(Received 4 November 1997; accepted for publication 30 September 1998)

We start from a natural generalization of the Born–Infeld Lagrangian which involves two constants h,k and two parameters s,θ_0 and show, by investigating static solutions of a first order approximation with respect to a small parameter ($\epsilon = h/k$) that $s=1/2$ and that h is directly proportional to Planck's constant. It seems reasonable to interpret $s=1/2$ as the spin of the electron and the angle θ_0 as its orientation. Thus we obtain solutions that appear to reflect the influence of the states of spin on the electromagnetic field. © *1999 American Institute of Physics.* [S0022-2488(99)02901-1]

I. A GENERALIZATION OF THE BORN–INFELD LAGRANGIAN

The equations of nonlinear electrodynamics are derived from a nonlinear Lagrangian density $L(Q,R)$ which is a function of the electromagnetic invariants

$$Q=\tfrac{1}{4}F^{\alpha\beta}F_{\alpha\beta}=\tfrac{1}{2}(\mathbf{B}^2-\mathbf{E}^2),\quad R=\tfrac{1}{4}F^{\alpha\beta}F^{*}_{\alpha\beta}=\mathbf{E}\cdot\mathbf{B}, \tag{1}$$

and are given by

$$\partial_t(L_Q\mathbf{E}-L_R\mathbf{B})-\nabla\times(L_Q\mathbf{B}+L_R\mathbf{E})=0, \tag{2}$$

$$\partial_t\mathbf{B}+\nabla\times\mathbf{E}=0, \tag{3}$$

$$\nabla\cdot(L_Q\mathbf{E}-L_R\mathbf{B})=0, \tag{4}$$

$$\boldsymbol{\nabla}\cdot\mathbf{B}=0. \tag{5}$$

We observe that $\mathbf{E}$ and

$$\mathbf{H}=L_Q\mathbf{B}+L_R\mathbf{E}, \tag{6}$$

are the components of the *main field*[1] that symmetrizes the system of the evolutive equations (2) and (3).

According to the Maxwell equations the static electric field of a charged particle is given by the Coulomb's law. To solve the paradox of the infinite field at the center of the particle Born and Infeld[2] introduced new field equations derived from the nonlinear Lagrangian,

$$L(Q,R)=\sqrt{-R^2+k(2Q+k)}, \tag{7}$$

where k is a positive constant. In this way they obtained the famous static solution with spherical symmetry,

[a)]Permanent address: Department of Applied Mathematics, University of Clermont.

$$\mathbf{E}_0=\frac{\sqrt{k}}{\sqrt{1+\xi^4}}\,\frac{\mathbf{r}}{r},\quad \mathbf{B}_0=0\,,\quad \xi=\frac{r}{r_0},\tag{8}$$

which for $r=0$ yields the finite value $\sqrt{k}$ of the electric field also called the *absolute field* and for $r \gg r_0$ is equivalent to the Coulomb's law, provided that

$$\sqrt{k}=\frac{e}{r_0^2},\tag{9}$$

where e is the charge of the electron and r_0 is interpreted as the *radius of the electron*.

Calculating the total energy of the electrostatic field by integrating the Hamiltonian density over the whole space and assuming that the rest energy of the electron is of electromagnetic origin, they also find the relation

$$m_0c^2=1.2361\,\frac{e^2}{r_0},$$

which shows that r_0 is larger than the classical electron radius by the factor 1.2361,

$$r_0=3.47\times 10^{-13}\ \text{cm}.$$

It follows by (9) that

$$\sqrt{k}=3.97\times 10^{15}\ \text{e.s.u.}=1.19\times 10^{20}\ \text{V/m}.$$

''The enormous magnitude of this field, observe the authors, justifies the application of Maxwell's equations in their classical form in all cases, except those where the inner structure of the electron is concerned (field of the order $b[=\sqrt{k}]$, distance of wavelength of the order r_0).''

Now, as a consequence of nonlinearity, the wave fronts $\varphi(x^\alpha)=0$ are no longer null surfaces $(g^{\alpha\beta}\partial_\alpha\varphi\partial_\beta\varphi=0)$, but satisfy the characteristic equations,

$$\{F^{\alpha\rho}F^{\beta}{}_{\rho}-(2Q+\zeta)g^{\alpha\beta}\}\partial_\alpha\varphi\partial_\beta\varphi=0,\tag{10}$$

where ζ takes on two values $\zeta_1(Q,R)$, $\zeta_2(Q,R)$ depending on the choice of the Lagrangian.[3]

These two values coincide and turn out to be equal to the positive constant k only if L is the Born–Infeld Lagrangian (7).[3–5]

Thus the velocities given by (10) are double and as a consequence the corresponding waves are *exceptional (linearly degenerated)*. This concept introduced by Lax[6] appears to be of special importance in the applications.[1] The waves behave in a linear way and characteristic shocks traveling with the wave velocities exist. Therefore it seemed quite natural to look for Lagrangians leading to this property for each family of waves (10). The most general one has the form

$$L=F(\zeta)f(Q,R;\zeta)+RG(\zeta)+H(\zeta),\tag{11}$$

with

$$f(Q,R;\zeta)=\sqrt{-R^2+\zeta(2Q+\zeta)},$$

where $\zeta(Q,R)$ is obtained by solving the equation

$$\frac{\partial L}{\partial\zeta}=F'f+RG'+H'+(Q+\zeta)\,\frac{F}{f}=0.\tag{12}$$

Clearly the field equations obtained in this way are a direct generalization of the Born–Infeld equations, condition (12) resulting from the variation of ζ in the variational principle. Now either ζ_1 or ζ_2 may be used to yield the (same) Lagrangian. As a result the functions F,G,H are completely determined and using for instance ζ_1 for ζ they read[3]

$$F^2=\frac{1}{s(1+\gamma^2)}\left\{\frac{\gamma^2}{\zeta^2}(k^2-h^2)+2K\frac{\gamma}{\zeta}-1\right\}, \tag{13}$$

$$G=-\frac{\gamma}{\zeta}H,$$

$$H^2=\frac{1}{s(1+\gamma^2)}\{h^2-(\zeta-k)^2\}, \tag{14}$$

with

$$2K=\frac{k}{\gamma}\{s+1+\gamma^2(s-1)\},\quad s>0.$$

Setting

$$\gamma=\tan\frac{\theta_0}{2},$$

the two values ζ_1,ζ_2 are obtained by the following change of constants:

$$\zeta_1=\zeta(Q,R;k,h,s,\theta_0),\quad \zeta_2=\zeta(Q,R;k,h,-s,\theta_0+\pi), \tag{15}$$

and

$$(\zeta_1-k)^2\leqslant h^2\leqslant(\zeta_2-k)^2.$$

From (14) it appears that $\zeta=k$ when $h=0$ and (11) becomes equivalent to the Lagrangian of Born–Infeld (7).

Let

$$h=\epsilon k,$$

where ϵ is a small dimensionless parameter. Having in mind a model of a single electron it seems reasonable to think that, in this case, h is related to the Planck constant and s to the spin of the electron. As a matter of fact by (9) and the formula of the fine-structure constant,

$$\alpha=\frac{e^2}{\hbar c}\approx\frac{1}{137},$$

it follows

$$h=\epsilon\frac{c}{137r_0^4}\hbar.$$

II. FIRST ORDER APPROXIMATION

To illustrate the role played by the additional constants s,θ_0 appearing in the generalized Lagrangian (11) we look for an extension to the first order in ϵ of the classical Born–Infeld solution (8).

Since the exact solution of Eqs. (12)–(14) is not easy to find we expand the various quantities in terms of ϵ. We set

$$\zeta = k(1+\epsilon u+\cdots),$$

and retaining only the first order terms we get

$$F = 1 - \frac{s+1}{2s}\,\epsilon u,$$

$$G = \frac{\gamma}{\sqrt{s(1+\gamma^2)}}\,\epsilon\sqrt{1-u^2},$$

$$H = -\frac{k}{\sqrt{s(1+\gamma^2)}}\,\epsilon\sqrt{1-u^2},$$

$$f = f(Q,R;k) + \frac{\epsilon k(k+Q)u}{f(Q,R;k)},$$

$$L = f(Q,R;k) + \epsilon\left[\frac{k(k+Q)u}{f(Q,R;k)} - \frac{s+1}{2s}\,u f(Q,R;k) - (k-\gamma R)\sqrt{\frac{1-u^2}{s(1+\gamma^2)}}\right].$$

As we shall see later in Sec. IV, the present sign of H corresponds to the choice of a positive ϵ.

By (12) equating to zero the derivative with respect to u we obtain

$$\frac{u}{\sqrt{1-u^2}} = \frac{\sqrt{s(1+\gamma^2)}}{k-\gamma R}\left[\frac{s+1}{2s}\,f(Q,R;k) - \frac{k(k+Q)}{f(Q,R;k)}\right].$$

Or, simply when $R=0$,

$$u = \frac{[2Q-k(s-1)]\sqrt{1+\gamma^2}}{\sqrt{[k(s+1)+2Q]^2+\gamma^2[k(s-1)-2Q]^2}}.$$

To the first order in ϵ we have

$$\mathbf{E} = \mathbf{E}_0 + \epsilon\mathbf{E}_1 + \cdots\,, \quad \mathbf{B} = \epsilon\mathbf{B}_1 + \cdots\,, \tag{16}$$

$$Q = Q_0 + \epsilon Q_1 + \cdots = Q_0 - \epsilon\mathbf{E}_0\cdot\mathbf{E}_1 + \cdots\,, \quad R = \epsilon R_1 + \cdots = \epsilon\mathbf{E}_0\cdot\mathbf{B}_1 + \cdots\,,$$

$$u = \frac{(\phi-s)\sqrt{1+\gamma^2}}{\sqrt{(s+\phi)^2+\gamma^2(s-\phi)^2}}, \quad \phi = \frac{\xi^4}{1+\xi^4}, \tag{17}$$

$$L_Q = \frac{F\zeta}{f(Q,R;\zeta)} = \frac{1}{\sqrt{\phi}}\left\{1 - \frac{\epsilon}{2}\left[\left(\frac{1}{\phi}+\frac{1}{s}\right)u + 2\,\frac{Q_1}{k\phi}\right]\right\} + \cdots\,, \tag{18}$$

$$L_R = -R\,\frac{F}{f(Q,R;\zeta)} + G = -\epsilon\left[\frac{R_1}{k\sqrt{\phi}} - \frac{\gamma}{\sqrt{s(1+\gamma^2)}}\,\sqrt{1-u^2}\right] + \cdots\,. \tag{19}$$

With the substitution of (17) into (18) and (19),

$$u=\frac{\phi-s}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}, \tag{20}$$

$$L_Q=\frac{1}{\sqrt{\phi}}\left\{1-\epsilon\left[\frac{Q_1}{k\phi}+\frac{1}{2\phi s}\,\frac{\phi^2-s^2}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right]\right\}, \tag{21}$$

$$L_R=-\epsilon\left(\frac{R_1}{k\sqrt{\phi}}-\frac{\sin\theta_0\sqrt{\phi}}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right). \tag{22}$$

According to (2) and (3) the static solutions we are interested in, are derived from scalar potentials. Hence, by (16), (21), and (22),

$$\mathbf{H}_1=(L_Q\mathbf{B}+L_R\mathbf{E})_1=\frac{1}{\sqrt{\phi}}\,\mathbf{B}_1-\left(\frac{R_1}{k\sqrt{\phi}}-\frac{\sin\theta_0\sqrt{\phi}}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right)\mathbf{E}_0=\nabla\chi, \tag{23}$$

$$\mathbf{E}_1=\nabla\psi,$$

$$(L_Q\mathbf{E}-L_R\mathbf{B})_1=\frac{1}{\sqrt{\phi}}\,\mathbf{E}_1-\frac{1}{\phi^{3/2}}\left(\frac{Q_1}{k}+\frac{1}{2s}\,\frac{\phi^2-s^2}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right)\mathbf{E}_0. \tag{24}$$

Further from (4) and (5) we have

$$\nabla\cdot\left[\frac{1}{\sqrt{\phi}}\,\mathbf{E}_1-\frac{1}{\phi^{3/2}}\left(\frac{Q_1}{k}+\frac{1}{2s}\,\frac{\phi^2-s^2}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right)\mathbf{E}_0\right]=0, \tag{25}$$

$$\boldsymbol{\nabla}\cdot\mathbf{B}_1=0. \tag{26}$$

Multiplying (23) by $\mathbf{E}_0$ we find

$$R_1=\frac{1}{\sqrt{\phi}}\,\mathbf{E}_0\cdot\nabla\chi-\frac{\mathbf{E}_0^2\sin\theta_0}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}, \tag{27}$$

$$\mathbf{B}_1=\sqrt{\phi}\nabla\chi+\mathbf{E}_0\left(\frac{1}{k\sqrt{\phi}}\,\mathbf{E}_0\cdot\nabla\chi-\frac{\sin\theta_0}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right). \tag{28}$$

Substituting (24) into (25) we get:

$$\nabla^2\psi+\frac{1}{\xi^4}\,\frac{\partial^2\psi}{\partial r^2}-\frac{4}{r_0\xi^5}\,\frac{\partial\psi}{\partial r}-\frac{\sqrt{k}}{2s\sqrt{1+\xi^4}}\,\frac{d}{dr}\left(\frac{\phi^2-s^2}{\phi\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right)=0,$$

or

$$\frac{\partial}{\partial r}\left[\frac{1}{\phi\sqrt{1-\phi}}\,\frac{\partial\psi}{\partial r}-\frac{\sqrt{k}}{2s}\,\frac{\phi^2-s^2}{\phi\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}\right]+\frac{1}{r_0^2\sqrt{\phi}}\,D\psi=0, \tag{29}$$

where the Laplacian, in spherical coordinates, is given by

$$\nabla^2\psi=\frac{1}{r^2}\,\frac{\partial}{\partial r}\left(r^2\,\frac{\partial\psi}{\partial r}\right)+\frac{1}{r^2}\,D\psi$$

with

$$D\psi = \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\,\frac{\partial\psi}{\partial\theta}\right) + \frac{1}{\sin^2\theta}\frac{\partial^2\psi}{\partial\varphi^2}.$$

III. ELECTRIC FIELD

The general solution to (29) is $\psi = \hat{\psi} + \psi_s$, where $\hat{\psi}$ satisfies

$$\nabla^2\hat{\psi} + \frac{1}{\xi^4}\frac{\partial^2\hat{\psi}}{\partial r^2} - \frac{4}{r_0\xi^5}\frac{\partial\overline{\psi}}{\partial r} = 0, \tag{30}$$

and $\psi_s(r)$ is a particular solution of the full equation.

From (8), (16), and (24) it follows that, at the first order, the electric field is given by

$$\mathbf{E} = \frac{\sqrt{k}}{\sqrt{1+\xi^4}}\frac{\mathbf{r}}{r} + \epsilon\left(\nabla\hat{\psi} + E_s\frac{\mathbf{r}}{r}\right), \tag{31}$$

where

$$\mathbf{E}_s = \boldsymbol{\nabla}\psi_s(r) = E_s\frac{\mathbf{r}}{r},$$

and E_s from (29) can be taken as

$$E_s(\xi;s,\theta_0) = \frac{\sqrt{k}}{2s}\frac{(\phi^2 - s^2)\sqrt{1-\phi}}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}. \tag{32}$$

On introducing the two vectors $\boldsymbol{\phi},\mathbf{s}$ of the respective moduli ϕ, s, making an angle θ_0, we can also write

$$E_s(\xi;s,\theta_0) = \frac{E_0(\xi)}{2s}\frac{\boldsymbol{\phi}+\mathbf{s}}{|\boldsymbol{\phi}+\mathbf{s}|}\cdot(\boldsymbol{\phi}-\mathbf{s}).$$

Since E_s is not a monotonic function of ϕ we require an extremum to take place on the sphere $r = r_0$, i.e., for $\xi = 1$, which implies

$$\cos\theta_0 = -\frac{1}{2}\frac{(4s^2+1)^2+(4s)^2}{4s(4s^2+1)},$$

a function of s which is always smaller than -1 except when

$$4s^2+1 = 4s \Leftrightarrow s = \tfrac{1}{2} \Leftrightarrow \theta_0 = \pi.$$

Thus the values of s, θ_0 are determined. This would not have been the case had the extremum occurred for another value of ξ (since a single equation—the vanishing of the derivative of E_s—is not sufficient, in general, to determine two quantities). Then the solution (32) becomes

$$E_s(\xi;1/2,\pi) = \sqrt{k}(\phi + \tfrac{1}{2})\sqrt{1-\phi}\ \mathrm{sgn}(\phi - \tfrac{1}{2}).$$

This electric field is a decreasing function of r inside the electron ($r < r_0$), is discontinuous across the surface $r = r_0$, decreases outside ($r > r_0$), and tends to zero at infinity like $1/r^2$ [see Fig. 1(f)]. To obtain the solution corresponding to the other orientation of the spin we take $\theta_0 = 0$ in (32) to get

$$E_s(\xi;1/2,0)=\sqrt{k}(\phi-\tfrac{1}{2})\sqrt{1-\phi}.$$

This field is continuous, vanishes on the surface $r=r_0$, has a maximum for $\phi=5/6$, and tends to zero like $1/r^2$ [see Fig. 1(a)]. Some intermediate states are illustrated in Fig. 1.

IV. ABSOLUTE FIELD

In nonlinear electrodynamics the quantities $\zeta_1^{1/2}$, $\zeta_2^{1/2}$ represent the absolute value of the electric field in a frame traveling at the ray velocity.[3]

From (15), (20),

$$\zeta_1=k+h\,\frac{\phi-s}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}=k+h\,\frac{|\boldsymbol{\phi}|-|\mathbf{s}|}{|\boldsymbol{\phi}+\mathbf{s}|},$$

$$\zeta_2=k+h\,\frac{\phi+s}{\sqrt{s^2+\phi^2+2s\phi\cos\theta_0}}=k+h\,\frac{|\boldsymbol{\phi}|+|\mathbf{s}|}{|\boldsymbol{\phi}+\mathbf{s}|},$$

and therefore with $s=1/2$,

$$\theta_0=\pi,\quad \zeta_1=\begin{cases}k-h, & r<r_0\\ k+h, & r>r_0\end{cases},\quad \zeta_2=\begin{cases}k+h(\tfrac{1}{2}+\phi)/(\tfrac{1}{2}-\phi) & r<r_0\\ k+h(\phi+\tfrac{1}{2})/(\phi-\tfrac{1}{2}) & r>r_0\end{cases},$$

$$\theta_0=0,\quad \zeta_1=k+h(\phi-\tfrac{1}{2})/(\phi+\tfrac{1}{2}),\quad \zeta_2=k+h.$$

Since both ζ's must be positive (for hyperbolicity),[3] also h is positive and this justifies the choice of the sign of H in Sec. II. Further $\zeta_1\leqslant\zeta_2$ and the inequality $\mathbf{E}^2\leqslant\zeta_1$ must hold, so that the wave and shock velocities do not exceed the speed of light.[1]

According to (10) a signal travels at light velocity when $r=r_0$ where ζ_2 is infinite.

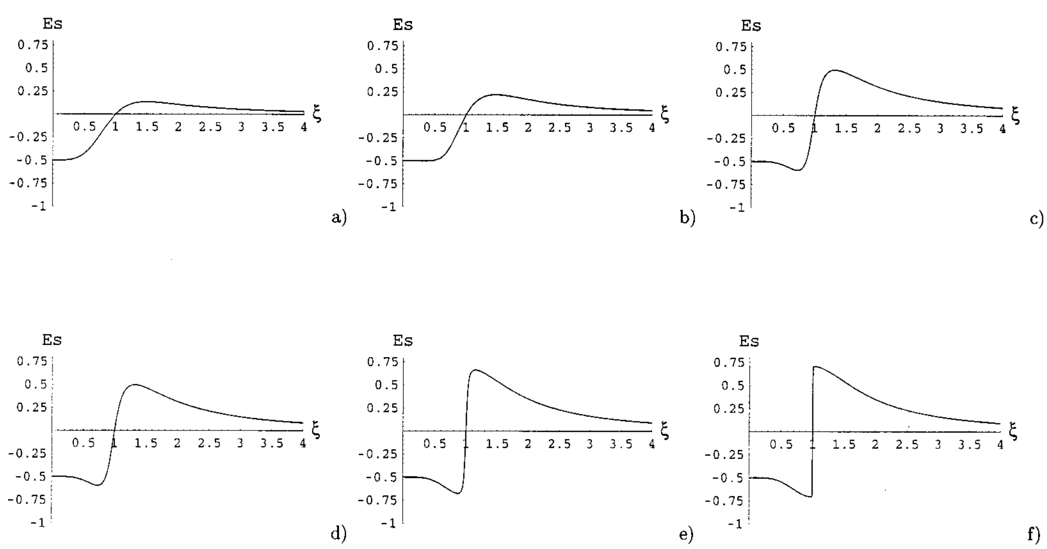

FIG. 1. Plot of E_s vs ξ, $(k=1)$: (a) $\theta_0=0$, (b) $\theta_0=\pi/5$, (c) $\theta_0=3\pi/5$, (d) $\theta_0=4.5\pi/5$, (e) $\theta_0=4.9\pi/5$, (f) $\theta_0=\pi$.

V. MAGNETIC FIELD

Turning back to the scalar field χ, substituting (28) into (26) we get

$$\frac{\partial}{\partial r}\left(\sqrt{1+\xi^4}\,\frac{\partial\chi}{\partial r}-\frac{\sqrt{k\phi}\,\sin\,\theta_0}{\sqrt{s^2+\phi^2+2s\phi\,\cos\,\theta_0}}\right)+\frac{\sqrt{\phi}}{r_0^2}\,D\chi=0.$$

The general solution is $\chi=\hat{\chi}+\chi_s$, where $\hat{\chi}$ is the general solution of the homogeneous equation and $\chi_s(r)$ is a particular solution of the full equation.

At the first order the field **H** is given by

$$\mathbf{H}=\epsilon\left(\nabla\hat{\chi}+H_s\,\frac{\mathbf{r}}{r}\right), \tag{33}$$

where

$$H_s(\xi;s,\theta_0)=\frac{\sqrt{k}}{\sqrt{1+\xi^4}}\,\frac{\sqrt{\phi}\,\sin\,\theta_0}{\sqrt{s^2+\phi^2+2s\phi\,\cos\,\theta_0}},$$

i.e.,

$$H_s=\frac{\sqrt{k}}{\xi^2}\,\frac{|(\boldsymbol{\phi}+\mathbf{s})\times\mathbf{s}|}{|\mathbf{s}||\boldsymbol{\phi}+\mathbf{s}|}.$$

This function vanishes together with its derivative for $\xi=0$ and inside the sphere of radius r_0 for

$$\xi^4=\frac{1}{\sqrt{5+4\,\cos\,\theta_0}}$$

has a positive maximum $H_s^{\max}$ defined by

$$(H_s^{\max})^2=\frac{2k}{1+2\,\cos\,\theta_0+\sqrt{5+4\,\cos\,\theta_0}}\,\sin^2\,\theta_0$$

(see Fig. 2).

When $\theta_0\rightarrow\pi$ this ratio, by L'Hospital's rule, tends to k. While for $\theta_0=0$ the H_s field is identically zero, for $\theta_0=\pi$ it is zero everywhere except on the sphere $r=r_0$, where it has a peak of height equal to $\sqrt{k}$ [see Fig. 2(f)].

To see this we write

$$s^2+\phi^2+2s\phi\,\cos\,\theta_0=(s-\phi)^2+4s\phi\,\cos^2\,\frac{\phi_0}{2}=\rho^2$$

with

$$s-\phi=\rho\,\cos\,\alpha,\quad 2\sqrt{s\phi}\,\cos\,\frac{\theta_0}{2}=\rho\,\sin\,\alpha,\quad 0\leqslant\alpha\leqslant\pi.$$

Then,

$$H_s=\frac{\sqrt{k}}{\sqrt{s(1+\xi^4)}}\,\sin\,\frac{\theta_0}{2}\,\sin\,\alpha.$$

When $\xi\to 1$, $\phi\to s=1/2$, $\theta_0\to\pi$, $H_s\to\sqrt{k}\,\sin\alpha$ for any value of α and therefore the maximum of H_s is $\sqrt{k}$. For another value of ξ then, $\rho\neq 0$, $\alpha=0$, $H_s=0$.

Now from (27) it follows

$$R_1=\frac{\sqrt{k}}{\xi^2}\,\frac{\partial\hat{\chi}}{\partial r}$$

and from (23),

$$\mathbf{B}_1=\frac{1}{\sqrt{1+\xi^4}}\left(\xi^2\nabla\hat{\chi}+\frac{1}{\xi^2}\,\frac{\partial\hat{\chi}}{\partial r}\,\frac{\mathbf{r}}{r}\right). \tag{34}$$

VI. SOLUTION TO THE HOMOGENEOUS EQUATIONS

The complete solutions for the electric (31) and magnetic field (33) include also the solutions to the homogenous equations for $\hat{\psi},\hat{\chi}$. Substituting (34) into (26) the latter equation can be written,

$$(1+\xi^4)\,\frac{\partial^2\hat{\chi}}{\partial\xi^2}+2\xi^3\,\frac{\partial\hat{\chi}}{\partial\xi}+\xi^2 D\hat{\chi}=0.$$

This means that $\hat{\chi}$ is a harmonic function with respect to the metric defined by

$$d\sigma^2=\phi d\xi^2+\xi^2(d\theta^2+\sin^2\,\theta\,d\varphi^2).$$

The former equation (31),

$$\left(1+\frac{1}{\xi^4}\right)\frac{\partial^2\hat{\psi}}{\partial\xi^2}+\frac{2}{\xi}\left(1-\frac{2}{\xi^4}\right)\frac{\partial\hat{\psi}}{\partial\xi}+\frac{1}{\xi^2}\,D\hat{\psi}=0$$

shows that $\hat{\psi}$ is a harmonic function for the conformal metric,

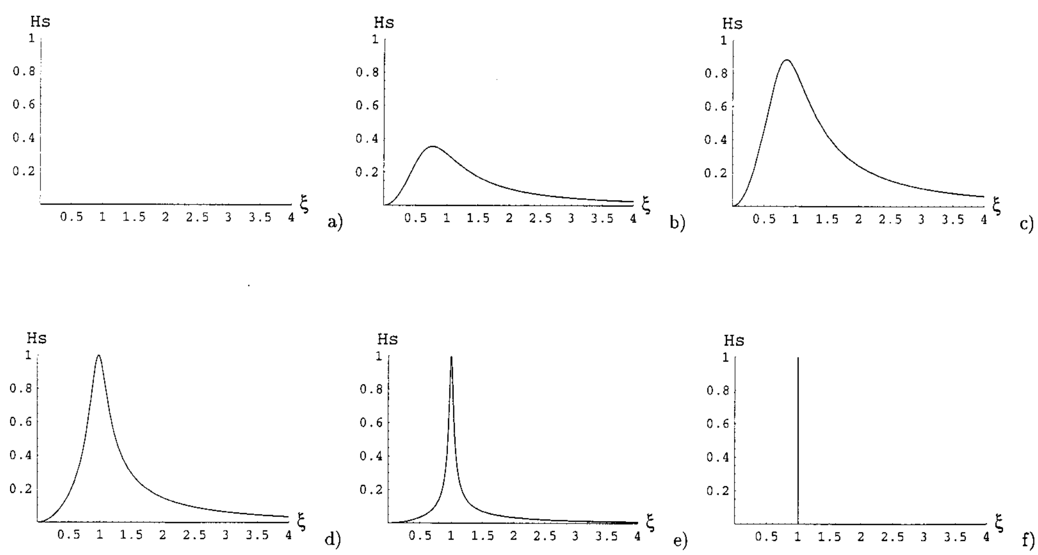

FIG. 2. Plot of H_s vs ξ, $(k=1)$: (a) $\theta_0=0$, (b) $\theta_0=\pi/5$, (c) $\theta_0=3\pi/5$, (d) $\theta_0=4.5\pi/5$, (e) $\theta_0=4.9\pi/5$, (f) $\theta_0=\pi$.

$$d\sigma^* = \frac{1}{\phi}\, d\sigma.$$

From (31), (32) we have:

$$\mathbf{E}^2 = \mathbf{E}_0^2 + 2\epsilon \mathbf{E}_0 \cdot \mathbf{E}_s + 2\epsilon \mathbf{E}_0 \cdot \nabla \hat{\psi}$$

and for $r=0$, at the center of the particle, we must have[3]

$$\mathbf{E}^2 = \zeta_1 = k - h,$$

i.e.,

$$\left(\frac{\partial \hat{\psi}}{\partial r}\right)_{r=0} = 0.$$

We point out that even if the potentials $\psi = \hat{\psi} + \psi_s$, $\chi = \hat{\chi} + \chi_s$ include the general solutions $\hat{\psi}, \hat{\chi}$ to the homogenous equations, of which nothing more at present can be said, the only terms which are completely determined, are the special solutions $\psi_s(\xi; s, \theta_0)$, $\chi_s(\xi; s, \theta_0)$ of the inhomogeneous equations, which have been analyzed in the previous sections.

VII. CONCLUSION

Recently there has been a renewal of interest for the Born–Infeld theory due partly to its link with relativistic strings, membranes[7] and gravitation theory[8] and partly to its nonlinear structure. In fact, in the last years, more researchers seem to be interested in the nonlinear nature of the physical phenomena.

In our investigation of the static field of a single electron we started from the observation that a natural generalization of the Born–Infeld Lagrangian involves, apart from the classical absolute field k (already introduced by Born and Infeld), a constant h, a dimensionless parameter s, and an angle θ_0.

By looking for static solutions at the first order of approximation with respect to the small parameter $\epsilon = h/k$ we find that the field is the sum of two contributions; one of them is a harmonic function in a suitable metric space, and not much can be said about it. The other one depends explicitly on the mentioned constants and can be studied. It results that a maximum for the electric field occurs on the surface of the electron $(r = r_0)$ only for the values $s = 1/2$, $\theta_0 = \pi$. Furthermore when $\theta_0 \neq \pi$ this solution vanishes for $r = r_0$ and this seems to reflect the influence of the states of spin on the electromagnetic field which is discontinuous when the angle θ_0 is equal to π.

So it appears reasonable, in this context (single electron), to relate s to the spin of the electron and θ_0 to its orientation (up and down), while h is proportional to the Planck's constant.

ACKNOWLEDGMENTS

We are grateful to Professor Tommaso Ruggeri for his kind hospitality at the C.I.R.A.M. We thank the referee whose observations were of great help in improving the manuscript. An exact stochastic model for the thermalization of quantum states is proposed. The model has various physically appealing properties. The dynamics are characterized by an underlying Schrödinger evolution, together with a nonlinear term driving the system toward an asymptotic equilibrium state and a stochastic term reflecting fluctuations. There are two free parameters, one of which can be identified with the heat bath temperature, while the other determines the characteristic time scale for thermalization. Exact expressions are derived for the evolutionary dynamics of the system energy, the system entropy, and the associated density operator. [S0022-2488(99)01901-5]

I. INTRODUCTION

The construction of a microscopic description for dynamical systems out of equilibrium is a topic of considerable interest in statistical mechanics. While many studies have been pursued in this direction,[1] the subject remains refractory owing to its nonlinear character. In particular, a realistic framework must be simple enough to be tractable, yet sufficiently sophisticated to capture some of the physical essentials. Our goal here is to propose in this spirit an elementary but compelling stochastic model that characterizes the thermalization process for a quantum system in an arbitrary given initial state.

The approach here, though carried out largely within the framework of standard quantum theory, involves a reexamination of the traditional hypotheses forming the basis of quantum statistical mechanics. In particular, we shall take the view that a quantum statistical ensemble, or ''state,'' is correctly described, not simply by a density matrix ρ^{α}_{β}, but rather by a probability distribution on the space of pure quantum mechanical states. For measurements associated with ordinary quantum mechanical observables, this description reduces to the usual one, for which the unconditional expectation of a linear observable is given by the familiar trace formula involving ρ^{α}_{β}. The advantage of the present formulation, however, is that we can give meaning to the concept of ensembles and other mixed states in nonlinear quantum mechanics.[2,3] Furthermore, the fact that the space of pure states has a symplectic structure allows us to introduce the concept of a quantum phase space Γ, and hence the use of probability distributions on Γ as ensembles. In particular, for thermal equilibrium in certain situations, we propose the distribution given in (12) below, which we call the canonical Γ ensemble. The corresponding density matrix differs in some respects from the conventional density matrix of quantum statistical mechanics, and thus the applicability of the theory may, in principle, be testable.

Our first step is to derive the Fokker–Planck equation for the time-dependent probability density function associated with a general Brownian motion with drift on the space of pure quantum states. Since Γ is compact, we can apply a theorem of Zeeman to show that there is a special class of drift terms for which, given any initial condition, the resulting asymptotic station-

[a)]Electronic mail: d.brody@damtp.cam.ac.uk
[b)]Electronic mail: lane_hughston@yahoo.com

ary solution is the canonical Γ ensemble described above. The nonequilibrium dynamics we consider here is governed by a nonlinear Schrödinger evolution coupled to a thermal noise term, described by the stochastic differential equation (14). This choice is the simplest possible that leads to thermal equilibrium for arbitrary initial states.

In what follows we use the dynamical law (14) to derive a formula for the total system energy (18), leading to a formula for the heat capacity (19). These ideas are applied, by way of illustration, to the case of a spin one-half particle in a heat bath. Then we derive an expression for the dynamics of the system entropy, given in (24), from which we are able to deduce a fundamental thermodynamic inequality (25). Finally, we study the evolution of the density matrix associated with the underlying process. We show that the time development of the density matrix involves a higher moment of the projection operator onto pure states.

II. QUANTUM HAMILTONIAN DYNAMICS

We begin by considering the quantum mechanical phase space CP^n. This is the space of pure quantum states, given by rays through the origin in the associated Hilbert space.[2] The quantum phase space can be viewed as a $2n$-dimensional real manifold Γ, endowed with the Fubini–Study metric g_{ab}. The reason that Γ plays the role of a quantum phase space is that Hamilton's equations on Γ can be lifted to the Hilbert space to give the Schrödinger dynamics. This follows from the fact that Γ has a natural symplectic structure, given by a nondegenerate antisymmetric tensor Ω_{ab}, compatible with the metric g_{ab} in the sense that $\nabla_a\Omega_{bc}=0$ and $\Omega_{ab}\Omega^{bc}=-\delta_a^c$, where $\Omega^{ab}=g^{ac}g^{bd}\Omega_{cd}$ and ∇_a denotes the standard covariant derivative, satisfying $\nabla_a g_{bc}=0$. Then the Schrödinger dynamics take the Hamiltonian form

$$dx^a=2\Omega^{ab}\ \nabla_b H\ dt, \tag{1}$$

where dx^a/dt is tangent to the quantum phase space trajectory. The Hamiltonian function $H(x)$ on Γ is given by the expectation of the energy operator at each point $x\in\Gamma$. More specifically, the expectation of the Hermitian operator H^α_β with respect to the Hilbert space vector ψ^α $(\alpha,\beta=0,1,...,n)$ is given by $H(x)=H^\alpha_\beta\bar{\psi}_\alpha\psi^\beta/\bar{\psi}_\gamma\psi^\gamma$. Since each point $x\in\Gamma$ corresponds to an equivalence class $\{\lambda\psi^\alpha,\lambda\in\mathbf{C}-0\}$ for some Hilbert space vector ψ^α, it follows that $H(x)$ is defined globally on Γ. Conversely, one can show that such functions correspond to global solutions of the equation

$$\nabla^2 H=(n+1)(\bar{H}-H), \tag{2}$$

where ∇^2 is the Laplace–Beltrami operator on Γ. Here $\bar{H}=H^\alpha_\alpha/(n+1)$, H^α_α being the trace of the Hamiltonian. Thus $\bar{H}$ is the uniform average of the energy eigenvalues, corresponding to the thermal equilibrium energy of the system at high temperature.

III. STOCHASTIC DYNAMICS

Now we generalize the Schrödinger dynamics by consideration of a diffusion process x_t taking values in Γ. For this purpose we make use of standard techniques of stochastic differential geometry.[4,5] We shall examine the case of a Brownian motion with drift on Γ, determined by the covariant stochastic differential equation,

$$dx^a=\mu^a\ dt+\kappa\sigma_i^a\ dW_t^i, \tag{3}$$

where κ is a constant, μ^a is a vector field, and the vectors σ_i^a $(i=1,2,...,2n)$ constitute an orthonormal basis in the tangent space of Γ such that $g^{ab}=\sigma_i^a\sigma_j^b\delta^{ij}$ and $\sigma_i^a\sigma_j^b g_{ab}=\delta_{ij}$. Here dx^a is the covariant Ito differential,[5] and the standard $2n$-dimensional Wiener process W_t^i satisfies $dW_t^i\ dW_t^j=\delta^{ij}\ dt$. In local coordinates $x^{\mathbf{a}}$ $(\mathbf{a}=1,2,...,2n)$, the Ito differential is given by

$$dx^a = \delta^a_{\mathbf{a}}(dx^{\mathbf{a}} + \tfrac{1}{2}\kappa^2 \Gamma^{\mathbf{a}}_{\mathbf{bc}} g^{\mathbf{bc}}\, dt). \tag{4}$$

Here $\delta^a_{\mathbf{a}}$ is a coordinate basis for the given patch of Γ, and $\delta^{\mathbf{a}}_a$ the dual basis, such that for the covariant derivative $\nabla_a \xi^b$ of a vector field ξ^a with components $\xi^{\mathbf{a}} = \delta^{\mathbf{a}}_a \xi^a$, we can write

$$\delta^b_{\mathbf{b}} \delta^{\mathbf{a}}_a (\nabla_b \xi^a) = \frac{\partial \xi^{\mathbf{a}}}{\partial x^{\mathbf{b}}} + \Gamma^{\mathbf{a}}_{\mathbf{bc}} \xi^{\mathbf{c}}. \tag{5}$$

The Ito differential (4) is constructed in such a way that the stochastic differential equation (3) is fully tensorial.

Suppose $\phi(x)$ is a smooth function on Γ, and define the process $\phi_t = \phi(x_t)$. It follows from Ito's lemma that $d\phi_t = \nabla_a \phi\, dx^a + \frac{1}{2}\nabla_a \nabla_b \phi\, dx^a\, dx^b$. Then the relation $dx^a\, dx^b = \kappa^2 g^{ab}\, dt$ implies

$$d\phi_t = (\mu^a\, \nabla_a \phi + \tfrac{1}{2}\kappa^2\, \nabla^2 \phi) dt + \kappa\, \nabla_a \phi\, \sigma^a_i\, dW^i_t, \tag{6}$$

where $\nabla^2 \phi = g^{ab} \nabla_a\, \nabla_b \phi$. Since the process x_t is Markovian, there is a normalized density function $\rho(x,t)$ for the state at time t, characterized by a partial differential equation subject to specified initial conditions. The expectation of the process ϕ_t is thus

$$E[\phi_t] = \int_\Gamma \phi(x) \rho(x,t) dV, \tag{7}$$

where dV denotes the volume element on Γ. On the other hand, it follows from Ito's lemma (6) that

$$\phi_t = \phi_0 + \int_0^t \left(\mu^a\, \nabla_a \phi + \frac{1}{2}\, \kappa^2\, \nabla^2 \phi \right) ds + \kappa \int_0^t \sigma^a_i\, \nabla_a \phi\, dW^i_s. \tag{8}$$

Here the integrands are valued at time s at the point $x_s \in \Gamma$. Since the second integral above has vanishing expectation, we obtain

$$E[\phi_t] = \phi_0 + E\left[\int_0^t \left(\mu^a\, \nabla_a \phi + \frac{1}{2}\, \kappa^2\, \nabla^2 \phi \right) ds \right]. \tag{9}$$

Hence, differentiating (7) and (9) with respect to t and equating the results, we have

$$\int_\Gamma \dot{\rho}(x,t) \phi(x) dV = \int_\Gamma \left(\mu^a\, \nabla_a \phi + \frac{\kappa^2}{2}\, \nabla^2 \phi \right) \rho(x,t) dV, \tag{10}$$

where $\dot{\rho} = \partial \rho / \partial t$. Integrating by parts, and using the fact that the resulting relation must hold for all $\phi(x)$, we find that $\rho(x,t)$ satisfies

$$\frac{\partial}{\partial t}\, \rho(x,t) = -\nabla_a(\mu^a \rho) + \frac{1}{2}\, \kappa^2\, \nabla^2 \rho. \tag{11}$$

This is the covariant Fokker–Planck equation for the density function on Γ, corresponding to the stochastic process (3). The solution of (11) thus characterizes the distribution of the diffusion (3) at time t, given an initial distribution $\rho(x,0)$. In the case of a singular initial distribution, e.g., an initially pure state, we interpret $\rho(x,t)$ as a generalized function, i.e., it has to satisfy (10) for all smooth $\phi(x)$.

The foregoing results are valid on arbitrary compact Riemannian manifolds. We are concerned, however, with the case where Γ is the quantum phase space CP^n, endowed with the Fubini–Study metric. Since Γ is compact, Eq. (11) may admit nontrivial asymptotic ($t \to \infty$)

stationary solutions. We shall examine a simple situation in which this is the case, namely, when the drift is given by a gradient flow $\mu^a = -(1/2)\kappa^2\beta\,\nabla^a H$ generated by $H(x)$, where β is a parameter. Then we can use a theorem of Zeeman[6] to show that there is a unique stationary solution for (11) of the form

$$\rho(x) = \frac{\exp(-\beta H(x))}{Z(\beta)}, \tag{12}$$

where $Z(\beta) = \int_\Gamma \exp(-\beta H(x))dV$. It follows that the probability density function $p(E)$ for the distribution of the energy function $H(x)$ is $P(E) = \Omega(E)\exp(-\beta E)/Z(\beta)$, where

$$\Omega(E) = \int_\Gamma \delta(H(x) - E)dV \tag{13}$$

is the density of states in Γ for which $E \leqslant H(x) < E + dE$, and $Z(\beta)$ is the partition function. Another way of characterizing the distribution (12) is that it maximizes the entropy $S = -\int_\Gamma \rho(x)\ln \rho(x)dV$ for a given value of system energy $U = \int_\Gamma \rho(x)H(x)dV$. The theorem of Zeeman implies in the present context that (12) is the asymptotic distribution of the process x_t under essentially arbitrary initial conditions, and that $p(E)$ is the asymptotic energy distribution.

We have so far considered a process of the form (3) with the drift $\mu^a = -(1/2)\kappa^2\beta\,\nabla^a H$. This process, as such, does not yet make reference to the Schrödinger dynamics. If we view the drift term as a nonlinear correction to the underlying quantum evolution, we can represent the complete dynamics according to the prescription

$$dx^a = \left(2\Omega^{ab}\,\nabla_b H - \frac{1}{2}\,\kappa^2\beta\,\nabla^a H\right)dt + \kappa\sigma_i^a\,dW_t^i, \tag{14}$$

which in the limit $\kappa \to 0$ reduces to the ordinary Schrödinger dynamics. Due to the antisymmetry of Ω_{ab}, inclusion of the symplectic term does not affect the resulting asymptotic state (12), since $\rho(x)$ is a function of $H(x)$. Hence, the analysis above shows that, given an arbitrary initial state (pure or general) on the quantum phase space, the dynamical law (14) necessarily takes that state into the thermal equilibrium state (12). In particular, the process (14) is ergodic on the energy surface, and asymptotically leads to a uniform distribution on each such surface. We note that (14) involves two parameters, β and κ. The stationary solution for $\rho(x,t)$ depends only on β, which we identify as the inverse of the heat bath temperature. The parameter κ, which has the units $s^{-1/2}$, and may depend on β, determines the thermalization time scale.

IV. HAMILTONIAN PROCESS

Our next step is to study the stochastic process $H_t = H(x_t)$ associated with the Hamiltonian function. From Ito's lemma (6) for the process (14) we find

$$dH_t = \tfrac{1}{2}\kappa^2(\nabla^2 H_t - \beta V_t)dt + \kappa\,\nabla_a H\,\sigma_i^a\,dW_t^i. \tag{15}$$

Here $V_t = V(x_t)$, where $V(x) = g^{ab}\,\nabla_a H\,\nabla_b H$ is the squared energy uncertainty at the point $x \in \Gamma$, conditional on the pure state to which x corresponds. Integrating (15) and taking its expectation, we have

$$E[H_t] = H_0 + \frac{1}{2}\,\kappa^2\int_0^t E[\nabla^2 H_s - \beta V_s]ds. \tag{16}$$

Let U_t denote $E[H_t]$, the unconditional energy expectation, which can be interpreted as the total system energy at time t. Then by differentiating (16) we obtain

$$\frac{\partial U_t}{\partial t} = \frac{1}{2}\kappa^2((n+1)(\overline{H}-U_t)-\beta E[V_t]), \tag{17}$$

by use of the Laplace–Beltrami equation for H_t. This relation can be integrated to yield the solution for the time development of the system energy:

$$U_t = \overline{H} + (H_0 - \overline{H})e^{-(1/2)\kappa^2(n+1)t} - \frac{1}{2}\kappa^2\beta\int_0^t\int_\Gamma e^{(1/2)\kappa^2(n+1)(s-t)}V(x)\rho(x,s)dV\,ds. \tag{18}$$

In the limit $t\to\infty$ the only contribution is given by the trace term $\overline{H}$ and the integral of $V(x)$, and the resulting energy approaches the internal energy of the system in thermal equilibrium. In particular, in the high-temperature limit $\beta\to 0$ the contribution from $V(x)$ vanishes, and we recover the uniform average of the energy eigenvalues. In the low-temperature limit $\beta\to\infty$, the gradient term in the drift of (14) dominates, and the system is forced to fall to the ground state. It is interesting to observe, as a consequence of (17), that once thermal equilibrium is reached, we have the identity

$$kT^2C = \mathrm{Var}[H] + (n+1)kT(U-\overline{H}), \tag{19}$$

for the heat capacity $C=\partial U/\partial T$, where $\beta = 1/kT$ and $\mathrm{Var}[H]=(\Delta H)^2_\rho$ is the unconditional energy variance. This follows from the conditional variance formula,

$$\mathrm{Var}[H] = E[\mathrm{Var}_x[H]] + \mathrm{Var}[E_x[H]], \tag{20}$$

where $E_x[H]$ and $\mathrm{Var}_x[H]$ are, respectively, the conditional expectation and the conditional variance of the energy, when the system is in the pure state x. This relation expresses the total energy uncertainty by the sum of terms corresponding to quantum and thermal uncertainties.

As an illustration, consider the case of a spin one-half particle in a heat bath. The state space is CP^1, which we view as a 2-sphere, the north and the south poles corresponding to the upper and lower energy eigenstates, with energies $+h$ and $-h$, where h is the magnetic moment of the particle times the external field strength. The symplectic flow gives rise to latitudinal circular orbits on the sphere, while the gradient flow is in the direction along the great circles passing through the two eigenstates, pushing the state toward the south pole. The equilibrium energy latitude is obtained by balancing the gradient flow and the Brownian fluctuations. If we let θ denote the angular coordinate for the state as measured from the north pole, then the squared energy uncertainty, given that the system is in a pure state at latitude θ, is $\mathrm{Var}_\theta[H]=h^2\sin^2\theta$. The conditional energy expectation is $E_\theta[H]=h\cos\theta$. Since $\overline{H}$ vanishes, the only contribution to the energy in (18) is from the volume integral, which gives $U=\beta^{-1}-h\coth(\beta h)$, in agreement with the result of a direct calculation of $E[E_\theta[H]]$. At infinite temperature the system energy corresponds to that of the equator, whereas for a finite temperature the system energy corresponds to that of a latitude in the southern hemisphere. At zero temperature, the system collapses to the ground state.

V. ENTROPY PRODUCTION

Next we shall consider the dynamics of the total entropy of the system, given by $S_t = -\int_\Gamma \rho(x,t)\ln\rho(x,t)dV$. Without loss of generality, we can write

$$\rho(x,t) = \frac{\exp(-\beta(H(x)+\eta(x,t)))}{\int_\Gamma \exp(-\beta(H(x)+\eta(x,t)))dV}, \tag{21}$$

for a general density function, where $\eta(x,t)$ determines the departure from thermal equilibrium. Substituting this expression into the formula for S_t, and making use of the Fokker–Planck equation (11) with drift as in (14), we find

$$\frac{\partial S_t}{\partial t} = \frac{1}{2}\,\kappa^2\beta^2 \int_\Gamma (\nabla^a\eta\,\nabla_a H + \nabla^a\eta\,\nabla_a\eta)\rho\,dV. \tag{22}$$

On the other hand, for the total energy U_t we have

$$\frac{\partial U_t}{\partial t} = \frac{1}{2}\,\kappa^2\beta \int_\Gamma (\nabla^a\eta\,\nabla_a H)\rho\,dV. \tag{23}$$

Therefore, we obtain

$$\frac{\partial S_t}{\partial t} = \beta\,\frac{\partial U_t}{\partial t} + \frac{1}{2}\,\kappa^2\beta^2 \int_\Gamma (\nabla^a\eta\,\nabla_a\eta)\rho\,dV. \tag{24}$$

This is the general formula for the entropy production associated with the process (14), which shows that

$$\frac{\partial S_t}{\partial t} \geqslant \beta\,\frac{\partial U_t}{\partial t}, \tag{25}$$

in all circumstances. In particular, if U_t increases as a consequence of heating, then the entropy of the system also necessarily increases.

VI. EVOLUTION OF THE DENSITY MATRIX

Finally, we derive the dynamics of the density matrix $\rho^\alpha_\beta(t)$ associated with the process (14). Let us revert to the use of homogeneous coordinates for the state space CP^n, and write $\Pi^\alpha_\beta(x) = \psi^\alpha(x)\overline{\psi}_\beta(x)/\psi^\gamma(x)\overline{\psi}_\gamma(x)$ for the projection operator onto the pure state $x\in\Gamma$ represented by the Hilbert space vector $\psi^\alpha(x)$. From Eqs. (7) and (10) it follows that for a general (possibly nonlinear) observable $\phi(x)$ on Γ we have

$$\frac{\partial}{\partial t}\,E[\phi(x_t)] = \int_\Gamma \left(2\Omega^{ab}\nabla_a\phi\,\nabla_b H + \frac{1}{2}\,\kappa^2\nabla^2\phi - \frac{1}{2}\,\kappa^2\beta g^{ab}\,\nabla_a\phi\,\nabla_b H \right)\rho(x,t)dV. \tag{26}$$

However, if $\phi(x)$ is given, more specifically, by the conditional expectation of an ordinary linear quantum mechanical observable ϕ^α_β, then $\phi(x) = \phi^\beta_\alpha\Pi^\alpha_\beta(x)$. Thus, for a linear observable we have $E[\phi(x_t)] = \phi^\beta_\alpha\rho^\alpha_\beta(t)$, where

$$\rho^\alpha_\beta(t) = \int_\Gamma \Pi^\alpha_\beta(x)\rho(x,t)dV \tag{27}$$

is the time-dependent density matrix associated with the state $\rho(x,t)$. To obtain the equation of motion for $\rho^\alpha_\beta(t)$ we need to evaluate the three terms in the integrand on the right of (26). These are given as follows. For the commutator term we have

$$\Omega^{ab}\,\nabla_a\phi\,\nabla_b H = \tfrac{1}{2}i(\phi^\beta_\gamma H^\gamma_\alpha - H^\beta_\gamma\phi^\gamma_\alpha); \tag{28}$$

for the term involving the Laplace–Beltrami operator we find

$$\nabla^2\phi = (\phi^\gamma_\gamma\delta^\beta_\alpha - (n+1)\phi^\beta_\alpha)\Pi^\alpha_\beta, \tag{29}$$

and for the anticommutator term we obtain

$$g^{ab}\,\nabla_a\phi\,\nabla_b H = \tfrac{1}{2}(\phi^\beta_\gamma H^\gamma_\alpha + H^\beta_\gamma\phi^\gamma_\alpha)\Pi^\alpha_\beta - (\phi^\beta_\alpha H^\delta_\gamma)\Pi^\alpha_\beta\Pi^\gamma_\delta. \tag{30}$$

Inserting these expressions into (26), and noting that the result must hold for arbitrary ϕ_α^β, we deduce that

$$\frac{\partial}{\partial t}\rho_\beta^\alpha = i[H_\gamma^\alpha\rho_\beta^\gamma - \rho_\gamma^\alpha H_\beta^\gamma] - \frac{1}{4}\kappa^2\beta(H_\gamma^\alpha\rho_\beta^\gamma + \rho_\gamma^\alpha H_\beta^\gamma) + \frac{1}{2}\kappa^2(\delta_\beta^\alpha - (n+1)\rho_\beta^\alpha + \beta H_\gamma^\delta\rho_{\beta\delta}^{\alpha\gamma}). \quad (31)$$

Here the density matrix $\rho_\beta^\alpha(t)$ is given by (27), the first moment of the projection operator $\Pi_\beta^\alpha(x)$, whereas $\rho_{\alpha\gamma}^{\beta\delta}(t)$ is the second moment of $\Pi_\beta^\alpha(x)$, given by

$$\rho_{\beta\delta}^{\alpha\gamma}(t) = \int_\Gamma \Pi_\beta^\alpha(x)\Pi_\delta^\gamma(x)\rho(x,t)dV. \quad (32)$$

Equation (31) is the dynamical law for the density operator, which takes an arbitrary initial state into an equilibrium state, with heat bath temperature *T*. The first term on the right of (31) leads to the Liouville equation of linear quantum dynamics, while the general nonequilibrium process has a richer structure. The emergence of the second moment term in (31) can also be interpreted by analogy with the renormalization group equations.

VII. DISCUSSION

The model we have described here is surprisingly tractable, and has many attractive features. Experimental support could be pursued in two stages. First, we point out that it is not difficult, in the case of the canonical Γ ensemble, to derive explicit formulas for the partition function $Z(\beta)$, the state density $\Omega(E)$, the density matrix ρ_β^α, and the second moment $\rho_{\beta\delta}^{\alpha\gamma}$. If these results turn out to give a better account of equilibrium phenomena than the conventional approach in some contexts, then the next step would be to look for effects resulting from the higher moment term in the nonequilibrium dynamical law (31).

In this paper we are devoted to proving the existence and nonexistence of self-dual equations arising in Chern–Simons–Higgs theory with a constant electric charge density. There are three kinds of boundary conditions that admit solitonic structures. It is shown that there exist solutions in two cases of them. In the other case, we prove that there is a critical electric charge density with negative value such that above the value there exists a solution and below it we have no solution. We also study asymptotic behaviors for solutions as the electric charge density goes to zero. It is found that they converge to solutions of a topological Chern–Simons system without constant electric charge density.
[S0022-2488(99)01801-0]

I. INTRODUCTION

It is well known that the $(2+1)$ Chern–Simons–Higgs model without a Maxwell term admits vortex solutions. These Chern–Simons (CS) vortices, called anyons, are different from Nielsen–Olesen-type vortices, in that they carry electric charge as well as magnetic flux due to the CS term. A special choice for the potential $V(|\phi|)$ produces a Bogomol'nyi-type energy lower bound, which is achieved by fields satisfying a set of first-order differential equations, so-called self-dual equations.[1,2] The Maxwell–Higgs system has self-dual configurations only when the coupling constant is equal to some critical value, but in CS theory such configurations hold for all coupling constants. These equations possess topological and nontopological soliton solutions according to asymptotic behaviors of the Higgs field.[3] The mathematical existence results of topological multivortex solutions for those equations can be found in Refs. 4 and 5. Unlikely to the Maxwell–Higgs system, whether the solution is uniquely determined by the zeros of the Higgs field remains open. In the nontopological case the existence of radially symmetric solutions was established in Ref. 6, and a rigorous result of the existence of arbitrary vortex solutions is established recently in Ref. 7. On the other hand, it is still open whether the first-order equations are equivalent to the second-order equations (the Euler–Lagrange equations of the energy functional).

An interesting generalization of such self-dual models arises when the system is coupled to an external charge density or an external magnetic field. For example, the Maxwell–Higgs system with the background electric charge density is more closely related to the real superconductor rather than the system without it. In that case the self-dual equations can be reduced to those of the pure Maxwell–Higgs system.[8] In this paper we consider the self-dual Chern–Simons models coupled to an external background charge density introduced in Ref. 9. In this situation the self-dual equations are quite different from those of the system without the background electric charge density, as we shall see.

The Higgs field $\phi \in \mathbf{C}$ is coupled to a CS gauge field $A_\mu \in \mathbf{R}$. The gauge field is coupled to a

[a]Electronic mail: dhchae@math.snu.ac.kr
[b]Electronic mail: jmhan@math.snu.ac.kr
[c]Electronic mail: oleg@kias.kaist.ac.kr

constant background electric charge density ρ, so that the Lagrangian of the model can be written as

$$\mathcal{L}=\frac{\kappa}{2}\,\epsilon^{\mu\nu\rho}A_\mu\partial_\nu A_p+|D_\mu\phi|^2-U-\rho A_0, \tag{1.1}$$

where the self-dual potential is given by

$$U=\frac{1}{4\kappa^2}\,|\phi|^2(2|\phi|^2-\sigma)^2-\frac{\rho}{2\kappa}\,(2|\phi|^2-\sigma). \tag{1.2}$$

Here $D_\mu\phi=(\partial_\mu+iA_\mu)\phi$ and $\epsilon^{\mu\nu\rho}$ is a totally skew-symmetric tensor with $\epsilon^{012}=1$. The parameters σ and ρ can be either positive or negative, but we assume that the Chern–Simons coupling constant $\kappa>0$. The system is invariant under the local gauge transformation. The static energy of the system is given by

$$E=E(\phi,A)=\int_{\mathbf{R}^2}(|D_j\phi|^2+|\phi|^2A_0^2+U)\,dx, \tag{1.3}$$

with the Gauss' constraint (the variational equation with respect to A_0):

$$\kappa F_{12}+2|\phi|^2A_0-\rho=0, \tag{1.4}$$

where $F_{12}=\partial_1A_2-\partial_2A_1$ is the magnetic field. We shall consider cases where the background charge density ρ is canceled at spatial infinity by either magnetic field F_{12} or the Higgs charge density $-2|\phi|^2A_0$. The first class of sectors are called the symmetric phase and the latter the asymmetric phase. We will pay attention to the asymmetric phase so that we have the boundary condition $F_{12}\to 0$ as $|x|\to\infty$. Using Gauss' constraint and integrating by parts, we rewrite the energy as

$$E=\int_{\mathbf{R}^2}|D_1\phi-iD_2\phi|^2+|\phi|^2\left((A_0-\frac{1}{2\kappa}\,(2|\phi|^2-\sigma))^2\right)dx+\frac{\sigma}{2}\int_{\mathbf{R}^2}F_{12}\,dx. \tag{1.5}$$

We consider the excited states of finite total magnetic flux $\Psi=\int_{\mathbf{R}^2}F_{12}\,dx$, and for those configurations we find the following self-dual bound:

$$E\geqslant\frac{\sigma}{2}\,\Psi.$$

This self-dual bound is saturated by the following self-dual equations:

$$D_1\phi-iD_2\phi=0, \tag{1.6}$$

$$\kappa F_{12}+\frac{1}{\kappa}\,|\phi|^2(2|\phi|^2-\sigma)-\rho=0. \tag{1.7}$$

Let $\phi=fe^{i\theta}/\sqrt{2}$, $f\geqslant 0$. A self-dual vortex-like configuration always consists of antivortices only,

$$\theta=-\sum_{k=1}^{N}\ \arg(x-p_k)+\eta,$$

where p_k's are the positions of the antivortices, not necessarily distinct, and η is a single-valued smooth function. We may combine the coupled first-order equations (1.6), (1.7) to obtain a single second-order elliptic equation for f;

$$-\Delta\ \ln f^2+\sum_k\ 4\pi\delta(x-p_k)+\frac{1}{\kappa^2}\, f^2(f^2-\sigma)-\frac{2\rho}{\kappa}=0. \tag{1.8}$$

There are three cases of boundary conditions that admit solitonic structure. These are obtained from the consideration of $F_{12}\to 0$;

$$(\text{BC}\ \ 1)\quad \sigma>0,\quad \rho>0,\quad f^2\to(f_*)^2=\frac{\sigma+\sqrt{\sigma^2+8\kappa\rho}}{2},$$

$$(\text{BC}\ \ 2)\quad \sigma>0,\quad -\sigma^2/8\kappa<\rho<0,\quad f^2\to(f_*)^2=\frac{gj+\sqrt{\sigma^2+8\kappa\rho}}{2},$$

$$(\text{BC}\ \ 3)\quad \sigma<0,\quad \rho>0,\quad f^2\to(f_*)^2=\frac{\sigma+\sqrt{\sigma^2+8\kappa\rho}}{2}.$$

If the boundary condition is given by (BC1) or (BC2), then the substitution

$$\ln\left(\frac{f^2}{\sigma}\right)=u,\quad \text{i.e.,}\ \frac{f^2}{\sigma}=e^u, \tag{1.9}$$

transforms (1.8) into the following form:

$$\begin{gathered}\Delta u=\frac{\sigma^2}{\kappa^2}\, e^u(e^u-1)-\frac{2\rho}{\kappa}+\sum_\kappa\ 4\pi\delta(x-p_k),\quad \text{in}\ \mathbf{R}^2,\\ u\to u_*=\ln\left(\frac{f_*^2}{\sigma}\right),\quad \text{as}\ |x|\to\infty,\end{gathered} \tag{1.10}$$

and u_* satisfies

$$\frac{\sigma^2}{\kappa^2}\, e^{u_*}(e^{u_*}-1)-\frac{2\rho}{\kappa}=0. \tag{1.11}$$

Let

$$v=u-u_*.$$

Then by (1.10) and (1.11) we have

$$\begin{gathered}\Delta v=\frac{\sigma^2}{\kappa^2}\, e^{2u_*}(e^v-1)(e^v+1-e^{-u_*})+\sum_k\ 4\pi\delta(x-p_k),\quad \text{in}\ \mathbf{R}^2,\\ v\to 0,\quad \text{as}\ |x|\to\infty.\end{gathered} \tag{1.12}$$

When the boundary condition is given by (BC3), a similar substitution is possible, and it will be induced in Sec. IV.

We state the main theorem.

Theorem 1.1: *Let $p_1,p_2,\dots,p_N$ be arbitrary points in $\mathbf{R}^2$ not necessarily distinct. Then the equations (1.6) and (1.7) with boundary conditions (BC1) or (BC3) have a solution (ϕ,A) so that the zeros of ϕ are exactly $p_1,p_2,\dots,p_N$ and the corresponding energy $E(\phi,A)$ is finite. Moreover, the energy E and the magnetic flux Ψ are quantized as*

$$E=2\sigma\pi N\quad \text{and}\quad \Psi=4\pi N. \tag{1.13}$$

If the boundary condition is given by (BC2), there is a critical electric charge density ρ_0 *depending on N so that (1.6) and (1.7) have a finite energy solution* (ϕ,A) *for all* $\rho_0<\rho<0$ *with zeros of* ϕ *being* $p_1,p_2,\ldots,p_N$ *and there holds (1.13), while we have no solution for all* ρ *satisfying* $-\sigma^2/8\kappa<\rho<\rho_0$.

When the boundary condition is given by (BC1) or (BC3), the existence of solutions are to be shown in Sec. II and IV by virtue of the super- and subsolution method. The existence and nonexistence for the case (BC2) are to be shown in Sec. III. In Sec. V we prove that solutions of (1.10) converge to solutions of topological CS vortex equations as ρ goes to 0.

For notations we denote the $L^2(\mathbf{R}^2)$-norm by $\|\cdot\|_2$. We use the notation $H^k(\mathbf{R}^2)=W^{k,2}(\mathbf{R}^2)$ for $k\in\mathbf{Z}$ as Sobolev spaces.

II. Existence in the case (BC 1)

In this section we proceed with the boundary condition (BC 1). If we define

$$u_0=-\sum_k \ln(1+|x-p_k|^{-2}),\quad \mu>0,$$

the substitution $w=v-u_0$ gives the following form:

$$\Delta w=\frac{\sigma^2}{\kappa^2}e^{2u_*}(e^{u_0+w}-1)(e^{0+w}+1-e^{-u_*})+g,\quad \text{in } \mathbf{R}^2,$$
$$w\to 0,\quad \text{as } |x|\to\infty, \tag{2.1}$$

where $u_*>0$ and

$$g=4\sum_k (1+|x-p_k|^2)^{-2}.$$

We will construct a solution to (2.1) by an iteration scheme. First of all, we recall some results in the Abelian Higgs model.

Theorem 2.1: *Consider the following equation:*

$$\Delta u=a(e^u-1)+\sum_{k=1}^N 4\pi\delta(x-p_k),\quad in\ \mathbf{R}^2,$$
$$u\to 0,\quad as\ |x|\to\infty, \tag{2.2}$$

where a is a positive constant. Let $u=u_0+w$ *and rewrite (2.2) as*

$$\Delta w=a(e^{u_0+w}-1)+g,\quad in\ \mathbf{R}^2,$$
$$w\to 0,\quad as\ |x|\to\infty. \tag{2.3}$$

Then (2.3) admits a unique solution in $C^\infty(\mathbf{R}^2)\cap H^k(\mathbf{R}^2)$ *for all* $k\geq 2$ *satisfying* $u_0+w<0$. *Moreover, for given* $0<\delta<1$ *there exists a constant* $M=M(a,\delta)$ *and* $m=m(a,\delta)$ *so that*

$$0<1-e^{u_0+w}\leq M\exp(-(1-\delta)m|x|). \tag{2.4}$$

Proof: See Ref. 10, Chap. 3.

Theorem 2.2: *There is a solution* $\bar{w}$ *to (2.1) satisfying* $\bar{w}\in C^\infty(\mathbf{R}^2)\cap H^k(\mathbf{R}^2)$ *for all* $k\geq 2$.

Proof: Let us consider the unique solutions U and W satisfying

$$\Delta U=\frac{\sigma^2}{\kappa^2}\, e^{2u_*}(1-e^{-u_*})(e^{u_0+U}-1)+g, \quad \text{in } \mathbf{R}^2,$$
$$U\to 0, \quad \text{as } |x|\to\infty, \tag{2.5}$$

and

$$\Delta W=\frac{\sigma^2}{\kappa^2}\, e^{2u_*}(2-e^{-u_*})(e^{u_0+W}-1)+g, \quad \text{in } \mathbf{R}^2,$$
$$W\to 0, \quad \text{as } |x|\to\infty. \tag{2.6}$$

It is easily checked that U and W are sub- and supersolutions to (2.1), respectively, and satisfy the inequality $U\leqslant W$.

Choosing a constant $K>2e^{2u_*}\sigma^2/\kappa^2$, we define the following iterative sequence:

$$\Delta w_{n+1}-Kw_{n+1}=\frac{\sigma^2}{\kappa^2}\, e^{2u_*}(e^{u_0+w_n}-1)(e^{u_0+w_n}+1-e^{-u_*})+g-Kw_n^-,$$
$$w_{n+1}\to 0, \quad \text{as } |x|\to\infty, \tag{2.7}$$
$$w_0=W.$$

For $n=1$,

$$\Delta w_1-Kw_1=\frac{\sigma^2}{\kappa^2}\, e^{2u_*}(e^{u_0+w_0}-1)(e^{u_0+w_0}+1-e^{-u_*})+g-Kw_0\in L^2(\mathbf{R}^2). \tag{2.8}$$

Here we used the fact that $u_0+w_0\in L^2$ and $|e^{u_0+w_0}-1|\leqslant|u_0+w_0|$, which follows from the fact that $u_0+w_0\leqslant 0$. Since $\Delta-K:H^2(\mathbf{R}^2)\to L^2(\mathbf{R}^2)$ is bijective, there exists $w_1\in H^2(\mathbf{R}^2)$ satisfying (2.8) so that w_1 goes to 0 as $|x|\to\infty$. Inductively $w_n\in H^2(\mathbf{R}^2)$ is well defined and vanishes at infinity.

Using standard iteration methods and a maximum principle, we find out that there exists a unique function $\overline{w}\in L^2(\mathbf{R}^2)$ satisfying

$$U\leqslant\overline{w}\leqslant\cdots\leqslant w_n\leqslant\cdots\leqslant w_1\leqslant w_0=W,$$

so that $w_n\to\overline{w}$ in $H^2(\mathbf{R}^2)$ and $\overline{w}\to 0$ as $|x|\to\infty$. Consequently, $\overline{w}$ is a solution to (2.1), and standard elliptic arguments show that $\overline{w}\in C^\infty(\mathbf{R}^2)\cap H^k(\mathbf{R}^2)$ for all $k\geqslant 2$. □

We can also construct an iterative sequence from below using the subsolution (2.5). Let us consider the following equation:

$$\Delta\tilde{w}_{n+1}-K\tilde{w}_{n+1}=\frac{\sigma^2}{\kappa^2}\, e^{2u_*}(e^{\tilde{w}_n+u_0}-1)(e^{\tilde{w}_n+u_0}+1-e^{-u_*})+g-K\tilde{w}_n,$$
$$\tilde{w}_{n+1}\to 0, \quad \text{as } |x|\to\infty, \tag{2.9}$$
$$\tilde{w}_0=U.$$

The constant K satisfies the inequality $K>2e^{2u_*}\sigma^2/\kappa^2$. Then as above we can find a solution to (2.1) $\underline{w}\in C^\infty(\mathbf{R}^2)\cap H^k(\mathbf{R}^2)$ for all $k\geqslant 2$, so that

$$U=\tilde{w}_0\leqslant\tilde{w}_1\leqslant\cdots\leqslant\underline{w}\leqslant W.$$

Proposition 2.3: Any solutions of (2.1) obtained by the iteration methods (2.7) are maximal in the $C^2(\mathbf{R}^2)$-solution class. In particular, the solutions $\overline{w}$ via iteration (2.7) are independent of K. Similarly $\underline{w}$ is a minimal solution and independent of K.

Proof: Let w be any given solution in $C^2(\mathbf{R}^2)$. It suffices to show that $w \leqslant w_n$ for all n, where w_n is given by (2.7). Let $u = u_* + u_0 + w$. We observe that $u \leqslant u_*$. Otherwise, $u(x') > u_*$ at the maximum point x' of u and $\Delta u(x') \leqslant 0$. But then

$$\Delta u(x') > \frac{\sigma^2}{\kappa^2} e^{u_*}(e^{u_*}-1) - \frac{2\rho}{\kappa} + \sum_k 4\pi\delta(x'-p_k) \geqslant 0,$$

a contradiction. Since $u_0 + w = u - u_* \leqslant 0$,

$$\Delta w \geqslant \frac{\sigma^2}{\kappa^2} e^{2u_*}(2-e^{-u_*})(e^{u_0+w}-1)+g,$$

and thus

$$\Delta(w-w_0) \geqslant \frac{\sigma^2}{\kappa^2} e^{2u_*}(2-e^{-u_*})(e^{u_0+w}-e^{u_0+w_0}) = \frac{\sigma^2}{\kappa^2} e^{2u_*}(2-e^{-u_*})e^{u_0+w'}(w-w_0),$$

for some w' between w and w_0. Hence $w \leqslant w_0$. Now suppose that $w \leqslant w_k$ for all $0 \leqslant k \leqslant n$. Then

$$(\Delta - K)(w-w_{n+1}) = \frac{\sigma^2}{\kappa^2} e^{2u_*+2u_0}(e^{2w}-e^{2w_n}) - \frac{\sigma^2}{\kappa^2} e^{u_*+u_0}(e^{w}-e^{w_n}) - K(w-w_n)$$

$$\geqslant K(e^{2u_0+2w'}-1)(w-w_n) \geqslant 0.$$

So $w \leqslant w_{n+1}$. □

Theorem 2.4: *Let w be any solution to (2.1). Then, given $0<\delta<1$, there are positive constants $M = M(w,\delta)$ and $m = m(w,\delta)$, so that*

$$0 < 1 - e^{u_0+w} \leqslant M \exp(-(1-\delta)m|x|). \tag{2.10}$$

Proof: By Theorem 2.1, there exist constants $M_1 = M_1(\overline{w},\delta)$, $M_2 = M_2(\underline{w},\delta)$, $m_1 = m_1(\overline{w},\delta)$, and $m_2 = m_2(\underline{w},\delta)$, so that

$$1 - e^{u_0+\overline{w}} \leqslant M_1 \exp(-(1-\delta)m_1|x|), \tag{2.11}$$

$$1 - e^{u_0+\underline{w}} \leqslant M_2 \exp(-(1-\delta)m_2|x|). \tag{2.12}$$

Since $\underline{w} \leqslant w \leqslant \overline{w}$, estimates (2.11) and (2.12) give (2.10). □

Now given any solution w to (2.1), we can construct a solution pair (ϕ,A) to (1.6) and (1.7) by standard arguments.[10] In fact, we have

$$\phi = \frac{1}{\sqrt{2}} f e^{i\theta} = \frac{\sqrt{\sigma}}{\sqrt{2}} \exp\left((u_0+w+u_*)/2 - i\sum_{k=1}^{N} \arg(x-p_k) \right), \tag{2.13}$$

$$A_1 = -2\,\mathrm{Re}(i\overline{\partial} \ln \overline{\phi}), \quad A_2 = -2\,\mathrm{Im}(i\overline{\partial} \ln \overline{\phi}), \tag{2.14}$$

where $\overline{\partial} = (\partial_1 + i\partial_2)/2$. We show that these solution pairs (ϕ,A) of the self-dual equations (1.6) and (1.7) are indeed of finite energy.

Theorem 2.5: *Let (ϕ,A) be any solution pairs of (1.6) and (1.7) with the boundary condition (BC1). Then (ϕ,A) is of finite energy, i.e., $E(\phi,A)<\infty$. Furthermore, the energy E and the magnetic flux Ψ are quantized as*

$$E=2\sigma\pi N \quad and \quad \Psi=4\pi N. \tag{2.15}$$

Proof: Since $u \leqslant u_*$ (Proposition 2.3), it follows that $f^2 \leqslant f_*^2$. For given $0<\delta<1$, Theorem 2.4 states that

$$0 \leqslant f_*^2 - f^2 \leqslant f_*^2 M \exp(-(1-\delta)m|x|), \tag{2.16}$$

for some positive constants M and m. From (1.4) and (1.7) it turns out that

$$f^2 A_0^2 = \frac{1}{4\kappa^2} f^2(f^2-\sigma)^2,$$

and hence

$$\frac{1}{2} f^2 A_0^2 + U = \frac{1}{4\kappa^2} f^2(f^2-\sigma)^2 - \frac{\rho}{2\kappa}(f^2-\sigma) = \frac{1}{4\kappa^2}(f_*^2-f^2)(f^2-\sigma)(f_*^2+f^2-\sigma).$$

This equation, combined with (2.16) and the fact that $f^2 \leqslant f_*^2$, yields

$$|\phi|^2 A_0^2 + U = \tfrac{1}{2} f^2 A_0^2 + U \in L^1(\mathbf{R}^2).$$

Next, using (1.6), we find that

$$|D_j\phi|^2 = \tfrac{1}{2}(\partial_j f\ )^2 + \tfrac{1}{2} f^2(\partial_j\theta + A_1)^2 = \tfrac{1}{2}|\nabla f|^2.$$

Since $f=\sqrt{\sigma}e^{u/2}=\sqrt{\sigma}e^{u_*/2}e^{(u_0+w)/2}$, we have

$$\partial_j f = \tfrac{1}{2}\sqrt{\sigma}e^{u_*/2}(\partial_j u_0 e^{u_0/2}\cdot e^{w/2} + \partial_j w \cdot e^{(u_0+w)/2}) \in L^2(\mathbf{R}^2).$$

Therefore $|D_1\phi|^2 + |D_2\phi|^2 = |\nabla f|^2 \in L^1(\mathbf{R}^2)$.

For the proof of (2.15) we return to the equation (2.1) and rewrite (2.1) as the following form:

$$\Delta w = F(e^{u_0+w}) + g.$$

Letting $v=u_0+w$, we have

$$\Delta \partial_j v = F'(e^v)\partial_j v,$$

for all $|x|>\sup|p_k|$. Since $F'(1)>0$, there exist constants $R>\sup|p_k|$ and $m>0$, such that $F'(e^v)\geqslant m$ for all $|x|\geqslant R$. Using a suitable comparison function, we can show that $\partial_j v$ is exponentially decreasing. Consequently, integrating (2.1), we get

$$\int_{\mathbf{R}^2} F(e^{u_0+w})dx = -4\pi N. \tag{2.17}$$

Now the equations (1.7) and (2.17) give (2.15). □

III. Existence and nonexistence in the case (BC2)

A similar background substitution of (1.12) as in Sec. II gives the final form of the equation with the boundary condition (BC2);

$$\Delta w=\frac{\sigma^2}{\kappa^2}e^{2u_*}(e^{u_0+w}-1)(e^{u_0+w}+1-e^{-u_*})+g,\quad \text{in } \mathbf{R}^2,$$
$$w\to 0,\quad \text{as } |x|\to\infty, \tag{3.1}$$

where

$$-\ln 2<u_*<0,$$

$$u_0=-\sum_k \ln(1+|x-p_k|^{-2}),$$

$$g=4\sum_k (1+|x-p_k|^2)^{-2}.$$

We rewrite (3.1) as

$$\Delta w=\lambda(e^{u_0+w}-1)^2+\lambda(1-\epsilon)(e^{u_0+w}-1)+g. \tag{3.2}$$

Here

$$\lambda=\lambda(\epsilon)=\frac{\sigma^2}{\kappa^2}e^{2u_*},\quad \epsilon=e^{-u_*}-1.$$

We note that $0<\epsilon<1$ and $0\leqslant\lambda<\lambda_0=\sigma^2/\kappa^2$.

Theorem 3.1: *For all sufficiently small $\epsilon>0$, (3.2) has a maximal solution $w\in C^\infty(\mathbf{R}^2)\cap H^k(\mathbf{R}^2)$ for all $k\geqslant 2$. There exist positive constants $R=R(\epsilon)$, $C=C(\epsilon)$, and $m=m(\epsilon)$ such that*

$$0\leqslant 1-e^{u_0+w}\leqslant Ce^{-m|x|},$$

for all $|x|\geqslant R$. Furthermore, the corresponding solution pair (ϕ,A) given by (2.13) and (2.14) is of finite energy and there holds (1.13).

Proof: Without loss of generality we may assume $0<\epsilon<1/2$ so that

$$\frac{4}{9}\lambda_0<\lambda<\lambda_0 \text{ and } \frac{\lambda}{2}(1-\epsilon)>\frac{1}{9}\lambda_0.$$

Let $R_0=2\sup_k|p_k|$ and choose a smooth function $\tilde{g}:\mathbf{R}^2\to\mathbf{R}$ so that $0\leqslant\tilde{g}\leqslant\lambda_0$, $\operatorname{supp}\tilde{g}\subset B(0,2R_0)$, and $\tilde{g}=\lambda_0$ on $B(0,R_0)$. Let us consider the following equation:

$$\Delta g=\frac{\lambda_0}{9}e^{u_0+q}(e^{u_0+q}-1)+g+\tilde{g},\quad \text{in } \mathbf{R}^2,$$

$$q\to 0,\quad \text{as } |x|\to\infty.$$

This is a slight variation of the topological CS equation and its existence result is established in Refs. 4 and 5.

For $|x|\leqslant R_0$ we have

$$\Delta q\geqslant\lambda(1-\epsilon)e^{u_0+q}(e^{u_0+q}-1)+g+\lambda_0\geqslant\lambda(e^{u_0+q}-1)^2+\lambda(1-\epsilon)(e^{u_0+q}-1)+g.$$

Since $u_0+q\to 0$ as $|x|\to\infty$, there exists $\epsilon_0=\epsilon_0(N)>0$ depending only on the number of vortices so that $e^{u_0+q}\geqslant 2\epsilon_0$ for $|x|\geqslant R_0$. Hence, if $0<\epsilon<\epsilon_0$, then

$$e^{u_0+q} \geqslant \frac{2\epsilon}{1+\epsilon},$$

which implies that for $|x| \geqslant R_0$,

$$\Delta q \geqslant \lambda(1-\epsilon)e^{u_0+q}(e^{u_0+q}-1)+g-\frac{\lambda}{2}(1-\epsilon)e^{u_0+q}(e^{u_0+q}-1)$$
$$\geqslant \lambda(e^{u_0+q}-1)^2+\lambda(1-\epsilon)(e^{u_0+q}-1)+g.$$

Consequently, q is a subsolution to $(3.2)_\epsilon$ for all $\epsilon \in (0,\epsilon_0)$. Since $-u_0$ is a supersolution, we can use monotone iteration techniques to obtain a maximal solution to (3.2).

It remains to show that the corresponding solution pair (ϕ,A) is of finite energy. Let $v=u_0+w \leqslant 0$. Then v goes to 0 as $|x| \to 0$, and since $0<\epsilon<1$, there is a constant $R>\sup_k|p_k|$ such that $-(1-\epsilon)/2 \leqslant v \leqslant 0$ and $e^v \geqslant 1/2$, if $|x| \geqslant R$.

For $|x| \geqslant R$, (3.2) can be rewritten as

$$\Delta v = \lambda(e^v-1)^2+\lambda(1-\epsilon)(e^v-1)$$
$$= \lambda e^{v'} v[e^{v'}v+(1-\epsilon)] \quad (v \leqslant v' \leqslant 0)$$
$$\leqslant \frac{\lambda(1-\epsilon)}{4} v \equiv m^2 v. \tag{3.3}$$

Comparing (3.3) with the function $Ce^{-m|x|}$, by a maximum principle we find that

$$-Ce^{-m|x|} \leqslant v \leqslant 0,$$

for $|x| \geqslant R$. Here $C=C(\epsilon)=-e^{mR}\inf\{v(x):|x|=R\}$. Hence

$$1-e^v \leqslant |v| \leqslant Ce^{-m|x|}.$$

As a consequence, we can prove as in Theorem 2.5 that $E(\phi,A)<\infty$ and the quantization (1.13) holds. □

Corollary 3.2: Let $0<\tilde{\epsilon}<1$ *be given so that there exist a solution* $\tilde{w}$ *to* $(3.2)_{\tilde{\epsilon}}$. *Then* $(3.2)_\epsilon$ *has a solution for each* $0<\epsilon<\tilde{\epsilon}$. *Consequently, there exists a critical number* $\epsilon_0=\epsilon_0(N) \in (0,1]$ *depending only on the number of vortices such that* $(3.2)_\epsilon$ *has a solution for all* $\epsilon \in (0,\epsilon_0)$ *and no solution for all* $\epsilon \in (\epsilon_0,1)$.

Proof: We see that $\tilde{w}$ is a subsolution to $(3.2)_\epsilon$. Thus we can construct a solution to $(3.2)_\epsilon$ by iteration arguments. □

Our next aim is to show that $\epsilon_0(N)$ is less than 1. Indeed, (3.2) has no solution when $\epsilon=1$. Since g is strictly positive, we may expect that (3.2) has no solution for all ϵ sufficiently close to 1. We first prove that $\epsilon_0(1)<1$, showing the nonexistence of a radially symmetric solution of an auxiliary equation by a shooting argument.

Theorem 3.3: *Suppose that* $N=1$ *and the vortex point is the origin. Then* $\epsilon_0(1)<1$.

Proof: We assume that $\epsilon \geqslant \frac{1}{2}$ and the vortex point is the origin. To clarify the dependence of the equation on ϵ, we rewrite (3.2) as

$$\Delta w_\epsilon = \lambda_\epsilon(e^{u_1+w_\epsilon}-1)^2+\lambda_\epsilon(1-\epsilon)(e^{u_1+w_e}-1)+g_1,$$
$$w_\epsilon \to 0, \quad \text{as } |x| \to \infty, \tag{3.4}$$

where

$$u_1=-\ln(1+|x|^{-2}), \quad g_1=4/(1+|x|^2)^2, \quad \lambda_\epsilon=\frac{\sigma^2}{\kappa^2}\frac{1}{(1+\epsilon)^2}.$$

Let us consider the function

$$f_\epsilon(a)=\lambda_\epsilon(e^a-1)^2+\lambda_\epsilon(1-\epsilon)(e^a-1).$$

We construct a function

$$h_\epsilon(a)=\begin{cases} m_\epsilon, & -\infty<a\leqslant -1,\\ f_\epsilon(a), & -1<a<\infty\end{cases}$$

where $m_\epsilon=f_\epsilon(-1)\geqslant m_0$ for some $m_0>0$ independent of ϵ. To prove the theorem we need the following lemma.

Lemma 3.4: There exists $\epsilon_1\in(0,1)$ *such that there is no radially symmetric solution of*

$$\Delta b_\epsilon=h_\epsilon(b_\epsilon)+4\pi\delta(x),\quad b_\epsilon\to 0,\quad as\quad |x|\to\infty, \tag{3.5}$$

for all $\epsilon\in(\epsilon_1,1)$.

Proof of lemma: The proof is given by contradiction. Let us assume that there is a solution to (3.5). We drop the subscript ϵ for simplicity. It is easily seen by a maximum principle that $b(x)<0$ for all $x\neq 0$. By definition of h, there exists $r_0=r_0(\epsilon)>0$ such that

$$\Delta b=m+4\pi\delta(x),\quad \text{for } |x|\leqslant r_0. \tag{3.6}$$

But the solution of (3.6) is given by the following form:

$$b(x)=2\ln|x|+\tfrac{1}{4}m|x|^2+H(x), \tag{3.7}$$

where $H(x)$ is harmonic in $B(0,r_0)$. Furthermore, by definition of h we also have the boundary condition

$$b(r_0)=-1,$$

and the harmonic function in (3.7) becomes $H(x)=\text{const}$. Since

$$\frac{\partial b}{\partial r}(r_0)=\frac{2}{r_0}+\frac{1}{2}mr_0,$$

we have

$$\frac{\partial b}{\partial r}(r_0)\geqslant 2\sqrt{m}\geqslant 2\sqrt{m_0}. \tag{3.8}$$

Since $f(a)>0$ for $-\infty<a<\ln\epsilon$, there is $r_1=r_1(\epsilon)>r_0$ satisfying $b(r_1)=\ln\epsilon$ such that

$$\Delta b=f(b)\geqslant 0, \tag{3.9}$$

for $r_0\leqslant|x|\leqslant r_1$. We wish to estimate $(\partial b/\partial r)(r_1)$. Let us define a function,

$$\tilde{b}(x)=r_0\frac{\partial b}{\partial r}(r_0)\ln\frac{|x|}{r_0}-1,$$

for $|x|\geqslant r_0$. We observe that

$$\tilde{b}(r_0)=b(r_0)=-1, \tag{3.10}$$

$$\frac{\partial\tilde{b}}{\partial r}(r_0)=\frac{\partial b}{\partial r}(r_0). \tag{3.11}$$

Since $\Delta\tilde{b}=0$, using (3.9) and (3.11), we have

$$\frac{\partial b}{\partial r}(r)\geqslant\frac{\partial\tilde{b}}{\partial r}(r), \tag{3.12}$$

for $r_0\leqslant r\leqslant r_1$. Let $\hat{r}=\hat{r}(\epsilon)$ be given by $\tilde{b}(\hat{r})=0$. Since $b(r)$ is negative, it follows from (3.10) and (3.12) that $\hat{r}\geqslant r_1$. Noting that $\partial\tilde{b}/\partial r$ is monotonically decreasing, we find that

$$\frac{\partial b}{\partial r}(r_1)\geqslant\frac{\partial\tilde{b}}{\partial r}(r_1)\geqslant\frac{\partial\tilde{b}}{\partial r}(\hat{r}). \tag{3.13}$$

Since

$$\ln\frac{\hat{r}}{r_0}=\frac{2}{4+mr_0^2}\leqslant\frac{1}{2},$$

we have

$$\frac{1}{\sqrt{e}}\leqslant\frac{r_0}{\hat{r}}.$$

Consequently, (3.8) and (3.13) yield

$$\frac{\partial b}{\partial r}(r_1)\geqslant\frac{2\sqrt{m_0}}{\sqrt{e}}. \tag{3.14}$$

Now for $|x|\geqslant r_1$, we rewrite (3.5) in polar coordinates as

$$\frac{\partial}{\partial r}\left(r\frac{\partial b}{\partial r}\right)=rh(b).$$

Integrating both sides and using (3.14), we have

$$\frac{\partial b}{\partial r}(r)=\frac{r_1}{r}\frac{\partial b}{\partial r}(r_1)+\frac{1}{r}\int_{r_1}^{r}sh(b(s))ds\geqslant\frac{r_1}{r}\frac{2\sqrt{m_0}}{\sqrt{e}}-(r-r_1)\sup_{s\in[r_1,r]}|h(b(s))|.$$

Since $\sup_{x\leqslant 0}|h(x)|$ is uniformly bounded with respect to ϵ, we can find a number $\alpha>0$ and a constant $C_0>0$ independent of ϵ, satisfying

$$\frac{\partial b}{\partial r}(r)\geqslant C_0,$$

for all $r\in[r_1,r_1+\alpha]$. Since $b(r_1)=\ln\epsilon\to 0$ as $\epsilon\to 1$, we conclude that $b(r_1+\alpha)>0$ for all ϵ sufficiently close to 1, which contradicts the fact that $b(r)$ is negative. □

Let us assume that there exists a solution w_ϵ of (3.4) for $\epsilon\in(\epsilon_1,1)$. If we make substitutions $y_\epsilon=b_\epsilon-u_1$ in (3.5), we get

$$\Delta y_\epsilon=h_\epsilon(u_1+y_\epsilon)+g_1,\quad y_\epsilon\to 0,\quad \text{as } |x|\to\infty. \tag{3.15}$$

By Lemma 3.4 the equation (3.15) has no radially symmetric solution for $\epsilon\in(\epsilon_1,1)$. Let us drop ϵ for brevity. We shall construct a radially symmetric solution of (3.15), using w_ϵ, to conclude a contradiction. Let us define an iterative sequence,

$$\Delta y_{n+1} - K y_{n+1} = h(u_1 + y_n) + g_1 - K y_n,$$
$$y_{n+1} \to 0, \quad \text{as } |x| \to \infty, \tag{3.16}$$

where

$$y_0 = -u_1, \quad K = \|h'\|_\infty + 1.$$

Since the right-hand side of (3.16) is radially symmetric, the unique solution of (3.16) is also radially symmetric. It is easily checked that $y_1 \leqslant y_0$. Moreover, inductively we have

$$(\Delta - K)(y_{n+1} - y_n) = h(u_1 + y_n) - h(u_1 + y_{n-1}) - K(y_n - y_{n-1})$$
$$= (h'(u_1 + \xi) - K)(y_n - y_{n-1}) \geqslant 0,$$

where $y_n \leqslant \xi \leqslant y_{n-1}$. Thus, by the maximum principle $y_{n+1} \leqslant y_n$. Now let us show that w is a subsolution of (3.15). It is easily seen that $w \leqslant y_0$. Inductively,

$$(\Delta - K)(w - y_{n+1}) = f(u_1 + w) - h(u_1 + y_n) - K(w - y_n)$$
$$\geqslant h(u_1 + w) - h(u_1 + y_n) - K(w - y_n)$$
$$= (h'(\xi + u_1) - K)(w - y_n) \geqslant 0,$$

where $w \leqslant \xi \leqslant y_n$. Therefore $y_{n+1} \geqslant w$. Consequently, we get a sequence of radially symmetric functions satisfying

$$y_0 \geqslant y_1 \geqslant \cdots \geqslant w.$$

Then it is easy to show that y_n converges to a radially symmetric solution of (3.15), a contradiction to Lemma 3.4.

We recall from Corollary 3.2 that $\epsilon_0(1)$ is the maximal number satisfying that there exists a solution to (3.4) for all $\epsilon \in (0, \epsilon_0(1))$. Since there is no solution to (3.4) for $\epsilon \in (\epsilon_1, 1)$, we conclude that $\epsilon_0(1) \leqslant \epsilon_1 < 1$. □

Corollary 3.5: Suppose that the number of vortices is $N > 1$. Then $\epsilon_0(N) < 1$.

Proof: By Theorem 3.3 it suffices to show that $\epsilon_0(N) \leqslant \epsilon_0(1)$. Let $\epsilon \in (0, \epsilon_0(N))$ and w be a solution of (3.2). Then returning to (1.12), we have a solution v and

$$\Delta v \geqslant \frac{\sigma^2}{\kappa^2} e^{2u_*}(e^v - 1)(e^v + 1 - e^{-u_*}) + 4\pi\delta(x - p_1).$$

We may assume that $p_1 = 0$. Letting $\tilde{w} = v - u_1$, we see that $\tilde{w}$ is a subsolution of (3.4). Since $-u_1$ is a supersolution to (3.4), we can construct a solution to (3.4) by standard iterative schemes we have developed. Hence $\epsilon_0(N) \leqslant \epsilon_0(1) < 1$. □

IV. EXISTENCE IN THE CASE (BC3)

In the (BC3) case, if we transform σ into $-\sigma$ so that $\sigma > 0$, then the background substitution as in Sec. I gives

$$\Delta w = \frac{\sigma^2}{\kappa^2} e^{2u_*}(e^{u_0 + w} - 1)(e^{u_0 + w} + 1 + e^{-u_*}) + g, \quad \text{in } \mathbf{R}^2,$$
$$w \to 0, \quad \text{as } |x| \to \infty, \tag{4.1}$$
$$-\infty < u_* < \infty,$$

where

$$u_0=-\sum_k \ln(1+|x-p_k|^{-2}), \quad \mu>0,$$

$$g=4\sum_k (1+|x-p_k|^2)^{-2},$$

and u_* satisfies that

$$\frac{\sigma^2}{\kappa^2} e^{u_*}(e^{u_*}+1)-\frac{2\rho}{\kappa}=0.$$

As in Sec. II, we consider the following two equations:

$$\Delta U=\frac{\sigma^2}{\kappa^2} e^{2u_*}(2+e^{-u_*})(e^{u_0+U}-1)+g, \tag{4.2}$$

$$U\to 0, \quad \text{as } |x|\to\infty,$$

and

$$\Delta W=\frac{\sigma^2}{\kappa^2} e^{2u_*}(1+e^{-u_*})(e^{u_0+W}-1)+g,$$
$$W\to 0, \quad \text{as } |x|\to\infty. \tag{4.3}$$

Then it is easily checked that U and W are sub- and supersolutions of (4.1) as in Sec. II. Now, all existence results via an iteration process are parallel to the case (BC1) so that we achieve the following theorem.

Theorem 4.1: *There exist maximal and minimal solutions of (4.1) for all parameters $-\infty<u_*<\infty$ satisfying (2.10). For any solution of (4.1) the corresponding pair (ϕ,A) given by (2.13) and (2.14) is a finite energy solution of (1.6) and (1.7). Moreover, there holds (1.13).*

V. ASYMPTOTICS FOR SOLUTIONS AS $\rho\to 0$

In this section we study asymptotics for solutions to (1.10) when the boundary conditions are given by (BC1) or (BC2). We first recall the existence results of topological CS vortex equations.

Theorem 5.1: *Consider the following equation:*

$$\Delta u=ae^u(e^u-1)+\sum_{k=1}^N 4\pi\delta(x-p_k), \quad in \ \mathbf{R}^2,$$
$$u\to 0, \quad as \ |x|\to\infty, \tag{5.1}$$

where a is a positive constant. Let $u=u_0+w$ and rewrite (5.1) as

$$\Delta w=ae^{u_0+w}(e^{u_0+w}-1)+g, \quad in \ \mathbf{R}^2,$$
$$w\to 0, \quad as \ |x|\to\infty. \tag{5.2}$$

Then (5.2) admits a maximal solution in $C^\infty(\mathbf{R}^2)\cap H^k(\mathbf{R}^2)$ for all $k\geqslant 2$ satisfying $u_0+w<0$. Moreover, for given $0<\delta<1$ there exist a constant $M=M(a,\delta)$ such that

$$0<1-e^{u_0+w}\leqslant M \exp(-(1-\delta)\sqrt{a}|x|). \tag{5.3}$$

Proof: See Ref. 4.

We established maximal solutions w to (2.1) and (3.1) in Secs. II and III, and hence maximal solutions u to (1.10) for all sufficiently small $|\rho|$. To clarify the dependence of solutions on ρ let us denote the maximal solutions w_ρ and rewrite (2.1) and (3.1) as

$$\Delta w_\rho = \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}(e^{u_0+w_\rho}-1)(e^{u_0+w_\rho}+1-e^{-u_*^\rho})+g, \quad \text{in } \mathbf{R}^2,$$
$$w_\rho \to 0, \quad \text{as } |x|\to\infty. \tag{5.4}$$

Let us choose $\rho_1>0$ such that (5.4) has a maximal solution for all $|\rho|\leqslant\rho_1$. We notice that $w_{\tilde\rho} \leqslant w_\rho$ if $\tilde\rho\leqslant\rho$. In fact, the proof of Corollary 3.2 can also be applied to the case that one or two of ρ and $\tilde\rho$ are positive or negative. In the sequel, there exist two functions w^+ and w^- so that, for $\tilde\rho<0<\rho$,

$$w_{\tilde\rho}\leqslant w^-\leqslant w^+\leqslant w_\rho,$$

and $w_{\tilde\rho}$ and w_ρ converge pointwise and in $L^2(\mathbf{R}^2)$ to w^+ and w^-, respectively.

Theorem 5.2: *The functions w^+ and w^- are solutions of the following topological CS vortex equation 8*

$$\Delta w = \frac{\sigma^2}{\kappa^2} e^{u_0+w}(e^{u_0+w}-1)+g, \quad \textit{in } \mathbf{R}^2,$$
$$w\to 0, \quad \textit{as } |x|\to\infty, \tag{5.5}$$

and w_ρ converges in $H^k(\mathbf{R}^2)$ for all $k\geqslant 1$ to w^+ as $\rho\to 0+$ and w^- as $\rho\to 0-$. Moreover, w^+ is the maximal solution appearing in Theorem 5.1 with $a=\sigma^2/k^2$.

Proof: First, we prove the theorem for the case $\rho>0$. Suppose that $0<\tilde\rho<\rho$. Then

$$\Delta(w_\rho - w_{\tilde\rho}) = \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}(e^{u_0+w_\rho}-1)(e^{u_0+w_\rho}+1-e^{-u_*^\rho})$$
$$-\frac{\sigma^2}{\kappa^2} e^{2u_*^{\tilde\rho}}(e^{u_0+w_{\tilde\rho}}-1)(e^{u_0+w_{\tilde\rho}}+1-e^{-u_*^{\tilde\rho}}). \tag{5.6}$$

Multiplying $-(w_\rho - w_{\tilde\rho})$ on both sides of (5.6) and integrating by parts, we get

$$\int_{\mathbf{R}^2}|\nabla w_\rho - \nabla w_{\tilde\rho}|^2\,dx \leqslant C\int_{\mathbf{R}^2}(|e^{u_0+w_\rho}-1|+|e^{u_0+w_{\tilde\rho}}-1|)|w_\rho - w_{\tilde\rho}|dx$$
$$\leqslant C(\|e^{u_0+w_\rho}-1\|_2+\|e^{u_0+w_{\tilde\rho}}-1\|_2)\|w_\rho - w_{\tilde\rho}\|_2$$
$$\leqslant C\|e^{u_0+w_{-\rho_1}}-1\|_2\|w_\rho - w_{\tilde\rho}\|_2 \to 0.$$

Here $C>0$ is a constant that may vary at different places. The last inequality follows from the inequality

$$0<1-e^{u_0+w_\rho}\leqslant 1-e^{u_0+w_{-\rho_1}}.$$

Consequently, $w_\rho\to w^+$ in $H^1(\mathbf{R}^2)$. A differentiation of (5.6) gives

$$\Delta(\partial_j w_\rho - \partial_j w_{\tilde\rho}) = \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}\partial_j(u_0+w_\rho)e^{u_0+w_\rho}(2e^{u_0+w_\rho}-e^{-u_*^\rho})$$
$$-\frac{\sigma^2}{\kappa^2} e^{2u_*^{\tilde\rho}}\partial_j(u_0+w_{\tilde\rho})e^{u_0+w_{\tilde\rho}}(2e^{u_0+w_{\tilde\rho}}-e^{-u_*^{\tilde\rho}}).$$

Multiplying $-(\partial_j w_\rho - \partial_j w_{\tilde\rho})$ on both sides and integrating by parts, we obtain

$$\int_{\mathbf{R}^2}|\nabla(\partial_j w_\rho - \partial_j w_{\tilde\rho})|^2\, dx \leqslant C\int_{\mathbf{R}^2}(2|\partial_j u_0 e^{u_0}|+|\partial_j w_\rho|+|\partial_j w_{\tilde\rho}|)|\partial_j w_\rho - \partial_j w_{\tilde\rho}|dx$$
$$\leqslant C(\|\partial_j u_0\; e^{u_0}\|_2+\|\partial_j w_\rho\|_2+\|\partial_j w_{\tilde\rho}\|_2)\|\partial_j w_\rho - \partial_j w_{\tilde\rho}\|_2 \to 0.$$

Thus, $w_\rho \to w^+$ in $H^2(\mathbf{R}^2)$. Successively, it is shown that $w_\rho \to w^+$ in $H^k(\mathbf{R}^2)$ for all $k \geqslant 3$, and we are led to

$$\Delta w^+ = \frac{\sigma^2}{\kappa^2} e^{u_0+w^+}(e^{u_0+w^+-1})+g, \quad \text{in } \mathbf{R}^2,$$

$$w_\rho \to 0, \quad \text{as } |x|\to\infty.$$

This implies that w^+ is a solution to (5.5). Similarly, w^- is a solution to (5.5) and $w_\rho \to w^-$ in $H^k(\mathbf{R}^2)$ for all $k \to 1$ when $\rho < 0$.

To verify that w^+ is a maximal solution to (5.5), it suffices to prove that $w \leqslant w_\rho$ for given any solution w to (5.5) because $\{w_\rho\}$ is a decreasing sequence converging to w^+ for $\rho > 0$. We recall that for $\rho > 0$, w_ρ was constructed by the iterative sequence w_n^ρ defined by (2.7). Thus, it is enough to show that $w \leqslant w_n^\rho$ for all $k \geqslant 0$.

Let W^ρ be the unique solution of (2.6) corresponding to $\rho > 0$, satisfying

$$\Delta W^\rho = \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}(2-e^{-u_*^\rho})(e^{u_0+W^\rho}-1)+g, \quad \text{in } \mathbf{R}^2,$$

$$W^\rho \to 0, \quad \text{as } |x|\to\infty.$$

Since $u_*^\rho > 0$, we have

$$\Delta w \geqslant \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}(2-e^{-u_*^\rho})(e^{u_0+w}-1)+g.$$

Hence

$$\Delta(w - W^\rho) \geqslant \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}(2-e^{-u_*^\rho})e^{u_0+w'}(w-W^\rho),$$

for some w' between w and W^ρ. The maximum principle implies that $w \leqslant W^\rho = w_0^\rho$. Suppose that $w \leqslant w_k^\rho$ for all $0 \leqslant k \leqslant n$. Then

$$(\Delta - K)(w - w_{n+1}^\rho) \geqslant \frac{\sigma^2}{\kappa^2} e^{2u_*^\rho}e^{2u_0}(e^{2w}-e^{2w_n^\rho}) - \frac{\sigma^2}{\kappa^2} e^{u_*^\rho}e^{u_0}(e^{w}-e^{w_n^\rho}) - K(w-w_n^\rho)$$
$$\geqslant K(e^{2u_0+2w'}-1)(w-w_n^\rho) \geqslant 0,$$

where $w \leqslant w' \leqslant w_n^\rho \leqslant w_0^\rho$. Now the maximum principle verifies that $w \leqslant w_{n+1}^\rho$, which completes the proof of maximality of w^+. □

(Received 20 June 1997; accepted for publication 14 September 1998)

In this work we describe a general class of dispersive *N*-body Hamiltonians for which we prove the Hunziker, van Winter, and Zislin (HWZ) theorem and a Mourre estimate outside a closed and countable set of energies called thresholds. As a consequence of the Mourre estimate we prove a strong form of the limiting absorption principle, which implies the absence of a singular continuous spectrum and gives criteria of local smoothness. © *1999 American Institute of Physics.* [S0022-2488(99)00901-9]

I. INTRODUCTION

The basic Hamiltonian describing *N* nonrelativistic interacting particles is

$$H=\sum_{i=1}^{N}\frac{-1}{2m_i}\Delta_{x_i}+\sum_{i<j}V_{ij}(x_i-x_j)=\sum_{i=1}^{N}\frac{1}{2m_i}P_i^2+\sum_{i<j}V_{ij}(x_i-x_j),$$

where $x_i\in\mathbb{R}^3$, $m_i>0$ and $P_i=-i\nabla_{x_i}$ are the position, mass, and momentum of particle number *i*. Important results concerning the spectral theory of this type of Hamiltonian have been obtained during the last years (see Ref. 1). One of the oldest (but fundamental results, the theorem of Hunziker, van Winter, and Zislin (HWZ) concerning the essential spectrum of such an operator, has been established in Refs. 2–4; also see Refs. 5–6. This theorem says that the bottom of the essential spectrum of a nonrelativistic multiparticle operator is determined by the two-cluster decompositions of the system of particles. In Ref. 7 Lewis, Siedentop, and Vugalter show that the result still holds for multiparticle relativistic Hamiltonians too, in this case the kinetic energy $(1/2m_i)P_i^2$ being replaced by $(P_i^2+m_i^2)^{1/2}$.

A fundamental step in the study of more subtle spectral properties of *N*-body Schrödinger operators *H* is the proof that they obey a Mourre estimate at all nonthreshold points. The first proof of this result is due to Mourre, Ref. 8, for $N=3$ and to Perry, Sigal, and Simon, Ref. 9, for general *N*; these proofs were simplified afterward by Froese–Herbst, Ref. 10.

Our purpose here is to prove the HWZ theorem and the Mourre estimate (outside a set of points called thresholds) for a rather general class of *N*-body dispersive systems, i.e., for Hamiltonians of the form

$$H=h(P)+\sum_{i<j}V_{ij}(x_i-x_j),$$

where $P=-i\nabla$ and *h* is a function continuous and divergent at infinity.

In particular, the relativistic and nonrelativistic Hamiltonians are included. The class of interactions that we consider is sensibly more general than usual, e.g., they can be nonlocal and quite singular. In the case of relativistic operators the Coulomb potentials are allowed.

The first proof that a dispersive *N*-body operator satisfies a Mourre estimate is due to Derezinski, Ref. 11, but his hypotheses contain implicit conditions that are difficult to check on examples. After this, Gerard, Ref. 12, gave a new proof of the estimate for what he called ‘‘regular dispersive systems.’’ Both proofs are geometric in nature, being natural extensions of the proof of

Froese and Herbst. Also, the proof of the HWZ theorem in the relativistic case due to Lewis, Siedentop, and Vugalter follows the geometric ideas introduced by Zislin in this context (see Ref. 6).

In this paper we use quite different methods, namely, the C^*-algebra techniques introduced in Refs. 13–14 that require neither partitions of unity in configuration space nor equations of the Weinberg–van Winter type. The algebraic techniques allows us to prove in a rather simple way the main results of this paper (Theorems III.1 and IV.1) for a very general class of kinetic energies. For example, in the HWZ theorem h is an arbitrary continuous function such that $h(k)\to\infty$ as $|k|\to\infty$. For the Mourre estimate the only regularity condition that we need is that h be of class C^1 and $|kh'(k)|\leqslant c(1+|h(k)|)$ (plus positivity conditions of the same nature as those of Gerard). Moreover, the interaction terms of our Hamiltonians can be nonlocal operators. The results of Lewis, Siedentop, and Vugalter cover only relativistic particles with two-body local interactions. Gerard requires h to be a smooth symbol and the interactions to be multiplication operators.

As a consequence of the Mourre estimate we get the absence of singular continuous spectrum, discreteness of eigenvalues outside the thresholds, and local (outside the thresholds) H smoothness of operators decaying like $\langle x\rangle^{-s}$ for all $s>\frac{1}{2}$.

The organization of this paper is as follows. In Sec. II we introduce the algebraic framework in which our investigations will be done. The main results of Sec. III are Theorem III.1, which is a general criterion for an operator to be affiliated to the C^*-algebra $\mathcal{I}$, and the dispersive HWZ theorem. We also show that the N-body relativistic Hamiltonians with Coulomb interactions are covered by our general results. Section IV is devoted to the proof of the Mourre estimate for a rather general class of N-body dispersive systems. Our conditions (both on the kinetic energy and on the interactions) are of the same nature as those of Gerard, but are simpler and more general. In Sec. IV.4 we present several explicit examples of dispersive Hamiltonians verifying all our conditions. Finally, the Appendix contains a proof of the fact that the algebras $\mathcal{I}(a)$ we are using are independent of the choice of the spaces X^a.

II. PRELIMINARIES

II.1. Throughout this paper $\mathcal{L}$ denotes a finite lattice, i.e., a finite partially ordered set such that for any two elements $a,b\in\mathcal{L}$ their upper and lower bounds $a\vee b, a\wedge b$ exist in $\mathcal{L}$. In the usual setting of the N-body problem, $\mathcal{L}$ is the lattice of partitions of the set $\{1,2,...,N\}$. The order relation in $\mathcal{L}$ is denoted $a\leqslant b$ and $a<b$ means strict inequality; $a_{\min}$ (resp., $a_{\max}$) are the least (resp., the largest) element of $\mathcal{L}$. We denote by $\mathcal{L}(2)$ the set of maximal elements of $\mathcal{L}\setminus\{a_{\max}\}$ (in the N-body case this is the set of two-cluster partitions).

II.2. Let X be a finite-dimensional real vector space equipped with a volume element dx, i.e., dx is a translation-invariant positive Radon measure on X. Equivalently, one may give a nonzero element e of the exterior product $\wedge^n X(n=\dim X)$, and if $(e_1,\ldots,e_n)$ is a basis in X such that $e_1\wedge\cdots\wedge e_n=e$ then one sets $\int f\,dx=\int_{\mathbb{R}^n} f(x_1e_1+\cdots+x_ne_n)dx_1\cdots dx_n$. Then $\mathcal{H}(X)$ will be the Hilbert space $L^2(X;dx)$ and we denote $\mathbb{B}(X)$ [resp., $\mathbb{K}(X)$] the C^*-algebra of bounded (resp., compact) operators in $\mathcal{H}(X)$. Note that $\mathbb{B}(X)$ and $\mathbb{K}(X)$ do not depend on the choice of the volume element.

Let X^* be the dual space of X. The Fourier transformation of a function $f:X\to\mathbb{C}$ is the function $\mathcal{F}f\equiv\hat{f}:X^*\to\mathbb{C}$ defined by $\hat{f}(k)=\int \exp[-i\langle x,k\rangle]f(x)dx$. There is a unique volume element dk on X^* such that $\mathcal{F}$ extends to an isometric operator of $L^2(X;dx)$ onto $L^2(X^*;dk)$. We shall always equip X^* with this volume element, and we set $\mathcal{H}(X^*)=L^2(X^*;dk)$.

If $f:X\to\mathbb{C}$ is a Borel function, we denote $f(Q)$ the operator of multiplication by f in the space $\mathcal{H}(X)$. If $g:X^*\to\mathbb{C}$ is a Borel function, then $g(P)$ is the operator in $\mathcal{H}(X)$ such that $\mathcal{F}g(P)\mathcal{F}^*$ is the operator of multiplication by g in $\mathcal{H}(X^*)$. Let $\mathbb{T}(X)$ be the C^*-subalgebra of $\mathbb{B}(X)$ consisting of operators of the form $f(P)$, where $f:X^*\to\mathbb{C}$ is continuous and convergent to zero at infinity.

II.3. If Y is a subspace of X provided with a volume element dy, then the Hilbert space $\mathcal{H}(Y)$, the Fourier transform $\mathcal{F}^Y$, and the C^*-algebras $\mathbb{B}(Y)$, $\mathbb{K}(Y)$, and $\mathbb{T}(Y)$ are well defined. By convention, if $Y=0\equiv\{0\}$ we put $\mathcal{H}(0)=\mathbb{K}(0)=\mathbb{T}(0)=\mathbb{C}$.

Now let Z be a subspace of X supplementary to Y, so $X=Y\oplus Z$. Then there is a unique volume element dz on Z such that $dx=dy\otimes dz$. Indeed, if e and u are elements of $\wedge^n X$ and $\wedge^k Y$ ($k=\dim Y$), which define the volume elements dx and dy, respectively, then there is a unique $v\in\wedge^m Z$ ($m=\dim Z$) such that $e=u\wedge v$; dz will be the volume element on Z associated to v. We then get a canonical isomorphism,

$$\mathcal{H}(X)\cong\mathcal{H}(Y)\otimes\mathcal{H}(Z)\cong L^2(Z;\mathcal{H}(Y)).$$

The decomposition $X=Y\oplus Z$ induces also a canonical identification $X^*=Y^*\oplus Z^*$, and if we make a Fourier transformation in the variable $z\in Z$ only we get a canonical isomorphism,

$$\mathcal{H}(X)\cong\mathcal{H}(Y)\otimes\mathcal{H}(Z^*)\cong L^2(Z^*;\mathcal{H}(Y)).$$

II.4. Let $\{X^a,X_a\}_{a\in\mathcal{L}}$ be a family of couples of vector subspace of X equipped with volume elements dx^a, dx_a such that the subspaces X^a and X_a are supplementary in X and $dx=dx^a\otimes dx_a$, $\forall a\in\mathcal{L}$. We suppose the following:
(i) if $b\leq a$ then $X^b\subset X^a$ and $X_a\subset X_b$;
(ii) $X^a+X^b=X^{a\vee b}$ and $X_a\cap X_b=X_{a\vee b}$;
(iii) $X^{a_{\max}}=X_{a_{\min}}=X$ and $X^{a_{\min}}=X_{a_{\max}}=\{0\}$.
Then for each a we have a canonical factorization,

$$\mathcal{H}(X)\cong\mathcal{H}(X^a)\otimes\mathcal{H}(X_a)\cong L^2(X_a;\mathcal{H}(X^a)).$$

If $S\in\mathbb{B}(X^a)$, $T\in\mathbb{B}(X_a)$ we shall denote by $S\otimes_a T$ the operator in $\mathcal{H}(X)$ that corresponds to $S\otimes T$ by the preceding isomorphism. If $\mathcal{C}_1\subset\mathbb{B}(X^a)$ and $\mathcal{C}_2\subset\mathbb{B}(X_a)$ are C^*-subalgebras, we denote by $\mathcal{C}_1\otimes_a\mathcal{C}_2$ the C^*-subalgebra of $\mathbb{B}(X)$ generated by the operators of the form $S\otimes_a T$ with $S\in\mathcal{C}_1$, $T\in\mathcal{C}_2$.

For each $a\in\mathcal{L}$, we introduce now the following C^*-subalgebra of $\mathbb{B}(X)$:

$$\mathcal{I}(a):=\mathbb{K}(X^a)\otimes_a\mathbb{T}(X_a),$$

and for each $a\in\mathcal{L}$ we define

$$\mathcal{I}_a:=\sum_{b\leq a,b\in\mathcal{L}}\mathcal{I}(b),\quad \mathcal{I}=\mathcal{I}_{a_{\max}}=\sum_{a\in\mathcal{L}}\mathcal{I}(a).$$

The sums that appear on the right-hand side (r.h.s.) have to be interpreted in the vector space sense. Note the following particular cases: $\mathcal{I}(a_{\min})=\mathbb{T}(X)$, $\mathcal{I}(a_{\max})=\mathbb{K}(X)$. The main property of these spaces are the following: $\mathcal{I}$ is a C^*-algebra, $\mathcal{I}(a)\mathcal{I}(b)\subset\mathcal{I}(a\vee b)$ for each $a,b\in\mathcal{L}$; the preceding sums are direct in the Banach space sense and each $\mathcal{I}_a$ is a C^*-subalgebra of $\mathcal{I}$.

These assertions can be proved without difficulty by mimicking the proof of Theorem 2.1 from Ref. 15 (or see Chap. 9 in Ref. 16). These facts can also be deduced from the more general formalism developed in Ref. 17 by observing that there are canonical isomorphisms between the algebras $\mathcal{I}(a)$ and the algebras denoted $\mathcal{C}(X_a^\sigma)$ in Sec. II of Ref. 17 (see pp. 35–36). This is interesting because it shows that *the C^*-algebras $\mathcal{I}(a)$ depend only on the choice of the subspace X_a of X; if other choices for the volume element on X_a and for the supplementary space X^a are made, then we get the same algebras $\mathcal{I}(a)$*. The freedom that one has in the choice of the subspaces X^a is quite useful in applications; cf. the examples at the end of Sec. IV. For this reason we shall give a direct and elementary proof of the independence of $\mathcal{I}(a)$ on X^a in an Appendix to this paper.

If $b\leq a$ then $X^b\subset X^a$ and we put $X_b^a=X^a\cap X_b$ so $X^a=X^b\oplus X_b^a$. We equip X_b^a with the volume element dx_b^a associated to dx^a and dx^b by the rule $dx^a=dx^b\otimes dx_b^a$, and we define

$$\mathcal{I}^a(b)=\mathbb{K}(X^b)\otimes\mathbb{T}(X^a_b),\quad \mathcal{I}^a=\sum_{b\leqslant a,b\in\mathcal{L}}\mathcal{I}^a(b).$$

The tensor product here is relative to the factorization $L^2(X^a)\cong L^2(X^b)\otimes L^2(X^a_b)$. Using the fact that $X=X^a\oplus X_a=X^b\oplus X^a_b\oplus X_a$ and $\mathbb{T}(X_b)=\mathbb{T}(X^a_b\oplus X_a)=\mathbb{T}(X^a_b)\otimes\mathbb{T}(X_a)$, it is easily shown that one has the following relation between $\mathcal{I}^a$ and $\mathcal{I}_a$:

$$\mathcal{I}_a=\mathcal{I}^a\otimes_a\mathbb{T}(X_a),$$

relative to the factorization $\mathcal{H}(X)\cong\mathcal{H}(X^a)\otimes\mathcal{H}(X_a)$.

II.5. Let $\mathcal{S}(X)$ be the space of a rapidly decreasing test function and $\mathcal{S}^*(X)$ its adjoint space, the space of temperate distributions on X. The operators $f(Q)$ and $g(P)$ have natural extensions to the space $\mathcal{S}^*(X)$ if f and g are of class C^∞ and are polynomially bounded together with all their derivatives. We denote $|\cdot|$ some Euclidean norms on X or X^* and we put $\langle x\rangle=(1+|x|^2)^{1/2}$. This allows us to define the operators $\langle Q\rangle^s$ and $\langle P\rangle^s$ for any $s\in\mathbb{R}$; they act in the space $\mathcal{S}^*(X)$. Then we define the Sobolev spaces $\mathcal{H}^s(X)=\{f\in\mathcal{S}^*(X)|\langle P\rangle^s f\in\mathcal{H}(X)\}$ with the natural topology. These spaces do not depend on the chosen norms.

We introduce now a class of weighted Sobolev spaces. Let $\theta\in C_0^\infty(X)$ be such that $\theta(x)>0$ if $2^{-1}<|x|<2$ and $\theta(x)=0$ otherwise. Choose one more function $\eta\in C_0^\infty(X)$ such that $\eta(x)>0$ if $|x|<1$. Then for any $s,\ t\in\mathbb{R}$ and $1\leqslant p\leqslant\infty$ let $\mathcal{H}^s_{t,p}$ be the space of distributions u that locally belong to $\mathcal{H}^s$, and such that

$$\|\eta(Q)u\|_{\mathcal{H}^s}+\left(\int_1^\infty\|r^t\theta(r^{-1}Q)u\|^p_{\mathcal{H}^s}\frac{dr}{r}\right)^{1/p}<\infty.$$

If $p=\infty$ the second term is interpreted as $\sup_{r\geqslant1}\|r^t\theta(r^{-1}Q)u\|_{\mathcal{H}^s}$. The left-hand side above is a norm on $\mathcal{H}^s_{t,p}$ that provides this space with a Banach space structure. We set $\mathcal{H}^s_t\equiv\mathcal{H}^s_{t,2}$; these are the usual weighted Sobolev spaces defined by the norms $\|\langle P\rangle^s\langle Q\rangle^t u\|$. If $t_1<t<t_2$, $t=(1-\lambda)t_1+\lambda t_2$ and $p,p_1,p_2\in[1,\infty]$, $s\in\mathbb{R}$, then

$$\mathcal{H}^s_{t,p}=(\mathcal{H}^s_{t_1,p_1},\mathcal{H}^s_{t_2,p_2})\lambda,p.$$

Moreover, if $1\leqslant p<\infty$ and $1/p+1/p'=1$, then $(\mathcal{H}^s_{t,p})^*=\mathcal{H}^{-s}_{-t,p'}$.

