlocal operator. Indeed, any analytical solutions are known for the spinless Salpeter equation. Thus, we do not discuss the problem of the ground state of the one-dimensional Coulomb problem. In Sec. III, we have shown that the extension to the whole x axis is not easy. Moreover, the ground state problem could persist.

To compare our result to the results of previous works, we can consider the Schrödinger and the Klein–Gordon equation for the Coulomb potential supplemented by a hard core interaction. The spectra and the wave functions remain unchanged but the ground state problem has disappeared. In the three cases we have the same kind of wave functions: an exponential (with different arguments) multiplied by a polynomial (with different coefficients). For the spectrum we have, in the limit of small κ,

$$E_{\text{Sch}}=m\left(1-\frac{\kappa^2}{2n^2}\right), \tag{48}$$

$$E_{\text{KG}}=m\left(1-\frac{\kappa^2}{2n^2}-\frac{\kappa^4}{n^3}+\frac{3\kappa^4}{8n^4}\right), \tag{49}$$

$$E_{\text{Sal}}=m\left(1-\frac{\kappa^2}{2n^2}+\frac{3\kappa^4}{8n^4}\right). \tag{50}$$

Thus we see that in the expansion of the Salpeter spectrum the term in n^3 is missing compared to the Klein–Gordon spectrum. So the difference between these two spectra is rather important. For an electron in an electromagnetic Coulomb potential, the splitting is about 10^{-3} eV.

Another characteristic of the spinless Salpeter spectrum is that κ can grow up without limit. This could come from the fact that we have another kinetic operator than in the Klein–Gordon equation and that the result could be quite different. But the main explanation is certainly that we do not solve the real Coulomb problem and that this spectrum could be different contrary to the Klein–Gordon equation, which keeps the same spectrum in both cases. Indeed, for the SSE, there exists a limit value for κ in three dimensions.[11]

V. CONCLUSION

The purpose of this work was to find an analytical solution of a particular kind of differential equations containing a nonlocal differential operator. The equation considered in this paper, the one-dimensional spinless Salpeter equation (SSE), is a simple relativistic version of the one-dimensional Schrödinger equation. The SSE is not a marginal equation. For three dimensions, this equation comes from the Bethe–Salpeter equation (Refs. 12, 13, p. 297), which gives the correct description of bound states of two particles. Moreover, despite the presence of a so particular operator, the SSE is often used in the potential models (see, for instance, Refs. 14–20), which give a phenomenological description of hadrons.

To find this analytical solution, we calculate, in Sec. II B, the action of the square-root operator on a polynomial multiplied by an exponential and we show that this constitutes the invariant space functions of this operator. To be able to perform this calculation, we have constructed, in Sec. II A, an integral representation of the square-root operator. In Sec. III, we have obtained, without solving any differential equation, a complete solution of the SSE with a Coulomb potential and a hard core interaction. This last interaction is introduced to keep the particle in the *x* positive region. We remark that the SSE wave functions have the same form than the Schrödinger and the Klein–Gordon wave functions. We remark also that the splitting between the SSE and the Klein–Gordon spectrum is rather important. Indeed, it is of the same order of the first relativistic correction given by these two equations.

(Received 28 July 1998; accepted for publication 11 November 1998)

An unexpected and very accurate scaling invariance of the Casimir energy of the piecewise uniform relativistic string is pointed out. The string consists of $2N$ pieces of equal length, of alternating type I/type II material, endowed with different tensions and mass densities but adjusted such that the velocity of transverse sound equals c. If $E_N(x)$ denotes the Casimir energy as a function of the tension ratio $x = T_{\mathrm{I}}/T_{\mathrm{II}}$, it turns out that the ratio $f_N(x)=E_N(x)/E_N(0)$, which lies between zero and one, will be practically *independent* of N for integers $N \geqslant 2$. Physical implications of this scaling invariance are discussed. Finite temperature theory is also considered. © *1999 American Institute of Physics.* [S0022-2488(99)02902-3]

I. INTRODUCTION

The purpose of the present paper is to discuss a rather unexpected scaling property of the Casimir energy for a piecewise uniform, relativistic string executing planar oscillations in its own plane. Both the zero temperature and the finite temperature theory will be considered.

First, some background material about the system: The string is taken to consist of $2N$ pieces of equal length, of alternating type I and type II material, and it is relativistic in the sense that the velocity of transverse sound is equal to the velocity of light. Figure 1 shows a sketch of the string in the case when $N=6$ (for clarity the thickness of the string is drawn finite in the figure). The center of mass of the string lies at rest. The total length of the string is L.

The piecewise uniform string model in its simplest version was introduced by Brevik and Nielsen in 1990,[1] and the model has since then been analyzed from various points of view.[2–10] The particular case of a $2N$-piece string was considered in Refs. 4, 7, and 10. In Ref. 7, a general formula for the Casimir energy $E_N(x)$ was derived, x meaning the ratio between the tensions T_{I} and T_{II} in the two kinds of material,

$$x=\frac{T_{\mathrm{I}}}{T_{\mathrm{II}}}. \tag{1}$$

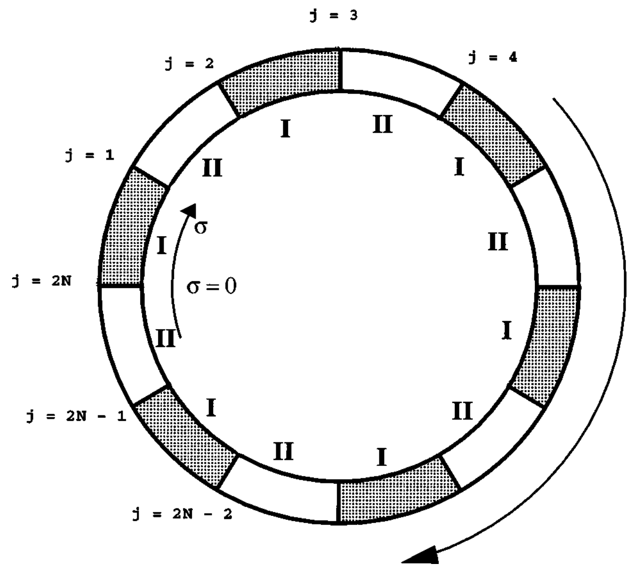

FIG. 1. Sketch of the composite $2N$ string, when $N=6$.

The formula reads, at zero temperature,

$$E_N(x)=\frac{N}{2\pi L}\int_0^\infty \ln\left|\frac{2(1-\alpha^2)^N-[\lambda_+^N(iq)+\lambda_-^N(iq)]}{4\sinh^2(Nq/2)}\right|dq. \tag{2}$$

Here α is defined as

$$\alpha=\frac{1-x}{1+x} \tag{3}$$

and $\lambda_\pm$ are the eigenvalues, for complex arguments iq, of the dispersion equation. Explicitly,

$$\lambda_\pm(iq)=\cosh q-\alpha^2\pm[(\cosh q-\alpha^2)^2-(1-\alpha^2)^2]^{1/2}. \tag{4}$$

We are now able to explain more closely the scaling property mentioned above: the Casimir energy, which is defined as the zero-point energy for the composite string minus the zero-point energy for the uniform string, turns out to be always nonpositive. And for a given value of the integer N, $E_N(x)$ becomes more negative the more the ratio x deviates from unity. [Note that the case $x=1$ corresponds to a uniform string, so that $E_N(1)=0$.]

Since the theory is invariant under the substitution $x\rightarrow 1/x$, we can limit ourselves to the case $x\leqslant 1$. The minimum energy for a given value of N is thus $E_N(0)$. In Ref. 7 the exact result in this case was calculated to be

$$E_N(0)=-\frac{\pi}{6L}(N^2-1). \tag{5}$$

Figure 2, which is equivalent to Fig. 4 in Ref. 7, shows how the ratio $f_N(x)$, defined as

$$f_N(x)=\frac{E_N(x)}{E_N(0)}, \tag{6}$$

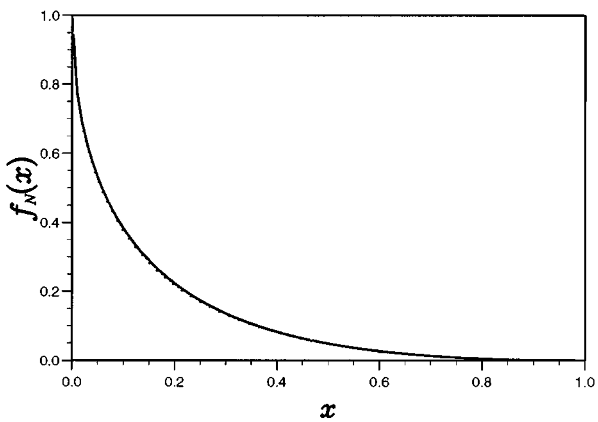

FIG. 2. The Casimir energy $f_N(x)=E_N(x)/E_N(0)$ versus tension ratio $x=T_{\rm I}/T_{\rm II}$, for $N=2,3,4,...,10$. The various curves collapse in practice into a single curve.

varies with x, for some different values of N $(N=2,3,4,...,10)$. It is seen that the various curves collapse in practice into a single curve. This is the scaling property. It means that for any x and $N\geqslant 2$ the Casimir energy, relative to the minimum obtainable energy, is to a very high accuracy independent of N.

This result—which is so far a property following from the numerics—is rather unexpected. It would be desirable to examine the issue more closely. This is the theme of the present paper. The problem is two-faceted. On the mathematical side one may ask: can we give at least a partial derivation of the scaling invariance in analytical terms? Moreover, can we give effective analytical expressions which reproduce the scaling invariance with satisfactory accuracy? And, on the physical side: what is the physical interpretation of the scaling invariance? Will it be possible to gain at least a partial physical understanding of *why* the scaling invariance exists? These issues are not merely of academic interest. The composite string model as such is quite an attractive model of two-dimensional quantum field theory in general. Moreover, the model may be of interest in connection with cosmology also, in string theories of the early universe.

II. POWER EXPANSIONS: PRELIMINARY REMARKS

From a mathematical viewpoint the simplest way of approach is to make some kind of power expansion of the integrand in Eq. (2). Numerically, it turns out that the scaling property becomes more pronounced the larger the value of N is. When N is large, obviously $e^{-Nq}\ll 1$ except in the limit $q\rightarrow 0$. It accordingly becomes natural, as a first approach, to adopt

$$z=e^{-q} \tag{7}$$

as an expansion parameter, keeping terms of order z^{N-1} while neglecting terms of order z^N and higher.

As a simple illustration, let us put $N=3$, and expand $\lambda_{\pm}$ up to relative order z^2. From Eq. (4) we have

$$\lambda_+=z^{-1}[1-2\alpha^2 z+\alpha^2(2-\alpha^2)z^2], \tag{8}$$

$$\lambda_-=(1-\alpha^2)^2 z[1+2\alpha^2 z+\alpha^2(5\alpha^2-2)z^2] \tag{9}$$

[it is useful to note that $\lambda_+\lambda_-=(1-\alpha^2)^2$]. That means, when expanding the integrand in Eq. (2) to order z^2 we can neglect λ_-^N. We get

$$\ln\left|\frac{2(1-\alpha^2)^N-[\lambda_+^N(iq)+\lambda_-^N(iq)]}{4\sinh^2(Nq/2)}\right|=-2N\alpha^2 z\left[1-\left(1-\frac{3}{2}\alpha^2\right)z+\mathcal{O}(z^2)\right]. \tag{10}$$

Using this expansion in Eq. (2) and replacing $E_N(0)$ with $-\pi N^2/(6L)$ we get as a first approximation

$$f_N(x)\simeq\frac{3\alpha^2}{\pi^2}\left(1+\frac{3}{2}\alpha^2\right). \tag{11}$$

This simple formula is actually quite useful. While derived for the case $N=3$, it may tentatively be applied for higher values of N also. This assumes, of course, that terms of order z^3 can be neglected also when $N>3$. We cannot expect high accuracy in this way, but note from Eq. (11) its most important property: it is *independent* of N. That is, we trace already on the present simple level of investigation the mentioned scaling invariance.

Consider some numerics of Eq. (11): for $x=1$ (uniform string) the formula gives $f_N(0)=1$ as it should, and for $x=0.5$, for instance, the formula gives $f_N(0.5)\simeq 0.039\,40$ instead of the ''exact'' result $f_3(0.5)=0.047\,72$ calculated numerically from Eqs. (2) and (5) with $N=3$. In the limit $x\to 0(\alpha\to 1)$, Eq. (11) yields $f_N(0)\simeq 0.760$ instead of $f_N(0)=1$ as it should. As expected it is the limit $x\to 0$ which is critical here; it is in this case that the inaccuracy of the formula (11) is largest.

It is to be observed that the case $N=1$ is an exceptional case: for a relativistic string composed of two pieces of equal length the Casimir energy is *zero*, irrespective of the value of x:[1]

$$E_1(x)=0. \tag{12}$$

One may imagine now to continue the expansion technique in z further, with the aim to increase the accuracy. We have actually done this, by means of the Mathematica and the Maple analytic programs, and have managed to expand the integrand of Eq. (2) up to the 12th order in z, within a reasonable computer time. The resulting expressions are complicated and will not be given here. It turns out, in fact, at least to moderate orders in z, that insufficient accuracy will be obtained in this way. For instance, if we choose $N=7$ and expand the integrand of Eq. (11) up to order $z^{N-1}=z^6$, we find that the power expansion for $f_7(x)$ yields the result 2.806 (instead of 1) in the limit $x\to 0$. That is, the accuracy actually becomes poorer than in the simple case considered above. Some reflection shows that this kind of behavior should not be so unexpected after all: our expansion procedure which employs $z=e^{-q}$ as the smallness parameter is good for large values of q, but becomes poorer in the region of small q. And it is precisely in the last-mentioned region that the magnitude of the integral of Eq. (2) is largest.

Although the accuracy can be improved by going to very high orders in z, it becomes clear that the present simple expansion procedure of the integrand of Eq. (2) in powers of z is not the most economic way of handling the integral. In the next section we shall turn to another mathematical method, which is numerically very accurate and which, moreover, helps us to construct a simple, *analytic*, expression for $f_N(x)$.

III. MORE ACCURATE NUMERICS. ANALYTICAL REPRESENTATIONS

It is both numerically and analytically advantageous to solve the integral (2) by an accurate numerical method, without relying simply on ''black box'' routines. To obtain a better control over the integrand in the whole integration domain, we shall first use the parameter $z=e^{-q}$ to express $f_N(x)$ (for $N\geqslant 2$) as an integral over z from 0 to 1:

$$f_N(x)=\int_0^1 I_N(x,z)\,dz. \tag{13}$$

Here

$$I_N(x,z)=\frac{-3N}{\pi^2(N^2-1)z}\ln\left|\frac{2(1-\alpha^2)^N z^N-[(z\lambda_+)^N+(z\lambda_-)^N]2^{-N}}{(1-z^N)^2}\right|. \tag{14}$$

It turns out that analytic solutions are, in fact, achievable, for small values of N and some special values of x. We give two examples, both evaluated by means of Maple: the first is for $x=3-2\sqrt{2}$ $(\alpha=1/\sqrt{2})$, the second is for $x=\frac{1}{3}$ $(\alpha=\frac{1}{2})$. The exact results are

$$f_2(3-2\sqrt{2})=\tfrac{1}{4},\quad f_2(\tfrac{1}{3})=\tfrac{1}{9},\quad f_4(3-2\sqrt{2})=\tfrac{23}{90}$$

(note that these cases correspond to a four-piece, and an eight-piece, string).

In looking for analytic solutions of (14), we may use the fact that $(z-1)^2$ is a factor both in the numerator and the denominator. In the denominator we get: $(z^N-1)^2/(z-1)^2=(z^{N-1}+z^{N-2}+\cdots+z+1)^2$ giving the following expression for the integral of the denominator:

$$\frac{3N}{\pi^2(N^2-1)}\int_0^1\frac{\ln(z^{N-1}+z^{N-2}+\cdots+z+1)^2}{z}\,dz=\frac{1}{N+1}. \tag{15}$$

We are then left with integrating the numerator of (14) divided by $(z-1)^2$. Note that the numerator simplifies considerably for $\alpha=1/\sqrt{N}$. We give two examples: first for $N=3$ and $\alpha=1/\sqrt{3}$ which means that $x=2-\sqrt{3}$, the second example is for $N=5$ and $\alpha=1/\sqrt{5}$ which means that $x=(3-\sqrt{5})/2$. The exact results are

$$f_3(2-\sqrt{3})=\tfrac{5}{32},$$

$$f_5\left(\frac{1}{2}(3-\sqrt{5})\right)=\frac{1}{8}\left[3+\frac{5}{\pi^2}\left(2\arctan\left(\frac{4}{3}\right)-2\pi\right)\arctan\left(\frac{1}{2}\right)-2\Re\,\mathrm{dilog}\left(\frac{-3+4i}{5}\right)\right]=0.0\,897\,261.$$

Consider now the numerics. It is important to get control over the integrand in Eq. (13) at the points $z=0$ and $z=1$. At first sight, one might conclude from the expression (14) that these points are singular points. However, a closer scrutiny shows that they are regular. Now, numerical integration routines are, in general, classified into closed and open routines, where the closed routines make use of the endpoints (here $z=0$ and 1) while the open routines approach these points but do not use them explicitly. In our case it turned out that even modern open FORTRAN routines (such as DQAGS from QUADPACK) ran into problems when approaching $z=0$ and $z=1$. By means of analytic Taylor expansions around these points we managed, however, to find the following exact expressions at $z=0$ and 1:

$$I_N(x,0)=\frac{6N^2\alpha^2}{\pi^2(N^2-1)}, \tag{16}$$

$$I_N(x,1)=-\frac{3N}{\pi^2(N+1)}\ln(1-\alpha^2). \tag{17}$$

In the critical limit $x\to 0(\alpha\to 1)$ it is seen that $I_N(x,1)$ diverges logarithmically; this is nevertheless compatible with the integrand itself being finite, $f_N(x\to 0)=1$. Moreover, the limit $N\to\infty$ is seen to correspond to the simple expressions

$$I_\infty(x,0)=\frac{6\alpha^2}{\pi^2},\quad I_\infty(x,1)=-\frac{3}{\pi^2}\ln(1-\alpha^2). \tag{18}$$

TABLE I. Numerical results for $f_N(x)$ versus x, for some representative values of N.

x	$N=2$	$N=10$	$N=100$
0.02	0.6742	0.6833	0.6837
0.10	0.3721	0.3814	0.3818
0.20	0.2158	0.2224	0.2227
0.40	0.0795	0.0823	0.0824
0.80	0.00 502	0.00 521	0.00 522
0.90	0.00 112	0.00 117	0.00 117

Armed with the expressions (16) and (17) at the endpoints it becomes easy now to calculate $f_N(x)$. Our calculations were done with the FORTRAN routine DQAGS (double precision). It turned out to be possible to continue the calculations up to very high N values (about 4000), which for practical purposes is equivalent to infinity.

Table I shows some results for $f_N(x)$ versus x, calculated for $N=2$, 10, and 100. Higher values of N, up to $N=4000$, gave the same answers as $N=100$, to the accuracy shown. The scaling invariance is seen to be so accurate that a usual graphical representation of $f_N(x)$, such as Fig. 2, is unable to distinguish between the various curves. As a further check of the numerical calculation, we wrote a separate program in Maple exploiting the possibility that this language offers to set $N=\infty$ directly. The values for $f_\infty(x)$ calculated in this way were compared with those calculated above for $N=4000$, and were found to agree to a very high accuracy (to 7, or 8, digits).

It is now of interest to ask: is it possible to represent the numerical results calculated above with analytic formulas, to a satisfactory accuracy? The answer turns out to be yes, and the formulas become actually surprisingly simple. Let us start from the ansatz

$$f_N(x) \to f(x) = (1-x^b)^c, \tag{19}$$

where b and c are constants. The expression (19) implies that the magnitudes of the logarithms of $f(x)$ and $(1-x^b)$ are predicted to be proportional. Figure 3 shows the outcome of one of our tests: the ordinate $|\ln f(x)|$, which is calculated numerically, is compared with the abscissa $|\ln(1-x^b)|$ for

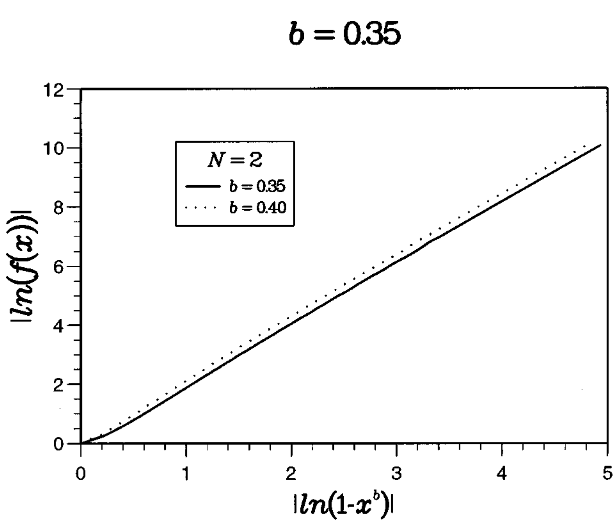

FIG. 3. Dependence of $\ln|f(x)|$, calculated numerically, upon $|\ln(1-x^b)|$ when $b=0.35$ and 0.40. The approximative linearity is evident.

$b=0.35$ and 0.40. The suggested linearity of the curve is seen to be verified quite accurately, although there is a weak change in slope around $x=0.45$. Numerical trials show that the simple form

$$f(x)=(1-\sqrt{x})^{5/2} \tag{20}$$

is a useful approximation when $0<x<0.45$. This form is intended to hold for all values of N.

We can analyze this behavior one step further, by considering the particular case $N=2$. Then we have from Eq. (13)

$$f_2(x)=-\frac{2}{\pi^2}\int_0^1 \ln\left|\frac{(1+z)^2-4\alpha^2 z}{(1+z)^2}\right|\frac{dz}{z}. \tag{21}$$

After some trials using Maple, we arrived at the following series expansion in x:

$$f_2(x)=1-\frac{8}{\pi}\sqrt{x}+\frac{16}{\pi^2}x+\frac{8}{3\pi}x^{3/2}-\frac{32}{3\pi^2}x^2-\frac{8}{5\pi}x^{5/2}+\frac{368}{45\pi^2}x^3$$
$$+\frac{8}{7\pi}x^{7/2}-\frac{704}{105\pi^2}x^4-\frac{8}{9\pi}x^{9/2}+\frac{9008}{1575\pi^2}x^5+\frac{8}{11\pi}x^{11/2}+\cdots. \tag{22}$$

This type of series is called a Puisseux series in mathematics. It is analogous to a Taylor series and is more accurate the smaller the value of x is. For $x=0.2$ the error is 0.015%; for $x=0.3$ it is 0.27%. For $x\geqslant 0.35$ the error becomes larger than 1%. Let us expand Eq. (22) around $x=0$:

$$f_2(x)=1-2.55\sqrt{x}+1.62\ x, \tag{23}$$

and similarly expand the empirical Eq. (20):

$$f_2(x)=1-\tfrac{5}{2}\sqrt{x}+\tfrac{15}{8}x\simeq 1-2.5\sqrt{x}+1.875\ x. \tag{24}$$

That is, we see from here the mathematical reason behind the structure of Eq. (20).

IV. ON THE PHYSICAL INTERPRETATION

The obvious question is now: what is the physical interpretation of the calculated scaling invariance?

Let us first remind ourselves about the main features of the string model: it is relativistic in the sense that the transverse sound velocity equals c; it consists of $2N$ pieces of alternating type I/II material but of equal length; and it is described by small amplitude wave theory since the condition that the transverse elastic force be continuous at the junctions is expressed as $T\partial\psi/\partial\sigma$ $=$continuous (ψ denotes the displacement, σ the length coordinate).

Assume now that there exists such a string somewhere in the universe (it is most natural to think about the early universe), and assume that it is possible to make use of zero temperature theory in the quantum mechanical sense. The Casimir energy of the string is caused entirely by its *inhomogeneity*. There are two factors contributing to this: the tension ratio x, and the integer N. It is natural to expect that a string, originally starting out with the Casimir energy $E_N(x)(<0)$, wishes to make this energy as low as possible. This can be done while maintaining N constant, if the tension ratio is made extreme, $x\to 0$. The string's energy becomes then lowered to $E_N(0)$ $=f^{-1}(x)E_N(x)=-(\pi/6L)(N^2-1)$, where the scaling invariance is being accounted for. Finally, the string may divide itself into a large number of pieces, implying a quadratic negative divergence when $N\to\infty$, $E_N(0)\to-(\pi/6L)N^2$.

The finite temperature case is more difficult to interpret (see Appendix), all the time that the Casimir energy in the case of extreme tension ratio is diverging, $E_N^T(0)\to-\infty$ for $N>1$, due to the classical contribution. It will not be further commented upon here.

Inhomogeneous strings of the type considered here have not been observed in nature. As mentioned, its most probable application seems to lie within cosmology. Perhaps particle physics can be a possible application also: it is rather striking to observe how closely the above relativistic theory is formally related to the electrodynamic (or gluo-dynamic) theory of a field propagating in a medium whose (color) permitivity ϵ and permeability μ satisfy the condition $\epsilon\mu=1$. See, for instance, Lee's model of the exterior hadronic vacuum.[11]

APPENDIX A: THE CASE OF FINITE TEMPERATURES

The formulation of the theory when the string is situated in a thermal bath of temperature T is done by replacing the integral over imaginary frequencies $\xi=qN/L$ by a sum over discrete Matsubara frequencies, $\xi\to\xi_n=2\pi nk_BT$, with n an integer and k_B Boltzmann's constant. Referring to Eq. (2) we make the replacement $q\to q_n=L\xi_n/N$. The general substitution to be made in finite temperature quantum field theory is

$$\int_0^\infty d\xi\to 2\pi k_BT\sum_{n=0}^{\infty}{}', \tag{A1}$$

where the prime means that the term $n=0$ is taken with half weight. The finite temperature Casimir energy becomes[7]

$$E_N^T(x)=k_BT\sum_{n=0}^{\infty}{}'\ln\left|\frac{2(1-\alpha^2)^N-[\lambda_+^N(iq_n)+\lambda_-^N(iq_n)]}{4\sinh^2(Nq_n/2)}\right|. \tag{A2}$$

This formal expression holds for all integers N.

In the special case $N=1$ we get, since

$$\lambda_+(iq_n)-\lambda_-(iq_n)=2(\cosh q_n-\alpha^2), \tag{A3}$$

that

$$E_1^T(x)=0 \tag{A4}$$

for all x. Thus, a two-piece string composed of two equal parts will also, for finite temperature, have zero Casimir energy. The behavior is just as for $T=0$; cf. Eq. (12).

Of particular interest is the limit $x\to 0$, i.e., the critical case corresponding to minimum Casimir energy. According to Eq. (1.4) we then have

$$\lambda_+(iq_n)\to 4\sinh^2\left(\frac{q_n}{2}\right),\quad \lambda_-(iq_n)\to 0, \tag{A5}$$

so that from Eq. (A2) we get

$$E_N^T(0)=2k_BT\sum_{n=0}^{\infty}{}'\ln\left|\frac{2^N\sinh^N(q_n/2)}{2\sinh(Nq_n/2)}\right|. \tag{A6}$$

For $N=1$ we recover the result (A4), but for $N>1$ the expression (A6) actually *diverges*. This result would not be easy to anticipate beforehand. The divergence is caused by the $n=0$ term, i.e., by the lowest of all Matsubara frequencies. Low Matsubara frequencies are generally associated with the classical limit and are not related to quantum mechanics. It is noticeable that it is just this limit that is responsible for the divergence of (A6).

Some further insight can be obtained if we separate out the $n=0$ contribution to the general expression (A2). To this end we treat q_n as a small analytic variable, and expand

$$\cosh q_n-\alpha^2=(1-\alpha^2)\left[1+\frac{\frac{1}{2}q_n^2}{1-\alpha^2}+\mathcal{O}(q_n^4)\right], \tag{A7}$$

implying

$$|2(1-\alpha^2)^N-\lambda_+^N(iq_n)-\lambda_-^N(iq_n)|=(1-\alpha^2)^{N-1}N^2q_n^2 \tag{A8}$$

to the leading order. From Eq. (A2) we then get the expression

$$E_N^T(x)=k_\mathrm{B}T\left[\frac{N-1}{2}\ln(1-\alpha^2)+\sum_{n=1}^{\infty}\ln\left|\frac{2(1-\alpha^2)^N-\lambda_+^N(iq_n)-\lambda_-^N(iq_n)}{4\sinh^2(Nq_n/2)}\right|\right], \tag{A9}$$

in which the classical, $n=0$, contribution is explicit in the first term. If $N=1$ and x arbitrary, we recover the result (A4). If $x\to 0$ and $N>1$, we obtain $E_N^T(0)\to-\infty$, in accordance with Eq. (A6).

It is helpful to compare the expressions (A9) and (17). In both cases, the term $\ln(1-\alpha^2)$ appears. Expression (17) holds for $z=1$, i.e., $q=-\ln z=0$, which means zero frequency. When $x\to 0$ the expression is diverging. As we have seen, this divergence does not lead to an infinite energy $E_N(0)$ because the divergence is suppressed by the *integration* over q in Eq. (2). In the finite temperature case the integration is replaced by a Matsubara *sum* in which the zero temperature term will have to appear explicit. This illustrates why $E_N^T(0)$ is diverging, while $E_N(0)$ stays finite.

Generally speaking, the precise meaning of the "high temperature" limit ought to be made clear. There are *two* characteristic frequencies in this system, viz. a thermal frequency $\omega_T=k_\mathrm{B}T$, and a geometric frequency which may be defined as $\omega_\mathrm{geom}=1/L$. The high-temperature limit should be defined by the inequality $\omega_T/\omega_\mathrm{geom}\gg 1$, which implies $Nq_n=L\xi_n\gg 1$ for all $N\geq 1$. In this case the classical $n=0$ term gives the dominant contribution to the Casimir energy, and we obtain from (A9)

$$E_N^{T\to\infty}(x)=\frac{N-1}{2}k_\mathrm{B}T\ln(1-\alpha^2). \tag{A10}$$

We mention finally for completeness that we have in this Appendix considered the Casimir energy itself, not the fractional energy relative to the case $x\to 0$. To construct a fractional quantity $f_N^T(x)$, analogously to Eq. (6), would be meaningless since $E_N^T(0)$ is infinite.

(Received 28 September 1998; accepted for publication 27 October 1998)

We make a numerical study of the classical solutions of the combined system consisting of the Georgi–Glashow model and the SO(3) gauged Skyrme model. Both monopole-Skyrmion and dyon-Skyrmion solutions are found. A new bifurcation is shown to occur in the gauged Skyrmion solution sector. © *1999 American Institute of Physics.* [S0022-2488(99)04302-9]

I. INTRODUCTION

Monopole-Skyrmion solitons can be important in a semiclassical study of the Callan–Rubakov[1,2] mechanism for catalyzing proton decay. Indeed, the first such approach was made by Callan and Witten[3] where the U(1) gauged Skyrmion was coupled to the electromagnetic field of a monopole. Here, we study the classical soliton solutions of a model which incorporates the full non-Abelian monopole field and the corresponding gauged Skyrmion, described by an SO(3) gauged Skyrme model interacting with the Georgi–Glashow (GG) model through the gauge field. The solutions we study include both monopole-Skyrmions and dyon-Skyrmions.

There are two $3+1$ dimensional SO(3) gauge field models which support static soliton solutions. One is the GG model which supports the well-known monopole,[4] and the other is the $SU(2)_{L+R}$, or vector, gauged Skyrme model[5,6] which also supports SO(3) gauged Skyrmions. In addition to the monopole, the GG model supports also dyon solutions[7] which in addition to the magnetic charge carry an electric charge as well. The topological stability of the monopole comes from the magnetic charge, which is descended from the second Chern–Pontryagin charge, while the topological charge of the gauged Skyrmion is the degree of the map.

Combining these two models, we have a new system whose topological charge is a sum of the respective charges, and it can reasonably be expected that this system also supports static finite energy solitons. Note that in this case the local SO(3) symmetry is broken down to U(1) via the Higgs mechanism, in contrast to the SO(3) gauged Skyrme model on its own, in which case the local SO(3) symmetry is not broken at all and three massless gauge bosons survive. In this preliminary investigation, this is precisely what we have done. Using numerical methods, we verify that such solutions exist. Moreover, we have sought and found both monopole-Skyrmion and dyon-Skyrmion solutions, and studied some of their properties. The combined system supports solutions also with zero monopole charge, unit baryon charge, as well as with unit monopole charge, zero baryon charge.

Even though this is a self-contained numerical study of the classical solutions alluded to above, it is in order to put it into context both in the background of previous work involving the gauging of the Skyrme model,[8] and, from the viewpoint of its potential physical relevance.

The Skyrme model was gauged by Witten in Ref. 9, and others, e.g., in Ref. 10. These works were carried out in the context of current algebra results, and were not concerned with the solitonic aspects of the gauged Skyrmion. That was done subsequently by many authors, see, e.g., Ref. 11, where gauged Skyrme solitons were studied with the aim of explaining the low energy properties of Hadrons. Also in the context of electroweak theory, which can be regarded as a gauged Skyrme model in the limit of very high Higgs mass, Rubakov[12] and Eilam *et al.*[13] considered the static classical solutions of the SU_L gauged Skyrme model. In all these cases, there is no topological lower bound and the classical solutions are metastable, but for certain values of the parameters in one of these models[12,13] a stable branch of solitons appears as a result of catastrophic behavior. The advantage of the gauging used in Refs. 12 and 13 is that the four divergence of the topological current does not vanish but equals the local chiral anomaly,[14,15] which can present itself as a mechanism for Baryon number violation as explained in Ref. 12.

In the context of Baryon number violation, there is an older mechanism suggested by Rubakov[1] and by Callan[2] where monopole-(left-handed massless) fermion interactions lead to fermion number nonconservation. The mechanism involves the fluctuations of the electric field, in the presence of the magnetic field of the monopole, giving rise to nonzero chiral anomaly and hence fermion number violation. This was shown for the case of massless (left-handed) fermions, by scattering with the monopole, which describes a high energy process. The approximation techniques employed[1,2] are neither perturbation theoretic nor semiclassical. To describe a low energy process such as a decay, it would be more appropriate to deal with a process that is susceptible to semiclassical analysis. To this end, Callan and Witten[3] replaced the massless fermions by the Skyrme soliton,[8] interacting with the (Abelian) magnetic field of the monopole. While they[3] did not seek to demonstrate the existence of a U(1) gauged Skyrmion, this is implicit in their work and has recently been verified numerically.[16] In the background of this it is hoped that the present work, which sets out to find the monopole-Skyrmion and dyon-Skyrmion solutions, would be of concrete usefulness to a semiclassical method of describing baryon number decay. In particular the dyon-Skyrmion excites a nonzero classical quantity for the chiral anomaly, which can lead to chirality breaking as pointed out long ago by Marciano and Pagels.[17]

In Sec. II we present the model and give the topological lower bounds on the static energy. In Sec. III we give the static spherically symmetric fields and the field equations in the static limit. Sections IV and V deal, respectively, with the results of the numerical analysis of the $\mathbf{A}_0=0$ and $\mathbf{A}_0\neq 0$ cases. Section V in particular, includes an in-depth analysis of the Julia-Zee dyon.[7] In Secs. IV and V, we also give an account of the SO(3) gauged Skyrmion studied previously in Ref. 6, because these solutions play a certain technical role in the construction of dyon-Skyrmion solutions in Sec. V. We summarize and discuss our results in Sec. VI.

II. THE MODEL

The model under consideration is the combination of the Georgi–Glashow (GG) model and of the SO(3) gauged O(4) (Skyrme) model studied previously in Refs. 5 and 6. We state the Lagrangian of each of these models separately, defined in four-dimensional Minkowski space, each being normalized properly so that the value of the energy of the static soliton in each case lies above its own topological lower bound. The static solutions in question satisfy the Euler–Lagrange equations of the static energy density functional, which is the static Hamiltonian in the temporal gauge. In the GG case, this is the 'tHooft–Polyakov[4] monopole, while in the latter case it is the soliton studied in Refs. 5 and 6.

The GG model is described by

$$\mathcal{L}_{\mathrm{GG}}=-\tfrac{1}{4}\lambda_0^4|F_{\mu\nu}^{\alpha}|^2+\tfrac{1}{2}\lambda_1^4|D_\mu\Phi^{\alpha}|^2-\tfrac{1}{4}\lambda_2^4(\eta^2-|\Phi^{\alpha}|^2)^2, \tag{1}$$

$$F_{\mu\nu}^{\alpha}=\partial_\mu A_\nu^{\alpha}-\partial_\nu A_\mu^{\alpha}+\epsilon^{\alpha\beta\gamma}A_\mu^{\beta}A_\nu^{\gamma},\quad D_\mu\Phi^{\alpha}=\partial_\mu\Phi^{\alpha}+\epsilon^{\alpha\beta\gamma}A_\mu^{\beta}\Phi^{\gamma}. \tag{2}$$

The late Greek indices μ, ν,... label the Minkowski space vectors, while the early Greek indices α, β, $\ldots=1,2,3$ label the elements of the algebra of the gauge group SO(3). The Latin letters a, b, $\ldots=1,2,3,4$ so that $a=(\alpha,4)$ are reserved for the O(4) Skyrme model. In Eq. (1) the constant η is the vacuum expectation value (VEV) of the Higgs field and like the latter has the inverse dimension of a length. The constants λ_0, λ_1, and λ_2 are all dimensionless.

The SO(3) gauged Skyrme model is described by

$$\mathcal{L}_{O(4)} = -\tfrac{1}{4}\kappa_0^4 |F_{\mu\nu}^{\alpha}|^2 + \tfrac{1}{2}\kappa_1^2 |D_\mu \phi^a|^2 - \tfrac{1}{8}\kappa_2^4 |D_{[\mu}\phi^a D_{\nu]}\phi^b|^2, \tag{3}$$

$$D_\mu \phi^\alpha = \partial_\mu \phi^\alpha + \epsilon^{\alpha\beta\gamma} A_\mu^\beta \phi^\gamma, \quad D_\mu \phi^4 = \partial_\mu \phi^4, \tag{4}$$

with $\phi^\alpha\phi^\alpha + \phi^4\phi^4 = 1$.

The constants κ_0 and κ_2 are dimensionless and the constant κ_1 has dimension of an inverse length. The reason we keep all the coupling constants arbitrary in Eqs. (1) and (3) will appear soon.

When we consider the static Hamiltonians corresponding to the Lagrangians above in the temporal gauge, i.e., $A_0 = 0$, we can write the following topological identities:

$$\int d\mathbf{r}\, \mathcal{H}_{GG} \geqslant 4\pi\eta\lambda_0^2\lambda_1^2 M, \tag{5}$$

$$\mathcal{H}_{GG} = \tfrac{1}{4}\lambda_0^4 |F_{jk}^{\alpha}|^2 + \tfrac{1}{2}\lambda_1^4 |D_j \Phi^\alpha|^2 + \tfrac{1}{4}\lambda_2^4 (\eta^2 - |\Phi^\alpha|^2)^2, \tag{6}$$

where the integer M, representing the index of the mapping $\Phi^\alpha(\vec{x})$, is the monopole topological charge. Similarly[6]

$$\int d\mathbf{r}\, \mathcal{H}_{O(4)} \geqslant 12\pi^2 \kappa_1 \kappa_2^2 \frac{1}{2\sqrt{1 + 9\left(\frac{\kappa_2}{\kappa_0}\right)^4}} T, \tag{7}$$

$$\mathcal{H}_{O(4)} = \tfrac{1}{4}\kappa_0^4 |F_{jk}^{\alpha}|^2 + \tfrac{1}{2}\kappa_1^2 |D_j \phi^a|^2 + \tfrac{1}{8}\kappa_2^4 |D_{[j}\phi^a D_{k]}\phi^b|^2, \tag{8}$$

where the integer T, representing the index of the mapping $\phi^a(\vec{x})$, is the Skyrmion topological charge. In the Skyrme description of hadrons, T is identified with the baryon number.

In the following we will consider also the equations resulting from the superposition of the two Lagrangians Eqs. (1) and (3)

$$\mathcal{L}_m = \mathcal{L}_{GG} + \mathcal{L}_{O(4)}. \tag{9}$$

The finite energy configurations of this mixed Lagrangian are characterized by the couple of integers M, T. Classical solutions corresponding to the two different topological excitations can then be constructed, they correspond to the configuration with minimal energy in a class M, T.

In order to normalize the fields conventionally, we have to choose

$$\lambda_0^2 = \frac{1}{e}\cos(\theta), \quad \kappa_0^2 = \frac{1}{e}\sin(\theta), \quad \lambda_1^4 = 1, \tag{10}$$

where e denotes the gauge coupling constant. With the choice $\theta = \pi/4$, the topological inequality relating $\mathcal{H}_m$ to the class of solutions of indexes M, T reads

$$\int d\mathbf{r}\, \mathcal{H}_m \geqslant \frac{4\pi\eta}{e}\left(\frac{1}{\sqrt{2}}M + \frac{3\pi}{2}\sqrt{\frac{\xi\kappa}{1+18\kappa}}T\right), \tag{11}$$

where

$$\lambda = \frac{\lambda_2^4}{e^2}, \quad \xi = \frac{1}{\eta^2}\kappa_1^2, \quad \kappa = e^2\kappa_2^4. \tag{12}$$

In Eq. (12), λ is defined for later convenience. Note that the topological lower bound Eq. (11) can be refined by an optimal value of the mixing angle θ, depending on the parameters λ_1, λ_2, κ_1, κ_2. To achieve this it is necessary to solve a complicated nonlinear equation, which we shall not pursue here.

III. STATIC SPHERICALLY SYMMETRIC EQUATIONS

The classical equations corresponding to Eqs. (1), (3), and (9) are in general intractable. We will restrict our search of solutions to the static and spherically symmetric case. If we choose to employ the temporal gauge in the static limit, the Euler–Lagrange equations will reduce to the variational equations arising from the static Hamiltonians pertaining to the Lagrangians Eqs. (1) and (3). The latter would be bounded from below by the monopole charge and the baryon number densities, respectively. Hence the solutions to the classical equations of each of these static Hamiltonians, separately, can describe the 'tHooft–Polyakov monopole[4] and the soliton of the SO(3) gauged Skyrme model.[5,6] The Euler–Lagrange equations of the Hamiltonian of the combined static system, i.e., GG-Skyrme, in the temporal gauge also supports soliton solutions since the Hamiltonian is again bounded from below by the two topological charges Eq. (11). This is one of the problems studied in the present work yielding the monopole-Skyrmion solitons.

If instead of employing the temporal gauge we proceed like Julia and Zee[7] and solve the Euler–Lagrange equations pertaining to the Lagrangian Eq. (9) defined on Minkowski space in the static limit, the resulting solutions of the GG-Skyrme system describe the dyon-Skyrmion. This is the other problem studied in this work. As in the case of the dyon[7] on its own, we shall restrict ourselves to the spherically symmetric solutions only. (In this case the classical equations simplify sufficiently to become tractable. To our knowledge the only dyon solutions known are the spherically symmetric Julia–Zee[7] dyons.)

The spherically symmetric ansatz employed is

$$A_i^\alpha=\frac{a(r)-1}{r}\,\epsilon_{i\alpha\beta}\hat{x}^\beta, \quad A_0^\alpha=e\,\eta g(r)\hat{x}^\alpha, \tag{13}$$

$$\Phi^\alpha=\eta h(r)\hat{x}^\alpha, \tag{14}$$

$$\phi^\alpha=\sin f(r)\hat{x}^\alpha, \quad \phi^4=\cos f(r). \tag{15}$$

Notice that the functions $a(r)$, $h(r)$, $g(r)$, and $f(r)$ are dimensionless. We find it useful to introduce a dimensionless radial variable

$$x=M_W r, \quad M_W\equiv e\,\eta. \tag{16}$$

Substituting the ansatz Eqs. (13)–(15) into the static limit of the Lagrangian Eq. (9), leads to the following one-dimensional (radial) Lagrangian density L_m, defined by

$$\int L_m\,dx=\int \mathcal{L}_m\,d\mathbf{r}=E_1-E_2 \tag{17}$$

with

$$E_p\equiv\frac{4\pi}{e}\,\eta\tilde{E}_p=\frac{4\pi}{e}\,\eta\int dx\,\mathcal{E}_p, \quad p=1,2, \tag{18}$$

$$\mathcal{E}_1=\tfrac{1}{2}x^2(g')^2+a^2g^2, \tag{19}$$

$$\mathcal{E}_2=(a')^2+\frac{(a^2-1)^2}{2x^2}+\frac{1}{2}x^2(h')^2+a^2h^2+\frac{\lambda}{4}x^2(h^2-1)^2$$
$$+\frac{\xi}{2}[x^2(f')^2+2a^2\sin^2 f]+\kappa a^2\sin^2 f\left[(f')^2+a^2\frac{\sin^2 f}{2x^2}\right], \tag{20}$$

where we have separated the contribution E_1 due to the electric field and the prime denotes the derivative with respect to x. The total energy is given by

$$E=\frac{4\pi}{e}\eta\tilde{E}=\frac{4\pi}{e}\eta(\tilde{E}_1+\tilde{E}_2). \tag{21}$$

The static classical equations corresponding to the Lagrangian density $\mathcal{L}_m$, in the spherically symmetric ansatz, turn out to be equivalent to the equations obtained by varying the effective one-dimensional density [see Eqs. (19) and (20)] $\mathcal{E}_1-\mathcal{E}_2$ with respect to the radial functions a, g, h, and f. These equations are obtained straightforwardly and we do not list them here. We note however, that for each function the corresponding variational equation can be solved trivially by setting this function to zero.

It will be useful to present their asymptotic forms in the $x\gg 1$ region, to facilitate subsequent explanations. They are, in order of the variations of a, g, h, and f:

$$a''=a\left(\frac{a^2-1}{x^2}+h^2-g^2+\xi\sin^2 f+\cdots\right), \tag{22}$$

$$(x^2g')'=2ga^2, \tag{23}$$

$$(x^2h')'=h(2a^2+\lambda x^2(h^2-1)), \tag{24}$$

$$(x^2f')'=2a^2\sin f\cos f+o(\kappa/\xi). \tag{25}$$

[Note that Eqs. (23), (24) are exact.]

Following Ref. 7, we define the energy of a configuration by $E=E_1+E_2$, which coincides with the volume integral of the static Hamiltonian obtained in the usual way from the gauge invariant stress tensor. The topological lower bound for E_2 follows immediately from Eqs. (5), (7), and (11).

IV. NUMERICAL RESULTS, CASE $A_0=0$

We first discuss the classical solutions in absence of the electric field, i.e., with $g(x)=0$. Equation (23) is trivially solved and we are left with a system of three nonlinear differential equations. Only the part E_2 of the action is relevant in this case. In the following, we will conveniently denote the value $\tilde{E}_2$ of the solution with given M and T by

$$E_{MT}(\lambda,\xi,\kappa). \tag{26}$$

We now describe the four cases with $M\leq 1$ and $T\leq 1$, namely $(M=0,\ T=0)$, $(M=1,\ T=0)$, $(M=0,\ T=1)$, and $(M=1,\ T=1)$. All but the third of these, namely that characterized by the topological charge $(M=0,\ T=1)$, are solutions of Eqs. (22), (24), and (25), arising from the variation of Eq. (20). The third one on the other hand is described by the solutions of the SO(3) gauged Skyrme model,[5,6] which are described by Eqs. (22) and (25) arising from the variation of the functional (20) with the Higgs function $h(r)$ and the coupling of the Higgs potential λ both set equal to zero. The reason for including this field configuration in Sec. IV C below is that it will become useful for the construction of some solutions in Sec. V, and, because we have given an enhanced numerical study of it.

TABLE I. The energies of the monopole, the monopole-Skyrmion, and the gauged Skyrmion for several values of the Higgs coupling constant λ.

λ	Monopole	Monopole-Skyrmion ($\xi=1,\ \kappa=0.4$)	Gauged Skyrmion ($\xi=1,\ \kappa=0.4$)
0.0	1.000	3.450	2.98
0.05	1.106	3.470	⋯
0.10	1.138	3.480	⋯
0.20	1.180	3.490	⋯
0.40	1.220	3.510	⋯
0.60	1.250	3.520	⋯
0.80	1.270	3.530	⋯
1.00	1.290	3.536	⋯

A. Case $M=0$, $T=0$

This corresponds to the class of the vacuum which is not spherically symmetric. It has a zero energy

$$E_{00}(\lambda,\xi,\kappa)=0. \tag{27}$$

B. Case $M=1$, $T=0$

This case corresponds to the celebrated SU(2) magnetic monopole.[4] Since $T=0$, it has $f(r)=0$; as a consequence, the parameters ξ and κ are irrelevant for this case. The boundary conditions and asymptotic behavior of the functions a,h read

$$a(0)=1, \quad h(0)=0, \tag{28}$$

$$a(x)\simeq Ae^{-x}, \quad h(x)\simeq 1-Be^{-\sqrt{2\lambda}x} \quad (x\to\infty), \tag{29}$$

where A,B,F are constants. The values of the energy of the monopole solution were computed long ago[18] (our numerics fully reproduces these values); the energy increases monotonically with λ as demonstrated in Table I.

In the Bogomol'nyi limit, $\lambda=0$, the energy coincides with the topological lower bound, i.e. (omitting the parameters ξ and κ),

$$E_{10}(\lambda)\geqslant E_{10}(0)=1. \tag{30}$$

The solution, the Prasad–Sommerfield monopole, is expressed in terms of elementary functions.[19] Its behavior near the origin is given by Eq. (28) but, for $x\to\infty$, we have

$$a(x)\simeq xe^{-x}, \quad h(x)\simeq 1-1/x, \tag{31}$$

instead of Eq. (29).

C. Case $M=0$, $T=1$

The classical solutions considered in this case excite only the gauge and Skyrme fields degrees of freedom; the Higgs field is identically vanishing. The static equations describe the gauged Skyrmion studied in Ref. 6; Eq. (23) is trivial since $h(r)=0$. The classical energy is computed from Eq. (20) and makes sense only if $\lambda=0$ (in fact, since the Higgs field is zero, the Higgs potential plays no role). The topological lower bound reads

$$E_{01}(\lambda=0,\xi,\kappa)\geqslant \frac{3\pi}{2}\frac{\sqrt{\xi\kappa}}{\sqrt{1+9\kappa}}. \tag{32}$$

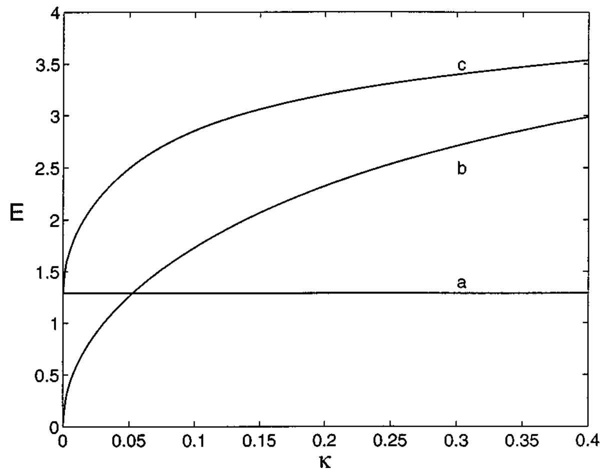

FIG. 1. The energies Eq. (26) of the monopole (line *a*), of the monopole-Skyrmion (line *c*) (for $\lambda = 1$, $\xi = 1$) and the energy of the gauged Skyrmion (line *b*) as functions of κ.

Due to the vanishing Higgs field, the parameter ξ can be changed by a rescaling of the radial variable x and it will be set equal to one. Comparison of the energies of the gauged Skyrmion and of the monopole is demonstrated in Table I and Fig. 1.

Let us now come to the detailed discussion of the solutions in the region $\kappa \approx 0.8$. For completeness, it is useful to summarize the possible boundary conditions available for the gauged Skyrmion. At the origin $x=0$ the behavior of the radial functions is uniquely determined by the condition of continuity of the fields at the origin:

$$a(x) = 1 + A_1 x^2 + o(x^3), \quad f(x) = \pi + F_1 x + o(x^2). \tag{33}$$

In contrast, in the $x \gg 1$ asymptotic region, several conditions are consistent with the finiteness of the energy. Classical solutions of the equations have been obtained[6] with the two following sets

$$\text{type A:} \quad a \approx 1 - \frac{A}{x}, \quad f \approx \frac{F}{x^2}, \tag{34}$$

$$\text{type B:} \quad a \approx \frac{A}{x^\alpha}, \quad f \approx \frac{F}{x}, \tag{35}$$

where $\alpha \equiv (\sqrt{4F^2 - 3} - 1)/2$.

The following results were obtained in Ref. 6. For small values of κ, the solution is of type A, its energy increases monotonically from $E=0$ (for $\kappa=0$) and the branch (say branch A) stops at a critical value $\kappa = \kappa_A^{cr} \approx 0.8091$. For large values of κ (in fact for $\kappa > \kappa_B^{cr} \approx 0.69122$) the solution is of type B. We call this branch B. By using arguments of catastrophe theory,[13] one can reasonably expect the occurrence of a third branch of solutions on the interval $\kappa \in [\kappa_B^{cr}, \kappa_A^{cr}]$, as was explained in Ref. 6.

A third branch indeed exists. The solutions on this branch obey the condition of type A and therefore we refer to it as branch $\tilde{A}$. The energies of the three branches of solutions are depicted in Fig. 2. The branches A and $\tilde{A}$ terminate at $\kappa = \kappa_A^{cr}$, forming a cusp catastrophy. The transitions of the profile of the solutions from branch A to branch $\tilde{A}$ is smooth.

In contrast, when the limit $\kappa \rightarrow \kappa_B^{cr}$ is considered, the solutions of the branch $\tilde{A}$ approach the limit of branch B in a subtle way. For instance, the value x_m for which the function $a(x)$ has a minimum (say a_m) tends to infinity, while a_m tends to zero. For values of κ close to κ_1, the solutions of branches $\tilde{A}$ and B coincide on a large interval of x (typically on $x \in [0, 10^7]$ for κ

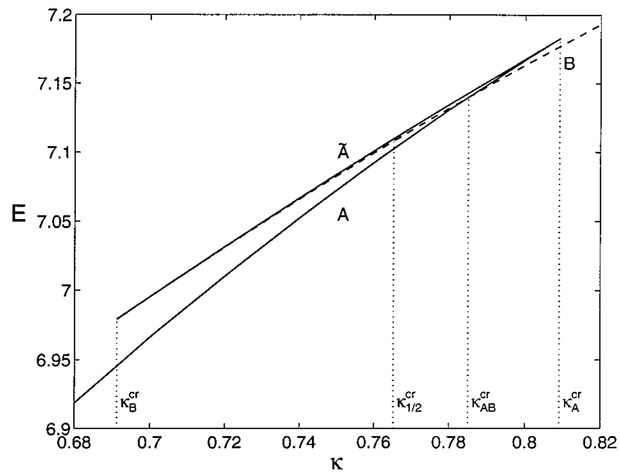

FIG. 2. The energy of the gauged Skyrmion as a function of κ in the region of the phase transition. The branches A, Ã are represented by the solid line and branch B by the dashed line.

$=0.6914$) and deviate from each other for larger values of x. In the limit $\kappa\to\kappa_B^{cr}$ this interval becomes infinitely large and the two solutions deviate at infinity. This can clearly be seen from Fig. 3. A similar demonstration can be made for the function $f(x)$, namely that near the critical point κ_B^{cr} these functions for the two solutions on branches B and Ã also coincide. We do not display the graphs analogous to Fig. 3 in this case. The behavior of the solutions is further illustrated by Figs. 4 and 5 where we plot respectively the value of F_1 [defined in Eq. (33)] for the three branches and the value of α as a function of κ.

Figure 2 furnishes a simple interpretation of the three solutions. To discuss it, we introduce κ_{AB}^{cr} as the value of κ where the energy of the branches A and B coincide ($\kappa_{AB}^{cr}\approx 0.785$). On the interval $\kappa\in[\kappa_B^{cr},\kappa_{AB}^{cr}]$ the solution on branch A constitutes the absolute minimum of the energy functional E_2, while the one on branch B is a local minimum. The solution on the branch Ã is a sphaleron corresponding to a saddle point which represents the energy barrier between the two minima. The situation is similar on the interval $\kappa\in[\kappa_{AB}^{cr},\kappa_A^{cr}]$; the absolute (respectively, local) minimum energy configuration is then on branch B (respectively, A). As κ approaches the critical value κ_B^{cr} the local minimum of branch B approaches the sattle point of branch Ã. At the critical

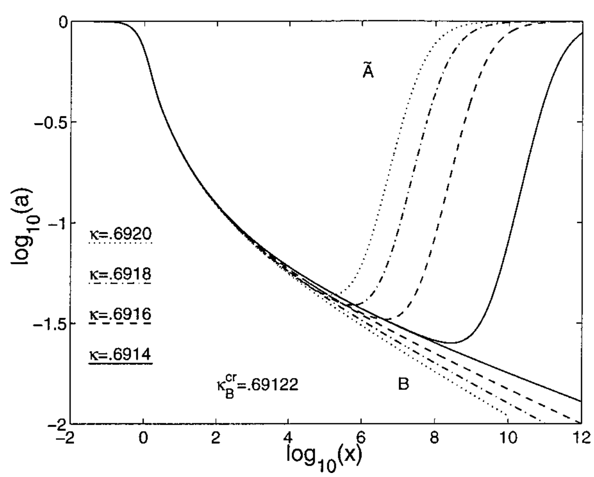

FIG. 3. The (logarithm of the) function $a(x)$ on the two branches B and Ã on a logarithmic scale for several values of κ approaching the critical value κ_B^{cr}.

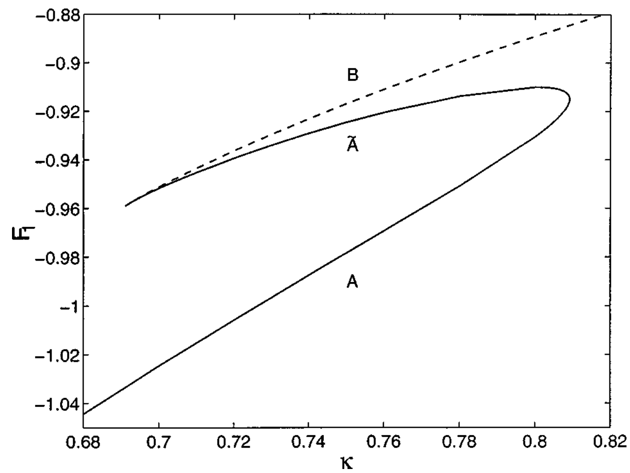

FIG. 4. The quantity F_1 defined in Eq. (33) is plotted as a function of κ for the branches A, $\tilde{\mathrm{A}}$ (the solid line) and for the branch B (the dashed line).

κ both coincide and form an inflection point. For $\kappa<\kappa_{\mathrm{B}}^{\mathrm{cr}}$ this point is no longer an extremum and the solutions of branches B and $\tilde{\mathrm{A}}$ cease to exist. The global minimum of branch A is then the only extremum and only branch A solutions exist. The same scenario applies at the other critical value $\kappa_{\mathrm{A}}^{\mathrm{cr}}$ where the solutions of branches A and $\tilde{\mathrm{A}}$ stop to exist and only branch B solutions exist.

D. Case $M=1$, $T=1$

It is natural to call this solution the ''monopole-Skyrmion.'' The three functions a, h, f are nontrivial and obey the following boundary conditions at $x=0$ and as $x\rightarrow\infty$, respectively,

$$a(0)=1,\quad h(0)=0,\quad f(0)=\pi, \tag{36}$$

$$a(x)\simeq Ae^{-x},\quad h(x)\simeq 1-Be^{-\sqrt{2\lambda}x},\quad f(x)\simeq\frac{F}{x}, \tag{37}$$

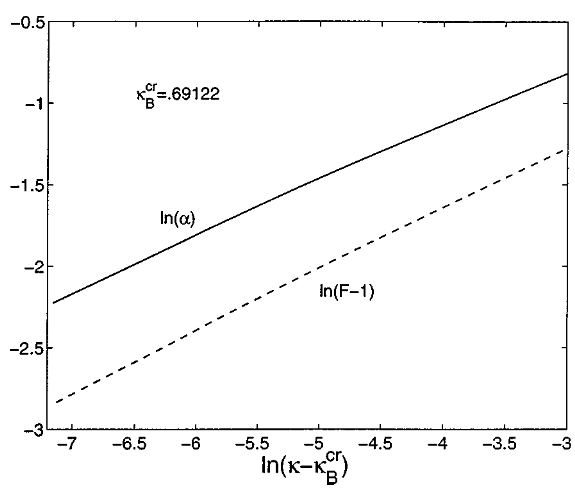

FIG. 5. The quantities $\ln(F-1)$ and $\ln(\alpha)$ [defined in Eq. (35)] are plotted as functions of the parameter $\ln(\kappa-\kappa_{\mathrm{B}}^{\mathrm{cr}})$.

where A, B and F are constants. In contrast to the case of the gauged Skyrmion solution,[6] the finite energy condition leads to a unique asymptotic behavior of the solution.

The energy of the solution is given in Table I for several values of λ (for $\xi=1$ and $\kappa=0.4$), indicating that the energy of the monopole-Skyrmion varies rather slightly with λ. The corresponding lower bound inequality reads

$$E_{11}(\lambda,\xi,\kappa) \geqslant \frac{1}{\sqrt{2}} + \frac{3\pi}{2}\frac{\sqrt{\xi\kappa}}{\sqrt{1+18\kappa}}. \tag{38}$$

Table I and Fig. 1 further exhibit a comparison between the energies of the monopole, the monopole-Skyrmion, and the gauged Skyrmion.

In Sec. IV C, we exposed the properties of the SO(3) gauged Skyrme model and depicted the bifurcations occurring in Fig. 2. The monopole-Skyrmion solution studied in this section is also expected to feature similar bifurcations, but this is not seen from Fig. 1. (Indeed, for that range of parameters, the $M=0$, $T=1$ solution also does not feature the bifurcations present in Fig. 2.) We have checked that for the value of the parameter $\xi=1$, there occur no bifurcations for all values of the parameter κ. On the other hand, if we change the values of the parameter ξ, then we would expect that similar bifurcations as in Fig. 2 will manifest themselves also for the monopole-Skyrmion. Since the main interest in the latter is the unwinding of the baryon number in the presence of the monopole, and since any bifurcations analogous to those in Fig. 2 would feature branches of the solution with the same ($T=1$) baryon number, we eschew a detailed discussion of these in the present work.

E. General properties

We have constructed numerically the three nontrivial topological solitons above for numerous values of the coupling constants λ, ξ, κ and computed their energies. In order to give an idea of the relative magnitudes for the different classes, let us choose $\lambda=0$, $\xi=1$, $\kappa=0.4$, then

$$E_{00}=0, \quad E_{10}=1.0, \quad E_{01}\approx 2.98, \quad E_{11}\approx 3.45. \tag{39}$$

Note that the monopole energy satisfies the topological lower bound.

The behavior of the solutions in the limit $\kappa\to 0$, with λ,ξ fixed, was carefully analyzed. Our numerical analysis strongly supports the following formula:

$$\lim_{\kappa\to 0} E_{M1}(\lambda,\xi,\kappa)=E_{M0}(\lambda,\xi,0) \quad \text{for } M=0,1 \tag{40}$$

as illustrated by Fig. 1. Indeed, in the limit $\kappa\to 0$, the functions $a(r),h(r)$ representing the solutions of the $M=T=1$ sector approach the profile of the monopole solution (i.e., $M=1$, $T=0$). At the same time, the function $f(r)$ is more and more peaked at $r=0$ (in particular $\lim_{\kappa\to 0} f'(0)=\infty$) and tends to zero if $r\neq 0$.

This result demonstrates in particular that the coupling of the Skyrmion to a monopole cannot stabilize the Skyrmion; the Skyrme term is necessary to guarantee a localized structure to the $T=1$ soliton.

The same phenomenon occurs with the branch of the gauged Skyrmion ($M=0$, $T=1$).[6] The energy in this limit tends to zero, namely to the energy of the vacuum ($M=T=0$).

A remark should be made concerning the interpretation of the monopole-Skyrmion as a bound system of a monopole with magnetic charge M and a gauged Skyrmion with baryon number T. Consider a monopole located in a region U_m centered at a point x_m and a gauged Skyrmion located in a region U_{Sk} centered at a point x_{Sk} far away from each other. Then the Skyrmion field and the corresponding gauge field will vanish outside the region U_{Sk}. Consequently, U_m contains a pure monopole, consisting of a gauge field and a Higgs field. Outside U_m the gauge field will vanish, however, the Higgs field does not vanish. Instead it will be equal to its VEV $\langle\Phi\rangle_{\mathrm{vac}}$. In the region U_{Sk} containing the Skyrmion the nonzero Higgs field is still present and we have to allow for interaction with the gauge field, $|D_j\langle\Phi\rangle^\alpha_{\mathrm{vac}}|^2$. The Higgs vacuum is a constant far away from the monopole and generates masses for the gauge fields. Furthermore, the Higgs vacuum breaks the rotational symmetry. Consequently, the gauged Skyrmion solutions in the presence of a constant Higgs field will no longer possess spherical symmetry. In addition, it might be expected that the electromagnetic flux will not vanish. If we impose the condition for the Higgs vacuum that the interaction with the gauge field has to vanish, $D_j\langle\Phi\rangle^\alpha_{\mathrm{vac}}=\epsilon^{\alpha\beta\gamma}A^\beta_j\langle\Phi\rangle^\gamma_{\mathrm{vac}}=0$, then we will find that the gauge field has to be parallel to the Higgs vacuum in isospace. This also breaks the spherical symmetry.

To conclude, the interpretation of the monopole-Skyrmions as a bound state of a spherically symmetric monopole and a spherically symmetric gauged Skyrmion seems to be misleading.

V. NUMERICAL RESULTS, CASE $A_0\neq 0$

In order to obtain a nontrivial function $g(x)$ from Eq. (23), a nonvanishing asymptotic value, say q, for this function has to be imposed.[7] In the asymptotic region $x\gg 1$ Eq. (23) is satisfied by

$$g(x)=q-\frac{c_1}{x}+o(x^{-2}), \tag{41}$$

where q,c_1 are constants and q plays a major role in the construction. The equations, together with the finite energy condition require $0\leqslant q\leqslant 1$, which can be seen as follows. In Eq. (22) the Higgs field and the dyon field contributions, $h^2(x)-g^2(x)$, generate asymptotically the mass term $m^2_{(a)}=1-q^2$ for the gauge field function $a(x)$. For $q>1$, $m^2_{(a)}$ becomes negative and leads to an oscillating function $a(x)$ in the asymptotic region. Consequently, the term a^2g^2 in Eq. (17) is not integrable and no dyon solution exists for $q>1$.

The electric charge, as defined in Ref. 7, is directly related to the constant c_1:

$$Q=\frac{1}{4\pi\eta}\int\vec{\Phi}\cdot\vec{F}_{0i}dS_i\equiv\frac{1}{e}\tilde{Q} \tag{42}$$

$$=\frac{1}{4\pi}\int\left(r^2\frac{dg}{dr}\right)\Big|_{r\to\infty}\sin\theta d\theta d\phi=\frac{1}{e}c_1, \tag{43}$$

having used the ansatz (13)–(14) and Eq. (41).

Another very interesting quantity is the chiral anomaly due to the dyon-Skyrmion soliton whose classical solutions will be studied numerically. The anomaly equation for the chiral charge is

$$\frac{dQ_5}{dt}=\frac{e^2}{8\pi^2}\int d\mathbf{x}\mathbf{E}_i\cdot\mathbf{B}_i=-\frac{e^2}{8\pi^2}4\pi[g(r)(a(r)-1)]^\infty_{r=0}=\frac{e^2}{2\pi}q, \tag{44}$$

having used the ansatz (13)–(14) and Eq. (41). We now discuss the solutions by adopting the same presentation as in Sec. IV. Again, in addition to the two types of solutions characterized by the nontrivial charges ($M=1$, $T=0$), and ($M=1$, $T=1$), we include the field configurations corresponding to ($M=0$, $T=0$), which is the dyonlike solution to the SO(3) gauged Skyrme model,[5,6] which as it happens in this case turns out to be the trivial field configuration.

A. Case $M=1$, $T=0$

The solutions are the dyons of Julia and Zee.[7] Here we present an in-depth analysis of this solution. The limit $\lambda=0$ corresponds to the Prasad–Sommerfield dyon[19] (PS dyon). It is worth analyzing this case separately because the solution can be computed analytically and it provides a good check of our numerical routines.

1. Case λ=0

The profile of the radial functions of the PS dyon reads[19]

$$a(x)=\frac{cx}{\sinh(cx)}, \tag{45}$$

$$g(x)=\frac{cq}{\sqrt{1-q^2}}\left(\coth cx-\frac{1}{cx}\right), \tag{46}$$

$$h(x)=\frac{c}{\sqrt{1-q^2}}\left(\coth cx-\frac{1}{cx}\right), \tag{47}$$

and the PS monopole is recovered for $q=0$. Our parameter q is related to γ of Ref. 19, by $q=\tanh(\gamma)$. We have chosen the arbitrary scale in the PS solution $c=\sqrt{1-q^2}$ so that the asymptotic value of the Higgs field function $h(x)$ of the PS solution given above be equal to 1, since we are also studying the dyons for the $\lambda>0$ case where the asymptotic value of $h(x)$ equals 1. The charge and energy of the PS dyon are given by

$$\tilde{Q}=\frac{q}{\sqrt{1-q^2}}, \quad \tilde{E}=\frac{1}{\sqrt{1-q^2}}, \tag{48}$$

$$\tilde{E}_1=\frac{q^2}{2\sqrt{1-q^2}}, \quad \tilde{E}_2=\left(1-\frac{1}{2}q^2\right)\frac{1}{\sqrt{1-q^2}}\approx 1+\frac{1}{8}q^4+o(q^6), \tag{49}$$

where the dimensionless quantities $\tilde{E}$, $\tilde{E}_p$ and $\tilde{Q}$ are defined in Eqs. (21), (18) and (42), respectively.

For small values of q the ''magnetic'' contribution to the energy, E_2, varies slightly with q, accounting for the feedback of the electric charge on the classical magnetic energy. We would like to stress that our numerical results are in full agreement with these exact formulas.

The dependence of the charge $\tilde{Q}$ of the PS dyon as a function of q is represented in Fig. 6 (curve a). Similarly we have reported in Fig. 7 (curve a) the energy $\tilde{E}$ of the PS dyon as a function of $\tilde{Q}$. Clearly the energy and the charge of the PS dyon can be arbitrarily large when $q\rightarrow 1$.

2. Case λ≠0

For the dyon solution, the boundary conditions for the function $g(x)$ can be read from Eq. (41), and those of the functions $a(x)$, $h(x)$ from Eqs. (28) and (29), with the exception of the behavior of the function $a(x)$ in the $x\gg 1$ region, which now takes the form

$$a(x)\simeq Ae^{-\sqrt{1-q^2}x}. \tag{50}$$

Our analysis demonstrates that the energy of the dyon obeys a Bogomol'nyi inequality $\tilde{E}(\lambda,Q)>\tilde{E}(0,0)=1$. The main distinguishing feature of the $\lambda\neq 0$ dyon versus the PS dyon is that its electric charge and its classical energy are bounded for $q\in[0,1]$.

This phenomenon appears clearly in Figs. 6 and 7, respectively, where the quantities $\tilde{Q}$ as a function of q, and $\tilde{E}$ as a function of $\tilde{Q}$, are plotted for $\lambda=0.5$. More generally, it appears that the electric charge of the dyon constructed with a given value of the parameter q decreases when λ increases. The three bullets on Fig. 7 represent the data given in Ref. 7; according to our numerical results they should lie on line *b*. Our numerical results therefore slightly disagree with Ref. 7.

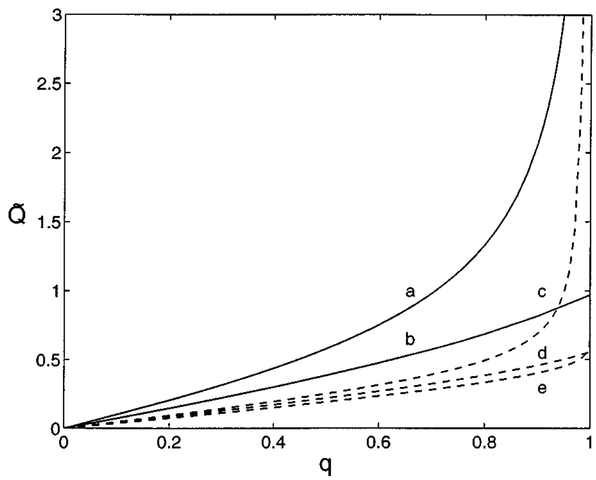

FIG. 6. The values of the electric charge $\tilde{Q}$ as a function of the parameter q. The solid lines represent the dyon for $\lambda=0$ (line a) and $\lambda=0.5$ (line b). The dashed lines represent the dyon-Skyrmion ($\xi=1$) for $\lambda=0$, $\kappa=0.4$ (line c), $\lambda=0.5$, $\kappa=0.4$ (line d) and $\lambda=0$, $\kappa=1$ (line e).

The star on line b of Fig. 7 indicates the maximal accessible charge of the dyon solutions for a fixed value of λ. This contrasts with line a which asymptotically tends to infinity, in agreement with Eqs. (48) and (49). The solutions with maximal electric charge and energy correspond to the case $q=1$ which we discuss next.

3. Case q=1

In the limit $q=1$ in Eq. (41) Eq. (22) ceases to impose the exponential decay Eq. (50) for the function $a(x)$; we have instead

$$a(x)\simeq Ae^{-\sqrt{8c_1x}} \quad \text{for } x\to\infty, \tag{51}$$

where c_1 is defined in Eq. (41).

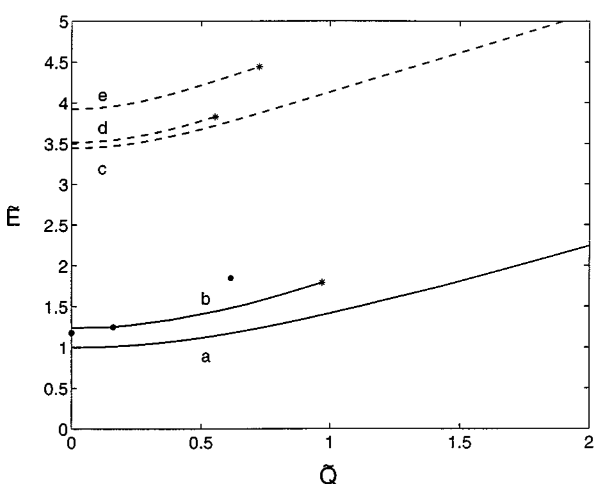

FIG. 7. The values of the energy $\tilde{E}$ as a function of the parameter $\tilde{Q}$. The solid lines represent the dyon for $\lambda=0$ (line a) and $\lambda=0.5$ (line b). The dashed lines represent the dyon-Skyrmion ($\xi=1$) for $\lambda=0$, $\kappa=0.4$ (line c), $\lambda=0.5$, $\kappa=0.4$ (line d) and $\lambda=0$, $\kappa=1$ (line e). The stars depict the points where the solution has maximal finite charge. The bullets correspond to the data of Ref. 7.

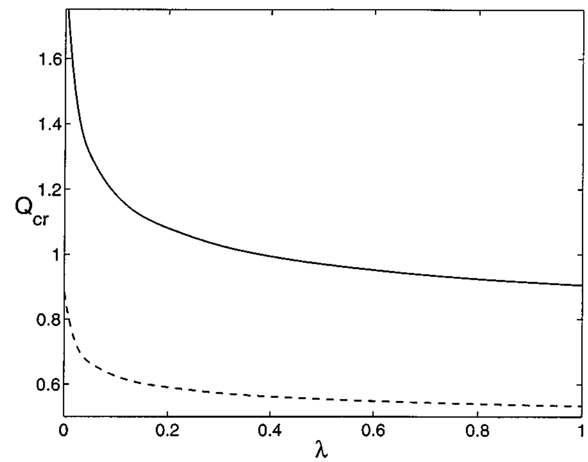

FIG. 8. The value of the critical charge Q_{cr} as a function of λ. The solid line refers to the dyon solution. The dashed line refers to the dyon-Skyrmion solution for $\xi=1$ and $\kappa=0.4$.

Fixing $\lambda \neq 0$, the electric charge (and similarly the classical energy) of the dyon cannot exceed a critical value, say $Q_{cr}(\lambda)$. This quantity is plotted against λ in Fig. 8 (solid line).

B. Case $M=0$, $T=1$

No finite energy dyonlike solutions supporting a nonvanishing (non-Abelian) electric field can be found in this case. Due to the absence of the Higgs field $(h=0)$, Eq. (22) leads to an oscillating asymptotic behavior of $a(x)$. The term a^2g^2 in the energy Eq. (17) cannot therefore be integrated.

C. Case $M=1$, $T=1$

The boundary conditions compatible with a finite energy solution in this case are identical to Eqs. (36), (37) and (41). It is possible to construct the dyon-Skyrmion solutions. The dyon-Skyrmion display many features of the dyons, discussed at length above. These features are illustrated by Figs. 6 and 7 (dashed curves c, d and e) and by Fig. 8 (the dashed line). In addition we illustrate the dependence of the energy on the Skyrme coupling constant κ in Fig. 9 (the dashed line) for $q=0.5$ and $\lambda=0$. The energy is an increasing function of κ. In the limit of vanishing κ

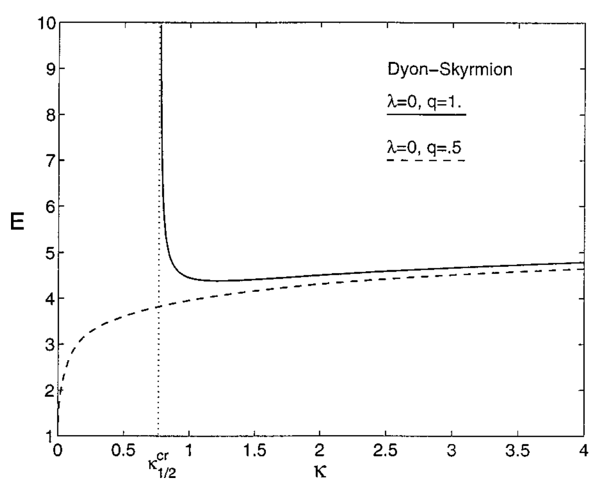

FIG. 9. The energies of the dyon-Skyrmions with $q=1$ (the solid line) and $q=0.5$ (the dashed line) as functions of $\kappa(\lambda=0, \xi=1)$. The vertical dotted line indicates the critical value of κ.

the energy of the dyon-Skyrmion converges to the energy of the dyon-monopole. This can be compared with the behavior of the energy of the monopole-Skyrmion, shown (for $\lambda=1$) in Fig. 1, where for vanishing κ the energy tends to the energy of the monopole. For our considerations leading to our conclusions in Fig. 9, we have chosen $q=0.5$ as a typical value in the allowed range $0\leqslant q\leqslant 1$. We expect that our results, summarized by the dashed curve in Fig. 9, are typical for any allowed value of q, and also for any value of the Higgs coupling constant λ, except in the important case of $\lambda=0$ and $q=1$. The dyon-Skyrmion characterized by the boundary value $q=1$ in the $\lambda=0$ model has peculiar and interesting properties which we analyze in the next paragraphs.

For $\lambda=0$ the solutions of Eqs. (23) and (24) are proportional to each other. Assuming that $h=1$ at infinity, the proportionality constant is given by q, Eq. (41). Thus for $q=1$ the functions $h(r)$ and $g(r)$ are identical. In this special case $h^2(r)$ and $g^2(r)$ cancel each other in Eq. (22). Consequently, Eqs. (22) and (25) reduce to the field equation of the gauged Skyrme model (Sec. IV C), and can be solved independently of $h(r)$, $g(r)$.

The solutions of these equations are now given by the branch B solutions of the gauged Skyrme model. Once a solution for the function $a(r)$ is found the equations for the functions $h(r)$ and $g(r)$ can be solved. Recalling that the branch B solutions exist for all $\kappa\geqslant\kappa_{\mathrm{B}}^{\mathrm{cr}}$, we expect the existence of the dyon-Skyrmion solution for the same range of coupling constants κ. However, not all of these solutions are finite energy solutions. This can be seen easily by inspecting the static Hamiltonian $\mathcal{E}=\mathcal{E}_1+\mathcal{E}_2$ given in Eqs. (19) and (20), where the contributions from the functions $h(r)$ and $g(r)$ do not cancel. The asymptotic behavior of these terms is dominated by $a^2(r)h^2(r)$, $a^2(r)g^2(r)$. Using the boundary conditions $h(\infty)=1$, $g(\infty)=1$, and the asymptotic form of the function $a(r)$, Eq. (35), these terms behave like $\approx A^2(\kappa)/x^{2\alpha(\kappa)}$ for large x, where $\alpha(\kappa)$ is a function determined numerically. Thus the integration of these terms will give finite contributions only if $\alpha(\kappa)>1/2$. This restricts the range of the coupling constant κ to $\kappa_{1/2}^{\mathrm{cr}}<\kappa<\infty$, where $\kappa_{1/2}^{\mathrm{cr}}$ is defined by $\alpha(\kappa_{1/2}^{\mathrm{cr}})=1/2$. For $\xi=1$ we find $\kappa_{1/2}^{\mathrm{cr}}=0.7652$.

In Fig. 9 we show the dependence of the energy on the coupling constant κ for $q=1$ (the solid line) and for $q=0.5$ (the dashed line). (For $q<1$, as stated above, solutions exist for all values of κ, the energy is a monotonic function of κ, and the limit $\kappa\to 0$ the energy approaches the energy of the dyon solution.) For $q=1$ the energy is an increasing function of κ for large values of κ only. It has a minimum at $\kappa=1.21$. As κ approaches its critical value $\kappa_{1/2}^{\mathrm{cr}}$ the energy becomes increasingly large and diverges at $\kappa=\kappa_{1/2}^{\mathrm{cr}}$.

The charge $\tilde{Q}$ of the solutions is determined by the asymptotic behavior of the function $g(r)$, Eq. (43). Solving Eq. (23) for large x we find the following expressions for the charge:

$$\tilde{Q}=\begin{cases}\lim\limits_{x\to\infty}\left(c_1-\dfrac{2A^2}{2\alpha-1}x^{-(2\alpha-1)}\right) & \text{for}\quad \alpha>\dfrac{1}{2}\\ \lim\limits_{x\to\infty}(2A^2\ln(x)) \quad \text{for}\quad \alpha=\tfrac{1}{2} & \\ \lim\limits_{x\to\infty}\left(-\dfrac{2A^2}{2\alpha-1}x^{-(2\alpha-1)}\right) & \text{for}\quad \alpha<\dfrac{1}{2}.\end{cases} \tag{52}$$

Thus solutions with finite charge exist only for $\alpha>1/2$, i.e., for the same range of the coupling constant κ where finite energy solutions exist.

In Fig. 6 we show the dependence of the charge on the parameter q for $\kappa=0.4$ and $\kappa=1.0$. For $\kappa=0.4$ ($<\kappa_{1/2}^{\mathrm{cr}}$) there is no finite charge solution for $q=1$. Consequently, the charge as a function of q diverges as q approaches the value 1. In contrast, for $\kappa=1$ ($>\kappa_{1/2}^{\mathrm{cr}}$) the solution with $q=1$ exists and the charge is finite for all values of $q\in[0,1]$.

In Fig. 7 the energy as a function of the charge is shown for $\kappa=0.4$ and $\kappa=1.0$. For $\kappa=0.4$ ($<\kappa_{1/2}^{\mathrm{cr}}$) the energy and the charge can take arbitrarily large values. In this case the energy is a monotonically increasing function of the charge with no end point. For $\kappa=1$ ($>\kappa_{1/2}^{\mathrm{cr}}$) the energy is again a monotonically increasing function of the charge. However, only finite energy and charge solutions exist for this value of κ. Thus the graph of the function $\tilde{E}(\tilde{Q})$ ends at the maximal value of the charge.

VI. SUMMARY AND DISCUSSION

We have found monopole-Skyrmion and dyon-Skyrmion solutions to an SO(3) gauged Higgs and O(4) sigma (Skyrme) model, in which both scalar matter fields interact with the gauge field but not with each other. The Higgs field is an isovector, like in the GG model, while the S^3 valued (sigma) field is gauged according to the prescription used in Refs. 5 and 6.

In the $A_0^\alpha = 0$ gauge the static Hamiltonian is bounded from below by the sum of the two topological charge densities, the monopole charge, and the degree of the map of the S^3 field on $\mathbb{R}_3$. Thus the imposition of spherical symmetry reduces the system to a one-dimensional subsystem, and the resulting differential equations are first integrated analytically in the asymptotic regions and then numerically. This yielded the monopole-Skyrmion. In addition to the monopole-Skyrmion solutions, we have made an enhanced numerical study of the SO(3) gauged Skyrmion, because these solutions are instrumental in constructing some of the dyon-Skyrmions given in the following paragraph.

In the $A_0^\alpha \neq 0$ gauge, the Euler–Lagrange equations arising from the variation of the static Hamiltonian density do not yield a soliton with nonvanishing A_0^α and hence have $E_0^\alpha = 0$. Instead, the variational equations arising from the (non-positive-definite) Lagrangian density in the static limit support spherically symmetric solutions with $E_i^\alpha \neq 0$. This is also what happens with the JZ dyon. There,[7] in spite of the nonpositive definiteness of the functional subjected to the variational principle, it happens that after taking the static limit and imposing spherical symmetry, these equations reduce to a set of consistent, i.e., not overdetermined, set of coupled ordinary differential equations. Their solutions support a nonvanishing A_0^α field. These ordinary differential equations also result from the variation of a certain one-dimensional (radial) functional which, in contrast to the one-dimensional energy functional, is not positive definite.

In the light of the surprisingly successful outcome for the JZ dyon, we were motivated to address the same question for the SO(3) gauged O(4) model.[5,6] Subjecting the Lagrangian to the variational principle and then taking the static limit and imposing spherical symmetry, we found that this also led to a consistent set of coupled ordinary differential equations. The same situation obtains with the composite model of this paper, and it is the dyonlike solitons of these last equations which yielded the dyon-Skyrmion. Concerning the SO(3) gauged Skyrme model on its own, while its equations of motion reduce to a consistent set of coupled ordinary differential equations, their solutions support only vanishing electric field.

As a byproduct of our study of the dyon-Skyrmion, we made a detailed reanalysis of the JZ dyon refining our understanding of the latter. Namely exploring the dependence of the energy of the dyon on its electric charge shows that the dyon energy is always higher than the energy of the PS monopole, extending the Bogomol'nyi identity available for monopole.

An important result of the numerical analysis of the monopole-Skyrmion solution is that, as the coupling strength of the Skyrme term is shrunk down to zero the monopole-Skyrmion reduces to the monopole, as depicted in Fig. 1. Thus the monopole does not stabilize the SO(3) gauged sigma model without a Skyrme term, something that is not prohibited by the Derrick scaling requirement.

Perhaps the most interesting aspect of the dyon-Skyrmion occurs for the model in the PS limit $(\lambda = 0)$ in the special case where the boundary value q of the function $g(r)$ parametrizing A_0^α equals 1. In this case, the equations governing the functions $a(r)$ (parametrizing the gauge field) and the function $f(r)$ (governing the Skyrme field) decouple from the fields $h(r)$ (parametrizing the Higgs field) and $g(r)$. As a consequence the solutions for the functions $a(r)$ and $f(r)$ are just the (branch B of the) gauged-Skyrmion solutions and exist only for values of the Skyrme coupling constant larger than a critical value $\kappa_{\mathrm{B}}^{\mathrm{cr}}$, as seen from Fig. 2. However, when the integrations of the Higgs field function $h(r)$ and of the dyon function $g(r)$ are taken into account, then finite energy solution only exists if the Skyrme coupling constant is larger than the critical value $\kappa_{1/2}^{\rm cr} > \kappa_{\rm B}^{\rm cr}$, see Fig. 9. The energy of the solution at this critical value is found to become infinite and for lower values of the Skyrme coupling constant no finite energy solution exists. The time rate of change of the chiral charge Eq. (44) is equal to the integer 1 (up to normalization) for all values of the Skyrme coupling constant κ down to the critical value $\kappa_{1/2}^{\rm cr}$, below which no finite energy solutions exist. We hope that this result may prove relevant to the semiclassical description of monopole catalysis of Fermion number nonconservation. If for example it could be argued that the dyon-Skyrmion favored by Nature is the solution to the system Eq. (9) in the PS limit, with the asymptotic constant $q=1$, i.e., for which the quantity dQ_5/dt is an integer (up to normalization), then it would follow that below the critical value $\kappa_{1/2}^{\rm cr}$ there will be no Q_5 violating rate. We intend to return to this question in the near future.

In this paper we are concerned with the existence of solutions to the compressible Heisenberg chain equations. By the vanishing viscosity method we prove that this system admits at least one measure-valued solution. [S0022-2488(98)03212-5]

I. INTRODUCTION

In 1982, Fivez[1] revisited the 1D classical compressible Heisenberg chain described by the Hamiltonian

$$\mathcal{H}=\sum_{i=1}^{N} P_i^2/2m+\frac{\alpha}{2}\sum_{i=1}^{N-1}(x_{i+1}-x_i)^2-J\sum_{i=1}^{N-1}\mathbf{Z}_i\cdot\mathbf{Z}_{i+1}-\varepsilon\sum_{i=1}^{N-1}(x_{i+1}-x_i)\mathbf{Z}_i\cdot\mathbf{Z}_{i+1}$$

considered earlier by Cieplak and Turski in 1980 where x_i is the displacement of the magnetic ion from equilibrium, without spin–phonon coupling, α is the spring constant and $\varepsilon=J_x$. In the continuum limit, which corresponds to long-wavelength excitations, the equations of motion deduced by Fivez read as

$$m\ddot{\eta}=\alpha\ddot{\eta}+\frac{\varepsilon}{2}\frac{\partial}{\partial x}(\mathbf{Z}')^2, \tag{I.1}$$

$$\dot{\mathbf{Z}}=\frac{\partial}{\partial x}\{(J+\varepsilon\eta')\mathbf{Z}\times\mathbf{Z}'\}, \tag{I.2}$$

where $\mathbf{Z}(x,t)=(Z^1(x,t),Z^2(x,t),Z^3(x,t))\in\mathbb{R}^3$ and the substitution $x_i\rightarrow\eta(x,t)$, $\mathbf{Z}_i\rightarrow\mathbf{Z}(x,t)$ has been made, a dot denotes derivation with respect to t, a prime with respect to x. Fivez tried the solution of the form $\mathbf{Z}=\{\sin\theta\cos\varphi,\sin\theta\sin\varphi,\cos\theta\}$, $\eta=ax+f(u)$ where $\theta(x,t)=\theta(u)$, $\varphi(x,t)=\overline{\varphi}(u)+\Omega t$ with $u=x-ct$ (the lattice and spin wave are assumed to travel at the same velocity c).

Equation (I.1) now becomes

$$(mc^2-\alpha)f''=\frac{\varepsilon}{2}\frac{\partial}{\partial x}(\mathbf{Z}')^2,$$

with boundary condition

$$f'(-\infty)=0,\quad \mathbf{Z}'(-\infty)=0,\quad Z^3(-\infty)=1.$$

By integration, one has

$$(mc^2-\alpha)f'=\frac{\varepsilon}{2}(\mathbf{Z}')^2,$$

$$(\mathbf{Z}')^2=\theta'^2+\sin^2\theta\varphi'^2.$$

Hence Fivez derived the following compressible Heisenberg chain equation:

$$\mathbf{Z}_t=(G(\mathbf{Z}_x)\mathbf{Z}\times\mathbf{Z}_x)_x, \tag{I.3}$$

in which $G(\xi)=A+B|\xi|^2$ with $A=J+\varepsilon\alpha$, $B=(\varepsilon^2/2)(mc^2-\alpha)$, where $mc^2>\alpha$.

The solitons of (I.3) were given by Magyari in Ref. 2. Equation (I.3) with $B=0$ called inhomogeneous Heisenberg chain equations was derived by Balakrishnan in 1982 in Ref. 3. When $B=0$, $A=g(x)$ is some given function, the existence and uniqueness of the smooth solution of (I.3) (the Cauchy problem) were obtained in Ref. 4 ($g(x)\equiv 1$) and in Ref. 5 ($g(x)\not\equiv$constant).

From the mathematical point of view, (I.3) is a strongly degenerate and strongly coupled parabolic system with strong nonlinearity; thus it is kind of important and hard to discuss evolutionary equations.

In this paper, for simplicity, we shall assume A,B are positive constants. We intend to establish the existence of measure-valued solution to the following periodic initial value problem:

$$\mathbf{Z}_t=(G(\mathbf{Z}_x)\mathbf{Z}\times\mathbf{Z}_x)_x, \quad x\in\mathbb{R}^1, \quad t\in\mathbb{R}_+, \tag{I.4}$$

$$\mathbf{Z}(x,0)=\mathbf{Z}_0(x), \quad \mathbf{Z}(x+D,t)=\mathbf{Z}(x-D,t), \quad |\mathbf{Z}_0(x)|\equiv 1, \quad x\in\mathbb{R}^1, \tag{I.5}$$

where $D>0$ is a constant.

To this aim, we use the vanishing viscosity method. Consider the viscosity problem

$$\mathbf{Z}_t=\varepsilon(G(\mathbf{Z}_x)\mathbf{Z}_x)_x+(G(\mathbf{Z}_x)\mathbf{Z}\times\mathbf{Z}_x)_x, \quad x\in\mathbb{R}^1, \quad t\in\mathbb{R}_+, \tag{I.6}$$

$$\mathbf{Z}(x,0)=\mathbf{Z}_0(x), \quad \mathbf{Z}(x+D,t)=\mathbf{Z}(x-D,t), \quad |\mathbf{Z}_0(x)|\equiv 1, \quad x\in\mathbb{R}^1. \tag{I.7}$$

We first prove that problem (I.6)–(I.7) admits at least one global weak solution, and then give the *a priori* estimates for such solutions uniformly in ε to get the existence of the measure-valued solution to (I.4)–(I.5) by letting $\varepsilon\to 0$.

Equations (I.4) and (I.6) are evolutionary p-Laplace like equations but with a ''$\times$'' term. This term gives rise to difficulties in the discussions. We first prove that problem (I.6)–(I.7) is solvable in the space $L^\infty(0,\infty;W^{1,4}(\Omega))\cap L^2(0,\infty;H^2(\Omega))$ when ε is fixed (by the difference method), then we give the *a priori* estimates uniformly in ε. We note that these uniform estimates do not allow us to get the weak solution to (I.4)–(I.5) because of the nonlinearity and the cross product. Hence we can only obtain the measure-valued solution.

II. $\varepsilon>0$: GLOBAL WEAK SOLUTION

To get the existence of the local solution of (I.6)–(I.7), we apply the difference method. We need the following well known lemmas. In the sequel, we denote $\Omega=(-D,D)$.

Lemma II.1 (Ref. 4): Let q, r be real numbers and j, m be integers such that $1\leqslant q,r\leqslant\infty$, $0\leqslant j<m$. *If* $u\in W^{m,r}(\Omega)\cap L^q(\Omega)$, *then*

$$\|D^j u\|_p\leqslant C\|u\|_q^{1-\alpha}\|D^m u\|_r^\alpha,$$

where $\|\cdot\|_p=\|\cdot\|_{L^p(\Omega)}$, $p\geqslant 1$, $j/m\leqslant\alpha\leqslant 1$ *and*

$$\frac{1}{p}-j=\frac{1-\alpha}{q}+\alpha\left(\frac{1}{r}-m\right), \quad \Omega\subset\mathbb{R}^1.$$

Lemma II.2 (Ref. 6): Let p be real number and j, m be integers such that $2 \leqslant p \leqslant \infty,\ 0 \leqslant j < m$. *Then*

$$\| \delta^j u_h \|_p \leqslant C \| u_h \|_2^{1-\alpha} \left(\| \delta^m u_h \|_2 + \frac{\| u_h \|_2}{(2D)^m} \right)^{\alpha},$$

where $u_h = \{ u_j = u(x_j) | j = 0,1,2, \ldots, J \},\ x_j = jh,\ h = 2D/J,\ \alpha = (1/m)(j + 1/2 - 1/p)$,

$$\| \delta^k u_h \|_p = \left(\sum_{i=0}^{J-k} \left| \frac{\Delta_+^k u_i}{h^k} \right|^p h \right)^{1/p}.$$

Lemma II.3 (Ref. 6): Let $u_h = \{ u_j | j = 0, \pm 1, \pm 2, \ldots, \pm J, \ldots \},\ v_h = \{ v_j | j = 0, \pm 1, \pm 2, \ldots, \pm J, \ldots \}$ *such that* $u_{j+J} = u_j,\ v_{j+J} = v_j$. *We have*

$$\text{(i)} \quad \sum_{j=0}^{J-1} u_j \Delta_+ v_j = -\sum_{j=1}^{J} v_j \Delta_- u_j,$$

$$\text{(ii)} \quad \sum_{j=1}^{J} u_j \Delta_+ \Delta_- v_j = -\sum_{j=0}^{J-1} \Delta_+ u_j \Delta_+ v_j,$$

$$\text{(iii)} \quad \Delta_+(u_j v_j) = u_{j+1} \Delta_+ v_j + v_j \Delta_+ u_j,$$

$$\text{(iv)} \quad \Delta_-(u_j v_j) = u_j \Delta_- v_j + v_{j-1} \Delta_- u_j,$$

$$\text{(v)} \quad \Delta_-(u_j \times v_j) = u_j \times \Delta_- v_j + \Delta_- u_j \times v_{j-1},$$

where Δ_+, Δ_- *denote the forward and backward differences respectively.*

We use the difference method to prove the local existence of solution of (I.6)–(I.7). For simplicity, we let $\varepsilon = 1$. We establish the following difference-differential equation:

$$\frac{d\mathbf{Z}_j}{dt} = \frac{\Delta_- \left(G\left(\frac{\Delta_+ \mathbf{Z}_j}{h} \right) \frac{\Delta_+ \mathbf{Z}_j}{h} \right)}{h} + \frac{\Delta_- \left(\mathbf{Z}_j \times G\left(\frac{\Delta_+ \mathbf{Z}_j}{h} \right) \frac{\Delta_+ \mathbf{Z}_j}{h} \right)}{h}, \tag{II.1}$$

$$\mathbf{Z}_j |_{t=0} = \mathbf{Z}_{0j} = \mathbf{Z}_0(jh), \tag{II.2}$$

$$\mathbf{Z}_{j+J} = \mathbf{Z}_j, \tag{II.3}$$

where $j = 0, \pm 1, \ldots, \pm J, \ldots,\ h = 2D/J,\ J > 0$.

It is clear that the initial value problem of ordinary differential equation (II.1)–(II.3) admits a local smooth solution. We shall give some estimates uniformly in h for such a solution, and then get the local solution to problems (I.6)–(I.7). In this section we always denote the solution of (II.1)–(II.3) by $\mathbf{Z}_j$.

Lemma II.4: If $\mathbf{Z}_0(x) \in W^{1,4}(\Omega)$, *there are constants* $T_0 > 0, C > 0$ *independent of h such that*

$$\sup_{0 \leqslant t \leqslant T_0} (\| \mathbf{Z}_h(t) \|_2 + \| \delta \mathbf{Z}_h(t) \|_2 + \| \delta \mathbf{Z}_h(t) \|_4) \leqslant C, \tag{II.4}$$

$$\int_0^t \int_\Omega \| \delta^2 \mathbf{Z}_h(t) \|_2 \leqslant C. \tag{II.5}$$

Proof: Multiplying (II.1) by $\mathbf{Z}_j h$ and summing from $j = 1$ to J, we have

$$\frac{1}{2}\frac{d}{dt}\sum_{j=1}^{J}|\mathbf{Z}_j|^2h=-\sum_{j=0}^{J-1}G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2h+\sum_{j=0}^{J-1}\left(\mathbf{Z}_j\times G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)\cdot\frac{\Delta_+\mathbf{Z}_j}{h}h$$
$$=-\sum_{j=0}^{J-1}\left(A+B\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2\right)\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2h.$$

Therefore, we have

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{Z}_h\|_2^2+A\|\delta\mathbf{Z}_h\|_2^2+B\|\delta\mathbf{Z}_h\|_4^4=0. \tag{II.6}$$

It follows from (II.1) that

$$\frac{d\Delta_+\mathbf{Z}_j}{dt}=\frac{\Delta_+\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}+\frac{\Delta_+\Delta_-\left(\mathbf{Z}_j\times G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}.$$

Multiply this equation by $G(\Delta_+\mathbf{Z}_j)/h)(\Delta_+\mathbf{Z}_j/h)$ and summing from $j=0$ to $j=J-1$ to give

$$\sum_{j=0}^{J-1}G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\frac{d\Delta_+\mathbf{Z}_j}{dt}=\sum_{j=0}^{J-1}\frac{\Delta_+\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}$$
$$+\sum_{j=0}^{J-1}\frac{\Delta_+\Delta_-\left(\mathbf{Z}_j\times G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}$$
$$=-\sum_{j=1}^{J}\left|\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}\right|^2h$$
$$-\sum_{j=1}^{J}\frac{\Delta_-\left(\mathbf{Z}_j\times G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}h. \tag{II.7}$$

We claim

$$\sum_{j=1}^{J}\frac{\Delta_-\left(\mathbf{Z}_j\times G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}h=0. \tag{II.8}$$

In fact, we have from Lemma II.3(v) that

$$\sum_{j=1}^{J}\frac{\Delta_-\left(\mathbf{Z}_j\times G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}h$$
$$=\sum_{j=1}^{J}\left(\frac{\Delta_-\mathbf{Z}_j}{h}\times G\left(\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right)\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right)\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}h$$

$$=\sum_{j=1}^{J}\left(\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\times G\left(\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right)\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right)\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}h=0,$$

since $\mathbf{a}\times\mathbf{a}=0$, $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b}=0$ and $\Delta_-\mathbf{Z}_j=\Delta_+\mathbf{Z}_{j-1}$. The claim is proved.

We have from (II.7)–(II.8) that

$$\frac{1}{2}A\frac{d}{dt}\sum_{j=0}^{J-1}\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2h+\frac{1}{4}B\frac{d}{dt}\sum_{j=0}^{J-1}\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^4h+\sum_{j=1}^{J}\left|\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}\right|^2h=0. \tag{II.9}$$

However, it follows from the definition of $G(\xi)$ and Lemma II.3 that

$$\begin{aligned}
\left|\frac{\Delta_-\left(G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\mathbf{Z}_j}{h}\right)}{h}\right|^2 &= \left|G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}+B\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\,\frac{\Delta_-\left(\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2\right)}{h}\right|^2\\
&=\Bigg|G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\\
&\quad+B\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\cdot\left(\frac{\Delta_+\mathbf{Z}_j}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}+\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right)\Bigg|^2\\
&=G^2\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2\\
&\quad+B^2\left|\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2\left|\frac{\Delta_+\mathbf{Z}_j}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}+\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2\\
&\quad+2BG\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\\
&\quad\cdot\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\left(\frac{\Delta_+\mathbf{Z}_j}{h}\cdot\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}+\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\cdot\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right)\\
&=G^2\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2\\
&\quad+B^2\left|\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2\left|\frac{\Delta_+\mathbf{Z}_j}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}+\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2\\
&\quad+2BG\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2\\
&\quad+2BG\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left(\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right)\left(\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_j}{h}\right).
\end{aligned} \tag{II.10}$$

Since

$$G^2\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2=\left(A^2+2AB\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2+B^2\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^4\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2, \tag{II.11}$$

and

$$\begin{aligned}&\left|2BG\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left(\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right)\left(\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_j}{h}\right)\right|\\&\quad\leqslant BG\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left(\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2+\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2\right)\\&\quad=BG\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\cdot\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2+\left(AB\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2+B^2\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^4\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2,\end{aligned} \tag{II.12}$$

we have from (II.9)–(II.12) that

$$\begin{aligned}&A\frac{d}{dt}\sum_{j=0}^{J-1}\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2h+\frac{1}{2}B\frac{d}{dt}\sum_{j=0}^{J-1}\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^4h+A^2\sum_{j=1}^{J}\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2h\\&\quad+AB\sum_{j=1}^{J}\left|\frac{\Delta_+\mathbf{Z}_j}{h}\right|^2\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2h+B\sum_{j=1}^{J}G\left(\frac{\Delta_+\mathbf{Z}_j}{h}\right)\left|\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\,\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2h\\&\quad+B^2\sum_{j=1}^{J}\left|\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\right|^2\left|\frac{\Delta_+\mathbf{Z}_j}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}+\frac{\Delta_+\mathbf{Z}_{j-1}}{h}\,\frac{\Delta_+\Delta_-\mathbf{Z}_j}{h^2}\right|^2h\leqslant 0.\end{aligned} \tag{II.13}$$

This inequality combined with (II.6) leads to

$$\frac{d}{dt}(\|\mathbf{Z}_h\|_2^2+\|\delta\mathbf{Z}_h\|_2^2+\|\delta\mathbf{Z}_h\|_4^4)+\|\mathbf{Z}_h\|_2^2+\|\delta\mathbf{Z}_h\|_2^2+\|\delta\mathbf{Z}_h\|_4^4+\|\delta^2\mathbf{Z}_h\|_2^2\leqslant 0. \tag{II.14}$$

Inequality (II.14) combined with Gronwall inequality implies that there exist constants $T_0,C>0$ independent of h such that

$$\|\mathbf{Z}_h(t)\|_2+\|\delta\mathbf{Z}_h(t)\|_2+\|\delta\mathbf{Z}_h(t)\|_4^4\leqslant C,\quad\forall t\in[0,T_0],$$

$$\int_0^{T_0}\|\delta^2\mathbf{Z}_h(t)\|_2^2\leqslant C.$$

Lemma II.4 is proved. □

Corollary II.1: Under the conditions in Lemma II.4, we have, for some constant C independent of h,

$$\sup_{0\leqslant t\leqslant T_0;1\leqslant j\leqslant J}|\mathbf{Z}_j|\leqslant C. \tag{II.15}$$

Now we have the local existence of the solution to (I.6)–(I.7).

Theorem II.1: *Let* $\varepsilon=1$, $\mathbf{Z}_0(x)\in W^{1,4}(\Omega)$. *Then (I.6)–(I.7) admits a local solution* $\mathbf{Z}(x,t)$ *in* $[0,T_0]$ *in the space*

$$\mathbf{Z}(x,t)\in L^\infty(0,T_0;W^{1,4}(\Omega))\cap L^2(0,T_0;H^2(\Omega)), \tag{II.16}$$

and the following estimates hold:

$$\sup_{0\leqslant t\leqslant T_0;x\in\Omega}|\mathbf{Z}|\leqslant C, \tag{II.17}$$

$$\|\mathbf{Z}(t)\|_2+\|\mathbf{Z}_x(t)\|_2+\|\mathbf{Z}_x\|_4^4\leqslant C,\quad \forall t\in[0,T_0], \tag{II.18}$$

$$\int_0^{T_0}\|\mathbf{Z}_{xx}(t)\|_2^2\leqslant C. \tag{II.19}$$

In order to prove the global existence, we need the following a priori estimates for the solution of (I.6)–(I.7).

Lemma II.5: Let $\varepsilon=1$, $\mathbf{Z}_0(x)\in W^{1,4}(\Omega)$, $T>0$ *and* $\mathbf{Z}(x,t)\in L^\infty(0,T;W^{1,4}(\Omega))\cap L^2(0,T;H^2(\Omega))$ *is a solution of (I.6)–(I.7). Then the following estimates hold*:

$$\sup_{0\leqslant t\leqslant T;1\leqslant j\leqslant J}|\mathbf{Z}|\leqslant C, \tag{II.20}$$

$$\|\mathbf{Z}(t)\|_2+\|\mathbf{Z}_x(t)\|_2+\|\mathbf{Z}_x\|_4^4\leqslant C,\quad \forall t\in[0,T], \tag{II.21}$$

$$\int_0^{T}\|\mathbf{Z}_{xx}(t)\|_2^2\leqslant C. \tag{II.22}$$

Proof: Multiplying (I.6) by $\mathbf{Z}(x,t)$ and integrating it over Ω, we get

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{Z}(\cdot,t)\|_2^2+A\|\mathbf{Z}_x\|_2^2+B\|\mathbf{Z}_x\|_4^4=0. \tag{II.23}$$

Differentiating (I.6) with respect to x and then testing it by $G(\mathbf{Z}_x)\mathbf{Z}_x$, one has

$$G(\mathbf{Z}_x)\mathbf{Z}_x\mathbf{Z}_{xt}=(G(\mathbf{Z}_x)\mathbf{Z}_x)_{xx}G(\mathbf{Z}_x)\mathbf{Z}_x+(G(\mathbf{Z}_x)\mathbf{Z}\times\mathbf{Z}_x)_{xx}G(\mathbf{Z}_x)\mathbf{Z}_x.$$

Integrating this equation by parts, we have

$$\frac{A}{2}\frac{d}{dt}\|\mathbf{Z}_x\|_2^2+\frac{B}{4}\frac{d}{dt}\|\mathbf{Z}_x\|_4^4+\int_\Omega|(G(\mathbf{Z}_x)\mathbf{Z}_x)_x|^2=-\int_\Omega(G(\mathbf{Z}_x)\mathbf{Z}\times\mathbf{Z}_x)_x(G(\mathbf{Z}_x)\mathbf{Z}_x)_x$$

which implies

$$\frac{1}{2}A\frac{d}{dt}\|\mathbf{Z}_x\|_2^2+\frac{1}{4}B\frac{d}{dt}\|\mathbf{Z}_x\|_4^4+\int_\Omega|(G(\mathbf{Z}_x)\mathbf{Z}_x)_x|^2=0. \tag{II.24}$$

Since

$$\begin{aligned}|(G(\mathbf{Z}_x)\mathbf{Z}_x)_x|^2&=|G(\mathbf{Z}_x)\mathbf{Z}_{xx}+2B(\mathbf{Z}_x\cdot\mathbf{Z}_{xx})\mathbf{Z}_x|^2=G^2(\mathbf{Z}_x)|\mathbf{Z}_{xx}|^2+4B^2|(\mathbf{Z}_x\cdot\mathbf{Z}_{xx})\mathbf{Z}_x|^2\\&\quad+4BG(\mathbf{Z}_x)|\mathbf{Z}_x\cdot\mathbf{Z}_{xx}|^2\geqslant A^2|\mathbf{Z}_{xx}|^2,\end{aligned}$$

where C depends only on $\|\mathbf{Z}_0\|_{W^{1,4}(\Omega)}$, it follows from (II.24) that

$$\frac{1}{2}A\frac{d}{dt}\|\mathbf{Z}_x\|_2^2+\frac{1}{4}B\frac{d}{dt}\|\mathbf{Z}_x\|_4^4+A^2\int_\Omega|\mathbf{Z}_{xx}|^2\leqslant 0.$$

Putting this inequality and (II.23) together, we get from the Gronwall inequality that (II.21) and (II.22) hold. (II.20) can be derived from these inequalities. Lemma II.5 is proved. □

Now, we can use the extension method to give a global solution. Repeating for general ε, we have the following.

Theorem II.2: *Let $\varepsilon>0$ be fixed and $\mathbf{Z}_0\in W^{1,4}(\Omega)$. Then problem (I.6)–(I.7) admits a global solution $\mathbf{Z}_\varepsilon(x,t)$ in the space*

$$\mathbf{Z}_\varepsilon(x,t)\in L^\infty(0,\infty;W^{1,4}(\Omega))\cap L^2(0,\infty;H^2(\Omega)), \tag{II.25}$$

and the following estimates hold:

$$\sup_{0\leqslant t<\infty;x\in\Omega}|\mathbf{Z}_\varepsilon(x,t)|\leqslant C_1, \tag{II.26}$$

$$\|\mathbf{Z}_\varepsilon(t)\|_2+\|\mathbf{Z}_{\varepsilon x}(t)\|_2+\|\mathbf{Z}_{\varepsilon x}(t)\|_4^4\leqslant C_1, \quad \forall t\in[0,\infty), \tag{II.27}$$

$$\|\mathbf{Z}_{\varepsilon t}\|_{L^{4/3}(0,\infty;W^{-1,4/3}(\Omega))}\leqslant C_1, \tag{II.28}$$

$$\int_0^\infty\|\mathbf{Z}_{\varepsilon xx}(t)\|_2^2\leqslant C_\varepsilon, \tag{II.29}$$

where C_1 depends only on $\|\mathbf{Z}_0\|_{W^{1,4}(\Omega)}$.

Remark: The fact that C_1 *is independent of* ε *can be seen from the proof of Lemma II. 5, but* C_ε *depends on* ε.

III. MEASURE–VALUED SOLUTION TO THE STRONGLY DEGENERATE EQUATIONS

Since we can only get the uniform estimates (in ε) (II.26)–(II.28) for the solutions of the viscosity equations (I.6) and these estimates are not enough to obtain the weak solution for (I.4)–(I.5), we apply the notion of the measure-valued solution as in Ref. 7.

Denote $M=C_1$ where C_1 is given in Theorem II.2 which depends only on $\|\mathbf{Z}_0\|_{W^{1,4}(\Omega)}$. Let $\mathcal{Z}^\varepsilon=(\mathbf{Z}_\varepsilon,\mathbf{Z}_{\varepsilon x})$, $\tau(\xi)=B|(\xi_4,\xi_5,\xi_6)|^2(\xi_1,\xi_2,\xi_3)\times(\xi_4,\xi_5,\xi_6):(\mathbb{R}^3\cap\{|(\xi_1,\xi_2,\xi_3)|\leqslant M\})\times\mathbb{R}^3\to\mathbb{R}^3$. Then $\mathcal{Z}^\varepsilon$ is uniformly bounded in $L^4(Q)^6$ where $Q=\Omega\times(0,T)\in\mathbb{R}^2$ and

$$|\tau(\xi)|\leqslant CM(1+|\xi|)^3,\forall\xi\in(\mathbb{R}^3\cap\{|(\xi_1,\xi_2,\xi_3)|\leqslant M\})\times\mathbb{R}^3.$$

The following Lemma can be proved by the same method as in Ref. 7.

Lemma III.1: Let $Q\subset\mathbb{R}^2$ be a bounded open set. Let $\mathcal{Z}^{\varepsilon_n}$ be uniformly bounded in $L^4(Q)^6$. Then there exists a subsequence, still denoted by $\mathcal{Z}^{\varepsilon_n}$, and a measure-valued function ν such that for all $\tau:(\mathbb{R}^3\cap\{|(\xi_1,\xi_2,\xi_3)|\leqslant M\})\times\mathbb{R}^3\to\mathbb{R}^3$ satisfying for some $q>0$ the growth condition

$$|\tau(\xi)|\leqslant C(1+|\xi|)^3, \quad \forall\xi\in(\mathbb{R}^3\cap\{|(\xi_1,\xi_2,\xi_3)|\leqslant M\})\times\mathbb{R}^3,$$

we have

$$\tau(\mathcal{Z}^{\varepsilon_n})\rightharpoonup\overline{\tau} \text{ weakly in } L^r(Q),$$

$$\overline{\tau}(y)=<\nu_y,\tau>a.e.y\in Q,$$

provided that

$$1<r\leqslant\frac{4}{3}.$$

Proof: It suffices to verify the condition (2.7) of Theorem 2.1 of Ref. 7. Taking the Young function $\Psi(u)=u^r$, we have

$$\int_Q \Psi(\tau|\mathcal{Z}^{\varepsilon_n}|) = \int_Q |\mathcal{Z}^{\varepsilon_n}|^r \leqslant C^r \int_Q (1+|\mathcal{Z}^{\varepsilon_n}|)^{3r},$$

and the last term is uniformly bounded (with respect to n) if $3r \leqslant 4$. The lower bound $r>1$ follows from the properties of Orlicz functions, namely from $\lim_{s\to\infty}\Psi(s)/s=\infty$. □

Definition: A pair $(\mathbf{Z},\nu)$ is called a measure-valued solution of (I.4)–(I.5) if

$$\mathbf{Z}\in L^{\infty}(0,\infty;W^{1,4}(\Omega)), \tag{III.1}$$

$$\nu\in L^{\infty}_{\omega}(Q;\mathrm{Prob}(\mathbb{R}^6)), \tag{III.2}$$

and if for any $\varphi\in\mathcal{D}(-\infty,T;C^{\infty}_{\mathrm{per}}(\Omega))$ there holds

$$\int_Q \mathbf{Z}_0\varphi = \int_Q \mathbf{Z}\varphi_t - A\int_Q \varphi_x \mathbf{Z}\times\mathbf{Z}_x - \int_Q \varphi_x \int_{\mathbf{R}^6} \tau(\lambda)\, d\nu_{t,x}(\lambda)\, dx\, dt, \tag{III.3}$$

where τ is defined as above, $Q=\Omega\times(0,T)$.

Theorem III.1: *Let $\mathbf{Z}_0\in W^{1,4}(\Omega)$. Then problem (I.4)–(I.5) admits a measure-valued solution.*

Proof: It follows from Lemma III.1 that there exists a subsequence $\mathcal{Z}^{\varepsilon_n}$ and a measure-valued function ν such that

$$\tau(\mathcal{Z}^{\varepsilon_n}) \rightharpoonup \overline{\tau} \text{ weakly in } L^r(Q), \quad 1<r\leqslant \frac{4}{3}, \tag{III.4}$$

$$\overline{\tau}(x,t) = \langle \nu_{t,x}, \tau\rangle, \quad a.e.\,(x,t)\in Q. \tag{III.5}$$

To finish the proof, we only need to prove, for some subsequence $\mathbf{Z}_{\varepsilon_n}$, that

$$\int_Q \mathbf{Z}_{\varepsilon_n t}\varphi \to -\int_Q \mathbf{Z}_t\varphi + \int_\Omega \mathbf{Z}_0\varphi(x,0), \tag{III.6}$$

$$\int_Q (\mathbf{Z}_{\varepsilon_n}\times\mathbf{Z}_{\varepsilon_n x})\varphi_x \to \int_Q (\mathbf{Z}\times\mathbf{Z}_x)\varphi_x, \tag{III.7}$$

$$Z^i_x = \int_{\mathbf{R}^6} \lambda_{i+3}\, d\nu_{t,x}(\lambda), \quad a.e.\,(x,t)\in Q, \quad i=1,2,3. \tag{III.8}$$

In view of (II.27), we have for some subsequence $\mathbf{Z}_{\varepsilon_n}$ that

$$\mathbf{Z}_{\varepsilon_n} \rightharpoonup \mathbf{Z} \text{ weakly in } L^r(0,T;L^2(\Omega)), \quad \forall r>1 \tag{III.9}$$

$$\mathbf{Z}_{\varepsilon_n x} \rightharpoonup \mathbf{Z}_x \text{ weakly in } L^r(0,T;L^4(\Omega)), \quad \forall r>1. \tag{III.10}$$

To prove (III.6), we take $\varphi\in\mathcal{D}(-\infty,T;C^{\infty}_{\mathrm{per}}(\Omega))$ to give

$$\int_0^T\int_\Omega \mathbf{Z}_{\varepsilon_n t}\varphi = -\int_0^T\int_\Omega \mathbf{Z}_{\varepsilon_n}\varphi_t + \int_\Omega \mathbf{Z}_0(x)\varphi(x,0) \to -\int_0^T\int_\Omega \mathbf{Z}\varphi_t + \int_\Omega \mathbf{Z}_0(x)\varphi(x,0);$$

this proves (III.6).

Now we prove (III.7). It follows from (II.27) and (II.28) that $\mathbf{Z}_{\varepsilon_n}$ is uniformly bounded in the space

$$\{v:v\in L^r(0,T;W^{1,4}_{\mathrm{per}}(\Omega)),v_t\in L^{4/3}(0,T;(W^{1,4}(\Omega))^*)\},\tag{III.11}$$

for any $r>1$. Since $W^{1,4}_{\mathrm{per}}(\Omega)\hookrightarrow\hookrightarrow L^r(\Omega)\hookrightarrow(W^{1,4}(\Omega))^*$, applying an Aubin–Lions Lemma[7] with $X_0=W^{1,4}_{\mathrm{per}}(\Omega)$, $X=L^r(\Omega)$, $X_1=(W^{1,4}(\Omega))^*$, $\alpha=r$ $(r>1)$, $\beta=4/3$, we know that the space defined in (III.11) is compactly imbedded into $L^r(0,T;L^r(\Omega))$, that is,

$$\mathbf{Z}_{\varepsilon_n}\to\mathbf{Z}\ \text{ strongly in }\ L^r(0,T;L^r(\Omega)).\tag{III.12}$$

Since

$$\int_Q((\mathbf{Z}_{\varepsilon_n}\times\mathbf{Z}_{\varepsilon_n x})\varphi_x-(\mathbf{Z}\times\mathbf{Z}_x)\varphi_x)=\int_Q((\mathbf{Z}_{\varepsilon_n}-\mathbf{Z})\times\mathbf{Z}_{\varepsilon_n x})\varphi_x+\int_Q(\mathbf{Z}\times(\mathbf{Z}_{\varepsilon_n x}-\mathbf{Z}_x))\varphi_x=I_1+I_2,$$

it follows from (II.26) and (III.10) that

$$I_2\to0\ \text{ as }\ n\to\infty,$$

and it follows from (II.27) and (III.12) that

$$|I_1|\le\left(\int_0^T\int_\Omega|\mathbf{Z}_{\varepsilon_n}-\mathbf{Z}|^4\right)^{1/4}\left(\int_0^T\int_\Omega|\varphi_x|^4\right)^{1/4}\left(\int_0^T\int_\Omega|\mathbf{Z}_{\varepsilon_n x}|^2\right)^{1/2}$$
$$\le C\left(\int_0^T\int_\Omega|\mathbf{Z}_{\varepsilon_n}-\mathbf{Z}|^4\right)^{1/4}\to0\ \text{ as }\ n\to\infty.$$

The proof of (III.7) is complete.

Since Lemma III.1 is true for all τ, if we let $\tau=\mathrm{Id}$, then for $r=4$, $q=1$, $\forall\psi\in L^{4/3}(Q)$, we have for $\mathcal{Z}^{\varepsilon_n}=(\mathbf{Z}_{\varepsilon_n},\mathbf{Z}_{\varepsilon_n x})$ that

$$\int_Q\mathcal{Z}^{\varepsilon_n}\psi\,dx\,dt\to\int_Q\psi\int_{\mathbf{R}^6}\lambda\,d\nu_{t,x}(\lambda)dx\,dt.$$

However, $\mathbf{Z}_{\varepsilon_n}\to\mathbf{Z}$ strongly in $L^r(Q)$ and $\mathbf{Z}_{\varepsilon_n x}\rightharpoonup\mathbf{Z}_x$ in $L^4(Q)$, we know

$$Z_x^i=\int_{\mathbf{R}^6}\lambda_{i+3}\nu_{t,x}(\lambda),\quad a.e.(x,t)\in Q,\quad i=1,2,3.$$

This verifies (III.8). □

Remark: Since the estimates obtained in section II are independent of D, we get by letting $D\to\infty$ that the Cauchy problem of (I.4) admits a solution in $L^\infty(\mathbb{R}_+;W^{1,4}(\mathbb{R}^1))\cap L^2(\mathbb{R}_+;H^2(\mathbb{R}^1))$.

Rectangular well as perturbation

Mariusz Dudek, Stefan Giller,[a] and Piotr Milczarski[b]
Theoretical Physics Department II, University of Łódź, Pomorska 149/153, 90-236 Łódź, Poland

(Received 13 March 1998; accepted for publication 10 November 1998)

We discuss a finite rectangular well of a depth λ^2 as a perturbation for the infinite one with λ as a perturbation parameter. In particular, we consider a behavior of energy levels in the well as functions of complex λ. It is found that all the levels of the same parity are defined on infinitely sheeted Riemann surfaces whose topological structures are described in detail. These structures differ considerably from those found in models investigated earlier. It is shown that perturbation series for all the levels converge what is in a contrast with the known results of Bender and Wu. The last property is shown to hold also for the infinite rectangular well with the Dirac delta barrier as a perturbation considered earlier by Ushveridze. © *1999 American Institute of Physics.* [S0022-2488(99)03103-5]

I. INTRODUCTION

Since the papers of Bender and Wu[1] we have known why the perturbation series were, in general, divergent. We have known also that in many cases investigations of perturbation series could be reduced to the investigations of the corresponding semiclassical series.[2] It was also realized that the divergent perturbation series could be summed and one of the summation methods applied here was very often the Borel one.[2,3]

One of the byproducts of these investigations was a discovery of so called level crossing, i.e., of the fact that in the case of confining polynomial potentials all the discrete energy levels they produce or only groups of them are no longer isolated of each other if considered as functions of a perturbation parameter.[1,3–6] Being a little bit more precise, the latter statement means that the levels inside each group appear as branches of ramified functions of the perturbation parameter considered as a complex variable. It means, in particular, that each energy level belonging to a group considered as a function of a real perturbation parameter can be analytically continued into the complex plane of the parameter so that any energy level of the group can be reached by the analytic continuation procedure of some arbitrary chosen level belonging to the group. This means also that the complex plane of the perturbation parameter converts rather into some (more or less) complicated Riemann surface.

It is also well known[7] that it is an existing symmetry group of the Hamiltonian considered which is completely responsible for a decay of the energy spectrum into disjoint (with respect to analytic continuation) groups of them. Therefore, a degree of complication of respective Riemann surfaces on which the energy levels are defined can give us information about an existence of the relevant symmetry group, i.e., the more levels appear as branches defined on respective sheets of the same Riemann surface the less rich a relevant symmetry group has to be. In particular, if the corresponding Riemann surfaces are all finitely sheeted (i.e., if there are finite numbers of energy levels attached to each of them) then they have to be defined by some algebraic conditions relating energies and a perturbation parameter, with the conditions being a clear sign of the existence of an underlying symmetry group.[7]

There are only a few examples of the analysis described above in the case when the relevant Riemann surface is infinitely sheeted.[1,6,8] The analysis performed is more or less numerical. This

[a]Electronic mail: sgiller@krysia.uni.lodz.pl
[b]Electronic mail: jezykmil@krysia.uni.lodz.pl

is mostly because it is very difficult to find an example of potential providing us with a closed functional form of the quantization condition being simultaneously sufficiently simple to perform an analysis in a ''classical,'' non-numerical way. According to these investigations a Riemann surface topology corresponding to a given perturbation parameter, i.e., loci of its branch points seems to be still mysterious and depending on a parameter chosen so needing still further studies.

In this paper we will consider a possibly simple but not a trivial example of a Hamiltonian provided by the familiar rectangular well of a finite height which allows us for such a classical analysis. As a perturbation parameter in this example we will choose its height $V=\lambda^2>0$; strictly speaking the square root of it. The perturbed potential is then the infinite rectangular well approached when $V^{-1}\rightarrow 0$.

There are several basic properties which differ the case of the finite rectangular well from the ones considered earlier. First it is just a finite number of energy levels existing for a given λ but varying with λ so that a potentially infinite number of levels can appear when $\lambda^{-1}\rightarrow 0$. The remaining properties are enumerated as points 2, 4 and 5. below.

The rectangular well is not an analytical potential and as such it provides us also with a nonanalytical quantization condition. However, an analytical extension of the latter into complex values of the quantities considered is possible and results of the relevant analysis are the following.

1. The system of energy levels of the well decays into two disjoint families (of different parities) with the levels inside each of the group being analytical continuations of each other with respect to the perturbation parameter.

2. The perturbation series for each level is convergent to the level itself, i.e., the property which is quite opposite to that of Bender and Wu for the unharmonic oscillator case. As such they are trivially Borel summable.

3. The Riemann surfaces for both the groups of levels are infinitely sheeted and their branch point structures can be understood by some simple properties of both the quantization conditions.

4. The energy level poles existing in the complex momentum plane corresponding to the case are accompanied by poles which do not represent discrete nor resonant parts of the energy spectrum [in particular, because resonances are absent in the case of the finite rectangular well independently of whether the latter is a real well (for real λ) or is a rectangular barrier (for imaginary λ)]. These second sort of poles we shall call pseudoenergy levels.

5. The level crossing which happens for *real* λ is not between two real energies but just between an energy and its pseudoenergy partner.

We will reconsider also an example of a numerical analysis performed earlier by Ushveridze[8] to show that its ''classical'' analysis is possible in its full size confirming the main results of the author mentioned but completed them with such an important conclusion as a convergence of both perturbation series corresponding to the weak and the strong couplings to the Dirac delta perturbation used in the example.

Another goal of our investigations was to look for rules governing distributions of energy level branch points on the perturbation parameter Riemann surface. It has been demonstrated by Ushveridze[8] that one can predict an existence of energy level crossing as well as arrange the crossing to join more than two levels but as in the case of the anharmonic potential[1] distributions of the corresponding branch points seemed to be unpredictable prior to direct calculations.

Our main conclusion in this respect is similar. Indeed, such distributions of branch points is rather strongly model (potential) dependent although it can happen that some properties of these distributions can be drawn just by an inspection of properties of investigated potentials. However, in this way only some crude procedure can be formulated to predict their presence or absence in some domains of the underlying Riemann surface (see also Ref. 2).

II. FINITE RECTANGULAR WELL AS A PERTURBATION

A. Analytic properties of energy levels as functions of perturbation parameter

A finite rectangular well as a perturbation sounds a little bit exotic but it can be considered as such for the infinite will in the same way as, for example, a finite potential well:

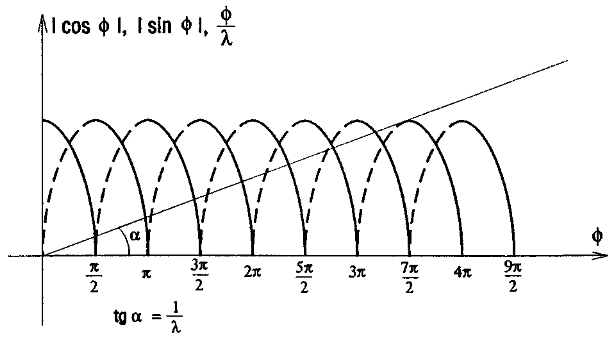

FIG. 1. The ϕ angles chosen by the quantization conditions (3).

$$\frac{1}{2}\frac{\omega^2}{\alpha^2}\left(1-\frac{1}{\cosh(\alpha x)}\right) \tag{1}$$

is a perturbation for the harmonic one, i.e., we get the latter from (1) for $\alpha\rightarrow 0$.

In the case of a finite rectangular potential given by

$$V(x)=\begin{cases} V(>0), & \text{for } |x|>1,\\ 0, & \text{for } |x|<1, \end{cases} \tag{2}$$

a perturbation parameter can be chosen to be $\lambda^2=V$ which together with the rescaled energy $E/V\equiv z^2$ leads us to the following quantization conditions:[9]

$$\begin{aligned} &\lambda|\cos\phi|=\phi, \quad z=|\cos\phi|, \quad \tan\phi>0, \quad \text{for positive parity levels;}\\ &\lambda|\sin\phi|=\phi, \quad z=|\sin\phi|, \quad \tan\phi<0; \quad \text{for negative parity levels.} \end{aligned} \tag{3}$$

All (positive) solutions $\phi_k(\lambda)$, $k=1,2,\ldots$, to Eqs. (3) are represented picturesquely in Fig. 1 as given by the points of intersections of the straight line ϕ/λ with the right arcs of $|\sin(\phi)|$ and $|\cos(\phi)|$ functions. The corresponding solutions for energy levels are then obtained as $E_k(\lambda)=\lambda^2 z^2(\phi_k(\lambda))$. It is just a dependence of E_k's on λ as a complex parameter which is the main interest of this paper.

To investigate this dependence it is, however, necessary to make an analytical continuation of the conditions (3) into the complex λ. Such a continuation of Eqs. (3) is possible when dropping the absolute value marks in (3), which provides us with following analytic conditions:

$$\begin{aligned} &\lambda\cos\phi=\phi, \quad z=\cos\phi, \quad \text{for } 0\leqslant\phi\leqslant\tfrac{1}{2}\pi \pmod{2\pi};\\ &\lambda\cos\phi=-\phi, \quad z=-\cos\phi, \quad \text{for } \pi\leqslant\phi\leqslant\tfrac{3}{2}\pi \pmod{2\pi};\\ &\lambda\sin\phi=\phi, \quad z=\sin\phi, \quad \text{for } \tfrac{1}{2}\pi\leqslant\phi\leqslant\pi \pmod{2\pi};\\ &\lambda\sin\phi=-\phi, \quad z=-\sin\phi, \quad \text{for } \tfrac{3}{2}\pi\leqslant\phi\leqslant 2\pi \pmod{2\pi} \end{aligned} \tag{4}$$

equivalent to (3) for positive ϕ.

According to (4) the energy spectrum for the potential (2) is formally divided into four groups. Each group contains every fourth member of the spectrum, starting from E_1^+, E_3^+, E_2^-, E_4^- energy levels in the corresponding group. The energy levels in the groups are defined by the conditions (4) in the order mentioned.

Dropping further the restrictions for the ranges of changing ϕ in the conditions (4) we get fully analytical quantization conditions but describing rather different spectra with respect to which our original ones are only parts of them. This is, however, the necessary price for investigating the complex analytical dependence of energy levels on λ.

Let us observe, however, that for both the parity levels it is enough to continue analytically only the first of the corresponding conditions (4) depriving them of the corresponding restrictions for ϕ (i.e., ϕ can now take any complex value in these conditions). This is because corresponding solutions $\phi^{\pm}(\lambda)$ to the first conditions generate solutions $\phi^{\pm}(-\lambda)$ to the second ones. [In fact, for the even parity both the solutions almost coincide since $\phi^{+}(-\lambda)=-\phi^{+}(\lambda)$].

Therefore we see that all energy levels of both parities: $E_k^{+}(\lambda)=\lambda^2\cos^2\phi_k^{+}(\lambda)=(\phi_k^{+}(\lambda))^2$ and $E_k^{-}(\lambda)=\lambda^2\sin^2\phi_k^{-}(\lambda)=(\phi_k^{-}(\lambda))^2$ can be obtained by solving only the first conditions (4) of the corresponding parities and performing analytic continuations in λ from its positive to its negative values.

We shall analyze first the even parity group determining the ground state energy level. An analysis of the odd parity case is quite similar.

1. Even parity energy spectrum case

Making in the first of the conditions (4) a change of variable $e^{i\phi}=\sigma$ we get instead

$$\lambda^{+}=-\frac{2i\sigma\ln\sigma}{\sigma^2+1},\qquad z^{+}=\frac{1}{2}\left(\sigma+\frac{1}{\sigma}\right). \tag{5}$$

Since a dependence of z^{+} on σ as given by (5) is rather simple then to get the corresponding dependence of z^{+} on λ it is necessary to invert the dependence of the latter variable on σ as given by (5). To do this one needs to know the following:

1^0 The Riemann surface structure for $\lambda^{+}(\sigma)$;

2^0 The loci of all zeros of $\lambda^{+'}(\sigma)$ on the surface; and

3^0 A pattern of lines $\mathrm{Re}\,\lambda^{+}=\mathrm{const}$ and $\mathrm{Im}\,\lambda^{+}=\mathrm{const}$ on the surface.

As it follows from (5) the Riemann surface structure for $\lambda^{+}(\sigma)$ is determined by

a. The logarithmic branch point at $\sigma=0$; and

b. A pair of simple poles at $\sigma=\pm i$ located on every sheet the latter being generated in an infinite number by the logarithm.

Zeros of $\lambda^{+'}(\sigma)$ are determined by the following equation:

$$\ln\sigma=\frac{\sigma^2+1}{\sigma^2-1}. \tag{6}$$

Putting $e^{i\phi+y}=\sigma$ (σ is now an arbitrary complex number on the surface) and assuming that $\phi,y\neq 0$ we transform (6) into

$$\frac{\sin 2\phi}{2\phi}=-\frac{\sinh 2y}{2y},\qquad \cos 2\phi=-\frac{\sinh 2y}{2y}+\cosh 2y, \tag{7}$$

$$\phi,\ \ y\neq 0,$$

from which it follows that all zeros of $\lambda^{+'}(\sigma)$ have to lie on the circle $|\sigma|=1$ and/or on the real half axis $\phi=0$. Therefore the corresponding conditions for them are

$$\cot\phi=-\phi,\qquad \ln\sigma=\frac{\sigma^2+1}{\sigma^2-1}, \tag{8}$$

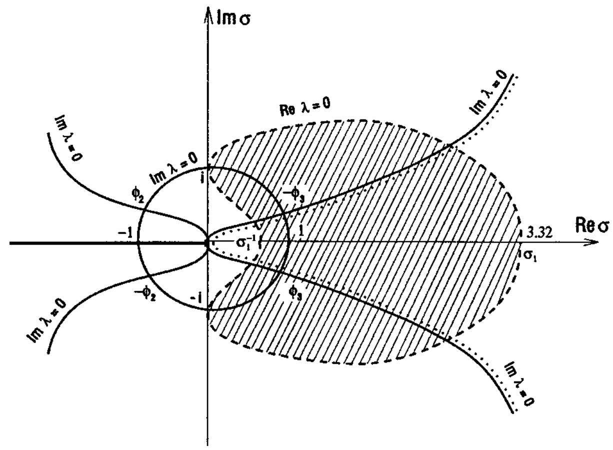

FIG. 2. The ''first'' sheet of the σ-Riemann surface corresponding to $\lambda^+(\sigma)$.

where in the last equation σ is real and positive.

Solutions to the first of Eqs. (8) (in fact, infinitely many of them) are given therefore as the intersection points of the functions $\cot\phi$ and $-\phi$. The form of the condition can be easily identified as the one for the straight line ϕ/λ of Fig. 1 to be tangent to $\cos\phi$. Therefore the points have to lie close to $\phi=2k\pi$ ones, $k=1,2,\ldots$, on the left to them, and close to $\phi=k\pi$, $k=-1,-3,\ldots$, on the right to the latter.

Two real solutions to the second of Eqs. (8) are placed on both the sides of $\sigma=1$ at $\sigma_1 \approx 3.32$ and at $\sigma_1^{-1}\approx 0.301$.

Let us note that the points on the unit circle at $\phi=k\pi, k=-1,+2,-3,+4,\ldots$, and the point $\sigma=1$ are all the physical ''thresholds'' for successive appearing of the corresponding even parity energy levels according to changing λ from zero to infinity. There is a temptation to understand the zeros provided by the conditions (8) as a shifting of these thresholds from their real physical positions mentioned to their actual ones because of the approximations which the analytical conditions (8) effectively are to our rectangular well quantization problem. This shifting of thresholds remains in a deep relation to analytical properties of reflection and transmission coefficients of the corresponding scattering problem arising when energy is higher than λ^2. We shall discuss this relation below.

Although the solutions to the condition (8) cannot be considered as thresholds for any real energy spectrum case (this is excluded by the absence of the energy level degeneracy in 1-dim SE) we shall consider them as such for convenience and call them pseudothresholds.

Thus the solutions to the first of the conditions (8) are the pseudothresholds for the energy levels lying inside the potential above the ground state one. These pseudothresholds as we have mentioned earlier coincide with results of demanding for the line ϕ/λ in Fig. 1 to be tangent to $\cos\phi$. The latter demand is just the lower limit for λ above which the real solutions for the higher energy levels can exist.

Both the solutions at σ_1 and σ_1^{-1} between which $\lambda^+(\sigma)$ is pure imaginary are then the corresponding limits for the ground state energy level E_1^+ to be a real quantity. However, for $E_1^+(\lambda)$ as well as for the higher energies the condition to be real is not enough to represent a real physical level. The sufficient conditions will be discussed below in Sec. II B.

A pattern of the lines $\mathrm{Re}\,\lambda^+=\mathrm{Im}\,\lambda^+=0$ is sketched on Fig. 2 together with the positions of all singular points of $\lambda^+(\sigma)$. Since all zeros of $\lambda^{+\prime}(\sigma)$ are simple they result as square root branch point singularities of $\sigma(\lambda)$ on its λ-Riemann surface. A consequence of this is a perpendicular crossing of two lines $\mathrm{Im}\,\lambda^+=0$ as well as the corresponding two lines $\mathrm{Re}\,\lambda^+=0$ in every such zero. All the lines $\mathrm{Im}\,\lambda^+=0$ emanating outside the unit circle run to infinity on the corresponding sheets of the σ-Riemann surface parallel to the line $\mathrm{Re}\,\sigma=0$. These emanating inside the circle have to cross the logarithmic branch point at $\sigma=0$ being tangent at this point to the line

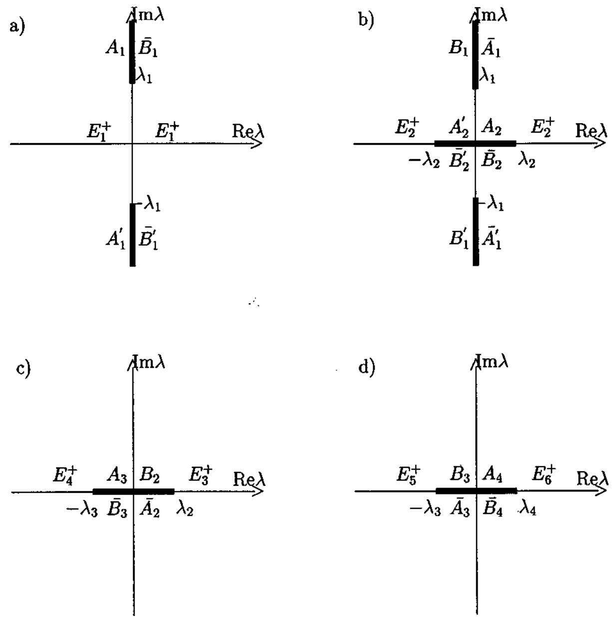

FIG. 3. The few first λ-Riemann surface sheets for $\sigma^+(\lambda)(E^+(\lambda))$.

Re $\sigma=0$. The remaining lines Im $\lambda^+=0$ coincide with all semicircles of the unit circle lying between the poles at $\sigma=\pm i$ on every logarithmic sheet of the σ-Riemann surface.

The λ-Riemann surface on which the inverse function $\sigma^+(\lambda)$ is defined is now easy to construct. It is also an infinitely sheeted surface. Its first sheet is a map of the dashed area in Fig. 2 and is shown in Fig. 3(a). This is the sheet on which the ground state energy level is defined, i.e., for λ changing along the real axis of the sheet or along a segment $[\lambda_1,-\lambda_1]\equiv[-\lambda^+(\sigma_1),\lambda^+(\sigma_1^{-1})]$ on the imaginary axis where the corresponding energy E_1^+ is real. On the rest of the sheet the energy is complex.

There are two cuts on the sheet emanating of the two complex conjugate imaginary branch points at $\lambda_1=\lambda^+(\sigma_1)=-\lambda^+(\sigma_1^{-1})$ and running to infinity along its imaginary axis. The function $\sigma^+(\lambda)$ is holomorphic on the sheet approaching $\pm i$ for λ escaping to the infinity on the right or on the left half planes of the sheet, respectively.

The second sheet corresponds to the second energy level. This sheet can be achieved by crossing (in any direction) one of the two cuts described above. Despite these two latter cuts there are another two square root branch points on the sheet lying on the real axis at $\lambda=\pm\lambda_2=\lambda^+(e^{\mp i\phi_2})=\mp\phi_2/\cos\phi_2$. The energy level E_2^+ is given by the values of λ changing on both the sides of the real axis from the real branch points mentioned up to the corresponding infinities. On the σ-Riemann surface of Fig. 2 these ranges of changing λ correspond to varying σ along the two left unit semicircles between the poles at $\sigma=\pm i$.

There is still an additional branch point on the discussed sheet at $\lambda=0$ which is also present at all the other sheets except the first one. It is a common picture of the point $\sigma=0$ and all the infinity points of the σ-Riemann surface of Fig. 2. Therefore this point gives rise to an infinite branching of $\sigma^+(\lambda)$ around it.

Starting from the third energy level, every one of the levels is represented on two different sheets which can communicate with themselves by the branch point at $\lambda=0$. Each of these two sheets belongs to two different families of them the latter being generated by the two branch points of the second sheet at $\lambda=\pm\lambda_2$ [see Fig. 3(b)]. One of these two families corresponds to mapping of the σ-Riemann surface of Fig. 2 into the λ one in the clockwise direction moving around the logarithmic branch point of $\lambda^+(\sigma)$ at $\sigma=0$. The second family of sheets in the corresponding mapping in the opposite direction.

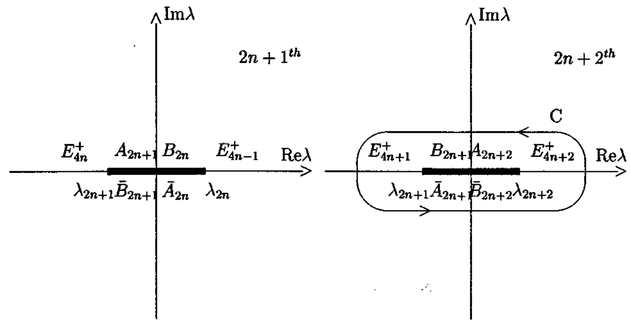

FIG. 4. The general structure of λ-Riemann surface sheets for $\sigma^+(\lambda)(E^+(\lambda))$.

Let us analyze the family generated by the branch point at $\lambda=\lambda_2$. The other family is a twin picture of this one obtained by a transformation $\lambda\to-\lambda$.

Going around λ_2 through the cut $A_2/\overline{B_2}$ we find ourselves on the sheet shown in Fig. 3(c). There is an additional cut on the sheet generated by the branch point at $\lambda=\lambda_3=\lambda^+(e^{-i\phi_3})=-\phi_3/\cos\phi_3$. The branch point opens the possibility for the fourth and the fifth energy levels to appear. The ranges of the energy levels E_3^+ and E_4^+ are shown on the figure.

To achieve a sheet corresponding to a pair E_5^+, E_6^+ of the levels we have to cross the cut $A_3/\overline{B_3}$ in Fig. 3(c) (in any direction). The sheet is shown in Fig. 3(d) together with corresponding ranges for the energies.

A full structure of the considered family of sheets of the λ-Riemann surface is now obvious. The n^{th} sheet, $n=3,4,\ldots,$ contains three branch points lying at $\lambda=0$, $\lambda=\lambda_{n-1}=-\phi_{n-1}/\cos\phi_{n-1}$ and at $\lambda=\lambda_n=-\phi_n/\cos\phi_n$. Each of the last two branch points opens a pair of energy levels: E^+_{2n-4}, E^+_{2n-3} and E^+_{2n-2}, E^+_{2n-1}, respectively, the levels in each pair lying on different sheets.

And inversely, the energy levels appear on every sheet in pairs. A $2n+1$th sheet corresponding to energy levels E^+_{4n-1}, E^+_{4n}, $n=1,2,\ldots$ (see Fig. 4) is cut by two cuts: $B_{2n}/\overline{A}_{2n}$ beginning at $\lambda=\lambda_{2n}=-\phi_{2n}/\cos\phi_{2n}>0$ and opening the level E^+_{4n-1} and $B_{2n+1}/\overline{A}_{2n+1}$ beginning at $\lambda=\lambda_{2n+1}=-\phi_{2n+1}/\cos\phi_{2n+1}<0$ and opening the level E^+_{4n}. Both the cuts end at $\lambda=0$. A corresponding sheet for the levels E^+_{4n+1}, E^+_{4n+2} is cut from λ_{2n+1} to 0 and from 0 to $\lambda=\lambda_{2n+2}=-\phi_{2n+2}/\cos\phi_{2n+2}>0$ with the latter branch point opening the second of the considered levels (see Fig. 4). Note also that a pair E^+_{4n-1}, E^+_{4n} is determined by the crossing line ϕ/λ with $4n-1$th and $4n$th arcs of $|\cos\phi|$ of Fig. 1, respectively, and a pair E^+_{4n+1}, E^+_{4n+2} with the arcs $4n+1$th, $4n+2$th correspondingly. This is why the members of each such a pair have to approach the same limit when $\lambda\to+\infty$.

The structure of the second family of sheets generated by the branch point at $\lambda=-\lambda_2$ is obtained by an inversion: $\lambda\to-\lambda$ from the first one discussed above.

2. Odd parity energy spectrum case

Making in the third of the conditions (4) a change of variable $\sigma=e^{i\phi}$ we get the condition in the form:

$$\lambda^-=\frac{2\sigma\ln\sigma}{\sigma^2-1},\quad z^-=\frac{1}{2i}\left(\sigma-\frac{1}{\sigma}\right). \tag{9}$$

It follows from (9) that $\lambda^-(\sigma)$ is a meromorphic function of σ on the σ-Riemann surface with the logarithmic branch point at $\sigma=0$ and with simple poles at $\sigma=\pm1$ on every logarithmic sheet except the first one where the pole at $\sigma=1$ is absent. The surface is shown in Fig. 5 where the lines $\mathrm{Im}\,\lambda^-(\sigma)=0$ are also shown schematically. Zeros of $\lambda^{-\prime}(\sigma)$ are distributed in this case only

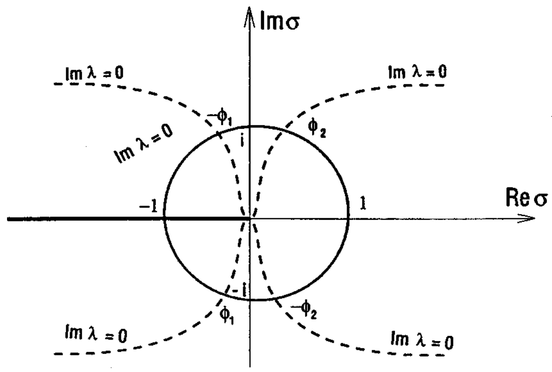

FIG. 5. The ''first'' sheet of the σ-Riemann surface corresponding to $\lambda^-(\sigma)$.

on the unit circle $|\sigma|=1$ at the point $\sigma=1$ on the first sheet and at points $\sigma=e^{i\phi_k}$ with $\phi_k(=-\phi_{-k}>0)$ satisfying the condition $\phi_{\pm k}=\tan\phi_{\pm k}$, $k=2,\ldots,$ on the remaining sheets so that the first two of the latter singular points lie on the second sheet of Fig. 5.

On the other hand, the inverse function $\sigma^-(\lambda)$ is holomorphic on the λ-Riemann surface with branch points at $\lambda=1$ and at $\lambda_k=\lambda^-(e^{i\phi_k})$ which are images of zeros of $\lambda^{-\prime}(\sigma)$.

The spectrum is opened with the level $E_2^-(\lambda)$ which belongs to the odd parity spectrum of the rectangular well contrary to the next level $E_3^-(\lambda)$ which does not.

An interesting property of $E_2^-(\lambda)$ is a singularity which it has to have at $\lambda=0$, i.e., the level $E_2^-(\lambda)$ as a function of λ is not bounded from below at this point. This conclusion follows from an observation that although the point $\lambda=1$ is a branch one for $\sigma^-(\lambda)$ [below which $\sigma^-(\lambda)$ has two values: σ and σ^{-1} for every λ, $0\leqslant\lambda\leqslant 1$] it is not as such for the level $E_2^-(\lambda)$. On the other hand, $E_2^-(\lambda)(=-\ln^2\sigma)$ for $0<\lambda<1$ $(0<\sigma<+\infty)$ is real and negative. Therefore a pseudothreshold for the latter appears to be at the point $\lambda=0$ at which $E_2^-(\lambda)$ becomes infinitely large and negative. Here again we want to stress, however, that the reality of $E_2^-(\lambda)$ does not mean automatically, its existence as a real physical energy level (see a discussion below, Sec. II C) and, in fact, in the case considered $E_2^-(\lambda)$ disappears as a physical level below $\lambda=\pi/2$ as it follows from Fig. 1.

Properties of the remaining levels are the following.

The level $E_3^-(\lambda)$ starts with a pseudothreshold $E_3^-(e^{i\phi_1})$. A sheet on which both the levels vary is shown in Fig. 6. It emerges as a map of an area of Fig. 5. lying between the real half line $\sigma\geqslant 0$ and the line $\mathrm{Im}\,\lambda^-(\sigma)=0$ crossing the point $\sigma=e^{i\phi_1}$. The map is provided by $\lambda^-(\sigma)$.

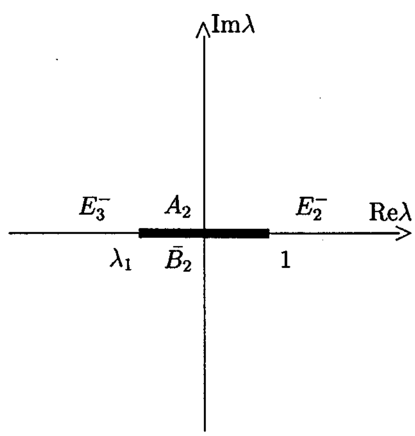

FIG. 6. The sheet of the λ-Riemann surface corresponding to the level $E_2^-(\lambda)$ and its pseudolevelcompartner $E_3^-(\lambda)$.

The second sheet and all the next ones are arranged in a very similar way to the corresponding sheets in the even parity energy level case. To achieve the second sheet on which the levels $E_4^-(\lambda)$ and $E_5^-(\lambda)$ are defined, we should cross a cut $A_2/\overline{B_2}$ of Fig. 6 in any direction close to the branch point $\lambda_1=\lambda^-(e^{i\phi_1})=\phi_1/\sin\phi_1<0$. The point opens the level $E_4^-(\lambda)$ on the sheet for $-\propto<\lambda<\lambda_1$. There is a second branch point on the sheet at $\lambda=\lambda_2=\phi_2/\sin\phi_2>0$, opening the level $E_5^-(\lambda)$ for $\lambda_2<\lambda<+\propto$. The sheet emerges as a map of an area of Fig. 5 lying between two successive lines $\mathrm{Im}\,\lambda^-(\sigma)=0$, the first one crossing the singular point $\sigma_1=e^{i\phi_1}$ and the next one crossing the unit circle at $\sigma_2=e^{i\phi_2}$.

All the next sheets appear as maps of successive areas bounded by the corresponding pairs of the lines $\mathrm{Im}\,\lambda^-(\sigma)=0$ crossing the successive singular points $\sigma_k=e^{i\phi_k}$, $k=2,3,\ldots,$ in the direction of an increasing argument of σ. However, contrary to the even parity case maps of the negative argument sheets of the σ-Riemann surface do not produce additional (twin in forms) sheets on the λ-Riemann surface, which corresponds to the absence of relevant right cut on the first sheet of the latter surface. It means that the complex conjugated positive and negative argument sheets of the σ-Riemann surface map into the same sheets of the λ-Riemann surface for the odd energy function $E^-(\lambda)$.

B. Relation between analytical properties of energy levels and analytical properties of transmission coefficient

It is a standard result of the 1-dim quantum mechanics that energy levels of bound states are simple poles for a transmission coefficient of the corresponding 1-dim scattering problem.[9] These poles have to occupy the positions on the positive imaginary axis of the complex momentum corresponding to an infinite motion. In fact, this last property is the main criterion for selecting the real bound state energies from the whole set of poles the transmission coefficient can have.

Since the analysis of the analytical quantization conditions of the previous section provided us with a variety of the solutions which all have to be poles for a transmission coefficient, then to select out those of them which are the physical bound state levels we have to discuss roles played by them in the corresponding transmission coefficient.

We shall give to our considerations a standard formulation shifting all energy levels by $-\lambda^2$ so that the infinite motion takes place for $E>0$ with the momentum $k=\sqrt{E}$ outside the well and with the momentum $k'=(k^2+\lambda^2)^{1/2}$ inside it (the bottom of the well is now at $V=-\lambda^2$, of course). Then the reflection (R) and transmission (T) coefficients for the case are the following:

$$T(k)=\frac{kk'e^{-2ik}}{(k\cos k'-ik'\sin k')(k'\cos k'-ik\sin k')},$$
$$R(k)=\frac{i\lambda^2\sin 2k'}{2kk'}T(k). \tag{10}$$

It is seen from (10) that T (and R as well) as a function of complex k is meromorphic with their poles coinciding with roots of the T-denominator. Clearly these poles occupy exactly the positions of energy levels in the k-plane we have found in the previous paragraphs. The denominator factorization in (10) occurs due to the reflection symmetry of the potential well. In particular, the first denominator factor in (10) corresponds to the odd parity levels and the second to the even ones.

We can separate the investigations of the levels of different parities (according to what we have done earlier) by considering instead of the coefficients (10) two pairs of the following ones:

$$T^+(k)=\frac{k}{k'\cos k'-ik\sin k'},\quad R^+(k)=\frac{i\lambda\cos k'}{k}T^+(k), \tag{11}$$

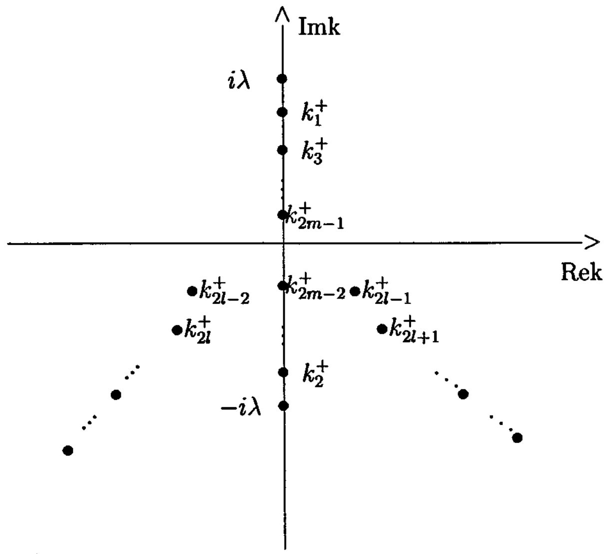

FIG. 7. The k-plane of the transmission coefficient $T^+(k)$.

$$T^-(k)=\frac{k}{k\cos k'-ik'\sin k'},\quad R^-(k)=\frac{i\lambda\sin k'}{k}T^-(k).$$

Of course, the two above pairs of coefficients correspond now to two different potential wells: $V^+(x,\lambda)$ and $V^-(x,\lambda)$, respectively, which can be reconstructed with the help of the inverse scattering method.[10]

Let us consider first a pole structure of the k-plane corresponding to the even parity case. The corresponding analysis of the odd one is analogous.