III. A DISPERSIVE HWZ THEOREM

We describe now some explicit classes of self-adjoint operators affiliated to $\mathcal{I}$. We shall keep the notations introduced above. Let us fix a continuous function $h:X^*\to\mathbb{R}$ such that $h(k)\to+\infty$ as $|k|\to\infty$. We denote by H_0 the self-adjoint operator $h(P)$ in the Hilbert space $\mathcal{H}(X)$. Since h is bounded from below H_0 is bounded from below too.

Recall the canonical isomorphism $X^*=X^{a*}\oplus X_a^*$. For each $a\in\mathcal{L}$, we define $h^a:X^{a*}\to\mathbb{R}$ by $h^a(k^a)=\inf\{h(k^a+k_a)|k_a\in X_a^*\}$. Observe that h^a is continuous and divergent at infinity. Then let $\mathcal{H}^h(X^a)$ be the form domain in $\mathcal{H}(X^a)$ of the operator $h^a(P^a)$ [we denote by P^a the momentum operator in $\mathcal{H}(X^a)$] equipped with the graph norm $\langle f,(1+|h^a(P^a)|)f\rangle^{1/2}$. After identifying $\mathcal{H}(X^a)$ and $\mathcal{H}(X^a)^*$, we get

$$\mathcal{H}^h(X^a)\subset\mathcal{H}(X^a)\subset\mathcal{H}^h(X^a)^*.$$

We shall consider Hamiltonians H of the form $H=H_0+V$ with perturbations of the form $V=\Sigma_a V^a\otimes_a 1$, where $\otimes_a$ is the tensor product determined by the factorization $\mathcal{H}(X)\cong\mathcal{H}(X^a)\otimes\mathcal{H}(X_a)$ and V^a is a sesquilinear form in $\mathcal{H}(X^a)$. Since $\mathcal{H}(X^{a_{\min}})=\mathbb{C}$, $V^{a_{\min}}$ is a real constant.

The next lemma allows us to define the total Hamiltonian for the interactions we have in mind.

Lemma III.1: Let V^a be a symmetric form on $\mathcal{H}(X^a)$ that is $h^a(P^a)$-form bounded with relative bound $\nu \geqslant 0$. Then $V_a = V^a \otimes_a 1$ is a symmetric form in $\mathcal{H}(X)$, $h(P)$-form bounded with relative bound equal to ν.

Proof: By hypothesis, V^a is a continuous sesquilinear form on the Hilbert space $\mathcal{H}^h(X^a)$ and there is a constant $c < \infty$ such that $|\langle u, V^a u\rangle| \leqslant \nu \langle u, h^a(P^a)u\rangle + c\|u\|^2$ for all $u \in \mathcal{H}^h(X^a)$. Then $V_a = V^a \otimes_a 1$ is a continuous symmetric form on $\mathcal{H}^h(X^a)\otimes \mathcal{H}(X_a)$. $\mathcal{H}^h(X)$ is the form domain of $h(P)$ and $\mathcal{H}^h(X) \subset \mathcal{H}^h(X^a)\otimes\mathcal{H}(X_a)$. We work in the representation $\mathcal{H}(X) \cong L^2(X_a; \mathcal{H}(X^a))$ and we make a Fourier transformation in the variable $x_a \in X_a$. Then we have $(V_a \hat{f})(k_a) = V^a \hat{f}(k_a)$ for $\hat{f} \in L^2(X_a^*; \mathcal{H}^h(X^a))$ and $k_a \in X_a^*$, while the operator $h(P)$ becomes the operator of multiplication by the operator valued function $k_a \mapsto h(P^a + k_a)$. Then, for each $\epsilon > 0$ there is a constant $c_\epsilon < \infty$ such that

$$
\begin{aligned}
\pm\langle f, V_a f\rangle &= \pm \int_{X_a^*} \langle \hat{f}(k_a), V^a \hat{f}(k_a)\rangle dk_a \\
&\leqslant (\nu+\epsilon)\int_{X_a^*}\langle \hat{f}(k_a), h^a(P^a)\hat{f}(k_a)\rangle dk_a + c_\epsilon \int_{X_a^*} \|\hat{f}(k_a)\|^2\, dk_a \\
&\leqslant (\nu+\epsilon)\int_{X_a^*}\langle \hat{f}(k_a), h(P^a+k_a)\hat{f}(k_a)\rangle dk_a + c_\epsilon \int_{X_a^*} \|\hat{f}(k_a)\|^2\, dk_a \\
&\leqslant (\nu+\epsilon)\langle f, h(P)f\rangle + c_\epsilon \|f\|^2, \quad \text{for all } f \in \mathcal{H}^h(X).
\end{aligned}
$$

This proves the lemma. ■

Let us recall the notion of smallness at infinity that is the weak decay assumption that we need.

Definition: Let s, $t \in \mathbb{R}$, let Y be a vector space and let L: $\mathcal{H}^s(Y) \to \mathcal{H}^t(Y)$ a linear continuous operator. We shall say that L is small at infinity if it satisfies one (and therefore all) of the following equivalent conditions:
(a) L: $\mathcal{H}^s(Y) \to \mathcal{H}^{t'}(Y)$ is compact for some $t' < t$;
(a') the preceding assertion holds for all $t' < t$;
(b) there is $\theta \in C^\infty(Y)$ with $\theta(y) = 0$ (resp., 1) if $|y| \leqslant 1$ (resp., $|y| \geqslant 2$) and there is $t' < t$ such that $\lim_{r\to\infty}\|\theta(Qr^{-1})L\|_{\mathbb{B}(\mathcal{H}^s, \mathcal{H}^{t'})} = 0$;
(b') L has the preceding property for all $\theta \in C^\infty(Y)$ with $\theta(y) = 0$ (resp., 1) near zero (resp., near ∞) and all $t' < t$.

For the proof of the equivalence see Definition 3.5 in Ref. 15. If $t = -s$ then giving a continuous linear operator $\mathcal{H}^s \to \mathcal{H}^{-s}$ is equivalent with giving a continuous sesquilinear form on $\mathcal{H}^s$. In particular, we get the notion of sesquilinear form on $\mathcal{H}^s$ small at infinity.

The algebraic techniques developed in Ref. 16 apply only to the self-adjoint operators H on $\mathcal{H}$ that are affiliated to the C^*-algebra $\mathcal{I}$. One says that H is *affiliated* to $\mathcal{I}$ if $(H-z)^{-1} \in \mathcal{I}$ for some complex number z outside the spectrum of H. If this is the case then $\varphi(H) \in \mathcal{I}$ for each continuous function on $\mathbb{R}$, which tends to zero at infinity.

Now we state and prove a criterion for an operator to be affiliated to $\mathcal{I}$. Observe that V^a may be nonlocal and that it could be a pseudodifferential operator of the same order as $h(P)$.

Let $\mu = 2s$, $s > 0$. From now on we suppose that *there are two constants c_1 and c_2 such that*

$$c_1\langle k\rangle^\mu \leqslant h(k) \leqslant c_2 \langle k\rangle^\mu, \quad \text{for all } k \in X^*.$$

Then we also have $c_1'\langle k^a\rangle^\mu \leqslant h^a(k^a) \leqslant c_2'\langle k^a\rangle^\mu$ for all $k^a \in X^{a*}$. It is clear that $\mathcal{H}^h(X^a) = \mathcal{H}^s(X^a)$.

Theorem III.1: *Assume that for each $a \in \mathcal{L}$ a continuous symmetric and small at infinity sesquilinear form V^a with domain $\mathcal{H}^s(X^a)$ is given such that $\Sigma_a \mu_a < 1$, where μ_a is the relative* *form bound of* V^a *with respect to* $h^a(P^a)$. *Identify* V^a *with an operator* $\mathcal{H}^s(X^a)\to\mathcal{H}^{-s}(X^a)$ *and assume that there is a* $t>s$ *such that* $V^a\mathcal{H}^t(X^a)\subset\mathcal{H}^{t-2s}(X^a)$. *Then* $H:=h(P)+\Sigma_{a\in\mathcal{L}}V_a$ *is a self-adjoint operator in* $\mathcal{H}(X)$ *with form domain equal to* $\mathcal{H}^s(X)$. *The same assertion holds for each* $H_a=h(P)+\Sigma_{b\leqslant a}V_b$. *The operator H is a affiliated to* $\mathcal{I}$ *and* H_a *is affiliated to* $\mathcal{I}_a$.

Proof: Our proof is similar to that of Proposition 3.6 in Ref. 15. By the closed graph theorem, V^a is continuous when considered as operator $V^a:\mathcal{H}^t(X^a)\to\mathcal{H}^{t-2s}(X^a)$. Without loss of generality we assume $s<t\leqslant 2s$. For any $\epsilon>0$ let us define $V^a_\epsilon=(1+\epsilon h^a(P^a))^{-1}V^a(1+\epsilon h^a(P^a))^{-1}$. Since $V^a:\mathcal{H}^{2s}(X^a)\to\mathcal{H}^{-s}(X^a)$ is a compact symmetric operator, we have $V^a_\epsilon\in\mathbb{K}(X^a)$ and V^a_ϵ is symmetric too. Since $(1+\epsilon h^a(P^a))^{-1}\to 1$ as $\epsilon\to 0$ strongly in each $\mathcal{H}^r(X^a)$, we see that $V^a_\epsilon\to V^a$ strongly in $B(\mathcal{H}^r(X^a),\mathcal{H}^{r-2s}(X^a))$ for all $r\in[2s-t,t]$ and in norm in $B(\mathcal{H}^r(X^a),\mathcal{H}^{r-2s-\delta}(X^a))$ for $r\in[2s-t,t]$ and $\delta>0$. Let $H_\epsilon:=h(P)+V_\epsilon$ with $V_\epsilon=\Sigma_a(V_a)_\epsilon$ and $(V_a)_\epsilon=V^a_\epsilon\otimes_a 1$. Then $(H_\epsilon)_a:=h(P)+\Sigma_{b\leqslant a}(V_b)_\epsilon$. Proposition 9.3.4 in Ref. 16 implies that H_ϵ is affiliated to $\mathcal{I}$. Hence, it is enough to show that $\lim_{\epsilon\to 0}H_\epsilon=H$ in a norm-resolvent sense. For this we use the identity ($\lambda>0$ large enough)

$$(\lambda+H_\epsilon)^{-1}-(\lambda+H)^{-1}=(\lambda+H_\epsilon)^{-1}[V-V_\epsilon](\lambda+H)^{-1}.$$

Since $(\lambda+H)^{-1}$ and $(\lambda+H_\epsilon)^{-1}$ are isomorphisms of $\mathcal{H}^{-s}(X)$ onto $\mathcal{H}^s(X)$ and $V-V_\epsilon:\mathcal{H}^s(X)\to\mathcal{H}^{-s}(X)$ the identity holds in $B(\mathcal{H}^{-s}(X),\mathcal{H}^s(X))$. We shall show two things: $(\lambda+H)^{-1}\mathcal{H}(X)\subset\mathcal{H}^r(X)$ for some $r>s$ and $\|(\lambda+H_\epsilon)^{-1}\|_{B(\mathcal{H}^{-s},\mathcal{H}^s)}\leqslant$const independently of ϵ; here λ is large enough and also independent of ϵ. Assuming these facts are true, we get

$$\|(\lambda+H_\epsilon)^{-1}-(\lambda+H)^{-1}\|_{B(\mathcal{H},\mathcal{H}^s)}\leqslant c\|V-V_\epsilon\|_{B(\mathcal{H}^r,\mathcal{H}^{-s})}\to 0,$$

because we may take $\delta=r-s>0$ above. Observe that $V^a_\epsilon\to V^a$ in norm in $B(\mathcal{H}^r(X^a),\mathcal{H}^{-s}(X^a))$, which implies $(V_a)_\epsilon\to V_a$ in norm in $B(\mathcal{H}^r(X),\mathcal{H}^{-s}(X))$.

Now we prove the assertion concerning $(\lambda+H_\epsilon)^{-1}$. Using the equality $(\lambda+H_\epsilon)^{-1}=(\lambda+h(P))^{-1/2}[1+(\lambda+h(P))^{-1/2}V^\epsilon(\lambda+h(P))^{-1/2}]^{-1}(\lambda+h(P))^{-1/2}$ it is enough to show that there are λ and $\mu<1$ independent of ϵ, such that $\|(\lambda+h(P))^{-1/2}V_\epsilon(\lambda+h(P))^{-1/2}\|\leqslant\mu<1$. But

$$(\lambda+h(P))^{-1/2}V_\epsilon(\lambda+h(P))^{-1/2}=\sum_a(\lambda+h(P))^{-1/2}(\lambda+\epsilon h^a(P^a))^{-1}V^a(\lambda+\epsilon h^a(P^a))^{-1}\otimes_a 1.(\lambda+h(P))^{-1/2};$$

hence

$$\|(\lambda+h(P))^{-1/2}V_\epsilon(\lambda+h(P))^{-1/2}\|\leqslant\sum_a\|(\lambda+h(P))^{-1/2}V_a(\lambda+h(P))^{-1/2}\|\leqslant\sum_a\left(\mu_a+\frac{c}{\lambda}\right),$$

where c/λ can be made as small as we want by choosing λ large enough. Finally, the proof of the assertion concerning $(\lambda+H_\epsilon)^{-1}$ is the same as in Ref. 15. ■

The main result of this section is the following generalization of the HWZ Theorem.

Theorem III.2: *For each* $a\in\mathcal{L}$ *define* $\tau_a=inf\ \sigma(H_a)$ *and let* $\tau=\min_{a\in\mathcal{L}(2)}\tau_a$. *If the hypotheses of Theorem III.1 hold, then* $\sigma_{ess}(H)=[\tau,\infty)$.

Proof: By Theorem III.1, H is affiliated to $\mathcal{I}$ and H_a is affiliated to $\mathcal{I}_a$. According to Proposition 8.4.2 in Ref. 16 (see also Theorem 3.2 in Ref. 15) we shall then have $\sigma_{ess}(H)=\cup_{a\in\mathcal{L}(2)}\sigma(H_a)$. So it suffices to show that for each $a\in\mathcal{L}(2),\sigma(H_a)$ is a half-line. Since H is bounded from below we may assume, without loss of generality, that H is positive; this implies $H_a\geqslant 0$. $\mathcal{I}_a$ is the tensor product of $\mathcal{I}^a$ with the Abelian C^*-algebra $\mathbb{T}(X_a)$. Working in the spectral representation of $\mathbb{T}(X_a)$ we see that there is a family $\{H^a(k_a),\ k_a\in X^*_a\}$ of Hamiltonians $H^a(k_a)$ affiliated to $\mathcal{I}^a$ such that $\mathcal{F}_a(H_a+1)^{-1}\mathcal{F}^*_a$ (where $\mathcal{F}_a=1\otimes_a\mathcal{F}^{X_a}$ is the operator of Fourier transformation in the variable $x_a\in X_a$ only) is the operator of multiplication by the operator-valued function $k_a\mapsto(H^a(k_a)+1)^{-1}\equiv F(k_a)$ (see remark 9.2.6 in Ref. 16). Moreover, this function is norm continuous, tends in norm to zero at infinity, and $0<F(k_a)\leqslant 1$. So $m(k_a)\equiv\sup F(k_a)=\|F(k_a)\|\to 0$ as $k_a\to\infty$. But $m(k_a)$ is the upper bound of the spectrum of $F(k_a)$ and depends continuously on k_a (by the norm continuity of F). Since X_a^* is a connected set we see that the range of m has to be an interval. Finally, one has $\sigma(H_a)=\cup_{k_a\in X_a^*}\sigma(H^a(k_a))$ (see Sec. 8.2.4 in Ref. 16), which clearly shows that $\sigma(H_a)$ is an interval which has to be a half-line. This finishes the proof. ■

Application: Relativistic Hamiltonians with Coulomb potentials

We consider the quantum mechanical many-body problem of electrons and fixed nuclei interacting via Coulomb forces with a relativistic form for the kinetic energy. The HWZ theorem for this model has been established in Ref. 7; here we show that this situation is covered by our general theorem, Theorem III.2.

We recall the framework from Ref. 7. The system consists of N_n identical nuclei of mass M and charge Z, and N_e electrons of mass m; let $N=N_n+N_e$. If the coordinates of the electrons and nuclei are denoted by $r_1,\ldots,r_{N_e}$ and $R_1,\ldots,R_{N_n}$, respectively, then the potential energy is

$$V=-\sum_{\nu=1}^{N_e}\sum_{\kappa=1}^{N_n}\frac{\alpha Z}{|r_\mu-R_\kappa|}+\sum_{1\leqslant\mu<\nu\leqslant N_e}\frac{\alpha}{|r_\mu-r_\nu|}+\sum_{1\leqslant\kappa<\lambda\leqslant N_n}\frac{\alpha Z^2}{|R_\kappa-R_\lambda|},$$

where α is the fine structure constant. Then the total Hamiltonian is

$$H=\sum_{\nu=1}^{N_e}\sqrt{|P_\nu|^2+m^2}+\sum_{\kappa=1}^{N_n}\sqrt{|P_\kappa|^2+M^2}+V,$$

with natural notations. It is convenient to introduce new notations: $x_i=r_i$, $m_i=m$ if $1\leqslant i\leqslant N_e$, and $x_{N_e+i}=R_i$, $m_{N_e+i}=M$ if $1\leqslant i\leqslant N_n$. We work in $L^2(X)$ with $X=\{x\in\mathbb{R}^{3N}|\Sigma_{i=1}^N m_i x_i=0\}$. Then $\mathcal{L}$ is the lattice of partitions of the set $\{1,2,...,N\}$, and for $a\in\mathcal{L}$ we take $X^a=\{x\in X|\Sigma_{k\in C}m_k x_k=0,\ \text{for each}\ C\in a\}$; $X_a=\{x\in X|x_i=x_j$ if i,j belong to the same cluster of $a\}$.

As we explained in II.4 only the choice of the spaces X_a is really important.

Theorem III.3: If $\alpha Z<2/\pi$ and $\alpha<\frac{1}{47}$, then $\sigma_{ess}(H)=[\tau,\infty)$, where $\tau=\min_{a\in\mathcal{L}(2)}\inf\sigma(H_a)$.

Remark: In corollary 2 (p. 24) of Ref. 7 two different sets of conditions are imposed. We have chosen the simplest one, the second being treated in the same way.

Proof: We define the function $h:X^*\to\mathbb{R}$ by $h(k)=\Sigma_{i=1}^N\sqrt{|k_i|^2+m_i^2}$, where $X^*=\{k\in\mathbb{R}^{3N}|\Sigma_{i=1}^N k_i=0\}$ is the dual (momentum) space of X. Then h is continuous and divergent at infinity, $\mathcal{H}^h(X^a)=\mathcal{H}^{1/2}(X^a)$ and $\mathcal{H}^h(X^a)^*=\mathcal{H}^{-1/2}(X^a)$ $(s=\frac{1}{2})$. Since, in our case H contains only two-body forces (i.e., $V^a\neq 0$ only if $a=l$ is a pair) each $V^a:\mathcal{H}^{1/2}(X^a)\to\mathcal{H}^{-1/2}(X^a)$ is small at infinity. Indeed, if $V^a\neq 0$ then $X^a\cong\mathbb{R}^3$ and each V^a is of the form $\gamma/|x|(\gamma\in\mathbb{R})$, which be may written as $V^a(x)=V_1(x)+V_2(x)$ with $V_1\in L^2(\mathbb{R}^3)$ and $V_2\in C_\infty(\mathbb{R}^3)$. We also have that $V^a\mathcal{H}^1(\mathbb{R}^3)\subset\mathcal{H}(\mathbb{R}^3)$ $(t=1>\frac{1}{2})$. If α is small the relative bound of V will be less than one, and we may apply directly Theorem III.2 to finish the proof. In order to get the stated result we argue as follows.

Let $V_-=\sup(0,-V)$ and $V_+=V+V_-$; then $V=V_+-V_-$ and $V_\pm\geqslant 0$. As it is explained in Ref. 7, it follows from the results of Lieb and Yau (Ref. 18) that there are constants $0<\mu<1$ and $\delta>0$ such that $0\leqslant V_-\leqslant\mu H_0+\delta$. Let $c>0$ and $H^c=H_0+cV_+-V_-$. Since $V_\pm$ are positive H_0-form bounded perturbations and the H_0-form bound of V_- is strictly less than 1, it follows that for each $c\geqslant 0$ (in fact, small negatives c are allowed) the operator H^c (defined as a form sum) is self-adjoint. Moreover, the resolvent of H^c depends analytically on $c\in(0,\infty)$. For small c we may apply now the theorems III.1 and III.2. But the result will remain true for all $c>0$ for analyticity reasons. Indeed, by series expansion (in c) one sees that the resolvent of H^c remains in the algebra

$\mathcal{I}$ (which is norm closed) for all c. Similarly, the resolvent of H_a^c will belong to $\mathcal{I}_a$ and the equality $\mathcal{P}_a[(H^c-z)^{-1}]=(H_a^c-z)^{-1}$, valid for small c, will hold for all $c>0$. So the HWZ Theorem holds for all $c>0$.

IV. THE MOURRE ESTIMATE

In this section we prove that for N-body dispersive systems the Mourre estimate holds outside a set of points (called thresholds), which can be described explicitly in terms of eigenvalues of some sub-Hamiltonians. The conjugate operator is the generator of dilations $D=\frac{1}{2}(\langle Q,P\rangle+\langle P,Q\rangle)$ on X. We will denote by D^a the generator of dilations on X^a ($D=D^{a_{\max}}$). We shall keep the notations introduced above.

IV.1. We recall some results concerning the conjugate operator method (see Ref. 16 for details). Let $\mathcal{H}$ be a Hilbert space and A a self-adjoint, densely defined operator in $\mathcal{H}$. If $S\in B(\mathcal{H})$, we denote $\mathcal{W}_\tau(S)=e^{-iA\tau}Se^{iA\tau}$; then $\{\mathcal{W}_\tau\}_{\tau\in\mathbb{R}}$ is a group of automorphisms of $B(\mathcal{H})$. The derivative $(d/d\tau)\mathcal{W}_\tau(S)|_{\tau=0}=i[S,A]$ exists as a sesquilinear form on $D(A)$, and it exists in the strong topology of $B(\mathcal{H})$ if and only if the sesquilinear form $[S,A]$ extends to a bounded operator in $\mathcal{H}$ (which will be denoted by the same symbol). In this case we say that S is of class $C^1(A)$ and we write $S\in C^1(A)$. If the derivative exists in the norm topology of $B(\mathcal{H})$, we say that S is of class $C_u^1(A)$. For the development of the theory, for example, in order to show that the limiting absorption principle holds, one has to require more regularity than C_u^1 (see Ref. 16 and references there). We say that $S\in B(\mathcal{H})$ is of class $\mathcal{C}^{1,1}(A)$ if $\int_0^1\|(\mathcal{W}_\tau-1)^2S\|(d\tau/\tau^2)<\infty$. If S is of class $\mathcal{C}^{1,1}(A)$ it will be automatically of class $C_u^1(A)$.

Now let H be a self-adjoint operator in $\mathcal{H}$. We shall say that H is of class $C^1(A)$, $C_u^1(A)$ or $\mathcal{C}^{1,1}(A)$ if $R(z)=(H-z)^{-1}$ has the corresponding property for some $z\in\mathbb{C}\setminus\sigma(H)$.

The proof of the Mourre estimate is simplified by the introduction of two functions $\rho_H\equiv\rho_H^A$ and $\tilde{\rho}_H\equiv\tilde{\rho}_H^A$ defined on $\mathbb{R}$ with values in $(-\infty,+\infty]$. Let H be any self-adjoint operator of class $C^1(A)$. For any $\lambda\in\mathbb{R}$ we denote the following:

$$\rho_H(\lambda)=\sup\{\alpha\in\mathbb{R}|\exists\varphi\in C_0^\infty(\mathbb{R})\text{real},\ \ \varphi(\lambda)\neq0,\ \text{ such that }\ \varphi(H)[H,iA]\varphi(H)\geqslant\alpha\varphi(H)^2\},$$

$$\tilde{\rho}_H(\lambda)=\sup\{\alpha\in\mathbb{R}|\exists\varphi\in C_0^\infty(\mathbb{R})\text{real},\ \ \varphi(\lambda)\neq0,\ \text{ and } K \text{ a compact operator, such that}$$
$$\varphi(H)[H,iA]\varphi(H)\geqslant\alpha\varphi(H)^2+K\}.$$

For a detailed description of the properties of the functions ρ and $\tilde{\rho}$, see Ref. 16.

We say that A is conjugate to H at the point $\lambda\in\mathbb{R}$ if $\tilde{\rho}_H(\lambda)>0$. Let $J\subset\mathbb{R}$ a Borel set; if $\tilde{\rho}_H(\lambda)>0$ for all $\lambda\in J$ we say that A is locally conjugate to H on J.

IV.2. For each $a\in\mathcal{L}$, we define the operator $H^a=h(P^a)+\Sigma_{b\leqslant a}V_b^a$ where $V_b^a=V^b\otimes1$, the tensor product being determined by the factorization $L^2(X^a)\cong L^2(X^b)\otimes L^2(X_b^a)$. We use the notation $\sigma_p(H)$ for the set of eigenvalues of a self-adjoint operator H. If H is a dispersive N-body Hamiltonian, one associates to it two sets: the set of thresholds of H, defined as $\tau(H):=\cup_{a<a_{\max}}\sigma_p(H^a)$, and the critical set of H, defined as $\kappa(H):=\cup_{a\in\mathcal{L}}\sigma_p(H^a)$. We define also the set $\mu^D(H)=\mathbb{R}\setminus\kappa(H)$.

The next lemma contains a technical results that will be needed in the proof of the main theorem of this section.

Lemma IV.1: Let X be a vector space, A a self-adjoint operator in a Hilbert space $\mathcal{H}$ and $\{H_x\}_{x\in X}$ a family of self-adjoint operators of class $C^1(A)$. Assume that for some (hence for all) $z\in\mathbb{C}\setminus\mathbb{R}$ the maps $x\mapsto(H_x-z)^{-1}$ and $x\mapsto[(H_x-z)^{-1},A]$ are norm continuous. Let $\lambda\in\mathbb{R}$; then
(a) The function $x\mapsto\rho_{H_x}(\lambda)$ is lower semicontinuous.
(b) Let U be a compact subset of X and $c_0>0$ a constant such that $c_0<\rho_{H_x}(\lambda)$ for all $x\in U$. For each $c_1\in(0,c_0)$ there exists $\varphi\in C_0^\infty(\mathbb{R})$ real, with $\varphi(\lambda)\neq0$, such that for all $x\in U$: $\varphi(H_x)[H_x,iA]\varphi(H_x)\geqslant c_1\varphi^2(H_x)$.

Proof: (a) By using, for example, the Helfer–Sjöstrand formula [or see (8.1.1) in Ref. 16]. One easily sees that the functions $x\mapsto\varphi(H_x)$ and $x\mapsto[\psi(H_x),iA]$ are continuous in norm for all

$\varphi,\ \psi\in C_0^\infty(\mathbb{R})$. On the other hand $\varphi(H_x)[H_x,iA]\varphi(H_x)=\varphi(H_x)[\psi(H_x),iA]\varphi(H_x)$ where ψ is any function in $C_0^\infty(\mathbb{R})$ such that $\psi(x)=x$ on supp φ, so the function $x\mapsto\varphi(H_x)[H_x,iA]\varphi(H_x)$ is also norm continuous.

Let $x_0\in X$ and $r\in\mathbb{R}$ be such that $\rho_{H_{x_0}}(\lambda)>r$. We must show that there is a neighborhood of x_0 on which $\rho_{H_x}(\lambda)>r$. There exist $a_2>a_1>r$ and $\varphi_0\in C_0^\infty(\mathbb{R})$ real with $\varphi_0(\mu)=1$ on a neighborhood of λ and such that $\varphi_0(H_{x_0})[H_{x_0},iA]\varphi_0(H_{x_0})\geqslant a_2\varphi_0^2(H_{x_0})$.

Let $\epsilon_0>0$. By a continuity argument there is a neighborhood V_0 of x_0 in X such that $\varphi_0(H_x)[H_x,iA]\varphi_0(H_x)\geqslant a_2\varphi_0^2(H_x)-\epsilon_0$ for all $x\in V_0$. Let $\psi_0\in C_0^\infty(\mathbb{R})$ be real with $\psi_0(\lambda)\neq 0$ and $\varphi_0(\mu)=1$ on supp ψ_0. Multiplying left and right the preceding inequality by $\psi_0(H_x)$ we get $\psi_0(H_x)[H_x,iA]\psi_0(H_x)\geqslant(a_2-\epsilon_0)\psi_0^2(H_x)$ for all $x\in V_0$. Finally, choose ϵ_0 such that $a_2-\epsilon_0=a_1$. Then $\psi_0(H_x)[H_x,iA]\psi_0(H_x)\geqslant a_1\psi_0^2(H_x)$; hence $\rho_{H_x}(\lambda)\geqslant a_1>r$ for all $x\in V_0$.

(b) As in the proof of (a) we show that each $x_0\in U$ has a neighborhood $U(x_0)$ in U such that there is $\varphi_0\in C_0^\infty(\mathbb{R})$ real with $\varphi_0(\mu)=1$ on a neighborhood of λ, with the property

$$x\in U(x_0)\Rightarrow c_1\varphi_0^2(H_x)\leqslant\varphi_0(H_x)[H_x,iA]\varphi_0(H_x).$$

Now the proof can be completed as follows. Since U is compact, on may choose a finite number of neighborhoods $U(x_1),\ldots,U(x_n)$ covering U. Let $\varphi_1,\ldots,\varphi_n$ be the corresponding functions constructed as above. Then for each $k\in\{1,...,n\}c_1\varphi_k^2(H_x)\leqslant\varphi_k(H_x)[H_x,iA]\varphi_k(H_x)$ for all $x\in U(x_k)$. Finally, let $\varphi\in C_0^\infty(\mathbb{R})$ real with $\varphi(\lambda)\neq 0$ and $\varphi_k(\mu)=1$ on supp φ for all k. Multiplying left and right the preceding inequality by $\varphi(H_x)$, we get $c_1\varphi^2(H_x)\leqslant\varphi(H_x)[H_x,iA]\varphi(H_x)$ for all $x\in U$. ■

We now state the main result of this section. Note that we only need that H to be of class $C_u^1(A)$. For physically interesting and nontrivial functions h satisfying all the conditions below (e.g., relativistic three-body kinetic energy) see Ref. 12.

Theorem IV.1: *Besides the hypotheses of Theorem III.1 we assume that h is of class* $C^1,|kh'(k)|\leqslant c(1+|h(k)|)$ *for all* $k\in X^*$, *and that* $k_b^a h'(k^b+k_b^a+k_a)\geqslant 0$ *for all* $a,b\in\mathcal{L}$ *with* $b<a$ *and all* $k^b\in X^{b*}, k_b^a\in X_b^{a*}, k_a\in X_a^*$. *Moreover, in the case* $a=\max\mathcal{L}$ *assume that the stronger inequality* $k_b h'(k^b+k_b)>0$ *holds if* $k_b\neq 0$. *Finally, assume that* $[D^a,V^a]$ *is a compact operator* $\mathcal{H}^{2s}(X^a)\to\mathcal{H}^{-2s}(X^a)$. *Then*
(i) $\tau(H)$ *is a closed and countable real set;*
(ii) the eigenvalues of H which do not belong to $\tau(H)$ *[i.e., the points of* $\kappa(H)\setminus\tau(H)$*] are of finite multiplicity and can accumulate only to points from* $\tau(H)$;
(iii) D is locally conjugate to H on $\mathbb{R}\setminus\tau(H)$.

Proof: At steps (a)–(e) below we shall prove that D is locally conjugate to H on $\mathbb{R}\setminus\tau(H)$. Now we explain the ''standard'' proof of (i) and (ii). The assertion (ii) is a consequence of the abstract results of Mourre (see, for example, Corollary 7.2.11 in Ref. 16). The set $\tau(H)$ is clearly countable, but the fact that it is closed is far from obvious. But note that the operators H^a on $L^2(X^a)$ have the same properties as the operator H on $L^2(X)$ [see step (c) below]. If $a\neq\max\mathcal{L}$ then the lattice $\mathcal{L}_a=\{b\in\mathcal{L}|b\leqslant a\}$ associated to H^a is strictly smaller than $\mathcal{L}$. So one can make the induction hypothesis that $\tau(H^a)=\cup_{b<a}\sigma_p(H^b)$ is closed and that the generator of dilations on $L^2(X^a)$ is locally conjugate to H^a on $\mathbb{R}\setminus\tau(H^a)$ (for $a=\min\mathcal{L}$ this is trivial). Then $\kappa(H^a)$ is closed and $\tau(H)=\cup_{a<\max\mathcal{L}}\kappa(H^a)$ is closed too.

(a) By a simple calculation one shows that $e^{-iDt}\mathcal{I}(a)e^{iDt}\subset\mathcal{I}(a)$, $\forall a\in\mathcal{L}$ and $t\in\mathbb{R}$. Moreover, one can see easily that $[(H+1)^{-1},iD]\in\mathcal{I}$, which implies that H is of class $C_u^1(D)$ (see p. 420 of Ref. 16). Hence, from Theorem 5.10 in Ref. 15 (or see Theorem 8.4.3 in Ref. 16), it follows that $\tilde{\rho}_H(\lambda)=\min_{a\in\mathcal{L}(2)}\rho_{H_a}(\lambda)$, so for the proof of (iii) it is sufficient to show that if $\lambda\notin\tau(H)$, then $\rho_{H_a}(\lambda)>0$ for all $a\in\mathcal{L}(2)$.

(b) Using the relation $D=D^a\otimes_a 1+1\otimes_a D_a$ (where D_a is the generator of dilations on X_a) we write $[H_a,iD]=[H_a,iD^a\otimes_a 1]+[H_a,i(1\otimes_a D_a)]$. If we work in the representation $\mathcal{H}(X)\cong L^2(X_a;\mathcal{H}(X^a))$ and we make a Fourier transformation in the variable $x_a\in X_a$; then for each real function $\varphi \in C_0^\infty(\mathbb{R})$ the operator $\varphi(H_a)[H_a, iD]\varphi(H_a)$ becomes the operator of multiplication by the operator-valued function:

$$k_a \mapsto \varphi(H^a(k_a))\{[H^a(k_a), iD^a] + k_a h'(P^a + k_a)\}\varphi(H^a(k_a)). \tag{1}$$

Since the family $\{H^a(k_a)\}_{k_a \in X_a^*}$ is proper ($a \neq a_{\max}$), we have $\varphi(H^a(k_a)) = 0$ if k_a is large enough and if φ has support in a fixed compact. Let us fix $\lambda \notin \tau(H)$ and a compact neighborhood K of λ. Then for each $a \in \mathcal{L}(2)$ there is a compact set U_a in X such that $\varphi(H^a(k_a)) = 0$ if $k_a \notin U_a$ and supp $\varphi \subset K$. So it is enough to show that there are $c_0 > 0$ and $\varphi \in C_0^\infty(\mathbb{R})$ with $\varphi(\lambda) \neq 0$ and supp $\varphi \subset K$ such that the r.h.s of (1) is larger than $c_0 \varphi^2(H^a(k_a))$ for all $k_a \in U_a$.

(c) Since $\lambda \notin \tau(H)$, the inequality $\rho_{H^a(0)}(\lambda) > 0$ is a straightforward consequence of the definition of $\tau(H)$. Note that $H^a(0) = H^a$. From (a) of the preceding lemma we conclude that the function $k_a \mapsto \rho_{H^a(k_a)}$ is lower semicontinuous. So there exists a compact neighborhood $\mathcal{V}_a$ of 0 in X_a^* and a constant $c_1 > 0$ such that $\rho_{H^a(k_a)}(\lambda) \geq c_1$ for each $k_a \in \mathcal{V}_a$. Now, from (b) of the preceding lemma, if we choose $c_2 \in (0, c_1)$, then there exists $\varphi \in C_0^\infty(\mathbb{R})$ with $\varphi(\lambda) \neq 0$ and supp $\varphi \subset K$, such that

$$\forall k_a \in \mathcal{V}_a, \varphi(H^a(k_a))[H^a(k_a), iD^a]\varphi(H^a(k_a)) \geq c_2 \varphi^2(H^a(k_a)). \tag{2}$$

(d) By induction over a and by using the equality $\tilde{\rho}_H(\lambda) = \min_{a \in \mathcal{L}(2)} \rho_{H_a}(\lambda)$, we easily get that $\tilde{\rho}_H(\lambda) \geq 0$. From the decomposition $\mathcal{I}_a = \mathcal{I}^a \otimes_a \mathbb{T}(X_a)$ we see that $H^a(k_a)$ has in $\mathcal{H}(X^a)$ properties similar to those of H in $\mathcal{H}(X)$. More precisely, the kinetic energy part of $H^a(k_a)$ is given by the function $k^a \mapsto h(k^a + k_a)$, and by hypothesis we have $k_b^a h'(k^b + k_b^a + k_a) \geq 0$ if $b < a$. It follows that $\tilde{\rho}_{H^a(k_a)}(\lambda) \geq 0$. Now, as a consequence of Lemma 7.2.12 in Ref. 16 we get $\forall \epsilon > 0$, $\exists \varphi \in C_0^\infty(\mathbb{R})$ with $\varphi(\lambda) \neq 0$, such that

$$\forall k_a \in U_a, \varphi(H^a(k_a))[H^a(k_a), iD^a]\varphi(H^a(k_a)) \geq -\epsilon \varphi^2(H^a(k_a)). \tag{3}$$

(e) From our hypotheses it follows that there is $c_3 > 0$ such that $k_a h'(P^a + k_a) \geq c_3 > 0$ for each $k_a \notin \mathcal{V}_a$. Note that this strict positivity condition has not been used until now.

Finally, if we take $\epsilon_0 \leq \inf(c_2, c_3)$ and $\varphi_0 \in C_0^\infty(\mathbb{R})$ with $\varphi_0(\lambda) \neq 0$, such that (3) holds for ϵ_0 and φ_0, we get

$$\varphi_0(H^a(k_a))\{[H^a(k_a), iD^a] + k_a h'(P^a + k_a)\}\varphi_0(H^a(k_a)) \geq \inf(c_2, c_3)\varphi_0^2(H^a(k_a));$$

this completes the proof of the theorem. ■

IV.3. We summarize in the next theorem some consequences concerning the spectral properties of the dispersive N-body Hamiltonian H. Here we need that H be of class $\mathcal{C}^{1,1}(D)$.

Theorem IV.2: *Besides the hypotheses of Theorem III.1 we assume that h is of class* C^2, $(|kh'(k)| + |k^2 h''(k)|) \leq c(1 + |h(k)|)$ *for all* $k \in X^*$, *and that* $k_b^a h'(k^b + k_b^a + k_a) \geq 0$ *for all* $a, b \in \mathcal{L}$ *with* $b < a$ *and all* $k^b \in X^{b*}$, $k_b^a \in X_b^{a*}$, $k_a \in X_a^*$. *Moreover, in the case* $a = \max \mathcal{L}$ *assume that the stronger inequality* $k_b h'(k^b + k_b) > 0$ *holds if* $k_b \neq 0$. *Assume also that* V^a *can be decomposed into a sum* $V^a = V_S^a + V_L^a$, *where* V_S^a: $\mathcal{H}^s(X^a) \to \mathcal{H}^{-s}(X^a)$ *(the short-range component) and* V_L^a: $\mathcal{H}^s(X^a) \to \mathcal{H}^{-s}(X^a)$ *(the long-range component) are symmetric operators satisfying the following decay conditions at infinity. Choose* $\theta \in C_0^\infty(X)$ *such that* $\theta(x) > 0$ *if* $0 < 1 < |x| < 2$ *and* $\theta(x) = 0$ *otherwise and denote* $\|\cdot\|_{\mathcal{X}}$ *is the norm in* $\mathcal{X} \equiv B(\mathcal{H}^s(X^a), \mathcal{H}^{-s}(X^a))$. *Then we assume* $[V_L^a, iD^a] \in \mathcal{X}$ *and*

$$\int_1^\infty \left\{ \left\| \theta\left(\frac{Q^a}{r}\right) V_S^a \right\|_{\mathcal{X}} + \left\| \frac{1}{r}\, \theta\left(\frac{Q^a}{r}\right)[V_L^a, iD^a] \right\|_{\mathcal{X}} \right\} dr < \infty.$$

Then $\tau(H)$ *is a closed countable set, the eigenvalues of H outside* $\tau(H)$ *are of finite multiplicity and can accumulate only at points belonging to* $\tau(H)$, *and H has no singularly continuous spectrum.*

The limits $\lim_{\mu\to\pm 0}(H-\lambda-i\mu)^{-1}$ *exist in the* weak* *topology of* $B(\mathcal{H}^{-s}_{1/2,1},\mathcal{H}^{s}_{-1/2,\infty})$ *uniformly in* λ *on each compact subset of the open real set* $\mu^D(H)$. *Finally, if* $\mathcal{K}$ *is a Hilbert space and T:* $\mathcal{H}(X)\to\mathcal{K}$ *is a linear operator that is continuous when* $\mathcal{H}(X)$ is equipped with the topology induced by $\mathcal{H}^{s}_{-1/2,\infty}$, *then T is locally H-smooth on* $\mu^D(H)$.

Proof: The first assertion will hold inductively given the conclusion of the second assertion for subsystems and the definition of thresholds. Our hypotheses imply that H is of class $\mathcal{C}^{1,1}(D)$; for this we use Proposition 7.5.7 and Theorem 7.5.8 in Ref. 16 with $\Lambda=\langle Q\rangle$. Since H is bounded from below, it has a spectral gap. Then the second and the third assertion are consequences of Theorem 7.3.1 and Theorem 7.4.2 of Ref. 16 and also of the first assertion. The last assertion follows from Theorem 7.4.1 and Proposition 7.4.4 of Ref. 16. ■

IV.4. We give now three classes of examples of dispersive systems, for which we prove that the hypotheses of Theorem IV.1 hold.

Example 1: Assume that X is an Euclidean space identified with X^* and let g be a function g: $[0,\infty)\to\mathbb{R}$, such that

$$g'(t)\geqslant c>0,$$

$$tg'(t)\leqslant \mathrm{const}(1+g(t)),$$

for all $t\geqslant 0$. Then all the hypotheses of Theorem IV.1 hold for $h(k)=g(|k|)$ if we take $X^a=X_a^\perp$ $(\forall a)$.

Example 2: Let $X=\mathbb{R}^\nu\times\mathbb{R}^\nu$ where $\nu\geqslant 1$, and let

$$H=\omega(P_1)+\omega(P_2)+V_1(x_1)+V_2(x_2)+V_{12}(x_1-x_2).$$

We assume that $\omega:\mathbb{R}^\nu\to\mathbb{R}$ is a function such that $\omega(k)=U(|k|)$ for some increasing and convex function U. In particular, the Hamiltonian of two relativistic particles with the same mass is included.

We identify $X^*=X$, so $h:X^*\to\mathbb{R}$ is given by $h(k)=\omega(k_1)+\omega(k_2)$ for $k=(k_1,k_2)$. The set of subspace $\{X_a\}$ is the following: if $a=\{(1,2)\}$ then $X_a=\{x\in X|x_1=x_2\}$; if $a=i$ $(i=1,2)$ then $X_a=\{x\in X|x_i=0\}$. We take $X_{a_{\max}}=0$ and $X_{a_{\min}}=X$.

Let us check that (1) if $a<b$ then $k_a^b h'(k^a+k_a^b+k_b)\geqslant 0$;

(2) if $b=a_{\max}$ then $k_a h'(k^a+k_a)>0$ for $k_a\neq 0$.

(i) For $a=a_{\min}$: we have $X^{a_{\min}}=0$.
(a) $kh'(k)=k_1\omega'(k_1)+k_2\omega'(k_2)=|k_1|U'(|k_1|)+|k_2|U'(|k_2|)>0$ if $k\neq 0$ because U is increasing, so (2) holds.
(b) In this case, (1) is equivalent to check that $k^b h'(k^b+k_b)\geqslant 0$ if $b=1,2,\{(1,2)\}$. For $b=i$, $(i=1,2)$ we take $X^b=\{x\in X|x_j=0, j\neq b\}$ and we check easily that $k^b h'(k^b+k_b)\geqslant 0$. For example, if $b=1$, then $k^b=(k_1,0)$, $k_b=(0,k_2)$ and $k^b h'(k^b+k_b)=k_1\omega'(k_1)=|k_1|U'(|k_1|)\geqslant 0$.

For $b=\{(1,2)\}$ we take $X^b=\{x\in X|x_1=-x_2\}$, then $k^b=(k_2,-k_2)$, $k_b=(k_1,k_1)$. Let us set $x=k_1+k_2$ and $y=k_1-k_2$; then

$$k^b h'(k^b+k_b)=k_2\omega'(k_1+k_2)-k_2\omega'(k_1-k_2)=1/2\left[(x-y)\,\frac{x}{|x|}\,U'(|x|)-(x-y)\,\frac{y}{|y|}\,U'(|y|)\right].$$

We use polar coordinates: $x=re$, $y=\rho f$, where e,f are two unitary vectors and $r,\rho\geqslant 0$, and we set $\theta=e\cdot f\in[-1,1]$. Then $k^b h'(k^b+k_b)\geqslant 0$ is equivalent to $rU'(r)+\rho U'(\rho)\geqslant\theta(rU'(\rho)+\rho U'(r))$. So it suffices to check that the last inequality holds for $\theta=1$, which is true because U' is increasing.

(ii) If $a=1,2$ then $b=a_{\max}$ and the hypotheses (1) and (2) are easy to check. For example, if $a=1$ then $k^a=(k_1,0)$, $k_a=(0,k_2)$ and $k_a h'(k^a+k_a)=k_2\omega'(k_2)=|k_2|U'(|k_2|)>0$ for $k_2\neq 0$.

(iii) For $a=\{(1,2)\}$ then $k^a=(k_1,-k_1)$, $k_a=(k_2,k_2)$, and as in (i) we have that $k_a h'(k^a+k_a)=k_2\omega'(k_1+k_2)+k_2\omega'(k_2-k_1)=k_2\omega'(k_1+k_2)-k_2\omega'(k_1-k_2)>0$ if $k_a\neq 0$.

Example 3: In this example we show the usefulness of the freedom one has in the choice of the spaces X^a supplementary to X_a. We consider two models of Hamiltonians describing particles with distinct kinetic energy:

$$H=\omega_1(P_1)+\omega_2(P_2)+V_1(x_1)+V_2(x_2)+V_{12}(x_1-x_2).$$

Then $h(k)=\omega_1(k_1)+\omega_2(k_2)$ for $k=(k_1,k_2)$. We shall keep the space X and the set of subspaces $\{X_a\}$ introduced in Example 2.

(a) The first model is simply the Hamiltonian of nonrelativistic particles. Then $\omega_i(k_i)=|k_i|^2/2m_i$ ($i=1,2$), where $m_i>0$ is the mass of particles i. By Example 2, we have to check only that: $k^a h'(k^a+k_a)\geqslant 0$ and $k_a h'(k^a+k_a)>0$ if $k_a\neq 0$ for $a=\{(1,2)\}$. Let $X^a=\{x\in X|x=(y,\alpha y),y\in\mathbb{R}^\nu\}$, with some $\alpha\in\mathbb{R}$. Then $k^a=(k_1,\alpha k_1)$, $k_a=(k_2,k_2)$ and

$$\begin{aligned}k^a h'(k^a+k_a)&=\langle k_1,\omega_1'(k_1+k_2)\rangle+\langle \alpha k_1,\omega_2'(\alpha k_1+k_2)\rangle\\&=\frac{1}{m_1}\langle k_1,(k_1+k_2)\rangle+\frac{\alpha}{m_2}\langle k_1,(\alpha k_1+k_2)\rangle.\end{aligned}$$

Let us set $t=|k_1|^2$ and $s=\langle k_1,k_2\rangle$. Then the last expression is positive for all $k_1,k_2\in\mathbb{R}^\nu$ if and only if $(m_2+\alpha^2 m_1)t+(m_2+\alpha m_1)s\geqslant 0$ for all $t\geqslant 0$ and $s\in\mathbb{R}$. But for a fixed t this is true for all $s\in\mathbb{R}$ only if $\alpha=-m_2/m_1$. Now with this α it is easy to check the second assertion.

(b) The second model appears in the theory of elasticity: we take $\omega_i(k_i)=c_i|k_i|^4$ ($i=1,2$) where $c_i>0$ is a constant. Here we suppose that $\nu=1$ and as in the last example we take $X^a=\{x\in X|x=(s,\alpha s),s\in\mathbb{R}\}$, with some $\alpha\in R$. Then $k^a=(s,\alpha s)$, $k_a=(t,t)$, and

$$\begin{aligned}k^a h'(k^a+k_a)&=s\omega_1'(s+t)+\alpha s\omega_2'(\alpha s+t)\\&=4(c_1+c_2\alpha^4)s^4+12(c_1+c_2\alpha^2)s^2t^2+4(c_1+c_2\alpha)st^3+12(c_1+c_2\alpha^3)s^3t.\end{aligned}$$

Then it is clear that (1) and (2) hold if $\alpha=-c_1/c_2$.

ACKNOWLEDGMENTS

The author takes this opportunity to express his gratitude to Vladimir Georgescu for suggesting to him the subject of this work and for many helpful discussions and to Anne Boutet de Monvel for useful advices and for the inspiring environment of the Laboratoire de Physique Mathématique et Géométrie. Finally, I am indebted to the referee for comments and criticism that allowed me to correct and clarify several points of the initial version of the paper.

APPENDIX

We shall prove here that the algebra $\mathcal{I}(a)$ is independent of the choice of the supplementary space X^a and of the various volume elements (see II.4).

Let us fix a vector subspace Y of X and let us choose a supplementary subspace Z to Y in X (so $X=Y+Z$, $Y\cap Z=\{0\}$) and some volume elements dy, dz on Y and Z. We identify $L^2(X)=L^2(Z)\otimes L^2(Y)$ and we define the C^*-algebra $\mathbb{K}(Z)\otimes\mathbb{T}(Y)$ as the norm closure in $\mathbb{B}(X)$ of the linear space $\mathcal{K}(Z,Y)$ generated by the operators of the form $S\otimes T$ with S compact in $L^2(Z)$ and $T\in\mathbb{T}(Y)$. The space $\mathcal{K}(Z,Y)$ depends on the choice of Z (see the last identity in the proof of the next lemma). Our purpose here is to show that its norm closure $\mathbb{K}(Z)\otimes\mathbb{T}(Y)$ is, however, independent of Z. For this we shall introduce a class of operators K, which clearly has the same norm closure as $\mathcal{K}(Z,Y)$, and then we show that this class of operators is independent of Z.

If $k\in C_c(Y\times Z\times Z)$ (spaces of continuous functions with compact support on $Y\times Z\times Z$) then

$$(Kf)(y+z)=\int_Y\int_Z k(y-y',z,z')f(y'+z')dy'\ dz'$$

defines an element of $\mathbb{B}(X)$. Indeed, if K_y is the operator in $L^2(Z)$ defined by the kernel $k(y,\cdot,\cdot)$ with respect to the volume element *dz*, then K_y is a Hilbert–Schmidt operator and

$$\|(Kf)(y+\cdot)\|_{L^2(Z)}\leqslant\int_Y\|K_{y-y'}f(y'+\cdot)\|_{L^2(Z)}\ dy'\leqslant\int_Y\|K_{y'}\|_{\mathbb{B}(Z)}\|f(y-y'+\cdot)\|_{L^2(Z)}\ dy'.$$

We may assume that $dx=dy\otimes dz$. Then we get

$$\|Kf\|_{L^2(X)}=\left[\int_Y\|(Kf)(y+\cdot)\|^2_{L^2(Z)}\ dy\right]^{1/2}\leqslant\int_Y\|K_{y'}\|_{\mathbb{B}(Z)}\ dy'\cdot\|f\|_{L^2(X)},$$

and the r.h.s. is a finite number.

Lemma: The class of operators of the form K is independent of the choice of Z, dy, dz.

Proof: Let Z_1,Z_2 be two supplemenary spaces to *Y* in *X* and let p_1 be the projection of *X* onto *Y* defined by Z_1. If $x\in X$ and $x=y_1+z_1=y_2+z_2$ with $y_1,\ y_2\in Y$ and $z_1\in Z_1,\ z_2\in Z_2$ then $p_1z_1=0$, $p_1y_2=y_2$, hence $y_1=y_2+p_1z_2$. Moreover, if we set $q_1=1-p_1$ then $q_1y_2=0$, so $z_1=q_1z_2$. Observe that $q_1|Z_2$ is a bijective linear map of Z_2 onto Z_1.

Now let $k_1\in C_c(Y\times Z_1\times Z_1)$ and choose some volume elements *dy*, dz_1 on *Y* and Z_1. Then define *K* by

$$(Kf)(x)=(Kf)(y_1+z_1)=\int_Y\int_{Z_1}k_1(y_1-y_1',z_1,z_1')f(y_1'+z_1')dy_1'\ dz_1'.$$

In the integral over Z_1 we make the change of variable $z_1'=q_1z_2'$. The volume element dz_1' is the image of a volume element z_2' on Z_2 through this map and we get

$$(Kf)(x)=\int_Y\int_{Z_2}k_1(y_1-y_1',z_1,q_1z_2')f(y_1'+q_1z_2')dy_1'\ dz_2'.$$

In the integral over *Y* (for a fixed z_2') we make the translation $y_1'=y_2'+p_1z_2'$ and get

$$(Kf)(x)=\int_Y\int_{Z_2}k_1(y_1-y_2'-p_1z_2',z_1,q_1z_2')f(y_1'+p_1z_2'+q_1z_2')dy_2'\ dz_2'.$$

We have $p_1z_2'+q_1z_2'=z_2'$. Now $x=y_1+z_1=y_2+z_2$ and $y_1=y_2+p_1z_2$, $z_1=q_1z_2$. We get

$$(Kf)(y_2+z_2)=\int_Y\int_{Z_2}k_1(y_2-y_2'+p_1(z_2-z_2',q_1z_2,q_1z_2')f(y_2'+z_2')dy_2'\ dz_2'$$

$$\equiv\int_Y\int_{Z_2}k_2(y_2-y_2',q_1z_2,q_1z_2')f(y_2'+z_2')dy_2'\ dz_2'.$$

The function $k_2:Y\times Z_2\times Z_2\to\mathbb{C}$ defined by $k_2(y,z_2,z_2')=k_1(y+p_1(z_2-z_2',q_1z_2,q_1z_2'))$ is continuous with compact support because $q_1|Z_2:Z_2\to Z_1$ is a bijective linear map. Now the assertion of the lemma is clear. ■

(Received 29 September 1997; accepted for publication 1 July 1998)

Beginning with ordinary quantum mechanics for spinless particles, together with the hypothesis that all experimental measurements consist of positional measurements at different times, we characterize directly a class of nonlinear quantum theories physically equivalent to linear quantum mechanics through nonlinear gauge transformations. We show that under two physically motivated assumptions, these transformations are uniquely determined: they are exactly the group of time-dependent, nonlinear gauge transformations introduced previously for a family of nonlinear Schrödinger equations. The general equation in this family, including terms considered by Kostin, by Bialynicki-Birula and Mycielski, and by Doebner and Goldin, with time-dependent coefficients, can be obtained from the linear Schrödinger equation through gauge transformation and a subsequent process we call *gauge generalization*. We thus unify, on fundamental grounds, a rather diverse set of nonlinear time evolutions in quantum mechanics. © *1999 American Institute of Physics.* [S0022-2488(98)04011-0]

I. INTRODUCTION

Recently a group $\mathscr{N}$ of nonlinear gauge transformations was introduced and shown to act as a transformation group in a family $\mathscr{F}$ of nonlinear Schrödinger equations (NLSEs).[1] The family $\mathscr{F}$ consists of equations with nonlinear terms of the type introduced by Kostin,[2] by Bialynicki-Birula and Mycielski,[3] by Guerra and Pusterla,[4] and by Doebner and Goldin,[5,6] with time-dependent coefficients.

A transformation $N_{(\gamma,\Lambda)}\in\mathscr{N}$ is labeled by two real, time-dependent parameters γ and Λ (with $\Lambda\neq 0$), and acts as a nonlinear analog of a gauge transformation in quantum mechanics. Letting the time-dependent wave function $\psi(\mathbf{x},t)$ on $\mathbf{R}^3$ be an arbitrary solution of any particular NLSE in $\mathscr{F}$, $N_{(\gamma,\Lambda)}$ is given by

$$\psi' = N_{(\gamma,\Lambda)}[\psi] = |\psi| \exp[i(\gamma \ln|\psi| + \Lambda \arg \psi)]. \tag{1}$$

Then ψ' solves a transformed equation that also belongs to $\mathscr{F}$.

The physical interpretation of this construction, developed briefly below, was elaborated on in some detail in Ref. 1. However, the underlying mathematical structure, and the physical reasons for the form of (1), remained somewhat hidden. Equation (1) was motivated in earlier work by the

b)Electronic mail: gagoldin@dimacs.rutgers.edu
c)Electronic mail: aspn@pt.tu-clausthal.de

desire to linearize the equations in a special subset of $\mathscr{F}$, and to obtain stationary and nonstationary solutions.[6–11] The present paper takes a different, more fundamental approach to nonlinear gauge transformations and their consequences.

We begin with linear, nonrelativistic quantum mechanics for spinless particles in $\mathbf{R}^3$, together with the assumption, advocated for instance in Refs. 12–14, and discussed in Refs. 1, 9, 10, 15, and 16, that all experimental measurements consist fundamentally of positional measurements made at different times. Defining as usual the positional probability density $\rho(\mathbf{x},t) = \overline{\psi(\mathbf{x},t)}\psi(\mathbf{x},t)$, where ψ conventionally is a normalized solution of the linear Schrödinger equation, we are therefore interested in transformations N which leave $\rho(\mathbf{x},t)$ invariant—i.e., such that for all ψ in an appropriate domain of the unit sphere in the Hilbert space $\mathscr{H}$,

$$\overline{N[\psi](\mathbf{x},t)}N[\psi](\mathbf{x},t) = \overline{\psi(\mathbf{x},t)}\psi(\mathbf{x},t). \tag{2}$$

In addition, N should respect the prescription for writing the wave function subsequent to an ideal positional measurement. A conventional prescription for such a measurement at time t_1 consists of a projection in a region B of position space (a Borel subset of $\mathbf{R}^3$), with normalization,

$$\psi_s(\mathbf{x},t_1) = \begin{cases} \dfrac{\psi(\mathbf{x},t_1)}{(\int_B |\psi(\mathbf{x},t_1)|^2 d^3x)^{1/2}}, & \mathbf{x} \in B \\ 0, & \mathbf{x} \notin B \end{cases} \tag{3}$$

followed by time-evolution of $\psi_s(\mathbf{x},t)$ for $t > t_1$ (here the subscript ''s'' stands for ''subsequent''). As N should respect this prescription, we need for all ψ, $\mathbf{x}$ and $t \geqslant t_1$,

$$|N[\psi]_s(\mathbf{x},t)|^2 = |\psi_s(\mathbf{x},t)|^2, \tag{4}$$

and because of (2),

$$|N[\psi]_s(\mathbf{x},t)|^2 = |N[\psi_s](\mathbf{x},t)|^2. \tag{5}$$

We remark that in writing (3) we do not intend to express a commitment to a particular formalism for describing measurement. We merely note that the justification of N as a gauge transformation requires that in addition to (2) it leave invariant the outcomes of *sequences* of positional measurements at various times. Equation (3) is one prescription for predicting such outcomes in quantum mechanics.

Now if all actual measurements (outcomes of experiments) are obtained from positional measurements performed at various times, it can be argued that a system with states ψ obeying the Schrödinger equation, and one with states $N[\psi]$ obeying a transformed equation, have the same physical content. But we make two essential observations:

(a) Equations (2) and (4)–(5) do not require N to be a linear transformation—nonlinear N are also possible.
(b) Such nonlinear choices of N will transform a system governed by the usual, linear Schrödinger equation to physically equivalent systems obeying NLSEs that are, of course, linearizable (by construction).

The usual formulation and interpretation of quantum mechanics is based quite deeply on linearity and linear structures—superposition principle, on observables modeled by self-adjoint linear operators, on a linear time-evolution equation for the states, on a measurement process involving orthogonal projection onto linear subspaces for all sorts of observables, and on the description of mixed states by density matrices. Any proposal for nonlinearity in quantum mechanics requires a revised mathematical formulation and physical interpretation of all these ideas.

Here the linearizable NLSEs obtained using N can be useful. Due to their physical equivalence with linear quantum mechanics, they serve as a kind of ''laboratory'' for exploring how to generalize quantum mechanics to accommodate nonlinearities.

When N is *assumed* to be linear (and densely defined), Eq. (2) implies that it is a *unitary multiplication operator* for each t. Then N is labeled by a measurable function $\theta(\mathbf{x},t)$, and we have

$$\psi'(\mathbf{x},t)=(\mathbf{U}_\theta\psi)(\mathbf{x},t)=\exp[i\theta(\mathbf{x},t)]\psi(\mathbf{x},t). \tag{6}$$

Any such $\mathbf{U}_\theta$ commutes with the projection in (3), thus ensuring (5) and respecting the conventional prescription for wave functions subsequent to a positional measurement.

If θ is independent of $\mathbf{x}$ and t, we have just introduced a fixed phase, sometimes called a ''gauge transformation of the first kind.'' This changes neither the Schrödinger equation nor the form of position and momentum operators. A space- and time-dependent, linear $U(1)$-gauge transformation, implemented by (6), is sometimes called a ''gauge transformation of the second kind.'' Such transformations constitute an Abelian group $\mathscr{U}_{\mathrm{loc}}$ of *local* unitary operators acting on $\mathscr{H}$. The physical equivalence of the two theories, with states ψ and ψ', respectively, is guaranteed by the invariance of the outcomes of sequences of positional observations at all times.

A system with wave functions governed by the (linear) Schrödinger equation

$$i\hbar\partial_t\psi=-\frac{\hbar^2}{2m}\nabla^2\psi+V\psi \tag{7}$$

is transformed by (6) to a physically equivalent system, with wave function ψ' and Schrödinger equation

$$i\hbar\partial_t\psi'=\frac{1}{2m}\left(\frac{\hbar}{i}\nabla-\hbar\nabla\theta\right)^2\psi'+(V-\hbar\partial_t\theta)\psi'. \tag{8}$$

This observation suggests a *generic way* to construct new systems that are *not* physically equivalent to the original family given by (7) and (8). The scalar term $-\hbar\partial_t\theta$ and the vector term $\hbar\nabla\theta$ are merely special choices. If we replace $-\hbar\partial_t\theta$ by a *general* scalar field $\hat{\Phi}(\mathbf{x},t)$ and $\hbar\nabla\theta$ by a *general* vector field $\hat{\mathbf{A}}(\mathbf{x},t)$, calling them (Abelian) *gauge fields*, we obtain two well-known and well-established structures:

(a) a family $\mathscr{F}_{(\hat{\Phi},\hat{\mathbf{A}})}$ of time-evolution equations labeled by the gauge fields $\hat{\Phi}$ and $\hat{\mathbf{A}}$:

$$i\hbar\partial_t\psi=\frac{1}{2m}\left(\frac{\hbar}{i}\nabla-\hat{\mathbf{A}}\right)^2\psi+(V+\hat{\Phi})\psi; \tag{9}$$

and

(b) an action on this family by the gauge transformations $\mathbf{U}_\theta$, to establish equivalence classes—so that Schrödinger equations with $(\hat{\Phi},\hat{\mathbf{A}})$ and with $(\hat{\Phi}',\hat{\mathbf{A}}')=(\hat{\Phi}-\hbar\partial_t\theta,\hat{\mathbf{A}}+\hbar\nabla\theta)$ describe physically equivalent systems—with the family being closed under the action of gauge transformations.

This generic construction, which we here call *gauge generalization*, is physically relevant because external electromagnetic fields $(\Phi,\mathbf{A})$ interacting with a charged particle provide a realization of $(\hat{\Phi},\hat{\mathbf{A}})$ in nature: In Gaussian units, $\hat{\Phi}=e\Phi$ and $\hat{\mathbf{A}}=(e/c)\mathbf{A}$, where e is the charge of the particle. The gauge-transformed Schrödinger equations are physically equivalent to the original, but those obtained from them by gauge generalization are not. These well-known results provide a model for similar arguments involving the nonlinear transformations N.

In Sec. II, we demonstrate that two straightforward, physically motivated conditions precisely specify the group $\mathcal{N}$ of time-dependent, nonlinear gauge transformations introduced in Ref. 1. These assumptions are: (a) strict locality and (b) a separation condition. We observe that (5) is then ensured.

In Sec. III, we apply various subgroups of $\mathcal{N}$ to the linear Schrödinger equation (7). This leads to physically equivalent systems satisfying NLSEs, where the coefficients obey certain constraints. Then, in structural analogy to the way (8) motivates (9), we construct new, physically *inequivalent* systems by generalizing the parameters so as to break the constraints.

In Sec. IV, following this analogy, we consider the parameters as *gauge parameters*. We thus obtain a family of NLSEs through gauge generalization and gauge closure, labeled by the gauge parameters, on which the gauge group acts to establish physical equivalence classes. In this way, we derive naturally—as a unified class—equations containing the terms proposed by Kostin, Bialynicki-Birula and Mycielski, and Doebner and Goldin, with coefficients that are (in general) time dependent. The subfamily that includes the equations of Guerra and Pusterla turns out to be equivalent to linear quantum mechanics.

We believe this to offer a fundamentally new perspective, partially elucidating the hidden mathematical and physical structure behind certain nonlinear quantum time evolutions.

II. CONDITIONS ON NONLINEAR GAUGE TRANSFORMATIONS

A. Locality

We have from Eq. (2) that

$$N[\psi](\mathbf{x},t)=\exp[iG_{\psi}(\mathbf{x},t)]|\psi(\mathbf{x},t)|, \tag{10}$$

where G_ψ is a real-valued function of $\mathbf{x}$ and t depending on ψ. It is apparent that G_ψ must be further restricted if for instance we hope to ensure (5) for all Borel subsets B of $\mathbf{R}^3$. Suppose the value of $G_\psi(\mathbf{x},t)$ at $\mathbf{x}=\mathbf{x}_1$ depends nontrivially on values of $\psi(\mathbf{x},t)$ for $\mathbf{x}\neq\mathbf{x}_1$ and the evolution equation is local. Then we will be unable to satisfy (4) and (5) in the general case of a region B where $\mathbf{x}_1\in B$ but $\mathbf{x}\notin B$. Therefore let us assume N to be a *local* transformation, in analogy with the linear gauge transformations $\mathbf{U}_\theta$. This is taken here in the strict sense that the value of $N[\psi]$ at $(\mathbf{x},t)$ should depend only on $\mathbf{x}$, t, and the value of $\psi(\mathbf{x},t)$—not on any other space or time points, and not on derivatives of ψ. Then we must have

$$\psi'(\mathbf{x},t)=N_F[\psi](\mathbf{x},t)=\exp[iF(\psi(\mathbf{x},t),\mathbf{x},t)]|\psi(\mathbf{x},t)|, \tag{11}$$

where F is a real-valued function (defined up to integer multiples of 2π) of the three variables whose values are provided by $\psi(\mathbf{x},t)$, $\mathbf{x}$, and t. The possible dependence of F on the value of $\psi(\mathbf{x},t)$ allows nonlinearity in N_F. With $R(\mathbf{x},t)=|\psi(\mathbf{x},t)|$ and $S(\mathbf{x},t)=\arg\psi(\mathbf{x},t)$, we can consider F to be a function of the real variables R, S, $\mathbf{x}$, and t, relaxing for now the requirement that F take the same value at S and $S+2\pi n$.

Note that a weaker assumption, in which F is permitted to depend on finitely many derivatives of ψ at $(\mathbf{x},t)$, may still be compatible with (5). We make a stricter assumption here, which limits the resulting time-evolution equations to second order.

B. A separation condition

We consider now systems of n particles described by normalized states in $\mathcal{H}^{(n)}=L^2(\mathbf{R}^{3n},d^{3n}x)$. For simplicity, take each individual particle to evolve under the same time-evolution operator $T^{(1)}$. We suppose a hierarchy of time-evolutions $T^{(n)}$ of n-particle states, fulfilling the *separation condition*. For linear time evolutions this condition requires that product states $\psi^{(n)}=\psi_1\otimes\ldots\otimes\psi_n$, $\|\psi_j\|=1$, $j=1,\ldots,n$, evolve into product states:

$$T^{(n)}[\psi^{(n)}]=T^{(1)}[\psi_1]\otimes T^{(1)}[\psi_2]\otimes\cdots\otimes T^{(1)}[\psi_n]. \tag{12}$$

It ensures that in the absence of interaction terms, initially uncorrelated subsystems remain uncorrelated, and $T^{(n)}$ is extended (by linearity) from product states to all of $\mathscr{H}^{(n)}$.

It is physically plausible to assume (12) for nonlinear time evolutions $T^{(n)}$ as well.[3,17] Then nonlinear gauge transformations $N_F^{(n)}$ should respect this condition. Here, the states $\psi_j'(\mathbf{x},t) = N_F[\psi_j]$ in (11) are governed by a nonlinear time evolution $T^{(1)'}$, and our separation condition becomes for product states $\psi^{(n)'} = \psi_1' \otimes \ldots \otimes \psi_n'$, $\|\psi_j'\| = 1$, $j = 1,\ldots,n$,

$$T^{(n)'}[\psi^{(n)'}] = T^{(1)'}[\psi_1'] \otimes \cdots \otimes T^{(1)'}[\psi_n']. \tag{13}$$

We thus want a nonlinear gauge transformation $N_F^{(n)}$ acting on the unit sphere in $\mathscr{H}^{(n)}$, with $\|N_F^{(n)}[\psi]\| = 1$, so that on the product states $\psi^{(n)}$

$$N_F^{(n)}[\psi] = N_F[\psi_1] \otimes \cdots \otimes N_F[\psi_n]. \tag{14}$$

Unitary gauge transformations $\mathbf{U}^{(n)}$ in $\mathscr{H}^{(n)}$ may be written as

$$(\mathbf{U}\psi^{(n)})(\mathbf{x}_1,\ldots,\mathbf{x}_n,t) = \exp[i\,\theta_n(\mathbf{x}_1,\ldots,\mathbf{x}_n,t)]\,\psi(\mathbf{x}_1,\ldots,\mathbf{x}_n,t). \tag{15}$$

On product states, using (6), we want

$$\mathbf{U}^{(n)}\psi^{(n)} = (\mathbf{U}_\theta\psi_1) \otimes (\mathbf{U}_\theta\psi_2) \otimes \cdots \otimes (\mathbf{U}_\theta\psi_n), \tag{16}$$

so that

$$\theta_n(\mathbf{x}_1,\mathbf{x}_2,\ldots,\mathbf{x}_n,t) = \sum_{j=1}^{n} \theta(\mathbf{x}_j,t). \tag{17}$$

And of course, for this case, the operators are linear and can be extended by linearity from product states to the whole Hilbert space. But $N_F^{(n)}$ in Eq. (14) is nonlinear, so we cannot extend it uniquely to $\mathscr{H}^{(n)}$.

The apparently weak condition (14) leads nevertheless to a sharp restriction on F. To see this it is sufficient to discuss the case $n=2$. With $R_j = |\psi_j|$, $S_j = \arg\psi_j$, $j = 1,2$, Eqs. (11) and (14) imply that

$$F(R_1,S_1,\mathbf{x}_1,t) + F(R_2,S_2,\mathbf{x}_2,t) \tag{18}$$

depends only on the product $R = R_1R_2$ and the sum $S = S_1 + S_2$. Thus

$$F(R_1,S_1,\mathbf{x}_1,t) + F(R_2,S_2,\mathbf{x}_2,t) = F(R,S,\mathbf{x}_1,t) + F(1,0,\mathbf{x}_2,t), \tag{19}$$

for all $R,S,\mathbf{x}_1,\mathbf{x}_2,t$, whence $F(R_2,S_2,\mathbf{x}_2,t) - F(1,0,\mathbf{x}_2,t)$ must be independent of $\mathbf{x}_2$. Setting $F(1,0,\mathbf{x},t) = \theta(\mathbf{x},t)$ and $L(R,S,t) = F(R,S,\mathbf{x},t) - \theta(\mathbf{x},t)$, we have the functional equation

$$L(R_1,S_1,t) + L(R_2,S_2,t) = L(R_1R_2,S_1+S_2,t). \tag{20}$$

The smooth solutions of (20) are given by $L(R,S,t) = \gamma(t)\ln R + \Lambda(t)S$, where γ,Λ are real functions of t. Nondegeneracy of the transformation requires $\Lambda(t) \neq 0$. Finally, we have

$$F(R,S,\mathbf{x},t) = \gamma(t)\ln R + \Lambda(t)S + \theta(\mathbf{x},t). \tag{21}$$

The above argument is similar to the way in which generalized homogeneity of the time evolution is deduced from the separation property.[17]

Note that our separation condition is *weak* in the sense that for nonlinear $T^{(n)}$ and $N_F^{(n)}$ it is only defined on product states; for nonproduct (entangled) initial states, noninteracting subsystems may yet acquire new correlations. The nonlocal effects in some nonlinear evolution equations can be traced back to this fact.[18] A *strong* version of the separation condition, more adapted to the physical situation and valid for general states, can be formulated along the lines given in Ref. 18.

C. The result

In short, the locality and the separation condition required on n-particle product states boil down the transformations N_F for single particle states to those labeled by two real functions γ and Λ of time, with Λ nonvanishing, and a real function θ of space and time:

$$(N_{(\gamma,\Lambda,\theta)}[\psi])(\mathbf{x},t)=|\psi(\mathbf{x},t)|\exp[i(\gamma(t)\ln|\psi(\mathbf{x},t)|+\Lambda(t)\arg\,\psi(\mathbf{x},t)+\theta(\mathbf{x},t))]. \tag{22}$$

The set $N_{(\gamma,\Lambda,\theta)}$ forms a group $\mathscr{G}$, with multiplication law

$$N_{(\gamma',\Lambda',\theta')}\circ N_{(\gamma,\Lambda,\theta)}=N_{(\gamma'+\Lambda'\gamma,\Lambda'\Lambda,\theta'+\Lambda'\theta)}\,. \tag{23}$$

This can be expressed in terms of 3×3 matrices,

$$N_{(\gamma,\Lambda,\theta)}\simeq\begin{pmatrix}1&0&0\\ \theta&\Lambda&0\\ \gamma&0&\Lambda\end{pmatrix} \tag{24}$$

with entries $\Lambda=\Lambda(t)$, $\gamma=\gamma(t)$, and $\theta=\theta(\mathbf{x},t)$ taken from the corresponding function spaces. We thus have here a group $\mathscr{G}$ of nonlinear gauge transformations, strictly local and separating on n-particle product states, labeled by time-dependent parameters γ and Λ together with a function $\theta(\mathbf{x},t)$. The group is a semidirect product of the group of gauge transformations of the second kind $\mathscr{U}_{\mathrm{loc}}=\{\mathbf{U}_\theta\}$ and the group $\mathscr{N}$, mentioned in Sec. I, of ''pure nonlinear'' gauge transformations (where $\theta\equiv0$):

$$\mathscr{G}=\mathscr{N}\otimes_s\mathscr{U}_{\mathrm{loc}}\,. \tag{25}$$

$\mathscr{G}$ can be viewed as a *nonlinear generalization* of $\mathscr{U}_{\mathrm{loc}}$, i.e., as the group of ''gauge transformations of the *third kind*.'' [1]

The transformations $N_{(\gamma,\Lambda,\theta)}$ are not uniquely defined on the Hilbert space. If we restrict the range of Λ to the integers, $\Lambda(t)\in\mathbf{Z}$, then $N_{(\gamma,\Lambda,\theta)}$ is well defined. Then if Λ is a continuous function of time, Λ has to be a constant; $N_{(\gamma,\Lambda,\theta)}$ is invertible with this restriction only for $\Lambda=\pm1$. $\Lambda=-1$ corresponds to complex conjugation: $N_{(0,-1,0)}\psi=\overline{\psi}$. $N_{(\gamma,1,\theta)}$ is strongly continuous,[15] and the set of these transformations is an Abelian subgroup of $\mathscr{G}$,

$$\mathscr{G}\supset\mathscr{G}_0=\mathscr{N}_0\otimes\mathscr{U}_{\mathrm{loc}}, \tag{26}$$

where $\mathscr{N}_0:=\{N_\gamma:=N_{(\gamma,\Lambda\equiv1,\theta\equiv0)}\}$.

For noninteger Λ, $N_{(\gamma,\Lambda,\theta)}$ may be specified uniquely on certain domains in the Hilbert space, e.g., by imposing continuity of the phase of $N[\psi]$ on a domain of nonvanishing functions ψ. However, such a domain is not needed explicitly for our further considerations.

D. A generalization

Because of the difficulties with the separation condition mentioned above, a more general group structure is also of interest. This can be obtained, without assuming separation, by making a physically motivated, weaker assumption: an intertwining relation that follows from requiring compatibility with linear gauge transformations.

The group of linear gauge transformations $\mathscr{U}_{\mathrm{loc}}$ is commutative, but this need not be the case for the set $\{N_F\}\supset\mathscr{U}_{\mathrm{loc}}$. In particular, $\mathbf{U}_\theta$ might not commute with N_F. We explore the condition that N_F be consistent with the usual notion of physical equivalence under gauge transformations of the second kind. That is, the result of applying N_F to a gauge-transformed theory with wave functions $\mathbf{U}_\theta\psi$ should be expressible as a transform by $\mathbf{U}_{\theta'}$ of the theory with wave functions $N_F[\psi]$, where, in general, $\theta'(\mathbf{x},t)\neq\theta(\mathbf{x},t)$. Thus we require an *intertwining relation*

$$N_F[\mathbf{U}_\theta\psi]=\mathbf{U}_{\theta'}N_F[\psi]. \tag{27}$$

Here the function $\theta'(\mathbf{x},t)$ depends on both of the functions F and θ.

Then Eq. (27) implies the functional equation

$$\exp\, i[F(R,S+\theta;\mathbf{x},t)]=\exp\, i[\theta'(\mathbf{x},t)+F(R,S;\mathbf{x},t)], \tag{28}$$

valid for each R, S, $\mathbf{x}$, and t. It is straightforward to show that smooth solutions F of (28) take the form $F(R,S;\mathbf{x},t)=k(R,\mathbf{x},t)+\lambda(\mathbf{x},t)S$, where k and λ are real-valued functions of the indicated variables. Nondegeneracy of the transformation requires $\lambda(\mathbf{x},t)\neq 0$ for all $\mathbf{x},t$. Thus N_F is parametrized by k and λ, and given by

$$N_{(k,\lambda)}[\psi](\mathbf{x},t)=\exp\, i[k(|\psi(\mathbf{x},t)|,\mathbf{x},t)+\lambda(\mathbf{x},t)\arg\,\psi(\mathbf{x},t)]|\psi(\mathbf{x},t)|. \tag{29}$$

One easily checks that (2), (11), and (27) are fulfilled, with

$$\theta'(\mathbf{x},t)=\lambda(\mathbf{x},t)\theta(\mathbf{x},t). \tag{30}$$

The set $\{N_{(k,\lambda)};\lambda(\mathbf{x},t)\neq 0\}$ is a noncommutative, infinite dimensional group $\tilde{\mathscr{G}}$ with multiplication law

$$N_{(k,\lambda)}\circ N_{(k',\lambda')}=N_{(k+k'\lambda,\lambda\lambda')}. \tag{31}$$

$N_{(0,1)}$ acts as the identity on ψ, and $N_{(-k/\lambda,1/\lambda)}$ is the (formal) inverse of $N_{(k,\lambda)}$. The group law may be expressed as multiplication of 2×2 matrices

$$N_{(k,\lambda)}\simeq\begin{pmatrix}1 & 0\\ k & \lambda\end{pmatrix} \tag{32}$$

with entries $k(|\psi|,\mathbf{x},t)$ and $\lambda(\mathbf{x},t)$ taken from suitable function spaces. Such matrices span a linear representation Aff(1) of the one-dimensional affine group.

The nonlinear transformations $N_{(\gamma,\Lambda,\theta)}$ are special cases of $N_{(k,\lambda)}$, i.e., the separation condition restricts k and λ to the form

$$k(|\psi|,\mathbf{x},t)=\gamma(t)\ln|\psi|+\theta(\mathbf{x},t), \tag{33}$$

$$\lambda(\mathbf{x},t)=\Lambda(t); \tag{34}$$

and $\mathscr{G}$ is a subgroup of $\tilde{\mathscr{G}}$.

III. NONLINEAR QUANTUM-MECHANICAL EVOLUTION EQUATIONS FROM GAUGE GENERALIZATION

A. Linearizable NLSEs

In accordance with the discussion in Sec. I, we are now interested in the evolution equation of

$$\psi'(\mathbf{x},t)=N_{(\gamma,\Lambda,\theta)}[\psi](\mathbf{x},t), \tag{35}$$

when $\psi(\mathbf{x},t)$ is a solution of a linear Schrödinger equation

$$i\partial_t\psi=(\nu_1\Delta+\mu_0 V)\psi. \tag{36}$$

Let us regard (36) as belonging to a parametrized family $\mathscr{F}_0(\nu_1,\mu_0)$, $\nu_1\neq 0$, depending on the two real parameters ν_1,μ_0; in Eq. (7), $\nu_1=-\hbar/2m$ and $\mu_0=1/\hbar$.

Due to (27) linear gauge transformations can be treated independently, and we shall here restrict ourselves to the case $\theta\equiv 0$. Applying the group $\mathscr{N}$ to $\mathscr{F}_0$, we obtain a family $\overline{\mathscr{F}_0}$ of NLSEs,

$$i\partial_t\psi'=(\nu_1'(t)\Delta+\mu_0'(t)V+F_{\mathrm{DG}}^{(0)}[\psi']+F_{\mathrm{BM}}[\psi']+F_{\mathrm{K}}[\psi'])\psi', \tag{37}$$

where the subscripts DG, BM, and K, refer to terms of types considered respectively by Doebner and Goldin, Bialynicki-Birula and Mycielski, and Kostin; specifically:

$$F_{\mathrm{DG}}^{(0)}[\psi']=\mu_1'(t)\left(\nabla\left(\mathrm{Im}\left\{\frac{\nabla\psi'}{\psi'}\right\}\right)+\frac{i}{2}\,\frac{\Delta|\psi'|^2}{|\psi'|^2}\right)+2\kappa'(t)\,\frac{\Delta|\psi'|}{|\psi'|}, \tag{38}$$

$$F_{\mathrm{BM}}[\psi']=\alpha_1'(t)\log|\psi'|^2, \tag{39}$$

$$F_{\mathrm{K}}[\psi']=\alpha_2'(t)\arg\,\psi'. \tag{40}$$

The coefficients ν_1', μ_0', μ_1', κ', α_1', and α_2' are constrained, and depend on both ν_1,μ_0, and on $\Lambda(t),\gamma(t)$:

$$\nu_1'(t)=\frac{1}{\Lambda(t)}\nu_1,\quad \mu_0'(t)=\Lambda(t)\mu_0,\quad \mu_1'(t)=-\frac{\gamma(t)}{\Lambda(t)}\nu_1,\quad \kappa'(t)=\frac{\gamma(t)^2+\Lambda(t)^2-1}{2\Lambda(t)}\nu_1,$$
$$\alpha_1'(t)=\gamma(t)\frac{\dot\Lambda(t)}{2\Lambda(t)}-\frac{1}{2}\,\dot\gamma(t),\quad \alpha_2'(t)=-\frac{\dot\Lambda(t)}{\Lambda(t)}. \tag{41}$$

This family $\overline{\mathscr{F}_0}$ is closed under $\mathscr{N}$, i.e., it is the *gauge closure* of $\mathscr{F}_0(\nu_1,\mu_0)$ under the action of the group $\mathscr{N}$. It is, up to questions of domain mentioned above, linearizable. It depends on the independent quantities ν_1, μ_0, $\gamma(t)$ and $\Lambda(t)$. One could also write $\overline{\mathscr{F}_0}$ as $\mathscr{F}(\nu_1,\mu_0,\mu_1,\kappa,\alpha_1,\alpha_2)$ labeled by time-dependent coefficients that are constrained.

Note that if Λ and γ are independent of t, the coefficients are time independent, and $\alpha_1'=\alpha_2'=0$.

If we restrict $\mathscr{N}$ to the subgroup $\mathscr{N}_0$, then starting with $\mathscr{F}_0(\nu_1,\mu_0)$, we obtain a family $\overline{\mathscr{F}_0}^0$ closed under $\mathscr{N}_0$ and contained in $\overline{\mathscr{F}_0}$; here the indexed bar denotes the closure with respect to $\mathscr{N}_0$. The elements in $\overline{\mathscr{F}_0}^0$ are by construction linearizable NLSEs. The parameters are

$$\nu_1'=\nu_1,\quad \mu_0'=\mu_0,\quad \mu_1'(t)=\gamma(t)\nu_1,\quad \kappa'(t)=\frac{\gamma(t)^2}{2}\nu_1,$$
$$\alpha_1'(t)=-\tfrac{1}{2}\dot\gamma(t),\quad \alpha_2'(t)=0. \tag{42}$$

Now the term F_{K} disappears, everything is well-defined, and ν_1' and μ_0' are time-independent invariants. Strictly speaking, these NLSEs are *defined* using the continuity and invertibility of $N_{(\gamma,1,0)}$.

For later purposes we mention that $F_{\mathrm{DG}}^{(0)}$ decomposes into independent nonlinear real functionals R with the following properties: $R[\psi]$ is Euclidean invariant, complex homogeneous of degree zero and a rational function of $\psi,\overline{\psi}$ with derivatives not higher than second order in the numerator only. There exist five functionals of this type (see Ref. 6):

$$R_1[\psi]=\frac{\nabla\cdot\mathbf{J}}{\rho},\quad R_2[\psi]=\frac{\Delta\rho}{\rho},$$
$$R_3[\psi]=\frac{\mathbf{J}^2}{\rho^2},\quad R_4[\psi]=\frac{\mathbf{J}\cdot\nabla\rho}{\rho^2},\quad R_5[\psi]=\frac{(\nabla\rho)^2}{\rho^2}, \tag{43}$$

where $\rho=\bar{\psi}\psi$ and $\mathbf{J}=(1/2i)(\bar{\psi}\nabla\psi-(\nabla\bar{\psi})\psi)$ are the probability density and current corresponding to ψ. With this notation $F_{\mathrm{DG}}^{(0)}$ in (38) is a complex linear combination:

$$F_{\mathrm{DG}}^{(0)}[\psi]=\mu_1(t)(R_1[\psi]-R_4[\psi])+i\nu_2(t)R_2[\psi]+\kappa(t)(R_2[\psi]-\tfrac{1}{2}R_5[\psi]), \tag{44}$$

with

$$\nu_2(t)=-\tfrac{1}{2}\mu_1(t). \tag{45}$$

The term $R_3[\psi]$ will appear in Sec. III B.

B. Generalizing linearizable NLSEs; gauge parameters

The nonlinear gauge transformations $N_{(\gamma,\Lambda)}$ generate special linearizable NLSEs, i.e., nonlinear partial differential equations with constrained coefficients, physically equivalent to linear Schrödinger equations. Hence the situation is similar to the case of gauge transformations $\mathbf{U}_\theta$ in Sec. I. It is possible to construct generically through *gauge generalizations* and *gauge closures* a sequence of new families of evolution equations physically *in*equivalent to the linear Schrödinger equation. We obtain the sequence of these families in three steps:

Step 1: We break the constraints (41) in $\overline{\mathscr{F}_0}$ (gauge generalization), i.e., we take the six constrained coefficients $\nu_1',\mu_0',\mu_1',\kappa',\alpha_1',\alpha_2'$ as independent functions of time. Thus we obtain a family $\mathscr{F}_1(\nu_1,\mu_0,\mu_1,\kappa,\alpha_1,\alpha_2)$ with six independent parameters. The gauge transformations $\mathscr{N}$ are automorphisms of this family. That is, $\overline{\mathscr{F}_1}=\mathscr{F}_1$; the family is gauge closed. In the notation of Ref. 1, $\kappa=\mu_2-\frac{1}{2}\nu_1$.

Step 2: We break the constraint (45) for F_{DG}^0 in $\mathscr{F}_1$ (gauge generalization),

$$F_{\mathrm{DG}}^{(1)}[\psi]=i\nu_2(t)R_2[\psi]+\mu_1(t)(R_1[\psi]-R_4[\psi])+\kappa(t)(R_2[\psi]-\tfrac{1}{2}R_5[\psi]), \tag{46}$$

and obtain a seven-parameter family $\mathscr{F}_2(\nu_1,\nu_2,\mu_0,\mu_1,\kappa,\alpha_1,\alpha_2)$ of NLSEs (37), with $F_{\mathrm{DG}}^{(1)}$ replacing $F_{\mathrm{DG}}^{(0)}$.

The action of the group $\mathscr{N}$, however, does not leave this family invariant. The gauge closure $\overline{\mathscr{F}_2}$ of $\mathscr{F}_2$ consists of NLSEs (37) with

$$F_{\mathrm{DG}}^{(2)}[\psi]=i\nu_2'(t)R_2[\psi]+\mu_1'(t)(R_1[\psi]-R_4[\psi])+\kappa'(t)R_2[\psi]+\xi'(t)R_5[\psi] \tag{47}$$

in place of $F_{\mathrm{DG}}^{(1)}$. Now there are eight coefficients which already are unconstrained. Thus we write $\overline{\mathscr{F}_2}$ as a family $\mathscr{F}_3(\nu_1,\nu_2,\mu_0,\mu_1,\kappa,\xi,\alpha_1,\alpha_2)$ with eight time-dependent parameters, that is invariant by construction under $\mathscr{N}$, i.e., $\overline{\mathscr{F}_2}=\mathscr{F}_3=\overline{\mathscr{F}_3}$. In the notation of Ref. 1, $\xi=\mu_5+\frac{1}{4}\nu_1$. The explicit formula for these coefficients is given by Eq. (50) below, with $\mu_3=-\nu_1$ and $\xi=-\frac{1}{2}\kappa$.

Step 3: We write $\Delta\psi$ as a complex linear combination of $R_j[\psi]\psi$,

$$\Delta\psi=(iR_1[\psi]+\tfrac{1}{2}R_2[\psi]-R_3[\psi]-\tfrac{1}{4}R_5[\psi])\psi, \tag{48}$$

insert into (37) and obtain an additional term $(\mu_3+\nu_1)R_3[\psi]$ in F_{DG}, and a constraint $\mu_3(t)=-\nu_1(t)$.

We break this constraint, and obtain from $\mathscr{F}_3$ a family $\mathscr{F}_4(\nu_1,\nu_2,\mu_0,\mu_1,\kappa,\mu_3,\xi,\alpha_1,\alpha_2)$ depending on nine time-dependent parameters.

The closure $\overline{\mathscr{F}_4}$ is larger than $\mathscr{F}_4$ and contains all NLSEs (37) with

$$F_{\mathrm{DG}}[\psi]=i\nu_2'R_2[\psi]+\mu_1'R_1[\psi]+\kappa' R_2[\psi]+(\mu_3'+\nu_1')R_3[\psi]+\mu_4'R_4[\psi]+\xi' R_5[\psi], \quad (49)$$

where the time-dependent coefficients are given by

$$\nu_1'=\frac{\nu_1}{\Lambda},\quad \nu_2'=-\frac{\gamma}{2\Lambda}\nu_1+\nu_2,\quad \mu_0'=\Lambda\mu_0,\quad \mu_1'=-\frac{\gamma}{\Lambda}\nu_1+\mu_1,$$

$$\kappa'=\frac{\gamma^2+\Lambda^2-1}{2\Lambda}\nu_1-\gamma\nu_2-\frac{\gamma}{2}\mu_1+\Lambda\kappa,\quad \mu_3'=\frac{1}{\Lambda}\mu_3,\quad \mu_4'=\frac{\gamma}{\Lambda}\nu_1-\mu_1-\frac{\gamma}{\Lambda}\mu_3,$$

$$\xi'=\frac{1-\gamma^2-\Lambda^2}{4\Lambda}\nu_1+\frac{\gamma}{2}\mu_1+\frac{\gamma^2}{4\Lambda}\mu_3+\Lambda\xi, \quad (50)$$

$$\alpha_1'=\Lambda\alpha_1-\frac{\gamma}{2}\alpha_2+\gamma\frac{\dot\Lambda}{2\Lambda}-\frac{1}{2}\dot\gamma,\quad \alpha_2'=\alpha_2-\frac{\dot\Lambda}{\Lambda}.$$

These coefficients are actually independent, so that $\overline{\mathscr{F}_4}$ is a ten-parameter family. For a more symmetrical notation, we now go over to using $\mu_2=\kappa+\frac{1}{2}\nu_1$ and $\mu_5=\xi-\frac{1}{4}\nu_1$, denoting the family by $\mathscr{F}_5(\nu_1,\nu_2,\mu_0,\ldots,\mu_5,\alpha_1,\alpha_2)$:

$$i\partial_t\psi=i\sum_{j=1}^{2}\nu_jR_j[\psi]\psi+\sum_{k=1}^{5}\mu_kR_k[\psi]\psi+\mu_0V\psi+\alpha_1\log|\psi|^2\psi+\alpha_2(\arg\psi)\psi, \quad (51)$$

or in a form which exhibits the linear part separately, with Laplacian Δ,

$$i\partial_t\psi=(\nu_1\Delta+\mu_0V)\psi+i\nu_2R_2[\psi]\psi+\mu_1R_1[\psi]\psi+(\mu_2-\tfrac{1}{2}\nu_1)R_2[\psi]\psi+(\mu_3+\nu_1)R_3[\psi]\psi$$
$$+\mu_4R_4[\psi]\psi+(\mu_5+\tfrac{1}{4}\nu_1)R_5[\psi]\psi+\alpha_1\log|\psi|^2\psi+\alpha_2(\arg\psi)\psi. \quad (52)$$

$\mathscr{F}_5$ is invariant under the action of the group $\mathscr{N}$, i.e., $\overline{\mathscr{F}_5}=\mathscr{F}_5$.

Starting with the linear family $\mathscr{F}_0$, through iterated gauge generalizations and gauge closures with respect to the pure nonlinear gauge group $\mathscr{N}$, we have thus obtained a sequence

$$\mathscr{F}_0\subset\overline{\mathscr{F}_0}\subset\mathscr{F}_1=\overline{\mathscr{F}_1}\subset\mathscr{F}_2\subset\overline{\mathscr{F}_2}=\mathscr{F}_3=\overline{\mathscr{F}_3}\subset\mathscr{F}_4\subset\overline{\mathscr{F}_4}=\mathscr{F}_5 \quad (53)$$

of families of nonlinear Schrödinger equations.

The same procedure can be followed for the restricted gauge group $\mathscr{N}_0$. It turns out that there is an analogous sequence of families $\mathscr{R}_j$ of NLSEs:

$$\mathscr{F}_0\equiv\mathscr{R}_0\subset\overline{\mathscr{R}_0}^0\subset\mathscr{R}_1=\overline{\mathscr{R}_1}^0\subset\mathscr{R}_2\subset\overline{\mathscr{R}_2}^0=\mathscr{R}_3=\overline{\mathscr{R}_3}^0\subset\mathscr{R}_4\subset\overline{\mathscr{R}_4}^0=\mathscr{R}_5. \quad (54)$$

The families $\mathscr{R}_j$ are subsets of the $\mathscr{F}_j$:

$$\mathscr{R}_j=\mathscr{F}_j\restriction_{\nu_1(t)=\nu_1,\mu_0(t)=\mu_0,\mu_3(t)=-\nu_1,\alpha_2(t)=0}. \quad (55)$$

The only type of term that is not obtained in these families is the term F_{K} (which is technically not well defined). Note furthermore that here the parameters of the original linear family $\mathscr{R}_0\equiv\mathscr{F}_0$ remain invariant, $\nu_1'=\nu_1$ and $\mu_0'=\mu_0$.

IV. DISCUSSION OF THE GAUGE-GENERALIZED NLSE

A. Gauge-invariant parameters, Ehrenfest relations, and Galilei invariance

The group $\mathscr{N}$ transforms the family $\mathscr{F}_5$ into itself. In fact, $N_{(\gamma,\Lambda)}$ acts (for all t) linearly on the eight gauge parameters $\boldsymbol{\nu} = (\nu_1,\ldots,_5)$,

$$\begin{pmatrix} \nu_1' \\ \nu_2' \\ \mu_0' \\ \mu_1' \\ \mu_2' \\ \mu_3' \\ \mu_4' \\ \mu_5' \end{pmatrix} = \begin{pmatrix} \frac{1}{\Lambda} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -\frac{\gamma}{2\Lambda} & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \Lambda & 0 & 0 & 0 & 0 & 0 \\ -\frac{\gamma}{\Lambda} & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ \frac{\gamma^2}{2\Lambda} & -\gamma & 0 & -\frac{\gamma}{2} & \Lambda & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{\Lambda} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -\frac{\gamma}{\Lambda} & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{\gamma^2}{4\Lambda} & -\frac{\gamma}{2} & \Lambda \end{pmatrix} \begin{pmatrix} \nu_1 \\ \nu_2 \\ \mu_0 \\ \mu_1 \\ \mu_2 \\ \mu_3 \\ \mu_4 \\ \mu_5 \end{pmatrix}. \tag{56}$$

One can show that the orbits of $\mathscr{N}$, for a fixed time t, are two dimensional on the space $\dot{\mathbf{R}}_t^8 := \{\boldsymbol{\nu} \in \mathbf{R}_t^8 | \nu_1 \neq 0\}$, and foliate $\dot{\mathbf{R}}_t^8$ in two-dimensional leaves. Hence there exist (in general, at least locally; but here in fact globally) six functionally independent parameters $\iota_0,\ldots,\iota_5$ invariant under the action of $\mathscr{N}$,[8,9]

$$\begin{gathered} \iota_0 = \nu_1\mu_0, \quad \iota_1 = \nu_1\mu_2 - \nu_2\mu_1, \quad \iota_2 = \mu_1 - 2\nu_2, \quad \iota_3 = 1 + \mu_3/\nu_1, \\ \iota_4 = \mu_4 - \mu_1\mu_3/\nu_1, \quad \iota_5 = \nu_1(\mu_2 + 2\mu_5) - \nu_2(\mu_1 + 2\mu_4) + 2\nu_2^2\mu_3/\nu_1. \end{gathered} \tag{57}$$

On the remaining two parameters $\boldsymbol{\alpha} = (\alpha_1,\alpha_2)$, the transformation $N_{(\gamma,\Lambda)}$ acts as an affine transformation,

$$\begin{pmatrix} \alpha_1' \\ \alpha_2' \end{pmatrix} = \begin{pmatrix} \Lambda & -\frac{\gamma}{2} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \alpha_2 \end{pmatrix} + \begin{pmatrix} \frac{1}{2}\left(\gamma\frac{\dot{\Lambda}}{\Lambda} - \dot{\gamma}\right) \\ -\frac{\dot{\Lambda}}{\Lambda} \end{pmatrix}. \tag{58}$$

Thus there are two further independent parameters invariant under the action of $\mathscr{N}$ on the *control space* $\dot{\mathbf{R}}_t^{10}$ spanned by $\boldsymbol{\nu}$ and $\boldsymbol{\alpha}$,

$$\iota_6 = \nu_1\alpha_1 - \nu_2\alpha_2 + \nu_2\frac{\dot{\nu}_1}{\nu_1} - \dot{\nu}_2, \quad \iota_7 = \alpha_2 - \frac{\dot{\nu}_1}{\nu_1}, \tag{59}$$

generalizing the result in Refs. 8 and 9 for the family of NLSEs derived in Refs. 5 and 6. We call $\boldsymbol{\iota} = (\iota_0,\ldots,\iota_7)$ *gauge-invariant parameters*. They are important for interpreting $\mathscr{F}_5$ and its subfamilies; for details, we refer to Ref. 1, where gauge-invariant parameters have been discussed in a slightly different context.

TABLE I. Classification of subfamilies of $\mathscr{F}_5$ using gauge invariants.

	ι_0	ι_1	ι_2	ι_3	ι_4	ι_5	ι_6	ι_7
$\mathscr{F}_0$	×	×	0	0	0	0	0	0
$\mathscr{F}_1$	×	×	0	0	0	0	×	×
$\mathscr{F}_3$	×	×	×	0	0	×	×	×
$\mathscr{F}_5$	×	×	×	×	×	×	×	×

The subfamilies $\mathscr{F}_j$ and $\mathscr{R}_j$, that are closed under the gauge groups $\mathscr{N}$ and $\mathscr{N}_0$ respectively, can now be characterized in terms of the vanishing of gauge-invariant parameters. Such a characterization is given in Tables I and II, respectively. Note that ν_1 and μ_3 are themselves gauge-invariant parameters of the subfamilies $\mathscr{R}_j$.

Some of these families show interesting behavior. In the family $\mathscr{F}_1$ consider the time dependence of the expectation values $\langle \mathbf{x}\rangle_{\psi(t)} = \int_{\mathbf{R}^3} \mathbf{x}\rho_t(\mathbf{x})d^3x = \int_{\mathbf{R}^3} \mathbf{x}\overline{\psi(\mathbf{x},t)}\psi(\mathbf{x},t)d^3x$. Then

$$\frac{d}{dt}\langle \mathbf{x}\rangle_{\psi(t)} = -2\nu_1\langle -i\nabla\rangle_{\psi(t)}, \tag{60}$$

$$\frac{d^2}{dt^2}\langle \mathbf{x}\rangle_{\psi(t)} = -2\iota_0\langle - \ V\rangle_{\psi(t)} + \iota_7\frac{d}{dt}\langle \mathbf{x}\rangle_{\psi(t)}, \tag{61}$$

i.e., we have the analog of the first and second Ehrenfest relations for $\mathscr{F}_1$. The center of a nonstationary solution behaves like a classical system under a conservative force and a frictional force proportional to the velocity. For the linearizable subfamily $\overline{\mathscr{F}_0} \subset \mathscr{F}_1$, the frictional term disappears ($\iota_7 = 0$). This is plausible: A linear or nonlinear quantum-mechanical evolution equation and its $\mathscr{N}$ transform describe physically equivalent systems.[1]

The first Ehrenfest relation (60) holds for all members of $\mathscr{F}_5$. This shows that the physical systems described by $\mathscr{F}_5$ have something in common. For $\mathscr{F}_2,\dots,\mathscr{F}_5$ there are additional terms in the second Ehrenfest relation (61), which are connected with the quantum-mechanical diffusion current.[5,6]

The free linear SE ($V\equiv 0$) is invariant under the centrally extended Galilei group $G_e(3)$ including time translations. Consider the $G_e(3)$ invariance of $\mathscr{F}_5$ and its subfamilies. $\mathscr{F}_5$ is invariant under $T(t)$ if the gauge-invariant parameters $\boldsymbol{\iota}$ are time independent. If in addition $\iota_3 = \iota_4 = \iota_7 = 0$, the equations are invariant under $G_e(3)$. The generator of time translations is represented via a nonlinear operator H_{nl}, $i\partial_t\psi = H_{\mathrm{nl}}[\psi]$, as in Eqs. (51) and (52), while all other generators of $G_e(3)$ are as usual represented linearly. Hence, one has a nonlinear representation of $G_e(3)$ (see also Refs. 8, 19, and 20).

B. Gauge-generalized NLSE as a unification

Now we are ready to understand the connection between various proposals for nonlinear terms to be added to the linear Schrödinger equation. Such terms have often been chosen in a physically guided, but *ad hoc* way. Some proposed terms have been based directly on fundamental considerations. Our attempt is of the latter type. Its foundation, the physical equivalence of theories and

TABLE II. Classification of subfamilies of $\mathscr{R}_5$ using gauge invariants.

$\mathscr{R}_5$	×	×	×	×	×	×	×	×

the resulting group of nonlinear gauge transformations (together with gauge generalization and gauge closure), reflects some of the structure of quantum mechanics. Consequently the family $\mathscr{F}_5$ exhibits a common, fundamental basis for some of the proposed NLSEs. Let us consider some of the particular nonlinearities that have been proposed.

1. Logarithmic nonlinearity

Based on the observation that all linear evolution equations for physical quantities are known to be approximations of nonlinear evolutions (except for the Schrödinger equation), Bialynicki-Birula and Mycielski[3] added a (local) nonlinear term $F(|\psi|^2)$. They used the separation property to show that F has to be logarithmic, $F(|\psi|^2) = -b \ln|\psi|^2$. Their NLSE (the BM family) is

$$i\hbar\partial_t\psi = \left(-\frac{\hbar^2}{2m}\Delta + V - b \ln|\psi|^2 \right)\psi. \tag{62}$$

This NLSE is contained in $\mathscr{F}_5$ with

$$\nu_1 = \frac{\hbar}{2m}, \quad \mu_2 = \frac{\hbar}{4m}, \quad \mu_3 = -\frac{\hbar}{2m}, \quad \mu_5 = -\frac{\hbar}{8m}, \quad \mu_0 = \frac{1}{\hbar}, \quad \alpha_1 = -\frac{b}{\hbar}, \tag{63}$$

and the other coefficients vanishing. Note that in order to obtain this logarithmic term in our gauge generalization, we had to allow for a time-dependent group parameter $\gamma = \gamma(t)$.

2. Nonlinearity proportional to the phase

One of many examples of a heuristic implementation of dissipation in quantum mechanics is the approach by Kostin.[2] Starting with a frictional term proportional to the expectation of the momentum operator in the (second) Ehrenfest relation, Kostin motivated adding a nonlinear term proportional to the phase of ψ to the linear Schrödinger equation, i.e. (with $f \in \mathbf{R}$),

$$i\hbar\partial_t\psi = \left(-\frac{\hbar^2}{2m}\Delta + V + \frac{\hbar f}{m} \arg \psi \right)\psi. \tag{64}$$

Kostin's NLSE (the K family) is contained in $\mathscr{F}_5$ with

$$\nu_1 = \frac{\hbar}{2m}, \quad \mu_2 = \frac{\hbar}{4m}, \quad \mu_3 = -\frac{\hbar}{2m}, \quad \mu_3 = -\frac{\hbar}{8m}, \quad \mu_0 = \frac{1}{\hbar}, \quad \alpha_2 = \frac{f}{m}, \tag{65}$$

and the other coefficients vanishing. To obtain this term in our approach, we had to assume that $\Lambda = \Lambda(t)$ can be a function of time. Obviously, arg ψ is not well defined; this is reflected in the problem of gauge transformations with $\Lambda \neq \pm 1$, discussed in Sec. II C.

3. Nonlinearity from diffeomorphism group representations

The approach of Doebner and Goldin[5,6] is motivated by fundamental considerations. The generic kinematical symmetry algebra $S(\mathbf{R}^3)$ on $\mathbf{R}^3$ is a semidirect sum of the Lie algebra of real smooth functions $f \in C^\infty(\mathbf{R}^3)$, and the Lie algebra of vector fields $X \in \mathrm{Vect}(\mathbf{R}^3)$, or equivalently a local current algebra on $\mathbf{R}^3$.[21–23] Vect($\mathbf{R}^3$) is the Lie algebra of a subgroup of the group of diffeomorphisms of $\mathbf{R}^3$ (diffeomorphisms trivial at infinity). The functions $f \in C^\infty(\mathbf{R}^3)$ can be interpreted physically as classical position observables and the vector fields $X \in \mathrm{Vect}(\mathbf{R}^3)$ as classical kinematical momenta. Then a quantization map $\mathscr{Q}$ represents the kinematical algebra $S(\mathbf{R}^3)$ by self-adjoint operators in the single particle Hilbert space $\mathscr{H}^{(1)}$. Under physically motivated assumptions, all such representations $\mathscr{Q}$ can be classified up to unitary equivalence by a real parameter D with the dimensionality of a diffusion coefficient $[\text{length}^2/\text{time}]$. The presence of such a family of inequivalent representations reflects the richness of Vect($\mathbf{R}^3$). The method can be generalized to any smooth manifold.[24–26]

To obtain some information about the evolution equation of ψ, local probability conservation (for pure states) is assumed,[5] or a generalized first Ehrenfest relation is postulated.[25,26] Then the time-dependent probability density and current are related through an equation of Fokker–Planck type,

$$\partial_t \rho = -\frac{\hbar}{m}\nabla\cdot\mathbf{J} + D\Delta\rho. \tag{66}$$

This restricts the evolution equation of ψ to the form

$$i\hbar\,\partial_t\psi = \left(-\frac{\hbar^2}{2m}\Delta + V\right)\psi + i\,\frac{\hbar D}{2}\,\frac{\Delta\rho}{\rho}\,\psi + R[\psi]\psi, \tag{67}$$

where $R[\psi]$ is an arbitrary real-valued (nonlinear) operator. The form of the pure imaginary functional, $\Delta\rho/\rho$, is enforced. If $R[\psi]$ is assumed to be of a similar form, i.e., if it is (i) complex homogeneous of degree zero, (ii) a rational function with derivatives of no more than second order occurring only in the numerator, and (iii) invariant under the three-dimensional Euclidean group $E(3)$, then a five-parameter family of NLSEs (the DG family) is obtained:

$$R[\psi] = \hbar D' \sum_{j=1}^{5} c_j R_j[\psi], \tag{68}$$

with the R_j as in Eq. (43). Obviously this is a special case of $\mathscr{F}_5$, where $\alpha_1 = \alpha_2 = 0$ and all gauge parameters are time-independent:

$$\begin{gathered}\nu_1 = -\frac{\hbar}{2m},\quad \nu_2 = \frac{\hbar D}{2},\quad \mu_0 = \frac{1}{\hbar},\quad \mu_1 = \hbar D' c_1,\quad \mu_2 = \hbar D' c_2 - \frac{\hbar}{4m},\\ \mu_3 = \hbar D' c_3 + \frac{\hbar}{2m},\quad \mu_4 = \hbar D' c_4,\quad \mu_5 = \hbar D' c_5 + \frac{\hbar}{8m},\quad \alpha_1 = \alpha_2 = 0.\end{gathered} \tag{69}$$

The equation proposed by Guerra and Pusterla in connection with de Broglie's double solution theory[4] is contained in this family, with $D=0$, $c_1 = c_3 = c_4 = 0$, $c_5 = -\frac{1}{2}c_2$.

V. SUMMARY

To summarize, we have taken a small step toward a nonlinear quantum theory which could be physically relevant by discussing nonlinear evolution equations derived from fundamental considerations.

Under the assumption that all measurements are positional measurements performed at different times, we derived a group of nonlinear gauge transformations $\mathscr{G}$, including the usual linear ones. Applying these transformations to a linear Schrödinger equation, we obtained nonlinear ones, and after gauge generalization and gauge closure we reached a family $\mathscr{F}_5$ of nonlinear Schrödinger equations. Certain subfamilies of $\mathscr{F}_5$ were motivated originally by different physical ideas and different mathematical structures. Thus $\mathscr{F}_5$ is a *unification* of these NLSEs: the BM family, the K family, and the DG family. It is surprising, and also satisfying, when different structures and lines of reasoning yield the same or compatible results. This is an indication that these structures have a common origin. If there is some deeper reason for this, beyond the gauge generalization process described here, we have not yet unveiled it.

Moreover, our discussion may show how to circumvent some formal arguments against nonlinear quantum theory put forth by Gisin and others;[27–29] in connection with nonlocal effects, we refer especially to Ref. 18. We have not touched on other problems of nonlinear quantum theory, such as the concept of mixed states (see Ref. 16), or discussed the physical interpretation of a (necessarily non-self-adjoint) nonlinear Hamiltonian.

A rigorous real time Feynman path integral

Ken Loo[a)]
P.O. Box 9160, Portland, Oregon 97207

(Received 24 June 1998; accepted for publication 21 September 1998)

Using improper Riemann integrals, we will formulate a rigorous version of the real-time, time-sliced Feynman path integral for the L^2 transition probability amplitude. We will do this for nonvector potential Hamiltonians with potential which has, at most, a finite number of discontinuities and singularities. We will also provide a Nonstandard Analysis version of our formulation. © *1999 American Institute of Physics.* [S0022-2488(99)03801-3]

I. INTRODUCTION AND NOTATIONS

In this paper, we will formulate a rigorous version of the real-time, time-sliced Feynman path integral for the L^2 transition probability amplitude,

$$\left\langle \phi^*, \exp\left(\frac{-it\overline{H}}{\hbar}\right)\psi\right\rangle_{L^2} = \int_{\mathbb{R}^n} \phi(\mathbf{x})\left[\exp\left(\frac{-it\overline{H}}{\hbar}\right)\psi\right](\mathbf{x})\,d\mathbf{x}, \tag{1.1}$$

where $\phi,\psi\in L^2$, $H=(-\hbar^2/2m)\Delta+V(\mathbf{x})$ is essentially self-adjoint, $\overline{H}$ is the closure of H, and ϕ, ψ, V each carries, at most, a finite number of singularities and discontinuities. In favor of physics literature, we will formulate the Feynman path integral with improper Riemann integrals. In hope that with further research we can formulate a rigorous polygonal path integral, we will also provide a Nonstandard Analysis version of the Feynman path integral. Using Nonstandard Analysis is not essential to our formulation, and the idea of using Nonstandard Analysis on the Feynman path integral is not a new concept. For readers interested in Nonstandard Analysis, and its applications to Feynman path integrals, see Refs. 1–5 and references within. We will assume that the reader is familiar with Nonstandard Analysis.

In physics, the Feynman path integral is formulated on the propagator, and it is formally given by (see Refs. 6–8)

$$K_t(\mathbf{x},\mathbf{x}_0)=\lim_{k\to\infty} w_{n,k}\int_{\mathbb{R}^{(k-1)n}} \exp\left[\frac{i\epsilon}{\hbar}S_k(\mathbf{x},\ldots,\mathbf{x}_0)\right]d\mathbf{x}_1\cdots d\mathbf{x}_{k-1}, \tag{1.2}$$

where

$$w_{n,k}=\left(\frac{m}{2i\pi\hbar\epsilon}\right)^{nk/2}, \qquad \epsilon=\frac{t}{k},$$
$$S_k(\mathbf{x}=\mathbf{x}_k,\ldots,\mathbf{x}_0)=\sum_{j=1}^{k}\left[\frac{m}{2}\left(\frac{\mathbf{x}_j-\mathbf{x}_{j-1}}{\epsilon}\right)^2-V(\mathbf{x}_j)\right], \tag{1.3}$$

and all integrals are improper Riemann integrals.

In mathematics, there is a rigorous time-sliced Feynman path integral for the wave function (see Refs. 9 and 10)

---

a)Electronic mail: look@math.purdue.edu

$$\left[\exp\left(\frac{-it}{\hbar}\right)\psi\right](\mathbf{x})=\lim_{k\to\infty}w_{n,k}\int_{\mathbb{R}^{kn}}\exp\left[\frac{i\epsilon}{\hbar}S_k(\mathbf{x},\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_{k-1}, \tag{1.4}$$

where the integrals in (1.4) are improper Lebesgue integrals and their convergence is in the L^2 norm. Other popular rigorous versions of the Feynman path integral are the Wiener integral (see Refs. 11–14 and 10), generalization of Fresnel integrals (see Ref. 15), and Henstock integrals (see Ref. 16). For a more detailed exposition and further references, see Refs. 15 and 17.

Our main concern in this paper is to provide a rigorous version of (1.2) for the transition probability amplitude given in (1.1) by using (1.4). We will show that for any essentially self-adjoint Hamiltonian with potential that carries a finite number of singularities and discontinuities, and for any $\phi,\psi\in L^2$ which also has a finite number of singularities and discontinuities the following holds:

$$\int_{\mathbb{R}^n}\phi(\mathbf{x})\left[\exp\left(\frac{-it\overline{H}}{\hbar}\right)\psi\right](\mathbf{x})d\mathbf{x}$$
$$=\lim_{k\to\infty}w_{n,k}\int_{\mathbb{R}^{(k+1)n}}\phi(\mathbf{x}_k)\exp\left[\frac{i\epsilon}{\hbar}S_k(\mathbf{x}_k,\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_k. \tag{1.5}$$

In the last line of (1.5), the integral is an improper Riemann integral over $\mathbb{R}^{(k+1)n}$.

A trivial application of Nonstandard Analysis on the k limit in (1.5) yields (1.6),

$$\int_{\mathbb{R}^n}\phi(\mathbf{x})\left[\exp\left(\frac{-it\overline{H}}{\hbar}\right)\psi\right](\mathbf{x})d\mathbf{x}$$
$$=st\left\{w_{n,\omega}\int_{{}^*\mathbb{R}^{(\omega+1)n}}\phi(\mathbf{x}_\omega)\exp\left[\frac{i\epsilon}{\hbar}S_\omega(\mathbf{x}_\omega,\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_\omega\right\}, \tag{1.6}$$

where the integral in the last line of (1.6) is a $*$-transformed improper Riemann integral over ${}^*\mathbb{R}^{(\omega+1)n}$, and $\omega\in{}^*\mathbb{N}-\mathbb{N}$.

The main idea in the proof of (1.5) is the following. For simplicity, suppose $f(x)\in L^2(\mathbb{R})$, $g(x,y)\in L^2(\mathbb{R}\times\mathbb{R})$ are such that they are bounded and continuous. Further, suppose that both

$$h(x)=\int_{-a}^{b}g(x,y)dy,$$
$$p(x)=\lim_{a,b\to\infty}\int_{-a}^{b}g(x,y)dy \tag{1.7}$$

are in $L^2(\mathbb{R})$ as a function of x. In (1.7), we take the integral to be Lebesgue integrals and the limits are taken independent of each other in the L^2 topology. Notice that for $p(x)$, we can interpret the integral as an improper Lebesgue integral with convergence in the L^2 topology. Let us denote $\chi_{[-c,d]}$ to be the characteristic function on $[-c,d]$. Schwarz's inequality then implies

$$\left|\int_{\mathbb{R}}f(x)p(x)-\int_{-c}^{d}\int_{-a}^{b}f(x)g(x,y)dx\;dy\right|\leqslant\|f\|_2\|p-h\|_2+\|f-\chi_{[-c,d]}\,f\,\|_2\|h\|_2\to 0. \tag{1.8}$$

Thus, we can write

$$\int_{\mathbb{R}}f(x)p(x)=\lim_{a,b,c,d\to\infty}\int_{-c}^{d}\int_{-a}^{b}f(x)g(x,y)dx\;dy, \tag{1.9}$$

where the limits are all taken independent of each other. Since f and g are bounded and continuous, the Lebesgue integral over $[-a,b]\times[-c,d]$ in (1.9) can be replaced by a Riemann integral. Since the limits are taken independent of each other, we can then interpret the right-hand side of (1.9) as an improper Riemann integral. If f and g carry singularities and discontinuities, care must be taken in the region of integration so that the replacement of the Lebesgue integral with Riemann integrals can be done.