This structure is shown in Fig. 7 and follows from an observation that $\phi_l^+(\lambda)$ as an lth analytical solution to the first of the conditions (4) defines a pole of $T^+(k)$ on the k-plane at $k_l^+(\lambda)=i\lambda\sin\phi_l^+(\lambda)$.

According to our earlier observation together with solutions we have for a given $\lambda>0$, we have to consider also the ones we have for $-\lambda$.

There is a finite number m ($|\phi_m^+(\pm\lambda)|\leqslant m\pi\leqslant\lambda$) of solutions to (4) for which $\phi_l^+(\pm\lambda)$ are real and $\pm\lambda\sin\phi_m^+(\pm\lambda)>0$. Poles corresponding to these solutions [including the one for the ground state (for $l=1$)] are distributed on the segment $(0,i\lambda)$ of the positive imaginary axis and represent the physical bound states of the potential $V^+(x,\lambda)$.

There are also m-1 real solutions to (4), but with $\pm\lambda\sin\phi_m^+(\pm\lambda)<0$ generating in this way poles lying in the k-plane on the segment $(0,-i\lambda)$ (i.e., *below* the real axis of the plane). Therefore the latter which we call pseudoenergy levels cannot represent the bound states in $V^+(x,\lambda)$. These poles appear as branch partners of the previous ones (except the ground state partner which does not exist) which therefore can coincide with the latter at the corresponding pseudothresholds $\lambda=\lambda_l$ (see Figs. 3–4). However, loci of these pseudothresholds in the k-plane are just below the real axis not contradicting therefore the physical level nondegeneracy theorem. According to our previous notation (see Figs. 3–4) these $2m-1$ poles are $k_1^+(\lambda)$, $(k_2^+(\lambda),k_3^+(\lambda))$, $(k_4^+(\lambda),k_5^+(\lambda))$, ..., $(k_{2m-2}^+(\lambda),k_{2m-1}^+(\lambda))$ where the branch partners are paired and the poles with odd indices represent the physical levels (lie above the real axis).

Finally, there are infinitely many poles of $T^+(k,\lambda)$ lying below the real axis of the k-plane on both sides of the imaginary one and symmetrically with respect to it [due to the relation $k_l(\lambda)=-k_l^*(\lambda^*)$ considered for real λ] but outside of it with finite distances between any two of them and because of this distributed up to infinity. These are, of course, the poles $(k^+_{2l-2}(\lambda),k^+_{2l-1}(\lambda))$, $l=m+1,m+2,\ldots$.

If λ varies through real positive values increasing all the poles lying outside the segment $(-i\lambda,i\lambda)$ move towards it and a symmetric pair of them $(k^+_{2l-2}(\lambda),k^+_{2l-1}(\lambda))$ achieves the segment just for λ approaching λ_l a value being a corresponding pseudothreshold for the pair. While achieving the segment the pair disjoints again with its member $k^+_{2l-1}(\lambda)$ moving upwards of the imaginary axis and with the member $k^+_{2l-2}(\lambda)$ moving downwards. The first one crosses eventually the real axis becoming a bound state whilst the second one does it never, becoming a pseudoenergy level.

The above description works for every pair of the pole partners except the one corresponding to the ground state energy which is single. This for real positive λ [as well as for the negative one due to a relation $k_l(\lambda)=k_l(-\lambda)$ valid for any λ] is above the real k-axis and thus represents the ground state energy. However, for imaginary $\lambda(\sigma)$, when $0<\sigma<1$ or $1<\sigma<+\propto$, $E^+_1(\lambda)=\lambda^2$ is real (and, of course, negative) but $k^+_1(\lambda)$ has a negative imaginary part and therefore $E^+_1(\lambda)$ cannot represent a bound state. This fits well our intuition, since for imaginary λ the rectangular well become rather a rectangular barrier excluding, of course, any bound state.

A similar analysis of the odd parity levels corresponding to the potential $V^-(x,\lambda)$ leads us to the following conclusions.

For a given $\lambda>0$ and $m\pi\leqslant\lambda$ poles: $k^-_2(\lambda)$, $(k^-_3(-\lambda),k^-_4(-\lambda))$, $(k^-_5(\lambda),k^-_6(\lambda))$, $(k^-_7(-\lambda),k^-_8(-\lambda)),\ldots,(k^-_{2m-1}((-1)^{m-1}\lambda),k^-_{2m}((-1)^{m-1}\lambda))$ lie in the segment $(-i\lambda,i\lambda)$ whilst the remaining ones $(k^-_{2l-1}((-1)^{l-1}\lambda),k^-_{2l}((-1)^{l-1}\lambda))$, $l=m+1,m+2,\ldots$, lie outside the segment, below the real axis and symmetrically with respect to the imaginary axis.

A behavior of all the paired poles with λ varying along the positive real axis is exactly the same as in the even parity level case. Only the pole $k^-_2(\lambda)$ seems to differ with this respect in comparison with $k^-_1(\lambda)$ escaping to infinity along the negative imaginary axis when $\lambda\to 0_+$. However, if one considers a behavior of the levels rather as functions of σ for $\sigma\to 0_+$ (or for $\sigma\to+\propto$) on the corresponding first sheets of Figs. 5 and 2, respectively (this corresponds to $\lambda\to 0_+$ for the odd level but describes a little bit more complex path for the even one ending, however, at $\lambda=0$) then one can find that both the levels behave identically.

C. Perturbation series for energy levels and their summability

Since the finite rectangular well considered is a perturbation for the infinite rectangular one when $\lambda^{-2}\to 0$ then the corresponding energy levels of the former should approach in this limit the corresponding levels of the latter potential. It is interesting that with the previous considerations we are able to conclude that all the corresponding perturbation series expansions are convergent. The corresponding conclusions are, in fact, obvious for all the energy levels higher than the ground state one. To show this let us consider a pair of levels E^+_{4n+1}, E^+_{4n+2} lying on the $2n+2^{th}$ sheet shown in Fig. 4, with the level E^+_{4n+1} belonging to the even spectrum of the finite rectangular well. A function $E^+(\lambda)=\lambda^2z^2(\lambda)$ being a holomorphic extension of both the levels considered is holomorphic on the $2n+2$th sheet outside any closed contour C containing the branch points $\lambda=0$, λ_{2n+1} and λ_{2n+2} inside (see Fig. 4). For $\lambda\to\infty$ on the sheet $E^+(\lambda)\sim E^+_{4n+1}(\lambda)\sim\pi^2(8n+1)^2/4$ and therefore according to the Cauchy theorem we get for $E^+(\lambda)$,

$$E^+(\lambda)=\frac{((8n+1)\pi)^2}{4}-\frac{1}{2\pi i}\oint_C\frac{E^+(\lambda')}{\lambda'-\lambda}d\lambda'. \qquad (12)$$

It follows from (12) that the series

$$\frac{((8n+1)\pi)^2}{4}+\sum_{k\geqslant 0}\frac{a_{2n+1,k}}{\lambda^{k+1}},$$

with

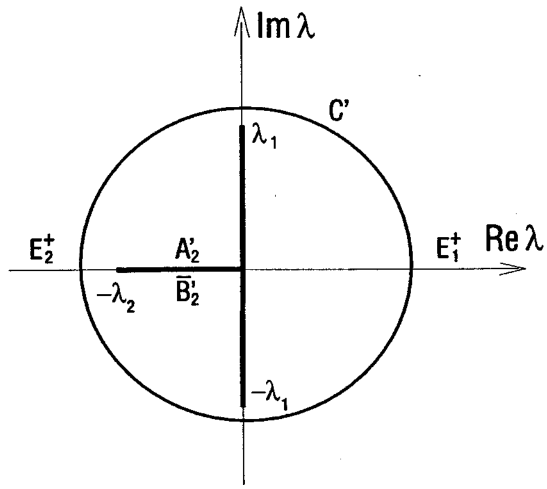

FIG. 8. The cut structure of the sheet on which the perturbative series for $E_1^+(\lambda)$ is studied.

$$a_{2n+1,k}=\frac{(-1)^k}{2\pi i}\oint_C E^+(\lambda)\lambda^k\,d\lambda, \tag{13}$$

which is the perturbative one for the $E_{4n+1}^+(\lambda)$ level is convergent to the level for $|\lambda|>|\lambda_{2n+2}|$, i.e., for all λ's just above its pseudothreshold.

For the ground state energy level $E_1^+(\lambda)$ an analogous conclusion can be obtained by considering instead the cut pattern shown in Fig. 3(a) the one when the upper and the lower left cut boundaries in the figure are rotated by $\pm\pi$, respectively, providing us with a sheet arranged according to Fig. 8. It follows from the figure that the perturbative series for $E_1^+(\lambda)$ is obtained from (12) by putting there $n=1$ and $C=C'$ with its convergence radius given by $\max(|\lambda_1|,|\lambda_2|)$.

The same conclusions can be drawn for the perturbative series constructed for the odd parity energy levels, applying exactly the same technique of considerations as we did in the case of the even parity levels. The series constructed for a level $E_n^-(\lambda)$ is therefore convergent for $|\lambda|$ sufficiently large on the sheet on which the level is defined.

III. DIRAC DELTA BARRIER AS PERTURBATION

A second example of a perturbation which can be analyzed analytically is provided by the Dirac delta barrier introduced into the infinite rectangular well, i.e., it is given by

$$V(x,g)=2g\,\delta(x), \quad |x|<1 \quad \psi(\pm 1)=0, \tag{14}$$

where $\psi(x)$ is a wave function for the case. A role of a perturbation parameter is played by g. For $g=0$ we get a problem of the energy spectrum in the infinite rectangular well, i.e., an asymptotic limit of any energy level $E_n(g)$ of the potential (14) is just a corresponding level E_n of the rectangular well. In the limit $g\to+\infty$ we get instead two infinite rectangular wells with the half of the size of the well we started with for which their energy spectra should coincide with the corresponding limit of $E_n(g)$. This is not unexpected. What is interesting in this example is the fact that every even parity level of the potential (14) is a branch of some ramified function $E(g)$ considered as a function of complex g (odd parity energy levels decouple of g and therefore coincide with the odd ones of the infinite rectangular well).[8]

The last property makes to some extent the considered case similar to the previous one. However, there is one considerable difference between them. This is that the existence of all the even energy levels $E_n(g)$ does not depend on g, i.e., each level exists for any g, including $g=0$. Therefore, we cannot expect on a g-Riemann surface $\mathbf{R}_g$ of $E(g)$ the real branch points to

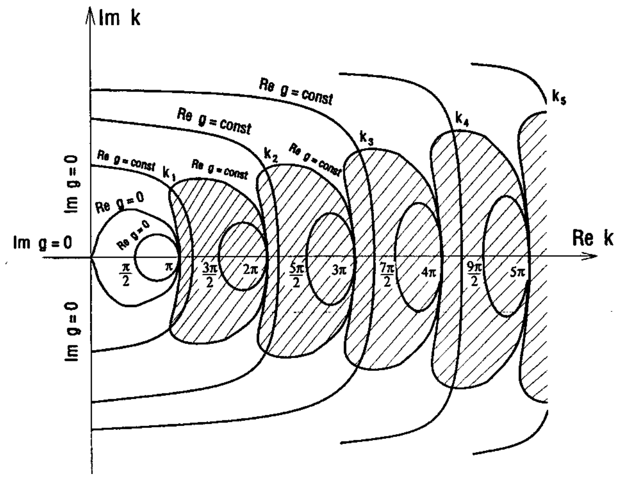

FIG. 9. The pattern of lines Reg(k) = const and Im $g(g)$ = const for $g(k) = -k \cot k$.

appear having meanings of pseudothresholds for the levels $E_n(g)$. On the other hand, there are branch points on $\mathbf{R}_g$ [as they have to be because $E(g)$ is a ramified function] which are complex but which physical meaning seems to be a puzzle.

Nevertheless, there is also a property of the considered case which is a copy of the corresponding one for the finite rectangular well. Namely, the perturbative series for even $E_n(g)$ are all convergent. All these follow from the quantization condition for even energy levels:

$$k \cot k = -g, \quad k = \sqrt{E}. \tag{15}$$

The condition (15) defines g as a meromorphic function of k with simple poles on the k-plane at $k = r\pi$, $r = \pm 1, \pm 2, \ldots$. Therefore, an inversion of the relation (15) will be easy if we know positions of zeros of $g'(k)$ in the k-plane. These positions are determined by (15) and by the following condition:

$$g^2 + g + k^2 = 0. \tag{16}$$

Both the last equations are equivalent to

$$\sin 2k = 2k, \quad g = -k \cot k. \tag{17}$$

The first of Eqs. (17) has a solution for $k = 0$ and an infinite number of complex solutions in the k-plane (i.e., $\mathrm{Im}\, k \neq 0$ for all these solutions) with the property that if k_l, $l = 1,2, \ldots$, is a solution to it then $-k_l$, k_l^* and $-k_l^*$ are also. It is easy to show that for large l $\mathrm{Im}\, k_l$ increases as $\ln l$ and $\mathrm{Re}\, k_l$ as $l\pi$.[8] A corresponding pattern of lines $\mathrm{Re}\, g = $ const, taking into account the distribution of singular points described above is shown in Fig. 9. The pattern allows for an easy construction of a g-Riemann surface $\mathbf{R}_g$ for an inverse function $k(g)$. Namely, we can arrange cuts on $\mathbf{R}_g$ in such a way as to map an lth dashed area of Fig. 9 into a sheet of $\mathbf{R}_g$ corresponding to E_lth even energy level of the potential considered. This is shown in Fig. 11.

Because $g(k)$ is a symmetric function of k, i.e., $g(k) = g(-k)$ with the singular point at $k = 0$ [i.e., $g'(0) = 0$] its inverse function $k(g)$ is defined on the Riemann surface $\mathbf{R}_g$ which consists of two twin systems of sheets joined by a single cut beginning at $g = -1$ and running to $-\infty$. These two systems of sheets are maps of the right and the left k-half planes of Fig. 9, respectively. The two sheets opening the systems and joined by the cut described above are the ones on which the ground state energy level is defined, taking the same values in the corresponding points of the

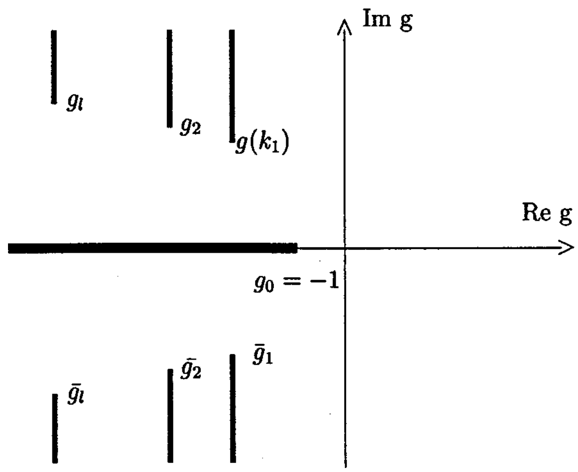

FIG. 10. The cut structure of the g-Riemann surface for k(g) determining the surface.

sheets. This is because $E(g)=k^2(g)$. Therefore, for $E(g)$ the point $g=-1$ on the first sheet considered is not a branch one and we can consider only one of the two systems of sheets corresponding, for example to $\mathrm{Re}\, k \geqslant 0$ what is assumed from now on.

In accordance with the results of Ushveridze,[8] all singular points of $E(g)$ lie on the first sheet corresponding to the ground state energy level of the potential (11). The sheet is an image of an area which completes the dashed ones of Fig. 9 to the full right k-half plane and is sketched in Fig. 10.

As it has been already explained earlier on the lth sheet on which the lth energy level $E_l(g)$ is defined, there is a unique pair of complex conjugated branch points at $g_l(=g(k_l))$ and $\overline{g_l}$ by which the level contacts with the ground state one (see Fig. 11). The level is holomorphic on its sheet at $g=0$ and approaches $[(l+1)\pi]^2$ or $(l\pi)^2$ for $g\rightarrow\infty$ in the half planes $\mathrm{Re}\, g>\mathrm{Re}\, g_l$ or $\mathrm{Re}\, g<\mathrm{Re}\, g_l$, respectively.

Because of the holomorphicity of $E_l(g)$ at $g=0$ its perturbative series with respect to g converges inside the circle $|g|=|g_l|$.

For large g, however, we have to consider together with $E_l(g)$ also its neighbor $E_{l+1}(g)$ for which its limit for g in the half plane $\mathrm{Re}\, g<\mathrm{Re}\, g_l$ is the same as for $E_l(g)$ in the half plane $\mathrm{Re}\, g>\mathrm{Re}\, g_l$. A common sheet for both the levels is shown in Fig. 12. It is obvious that we can apply here the Cauchy integral technique to show the convergence of the asymptotic series for $E_l(g)$ and for $E_{l+1}(g)$ for large g with $|g|>|g_{l+1}|$, $l=1,2,\ldots$.

The corresponding statement for the ground state energy level perturbation series is also true for $|g|>|g_1|$.

IV. DISCUSSION AND CONCLUSIONS

The model of the finite rectangular well which we have considered provided us with several properties, differing it from the previous ones.

First it was a number of energy levels varying with a perturbation parameter thus changing a quality of the levels of being real to becoming only potential ones.

Secondly, it was the existence of the pseudoenergy levels in the model the main role of which was just to allow the level crossing phenomenon to appear.

It was also an easiness of predictions of the pseudothreshold distribution as a part of all the level crossing loci. The latter property followed, however, from the simplicity of the quantization conditions for the case as illustrated by Fig. 1. In fact, the remaining three branch points, the two for the ground state level at $\lambda = \pm i$ and the logarithmic one for all the levels at $\lambda = 0$, could be identified only by detailed calculations.

Finally, it was the convergence of the perturbation series for large λ and for all the levels. This property could not be deduced prior to the detailed knowledge of the λ-Riemann surface topology just because for imaginary λ (no matter small or large) the rectangular well became the rectangular barrier, suggesting rather a possibility for the perturbation series to be divergent in these directions because of a repelling character of the barrier. However, the repulsion of the rectangular barrier appears to be not enough strong to destroy the convergence of the perturbation series.

The property of the perturbation series to be convergent was shared also by the corresponding series constructed for the levels in the infinite rectangular well perturbed by the Dirac delta barrier.

In general, there is a question about the possibilities to predict some basic properties of analytical dependence of energy levels on a parameter considered as the perturbation one prior to any detailed calculation, i.e., relying only on some general properties of the potential given. Obviously, such qualitative predictions are possible in some simpler cases. There are, however, also many traps and puzzles which one can meet trying to proceed in this way.

Consider, for example, the case of the potential (1). Its properties remind many of those of the finite rectangular well if we consider $\lambda = \alpha^{-2}$ as a perturbation parameter (an obvious choice after a rescaling $x \rightarrow \alpha^{-1} x$ in the corresponding Schrödinger equation).

First, a corresponding quantization condition is given by a nonalgebraic dependence between energy E and λ which can be readily continued to complex λ.[11] We can expect therefore $E(\lambda)$ to be defined on infinitly sheeted Riemann surfaces for both the parities.

Secondly, a number of its energy level depends on its actual height (equal to $\lambda \omega^2/2$) and therefore the levels of this well should have real and positive thresholds as their branch points and therefore should be accompanied by the corresponding pseudolevels.

Third, its levels approach the ones of the harmonic oscillator when $\lambda \rightarrow +\infty$.

Next, changing $\lambda \rightarrow -\lambda$ in (1) we find that the spectrum of the finite well (1) is transformed into the corresponding spectrum of the infinite well defined by $\cos(\alpha x)$, the latter arising from $\cosh(\alpha x)$ after the transformation. The spectrum of this infinite well approaches again the harmonic one when $\lambda \rightarrow +\infty$ (after the above change of sign of λ). On the other hand, when $\lambda \rightarrow 0$ each level of the considered infinite well goes to infinity (since the well becomes infinitely narrow), i.e., $E(\lambda)$ has to have a singularity at $\lambda = 0$ for each level. However, such a singularity

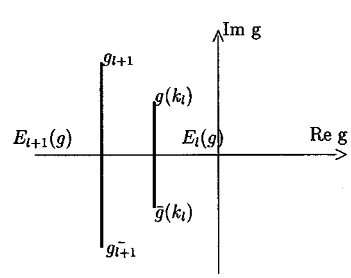

FIG. 12. The cut structure of the sheet on which the perturbative series for $E_l(g)$ is studied.

should not be detected on the sheet on which the ground state level of the finite well is represented since this level vanishes (amounts to zero) at $\lambda=0$. This suggests that both the families of levels are distributed on different sheets.

Finally, using the standard analysis[2] to establish the maximal sectors of analyticity of $E(\lambda)$, one can find that for each level sheet in the finite well case $|\arg\lambda|$ in such a sector does not exceed $\pi/2$ and for the level sheets in the infinite well case the latter value is not exceeded by $|\arg\lambda-\pi|$, which means that in both the cases there are singularities on both the positive and negative imaginary half axes for each level sheet.

It seems that the above qualitative analysis is all this that can be concluded not involving oneself into a further detailed analysis of the exact quantization condition corresponding to the case. The latter condition, however, is complicated enough[11] to allow only a numerical approach. In particular, having the above conclusions it is not possible to say whether the corresponding perturbation series both for the levels in the finite well and in the infinite one are convergent or asymptotic only. The last properties are determined uniquely in the case considered by a distribution of singularities on the imaginary axis of each level sheet and whether there is a finite number of them on the axis (the perturbation series on such a sheet converges then) or they are distributed on the axis up to infinity (the series is asymptotic) cannot be inferred without a detailed analysis of the quantization condition.

In the considered case the singularities lying on the imaginary axes of the level sheets are certainly the branch points for $E(\lambda)$ and describe the way the different levels can communicate with themselves by analytical continuations. If there is a finite number of such branch points on the axis then the level attached to the sheet can contact directly with only a finite number of other levels. (The remaining levels can be achieved in such a case via the former reached directly.) This is the case of the finite rectangular well and the Dirac delta barrier in the infinite well considered in this paper.

In the case of an infinite number of the branch points, the directly contacted levels are also infinite in number. This is the case of the anharmonic oscillator of Bender and Wu.

Unfortunately, we could not find some visible and general criterion allowing us to judge between any of these two possibilities prior to any detailed calculations of the distribution of such singularities.

The following ''small'' modification of the previous example show us, however, that the qualitative analysis as demonstrated above can be misleading if not supported by the detailed calculations.

Namely, let us substitute $\cosh(\alpha x)$ in the potential (1) by its square $\cosh^2(\alpha x)$. No doubt one can repeat all the previous reasonings also in this case with the identical conclusions. However, the case is known to be integrable,[11–14] i.e., its corresponding quantization condition, is obtained as an algebraical equation for $E(\lambda)$ which can be easily solved to give

$$E_n(\lambda)=\left(n+\frac{1}{2}\right)\sqrt{(\omega\hbar)^2+\frac{\hbar^4}{4\lambda^2}}-\left(n+\frac{1}{2}\right)^2\frac{\hbar^2}{2\lambda}-\frac{\hbar^2}{8\lambda},$$
$$\lambda\geqslant\lambda_n=\frac{\hbar}{\omega}\sqrt{n(n+1)},n=0,1,\ldots, \tag{18}$$

where λ_n, $n=0,1,\ldots,$ are thresholds below which the corresponding energies $E_n(\lambda)$ become unphysical.

It is seen from (18) that $E(\lambda)$ for the case considered enjoys all the properties postulated earlier for the energy levels of the potential (1) except the following two of them: 1^0 that it is defined on the infinitely sheeted λ-Riemann surface(s), and 2^0 that there are branch points (thresholds) on the positive real half axes and the corresponding pseudoenergy levels. The lack of the latter two properties follows, of course, as a result of decoupling from each other of all the level sheets so that each level is defined on a separate double sheeted Riemann surface.

It is still worth noting that as it follows from (18) for each n, $n=0,1,\ldots,$ the levels $E_n^{fin}(\lambda)$ and $E_n^{inf}(\lambda)$ corresponding to the finite and infinite wells, respectively, are defined on the same double sheeted Riemann surface R_n. The first of the levels is defined on the positive real half axis of the first sheet of R_n, whilst the second—on the negative real one of the second sheet of R_n. The level $E_n(\lambda)$ branches at the points $\lambda=\pm\imath\hbar/(2\omega)$. The ground state level of the finite well is finite (vanishes) at $\lambda=0$ whilst all the remaining ones (for both the wells) have a simple pole at this point on their sheets. Of course, the convergence of the corresponding perturbation series for the levels considered when λ is close to infinity is a trivial conclusion from (18).

We can conclude therefore that generally the analytical properties of energy levels considered above show that they depend strongly on the model used. Crossing of levels considered as the main cause for the presence of branch points in the dependence of levels on a chosen perturbation parameter seems to be as obvious as puzzled in most of the models. In particular, these are the distributions of branch points in investigated models which does not seem to be covered by some universal rules. Needless to say it is just this distribution which decides whether the corresponding pertubation series are convergent or only asymptotic. Both the latter statements are true also in both the cases of potentials investigated in this paper. In particular, the existence of pseudothreshold branch points cannot be considered as a universal rule as it is shown by the formula (18). On the other hand, the case of the Dirac δ-function barrier in the infinite rectangular well demonstrates the unpredictibility of the branch point distributions prior to the detailed calculations.

It is worth mentioning in this context, however, that there is a group of ''perturbed'' potentials (depending on a ''large'' perturbation parameter) for which one can predict with the certainty that for some families of their energy levels the corresponding perturbation series have to be convergent. Namely, these are so called quasi exactly solvable potentials mentioned in the Introduction.[7] For them, both the corresponding families of energy levels and the perturbation parameters satisfy algebraic equations so that these families are defined on finite sheeted Riemann surfaces of the perturbation parameter and therefore there can be only a finite number of singular points of the levels on the surface. Because of that the corresponding perturbation series have to be convergent.

In general, however, it seems that both a large variety of different parameters which were used as perturbation ones in the models considered so far and the models themselves do not allow us to formulate some common rules covering the distributions of branch points and giving them in this way some common sense.

Nevertheless, guided by a detailed knowledge of a considered potential and a corresponding quantization condition as well as by a meaning and a role some particular perturbation parameter of the potential can play in it, we can in many cases predict qualitatively much of the actual dependence of the levels on the perturbative parameter prior to detailed calculations.

A braided interpretation of fractional supersymmetry in higher dimensions

R. S. Dunne[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge CB3 9EW, United Kingdom

(Received 19 March 1997; accepted for publication 10 March 1998)

A many variable q-calculus is introduced using the formalism of braided covector algebras. Its properties are discussed in detail and related to fractional supersymmetry when certain of its deformation parameters are roots of unity. The special cases of two-dimensional supersymmetry and fractional supersymmetry are developed in detail. [S0022-2488(98)01806-4]

I. INTRODUCTION

In four recent papers[1–4] the properties of the braided line,[5,6] when its deformation parameter is a root of unity, were discussed. Most notably, these studies led to a novel understanding of one-dimensional supersymmetry and fractional supersymmetry.[7–9] Our aim in the present paper is to extend these results to the many variable case. In order to do this we construct a many variable, generic q, generalized Grassmann algebra using the formalism of braided covector algebras[5,6] with suitable R and R' matrices. Within the framework provided by this formalism the construction of the corresponding many variable left q-calculus is straightforward. After a little further work the corresponding right q-calculus is also obtained.

In this many variable case it is convenient to generalize the graded brackets used in Ref. 2 to a pair of braided brackets (left and right), which we introduce in Sec. II. This change has several, in general useful, consequences. In particular, left and right differentiation and integration become truly distinct, rather than being the same thing induced by different algebraic operators as was the case in Ref. 2. There are well-defined and simple commutation relations between all of these operations. Another advantage over the approach of Ref. 2 is that the conditions which govern the commutation relations of noncommuting constants are built into the many variable algebra, so that they are no longer additional constraints. In contrast to the situation with graded brackets, the conditions necessary in order that left and right differentiation be induced are compatible. A consequence of this is that we can now work quite generally with both left and right differentiation/integration, rather than being restricted to one or the other, as was the case for graded-bracket-based q-calculus.

In Sec. III we take the $q_a \to \tilde{q}_a$ limit ($\tilde{q}_a$ is a root of unity) of the many variable q-calculus, and obtain many variable analogs of the structures and decompositions seen in Refs. 2–4. A full set of commutation relations between the different algebraic elements, derivatives, and integrals is also given. At the end of Sec. III the braided Hopf structure of both the coordinates and the derivatives is given, as well as the duality between them. Further details of this duality, as well as an alternative discussion of the braided line Hopf algebra (at generic q and at q a root of unity) are give in the Appendix.

Section IV deals with the case of two-dimensional supersymmetry. This plays an important role in superstring theory,[10] in which it corresponds to supersymmetry on the world sheet of the string. The full two-dimensional supersymmetry algebra and transformations are recovered, and all of the transformation properties of the bosonic spacetime variables x and t emerge as consequences of their definition as different combinations of the $q_a \to -1$ limits of two braided line coordinates $\{\theta_a\}$ $(a=1,2)$. Together these two braided lines make up a braided plane, but we note that this is not the braided/quantum plane which is usually encountered in the literature.[5,6] In the limit, translations within this braided plane induce supersymmetry transformations of x and t.

[a)]Electronic mail: r.s.dunne@damtp.cam.ac.uk

Furthermore, once the Lorentz transformations of θ_1 and θ_2 are specified, those of x and t follow automatically. The results are in agreement with the standard version of the two-dimensional super-Poincaré transformation.

Section V extends the results of Sec. IV to the case of *mixed* fractional supersymmetry in two dimensions. The word mixed is used to indicate that the deformation parameters of the two braided plane coordinates on which the fractional supersymmetry is based are not necessarily at the same root of unity. All of the algebraic and transformation properties are worked out, and as in the supersymmetric case, spacetime Lorentz transformations are induced by suitable transformations of the braided plane coordinates. We are thus able to introduce full two-dimensional mixed fractional super-Poincaré transformations. Finally we extend the arguments of Ref. 2 concerning the Berezin integral to the two-dimensional case.

II. *q*-CALCULUS FOR AN ARBITRARY NUMBER OF VARIABLES

In this section we develop the q-calculus associated with r generalized Grassmannian variables. This calculus can be viewed as a particular example of the braided differential calculus described in Refs. 5 and 6 and we present it from this point of view.

Given any matrix $R_{12}\in M_r\otimes M_r$ which satisfies the quantum Yang–Baxter equation,

$$R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12}, \tag{1}$$

as well as an associated matrix $R'_{12}\in M_r\otimes M_r$ satisfying

$$R_{12}R_{13}R'_{23}=R'_{23}R_{13}R_{12}, \quad R_{23}R_{13}R'_{12}=R'_{12}R_{13}R_{23}, \tag{2}$$

$$R_{21}R'_{12}=R'_{12}R_{21}, \tag{3}$$

$$(PR+1)(PR'-1)=0, \tag{4}$$

where P is the permutation matrix, we can define a braided covector algebra[5,6] with elements $\{x_i,1\}$. This has a braided Hopf algebraic structure given by

$$\begin{gathered}\mathbf{x}_1\mathbf{x}_2=\mathbf{x}_2\mathbf{x}_1R'_{12}, \quad \text{i.e.,} \quad x_ix_j=x_cx_bR'^{bc}_{ij}, \\ \Delta x_i=x_i\otimes 1+1\otimes x_i, \quad \epsilon(x_i)=0, \\ S(x_i)=-x_i, \quad \Psi_{12}(\mathbf{x}_1\otimes\mathbf{x}_2)=\mathbf{x}_2\otimes\mathbf{x}_1R_{12},\end{gathered} \tag{5}$$

as well as $\Delta(1)=1\otimes 1$, $\epsilon(1)=1$, $S(1)=1$, $\Psi_{12}(1\otimes x_i)=x_i\otimes 1$, $\Psi_{12}(x_i\otimes 1)=1\otimes x_i$. It is convenient to use the notation $\mathbf{w}=\mathbf{x}\otimes 1$, $\mathbf{x}=1\otimes\mathbf{x}$ so that the $\{w_i\}$ satisfy the same algebra as the $\{x_i\}$. In this notation[6] the coproduct Δ above is just

$$\Delta\mathbf{x}=\mathbf{w}+\mathbf{x}, \tag{6}$$

and the braiding Ψ_{12} is equivalent to the following braid statistics between $\mathbf{x}$ and $\mathbf{w}$:

$$\mathbf{x}_1\mathbf{w}_2=\mathbf{w}_2\mathbf{x}_1R_{12}, \quad \text{i.e.,} \quad x_iw_j=w_cx_bR^{bc}_{ij}. \tag{7}$$

The notation (6) suggests that we regard the coproduct as generating left translations within the braided covector space, and motivates its alternative name *coaddition*.[5,6] No additional information is needed to construct the corresponding braided left differential calculus. The left derivatives form a braided vector algebra, with commutation relations given by

$$\partial_{l1}\partial_{l2}=R'_{12}\partial_{l2}\partial_{l1}, \tag{8}$$

and the cross relations giving their action on the covectors are

$$\partial_{l1}\mathbf{x}_2-\mathbf{x}_2R_{21}\partial_{l1}=\delta_{12}. \tag{9}$$

The reason for the form of the second of these relations is that along with (7) it implies that $[\mathbf{w}_1\partial_{l1},\mathbf{x}_2]=\delta_{12}\mathbf{w}_1$, so that $\mathbf{w}_1\partial_{l1}$ can be viewed as the generator of the left translation (6). Equation (9) can be viewed as giving the braiding between the covectors and their derivatives.[11] To see this we identify

$$\Psi_{12}^{-1}(\partial_{l1}\otimes\mathbf{x}_2)=\mathbf{x}_2\otimes R_{21}\partial_{l1}, \tag{10}$$

so that we can rewrite (9) as

$$\partial_{l1}\mathbf{x}_2-\cdot\Psi_{12}^{-1}(\partial_{l1}\otimes\mathbf{x}_2)=\delta_{12}. \tag{11}$$

It is not difficult to extend this formalism so that it includes right derivatives, and since these play an important role in supersymmetric and fractional supersymmetric theories, we will do so explicitly. Among themselves the right derivatives have the same commutation relations as the left derivatives, and thus also form a braided vector algebra so that

$$\partial_{r1}\partial_{r2}=R'_{12}\partial_{r2}\partial_{r1}. \tag{12}$$

To find the cross relations between these derivatives and the covectors we must first reinterpret Δ as the generator of a right shifts. We can do this by writing

$$\Delta\mathbf{x}=\mathbf{x}+\mathbf{y}, \tag{13}$$

where we have introduced the alternative notation $\mathbf{x}=\mathbf{x}\otimes 1$ and $\mathbf{y}=1\otimes\mathbf{x}$. From the braiding Ψ_{12} given by (5) we obtain the braid statistics

$$\mathbf{y}_1\mathbf{x}_2=\mathbf{x}_2\mathbf{y}_1R_{12}. \tag{14}$$

In order for the right derivatives to generate the translation (13) they must satisfy $[\mathbf{y}_1\partial_{r1},\mathbf{x}_2]=\delta_{12}$. In combination with the braid statistics (14) this implies that

$$\mathbf{y}_1\partial_{r1}\mathbf{x}_2-\mathbf{y}_1\mathbf{x}_2R_{12}^{-1}\partial_{r1}=\delta_{12}\mathbf{y}_1, \tag{15}$$

from which it is clear that suitable cross relations are

$$\partial_{r1}\mathbf{x}_2-\mathbf{x}_2R_{12}^{-1}\partial_{r1}=\delta_{12}. \tag{16}$$

As in the case of left derivatives we can interpret this as giving the braiding between the right derivatives and the covectors. Thus by identifying

$$\Psi_{21}(\partial_{r1}\otimes\mathbf{x}_2)=\mathbf{x}_2\otimes R_{12}^{-1}\partial_{r1}, \tag{17}$$

we can rewrite (16) as

$$\partial_{r1}\mathbf{x}_2-\cdot\Psi_{21}(\partial_{r1}\otimes\mathbf{x}_2)=\delta_{12}. \tag{18}$$

Relationships (11) and (18) motivate the introduction of bilinear left and right braided brackets,

$$\begin{aligned}[][A,B]_L&:=AB-\cdot\Psi_{12}^{-1}(A\otimes B),\\ [A,B]_R&:=AB-\cdot\Psi_{21}(A\otimes B).\end{aligned} \tag{19}$$

The bilinearity follows from the bilinearity of Ψ. This bracket is well defined on products as long as we remember the expansion rule for the braiding. From Ref. 12 this is

$$\begin{aligned}\Psi(AB\otimes C)&=(1\otimes\cdot)(\Psi\otimes 1)(A\otimes\Psi(B\otimes C)),\\ \Psi(A\otimes BC)&=(\cdot\otimes 1)(1\otimes\Psi)(\Psi(A\otimes B)\otimes C).\end{aligned} \tag{20}$$

Note that (as one would expect) Ψ_{12}^{-1} and Ψ_{21} expand in the same way. Using these brackets we can define left and right differentiation as follows:

$$\left(\frac{d}{d\mathbf{x}_1}\right)_L f := [\partial_{l1}, f]_L,$$
$$\left(\frac{d}{d\mathbf{x}_1}\right)_R f := [\partial_{r1}, f]_R. \tag{21}$$

Here $f=f\{x_i\}$. We will provide a specific example shortly. We are now able to introduce the generalized Grassmann algebra, which we define as the braided covector algebra in which R and R' are the following r dimensional matrices:

$$R'_{12}=W_{12}, \quad R_{12}=W_{12}+(Q_1-1)\delta_{12}=T_{12}, \tag{22}$$

the coordinate form of which is:

$$R'^{ij}_{ab}=\omega_{ab}\delta^i_a\delta^j_b, \quad R^{ij}_{ab}=(\omega_{ab}+(q_a-1)\delta_{ab})\delta^i_a\delta^j_b=t_{ab}\delta^i_a\delta^j_b. \tag{23}$$

Here $\omega_{ba}=\omega_{ab}^{-1}$ so that $\omega_{aa}=1$, $\omega_{ab}\neq 0$, and $q_a\neq 0$. It follows directly from the fact that R and R' are diagonal that (1)–(3) are satisfied. To show that (4) is also satisfied we expand it explicitly,

$$\begin{aligned}(PR+1)(PR'-1)&=R_{21}R'_{12}+R'_{21}+R_{21}-1\\&=(W_{21}+(Q_2-1)\delta_{21})W_{12}+W_{21}-W_{21}-(Q_2-1)\delta_{21}-1\\&=1+(Q_2-1)\delta_{21}-(Q_2-1)\delta_{21}-1=0.\end{aligned} \tag{24}$$

Putting this R' into (5) we obtain the defining algebra of r generalized Grassmann variables,

$$\theta_a\theta_b=\theta_j\theta_i\omega_{ab}\delta^i_a\delta^j_b, \tag{25}$$

which is equivalent to

$$[\theta_a,\theta_b]\omega_{ab}=0. \tag{26}$$

For left shifts we use the notation $\theta_a=1\otimes\theta_a$ and $\boldsymbol{\epsilon}_a=\theta_a\otimes 1$. From (7) we obtain

$$\theta_a\boldsymbol{\epsilon}_b-\boldsymbol{\epsilon}_j\theta_i\delta^i_a\delta^j_b t_{ij}=0, \tag{27}$$

which is equivalent to

$$[\boldsymbol{\epsilon}_a,\theta_b]_{t_{ba}^{-1}}=0. \tag{28}$$

For the corresponding derivatives $\mathscr{D}_{La}$ we obtain from (8) and (9) the following commutation and cross relations:

$$[\mathscr{D}_{La},\mathscr{D}_{Lb}]_{\omega_{ab}}=0,$$
$$[\mathscr{D}_{La},\theta_b]_{t_{ba}}=\delta_{ab}. \tag{29}$$

For right shifts we use the notation $\theta_a=\theta_a\otimes 1$ and $\eta_a=1\otimes\theta_a$. Then from (14) we obtain

$$[\eta_a,\theta_b]_{t_{ab}}=0, \tag{30}$$

while (12) and (16) give us

$$[\mathscr{D}_{Ra},\mathscr{D}_{Rb}]_{\omega_{ab}}=0,$$
$$[\mathscr{D}_{Ra},\theta_b]_{t_{ab}^{-1}}=\delta_{ab}. \tag{31}$$

These derivatives are generated by the left and right braided brackets, thus from (19),

$$\left(\frac{d}{d\theta_a}\right)_L\theta_b=[\mathscr{D}_{La},\theta_b]_L=[\mathscr{D}_{La},\theta_b]_{t_{ba}}=\delta_{ab},$$
$$\left(\frac{d}{d\theta_a}\right)_R\theta_b=[\mathscr{D}_{Ra},\theta_b]_R=[\mathscr{D}_{Ra},\theta_b]_{t_{ab}^{-1}}=\delta_{ab}. \tag{32}$$

As an example of differentiation induced by the braided brackets (19) we consider the case of $r=2$, and functions $f(\theta_1,\theta_2)$ which can be expanded as positive power series of the form

$$f(\theta_1,\theta_2)=\sum_{l,m=0}^{\infty}C_{l,m}\theta_1^l\theta_2^m. \tag{33}$$

Then using definitions (21) we find that

$$\left(\frac{d}{d\theta_1}\right)_L f(\theta_1,\theta_2)=[\mathscr{D}_{L1},f(\theta_1,\theta_2)]_L=\left[\mathscr{D}_{L1},\sum_{l,m=0}^{\infty}C_{l,m}\theta_1^l\theta_2^m\right]_L$$
$$=\sum_{l,m=0}^{\infty}C_{l,m}[\mathscr{D}_{L1},\theta_1^l\theta_2^m]_{q_1^l t_{21}^m}$$
$$=\sum_{l,m=0}^{\infty}[l+1]_{q_1}C_{l+1,m}\theta_1^l\theta_2^m. \tag{34}$$

Similarly, for right differentiation we find

$$\left(\frac{d}{d\theta_i}\right)_R f(\theta_1,\theta_2)=[\mathscr{D}_{R1},f(\theta_1,\theta_2)]_R=\sum_{l,m=0}^{\infty}[l+1]_{q_1^{-1}}C_{l+1,m}\theta_1^l\theta_2^m. \tag{35}$$

More generally the $C_{l,m}$ can be functions of θ_j where $j\neq 1,2$. This does not affect the result of the above differentiation, but of course the explicit form given in the third line of (34) is no longer valid. In fact, since for $a\neq b$, $t_{ab}=t_{ba}=\omega_{ab}$, we have for $C=C(\theta_j)$ with $j\neq i$,

$$[\mathscr{D}_{Li},C]_L=[\mathscr{D}_{Li},C]_{q_{ci}}=0,$$
$$[\mathscr{D}_{Ri},C]_R=[\mathscr{D}_{Ri},C]_{q_{ci}}=0, \tag{36}$$

which are the braided bracket analogs of (3.10) and (3.11). Note that unlike in the graded bracket case considered in Ref. 2 these conditions are not additional constraints on C, but instead follow directly from our definition of the many variable q-calculus. Note also that the conditions for induced left and right differentiation are compatible, so that in the many variable case, working with braided brackets, it is not necessary to choose between these. Another difference between the graded bracket induced derivatives of Ref. 2 and the braided bracket induced derivatives of the present paper is that in the latter case $\mathscr{D}_{Ra}$ appears on the left of the braided bracket. One consequence of this is that here $\mathscr{D}_{Ra}$ has a different normalization. In the many variable case, and with the new normalization, the number and shift operators are as follows:

$$N_a=\sum_{m=0}^{\infty}\frac{(1-(q_a)^{m-1})}{[m]_{q_a}}\theta_a^m\mathscr{D}_{La}^m=\sum_{m=0}^{\infty}\frac{(1-(q_a)^{1-m})}{[m]_{q_a^{-1}}}\theta_a^m\mathscr{D}_{Ra}^m, \tag{37}$$

$$q_a^{kN_a}=\sum_{m=0}^{\infty}\frac{1}{[m]_{q_a}}\left(\prod_{l=1}^{m-1}(q_a^k-q_a^l)\right)\theta_a^m\mathscr{D}_{La}^m,$$
$$q_a^{-kN_a}=\sum_{m=0}^{\infty}\frac{1}{[m]_{q_a^{-1}}}\left(\prod_{l=1}^{m-1}(q_a^{-k}-q_a^{-l})\right)\theta_a^m\mathscr{D}_{Ra}^m,\tag{38}$$

$$G_{La}=\exp_{q_a^{-1}}(\epsilon_a\mathscr{D}_{La}),\quad G_{Ra}=\exp_{q_a}(\eta_a\mathscr{D}_{Ra}).\tag{39}$$

These satisfy

$$[N_a,\theta_b]=\delta_{ab}\theta_a,\quad [N_a,\mathscr{D}_{Lb}]=-\delta_{ab}\mathscr{D}_{Lb},\quad [N_a,\mathscr{D}_{Rb}]=-\delta_{ab}\mathscr{D}_{Rb},\tag{40}$$

$$G_{La}\theta_bG_{La}^{-1}=\delta_{ab}\epsilon_a+\theta_b,\quad G_{Ra}\theta_bG_{Ra}^{-1}=\theta_b+\delta_{ab}\eta_a.\tag{41}$$

Using the identity $\mathscr{D}_{La}\theta_a-\theta_a\mathscr{D}_{La}=q_a^{N_a}$ which follows from (38), it is clear that with the braided bracket normalization the relationship between the left and right algebraic derivatives is

$$\mathscr{D}_{Ra}=q_a^{-N_a}\mathscr{D}_{La}.\tag{42}$$

It follows immediately from this and (29) or (31) that

$$[\mathscr{D}_{Ra},\mathscr{D}_{Lb}]_{t_{ab}}=0.\tag{43}$$

Another consequence of this change of normalization is that the Q_a and D_a are related by

$$Q_a=\mathscr{D}_{La},\quad D_a=\mathscr{D}_{Ra}.\tag{44}$$

Left and right integrals[13] can also be introduced. As in the one-dimensional case these are defined so as to invert the effect of the corresponding derivatives. Another important advantage of the switch to braided brackets is that the left and right integrals are truly distinct, and that there are simple and well-defined commutation relations among these as well as between them and the derivatives. Specifically, the left integrals are defined by

$$\int(d\theta_a)_L\theta_a^m=\frac{\theta_a^{m+1}}{[m+1]_{q_a}},\tag{45}$$

and the right integrals by

$$\int(d\theta_a)_R\theta_a^m=\frac{\theta_a^{m+1}}{[m+1]_{q_a^{-1}}}.\tag{46}$$

To integrate functions of many variables we also need the cross relations

$$\left[\int(d\theta_a)_L,\theta_b\right]_{\omega_{ab}}=\left[\int(d\theta_a)_R,\theta_b\right]_{\omega_{ab}}=0,\tag{47}$$

which hold for $a\neq b$. It is also straightforward to show, for example by comparing

$$\left(\frac{d}{d\theta_a}\right)_L\int(d\theta_a)_R\theta_a^m=\frac{[m+1]_{q_a}}{[m+1]_{q_a^{-1}}}\ \theta_a^m,\tag{48}$$

with

$$\int (d\theta_a)_R \left(\frac{d}{d\theta_a}\right)_L \theta_a^m = \frac{[m]_{q_a}}{[m]_{q_a^{-1}}} \theta_a^m, \tag{49}$$

that the commutation relations between differentiation and integration are as follows:

$$\begin{aligned} &\left[\left(\frac{d}{d\theta_a}\right)_L, \int (d\theta_b)_L\right]_{\omega_{ba}} = 0, \quad \left[\left(\frac{d}{d\theta_a}\right)_L, \int (d\theta_b)_R\right]_{t_{ba}} = 0, \\ &\left[\left(\frac{d}{d\theta_a}\right)_R, \int (d\theta_b)_R\right]_{\omega_{ba}} = 0, \quad \left[\left(\frac{d}{d\theta_a}\right)_R, \int (d\theta_b)_L\right]_{t_{ab}^{-1}} = 0. \end{aligned} \tag{50}$$

By similar methods we also find

$$\left[\int (d\theta_a)_L, \int (d\theta_b)_L\right]_{\omega_{ab}} = 0, \quad \left[\int (d\theta_a)_R, \int (d\theta_b)_R\right]_{\omega_{ab}} = 0, \quad \left[\int (d\theta_a)_R, \int (d\theta_b)_L\right]_{t_{ab}} = 0, \tag{51}$$

which are the integral analogs of (29), (31), and (43).

III. GENERALIZED GRASSMANN CALCULUS AT q_a A ROOT OF UNITY

One of the central results of Ref. 2 was that if $\tilde{q}_a$ is a primitive n_ath root of unity, and z_a, ∂_{z_a} are defined by

$$z_a = \lim_{q_a \to \tilde{q}_a} \frac{(\theta_a)^{n_a}}{[n_a]_{q_a}!}, \quad \partial_{z_a} = \mathscr{D}_{La}^{n_a} = -(-1)^{n_a} \mathscr{D}_{Ra}^{n_a}, \tag{52}$$

in which (42) has been used, and it is assumed that $(\theta_a)^{n_a} \to 0$ as $q_a \to \tilde{q}_a$ in such a way that z_a is well defined in this limit, then

$$[\partial_{z_a}, z_a] = 1. \tag{53}$$

Using these definitions and the results of Sec. IV B it is easy to establish the full commutation relations in the limit as $q_a \to \tilde{q}_a$ (note that this limit need not be taken for all a). When $q_a \to \tilde{q}_a$ and $q_b \to \tilde{q}_b$ we find from (26), (29), and (53) that

$$[\partial_{z_a}, z_b]_{(t_{ba})^{n_a n_b}} = \delta_{ab}, \quad [z_a, z_b]_{(\omega_{ab})^{n_a n_b}} = 0, \quad [\partial_{z_a}, \partial_{z_b}]_{(\omega_{ab})^{n_a n_b}} = 0. \tag{54}$$

This clearly reduces to ordinary calculus if $(\omega_{ba})^{n_a n_b} = 1$. It will often be sensible to make this choice. It also follows from (29), (31), and (52) that

$$\begin{aligned} [\mathscr{D}_{La}, z_b]_{(t_{ba})^{n_b}} &= \delta_{ab} \frac{(\theta_b)^{n_b - 1}}{[n_b - 1]_{q_b}!}, \\ [\mathscr{D}_{Ra}, z_b]_{(t_{ab})^{-n_b}} &= -(-1)^{n_b} \delta_{ab} \frac{(\theta_b)^{n_b - 1}}{[n_b - 1]_{q_b^{-1}}!}, \end{aligned} \tag{55}$$

and that

$$[\mathscr{D}_{La}, \partial_{z_b}]_{(\omega_{ab})^{n_b}} = 0, \quad [\mathscr{D}_{Ra}, \partial_{z_b}]_{(\omega_{ab})^{n_b}} = 0, \quad [\partial_{z_b}, \theta_a]_{(t_{ab})^{n_b}} = 0. \tag{56}$$

Note that (55) and (56) hold even when q_a is not a root of unity, as long as q_b is. Following Ref. 2 we can, when q_a is a root of unity, expand the algebraic *total* derivatives $\mathscr{D}_{La}$ and $\mathscr{D}_{Ra}$ by using the algebraic partial derivatives ∂_{θ_a} and δ_{θ_a}. These satisfy

$$(\partial_{\theta_a})^{n_a}=(\delta_{\theta_a})^{n_a}=0, \quad [\delta_{\theta_a},\partial_{\theta_b}]_{t_{ab}}=0,$$
$$[\partial_{\theta_a},\partial_{\theta_b}]_{\omega_{ab}}=0, \quad [\delta_{\theta_a},\delta_{\theta_b}]_{\omega_{ab}}=0, \tag{57}$$

as well as

$$[\partial_{\theta_a},\theta_b]_{t_{ba}}=\delta_{ab}, \quad [\partial_{\theta_a},z_b]_{(t_{ba})^{n_b}}=0, \quad [\partial_{\theta_a},\partial_{zb}]_{(t_{ba})^{-n_b}}=0,$$
$$[\delta_{\theta_a},\theta_b]_{(t_{ab})^{-1}}=\delta_{ab}, \quad [\delta_{\theta_a},z_b]_{(t_{ab})^{-n_b}}=0, \quad [\delta_{\theta_a},\partial_{z_b}]_{(t_{ab})^{n_b}}=0. \tag{58}$$

So that if we expand $\mathscr{D}_{La}$ and $\mathscr{D}_{Rb}$ as follows:

$$\mathscr{D}_{La}=\partial_{\theta_a}+\frac{\theta_a^{n_a-1}}{[n_a-1]_{q_a}!}\,\partial_{z_a},$$
$$\mathscr{D}_{Ra}=\delta_{\theta_a}-(-1)^{n_a}\frac{\theta_a^{n_a-1}}{[n_a-1]_{q_a^{-1}}!}\,\partial_{z_a}, \tag{59}$$

then (54) and (55) are implied by (57)–(59).
If we note the identity

$$\lim_{q_a\to\tilde{q}_a}\frac{\theta_a^{rn_a+p}}{[rn_a+p]_{q_a}}=\frac{z_a^r\theta^p}{r![p]!}, \tag{60}$$

then we can take the limit of (45) and (46) to obtain

$$\int (d\theta_a)_L z_a^r\theta_a^p=(1-\delta_{p,n-1})\frac{z_a^r\theta_a^{p+1}}{[p+1]_{q_a}}+\delta_{p,n-1}[n_a-1]_{q_a}!\,\frac{z_a^{r+1}\theta_a^p}{(r+1)},$$
$$\int (d\theta_a)_R z_a^r\theta_a^p=(1-\delta_{p,n-1})\frac{z_a^r\theta_a^{p+1}}{[p+1]_{q_a^{-1}}}-(-1)^{n_a}\delta_{p,n-1}[n_a-1]_{q_a^{-1}}!\,\frac{z_a^{r+1}\theta_a^p}{(r+1)}. \tag{61}$$

In analogy with the introduction of partial derivatives, we introduce the following ''partial'' integrals:

$$\int d\theta_a z_a^r\theta_a^p=(1-\delta_{p,n-1})\frac{z_a^r\theta_a^{p+1}}{[p+1]_{q_a}},$$
$$\int \delta\theta_a z_a^r\theta_a^p=(1-\delta_{p,n-1})\frac{z_a^r\theta_a^{p+1}}{[p+1]_{q_a^{-1}}}, \tag{62}$$
$$\int dz_a z_a^r\theta_a^p=\frac{z_a^{r+1}\theta_a^p}{(r+1)}.$$

Using these and (61) we can write

$$\int (d\theta_a)_L=\int d\theta_a+\frac{\partial^{n_a-1}}{\partial^{n_a-1}\theta_a}\int dz_a,$$
$$\int (d\theta_a)_R=\int \delta\theta_a-(-1)^{n_a}\frac{\delta^{n_a-1}}{\delta^{n_a-1}\theta_a}\int dz_a, \tag{63}$$

which are the integral analogs of (59). We also note the identities

$$\int (d\theta_a)_L^n = \int dz_a, \quad \int (d\theta_a)_R^n = -(-1)^{n_a} \int dz_a, \quad \int d\theta_a^n = \int \delta\theta_a^n = 0. \tag{64}$$

We conclude this section with some comments on the braided Hopf structure of the generalized Grassmann algebra and the dual algebra of derivatives as $q_a \to \tilde{q}_a$. For an alternative derivation of (52) as well as a derivation of the duality properties in the single variable case see the Appendix. The results of the Appendix are easily extended to the many variable case, and we give the results below. For generic q_a the braided Hopf structure of θ_a, which follows directly from (5) is as follows:

$$\Delta\theta_a = \theta_a \otimes 1 + 1 \otimes \theta_a, \quad \epsilon(\theta_a) = 0, \quad S(\theta_a^m) = q^{m(m-1)/2}(-\theta_a)^m. \tag{65}$$

When $q_a \to \tilde{q}_a$ it follows directly from this and (52) that in addition to (65), which holds as in the generic case, we have the following braided Hopf structure for z_a:

$$\Delta z_a = z_a \otimes 1 + 1 \otimes z_a + \sum_{m=1}^{n_a-1} \frac{\theta_a^m \otimes \theta_a^{n_a-m}}{[m]_{q_a}![n_a-m]_{q_a}!},$$

$$\epsilon(z_a) = 0, \quad S(z_a) = -z_a. \tag{66}$$

In the dual Hopf algebra with elements $\mathscr{D}_{La}$, the braided Hopf structure is as follows:

$$\Delta\mathscr{D}_{La} = \mathscr{D}_{La} \otimes 1 + 1 \otimes \mathscr{D}_{La},$$

$$\epsilon(\mathscr{D}_{La}) = 0, \quad S(\mathscr{D}_{La}) = q^{m(m-1)/2}(-\mathscr{D}_{La})^m. \tag{67}$$

The duality is given by the inner product

$$\langle \mathscr{D}_{La}, \theta_b \rangle = \delta_{ab}, \tag{68}$$

which satisfies/is extended to products by all of the usual identities (see the Appendix)—Eq. (A8). When $q_a \to \tilde{q}_a$ the Hopf structure is extended to include

$$\Delta\partial_{za} = \partial_{za} \otimes 1 + 1 \otimes \partial_{za}, \quad \epsilon(\partial_{za}) = 0, \quad S(\partial_{za}) = -\partial_{za}. \tag{69}$$

In this case the duality is given by

$$\langle \mathscr{D}_{La}, \theta_b \rangle = \delta_{ab}, \quad \langle \partial_{za}, z_b \rangle = \delta_{ab}, \quad \langle \partial_{za}, \theta_b \rangle = 0, \quad \langle \mathscr{D}_{La}, z_b \rangle = 0, \tag{70}$$

which follow directly from (52) and (68). Note that we could equally well have worked with $\mathscr{D}_{Ra}$, the only advantage of using $\mathscr{D}_{La}$ being that we avoid the factors of $(-1)^{n_a+1}$ which would arise due to (52).

IV. THE BRAIDED INTERPRETATION OF TWO-DIMENSIONAL SUSY

We can use the work in the previous sections to extend our new interpretation of supersymmetry (SUSY) to the two-dimensional case. This is of great interest in physics since it is related to world sheet supersymmetry in superstring theory. The most interesting new feature in two dimensions is the presence of Lorentz transformations. We consider a two-dimensional generalized Grassmann algebra $\{\theta_a\}$, $a=1,2$, and its associated calculus, examining first the case of $q_1 = q_2 = \omega_{12} = q$. We begin by *defining*

$$p_\mu = -\tfrac{1}{2}\mathscr{D}_{La}(\gamma_\mu\gamma_0)_{ab}\mathscr{D}_{Lb},$$

$$x_\mu = \lim_{q\to -1} \frac{i}{[2]_q}\, \theta_a(\gamma_0\gamma_\mu)_{ab}\theta_b. \tag{71}$$

Here $\mu=0,1$ and $\gamma_0=\sigma_2$, $\gamma_1=i\sigma_1$, where σ_a are the usual Pauli matrices, so that we are working in the Majorana–Weyl basis for the Dirac gamma matrices. Note that other than those implied by the right-hand side, no transformation properties are assigned to p_μ and x_μ. Since $\gamma_0\gamma_\mu$ is diagonal, the above can be written as

$$x_0=i(z_1+z_2), \quad p_0=-\tfrac{1}{2}(\partial_{z_1}+\partial_{z_2}),$$
$$x_1=i(z_1-z_2), \quad p_1=\tfrac{1}{2}(\partial_{z_1}-\partial_{z_2}), \tag{72}$$

from which, using (54), it is clear that

$$[p_\mu,x_\nu]=-ig_{\mu\nu}, \quad [p_\mu,p_\nu]=0, \quad [x_\mu,x_\nu]=0. \tag{73}$$

Here $g_{\mu\nu}=\text{diag}\{1,-1\}$ so that $\{p_\mu\}$ and $\{x_\mu\}$ behave just like the quantized momenta and coordinates of two-dimensional spacetime. To establish their transformation properties, we proceed as follows. Under a translation

$$\theta_a\to\epsilon_a+\theta_a, \tag{74}$$

we find from (71) that the coordinates $\{x_\mu\}$ transform as follows:

$$x_\mu\to\lim_{q\to-1}\frac{i}{[2]_q}(\epsilon_a+\theta_a)(\gamma_0\gamma_\mu)_{ab}(\epsilon_b+\theta_b)$$
$$=\lim_{q\to-1}\frac{i}{[2]_q}\theta_a(\gamma_0\gamma_\mu)_{ab}\theta_b$$
$$+\lim_{q\to-1}\frac{i}{[2]_q}\epsilon_a(\gamma_0\gamma_\mu)_{ab}\epsilon_b+i\epsilon_a(\gamma_0\gamma_\mu)_{ab}\theta_b=x_\mu+x'_\mu+i\epsilon_a(\gamma_0\gamma_\mu)_{ab}\theta_b. \tag{75}$$

Together (74) and (75) constitute the usual two-dimensional SUSY transformation,[10] only now we can see that just as the $\{x_\mu\}$ are defined by (71) in terms of the $\{\theta_a\}$, the $\{x'_\mu\}$ are defined by

$$x'_\mu=\lim_{q\to-1}\frac{i}{[2]_q}\epsilon_a(\gamma_0\gamma_\mu)_{ab}\epsilon_b, \tag{76}$$

which is the same as (71) but with θ_a replaced by ϵ_a. In the notation of generalized Grassmann calculus, the infinitesimal generators of the translation (74) are $\epsilon_a\mathscr{D}_{La}$. On the other hand, in the usual SUSY notation, this transformation is generated by the supercharge Q_a, and thus (as expected) we can make the identification

$$\mathscr{D}_{La}=Q_a. \tag{77}$$

Using this we can write the definition (71) of p_μ as

$$p_\mu=-\tfrac{1}{2}Q_a(\gamma_\mu\gamma_0)_{ab}Q_b, \tag{78}$$

which can easily be inverted to yield

$$\{Q_a,Q_b\}=-2(\gamma_0\gamma_\mu)_{ab}p^\mu, \tag{79}$$

where $p^\mu=g^{\mu\nu}p_\mu$. Along with $[p_\mu,p_\nu]=0$ from (73), this is just the two-dimensional supersymmetry algebra in its usual form. The usual superspace realization of this algebra can be obtained by using (59) and (71). We find

$$Q_a=\mathscr{D}_{La}=\partial_{\theta_a}+\theta_a\partial_{z_a}=\partial_{\theta_a}-(\gamma_0\gamma_\mu)_{ab}\theta_b p^\mu. \tag{80}$$

The covariant derivatives D_a from two-dimensional SUSY also arise naturally in the $q\to -1$ limit of two-dimensional q-calculus. To see this, we write down their usual superspace realization,

$$D_a = \partial_{\theta_a} + (\gamma_0\gamma_\mu)_{ab}\theta_b p^\mu. \tag{81}$$

Then, using (38) and (57)

$$\partial_{\theta_a} = (-1)^{N_a}\delta_{\theta_a} = (\mathscr{D}_{La}\theta_a - \theta_a\mathscr{D}_{La})\delta_{\theta_a} = (\partial_{\theta_a}\theta_a - \theta_a\partial_{\theta_a})\delta_{\theta_a} = \delta_{\theta_a}, \tag{82}$$

we can write this as

$$D_a = \delta_{\theta_a} + (\gamma_0\gamma_\mu)_{ab}\theta_b p^\mu, \tag{83}$$

and thus from (59) and (71) we have

$$D_a = \mathscr{D}_{Ra}. \tag{84}$$

These satisfy

$$\{D_a, D_b\} = 2(\gamma_0\gamma_\mu)_{ab}p^\mu. \tag{85}$$

The cross relations $\{D_a, Q_b\} = 0$ follow directly from (43). Thus the supercharges and covariant derivatives used in two-dimensional supersymmetry, correspond, respectively, to the left and right *total* derivatives in the $q_a \to -1$ limit of two-dimensional q-calculus.

In two-dimensional SUSY, the Grassmann variables θ_a transform as the components of a Lorentz spinor,

$$\theta_a \to S_{ab}\theta_b, \tag{86}$$

where

$$S_{ab} = \begin{pmatrix} \exp\left(\frac{\phi}{2}\right) & 0 \\ 0 & \exp\left(\frac{-\phi}{2}\right) \end{pmatrix}. \tag{87}$$

Due to (71), the transformation properties of the coordinates $\{x_\mu\}$ are entirely determined by those of the θ_a. To find these explicitly we first note that

$$\gamma_0^2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \gamma_0\gamma_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{88}$$

so that

$$\begin{aligned} S\gamma_0^2 S^T &= \begin{pmatrix} \exp\phi & 0 \\ 0 & \exp(-\phi) \end{pmatrix} = \gamma_0^2 \cosh\phi + \gamma_0\gamma_1 \sinh\phi, \\ S\gamma_0\gamma_1 S^T &= \begin{pmatrix} \exp\phi & 0 \\ 0 & -\exp(-\phi) \end{pmatrix} = \gamma_0^2 \sinh\phi + \gamma_0\gamma_1 \cosh\phi. \end{aligned} \tag{89}$$

Now from (71) and (86), we find that under a Lorentz transformation the coordinates $\{x_\mu\}$ behave as follows:

$$x_\mu \to \lim_{q\to -1} \frac{i}{[2]_q}\theta_b S_{ab}(\gamma_0\gamma_\mu)_{ab}S_{cd}\theta_d = \lim_{q\to -1}\frac{i}{[2]_q}\theta_a \Lambda_\mu^\nu(\gamma_0\gamma_\nu)_{ab}\theta_b = \Lambda_\mu^\nu x_\nu, \tag{90}$$

in which from (89) Λ_μ^ν has the form

$$\Lambda_\mu^{\ \nu}=\begin{pmatrix}\cosh\phi & \sinh\phi\\ \sinh\phi & \cosh\phi\end{pmatrix}, \tag{91}$$

so we have shown that, as expected, the coordinates $\{x_\mu\}$ transform like the components of a covariant Lorentz vector. Note that $x^\mu:=g^{\mu\nu}x_\nu$ also has the expected transformation properties, i.e., the $\{x^\mu\}$ transform like the components of a contravariant Lorentz vector

$$x'^\mu=(\Lambda_\nu^\mu)^{-1}x^\nu, \tag{92}$$

so that the length $x_\mu x^\mu$ is invariant. Note also that from $\{D_{La},\theta_b\}=\delta_{ab}$ and (86) it follows that under a Lorentz transformation $D_{La}\rightarrow D_{Lb}S_{ba}^{-1}$, and that through definition (71), this leads to the correct transformation properties for the $\{p_\mu\}$. By combining the translation and Lorentz transformation above, we can consider the effect on the coordinates $\{x_\mu\}$ of a general super-Poincaré transformation of θ:

$$\theta_a\rightarrow\epsilon_a+S_{ab}\theta_b. \tag{93}$$

Under such a transformation we have, from (71)

$$\begin{aligned}x_\mu\rightarrow&\lim_{q\rightarrow-1}\frac{i}{[2]_q}(\epsilon_a+S_{ab}\theta_b)^2\\ =&\lim_{q\rightarrow-1}\frac{i}{[2]_q}\epsilon_a(\gamma_0\gamma_\mu)_{ab}\epsilon_b\\ &+\lim_{q\rightarrow-1}\frac{i}{[2]_q}\theta_bS_{ab}(\gamma_0\gamma_\mu)_{ac}S_{cd}\theta_d+i\epsilon_a(\gamma_0\gamma_\mu)_{ab}S_{bc}\theta_c,\end{aligned} \tag{94}$$

which by (75) and (90) reduces to

$$x_\mu\rightarrow x'_\mu+\Lambda_\mu^{\ \nu}x_\nu+i\epsilon_a(\gamma_0\gamma_\mu)_{ab}S_{bc}\theta_c, \tag{95}$$

which is in exact agreement with the usual super-Poincaré transformation of $\{x_\mu\}$.

Although it seems reasonable to expect that there is an analogous interpretation of super-Poincaré transformations in higher dimensions, based on (71) or some similar relationship, and it is indeed straightforward to construct higher dimensional algebras with supersymmetric properties using our techniques, the generalization of our work in this section to $d>2$ is a nontrivial problem, and at present it remains unsolved.

V. MIXED FSUSY IN TWO DIMENSIONS

Using (72) it is clear that in terms of $\{\theta_a\}$ and $\{z_a\}$ the general super-Poincaré transformation (95) of the coordinates $\{x_\mu\}$ which follows from (93) takes on the following simple form:

$$\begin{aligned}z_1&\rightarrow z_1\exp\phi+z'_1+\epsilon_1\theta_1\exp(\phi/2),\\ z_2&\rightarrow z_2\exp(-\phi)+z'_2+\epsilon_2\theta_2\exp(-\phi/2).\end{aligned} \tag{96}$$

The fact that the pairs $\{z_1,\theta_1\}$ and $\{z_2,\theta_2\}$ are not mixed by this transformation has the consequence that in this basis the generalization to fractional supersymmetry (FSUSY) is straightforward. To construct the most general two-dimensional FSUSY, we consider a two-dimensional q-calculus in the limit as $q_i\rightarrow\tilde{q}_i$, and choose ω_{12} so that $\omega_{12}^{n_1}=\omega_{12}^{n_2}=1$. We have included the $n_1\neq n_2$ case, and for this reason refer to our construction as *mixed* FSUSY. A suitable definition for S_{ab} in the Lorentz transformation $\theta_a\rightarrow S_{ab}\theta_b$ of mixed anyonic spinors, such as θ_a is

$$S_{ab}=\begin{pmatrix} \exp\left(\frac{\phi}{n_1}\right) & 0 \\ 0 & \exp\left(\frac{-\phi}{n_2}\right) \end{pmatrix}. \tag{97}$$

As we will see, this ensures that $\{x_\mu\}$ transform as the components of a Lorentz vector. Under a mixed anyonic Poincaré transformation

$$\theta_a \to \epsilon_a + S_{ab}\theta_b, \tag{98}$$

it follows from (52) that z_1 and z_2 transform as follows:

$$\begin{aligned} z_1 &\to z_1 \exp \phi + z_1' + \sum_{m=1}^{n_1-1} \frac{\epsilon_1^m \theta_1^{n_1-m}}{[n_1-m]_{q_1}![m]_{q_1}!} \exp\left(\frac{(n_1-m)\phi}{n_1}\right), \\ z_2 &\to z_2 \exp(-\phi) + z_1' + \sum_{m=1}^{n_2-1} \frac{\epsilon_2^m \theta_2^{n_2-m}}{[n_2-m]_{q_2}![m]_{q_2}!} \exp\left(\frac{(m-n_2)\phi}{n_2}\right). \end{aligned} \tag{99}$$

To make contact with the usual spacetime coordinates $\{x_\mu\}$ we note that as in the $n_a=n_b=2$ case z_1z_2 is invariant under a pure Lorentz transformation $(\epsilon_1=\epsilon_2=0)$. Thus we have $z_1z_2 \propto x_0^2-x_1^2$. In fact the definitions of x_0 and x_1 in terms of z_1 and z_2 are

$$\begin{aligned} x_0 &= F(z_1+z_2), \quad p_0=-\frac{i}{2F}(\partial_{z_1}+\partial_{z_2}), \\ x_1 &= F(z_1-z_2), \quad p_1=\frac{i}{2F}(\partial_{z_1}-\partial_{z_2}), \end{aligned} \tag{100}$$

with $F=i$ for even n as in (72) and $F=1$ for odd n. These factors correspond to those relating t to z in Refs. 1–4 and ensure the reality of p_μ and x_μ. From (54) it follows that the operators defined by (100) satisfy (73) as in the supersymmetric case covered in Sec. IV. After a little algebra we obtain the mixed anyonic transformation of the $\{x_\mu\}$ coordinates,

$$x_\mu \to x_\mu' + \Lambda_\mu^{\ \nu} x_\nu + \sum_{a,b=1}^{2} \sum_{m=1}^{n_a-1} \frac{F\epsilon_a^m (\gamma_0\gamma_\mu)_{ab}(S_{bc}\theta_c)^{n_a-m}}{[n_a-m]_{q_a}![m]_{q_a}!}. \tag{101}$$

Here $\Lambda_\mu^{\ \nu}$ is the same as in (91). The fractional supercharge and covariant derivative are also easy to deduce. From (59) and (100) we find

$$Q_a=\mathscr{D}_{La}=\partial_{\theta_a}+\frac{\theta_a^{n_a-1}}{[n_a-1]_{q_a}!}\partial_{za}=\partial_{\theta_a}+\frac{iF}{[n_b-1]_{q_b}!}(\gamma_0\gamma_\mu)_{ab}\theta_b^{n_b-1}p^\mu, \tag{102}$$

and

$$D_a=\mathscr{D}_{Ra}=\delta_{\theta_a}-(-1)^{n_a}\frac{\theta_a^{n_a-1}}{[n_a-1]_{q_a^{-1}}!}\partial_{za}=\delta_{\theta_a}-\frac{iF(-1)^{n_a}}{[n_b-1]_{q_b^{-1}}!}(\gamma_0\gamma_\mu)_{ab}\theta_b^{n_b-1}p^\mu. \tag{103}$$

The algebraic (left) integral of a function $f(z_1,z_2,\theta_1,\theta_2)$ on two-dimensional fractional superspace is

$$\int (d\theta_2)_L \int (d\theta_1)_L f(z_1,z_2,\theta_1,\theta_2). \tag{104}$$

Note that this integral would change by an overall multiplicative factor if we reversed the order of $\int(d\theta_2)_L$ and $\int(d\theta_1)_L$, so that in writing down (104), we have made a choice of convention. This integral can be expanded using (61) to yield

$$\int d\theta_2 \int d\theta_1 f + \int d\theta_2 \frac{\partial^{n_1-1}}{\partial^{n_1-1}\theta_1} \int dz_1 f + \frac{\partial^{n_2-1}}{\partial^{n_2-1}\theta_2} \int dz_2 \int d\theta_1 f + \frac{\partial^{n_2-1}}{\partial^{n_2-1}\theta_2} \frac{\partial^{n_1-1}}{\partial^{n_1-1}\theta_1} \int dz_2 \int dz_1 f. \tag{105}$$

To obtain a numerical measure from this algebraic integral we now make use of an argument similar to that given in Ref. 2. θ_1 and θ_2 are nilpotent and thus all of their eigenvalues are zero. On the other hand, the bosonic limits denoted by z_1 and z_2 are non-nilpotent and thus do have nonzero eigenvalues. After integration, the first three terms in (105) always involve θ_1 or θ_2 raised to some nonzero power, whereas the last term involves z_1 and z_2 only. Any numerical measure based on the integral (105) must be based on its eigenvalues in some representation. Consequently only the last term contributes and thus the first three can be dropped. It is convenient at this point to introduce a fractional Berezin integral as in Ref. 2,

$$\int (d\theta_a)_{\mathrm{Ber}} = \frac{\partial^{n_a-1}}{\partial^{n_a-1}\theta_a}. \tag{106}$$

The resulting numerical integral measure on two-dimensional fractional superspace can now be written as

$$I(f) = \int dz_2 dz_1 (d\theta_2)_{\mathrm{Ber}} (d\theta_1)_{\mathrm{Ber}} f(z_1, z_2, \theta_1, \theta_2). \tag{107}$$

If we expand f as a power series

$$f(z_1, z_2, \theta_1, \theta_2) = \sum_{m_1=0}^{n_1-1} \sum_{m_2=0}^{n_2-1} C_{m_1,m_2}(z_1, z_2) \frac{\theta_1^{m_1}}{[m_1]_{q_1}!} \frac{\theta_2^{m_2}}{[m_2]_{q_2}!}, \tag{108}$$

then (107) reduces to

$$I(f) = \int dz_2 dz_1 C_{n_1-1, n_2-1}(z_1, z_2). \tag{109}$$

Note that up to a constant Jacobian factor this is equal to

$$\int dx_0 dx_1 C_{n_1-1, n_2-1}(z_1, z_2), \tag{110}$$

which, for $n=2$, is just the integral which arises in supersymmetric field theories involving one space and one time dimension.

ACKNOWLEDGMENTS

Thanks to Alan Macfarlane, José de Azcárraga, and Carlos Pérez Bueno for many helpful discussions and communications. I gratefully acknowledge the financial support provided by the E.P.S.R.C. and St John's College, Cambridge during the preparation of this paper.

APPENDIX

The results of Refs. 1–4 can also be derived from a different and in some ways mathematically nicer point of view. Our work here uses a technique similar to that employed by G. I. Lusztig in his work on the properties of deformed universal enveloping algebras with deformation parameter equal to a root of unity.[14,15] To the best of our knowledge this is the first time such a technique has been applied to a braided object. Let us begin by introducing the braided Hopf algebra $\mathscr{A}$, which we define for all q. This has elements $\{\theta^{(m)}\}$, $m=0,1,2,...,\infty$ with $\theta^{(0)}=1$, and relations

$$\theta^{(m)}\theta^{(p)}=\frac{[m+p]_q!}{[m]_q![p]_q!}\,\theta^{(m+p)}, \tag{A1}$$

as well as

$$\Delta\theta^{(m)}=\sum_{r=0}^{m}\theta^{(m-r)}\otimes\theta^{(r)},\quad \epsilon(\theta^{(m)})=\delta_{m,0}, \tag{A2}$$

$$S(\theta^{(m)})=(-1)^m q^{m(m-1)/2}\theta^{(m)}.$$

The braiding is given by

$$\psi(\theta^{(m)}\otimes\theta^{(s)})=q^{ms}\theta^{(m)}\otimes\theta^{(s)}, \tag{A3}$$

so that

$$(\theta^{(r)}\otimes\theta^{(m)})(\theta^{(s)}\otimes\theta^{(s)})=q^{ms}\theta^{(r)}\theta^{(s)}\otimes\theta^{(m)}\theta^{(t)}. \tag{A4}$$

We also define $\mathscr{H}$ the braided Hopf algebra dual to $\mathscr{A}$ as follows. This has elements $\{\mathscr{D}_L^{(m)}\}$, $m=0,1,2,...,\infty$ with $\mathscr{D}_L^{(0)}=1$, and relations

$$\mathscr{D}_L^{(m)}\mathscr{D}_L^{(p)}=\mathscr{D}_L^{(m+p)}, \tag{A5}$$

as well as

$$\Delta\mathscr{D}_L^{(m)}=\sum_{r=0}^{m}\frac{[m]_q!}{[r]_q![m-r]_q!}\,\mathscr{D}_L^{(m-r)}\otimes\mathscr{D}_L^{(r)},$$

$$\epsilon(\mathscr{D}_L^{(m)})=\delta_{m,0}, \tag{A6}$$

$$S(\mathscr{D}_L^{(m)})=(-1)^m q^{m(m-1)/2}\mathscr{D}_L^{(m)}.$$

The braiding is given by

$$\psi(\mathscr{D}_L^{(m)}\otimes\mathscr{D}_L^{(s)})=q^{ms}\mathscr{D}_L^{(m)}\otimes\mathscr{D}_L^{(s)}. \tag{A7}$$

These two braided Hopf algebras are dual in the sense that there is a bilinear map $\langle,\rangle$: $\mathscr{A}\otimes\mathscr{H}\mapsto$ the complex plane, such that

$$\langle a,xy\rangle=\langle\Delta a,x\otimes y\rangle,\quad \langle ab,x\rangle=\langle a\otimes b,\Delta x\rangle,\quad \langle 1,x\rangle=\epsilon_{\mathscr{H}}(x),$$

$$\langle a,1\rangle=\epsilon_{\mathscr{A}}(a),\quad \langle S(a),x\rangle=\langle a,S(x)\rangle. \tag{A8}$$

Specifically, in this case we have

$$\langle\theta^{(m)},\mathscr{D}_L^{(p)}\rangle=\delta_{mp}, \tag{A9}$$

the compatibility of which with (A8) is easy to verify. We now consider the cases of generic q and q a root of unity separately.