We now set some notations to deal with n-dimensional integrations, singularities and discontinuities. Let $k\in\mathbb{N}$ and $0\leqslant l\leqslant k$. We will denote the interior of the lth box by

$$A^l=(-a_1^l,b_1^l)\times\cdots\times(-a_n^l,b_n^l), \tag{1.10}$$

for positive and large a's and b's. Let $K=\{\mathbf{y}_1\cdots\mathbf{y}_p\}$ be the set of discontinuous and singular points of ϕ, ψ and V. For each $\mathbf{y}_q=(y_1^q,\ldots,y_n^q)\in K$, denote the lth box centered at $\mathbf{y}_q$ by

$$B_q^l=\left(y_1^q-\frac{1}{c_1^{q,l}},y_1^q+\frac{1}{d_1^{q,l}}\right)\times\cdots\times\left(y_n^q-\frac{1}{c_n^{q,l}},y_n^q+\frac{1}{d_n^{q,l}}\right), \tag{1.11}$$

for positive and large c's and d's. Let

$$C^l=A^l-\left\{\bigcup_{q=1}^{p}B_q^l\right\}. \tag{1.12}$$

For arbitrary large a's, b's, c's and d's, C^l is a box which encloses the set K and at each point of K, a small box centered at that point is taken out. Associated with C^l is a set of indices,

$$\{j_l\}=\{a_1^l,\ldots,a_n^l,b_1^l,\ldots,b_n^l,c_1^{1,l},\ldots,c_n^{1,l},\ldots,c_1^{p,l},\ldots,c_n^{p,l},d_1^{1,l},\ldots,d_n^{1,l},\ldots,d_1^{p,l},\ldots,d_n^{p,l}\}. \tag{1.13}$$

We will denote by $\{j_l\}\rightarrow\infty$ to mean

$$a_1^l,\ldots,a_n^l,b_1^l,\ldots,b_n^l,c_1^{1,l},\ldots,c_n^{1,l},\ldots,c_1^{p,l},\ldots,c_n^{p,l},d_1^{1,l},\ldots,d_n^{1,l},\ldots,d_1^{p,l},\ldots,d_n^{p,l}\rightarrow\infty, \tag{1.14}$$

where all indices go to infinity independent of each other. Notice that as $\{j_l\}\rightarrow\infty$, we recover $\mathbb{R}^n$ *a.e.* from C^l. We will denote by $\chi_{\{j_l\}}$ the characteristic function on C^l. Notice that for $f\in L^2(\mathbb{R}^n)$,

$$\lim_{\{j_l\}\rightarrow\infty}\chi\{j_l\}f=f,\quad a.e. \tag{1.15}$$

Last, let us write

$$D_{\{J_0^k\}}=C^0\times\cdots\times C^k. \tag{1.16}$$

Associated with $D_{\{J_0^k\}}$ is a set of indices,

$$\{J_0^k\}=\bigcup_{l=0}^{k}\{j_l\}, \tag{1.17}$$

and as before, we will use the notation $\{J_0^k\}\rightarrow\infty$ to mean

$$\{j_0\}\rightarrow\infty,\ldots,\{j_k\}\rightarrow\infty, \tag{1.18}$$

where the indices are taken to infinity independent of each other.

From here on, we will assume that $\phi,\psi\in L^2$ and V are such that they have, at most, a finite number of singularities and discontinuities and the set of those points are denoted as $K=\{\mathbf{y}_1\cdots\mathbf{y}_p\}$. Finally, we will denote by $\int_{rO}$ to be Riemann or improper Riemann integration over the region O and $\int_O$ to be Lebesgue integration over the region O.

II. FEYNMAN PATH INTEGRALS

The standard derivation of (1.4) is via the Trotter product formula (see Refs. 9, 14, and 10), which says that for any essentially self-adjoint $H=H_0+V$ with $H_0=(-\hbar^2/2m)\Delta$ and any $\psi\in L^2$,

$$\exp\left(\frac{-it\overline{H}}{\hbar}\right)\psi=\lim_{k\to\infty}\left\{\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right)\right\}^k\psi, \tag{2.1}$$

where the limit is taken in the L^2 norm.

Thus, we have the following.

Lemma 2.1: Suppose $H=H_0+V$ is essentially self-adjoint. Let $\psi,\phi\in L^2$; then

$$\int_{\mathbb{R}^n}\phi(\mathbf{x})\left[\exp\left(\frac{-it\overline{H}}{\hbar}\right)\psi\right](\mathbf{x})d\mathbf{x}=\lim_{k\to\infty}\int_{\mathbb{R}^n}\phi(\mathbf{x})\left[\left\{\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right)\right\}^k\psi\right](\mathbf{x})d\mathbf{x}, \tag{2.2}$$

where the limit in (2.2) is taken pointwise in t.

Proof: The proof is just an application of (2.1) and Schwarz's inequality. □

It is well known that (see Refs. 9 and 10) for $\nu\in L^1(\mathbb{R}^n)\cap L^2(\mathbb{R}^n)$,

$$\left[\exp\left(\frac{-i\epsilon H_0}{\hbar}\right)\nu\right](\mathbf{x}_1)=\left(\frac{m}{2i\pi\hbar\epsilon}\right)^{n/2}\int_{\mathbb{R}^n}\exp\left[\frac{im\epsilon}{2\hbar}\left(\frac{\mathbf{x}_1-\mathbf{x}_0}{\epsilon}\right)^2\right]\nu(\mathbf{x}_0)d\mathbf{x}_0, \tag{2.3}$$

and that the operator $\exp(-i\epsilon H_0/\hbar)$ is unitary. Thus, we can write

$$\begin{aligned}\left[\exp\left(\frac{-i\epsilon H_0}{\hbar}\right)\psi\right](\mathbf{x}_1)&=\left[\exp\left(\frac{-i\epsilon H_0}{\hbar}\right)[\lim_{\{j_0\}\to\infty}\chi\{j_0\}\psi]\right](\mathbf{x}_1)\\&=\lim_{\{j_0\}\to\infty}\left[\exp\left(\frac{-i\epsilon H_0}{\hbar}\right)\chi_{\{j_0\}}\psi\right](\mathbf{x}_1)\\&=\lim_{\{j_0\}\to\infty}\left(\frac{m}{2i\pi\hbar\epsilon}\right)^{n/2}\int_{C^0}\exp\left[\frac{im\epsilon}{2\hbar}\left(\frac{\mathbf{x}_1-\mathbf{x}_0}{\epsilon}\right)^2\right]\psi(\mathbf{x}_0)d\mathbf{x}_0,\end{aligned} \tag{2.4}$$

where the limits are taken in L^2. Notice that by construction of the region C^0, ψ is bounded and continuous on C^0, hence the Lebesgue integral in the last line of (2.4) can be replaced by a Riemann integral.

For notation convenience, we will denote

$$\begin{gathered}\rho(\mathbf{x}_k,\{J_0^{k-1}\})=w_{n,k}\int_{D_{\{J_0^{k-1}\}}}\exp\left[\frac{it}{(k+1)\hbar}S_k(\mathbf{x}_k,\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_{k-1},\\T=\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right),\quad T^k=\left\{\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right)\right\}^k.\end{gathered} \tag{2.5}$$

Lemma 2.2: Suppose $H=H_0+V$ is essentially self-adjoint. Let $\psi\in L^2$, then for $k\in\mathbb{N}$ the following holds:

$$\left\{\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right)\right\}^k\psi = \lim_{\{J_0^{k-1}\}\to\infty} w_{n,k}\int_{D_{\{J_0^{k-1}\}}}\exp\left[\frac{i\epsilon}{\hbar}S_k(\mathbf{x}_k,\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_{k-1}, \tag{2.6}$$

where the limits are taken in the L^2 norm.

Proof: We will proof (2.6) by induction. Suppose $k=2$; then (2.4) implies

$$T^2\psi = T\left\{\lim_{\{J_0^0\}\to\infty}\rho(\mathbf{x}_1,\{J_0^0\})\right\} = \exp\left(\frac{-itV}{2\hbar}\right)\exp\left(\frac{-itH_0}{2\hbar}\right)\left\{\lim_{\{j_1\}\to\infty}\chi_{\{j_1\}}\left[\lim_{\{J_0^0\}\to\infty}\rho(\mathbf{x}_1,\{J_0^0\})\right]\right\}. \tag{2.7}$$

Since multiplication by a characteristic function $\exp(-itV/2\hbar)$, and $\exp(-itH_0/2\hbar)$ are all continuous operators from L^2 to L^2, we can take the L^2 limits in (2.7) outside of the operators and we can do this in any order we wish. Hence, (2.6) is true for $k=2$. Assuming (2.6) to be true for k, then

$$T^{k+1}\psi = \exp\left(\frac{-itV}{(k+1)\hbar}\right)\exp\left(\frac{-itH_0}{(k+1)\hbar}\right)\left\{\lim_{\{j_k\}\to\infty}\chi_{\{j_k\}}\left[\lim_{\{J_0^{k-1}\}\to\infty}\rho(\mathbf{x}_k,\{J_0^{k-1}\})\right]\right\}. \tag{2.8}$$

By the same reasoning as for the case of $k=2$, we can take all the L^2 limits in (2.8) outside of the operators, and we can do this in any order we wish. Hence, (2.6) is true for all $k\in\mathbb{N}$. □

Proposition 2.3: Suppose $H=H_0+V$ is essentially self-adjoint. Let $\psi,\phi\in L^2$; Let ψ, ϕ, V be such that they have at most a finite number of discontinuities and singularities then for all $k\in\mathbb{N}$ the following is true:

$$\int_{\mathbb{R}^n}\phi(\mathbf{x})\left[\left\{\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right)\right\}^k\psi\right](\mathbf{x})d\mathbf{x} = w_{n,k}\int_{r\mathbb{R}^{(k+1)n}}\phi(\mathbf{x}_k)\exp\left[\frac{i\epsilon}{\hbar}S_k(\mathbf{x}_k,\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_k. \tag{2.9}$$

Proof: Lemma 2.2 implies that

$$\begin{aligned}\int_{\mathbb{R}^n}\phi(\mathbf{x})\left[\left\{\exp\left(\frac{-itV}{k\hbar}\right)\exp\left(\frac{-itH_0}{k\hbar}\right)\right\}^k\psi\right](\mathbf{x})d\mathbf{x} &= w_{n,k}\int_{\mathbb{R}^n}\left\{\lim_{\{j_k\}\to\infty}\chi_{\{j_k\}}\phi(\mathbf{x}_k)\right\}\\ &\times\left\{\lim_{\{J_0^{k-1}\}\to\infty}w_{n,k}\int_{D_{\{J_0^{k-1}\}}}\exp\left[\frac{i\epsilon}{\hbar}S_k(\mathbf{x}_k,\ldots,\mathbf{x}_0)\right]\psi(\mathbf{x}_0)d\mathbf{x}_0\cdots d\mathbf{x}_{k-1}\right\}d\mathbf{x}_k.\end{aligned} \tag{2.10}$$

We now apply the idea in (1.8) and (1.9). Since all limits in (2.10) are taken independent of each other, we can use Schwarz's inequality and take all the L^2 limits outside of the integral as pointwise limits. Thus,

$$\int_{\mathbb{R}^n} \phi(\mathbf{x}) \left[\left\{ \exp\left(\frac{-itV}{k\hbar} \right) \exp\left(\frac{-itH_0}{k\hbar} \right) \right\}^k \psi \right](\mathbf{x}) d\mathbf{x}$$

$$= w_{n,k} \lim_{\{J_0^k\} \to \infty} \int_{D_{\{J_0^k\}}} \phi(\mathbf{x}_k) \exp\left[\frac{i\epsilon}{\hbar} S_k(\mathbf{x}_k, \ldots, \mathbf{x}_0) \right] \psi(\mathbf{x}_0) d\mathbf{x}_0 \cdots d\mathbf{x}_k, \tag{2.11}$$

where the limits are pointwise in t.

By construction of $D_{\{J_0^k\}}$, the integrand $\phi(\mathbf{x}_k)\exp[(i\epsilon/\hbar)S_k(\mathbf{x}_k,\ldots,\mathbf{x}_0)]\psi(\mathbf{x}_0)$ in (2.11) is a bounded and continuous function on $D_{\{J_0^k\}}$. Hence, we can replace the Lebesgue integrals in (2.11) by Riemann integrals. Since all limits in (2.11) are taken independent of each other, we can interpret (2.11) as an improper Riemann integral. □

We are now ready to prove (1.5).

Theorem 2.4: *Suppose $H = H_0 + V$ is essentially self-adjoint. Let $\psi, \phi \in L^2$. Furthermore, suppose that ψ, ϕ and V have, at most, a finite number of singularities and discontinuities. With our previously defined notations, the following is true:*

$$\int_{\mathbb{R}^n} \phi(\mathbf{x}) \left[\exp\left(\frac{-it\overline{H}}{\hbar} \right) \psi \right](\mathbf{x}) d\mathbf{x}$$

$$= \lim_{k \to \infty} w_{n,k} \int_{r\mathbb{R}^{(k+1)n}} \phi(\mathbf{x}_k) \exp\left[\frac{i\epsilon}{\hbar} S_k(\mathbf{x}_k, \ldots, \mathbf{x}_0) \right] \psi(\mathbf{x}_0) d\mathbf{x}_0 \cdots d\mathbf{x}_k. \tag{2.12}$$

Proof: Follows from Lemma 2.1 and Proposition 2.3. □

III. NONSTANDARD FEYNMAN PATH INTEGRALS

A trivial application of Nonstandard Analysis on the K limit in (2.2) will produce (1.6). It is our hope that with further research, a rigorous nonstandard polygonal path integral can be formulated.

Theorem 3.1: *Suppose $H = H_0 + V$ is essentially self-adjoint. Let $\psi, \phi \in L^2$. Furthermore, suppose that ψ, ϕ and V has, at most, a finite number of singularities and discontinuities. With our previously defined notations, the following is true:*

$$\int_{\mathbb{R}^n} \phi(\mathbf{x}) \left[\exp\left(\frac{-it\overline{H}}{\hbar} \right) \psi \right](\mathbf{x}) d\mathbf{x}$$

$$= st \left\{ w_{n,\omega} \int_{r{}^*\mathbb{R}^{(\omega+1)n}} \phi(\mathbf{x}_\omega) \exp\left[\frac{i\epsilon}{\hbar} S_\omega(\mathbf{x}_\omega, \ldots, \mathbf{x}_0) \right] \psi(\mathbf{x}_0) d\mathbf{x}_0 \cdots d\mathbf{x}_\omega \right\}, \tag{3.1}$$

where the integral in the last line of (3.1) is a $*$-transformed improper Riemann integral over ${}^*\mathbb{R}^{(\omega+1)n}$, and $\omega \in {}^*\mathbb{N} - \mathbb{N}$.

Proof: The nonstandard equivalent of Lemma 2.1 is that, for any $\omega \in {}^*\mathbb{N} - \mathbb{N}$,

$$\int_{\mathbb{R}^n} \phi(\mathbf{x}) \left[\exp\left(\frac{-it\overline{H}}{\hbar} \right) \psi \right](\mathbf{x}) d\mathbf{x} = st \left\{ \int_{\mathbb{R}^n} \phi(\mathbf{x}) \left[\left\{ \exp\left(\frac{-itV}{\omega\hbar} \right) \exp\left(\frac{-itH_0}{\omega\hbar} \right) \right\}^\omega \psi \right](\mathbf{x}) d\mathbf{x}. \tag{3.2}$$

After $*$-transforming Proposition 2.3, Eq. (3.1) follows from (3.2). □

Second-order mixtures in relativistic Schrödinger theory

M. Mattes and M. Sorg
II. Institut für Theoretische Physik der Universität Stuttgart, Pfaffenwaldring 57, D 70550 Stuttgart, Germany

(Received 24 September 1997; accepted for publication 19 August 1998)

In relativistic Schrödinger theory the mixtures and pure states can be treated from a unified point of view such that a pure state merely emerges as a special case of a mixture. Here the concept of mixture is of purely local nature and therefore the mixture character (*degree of order*) can change over space and time. Although the general dynamics does not forbid the transitions from mixtures to pure states (and vice versa), the considered models do admit these transitions only in an asymptotic sense. The general concepts and results are demonstrated by considering the four-component Dirac theory for spinning matter over the Robertson–Walker universes. A detailed study is made for a specific subclass of second-order mixtures sharing many of their properties with the pure states (i.e., wave functions). © *1999 American Institute of Physics.* [S0022-2488(98)01312-7]

I. INTRODUCTION AND SURVEY

The right interpretation of quantum theory was a permanent point of concern for those people who were not satisfied with merely extracting numerical predictions from the quantum formalism. The recent controversy[1] may be especially considered as further evidence for the fact that no commonly accepted viewpoint among physicists exists about such fundamental questions as the following.

(i) Are the true laws of physics time symmetric? (If yes, how do you then explain the time-asymmetric reduction of the wave function during the measuring process?)
(ii) Is there some continuous dynamical process which links a pure state to a mixture with progression of time?

The last problem in particular, originally put forward by Schrödinger[2] in the form of his famous cat paradox, acquires more and more experimental relevance. The reason is that certain features of the wave function (e.g., its phase) increasingly become accessible to experimental observation[3] and this provides us with the certainty that physical systems can actually occur as pure states, even in the macroscopic domain. Moreover, the experimental situation also supports Schrödinger's claim that the wave function ψ must develop according to his famous equation

$$i\hbar\,\frac{\partial\psi}{\partial t}=\hat{H}\psi. \tag{I.1}$$

On the other hand, it was already pointed out by von Neumann[4] that not any quantum system can be described by some wave function (or state vector) ψ, but rather must be characterized by a more general concept: the density matrix $\hat{\rho}$. Its equation of motion was written down by von Neumann as

$$i\hbar\,\frac{d\hat{\rho}}{dt}=[\hat{H},\ \hat{\rho}], \tag{I.2}$$

so that Schrödinger's approach (I.1) was recovered as a special subcase hereof, namely when the density matrix is composed of a single wave function only:

$$\hat{\rho}\rightarrow\psi\otimes\overline{\psi}. \tag{I.3}$$

The density matrix approach to the quantum phenomena has received much credit (for a review see, e.g., Ref. 5), but nevertheless the pure states (to be described by a single wave function) must retain their physical significance. In such a situation, one could have expected that some unified theory would have been readily established so that one can predict when a pure state decays into a mixture (and vice versa). Indeed there were a few attempts to construct such a combined theory, which were especially aimed at the resolution of the well-known ''*quantum paradoxes*,'' e.g., the Einstein–Podolsky–Rosen paradox (for a review, see Ref. 6). However, it seems that the relatively moderate success of these attempts is due to the fact that some basic structural elements of the conventional quantum theory have been unduly distorted [e.g., Eq. (I.1) itself or the conservation laws]. Thus it seems reasonable to look for a completely new modification of the conventional theory so that its truly basic structure is preserved to a larger extent (albeit only in a more formal respect).

The present paper is concerned with such a completely new modification and presents an investigation of the relationships between mixtures and pure states within the framework of the recently established relativistic Schrödinger theory.[7–9] In particular, the smooth transitions from mixtures into pure states (and vice versa) are considered in detail. Here, the original Schrödinger equation (I.1) is replaced by its relativistic counterpart

$$i\hbar c\mathcal{D}_\mu\psi=\mathcal{H}_\mu\psi. \tag{I.4}$$

The (gauge plus coordinate) covariant derivative $\mathcal{D}_\mu$ is defined as usual through

$$\mathcal{D}_\mu\psi:=\partial_\mu\psi+\mathcal{A}_\mu\cdot\psi, \tag{I.5}$$

where the anti-Hermitian gauge potential $\mathcal{A}_\mu(=-\overline{\mathcal{A}}_\mu)$ generates the ''field strength'' (i.e., bundle curvature) $\mathcal{F}_{\mu\nu}$ in the standard way

$$\mathcal{F}_{\mu\nu}=\nabla_\mu\mathcal{A}_\nu-\nabla_\nu\mathcal{A}_\mu+[\mathcal{A}_\mu,\ \mathcal{A}_\nu]. \tag{I.6}$$

The Hamiltonian $\mathcal{H}_\mu$, corresponding to Schrödinger's $\hat{H}$ (I.1), is now a $\mathcal{GL}(N,\mathbb{C})$-valued one-form and acts upon the N_f-component wave function ψ as a section of the underlying complex vector bundle. However, contrary to Schrödinger's $\hat{H}$, the present relativistic Hamiltonian $\mathcal{H}_\mu$ is itself a dynamical object to be first determined from its field equations. These consist of the ''*integrability condition*''

$$\mathcal{D}_\mu\mathcal{H}_\nu-\mathcal{D}_\nu\mathcal{H}_\mu+\frac{i}{\hbar c}[\mathcal{H}_\mu,\ \mathcal{H}_\nu]=i\hbar c\mathcal{F}_{\mu\nu} \tag{I.7}$$

and of the ''*conservation equation*'' which reads in the present case of the four-component Dirac theory $(N_f=4)$

$$\gamma^\mu\cdot\mathcal{H}_\mu=Mc^2\cdot\mathbf{1}. \tag{I.8}$$

Clearly, M is the mass parameter and the objects $\gamma^\mu(\mu=0,1,2,3)$ are the Dirac matrices generating the Clifford algebra $\mathbb{C}(1,3)$ over pseudo-Riemannian space–time. Thus, any solution $\psi(x)$ of the relativistic Schrödinger's equation (I.4) also obeys the Dirac equation

$$i\gamma^\mu\mathcal{D}_\mu\psi=m\psi,\quad \left(m:=\frac{Mc}{\hbar}\right). \tag{I.9}$$

After Schrödinger's ideas have thus been incorporated into the new framework, let us now turn to von Neumann's equation (I.2). (The equation of motion for the field strength $\mathcal{F}_{\mu\nu}$ is of the Yang–Mills type not to be considered here.) The relativistic analog of $\hat{\rho}$ is the ''*intensity matrix*'' $\mathcal{I}$ and obeys the following equation of motion:

$$i\hbar c\mathcal{D}_\mu\mathcal{I}=[\mathcal{H}_\mu\cdot\mathcal{I}-\mathcal{I}\cdot\overline{\mathcal{H}}_\mu]. \tag{I.10}$$

Observe here that the Hamiltonian in general, will not be Hermitian ($\mathcal{H}_\mu \neq \overline{\mathcal{H}_\mu}$), but nevertheless the conservation laws do apply. For instance, consider the continuity equation

$$\nabla^\mu j_\mu = 0, \tag{I.11}$$

and define the current density j_μ through

$$j_\mu = \mathrm{tr}\,(\mathcal{I}\cdot\gamma_\mu), \tag{I.12}$$

resp. for the case of a pure state

$$j_\mu = \overline{\psi}\cdot\gamma_\mu\cdot\psi, \tag{I.13a}$$

$$(\mathcal{I}\rightarrow\psi\otimes\overline{\psi}). \tag{I.13b}$$

Now carry through the differentiation process (I.10), i.e.,

$$\nabla^\mu j_\mu = \mathrm{tr}\,(\gamma^\mu(\mathcal{D}_\mu\mathcal{I})), \quad (\mathcal{D}_\mu\gamma_\nu \equiv 0). \tag{I.14}$$

Furthermore, observe the relativistic von Neumann equation (I.10) as well as the conservation equation (I.8) and then find that the continuity equation (I.11) actually is valid. Thus, we simultaneously can attain the relativistic realization of both Schrödinger's and von Neumann's ideas together with the validity of the conservation laws!

Thus, Hermiticity of the Hamiltonian is not necessary and not even desirable for the present approach, contrary to the nonrelativistic Schrödinger theory (where $\hat{H}=\hat{H}^{+}$). Neither is the Hermiticity of the Hamiltonian in our theory needed for obtaining real energy eigenvalues because the nonrelativistic concept of energy eigenvalue must in any case be incorporated into a more general relativistic context. Consequently, the ''energy'' will emerge here by solving the nonlinear field equations for the Hamiltonian $\mathcal{H}_\mu$ (see below), but not by solving some linear eigenvalue problem for $\mathcal{H}_\mu$ which, in fact, would have required its Hermiticity. It is well known for the nonrelativistic approach that it is just the Hermiticity of the Hamiltonian $\hat{H}$ which forbids the possibility of transitions from mixtures into pure states (and vice versa).[10] However, since the relativistic Hamiltonian $\mathcal{H}_\mu$ is not Hermitian, it becomes possible in relativistic Schrödinger theory (RST) to study those transitions between mixtures and pure states. More precisely, one expects that a physical system may be a true mixture over one part of space–time [→general $\mathcal{I}(x)$], but may be in a pure state (I.13b) in some other part. The purely temporal transitions have been studied for a scalar Higgs doublet in a preceding paper,[9] and it has been found that a mixture cannot evolve into a pure state, except if one admits the existence of a ''Fierz potential.'' Such a potential minimizes the energy of the system for the pure states but equips the mixtures with an additional energy content. Although the system is pressed into a pure state by such a potential, the pure-state configuration could be attained only asymptotically after sufficiently large expansion of the universe.

In the present paper, we are concerned with the analogous questions for Dirac's theory of spinning matter; especially we want to know whether RST admits *spatial* changes of the mixture character.

First, in Sec. II we present a collection of the kinematical properties of the pure states (i.e., Dirac spinors) which are most concisely expressed by the well-known Fierz identities for the physical densities [see Eqs. (II.5a)–(II.5c)]. From this presentation arises a natural classification of the mixtures in terms of their ''*degree of order*'' $N'(\geqslant 1)$ so that the pure states appear as ''mixtures of order $N'=1$.'' Such a unified view of mixtures and pure states is convenient for the study of transitions between different order parameters N'! Moreover, it thus becomes obvious that for any order N' there must exist the corresponding generalization of the Fierz identities.

In Sec. III we introduce the deviation operator $\mathfrak{D}_\mathrm{F}$ (''*deviator*'') which measures the deviation of a mixture from a pure-state configuration [see Eq. (III.1)]. For the Dirac fiber dimension $N_f=4$ there arise $4\times 4=16$ deviation fields $\{\Delta_\mathrm{F},\tilde{\Delta}_F,\Delta_\mu,\tilde{\Delta}_\mu,\Delta_{\mu\nu}\}$. It turns out that there is a special subclass of *second-order mixtures* ($N'=2$) whose kinematic structure is especially similar to that of the pure states and which is characterized by vanishing tensor deviation ($\Delta_{\mu\nu}\equiv 0$). For instance, the polarization density $S_{\mu\nu}$ is the same as for the pure states, if expressed in terms of the scalar and vector densities [see Eq. (II.5c)], and, moreover, the remaining deviation fields can all be parametrized by the single scalar Δ_F. Thus for $\Delta_F = 0$ one can be sure to deal with a pure state. Because of these nice properties, such a mixture is chosen for the subsequent investigations.

In Sec. IV we present the dynamical equation for the deviator $\mathfrak{D}_F$ [see Eq. (IV.1)]. Clearly, *any* pure state ($\mathfrak{D}_F \equiv 0$) must fit into this equation of motion, otherwise it could not be the final stage of a mixture. However, this does not guarantee the *stability* of the pure states and this question cannot be settled here in full generality.

In Sec. V the fiber distributions are studied in terms of projectors. The latter objects are relevant for the relationship between mixtures and pure states because any pure state is associated to some one-dimensional projector. Thus it becomes important to elaborate the field equation for the projectors [see Eqs. (V.3a)–(V.3b)].

In Sec. VI we specify our model Hamiltonian for the subsequent investigation of the space–time behavior of the second-order mixtures [see Eq. (VI.1)]. It is true that this Hamiltonian may appear somewhat unsuitable for the present purpose because it originally was set up to describe the homogeneous and isotropic matter distributions in agreement with the cosmological principle.[7] However, it turns out that this Hamiltonian can also account for SO(3) symmetric, localized matter distributions which are then used in Sec. VII for the study of the spatial behavior of mixtures. Concerning their temporal evolution, the selected class of Hamiltonians forbids the transition into a pure state and the situation is somewhat similar to the previous case of the Klein–Gordon–Higgs fields.[9]

In the final section (Sec. VII), the difference between mixtures and pure states is elaborated with respect to some specific spatial pattern. As expected, the relativistic von Neumann equation (I.10) admits more physically meaningful configurations than the Schrödinger equation (I.4). For instance, for the considered SO(3) symmetric configuration the wave function $\psi(x)$, as a solution of (I.4), would develop a singularity at the symmetry center and therefore would forbid itself whereas the more general equation (I.10) admits mixtures with completely regular behavior.

II. FIRST-ORDER IDENTITIES

In Dirac's one-particle theory, the wave function $\psi(x)$ is some section of a complex vector bundle over pseudo-Riemannian space–time with the complex vector space $\mathbb{C}^4$ as typical fiber. Such a fiber space admits the existence of 16 Hermitian operators ($\mu=0,1,2,3$), namely $\mathbf{1}$, γ^μ, $\varepsilon = (1/4!)\varepsilon_{\mu\nu\lambda\sigma}\gamma^\mu\gamma^\nu\gamma^\lambda\gamma^\sigma$, $\tilde{\gamma}^\mu = \varepsilon\cdot\gamma^\mu$, and $\Sigma^{\mu\nu} = \frac{1}{4}[\gamma^\mu, \gamma^\nu]$. Any other Hermitian operator essentially is a linear combination of these basic elements e.g.,

$$ {}^*\Sigma^{\mu\nu} := -\varepsilon\cdot\Sigma^{\mu\nu} = \tfrac{1}{2}\varepsilon^{\mu\nu}{}_{\lambda\sigma}\Sigma^{\lambda\sigma} \tag{II.1} $$

or

$$ \{\Sigma^{\mu\nu}, \gamma^\lambda\} \equiv \Sigma^{\mu\nu}\gamma^\lambda + \gamma^\lambda\Sigma^{\mu\nu} = \varepsilon^{\mu\nu\lambda}_{\sigma}\tilde{\gamma}^\sigma. \tag{II.2} $$

These (and similar) relations may easily be verified by referring to the defining equations of the Clifford algebra $\mathbb{C}(1,3)$,

$$ \gamma_\mu\cdot\gamma_\nu + \gamma_\nu\cdot\gamma_\mu = 2g_{\mu\nu}\cdot\mathbf{1}, \tag{II.3} $$

with $g_{\mu\nu}$ denoting the pseudo-Riemannian metric tensor.

As soon as a vector section $\psi(x)$ is at hand together with these operator sections, one can immediately form the corresponding physical densities, i.e.,

$$ \rho(x) := \bar{\psi}\cdot\psi, \tag{II.4a} $$

$$ \tilde{\rho}(x) := \bar{\psi}\cdot\varepsilon\cdot\psi, \tag{II.4b} $$

$$ j_\mu(x) := \bar{\psi}\cdot\gamma_\mu\cdot\psi, \tag{II.4c} $$

$$\tilde{j}_\mu(x) := i\bar{\psi}\cdot\tilde{\gamma}_\mu\cdot\psi, \tag{II.4d}$$

$$S_{\mu\nu}(x) := \frac{i}{2}\bar{\psi}\cdot\Sigma_{\mu\nu}\cdot\psi. \tag{II.4e}$$

Since these 16 real densities have been built up by the four-component wave function ψ, there must exist certain constraints among them, the ‘‘*Fierz identities*.’’[11,12] In compact notation, these relations read

$$j^\mu j_\mu \equiv -\tilde{j}^\mu\tilde{j}_\mu \equiv \rho^2+\tilde{\rho}^2, \tag{II.5a}$$

$$j^\mu\tilde{j}_\mu \equiv 0, \tag{II.5b}$$

$$S_{\mu\nu} \equiv \frac{1}{4}\frac{\tilde{\rho}}{\rho^2+\tilde{\rho}^2}[j_\mu\tilde{j}_\nu - j_\nu\tilde{j}_\mu] - \frac{1}{4}\frac{\rho}{\rho^2+\tilde{\rho}^2}\varepsilon_{\mu\nu\lambda\sigma}j^\lambda\tilde{j}^\sigma. \tag{II.5c}$$

Further relationships between the densities are immediately deduced hereof, e.g., the *vector* identities

$$\tilde{\rho}j_\mu \equiv -4S_{\mu\nu}\tilde{j}^\nu, \tag{II.6a}$$

$$\tilde{\rho}\tilde{j}_\mu \equiv -4S_{\mu\nu}j^\nu, \tag{II.6b}$$

$$\rho\tilde{j}_\mu \equiv -4{}^*S_{\mu\nu}j^\nu, \tag{II.6c}$$

$$\rho j_\mu \equiv -4{}^*S_{\mu\nu}\tilde{j}^\nu, \tag{II.6d}$$

$$({}^*S_{\mu\nu} := \tfrac{1}{2}\varepsilon_{\mu\nu\lambda\sigma}S^{\lambda\sigma}),$$

the *scalar* identities

$${}^*S_{\mu\nu}S^{\mu\nu} \equiv -\tfrac{1}{4}\rho\tilde{\rho}, \tag{II.7a}$$

$$S^{\mu\nu}S_{\mu\nu} = \tfrac{1}{8}(\rho^2-\tilde{\rho}^2); \tag{II.7b}$$

or the *tensor* identities

$$S_{\lambda\mu}S^\lambda_\nu \equiv \tfrac{1}{16}(\rho^2 g_{\mu\nu} + \tilde{j}_\mu\tilde{j}_\nu - j_\mu j_\nu). \tag{II.8}$$

[Hint: Check the consistency of the scalar identity (II.7b) with the tensor case (II.8) by contracting the latter equation with the metric tensor $g^{\mu\nu}$, etc.]. Concerning the number of independent field degrees of freedom, we observe that the nine constraints (II.5a)–(II.5c) for the 16 densities (II.4a)–(II.4e) leave us with seven independent field variables which are represented by the four complex components of the spinor field ψ minus an irrelevant U(1) phase factor dropping out of the bispinor densities. In view of this circumstance, it is convenient to reparametrize the ten densities ρ, $\tilde{\rho}$, j_μ, $\tilde{j}_\mu$ by ten other variables in such a way that the three constraints (II.5a)+(II.5b) are automatically satisfied. Choosing here the ten new variables as the scalar density ρ itself, further some orthonormal tetrad $\{b_\mu, \hat{g}_\mu, \hat{\pi}_\mu, \hat{\lambda}_\mu\}$ with its six degrees of freedom

$$b^\mu b_\mu = -\hat{g}^\mu\hat{g}_\mu = -\hat{\pi}^\mu\hat{\pi}_\mu = -\hat{\lambda}^\mu\hat{\lambda}_\mu = +1, \tag{II.9a}$$

$$b^\mu\hat{g}_\mu = b^\mu\hat{\pi}_\mu = \hat{g}^\mu\hat{\lambda}_\mu = \cdots = 0, \tag{II.9b}$$

and three additional scalar fields z, κ, χ, the reparametrization looks as follows:

$$\tilde{\rho} = z\rho\sinh 2\kappa\sin\chi, \tag{II.10a}$$

$$j_\mu = \rho(\cosh 2\kappa b_\mu + \sinh 2\kappa[\hat{g}_\mu \cdot \cos \chi + \hat{\pi}_\mu (1-z^2)^{1/2} \cdot \sin \chi]), \tag{II.10b}$$

$$\tilde{j}_\mu = -\rho(z \sinh 2\kappa \cdot \cos \chi b_\mu + z \cosh 2\kappa \cdot \hat{g}_\mu + (1-z^2)^{1/2} \cdot \hat{\lambda}_\mu). \tag{II.10c}$$

The polarization density $S_{\mu\nu}$ (II.5c) is then easily found by use of the results (II.10a)–(II.10c) but need not be reproduced here (cf. Ref. 13).

Clearly, the Fierz identities (II.5a)–(II.5c) with all its implications do apply only because the physical densities (II.4a)–(II.4e) have been constructed by means of the wave function ψ. However, the very concept of a ''wave function'' ψ can easily be generalized to the notion of ''intensity matrix'' $\mathcal{I}$ which accounts for the simultaneous presence of several wave functions. In a purely formal respect, this generalization process is mathematically equivalent to the replacement of the state vector $|\psi\rangle$ by the intensity matrix $\hat{\rho}$ in nonrelativistic quantum mechanics.[14] For the present context one observes that the physical densities (II.4a)–(II.4e) can be generated also in the following alternative way: first form the tensor product of the wave function ψ and its Hermitian adjoint $\bar{\psi}$

$$\mathcal{I} = \psi \otimes \bar{\psi} \tag{II.11}$$

and then find the physical densities in terms of the intensity matrix $\mathcal{I}$ (II.11) as

$$\rho = \mathrm{tr}\,(\mathcal{I} \cdot \mathbf{1}), \tag{II.12a}$$

$$\tilde{\rho} = \mathrm{tr}\,(\mathcal{I} \cdot \varepsilon), \tag{II.12b}$$

$$j_\mu = \mathrm{tr}\,(\mathcal{I} \cdot \gamma_\mu), \tag{II.12c}$$

$$\tilde{j}_\mu = i\ \mathrm{tr}\,(\mathcal{I} \cdot \tilde{\gamma}_\mu), \tag{II.12d}$$

$$S_{\mu\nu} = \frac{i}{2}\ \mathrm{tr}\,(\mathcal{I} \cdot \Sigma_{\mu\nu}). \tag{II.12e}$$

Of course the Fierz identities (II.5a)–(II.5c) are still valid here, because both densities (II.4a)–(II.4e) and (II.12a)–(II.12e) are identical, but the identities can now be recast into the compact form

$$\mathcal{I}^2 = \rho \mathcal{I} \tag{II.13}$$

with the intensity matrix $\mathcal{I}$ being given by[15]

$$\mathcal{I} = \tfrac{1}{4}(\rho \cdot \mathbf{1} - \tilde{\rho} \cdot \varepsilon + j_\mu \gamma^\mu - i \tilde{j}_\mu \tilde{\gamma}^\mu + 4 i S_{\mu\nu} \Sigma^{\mu\nu}). \tag{II.14}$$

[Hint: Check the consistency of this new operator form (II.13) for the Fierz identities by action upon the wave function ψ which is an eigenvector of $\mathcal{I}$ with eigenvalue ρ, i.e., $\mathcal{I} \cdot \psi = \rho \psi$].

However, once we are equipped with an intensity matrix $\mathcal{I}$ as a Hermitian operator ($\bar{\mathcal{I}} = \mathcal{I}$) over the fiber space $\mathbb{C}^4$, we can construct the physical densities (II.12a)–(II.12e) also in those cases where $\mathcal{I}$ is built up by more than one single wave function

$$\mathcal{I} = \psi_1 \otimes \bar{\psi}_1 + \psi_2 \otimes \bar{\psi}_2 + \cdots \tag{II.15}$$

($\psi_1, \psi_2, \ldots$ being neither orthogonal nor normalized in general). However, as a consequence of this generalization, the Fierz identity (II.13), or (II.5a)–(II.5c) resp., will no longer apply as it stands. Is it possible that those constraints (II.5a)–(II.5c) survive in some generalized form corresponding to the generalized intensity matrix $\mathcal{I}$ (II.15)? Obviously, it becomes desirable to subdivide the whole set of all possible intensity matrices into different classes, being characterized by some ''degree of order'' N', so that for any $N' \leq N_f$ (presently $N=4$) there exists the corresponding ''*Fierz identity of order* N''' for the physical densities (II.12a)–(II.12e). The desired classification is obtained in a most natural way by identifying the *order parameter* N' with the number of nonzero eigenvalues of the intensity matrix $\mathcal{I}$. Thus the previous case (II.13), from which we started off, has order parameter $N'=1$ (''*pure state*''). For $N'>1$ we have a ''*mixture*.''

For $N'>1$ the first-order identities (II.5a)–(II.5c) are generalized in some way, but whenever some nonzero eigenvalue for a higher-order mixture tends to zero, the physical densities must (at least asymptotically) obey the Fierz identities of the next lower order. In this sense the discrete order parameter N' can undergo a (discontinuous) change. Clearly, such a specific process represents some kind of intrinsic transition of the physical system and must be expected to be accompanied by some singular effects. In order to see this phenomenon in some more detail, we briefly consider the transition of a second-order mixture ($N'=2$) into a pure state ($N'=1$). By the very definition of the second order, there must exist *two* nonzero eigenvalues of $\mathcal{I}$, say ζ_e and η_e:

$$\mathcal{I}\cdot\psi=\zeta_e\psi, \tag{II.16a}$$

$$\mathcal{I}\cdot\phi=\eta_e\phi. \tag{II.16b}$$

[Since $\mathcal{I}$ is (pseudo-)Hermitian, $\mathcal{I}=\overline{\mathcal{I}}$, the eigenvalues ζ_e, η_e are real.] Consequently, the *second-order* generalization of the *first-order* identities (II.13) must read

$$\mathcal{I}^3-(\zeta_e+\eta_e)\mathcal{I}^2+(\zeta_e\cdot\eta_e)\mathcal{I}\equiv 0. \tag{II.17}$$

[Hint: Convince yourself by applying this operator relation to the eigenvalue system (II.16a) and (II.16b).] Now, remember here that the sum of the eigenvalues must always equal the trace ρ (II.12a) of the intensity matrix $\mathcal{I}$, i.e.,

$$\zeta_e+\eta_e\equiv\rho. \tag{II.18}$$

However, this result recasts the second-order identity (II.17) into the following form:

$$\mathcal{I}^3-\rho\mathcal{I}^2+(\zeta_e\cdot\eta_e)\mathcal{I}\equiv 0. \tag{II.19}$$

(For expressing the product of eigenvalues in terms of the physical densities, see below.) Now it may be possible that in some region of space–time (distant past or future, say) one of the eigenvalues tends to zero and the other to the density ρ, according to Eq. (II.18). For such a situation the second-order identity (II.19) leaves us with the truncated form

$$\mathcal{I}^3-\rho\mathcal{I}^2\equiv 0, \tag{II.20}$$

which immediately leads us back to the first-order identity (II.13). Thus we see that the degree of order N' is truly indicated by the corresponding Fierz identities for the physical densities.

After the kinematics of those order transitions has been settled, we next have to inquire whether they are really admitted by the dynamics of the system. (In conventional quantum theory they are forbidden.) In parlicular, one would like to know whether the dynamics equips the mixtures or the pure states with a higher stability. For a Higgs doublet of scalar fields (i.e., $N_f=2$), the pure states have already been shown to be unstable[9] and this leads us to study a similar question for the spinor fields. However, before turning to the general equation of motion, let us first look for a convenient parametrization of the second-order mixtures in order to get some variable measuring the ''distance'' from a pure state.

III. SECOND-ORDER MIXTURES

The most general mixture evidently is encountered when the degree of order (N') coincides with the ''degree of complexity'' (N_f), i.e., when the number of nonzero eigenvalues of $\mathcal{I}$ agrees with the fiber dimension N_f and thus the intensity matrix is regular ($\det\mathcal{I}\neq 0$). If the physical system tends now to adopt all the properties of a pure state, there may exist various routes to ultimately reach such a state. For instance, the order parameter N' could be lowered successively by one unit until the pure state value $N'=1$ is reached, or N' may continue to equal N_f during the ''distance'' from the final pure state shrinks to zero. Conversely, if at the beginning the system is already in a pure state, one wants to know whether the dynamics admits the persistence of such a special state or whether the pure state has to decay into a mixture. In any case we need some measure over the configuration space for those deviations.

For that purpose, we define the *deviation operator* (''deviator''[9]) $\mathfrak{D}_{\mathrm{F}}$ through

$$\mathfrak{D}_{\mathrm{F}}=\rho\mathcal{I}-\mathcal{I}^2, \tag{III.1}$$

so that the pure states are uniquely characterized by the vanishing of $\mathfrak{D}_{\mathrm{F}}$. Like any operator over the typical fiber $\mathbb{C}^N$, $\mathfrak{D}_{\mathrm{F}}$ may be decomposed with respect to the basic operators, i.e., for $N_f=4$,

$$\mathfrak{D}_{\mathrm{F}}=\tfrac{1}{4}(\Delta_{\mathrm{F}}\cdot\mathbf{1}-\tilde{\Delta}_{\mathrm{F}}\cdot\varepsilon+\Delta_\mu\gamma^\mu-i\tilde{\Delta}_\mu\tilde{\gamma}^\mu+4i\Delta_{\mu\nu}\Sigma^{\mu\nu}). \tag{III.2}$$

The deviation densities occurring here are then easily found in terms of the physical densities as

$$\Delta_{\mathrm{F}}\equiv\mathrm{tr}\,(\mathfrak{D}_{\mathrm{F}}\cdot\mathbf{1})=\tfrac{1}{4}(3\rho^2+\tilde{\rho}^{\,2}-j^\mu j_\mu+\tilde{j}^\mu\tilde{j}_\mu-8S^{\mu\nu}S_{\mu\nu}), \tag{III.3a}$$

$$\tilde{\Delta}_{\mathrm{F}}\equiv\mathrm{tr}\,(\mathfrak{D}_{\mathrm{F}}\cdot\varepsilon)=\tfrac{1}{2}(\rho\tilde{\rho}+4{}^*S^{\mu\nu}S_{\mu\nu}), \tag{III.3b}$$

$$\Delta_\mu\equiv\mathrm{tr}\,(\mathfrak{D}_{\mathrm{F}}\cdot\gamma_\mu)=\tfrac{1}{2}(\rho j_\mu+4{}^*S_{\mu\nu}\tilde{j}^\nu), \tag{III.3c}$$

$$\tilde{\Delta}_\mu=i\;\mathrm{tr}\,(\mathfrak{D}_{\mathrm{F}}\cdot\tilde{\gamma}_\mu)=\tfrac{1}{2}(\rho\tilde{j}_\mu+4{}^*S_{\mu\nu}j^\nu), \tag{III.3d}$$

$$\Delta_{\mu\nu}=\tfrac{1}{2}(\rho S_{\mu\nu}-\tilde{\rho}{}^*S_{\mu\nu}+\tfrac{1}{4}\varepsilon_{\mu\nu\lambda\sigma}j^\lambda\tilde{j}^\sigma). \tag{III.3e}$$

Clearly, all the deviation fields Δ_{F}, $\tilde{\Delta}_{\mathrm{F}}$, Δ_μ, $\tilde{\Delta}_\mu$, $\Delta_{\mu\nu}$ must vanish whenever the system is in a pure state, i.e., when the Fierz identities for the physical densities (II.5a)–(II.5c) do apply. [Hint: Check this by use of the implications (II.6a)–(II.8)]. Observe here again that though the vanishing of all the deviation fields (III.3a)–(III.3e) is equivalent to the existence of a pure state, there are further deviation variables not being contained in the set (III.3a)–(III.3e). For instance, it is easily verified that for a pure state also the following deviations have to vanish:

$$\Delta'_\mu:=\tfrac{1}{2}(\tilde{\rho}\tilde{j}_\mu+4S_{\mu\nu}j^\nu), \tag{III.4a}$$

$$\tilde{\Delta}'_\mu:=\tfrac{1}{2}(\tilde{\rho}j_\mu+4S_{\mu\nu}\tilde{j}^\nu), \tag{III.4b}$$

$$Z_{\mu\nu}:=j_\mu j_\nu-\tilde{j}_\mu\tilde{j}_\nu-\rho^2 g_{\mu\nu}+16S_{\mu\lambda}S^\lambda_{\ \nu}. \tag{III.4c}$$

Here the situation is somewhat similar to that for the Fierz identities (II.5a)–(II.5c) which themselves are the necessary and sufficient conditions for the existence of a pure state but nevertheless admit the additional identities (II.6a)–(II.8).

Now we want to restrict ourselves to mixtures of the *second* order. Here the intensity matrix $\mathcal{I}$ obeys the algebraic condition (II.17). Eliminating from that equation $\mathcal{I}^2$ in favor of the deviator $\mathfrak{D}_{\mathrm{F}}$ yields

$$\{\mathcal{I},\mathfrak{D}_{\mathrm{F}}\}=2\zeta_e\eta_e\cdot\mathcal{I}, \tag{III.5}$$

or in coefficient form

$$(\Delta_{\mathrm{F}}-4\zeta_e\eta_e)\rho-\tilde{\rho}\tilde{\Delta}_{\mathrm{F}}+\Delta_\mu j^\mu-\tilde{\Delta}_\mu\tilde{j}^\mu-8\Delta_{\mu\nu}S^{\mu\nu}=0, \tag{III.6a}$$

$$(\Delta_{\mathrm{F}}-4\zeta_e\eta_e)\tilde{\rho}+\rho\tilde{\Delta}_{\mathrm{F}}-{}^8\Delta_{\mu\nu}{}^*S^{\mu\nu}=0, \tag{III.6b}$$

$$(\Delta_{\mathrm{F}}-4\zeta_e\eta_e)j_\mu+\rho\Delta_\mu-4{}^*S_{\mu\nu}\tilde{\Delta}^\nu-4{}^*\Delta_{\mu\nu}\tilde{j}^\nu=0, \tag{III.6c}$$

$$(\Delta_{\mathrm{F}}-4\zeta_e\eta_e)\tilde{j}_\mu+\rho\tilde{\Delta}_\mu-4{}^*S_{\mu\nu}\Delta^\nu-4{}^*\Delta_{\mu\nu}j^\nu=0, \tag{III.6d}$$

$$(\Delta_{\mathrm{F}}-4\zeta_e\eta_e)S_{\mu\nu}+\tilde{\Delta}_{\mathrm{F}}{}^*S_{\mu\nu}+\tilde{\rho}{}^*\Delta_{\mu\nu}+\rho\Delta_{\mu\nu}+\tfrac{1}{4}\varepsilon_{\mu\nu\lambda\sigma}(\tilde{j}^{\,\lambda}\Delta^\sigma-j^\lambda\tilde{\Delta}^\sigma)=0. \tag{III.6e}$$

Finally, after expressing here the product of the eigenvalues in terms of the physical and deviation densities by taking the trace in Eq. (III.5),

$$\Delta_{\mathrm{F}}-4\cdot\zeta_e\eta_e=\frac{1}{\rho}\,(\tilde{\rho}\tilde{\Delta}_{\mathrm{F}}+\Delta_\mu j^\mu-\tilde{\Delta}_\mu\tilde{j}^\mu+8\Delta_{\mu\nu}S^{\mu\nu}) \tag{III.7}$$

then leaves us with a certain set of identities (III.6a)–(III.6e) which are generally valid for all mixtures of the second order. Obviously, these ''*Fierz identities of second order*'' (III.6a)–(III.6e) are nothing else than a set of constraints between the 16 deviation variables Δ_{F}, $\tilde{\Delta}_{\mathrm{F}}$, Δ_μ, $\tilde{\Delta}_\mu$, $\Delta_{\mu\nu}$.

For our subsequent investigation of the transitions between mixtures and pure states we do not only want to restrict ourselves to the present second-order mixtures $N_f=4$ and $N'=2$, but we additionally confine the discussions to those cases where the deviation tensor $\Delta_{\mu\nu}$ (III.3e) vanishes identically: $\Delta_{\mu\nu}\equiv 0$. Here, it immediately follows from the very definition (III.3e) that the polarization density $S_{\mu\nu}$ adopts just that form for a pure state, cf. (II.5c). Clearly the idea is that if transitions from mixtures into pure states are possible, then they should be observable most easily for those situations where the mixture is already as ''close'' as possible to the pure state. Without defining a rigorous measure for this ''closeness,'' one surely may expect that the closer a mixture is to a pure state, the more identities of the first order are satisfied. In this sense, our choice $\Delta_{\mu\nu}\equiv 0$ for a second-order mixture ($N'=2$) has put us already fairly ''close'' to the pure states! The pure states can differ from these specific second-order mixtures ($\Delta_{\mu\nu}\equiv 0$) only through the invalidation of the first two identities (II.5a) and (II.5b)! However, this implies that all the remaining deviation variables can be expressed in terms of three scalar deviation parameters (a_0, $\tilde{a}_1$, and a_2, say).

A convenient choice for these parameters is the following:

$$a_0=\frac{j^\mu j_\mu}{\rho^2+\tilde{\rho}^2}-1, \tag{III.8a}$$

$$\tilde{a}_1=\frac{j^\mu\tilde{j}_\mu}{\rho^2+\tilde{\rho}^2}, \tag{III.8b}$$

$$a_2=\frac{\tilde{j}^\mu\tilde{j}_\mu}{\rho^2+\tilde{\rho}^2}+1. \tag{III.8c}$$

However, the situation becomes even further simplified because the second-order identities (III.6a)–(III.6e) impose the following constraint:

$$a_0\cdot a_2=\tilde{a}_1^{\,2}. \tag{III.9}$$

Consequently, we need only two parameters (a_0,a_2) for rewriting the remaining deviation fields (III.3a)–(III.3e):

$$\Delta_{\mathrm{F}}=\tfrac{1}{2}\rho^2(a_2-a_0), \tag{III.10a}$$

$$\tilde{\Delta}_{\mathrm{F}}=\frac{1}{2}\,\rho\tilde{\rho}(a_2-a_0)=\frac{\tilde{\rho}}{\rho}\,\Delta_{\mathrm{F}}, \tag{III.10b}$$

$$\Delta_\mu=\tfrac{1}{2}\rho(a_2\cdot j_\mu-\tilde{a}_1\cdot\tilde{j}^\mu), \tag{III.10c}$$

$$\tilde{\Delta}_\mu=\frac{1}{2}\,\rho(\tilde{a}_1\cdot j_\mu-a_0\tilde{j}_\mu)=\frac{a_0}{\tilde{a}_1}\,\Delta_\mu\,. \tag{III.10d}$$

Moreover, the product of eigenvalues (III.7) is found in terms of the new parameters as

$$\zeta_e \cdot \eta_e = \tfrac{1}{4}\rho^2(a_2 - a_0) \equiv \tfrac{1}{2}\Delta_{\mathrm{F}}, \tag{III.11}$$

or, similarly, the additional deviation fields (III.4a)–(III.4c) read now

$$\Delta'_\mu = \frac{1}{2}\,\tilde{\rho}(\tilde{a}_1 \cdot j_\mu - a_0 \tilde{j}_\mu) = \frac{\tilde{\rho}}{\rho}\,\tilde{\Delta}_\mu, \tag{III.12a}$$

$$\tilde{\Delta}'_\mu = \frac{1}{2}\,\tilde{\rho}(a_2 \cdot j_\mu - \tilde{a}_1 \cdot \tilde{j}_\mu) = \frac{\tilde{\rho}}{\rho}\,\Delta_\mu, \tag{III.12b}$$

$$Z_{\mu\nu} = a_2 \cdot j_\mu j_\nu + a_0 \tilde{j}_\mu \tilde{j}_\nu - \tilde{a}_1(j_\mu \tilde{j}_\nu + j_\nu \tilde{j}_\mu) + (a_0 - a_2)\rho^2 g_{\mu\nu}. \tag{III.12c}$$

Summarizing, we can say that there are specific mixtures of the second order ($N' = 2$) which are characterized by only two scalar deviation degrees of freedom (i.e., a_0 and a_2) and thus it may be expected that the deviation dynamics (for the transition between mixtures and pure states) will be cut down to an effectively two-dimensional problem. It is very instructive to see in some more detail to what extent the present second-order mixtures differ, if at all, from the pure states. To this end, we start with the observation that all the deviation vectors point into the same four-direction, cf. (III.10d), (III.12a), and (III.12b). Thus, let this common direction be denoted by the timelike unit vector field $b_\mu (\rightarrow b^\mu b_\mu = +1)$,

$$\Delta_\mu = a b_\mu . \tag{III.13a}$$

One directly concludes from the reparametrizations (III.10a)–(III.10d)

$$(\rho^2 + \tilde{\rho}^{\,2}) b_\mu = I \cdot j_\mu - \tilde{I} \cdot \tilde{j}_\mu, \tag{III.13b}$$

where we have put

$$I := b^\mu j_\mu, \tag{III.14a}$$

$$\tilde{I} := b^\mu \tilde{j}_\mu . \tag{III.14b}$$

Now multiply through the new result (III.13b) by b_μ and find the scalar relationship

$$\rho^2 + \tilde{\rho}^{\,2} = I^2 - \tilde{I}^{\,2}. \tag{III.15}$$

On the other hand, look at the pure-state densities (II.10a)–(II.10c) and find that the latter relation (III.15) also holds for those pure states which have $z = 1$. As a consequence, the interrelationship between the present second-order mixtures ($\Delta_{\mu\nu} \equiv 0$) and the $z = 1$ subset of pure states is threefold: both configurations

(i) share the same form of the polarization density $S_{\mu\nu}$, cf. (II.5c),
(ii) are characterized by a timelike unit vector b_μ, and
(iii) obey the same scalar relationship (III.15).

It does not seem possible to find mixtures which have more than these three *structural* elements in common with the pure states! For later purpose, the situation may even be made somewhat more transparent by reformulating the deviation fields in terms of the new elements b_μ and a of (III.13a). Here the new factor a is found to be related to the former deviation parameters (III.8a)–(III.8c) through

$$a = \frac{1}{2}\,\frac{\rho}{\tilde{I}}\,(\rho^2 + \tilde{\rho}^{\,2})\tilde{a}_1 = \frac{1}{2}\,\frac{\rho}{I}\,(\rho^2 + \tilde{\rho}^{\,2}) a_2 = \frac{1}{2}\,\frac{I \cdot \rho}{\tilde{I}^{\,2}}\,(\rho^2 + \tilde{\rho}^{\,2}) a_0, \tag{III.16}$$

and this yields the desired result, namely,

$$\Delta_F = \frac{\rho}{I} a, \tag{III.17a}$$

$$\Delta_\mu = a b_\mu = \frac{I}{\rho} \Delta_F b_\mu, \tag{III.17b}$$

$$\tilde{\Delta}_\mu = \frac{\tilde{I}}{I} \Delta_\mu = \frac{\tilde{I}}{\rho} \Delta_F b_\mu, \tag{III.17c}$$

$$\Delta'_\mu = \frac{\tilde{\rho} \cdot \tilde{I}}{\rho^2} \Delta_F b_\mu, \tag{III.17d}$$

$$\tilde{\Delta}'_\mu = \frac{\tilde{\rho} \cdot I}{\rho^2} \Delta_F b_\mu, \tag{III.17e}$$

$$Z_{\mu\nu} = \frac{2}{\rho^2} \Delta_F [(\rho^2 + \tilde{\rho}^2) b_\mu b_\nu - \rho^2 g_{\mu\nu}]. \tag{III.17f}$$

Indeed, this is a nice result because it says that all the relevant deviation fields are proportional to the scalar deviation Δ_F so that they must tend to zero if only Δ_F does ($\rightarrow$ pure state). As a consequence, we merely have to look for one single dynamical equation (for Δ_F, namely) in order to describe the transition dynamics for mixtures and pure states.

IV. DEVIATION DYNAMICS

Once the kinematical presumptions have been settled, one can now take the next step towards the central question of whether the dynamics will admit the transitions between mixtures of different order N'. Of course the integer N' cannot change continuously but a transition between different orders N' may be understood in the sense that some of the nonzero eigenvalues of the intensity matrix $\mathcal{I}$ become infinitely small (albeit not exactly zero), or conversely, an initially very small eigenvalue raises to the order of magnitude of the others. It must be expected that the answer to the questions of this kind will strongly depend upon the specific dynamics to be applied to the intensity matrix $\mathcal{I}$. The proper choice of dynamics (Sec. VI) has already been attained through some previous work[7,16] and therefore it need not be further discussed here. Instead, let us readily try to transfer the equation of motion for the intensity matrix $\mathcal{I}$ of (I.10) to the general deviator $\mathfrak{D}_F$ of (III.1) and see whether there arises a homogeneous or an inhomogeneous equation for $\mathfrak{D}_F$. Clearly, if we find a homogeneous equation, there exists a permanently pure state ($\mathfrak{D}_F \equiv 0$) as a solution of the equation of motion whereas in the inhomogeneous case the inhomogeneity will act as a force driving the initially pure state ($N' = 1$) into the configuration space of the mixtures $N' > 1$. Evidently this leads to the question of stability of the pure states with respect to their decay into a mixture.

Thus the dynamical equation for the deviator $\mathfrak{D}_F(\mathcal{I})$ in (III.1) is deduced from the original equation of motion (I.10) as

$$\mathcal{D}_\mu \mathfrak{D}_F = \frac{i}{\hbar c} [\mathfrak{D}_F \cdot \overline{\mathcal{H}}_\mu - \mathcal{H}_\mu \cdot \mathfrak{D}_F] + \{\mathcal{L}_\mu, \mathfrak{D}_F\} + \mathfrak{C}_\mu . \tag{IV.1}$$

Here, the Hamiltonian $\mathcal{H}_\mu$ has been split up into its (anti-) Hermitian constituents $\mathcal{K}_\mu$, $\mathcal{L}_\mu$ as usual,

$$\mathcal{H}_\mu = \hbar c (\mathcal{K}_\mu + i \mathcal{L}_\mu), \tag{IV.2}$$

and the inhomogeneous term $\mathfrak{C}_\mu$ on the right of (IV.1) is found in terms of the ''localization field'' $\mathcal{L}_\mu$ as

$$\mathfrak{E}_\mu=[\mathcal{I},\ [\mathcal{I},\ \mathcal{L}_\mu]]+\mathcal{I}\cdot \mathrm{tr}\ \{\mathcal{I},\mathcal{L}_\mu\}-\{\mathcal{I},\mathcal{L}_\mu\}\cdot \mathrm{tr}\ \mathcal{I}. \tag{IV.3}$$

Now, as a consequence of the emergence of the inhomogeneity $\mathfrak{E}_\mu$, it may appear that the permanency of a pure state ($\mathfrak{D}_\mathrm{F}\equiv 0$) would not be admitted by the deviation dynamics (IV.1). However, we have to remember here that the characterization of a pure state by the vanishing of the deviator $\mathfrak{D}_\mathrm{F}(\equiv 0)$ entails further identities, e.g., Eqs. (III.4a)–(III.4c). Therefore one cannot exclude that the inhomogeneous term $\mathfrak{E}_\mu$ in (IV.3) eventually is built up completely by those secondary deviation objects which, in fact, are not contained in the original set of deviation fields (III.3a)–(III.3e), but nevertheless ensure the vanishing of the inhomogeneous term $\mathfrak{E}_\mu$ for the case of a pure state.

Let us inspect this supposition in more detail for Dirac's spinor field ($N_f=4$). Here the $\mathbb{C}(1,3)$-valued localization field $\mathcal{L}_\mu$ is decomposed with respect to the basis operators, mentioned at the beginning of Sec. II, according to

$$\mathcal{L}_\mu=L_\mu\cdot \mathbf{1}+\tilde{L}_\mu\cdot\varepsilon+L_{\lambda\mu}\gamma^\lambda+i\tilde{L}_{\lambda\mu}\tilde{\gamma}^\lambda+iL_{\lambda\sigma\mu}\Sigma^{\lambda\sigma}, \tag{IV.4}$$

where the coefficients L_μ, $\tilde{L}_\mu$, etc. are ordinary tensor fields. However, since the inhomogeneity $\mathfrak{E}_\mu$ (IV.3) is linear with respect to the localization field $\mathcal{L}_\mu$,

$$\mathfrak{E}_\mu=\mathfrak{E}(\mathcal{L}_\mu)=L_\mu\cdot\mathfrak{E}(\mathbf{1})+\tilde{L}_\mu\cdot\mathfrak{E}(\varepsilon)+L_{\lambda\mu}\cdot\mathfrak{E}(\gamma^\lambda)+i\tilde{L}_{\lambda\mu}\cdot\mathfrak{E}(\tilde{\gamma}^\lambda)+iL_{\lambda\sigma\mu}\mathfrak{E}(\Sigma^{\lambda\sigma}), \tag{IV.5}$$

it is sufficient for its vanishing that the value of $\mathcal{E}$ upon any one of the basis operators be zero, i.e.,

$$\mathfrak{E}(\mathbf{1})=\mathfrak{E}(\varepsilon)=\mathfrak{E}(\gamma_\lambda)=\mathfrak{E}(\tilde{\gamma}_\lambda)=\mathfrak{E}(\Sigma_{\lambda\sigma})=0. \tag{IV.6}$$

Indeed, the case for the identity operator is trivial: $\mathfrak{E}(\mathbf{1})\equiv 0$; next for the pseudo-scalar case one finds with a little bit of Clifford algebra and by use of the intensity matrix $\mathcal{I}$ in (II.14),

$$\begin{aligned}\mathfrak{E}(\varepsilon):&=[\mathcal{I},\ [\mathcal{I},\ \varepsilon]]+\mathcal{I}\cdot \mathrm{tr}\ \{\mathcal{I},\varepsilon\}-\{\mathcal{I},\varepsilon\}\cdot \mathrm{tr}\ \mathcal{I}\\ &=\frac{1}{4}\ (j_\lambda j^\lambda-\tilde{j}^\lambda\tilde{j}_\lambda-2(\rho^2+\tilde{\rho}^2))\cdot\varepsilon+\frac{1}{2}\ \tilde{\Delta}'_\mu\cdot\gamma^\mu-\frac{i}{2}\ \Delta'_\mu\cdot\tilde{\gamma}^\mu+4i{}^*\Delta_{\mu\nu}\cdot\Sigma^{\mu\nu}.\end{aligned} \tag{IV.7}$$

However, remember here the first-order identities (II.5a) as well as the vanishing of the deviation fields $\Delta_{\mu\nu}$ [(III.3e)], Δ'_μ [(III.4a)], and $\tilde{\Delta}'_\mu$ [(III.4b)] for a pure state and thus actually find $\mathcal{E}(\varepsilon)\equiv 0$ as required by Eq. (IV.6). Quite similar arguments do apply also to the vector inhomogeneity, e.g.,

$$\begin{aligned}\mathfrak{E}(\gamma^\mu)&:=[\mathcal{I},\ [\mathcal{I},\ \gamma^\mu]]+\mathcal{I}\ \mathrm{tr}\ \{\mathcal{I},\gamma^\mu\}-\{\mathcal{I},\gamma^\mu\}\cdot \mathrm{tr}\ \mathcal{I}\\ &=-\tfrac{1}{2}\ \tilde{\Delta}'^\mu\cdot\varepsilon+\tfrac{1}{4}\ (j^\nu j_\nu-\rho^2-\tilde{\rho}^2)\cdot\gamma^\mu+\tfrac{1}{4}\ Z^\mu_\nu\\ &\quad\cdot\gamma^\nu-\frac{i}{4}\ (j_\nu\cdot\tilde{j}^\nu)\cdot\tilde{\gamma}^\mu-4i{}^*\Delta^\mu_\nu\cdot\tilde{\gamma}^\nu-i\Delta'_\nu\cdot\Sigma^{\mu\nu}-2i\tilde{\Delta}_\nu\cdot{}^*\Sigma^{\nu\mu}.\end{aligned} \tag{IV.8}$$

Observe here again that all the coefficient fields must vanish for a pure state either on account of the first-order identities (II.5a) and (II.5b) or because they directly coincide with one of the deviation fields (III.3a)–(III.3e) or (III.4a)–(III.4c). Thus we actually end up again with $\mathfrak{E}(\gamma^\mu)\equiv 0$ in agreement with the claim (IV.6). Finally, it can be shown by quite similar arguments that the two remaining objects of inhomogeneity $\mathfrak{E}(\tilde{\gamma}^\mu)$ and $\mathcal{E}(\Sigma^{\mu\nu})$ do indeed also vanish for a pure state, but for the sake of brevity the corresponding formulas are not reproduced here. What is more important lies in the fact that the inhomogeneous term $\mathfrak{E}_\mu$ in (IV.3) *always* vanishes for a pure state and therefore $\mathfrak{D}_\mathrm{F}\equiv 0$ becomes an exact solution of the deviation dynamics (IV.1).

However, even if we have to concede now the theoretical persistency of the pure states, it remains to be clarified whether the pure states are stable or unstable configurations. The qualitative computation for a Higgs doublet of scalar fields ($N_f=2$) have shown that the pure state submanifold of the configuration space for the physical densities (i.e., the ''*Fierz cone*'') is equipped with some repulsive potential of singular nature.[9] As a consequence, a pure-state configuration could never be reached exactly. Thus, the repulsive potential appears as the physical counterpart of the mathematical fact which says that an integer (N') cannot change continuously. It is just from this purely formal reason that one tends to believe the repulsive phenomena occurring also in connection with the present spinor fields.

For the subsequent study of this effect we return again to those second-order mixtures described in the preceding section. Moreover, we further simplify the situation by considering a $\Delta_{\mu\nu}=0$ mixture which admitted the introduction of some unit vector field b_μ [(III.13a)] and finally led to that specific form of the deviation fields [see Eqs. (III.17a)–(III.17f)]. As a consequence, the deviator $\mathfrak{D}_\mathrm{F}$ in (III.2) also adopts a very specific shape, namely,

$$\mathfrak{D}_\mathrm{F}=\tfrac{1}{2}\,\Delta_\mathrm{F}\cdot\mathcal{P}_\parallel, \tag{IV.9}$$

and thus becomes proportional to some two-dimensional projector $\mathcal{P}_\parallel$:

$$\mathcal{P}_\parallel=\frac{1}{2}\left(\mathbf{1}-\frac{\tilde{\rho}}{\rho}\,\varepsilon+\frac{I}{\rho}\,\beta-i\,\frac{\tilde{I}}{\rho}\,\tilde{\beta}\right), \tag{IV.10}$$

i.e.,

$$\mathcal{P}_\parallel\cdot\mathcal{P}_\parallel=\mathcal{P}_\parallel, \tag{IV.11a}$$

$$\mathrm{tr}\,\mathcal{P}_\parallel=2. \tag{IV.11b}$$

These projector properties are easily verified by observing the constraint (III.15) together with the fact that the corresponding operators $\{1,\varepsilon,\beta:=b^\mu\gamma_\mu,\tilde{\beta}:=b^\mu\tilde{\gamma}_\mu\}$ obey a very simple subalgebra of $\mathbb{C}(1,3)$, namely,

$$\beta\cdot\beta=\tilde{\beta}\cdot\tilde{\beta}=-\varepsilon\cdot\varepsilon=+\mathbf{1}, \tag{IV.12a}$$

$$\varepsilon\cdot\beta=-\beta\cdot\varepsilon=\tilde{\beta}, \tag{IV.12b}$$

$$\varepsilon\cdot\tilde{\beta}=-\tilde{\beta}\cdot\varepsilon=-\beta, \tag{IV.12c}$$

$$\tilde{\beta}\cdot\beta=-\beta\cdot\tilde{\beta}=\varepsilon. \tag{IV.12d}$$

Clearly the projector $\mathcal{P}_\parallel$ in (IV.10) is nothing else than the identity operator for that subspace in which the intensity matrix $\mathcal{I}$ is living in, i.e.,

$$\mathcal{P}_\parallel\cdot\mathcal{I}=\mathcal{I}. \tag{IV.13}$$

Here, it is a nice check to reassure that all the algebraic properties (including $\Delta_{\mu\nu}\equiv0$) of the present second-order mixture just follow from that compact characterization (IV.13). For instance, insert the projector result for the deviator $\mathfrak{D}_\mathrm{F}$ (IV.9) into the second-order identity (III.5), then observe the projective relation (IV.13) and thus readily verify that the scalar deviation Δ_F just equals twice the product of the eigenvalues $\zeta_e\eta_e$, cf. Eq. (III.11).

However, when the central dynamical equation (I.10) respects the permanency of the pure states, does it also respect the permanency of those second-order mixtures which have vanishing tensor deviation $(\Delta_{\mu\nu}=0)$? Obviously, this question must first be clarified now before we legitimately can restrict ourselves to that subclass of mixtures.

V. FIBER DISTRIBUTIONS

The emergence of the projector $\mathcal{P}_\parallel$ indicates the significance of certain subspaces of the typical fiber $\mathbb{C}^4$ over space–time. More concretely, consider all $\mathbb{C}^4$ elements $\psi(x)$ at any event x of space–time such that

$$\mathcal{P}_\parallel\cdot\psi=\psi. \tag{V.1}$$

Obviously, this set $\{\psi\}_x$ defines some two-dimensional moving subspace of $\mathbb{C}^4$ (''distribution''). Let the orthogonal projector be $\mathcal{P}_\perp$,

$$\mathcal{P}_\parallel + \mathcal{P}_\perp = \mathbf{1}, \tag{V.2a}$$

$$\mathcal{P}_\perp^2 = \mathcal{P}_\perp, \tag{V.2b}$$

$$\mathcal{P}_\perp \cdot \mathcal{P}_\parallel = 0, \tag{V.2c}$$

$$\mathrm{tr}\ \mathcal{P}_\perp = 2; \tag{V.2d}$$

we get a moving (2+2)-splitting of the typical fiber. More generally, a $(N_\parallel + N_\perp)$-splitting is generated by the orthogonal projectors $\mathcal{P}_\parallel(x)$ and $\mathcal{P}_\perp(x)$ such that $\mathrm{tr}\ \mathcal{P}_\parallel + \mathrm{tr}\ \mathcal{P}_\perp = N_\parallel + N_\perp = N_f$, where N_f is the dimension of the typical vector fiber $\mathbb{C}^{N_f}$ in which the wave functions (i.e., sections) are living.

The question with these fiber distributions is now whether they are consistent with the general dynamics, or, more concretely: let the intensity matrix $\mathcal{I}$ be a solution of the general equation of motion (I.10). How then must the field equation for $\mathcal{P}_\parallel$ look in order that those relations as, e.g., (IV.13), do hold over the whole space–time? A possible answer is the following:

$$\mathcal{D}_\mu \mathcal{P}_\parallel = \frac{i}{\hbar c}\left(\mathcal{P}_\parallel \cdot \overline{\mathcal{H}}_\mu - \mathcal{H}_\mu \cdot \mathcal{P}_\parallel\right) - 2 \overset{(\parallel)}{\mathcal{L}}_\mu, \tag{V.3a}$$

$$\mathcal{D}_\mu \mathcal{P}_\perp = \frac{i}{\hbar c}\left(\mathcal{P}_\perp \cdot \mathcal{H}_\mu - \overline{\mathcal{H}}_\mu \cdot \mathcal{P}_\perp\right) + 2 \overset{(\perp)}{\mathcal{L}}_\mu, \tag{V.3b}$$

where the projective localization fields have been defined in a nearby manner, i.e.,

$$\overset{(\parallel)}{\mathcal{L}}_\mu = \mathcal{P}_\parallel \cdot \mathcal{L}_\mu \cdot \mathcal{P}_\parallel, \tag{V.4a}$$

$$\overset{(\perp)}{\mathcal{L}}_\mu = \mathcal{P}_\perp \cdot \mathcal{L}_\mu \cdot \mathcal{P}_\perp. \tag{V.4b}$$

It is a nice exercise to make sure that all the projector properties (IV.11a), (IV.11b), (IV.13), and (V.2a)–(V.2d) are correctly respected by the proposed equations of motion (V.3a) and (V.3b). Furthermore, the necessary bundle identities[8] are also valid:

$$(\mathcal{D}_\mu \mathcal{D}_\nu - \mathcal{D}_\nu \mathcal{D}_\mu)\mathcal{P}_\parallel = [\mathcal{F}_{\mu\nu}, \mathcal{P}_\parallel], \tag{V.5a}$$

$$(\mathcal{D}_\mu \mathcal{D}_\nu - \mathcal{D}_\nu \mathcal{D}_\mu)\mathcal{P}_\perp = [\mathcal{F}_{\mu\nu}, \mathcal{P}_\perp]. \tag{V.5b}$$

Thus we see that if the Hamiltonian $\mathcal{H}_\mu$ admits some fiber splitting (V.3a) and (V.3b), such that $N_\parallel + N_\perp = N_f$, then the dimensions of the corresponding distributions must necessarily remain constant ($\rightarrow N_\perp = \text{const}$, $N_\parallel = \text{const}$). [Hint: Take the traces for the equations (V.3a) and (V.3b)]. However, since an intensity matrix $\mathcal{I}(x)$ of order degree $N'(\equiv N_\parallel)$ always annihilates the complementary fiber space

$$\mathcal{P}_\perp \cdot \mathcal{I} \equiv 0, \tag{V.6}$$

and this constraint must then be valid at any event, we conclude that the mixture's degree of order (N') can *never* be *changed*. In any case, a pure state $(N'=1)$ cannot decay into a mixture $(N' > 1)$, at least in the strict sense which confirms the result of the preceding section. Thus we conjecture that the relativistic Schrödinger theory could eventually admit the transition from a mixture $(N'>1)$ into a pure state $(N'=1)$ only in the asymptotic sense. Observe, however, that the present conclusions heavily rely upon the validity of the splitting dynamics (V.3a) and (V.3b) and, therefore, they readily have to be abandoned if such a fiber distribution does not exist.

In order to keep the situation as simple as possible, we shall restrict ourselves to the second-order mixtures with vanishing tensor deviation. Since this subclass of mixtures has its deviator $\mathfrak{D}_{\mathrm{F}}$

proportional to the projector $\mathcal{P}_\|$, remember (IV.9), we have to make sure that both field equations for the deviator $\mathfrak{D}_F$ in (IV.1) and for the projector $\mathcal{P}_\|$ in (V.3a) are really compatible with each other.

To this end, the special result for the deviator $\mathfrak{D}_F$ in (IV.9) is introduced into its general dynamical equation (IV.1). This first yields for the derivative by use of Eq. (V.3a)

$$\mathcal{D}_\mu \mathfrak{D}_F = \frac{1}{2}(\partial_\mu \Delta_F)\cdot \mathcal{P}_\| - \Delta_F \cdot \overset{(\|)}{\mathcal{L}}_\mu + \frac{i}{\hbar c}(\mathfrak{D}_F \cdot \overline{\mathcal{H}}_\mu - \mathcal{H}_\mu \cdot \mathfrak{D}_F). \tag{V.7}$$

Comparing this now to the original equation (IV.1) puts the inhomogeneous term $\mathfrak{E}_\mu$ into the following form:

$$\mathfrak{E}_\mu = \tfrac{1}{2}(\partial_\mu \Delta_F)\cdot \mathcal{P}_\| - \Delta_F \cdot \overset{(\|)}{\mathcal{L}}_\mu - \tfrac{1}{2}\Delta_F \{\mathcal{L}_\mu, \mathcal{P}_\|\}. \tag{V.8}$$

Now observe here that the trace of the inhomogeneous term $\mathfrak{E}_\mu$ just yields the derivative of the scalar Δ_F, cf. (IV.1),

$$\partial_\mu \Delta_F = 4 \operatorname{tr}(\mathfrak{D}_F \cdot \mathcal{L}_\mu) = 2\Delta_F \operatorname{tr}(\overset{(\|)}{\mathcal{L}}_\mu), \tag{V.9}$$

and thus rewrite the inhomogeneous term $\mathfrak{E}_\mu$ (V.8) in its final form as

$$\mathfrak{E}_\mu = \Delta_F(\mathcal{P}_\| \cdot \operatorname{tr} \overset{(\|)}{\mathcal{L}}_\mu - \overset{(\|)}{\mathcal{L}}_\mu - \tfrac{1}{2}\mathcal{L}_\mu \cdot \mathcal{P}_\| - \tfrac{1}{2}\mathcal{P}_\| \cdot \mathcal{L}_\mu). \tag{V.10}$$

From here it is realized once more that $\mathfrak{E}_\mu$ must vanish for a pure state ($\Delta_F = 0$) [see the arguments below (IV.6)].

However, the significance of Eq. (V.10) rather lies in the fact that it appears to establish some constraint upon the localization field $\mathcal{L}_\mu$. The reason is that the object $\mathfrak{E}_\mu$ has been already defined in terms of $\mathcal{L}_\mu$ through the equation (IV.3) and, therefore, it may be possible that both Eqs. (IV.3) and (V.10) are compatible only if $\mathcal{L}_\mu$ obeys some restrictive condition. This would readily imply the conclusion that our specific second-order mixtures are preserved only when the corresponding Hamiltonian $\mathcal{H}_\mu$ (IV.2) is of some special form. However, we want to stress here that such a constraint upon $\mathcal{H}_\mu$ does not actually exist. In order to verify this claim we merely decompose the localization field $\mathcal{L}_\mu$ into its parallel and orthogonal parts

$$\mathcal{L}_\mu = \overset{(\|)}{\mathcal{L}}_\mu + \overset{(\perp)}{\mathcal{L}}_\mu + \mathcal{P}_\| \cdot \mathcal{L}_\mu \cdot \mathcal{P}_\perp + \mathcal{P}_\perp \cdot \mathcal{L}_\mu \cdot \mathcal{P}_\|, \tag{V.11}$$

and use this decomposition for the compatibility test of both Eqs. (V.10) and (IV.3). This test leads to the following remaining requirement of purely parallel character:

$$[\mathcal{I}, [\mathcal{I}, \overset{(\|)}{\mathcal{L}}_\mu]] + \mathcal{I} \cdot \operatorname{tr}\{\mathcal{I}, \overset{(\|)}{\mathcal{L}}_\mu\} - \{\mathcal{I}, \overset{(\|)}{\mathcal{L}}_\mu\} \cdot \operatorname{tr} \mathcal{I} = -2\Delta_F(\overset{(\|)}{\mathcal{L}}_\mu - \tfrac{1}{2}\mathcal{P}_\| \cdot \operatorname{tr} \overset{(\|)}{\mathcal{L}}_\mu). \tag{V.12}$$

Though this may appear as a rather unwieldy constraint binding together the intensity matrix $\mathcal{I}$ and the parallel part $\overset{(\|)}{\mathcal{L}}_\mu$ of the localization field, it actually is an *identity* (for $N_\| = 2$) which holds for all matrices $\mathcal{I}$ of the type (II.17) with (IV.13) and for *all* localization fields $\mathcal{L}_\mu$. (For a quick check put $\mathcal{L}_\mu$ proportional to the identity operator: $\mathcal{L}_\mu \rightarrow l_\mu \cdot \mathbf{1}$.)

Consequently, the original presumption was correct, i.e., the special second-order mixtures ($\Delta_{\mu\nu} \equiv 0$) with their characteristic deviator $\mathfrak{D}_F$ in (IV.9) are preserved by *any* Hamiltonian $\mathcal{H}_\mu$! Observe that this result is not quite trivial because, in general, it is only the order (N') of the mixture which is preserved in the strict sense during the Hamiltonian space–time evolution, but the preservation of certain specific subclasses (due to the same N') cannot be expected. In any case, the present result provides us with a very convenient possibility to study the (asymptotic) transitions between mixtures and pure states within that specific subclass ($\Delta_{\mu\nu} = 0$) characterized by only one single deviation variable (Δ_F).

VI. HAMILTONIAN DYNAMICS

The preceding result provides us with the freedom to choose an arbitrary Hamiltonian $\mathcal{H}_\mu$ being subject only to the field equations (I.7) and (I.8). Clearly one will select an object $\mathcal{H}_\mu$ whose properties have already been studied in sufficient detail:[16]

$$\frac{1}{\hbar c}\cdot\mathcal{H}_\mu=\frac{m}{4}\gamma_\mu+\frac{3}{2}ib_\mu(N\cdot\mathbf{1}-\tilde{N}\cdot\varepsilon)+(4b_\mu b_\lambda-g_{\mu\lambda})(W\cdot\mathbf{1}+\tilde{W}\cdot\varepsilon)\gamma^\lambda$$
$$-ib^\lambda(N\cdot\Sigma_{\mu\lambda}+\tilde{N}\cdot{}^*\Sigma_{\mu\lambda}). \tag{VI.1}$$

This Hamiltonian is due to a Robertson–Walker (RW) universe whose Hubble flow vector b_μ is thus identified with the present deviation vector (III.13a). Furthermore, m is the rescaled mass $M(:=\hbar m/c)$ and, according to the RW symmetry, the four complex scalar fields $W,\tilde{W},N,\tilde{N}$ are homogeneous, i.e., they exclusively depend upon the cosmic time θ $(\partial_\mu\theta\equiv b_\mu)$.

Introducing the present ansatz for $\mathcal{H}_\mu$ (VI.1) into the field equations (I.7) and (I.8) must yield the field equations for those four ansatz scalars $W,\tilde{W},N,\tilde{N}$, i.e.,

$$b^\mu\partial_\mu W:=\dot{W}=-H\cdot\left(W-\frac{m}{4}\right)-(N+H)\left(3W+\frac{m}{4}\right), \tag{VI.2a}$$

$$\dot{\tilde{W}}=-H\cdot\tilde{W}-3(N+H)\cdot\tilde{W}, \tag{VI.2b}$$

$$\dot{\tilde{N}}=-H\cdot\tilde{N}, \tag{VI.2c}$$

$$\dot{N}+\dot{H}+\frac{\sigma}{\mathcal{R}^2}=N\cdot(N+H)+16W^2+16\tilde{W}^2-4mW-\tilde{N}^2. \tag{VI.2d}$$

However, besides these dynamical equations one also finds some algebraic constraints for the ansatz fields:

$$\tilde{N}\cdot\tilde{W}=0, \tag{VI.3a}$$

$$\tilde{N}\cdot\left(W-\frac{m}{4}\right)=0, \tag{VI.3b}$$

$$\tilde{N}\cdot(N+H)=0, \tag{VI.3c}$$

$$\frac{\sigma}{\mathcal{R}^2}=(N+H)^2+4\left(W-\frac{m}{4}\right)^2+4\tilde{W}^2-\tilde{N}^2. \tag{VI.3d}$$

Here, the scale parameter of the RW line-element has been denoted by $\mathcal{R}$ (''radius of the universe''), $H(\equiv\dot{\mathcal{R}}/\mathcal{R})$ is the Hubble expansion rate, and σ is the topological index ($\sigma=+1$: open universe; $\sigma=0$: flat; $\sigma=-1$: closed). Perhaps the most striking feature of the present Hamiltonian $\mathcal{H}_\mu$ in (VI.1) is the fact that it falls apart into two subsets, which are rather different from the topological point of view, according to whether the ansatz scalar $\tilde{N}$ does vanish or not, cf. Ref. 16.

However, for the present context it is more important to consider the splitting of $\mathcal{H}_\mu$ into its (anti-)Hermitian parts $\mathcal{K}_\mu$, $\mathcal{L}_\mu$, of (IV.2) because the localization field $\mathcal{L}_\mu$ explicitly governs the deviation dynamics [see Eq. (V.7)]. The kinetic field $\mathcal{K}_\mu$ as the Hermitian part of the Hamiltonian $\mathcal{H}_\mu$ of (VI.1) is found as

$$\mathcal{K}_\mu=\frac{m}{4}\gamma_\mu+\frac{3}{2}N_r b_\mu\cdot\mathbf{1}-\frac{3}{2}\tilde{N}_r b_\mu\cdot\varepsilon+(4b_\mu b_\lambda-g_{\mu\lambda})(W_r\cdot\mathbf{1}+i\tilde{W}_c\cdot\varepsilon)\gamma^\lambda$$
$$-ib^\lambda(N_c\cdot\Sigma_{\mu\lambda}+\tilde{N}_c\cdot{}^*\Sigma_{\mu\lambda}) \tag{VI.4}$$

and similarly for the anti-Hermitian part:

$$\mathcal{L}_\mu = \frac{3}{2} N_c b_\mu \cdot \mathbf{1} - \frac{3}{2} \tilde{N}_c b_\mu \cdot \varepsilon + (4 b_\mu b_\lambda - g_{\mu\lambda})(W_c \cdot \gamma^\lambda - i \tilde{W}_r \tilde{\gamma}^\lambda) + i b^\lambda (N_r \cdot \Sigma_{\mu\lambda} + \tilde{N}_r \cdot {}^*\Sigma_{\mu\lambda}). \tag{VI.5}$$

Observe here that the ansatz scalars have been split up into their real and imaginary parts according to

$$W = W_r + i W_c , \tag{VI.6a}$$

$$\tilde{W} = \tilde{W}_r + i \tilde{W}_c , \tag{VI.6b}$$

$$N = N_c - i N_r , \tag{VI.6c}$$

$$\tilde{N} = \tilde{N}_c - i \tilde{N}_r , \tag{VI.6d}$$

and that the Spin(1,3) generators $\Sigma_{\mu\nu} = \frac{1}{4}[\gamma_\mu , \gamma_\nu]$ are anti-Hermitian ($\overline{\Sigma}_{\mu\nu} = -\Sigma_{\mu\nu}$) as well as the axial velocity operator $\tilde{\gamma}_\lambda := \varepsilon \gamma_\lambda = -\bar{\tilde{\gamma}}_\lambda$.

Once the Hamiltonian $\mathcal{H}_\mu$ is known, one can now study the dynamics for the deviation scalar Δ_{F} (V.9). However, the information carried by Δ_{F} (with respect to the existence of a pure state) can be improved by relating it to the scalar density ρ. As the physical densities (II.10a)–(II.10c) are demonstrating clearly, the scalar ρ essentially determines their absolute magnitudes; and since the deviation fields (III.3a)–(III.3e) are certain combinations of these physical densities, their magnitude will also be determined by the scalar ρ. Thus if we want to have an adequate measure for the presence of a pure state, it is better to consider the *reduced* deviation field $\Delta_{\mathrm{F}}/\rho^2$. Therefore, let us combine the derivative for Δ_{F} of (V.9) with that of ρ,

$$\partial_\mu \rho = \mathrm{tr}\, (\mathcal{D}_\mu \mathcal{I}) = 2\, \mathrm{tr}\, (\mathcal{I} \cdot \mathcal{L}_\mu), \tag{VI.7}$$

to find

$$\partial_\mu \left(\frac{\Delta_{\mathrm{F}}}{\rho^2} \right) = \frac{4}{\rho^2}\, \mathrm{tr} \left[\left(\mathfrak{D}_{\mathrm{F}} - \frac{\Delta_{\mathrm{F}}}{\rho} \mathcal{I} \right) \cdot \mathcal{L}_\mu \right]. \tag{VI.8}$$

Introducing here the intensity matrix $\mathcal{I}$ of (II.14), the specific deviation fields (III.17a)–(III.17f), and the present localization field $\mathcal{L}_\mu$ (VI.5) then yield

$$\partial_\mu \left(\frac{\Delta_{\mathrm{F}}}{\rho^2} \right) = \frac{4}{\rho} \left(\frac{\Delta_{\mathrm{F}}}{\rho^2} \right) [-W_c (I b_\mu - j_\mu) + \tilde{W}_r (\tilde{I} b_\mu - \tilde{j}_\mu) + 2 N_r b^\lambda S_{\lambda\mu} + 2 \tilde{N}_r b^\lambda {}^*S_{\lambda\mu}]. \tag{VI.9}$$

This is the desired result because, if we succeed in integrating this equation, we can judge in which region of space–time there prevails a pure state ($\Delta_{\mathrm{F}}/\rho^2 \ll 1$) and where one has a mixture ($\Delta_{\mathrm{F}}/\rho^2 \sim 1$). A special property of the result (VI.9) consists in the fact that the reduced deviation does not change with cosmic time θ. Indeed, multiply through the equation (VI.9) by the Hubble flow b^μ and find

$$b^\mu \partial_\mu \left(\frac{\Delta_{\mathrm{F}}}{\rho^2} \right) = \frac{d}{d\theta} \left(\frac{\Delta_{\mathrm{F}}}{\rho^2} \right) \equiv 0. \tag{VI.10}$$

Clearly, this time independence of the reduced deviation $\Delta_{\mathrm{F}}/\rho^2$ is due to our special assumptions concerning the choice of Hamiltonian $\mathcal{H}_\mu$, and will not apply in the general case. However, on account of the time independence, one can concentrate now upon the study of the purely spatial variations of $\Delta_{\mathrm{F}}/\rho^2$.

VII. SO(3) SYMMETRIC MIXTURES

The most striking difference between mixtures and pure states lies in the fact that certain configurations of the physical densities cannot be generated by a pure state but are available only by a mixture. This circumstance becomes especially clear in the context of certain symmetries of the physical densities. For instance, in the present case of spinning (Dirac) matter, one would expect that spin effects should show up in (at least some of) the physical densities which therefore could not be isotropic. The cosmological principle, requiring strict isotropy and homogeneity, should therefore not apply to all of the physical densities carried by spinning matter.[17] However, even if one admits some lower symmetry, the mixtures develop a higher potentiality for realizing those symmetries.

As an example, return for a moment to the former relationship (III.13b) which establishes a linear dependence of three vector fields $\{b_\mu, j_\mu \tilde{j}_\mu\}$ and also implies the scalar relationship (III.15). However, though the latter scalar constraint does apply also for the pure state densities (II.10a)–(II.10c) (for $z=1$), the former vector relationship (III.13b) does not hold in general for the pure-state case (II.10a)–(II.10c)! Consequently, the immediate conclusions, to be drawn from that vector relationship (III.13b), cannot be obeyed by the pure-state configurations. We now demonstrate that among those properties, not being available for the pure states, is just the SO(3) symmetry of certain physical densities. Clearly, one furthermore needs the breaking of homogeneity down to (e.g.) the SO(3) symmetry in order to demonstrate the spatial variations of the reduced deviation Δ_F/ρ^2 as a measure for the ''distance'' between mixtures and pure states.

The point of departure for this demonstration is the observation that the crucial vector relation (III.13b) admits the introduction of a space–like vector $\tilde{c}_\mu$:

$$\tilde{c}_\mu = \frac{I}{\rho^2+\tilde{\rho}^2}\cdot \tilde{j}_\mu - \frac{\tilde{I}}{\rho^2+\tilde{\rho}^2}\cdot j_\mu . \tag{VII.1}$$

Evidently this vector field is orthogonal to the Hubble flow b_μ,

$$b^\mu \cdot \tilde{c}_\mu \equiv 0, \tag{VII.2}$$

and is found to be of length $\tilde{c}$

$$\tilde{c}^{\,2} := -\tilde{c}^\mu \tilde{c}_\mu = 1 - 2\,\frac{\Delta_F}{\rho^2}, \tag{VII.3}$$

when the properties of the second-order mixtures (Sec. III) are used. Thus the values of the reduced deviation are restricted to the following range:

$$0 \leqslant \frac{\Delta_F}{\rho^2} \leqslant \frac{1}{2}. \tag{VII.4}$$

Indeed, this result is now the crucial point for the emergence of new spatial structures which are *forbidden for the pure states* $(\Delta_F \equiv 0)$. The reason is that for $\Delta_F \to 0$ the vector $\tilde{c}_\mu$ (VII.1) becomes a unit vector which, by its very definition, can nowhere vanish. However, the existence of a zero of the vector field $\tilde{c}_\mu$ is *necessary*, e.g., for the case of a rotationally symmetric configuration, otherwise $\tilde{c}_\mu$ would not be differentiable at the symmetry center. However, this is *no problem for a mixture* because, in view of Eq. (VII.3), one merely has to demand for the center $(r=0)$

$$\lim_{r\to 0} \frac{\Delta_F}{\rho^2} = \frac{1}{2} \tag{VII.5}$$

and the vector field $\tilde{c}_\mu$ becomes zero there as desired.

In what follows we want to elaborate this point in some more detail but, in order to see the essential point, it will be sufficient to select the most simple Hamiltonian from the set (VI.1), namely the case of nonvanishing scalar $\tilde{N}$ for an open RW universe (i.e., $\sigma=+1$). For this presumption the Hamiltonian constraint (VI.3d) yields

$$\frac{1}{\mathcal{R}^2}=-\tilde{N}^2=-\tilde{N}_c^2+\tilde{N}_r^2+2i\tilde{N}_c\cdot\tilde{N}_r\,. \tag{VII.6}$$

Thus $\tilde{N}_c$ must be zero and the derivative of the scalar density ρ (VI.7), with the localization field $\mathcal{L}_\mu$ being given by (VI.5), tells us that we will then get some nontrivial spatial structure over the time slices $\theta=$const. Consequently, the choice for the localization field $\mathcal{L}_\mu$ is the following:

$$\mathcal{L}_\mu\rightarrow{}^{(\sim)}\mathcal{L}_\mu=-\tfrac{3}{2}Hb_\mu\cdot\mathbf{1}+i\tilde{N}_r\cdot{}^*\Sigma_{\mu\lambda}b^\lambda, \tag{VII.7}$$

and the corresponding kinetic field $\mathcal{K}_\mu$ (VI.4) becomes

$$\mathcal{K}_\mu\rightarrow{}^{(\sim)}\mathcal{K}_\mu=-\tfrac{3}{2}\tilde{N}_rb_\mu\cdot\varepsilon+mb_\mu\cdot\beta+iH\cdot\Sigma_{\mu\lambda}b^\lambda. \tag{VII.8}$$

Next, the RW homogeneity on the time slices must be broken down to SO(3) symmetry. This is attained most conveniently by rewriting the RW line-element in terms of ''polar coordinates'' $\{r,\vartheta,\phi\}$ (Ref. 18) as

$$ds^2=d\theta^2-\mathcal{R}^2(dr^2+\sinh^2\, r(d\vartheta^2+\sin^2\,\vartheta\;d\phi^2)) \tag{VII.9}$$

such that the origin $(r=0)$ becomes the symmetry center. The radial coordinate r may be considered as a scalar field over space–time, whose unit normal r_μ is then given by[17]

$$r_\mu=\mathcal{R}\cdot\partial_\mu r, \tag{VII.10a}$$

$$r^\mu r_\mu=-1, \tag{VII.10b}$$

$$b^\mu r_\mu=0. \tag{VII.10c}$$

Clearly the coordinate vector r_μ is an SO(3) symmetric vector field and obeys the field equation[17]

$$\nabla_\mu r_\nu=\frac{1}{\mathcal{R}\cdot\tanh\, r}\,(g_{\mu\nu}-b_\mu b_\nu+r_\mu r_\nu)-Hb_\nu r_\mu\,. \tag{VII.11}$$

Therefore, if the physical densities (II.12a)–(II.12e) are coined SO(3) symmetric by the present Hamiltonian ${}^{(\sim)}\mathcal{H}_\mu=\hbar c({}^{(\sim)}\mathcal{K}_\mu+i{}^{(\sim)}\mathcal{L}_\mu)$ via the relativistic von-Neumann equation (I.10), then the spacelike vector field $\tilde{c}_\mu$ (VII.1) must obey the SO(3) symmetry condition

$$\nabla_\nu\tilde{c}_\mu=\tilde{N}_r(g_{\mu\nu}-b_\mu b_\nu+\tilde{c}_\mu\tilde{c}_\nu)-Hb_\mu\tilde{c}_\nu \tag{VII.12a}$$

or, resp., for its normalized version $\hat{c}_\mu(:=\tilde{c}^{-1}\cdot\tilde{c}_\mu,\hat{c}^\mu\hat{c}_\mu=-1)$:

$$\nabla_\nu\hat{c}_\mu=\tilde{N}_r\cdot\frac{g_{\mu\nu}-b_\mu b_\nu+\hat{c}_\mu\hat{c}_\nu}{\tilde{c}}-Hb_\mu\hat{c}_\nu\,. \tag{VII.12b}$$

Here, the origin of the symmetry claim (VII.12a) lies in the observation that the spatial derivatives of the physical densities are governed mainly by the vector field $\tilde{c}_\mu$. However, it is then immediately obvious that the total density configuration will be SO(3) symmetric if $\tilde{c}_\mu$ obeys that symmetry condition (VII.12a) (observe that the geometric background remains RW symmetric). In order to present a few examples, consider first the reduced deviation $\Delta_{\mathrm{F}}/\rho^2$ (VI.9). Since our choice of Hamiltonians (VII.7) and (VII.8) lets only the ansatz scalar $\tilde{N}_r$ survive, the derivative (VI.9) is first simplified to

$$\partial_\mu\left(\frac{\Delta_F}{\rho^2}\right)=\frac{8}{\rho}\frac{\Delta_F}{\rho^2}\,\tilde{N}_r b^{\lambda *}S_{\lambda\mu}\,. \tag{VII.13}$$

But on the other hand, the former second-order identities (III.6a)–(III.6e) imply

$$b^{\lambda *}S_{\lambda\mu}=\tfrac{1}{4}\rho\tilde{c}_\mu\,, \tag{VII.14a}$$

$$b^{\lambda}S_{\lambda\mu}=\tfrac{1}{4}\tilde{\rho}\tilde{c}_\mu\,, \tag{VII.14b}$$

so that the polarization density $S_{\mu\nu}$ of (II.5c) becomes

$$S_{\mu\nu}=\tfrac{1}{4}\tilde{\rho}(b_\mu\tilde{c}_\nu-b_\nu\tilde{c}_\mu)-\tfrac{1}{4}\rho\varepsilon_{\mu\nu\lambda\sigma}b^\lambda\tilde{c}^\sigma. \tag{VII.15}$$

Thus the derivative of the reduced deviation (VII.13) is actually found proportional to the vector $\tilde{c}_\mu$,

$$\partial_\mu\left(\frac{\Delta_F}{\rho^2}\right)=2\,\frac{\Delta_F}{\rho^2}\,\tilde{N}_r\tilde{c}_\mu\,, \tag{VII.16}$$

as expected. Further examples refer to the case of the scalar density ρ of (VI.7), pseudo-scalar $\tilde{\rho}$ of (II.12b), or the other scalar products I of (III.14a) and $\tilde{I}$ of (III.14b):

$$\partial_\mu\rho=-3H\rho b_\mu-\tilde{N}_r\rho\tilde{c}_\mu\,, \tag{VII.17a}$$

$$\partial_\mu\tilde{\rho}=-(2m\tilde{I}+3H\tilde{\rho})b_\mu-\tilde{N}_r\tilde{\rho}\tilde{c}_\mu\,, \tag{VII.17b}$$

$$\partial_\mu I=-3(HI+\tilde{N}_r\tilde{I})b_\mu-\tilde{N}_r I\tilde{c}_\mu\,, \tag{VII.17c}$$

$$\partial_\mu\tilde{I}=-3(H\tilde{I}+\tilde{N}_r I-\tfrac{2}{3}m\tilde{\rho})b_\mu-\tilde{N}_r\tilde{I}\tilde{c}_\mu\,. \tag{VII.17d}$$

Moreover, the space parts of both current densities j_μ of (II.12c) and $\tilde{j}_\mu$ of (II.12d) also point to the direction of $\tilde{c}_\mu$:

$$j_\mu=Ib_\mu+\tilde{I}\tilde{c}_\mu\,, \tag{VII.18a}$$

$$\tilde{j}_\mu=\tilde{I}b_\mu+I\tilde{c}_\mu\,, \tag{VII.18b}$$

which is easily found by inverting both Eqs. (III.13b) for b_μ and (VII.1) for $\tilde{c}_\mu$. Thus, the whole matter configuration is safely SO(3) symmetric if only the SO(3) symmetry condition (VII.12a) upon the vector field $\tilde{c}_\mu$ is valid. But observe again here that the vector and tensor objects (VII.15) and (VII.18a) and (VII.18b) can be nonsingular at the symmetry center $r=0$ only for a mixture $(\Delta_F\neq 0)$ [see the arguments following (VII.4)].

However, the desired symmetry is readily established by explicit differentiation. It may be sufficient to demonstrate the technique for the current-density j_μ. Differentiating the defining equation (II.12c) yields first

$$\nabla_\nu j_\mu=\mathrm{tr}\,((\mathcal{D}_\nu\mathcal{I})\cdot\gamma_\mu) \tag{VII.19}$$

or, by use of the relativistic von-Neumann equation (I.10),

$$\nabla_\nu j_\mu=\frac{i}{\hbar c}\,\mathrm{tr}\,(\mathcal{I}[\overline{\mathcal{H}}_\nu\cdot\gamma_\mu-\gamma_\mu\cdot\mathcal{H}_\nu])=i\,\mathrm{tr}\,(\mathcal{I}\cdot[\mathcal{K}_\nu,\gamma_\mu])+\mathrm{tr}\,(\mathcal{I}\cdot\{\mathcal{L}_\nu,\gamma_\mu\}). \tag{VII.20}$$

Then, introducing here the adopted form for the kinetic field $\mathcal{K}_\mu$ (VII.8) and localization field $\mathcal{L}_\mu$ (VII.7) finally leads to the result

$$\nabla_\nu j_\mu = 2m\tilde{\rho} b_\nu \tilde{c}_\mu + (\tilde{N}_r \cdot \tilde{I} + H \cdot I) g_{\mu\nu} - 3(\tilde{N}_r \cdot \tilde{j}_\mu + H \cdot j_\mu) b_\nu - (\tilde{N}_r \cdot \tilde{j}_\nu + H \cdot j_\nu) b_\mu . \tag{VII.21}$$

As a consistency check one immediately verifies here the validity of the continuity equation

$$\nabla^\mu j_\mu = 0, \tag{VII.22}$$

or multiply through the equation (VII.23) with the Hubble flow b_μ, whose derivative reads

$$\nabla_\mu b_\nu = H B_{\mu\nu} \equiv H(g_{\mu\nu} - b_\mu b_\nu), \tag{VII.23}$$

and just find the equation (VII.17c) for the derivative of the scalar product $I(\equiv j^\mu b_\mu)$.

In any case, with this technique of computing the derivatives of the physical densities one can actually verify the correctness of the SO(3) symmetry condition (VII.12a). In the next step, one then wants to see the dependence of the reduced deviation Δ_F/ρ^2 upon the radial variable r (VII.9). For that purpose, the corresponding derivative (VII.16) is recast into the following form:

$$\hat{c}^\mu \partial_\mu \left(\frac{\Delta_F}{\rho^2} \right) \equiv \frac{1}{\mathcal{R}} \frac{d}{dr} \left(\frac{\Delta_F}{\rho^2} \right) = -2\tilde{N}_r \cdot \frac{\Delta_F}{\rho^2} \cdot \tilde{c}(r). \tag{VII.24}$$

On the other hand, the length $\tilde{c}(r)$ of the surface vector $\tilde{c}_\mu$ depends upon the reduced deviation as is shown in Eq. (VII.3) so that we end up with a closed equation for Δ_F/ρ^2.

$$\frac{d}{dr} \left(\frac{\Delta_F}{\rho^2} \right) = -2\mathcal{R}\tilde{N}_r \frac{\Delta_F}{\rho^2} \sqrt{1 - 2\frac{\Delta_F}{\rho^2}}. \tag{VII.25}$$

Putting here [in agreement with the Hamiltonian constraint (VII.6)]

$$\mathcal{R}\tilde{N}_r = +1, \tag{VII.26}$$

the obvious solution of (VII.25) for the reduced deviation is found as

$$\frac{\Delta_F}{\rho^2} = \frac{1}{2} (1 - \tanh^2 r) = \frac{1}{2\cosh^2 r}. \tag{VII.27}$$

Since this solution just obeys the smoothness condition (VII.5) for the radially symmetric tensor objects [e.g., $j_\mu, \tilde{j}_\mu$ (VII.18a) and (VII.18b) or $S_{\mu\nu}$ (VII.15)], it seems as if one would have found the desired SO(3) symmetric mixture configuration which in the outside region ($r \to \infty$) becomes a pure state ($\Delta_F/\rho^2 \to 0$).

However, the situation here is not quite so favorable because we applied a certain type of Hamiltonian $\mathcal{H}_\mu$ (VII.7) and (VII.8) which originally was designed for cosmological purposes (Ref. 19). For such a situation, the cosmological principle demands homogeneity and isotropy of the matter distribution, which is just the contrary of a well-localized distribution of the physical densities, as it is desired for the present context. Therefore one should not be surprised that the spatial concentration of the reduced deviation (VII.27) is actually spurious, namely in the sense that the scalar deviation Δ_F is constant and the scalar density ρ is increasing exponentially in the outside region ($r \to \infty$). These assertions can immediately be checked by explicitly solving the field equation for the scalar density ρ (III.17a) to yield

$$\rho(\theta, r) = \rho_{in} \left(\frac{\mathcal{R}_{in}}{\mathcal{R}(\theta)} \right)^3 \cosh r, \tag{VII.28}$$

which implies the spatial constancy for the scalar deviation Δ_F:

$$\Delta_F = \frac{1}{2} \rho_{in}^2 \left(\frac{\mathcal{R}_{in}}{\mathcal{R}(\theta)} \right)^6 . \tag{VII.29}$$

However, this drawback of the present model should not be taken too seriously. It is expected that the unboundedness of the physical densities will be removed by considering a closed universe ($\sigma=-1$) or by applying some Hamiltonian due to an attractive potential. Therefore, despite its deficiencies, the results for the present model may be understood as a distinct hint upon the existence of well-localized mixtures which become pure states in the outside region ($\Delta_F/\rho^2 \to 0$).

8*D* oscillator and 5*D* Kepler problem: The case of nontrivial constraints

M. V. Pletyukhov[a)] and E. A.Tolkachev[b)]
Institute of Physics, National Academy of Sciences of Belarus, Minsk 220072 Scorina av. 70, Belarus

(Received 29 December 1997; accepted for publication 22 September 1998)

The topologically nontrivial correspondence between the $5D$ $SU(2)$-Kepler problem and the $8D$ singular oscillator is considered. It is shown that both ''isospinor'' and ''isovector'' particles on the $SU(2)$ instanton + $1/R$ background in $5D$ can be described in terms of an $8D$ singular oscillator. The energy spectrum is calculated for an arbitrary ''isospin'' case. © *1999 American Institute of Physics.* [S0022-2488(99)01301-8]

I. INTRODUCTION

Nonbijective bilinear transformations of Levi-Civita (LCT) $R^2 \to R^2$, Kustaanheimo–Stiefel (KST) $R^4 \to R^3$, Hurwitz (HT) $R^8 \to R^5$ and the transformation $R^{16} \to R^9$, their extensions and applications have been the objects of numerous studies (e.g., see Refs. 1–4 and references therein). These transformations constitute a series of mappings $R^{2p} \to R^{p+1}$ which possess the property $r_\mu r_\mu = (x_m x_m)^2$ for $r_\mu \in R^{p+1}$, $\mu = 0, \ldots, p$; $x_m \in R^{2p}$, $m = 1, \ldots, 2p$; $p = 2^q = 1,2,4,8$. They are closely connected with division algebras of real, complex numbers, quaternions and octonions. The LCT, KST and HT are inherent to the Hopf fibrations, namely real $S^1/Z_2 = S^1$, complex $S^3/S^1 = S^2$ and quaternion $S^7/S^3 = S^4$, respectively.

In particular, these transformations are exploited to establish the correspondence between oscillator and Kepler problems, both classical and quantum, in the respective dimensions.[5] Moreover, using KST it has been shown (e.g., see Refs. 6,7) that the Schrödinger equation for a $4D$ isotropic oscillator with a constraint is equivalent to that for a $3D$ particle on the background of the $U(1)$ Dirac monopole+Kepler (Coulomb) $1/R$+extra $1/R^2$. The latter is known as MIC-Kepler problem.[8] Introducing the corresponding singular term into the $4D$ equation one can remove the extra centrifugal—Zwanziger's[9]—potential in $3D$ and the equation for the dyogen atom arises.[10] Its energy spectrum and eigenfunctions have been obtained on the basis of the dynamical symmetries of the $4D$ singular isotropic oscillator.[11]

As for HT, it establishes the relation between an $8D$ oscillator and $5D$ Kepler problems. In the quantum case it is usually supposed[5,12,13] that the corresponding wavefunctions are related as $\Psi^{(8)}(x_m) = \Psi^{(5)}(r_\mu)$. Thus, the Hilbert space of the $8D$ oscillator appears to be in one-to-one correspondence with that of a $5D$ problem. A geometric quantization procedure for this case has been developed in Ref. 14.

Recently attempts to consider a topologically nontrivial version imposing a less strict constraint on $\Psi^{(8)}(x_m)$ have been made.[15,16] The results obtained allow us to describe a $5D$ ''isospin'' particle on the background of $SU(2)$ instanton+Kepler $1/R$+extra $1/R^2$ in the oscillator framework as well. To make it explicit, it is necessary to choose the certain parametrization for $SU(2)$ representations of the gauge group. The Eulerian one complicates computations and therefore seems to be inefficient for explicit usage of nontrivial constraints.[17] Those introduced in Refs. 18,19 makes the geometric nature of the problem less transparent. The parametrization proposed by the authors[15] helped to choose the fiber coordinate in a simple form and to fulfill the straight-

[b)]Electronic mail: tea@dragon.bas-net.by

forward transition to Hilbert space of the $SU(2)$ Kepler problem in the ''isovector'' (integer ''isospins'') case.

In this paper, in Sec. II, we describe the well-known correspondence between an $8D$ harmonic oscillator and a $5D$ $SU(2)$-Kepler problem on the background of a centrifugal Zwanziger-like term ($5D$ MIC-Kepler problem) in suitable parametrization, half-integer ''isospins'' being treated as well. Then, in Sec. III, we introduce the singular term into the oscillator's Hamiltonian and show that this ''corrected'' equation is associated with the $5D$ Kepler problem on $SU(2)$ instanton background (a higher dimensional dyogen atom's counterpart). The energy spectrum of the latter problem is obtained for the first time.

II. 8*D* OSCILLATOR AND 5*D* KEPLER PROBLEM

Let us start with the Schrödinger equation for an $8D$ isotropic oscillator,

$$-\frac{1}{2}\Delta_8\Psi^{(8)}+\frac{\omega^2}{2}(u^2+v^2)\Psi^{(8)}=E\Psi^{(8)}, \tag{1}$$

where $\Psi^{(8)}=\Psi^{(8)}(u_i,v_i)$ is a scalar wave function.

It is well-known that Hurwitz transformation (HT) mapping $\dot{R}^8\equiv R^8\setminus\{0\}\to\dot{R}^5\equiv R^5\setminus\{0\}$,

$$\begin{gathered} r_0=u_iu_i-v_iv_i\equiv u^2-v^2, \\ r_a=2(-u_0v_a+u_av_0-\varepsilon_{abc}u_bv_c), \quad r_4=2u_iv_i, \end{gathered} \tag{2}$$

$(a,b,c=1,2,3;\ i=0,1,2,3)$, possesses the property

$$(u^2+v^2)^2=r_0^2+r_a^2+r_4^2\equiv r_\mu^2\equiv R^2 \quad (\mu=0,\ldots,4). \tag{3}$$

HT makes projection in the principal fiber bundle, $\dot{R}^8$, $\dot{R}^5$ and $SU(2)$ being total bundle, base, and structure group, respectively. The operators removing the function, which depends on the base coordinates r_μ only, i.e., $X_af(r_\mu)=0$, are called vertical and have the form[20]

$$X_a=-u_a\frac{\partial}{\partial u_0}+u_0\frac{\partial}{\partial u_a}-\varepsilon_{abc}u_b\frac{\partial}{\partial u_c}-v_a\frac{\partial}{\partial v_0}+v_0\frac{\partial}{\partial v_a}-\varepsilon_{abc}v_b\frac{\partial}{\partial v_c}. \tag{4}$$

The operators $\hat{X}_a\equiv(i/2)X_a$ obey standard $SU(2)$ commutation relations.

It is convenient to introduce fiber coordinates $z_a=u_a/u_0$ and pass from one set (u_0,u_a,v_0,v_a) to another (r_0,r_a,r_4,z_a). This transformation is valid locally, i.e., in the region, where $|u|\neq 0$, or $R\neq -r_0$, only. Then

$$\hat{X}_a\to T_a=\frac{i}{2}\left(z_az_b\frac{\partial}{\partial z_b}+\frac{\partial}{\partial z_a}-\varepsilon_{abc}z_b\frac{\partial}{\partial z_c}\right). \tag{5}$$

These vertical operators exactly coincide with $SU(2)$ generators acting in the group space expressed in terms of vector-parameters.[21] Note that vector parametrization of $SU(2)(SO(3))$ is related with Eulerian one via

$$\begin{gathered} z_1=\tan\frac{\theta}{2}\cos\frac{\varphi-\psi}{2}\Big/\cos\frac{\varphi+\psi}{2}, \\ z_2=\tan\frac{\theta}{2}\sin\frac{\varphi-\psi}{2}\Big/\cos\frac{\varphi+\psi}{2}, \quad z_3=\tan\frac{\varphi+\psi}{2}. \end{gathered} \tag{6}$$

In the new set of coordinates the $8D$ Laplacian reads as

$$\Delta_8=-4R(-i\partial_\mu+A_\mu^a O_{ab}(\mathbf{z})T_b(\mathbf{z}))^2-\frac{4}{R}\mathbf{T}^2, \tag{7}$$

where

$$A_\mu^a dr_\mu=\frac{1}{R(R+r_0)}(-r_4 dr_a+r_a dr_4-\varepsilon_{abc}r_b dr_c) \tag{8}$$

is an instantonic connection form;[22]

$$O_{ab}(\mathbf{z})=\delta_{ab}+\frac{2}{1+\mathbf{z}^2}(z_a z_b-\mathbf{z}^2\delta_{ab}+\varepsilon_{adb}z_d) \tag{9}$$

is the orthogonal matrix in the vector parametrization.[21]

It can be readily shown that

$$O_{ab}(\mathbf{z})T_b(\mathbf{z})=\frac{i}{2}\left(z_a z_b\frac{\partial}{\partial z_b}+\frac{\partial}{\partial z_a}+\varepsilon_{abc}z_b\frac{\partial}{\partial z_c}\right)=-T_a(-\mathbf{z})\equiv -K_a(\mathbf{z})\equiv -K_a. \tag{10}$$

The following relations are valid:

$$[K_a,T_b]=0,\quad [K_a,K_b]=i\varepsilon_{abc}K_c,\quad \mathbf{K}^2\equiv K_aK_a=\mathbf{T}^2\equiv T_aT_a. \tag{11}$$

Then the initial equation (1) can be identically rewritten as

$$\frac{1}{2}(-i\partial_\mu-A_\mu^a K_a)^2\Psi^{(8)}+\left(\frac{\mathbf{K}^2}{2R^2}-\frac{\alpha}{R}\right)\Psi^{(8)}=\varepsilon\Psi^{(8)}, \tag{12}$$

where $\varepsilon=-\omega^2/8$, $\alpha=E/4$.

To complete the transition to $\dot{R}^5$, one should impose additional constraints onto the function $\Psi^{(8)}(r_\mu,\mathbf{z})$. Instead of the topologically trivial condition—the independence of $\Psi^{(8)}$ upon the fiber coordinates[5,12,13]—we require the equivariance condition to hold:[15,16]

$$\mathbf{K}^2\Psi^{(8)}=l(l+1)\Psi^{(8)}. \tag{13}$$

Note that the trivial case corresponds to ''isospin'' $l=0$.

Consider now the $SU(2)$ Wigner representation constructed according to the classic scheme:

$$\begin{gathered}\mathbf{K}^2\psi^l_{mm'}=l(l+1)\psi^l_{mm'},\quad K_3\psi^l_{mm'}=m\psi^l_{mm'},\\ (-T_3)\psi^l_{mm'}=m'\psi^l_{mm'},\quad -l\leqslant m,m'\leqslant l.\end{gathered} \tag{14}$$

For $\psi=(\psi^l_{mm'})$, the identity

$$K_a\psi^T=\psi^T\Lambda_a \tag{15}$$

is valid, provided that Λ_a are the generators of the respective representation with ''isospin'' l.

Let us expand $\Psi^{(8)}$ in a series of $\psi^l_{mm'}$,

$$\Psi^{(8)}=\sum_{m,m'}\psi^l_{mm'}\Phi_{mm'}=Sp[\psi^T(\mathbf{z})\Phi(r_\mu)]. \tag{16}$$

Then

$$(-i\partial_\mu - A_\mu^a K_a)\Psi^{(8)} = Sp[\psi^T(\mathbf{z})(-i\partial_\mu - A_\mu^a \Lambda_a)\Phi(r_\mu)]. \tag{17}$$

Substituting (17) into (12), we obtain the equation for $\phi \equiv \Phi_{ml}$ (without loss of generality it is chosen as $m' = l$):

$$\left(\frac{\pi_\mu^2}{2} + \frac{l(l+1)}{2R^2} - \frac{\alpha}{R}\right)\phi = \varepsilon \phi, \tag{18}$$

where $\pi_\mu = -i\partial_\mu - A_\mu^a \Lambda_a$. Equation (18) is the $5D$ counterpart of the MIC-Kepler problem arising in electrodynamics with magnetic charge.[8] The energy spectrum of (18) is known[16] to be

$$\varepsilon_N = -\frac{\alpha^2}{2[(N/2)+2)^2}, \quad N = 0,1,2,\ldots. \tag{19}$$

Though there is no explicit dependence on l, N takes only even values: $N = 0,2,4,\ldots$, for $l = 0$.[12]

To finish this section, we recall the relation between the Hermitian products in $\dot{R}^8$ and $\dot{R}^5$ (see, for instance, Ref. 13). From the definition

$$\langle \Psi_1 | \Psi_2 \rangle_8 = \frac{2^7}{\pi^2} \int \Psi_1^*(u_i, v_i)\Psi_2(u_i, v_i)(|u|^2 + |v|^2) d^4u_i d^4v_i, \tag{20}$$

and the natural requirement

$$\langle \Psi_1 | \Psi_2 \rangle_8 = \langle \varphi_1 | \varphi_2 \rangle_5,$$

one obtains

$$\langle \varphi_1 | \varphi_2 \rangle_5 = \int \varphi_1^+(r_\mu)\varphi_2(r_\mu) d^5 r_\mu. \tag{21}$$

The latter is valid because

$$\frac{2^7}{\pi^2} \int_{S^3} (|u|^2 + |v|^2) d^4u_i d^4v_i = d^5 r_\mu, \tag{22}$$

where factor 2^8 is due to the bilinearity of HT and $2\pi^2$ is $SU(2)$ group volume.

III. ENERGY SPECTRUM OF $SU(2)$ KEPLER PROBLEM

In Ref. 11 it has been shown that introduction of the certain singular term into the $4D$ oscillator's equation leads to the $3D$ dyogen atom's problem. The Hamiltonian of the latter does not contain a nonphysical Zwanziger's term.

Let us consider on the analogy a singular $8D$ Hamiltonian,

$$H = -\frac{1}{2}\sum_{s=1}^{8} \frac{\partial^2}{\partial x_s^2} + \frac{\omega^2 x^2}{2} - \frac{2l(l+1)}{x^2} \quad \left(x^2 = \sum_{s=1}^{8} x_s x_s\right). \tag{23}$$

Here and below we mean $(x_1,\ldots,x_4,x_5,\ldots,x_8) = (u_0,\ldots,u_3,v_0,\ldots,v_3)$. The eigenvalues of (23) are given by[23,24]

$$E_{nj} = 2\omega(n + 1/2 + \sqrt{-l(l+1) + j(j+3) + 9/4}), \tag{24}$$

where j takes integer and half-integer values.

Under the HT Hamiltonian (23) is associated with a $5D$ counterpart of the dyogen atom:

$$\left(\frac{\pi_\mu^2}{2}-\frac{\alpha}{R}\right)\varphi=\varepsilon\varphi. \tag{25}$$

Since $\varepsilon=-\omega^2/8$ and $\alpha=E/4$, one can readily find

$$\varepsilon_{nj}=-\frac{\alpha^2}{2(n+1/2+\sqrt{-l(l+1)+j(j+3)+9/4})^2}. \tag{26}$$

But such treatment does not clarify what values j *exactly* takes.

To obtain the expression (26) in the closed form, we shall use the ideas based on the dynamical symmetry approach. Consider the operators

$$B_2^+=B_{20}^+-i\frac{2l(l+1)}{x^2},\quad B_2=B_{20}+i\frac{2l(l+1)}{x^2},$$
$$H=H_0-\frac{2l(l+1)}{x^2}, \tag{27}$$

expressed via nonsingular (harmonic) ones,

$$B_{20}^+=-i\omega a_s^+a_s^+,\quad B_{20}=i\omega a_s a_s,\quad H_0=\omega(a_s^+a_s+4). \tag{28}$$

The creation a_s^+ and annihilation a_s operators obey $[a_s,a_t^+]=\delta_{st}$ as usual.

The operators (28) satisfy the relations

$$[H,B_2^+]=2\omega B_2^+,\quad [H,B_2]=-2\omega B_2,\quad [B_2,B_2^+]=4\omega H, \tag{29}$$

as well as the operators (28) do,

$$[H_0,B_{20}^+]=2\omega B_{20}^+,\quad [H_0,B_{20}]=-2\omega B_{20},\quad [B_{20},B_{20}^+]=4\omega H_0. \tag{30}$$

Let us introduce

$$K_0=\frac{H}{2\omega},\quad K_+=\frac{B_2^+}{2\omega},\quad K_-=\frac{B_2}{2\omega}, \tag{31}$$

which satisfy $SU(1,1)$ commutation relations,

$$[K_0,K_\pm]=\pm K_\pm,\quad [K_-,K_+]=2K_0. \tag{32}$$

The representation of $SU(1,1)$ is constructed as follows:[24]

$$K_0|n,k\rangle=(n+k)|n,k\rangle,$$
$$K_+|n,k\rangle=\sqrt{(n+1)(n+2k)}|n+1,k\rangle, \tag{33}$$
$$K_-|n,k\rangle=\sqrt{n(n+2k-1)}|n-1,k\rangle,$$

where $n=0,1,\ldots,$ and $k(k-1)$ are the eigenvalues of the Casimir operator,

$$C_2=K_0^2-K_0-K_+K_-. \tag{34}$$

From the formal relation

$$\frac{E}{2\omega}=n+k, \tag{35}$$

it follows that

$$\varepsilon_{nk}=-\frac{\omega_{nk}^2}{8}=-\frac{\alpha^2}{2(n+k)^2}. \tag{36}$$

Here n takes the arbitrary integer non-negative values. One should figure out what values k takes.

The Casimir operators C_2 of $SU(1,1)$ (34) and C_{20} of $SU(1,1)$ generated by $H_0/2\omega$, $B_{20}^+/2\omega$, $B_{20}/2\omega$, are related as

$$C_2=C_{20}-l(l+1), \tag{37}$$

where

$$C_{20}=\frac{1}{4\omega^2}(\omega^2(a_s^+a_s+4)^2-2\omega^2(a_s^+a_s+4)-\omega^2(a_s^+)^2(a_t)^2)=-\frac{1}{8}(a_s^+a_t-a_t^+a_s)^2+2. \tag{38}$$

Taking into account $x_s\partial_t-x_t\partial_s=a_s^+a_t-a_t^+a_s$ it is equal,

$$C_{20}=-\frac{1}{8}(x_s\partial_t-x_t\partial_s)^2+2=\frac{1}{4}(-x^2\Delta_8+7x_s\partial_s+x_sx_t\partial_s\partial_t)+2. \tag{39}$$

The spatial symmetry of the Hamiltonian (23) is $SO(8)$. Its 28 generators are $F_{st}=i(x_s\partial_t-x_t\partial_s)$, $1\leqslant s<t\leqslant 8$. One can express C_{20} through the operator of the squared $SO(8)$ angular momentum F^2,

$$C_{20}=\frac{1}{8}(F_{st})^2+2=\frac{1}{4}\sum_{s<t}F_{st}F_{st}+2=\frac{1}{4}F^2+2. \tag{40}$$

The complete set of the wavefunctions of the $8D$ harmonic oscillator has been constructed[21] by means of the consideration of the subgroup chain $SO(8)\supset SO(4)\times SO(4)\supset U(1)\times U(1)\times U(1)\times U(1)$. The obtained wavefunctions $Y^j_{j_1m_{11}m_{12}j_2m_{21}m_{22}}$ are the simultaneous eigenfunctions of the mutually commuting operators F^2, $\mathbf{I}^2=\mathbf{I}_1^2=\mathbf{I}_2^2$, $\mathbf{N}^2=\mathbf{N}_1^2=\mathbf{N}_2^2$, I_{1_3},I_{2_3}, N_{1_3},N_{2_3} with eigenvalues

$$\begin{gathered}F^2Y^f=f(f+6)Y^f,\quad \mathbf{I}^2Y^f=j_1(j_1+1)Y^f,\\ \mathbf{N}^2Y^f=j_2(j_2+1)Y^f,\quad I_{1_3}Y^f=m_{11}Y^f,\\ I_{2_3}Y^f=m_{12}Y^f,\quad N_{1_3}Y^f=m_{21}Y^f,\quad N_{2_3}Y^f=m_{22}Y^f,\end{gathered} \tag{41}$$

where

$$0\leqslant f\leqslant N,\ N \text{ even},\ f \text{ even},$$

$$1\leqslant f\leqslant N,\ N \text{ odd},\ f \text{ odd};$$

$$0\leqslant j_1+j_2\leqslant f/2,\ f \text{ even},\ j_1+j_2 \text{ integer},$$

$$1/2 \leqslant j_1 + j_2 \leqslant f/2, \quad f \text{ odd}, \quad j_1 + j_2 \quad \text{half-integer};$$

$$-j_1 \leqslant m_{11}, m_{12} \leqslant j_1,$$

$$-j_2 \leqslant m_{21}, m_{22} \leqslant j_2,$$

and N is the oscillator's occupation number: $E_N = \omega(N+4)$, $N = 0,1,2,\ldots$.

Comparing the explicit form of the operators $\hat{\mathbf{X}}$ (4) and $\mathbf{I}_1$, $\mathbf{I}_2$, $\mathbf{N}_1$, $\mathbf{N}_2$,

$$I_{1_a} = \frac{i}{2}\left(-u_a \frac{\partial}{\partial u_0} + u_0 \frac{\partial}{\partial u_a} - \varepsilon_{abc} u_b \frac{\partial}{\partial u_c} \right),$$

$$I_{2_a} = \frac{i}{2}\left(-u_a \frac{\partial}{\partial u_0} + u_0 \frac{\partial}{\partial u_a} + \varepsilon_{abc} u_b \frac{\partial}{\partial u_c} \right),$$

$$N_{1_a} = \frac{i}{2}\left(-v_a \frac{\partial}{\partial v_0} + v_0 \frac{\partial}{\partial v_a} - \varepsilon_{abc} v_b \frac{\partial}{\partial v_c} \right),$$

$$N_{2_a} = \frac{i}{2}\left(-v_a \frac{\partial}{\partial v_0} + v_0 \frac{\partial}{\partial v_a} + \varepsilon_{abc} v_b \frac{\partial}{\partial v_c} \right),$$

we deduce that $\hat{\mathbf{X}} = \mathbf{I}_1 + \mathbf{N}_1$.

We recall that there exist the constraint (13) which in this context can be written as

$$\hat{\mathbf{X}}^2 Y^f = l(l+1) Y^f. \tag{42}$$

According to the angular momentum addition rules $l = j_1 - j_2, j_1 - j_2 + 1, \ldots, j_1 + j_2$ (we put $j_1 \geqslant j_2$ for certainty), i.e., l takes values which depend on j_1 and j_2. We shall rearrange the scheme (65) in order to make l the free index, i.e., taking the arbitrary integer and half-integer values: $l = 0,1/2,1,\ldots$.

Let us define $j = f/2$ and put $l = q - p$, where $q = j_1 + j_2$, $p = 0,1,\ldots,2j_2$. From the comment to (41) it follows that $j = q, q+1, \ldots = q + p'$, where $p' = 0,1,2,\ldots$. Fixing l we find $j = l + (p + p')$, where $p'' \equiv p + p' = 0,1,2,\ldots$. At fixed j, one has $N = 2j, 2j+1, \ldots$. It is natural to define the free quantum number $n = N/2 - j = 0,1,2,\ldots$.

From (37), (40) and (41) it follows that the relation

$$k(k-1) = j(j+3) + 2 - l(l+1), \tag{43}$$

which allows us to express k through j,

$$k = 1/2 + \sqrt{-l(l+1) + j(j+3) + 9/4}. \tag{44}$$

Substituting (44) into (36), we obtain the energy spectrum for the $5D$ Kepler problem on the background of the $SU(2)$ instanton,

$$\varepsilon_{nk} \to \varepsilon_{nj} = -\frac{\alpha^2}{2(n + 1/2 + \sqrt{-l(l+1) + j(j+3) + 9/4})^2}. \tag{45}$$

It exactly coincides with (26), but now we are convinced that

$$j = l, l+1, \ldots .$$

In the particular case $l = 0$,

$$\varepsilon_{nj} = -\frac{\alpha^2}{2(n+j+2)^2}, \quad n=0,1,2,\ldots, \quad j=0,1,2,\ldots. \tag{46}$$

Taking into account the relation between n,j and N, one can conclude that (46) is in full correspondence with (19) considered at $l=0$ as well.

In conclusion, we note that the Hurwitz transformation and related topics may be useful in some nuclear models (see the references in Ref. 20).

Isolated versus nonisolated periodic orbits in variants of the two-dimensional square and circular billiards

R. W. Robinett
Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802

(Received 20 July 1998; accepted for publication 5 October 1998)

Square and circular infinite wells are among the simplest two-dimensional potentials which can completely solved in both classical and quantum mechanics. Using the methods of periodic orbit theory, we study several variants of these planar billiard systems which admit both singular isolated and continuous classes of nonisolated periodic orbits. (In this context, isolated orbits are defined as those which are *not* members of a continuous family of paths whose orbits are all of the same length.) Examples include (i) various ''folded'' versions of the standard infinite wells (i.e., potentials whose geometrical shapes or ''footprints'' can be obtained by repeated folding of the basic square and circular shapes) and (ii) a square well with an infinite-strength repulsive δ-function ''core,'' which is a special case of a Sinai billiard. In each variant case considered, new isolated orbits are introduced and their connections to the changes in the quantum mechanical energy spectrum are explored. Finally, we also speculate about the connections between the periodic orbit structure of supersymmetric partner potentials, using the two-dimensional square well and it superpartner potential as a specific example. © *1999 American Institute of Physics.* [S0022-2488(99)03101-1]

I. INTRODUCTION

Many of the physical principles and mathematical tools necessary to understand quantum mechanics are first approached through a variety of familiar one-dimensional examples, including problems involving infinite potential wells. The extension to two-dimensional (2D) systems, such as square and circular infinite wells, allows for the study of new features such as degeneracy of energy levels (accidental or otherwise) as well as providing some of the simplest systems which exhibit both classical and quantum mechanical chaos.

It is also in such two-dimensional systems that several novel methods of analysis become nontrivially applicable, with examples including the study of energy-level statistics[1] and periodic orbit (PO) theory.[2] In this report, we study how the second method, namely periodic orbit theory, can be applied to a variety of variants of the simplest square and circular well geometries and our main focus will be on the relationship between the symmetries of the potential well system (geometrical and otherwise), the structure of the allowed energy eigenvalue space, and their relationships to the presence of isolated periodic orbits, that is, orbits which are *not* part of a continuous family of paths, all of which are characterized by identical path lengths.

The infinite well potentials upon which we will first focus our attention are the familiar square and circular wells,[3] as well as several variants thereon which can be constructed by ''folding'' the basic geometrical footprints in obviously symmetrical ways. Specifically we will derive results for rectangular (2×1 aspect ratio) wells (which do not have new isolated orbits) and triangular (isosceles) wells (which do!), both of which can be obtained from the square well by folding along horizontal (vertical) or diagonal axes respectively, as well as the half- and quarter-circular wells obtained by repeated foldings of the circle along an axis of symmetry. We concentrate on these examples for several reasons:

(i) Because of the high degree of symmetry involved in all these cases, there will be simple connections between both the energy eigenvalues of the folded wells and their more standard precursors, as well as for the classes of allowed periodic orbits in these geometries. As we will see, the way in which the energy eigenvalue spectrum and the periodic orbits are changed are remarkably similar for the ''half'' circular well and the triangular folding of the square billiard.

(ii) Folded versions of the basic well shapes will have a reduced amount of degeneracy compared to their original counterparts and this will allow us to study the effects that such degeneracies have on the appearance of new features corresponding to isolated periodic orbits.

(iii) The use of square and circular well geometries ensures that, due to the infinite number of bound state energies, one can readily obtain a large number of energy levels to increase the statistical sample in any numerical analysis. In addition, these simple geometries allow one to easily calculate the energy levels using standard mathematical techniques. More complex geometries, such as stadium-shaped billiards[4] or even elliptical wells,[5,6] require more sophisticated mathematical methods (or even experimental[7] techniques) in order to evaluate the energy eigenvalues.

In addition to these folded-wells, we will also consider a 2D square well with an infinite-strength repulsive δ-function ''core'' placed at the center of the well which will be seen to also induce new isolated periodic orbits in an even more dramatic fashion. For this case, which is a limiting case of the Sinai billiard,[8] we find that an infinite number of isolated new periodic orbits are generated, with a correspondingly more dramatic change in the energy eigenvalue spectrum.

Finally, we will speculate on the connections between the periodic orbit structure of systems whose potential energy functions are related by supersymmetric quantum mechanics. Because of the high degree of correlation between the energy eigenvalue spectra of two systems whose potentials are related by supersymmetry, we expect similarly close connections between the allowed periodic orbits in the classical theory. This somewhat obvious, but nonetheless interesting question, deserves to be examined more fully and formally, but as a starting point we will consider the superpartner potential of the 2D infinite square well and we will note that the relative importance of isolated versus nonisolated orbits may also play a significant role there as well.

In the next sections, we first briefly review the main ideas of periodic orbit theory and their applications in the circular and square well (Secs. II A and II B). We then apply these ideas to two folded versions of the square well, namely the triangular well (Sec. II C) and the rectangular well (Sec. II D). We discuss in some detail the square well plus repulsive δ-function ''core'' in Sec. II E, while we present a discussion of the relationship between quantum mechanical supersymmetry and periodic orbit theory in Sec. II F, with our conclusions appearing in Sec. II G. Finally, in the Appendix, we discuss some of the technical details required to evaluate the energy eigenvalue spectrum we use in Sec. II E, using a matrix mechanics formulation of quantum theory.

II. PERIODIC ORBIT THEORY

Of the possible approaches which can be used to explore the many relationships between the classical and quantum mechanical descriptions of nature, periodic orbit (PO) theory[2] is certainly one of the most compelling. An intimate connection between the quantum mechanical density of energy eigenvalues and the set of classical closed paths has been discussed by Gutzwiller and others[9–11] and is described by the formula

$$\sum_n \delta(E-E_n) \equiv \rho(E) = \rho_0(E) + \sum_{p=1}^{\infty} \sum_{\gamma} \rho_{(\gamma,p)} \cos\left[p\left(\frac{S_\gamma(E)}{\hbar} - \phi_\gamma \right) \right]. \tag{1}$$

In this expression, the E_n are the quantized energy eigenvalues in the bound state system which therefore define the energy level density, $\rho(E)$. This can be decomposed into a smooth part, $\rho_0(E)$, which has no information on the classical orbits, and an oscillatory piece depending on the

S_γ which are the values of the classical action corresponding to all possible closed paths (characterized by the label γ) of the classical motion; the integral values of $p=1,2,\ldots$ simply correspond to repetitions or recurrences of the basic ''primitive'' periodic orbits or closed trajectories. In this context, Eq. (1) has been used to make connections with the energy level structure of important physical systems, such as metallic clusters[12] or the hydrogen atom in large magnetic fields.[13]

This connection can be simplified even more in so-called billiard systems, two- and three-dimensional free particle systems confined in infinite well type potentials. There one finds for the quantity $\rho(L)$ [essentially the Fourier transform of $\rho(E)$]

$$\rho(L) \equiv \sum_{n=1}^{\infty} e^{ik_n L} = \rho_0(L) + \sum_{p=1}^{\infty} \sum_{\gamma} \rho_{(\gamma,p)}\, \delta(L - pL_\gamma). \tag{2}$$

(We note that Balian and Bloch[11] use a slightly different weighting in their study of the three-dimensional spherical billiard system.) In this relation, L_γ is the length of an individual primitive (or ''once-around'') periodic or closed orbit and $p=1,2,3,\ldots$ once again label the recurrences. [The $\rho_{(\gamma,\rho)}$ are constants which will not be relevant to our present discussion; the $\rho_0(L)$ term arises from the smooth $\rho_0(E)$ term and is highly peaked around $L=0$.] Thus, the Fourier transform of the quantum energy spectrum, defined via $\rho(L)$ using knowledge of the quantized k_n values, will show features at values of L corresponding to the lengths of classical periodic orbits (and their repetitions). [We recall that one of our interests is in exploring the relative importance of isolated versus nonisolated periodic orbits whose path lengths will both appear as features in the right hand side of Eq. (2).] Since we necessarily use a finite number of energy eigenvalues in a numerical evaluation of $\rho(L)$, we will actually evaluate

$$\rho(L, N_{\mathrm{TOT}}) \equiv \sum_{n=1}^{N_{\mathrm{TOT}}} e^{ik_n L} \tag{3}$$

and we will find it useful to examine the scaling properties of $\rho(L,N_{\mathrm{TOT}})$, as a function of N_{TOT}, for various obvious features corresponding to both isolated and nonisolated orbits.

The analysis of simple billiard systems such as 2D square[3] and rectangular[14] wells as well as 2D circular wells[3] rely heavily on geometrical ideas and symmetry principles to visualize both the patterns of energy eigenvalues and periodic orbits. Using just such ideas, it was possible in Ref. 3 to extend the PO theory analysis of the circular well to simple variants thereof, such as the half- and quarter-well cases. (A much more complete analysis of the general case of an ''angular slice'' well, characterized by an infinite well with a circular arc boundary and walls separated by an arbitrary angle Θ was performed in Ref. 14; the half- and quarter-well cases are then special cases of this more general result corresponding to $\Theta=\pi$ and $\Theta=\pi/2$, respectively.) For both completeness sake, as well as for use in later discussions, we very briefly review these results for various versions of the circular well before proceeding to variants on the square well.

A. Circular and half-circular well

The periodic orbits or closed trajectories in a circular infinite well (of radius R) or billiard can be characterized by two integers, p (which counts the number of ''hits'' on the inner wall) and q (which counts the number of net revolutions made by the particle before it returns to the same location in phase space) and the two are related by the condition $p\Theta = q(2\pi)$, where Θ is the angle subtended by the chord length between bounces. The total path length for such a primitive or once-around closed orbit is

$$L(p,q) = 2pR \sin\left(\frac{\pi q}{p}\right) \tag{4}$$

and integral multiples of this, corresponding to multiple repetitions of the basic trajectory, are also allowed. Each set of (p,q) actually corresponds to a continuous set of closed paths, each equivalent to each other in length, and only differing in the initial angle. These continuous families of trajectories are our first example of sets of nonisolated orbits.

The corresponding quantum mechanical system has an energy spectrum given by

$$E_{(m,n_r)}=\frac{\hbar^2[a_{(m,n_r)}]^2}{2\mu R^2}=\left(\frac{\hbar^2}{2\mu}\right)k_n^2, \tag{5}$$

where we denote the particle mass by μ in order to avoid confusion with the angular momentum quantum number, m. The $a_{(m,n_r)}$ denote the n_rth zero of the $|m|$th regular cylindrical Bessel function and the orbital angular momentum is given by $L_z=m\hbar$. The angular wave functions are given by $\Theta_m(\theta)\propto\cos(m\theta)$ and $\sin(\theta)$ so that for each value of $m>0$ there is a twofold degeneracy (corresponding to the indistinguishability of clockwise versus counterclockwise motion), while for $m=0$ only one copy of the constant cos(0) solutions is present.

Using the values of the $a_{(m,n_r)}$, the Fourier transform defined by Eq. (2) is shown in Fig. 1 for the full well case where many of the path lengths described by Eq. (4) are clearly visible. The large feature at $L=0$ corresponds to the Fourier transform of the smooth $\rho_0(E)$ piece, while the dashed vertical line shows the limiting value of $(p,q)\rightarrow(\infty,1)$ where $L(\infty,1)=2\pi R$; evaluating $\rho(L)$ with a finite number of eigenvalues implies limited resolution near such locations where the path-length features are increasingly closely spaced.

For the half-circular well, defined by folding the circular well along a diameter, simple geometrical constructions guarantee that any periodic orbit in the full well will continue to exist as a closed trajectory in the half-well, due to the mirroring effect of the new infinite wall along the diameter. The only new feature to be expected is an isolated ''back-and-forth'' orbit through the center of the well, perpendicular to the diametrical infinite wall; this is our first example of an isolated periodic orbit. This singular new feature will have $L/R=2.0$ (and recurrences) in addition

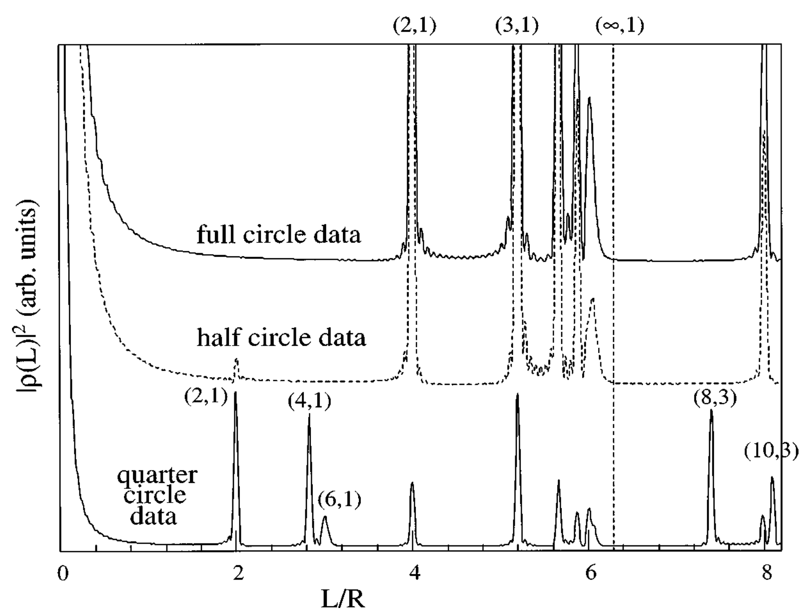

FIG. 1. Fourier transform of the energy level density $|\rho(L)|^2$ [defined by Eq. (3)] versus L/R for the circular well (top), the half-circular well (middle) and quarter-circular well (bottom) geometries. The lowest-lying 2000, 1500, and 860 energy levels have been used in each case, respectively. Note the emergence of a path length feature at $L/R=2.00$ corresponding to an isolated, ''back-and-forth'' orbit in the half-well case.

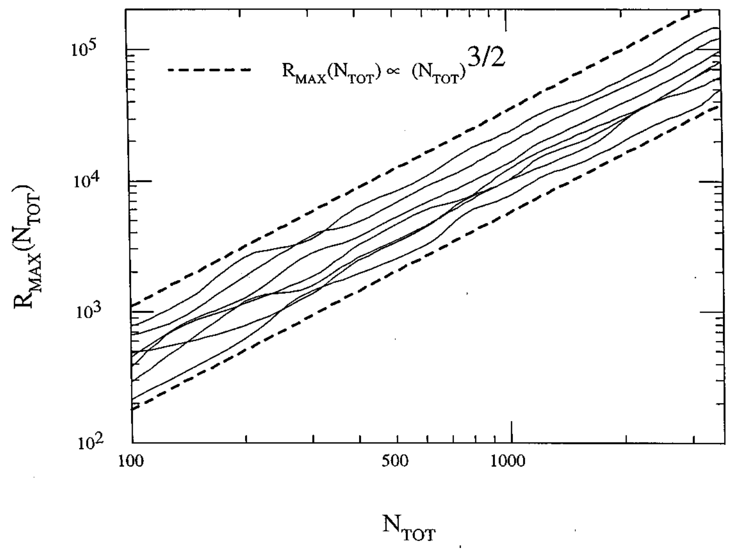

FIG. 2. Scaling behavior of $R_{MAX}(N_{TOT})$ [defined in Eq. (7)] for the first seven nonisolated orbit features as a function of N_{TOT} illustrating the power law behavior consistent with an exponent of $\alpha=3/2$.

to the continuous set of $(p,q)=(2,1)$ features with $L/R=4.0$ (and recurrences) and would be expected to show up, if at all, in the $\rho(L)$ plots as a much smaller ''bump.'' To confirm this, we require knowledge of the quantum energy spectrum in the half-well which we can easily obtain from the solutions of the full well. The $\Theta_m(\theta)\propto\sin(m\theta)$ solutions will remain solutions of the half-well as they satisfy the new boundary condition of vanishing along the diametrical wall. Thus, the energy spectrum consists of one-half of the $m>0$ spectrum for the full well, with no contributions from the nondegenerate $m=0$ eigenstates. The large amount of degeneracy present in the full well is completely lost in the half-well as there are no ''accidental'' degeneracies in this system as there are in the square well.[16]

The resulting $\rho(L)$ versus L plot for the half-well using this set of eigenvalues is also shown in Fig. 1 (middle data) and does indeed show ''spikes'' at the same locations as in the full circular well, plus the expected additional small feature at $L/R=2.0$; recurrences of this new feature at $L/R=4.0$ and 6.0 are hidden by more standard $(p,q)=(2,1)$ and (6,1) spikes.

In order to examine any differences between the features corresponding to isolated orbits (such as the $L/R=2.0$ feature) and nonisolated paths, we also explore the dependence of all the observed features in the $\rho(L)$ spectrum as the number of energy eigenvalues N_{TOT} used in the evaluation of Eq. (3) is increased. We evaluate the ''peak height'' for the first seven recognizable features corresponding to obvious nonisolated paths for increasing values of N_{TOT}, namely,

$$R_{MAX}(N_{TOT})\equiv|\rho(L(p,q),N_{TOT})|^2 \tag{6}$$

and we plot the results in Fig. 2. We note that the behavior of $R_{MAX}(N_{TOT})$ for these features is consistent with a power law scaling of the form

$$R_{MAX}(N_{TOT})\sim A(N_{TOT})^{\alpha} \tag{7}$$

with $\alpha=3/2$ so that the magnitude of these path length features certainly increases with N_{TOT}. In order to compare this dependence with that for the isolated orbits as well as the ''background,'' we evaluate $|\rho(L,N_{TOT})|^2$ for several values of N_{TOT} (namely, 100, 200, 400, 800, 1600, and 3200) for each value of L in the range $0.0\leqslant L/R\leqslant 14.0$, fit each data set to a power law of the form in Eq. (7), and plot the resulting fitted values of α versus L/R in Fig. 3. Directly below each such plot, we also show $|\rho(L)|^2$ itself using a larger ($N_{TOT}=3200$) data set than in Fig. 1 for the half-well for comparison. We immediately note several features:

(i) Even with the increased statistics used, obvious features corresponding to isolated back-and-forth orbits with $L/R=2.0$ and even 10.0 are still obvious (indicated by bold arrows). Contributions of these orbits to features at $L/R=4.0$, 8.0, and 12.0 are, as mentioned above, hidden under the larger peaks corresponding to $L(p,q)$ features with $(p,q)=(2,1)$ and $(6,1)$. It is sometimes possible, however, to separate the otherwise ''degenerate'' contributions from various types of periodic orbits in the circular well by using only appropriate subsets of energy eigenvalues, corresponding in obvious ways to the appropriate classical orbits[15] and that same observation can be used in this case to observe separately the contributions of the isolated orbits.

(ii) The effective value of α drops rapidly from its $L=0$ value of $\alpha=2$ to something consistent with unity or smaller, except for isolated features. [Recall that the definition in Eq. (3) implies that $\rho(L=0,N_{\mathrm{TOT}})\equiv N^2$.] This means that the scaling behavior of the (uninteresting) $\rho_0(L)$ term is relatively unimportant for $L/R\gtrsim 0.1$.

(iii) As noted above, peaks in the α versus L/R plot with values of $\alpha\approx 1.5$ are obvious for each resolvable, nonisolated path length feature in the $\rho(L)$ spectrum, implying that the standard $L(p,q)$ features in the $\rho(L,N_{\mathrm{TOT}})$ spectrum will grow in relative importance in the $N_{\mathrm{TOT}}\to\infty$ limit, just as expected.

(iv) Small features in the α versus L/R spectrum near $L/R=2.0$ and 10.0 indicate that the scaling properties of these features are different from the ''background'' values nearby; in

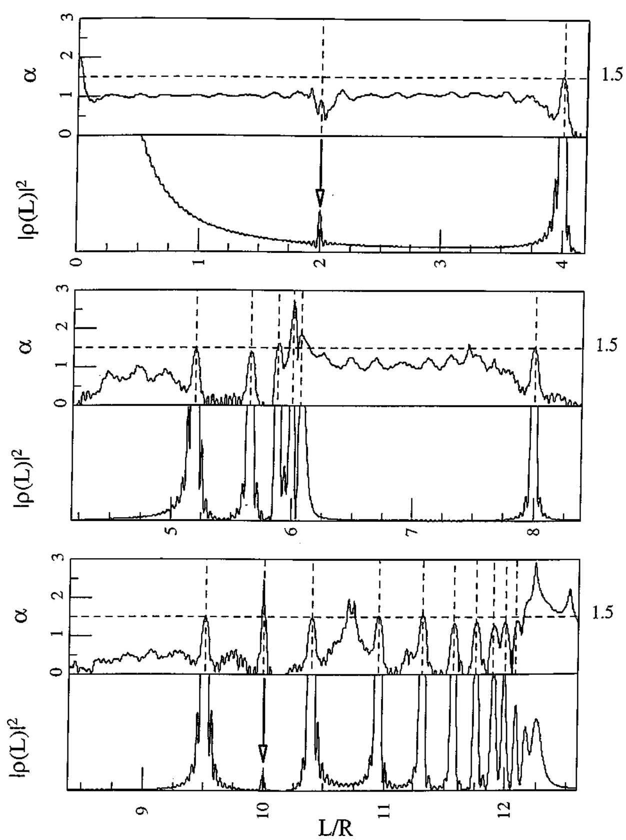

FIG. 3. Fitted values of the power law exponent α [from Eq. (7)] versus L/R for the half-circular well (top plots) with corresponding values of $|\rho(L)|^2$ directly below. A total of $N_{\mathrm{TOT}}=3200$ eigenvalues was used in the numerical evaluation of $\rho(L)$ in this case compared to $N_{\mathrm{TOT}}=1500$ in Fig. 1. Only standard nonisolated path length features given by the $L(p,q)$ in Eq. (4) (indicated by vertical dashed lines) and a new isolated back-and-forth orbit feature at $L/R=2.00,10.00$ are visible. The horizontal dashed line indicates the value of $\alpha=3/2$.

the case of the $L/R=2.0$ feature, the value of $\alpha\approx 1$ is separated from the nearby values, while the $L/R=10.0$ value of $\alpha\approx 2.5$ indicates that the feature will continue to remain significant as $N_{\mathrm{TOT}}\to\infty$.

(v) No other new features (due, for example, to diffraction effects) are obvious in the $\rho(L)$ spectrum in the region explored, except those due to isolated orbits introduced by the folding.

Finally, a second folding, resulting in a quarter-well yields qualitatively new path length features. Orbits in the half-well corresponding to values of p which are *even* can be mirrored in the quarter-well with resulting path lengths which are half as long as in the precursor well, while the features for *odd* values of q remain unchanged in length. (This geometry is not so different from the familiar optics problem of counting the number of images visible when an object is placed between two pivoted mirrors with an opening angle Θ or other similarly kaleidoscopic arrangements of mirrors.) The quantized energy eigenvalues required to evaluate $\rho(L)$ for this geometry can be obtained from those of the standard circular well by choosing one copy of the $m>0$ eigenvalues for *even* values of m as the corresponding eigenfunctions will then satisfy the boundary conditions along both the x- and y-axes. The Fourier transform $\rho(L)$ using these values is also shown in Fig. 1 and shows the expected pattern. Continued foldings into quarter-wells and beyond can be analyzed in a very general manner and the results have been extensively discussed and visualized in Ref. 14.

B. Square well

The general pattern of allowed orbits in a two-dimensional square well will consist of a ''plaid'' pattern of line segments traced by the particles trajectory. This pattern will come to increasingly ''paint'' the square area of the well increasingly uniformly (for the visualization of such orbits, see Ref. 3) unless certain conditions are satisfied which lead to closed orbits. In order for trajectories to eventually close on themselves, we require that

$$\frac{v_y}{v_x}=\frac{n_y}{n_x}, \tag{8}$$

where v_x, v_y are the magnitudes of the classical velocity components in the x,y directions and $n_x, n_y=0,1,2,\ldots$ take on integer values. This condition is then independent of the total energy of the particle, depending only on geometry as it should for a billiard system of this type. The integers (n_x, n_y) give the number of bounces experienced by the particle (during a single primitive periodic orbit) from the vertical (horizontal) walls as $2n_x$ $(2n_y)$. As with the circular well, each label corresponds to a continuous family of paths, of identical path length, differing only by initial position; once again this is a continuous set of nonisolated periodic orbits, one family for each

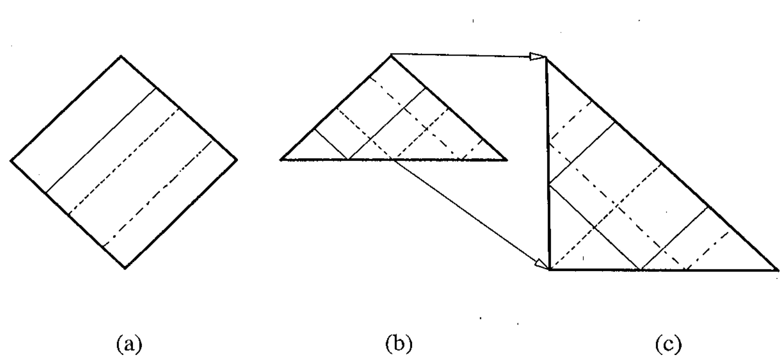

FIG. 4. Typical periodic orbits for the square well (a), the once-folded triangular well (b), and the twice-folded triangular well (c) corresponding to the integer labels $(n_x, n_y)=(1,0)/(0,1)$.

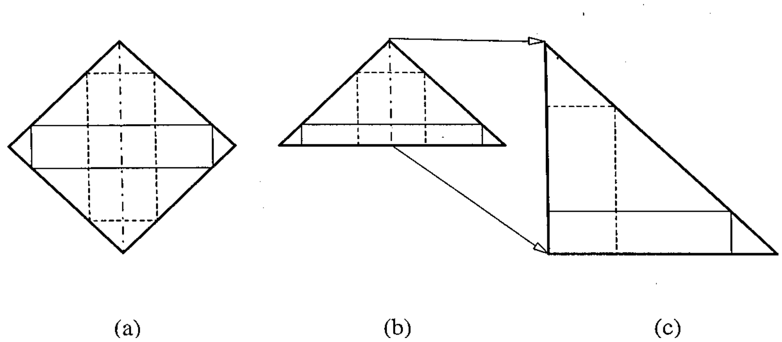

FIG. 5. Same as Fig. 4, but for $(n_x,n_y)=(1,1)$. For case (b), note the appearance of an isolated orbit of length $L/a=\sqrt{2}$ (dotted-dashed line) in addition to the continuous family of nonisolated paths with $L/a=2\sqrt{2}$ (exemplified by the solid and dashed paths.)

(n_x,n_y) label. A few of the simplest such patterns are shown in Figs. 4(a), 5(a), and 6(a). The corresponding primitive or once-around path lengths are then given by a simple geometrical construction to be

$$L(n_x,n_y;a)=2a\sqrt{n_x^2+n_y^2}. \tag{9}$$

A simple extension of this system is to a rectangular well (of dimensions $a_x\times a_y$) where the classification of closed orbits can still be described by an (n_x,n_y) pair, but where the path lengths are now given by

$$L(n_x,n_y;a_x,a_y)=2\sqrt{(n_xa_x)^2+(n_ya_y)^2}. \tag{10}$$

The quantum mechanical case is equally simple to analyze with bound state energies (with wave numbers k_n) given by

$$E_{(i,j)}=\frac{\hbar^2\pi^2}{2ma^2}(i^2+j^2)=\frac{\hbar^2k_n^2}{2m} \qquad \text{or} \qquad k_n=\frac{\pi}{a}\sqrt{i^2+j^2} \tag{11}$$

and wave functions

$$\psi_{(i,j)}(x,y)=\left[\sqrt{\frac{2}{a}}\sin\left(\frac{i\pi x}{a}\right)\right]\left[\sqrt{\frac{2}{a}}\sin\left(\frac{j\pi y}{a}\right)\right], \tag{12}$$

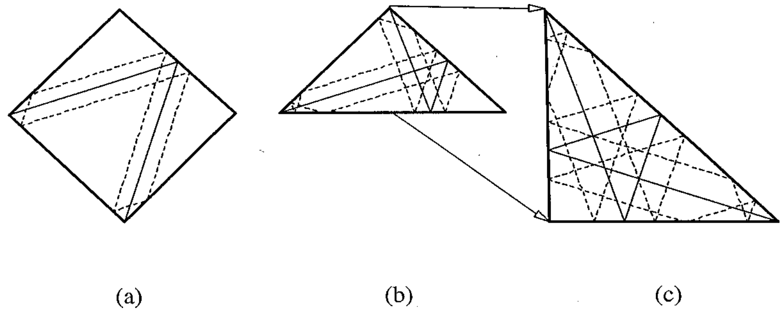

FIG. 6. Same as Fig. 4, but for $(n_x,n_y)=(2,1)/(2,1)$.

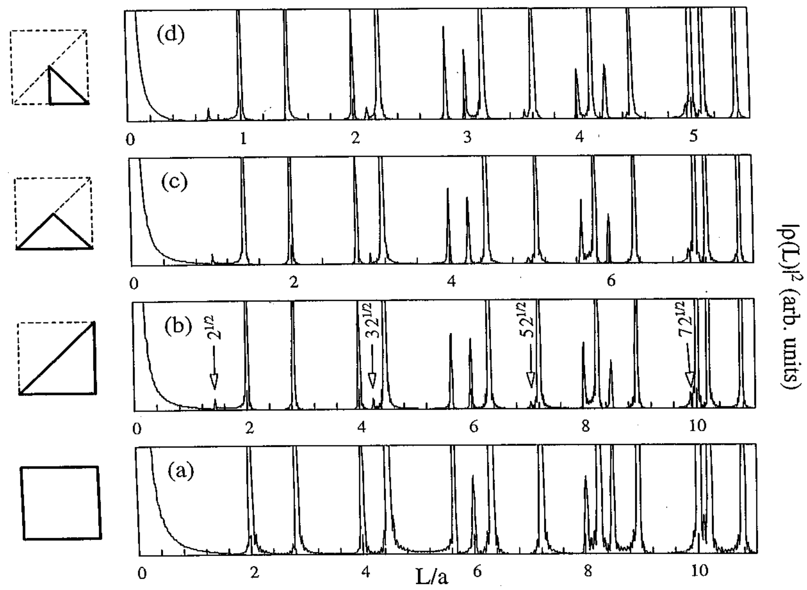

FIG. 7. Fourier transform of the energy level density, $|\rho(L)|^2$ [defined by Eq. (3)] versus L/a for the full square well (a), the once-folded triangular well (b), the twice-folded triangular well (c), and the three-times-folded triangular well (d). Note that the path length spectrum of the once-folded well is basically identical to the square well except for the appearance of new small features at $L/a=n\sqrt{2}$ where n is odd, corresponding to the isolated back-and-forth orbits shown in Fig. 5(b). Cases (c) and (d) are shown with the horizontal axis scaled down by factors of $\sqrt{2}$ and 2, respectively, to show that the same structures are visible for all three isosceles triangles, but with L scaled appropriately.

where $i,j=1,2,3,\ldots$. For future reference we note that odd (even) values of i,j correspond to wave functions which are even (odd) with respect to a parity operation about horizontal or vertical lines through the center of the square. One of the most important features of this spectrum is the large degree of degeneracy, since $E_{(i,j)}=E_{(j,i)}$, and a symmetry group analysis of this double degeneracy has recently been presented in Ref. 16.

A standard periodic orbit theory analysis applied to such a billiard system then proceeds by taking a large number of low-lying energy eigenvalues (in this case we use $N_{\mathrm{TOT}}=4000$) and evaluating Eq. (3) using the corresponding k_n in Eq. (11). The resulting plot of $|\rho(L)|^2$ versus L/a is shown (at the bottom) in Fig. 7, with the (a) label corresponding to the initial square well. All of the expected features at values of $L/a=\sqrt{n_x^2+n_y^2}$ (and recurrences) are observed in the region shown.

C. Triangular foldings of the square well

The basic square well geometry can be folded in a variety of ways which result in soluble quantum mechanical and classical systems and the ''triangular'' foldings illustrated in Figs. 4, 5 and 6 are closest in spirit to the half-circular well case considered above. If we fold the square well footprint along a diagonal, we obtain an isosceles triangle and the allowed set of closed orbits in the full well is reproduced in this triangular half-well; this is shown in parts (a) and (b) of those figures where we consider cases corresponding to the $(n_x,n_y)=(1,0)/(0,1)$ (Fig. 4), (1,1) (Fig. 5), and (1,2)/(2,1) (Fig. 6) cases, respectively. In each case shown there, an allowed orbit in the square well is supported by the triangular well with the identical overall path length. The only new feature arises from a special isolated orbit of the type shown in Fig. 5(b) (as the vertical dot-dash line) for the (1,1) case. This back-and-forth orbit is very similar to that seen in the half-circular well case and should give rise to a small feature at integral multiples of $L/a=\sqrt{2}$ and the *odd* multiples $(1,3,5,\ldots)$ of this feature will not be hidden under the recurrences of the more standard $(n_x,n_y)=(1,1)$ features at integral multiples of $L/a=2\sqrt{2}$.

Although it is seldom stressed in textbooks, the energy eigenvalues and eigenfunctions of the isosceles triangular well can be easily obtained from those of the square well. Taking for definiteness a square well defined over the intervals $x,y \in (0,a)$, we can form a triangular well by restricting the area further to satisfy $y \leqslant x$ with the $y = x$ line defining another infinite potential wall. While eigenfunctions of the type in Eq. (12) do not satisfy the necessary boundary conditions, appropriate linear combinations of pairs of degenerate solutions, defined by

$$\psi^{(b)}_{(i,j)}(x,y) \;\propto\; \psi_{(i,j)}(x,y) - \psi_{(j,i)}(x,y) \tag{13}$$

(with $i > j$ and $x \geqslant y$), do vanish on all infinite wall boundaries and so are the appropriate wave functions. The corresponding energy eigenvalues are then given by Eq. (11), but with the restriction that $i > j$. In this way, a large amount of the degeneracy which is obvious in the square well is removed. (In fact, linear combinations of just this type have been recently used in discussions of the symmetry group for the square well potential.[16]) The ground state probability density in the triangular well [corresponding to $(i,j) = (2,1]$, as well as its ''precursor'' in the full well are shown in Fig. 8 (left column) as a contour plot; the wave function in the once-folded triangular well (lower left) is more peaked (note the contours!), since in order to be properly normalized in the smaller well it must have a larger magnitude.

In this regard, the energy spectrum of the triangular folding is obtained in a very similar manner to the half-circular well considered above. The nondegenerate states ($m = 0$ in the circular case, $i = j$ in the square case) are not used and one-half of the remaining degenerate eigenvalues ($m \neq 0$ in the circular case, $i \neq j$ in the square case) are retained. Because of this, much of the original degeneracy of the system is removed. Some of the original accidental degeneracies[16] are also eliminated, such as those degenerate states labeled by $(i,j) = (1,7)/(5,5)$ or $(7,17)/(13,13)$,

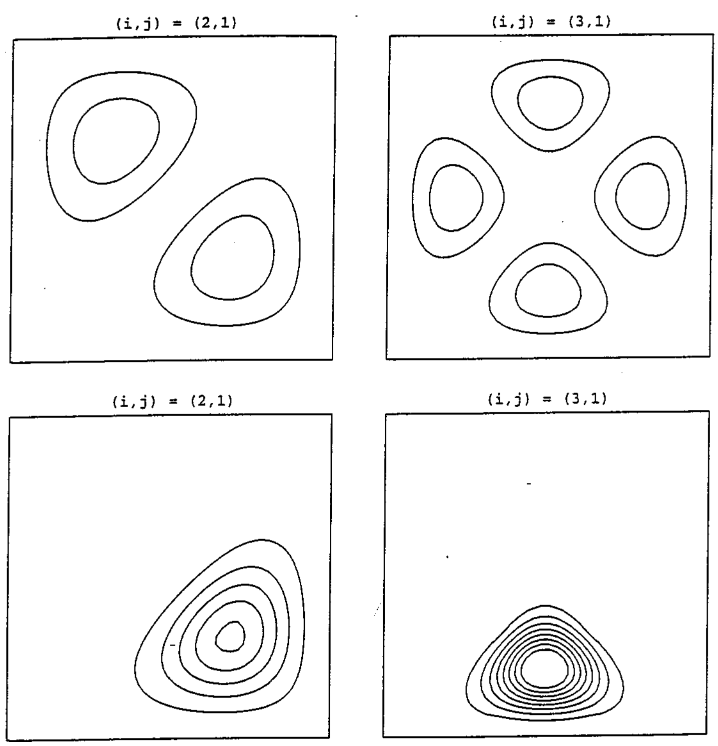

FIG. 8. Contour plots of the full square well probability densities from Eq. (13) for $(i,j) = (2,1)$ (upper left) and (3,1) (upper right). The corresponding ground state wave functions for the once-folded triangular well (lower left) and twice-folded triangular well (lower right) are also shown.

TABLE I. Energy eigenvalues, $E_n = E_{(i,j)} = (\hbar^2\pi^2/2ma^2)(i^2+j^2)$, for the triangular wells resulting from the first (b), second (c), and third (d) triangular foldings of the square well, scaled to the value of $E_0 = \hbar^2\pi^2/2ma^2$. The values of (i,j) for the second-folded triangular well are given by $(i+j, i-j)$ which explains why $E_n^{(c)} = 2E_n^{(b)}$.

First triangle		Second triangle		Third triangle	
(i,j) $i>j$	$E_n^{(b)}/E_0$	(i,j) $i>j$ and either both even or both odd	$E_n^{(c)}/E_0$	(i,j) $i>j$ and both even	$E_n^{(d)}/E_0$
(2,1)	5	(3,1)	10	(4,2)	20
(3,1)	10	(4,2)	20	(6,2)	40
(3,2)	13	(5,1)	26	(6,4)	52
(4,1)	17	(5,3)	34	(8,2)	68
(4,2)	20	(6,2)	40	(8,4)	80
(4,3)	25	(7,1)	50	(8,6)	100
(5,1)	26	(6,2)	52	(10,2)	104
(5,2)	29	(7,3)	58	(10,4)	116
(5,3)	34	(8,2)	68	(10,6)	136
(6,1)	37	(7,5)	74	(12,2)	148

because (i,i) states are no longer present. However, the majority of such accidental degeneracies are still present, for example, those of the form (4,7)/(1,8), (2,9)/(6,7), and (5,20)/(8,19)/13/16). (We note that a large fraction of such accidental degeneracies are, in fact, lifted in the square well variant considered in Sec. II E as discussed in detail in the Appendix.)

Given these simple connections between the energy eigenvalues for the full square well and its triangular folding, it is then perhaps not surprising that when we evaluate $\rho(L)$ using this energy spectrum, we obtain the result shown in Fig. 7(b) which shows all of the same path length features as the full square well, but with additional small features obvious at $L/a = \sqrt{2}, 3\sqrt{2}, 5\sqrt{2}$; the next feature at $L/a = 7\sqrt{2} \approx 9.9$ is almost hidden under the more standard 5(1,0) and 1(3,4) peaks which fall at $L/a = 10.0$.

Further foldings of the isosceles triangular well along a perpendicular bisector result in congruent isosceles triangular footprints, but with an area of half the size and edges a factor $1/\sqrt{2}$ as long. The closed paths allowed in the first-folded wells in Figs. 4(b), 5(b), and 6(b), upon a second folding, are mirrored into periodic orbits in the smaller versions of the triangular wells, but corresponding to a different set of (n_x, n_y) labels. For example, in going from (b) to (c) in Figs. 4, 5, and 6, we find that the (n_x, n_y) labels correspond to $(1,0)/(0,1) \rightarrow (1,1)$, $(1,1) \rightarrow (1,0)/(0,1)$, and $(1,2)/(2,1) \rightarrow (3,1)/(1,3)$ respectively. Thus, the entire set of allowed orbits are indeed reproduced, with path length features reduced by a factor of $1/\sqrt{2}$.

The quantum mechanical eigenvalues in the ''second-folded'' triangular well can also be obtained from the first-folded triangular well by further restrictions in the allowed values of i,j using symmetry arguments. If one restricts the second-folded well to lie below the line $y = a - x$ (i.e., the other diagonal of the original square), then a subset of the states in Eq. (13) will still be solutions in the restricted well and also satisfy the necessary boundary conditions on the new infinite wall boundary. Specifically, those $i>j$ states with (i,j) either both even *or* both odd will have a nodal line along $y = a - x$ and comprise the allowed solution space. We compile, in Table I, the lowest-lying energy eigenvalues with the corresponding (i,j) labels for the first-folded (b) and second-folded (c) triangular wells. To visualize the new ground state wave function in the second-folded well, we show in Fig. 8 (right column) the $(i,j) = (3,1)$ state, both in the full precursor well (upper right) and in the second-folded triangular well (lower right). Note that the ground state wave function is even more highly peaked than in the larger triangular well due to normalization constraints, but its shape is identical to that in the first-folded triangular case.

From Table I, we see that the pattern of allowed i,j values in the second-folded well is given by $(i+j, i-j)$ in which case the energies are related to those in the first-folded well by

$$E^{(c)}_{(i,j)}=\frac{\hbar^2\pi^2}{2ma^2}[(i+j)^2+(i-j)^2]=2\left[\frac{\hbar^2\pi^2}{2ma^2}(i^2+j^2)\right]=2E^{(b)}_{(i,j)}. \tag{14}$$

[The combination $(i+j,i-j)$ which arises in this case is easily seen, either via Fig. 8 or using analytic constructions, to be connected to the fact that the wave functions in the once-folded well can be related to those in the twice-folded well by rotations through various multiples of 45° and subsequent scaling of lengths by factors of $1/\sqrt{2}$.] So, since the energy spectrum in the second-folded well consists of values which are exactly twice those in the once-folded well, i.e., $\{E_n^{(c)}\}=\{2E_n^{(b)}\}$, we also know that the allowed wave numbers satisfy $\{k_n^{(c)}\}=\{\sqrt{2}k_n^{(b)}\}$. This simple scaling result implies that the Fourier transform defining $\rho(L)$ in case (c) will then have the identical spectral features in case (b), simply scaled down in L by the appropriate factor of $1/\sqrt{2}$. We illustrate this in Fig. 7 where the horizontal $\rho(L)$ ''spectrum'' for part (c) is identical to that for part (b) when plotted with the appropriately scaled value of L/a.

Finally, additional foldings along axes of symmetry result in ever smaller isosceles triangular wells, with appropriately smaller path lengths and increasingly large energy eigenvalues. For example, the third-folding (not shown in Figs. 4, 5, or 6) will give path length features at half the original lengths. The energy eigenvalues which lead to this are obtained from the original well by further restricting the $E^{(b)}_{(i,j)}$ to (i,j) values which are *both* even and the resulting energy spectrum (see Table I once again) consists of values which are obviously 4 times the original, with twice the resulting k_n values and path length features at half the precursor values. Examples of such path length features are shown in Fig. 7(d).

We have also performed a scaling analysis of $\rho(L,N_{\text{TOT}})$ versus N_{TOT} similar to that for the half-circle as shown in Figs. 2 and 3, and we find very similar results, specifically, the scaling coefficient for the standard, nonisolated features is completely consistent with $\alpha=3/2$ for all of the path length features shown in Fig. 7.

D. Rectangular foldings of the square well

As another simple example of a folding of the square well, let us examine both the energy eigenvalue spectrum and the periodic orbit structure of the rectangular well of dimensions $a\times a/2$ obtained by restricting ourselves to the region of the initial square well defined by y

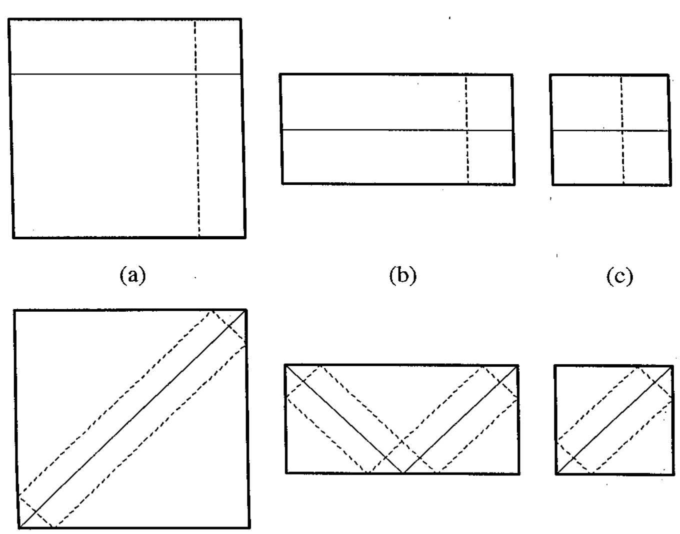

FIG. 9. Typical periodic orbits for the square well (a), the once-folded rectangular well (b), and the twice-folded square well of half the original size (c). The plots correspond to the integer labels $(n_x,n_y)=(1,0)$ (solid) and (0,1) (dashed) at the top, and to several versions of $(n_x,n_y)=(1,1)$ on the bottom.

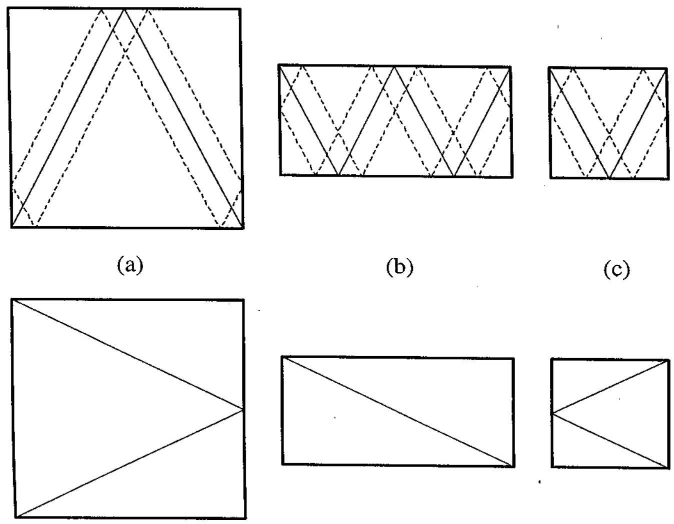

FIG. 10. Same as Fig. 9, but for $(n_x, n_y) = (1,2)$ (top) and (2,1) (bottom).

$\geqslant a/2$, i.e., the upper half. (We will find no isolated orbits in this ''folding,'' but we consider this case for completeness.) The wave functions in Eq. (12) are still solutions of the appropriate Schrödinger equation within the restricted well and those with even j values also satisfy the boundary condition that $\psi(x,y=a/2)=0$ on the new boundary. Thus, the appropriate energy eigenvalues are still given by Eq. (11), but with j restricted to be an even integer.

The corresponding path lengths, given by Eq. (10), can be written in the form

$$L_{(b)}(n_x,n_y)=2\sqrt{(n_x a)^2+n_y(a/2)^2}=\tfrac{1}{2}[2a\sqrt{(2n_x)^2+n_y^2}]=\tfrac{1}{2}L_{(a)}(2n_x,n_y;a). \tag{15}$$

The changes in path lengths for allowed orbits can also be visualized by folding over allowed trajectories in the square box as shown in Figs. 9 and 10. The corresponding spectrum of allowed path lengths, L, will then be somewhat similar to that of the square well, but with the following changes:

(i) For each path length feature in the full square well characterized by a value of (n_x, n_y), there will be a corresponding feature in the once-folded, rectangular well with half the path length, provided that n_x and n_y are not both odd.

This pattern can be confirmed by evaluating $\rho(L)$ using Eq. (2), but with the $N_{\mathrm{TOT}}=4000$ lowest eigenvalues given by Eq. (11), but where j is an even integer. The resulting plot for the rectangular well is shown in Fig. 11, directly above that for the square well, and with an appropriately scaled horizontal axis. One sees immediately that the resulting path length spectrum is as described above, similar to the square well result, scaled down by a factor of 2, but with the appropriate $(n_x, n_y) = (\mathrm{odd}, \mathrm{odd})$ peaks missing.

A subsequent second folding of the rectangular well into a square well of one-quarter the area of the original square is an obvious continuation of the pattern. The resulting possible path lengths can be obtained by folding or reflections as shown in Figs. 9(c) and 10(c) and are, of course, identical to the original well, but with path lengths given by

$$L_{(c)}(n_x,n_y)=2\sqrt{(n_x a/2)^2+(n_y a/2)^2}=\tfrac{1}{2}[2a\sqrt{n_x^2+n_y^2}]=\tfrac{1}{2}L_{(a)}(n_x,n_y), \tag{16}$$

i.e., simply scaled down by the appropriate factor of 2. The energy eigenvalues are given by Eq. (11), but in order to satisfy the boundary conditions along $y=a/2$ and $x=a/2$, we require that *both i and j* be even integers, so that $\tilde{i}=2i$, $\tilde{j}=2j$ which gives

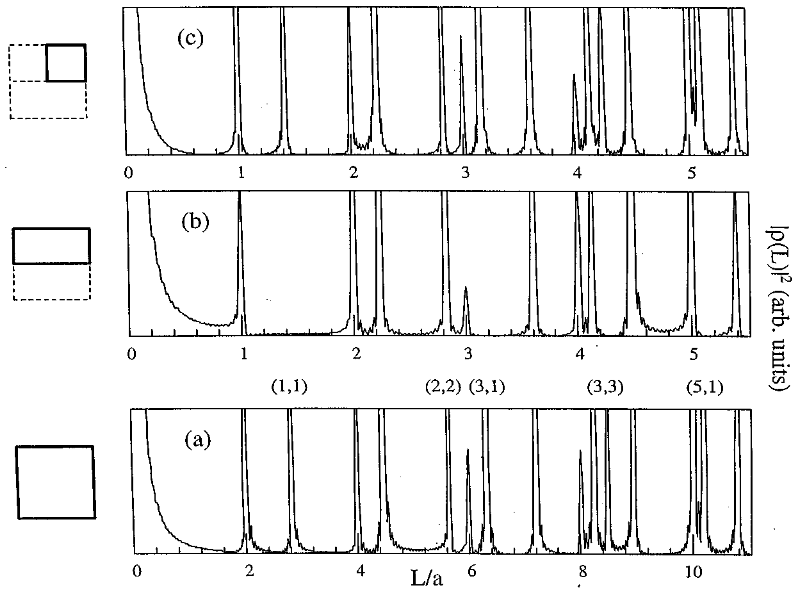

FIG. 11. Fourier transform of the energy level density, $|\rho(L)|^2$ [defined by Eq. (2)] versus L/a for the full square well (a), the once-folded rectangular well (b) and the twice-folded square well of half the original size (c). Note the different horizontal scales used in (b) and (c) compared to case (a). Labels corresponding to (n_x, n_y) both odd are shown.

$$\tilde{E}_{(\tilde{i},\tilde{j})}=\frac{\hbar^2\pi^2}{2ma^2}(\tilde{i}^2+\tilde{j}^2)=4\left[\frac{\hbar^2\pi^2}{2ma^2}(i^2+j^2)\right]=4E_{(i,j)} \tag{17}$$

so that the wave numbers required in Eq. (2) satisfy $\tilde{k}_n=2k_n$. This immediately implies that the $\rho(L)$ evaluated with this $\tilde{k}_n$ spectrum will have peaks at values of $\tilde{L}=L/2$ as expected. Additional foldings will continue to reproduce these patterns, but with 2×1 rectangles and squares of increasingly smaller dimensions. For example, after $2n$ foldings, the allowed energy eigenvalues in the smaller square well will, by symmetry considerations alone, be given by $\tilde{E}_{(\tilde{i},\tilde{j})}=(2n)^2E_{(i,j)}$ and wave numbers related by $\tilde{k}_n=(2n)k_n$ immediately implying square well path length features given by $\tilde{\rho}_{(2n)}(L)=\rho(L/2n)$.

E. Another variant of the square well

Other variants of the square well which also exhibit induced isolated periodic orbits are possible beyond those derived by foldings and the next such system we consider is the square well with an ''infinite-strength'' repulsive δ-function potential at the center. This variant is similar in spirit to the study of the annular circular well or circular disk considered in Ref. 17 with the radius of the inner annulus made vanishingly small. It can also be obtained by adding a repulsive potential of the form

$$V_{\mathrm{REP}}(x,y)=+\tilde{g}\,\delta(\mathbf{r}-\mathbf{r}_0), \tag{18}$$

where $\mathbf{r}_0$ defines the center of the square well and we then let $\tilde{g}\to\infty$.

The structure of the classical periodic orbits in this slightly modified system is clear. Any standard orbit of the type in Sec. II B will still be allowed, provided it misses the central obstruction. Exactly one isolated orbit for each value of (n_x, n_y) which *does* hit the center will also form a closed trajectory, but with half the path length. Thus, the path length spectrum exhibited in $\rho(L)$ should consist of the standard large spike features at values given by $L/a=2\sqrt{n_x^2+n_y^2}$ (and repetitions), but will also show much smaller features (similar in magnitude to the isolated path length features for special back-and-forth orbits in the half-circular and triangular wells) at values of L/a equal to half the standard ones. (We note that for a square well with a repulsive core consisting of a circular infinite barrier with a finite radius, one obtains a Sinai billiard[8] which is known to exhibit classical chaotic motion; we are therefore considering a very simple special case.)

A large part of the quantum mechanical energy spectrum for this problem can once again be trivially obtained by symmetry arguments. Energy eigenfunctions in the original square well with either *i or j* even will have an appropriate node at the middle of the well and will be unaffected by the presence of the central δ-function ''core.'' States characterized by (i,j) both *odd* can, in principle, be increased in energy, but once again symmetry arguments restrict the states which are affected. For such (odd,odd) states which have $i\neq j$, we can construct two linear combinations of the standard eigenfunctions in Eq. (12), namely the one already discussed in Eq. (13) and the orthogonal state corresponding to the sum of the two basic states. The antisymmetric linear combinations vanish at the center of the well and so are unaffected by the δ-function addition; thus, something just less than (1/2) of the remaining (odd, odd) states remain eigenstates of the new problem since the $i=j$ (odd, odd) states will be affected. There then remain a set of states characterized by (i,j) with $i\leqslant j$ and both odd which will be shifted up in energy, but in contrast to the much simpler one-dimensional case, the resulting spectrum is not easily related to the standard spectrum in the same obvious way. (The one-dimensional case[18] is reviewed in the Appendix as a model upon which we base our solution for the 2D problem of interest here.) Crudely speaking then, something like $(3/4)+(1/8)_{-}\approx 7/8$ of the energy values in the square well plus core problem are identical to the standard square well and will obviously contribute to the large array of standard path length features when used to evaluate $\rho(L)$. In order to obtain estimates for the remaining energy eigenstates which *are* affected by the central core, we will make use of the matrix mechanics approach which is discussed at some length in the Appendix. (We note that a perturbative approach is not useful in the case when $\tilde{g}\rightarrow\infty$, but we can check the results of the matrix approach for small values of $\tilde{g}$ using perturbation theory as a consistency check on our method; we find complete agreement in that limit.)

Using the lowest 800 eigenvalues (roughly 100 or 1/8 of which are those affected by the additional δ-function), we numerically evaluate $\rho(L)$ as usual and obtain the results shown in Fig. 12. The spectrum including the infinite-strength δ-function is shown in part (b) and does indeed exhibit many new features [most of which are labeled by the appropriate values of (n_x,n_y)] at half the ordinary path length values familiar from the ordinary 2D well spectrum which is shown in Fig. 12(a) for comparison. The new spectrum is also shown in part (c) on an expanded scale. In this case there is now a large array of new (smaller) features corresponding to a large class of distinct new isolated orbits.

F. Supersymmetric version of the square well

We have focused extensively in this report on the connections between systems with geometries which are related by simple symmetry operations and have found, not surprisingly, that the structure of the allowed space of periodic orbits and the quantized energy eigenvalues are highly correlated with one another. In several such cases, we have found that the energy spectra in two related systems are almost identical to one another, but with special strings of eigenvalues not appearing in one case or the other. One of the most familiar examples of a symmetry for which this pattern is known to happen quite generally is found in supersymmetric quantum mechanics.[19] In more familiar one-dimensional supersymmetry (SUSY) problems, the energy spectra of two superpartner potentials, $V_{(-)}(x)$ and $V_{(+)}(x)$, are identical except that the zero-energy ground state in $V_{(-)}(x)$ is missing for $V_{(+)}(x)$. While commonly discussed for one-dimensional problems, it is just as easy to derive the supersymmetric pair potentials corresponding to the two-dimensional square well under discussion here. Since the problem is separable, we need only consider the 1D SUSY partner potentials for the standard square well[20] and combine results.

In order to obtain a ground state solution with vanishing energy (necessary for the construc-

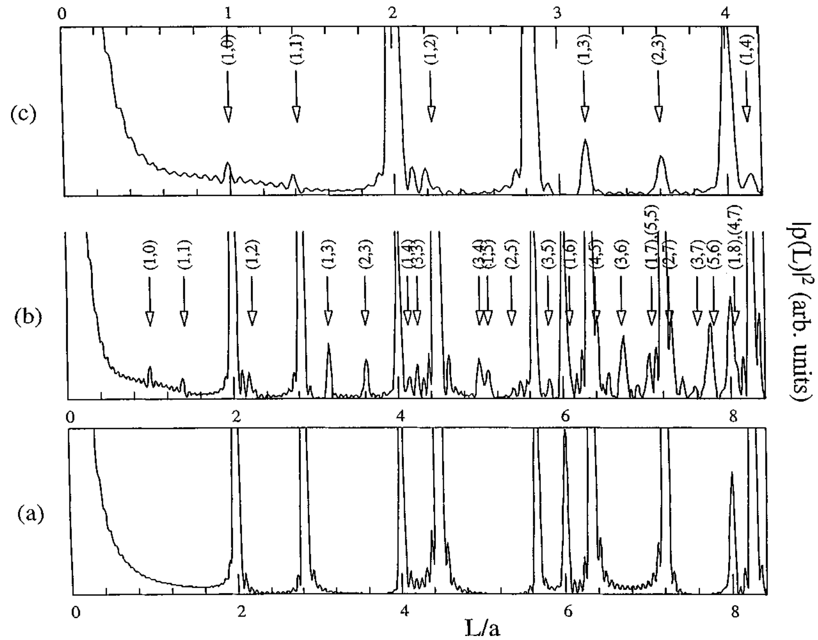

FIG. 12. Comparison of $|\rho(L)|^2$ versus L/a for the standard square well [bottom plot labeled (a)], and the square well with an infinite-strength δ-function spike at the center (middle and top plots). New features due to isolated orbits which hit the central spike are present in case (b) and (c) at half the path lengths of the more standard nonisolated orbits. Case (c) is identical to case (b), but with an expanded scale for easier comparison.

tion of the superpotential), we subtract the ground state energy from the standard 1D infinite square potential ($V_\square(x)$) thus defining

$$V_{(-)}(x)=V_\square(x)-\frac{\hbar^2\pi^2}{2ma^2} \tag{19}$$

with a similar result for the y coordinate. The resulting energy spectrum is then given by

$$E^{(-)}_{(i,j)}=\frac{\hbar^2\pi^2}{2ma^2}[i(i+2)+j(j+2)], \quad \text{where} \quad i,j=0,1,2,3,\ldots . \tag{20}$$

The supersymmetric partner potentials for either coordinate can be derived using standard results[20] and we find that

$$V_{(+)}(x)=\frac{\hbar^2\pi^2}{2ma^2}\left[2\csc^2\left(\frac{\pi x}{a}\right)-1\right] \tag{21}$$

so that $V_{(+)}(x,y)=V_{(+)}(x)+V_{(-)}(y)$.

A contour plot of this potential is shown in Fig. 13 and the limiting case of very high energies approaches the dashed (square well) boundary shown; thus, when $E^{(+)}_{(i,j)}\gg\hbar^2\pi^2/2ma^2$ we recover the familiar 2D square well geometry. If, for example, we set $(\hbar^2\pi^2/2ma^2)(i(i+2)+j(j+2))=V_{(+)}(x,y)$, the distance from the (smooth) corner of the corresponding contour of $V_{(+)}(x,y)$ to the (sharp) corner of the $V_{(-)}(x,y)$ potential is approximately

$$x\approx a\left(\frac{2}{\pi\sqrt{i^2+j^2}}\right)\to 0 \quad \text{as} \quad i,j\to\infty. \tag{22}$$

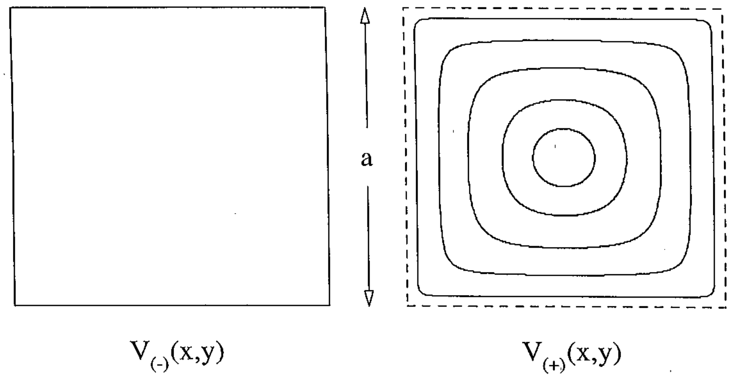

FIG. 13. Plots of the supersymmetric partner potentials defined by the two-dimensional square well problem. A contour plot of the supersymmetric partner potential, $V_+(x,y)$ [defined by Eq. (21)], is shown on the right along with the dashed (square well) boundaries which is the limiting case for $E \gg \hbar^2\pi^2/2ma^2$.

The corresponding energy eigenvalues are given by Eq. (20), but now with the restriction that $i,j=1,2,3,\ldots$ since the zero-energy ground state in each direction is excluded.

An obvious question is how the periodic orbits in the two wells are related to each other, since given Eq. (1), the energy level densities, $\rho(E)$, for the two systems are very highly correlated. Because the SUSY partner potential defined by $V_{(+)}(x,y)$ is not a purely free-particle billiard-like system, we cannot use Eq. (2) directly. However, because the system does approach the square well case in the limit of high energies, we do expect a very close correspondence between the structure of the periodic orbits in the two systems. In order to model what the likely differences are in the two model systems, we calculate $\rho(L)$ using Eq. (2), but instead of using the full energy spectrum in Eq. (20), we evaluate $\rho(L)$ using the energy (and wave number) values with the case $i,j=0$ excluded. We compare the two evaluations of $\rho(L)$ in Fig. 14 the dashed (solid) curves correspond to the $V_{(-)}$ ($V_{(+)}$) spectrum.

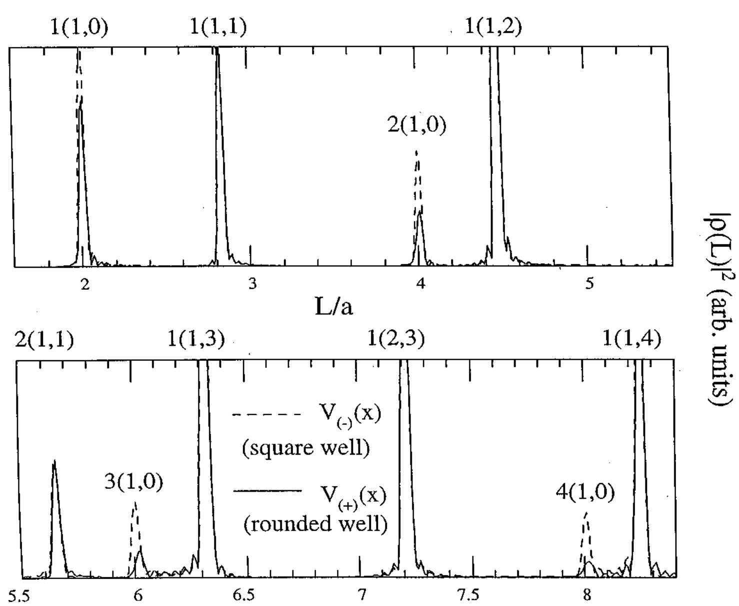

FIG. 14. Comparison of $|\rho(L)|^2$ versus L/a using the energy eigenvalues, $E^{(-)}_{(i,j)}$ with $i,j=0,1,2,\ldots$ defined by Eq. (20) (dashed curve) versus those in the supersymmetric partner potential, $E^{(+)}_{(i,j)}$ for $i,j=1,2,3,\ldots$ (solid curve). Only the path length features corresponding to the (1,0),(0,1) purely horizontal or vertical closed orbits are seemingly affected.

Perhaps not surprisingly, the only observable differences are the relative importance of the (1,0)/(0,1) features corresponding to purely back-and-forth or up-and-down motions. In the full square well, the paths characterized by these integer labels form a continuous set and so appear as ''full spikes'' in the $\rho(L)$ spectrum; in the SUSY partner case, the relative importance of these features, and especially of their recurrences, become increasingly smaller. This can likely be attributed to the fact that only purely horizontal or vertical closed paths *through* the center of the ''rounded'' $V_{(+)}(x,y)$ potential will support closed orbits and paths which are only *near* the center will increasingly become ''defocused,'' repetition after repetition. We reiterate that this is not, in any sense, a complete or rigorous analysis of this problem, but it does point out that, because of Eq. (1), there will likely be a very interesting relationship between the classes of allowed periodic orbits in superpartner potentials. In cases where the 2D potential is separable, as here, we do expect the general pattern of energy level differences, namely that the $E^{(+)}$ spectrum will be identical to the $E^{(-)}$ one, but with two one-dimensional arrays of eigenvalues missing (those corresponding here to $i,j=0$.) Examples for further study could also include the SUSY partner potentials for the circular infinite well, in which case one would likely have to construct $V_{(-)}^{(m)}(r)$ and $V_{(+)}^{(m)}(r)$ potentials (for the corresponding radial equation) separately for each value of the orbital angular momentum quantum number *m*.

One can already see, in broad strokes, how the construction of a superpartner potential, $V_{(+)}(x,y)$, from a zero-energy version of any infinite well potential, $V_{(-)}(x,y)$, using superpotentials will ensure that the resulting $V_{(+)}(x,y)$ will have the same set of infinite wall boundaries for large energies. The vanishing of the ground state solution in $V_{(-)}(x,y)=V_{(-)}(\mathbf{r})$ on the boundary (labeled *C*), schematically given by $\psi(\mathbf{r})_C=0$, ensures that the superpotential, which consists of factors such as $\psi'(\mathbf{r})/\psi(\mathbf{r})$ will give a partner potential which will diverge (due to the vanishing denominator) on the boundary of the original infinite well geometry. This connection between the two potential wells is a specific example of the shape invariance relationship for SUSY partner potentials discussed in Ref. 20 and a general analysis of the periodic orbit theory interpretation of supersymmetric quantum mechanics will, no doubt, rely heavily on this property.

G. Conclusions

We have studied two folded versions of standard two-dimensional billiard systems, namely the half-circular well and the ''triangular'' folding of the square well, and found that the changes in the energy eigenvalue spectrum and the new classical periodic orbits induced by the folding are very similar. We have discussed the scaling properties of the isolated and nonisolated orbit features as a function of N_{TOT} and have found that the values of $|\rho(L)|^2$ for standard, nonisolated path length features increase as $(N_{\mathrm{TOT}})^{3/2}$ in both cases, at least with the simple normalization used in Eq. (3); the isolated path ''spikes'' also exhibit well-separated local maxima in plots of α versus *L*. In each case, with the largest number of states used, the only new features obvious in the $\rho(L)$ spectra are those corresponding to the back-and-forth orbits and these new features corresponding to isolated orbits continue to be apparent above the background as N_{TOT} is increased.

For the case of the square well plus δ-function, we find that a much larger fraction of the energy eigenstates are affected by the introduction of the central barrier with a corresponding effect on the number of new isolated orbits. Compared to the folded cases where a one-dimensional set of energy eigenvalues is changed (discarded) and a single isolated periodic orbit (and its repetitions) are induced, in this case a significant fraction of the energy spectrum is altered and an infinite series of new path length features (as well as their repetitions) are then observed in the $\rho(L)$ spectrum.

Finally, we have discussed some possible connections between the periodic orbits in pairs of partner potentials related by supersymmetry and the corresponding energy eigenvalue spectra, focusing on the 2D square well and its superpartner as a specific example, in the context of the other cases considered here. We consider this discussion as motivation for a more thorough study of this interesting connection.

APPENDIX A:

For the discussion of the square well variant in Sec. II E, we require the energy eigenvalue spectrum for the case of a square well of side a with the addition of an infinite strength, repulsive δ-function potential of the form

$$V_{\mathrm{REP}}(x,y)=+\tilde{g}\,\delta(\mathbf{r}-\mathbf{r}_0)=+\tilde{g}\,\delta(x-a/2)\,\delta(y-a/2), \tag{A1}$$

where we let $\tilde{g}\to\infty$. To gain some guidance on how to solve this problem, we can consider the simpler one-dimensional analog of this case, namely a particle in a 1D well with an additional potential

$$\tilde{V}(x)=g\,\delta(x-a/2). \tag{A2}$$

This problem is solvable analytically (by simple matching of the appropriate boundary conditions at the central δ-function) and one can therefore take the limit where $g\to\infty$ exactly. [We note that the dimensions of $\tilde{g}$ (in 2D) and g (in 1D) are different.] In that case one finds that the 1D states labeled by odd values of the integer i, i.e., those states which are nonvanishing at the center of the well and are thus affected by the δ-function at all, are increased in energy until they become degenerate with the even i states just above them in the spectrum. This problem can also be approached by using perturbation theory, with expansions up at least third-order[21] having appeared in the literature. In our case, where we are interested in the nonperturbative limit where $g\to\infty$, this approach is not useful, but we can check our matrix results with a similar perturbative expansion in the limit of small $\tilde{g}$ as a consistency check on our method.

For the 2D case under consideration in this study, an analytic solution is not possible since the potential defined by Eq. (A1) is not separable and a different approach must be followed. A relatively straightforward matrix mechanics approach to the 1D problem[22] can be extended to the two-dimensional case under consideration and that is the approach we follow in obtaining our estimates of the energy eigenvalue spectrum used in Sec. II E. In this Appendix, we briefly describe the method used in the 1D case and then discuss how it is extended to the two-dimensional problem.

In the purely one-dimensional case, we only consider the basis states given by

$$\psi_{(i)}(x)=\sqrt{\frac{2}{a}}\sin\left(\frac{i\pi x}{a}\right) \tag{A3}$$

with i odd as these are the states which are affected by the new potential. The matrix elements required are given by

$$\mathcal{H}_{ij}(g)=\langle\psi_i|\hat{H}_0+g\,\delta(x-a/2)|\psi_j\rangle=(i^2E_0)\,\delta_{i,j}+\Delta\,\sin\left(\frac{i\pi}{2}\right)\sin\left(\frac{j\pi}{2}\right), \tag{A4}$$

where

$$E_0=\frac{\hbar^2\pi^2}{2ma^2}\quad\text{and}\quad\Delta=\Delta(g)=\frac{2g}{a} \tag{A5}$$

or in matrix form

TABLE II. Estimated energy eigenvalues for the one-dimensional square well plus repulsive δ-function potential of the form Eq. (A2) using the matrix diagonalization method discussed in the Appendix. The unperturbed energies are characterized by odd values of i and are given by $E_{(i)}=i^2E_0$, where $E_0=\hbar^2\pi^2/2ma^2$. The exact solutions as $g\rightarrow\infty$ correspond to each such odd state approaching the even state just above it in energy. We show the resulting estimate for increasing values of N_{TOT} and g as well as the ratio of the approximate result to the limiting value of $(i+1)^2E_0$.

Unperturbed energies (in units of E_0)	$N_{\mathrm{TOT}}=5$	$N_{\mathrm{TOT}}=10$	$N_{\mathrm{TOT}}=20$	$N_{\mathrm{TOT}}=40$	Exact values for $g\rightarrow\infty$
1	4.34 (1.08)	4.17 (1.04)	4.08 (1.02)	4.04 (1.01)	4.00
9	17.41 (1.09)	16.67 (1.04)	16.39 (1.02)	16.16 (1.01)	16.00
25	39.38 (1.09)	37.53 (1.04)	36.74 (1.02)	36.37 (1.01)	36.00
49	70.76 (1.10)	66.76 (1.04)	65.32 (1.02)	64.65 (1.01)	64.00

$$\mathcal{H}(g)=\begin{pmatrix} E_0+\Delta & -\Delta & +\Delta & \cdots \\ -\Delta & 9E_0+\Delta & -\Delta & \cdots \\ +\Delta & -\Delta & 25E_0+\Delta & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{A6}$$

In order to obtain increasingly accurate values for the eigenvalues of this system, we diagonalize $\mathcal{H}(g)$ for increasingly larger values of N_{TOT} where N_{TOT} is the dimensionality of the matrix. At the same time, we also use increasingly large values of g to approach the desired $g\rightarrow\infty$ limit. Specifically, we use a value of g given by

$$\frac{\Delta(g)}{E_0}=10\cdot(2N_{\mathrm{TOT}}-1)^2 \tag{A7}$$

which corresponds to off-diagonal terms, Δ, which are ten times larger than the largest diagonal energy term used in the matrix diagonalization. In this way, the lowest $N_{\mathrm{TOT}}-1$ eigenvalues approach the desired energies, while the largest eigenvalue increases without bound, going roughly as N_{TOT}^3, as we increase g via Eq. (A7); this special eigenvalue is an artifact of the diagonalization process we use. As an estimate of the convergence of this method as N_{TOT} and g are increased, we show the values of the first 4 eigenvalues (and their ratio to the expected values in the large g limit) for several values of N_{TOT} in Table II. We see that the convergence is fairly rapid and uniform.

For the two-dimensional case, we employ the same strategy, but as a basis set we use only those 2D wave functions which are affected by the presence of the central δ-function, namely those characterized by integer labels (i,j) where *both* i and j are odd. When $i=j$, we simply use the standard basis states given in Eq. (12), while for $i\neq j$, we use the linear combination which is orthogonal to the antisymmetric states given by Eq. (13), namely

$$\psi_{(i,j)}^{(+)}(x,y)\propto\psi_{(i,j)}(x,y)+\psi_{(j,i)}(x,y) \tag{A8}$$

as these states are the ones which are nonvanishing at the center of the potential well before the δ-function is added. (The normalized version of this combination is used.) We evaluate the Hamiltonian matrix just as above, sorting the states in order of increasing (unperturbed) energies as N_{TOT} increases. We show in Table III the results of such a resulting diagonalization process, up to values of $N_{\mathrm{TOT}}=80$, along with the corresponding values of energies for the $\tilde{g}=0$ case for comparison. The convergence is not quite so rapid as in the 1D case where the unperturbed energy eigenvalues are initially more separated in energy. For the numerical application required in Sec.

TABLE III. Estimated energy eigenvalues for the two-dimensional square well plus repulsive δ-function potential of the form Eq. (A1) using the matrix diagonalization technique discussed in the Appendix. The matrix diagonalization is made using basis states characterized by those states with i and j both odd; for the case of $i \neq j$, we use the symmetric combination wave function in Eq. (A8). For states with an accidental pairwise degeneracy (such as the (5,5) and (1,7) states), the numerical calculation finds the appropriate linear combination which vanishes at the origin (and is thus unaffected by the δ-function potential); we see this for the (1,7),(5,5) case where one eigenvalue given by $E=50E_0$ is always found, within the numerical accuracy of the program.

(i,j)	Unperturbed energies (in units of E_0)	$N_{\mathrm{TOT}}=10$	$N_{\mathrm{TOT}}=20$	$N_{\mathrm{TOT}}=40$	$N_{\mathrm{TOT}}=80$
(1,1)	2	3.46	3.22	3.05	2.92
(1,3)	10	13.45	12.87	12.44	12.12
(3,3)	18	20.17	19.71	19.40	19.19
(1,5)	26	29.69	29.06	28.60	28.25
(3,5)	34	40.92	39.03	37.92	37.20
(1,7)	50	50.00	50.00	50.00	50.00
(5,5)	50	55.02	54.24	53.69	53.26

II E, we make use of the lowest-lying 99 energy eigenvalues of this type in addition to as many of the ''unaffected'' energy eigenvalues as required so as to make a total of 800 energies in the numerical evaluation of Eq. (2).

As a check on the program used to numerically evaluate the eigenvalues and eigenvectors in this matrix approach (we use MATHEMATICA®), we note that when we use this set of basis functions, there still are a number of ''accidental'' pairwise degeneracies[23] present in the original spectrum; for example $(i,j)=(5,5)$ and (7,1) both give $E_{(i,j)}/E_0=50$ for the unperturbed states. We note that when we examine the resulting energy eigenvalues, the appropriate linear combination of such states is found which is *unaffected* by the δ-function perturbation and its energy

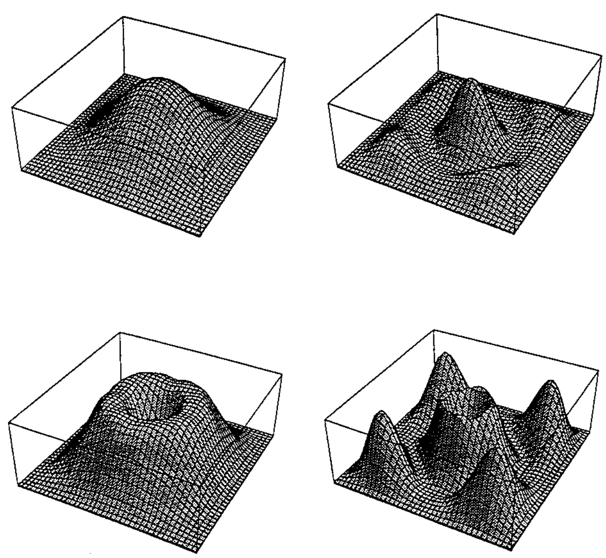

FIG. 15. Plots of $|\psi(x,y)|^2$ versus (x,y) for the two lowest energy states in the 2D well which are nonvanishing at the center of the well. The top row shows the $(i,j)=(1,1)$ state (the true ground state) on the upper left and the $(i,j)=(3,1)$ symmetric state [as defined in Eq. (A8)], for the unperturbed square well. The bottom row shows the same states now including the effect of the infinite δ-function at the origin given by Eq. (A1). In the evaluation of the perturbed eigenstates, the lowest-lying $N_{\mathrm{TOT}}=20$ states are used in the matrix diagonalization approach followed in the Appendix. We note that while each wave function is properly normalized, different scales are used in each figure to emphasize the shape of $|\psi(x,y)|^2$.

eigenvalue is, within machine errors, the same as the unperturbed value. For an example, see Table III for the case of $(1,7),(5,5)$.

As a final visualization of the effect of the infinite strength δ-function addition to the 2D well, we plot $|\psi(x,y)|^2$ versus (x,y) in Fig. 15 the $(i,j)=(1,1)$ and $(3,1)$ states, both without the δ-function (top row) and with $V_{\text{REP}}(x,y)$ added in the limit where $\tilde{g}\rightarrow\infty$ (bottom row). The presence of the cusp in the wave function at the center of the well due to $V_{\text{REP}}(x,y)$ is obvious.

Chaotic observables for a free quantum particle

Clasine van Winter
Department of Mathematics and Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506

(Received 14 April 1998; accepted for publication 14 September 1998)

This paper is devoted to the time evolution of observables in the quantum mechanics of a single particle without interaction. It is assumed that wave functions belong to a certain set K^2 that is dense in L^2. The paper applies to observables represented by positive self-adjoint operators A on L^2 with the property that $A^{1/2}$ maps K^2 into L^2. Quadratic forms with form domains K^2 are used to generate a topology for operators A, defining a topological space X. The space X provides the framework to define sensitive dependence on initial conditions, topological transitivity, and existence of a dense set of periodic points, the three aspects of chaos in Devaney's definition of chaos for maps on metric spaces. It is shown that every neighborhood of every operator A in X contains operators that establish sensitive dependence on initial conditions, and similarly for the other aspects of chaos. Hence, the time evolution of operators in the Heisenberg picture is chaotic in the sense of this paper.
[S0022-2488(99)00101-2]

I. INTRODUCTION

Chaos in classical dynamical systems is characterized by three distinctive features.

Definition 1.1 (Devaney):[1] Let X be a set. A map $F:X\to X$ is said to be chaotic on X if

(1) F has sensitive dependence on initial conditions.

(2) F is topologically transitive.

(3) Periodic points are dense in X.

Definition 1.2 (Devaney):[1] Let X be a metric space. Let $F:X\to X$ be a map.

(1) F has sensitive dependence on initial conditions if there exists $\delta>0$ such that, for any $x\in X$ and any neighborhood V of x, there exists $y\in V$ and $n\geqslant 0$ such that $|F^{(n)}(x)-F^{(n)}(y)|>\delta$.

(2) F is said to be topologically transitive if for any pair of open sets $V,W\subset X$ there exists $n>0$ such that $F^{(n)}(V)\cap W\neq\emptyset$.

(3) A point $x\in X$ is a periodic point of period n if $F^{(n)}(x)=x$.

In this paper a version of chaos is introduced that applies to quantum mechanics. The points x become operators; the map F is replaced by the time evolution. The quantities corresponding to $F^{(n)}(x)$ are time-dependent operators representing observables in the Heisenberg picture. The time evolution of such observables is examined in a one-particle system without interaction.

Let f be a wave function in L^2; let H_0 be the Hamiltonian. In the Schrödinger picture the time evolution is represented by $f(t)=\exp(-iH_0t)f$. Let A be a self-adjoint operator on L^2. In the Heisenberg picture the time-dependent operator,

$$A(t):=\exp(iH_0t)A\exp(-iH_0t),$$

acts on time-independent wave functions f.

To find quantum analogs of the concepts in Definitions 1.1 and 1.2, we make some restrictive assumptions on wave functions f and observables A. It is assumed that f belongs to a set K^2 which is dense in L^2 in the L^2-norm, in addition to being a Hilbert space in its own right. If $f \in K^2$, then $\exp(-iH_0 t) f \in K^2$ if $t>0$, but not necessarily if $t<0$. Hence $t \geqslant 0$ in all of the following, corresponding to $n \geqslant 0$ in Definitions 1.1 and 1.2. If A corresponds to $x \in X$, then $A(t)$ corresponds to $F^{(n)}(x)$.

We only consider positive operators A. Hence, let A be a positive self-adjoint operator on L^2. Let $\{E(\lambda)\}$ be the corresponding family of spectral projections. Suppose we have a system in state f and we measure the observable represented by A. The probability of finding the measured value in a Borel set Δ is $\int_\Delta d(E(\lambda)f,f)$. If $A^{1/2} f \in L^2$, the expectation value of A is

$$\begin{aligned}\int_0^\infty \lambda \; d(E(\lambda)f,f) &= \int_0^\infty \lambda^{1/2} d_\lambda \int_0^\lambda \mu^{1/2} \; d(E(\mu)f,f)\\ &= \int_0^\infty \lambda^{1/2} \; d_\lambda \int_0^\infty \mu^{1/2} d_\mu (E(\lambda)f, E(\mu)f)\\ &= \int_0^\infty \lambda^{1/2} \; d(E(\lambda)f, A^{1/2}f)\\ &= (A^{1/2}f, A^{1/2}f).\end{aligned}$$

Hence we allow all positive self-adjoint operators A on L^2 with the property that $A^{1/2} f \in L^2$ for every $f \in K^2$. For the purpose of calculating expectation values with $f,g \in K^2$, the set of allowed A can be divided into equivalence classes characterized by positive self-adjoint A such that K^2 is a core for $A^{1/2}$. The set of operators A with the latter properties is denoted by Γ. All bounded positive A belong to Γ. If $A \in \Gamma$, then $A(t) \in \Gamma$ if $t>0$. For $f,g \in K^2$, we define

$$\begin{aligned}\langle f|A|g\rangle &:= (A^{1/2}f, A^{1/2}g),\\ \langle f|A(t)|g\rangle &:= (A^{1/2} \exp[-iH_0 t] f, A^{1/2} \exp[-iH_0 t] g).\end{aligned} \tag{1.1}$$

There is a one-to-one correspondence between operators $A \in \Gamma$ and operators $\tilde{A}$ in a cone $\tilde{\Gamma}$ in the space of bounded self-adjoint operators on K^2. This fact is used to define a topology on Γ. The result is a topological space X to replace the metric space X in Definition 1.2. If a net $\{Z_\tau\}(\tau \geqslant 0)$ of operators in X tends to $A \in X$ as $\tau \to \infty$, then $\langle f|Z_\tau|g\rangle$ tends to $\langle f|A|g\rangle$ for every fixed $f,g \in K^2$.

The above framework leads to the following quantum analogs of the three parts of Devaney's definition of chaos. Instead of one $\delta>0$ as in Definition 1.2, we may allow any $N>0$.

Theorem S (sensitive dependence on initial conditions): *Given $A \in X$ and $N>0$, there is a net $\{Z_{N\tau}\} \in X(\tau \geqslant 0)$ with the property that $f,g \in K^2$ and $\epsilon>0$ determine $T>0$ such that*

$$|\langle f|A|g\rangle - \langle f|Z_{N\tau}|g\rangle| < \epsilon \quad \text{if} \quad \tau > T,$$

$$|\langle f|A(t)|f\rangle - \langle f|Z_{N\tau}(t)|f\rangle| > N||f||^2, \quad \text{if} \quad t \geqslant \tau.$$

Theorem T (topological transitivity): *Given $A,B \in X$, there is a net $\{Z_\tau\} \in X(\tau \geqslant 0)$ with the property that $f,g \in K^2$ and $\epsilon>0$ determine $T>0$ such that*

$$|\langle f|A|g\rangle - \langle f|Z_\tau|g\rangle| < \epsilon, \quad \text{if} \quad \tau > T,$$

$$|\langle f|B|g\rangle - \langle f|Z_\tau(\tau)|g\rangle| < \epsilon, \quad \text{if} \quad \tau > T.$$

Theorem P (existence of a dense set of periodic points): *Given $A \in X$, there is a net $\{Z_\tau\} \in X(\tau \geqslant 0)$ with the property that $f,g \in K^2$ and $\epsilon>0$ determine $T>0$ such that*

$$|\langle f|A|g\rangle - \langle f|Z_\tau|g\rangle| < \epsilon, \text{ if } \tau > T.$$

Moreover,

$$Z_\tau(t+n\tau) = Z_\tau(t), \text{ if } t \geqslant 0, \; n = 0,1,2, \ldots$$

In each theorem, Z_τ belongs to an ϵ-neighborhood of A when $\tau > T$. Hence, suppose an experiment is meant to determine $\langle f|A(t)|f\rangle$, but actually measures $\langle f|Z_\tau(t)|f\rangle$. The error could be due to design imperfections. If ϵ is of the order of the error in reading off experimental data, one cannot distinguish between the two expectation values at time $t=0$, but at later times the difference may be substantial. In the case of Theorem S, the error may increase to any value $N||f||^2$. Theorem T says that Z_τ in an ϵ-neighborhood V of A may develop into $Z_\tau(\tau)$ in an ϵ-neighborhood W of B. This corresponds to $F^{(n)}(V) \cap W \neq \emptyset$ in Definition 1.2. According to Theorem P, cases may occur in which $Z_\tau(t)$ is periodic with period τ. Since there is an operator Z_τ with this property in any neighborhood of any $A \in X$, periodic operators Z_τ form a dense set in X.

The nets $\{Z_\tau\}$ to which our theorems refer do not depend on $f,g \in K^2$. It is a property of the topological space X that convergence of $\{Z_\tau\}$ in X implies convergence of expectation values $\langle f|Z_\tau|g\rangle$ for fixed $f,g \in K^2$. The proofs of Theorems T and P are carried out in the language of the space X. This determines the topology of these results, although it might appear that the theorems are formulated in terms of the weak operator topology on L^2.

Sensitive dependence on initial conditions calls for a distance concept, but it is not necessary that this distance generates the topology. In Theorem S the topology of X is augmented by a distance measured in terms of the diagonal matrix elements of the identity operator. Once we adopt this augmented topology, the time evolution of operators $A(t) \in X$ is chaotic in the sense of Definitions 1.1 and 1.2.

The space of wave functions K^2 is described in Sec. II. Section III is devoted to quadratic form techniques to be used later on. The topological space X is defined in Sec. IV. That operators Z_τ exist as desired is due to properties of the time evolution on K^2 derived in Sec. V. It is shown in Sec. VI that the time evolution takes $A \in X$ into $A(t) \in X$. Theorems S, T, and P are proved in Secs. VII, VIII, and IX. The method of proof is inspired by symbolic dynamics. To indicate the relation, in Sec. X a comparison is made between the time evolution on K^2 and canonical models of chaos in classical dynamical systems.

There is an extensive literature on chaos in quantum mechanics from an entirely different point of view.[2–4] Its focus is on quantum systems with chaotic classical limits. There is strong evidence that such systems have spectral properties and other characteristics that do not occur if the underlying classical system is integrable. It is not clear, however, whether these quantum signatures of chaos can be related to the definition of chaos in classical dynamical systems.

II. THE SPACE OF WAVE FUNCTIONS

This paper is best understood in the momentum representation. Wave functions $f(\mathbf{k})$ belong to $L^2(\mathbf{R}^3)$. We write $|\mathbf{k}| = k$ and introduce two spherical polar coordinates ω. Identifying $f(\mathbf{k})$ and $f(k,\omega)$, we write L^2 instead of $L^2(\mathbf{R}^3)$. Units are chosen so that the Hamiltonian H_0 acts as multiplication by k^2.

The dilation operator D is the self-adjoint operator on L^2 which acts on C_0^∞-functions $f \in L^2$ as the differential operator,

$$D = \frac{i}{2}(\mathbf{k}\cdot\nabla_k + \nabla_k\cdot\mathbf{k}).$$

In a previous paper[5] we defined $J := \exp(-\pi D/2)$. The operator J is positive and self-adjoint but not bounded. The set of all $f \in L^2$ with the property that $Jf \in L^2$ was denoted by K^2. This set is dense in L^2 in the L^2-norm. It was shown that $f(k,\omega)\in K^2$ if and only if $f(k,\omega)$ is the mean-square boundary value of a function $f(ke^{i\phi},\omega)$ which is analytic in the sector $-\pi/2<\phi<0$ for almost every $\omega\in S^2$ and has the property that the integral,

$$\int_{S^2}\int_0^\infty |ke^{i\phi}f(ke^{i\phi},\omega)|^2\, dk\, d\omega,$$

is bounded uniformly in the sector.

It is known[6,7] that all functions $f(ke^{i\phi},\omega)$ with the above properties have mean-square boundary values $f(k,\omega)$ and $f(ke^{-i\pi/2},\omega)$. Under the inner product,

$$\langle f,g\rangle=\int_{S^2}\int_0^\infty [f(k,\omega)\overline{g}(k,\omega)+f(ke^{-i\pi/2},\omega)\overline{g}(ke^{-i\pi/2},\omega)]k^2\, dk\, d\omega, \tag{2.1}$$

the set is a Hilbert space which we denote by G^2.

It was shown before[5] that boundary values of $f\in G^2$ satisfy

$$Jf(k,\omega)=e^{-3i\pi/4}f(ke^{-i\pi/2},\omega). \tag{2.2}$$

In terms of inner products $(\cdot,\cdot)$ on L^2, we may therefore rewrite Eq. (2.1) as

$$\langle f,g\rangle=(f,g)+(Jf,Jg). \tag{2.3}$$

Since G^2 is a Hilbert space and $f\in K^2$ if and only if $f(k,\omega)$ is the boundary value at $\phi=0$ of $f\in G^2$, the set K^2 is complete under the inner product (2.3), hence a Hilbert space. We denote the Hilbert space by K^2. It is easy to verify that

$$\langle f,g\rangle=([1+J^2]^{1/2}f,[1+J^2]^{1/2}g). \tag{2.4}$$

Summarizing, inner products on L^2 are denoted by $(\cdot,\cdot)$, inner products on K^2 by $\langle\cdot,\cdot\rangle$. The expressions in Eqs. (2.3) and (2.4) are linear in f, antilinear in g. Henceforth norms on L^2 are denoted by $||\cdot||$, norms on K^2 by $|||\cdot|||$. The restriction to K^2 of an operator $T:L^2\to L^2$ is $T\restriction K^2$. The domain of T is $\mathrm{Dom}(T)$. The adjoint on L^2 of an operator $T:L^2\to L^2$ is denoted by T^*, the adjoint on K^2 of an operator $S:K^2\to K^2$ is denoted by $S^\dagger$. For example, if T is a bounded operator on L^2 and $f\in K^2$ is such that $(1+J^2)f\in L^2$, it follows from the definition of an adjoint that

$$T^\dagger f=(1+J^2)^{-1}T^*(1+J^2)f. \tag{2.5}$$

Lemma 2.1: If T is a closed operator on L^2 with $\mathrm{Dom}(T)\supseteq K^2$, *then* $(1+J^2)^{-1/2}T$ *is a bounded operator on* K^2.

Proof: Suppose $f\in K^2$. By the data and Eq. (2.4), $(1+J^2)^{-1/2}Tf$ belongs to K^2. Hence $S:=(1+J^2)^{-1/2}T$ can be viewed as an operator on K^2. If we can show that S is closed, the proposition follows from the closed-graph theorem.

To verify that S is closed, consider a Cauchy sequence $\{g_n\}(n=1,2,\dots)$ in K^2 with the property that $|||Sg_n-Sg_m|||\to 0$. Since $|||g_n-g_m|||\to 0$, an element $g\in K^2$ exists such that $|||g_n-g|||\to 0$. Since $g\in K^2$, the data imply that $Tg\in L^2$, hence $Sg\in K^2$. We have to show that $|||Sg_n-Sg|||\to 0$.

Since the L^2-norm is weaker that the K^2-norm, $||g_n-g||\to 0$. Due to Eq. (2.4), $|||Sg_n-Sg_m|||\to 0$ implies $||Tg_n-Tg_m||\to 0$. Hence $h\in L^2$ exists such that $||Tg_m-h||\to 0$. Because T is closed by assumption, it follows not only that $Tg\in L^2$, but also that $Tg=h$. This means that $||Tg_n-Tg||\to 0$. With Eq. (2.4) it follows that $|||Sg_n-Sg|||\to 0$. Hence S is closed. The closed-graph theorem completes the proof. □

III. QUADRATIC FORMS

Let A be a positive self-adjoint operator on L^2 such that Dom $(A^{1/2}) \supseteq K^2$. It follows from Lemma 2.1 that $(1+J^2)^{-1/2}A^{1/2}$ is a bounded operator on K^2.

Now consider the positive quadratic form,

$$q[f,g]:=(A^{1/2}f,A^{1/2}g), \tag{3.1}$$

on L^2 with form domain $\mathrm{Dom}(q)=K^2$. If K^2 happens to be equal to $\mathrm{Dom}(A^{1/2})$, the form q is closed. Otherwise q is closable.[8] In any case,

$$q[f,g]=\langle (1+J^2)^{-1/2}A^{1/2}f,(1+J^2)^{-1/2}A^{1/2}g\rangle=\langle [(1+J^2)^{-1/2}A^{1/2}]^{\dagger}(1+J^2)^{-1/2}A^{1/2}f,g\rangle. \tag{3.2}$$

In an obvious notation, we write

$$q[f,g]=\langle \tilde{A}f,g\rangle. \tag{3.3}$$

This defines a bounded positive operator $\tilde{A}$ on K^2. In case A is bounded on L^2, it follows with Eq. (2.5) that $\tilde{A}=(1+J^2)^{-1}A$.

In Eq. (3.1) the operator A determines the form q. We now let $q[f,g]$ be a positive quadratic form on L^2 with form domain $\mathrm{Dom}(q)=K^2$. Suppose q is closed or closable. Denote the closure by $\overline{q}$ and its form domain by $\mathrm{Dom}(\overline{q})$. The form $\overline{q}$ determines a positive self-adjoint operator A on L^2 with domain $\mathrm{Dom}(A)\subset\mathrm{Dom}(\overline{q})$ and

$$\overline{q}[f,g]=(Af,g), \tag{3.4}$$

for every $f\in\mathrm{Dom}(A)$ and $g\in\mathrm{Dom}(\overline{q})$. Moreover, $\mathrm{Dom}(A^{1/2})=\mathrm{Dom}(\overline{q})$ and

$$\overline{q}[f,g]=(A^{1/2}f,A^{1/2}g), \tag{3.5}$$

for every $f,g\in\mathrm{Dom}(\overline{q})$. A subset D' of $\mathrm{Dom}(\overline{q})$ is a core for $\overline{q}$ if and only if it is a core for $A^{1/2}$.

The above propositions follow from two representation theorems for quadratic forms.[9] The assumption that q with form domain K^2 has closure $\overline{q}$ means that K^2 is a core for $\overline{q}$. Hence we may let D' be K^2, showing that K^2 is a core for $A^{1/2}$ in Eq. (3.5).

Restricting Eq. (3.5) to K^2, we find Eq. (3.1). On the other hand, in setting up Eq. (3.1) we did not assume that K^2 was a core for $A^{1/2}$. Given the operator A that was the starting point for Eq. (3.1), it may happen that $A^{1/2}\restriction K^2$ has more than one self-adjoint extension. Among all possibilities, the representation theorems select $(A^{1/2}\restriction K^2)^*$. This is the operator $A^{1/2}$ in Eq. (3.5) whose square is A in Eq.(3.4).

Since we are looking only at expectation values of the form (3.1), with $f,g\in K^2$, all positive self-adjoint operators A with the same $A^{1/2}\restriction K^2$ form an equivalence class characterized by the particular A that satisfies the representation theorems. Hence we denote by Γ the set of all positive self-adjoint operators A on L^2 with the property that K^2 is a core for $A^{1/2}$.

The set of positive closable forms on L^2 with form domain K^2 is denoted by Γ_q. Since $q\in\Gamma_q$ determines $A\in\Gamma$ and $A\in\Gamma$ determines the bounded positive operator $\tilde{A}$ on K^2 as in Eqs. (3.2) and (3.3), each $q\in\Gamma_q$ is of the form $\langle\tilde{A}f,g\rangle$ with some $\tilde{A}$. We denote the set of operators $\tilde{A}$ by $\tilde{\Gamma}$. Given $\tilde{A}\in\tilde{\Gamma}$, we can construct $q\in\Gamma_q$ which determines $A\in\Gamma$. In this sense A is a function of $\tilde{A}$. For future reference we write $A=\gamma(\tilde{A})$. The inverse relation $\tilde{A}=\gamma^{-1}(A)$ is illustrated by Eqs. (3.2) and (3.3).

In proving Theorems S, T, and P, our strategy is to construct operators $\tilde{Z}_\tau\in\tilde{\Gamma}$ giving rise to forms $q\in\Gamma_q$. Via the representation theorems, the forms determine operators $Z_\tau\in\Gamma$ and expectation values $\langle f|Z_\tau(t)|g\rangle$ as desired.

IV. THE TOPOLOGY

Let $A,B \in \Gamma$ determine the forms $q_A, q_B \in \Gamma_q$. The form $q := q_A + q_B$ with domain Dom(q) $= K^2$ is closable.[8] Hence $q \in \Gamma_q$. The closure $\overline{q}$ determines an operator[9] $A \dotplus B \in \Gamma$ known as the form sum of A and B. For $f,g \in K^2$, it follows from Eqs. (3.1) and (3.3) that

$$\begin{aligned}(A^{1/2}f, A^{1/2}g) + (B^{1/2}f, B^{1/2}g) &= \langle \tilde{A}f,g\rangle + \langle \tilde{B}f,g\rangle \\ &= \langle [\tilde{A}+\tilde{B}]f,g\rangle \\ &= ([A \dotplus B]^{1/2}f, [A \dotplus B]^{1/2}g).\end{aligned}$$

Expectation values satisfy

$$\langle f|A|g\rangle + \langle f|B|g\rangle = \langle f|A \dotplus B|g\rangle.$$

This shows that we can define a sum on Γ. If $A \in \Gamma$ and c is a positive constant, $cA \in \Gamma$. Hence multiplication by positive constants is defined on Γ. Summarizing, Γ is a cone corresponding to a cone $\tilde{\Gamma}$ in the vector space $\tilde{B}$ consisting of bounded self-adjoint operators on K^2.

The weak operator topology on $\tilde{B}$ is a suitable starting point for defining a topology on Γ. It is generated by the family of seminorms,

$$\rho := \{f,g \in K^2, \tilde{T} \in \tilde{B}, \rho_{fg}(\tilde{T}) := |\langle \tilde{T}f,g\rangle|\}.$$

A neighborhood base at 0 is formed by the sets

$$\tilde{W}_\epsilon(K_m^2, K_n^2) := \{\tilde{T} \in \tilde{B} | \rho_{fg}(\tilde{T}) < \epsilon, f \in K_m^2, g \in K_n^2\},$$

for all $\epsilon > 0$ and any finite sets $K_m^2 \in K^2, K_n^2 \in K^2$.

Let us denote the topology by w and let $\tilde{W}$ be a typical open set. The pair $(\tilde{B},w)$ is a locally convex space. It induces on $\tilde{\Gamma}$ the relative topology[10] v with open sets $\tilde{W} \cap \tilde{\Gamma}$,

$$v := \{\tilde{W} \cap \tilde{\Gamma} | \tilde{W} \in w\}.$$

We denote the topological space $(\tilde{\Gamma}, v)$ by $\tilde{X}$. A net $\{\tilde{Z}_\tau\} \in \tilde{X} (\tau \geqslant 0)$ tends to $\tilde{A} \in \tilde{X}$ as $\tau \to \infty$ if and only if $\langle \tilde{Z}_\tau f,g\rangle$ tends to $\langle \tilde{A}f,g\rangle$ for every fixed $f,g \in K^2$. By Eqs. (3.1) and (3.3),

$$\lim_{\tau \to \infty} (Z_\tau^{1/2}f, Z_\tau^{1/2}g) = (A^{1/2}f, A^{1/2}g). \tag{4.1}$$

Conversely, if Eq. (4.1) is true for every $f,g \in K^2$, then $\tilde{Z}_\tau$ tends to $\tilde{A}$ in $\tilde{X}$. Hence we want Eq. (4.1) to express what it means for a net $\{Z_\tau\}$ to converge to A. This convergence concept makes the function $\gamma: \tilde{\Gamma} \to \Gamma$ introduced at the end of Sec. III continuous with a continuous inverse. Since γ maps $\tilde{\Gamma}$ onto Γ, the only topology on Γ to make γ and γ^{-1} continuous is the quotient topology[10] defined by

$$v_\gamma := \{W \subseteq \Gamma | \gamma^{-1}(W) \in v\}.$$

The topological space (Γ, v_γ) is denoted by X. This is our space of observables A.

As a map between topological spaces, the function $\gamma: \tilde{X} \to X$ is continuous and maps open sets onto open sets. In addition γ is one-to-one and onto. Hence γ is a homeomorphism. A net $\{Z_\tau\} \in X$ tends to $A \in X$ if and only if $\{\tilde{Z}_\tau\} \in \tilde{X}$ tends to $\tilde{A} \in \tilde{X}$. By Equation (1.1), this condition is necessary and sufficient in order that expectation values $\langle f|Z_\tau|g\rangle$ tend to $\langle f|A|g\rangle$.

V. THE TIME EVOLUTION

In order that we can use operators on K^2 as intermediate steps in proving Theorems S, T, and P, we need to know how the time evolution $\exp(-iH_0t)$ acts on K^2. Since H_0 acts as multiplication by k^2, the operator $\exp(-iH_0t)$ acts on L^2 as multiplication by $\exp(-ik^2t)$. If $-\pi/2<\phi<0$, then $\exp(-ik^2e^{2i\phi}t)$ is bounded if and only if $t\geqslant 0$. Hence, if $f(ke^{i\phi},\omega)\in G^2$, then $\exp(-ik^2e^{2i\phi}t)f(ke^{i\phi},\omega)\in G^2$ if $t\geqslant 0$, but not necessarily if $t<0$. By the same token, if $f(k,\omega)\in K^2$, then $\exp(-ik^2t)f(k,\omega)\in K^2$ if $t\geqslant 0$ but not necessarily if $t<0$. Hence $t\geqslant 0$ in all of the following.

If $f\in K^2$ and $t\geqslant 0$, it follows from Eq. (2.2) that

$$J \exp\,(-ik^2t)f(k,\omega)=\exp(ik^2t)Jf(k,\omega). \tag{5.1}$$

For $t\geqslant 0$ only, we define the operator $U(t)$ on L^2 by

$$U(t)f(k,\omega):=\exp(-ik^2t)f(k,\omega). \tag{5.2}$$

This operator is unitary. Its adjoint $U^*(t)$ acts as multiplication by $\exp(ik^2t)$. Due to Eqs. (2.3) and (5.1),

$$\langle U(t)f,U(t)g\rangle=\langle f,g\rangle. \tag{5.3}$$

Hence $U(t)$ is an isometry on K^2. It follows that $U^\dagger(t)U(t)$ acts on K^2 as the identity. By Eq. (2.5), $U^\dagger(t)$ is not the same as $U^*(t)$. Since $U(t)$ is an isometry on K^2, the set $U(t)K^2$ is a subspace of K^2 which is closed in the K^2-norm. Let the subspace be denoted by $K^2(t)$ and let $Q(t)$ be the orthogonal projection of K^2 onto $K^2(t)$. By general properties of isometries,[11]

$$U(t)U^\dagger(t)=Q(t). \tag{5.4}$$

To see how $Q(t)$ acts on K^2, we first consider the space G^2 and use the fact that G^2 is isometrically isomorphic to the Hardy space H^2 of the lower half-plane.[6] For $f\in G^2$, we define

$$v+iw:=k^2e^{2i\phi},\quad F(v+iw,\omega):=(ke^{i\phi}/2)^{1/2}f(ke^{i\phi},\omega).$$

When $ke^{i\phi}$ varies in the sector $-\pi/2<\phi<0$, then $v+iw$ runs through the lower half-plane. If $f,g\in G^2$, the inner product $\langle f,g\rangle$ satisfies

$$\langle f,g\rangle=\int_{S^2}\int_{-\infty}^{\infty}F(v-i0,\omega)\overline{G}(v-i0,\omega)\;dv\;d\omega.$$

Now define the Fourier transform,

$$\hat{f}(s,\omega)=(2\pi)^{-1/2}\int_{-\infty}^{\infty}\exp(ivs)F(v-i0,\omega)\;dv.$$

By the Paley–Wiener theorem,[12] $\hat{f}(s,\omega)=0$ if $s<0$, for almost every ω. The Fourier transform is a unitary map taking $f\in G^2$ into $\hat{f}(s,\omega)\in L^2(\mathbf{R}^+\times S^2)$.

If $f\in K^2$, then $U(t)f(k,\omega)\in K^2$ is the boundary value at $\phi=0$ of $\exp(-ik^2e^{2i\phi}t)f(ke^{i\phi},\omega)$. The latter function corresponds to $\exp(-ivt+wt)F(v+iw,\omega)$ with Fourier transform

$$(2\pi)^{-1/2}\int_{-\infty}^{\infty}\exp(-ivt+ivs)F(v-i0,\omega)\;dv=\hat{f}(s-t,\omega). \tag{5.5}$$

For fixed $t\geqslant 0$, this Fourier transform vanishes if $s<t$.

We now return to the space K^2. Since K^2 and G^2 are isometrically isomorphic, the Fourier transform on G^2 gives rise to a unitary map taking $f(k,\omega)\in K^2$ into $\hat{f}(s,\omega)\in L^2(\mathbf{R}^+\times S^2)$. With Eq. (5.5) this point of view yields

$$\begin{aligned}\langle U(t)f,g\rangle &= \int_{S^2}\int_t^\infty \hat{f}(s-t,\omega)\overline{\hat{g}}(s,\omega)\,ds\,d\omega\\ &=\langle f,U^\dagger(t)g\rangle\\ &=\int_{S^2}\int_0^\infty \hat{f}(s,\omega)\overline{\hat{g}}(s+t,\omega)\,ds\,d\omega.\end{aligned} \tag{5.6}$$

Replacing f by $U^\dagger(t)f$ gives

$$\langle Q(t)f,g\rangle=\int_{S^2}\int_t^\infty \hat{f}(s,\omega)\overline{\hat{g}}(s,\omega)\,ds\,d\omega.$$

Since $Q(t)$ is an orthogonal projection,

$$|||Q(t)f|||^2=\int_{S^2}\int_t^\infty |\hat{f}(s,\omega)|^2\,ds\,d\omega. \tag{5.7}$$

This quantity tends to 0 as $t\to\infty$.

Since $U(t)$ takes K^2 into K^2 and $U(s)U(t)$ equals $U(s+t)$, the family $\{U(t)|0\leqslant t<\infty\}$ is a semigroup of operators on K^2. If $0\leqslant t<s$, it follows from the semigroup property and Eq. (5.4) that

$$\begin{aligned}Q(s)U(t)&=U(s)U^\dagger(s)U(t)\\ &=U(t)U(s-t)U^\dagger(s-t)U^\dagger(t)U(t)\\ &=U(t)U(s-t)U^\dagger(s-t)\\ &=U(t)Q(s-t),\end{aligned}$$

$$\begin{aligned}Q(s)Q(t)&=U(s)U^\dagger(s)U(t)U^\dagger(t)\\ &=U(s)U^\dagger(s-t)U^\dagger(t)U(t)U^\dagger(t)\\ &=U(s)U^\dagger(s-t)U^\dagger(t)=U(s)U^\dagger(s)=Q(s).\end{aligned}$$

With similar calculations for $0\leqslant s\leqslant t$, we find

$$\begin{aligned}Q(s)U(t)&=U(t),\ \text{if }0\leqslant s\leqslant t,\\ &=U(t)Q(s-t),\ \text{if }0\leqslant t<s,\end{aligned} \tag{5.8}$$

$$Q(s)Q(t)=Q(\max s,t). \tag{5.9}$$

VI. THE HEISENBERG PICTURE

An operator $A\in\Gamma$ gives rise to a form q as in Eqs. (3.1) and (3.3). Replacing $f,g\in K^2$ by $U(t)f,U(t)g\in K^2$ gives

$$q_t[f,g]:=\langle U^\dagger(t)\tilde{A}U(t)f,g\rangle=(A^{1/2}U(t)f,A^{1/2}U(t)g), \tag{6.1}$$

with form domain K^2. According to Lemma 6.1 below, q_t is closable, hence determines $A_t \in \Gamma$. On the other hand, we can apply $U^*(t)AU(t)$ to $U^*(t)\mathrm{Dom}(A)$. The operator $A(t)$ so defined is symmetric. By Lemma 6.2 it is self-adjoint and equal to A_t. Hence $A(t) \in \Gamma$ if $A \in \Gamma$. This means that the Heisenberg picture can be used without ambiguity. Given a form $q \in \Gamma_q$, we can extract $A \in \Gamma$, then construct $A(t) \in \Gamma$. Or we can let q develop into q_t, then determine $A_t \in \Gamma$. The result is the same. Similarly, $A(t)$ and A_t act in the same way as elements of the topological space X.