(i) Generic q or $q=1$. From (A1) it follows that

$$\theta^{(m)}=\frac{\theta^{(1)}\theta^{(m-1)}}{[m]_q}=\frac{\theta^{(1)2}\theta^{(m-2)}}{[m]_q[m-1]_q}=\frac{(\theta^{(1)})^m}{[m]_q!}, \tag{A10}$$

and similarly

$$\mathscr{D}_L^{(m)}=(\mathscr{D}_L^{(1)})^m. \tag{A11}$$

Consequently, at generic q the braided Hopf algebra $\mathscr{A}$ and its dual $\mathscr{K}$ are both finite dimensional, each containing the identity, and only one other element. If we define $\theta=\theta^{(1)}$ and $\mathscr{D}_L=\mathscr{D}_L^{(1)}$ then we can write the generic q braided Hopf structure as follows. For $\mathscr{A}$ we have

$$\Delta\theta=\theta\otimes 1+1\otimes\theta,\quad \epsilon(\theta)=0,\quad S(\theta)=-\theta, \tag{A12}$$

which recovers the braided line at generic q, and for $\mathscr{K}$ we have

$$\Delta\mathscr{D}_L=\mathscr{D}_L\otimes 1+1\otimes\mathscr{D}_L,\quad \epsilon(\mathscr{D}_L)=0,\quad S(\mathscr{D}_L)=-\mathscr{D}_L. \tag{A13}$$

The duality simplifies to

$$\langle\theta,\mathscr{D}_L\rangle=1, \tag{A14}$$

and is extended to products via (A8). By comparing (A12) and (A13) with one of Refs. 5, 6, 16 we are able to identify both the braided Hopf algebra $\mathscr{A}$ and its dual $\mathscr{K}$ with the braided line when q is not a root of unity.

(ii) q a primitive nth root of unity. As in the generic q case we can use (A1) to obtain

$$\theta^{(p)}=\frac{(\theta^{(1)})^p}{[p]_q!}, \tag{A15}$$

but since $[n]_q=0$ this only works for $p=0,1,...,n-1$. However we are able to write

$$\theta^{(rn+p)}=\theta^{(rn)}\theta^{(p)}\lim_{q\to\epsilon}\frac{[rn]_q![p]_q!}{[rn+p]_q!}=\theta^{(rn)}\theta^{(p)}, \tag{A16}$$

where $r\geqslant 0$ and $0\leqslant p\leqslant n-1$. Also using (A1) we find that

$$\theta^{(rn)}=\theta^{(n)}\theta^{((r-1)n)}\lim_{q\to\epsilon}\frac{[(r-1)n]_q![n]_q!}{[rn]_q!}=\frac{\theta^{(n)}\theta^{((r-1)n)}}{r}. \tag{A17}$$

Iterating we finally obtain

$$\theta^{(rn)}=\frac{(\theta^{(n)})^r}{r!}, \tag{A18}$$

so that

$$\theta^{(rn+p)}=\frac{(\theta^{(n)})^r\theta^{(p)}}{r!}. \tag{A19}$$

Similarly, for the dual we find that

$$\mathscr{D}_L^{(rn+p)}=(\mathscr{D}_L^{(n)})^r\mathscr{D}_L^{(p)}. \tag{A20}$$

Thus when q is a root of unity ($q\neq 1$) the braided Hopf algebra $\mathscr{A}$ is finite dimensional, having two independent elements $\theta^{(1)}$ and $\theta^{(n)}$ besides the identity. The dual $\mathscr{K}$ is also finite dimensional, but it has only one independent element $\mathscr{D}_L^{(1)}$ besides the identity. It is convenient to define

$$\theta=\theta^{(1)},\quad z=\theta^{(n)},\quad \mathscr{D}_L=\mathscr{D}_L^{(1)},\quad \partial_z=\mathscr{D}_L^{(n)}. \tag{A21}$$

Using this notation, the algebraic relations (A1) reduce to $[\theta,z]=0$ and $\theta^n=0$, and the braided Hopf structure (A2) reduces to

$$\Delta\theta=\theta\otimes 1+1\otimes\theta,\quad \epsilon(\theta)=0,\quad S(\theta)=-\theta, \tag{A22}$$

and

$$\Delta z = z\otimes 1 + 1\otimes z + \sum_{m=1}^{n-1} \frac{\theta^m \otimes \theta^{n-m}}{[n-m]_q![m]_q!},$$

$$\epsilon(z)=0, \quad S(z)=-z. \tag{A23}$$

The braided Hopf structure of the dual $\mathscr{K}$ is given by

$$\Delta \mathscr{D}_L = \mathscr{D}_L \otimes 1 + 1 \otimes \mathscr{D}_L, \quad \epsilon(\mathscr{D}_L)=0, \quad S(\mathscr{D}_L) = -\mathscr{D}_L, \tag{A24}$$

which, using $\partial_z = \mathscr{D}_L^n$, implies the following braided Hopf structure for ∂_z;

$$\Delta \partial_z = \partial_z \otimes 1 + 1 \otimes \partial_z, \quad \epsilon(\partial_z)=0, \quad S(\partial_z) = -\partial_z.$$

The duality (A9) now takes on the form

$$\langle z^r \theta^p, \mathscr{D}_L^{r'n+p'} \rangle = \langle z^r \theta^p, \partial_z^r \mathscr{D}_L^{p'} \rangle = \delta_{r,r'} \delta_{p,p'} r! [p]_q!, \tag{A26}$$

so that in particular

$$\langle \theta, \mathscr{D}_L \rangle = 1, \quad \langle z, \partial_z \rangle = 1. \tag{A27}$$

Thus when q is a root of unity $\mathscr{A}$ coincides with the braided Hopf algebra which was associated in previous work with a limit of the braided line as its deformation parameter goes to a root of unity. Using this approach we have also obtained the braided Hopf structure of the dual and details of the duality when q is a root of unity (this is an alternative form of the braided line when q is a root of unity). Note also that the θ part of $\mathscr{A}$ forms a braided sub-Hopf algebra, but that the z part does not.

The advantage of the approach adopted here is that it enables us to restrict the taking of limits to purely numerical quantities, for which they are manifestly well defined. In this Appendix we have worked with left derivatives $\mathscr{D}_L$ only, but we could equally well have chosen right derivatives $\mathscr{D}_R$, for which a closely analogous treatment exists.

The relationship between the work in this Appendix and the work of Refs. 14 and 15 suggests that the latter might also have a physical interpretation in terms of supersymmetry and fractional supersymmetry. This idea will be developed further in Ref. 17.

(Received 16 March 1998; accepted for publication 12 August 1998)

We study spectral properties of Harper-like models by algebraic and combinatorial methods and derive sufficient conditions for the existence of spectral gaps with qualitative estimates. For this class the Chambers relation holds and we obtain an analytic expression for the representation dependent part. Models corresponding to the rectangular and triangular lattice are studied. In the second case we show that one class of spectral gaps is open for magnetic fields with ''rational magnetic flux per unit cell.'' A quantitative estimate for the gap widths is given for the anisotropic case and for ''irrational magnetic flux'' fulfilling some Liouville condition the spectrum is a Cantor set.
[S0022-2488(99)03401-5]

I. INTRODUCTION

Spectral properties of Hamiltonians describing charged particles on a two-dimensional (2D) lattice with an external magnetic field perpendicular to the lattice play a crucial role in various 2D problems of physical interest,[1] for the quantum Hall effect see also Ref. 2. In his famous work Hofstadter[3] found for the square lattice case a puzzling nesting structure of the spectra for rational values of the magnetic strength and gave some formal rules for the self-similarity of this so-called Hofstadter butterfly. This model has been investigated in several papers and rigorous results on spectral gaps, measures and other properties have been obtained, see Refs. 4–6 for more details. However, less is known about the analogous model on the triangular lattice, first discussed by Claro and Wannier.[7] It describes the situation in a crystal with hexagonal symmetry and similar behavior of the spectra has been observed.[8,9] We generalize a method used by Choi *et al.*[10] for the square lattice case and derive, under some mild extra conditions, a quantitative estimate for the gap widths of the class of Hamiltonians discussed below. In the case of the triangular lattice this leads to an explicit estimate for one class of spectral gaps.

The behavior of a Bloch electron in an external magnetic field is usually described by a tight-binding approximation. Without electron–electron interaction and with nearest-neighbor interaction only one obtains the following Hamiltonian for the square lattice:

$$H_{\mathrm{sq}}\Psi(k,l)=e^{i\eta_1(k,l)}\Psi(k+1,l)+e^{-i\eta_1(k-1,l)}\Psi(k-1,l)+e^{i\eta_2(k,l)}\Psi(k,l+1)+e^{-i\eta_2(k,l-1)}\Psi(k,l-1), \tag{1}$$

where $\eta_{1,2}(k,l)$ denotes the line integral of the vector potential of the external magnetic field from (k,l) to $(k+1,l)$ and from (k,l) to $(k,l+1)$, respectively (the compensating gauge transformation[11]). Since the magnetic field is uniform, we have the constraint

$$\eta_1(k,l)+\eta_2(k+1,l)-\eta_1(k,l+1)-\eta_2(k,l)=2\pi\frac{\Phi}{\Phi_0}\equiv\theta,$$

[a)]Electronic mail: danielh@sci.kun.nl

where Φ is the flux through the unit cell and $\Phi_0 = hc/e$. Using Landau's gauge $\eta_1(k,l)=0$, $\eta_2(k,l)=\theta k$ and the separation ansatz $\Psi(k,l)=e^{i\beta l}g(k)$ we derive the well-known Harper equation

$$g(k+1)+g(k-1)+2\cos(2\pi\theta k+\beta)g(k)=Eg(k).$$

In the mathematical literature the corresponding operator is called the (discrete) almost-Mathieu operator.

Let us describe H_{sq} in a more algebraic way by introducing the magnetic translation operators[12]

$$\begin{aligned} U\Psi(k,l) &= e^{i\eta_1(k,l)}\Psi(k+1,l), \\ V\Psi(k,l) &= e^{i\eta_2(k,l)}\Psi(k,l+1), \end{aligned} \tag{2}$$

which obey the Heisenberg commutation relation $UV=e^{2\pi i\theta}VU$. So we can write the Hamiltonian of (1) as $H_{\mathrm{sq}}=U+U^*+V+V^*$. In fact, (2) can be seen as a representation of the rotation algebra

$$A(\theta)=\left\{ \sum_{-\infty}^{\infty} a_{kl}v^k u^l \,\middle|\, a_{kl} \text{ rapidly decreasing} \right\},$$

generated by two abstract unitaries u and v satisfying

$$uv=\exp[2\pi i\theta]vu \tag{3}$$

first introduced for purely mathematical reasons.

Let us introduce some convenient notation for products of the unitaries u and v. These operators may be viewed as Weyl operators $w(m)$, $m\in\mathbb{Z}^2$ for discrete position and momentum, where the flux plays the role of the Planck constant.[13]

$$\begin{gathered} w(1,0)=u, \quad w(0,1)=v, \\ w(m+n)=\gamma^{-\sigma(m,n)}w(m)w(n) \quad (m,n\in\mathbb{Z}^2), \\ \gamma=\exp[i\pi\theta], \end{gathered} \tag{4}$$

where σ denotes the standard discrete symplectic form, $\sigma(m,n)=m_1n_2-m_2n_1$. The adjoint operation is simply expressed as

$$w(n)^*=w(n)^{-1}=w(-n). \tag{5}$$

We study the following family of Hamiltonians (self-adjoint operators):

$$\mathcal{H}_c=\sum_{m\in\mathcal{D}} c_m w(m) \tag{6}$$

with $\mathcal{D}=\{(0,\pm1),(\pm1,0),(\pm1,\pm1)\}$ and $c_m^*=c_{-m}\in\mathbb{C}$.

The article is organized as follows. Section II is devoted to the expansion coefficients of powers of $\mathcal{H}_c$ with respect to the Weyl operators (4), since they play a crucial role in our treatment. Actually, all interpretations and results of this section extend to more general Hamiltonians. In Sec. III we study $\mathcal{H}_c$ as element of the rotation algebra $A(\theta)$ and the behavior of spectral properties depending on θ. In Sec. IV we discuss the model with next nearest-neighbor interaction on the rectangular lattice and the model with nearest-neighbor interaction on the triangular lattice in a unified view. This is followed by some concluding remarks.

II. EXPANSION COEFFICIENTS

The expansion coefficients of powers of $\mathcal{H}_c$ with respect to the Weyl operators can be seen as a generalization of the binomial coefficients, leading to a geometric interpretation of them. We derive an analytic expression for the expansion coefficients.

A. Definition and symmetries

The well-known binomial coefficient has many different enumerative, geometric and algebraic meanings. Newton's binomial formula is one way to define it,

$$(a+b)^n=\sum_{k=0}^{n}\binom{n}{k}a^k b^{n-k},$$

where a and b commute. Straightforward generalization yields to the multinomial coefficient. A ''q analog'' of the binomial coefficient first appeared in the literature in Ref. 14. Denote $\mathbb{Z}[u,v,\gamma]$ the ring generated by elements u, v and γ with relations[15]

$$uv=\gamma^2 vu, \quad \gamma u=u\gamma, \quad \gamma v=v\gamma,$$

then the ''q-binomial coefficient'' is uniquely defined by

$$(u+v)^n=\sum_{k=0}^{n}\binom{n}{k}_{\gamma}u^k v^{n-k},$$

where $\binom{n}{k}_\gamma$ is an element in $\mathbb{Z}[\gamma]$ (=the center of $\mathbb{Z}[u,v,\gamma]$). For the q-binomial coefficient a formula is known.[10,16] However, less is known about the q-multinomial coefficient or other sorts of generalizations.

The expansion coefficients for powers of $u+u^{-1}+v+v^{-1}$ lie also in $\mathbb{Z}[\gamma]$ and can be seen as a generalization of the q-binomial coefficients. This idea extends to any (self-adjoint) element $\mathcal{H}$ in the (finite) span of $\{w(n)|n\in\mathbb{Z}^2\}$. The expansion coefficient $(n;k)_{\mathcal{H}}$ for the kth power of $\mathcal{H}$ is uniquely defined by

$$\mathcal{H}^k=\left(\sum_{n\in\mathbb{Z}^2}c_n w(n)\right)^k=\sum_{n\in\mathbb{Z}^2}(n;k)_{\mathcal{H}}w(n), \tag{7}$$

where $(n;k)_{\mathcal{H}}$ again belongs to $\mathbb{Z}[\gamma]$. The second sum is also finite, since only a finite number of $(n;k)_{\mathcal{H}}$ are nonzero.

We are especially interested in the expansion coefficients for the powers of $\mathcal{H}_c$ defined in (6). In the following we restrict ourselves to this class and suppress the dependence on $\mathcal{H}_c$ whenever there is no ambiguity.

Writing ${\mathcal{H}_c}^{k+1}$ as ${\mathcal{H}_c}^k\mathcal{H}_c$ and $\mathcal{H}_c{\mathcal{H}_c}^k$ with coefficients $(n;k+1)$ and $(n;k)$ we get two ''conjugated'' recurrence relations

$$(n;k+1)=\sum_{m\in\mathcal{D}}c_m\gamma^{\sigma(n,m)}(n-m;k)=\sum_{m\in\mathcal{D}}c_m\gamma^{-\sigma(n,m)}(n-m;k) \tag{8}$$

with initial condition $(n;0)=\delta_n$.

Proposition 2.1: Let $\mathcal{H}_c$ be defined by (6). Then $(n;k)$ is a polynomial in c_m with real coefficients and therefore $(n;k)_{\mathcal{H}_c}=\overline{(-n;k)}_{\mathcal{H}_c}$ holds, particularly $(n;k)_{\mathcal{H}_c}=(-n;k)_{\mathcal{H}_c}\in\mathbb{R}$ for $c_{m\in\mathcal{D}}\in\mathbb{R}$.

Proof: Since we have the real initial condition $(n;0)=\delta_n$ and the recurrence relation

$$(n;k+1)=\sum_{m\in\mathcal{D}}c_m(\gamma^{\sigma(n,m)}+\gamma^{-\sigma(n,m)})/2(n-m;k), \tag{9}$$

obtained from (8), we get by induction that $(n;k)$ is a polynomial in c_m with real coefficients. The second property follows from (5) and the self-adjointness of $\mathcal{H}_c$,

$$\sum_{n\in\mathbb{Z}^2}(n;k)w(n)=\mathcal{H}_c{}^k=(\mathcal{H}_c{}^k)^*=\sum_{n\in\mathbb{Z}^2}\overline{(-n;k)}w(n). \qquad \square$$

Remark: The Hamiltonian $\mathcal{H}_c$ for a particle on a lattice in a homogeneous magnetic field has real coefficients c_m. For Hamiltonians $\mathcal{H}_c$ with additional symmetries in the parameters c_m we get further relations for the coefficients $(n;k)_{\mathcal{H}_c}$.

Proposition 2.2: Let $\Phi\in GL(2,\mathbb{Z})$. If c is such that for all $m\in\mathcal{D},c_m=s^{-1}c_{\Phi(m)}$ holds, then $(n;k)_{\mathcal{H}_c}=s^k(\Phi(n);k)_{\mathcal{H}_c}$.

A symmetry of $\mathcal{H}_c$ gives rise to such an automorphism. For example in the square lattice case the rotation by $\pi/2$ induces $((n_1,n_2);k)=((-n_2,n_1);k)$.

B. Geometric interpretation

Each coefficient $(n;k)$ may be identified with a weighted sum of all paths from (0,0) to (n_1,n_2) in $\mathbb{Z}^2$ in exactly k steps belonging to $\mathcal{D}$ — now regarded as a set of steps. This can be seen in the following way. If one expands the product $\mathcal{H}_c{}^k$ each summand may be mapped on a path of length k starting at (0,0) by identifying $w(m)$ with the step $m\in\mathcal{D}$. This is obviously a one to one mapping between the summands of $\mathcal{H}_c{}^k$ and the set $\mathcal{D}_k$={paths of length k starting at (0,0) with steps in $\mathcal{D}$ only}.

Further one can extend the map from $\mathcal{D}_k$ to the summands in the following way. Every path of length k with steps only in $\mathcal{D}$ is mapped on a summand of $\mathcal{H}_c$ such that two paths have the same image if and only if they differ by a translation. We index a summand by its (up to the translation) unique path v, i.e., S_v. Let the path v be composable with ω, i.e., the end point of ω agrees with the starting point of v and let us denote the composition by $v\circ\omega$. Then we have $S_vS_\omega=S_{v\circ\omega}$ and $S_v^{-1}=S_{v^{-1}}$. Therefore the map is a groupoid homomorphism with the composition of two paths as groupoid structure in the domain and the usual multiplication in the range. Next we define the standard path ρ_n from (0,0) to (n_1,n_2) as the unique path of length $|n_1|+|n_2|$ changing its direction only at the vertex $(n_1,0)$. Let $\mathcal{D}_k(n)=\{v\in\mathcal{D}_k|v$ and ρ_n^{-1} are composable}. Since $w(n)=\gamma^{-n_1n_2}S_{\rho_n}$, the coefficient $(n;k)$ can be written as

$$(n;k)=\gamma^{n_1n_2}\sum_{v\in\mathcal{D}_k(n)}S_{\rho_n^{-1}}S_v=\gamma^{n_1n_2}\sum_{v\in\mathcal{D}_k(n)}S_{\rho_n^{-1}\circ v}\,.$$

For a path v let $\tilde{c}_v=\Pi_{m\in\mathcal{D}}\,c_m^{m(v)}$, where $m(v)$ is the number of steps of sort m in v. Then we define the weight of a closed path σ by $\tilde{c}_\sigma\gamma^{2A(\sigma)}$, where the oriented area $A(\sigma)$ enclosed by σ is defined by $A(\sigma)=\int_\sigma x\,dy$. The motivation for this definition is, that every path from (0,0) to (n_1,n_2) can be transformed into the standard path ρ_n by interchanging steps, reducing consecutive forward and backward steps and splitting the steps $(\pm1,\pm1)$ into $(\pm1,0)$ and $(0,\pm1)$. Every action gives a factor, such that in the end $S_v=\tilde{c}_{\rho_n^{-1}\circ v}\gamma^{2A(\rho_n^{-1}\circ v)}S_{\rho_n}$ holds, i.e.,

Proposition 2.3: $(n;k)$ is equal to the weighted sum over all paths v in $\mathcal{D}_k(n)$ as follows

$$(n;k)=\tilde{c}_{\rho_n}\gamma^{n_1n_2}\sum_{v\in\mathcal{D}_k(n)}S_{v_n}S_{\rho_n^{-1}}=\gamma^{\,n_1n_2}\sum_{v\in\mathcal{D}_k(n)}\tilde{c}_v\,\gamma^{2A(\rho_n^{-1}\circ v)}.$$

Proof: For $k=0$ the agreement is obvious. Further one verifies that the weighted sum of paths defined above fulfill the same recurrence relation as $(n;k)$, see (8). Therefore, by induction over k the proof is complete. $\square$

C. An analytic expression for $(n;k)$

The recurrence relation (8) involves two degrees of freedom and has complex coefficients. It seems that there exists no canonical way in the literature to solve it. We make some kind of discrete Fourier transform in such a way that the new coefficients obey a recurrence relation in which one (out of two) degree of freedom is constant. This leads to a closed formula for the expansion coefficients.

Let $\mu\in\mathcal{D}$. We define the (partial) ''Fourier transform'' in direction μ by

$$[d;k]_{(\omega,\mu)}=\sum_{\langle\mu,n\rangle=d}\gamma^{\sigma(\mu,n)(\omega+d)/\langle\mu,\mu\rangle}(n;k), \tag{10}$$

where σ is the symplectic form of (4) and the sum runs over n. If γ is a qth root of unity, then the inverse of this transformation is given by

$$(n;k)=\frac{1}{2q}\int_0^{2q}\gamma^{-\sigma(\mu,n)(\omega+\langle\mu,n\rangle)/\langle\mu,\mu\rangle}[\langle\mu,n\rangle;k]_{(\omega,\mu)}d\omega \tag{11}$$

and by continuous prolongation otherwise. Actually, for a given k, the integral can be replaced by a finite sum. The ''Fourier-transformed'' coefficients fulfill a recurrence relation induced by (8). Fix $\omega\in\mathbb{Z}$, $\mu\in\mathcal{D}$, then we get

$$\begin{aligned}[d;k+1]&=\sum_{\langle\mu,n\rangle=d}\gamma^{\sigma(\mu,n)(\omega+d)/\langle\mu,\mu\rangle}\sum_{m\in\mathcal{D}}c_m\gamma^{-\sigma(m,n-m)}(n-m;k)\\
&=\sum_{\substack{m\in\mathcal{D}\\ \langle\mu,n\rangle=d}}\sum c_m\gamma^{[\sigma(\mu,n)(\omega+d)-\langle\mu,m\rangle\sigma(\mu,n-m)+\sigma(\mu,m)(d-\langle\mu,m\rangle)]/\langle\mu,\mu\rangle}(n-m;k)\\
&=\sum_{\substack{m\in\mathcal{D}\\ \langle\mu,n\rangle=d}}\sum c_m\gamma^{\sigma(\mu,m)[\omega+2d-\langle\mu,m\rangle]/\langle\mu,\mu\rangle+\sigma(\mu,n-m)[\omega+d-\langle\mu,m\rangle]/\langle\mu,\mu\rangle}(n-m;k)\\
&=\sum_{m\in\mathcal{D}}c_m\gamma^{\sigma(\mu,m)[\omega+2d-\langle\mu,m\rangle]/\langle\mu,\mu\rangle}[d-\langle\mu,m\rangle;k],\end{aligned} \tag{12}$$

where we first used the recurrence relation (8) and second the identity $\langle\mu,\mu\rangle m=\langle\mu,m\rangle\mu+\langle\mu_s,m\rangle\mu_s$ with $\mu_s=(\mu_2,-\mu_1)$ and therefore

$$\sigma(\langle\mu,\mu\rangle m,n-m)=\langle\mu,m\rangle\sigma(\mu,n-m)-\sigma(\mu,m)(d-\langle\mu,m\rangle).$$

Obviously, ω is constant in the recurrence relation (12). The initial condition transforms to $[d;0]=\delta_d$, hence it is independent of the ''frequency'' ω. Notice that $\langle\mu,m\rangle$ have values only in $\{0,\pm1,\pm2\}$. Therefore the recurrence relation has at most five terms and is solved by using the path picture. We will do this for $\mu=(1,0)$. Let $P_d^k:=\{v\in\{-1,0,1\}^k|\Sigma_l v_l=d\}$, then

$$[d;k]_{(\omega,\mu)}=\sum_{v\in P_d^k}\prod_{l=1}^{k}a_v(l)=\langle e_d,A^ke_0\rangle$$

with $a_v(l):=\tilde{a}(t,v_l):=c_{(v_l,1)}\gamma^{\omega+2t-v_l}+c_{(v_l,-1)}\gamma^{-(\omega+2t-v_l)}+c_{(v_l,0)}$ and $t=\Sigma_{s=1}^{l}v_s$, where all $c_m=0$ for $m\notin\mathcal{D}$. In the last expression A is the tridiagonal matrix $A_{ts}=\tilde{a}(t,t-s)$ and e_d denote the canonical basis vectors in $\ell^2(\mathbb{Z})$. The inverse Fourier transform (11) leads to an involved but analytic expression for $(n;k)$, see also the Appendix.

III. ON SPECTRAL PROPERTIES OF $\mathcal{H}_c$

The spectral properties of $\mathcal{H}_c$ depend strongly on θ (i.e., on the magnetic flux). For rational θ the spectrum is the union of a finite number of closed intervals. Whether these intervals are separated by a gap for arbitrary rational θ, is the subject of Sec. III A. We reformulate this question in algebraic words and give an answer in terms of the generalized binomial coefficients. Then we show that the quantitative estimate of the gap widths in the rational case implies the Cantor set property for some irrational values of θ.

A. Rational magnetic flux

Let us recall some elementary properties of the (C^*-) algebra $A(\theta)$, defined in Sec. I. Let $\mathbb{T}$ denote the unit circle in the complex plane. There exists a canonical action $z\rightarrow\phi_z$ of $\mathbb{T}^2$ on $A(\theta)$, such that $\phi_z(u)=z_1 u$ and $\phi_z(v)=z_2 v$. Any element of $A(\theta)$ fixed by ϕ is a scalar multiple of the identity id. There is a unique tracial state τ of $A(\theta)$ invariant under ϕ. This yields to a noncommutative differential structure and by analogy $A(\theta)$ is called the noncommutative torus, for further properties see Ref. 17.

If θ is rational, $\theta=p/q$ with p and q relative prime integers, then there is an irreducible representation Π of $A(p/q)$ on $\mathbb{C}^q$ such that Πv is the cyclic shift and $\Pi u=\mathrm{diag}(1,\gamma^2,\ldots,\gamma^{2q-2})$. It is not difficult to see, that every irreducible representation of $A(p/q)$ is unitarily equivalent to $\Pi_z=\Pi\phi_z$ for some $z\in\mathbb{T}^2$, and that two such representations Π_z and $\Pi_{\tilde{z}}$ are unitarily equivalent if, and only if, $\tilde{z}_i=\gamma^{2n_i}z_i$ for some $n\in\mathbf{I}_q=\{0,1,...,q-1\}^2$. [Since u^q and v^q are central in $A(p/q)$ if $\gamma^{2q}=1$, the image of $A(p/q)$ in any irreducible representation is linearly spanned by q^2 monomials $w(n)$, $n\in\mathbf{I}_q$ defined in Sec. II. Hence the representation is at most of dimension q. Because of the commutation relation (3) $vuv^{-1}=\gamma^2u$ we have the property, that if $z_1\in\mathbb{T}$ is an eigenvalue of u then so is γ^2z_1. Hence there must be a basis in which the image of u is $z_1\Pi u$, and then, after changing the basis element by a phase factor, the image of v is $z_2\Pi v$, as desired.]

The roles of u and v are completely symmetric, the corresponding bases are related by discrete Fourier transform.[13] Let $w(n)$ be defined by (4) in Sec. I.

Lemma 3.1: $\{\Pi_z w(n)\}_{n\in\mathbf{I}_q}$ *form a basis of* $\Pi_z A(p/q)\cong M_q(\mathbb{C})$.

Proof: Without loss of generality we may assume $z_1=z_2=1$. Since the representation $\Pi A(p/q)$ has dimension q, we have to prove the linear independence of $\{\Pi w(n)\}_{n\in\mathbf{I}_q}$ only.

Let $a_n\in\mathbb{C}$ such that $\Sigma_{n\in\mathbf{I}_q}a_n\Pi w(n)=0$ holds, then all its matrix elements $(d,d+s(\mathrm{mod}\ q))$ are zero $(0\leqslant d,s\leqslant q-1)$, i.e.,

$$0=\sum_{n\in\mathbf{I}_q}a_n\gamma^{-n_1n_2+2n_1d}\delta(s-n_2)=\sum_{n_1=0}^{q-1}a_{(n_1,s)}\gamma^{n_1(2d+s)}.$$

Hence we are left with

$$\begin{aligned}0&=\sum_{d=0}^{q-1}\gamma^{2dt}\sum_{n_1=0}^{q-1}a_{(n_1,s)}\gamma^{n_1(2d+s)}\\&=\sum_{n_1=0}^{q-1}a_{(n_1,s)}\gamma^{n_1s}\sum_{d=0}^{q-1}\gamma^{2d(n_1-t)}\\&=\sum_{n_1=0}^{q-1}a_{(n_1,s)}\gamma^{n_1s}q\,\delta(n_1-t)=a_{(t,s)}\gamma^{ts}q\end{aligned}$$

and therefore all a_n are zero. □

The spectrum of $\mathcal{H}_c$ [in $A(\theta)$] is of course the union of the images of $\mathcal{H}_c$ in a complete set of irreducible representations of $A(\theta)$. With the representations for rational θ above we have

$$\mathrm{Spec}(\mathcal{H}_c)=\bigcup_{z\in\mathbb{T}^2}\mathrm{Spec}(\Pi_z\mathcal{H}_c)$$

and for finite dimension, the spectra are determined by the characteristic polynomials. For $\mathcal{H}_c$ defined in (6) these polynomials behave nicely as a function of the irreducible representations. In the case of the square lattice Hamiltonian this was first observed in Ref. 18, and afterwards in several other cases similar behavior has also been observed (see Refs. 8 and 13).

Theorem 3.2: *Let $\theta=p/q$, p and q being relative prime integers. Then the characteristic polynomial* ch_z *of* $\Pi_z\mathcal{H}_c$ *as a function of* $z\in\mathbb{T}^2:z\to\mathrm{ch}_z(\cdot)$ *fulfills the Chambers relation*[18]

$$\mathrm{ch}_z(x)=f(x)-h(z), \tag{13}$$

where $f(x)=a_0+a_1x+\ldots+a_qx^q$, $h(z)=\Sigma_{m\in\mathcal{D}}b_mz^{qm}$ *and* $z^{qm}=z_1^{qm_1}z_2^{qm_2}$. *The coefficients are given by*

$$b_m=(-1)^{pq}(qm;q)=(-1)^{pq}c_m^q \quad \text{for } m\in\{-1,1\}^2,$$

$$b_m=(qm;q)=2\varepsilon^qT_q(c_m/2\varepsilon) \quad \text{for } m\in\{(\pm1,0),(0,\pm1)\}$$

with $\varepsilon=\sqrt{c_{(m_1+m_2,m_2+m_1)}c_{(m_1-m_2,m_2-m_1)}}$ *and T_q is the Chebyshev polynomial of degree q. Further the a_k fulfill*

$$\sum_{k=0}^{q}a_k(n;k)_{\mathcal{H}_c}=0 \quad \text{for } \|n\|_\infty<q. \tag{14}$$

Note that b_m is also well defined at $\varepsilon=0$ by continuous prolongation.

Proof: Using the properties of the rotation algebra $A(\theta)$, the characteristic polynomial can be written

$$\mathrm{ch}_z(x)=\det(x\ \mathrm{id}-\Pi_z\mathcal{H}_c)=\det\left(x\ \mathrm{id}-\sum_{m\in\mathcal{D}}c_mz^m\Pi w(m)\right).$$

First observe, because of $\mathrm{ch}_z(x)=\mathrm{ch}_{z\gamma^{2n}}(x)$, where $z\gamma^{2n}=(z_1\gamma^{2n_1},z_2\gamma^{2n_2})$, the characteristic polynomial has only powers of the form z^{qn}, $n\in\mathbb{Z}^2$. Since the determinant is homogeneous of degree q and any entry is of the form $t_0x+\Sigma_{m\in\mathcal{D}}\,t_mz^m$, $\mathrm{ch}_z(x)$ is a Laurent polynomial in z_1, z_2 and x with $\max\{\deg_{z_1},\deg_{z_2}\}+\deg_x\leq q$, where $\deg_*$ is the degree with respect to the variable. Hence the dependence on x and z splits

$$\mathrm{ch}_z(x)=f(x)-h(z)=\sum_{k=0}^{q}a_kx^k-\sum_{m\in\mathcal{D}}b_mz^{qm}.$$

Now we calculate the coefficients. The map $z\to\mathrm{ch}_z(\Pi_z\mathcal{H}_c)$ extends uniquely to an analytic function $\mathbb{C}^2\backslash\{0\}\to M_q(\mathbb{C}):z\to\Sigma_{n\in\mathbb{Z}^2}\,d_nz^n$, which is zero for $|z_1|=|z_2|=1$ and hence everywhere. In other words $d_n=0$, for every $n\in\mathbb{Z}^2$. Since

$$\begin{aligned}\mathrm{ch}_z(\Pi_z\mathcal{H}_c)&=\sum_{k=0}^{q}a_k\Pi_z\mathcal{H}_c^k-h(z)\Pi_z\mathrm{id}\\&=\sum_{k=0}^{q}a_k\sum_{n\in\mathbb{Z}^2}(n;k)\Pi_zw(n)-\sum_{m\in\mathcal{D}}b_mz^{qm}\Pi_z\mathrm{id}\\&=\sum_{n\in\mathbb{Z}^2}\sum_{k=0}^{q}a_k(n;k)z^n\Pi w(n)-\sum_{m\in\mathcal{D}}b_mz^{qm}\Pi\mathrm{id},\end{aligned}$$

the vanishing of the d_n's imply for $m\in\mathcal{D}$

$$0=\sum_{k=0}^{q} a_k(qm;k)\Pi w(qm)-b_m\Pi \mathrm{id}=(-1)^{pqm_1m_2}(qm;q)\Pi \mathrm{id}-b_m\Pi \mathrm{id},$$

and $0=\Sigma_{k=0}^{q}a_k(n;k)\ \Pi w(n)$, for $\|n\|_\infty<q$. Remember $\Pi w(qm)=(-1)^{pqm_1m_2}\Pi \mathrm{id}$, for $m\in\mathcal{D}$ and $a_q=1$ by the very definition of $\mathrm{ch}_z(x)$ and $(n;k)=0$ for $\|n\|_\infty>k$.

Since all $\Pi w(n)\neq 0$, we obtain (14). The value of $b_m=(-1)^{pqm_1m_2}(qm;k)$ is calculated in the Appendix. □

Remark: By the above argument, the coefficients $(n;q)$ vanish for $n\in\mathbb{Z}^2\{qm|m\in D\}$ with $\|n\|_\infty=q$ as already calculated in the Appendix.

For the doubly discrete quantum pendulum the above expression has been derived in Ref. 13 employing a different method. The Chambers relation (13) is crucial to prove the existence and estimate the size of the spectral gaps, since it reduces the problem to a finite-dimensional eigenvalue problem.

Theorem 3.3: *The spectrum of $\mathcal{H}_c\in A(p/q)$ consists of q disjoint bands if and only if*

$$\inf_{z\in\mathbb{T}^2}\{|a-b|\,\big|\,a\neq b\in \mathrm{Spec}(\Pi_z\mathcal{H}_c)\}>0. \tag{15}$$

Further this is a lower bound for the gap widths.

Proof: By the Chambers relation (13) we know that the spectrum of $\mathcal{H}_c$ is the preimage of the interval $[h_{\min},h_{\max}]=\{h(z)|z\in\mathbb{T}^2\}$ under the polynomial $f(x)$ of degree q, i.e., it is the union of q bands. They are disjoint if and only if the spectrum of $\Pi_z\mathcal{H}_c$ is not degenerate for the representation corresponding to $h_{\min}$ and $h_{\max}$. By continuity of $z\to\Pi_z$ these representations are not degenerate if and only if (15) holds. Obviously $\inf_{z\in\mathbb{T}^2}\{|a-b|\,\big|\,a\neq b\in \mathrm{Spec}(\Pi_z\mathcal{H}_c)\}$ is also an optimal lower bound for the gap widths. □

This also proves the following Corollary.

Corollary 3.4: The spectrum of $\mathcal{H}_c\in A(p/q)$ can only be degenerate in representations Π_z corresponding to extreme values of $h(z)$ and if it is not degenerate, then the infimum (15) is reached for every $z'\in\mathbb{T}^2$ with $h(z')=\max h(z)$ or for every $z''\in\mathbb{T}^2$ with $h(z'')=\min h(z)$.

For the almost Mathieu operator, Choi *et al.*[10] used an elegant method to obtain an estimate for (15). We employ and generalize it.

Lemma 3.5: Let B be a self-adjoint operator in a complex Hilbert space of dimension q. Then every eigenvalue of B is simple if and only if $\|g(B)\|\neq 0$ for every monic polynomial g of degree $q-1$. A lower bound for the difference of two (different) eigenvalues of B is given by

$$|a-b|\geq\frac{\inf\{\|g(B)\|\}}{(2\|B\|)^{q-2}},$$

where the infimum is taken over the set of monic polynomials g of degree $q-1$.

Proof: A monic polynomial of degree $q-1$ can be written as

$$g(x)=\prod_{j=1}^{q-1}(x-\varrho_j),$$

where $\varrho_j\in\mathbb{C}$ are the roots of g. Denote by $\kappa_1\leq\kappa_2\leq\cdots\leq\kappa_q$ the eigenvalues of B with each eigenvalue counted according to its multiplicity. As a consequence of the spectral theorem, the spectrum of $g(B)$ is given by the $1\leq k\leq q$ values $\Pi_{j=1}^{q-1}(\kappa_k-\varrho_j)$. Since $g(B)$ is normal we have

$$\|g(B)\|=\max_{1\leq k\leq q}\left\{\prod_{j=1}^{q-1}|\kappa_k-\varrho_j|\right\}$$

and therefore $\|g(B)\|=0$ if and only if $\{\kappa_1,\kappa_2,\ldots,\kappa_q\}\subset\{\varrho_1,\varrho_2,\ldots,\varrho_{q-1}\}$. Hence, if at least one eigenvalue of B is not simple then there exists one monic polynomial g of degree $q-1$ with $g(B)=0$. On the other hand, if all eigenvalues of B are simple, obviously $\{\kappa_1,\kappa_2,\ldots,\kappa_q\}\subset\{\varrho_1,\varrho_2,\ldots,\varrho_{q-1}\}$ can never happen.

Let $N\neq M\in\{1,...,q\}$. With $|\kappa_i-\kappa_j|\leqslant 2\|B\|$ we get for the monic polynomial $g_N(x)=\Pi_{j=1,j\neq N}^{q}(x-\kappa_j)$

$$\begin{aligned}\|g_N(B)\| &= \max_{1\leqslant k\leqslant q}\left\{\prod_{j=1,j\neq N}^{q}|\kappa_k-\kappa_j|\right\}\\ &=\prod_{j=1,j\neq N}^{q}|\kappa_N-\kappa_j|\\ &=|\kappa_N-\kappa_M|\prod_{\substack{j=1\\ j\neq N,M}}^{q}|\kappa_N-\kappa_j|\leqslant|\kappa_N-\kappa_M|(2\|B\|)^{q-2}\end{aligned}$$

by applying the spectral theorem and using that $g_N(B)$ is normal. Therefore $\inf\{\|g(B)\|\}$ over all monic polynomials of degree $q-1$ fulfill the inequality of the lemma.

Now we are left with the following situation. Let g be an arbitrary monic polynomial $g(x)=a_0+a_1x+\cdots+a_{q-1}x^{q-1}$ of degree $q-1$. Then a lower bound of $\|g(\Pi_z\mathcal{H}_c)\|$ leads to a lower bound for the spectral gaps of $\mathcal{H}_c$. By Corollary 3.4 we need only to consider representations Π_z, where $h(z)$ has a global extremum.

First we give an argument for $g(\Pi_z\mathcal{H}_c)\neq 0$. Suppose that there exists such a g with $g(\Pi_z\mathcal{H}_c)\equiv 0$. This means that the system of linear equations, arising from the coefficients of the basis $(w(n))_{n\in\mathbf{I}_q}$

$$\begin{aligned}0&=\sum_{m\in\mathbb{Z}^2}\sum_{k=0}^{q-1}z^{qm}\gamma^{q\sigma(n,m)+q^2m_1m_2}(n-qm;\kappa)a_k\\ &=\sum_{m\in\mathcal{D}_+}\sum_{k=0}^{q-1}z^{qm}(-1)^{p\sigma(n,m)+pqm_1m_2}(n-qm;\kappa)a_k,\end{aligned}\tag{16}$$

with $z^{qm}=z_1^{qm_1}z_2^{qm_2}$ and $\mathcal{D}_+=\{0,1\}^2$ has a nontrivial solution $(a_0,..,a_{q-1})$.[19] Whenever a nontrivial solution exists, there is at least one with $a_{q-1}=1$ [since $g(x)|_{x=\Pi_z\mathcal{H}_c}=0\Rightarrow g(x)(x-b)|_{x=\Pi_z\mathcal{H}_c}=0$].

Hence $g(\Pi_z\mathcal{H}_c)\neq 0$ if we find a linear combination (α_l) of the equations $(16)_n$ such that

$$\left|\sum_{l=1}^{s}\alpha_l\sum_{m\in\mathcal{D}_+}\sum_{k=0}^{q-1}z^{qm}(-1)^{p\sigma(n,m)-pqm_1m_2}(n_l-qm;k)a_k\right|\geqslant 1\tag{17}$$

holds. Moreover, such a linear combination already gives a lower bound for $\|g(\Pi_z\mathcal{H}_c)\|$.

Lemma 3.6: Let $\theta=p/q$ with p and q relative prime integers and $z\in\mathbb{T}^2$. Suppose there exists a linear combination $\alpha_l(z)$, such that (17) holds for any arbitrary monic polynomial g of degree $q-1$, then the eigenvalues of $\Pi_z\mathcal{H}_c$ are not degenerate and a lower bound for the distance between two of them is given by

$$(2^{q-2}s\|\Pi_z\mathcal{H}_c\|^{q-2}\|\alpha(z)\|_\infty)^{-1},$$

where s is the number of nonzero coefficients $\alpha_l(z)$ and $\|\alpha(z)\|_\infty$ its supremum.

Proof: We calculate a lower bound for $\|g(\Pi_z\mathcal{H}_c)\|$ and then apply Lemma 3.5. For a given linear combination (α_l) of Eq. (16) and fixed z we have

$$\left\| \sum_{l=1}^{s} \alpha_l w(-n_l) \right\| \leqslant \sum_{l=1}^{s} |\alpha_l| \|w(-n_l)\| \leqslant s \|\alpha\|_\infty .$$

Since $\|\Pi_z w(n)\| \geqslant \sqrt{\mathbf{Tr}}(\Pi_z w(n)) = \delta_n q^{-1}$ for every $n \in \mathbf{I}_q$, we have with $\tau := p\sigma(n,m) - pqm_1 m_2$,

$$\begin{aligned}
\|g(\Pi_z \mathcal{H}_c)\| \|\alpha\|_\infty s &\geqslant \|g(\Pi_z \mathcal{H}_c)\| \left\| \sum_{l=1}^{s} \alpha_l \Pi_z w(-n_l) \right\| \\
&\geqslant \left\| \sum_{n \in \mathbf{I}_q} \sum_{m \in D_+} \sum_{k=0}^{q-1} z^{qm}(-1)^\tau a_k(n-qm;k) \Pi_z w(n) \sum_{l=1}^{s} \alpha_l \Pi_z w(-n_l) \right\| \\
&\geqslant q^{-1} \left| \mathbf{Tr} \left(\sum_{k=0}^{q-1} \sum_{l=1}^{s} \alpha_l \sum_{m \in \mathcal{D}_+} z^{qm}(-1)^\tau a_k(n_l-qm;k) \Pi_z w(0) \right) \right| \\
&\geqslant \left| \sum_{k=0}^{q-1} \sum_{l=1}^{s} \alpha_l \sum_{m \in \mathcal{D}_+} z^{qm}(-1)^\tau a_k(n_l-qm;k) \right| .
\end{aligned}$$

Under the assumption of the Lemma the last term is greater than 1 and therefore we obtain an estimate for $\|g(\Pi_z \mathcal{H}_c)\|$. By Lemma 3.5 the spectrum of $\Pi_z \mathcal{H}_c$ is not degenerate and two eigenvalues are separated at least by □

$$(2^{q-2} s \|\Pi_z \mathcal{H}_c\|^{q-2} \|\alpha(z)\|_\infty)^{-1}.$$

Because of the Chambers relation (13) the spectrum of $\mathcal{H}_c$ is the union of the q bands $[\lambda_1,\mu_1]$, $[\mu_2,\lambda_2]$, $[\lambda_3,\mu_3]$,… where $\lambda_1 \leqslant \mu_1 \leqslant \mu_2 \leqslant \lambda_2 \leqslant \dots$ is the spectrum of $\Pi_z \mathcal{H}_c$ with $h(z)$ maximal and with $h(z)$ minimal, respectively. Thus the spectral gaps can be divided into two classes, one corresponding to the maximum and the other to the minimum of $h(z)$. An estimate for the gap widths in such a class can be calculated in the corresponding representation. Therefore by Lemma 3.6 the following Theorem holds.

Theorem 3.7: *Let $\theta = p/q$ with p and q relative prime integers. Suppose for $z \in \mathbb{T}^2$ with $h(z) = \min_{z'} h(z')$ or $h(z) = \max_{z'} h(z')$ there exists a linear combination α_l, such that (17) holds for z and any arbitrary monic polynomial g of degree $q-1$, then the spectral gaps of the corresponding class are open and are at least of size*

$$(2^{q-2} s \|\Pi_z \mathcal{H}_c\|^{q-2} \|\alpha(z)\|_\infty)^{-1}, \tag{18}$$

where s is the number of nonzero coefficients α_l and $\|\alpha\|_\infty$ its supremum.

At first sight it seems difficult to find such a linear combination $\alpha_l(z)$, since the a_n are arbitrary except for $a_{q\text{-}1} = 1$ and the ''behavior'' of coefficients $(n;k)$ is complex. Moreover, this has to be done for every ''periodic length'' $q \in \mathbb{N}$. A solution is provided in many cases as follows.

Theorem 3.8: *Let $\theta = p/q$ with p and q relative prime integers and $\mathcal{H}_c$ with $c_\mu \in \mathbb{R}$. Then for every $z \in \mathbb{T}^2$ with $z_m^{2q} \neq 1$, $(qm-m;q-1)_{\mathcal{H}_c} \neq 0$ and $m = (1,0)$ or $(0,1)$, there exists a linear combination $\alpha_l(z)$ of two equations such that (17) holds and*

$$\|\alpha(z)\|_\infty = |(1 - z_m^{2q})(qm-m;q-1)_{\mathcal{H}_c}|^{-1}.$$

Proof: First let $m = (1,0)$ and $z_1^{2q} \neq 1$. Because of Proposition 2.1 we have $(n;k) = (-n;k)$. Therefore Eq. (16) with $n = m$ and $n = (q-1)m$, respectively, leads to

$$0 = \sum_{k=0}^{q-1} (m;k) a_k + z_1^q (qm-m;q-1) a_{q-1},$$

$$0 = \sum_{k=0}^{q-1} z_1^q(m;k)a_k + (qm-m;q-1)a_{q-1}.$$

Taking $\alpha_{(q-1,0)} = 1/(1-z_1^{2q})(qm-m;q-1)$ and $\alpha_{(1,0)} = -z_1^q\alpha_{(q-1,0)}$, we obtain such a linear combination.

If $z_2^{2q} \neq 1$ we repeat the above argument for $m=(0,1)$. □

The coefficients $(qm-m;q-1)$ are given by a straightforward calculation. For $m=(1,0)$ the partial Fourier transformed coefficient $[q-1;q-1]_{(m,\omega)}$ is given by $[q;q]_{(m,\omega)}/(c_{(10)} + c_{(11)}\gamma^{\omega-1} + c_{(1-1)}\gamma^{-\omega+1})$, where $[q;q]_{(m,\omega)}$ has been calculated in the Appendix. The inverse Fourier transformation leads then to $(qm-m;q-1)$, thereby several cases depending on c have to be distinguished.

B. Quantitative continuity of the spectrum

The spectral gap boundaries of a normal element in $A(\theta)$ are continuous in the Hausdorff metric as a function of the magnetic field.[20] For a large class of them even more qualitative properties have been proved. It was first shown in Ref. 10 that the spectral gap boundaries of the almost Mathieu operator is Hölder continuous with exponent 1/3. This result was extended in Ref. 21 to a larger class and improved to the Hölder exponent 1/2, which is optimal in view of the semiclassical analysis as pointed out in Ref. 22. Therein Lipshitz continuity of the spectrum was proven for elements in certain ''Sobolev classes'' of $A(\theta)$. The Lipshitz constant depends on the width of the corresponding spectral gap and diverges near values of θ for which the gap closes. For the almost Mathieu operator more about the continuity and measure of its spectrum is known, see, e.g., Ref. 5 and references therein. Following Ref. 10, we use the quantitative continuity to conclude from spectral gaps for rational values of θ to a possibly large class of irrational values.

The result in Ref. 21 does not cover all Hamiltonians $\mathcal{H}_c$, though the extension to it is possible.[23] We will state the result only. Let $f:\mathbb{R}\to\mathbb{R}$ and $h:\mathbb{R}\to\mathbb{C}$ continuous differentiable 2π-periodic functions. For θ, $\beta\in\mathbb{R}$ and $h_n = h(2\pi\theta n-\beta)$, $f_n = f(2\pi\theta n-\beta)$ define a Jacobi matrix by

$$(H_{f,h}^{\theta,\beta}\phi)(n) = \overline{h_{n+1}}\phi(n+1) + f_n\phi(n) + h_n\phi(n-1)$$

and denote the union of spectra $\cup_{\beta\in\mathbb{R}}\mathrm{Spec}(H_{f,h}^{\theta,\beta})$ by $\sigma_{fh}(\theta)$.

Theorem 3.9: *Let f, h as above and $M_{fh} = 2\pi(2\|h'\|_\infty + \|f'\|_\infty)$. Then the Hausdorff distance between $\sigma_{fh}(\theta)$ and $\sigma_{fh}(\theta')$, with $\theta,\theta'\in\mathbb{R}$ is bounded by*

$$\mathrm{Dist}(\sigma_{fh}(\theta),\sigma_{fh}(\theta')) \leq 2\sqrt{5\|h\|_\infty M_{fh}|\theta-\theta'|} + M_{fh}|\theta-\theta'|.$$

For suitable f and h, the spectrum of $\mathcal{H}_c$ is given by $\sigma_{fh}(\theta)$ as follows. Let $\beta\in\mathbb{R}$ and Π_β be the representation of $A(\theta)$ in $l^2(\mathbb{Z})$ taking u into the twosided shift and v into the operator of multiplication by the function $s\to\exp 2\pi i(s\theta+\beta)$. The direct integral of these representations is faithful, and so

$$\mathrm{Spec}\ \mathcal{H}_c(\theta) = \bigcup_{\beta\in\mathbb{R}} \mathrm{Spec}\ \Pi_\beta\mathcal{H}_c(\theta).$$

For convenience write h_θ^β for $\Pi_\beta\mathcal{H}_c(\theta)$. [Since $A(\theta)$ is simple if θ is irrational, for any β, Π_β is faithful and $\mathrm{Spec}\ \mathcal{H}_c = \mathrm{Spec}\ h_\theta^\beta$, in that case. In any case, the set of representations $\{(\mathrm{Ad}\ M_y)\Pi_\beta; y\in\mathbb{T},\beta\in\mathbb{R}\}$, where M_y denotes the multiplication operator $s\to y^s$, is invariant under the canonical action ϕ of $\mathbb{T}^2$ on $A(\theta)$, and so the proper ideal $\cap_\beta \ker\Pi_\beta$ of $A(\theta)$ is invariant under this action. If this ideal were nonzero, it would contain a positive element fixed under Φ (since $\mathbb{T}^2$ is compact), which would be a nonzero scalar, and the ideal would be all of $A(\theta)$. This shows $\cap_\beta\ker\Pi_\beta = 0$ as desired.]

Corollary 3.10: For $\theta,\theta'\in\mathbb{R}$,

$$\mathrm{Dist}(\mathrm{Spec}\ \mathcal{H}_c(\theta),\mathrm{Spec}\ \mathcal{H}_c(\theta'))\leqslant 4\tilde{c}\sqrt{5\pi|\theta-\theta'|}+4\pi\tilde{c}|\theta-\theta'|,$$

with $\tilde{c}=|c_{(1,1)}|+|c_{(1,-1)}|+\max(|c_{(1,0)}|,|c_{(0,1)}|)$.

Proof: Obviously h_θ^β is a Jacobi matrix of the form $H_{f,h}^{\theta,\beta}$ with estimates $\|h\|_\infty\leqslant|c_{(1,1)}|+|c_{(1,-1)}|+|c_{(1,0)}|$ and $M_{fh}\leqslant 4\pi(|c_{(1,1)}|+|c_{(1,-1)}|+|c_{(0,1)}|)$. Substitution of these values into the inequality of Theorem 3.9 completes the proof. □

C. On spectral gaps for certain Liouville numbers

In this section we prove the existence of the spectral gaps for irrational θ under the condition that this is true for all rational numbers in a neighborhood of θ. This argument works only for irrational numbers, which are sufficiently well approximated by the rationales, i.e., some Liouville numbers.

Theorem 3.11: *Let I be an open interval, such that for every* $p/q\in I$ *all* $q-1$ *gaps in the spectrum of* $\mathcal{H}_c\in A(p/q)$ *are at least of size* $s_I(q)\in\mathbb{R}_+$ *with p and q relative prime integers. If for* $\theta\in I$ *an arbitrarily large q exists with* $|\theta-p/q|\leqslant\{3^4\sqrt{5\pi}\ \tilde{c}^{\ 2}\}^{-1}s_I(q)^2$, *then all gaps of the spectrum of* $\mathcal{H}_c\in A(\theta)$ *are open.*

Recall, $\tilde{c}=|c_{(1,1)}|+|c_{(1,-1)}|+\max(|c_{(1,0)}|,|c_{(0,1)}|)$.

Proof: Fix $\varepsilon>0$. Let be $p/q\in I$, such that $|\theta-p/q|\leqslant\min\{[s_\theta(q)^2/3^4 5\pi\tilde{c}^2];5\varepsilon^2/\pi\}$, then by Theorem 3.9 we have

$$\begin{aligned}\mathrm{Dist}(\mathrm{Spec}\ \mathcal{H}_c(\theta),\mathrm{Spec}\ \mathcal{H}_c(p/q))&\leqslant 4\tilde{c}\sqrt{5\pi|\theta-\theta'|}+4\pi\tilde{c}|\theta-\theta'|\\&\leqslant 4\tilde{c}\sqrt{5\pi}(1+\varepsilon)\sqrt{|\theta-\theta'|}\\&\leqslant 4/9(1+\varepsilon)s_\theta(q).\end{aligned}$$

Furthermore, $\mathrm{Dist}(\mathrm{Spec}\ \mathcal{H}_c(\theta),\mathrm{Spec}\ \mathcal{H}_c(\theta'))\leqslant 4/9(1+\varepsilon)s_\theta(q)$ for any θ' between θ and p/q. Therefore, for $|\theta-p/q|<\min\{[s_\theta(q)^2/3^4 5\pi\tilde{c}^2];5\varepsilon^2/\pi\}$ some part of a gap from $\mathcal{H}_c\in A(p/q)$ is contained in a gap from $\mathcal{H}_c\in A(\theta')$ and hence open. □

For those values θ we obtain a topological description for Spec $\mathcal{H}_c$.

Corollary 3.12: Suppose the conditions of Theorem 3.11 hold, then the spectrum of $\mathcal{H}_c(\theta)$ *is a Cantor set for those irrational numbers* θ.

Proof: By Theorem 3.11 we have to prove that the gaps are dense in Spec $\mathcal{H}_c(\theta)$. This would follow from knowing that for $\theta=p/q\in I$ with $(p,q)=1$, the gaps in Spec $\mathcal{H}_c(\theta)$ are at most a distance $12\pi c_s/q$ apart, where we used $c_s=\sup_{m\in\mathcal{D}}|c_m|$. With other words, the length of any interval in the spectrum is at most $12\pi c_s/q$.

By the Weyl spectral variation inequality for Hermitian matrices (see Ref. 24), the distance between corresponding eigenvalues of $\Pi_z\mathcal{H}_c$ and $\Pi_{(1,1)}\mathcal{H}_c$ (numbered in decreasing order) is at most

$$\begin{aligned}\|\Pi_z\mathcal{H}_c-\Pi_{(1,1)}\mathcal{H}_c\|&\leqslant 2c_s(|1-z_1|+|1-z_2|+|1-z_1z_2|+|1-z_1/z_2|)\\&\leqslant 4c_s(|1-\exp(\pi i/q)|+|1-\exp(2\pi i/q)|)\leqslant 12c_s\pi/q,\end{aligned}$$

where we used that every irreducible representation is unitarily equivalent to one representation Π_z with $0\leqslant\arg(z_1)$, $\arg(z_2)\leqslant\pi/q$. Since each interval in Spec $\mathcal{H}_c$ consists of a set of such corresponding eigenvalues, the length of any interval is at most $12c_s\pi/q$. □

IV. MODEL DISCUSSION

In this section we investigate classes of $\mathcal{H}_c$ corresponding to tight-binding models on different lattices. In principle it is possible to calculate, for arbitrary parameters c, the critical point of the representation depending on part $h(z)$ of the Chambers relation (13) for every $\theta=p/q$. However many cases have to be distinguished and therefore no good insight of the behavior is obtained. In the following we make the substitution $z_1 \to \exp(i\alpha/q)$, $z_2 \to \exp(i\beta/q)$ and understand h as a function of α and β.

A. Rectangular lattice

Consider a tight-binding model on a rectangular lattice with next-nearest-neighbor interaction. The symmetry of a rectangular lattice and a homogenous magnetic field yields to $H_{\mathrm{rec}} = Au + Bv + C(\overline{\gamma} uv + \gamma uv^*) + \text{h.c.}$ with $A, B, C \in \mathbb{R}$.

Without second neighbor interaction $(C=0)$, the model reduces to the well-known Harper model (see Sec. I). It has been extensively studied by many authors. Results on the spectral measure, continuity of the gaps and Anderson localization are obtained with various methods.[4,21,22,25,10,20,5,6,26] For ''rational values'' of the magnetic flux the existence and width of the spectral gaps have been proved, using different methods.[25,10,26]

We will derive an analytic expression for the characteristic polynomials (13) in terms of the coefficients $(n;k)$. Because of (14) we get

$$\sum_{k=s}^{q-1} (s,0;k) a_k = -(s,0;q)$$

and therefore

$$\begin{pmatrix} a_0 \\ \vdots \\ a_{q-1} \end{pmatrix} = -((s,0;k))_{sk}^{-1} \begin{pmatrix} (0,0;q) \\ \vdots \\ (q,0;q) \end{pmatrix}.$$

The inverse exists, since it is an upper triangular matrix with diagonal elements of the form $A^s \neq 0$. For lq odd all coefficients a_l vanishes, since $(s,0;k)$ vanish, if sk is odd. This also follows from symmetry considerations. Obviously, we can derive for any $\mathcal{H}_c$ such a formula.

This fact can be used to derive an analytic expression for the density of states of the almost Mathieu operator with $A=B=1$. The integrated density of states is given by

$$N(E) = \int_0^{2\pi} \int_0^{2\pi} d\alpha \; d\beta \; \mathbf{Tr}(\chi_{[-4,E]}(\pi_z \mathcal{H}_c)), \tag{19}$$

where χ_I is the characteristic function of $I \in \mathbb{R}$ and is expressed in terms of the density of states (DOS) $g(\mu)$ at energy μ as

$$N(E) = \int_{-4}^{E} d\mu \; g(\mu).$$

Wannier, Obermair and Ray[27] derived from (19) and the Chambers relation (13) that

$$g(\mu) = \begin{cases} \dfrac{1}{2\pi^2 q} \dfrac{d}{d\mu} f(\mu) K'(\tfrac{1}{4}|f(\mu)|) & \text{for } |f(\mu)| \leq 4 \\ 0 & \text{otherwise,} \end{cases}$$

where $f(\mu)$ is given in the Chambers relation (13) and

$$K'(x) = \mathcal{F}\left(\frac{\pi}{2}, \sqrt{1-x^2}\right) = \int_0^{\pi/2} (1-(1-x^2)\sin^2 y)^{-1/2} dy$$

is the complete elliptic integral of the first kind. Since we have computed the coefficients of $f(\mu)$ analytically, this gives an analytic expression for the density of states.

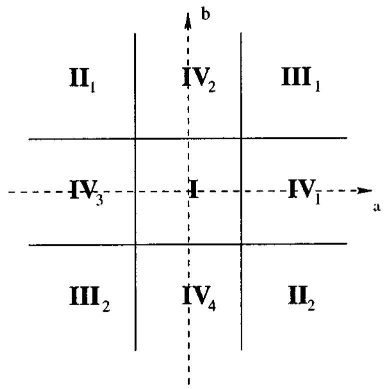

FIG. 1. Phase diagram for the rectangular lattice: $a=4C^qT_q(A/2C)$ and $b=4C^qT_q(B/2C)$ and region I $=[-4C^q,4C^q]^2$.

For nontrivial second neighbor interaction $(-1)^\rho C$ the representation dependent part of the Chambers relation is given by

$$\frac{1}{4C^q}\,h(\alpha,\beta)=T_q\left(\frac{A}{2C}\right)\cos\,\alpha+T_q\left(\frac{B}{2C}\right)\cos\,\beta+(-1)^{(p+\rho)q}\,\cos(\alpha)\cos(\beta).$$

Notice that changing the second neighbor coupling, the phase diagram is only rescaled and therefore we keep C in our discussion constant. The case $(p+\rho)q$ odd can be derived from the even one by variable transformation $\alpha\rightarrow\alpha+\pi,\beta\rightarrow\beta+\pi$. In the following we assume $(p+\rho)q$ even. Let us describe the phase diagram for the critical point of h with respect to A, B and C. First, the phase diagram of the critical points of h in terms of $a=4C^qT_q(A/2C)$ and $b=4C^qT_q(B/2C)$ is given by Fig. 1. Since a and b are the qth Chebyshev polynomials in A and B, respectively, the $A-B$ phase diagram is easily derived from this one.

Consider a path in the $A-B$ phase diagram with A running from $-\infty$ to $+\infty$ and B constant. The corresponding image of this path in the $a-b$ phase diagram lies again on a straight line parallel to the a axis and $b=4C^qT_q(B/2C)$. Recall, the $q-1$ extrema of the Chebyshev polynomials have the value ±1 in the interval $[-1,1]$. For q odd and $|B|<2C$ the path for $A<-2C$ lies in the region IV_3, then $(-2C<A<2C)$ oscillates exactly $q/2$ times in region I. The path touches the border of the neighbor region at the turning points of the oscillation. For $A>2C$ the path lies in IV_1. For $|B|>2C$ we have similar behavior. Therefore, up to this touching, the phase diagram in terms of A and B is a homeomorphic image of Fig. 1. For q even, the path lies on the same straight line and oscillates again exactly $q/2$ times in the corresponding region, but will disappear again to $+\infty$. Hence, for q even, regions $\Pi_{1/2}$, $\mathrm{IV}_{3/4}$ and III_2 do not appear in the $A-B$ phase diagram.

On such a path the width of the range of $h(\alpha,\beta)$ oscillates and because of the Chambers relation, this should be reflected on the total bandwidth of the spectrum. Numerical calculations confirm this behavior, the roots of $T_q(A/2C)$ correspond to the minima of the total bandwidth and the extrema to the maxima, respectively. Recognize, though $h(\alpha,\beta)$ scales with C^q, the spectrum does not.

The critical points are listed in Table I. Consider region I, there are two minima and maxima. The maximum at $(\alpha,\beta)=(0,0)$ is global for $T_q(A/2C)+T_q(B/2C)>0$ and local otherwise. Similarly, the minimum at $(\alpha,\beta)=(\pi,0)$ is global for $T_q(A/2C)-T_q(B/2C)>0$ and local otherwise.

B. Triangular lattice

The (anisotropic) tight-binding Hamiltonian for a particle on the triangular lattice can be expressed as

TABLE I. Critical points for the rectangular lattice model with next-nearest-neighbor interaction and pq even. $e_1 = T_q(A/2C) + T_q(B/2C)$, $e_2 = T_q(A/2C) - T_q(B/2C)$ and sad=saddle point.

$$\mathcal{H}_{\text{tri}} = A(u+u^*) + B(v+v^*) + C\gamma(vu+v^*u^*). \tag{20}$$

The model can be generalized by introducing different fluxes in the two classes of triangles.[8] The representation dependent part of the Chambers relation (13) is given by

$$h(\alpha,\beta) = 2A^q \cos\alpha + 2B^q \cos\beta + (-1)^{pq} 2C^q \cos(\alpha+\beta).$$

We describe the critical points of $h(\alpha,\beta)$ only in the generic case $1 = (-1)^{pq} 2C^q \geqslant 2A^q$, $2B^q \geqslant 0$, all other cases can be derived from this one by suitable transformation of α and β and rescaling of $h(\alpha,\beta)$. The critical points are listed in Table II and the phase diagram is shown in Fig. 2. In region II an extra critical point of $h(\alpha,\beta)$ appears, not being multiples of π. The point (1,1) in the phase diagram correspond to the case of hexagonal symmetry, so that the different phases help to distinguish strongly and weakly anisotropic interaction for the triangular lattice model. We call region II the ''weakly anisotropic'' triangular phase. Obviously, for fixed $0 < A,B < 1$ the phase depends on the magnetic flux $\theta = p/q$. The sequence (A^q,B^q) converges to (0,0). For large enough q the phase becomes in any case — except $A = B \leqslant 1$ — strongly anisotropic.

C. Weakly anisotropic triangular phase

In this section, we analyze for the weakly anisotropic triangular phase the gap structure of the spectrum for the corresponding Hamiltonian. By applying the theory of Sec. III we show the existence of gaps for rational and certain irrational values of the magnetic flux per unit cell. For convenience let in the following $C \geqslant A,B > 0$. Since $\mathcal{H}_{\text{tri}}$ has real coefficients in the sense of Proposition 2.1, the generalized coefficients $(n;k)_{\mathcal{H}_{\text{tri}}}$ defined by (7) are real. Let g be an arbitrary monic polynomial of degree $q-1$ with real coefficients.[28] A lower bound for the spectral gaps of $\mathcal{H}_{\text{tri}} \in A(p/q)$ is given by Theorem 3.6, if we find a linear combination α_l, such that (17) holds.

Theorem 4.1: *For every $\theta = p/q$ with p and q relative prime integers and A,B,C in a weakly anisotropic phase the spectral gaps of $\mathcal{H}_{\text{tri}}$ corresponding to the minimum of $h(z)$ if pq even and to the maximum if pq odd, are open.*

TABLE II. Critical points $(\alpha,\beta) \in]-\pi,\pi]^2$ for the triangular lattice model with anisotropic nearest-neighbor interaction and $w_\alpha = \arccos(1/2a^2b^2)(b^3 - b^3a^2 - ba^2)$, $w_\beta = \arccos(1/2a^2b^2)(a^3 - a^3b^2 - ab^2)$.

(α,β)	Energy	I	II	III
(0,0)	$a+b+1$	max	max	max
(π,0)	$-a+b-1$	min	loc min	loc min
(0,π)	$a-b-1$	loc min	loc min	min
(π,π)	$-a-b+1$	loc max	loc max	loc max
$\pm(w_\alpha, w_\beta)$	$-\dfrac{a^2+a^2b^2+b^2}{2ab}$	—	min	—

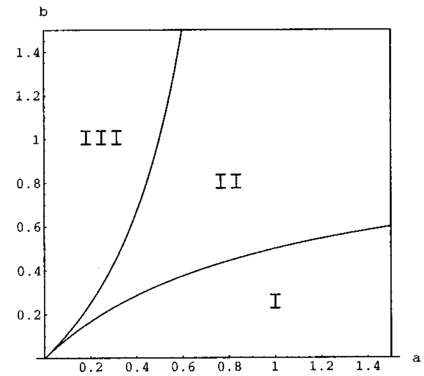

FIG. 2. Phase diagram for the triangular lattice, with $a = A^q$, $b = B^q$ and $b < a/(1+a)$ in region I, $a < b/(1+b)$ in region III.

Proof: For pq even and A,B,C in a weakly anisotropic phase, i.e., $A^q > B^q/(B^q + C^q)$ and $B^q > A^q/(A^q + C^q)$ the minimum of $h(z)$ is reached at $z = (\exp(iw_\alpha/q),\exp(iw_\beta/q))$, see Table II and hence not a $2q$th root of unity. Therefore one can apply Theorem 3.8 and gets with Theorem 3.7 the following estimate for the gap widths:

$$\max\left(\frac{A|\sin w_\alpha|}{2^{2q-4}(1+B/A+C/A)^{q-2}}, \frac{B|\sin \omega_\beta|}{2^{2q-4}(1+A/B+C/B)^{q-2}}\right) > 0.$$

For pq odd the proof is after rescaling of $h(z)$ analogous. □

Remark: Because of the Chambers relation (13) one of two consecutive gaps in the spectrum corresponds to $h_{\min}$ and the other to $h_{\max}$. Therefore Theorem 4.1 implies that at least one of two consecutive gaps is open.

As already mentioned above only those $\mathcal{H}_{\text{tri}}$ with $0 < A = B \leq C$ stay in the weakly anisotropic phase for any rational value of θ. In this case the following Corollary is a direct consequence of Theorem 4.1.

Corollary 4.2: For every $\theta = p/q$ with p and q relative prime integers and $0 < A = B \leq C$ the spectral gaps of $\mathcal{H}_{\text{tri}}$ corresponding to the minimum of $h(z)$ if pq even and to the maximum if pq odd, are open and have length at least

$$\frac{\sqrt{4-(A/C)^{2q}}A^{q-1}}{2^{2q-5}(2A+C)^{q-2}}.$$

Proof: Since $\sin w_\alpha = \sqrt{1-(A/C)^{2q}/4}$ the estimate follows from the one in the proof of Theorem 4.1. □

The analysis of the spectra for rational values of the magnetic flux per unit cell above does not yield all conditions needed in Theorem 3.11 and particularly Corollary 3.12. But looking at the proof again we see that nevertheless Corollary 3.12 holds.

Theorem 4.3: *Let $0 < A/C = \kappa \leq 1$, then for all $\theta \in \mathbb{R}$ with $|\theta - p/q| \leq \kappa^{2q-2}/\sqrt{5\pi}2^{4q-12}3^{2q}$, for arbitrarily large q, the spectrum of $\mathcal{H}_{\text{tri}}(\theta)$ is a Cantor set.*

Proof: Suppose θ fulfills the Liouville condition of the theorem. Take p and q. For pq even the gaps of Spec $\mathcal{H}_c(p/q)$ corresponding to the minimum of $h(z)$ are by Corollary 4.2 at least of size $\kappa^{q-2}A/2^{2q-5}3^{q-2}$. Since between such two gaps lies exactly one gap (possibly degenerated) corresponding to the maximum of $h(z)$, one gap of two consecutive gaps is at least of the size above. This is also true for pq odd. This fact induces analogous to the proof of Theorem 3.11 that there are at least $\lfloor (q-1)/2 \rfloor$ open gaps in the spectrum of $\mathcal{H}_{\text{tri}}(\theta)$ for every such p/q. For deducing that the gaps in Spec $\mathcal{H}_c(\theta)$ are dense the proof of Corollary 3.12 have to be altered at one point only. The estimate for the length of any interval in Spec $\mathcal{H}_{\text{tri}}$ for θ' rational is altered by a factor 2. □

V. CONCLUDING REMARKS

We have presented a derivation for an estimate of the gap widths in the spectrum of the Hamiltonians investigated here (6), using an algebraic and combinatorial approach. The Chambers relation extends to this class of Hamiltonians and its explicit form is described in terms of generalized binomial coefficients. Rather little is known about such kind of coefficients, especially the analytic formula for them (11) seems to be a new result. In the way the Chambers relation is derived, one easily gets conditions under which a general self-adjoint element in $A(\theta)$ fulfills the Chambers relation. So one recognizes that the class of Hamiltonians (6) contains essentially the most general type of Hamiltonians fulfilling the Chambers relation. A limitation of this method is given by the fact that the estimates derived for the spectral gaps vanish for critical points that are multiples of π. Numerical calculations suggest that, for arbitrary rational magnetic field and interaction, occasional ''gap closing'' occurs. So it is unlikely that the existence of a much more general estimate can be derived within this approach. However, we know from the derived estimate that this occasional ''gap closing'' can only occur if the relative location of the critical points are multiples of π or the generalized binomial coefficient in the estimate vanishes.

ACKNOWLEDGMENTS

We learned from P. van Mouche the idea to formulate the coexistence problem for the triangular lattice Hamiltonian in the algebraic setting and had stimulating discussions with him. This work was supported in part by the Studienstiftung des deutschen Volkes.

APPENDIX

Since the coefficients of the form $(qm;q)$ appear in the Chambers relation in Sec. III, we calculate them here using formula (2). Let $m=(1,0)$, then

$$
\begin{aligned}
[q;q]_{(m,\omega)} &= \prod_{k=1}^{q} \left(c_{(1,0)}+c_{(1,1)}\gamma^{\omega+2k-1}+c_{(1,-1)}\gamma^{-\omega-2k+1}\right) \\
&= \gamma^{-q(q+2-\omega)}c_{(1,1)}^{q}\prod_{k=1}^{q}(\lambda_1-\gamma^{2k})(\lambda_2-\gamma^{2k}) \\
&= \gamma^{-q(q+2-\omega)}c_{(1,1)}^{q}(\lambda_1^{q}-1)(\lambda_2^{q}-1) \\
&= \gamma^{q(q-\omega)}c_{(1,-1)}^{q}+2^{-q}\left(c_{(1,0)}+\sqrt{c_{(1,0)}^{2}-4c_{(1,1)}c_{(1,-1)}}\right)^{q} \\
&\quad+\gamma^{q(q+\omega)}c_{(1,1)}^{q}+2^{-q}\left(c_{(1,0)}-\sqrt{c_{(1,0)}^{2}-4c_{(1,1)}c_{(1,-1)}}\right)^{q}.
\end{aligned}
$$

The inverse transformation leads to

$$
(qm;q)=\begin{cases} 2\varepsilon^{q}T_q(c_m/2\varepsilon) & \text{for } \varepsilon=\sqrt{c_{(1,1)}c_{(1,-1)}}\neq 0 \\ c_m^{q} & \text{otherwise,} \end{cases}
$$

where $T_q(x)=\cos q \arccos x=1/2(x+\sqrt{x^2-1})^q+1/2(x-\sqrt{x^2-1})^q$ denotes the Chebyshev polynomial of degree q. Similarly we obtain an analogous expression for $(qm;q)$ with $m=(0,1)$. For $m=(\pm 1,\pm 1)$ the coefficients $(qm;q)$ are given by $(-1)^{pq}c_m^{q}$. Further we see that any other coefficient $(n;q)$ with $\max_l|n_l|=q$ is zero.

Weak coupling limit and removing an ultraviolet cutoff for a Hamiltonian of particles interacting with a quantized scalar field

Fumio Hiroshima[a),b)]
Institute of Applied Mathematics, University of Bonn, Wegeler str. 6, D53115 Bonn, Germany

(Received 6 April 1998; accepted for publication 4 September 1998)

An interaction system consisting of particles and a quantized scalar field is considered. The Hamiltonian of the system is defined as a self-adjoint operator in a Hilbert space. An ultraviolet cutoff is imposed on the Hamiltonian. A renormalized Hamiltonian is defined by subtracting a renormalization term from the Hamiltonian. Our aim in this paper is to remove the ultraviolet cutoff and take the weak coupling limit *simultaneously* for the renormalized Hamiltonian. By using a functional integral that contains a vector-valued stochastic integral, a Schrödinger Hamiltonian with a many-body Coulomb potential (resp., Yukawa potential) is derived, if the mass of the quantized scalar field is zero (resp., positive). © *1999 American Institute of Physics.* [S0022-2488(99)00202-9]

I. INTRODUCTION

In this paper, we pursue the study of an interaction system consisting of an arbitrary but conserved number of particles and a quantized scalar field with *non-negative mass*. An ultraviolet cutoff is imposed on the quantized scalar field. The Hamiltonian of the system is defined as a self-adjoint operator in a Hilbert space. A renormalized Hamiltonian is defined by subtracting a renormalization term from the Hamiltonian. Our aim in this paper is ''to remove the ultraviolet cutoff and take weak coupling limit *simultaneously*'' (we call it ''WCL-RUV'' for short) for the renormalized Hamiltonian. Then we derive a Schrödinger Hamiltonian with a many-body Coulomb potential (or Yukawa potential) in its WCL-RUV.

In Ref. 1, the author elaborates WCL-RUV for a model[2] with a *massive* quantized scalar field and shows that a Schrödinger Hamiltonian with a many-body Yukawa potential appears in its WCL-RUV (also see Refs. 3–5). In Ref. 1, it is crucial that the quantized scalar field has positive mass. Our main purpose in this paper is to extend the result in Ref. 1 to the case where the quantized scalar field has non-negative mass.