Lemma 6.1: Let T be a symmetric operator on L^2 with domain K^2. Let $U(t)$ be defined by Eq. (5.2). Let q and q_t be the forms defined by

$$q[f,g]:=(Tf,Tg),$$

$$q_t[f,g]:=(TU(t)f,TU(t)g),$$

each with form domain K^2.

The forms are closable. The form domains of the closures satisfy

$$\mathrm{Dom}(\overline{q})=U(t)\mathrm{Dom}(\overline{q_t}),\ \ \mathrm{Dom}(\overline{q_t})=U^*(t)\mathrm{Dom}(\overline{q}). \tag{6.2}$$

Let A and A_t be the positive self-adjoint operators defined by q and q_t, respectively. Then

$$A_t^{1/2}=U^*(t)A^{1/2}U(t), \tag{6.3}$$

where each side is self-adjoint with domain $\mathrm{Dom}(\overline{q_t})$.

Proof: Since T is symmetric, T is closable. Hence q is closable. Since $U(t)K^2 \subseteq K^2$, the operator $U^*(t)TU(t)\restriction K^2$ is symmetric, hence closable. This is sufficient for q_t to be closable.

By the representation theorems,[9] A and A_t are well-defined. The domains of $A^{1/2}$ and $A_t^{1/2}$ are equal to $\mathrm{Dom}(\overline{q})$ and $\mathrm{Dom}(\overline{q_t})$, respectively. The common domain $\mathrm{Dom}(q)=\mathrm{Dom}(q_t)=K^2$ is a core for both $A^{1/2}$ and $A_t^{1/2}$.

Choose $f \in \mathrm{Dom}(\overline{q_t})$. Since K^2 is a core for $A_t^{1/2}$, there exists a sequence $\{f_n\} \in K^2 (n=1,2,\dots)$ such that $\|f_n - f\| \to 0$ and $\|A_t^{1/2}(f_n-f_m)\| \to 0$ as $n,m \to \infty$. Since $U(t)f_n \in K^2$, the sequence $\{f_n\}$ has the property that $\|U(t)f_n - U(t)f\| \to 0$ and

$$\begin{aligned}\|A_t^{1/2}(f_n-f_m)\| &= \|TU(t)(f_n-f_m)\| \\ &= \|T[U(t)f_n - U(t)f_m]\| \\ &= \|A^{1/2}[U(t)f_n - U(t)f_m]\| \to 0.\end{aligned}$$

Since $A^{1/2}$ is closed, it follows that $U(t)f \in \mathrm{Dom}(A^{1/2})$. Hence

$$U(t)\mathrm{Dom}(\overline{q_t}) \subseteq \mathrm{Dom}(\overline{q}). \tag{6.4}$$

That K^2 is a core for $A_t^{1/2}$ also implies that

$$A_t^{1/2}=[U^*(t)TU(t)\restriction K^2]^*. \tag{6.5}$$

Likewise $A^{1/2}=T^*$. Now choose $g \in U^*(t)\mathrm{Dom}(\overline{q})$. Clearly $g=U^*(t)h$ with $h=U(t)g \in \mathrm{Dom}(\overline{q})$. If $f \in K^2$,

$$\begin{aligned}(U^*(t)TU(t)f,g) &= (TU(t)f,h) \\ &= (f,U^*(t)T^*h) \\ &= (f,U^*(t)A^{1/2}h) \\ &= (f,U^*(t)A^{1/2}U(t)g).\end{aligned} \tag{6.6}$$

Due to Eq. (6.5), this shows that $g \in \mathrm{Dom}(A_t^{1/2})$, hence

$$U^*(t)\mathrm{Dom}(\overline{q}) \subseteq \mathrm{Dom}(\overline{q_t}). \tag{6.7}$$

The relations (6.4) and (6.7) give the desired equality (6.2). Hence g in Eq. (6.6) may be any element of $\mathrm{Dom}(\overline{q_t})$. With Eq. (6.5), it follows that $A_t^{1/2}$ acts on $\mathrm{Dom}(\overline{q_t})$ in the same way as $U^*(t)A^{1/2}U(t)$, confirming Eq. (6.3). It is known from the representation theorems that $A_t^{1/2}$ with domain $\mathrm{Dom}(\overline{q_t})$ is self-adjoint.

It remains to show that $U^*(t)A^{1/2}U(t)$ with domain $U^*(t)\mathrm{Dom}(\overline{q})$ is self-adjoint. It is easy to see that the operator is symmetric. To prove that it is self-adjoint, it is sufficient to show that the operators $U^*(t)A^{1/2}U(t) \pm i$ have range L^2. Hence we let f run through $\mathrm{Dom}(\overline{q})$ and examine

$$U^*(t)(A^{1/2} \pm i)U(t)U^*(t)f = U^*(t)(A^{1/2} \pm i)f.$$

Since $A^{1/2}$ with domain $\mathrm{Dom}(\overline{q})$ is self-adjoint, $(A^{1/2} \pm i)f$ runs through L^2. This is sufficient for $U^*(t)(A^{1/2} \pm i)f$ to run through L^2, as we wanted to show. □

Lemma 6.2: Let the data be as in Lemma 6.1. The operator

$$A(t) := U^*(t)AU(t)$$

with domain $U^*(t)\mathrm{Dom}(A)$ *is self-adjoint and equal to* A_t.

Proof: The reasoning applied to $U^*(t)A^{1/2}U(t)$ at the end of the proof of Lemma 6.1, can be repeated to show that $A(t)$ with domain $U^*(t)\mathrm{Dom}(A)$ is self-adjoint. The operator on the right-hand side of Eq. (6.3) is the square root $[A(t)]^{1/2}$. Since it is equal to $A_t^{1/2}$, it follows that $A(t) = A_t$. □

Corollary 6.3: If $A \in X$ *and* $t \geqslant 0$, *then* $A(t) \in X$. □

For future reference we define

$$\tilde{A}(t) := U^\dagger(t)\tilde{A}U(t).$$

By Eq. (6.1), this is the operator in $\tilde{X}$ determined by $A(t)$ in X.

Since $\tilde{A}(t)$ is a bounded operator on K^2 whenever $t \geqslant 0$, this quantity is easy to work with. In the notation of Lemma 6.1, the domain of $A(t)$ is a subset of $U^*(t)\mathrm{Dom}(\overline{q})$. We do not know whether the intersection $\cap_{t\geqslant 0}\mathrm{Dom}[A(t)]$ is sufficiently large to be useful. On the other hand, the operator $[A(t)]^{1/2}$ can be applied to every $f \in K^2$ at all times $t \geqslant 0$. This is the reason why it is convenient to express expectation values of observables in the form (1.1).

VII. SENSITIVE DEPENDENCE ON INITIAL CONDITIONS

Proof of Theorem S: The operator $A \in X$ determines the positive operator $\tilde{A}$ on K^2 as in Eqs. (3.2) and (3.3). For $N > 0$ and $\tau \geqslant 0$, define

$$\tilde{Z}_{N\tau} := \tilde{A} + (1+\tau)^{-1} + NQ(\tau). \tag{7.1}$$

This is a positive operator on K^2. Since $\tilde{A}$ is bounded by Lemma 2.1 and $Q(\tau)$ is a projection operator, $\tilde{Z}_{N\tau}$ is bounded.

We claim that the form

$$q[f,g] := \langle \tilde{Z}_{N\tau}f, g\rangle$$

with form domain K^2 is closed for every fixed N, τ. To prove this, we choose a sequence $\{f_n\} \in K^2 (n=1,2,\ldots)$ such that $\|f_n - f_m\| \to 0$ and

$$\langle \tilde{Z}_{N\tau}(f_n - f_m), f_n - f_m \rangle \to 0, \tag{7.2}$$

as $n,m \to \infty$. It follows that $f \in L^2$ exists such that $\|f_n - f\| \to 0$. We have to show that $f \in K^2$ and $\langle \tilde{Z}_{N\tau}(f_n - f), f_n - f \rangle \to 0$.

By Eq. (7.1),

$$\langle \tilde{Z}_{N\tau}(f_n - f_m), f_n - f_m \rangle \geq (1+\tau)^{-1} |||f_n - f_m|||^2. \tag{7.3}$$

Hence $|||f_n - f_m||| \to 0$. Since K^2 is a Hilbert space, it follows that $g \in K^2$ exists such that $|||f_n - g||| \to 0$. From this it follows that $\|f_n - g\| \to 0$. Hence $f = g$ and $f \in K^2$. Moreover,

$$|\langle \tilde{Z}_{N\tau}(f_n - f), f_n - f \rangle| \leq [|||\tilde{A}||| + (1+\tau)^{-1} + N] |||f_n - f|||^2 \to 0. \tag{7.4}$$

This is sufficient for the form $q[f,g]$ to be closed.

By the representation theorems[9] and Lemmas 6.1, 6.2, the form $q[f,g]$ determines operators $Z_{N\tau} \in X$ and $Z_{N\tau}(t) \in X$. The operator $[Z_{N\tau}(t)]^{1/2}$ has domain $U^*(t)K^2$ $(t \geq 0)$.

Given any fixed $f \in K^2$, it is clear that $(1+\tau)^{-1}|||f|||$ tends to 0 as $\tau \to \infty$. By Equation (5.7) $|||Q(\tau)f||| \to 0$. Since N is fixed, it follows that $|||(\tilde{Z}_{N\tau} - \tilde{A})f||| \to 0$ as $\tau \to \infty$. Hence $\tilde{Z}_{N\tau} \to \tilde{A}$ in $\tilde{X}$ and $Z_{N\tau} \to A$ in X. Given $f,g \in K^2$ and $\epsilon > 0$, we can find T such that

$$|\langle \tilde{Z}_{N\tau} f, g \rangle - \langle \tilde{A} f, g \rangle| < \epsilon, \quad \text{if } \tau > T. \tag{7.5}$$

Via Eqs. (1.1) and (3.1), (3.3), this proves that expectation values at time $t = 0$ agree with Theorem S.

At time $t \geq \tau$ we have to examine

$$\langle \tilde{Z}_{N\tau}(t) f, f \rangle - \langle \tilde{A}(t) f, f \rangle = (1+\tau)^{-1} \langle f, f \rangle + N \langle U^\dagger(t) Q(\tau) U(t) f, f \rangle.$$

By Eqs. (5.3) and (5.8),

$$U^\dagger(t) Q(\tau) U(t) = U^\dagger(t) U(t) = I,$$

where I is the identity operator. Hence

$$|\langle f|A(t)|f\rangle - \langle f|Z_{N\tau}(t)|f\rangle| \geq N|||f|||^2 \geq N\|f\|^2,$$

as desired. □

Chaos in classical dynamical systems can often be characterized in terms of Lyapunov exponents related to the rate at which the distance between nearby orbits increases.[4,13–17] In an experiment in which we want to measure $\langle f|A(t)|f\rangle$ but actually observe $\langle f|Z_{N\tau}(t)|f\rangle$, the operator $(1+\tau)^{-1} + NQ(\tau)$ on K^2 represents the error. Let us examine the rate at which its expectation value increases. If ϵ in Eq. (7.5) is small and $\tau > T$, then τ is large. This makes $(1+\tau)^{-1}\langle f, f \rangle$ small. Hence we focus on the error

$$E_\tau(t) := N \langle U^\dagger(t) Q(\tau) U(t) f, f \rangle.$$

As long as $0 \leq t \leq \tau$, it follows from Eqs. (5.7) and (5.8) that

$$E_\tau(t) = N \langle U^\dagger(t) U(t) Q(\tau - t) f, f \rangle = N \langle Q(\tau - t) f, f \rangle = N \int_{S^2} \int_{\tau - t}^{\infty} |\hat{f}(s,\omega)|^2 \, ds \, d\omega.$$

This is a nondecreasing function of t which reaches its maximum $N|||f|||^2$ at time $t = \tau$. By Eq. (5.8), $E_\tau(t)$ is constant and equal to $N|||f|||^2$ if $t \geq \tau$.

When $0 \leq t \leq \tau$, the relative rate of increase at time t is

$$R_\tau(t)=[E_\tau(t)]^{-1}\ dE_\tau(t)/dt=|||Q(\tau-t)f|||^{-2}\int_{S^2}|\hat{f}(\tau-t,\omega)|^2\ d\omega.$$

Averaging over the time period $0\leqslant t\leqslant\tau$ yields

$$R_\tau=\tau^{-1}\int_0^\tau R_\tau(t)\ dt=\tau^{-1}\ln\,[|||f|||^2\ |||Q(\tau)f|||^{-2}].$$

Take $\tau>T$ as in Eq. (7.5). As an example, now suppose that

$$\int_{S^2}|\hat{f}(s,\omega)|^2\ d\omega=C\ \exp(-\lambda^p s^p) \tag{7.6}$$

when $s>T$, with some positive constants C,λ, and p. This gives

$$R_\tau=\tau^{-1}\ \ln\ |||f|||^2-\tau^{-1}\ \ln\int_\tau^\infty C\ \exp(-\lambda^p s^p)\ ds.$$

To get an estimate of R_τ at large τ, we evaluate $\lim_{\tau\to\infty}R_\tau$ by applying L'Hospital's rule twice. The result is

$$\lim_{\tau\to\infty}R_\tau=\lim_{\tau\to\infty}p\lambda^p\tau^{p-1}=0,\ \text{if}\ \ 0<p<1;=\lambda,\ \text{if}\ \ p=1;=\infty,\ \text{if}\ \ p>1.$$

If $0<p<1$ and the equality sign in Eq. (7.6) is replaced by $\geqslant$, it remains true that R_τ tends to 0. Similarly, if $p>1$ and the equality sign is replaced by $\leqslant 1$, it remains true that R_τ tends to ∞.

A more complicated example is

$$\int_{S^2}|\hat{f}(s,\omega)|^2\ d\omega=\exp(-\lambda s)\ \cos^2\ \mu s.$$

In this case $\lim_{\tau\to\infty}R_\tau$ does not exist. On the other hand, since

$$|||Q(\tau)f|||^2\leqslant\int_\tau^\infty\exp(-\lambda s)\ ds=\lambda^{-1}\exp(-\lambda\tau),$$

we find that

$$R_\tau\geqslant\tau^{-1}\ \ln\ |||f|||^2+\tau^{-1}\ \ln\ \lambda+\lambda.$$

Given any $\delta>0$, it follows that Θ exists such that $R_\tau>\lambda-\delta$ if $\tau>\Theta$.

VIII. TOPOLOGICAL TRANSITIVITY

Proof of Theorem T: Let $\tilde{A}$ and $\tilde{B}$ be the operators in $\tilde{X}$ determined by A and B in X. Define

$$\tilde{Z}_\tau:=[1-Q(\tau)]\tilde{A}[1-Q(\tau)]+U(\tau)\tilde{B}U^\dagger(\tau)+(1+\tau)^{-1}. \tag{8.1}$$

This is a bounded operator on K^2 satisfying

$$|||\tilde{Z}_\tau|||\leqslant|||\tilde{A}|||+|||\tilde{B}|||+(1+\tau)^{-1}. \tag{8.2}$$

The form $\langle\tilde{Z}_\tau f,g\rangle$ with form domain K^2 is closed. To show this, we choose a sequence $\{f_n\}\in K^2(n=1,2,\dots)$ such that $||f_n-f_m||\to 0$ and the analog of Eq. (7.2) is satisfied. As with Eq. (7.3), it follows that $f\in K^2$ exists such that $|||f_n-f|||\to 0$. In fact, the term $(1+\tau)^{-1}$ is included in $\tilde{Z}_\tau$ to make sure the form is closed or closable, even in case $\tilde{A}$ and $\tilde{B}$ have nonempty nullspaces. Due to Eq. (8.2), the analog of Eq. (7.4) is true. Hence the form is closed.

At time $t=0$, we examine

$$|||(\tilde{Z}_\tau-\tilde{A})f|||=|||[-Q(\tau)\tilde{A}-\tilde{A}Q(\tau)+Q(\tau)\tilde{A}Q(\tau)+U(\tau)\tilde{B}U^\dagger(\tau)+(1+\tau)^{-1}]f|||$$
$$\leqslant|||Q(\tau)\tilde{A}f|||+2|||\tilde{A}|||\ |||Q(\tau)f|||+|||\tilde{B}|||\ |||U^\dagger(\tau)f|||+(1+\tau)^{-1}|||f|||.$$

Since $\tilde{A}f$ is fixed, $|||Q(\tau)\tilde{A}f|||\to 0$ as $\tau\to\infty$. Similarly, $|||Q(\tau)f|||\to 0$. Furthermore,

$$|||U^\dagger(\tau)f|||^2=\langle U(\tau)U^\dagger(\tau)f,f\rangle=\langle Q(\tau)f,f\rangle=|||Q(\tau)f|||^2\to 0.$$

Hence $\tilde{Z}_\tau\to\tilde{A}$ in $\tilde{X}$.

At time $t=\tau$, we have

$$\tilde{Z}_\tau(\tau)=\tilde{B}+(1+\tau)^{-1}.$$

This is true because $[1-Q(\tau)]U(\tau)=0$ by Eq. (5.8) and $U^\dagger(\tau)U(\tau)=I$ by Eq. (5.3). It follows that $\tilde{Z}_\tau(\tau)\to\tilde{B}$ in $\tilde{X}$. To be specific, if $f,g\in K^2$ and T is so large that $(1+T)^{-1}|\langle f,g\rangle|<\epsilon$, then

$$|\langle\tilde{Z}_\tau(\tau)f,g\rangle-\langle\tilde{B}f,g\rangle|<\epsilon,\ \text{if}\quad \tau>T.$$

By choosing T sufficiently large, we can also arrange for Eq. (7.5) to be true (with $\tilde{Z}_\tau$ instead of $\tilde{Z}_{N\tau}$). That expectation values agree with Theorem T can now be proved as in Sec. VII. □

Recall Definitions 1.1 and 1.2. In classical dynamical systems, topological transitivity means that the space X does not contain disjoint sets V and W that are each invariant under the map F. As a corollary, if a continuous function $\psi:X\to\mathbf{R}$ is invariant under F, it has to be constant on X. In Hamiltonian systems the implication is that conserved quantities must be constant throughout the phase space.

In the present context there are operators representing conserved quantities, but there are no nontrivial invariant sets. For example, $A\in X$ may be the projection onto angular momentum l_A. In that case $\text{Dom}(A)=L^2$ and $A(t)=A$. The proof of Theorem T shows that any neighborhood of A contains operators Z_τ with the property that $Z_\tau(t)\neq Z_\tau$ for some or all $t>0$. Hence, although $A(t)$ is invariant, typical neighborhoods of $A(t)$ are not. The only exception is X interpreted as a neighborhood of $A(t)$. By Corollary 6.3, the time evolution takes X into X.

Suppose we want to measure $\langle f|A(t)|f\rangle$ in the above example, but inadvertedly measure $\langle f|Z_\tau(t)|f\rangle$ as in Eq. (8.1), with B projecting onto angular momentum $l_B\neq l_A$. The error causes measurements taken at different times to have entirely different outcomes, although the objective is to determine a conserved quantity.

IX. EXISTENCE OF A DENSE SET OF PERIODIC POINTS

Proof of Theorem P: For any $\tau>0$, define $Q(0):=I$ and

$$\Delta Q(n):=Q(n\tau)-Q([n+1]\tau)\ (n=0,1,2,\dots). \tag{9.1}$$

By Eq. (5.9),

$$\Delta Q(n)\Delta Q(m)=\delta_{mn}\Delta Q(n).$$

The operators $\Delta Q(n)$ are projections on K^2 with mutually orthogonal ranges.

Let $\tilde{A}\in\tilde{X}$ be the operator determined by $A\in X$ and define

$$\tilde{Z}_\tau := \sum_{n=0}^{\infty} \Delta Q(n) U(n\tau)[\tilde{A} + (1+\tau)^{-1}] U^\dagger(n\tau) \Delta Q(n). \tag{9.2}$$

The sum converges in the strong operator topology on K^2. To show this, we introduce the abbreviation

$$\tilde{A}_n := U(n\tau)[\tilde{A} + (1+\tau)^{-1}] U^\dagger(n\tau).$$

This gives

$$\begin{aligned} \left|\left|\left| \sum_{n=N}^{M} \Delta Q(n) \tilde{A}_n \Delta Q(n) f \right|\right|\right|^2 &= \sum_{n=N}^{M} |||\Delta Q(n) \tilde{A}_n \Delta Q(n) f|||^2 \\ &\leqslant \sum_{n=N}^{M} |||\tilde{A}_n \Delta Q(n) f|||^2 \\ &\leqslant [|||\tilde{A}||| + (1+\tau)^{-1}]^2 \sum_{n=N}^{M} |||\Delta Q(n) f|||^2 \\ &\leqslant [|||\tilde{A}||| + (1+\tau)^{-1}]^2 \, |||Q(N\tau) f|||^2. \end{aligned} \tag{9.3}$$

Since $|||Q(N\tau)f|||$ tends to 0 as $N \to \infty$, the sum for $\tilde{Z}_\tau$ converges. Moreover,

$$|||\tilde{Z}_\tau||| \leqslant |||\tilde{A}||| + (1+\tau)^{-1}. \tag{9.4}$$

By Eq. (5.9),

$$\Delta Q(n) U(n\tau) U^\dagger(n\tau) \Delta Q(n) = \Delta Q(n) Q(n\tau) \Delta Q(n) = \Delta Q(n).$$

It follows that the terms with $(1+\tau)^{-1}$ in Eq. (9.2) add up to $(1+\tau)^{-1}$. Since each term with $\tilde{A}$ is non-negative,

$$\langle \tilde{Z}_\tau f, f \rangle \geqslant (1+\tau)^{-1} \, |||f|||^2. \tag{9.5}$$

Using Eqs. (9.4) and (9.5), we can repeat the reasoning in Secs. VII and VIII to show that the form $\langle \tilde{Z}_\tau f, g \rangle$ with form domain K^2 is closed.

By Eq. (5.8),

$$\Delta Q(n) U(n\tau) = U(n\tau) \Delta Q(0).$$

It follows that

$$U^\dagger(\tau) \tilde{Z}_\tau U(\tau) = \sum_{n=0}^{\infty} U^\dagger(\tau) U(n\tau) \Delta Q(0) [\tilde{A} + (1+\tau)^{-1}] \Delta Q(0) U^\dagger(n\tau) U(\tau).$$

The term with $n=0$ actually vanishes. This is due to

$$\Delta Q(0) U^\dagger(0) U(\tau) = \Delta Q(0) U(\tau) = [1 - Q(\tau)] U(\tau) = 0,$$

where we have used Eqs. (5.8) and (9.1). In the terms with $n = 1, 2, \ldots,$ we have

$$U^\dagger(n\tau) U(\tau) = U^\dagger([n-1]\tau) U^\dagger(\tau) U(\tau) = U^\dagger([n-1]\tau).$$

Hence

$$U^{\dagger}(\tau)\tilde{Z}_{\tau}U(\tau)=\tilde{Z}_{\tau}.$$

By iteration and the semigroup property of $\{U(t)\}$,

$$\tilde{Z}_{\tau}(t+n\tau)=U^{\dagger}(t)U^{\dagger}(n\tau)\tilde{Z}_{\tau}U(n\tau)U(t)=\tilde{Z}_{\tau}(t)\ (n=0,1,2,\dots).$$

We now show that $\tilde{Z}_{\tau}\to\tilde{A}$ in $\tilde{X}$ when $\tau\to\infty$. To this end, we denote $\Sigma_{n=1}^{\infty}\ \dots$ in Eq. (9.2) by $\Delta\tilde{Z}_{\tau}$. By the reasoning in Eq. (9.3),

$$|||\Delta\tilde{Z}_{\tau}|||\leqslant|||\tilde{A}|||+(1+\tau)^{-1}.$$

By Eqs. (5.9) and (9.1),

$$\Delta Q(n)Q(\tau)=\Delta Q(n)\ (n=1,2,\dots),$$

hence

$$\Delta\tilde{Z}_{\tau}=Q(\tau)(\Delta\tilde{Z}_{\tau})Q(\tau).$$

It follows that

$$\begin{aligned}|||(\tilde{Z}_{\tau}-\tilde{A})f|||&=|||\{[1-Q(\tau)][\tilde{A}+(1+\tau)^{-1}][1-Q(\tau)]+Q(\tau)(\Delta\tilde{Z}_{\tau})Q(\tau)-\tilde{A}\}f|||\\&=|||\{-Q(\tau)\tilde{A}-\tilde{A}Q(\tau)+Q(\tau)(\tilde{A}+\Delta\tilde{Z}_{\tau})Q(\tau)+(1+\tau^{-1})[1-Q(\tau)]\}f|||\\&\leqslant|||Q(\tau)\tilde{A}f|||+[3|||\tilde{A}|||+(1+\tau)^{-1}]|||Q(\tau)f|||+(1+\tau)^{-1}\ |||f|||.\end{aligned}$$

This tends to 0 as $\tau\to\infty$.

Given $f,g\in K^2$ and $\epsilon>0$, we first find T such that

$$|\langle\tilde{Z}_{\tau}f,g\rangle-\langle\tilde{A}f,g\rangle|<\epsilon,\quad\text{if}\quad\tau>T.$$

As in Secs. VII and VIII, this guarantees that the expectation values of A and Z_{τ} are close if $\tau>T$. Next we choose τ. This results in a periodic operator $\tilde{Z}_{\tau}(t)$ with period τ. By Lemmas 6.1 and 6.2, the quadratic form,

$$q_t[f,g]:=\langle U^{\dagger}(t)\tilde{Z}_{\tau}U(t)f,g\rangle=(Z_{\tau}^{1/2}U(t)f,Z_{\tau}^{1/2}U(t)g),$$

uniquely determines $Z_{\tau}(t)$. Notice that the form is equal to $\langle\tilde{Z}_{\tau}(t)f,g\rangle$. By the periodicity of $\tilde{Z}_{\tau}(t)$, the operators $Z_{\tau}(t)$ determined at times t and $t+n\tau$ are equal. Hence $Z_{\tau}(t)$ has the same periodicity as $\tilde{Z}_{\tau}(t)$. □

Since there is an operator Z_{τ} with periodic time evolution in any ϵ-neighborhood of any $A\in X$, the set of periodic operators is dense in X.

X. CONCLUDING REMARKS

The set of operators A to which this paper applies contains all bounded positive operators on L^2. In particular, all orthogonal projections are included. It is assumed that wave functions belong to the space K^2 which is dense in L^2.

The important point about K^2 is that the time evolution $\{U(t)\ |0\leqslant t<\infty\}$ on K^2 is unitarily equivalent to a semigroup of shift operators, as shown by Eq. (5.6). This is suggestive of Bernoulli systems and other K-maps in which the dynamics can be represented by a shift on sequences of symbols.[1,13,15–18] Our construction of operators $\tilde{Z}_{\tau}$ is based on ideas from the symbolic dynamics[1,13,15–18] used in choas proofs for K-maps. A canonical model for K-flows is due to Sinai.[19] On the orthogonal complement of the constant functions, a K-flow can be represented in terms of Hilbert spaces N and $L^2(\mathbf{R})\otimes N$, and a unitary group $\{V(t)|-\infty<t<\infty\}$ such that $\hat{g}(s)\in L^2(\mathbf{R})\otimes N$ transforms according to

$$(V(t)\hat{g})(s)=\hat{g}(s-t). \tag{10.1}$$

The same canonical form occurs in the Lax–Phillips scattering theory,[20] where it is called the translation representation.

Although this paper has captured some of the chaos-related features of the translation representation, it must be emphasized that the Lax–Phillips theory was developed for the wave equation. It cannot be used in quantum mechanics. Corresponding to the Hilbert space N, we have $L^2(S^2)$, the space of square-integrable functions on the unit sphere in $\mathbf{R}^3$. It makes a difference, however, that we have a translation semigroup on $L^2(\mathbf{R}^+)$, not a group on $L^2(\mathbf{R})$.

The starting point for this paper is the group $\{\exp(-iH_0t)\}$ on L^2 with self-adjoint generator H_0. The spectrum of the generator is $[0,\infty)$. The group $\{V(t)\}$ in Eq. (10.1) has self-adjoint generator $-id/ds$ with spectrum $(-\infty,\infty)$. The semigroup $\{U(t)\}$ on K^2 has generator k^2. If we let Dom(k^2) be the set of all $f\in K^2$ with the property that $k^2f(k,\omega)\in K^2$, it follows from Eq. (2.2) that $Jk^2f=-k^2Jf$ for all $f\in\text{Dom}(k^2)$. This makes it easy to show that the operator k^2 is closed and symmetric. To identify its spectrum, we examine the resolvent $(k^2-\lambda)^{-1}$. For fixed λ, the resolvent is a bounded operator on K^2 if and only if $(k^2e^{2i\phi}-\lambda)^{-1}f(ke^{i\phi},\omega)\in G^2$ for every $f\in G^2$. Since $k^2e^{2i\phi}$ runs through the lower half-plane, the open upper half-plane is the resolvent set, and the closed lower half-plane is the spectrum of the operator k^2 on K^2. This is an example of an operator that does not have self-adjoint extensions.

Although the Hamiltonian H_0 does not belong to the cone Γ consisting of allowed operators A on L^2, we can define its counterpart $\tilde{H}_0$ on K^2 as follows. Let Dom(q) be the set of all $f\in K^2$ with the property that $kf\in L^2$. Define the quadratic form

$$q[f,g]:=(kf,kg) \tag{10.2}$$

on K^2 with form domain Dom(q). This form is densely defined and positive. By Lemma 10.1 below, the form is closed. Hence it defines a positive self-adjoint operator $\tilde{H}_0$ on K^2 with $\text{Dom}(\tilde{H}_0)\subset\text{Dom}(q)$. For $f\in\text{Dom}(\tilde{H}_0)$ and $g\in\text{Dom}(q)$,

$$q[f,g]=\langle\tilde{H}_0f,g\rangle.$$

For $f,g\in\text{Dom}(q)$ we have Eq. (10.2) and

$$q[f,g]=\langle\tilde{H}_0^{1/2}f,\tilde{H}_0^{1/2}g\rangle.$$

If $f,g\in K^2$ and both $k^2f\in L^2$ and $k^2g\in L^2$,

$$q[f,g]=(k^2f,g)=\langle(1+J^2)^{-1}k^2f,g\rangle=(f,k^2g)=\langle f,(1+J^2)^{-1}k^2g\rangle.$$

Hence $\tilde{H}_0$ is the Friedrichs extension[9] of $(1+J^2)^{-1}k^2$.

The foregoing illustrates that the generator of the semigroup $\{U(t)\}$ is very different from $\tilde{H}_0$. If $f\in\text{Dom}(q)$, then $U(t)f\in\text{Dom}(q)$. For $f,g\in\text{Dom}(q)$,

$$\langle\tilde{H}_0^{1/2}U(t)f,\tilde{H}_0^{1/2}U(t)g\rangle=(kU(t)f,kU(t)g)=(kf,kg)=\langle\tilde{H}_0^{1/2}f,\tilde{H}_0^{1/2}g\rangle.$$

Hence the energy represented by $\tilde{H}_0$ on K^2 is conserved under the time evolution represented by the semigroup $\{U(t)\}$ on K^2.

It remains to prove that the form (10.2) is closed.

Lemma 10.1: Let Dom(q) *be the set of all* $f\in K^2$ *with the property that* $kf\in L^2$*. The form (10.2) on* K^2 *with form domain* Dom(q) *is closed.*

Proof: Let $\{f_n\}(n=1,2,\ldots)$ be a sequence in Dom(q) such that $|||f_n-f|||\to 0$ and $q[f_n-f_m,f_n-f_m]\to 0$ as $n,m\to\infty$. We have to show that $f\in$ Dom(q) and $q[f_n-f,f_n-f]\to 0$.

By assumption $f\in K^2$. Moreover, $||f_n-f||\to 0$ and $||k(f_n-f_m)||\to 0$. Since k is a closed operator on L^2, it follows that $kf\in L^2$ and $||k(f_n-f)||\to 0$. The last statement means that $q[f_n-f,f_n-f]\to 0$. Since $f\in K^2$ and $kf\in L^2$, we have $f\in$ Dom(q). Hence all requirements for the form to be closed are satisfied. □

(Received 22 June 1998; accepted for publication 15 September 1998)

A compact expression for the calculation of phase shifts is derived for a potential which is the sum of local and nonlocal parts. Nonlocal potentials can support positive energy bound states, that is, states embedded in the continuous energy spectrum. These states, sometimes referred to as ''isolated'' states, are not associated with any poles of the S matrix. Some controversy exists in the literature on how such bound states are included in Levinson's theorem; it is found that the phase shift should be taken continuous at the energy of the bound state rather than taken to have a discontinuity of π. For simplicity, the analysis is restricted to the radial s wave Schrödinger equation and separable nonlocal potentials. © *1999 American Institute of Physics.* [S0022-2488(99)03601-4]

I. INTRODUCTION

As is well known, in an attempt to account for the suppression of degrees of freedom, nonlocal potentials are used in the description of many particle systems to create an effective equation for the relative motion of two particles. Such potentials are also useful in creating phase-equivalent potentials for the study of nucleon–nucleus and nucleus–nucleus scattering and cluster models of light nuclei. For these reasons it would be advantageous to have a compact expression from which the phase shifts could be found so that the effect of changes in the potential could more easily be gauged.

Nonlocal potentials can support bound states with energy embedded in the continuous spectrum. These states are sometimes called ''isolated'' since the S matrix element does not have a pole at the energy of such a state.[1] How to include such states in Levinson's theorem has been controversial.

In the rest of Sec. I, the standard analysis of nonlocal potentials[2] is reviewed. Then in Sec. II, it is shown that, for Levinson's theorem to hold, the phase shift should be taken continuous at bound states with energy embedded in the continuum. In Secs. III and IV, the potential is extended to include the addition of a local potential and in Sec. V, it is shown that the phase shift is just the negative of the phase of a compact expression which plays the same role as the Jost function does for local potentials. It is seen that Levinson's theorem also holds for this general case. And finally, in Sec. VI, an example is given.

The analysis is restricted to the radial s wave Schrödinger equation

$$-\frac{d^2}{dr^2}\,\psi(r)+V(r)\psi(r)+\int_0^\infty U(r,r')\psi(r')dr'=k^2\psi(r), \tag{1}$$

where $\hbar=2m=1$ and $E=k^2$.

The nonlocal potential is taken to be separable,

$$U(r,r')=\sum g_i v_i(r)v_i(r'), \tag{2}$$

where $v_i(r)$ are real and well behaved, and the g_i are real constants, positive or negative. These conditions ensure that the Hamiltonian is Hermitian. Only one term in the sum will be used in the following analysis; the results are easily generalized.

The physical solution of Eq. (1) is defined by the mixed boundary conditions,

$$\psi(k,0)=0, \tag{3a}$$

and, for large r,

$$\psi(k,r)\rightarrow \tfrac{1}{2}i[e^{-ikr}-S(k)e^{ikr}], \tag{3b}$$

where $S(k)$ is the scattering matrix element which can be written in terms of the phase shift,

$$S(k)=e^{2i\delta(k)}. \tag{4}$$

In these equations, k is taken to be real positive. The usual notation of a superscript ''+'' indicating the physical solution and the corresponding Green's function is not used here since there is little likelihood of confusion. In the following, the Fredholm determinant of the physical solution, written as an integral equation, is constructed. The zeros of this determinant give the energies of solutions to the homogeneous equation and these solutions, if normalizable, are bound states. In this section the local potential is taken to be zero.

Taking the nonlocal potential to have only one term, the physical solution to the Schrödinger equation is

$$\psi(k,r)=\sin kr+\int_0^\infty ds\ K(r,s)\psi(k,s), \tag{5}$$

with kernel,

$$K(r,s)=gv(s)\int_0^\infty dr'\ G(k,r,r')v(r'), \tag{6}$$

and Green's function,

$$G(k,r,r')=-\frac{1}{k}\, e^{ikr_>}\sin kr_<, \tag{7}$$

where $r_>$ indicates the larger of r and r' while $r_<$ denotes the smaller. Note that the integral for the kernel is convergent for Im $k>0$, that is, the solutions will be analytic in the upper-half of the complex k plane. If $v(r)$ is of finite range, the solutions will also be analytic functions of k in the lower half plane while if $v(r)$ is exponentially damping, the solutions will be analytic in a strip along the real k axis in the lower half plane.

The Fredholm determinant is easily found to be

$$D(k)=1-\int_0^\infty K(r,r)dr=1-g\int_0^\infty dr\ v(r)\int_0^\infty dr'\ G(k,r,r')v(r'). \tag{8}$$

This determinant can be written in the momentum representation on the half-line using the transform

$$v(r)=\frac{2}{\pi}\int_0^\infty p\ dp\ \tilde{v}(p)\sin pr, \tag{9}$$

with

$$\tilde{v}(p)=\int_0^\infty v(r)\ \frac{\sin pr}{p}\ dr. \tag{10}$$

In the resulting integrals, it is assumed that k has a positive imaginary part so that the need for distributions is avoided. The result,

$$D(k)=1+\frac{2g}{\pi}\int_0^\infty p^2\ dp\ \frac{\tilde{v}^2(p)}{p^2-k^2}, \tag{11}$$

can be easily generalized to the sum of separable terms by replacing in the integrand,

$$g\tilde{v}^2 \Rightarrow g_1\tilde{v}_1^2(p)+g_2\tilde{v}_2^2(p)+\cdots\ . \tag{12}$$

The expression for the Fredholm determinant given in Eq. (11) is analytic in the upper half complex k plane. To evaluate $D(k)$ for real momentum values, k is taken to approach the real positive axis from above. Then,

$$D(k)=1+\frac{2g}{\pi}\ \wp\int_0^\infty p^2\ dp\ \frac{\tilde{v}^2(p)}{p^2-k^2}+igk\ \tilde{v}^2(k), \tag{13}$$

where k is real positive and $\wp$ indicates the Cauchy principal part. For the conjugate physical solution, k is taken to approach the negative real axis.

The determinant $D(k)$ will be analytic in the lower half k plane within a strip along the real axis provided $v(r)$ is exponentially damping for large r. To continue $D(k)$ into the lower half plane, the path of integration is distorted around the simple pole at k as k is moved from the upper half plane to the lower. Finally the contour of integration is pinched off as k passes into the lower half plane. The result is exactly the same as given in Eq. (11) but with the addition of the residue at the pole:

$$D(k)=1+\frac{2g}{\pi}\int_0^\infty p^2\ dp\ \frac{\tilde{v}^2(p)}{p^2-k^2}+2igk\ \tilde{v}^2(k). \tag{14}$$

It is not difficult to show that $D(k)$ given by Eq. (11) or the continuation given in Eq. (14) satisfies the condition,

$$D(k)=D^*(-k^*), \tag{15}$$

where (*) indicates complex conjugate.

For a solution of the homogeneous equation at k_0 real and positive, both the real and imaginary parts of the Fredholm determinant given in Eq. (13) must be zero,

$$1+\frac{2g}{\pi}\ \wp\int_0^\infty p^2\ dp\ \frac{\tilde{v}^2(p)}{p^2-k_0^2}=0, \tag{16a}$$

and

$$\tilde{v}^2(k_0)=0. \tag{16b}$$

Such a solution may represent a bound state in the continuous spectrum provided it is normalizable. The homogeneous equation is

$$\psi(k,r)=-\frac{g}{k}\int_0^\infty ds'\ v(s)\psi(k,s)\left[e^{ikr}\int_0^r dr'\ \sin kr' v(r')+\sin kr\int_r^\infty dr'\ e^{ikr'}\ v(r')\right]. \tag{17}$$

From Eq. (16b) it is seen that this solution is zero for $r \to \infty$. If this approach to zero is fast enough, there will be a bound state which can be written as

$$\psi(k_0, r) = C \int_0^\infty d\xi \sin k_0 \xi \ v(\xi + r), \tag{18}$$

where C is a constant. It is apparent that if $v(r)$ is of finite range or decreases exponentially, the solution will be normalizable. If $v(r)$ goes as $r^{-\alpha}$ then the wave function also goes as $r^{-\alpha}$ so that, if α is greater than 1/2, the solution will be normalizable. These normalizable wave functions represent bound states with energy embedded in the continuous spectrum.

II. THE PHASE SHIFT AND LEVINSON'S THEOREM

Levinson's theorem states that

$$\delta(0) = \pi(n + q/2), \tag{19}$$

where the phase shift $\delta(k)$ is evaluated at zero momentum, n is the number of bound states, and q is either 1 or 0 depending on whether or not a ''half bound'' state exists. There has been some disagreement in the literature on the application of this theorem to the case of nonlocal potentials which support bound states with energy embedded in the continuous spectrum. Bolsterli[3] suggests that a jump of π should be added to the phase shift at the energy of the bound state whereas Newton[4] states that the phase shift should be taken continuous. The following derivation confirms Newton's analysis.

It is not difficult to show that the t matrix is proportional to the reciprocal of the Fredholm determinant and that the Jost function is proportional to the determinant[3] with a real proportionality factor.[5] Therefore, the phase shift can be taken to be the negative phase of $D(k)$, that is,

$$D(k) = |D(k)| e^{-i\delta(k)}. \tag{20}$$

This phase shift has a discontinuity of π at k_0, the value of k associated with the bound state in the continuum. This jump of π comes about because $D(k)$ goes through zero at k_0 where the real part changes sign but not the imaginary. But the S matrix element,

$$S(k) = \frac{D^*(k)}{D(k)} = e^{2i\delta(k)}, \tag{21}$$

is continuous at k_0. There are no zeros for $D(k)$ in the upper half plane except possibly on the positive imaginary k axis. Such zeros correspond to conventional bound states with negative real energies. If the continuation to the lower half plane is possible then $D(k)$, given by Eq. (14), may also have zeros there. In the rest of the analysis, it will be assumed that $D(k)$ has a zero at k_0 which may be complex. Then it follows from Eq. (15) that $D(k)$ has a zero at $-k_0^*$, symmetrically placed with respect to the imaginary axis, and that for real k,

$$\delta(k) = -\delta(-k). \tag{22}$$

Suppose that these two zeros at k_0 and $-k_0^*$ can be moved around in the complex k plane by varying the parameters of the potential. With zeros only in the lower half plane, that is, no bound states, the following integral is zero:

$$I = \int_{-\infty}^{\infty} d \ln D(k) = \int_{-\infty}^{\infty} \frac{1}{D(k)} \frac{dD(k)}{dk} dk = 0. \tag{23}$$

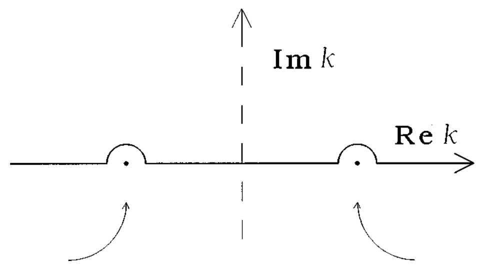

FIG. 1. Path of integration for Levinson's theorem. The zeros of $D(k)$, symmetric about the imaginary axis, approach the real axis from below.

This is readily seen by closing the contour of integration by a large semicircle in the upper half plane and letting the radius go to infinity. Doing the integral along the real axis and noting the definition of the phase shift in terms of $D(k)$, one obtains

$$\delta(0)-\delta(\infty)=0. \tag{24}$$

As usual, the phase shift for infinite wave number is taken to be zero and, since there are no zeros on the real axis, the phase shift is continuous. In the following, continuous phase shifts will be denoted by a subscript c.

Imagine how the phase shift changes when k is varied along the real axis and passes near a simple pole due to a zero of $D(k)$ in the lower half k plane. The phase shift will increase sharply but continuously through $\pi/2$. This behavior of the phase shift is usually taken to indicate a resonance at the real part of the wave number of the zero.

Now suppose that the parameters are varied such that the zeros approach the real axis from below. The path of integration is deformed around the zeros as shown in Fig. 1. It should be noted that it is not possible to have the zero pop up into the upper half k plane for Re $k>0$ and still have a Hermitian Hamiltonian. The integral is again zero as can be seen by closing the contour by a large semicircle. Assuming that the zeros are simple, one obtains

$$I=\wp\int_{-\infty}^{\infty} d\ \ln D(k)-2i\pi=2i\delta_c(0)-2\pi i, \tag{25}$$

where the $-2\pi i$ comes from the integration around the two semicircles and the principal part defines a continuous phase shift,

$$\wp\int_{-\infty}^{\infty} d\ \ln D(k)=2i\delta_c(0). \tag{26}$$

Since I given in Eq. (25) is zero, Levinson's theorem reads, for a bound state with energy embedded in the continuum,

$$\delta_c(0)=\pi, \tag{27}$$

with the phase shift defined continuously. If the zero is of order m then

$$\delta_c(0)=m\pi. \tag{28}$$

It may surprise one that the principal part defines a continuous phase shift since, for a simple pole at k_0 real and positive, the integration from 0 to k_0 will give a logarithmic singularity. But one must remember to include the integration from $-k_0$ to 0 which results in a cancellation of the logarithmic singularity and gives a continuous phase shift as k passes through k_0.

In an actual experiment, the measurement of the phase shift will be continuous since any jump of π will not affect the cross section. There appears to be nothing in the phase shift at the energy of the bound state that would signify its existence. The existence of the bound state, however, shows up in the modification of the phase shift at zero energy as described by Levinson's theorem.

III. CASE WITH AN ADDITIONAL LOCAL POTENTIAL

The basis functions to be used for the case of a local plus a nonlocal potential are the solutions of the Schrödinger equation with only the local potential. These solutions will be denoted by a subscript 0. The Fredholm determinant for the integral equation of the physical solution for the combined potentials is

$$D(k)=1-g\int dr\ dr'\ G(k,r,r')v(r)v(r'), \tag{29}$$

where the Green's function is

$$G(k,r,r')=-\frac{f_0(k,r_>)\phi_0(k,r_<)}{\mathcal{F}_0(k)}. \tag{30}$$

The Jost solution is defined by its asymptotic form for large r

$$f_0(k,r)\rightarrow e^{ikr}, \tag{31}$$

while the regular solution, $\phi_0(k,r)$, is defined such that, at the origin, the function and its first derivative are zero and one, respectively. The Jost function,

$$\mathcal{F}_0(k)=f_0(k,0), \tag{32}$$

will have zeros on the imaginary axis in the upper half complex k plane at the location of bound states of the local potential.

For reference,

$$\phi_0(k,r)=\frac{1}{2ik}\,[\mathcal{F}_0^*(k)f_0(k,r)-\mathcal{F}_0(k)f_0^*(k,r)], \tag{33}$$

for real values of k. Furthermore, the regular solution is real for real k or for purely imaginary k and, for the usual restrictions on the potential, it is regular for all k while the Jost solution is analytic in the upper half k plane. For a discussion of these properties see Newton.[6]

The nonlocal potential function $v(r)$ can be expanded in terms of the Jost solution and the regular solution of the local potential by use of the completeness relation,[7]

$$\int_C \frac{k\ dk\ \phi_0(k,r)f_0(k,r')}{\mathcal{F}_0(k)}=i\pi\delta(r-r'), \tag{34}$$

where the contour C goes along the real k axis from minus infinity, over any zeros of $\mathcal{F}_0(k)$ in the upper half plane, to plus infinity and as shown in Fig. 2. In this way the bound states of the local potential are included in the expansion.

Using the completeness relation gives

$$v(r)=\int_C \frac{p\ dp}{\mathcal{F}_0(p)}\ \phi_0(p,r)\overline{v}(p), \tag{35}$$

where

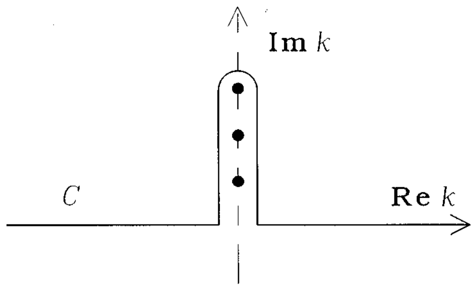

FIG. 2. Integration contour for the completeness relation. The dots on the imaginary axis represent the zeros of the Jost function.

$$\overline{v}(p)=\frac{1}{\pi i}\int_0^\infty dr\ v(r)f_0(p,r). \tag{36}$$

Substituting for $v(r)$ from Eq. (35) into $D(k)$ gives

$$D(k)=1+g\int_C \frac{p\ dp}{\mathcal{F}_0(p)}\frac{\overline{v}(p)\tilde{v}(p)}{p^2-k^2}, \tag{37}$$

where

$$\tilde{v}(p)=\int_0^\infty dr\ v(r)\phi_0(p,r). \tag{38}$$

To arrive at this result it is useful to use the relation

$$\frac{d}{dr}W[\phi_0(k_1,r),\psi_0(k_2,r)]=(k_1^2-k_2^2)\phi_0(k_1,r)\psi_0(k_2,r), \tag{39}$$

for the Wronskian, valid for any solution to the Schrödinger equation with the local potential regardless of boundary conditions.

For the particular case of no bound states of the local potential, Eq. (37) reduces to

$$D(k)=1+\frac{2g}{\pi}\int_0^\infty \frac{p^2\ dp\ \tilde{v}^2(p)}{(p^2-k^2)|\mathcal{F}_0(p)|^2}, \tag{40}$$

as given in Ref. 2.

But $D(k)$ given in Eq. (37) cannot tell the whole story since for $v(r)=0$, $D(k)=1$. This appears to say there are no bound states even if the local potential supports a bound state. Examination of the t matrix[8] suggests that for the local and nonlocal potentials combined, Eq. (37) should be modified by the overall factor $\mathcal{F}_0(k)$ on the right-hand side.

IV. GENERAL CASE WITH ALL ZEROS OF BOUND STATES CONTAINED IN $D(k)$

For the general case, one could proceed by finding the Fredholm determinant for the integral equation of the physical solution with the free particle states as the basis. But then to get an expression like Eq. (37) would require changing the basis. Rather than searching for the Fredholm determinant, it is simpler to find the Jost function for the combined potentials in the basis of the solutions of the local potentials. The integral equation for the Jost solution is

$$f(k,r)=f_0(k,r)+\int_r^\infty dr'\ G(k,r,r')\int_0^\infty ds\ U(r',s)f(k,s), \tag{41}$$

where the subscript 0 denotes solutions for the local potential. Substituting the nonlocal potential given in Eq. (2) yields

$$f(k,r)=f_0(k,r)+gI(k)\int_r^\infty dr'\ G(k,r,r')v(r'), \tag{42}$$

where

$$I(k)\equiv\int_0^\infty ds\ v(s)f_0(k,s). \tag{43}$$

The function $I(k)$ is found by multiplying Eq. (42) by $v(r)$, integrating, and then solving the resulting algebraic equation to get

$$I(k)=\frac{\int_0^\infty dr\ f_0(k,r)v(r)}{1-g\int_0^\infty dr'\ v(r')\int_{r'}^\infty dr\ v(r)G(k,r,r')}. \tag{44}$$

The Green's function that is 0 for $r'<r$ and satisfies

$$\left[-\frac{d^2}{dr^2}+V(r)-k^2\right]G(k,r,r')=-\delta(r-r') \tag{45}$$

can be constructed out of solutions of the Schrödinger equation with the local potential. One finds that

$$G(r,r',k)=-\frac{\phi_0(k,r)f_0(k,r')}{\mathcal{F}_0(k)}+\frac{\phi_0(k,r')f_0(k,r)}{\mathcal{F}_0(k)} \quad \text{for } r<r',$$

$$=0 \quad \text{for } r'<r, \tag{46}$$

which has the necessary unit step at $r=r'$ in the first derivative.

The relation given in Eq. (39) is useful for doing the integrals involving the Green's function. Again the function $v(r)$ is expanded in terms of the basis functions using the completeness relation, Eq. (34). After some straightforward manipulation it is found that

$$I(k)=\pi i\left[\overline{v}(k)\Big/\left(1+g\int_C\frac{pdp}{\mathcal{F}_0(p)}\frac{\tilde{v}(p)}{p^2-k^2}[\overline{v}(p)-\overline{v}(k)]\right)\right], \tag{47}$$

so that the Jost function, found by evaluating the Jost solution at $r=0$, is

$$\mathcal{F}(k)=\mathcal{F}_0(k)\left(1+g\int_C\frac{pdp}{\mathcal{F}_0(p)}\frac{\overline{v}(p)\tilde{v}(p)}{p^2-k^2}\right)\Big/\left(1+g\int_C\frac{pdp}{\mathcal{F}_0(k)}\frac{\tilde{v}(p)}{p^2-k^2}[\overline{v}(p)-\overline{v}(k)]\right). \tag{48}$$

It is not difficult to show that the denominator of the Jost solution on the right-hand side of Eq. (48) is the Fredholm determinant of the regular solution in the basis of the solutions for the local potential. Hence the Jost function for the general case is just the product of the Jost function for the local potential by itself times the ratio of the Fredholm determinants of the physical solution and the regular solution. For a bound state in the continuous spectrum, say at k_0, the numerator of the Jost function or equivalently $D(k)$ given in Eq. (37) must be zero. This requires that the real and imaginary parts must be separately zero, that is,

$$1+g\wp\int_C\frac{pdp}{\mathcal{F}_0(p)}\frac{\overline{v}(p)\tilde{v}(p)}{p^2-k_0^2}=0, \tag{49a}$$

and

$$\tilde{v}^2(k_0)=0. \tag{49b}$$

These conditions also imply that the denominator of the Jost function is also zero at k_0. For the Jost function, there is a jump in phase of π at k_0 for both the denominator and the numerator. Thus the Jost function is continuous at k_0 unlike the function $D(k)$.

Since the Fredholm determinant of the regular solution is real for real values of k, the denominator of the Jost function is real so that it can be dropped in calculating the S matrix element formed by the ratio $\mathcal{F}^*(k)/\mathcal{F}(k)$. This justifies using

$$D(k)=\mathcal{F}_0(k)\left[1+g\int_C \frac{p\ dp}{\mathcal{F}_0(p)}\,\frac{\overline{v(p)}\tilde{v}(p)}{p^2-k^2}\right], \tag{50}$$

for calculating the phase shift. Note that the results of Sec. II on Levinson's theorem apply here also and therefore the phase shift is taken continuous at bound states in the continuous spectrum. This compact form for $D(k)$ is the main result of this paper.

V. EXAMPLE

It is simple to arrange things so that the only effect of the nonlocal potential is to shift the energies of any bound state of the local potential. Take $v(r)$ for the nonlocal potential to be the same as one of the bound states eigenfunctions of the local potential, say at $E=k_0^2<0$. Then the contour of integration for completeness reduces to a contour around the simple pole due to the zero of $\mathcal{F}_0(k)$ at k_0. Using the linear dependence of $f_0(k,r)$ and $\phi_0(k,r)$ at a zero of $\mathcal{F}_0(k)$, one obtains

$$D(k)=\mathcal{F}_0(k)\left\{1+\frac{4ig\ k_0^2\tilde{v}^2(k_0)}{\mathcal{F}_0^*(k_0)[d\mathcal{F}_0(k)/dk]_{k_0}(k^2-k_0^2)}\right\}. \tag{51}$$

That this function is not equal to zero at k_0 can be seen by rewriting $D(k)$ as

$$D(k)=\mathcal{F}_0(k)\left[\frac{k^2+K^2-gN^2\tilde{v}^2(k_0)}{k^2+K^2}\right], \tag{52}$$

where

$$k_0=iK, \tag{53}$$

with K real and positive, and N the normalization of the regular solution of the local potential,

$$N^2\int\ dr\ \phi_0^2(k_0,r)=1. \tag{54}$$

It is apparent that the zero of $D(k)$ now appears at

$$k^2=-K^2+gN^2\tilde{v}^2(k_0), \tag{55}$$

which, for a positive g large enough, is a bound state embedded in the continuous spectrum. In a specific example studied in an earlier paper,[9] a bound state of the local potential was moved to positive energy by use of a nonlocal potential. The phase shift was found to be the negative phase of the Jost function of the local potential, that is, the term in braces in Eq. (51) was missing. The resulting cross section is the same in either case since the missing term is real. But in the earlier work, Levinson's theorem held because of the zero in the Jost function at the original energy of the bound state, as if its ghost remained. The situation described in this paper is much more satisfying.

(Received 24 June 1998; accepted for publication 28 August 1998)

Suppose that there are N electrons in a disk of radius R with a perpendicular magnetic field. We give an estimate for the ground state energy of such a system in the case $N \approx \nu R^2$. © *1999 American Institute of Physics.* [S0022-2488(99)02101-5]

I. INTRODUCTION

In the study of the fractional quantum Hall effect,[1] one considers the two-dimensional Coulomb interactions of electrons in a magnetic field. In this paper we will give an estimate for the ground state energy of such a system. Suppose that N electrons are confined to a disk of radius R. We will show that in the limit $R \to \infty$ and $N/R^2 \to \nu$, where ν is the *Landau level filling factor*, the ground state energy is on the order of $N^{3/2}$. Our result is motivated by the observation that, in the Hamiltonian for N electrons, there are $N(N-1)/2$ terms of Coulomb potentials compared with only N terms for kinetic energy. Therefore, for large N, the total energy of the system can be close to its minimum, even when the kinetic energy is not. This will be seen from the state we use to obtain the estimate $N^{3/2}$, which imposes a uniform spacing between the electrons and is considerably different from the Laughlin state.[2]

More specifically, let us consider N electrons in the plane $\mathbf{R}^2$ interacting with each other, with a randomly distributed, bounded potential, and with a constant magnetic field $\mathbf{B}$ in the perpendicular direction. In units of magnetic length $(2c\hbar/e|\mathbf{B}|)^{1/2}$ and cyclotron energy $e|\mathbf{B}|\hbar/2m_e c$, the Hamiltonian representing this system reads as

$$H_N = \sum_{j=1}^{N} \left(\frac{1}{2} D_j + Q(z_j) \right) + \lambda \sum_{1 \leq j < k \leq N} |z_j - z_k|^{-1}.$$

Here, $D_j = (-i(\partial/\partial x_j) + y_j)^2 + (-i(\partial/\partial y_j) - x_j)^2$, $z_j = (x_j, y_j) \in \mathbf{R}^2$, Q is a bounded, real-valued function, and $\lambda = (2e^3 m_e^2 c/\hbar^3 |\mathbf{B}|)^{1/2}$. Since $e^3 m_e^2 c/\hbar^3 \approx 2.43 \times 10^9$ G, the dimensionless constant λ is large under earthly conditions.

For $R > 0$, let $\Delta(N,R)$ be the polydisk $\{(z_1, \ldots, z_N) : |z_j| < R,\ j = 1,...,N\}$ in $(\mathbf{R}^2)^N$. Let $H(N,R)$ be the restriction of H_N to $\Delta(N,R)$ with the Dirichlet boundary condition. By a well-known construction[3,4] of Friedrichs, $H(N,R)$ is realized as a self-adjoint operator [which we also denote by $H(N,R)$] on a dense domain in the Hilbert space $L^2(\Delta(N,R))$. Let $\mathcal{D}_a(N,R)$ be the collection of the functions in the domain of $H(N,R)$ that are antisymmetric under the interchange of any two variables. We define

$$H_a(N,R) = H(N,R) | \mathcal{D}_a(N,R),$$

the restriction of $H(N,R)$ to $\mathcal{D}_a(N,R)$. If the electrons are confined to the disk $\{z \in \mathbf{R}^2 : |z| < R\}$, then, taking the exclusion principle into account, the more appropriate operator to consider is $H_a(N,R)$ rather than H_N.

Let $I(N,R)$ be the ground state energy of $H_a(N,R)$. That is,

[a)]jxia@acsu.buffalo.edu

$$I(N,R)=\inf\{\langle H_a(N,R)f,f\rangle : f\in\mathcal{D}_a(N,R), \|f\|=1\}.$$

A natural question concerning the operator $H_a(N,R)$ is, what is $I(N,R)$? Or, at the very least we would like to know the asymptotics of $I(N,R)$ as $R\to\infty$ and $N/R^2\to\nu$, where $\nu>0$ is the Landau level filling factor of the system under consideration. This is precisely the situation that arises in the study of the fractional quantum Hall effect (FQHE). See Ref. 1 and Sec. VII in Ref. 5.

The Dirichlet boundary condition guarantees that the operator $\Sigma_{j=1}^N D_j$ is positive. Hence, it follows that $I(N,R)\geqslant -\|Q\|_\infty N+(\lambda N(N-1)/2)\inf_{|z|<R,|w|<R}|z-w|^{-1}\geqslant -\|Q\|_\infty N+\lambda(N(N-1)/4R)$. Thus, for large R, if $N/R^2\approx\nu$, then $I(N,R)\geqslant\frac{1}{4}\lambda\sqrt{\nu}N^{3/2}-KN$ for some $0<K<\infty$, which is independent of N. That is,

$$\liminf_{\substack{R\to\infty\\ N/R^2\to\nu}} N^{-3/2}I(N,R)\geqslant 0.25\times\lambda\sqrt{\nu}.$$

Note that this lower-bound estimate for $I(N,R)$ is extremely crude; it does not even take the exclusion principle into account. What is amazing is that crude as it is, this estimate is only off by a factor of less than 4. The purpose of this paper is to report the following.

Theorem: *Suppose that* $\nu>0$. *Then*

$$\limsup_{\substack{R\to\infty\\ N/R^2\to\nu}} N^{-3/2}I(N,R)\leqslant\frac{8}{3\pi}\lambda\sqrt{\nu}=0.8488...\times\lambda\sqrt{\nu}. \tag{1}$$

A consequence of our theorem is that it sets a cap on the energy of any approximation to the ground state of the FQHE. In particular, this cap applies to the Laughlin state, which lies at the heart of the incompressible quantum fluid approach to the FQHE. Recall that the Laughlin m state for N electrons is

$$\Phi_N^m(z_1,\ldots,z_N)=\exp\left(-\sum_{j=1}^N\frac{1}{2}|z_j|^2\right)\prod_{1\leqslant j<k\leqslant N}(z_j-z_k)^m,$$

where $m>1$ is an odd integer.[1,2] This function is generally taken as an approximation to the ground state of FQHE with Landau level filling factor $1/m$. In light of our theorem, if Φ_N^m truly approximates the ground state of FQHE, then we should have

$$\limsup_{N\to\infty}\sum_{1\leqslant j<k\leqslant N}\frac{\langle|z_j-z_k|^{-1}\Phi_N^m,\Phi_N^m\rangle}{N^{3/2}\|\Phi_N^m\|^2}\leqslant\frac{8}{3\pi}\sqrt{\frac{1}{m}}. \tag{2}$$

So far, our attempts have failed to produce a proof of this. In fact, we are not even able to ascertain that the left-hand side of (2) is finite. But this seems to be an interesting problem, for it serves to test how closely Φ_N^m approximates the ground state of FQHE.

The original version of our theorem was stated as

$$\limsup_{\substack{R\to\infty\\ N/R^2\to\nu}} N^{-3/2}I(N,R)\leqslant C\lambda\sqrt{\nu}, \tag{3}$$

with a finite C that was not explicitly determined. And this was derived with a proof that involves the eigenfunctions of $D_1,\ldots,D_N$ and that is rather long and technical. Friesecke subsequently found a much simpler and shorter proof of (3). Using local gauge transformations, his proof avoids the eigenfunctions of $D_1,\ldots,D_N$ completely and circumvents several technical difficulties. More important, his use of local gauge transformations makes it possible to impose a uniform spacing between the electrons. As it turns out, with the electrons uniformly spaced, it is possible to obtain a reasonably good value for C. The proof of our theorem presented here is a refinement of

Friesecke's proof of (3). That is, by carefully tracking the various constants that appear in Friesecke's proof of (3), we are able to show that $8/3\pi$ will do for C. We thank Friesecke for the permission to use his proof of (3) here.

The proof of our theorem involves estimates that are quite technical. In order not to lose sight of the main idea, therefore, it is perhaps desirable to give a general outline before presenting the details.

Given N electrons in a disk of radius $R=O(\sqrt{N})$, we need to find a state Ψ whose total energy is $O(N^{3/2})$. If at all possible, one tries to achieve this in the form of a single Slater determinant,

$$\Psi(z_1,\ldots,z_N)=(N!)^{-1/2}\det(\varphi_i(z_j))_{i,j=1}^N.$$

The arrangement of the electrons, $\varphi_1,\ldots,\varphi_N$, are determined by the following considerations: If there is a cap on the kinetic energy of each electron, then the total kinetic energy will only be $O(N)$, which is negligible in comparison to $O(N^{3/2})$. The simplest way to obtain such a cap is to take an equally spaced lattice Γ of N points in the disk of radius R and translate a single electron state (which we call χ_β below) by the vectors in Γ. Because of the presence of the magnetic field, we also need to apply gauge transformations to the translated electron states to ensure that their kinetic energy is the same as that for χ_β, which provides the desired cap. Thus $\varphi_1,\ldots,\varphi_N$ are simply an enumeration of

$$\{U_kT_k\chi_\beta : k\in\Gamma\},$$

where T_k is the translation determined by the vector k and U_k the corresponding gauge transformation. This takes care of the kinetic part of the Hamiltonian. Since the random potential Q is assumed to be bounded, its contribution to the Hamiltonian is also $O(N)$.

To facilitate the estimate of the potential energy of Ψ, which is the dominant part, we confine the original state χ_β to a small disk so that there is no overlapping among $\varphi_1,\ldots,\varphi_N$. With such an arrangement of the electrons, when N is large, each individual electron sees a charge distribution on the disk that is approximately uniform. Accordingly, because of the $1/r$ falloff of the Coulomb potential, the potential energy attributable to each electron is on the order of

$$\int_{|z|\leqslant R}\frac{1}{|z|}\,dA(z)=O(R)=O(\sqrt{N}).$$

Hence, the total potential energy is $N\times O(\sqrt{N})=O(N^{3/2})$. By carefully working out the details of this argument, we obtain the numerical factor $8/3\pi$ in (1).

II. PROOF OF THEOREM

Throughout the proof, we let $B_r(w)$ denote the open disk $\{z\in\mathbf{R}^2 : |w-z|<r\}$ in $\mathbf{R}^2$. We start by picking an ϵ such that $0<\epsilon<\nu$. Suppose that $N\geqslant 10^6$ and R are so large that

$$N/R^2\leqslant\nu+\epsilon. \tag{4}$$

Note that $4(N^{1/6}-4)^{-1}<1$, which will be relevant later. Let $\alpha>0$ be such that

$$(N+17\sqrt{N})\alpha^2=\pi R^2. \tag{5}$$

We have $1/\alpha^2=(N/R^2)(1+17N^{-1/2})/\pi\leqslant(\nu+\epsilon)(1+17N^{-1/2})/\pi\leqslant 2\nu$.

Let η be a C^∞ function on $[0,\infty)$ such that $\eta=0$ on $[\frac{1}{3},\infty)$, $\eta=\text{const}$ on $[0,\frac{1}{4}]$, and $2\pi\int_0^\infty|\eta(r)|^2r\,dr=1$. Define $\chi(z)=\eta(|z|)$, $z\in\mathbf{R}^2$. Then $\chi(z)=0$ if $|z|\geqslant\frac{1}{3}$ and χ is a unit vector in $L^2(\mathbf{R}^2)$. Let $\beta=\min\{1,\alpha\}$ and $\chi_\beta(z)=\beta^{-1}\chi(\beta^{-1}z)$. Then $\|\chi_\beta\|=\|\chi\|=1$. Since χ_β is a radial function, we have $(y(\partial/\partial x)-x(\partial/\partial y))\chi_\beta=0$. Now $\chi_\beta(z)=0$ if $|z|\geqslant\beta/3$. Therefore $\||z|^2\chi_\beta\|\leqslant\beta^2\|\chi_\beta\|=\beta^2\leqslant 1$. Also, $(\Delta\chi_\beta)(z)=\beta^{-2}\{\beta^{-1}(\Delta\chi)(\beta^{-1}z)\}$, which implies $\|\Delta\chi_\beta\|=\beta^{-2}\|\Delta\chi\|\leqslant(1+2\nu)\|\Delta\chi\|$. Let $D=(-i(\partial/\partial x)+y)^2+(-i(\partial/\partial y)-x)^2$. Then

$$\|D\chi_\beta\|\leqslant\|\Delta\chi_\beta\|+\||z|^2\chi_\beta\|\leqslant(1+2\nu)\|\Delta\chi\|+1. \tag{6}$$

For each $k=(k_1,k_2)\in\mathbf{R}^2$, define the unitary operators

$$(T_k f)(x,y)=f(x-k_1,y-k_2) \quad \text{and} \quad (U_k f)(x,y)=e^{i(k_1y-k_2x)}f(x,y),$$

on $L^2(\mathbf{R}^2)$. If we set $D(k)=(-i(\partial/\partial x)+y-k_2)^2+(-i(\partial/\partial y)-x+k_1)^2$ for $k=(k_1,k_2)$, then it is easy to verify that $DU_k=U_kD(k)$ and $D(k)T_k=T_kD$. Thus, by (6),

$$\|DU_k\,T_k\chi_\beta\|=\|U_kD(k)T_k\chi_\beta\|=\|U_kT_k\,D\chi_\beta\|=\|D\chi_\beta\|\leqslant(1+2\nu)\|\Delta\chi\|+1. \tag{7}$$

Let

$$\Gamma=\left\{\left(\alpha i+\frac{\alpha}{2},\alpha j+\frac{\alpha}{2}\right):i,j\in\mathbf{Z},\alpha^2(i+a)^2+\alpha^2(j+b)^2<R^2 \quad \text{for all} \quad a,b\in\{0,1\}\right\}.$$

We claim that $\mathrm{Card}(\Gamma)\geqslant N$. For this purpose let N' be the number of squares of the size $\alpha\times\alpha$ with vertices of the form $(\alpha i,\alpha j)$, $i,j\in\mathbf{Z}$, which have a nonempty intersection with $\overline{B_R(0)}$, and let N'' be the number of such squares that are contained in $B_R(0)$. That is, $N''=\mathrm{Card}(\Gamma)$. If such a square intersects the circle $|z|=R$, then it is contained in the annulus $\{z\in\mathbf{R}^2:R-\sqrt{2}\alpha\leqslant|z|\leqslant R+\sqrt{2}\alpha\}$ since the diagonal of the square is $\sqrt{2}\alpha$. Hence $(N'-N'')\alpha^2\leqslant4\sqrt{2}\pi\alpha R$. That is, $N'-N''\leqslant4\sqrt{2}\pi R/\alpha\leqslant4\sqrt{2}\pi\sqrt{2N/\pi}=8\sqrt{\pi}\sqrt{N}\leqslant16\sqrt{N}$. On the other hand, $N'\alpha^2\geqslant\pi R^2=(N+17\sqrt{N})\alpha^2$. That is, $N'\geqslant N+17\sqrt{N}\geqslant N+N'-N''$. This proves that $\mathrm{Card}(\Gamma)=N''\geqslant N$.

Thus we can choose a subset $\Omega\subset\Gamma$ such that $\mathrm{Card}(\Omega)=N$. For each $k\in\Omega$, let $\psi_k=U_kT_k\chi_\beta$. Thus, each ψ_k is supported in $B_{\beta/3}(k)\subset B_{\alpha/3}(k)\subset B_R(0)$ and $\psi_k\psi_{k'}=0$ for all $k\neq k'$ in Ω. Let $\varphi_1,\ldots,\varphi_N$ be an enumeration of $\{\psi_k:k\in\Omega\}$, which is an orthonormal set. Define the Slater determinant $\Psi(z_1,\ldots,z_N)=(N!)^{-1/2}\det(\varphi_i(z_j))_{i,j=1}^N$. Since $\langle\Sigma_{j=1}^N D_j\Psi,\Psi\rangle=N\langle D_1\Psi,\Psi\rangle=N\Sigma_{\sigma\in S_N}\langle D\varphi_{\sigma(1)},\varphi_{\sigma(1)}\rangle/N!$, where S_N is the group of permutations of $\{1,...,N\}$, and since each $\varphi_{\sigma(1)}$ is some $U_kT_k\chi_\beta$, it follows from (7) that

$$\sum_{j=1}^N\langle D_j\Psi,\Psi\rangle\leqslant\{(1+2\nu)\|\Delta\chi\|+1\}N.$$

Next, we estimate the repulsive potential $Y=\Sigma_{1\leqslant i<j\leqslant N}\langle|z_i-z_j|^{-1}\Psi,\Psi\rangle$.

Clearly $Y_{ij}=\langle|z_i-z_j|^{-1}\Psi,\Psi\rangle$ is independent of the indices $i<j$. Hence $Y=N(N-1)Y_{12}/2$. Now, if σ, $\sigma'\in S_N$ are such that $\sigma(j)\neq\sigma'(j)$ for some $j>2$, then $\langle|z_1-z_2|^{-1}\varphi_{\sigma(1)}(z_1)\cdots\varphi_{\sigma(N)}(z_N),\ \varphi_{\sigma'(1)}(z_1)\cdots\varphi_{\sigma'(N)}(z_N)\rangle=0$. That is,

$$Y_{12}=\frac{1}{N!}\sum_{\sigma\in S_N}\langle|z-w|^{-1}\varphi_{\sigma(1)}(z)\varphi_{\sigma(2)}(w),\{\varphi_{\sigma(1)}(z)\varphi_{\sigma(2)}(w)-\varphi_{\sigma(2)}(z)\varphi_{\sigma(1)}(w)\}\rangle.$$

Since $\varphi_1,\ldots,\varphi_N$ are an enumeration of $\{\psi_k:k\in\Omega\}$, we can write $Y_{12}=(Z-Z')/N(N-1)$ with

$$Z=\sum_{\substack{k,k'\in\Omega\\k\neq k'}}\langle|z-w|^{-1}\psi_k(z)\psi_{k'}(w),\psi_k(z)\psi_{k'}(w)\rangle,$$

$$Z'=\sum_{\substack{k,k'\in\Omega\\k\neq k'}}\langle|z-w|^{-1}\psi_k(z)\psi_{k'}(w),\psi_{k'}(z)\psi_k(w)\rangle.$$

Now, if $k\neq k'$, then $\psi_k(z)\psi_{k'}(w)\overline{\psi_{k'}(z)\psi_k(w)}=0$ because the supports of ψ_k and $\psi_{k'}$ are disjoint. Therefore $Z'=0$. That is, $Y=N(N-1)Y_{12}/2=Z/2$. Thus, recalling that $\epsilon\in(0,\nu)$ is arbitrary, the theorem will follow once we establish

$$Z \leqslant \frac{16}{3\pi} \cdot \frac{(1+17N^{-1/2})^2}{1-4(N^{1/6}-4)^{-1}} \sqrt{\nu+\epsilon} N^{3/2} + O(N^{4/3}). \tag{8}$$

To prove (8), let $P=\{(k,k'):k,k' \in \Omega, k \neq k', |k-k'| > \alpha N^{1/6}\}$ and $L=\{(k,k'):k,k' \in \Omega, k \neq k', |k-k'| \leqslant \alpha N^{1/6}\}$. Then $Z=U+V$, where

$$U=\sum_{(k,k') \in P} \langle |z-w|^{-1} \psi_k(z)\psi_{k'}(w), \psi_k(z)\psi_{k'}(w)\rangle,$$

$$V=\sum_{(k,k') \in L} \langle |z-w|^{-1} \psi_k(z)\psi_{k'}(w), \psi_k(z)\psi_{k'}(w)\rangle.$$

For each $k \in \Omega$, if $n(k)$ is the number of k''s in Ω such that $|k-k'| \leqslant \alpha N^{1/6}$, then $n(k)\alpha^2 \leqslant \pi(2\alpha N^{1/6})^2$. That is, $n(k) \leqslant 4\pi N^{1/3}$. Thus, $\mathrm{Card}(L) \leqslant 4\pi N^{4/3}$. Now every term in V is bounded by $(3/\alpha)\cdot\beta^4\cdot(\|\chi\|_\infty/\beta)^4$. Therefore V is accounted for by the $O(N^{4/3})$ term in (8).

For each $k=(\alpha i(k)+(\alpha/2), \alpha j(k)+(\alpha/2)) \in \Omega$, where $i(k)$, $j(k) \in \mathbf{Z}$, let $\Sigma(k)$ be the $\alpha \times \alpha$ square whose vertices are $(\alpha(i(k)+a),\ \alpha(j(k)+b))$, a, $b \in \{0,1\}$. Of course, $\Sigma(k)$ contains the support of ψ_k. Suppose that $(k,k') \in P$ and (z,w), $(u,v) \in \Sigma(k)\times\Sigma(k')$. Then $|z-w| \geqslant |u-v|-4\alpha=(1-4\alpha|u-v|^{-1})|u-v| \geqslant (1-4(N^{1/6}-4)^{-1})|u-v|$. This shows that, if $(k,k') \in P$, then

$$\left\langle \frac{1}{|z-w|} \psi_k(z)\psi_{k'}(w), \psi_k(z)\psi_{k'}(w) \right\rangle \leqslant \frac{\alpha^{-4}}{1-4(N^{1/6}-4)^{-1}} \int_{\Sigma(k)} \int_{\Sigma(k')} |u-v|^{-1}\, dA(u)dA(v),$$

where dA is the area measure on $\mathbf{R}^2$. Because $\cup_{(k,k') \in P}\Sigma(k)\times\Sigma(k') \subset B_R(0)\times B_R(0)$,

$$U \leqslant \frac{\alpha^{-4}}{1-4(N^{1/6}-4)^{-1}} \int_{|z| \leqslant R} \int_{|w| \leqslant R} |z-w|^{-1}\, dA(z)dA(w) = \frac{R^3/\alpha^4}{1-4(N^{1/6}-4)^{-1}} \cdot J,$$

where

$$J=\int_{|z| \leqslant 1} \int_{|w| \leqslant 1} |z-w|^{-1}\, dA(z)dA(w).$$

It follows from (4) and (5) that $R^3/\alpha^4=(R/\alpha)^3(1/\alpha) \leqslant \pi^{-2}N^{3/2}(1+17N^{-1/2})^2\sqrt{\nu+\epsilon}$. Thus, the proof of (8) will be complete once we show that $J=16\pi/3$.

Define $f(w)=\int_{|z| \leqslant 1}|z-w|^{-1}\, dA(z)=\int_{|z+w| \leqslant 1}|z|^{-1}\, dA(z)$ for $|w| \leqslant 1$ and consider z and w also as complex variables. For $0 \leqslant r < 1$, the equation

$$\rho=-r\cos\theta+\sqrt{1-r^2\sin^2\theta}$$

describes the circle $\{z:|z+r|=1\}$ in the polar coordinates (θ,ρ). Thus

$$f(r)=\int_0^{2\pi}\int_0^{-r\cos\theta+\sqrt{1-r^2\sin^2\theta}} \frac{1}{\rho}\,\rho\, d\rho\, d\theta=4\int_0^{\pi/2}\sqrt{1-r^2\sin^2\theta}\,d\theta.$$

It is obvious that $f(w)=f(e^{it}w)$ if $t \in \mathbf{R}$. Therefore

$$J=\int_{|w| \leqslant 1} f(w)dA(w)=2\pi\int_0^1 f(r)r\, dr=8\pi\int_0^{\pi/2}\left(\int_0^1 r\sqrt{1-r^2\sin^2\theta}\,dr\right)d\theta.$$

Evaluate the double integral in the order indicated, and we obtain $J=16\pi/3$. This completes the proof of the theorem.

Rigorous application of the stochastic functional method to plane-wave scattering from a random cylindrical surface

(Received 16 March 1998; accepted for publication 2 October 1998)

The stochastic functional method is applied to plane-wave scattering from a random cylindrical surface, whereupon the Dirichlet boundary condition is rigorously imposed. Analytical results, accurate to second and fourth order in surface roughness, are obtained for the coefficients of the Wiener–Hermite expansion of the secondary scattered wave field. The validity of approximate solutions is numerically investigated by means of the boundary condition criterion and of the energy consistency criterion. The former, which is introduced herein, states that any approximate solution should be in conformity with the boundary condition, whereas the latter pertains to the energy conservation law. The numerical investigation indicates that the rigorous application of the stochastic functional method yields more accurate results in terms of both criteria than did previous treatments of the problem under consideration. Moreover, it is suggested that applicability limits should be set through the mean boundary condition criterion instead of the energy consistency criterion; the latter may lead to underestimating deficiencies of the approximate solution under test.
[S0022-2488(99)02401-9]

I. INTRODUCTION

Several studies of wave scattering from random surfaces were lately based on the stochastic functional method,[1–6] which may be summarized as follows. The scattering surface is represented by a homogeneous, Gaussian random field; the scattered wave field is regarded as a nonlinear stochastic functional of surface roughness and it is expanded into a series of orthogonal Wiener–Hermite (WH) functionals by application of the Cameron–Martin theorem[7] and extensions thereof.[8,9] The expansion coefficients are determined through an approximation of the boundary condition that is imposed upon the random surface. By use of the orthogonality properties of the WH functionals, the approximate boundary condition is transformed into a set of linear deterministic equations that yields the expansion coefficients. Algebraic manipulations are greatly facilitated via a group-theoretic consideration of the stochastic homogeneity of surface roughness, which accounts for the symmetries of the scattered wave field.[5]

Previous applications of the stochastic functional method include studies of wave scattering from a random planar surface,[1–3] as well as from a random cylindrical[4] or spherical[5] surface; a detailed list of pertinent references can be found in Ref. 6. Thus far, the expansion coefficients have been determined through a first-order approximation of the boundary condition and, as a rule, the accuracy of the resulting solution has been evaluated through tests of energy consistency.

In the present paper, it is shown that the expansion coefficients can be more accurately determined, should the boundary condition be rigorously imposed on the random surface. The application of the stochastic functional method presented herein makes use of the complete Taylor series expansion of the boundary condition; the truncation of that series is deferred until the

[a]Electronic mail: dpchriss@vergina.eng.auth.gr

formulation of a hierarchical set of linear equations for the expansion coefficients. The resulting second- and fourth-order approximations of that set of equations include terms that would have been unnecessarily discarded otherwise and they yield more accurate expressions for the expansion coefficients.

Moreover, it is argued that energy conservation may not always be an adequate criterion for the validity of approximate solutions under test. Apart from energy consistency, conformity with the boundary condition on the random surface should be examined. To this end, a boundary condition test, which consists in numerically investigating whether the mean field satisfies the boundary condition on the random surface, is introduced herein; conformity of higher-order statistical moments of the field with the boundary condition could also be investigated.

The above are applied to the two-dimensional problem of plane-wave scattering from a random cylindrical surface, whereupon the Dirichlet boundary condition is imposed; other scattering surfaces and boundary conditions could also be treated, yet more complicated cases are deferred to future work. The numerical results indicate that the approximate solutions obtained by use of the rigorous application of the stochastic functional method are more accurate than those of a previous treatment of the problem in hand,[4] both in terms of the boundary condition criterion and of the energy consistency criterion. Furthermore, it is seen that the limits of validity should be set by means of the boundary condition criterion instead of the energy consistency criterion; the latter may lead to underestimating the inherent error of the approximate solution under test.

The paper is organized as follows: in Sec. II we deal with the analytical formulation of the stochastic functional method, second- and fourth-order approximations of the expansion coefficients are obtained in Sec. III, expressions for the characteristics of farfield scatter are determined in Sec. IV, and a numerical application is presented in Sec. V.

II. ANALYTICAL FORMULATION

A. Homogeneous random circular surface

A two-dimensional (2-D) random rough surface S, circular in the mean and centered at the origin O of a cylindrical coordinate system $(O;r\theta)$ (Fig. 1), is considered. S may be described by the equation $r_s=a+f(\theta,\omega)$, where a stands for the mean radius and $f(\theta,\omega)$ is a zero-mean random field on the circle S_2; the parameter $\omega\in\Omega$, denoting a sample point in the space Ω, will be suppressed from this point onward. Assuming that $f(\theta)$ is a homogeneous Gaussian random field, the following spectral representation can be written:[4]

$$f(\theta)=\sum_{n=-\infty}^{\infty} e^{in\theta}F_nB_n; \tag{1}$$

$\{B_n,n\in Z\}$ is a set of zero-mean, mutually orthogonal, Gaussian random variables; orthogonality suggests that $\langle\overline{B_m}B_n\rangle=\delta_{m,n}$, the overbar implying the complex conjugate; $\delta_{m,n}$ is the Kronecker delta. Since $f(\theta)$ is real valued, $B_{-n}=\overline{B_n}$ and $F_{-n}=\overline{F_n}$. As can be verified from the corresponding spectral representation of the correlation function,

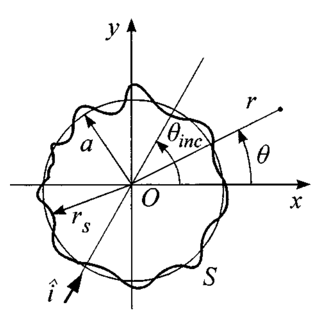

FIG. 1. Geometric configuration.

$$R(\theta_1,\theta_2)=\langle f(\theta_1)f(\theta_2)\rangle=\sum_{n=-\infty}^{\infty}|F_n|^2 e^{in(\theta_1-\theta_2)}, \tag{2}$$

the coefficients F_n of (1), actually the squared magnitude thereof, constitute the power spectrum of $f(\theta)$. Accordingly, the variance σ^2 of the roughness of the random surface S can be expressed as follows:

$$\sigma^2=\langle f^2(\theta)\rangle=\sum_{n=-\infty}^{\infty}|F_n|^2. \tag{3}$$

B. Wave field expressions

A random wave field $\psi(kr,\theta)$ outside S (i.e., for $r\geqslant r_s$) is a solution to the 2-D Helmholtz equation,

$$(\nabla^2+k^2)\psi(kr,\theta)=0, \tag{4}$$

where k stands for the wave number. By use of the shorthand notation $\rho=kr$, a boundary condition of the Dirichlet type on S is expressed as follows:

$$\psi(\rho,\theta)|_{\rho=\rho_s=kr_s}=0. \tag{5}$$

The wave field $\psi=\psi^{\text{inc}}+\psi^{\text{sca}}$ consists of two terms, which represent the incident and the scattered wave field, respectively. If excitation by a plane wave, propagated along the direction $\hat{i}=\hat{x}\cos\theta_{\text{inc}}+\hat{y}\sin\theta_{\text{inc}}$ (Fig. 1), is considered, ψ^{inc} can be written as follows:

$$\psi^{\text{inc}}(\rho,\theta)=\sum_{m=-\infty}^{\infty} i^m \psi_m^{\text{inc}}(\rho,\theta)e^{-im\theta_{\text{inc}}}, \tag{6}$$

where $\psi_m^{\text{inc}}(\rho,\theta)=J_m(\rho)e^{im\theta}$ is the mth-order cylindrical wave function and $J_m(\cdot)$ is the mth-order cylindrical Bessel function of the first kind.[10] A similar expression can be written for the scattered wave field:

$$\psi^{\text{sca}}(\rho,\theta)=\sum_{m=-\infty}^{\infty} i^m \psi_m^{\text{sca}}(\rho,\theta)e^{-im\theta_{\text{inc}}}; \tag{7}$$

(6) and (7) imply that ψ_m^{inc} gives rise to ψ_m^{sca}. Such simple coupling between excitation and scatter results from the statistical homogeneity of the random surface S; a proof, based on group-theoretic considerations, may be found in Ref. 4. The mth-order term of the scattered wave field, $\psi_m^{\text{sca}}={}_{(p)}\psi_m^{\text{sca}}+{}_{(s)}\psi_m^{\text{sca}}$, consists of two terms, which are referred to as the primary and the secondary wave. On the one hand, the primary wave ${}_{(p)}\psi_m^{\text{sca}}$ corresponds to unperturbed scatter from a smooth cylindrical surface of radius a, and it is expressed as follows:

$${}_{(p)}\psi_m^{\text{sca}}(\rho,\theta)=a_m^0 H_m^{(1)}(\rho)e^{im\theta}, \tag{8}$$

$a_m^0=-J_m(\rho_0)/H_m^{(1)}(\rho_0)$, $\rho_0=ka$, and $H_m^{(1)}(\cdot)$ is the mth-order cylindrical Hankel function of the first kind.[10] On the other hand, the secondary wave ${}_{(s)}\psi_m^{\text{sca}}$ incorporates the effect of surface roughness, and it can be regarded as a nonlinear functional of the random surface S. By use of the Cameron–Martin theorem,[7–9] ${}_{(s)}\psi_m^{\text{sca}}$ can be expanded in a series of complex, orthogonal, n-variate, Wiener–Hermite (WH) functionals $\hat{H}_n$ of the complex Gaussian random sequence B_n,[4,11]

$$ {}_{(s)}\psi_m^{\text{sca}}(\rho,\theta)=\sum_{n=0}^{\infty}\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}\cdots\sum_{j_n=-\infty}^{\infty}A_m^n(j_1,j_2,\ldots,j_n)H^{(1)}_{m+j_1+j_2+\cdots+j_n}(\rho) \times e^{i(m+j_1+j_2+\cdots+j_n)\theta}\hat{H}_n(B_{j_1},B_{j_2},\ldots,B_{j_n}), \tag{9} $$

where $\hat{H}_n$ are defined by

$$ \hat{H}_0=1,\quad \hat{H}_1(B_{j_1})=B_{j_1},\quad \hat{H}_2(B_{j_1},B_{j_2})=B_{j_1}B_{j_2}-\delta_{-j_1,j_2}, \tag{10} $$

and the recurrence relation:

$$ \hat{H}_{n+1}(B_{j_1},B_{j_2},\ldots,B_{j_{n+1}})=\hat{H}_1(B_{j_1})\hat{H}_n(B_{j_2},\ldots,B_{j_{n+1}}) -\sum_{k=2}^{n}\hat{H}_{n-1}(B_{j_2},\ldots,B_{j_{k-1}},B_{j_{k+1}},\ldots,B_{j_n})\,\delta_{-j_1,j_k}. \tag{11} $$

The cylindrical wave function $H^{(1)}_{m+j_1+j_2+\cdots+j_n}(\rho)e^{i(m+j_1+j_2+\cdots+j_n)\theta}$ satisfies the 2-D Helmholtz equation as well as the radiation condition at infinity; hence, so does ${}_{(s)}\psi_m^{\text{sca}}$, as expanded in (9). A_m^n are deterministic n-variate coefficients, which are symmetric with respect to their arguments; these coefficients are determined in Sec. III by application of the Dirichlet boundary condition on S.

III. CALCULATION OF THE EXPANSION COEFFICIENTS

A. Taylor series expansion of boundary condition

The first step toward the determination of A_m^n is taken by expanding the left-hand side of (5) into a Taylor series around the point $\rho=\rho_0$:

$$ \sum_{p=0}^{\infty}\frac{1}{p!}\,k^p f^p(\theta)\,\psi^{(p)}(\rho,\theta)\big|_{\rho=\rho_0}=0\,. \tag{12} $$

The abbreviation $\psi^{(p)}=\partial^p\psi/\partial\rho^p$ has been used in (12). By use of (6)–(9), (12) yields

$$ \sum_{p=1}^{\infty}\frac{1}{p!}\,k^p W_m{}^{(p)}(\rho_0)\sum_{n_1=-\infty}^{\infty}\sum_{n_2=-\infty}^{\infty}\cdots\sum_{n_p=-\infty}^{\infty}e^{i(n_1+n_2+\cdots+n_p)\theta}\prod_{i=1}^{p}F_{n_i}\hat{H}_1(B_{n_i}) + \sum_{n=0}^{\infty}\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}\cdots\sum_{j_n=-\infty}^{\infty}A_m^n(j_1,j_2,\ldots,j_n)e^{i(j_1+j_2+\cdots+j_n)\theta}\hat{H}_n(B_{j_1},B_{j_2},\ldots,B_{j_n}) \times\Bigg[H^{(1)}_{m+j_1+j_2+\cdots+j_n}(\rho_0)+\sum_{p=1}^{\infty}\frac{1}{p!}\,k^p(H^{(1)}_{m+j_1+j_2+\cdots+j_n})^{(p)}(\rho_0) \times\sum_{n_1=-\infty}^{\infty}\sum_{n_2=-\infty}^{\infty}\cdots\sum_{n_p=-\infty}^{\infty}e^{i(n_1+n_2+\cdots+n_p)\theta}\prod_{i=1}^{p}F_{n_i}\hat{H}_1(B_{n_i})\Bigg]=0, \tag{13} $$

where $W_m=J_m+a_m^0H_m^{(1)}$. It should be pointed out that in the present paper the complete Taylor series expansion of the boundary condition is used instead of the first-order approximation thereof, which was used in the previous treatment of this problem[4] as well as in other applications of the stochastic functional method.[1–3,5,6] The truncation of the infinite Taylor series is postponed until the formulation of a hierarchical set of equations for A_m^n. As shown in Sec. V, this approach results in more accurate expressions for the expansion coefficients.

B. Hierarchy of equations

Linear equations for A_m^n can be obtained from (13) by multiplying both sides by $\overline{\hat{H}_l(B_{k_1},B_{k_2},\ldots,B_{k_l})}$, where $l=0,1,\ldots$, and averaging over Ω. Use is then made of the following formula for the expectation value of a product of WH functionals:[11]

$$\langle \hat{H}_{n_1}(B_{j_1},\ldots,B_{j_{n_1}})\hat{H}_{n_2}(B_{j_{n_1+1}},\ldots,B_{j_{n_1+n_2}})\cdots\overline{\hat{H}_{n_m}(B_{j_{n_1+\ldots+n_{m-1}+1}},\ldots,B_{j_{n_1+\ldots+n_m}})}\rangle$$
$$=\begin{cases}\displaystyle\sum_{\substack{\text{distinct}\\ \text{exogamous}\\ \text{pairs}}}\prod_{\substack{\text{exogamous}\\ \text{pairs}}}\delta_{-j_k,j_l}, & \text{if } (n_1+n_2+\cdots+n_m) \text{ is } \begin{cases}\text{even,}\\ \text{odd.}\end{cases}\\ 0 \end{cases} \tag{14}$$

Each one of δ_{-j_k,j_l} on the right-hand side of (14) has an exogamous pair of indices, which means that j_k,j_l do not originate from the same $\hat{H}$ function; if either of j_k,j_l originates from an $\overline{\hat{H}}$ function, δ_{j_k,j_l}, instead of δ_{-j_k,j_l}, should be used. The indices $j_1,j_2,\ldots,j_{n_1+\ldots+n_m}$ are used once in any product of Kronecker deltas, and the summation is taken over all possible arrangements of all indices into distinct exogamous pairs. According to these constraints, $\langle \hat{H}_1(B_{j_1})\overline{\hat{H}_1(B_{j_2})}\hat{H}_2(B_{j_3},B_{j_4})\rangle$ is equal to $\delta_{-j_1,j_3}\delta_{-j_2,j_4}+\delta_{-j_1,j_4}\delta_{-j_2,j_3}$, whereas $\langle \hat{H}_1(B_{j_1})\hat{H}_1(B_{j_2})\hat{H}_2(B_{j_3},B_{j_4})\rangle$ equals $\delta_{j_1,j_3}\delta_{j_2,j_4}+\delta_{j_1,j_4}\delta_{j_2,j_3}$.

C. Second-order approximation

Approximate expressions for A_m^n, accurate to $O((k\sigma)^2)$, are determined next. Since, as suggested by (3), $kF_j=O(k\sigma)$, the triad of equations obtained for $l=0,\ 1,\ 2$ is the following:

$$\frac{1}{2}(k\sigma)^2W_m^{(2)}(\rho_0)+A_m^0H_m^{(1)}(\rho_0)+\sum_{j_1=-\infty}^{\infty}k\overline{F_{j_1}}A_m^1(j_1)(H_{m+j_1}^{(1)})^{(1)}(\rho_0)=0, \tag{15a}$$

$$kF_{k_1}W_m^{(1)}(\rho_0)+A_m^1(k_1)H_{m+k_1}^{(1)}(\rho_0)=0, \tag{15b}$$

$$k^2F_{k_1}F_{k_2}W_m^{(2)}(\rho_0)+kF_{k_2}A_m^1(k_1)(H_{m+k_1}^{(1)})^{(1)}(\rho_0)+kF_{k_1}A_m^1(k_2)(H_{m+k_2}^{(1)})^{(1)}(\rho_0)$$
$$+2A_m^2(k_1,k_2)H_{m+k_1+k_2}^{(1)}(\rho_0)=0. \tag{15c}$$

The second-order approximations to A_m^n are readily obtained from (15),

$$A_m^0=-(k\sigma)^2\frac{W_m^{(2)}(\rho_0)}{2H_m^{(1)}(\rho_0)}+\frac{W_m^{(1)}(\rho_0)}{H_m^{(1)}(\rho_0)}\sum_{j_1=-\infty}^{\infty}|kF_{j_1}|^2\frac{(H_{m+j_1}^{(1)})^{(1)}(\rho_0)}{H_{m+j_1}^{(1)}(\rho_0)}, \tag{16a}$$

$$A_m^1(j_1)=-kF_{j_1}\frac{W_m^{(1)}(\rho_0)}{H_{m+j_1}^{(1)}(\rho_0)}, \tag{16b}$$

$$A_m^2(j_1,j_2)=-k^2F_{j_1}F_{j_2}$$
$$\times\frac{\left(W_m^2(\rho_0)-\frac{(H_{m+j_1}^{(1)})^{(1)}(\rho_0)}{H_{m+j_1}^{(1)}(\rho_0)}W_m^{(1)}(\rho_0)-\frac{(H_{m+j_2}^{(1)})^{(1)}(\rho_0)}{H_{m+j_2}^{(1)}(\rho_0)}W_m^{(1)}(\rho_0)\right)}{2H_{m+j_1+j_2}^{(1)}(\rho_0)}, \tag{16c}$$

and, evidently, $A_m^n = 0$, if $n \geqslant 3$. The expressions of (16) are identical to those obtained through the single-scattering approximation of the previous treatment of this problem,[4] apart from the first term on the right-hand side of (16a), which does not appear in the corresponding result of Ref. 4; this is due to the first-order approximation of the boundary condition used therein. Furthermore, it should be noted that Eqs. (15) were obtained with the *a priori* assumptions $A_m^0 = O((k\sigma)^2)$ and $A_m^n = O((k\sigma)^n)$, $n \geqslant 1$, which are *a posteriori* justified by the results of (16).

D. Fourth-order approximation

A similar procedure yields fourth-order approximations to A_m^n. The tetrad of equations obtained for $l = 0, 1, 2, 3$ is given below:

$$\begin{aligned}
&\tfrac{1}{2}(k\sigma)^2 W_m^{(2)}(\rho_0) + \tfrac{1}{8}(k\sigma)^4 W_m^{(4)}(\rho_0) + A_m^0[H_m^{(1)}(\rho_0) + \tfrac{1}{2}(k\sigma)^2 (H_m^{(1)})^{(2)}(\rho_0)]\\
&\quad + \sum_{j_1=-\infty}^{\infty} k\overline{F_{j_1}} A_m^1(j_1)((H_{m+j_1}^{(1)})^{(1)}(\rho_0) + \tfrac{1}{2}(k\sigma)^2 (H_{m+j_1}^{(1)})^{(3)}(\rho_0))\\
&\quad + \sum_{j_1=-\infty}^{\infty} \sum_{j_2=-\infty}^{\infty} k^2 \overline{F_{j_1} F_{j_2}} A_m^2(j_1, j_2)(H_{m+j_1+j_2}^{(1)})^{(2)}(\rho_0) = 0,
\end{aligned} \tag{17a}$$

$$\begin{aligned}
&kF_{k_1}[W_m^{(1)}(\rho_0) + \tfrac{1}{2}(k\sigma)^2 W_m^{(3)}(\rho_0)] + kF_{k_1} A_m^0 H_m^{(1)}(\rho_0) + A_m^1(k_1)[H_{m+k_1}^{(1)}(\rho_0)\\
&\quad + \tfrac{1}{2}(k\sigma)^2 (H_{m+k_1}^{(1)})^{(2)}(\rho_0)] + \sum_{j_1=-\infty}^{\infty} k\overline{F_{j_1}}[kF_{k_1} A_m^1(j_1)(H_{m+j_1}^{(1)})^{(2)}(\rho_0)\\
&\quad + 2A_m^2(k_1, j_1)(H_{m+k_1+j_1}^{(1)})^{(1)}(\rho_0)] = 0,
\end{aligned} \tag{17b}$$

$$\begin{aligned}
&k^2 F_{k_1} F_{k_2}[W_m^{(2)}(\rho_0) + \tfrac{1}{2}(k\sigma)^2 W_m^{(4)}(\rho_0) + A_m^0 (H_m^{(1)})^{(2)}(\rho_0)] + kF_{k_2} A_m^1(k_1)[(H_{m+k_1}^{(1)})^{(1)}(\rho_0)\\
&\quad + \tfrac{1}{2}(k\sigma)^2 (H_{m+k_1}^{(1)})^{(3)}(\rho_0)] + kF_{k_1} A_m^1(k_2)[(H_{m+k_2}^{(1)})^{(1)}(\rho_0) + \tfrac{1}{2}(k\sigma)^2 (H_{m+k_2}^{(1)})^{(3)}(\rho_0)]\\
&\quad + \sum_{j_1=-\infty}^{\infty} k^3 F_{k_1} F_{k_2} \overline{F_{j_1}} A_m^1(j_1)(H_{m+j_1}^{(1)})^{(3)}(\rho_0) + 2A_m^2(k_1, k_2)[H_{m+k_1+k_2}^{(1)}(\rho_0)\\
&\quad + \tfrac{1}{2}(k\sigma)^2 (H_{m+k_1+k_2}^{(1)})^{(2)}(\rho_0)] + 2\sum_{j_1=-\infty}^{\infty} k^2 F_{k_2} \overline{F_{j_1}} A_m^2(k_1, j_1)(H_{m+k_1+j_1}^{(1)})^{(2)}(\rho_0)\\
&\quad + 2\sum_{j_1=-\infty}^{\infty} k^2 F_{k_1} \overline{F_{j_1}} A_m^2(k_2, j_1)(H_{m+k_2+j_1}^{(1)})^{(2)}(\rho_0) + 6\sum_{j_1=-\infty}^{\infty} k\overline{F_{j_1}} A_m^3(k_1, k_2, j_1)\\
&\quad \times (H_{m+k_1+k_2+j_1}^{(1)})^{(1)}(\rho_0) = 0,
\end{aligned} \tag{17c}$$

$$\begin{aligned}
&k^3 F_{k_1} F_{k_2} F_{k_3} W_m^{(3)}(\rho_0) + k^2 F_{k_2} F_{k_3} A_m^1(k_1)(H_{m+k_1}^{(1)})^{(2)}(\rho_0) + k^2 F_{k_1} F_{k_3} A_m^1(k_2)(H_{m+k_2}^{(1)})^{(2)}(\rho_0)\\
&\quad + k^2 F_{k_1} F_{k_2} A_m^1(k_3)(H_{m+k_3}^{(1)})^{(2)}(\rho_0) + 2kF_{k_1} A_m^2(k_2, k_3)(H_{m+k_2+k_3}^{(1)})^{(1)}(\rho_0) + 2kF_{k_2} A_m^2(k_1, k_3)\\
&\quad \times (H_{m+k_1+k_3}^{(1)})^{(1)}(\rho_0) + 2kF_{k_3} A_m^2(k_1, k_2)(H_{m+k_1+k_2}^{(1)})^{(1)}(\rho_0) + 6A_m^3(k_1, k_2, k_3)\\
&\quad \times H_{m+k_1+k_2+k_3}^{(1)}(\rho_0) = 0.
\end{aligned} \tag{17d}$$

Elimination of A_m^0 and A_m^3 from (17a) and (17d), respectively, yields an infinite set of linear equations for A_m^1 and A_m^2:

$$\sum_{j_1=-\infty}^{\infty}\left[C_1(j_1;m,k_1)A_m^1(j_1)+\sum_{j_2=-\infty}^{\infty}C_2(j_1,j_2;m,k_1)A_m^2(j_1,j_2)\right]=B_1(m,k_1), \tag{18a}$$

$$\sum_{j_1=-\infty}^{\infty}\left[C_3(j_1;m,k_1,k_2)A_m^1(j_1)+\sum_{j_2=-\infty}^{\infty}C_4(j_1,j_2;m,k_1,k_2)A_m^2(j_1,j_2)\right]=B_2(m,k_1,k_2). \tag{18b}$$

The following abbreviations are used in (18):

$$\begin{aligned}C_1(j_1;m,k_1)=&\delta_{j_1,k_1}[H_{m+k_1}^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_{m+k_1}^{(1)})^{(2)}(\rho_0)][H_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]\\&-k^2F_{k_1}\overline{F_{j_1}}[(H_{m+j_1}^{(1)})^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_{m+j_1}^{(1)})^{(3)}(\rho_0)](H_m^{(1)})^{(1)}(\rho_0)\\&+k^2F_{k_1}\overline{F_{j_1}}[H_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)](H_{m+j_1}^{(1)})^{(2)}(\rho_0),\end{aligned} \tag{19a}$$

$$\begin{aligned}C_2(j_1,j_2;m,k_1)=&2\delta_{j_2,k_1}k\overline{F_{j_1}}(H_{m+j_1+j_2}^{(1)})^{(1)}(\rho_0)[H_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]\\&-k^3F_{k_1}\overline{F_{j_1}F_{j_2}}(H_{m+j_1+j_2}^{(1)})^{(2)}(\rho_0)(H_m^{(1)})^{(1)}(\rho_0),\end{aligned} \tag{19b}$$

$$\begin{aligned}C_3(j_1;m,k_1,k_2)=&k(F_{k_2}\delta_{j_1,k_1}+F_{k_1}\delta_{j_1,k_2})[H_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]\\&\times\left[(H_{m+j_1}^{(1)})^{(1)}(\rho_0)-(H_{m+j_1}^{(1)})^{(2)}(\rho_0)\sum_{j=-\infty}^{\infty}|kF_j|^2\frac{(H_{m+k_1+k_2+j}^{(1)})^{(1)}(\rho_0)}{H_{m+k_1+k_2+j}^{(1)}(\rho_0)}\right.\\&\left.+\frac{1}{2}(k\sigma)^2(H_{m+j_1}^{(1)})^{(3)}(\rho_0)\right]-k^3F_{k_1}F_{k_2}\overline{F_{j_1}}(H_m^{(1)})^{(2)}(\rho_0)\\&\times[(H_{m+j_1}^{(1)})^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_{m+j_1}^{(1)})^{(3)}(\rho_0)]+k^3F_{k_1}F_{k_2}\overline{F_{j_1}}[H_m^{(1)}(\rho_0)\\&+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]\\&\times\left[(H_{m+j_1}^{(1)})^{(3)}(\rho_0)-(H_{m+j_1}^{(1)})^{(2)}(\rho_0)\frac{(H_{m+k_1+k_2+j_1}^{(1)})^{(1)}(\rho_0)}{H_{m+k_1+k_2+j_1}^{(1)}(\rho_0)}\right],\end{aligned} \tag{19c}$$

$$\begin{aligned}&C_4(j_1,j_2;m,k_1,k_2)\\&=2\delta_{j_1,k_1}\delta_{j_2,k_2}[H_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]\\&\times\left[H_{m+k_1+k_2}^{(1)}(\rho_0)-(H_{m+k_1+k_2}^{(1)})^{(1)}(\rho_0)\sum_{j=-\infty}^{\infty}|kF_j|^2\frac{(H_{m+k_1+k_2+j}^{(1)})^{(1)}(\rho_0)}{H_{m+k_1+k_2+j}^{(1)}(\rho_0)}\right.\\&\left.+\frac{1}{2}(k\sigma)^2(H_{m+k_1+k_2}^{(1)})^{(2)}(\rho_0)\right]+2k^2\overline{F_{j_1}}(F_{k_2}\delta_{j_2,k_1}+F_{k_1}\delta_{j_2,k_2})\\&\times\left[H_m^{(1)}(\rho_0)+\frac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)\right]\\&\times\left[(H_{m+j_1+j_2}^{(1)})^{(2)}(\rho_0)-(H_{m+j_1+j_2}^{(1)})^{(1)}(\rho_0)\frac{(H_{m+k_1+k_2+j_1}^{(1)})^{(1)}(\rho_0)}{H_{m+k_1+k_2+j_1}^{(1)}(\rho_0)}\right]\\&-k^4F_{k_1}F_{k_2}\overline{F_{j_1}F_{j_2}}(H_m^{(1)})^{(2)}(\rho_0)(H_{m+j_1+j_2}^{(1)})^{(2)}(\rho_0),\end{aligned} \tag{19d}$$

$$B_1(m,k_1)=-kF_{k_1}[W_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2W_m^{(3)}(\rho_0)][H_m^{(1)}(\rho_0)+\tfrac{1}{2}(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]$$
$$+\tfrac{1}{2}(k\sigma)^2kF_{k_1}(H_m^{(1)})^{(1)}(\rho_0)[W_m^{(2)}(\rho_0)+\tfrac{1}{4}(k\sigma)^2W_m^{(4)}(\rho_0)], \tag{20a}$$

$$B_2(m,k_1,k_2)=-k^2F_{k_1}F_{k_2}[H_m^{(1)}(\rho_0)+\tfrac{1}{2}\,(k\sigma)^2(H_m^{(1)})^{(2)}(\rho_0)]$$
$$\times\left[W_m^{(2)}(\rho_0)-W_m^{(3)}(\rho_0)\sum_{j=-\infty}^{\infty}|kF_j|^2\,\frac{(H^{(1)}_{m+k_1+k_2+j})^{(1)}(\rho_0)}{H^{(1)}_{m+k_1+k_2+j}(\rho_0)}\right.$$
$$\left.+\frac{1}{2}\,(k\sigma)^2W_m^{(4)}(\rho_0)\right]+\tfrac{1}{2}(k\sigma)^2k^2F_{k_1}F_{k_2}(H_m^{(1)})^{(2)}(\rho_0)[W_m^{(2)}(\rho_0)$$
$$+\tfrac{1}{4}(k\sigma)^2W_m^{(4)}(\rho_0)]. \tag{20b}$$

The set of (18) may be solved by truncation of the infinite summations and numerical inversion. Let M be the appropriate truncation number; the choice of M is discussed in Sec. V. Since the coefficients $A_m^2(j_1,j_2)$ are symmetric with respect to j_1,j_2, there are $(2M+1)(M+2)$ unknowns in (18) with j_1 and j_2 varying in the range $[-M,M]$ and $[-M,j_1]$, respectively. A set of $(2M+1)(M+2)$ equations can be obtained by allowing k_1 to vary in the range $[-M,M]$ and k_2 to vary in the range $[-M,k_1]$. This set yields $A_m^1(j_1)$ and $A_m^2(j_1,j_2)$ for $j_1,j_2\in[-M,M]$.

IV. CHARACTERISTICS OF FARFIELD SCATTER

A. Scattering amplitude

The scattered wave field far from the origin of coordinates (i.e., for $\rho\gg1$), is usually expressed as a diverging cylindrical wave $\psi^{\mathrm{sca}}(\rho,\theta)=e^{i\rho}\Phi(\theta)/\sqrt{\rho}$. The direction-dependent factor,

$$\Phi(\theta)=\sqrt{\frac{2}{\pi i}}\sum_{m=-\infty}^{\infty}e^{im\theta}\left(a_m^0+\sum_{n=0}^{\infty}\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}\cdots\sum_{j_n=-\infty}^{\infty}A_m^n(j_1,j_2,\ldots,j_n)\right.$$
$$\left.\times\frac{e^{i(j_1+j_2+\cdots+j_n)\theta}}{i^{(j_1+j_2+\cdots+j_n)}}\,\hat{H}_n(B_{j_1},B_{j_2},\ldots,B_{j_n})\right) \tag{21}$$

is the scattering amplitude, which is given above for $\theta_{\mathrm{inc}}=0$; this assumption implies that incidence is along the x axis (Fig. 1), and it has no effect on generality whatsoever.

B. Coherent scattering

The coherent part of the scattering amplitude $\langle\Phi(\theta)\rangle$ can be obtained from (21) by averaging

$$\langle\Phi(\theta)\rangle=\sqrt{\frac{2}{\pi i}}\sum_{m=-\infty}^{\infty}e^{im\theta}(a_m^0+A_m^0). \tag{22}$$

The coherent differential scattering cross section is defined as $\sigma_c(\theta)=|\langle\Phi(\theta)\rangle|^2$ and, if integrated with respect to θ in the range $[0,\pi]$, it yields the coherent scattering cross section:

$$\sigma_c=4\sum_{m=-\infty}^{\infty}|a_m^0+A_m^0|^2. \tag{23}$$

C. Incoherent scattering

The incoherent differential scattering cross section is defined as $\sigma_{ic}(\theta)=\langle|\Phi(\theta)|^2\rangle-|\langle\Phi(\theta)\rangle|^2$ and, by use of (21), the following expression can be obtained:

$$\sigma_{ic}(\theta)=\frac{2}{\pi}\sum_{n=1}^{\infty} n!\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}\cdots\sum_{j_n=-\infty}^{\infty}\left|\sum_{m=-\infty}^{\infty} A_m^n(j_1,j_2,\ldots,j_n)e^{im\theta}\right|^2. \tag{24}$$

Integration of (24) with respect to θ in the range $[0,\pi]$ yields the incoherent scattering cross section:

$$\sigma_{ic}=4\sum_{m=-\infty}^{\infty}\sum_{n=1}^{\infty} n!\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}\cdots\sum_{j_n=-\infty}^{\infty}|A_m^n(j_1,j_2,\ldots,j_n)|^2. \tag{25}$$

V. NUMERICAL RESULTS

The numerical results are aimed at investigating the accuracy and applicability of the second- and fourth-order solutions obtained in Sec. III; these solutions are compared to those obtained in a previous treatment of the problem under consideration.[4] The validity of approximate solutions is tested by means of the following two criteria: first, that any approximate solution should be in conformity with the boundary condition and, second, that it should be energy consistent. All calculations make use of the following coefficients:

$$|F_n|^2=\sigma^2\left(e^{-K^2n^2/2}\bigg/\sum_{n=-\infty}^{\infty} e^{-K^2n^2/2}\right), \tag{26}$$

for the power spectrum of $f(\theta)$; K (rad) is the correlation distance of surface roughness. With regard to the infinite summations of the expressions for the characteristics of farfield scatter, three-digit convergence can be achieved in all cases with truncation number $M\leqslant 12$.

A. Boundary condition test

The boundary condition test is performed by means of the following equation, which is obtained from the Dirichlet boundary condition (5) by averaging and by use of (14):

$$\begin{aligned}\sum_{l=1}^{\infty}\frac{(2l-1)!!}{(2l)!}(k\sigma)^{2l}W_m^{(2l)}(\rho_0)=A_m^0&\left[H_m^{(1)}(\rho_0)+\sum_{l=1}^{\infty}\frac{(2l-1)!!}{(2l)!}(k\sigma)^{2l}(H_m^{(1)})^{(2l)}(\rho_0)\right]\\&+\sum_{j_1=-\infty}^{\infty}k\overline{F_{j_1}}A_m^1(j_1)\sum_{l=0}^{\infty}\frac{(2l+1)!!}{(2l+1)!}(k\sigma)^{2l}(H_{m+j_1}^{(1)})^{(2l+1)}(\rho_0)\\&+\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}k^2\overline{F_{j_1}F_{j_2}}A_m^2(j_1,j_2)\\&\times\sum_{l=1}^{\infty}\frac{(2l-1)!!}{(2l-1)!}(k\sigma)^{2l-2}(H_{m+j_1+j_2}^{(1)})^{(2l)}(\rho_0)\\&+\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}\sum_{j_3=-\infty}^{\infty}k^3\overline{F_{j_1}F_{j_2}F_{j_3}}A_m^3(j_1,j_2,j_3)\\&\times\sum_{l=1}^{\infty}\frac{(2l-1)!!}{(2l-1)!}(k\sigma)^{2l-2}(H_{m+j_1+j_2+j_3}^{(1)})^{(2l+1)}(\rho_0).\end{aligned} \tag{27}$$

The abbreviation $(2l-1)!!=1.3\cdots(2l-1)$ has been used in (27). The left-hand side of (27) represents the mean value of $\psi_m^{\text{inc}}+{}_{(p)}\psi_m^{\text{sca}}$ at $\rho=\rho_s$, whereas the right-hand side represents the mean value of $-{}_{(s)}\psi_m^{\text{sca}}$, also at $\rho=\rho_s$. The former can be calculated exactly, thus serving as a reference for approximate calculations of the latter, which involves the approximate expressions for A_m^n. Results for the modulus of both sides of (27) are shown in Fig. 2. It may be seen that curves 1 and 2, corresponding to approximate calculations of the right-hand side of (27) by use of

(16) and (17), respectively, follow closely the reference curve for the left-hand side as long as $k\sigma$ is small; the deviation of the approximate curves from the reference curve increases with $k\sigma$. The fourth-order approximation is evidently more accurate than the second-order approximation, roughly up to $k\sigma=0.1$; from that value onward the fourth-order solution deteriorates. Curves 3 and 4, corresponding to the previous treatment of this problem,[4] are quite far from the reference curve, which is probably due to the first-order approximation of the boundary condition that is used therein.

B. Energy consistency test

Energy consistency can be checked through the optical theorem,[4] which states that $\sigma_c+\sigma_{ic}=\sqrt{8\pi}\ \mathrm{Im}\{\langle\Phi(0)\rangle/\sqrt{i}\}$. The ratio of the left- to right-hand side of this equation may serve as a measure of energy consistency, any deviation from the value 1 revealing deficiencies of the approximate solution under test. The energy consistency test can be performed more effectively by discarding the dominant zeroth-order terms from both sides of the optical theorem by use of the identity $\Sigma_{m=-\infty}^{\infty}|a_m^0|^2=-\Sigma_{m=-\infty}^{\infty}\mathrm{Re}\{a_m^0\}$; thus, the following equations, which are accurate to $O((k\sigma)^2)$ and $O((k\sigma)^4)$ respectively, are obtained:

$$\sum_{m=-\infty}^{\infty}\left[|A_m^0|^2+2\ \mathrm{Re}\{\overline{a_m^0}A_m^0\}+\sum_{j_1=-\infty}^{\infty}|A_m^1(j_1)|^2\right]=-\sum_{m=-\infty}^{\infty}\mathrm{Re}\{A_m^0\}, \tag{28a}$$

$$\sum_{m=-\infty}^{\infty}\left[|A_m^0|^2+2\ \mathrm{Re}\{\overline{a_m^0}A_m^0\}+\sum_{j_1=-\infty}^{\infty}|A_m^1(j_1)|^2+4\sum_{j_1=-\infty}^{\infty}\sum_{j_2=-\infty}^{\infty}|A_m^2(j_1,j_2)|^2\right]$$
$$=-\sum_{m=-\infty}^{\infty}\mathrm{Re}\{A_m^0\}. \tag{28b}$$

Numerical results for the ratio of the left- to right-hand side of (28a) or (28b) are displayed in Fig. 3. It is readily seen that curve 1 is constantly equal to 1 regardless of $k\sigma$; the second-order approximation is, therefore, energy consistent, which can also be verified analytically. The fourth-order approximation results in a nonzero energy error, which is, however, less than 1% in all

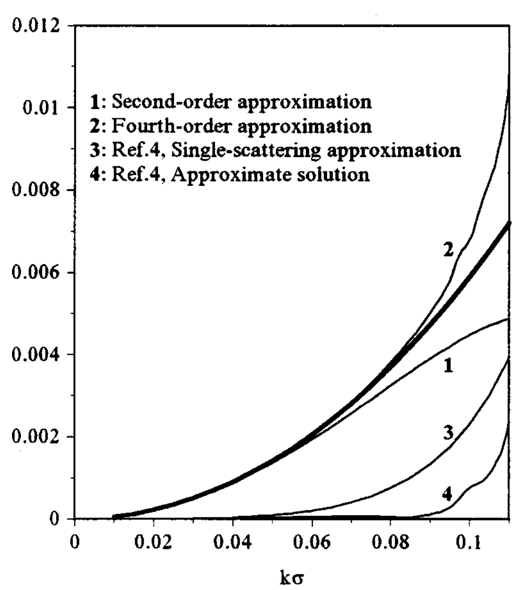

FIG. 2. Boundary condition test ($ka=1, K=0.6$ rad): the thick curve depicts the modulus of the left-hand side of (25) and serves as reference; curves 1–4 correspond to approximate calculations of the modulus of the right-hand side of (25).

cases. In general, all approximate solutions meet the energy consistency criterion more satisfactorily than they meet the boundary condition criterion. This is more evident for the approximate solutions of Ref. 4, which were seen in Fig. 2 to fail with regard to the latter criterion.

C. Applicability limit

It can be argued, after inspection of Figs. 2 and 3, that the boundary condition test is more sensitive than the energy conservation test to inherent errors of approximate solutions. It is, therefore, plausible to investigate the limit of applicability of approximate solutions through calculations of the relative mean boundary condition error, which is defined as the ratio of the left- minus the right- to left-hand side of (27). Numerical results for the relative mean boundary condition error are displayed in Fig. 4, the main conclusion being that it increases rapidly with $k\sigma$, especially for $K=0.4$ rad. The applicability limit, defined as the highest value of $k\sigma$ for the small mean boundary condition error, is well below the corresponding value that would have been estimated by use of the energy consistency criterion. This argument is most convincing when applied to the second-order approximate solution of this paper, which yields a substantial mean boundary condition error, even for small $k\sigma$, although, as mentioned above, it is energy consistent for any $k\sigma$.

D. Angular distribution of farfield scatter

Calculations of the angular distribution of farfield scatter are presented in Fig. 5. It can be observed that the effect of surface roughness is most pronounced in the backscattering direction (i.e., for $\theta=180°$), where it manifests itself as a reduction of coherent scatter; this is a well-known result from studies of light scattering from irregular particles.[12] Incoherent scatter is strongest in the backscattering direction, but it is roughly two orders of magnitude weaker than coherent scatter.

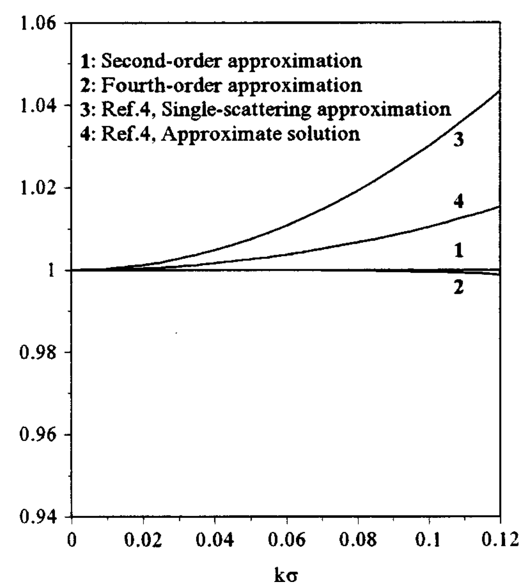

FIG. 3. Energy consistency test ($ka=1, K=0.6$ rad): plots of the ratio of the left- to right-hand side of (26), which should equal 1 for an energy consistent solution. Curve 1 corresponds to (26a); the expressions for $A_m^0, A_m^1(j_1)$ are those of (14). Curve 2 corresponds to (26b); $A_m^1(j_1), A_m^2(j_1, j_2)$ are determined from (16), whereas A_m^0 are obtained from (15a). Curves 3 and 4 correspond to (26a) and (26b), respectively, with A_m^n as expressed in Ref. 4.

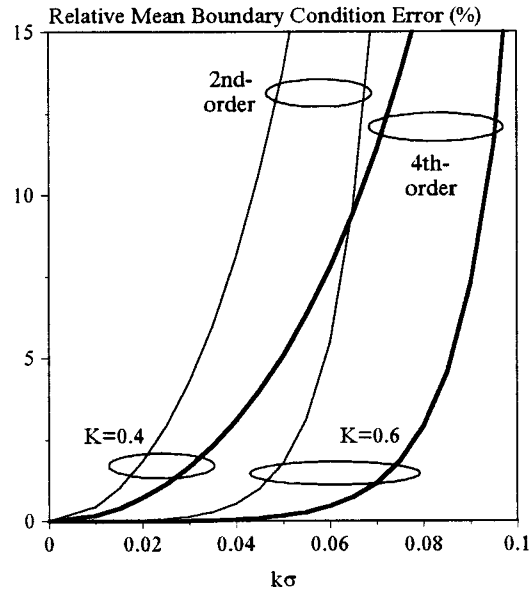

FIG. 4. Relative mean boundary condition error versus normalized variance $k\sigma$ ($ka=1$). This error is defined as the modulus of the ratio of the left- minus the right- to left-hand side of (25), and it should equal 0 for an accurate solution.

VI. CONCLUSIONS

The rigorous application of the boundary condition improves the results obtained by the stochastic functional method, both in terms of the boundary condition criterion and of the energy consistency criterion. The former places stricter restrictions to the applicability of approximate solutions and it is, therefore, more reliable than the latter. The second-order approximate solution obtained herein exhibits considerable boundary condition error and, yet, it is energy consistent,

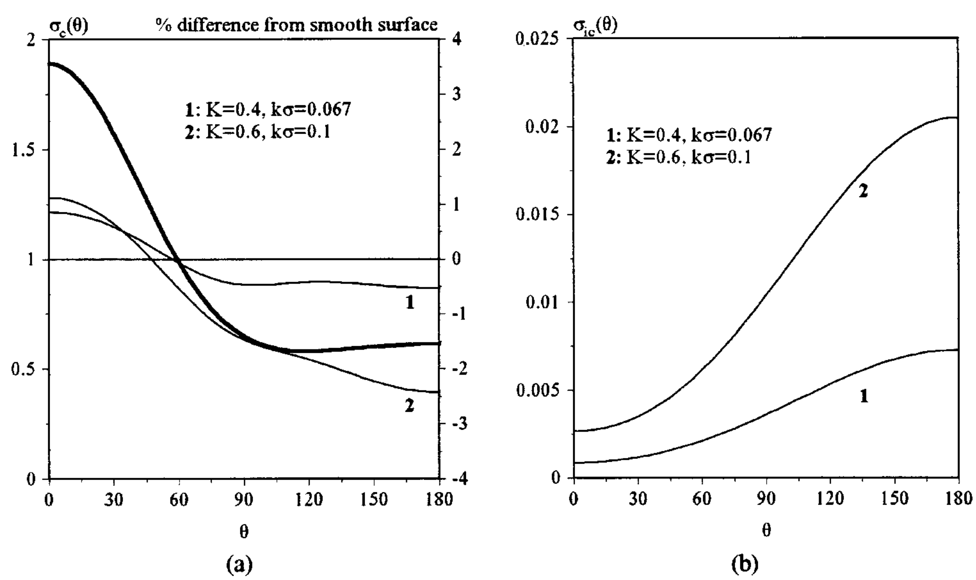

FIG. 5. Angular distribution of farfield scatter ($ka=1$). (a) Coherent differential scattering cross section versus scattering angle θ(°). The thick curve is associated with the left-hand vertical axis, and it corresponds to scattering from a smooth cylindrical surface ($k\sigma=0$); curves 1 and 2 are associated with the right-hand vertical axis and they display the percentage difference in $\sigma_c(\theta)$ of a random cylindrical surface from the corresponding smooth surface. (b) Incoherent differential scattering cross section.

which indicates the limitations of the energy consistency criterion as a means of validating approximate solutions. The fourth-order approximate solution exhibits negligible energy error and it is more accurate with respect to the boundary condition criterion than the second-order solution of this paper and the solutions obtained in Ref. 4.

Lattice electromagnetic theory from a topological viewpoint[a]

F. L. Teixeira[b] and W. C. Chew

(Received 7 July 1998; accepted for publication 25 September 1998)

The language of differential forms and topological concepts are applied to study classical electromagnetic theory on a lattice. It is shown that differential forms and their discrete counterparts (cochains) provide a natural bridge between the continuum and the lattice versions of the theory, allowing for a natural factorization of the field equations into topological field equations (i.e., invariant under homeomorphisms) and metric field equations. The various potential sources of inconsistency in the discretization process are identified, distinguished, and discussed. A rationale for a consistent extension of the lattice theory to more general situations, such as to irregular lattices, is considered.
[S0022-2488(99)02301-4]

I. INTRODUCTION

For historical reasons, the prevalent approach to study initial and/or boundary value problems for Maxwell's equations is based on the vector calculus language. Relatively few references make use of differential forms[1–23] as an alternative mathematical language to describe classical electromagnetic (EM) field theory, despite its adequacy and strong geometrical content. This is in marked contrast with the current tendency of geometrization of other areas of physics.[13–23]

The classical approach for deriving a lattice electromagnetic (EM) theory utilizes the vector calculus language. Such description assumes a space (and time) infinitely divisible. The discrete theory is then obtained by a finite-difference, finite-volume, or finite-element approximation. There has been a number of consistent (in the sense that properties exhibited by the continuum theory, such as divergence-preserving conditions, reciprocity, and conservation laws, are retained) and self-contained formulations of a lattice EM theory in the past.[24–26] However, until recently, these formulations were restricted for the finite-difference case and regular lattices.[24,26]

Apart from exhibiting some interesting physical phenomena not present in its continuum counterpart (such as high-frequency cutoff and rotational symmetry breaking), the interest in the development of a discrete EM theory is driven basically by the recent surge of interest in the numerical simulation of EM fields in complex environments using differential equation solvers, made possible by advances in computer technology. The absence of consistency in more general lattices usually leads to harmful effects on the numerical simulations for hyperbolic equations (time–domain simulations), such as unconditional late-time instabilities.[11,27] In the case of elliptic equations (frequency–domain simulations), they are usually associated with the presence of spurious modes.[3]

Traditionally, the derivation of a lattice EM theory using the classical, vector calculus approach has some inherent drawbacks, which hamper its application for developing more general discrete models on irregular lattices. First, it involves an approximation whereby derivatives are replaced by finite differences (e.g., in the finite-difference method). Second, in the case of structured lattices, the discretization is dependent on the underlying coordinate system; in the case of

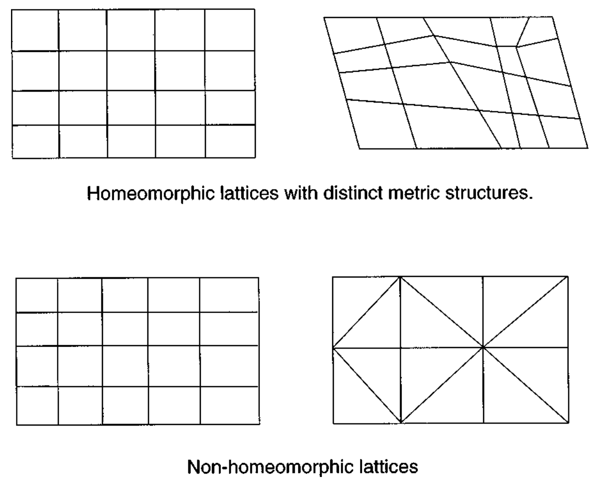

FIG. 1. Topological and metric structure of general, irregular lattices. The differential form language reveals the metric independence of Maxwell's equations. When put on a lattice, Maxwell's equations (but not Maxwell's system) become invariant for any lattice with the same topology.

unstructured lattices, the differential operators are replaced by integral operators and the evaluation of fields involves an averaging procedure (e.g., in the finite-volume method) or a projection on a functional space (e.g., in the finite-element method). More importantly, the use of vector calculus implies that the placement of the theory on the lattice depends on the metric on which the continuum field theory was first cast. This leads, in most cases, to lengthy formulas. Furthermore, the underlying geometrical concepts and the metric independence of Maxwell's equations are not explored. When written in the vector calculus language, the metric independence of Maxwell's equations is hidden because the topological structure is intertwined with their metric structure.

More recently, an alternative approach to the finite-difference discretization of Maxwell's equations for irregular quadrilateral lattices based on the support operator method (SOM)[28,29] has been described in Ref. 30. Such an approach is still based on the vector calculus language, but, compared to traditional discretization schemes, has the distinct advantage of being consistent *by construction* and, therefore, free from spurious solutions and numerical instabilities. Moreover, such an approach also explores the metric independence of Maxwell's equations, since the resulting discrete operators can be written as a composition of a topological part (formal differences) and a metric part.[28]

Here, we explore and discuss the application of differential forms and their discrete counterparts (cochains) to study lattice EM theory. One of the advantages of using differential forms is that the metric independence of Maxwell's equations is already factored out in the continuum, and, therefore, explicitly manifested.[2] This fact implies that the continuum Maxwell's equations written in the differential forms language are invariant under diffeomorphisms, while their lattice counterparts are invariant under homeomorphisms (in Fig. 1, we illustrate the concepts of the topological and metric structure of a lattice). Metric concepts are present only in the so-called Hodge star operators, which also generalize the constitutive relations of the medium. In the lattice, these operators can be thought of either defining *a priori* the local metric structure of the lattice, or being defined *a posteriori* by a given metric structure of the lattice.

In the discrete counterpart of the differential forms language, the continuum derivative operations are replaced not by finite-difference approximations, but as exact exterior derivatives on the lattice cell complex. The discrete exterior derivative corresponds not to a discrete *approximation*, but to a discrete *counterpart*. The exterior derivative is an operator that can be related to a simple evaluation of quantities on the boundary of the elements of the lattice complex, and which makes no assumptions about differentiability. These observations illustrate yet another advantage of the use of differential forms: their discrete counterparts are objects amenable to analysis using the powerful tools of algebraic topology.

Algebraic topological tools have been used to study discrete models for many years (see, e.g., Ref. 17 and references therein). The generality achieved by using algebraic topology was recently illustrated in Ref. 23, where it provided a conceptual basis to analyze the general similarities and differences among various discretization schemes, in the context of thermostatics.

The main objective of this paper is to tackle the general problem of the consistency of lattice EM theory within the framework of algebraic topology. By *general*, we mean lattices with arbitrary *metric* and *topological* structures. We distinguish three basic classes of consistency requirements. The first class (based on topological considerations only) is common to all field theories cast on a discrete form, and it is associated with the correct implementation of the boundary operator on the lattice. Discrete schemes that satisfy this first class can be classified as divergence-preserving schemes. The second class (also based on topological considerations only) is related to the topological structure of EM theory and the dual nature of ordinary and twisted cell complexes. The third class is the metric-dependent one, associated with the Hodge operators. We point out that each requirement is a separate, necessary condition for an overall consistent lattice EM theory.

The remainder of this work is organized as follows. In Sec. II, we write Maxwell's equations using the language of differential forms and discuss their factorization into topological and metric equations. In Sec. III, we review the discretization of differential forms on a lattice using algebraic topological tools. In Sec. IV, we put Maxwell's equations on the lattice using the concepts of the previous sections, stressing that it provides an exact counterpart to the continuum theory that is invariant under homeomorphisms. We also discuss the topological consistency requirements associated with the correct implementation of the boundary operator, and their connection with the usual theorems of vector calculus. In Sec. V, we discuss the concept of dual lattices and how it arises from the necessity of a proper discretization of the different geometrical objects representing the EM fields. In Sec. VI, we treat some additional algebraic properties of the resulting discrete Maxwell's equations by discussing additional topological consistency requirements associated with the dual structure of the ordinary and twisted cell complexes (important to guarantee reciprocity of the discrete Maxwell's equations). In Sec. VII, we discuss the problem of the discretization of the constitutive relations, where metric concepts are present and approximations are involved through the discretization of the Hodge operators. We do not present explicit constructions for the Hodge operators (these are highly problem specific); instead, we discuss general rationales for this, and describe basic requirements that *any* consistent version of the discrete Hodge should satisfy. Finally, in Sec. VIII, we summarize the conclusions. We use a $(3+1)$ representation with the $e^{-i\omega t}$ time convention assumed. Throughout this work, the term discretization refers to *spatial* discretization, unless indicated otherwise.

II. MAXWELL'S EQUATIONS AND DIFFERENTIAL FORMS

In the language of differential forms,[1–23] Maxwell's equations are written as

$$dE = i\omega B, \tag{1}$$

$$dH = -i\omega D + J_E, \tag{2}$$

$$dB = 0, \tag{3}$$

$$dD = \rho_E. \tag{4}$$

In the above, E and H are electric and magnetic field intensity 1-forms, D and B are electric and magnetic flux density 2-forms, J_E is the electric current density 2-form, and ρ_E is the electric charge density 3-form.

The operator d is the usual exterior derivative, which simultaneously plays the role of the curl and div operators of vector calculus. The exterior derivative is an operator applicable to any differentiable manifold, even without a metric defined on it. This is in contrast to the vector calculus operators, which depend on metric factors and have different expressions when written in different coordinate systems. The Maxwell's equations in the above form (27)–(30) are metric independent and retain the same form irrespective of the coordinate system used.[1,2]

Constitutive parameters of a given medium relate the 1-forms E,H to the 2-forms D,B and are given in terms of *Hodge operators*, $\star_e$ and $\star_h$,[6–8] as

$$D = \star_e E, \tag{5}$$

$$B = \star_h H. \tag{6}$$

These relations close the Maxwell's system. In this paper, the term Maxwell's equations will refer to Eqs. (1)–(4), while the term Maxwell's system will refer to (1)–(6). In the case of a three-dimensional manifold, the Hodge operator establishes a natural isomorphism between the space of 1-forms as E and H and the space of 2-forms as D and B. This isomorphism is usually called a Hodge duality map. The Hodge operators depend on a metric and, in the equations (1)–(6), all the information about the metric of space is contained in the constitutive relations (5) and (6). Any modification on the metric tensor preserves the form of Maxwell's equations.

The possibility of decomposing the field equations into a purely topological part and a metric one is not a special property of the EM theory. Such a decomposition is equally possible in the context of other classical field theories.[23]

III. DIFFERENTIAL FORMS ON A LATTICE

In this section, we will briefly review the correspondence between continuum and lattice equations provided by the known mapping of differential forms onto linear functions on the space of some lattice elements. For brevity, we have deliberately chosen a somewhat sloppy approach to any topological subtleties (these are discussed elsewhere, e.g., in Refs. 17–20), by focusing on the important concepts behind the terminology.

To make the right correspondence between the continuum and the lattice, the latter should be considered as a *cell complex* (or cell decomposition).[13,14,16–20,22,23] A cell complex is a partitioning of some space X into a finite number of k cells of different sizes, covering X without overlap), which form a set χ. In our case of interest, X is just a region of the three-dimensional Euclidean space. A k-cell s_i^k is an object homeomorphic to $\mathbf{R}^k$ so that, a 0-cell is a point, a 1-cell is a link (edge), etc. In general, k-cells are k-dimensional ($k=0,1,2,3$) elements of the lattice. The set of all k-cells is denoted by χ^k. The cell complex is the direct sum of such sets,

$$\chi = \bigoplus_{k=0}^{n} \chi^k. \tag{7}$$

Each k-dimensional element of χ^k, for $k=0,1,2,3$, corresponds to a point (vertex), link (edge), plaquette (face), and polyhedron (volume), respectively.

We assume a fixed orientation for each k-cell s_i^k on χ^k, which results in an *oriented cell complex*. For brevity, the term complex will refer to oriented complex in the remaining of this work. With this assumption, a *cell k-chain*, or simply k-chain, is defined as a linear combination of k-cells in χ^k through

$$S^k = \sum_i \alpha_i s_i^k \in \chi^k. \tag{8}$$

The weights α_i belong, in general, to any additive Abelian group. For our purposes, we do not need such a generality and assume that they are just integer numbers. From this definition, a 0-chain is a linear combination of points, a 1-chain is a linear combination of links, etc. A chain is always one of these types; there are no mixed chains.

The k-cells s_i^k form a basis for the space of k-chains. An arbitrary decomposition of X is not a cell complex χ. To characterize a cell complex, certain conditions must be observed. In particular, the *boundary* of any k-cell on χ should be the union of lower-dimensional cells in χ, and no overlapping cells are allowed. The boundary operator ∂ is an operator on χ, ∂: $\chi^k \mapsto \chi^{k-1}$, which carries the usual geometric interpretation and is subject to the requirement $\partial^2 \equiv \partial \circ \partial = 0$. It connects the algebra of k-chains with the algebra of $(k-1)$-chains on the lattice: if S^k is a k-chain, then ∂S^k is a $(k-1)$-chain. Moreover, the boundary operator acts linearly on the space of chains.

If Ω is a k-form and γ is a k-dimensional integration surface, then integration defines a pairing,

$$\int_\gamma \Omega, \tag{9}$$

which gives a scalar as a result. Therefore, the space of k-forms can be thought of as being *dual* to the space of k-dimensional surfaces. This motivates the definition of *cochains*: if the space of k-dimensional surfaces on the continuum is identified with the space of k-chains on the lattice; then the space of k-forms in the continuum is identified as the space of cochains, which are linear functionals on the space of chains. Cochains constitute the discrete representation for the differential forms on the lattice, or the discrete counterparts of forms. Here, to emphasize the connection between the lattice and the continuum, we will also refer to cochains as *lattice differential forms*.

The continuum pairing given by the previous equation has the following *exact counterpart* on the lattice, in terms of a k-chain S^k and a k-lattice form Θ^k,

$$\int_\gamma \Omega \rightarrow \langle S^k, \Theta^k \rangle. \tag{10}$$

Such pairing defines a *contraction* between S^k and Θ^k. From the basis for k-chains, s_i^k, we define a dual basis of lattice forms, θ_i^k, such that $\langle s_i^k, \theta_j^k \rangle = \delta_{ij}$. This basis generates the space of k-lattice forms so that the generic k-lattice form Θ^k is written as

$$\Theta^k = \sum_i \beta_i \theta_i^k. \tag{11}$$

In the above, $\beta_i \in G$, where G is some Abelian group. To make the correspondence with the continuum, G is assumed to be **R**, and the composition law assumed to be the usual algebraic law of addition. The contraction of chains and lattice forms then gives

$$\langle S^k, \Theta^k \rangle = \left\langle \sum_i \alpha_i s_i^k, \sum_j \beta_j \theta_j^k \right\rangle = \sum_i \sum_j \alpha_i \beta_j \langle s_i^k, \theta_j^k \rangle = \sum_i \alpha_i \beta_i. \tag{12}$$

From Eqs. (1)–(4), we see that the only spatial operator present in the differential forms language version of Maxwell's equations is the exterior derivative. The concept of duality makes the definition of the exterior derivative on a lattice very natural, usually called the *coboundary operator*. Here, to emphasize the connection between the lattice and the continuum, we will also refer to it as the *lattice exterior derivative* and write it with the same symbol, d, as in the continuum case. The lattice exterior derivative d is defined in terms of its adjoint, the boundary operator ∂, as

$$\langle S^k, d\Theta^{k-1} \rangle = \langle \partial S^k, \Theta^{k-1} \rangle. \tag{13}$$

This definition has some interesting properties. First, it defines d on a lattice in an *exact* manner. The coboundary does not correspond to an approximation to the continuum exterior derivative d, but instead, as a counterpart to it. Second, it is defined without any need for differentiability. Third, it automatically satisfies the generalized Stokes' theorem.

In this framework, the usual differential operators of vector calculus are replaced by a *single* operator on the lattice: the boundary operator ∂ acting on the elements of the lattice (cell complex). The div operator corresponds to the action of ∂ on a 3-cell, the curl to the action of ∂ on a 2-cell, and the grad to the action of ∂ on a 1-cell. Furthermore, in this sense, these operators are distilled from an unnecessary metric structure, becoming purely topological operations.

In the next section, these remarks will be substantiated when discussing Maxwell's equations on a lattice.

IV. MAXWELL'S EQUATIONS ON A LATTICE

In this section Maxwell's equations are put on a lattice using the previously discussed concepts. The lattice counterpart to Maxwell's equations (1)–(4) are formally the same as the continuum ones, written as

$$dE = i\omega B, \tag{14}$$

$$dH = -i\omega D + J_E, \tag{15}$$

$$dB = 0, \tag{16}$$

$$dD = \rho_E, \tag{17}$$

but with E and H properly interpreted as lattice 1-forms, B and D interpreted as lattice 2-forms, and d interpreted as the coboundary operator. Since lattice forms are operators on the space of chains, we need to contract the above equations with any 2- and 3-chains $S^2, \tilde{S}^2 S^3, \tilde{S}^3$ to get actual numbers,

$$\langle S^2, dE \rangle = i\omega \langle S^2, B \rangle, \tag{18}$$

$$\langle \tilde{S}^2, dH \rangle = -i\omega \langle \tilde{S}^2, D \rangle + \langle \tilde{S}^2, J_E \rangle, \tag{19}$$

$$\langle S^3, dB \rangle = 0, \tag{20}$$

$$\langle \tilde{S}^3, dD \rangle = \langle \tilde{S}^3, \rho_E \rangle. \tag{21}$$

Using the definition of the coboundary operator (the generalized Stokes' theorem), we get

$$\langle \partial S^2, E \rangle = i\omega \langle S^2, B \rangle, \tag{22}$$

$$\langle \partial \tilde{S}^2, H \rangle = -i\omega \langle \tilde{S}^2, D \rangle + \langle \tilde{S}^2, J_E \rangle, \tag{23}$$

$$\langle \partial S^3, B \rangle = 0, \tag{24}$$

$$\langle \partial \tilde{S}^3, D \rangle = \langle \tilde{S}^3, \rho_E \rangle. \tag{25}$$

We use an overtilde to distinguish between the chains belonging to the cell complex, χ (i.e., the cell complex over which E and B live), from the chains belonging the cell complex, $\tilde{\chi}$ (i.e., the cell complex over which D and H live). *These cell complexes are not necessarily the same* since the pair of equations for (E,B) and for (D,H) are independent of each other. Indeed, we will show that there are strong reasons to use different cell complexes for these quantities (this is discussed in the next section). To find the lattice forms at each edge or face, we apply the above procedure for each edge or face of the cell complex, or, equivalently, to each element s_i^k of the basis of k-chains,

$$\langle \partial s_i^2, E \rangle = i\omega \langle s_i^2, B \rangle, \tag{26}$$

$$\langle \partial \tilde{s}_i^2, H \rangle = -i\omega \langle \tilde{s}_i^2, D \rangle + \langle \tilde{s}_i^2, J_E \rangle, \tag{27}$$

$$\langle \partial s_i^3, B \rangle = 0, \tag{28}$$

$$\langle \partial \tilde{s}_i^3, D \rangle = \langle \tilde{s}_i^3, \rho_E \rangle. \tag{29}$$

Since ∂ is an operator from χ^k to χ^{k-1} (or $\tilde{\chi}^k$ to $\tilde{\chi}^{k-1}$), the boundaries $\partial s_i^1, \partial s_i^2, \partial s_i^3$ (or $\partial \tilde{s}_i^2, \partial \tilde{s}_i^2, \partial \tilde{s}_i^3$) can be expressed in terms of a basis of 0-, 1-, and 2-chains, respectively,

$$\partial s_i^1 = \sum_j \alpha_{ij} s_j^0, \tag{30}$$

$$\partial s_i^2 = \sum_j \beta_{ij} s_j^1, \tag{31}$$

$$\partial s_i^3 = \sum_j \gamma_{ij} s_j^2, \tag{32}$$

$$\partial \tilde{s}_i^1 = \sum_j \tilde{\alpha}_{ij} \tilde{s}_j^0, \tag{33}$$

$$\partial \tilde{s}_i^2 = \sum_j \tilde{\beta}_{ij} \tilde{s}_j^1, \tag{34}$$

$$\partial \tilde{s}_i^3 = \sum_j \tilde{\gamma}_{ij} \tilde{s}_j^2. \tag{35}$$

The matrices $\alpha_{ij}, \beta_{ij}, \gamma_{ij}$ (and $\tilde{\alpha}_{ij}, \tilde{\beta}_{ij}, \tilde{\gamma}_{ij}$) define the *incidence relations* for the operator ∂ in a given complex χ (and $\tilde{\chi}$). They are the discrete-topological counterpart to the grad, curl, and div operators, respectively. The elements of these matrices are integers having the values ± 1 (depending on their relative chosen orientation) when $s_j^{(k-1)} \in \partial s_i^k$, and zero otherwise. Furthermore, for any χ, the identity $\partial^2 = 0$ implies

$$\sum_j \beta_{ij} \alpha_{jk} = 0, \tag{36}$$

$$\sum_j \gamma_{ij} \beta_{jk} = 0, \tag{37}$$

and similar relations in $\tilde{\chi}$. Equations (36)–(37) are the topological equivalents on χ of the familiar identities curl $=0$ and div curl$=0$, respectively. The fact that these identities are preserved in the numerical discretization scheme are necessary to ensure that the theorems of the continuum are preserved, although not sufficient. Schemes satisfying (36)–(37) may be classified as divergence-preserving schemes, for obvious reasons.

Substituting (30)–(35) in (26)–(29), we have

$$\sum_j \beta_{ij} \langle s_j^1, E \rangle = i\omega \langle s_i^2, B \rangle, \tag{38}$$

$$\sum_j \tilde{\beta}_{ij} \langle \tilde{s}_j^1, H \rangle = -i\omega \langle \tilde{s}_i^2, D \rangle + \langle \tilde{s}_i^2, J_E \rangle, \tag{39}$$

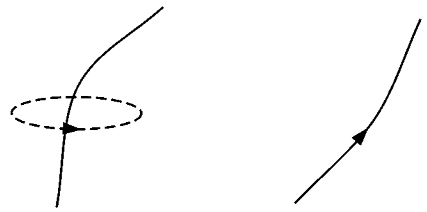

FIG. 2. The concept of two orientations applied for one-dimensional objects on a three-dimensional space. The external orientation is based on the circulation around the object and makes use of additional dimensions. The internal orientation is based on a direction along the object and does not require additional dimensions other than that of the object itself. The two orientations can be related to each other if a screw sense is defined. If the right-hand rule is adopted, the orientations chosen in this figure become equivalent. In the differential form language, two different objects may be defined according to the orientation they possess. Ordinary forms have an internal orientation. Twisted forms have an external orientation.

$$\sum_j \gamma_{ij}\langle s_j^2,B\rangle=0, \tag{40}$$

$$\sum_j \tilde{\gamma}_{ij}\langle \tilde{s}_j^2,D\rangle=\langle \tilde{s}_i^3,\rho_E\rangle. \tag{41}$$

These equations gives the *exact* lattice counterparts of Maxwell's equations in terms of the lattice variables $\langle s_i^2,B\rangle$, $\langle \tilde{s}_i^2,D\rangle$, $\langle \tilde{s}_i^1,H\rangle$, and $\langle s_i^1,E\rangle$. The lattice 2-forms *B, D* that live on 2-chains $s_i^2,\tilde{s}_i^2$ are related to the lattice 1-forms *E, D*, respectively, which live on 1-chains $\partial s_i^2,\partial\tilde{s}_i^2$.

The above equations in terms of lattice variables are the same for *any* lattice with the same topological structure. Maxwell's equations in this form are invariant under homeomorphisms. This topological equivalence leads to an equivalence relation among lattices.

We also note that the fundamental dynamic variables in the lattice theory are not the lattice forms *E,H,D,B* (i.e., the field values themselves) anymore, but their contraction with the cell complex elements. The latter quantities are the usual ones of interest associated with a finite region of space (i.e., global quantities like electric voltages and magnetic fluxes). The discretization process just described can be viewed as a process of limiting the (originally infinite) degrees of freedom in accessing these global quantities.

The problem of obtaining a *continuum* representation for the *continuum* forms *E,H,D,B* over *X* from the knowledge of $\langle s_i^1,E\rangle,\langle \tilde{s}_i^1,H\rangle,\langle \tilde{s}_i^2,D\rangle,\langle s_i^2,B\rangle$ over χ, $\tilde{\chi}$, is nevertheless important for discretizing the Hodge operators (constitutive relations) in (5) and (6) and to achieve the full discretization of the Maxwell's system (1)–(6). This is a part of the general problem of obtaining a consistent but approximate continuum representation for a differential *k*-form Ω on *X* from the knowledge of its discrete counterpart (*k*-cochain) Θ^k on χ^k. The discussion of this general problem is postponed until Sec. VII.

V. DUAL LATTICES AND TWISTED FORMS

In this section, we will discuss the concept of dual lattices for EM field simulations (such as in the Yee scheme[31] or usual finite-volume discretizations[32]) and show that its convenience arises not only for computational purposes, but also from geometrical reasons not obviated by the vector language. These reasons are connected with the concept of *orientation*.

We start by noting that there are two fundamental ways to define an orientation in three dimensions.[22,23] This is illustrated in Fig. 2 in the case of a one-dimensional object (line) in a three-dimensional space. The first way is to specify a (inner) *direction* along the line. This does not make use of additional dimensions other than the one defined by the line itself (one dimensional) and is referred to as *internal* orientation. The second way is to specify a (transversal)

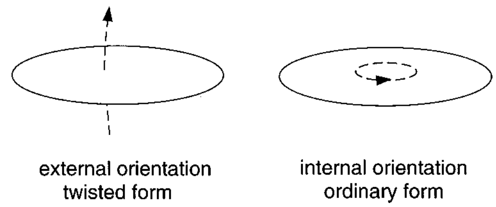

FIG. 3. The concept of two orientations now applied for two-dimensional objects on a three-dimensional space. The same observations made for Fig. 2 also apply here.

circulation along the line. In this case, additional dimensions are required and is referred to as *external* orientation. Internal and external orientations behave differently under coordinate reflection. These two kinds of orientations necessitate the definition of two different kinds of forms. Forms with internal orientation are called *ordinary* differential forms (for historical reasons only, since there is nothing about them to make them more ''ordinary'' than the twisted forms). Forms with external orientation are called *twisted* differential forms.[22] In the case of vectors, this distinction is not present because the vector calculus language comes with a predefined *screw sense* (in addition to a metric structure). For instance, if the right-hand rule is used for the objects (1-forms) of Fig. 2, then their vector counterparts automatically will have the same orientation. However, using the concept of two different kinds of orientations, no *a posteriori* right-hand rules are necessary.

Figure 3 illustrates the concept of internal and external orientation for two-dimensional objects in the three-dimensional space (this concept may also be applied for zero and three-dimensional objects[22,23]).

As expected, the boundary operator ∂ preserves orientation in the sense that the boundary of an ordinary/twisted form is another ordinary/twisted form. More interestingly, we note from Figs. 2 and 3 that the same concept (direction) that gives the internal orientation for one-dimensional objects gives the external orientation for two-dimensional objects. Similarly, the second concept (circulation), while giving internal orientation for two-dimensional objects, gives external orientation for one-dimensional ones.

If a given cell complex χ is chosen to discretize the space X so that its links (edges) have internal orientation and its faces have external orientation (consistently through the boundary operator), then there is a dual cell complex $\tilde{\chi}$ where edge orientations are given by circulations and the face orientations given by directions. This is depicted in Fig. 4. The edges (faces) of the dual cell complex are associated with faces (edges) of the primary cell complex. If the lattice ordinary forms live on the primary cell complex χ, then the lattice twisted forms should live on the dual cell complex $\tilde{\chi}$. This is one important distinction between differential forms in the continuum and the

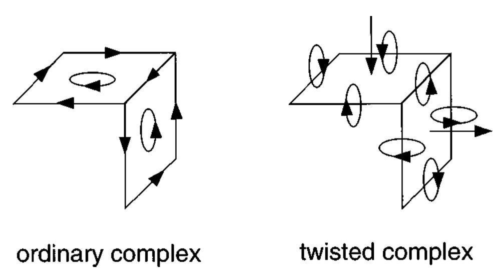

FIG. 4. Oriented cell complexes give rise to two distinct kinds of cell complexes. In the ordinary complex, each cell complex is endowed with an internal orientation and the associated lattice forms (cochains) are ordinary forms. In the twisted complex, each cell complex is endowed with an external orientation and the associated lattice forms (cochains) are twisted forms. On an EM lattice, these ordinary and twisted cell complexes are combined such that k-cells of one complex are associated to $(n-k)$-cells of the other, where n is the dimensionality of the space. This gives rise to the concept of a dual lattice (complex). The fields E and B live on the ordinary complex, while D and H live on the twisted complex (also see Fig. 5).

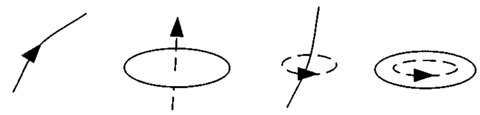

FIG. 5. Each EM field is a different geometrical object with distinct properties. This is hidden in the vector calculus language and best revealed through the use of the differential form language. In the continuum theory this distinction (usually) does not have an important role, but on a lattice, where the degrees of freedom in accessing global quantities are limited and exhibit a specific interdependence (e.g., edges as a boundary of faces) each field must be associated with a proper geometric object (1- or 2-cell) on the proper lattice (ordinary or twisted).

lattice forms. For the continuum forms, ordinary and twisted forms live on the same space X; but for the lattice forms, ordinary and twisted forms live on different spaces, χ and $\tilde{\chi}$. The role of the orientation concept in defining dual lattices was first discussed in Ref. 23.

To stress their geometrical properties, we will refer to the primary cell complex, χ, as the *ordinary cell complex* and to the dual cell complex, $\tilde{\chi}$, as the *twisted cell complex*.

The concept of distinct orientations applies directly to three-dimensional EM fields. The electric field E is associated with internally oriented lines (ordinary 1-form), the magnetic field H is associated with externally oriented lines (twisted 1-form), the electric flux D with externally oriented surfaces (twisted 2-form), and the magnetic flux B with internally oriented surfaces (ordinary 2-form). In addition, electric charge density is associated with externally oriented volumes (twisted 3-form), and the electric current density is associated with externally oriented surfaces (twisted 2-form). Figure 5 illustrates this classification for EM fields. The E and B lattice forms live on χ, while D and H (and J_E, ρ_E, which are also twisted forms) live on $\tilde{\chi}$.

The ordinary EM forms (E and B) are associated with the concept of forces (Lorentz formula), while the twisted EM forms (D and H) are associated with the concept of sources (ρ_E and J_E). Indeed, in the four-dimensional space–time notation, the forms E and B are components of a single two-form F (Faraday), while the forms D and H are components of its Hodge dual, $\star F$ (Maxwell two-form).[1]

Here, we appreciate the amount of geometric structure that is lost when representing the EM fields in the vector language. Each EM field is a distinct geometric object (Fig. 5), but in vector calculus, all are under the same umbrella as three-dimensional (contravariant) vectors. The need for two cell complexes arises not only as a computational device but also to account for the inherent geometric differences among the electromagnetic fields.

VI. ALGEBRAIC PROPERTIES OF MAXWELL'S EQUATIONS ON A LATTICE

The expansions (30)–(35) should satisfy, by construction, some conditions resulting from the properties of the boundary operator ∂ and from the dual complex construction. In this section, we shall describe and discuss these conditions. The fact that they are preserved in the lattice theory is important to preserve the continuum theorems and ensure an overall consistent theory.

The dual complex construction is such that, in the three-dimensional case, to each 2-cell of the ordinary cell complex, there corresponds a 1-cell on the twisted cell complex, and vice-versa. In this natural one-to-one pairing, the 1-cells (links), on the ordinary complex cross associate 2-cells (faces) on the dual complex, and vice-versa. A similar pairing also exist between 0-cells and 3-cells and vice-versa. For the two-dimensional case, the pairing is between ordinary 0-cells and twisted 2-cells (and vice-versa), and between ordinary and twisted 1-cells. This is true not only for hexahedral cells but for cell complexes with different cell topologies.

If the indices chosen for the basis elements of the cell complexes χ and $\tilde{\chi}$ reflects this natural pairing, i.e., if the cell s_i^k on the ordinary cell complex has the same i index of the associated cell $\tilde{s}_i^{(n-k)}$ (on an n-dimensional space) on the twisted cell complex, then it is easy to show that the coefficients for the incidence relations in (30)–(35) are related through (see Fig. 6)

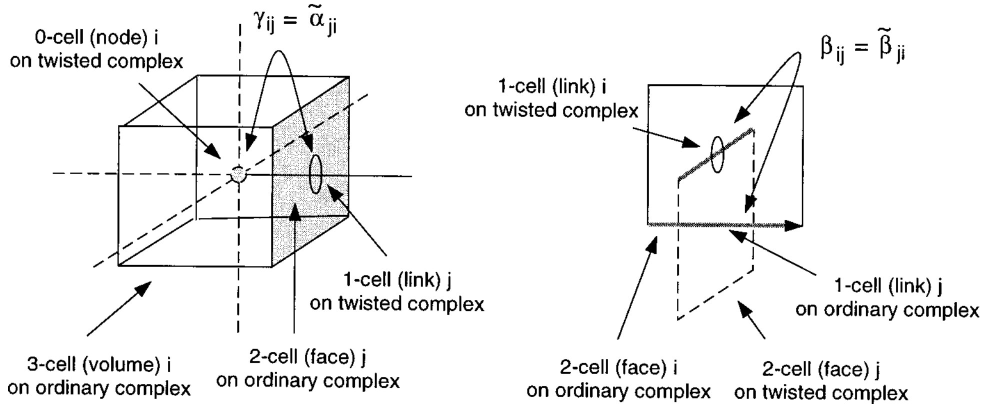

FIG. 6. Illustration of the reciprocal relationship between the boundary operator coefficients (incidence relations) for the ordinary and twisted lattices. At the left, we illustrate that a volume-to-face incidence relation on the ordinary complex is mirrored by a link-to-node incidence relation in the twisted complex. At the right, we illustrate that a face-to-link incidence relation in the ordinary complex is mirrored by another face-to-link incidence relation in the twisted complex. For visualization purposes, we depicted a regular hexahedral lattice, but this is valid for general lattices as well.

$$\alpha_{ij}=\tilde{\gamma}_{ji}, \tag{42}$$

$$\beta_{ij}=\tilde{\beta}_{ji}, \tag{43}$$

$$\gamma_{ij}=\tilde{\alpha}_{ji}. \tag{44}$$

These relations do not depend on the primary orientation chosen for χ and $\tilde{\chi}$. Similar to Eqs. (36)–(37), Eqs. (42)–(44) are another example of consistency relations derived from topological considerations only. The fact that these relations are satisfied in a particular discretization scheme is of key importance to preserve symmetry and positive definiteness of the resulting matrix systems, and, consequently, stability in time–domain updates of numerical methods. Combined with symmetry properties to be observed on the discrete representation for the Hodge operators $\star_\epsilon,\star_\mu$ (discussed in Sec. VII), they mimic, on a lattice, the reciprocal nature of the continuum Maxwell's equations. Equations (42)–(44) are also related with the consistency requirements for the boundary operator on the twisted complex $\tilde{\chi}$. This can be seen by substituting Eqs. (42)–(44) into Eqs. (36), (37),

$$\sum_j \beta_{ij}\alpha_{jk}=\sum_j \tilde{\beta}_{ji}\tilde{\gamma}_{kj}=\sum_j \tilde{\gamma}_{kj}\tilde{\beta}_{ji}=0, \tag{45}$$

$$\sum_j \gamma_{ij}\beta_{jk}=\sum_j \tilde{\alpha}_{ji}\tilde{\beta}_{kj}=\sum_j \tilde{\beta}_{kj}\tilde{\alpha}_{ji}=0, \tag{46}$$

which is equivalent to having the identity $\partial^2=0$ fulfilled on $\tilde{\chi}$.

For lattices with simple topology, the relations (42)–(44) hold true because of the staggered nature of the ordinary and twisted cells. However, for more exotic lattices, such as those encountered in subgridding or in modeling curved boundaries through locally distorted lattice elements, they do not necessarily hold true in commonly employed discretizations schemes (with naive interpolatory rules), so that the reciprocity of the continuum Maxwell's equations is lost. In these cases, the relations (42)–(44) should be enforced by construction to ensure that reciprocity is maintained. This is also discussed in Refs. 33–35, but from a completely different point of view.

VII. HODGE OPERATORS ON A LATTICE

The discretization of the Hodge operators $\star_\epsilon, \star_\mu$ (constitutive relations) is a central step for the formulation a general lattice EM theory. The discrete Hodge operators relate the lattice forms of the ordinary grid to the lattice forms of the twisted grid, and involve material properties of the particular medium. From the continuum equations, where the Hodge operators are metric-dependent objects, such relationship should also involve concepts such as lengths, angles, etc. Contrary to the topological equations treated before, the discrete Hodge operators are *approximations* to the continuum operators. The continuum Hodge operators are linear mapping of the space of k-forms into the space of $(n-k)$-forms, where n is the dimensionality of the space. In the EM case, the constitutive relations are written in terms of those operators, $D=\star_\epsilon E$, $B=\star_\mu H$, connecting the 2-forms D,B on one cell complex with the 1-forms E,H on the other cell complex. Since they are linear mappings, the discrete version of the Hodge operators in the lattice can be represented as a generic linear mapping connecting the dynamical discrete variables on χ and $\tilde{\chi}$ as follows:

$$[\star_\epsilon]:\chi\rightarrow\tilde{\chi},$$

$$\langle \tilde{s}_i^2, D\rangle = \sum_j [\star_\epsilon]_{ij}\langle s_j^1, E\rangle, \tag{47}$$

$$[\star_\mu]:\tilde{\chi}\rightarrow\chi,$$

$$\langle s_i^2, B\rangle = \sum_j [\star_\mu]_{ij}\langle \tilde{s}_j^1, H\rangle. \tag{48}$$

In the above, $[\star_\epsilon]$ and $[\star_\mu]$, are square, nonsingular, sparse matrices representing the discrete Hodge operators for a general dispersive and anisotropic linear media (in the general case of bianisotropic media, the following discussion remains essentially unchanged, except for the appearance of cross terms, $[\star_\zeta]$ and $[\star_\xi]$, in the above equations, relating quantities on the same cell complex). These approximate equations close the Maxwell's system (1)–(6) and, along with the exact discrete Maxwell's equations (38)–(41), constitute the discrete *approximation* to the Maxwell's system.

We now discuss some rationales for the construction of the Hodge operator on a lattice, but we do not claim such rationales to be unique. More importantly, we draw attention to the basic consistency requirements that any discrete Hodge should obey.

A rationale for a systematic construction of the discrete Hodge operators for a particular lattice geometry (metric) is described in Route *A* below.

Route A:

(i) An *approximate* continuum representation for the electromagnetic forms E and H is built from the knowledge of the discrete quantities $\langle s_i^1, E\rangle$ and $\langle \tilde{s}_i^1, H\rangle$ over χ and $\tilde{\chi}$, respectively (this will be discussed shortly).

(ii) The Hodge star operators $\star_\epsilon$ and $\star_\mu$ are applied to the resultant continuum representation for E and H, respectively, to yield the corresponding approximate continuum representations for D and B.

(iii) These resulting approximate representations for D and B are then paired with the elements of the cell complexes $\tilde{\chi}$ and χ, respectively, to yield $\langle \tilde{s}_i^2, D\rangle$ and $\langle s_i^2, B\rangle$. When $\langle \tilde{s}_i^2, D\rangle$ and $\langle s_i^2, B\rangle$ are written as functions of $\langle s_i^1, E\rangle$ and $\langle \tilde{s}_i^1, H\rangle$, respectively, we have determined the matrix elements $[\star_\epsilon]_{ij}$ and $[\star_\mu]_{ij}$. Note that in Eqs. (47), (48), the approximate continuum representations for the electromagnetic forms E,B,D,H do not appear. They are used only as an auxiliary tool to obtain $[\star_\epsilon]$ and $[\star_\mu]$. This is only natural, since, in a true discrete theory, E,B,D,H are not primary quantities and $[\star_\epsilon]$, $[\star_\mu]$ should be treated as being given *a priori*, in the same manner as the material constitutive tensors, $\overline{\boldsymbol{\epsilon}}$ and $\overline{\boldsymbol{\mu}}$, for the continuum theory.

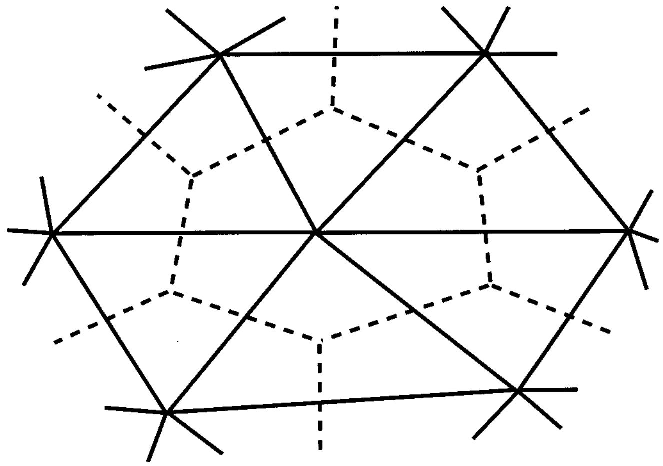

FIG. 7. A two-dimensional, irregular simplicial lattice (solid lines) and its dual lattice (dashed lines), which is not simplicial anymore (hexagonal elements).

As a result, an alternative route to (i)–(iii) can be followed by using, instead of *E,B,D,H*, their vector counterparts **E**,**B**,**D**,**H**, without changing the final formalism. This alternative route translates the metric dependency of the Hodge operators isolated in step (ii) to the metric-dependent notions of vector fields and surface integrals in modified versions of steps (i) and (iii). In this case, the modified step (ii) becomes just a tensorial product on vectors. This alternative route to determine the discrete Hodge operator may be summarized as follows.

Route B:

(i) An *approximate* continuum representation for the electromagnetic vector fields **E** and **H** is built from the knowledge of the discrete quantities $\langle s_i^1,E\rangle$ and $\langle \tilde{s}_i^1,H\rangle$ over χ and $\tilde{\chi}$, respectively.

(ii) The approximate continuum representations for **D** and **B** are found using the tensorial products $\mathbf{D}=\overline{\boldsymbol{\epsilon}}\cdot\mathbf{E}$ and $\mathbf{B}=\overline{\boldsymbol{\mu}}\cdot\mathbf{H}$.

(iii) These resulting approximate representations for the vector fields **D** and **B** are then integrated over 2-cells to give $\langle \tilde{s}_i^2,D\rangle$ and $\langle s_i^2,B\rangle$.

Variant schemes from the above are possible, where instead of first using the contractions of 1-forms, $\langle s_i^1,E\rangle$ and $\langle \tilde{s}_i^1,H\rangle$ over χ and $\tilde{\chi}$, to find the approximate continuum representations, the contractions used are located over the same cell complex, say χ. In such a case, the continuum representations are derived from $\langle s_i^1,E\rangle$ and $\langle s_i^2,B\rangle$ and the discrete operators obtained are approximations to $\star_\epsilon$ and $\star_\mu{}^{-1}$. This does not result in equivalence, however, because, in general, $[\star_\mu{}^{-1}]\neq[\star_\mu]^{-1}$. In particular, the matrix $[\star_\mu{}^{-1}]$ is sparse, but $[\star_\mu]^{-1}$ is not. The use of a same cell complex to obtain the continuum field representation from the contractions is sometimes of interest because, in general, the primary and dual cell complexes have different topological structures (not only metric structure), as illustrated in Fig. 7. As will become clear shortly, a proper continuum representation construction at step (i) depends directly on the topology of the cell complex over which the contractions are defined.

Both Routes *A* and *B* above are inevitably metric dependent, and, in principle, there is no conceptual advantage in adopting one over another. However, since Route *B* involves vector calculus concepts only, which supposedly results in a more familiar operational approach, we will base our remaining discussion mainly on it.

To find the continuum approximation for the vector fields **E** and **H**, a continuum basis of *k*-forms $\Omega_{s_i^k}$, counterpart to the basis of *k*-cochains θ_i^k (duals to s_i^k) should be constructed. Such a basis is built to obey the following properties.

(i) $\Omega_{s_i^k}=0$ outside s_i^k and its neighborhood (i.e., such forms should be compactly supported), which ensures the sparsity of $[\star_\epsilon]$, $[\star_\mu]$.

(ii) $\Omega_{s_i^k} = d\Omega_{\partial s_i^k}$, consistent with Eq. (13) and indicating a proper relationship between the $\Omega_{s_i^k}$'s for the different k's and a hierarchical construction that can be invoked.

(iii) The lattice form θ_i^k and its continuum counterpart $\Omega_{s_i^k}$ give the same results when contracted or integrated, respectively, over corresponding elements of χ and X, i.e.,

$$\int_\gamma \Omega_{s_i^k} = \langle s_j^k, \theta_i^k \rangle, \tag{49}$$

where γ is the k-dimensional region in X corresponding to the k-cell s_j^k in χ.

A basis for the space of forms obeying (i)–(iii) is introduced in Ref. 13 for a *simplicial* lattice (cell complex), and the resulting continuum forms are usually called *Whitney forms*. A simplicial lattice is one having the property that *all* its cell elements are *simplices*, i.e., cells whose boundaries are the union of a minimal number of lower-dimensional cells. Therefore, in a simplicial lattice, a 0-cell is a point (0-simplex), a 1-cell a link (1-simplex), a 2-cell a triangle (2-simplex), a 3-cell a tetrahedron (3-simplex), etc. The Whitney form associated with k-cell (simplex) s_i^k is written as[3,13]

$$\Omega_{s_i^k} = k! \sum_{j=0}^{k} (-1)^j \zeta_{i,j} d\zeta_{i,0} \wedge \cdots d\zeta_{i,j-1} \wedge d\zeta_{i,j+1} \wedge \cdots \wedge d\zeta_{i,k}, \tag{50}$$

where $\zeta_{i,j}$, $0 \leqslant j \leqslant k$, are the barycentric coordinates of the simplex s_i^k, and the wedge denotes the usual exterior product. These are piecewise linear forms. Higher-order forms are also possible. The Whitney k-forms are just linear interpolants for simplicial cochains and are uniquely determined from their integration over the k-simplices, which completely defines their degrees of freedom.

Using a Euclidean metric for the continuum three-dimensional case, the Whitney forms for the various degrees can be easily written using the vector calculus language[3] as basis functions for **E** and **H** [step (i) of Route *B* above]. For the $k=0$ case, we simply have, for each node i,

$$\Omega_{s_i^0} \overset{g_E}{\rightarrow} \tau_{s_i^0} = \zeta_{i,0}, \tag{51}$$

where $\zeta_{i,0}$ is the (single) barycentric coordinate associated with the 0-simplex s_i^0 (node), and g_E denotes the isomorphism (0-form to scalar) governed by the Euclidean metric. In this case, the Whitney form is the barycentric coordinate itself (a scalar) and the continuum approximation for a lattice 0-form is the usual node (point-based) interpolation through scalar functions $\tau_{s_i^0}$. The value of this function is equal to unity at s_i^0, and equal to zero at all other 0-cells s_j^0, $j \neq i$.

For the $k=1$ case, we have, for each edge i,

$$\Omega_{s_i^1} \overset{g_E}{\rightarrow} \boldsymbol{\tau}_{s_i^1} = \zeta_{i,0} \nabla \zeta_{i,1} - \zeta_{i,1} \nabla \zeta_{i,0}, \tag{52}$$

where $\zeta_{i,0}$ and $\zeta_{i,1}$ are the barycentric coordinates associated with the *two* vertices of the 1-simplex s_i^1 (edge). The Whitney forms (1-forms) in this case translate to a vector field, $\boldsymbol{\tau}_{s_i^1}$ (from the isomorphism between 1-forms and vectors governed by the Euclidean metric). The resultant interpolation scheme for a lattice 1-form using the above elements is the so-called edge interpolation. The line integral of this function is equal to unity along its associated edge s_i^1, and equal to zero at all other 1-cells s_j^1, $j \neq i$.

For the $k=2$ case, we have, for each face i,

$$\Omega_{s_i^2} \overset{g_E}{\rightarrow} \boldsymbol{\tau}_{s_i^2} = 2(\zeta_{i,0} \nabla \zeta_{i,1} \times \nabla \zeta_{i,2} + \zeta_{i,1} \nabla \zeta_{i,2} \times \nabla \zeta_{i,0} + \zeta_{i,2} \nabla \zeta_{i,0} \times \nabla \zeta_{i,1}), \tag{53}$$

where now $\zeta_{i,j}$, $j=0,1,2$ are the barycentric coordinates associated with the three vertices of the 2-simplex s_i^2 (triangular face). The Whitney forms (2-forms) in this case translate to a (pseudo-) vector field, $\boldsymbol{\tau}_{s_i^2}$ (from the isomorphism between 2-forms and pseudovectors governed by the Euclidean metric). The surface integral of this function is equal to unity over its associated face s_i^2, and equal to zero at all other 2-cells s_j^2, $j\neq i$.

The $k=3$ case, we have, for each volume i,

$$\Omega_{s_i^3}\overset{g_E}{\rightarrow}\tau_{s_i^3}=6[(\zeta_{i,0}\,\nabla\zeta_{i,1}\times\nabla\zeta_{i,2})\cdot\nabla\zeta_{i,3}+(\zeta_{i,1}\,\nabla\zeta_{i,2}\times\nabla\zeta_{i,3})\cdot\nabla\zeta_{i,0}+(\zeta_{i,2}\,\nabla\zeta_{i,3}\times\nabla\zeta_{i,0})\cdot\nabla\zeta_{i,1}$$
$$+(\zeta_{i,3}\,\nabla\zeta_{i,0}\times\nabla\zeta_{i,1})\cdot\nabla\zeta_{i,2}], \tag{54}$$

which results in a (pseudo-)scalar function, $\tau_{s_i^3}$ (from the isomorphism between 3-forms and pseudoscalars governed by the Euclidean metric) associated with each 3-simplex (tetrahedron). Despite the complicated appearance of Eq. (54), these are simple, step-like functions, which are constant on the associated tetrahedron and zero elsewhere. The corresponding volume integral is equal to unity over its associated volume s_i^3, and equal to zero over all other 3-cells s_j^3, $j\neq i$.

Using the Whitney forms, we may write the 1-chain approximation for the **E** fields as a sum of the $k=1$ vector basis functions running over all 1-simplices s_i^1 of the simplicial cell complex χ,

$$\mathbf{E}=\sum_i \langle s_i^1,E\rangle\boldsymbol{\tau}_{s_i^1}. \tag{55}$$

For the **H** field, the sum runs over the 1-cells of the dual complex $\tilde{\chi}$ (not simplicial anymore),

$$\mathbf{H}=\sum_i \langle \tilde{s}_i^1,H\rangle\boldsymbol{\tau}_{\tilde{s}_i^1}. \tag{56}$$

Alternatively, as discussed before, a discrete approximation may be first sought for the inverse operator $\star_\mu{}^{-1}$, so that

$$[\star_\mu{}^{-1}]:\chi\rightarrow\tilde{\chi},$$

$$\langle\tilde{s}_i^1,H\rangle=\sum_j [\star_\mu{}^{-1}]_{ij}\langle s_j^2,B\rangle, \tag{57}$$

and **B** is expanded over 2-simplices s_i^2 of the simplicial cell complex χ,

$$\mathbf{B}=\sum_i \langle s_i^2,B\rangle\boldsymbol{\tau}_{s_i^2}. \tag{58}$$

Note that Eqs. (55), (56), and (58) are approximations for the total vector fields (and not for each of their components separately).

The Whitney functions are commonly used as vector basis functions for the finite-element method to avoid the appearance of spurious solutions.[3] According to their order, k, they are sometimes referred to as node interpolants $(k=0)$, edge elements $(k=1)$, or face elements $(k=2)$. Such elements have been generalized for other types of complexes also (e.g., with hexahedral cells). However, as opposed to the simplicial case, there are no established mathematical results behind such generalizations. More importantly, some of the basic properties of Whitney forms on a simplicial lattice are not preserved in more general lattices. Among them is the divergence-free condition. It can be shown that, although for *regular* hexahedral lattices, these vector basis functions are divergence-free inside each element, in the case of general hexahedral elements, this is not true.[36] The divergence in this case is proportional to the amount of deviation from a regular lattice.

For the general cell complex case, i.e., not necessary simplicial [note that even for the simplicial case, its dual lattice is not simplicial anymore, as exemplified by Fig. 7 and Eq. (56)], and in the present absence of definitive mathematical results, the use of simpler *ad hoc* interpolatory schemes to obtain $[\star_\epsilon]$ and $[\star_\mu]$ are of interest for practical purposes. Any such scheme is highly dependent on the type of problem and geometry considered. However, *any* interpolatory scheme should meet some basic consistency requirements, described next.

For a reciprocal medium, $\overline{\boldsymbol{\mu}}=\overline{\boldsymbol{\mu}}^t$, $\overline{\boldsymbol{\epsilon}}=\overline{\boldsymbol{\epsilon}}^t$, the continuum Hodge operators $\star_\mu$, $\star_\epsilon$ on a Riemannian manifold are symmetric, nondegenerate, and positive definite operators. These properties are a simple consequence from the fact that a Riemannian metric tensor itself is a symmetric, nondegenerate, positive definite tensor.

However, for nonorthogonal lattices, usual interpolatory schemes for the discrete Hodge operators do not generally preserve the symmetry of the continuum operators. This is because the discrete versions of the Hodge are not strictly local. The lattice variables $\langle s_i^1, E\rangle$, $\langle \tilde{s}_i^1, H\rangle$, $\langle s_i^2, B\rangle$, $\langle \tilde{s}_i^2, D\rangle$ are defined over different geometric elements that span *finite* regions of space. Elements of the ordinary (twisted) cell complex that contribute to a given element of the twisted (ordinary) cell complex (and therefore define the local interpolatory stencil) are associated with metric elements defined at different points of space. Since the metric itself is a function of position, the *local* symmetry of $\star_\mu$, $\star_\epsilon$ may be lost on $[\star_\mu]$, $[\star_\epsilon]$, if not enforced by construction.[27] In addition, even if symmetry is enforced by construction on $[\star_\mu]$, $[\star_\epsilon]$, the positive definiteness condition on the discrete Hodge may be violated when highly skewed lattices are employed.[11,27]

Symmetric, positive-definite discrete Hodge operators yield real, positive eigenvalues for the matrices $[\star_\mu]$, $[\star_\epsilon]$. This means the resultant discrete Maxwell's system will not contain spurious eigenmodes with exponential growth in time. Nonsymmetric, nonpositive definite matrices would give rise to negative or complex eigenvalues. Regardless of their magnitude, negative or complex eigenvalues lead to spurious eigenmodes with *unconditional* exponential time growth that eventually contaminate the solution (late-time instabilities). This can be seen by substituting Eqs. (47), (48) into Eqs. (38)–(41) and solving, e.g., for $\langle s_i^1, E\rangle$. As a result, we get

$$\sum_m \left(\sum_{j,k,l} ([\star_\epsilon]^{-1})_{ij} \tilde{\beta}_{jk} ([\star_\mu]^{-1})_{kl} \beta_{lm} - \omega^2 \delta_{im} \right) \langle s_m^1, E\rangle = 0, \tag{59}$$

for all *i*. The eigenfunctions of the corresponding system of differential equations for $\langle s_i^1, E\rangle$ in the time–domain are given by

$$\langle s_i^1, E\rangle \rightarrow \boldsymbol{\phi}(t) = e^{\pm i \overline{\mathbf{A}}^{1/2} t} \boldsymbol{\phi}^0, \tag{60}$$

where $\boldsymbol{\phi}(t)$ is the column vector of eigenfunctions, $\boldsymbol{\phi}^0$ is the initial value of $\boldsymbol{\phi}(t)$ at $t=0$, and the elements of the matrix $\overline{\mathbf{A}}$ are given by

$$A_{im} = \sum_{j,k,l} ([\star_\epsilon]^{-1})_{ij} \tilde{\beta}_{jk} ([\star_\mu]^{-1})_{kl} \beta_{lm}. \tag{61}$$

The above functional operations on matrices are understood in the usual manner, by using similarity transformations and operating on the matrix eigenvalues. We let $\overline{\mathbf{A}}=\overline{\mathbf{W}}\cdot\overline{\boldsymbol{\lambda}}\cdot\overline{\mathbf{V}}^t$, or $\overline{\mathbf{A}}\cdot\overline{\mathbf{W}} = \overline{\mathbf{W}}\cdot\overline{\boldsymbol{\lambda}}$, where $\overline{\mathbf{W}}$ contains the right eigenvectors of $\overline{\mathbf{A}}$, while $\overline{\mathbf{V}}$ contains the left eigenvectors (for a symmetric $\overline{\mathbf{A}}$, they are the same), and $\overline{\mathbf{V}}^t\cdot\overline{\mathbf{W}}=\overline{\mathbf{I}}$. Consequently, $\overline{\mathbf{A}}\cdot\overline{\mathbf{W}}\cdot\mathbf{u}=\overline{\mathbf{W}}\cdot\overline{\boldsymbol{\lambda}}\cdot\mathbf{u}$, and $\overline{\mathbf{A}}^n\cdot\overline{\mathbf{W}}\cdot\mathbf{u}=\overline{\mathbf{W}}\cdot\overline{\boldsymbol{\lambda}}^n\cdot\mathbf{u}$, or, in general, $f(\overline{\mathbf{A}})\cdot\overline{\mathbf{W}}\cdot\mathbf{u}=\overline{\mathbf{W}}\cdot f(\overline{\boldsymbol{\lambda}})\cdot\mathbf{u}$, by using a Taylor expansion on $f(\cdot)$, where $\overline{\boldsymbol{\lambda}}$ is a diagonal matrix containing the eigenvalues of $\overline{\mathbf{A}}$. Using $\overline{\mathbf{V}}^t\cdot\overline{\mathbf{W}}=\overline{\mathbf{I}}$, we can let $\boldsymbol{\phi}^0=\overline{\mathbf{V}}^t\cdot\overline{\mathbf{W}}\cdot\boldsymbol{\phi}^0$, i.e., expand $\overline{\mathbf{f}}^0$ in terms of the eigenvectors of $\overline{\mathbf{W}}$. Equation (60) then becomes

$$\boldsymbol{\phi}(t) = \overline{\mathbf{W}}\cdot e^{\pm i \overline{\boldsymbol{\lambda}}^{1/2} t} \overline{\mathbf{V}}^t \cdot \boldsymbol{\phi}^0. \tag{62}$$

Equation (62) gives the solutions of the semidiscrete problem, i.e., without considerations about the time discretization. For any convergent time-discretization scheme (e.g., independent of the time step chosen), Eq. (62) will lead to *bounded* solutions, $\boldsymbol{\phi}(t)$, if all the eigenvalues of $\overline{\mathbf{A}}$ are real and positive (note that for a lossless, dispersionless media, $\overline{\mathbf{A}}$ is real and, therefore, any complex eigenvalues will occur in conjugate pairs). If $\tilde{\beta}_{ij}=\beta_{ji}$ [Eq. (43)], it can be easily shown that this is true if $[\star_\epsilon]^{-1}$ and $[\star_\mu]^{-1}$ (and, consequently, $[\star_\epsilon]$ and $[\star_\mu]$) are *simultaneously* nonsingular, symmetric, negative definite or positive definite. The positive definite is the case of interest to recover the continuum Hodge operators.

As observed in Sec. IV, the discretization process can be viewed as a process of limiting the degrees of freedom in accessing global dynamic quantities of interest. The original infinite degrees of freedom in the continuum theory are reduced to a finite number over the cell complex elements. In the semidiscrete dynamic equations, Eq. (59), this is reflected in the reduction of the spectral content of the solution to a finite number of poles (eigenfrequencies). Usually this may also be viewed as a low-pass filtering, which is determined by the lattice spacing size and nature of approximation; but in general terms corresponds to a rearrangement of the spectral content. The requirement for symmetric, positive definite discrete Hodge operators corresponds to assuring (in lossless media) that no spurious poles are introduced in the upper-half complex ω plane after discretization.

An additional, interesting point revealed by the differential forms language is that, since the metric is entirely defined in the Hodge operators, the simulation of Maxwell's equations on an *irregular* lattice and homogeneous medium can be mimicked by a dual theory, where we view the simulation performed on a *regular* lattice, but on an inhomogeneous, particular class of orthotropic medium with electric and magnetic constitutive tensors proportional to each other, i.e., $\overline{\boldsymbol{\epsilon}}=\epsilon\overline{\boldsymbol{\Gamma}}$, $\overline{\boldsymbol{\mu}}=\mu\overline{\boldsymbol{\Gamma}}$. In this latter case, metric factors are incorporated into the medium properties so that lattice irregularities become orthotropic inhomogeneities. By making use of such an observation, the properties that should be explicitly enforced on the final, approximate matrix representation of the discrete Hodge operators on a general irregular lattice can be established on very simple physical grounds only. This is simply because the violation of symmetry or positive definiteness would render the orthotropic media of the dual theory nonreciprocal or active, giving rise to spurious numerical artifacts.

As mentioned, symmetry and positive definiteness for $[\star_\epsilon]$ and $[\star_\mu]$ (or their procedural equivalents in the vector calculus language) are not always met by some of the commonly employed interpolations for finite-volume or finite-difference simulations. Symmetry is guaranteed only if it is explicitly enforced at each lattice point (e.g., through a perfectly symmetric numerical evaluation of the metric coefficients[27]) and the positive definiteness is usually violated when using highly skewed or curved meshes.[11,27]

It should be stressed that these (metric-dependent) conditions over $[\star_\epsilon]$ and $[\star_\mu]$ are not sufficient for the consistency of the lattice theory. They should be enforced *in addition to* the topological consistency conditions previously discussed in Secs. IV and VI.

VIII. CONCLUSIONS

In this work, we discussed the application of differential forms and topological concepts to the study of lattice EM theory.

Differential forms provide a very concise and elegant language to treat the classical EM theory on a lattice. It allows for the factorization of the field equations into a topological part and a metric part. The resultant topological equations are invariant under homeomorphisms, viz., invariant for lattices with the same topological structure. All the usual vector calculus operators are unified by a single operator, the exterior derivative, which admits a trivial and exact discretization on an arbitrary lattice through the use of its discrete adjoint, the boundary operator. This allows for a more general interpretation for the derivative on the lattice, not as a finite-difference approximation, but as an evaluation of fields at boundaries.

Consistency conditions for the lattice theory, such as divergence-free conditions and reciprocity, are discussed in a very general setting using purely topological concepts. Metric concepts need to be invoked only in connection with the Hodge operators, which also generalize the constitutive relations of the medium. General consistency requirements on the discrete Hodge operator are also discussed.

Lattice differential forms provide a richer geometrical language to discuss some aspects of the discretization procedure. The potential sources of inconsistency can be adequately identified and classified. The treatment of the EM fields E and B as ordinary forms, and D and H as twisted forms reveals a geometric reason of the dual lattice construction, common to EM discretization schemes for numerical simulations, such as the celebrated Yee scheme.[31]

ACKNOWLEDGMENTS

G. A. Deschamps was among the first to advocate the use of forms as a natural language for electromagnetic theory.[2] He passed away on June 20, 1998, while this paper was being prepared. This paper is dedicated to his memory. The authors would like to acknowledge the reviewers for suggestions, E. A. Forgy for discussions and for pointing out Ref. 16, and M. Shashkov and R. Schuhmann for providing preprints of their recent works. Integrable systems in low dimensions, constructed through the symmetry reduction method, are studied using phase portrait and variable separation techniques. In particular, invariant quantities and explicit periodic solutions are determined. Widely applied models in Physics are shown to appear as particular cases of the method. © *1999 American Institute of Physics.* [S0022-2488(99)01201-3]

I. INTRODUCTION

Integrable Hamiltonian systems play a fundamental role in the study and description of physical systems, due to their many interesting properties, both from the mathematical and physical points of view. The construction of such models represents a contribution to this field, and many of them have proved to be of an extraordinary physical interest. Let us be reminded here of the Morse[1] and Pöschl–Teller[2] potentials in one dimension, or the Calogero[3–5] and Sutherland[6] potentials. These constructions have also been considered from many points of view. See, for instance, the reviews in Refs. 7 and 8.

A method used to construct these systems is the Marsden–Weinstein reduction procedure,[9] or its extensions,[10] to free Hamiltonians lying on an N-dimensional homogeneous space under a suitable Lie group. In this way (using an appropriate momentum map), one assures the integrability, or even the superintegrability[11] of the system. In the first case, there exists N constants of motion in involution, one of them the Hamiltonian. The superintegrability requires more than N constants of motion (not all of them in involution) and more than one subset of N constants in involution. There are good reasons to suspect that any integrable system may be constructed in this way, as a reduction of a free one,[10] so the problem to construct these systems and study their properties is a profitable and very interesting field. A related topic is the problem of separation of variables for the associated Hamilton–Jacobi (HJ) equations. As it is well known, the existence of quadratic invariants allows us to classify and construct these systems,[12,13] relating them in many occasions to subgroups of the invariance group.

A series of articles appeared in the last years, and has been devoted to the study of these superintegrable systems constructed using homogeneous spaces over the pseudounitary groups SU (p,q).[14,15] In particular, using the maximal Abelian subalgebras (MASA) of the corresponding algebras, one can build a family of integrable systems of arbitrary dimension, and present their invariants and the coordinate systems in which the HJ equation is separated. The explicit solutions and a unifying view of the compact Cartan subalgebra case have been presented in Ref. 16.

b)Electronic mail: olmo@fta.uva.es
c)Electronic mail: rodrigue@eucmos.sim.ucm.es

Our aim in this article is to work in detail with the low dimensional cases. The reason is twofold. On one side, the one-dimensional case allows an easy geometric description of the systems, through their phase portrait. The potentials we obtain are not new, but have been applied successfully in many physical models (for instance, the Pöschl–Teller and Morse potentials). They also appear in the study of quasi-exactly solvable (QES) models,[17,18] as the case of exactly solvable systems, providing examples in which, from the quantum point of view, the corresponding Schrödinger equation can be solved algebraically (a part of the spectrum for QES systems or an arbitrary number of states for the exactly solvable ones). On the other side, the two-dimensional case can be studied from the point of view of variable separation, and we can solve the HJ equation in a wide class of coordinate systems, especially in the noncompact case.[19,20] The results we present here (in the two-dimensional case) should be considered in a local context. Considerations about global behavior, which will differ from the compact to the noncompact case, will not be addressed in this work.

The article is organized as follows. In Sec. II we present a concise description of the method used to construct these Hamiltonian systems. Section III is devoted to the one-dimensional case, while the two-dimensional case is studied in Sec. IV. In each case we present the list of all the conserved quantities for these systems in terms of the generators of the corresponding algebras, and the explicit form in the chosen coordinate system. Conclusions and further outlook of this research are discussed in Sec. V.

II. INTEGRABLE HAMILTONIAN SYSTEMS AND PSEUDOUNITARY GROUPS

The results presented in this section are a summary of the contents of Refs. 14 and 15. We will include some of them to set the notations which will be used in the following sections.

We will consider the free Hamiltonian ($\mu,\nu=0,\dots,N=p+q-1$),

$$H=4cg^{\mu\bar{\nu}}p_\mu\overline{p_\nu} \tag{2.1}$$

(the bar denoting complex conjugate) defined in the Hermitian hyperbolic space (with coordinates $y^\mu\in\mathbf{C}$, satisfying $g_{\bar{\mu}\nu}\overline{y^\mu}y^\nu=1$, and conjugate momenta p_μ),

$$\mathrm{SU}(p,q)/\mathrm{SU}(p-1,q)\times\mathrm{U}(1) \tag{2.2}$$

whose geometry is described in Ref. 21. The real constant c is related to the sectional curvature of the Hermitian space. See also Ref. 16 for a detailed analysis of this space and its properties.

Using a maximal Abelian subalgebra of $su(p,q)$,[22] we carry a reduction procedure,[9] in order to obtain a reduced Hamiltonian (which is not free) in the reduced space, a homogeneous $\mathrm{SO}(p,q)$ space,

$$H=c\left(\tfrac{1}{2}g^{\mu\nu}p_{s^\mu}p_{s^\nu}+V(s)\right), \tag{2.3}$$

where $V(s)$ is a potential depending on the real coordinates s^μ. The set of complex coordinates y^μ is transformed in the reduction procedure into a set of ignorable variables x^μ (which are the parameters of the transformation associated to the MASA of $u(p,q)$ used in the reduction) and the coordinates s^μ with the constraint $g_{\mu\nu}s^\mu s^\nu=1$.

If Y_μ, $\mu=0,\dots,N$, is a basis of the considered MASA of $u(p,q)$, formed by pure imaginary matrices, the relation between old (y^μ) and new coordinates (x^μ,s^μ) is

$$y^\mu=B(x)^\mu_\nu s^\nu,\quad B(x)=\exp(x^\mu Y_\mu), \tag{2.4}$$

which assures the ignorability of the x coordinates (the vector fields corresponding to the MASA are straightened out in these coordinates). The Jacobian matrix, J, is easily obtained. If

$$A^{\mu}_{\nu}=\frac{\partial y^{\mu}}{\partial x^{\nu}}=(Y_{\nu})^{\mu}_{\rho}y^{\rho}, \tag{2.5}$$

then

$$J=\frac{\partial(y,\overline{y})}{\partial(x,s)}=\begin{pmatrix} A & B \\ \overline{A} & \overline{B} \end{pmatrix}. \tag{2.6}$$

The Hamiltonian calculated in the new coordinates is written as

$$H=c(\tfrac{1}{2}g^{\mu\nu}p_{\mu}p_{\nu}+V(s)), \quad V(s)=p_x^T(A^{\dagger}KA)^{-1}p_x, \tag{2.7}$$

where p_x are the constant momenta associated to the ignorable coordinates x and K is the matrix defined by the metric g.

Note that, to obtain these Hamiltonians, we need MASAs of $su(p,q)$ of dimension $N=p+q-1$ (corresponding to MASAs of $u(p,q)$ of dimension $p+q$). We also require that these MASAs have a representation in terms of imaginary matrices that allows to write the Hamiltonian in the form (2.7). Once we have chosen a particular MASA, we can obtain a set of invariants and also the corresponding coordinate systems in which the HJ equation separates. The MASAs of $su(p,q)$ are classified in Ref. 22, and for low ranks are completely determined. The corresponding potentials have been obtained for SU(N) in Ref. 19, for SU(2,1) in Ref. 20, for SU(2,2) in Ref. 15 and for any SU(p,q), choosing as the MASA one of the Cartan subalgebras, in Ref. 14. From now on, we will always use contravariant coordinates, but we will write the indices as subscripts in order to simplify the notation and avoid the use of unnecessary brackets.

III. ONE-DIMENSIONAL HAMILTONIANS

One-dimensional Hamiltonians are always integrable and the phase portrait gives a complete description of the allowed motions. We shall expose the main ideas in order to achieve a better understanding of the more complicate systems we will study in the next section. We have two cases: $su(2)$ and $su(1,1)$.

A. $su(2)$

We will use as a basis for $su(2)$ the operators X_1,X_2,X_3, which are given in the natural 2×2 matrix representation by

$$X_1\rightarrow\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad X_2\rightarrow\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad X_3\rightarrow\begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}$$

in the metric $K=\mathrm{diag}(1,1)$.

In the compact algebra $su(2)$ there is only one class of MASAs, corresponding to the Cartan subalgebra (CC).[22] A basis of a representative of this class of MASA is

$$\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}. \tag{3.1}$$

A basis of the corresponding MASA of $u(2)$ can be chosen as

$$Y_0=\begin{pmatrix} i & 0 \\ 0 & 0 \end{pmatrix}, \quad Y_1=\begin{pmatrix} 0 & 0 \\ 0 & i \end{pmatrix}. \tag{3.2}$$

The relation between old and new coordinates is given by the matrix $B(x)$ in (2.4). Note that a change of basis in the corresponding MASA of $u(2)$ changes only the parameters appearing in the potential,

$$y_0 = s_0 e^{ix_0}, \quad y_1 = s_1 e^{ix_1}. \tag{3.3}$$

The Hamiltonian, following the general expression (2.7), is

$$H = c\left[\tfrac{1}{2}(p_{s_0}^2 + p_{s_1}^2) + V(s)\right], \quad V(s) = \frac{m_0^2}{s_0^2} + \frac{m_1^2}{s_1^2} \tag{3.4}$$

with the constraint $s_0^2 + s_1^2 = 1$. Parameterizing the circle S^1 in spherical coordinates, $s_0 = \cos\phi$, $s_1 = \sin\phi$, we get the Hamiltonian $(c=1)$,

$$H(\phi) = \frac{1}{2}p_\phi^2 + V(\phi), \quad V(\phi) = \frac{m_0^2}{\cos^2\phi} + \frac{m_1^2}{\sin^2\phi}. \tag{3.5}$$

We have only one second order conserved quantity, the Hamiltonian, which is equal to the Casimir of the algebra, C, up to an additive constant,

$$\hat{Q}_1 = X_2^2 + X_3^2. \tag{3.6}$$

The square of the generator in the compact Cartan subalgebra, $C_1 = X_1^2$, is constant after the reduction and $C = C_1 + \hat{Q}_1$.

The specific values of the real positive constants m_0, m_1 play no essential role in the qualitative description of the orbits and trajectories of this system. The potential has singularities (in the generic case) in $\phi = 0, \pi/2, \pi, 3\pi/2$. When m_0 or m_1 are equal to zero we have only two singularities in $0,\pi$ or $\pi/2, 3\pi/2$, respectively.

The particles are confined inside a sector, and there, the motion is periodic, with an equilibrium point (a center in the phase space) corresponding to the unique minimum of the potential, in $\tan\phi = \sqrt{m_1/m_0}$. The solution can be easily computed, using Hamilton equations. The potential is bounded from below, and the energy is always positive $(E \geqslant (m_0 + m_1)^2)$. Though the use of the HJ equation is not necessary in this context of one-dimensional systems, we will write down the equation in order to compare it to the two dimensional cases. In fact, when we will make separation of variables there, we will find again this equation,

$$\frac{1}{2}\left(\frac{\partial S}{\partial \phi}\right)^2 + \frac{m_0^2}{\cos^2\phi} + \frac{m_1^2}{\sin^2\phi} = E \tag{3.7}$$

with the solution $(u = \cos^2\phi)$,

$$u = \frac{1}{2E}\left(b + \sqrt{b^2 - 4m_0^2 E}\cos 2\sqrt{2E}t\right) \tag{3.8}$$

and $b = m_0^2 - m_1^2 + E$. This solution is obviously much simpler to find if we consider the equation of orbits in the phase portrait of this system.

For instance, if $m_0 = 0$, $m_1 = 1$, the solution is

$$s_0 = \cos\phi = \sqrt{1 - \frac{1}{E}}\cos\sqrt{2E}t, \tag{3.9}$$

that is, a system with similar solutions to a harmonic oscillator, but now the frequency depends on the energy.

B. $su(1,1)$

The noncompact algebra $su(1,1)$ has three nonconjugate classes of MASAs, compact Cartan subalgebra, noncompact Cartan subalgebra and a class of nilpotent maximal Abelian subalgebras (MANS).[22] We will fix the metric to be

$$K=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{3.10}$$

and the basis $\{X_1,X_2,X_3\}$ is given in the 2×2 matrix representation through the correspondence

$$X_1\to\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix},\quad X_2\to\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},\quad X_3\to\begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}.$$

1. Compact Cartan subalgebra (CC)

We choose, as a representative of this class, the same matrices as in (3.2). Hence, the old and new coordinates are related in the same way they did in the $su(2)$ case (3.3), and the Hamiltonian is now

$$H=c[\tfrac{1}{2}(p_{s_0}^2-p_{s_1}^2)+V(s)],\quad V(s)=\frac{m_0^2}{s_0^2}-\frac{m_1^2}{s_1^2}, \tag{3.11}$$

with the constraint $s_0^2-s_1^2=1$. This hyperbola can be described with a coordinate ϕ varying in the real line, $s_0=\cosh\phi$, $s_1=\sinh\phi$, and the Hamiltonian in these coordinates is $(c=-1)$,

$$H(\phi)=\tfrac{1}{2}p_\phi^2+V(\phi),\quad V(\phi)=-\frac{m_0^2}{\cosh^2\phi}+\frac{m_1^2}{\sinh^2\phi}. \tag{3.12}$$

The second order invariant (the Hamiltonian) is

$$\hat{Q}_1=X_2^2+X_3^2 \tag{3.13}$$

and the trivial constant associated to the MASA is $C_1=X_1^2$. Hence, the Casimir in terms of these two quantities is $C=C_1-\hat{Q}_1$.

The HJ equation is

$$\frac{1}{2}\left(\frac{\partial S}{\partial\phi}\right)^2-\frac{m_0^2}{\cosh^2\phi}+\frac{m_1^2}{\sinh^2\phi}=E \tag{3.14}$$

and the solution depends on the values of E and the parameters.

Considering different values of the parameters m_0,m_1 we obtain three different systems.

(a) If $m_1\neq 0$ the potential has a singularity in $\phi=0$. It is easy to check that, if $m_1\geqslant m_0$, there are no minima for the potential and all the motions are unbounded (with a turning point). The energy is always positive. The parameters m_0,m_1 do not modify qualitatively the phase portrait or the form of the solutions. The solution can be written as $(u=\cosh^2\phi)$

$$u=\frac{1}{2E}(-b+\sqrt{b^2+4m_0^2E}\cosh 2\sqrt{2E}t) \tag{3.15}$$

and $b=m_0^2-m_1^2-E$. If $m_0=0$, $m_1=1$, the solution is

$$s_0(t)=\sqrt{1+\frac{1}{E}\cosh\sqrt{2E}t}. \tag{3.16}$$

(b) If $m_0 > m_1 > 0$, the potential has two minima, symmetric respect to the origin where it has the singularity. The energy is bounded from below, $E \geqslant -(m_0 - m_1)^2$, the value $E = -(m_0 - m_1)^2$ corresponding to the equilibrium solution in the center of the phase space. The other solutions are easily calculated (b has the same value as in case a),

(i) $-(m_0 - m_1)^2 < E < 0$

$$s_0 = \frac{1}{\sqrt{2|E|}} [b + \sqrt{b^2 + 4Em_0^2} \cos 2\sqrt{2|E|}t]^{1/2}. \tag{3.17}$$

(ii) $E = 0$

$$s_0 = \left[\frac{m_0^2}{m_0^2 - m_1^2} + 2(m_0^2 - m_1^2)t^2 \right]^{1/2}. \tag{3.18}$$

When $E > 0$ we get the solution (3.15).

(c) If $m_1 = 0$ there is no singularity in the potential, which has a minimum in $\phi = 0$, with periodic motions of negative energy and unbounded motions of positive or zero energy. The multiplicative constant m_0 plays no essential role for the qualitative description of the system. The solutions can be read off from case (b) with $m_1 = 0$.

2. Noncompact Cartan subalgebra (NC)

A representative subalgebra of this class has the basis [in the metric (3.10)],

$$Y_1 = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} \tag{3.19}$$

and we will add the matrix $Y_0 = iI$ to get a MASA of $u(1,1)$. The new and old coordinates are related in a slightly more complicated way,

$$y_0 = e^{ix_0}(s_0 \cosh x_1 + is_1 \sinh x_1), \quad y_1 = e^{ix_0}(-is_0 \sinh x_1 + s_1 \cosh x_1) \tag{3.20}$$

and the Hamiltonian is written in the new coordinates as

$$H = c[\tfrac{1}{2}(p_{s_0}^2 - p_{s_1}^2) + V(s)], \quad V(s) = \frac{m_0^2 - m_1^2 + 4m_0 m_1 s_0 s_1}{1 + 4s_0^2 s_1^2}, \tag{3.21}$$

and the constraint $s_0^2 - s_1^2 = 1$. Using again the ϕ coordinate as in the previous case, we get

$$H(\phi) = \frac{1}{2} p_\phi^2 + V(\phi), \quad V(\phi) = -\frac{m_0^2 - m_1^2 + 2m_0 m_1 \sinh 2\phi}{\cosh^2 2\phi}. \tag{3.22}$$

The Casimir is written as $C = \hat{Q}_1 - C_1$, where $C_1 = X_3^2$, the square of the generator of the noncompact Cartan subalgebra, and

$$\hat{Q}_1 = X_1^2 - X_2^2, \tag{3.23}$$

which is equal to the Hamiltonian.

We will also write down HJ equation for future references,

$$\frac{1}{2}\left(\frac{\partial S}{\partial \phi}\right)^2 - \frac{m_0^2 - m_1^2 + 2m_0 m_1 \sinh 2\phi}{\cosh^2 2\phi} = E. \tag{3.24}$$

If m_0 or m_1 are equal to 0, we obtain similar results to those of the case of compact Cartan MASA, an attractive potential if $m_0^2 > m_1^2$ and a repulsive one in the opposite case. If $m_0 m_1 \neq 0$, the potential is qualitatively the same for all values of m_0 and m_1.

The potential $V(\phi)$ has two extrema in $\sinh 2\phi = m_1/m_0, -m_0/m_1$. The first point corresponds to a minimum (a center in the phase portrait), and the potential takes the value $V = -m_0^2$. The second point is a maximum (a saddle point in the phase portrait), and $V = m_1^2$ there. The energy is bounded from below ($E \geqslant -m_0^2$) and the explicit solutions are ($u = \sinh 2\phi$),

(i) $-m_0^2 < E < 0$

$$u = \frac{1}{|E|}\left[m_0 m_1 + \sqrt{(E+m_0^2)(m_1^2 - E)} \cos 2\sqrt{2|E|}t\right]. \tag{3.25}$$

(ii) $E = 0$

$$u = -\frac{m_0^2 - m_1^2}{2m_0 m_1} + 4m_0 m_1 t^2. \tag{3.26}$$

(iii) $0 < E < m_1^2$

$$u = \frac{1}{E}\left[-m_0 m_1 + \sqrt{(E+m_0^2)(m_1^2 - E)} \cosh 2\sqrt{2|E|}t\right]. \tag{3.27}$$

(iv) $E = m_1^2$

$$u = -m_0 + e^{2\sqrt{2}m_1 t}. \tag{3.28}$$

(v) $E > m_1^2$

$$u = \frac{1}{E}\left[-m_0 m_1 + \sqrt{(E+m_0^2)(E - m_1^2)} \sinh 2\sqrt{2E}t\right]. \tag{3.29}$$

3. Nilpotent subalgebra (NIL)

Though the simplest representative of this class of subalgebras is obtained in the skew-diagonal metric, we will use again the diagonal one, because in this way, the kinetic term is also diagonal. We will take as a basis,

$$Y_1 = \begin{pmatrix} i & i \\ -i & -i \end{pmatrix}, \tag{3.30}$$

which is a nilpotent matrix. As in the noncompact case we will also use $Y_0 = iI$ to complete the basis of a $u(1,1)$ MASA. Old and new coordinates satisfy

$$y_0 = e^{ix_0}((1+ix_1)s_0 + ix_1 s_1), \quad y_1 = e^{ix_0}(-ix_1 s_0 + (1-ix_1)s_1). \tag{3.31}$$

The Hamiltonian is

$$H = c\left[\tfrac{1}{2}(p_{s_0}^2 - p_{s_1}^2) + V(s)\right], \quad V(s) = \frac{2m_0 m_1}{(s_0+s_1)^2} - \frac{m_1^2}{(s_0+s_1)^4}, \tag{3.32}$$

with the constraint (which is the same for all the subalgebras in the $su(1,1)$ case, as we are using the same metric), $s_0^2 - s_1^2 = 1$. The expression of the Hamiltonian in terms of the ϕ coordinate $(c = -1)$ is

TABLE I. One-dimensional potentials.

Algebra	MASA	Kinetic term	Potential
$su(2)$	Compact Cartan	p_ϕ^2	$\dfrac{m_0^2}{\cos^2\phi}+\dfrac{m_1^2}{\sin^2\phi}$
$su(1,1)$	Compact Cartan	p_ϕ^2	$-\dfrac{m_0^2}{\cosh^2\phi}+\dfrac{m_1^2}{\sinh^2\phi}$
	Noncompact Cartan	p_ϕ^2	$-\dfrac{m_0^2-m_1^2+2m_0m_1\sinh 2\phi}{\cosh^2 2\phi}$
	Nilpotent	p_ϕ^2	$m_1^2e^{-4\phi}-2m_0m_1e^{-2\phi}$

$$H(\phi)=\frac{1}{2}p_\phi^2+V(\phi),\quad V(\phi)=m_1^2e^{-4\phi}-2m_0m_1e^{-2\phi}. \tag{3.33}$$

The Hamiltonian in terms of the second order operators in the enveloping algebra is again ($\{X_i,X_j\}=X_iX_j+X_jX_i$)

$$\hat{Q}_1=2X_1^2+\{X_1,X_3\}-X_2^2 \tag{3.34}$$

and the trivial constant C_1 is equal to $(X_1+X_3)^2$, with $C=\hat{Q}_1-C_1$.

The HJ equation is

$$\frac{1}{2}\left(\frac{\partial S}{\partial\phi}\right)^2-2m_0m_1e^{-2\phi}+m_1^2e^{-4\phi}=E. \tag{3.35}$$

We will assume $m_1\neq 0$ to obtain nontrivial results. Depending on the constants m_0,m_1 we get essentially two classes of systems.

(1) If $m_0m_1\leqslant 0$ there is no extremum for the potential, and the energy is always positive. The solutions, with a unique turning point, are given by

$$e^{2\phi}=\frac{m_1}{E}[-m_0+\sqrt{E+m_0^2}\cosh\sqrt{2E}t]. \tag{3.36}$$

(2) If $m_0m_1>0$ the potential has a minimum, in $\phi=(1/2)\log(m_1/m_0)$ and the energy is bounded from below, $E>-m_0^2$. As in the first case, the values of the parameters are not essential if they satisfy the constraints. The solutions for the different values of the energy are

(i) $-m_0^2<E<0$

$$e^{2\phi}=\frac{m_1}{|E|}[m_0+\sqrt{E+m_0^2}\cos\sqrt{2E}t]. \tag{3.37}$$

(ii) $E=0$

$$e^{2\phi}=\frac{m_1}{2m_0}+4m_0m_1t^2. \tag{3.38}$$

If $E>0$ the solution is the same as (3.36).

This case completes the set of one-dimensional Hamiltonians obtained through a reduction procedure out of free Hamiltonians, invariant under SU(p,q), $p+q=2$, and defined over a homogeneous space of the corresponding group. In Table I, we present a summary of these

Hamiltonians in the one-dimensional case.

In the next section we will treat the two-dimensional Hamiltonians associated with the rank 2 algebras $su(3)$ and $su(2,1)$.

IV. THE TWO-DIMENSIONAL CASE

There are two pseudounitary algebras to be used to construct superintegrable Hamiltonians of dimension 2, $su(3)$ and $su(2,1)$. We will treat separately both cases.

A. $su(3)$

We will use as a basis for $su(3)$ the operators $\{X_1,\dots,X_8\}$ which are given in the 3×3 matrix representation by

$$X_1\to\begin{pmatrix} i & 0 & 0\\ 0 & -i & 0\\ 0 & 0 & 0\end{pmatrix},\quad X_2\to\begin{pmatrix} 0 & 0 & 0\\ 0 & i & 0\\ 0 & 0 & -i\end{pmatrix},\quad X_3\to\begin{pmatrix} 0 & 1 & 0\\ -1 & 0 & 0\\ 0 & 0 & 0\end{pmatrix},$$

$$X_4\to\begin{pmatrix} 0 & i & 0\\ i & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\quad X_5\to\begin{pmatrix} 0 & 0 & 1\\ 0 & 0 & 0\\ -1 & 0 & 0\end{pmatrix},\quad X_6\to\begin{pmatrix} 0 & 0 & i\\ 0 & 0 & 0\\ i & 0 & 0\end{pmatrix},$$

$$X_7\to\begin{pmatrix} 0 & 0 & 0\\ 0 & 0 & 1\\ 0 & -1 & 0\end{pmatrix},\quad X_8\to\begin{pmatrix} 0 & 0 & 0\\ 0 & 0 & i\\ 0 & i & 0\end{pmatrix},$$

when the metric is $K=\mathrm{diag}(1,1,1)$.

In the compact case there is only one MASA, the Cartan subalgebra, generated by the matrices

$$\begin{pmatrix} i & & \\ & -i & \\ & & 0\end{pmatrix},\quad \begin{pmatrix} 0 & & \\ & i & \\ & & -i\end{pmatrix}, \tag{4.1}$$

and we shall use the following basis for the corresponding MASA in $u(3)$:

$$Y_0=\begin{pmatrix} i & & \\ & 0 & \\ & & 0\end{pmatrix},\quad Y_1=\begin{pmatrix} 0 & & \\ & i & \\ & & 0\end{pmatrix},\quad Y_2=\begin{pmatrix} 0 & & \\ & 0 & \\ & & i\end{pmatrix}. \tag{4.2}$$

The coordinates s are related to the coordinates y in the same way as in $su(2)$, (3.3),

$$y_0=s_0e^{ix_0},\quad y_1=s_1e^{ix_1},\quad y_2=s_2e^{ix_2}, \tag{4.3}$$

and the Hamiltonian has also the same form of all cases using compact Cartan subalgebras (3.4),

$$H=\tfrac{1}{2}(p_0^2+p_1^2+p_2^2)+V(s),\quad V(s)=\frac{m_0^2}{s_0^2}+\frac{m_1^2}{s_1^2}+\frac{m_2^2}{s_2^2}, \tag{4.4}$$

with the constraint $s_0^2+s_1^2+s_2^2=1$.

In the one-dimensional case, there was only one invariant, which was the Hamiltonian. In this case, we can construct three invariants, only two of them in involution at the same time (one of them the Hamiltonian). The system is superintegrable in the sense of Ref. 12. These invariants are[14]

$$R_{01}=(s_0p_1-s_1p_0)^2+\left(m_0\frac{s_1}{s_0}+m_1\frac{s_0}{s_1}\right)^2,$$
$$R_{02}=(s_0p_2-s_2p_0)^2+\left(m_0\frac{s_2}{s_0}+m_2\frac{s_0}{s_2}\right)^2, \tag{4.5}$$
$$R_{12}=(s_1p_2-s_2p_1)^2+\left(m_1\frac{s_2}{s_1}+m_2\frac{s_1}{s_2}\right)^2.$$

The sum of these three invariants is the Hamiltonian up to an additive constant. In order to study the solutions of this problem we need construct a coordinate system in which the corresponding HJ equation separates into a system of ordinary differential equations. As in Ref. 16 we will use spherical coordinates,[19] defined by

$$s_0=\cos\phi_2\cos\phi_1,\quad s_1=\cos\phi_2\sin\phi_1,\quad s_2=\sin\phi_2, \tag{4.6}$$

and the Hamiltonian is written as $(c=1)$

$$H=\frac{1}{2}\left(p_{\phi_2}^2+\frac{p_{\phi_1}^2}{\cos^2\phi_2}\right)+V(\phi_1,\phi_2),$$
$$V(\phi_1,\phi_2)=\frac{1}{\cos^2\phi_2}\left(\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1}\right)+\frac{m_2^2}{\sin^2\phi_2}, \tag{4.7}$$

where the constants m_0, m_1, m_2 are chosen to be non-negative.

The second order conserved quantities (4.5) (we will follow the notation $\hat{Q}$ for these operators) can be written in terms of the basis $\{X_1, \ldots, X_8\}$,

$$\hat{Q}_1=X_3^2+X_4^2,\quad \hat{Q}_2=X_5^2+X_6^2,\quad \hat{Q}_3=X_7^2+X_8^2 \tag{4.8}$$

with commutation relations (the commutator is a third order element which plays no essential role in the method),

$$[\hat{Q}_1,\hat{Q}_2]=[\hat{Q}_2,\hat{Q}_3]=[\hat{Q}_3,\hat{Q}_1].$$

The Casimir is

$$C=4C_1+2C_2+4C_3+3\hat{Q}_1+3\hat{Q}_2+3\hat{Q}_3,$$

where

$$C_1=X_1^2,\quad C_2=\{X_1,X_2\},\quad C_3=X_2^2$$

are the second order operators in the enveloping algebra of the compact Cartan subalgebra.

The Hamiltonian is

$$H=Q_1+Q_2+Q_3+\text{constant}$$

where Q_i is the expression of $\hat{Q}_i$ in spherical coordinates,[19]

$$Q_1=\frac{1}{2}p_{\phi_1}^2+\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1},$$

$$Q_2=\tan^2\phi_2\left(\frac{1}{2}p_{\phi_1}^2\sin^2\phi_1+\frac{m_0^2}{\cos^2\phi_1}\right)+\cos^2\phi_1\left(\frac{1}{2}p_{\phi_2}^2+\frac{m_2^2}{\tan^2\phi_2}\right)$$
$$+\frac{1}{2}p_{\phi_1}p_{\phi_2}\sin 2\phi_1\tan\phi_2,$$

$$Q_3=\tan^2\phi_2\left(\frac{1}{2}p_{\phi_1}^2\cos^2\phi_1+\frac{m_1^2}{\sin^2\phi_1}\right)+\sin^2\phi_1\left(\frac{1}{2}p_{\phi_2}^2+\frac{m_2^2}{\tan^2\phi_2}\right)$$
$$-\frac{1}{2}p_{\phi_1}p_{\phi_2}\sin 2\phi_1\tan\phi_2.$$

The HJ equation is

$$\frac{1}{2}\left(\frac{\partial S}{\partial\phi_2}\right)^2+\frac{m_2^2}{\sin^2\phi_2}+\frac{1}{\cos^2\phi_2}\left(\frac{1}{2}\left(\frac{\partial S}{\partial\phi_1}\right)^2+\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1}\right)=E, \tag{4.9}$$

and separates into two ordinary differential equations using $S(\phi_1,\phi_2)=S_1(\phi_1)+S_2(\phi_2)-Et$,

$$\frac{1}{2}\left(\frac{\partial S_1}{\partial\phi_1}\right)^2+\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1}=\alpha_1, \tag{4.10}$$

$$\frac{1}{2}\left(\frac{\partial S_2}{\partial\phi_2}\right)^2+\frac{m_2^2}{\sin^2\phi_2}+\frac{\alpha_1}{\cos^2\phi_2}=\alpha_2, \tag{4.11}$$

where $\alpha_2=E$ and α_1 are the separation constants (which are positive). These equations have the same form as those in (3.7) The solutions are easily computed and can be found as particular cases in Ref. 16. The potential has singularities along the coordinate lines, $\phi_1=0,\pi/2,\pi,3\pi/2$, and $\phi_2=\pi/2,3\pi/2$ in the generic case. It has a unique minimum inside each regularity domain. An analysis of the associated dynamical system (Hamilton equations) shows that all the orbits in a neighborhood of the critical point (center) are closed and hence, the corresponding trajectories are periodic (a direct consequence of the correspondence between extrema of the potential and critical points of the phase space). Let us restrict to the domain $0<\phi_1,\phi_2<\pi/2$, where the minimum is $\tan\phi_1=\sqrt{m_1/m_0}$, $\tan\phi_2=\sqrt{m_2/(m_0+m_1)}$. The value of the potential at this point is $(m_0+m_1+m_2)^2$, hence the energy E is bounded from below ($E\geqslant(m_0+m_1+m_2)^2$). The explicit solutions are

$$\cos^2\phi_2=\frac{1}{2E}[b_2+\sqrt{b_2^2-4\alpha_1E}\cos 2\sqrt{2E}t], \tag{4.12}$$

$$\cos^2\phi_1=\frac{1}{2\alpha_1}\left[b_1+\frac{1}{\cos^2\phi_2}\left[\frac{b_1^2-4\alpha_1m_0^2}{b_2^2-4\alpha_1E}\right]^{1/2}((b_2\cos^2\phi_2-2\alpha_1)\sin 2\sqrt{2\alpha_1}\beta_1\right.$$
$$\left.+2\sqrt{\alpha_1}[(b_2-E\cos^2\phi_2)\cos^2\phi_2-\alpha_1]^{1/2}\cos 2\sqrt{2\alpha_1}\beta_1)\right], \tag{4.13}$$

where $b_1=\alpha_1+m_0^2-m_1^2$ and $b_2=E+\alpha_1-m_2^2$.

Let us remark that these results reflect essentially the case $su(2)$. In fact all systems we can construct using Cartan subalgebras can be described in a unified way as it was shown in Refs. 14 and 16.

B. $su(2,1)$

The basis we will use is formed by the set of operators $\{X_1, \ldots, X_8\}$ which are given in the 3×3 matrix representation by

$$X_1 \to \begin{pmatrix} i & 0 & 0 \\ 0 & -i & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad X_2 \to \begin{pmatrix} 0 & 0 & 0 \\ 0 & i & 0 \\ 0 & 0 & -i \end{pmatrix}, \quad X_3 \to \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

$$X_4 \to \begin{pmatrix} 0 & i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad X_5 \to \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad X_6 \to \begin{pmatrix} 0 & 0 & i \\ 0 & 0 & 0 \\ -i & 0 & 0 \end{pmatrix},$$

$$X_7 \to \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad X_8 \to \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & i \\ 0 & -i & 0 \end{pmatrix}.$$

According to general results,[22] $su(2,1)$ has four MASAs, two of them Cartan subalgebras (compact and noncompact), one orthogonally decomposable subalgebra, with one nilpotent element, and one nilpotent subalgebra. We will discuss these four cases in the following. Although some of these subalgebras have a simpler expression in some skew diagonal metrics, we will always use the diagonal one,

$$K = \begin{pmatrix} 1 & & \\ & 1 & \\ & & -1 \end{pmatrix} \tag{4.14}$$

because, in this way, the kinetic part is always diagonal. There are nine coordinate systems associated with $O(2,1)$ free Hamiltonians, spherical, hyperbolic, elliptic (I and II), complex elliptic, horospheric, elliptic parabolic, hyperbolic parabolic, and semicircular parabolic.[20,23] Not all of them will separate our systems because these are not free. However, the appropriate systems have been computed in Ref. 20 and we will use their results.

1. Compact Cartan subalgebra (CC)

The compact Cartan subalgebra has a basis formed by the same two matrices we used in $su(3)$, and the same situation happens for the corresponding MASA in $u(2,1)$ (4.2). The coordinates s are also related to the coordinates y as they did in the compact case $su(3)$ (4.3).

However, the Hamiltonian reflects the noncompact character of $su(2,1)$

$$H = c\left(\tfrac{1}{2}(p_0^2 + p_1^2 - p_2^2) + V(s)\right), \quad V(s) = \frac{m_0^2}{s_0^2} + \frac{m_1^2}{s_1^2} - \frac{m_2^2}{s_2^2}, \tag{4.15}$$

where the constraint $s_0^2 + s_1^2 - s_2^2 = 1$ must be satisfied.

This Hamiltonian separates in four coordinate systems, spherical, hyperbolic, and elliptic I and II.[20] We will use spherical coordinates to discuss the explicit solution,

$$s_0 = \cosh\phi_2 \cos\phi_1, \quad s_1 = \cosh\phi_2 \sin\phi_1, \quad s_2 = \sinh\phi_2. \tag{4.16}$$

Choosing $c = -1$, we have the Hamiltonian in these coordinates,

$$H=\frac{1}{2}\left(p_{\phi_2}^2-\frac{p_{\phi_1}^2}{\cosh^2\phi_2}\right)+V(\phi_1,\phi_2),$$
$$V(\phi_1,\phi_2)=-\frac{1}{\cosh^2\phi_2}\left(\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1}\right)+\frac{m_2^2}{\sinh^2\phi_2}. \tag{4.17}$$

Due to the form of the potential the constants m_0, m_1, m_2 can be chosen to be non-negative. The potential is regular inside the domain $0<\phi_1<\pi/2$, $0<\phi_2<\infty$. It has a saddle point, $\tan\phi_1=\sqrt{m_1/m_0}$, $\tanh\phi_2=\sqrt{m_2/(m_0+m_1)}$, if $m_0+m_1>m_2$. However, due to the special form of the kinetic term (which is not positive definite), it is easy to check that the associated dynamical system has all the orbits in a neighborhood of the critical point (which is also a center as in the compact case) closed and again, the corresponding trajectories are periodic.

The second order operators in the enveloping algebra of this MASA are

$$C_1=X_1^2,\quad C_2=\{X_1,X_2\},\quad C_3=X_2^2.$$

The quadratic constants of motion lying in the enveloping algebra of $su(2,1)$ and commuting with the elements in the compact Cartan subalgebra are

$$\hat{Q}_1=X_3^2+X_4^2,\quad \hat{Q}_2=X_5^2+X_6^2,\quad \hat{Q}_3=X_7^2+X_8^2 \tag{4.18}$$

with commutation relations

$$[\hat{Q}_1,\hat{Q}_2]=[\hat{Q}_3,\hat{Q}_2]=-[\hat{Q}_3,\hat{Q}_1].$$

The Casimir is written in terms of these second order operators as

$$C=4C_1+2C_2+4C_3+3\hat{Q}_1-3\hat{Q}_2-3\hat{Q}_3,$$

and the Hamiltonian is

$$H=-Q_1+Q_2+Q_3+\text{constant}$$

where Q_i are the conserved quantities in spherical coordinates,

$$Q_1=\frac{1}{2}p_{\phi_1}^2+\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1},$$

$$Q_2=\tanh^2\phi_2\left(\frac{1}{2}p_{\phi_1}^2\sin^2\phi_1+\frac{m_0^2}{\cos^2\phi_1}\right)+\cos^2\phi_1\left(\frac{1}{2}p_{\phi_2}^2+\frac{m_2^2}{\tanh^2\phi_2}\right)$$
$$-\frac{1}{2}p_{\phi_1}p_{\phi_2}\sin 2\phi_1\tanh\phi_2,$$

$$Q_3=\tanh^2\phi_2\left(\frac{1}{2}p_{\phi_1}^2\cos^2\phi_1+\frac{m_1^2}{\sin^2\phi_1}\right)+\sin^2\phi_1\left(\frac{1}{2}p_{\phi_2}^2+\frac{m_2^2}{\tanh^2\phi_2}\right)$$
$$+\frac{1}{2}p_{\phi_1}p_{\phi_2}\sin 2\phi_1\tanh\phi_2.$$

The HJ equations corresponding to the Hamiltonian (4.17) are

$$\frac{1}{2}\left(\frac{\partial S_1}{\partial \phi_1}\right)^2+\frac{m_0^2}{\cos^2\phi_1}+\frac{m_1^2}{\sin^2\phi_1}=\alpha_1, \tag{4.19}$$

$$\frac{1}{2}\left(\frac{\partial S_2}{\partial \phi_2}\right)^2+\frac{m_2^2}{\sinh^2\phi_2}-\frac{\alpha_1}{\cosh^2\phi_2}=\alpha_2. \tag{4.20}$$

The first one is the same as we got in $su(3)$ (4.10), α_1 is always positive and $\alpha_2=E$.

The solutions depend on the values of the parameters and energy

(i) $E<0$

$$u_2=\frac{1}{2|E|}\left[-b_2+\sqrt{b_2^2+4\alpha_1 E}\cos 2\sqrt{2|E|}t\right]. \tag{4.21}$$

(ii) $E=0$

$$u_2=\frac{\alpha_1}{\alpha_1-m_2^2}+2(\alpha_1-m_2^2)t^2. \tag{4.22}$$

(iii) $E>0$

$$u_2=\frac{1}{2E}\left[b_2+\sqrt{b_2^2+4\alpha_1 E}\cosh 2\sqrt{2E}t\right], \tag{4.23}$$

where $u_2=\cosh^2\phi_2$, $b_2=E-\alpha_1+m_2^2$. The other equation can be solved as we did in the previous cases. The result is

$$u_1=\frac{1}{2\alpha_1}\left[b_1+\frac{1}{u_2}\left[\frac{b_1^2-4\alpha_1 m_0^2}{b_2^2+4\alpha_1 E}\right]^{1/2}(-(b_2u_2+2\alpha_1)\sin 2\sqrt{2\alpha_1}\beta_1\right.$$
$$\left.+2\sqrt{\alpha_1}[(Eu_2-b_2)u_2-\alpha_1]^{1/2}\cos 2\sqrt{2\alpha_1}\beta_1)\right], \tag{4.24}$$

where $u_1=\cos^2\phi_1$ and $b_1=\alpha_1+m_0^2-m_1^2$.

2. Noncompact Cartan subalgebra (NC)

There is only one noncompact Cartan subalgebra. A representative can be chosen according to the same criteria we used in $su(1,1)$ (3.19), keeping one element compact and the other (as in $su(1,1)$) noncompact,

$$\begin{pmatrix} 2i & & \\ & -i & \\ & & -i \end{pmatrix},\quad \begin{pmatrix} 0 & & \\ & 0 & i \\ & -i & 0 \end{pmatrix}, \tag{4.25}$$

and the basis for the corresponding MASA of $u(2,1)$ will be

$$Y_0=\begin{pmatrix} i & & \\ & 0 & \\ & & 0 \end{pmatrix},\quad Y_1=\begin{pmatrix} 0 & & \\ & i & \\ & & i \end{pmatrix},\quad Y_2=\begin{pmatrix} 0 & & \\ & 0 & i \\ & -i & 0 \end{pmatrix}. \tag{4.26}$$

The coordinates are as in $su(1,1)$,

$$y_0=e^{ix_0}s_0,$$

$$y_1 = e^{ix_1}(s_1 \cosh x_2 + i s_2 \sinh x_2), \tag{4.27}$$
$$y_2 = e^{ix_1}(-i s_1 \sinh x_2 + s_2 \cosh x_2).$$

The Hamiltonian is

$$H = c\left(\tfrac{1}{2}(p_0^2 + p_1^2 - p_2^2) + V(s)\right),$$
$$V(s) = \frac{m_0^2}{s_0^2} + \frac{(m_1^2 - m_2^2)(s_1^2 - s_2^2) + 4 m_1 m_2 s_1 s_2}{(s_1^2 + s_2^2)^2}, \tag{4.28}$$

where we will take $m_0 > 0$ and m_1, m_2 can take any value, and the coordinates satisfy the constraint (the same for all $su(2,1)$ MASAs, as we have chosen the same metric in all cases), $s_0^2 + s_1^2 - s_2^2 = 1$.

There are two systems of coordinates in which the associated HJ equation separates, hyperbolic and complex elliptic.[20] We will use hyperbolic coordinates, defined as

$$s_0 = \cosh \phi_2, \qquad s_1 = \sinh \phi_2 \sinh \phi_1, \qquad s_2 = \sinh \phi_2 \cosh \phi_1, \tag{4.29}$$

and the new Hamiltonian is $(c = -1)$

$$H = \frac{1}{2}\left(p_{\phi_2}^2 - \frac{p_{\phi_1}^2}{\sinh^2 \phi_2} \right) + V(\phi_1, \phi_2),$$
$$V(\phi_1, \phi_2) = -\frac{m_0^2}{\cosh^2 \phi_2} + \frac{1}{\sinh^2 \phi_2}\left(\frac{m_1^2 - m_2^2 - 2 m_1 m_2 \sinh 2\phi_1}{\cosh^2 2\phi_1} \right). \tag{4.30}$$

Note that the potential follows the same pattern as the corresponding case in $su(1,1)$. It is regular inside the domain, $-\infty < \phi_1 < \infty$, $0 < \phi_2 < \infty$, and has also a saddle point at $\sinh 2\phi_1 = -m_2/m_1$, $\tanh \phi_2 = \sqrt{|m_1/m_0|}$, when $|m_1| < |m_0|$. As in the previous case, the associated dynamical system has a center and the trajectories in a neighborhood of it are periodic.

The basis for this MASA is $\{2X_1 + X_2, X_8\}$, and the corresponding second order elements are

$$C_1 = (2X_1 + X_2)^2, \quad C_2 = \{2X_1 + X_2, X_8\}, \quad C_3 = X_8^2.$$

The second order conserved quantities, commuting with $2X_1 + X_2$ and X_8, and belonging to the enveloping algebra of $su(2,1)$ are

$$\hat{Q}_1 = X_2^2 - X_7^2,$$
$$\hat{Q}_2 = X_3^2 + X_4^2 - X_5^2 - X_6^2, \tag{4.31}$$
$$\hat{Q}_3 = \{X_3, X_5\} + \{X_4, X_6\},$$

with commuting relations,

$$[\hat{Q}_3, \hat{Q}_1] = [\hat{Q}_2, \hat{Q}_3], \;\; [\hat{Q}_1, \hat{Q}_2] = 0.$$

The Casimir is written as

$$C = C_1 - 3C_3 + 3\hat{Q}_1 + 3\hat{Q}_2,$$

and the Hamiltonian is

$$H = Q_1 + Q_2 + \text{constant}.$$

Finally, the conserved quantities are expressed in hyperbolic coordinates by

$$Q_1 = \frac{1}{2} p_{\phi_1}^2 - \frac{m_1^2 - m_2^2 - 2m_1 m_2 \sinh 2\phi_1}{\cosh^2 2\phi_1},$$

$$Q_2 = \frac{1}{2} p_{\phi_2}^2 - \frac{m_0^2}{\cosh^2 \phi_2} - \frac{1}{\tanh^2 \phi_2}\left(\frac{1}{2} p_{\phi_1}^2 - \frac{m_1^2 - m_2^2 - 2m_1 m_2 \sinh 2\phi_1}{\cosh^2 2\phi_1}\right),$$

$$Q_3 = \frac{1}{2} \sinh 2\phi_1 \left(p_{\phi_2}^2 + \frac{1}{\tanh^2 \phi_2} p_{\phi_1}^2\right) - \frac{\cosh 2\phi_1}{\tanh \phi_2} p_{\phi_1} p_{\phi_2}$$
$$+ m_0^2 \tanh^2 \phi_2 \sinh 2\phi_1 - \frac{(m_1^2 - m_2^2)\sinh 2\phi_1 + 2m_1 m_2}{\tanh^2 \phi_2 \cosh^2 2\phi_1}.$$

The Hamilton–Jacobi equation separates into two ordinary differential equations,

$$\frac{1}{2}\left(\frac{\partial S_1}{\partial \phi_1}\right)^2 - \frac{m_1^2 - m_2^2 - 2m_1 m_2 \sinh 2\phi_1}{\cosh^2 2\phi_1} = \alpha_1, \tag{4.32}$$

$$\frac{1}{2}\left(\frac{\partial S_2}{\partial \phi_2}\right)^2 - \frac{m_0^2}{\cosh^2 \phi_2} - \frac{\alpha_1}{\sinh^2 \phi_2} = E. \tag{4.33}$$

The solutions have the same form we have found before.

(i) $E<0$

$$u_2 = \frac{1}{2|E|}\left[b_2 + \sqrt{b_2^2 - 4\alpha_1 E} \cos 2\sqrt{2|E|}t\right]. \tag{4.34}$$

(ii) $E=0$

$$u_2 = -\frac{\alpha_1}{\alpha_1 + m_0^2} + 2(\alpha_1 + m_0^2)t^2. \tag{4.35}$$

(iii) $E>0$

$$u_2 = \frac{1}{2E}\left[-b_2 + \sqrt{b_2^2 - 4\alpha_1 E} \cosh 2\sqrt{2E}t\right], \tag{4.36}$$

where $u_2 = \sinh^2 \phi_2$, $b_2 = E + \alpha_1 + m_0^2$.

The solution for the other coordinate is obtained in the same way (with the change $u_1 = \sinh 2\phi_1$). The equation for this coordinate is the same as that given in formula (3.24) and its solutions can be found in formulas (3.25)–(3.29). Due to the possible different signs of the energy and the constant α_1, one should take care of the square roots appearing in all the formulas.

3. Orthogonally decomposable subalgebra (OD)

The orthogonally decomposable subalgebra (a representative of the class) has a basis formed by a compact element and a nilpotent one,

$$\begin{pmatrix} 2i & & \\ & -i & \\ & & -i \end{pmatrix}, \quad \begin{pmatrix} 0 & & \\ & i & i \\ & -i & -i \end{pmatrix}, \tag{4.37}$$

and the basis for the corresponding MASA of $u(2,1)$ is

$$Y_0 = \begin{pmatrix} i & & \\ & 0 & \\ & & 0 \end{pmatrix}, \quad Y_1 = \begin{pmatrix} 0 & & \\ & i & \\ & & i \end{pmatrix}, \quad Y_2 = \begin{pmatrix} 0 & & \\ & i & i \\ & -i & -i \end{pmatrix}. \tag{4.38}$$

The coordinates have also a similar form to those in $su(1,1)$ (3.31)

$$\begin{aligned} y_0 &= e^{ix_0} s_0, \\ y_1 &= e^{ix_1}((1+ix_2)s_1 + ix_2 s_2), \\ y_2 &= e^{ix_1}(-ix_2 s_1 + (1-ix_2)s_2). \end{aligned} \tag{4.39}$$

The Hamiltonian is

$$\begin{aligned} H &= c\left(\tfrac{1}{2}(p_0^2 + p_1^2 - p_2^2) + V(s)\right), \\ V(s) &= \frac{m_0^2}{s_0^2} - \frac{m_2^2(s_1 - s_2)}{(s_1+s_2)^3} + \frac{2m_1 m_2}{(s_1+s_2)^2} \end{aligned} \tag{4.40}$$

with $s_0^2 + s_1^2 - s_2^2 = 1$.