A mathematical formulation of the physical description of the interaction system is reduced to the theory of self-adjoint operators acting in the tensor product $\tilde{\mathcal{L}}$ of two Hilbert spaces. The statistics of the particles does not play any role. However, in this paper, we assume that the particles are fermions. (Naturally all the results extend to the case where the particles are bosons.) Let $\mathcal{F}_b$ and $\mathcal{F}_a$ be the Boson Fock space and the Fermion Fock space over $L^2(\mathbb{R}^3)$, respectively,

$$\mathcal{F}_b \equiv \bigoplus_{N=0}^{\infty} L_s^2(\mathbb{R}^{3N}), \quad \mathcal{F}_a \equiv \bigoplus_{N=0}^{\infty} L_{as}^2(\mathbb{R}^{3N}),$$

where $L_s(\mathbb{R}^{3N})$ [resp., $L_{as}(\mathbb{R}^{3N})$], $N \geqslant 1$, denotes the set of symmetric (resp., antisymmetric) functions in $L^2(\mathbb{R}^3)$ and $L_s^2(\mathbb{R}^0) = L_{as}^2(\mathbb{R}^0) \equiv \mathbb{C}$. Then

a)Electronic mail: hiro@mailcip.iam.uni-bonn.de
b)Permanent address: Department of Mathematics, Faculty of Science, Hokkaido University, Sapporo 060 Japan; Electronic mail: f-hirosh@math.sci.hokudai.ac.jp

$$\tilde{\mathcal{L}} \equiv \mathcal{F}_a \otimes \mathcal{F}_b \cong \bigoplus_{Z=0}^{\infty} \tilde{\mathcal{H}}_Z, \quad \tilde{\mathcal{H}}_Z = L^2_{as}(\mathbb{R}^{3Z}) \otimes \mathcal{F}_b.$$

The number Z counts the number of the particles. Let $a(k)$, $a^\dagger(k)$, $b(k)$, and $b^\dagger(k)$ be the formal annihilation and creation operators in $\mathcal{F}_b$ and the formal annihilation and creation operators in $\mathcal{F}_a$, respectively. Formally, we define

$$\Psi(x) = \frac{1}{\sqrt{(2\pi)^3}} \int b(k) e^{ikx}\, dk, \quad \Psi^\dagger(x) = \frac{1}{\sqrt{(2\pi)^3}} \int b^\dagger(k) e^{-ikx}\, dk.$$

The Hamiltonian $\tilde{H}$ of the system is explained as an operator acting in the Hilbert space $\tilde{\mathcal{L}}$. Formally, $\tilde{H}$ has the following form [see (4.16) for rigorous definition]:

$$\tilde{H} = \left(\int \Psi^\dagger(x) \left(-\frac{1}{2m} \Delta \right) \Psi(x) dx \right) \otimes I - g \int \Psi^\dagger(x) \phi_F(x) \Psi(x) dx + I \otimes \tilde{H}_b,$$

where Δ is the Laplacian in $L^2(\mathbb{R}^3)$, $g \in \mathbb{R}$ a coupling constant, $m>0$ the mass of the particle, $\omega(k) = \sqrt{k^2+\mu^2}$, $\mu \geqslant 0$, $\phi_F(x)$ a time-zero quantized scalar field in $\mathcal{F}_b$ and

$$\tilde{H}_b = \int \omega(k) a^\dagger(k) a(k) dk.$$

The restriction of $\tilde{H}$ to the sector $\tilde{\mathcal{H}}_Z$, $Z \geqslant 1$, has the form

$$\tilde{H}|_{\tilde{\mathcal{H}}_Z} = \frac{1}{2m} \mathbf{p}_Z^2 \otimes I - g \sum_{j=1}^{Z} \phi_F(x_j) + I \otimes \tilde{H}_b \Big|_{\tilde{\mathcal{H}}_Z}.$$

Here $\mathbf{p}_Z = (\mathbf{p}^1, \ldots, \mathbf{p}^Z)$, $\mathbf{p}^j = (-i(\partial/\partial x_1^j), -i(\partial/\partial x_2^j), -i(\partial/\partial x_3^j))$, $j=1,\ldots,Z$. In Ref. 1, for each fixed $Z \geqslant 1$, the author defines a scaling Hamiltonian $\tilde{H}^Z(\Lambda)$ in $\tilde{\mathcal{L}}_Z = L^2(\mathbb{R}^{3Z}) \otimes \mathcal{F}_b$ by

$$\tilde{H}^Z(\Lambda) = \frac{1}{2m} \mathbf{p}_Z^2 \otimes I - \Lambda g \tilde{H}_I^Z(\Lambda^\alpha) + \Lambda^2 I \otimes \tilde{H}_b, \quad \Lambda > 0, \quad \alpha > 0, \tag{1.1}$$

where $\tilde{H}_I^Z(\Lambda^\alpha)$ is defined by introducing an ultraviolet cutoff, which is parametrized by a parameter $\Lambda^\alpha > 0$, in $\Sigma_{j=1}^Z \phi_F(x_j)$. In (1.1), in the case where we make Λ's in the coefficients of $I \otimes \tilde{H}_b$ and $\tilde{H}_I^Z(\Lambda^\alpha)$ tend to infinity with Λ^α in $\tilde{H}_I^Z(\Lambda^\alpha)$ replaced by a fixed parameter, we call the limit ''weak coupling limit.'' [6,7] Conversely, the case where Λ^α in $\tilde{H}_I^Z(\Lambda^\alpha)$ tends to infinity with the other Λ's replaced by fixed parameters corresponds to removing the ultraviolet cutoff.[2] In Ref. 1, only in the case of *positive mass* $\mu > 0$, the author obtains the following (WCL-RUV):

$$s-\lim_{\Lambda \to \infty} e^{-t(\tilde{H}^Z(\Lambda) + V \otimes I - g^2 Z E(\Lambda^\alpha))} = e^{-t(H_{\text{eff}}^Z + V)} \otimes P_b, \quad 0 < \alpha < \tfrac{1}{2}, \tag{1.2}$$

where the potential V is infinitesimally small with respect to $\mathbf{p}_Z^2$, $E(\Lambda^\alpha)$ a renormalization term that goes to minus infinity as $\Lambda \to \infty$, P_b the projection operator onto the closed subspace generated by the vacuum vector in $\mathcal{F}_b$ and H_{eff}^Z is as follows:

$$H_{\text{eff}}^Z = \frac{1}{2m} \mathbf{p}_Z^2 - \frac{g^2}{4\pi} \sum_{1 \leqslant i < j \leqslant Z} \frac{e^{-\mu|x^i - x^j|}}{|x^i - x^j|}, \quad Z \geqslant 2, \quad \mu > 0.$$

[In Ref. 1, actually, the strong limit of the resolvent of $\tilde{H}^Z(\Lambda)+V_Z\otimes I-g^2ZE(\Lambda^\alpha)$ is considered.] In this paper, we consider WCL-RUV for the case of non-negative mass $\mu\geqslant 0$. We take the Schrödinger representation, $\mathcal{F}$, of $\mathcal{F}_b$.[8–10] The operators and spaces in the Schrödinger representation corresponding to $\tilde{H}^Z(\Lambda)$, $\tilde{H}_b$, $\tilde{H}_I^Z(\Lambda)$, $\tilde{\mathcal{L}}$, $\tilde{\mathcal{L}}_Z$, and $\tilde{\mathcal{H}}_Z$ are denoted by $H^Z(\Lambda)$, H_b, $H_I^Z(\Lambda)$, $\mathcal{L}$, $\mathcal{L}_Z$, and $\mathcal{H}_Z$, respectively, in what follows.

The basic method presented here is as follows: In the massive case, $\mu>0$, the author in Ref. 1 introduces a unitary operator that separates a renormalization term and transforms the Hamiltonian $H^Z(\Lambda)$ to an operator handled easily. Nevertheless, in the massless case, $\mu=0$, we cannot define such a unitary operator. To avoid this difficulty, we introduce a unitary operator with an infrared cutoff $K>0$, which transforms the renormalized Hamiltonian $H^Z(\Lambda)-gZE(\Lambda^\alpha)$ to an operator $H^Z(K,\Lambda)$. We shall prove that, for sufficiently large $\Lambda>0$, it is possible to construct a functional integral representation of $e^{-tH^Z(K,\Lambda)}$. The functional integral representation gives a good way to analyze the strong limit of $e^{-tH^Z(K,\Lambda)}$ as $\Lambda\to\infty$.

We organize this paper as follows. In Sec. II, we present the basic notation and facts. Section III is devoted to constructing a functional integral representation of $e^{-tH_{\mathrm{formal}}}$,

$$H_{\mathrm{formal}}=\frac{1}{2m}(\mathbf{p}_Z\otimes I-A)^2+U+V\otimes I+I\otimes H_b, \tag{1.3}$$

where A and U are defined in Sec. III. The operator H_{formal} is an abstract version of $H^Z(K,\Lambda)$. Section IV is the main section of this paper. In this section, we give the definition of the Hamiltonian $H(V,\Lambda)$ of the system in the Schrödinger representation and analyze its WCL-RUV. Theorem 4.11 is the main theorem in this paper. In Sec. V, we give some remarks.

II. SCHRÖDINGER REPRESENTATION

In this section we define basic notation and prepare some concepts on Schrödinger representation of a Boson Fock space and on a functional integral representation of a heat semigroup. For a Hilbert space $\mathcal{H}$ over $\mathbb{C}$, we denote the scalar product by $\langle f,g\rangle_{\mathcal{H}}$ and the associated norm by $\|f\|_{\mathcal{H}}$, where the scalar product is linear in g and antilinear in f. For a tempered distribution f, $\overline{f}$ denotes the complex conjugate of f and $\hat{f}$ (resp., $\check{f}$) the Fourier transform of f (resp., the inverse Fourier transform of f). We denote the domain of an operator A by $D(A)$. We denote by $C_b^n(\mathbb{R}^d;\mathcal{H})$ the set of n times strongly continuously differentiable functions, together with bounded up to n times derivative, from $\mathbb{R}^d$ to a Hilbert space $\mathcal{H}$ and $C_b(\mathbb{R}^d)$ the set of bounded continuous functions on $\mathbb{R}^d$. Let $\mathcal{S}_r'(\mathbb{R}^m)$ be the set of real tempered distributions on $\mathbb{R}^m$ and define

$$\mathcal{H}_{-1/2}=\left\{ f\in\mathcal{S}_r'(\mathbb{R}^3)\,\middle|\, \|f\|^2_{\mathcal{H}_{-1/2}}\equiv\int_{\mathbb{R}^3}\frac{|\hat{f}(k)|^2}{\omega(k)}\,dk<\infty\right\},$$

$$\mathcal{W}=\left\{ f\in\mathcal{S}_r'(\mathbb{R}^{3+1})\,\middle|\, \|f\|^2_{\mathcal{W}}\equiv 2\int_{\mathbb{R}^{3+1}}\frac{|\hat{f}(k,k_0)|^2}{\omega(k)^2+k_0^2}\,dk\,dk_0<\infty\right\}.$$

For simplicity, we put $\|f\|_{\mathcal{H}_{-1/2}}=\|f\|_{-1/2}$. Let $\{\phi(f)\,|\,f\in\mathcal{H}_{-1/2}\}$ be the Gaussian mean zero random process indexed by $\mathcal{H}_{-1/2}$ so that

$$\int_Q e^{i\phi(f)}\,d\mu=e^{-(1/4)\|f\|^2_{-1/2}},\quad f\in\mathcal{H}_{-1/2},$$

where (Q,μ) denotes a probability measure space. We regard ϕ as the variable of the Gaussian random process $\phi(f)$. Similarly, let $\{\Phi(f)\,|\,f\in\mathcal{W}\}$ be the Gaussian mean zero random process indexed by $\mathcal{W}$ on a probability measure space (Q_E,μ_E) with

$$\int_{Q_E} e^{i\Phi(f)}\, d\mu_E = e^{-(1/4)\|f\|^2_{\mathcal{W}}}, \quad f\in\mathcal{W}.$$

We set $\mathcal{F}=L^2(Q,d\mu)$ and $\mathcal{E}=L^2(Q_E,d\mu_E)$. The "Wick product" $:\phi(f_1)\cdots\phi(f_n):$ in $\mathcal{F}$ is defined by recurrences as follows:

$$:\phi(f):=\phi(f),$$

$$:\phi(f_1)\cdots\phi(f_n):=\phi(f_1):\phi(f_2)\cdots\phi(f_n):-\sum_{j=2}^{n}\frac{1}{2}\langle f_1,f_j\rangle_{-1/2}:\phi(f_2)\cdots\widehat{\phi(f_j)}\cdots\phi(f_n): \quad n\geqslant 2,$$

where $\widehat{\phi(f)}$ means the omission of the term $\phi(f)$. Set

$$\Gamma_0(\mathcal{F})=\mathbb{C},$$

$$\Gamma_n(\mathcal{F})=\overline{\mathbf{L}\{:\phi(f_1)\cdots\phi(f_n):|f_j\in\mathcal{H}_{-1/2},\ j=1,...,n\}}, \quad n\geqslant 1.$$

Here $\mathbf{L}\{\cdots\}$ denotes the complex linear hull of the vectors in $\{\cdots\}$ and $\overline{\{\cdots\}}$ the closure in $\mathcal{F}$. Then one sees that

$$\mathcal{F}=\bigoplus_{n=0}^{\infty}\Gamma_n(\mathcal{F}).$$

"The finite particle subspace" in $\mathcal{F}$ is defined by

$$\mathcal{F}_0=\bigcup_{N=0}^{\infty}\Big[\bigoplus_{n=0}^{N}\Gamma_n(\mathcal{F})\bigoplus_{n=N+1}^{\infty}\{0\}\Big],$$

which is dense in $\mathcal{F}$. Let T be a contraction linear operator from $\mathcal{H}_{-1/2}$ to $\mathcal{W}$ and h a non-negative self-adjoint operator in $\mathcal{H}_{-1/2}$. Then a linear operator $\Gamma(T)$ from $\mathcal{F}$ to $\mathcal{E}$ and a linear operator $d\Gamma(h)$ in $\mathcal{F}$ are defined by

$$\Gamma(T)\Omega_{\mathcal{F}}=\Omega_{\mathcal{E}},$$

$$\Gamma(T):\phi(f_1)\cdots\phi(f_n):=:\Phi(Tf_1)\ldots\Phi(Tf_n):, \quad f_1,\ldots,f_n\in\mathcal{H}_{-1/2}, \quad n\geqslant 1,$$

$$d\Gamma(h)\Omega_{\mathcal{F}}=0,$$

$$d\Gamma(h):\phi(f_1)\cdots\phi(f_n):=\sum_{j=1}^{n}:\phi(f_1)\cdots\phi(hf_j)\cdots\phi(f_n):, \quad f_1,\ldots,f_n\in D(h), \quad n\geqslant 1.$$

Here $\Omega_{\mathcal{F}}\equiv 1\in\mathcal{F}$, $\Omega_{\mathcal{E}}\equiv 1\in\mathcal{E}$. It is checked that $\Gamma(T)$ uniquely extends to a contraction linear operator from $\mathcal{F}$ to $\mathcal{E}$. We denote its extension by the same symbol. Moreover, we see that $d\Gamma(h)$ is essentially self-adjoint on $\mathcal{F}_0$. We also denote its self-adjoint extension by the same symbol. We define a non-negative self-adjoint operator $\tilde{\omega}$ in $\mathcal{H}_{-1/2}$ by

$$\widehat{\tilde{\omega}f}(k)=\omega(k)\hat{f}(k), \quad f\in\mathcal{H}_{-1/2},$$

with $D(\tilde{\omega})=\{f\in\mathcal{H}_{-1/2}|\sqrt{\omega}\hat{f}\in L^2(\mathbb{R}^3)\}$. The family of operators j_t: $\mathcal{H}_{-1/2}\to\mathcal{W}$, $t\geqslant 0$, is defined by

$$j_t f=\delta_t\otimes f, \quad f\in\mathcal{H}_{-1/2},$$

where δ_t is the delta function with mass at $t \in \mathbb{R}$. It is well known that j_t is isometry. We define the family of isometries J_t and a non-negative self-adjoint operator H_b by

$$J_t = \Gamma(j_t), \quad t \geqslant 0,$$

$$H_b = d\Gamma(\tilde{\omega}).$$

The following relation is crucial in the next section:

$$J_t^* J_s = e^{-|t-s|H_b}, \quad t,s > 0. \tag{2.1}$$

We shall give a unitary equivalence between $\mathcal{F}$ and $\mathcal{F}_b$. Define $\Omega = \{1,0,0,0,...\} \in \mathcal{F}_b$. Let the annihilation operator and the creation operator in $\mathcal{F}_b$ denote by $a(f), f \in L^2(\mathbb{R}^3)$, and $a^\dagger(g), g \in L^2(\mathbb{R}^3)$, respectively, which satisfy the canonical commutation relations on a dense domain:

$$[a(f), a^\dagger(g)] = \langle \overline{f}, g \rangle_{L^2(\mathbb{R}^3)}, \quad [a^\dagger(f), a^\dagger(g)] = [a(f), a(g)] = 0.$$

We define

$$\phi_F(\hat{f}) = \frac{1}{\sqrt{2}} \left\{ a^\dagger\left(\frac{\tilde{\hat{f}}}{\sqrt{\omega}} \right) + a\left(\frac{\hat{f}}{\sqrt{\omega}} \right) \right\}, \quad \frac{\hat{f}}{\sqrt{\omega}} \in L^2(\mathbb{R}^3),$$

$$\pi_F(\hat{f}) = \frac{i}{\sqrt{2}} \{ a^\dagger(\sqrt{\omega}\tilde{\hat{f}}) - a(\sqrt{\omega}\hat{f}) \}, \quad \sqrt{\omega}\hat{f} \in L^2(\mathbb{R}^3).$$

Here $\tilde{g}(k) = g(-k)$. Define a map $\mathcal{T}$ from $\mathcal{F}_b$ to $\mathcal{F}$ by

$$\mathcal{T}\Omega = \Omega_{\mathcal{F}},$$

$$\mathcal{T}: \phi_F(\hat{f}_1) \cdots \phi_F(\hat{f}_n): \Omega = :\phi(f_1) \cdots \phi(f_n):, \quad f_1, \ldots, f_n \in \mathcal{H}_{-1/2},$$

and extend $\mathcal{T}$ by linearity. Here the "Wick product" $:\phi_F(f_1) \cdots \phi_F(f_n):$ in $\mathcal{F}_b$ is defined by moving all the creation operators to the left side and all the annihilation operators to the right side without commutation relations. The operator $\mathcal{T}$ uniquely extends to a unitary operator from $\mathcal{F}_b$ to $\mathcal{F}$. We denote its extension by the same symbol. We see that

$$\mathcal{T}^{-1}\phi(\hat{f})\mathcal{T} = \phi_F(f), \quad f \in \mathcal{H}_{-1/2}, \quad \mathcal{T}^{-1} H_b \mathcal{T} = \tilde{H}_b. \tag{2.2}$$

Moreover, $\mathcal{T}$ implements the following unitary equivalence:

$$\tilde{\mathcal{L}} \cong \mathcal{F}_a \otimes \mathcal{F} \equiv \mathcal{L}.$$

The Hilbert space $\mathcal{L}$ can be decomposed as follows:

$$\mathcal{L} = \bigoplus_{Z=0}^{\infty} \mathcal{H}_Z, \quad \mathcal{H}_Z = L^2_{as}(\mathbb{R}^{3Z}) \otimes \mathcal{F}.$$

III. FUNCTIONAL INTEGRAL

In this section, we derive a functional integral representation of the heat semigroup generated by self-adjoint operators in (1.3) acting in the Hilbert space,

$$\mathcal{L}_Z \equiv L^2(\mathbb{R}^{3Z})\otimes\mathcal{F}\cong\int_{\mathbb{R}^{3Z}}^{\oplus}\mathcal{F}\,dx.$$

Throughout this section, we suppose that $A(x)=(A_1(x),\ldots,A_{3Z}(x))$ has the form

$$A_\mu(x)=P_\mu(\phi(f_{\mu,1}(x)),\ldots,\phi(f_{\mu,M_\mu}(x)))+A_\mu^0(x)\otimes I,\quad \mu=1,\ldots,3Z, \tag{3.1}$$

where $P_\mu(y_1,\ldots,y_{M_\mu})$ is a real polynomial, $f_{\mu,j}\in C_b^2(\mathbb{R}^{3Z};\mathcal{H}_{-1/2})$, and $A_\mu^0\in C_b^2(\mathbb{R}^{3Z};\mathbb{R})$. The operator H_{formal} in (1.3) is well defined on $\mathcal{L}_Z^\infty=C_0^\infty(\mathbb{R}^{3Z})\hat{\otimes}[\mathcal{F}_0\cap D(H_b)]$, but it is not known whether $\mathcal{L}_Z^\infty$ is a core for H_{formal} or not. Here, $\hat{\otimes}$ denotes algebraic tensor product. Thus, it is possible for $H_{\text{formal}}|_{\mathcal{L}_Z^\infty}$ not to have a unique self-adjoint extension. Then we have to make it clear which self-adjoint extensions we choose in consideration. We shall take the following strategy: At the beginning, we construct the family of contraction self-adjoint operators, Q_s, $s\geqslant 0$, from which we derive a strongly continuous symmetric one-parameter contraction semigroup, G_t, $t\geqslant 0$. Second, we show that its generator, $H_{00}(A)$, i.e., $e^{-tH_{00}(A)}=G_t$, which is a non-negative self-adjoint operator, has the same action on the domain $\mathcal{L}_Z^\infty$ as that of

$$\tilde{H}(A)=\frac{1}{2m}(\mathbf{p}_Z\otimes I-A)^2.$$

Next, we define $H_0(A)$ by the quadratic form sum of $H_{00}(A)$ and $I\otimes H_b$:

$$H_0(A)=H_{00}(A)\dot{+}I\otimes H_b. \tag{3.2}$$

Finally, by using a diamagnetic inequality[8,11] for $e^{-tH_0(A)}$, we shall show that the following self-adjoint operator can be defined:

$$H(A)=H_0(A)\dot{+}U\dot{+}(V_+\otimes I)\dot{-}(V_-\otimes I), \tag{3.3}$$

where U is a relatively form bounded operator with respect to

$$H_F^Z=\frac{1}{2m}\mathbf{p}_Z^2\otimes I+I\otimes H_b,$$

with relative bound <1 so that $U(\cdot)$ is an $\mathcal{F}$-valued continuous function on $\mathbb{R}^{3Z}$, $V_+\in L^1_{\text{loc}}(\mathbb{R}^{3Z})$ and V_- a relatively $\mathbf{p}_Z^2$ form bounded real multiplication operator. We adopt $H(A)$ as a mathematically rigorous definition of the formally defined Hamiltonian H_{formal} in (1.3). We shall give a functional integral representation of $e^{-tH(A)}$.

In what follows, for simplicity, we put $m=1$. For each $x,y\in\mathbb{R}^{3Z}$, we define a unitary operator on $\mathcal{F}$ by

$$U(x,y)=\exp\left\{\frac{i}{2}(A(x)+A(y))(x-y)\right\}.$$

Let $p_s(x)$ be a heat kernel, i.e., the integral kernel of $e^{-s(-(1/2)\Delta)}$ in $L^2(\mathbb{R}^{3Z})$:

$$p_s(x)=(2\pi s)^{-(3Z/2)}\exp\left(-\frac{1}{2s}|x|^2\right),\quad s>0,\quad x\in\mathbb{R}^{3Z}.$$

We define the family of contraction self-adjoint operators $\{Q_s\}_{s\geqslant 0}$ by Bochner integrals,

$$(Q_sF)(x)=\int_{\mathbb{R}^{3Z}}p_s(x-y)U(x,y)F(y)dy,$$

$$(Q_0F)(x)=F(x),\quad F\in\mathcal{L}_Z,\quad x\in\mathbb{R}^{3Z}.$$

Note that Q_sF is weakly right continuous at $s=0$, i.e.,

$$\lim_{s\downarrow 0}\langle Q_sF,G\rangle_{\mathcal{L}_Z}=\langle F,G\rangle_{\mathcal{L}_Z},\quad F,G\in\mathcal{L}_Z. \tag{3.4}$$

We show the following key lemma.

Lemma 3.1: Let $G\in\mathcal{L}_Z$ *and* $F\in\mathcal{L}_Z^\infty$. *Then* $\langle Q_sF,G\rangle$ *is differentiable at* $s>0$ *and right differentiable at* $s=0$, *with*

$$\lim_{s\downarrow 0}\left\langle \frac{Q_s-Q_0}{s}F,G\right\rangle_{\mathcal{L}_Z}=-\langle\tilde{H}(A)F,G\rangle_{\mathcal{L}_Z}. \tag{3.5}$$

Proof: We show an outline of a proof. Put

$$A_\mu^{(1)}(x,y)=\sum_{n=1}^{3Z}\left(\frac{\partial A_n(y)}{\partial y_\mu}(x_n-y_n)-(A_\mu(x)+A_\mu(y))\right),$$

$$A_\mu^{(2)}(x,y)=\sum_{n=1}^{3Z}\left(\frac{\partial^2 A_n(y)}{\partial y_\mu^2}(x_n-y_n)-2\frac{\partial A_\mu(y)}{\partial y_\mu}\right),\quad \mu=1,...,3Z.$$

By the Fubini theorem, one sees that

$$\frac{d}{ds}\langle Q_s,F,G\rangle_{\mathcal{L}_Z}=\int_{\mathbb{R}^{3Z}}p_s(X)dX\int_{\mathbb{R}^{3Z}}\Gamma(x,x-X)dx,$$

where

$$\Gamma(x,y)=\left\langle U(x,y)\frac{\partial^2F(y)}{\partial y_\mu^2},G(x)\right\rangle_{\mathcal{F}}+2\left\langle U(x,y)A_\mu^{(1)}(x,y)\frac{\partial F(y)}{\partial y_\mu},G(x)\right\rangle_{\mathcal{F}}$$
$$+\langle U(x,y)\{A_\mu^{(1)}(x,y)^2+A_\mu^{(2)}(x,y)\}F(y),G(x)\rangle_{\mathcal{F}}.$$

By a direct calculation, we show that

$$\left|\int_{\mathbb{R}^{3Z}}\Gamma(x,x-X)dx\right|\leqslant\epsilon_1+\epsilon_2|X|+\epsilon_3|X|^2.$$

Here $\epsilon_1,\epsilon_2,\epsilon_3$ are positive constants (see Ref. 8, Lemma 4.1 for details). Hence, we have

$$\lim_{s\downarrow 0}\int_{\mathbb{R}^{3Z}}p_s(X)dX\int_{\mathbb{R}^{3Z}}\Gamma(x,x-X)dx=\int_{\mathbb{R}^{3Z}}\Gamma(x,x)dx=-\langle\tilde{H}(A)F,G\rangle_{\mathcal{L}_Z},$$

which, together with (3.4), implies (3.5). The proof is complete. □

We fix probabilistic notation. Let (Ω,db) be a probability space for the $3Z$-dimensional Brownian motion $(b(t))_{t\geqslant 0}=(b_\mu(t))_{t\geqslant 0,\mu=1,...,3Z}$. Put $x_\mu+b_\mu(t)=\omega_\mu(t)$, $\mu=1,...,3Z$, and $\omega(t)=(\omega_1(t),\ldots,\omega_{3Z}(t))$. We define measure spaces $(\tilde{Q},\nu)$ and $(\tilde{Q}_E,\nu_E)$ by

$$\widetilde{Q}=\mathbb{R}^{3Z}\times\Omega\times Q,\quad d\nu=dx\otimes db\otimes d\mu,$$

$$\widetilde{Q}_E=\mathbb{R}^{3Z}\times\Omega\times Q_E,\quad d\nu_E=dx\otimes db\otimes d\mu_E.$$

Lemma 3.2: For all $t\geqslant 0$, the strong limit,

$$s-\lim_{n\to\infty}(Q_{t/2^n})^{2^n}\equiv G_t,$$

exists. Moreover, G_t is a strongly continuous symmetric one-parameter contraction semigroup on $\mathcal{L}_Z$ and has the following functional integral representation:

$$\langle F,G_tG\rangle_{\mathcal{F}}=\int_{\widetilde{Q}}d\nu\,\overline{F(\omega(t))}G(\omega(0))e^{i\widetilde{K}(A,t)},\quad F,G\in\mathcal{L}_Z,\tag{3.6}$$

where

$$\widetilde{K}(A,t)=\sum_{\mu=t}^{3Z}\int_0^t A_\mu(\omega(s))db_\mu(s)+\frac{1}{2}\sum_{\mu=1}^{3Z}\int_0^t\frac{\partial A_\mu}{\partial x_\mu}(\omega(s))ds\equiv\int_0^t A(\omega(s))\circ db(s),$$

where $\int\cdots db_\mu(s)$ is an $\mathcal{F}$-valued stochastic integral.

Proof: By the definition of Q_t, one sees that

$$\langle F,(Q_{t/2^n})^{2^n}(Q_{s/2^m})^{2^m}G\rangle_{\mathcal{L}_Z}=\int_{\mathbb{R}^{3Z}}dx\langle F(\omega(t+s)),e^{i\widetilde{K}_{m,n}(A,t,s)}G(\omega(0))\rangle_{L^2(\Omega;\mathcal{F})},$$

where $L^2(\Omega;\mathcal{F})$ is the set of $\mathcal{F}$-valued L^2 functions on Ω and

$$2\widetilde{K}_{m,n}(A,t,s)=\sum_{k=1}^{2^m}\left\{A\left(\omega\left(\frac{sk}{2^m}\right)\right)+A\left(\omega\left(\frac{s(k-1)}{2^m}\right)\right)\right\}\left\{\omega\left(\frac{sk}{2^m}\right)-\omega\left(\frac{s(k-1)}{2^m}\right)\right\}$$
$$+\sum_{k=1}^{2^n}\left\{A\left(\omega\left(\frac{tk}{2^n}+s\right)\right)+A\left(\omega\left(\frac{t(k-1)}{2^n}+s\right)\right)\right\}\left\{\omega\left(\frac{tk}{2^n}+s\right)-\omega\left(\frac{t(k-1)}{2^n}+s\right)\right\}.$$

Since, by (3.1), $A_\mu\in C_b^1(\mathbb{R}^{3Z};\mathcal{F})$, $\mu=1,...,3Z$, it is seen that

$$s-\lim_{m\to\infty}\lim_{n\to\infty}\widetilde{K}_{m,n}(A,t,s)=\widetilde{K}(A,t+s),$$

in $L^2(\Omega;\mathcal{F})$. Then we have, by the Lebesgue dominated convergence theorem,

$$\lim_{m\to\infty}\lim_{n\to\infty}\langle F,(Q_{t/2^n})^{2^n}(Q_{s/2^m})^{2^m}G\rangle_{\mathcal{L}_Z}=\int_{\widetilde{Q}}d\nu\,\overline{F(\omega(t+s))}G(\omega(0))e^{i\widetilde{K}(A,t+s)}.$$

Hence, it follows that $(Q_{t/2^n})^{2^n}$ is a Cauchy sequence in $\mathcal{L}_Z$ and $s-\lim_{n\to\infty}(Q_{t/2^n})^{2^n}$ has the functional integral representation (3.6). The semigroup property, and the strong continuity of G_t in t can be checked by (3.6). Thus, the proof is complete. □

Lemma 3.2 and Stone's theorem yield that there exists a non-negative self-adjoint operator $H_{00}(A)$, so that

$$G_t=e^{-tH_{00}(A)},\quad t\geqslant 0.$$

Lemma 3.3: The self-adjoint operator $H_{00}(A)$ is a self-adjoint extension of $\widetilde{H}(A)|_{\mathcal{L}_Z^\infty}$.

Proof: Let $F\in D(H_{00}(A))$ and $G\in\mathcal{L}_Z^\infty$. Then we see that, by Lemma 3.1,

$$\left\langle \frac{1}{t}\,(e^{-tH_{00}(A)}-I)G,F\right\rangle_{\mathcal{L}_Z}=\lim_{n\to\infty}\left\langle \frac{1}{t}\,\{(Q_{t/2^n})^{2^n}-I\}G,F\right\rangle_{\mathcal{L}_Z}$$

$$=\lim_{n\to\infty}\sum_{j=0}^{2^n-1}\frac{1}{2^n}\left\langle \frac{2^n}{t}\,\{Q_{t/2^n}-I\}G,(Q_{t/2^n})^jF\right\rangle_{\mathcal{L}_Z}$$

$$=-\int_0^1\langle\tilde{H}(A)G,e^{-tsH_{00}(A)}F\rangle_{\mathcal{L}_Z}\,ds.$$

As $t\to 0$, we get

$$\langle G,H_{00}(A)F\rangle_{\mathcal{L}_Z}=\langle\tilde{H}(A)G,F\rangle_{\mathcal{L}_Z}.$$

Thus, the proof is complete. □

Remark 3.4: Since the operator H_{formal} is defined on a larger domain than $\mathcal{L}_Z^\infty$, one can extend Lemma 3.3 to a larger domain. Actually, putting

$$\mathcal{M}_Z^\infty=\{u\in C_b^1(\mathbb{R}^{3Z};\mathbb{R})\,|\,\|\partial^k u\|_{L^2(\mathbb{R}^{3Z})}<\infty,|k|\leqslant 2\}\hat{\otimes}\mathcal{F}_0,$$

we also show that Lemmas 3.1 and 3.3 hold with $\mathcal{L}_Z^\infty$ replaced by $\mathcal{M}_Z^\infty$.[8]

Define $H_0(A)$ as (3.2). We state the main theorem in this section.

Theorem 3.5: *Let $A_\mu(x)\in D(H_b)$, $\mu=1,...,3Z$, for all $x\in\mathbb{R}^{3Z}$, and*

$$\sup_{x\in\mathbb{R}^{3Z}}\|H_bA_\mu(x)\|_{\mathcal{F}}<\infty. \tag{3.7}$$

Furthermore, we suppose that a multiplication operator U is a bounded operator on $\mathcal{L}_Z$ and $U(\cdot)$ is an $\mathcal{F}$-valued continuous function on $\mathbb{R}^{3Z}$. Then, for F, $G\in\mathcal{L}_Z$,

$$\langle F,e^{-t(H_0(A)+U)}G\rangle_{\mathcal{L}_Z}=\int_{\tilde{Q}_E}d\nu_E\,\overline{J_tF(\omega(t))}J_0G(\omega(0))e^{i\mathcal{K}(A,t)}e^{-E(U,t)}, \tag{3.8}$$

where

$$\mathcal{K}(A,t)=\sum_{\mu=1}^{3Z}\int_0^t J_sA_\mu(\omega(s))db_\mu(s)+\sum_{\mu=1}^{3Z}\frac{1}{2}\int_0^t J_s\,\frac{\partial A_\mu}{\partial x_\mu}\,(\omega(s))ds\equiv\int_0^t J_sA(\omega(s))\circ db(s),$$

$$E(U,t)=\int_0^t J_sU(\omega(s))ds,$$

where $\int_0^t\ldots db_\mu(s)$ is an $\mathcal{E}$-valued stochastic integral.

Proof: By the strong Trotter product formula,[12] we see that

$$\langle F,e^{-t(H_0(A)+U)}G\rangle_{\mathcal{L}_Z}=\lim_{n\to\infty}\langle F,(e^{-(t/2^n)H_{00}(A)}e^{-(t/2^n)I\otimes H_b}e^{-(t/2^n)U})^{2^n}G\rangle_{\mathcal{L}_Z}\equiv\lim_{n\to\infty}S_{2^n}.$$

Put $t/2^n=\epsilon$. From the definition of $H_{00}(A)$ and (2.1), it follows that

$$S_{2^n} = \lim_{k\to\infty} \langle F, J_t^*(J_t(Q_{\epsilon/2^k})^{2^k}J_t^*)(J_{t-\epsilon}e^{-\epsilon U}J_{t-\epsilon}^*)(J_{t-\epsilon}(Q_{\epsilon/2^k})^{2^k}J_{t-\epsilon}^*)(J_{t-2\epsilon}e^{-\epsilon U}J_{t-2\epsilon}^*)$$
$$\cdots(J_\epsilon e^{-\epsilon U}J_\epsilon^*)(J_\epsilon(Q_{\epsilon/2^k})^{2^k}J_\epsilon^*)(J_0 e^{-\epsilon U}J_0^*)J_0 G\rangle_{\mathcal{L}_Z}$$
$$= \lim_{k\to\infty} \int_{\mathbb{R}^{3Z}\times\underbrace{\mathbb{R}^{3Z\cdot 2^k}\times\cdots\times\mathbb{R}^{3Z\cdot 2^k}}_{2^n}} dx\, d\vec{x}_1\cdots d\vec{x}_{2^n}\, P_\epsilon(\vec{x}_1)\cdots P_\epsilon(\vec{x}_{2^n})$$
$$\times\langle F(x), J_t^*(E_t W_t(\vec{x}_1)E_t)(E_{t-\epsilon}U_{t-\epsilon}(x_1^{2^k})E_{t-\epsilon})(E_{t-\epsilon}W_{t-\epsilon}(\vec{x}_2)E_{t-\epsilon})$$
$$\cdots(E_\epsilon U_\epsilon(x_{2^n-1}^{2^k})E_\epsilon)(E_\epsilon W_\epsilon(\vec{x}_{2^n})E_\epsilon)(E_0 U_0(x_{2^n}^{2^k})E_0)J_0 G(x_{2^n}^{2^k})\rangle_{\mathcal{F}}$$
$$\equiv \lim_{k\to\infty} S_{2^n,2^k}, \tag{3.9}$$

where $J_sJ_s^* = E_s$ and $\vec{x}_j = (x_j^1,\ldots,x_j^{2^k}) \in \mathbb{R}^{3Z\cdot 2^k}$, $j=1,\ldots,2^n$,

$$P_\epsilon(\vec{x}_j) = p_\epsilon(x_{j-1}^{2^k} - x_j^1)p_\epsilon(x_j^1 - x_j^2)\cdots p_\epsilon(x_j^{2^k-1} - x_j^{2^k}),$$

$$W_s(\vec{x}_j) = \exp\left\{\frac{i}{2} J_s \sum_{l=1}^{2^k} (A(x_j^{l-1}) + A(x_j^l))(x_j^{l-1} - x_j^l)\right\}, \quad x_j^0 = x_{j-1}^{2^k}, \quad x_0^{2^k} \equiv x,$$

$$U_s(x_j^i) = \exp(-\epsilon J_s U(x_j^i)).$$

By the Markov property of E_s,[10] one can neglect E_s's in (3.9). Then it holds that

$$S_{2^n,2^k} = \int_{\mathbb{R}^{3Z}} dx \langle J_t F(\omega(t)), e^{\{i\Sigma_{j=0}^{2^n-1} J_{jt/2^n}\mathcal{K}_k(jt/2^n) - (t/2^n)\Sigma_{j=1}^{2^n} J_{jt/2^n}U(\omega(jt/2^n))\}} J_0 G(x)\rangle_{L^2(\Omega;\mathcal{E})},$$

where

$$\mathcal{K}_k(T) = \frac{1}{2}\sum_{m=1}^{2^k}\left\{A\left(\omega\left(\frac{m}{2^k}\frac{t}{2^n} + T\right)\right) + A\left(\omega\left(\frac{(m-1)}{2^k}\frac{t}{2^n} + T\right)\right)\right\}$$
$$\times\left\{\omega\left(\frac{m}{2^k}\frac{t}{2^n} + T\right) - \omega\left(\frac{(m-1)}{2^k}\frac{t}{2^n} + T\right)\right\}, \quad j = 0,\ldots,2^n - 1.$$

As is seen in the proof of Lemma 3.2, since $A_\mu(\cdot) \in C_b^2(\mathbb{R}^{3Z},\mathcal{F})$, we have

$$\lim_{k\to\infty} S_{2^n,2^k} = \int_{\mathbb{R}^{3Z}} dx \langle J_t F(\omega(t)), e^{\{i\Sigma_{j=0}^{2^n-1}\mathcal{K}(jt/2^n) - (t/2^n)\Sigma_{j=1}^{2^n} J_{jt/2^n}U(\omega(jt/2^n))\}} J_0 G(x)\rangle_{L^2(\Omega;\mathcal{E})},$$

where

$$\mathcal{K}(T) = \int_T^{T+t/2^n} J_T A(\omega(s))\circ db(s).$$

Since J_s is isometry, (2.1) and (3.7) implies that

$$\|J_sA(x) - J_{s'}A(x)\|_{\mathcal{F}}^2 \leq 2|s-s'| \sup_{x\in\mathbb{R}^{3Z}} \|A(x)\|_{\mathcal{F}} \|H_bA(x)\|_{\mathcal{F}}, \quad s,s' \in \mathbb{R}.$$

Thus one sees that (see Ref. 8, Theorem 2.5 for details)

$$s-\lim_{n\to\infty}\sum_{j=0}^{2^n-1}\mathcal{K}\left(\frac{jt}{2^n}\right)=\int_0^t J_sA(\omega(s))\circ db(s)$$

in $L^2(\Omega;\mathcal{E})$. Since $J.U(\cdot)$ is an $\mathcal{E}$-valued continuous function on $\mathbb{R}\times\mathbb{R}^{3Z}$, we have

$$\lim_{n\to\infty}\frac{t}{2^n}\sum_{j=0}^{2^n-1}J_{jt/2^n}U\left(\omega\left(\frac{jt}{2^n}\right)\right)=\int_0^t J_sU(\omega(s))ds,$$

in $L^2(\Omega;\mathcal{E})$. Hence, again by the Lebesgue dominated convergence theorem, we get the desired result. □

Remark 3.6: It is enough to assume that $A_\mu(\cdot)\in C_b^1(\mathbb{R}^{3Z};\mathcal{F})$, $\mu=1,...,3Z$ *and (3.7) to define the* $\mathcal{E}$*-valued stochastic integral* $\int_0^t J_sA(\omega(s))\circ db(s)$. *However, it is difficult to prove (3.8) under the above conditions. One of the reasons is that, since we do not know a concrete core for* H_{formal}, *we cannot use a limiting argument. Thus, we need the additional condition that* $f_{\mu,j}\in C_b^2(\mathbb{R}^{3Z};\mathcal{H}_{-1/2})$ *and* $A_\mu^0\in C_b^2(\mathbb{R}^{3Z};\mathbb{R})$, $\mu=1,\ldots,3Z, j=1,\ldots,M_\mu$, which implies that $A_\mu(\cdot)\in C_b^2(\mathbb{R}^{3Z};\mathcal{F})$ *to verify (3.8).*

We consider an extension of Theorem 3.5 to a much more general multiplication operator U. From Theorem 3.5 and the fact that J_t is positivity preserving, the following inequality follows:

$$|\langle F,e^{-t(H_0(A)+U)}G\rangle_{\mathcal{L}_Z}|\leqslant\langle|F|,e^{-t(H_F^Z+U)}|G|\rangle_{\mathcal{L}_Z}. \tag{3.10}$$

Let us define for $G\in\mathcal{L}_Z$,

$$\text{sgn } G(x)=\begin{cases}\dfrac{G(x)}{|G(x)|}, & |G(x)|\neq 0,\\ 0, & \text{otherwise.}\end{cases}$$

Lemma 3.7: Let $|U|$ *be a multiplication operator that is* H_F^Z*-form bounded with relative bound* ϵ. *Then* $|U|$ *is* $H_0(A)$*-form bounded with relative bound* $\leqslant\epsilon$.

Proof: Set $\tilde{G}=\text{sgn}(e^{-tH_0(A)}G)$. Putting $F=\tilde{G}K$, $K\geqslant 0$, and $U=0$ in (3.10), we have

$$\langle K,|e^{-tH_0(A)}G|\rangle_{\mathcal{L}_Z}\leqslant\langle K,e^{-tH_F^Z}|G|\rangle_{\mathcal{L}_Z}.$$

Hence, it follows that for a.e. $(x,\phi)\in\mathbb{R}^{3Z}\times Q$, $|e^{-tH_0(A)}G|(x,\phi)\leqslant(e^{-tH_F^Z}|G|)(x,\phi)$. Then a fundamental calculation shows that, for $E>0$,

$$|(H_0(A)+E)^{-1/2}G|(x,\phi)\leqslant((H_F^Z+E)^{-1/2}|G|)(x,\phi),\quad \text{a.e.}\quad (x,\phi)\in\mathbb{R}^{3Z}\times Q.$$

Hence, we have

$$\sup_{\|G\|_{\mathcal{L}_Z}=1}\||U|^{1/2}(H_0(A)+E)^{-1/2}G\|_{\mathcal{L}_Z}\leqslant\sup_{\|G\|_{\mathcal{L}_Z}=1}\||U|^{1/2}(H_F^Z+E)^{-1/2}|G|\,\|_{\mathcal{L}_Z}.$$

Thus, the lemma follows. □

We define a class of multiplication operators in $L^2(\mathbb{R}^{3Z})$.

Definition 3.8: We say that a multiplication operator $W\in\mathcal{M}_\pm(Z)$, $Z\geqslant 1$, *if* W_- *is relatively form bounded with respect to* $\mathbf{p}_Z^2$ *with relative bound* <1 *and* $W_+\in L^1_{loc}(\mathbb{R}^{3Z})$, *where* $W=W_+-W_-$ *(*W_+ *is the non-negative part of W and* $-W_-$ *is the negative part of W). Moreover, we say that* $W\in\mathcal{M}_\pm(Z)_r$ *if* $W\in\mathcal{M}_\pm(Z)$ *and* W_- *and* W_+ *are reduced by the closed subspace* $L^2_{as}(\mathbb{R}^{3Z})$ *in* $L^2(\mathbb{R}^{3Z})$, *respectively.*

Theorem 3.9: *Let U be an H_F^Z-form bounded multiplication operator with relative bound* <1 *so that* $U(\cdot)$ *is an* $\mathcal{F}$*-valued continuous function on* $\mathbb{R}^{3Z}$*, and* $V\in\mathcal{M}_\pm(Z)$*. Then Theorem 3.5 holds with* $H_0(A)+U$ *replaced by* $H_0(A)\dot{+}U\dot{+}(V_+\otimes I)\dot{-}(V_-\otimes I)$*.*

Proof: First, we assume that $V\in L^\infty(\mathbb{R}^{3Z})$. Then, by virtue of Lemma 3.7, $H_0(A)\dot{+}U+V\otimes I$ is a well-defined self-adjoint operator (Ref. 13 KLMN Theorem). The strong Trotter product formula for forms and a limiting argument with respect to V yield (3.8) with $H_0(A)+U$ replaced by $H_0(A)\dot{+}U+V\otimes I$ in the same way as the proof of Theorem 3.5. Next, for any $V\in\mathcal{M}_\pm(Z)$, defining

$$V_{+n}=\begin{cases} V_+, & V_+<n,\\ n, & \text{otherwise,}\end{cases}\quad V_{-m}\begin{cases} V_{-1}, & V_-<m,\\ m, & \text{otherwise,}\end{cases}$$

one sees that (3.8) holds with $H_0(A)+U$ replaced by $H_0(A)\dot{+}U+(V_{+n}\otimes I)-(V_{-m}\otimes I)$. By using convergence theorems for forms as $n,m\to\infty$ (Ref. 8, Theorem 4.13; Ref. 14, Theorem 6.2), we get the desired result. □

We conclude this section with giving a typical example of functional integral representations. Let $f=(f_1,\ldots,f_{3Z})$ satisfy

$$\frac{f_\mu}{\sqrt{\omega}}\in L^2(\mathbb{R}^3),\quad \overline{f_\mu(k)}=f_\mu(-k),\quad \mu=1,...,3Z. \tag{3.11}$$

We introduce a notation $\tilde{f}_\mu(x)$ for $x=(x^1,\ldots,x^N)\in\mathbb{R}^{3Z}$ as follows:

$$\tilde{f}_\mu(x)=\frac{1}{\sqrt{(2\pi)^3}}\,(f_\mu(k)e^{-ikx^{[(\mu/3)+1]}})^\vee,\quad \mu=1,..,3Z,$$

where $[s]$ is the integer part of s, the inverse Fourier transformation $\vee$ is taken with respect to the variable $k\in\mathbb{R}^3$. Because of (3.11), for each $x\in\mathbb{R}^{3Z}$, $\tilde{f}_\mu(x)\in\mathcal{H}_{-1/2}$. Thus, the multiplication operator $\phi(\tilde{f}_\mu(x))$ is well defined and set

$$A_\mu(f)=A_\mu(f(x))\equiv\phi(\tilde{f}_\mu(x)).$$

Put $A(f)=(A_1(f),\ldots,A_{3Z}(f))$. Let $\hat{\varrho}=(\hat{\varrho}_1,\ldots,\hat{\varrho}_{3Z})$, $\hat{\tau}=(\hat{\tau}_1,\ldots,\hat{\tau}_{3Z})$, and $\hat{\eta}=(\hat{\eta}_1,\ldots,\hat{\eta}_{3Z})$ satisfy that $\overline{\hat{\varrho}_\mu(k)}=\hat{\varrho}_\mu(-k)$, $\overline{\hat{\tau}_\mu(k)}=\hat{\tau}_\mu(-k)$ and $\overline{\hat{\eta}_\mu(k)}=\hat{\eta}_\mu(-k)$, and $\hat{\varrho}_\mu/(\sqrt{\omega})^n$, $\hat{\eta}_\mu/(\sqrt{\omega})^m$, $\hat{\tau}_\mu/(\sqrt{\omega})^l\in L^2(\mathbb{R}^3)$, $n,m=-1,0,1,2$, $l=1,2$, $\mu=1,...,3Z$. We fix $\hat{\varrho}$, $\hat{\tau}$, and $\hat{\eta}$. Define

$$H_{\hat{\varrho},\hat{\tau},\hat{\eta}}=\frac{1}{2m}(\mathbf{p}_Z\otimes I-\gamma A(\hat{\varrho}))^2+\alpha\sum_{\mu=1}^{3Z}A_\mu(\hat{\tau})+\beta\sum_{\mu=1}^{3Z}A_\mu(\hat{\eta})^2+I\otimes H_b,$$

where α, β, and γ are real constants.

Theorem 3.10: *Suppose that the absolute value of coupling constants* γ *and* β *are sufficiently small. Then* $H_{\hat{\varrho},\hat{\tau},\hat{\eta}}$ *is self-adjoint on* $D(H_F^Z)$*, bounded from below and essentially self-adjoint on any core for* H_F^Z*. Moreover we have, for* $V\in\mathcal{M}_\pm(Z)$*,*

$$\langle F,e^{-t(H_{\hat{\varrho},\hat{\tau},\hat{\eta}}\dot{+}(V_+\otimes I)\dot{-}(V_-\otimes I))}G\rangle_{\mathcal{L}_Z}=\int_{\tilde{Q}_E}d\nu_E\,\overline{J_tF(\omega(t/m))}J_0G(\omega(0))e^{\mathcal{K}_{\hat{\varrho},\hat{\tau},\hat{\eta}}(t)}e^{-\int_0^tV(\omega(s))ds}, \tag{3.12}$$

where

$$\mathcal{K}_{\hat{\varrho},\hat{\tau},\hat{\eta}}(t)=\sum_{\mu=1}^{3Z}\left\{i\gamma\Phi\left(\int_0^{t/m}j_{ms}\tilde{\hat{\varrho}}_\mu(\omega(s))\circ db_\mu(s)\right)\right.$$
$$\left.-\alpha\Phi\left(\int_0^t j_s\tilde{\hat{\tau}}_\mu(\omega(s))ds\right)-\beta\int_0^t J_s\phi(\tilde{\hat{\eta}}_\mu(\omega(s)))^2 ds\right\}.$$

Proof: For simplicity, we put $\|\cdot\|_{L^2(\mathbb{R}^3)}=\|\cdot\|_2$ and $H_{\hat{\varrho},\hat{\tau},\hat{\eta}}=H_F^Z+H_R+\alpha H_I+\beta H_{II}$ in this proof. Suppose that $V\in C_b(\mathbb{R}^{3Z})$. Note that, for $\Psi\in\mathcal{F}_0\cap D(H_b^{1/2})$,

$$\|\phi(f)\Psi\|_{\mathcal{F}}\leqslant\frac{1}{\sqrt{2}}\left(2\left\|\frac{\hat{f}}{\omega}\right\|_2\|H_b^{1/2}\Psi\|_{\mathcal{F}}+\left\|\frac{\hat{f}}{\sqrt{\omega}}\right\|_2\|\Psi\|_{\mathcal{F}}\right),$$

$$\|[(H_b+I)^{1/2},\phi(f)]\Psi\|_{\mathcal{F}}\leqslant\frac{1}{\sqrt{2}}\left(\frac{1}{2\pi}\int_0^\infty\frac{\sqrt{\lambda}}{(\lambda+1)^2}\,d\lambda\right)(\|\hat{f}\|_2\|H_b^{1/2}\Psi\|_{\mathcal{F}}+\|\sqrt{\omega}\hat{f}\|_2\|\Psi\|_{\mathcal{F}}).$$

By assumptions $\hat{\tau}_\mu/\omega,\ \hat{\tau}_\mu/\sqrt{\omega}\in L^2(\mathbb{R}^3)$, one sees that H_I is infinitesimally small with respect to $I\otimes H_b$. Moreover, we see that, by the above inequalities, for $\Psi\in D(H_F^Z)$,

$$\|H_R\Psi\|_{\mathcal{L}_Z}\leqslant\sum_{\mu=1}^{3Z}\left\{\gamma^2\left(\left\|\frac{\hat{\varrho}_\mu}{\omega}\right\|_2\sum_{n=-1}^{2}\left\|\frac{\hat{\varrho}_\mu}{(\sqrt{\omega})^n}\right\|_2+\left\|\frac{\hat{\varrho}_\mu}{\sqrt{\omega}}\right\|_2\sum_{n=1}^{2}\left\|\frac{\hat{\varrho}_\mu}{(\sqrt{\omega})^n}\right\|_2\right)+|\gamma|\sum_{n=-1}^{2}\left\|\frac{\hat{\varrho}_\mu}{(\sqrt{\omega})^n}\right\|_2\right\}$$
$$\times\|(H_F^Z+I)\Psi\|_{\mathcal{L}_Z}\times C_1,$$
$$\|H_{II}\Psi\|_{\mathcal{L}_Z}\leqslant\sum_{\mu=1}^{3Z}|\beta|\left(\left\|\frac{\hat{\eta}_\mu}{\omega}\right\|_2\sum_{n=-1}^{2}\left\|\frac{\hat{\eta}_\mu}{(\sqrt{\omega})^n}\right\|_2+\left\|\frac{\hat{\eta}_\mu}{\sqrt{\omega}}\right\|_2\sum_{n=1}^{2}\left\|\frac{\hat{\eta}_\mu}{(\sqrt{\omega})^n}\right\|_2\right)\|(H_F^Z+I)\Psi\|_{\mathcal{L}_Z}\times C_2,$$

where C_1 and C_2 are positive constants. Since γ and β are sufficiently small, it holds that $H_R+\alpha H_I+\beta H_{II}$ is relatively bounded with respect to H_F^Z with relative bound <1. Hence, the Kato–Rellich theorem[13] yields that $H_{\hat{\varrho},\hat{\tau},\hat{\eta}}$ is self-adjoint on $D(H_F^Z)$, bounded from below and essentially self-adjoint on any core for H_F^Z. Next we prove (3.12). We suppose that $\omega\sqrt{\omega}\hat{\varrho}_\mu\in L^2(\mathbb{R}^3)$. Then $\hat{\varrho}_\mu/\sqrt{\omega}$, $\sqrt{\omega}\hat{\varrho}_\mu$, $\omega\sqrt{\omega}\hat{\varrho}_\mu\in L^2(\mathbb{R}^3)$ implies that $A_\mu(\hat{\varrho}(\cdot))\in C_b^2(\mathbb{R}^{3Z};\mathcal{F})$, and $A_\mu(\hat{\varrho}(x))\in D(H_b)$ for $x\in\mathbb{R}^{3Z}$, with $\sup_{x\in\mathbb{R}^{3Z}}\|H_bA_\mu(\hat{\varrho}(x))\|_{\mathcal{F}}<\infty$, $\mu=1,2,\ldots,3Z$. Hence, noting that H_I and H_{II} are regarded as $\mathcal{F}$-valued continuous functions on $\mathbb{R}^{3Z}$, by Theorem 3.5, one sees that

$$\text{the right-hand side of (3.12)}=\langle F,e^{-t(H_0(\gamma A(\hat{\varrho}))\dot{+}(\alpha H_I+\beta H_{II})+V\otimes I)}G\rangle_{\mathcal{L}_Z}.$$

Since $\mathcal{L}_Z^\infty$ is a core for $H_{\hat{\varrho},\hat{\tau},\hat{\eta}}$, by Lemma 3.3, we can see that

$$H_0(\gamma A(\hat{\varrho}))\dot{+}(\alpha H_I+\beta H_{II})+V\otimes I=H_{\hat{\varrho},\hat{\tau},\hat{\eta}}+V\otimes I,$$

as self-adjoint operators in $\mathcal{L}_Z$. Hence, (3.12) follows for such $\hat{\varrho}$'s. Let $\omega\sqrt{\omega}\hat{\varrho}_\mu\notin L^2(\mathbb{R}^3)$. We find sequences $\hat{\varrho}^{(n)}=(\hat{\varrho}_1^{(n)},\ldots,\hat{\varrho}_{3Z}^{(n)})$ so that $\omega\sqrt{\omega}\hat{\varrho}_\mu^{(n)}\in L^2(\mathbb{R}^3)$ and

$$\lim_{n\to\infty}\left\|\frac{\hat{\varrho}_\mu}{(\sqrt{\omega})^m}-\frac{\hat{\varrho}_\mu^{(n)}}{(\sqrt{\omega})^m}\right\|_2=0,\quad \mu=1,2,\ldots,3Z,\quad m=2,1,0,-1.$$

For sufficiently small β and γ, $\mathcal{L}_Z^\infty$ is a common core for $H_{\hat{\varrho}^{(n)},\hat{\tau},\hat{\eta}}+V\otimes I$ and

$$s-\lim_{n\to\infty}(H_{\hat{\varrho}^{(n)},\hat{\tau},\hat{\eta}}+V\otimes I)\Psi=(H_{\hat{\varrho},\hat{\tau},\hat{\eta}}+V\otimes I)\Psi,\quad \Psi\in\mathcal{L}_Z^\infty,$$

which implies that, on $\mathcal{L}_Z$,

$$s-\lim_{n\to\infty} e^{-t(H_{\hat{\varrho}^{(n)},\hat{\tau},\hat{\eta}}+V\otimes I)}=e^{-t(H_{\hat{\varrho},\hat{\tau},\hat{\eta}}+V\otimes I)}. \tag{3.13}$$

Since one sees that

$$\left\|\Phi\left(\int_0^t j_s\tilde{\hat{\varrho}}_\mu(\omega(s))db_\mu(s)-\int_0^t j_s\widetilde{\hat{\varrho}_\mu^{(n)}}(\omega(s))db_\mu(s)\right)\right\|^2_{L^2(\Omega;\mathcal{E})}\leqslant C_3\left\|\frac{\hat{\varrho}_\mu}{\sqrt{\omega}}-\frac{\hat{\varrho}_\mu^{(n)}}{\sqrt{\omega}}\right\|_2^2,$$

$$\left\|\Phi\left(\int_0^t j_s\frac{\partial\tilde{\hat{\varrho}}_\mu}{\partial x_\mu}(\omega(s))ds-\int_0^t j_s\frac{\partial\widetilde{\hat{\varrho}_\mu^{(n)}}}{\partial x_\mu}(\omega(s))ds\right)\right\|^2_{L^2(\Omega;\mathcal{E})}\leqslant C_4\|\sqrt{\omega}\hat{\varrho}_\mu-\sqrt{\omega}\hat{\varrho}_\mu^{(n)}\|_2^2,$$

where C_3 and C_4 are positive constants, we have

$$s-\lim_{n\to\infty}\mathcal{K}_{\hat{\varrho}^{(n)},\hat{\tau},\hat{\eta}}(t)=\mathcal{K}_{\hat{\varrho},\hat{\tau},\hat{\eta}}(t),$$

in $L^2(\Omega;\mathcal{E})$. Putting the right-hand side of (3.12) with $\hat{\rho}$ replaced by $\hat{\varrho}^{(n)}$ by $I(n)$, we show that $I(n)$ converges to the right-hand side of (3.12) as $n\to\infty$. Hence, we get (3.12) with $V\in C_b(\mathbb{R}^{3Z})$. For any $V\in\mathcal{M}_\pm(Z)$, by the same limiting argument as in Theorem 3.9, we get the desired result. □

IV. WCL-RUV FOR THE MODEL

In this section, our task is to define the Hamiltonian $H(V,\Lambda)$ of the system with non-negative mass $\mu\geqslant 0$ and a scaling parameter $\Lambda>0$ in the Schrödinger representation in a rigorous manner. Moreover, we investigate the WCL-RUV for the Hamiltonian $H(V,\Lambda)$. Set

$$\Xi_\Lambda(k)=\begin{cases}1, & |k|<\Lambda,\\ 0, & \text{otherwise.}\end{cases}$$

For each $x\in\mathbb{R}^{3Z}$ and $K>0$, put

$$\tilde{\Xi}_K^Z(x)=\frac{1}{\sqrt{(2\pi)^3}}\sum_{j=1}^Z(\Xi_K(k)e^{-ikx^j})^\vee,$$

$$(\Xi_{\Lambda^\alpha})^j_{K,\mu}(x)=\frac{1}{\sqrt{(2\pi)^3}}\left(\frac{\Xi_{\Lambda^\alpha}(k)(I-\Xi_K(k))e^{-ikx^j}k_\mu}{\omega(k)}\right)^\vee,\quad \mu=1,2,3,j=1,\ldots,Z,$$

where the inverse Fourier transformation $\vee$ is taken with respect to the variable $k\in\mathbb{R}^3$. An operator $H^Z(\Lambda)$, $Z\geqslant 1$, acting in $\mathcal{L}_Z$ is defined by

$$H^Z(\Lambda)=\frac{1}{2m}\mathbf{p}_Z^2\otimes I-\Lambda g H_I^Z(\Lambda^\alpha)+\Lambda^2 I\otimes H_b,$$

where

$$H_I^Z(\Lambda^\alpha)=\int_{\mathbb{R}^{3Z}}^\oplus \phi(\tilde{\Xi}^Z_{\Lambda^\alpha}(x))dx,\quad Z\geqslant 1,\quad \alpha>0.$$

Proposition 4.1 (Ref. 2): For any $\Lambda>0$, the operator $H^Z(\Lambda)$ is self-adjoint on $D(H_F^Z)$ and bounded from below. Moreover, it is essentially self-adjoint on any core for H_F^Z.

Set

$$E(\Lambda^\alpha) = -\frac{1}{2(2\pi)^3}\int_{\mathbb{R}^3}\frac{\Xi_{\Lambda^\alpha}(k)}{\omega^2(k)}\,dk,$$

$$\pi_K = \int_{\mathbb{R}^{3Z}}^{\oplus}\mathcal{T}\left\{\pi_F\left(\frac{1}{\sqrt{(2\pi)^3}}\sum_{j=1}^{Z}\frac{\Xi_{\Lambda^\alpha}(I-\Xi_K)e^{ikx^j}}{\omega^2}\right)\right\}\mathcal{T}^{-1}\,dx.$$

We define a unitary operator $\mathcal{U}_K(\Lambda)$ on $\mathcal{L}_Z$ with an infrared cutoff $K>0$ by

$$\mathcal{U}_K(\Lambda) = \exp\left(-i\,\frac{g}{\Lambda}\,\pi_K\right).$$

Here the symbols π_F and $\mathcal{T}$ are defined in Sec. II.

Lemma 4.2: The unitary operator $\mathcal{U}_K(\Lambda)$ maps $\mathcal{L}_Z^\infty$ to $D(H_F^Z)$ with

$$\mathcal{U}_K(\Lambda)^{-1}(H^Z(\Lambda) - g^2 ZE(\Lambda^\alpha))\mathcal{U}_K(\Lambda)|_{\mathcal{L}_Z^\infty}$$

$$= \frac{1}{2m}\left(\mathbf{p}_Z\otimes I - \frac{g}{\Lambda}\,A_K(\Lambda)\right)^2 + U_K^Z(\Lambda) + \Lambda^2 I\otimes H_b\Big|_{\mathcal{L}_Z^\infty}, \tag{4.1}$$

where

$$A_K(\Lambda) = \left(\int_{\mathbb{R}^{3Z}}^{\oplus}\phi((\Xi_{\Lambda^\alpha})_{K,1}^1(x))dx, \int_{\mathbb{R}^{3Z}}^{\oplus}\phi((\Xi_{\Lambda^\alpha})_{K,2}^1(x))dx,\dots,\int_{\mathbb{R}^{3Z}}^{\oplus}\phi((\Xi_{\Lambda^\alpha})_{K,3}^Z(x))dx\right),$$

$$U_K^Z(\Lambda) = -g\Lambda H_I^Z(K) + g^2 V_K^Z(\Lambda)\otimes I - g^2 ZE(K),$$

$$V_K^Z(\Lambda) = V_K^Z(\Lambda,x) = -\frac{1}{2(2\pi)^3}\sum_{i\neq j}^{Z}\int_{\mathbb{R}^3}\frac{\Xi_{\Lambda^\alpha}(k)(1-\Xi_K(k))e^{-ik(x^i-x^j)}}{\omega^2(k)}\,dk,\quad Z\geqslant 2,\quad V_K^1(\Lambda)=0.$$

Proof: Note that $[[-i(\partial/\partial x_\mu^j)\otimes I,\pi_K],\pi_K]=0$, $\mu=1,2,3$, $j=1,\dots,N$. Then (4.1) follows from a direct calculation. □

Remark 4.3: If $\mu>0$, we can put $K=0$ in π_K. Since $\Xi_{\Lambda^\alpha}/\omega\sqrt{\omega}\notin L^2(\mathbb{R}^3)$, in the case $\mu=0$, we need to introduce the infrared cutoff $K>0$.

Since the right-hand side of (4.1) is closable, we denote the closed extension of the right-hand side of (4.1) by $H^Z(K,\Lambda)$ and

$$H_F^Z(\Lambda) = \frac{1}{2m}\,\mathbf{p}_Z^2\otimes I + \Lambda^2 I\otimes H_b.$$

Define a symmetric operator $R(\Lambda,K)$ by

$$H^Z(K,\Lambda) = H_F^Z(\Lambda) + U_K^Z(\Lambda) + R(\Lambda,K).$$

Let

$$V_\mu^Z(x) = -\frac{1}{4\pi}\sum_{1\leqslant i<j\leqslant Z}\frac{e^{-\mu|x^i-x^j|}}{|x^i-x^j|},\quad V_K^Z(x) = -\frac{1}{2(2\pi)^3}\sum_{i\neq j}^{Z}\int_{\mathbb{R}^3}\frac{\Xi_K(k)e^{-ik(x^i-x^j)}}{\omega^2(k)}\,dk,$$

$$V_K^{Zc}(x) = -\frac{1}{2(2\pi)^3}\sum_{i\neq j}^{Z}\int_{\mathbb{R}^3}\frac{(I-\Xi_K(k))e^{-ik(x^i-x^j)}}{\omega^2(k)}\,dk,\quad Z\geqslant 2,$$

$$V_\mu^1(x) = V_K^1(x) = V_K^{1c}(x) = 0.$$

Note that $V_K^Z + V_K^{Zc} = V_\mu^Z$ and V_K^Z is bounded.

Lemma 4.4: For any $\epsilon>0$, there exist Λ_0 and $b(\epsilon)>0$ so that for all $\Lambda>\Lambda_0$, $D(H_F^Z)\subset D(U_K^Z(\Lambda)+R(\Lambda,K))$, and for $\Psi\in D(H_F^Z)$,

$$\|(U_K^Z(\Lambda)+R(\Lambda,K))\Psi\|_{\mathcal{L}_Z}\leqslant\epsilon\|H_F^Z(\Lambda)\Psi\|_{\mathcal{L}_Z}+b(\epsilon)\|\Psi\|_{\mathcal{L}_Z}.$$

Proof: From Ref. 1, Theorem 3.8(1), it follows that, with constant $b_1(\epsilon)\geqslant 0$ and $b_2(\epsilon)\geqslant 0$,

$$\|(g^2V_K^Z(\Lambda)\otimes I+R(\Lambda,K))\Psi\|_{\mathcal{L}_Z}\leqslant\epsilon\|H_F^Z\Psi\|_{\mathcal{L}_Z}+b_1(\epsilon)\|\Psi\|_{\mathcal{L}_Z},$$

$$\|-g\Lambda H_I^Z(K)\Psi\|_{\mathcal{L}_Z}\leqslant\epsilon\|(I\otimes\Lambda^2H_b)\Psi\|_{\mathcal{L}_Z}+b_2(\epsilon)\|\Psi\|_{\mathcal{L}_Z}.$$

Combining above two inequalities, we get the desired result. □

It follows from Lemma 4.4 that, for sufficiently large $\Lambda>0$ and $0<\alpha<\frac{1}{2}$, $H^Z(K,\Lambda)$ is self-adjoint on $D(H_F^Z)$ and essentially self-adjoint on any core for H_F^Z.

Lemma 4.5: Suppose that $0<\alpha<\frac{1}{2}$ and Λ is sufficiently large. Then $\mathcal{U}_K(\Lambda)$ maps $D(H^Z(K,\Lambda))$ onto $D(H^Z(\Lambda))$, with

$$\mathcal{U}_K(\Lambda)^{-1}e^{-tH^Z(\Lambda)}\mathcal{U}_K(\Lambda)=e^{-tH^Z(K,\Lambda)},\quad t\geqslant 0. \tag{4.2}$$

Proof: Since Λ is sufficiently large, $\mathcal{L}_Z^\infty$ is a core for $H^Z(K,\Lambda)$. Then the equality (4.1) extends to the equality on the domain $D(H^Z(K,\Lambda))$. Then (4.2) follows. □

Lemma 4.6: For sufficiently large Λ, $e^{-tH^Z(K,\Lambda)}$ has a functional integral representation:

$$\langle F,e^{-tH^Z(K,\Lambda)}G\rangle_{\mathcal{L}_Z}=\int_{\tilde{Q}_E}d\nu_E\,\overline{J_{\Lambda^2t}F(\omega(t/m))}J_0G(\omega(0))e^{\mathcal{K}_\Lambda^Z(t)}e^{-E_\Lambda^Z(t)}, \tag{4.3}$$

where

$$\mathcal{K}_\Lambda^Z(t)=g\left\{\frac{i}{\Lambda}\sum_{j=1}^{Z}\sum_{\mu=1}^{3}\Phi\left(\int_0^{t/m}j_{m\Lambda^2s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\circ db_\mu^j(s)\right)-\Lambda\Phi\left(\int_0^t j_{\Lambda^2s}\tilde{\tilde{\Xi}}_K(\omega(s))ds\right)\right\},$$

$$E_\Lambda^Z(t)=g^2\int_0^t(V_K^Z(\Lambda,\omega(s))-ZE(K))ds.$$

Proof: From Theorem 3.10, (4.3) follows. □

Theorem 4.7: *Let $0<\alpha<\frac{1}{2}$. Then*

$$s-\lim_{\Lambda\to\infty}e^{-t(H^Z(\Lambda)-g^2ZE(\Lambda^\alpha))}=e^{-t((1/2m)\mathbf{p}_Z^2+g^2V_\mu^Z)}\otimes P_b,$$

where P_b denotes the projection operator onto the subspace $\{z\Omega_{\mathcal{F}}|z\in\mathbb{C}\}\subset\mathcal{F}$.

Before proving Theorem 4.7, we show some lemmas. We denote by $\mathcal{S}(\mathbb{R}^m)$ the set of rapidly decreasing infinitely many times differentiable functions on $\mathbb{R}^m$ and define

$$\mathcal{F}^\infty=\{F(\phi(f_1),\dots,\phi(f_m))|F\in\mathcal{S}(\mathbb{R}^m),f_j\in\mathcal{H}_{-1/2},j=1,...,m,m\geqslant 1\}.$$

Lemma 4.8: Let $0<\alpha<\frac{1}{2}$ and $F_l=e^{i\phi(f_l)}$, $f_l\in\mathcal{H}_{-1/2}$, $l=1,...,M$. Suppose that $0\leqslant t_1<t_2<\cdots<t_M\leqslant t$ and put $F_\Lambda^E(t)=e^{i\Sigma_{l=1}^M\Phi(j_{\Lambda^2t_l}f_l)}$. Then for *u* so that

$$\int_\Omega u(b)^2e^{-2\int_0^tg^2V_K^Z(\omega(s))ds}db<\infty,$$

we have

$$\lim_{\Lambda\to\infty}\int_\Omega db\; u(b)\int_{Q_E} d\mu_E\; F_\Lambda^E(t)e^{\mathcal{K}_\Lambda^Z(t)}=\Pi_{l=1}^M\langle\Omega_{\mathcal{F}},F_l\rangle_{\mathcal{F}}\int_\Omega db\; u(b)e^{-\int_0^t g^2 V_K^Z(\omega(s))ds}e^{-g^2 ZE(K)}. \tag{4.4}$$

Proof: For simplicity, we put $m=1$ in this proof. Let $Z\geqslant 2$. The case of $Z=1$ is similarly proved. The integral on the left-hand side (lhs) of (4.4) is calculated as follows:

$$\text{lhs of (4.4)}=\lim_{\Lambda\to\infty}\int_\Omega u(b)\exp\{-\tfrac{1}{4}(I_\Lambda-II_\Lambda+2iIII_\Lambda)\}db,$$

where

$$I_\Lambda=\left\|\sum_{l=1}^M j_{\Lambda^2 t_l}f_l+\sum_{j=1}^Z\sum_{\mu=1}^3\frac{g}{\Lambda}\int_0^t j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\circ db_\mu^j(s)\right\|_{\mathcal{W}}^2,$$

$$II_\Lambda=\left\|\Lambda g\int_0^t j_{\Lambda^2 s}\tilde{\Xi}_K^Z(\omega(s))ds\right\|_{\mathcal{W}}^2,$$

$$III_\Lambda=\left\langle\sum_{l=1}^M j_{\Lambda^2 t_l}f_l+\sum_{j=1}^Z\sum_{\mu=1}^3\frac{g}{\Lambda}\int_0^t j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\circ db_\mu^j(s),-\Lambda g\int_0^t j_{\Lambda^2 s}\tilde{\Xi}_K^Z(\omega(s))ds\right\rangle_{\mathcal{W}}.$$

We shall estimate $I_\Lambda, II_\Lambda, III_\Lambda$ separately. We see that

$$\begin{aligned}I_\Lambda&=\left\|\sum_{l=1}^M j_{\Lambda^2 t_l}f_l\right\|_{\mathcal{W}}^2+\left\|\sum_{j=1}^Z\sum_{\mu=1}^3\frac{g}{\Lambda}\int_0^t j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\circ db_\mu^j(s)\right\|_{\mathcal{W}}^2\\&\quad+2\Re\left\langle\sum_{l=1}^M j_{\Lambda^2 t_l}f_l,\sum_{j=1}^Z\sum_{\mu=1}^3\frac{g}{\Lambda}\int_0^t j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\circ db_\mu^j(s)\right\rangle_{\mathcal{W}}^2\\&=I_\Lambda^{(1)}+I_\Lambda^{(2)}+2\Re I_\Lambda^{(3)}.\end{aligned}$$

Then one can see that, by the definition of the operator j_t,

$$\lim_{\Lambda\to\infty}I_\Lambda^{(1)}=\lim_{\Lambda\to\infty}\sum_{i,j=1}^M\langle f_i,e^{-\Lambda^2|t_i-t_j|\omega}f_j\rangle_{-1/2}=\sum_{i=1}^M\|f_i\|_{-1/2}^2. \tag{4.5}$$

Moreover, we have

$$\|j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\|_{\mathcal{W}}^2\leqslant\frac{\mathbf{S}^2}{(2\pi)^3}\int_K^{\Lambda^\alpha}r\,dr,$$

$$\left\|j_{\Lambda^2 s}\frac{\partial(\Xi_{\Lambda^\alpha})_{K,\mu}^j}{\partial x_\mu^j}(\omega(s))\right\|_{\mathcal{W}}^2\leqslant\frac{\mathbf{S}^2}{(2\pi)^3}\int_K^{\Lambda^\alpha}r^3\,dr,$$

where $\mathbf{S}^2$ denotes the volume of the two-dimensional sphere. Since $0<\alpha<\frac{1}{2}$, it holds that

$$\begin{aligned}&\lim_{\Lambda\to\infty}\int_\Omega d\mu\left\|\sum_{j=1}^Z\sum_{\mu=1}^3\frac{g}{\Lambda}\int_0^t j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))db_\mu^j(s)\right\|_{\mathcal{W}}^2\\&\quad=\lim_{\Lambda\to\infty}\int_\Omega d\mu\sum_{j=1}^Z\sum_{\mu=1}^3\frac{g^2}{\Lambda^2}\int_0^t ds\|j_{\Lambda^2 s}(\Xi_{\Lambda^\alpha})_{K,\mu}^j(\omega(s))\|_{\mathcal{W}}^2\leqslant\lim_{\Lambda\to\infty}\frac{3Ztg^2\mathbf{S}^2}{(2\pi)^3}\frac{1}{\Lambda^2}\int_K^{\Lambda^\alpha}r\,dr=0,\end{aligned}$$

moreover

$$\lim_{\Lambda\to\infty}\left\|\sum_{j=1}^{Z}\sum_{\mu=1}^{3}\frac{g}{\Lambda}\int_0^t j_{\Lambda^2 s}\frac{\partial(\Xi_{\Lambda^\alpha})_{K,\mu}^j}{\partial x_\mu^j}(\omega(s))ds\right\|_{\mathcal{W}}^2\leqslant\lim_{\Lambda\to\infty}\frac{3Ztg^2\mathbf{S}^2}{(2\pi)^3}\frac{1}{\Lambda^2}\int_K^{\Lambda^\alpha}r^3\,dr=0.$$

Hence we have

$$\lim_{\Lambda\to\infty}\int_\Omega|e^{-(1/4)I_\Lambda^{(2)}}-1|^2db=0. \tag{4.6}$$

By (4.5) and (4.6), we have

$$\lim_{\Lambda\to\infty}\int_\Omega|e^{-(1/4)I_\Lambda^{(3)}}-I|^2db=0.$$

Consequently,

$$\lim_{\Lambda\to\infty}\int_\Omega e^{-(1/4)I_\Lambda}db=\int_\Omega e^{-(1/4)\Sigma_{t=1}^M\|f_l\|_{-1/2}^2}db. \tag{4.7}$$

Next, we consider II_Λ, which is essential to derive a Z-body Coulomb (or Yukawa) potential. Note that $\widehat{j_t f}(k,k_0)=(1/\sqrt{2\pi})e^{-ik_0t}\hat{f}(k)$. Then

$$\begin{aligned}II_\Lambda&=\Lambda^2\frac{2g^2}{(2\pi)^3}\int_{\mathbb{R}^3\times\mathbb{R}}\frac{dk\,dk_0}{\omega^2(k)+k_0^2}\left|\frac{1}{\sqrt{2\pi}}\int_0^t e^{-ik_0\Lambda^2 s}\sum_{j=1}^{Z}\Xi_K(k)e^{-ik\omega^j(s)}\,ds\right|^2\\&=\frac{2g^2}{(2\pi)^3}\int_{\mathbb{R}^3}\Xi_K(k)dk\int_{\mathbb{R}}\frac{dk_0}{\omega^2(k)+\dfrac{k_0^2}{\Lambda^4}}\left|\frac{1}{\sqrt{2\pi}}\int_0^t e^{-ik_0 s}\sum_{j=1}^{Z}e^{-ik\omega^j(s)}\,ds\right|^2.\end{aligned}$$

By the Lebesgue dominated convergence theorem, one sees that

$$\begin{aligned}\lim_{\Lambda\to\infty}II_\Lambda&=\frac{2g^2}{(2\pi)^3}\int_{\mathbb{R}^3}\frac{\Xi_K(k)dk}{\omega^2(k)}\int_{\mathbb{R}}dk_0\left|\frac{1}{\sqrt{2\pi}}\int_0^t e^{-ik_0 s}\sum_{j=1}^{Z}e^{-ik\omega^j(s)}\,ds\right|^2\\&=\frac{2g^2}{(2\pi)^3}\int_{\mathbb{R}^3}\frac{\Xi_K(k)dk}{\omega^2(k)}\int_0^t\left|\sum_{j=1}^{Z}e^{-ik\omega^j(s)}\right|^2ds\\&=4\left\{\int_0^t ds\,\frac{g^2}{2(2\pi)^3}\sum_{i\neq j}^{Z}\int_{\mathbb{R}^3}\frac{\Xi_K(k)e^{-ik(\omega^i(s)-\omega^j(s))}}{\omega^2(k)}\,dk-g^2Z\int_0^t ds\,E(K)\right\}\\&=-4\int_0^t(g^2V_K^Z(\omega(s))+g^2ZE(K))ds.\end{aligned} \tag{4.8}$$

Here, in the second equality in (4.8) we use that the Fourier transformation with respect to k_0 is unitary on $L^2(\mathbb{R}^3)$. Note that II_Λ is monotonously increasing as $\Lambda\to\infty$. Finally, we consider III_Λ. From (4.6) and (4.8), it follows that

$$\lim_{\Lambda\to\infty} III_\Lambda = \lim_{\Lambda\to\infty}\left\langle \sum_{l=1}^{M} j_{\Lambda^2 t_l} f_l, -\Lambda g\int_0^t j_{\Lambda^2 s}\tilde{\Xi}_K(\omega(s))ds\right\rangle_{\mathcal{W}}$$

$$= \lim_{\Lambda\to\infty}\frac{-2\Lambda g}{\sqrt{(2\pi)^3}}\int_{\mathbb{R}^3\times\mathbb{R}}\frac{dk\ dk_0}{\sqrt{2\pi}}\sum_{l=1}^{M}\frac{e^{ik_0\Lambda^2 t_l}\overline{\hat{f}_l}(k)}{\omega^2(k)+k_0^2}\int_0^t\frac{ds}{\sqrt{2\pi}}e^{-i\Lambda^2 sk_0}\Xi_K(k)\sum_{j=1}^{Z}e^{-ik\omega^j(s)}$$

$$= \lim_{\Lambda\to\infty}\frac{-1}{\sqrt{(2\pi)^3}}\frac{g}{\Lambda}\int_{\mathbb{R}^3}dk\sum_{l=1}^{M}\frac{e^{-\Lambda^2|t_l-s|\omega(k)}\overline{\hat{f}_l}(k)\Xi_K(k)}{\omega(k)}\int_0^t\sum_{j=1}^{Z}e^{-ik\omega^j(s)}\ ds.$$

Hence, by the Schwartz inequality,

$$\lim_{\Lambda\to\infty}|III_\Lambda|\leqslant\lim_{\Lambda\to\infty}\frac{Zt}{\sqrt{(2\pi)^3}}\sum_{l=1}^{M}\|f_l\|_{-1/2}\frac{g}{\Lambda}\left(\int_{\mathbb{R}^3}e^{-2\Lambda^2|t_l-s|\omega(k)}\frac{\Xi_K(k)}{\omega(k)^2}dk\right)^{1/2}=0. \qquad (4.9)$$

Then by (4.7), (4.8), and (4.9) and the assumption of u, it holds that

$$\lim_{\Lambda\to\infty}\int_\Omega u(b)e^{-(1/4)(I_\Lambda-II_\Lambda+2iIII_\Lambda)}db=\int_\Omega u(b)e^{-\int_0^t g^2V_K^Z(\omega(s))ds}e^{-g^2ZE(K)}e^{-(1/4)\Sigma_{l=1}^M\|f_l\|_{-1/2}^2}db.$$

Thus, the proof is complete. □

Lemma 4.9: Let $0<\alpha<\frac{1}{2}$ *and* u *as in Lemma 4.8. Then, for* $F,G\in\mathcal{F}$, *we have*

$$\lim_{\Lambda\to\infty}\int_\Omega db\ u(b)\int_{Q_E}d\mu_E(\overline{J_{\Lambda^2 t}F})(J_0G)e^{\mathcal{K}_\Lambda(t)}=\langle F,P_bG\rangle_{\mathcal{F}}\int_\Omega db\ u(b)e^{-\int_0^t g^2V_K^Z(\omega(s))ds}e^{-g^2ZE(K)}. \qquad (4.10)$$

Proof: First we assume that $F,G\in\mathcal{F}^\infty$ so that, with $f\in\mathcal{S}(\mathbb{R}^n)$, $g\in\mathcal{S}(\mathbb{R}^m)$,

$$F=\frac{1}{\sqrt{(2\pi)^n}}\int_{\mathbb{R}^n}\check{f}(t_1,\ldots,t_n)e^{i\Sigma_{j=1}^n\phi(f_j)t_j}\ dt_1\cdots dt_n,$$

$$G=\frac{1}{\sqrt{(2\pi)^m}}\int_{\mathbb{R}^m}\check{g}(s_1,\ldots,s_m)e^{i\Sigma_{j=1}^m\phi(g_j)s_j}\ ds_1\cdots ds_m.$$

Then from Lemma 4.8 (4.10) follows. Since $\mathcal{F}^\infty$ is dense in $\mathcal{F}$, one sees (4.10) for any $F,G\in\mathcal{F}$ by an approximation argument. □

Proof of Theorem 4.7: Let $Z\geqslant 2$. The case of $Z=1$ is similarly proved. It is seen that

$$s-\lim_{\Lambda\to\infty}\mathcal{U}_K(\Lambda)=I.$$

Hence, by Lemma 4.5, and uniform boundedness of $e^{-tH^Z(K,\Lambda)}$ and $e^{-t((1/2m)\mathbf{p}_Z^2+g^2V_\mu^Z)}\otimes P_b$, it is enough to show that for any Θ, $\Psi\in C_0^\infty(\mathbb{R}^{3Z})\hat{\otimes}\mathcal{F}^\infty$,

$$\lim_{\Lambda\to\infty}\langle\Theta,e^{-tH^Z(K,\Lambda)}\Psi\rangle_{\mathcal{L}_Z}=\langle\Theta,e^{-t((1/2m)\mathbf{p}_Z^2+g^2V_\mu^Z)}\otimes P_b\Psi\rangle_{\mathcal{L}_Z}.$$

Let $\Theta=u\otimes F$, $\Psi=v\otimes G$, where F and G have the same forms as those in the proof of Lemma 4.9 and $u,v\in C_0^\infty(\mathbb{R}^{3Z})$. Then

$$\langle\Theta,e^{-tH^Z(K,\Lambda)}\Psi\rangle_{\mathcal{L}_Z}=\int_{\mathbb{R}^{3Z}\times\Omega}dx\ db\ \overline{u(\omega(t/m))}v(\omega(0))e^{-E_\Lambda^Z(t)}\int_{Q_E}d\mu_E(\overline{J_{\Lambda^2 t}F})(J_0G)e^{\mathcal{K}_\Lambda^Z(t)}.$$

First we estimate $E_\Lambda^Z(t)$. Since

$$V_K^Z(\Lambda,x^1,\ldots,x^Z)=-\frac{1}{2\pi^2}\sum_{1\leqslant i<j\leqslant Z}\frac{1}{|x^i-x^j|}\int_K^{\Lambda^\alpha}\frac{r}{r^2+\mu^2}\sin(r|x^i-x^j|)dr,$$

using a contour integral, one can check that there exist $\delta_1>0$ and $\delta_2>0$, which are independent of $\Lambda>0$, so that

$$|V_K^Z(\Lambda,\omega(s))|\leqslant\delta_1|V_\mu^Z(\omega(s))|+\delta_2,\quad \mu\geqslant 0. \tag{4.11}$$

Set

$$\Omega_0=\left\{(x,b)\in\mathbb{R}^{3Z}\times\Omega\;\middle|\;\int_0^t\frac{e^{-\mu|\omega^i(s)-\omega^j(s)|}}{|\omega^i(s)-\omega^j(s)|}ds=\infty,\quad i\neq j,i,j=1,\ldots,Z\right\}.$$

The measure of Ω_0 is zero. One can check that for $(x,b)\in[\mathbb{R}^{3Z}\times\Omega]\backslash\Omega_0$,

$$\lim_{\Lambda\to\infty}V_K^Z(\Lambda,\omega(s))=V_K^{Zc}(\omega(s))<\infty,\quad a.e.s\in[0,t]. \tag{4.12}$$

Combining (4.11) and (4.12), one can see that, for $(x,b)\in[\mathbb{R}^{3Z}\times\Omega]\backslash\Omega_0$, by the Lebesgue dominated convergence theorem,

$$\lim_{\Lambda\to\infty}\int_0^t ds\ V_K^Z(\Lambda,\omega(s))=\int_0^t ds\ V_K^{Zc}(\omega(s)).$$

Hence, for almost everywhere $(x,b)\in\mathbb{R}^{3Z}\times\Omega$,

$$\lim_{\Lambda\to\infty}e^{-E_\Lambda^Z(t)}=e^{-\int_0^t g^2V_K^{Zc}(\omega(s))ds}e^{g^2ZE(K)}.$$

On the other hand, under the notation in the proof of Lemma 4.8, we see that

$$|e^{\mathcal{K}_\Lambda^Z(t)}|\leqslant e^{(1/4)II_\Lambda}. \tag{4.13}$$

As is seen in the proof of Lemma 4.8, the right-hand side of (4.13) is monotonously increasing as $\Lambda\to\infty$. Hence we have, from the definition of F and G,

$$\left|\int_{Q_E}d\mu_E(\overline{J_{\Lambda^2 t}F})(J_0G)e^{\mathcal{K}_\Lambda^Z(t)}\right|\leqslant\left|\int_{\mathbb{R}^{n+m}}\overline{\check{f}(t)}\check{g}(s)dt\ ds\right|e^{-\int_0^t g^2V_K^Z(\omega(s))ds}e^{-g^2ZE(K)}.$$

Then, by (4.11), we have for almost everywhere $(x,b)\in\mathbb{R}^{3Z}\times\Omega$,

$$\left|\overline{u(\omega(t/m))}v(\omega(0))e^{-E_\Lambda^Z(t)}\int_{Q_E}d\mu_E(\overline{J_{\Lambda^2 t}F})(J_0G)e^{\mathcal{K}_\Lambda^Z(t)}\right|$$
$$\leqslant|\overline{u(\omega(t/m))}v(\omega(0))|C_{fg}e^{-\int_0^t(g^2V_K^Z(\omega(s))-\delta_1|V_\mu^Z(\omega(s))|-\delta_2)ds}, \tag{4.14}$$

where $C_{fg}=|\int_{\mathbb{R}^{n+m}}\overline{\check{f}(t)}\check{g}(s)dt\ ds|$. The right-hand side of (4.14) is integrable. By (4.10) and the Lebesgue dominated convergence theorem, we have

$$\lim_{\Lambda\to\infty}\int_{\mathbb{R}^{3Z}\times\Omega}dx\ db\ \overline{u(\omega(t/m))}v(\omega(0))|e^{-E_\Lambda^Z(t)}-e^{-\int_0^t g^2V_K^{Zc}(\omega(s))ds}e^{g^2ZE(K)}|$$
$$\times\int_{Q_E}d\mu_E(\overline{J_{\Lambda^2 t}F})(J_0G)e^{K_\Lambda^Z(t)}=0.$$

While, by Lemma 4.9, we have

$$\lim_{\Lambda\to\infty}\int_{\mathbb{R}^{3Z}\times\Omega}dx\ db\,\overline{u(\omega(t/m))}v(\omega(0))e^{-\int_0^t g^2V_K^{Zc}(\omega(s))ds}e^{g^2ZE(K)}\int_{Q_E}d\mu_E(\overline{J_{\Lambda^2 t}F})(J_0G)e^{K_\Lambda^Z(t)}$$

$$=\int_{\mathbb{R}^{3Z}\times\Omega}dx\ db\overline{u(\omega(t/m))}v(\omega(0))e^{-\int_0^t g^2V_\mu^Z(\omega(s))ds}\langle F,P_bG\rangle_{\mathcal{F}}.$$

Thus

$$\lim_{\Lambda\to\infty}\langle\Theta,e^{-tH^Z(K,\Lambda)}\Psi\rangle_{\mathcal{L}_Z}=\langle u,e^{-t((1/2m)\mathbf{p}_Z^2+g^2V_\mu^Z)}v\rangle_{L^2(\mathbb{R}^{3Z})}\langle F,P_bG\rangle_{\mathcal{F}}.$$

The proof is complete. □

Next, we study the interaction system consisting of the arbitrary but conserved number of particles and the quantized scalar field.

Lemma 4.10: Suppose that $V_Z\in\mathcal{M}_\pm(Z)_r$, $Z\geqslant 1$. *Then* $H^Z(\Lambda)\dot{+}(V_{Z+}\otimes I)\dot{-}(V_{Z-}\otimes I)$ *is reduced by* $\mathcal{H}_Z$.

Proof: Let S be the projection operator from $L^2(\mathbb{R}^{3Z})$ onto $L^2_{as}(\mathbb{R}^{3Z})$. It is seen that

$$H^Z(\Lambda)(S\otimes I)\Psi=(S\otimes I)H^Z(\Lambda)\Psi,\tag{4.15}$$

where $\Psi\in C_0^\infty(\mathbb{R}^{3Z})\hat{\otimes}\mathcal{F}_0$. Since $C_0^\infty(\mathbb{R}^{3Z})\hat{\otimes}\mathcal{F}_0$ is a core for $H^Z(\Lambda)$, (4.15) also holds on $D(H^Z(\Lambda))$. Thus $H^Z(\Lambda)$ is reduced by $\mathcal{H}_Z$. Hence $H^Z(\Lambda)\dot{+}(V_{Z+}\otimes I)\dot{-}(V_{Z-}\otimes I)$ is also reduced by $\mathcal{H}_Z$. □

For the set of potentials $V=\{V_Z\}_{Z=1}^\infty$ with $V_Z\in\mathcal{M}_\pm(Z)_r$, $Z\geqslant 1$, a scaling Hamiltonian $H(V,\Lambda)$ of the system and a self-adjoint operator H_{∞,V,V_μ} in $\otimes_{Z=1}^\infty\mathcal{H}_Z$ are defined by

$$H(V,\Lambda)\equiv\bigoplus_{Z=1}^\infty[H^Z(\Lambda)\dot{+}(V_{Z+}\otimes I)\dot{-}(V_{Z-}\otimes I)|_{\mathcal{H}_Z}],$$

$$H_{\infty,V,V_\mu}\equiv\bigoplus_{Z=1}^\infty\left[\frac{1}{2m}\mathbf{p}_Z^2\dot{+}V_{Z+}\dot{-}V_{Z-}+g^2V_\mu^Z\Big|_{L^2_{as}(\mathbb{R}^{3Z})}\right].\tag{4.16}$$

Let N_a be the number operator in $\mathcal{F}_a$, i.e.,

$$(N_a\Psi)_Z=Z\Psi_Z,\quad D(N_a)=\left\{\Psi=\{\Psi_Z\}_{Z=0}^\infty\,\middle|\,\sum_{Z=0}^\infty Z^2\|\Psi_Z\|^2_{L_{as}(\mathbb{R}^{3Z})}<\infty\right\}.$$

Since $-g^2E(\Lambda^\alpha)N_a\otimes I$ is a non-negative self-adjoint operator and reduced by $\otimes_{Z=1}^\infty L^2_{as}(\mathbf{R}^{3Z})\equiv\mathcal{F}_p$, $H(V,\Lambda)\dot{+}(-g^2E(\Lambda^\alpha)N_a|_{\mathcal{F}_p}\otimes I)$ is well defined. We state the main theorem in this paper.

Theorem 4.11: *Let* $0<\alpha<\frac{1}{2}$ *and* $V=\{V_Z\}_{Z=1}^\infty$ *with* $V_Z\in\mathcal{M}_\pm(Z)_r$, $Z\geqslant 1$. *Then*

$$s-\lim_{\Lambda\to\infty}e^{-t(H(V,\Lambda)\dot{+}(-g^2E(\Lambda^\alpha)N_a|_{\mathcal{F}_p}\otimes I))}=e^{-tH_{\infty,V,V_\mu}}\otimes P_b.$$

Proof: For $\Psi=(\Psi_0,\Psi_1,\ldots.)\in\mathcal{L}$, it follows that, by Theorem 4.7 and the Lebesgue dominated convergence theorem,

$$s-\lim_{\Lambda\to\infty}e^{-t(H(V,\Lambda)\dot{+}(-g^2E(\Lambda^\alpha)N_a|_{\mathcal{F}_p}\otimes I))}\Psi=s-\lim_{\Lambda\to\infty}\bigoplus_{Z=1}^\infty e^{-t(H^Z(\Lambda)\dot{+}(V_{Z+}\otimes I)\dot{-}(V_{Z-}\otimes I)-g^2ZE(\Lambda^\alpha))}\Psi_Z$$

$$=\bigoplus_{Z=1}^\infty[e^{-t((1/2m)\mathbf{p}_Z^2\dot{+}V_{Z+}\dot{-}V_{Z-}+g^2V_\mu^Z)}\otimes P_b]\Psi_Z$$

$$=e^{-tH_{\infty,V,V_\mu}}\otimes P_b\Psi_Z.$$

Thus, the proof is complete. □

TABLE I.

	$V_\mu^Z(Z\geqslant 2)$	$E(\Lambda^\alpha)$	μ	α
$d=3$	$-\frac{1}{4\pi}\Sigma_{1\leqslant i<j\leqslant Z}\frac{e^{-\mu\lvert x^i-x^j\rvert}}{\lvert x^i-x^j\rvert}$	$-\frac{1}{2(2\pi)^3}\int_{\mathbb{R}^3}\frac{\Xi_\Lambda{}^\alpha(k)}{k^2+\mu^2}\,dk$	$\mu\geqslant 0$	$0<\alpha<\frac{1}{2}$

V. CONCLUDING REMARKS

(1) Let $V_Z=0$, $Z\geqslant 1$, in Theorem 4.11. Formally, we may write

$$H_{\infty,0,V_\mu}=\int\Psi^\dagger(x)\left(-\frac{1}{2m}\Delta\right)\Psi(x)dx-\frac{g^2}{4\pi}\int\Psi^\dagger(x)\Psi^\dagger(y)\frac{e^{-\mu\lvert x-y\rvert}}{\lvert x-y\rvert}\Psi(y)\Psi(x)dx\,dy.$$

(2) We can also investigate the WCL-RUV for models in the space dimension $d=1,2$. Without proofs, we only show results in the space dimension $d=1,2$ in Table I.
Here J_0 is the Bessel function: $J_0(x)=\Sigma_{n=0}^\infty[(-1)^n/n!\Gamma(n+1)](x/2)^{2n}$. Since, in the case where $d=1,2$, each potential V_μ^Z does not converge as $\mu\to 0$, we cannot expect to get their WCL-RUV with $\mu=0$.

(Received 6 July 1998; accepted for publication 19 November 1998)

We review Bohr's reasoning in the Bohr–Einstein debate on the photon box experiment. The essential point of his reasoning leads us to an uncertainty relation between the proper time and the rest mass of the clock. It is shown that this uncertainty relation can be derived if only we take the fundamental point of view that the proper time should be included as a dynamic variable in the Lagrangian describing the system of the clock. Some problems and some positive aspects of our approach are then discussed. © *1999 American Institute of Physics.*

I. INTRODUCTION

In various arguments about time, perhaps the most spectacular is the Einstein–Bohr debate on the photon box experiment.[1,2] Their concern in the debate was Heisenberg's time–energy uncertainty relation. However, Bohr's reasoning reveals, as shown in the following, an uncertainty relation between the proper time and the rest mass of a clock. In fact, his essential point was simply that the very act of weighing a clock, according to general relativity, interferes with the rate of the clock.

In order to review Bohr's reasoning, we consider an experiment in which we measure the rest mass of a clock. We assume, of course, that the clock keeps its own proper time.

Following Einstein's stratagem, we try to weigh the clock by suspending it with a spring. That is to say, if the spring stretches by the length l, we can calculate the mass m of the clock from the relation

$$kl = mg,$$

where g is the gravitational acceleration and k is a constant characterizing the spring.

Assume that a scale is fixed to the spring support, and that we read the length l on it with an accuracy Δq. Then the determination of l involves a minimum latitude Δp in the momentum of the clock, related to Δq by the equation $\Delta q\, \Delta p \approx h$. Let t be the time interval in which we read the length l. (We should note that t is measured by a clock other than the suspended clock.) Then we cannot determine the force exerted by the gravitational field on the clock to a finer accuracy than $\Delta p/t$. Therefore we cannot determine the mass m to a finer accuracy than Δm given by the relation

$$\frac{\Delta p}{t} \approx g\, \Delta m. \qquad (1)$$

Now, according to general relativity theory, a clock, when displaced in the direction of the gravitational force by an amount Δq, changes its rate in such a way that its reading in the course of a time interval t differs by an amount $\Delta \tau$ given by the relation

[a)]Electronic mail: shuichi@edu.u-ryukyu.ac.jp

$$\frac{\Delta\tau}{t}=\frac{g\,\Delta q}{c^2}. \tag{2}$$

By combining (1), (2) and the relation $\Delta q\,\Delta p \approx h$, we see, therefore, that there is an uncertainty relation,

$$c^2\,\Delta m\,\Delta\tau \approx h \tag{3}$$

between the rest mass m and the proper time τ of the clock.

The relativistic redshift formula (2) was, of course, essential in Bohr's reasoning above. The more essential it seems to be, however, the stronger the apprehension we feel that the uncertainty relation (3) may fail if we can think of a weighing procedure not resorting to any interaction between the clock and the gravitational field. We check one such case in the following.

Assume that the clock has been brought to rest after being charged with an electric charge e, and that a uniform electric field $\mathcal{E}$ is then switched on. After a short time t, we measure the distance the clock has moved. (Again t is the time measured by a clock other than our clock in the electric field.) Then we can know the average velocity v of the clock by dividing the distance by the value of t, and we can determine the mass m of the clock by virtue of the formula

$$e\mathcal{E}=m\frac{v}{t}.$$

Assume that the determination of the distance is made with a given accuracy Δq. Then it implies a minimum latitude Δp in the momentum of the clock, where $\Delta q\,\Delta p \approx h$. Hence, we cannot determine the force exerted by the electric field on the clock to a finer accuracy than $\Delta p/t$. Therefore, even when the velocity v is obtained, we cannot determine the mass m to a finer accuracy than Δm given by the relation

$$\frac{\Delta p}{t}\approx \Delta m\frac{v}{t}, \quad \text{i.e.}\ \ \Delta p \approx v\,\Delta m. \tag{4}$$

Now, according to special relativity theory, when a clock has a speed v, its rate τ in the course of a time interval t is given by the relation

$$\tau = t\sqrt{1-(v/c)^2}. \tag{5}$$

On the other hand, the average velocity v has an uncertainty Δv given by the relation

$$t\,\Delta v \approx \Delta q.$$

Correspondingly, the clock has an uncertainty in its rate τ of the order $\Delta\tau$ given by

$$\Delta\tau = t\cdot\Delta\sqrt{1-(v/c)^2}\approx \frac{v}{c^2}t\Delta v \approx \frac{v}{c^2}\Delta q. \tag{6}$$

By combining (4), (6), and the relation $\Delta q\,\Delta p \approx h$, we arrive, therefore, at the same uncertainty relation,

$$c^2\,\Delta m\,\Delta\tau \approx h,$$

as (3) obtained by Bohr's reasoning.

Thus, the uncertainty relation (3) has been confirmed for a weighing procedure that does not rely on any gravitational interaction. Moreover, in this case, the time-shift formula (5) played an essential role in place of the relativistic redshift formula.

Each of these formulas is, of course, one of the deepest and most important results in relativistic theory. The fact that these important formulas play essential roles in deriving the uncertainty relation (3) lends some confidence as to its universality.

Our objective in this article is to show the following: The uncertainty relation (3) can be derived satisfactorily only if we describe the system of the clock by using a Lagrangian that includes the proper time as a dynamic variable.

In the next section, selecting the simplest Lagrangian that is in accord with the above approach, we examine the Hamiltonian formalism of the clock. Our conclusion is that the rest energy can be considered the momentum conjugate to the proper time. In the third section, following Dirac's procedure, we quantize the system of the clock, and we obtain the same uncertainty relation as (3). Some comments then follow on our quantization.

II. LAGRANGIAN AND HAMILTONIAN FORMALISM

A gravitational field $g_{\mu\nu}$ and an electromagnetic field A_μ are assumed to be given, and we consider our clock to be one material particle moving in those fields with electric charge e.

The Lagrangian that is generally used in such a case is the following:

$$L_0 = -mc\sqrt{-g_{\mu\nu}(x)\dot{x}^\mu \dot{x}^\nu} + eA_\mu(x)\dot{x}^\mu,$$

where x^μ ($\mu = 0,1,2,3$) are the variables and the overdot denotes the differential with respect to an arbitrary parameter λ. It goes without saying that m is the rest mass of the clock and that c is the speed of light.

We, however, cannot consider the proper time τ a physical quantity if we describe the system by using the Lagrangian L_0. On the other hand, it is clear that the proper time of a clock is a measurable physical quantity. (It is why a clock is so named.) Hence, we have to find another Lagrangian that is in accord with the system of the clock.

Our first purpose in this section is to find a Lagrangian L that satisfies the following conditions: (1) The Lagrangian L has the proper time τ as a new variable, in addition to x^μ. (2) The motion equations for the variables x^μ are invariant between L and L_0.

As a candidate, we consider the Lagrangian defined by

$$L = M(\dot{\tau} - \sqrt{-g_{\mu\nu}(x)\dot{x}^\mu \dot{x}^\nu}/c) + eA_\mu(x)\dot{x}^\mu,$$

where the dynamic variables are τ, M, and x^μ.

The Lagrange's equations of motion are as follows:

$$\dot{M} = 0, \tag{7}$$

$$\dot{\tau} = \sqrt{-g_{\mu\nu}(x)\dot{x}^\mu \dot{x}^\nu}/c, \tag{8}$$

$$\frac{d}{d\lambda}\left[\frac{M}{c}\frac{g_{\rho\mu}\dot{x}^\mu}{\sqrt{-g_{\mu\nu}(x)\dot{x}^\mu \dot{x}^\nu}} + eA_\rho(x)\right] - \frac{M}{c}\frac{g_{\mu\nu,\rho}\dot{x}^\mu \dot{x}^\nu}{2\sqrt{-g_{\mu\nu}\dot{x}^\mu \dot{x}^\nu}} - eA_{\mu,\rho}(x)\dot{x}^\mu = 0. \tag{9}$$

The second equation (8) means that we can identify the variable τ with the proper time of this clock. Moreover, we have $d\tau/d\lambda > 0$, and therefore it is possible to change the differential with respect to λ to one with respect to τ in the third equation (9). As a result, we find that

$$\frac{d}{d\tau}\left[\frac{M}{c^2}g_{\rho\mu}\dot{x}^\mu + eA_\rho(x)\right] - \frac{M}{2c^2}g_{\mu\nu,\rho}\dot{x}^\mu \dot{x}^\nu - eA_{\mu,\rho}(x)\dot{x}^\mu = 0,$$

where the overdot denotes the differential with respect to τ. Rewriting this equation, we get

$$\frac{M}{c^2}[\ddot{x}^\rho+\Gamma^\rho{}_{\mu\nu}\dot{x}^\mu\dot{x}^\nu]=ef^{\rho\mu}\dot{x}_\mu, \tag{10}$$

where $\Gamma^\rho_{\mu\nu}$ and $f_{\mu\nu}$ are defined by

$$\Gamma^\rho{}_{\mu\nu}=\tfrac{1}{2}g^{\rho\sigma}(-g_{\mu\nu,\sigma}+g_{\nu\sigma,\mu}+g_{\sigma\mu,\nu}),\quad f_{\mu\nu}=A_{\nu,\mu}-A_{\mu,\nu}.$$

On the other hand, the motion equation derived from the original Lagrangian L_0 is

$$m[\ddot{x}^\rho+\Gamma^\rho{}_{\mu\nu}\dot{x}^\mu\dot{x}^\nu]=ef^{\rho\mu}\dot{x}_\mu. \tag{11}$$

Equation (10) is just the same as Eq. (11) if we identify M with the constant mc^2. Equation (7) indicates that this identification is possible.

Thus, our first purpose has been achieved. Moreover, this Lagrangian L is the simplest of those that satisfy the above two conditions.

The second purpose in this section is to investigate, by using the Lagrangian L, the consequences of our assertion that the proper time should be considered a dynamic variable.

We note that it is possible to propose an argument without imposing any limitation on the fields $g_{\mu\nu}$ and A_μ. In such an argument, however, we have to handle the coordinate time $x^0=ct$ as a dynamic variable, and then determine certain constraint conditions for the variables. A discussion of such constraints is not essential for our purpose. We therefore assume for simplicity hereafter that the fields $g_{\mu\nu}$ and A_μ are so-called static in the following sense: (1) The functions $g_{\mu\nu}$ and A_μ depend on only x^1, x^2, x^3. (2) For $i=1,2,3$, we have $g_{i0}(=g_{0i})=0$.

Assuming the above conditions, we get

$$L=M(\dot{\tau}-\sqrt{f(x)^2-g_{ij}(x)\dot{x}^i\dot{x}^j/c^2})+ceA_0(x)+eA_i(x)\dot{x}^i,$$

where f is defined by $g_{00}=-f^2$ $(f>0)$. The dynamic variables are τ, M, x^i $(i=1,2,3)$, and the overdot denotes the differential with respect to t.

The momentum conjugate to those variables are given by

$$p_\tau\equiv\frac{\partial L}{\partial\dot{\tau}}=M,\quad p_M\equiv\frac{\partial L}{\partial\dot{M}}=0$$

and

$$p_i\equiv\frac{\partial L}{\partial\dot{x}^i}=\frac{M}{c^2}\frac{g_{ij}\dot{x}^j}{\sqrt{f^2-g_{jk}\dot{x}^j\dot{x}^k/c^2}}+eA_i.$$

We have

$$H_0=p_\tau\dot{\tau}+p_M\dot{M}+p_i\dot{x}^i-L=f\sqrt{M^2+c^2g^{ij}(p_i-eA_i)(p_j-eA_j)}-ceA_0.$$

If M is replaced by mc^2, then H_0 is identical with the Hamiltonian that is derived from the original Lagrangian L_0. In our case, however, there exist two constraints:

$$\phi_1\equiv M-p_\tau=0,\quad \phi_2\equiv p_M=0.$$

Taking account of these constraints, we have to consider the total Hamiltonian:

$$H\equiv H_0+u_1\phi_1+u_2\phi_2,$$

where u_1 and u_2 are Lagrange's undetermined multipliers.

The multipliers u_1 and u_2 are determined in the following manner:[3] Poisson's bracket of ϕ_1 and ϕ_2 is

$$\{\phi_1, \phi_2\} = 1,$$

and therefore we have

$$\dot{\phi}_1 = \{\phi_1, H\} \approx u_2,$$

$$\dot{\phi}_2 = \{\phi_2, H\} \approx -u_1 - \frac{fM}{\sqrt{M^2 + c^2 g^{ij}(p_i - eA_i)(p_j - eA_j)}},$$

where the symbol ''≈'' denotes the weak equality defined by the constraints $\phi_1 = \phi_2 = 0$. Hence, the consistency conditions

$$\dot{\phi}_1 \approx 0 \quad \text{and} \quad \dot{\phi}_2 \approx 0$$

require the multipliers u_1 and u_2 to be

$$u_1 = -\frac{fM}{\sqrt{M^2 + c^2 g^{ij}(p_i - eA_i)(p_j - eA_j)}} \quad \text{and} \quad u_2 = 0,$$

which give

$$H = H_0 - \frac{fM(M - p_\tau)}{\sqrt{M^2 + c^2 g^{ij}(p_i - eA_i)(p_j - eA_j)}}. \tag{12}$$

Hamilton's canonical equations of motion are as follows:

$$\dot{\tau} = \frac{\partial H}{\partial p_\tau} = \frac{fM}{\sqrt{M^2 + c^2 g^{ij}(p_i - eA_i)(p_j - eA_j)}},$$

$$\dot{p}_\tau = -\frac{\partial H}{\partial \tau} = 0,$$

$$\dot{M} = \frac{\partial H}{\partial p_M} = 0,$$

$$\dot{p}_M = -\frac{\partial H}{\partial M} \approx 0,$$

$$\dot{x}^i = \frac{\partial H}{\partial p_i} \approx \frac{\partial H_0}{\partial p_i},$$

$$\dot{p}_i = -\frac{\partial H}{\partial x^i} \approx -\frac{\partial H_0}{\partial x^i}.$$

Defining a matrix W_{ij} by

$$W_{ij} \equiv \{\phi_i, \phi_j\} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

we can write Dirac's bracket:

$$\{A,B\}_{\mathrm{D}}=\{A,B\}-\sum_{i,j=1}^{2}\{A,\phi_i\}W_{ij}^{-1}\{\phi_j,B\}=\{A,B\}+\{A,\phi_1\}\{\phi_2,B\}-\{A,\phi_2\}\{\phi_1,B\}.$$

We can easily calculate Dirac's brackets between the canonical variables:

$$\{\tau,p_\tau\}_{\mathrm{D}}=\{\tau,M\}_{\mathrm{D}}=1,\quad \{x^i,p_j\}_{\mathrm{D}}=\delta^i{}_j,\quad \text{the others}=0.$$

We are now in a position to be able to state our conclusions in this section.

It is easily shown that

$$\phi_1,\ \ \phi_2,\ \ T\equiv\tau-p_M,\quad E\equiv p_\tau,\ \ x^i,\ \ p_i\quad (i=1,2,3)$$

are canonical variables, and, therefore, the variables T,E,x^i,p_i $(i=1,2,3)$ can be interpreted as canonical variables on the submanifold defined by the constraints $\phi_1=\phi_2=0$. We can show also that

$$\{A,B\}_{\mathrm{D}}=\frac{\partial A}{\partial T}\frac{\partial B}{\partial E}-\frac{\partial A}{\partial E}\frac{\partial B}{\partial T}+\sum_{i=1}^{3}\left(\frac{\partial A}{\partial x^i}\frac{\partial B}{\partial p_i}-\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial x^i}\right),$$

on the submanifold.

Since we have that

$$T=\tau\quad\text{and}\quad E=M(=mc^2)$$

on the submanifold defined by $\phi_1=\phi_2=0$, it follows from the above that the rest energy mc^2 is considered the momentum conjugate to the proper time τ.

III. QUANTIZATION AND DISCUSSIONS

Thus, we have arrived at the following conclusion: If we accept the view that we should describe a clock by using a Lagrangian, which includes the proper time as a dynamic variable like the positions x^i, then we find that the rest energy $E=mc^2$ turns out to be the general momentum conjugate to the proper time, and that τ, E, x^i, and p_i are canonical variables of the system.

Since τ,E,x^i,p_i are the canonical variables, if we quantize the system by Dirac's procedure, there are corresponding operators:

$$\hat\tau,\quad \hat E,\quad \hat x^i,\quad \hat p_i\quad (i=1,2,3),$$

which satisfy the commutation relations

$$[\hat\tau,\hat E]=[\hat x^i,\hat p_i]=i\hbar. \tag{13}$$

The relation $[\hat\tau,\hat E]=i\hbar$ in (13) leads us to the uncertainty relation,

$$c^2\,\Delta m\,\Delta\tau\geqslant\hbar/2, \tag{14}$$

which was argued in the Introduction to this article.

Our quantization leads to some desirable results besides the uncertainty relation (14), but at the same time gives rise to some problems.

First, we should make some comment on the problems. In our quantization, the operators $\hat\tau$, $\hat E$, $\hat x^i$ and $\hat p_i$ $(i=1,2,3)$ can be represented in the Hilbert space composed of square integrable functions of τ, x^1, x^2, and x^3. In particular, the operator $\hat E$ is represented by the differential operator $-i\hbar\partial/\partial\tau$, and, therefore, the rest energy $\hat{E}$ cannot have any discrete spectrum. Furthermore, this Hilbert space includes some states in which the mean values of $\hat{E}$ are negative.

The problems of the continuous mass spectrum and of the negative mass are inevitable in our formulation. The authors cannot, at present, judge whether these characteristics are desirable or not. These problems will be discussed in a subsequent paper from a rather different viewpoint.

Second, we focus our attention on some positive aspects of our quantization. We restrict ourselves, for simplicity, to the case in which the space–time metric is flat and $A_\mu=0$. Then the Hamiltonian in (12) is rather simple and the Hamiltonian operator has the form

$$\hat{H}\equiv\sqrt{\hat{E}^2+c^2\hat{\mathbf{p}}^2}.$$

(We omit, hereafter, the overcarets representing the operators, since there is no possibility of misunderstanding.)

For the Heisenberg representation of the operator τ,

$$\tau(t)=e^{itH/\hbar}\tau e^{-itH/\hbar},$$

we find that

$$\frac{d}{d\tau}\tau(t)=\frac{i}{\hbar}e^{itH/\hbar}[H,\tau]e^{-itH/\hbar}=\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}, \tag{15}$$

by virtue of

$$[\tau,H]=i\hbar\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}.$$

Hence, we have

$$\tau(t)=\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}t+\tau. \tag{16}$$

We note that the last term of (15) is the operator that represents the time delay of the moving clock.

We can, moreover, show that

$$\frac{d}{dt}\tau(t)^2=\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}\tau(t)+\tau(t)\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}=2\frac{E^2}{E^2+c^2\mathbf{p}^2}t+\left[\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}},\tau\right]_+,$$

where we have used Eq. (16), and where $[A,B]_+$ denotes the anticommutator of operators A and B. Integrating this, we have

$$\tau(t)^2=\frac{E^2}{E^2+c^2\mathbf{p}^2}t^2+\left[\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}},\tau\right]_+t+\tau^2.$$

Hence, the standard deviation $\Delta\tau(t)$ in a state ψ is given by

$$(\Delta\tau(t))^2\equiv\langle\tau(t)^2\rangle-\langle\tau(t)\rangle^2=\left(\left\langle\frac{E^2}{E^2+c^2\mathbf{p}^2}\right\rangle-\left\langle\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}\right\rangle^2\right)t^2+\left(\left\langle\left[\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}},\tau\right]_+\right\rangle\right.$$
$$\left.-2\left\langle\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}\right\rangle\langle\tau\rangle\right)t+(\langle\tau^2\rangle-\langle\tau\rangle^2), \tag{17}$$

where $\langle A\rangle$ denotes the mean value of an operator A in the state ψ.

Here we must introduce some approximations: We assume that the Hamiltonian operator has a very sharp value (say $\mathcal{E}$) in the state ψ. This assumption seems to be natural since the clock is moving as a free particle. Under this assumption, we can approximately estimate the two terms in (17) in the following manner;

$$\left\langle \frac{E^2}{E^2+c^2\mathbf{p}^2}\right\rangle - \left\langle \frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}\right\rangle^2 \approx \frac{1}{\mathcal{E}^2}(\langle E^2\rangle - \langle E\rangle^2),$$

$$\left\langle \left[\frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}},\tau\right]_+\right\rangle - 2\left\langle \frac{E}{\sqrt{E^2+c^2\mathbf{p}^2}}\right\rangle\langle\tau\rangle \approx \frac{1}{\mathcal{E}}(\langle[E,\tau]_+\rangle - 2\langle E\rangle\langle\tau\rangle). \tag{18}$$

On the other hand, the term $\langle[E,\tau]_+\rangle - 2\langle E\rangle\langle\tau\rangle$ in (18) often vanishes, as it does in the case of all optimal simultaneous measurements of E and τ. (We can easily check it by setting, for example, $\tau = i\hbar\,\partial/\partial E$ and ψ=a Gaussian function of E.) Taking this cancellation into account, we neglect the second term in (17).

Thus, we have arrived at

$$(\Delta\tau(t))^2 \approx \frac{1}{\mathcal{E}^2}(\Delta E)^2 t^2 + (\Delta\tau)^2,$$

and, by virtue of the inequality

$$\frac{1}{\mathcal{E}^2}(\Delta E)^2 t^2 + (\Delta\tau)^2 \geqslant \frac{2}{\mathcal{E}}\Delta\tau\,\Delta E\, t,$$

we finally have

$$(\Delta\tau(t))^2 \geqslant \frac{\hbar}{\mathcal{E}}t, \tag{19}$$

where we have used the uncertainty relation $\Delta\tau\,\Delta E \geqslant \hbar/2$ of (14).

When the motion of the clock is so slow that the value of $\mathcal{E}$ is approximately equal to mc^2, then our inequality (19) has the form

$$(\Delta\tau(t))^2 \geqslant \frac{\hbar}{mc^2}t, \tag{20}$$

which exactly coincides with an inequality derived by Salecker and Wigner from another point of view [see Eq. (6) in Ref. 4].

In conclusion, we should make some comment on the meaning of our results to physics.

Bohr and Rosenfeld stressed the principle that every proper theory should provide in and by itself its own means for defining the quantities with which it deals. One of the key points this principle makes is that we should analyze the means of measuring those quantities in order to argue the consistency of a physical theory. In their case, they succeeded in showing that the definition of the standard quantization of electromagnetic field is consistent in the above sense by discussing the means of measuring the classical electromagnetic field.[5,6]

Several authors have applied this principle to the theory of relativity to find a consistent quantization of the space–time geometry. The theory deals with such quantities as the metric tensor, the curvature tensor, the covariant derivative, and connection coefficients. The measurement of the distance between two events is most fundamental in the procedures by which we measure these quantities. For this we require the concept of a clock,[7,8] and the clock cannot be independent of the various physical laws. Thus, if the above principle should be a general feature of physical theory, a consistent formulation of the quantization of the space–time geometry should have some inherent relation with various limitations on the accuracy of the clock resulting from the physical laws.

Various gedanken experiments on such limitations have been proposed and elaborated on for some 50 years.[4,7–16] In many of them, however, the clock is assumed to have some structure, from which starting point the argument is developed. It seems uncertain therefore whether their results are universal or not. Moreover, different studies sometimes reach different conclusions. Our objective in the present paper was to propose an attempt to dispose of this ambiguity. We showed the following: (a) There is an uncertainty relation between the proper time and the rest mass of a clock independent of its structure [see Eq. (3)]. (b) A limitation on the accuracy of the clock is derived from the uncertainty relation in a natural way [see Eqs. (19) and (20)].

The subject raised here has been argued, despite its importance, only at the level of thought experiments. The authors are uneasy with this situation, and think that the time has come to argue it at a more positive level. We hope that the importance of this subject is recognized and that, for example, the relation (20) is verified by experiment in the near future.

Path integral for the relativistic three-dimensional Aharonov–Bohm–Coulomb system

De-Hone Lin[a)]
Department of Physics, National Tsing Hua University, Hsinchu 30043, Taiwan

(Received 2 December 1997; accepted for publication 19 October 1998)

The path integral for the relativistic three-dimensional spinless Aharonov–Bohm–Coulomb system is solved, and the energy spectra are extracted from the resulting amplitude. [S0022-2488(99)00403-X]

I. INTRODUCTION

With the help of Duru and Kleinert's path-dependent time transformation,[1] the list of solvable path integrals has been extended to essentially all potential problems that possess a solvable Schrödinger equation.[2,3] Only recently has the technique been extended to relativistic potential problems.[2,4–9] In this paper, we perform the path integral of the relativistic particle in three dimensions in the presence of both an infinitely thin Aharonov–Bohm magnetic field along the z axis[10] and a $1/r$ Coulomb potential centered at the origin (ABC system). The energy spectra of the system are extracted from the resulting amplitude.

II. THE RELATIVISTIC PATH INTEGRAL

Adding a vector potential $\mathbf{A}(\mathbf{x})$ to Kleinert's path integral for a relativistic particle in a potential $V(\mathbf{x})$,[4] we find that the expression of the fixed-energy amplitude of a relativistic particle in external static electromagnetic fields is given by[6]

$$G(\mathbf{x}_b,\mathbf{x}_a;E)=\frac{i\hbar}{2Mc}\int_0^\infty dL\int \mathcal{D}\rho(\lambda)\Phi[\rho(\lambda)]\int \mathcal{D}^D x(\lambda)e^{-A_E/\hbar}, \tag{2.1}$$

with the action

$$A_E=\int_{\lambda_a}^{\lambda_b} d\lambda\left[\frac{M}{2\rho(\lambda)}\mathbf{x}'^2(\lambda)-i(e/c)\mathbf{A}(\mathbf{x})\cdot\mathbf{x}'(\lambda)-\rho(\lambda)\frac{(E-V(\mathbf{x}))^2}{2Mc^2}+\rho(\lambda)\frac{Mc^2}{2}\right]. \tag{2.2}$$

For the ABC system under consideration, the potential is

$$V(r)=-e^2/r, \tag{2.3}$$

and the vector potential reads as

$$A_i=2g\,\partial_i\varphi, \tag{2.4}$$

where e is the charge and φ is the azimuthal angle around the tube:

$$\varphi(\mathbf{x})=\arctan(x_2/x_1). \tag{2.5}$$

The associated magnetic field lines are confined to an infinitely thin tube along the z axis:

$$B_3=2g\epsilon_{3jk}\partial_j\,\partial_k\varphi=2g2\pi\delta^{(2)}(\mathbf{x}_\perp), \tag{2.6}$$

[a)]Electronic mail: d793314@phys.nthu.edu.tw

where $\mathbf{x}_\perp$ is the transverse vector $\mathbf{x}_\perp \equiv (x_1, x_2)$.

To obtain a tractable path integral for the potential $V(\mathbf{x})$, we have to regularize it via a so-called f transformation,[2,5] which exchanges the path parameter λ by a new one s:

$$d\lambda = ds\, f_l(\mathbf{x}_n) f_r(\mathbf{x}_{n-1}), \tag{2.7}$$

where $f_l(\mathbf{x})$ and $f_r(\mathbf{x})$ are invertible functions whose product is positive. The freedom in choosing $f_{l,r}$ amounts to an invariance under path-dependent reparametrizations of the path parameter λ in the fixed-energy amplitude of Eq. (2.1).[2] By this transformation, the $(D+1)$-dimensional relativistic fixed-energy amplitude for arbitrary time-independent potential turns into[2,5,6]

$$G(\mathbf{x}_b, \mathbf{x}_a; E) \approx \frac{i\hbar}{2Mc} \int_0^\infty dS \prod_{n=1}^{N+1} \left[\int d\rho_n\, \Phi(\rho_n) \right] \frac{f_l(\mathbf{x}_a) f_r(\mathbf{x}_b)}{(2\pi\hbar \epsilon_b^s \rho_b f_l(\mathbf{x}_b) f_r(\mathbf{x}_a)/M)^{D/2}} \times \prod_{n=1}^{N} \left[\int_{-\infty}^{\infty} \frac{d^D x_n}{(2\pi\hbar \epsilon_n^s \rho_n f(\mathbf{x}_n)/M)^{D/2}} \right] \exp\left\{ -\frac{1}{\hbar} A^N \right\}, \tag{2.8}$$

with the s-sliced action

$$A^N = \sum_{n=1}^{N+1} \left[\frac{M(\mathbf{x}_n - \mathbf{x}_{n-1})^2}{2\epsilon_n^s \rho_n f_l(\mathbf{x}_n) f_r(\mathbf{x}_{n-1})} - i\frac{e}{c} \mathbf{A}(\mathbf{x}_n) \cdot (\mathbf{x}_n - \mathbf{x}_{n-1}) - \epsilon_n^s \rho_n f_l(\mathbf{x}_n) f_r(\mathbf{x}_{n-1}) \frac{(E - V(\mathbf{x}_n))^2}{2Mc^2} + \epsilon_n^s \rho_n f_l(\mathbf{x}_n) f_r(\mathbf{x}_{n-1}) \frac{Mc^2}{2} \right]. \tag{2.9}$$

A family function that regulates the ABC system is

$$f_l(\mathbf{x}) = f(\mathbf{x}), \quad f_r(\mathbf{x}) = 1, \tag{2.10}$$

whose product satisfies $f_l(\mathbf{x}) f_r(\mathbf{x}) = f(\mathbf{x}) = r$. Thus, arrive at the amplitude

$$G(\mathbf{x}_b, \mathbf{x}_a; E) \approx \frac{i\hbar}{2Mc} \int_0^\infty dS \prod_{n=1}^{N+1} \left[\int d\rho_n\, \Phi(\rho_n) \right] \frac{r_a}{(2\pi\hbar \epsilon_b^s \rho_b r_b/M)^{3/2}} \times \prod_{n=2}^{N+1} \left[\int_{-\infty}^{\infty} \frac{d^3 \triangle x_n}{(2\pi\hbar \epsilon_n^s \rho_n r_{n-1}/M)^{3/2}} \right] \exp\left\{ -\frac{1}{\hbar} A^N \right\}, \tag{2.11}$$

where the action is

$$A^N = \sum_{n=1}^{N+1} \left[\frac{M(\mathbf{x}_n - \mathbf{x}_{n-1})^2}{2\epsilon_n^s \rho_n r_n} - i(e/c) \mathbf{A}(\mathbf{x}_n) \cdot (\mathbf{x}_n - \mathbf{x}_{n-1}) - \epsilon_n^s \rho_n r_n \frac{(E - V(\mathbf{x}_n))^2}{2Mc^2} + \epsilon_n^s \rho_n r_n \frac{Mc^2}{2} \right]. \tag{2.12}$$

In Eq. (2.11), we have changed the notation of the measure of integration, since x_n are Cartesian coordinates and are certainly identical in the time-sliced expressions:[2]

$$\prod_{n=1}^{N} \left[\int_{-\infty}^{\infty} d\mathbf{x}_n \right] = \prod_{n=2}^{N+1} \left[\int_{-\infty}^{\infty} d\triangle \mathbf{x}_n \right], \tag{2.13}$$

where the integrals over $\triangle \mathbf{x}_n$ may be performed successively from $n=N$ down to $n=1$. To apply the Kustaanheimo–Stiefel (KS) transformation (e.g., Ref. 2), we now incorporate the dummy fourth dimension into the action by replacing $\mathbf{x}$ in the kinetic term by the four-vector $\vec{x}$ and extending the kinetic action to

$$A_{\rm kin}^{N}=\sum_{n=1}^{N+1}\frac{M}{2}\frac{(\vec{x}_n-\vec{x}_{n-1})}{\epsilon_n^s\rho_n r_n}. \tag{2.14}$$

This is achieved by inserting the following trivial identity:

$$\prod_{n=1}^{N+1}\left[\int\frac{d(\triangle x^4)_n}{(2\pi\hbar\epsilon_n^s\rho_n r_n/M)^{1/2}}\right]\exp\left\{-\frac{1}{\hbar}\sum_{n=1}^{N+1}\frac{M}{2}\frac{(\triangle x_n^4)^2}{\epsilon_n^s\rho_n r_n}\right\}=1. \tag{2.15}$$

Hence the fixed-energy amplitude of the ABC system in three dimensions can be rewritten as the four-dimensional path integral,

$$G(\mathbf{x}_b,\mathbf{x}_a;E)\approx\frac{i\hbar}{2Mc}\int_0^\infty dS\prod_{n=1}^{N+1}\left[\int d\rho_n\,\Phi(\rho_n)\right]\int dx_a^4\frac{r_a}{(2\pi\hbar\epsilon_b^s\rho_b r_b/M)^2}$$
$$\times\prod_{n=2}^{N+1}\left[\int_{-\infty}^{\infty}\frac{d^4\triangle x_n}{(2\pi\hbar\epsilon_n^s\rho_n r_{n-1}/M)^2}\right]\exp\left\{-\frac{1}{\hbar}A^N\right\}, \tag{2.16}$$

where A^N is the action of Eq. (2.12) in which the three-vectors $\mathbf{x}_n$ of the kinetic term are replaced by the four-vectors $\vec{x}_n$. With the help of the following approximation:

$$\frac{r_a}{(2\pi\hbar\epsilon_b^s\rho_b r_b/M)^2}\prod_{n=2}^{N+1}\left[\int_{-\infty}^{\infty}\frac{d^4\triangle x_n}{(2\pi\hbar\epsilon_n^s\rho_n r_{n-1}/M)^2}\right]$$
$$\approx\frac{1}{r_a}\frac{1}{\left(2\pi\hbar\epsilon_b^s\rho_b/M\right)^2}\prod_{n=2}^{N+1}\left[\int_{-\infty}^{\infty}\frac{d^4\triangle x_n}{(2\pi\hbar\epsilon_n^s\rho_n r_n/M)^2}\right], \tag{2.17}$$

we arrive at

$$G(\mathbf{x}_b,\mathbf{x}_a;E)\approx\frac{i\hbar}{2Mc}\int_0^\infty dS\prod_{n=1}^{N+1}\left[\int d\rho_n\,\Phi(\rho_n)\right]\int dx_a^4\frac{1}{r_a}\frac{1}{(2\pi\hbar\epsilon_b^s\rho_b/M)^2}$$
$$\times\prod_{n=2}^{N+1}\left[\int_{-\infty}^{\infty}\frac{d^4\triangle x_n}{(2\pi\hbar\epsilon_n^s\rho_n r_n/M)^2}\right]\exp\left\{-\frac{1}{\hbar}\sum_{n=1}^{N+1}A^N\right\}. \tag{2.18}$$

We now solve the ABC system by introducing the KS transformation,

$$\begin{pmatrix}x_1\\x_2\\x_3\end{pmatrix}=A(\vec{u})\begin{pmatrix}u^1\\u^2\\u^3\\u^4\end{pmatrix}, \tag{2.19}$$

with the 3×4 matrix

$$A(\vec{u})=\begin{pmatrix} u^3 & u^4 & u^1 & u^2 \\ u^4 & -u^3 & -u^2 & u^1 \\ u^1 & u^2 & -u^3 & -u^4 \end{pmatrix}. \tag{2.20}$$

The transformation maps $R^4 \rightarrow R^3$, which means that the transformation is not one to one and no Jacobian exists. Since

$$r=(u^1)^2+(u^2)^2+(u^3)^2+(u^4)^2 \equiv (\vec{u})^2, \tag{2.21}$$

after replacing the Coulomb potential $V(r)$ with $1/r$ in Eq. (2.18), the KS transformation certainly transforms the potential terms r and $1/r$ in Eq. (2.18) into harmonic in $\vec{u}$ and $1/\vec{u}^2$, respectively. The mapping of the tangent vectors du^μ into dx^i is given by

$$\begin{pmatrix} dx_1 \\ dx_2 \\ dx_3 \end{pmatrix} = 2\begin{pmatrix} u^3 & u^4 & u^1 & u^2 \\ u^4 & -u^3 & -u^2 & u^1 \\ u^1 & u^2 & -u^3 & -u^4 \end{pmatrix}\begin{pmatrix} du^1 \\ du^2 \\ du^3 \\ du^4 \end{pmatrix}. \tag{2.22}$$

To make the mapping unique, let us embed the tangent vector (dx_1, dx_2, dx_3) into a fictitious four-dimensional space and define a new, fourth component dx_4 by an additional fourth row in the matrix, thereby extending Eq. (2.22) to the four-vector equation,

$$d\vec{x}=2A(\vec{u})d\vec{u}. \tag{2.23}$$

The arrow on the top of the x indicates that x has become a four-vector. For symmetry reasons, the 4×4 matrix $A(\vec{u})$ is chosen as

$$A(\vec{u})=\begin{pmatrix} u^3 & u^4 & u^1 & u^2 \\ u^4 & -u^3 & -u^2 & u^1 \\ u^1 & u^2 & -u^3 & -u^4 \\ u^2 & -u^1 & u^4 & -u^3 \end{pmatrix}. \tag{2.24}$$

The transformation of the coordinate difference is given by

$$(\triangle \mathbf{x}_n^i)^2 = 4\overline{\mathbf{u}_n^2}(\triangle \mathbf{u}_n^i)^2, \tag{2.25}$$

where $\overline{\mathbf{u}_n} \equiv (\mathbf{u}_n + \mathbf{u}_{n-1})/2$. In the continuum limit, this amounts to

$$d^4x_n = 16\mathbf{u}_n^2\, d^4u_n = 16 r_n\, d^4u_n, \tag{2.26}$$

$$\vec{x}'^2 = 4\vec{u}^2\vec{u}'^2 = 4r\vec{u}'^2. \tag{2.27}$$

The magnetic interaction under the KS transformation turns into

$$\mathbf{A}(\mathbf{x}_n)\cdot(\mathbf{x}_n-\mathbf{x}_{n-1}) = -2g\,\frac{x_n^2\triangle x_n^1 - x_n^1\triangle x_n^2}{r_n^2} = -2g\left[\frac{u_n^1\triangle u_n^2 - u_n^2\triangle u_n^1}{(u_n^1)^2+(u_n^1)^2} + \frac{u_n^4\triangle u_n^3 - u_n^3\triangle u_n^4}{(u_n^3)^2+(u_n^4)^2}\right]. \tag{2.28}$$

We obtain a path integral equivalent to Eq. (2.16),

$$G(\mathbf{x}_b, \mathbf{x}_a; E) = \frac{i\hbar}{2Mc}\int_0^\infty dS\, e^{SEe^2/\hbar Mc^2} G(\vec{u}_b, \vec{u}_a; S), \tag{2.29}$$

where $G(\vec{u}_b,\vec{u}_a;S)$ denotes the s-sliced amplitude,

$$\prod_{n=1}^{N+1}\left[\int d\rho_n\,\Phi(\rho_n)\right]\frac{1}{16}\int\frac{dx_a^4}{r_a}\frac{1}{(2\pi\hbar\epsilon_b^s\rho_b/m)^2}\prod_{n=1}^{N}\left[\int_{-\infty}^{\infty}\frac{d^4u_n}{(2\pi\hbar\epsilon_n^s\rho_n/m)^2}\right]\exp\left\{-\frac{1}{\hbar}A^N\right\}, \tag{2.30}$$

with the action

$$A^N=\sum_{n=1}^{N+1}\left\{\frac{m(\triangle\vec{u}_n)^2}{2\epsilon_n^s\rho_n}-i(e/c)(\vec{A}(u_n)\cdot\triangle\vec{u}_n)+\epsilon_n^s\rho_n\frac{m\omega^2\vec{u}_n^2}{2}-\epsilon_n^s\rho_n\frac{\hbar^2 4\alpha^2}{2m\vec{u}_n^2}\right\}. \tag{2.31}$$

Here

$$m=4M,\quad \omega^2=\frac{M^2c^4-E^2}{4M^2c^2}, \tag{2.32}$$

and

$$\vec{A}(u_n)\cdot\triangle\vec{u}_n=-2g\left[\frac{u_n^1\triangle u_n^2-u_n^2\triangle u_n^1}{(u_n^1)^2+(u_n^1)^2}+\frac{u_n^4\triangle u_n^3-u_n^3\triangle u_n^4}{(u_n^3)^2+(u_n^4)^2}\right]. \tag{2.33}$$

We now choose the gauge $\rho(s)=1$ in Eq. (2.30). This leads to the Duru–Kleinert transformed action,

$$A=\int_0^S ds\left[\frac{m\vec{u}'^2}{2}-2i(e/c)(\vec{A}\cdot\vec{u}')+\frac{m\omega^2\vec{u}^2}{2}-\frac{4\hbar^2\alpha^2}{2m\vec{u}^2}\right]. \tag{2.34}$$

It describes a particle, forgetting the magnetic interaction term for awhile, of mass $m=4M$ moving as a function of the ''pseudotime'' s in a four-dimensional harmonic oscillator potential of frequency,

$$\omega^2=\frac{M^2c^4-E^2}{4M^2c^2}. \tag{2.35}$$

The oscillator possesses an additional attractive potential $-4\hbar^2\alpha^2/2m\vec{u}^2$, which is conveniently parametrized in the form of a centrifugal barrier,

$$V_{\text{extra}}=\hbar^2\frac{l_{\text{extra}}^2}{2m\vec{u}^2}, \tag{2.36}$$

whose squared angular momentum has the negative value $l_{\text{extra}}^2\equiv-4\alpha^2$, where α denotes the fine-structure constant $\alpha\equiv e^2/\hbar c\approx\frac{1}{137}$.

There are no s-slicing corrections. This is ensured by the affine connection of the KS transformation, satisfying

$$\Gamma_\mu{}^{\mu\lambda}=g^{\mu\nu}e_i{}^\lambda\partial_\mu e^i{}_\nu=0, \tag{2.37}$$

and the transverse gauge $\partial_\mu A^\mu=0$.[2,5] We now analyze the effect coming from the magnetic interaction. Note that the system becomes separable like $R^4\to R^2\times R^2$ if the centrifugal term is not considered for awhile. Therefore the path integral in u space becomes two independent two-dimensional AB plus a harmonic oscillator. This makes the path integral calculation of

$G(\vec{u}_b,\vec{u}_a;S)$ extremely simple. For each two-dimensional system, the derivatives in front of φ in Eq. (2.6) commute everywhere, except at the origin, where Stokes' theorem yields

$$\int d^2u(\partial_1\partial_2-\partial_2\partial_1)\varphi=\oint d\varphi=2\pi. \tag{2.38}$$

The magnetic flux through the tube is defined by the integral

$$\Phi=\int d^2u\, B_3. \tag{2.39}$$

A comparison with Eq. (2.6) shows that the coupling constant g in Eq. (2.4) is related to the magnetic flux by

$$g=\frac{\Phi}{4\pi}. \tag{2.40}$$

When inserting $A_i=2g\,\partial_i\varphi$ into Eq. (2.34), the interaction takes the form

$$\mathcal{A}_{\mathrm{mag}}=-\hbar\beta_0\int_0^S ds\,\varphi', \tag{2.41}$$

where β_0 is the dimensionless number,

$$\beta_0\equiv-\frac{2eg}{\hbar c}. \tag{2.42}$$

The minus sign is a matter of convention. Since the particle orbits are present at all times, their world lines in space–time can be considered as being closed at infinity, and the integral

$$n=\frac{1}{2\pi}\int_0^S ds\,\varphi' \tag{2.43}$$

is the topological invariant with integer values of the winding number n. The magnetic interaction is therefore a purely topological one, its value being

$$\mathcal{A}_{\mathrm{mag}}=-\hbar\beta_0 2\pi n. \tag{2.44}$$

After adding this to the action of Eq. (2.34) in the radial decomposition of the relativistic path integral,[2,5,6] we rewrite the sum over the azimuthal quantum numbers m via Poisson's summation formula, and obtain

$$G(\mathbf{u}_b,\mathbf{u}_a;S)=\int_{-\infty}^{\infty}d\beta\frac{1}{\sqrt{u_bu_a}}G(u_b,u_a;S)_\beta\sum_{n=-\infty}^{\infty}\frac{1}{2\pi}e^{i(\beta-\beta_0)(\varphi_b+2n\pi-\varphi_a)}. \tag{2.45}$$

Since the winding number n is often not easy to measure experimentally, let us extract observable consequences that are independent of n. The sum over all n forces β to be equal to β_0 modulo an arbitrary integer number. The result, for each R^2, is

$$G(\mathbf{u}_b,\mathbf{u}_a;S)=\sum_{k=-\infty}^{\infty}\frac{1}{\sqrt{u_bu_a}}G(u_b,u_a;S)_{k+\beta_0}\frac{1}{2\pi}e^{ik(\varphi_b-\varphi_a)}. \tag{2.46}$$

Therefore we obtain the fixed-energy amplitude,

$$G(\mathbf{x}_b,\mathbf{x}_a;E)=\frac{i\hbar}{2Mc}\int_0^\infty dS\, e^{SEe^2/\hbar Mc^2}\frac{1}{16}\int\frac{dx_a^4}{r_a}\left(\frac{m\omega}{\hbar\sinh\omega s}\right)^2$$
$$\times\sum_{k_1=-\infty}^{\infty}\sum_{k_2=-\infty}^{\infty}e^{ik_1(\varphi_{1,b}-\varphi_{1,a})}e^{ik_2(\varphi_{2,b}-\varphi_{2,a})}\exp\left\{-\frac{m\omega}{2\hbar}(\sigma_{1,b}^2+\sigma_{1,a}^2+\sigma_{2,b}^2\right.$$
$$\left.+\sigma_{2,a}^2)\coth\omega s\right\}I_{|k_1+\beta_0|}\left(\frac{m}{\hbar}\frac{\omega\sigma_{1,b}\sigma_{1,a}}{\sinh\omega s}\right)I_{|k_2+\beta_0|}\left(\frac{m}{\hbar}\frac{\omega\sigma_{2,b}\sigma_{2,a}}{\sinh\omega s}\right),\tag{2.47}$$

where (σ_1,φ_1) and (σ_2,φ_2) are defined by

$$u^1=\sigma_1\sin\varphi_1,\quad u^2=\sigma_1\cos\varphi_1,\quad u^3=\sigma_2\cos\varphi_2,\quad u^4=\sigma_2\sin\varphi_2.\tag{2.48}$$

In order to perform the x_a^4 integration, we express $(\sigma_1,\varphi_1,\sigma_2,\varphi_2)$ in terms of a three-dimensional spherical coordinate with an auxiliary angle γ:

$$\begin{array}{l}u^1=\sqrt{r}\cos(\theta/2)\cos[(\varphi+\gamma)/2]\\u^2=\sqrt{r}\cos(\theta/2)\sin[(\varphi+\gamma)/2]\\u^3=\sqrt{r}\sin(\theta/2)\cos[(\varphi-\gamma)/2]\\u^4=\sqrt{r}\sin(\theta/2)\sin[(\varphi-\gamma)/2]\end{array}\left(\begin{array}{c}0\leqslant\theta\leqslant\pi\\0\leqslant\varphi\leqslant2\pi\\0\leqslant\gamma\leqslant4\pi\end{array}\right),\tag{2.49}$$

and identify

$$\sigma_1=\sqrt{r}\cos(\theta/2),\quad\varphi_1=(\varphi+\gamma+\pi)/2,\quad\sigma_2=\sqrt{r}\sin(\theta/2),\quad\varphi_2=(\varphi-\gamma)/2.\tag{2.50}$$

Then one can change the x_a^4 integration into the γ_a integration, whose result is easily represented as the Kronecker delta δ_{k_1,k_2}. Hence, one can carry out k_2 summation and it finally becomes

$$G(\mathbf{x}_b,\mathbf{x}_a;E)=\frac{i\hbar}{2Mc}\frac{M^2\omega}{\pi\hbar^2}\sum_{k=-\infty}^{\infty}e^{ik(\varphi_b-\varphi_a)}\int_0^\infty dy\, e^{2(Ee^2/2\omega\hbar Mc^2)y}\frac{1}{\sinh^2 y}e^{-(m\omega/2\hbar)(r_b+r_a)\coth y}$$
$$\times I_{|k+\beta_0|}\left(\frac{m\omega\sqrt{r_br_a}}{\hbar\sinh y}\cos\theta_b/2\cos\theta_a/2\right)I_{|k+\beta_0|}\left(\frac{m\omega\sqrt{r_br_a}}{\hbar\sinh y}\sin\theta_b/2\sin\theta_a/2\right),\tag{2.51}$$

where we have defined the new variable $y=\omega s$. We now make use of the addition theorem, Ref. 11, Vol. II, p. 99:

$$\frac{z}{2}J_\nu(z\sin\alpha\sin\beta)J_\mu(z\cos\alpha\cos\beta)$$
$$=(\sin\alpha\sin\beta)^\nu(\cos\alpha\cos\beta)^\mu\sum_{l=0}^\infty(-1)^l(\mu+\nu+2l+1)\frac{\Gamma(\mu+\nu+l+1)\Gamma(\nu+l+1)}{l!\Gamma(\mu+l+1)\Gamma^2(\nu+1)}$$
$$\times J_{\mu+\nu+l+1}(z)\,{}_2F_1(-l,\mu+\nu+l+1,\nu+1;\sin^2\alpha)\,{}_2F_1(-l,\mu+\nu+l+1,\nu+1;\sin^2\beta),\tag{2.52}$$

and the relation between hypergeometric function and Jacobi polynomials,

$$P_l^{(\alpha,\beta)}(z)=\frac{\Gamma(\alpha+l+1)}{\Gamma(\alpha+1)l!}\,{}_2F_1\left(\alpha+\beta+l+1,-l;1+\alpha;\frac{1-z}{2}\right).\tag{2.53}$$

We arrive at

$$G(\mathbf{x}_b,\mathbf{x}_a;E)=\frac{i\hbar}{2Mc}\,\frac{M}{2\pi\hbar\sqrt{r_b r_a}}\sum_{k=-\infty}^{\infty}\sum_{n=0}^{\infty}e^{ik(\varphi_b-\varphi_a)}$$
$$\times(\cos\theta_b/2\cos\theta_a/2)^{|k+\beta_0|}(\sin\theta_b/2\sin\theta_a/2)^{|k+\beta_0|}$$
$$\times\frac{n!\,\Gamma(n+2|k+\beta_0|+1)(2n+2|k+\beta_0|+1)}{\Gamma^2(n+2|k+\beta_0|+1)}$$
$$\times\left\{\int_0^\infty dy\, e^{2(Ee^2/2\omega\hbar Mc^2)y}\frac{1}{\sinh y}e^{-m\omega/2\hbar\,(r_b+r_a)\coth y}I_{2n+2|k+\beta_0|+1}\left(\frac{m\omega\sqrt{r_b r_a}}{\hbar\sinh y}\right)\right\}$$
$$\times P_n^{(|k+\beta_0|,|k+\beta_0|)}(\cos\theta_b)P_n^{(|k+\beta_0|,|k+\beta_0|)}(\cos\theta_a). \tag{2.54}$$

At this place, the additional centrifugal barrier (2.36) is incorporated via the replacement[12]

$$(2n+2|k+\beta_0|+1)\to\sqrt{(2n+2|k+\beta_0|+1)^2-4\alpha^2}. \tag{2.55}$$

This integral can be calculated by employing the formula

$$\int_0^\infty dy\,\frac{e^{2\nu y}}{\sinh y}\exp\left[-\frac{t}{2}(\zeta_a+\zeta_b)\coth y\right]I_\mu\left(\frac{t\sqrt{\zeta_b\zeta_a}}{\sinh y}\right)=\frac{\Gamma((1+\mu)/2-\nu)}{t\sqrt{\zeta_b\zeta_a}\,\Gamma(\mu+1)}W_{\nu,\mu/2}(t\zeta_b)M_{\nu,\mu/2}(t\zeta_b), \tag{2.56}$$

with the range of validity

$$\zeta_b>\zeta_a>0,\quad \mathrm{Re}[(1+\mu)/2-\nu]>0,\quad \mathrm{Re}(t)>0,|\arg t|<\pi,$$

where $M_{\mu,\nu}$ and $W_{\mu,\nu}$ are the Whittaker functions, we complete the integration of Eq. (2.54), and find the amplitude for $r_b>r_a$ in the closed form

$$G(\mathbf{x}_b,\mathbf{x}_a;E)=\frac{i\hbar}{2Mc}\,\frac{Mc}{4\pi r_b r_a\sqrt{M^2c^4-E^2}}\sum_{k=-\infty}^{\infty}\sum_{n=0}^{\infty}e^{ik(\varphi_b-\varphi_a)}$$
$$\times(\cos\theta_b/2\cos\theta_a/2)^{|k+\beta_0|}(\sin\theta_b/2\sin\theta_a/2)^{|k+\beta_0|}\,\frac{n!(2n+2|k+\beta_0|+1)}{\Gamma(n+2|k+\beta_0|+1)}$$
$$\times\frac{\Gamma((1/2)+(1/2)\sqrt{(2n+2|k+\beta_0|+1)^2-4\alpha^2}-(E\alpha/\sqrt{M^2c^4-E^2}))}{\Gamma(\sqrt{(2n+2|k+\beta_0|+1)^2-4\alpha^2}+1)}$$
$$\times W_{E\alpha/\sqrt{M^2c^4-E^2},\sqrt{(2n+2|k+\beta_0|+1)^2-4\alpha^2}/2}\left(\frac{2}{\hbar c}\sqrt{M^2c^4-E^2}\,r_b\right)$$
$$\times M_{E\alpha/\sqrt{M^2c^4-E^2},\sqrt{(2n+2|k+\beta_0|+1)^2-4\alpha^2}/2}\left(\frac{2}{\hbar c}\sqrt{M^2c^4-E^2}\,r_a\right)$$
$$\times P_n^{(|k+\beta_0|,|k+\beta_0|)}(\cos\theta_b)P_n^{(|k+\beta_0|,|k+\beta_0|)}(\cos\theta_a). \tag{2.57}$$

The energy spectra can be extracted from the poles. They are determined by

$$\frac{1}{2}+\frac{1}{2}\sqrt{(2n+2|k+\beta_0|+1)^2-4\alpha^2}-\frac{E\alpha}{\sqrt{M^2c^4-E^2}}=-n_r,\quad n_r=0,1,2,\ldots. \tag{2.58}$$

Expanding this equation into a power of α, we get

$$E_{n_r,n,k}=\pm Mc^2\left\{1-\frac{1}{2}\left(\frac{\alpha}{n_r+n+|k+\beta_0|+1}\right)^2-\frac{\alpha^4}{(n_r+n+|k+\beta_0|+1)^3}\right.$$
$$\left.\times\left[\frac{1}{2n+2|k+\beta_0|+1}-\frac{3}{8(n_r+n+|k+\beta_0|+1)}\right]+O(\alpha^6)\right\},$$
$$n_r,n=0,1,2,3,\ldots. \tag{2.59}$$

In the nonrelativistic limit, the spectra is in agreement with the result in Refs. 13–15. It is worth noting that if the flux is quantized, i.e., $4\pi g=2\pi\hbar c/e\times$ integer, $|k+\beta_0|$ is an integer and the spectrum is that of the relativistic hydrogen atom. In this case, there is no Aharonov–Bohm effect.

ACKNOWLEDGMENT

The author is grateful to Professor H. Kleinert for his critical reading and correcting of the manuscript.

Metric symmetries and spin asymmetries of Ricci-flat Riemannian manifolds

Brett McInnes,[a]
Department of Mathematics, National University of Singapore, 10 Kent Ridge Crescent, Singapore 119260, Republic of Singapore

(Received 31 March 1998; accepted for publication 29 October 1998)

The Calabi–Yau and Joyce manifolds used in string and *M*-theory compactifications have no continuous groups of isometries, but they often have nontrivial discrete (actually finite) isometry groups. Discrete isometries of nonsimply connected Riemannian manifolds do not necessarily map spin structures into themselves, however; thus, inconsistencies are possible if a spin connection is used to construct the gauge vacuum. We consider this problem in detail and show how it may be avoided. [S0022-2488(99)00103-6]

I. INTRODUCTION

The ''duality revolution'' in string and *M* theories[1] has revealed that the large discrete symmetry groups of these theories impose extremely powerful consistency conditions. The status of some of these symmetries remains conjectural, however, and much remains to be clarified regarding the *meaning* of symmetry in the string context.

There is no doubt that the most comprehensible symmetries of any higher-dimensional theory are the *geometric* symmetries of the underlying Riemannian and semi-Riemannian manifolds. As we shall see, even these most familiar symmetries can give rise to surprises; it is beneficial to have these complications under control before embarking on the analysis of the far more general, but much less well understood, duality symmetries. More generally, the Ricci-flat Riemannian manifolds that are our primary concern here are of continuing interest in various applications (see, for example, Ref. 2), and one wishes to understand their geometry, particularly their spin geometry,[3] as well as possible.

String and brane theories are often formulated on background manifolds of the form $M_4 \times M$, where M_4 is Minkowski space and M is a compact, locally irreducible, Riemannian, Ricci-flat, henceforth CLIRRF, manifold. (Recall that M is said to be locally irreducible if its universal Riemannian cover is irreducible, that is, not isometric to a product manifold.) Orientation-preserving isometries of $M_4 \times M$ are symmetries of the corresponding physical theory.[4] (Notice, however, that an orientation-preserving isometry of $M_4 \times M$ need *not* be orientation-preserving when restricted to M_4 or to M. Since Minkowski space admits orientation-reversing isometries, this means that we must consider all isometries of M, whether orientation preserving or orientation reversing.) The Poincaré group of symmetries of a string or brane theory is, of course, incorporated through the isometry group of M_4. It is natural to ask whether the isometry group of the internal manifold M has a similarly profound significance. Here we encounter one of the basic properties of CLIRRF manifolds: their isometry groups are necessarily *finite*.[5] Thus, there is a remarkable contrast between the external manifold M_4, which has a large group of isometries, and the internal space, which has only a discrete symmetry group—despite being a vacuum manifold. The message of ''duality,'' however, is that discrete symmetries are not to be neglected. In fact, we shall see that, precisely because they are discrete, the symmetries of CLIRRF manifolds can behave in ways that are not possible for continuous groups of isometries.

In Riemannian geometry, the metric tensor is the basic object. One expects its symmetries to be communicated to the other structures defined by it, and this is indeed true of the Levi-Civitá connection and its curvature. We wish to ask, however, whether it is also true of the *spin connection*, the connection used to define derivatives of spinor fields. (This is a completely different object to the Levi-Civitá connection, of course, though for the purposes of strictly local calculations one often pretends that the spin connection is just the Levi-Civitá connection referred to a local orthonormal basis. See below). This is an important question, not merely because spinor fields are so important in physics, but because the spin connection itself often plays a direct role in applications. Most notably, in heterotic string compactifications[4] on Calabi–Yau manifolds, the spin connection defines the gauge vacuum. This procedure (''embedding the spin connection in the gauge group'') still plays an important role in string phenomenology.[6] Our question can be phrased as follows. Must a *metric symmetry* of a Riemannian manifold also be a *spin symmetry*? That is, do isometries necessarily induce maps that preserve spin connections?

The answer to this question is usually yes. In particular, if the isometry group in question is continuous (that is, associated with Killing vector fields in the familiar manner) or if the manifold itself is simply connected, then (apart from minor technicalities to be discussed below) every metric symmetry is a spin symmetry. The CLIRRF manifolds often used in string and brane theories—the Calabi–Yau[4] and Joyce[7] manifolds—often violate *both* of these conditions, however, and so a further investigation is needed. We find that, in general, one must expect that metric symmetries of nonsimply connected CLIRRF manifolds will *not* be spin symmetries. The reason for this is that while an isometry must necessarily induce a map from the bundle of orthonormal frames to itself, there is no reason to expect that a (discrete) isometry group will map a given spin structure[3] to itself. For, in general, a nonsimply connected Riemannian manifold will have *many* spin structures, and a discrete isometry group will tend to permute these. (In this discussion, we have been tacitly assuming that the isometries in question are orientation preserving. The orientation-reversing case is similar, though technically more complicated.)