There are four coordinate systems associated to this subalgebra, hyperbolic, horospheric, elliptic parabolic, and hyperbolic parabolic.[20] We will use again the hyperbolic ones, defined as in (4.29).

The Hamiltonian is $(c=-1)$

$$\begin{aligned} H &= \frac{1}{2}\left(p_{\phi_2}^2 - \frac{p_{\phi_1}^2}{\sinh^2 \phi_2} \right) + V(\phi_1, \phi_2), \\ V(\phi_1, \phi_2) &= -\frac{m_0^2}{\cosh^2 \phi_2} - \frac{1}{\sinh^2 \phi_2}(m_2^2 e^{-4\phi_1} + 2m_1 m_2 e^{-2\phi_1}). \end{aligned} \tag{4.41}$$

The potential is regular inside the domain, $-\infty < \phi_1 < \infty$, $0 < \phi_2 < \infty$, and, as it happens in all the $su(2,1)$ cases, has a saddle point at $\phi_1 = (1/2)\log(|m_2/m_1|)$, $\tanh \phi_2 = \sqrt{|m_1/m_0|}$, when $|m_0| > |m_1|, m_1 m_2 < 0$. The situation is the same as in all other cases in $su(2,1)$.

The second order operators in the enveloping algebra of the MASA under consideration are given by

$$C_1 = (2X_1 + X_2)^2, \quad C_2 = \{2X_1 + X_2, X_2 + X_8\}, \quad C_3 = (X_2 + X_8)^2,$$

and the quadratic constants of motion,

$$\begin{aligned} \hat{Q}_1 &= X_3^2 + X_4^2 - X_5^2 - X_6^2, \\ \hat{Q}_2 &= (X_3 + X_5)^2 + (X_4 + X_6)^2, \end{aligned} \tag{4.42}$$

$$\hat{Q}_3 = X_7^2 + 2\{X_1, X_2 + X_8\},$$

satisfy the commutation relations

$$[\hat{Q}_1, \hat{Q}_2] = [\hat{Q}_2, \hat{Q}_3], \quad [\hat{Q}_1, \hat{Q}_3] = 0.$$

The Casimir is given in terms of these operators by

$$C = C_1 + 3C_2 - 3C_3 + 3\hat{Q}_1 - 3\hat{Q}_3$$

and the Hamiltonian is

$$H = -Q_1 + Q_3 + \text{constant}.$$

We can write the conserved quantities in hyperbolic coordinates,

$$Q_1 = \frac{1}{\tanh^2 \phi_2}\left(\frac{1}{2} p_{\phi_1}^2 + m_2^2 e^{-4\phi_1} + 2 m_1 m_2 e^{-2\phi_1}\right) - \left(\frac{1}{2} p_{\phi_2}^2 - \frac{m_0^2}{\cosh^2 \phi_2}\right),$$

$$Q_2 = e^{2\phi_1}\left(\frac{1}{2} p_{\phi_2}^2 + m_0^2 \tanh^2 \phi_2 + \frac{1}{\tanh^2 \phi_2}\left(\frac{1}{2} p_{\phi_1}^2 + m_2^2 e^{-4\phi_1}\right) - \frac{1}{\tanh \phi_2} p_{\phi_1} p_{\phi_2}\right),$$

$$Q_3 = \frac{1}{2} p_{\phi_1}^2 + m_2^2 e^{-4\phi_1} + 2 m_1 m_2 e^{-2\phi_2}.$$

The HJ equation is separated into the following equations:

$$\frac{1}{2}\left(\frac{\partial S_1}{\partial \phi_1}\right)^2 + (m_2^2 e^{-4\phi_1} + 2 m_1 m_2 e^{-2\phi_1}) = \alpha_1, \tag{4.43}$$

$$\frac{1}{2}\left(\frac{\partial S_2}{\partial \phi_2}\right)^2 - \frac{m_0^2}{\cosh^2 \phi_2} - \frac{\alpha_1}{\sinh^2 \phi_2} = E. \tag{4.44}$$

Equation (4.44) is integrated using $u_2 = \sinh^2 \phi_2$. The result is the same as in the previous case (4.33). Equation (4.43) is solved using $u_1 = e^{2\phi_1}$ (the same change we use in the nilpotent MASA of the $su(1,1)$ case), and the results are essentially the same we have found above (see 3.35).

4. Nilpotent subalgebra (NIL)

The nilpotent subalgebra has a basis formed by two nilpotent elements (one of order 2 and the other of order 3),

$$\begin{pmatrix} 0 & & \\ & i & i \\ & -i & -i \end{pmatrix}, \quad \begin{pmatrix} 0 & i & i \\ i & 0 & 0 \\ -i & 0 & 0 \end{pmatrix}, \tag{4.45}$$

and the basis for the MASA of $u(2,1)$ can be obtained adding to these two matrices the identity times the imaginary unit.

The new coordinates are defined through

$$y_0 = e^{ix_0}(s_0 + i x_2(s_1 + s_2)),$$

$$y_1 = e^{ix_0}\left(ix_2 s_0 + \left(1 - \frac{x_2^2}{2} + ix_1\right)s_1 + \left(-\frac{x_2^2}{2} + ix_1\right)s_2\right), \tag{4.46}$$

$$y_2 = e^{ix_0}\left(-ix_2 s_0 + \left(\frac{x_2^2}{2} - ix_1\right)s_1 + \left(1 + \frac{x_2^2}{2} - ix_1\right)s_2\right).$$

The Hamiltonian is

$$H = C(\tfrac{1}{2}(p_0^2 + p_1^2 - p_2^2) + V(s)),$$
$$V(s) = \frac{2m_0 m_1 + m_2^2}{(s_1+s_2)^2} - \frac{4m_1 m_2 s_0}{(s_1+s_2)^3} + \frac{m_1^2(4s_0^2-1)}{(s_1+s_2)^4}, \tag{4.47}$$

with the constraint, $s_0^2 + s_1^2 - s_2^2 = 1$.

We have now two separable coordinate systems: horospheric and semicircular parabolic.[20] We will use now the horospheric ones, defined by

$$s_0 = \phi_1 e^{\phi_2}, \quad s_1 = \cosh \phi_2 - \tfrac{1}{2}\phi_1^2 e^{\phi_2}, \quad s_2 = \sinh \phi_2 + \tfrac{1}{2}\phi_1^2 e^{\phi_2}. \tag{4.48}$$

The Hamiltonian is $(c = -1)$

$$H = \tfrac{1}{2}(p_{\phi_2}^2 - e^{-2\phi_2} p_{\phi_1}^2) + V(\phi_1, \phi_2),$$
$$V(\phi_1,\phi_2) = m_1^2 e^{-4\phi_2} - e^{-2\phi_2}(m_2^2 + 2m_0 m_1 + 4m_1\phi_1(m_1\phi_1 - m_2)). \tag{4.49}$$

The potential has no singularity in the whole plain (ϕ_1, ϕ_2). It has a saddle point at $\phi_1 = m_2/2m_1$, $\phi_2 = (1/2)\log(m_1/m_0)$, when $m_0 m_1 > 0$. The situation is the same as in all other cases in $su(2,1)$.

The second order elements in the enveloping algebra of the nilpotent subalgebra are

$$C_1 = (X_2 + X_8)^2, \quad C_2 = \{X_2 + X_8, X_4 + X_6\}, \quad C_3 = (X_4 + X_6)^2,$$

and the constants of motion

$$\hat{Q}_1 = 3(X_3 + X_5)^2 - 2\{2X_1 + X_2, X_2 + X_8\},$$
$$\hat{Q}_2 = \{2X_1 + X_2, X_4 + X_6\} + 6\{X_4, X_2 + X_8\} - 3\{X_7, X_3 + X_5\}, \tag{4.50}$$
$$\hat{Q}_3 = 4X_1^2 + 3X_2^2 - 2\{X_1, X_2\} + 6X_3^2 + 6X_4^2 - 3X_7^2 - \{4X_1 - X_2, X_8\} + 3\{X_3, X_5\} + 3\{X_4, X_6\},$$

have the following commutation relations:

$$[\hat{Q}_1, \hat{Q}_2] = [\hat{Q}_3, \hat{Q}_2], \quad [\hat{Q}_1, \hat{Q}_3] = 0.$$

The Casimir is

$$C = -3C_1 - 3C_3 - \hat{Q}_1 + \hat{Q}_3,$$

and the Hamiltonian

$$H = Q_1 - Q_3 + \text{constant}.$$

Finally, the second order constant of motion are given in horospheric coordinates by the following expressions:

$$Q_1=\tfrac{1}{2}p_{\phi_1}^2+4m_1\phi_1(m_1\phi_1-m_2),$$

$$Q_2=\tfrac{1}{2}\phi_1 p_{\phi_1}^2-\tfrac{1}{2}p_{\phi_1}p_{\phi_2}+(m_2^2+2m_0m_1)\phi_1$$
$$-m_1e^{-2\phi_2}(2m_1\phi_1-m_2)+4m_1\phi_1^2(m_1\phi_1-m_2),$$

$$Q_3=(1+e^{-2\phi_2})(\tfrac{1}{2}p_{\phi_1}^2+4m_1\phi_1(m_1\phi_1-m_2))$$
$$-(\tfrac{1}{2}p_{\phi_2}^2+m_1^2e^{-4\phi_2}-(m_2^2+2m_0m_1)e^{-2\phi_2}).$$

This is the most interesting case, in the sense that the others are easily reduced to the cases in dimension 1, while this nilpotent subalgebra does not appear in the $su(1,1)$ case. However, the solutions are still very similar to those found before. It is worth mentioning here, that all the potentials we have constructed (and any potential we could construct by using this method) are always inverse quadratic potentials in the coordinates, and the solutions have always similar forms (though they depend on the specific characteristics of these potentials and the constants involved).

The HJ equation is separated into the following equations:

$$\frac{1}{2}\left(\frac{\partial S_1}{\partial\phi_1}\right)^2+m_2^2+2m_0m_1+4m_1\phi_1(m_1\phi_1-m_2)=\alpha_1, \tag{4.51}$$

$$\frac{1}{2}\left(\frac{\partial S_2}{\partial\phi_2}\right)^2+m_1^2e^{-4\phi_2}-\alpha_1e^{-2\phi_2}=E. \tag{4.52}$$

The change $u_2=e^{2\phi_2}$ allows us to solve the second equation, and the other one is solved directly. The solutions are

(i) $E<0$

$$u_2=\frac{1}{2|E|}[\alpha_1+\sqrt{\alpha_1^2+4m_1^2E}\cos 2\sqrt{2|E|}t]. \tag{4.53}$$

(ii) $E=0$

$$u_2=\frac{m_1^2}{\alpha_1}+2\alpha_1t^2. \tag{4.54}$$

(iii) $E>0$

$$u_2=\frac{1}{2E}[-\alpha_1+\sqrt{\alpha_1^2+4m_1^2E}\cosh 2\sqrt{2E}t]. \tag{4.55}$$

The first equation gives the value of the ϕ_1 coordinate,

$$\phi_1=\frac{1}{2m_1}\left[m_2+\frac{1}{u_2}\left[\frac{\alpha_1-2m_0m_1}{\alpha_1^2+4m_1^2E}\right]^{1/2}((\alpha_1u_2-2m_1^2)\sin 2\sqrt{2}\beta_1m_1\right.$$
$$\left.+2m_1[(Eu_2-\alpha_1)u_2-m_1^2]^{1/2}\cos 2\sqrt{2}\beta_1m_1)\right]. \tag{4.56}$$

In Table II, we present a summary of these Hamiltonians in the two-dimensional case.

TABLE II. Two-dimensional potentials.

V. CONCLUSIONS

We have presented in this work a complete analysis of a series of one- and two-dimensional integrable Hamiltonians, which in the two-dimensional case are superintegrable in the sense described in the Introduction. Though the one-dimensional case is always an integrable system, let us remark the importance and applications of the potentials described in Sec. II. Regarding the two-dimensional ones, we have provided them with a set of conserved quantities which allows us to study the HJ equations in several separable coordinate systems and compute in some interesting cases the explicit solutions.

The one-dimensional Hamiltonians obtained here have been extensively studied in the literature from many other points of view. See for instance Ref. 24 for a recent application of Morse potentials. As an example of these different approaches, all of them appear in the classification of quasi-exactly solvable Schrödinger operators,[17,18] as particular types of these systems corresponding to the so called exactly solvable systems. Following the classification in Ref. 18, the exactly solvable potentials of Cases 1 and 2 are just the ones we have obtained associated to $su(1,1)$ and its compact and noncompact Cartan subalgebras. The first one (3.12) is the celebrated Pöschl–Teller potential. That appearing in case 3 is the Morse potential (3.33), which we get using the nilpotent subalgebra of $su(1,1)$. Finally the potential (3.5), associated to the Cartan subalgebra of $su(2)$ is related to the modified harmonic oscillators appearing in Ref. 18 as cases 4 and 5. One has to take into account in this case, that QES potentials, as studied in Ref. 18, are defined in the line (or half-line), and we are working here in a sector of S^1 (see also Ref. 25 for a study of harmonic oscillators in a sector). The relation is not surprising at all if one considers that QES systems in the line are related to the complex Lie algebra $sl(2)$,[17] and the ones we get here reflect the invariance under $su(2)$ and $su(1,1)$, the real forms of $sl(2)$. In the QES setting, Schrödinger operators belong to the enveloping algebra of a Lie algebra, while in our approach, the corresponding classical Hamiltonians are second order Casimirs of the algebra, and hence, they are particular cases (exactly solvable) of the former.

Two prolongations of this study are now in progress. One of them is the use of contractions in Lie algebras to obtain other Hamiltonian systems associated to different algebras, not necessarily semisimple. In this sense, the Hamiltonians, the conserved quantities and the coordinate systems can be obtained by contraction.[26,27] The second one is to apply this approach to the quantum case, considering the Schrödinger equation with these potentials.[28] We also plan to study the links of this theory with QES systems and the possibility of considering partial integrability and partial variable separation in HJ equations.[29]

Symmetries of Hamiltonian systems with two degrees of freedom

P. A. Damianou[a] and C. Sophocleous[b]
Department of Mathematics and Statistics, University of Cyprus, P. O. Box 537, Nicosia, Cyprus

(Received 11 June 1998; accepted for publication 25 September 1998)

We classify the Lie point symmetry groups for an autonomous Hamiltonian system with two degrees of freedom. With the exception of the harmonic oscillator or a free particle where the dimension is 15, we obtain all dimensions between 1 and 7. For each system in the classification we examine integrability. © *1999 American Institute of Physics.* [S0022-2488(99)01101-9]

I. INTRODUCTION

The objective of this paper is a complete classification of the Lie point symmetry groups for a Hamiltonian system with two degrees of freedom. We should clarify that we are dealing only with point transformations. In other words, the generators are functions of the dependent and independent variables; there is no dependence on the derivatives. We study the equations in Newtonian form since a first order system always has an infinite number of symmetries. We consider the motion of a particle of unit mass in the plane (q_1,q_2) under the influence of a potential of the form $V(q_1,q_2)$. We will assume that the Hamiltonian is time independent. This is not really a restriction because a time-dependent n-dimensional system is equivalent to a time-independent $(n+1)$-dimensional system by regarding the time variable as the new coordinate. For the most part we assume that the system is two-dimensional with Hamiltonian

$$H(q_1,q_2,p_1,p_2)=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+V(q_1,q_2). \tag{1}$$

However, in Sec. VI we generalize some of the results to the n-dimensional case. The real valued function $V(q_1,q_2)$ is assumed to be smooth on some open, connected subset of $\mathbf{R}^2$.

Hamilton's equations, in Newtonian form, become

$$\ddot{q}_1=-\frac{\partial V}{\partial q_1},\quad \ddot{q}_2=-\frac{\partial V}{\partial q_2}. \tag{2}$$

We search for point symmetries of the system (2). That is, we search for the infinitesimal transformations of the form

$$\begin{aligned} t'&=t+\epsilon\ T(t,q_1,q_2)+O(\epsilon^2),\\ q_1'&=q_1+\epsilon\ Q_1(t,q_1,q_2)+O(\epsilon^2),\\ q_2'&=q_2+\epsilon\ Q_2(t,q_1,q_2)+O(\epsilon^2). \end{aligned} \tag{3}$$

The functions $V(q_1,q_2)$ such that the system (2) admit such transformations are completely classified. Therefore, in the following analysis we determine the functions V, T, Q_1 and Q_2.

Equations (2) admit Lie transformations of the form (3) if and only if

[a]Electronic mail: damianou@ucy.ac.cy
[b]Electronic mail: christod@ucy.ac.cy

$$\Gamma^{(2)}\{\ddot{q}_1+V_{q_1}\}=0, \quad \Gamma^{(2)}\{\ddot{q}_2+V_{q_2}\}=0, \tag{4}$$

where $\Gamma^{(2)}$ is the second prolongation of

$$\Gamma=T\frac{\partial}{\partial t}+Q_1\frac{\partial}{\partial q_1}+Q_2\frac{\partial}{\partial q_2}. \tag{5}$$

For the reader who is unfamiliar with the definition and properties of Lie point symmetries, there are a number of excellent books on the subject, e.g., Refs. 1–4.

Equations (4) give two identities of the form

$$E_1(t,q_1,q_2,\dot{q}_1,\dot{q}_2)=0, \quad E_2(t,q_1,q_2,\dot{q}_1,\dot{q}_2)=0, \tag{6}$$

where we have used that $\ddot{q}_1=-\partial V/\partial q_1$ and $\ddot{q}_2=-\partial V/\partial q_2$. The functions E_1 and E_2 are explicit polynomials in $\dot{q}_1$ and $\dot{q}_2$. We impose the condition that Eqs. (6) are identities in five variables t, q_1, q_2, $\dot{q}_1$ and $\dot{q}_2$ which are regarded as independent. These two identities enable the infinitesimal transformations to be derived and ultimately impose restrictions on the functional forms of V, T, Q_1 and Q_2.

After some straightforward calculations one can show, see, e.g., Ref. 5, that the generators necessarily have the following form:

$$\begin{aligned} T&=a(t)+b_1(t)q_1+b_2(t)q_2, \\ Q_1&=b_1'(t)q_1^2+b_2'(t)q_1q_2+c_{11}(t)q_1+c_{12}(t)q_2+d_1(t), \\ Q_2&=b_1'(t)q_1q_2+b_2'(t)q_2^2+c_{21}(t)q_1+c_{22}(t)q_2+d_2(t). \end{aligned} \tag{7}$$

In this paper we classify the symmetry groups of the system according to the form of the generators. Here is a preview of the various cases and the potentials that appear.

Case 1. $b_1\neq 0$, $b_2\neq 0$.

In this case the potential is of the form

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\lambda_1 q_1+\lambda_2 q_2.$$

The symmetry group has maximum dimension. It is a 15-parameter group of transformations isomorphic to $sl(4,\mathbf{R})$.

Case 2. $b_1=b_2=0$.

In other words, T is function of time only. We consider two possibilities according to $a''\neq 0$ or $a''=0$.

First subcase: $a''\neq 0$

(2a)

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{(q_1+\kappa q_2)^2}.$$

In this case we obtain a 6-parameter group.

(2b)

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{q_2^2}.$$

This is a special case of the previous one with $\kappa=0$.
(2c)

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{1}{q_2^2}\Phi(\xi),$$

where $\xi=q_1/q_2$. For Φ arbitrary we end up with a 3-parameter symmetry group. For special types of Φ we obtain a 4-parameter group.
Second subcase: $a''=0$
This is the case where T is a linear function of time.
(2d)

$$V=q_2^2+\lambda_1 q_1 q_2+\Phi(\xi),$$

where $\xi=q_1-\lambda q_2$. For Φ arbitrary we end up with a 4-parameter symmetry group. For Φ quadratic we obtain a 7-parameter group and setting $\lambda_1=0$, for some special forms of Φ (exponential, logarithmic, nth power) results in a 5-parameter group of symmetries.
(2e)

$$V=\lambda_1 q_2^2+\Phi(q_1).$$

The case $\lambda_1=0$ is the case of a separable potential with one variable missing. We will comment on this case separately. If $\lambda_1\neq 0$, we end up with a 4-parameter group.
(2f) The dimensions of the symmetry groups in this case are all equal to 2 except for the last three systems where the dimension is 3. Specifically, we obtain the following list of potentials.

1.

$$V=q_2^N\Phi\left(\frac{q_1}{q_2}\right).$$

2.

$$V=\lambda_1\log q_2+\Phi\left(\frac{q_1}{q_2}\right).$$

3.

$$V=e^{\mu q_1}\Phi(q_2).$$

4

$$V=e^{\mu q_1}\Phi(q_1-\lambda q_2).$$

5–10.

$$V=\lambda_1 f_1(q_1)+\lambda_2 f_2(q_2),$$

where $f_1(q_1)=q_1^n$, $\log q_1$, $e^{\mu q_1}$ and $f_2(q_2)=q_2^m$, $\log q_2$, $e^{\mu q_2}$.

11.

$$V=\Phi(q_1^2+q_2^2).$$

12.

$$V=\lambda(q_1^2+q_2^2)^n,\quad n\neq -1,0,1\,.$$

13.

$$V=\lambda \log(q_1^2+q_2^2)$$

14.

$$V=\lambda \sin^{-1}\frac{q_1^2-q_2^2}{q_1^2+q_2^2}.$$

Finally, we note that the potential $V(q_1,q_2)=q_1^k$ has a 15-parameter group of symmetries for $k=0,1$, a 7-parameter group for $k=2$, a 6-parameter group for $k=-2$ and a 5-parameter group of symmetries otherwise. These dimensions generalize for arbitrary $n\geqslant 2$ to $(n+2)^2-1$, n^2+3, n^2+2, n^2+1 respectively.

In this paper we will not consider the general case of motion in $\mathbf{R}^n$, however, for the case $n=3$, the classification of symmetry groups is in progress; see Ref. 6. In this case, we end up again with a maximal dimension of $(n+2)^2-1=24$ for the harmonic oscillator or a free particle, but the dimensions of the other groups in the classification vary from 1 to 12 (n^2+3). We did not obtain the dimension 8 and any dimension between 13 and 23. For $n=4$ the dimensions 13 and 14 are probably missing.

In Sec. II we will also consider the simplest system, with one degree of freedom, mainly to illustrate the procedure we use for the two-dimensional case. The classification for a general ordinary differential equation of second order with one dependent and one independent variable goes back to Sophus Lie.[7] He showed that the dimensions of a maximal admitted algebra take only the values 1, 2, 3 and 8. Lie actually gave a group classification of all arbitrary order O.D.E.s. In this way he identified all equations that can be reduced to lower-order equations or completely integrated by group theoretical methods.[8] The problem of classifying symmetry groups for a system of differential equations is open. This is mentioned in Ref. 9 where some known facts are presented. Some results for linear systems of second order ordinary differential equations can be found in Ref. 10.

Of course, the ultimate goal in classical mechanics is to integrate explicitly the equations of motion. Such systems are called integrable. For the definition and basic concepts of Hamiltonian Systems and Symplectic Geometry there are a number of good references, e.g., Refs. 11–15. The key result is the following theorem of Liouville which in the 2-dimensional case translates as follows: *Consider a Hamiltonian system with two degrees of freedom. If in addition to the Hamiltonian H there is a second integral of motion I, independent of H, then the system is integrable, i.e., in principle one can solve the equations by quadratures.* Even though most of the well known systems of classical mechanics are Liouville integrable, the fact is that most Hamiltonian systems are not integrable, a result demonstrated by Poincaré. It is not surprising that most of the symmetry groups that appear in our classification correspond to integrable potentials. The nonintegrable potentials appear mainly in case 2f, where the size of the symmetry group is small. The integrability of two-dimensional systems has been the subject of numerous investigations; see, for example, Refs. 16–22. Of course, a system with symmetries should be expected to be integrable, after all this is the essence of Noether's theorem; in this direction see, for example, the review.[23] On the other hand, one can give a number of examples of integrable systems whose symmetry group is trivial (i.e., one-dimensional). Some of the chaotic systems that do not appear in our list, for example, the famous Hénon–Heiles system, are known to have only $\partial/\partial t$ as a single symmetry. Of course, we should point out that all the systems which do not appear in our classification will have $\partial/\partial t$ as a single symmetry. One can construct a number of systems possessing only one symmetry. For example, one can take

$$V=q_1^2+2q_2^2+q_1^kq_2, \tag{8}$$

with $k>1$.

As was discussed in Ref. 24 there are integrable systems which possess only one symmetry. This situation is also investigated in Ref. 25. We would like to point out another example:

$$V=4q_1^2+q_2^2+\frac{r_1}{q_1}+\frac{r_2}{q_2^2}. \tag{9}$$

In this system the associated Hamilton–Jacobi equation is separable in Cartesian coordinates. We should point out that integrable systems have symmetries other than point symmetries. One may allow the infinitesimals T, Q_i to depend on t, q_i and the derivatives of q_i. Transformations of this type are commonly called Lie–Bäckland or generalized transformations. For more details see, for example, Refs. 26–28 or the books Refs. 1–4. There is also the notion of dynamical or contact symmetries (a subset of Lie–Bäckland transformations) where the generators are velocity dependent. The connection between first integrals and symmetries is more transparent when these types of symmetries are used. Furthermore, these generalizations cover a wider range of systems. The drawback, of course, is the complexity of calculating and classifying these types of symmetry groups. This is an obvious direction of future research. Another direction is to consider velocity-dependent potentials.

For the integrable systems that appear in the list we actually give the second integral (whenever it is not obvious) or a reference. Since integrability is preserved under various transformations, e.g., translations, rotations, scalings, time reflections, we construct the second invariant for a representative of that class. Generally we choose the potential to be as simple as possible in order to illustrate the symmetry group and demonstrate integrability.

II. SYSTEMS WITH ONE DEGREE OF FREEDOM

Before attacking the two-dimensional case, we classify the symmetries for a one-dimensional system, just to illustrate the techniques we use on the two-dimensional case. We consider a Hamiltonian of the form

$$H=1/2p^2+V(q). \tag{10}$$

The equation of motion of the particle is

$$\ddot{q}=-\frac{\partial V}{\partial q}. \tag{11}$$

We search for symmetries for Eq. (11) of the form

$$t'=t+\epsilon T(t,q)+O(\epsilon^2), \quad q'=q+\epsilon Q(t,q)+O(\epsilon^2). \tag{12}$$

Equation (11) admits symmetries of the form (12) if and only if

$$\Gamma^{(2)}\{\ddot{q}+V_q\}=0, \tag{13}$$

where $\Gamma^{(2)}$ is the second prolongation of

$$\Gamma=T\frac{\partial}{\partial t}+Q\frac{\partial}{\partial q}. \tag{14}$$

The definition of the second prolongation is the following: First we define the first prolongation,

$$\Gamma^{(1)}=\Gamma+[-T_q\dot{q}^2+(Q_q-T_t)\dot{q}+Q_t]\frac{\partial}{\partial \dot{q}}. \tag{15}$$

The second prolongation of Γ is an extension of $\Gamma^{(1)}$ given by

$$\Gamma^{(2)}=\Gamma^{(1)}+[(Q_q-2T_t-3T_q\dot{q})\ddot{q}-T_{qq}\dot{q}^3+(Q_{qq}-2T_{tq})\dot{q}^2+(2Q_{tq}-T_{tt})\dot{q}+Q_{tt}]\frac{\partial}{\partial\ddot{q}}. \tag{16}$$

Equation (13) becomes an identity of the form

$$E(t,q,\dot{q})=0, \tag{17}$$

using the fact that $\ddot{q}=-V_q$.

The coefficient of $\dot{q}^3$ in (17) gives $T_{qq}=0$. Similarly, the coefficient of $\dot{q}^2$ gives $Q_{qq}=2T_{tq}$. Therefore,

$$T=a(t)+b(t)q, \quad Q=b'(t)q^2+c(t)q+d(t). \tag{18}$$

Using Eqs. (18), identity (17) becomes

$$\left[3b\frac{\partial V}{\partial q}+3qb''-a''+2c'\right]\dot{q}+(q^2b'+qc+d)\frac{\partial^2 V}{\partial q^2}+(2a'-c)\frac{\partial V}{\partial q}+q^2b'''+qc''+d''=0. \tag{19}$$

The coefficient of $\dot{q}$ in (19) gives

$$3b\frac{\partial V}{\partial q}+3qb''-a''+2c'=0. \tag{20}$$

We split the analysis into two exclusive cases: Case 1. $b\neq 0$. Case 2. $b=0$.

Case 1. $b\neq 0$.

From Eq. (20) we obtain

$$V=\frac{\lambda_1}{2}q^2+\lambda_2 q+\lambda_3. \tag{21}$$

One easily calculates that the algebra of symmetries has dimension 8. It is a simple Lie algebra isomorphic to $sl(3,\mathbf{R})$.

Case 2. $b=0$.

From (20) we have

$$c=\tfrac{1}{2}a'+c_1,$$

and Eq. (19) becomes

$$[q(a'+2c_1)+2d]\frac{\partial^2 V}{\partial q^2}+(3a'-2c_1)\frac{\partial V}{\partial q}+a'''q+2d''=0. \tag{22}$$

From Eq. (22) we deduce that V satisfies an o.d.e. of the form

$$(\lambda_1 q+\lambda_2)V_{qq}+\lambda_3 V_q=\lambda_4 q+\lambda_5. \tag{23}$$

In order to solve Eq. (23) we consider the following five possibilities.

1. $\lambda_1=\lambda_2=\lambda_3=\lambda_4=\lambda_5=0$. In this case we get $a(t)=\text{constant}$, $c_1=0$ and $d(t)=0$. Therefore for V arbitrary we have $T=c_2$, $Q=0$. In other words the symmetry group is trivial (one-dimensional).
2. $\lambda_1=\lambda_3=0$, $\lambda_2\neq 0$. In this case, V is quadratic, a case already examined.

3. $\lambda_1=0$, $\lambda_2\neq 0$, $\lambda_3\neq 0$. From (23) we get $V=\lambda e^{\mu q}$, where we have ignored linear terms. We obtain a 2-parameter group of symmetries with $T=-2c_1t+c_2$ and $Q=4c_1/\mu$.
4. $\lambda_1\neq 0$, $\lambda_3=0$. From (23) we obtain $V=q\log q$. The symmetry group here is also trivial.
5. $\lambda_1\neq 0$, $\lambda_3\neq 0$. Without loss of generality we take $\lambda_2=0$ in (23) and we obtain either (i) $V=\lambda q^n$, $n\neq 0,1,2$, or (ii) $V=\lambda \log q$.

(i) We substitute $V=\lambda q^n$ into (22) to obtain $a(t)=c_2t^2+2c_3t+c_4$, $d(t)=c_1=0$ if $n=-2$ and $a(t)=[2(2-n)/n+2]c_1t+c_2$, $d(t)=0$ if $n\neq -2$. To summarize, we have for $V=\lambda/q^2$,

$$T=c_2t^2+2c_3t+c_4,\quad Q=(c_2t+c_3)q, \tag{24}$$

and for $V=\lambda q^n$, $n\neq -2,0,1,2$ the generators have the following form:

$$T=\frac{2(2-n)}{n+2}c_1t+c_2,\quad Q=\frac{4c_1}{n+2}q. \tag{25}$$

In other words, we obtain either a two-parameter or a three-parameter group of symmetries.
(ii) When $V=\lambda\log q$ we get $a(t)=2c_1t+c_2$ and $d(t)=0$. Therefore,

$$T=2c_1t+c_2,\quad Q=2c_1q. \tag{26}$$

This is a two-parameter group of symmetries.

To summarize the results: In the case of one degree of freedom we obtain a maximal dimension of 8 for the harmonic oscillator or a free particle, but the dimensions in the other groups in the classification vary from 1 to 3. We do not obtain any dimension between 4 and 7.

III. SYSTEMS WITH TWO DEGREES OF FREEDOM

We return now to the case of two-degrees of freedom. The analysis is analogous to the one used in the case of one-degree of freedom. We substitute the forms of T, Q_1, Q_2 in (7) into Eqs. (6).

The coefficient of $\dot{q}_1$ in Eq. (6) $[E_2=0]$ gives

$$2\left(\frac{\partial V}{\partial q_2}b_1+\frac{\partial^2 b_1}{\partial t^2}q_2+\frac{\partial c_{21}}{\partial t}\right)=0. \tag{27}$$

On the other hand, the coefficient of $\dot{q}_2$ in Eq. (6) $[E_1=0]$ implies

$$2\left(\frac{\partial V}{\partial q_1}b_2+\frac{\partial^2 b_2}{\partial t^2}q_1+\frac{\partial c_{12}}{\partial t}\right)=0. \tag{28}$$

Similarly, the coefficient of $\dot{q}_1$ in Eq. (6) $[E_1=0]$ gives

$$3b_1\frac{\partial V}{\partial q_1}+b_2\frac{\partial V}{\partial q_2}+3q_1\frac{\partial^2 b_1}{\partial t^2}+q_2\frac{\partial^2 b_2}{\partial t^2}-\frac{\partial^2 a}{\partial t^2}+2\frac{\partial c_{11}}{\partial t}=0, \tag{29}$$

while the coefficient of $\dot{q}_2$ in Eq. (6) $[E_2=0]$ implies

$$3b_2\frac{\partial V}{\partial q_2}+b_1\frac{\partial V}{\partial q_1}+3q_2\frac{\partial^2 b_2}{\partial t^2}+q_1\frac{\partial^2 b_1}{\partial t^2}-\frac{\partial^2 a}{\partial t^2}+2\frac{\partial c_{22}}{\partial t}=0. \tag{30}$$

If $b_1(t)\neq 0$ and $b_2(t)\neq 0$, then from Eqs. (27) and (28) we deduce that V is quadratic in q_1 and q_2. We also note that if $b_1=0$, $b_2\neq 0$ (or $b_1\neq 0$, $b_2=0$), then from Eqs. (28) and (29) V has again a quadratic form. We therefore split the analysis into two exclusive cases: **Case 1.** $b_1\neq 0$, $b_2\neq 0$. **Case 2.** $b_1=b_2=0$.

IV. CASE 1

From Eqs. (27) and (28) we deduce that

$$V=\lambda_1 q_1^2+\lambda_2 q_2^2+\lambda_3 q_1+\lambda_4 q_2+\lambda_5. \tag{31}$$

Now, substituting (31) into (6) the coefficients of $q_1\dot{q}_1$ in E_1 and $q_2\dot{q}_1$ in E_2 give, respectively,

$$3(b_1''+2\lambda_1 b_1)=0, \quad 3(b_1''+2\lambda_2 b_1)=0. \tag{32}$$

Hence, it follows that $\lambda_1=\lambda_2=0$ or $\lambda_1=\lambda_2\neq 0$.

In the case $\lambda_1=\lambda_2=0$, V is linear. We shall present the symmetries for this case, but in the remaining part of the analysis we shall ignore linear terms in the form of V. Adding a constant to Eqs. (2) has no effect on the symmetry groups.

Subcase 1a: $V=\lambda_1 q_1+\lambda_2 q_2+\lambda_3$.

Note that we have taken $\lambda_1=\lambda_2=0$ in (31) and then renamed the constants. Without presenting any calculations, we state that the system (2) with V linear has the following 15 symmetries:

$$\Gamma_1=\frac{\partial}{\partial t}, \quad \Gamma_2=\frac{\partial}{\partial q_1}, \quad \Gamma_3=\frac{\partial}{\partial q_2},$$

$$\Gamma_4=q_1\frac{\partial}{\partial t}-\left(\frac{\lambda_1^2}{4}t^3+\frac{3}{2}\lambda_1 t q_1\right)\frac{\partial}{\partial q_1}-\left(\frac{\lambda_1\lambda_2}{4}t^3+\frac{1}{2}\lambda_1 t q_2+\lambda_2 t q_1\right)\frac{\partial}{\partial q_2},$$

$$\Gamma_5=t\frac{\partial}{\partial t}+\left(\frac{1}{2}q_1-\frac{3}{4}\lambda_1 t^2\right)\frac{\partial}{\partial q_1}+\left(\frac{1}{2}q_2-\frac{3}{4}\lambda_2 t^2\right)\frac{\partial}{\partial q_2},$$

$$\Gamma_6=t^2\frac{\partial}{\partial t}+\left(q_1 t-\frac{\lambda_1}{2}t^3\frac{\partial}{\partial q_1}+\left(q_2 t-\frac{\lambda_2}{2}t^3\right)\frac{\partial}{\partial q_2},\right.$$

$$\Gamma_7=q_2\frac{\partial}{\partial t}-\left(\frac{\lambda_1\lambda_2}{4}t^3+\lambda_1 t q_2+\frac{1}{2}\lambda_2 t q_1\right)\frac{\partial}{\partial q_1}-\left(\frac{\lambda_2^2}{4}t^3+\frac{3}{2}\lambda_2 t q_2\right)\frac{\partial}{\partial q_2},$$

$$\Gamma_8=(2tq_2+\lambda_2 t^3)\frac{\partial}{\partial t}+\left(2q_1 q_2+\lambda_2 t^2 q_1-\lambda_1 t^2 q_2-\frac{1}{2}\lambda_1\lambda_2 t^4\right)\frac{\partial}{\partial q_1}+\left(2q_2^2-\frac{1}{2}\lambda_2^2 t^4\right)\frac{\partial}{\partial q_2},$$

$$\Gamma_9=(2tq_1+\lambda_1 t^3)\frac{\partial}{\partial t}+\left(2q_1^2-\frac{1}{2}\lambda_1^2 t^4\right)\frac{\partial}{\partial q_1}+\left(2q_1 q_2+\lambda_1 t^2 q_2-\lambda_2 t^2 q_1-\frac{1}{2}\lambda_1\lambda_2 t^4\right)\frac{\partial}{\partial q_2},$$

$$\Gamma_{10}=\left(q_2+\frac{1}{2}\lambda_2 t^2\right)\frac{\partial}{\partial q_1}, \quad \Gamma_{11}=\left(q_1+\frac{1}{2}\lambda_1 t^2\right)\frac{\partial}{\partial q_2}, \quad \Gamma_{12}=t\frac{\partial}{\partial q_1},$$

$$\Gamma_{13}=t\frac{\partial}{\partial q_2}, \quad \Gamma_{14}=\left(q_1+\frac{1}{2}\lambda_1 t^2\right)\frac{\partial}{\partial q_1}, \quad \Gamma_{15}=\left(q_2+\frac{1}{2}\lambda_2 t^2\right)\frac{\partial}{\partial q_2}.$$

Remark: This system is, of course, integrable. The second integral is $I=1/2\,p_1^2+\lambda_1 q_1$ *or* $I=1/2\,p_2^2+\lambda_2 q_2$. *It also has constants of motion linear in the momenta, for example,* $I=-\lambda_2 p_1+\lambda_1 p_2$.

Subcase 1b: $V=(\lambda/2)(q_1^2+q_2^2)$.

We will choose $\lambda=1$. We substitute the form of V into Eqs. (6) and equate coefficients.

In E_1, $\dot{q}_1 q_1=0$ implies

$$\frac{d^2 b_1}{dt^2}+b_1=0.$$

In E_1, $\dot{q}_1 q_2=0$ implies

$$\frac{d^2 b_2}{dt^2}+b_2=0.$$

In E_1, $\dot{q}_2=0$ implies

$$\frac{dc_{12}}{dt}=0,$$

therefore c_{12} is constant. Similarly, by examining the coefficient of $\dot{q}_1$ in E_2 we see that c_{21} is also constant.

In E_1, $\dot{q}_1=0$ and in E_2, $\dot{q}_2=0$, imply that

$$\frac{d^2 a}{dt^2}-2\frac{dc_{11}}{dt}=0,$$

and

$$\frac{d^2 a}{dt^2}-2\frac{dc_{22}}{dt}=0.$$

Similarly, using the coefficient of $q_1=0$ in E_1 and $q_2=0$ in E_2, we obtain

$$\frac{d^2 c_{11}}{dt^2}+2\frac{da}{dt}=0,$$

and

$$\frac{d^2 c_{22}}{dt^2}+2\frac{da}{dt}=0.$$

Finally, $E_1=0$ and $E_2=0$ imply that the functions $d_1(t)$ and $d_2(t)$ are solutions of the equation

$$\frac{d^2 x}{dt^2}+x=0.$$

Therefore the form of the generators in this case is the following:

$$T=k_1+k_2\cos 2t+k_3\sin 2t+(k_4\cos t+k_5\sin t)q_1+(k_6\cos t+k_7\sin t)q_2,$$

$$Q_1=(-k_4\sin t+k_5\cos t)q_1^2+(-k_6\sin t+k_7\cos t)q_1q_2 +(-k_2\sin 2t+k_3\cos 2t+c_{11})q_1+c_{12}q_2+k_8\cos t+k_9\sin t,$$

$$Q_2=(-k_4\sin t+k_5\cos t)q_1q_2+(-k_6\sin t+k_7\cos t)q_2^2+c_{21}q_1 +(-k_2\sin 2t+k_3\cos 2t+c_{22})q_2+k_{10}\cos t+k_{11}\sin t.$$

We note that the system (2) with $V=(\lambda/2)(q_1^2+q_2^2)$ admits a 15-parameter group of transformations isomorphic to $sl(4,\mathbf{R})$.

Remark: This system is the 2-dimensional isotropic oscillator. A second integral is $I_1=1/2\,p_1^2+1/2\,q_1^2$ *or* $I_2=1/2\,p_2^2+\frac{1}{2}q_2^2$. *We also have constants of motion linear in the momenta, for example,* $I_3=q_2p_1-q_1p_2$.

Remark: Cases 1a and 1b give the most general form of Hamiltonian for which the second invariant is linear in the momenta.[21]

V. CASE 2

We use the identities $E_1=0$ and $E_2=0$ in (6) to obtain

$$E_1:\ \dot{q}_2=0\ \Leftrightarrow\ c_{12}'=0,\quad E_2:\ \dot{q}_1=0\Leftrightarrow c_{21}'=0,$$
$$E_1:\dot{q}_1=0\ \Leftrightarrow\ 2c_{11}'-a''=0,\quad E_2:\dot{q}_2=0\ \Leftrightarrow\ 2c_{22}'-a''=0. \tag{33}$$

Therefore, $c_{12}=c_1$, $c_{21}=c_2$, $c_{11}=1/2\,a'+c_3$ and $c_{22}=1/2\,a'+c_4$. Here and elsewhere the c_i are constants. Using these results, Eqs. (6) take the form

$$(a'q_2+2c_2q_1+2c_4q_2+2d_2)V_{q_1q_2}+(a'q_1+2c_3q_1+2c_1q_2+2d_1)V_{q_1q_1} +(3a'-2c_3)V_{q_1}-2c_1V_{q_2}+a'''q_1+2d_1''=0, \tag{34}$$

and

$$(a'q_1+2c_3q_1+2c_1q_2+2d_1)V_{q_1q_2}+(a'q_2+2c_2q_1+2c_4q_2+2d_2)V_{q_2q_2} +(3a'-2c_4)V_{q_2}-2c_2V_{q_1}+a'''q_2+2d_2''=0. \tag{35}$$

We differentiate Eqs. (34) and (35) with respect to t to obtain, respectively,

$$(a''q_2+2d_2')V_{q_1q_2}+(a''q_1+2d_1')V_{q_1q_1}+3a''V_{q_1}+a'''{}'q_1+2d_1'''=0, \tag{36}$$

$$(a''q_1+2d_1')V_{q_1q_2}+(a''q_2+2d_2')V_{q_2q_2}+3a''V_{q_2}+a'''{}'q_2+2d_2'''=0. \tag{37}$$

We now split the analysis into two parts: $a''\neq 0$ or $a''=0$.

Nonlinear *T*: $a''\neq 0$

We divide Eqs. (36) and (37) by a'' and then differentiate with respect to t to obtain, respectively,

$$2\left(\frac{d_2'}{a''}\right)'V_{q_1q_2}+2\left(\frac{d_1'}{a''}\right)'V_{q_1q_1}+\left(\frac{a'''{}'}{a''}\right)'q_1+2\left(\frac{d_1'''}{a''}\right)'=0, \tag{38}$$

$$2\left(\frac{d_1'}{a''}\right)' V_{q_1q_2}+2\left(\frac{d_2'}{a''}\right)' V_{q_2q_2}+\left(\frac{a''''}{a''}\right)' q_2+2\left(\frac{d_2'''}{a''}\right)'=0. \tag{39}$$

From Eqs. (38) and (39) we deduce that the function $V(q_1,q_2)$ satisfies two partial differential equations of the form

$$\lambda_1 V_{q_1q_2}+\lambda_2 V_{q_1q_1}+\lambda_3 q_1+\lambda_4=0, \tag{40}$$

$$\lambda_2 V_{q_1q_2}+\lambda_1 V_{q_2q_2}+\lambda_3 q_2+\lambda_5=0. \tag{41}$$

In order to solve Eqs. (40) and (41) we consider the following cases:

(i) $\lambda_1\neq 0,\ \lambda_2\neq 0$

(ii) $\lambda_1=0,\ \lambda_2\neq 0\ \ (\text{or}\ \lambda_1\neq 0,\ \lambda_2=0)$

(iii) $\lambda_1=\lambda_2=\lambda_3=\lambda_4=0$.

In the following three subcases we determine the form of V from Eqs. (40) and (41). The corresponding generators may be obtained with the employment of Eqs. (34)–(39).

Subcase 2a:

In this case, V takes the form

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{(q_1+\kappa q_2)^2}, \tag{42}$$

with the corresponding generators

$$\begin{gathered} T=a(t),\\ Q_1=\tfrac{1}{2}a'(t)q_1+\kappa^2 c_4 q_1-\kappa c_4 q_2+\kappa d_2(t),\\ Q_2=\tfrac{1}{2}a'(t)q_2-\kappa c_4 q_1+c_4 q_2-d_2(t), \end{gathered} \tag{43}$$

where $a''+4\lambda a=c_8$ and d_2 is a solution of $d_2''+\lambda d_2=0$ (6-parameter group).

Subcase 2b:

Setting $\lambda_1=0$ in (40) and (41) we deduce that V has the form

$$V=k_1q_1^3+k_2q_1^2+k_3q_1q_2^2+k_4q_1q_2+k_5q_1+\Phi(q_2). \tag{44}$$

Using Eqs. (36) and (37) we get $k_1=k_3=k_4=0$ and $\Phi=k_2q_2^2+k_6q_2+k_7+\mu/q_2^2$. Therefore, ignoring the linear terms, V takes the form

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{q_2^2}. \tag{45}$$

Finally, using Eqs. (34) and (35) we obtain the forms of the group generators:

$$\begin{gathered} T=a(t),\quad Q_1=c_3q_1+\tfrac{1}{2}a'(t)q_1+d_1(t),\\ Q_2=\tfrac{1}{2}a'(t)q_2, \end{gathered} \tag{46}$$

where $a''+4\lambda a=c_8$ and $d_1''+\lambda d_1=0$ (6-parameter group).

The case $\lambda=0$ is equivalent to the system $V(q_1,q_2)=1/q_1^2$ with generators

$$\begin{aligned} T&=c_1t^2+2c_2t+c_3, \quad Q_1=(c_1t+c_2)q_1, \\ Q_2&=(c_1t+c_2+c_4)q_2+c_5t+c_6. \end{aligned} \tag{47}$$

We choose the following basis for the Lie algebra of symmetries:

$$X_1=\frac{\partial}{\partial t},$$

$$X_2=2t\frac{\partial}{\partial t}+q_1\frac{\partial}{\partial q_1}+q_2\frac{\partial}{\partial q_2},$$

$$X_3=t^2\frac{\partial}{\partial t}+q_1t\frac{\partial}{\partial q_1}+q_2t\frac{\partial}{\partial q_2},$$

$$X_4=q_2\frac{\partial}{\partial q_2}, \quad X_5=t\frac{\partial}{\partial q_2}, \quad X_6=\frac{\partial}{\partial q_2},$$

with (nonzero) bracket relations

$$\begin{aligned} &[X_1,X_2]=2X_1, \quad [X_1,X_3]=X_2, \\ &[X_1,X_5]=X_6, \quad [X_2,X_3]=2X_3, \\ &[X_2,X_5]=X_5, \quad [X_2,X_6]=-X_6, \\ &[X_3,X_6]=-X_5, \quad [X_4,X_5]=-X_5, \quad [X_4,X_6]=-X_6. \end{aligned} \tag{48}$$

This algebra is not semi-simple since the ideal generated by X_5, X_6 is Abelian. It is not solvable either because $L^{(1)}=\{X_1,X_2,X_3,X_5,X_6\}$, and $L^{(2)}=L^{(1)}$.

Remark: It is clear that Subcase 2b is a special case of Subcase 2a by setting $\kappa=0$.

Subcase 2c:

Since all the coefficients of the terms in Eqs. (38) and (39) vanish, the functions $a(t)$, $d_1(t)$ and $d_2(t)$ may be determined. From Eqs. (36) and (37) we deduce that

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{1}{q_2^2}\Phi(\xi), \tag{49}$$

where $\xi=q_1/q_2$. We now use Eqs. (34) and (35) to determine the forms of the generators.

Without presenting any more calculations we state the following results.

Φ *arbitrary:*

$$T=a(t), \quad Q_1=\tfrac{1}{2}a'(t)q_1, \quad Q_2=\tfrac{1}{2}a'(t)q_2, \tag{50}$$

where $a''+4\lambda a=c_8$ (3-parameter group).

For $\lambda=0$ the Lie algebra has a basis given by

$$X_1=\frac{\partial}{\partial t}, \quad X_2=2t\frac{\partial}{\partial t}+q_1\frac{\partial}{\partial q_1}+q_2\frac{\partial}{\partial q_2},$$

$$X_3=t^2\frac{\partial}{\partial t}+tq_1\frac{\partial}{\partial q_1}+tq_2\frac{\partial}{\partial q_2},$$

with bracket relations of a simple Lie algebra:

$$[X_1,X_2]=2X_1,\quad [X_1,X_3]=X_2,\quad [X_2,X_3]=2X_3.$$

$\Phi=\mu/\xi^2=\mu(q_2^2/q_1^2)$:

It follows from (49) that

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{q_1^2}. \tag{51}$$

This potential already appeared in 2b.

$\Phi=\mu=$constant:

It follows from (49) that

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{q_2^2}. \tag{52}$$

This system is not different from the previous one.

$\Phi=\mu/(\xi^2+1)]\,e^{c\tan^{-1}\xi}$:

It follows from (49) that

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{\mu}{q_1^2+q_2^2}e^{c\tan^{-1}(q_1/q_2)}. \tag{53}$$

The generators take the form

$$T=a(t),\quad Q_1=\tfrac{1}{4}cc_1q_1+c_1q_2+\tfrac{1}{2}a'(t)q_1, \tag{54}$$

$$Q_2=\tfrac{1}{4}cc_1q_2-c_1q_1+\tfrac{1}{2}a'(t)q_2,$$

where $a''+4\lambda a=c_8$ (4-parameter group).

The Lie algebra for this system is a direct sum of an $sl(2,\mathbf{R})$ and a one-dimensional Lie algebra. It has a basis consisting of the vectors

$$X_1=\frac{\partial}{\partial t},$$

$$X_2=2t\frac{\partial}{\partial t}+q_1\frac{\partial}{\partial q_1}+q_2\frac{\partial}{\partial q_2},$$

$$X_3=t^2\frac{\partial}{\partial t}+tq_1\frac{\partial}{\partial q_1}+tq_2\frac{\partial}{\partial q_2},$$

$$X_4=\left(\frac{1}{4}cq_1+q_2\right)\frac{\partial}{\partial q_1}+\left(\frac{1}{4}cq_2-q_1\right)\frac{\partial}{\partial q_2},$$

with bracket relations

$$[X_1,X_2]=2X_1,\quad [X_1,X_3]=X_2,$$

$$[X_2,X_3]=2X_3,\quad [X_i,X_4]=0,\quad i=1,2,3.$$

This example generalizes an n dimension to a Lie algebra which is a direct sum $sl(2,\mathbf{R})\oplus so(n,\mathbf{R})$.

Remark: In polar coordinates this system is

$$V=\frac{\lambda}{2}(r^2)+\frac{\mu}{r^2}e^{c\theta}.$$

It is integrable, by taking $B(\theta)=\mu e^{c\theta}$ *and* $I=\frac{1}{2}l^2+B(\theta)$, *where* $l=q_1p_2-p_1q_2$.

Taking $\Phi(\xi)=r_1/\xi^2+r_2$ *we end up with the system*

$$V=\frac{\lambda}{2}(q_1^2+q_2^2)+\frac{r_1}{q_1^2}+\frac{r_2}{q_2^2}.$$

The associated Hamilton–Jacobi equation is separable in Cartesian and polar coordinates. This system is an example of a system with closed trajectories under the influence of a Noncentral field.[29] *For* $\lambda=1$, *the generators take the form*

$$T=c_1+c_2\cos 2t+c_3\sin 2t,$$

$$Q_1=(-c_2\sin 2t+c_3\cos 2t)q_1,$$

$$Q_2=(-c_2\sin 2t+c_3\cos 2t)q_2.$$

They form a 3-dimensional Lie algebra,

$$X_1=\frac{\partial}{\partial t},$$

$$X_2=\cos 2t\frac{\partial}{\partial t}-q_1\sin 2t\frac{\partial}{\partial q_1}-q_2\sin 2t\frac{\partial}{\partial q_2},$$

$$X_3=\sin 2t\frac{\partial}{\partial t}+q_1\cos 2t\frac{\partial}{\partial q_1}+q_2\cos 2t\frac{\partial}{\partial q_2},$$

with bracket relations

$$[X_1,X_2]=-2X_3,\quad [X_1,X_3]=2X_2,\quad [X_2,X_3]=2X_1. \tag{55}$$

In other words, it is a simple Lie algebra of type A_1 *isomorphic to* $so(3,\mathbf{R})$. *For* $\lambda=0$ *we obtain a Lie algebra isomorphic to* $sl(2,\mathbf{R})$. *In Ref.* 30 *the most general form of a differential equation invariant under the action of the generators of* $sl(2,\mathbf{R})$ *is determined.*

We note that the similar system,

$$V=\frac{\lambda}{2}(4q_1^2+q_2^2)+\frac{r_1}{q_1}+\frac{r_2}{q_2^2}, \tag{56}$$

has $\partial/\partial t$ *as the only symmetry.*

In general, the system $V=(\lambda/2)(q_1^2+q_2^2)+(1/q_2^2)\Phi(q_1/q_2)$ *is integrable: Changing to polar coordinates* $q_1=r\cos\theta$, $q_2=r\sin\theta$ *we find that*

$$V=\frac{\lambda}{2}r^2+\frac{\Phi(\cot\theta)}{r^2\sin^2\theta}=\frac{\lambda}{2}r^2+\frac{B(\theta)}{r^2}.$$

Letting $l=q_1p_2-p_1q_2$, *the second integral is* $I=1/2\,l^2+B(\theta)$.

The system $V=(\lambda/2)(q_1^2+q_2^2)+\mu/(q_1+\kappa q_2)^2$ *is integrable. It is a special case of (49) with* $\Phi(\xi)=\mu/(\xi+\kappa)^2$.

T linear: $a''=0$

In this case $a(t)$ is a linear function of time.

From Eqs. (36) and (37) we deduce that the function $V(q_1,q_2)$ satisfies two partial differential equations of the form

$$\lambda_1 V_{q_1 q_1}+\lambda_2 V_{q_1 q_2}+\lambda_3=0, \tag{57}$$

$$\lambda_1 V_{q_1 q_2}+\lambda_2 V_{q_2 q_2}+\lambda_4=0. \tag{58}$$

In order to solve these equations, we consider the following cases:

(i) $\lambda_1\neq 0,\ \lambda_2\neq 0,$

(ii) $\lambda_1=0,\ \lambda_2\neq 0\ \ (\text{or}\ \ \lambda_1\neq 0,\ \lambda_2=0),$

(iii) $\lambda_1=\lambda_2=\lambda_3=\lambda_4=0.$

Without giving any more details, using Eqs. (34) and (35), we are led to the following results:

Subcase 2d: $V=\lambda_1 q_2^2+\lambda_2 q_1 q_2+\Phi(\xi)$,

where $\xi=q_1-\lambda q_2$. We obtain various forms of the generators depending on the form of the function Φ.

$\Phi=\lambda_3\xi^2$:

That is, V is quadratic of the form

$$V=\lambda_1 q_2^2+\lambda_2 q_1 q_2+\lambda_3 q_1^2. \tag{59}$$

We have followed the common practice of renaming the constants. The corresponding generators are

$$\begin{gathered} T=c_6,\quad Q_1=c_1 q_2+c_3 q_1+d_1(t),\\ Q_2=c_1 q_1+\left(2\left(\frac{\lambda_1}{\lambda_2}-\frac{\lambda_3}{\lambda_2}\right)c_1+c_3\right)q_2+d_2(t), \end{gathered} \tag{60}$$

where $d_1(t)$ and $d_2(t)$ satisfy the o.d.e.'s $d_1''+2\lambda_3 d_1(t)+\lambda_2 d_2(t)=0$, and $d_2''+2\lambda_1 d_2(t)+\lambda_2 d_1(t)=0$ (7-parameter group).

If $\lambda_2=0$ then $\lambda_1\neq\lambda_3$, $Q_1=c_3 q_1+d_1(t)$, $Q_2=c_4 q_2+d_2(t)$ and $d_1(t)$, $d_2(t)$ satisfy the same o.d.e.'s with $\lambda_2=0$.

We describe explicitly the Lie algebra for the potential $V(q_1,q_2)=-\frac{1}{2}q_1^2+\frac{1}{2}q_2^2$. The Lie algebra is 7-dimensional with generators:

$$X_1=\frac{\partial}{\partial t},\quad X_2=q_1\frac{\partial}{\partial q_1},\quad X_3=e^t\frac{\partial}{\partial q_1},$$

$$X_4=e^{-t}\frac{\partial}{\partial q_1},\quad X_5=q_2\frac{\partial}{\partial q_2},\quad X_6=\cos t\,\frac{\partial}{\partial q_2},\quad X_7=\sin t\,\frac{\partial}{\partial q_2},$$

with (nonzero) bracket relations

$$[X_1,X_3]=X_3, \quad [X_1,X_4]=-X_4, \quad [X_1,X_6]=-X_7,$$

$$[X_1,X_7]=X_6, \quad [X_2,X_3]=-X_3,$$

$$[X_2,X_4]=-X_4, \quad [X_5,X_6]=-X_6, \quad [X_5,X_7]=-X_7.$$

This Lie algebra L is solvable with $L^{(1)}=[L,L]=\{X_3,X_4,X_6,X_7\}$ and $L^{(2)}=\{0\}$.

Remark: The system with the Hamiltonian,

$$H=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+\lambda_1 q_1^2+\lambda_2 q_1 q_2+\lambda_3 q_2^2, \tag{61}$$

is integrable. We can actually rotate the Hamiltonian to a separable one, obtain the second integral and then rotate back to obtain the invariant in the original coordinates. So, we set

$$q_1=\cos\theta\ \ Q_x+\sin\theta\ \ Q_y,$$

$$q_2=-\sin\theta\ \ Q_x+\cos\theta\ \ Q_y,$$

$$p_1=\cos\theta\ \ p_x+\sin\theta\ \ p_y,$$

$$p_2=-\sin\theta\ \ p_x+\cos\theta\ \ p_y.$$

The Hamiltonian H will be transformed to a new Hamiltonian which is a function of Q_x, Q_y, p_x and p_y. The coefficient of Q_xQ_y in the rotated Hamiltonian is

$$(\lambda_1-\lambda_3)\sin 2\theta+\lambda_2\cos 2\theta.$$

If $\lambda_1=\lambda_3$, we choose $\theta=\pi/4$. If $\lambda_1\neq\lambda_3$, then we choose θ to satisfy

$$\tan 2\theta=\frac{\lambda_2}{\lambda_3-\lambda_1}.$$

Therefore, in the new coordinates the Hamiltonian is separable of the form

$$\tfrac{1}{2}p_x^2+\tfrac{1}{2}p_y^2+\mu_1 Q_x^2+\mu_2 Q_y^2.$$

We may choose the second integral to be $p_x^2+\mu_1 Q_x^2$. The second integral for the original system is

$$I=(\cos\theta\, p_1-\sin\theta\, p_2)^2+\mu_1(\cos\theta\, q_1-\sin\theta\, q_2)^2.$$

Φ arbitrary:

In this case, V has the form

$$V=\lambda_2\left(q_1q_2+\frac{1-\lambda^2}{2\lambda}q_2^2\right)+\Phi(q_1-\lambda q_2). \tag{62}$$

The corresponding generators are

$$T=c_6,$$

$$Q_1=\lambda c_2 q_1+c_2 q_2+\lambda d_2(t), \tag{63}$$

$$Q_2=c_2 q_1+\frac{1}{\lambda}c_2 q_2+d_2(t),$$

where $d_2(t)$ satisfies the o.d.e. $d_2''+(\lambda_2/\lambda)d_2(t)=0$ (4-parameter group).

Remark: Assume $\lambda=1$. *The system with Hamiltonian*

$$H=\tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+\lambda_2 q_1 q_2+\Phi(q_1-q_2), \tag{64}$$

is integrable. We can actually transform the Hamiltonian to a separable one, obtain the second integral and then rotate back to obtain the invariant in the original coordinates. So, we set

$$q_1=\frac{1}{\sqrt{2}}\ Q_x+\frac{1}{\sqrt{2}}\ Q_y,\quad q_2=-\frac{1}{\sqrt{2}}\ Q_x+\frac{1}{\sqrt{2}}\ Q_y,$$

$$p_1=\frac{1}{\sqrt{2}}\ p_x+\frac{1}{\sqrt{2}}\ p_y,\quad p_2=-\frac{1}{\sqrt{2}}\ p_x+\frac{1}{\sqrt{2}}\ p_y.$$

The Hamiltonian H will be transformed to a new Hamiltonian which is a function of Q_x, Q_y, p_x *and* p_y. *Therefore, in the new coordinates the Hamiltonian is separable of the form*

$$\frac{1}{2}p_x^2+\frac{1}{2}p_y^2+\Phi(\sqrt{2}Q_x)+\frac{\lambda_2}{2}(Q_y^2-Q_x^2).$$

We may choose the second integral to be $\frac{1}{2}p_x^2+\Phi(\sqrt{2}Q_x)-(\lambda_2/2)Q_x^2$. *The second integral for the original system is*

$$I=\frac{1}{4}(p_1-p_2)^2+\Phi(q_1-q_2)-\frac{\lambda_2}{4}(q_1-q_2)^2.$$

$\Phi=\lambda_3\xi^n$, $n\neq 0,1,2$:

In this case, V has the form

$$V=\lambda_2\left(q_1q_2+\frac{1-\lambda^2}{2\lambda}q_2^2\right)+\lambda_3(q_1-\lambda q_2)^n, \tag{65}$$

with $n\neq 0,1,2$.

The generators are

$$T=2c_5t+c_6,$$

$$Q_1=c_2(\lambda q_1+q_2)-\frac{4}{n-2}c_5q_1+\lambda d_2(t), \tag{66}$$

$$Q_2=c_2\left(q_1+\frac{1}{\lambda}q_2\right)-\frac{4}{n-2}c_5q_2+d_2(t),$$

where $d_2(t)$ satisfies the o.d.e. $d_2''+\lambda_2/\lambda\, d_2(t)=0$.

If $\lambda_2=0$ then $d_2(t)=c_3+c_4t$ and we end-up with a 5-parameter group. Note that for $n=-2$ we are in subcase 2a with a 6-parameter group.

If $\lambda_2\neq 0$, then we set $c_5=0$ and we end up with a 4-parameter group (the same as Φ arbitrary).

For example, if $V(q_1,q_2)=q_1q_2+(q_1-q_2)^3$ then the Lie algebra is generated by

$$X_1=\frac{\partial}{\partial t},\quad X_2=(q_1+q_2)\left(\frac{\partial}{\partial q_1}+\frac{\partial}{\partial q_2}\right),$$

$$X_3=\cos t\left(\frac{\partial}{\partial q_1}+\frac{\partial}{\partial q_2}\right),\quad X_4=\sin t\left(\frac{\partial}{\partial q_1}+\frac{\partial}{\partial q_2}\right),$$

with (nonzero) bracket relations

$$[X_1,X_3]=-X_4,\quad [X_1,X_4]=X_3,$$

$$[X_2,X_3]=-2X_3,\quad [X_2,X_4]=-2X_4.$$

This Lie algebra L is solvable with $L^{(1)}=[L,L]=\{X_3,X_4\}$ and $L^{(2)}=\{0\}$.

On the other hand, the potential $V(q_1,q_2)=(q_1-q_2)^3$ gives a five-dimensional Lie algebra. This Lie algebra is isomorphic with the symmetry Lie algebra for the potential $V(q_1,q_2)=q_1^3$ which we examine later.

$\Phi=\lambda_3 e^{\mu\xi}$:

In this case, V has the form

$$V=\lambda_2\left(q_1q_2+\frac{1-\lambda^2}{2\lambda}q_2^2\right)+\lambda_3 e^{\mu(q_1-\lambda q_2)}. \tag{67}$$

The generators are

$$T=2c_5t+c_6,$$

$$Q_1=c_2(\lambda q_1+q_2)-\frac{4}{\mu}c_5+\lambda d_2(t), \tag{68}$$

$$Q_2=c_2\left(q_1+\frac{1}{\lambda}q_2\right)+d_2(t),$$

where $d_2(t)$ satisfies the o.d.e. $d_2''+(\lambda_2/\lambda)d_2=0$.

If $\lambda_2=0$ then $d_2(t)=c_3+c_4t$ and we end up with a 5-parameter group.

If $\lambda_2\neq 0$, then we set $c_5=0$ and we end up with a 4-parameter group (the same as Φ arbitrary).

The case $\lambda=\mu=1$ and $\lambda_2=0$ is the Toda Lattice, a well-known integrable system.[31,32] We will calculate the Lie algebra of symmetries for the potential of the Toda lattice $V(q_1,q_2)=e^{q_1-q_2}$. We obtain a five-dimensional Lie algebra with generators

$$X_1=\frac{\partial}{\partial t},\quad X_2=2t\frac{\partial}{\partial t}-4\frac{\partial}{\partial q_1},$$

$$X_3=(q_1+q_2)\left(\frac{\partial}{\partial q_1}+\frac{\partial}{\partial q_2}\right),\quad X_4=\left(\frac{\partial}{\partial q_1}+\frac{\partial}{\partial q_2}\right),$$

$$X_5=t\left(\frac{\partial}{\partial q_1}+\frac{\partial}{\partial q_2}\right),$$

with (nonzero) bracket relations

$$[X_1,X_2]=2X_1,\quad [X_1,X_5]=X_4,$$

$$[X_2,X_3]=-4X_4,\quad [X_2,X_5]=2X_5,$$

$$[X_3,X_4]=-2X_4,\quad [X_3,X_5]=-2X_5.$$

This Lie algebra L is solvable with $L^{(1)}=[L,L]=\{X_1,X_4,X_5\}$, $L^{(2)}=\{X_4\}$ and $L^{(3)}=\{0\}$.

For the case $\lambda_2\neq 0$ we obtain a Lie algebra which is identical with the one in Φ arbitrary.

$\Phi=\lambda_3\log\xi$:

Setting $\lambda_2=0$, V takes the form

$$V=\lambda_3\log(q_1-\lambda q_2), \tag{69}$$

$$T=2c_5t+c_6,$$

$$Q_1=\lambda c_2q_1+c_2q_2+2c_5q_1+\lambda d_2(t), \tag{70}$$

$$Q_2=c_2q_1+\frac{1}{\lambda}c_2q_2+2c_5q_2+d_2(t),$$

where $d_2(t)=c_3t+c_4$ (5-parameter group).

If $\lambda_2\neq 0$ the result again is the same as in Φ arbitrary.

Subcase 2e: $V=\lambda_1q_2^2+\Phi(q_1)$.

We obtain various forms of the generators depending on the form of the function Φ.

Φ arbitrary:

The generators take the form

$$T=c_6,\quad Q_1=0,\quad Q_2=c_4q_2+d_2(t), \tag{71}$$

where $d_2(t)$ satisfies the o.d.e. $d_2''+2\lambda_1d_2(t)=0$ (4-parameter group).

$\Phi=\lambda_2q_1^n$, $n\neq-2,0,1,2$:

If $\lambda_1=0$, then

$$T=2c_5t+c_6,\quad Q_1=\frac{4}{2-n}c_5q_1,\quad Q_2=c_4q_2+c_1t+c_2 \tag{72}$$

(5-parameter group).

If $\lambda_1\neq 0$, we set $c_5=0$. We end up with a 4-parameter group. It is the same as in Φ arbitrary.

We will calculate explicitly the Lie algebra for the potential $V(q_1,q_2)=q_1^3$. For a basis we choose the following five vector fields:

$$X_1=\frac{\partial}{\partial t},\quad X_2=t\frac{\partial}{\partial t}-2q_1\frac{\partial}{\partial q_1},$$

$$X_3=q_2\frac{\partial}{\partial q_2},\quad X_4=t\frac{\partial}{\partial q_2},\quad X_5=\frac{\partial}{\partial q_2},$$

with (nonzero) bracket relations

$$[X_1,X_2]=X_1,\quad [X_1,X_4]=X_5,$$

$$[X_2,X_4]=X_4,\quad [X_3,X_4]=-X_4,\quad [X_3,X_5]=-X_5.$$

This Lie algebra L is solvable with $L^{(1)}=[L,L]=\{X_1,X_4,X_5\}$, $L^{(2)}=\{X_5\}$ and $L^{(3)}=\{0\}$.

On the other hand, for the potential $V(q_1,q_2)=\frac{1}{2}q_2^2+q_1^3$ we obtain a 4-parameter group with basis

$$X_1=\frac{\partial}{\partial t},\quad X_2=q_2\frac{\partial}{\partial q_2},\quad X_3=\cos t\,\frac{\partial}{\partial q_2},\quad X_4=\sin t\,\frac{\partial}{\partial q_2}.$$

This Lie algebra L is also solvable with $L^{(1)}=[L,L]=\{X_3,X_4\}$ and $L^{(2)}=\{0\}$. It is isomorphic with the algebra of symmetries of potential (65) which we already examined.

$\Phi=\lambda_2 e^{\mu q_1}$:

If $\lambda_1=0$, then

$$T=2c_5t+c_6,\quad Q_1=\frac{-4}{\mu}c_5,\quad Q_2=c_4q_2+d_2(t),\tag{73}$$

where $d_2(t)$ satisfies the o.d.e. $d_2''+2\lambda_1 d_2=0$ (5-parameter group).

If $\lambda_1\neq 0$, we set $c_5=0$. It is the same case as in Φ arbitrary.

$\Phi=\lambda_2\log q_1$:

We set $\lambda_1=0$. Then $V=\lambda_2\log q_1$ and the generators take the form

$$T=2c_5t+c_6,\quad Q_1=2c_5q_1,\quad Q_2=c_4q_2+c_7t+c_8,\tag{74}$$

(5-parameter group).

Remark: The potentials that appear in this case are clearly integrable, being separable potentials. At this point we have completed the analysis of a separable potential with one variable missing. The potential $1/q_1^2$ was considered in subcase 2b. The potentials q_1^n for $n=0,1$ are covered by Case 1. The potential q_1^2 was considered in subcase 2d. The potential $f(q_1)$ falls under subcase 2e.

Subcase 2f:

Equations (36) and (37) are satisfied $[d_1(t)=\text{constant}$, $d_2(t)=\text{constant}]$. From Eqs. (34) and (35) we obtain the following results.

1.

$$V=q_2^N\Phi\left(\frac{q_1}{q_2}\right),\quad T=\tfrac{1}{2}c_3(2-N)t+c_6,\quad Q_1=c_3q_1,\quad Q_2=c_3q_2,\tag{75}$$

a 2-parameter group of transformations. The Lie algebra in this case is the two-dimensional non-Abelian Lie algebra with bracket $[X_1,X_2]=\tfrac{1}{2}(2-N)X_1$ if $N\neq 2$ and an Abelian 2-dimensional Lie algebra if $N=2$. We should mention that for certain choices of Φ we may obtain a larger symmetry group, e.g., for $\Phi(x)=x^N$, but generically the Lie algebra is 2-dimensional. Some values of N will also give different results. For example, $N=-2$ falls under subcase 2c.

Remark: In general, this system is not integrable, however, there are some integrable examples. We mention the Holt potentials,[19,20,33]

$$V(q_1,q_2)=q_2^{-2/3}(cq_2^2+q_1^2),\tag{76}$$

where $c=\frac{3}{4}$, $c=\frac{9}{2}$ and $c=12$.

Also the Fokas–Lagerström potential,[34]

$$V(q_1,q_2)=\frac{1}{(q_1^2-q_2^2)^{-2/3}}.\tag{77}$$

Case 2f includes Hénon–Heiles type potentials of the form $cq_2^3+q_1^2q_2$. They are integrable for the following values of c: $c=\frac{1}{3}$, $c=2$ and $c=\frac{16}{3}$.[35–37]

Finally, we mention the potential

$$V(q_1,q_2)=\frac{q_1}{q_2}.\tag{78}$$

It was shown by Hietarinta[38] *that the second integral for this potential is a transcendental function. It can be expressed as a combination of* W_+ *and* W_-, *the standard Whittaker functions, i.e., the solutions of the equation*

$$y'' + (\tfrac{1}{4}x^2 - a)y = 0. \tag{79}$$

2.

$$V = \lambda_1 \log q_2 + \Phi\left(\frac{q_1}{q_2}\right), \quad T = c_3 t + c_6,$$
$$Q_1 = c_3 q_1, \quad Q_2 = c_3 q_2, \tag{80}$$

a 2-parameter group of transformations. The Lie algebra in this case is the two-dimensional non-Abelian Lie algebra with bracket $[X_1, X_2] = X_1$.

3.

$$V = e^{\mu q_1}\Phi(q_2), \quad T = \tfrac{1}{2}c_5 t + c_6,$$
$$Q_1 = -\frac{c_5}{\mu}, \quad Q_2 = 0, \tag{81}$$

a 2-parameter group of transformations.

Remark: Taking $\Phi(q_2) = e^{-\mu q_2}$ *we obtain again the Toda lattice. However, we already have seen that this system has a 5-parameter group of transformations. Therefore, for the specific potential we do not obtain a maximal admitted algebra. Generically, the symmetry group is 2-dimensional. For example, taking* $V(q_1, q_2) = e^{q_1} q_2^3$ *gives a two-dimensional non-Abelian algebra with basis* $X_1 = \partial/\partial t$ *and* $X_2 = t(\partial/\partial t) - 2(\partial/\partial q_1)$.

4.

$$V = e^{\mu q_1}\Phi(q_1 - \lambda q_2), \quad T = -\tfrac{1}{2}\lambda\mu c_8 t + c_6$$
$$Q_1 = \lambda c_8, \quad Q_2 = c_8, \tag{82}$$

a 2-parameter group of transformations. The Lie algebra is again the two-dimensional non-Abelian Lie algebra with bracket $[X_1, X_2] = -\tfrac{1}{2}\lambda\mu X_1$.

Remark: We should mention that because of symmetry we do not list potentials of the form $V(q_1, q_2) = e^{\mu q_2}\Phi(q_2 - \lambda q_1)$. *We can also replace* $q_1 - \lambda q_2$ *with* $\alpha q_1 + \beta q_2$. *Taking* $\mu = 1$, $\alpha = 1$ *and* $\beta = -2$ *we obtain the potential* $V(q_1, q_2) = e^{q_1 - q_2} + e^{q_2}$. *This is a generalized Toda lattice associated with a Lie algebra of type* B_2, *first considered by Bogoyavlensky in Ref. 39.*

5.

$$V = \lambda_1 q_1^n + \lambda_2 q_2^m, \quad T = \tfrac{1}{2}c_5 t + c_6,$$
$$Q_1 = \frac{c_5}{2-n} q_1, \quad Q_2 = \frac{c_5}{2-m} q_2, \tag{83}$$

a 2-parameter group of transformations. Here, $n \neq 0,1,2$ and $m \neq 0,1,2$ and m, n not both equal to

-2. The Lie algebra in this case is the two-dimensional non-Abelian Lie algebra with bracket $[X_1,X_2]=\frac{1}{2}X_1$. The symmetry Lie algebra for the potentials 6–10 satisfies precisely the same bracket relation.

6.

$$V=\lambda_1 q_1^n+\lambda_2 \log q_2, \quad n\neq 0,1,2, \quad T=\tfrac{1}{2}c_5 t+c_6, \quad Q_1=\frac{c_5}{2-n}q_1, \quad Q_2=\frac{c_5}{2}q_2. \tag{84}$$

7.

$$V=\lambda_1 q_1^n+\lambda_2 e^{\mu q_2}, \quad n\neq 0,1,2, \quad T=\tfrac{1}{2}c_5 t+c_6, \quad Q_1=\frac{c_5}{2-n}q_1, \quad Q_2=-\frac{c_5}{\mu}. \tag{85}$$

8.

$$V=\lambda_1 \log q_1+\lambda_2 \log q_2, \quad T=\tfrac{1}{2}c_5 t+c_6, \quad Q_1=\frac{c_5}{2}q_1, \quad Q_2=\frac{c_5}{2}q_2. \tag{86}$$

9.

$$V=\lambda_1 \log q_1+\lambda_2 e^{\mu q_2}, \quad T=\tfrac{1}{2}c_5 t+c_6, \quad Q_1=\frac{c_5}{2}q_1, \quad Q_2=-\frac{c_5}{\mu}. \tag{87}$$

10.

$$V=\lambda_1 e^{\mu_1 q_1}+\lambda_2 e^{\mu_2 q_2}, \quad T=\tfrac{1}{2}c_5 t+c_6, \quad Q_1=-\frac{c_5}{\mu_1}, \quad Q_2=-\frac{c_5}{\mu_2}. \tag{88}$$

11.

$$V=\Phi(q_1^2+q_2^2), \quad T=c_6, \quad Q_1=c_1 q_2, \quad Q_2=-c_1 q_1, \tag{89}$$

a 2-parameter group of transformations. This is a unit mass in 2-dimensional space moving in a central field, i.e., a potential which is a function of r only. The function $q_1p_2-q_2p_1$ is a second integral. Note that in this case the Lie algebra is Abelian.

12.

$$V=\lambda(q_1^2+q_2^2)^n, \quad n\neq -1,0,1,$$

$$T=2c_5 t+c_6, \quad Q_1=c_1 q_2-\frac{2}{n-1}c_5 q_1, \quad Q_2=-c_1 q_1-\frac{2}{n-1}c_5 q_2, \tag{90}$$

a 3-parameter group of transformations. The Lie algebra is 3-dimensional with only nonzero bracket $[X_1,X_2]=2X_1$. The case $n=-\frac{1}{2}$ is a Kepler problem. For $n=-1$ the Lie algebra is 4-dimensional; it falls under subcase 2c. See (53) with $\lambda=c=0$ and $\mu=1$.

Remark: This potential is a special case of system 1 with $N=2n$. Taking $n=2$, we have a system of the form $aq_1^4+bq_1^2q_2^2+cq_2^4$. In general (for a, b, c non-zero) this system has a 2-dimensional group of symmetries unless $b=2a=2c$. Generically the potential $V(q_1,q_2)=aq_1^4+bq_1^2q_2^2+cq_2^4$ is not integrable, but for certain values of the parameters it becomes integrable. That is the case when $b=6a=6c$ or $a=16c$, $b=12c$ or $b=6a$, $c=8a$.[19,21,40]

13.

$$V=\lambda \log(q_1^2+q_2^2),$$

$$T=2c_5 t+c_6, \quad Q_1=c_1 q_2+2c_5 q_1, \quad Q_2=-c_1 q_1+2c_5 q_2, \tag{91}$$

a 3-parameter group of transformations. The Lie algebra, which is the same as in the previous case, may not seem interesting, but in n dimensions it is a direct sum of a 2-dimensional Lie algebra with $so(n, \mathbf{R})$.

14.

$$V=\lambda \sin^{-1}\frac{q_1^2-q_2^2}{q_1^2+q_2^2},$$
$$T=2c_5t+c_6, \quad Q_1=c_1q_2+2c_5q_1, \quad Q_2=-c_1q_1+2c_5q_2, \tag{92}$$

a 3-parameter group of transformations. This potential can be written in the form $\lambda_1+\lambda_2\theta$, in polar coordinates. In other words, it is a linear function of θ.

VI. GENERALIZATIONS

Case 1 generalizes in n dimensions. Consider a Hamiltonian with n degrees of freedom,

$$H=\frac{1}{2}\sum_{i=1}^{n} p_i^2+V(q_1,q_2,\ldots,q_n),$$

and the associated Lagrange–Newton equations,

$$\ddot{q}_i+V_{q_i}=0, \qquad i=1,2,\ldots,n \ . \tag{93}$$

As in the case of two degrees of freedom we seek point symmetries of Eqs. (93). We consider the equations

$$\Gamma^{(2)}\{\ddot{q}_i+V_{q_i}\}=0, \quad i=1,2,\ldots,n, \tag{94}$$

where $\Gamma^{(2)}$ is the second prolongation of

$$\Gamma=T\frac{\partial}{\partial t}+\sum_{i=1}^{n} Q_i\frac{\partial}{\partial q_i}. \tag{95}$$

Equations (94) give n identities of the form

$$E_i(t,q_1,q_2,\ldots,q_n,\dot{q}_1,\dot{q}_2,\ldots,\dot{q}_n)=0, \qquad i=1,2,\ldots,n, \tag{96}$$

where, we have used that $\dot{q}_i=-\partial V/\partial q_i$. The functions E_i are explicit polynomials in $\dot{q}_1,\dot{q}_2,\ldots,\dot{q}_n$. We impose the condition that Eqs. (96) are identities in the variables t, q_i, $\dot{q}_i$ which are regarded as independent.

Again, the functions T and Q_i must be of the form

$$T=a(t)+\sum_{i=1}^{n} b_i(t)q_i,$$
$$Q_i=\sum_{k=1}^{n} b_k'(t)q_iq_k+\sum_{k=1}^{n} c_{ik}(t)q_k+d_i(t), \quad i=1,2,\ldots,n \ . \tag{97}$$

We substitute (97) into (96). By considering the coefficient of $\dot{q}_k$ in E_j we obtain the following n^2 equations:

For $j\neq k$,

$$b_k''(t)q_j+c_{jk}'(t)+\frac{\partial V}{\partial q_j}b_k=0, \tag{98}$$

and for $j=k$,

$$2c_{jj}'(t)-a''(t)+3b_j''(t)q_j+3\frac{\partial V}{\partial q_j}b_j+\sum_{i\neq j}\left(b_i''(t)q_i+\frac{\partial V}{\partial q_i}b_i(t)\right)=0. \tag{99}$$

It follows from Eqs. (98) that V is quadratic of the form

$$V=\sum_{i=1}^{n}\lambda_i q_i^2+\sum_{i=1}^{n}\mu_i q_i, \tag{100}$$

unless $b_i(t)=0$ for $i=1,2,\ldots,n$.

Substituting (100) into (99), we obtain

$$b_i''+2\lambda_i b_i=0, \quad i=2,3,\ldots,n$$

and

$$b_i''+2\lambda_1 b_i=0, \quad i=2,3,\ldots,n.$$

Therefore for nonzero $b_i(t)$, we necessarily have

$$\lambda_1=\lambda_2=\cdots=\lambda_n.$$

Hence, V is of the form

$$V=\frac{\lambda}{2}\sum_{i=1}^{n}q_i^2,$$

where the linear terms are ignored.

One can easily deduce the form of the generators $a(t)$ is a solution of a second order equation of the form $a''+4\lambda a=c$. (3 parameters); $b_i(t)$ is a solution of $b_i''+\lambda b_i=0$. ($2n$ parameters); $d_i(t)$ is a solution of $d_i''+\lambda d_i=0$. ($2n$ parameters); $c_{ij}(t)$ are constant for $i\neq j$ and $c_{kk}=ct+c_k-2\lambda\int a(t)dt$ (n^2 parameters).

Therefore, the dimension of the symmetry algebra is $3+2n+2n+n^2=(n+2)^2-1$.

The case of the harmonic oscillator has been studied in Ref. 41 where it is shown that the symmetry group for a time-dependent harmonic oscillator is $SL(n+2, \mathbf{R})$.

When $\lambda=0$, the potential energy is zero and we have a free particle moving in $\mathbf{R}^n$. In this case the generators take the following simple form:

$$\begin{gathered} a(t)=c_1+c_2t+ct^2, \quad b_i(t)=\alpha_i+\beta_i t, \\ d_i(t)=\gamma_i+\delta_i t, \quad c_{ii}=\epsilon_i+ct, \\ c_{ij}=\kappa_{ij}, \quad i\neq j. \end{gathered} \tag{101}$$

The dimension is again $(n+2)^2-1$.

This dimension is in agreement with the results in Ref. 42, where upper bounds for the dimension of symmetry groups are obtained.

In case 2, $b_i(t)=0$ for $i=1,2,\ldots,n$ and Eqs. (99) and (100) imply that

$$c_{jk}(t)=c_{jk}, \quad \text{for } j\neq k,$$

$$c_{jj}(t)=\tfrac{1}{2}a'(t)+c_{jj},$$

where c_{jk} are constants. Equations (96) now become

$$\frac{1}{2}a'''(t)q_i+d_i''(t)+\sum_{k=1}^{n}\frac{\partial^2 V}{\partial q_i \partial q_k}\gamma_k+\frac{3}{2}a'(t)\frac{\partial V}{\partial q_i}-\sum_{k=1}^{n}c_{ik}\frac{\partial V}{\partial q_k}=0, \tag{102}$$

for $i=1,2,\ldots,n$, where

$$\gamma_k=\frac{1}{2}q_k a'(t)+\sum_{j=1}^{n}c_{kj}q_j+d_k(t). \tag{103}$$

Using Eqs. (102) we can prove the following.

(1) The potential q_1^2 has an n^2+3 parameter group of symmetries.
(2) The potential $1/q_1^2$ has an n^2+2 parameter group of symmetries.
(3) The potential $q_1^k, k\notin\{-2,0,1,2\}$ has an n^2+1 parameter group of symmetries.
(4) The potential $f(q_1)$ where f is arbitrary but not exponential, logarithmic or a power has an n^2 parameter group of symmetries.

We give the proof for the potential

$$V(q_1,q_2,\ldots,q_n)=\tfrac{1}{2}q_1^2.$$

The proof for the other three cases is similar. Since the variables $q_2,q_3,\ldots,q_n$ are missing, Eqs. (102) for $k=2,3,\ldots,n$ become

$$\tfrac{1}{2}a'''q_k+d_k''-c_{k1}q_1=0.$$

Therefore, $a'''=0$, $d_k(t)=\xi_k+\eta_k t$, and $c_{k1}=0$ for $k=2,3,\ldots,n$. On the other hand, the first equation in (102) gives

$$d_1''+\gamma_1+\left(\frac{3}{2}a'-c_{11}\right)q_1=0,$$

where

$$\gamma_1=\frac{1}{2}q_1 a'+\sum_{j=1}^{n}c_{1j}q_j+d_1.$$

Therefore, $a'(t)=0$, $d_1(t)=c_2\cos t+c_3\sin t$, and $c_{1j}=0$ for $j=2,3,\ldots,n$.

We obtain the following form for the generators:

$$\begin{aligned}T&=c_1,\\ Q_1&=c_{11}q_1+c_2\cos t+c_3\sin t,\\ Q_k&=\sum_{j=2}^{n}c_{kj}q_j+\xi_k+\eta_k t,\quad k=2,\ldots,n.\end{aligned} \tag{104}$$

Therefore, the dimension of the algebra of symmetries is $4+(n-1)^2+2(n-1)=n^2+3$.

ACKNOWLEDGMENTS

We would like to thank Peter Leach for sending us preprints of his work and also for some valuable remarks on the transcript. We would also like to thank Rui Fernandes, Giuseppe Gaeta, Peter Olver and the Referee for some helpful comments.

Superintegrability of the Calogero–Moser system: Constants of motion, master symmetries, and time-dependent symmetries

Manuel F. Rañada[a)]
Departamento de Física Teórica, Facultad de Ciencias, Universidad de Zaragoza, 50009 Zaragoza, Spain

(Received 4 June 1998; accepted for publication 9 July 1998)

The classical n-dimensional Calogero–Moser system is a maximally superintegrable system endowed with a rich variety of symmetries and constants of motion. In the first part of the article some properties related with the existence of several families of constants of motion are analyzed. In the second part, the master symmetries and the time-dependent symmetries of this system are studied. © *1999 American Institute of Physics.* [S0022-2488(99)01401-2]

I. INTRODUCTION

A superintegrable system is a system that is integrable (in the sense of Liouville–Arnold) and that, in addition to this, possesses more globally defined constants of motion than degrees of freedom. If the number N of independent constants takes the value $N=2n-1$ (n the number of degrees of freedom) then the system is called maximally superintegrable (see Refs. 1–19). There are three well known cases of this very particular class of systems, namely, the Kepler problem, the isotropic harmonic oscillator, and the nonisotropic oscillator with rational frequencies. The Kepler possesses not only the energy and the angular momentum but also the Runge–Lenz vector; five of these integrals are functionally independent. The harmonic oscillator is a system trivially integrable since it is a direct sum of one degree of freedom systems. If the oscillator is isotropic then it has the angular momentum as an additional integral of motion. If the oscillator is nonisotropic then the angular momentum is not preserved but in the very particular case in which the quotients of the frequencies are rational the system has other additional nonlinear integrals. In all these three cases it is known that all the orbits became closed for the case of bounded motions. This high degree of regularity (the existence of periodic motions) is a consequence of the superintegrable character.

The system of Calogero–Moser[20–26] is a system of n particles in which the interaction force between every two particles is given by the inverse of the square of their relative distance. The Lagrangian of this system is given by

$$L_{CM}=\frac{1}{2}\sum_{j=1}^{n} v_j^2-\sum_{i<j} V_{ij}, \quad V_{ij}=\frac{c_0^2}{q_{ij}^2},$$

where $q_{ij}=q_i-q_j$, $i,j=1,2,\ldots,n$, and c_0 is an arbitrary constant (the masses of the particles are set equal to unity). This system has been extensively studied from many different viewpoints (see Refs. 27–29 for general reviews on the Calogero–Moser system and Refs. 30–36 for some articles published in these last years). Wojciechowsky proved in Ref. 4 that the Calogero–Moser system is not only integrable but even maximally superintegrable, that is, there exist $N=2n-1$ independent integrals of motion. More recently Kutnetsov[33] and Gonera[35] have also proved that the corresponding quantum system is superintegrable as well.

[a)]Electronic mail: mfran@posta.unizar.es

In this article we will study some properties closely related with the superintegrability of the Calogero–Moser system. The article is organized as follows: In Sec. II we discuss the existence and properties of the additional families of constants of motion. In Sec. III, we discuss the existence and the geometric properties of master symmetries, and in Sec. IV we study the existence of time-dependent constants of motion. Finally, in Sec. V we make some final comments.

II. SUPERINTEGRABILITY OF THE CALOGERO–MOSER SYSTEM

Moser proved[26] that the Calogero system can be presented as a Lax equation,

$$\frac{dA}{dt}=[A,B], \quad A=A_1+\mathrm{i}c_0A_2, \quad B=\mathrm{i}c_0(B_1-B_2),$$

where A_1 and B_1 denote the diagonal matrices,

$$A_1=\mathrm{diagonal}[v_1,v_2,\ldots,v_n], \quad B_1=\mathrm{diagonal}\left[\sum_{j\neq 1} x_{1j}^2,\sum_{j\neq 2} x_{2j}^2,\ldots,\sum_{j\neq n} x_{nj}^2\right]$$

and A_2 and B_2 take the form

$$A_2=[(1-\delta_{ij})x_{ij}], \quad B_2=[(1-\delta_{ij})x_{ij}^2],$$

where, for ease of notation, we use x_{ij} for denoting $1/q_{ij}$. The important point is that, because of the Lax equation, the traces of the powers of the matrix A are constants of motion,

$$I_k=\left(\frac{1}{k}\right)\mathrm{tr}\,A^k, \quad \frac{d}{dt}\,I_k=0, \quad k=1,2,\ldots,n.$$

Moreover, these n functions I_k, $k=1,2,\ldots,n$, are globally defined, independent, and in involution. They take the form

$$I_k=\left(\frac{1}{k}\right)(v_1^k+v_2^k+\cdots+v_n^k)+\text{terms of lower order in the velocities}.$$

Wojciechowsky proved in Ref. 4 the existence of an additional family of integrals K_j, $j=2,3,\ldots,n$. One of the main differences between this new family and the old one is that the first or leading term of the n functions I_k is q-independent (this term is dominant for large values of the q_i); whereas the first term of the $n-1$ functions K_j is linear in the coordinates q.

It is known (see, e.g., Refs. 18, 19) that the potential $V(x,y)=k/x^2$ (k is an arbitrary constant) is superintegrable. Two fundamental constants of motion, I_1 and I_2, are

$$I_1=v_y, \quad I_2=\left(\frac{1}{2}\right)(v_x^2+v_y^2)+\left(\frac{k}{x^2}\right),$$

and, concerning the third constant, one can choose any one of the two following quadratic functions:

$$K_2=(xv_y-yv_x)v_x-2k\left(\frac{y}{x^2}\right),$$

$$J_2=(xv_y-yv_x)^2+2k\left(\frac{y}{x}\right)^2.$$

This potential can be transformed into the $n=2$ Calogero–Moser potential by a rotation. Then the function K_2 becomes the $n=2$ particular case of the integral obtained by Wojciechowsky. Next we will prove that J_2, which is quadratic in the angular momentum, can also be considered as a very particular case of a family of integrals for the general n-particle Calogero–Moser system.

In the following we will make use of the matrix Q defined by

$$Q=\text{diagonal}[q_1,q_2,\dots,q_n].$$

Notice that the time-evolution of Q can be written as follows:

$$\dot{Q}=[Q,B]+A.$$

Let us denote by $T_r^{(q)}$ the following functions:

$$T_r^{(q)}=\text{tr}(Q^qA^r).$$

Then we have the following proposition.

Proposition 1: The traces $T_r^{(2)}$ and $T_r^{(1)}$ satisfy the following two properties:

$$(a)\quad \frac{d}{dt}T_r^{(2)}=2T_{r+1}^{(1)},$$

$$(b)\quad \frac{d}{dt}T_r^{(1)}=T_{r+1}^{(0)}.$$

Proof: The time derivative of $T_r^{(2)}$ can be written as

$$\frac{d}{dt}T_r^{(2)}=\frac{d}{dt}[\text{tr}(Q^2A^r)]=\text{tr}\left[\frac{d}{dt}(Q^2A^r)\right]=\text{tr}(M_1+M_2),$$

where the two matrices, M_1 and M_2, are given by

$$\begin{aligned}M_1=\dot{Q}QA^r+Q\dot{Q}A^r&=([Q,B]+A)QA^r+Q([Q,B]+A)A^r\\&=(Q^2BA^r-BQ^2A^r)+(AQA^r+QA^{r+1})\end{aligned}$$

and

$$M_2=\sum_{p=1}^{r}Q^2A^{p-1}\dot{A}A^{r-p}=\sum_{p=1}^{r}Q^2A^{p-1}[A,B]A^{r-p}=Q^2A^rB-Q^2BA^r.$$

Hence

$$\begin{aligned}\text{tr}(M_1+M_2)&=\text{tr}(Q^2A^rB-BQ^2A^r)+\text{tr}(AQA^r+QA^{r+1})\\&=\text{tr}([Q^2A^r,B])+2\,\text{tr}(QA^{r+1})=2T_{r+1}^{(1)}.\end{aligned}$$

Property (b) is proved in a similar way:

$$\frac{d}{dt}T_r^{(1)}=\frac{d}{dt}[\text{tr}(QA^r)]=\text{tr}\left[\frac{d}{dt}(QA^r)\right]=\text{tr}(N_1+N_2),$$

where the two matrices, N_1 and N_2, take the form

$$N_1=\dot{Q}A^r=(QB-BQ)A^r+A^{r+1}$$

and

$$N_2 = \sum_{p=0}^{r} QA^{p-1}\dot{A}A^{r-p} = \sum_{p=0}^{r} QA^{p-1}[A,B]A^{r-p} = QA^rB - QBA^r.$$

Hence

$$\mathrm{tr}(N_1+N_2) = \mathrm{tr}(QA^rB - BQA^r) + \mathrm{tr}\ A^{r+1} = \mathrm{tr}([QA^r,B]) + \mathrm{tr}\ A^{r+1} = T^{(0)}_{r+1}.$$

Notice that this proposition means that the traces $T^{(1)}_r$ are nonconstant functions generating integral of motion by a time derivation. Similarly, the $T^{(2)}_r$ generate also constants of motion but now making use of two successive time derivations.

Making use of the above proposition, it is easy to prove that the following two families of functions, K_{rs} and J_{rs}, defined by

$$K_{rs} = rI_rT^{(1)}_{s-1} - sI_sT^{(1)}_{r-1},$$

$$J_{rs} = (r+1)I_{r+1}T^{(2)}_{s-1} + (s+1)I_{s+1}T^{(2)}_{r-1} - 2T^{(1)}_rT^{(1)}_s,$$

are constants of motion. The first family of integrals, K_{rs}, $r,s=1,2,\ldots,n$, has been studied in Ref. 4.

Of course, the existence of these two families means an excessive number of integrals since the maximum number of (time-independent) functionally independent integrals is $N=2n-1$. Notice that $K_{sr}=-K_{rs}$ and $J_{sr}=J_{rs}$; so the total number of elements in every one of these two-parametric families is $(1/2)n(n-1)$ and $(1/2)n(n+1)$, respectively. We will focus our attention in the following more reduced one-parameter families $K_r \equiv K_{1r}$ and $J_{2r} \equiv (1/2)J_{rr}$. That is

$$K_r = I_1T^{(1)}_{r-1} - rI_rT^{(1)}_0,$$

$$J_{2r} = (r+1)I_{r+1}T^{(2)}_{r-1} - (T^{(1)}_r)^2.$$

The functions J_{2r}, $r=1,2\ldots,n$, generalize the above-mentioned function J_2 of the $n=2$ particle system.

Next we present the form of the integrals K_r and J_{2r} for the particular case $n=3$. We denote by L_{kj} the components of the angular momentum, that is, $L_{kj}=q_kv_j-q_jv_k$.

(a) The functions K_r have the following expressions:

$$\begin{aligned} K_2 &= [\mathrm{tr}(QA)]I_1 - [\mathrm{tr}(Q)](2I_2) \\ &= L_{21}(v_2-v_1) + L_{32}(v_3-v_2) + L_{13}(v_1-v_3) \\ &\quad + \text{other terms of lower order}, \end{aligned}$$

$$\begin{aligned} K_3 &= [\mathrm{tr}(QA^2)]I_1 - [\mathrm{tr}(Q)](3I_3) \\ &= L_{21}(v_2^2-v_1^2) + L_{32}(v_3^2-v_2^2) + L_{13}(v_1^2-v_3^2) \\ &\quad + \text{other terms of lower order}, \end{aligned}$$

$$\begin{aligned} K_4 &= [\mathrm{tr}(QA^3)]I_1 - [\mathrm{tr}(Q)](4I_4) \\ &= L_{21}(v_2^3-v_1^3) + L_{32}(v_3^3-v_2^3) + L_{13}(v_1^3-v_3^3) + \cdots. \end{aligned}$$

(b) The functions J_{2r} have the following expressions:

$$J_2 = [\mathrm{tr}(Q^2)](2I_2) - [\mathrm{tr}(QA)]^2 = L_{21}^2 + L_{32}^2 + L_{13}^2 + \text{other terms of lower order},$$

$$J_4=[\mathrm{tr}(Q^2A)](3I_3)-[\mathrm{tr}(QA^2)]^2$$
$$=L_{21}^2(v_2v_1)+L_{32}^2(v_3v_2)+L_{13}^2(v_1v_3)$$
$$+\text{other terms of lower order,}$$

$$J_6=[\mathrm{tr}(Q^2A^2)](4I_4)-[\mathrm{tr}(QA^3)]^2=L_{21}^2(v_2v_1)^2+L_{32}^2(v_3v_2)^2+L_{13}^2(v_1v_3)^2+\cdots .$$

Therefore, the leading term of the the family K_r is linear in the angular momentum, and the leading term of the family J_{2r} is quadratic.

III. MASTER SYMMETRIES

From this point we will make use of the Hamiltonian formalism.

The Hamiltonian phase space M is the $2n$-dimensional cotangent bundle $M=T^*Q$ of the n-dimensional configuration space Q. Cotangent bundles are manifolds endowed, in a natural or canonical way, with a symplectic structure ω_0 that in coordinates, $\{(q_i,p_i);\ i=1,2,\ldots,n\}$, is given by[37–40]

$$\omega_0=dq_i\wedge dp_i$$

(summation on the index i is understood). This symplectic structure defines a one-to-one relationship between the set $\mathfrak{X}(M)$ of vector fields on M and the set $\wedge^1(M)$ of one-forms on M as follows: To every vector field X we associate a one-form α_X given by the contraction of X with ω_0; that is, $X\mapsto\alpha_X=i(X)\omega_0$. Conversely, to every one-form α we can associate the vector field X_α uniquely determined as a solution of the equation $i(X_\alpha)\omega_0=\alpha$.

Given a differentiable function $F=F(q,p)$, the vector field X_F defined as the solution of the equation

$$i(X_F)\omega_0=dF,$$

is called the Hamiltonian vector field of the function F. At this point we make following three observations.

(1) The Hamiltonian vector field of a given function is uniqueley defined (without ambiguities). This uniqueness is a consequence of the symplectic character of the two-form ω_0.

(2) Suppose that we are given a Hamiltonian $H=H(q,p)$. Then the dynamics is given by the Hamiltonian vector field Γ_H of the Hamiltonian function. That is, $i(\Gamma_H)\omega_0=dH$.

(3) If I is a constant of motion for H then, according to the Noether approach to the dynamics, we can consider that I arises from a symmetry. In this case the symmetry is geometrically represented by the Hamiltonian vector field X_I of the function I.

Let us now return to the Calogero–Moser system. For ease of notation, we will frequently denote $T_r^{(1)}$ just by T_r, and we write rI_r instead of $T_r^{(0)}$. We will not change the notation for the constants of motion and we will continue writing I_r, K_r, J_{2r}, $r=1,2,\ldots,n$, for the corresponding functions but now considered as functions of the momenta. We will denote by Γ_r the Hamiltonian vector field of I_r except for the case Γ_2 corresponding to $I_2=H$ that will be denoted just by Γ.

Proposition 2: Let $X_r^{(1)}$ be the Hamiltonian vector field of the function $T_r^{(1)}$ with respect the canonical symplectic structure ω_0, and let $\widetilde{X}_r^{(1)}$ be the vector field defined by $\widetilde{X}_r^{(1)}=[X_r^{(1)},\Gamma]$. Then the vector field $\widetilde{X}_r^{(1)}$ is a symmetry of the dynamical vector field Γ.

Proof: Let us denote by Γ_r^K the Hamiltonian vector field of the function K_r,

$$i(\Gamma_r^K)\omega_0=dK_r.$$

The function K_r is given by

$$K_r = I_1 T_{r-1} - r I_r T_0 ;$$

therefore

$$dK_r = I_1 dT_{r-1} - (rI_r) dT_0 + T_{r-1} dI_1 - (rT_0) dI_r .$$

Thus the vector field Γ_r^K takes the form

$$\Gamma_r^K = I_1 X_{r-1}^{(1)} - (rI_r) X_0^{(1)} + T_{r-1}\Gamma_1 - (rT_0)\Gamma_r .$$

Hence, the Lie bracket of Γ_r^K with the dynamical vector field Γ can be written as follows:

$$[\Gamma_r^K,\Gamma] = I_1[X_{r-1}^{(1)},\Gamma] - (rI_r)[X_0^{(1)},\Gamma] + T_{r-1}[\Gamma_1,\Gamma] - (rI_0)[\Gamma_r,\Gamma]$$
$$-\Gamma(I_1)X_{r-1}^{(1)} + r\Gamma(I_r)X_0^{(1)} - \Gamma(T_{r-1})\Gamma_1 + r\Gamma(T_0)\Gamma_r .$$

The functions I_r, K_r, $r=1,2,\dots,n$, are constants of motion, and the associated vector fields Γ_r, Γ_r^K, are symmetries of Γ,

$$\Gamma(I_r)=0, \quad [\Gamma_r,\Gamma]=0, \quad [\Gamma_r^K,\Gamma]=0, \quad r=1,2,\dots,n,$$

Thus, if we denote by $\tilde{X}_r^{(1)}$ the vector fields,

$$\tilde{X}_r^{(1)} = [X_r^{(1)},\Gamma], \quad r=1,2,\dots,n,$$

we arrive at

$$I_1\tilde{X}_{r-1}^{(1)} = (rI_r)\tilde{X}_0^{(1)} + \Gamma(T_{r-1})\Gamma_1 - r\Gamma(T_0)\Gamma_r = (rI_r)[\tilde{X}_0^{(1)} + \Gamma_1] - rI_1\Gamma_r .$$

Notice that Γ_1 and $X_0^{(1)}$ that are the Hamiltonian vector fields of the functions $I_1 = \mathrm{tr}(A) = p_1 + p_2 + \cdots + p_n$, and $T_0^{(1)} = \mathrm{tr}(Q) = q_1 + q_2 + \cdots + q_n$, take the following form in coordinates:

$$\Gamma_1 = \frac{\partial}{\partial q_1} + \frac{\partial}{\partial q_2} + \cdots + \frac{\partial}{\partial q_n}, \qquad X_0^{(1)} = -\frac{\partial}{\partial p_1} - \frac{\partial}{\partial p_2} - \cdots - \frac{\partial}{\partial p_n}.$$

Making use of these two expressions we obtain

$$[X_0^{(1)},\Gamma] = -\Gamma_1 .$$

So, we thus arrive at the following two equations:

$$\tilde{X}_{r-1}^{(1)} = -r\Gamma_r , \quad [\tilde{X}_{r-1}^{(1)},\Gamma]=0,$$

and the proposition is proved.

In differential geometric terms, a symmetry of the dynamics is a vector field $X \in \mathfrak{X}(M)$ such that $[X,\Gamma_H]=0$ (this geometric approach is also valid in the Lagrangian case but then M is given by the tangent bundle $M=TQ$). A vector field X that satisfies the following two properties:

$$[X,\Gamma_H] \neq 0, \quad [[X,\Gamma_H],\Gamma_H]=0,$$

is called a ''master symmetry'' or a ''generator of symmetries'' of degree $m=1$ for Γ_H (see Refs. 41–43). If X is such that

$$[X,\Gamma_H] \neq 0, \;\; [[X,\Gamma_H],\Gamma_H] \neq 0, \quad \text{and } [[[X,\Gamma_H],\Gamma_H],\Gamma_H]=0,$$

then it is called a ''master symmetry'' or a ''generator of symmetries'' of degree $m=2$.

Next we illustrate this situation with a simple example. The Hamiltonian H and the vector field Γ_H of the $n=1$ free particle are given by

$$H=\left(\frac{1}{2}\right)p^2, \quad \Gamma_H=p\,\frac{\partial}{\partial q}.$$

Then the vector field $X=\partial/\partial p$ satisfies

$$\left[\frac{\partial}{\partial p},p\,\frac{\partial}{\partial q}\right]=\frac{\partial}{\partial q}, \quad \text{and} \left[\frac{\partial}{\partial q},p\,\frac{\partial}{\partial q}\right]=0.$$

So $X=\partial/\partial p$ is a ''master symmetry'' of degree $m=1$ for the free particle.

Consequently, and according to proposition 2, the vector fields $X_r^{(1)}$, $r=1,2\ldots,n$, are ''master symmetries'' of degree $m=1$ for the Calogero-Moser system. Now we consider the case of the functions $T_r^{(2)}$.

Proposition 3: The Hamiltonian vector field $X_r^{(2)}$ of the function $T_r^{(2)}$ is a ''generator of symmetries'' of degree $m=2$.

Proof: Let us denote by Γ_{2r}^J the Hamiltonian vector field of the function J_{2r},

$$i(\Gamma_{2r}^J)\omega_0=dJ_{2r}.$$

The function J_{2r} is given by

$$J_{2r}=(r+1)\,I_{r+1}T_{r-1}^{(2)}-(T_r)^2;$$

therefore

$$dJ_{2r}=(r+1)I_{r+1}dT_{r-1}^{(2)}+(r+1)T_{r-1}^{(2)}dI_{r+1}-2T_r dT_r.$$

Hence the vector field Γ_{2r}^J takes the form

$$\Gamma_{2r}^J=(r+1)I_{r+1}X_{r-1}^{(2)}+(r+1)T_{r-1}^{(2)}\Gamma_{r+1}-2T_rX_r^{(1)}.$$

The Lie bracket of Γ_{2r}^J with the dynamical vector field Γ is given by

$$\begin{aligned}[\Gamma_{2r}^J,\Gamma]&=(r+1)I_{r+1}[X_{r-1}^{(2)},\Gamma]+(r+1)T_{r-1}^{(2)}[\Gamma_{r+1},\Gamma]-2T_r[X_r^{(1)},\Gamma]\\&\quad-(r+1)\Gamma(I_{r+1})X_{r-1}^{(2)}-(r+1)\Gamma(T_{r-1}^{(2)})\Gamma_{r+1}+2\Gamma(T_r)X_r^{(1)}.\end{aligned}$$

We recall first that the functions I_r, $r=1,2,\ldots,n$ are constants of motion, and that the associated vector fields Γ_r are symmetries of Γ, and second that the Lie derivatives of $T_r^{(1)}$ and $T_r^{(2)}$ with respect to Γ are given by

$$\Gamma(T_r^{(1)})=T_{r+1}^{(0)}=(r+1)I_{r+1}, \qquad \Gamma(T_r^{(2)})=2T_{r+1}^{(1)}.$$

Thus, if we denote by $\widetilde{X}_r^{(1)}$ and $\widetilde{X}_r^{(2)}$ the following vector fields:

$$\widetilde{X}_r^{(1)}=[X_r^{(1)},\Gamma], \quad \widetilde{X}_r^{(2)}=[X_r^{(2)},\Gamma], \quad r=1,2,\ldots,n,$$

the Lie bracket of Γ_{2r}^J with Γ becomes

$$\begin{aligned}[\Gamma_{2r}^J,\Gamma]&=(r+1)I_{r+1}\widetilde{X}_{r-1}^{(2)}-2T_r\widetilde{X}_r^{(1)}-2(r+1)T_r^{(1)}\Gamma_{r+1}+2(r+1)I_{r+1}X_r^{(1)}\\&=(r+1)I_{r+1}[\widetilde{X}_{r-1}^{(2)}+2X_r^{(1)}].\end{aligned}$$

The vector field Γ_{2r}^J is a symmetry of the dynamics; so it satisfies, $[\Gamma_{2r}^J,\Gamma]=0$. Therefore, we have arrived at the following three properties:

$$[X_r^{(2)},\Gamma]=\tilde{X}_r^{(2)}\neq 0,\quad r=1,2,\ldots,n,$$

$$[\tilde{X}_r^{(2)},\Gamma]=-2\tilde{X}_{r+1}^{(1)}=2(r+2)\Gamma_{r+2},$$

$$[[\tilde{X}_r^{(2)},\Gamma],\Gamma]=0,$$

which state that $X_r^{(2)}$ is a ''generator of symmetries'' for Γ of degree $m=2$.

We close this section with the following observations.

It is known that if R and S are constants of motion for a Hamiltonian system then so is the Poisson bracket $\{R,S\}$. For the Calogero–Moser system the situation is more general since the functions M_{rs} defined by $M_{rs}=\{T_r,I_s\}$ are also constants of motion,

$$\frac{d}{dt}M_{rs}=\left\{\frac{dT_r}{dt},I_s\right\}+\left\{T_r,\frac{dI_s}{dt}\right\}=0.$$

Nevertheless they do not represent new functions. We have directly verified that

$$M_{rs}=(r+s-1)I_{r+s-1},\quad r,s=1,2,3.$$

In geometric terms this property is as follows. The vector field Z_{rs} defined by $Z_{rs}=[X_r,\tilde{X}_s]$ is a symmetry of the dynamics

$$[Z_{rs},\Gamma]=[[\Gamma,\tilde{X}_s],X_r]+[\tilde{X}_r,\tilde{X}_s]=0.$$

Then it can be proven that

$$i(Z_{rs})\omega_0=(s+1)d\{T_r,I_{s+1}\}.$$

Consequently, the constant M_{rs+1} is the Hamiltonian function of the vector field Z_{rs}.

An important point is that if H is an arbitrary Hamiltonian, and F a function such that its Hamiltonian vector field X_F is a master symmetry for Γ_H, then $I_F=\Gamma_H(F)$ is a constant of motion for H. Conversely, if I is a constant of motion for H, and if the two equations,

$$i(X_I)\omega_0=dI,\quad [X,\Gamma_H]=X_I,$$

admit as a solution a well defined complete vector field X, then X is a master symmetry for Γ_H.

Therefore, the existence of master symmetries can be considered as a property closely related with the theory of constants of motion. Nevertheless, in most of cases, obtaining master symmetries implies a very difficult calculus. The important point concerning the Calogero–Moser system is that, as this system is very peculiar, we can obtain, in a simple and direct way, the Hamiltonian functions, $T_r^{(1)}$ and $T_r^{(2)}$, of the master symmetries of the system.

IV. TIME-DEPENDENT SYMMETRIES

The time-dependent Hamiltonian formalism has as phase space the manifold M defined as $M=T^*Q\times\mathbb{R}$, and as a fundamental geometric structure the (nonsymplectic) two-form Ω_H defined as

$$\Omega_H=\omega_0+dH\wedge dt.$$

The dynamics is now given by the unique time-dependent vector field Γ_H defined as solution of the following two equations:

$$i(\Gamma_H)\Omega_H=0, \quad i(\Gamma_H)dt=1.$$

Notice that, in fact, the dynamical equation is the first one; the second equation must be considered as a restriction that leads to the uniqueness of the solution. In coordinates Γ_H takes the form

$$\Gamma_H=\left(\frac{\partial H}{\partial p_i}\right)\frac{\partial}{\partial q_i}-\left(\frac{\partial H}{\partial q_i}\right)\frac{\partial}{\partial p_i}+\frac{\partial}{\partial t}.$$

We now apply the results obtained in Sec. III to the theory of time-dependent symmetries of the Calogero–Moser system. We first recall that a time-independent Hamiltonian $H=H(q,p)$ can also be endowed with time-dependent constants of motion $I=I(q,p,t)$.

Let H be a time-independent Hamiltonian, and X a (time-independent) master symmetry for Γ_H. Then the time-dependent vector field Y_X defined by[42–43]

$$Y_X=X+t[X,\Gamma_H]+(\tfrac{1}{2})t^2[[X,\Gamma_H],\Gamma_H]$$

is a time-dependent symmetry of H. If the degree of X is $m=1$ then Y_X will determine a time-dependent constant of motion I^t linear in the time t; if $m=2$ then this constant will be quadratic in t.

As an example, let us consider once more the case of the $n=1$ free particle. Then we have

$$X=\frac{\partial}{\partial p}, \quad Y_X=t\frac{\partial}{\partial q}+\frac{\partial}{\partial p}$$

and

$$\left[t\frac{\partial}{\partial q}+\frac{\partial}{\partial p},p\frac{\partial}{\partial q}+\frac{\partial}{\partial t}\right]=0.$$

Notice that in this case,

$$i(Y_X)\Omega_H=-d(q-tp),$$

so, the time-dependent constant of motion $I=I(q,p,t)$ arising from the vector field Y_X is $I=q-tp$.

We denote by $Y_r^{(1)}$ the time-dependent symmetry of the Calogero–Moser system determined by $X_r^{(1)}$,

$$Y_r^{(1)}=X_r^{(1)}+t[X_r^{(1)},\Gamma].$$

In order to obtain the associated time-dependent constant of motion, we must calculate the contraction of the vector field $Y_r^{(1)}$ with the two-form Ω_H,

$$i(Y_r^{(1)})\Omega_H=i(X_r^{(1)})\omega_0+[i(X_r^{(1)})dH]dt+ti(\tilde{X}_r^{(1)})\omega_0+t[i(\tilde{X}_r^{(1)})dH]dt.$$

We have

$$i(X_r^{(1)})\omega_0=dT_r^{(1)},$$

$$i(X_r^{(1)})dH=X_r^{(1)}(dH)=-\Gamma(T_r^{(1)})=-(r+1)I_{r+1},$$

$$i(\tilde{X}_r^{(1)})\omega_0=-(r+1)i(\Gamma_{r+1})\omega_0=-(r+1)dI_{r+1},$$

$$i(\tilde{X}_r^{(1)})dH=\tilde{X}_r^{(1)}(H)=-(r+1)\Gamma_{r+1}(H)=0.$$

Thus, we arrive at

$$i(Y_r^{(1)})\Omega_H = d[T_r^{(1)} - (r+1)tI_{r+1}].$$

Consequently the time-dependent functions I_r^t, $r=1,2,\ldots,n$, defined by

$$I_r^t = T_{r-1}^{(1)} - rtI_r,$$

are time-dependent constants of motion for the Calogero–Moser system.

Next we consider the time-dependent symmetry of the Calogero–Moser system determined by $X_r^{(2)}$,

$$Y_r^{(2)} = X_r^{(2)} + t\tilde{X}_r^{(2)} + (\tfrac{1}{2})t^2[\tilde{X}_r^{(2)},\Gamma].$$

In this second case the contraction of the vector field $Y_r^{(2)}$ with the two-form Ω_H is given by

$$i(Y_r^{(2)})\Omega_H = i(X_r^{(2)})\omega_0 + [i(X_r^{(2)})dH]dt + ti(\tilde{X}_r^{(2)})\omega_0 + t[i(\tilde{X}_r^{(2)})dH]dt$$
$$+ (\tfrac{1}{2})t^2 i([\tilde{X}_r^{(2)},\Gamma])\omega_0 + (\tfrac{1}{2})t^2[i([\tilde{X}_r^{(2)},\Gamma])dH]dt.$$

Now we have

$$i(X_r^{(2)})\omega_0 = dT_r^{(2)},$$

$$i(X_r^{(2)})dH = X_r^{(2)}(H) = -\Gamma(T_r^{(2)}) = -2T_{r+1}^{(1)},$$

$$i(\tilde{X}_r^{(2)})\omega_0 = -2i(X_{r+1}^{(1)})\omega_0 = -2dT_{r+1}^{(1)},$$

$$i(\tilde{X}_r^{(2)})dH = -2i(X_{r+1}^{(1)})(dH) = 2\Gamma(T_{r+1}^{(1)}) = 2(r+2)I_{r+2},$$

$$i([\tilde{X}_r^{(2)},\Gamma])\omega_0 = 2(r+2)i(\Gamma_{r+2})\omega_0 = 2(r+2)dI_{r+2},$$

$$i([\tilde{X}_r^{(2)},\Gamma])dH = 2(r+2)\Gamma_{r+2}(H) = 0.$$

Thus, we arrive at

$$i(Y_r^{(2)})\Omega_H = d[T_r^{(2)} - 2tT_{r+1}^{(1)} + (r+2)t^2 I_{r+2}].$$

Consequently the time-dependent functions J_r^t, $r=1,2,\ldots,n$, defined by

$$J_r^t = T_{r-1}^{(2)} - 2tT_r^{(1)} + (r+1)t^2 I_{r+1},$$

are time-dependent constants of motion for the Calogero–Moser system.

Now, with the knowledge of these time-dependent integrals, we can consider a new approach to the two time-independent families of constants obtained in Sec. II.