The consequences of having a spin asymmetry in a string compactification are potentially dire. For example, it would introduce a subtle inconsistency into the anomaly cancellation mechanism: it would no longer make sense to speak of embedding ''the'' spin connection in the gauge group. Again, some Calabi–Yau manifolds have isometries with a definite physical meaning, connected, for example, with CP invariance.[8] A spin asymmetry in this case would mean that CP is not well defined when acting on fermionic fields.

The purpose of this work is to explain the methods of global differential geometry relevant to the spin asymmetry problem, and to discuss how this problem may be avoided. We begin with a rapid survey of the spin geometry of the known CLIRRF manifolds.

II. THE SPIN GEOMETRY OF CLIRRF MANIFOLDS OF NONGENERIC HOLONOMY

The only known way—and perhaps the only possible way—to obtain examples of CLIRRF manifolds is to constrain the linear holonomy group.[9] Some caution is required here, because we are interested in nonsimply connected Riemannian manifolds, and the holonomy theory of these spaces is considerably more intricate than that of their simply connected counterparts.[10,11] The spin geometry is particularly delicate in this case, so we shall briefly summarize the main points here.

Recall[5] that the *restricted* linear holonomy group of a Riemannian manifold is defined by parallel transport of vectors around contractible loops. This group, a subgroup of the full linear holonomy group, is the one classified by the classical Berger theorem.[9] A classification of the full holonomy group, which is typically a *disconnected* Lie group, has yet to be given, except in special cases. We shall say that a Riemannian manifold M is of *nongeneric* linear holonomy if its restricted linear holonomy group is a proper subgroup of the special orthogonal group $\mathrm{SO}(n)$, where here and henceforth n denotes the (real) dimension of M. Notice that such a manifold need not be orientable, since the full holonomy group may not be contained in $\mathrm{SO}(n)$. [Of course, it is always a subgroup of $\mathrm{O}(n)$.]

Now it is easy to prove that every CLIRRF manifold of nongeneric holonomy is a spin manifold,[3] *provided that it is simply connected*. It is important to note, however, that the corresponding statement is certainly *false* in the nonsimply connected case: for example, Yau's theorem[9] implies that there are Ricci-flat Kähler metrics (which are therefore of nongeneric holonomy) on the Enriques surfaces,[12] but Rochlin's theorem[3] shows at once that these are not spin manifolds. In fact, it is possible to prove that, in all dimensions that are a multiple of four, a CLIRRF manifold of nongeneric holonomy can be spin only if its fundamental group satisfies certain extremely restrictive conditions. In other dimensions, however, the restrictions are far milder.

Theorem 1: Let M be a compact, locally irreducible, Riemannian, Ricci-flat manifold of nongeneric linear holonomy. Suppose that the real dimension of M is *not* a multiple of four. Then M is spin if and only if it is orientable.

Henceforth we shall concentrate on manifolds such that n is not a multiple of four, and particularly on the cases $n=6$ and $n=7$. The full linear holonomy groups of *orientable* CLIRRF manifolds in these cases are, respectively, SU(3) and the exceptional group G_2. By the above theorem, these manifolds are always spin manifolds, whether they be simply connected or not. In fact, if they are not simply connected, they will typically (but not invariably) have *several* spin structures. The spin structures are counted[3] by the cohomology group $H^1(M,\mathbb{Z}_2)$. For example, Joyce[13] gives examples of compact seven-dimensional manifolds of linear holonomy G_2 and fundamental group isomorphic to $\mathbb{Z}_2$. Here $H^1(M,\mathbb{Z}_2)=\mathbb{Z}_2$, and so these manifolds have two distinct spin structures. In general, we denote the spin structures over M by $\mathrm{Spin}^{(i)}(M)$, where the superscript runs from one to the order of $H^1(M,\mathbb{Z}_2)$.

Each $\mathrm{Spin}^{(i)}(M)$ is a $\mathbb{Z}_2$ principal bundle over $\mathrm{SO}(M)$, a bundle of oriented orthonormal frames over M. Now because M is, in the six-dimensional case, a Kähler manifold, SO(M) reduces[5] to a sub-bundle, the bundle of unitary frames $\mathrm{U}(M)$, with structural group U(3). For each i, $\mathrm{Spin}^{(i)}(M)$ has a sub-bundle $\mathrm{Spin}^{(i)}\mathrm{U}(M)$, which projects onto $\mathrm{U}(M)$. The structural group of $\mathrm{Spin}^{(i)}\mathrm{U}(M)$ is isomorphic to U(3), since this is the subgroup of Spin(6) which projects onto the U(3) subgroup of SO(6). The existence of the bundles $\mathrm{Spin}^{(i)}\mathrm{U}(M)$ is the spin-geometric expression of the fact that M is a Kähler manifold.

For six-dimensional Calabi–Yau manifolds, the holonomy reduction theorem[5] implies a further reduction of $\mathrm{U}(M)$ to an SU(3) sub-bundle, $\mathrm{SU}(M)$. For each i, $\mathrm{Spin}^{(i)}\mathrm{U}(M)$ has a sub-bundle $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$ that projects onto $\mathrm{SU}(M)$. The structural group of $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$ is the disconnected group $\mathbb{Z}_2\times\mathrm{SU}(3)$, this being the subgroup of Spin(6) that projects onto the SU(3) subgroup of SO(6). The existence of the bundles $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$ is the spin-geometric expression of the fact that M is a *Ricci-flat* Kähler manifold.

The Levi-Civitá connection of such a manifold can be regarded as a one-form ω_L on $\mathrm{SU}(M)$. The projection $\mathrm{Spin}^{(i)}\mathrm{SU}(M)\rightarrow\mathrm{SU}(M)$ allows us to pull ω_L back to a one-form $\omega_D^{(i)}$ on $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$, and, because $\mathbb{Z}_2\times\mathrm{SU}(3)$ and SU(3) have isomorphic Lie algebras, $\omega_D^{(i)}$ defines a connection on $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$. This, in turn, defines connections, also denoted by $\omega_D^{(i)}$, on $\mathrm{Spin}^{(i)}\mathrm{U}(M)$ and $\mathrm{Spin}^{(i)}(M)$. These connections are called the Dirac or *spin connections* on M: notice that there is one spin connection for each spin structure. In seven dimensions the situation is similar: $\mathrm{SO}(M)$ reduces to a G_2 sub-bundle $G_2(M)$, and each spin structure $\mathrm{Spin}^{(i)}(M)$ reduces to a sub-bundle $\mathrm{Spin}^{(i)}G_2(M)$ with structural group $\mathbb{Z}_2\times G_2$; the Levi-Civitá connection of the Joyce metric defines a spin connection on each spin structure.

In heterotic string compactifications,[4] a spin connection is used to define an E_8 gauge configuration. (Strictly, the gauge group is $E_8\times E_8$, but we can ignore the second E_8.) The natural way to interpret this is to suppose that the bundle representing the E_8 vacuum configuration is constructed by *extending* the structural group[14] of $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$, for some fixed i, from $\mathbb{Z}_2\times\mathrm{SU}(3)$ to E_8. In this way we represent $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$ as a sub-bundle of the vacuum E_8 bundle E, and then $\omega_D^{(i)}$ defines an E_8 connection on E (by the push-forward). This is the obvious global formulation of "embedding the spin connection in the gauge group." But now we arrive at the crux: if this construction of the gauge vacuum is to be consistent with the known symmetries of string theory, we must show that isometries of M induce mappings of $\mathrm{Spin}^{(i)}\mathrm{SU}(M)$ to itself.

However, this is, in general, not the case. In order to address this problem, we need techniques for analyzing isometries of CLIRRF manifolds, and we now turn to these.

III. GLOBAL GEOMETRY OF ISOMETRIES OF CLIRRF MANIFOLDS

The most striking property of metric symmetries of CLIRRF manifolds is the fact that the corresponding groups are necessarily *finite*, like the symmetry groups of the Platonic solids. (One can see the reason for this in a very rough, intuitive way by recalling that the Ricci tensor is a kind of average sectional curvature, and that the latter controls geodesic deviation. The geodesics emanating from a typical point of a CLIRRF manifold therefore cannot deviate in a consistent way, indicating that continuous symmetries are unlikely to be found.) A familiar consequence of this absence of Killing vectors is the fact that the metrics of these spaces are not known explicitly. Surprisingly, however, this does not prevent an analysis of the isometry groups. For example, let M be a compact Kähler manifold with a vanishing first Chern class,[9] and let Γ be a finite group of holomorphic or antiholomorphic diffeomorphisms of M. Then it is possible to prove that there exists a Ricci-flat Kähler metric on M with respect to which Γ acts isometrically.[9] The isometries of these manifolds can thus be discussed quite explicitly, if need be.

CLIRRF manifolds of nongeneric holonomy have a second peculiarity, of equal importance to us. Let M be any Riemannian manifold, and let $f:M\rightarrow M$ be an isometry. If $\mathrm{O}(M)$ is the bundle of orthonormal frames[5] over M, then $\tilde{f}$, the *natural lift* of f, is an $\mathrm{O}(M)$ bundle automorphism defined by

$$\tilde{f}(u)\xi=f_*(u\xi),$$

where $u\in\mathrm{O}(M)$, $\xi\in\mathbb{R}^n$ (with $n=\dim M$), $u\xi$ is the tangent vector with components ξ with respect to u, and f_* is the differential of f. For a generic (not necessarily orientable) M, $\mathrm{O}(M)$ is not reducible, and nothing more can be said. But if M, for example, is a six-dimensional Calabi–Yau manifold, then $\mathrm{O}(M)$ reduces to the SU(3) bundle $\mathrm{SU}(M)$ and the Levi-Civitá connection ω_L may be regarded as a connection on $\mathrm{SU}(M)$. It is natural to ask whether $\tilde{f}$ restricts to an automorphism of $\mathrm{SU}(M)$—this is related to the question raised at the end of the preceding section. The answer, in general, is no. For while it is true that symmetries of the metric are also symmetries of ω_L, this merely implies that $\tilde{f}$ maps holonomy bundles[5] to *other* holonomy bundles, not necessarily to themselves. Thus $\mathrm{SU}(M)$ does not respect (all of) the symmetries of M.

We can deal with this problem as follows. Let M be any Riemannian manifold, let Γ be a group of isometries, and let P be a sub-bundle of $\mathrm{O}(M)$ with a connection that induces the Levi-Civitá connection on $\mathrm{O}(M)$. We shall say that P is *minimal* for Γ if Γ induces (through the natural lifts) bundle automorphisms of P, but not of any proper sub-bundle of P. Our task is to construct, for CLIRRF manifolds of nongeneric holonomy, the sub-bundles of $\mathrm{O}(M)$ that are minimal for a given group of isometries. Let us do this explicitly for the six- and seven-dimensional cases.

Let U(3) be regarded as a subgroup of SO(6) as usual, and let $\mathrm{SU}_k(3)$, for any positive integer k, be the subgroup of U(3) consisting of all 3×3 unitary matrices A such that

$$[\det A]^k=1.$$

This is, for all $k>1$, a disconnected group with SU(3) as an identity component. Next, let, for any even n, $\theta_{n/2}$ denote the diagonal $n\times n$ matrix with the first $n/2$ entries equal to $+1$, and the remainder equal to -1. Conjugation by $\theta_{n/2}$ maps $\mathrm{U}(n/2)$, as a subgroup of $\mathrm{SO}(n)$, to itself, by complex conjugation; therefore it is possible to define a group $\mathrm{SU}_k^*(3)$ by

$$\mathrm{SU}_k^*(3)=\mathrm{SU}_k(3)\cup\mathrm{SU}_k(3)\cdot\theta_3.$$

This is a disconnected subgroup of O(6) with SU(3) as an identity component. Abstractly it is $[\mathbb{Z}_{3k}\cdot\mathrm{SU}(3)]\rtimes\mathbb{Z}_2$, where the dot denotes the local direct product, and the product with $\mathbb{Z}_2$ is semidirect. Thus, $SU_k^*(3)$ has $2k$ connected components. Now, for a Calabi–Yau manifold, $O(M)$ is reducible to $SU(M)$, and so the structural group O(6) is reducible to any subgroup of O(6) containing SU(3). Hence we can find, for any k, a sub-bundle of $O(M)$ with $SU_k(3)$ or $SU_k^*(3)$ as a structural group, and the Levi-Civitá connection can be regarded as a connection on any of these bundles, which we denote by $SU_k(M)$ and $SU_k^*(M)$, respectively. Similarly, for seven-manifolds of linear holonomy G_2, we set

$$G_2^* = \mathbb{Z}_2 \times G_2,$$

where $\mathbb{Z}_2$, the center of O(7), is generated by $-I_7$, where I_7 is the 7×7 identity matrix; and we define $G_2^*(M)$ as a G_2^* sub-bundle of $O(M)$ in the obvious way. The result we need is as follows.

Theorem 2: Let M be a compact Riemannian six-manifold of linear holonomy SU(3), or a compact Riemannian seven-manifold of linear holonomy G_2, and let Γ be any group of isometries of M. In the six-dimensional case, let Γ_0 be the subgroup of Γ generated by holomorphic isometries. If $\Gamma = \Gamma_0$, then there exists an integer k such that $SU_k(M)$ is minimal for Γ, and there is a homomorphism from Γ_0 onto $\mathbb{Z}_k$. If $\Gamma \neq \Gamma_0$, then there exists an integer k such that $SU_k^*(M)$ is minimal for Γ, and again there is a homomorphism from Γ_0 onto $\mathbb{Z}_k$. In the seven-dimensional case, the holonomy bundle $G_2(M)$ is minimal for any orientation-preserving Γ, while $G_2^*(M)$ is minimal for any Γ containing an orientation-reversing isometry.

The proof will not be given here; see Ref. 15 for the relevant techniques.

This theorem marks the first step toward solving the problem raised at the end of Sec. II, namely, the fact that metric symmetries do not, in general, induce maps from $\mathrm{Spin}^{(i)}\,SU(M)$ to itself. For example, in the six-dimensional case, suppose that Γ is generated by a single antiholomorphic involution f. (That is, f_* anticommutes with the complex structure, and $f^2 = 1$, the identity map.) Then Γ_0 is trivial, so $k=1$, and $SU_1^*(M)$ is minimal for Γ. Thus, if we replace $SU(M)$ by $SU_1^*(M)$, we obtain a bundle that *is* mapped into itself by Γ. But now we encounter another problem, when we go to the level of spin and pin structures.

IV. SPIN SYMMETRIES AND ASYMMETRIES

In this section we introduce the concept of *spin asymmetries:* that is, maps $f: M \to M$ on a Riemannian manifold that preserve the metric but not the spin structure. To see how this is possible, let M be *any* six-dimensional orientable spin manifold. Then M is also a pin manifold, that is, the full bundle of orthonormal frames $O(M)$ has at least one nontrivial double cover that is also a Pin(6) bundle over M. [Here Pin(6) is the usual[3] double cover of O(6).] The pin structures can be expressed in terms of the spin structures in the following useful way. Let $\{e_i\}$, $i = 1\cdots 6$ generate the Clifford algebra, and set

$$\hat{\theta}_3 = e_4 e_5 e_6,$$

so that $\hat{\theta}_3$ projects onto the O(6) matrix θ_3 introduced earlier. Clearly, $\hat{\theta}_3$ is an element of Pin(6) but not of Spin(6), and $(\hat{\theta}_3)^2 = 1$. [In ten dimensions, we have $(\hat{\theta}_5)^2 = -1$, so the pin element corresponding to $\theta_{n/2}$ need not be of order two. This point will arise again, below.] Now we have

$$\mathrm{Pin}(6) = \mathrm{Spin}(6) \cup \mathrm{Spin}(6) \cdot \hat{\theta}_3,$$

and one can prove that the pin structures over M can be expressed as

$$\mathrm{Pin}^{(i)}(M) = \mathrm{Spin}^{(i)}(M) \cup \mathrm{Spin}^{(i)}(M) \cdot \hat{\theta}_3.$$

Spinors of type i on M are sections of associated bundles of $\mathrm{Spin}^{(i)}(M)$, the standard fibre being the representation space V corresponding to a specified representation ρ of Spin(6). A spinor may therefore also be regarded as a V-valued function ψ on $\mathrm{Spin}^{(i)}(M)$ satisfying $\psi(sg) = \rho(g^{-1})\psi(s)$ for each s in $\mathrm{Spin}^{(i)}(M)$ and each g in Spin(6). ''Pinors'' are defined in the obvious way. This way of thinking about spinors and pinors [as objects defined directly on $\mathrm{Spin}^{(i)}(M)$ or $\mathrm{Pin}^{(i)}(M)$] makes it clear that an isometry of M has a well-defined action on fermionic fields if and only if it induces a bundle automorphism of $\mathrm{Spin}^{(i)}(M)$ or, in the orientation-reversing case, $\mathrm{Pin}^{(i)}(M)$. Now for each i, $\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3$ is a principal bundle over $\mathrm{SO}(M)\cdot\theta_3$ with structural group $\mathbb{Z}_2$. The assumed orientability of M means that $\mathrm{O}(M)$ is the disjoint union of $\mathrm{SO}(M)$ and $\mathrm{SO}(M)\cdot\theta_3$; if f is an orientation-reversing isometry of M, then the natural lift $\tilde{f}$ maps $\mathrm{SO}(M)$ to $\mathrm{SO}(M)\cdot\theta_3$. Now the *induced bundle construction*[5] allows us to pull $\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3$ back to a $\mathbb{Z}_2$ bundle, conventionally denoted $\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)$, over $\mathrm{SO}(M)$. The construction also supplies us with a $\mathbb{Z}_2$ bundle homomorphism $\hat{f}$,

$$\hat{f}:\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)\rightarrow\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3,$$

covering $\tilde{f}:\mathrm{SO}(M)\rightarrow\mathrm{SO}(M)\cdot\theta_3$. Clearly $\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)$ is just a spin structure over M. If it were possible to deform f continuously (through isometries) to the identity map, then we could try to argue that $\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)$ must be none other than $\mathrm{Spin}^{(i)}(M)$ itself. (In fact, even in the continuous case, there can be a slight complication if the group is not simply connected; but this problem can always be resolved by replacing the group by a suitable double cover.) But if the isometry group of M is finite, we cannot argue in this way: we have

$$\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)=\mathrm{Spin}^{(j)}(M),$$

for some j that may or may not be equal to i. The map $\hat{f}$ therefore sends $\mathrm{Spin}^{(j)}(M)$ to $\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3$, and so it does not map $\mathrm{Pin}^{(j)}(M)$ into itself unless it so happens that $i=j$. We conclude that, if $i\neq j$, then f disrupts the structure of $\mathrm{Pin}^{(i)}(M)$ and $\mathrm{Pin}^{(j)}(M)$: the very existence of f is inconsistent with any gauge vacuum built from $\mathrm{Pin}^{(i)}(M)$ or $\mathrm{Pin}^{(j)}(M)$, and f has no well-defined action on fermions of type i or j. Similarly, if f is an orientation-preserving isometry that cannot be deformed through isometries to the identity, then we expect it to permute spin structures rather than map them into themselves. This is the phenomenon of a *spin asymmetry*. Such asymmetries have arisen, at least implicitly, in the spin geometry literature: for example, the G-spin theorem (see Ref. 3, p. 267) can be made to work only if one explicitly *assumes* that the isometry in question maps a specific spin structure into itself. The question then arises as to how one can verify this assumption.

In fact, for a generic Riemannian manifold, it is very difficult to do this; both the metric and the topology of $\mathrm{O}(M)$ would have to be specified in great detail. *The possible existence of spin asymmetries should be considered very carefully in any physical theory involving nonsimply connected Riemannian manifolds*. Spin asymmetries are particularly troublesome for CLIRRF manifolds, since the metric cannot be given explicitly. We shall return to this problem in Sec. VI. Let us first, however, consider the consequences if a metric symmetry *does* happen to be a spin (or pin) symmetry.

V. EMBEDDING THE SPIN CONNECTION IN THE GAUGE GROUP

As usual, we shall discuss the more complicated, orientation-reversing case. Suppose, then, that f is an orientation-reversing isometric involution of a six-dimensional Riemannian manifold M, and suppose further that, for some i, we have

$$\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)=\mathrm{Spin}^{(i)}(M).$$

Thus, f can be a pin symmetry as well as a metric symmetry. As above, we have a $\mathbb{Z}_2$ bundle homomorphism $\hat{f}$,

$$\hat{f}:\mathrm{Spin}^{(i)}(M)\rightarrow\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3,$$

covering $\tilde{f}\colon \mathrm{SO}(M) \to \mathrm{SO}(M)\cdot\theta_3$. Now $\tilde{f}$ also defines a map from $\mathrm{SO}(M)\cdot\theta_3$ to $\mathrm{SO}(M)$, and if f is to be a pin symmetry we must have

$$\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)) = \mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3.$$

This gives us another $\mathbb{Z}_2$ bundle homomorphism, in this case from $\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3$ to $\mathrm{Spin}^{(i)}(M)$. Combining these, we obtain an automorphism $\hat{f}\colon \mathrm{Pin}^{(i)}(M) \to \mathrm{Pin}^{(i)}(M)$. As defined, $\hat{f}$ is only an automorphism of $\mathrm{Pin}^{(i)}(M)$ as a $\mathbb{Z}_2$ bundle over $\mathrm{O}(M)$, not as a Pin(6) bundle over M. However, using the fact that $\tilde{f}$ is an automorphism of $\mathrm{O}(M)$ as an O(6) bundle over M, we see that $\hat{f}(sg) = \pm\hat{f}(s)g$ for all s in $\mathrm{Pin}^{(i)}(M)$ and g in Pin(6). If g is actually in Spin(6), a continuity argument rules out the minus sign, while if $g = \hat{\theta}_3$, the minus can be consistently absorbed into the definition of $\hat{f}$. Thus, f does have a well-defined action on $\mathrm{Pin}^{(i)}(M)$ if there is no pin asymmetry. Finally, we have the commuting diagram shown, valid for this particular value of i:

$$\begin{array}{ccc} \mathrm{Pin}^{(i)}(M) & \xrightarrow{\hat{f}} & \mathrm{Pin}^{(i)}(M) \\ \downarrow & & \downarrow \\ \mathrm{O}(M) & \xrightarrow{\tilde{f}} & \mathrm{O}(M) \\ \downarrow & & \downarrow \\ M & \xrightarrow{f} & M \end{array}.$$

Note that since f is an involution, so (by the chain rule) is $\tilde{f}$; but from this we can deduce only that $(\hat{f})^2 = \pm 1$, where, as usual, -1 denotes the automorphism of $\mathrm{Pin}^{(i)}(M)$ induced by the right action of -1, the generator of the center of Pin(6). If f is an antiholomorphic involution of a Calabi–Yau manifold, corresponding[4] to the CP operator in a heterotic string compactification, then having $(\hat{f})^2 = -1$ would mean that CP is represented by an operator of order four rather than two. For generic M it is difficult to resolve this ambiguity, but more can be said precisely when M is a CLIRRF manifold; see Theorem 3 below.

As f is a symmetry of the metric, it is also a symmetry of the Levi-Civitá connection: we have $\tilde{f}^*\omega_L = \omega_L$, where we regard[5] the Levi-Civitá connection as a one-form on $\mathrm{O}(M)$. Now let $p^{(i)}$ be the canonical projection $p^{(i)}\colon \mathrm{Pin}^{(i)}(M) \to \mathrm{O}(M)$; then the spin connection is $p^{(i)*}\omega_L = \omega_D^{(i)}$, and we have

$$\hat{f}^*\omega_D^{(i)} = (p^{(i)}\circ\hat{f})^*\omega_L = (\tilde{f}\circ p^{(i)})^*\omega_L = p^{(i)*}\tilde{f}^*\omega_L = \omega_D^{(i)}.$$

Thus, $\hat{f}$ is indeed a symmetry of the spin connection.

We shall now use these ideas to give a rigorous formulation of ''embedding the spin connection in the gauge group.''[4] It would be easy to ''embed the *linear* connection in the gauge group''—that is, to use ω_L to construct an E_8 gauge vacuum. The only complication is that, if M is a Calabi–Yau manifold and f is an antiholomorphic isometric involution on M, then $\tilde{f}$ is not an automorphism of $\mathrm{SU}(M)$. But we saw in Sec. III that this problem can always be solved—in this case, by using the bundle $\mathrm{SU}_1^*(M)$ instead of $\mathrm{SU}(M)$. But here we wish to use a *spin* connection to construct the gauge vacuum. [In heterotic string compactifications, when the ''holonomy group'' SU(3) is embedded in E_8, this embedding is through a Spin(6) subgroup of E_8, *not* through SO(6): therefore the E_8 vacuum configuration is indeed constructed from some Dirac connection $\omega_D^{(i)}$, and *not* from the Levi-Civitá connection directly.] Hence, we need to study a pin bundle over $\mathrm{SU}_1^*(M)$.

Recalling that $\mathrm{SU}_1^*(3)$ was defined as the subgroup of O(6) given by $\mathrm{SU}(3)\cup\mathrm{SU}(3)\cdot\theta_3$, we can define, for each spin structure, a sub-bundle of $\mathrm{Pin}^{(i)}(M)$ by

$$\mathrm{Spin}^{(i)}\mathrm{SU}_1^*(M)=\mathrm{Spin}^{(i)}\,\mathrm{SU}(M)\cup\mathrm{Spin}^{(i)}\,\mathrm{SU}(M)\cdot\hat{\theta}_3.$$

This is a $\mathbb{Z}_2\times\mathrm{SU}(3)\rtimes\mathbb{Z}_2$ bundle over M, where the first $\mathbb{Z}_2$ is $\{\pm 1\}$, and the second is $\{1,\hat{\theta}_3\}$. Just as $\mathrm{SU}_1^*(M)$ is the smallest sub-bundle of $\mathrm{O}(M)$ on which f induces an automorphism, so $\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)$ is the smallest sub-bundle of $\mathrm{Pin}^{(i)}(M)$ on which f induces an automorphism—*provided*, of course, that the spin asymmetry problem does not arise for this pin structure. That is, *if* we have $\tilde{f}^{-1}(\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3)=\mathrm{Spin}^{(i)}(M)$ for some i, then the pin automorphism $\hat{f}\cdot\mathrm{Pin}^{(i)}(M)\to\mathrm{Pin}^{(i)}(M)$ restricts to an automorphism $\hat{f}:\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)\to\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)$. Regarding the spin connection $\omega_D^{(i)}$ as a connection on $\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)$ [which we can do, since the latter has $\mathrm{Spin}^{(i)}\,\mathrm{SU}(M)$ as a sub-bundle], we have $\hat{f}^*\omega_D^{(i)}=\omega_D^{(i)}$. Thus, we have found a bundle on which the spin connection is well defined, and that is mapped into itself by f. [By considering $\mathrm{Spin}^{(i)}\,\mathrm{SU}_k^*(M)$ for suitable k, we can deal with isometry groups containing both holomorphic and antiholomorphic maps.] Clearly, we must use $\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)$ to construct a gauge vacuum consistent with the existence of f.

To do this, note that E_8 contains a disconnected group[16] of the form $[\mathrm{SU}(3)\cdot E_6]\rtimes\mathbb{Z}_2$, where $\mathrm{SU}(3)\cdot E_6=[\mathrm{SU}(3)\times E_6]/\mathbb{Z}_3$, and $\mathbb{Z}_2$ is generated by γ such that $\mathrm{Ad}(\gamma)$ induces complex conjugation on SU(3), together with an outer automorphism of E_6. By choosing a $\mathbb{Z}_2$ subgroup of the fixed point set of $\mathrm{Ad}(\gamma)$ in E_6 (this subgroup is of nonzero rank, so this can be done) we obtain $\mathbb{Z}_2\times\mathrm{SU}(3)\rtimes\mathbb{Z}_2$ as a closed subgroup of E_8. It follows that $\mathrm{Spin}^{(i)}\,SU_1^*(M)$ can be extended[14] to an E_8 bundle E over M. It is easy to see that $\hat{f}$ extends to an automorphism of E, that the spin connection extends to an E_8 gauge connection on E, and that the extended objects satisfy $\hat{f}^*\omega_D^{(i)}=\omega_D^{(i)}$. In short, the spin connection has been embedded in the gauge group *in a way that is consistent with the symmetries of the theory*. Similarly, if f has a physical interpretation in terms of the CP operator, then the latter has a well-defined action on fermionic fields.

In summary, then, the existence of isometries of M poses no problems, *provided* that there are no spin asymmetries. Let us now consider how to ensure this.

VI. AVOIDING SPIN ASYMMETRIES ON CLIRRF MANIFOLDS

Let M be any CLIRRF manifold of nongeneric linear holonomy. There are, in general, three simple, practical ways of ensuring that every metric symmetry of M is a spin symmetry.

The first approach is to apply nonisometric diffeomorphisms to M so that, in fact, M has no nontrivial isometries. For a Calabi–Yau manifold represented as a projective variety, this is simply a matter of adjusting the coefficients of the defining equations in such a way that M admits no holomorphic or antiholomorphic self-maps.

A second, less brutal approach involves verifying that M has only one spin structure: clearly, spin asymmetries are impossible in this case. It is quite easy to compute the number of spin structures on M if the fundamental group, $\pi_1(M)$, is known. First, $\pi_1(M)$ must be Abelianized. In the decomposition of the resulting group into finite cyclic factors, discard the factors of odd order and replace each of the others by $\mathbb{Z}_2$. The result is $H^1(M,\mathbb{Z}_2)$, which counts the spin structures over M. Clearly the spin structure is unique if $\pi_1(M)$ is of odd order; sometimes it is also unique when $\pi_1(M)$ is of even order (because a group of even order can have an Abelianization of odd order). Usually, however, M will have several spin structures if $\pi_1(M)$ is of even order.

If M does have several spin structures, we have a third approach based on the following observation. One of the most important properties of spin CLIRRF manifolds of nongeneric linear holonomy is that they always satisfy, *locally*, the integrability conditions for the existence of a parallel (covariant constant) spinor field. The existence of a *local* parallel spinor, serving as a supersymmetry generator, is essential in heterotic string phenomenology.[4] While it can be argued that it is not physically necessary to extend the local parallel spinor to a *global* field, it is natural to ask whether this can indeed be done. One finds that local parallel spinors can always be extended globally *if M* is simply connected; but if M is not simply connected, one must ask *which* spin structure is being used to make the extension. For, in fact, if *M* has more than one spin structure, there will always be spin structures that do not allow the extension to be made. On a given *M*, we shall describe a spin structure as a GPS spin structure if it admits a Global Parallel Spinor. The existence of GPS spin structures is of interest in its own right,[17] but for our purposes their importance derives from the fact that they behave well under the action of metric symmetries.

Theorem 3: Let *M* be any CLIRRF spin manifold of nongeneric linear holonomy, and let Γ be any group of isometries of *M*. There exists a GPS spin structure on *M* such that each $f\in\Gamma$ induces an automorphism $\hat{f}$ either on that spin structure or on the corresponding pin structure. Furthermore, the group generated by these automorphisms is isomorphic to Γ.

Proof: We give the proof in the case where *M* is a six-dimensional Calabi–Yau manifold and *f* is an antiholomorphic involution; the other cases are similar or easier.

Given any six-dimensional Kähler spin manifold *M*, we define

$$\mathrm{U}^*(M)=\mathrm{U}(M)\cup\mathrm{U}(M)\cdot\theta_3,$$

a sub-bundle of $\mathrm{O}(M)$ with structural group $\mathrm{U}^*(3)$ defined in the obvious way. For each spin structure, we have a spin bundle $\mathrm{Spin}^{(i)}\,\mathrm{U}(M)$ over $\mathrm{U}(M)$, and similarly we set

$$\mathrm{Spin}^{(i)}\,\mathrm{U}^*(M)=\mathrm{Spin}^{(i)}\,\mathrm{U}(M)\cup\mathrm{Spin}^{(i)}\,\mathrm{U}(M)\cdot\hat{\theta}_3.$$

Now SU(3) is a normal subgroup of U(3) [regarded as a subgroup of SO(6)], so we can define a canonical U(1) bundle over *M* by

$$K(M)=\mathrm{U}(M)/\mathrm{SU}(3).$$

Similarly, SU(3) is normal in U(3) regarded as a subgroup of Spin(6), so we can define, for each spin structure, a *spin canonical bundle*, by

$$\mathrm{Spin}^{(i)}\,K(M)=\mathrm{Spin}^{(i)}\,\mathrm{U}(M)/\mathrm{SU}(3).$$

Again, SU(3) is actually normal in $\mathrm{U}^*(3)$, so we can define

$$K^*(M)=\mathrm{U}^*(M)/\mathrm{SU}(3).$$

$$\mathrm{Spin}^{(i)}\,K^*(M)=\mathrm{Spin}^{(i)}\,U^*(M)/\mathrm{SU}(3).$$

These bundles decompose into connected components as follows:

$$K^*(M)=K(M)\cup K(M)\cdot\sigma_3,$$

where σ_3 is the SU(3) projection of θ_3, and

$$\mathrm{Spin}^{(i)}\,K^*(M)=\mathrm{Spin}^{(i)}\,K(M)\cup\mathrm{Spin}^{(i)}\,K(M)\cdot\hat{\sigma}_3,$$

where $\hat{\sigma}_3$ is the SU(3) projection of $\hat{\theta}_3$. Note that $(\sigma_3)^2=(\hat{\sigma}_3)^2=1$.

The point of passing to the SU(3) quotients of all of these structures is that when *M* is a Calabi–Yau manifold, $K(M)$ [unlike $\mathrm{U}(M)$] is actually *trivial*.[9] This allows us to describe the spin canonical bundles and hence to analyze the behavior of the spin structures.

Now *f* is an antiholomorphic, orientation-reversing isometry, so its natural lift $\tilde{f}$ is a homomorphism of U(3) bundles, $\tilde{f}:\mathrm{U}(M)\to\mathrm{U}(M)\cdot\theta_3$. Hence, it factors through the SU(3) projection and defines a U(1) homomorphism, which we also denote by $\tilde{f}$, from $K(M)$ to $K(M)\cdot\sigma_3$. Similarly, the bundle homomorphism $\hat{f}:\mathrm{Spin}^{(j)}\mathrm{U}(M)\to\mathrm{Spin}^{(i)}\,\mathrm{U}(M)\cdot\hat{\theta}_3$ defines a homomorphism

$\hat{f}$:$\mathrm{Spin}^{(j)}K(M)\rightarrow\mathrm{Spin}^{(i)}K(M)\cdot\hat{\sigma}_3$, with $j\neq i$, in general, of course. We obtain the commuting diagram shown, where the vertical arrows correspond to the $\mathbb{Z}_2$ projection π, and $\mathrm{Spin}^{(j)}K(M)$ may be regarded as the pull-back $\tilde{f}^{-1}(\mathrm{Spin}^{(i)}K(M)\cdot\hat{\sigma}_3)$,

$$\begin{array}{ccc} \mathrm{Spin}^{(j)}K(M) & \overset{\hat{f}}{\rightarrow} & \mathrm{Spin}^{(i)}K(M)\cdot\hat{\sigma}_3 \\ \downarrow & & \downarrow\pi \\ K(M) & \overset{\tilde{f}}{\rightarrow} & K(M)\cdot\sigma_3 \end{array}.$$

Now, while $K(M)$ is trivial over M, the same is *not* true, in general, of the spin canonical bundles. These last are constructed by recalling that they satisfy $\mathrm{Spin}^{(i)}K(M)/\mathbb{Z}_2=K(M)$. Typically, therefore, $\mathrm{Spin}^{(i)}K(M)$ will take the form $(\overline{M}\times\mathrm{U}(1))/\mathbb{Z}_2$, where $\overline{M}$ is some nontrivial double cover of M and $\mathbb{Z}_2$ acts diagonally. In such a case, the holonomy group[5] of the spin connection $\omega_D^{(i)}$ will be isomorphic to $\mathbb{Z}_2\times\mathrm{SU}(3)$. [This is possible because this holonomy group must project onto the *linear* holonomy group, which is SU(3), of course.] The presence of the $\mathbb{Z}_2$ factor means that there are noncontractible loops on M such that a locally constant spinor reverses sign when parallel transported around those loops. Clearly, global parallel spinors cannot be defined in such a case. Conversely, the spin structure with a trivial spin canonical bundle has SU(3) as holonomy group, and so it is a GPS spin structure. Fix i as the label for this spin structure, and let ϕ be a global cross section of $\mathrm{Spin}^{(i)}K(M)$. Consider the map $\overline{\phi}:M\rightarrow\mathrm{Spin}^{(j)}K(M)$, defined by

$$\overline{\phi}:x\rightarrow[\tilde{f}(\pi(\phi(f(x))\cdot\hat{\sigma}_3)),\phi(f(x))\cdot\hat{\sigma}_3],$$

for each $x\in M$. Here we regard $\mathrm{Spin}^{(j)}K(M)$ as the pull-back of $\mathrm{Spin}^{(i)}K(M)\cdot\hat{\sigma}_3$, so that elements of $\mathrm{Spin}^{(j)}K(M)$ are represented[5] as pairs $[k,s]$ in $K(M)\times\mathrm{Spin}^{(i)}K(M)\cdot\hat{\sigma}_3$, such that $\tilde{f}(k)=\pi(s)$. The projection for the pull-back, as a bundle over $K(M)$, is defined by $[k,s]\rightarrow k$, and since the map $x\rightarrow\tilde{f}(\pi(\phi(f(x))\cdot\hat{\sigma}_3))$ is a global cross section of $K(M)$, we see that $\overline{\phi}$ is a global cross section of $\mathrm{Spin}^{(j)}K(M)$. Thus $\mathrm{Spin}^{(j)}(M)$ is the spin structure with a trivial spin canonical bundle: that is, $j=i$, and so f induces a spin symmetry, $\hat{f}$:$\mathrm{Spin}^{(i)}(M)\rightarrow\mathrm{Spin}^{(i)}(M)\cdot\hat{\theta}_3$.

Our final task is to show that the group generated by $\hat{f}$ is isomorphic to the group generated by f: that is, we must show that $(\hat{f})^2=1$ rather than -1. Recall from Sec. V that $\hat{f}$ restricts to a map $\hat{f}$:$\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)\rightarrow\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)$. In general, $\mathrm{Spin}^{(i)}\,\mathrm{SU}(M)$ is a $\mathbb{Z}_2\times\mathrm{SU}(3)$ bundle that is not further reducible; but in the present case, since the spin holonomy group is SU(3), $\mathrm{Spin}^{(i)}\,\mathrm{SU}(M)$ decomposes as a disjoint union $P\cup(-P)$, where P is a holonomy bundle.[5] Therefore we have

$$\hat{f}(P)=\pm P\cdot\hat{\theta}_3,$$

and so, since $(\hat{\theta}_3)^2=+1$, we find that $(\hat{f})^2P=P$. That is, $(\hat{f})^2$ is an automorphism of P. But then if $(\hat{f})^2=-1$, we conclude that SU(3), the structural group of P, contains a central element of order two. Since this is not the case, we conclude that $(\hat{f})^2=+1$. This completes the proof of Theorem 3.

Evidently Theorem 3 provides us, *in the case where M* is a CLIRRF *manifold of nongeneric linear holonomy*, with another way of avoiding the spin asymmetry problem: if we insist that the local parallel spinors (corresponding, in the applications to string theory, to generators of local supersymmetries) on such manifolds must be extended to global parallel spinors, then a spin structure is automatically selected such that all metric symmetries become spin symmetries. In practice, this is perhaps the easiest way to avoid spin asymmetries; but one should bear in mind the possibility that the other spin structures may play some physical role (perhaps in a path integral in the quantum gravity context), in which case spin asymmetries will have to be considered anew.

VII. IS CP A GAUGE SYMMETRY?

The realization[18,19] that wormhole fluctuations can violate global discrete symmetries leads one to ask how these symmetries have survived into the relatively low-energy era. The most satisfactory answer[20,21] is that discrete symmetries are, in fact, *gauge* symmetries. This works very well for internal symmetries, but it is not easy to see what this proposal means in the case of the charge-parity operator CP, which is partly a geometric, space–time symmetry. In heterotic string compactifications, CP can be completely geometric, since it corresponds to a combination of the usual orientation-reversing isometry of Minkowski space with an antiholomorphic isometric involution of a Calabi–Yau manifold.[4] Nevertheless, Choi *et al.*[8] have proposed that CP is a gauge symmetry, precisely in this context. As an application of the formalism developed above, let us analyze the meaning of this proposal.

Let M be a six-dimensional Calabi–Yau manifold, and let $\mathrm{Pin}^{(i)}(M)$ be the GPS pin structure discussed in the proof of Theorem 3, so that the antiholomorphic involution f corresponding to CP induces an automorphism $\hat{f}:\mathrm{Pin}^{(i)}(M)\rightarrow\mathrm{Pin}^{(i)}(M)$ with $(\hat{f})^2=1$. As in Sec. V, we use $\mathrm{Pin}^{(i)}(M)$ to construct an E_8 bundle E over M, and we regard $\hat{f}$ as an automorphism of E. Recall that the spin connection defines a gauge connection $\omega_D^{(i)}$ on E, satisfying $\hat{f}^*\omega_D^{(i)}=\omega_D^{(i)}$. The point to be emphasized here is that, because of the special way in which the gauge bundle E is constructed, CP has a natural interpretation as *an automorphism of E that preserves the (vacuum) gauge connection*.

As is well known, the nontriviality of the vacuum gauge connection breaks E_8 to a subgroup. The precise meaning of this statement is as follows. Let M be any Riemannian manifold, let Γ by any group of isometries of M, and let $Q(M,G,\omega)$ be any principal G bundle over M with a connection ω. Following Fischer,[22] we define the *generalized gauge group* of this system as the group $A(Q,\Gamma,\omega)$ consisting of all those automorphisms $F:Q\rightarrow Q$ such that F induces an element of Γ and $F^*\omega=\omega$. The usual gauge group is the subgroup consisting of those F that cover the identity isometry of M. Notice that the gauge group is not, strictly speaking, a subgroup of the structural group G; however, it is naturally isomorphic to such a subgroup, namely, the centralizer of the holonomy group of ω. [In our case, with $G=E_8$, this centralizer is isomorphic either to $[\mathrm{U}(1)\times\mathrm{Spin}(10)]/\mathbb{Z}_4$ if the holonomy group of the spin connection is $\mathbb{Z}_2\times\mathrm{SU}(3)$, or to E_6 if—as is the case for the GPS spin structure—the spin holonomy group is SU(3).]

The *generalized* gauge group construction extends the usual gauge group by allowing F to have some ''horizontal'' as well as ''vertical'' action on the gauge bundle. As long as the induced action on M is isometric, this is a reasonable and natural extension of the gauge symmetry concept. Furthermore, like the usual gauge group, $A(Q,\Gamma,\omega)$ is naturally associated with a subgroup of G. Let P be any holonomy bundle[5] of ω in Q, and let F be any element of $A(Q,\Gamma,\omega)$; then $F^*\omega=\omega$ implies that $F(P)$ is another holonomy bundle, and so we have

$$F(P)=P\alpha(F),$$

for some $\alpha(F)\in G$. Let H_A be the subgroup of G generated by all elements of the form $\alpha(F)$: we shall say that H_A is the subgroup of G associated with $A(Q,\Gamma,\omega)$. It is not difficult to show[23] that the subgroup of G associated in this way with $V(Q,\omega)$ [the normal subgroup of $A(Q,\Gamma,\omega)$ consisting of ω-preserving, purely vertical automorphisms of Q] contains the centralizer of the holonomy group of ω, so this construction generalizes the usual isomorphism of $V(Q,\omega)$ with a subgroup of G.

The generalized gauge group construction seems ideally suited to the problem of ''gauging'' CP. Unfortunately, for a generic bundle Q, this does not work well. Note first that $A(Q,\Gamma,\omega)$ is defined as a group of automorphisms that induce some element of Γ—but this is not to say that *every* element of Γ is covered by some element of $A(Q,\Gamma,\omega)$. In general, this is not so. Even if

Γ is completely covered by $A(Q,\Gamma,\omega)$, the group structure of $A(Q,\Gamma,\omega)$ may not be reasonable from a physical point of view. For example, it would not be physically acceptable, in the string case, for an element of $A(Q,\Gamma,\omega)$ representing CP to commute with every element of E_6: in fact, we should find that $A(Q,\Gamma,\omega)$ is a semidirect product of E_6 with a $\mathbb{Z}_2$ generated by an automorphism covering CP. However, this will *not* be the case for all Q. Finally, the subgroup of G associated with $A(Q,\Gamma,\omega)$ may not contain an isomorphic copy of it, so that CP can fail to correspond to any element of the structural group.

Happily, ''embedding the spin connection in the gauge group'' eliminates all of these objections. This is the content of the following result, the proof of which is a straightforward application of Theorem 3 and will not be given here.

Theorem 4: Let M be a six-dimensional Calabi–Yau manifold, let f be an antiholomorphic isometric involution on M, let $\mathrm{Pin}^{(i)}(M)$ be a GPS pin structure on M such that f induces an automorphism $\hat{f}$ on $\mathrm{Pin}^{(i)}(M)$, and let E be the E_8 bundle over M constructed by extending $\mathrm{Spin}^{(i)}\,\mathrm{SU}_1^*(M)$ through $[\mathrm{SU}(3)\cdot E_6]\rtimes\mathbb{Z}_2$. If $\omega_D^{(i)}$ is the extension of the $\mathrm{Pin}^{(i)}(M)$ spin connection to E, then the generalized gauge group $A(E,\{1,f\},\omega_D^{(i)})$ covers $\{1,f\}$, and it is naturally isomorphic to the $E_6\rtimes\mathbb{Z}_2$ subgroup of E_8.

In simple terms, $\hat{f}$ *is the same kind of mathematical object* as the usual gauge transformations—namely, an automorphism of E that preserves the vacuum gauge fields. It is therefore perfectly natural to unify it with the gauge group, and Theorem 4 asserts that it then behaves in a physically acceptable manner. In this sense, CP is indeed a gauge symmetry, *provided* that the spin connection is embedded in the gauge group, and *provided* that we avoid spin asymmetries.

VIII. CONCLUSION

Spin connections are deceptively simple objects. Locally, they can be regarded as nothing more than the Levi-Civitá connection referred to an orthonormal basis. Globally, however, they can give rise to several interesting pathologies: in particular, they can misbehave under the action of isometries. In view of their importance for applications, it is desirable to have techniques available for dealing with their global properties. A few such techniques have been introduced here, in the context of CLIRRF manifolds.

One of the surprising byproducts of our investigation has been the discovery that it does not always make sense to speak of ''the'' spin holonomy group of a CLIRRF spin manifold: a given, fixed Calabi–Yau or Joyce manifold can have two distinct spin holonomy groups. This leads us to ask whether it is feasible to classify the spin holonomy groups of compact, locally irreducible Riemannian manifolds, after the manner of Berger's classification of linear holonomy in the simply connected case.[9] Our results in that direction will be reported elsewhere.

The imperfect Boson gas supplemented with a gentle repulsive interaction is completely solved. In particular, it is proved that it has nonextensive Bose–Einstein condensation, i.e., there is condensation without macroscopic occupation of the ground ($k=0$) state level. © *1999 American Institute of Physics.* [S0022-2488(99)03902-X]

I. INTRODUCTION

The search for microscopic models of interacting bosons showing Bose–Einstein condensation is an ever challenging problem. It is known that the phenomenon only appears for space dimensions $d \geqslant 3$.[1] A general two-body interacting Bose system in a finite centered cubic box $\Lambda \subset \mathbb{R}^d$, with volume $V = L^d$, is given by a Hamiltonian,

$$H_\Lambda = T_\Lambda + U_\Lambda, \tag{1}$$

where

$$T_\Lambda = \sum_{k \in \Lambda^*} \epsilon_k a_k^* a_k, \quad \epsilon_k = \frac{|k|^2}{2m},$$

$$U_\Lambda = \frac{1}{2V} \sum_{q,k,k' \in \Lambda^*} v(q) a_{k+q}^* a_{k'-q}^* a_{k'} a_k, \quad a(x) = \frac{1}{\sqrt{V}} \sum_{k \in \Lambda^*} a_k e^{ik \cdot x}.$$

The $a^\sharp(x)$ are the Boson operators satisfying the commutation rules

$$[a(x), a^*(y)] = \delta(x-y), \quad [a(x), a(y)] = 0,$$

and

$$\Lambda^* = \left\{ k : k = \frac{2\pi}{L} n, n \in \mathbb{Z}^d \right\}.$$

We limit ourself to periodic boundary conditions.

Rigorous results on the existence of Bose–Einstein condensation are known for very special potentials v in (1), in particular, of course, for $v=0$, the free Bose gas, and for v in the δ-function limit[2] or in the van der Waals limit.[3] Another class of models that are treatable is this for which the Hamiltonian is a function of the number operators $N_k = a_k^* a_k$ only. These models are called the diagonal models.[4] The Hamiltonian is a function of a set of mutually commuting operators with a spectrum consisting of the integers. The operators can be considered as random variables taking values in the integers. The equilibrium states are looked for among the measures minimizing the

free energy. This method, developed in a series of papers (Ref. 4, and references therein), opened the possibility to derive rigorous results for so far unsolved interacting Bose gas models. The method is a powerful application of the large deviation principle for quantum systems.

In this paper we derive some rigorous results for another diagonal model, inspired by Ref. 5, where the pressure is computed. We are not using the large deviation technique of Ref. 4, but the full quantum mechanical technology, in particular, correlation inequalities, in order to prove the existence of Bose–Einstein condensation. In Sec. II, we first rederive the result of Ref. 5, and give a concise, rigorous, and direct proof of the pressure formula. Some arguments of Ref. 6 are translated into our situation. Our main contribution is in Sec. III, where we prove the occurrence of Bose–Einstein condensation, and where we study in detail the type of condensation.

There exist different types of condensation. The best known is macroscopic occupation of the ground state, but there is also so-called generalized condensation, when the number of particles distributed over a set of arbitrary small energies above the lowest energy level becomes macroscopic, proportional to the volume. This notion has been put into a rigorous and workable form in Ref. 7.

As far as our results are concerned, this notion of generalized condensation is crucial. We prove that in our model generalized condensation occurs without macroscopic occupation of the ground state. As far as we know, this is the first model of an interacting Bose gas for which this type of condensation is found. The only existing result is for the free Bose gas, considering a special thermodynamic limit, not of the type of increasing, absorbing cubes.[8,9]

The result of Sec. III also allows us, using the technique of Ref. 10, to give an explicit form of the equilibrium states in the thermodynamic limit. One verifies that they are of the same type as the equilibrium state of the imperfect Bose gas.

II. THE MODEL

In Ref. 5 Schröder considers a Bose gas contained in a d-dimensional $(d\geqslant 3)$ cubic box with Dirichlet boundary conditions on two opposite faces and periodic boundary conditions on the remaining surface. This can be interpreted as the model of a Bose gas enclosed between two hard walls at a macroscopic distance. An interaction term is introduced that behaves locally like the mean field interaction. This gives rise to the following Hamiltonian:

$$H_\Lambda=\sum_{k\in\Lambda^*}\epsilon_k N_{k,\Lambda}+\frac{\lambda}{V}\left(N_\Lambda^2+\frac{1}{2}\sum_{j\in\mathbb{N}}\tilde{N}_{j,\Lambda}^2\right), \tag{2}$$

where

$$\Lambda=\left\{x\in\mathbb{R}^d:-\frac{L}{2}\leqslant x_i\leqslant\frac{L}{2}, i=1,\dots,d-1; 0\leqslant x_d\leqslant L\right\}; V=L^d,$$

$$\Lambda^*=\frac{2\pi}{L}\mathbb{Z}^{d-1}\times\frac{\pi}{L}\mathbb{N},\quad N_{k,\Lambda}=a^*(f_{k,\Lambda})a(f_{k,\Lambda}),$$

$$f_{k,\Lambda}=\left(\frac{2}{V}\right)^{1/2}\exp[i(k_1x_1+\cdots+k_{d-1}x_{d-1})]\sin(k_dx_d),$$

$$\lambda\in\mathbb{R}^+,\quad \tilde{N}_{j,\Lambda}=\sum_{\{k\in\Lambda^*:k_d=(\pi/L)j\}}N_{k,\Lambda},$$

$$N_\Lambda=\sum_{k\in\Lambda^*}N_{k,\Lambda}.$$

Schröder shows that the grand-canonical pressure of this so-called local mean field model coincides with the grand-canonical pressure of the usual mean field model, or imperfect Bose gas, with Hamiltonian

$$H_\Lambda^{\mathrm{MF}} = \sum_{k\in\Lambda^*} \epsilon_k N_{k,\Lambda} + \frac{\lambda}{V} N_\Lambda^2, \tag{3}$$

which is a soluble model.

From this result, Schröder concludes that his model exhibits a phase transition with the same critical behavior as the imperfect Bose gas, although macroscopic occupation of the ground state may not occur, and opens the question of whether generalized condensation, as defined in Ref. 7, does take place.

We study a model of an interacting Bose gas that is inspired by Schröder's model, but that contains a nontrivial part of the self-interaction terms appearing in the general two-body repulsive interaction (1). More precisely, we consider a system of identical bosons in a centered cubic box $\Lambda \in \mathbb{R}^d$, $d \geqslant 3$, with volume $V = L^d$, with periodic boundary conditions for the wave functions, and described by the Hamiltonian

$$H_\Lambda = \sum_{k\in\Lambda^*} \epsilon_k N_{k,\Lambda} + \frac{\lambda}{V}\left(N_\Lambda^2 + \frac{1}{2}\sum_{k\in\Lambda^*} N_{k,\Lambda}^2 \right), \tag{4}$$

where now

$$\Lambda^* = \frac{2\pi}{L}\mathbb{Z}^d, \quad N_{k,\Lambda} = a_{k,\Lambda}^* a_{k,\Lambda},$$

$$a_{k,\Lambda}^* = \frac{1}{\sqrt{V}} \int_\Lambda dx\, e^{ik\cdot x} a^*(x),$$

$$\lambda \in \mathbb{R}^+, \quad N_\Lambda = \sum_{k\in\Lambda^*} N_{k,\Lambda}.$$

Our model can also be compared to the Huang–Yang–Luttinger model, rigorously studied in Ref. 11. Compared to our model, here the interaction terms $N_{k,\Lambda}^2$ appear with a minus sign and are therefore attractive perturbations of the imperfect Bose gas. The attractive character enhances (see Ref. 11) the condensation in the zero mode. The repulsive character of these terms in our model should make condensation in the zero mode more difficult. Heuristically one might expect that our model is a candidate for nonextensive Bose–Einstein condensation.

First we give a new proof, inspired by a proof in Ref. 6, of the main result of Schröder, i.e., the equality of the grand-canonical pressure of this model and the grand-canonical pressure of the imperfect Bose gas. From this we can immediately prove that there is no macroscopic occupation of any single-particle state.

For every μ in $\mathbb{R}$, denote

$$H_\Lambda(\mu) = \sum_{k\in\Lambda^*} \epsilon_k N_{k,\Lambda} + \frac{\lambda}{V}\left(N_\Lambda^2 + \frac{1}{2}\sum_{k\in\Lambda^*} N_{k,\Lambda}^2 \right) - \mu N_\Lambda, \tag{5}$$

and

$$H_\Lambda^{\mathrm{MF}}(\mu) = \sum_{k\in\Lambda^*} \epsilon_k N_{k,\Lambda} + \frac{\lambda}{V} N_\Lambda^2 - \mu N_\Lambda. \tag{6}$$

For $\alpha \leqslant 0$, let

$$\mathcal{C}^{\alpha} = \{ t \in \mathcal{C}^{b}(\mathbb{R}^{d}) : \inf_{k \in \mathbb{R}^{d}} (\epsilon_k - t_k - \alpha) > 0 \},$$

with $\mathcal{C}^{b}(\mathbb{R}^{d})$ the space of continuous bounded functions on $\mathbb{R}^{d}$. For $t \in \mathcal{C}^{\alpha}$, let

$$H_{\Lambda}^{t+\alpha} = \sum_{k \in \Lambda^*} (\epsilon_k - t_k - \alpha) N_{k,\Lambda}.$$

First, we prove the following.

Lemma 1:

$$\frac{1}{\beta V} \ln \operatorname{tr} e^{-\beta H_{\Lambda}(\mu)} \geqslant \frac{1}{\beta V} \ln \operatorname{tr} e^{-\beta H_{\Lambda}^{t+\alpha}} - \frac{1}{V} \omega_{\Lambda}^{t+\alpha}(H_{\Lambda}(\mu) - H_{\Lambda}^{t+\alpha}), \tag{7}$$

with

$$\omega_{\Lambda}^{t+\alpha}(A) = \frac{\operatorname{tr} e^{-\beta H_{\Lambda}^{t+\alpha}} A}{\operatorname{tr} e^{-\beta H_{\Lambda}^{t+\alpha}}}.$$

Proof: The function $x \in [0,1] \mapsto \ln \operatorname{tr} e^{C+xD}$, for C and D self-adjoint is convex. Hence, define the convex function f on $[0,1]$ by

$$f(x) = \ln \operatorname{tr} e^{-\beta(x H_{\Lambda}(\mu) + (1-x) H_{\Lambda}^{t+\alpha})}.$$

For all a,b in $[0,1]$, $f(a) - f(b) - (a-b) f'(b) \geqslant 0$, in particular,

$$f(1) \geqslant f(0) + f'(0),$$

which immediately yields the stated inequality. □

We can now prove a first result.

Theorem 1: *The grand-canonical pressure at chemical potential μ,*

$$\tilde{p}(\mu) = \lim_{V \to \infty} \tilde{p}_{\Lambda}(\mu) = \lim_{V \to \infty} \frac{1}{\beta V} \ln \operatorname{tr} e^{-\beta H_{\Lambda}(\mu)},$$

exists for every μ in $\mathbb{R}$ and is given by

$$\tilde{p}(\mu) = p^{\mathrm{MF}}(\mu) = \inf_{\alpha \leqslant 0} \left(p(\alpha) + \frac{(\mu - \alpha)^2}{4\lambda} \right),$$

with $p^{MF}(\mu)$ the grand-canonical pressure of the imperfect Bose gas at chemical potential μ and $p(\alpha)$ the free-gas grand-canonical pressure at chemical potential α.

[The expression for $p^{\mathrm{MF}}(\mu)$ is computed in Ref. 3.]

Proof: Since for every $\mu \in \mathbb{R}$, $H_{\Lambda}(\mu) \geqslant H_{\Lambda}^{\mathrm{MF}}(\mu)$, we have

$$\tilde{p}_{\Lambda}(\mu) \leqslant p_{\Lambda}^{\mathrm{MF}}(\mu),$$

and hence

$$\limsup_{V \to \infty} \tilde{p}_{\Lambda}(\mu) \leqslant \lim_{V \to \infty} p_{\Lambda}^{\mathrm{MF}}(\mu) = p^{\mathrm{MF}}(\mu).$$

To prove the lower bound, we make use of Lemma 1. For $\alpha \leqslant 0$ and $t \in \mathcal{C}^{\alpha}$, let

$$\rho(k;t,\alpha)=\frac{1}{e^{\beta(\epsilon_k-t_k-\alpha)}-1}.$$

Then

$$\omega_\Lambda^{t+\alpha}(N_{k,\Lambda})=\rho(k;t,\alpha),$$

$$\omega_\Lambda^{t+\alpha}(N_{k,\Lambda}N_{k',\Lambda})=\rho(k;t,\alpha)\rho(k';t,\alpha),\quad \text{if } k\neq k',$$

$$\omega_\Lambda^{t+\alpha}(N_{k,\Lambda}^2)=\rho(k;t,\alpha)(2\rho(k;t,\alpha)+1).$$

We calculate the rhs of (7). The first term gives

$$\frac{1}{\beta V}\ln \operatorname{tr} e^{-\beta H_\Lambda^{t+\alpha}}=-\frac{1}{\beta V}\sum_{k\in\Lambda^*}\ln(1-e^{-\beta(\epsilon_k-t_k-\alpha)}).$$

To calculate $(1/V)\omega_\Lambda^{t+\alpha}(H_\Lambda(\mu))$, we write

$$H_\Lambda(\mu)=\sum_{k\in\Lambda^*}(\epsilon_k-\mu)N_{k,\Lambda}+\frac{\lambda}{V}\sum_{k\in\Lambda^*}\sum_{k'\neq k\in\Lambda^*}N_{k,\Lambda}N_{k',\Lambda}+\frac{3\lambda}{2V}\sum_{k\in\Lambda^*}N_{k,\Lambda}^2,$$

hence

$$\frac{1}{V}\omega_\Lambda^{t+\alpha}(H_\Lambda(\mu))=\frac{1}{V}\sum_{k\in\Lambda^*}(\epsilon_k-\mu)\rho(k;t,\alpha)+\frac{\lambda}{V^2}\sum_{k\in\Lambda^*}\sum_{k'\neq k\in\Lambda^*}\rho(k;t,\alpha)\rho(k';t,\alpha)+\frac{c_V}{V},$$

where

$$c_V=\frac{3\lambda}{2V}\sum_{k\in\Lambda^*}\rho(k;t,\alpha)(2\rho(k;t,\alpha)+1).$$

Also,

$$\frac{1}{V}\omega_\Lambda^{t+\alpha}(H_\Lambda^{t+\alpha})=\frac{1}{V}\sum_{k\in\Lambda^*}(\epsilon_k-t_k-\alpha)\rho(k;t,\alpha).$$

Substituting all this in (7), we get

$$\begin{aligned}\tilde{p}_\Lambda(\mu)\geq&-\frac{1}{\beta V}\sum_{k\in\Lambda^*}\ln(1-e^{-\beta(\epsilon_k-t_k-\alpha)})+\frac{1}{V}\sum_{k\in\Lambda^*}(\mu-t_k-\alpha)\rho(k;t,\alpha)\\&-\frac{\lambda}{V^2}\sum_{k\in\Lambda^*}\sum_{k'\neq k\in\Lambda^*}\rho(k;t,\alpha)\rho(k';t,\alpha)-\frac{c_V}{V}.\end{aligned}$$

Since $\rho(k;t,\alpha)$ and c_V, for V large enough, are bounded

$$\begin{aligned}\liminf_{V\to\infty}\tilde{p}_\Lambda(\mu)\geq&-\beta^{-1}\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\ln(1-e^{-\beta(\epsilon_k-t_k-\alpha)})\\&+\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}(\mu-t_k-\alpha)\rho(k;t,\alpha)-\lambda\left(\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\rho(k;t,\alpha)\right)^2.\end{aligned}\tag{8}$$

For $\alpha\leq 0$ the free-gas pressure is given by

$$p(\alpha) = -\beta^{-1}\int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \ln(1 - e^{-\beta(\epsilon_k - \alpha)})$$

and

$$p'(\alpha) = \int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \frac{1}{e^{\beta(\epsilon_k-\alpha)} - 1}.$$

Also, let $\rho_c = p'(0)$ as usual.

First, consider the case $\mu < 2\lambda\rho_c$. Taking $\alpha < 0$ and $t = 0$ in (8) we get

$$\liminf_{V\to\infty} \tilde{p}_\Lambda(\mu) \geq p(\alpha) + (\mu - \alpha)p'(\alpha) - \lambda(p'(\alpha))^2. \tag{9}$$

For $\mu < 2\lambda\rho_c$, since $p'(\alpha)$ is increasing and $p'(0) = \rho_c$, the equation

$$p'(\alpha) = \frac{\mu - \alpha}{2\lambda}$$

has a unique solution $\alpha^* < 0$. Taking $\alpha = \alpha^*$ in (9), we get

$$\liminf_{V\to\infty} \tilde{p}_\Lambda(\mu) \geq p(\alpha^*) + \frac{(\mu - \alpha^*)^2}{4\lambda} = \inf_{\alpha \leq 0}\left\{ p(\alpha) + \frac{(\mu-\alpha)^2}{4\lambda}\right\} = p^{\mathrm{MF}}(\mu),$$

which proves the theorem for $\mu < 2\lambda\rho_c$.

Consider now the case $\mu \geq 2\lambda\rho_c$. Take $\alpha = 0$ and an appropriate t in (8):

$$\liminf_{V\to\infty} \tilde{p}_\Lambda(\mu) \geq -\beta^{-1}\int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \ln(1 - e^{-\beta(\epsilon_k - t_k)}) + \int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} (\mu - t_k)\rho(k;t) - \lambda\left(\int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \rho(k;t)\right)^2, \tag{10}$$

with

$$\rho(k;t) = \frac{1}{e^{\beta(\epsilon_k - t_k)} - 1}.$$

For all $\delta > 0$, take $t_\delta \in \mathcal{C}^0$ such that

$$t_\delta(k) = 0, \quad |k| > \delta.$$

Then

$$\int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \rho(k;t_\delta) = \int_{|k|\leq\delta} \frac{dk}{(2\pi)^d} \rho(k;t_\delta) + \int_{|k|>\delta} \frac{dk}{(2\pi)^d} \frac{1}{e^{\beta\epsilon_k} - 1}.$$

Letting $\delta \to 0$, the second term on the rhs converges to ρ_c. Take t_δ such that the first term on the rhs converges to $\mu/2\lambda - \rho_c$ as $\delta \to 0$. Such a sequence of t_δ's can be constructed rigorously by using the Approximation theorem proved in Ref. 12. It certainly means that $t_\delta \to 0$ as $\delta \to 0$. Hence we get

$$\int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \rho(k;t_\delta) \to \frac{\mu}{2\lambda},$$

as $\delta\rightarrow 0$, and thus

$$\liminf_{V\rightarrow\infty}\tilde{p}_\Lambda(\mu)\geqslant p(0)+\frac{\mu^2}{4\lambda}\geqslant\inf_{\alpha\leqslant 0}\left\{p(\alpha)+\frac{(\mu-\alpha)^2}{4\lambda}\right\}=p^{\mathrm{MF}}(\mu),$$

so that the theorem is proved for $\mu\geqslant 2\lambda\rho_c$ as well. □

From Theorem 1 we can immediately derive that there is no macroscopic occupation of any single-particle state, in particular, the following.

Theorem 2: *For every* $\epsilon>0$ *and for* V *large enough, we have, for every* $k\in\Lambda^*$:

$$\frac{1}{V}\omega_\Lambda(N_{k,\Lambda})<\epsilon,$$

where ω_Λ *is the finite-volume Gibbs state of* $H_\Lambda(\mu)$.

Proof: We have

$$e^{\beta V p_\Lambda^{\mathrm{MF}}(\mu)}=\mathrm{tr}\, e^{-\beta H_\Lambda^{\mathrm{MF}}(\mu)}=\mathrm{tr}(e^{-\beta H_\Lambda(\mu)}e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}N_{k,\Lambda}^2})=\omega_\Lambda(e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}N_{k,\Lambda}^2})e^{\beta V\tilde{p}_\Lambda(\mu)}.$$

Hence,

$$p_\Lambda^{\mathrm{MF}}=\tilde{p}_\Lambda(\mu)+\frac{1}{\beta V}\ln\omega_\Lambda(e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}N_{k,\Lambda}^2}).$$

By Theorem 1 we get

$$\lim_{V\rightarrow\infty}\frac{1}{\beta V}\ln\omega_\Lambda(e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}N_{k,\Lambda}^2})=0.$$

From the Jensen inequality, i.e., for F a convex function and ω a normal state,

$$\omega(F(X))\geqslant F(\omega(X)),$$

we get

$$\omega_\Lambda(e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}N_{k,\Lambda}^2})\geqslant e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}\omega_\Lambda(N_{k,\Lambda}^2)},$$

or

$$0\leqslant\frac{\lambda}{2V^2}\sum_{k\in\Lambda^*}\omega_\Lambda(N_{k,\Lambda}^2)\leqslant\frac{1}{\beta V}\ln\omega_\Lambda(e^{(\beta\lambda/2V)\Sigma_{k\in\Lambda^*}N_{k,\Lambda}^2}).$$

Hence

$$\lim_{V\rightarrow\infty}\frac{1}{V^2}\sum_{k\in\Lambda^*}\omega_\Lambda(N_{k,\Lambda}^2)=0.$$

Since for each $k\in\Lambda^*$,

$$0\leqslant\left(\frac{1}{V}\omega_\Lambda(N_{k,\Lambda})\right)^2\leqslant\frac{1}{V^2}\omega_\Lambda(N_{k,\Lambda}^2)\leqslant\frac{1}{V^2}\sum_{k'\in\Lambda^*}\omega_\Lambda(N_{k',\Lambda}^2),$$

we get the Theorem. □

III. BOSE–EINSTEIN CONDENSATION

In Ref. 7 it is stressed that Bose condensation does not necessarily manifest itself through a macroscopic occupation of a single-particle state (the ground state usually), but that there are, in fact, two good candidates for the concept of macroscopic occupation of the zero-kinetic energy state. Macroscopic occupation of the ground state is said to occur when the number of particles in the ground state becomes proportional to the volume; generalized condensation is said to occur when the number of particles whose energy levels lie in an arbitrary small band above zero becomes proportional to the volume. Obviously, the first implies the second. However, the second can occur without the first; this is called nonextensive condensation. The concept of generalized condensation was first introduced in Ref. 13. More precisely, we have the following.

(i) Macroscopic occupation of the ground state if the limit

$$\lim_{V\to\infty}\frac{1}{V}\,\omega_\Lambda(N_{0,\Lambda})$$

exists and is strictly positive; (ii) generalized condensation if the limit

$$\lim_{\delta\to 0}\lim_{V\to\infty}\frac{1}{V}\sum_{\{k\in\Lambda^*:\epsilon_k<\delta\}}\omega_\Lambda(N_{k,\Lambda})$$

exists and is strictly positive; (iii) nonextensive condensation if the limit

$$\lim_{V\to\infty}\frac{1}{V}\,\omega_\Lambda(N_{0,\Lambda})=0,$$

but nevertheless the limit

$$\lim_{\delta\to 0}\lim_{V\to\infty}\frac{1}{V}\sum_{\{k\in\Lambda^*:\epsilon_k<\delta\}}\omega_\Lambda(N_{k,\Lambda})$$

exists and is strictly positive.

Examples of these different occurrences of Bose condensation in the free Bose gas, depending on how the bulk limit is taken, can be found in Refs. 7–9.

As is proved in Theorem 2, there is no macroscopic occupation of the ground state in our system. However, as we will show, there is generalized condensation. In other words, we have a model for an interacting Bose gas displaying nonextensive condensation.

Our approach is based on Ref. 10, where the imperfect Bose gas is treated. The system is given by the local Hamiltonian H_Λ, with periodic boundary conditions

$$H_\Lambda=\sum_{k\in\Lambda^*}\epsilon_k N_{k,\Lambda}+\frac{\lambda}{V}\left(N_\Lambda^2+\frac{1}{2}\sum_{k\in\Lambda^*}N_{k,\Lambda}^2\right)-\mu_\Lambda N_\Lambda, \tag{11}$$

as specified before, and μ_Λ is determined by the constant density $\rho>0$ equation:

$$\frac{1}{V}\,\omega_\Lambda(N_\Lambda)=\rho.$$

We study the equilibrium state of this system in the grand-canonical ensemble. The key technique is the equivalence of the equilibrium condition or Gibbs state ω_Λ with the correlation inequalities[14,15]

$$\beta\omega_\Lambda(X^*[H_\Lambda,X])\geqslant\omega_\Lambda(X^*X)\ln\frac{\omega_\Lambda(X^*X)}{\omega_\Lambda(XX^*)},\tag{12}$$

for all local observables X belonging to the domain of $[H_\Lambda,\cdot]$. In particular, we take for X polynomials in the creation and annihilation operators. We prove the occurrence of nonextensive condensation in this model, and follow closely the method used in Ref. 10.

Lemma 2: $\forall k,\ j\in\Lambda^*$:

(i)

$$\beta\omega_\Lambda\left(-\epsilon_k N_{k,\Lambda}+\left(\mu_\Lambda-\frac{2\lambda}{V}N_\Lambda\right)N_{k,\Lambda}-\frac{\lambda}{V}N_{k,\Lambda}^2+\frac{3\lambda}{2V}N_{k,\Lambda}\right)\geqslant\omega_\Lambda(N_{k,\Lambda})\ln\frac{\omega_\Lambda(N_{k,\Lambda})}{\omega_\Lambda(N_{k,\Lambda})+1};\tag{13}$$

(ii)

$$\omega_\Lambda\left(\left(\mu_\Lambda-\frac{2\lambda}{V}N_\Lambda\right)N_{k,\Lambda}\right)\leqslant\omega_\Lambda\left(\epsilon_j N_{k,\Lambda}+\frac{4\lambda}{V}N_{j,\Lambda}N_{k,\Lambda}+\frac{3\lambda}{2V}N_{k,\Lambda}\right).\tag{14}$$

Proof: For *(i)*, the result follows by taking $X=a_k$ in the correlation inequality (12). One gets *(ii)* by taking

$$X=a_j N_{k,\Lambda}^{1/2},$$

in the inequality

$$\omega_\Lambda([X^*,[H_\Lambda,X]])\geqslant 0,$$

which follows immediately from (12) by adding the correlation inequality for X and the complex conjugate of the correlation inequality for X^*. □

Lemma 3: For every $\delta>0$, *for every* V *and for every* $k\in\Lambda^*$, $|k|\geqslant\delta$,

$$\omega_\Lambda(N_{k,\Lambda})\leqslant\frac{1}{e^{c_k(\Lambda)}-1}+\frac{4\lambda}{V}\omega_\Lambda(N_{j,\Lambda}N_{k,\Lambda})\frac{1}{1-e^{-c_\delta(\Lambda)}},$$

with

$$c_k(\Lambda)=\beta\left(\epsilon_k-\frac{\delta^2}{8m}-\frac{3\lambda}{V},\right),$$

$c_\delta(\Lambda)=c_k(\Lambda)|_{|k|=\delta}$ *and* $j\in\Lambda^*$, $|j|\leqslant\delta/2$.

Proof: Substitution of (14) in (13), changing the sign, and using the trivial bound $\omega_\Lambda(N_{k,\Lambda}^2)\geqslant 0$ we get

$$\beta\left(\epsilon_k-\epsilon_j-\frac{3\lambda}{V}\right)\omega_\Lambda(N_{k,\Lambda})-\frac{4\lambda}{V}\omega_\Lambda(N_{j,\Lambda}N_{k,\Lambda})\leqslant\omega_\Lambda(N_{k,\Lambda})\ln\frac{\omega_\Lambda(N_{k,\Lambda})+1}{\omega_\Lambda(N_{k,\Lambda})}.\tag{15}$$

Take $\delta>0$ arbitrary, $|k|\geqslant\delta$, and $|j|\leqslant\delta/2$.

Using $\epsilon_j\leqslant\delta^2/8m$, (15) becomes

$$c_k(\Lambda)\omega_\Lambda(N_{k,\Lambda})-\frac{4\lambda}{V}\omega_\Lambda(N_{j,\Lambda}N_{k,\Lambda})\leqslant\omega_\Lambda(N_{k,\Lambda})\ln\frac{\omega_\Lambda(N_{k,\Lambda})+1}{\omega_\Lambda(N_{k,\Lambda})}.$$

The lemma now follows from convexity arguments on the rhs: we want to solve for t the inequality

$$ct-b\leqslant t\ln\frac{t+1}{t},$$

with c and b positive constants and $t\in\mathbb{R}^+$. It follows that $t\leqslant t_2$, with t_2, satisfying

$$ct_2-b=t_2\ln\frac{t_2+1}{t_2}.$$

One can write this as $t\leqslant t_1+(t_2-t_1)$, with

$$t_1=\frac{1}{e^c-1}.$$

Let $f(t)=t\ln(t+1)/t$, f is concave, hence

$$f(t_2)-f(t_1)-(t_2-t_1)f'(t_1)\leqslant 0,$$

and

$$t_2-t_1\leqslant b\,\frac{1}{t-e^{-c}}.$$

Substitute this into the inequality $t\leqslant t_1+(t_2-t_1)$, one gets

$$t\leqslant\frac{1}{e^c-1}+b\,\frac{1}{1-e^{-c}}.$$

Finally, use $|k|\geqslant\delta$ in the second term on the rhs to prove the lemma. □

Lemma 4: For every $\epsilon>0$, *V large enough and* $j\in\Lambda^*$:

$$\frac{1}{V^2}\,\omega_\Lambda(N_\Lambda N_{j,\Lambda})<\epsilon.$$

Proof: (13) gives

$$\beta\omega_\Lambda\left(-\epsilon_j N_{j,\Lambda}+\left(\mu_\Lambda-\frac{2\lambda}{V}N_\Lambda\right)N_{j,\Lambda}+\frac{3\lambda}{2V}N_{j,\Lambda}\right)\geqslant\omega_\Lambda(N_{j,\Lambda})\ln\frac{\omega_\Lambda(N_{j,\Lambda})}{\omega_\Lambda(N_{j,\Lambda})+1}\geqslant-1.$$

This can be rewritten in the form

$$\frac{2\lambda}{V^2}\,\omega_\Lambda(N_\Lambda N_{j,\Lambda})\leqslant\frac{1}{\beta V}+\left(\mu_\Lambda+\frac{3\lambda}{2V}-\epsilon_j\right)\frac{1}{V}\,\omega_\Lambda(N_{j,\Lambda}).\tag{16}$$

Taking $X=a_j$ in the inequality

$$\omega_\Lambda([X^*,[H_\Lambda,X]])\geqslant 0,$$

gives

$$\mu_\Lambda\leqslant 2\lambda\rho+\epsilon_j+\frac{4\lambda}{V}\,\omega_\Lambda(N_{j,\Lambda})+\frac{3\lambda}{2V}.$$

Putting this into (16) gives

$$\frac{2\lambda}{V^2}\,\omega_\Lambda(N_\Lambda N_{j,\Lambda})\le \frac{1}{\beta V}+\left(2\lambda\rho+\frac{3\lambda}{V}\right)\frac{1}{V}\,\omega_\Lambda(N_{j,\Lambda})+\frac{4\lambda}{V^2}\,\omega_\Lambda(N_{j,\Lambda})^2.$$

Using Theorem 2 proves the lemma. □

We now prove the existence of generalized condensation in the thermodynamic limit $V\to\infty$, taken with constant particle density ρ.

Theorem 3: *One has (i)*

$$\lim_{\delta\to 0}\lim_{V\to\infty}\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|<\delta\}}\omega_\Lambda(N_{k,\Lambda})\ge\rho-\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\,\frac{1}{e^{\beta\epsilon_k}-1};$$

(ii) for every $\rho>0$, there is a β_c such that for all $\beta>\beta_c$:

$$0<\lim_{\delta\to 0}\liminf_{V\to\infty}\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|<\delta\}}\omega_\Lambda(N_{k,\Lambda})\le\lim_{\delta\to 0}\limsup_{V\to\infty}\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|<\delta\}}\omega_\Lambda(N_{k,\Lambda})\le\rho.$$

Proof: We have clearly

$$\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|<\delta\}}\omega_\Lambda(N_{k,\Lambda})=\rho-\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|\ge\delta\}}\omega_\Lambda(N_{k,\Lambda}).$$

Applying Lemma 3 gives

$$\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|<\delta\}}\omega_\Lambda(N_{k,\Lambda})\ge\rho-\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|\ge\delta\}}\frac{1}{e^{c_k(\Lambda)}-1}-\frac{4\lambda}{V^2}\sum_{\{k\in\Lambda^*:|k|\ge\delta\}}\omega_\Lambda(N_{j,\Lambda}N_{k,\Lambda})\,\frac{1}{1-e^{-c_\delta(\Lambda)}}. \tag{17}$$

Take $\epsilon>0$ arbitrary, and V large enough such that Lemma 4 is satisfied. This implies that

$$\frac{1}{V^2}\sum_{\{k\in\Lambda^*:|k|\ge\delta\}}\omega_\Lambda(N_{j,\Lambda}N_{k,\Lambda})\le\frac{1}{V^2}\,\omega_\Lambda(N_\Lambda N_{j,\Lambda})<\epsilon.$$

Hence taking V large enough, the second term on the rhs of (17) can be made arbitrarily close to

$$\int_{|k|\ge\delta}\frac{dk}{(2\pi)^d}\,\frac{1}{e^{\beta(\epsilon_k-\delta^2/8m)}-1},$$

whereas the third term is made arbitrarily small.

Hence in the limit $V\to\infty$, one gets

$$\lim_{V\to\infty}\frac{1}{V}\sum_{\{k\in\Lambda^*:|k|<\delta\}}\omega_\Lambda(N_{k,\Lambda})\ge\rho-\int_{|k|\ge\delta}\frac{dk}{(2\pi)^d}\,\frac{1}{e^{\beta(\epsilon_k-\delta^2/8m)}-1}.$$

Now take the limit $\delta\to 0$ to get *(i)*.

The function

$$\beta\mapsto f(\beta)=\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\,\frac{1}{e^{\beta\epsilon_k}-1}$$

is clearly decreasing in $\beta>0$ and, furthermore, $f(\beta)\to\infty$ for $\beta\to 0$, and $f(\beta)\to 0$ for $\beta\to\infty$. Hence, for every $\rho>0$ there exists $\beta_c>0$, defined by

$$\rho=\int_{\mathbb{R}^d}\frac{dk}{(2\pi)^d}\,\frac{1}{e^{\beta_c\epsilon_k}-1}.$$

Together with *(i)* this proves *(ii)*. □

Theorem 1 proves that the model (11) has the same pressure as the imperfect Bose gas. Theorems 2 and 3 prove that the model (11) shows a Bose–Einstein condensation exactly as the imperfect Bose gas, be it that the nature of the condensation is different. One aspect of this is that the ground state $(k=0)$ condensation of the imperfect Bose gas is unstable against any arbitrary small repulsive perturbation of the type $(\gamma/V)\Sigma_{k\in\Lambda*}N_{k,\Lambda}^2$, for any $\gamma>0$. The condensation becomes nonextensive. However, on the level of the thermodynamics the models are similar.

The natural question to ask is, whether the equilibrium states of the two models coincide. For the imperfect Bose gas, this problem is solved, e.g., in Ref. 10. We are not going into the details, but the technique of Ref. 10 can also be used in order to solve rigorously the equilibrium—or KMS—equations of our model. The result is that all equilibrium states are of the same type as the ones of the imperfect Bose gas. In particular, the equilibrium states are also integrals over a set of quasifree or generalized free states.

On the other hand, it is interesting to remark the following. Given this result, one might ask whether the variational principle of statistical mechanics, formulated in the thermodynamic limit, but restricted to the set of quasifree states, does also give the results of this paper, namely, the existence of condensation and the equilibrium states. Performing this program, one remarks that the particular type of condensation is not recovered by this method. Hence, for the time being, the only way to keep track of it is to follow closely the details of the thermodynamic limit, as is done above. In this work we illustrate clearly that care must be taken of this limit and that statistical mechanics remains the theory of really handling the thermodynamic limit.

ACKNOWLEDGMENT

The authors thank the referee for his careful reading of the paper, leading to a better version of it.

(Received 5 September 1997; accepted for publication 16 April 1998)

It is argued that extended, reducible, and generalized supersymmetry (SUSY) are common in many systems of standard nonrelativistic quantum mechanics. For example, it is proved that a well-studied quantum mechanical system of a spin-$\frac{1}{2}$ particle interacting with constant and homogeneous magnetic field admits the $N=4$ SUSY and has the internal symmetry so(3,3). Then an approach of energy spectra of a SUSY nature is presented and developed. It is applied to a wide class of systems described by the Schrödinger–Pauli equation admitting $N=3$, $N=4$, and $N=5$ SUSY. Some of these supersymmetries have a very peculiar property—their supercharges are realized without usual fermionic variables. It is shown that for them, the usual extension $N=3$ to $N=4$ SUSY is no longer guaranteed.

I. INTRODUCTION

A beautiful and rich concept of supersymmetry (SUSY) has been introduced by several authors in various contexts (see Refs. 1 but also Refs. 2, where the idea of SUSY was formulated in a somewhat rudimental form). Since that time it has played a more and more important role in physics and mathematics, in general, and in modern particle physics and quantum mechanics,[3] in particular. This is due to the fact that SUSY presents a powerful tool for transforming bosons to fermions, and vice versa, for formulating theories with nontrivial unification of space–time and internal symmetries, for formulating string theories and their most powerful dualities (refer, e.g., to Refs. 4–6), for understanding the relations between spectra of different Hamiltonians as well as for explaining degeneracy of their spectra, for constructing exactly or quasiexactly solvable systems, for justifying formulations of initial and bound problems, etc.; see, e.g., surveys.[4,7,8]

In this work we shall concentrate on quantum mechanical systems since they provide a ground for testing the principal question: whether SUSY is realized in nature or not, free of the complexities of field theories. Examples of such systems (like interaction of a spin-$\frac{1}{2}$ particle with the Coulomb or constant and inhomogeneous magnetic field), which admit exact $N=2$ SUSY, are well known[9,10] (see also Refs. 7, 8 and references therein). Here we search for problems with *extended* ($N=3$ and $N=4$) SUSY.

In this connection let us remind you that the quantum mechanical models that include $N>2$ supercharges were investigated, e.g., in Refs. 11, and examples of quantum mechanical systems with extended SUSY were discussed in Refs. 12–16. In Refs. 17 the so-called ''generalized SUSY'' was proposed; it includes extended SUSY as a particular case. It was pointed out in Refs. 12–14 that some quantum mechanical models are invariant wrt reducible representations of SUSY algebra; we will refer to the related symmetry as ''reducible SUSY.''

Of course it is interesting to search for physical systems that admit exact (especially extended,

[a)]Electronic mail: niederle@fzu.cz

reducible, or generalized) SUSY. First, they bring additional indications that SUSY is indeed the symmetry of nature, and second, for such systems we have standard methods for their analysis at our disposal.

In fact, it will be shown in the present paper that the extended, reducible, and generalized SUSYs are common in many problems of standard nonrelativistic quantum mechanics. For example, we prove that the well-studied system of a spin-$\frac{1}{2}$ particle interacting with a constant and homogeneous magnetic field, which can be described by the Schrödinger–Pauli equation, admits $N=4$ SUSY and $N=2$ reducible SUSY as well.

In Sec. II we show that the extended, reducible, and generalized SUSY appear naturally in a wide class of problems of standard one-dimensional SUSY quantum mechanics. In Sec. III we consider the quantum mechanical system of a spin-$\frac{1}{2}$ particle interacting with a constant and homogeneous magnetic field and prove that it has $N=4$ extended SUSY. The reducible SUSY and so(3,3) symmetry of this model are discussed in Sec. III C.

In Sec. IV we search for extended and reducible SUSY of the Schrödinger–Pauli equation for a particle interacting with a static inhomogeneous magnetic field. We find a wide class of systems admitting these supersymmetries and discuss briefly their physical consequences.

II. ADDITIONAL EXTENDED AND REDUCIBLE SUSY OF SUPERSYMMETRIC QUANTUM MECHANICS

Supersymmetric quantum mechanical systems are described by the Schrödinger equation with a matrix potential,[3]

$$\hat{H}\psi \equiv \tfrac{1}{2}(p^2+W^2+\sigma_3 W')\psi = E\psi, \tag{2.1}$$

where $p=-i(\partial/\partial x)$, $W=W(x)$ is a superpotential, $W'=\partial W/\partial x$, and σ_3 is the Pauli matrix of the form

$$\sigma_3=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

It is well known that Eq. (2.1) admits the following specific supersymmetries (supercharges):

$$Q_1=\frac{1}{\sqrt{2}}(\sigma_1 p+\sigma_2 W), \quad Q_2=\frac{1}{\sqrt{2}}(\sigma_2 p-\sigma_1 W), \tag{2.2}$$

which satisfy the superalgebra

$$\{Q_a,Q_b\}=2\delta_{ab}H, \quad [Q_a,H]=0, \tag{2.3}$$

where $a,b=1,2$ and $[\cdot,\cdot]$ and $\{\cdot,\cdot\}$ denote a commutator and anticommutator, respectively.

Let us demonstrate that, in addition to the transparent $N=2$ SUSY, Eq. (2.1) admits $N=3$ extended SUSY provided the corresponding superpotential $W(x)$ is an even function of x.

Proposition 1 (*Ref. 12*): Let $W(-x)=W(x)$, then there exists the third supercharge,

$$Q_3=i\sigma_1 R Q_1, \tag{2.4}$$

satisfying relations (2.3) for $a=1,2,3$, together with operators (2.2). Here R is defined by

$$R\psi(x)=\psi(-x). \tag{2.5}$$

Proof: The proposition can be proved by a simple direct calculation, taking into account the relations

$$[\sigma_1 R,Q_2]=\{\sigma_1 R,Q_1\}=0, \quad (\sigma_1 R)^2=1.$$

Thus, even the simplest SUSY model (2.1) can admit the extended SUSY generated by three supercharges.

Another interesting possibility is connected with the fact that the representation of superalgebra (2.2), (2.3) can be reducible. This occurs for the systems described by Eq. (2.1) with odd superpotentials.

Proposition 2 (*Refs. 12,13*): Let $W(-x)=-W(x)$; then the representation (2.2) of superalgebra (2.3) is reducible.

Proof: For odd $W(x)$ there exists an invariant operator, namely,

$$I=\sigma_3 R, \tag{2.6}$$

which commutes with any element of algebra (2.3).

Using the mapping $I\rightarrow I'=UIU^\dagger$, where

$$U=R_+-i\sigma_2 R_-, \quad R_\pm=\tfrac{1}{2}(1\pm R), \tag{2.7}$$

the operator (2.6) is transformed to the diagonal matrix,

$$I_3'=\sigma_3. \tag{2.8}$$

The corresponding transformed supercharges $Q_\alpha'=UQ_\alpha U'$ and the Hamiltonian $H'=UHU^\dagger$ commute with σ_3 and thus are diagonal too:

$$Q_\alpha'=\begin{pmatrix} q_+^\alpha & 0\\ 0 & q_-^\alpha\end{pmatrix}, \quad \hat{H}'=\begin{pmatrix}\hat{H}_+ & 0\\ 0 & \hat{H}_-\end{pmatrix}, \quad \alpha=1,2. \tag{2.9}$$

Here

$$q_\pm^1=iRP\pm W, \quad q_\pm^2=\pm p-iRW, \quad H_\pm=\tfrac{1}{2}(p^2+W^2\pm W'R). \tag{2.10}$$

Thus, supercharges $Q_{\alpha,\alpha}'=1,2$, are expressed as the direct sum of q_+^α and q_-^α Q.E.D.

Propositions 1 and 2 indicate how to find extended and reducible SUSY of realistic three-dimensional systems by first determining and then applying the appropriate involutive *discrete symmetries* (e.g., parities) of the system.

It is easy to see that the above-obtained extended and reducible supersymmetries imply the existence of some generalized ones,[17] i.e., supersymmetries satisfying the relations[17]

$$Q^2=\hat{H}, \quad \{I_a,Q\}=0, \quad I_a^2=1, \quad I_aI_b=\pm I_bI_a, \quad a=1,2,..., \tag{2.11}$$

where all involutions I_a either commute among themselves *or* anticommute.

Indeed, for even superpotentials there exist the anticommuting involutions $I_1=\sigma_3$ and $I_2=\sigma_1 R$, which, together with $Q=Q_1$, satisfy relations (2.11). In the case of odd superpotentials, relations (2.11) are satisfied by supercharge Q equal to Q_1, together with the commuting involutions $I_1=\sigma_3$ and $I_2=R$ (compare with Refs. 17).

In the systems analyzed later on we shall find their extended and reducible SUSY too. However, in contradistinction to the systems studied in the present section, the existence of these SUSYs will not imply the existence of the corresponding generalized SUSY.

III. SPIN-$\frac{1}{2}$ PARTICLE IN CONSTANT, HOMOGENEOUS MAGNETIC FIELD

A. Degeneracy of the spectrum of energy

Consider a quantum mechanical system consisting of the spin-$\frac{1}{2}$ charged particle interacting with a constant and homogeneous magnetic field. In a nonrelativistic approximation, this system is described by the Schrödinger–Pauli equation,

$$2mE\psi=\hat{H}\psi, \quad \hat{H}=\boldsymbol{\pi}^2-\tfrac{1}{2}eg\boldsymbol{\sigma}\cdot\mathbf{H}, \tag{3.1}$$

with

$$\pi_a=-i\frac{\partial}{\partial x_a}-eA_a, \quad a=1,2,3, \quad \boldsymbol{\sigma}=(\sigma_1,\sigma_2,\sigma_3), \quad g=2, \tag{3.2a}$$

and

$$A_1=eHx_2, \quad A_2=A_3=0, \quad e\mathbf{H}=i\boldsymbol{\pi}\times\boldsymbol{\pi}=e(0,0,H). \tag{3.2b}$$

Here σ_a are the Pauli matrices, and H is a constant characterizing the strength of the magnetic field $\mathbf{H}$.

The system (3.1) is exactly solvable.[18] The corresponding eigenvalues of energy E (Landau levels) are given by

$$2mE=2neH+p_3^2, \quad n=0,1,2,\dots. \tag{3.3}$$

For any $n\neq 0$ there exist two independent eigenfunctions (see, e.g., Ref. 19):

$$\begin{aligned}\psi_{1,p_1,p_3}&=\exp(ip_1x_1+ip_3x_3)\exp(-y^2/2)\begin{pmatrix}H_n(y)\\ H_{n-1}(y)\end{pmatrix},\\ \psi_{2,p_1,p_3}&=\exp(ip_1x_1+ip_3x_3)\exp(-y^2/2)\begin{pmatrix}H_n(y)\\ -H_{n-1}(y)\end{pmatrix},\end{aligned} \tag{3.4}$$

with H_n being Hermite polynomials, $H_{-1}=0$ and

$$y=\sqrt{eH}x_2-\frac{p_1}{\sqrt{eH}}. \tag{3.5}$$

For $n=0$ the eigenfunctions ψ_1 and ψ_2 coincide.

Thus, any energy levels (except the ground one) are two-fold degenerate due to the $N=2$ SUSY of Eq. (3.1). Moreover, there exists the infinite degeneracy of any energy level due to independence of E on p_1.[18]

In spite of the fact that symmetries and supersymmetries of Eq. (3.1) have been studied quite intensively (see, e.g., Refs. 6–8, 20, 21), we shall find a new, additional (extended) SUSY for this equation.

Starting with (3.4) and taking into account the quadratic dependence of energy E on p_3 and independence of E on p_1, we can write, for instance, six additional solutions corresponding to the same energy (3.3), namely

$$\begin{aligned}&\psi_{3,p_1,p_3}=\psi_{1,-p_1,p_3}, \quad \psi_{4,p_1,p_3}=\psi_{1,-p_1,-p_3}, \quad \psi_{5,p_1,p_3}=\psi_{1,p_1,-p_3},\\ &\psi_{6,p_1,p_3}=\psi_{2,-p_1,p_3}, \quad \psi_{7,p_1,p_3}=\psi_{2,-p_1,-p_3}, \quad \psi_{8,p_1,p_3}=\psi_{1,p_1,-p_3}.\end{aligned} \tag{3.6}$$

A bit surprisingly, the corresponding eight-fold degeneracy of energy levels can be interpreted as caused by $N=4$ *extended SUSY* of the system (3.1).

B. Extended SUSY

It is well known that whenever the gyromagnetic ratio g of the particle is equal to 2, Eq. (3.1) admits $N=2$ SUSY.[10] Here we demonstrate that this SUSY is reducible and that there exists a more extended, namely, $N=4$ SUSY for (3.1) in addition.

A standard supercharge for Eq. (3.1) has the form[4]

$$Q_1 = \boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_1^2 = \hat{H}. \tag{3.7}$$

The remaining three additional supercharges can be constructed using the fact that (3.1) is invariant wrt the following three discrete transformations:

$$\psi \to iR_3\psi, \quad \psi \to CR_1\psi, \quad \psi \to CR_2\psi, \tag{3.8}$$

where R_a $(a=1,2,3)$ are the space reflection transformations,

$$R_a\psi(\mathbf{x}) = \sigma_a\theta_a\psi(\mathbf{x}), \quad \theta_a\psi(\mathbf{x}) = \psi(r_a\mathbf{x}). \tag{3.9a}$$

Here

$$r_1\mathbf{x} = (-x_1, x_2, x_3), \quad r_2\mathbf{x} = (x_1, -x_2, x_3), \quad r_3\mathbf{x} = (x_1, x_2, -x_3), \tag{3.9b}$$

and $C = i\sigma_2 c$, where c is the operator of complex conjugation,

$$c\psi(\mathbf{x}) = \psi^*(\mathbf{x}). \tag{3.10}$$

Note that operators defined in (3.8)–(3.10) satisfy the following relations:

$$\begin{gathered}\{R_a, \boldsymbol{\sigma}\cdot\boldsymbol{\pi}\} = \{R_a, C\} = \{CR_1, \boldsymbol{\sigma}\cdot\boldsymbol{\pi}\} = \{CR_2, \boldsymbol{\sigma}\cdot\boldsymbol{\pi}\} = 0,\\ R_a^2 = -C^2 = 1, \quad a = 1,2,3.\end{gathered} \tag{3.11}$$

Thus, using (3.7), (3.11) we can see that the operators

$$Q_1 = \boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2 = iR_3\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_3 = CR_1\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_4 = CR_2\boldsymbol{\sigma}\cdot\boldsymbol{\pi} \tag{3.12}$$

fulfill the following relations:

$$\{Q_k, Q_l\} = 2g_{kl}\hat{H}, \quad [Q_k, \hat{H}] = 0, \tag{3.13}$$

where $k,l = 1,2,3,4$, $g_{11} = g_{22} = -g_{33} = -g_{44} = 1$; $g_{kl} = 0$, $k \neq l$. In other words, operators (3.12) are supercharges generating the $N=4$ extended SUSY of Eq. (3.1).

We notice that choosing the basis

$$\hat{Q}_1 = \frac{1}{\sqrt{2}}(Q_1 + Q_3), \quad \hat{Q}_2 = \frac{1}{\sqrt{2}}(Q_2 + Q_4), \quad \hat{Q}_1^\dagger = \frac{1}{\sqrt{2}}(Q_1 - Q_3), \quad \hat{Q}_2^\dagger = \frac{1}{\sqrt{2}}(Q_2 - Q_4), \tag{3.14}$$

it is possible to represent the commutation and anticommutation relations (3.13) in a more familiar form,

$$\{\hat{Q}_\alpha, \hat{Q}_\beta\} = 0, \quad \{\hat{Q}_\alpha, \hat{Q}_\beta^\dagger\} = 2\delta_{\alpha\beta}\hat{H},$$

$$[\hat{Q}_\alpha, \hat{H}] = 0, \quad \alpha, \beta, = 1,2.$$

Thus, we have proved that the well-known $N=2$ SUSY of Eq. (3.1) can be extended to $N=4$ SUSY, taking into account involutive symmetries (3.8). Acting by supercharges (3.12) on standard solutions (3.4) we obtain the set of eight linearly independent solutions (3.4), (3.6). The interpretation of the corresponding eight-fold degeneracy is given in the next section.

C. Internal symmetries and reducible SUSY

A direct consequence of the $N=4$ SUSY is a specific four-fold degeneracy of the corresponding nonground states.[11] However, we have shown that system (3.1) has eight-fold degeneracy. Let us demonstrate that this is due to the existence of a special internal symmetry algebra. This algebra appears as follows.

First, for any nonzero eigenvalue E of Hamiltonian (3.1) we can choose the following set of symmetry operators:

$$S_{6k}=\frac{1}{2\sqrt{E}}Q_k, \quad S_{65}=\frac{1}{2}R_3, \quad S_{mn}=[S_{6m},S_{6n}]. \tag{3.15}$$

Here Q_k and R_3 are operators defined in (3.9), (3.12), $k=1,2,3,4$ and $m,n=1,2,3,4,5$. However, there exists an additional symmetry operator, namely, the operator

$$I_1=i(\sigma_1\pi_2-\sigma_2\pi_1)p_3R_3, \tag{3.16}$$

which commutes with any of the operators (3.15).

Thus, taking into account that operators S_{6n} form the Clifford algebra

$$\{2S_{6n},2S_{6m}\}=2g_{mn}, \tag{3.17}$$

with nonzero components of g_{mn} being $g_{11}=g_{22}=-g_{33}-g_{44}=g_{55}=1$, we can easily find that the symmetry operators (3.15) and (3.16) satisfy the following commutation relations:

$$[S_{kl},S_{mn}]=g_{kl}S_{ln}+g_{ln}S_{kl}-g_{kn}S_{lm}-g_{lm}S_{kn}, \tag{3.18a}$$

$$[S_{kl},I_1]=0 \tag{3.18b}$$

(with $k,l,m,n=1,2,3,4,5,6$ and $g_{66}=-1$), i.e., they form the central extension of Lie algebra $so(3,3)$ by I_1.[22] Its invariant operators are given by

$$C_1=\tfrac{1}{2}S_{kl}S^{kl}\equiv\tfrac{15}{4}, \quad C_2=\tfrac{1}{2}S_{kl}S^{ln}S_{nf}S^{fk}\equiv\tfrac{315}{16},$$
$$C_3=\frac{1}{6!}\epsilon_{mnrslk}S^{mn}S^{rs}S^{lk}\equiv\frac{1}{8}R_1R_2, \quad C_4=I_1. \tag{3.19}$$

Using (3.11), (3.12) it is easy to show that the eigenvalues of operators C_3 and C_4 are $\pm\frac{1}{8}$ and $\pm p_3\sqrt{2neH}$, respectively. Four possible combinations of these eigenvalues specify four orthogonal subspaces of the solutions of Eq. (3.1) for p_3 and n different from zero. Thus, operators (3.15) appear to realize a reducible representation of $so(3,3)$, namely, the direct sum of irreducible representations $2D(\frac{1}{2}\,\frac{1}{2}\,\frac{1}{2})\oplus 2D(\frac{1}{2}\,\frac{1}{2}\,-\frac{1}{2})$ of the algebra so(3,3).[23] The corresponding representation space is 16-dimensional over $\mathbb{R}$, so effectively we have the eight-fold degeneracy over the field of complex numbers.

Restricting ourselves to linear symmetries (i.e., to those including no antilinear operator of complex conjugation), $N=4$ SUSY is reduced to $N=2$ SUSY, which is generated by supercharges Q_1 and Q_2 specified in (3.12). However, this SUSY is reducible since there exist two linear symmetries for (3.1), namely, C_3 and C_4 (3.19), which are involutive up to constant factors and commute with supercharges Q_1 and Q_2:

$$[C_3,Q_a]=[I_1,Q_a]=0, \quad [I_1,C_3]=0, \quad a=1,2. \tag{3.20}$$

Analogously, as in the proof of Proposition 2 we can diagonalize C_3 and C_4 and reduce each of supercharges Q_1, Q_2 to a direct sum of four supercharges. This yields four invariant spaces $\Phi^{(\alpha)}$ ($\alpha=1,2,3,4$) of supercharges Q_1 and Q_2 with basis elements $\Phi_1^{(\alpha)}$, $\Phi_2^{(\alpha)}$, where

$$\Phi_1^{(1)}=\psi_{1,p_1,p_3}+\psi_{1,-p_1,p_3}+i\psi_{1,p_1,-p_3}+i\psi_{1,-p_1,-p_3},$$
$$\Phi_2^{(1)}=\psi_{2,p_1,p_3}+\psi_{2,-p_1,p_3}-i\psi_{2,p_1,-p_3}-i\psi_{2,-p_1,-p_3}; \tag{3.21}$$

$$\Phi_1^{(2)}=\psi_{1,p_1,-p_3}+\psi_{1,-p_1,-p_3}+i\psi_{1,p_1,p_3}+i\psi_{1,-p_1,p_3},$$
$$\Phi_2^{(2)}=\psi_{2,p_1,-p_3}+\psi_{2,-p_1,-p_3}-i\psi_{2,p_1,p_3}-i\psi_{2,-p_1,p_3}; \tag{3.22}$$

$$\Phi_1^{(3)}=-\psi_{1,p_1,p_3}+\psi_{1,-p_1,p_3}-i\psi_{1,p_1,-p_3}+i\psi_{1,-p_1,-p_3},$$
$$\Phi_2^{(3)}=-\psi_{2,p_1,p_3}+\psi_{2,-p_1,p_3}+i\psi_{2,p_1,-p_3}-i\psi_{2,-p_1,-p_3}; \tag{3.23}$$

$$\Phi_1^{(4)}=-\psi_{1,p_1,-p_3}+\psi_{1,-p_1,-p_3}-i\psi_{1,p_1,p_3}-i\psi_{1,-p_1,p_3},$$
$$\Phi_1^{(4)}=-\psi_{2,p_1,-p_3}+\psi_{2,-p_1,-p_3}+i\psi_{2,p_1,p_3}-i\psi_{1,-p_1,p_3}; \tag{3.24}$$

where ψ_{1,p_1,p_3} and ψ_{2,p_1,p_3} are functions defined in (3.4).

IV. SPIN-$\frac{1}{2}$ PARTICLE IN A STATIC, NONHOMOGENEOUS MAGNETIC FIELD

A. Extended SUSY

In this section we shall show that the system of a spin-$\frac{1}{2}$ particle interacting with various magnetic fields has extended SUSY too, provided the external magnetic field has definite parities.

Starting with reflections (3.9b) we find that the corresponding parity properties of vector function $A(x)$ (3.2b) are of the form

$$\mathbf{A}(r_1\mathbf{x})=-r_1A(\mathbf{x}),\quad \mathbf{A}(r_2\mathbf{x})=-r_2\mathbf{A}(\mathbf{x}),\quad \text{and}\ \mathbf{A}(r_3\mathbf{x})=r_3\mathbf{A}(\mathbf{x}). \tag{4.1}$$

Relations (4.1) are satisfied by a large class of potentials, which includes (3.2b) as a particular case. For all such potentials the corresponding equation (3.1) is invariant wrt involutions (3.8), and so admits the extended SUSY generated by supercharges (3.12). Moreover, Eq. (3.1) for $g=2$ and an arbitrary uniform magnetic field, i.e., the field

$$A_1=A_1(x_1,x_2),\quad A_2=A_2(x_1,x_2),\quad A_3=0, \tag{4.2}$$

admits all internal symmetries described in Sec. III B, provided $\mathbf{A}(\mathbf{x})$ satisfies relations (4.1).

Other systems with extended SUSY can be found by extending reflections (3.9b) to the eight-dimensional group of involutions, i.e., by adding the transformations

$$r_{12}\mathbf{x}=(-x_1,-x_2,x_3),\quad r_{31}\mathbf{x}=(-x_1,x_2,-x_3),\quad r_{23}\mathbf{x}=(x_1,-x_2,-x_3),$$
$$r_{123}\mathbf{x}=(-x_1,-x_2,-x_3),\quad I\mathbf{x}=\mathbf{x}, \tag{4.3}$$

to reflections (3.9b).

We notice that r_a $(a=1,2,3)$ and r_{123} are reflections while r_{ab} $(a,b=1,2,3)$ are rotations.

Let us suppose now that the vector potential $\mathbf{A}(\mathbf{x})$ has definite parities wrt a subset of transformations (3.9b) and (4.3). All possible transformations for the vector potential with definite parities wrt (9.3b) and (4.3), which are compatible with the Lorentz gauge $\mathbf{p}\cdot\mathbf{A}=0$, can be expressed as follows:

$$\mathbf{A}(r_{ab}\mathbf{x})=r_{ab}\mathbf{A}(\mathbf{x}),\quad a,b,=1,2,3, \tag{4.4a}$$

$$\mathbf{A}(r_a\mathbf{x})=r_a\mathbf{A}(\mathbf{x}), \tag{4.4b}$$

$$\mathbf{A}(r_{123}\mathbf{x}) = -\mathbf{A}(\mathbf{x}), \tag{4.4c}$$

and

$$\mathbf{A}(r_{ab}\mathbf{x}) = -r_{ab}\mathbf{A}(\mathbf{x}), \tag{4.5a}$$

$$\mathbf{A}(r_a\mathbf{x}) = -r_a\mathbf{A}(\mathbf{x}), \tag{4.5b}$$

$$\mathbf{A}(r_{123}\mathbf{x}) = \mathbf{A}(\mathbf{x}). \tag{4.5c}$$

It is easy to see that whenever $\mathbf{A}(\mathbf{x})$ transforms according to one of the relations (4.4a)–(4.4c) or (4.5a)–(4.5c) (for fixed values of indices a,b) the equation (3.1) remains invariant wrt this transformation provided $\psi(\mathbf{x})$ cotransforms accordingly, i.e., via the relations

$$\psi(\mathbf{x}) \to iR_aR_b\psi(\mathbf{x}) \equiv R_{ab}\psi(\mathbf{x}), \tag{4.6a}$$

$$\psi(\mathbf{x}) \to R_a\psi(\mathbf{x}), \tag{4.6b}$$

$$\psi(\mathbf{x}) \to R_1R_2R_3\psi(\mathbf{x}) \equiv R\psi(\mathbf{x}), \tag{4.6c}$$

or

$$\psi(\mathbf{x}) \to i\sigma_2 cR_a\psi(\mathbf{x}) \equiv CR_{ab}\psi(\mathbf{x}), \tag{4.7a}$$

$$\psi(\mathbf{x}) \to i\sigma_2 cR_a\psi(\mathbf{x}) \equiv CR_a\psi(\mathbf{x}), \tag{4.7b}$$

$$\psi(\mathbf{x}) \to i\sigma_2 cR\psi(\mathbf{x}) \equiv CR\psi(\mathbf{x}), \tag{4.7c}$$

respectively. Here R_a and c are the operators introduced in (3.9), (3.10).

Transformations (4.6b)–(4.7c) are involutions anticommuting with $\boldsymbol{\sigma}\cdot\boldsymbol{\pi}$, so yielding $N=2$ SUSY with supercharges given by

$$Q_1 = \boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2 = i\hat{R}\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \tag{4.8}$$

where $\hat{R}$ denotes the relevant operators from (4.6b)–(4.7c) [i.e., for the symmetry (4.4b) the operator $\hat{R} = R_{a'}$, for (4.4c) the operator $\hat{R} = R$, etc.].

More complicated cases, in which the vector $\mathbf{A}(\mathbf{x})$ has the definite transformation properties wrt combined parities, can be discussed analogously. First, using the group properties of involutions (3.9b), (4.3), it is easy to show that whenever $\mathbf{A}(\mathbf{x})$ has definite parities wrt two of these involutions, it has also the definite parity wrt their product. Requiring definite parities wrt various triplets of involutions enumerated in (3.9b), (4.3), we receive cases that are either equivalent to those with the definite transformation properties wrt doublets of parities or wrt all eight involutions (3.9b), (4.3).

If $\mathbf{A}(\mathbf{x})$ satisfies two compatible relations from (4.4) and (4.5) simultaneously, then Eq. (3.1) with $g=2$ admits $N=2$ or $N=3$ SUSY. All these nonequivalent possibilities are enumerated in the Appendix. Here we consider only one example, namely, when the vector potential has the property

$$\mathbf{A}(r_1\mathbf{x}) = r_1\mathbf{A}(\mathbf{x}), \quad \mathbf{A}(r_2\mathbf{x}) = r_2\mathbf{A}(\mathbf{x}), \tag{4.9}$$

but has no definite parity wrt reflection r_3. The related supercharges are of the form

$$Q_1 = \boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2 = iR_1\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \qquad \text{and} \quad Q_3 = iR_2\boldsymbol{\sigma}\cdot\boldsymbol{\pi}. \tag{4.10}$$

They satisfy relations (2.3) [where $\hat{H}$ is Hamiltonian (3.1), $a,b=1,2,3$] and thus generate the symmetry algebra equal to $N=3$ SUSY for the system. This SUSY causes a four-fold degeneracy of the corresponding (nonground) energy levels, since for any nonzero E it yields the four-dimensional representation $D(\frac{1}{2}\,\frac{1}{2})\oplus D(\frac{1}{2}-\frac{1}{2})$ of the Lie algebra $so(4)$ generated by

$$S_{4a}=\frac{1}{2\sqrt{E}}Q_a, \quad S_{ab}=-i[S_{4a},S_{4b}]. \tag{4.11}$$

The most extended, $N=4$ and $N=5$ SUSY appears in the cases for which the vector potential has definite parities wrt all involutions (3.9b), (4.3). In addition to (4.1), there are three more possible transformation properties of $\mathbf{A}(\mathbf{x})$:

$$\mathbf{A}(r_a\mathbf{x})=\mathbf{A}(\mathbf{x}), \quad a=1,2,3, \tag{4.12}$$

$$\begin{gathered}\mathbf{A}(r_a\mathbf{x})=\mathbf{A}(\mathbf{x}),\ \ \mathbf{A}(r_b\mathbf{x})=\mathbf{A}(\mathbf{x}),\ \ \mathbf{A}(r_c\mathbf{x})=-\mathbf{A}(\mathbf{x}),\\ a\neq b, \quad b\neq c, \quad c\neq a, \quad c \ \text{ is fixed,}\end{gathered} \tag{4.13}$$

and

$$\mathbf{A}(r_a\mathbf{x})=-\mathbf{A}(\mathbf{x}), \quad a=1,2,3. \tag{4.14}$$

They allow us to construct the corresponding supercharges, namely,

$$Q_1=iR_1\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2=iR_2\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_3=iR_3\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_4=\boldsymbol{\sigma}\cdot\boldsymbol{\pi}; \tag{4.15}$$

$$Q_0=CR_c\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_1=\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2=iR_a\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_3=iR_b\boldsymbol{\sigma}\cdot\boldsymbol{\pi}; \tag{4.16}$$

and

$$Q_1=CR_1\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2=CR_2\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_3=CR_3\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_4=CR\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_5=\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \tag{4.17}$$

for the cases (4.12), (4.13), and (4.14), respectively.

Operators (4.15) and Hamiltonian (3.1) satisfy relations (2.3) for $a,b=1,2,3,4$ and thus generate $N=4$ extended SUSY. The corresponding internal symmetries reduce to the algebra $so(5)$ whose basis elements [constructed analogously to (4.11)] generate the four-dimensional irreducible representation $D(1/2\,1/2\,1/2)$. Thus, for the system (3.1), (3.2a) we can expect a four-fold degeneracy of nonground energy levels whenever the vector potential of an external field satisfies the relations (4.12).

The operators in (4.16) and (4.17) satisfy the relations (3.13) for $g_{00}=-g_{11}=-g_{22}=-g_{33}=1$ and $-g_{11}=-g_{22}=-g_{33}=g_{44}=g_{55}=1$, respectively, and thus generate $N=4$ and $N=5$ SUSY.

B. Reducible SUSY

In this section the involutions (4.6), (4.7) are used to find out reducible SUSY for systems described by the equations (3.1) with $g=2$ and vector potentials $\mathbf{A}(\mathbf{x})$.

First, let us assume that the parity properties of the vector potential are specified by relations (4.12) and (4.13). Then the corresponding equation (3.1) admits $N=4$ SUSY. Moreover, there exist the involutions

$$I=R_{23} \tag{4.18}$$

and

$$I^{(c)}=CR_{ab}, \quad a,b\neq c, \tag{4.19}$$

commuting with pairs of supercharges Q_1, Q_2 from (4.15) and Q_0, Q_1 from (4.16), respectively, so that the corresponding $N=2$ SUSY is reducible.

If parities of the vector potential are specified by relations (4.14), then there exists the involution

$$I=R_{23}, \tag{4.20}$$

which commutes with a triplet of supercharges, namely, with supercharges Q_1, Q_2, and Q_3 of (4.16). Consequently, the related equation (3.1) admits $N=3$ reducible SUSY.

If the vector potential satisfies all relations (4.1) then there exists the involution

$$I=R_{12}, \tag{4.21}$$

commuting with all four supercharges (3.12), and so the corresponding system has $N=4$ reducible SUSY.

Indeed, diagonalizing involutions (4.18)–(4.21), the corresponding supercharges are transformed to block diagonal forms. For instance, for involutions (4.18) and supercharges (4.15), we obtain

$$I\rightarrow UIU^{\dagger}=\sigma_3, \quad Q_a\rightarrow UQ_aU^{\dagger}=\tfrac{1}{2}(1+\sigma_3)Q_a^{+}+\tfrac{1}{2}(1-\sigma_3)Q_a^{-}, \quad a=1,2, \tag{4.22}$$

where

$$U=\frac{1}{\sqrt{2}}(1+\sigma_3 I), \quad U^{\dagger}=\frac{1}{\sqrt{2}}(1-\sigma_3 I), \tag{4.23}$$

and

$$Q_1^{+}=(\pi_1-i\pi_2)\theta_{23}+\pi_3, \quad Q_2^{+}=(i\pi_1+\pi_2)\theta_1+i\pi_3\theta_{123}, \tag{4.24}$$

$$Q_1^{-}=(-\pi_1-i\pi_2)\theta_{23}-\pi_3, \quad Q_2^{+}=(i\pi_1-\pi_2)\theta_1-i\pi_3\theta_{123}, \tag{4.25}$$

with $\theta_{ab}=\theta_a\theta_b$, $\theta_{123}=\theta_1\theta_2\theta_3$, and operators θ_a defined in (3.9a).

The operators (4.23), together with

$$\hat{H}=\hat{H}^{+}=\pi^2-2e[H_3+(iH_2-H_1)\theta_{23}], \tag{4.26}$$

form superalgebra (2.3), while operators (4.24) satisfy (2.3) with the Hamiltonian of the form

$$\hat{H}=\hat{H}^{-}=\pi^2+2e[H_3-(H_1+iH_2)\theta_{23}]. \tag{4.27}$$

Here H_1, H_2, and H_3 denote the components of the magnetic field strength.

The supercharges generating reducible SUSY for other systems described by (3.1) can be diagonalized in a similar way. The explicit form of the corresponding transformation operators is given in the Appendix.

Let us note that supercharges (4.23), (4.24) depend on three variables x_1,x_2,x_3 and have a very peculiar property: they include no fermionic variables.

V. DISCUSSION

In this article we have described the approach for a systematical study of quantum systems whose symmetry group includes extended SUSY and whose degeneracy of energy spectra is of a SUSY nature.

In Sec. IV, requiring definite parity properties of the vector potential, we find a number of quantum mechanical systems with $N=3$, $N=4$, and $N=5$ SUSY.

It is necessary to stress that there exist a lot of realistic physical systems whose parities satisfy required relations (4.1), (4.12)–(4.14). In addition to the vector potential of the constant magnetic field, given by relations (3.2b), we present here as examples the potential of an infinite straight conductor with the constant current I directed along the third coordinate axis,

$$A_1=A_2=0, \quad A_3=-\frac{I}{2\pi}\ln(x_1^2+x_2^2), \tag{5.1}$$

superpositions of potentials (5.1) that are generated by two or four infinite straight conductors shifted by distance $2b$ (two neighbor currents have opposite directions),

$$A_1=A_2=0, \quad A_3=-\frac{I}{4\pi}\ln\left[\frac{(x_1-b)^2+x_2^2}{(x_1+b)^2+x_2^2}\right], \tag{5.2}$$

$$A_1=A_2=0, \quad A_3=-\frac{I}{4\pi}\ln\frac{[(x_1+b)^2+(x_2+b)^2][(x_1-b)+(x_2-b)^2]}{[(x_1+b)^2+(x_2-b)^2][(x_1-b)^2+(x_2+b)^2]}, \tag{5.3}$$

and the magnetic octopole potential,[16]

$$A_1=\frac{a^2m}{4\pi}\,\frac{x_1(x^2-x_2^2)}{x^7}, \quad A_2=\frac{a^2m}{4\pi}\,\frac{x_2(x^2-x_1^2)}{x^7}, \quad A_3=0. \tag{5.4}$$

Parities of potentials (5.1), (5.2), (5.3), and (5.4) are given by relations (4.1), (4.13), (4.14), and (4.12), respectively.

Moreover, analyzing various superpositions of magnetic dipole and straight conductor potentials, it is possible to generate models of physical systems with any parity properties enumerated in (A1)–(A3), (A8)–(A12).

The very existence of such systems presents a strong indication that the extended SUSY is indeed realized in nature. Moreover, knowledge of extended SUSY for systems described by the Schrödinger–Pauli equation enables us to predict the specific degeneracy of the corresponding energy levels. This degeneracy can be removed by adding a small symmetry-breaking term corresponding, e.g., to the interaction with a weak external electric field and thus experimentally verified.

We did not discuss the question of whether the found extended SUSY is exact or broken. To this end it is necessary to analyze degeneracy of the ground state of the considered systems. For two-dimensional quantum systems, such an analysis was made in Refs. 24 and 25.

Our approach to extended SUSY can be compared with that using generalized SUSY[17] whenever all supercharges of the considered systems are linear operators (i.e., not including complex conjugation) and can be constructed starting with involutions satisfying (2.11). Since for some of our systems the corresponding supercharges include the antilinear operator of complex conjugation, the above-mentioned correspondence does not exist [in this case (2.11) does not hold]. Consequently, our approach covers more general situations than the approach proposed in Ref. 17.

It is well known that $N=3$ SUSY can always be extended to that of $N=4$[26] for systems in which SUSY is realized by Grassmanian variables. In our paper we show that such an extension of odd N SUSY to even one is not guaranteed in general.

Analogous to the above-mentioned cases with time-independent magnetic fields, it is possible to search for systems with extended SUSY described by the Schrödinger–Pauli equation with a time-dependent magnetic field. The case with $N=2$ SUSY was discussed in Ref. 27.

We notice that our approach can be extended to the relativistic Dirac equation with a similar result (for particular examples, see Refs. 13 and 14). However, Dirac's equation admits an extended SUSY also for the cases with external electric fields and scalar potentials.[15]

Another intriguing problem is to generalize the above results for particles with spin $s > \frac{1}{2}$. This can be done, e.g., in the framework of the weak SUSY approach.[28]

APPENDIX: COMBINED PARITIES, SUPERCHARGES, AND EXPLICIT REDUCTIONS

Here explicit forms of supercharges are presented for the cases when $\mathbf{A}(\mathbf{x})$ satisfies all possible combinations of relations (4.6), (4.7).

First, we shall consider systems with $N=2$ SUSY. They correspond to the following parity properties of the electromagnetic field:

$$\mathbf{A}(r_a\mathbf{x}) = r_a\mathbf{A}(\mathbf{x}), \quad \mathbf{A}(r_{bc}\mathbf{x}) = r_{bc}\mathbf{A}(\mathbf{x}), \tag{A1}$$

$$\mathbf{A}(r_a\mathbf{x}) = -r_a\mathbf{A}(\mathbf{x}), \quad \mathbf{A}(r_{bc}\mathbf{x}) = r_{bc}\mathbf{A}(\mathbf{x}), \tag{A2}$$

and

$$\mathbf{A}(r_a\mathbf{x}) = -r_a\mathbf{A}(\mathbf{x}), \quad \mathbf{A}(r_{bc}\mathbf{x}) = -r_{bc}\mathbf{A}(\mathbf{x}), \tag{A3}$$

where $b,c \neq a$, a is fixed.

The related supercharges have the form

$$Q_1 = \boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2 = iR_a\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \tag{A4}$$

for parity properties (A1), and

$$Q_1 = \boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \quad Q_2 = CR_a\boldsymbol{\sigma}\cdot\boldsymbol{\pi}, \tag{A5}$$

for the cases when $\mathbf{A}(\mathbf{x})$ satisfies (A2) or (A3).

In all these cases the corresponding $N=2$ SUSY is reducible. The involutions commuting with supercharge (A4) and (A5) have the form

$$I_1 = R_{bc} \quad \text{and} \quad I_2 = R_{bc}, \quad I_3 = CR_{bc},$$

respectively. Particular cases of these involutions are expressed in the formulas (4.18)–(4.21).

The operators diagonalizing both I_1 and I_2 have the form

$$U = \frac{1}{2}(1 - i\sigma_2)(1 + i\sigma_2\theta_{12}), \quad \text{for } a=3; \quad U = \frac{1}{\sqrt{2}}(1 + \sigma_3 I_1), \quad \text{for } a \neq 3, \tag{A6}$$

whereas the expressions for the operators diagonalizing I_3 are

$$\begin{aligned} U = U_1 &= \tfrac{1}{2}(1 - i\sigma_2)(1 + i\sigma_2\theta_{23}), \quad \text{for } a=1, \\ U = U_2 &= \tfrac{1}{2}(1 + C)(1 - i\sigma_1\theta_{31}), \quad \text{for } a=2, \\ U = U_3 &= \frac{1}{\sqrt{2}}(1 + \sigma_3 I_3), \quad \text{for } a=3. \end{aligned} \tag{A7}$$

Now we shall present systems with $N=3$ SUSY. In addition to (4.11), we have the following nonequivalent combinations of parity properties:

$$\mathbf{A}(r_{12}\mathbf{x})=r_{12}\mathbf{A}(\mathbf{x}),\quad \mathbf{A}(r_{23}\mathbf{x})=r_{23}\mathbf{A}(\mathbf{x}),$$
$$Q_1=R_{23}\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_2=R_{31}\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_3=R_{12}\boldsymbol{\sigma}\cdot\boldsymbol{\pi}; \tag{A8}$$

$$\mathbf{A}(r_a\mathbf{x})=r_a\mathbf{A}(\mathbf{x}),\quad \mathbf{A}(r_{bc}\mathbf{x})=-r_{bc}\mathbf{A}(\mathbf{x}),$$
$$Q_1=i\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_2=iR_a\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_3=CR_{bc}\boldsymbol{\sigma}\cdot\boldsymbol{\pi}; \tag{A9}$$

$$\mathbf{A}(r_a\mathbf{x})=-r_a\mathbf{A}(\mathbf{x}),\quad \mathbf{A}(r_b\mathbf{x})=-r_b\mathbf{A}(\mathbf{x}),$$
$$Q_0=\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_1=CR_a\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_2=CR_b\boldsymbol{\sigma}\cdot\boldsymbol{\pi}; \tag{A10}$$

$$\mathbf{A}(r_a\mathbf{x})=r_a\mathbf{A}(\mathbf{x}),\quad \mathbf{A}(r_b\mathbf{x})=-r_b\mathbf{A}(\mathbf{x}),$$
$$Q_0=CR_b\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_1=\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_2=iR_a\boldsymbol{\sigma}\cdot\boldsymbol{\pi}; \tag{A11}$$

$$\mathbf{A}(r_{ab}\mathbf{x})=r_{ab}\mathbf{A}(\mathbf{x});\quad \mathbf{A}(r_{bc}\mathbf{x})=-r_{bc}\mathbf{A}(\mathbf{x}),$$
$$Q_0=iR_{ab}\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_1=CR_{bc}\boldsymbol{\sigma}\cdot\boldsymbol{\pi},\quad Q_2=CR_{ac}\boldsymbol{\sigma}\cdot\boldsymbol{\pi}. \tag{A12}$$

The supercharges in (A8) satisfy the relations (2.3) for $a,b=1,2,3$; the supercharges in (A9), (A10) and (A11), (A12) satisfy the relations (3.13) for $g_{11}=-g_{22}=-g_{33}=1$ and $-g_{11}=g_{22}=g_{33}=1$, respectively.

The supercharges in (A10) commute with the involution R_{ab} and thus generate the $N=3$ reducible SUSY. The supercharges Q_1 and Q_2 in (A12) commute with this involution too and generate the $N=2$ reducible SUSY. The remaining supercharges, i.e., those in (A8), (A9), and (A11) are irreducible.

(Received 23 July 1998; accepted for publication 12 November 1998)

In this work we present a theoretical study of the *d*-dimensional Coulomb problem in quantum phase space. A coordinate transformation in hyperspherical space is used that maps the *d*-dimensional Coulomb problem into the *D*-dimensional harmonic oscillator and the Wigner distribution function for the *d*-dimensional Coulomb problem is then obtained. This exactly soluble model can shed some light on finite-size features of Wigner's distribution, which will be a vital experience for various dynamic problems.
[S0022-2488(99)03502-1]

I. INTRODUCTION

The problems associated with the Coulomb and harmonic oscillator problems,[1,2] together with the connection between the two in arbitrary dimensions, which has been studied from various viewpoints,[3–11] have been discussed in detail by many authors. The purpose of this paper is to take advantage of the above connection in order to determine the Wigner distribution function for the *d*-dimensional Coulomb problem in quantum phase space.

The Wigner distribution function plays the central role in a reformulation of Schrödinger quantum mechanics, the phase space picture of quantum mechanics, which describes states by functions in configuration space. In this picture both the position and momentum variables are *c* numbers. In Sec. II the Schrödinger equation for the *d*-dimensional Coulomb problem and the *D*-dimensional harmonic oscillator in hyperspherical coordinates are solved and their energy eigenvalues and eigenfunctions are obtained. In Sec. III the Schrödinger equation for the *d*-dimensional Coulomb problem is mapped onto the *D*-dimensional harmonic oscillator by a coordinate transformation in hyperspherical space and then the connection between energy eigenfunctions of these two systems are obtained. In Sec. IV by using the above connection, the explicit Wigner phase space distribution function for the *d*-dimensional Coulomb problem is calculated.

II. SOLUTION OF THE SCHRÖDINGER EQUATION FOR COULOMB AND HARMONIC OSCILLATOR PROBLEMS IN ARBITRARY DIMENSIONS

The Schrödinger equation for the *d*-dimensional Coulomb problem is

$$\left(-\frac{\hbar^2}{2m}\nabla_d^2-\frac{e^2}{r}\right)\psi(\mathbf{r})=E\psi(\mathbf{r}), \tag{1}$$

where $\mathbf{r}$ is a *d*-dimensional position vector having Cartesian components $x_1, x_2, \ldots, x_d$ with magnitude $r=(\Sigma_{j=1}^{d} x_j^2)^{1/2}$ and the Laplacian ∇_d^2 given by

$$\nabla_d^2=\sum_{j=1}^{d}\frac{\partial^2}{\partial x_j^2}. \tag{2}$$

Because of the spherical symmetry of the problem it is convenient to introduce the hyperspherical coordinates, which are defined as follows:[12]

$$
\begin{aligned}
x_1 &= r\cos\theta_1 \sin\theta_2 \cdots \sin\theta_{d-1},\\
x_2 &= r\sin\theta_1 \sin\theta_2 \cdots \sin\theta_{d-1},\\
x_3 &= r\cos\theta_2 \sin\theta_3 \cdots \sin\theta_{d-1},\\
&\vdots\\
x_j &= r\cos\theta_{j-1} \sin\theta_j \cdots \sin\theta_{d-1},\\
&\vdots\\
x_{d-1} &= r\cos\theta_{d-2} \sin\theta_{d-1},\\
x_d &= r\cos\theta_{d-1},
\end{aligned}
\tag{3}
$$

where $d=2,3,...,$ $0\leqslant r\leqslant\infty$, $0\leqslant\theta_1\leqslant 2\pi$, $0\leqslant\theta_j\leqslant\pi$, and $j=1,2,...,d-1$. As in three dimensions, we substitute the following in Eq. (1):

$$\psi(\mathbf{r})=\mathcal{R}_{nl}(r)Y_{l_1,l_2,...,l_{d-1}}(\theta_1,\theta_2,\ldots,\theta_{d-1}), \tag{4}$$

where $\mathcal{R}_{nl}(r)$ is the radial wave function and $Y_{l_1,l_2,...,l_{d-1}}(\theta_1,\theta_2,\ldots,\theta_{d-1})$ is the generalized spherical harmonics, in which $l_{d-1}=0,1,2,...;$ $l_{d-2}=0,1,2,...,l_{d-1};$ $...;$ $l_2=0,1,2,...,l_3;$ $l_1=-l_2,$ $-l_2+1,...,l_2-1,l_2$. We obtain the radial part of Schrödinger equation as

$$\left\{-\frac{\hbar^2}{2m}\left[\frac{d^2}{dr^2}+\frac{d-1}{r}\frac{d}{dr}-\frac{l(l+d-2)}{r^2}\right]-\frac{e^2}{r}\right\}\mathcal{R}_{nl}(r)=E\mathcal{R}_{nl}(r). \tag{5}$$

Equation (5) can be written as[13]

$$\left[\frac{d^2}{du^2}+\frac{d-1}{u}\frac{d}{du}-\frac{l(l+d-2)}{u^2}+\frac{k}{u}-\frac{1}{4}\right]\phi(u,d,n,l)=0, \tag{6}$$

where $u=r/kr_0$, $r_0=\hbar^2/2me^2$, $k=n+\frac{1}{2}(d-3)$, $l=0,1,2,...,n-1$, and $n\geqslant l+1$.

The energy eigenvalues ϵ_n and their corresponding eigenfunctions $\phi(u,d,n,l)$ are given by

$$\epsilon_n=-\frac{\epsilon_0}{[n+\frac{1}{2}(d-3)]^2}, \tag{7}$$

where $\epsilon_0=me^4/2\hbar^2$, and principle quantum number $n=1,2,3,...,$ and

$$\phi(u;d,n,l)=c(d,n,l)e^{-u/2}u^l L_{n-l-1}^{(2l+d-2)}(u), \tag{8}$$

with the normalization constant

$$c(d,n,l)=r_0^{-d/2}[n+\tfrac{1}{2}(d-3)]^{-(d+1)/2}[\Gamma(n-1)]^{1/2}[2\Gamma(n+l+d-2)]^{-1/2}. \tag{9}$$

Note that the Laguerre polynomials $L_n^{(\alpha)}$ are those defined in handbooks on mathematical functions and are not the more limited $L_{n+\alpha}^{\alpha}$ often used in discussions of the hydrogen atom eigenfunctions.

In a similar way, the radial equation of the D-dimensional harmonic oscillator is given by[12]

$$\left\{-\frac{\hbar^2}{2m}\left[\frac{d^2}{dR^2}+\frac{D-1}{R}\frac{d}{dR}-\frac{L(L+D-2)}{R^2}\right]+\frac{1}{2}m\omega^2R^2\right\}\mathcal{R}_{nl}(R)=E\mathcal{R}_{nl}(R), \tag{10}$$

which can be written as[14]

$$\left[\frac{d^2}{dU^2}+\frac{D-1}{U}-\frac{L(L+D-2)}{U^2}-U^2+K\right]\Phi(U,D,N,L)=0, \tag{11}$$

where $U=R/R_0$, $R_0=(m\omega/\hbar)^2$, $K=2N+D$, and $N\geqslant L$.
The energy eigenvalues E_N and their corresponding eigenfunctions $\Phi(U,D,N,L)$ are given by

$$E_N=\tfrac{1}{2}\hbar\omega(2N+D), \tag{12}$$

$$\Phi(U,D,N,L)=C(D,N,L)e^{-U^2/2}U^L L_{N/2-L/2}^{(L+D/2-1)}(U^2), \tag{13}$$

with the normalization constant

$$C(D,N,L)=R_0^{-D/2}\left[2\Gamma\left(\frac{N}{2}-\frac{L}{2}+1\right)\right]^{1/2}\left[\Gamma\left(\frac{N}{2}+\frac{L}{2}+\frac{D}{2}\right)\right]^{-1/2}. \tag{14}$$

Having obtained the eigenfunctions for Coulomb and harmonic oscillator problems in arbitrary dimensions, Eqs. (8) and (13), we will, in Sec. III, set to link the two cases by writing the *d*-dimensional Coulomb problem eigenfunctions in terms of the *D*-dimensional harmonic oscillator eigenfunctions.

III. MAPPING OF THE COULOMB PROBLEM ONTO THE HARMONIC OSCILLATOR IN ARBITRARY DIMENSIONS

The connection between the Coulomb and harmonic oscillator problems has been studied from various viewpoints and has been discussed in detail by many authors. The main point in this section is the mapping of the *d*-dimensional Coulomb problem onto the *D*-dimensional harmonic oscillator. The map taking Eq. (6) into Eq. (11) is $u=U^2$. The appropriate relation between solutions of Eqs. (8) and (13) when restricting *D, N*, and *L* to integers is[9]

$$\phi(u,d,n,l)=\Lambda\Phi(U,2d-2,2n-2,2l), \tag{15}$$

where

$$\Lambda=\left\{\tfrac{1}{2}R_0^{2d-2}/r_0^d\left[n+\tfrac{1}{2}(d-3)\right]^{d+1}\right\}^{1/2}. \tag{16}$$

The *d*- and *n*-dependent constant Λ arises because $\phi(u,d,n,l)$ and $\Phi(U,D,N,L)$ are normalized to unity in *d* and *D* dimensions, respectively. The identification Eq. (15) yields the solution

$$D=2d-2,\quad N=2n-2,\quad L=2l. \tag{17}$$

It is a general feature of this mapping that the spectrum of the *d*-dimensional Coulomb problem is related to half the spectrum of the *D*-dimensional harmonic oscillator for any even integer *D*. However, the quantities in Eq. (17) have parameter spaces that are further restricted by the properties chosen for this mapping. From Eq. (17), we find that all states of the *d*-dimensional Coulomb problem with $n\geqslant 1$ and $l\geqslant 0$, can be mapped onto the appropriate harmonic oscillator with $N\geqslant 0$ and $L\geqslant 0$, except for $d=1$.

Now by using coordinates (3) and ignoring the constant Λ, we can write Eq. (15) in Cartesian space as

$$\phi_{N_1,\ldots,N_D}=\prod_{j=1}^{D}\,(\alpha/\sqrt{\pi}2^{N_j}N_j!)^{1/2}e^{-(\alpha^2/2)x_j^2}H_{N_j}(\alpha x_j), \tag{18}$$

where $H_N(\alpha x)$ is the Hermite polynomials of order N, and $\alpha=(m\omega/\hbar)^{1/2}$. Thus the d-dimensional Coulomb problem wave function is expanded as a linear combination of simple harmonic oscillator wave functions in Hermite polynomials.

IV. THE WIGNER DISTRIBUTION FUNCTION FOR THE *d*-DIMENSIONAL COULOMB PROBLEM

As the wave function plays the central role in the Schrödinger picture, the phase-space distribution function introduced by Wigner is the starting point in the phase-space picture of quantum mechanics. This distribution function is widely known as the Wigner function.

The Wigner function is constructed from the Schrödinger wave function. It is a function of both position and momentum variables and in d-dimensional phase space is defined as[15,16]

$$W(x_1,\ldots,x_d,p_1,\ldots,p_d;t)=(\pi\hbar)^{-d}\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}dy_1\cdots dy_d\exp[2i(p_1y_1+\cdots+p_dy_d)/\hbar]$$
$$\times\psi^*(x_1+y_1,\ldots,x_d+y_d;t)\psi(x_1-y_1,\ldots,x_d-y_d;t), \tag{19}$$

where $x_1,\ldots,x_d$ are independent coordinates and $p_1,\ldots,p_d$ are conjugate momentum variables in d-dimensional phase space. By using the coordinates (3), in the time-independent d-dimensional Coulomb problem which is equivalent to the D-dimensional harmonic oscillator we have

$$W(x_1,\ldots,x_D,p_1,\ldots,p_D)=(\pi\hbar)^{-D}\int_{-\infty}^{\infty}\cdots\int_{-\infty}^{\infty}dy_1\cdots dy_D\exp[2i(p_1y_1+\cdots+p_Dy_D)/\hbar]$$
$$\times\phi^*(x_1+y_1,\ldots,x_D+y_D)\phi(x_1-y_1,\ldots,x_D-y_D), \tag{20}$$

where $p_1,\ldots,p_D$ are conjugate momenta of $x_1,\ldots,x_D$, which satisfy the commutation relations $[x_j,p_k]=i\hbar\delta_{jk}$, where $p_j=-i\hbar\partial/\partial x_j$ and $j,k=1,2,\ldots,D$.

Now the wave function (18) is substituted in Eq. (20) and after some manipulations and using $H_N(-x)=(-1)^N H_N(x)$ we find

$$W(x_1,\ldots,x_D,p_1,\ldots,p_D)=(\pi\hbar)^{-D}\pi^{-D/2}\prod_{j=1}^{D}\frac{(-1)^{N_j}}{2^{N_j}N_j!}e^{-\alpha^2x_j^2+\beta_j^2}\int_{-\infty}^{\infty}dz_j\,e^{-z_j^2}$$
$$\times H_{N_j}(z_j+\beta_j+\alpha x_j)H_{N_j}(z_j+\beta_j-\alpha x_j), \tag{21}$$

where $z=\alpha(y-ip/\alpha^2\hbar)$ and $\beta=ip/\alpha\hbar$. By taking advantage of the expression[17]

$$\int_{-\infty}^{\infty}dz\,e^{-z^2}H_N(z+\beta+\alpha x)H_N(z+\beta-\alpha x)=\sqrt{\pi}2^N N!L_N(2(\alpha^2x^2-\beta^2)), \tag{22}$$

where L_N is Laguerre polynomials, we have

$$W_{N_1,\ldots,N_D}(\rho_1,\ldots,\rho_D)=(\pi\hbar)^{-D}\prod_{j=1}^{D}\,(-1)^{N_j}e^{-\rho_j^2/2}L_{N_j}(\rho_j^2), \tag{23}$$

where dimensionless quantity ρ is defined by $\rho=[2(\alpha^2x^2+p^2/\alpha^2\hbar^2)]^{1/2}$.

Since

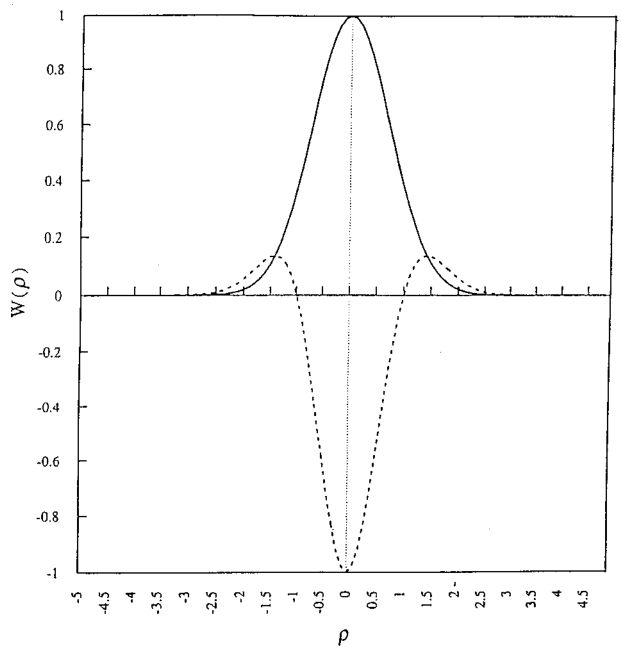

FIG. 1. Cross section of the Wigner distribution function $W(\rho)$ against ρ. Solid and dashed lines correspond to $W_{0,\ldots,0}(\rho_1,\ldots,\rho_D)$ and $W_{1,0,\ldots,0}(\rho_1,\ldots,\rho_D)$, respectively. $W(\rho)$ is given in units of $(\pi\hbar)^{-D}$.

$$\frac{\rho^2}{2}=\frac{2}{\hbar\omega}\left(\frac{p^2}{2m}+\frac{1}{2}m\omega^2x^2\right)=\frac{2}{\hbar\omega}\mathcal{H}(x,p),$$

where $\mathcal{H}(x,p)$ is the Hamiltonian of the harmonic oscillator,

$$W_{N_1,\ldots,N_D}(\rho_1,\ldots,\rho_D)=(\pi\hbar)^{-D}\prod_{j=1}^{D}(-1)^{N_j}\exp\left[\frac{-2}{\hbar\omega}\mathcal{H}(\rho_j)\right]L_{N_j}\left(\frac{4}{\hbar\omega}\mathcal{H}(\rho_j)\right), \tag{24}$$

which is the desired result. The three-dimensional representation of this result has been obtained by using a special mapping.[18]

For the ground state we have

$$W_{0,\ldots,0}(\rho_1,\ldots,\rho_D)=(\pi\hbar)^{-D}\exp[-\tfrac{1}{2}(\rho_1+\cdots+\rho_D)] \tag{25}$$

and for first excited state

$$W_{1,0,\ldots,0}(\rho_1,\ldots,\rho_D)=(\pi\hbar)^{-D}(\rho_1^2-1)\exp[-\tfrac{1}{2}(\rho_1^2+\cdots+\rho_D^2)]. \tag{26}$$

The ground state is positive everywhere in phase space. The first excited state is negative at the origin, but positive for sufficiently large values of $\rho_1+\cdots+\rho_D$ and both become vanishingly small for very large values of $\rho_1+\cdots,\rho_D$. Even though the first excited state is negative around the origin, the probability density in x is always positive. The cross section of variations of the ground and first excited states against ρ is shown in Fig. 1.

In view of the fact that the expression represented in Eq. (24) is a distribution function, then it is possible to calculate some physical and chemical quantities for the hydrogen atom as a special case of the d-dimensional Coulomb problem, using this function.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 3 MARCH 1999

Dynamical semigroups for interacting quantum and classical systems

R. Olkiewicz
Institute of Theoretical Physics, University of Wrocław, Pl. Maxa Borna 9, PL-50-204 Wrocław, Poland

(Received 22 October 1997; accepted for publication 4 December 1998)

A mathematical framework for the completely positive semigroup coupling between classical and quantum systems is proposed. The coupling ensures a flow of information from the quantum system to the classical one and the influence of the classics on the dynamics of the quantum system in a dissipative way. The classical evolution on average is modified by the expectation value of some quantum operator. Examples of a classical particle moving along a geodesic line in a curved space interacting with the quantum system, and the coupling of a two state quantum system to all pure states, are discussed.
[S0022-2488(99)00803-8]

I. INTRODUCTION

It is well known that using quantum mechanics one can analyze the behavior of electrons in atoms, molecules, and solids. It is also successful in investigating properties of chemical reactions, conductors, and many others. But the quantum dynamics based on the Schrödinger equation makes it difficult to describe irreversible processes like measurements or interactions with a classical environment. Moreover, it seems to be impossible to apply quantum mechanics to explain the occurrence of quantum macroscopic effects, which are expressed solely in classical terms. But the enthusiasm due to successes of quantum mechanics appeared to cover the lack of its completeness for many years.

The situation started to change when technological progress made it possible to make experiments with individual quantum systems. Because experimentalists see not the averages but individual samples, which are the next subject to averaging, the standard interpretation has become insufficient. The importance of the concept of an event and an intrinsic incapability of quantum mechanics to deal with this concept have been stressed by many authors (Ref. 1 and references therein). Haag[2,3] suggested the discreteness and irreversibility of an event in quantum theory and stressed that ''transformation of possibilities into facts must be an essential ingredient which must be included in the fundamental formulation of the theory.''

Recently a mathematically consistent description of the interaction between classical and quantum systems that permits the construction of a new model of quantum measurements has been proposed[4–8] (see also Refs. 9 and 10). From the structural and mathematical point of view the three most essential ingredients of the Blanchard and Jadczyk model are

(i) tensoring of a noncommutative quantum algebra of operators with a commutative classical algebra of functions,
(ii) renouncing pure states for density matrices and replacing Schrödinger unitary dynamics by a completely positive one, and
(iii) interpreting the continuous time evolution of statistical states in terms of a piecewise-deterministic random process on pure states.

In this model classical quantities become elements of the center of the total algebra. Because automorphisms of an algebra leave its center invariant, it was necessary to use completely positive semigroups to enable the transfer of information between the classical and quantum systems. Thus the evolution of the quantum object becomes dissipative and the modification of the dynamics of the classical system through some appropriate expectation value appears. With a given dynamical semigroup T_t we can associate a Markov–Feller process with values in the pure state space of the total system in such a way that $T_t(P_x)=\int P(t,x,dy)P_y$ is satisfied. Here P_x is a one-dimensional projector representing pure state x and $P(t,x,dy)$ is the transition probability function of a desired process. It consists of a mixture of deterministic motion with random jumps. In the case when a discrete classical system (a measuring apparatus) is coupled to a finite quantum system described by a matrix algebra it was shown in Ref. 11 that such a process exists and, moreover, contrary to the pure quantum case, that it is unique.

Clearly, the key point in the coupling is to construct a generator of a dynamical semigroup of the total system. Recently, an example of such a generator of the interaction between a classical system and a quantum one has been introduced in Ref. 12. The classical system was represented by an algebra of continuous functions on some symplectic manifold M while the quantum system was described by a von Neumann algebra acting in some separable Hilbert space. The generator has been built out of the following data:

(a) a self-adjoint quantum operator $\hat{P}$,
(b) a connection between the points of the spectrum of $\hat{P}$ and shifts on a classical phase space M,
(c) a function $f:M\times \mathrm{sp}(\hat{P})\to \mathbf{R}$ responsible for a junction between the classical system and the quantum one.

Such a generator turned out to be suitable for a rigorous discussion of the superconducting quantum interference device (SQUID) -tank model, which consists of an electric oscillatory circuit coupled via a mutual inductance to a superconducting ring containing a weak link constriction. In that system the oscillatory circuit acts as an external flux source for the SQUID ring, which induces a screening current in the ring. This screening current is coupled back to the classical circuit due to the mutual inductance. It results in the modification of the differential equation for the classical harmonic oscillator by the expectation value of the superconducting screening current operator.

However, quite often, a quantum system is characterized by a semispectral measure on some homogeneous space, like in the generalized coherent state approach,[13] or when we use the generalized systems of imprimitivity.[14] In that case there is no particular self-adjoint operator which could be responsible for the coupling, but all quantum states can affect the classical system. The purpose of this paper is to provide a mathematical framework, which could be used to describe such a coupling. Although it is only a mathematical model, we hope the proposed scheme can be applied to a large class of physical phenomena. The paper is organized as follows. In Sec. II the mathematical apparatus is presented. In Sec. III two examples are discussed. Concluding remarks are given in Sec. IV.

II. THE FRAMEWORK

At first we present the formal scheme of the classical-quantum coupling. Let us consider a classical system C with a finite number of degrees of freedom. Its phase space is a symplectic manifold (M,ω). The C^*-algebra $C_0(M)$ of continuous and vanishing at infinity functions represents complex observables of the system. Because it will be more convenient to consider von Neumann algebras we pass to the representation in the Hilbert space $\mathcal{H}_c=L^2(M,\mathcal{B},\mu)$, where $\mathcal{B}$ is the Borel σ-algebra and $d\mu$ is the unique Borel measure determined by the volume form ω^n, $n=\dim M/2$. We assume that the classical algebra $\mathcal{A}_c$ equals to $C_0(M)''=L^\infty(M,\mathcal{B},\mu)$. Statistical states of C are then normed and positive elements of $L^1(M,\mathcal{B},\mu)$. The time evolution of C is described by a flow on M, i.e., a mapping $g:(t,x)\to g_t(x)$ such that

(a) $g:\mathbf{R}\times M\to M$ is smooth,
(b) for any t, g_t is a diffeomorphism of M, and

(c) $t \to g_t$ is a group homomorphism.

Its generator is a complete vector field X on M. It gives an ultraweakly continuous one-parameter group of automorphisms of $\mathcal{A}_c : f(x) \to f(g_t^{-1}x)$, $x \in M$. Its generator we denote by δ_c.

Now we come to the quantum system. Let us consider a quantum particle moving on a homogeneous configuration space $Q = G/K$, where G is a locally compact topological group which satisfies the second axiom of countability and K is a closed subgroup. We assume moreover that G and K are both unimodular. The quantum theory of such a system may be introduced by the concept of generalized coherent states.[13] Let $(\pi, \mathcal{H}_q)$ be a unitary irreducible representation of G, such that for every $k \in K, \pi(k)\psi_0 = e^{i\alpha(k)}\psi_0$ for some unit vector $\psi_0 \in \mathcal{H}_q$. It follows that for each $q \in Q$ we have a one-dimensional projector $P_q = |\pi(g)\psi_0\rangle\langle\psi_0\pi(g)|$, where $[g] = q$. The quantum algebra $\mathcal{A}_q$ is defined as

$$\mathcal{A}_q = \left\{ \int f(q) P_q \, d\alpha(q), \quad f \in C_c(Q) \right\}'' = \{P_q, \quad q \in Q\}''.$$

If for any q' the reproducing kernel $q \to K(q',q)$ vanishes only on a set of α-measure zero, we show that $\mathcal{A}_q = L(\mathcal{H}_q)$. To see this it is enough to prove that every one-dimensional projector P on $\mathcal{H}_q$ belongs to $\mathcal{A}_q$. Let

$$D = \left\{ \sum_{i=1}^{m} z_i \pi(g_i)\psi_0 : \quad m \in \mathbf{N}, \ z_i \in \mathbf{C}, \quad g_i \in G \right\}.$$

Because the representation π is irreducible, ψ_0 is cyclic and D is dense in $\mathcal{H}_q$. Let $\psi_n \to \psi$, where $\psi_n \in D$ with $\|\psi_n\| = 1$ and $P = |\psi\rangle\langle\psi|$, $\|\psi\| = 1$. Then $P_n = |\psi_n\rangle\langle\psi_n|$ tends to P in the weak topology. But for any $n \in \mathbf{N}$ there is

$$P_n = \sum_{k,l}^{\text{finite}} \overline{z_k} z_l |\pi(g_k)\psi_0\rangle\langle\psi_0\pi(g_l)|.$$

Because $P_{qk}P_{ql} = K(q_k, q_l)|q_k\rangle\langle q_l|$, then $P_n \in \mathcal{A}_q$. Hence $P \in \mathcal{A}_q$, too, and $\mathcal{A}_q = L(\mathcal{H}_q)$.

In this case we can define a semispectral measure on Q by $E(B) = \int_B P_q \, d\alpha(q)$, where $B \in \mathcal{B}(Q)$, the Borel σ-algebra on Q, and $d\alpha$ is a unique (up to a positive constant) G-invariant and σ-finite Borel measure on Q. By a semispectral measure we understand a map $E : \mathcal{B}(Q) \to L(\mathcal{H}_q)_+$ such that for every $\psi \in \mathcal{H}_q$ and $B \in \mathcal{B}(Q)$ the map $B \to \langle\psi, E(B)\psi\rangle$ is a positive measure. Although the description of a quantum system by coherent states is sufficient in many cases, for further applications *we generalize this scheme and assume that the quantum algebra is generated (as a von Neumann algebra) by an arbitrary semispectral measure dE on Q*. Statistical states of the quantum system are given by non-negative density matrices $\rho \in \mathcal{A}_q$ with $\mathrm{Tr}(\rho) = 1$. The time evolution of a quantum observable A is given by $A \to e^{itH}Ae^{-itH}$, where H is a self-adjoint operator affiliated to $\mathcal{A}_q$. Its generator $i[H, \cdot]$ we denote by δ_q. The requirement that H is affiliated to the algebra $\mathcal{A}_q$, which represents the quantum system, follows from the need that all its spectral projectors should belong to $\mathcal{A}_q$.

Let us now consider the joint system. For the total algebra $\mathcal{A}_T$ we take the tensor product $\mathcal{A}_T = \mathcal{A}_c \otimes \mathcal{A}_q$ as von Neumann algebras on $\tilde{\mathcal{H}} = \mathcal{H}_c \otimes \mathcal{H}_q$. The set of states is equal to

$$\mathcal{S}_T = \left\{ \tilde{\rho} \in \mathcal{A}_{T*} : \tilde{\rho}(x) \in \mathrm{Tr}(\mathcal{H}_q)_+ \text{a.e. and } \int_M \mathrm{Tr}(\tilde{\rho}(x)) d\mu(x) = 1 \right\}.$$

The mean value of $\tilde{A} \in \mathcal{A}_T$ in a state $\tilde{\rho} \in \mathcal{S}_T$ is given by

$$\langle \tilde{A} \rangle_{\tilde{\rho}} = \int_M d\mu(x) \mathrm{Tr}[\tilde{A}(x)\tilde{\rho}(x)].$$

Now let us discuss the evolution of the total system. The total generator consists of three parts: $\delta_c \otimes \mathrm{id}$, $\mathrm{id} \otimes \delta_q$, and a superoperator L which describes the interaction between the classical and the quantum system.

To construct L we assume the following:

(a) Let to every point $x \in M$ correspond a finite and positive measure $\nu_x \in M(G) = C_0(G)^*$ such that $x \to \nu_x(G)$ is uniformly bounded and for every Borel set $B \subset G$ the map $x \to \nu_x(B)$ is Borel. The influence of the classical system on the quantum one is reflected by a map $dE \to d(\nu_x * E)$ which changes a quantum observable $\hat{f} = \int f(q) dE(q)$ to $\int f(q) d(\nu_x * E)(q)$. We assume that

$$\exists C > 0 \forall x \in M \forall B \in \mathcal{B}(Q) \text{ and } \alpha(B) < \infty \, \|(\nu_x * E)(B)\| \leqslant C\alpha(B).$$

(b) Let to every point $q \in Q$ corresponds a shift on the phase space. It will be responsible for an action of the quantum system on the classical one. By the shift we mean a morphism of $(M, \mathcal{B}, \mu)$, i.e., a bijective map $h_q : M \to M$ such that h_q and h_q^{-1} are measurable and leave the measure $d\mu$ invariant. Moreover, we demand that for any $f \in C_c(M)$ and any $x \in M$ a mapping $q \to f(h_q^{-1}x)$ is Borel measurable. Then $U_q : \mathcal{H}_c \to \mathcal{H}_c, (U_q \Psi)(x) = \Psi(h_q^{-1}x)$ is a unitary operator. Moreover, $q \to \langle f_1, U_q f_2 \rangle$ is measurable for any $f_1, f_2 \in C_c(M)$ and so $q \to U_q$ is weakly measurable.

At first we show that $\nu_x * E$ is a semispectral measure on Q and so the condition from the point (a) is well defined. Let $\psi_1, \psi_2 \in \mathcal{H}_q$ and

$$dE_{\psi_1, \psi_2}(q) = d\langle E(q)\psi_1, \psi_2 \rangle.$$

Let for $f \in C_0(Q)$

$$\phi(f) = \int_Q \int_G f(gq) d\nu_x(g) dE_{\psi_1, \psi_2}(q).$$

It is a continuous functional and so it determines the unique complex measure with finite variation $\nu_x * E_{\psi_1, \psi_2}$ defined on the Borel σ-algebra $\mathcal{B}(Q)$. Because for every $B \in \mathcal{B}(Q)(\psi_1, \psi_2) \to (\nu_x * E_{\psi_1, \psi_2})(B)$ is a positive and continuous sesquilinear form there is a bounded and positive operator $(\nu_x * E)(B)$ such that $B \to \langle \psi, (\nu_x * E)(B)\psi \rangle$ is a positive measure.

In the following two propositions we introduce situations in which assumption $\|(\nu_x * E) \times (B)\| \leqslant C\alpha(B)$ is satisfied.