It can be proven that, after some calculus, the integrals K_{rs} and J_{rs} can be rewritten as follows:

$$K_{rs} = (rI_r)I_s^t - (sI_s)I_r^t,$$

$$J_{rs} = (r+1)I_{r+1}J_s^t + (s+1)I_{s+1}J_r^t - 2I_{r+1}^t I_{s+1}^t.$$

So, in a sense, the existence of K_{rs} and J_{rs} can be considered as a consequence of the existence of I_r^t and J_r^t. Everyone of the K_{rs} (with the two indices) appears as arising from an algebraic pairing of I_r^t with I_s^t. Similarly, every one of the J_{rs} arises from a pairing of J_r^t and I_{r+1}^t with J_s^t and I_{s+1}^t. Notice that, in both constructions, the previous existence of the fundamental family I_r is necessary.

We close this section with the $n=3$ particular case as an example. In this simple case the time-dependent functions I_1^t, I_2^t, and J_1^t, have the following expressions:

$$I_1^t=(q_1+q_2+q_3)-t(p_1+p_2+p_3),$$

$$I_2^t=(q_1p_1+q_2p_2+q_3p_3)-t[p_1^2+p_2^2+p_3^2+2(V_{12}+V_{23}+V_{13})],$$

$$J_1^t=(q_1^2+q_2^2+q_3^2)-2t(q_1p_1+q_2p_2+q_3p_3)-t^2[p_1^2+p_2^2+p_3^2+2(V_{12}+V_{23}+V_{13})].$$

V. FINAL COMMENTS

The Calogero–Moser system is a maximally superintegrable system that is endowed with a great amount of different symmetries. The associated constants can be grouped in families. The first and fundamental family is the one studied by Moser in Ref. 26 which is directly related with the Lax equation. There exist, in addition to this fundamental one, other different families. In this article we have analyzed the properties of four families. Two of them are time-independent,

$$K_{rs}=rI_rT_{s-1}^{(1)}-sI_sT_{r-1}^{(1)},$$

$$J_{rs}=(r+1)I_{r+1}T_{s-1}^{(2)}+(s+1)I_{s+1}T_{r-1}^{(2)}-2T_r^{(1)}T_s^{(1)},$$

and the other two are time-dependent,

$$I_r^t=T_{r-1}^{(1)}-rtI_r,$$

$$J_r^t=T_{r-1}^{(2)}-2tT_r^{(1)}+(r+1)t^2I_{r+1}.$$

Finally, let us comment that the existence of some integrable Calogero-related systems, e.g., Calogero interacting particles in an external field have been proven. It is known that for the particular case $n=2$ the constant J_2 is compatible with a harmonic oscillator (see, e.g., Refs. 2, 18, 19). We think that a prolongation of this study could be the analysis of similar properties for the n-dimensional Calogero–Moser system wih harmonic oscillators.

Note added in proof. We have found the additional Ref. 44 that also studies the existence of master symmetries and the Calogero–Moser system.

(Received 18 May 1998; accepted for publication 9 September 1998)

Starting from a two-line soliton solution of an integrable $(2+1)$-dimensional system in bilinear form, one can find a dromion solution that is localized in all directions for a suitable potential. The interaction between two dromions is studied in detail through the method of figure analysis for a $(2+1)$-dimensional modified Korteweg–deVries (KdV) system, sine–Gordon system and Sawada–Kotera system. Except for a phase shift, there are no changes in the shape and velocity of the dromions after interactions for these models. The interactions of dromions for these models are not only elastic (there is no exchange of energy) but also irrotational (there is no exchange of angular momentum). © *1999 American Institute of Physics.* [S0022-2488(98)03112-0]

I. INTRODUCTION

Recently, since the pioneering work of Boiti *et al.*,[1] the study of the exponentially localized soltion solutions, called dromions, in $(2+1)$-dimensions has been attracting much attention from physicists and mathematicians. Usually, dromion solutions are driven by two or more nonparallel straight-line ghost solitons. For instance, for the Davey–Stewartson (DS)[2] and the Nizhnik–Novikov–Veselov (NVV)[3] equations, their dromion solutions are driven by two perpendicular line ghost solitons.[1,4] For the Kadomtsev–Petviashivili (KP) equation, the dromion solutions are driven by nonperpendicular line ghost solitons.[5] For one type of nonlinear models, say, the DS, NNV, and asymmetrical NNV(ANNV)[6] equations, the dromion solutions exist for the physical fields. However, for other types of equations like the KP and the breaking soliton equations, the dromion solutions exist only for some suitable potentials of the field.[5,7] More recently, even more generalized dromion solutions which are driven by curved and straight-line solitons for some types of $(2+1)$-dimensional nonlinear modes are found.[8]

In this paper, we are interested in the interaction of dromions for $(2+1)$-dimensional integrable systems. It is well known that the interactions of $(1+1)$-dimensional solitons are elastic. There is no exchange of energy (no change of shape and velocity) among interacting solitons. We hope to know whether the interactions among dromions for $(2+1)$-dimensional integrable systems are elastic or not. Different from $(1+1)$-dimensional cases, the interactions between two $(2+1)$-dimensional objects with finite size, say, dromions, may lead to rotations. So we hope to know also whether there are exchanges of angular momentum among interacting dromions. In other words, whether the interactions among dromions are rotational or irrotational.

The paper is organized as follows. In Sec. II, the multi-dromion solutions are given for three $(2+1)$-dimensional integrable systems, modified KdV (MKdV), Sawada–Kotera (SK), and sine–Gordon (SG) systems. The plots of interaction of two dromions for two systems are shown in Sec. III. Section IV includes a summary and discussion.

II. MULTI-DROMION SOLUTION OF A THREE (2+1)-DIMENSIONAL INTEGRABLE SYSTEM

A. Multi-dromion solutions of the MKdV system

The bilinear form of the $(2+1)$-dimensional MKdV system can be written as

$$A(D_X)(f\cdot f+g\cdot g)\equiv A(D_x,D_y,D_t)(f\cdot f+g\cdot g)=0, \tag{1}$$

$$B(D_X)f\cdot g\equiv B(D_x,D_y,D_t)f\cdot g=0, \tag{2}$$

where A and B are even and odd functions of their variables $X=(x,y,t)$ and $D_X=(D_x,D_y,D_t)$, respectively. The D-operators are defined by[9,10]

$$D_x^nD_y^mD_t^pf\cdot g\equiv(\partial_x-\partial_{x'})^n(\partial_y-\partial_{y'})^m(\partial_t-\partial_{t'})^p(f(X)\cdot g(X'))\big|_{X'=X}. \tag{3}$$

It can be proved that a single dromion solution of the equation system (1) and (2) exists if a physical field is defined suitably.

$$u=L(\partial_X)K(\partial_X)(\tan^{-1}(g/f))\equiv(a_1\partial_x+b_1\partial_y)(a_1\partial_x+b_2\partial_y)(\tan^{-1}(g/f)), \tag{4}$$

where a_1, b_1, a_2 and b_2, should be selected such that the linear operators $L(\partial_X)$ and $K(\partial_X)$ annihilate two-line solitons,

$$f=1+a_{12}\exp(\eta_1+\eta_2),\quad g=\exp(\eta_1)+\exp(\eta_2), \tag{5}$$

$$\eta_i=p_ix+q_iy+w_it+\text{const}\equiv P_i\cdot X+\text{const}, \tag{6}$$

with

$$P_i=(p_i,q_i,w_i)\quad(i=1,2),\quad B(P_i)=0,\quad a_{12}=-\frac{A(P_1-P_2)}{A(P_1+P_2)}. \tag{7}$$

That is to say, in the space–time (x,y,t), the dromion solutions are driven by ghost line solitons which are nonparallel to each other. Two-line solitons are annihilated by two-linear operators $L(\partial_X)$ and $K(\partial_X)$ while a dromion which is located at the cross point of the two-line solitons is survived. Taking a space transformation

$$p_1x+q_1y=px_1,\quad p_2x+q_2y=qy_1,\quad \Delta\equiv p_1q_2-p_2q_1\neq0, \tag{8}$$

and fixing the constants a_i and b_i, in Eq. (4) as $a_1=-q_1q/\Delta$, $b_1=p_1q/\Delta$, $a_2=q_2p/\Delta$, and $b_2=-p_2p/\Delta$, we can rewrite Eqs. (4)–(6) as

$$u=(a_1\partial_x+b_1\partial_y)(a_2\partial_x+b_2\partial_y)(\tan^{-1}(g/f))\equiv\partial_{x_1}\partial_{y_1}(\tan^{-1}(g/f)), \tag{9}$$

$$f=1+a_{12}\exp(\eta_1+\eta_2),\quad g=\exp(\eta_1)+\exp(\eta_2),\quad \eta_1=px_1+\text{const},\quad \eta_2=qy_1+\text{const}. \tag{10}$$

Now, let us discuss in detail the dromion structures for the following $(2+1)$-dimensional integrable MKdV equation:[11]

$$A(D_X)(f\cdot f+g\cdot g)=D_x^2(f\cdot f+g\cdot g)=0, \tag{11}$$

$$B(D_X)f\cdot g=(D_x^2D_t+D_x^5+D_y)f\cdot g=0. \tag{12}$$

By means of the general method developed by Hirota, the N-line soliton solution of the equation system (11) and (12) can be written as

$$f(x,y,t)=\sum_{n=0}^{N/2}\sum_{{}_NC_{2n}}a(i_1,i_2,\ldots,i_{2n})\exp(\eta_{i1}+\eta_{i2}+\cdots+\eta_{i2n}), \tag{13}$$

$$g(x,y,t)=\sum_{m=0}^{[(N-1)/2]}\sum_{{}_NC_{2m+1}} a(j_1,j_2,\ldots,j_{2m+1})\exp(\eta_{j1}+\eta_{j2}+\cdots+\eta_{j2m+1}), \tag{14}$$

$$a(i_1,i_2,\ldots,i_n)=\begin{cases}\prod_{k,l}^{(n)} a(i_k,i_l) & \text{for } n\geqslant 2,\\ 1, \quad n=0,1,\end{cases} \tag{15}$$

$$a(i_k,i_l)=-\frac{A(P_{ik}-P_{il})}{A(P_{ik}+P_{il})}=-\frac{(p_{ik}-p_{il})^2}{(p_{ik}+p_{il})^2}, \tag{16}$$

$$\eta_i=p_ix+q_iy+w_it+\eta_{i0}, \tag{17}$$

$$B(P_{ik})=p_i^2w_i^2+p_i^5+q_i=0. \tag{18}$$

Here $|N/2|$ denotes the maximum integer which does not exceed $N/2$ and n_{i0} is an arbitrary but finite real constant related to the phase of the ith soliton. ${}_NC_n$ indicates summation over all possible combination of n elements taken from N, and $\Pi_{i,1}^{(n)}$ indicates the product of all possible combinations of the n elements. It can be known from Eqs. (8) and (9) that the multi-dromion solutions for the potential u given by (9) are allowed only for a special form such that two linear operators $a_i\partial_x+b_i\partial_y(i=1,2)$ with fixed a_i and b_i annihilate all the line solitons, since a_i and b_i are dependent of q_i and p_i. In other words the only allowed line solitons must be perpendicular to the axes in the new space coordinates x_1 and y_1. So the multi-dromion solutions exist only for the following potential form.

$$u=\partial_{x1}\partial_{y1}(\tan^{-1}(g(x_1,y_1,t)/f(x_1,y_1,t))), \tag{19}$$

where the forms of $g(x_1,y_1,t)$ and $f(x_1,y_1,t)$ are the same as those of (13) and (14), but η_i should be taken as

$$\eta_i=p_ix+q_iy+w_it+\eta_{i0}=p_i'x_1+w_it+\eta_{i0} \quad \text{or} \quad \eta_i=p_ix+q_iy+w_it+\eta_{i0}=q_i'y_1+w_it+\eta_{i0}. \tag{20}$$

As an example, we write down the explicit forms of f and g for $N=3$:

$$f(x,y,t)=1+a(1,2)\exp(\eta_1+\eta_2)+a(1,3)\exp(\eta_1+\eta_3)+a(2,3)\exp(\eta_2+\eta_3), \tag{21}$$

$$g(x,y,t)=\exp(\eta_1)+\exp(\eta_2)+\exp(\eta_3)+a(1,2)a(1,3)a(2,3)\exp(\eta_1+\eta_2+\eta_3), \tag{22}$$

$$\eta_i=p_i'x+w_it+\eta_{i0} \quad \text{or} \quad \eta_i=q_iy+w_it+\eta_{i0}, \tag{23}$$

$$p_i^2w_i+p_i^5+q_i=0, \tag{24}$$

$$a(i,j)=-\frac{(p_i-p_j)^2}{(p_i+p_j)^2}. \tag{25}$$

B. Multi-dromion solutions of a $(2+1)$-dimensional sine-Gordon system

The bilinear form of a $(2+1)$-dimensional sine-Gordon system is given by

$$A(D_X)(f\cdot f-g\cdot g)\equiv A(D_x,D_y,D_t)(f\cdot f-g\cdot g)=0, \tag{26}$$

$$B(D_X)f\cdot g\equiv B(D_x,D_y,D_t)f\cdot g=0, \tag{27}$$

where A and B are even functions of their variables. For simplicity, we shall discuss the dromion structure of the sine–Gordon system for a special selection of the operators A and B:

$$A(D_X)(f\cdot f-g\cdot g)\equiv D_xD_t(f\cdot f-g\cdot g)=0, \tag{28}$$

$$B(D_X)f\cdot g=(D_x^3D_t+D_yD_t+a)f\cdot g=0. \tag{29}$$

Performing the similar procedure leading to Eqs. (13)–(15), we find that the N-line soliton solution of the equation system (28) and (29) possesses the same form as Eqs. (13)–(15) but with

$$a(i_k,i_l)=\frac{A(p_{ik}-p_{il})}{A(p_{ik}+p_{il})}=\frac{(p_{ik}-p_{il})(w_{ik}-w_{il})}{(p_{ik}+p_{il})(w_{ik}+w_{il})}, \tag{30}$$

$$\eta_i=p_ix+q_iy+w_it=\eta_{i0}, \tag{31}$$

$$B(P_{ik})=p_i^3w_i+q_iw_i+a=0. \tag{32}$$

From the dispersion relation (32), we see that both p_i and q_i can be selected as zero. So in order to obtain the dromion solution of the sine–Gordon system (28) and (29), we can simply take $\eta_i=p_ix+w_it+\eta_{i0}$, or $\eta_i=q_iy+w_it+\eta_{i0}$. In this case, the linear operators to annihilate all the line solitons can be taken as $L(\partial_X)=\partial_x$ and $K(\partial_X)=\partial_y$. Then the physical field with dromion solutions reads

$$u=\partial_x\partial_y(\tan^{-1}(g(x,y,t)/f(x,y,t))). \tag{33}$$

C. Multi-dromion solutions of a $(2+1)$-dimensional Sawada–Kotera equation

The n-line soliton solution of the following $(2+1)$-dimensional SK equation in bilinear form,

$$A(D_X)=(D_x^6+5D_yD_x^3-5D_y^2+D_xD_t)F\cdot F=0, \tag{34}$$

can be written as

$$F(x,y,t)=1+\sum_{i=1}^{n}\exp(\eta_i)+\sum_{i<j}^{n}a_{ij}\exp(\eta_i+\eta_j)+\sum_{i<j<k}a_{ij}a_{jk}a_{ik}\exp(\eta_i+\eta_j+\eta_k)+\cdots+\left(\prod_{i<j}a_{ij}\right)\exp\sum_{k=1}^{n}\eta_k, \tag{35}$$

where

$$a_{ij}=-\frac{A(P_i-P_j)}{A(P_i+P_j)}=-\frac{(p_i-p_j)^6+5(q_i-q_j)(p_i-p_j)^3-5(q_i-q_j)^2+(p_i-p_j)(w_i-w_j)}{(p_i+p_j)^6+5(q_i+q_j)(p_i+p_j)^3-5(q_i+q_j)^2+(p_i+p_j)(w_i+w_j)}, \tag{36}$$

$$\eta_i=p_ix+q_iy+w_it+\eta_{i0}, \tag{37}$$

$$p_i^6+5q_ip_i^3-5q_i^2+p_iw_i=0. \tag{38}$$

It may be proved that multi-dromion solutions of Eq. (33) exist if the physical field is defined as

$$u=\partial_{x1}\partial_{y1}\ln F(x_1,y_1,t), \tag{39}$$

where x_i and y_1 are new space coordinates. In the new space–time (x_1,y_1,t), the only allowed line solitons must be perpendicular to the axes and η_i in function $F(x_1,y_1,t)$ should be taken as

$$\eta_i=p_ix+q_iy+w_it+\eta_{i0}=p_i'x_1+w_it+\eta_{i0}\quad\text{or}\quad\eta_i=p_ix+q_iy+w_it+\eta_{i0}=q_i'y_1+w_it+\eta_{i0}. \tag{40}$$

Substituting (34) with (35), (37), and (39) into (38), we obtain a single $(2+1)$-dimensional dromion solution which is localized in all directions for $N=2$, two dromion solution for $N=3$,

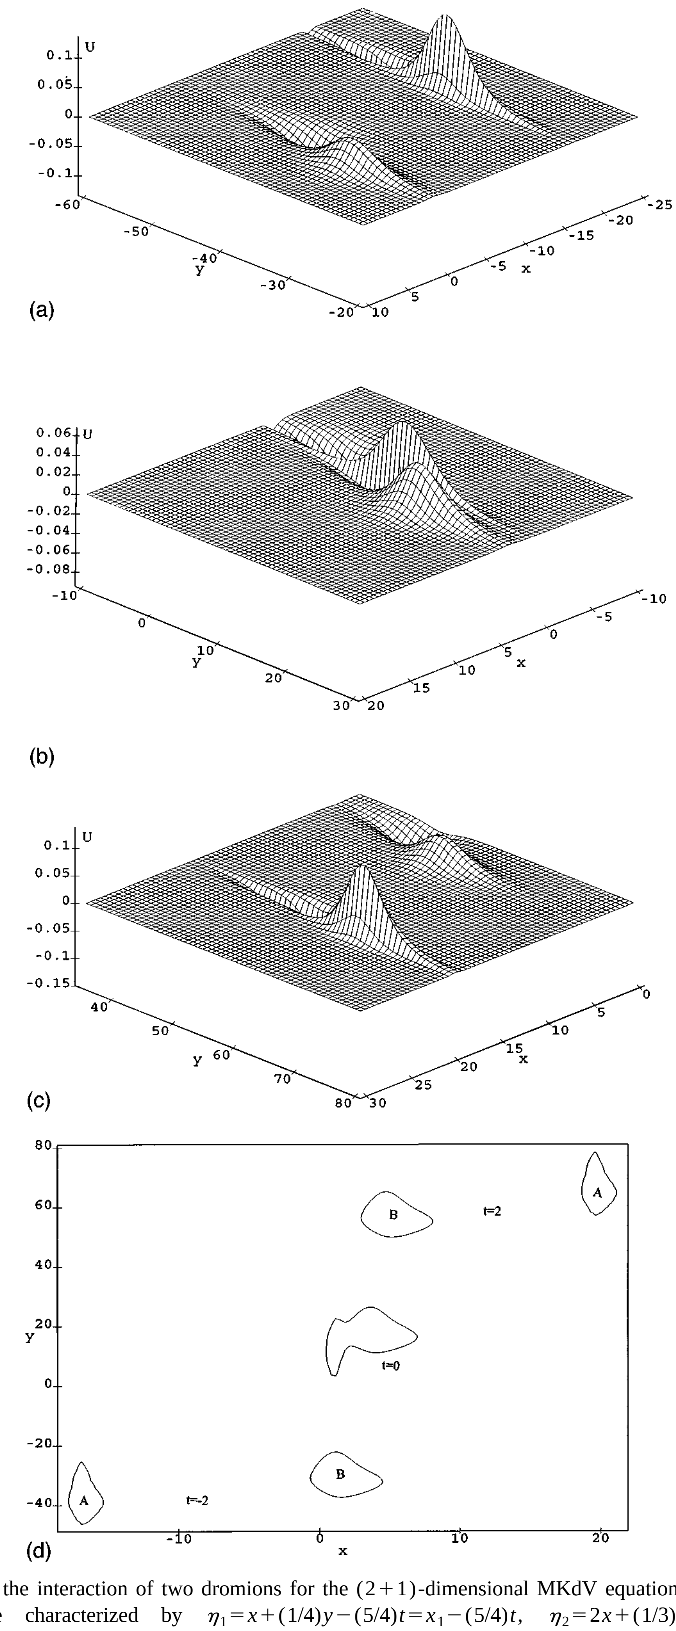

FIG. 1. The plots of the interaction of two dromions for the $(2+1)$-dimensional MKdV equation formed by three-line solitons which are characterized by $\eta_1 = x + (1/4)y - (5/4)t = x_1 - (5/4)t$, $\eta_2 = 2x + (1/3)y - (97/12)t = (1/3)y_1 - (97/12)t$, and $\eta_3 = 3x + (1/2)y - (487/18)t = 3x_1 - (487/18)t$. The times of the figures read: (a) $t = -2$, (b) $t = 0$, (c) $t = 2$, (d) is a cross-section plot $(u = 0.005)$ in correspondence with (a)–(c).

three or four dromion solutions for $N = 4$, and so on. The number of the dromions of an n-line soliton solution is determined by how many intersect points exist in the lines. As an example we write down the explicit forms of F for $N = 3$:

$$F(x_1,y_1,t)=1+\exp(\eta_1)+\exp(\eta_2)+\exp(\eta_3)+a_{12}\exp(\eta_1+\eta_2)+a_{13}\exp(\eta_1+\eta_3)$$
$$+a_{23}\exp(\eta_2+\eta_3)+a_{12}a_{13}a_{23}\exp(\eta_1+\eta_2+\eta_3), \tag{41}$$

$$\eta_i=p_ix+q_iy+w_it+\eta_{i0}=p_i'x_1+w_it+\eta_{i0} \quad \text{or} \quad \eta_i=p_ix+q_iy+w_it+\eta_{i0}=q_i'y_1+\eta_{i0}, \tag{42}$$

$$p_i^6+5q_ip_i^3-5q_i^2+p_iw_i=0, \tag{43}$$

$$a_{ij}=-\frac{A(p_i-p_j)}{A(p_i+p_j)}. \tag{44}$$

III. DROMION INTERACTIONS

It is known that in $(1+1)$-dimensions, there is no exchange of physical quantities like energy and momentum of the solitons after collision. Except for the phase shifts, the velocities and shapes all remained unchanged.

We hope to know whether the similar property is valid or not for the interactions among dromions. Especially, we hope to known whether the dromions rotate or not. In other words, is there exchange of angular momentum when the $(2+1)$-dimensional ''objects,'' dromions, collide?

It is difficult to study analytically the interaction of the dromions because of the complexity of the multi-dromion solutions. It is more straightforward to study the interaction of the dromions graphically.

Figure 1 is the interaction plot of two dromions (which are formed by three ghost line solitons) for the MKdV equation, where three ghost line solitons are characterized by

$$\eta_1=x+\frac{1}{4}y-\frac{5}{4}t=x_1-\frac{5}{4}t,$$
$$\eta_2=2x+\frac{1}{3}y-\frac{97}{12}t=\frac{1}{3}y_1-\frac{97}{12}t, \tag{45}$$
$$\eta_3=3x+\frac{1}{2}y-\frac{487}{18}t=\frac{1}{2}y_1-\frac{487}{18}t,$$

respectively. In Figs. 1(a)–(c), the time t is taken as -2, 0, and 2, respectively. Figure 1(d) is a cross-section plot of the two dromions before and after interaction in correspondence with Figs. 1(a)–(c), while $u=\text{const.}=0.005$. From Figs. 1(a)–(d), we see that the shapes of dromions are not changed. Especially from Fig. 1(d), one can see clearly that the shapes and the directions (if we locate a vector on every dromion) of two dromions are totally the same, which means there is also no exchange of the angular momentum between the dromions when they are interacting. The only change found from Fig. 1(d) is the phase shifts of the interacting dromions.

Figure 2 is the interaction plot of two dromions for sine–Gordon equation, where

$$\eta_1=x-t, \quad \eta_2=\frac{1}{2}y-2t, \quad \eta_3=\frac{3}{2}x-\frac{8}{27}t, \tag{46}$$

and Fig. 2(d) is a cross-section plot of the two dromions in correspondence with Figs. 2(a)–(c) at time $t=-15$, $t=0$, and $t=15$ for $u=\text{const}=-0.001$. As in Fig. 1, from the Figs. 2(a)–(d), we can see all interacting phenomenon between the interaction of the dromions for the sine–Gordon system (28) and (29). There are no exchanges of the energy, momentum, and angular momentum except the phase shifts.

For the same way, the interacting property between dromions for the SK equation is studied and the same conclusions are obtained. Except for the phase shifts, there is no change at all for the dromions after collision; especially, there is no rotation.

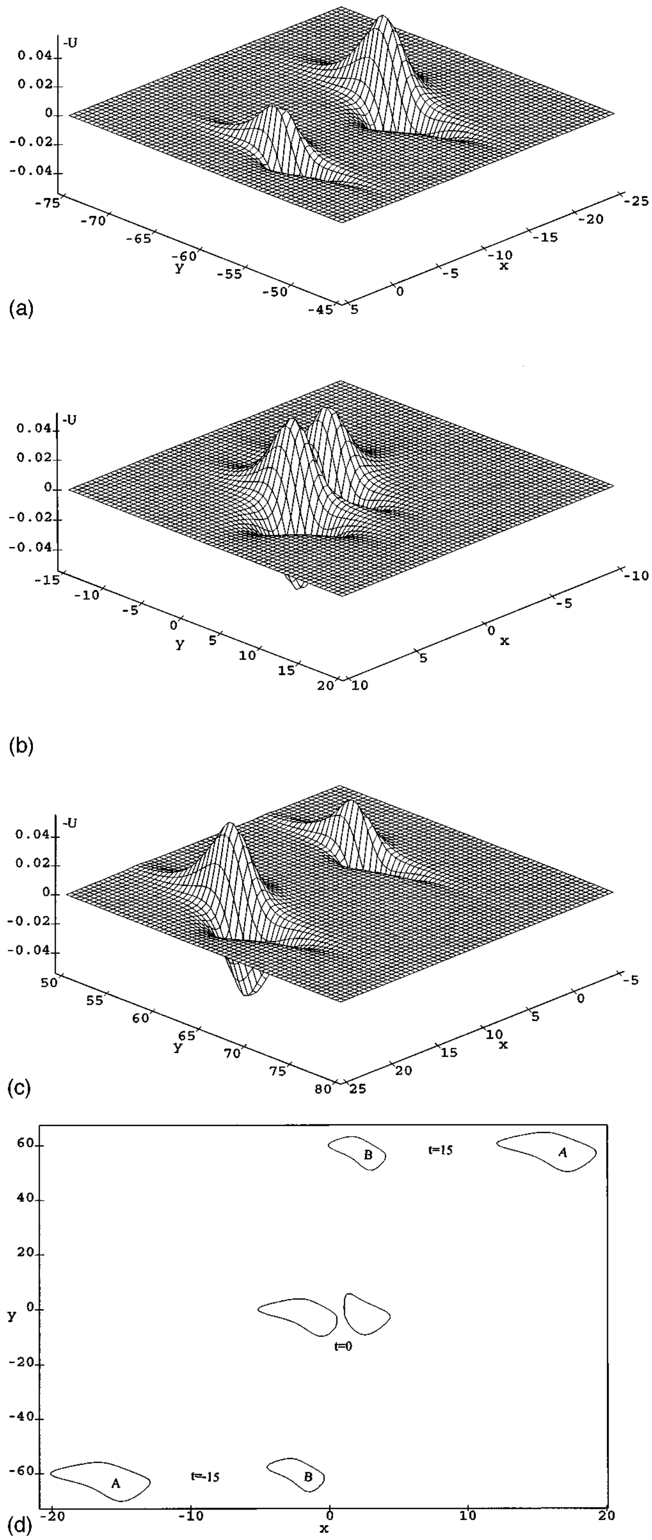

FIG. 2. The plots of the interaction of two dromions for a $(2+1)$-dimensional sine—Gordon equation. The related three-line solitons are determined by $\eta_1 = x - t$, $\eta_2 = (1/2)y - 2t$, and $\eta_3 = (3/2)x - (8/27)t$. The times of the figures read: (a) $t=-15$, (b) $t=0$, (c) $t=15$; (d) is a cross-section plot ($u=-0.001$) in correspondence with (a)–(c).

IV. SUMMARY AND DISCUSSIONS

In summary, we have constructed multidromion solutions of the $(2+1)$-dimensional MKdV-type, $(2+1)$-dimensional sine–Gordon-type, and the $(2+1)$-dimensional SK-type equations for some suitable potentials. The multidromions are constructed by multi-line solitons, say, a single dromion is constructed by two-line solitons, two-dromion solutions are constructed by three line solitons. All the line solitons should be parallel to the new axises $\{x_1, y_1\}$.

For $(1+1)$-dimensional integrable models, like the KdV equation, the interaction among solitons are completely elastic. There is no energy and momentum exchange among solitons when they are interacting. The only effect of the soliton interaction is the phase shifts. In $(2+1)$-dimensional cases, the similar conclusions for three types of models, MKdV, sine–Gordon, and SK models, are obtained. Figures 1(c) and 2(c) show us that the ''shapes'' and velocities of two dromions in the two systems are totally the same before and after interactions. The only effect observed from Figs. 1(d) and 2(d) of the interactions is the phase shifts. That is to say there is no energy and momentum exchange when the dromions finishing the interaction. Different from the $(1+1)$-dimensional case, there may be exchange of another physical quantity, angular momentum, for the collision of $(2+1)$-dimensional objects. However, for the three types of $(2+1)$-dimensional integrable models studied in this paper, we find that no rotations occur when the dromions are interacting. In other words, there is no angular momentum exchange among the interaction dromions of the three types of $(2+1)$-dimensional models.

We believe that the conclusions obtained in this paper are true for all $(2+1)$-dimensional integrable models and $(3+1)$-dimensional models (if there exist), though we obtained the results only from three types of $(2+1)$-dimensional models. We hope this conviction can be checked in a future study.

Spin and wave function as attributes of ideal fluid

Yuri A. Rylov[a)]

(Received 17 April 1998; accepted for publication 18 September 1998)

An ideal fluid whose internal energy depends on density, density gradient, and entropy is considered. Dynamic equations are integrated, and a description in terms of hydrodynamic (Clebsch) potentials occurs. All essential information on the fluid flow (including initial and boundary conditions) appears to be carried by the dynamic equations for hydrodynamic potentials. Information on initial values of the fluid flow is carried by arbitrary integration functions. Initial and boundary conditions for potentials contain only nonessential information concerning the fluid particle labeling. It is shown that the description in terms of n-component complex wave function is a kind of such description in terms of hydrodynamic potentials. Spin determined by the irreducible number n_m of the wave function components appears to be an attribute of the fluid flow. Classification of fluid flows by the spin appears to be connected with invariant subspaces of the relabeling group. [S0022-2488(99)01001-4]

I. INTRODUCTION

An ideal (nondissipative) fluid with the internal energy E of a very general form is considered. The internal energy E is supposed to depend on the fluid density ρ, density gradient $\nabla\rho$, and entropy per unit mass S. The stress tensor for such fluid has the form

$$P^{\alpha\beta}=\delta_{\alpha\beta}\left[\rho^2\,\frac{\partial E}{\partial\rho}+\frac{\partial(\rho E)}{\partial\rho_\gamma}\,\rho_\gamma\right]-\rho\partial_\alpha\,\frac{\partial(\rho E)}{\partial\rho_\beta},\quad \alpha,\beta=1,2,3$$

$$\rho_\alpha\equiv\partial_\alpha\rho,\quad \partial_i\equiv\frac{\partial}{\partial x^i},\quad i=0,1,2,3. \tag{1}$$

If $E=E(\rho,S)$ does not depend on $\nabla\rho$, the stress tensor has the form

$$P^{\alpha\beta}=p\,\delta^\alpha_\beta,$$

where $p=\rho^2\partial E/\partial\rho$ is the pressure. Conventionally the dependence of the internal energy on $\nabla\rho$ is not considered. There are two motives for the consideration of such an unusual fluid.

First, the proper dependence of E on $\nabla\rho$ prevents sound waves from tilting. Indeed, let the internal energy have the form

$$E=E_0(\rho,S)+a(\nabla\rho/\rho)^2, \tag{2}$$

where a is a small positive quantity. For usual laminar flows, where $\nabla\rho/\rho$ is small, the last term of (2) does not give a significant contribution to the stress tensor (1), and it is of no importance whether or not there is the last term in (2). In the case of the wave tilting the last term in (2) comes to be principal. At the front of the tilted sound wave E tends to ∞, and the tilting of the wave may be stopped.

[a)]Electronic mail: rylov@ipmnet.ru

Second, fluid models with an internal energy of a very general form are used for the description of statistical ensembles of stochastic particles. By definition a statistical ensemble $\mathcal{E}[\mathcal{S}_{st}]$ of stochastic particles $\mathcal{S}_{st}$ is a set of many independent identical stochastic particles $\mathcal{S}_{st}$. Usually the term ''statistical ensemble'' is associated with some tool for the calculation of average values of physical quantities. But this tool is effective, provided the statistical ensemble is a set of deterministic (nonstochastic) particles. In reality the principal property of the statistical ensemble is formulated as follows. *The statistical ensemble of many stochastic (or deterministic) particles is a deterministic dynamic system*. This statement seems rather unexpected, because for a statistical ensemble of deterministic systems this property looks like a trivial one. In statistical physics, statistical ensembles of deterministic systems are mainly considered (the only exception is the statistical ensemble of Brownian particles), and the statistical ensemble's property of being a deterministic dynamic system needs some explanation.[1,2]

The result of an experiment with a single stochastic particle $\mathcal{S}_{st}$ is irreproducible. But distributions of results of similar experiments with many independent stochastic particles are reproducible. Projecting many independent identical stochastic particles $\mathcal{S}_{st}$ to the same space–time region, one obtains a cloud $\mathcal{E}[N,\mathcal{S}_{st}]$ of N independent identical particles $\mathcal{S}_{st}$ moving randomly. With the number N of particles tending to ∞, this cloud $\mathcal{E}[\infty,\mathcal{S}_{st}]$ may be considered as a continuous medium, or as a fluid. This fluid is a deterministic dynamic system, because experiments with the fluid $\mathcal{E}[\infty,\mathcal{S}_{st}]$ are reproducible. Besides, any reproducible experiments with the stochastic particle can be described in terms of the fluid $\mathcal{E}[\infty,\mathcal{S}_{st}]$ without reference to any probabilistic construction (i.e., without reference to the statistical ensemble's property of being a tool for the calculation of average values). The probabilistic constructions are effective only if the statistical ensemble $\mathcal{E}[\infty,\mathcal{S}_d]$ consists of deterministic particles $\mathcal{S}_d$, whose properties can be determined independent of $\mathcal{E}[\infty,\mathcal{S}_d]$. In the case of $\mathcal{E}[\infty,\mathcal{S}_{st}]$ these probabilistic constructions (probability density, or probability amplitude) are needed only for the interpretation of the fluid in terms of a single stochastic particle (see Ref. 3 for details).

For instance, let us consider a single electron $\mathcal{S}_{st}$, flying from an electron gun, passing through a narrow slit in a diaphragm and hitting a screen at a point x_1. Another electron $\mathcal{S}_{st}$, prepared in the same way, hits the screen at another point x_2 which does not coincide with x_1. In other words, an experiment with a single electron is irreproducible in general. It means that a single electron is a stochastic particle. Let us consider a series of N ($N\rightarrow\infty$) experiments with identically prepared independent electrons. The distribution of N impact points over the screen is reproducible, i.e., it is approximately the same for other series of N experiments. It means that a set $\mathcal{E}[N,\mathcal{S}_{st}]$ of N ($N\rightarrow\infty$) independent identical electrons $\mathcal{S}_{st}$ is a deterministic dynamic system, although a single electron $\mathcal{S}_{st}$ is a stochastic system. If $\mathcal{E}[\infty,\mathcal{S}_{st}]$ can be considered to be a fluid, then by solving dynamic equations for this fluid and calculating the flux of the fluid $\mathcal{E}[\infty,\mathcal{S}_{st}]$ through the screen, one can calculate the diffraction picture (the distribution of the impact points over the screen). For such calculation one needs only characteristics of the dynamic system $\mathcal{E}[\infty,\mathcal{S}_{st}]$ (dynamic equations, expressions for the particle flux and the energy–momentum tensor). Any quantum axiomatics and corresponding probabilistic constructions (wave function, linear operators, commutation relations, etc.) are not needed. It means that quantum effects can be explained and calculated as purely dynamical effects.[3]

On the other hand, quantum particles are described conventionally in terms of wave functions. The wave function is considered to be a fundamental object which cannot be defined via other more fundamental objects. As a result, like any fundamental object, the wave function and its properties are defined by a system of axioms (quantum axiomatics, or quantum principles). Some connection of the wave function with the irrotational flow of some quantum (Madelung) fluid[4–10] has been known for a long time. (The connection of the wave function with the irrotational flow was discovered comparatively recently.[11]) But always the wave function is considered to be a fundamental object, whereas the quantum fluid is considered as a derivative object. In this paper the fluid is considered as a fundamental object, connected directly with the statistical description of stochastic particles, whereas the wave function is considered to be a derivative construction whose properties can be expressed via the properties of the fluid.

In general, the wave function as a property of the fluid satisfies the quantum principles (linearity of dynamic equations, etc.) only in some special cases. For instance, in the case when the internal energy (2) depends only on $\mathbf{v}_{\text{dif}}=-\hbar(2m)^{-1}\nabla\rho/\rho$ and has the form

$$E=E(\rho,\nabla\rho)=\frac{\mathbf{v}_{\text{dif}}^2}{2},\quad \mathbf{v}_{\text{dif}}=-\frac{\hbar\nabla\rho}{2m\rho}, \tag{3}$$

where m is the particle mass and $\hbar$ is the Planck constant. To avoid misunderstanding and to distinguish between the wave function as a fundamental object, satisfying the quantum axiomatics, and the wave function as a property of a fluid, we shall use two different terms—''wave function'' in the first case and ''ψ function'' in the second one.

It is very important that the quantum phenomena be connected directly with the fluid model, i.e., such connection does not contain any reference to the quantum principles. There is hope that quantum superfluids like liquid helium may be described as an ideal fluid with the internal energy depending on $\nabla\rho$.

In the present paper some mathematical properties of conservative dynamic systems are investigated. Such a system $\mathcal{S}$ is a continuous set of particles, interacting via some self-consistent potential force field V. The dynamic system $\mathcal{S}$ is described by the action of the form

$$\mathcal{A}_L[\mathbf{x}]=\int\left\{\frac{m}{2}\left(\frac{d\mathbf{x}}{dt}\right)^2-V\right\}\rho_0(\boldsymbol{\xi})dt\,d\boldsymbol{\xi}, \tag{4}$$

where $\mathbf{x}=\{x^\alpha(t,\boldsymbol{\xi})\}$, $\alpha=1,2,3$ are functions of time t and of particle labels $\boldsymbol{\xi}=\{\xi_1,\xi_2,\xi_3\}$. $\rho_0(\boldsymbol{\xi})$ is some non-negative weight function, and $m=\text{const}$ is the mass of the fluid particle. V is a self-consistent potential depending on $\mathbf{x}$ and the derivatives of $\mathbf{x}$ with respect to $\boldsymbol{\xi}$. This function is supposed to have such a form that the potential V is a given function of variables ρ, $\nabla\rho$, and S. Here

$$\rho\equiv m\rho_0(\boldsymbol{\xi})\,\frac{\partial(\xi_1,\xi_2,\xi_3)}{\partial(x^1,x^2,x^3)}, \tag{5}$$

and $S=S_0(\boldsymbol{\xi})$ is some fixed function of variables $\boldsymbol{\xi}$. In this case the dynamic system $\mathcal{S}$ may be considered to be some ideal fluid. It will be shown that in the Euler description, where $x=\{t,\mathbf{x}\}$ are independent variables, and $\boldsymbol{\xi},\rho,\mathbf{v}\equiv d\mathbf{x}/dt$, S are dependent variables, the action (4) generates dynamic equations of the form

$$\frac{\partial\rho}{\partial t}+\nabla(\rho\mathbf{v})=0, \tag{6}$$

$$\frac{\partial v^\alpha}{\partial t}+(\mathbf{v}\nabla)v^\alpha=-\frac{1}{\rho}\,\partial_\beta P^{\alpha\beta},\quad \alpha=1,2,3, \tag{7}$$

$$\frac{\partial S}{\partial t}+(\mathbf{v}\nabla)S=0, \tag{8}$$

where $x^0=t$ is the time, $\mathbf{x}=\{x^1,x^2,x^3\}$ is the position vector, ρ and $\mathbf{v}=\{v^1,v^2,v^3\}$ are the fluid mass density and the fluid velocity, respectively, considered to be functions of $x=\{t,\mathbf{x}\}$. $P^{\alpha\beta}$ is a stress tensor, defined by (1), and $E(\rho,\nabla\rho,S)=V(\rho,\nabla\rho,S)/m$ is the internal energy of a unit mass. E depends on the density ρ, on the density gradient $\nabla\rho$, and on the entropy S per unit mass.

In the case of a usual fluid, when V does not depend on $\nabla\rho$, the stress tensor $P^{\alpha\beta}$ is isotropic, and Eq. (7) turns to the Euler equations for the ideal fluid

$$\frac{\partial \mathbf{v}}{\partial t}+(\mathbf{v}\boldsymbol{\nabla})\mathbf{v}=-\frac{1}{\rho}\boldsymbol{\nabla}p, \quad p=\rho^2\frac{\partial E}{\partial \rho}, \tag{9}$$

where p is the pressure, and $E=E(\rho,S)$ is the internal energy of a unit mass considered as a function of ρ and S. Thus, if V depends only on variables $\rho,\boldsymbol{\nabla}\rho,S$ the dynamic system $\mathcal{S}$, described by the action (4) will be referred to as nondissipative (ideal) fluid.

The system of hydrodynamic equations (6)–(8), as well as the system (6), (9), and (8) is a closed system of differential equations which has a unique solution inside some space–time region Ω, provided dependent dynamic variables ρ and $\mathbf{v}=\{v^1,v^2,v^3\}$, S are given as functions of three arguments on the space–time boundary Γ of the region Ω. Nevertheless, being closed, system (6)–(8) is incomplete, because it describes only momentum-energetic characteristics of the fluid. The action (4) generates additional dynamic equations,

$$\frac{\partial \boldsymbol{\xi}}{\partial t}+(\mathbf{v}\boldsymbol{\nabla})\boldsymbol{\xi}=0, \tag{10}$$

known as Lin constraints.[12] These equations describe the motion of fluid particles along their trajectories.

If Eq. (10) is solved and $\boldsymbol{\xi}$ is determined as a function of $(t,\mathbf{x})$, the finite relations

$$\boldsymbol{\xi}(t,\mathbf{x})=\boldsymbol{\xi}_{\rm in}={\rm const}$$

describe implicitly a fluid particle trajectory and a motion along it.

The system of eight equations (6)–(8), (10) forms a complete system of dynamic equations describing a fluid, whereas the system of five equations (6)–(8) forms a curtailed system of dynamic equations. The last system is closed, but to be a complete system, it must be supplemented by the kinematic equations

$$\frac{d\mathbf{x}}{dt}=\mathbf{v}(t,\mathbf{x}), \quad \mathbf{x}=\mathbf{x}(t,\boldsymbol{\xi}), \tag{11}$$

or by the Lin constraints (10) which are equivalent to (11).

The fact that the complete system (6)–(8), (10) of dynamic equations admits a closed subsystem (6)–(8) is connected with the invariance of the system (6)–(8), (10) with respect to the group of relabeling transformations (relabeling group),

$$\xi_\alpha\to\tilde{\xi}_\alpha=\tilde{\xi}_\alpha(\boldsymbol{\xi}), \quad D=\det\|\partial\tilde{\xi}_\alpha/\partial\xi_\beta\|\neq 0, \quad \alpha,\beta=1,2,3, \tag{12}$$

$$\varphi=\xi_0\to\tilde{\xi}_0=\tilde{\varphi}=\tilde{\xi}_0(\xi_0)+a_0(\boldsymbol{\xi}), \quad \partial\tilde{\xi}_0/\partial\xi_0>0, \tag{13}$$

where $\xi=\{\xi_0,\boldsymbol{\xi}\}$ are curvilinear Lagrangian coordinates in the space–time and $\tilde{\xi}=\{\tilde{\xi}_0,\tilde{\boldsymbol{\xi}}\}$ is another system of curvilinear Lagrangian coordinates. $\tilde{\boldsymbol{\xi}}$ and a_0 are arbitrary functions of $\boldsymbol{\xi}$. $\tilde{\xi}_0$ is an arbitrary function of ξ_0. ξ_0 is a temporal Lagrangian coordinate, and $\boldsymbol{\xi}$ are spatial ones.

The relabeling group properties have been used in hydrodynamics comparatively recently.[13–20] The action (4) is invariant with respect to the relabeling group (12), (13), provided the weight function $\rho_0(\boldsymbol{\xi})$ transforms as a scalar density,

$$\rho_0(\boldsymbol{\xi})\to\tilde{\rho}_0(\tilde{\boldsymbol{\xi}})=D^{-1}\rho_0(\boldsymbol{\xi}), \quad D=\frac{\partial(\tilde{\boldsymbol{\xi}})}{\partial(\boldsymbol{\xi})}\equiv\frac{\partial(\tilde{\xi}_1,\tilde{\xi}_2,\tilde{\xi}_3)}{\partial(\xi_1,\xi_2,\xi_3)}. \tag{14}$$

The group of relabeling transformations appears to be a symmetry group of the dynamic system (fluid). Any special particle labeling is unessential from a physical viewpoint. It is a reason why several equations (6)–(8) of the complete system form a closed system describing conservation laws. This symmetry group also permits one to integrate the complete system (6)–(8), (10) in the form (see the proof below Sec. III)

$$S(t,\mathbf{x})=S_0(\boldsymbol{\xi}), \tag{15}$$

$$\rho(t,\mathbf{x})=\rho_0(\boldsymbol{\xi})\,\frac{\partial(\xi_1,\xi_2,\xi_3)}{\partial(x^1,x^2,x^3)}\equiv\rho_0(\boldsymbol{\xi})\,\frac{\partial(\boldsymbol{\xi})}{\partial(\mathbf{x})}, \tag{16}$$

$$\mathbf{v}(t,\mathbf{x})=\boldsymbol{\pi}(\varphi,\boldsymbol{\xi},\eta,S)\equiv\boldsymbol{\nabla}\varphi+g^{\alpha}(\boldsymbol{\xi})\boldsymbol{\nabla}\xi_\alpha-\eta\boldsymbol{\nabla}S, \tag{17}$$

where $S_0(\boldsymbol{\xi})$, $\rho_0(\boldsymbol{\xi})$, $\mathbf{g}(\boldsymbol{\xi})=\{g^{\alpha}(\boldsymbol{\xi})\}$, $\alpha=1,2,3$ are arbitrary integration functions of argument $\boldsymbol{\xi}$, and φ, η are new dependent variables, satisfying the dynamic equations

$$\frac{\partial\varphi}{\partial t}+\boldsymbol{\pi}(\varphi,\boldsymbol{\xi},\eta,S)\boldsymbol{\nabla}\varphi-\frac{1}{2}\,[\boldsymbol{\pi}(\varphi,\boldsymbol{\xi},\eta,S)]^2+\frac{\partial(\rho E)}{\partial\rho}-\partial_\alpha\,\frac{\partial(\rho E)}{\partial\rho_\alpha}=0, \tag{18}$$

$$\frac{\partial\eta}{\partial t}+\boldsymbol{\pi}(\varphi,\boldsymbol{\xi},\eta,S)\boldsymbol{\nabla}\eta=-\frac{\partial E}{\partial S}. \tag{19}$$

If five dependent variables $\varphi,\boldsymbol{\xi},\eta$ satisfy the system of equations (10), (18), (19), the five dynamic variables $S,\rho,\mathbf{v}$ (15)–(17) satisfy dynamic equations (6)–(8). Indefinite functions $S_0(\boldsymbol{\xi})$, $\rho_0(\boldsymbol{\xi})$, $\mathbf{g}(\boldsymbol{\xi})$ can be determined from initial and boundary conditions in such a way that the initial and boundary conditions for the variables $\varphi,\boldsymbol{\xi},\eta$ are universal in the sense that they do not depend on the fluid flow.

The integration of the complete system (6)–(8), (10) and some corollaries of this integration correlate with the Hamilton properties of the ideal fluid.[14,19,20,23,24,27] It is connected with the fact that the curtailed system (6)–(8) is not a Hamiltonian system in itself, whereas the complete system (6)–(8), (10) is a Hamiltonian one. Constructing Hamiltonian mechanics of the ideal fluid, one uses (implicitly or explicitly) the Lin constraints (or part of them). It is this expansion of the curtailed system (but not Hamiltonian properties) that is important for integration and derivation of other useful results. To show this, the Hamiltonian technique and Hamiltonian properties of the ideal fluid will not be used at all.

According to (16) and (17) the physical quantities $\rho,\mathbf{v}$ are obtained as a result of differentiation of the variables $\varphi,\boldsymbol{\xi},S$, and the variables $\varphi,\boldsymbol{\xi},\eta$ can be regarded as hydrodynamic potentials. These potentials appear in the Hamilton fluid dynamics[23] as dependent variables. They are associated with Clebsch,[21,22] who introduced these quantities for the incompressible fluid. Such quantities as $g^{\alpha}(\boldsymbol{\xi})$ also appear in the Hamilton fluid mechanics,[23] but they appear as dependent variables (Lagrange invariants) satisfying dynamic equations of the type (10). They also are regarded as hydrodynamic potentials. Note that in the Hamilton fluid mechanics[23] the quantities g^{α} are considered simply as dependent variables, but not as indefinite functions of $\boldsymbol{\xi}$ arising as a result of integration, although corresponding dynamic equations for g^{α} can be integrated easily.

Integration of the dynamic equations admits a description of any ideal fluid in terms of hydrodynamic potentials $\xi=\{\xi_0,\boldsymbol{\xi}\}$. The hydrodynamic potentials ξ are Lagrangian coordinates considered as functions of independent Eulerian coordinates $x=\{t,\mathbf{x}\}$. Spatial Lagrangian coordinates $\boldsymbol{\xi}=\{\xi_\alpha\}$, $\alpha=1,2,3$ label fluid particles, whereas the temporal Lagrangian coordinate $\xi_0=\xi_0(t,\mathbf{x})$ means some generalized time for the fluid particle placed at the space–time point $x=\{t,\mathbf{x}\}$.

The description of any ideal fluid in terms of hydrodynamic potentials ξ can transform into a description in terms of a complex n-component hydrodynamic potential $\psi=\{\psi_\alpha\}$, $\alpha=1,2,...,n$ which associates with the wave function, used in the quantum mechanics, whereas the irreducible (minimally possible) number n_m of ψ-function components associates with the spin of the flow (not of the particle).

In the presented paper it is shown that the wave function is a way of describing any ideal fluid. The spin is a natural property of any flow of the ideal fluid. The appearance of these enigmatic quantities at the description of quantum particles may be explained merely as a result of a quantum particle description in terms of an ideal fluid (statistical ensemble). Note that the curtailed system (6)–(8) has the same order as the integrated system (10), (18), (19), but takes into account neither initial conditions, nor kinematic equations (11). The fact that the ideal fluid considered as a dynamic system admits both the curtailed system (6)–(8) and the integrated system (10), (18), (19) is connected closely with the group of the relabeling transformation (12).

Section II is devoted to a presentation of the space–time symmetric Jacobian technique which is needed for the integration of hydrodynamic equations. Use of Jacobians in hydrodynamics has had a long history, dating back to the time of Clebsch.[21,22] It was the use of Jacobians that allowed us to introduce the Clebsch potentials and integrate hydrodynamic equations. The Jacobian technique has been used in Refs. 14, 20, 23, 24, 25, and many other papers. It seems that the progress in the integration of hydrodynamic equations is connected mainly with the developed Jacobian technique.

Further it will be proved (Sec. III) that the complete system of hydrodynamic equations (6)–(8), (10) can be integrated in the form (10), (15)–(19) that leads to a special form of a description in terms of hydrodynamic potentials (DTHP). In Sec. IV the initial and boundary conditions are used for a determination of function **g**. In Sec. V a special type of complex hydrodynamic potentials is considered and the fluid flows are classified on the irreducible number of wave function components which appears to be an invariant of the relabeling group.

II. JACOBIAN TECHNIQUE

Let us consider such a space–time symmetric mathematical object as the Jacobian

$$J \equiv \frac{\partial(\xi_0,\xi_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)} \equiv \det\|\xi_{i,k}\|, \quad \xi_{i,k} \equiv \partial_k \xi_i \equiv \frac{\partial \xi_i}{\partial x^k}, \quad i,k=0,1,2,3. \tag{20}$$

Here $\xi=\{\xi_0,\boldsymbol{\xi}\}=\{\xi_0,\xi_1,\xi_2,\xi_3\}$ are four scalars considered as functions $\xi=\xi(x)$ of $x=\{x^0,\mathbf{x}\}$. The functions $\{\xi_0,\xi_1,\xi_2,\xi_3\}$ are supposed to be independent in the sense that $J\neq 0$. It is useful to consider the Jacobian J as a four-linear function of variables $\xi_{i,k}\equiv\partial_k\xi_i$, $i,k=0,1,2,3$. Then one can introduce derivatives of J with respect to $\xi_{i,k}$. The derivative $\partial J/\partial \xi_{i,k}$ appears as a result of the substitution of ξ_i by x^k in relation (20),

$$\frac{\partial J}{\partial \xi_{i,k}} \equiv \frac{\partial(\xi_0,\dots,\xi_{i-1},x^k,\xi_{i+1},\dots,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}, \quad i,k=0,1,2,3. \tag{21}$$

For instance,

$$\frac{\partial J}{\partial \xi_{0,i}} \equiv \frac{\partial(x^i,\xi_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}, \quad i=0,1,2,3. \tag{22}$$

This rule is also valid for higher derivatives of J,

$$\begin{aligned}\frac{\partial^2 J}{\partial \xi_{i,k}\partial \xi_{s,l}} &\equiv \frac{\partial(\xi_0,\dots,\xi_{i-1},x^k,\xi_{i+1},\dots,\xi_{s-1},x^l,\xi_{s+1},\dots,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}\\ &\equiv \frac{\partial(x^k,x^l)}{\partial(\xi_i,\xi_s)}\,\frac{\partial(\xi_0,\xi_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}\\ &\equiv J\left(\frac{\partial x^k}{\partial \xi_i}\frac{\partial x^l}{\partial \xi_s}-\frac{\partial x^k}{\partial \xi_s}\frac{\partial x^l}{\partial \xi_i}\right), \quad i,k,l,s=0,1,2,3.\end{aligned} \tag{23}$$

It follows from (20) and (21) that

$$\frac{\partial x^k}{\partial \xi_i} \equiv \frac{\partial(\xi_0,\ldots,\xi_{i-1},x^k,\xi_{i+1},\ldots,\xi_3)}{\partial(\xi_0,\xi_1,\xi_2,\xi_3)}$$
$$\equiv \frac{\partial(\xi_0,\ldots,\xi_{i-1},x^k,\xi_{i+1},\ldots,\xi_3)}{\partial(x^0,x^1,x^2,x^3)} \frac{\partial(x^0,x^1,x^2,x^3)}{\partial(\xi_0,\xi_1,\xi_2,\xi_3)}$$
$$\equiv \frac{1}{J}\frac{\partial J}{\partial \xi_{i,k}}, \quad i,k=0,1,2,3 \tag{24}$$

and (23) may be written in the form

$$\frac{\partial^2 J}{\partial \xi_{i,k}\partial \xi_{s,l}} \equiv \frac{1}{J}\left(\frac{\partial J}{\partial \xi_{i,k}}\frac{\partial J}{\partial \xi_{s,l}} - \frac{\partial J}{\partial \xi_{i,l}}\frac{\partial J}{\partial \xi_{s,k}}\right), \quad i,k,l,s=0,1,2,3. \tag{25}$$

The derivative $\partial J/\partial \xi_{i,k}$ is a cofactor to the element $\xi_{i,k}$ of the determinant (20). Then one has the following identities:

$$\xi_{l,k}\frac{\partial J}{\partial \xi_{s,k}} \equiv \delta_l^s J, \quad \xi_{k,l}\frac{\partial J}{\partial \xi_{k,s}} \equiv \delta_l^s J, \quad l,s=0,1,2,3, \tag{26}$$

$$\partial_k \frac{\partial J}{\partial \xi_{i,k}} \equiv \frac{\partial^2 J}{\partial \xi_{i,k}\partial \xi_{s,l}}\partial_k\partial_l \xi_s \equiv 0, \quad i=0,1,2,3. \tag{27}$$

Here and subsequently a summation on two repeated indices is produced (0–3) for Latin indices and (1–3) for the Greek ones. The identity (27) can be considered as a corollary of the identity (25) and a symmetry of $\partial_k\partial_l\xi_s$ with respect to the permutation of indices k,l. The convolution of (25) with ∂_k, or ∂_l also vanishes.

Relations (20)–(25) are written for four independent variables x, but they are valid in an evident way for an arbitrary number $n+1$ of variables $x=\{x^0,x^1,\ldots,x^n\}$ and $\boldsymbol{\xi}=\{\xi_0,\boldsymbol{\xi}\}$, $\boldsymbol{\xi}=\{\xi_1,\xi_2,\ldots,\xi_n\}$.

Application of the Jacobian J to hydrodynamics is founded on the property that the fluid flux

$$j^i = m\frac{\partial J}{\partial \xi_{0,i}}, \quad j=\{j^i\}=\{\rho,\rho\mathbf{v}\}, \quad i=0,1,2,3 \tag{28}$$

constructed on the basis of the variables $\boldsymbol{\xi}=\{\xi_1,\xi_2,\xi_3\}$ satisfies Lin constraints (10) and the continuity equation

$$\partial_i j^i = 0 \tag{29}$$

identically for any choice of variables $\boldsymbol{\xi}$, as it follows from the identity (27) for $i=0$. The continuity equation (29) is used without approximations in all hydrodynamic models, and the change of variables $\{\rho,\rho\mathbf{v}\}\leftrightarrow\boldsymbol{\xi}$ described by (28) is very important.

In particular, in the case of two-dimensional established flow of incompressible fluid the variables $\boldsymbol{\xi}$ reduce to one variable $\xi_1=\psi$, known as the stream function. In this case there are only two essential dependent variables $x^0=x$, $x^1=y$, and the relations (28), (29) reduce to the relations

$$\rho^{-1}j_x = v_x = \frac{\partial\psi}{\partial y}, \quad \rho^{-1}j_y = v_y = -\frac{\partial\psi}{\partial x}, \quad \frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}=0. \tag{30}$$

Defining the stream line as a line tangent to the flux j,

$$\frac{dx}{j_x} = \frac{dy}{j_y}, \tag{31}$$

one obtains that the stream function is constant along the stream line, because according to the first two equations of (30), $\psi=\psi(x,y)$ is an integral of Eq. (31).

In the general case, when the space dimensionality is n and $x=\{x^0,x^1,\dots,x^n\}$, $\boldsymbol{\xi}=\{\xi_0,\boldsymbol{\xi}\}$, $\boldsymbol{\xi}=\{\xi_1,\xi_2,\dots,\xi_n\}$, the quantities $\boldsymbol{\xi}=\{\xi_\alpha\}$, $\alpha=1,2,...,n$ are constant along the line $\mathcal{L}$ tangent to the flux vector $j=\{j^i\}$, $i=0,1,...,n$,

$$\mathcal{L}: \quad \frac{dx^i}{d\tau}=j^i(x), \quad i=0,1,...,n, \tag{32}$$

where τ is a parameter along the line $\mathcal{L}$ which is described parametrically by the equation $x=x(\tau)$. This statement is formulated mathematically in the form

$$\frac{d\xi_\alpha}{d\tau}=j^i\partial_i\xi_\alpha=m\,\frac{\partial J}{\partial \xi_{0,i}}\,\partial_i\xi_\alpha=0, \quad \alpha=1,2,...,n.$$

The last equality follows from the first identity (26) taken for $s=0$, $l=1,2,...,n$

Interpretation of the line (32) tangent to the flux is different for different cases. If $x=\{x^0,x^1,\dots,x^n\}$ contains only spatial coordinates, the line (32) is a line in the usual space. It is regarded as a streamline, and $\boldsymbol{\xi}$ can be interpreted as quantities which are constant along the streamline (i.e., as a generalized stream function). If x^0 is the time coordinate, Eq. (32) describes a line in the space–time. This line (known as a world line of a fluid particle) determines a motion of the fluid particle. Variables $\boldsymbol{\xi}=\{\xi_1,\xi_2,\dots,\xi_n\}$ which are constant along the world line are different, generally, for different particles. If ξ_α, $\alpha=1,2,...,n$ are independent, they may be used for the fluid particle labeling.

Thus, although interpretation of the relation (28) considered as a replacement of dependent variables j by $\boldsymbol{\xi}$ may be different, from a mathematical viewpoint this transformation means a replacement of the continuity equation by some equations for the labeling (or generalized stream function) $\boldsymbol{\xi}$. The difference of the interpretation is of no importance in this context.

Note that the expressions

$$j^i=m\rho_0(\boldsymbol{\xi})\,\frac{\partial J}{\partial \xi_{0,i}}\equiv m\rho_0(\boldsymbol{\xi})\,\frac{\partial(x^i,\xi_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}, \quad i=0,1,2,3, \tag{33}$$

can be also considered as four-flux satisfying the continuity equation (29). Here m is a constant and $\rho_0(\boldsymbol{\xi})$ is an arbitrary function of $\boldsymbol{\xi}$. It follows from the identity

$$m\rho_0(\boldsymbol{\xi})\,\frac{\partial(x^i,\xi_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}\equiv m\,\frac{\partial(x^i,\tilde{\xi}_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}, \quad \tilde{\xi}_1=\int_0^{\xi_1}\rho_0(\xi_1',\xi_2,\xi_3)d\xi_1'.$$

As an example of the application of the Jacobian technique, let us show that (5) satisfies (6) by virtue of (10). Let us multiply (10) by (5) and introduce new variables $\mathbf{j}=\rho\mathbf{v}=\{j^1,j^2,j^3\}$. One obtains three equations

$$m\rho_0(\boldsymbol{\xi})\,\frac{\partial J}{\partial \xi_{0,0}}\,\xi_{\beta,0}+j^\alpha\xi_{\beta,\alpha}=0, \quad \beta=1,2,3. \tag{34}$$

Considering (34) as a system of three linear equations for j^α, $\alpha=1,2,3$ and resolving it with respect to j^α, one obtains

$$j^\alpha=m\rho_0(\boldsymbol{\xi})\,\frac{\partial J}{\partial \xi_{0,\alpha}}, \quad \alpha=1,2,3. \tag{35}$$

It is easy to verify this, substituting (35) into (34) and using (26). One obtains that $j=\{j^0,\mathbf{j}\}=\{\rho,\rho\mathbf{v}\}$ is described by the relations (33) which satisfy the continuity equation (29) identically. Thus, (6) is satisfied by (16) by virtue of (10).

III. VARIATIONAL PRINCIPLE

In general, the equivalency of the system (10), (18), (19) and the system (6)–(8), (10) can be verified by a direct substitution of the variables $\rho,S,\mathbf{v}$, defined by relations (15)–(17) into Eqs. (6)–(8). Using Eqs. (10), (18), and (19), one obtains identities after subsequent calculations. But such computations do not display a connection between the integration and the invariance with respect to the relabeling group (12). Besides, the meaning of the new variables φ,η is not clear. We shall use for our investigations a variational principle. Note that for a long time a derivation of a variational principle for hydrodynamic equations (6)–(8) existed as a self-dependent problem.[12,14,16,23,24,26,27] The existence of this problem was connected to a lack of understanding that the system of hydrodynamic equations (6)–(8) is a curtailed system, and the full system of dynamic equations (6)–(8), (10) includes equations (10) describing a motion of the fluid particles in the given velocity field. The variational principle can generate only the complete system of dynamic variables (but not its closed subsystem). Without understanding this, one tried to form the Lagrangian for the system (6)–(8) as a sum of some quantities taken with Lagrange multipliers. The left-hand side of dynamic equations (6)–(8) and some other constraints were taken as such quantities.

Now this problem has been solved (see the review by Salmon[23]) on the basis of the Eulerian version of the variational principle for the Lagrangian description (4), where equations (10) appear automatically and cannot be ignored. In our version of the variational principle we follow Ref. 23 with some modifications which underline a curtailed character of hydrodynamic equations (6)–(8), because an understanding of the curtailed character of the system (6)–(8) removes the problem of derivation of the variational principle for the hydrodynamic equations (6)–(8).

We consider the ideal fluid as a conservative dynamic system whose dynamic equations can be derived from the variational principle. This dynamic system is a continuous set of many identical particles moving in some self-consistent potential force field. The action functional has the form (4). Variation of the action with respect to $\mathbf{x}$ generates six first-order dynamic equations for six dependent variables $\mathbf{x},\mathbf{v}=d\mathbf{x}/dt$, considered as functions of t and of independent curvilinear Lagrangian coordinates $\boldsymbol{\xi}$. It is a Lagrangian representation of hydrodynamic equations.

We prefer to work with Eulerian representation, when Lagrangian coordinates (particle labeling) $\xi=\{\xi_0,\boldsymbol{\xi}\}$, $\boldsymbol{\xi}=\{\xi_1,\xi_2,\xi_3\}$ are considered as dependent variables, and Eulerian coordinates $x=\{x^0,\mathbf{x}\}=\{t,\mathbf{x}\}$, $\mathbf{x}=\{x^1,x^2,x^3\}$ are considered as independent variables. Here ξ_0 is a temporal Lagrangian coordinate which evolves along the particle trajectory in an arbitrary way. Now the ξ_0 is a fictitious variable, but after the integration of equations the ξ_0 stops being fictitious and turns to the variable φ, appearing in the integrated system (10), (18), (19).

Further, space–time symmetric designations will mainly be used, which simplifies considerably all computations. In the Eulerian description the action functional (4) is to be represented as an integral over independent variables $x=\{x^0,\mathbf{x}\}=\{t,\mathbf{x}\}$. One uses the Jacobian technique for such a transformation of the action (4),

Let us note that according to (22) the derivative $d\mathbf{x}/dt$ can be written in the form

$$v^\alpha=\frac{dx^\alpha}{dt}\equiv\frac{\partial J}{\partial\xi_{0,\alpha}}\left(\frac{\partial J}{\partial\xi_{0,0}}\right)^{-1},\quad \alpha=1,2,3.$$

Then components of the four flux $j=\{j^0,\mathbf{j}\}\equiv\{\rho,\rho\mathbf{v}\}$ can be written in the form (33), provided the designation (5)

$$j^0=\rho=m\rho_0(\boldsymbol{\xi})\,\frac{\partial J}{\partial\xi_{0,0}}\equiv m\rho_0(\boldsymbol{\xi})\,\frac{\partial(x^0,\xi_1,\xi_2,\xi_3)}{\partial(x^0,x^1,x^2,x^3)}\tag{36}$$

is used.

At such a form of the mass density ρ the four flux $j=\{j^i\}$, $i=0,1,2,3$ satisfies identically the continuity equation (29) which takes place by virtue of identities (26) and (27). Besides, by virtue of identities (26) and (27) the Lin constraints (10) are fulfilled identically,

$$j^i \partial_i \xi_\alpha = 0, \quad \alpha = 1,2,3. \tag{37}$$

The components j^i are invariant with respect to the relabeling group (12), provided the function $\rho^0(\boldsymbol{\xi})$ transforms according to (14).

One has

$$\rho_0(\boldsymbol{\xi}) dt\ d\boldsymbol{\xi} = \rho_0(\boldsymbol{\xi}) \frac{\partial J}{\partial \xi_{0,0}} dt\ d\mathbf{x} = \frac{\rho}{m} dt\ d\mathbf{x},$$

$$\frac{m}{2}\left(\frac{dx^\alpha}{dt}\right)^2 = \frac{m}{2}\left(\frac{\partial J}{\partial \xi_{0,\alpha}}\right)^2 \left(\frac{\partial J}{\partial \xi_{0,0}}\right)^{-2} = \frac{m}{2}\left(\frac{j^\alpha}{\rho}\right)^2,$$

and the variational problem with the action functional (4) is written as a variational problem with the action functional

$$\mathcal{A}_E[\boldsymbol{\xi}] = \int \left(\frac{\mathbf{j}^2}{2\rho} - \rho E\right) dt\ d\mathbf{x}, \quad E = \frac{V}{m}, \tag{38}$$

where $\rho = j^0$ and $\mathbf{j} = \{j^1, j^2, j^3\}$ are fixed functions of $\xi = \{\xi_0, \boldsymbol{\xi}\}$ and of $\xi_{\alpha,i} \equiv \partial_i \xi_\alpha$, $\alpha = 1,2,3$, $i = 0,1,2,3$, defined by relations (33). E is the internal energy of the fluid which is supposed to be a fixed function of $\rho, \boldsymbol{\nabla}\rho, S_0(\boldsymbol{\xi})$,

$$E = E(\rho, \boldsymbol{\nabla}\rho, S_0(\boldsymbol{\xi})), \tag{39}$$

where ρ is defined by (36) and $S_0(\boldsymbol{\xi})$ is some fixed function of $\boldsymbol{\xi}$, describing the initial distribution of the entropy over the fluid.

The action (38) is invariant with respect to the subgroup $\mathcal{G}_{S_0}$ of the relabeling group (12). The subgroup $\mathcal{G}_{S_0}$ is determined in such a way that any surface $S_0(\boldsymbol{\xi}) = \text{const}$ is invariant with respect to $\mathcal{G}_{S_0}$. In general, the subgroup $\mathcal{G}_{S_0}$ is determined by two arbitrary functions of $\boldsymbol{\xi}$.

The action (38) generates the six order system of dynamic equations, consisting of three second-order equations for three dependent variables $\boldsymbol{\xi}$. Invariance of the action (38) with respect to the subgroup $\mathcal{G}_{S_0}$ admits one to integrate the system of dynamic equations. The order of the system reduces, and two arbitrary integration functions appear. The order of the system reduces to five (but not to four), because the fictitious dependent variable ξ_0 stops being fictitious as a result of the integration.

Unfortunately, the subgroup $\mathcal{G}_{S_0}$ depends on the form of the function $S_0(\boldsymbol{\xi})$ and cannot be obtained in a general form. In the special case, when $S_0(\boldsymbol{\xi})$ does not depend on $\boldsymbol{\xi}$, the subgroup $\mathcal{G}_{S_0}$ coincides with the whole relabeling group $\mathcal{G}$, and the order of the integrated system reduces to four.

In the general case it is convenient to introduce a new dependent variable,

$$S = S_0(\boldsymbol{\xi}).$$

According to (37) the variable S satisfies the dynamic equation (8),

$$j^i \partial_i S = 0. \tag{40}$$

By virtue of designations (28) and identities (26) and (27), Eqs. (40) and (37) are fulfilled, identically. Hence, they can be added to the action functional (38) as side constraints without a change of the variational problem. Adding (40) to the Lagrangian of the action (38) by means of a Lagrange multiplier η, one obtains

$$\mathcal{A}_E[\boldsymbol{\xi},\eta,S]=\int\left\{\frac{\mathbf{j}^2}{2\rho}-\rho E+\eta j^k\partial_k S\right\}dt\ d\mathbf{x}, \tag{41}$$

where the quantities $j=\{\rho,\mathbf{j}\}$ are determined by (33), and $E=E(\rho,\boldsymbol{\nabla}\rho,S)$. The action (41) is invariant with respect to the relabeling group $\mathcal{G}$ which is determined by three arbitrary functions of $\boldsymbol{\xi}$.

To obtain the dynamic equations, it is convenient to introduce new dependent variables j^i, defined by (33). Let us introduce the new variables j^i by means of designations (33) taken with the Lagrange multipliers p_i, $i=0,1,2,3$. Then the action (41) takes the form

$$\mathcal{A}_E[\rho,\mathbf{j},\boldsymbol{\xi},p,\eta,S]=\int\left\{\frac{\mathbf{j}^2}{2\rho}-\rho E-p_k\left[j^k-m\rho_0(\boldsymbol{\xi})\ \frac{\partial J}{\partial\xi_{0,k}}\right]+\eta j^k\partial_k S\right\}dt\ d\mathbf{x}. \tag{42}$$

It is useful to keep in mind that four designations (33), introducing variables ρ, $\mathbf{j}=\rho\mathbf{v}$ via variables $\boldsymbol{\xi}$, are equivalent to three Lin constraints (10) together with the designation (36), as was shown at the end of Sec. II. The addition of relations (33) to the action (41) as side constraints is equivalent to the addition of relations (10) and (36) considered as side constraints.

For obtaining dynamic equations, the variables $\rho,\mathbf{j},\boldsymbol{\xi},p,\eta,S$ are to be varied. Let us eliminate the variables p_i from the action (42). Dynamic equations arising as a result of a variation with respect to ξ_α have the form

$$\frac{\delta\mathcal{A}_E}{\delta\xi_\alpha}\equiv\hat{\mathcal{L}}_\alpha p=-m\partial_k\left[\rho_0(\boldsymbol{\xi})\ \frac{\partial^2 J}{\partial\xi_{0,i}\partial\xi_{\alpha,k}}\ p_i\right]+m\ \frac{\partial\rho_0(\boldsymbol{\xi})}{\partial\xi_\alpha}\ \frac{\partial J}{\partial\xi_{0,k}}\ p_k=0,\quad \alpha=1,2,3, \tag{43}$$

where $\hat{\mathcal{L}}_\alpha$ are linear operators acting on variables $p=\{p_i\}$, $i=0,1,2,3$. These equations can be integrated in the form

$$p_i=bg^0(\xi_0)\partial_i\xi_0+bg^\alpha(\boldsymbol{\xi})\partial_i\xi_\alpha,\quad i=0,1,2,3, \tag{44}$$

where b is an arbitrary scale constant, ξ_0 is some new variable (temporal Lagrangian coordinate), $g^\alpha(\boldsymbol{\xi})$, $\alpha=1,2,3$ are arbitrary functions of the labels $\boldsymbol{\xi}$, $g^0(\xi_0)$ is an arbitrary function of ξ_0. The relations (44) satisfy equations (43) identically. Indeed, substituting (44) into (43) and using identities (25) and (26), one obtains

$$-m\partial_k\left\{\rho_0(\boldsymbol{\xi})\left[\frac{\partial J}{\partial\xi_{\alpha,k}}\ g^0(\xi_0)-\frac{\partial J}{\partial\xi_{0,k}}\ g^\alpha(\boldsymbol{\xi})\right]\right\}+m\ \frac{\partial\rho_0(\boldsymbol{\xi})}{\partial\xi_\alpha}\ Jg^0(\xi_0)=0,\quad \alpha=1,2,3. \tag{45}$$

Differentiating braces and using identities (27) and (26), one concludes that (45) is an identity.

Setting for simplicity

$$\partial_k\varphi=g^0(\xi_0)\partial_k\xi_0,\quad k=0,1,2,3$$

one obtains

$$p_k=b\partial_k\varphi+bg^\alpha(\boldsymbol{\xi})\partial_k\xi_\alpha,\quad k=0,1,2,3. \tag{46}$$

Substituting (46) in (42), one can eliminate variables p_i, $i=0,1,2,3$ from the functional (42). The term $g^\alpha(\boldsymbol{\xi})\partial_k\xi_\alpha\partial J/\partial\xi_{0,k}$ vanishes, the term $\partial_k\varphi\partial J/\partial\xi_{0,k}$ gives no contribution to the dynamic equations. The action functional takes the form

$$\mathcal{A}_g[\rho,\mathbf{j},\varphi,\boldsymbol{\xi},\eta,S]=\int\left\{\frac{\mathbf{j}^2}{2\rho}-\rho E-j^k[b\partial_k\varphi+bg^\alpha(\boldsymbol{\xi})\partial_k\xi_\alpha-\eta\partial_k S]\right\}dt\ d\mathbf{x},\tag{47}$$

where $g^\alpha(\boldsymbol{\xi})$ are considered as fixed functions of $\boldsymbol{\xi}$ which are determined from initial conditions. The action (47) is a functional of indefinite fixed functions $\mathbf{g}(\mathbf{x})$. Varying the action (47) with respect to $\varphi,\boldsymbol{\xi},\eta,S,\mathbf{j},\rho$, one obtains dynamic equations;

$$\delta\varphi:\quad \partial_k j^k=0,\tag{48}$$

$$\delta\xi_\alpha:\quad \Omega^{\alpha\beta}j^k\partial_k\xi_\beta=0,\quad \alpha=1,2,3,\tag{49}$$

$$\delta\eta:\quad j^k\partial_k S=0,\tag{50}$$

$$\delta S:\quad j^k\partial_k\eta=-\rho\frac{\partial E}{\partial S},\tag{51}$$

$$\delta\mathbf{j}:\quad \mathbf{v}\equiv\mathbf{j}/\rho=b\boldsymbol{\nabla}\varphi+bg^\alpha(\boldsymbol{\xi})\boldsymbol{\nabla}\xi_\alpha-\eta\boldsymbol{\nabla}S,\tag{52}$$

$$\delta\rho:\quad -\frac{\mathbf{j}^2}{2\rho^2}-\frac{\partial(\rho E)}{\partial\rho}+\partial_\alpha\frac{\partial(\rho E)}{\partial\rho_\alpha}-b\partial_0\varphi-bg^\alpha(\boldsymbol{\xi})\partial_0\xi_\alpha+\eta\partial_0 S=0.\tag{53}$$

Here $\Omega^{\alpha\beta}$ is defined by

$$\Omega^{\alpha\beta}=b\left(\frac{\partial g^\alpha(\boldsymbol{\xi})}{\partial\xi_\beta}-\frac{\partial g^\beta(\boldsymbol{\xi})}{\partial\xi_\alpha}\right),\quad \alpha,\beta=1,2,3.\tag{54}$$

Deriving relations (49) and (51), the continuity equation (48) was used. It is easy to see that (49) is equivalent to (10), provided

$$\det\|\Omega^{\alpha\beta}\|\neq 0.\tag{55}$$

Then Eqs. (50) and (48) can be integrated in the form of (15) and (16) respectively. Equations (51) and (52) are equivalent to (19) and (17). Finally, eliminating $\partial_0\xi_\alpha$ and $\partial_0 S$ from (53) by means of (49) and (50), one obtains Eq. (18) and, hence, the system of dynamic equations (10), (18), and (19), where designations (15)–(17) are used.

The curtailed system (6)–(8) can be obtained from Eqs. (48) to (53) as follows. Equations (48) and (50) coincide with (6) and (8). For deriving (7) let us note that the vorticity $\boldsymbol{\omega}\equiv\boldsymbol{\nabla}\times\mathbf{v}$ and $\mathbf{v}\times\boldsymbol{\omega}$ are obtained from (52) in the form

$$\boldsymbol{\omega}=\boldsymbol{\nabla}\times\mathbf{v}=\tfrac{1}{2}\Omega^{\alpha\beta}\boldsymbol{\nabla}\xi_\beta\times\boldsymbol{\nabla}\xi_\alpha-\boldsymbol{\nabla}\eta\times\boldsymbol{\nabla}S,\tag{56}$$

$$\mathbf{v}\times\boldsymbol{\omega}=\Omega^{\alpha\beta}\boldsymbol{\nabla}\xi_\beta(\mathbf{v}\boldsymbol{\nabla})\xi_\alpha+\boldsymbol{\nabla}S(\mathbf{v}\boldsymbol{\nabla})\eta-\boldsymbol{\nabla}\eta(\mathbf{v}\boldsymbol{\nabla})S.\tag{57}$$

Let us form a difference between the time derivative of (52) and the gradient of (53). Eliminating $\Omega^{\alpha\beta}\partial_0\xi_\alpha$, $\partial_0 S$, and $\partial_0\eta$ by means of Eqs. (49), (50), (51), one obtains

$$\begin{aligned}\partial_0\mathbf{v}+\boldsymbol{\nabla}\frac{\mathbf{v}^2}{2}+\frac{\partial^2(\rho E)}{\partial\rho^2}\boldsymbol{\nabla}\rho+\frac{\partial^2(\rho E)}{\partial\rho\partial S}\boldsymbol{\nabla}S+\boldsymbol{\nabla}\rho_\beta\frac{\partial^2(\rho E)}{\partial\rho_\beta\partial\rho}-\boldsymbol{\nabla}\partial_\beta\frac{\partial^2(\rho E)}{\partial\rho_\beta}-\frac{\partial E}{\partial S}\boldsymbol{\nabla}S\\ -\Omega^{\alpha\beta}\boldsymbol{\nabla}\xi_\beta(\mathbf{v}\boldsymbol{\nabla})\xi_\alpha+\boldsymbol{\nabla}\eta(\mathbf{v}\nabla)S-\boldsymbol{\nabla}S(\mathbf{v}\boldsymbol{\nabla})\eta=0.\end{aligned}\tag{58}$$

Using (56) and (57) expression (58) reduces to

$$\partial_0\mathbf{v}+\boldsymbol{\nabla}\frac{\mathbf{v}^2}{2}-\mathbf{v}\times(\boldsymbol{\nabla}\times\mathbf{v})+\frac{1}{\rho}\boldsymbol{\nabla}\left(\rho^2\frac{\partial E}{\partial\rho}\right)-\frac{1}{\rho}\partial_\beta\left[\rho\boldsymbol{\nabla}\frac{\partial^2(\rho E)}{\partial\rho_\beta}\right]=0.\tag{59}$$

By virtue of the identity

$$\mathbf{v}\times(\nabla\times\mathbf{v})\equiv\nabla\,\frac{\mathbf{v}^2}{2}-(\mathbf{v}\nabla)\mathbf{v}$$

the last equation is equivalent to (7). The form of the stress tensor (1) appears as a result of transformations of the relation (59) to the form (7). The stress tensor (1) is determined to within the tensor with a vanishing divergence.

Thus, differentiating Eqs. (52) and (53) and eliminating the variables $\varphi,\boldsymbol{\xi},\eta$, one obtains the curtailed system (6)–(8), whereas the system (10), (18), and (19) follows directly from the system (48) to (53) (i.e., without differentiating). It means that the system (10), (18), and (19) is an integrated system, whereas the curtailed system (6)–(8) is not, although formally they have the same order.

The action of the form (47), or close to this form was obtained by some authors,[23,27] but the quantities g^α, $\alpha=1,2,3$ are always considered as additional dependent variables (but not as indefinite functions of $\boldsymbol{\xi}$ which can be expressed via initial conditions). The action was not considered as a functional of fixed indefinite functions $g^\alpha(\boldsymbol{\xi})$.

The variable η was introduced to make the action invariant with respect to the transformations of the whole relabeling group (12). To understand what the η means from a mathematical viewpoint, let us return to the action (38), where the internal energy E has the form (39). Adding new variables j by means of designations (33), one obtains instead of (42)

$$\mathcal{A}_E[\rho,\mathbf{j},\boldsymbol{\xi},p]=\int\left\{\frac{\mathbf{j}^2}{2\rho}-\rho E-p_k\left[j^k-m\rho_0(\boldsymbol{\xi})\,\frac{\partial J}{\partial\xi_{0,k}}\right]\right\}dt\,d\mathbf{x}, \tag{60}$$

where E has the form (39).

Variation of (60) with respect to ξ_α leads to the equation

$$\hat{\mathcal{L}}_\alpha p=\rho\,\frac{\partial E(\rho,S_0(\boldsymbol{\xi}))}{\partial S_0}\,\frac{\partial S_0}{\partial\xi_\alpha},\quad \alpha=1,2,3, \tag{61}$$

where linear operators $\hat{\mathcal{L}}_\alpha$ are defined by (43). Equations (61) are linear nonuniform equations for the variables p. A solution of (61) is a sum of the general solution (46) of the uniform equations (43) and of a particular solution of the nonuniform equations (61). This particular solution depends on the form of the function S_0 and cannot be found in a general form. Adding to Eq. (41) an extraterm $-\eta j^k\partial_k S$ with η satisfying (51), a reduction of nonuniform equations (61) to uniform equations (43) appears to be possible. Thus, the extravariable η is responsible for the particular solution of (61).

From the viewpoint of the action (60) the dependence of the internal energy E on the entropy simply means a dependence of E on the labels $\boldsymbol{\xi}$ via a function $S(\boldsymbol{\xi})$. If such a dependence cannot be expressed through one function (for instance, $E=E[\rho,S_1(\boldsymbol{\xi}),S_2(\boldsymbol{\xi})]$) the ideal fluid is described by two entropies S_1 and S_2 and by two temperatures $T_1=\partial E/\partial S_1$, $T_2=\partial E/\partial S_2$. Such a situation may appear for a conducting fluid in a strong magnetic field, where there are two temperatures—longitudinal and transversal.

Thus five equations (10), (18), and (19) with S, ρ, and $\mathbf{v}$, defined, respectively, by (15), (16), and (17), constitute the fifth-order system for five dependent variables $\xi=\{\xi_0,\boldsymbol{\xi}\},\eta$. Equations (6), (8), (10), (18), (19) constitute the seventh-order system for seven variables ρ,ξ,φ,η,S.

IV. INITIAL AND BOUNDARY CONDITIONS

Boundary conditions describing vessel walls can be taken into account by means of a proper choice of the internal energy $E(x,\rho,\nabla\rho,S)$ which can include the energy of the fluid in an external potential U,

$$E = E_0(\rho, \nabla\rho, S) + U(t, \mathbf{x}),$$

where U is some given external potential. For instance, let the fluid move inside a volume $\mathcal{V}$. Then

$$U(\mathbf{x}) = \begin{cases} 0 & \text{inside } \mathcal{V} \\ \infty & \text{outside } \mathcal{V}. \end{cases}$$

Such a choice of energy E provides that the fluid does not escape the volume $\mathcal{V}$.

In this section let us set for simplicity the scale constant $b=1$, and consider the case when E does not depend on $\nabla\rho$, and the fluid flow is considered in the space–time region Ω defined by inequalities

$$\Omega: \quad t \geqslant 0, \quad x^3 \geqslant 0.$$

The region Ω has two boundaries: $\mathcal{I}$ defined by the relations $t=0$, $x^3 \geqslant 0$, and $\mathcal{B}$ defined by the relations $x^3=0$, $t \geqslant 0$. The initial conditions for the system of equations (6)–(8), and (10) have the form

$$\rho(0,\mathbf{x}) = \rho_{\text{in}}(\mathbf{x}), \quad v^{\alpha}(0,\mathbf{x}) = v^{\alpha}_{\text{in}}(\mathbf{x}), \quad \alpha = 1,2,3, \tag{62}$$

$$S(0,\mathbf{x}) = S_{\text{in}}(\mathbf{x}), \quad \xi_{\alpha}(0,\mathbf{x}) = \xi^{\alpha}_{\text{in}}(\mathbf{x}), \quad \alpha = 1,2,3 \tag{63}$$

at $\mathbf{x} \in \mathcal{I}$ ($t=0$, $x^3 \geqslant 0$). Here ρ_{in}, $\mathbf{v}_{\text{in}}$, S_{in}, and $\boldsymbol{\xi}_{\text{in}}$ are given functions of argument $\mathbf{x}$. The boundary conditions on the boundary $\mathcal{B}$ of Ω have the form:

$$\rho(x)|_{x^3=0} = \rho_b(t,\mathbf{y}), \quad S(x)|_{x^3=0} = S_b(t,\mathbf{y}), \quad \{t,\mathbf{y}\} \in \mathcal{B}, \tag{64}$$

$$v^{\alpha}(x)|_{x^3=0} = v^{\alpha}_b(t,\mathbf{y}), \quad \alpha = 1,2,3, \quad \{t,\mathbf{y}\} \in \mathcal{B}, \tag{65}$$

$$\xi_{\alpha}(x)|_{x^3=0} = \xi^{\alpha}_b(t,\mathbf{y}), \quad \alpha = 1,2,3, \quad \{t,y\} \in \mathcal{B}, \tag{66}$$

where

$$\mathbf{y} \equiv \{x^1, x^2\}. \tag{67}$$

Here ρ_b, S_b, $\mathbf{v}_b$, and $\boldsymbol{\xi}_b$ are given functions of the argument $\{t,\mathbf{y}\}$.

Let us show that indefinite functions $\mathbf{g}, S_0, \rho_0$ can be expressed via initial and boundary conditions (62)–(66). The initial conditions for the system (48)–(53) have the form

$$\xi_{\alpha}(0,\mathbf{x}) = \xi^{\alpha}_{\text{in}}(\mathbf{x}), \quad \alpha = 1,2,3, \tag{68}$$

$$\rho(0,\mathbf{x}) = \rho_{\text{in}}(\mathbf{x}), \quad S(0,\mathbf{x}) = S_0[\boldsymbol{\xi}_{\text{in}}(\mathbf{x})], \tag{69}$$

$$\varphi(0,\mathbf{x}) = \varphi_{\text{in}}(\mathbf{x}), \quad \eta(0,\mathbf{x}) = \eta_{\text{in}}(\mathbf{x}), \tag{70}$$

(68)–(70) take place at $\mathbf{x} \in \mathcal{I}$. The functions $\varphi_{\text{in}}(\mathbf{x})$, $\eta_{\text{in}}(\mathbf{x})$ as well $g^{\alpha}(\boldsymbol{\xi})$ are to be determined from the relations

$$\partial_{\alpha}\varphi_{\text{in}}(\mathbf{x}) + g^{\beta}[\boldsymbol{\xi}_{\text{in}}(\mathbf{x})]\partial_{\alpha}\xi^{\beta}_{\text{in}}(\mathbf{x}) - \eta_{\text{in}}(\mathbf{x}) \frac{\partial S_0[\boldsymbol{\xi}_{\text{in}}(\mathbf{x})]}{\partial \xi^{\beta}_{\text{in}}} \partial_{\alpha}\xi^{\beta}_{\text{in}}(\mathbf{x}) = v^{\alpha}_{\text{in}}(\mathbf{x}), \quad \alpha = 1,2,3, \quad \mathbf{x} \in \mathcal{I}. \tag{71}$$

It is clear that five functions $\mathbf{g}, \varphi_{\text{in}}, \eta_{\text{in}}$ cannot be determined unambiguously from three relations (71).

There are at least two different approaches for the determination of the functions $\boldsymbol{\xi}_{\text{in}}(\mathbf{x})$ and $\mathbf{g}(\boldsymbol{\xi}.)$

(1) One fixes the functions $\xi_{\rm in}^{\alpha}(\mathbf{x})$ in some conventional way, sets

$$\varphi_{\rm in}(\mathbf{x})=0, \quad \eta_{\rm in}(\mathbf{x})=0, \quad \mathbf{x}\in\mathcal{I}, \tag{72}$$

and determines functions $\mathbf{g}$ from the three relations (71).

(2) Functions $\mathbf{g}$ are fixed in some conventional way, and the remaining functions are determined from relations (71).

The first way. Let condition (68) be given in the form

$$\xi_{\alpha}(0,\mathbf{x})=\xi_{\rm in}^{\alpha}(\mathbf{x})=x^{\alpha}, \quad \alpha=1,2,3, \quad \mathbf{x}\in\mathcal{I}. \tag{73}$$

In other words, at $t=0$ the labels $\boldsymbol{\xi}$ coincide with the Eulerian coordinates. By virtue of (72), the relations (71) take the form

$$g^{\beta}[\boldsymbol{\xi}_{\rm in}(\mathbf{x})]=v_{\rm in}^{\beta}(\mathbf{x}), \quad \alpha=1,2,3, \quad \mathbf{x}\in\mathcal{I}, \tag{74}$$

which are resolved in the form

$$g^{\alpha}(\boldsymbol{\xi})=v_{\rm in}^{\alpha}(\boldsymbol{\xi}), \quad \alpha=1,2,3, \quad \xi_3>0. \tag{75}$$

Thus, the functions $\mathbf{g}$ are expressed through initial conditions (62).

The boundary conditions for the system of equations (48)–(53) have the form

$$\xi_{\alpha}(x)|_{x^3=0}=\xi_b^{\alpha}(t,\mathbf{y}), \quad \alpha=1,2,3, \quad \{t,\mathbf{y}\}\in\mathcal{B}, \tag{76}$$

$$S(x)|_{x^3=0}=S_0[\boldsymbol{\xi}_b(t,\mathbf{y})]=S_b(t,\mathbf{y}), \quad \{t,\mathbf{y}\}\in\mathcal{B}, \tag{77}$$

$$\rho(x)|_{x^3=0}=\rho_b(t,\mathbf{y}), \quad \mathbf{v}(x)|_{x^3=0}=\mathbf{v}_b(t,\mathbf{y}), \quad \{t,\mathbf{y}\}\in\mathcal{B}, \tag{78}$$

$$\varphi(x)|_{x^3=0}=\eta(x)|_{x^3=0}=0, \quad \{t,\mathbf{y}\}\in\mathcal{B}. \tag{79}$$

Let us set

$$\xi_b^{\alpha}(t,\mathbf{y})=x^{\alpha}, \quad \alpha=1,2, \quad \xi_b^{3}(t,\mathbf{y})=-ct, \quad (t,\mathbf{y})\in\mathcal{B}, \tag{80}$$

where c is a constant.

Writing relations (10) and (53) for $\xi_3<0$ on the boundary $\mathcal{B}$ and using (79) and (80), one obtains constraints for the functions $\mathbf{g}(\boldsymbol{\xi})$,

$$g^{\beta}[\boldsymbol{\xi}_b(t,\mathbf{y})]\partial_{\alpha}\xi_b^{\beta}(t,\mathbf{y})=v_b^{\alpha}(t,\mathbf{y}), \quad \alpha=1,2, \quad \{t,\mathbf{y}\}\in\mathcal{B}, \tag{81}$$

$$g^{\beta}[\boldsymbol{\xi}_b(t,\mathbf{y})]\partial_0\xi_b^{\beta}(t,\mathbf{y})=-K_b(t,\mathbf{y}), \quad \{t,\mathbf{y}\}\in\mathcal{B}, \tag{82}$$

where

$$K_b(t,\mathbf{y})\equiv\frac{\mathbf{v}_b^2(t,\mathbf{y})}{2}+\frac{\partial\{\rho_b(t,\mathbf{y})E[\rho_b(t,\mathbf{y}),S_b(t,\mathbf{y})]\}}{\partial\rho_b(t,\mathbf{y})}, \quad \{t,\mathbf{y}\}\in\mathcal{B}, \tag{83}$$

Substituting relations (80) into (81) and (82), one obtains three equations for the determination of functions $\mathbf{g}(\boldsymbol{\xi})$. Resolving this system of equations with respect to $\mathbf{g}$, one obtains

$$\begin{aligned} g^{\alpha}(\boldsymbol{\xi})&=v_b^{\alpha}(-\xi_3/c,\xi_1,\xi_2), \quad \alpha=1,2, \quad \xi_3<0,\\ g^{3}(\boldsymbol{\xi})&=c^{-1}K_b(-\xi_3/c,\xi_1,\xi_2), \quad \xi_3<0. \end{aligned} \tag{84}$$

Thus, $\mathbf{g}(\boldsymbol{\xi})$ is determined by (75) for $\xi_3>0$ and by (84) for $\xi_3<0$. In other words, the boundary conditions and the initial conditions determine the vector field $\mathbf{g}(\boldsymbol{\xi})$ in different regions of the argument $\boldsymbol{\xi}$. The field $\mathbf{g}(\boldsymbol{\xi})$ can describe both initial and boundary conditions. For any fluid flow the system (10), (18), and (19) of dynamic equations for variables φ, η, and $\boldsymbol{\xi}$ is to be solved under universal initial conditions (72) and (73) and under universal boundary conditions (79) and (80). All essential information on the fluid flow is found in the dynamic equations (10), (18), and (19), where the quantities $S,\rho,\mathbf{v}$ are determined by (15)–(17).

The second way. Let us choose the functions $\mathbf{g}$ in a simple form. Let for instance,

$$g^1(\boldsymbol{\xi})=\xi_2, \quad g^2(\boldsymbol{\xi})=0, \quad g^3(\boldsymbol{\xi})=0.$$

Let us set

$$\chi=\varphi, \quad \lambda=\xi_2, \quad \mu=\xi_1.$$

Then expression (17) takes the form

$$\mathbf{u}(\chi,\lambda,\mu,\eta,S)\equiv\nabla\chi+\lambda\nabla\mu-\eta\nabla S=\mathbf{v}, \tag{85}$$

where χ, λ, and μ, are Clebsch potentials.[21,22] Now six equations (6), (8), (49)–(53), and (55) [(49) for $\alpha=3$ is of no importance] for six dependent variables ρ, χ, λ, μ, η, and S do not contain indefinite functions and have an unambiguous form,

$$\partial_0\rho+\nabla(\rho\mathbf{u})=0, \quad \partial_0\lambda+(\mathbf{u}\nabla)\lambda=0, \quad \partial_0\mu+(\mathbf{u}\nabla)\mu=0, \quad \partial_0 S+(\mathbf{u}\nabla)S=0, \tag{86}$$

$$\partial_0\eta+(\mathbf{u}\nabla)\eta=-\frac{\partial E}{\partial S}, \quad \partial_0\chi+\lambda\partial_0\mu-\eta\partial_0 S+\frac{1}{2}\mathbf{u}^2+\frac{\partial(\rho E)}{\partial\rho}=0,$$

where $\mathbf{u}$ is defined by (85).

The initial conditions for variables ρ, χ, λ, μ, η, and S are determined by the relations

$$\rho(0,\mathbf{x})=\rho_{\text{in}}(0,\mathbf{x}), \quad S(0,\mathbf{x})=S_{\text{in}}(0,\mathbf{x}), \tag{87}$$

$$\nabla\chi_{\text{in}}+\lambda_{\text{in}}\nabla\mu_{\text{in}}-\eta_{\text{in}}\nabla S_{\text{in}}=-\mathbf{v}_{\text{in}}. \tag{88}$$

The three equations (87) and (88) do not determine the initial conditions

$$\chi(0,\mathbf{x})=\chi_{\text{in}}(\mathbf{x}), \quad \lambda(0,\mathbf{x})=\lambda_{\text{in}}(\mathbf{x}), \tag{89}$$

$$\mu(0,\mathbf{x})=\mu_{\text{in}}(\mathbf{x}), \quad \eta(0,\mathbf{x})=\eta_{\text{in}}(\mathbf{x}), \tag{90}$$

unambiguously.

If the fluid is described in terms of Clebsch potentials, the dynamic equations contain neither arbitrary functions, nor information about the initial conditions. It should be interpreted in the sense that the description (85)–(86) in terms of the Clebsch potentials is a result of a change of variables in dynamic equations (6)–(8), whereas the description (48)–(53) is a result of the integration of the dynamic equations (6)–(8) and (10). In other words, the description (85)–(86) in terms of Clebsch potentials relates to the description (48)–(53) in the same way, as a particular solution of a system of differential equations relates to a general solution of the same system. Let us note that there are many other ways for a determination of indefinite functions $\mathbf{g}(\boldsymbol{\xi})$.

V. WAVE FUNCTION AND SPIN

Equations (6), (8), (10), (18), and (19) can be derived from the action functional

$$\mathcal{A}[\rho,\varphi,\boldsymbol{\xi},\eta,S]=\int \rho\left[-\pi_0(\varphi,\boldsymbol{\xi},\eta,S)-\frac{1}{2}\boldsymbol{\pi}^2(\varphi,\boldsymbol{\xi},\eta,S)-E(x,\rho,\boldsymbol{\nabla}\rho,S)\right]d^4x, \tag{91}$$

where $\boldsymbol{\pi}=\{\pi_1,\pi_2,\pi_3\}$, and $\pi_k=p_k-\eta\partial_kS$, $k=0,1,2,3$ are determined by relations (46),

$$\pi_k(\varphi,\boldsymbol{\xi},\eta,S)\equiv b[\partial_k\varphi+g^\alpha(\boldsymbol{\xi})\partial_k\xi_\alpha]-\eta\partial_kS, \quad k=0,1,2,3. \tag{92}$$

The action (91) results from the action (47) after elimination of the variable $\mathbf{j}$ from the relations (47) and (52). The functions $\mathbf{g}=\{g^\beta(\boldsymbol{\xi})\}$, $\beta=1,2,3$ are considered as fixed functions of their arguments. Equations (6), (8), (10), (18), and (19) can be obtained as a result of variation with respect to φ, η, $\boldsymbol{\xi}$, S, and ρ, respectively. Equation (10) is obtained, provided the field $\mathbf{g}$ is nonpotential. If the field $\mathbf{g}$ is potential $g^\alpha(\boldsymbol{\xi})\doteq\partial\Phi/\partial\xi_\alpha$, it can be included in the variable φ by means of the substitution

$$\varphi+\Phi\rightarrow\varphi.$$

In this case the action (91) does not depend on $\boldsymbol{\xi}$, and (10) may be omitted.

Let us introduce an n-component complex function $\psi=\{\psi_\alpha\}$, $\alpha=1,2,\ldots,n$, defining it by the relations

$$\psi_\alpha=\sqrt{\rho}e^{i\varphi}u_\alpha(\boldsymbol{\xi}), \quad \psi_\alpha^*=\sqrt{\rho}e^{-i\varphi}u_\alpha^*(\boldsymbol{\xi}), \quad \alpha=1,2,\ldots,n,$$

$$\psi^*\psi\equiv\sum_{\alpha=1}^n\psi_\alpha^*\psi_\alpha,$$

where an asterisk (*) means the complex conjugate, $u_\alpha(\boldsymbol{\xi})$, $\alpha=1,2,\ldots,n$ are only functions of variables $\boldsymbol{\xi}$, and satisfy the relations

$$-\frac{i}{2}\sum_{\alpha=1}^n\left(u_\alpha^*\frac{\partial u_\alpha}{\partial\xi_\beta}-\frac{\partial u_\alpha^*}{\partial\xi_\beta}u_\alpha\right)=g^\beta(\boldsymbol{\xi}), \quad \beta=1,2,3, \quad \sum_{\alpha=1}^n u_\alpha^*u_\alpha=1. \tag{93}$$

n is such a natural number that equations (93) admit a solution. In general n may depend on the form of the arbitrary integration functions $\mathbf{g}=\{g^\beta(\boldsymbol{\xi})\}$, $\beta=1,2,3$.

It is easy to verify that

$$\rho\pi_k(\varphi,\boldsymbol{\xi},\eta,S)=-\frac{ib}{2}(\psi^*\partial_k\psi-\partial_k\psi^*\cdot\psi)-\eta\partial_kS\psi^*\psi, \quad k=0,1,2,3, \tag{94}$$

$$\rho=\psi^*\psi, \quad \mathbf{j}=-\frac{ib}{2}(\psi^*\boldsymbol{\nabla}\psi-\boldsymbol{\nabla}\psi^*\cdot\psi)-\eta\boldsymbol{\nabla}S\psi^*\psi. \tag{95}$$

The variational problem with the action (91) appears to be equivalent to the variational problem with the action functional

$$\mathcal{A}[\psi,\psi^*,\eta,S]=\int\left\{\frac{ib}{2}(\psi^*\partial_0\psi-\partial_0\psi^*\cdot\psi)+\eta\partial_0S\psi^*\psi-\frac{1}{2\psi^*\psi}\left[\frac{ib}{2}(\psi^*\boldsymbol{\nabla}\psi-\boldsymbol{\nabla}\psi^*\cdot\psi)\right.\right.$$
$$\left.\left.+\eta\boldsymbol{\nabla}S\psi^*\psi\right]^2-E[x,\psi^*\psi,\boldsymbol{\nabla}(\psi^*\psi),S]\psi^*\psi\right\}d^4x. \tag{96}$$

Note that the function ψ considered as a function of independent variables $\{t,\mathbf{x}\}$ is very indefinite in the sense that the same fluid flow may be described by different ψ functions. There are two reasons for such an indefiniteness. First, the functions $u_\alpha(\boldsymbol{\xi})$ are not determined uniquely by differential equations (93). Second, their arguments $\boldsymbol{\xi}$ as functions of x are determined only to within the transformation (12). Description of a fluid in terms of the function ψ is more indefinite than the description in terms of the hydrodynamic potentials $\boldsymbol{\xi}$. Information about initial and boundary conditions contained in the functions $\mathbf{g}(\boldsymbol{\xi})$ is lost at the description in terms of the ψ function. The ψ function can be obtained from the Clebsch variables by means of a proper change of variables.[11]

Let the function ψ have n components. Regrouping components of the function ψ in the action (96), one obtains the action in the form

$$\mathcal{A}_E[\psi,\psi^*,\eta,S]=\int\left\{\frac{1}{2}\,[\psi^*(ib\partial_0+A_0)\psi+(-ib\partial_0\psi^*+A_0\psi^*)\psi]\right.$$
$$-\frac{1}{2}\,(ib\boldsymbol{\nabla}\psi^*-\mathbf{A}\psi^*)(-ib\boldsymbol{\nabla}\psi-\mathbf{A}\psi)$$
$$\left.+\frac{b^2}{4}\sum_{\alpha,\beta=1}^{n}Q^*_{\alpha\beta,\gamma}Q_{\alpha\beta,\gamma\rho}+\frac{b^2}{8\rho}\,(\boldsymbol{\nabla}\rho)^2-\rho E\right\}d^4x,\quad \rho\equiv\psi^*\psi, \tag{97}$$

where

$$A=\{A_0,\mathbf{A}\},\quad A_0\equiv\eta\partial_0 S,\quad \mathbf{A}\equiv\eta\boldsymbol{\nabla}S,$$
$$Q_{\alpha\beta,\gamma}=\frac{1}{\psi^*\psi}\begin{vmatrix}\psi_\alpha & \psi_\beta\\ \partial_\gamma\psi_\alpha & \partial_\gamma\psi_\beta\end{vmatrix},\quad \alpha,\beta=1,2,...,n,\quad \gamma=1,2,3. \tag{98}$$

Corresponding dynamic equations have the form

$$\frac{\delta\mathcal{A}}{\delta\psi^*_\alpha}=(ib\partial_0+A_0)\psi_\alpha-\frac{1}{2}\,(ib\boldsymbol{\nabla}+\mathbf{A})^2\psi_\alpha-\frac{b^2}{4}\sum_{\mu,\nu=1}^{n}Q^*_{\mu\nu,\gamma}Q_{\mu\nu,\gamma}\psi_\alpha+\frac{b^2}{2}\sum_{\nu=1}^{n}Q_{\alpha\nu,\gamma}\partial_\gamma\psi^*_\nu$$
$$+\frac{b^2}{2}\sum_{\nu=1}^{n}\partial_\gamma(Q_{\alpha\nu,\gamma}\psi^*_\nu)+\frac{\partial}{\partial\rho}\left[\frac{b^2}{8\rho}\,(\boldsymbol{\nabla}\rho)^2-\rho E\right]\psi_\alpha$$
$$-\partial_\gamma\left\{\frac{\partial}{\partial\rho_\gamma}\left[\frac{b^2}{8\rho}\,(\boldsymbol{\nabla}\rho)^2-\rho E\right]\right\}\psi_\alpha=0,\quad \alpha=1,2,...,n, \tag{99}$$

$$\frac{\delta\mathcal{A}}{\delta S}=\partial_i(j^i\eta)-\frac{\partial(\rho E)}{\partial S}=0, \tag{100}$$

$$\frac{\delta\mathcal{A}}{\delta\eta}=-\partial_i(j^iS)=0, \tag{101}$$

where $j=\{\rho,\mathbf{j}\}=\{j^k\}$, $k=0,1,2,3$ is defined by (95).

In the case of the irrotational flow, when $g^\alpha(\boldsymbol{\xi})=\partial\Phi(\boldsymbol{\xi})/\partial\xi_\alpha$, equations (93) have a solution for $n=1$, and the function ψ may have one component. Then all $Q_{\alpha\beta,\gamma}\equiv 0$, as it follows from Eq. (98).

Let us consider an irrotational flow of a fluid with the internal energy per unit mass defined by relation (3), where m is the mass of a stochastic particle associated with the fluid. The internal energy does not depend on the entropy, and according to (3) and (100) the variable η is a function of only labels $\boldsymbol{\xi}$. Then the expression $\eta\partial_k S$ has the form $f^\alpha(\boldsymbol{\xi})\partial_k\xi_\alpha$. It may be included in the term $g^{\alpha}(\boldsymbol{\xi})\xi_{\alpha,k}$. It means that without a loss of generality one may set $\eta\equiv 0$, $S\equiv 0$. Then for an irrotational flow, when the ψ function is one component, Eq. (99) takes the form

$$\frac{\delta\mathcal{A}}{\delta\psi^*}=ib\partial_0\psi-\frac{b^2}{2}\boldsymbol{\nabla}^2\psi+\left(b^2-\frac{\hbar^2}{m^2}\right)\left\{\frac{\partial}{\partial\rho}\frac{(\boldsymbol{\nabla}\rho)^2}{8\rho}-\partial_{\gamma}\left[\frac{\partial}{\partial\rho_{\gamma}}\frac{(\boldsymbol{\nabla}\rho)^2}{8\rho}\right]\right\}\psi=0. \tag{102}$$

Choosing arbitrary constant b in the form $b=-\hbar/m$, one obtains instead of Eq. (102) the well-known Schrödinger equation

$$i\hbar\partial_0\psi+\frac{\hbar^2}{2m}\boldsymbol{\nabla}^2\psi=0,$$

where the complex variable ψ is known as the wave function. The Schrödinger equation describes an irrotational flow of the Madelung fluid.[4]

On this basis it is possible in general to identify the function ψ with the wave function and consider the wave function as a way of description of any ideal fluid. If the fluid flow is rotational, the dynamic equation in terms of the ψ function is nonlinear, even in the case (3) and at $b=-\hbar/m$. In this case the ψ function is not one component, and the quantities $Q_{\alpha\beta,\gamma}$ do not vanish generally.

In general, the dynamic equation (99) for the ψ function is nonlinear and rather complicated. But for a special form (3) of the internal energy and for a special form of the arbitrary phase constant b the dynamic equation in terms of the ψ function becomes linear and simple.

It is worth noting that the internal energy per unit mass (3) associates with the mean diffusion velocity $\mathbf{v}_{\text{dif}}=-D\boldsymbol{\nabla}\rho/\rho$ describing the mean motion of random wandering of stochastic particles (D is the diffusion coefficient). The diffusion velocity is characteristic for any stochastic particles (both Brownian and quantum). The Brownian fluid is dissipative, and the evolution of the fluid state ρ is described directly by $\mathbf{v}_{\text{dif}}$ by means of the continuity equation

$$\partial_0\rho+\boldsymbol{\nabla}(\rho\mathbf{v}_{\text{dif}})=0.$$

For the ideal Madelung fluid the diffusion velocity influences the fluid flow via the internal fluid energy per unit mass determined by means of relation (3). Besides, the diffusion coefficients D are different for Brownian particles and for quantum ones, because the origin of the stochasticity is different in the two cases.

The number n of the ψ-function components in the actions (96) and (97) is arbitrary. A formal variation of the action with respect to ψ_{α} and ψ^*_{α}, $\alpha=1,2,...,n$ leads to $2n$ real dynamic equations, but not all of them are independent. There are such combinations of variations $\delta\psi_{\alpha},\delta\psi^*_{\alpha}$, $\alpha=1,2,...,n$ which do not change expressions (94) and (95). Such combinations of variations $\delta\psi_{\alpha},\delta\psi^*_{\alpha}$, $\alpha=1,2,...,n$ do not change the action (96), and corresponding combinations of dynamic equations $\delta\mathcal{A}/\delta\psi_{\alpha}=0$, $\delta\mathcal{A}/\delta\psi^*_{\alpha}=0$ are identities that associate with a correlation between dynamic equations. Thus, increasing the number n, one increases the number of dynamic equations, but the number of independent dynamic equations remains the same.

In such a situation it is important to determine the minimal number n_m of the ψ-function components, sufficient for a description of the given vector field $g^{\beta}(\boldsymbol{\xi})$ in the space V_{ξ} of the labels $\boldsymbol{\xi}$.

Note that under the relabeling transformations (12) the quantity $\mathbf{g}(\boldsymbol{\xi})$ transforms as a vector

$$g^{\beta}(\boldsymbol{\xi})\to\tilde{g}^{\beta}(\tilde{\boldsymbol{\xi}})=\frac{\partial\xi_{\alpha}}{\partial\tilde{\xi}_{\beta}}g^{\alpha}(\boldsymbol{\xi}),\quad \beta=1,2,3.$$

It is necessary for the quantities (94), (95) and the action (91) to be invariant with respect to the transformation (12)

Let $\mathcal{G}$ be a set of all vector fields $g^{\beta}(\boldsymbol{\xi})$ in V_{ξ}, and $\mathcal{G}_n$ be a set of such vector fields $g^{\beta}(\boldsymbol{\xi})$ in V_{ξ} which can be presented in the form

$$g^{\beta}(\boldsymbol{\xi})=\sum_{k=1}^{n} \eta_k^2(\boldsymbol{\xi})\partial\zeta_k(\boldsymbol{\xi})/\partial\xi_{\beta}, \quad \beta=1,2,3, \quad \eta_1\equiv 1, \tag{103}$$

where n is a fixed natural number and the functions η_k, ζ_k, $k=1,2,...,n$ are scalars in V_{ξ}. Under the relabeling transformation (12) the functions (103) transform as follows:

$$\eta_k(\boldsymbol{\xi})\to\tilde{\eta}_k(\tilde{\boldsymbol{\xi}})=\eta_k(\boldsymbol{\xi}), \quad \zeta_k(\boldsymbol{\xi})\to\tilde{\zeta}_k(\tilde{\boldsymbol{\xi}})=\zeta_k(\boldsymbol{\xi}), \quad k=1,2,...,n,$$

$$g^{\beta}(\boldsymbol{\xi})\to\tilde{g}^{\beta}(\tilde{\boldsymbol{\xi}})=\frac{\partial\xi_{\alpha}}{\partial\tilde{\xi}_{\beta}}\,g^{\alpha}(\boldsymbol{\xi})=\frac{\partial\xi_{\alpha}}{\partial\tilde{\xi}_{\beta}}\sum_{k=1}^{n}\eta_k^2(\boldsymbol{\xi})\,\frac{\partial\zeta_k(\boldsymbol{\xi})}{\partial\xi_{\alpha}}=\sum_{k=1}^{n}\tilde{\eta}_k^2(\tilde{\boldsymbol{\xi}})\,\frac{\partial\tilde{\zeta}_k(\tilde{\boldsymbol{\xi}})}{\partial\tilde{\xi}_{\alpha}}.$$

In other words, a vector field $g^{\beta}(\boldsymbol{\xi})$ of the form (103) transforms into the vector field $\tilde{g}^{\beta}(\tilde{\boldsymbol{\xi}})$ of the same form (103), and the set $\mathcal{G}_n$ is invariant with respect to the group (12) of the relabeling transformations.

It is easy to see that

$$\mathcal{G}_{n-1}\subseteq\mathcal{G}_n, \quad \mathcal{G}_0=\varnothing, \quad n=1,2,...$$

because the nth term of the sum (103) can be combined with the first one, if ζ_n is a function of η_n. Let

$$\mathcal{S}_n=\mathcal{G}_n\backslash\mathcal{G}_{n-1}, \quad n=1,2,... .$$

Then

$$\mathcal{G}=\bigcup_{s=1}^{s=n_m}\mathcal{S}_s, \quad \mathcal{S}_l=\varnothing, \quad l=n_m+1,n_m+2,...,$$

where n_m is the number of nonempty invariant subsets of the set $\mathcal{G}$. Each subset $\mathcal{S}_k$ contains only such vector fields $g^{\beta}(\boldsymbol{\xi})$ which associate with the k-component ψ-function $\psi=\{\psi_{\alpha}\}$, $\alpha=1,2,...,k$, having the components

$$\psi_1=\left\{\left(1-\sum_{\alpha=2}^{k}\eta_{\alpha}^2\right)\rho\right\}^{1/2}\exp[i(\varphi+\zeta_1)],$$

$$\psi_{\alpha}=\eta_{\alpha}\sqrt{\rho}\,\exp[i(\varphi+\zeta_{\alpha}+\zeta_1)], \quad \alpha=2,3,...,k.$$

In particular, the set $\mathcal{S}_1$ associates with an irrotational flow, described by a one-component ψ function determined by one scalar ζ_1; and the set $\mathcal{S}_2$ associates with a rotational flow described by a two-component ψ function, determined by three scalar functions ζ_1, η_2, and ζ_2 (Clebsch variables).

In conventional quantum mechanics the number n of ψ-function components is connected with the spin s of the particle, described by the ψ, by means of the relation $s=(n-1)/2$. The spin is considered as an internal property of a quantum particle. Particles with different spins are considered as different physical objects, described by different dynamic equations.

In a like manner the irrotational flow, when $g^{\beta}(\boldsymbol{\xi})$ is described by one function ζ_1, associates with the kinematic spin (k-spin) $s=0$, whereas the rotational flow, when $g^{\beta}(\boldsymbol{\xi})$ is described by three scalar functions ζ_1, η_2, and ζ_2, associates with the kinematic spin $s=1/2$. The term ‘‘kinematic spin’’ (instead of ‘‘spin’’ simply) is used now for the following reasons.

First, the kinematic spin (k-spin) is determined by the form of the vector field $g^{\beta}(\boldsymbol{\xi})$, which arises essentially as a result of an integration of equations (43). The vector field $g^{\beta}(\boldsymbol{\xi})$ is a kinematic structure, because it does not depend on the form of the internal energy. At the same time the k-spin is not an internal property of a particle in itself, because the action (96) describes, at least, two different k-spins ($s=0$ and $s=1/2$) simultaneously, and the k-spin looks rather like an integration constant, than a property of single fluid particles.

Second, there is a distinction between the transformation properties of the spin and those of the k-spin under the space rotation group. Components of the n-component ψ function are scalars under the space rotation group for any value of n (and for any value of the k-spin s). In the conventional quantum mechanics the wave function transforms according to a representation of the rotation group. In particular, a one-component wave function $\psi(s=0)$ is a scalar, whereas the two-component ψ function $\psi(s=1/2)$ transforms as a spinor under the rotation group.

Taking into account the indefiniteness of the ψ function, it is possible to change transformation properties of the ψ function accompanying any spatial rotation by a proper transformation of the group (12). The additional transformations (12) can be chosen in such a way that the two-component ψ function becomes a spinor under spatial rotations. Then the formal distinction between the ''k-spin'' and the ''spin'' vanishes, and one can identify them.

For instance, let the two-component ψ function be written in the form

$$\psi=\sqrt{\rho}\,\exp[i(\varphi+\boldsymbol{\sigma}\boldsymbol{\xi})]\chi,$$

where ρ, φ, and $\boldsymbol{\xi}$ are scalar functions of x, $\boldsymbol{\sigma}=\{\sigma_{\alpha}\}$, $\alpha=1,2,3$ are the Pauli matrices

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},$$

and χ is a two-component constant column $(\chi^{*}\chi=1)$.

Let any infinitesimal spatial rotation

$$x^0\to\tilde{x}^0=x^0,\quad \mathbf{x}\to\tilde{\mathbf{x}}=\mathbf{x}+\boldsymbol{\omega}\times\mathbf{x}+O(\boldsymbol{\omega}^2),\quad |\omega|\ll 1 \tag{104}$$

be accompanied by an infinitesimal transformation

$$\boldsymbol{\xi}\to\tilde{\boldsymbol{\xi}}=\boldsymbol{\xi}-\boldsymbol{\omega}/2. \tag{105}$$

Then the ψ function transforms as a spinor with respect to the combined transformation (104) and (105),

$$\psi(x)\to\tilde{\psi}(\tilde{x})=\sqrt{\tilde{\rho}(\tilde{x})}\,\exp[i(\tilde{\varphi}(\tilde{x})+\boldsymbol{\sigma}\tilde{\boldsymbol{\xi}}(\tilde{x}))]\chi=\exp(-i\boldsymbol{\omega}\boldsymbol{\sigma}/2)\psi(x)+O(\boldsymbol{\omega}^2),$$

and as a scalar with respect to the space rotation (104) alone.

If the dynamic system is described in terms of a two-component ψ function, the labels $\boldsymbol{\xi}$ are not mentioned at all, and the ψ function can be considered equally ready as a scalar and as a spinor.

For the two-component ψ function the following identity takes place:

$$(\boldsymbol{\nabla}\rho)^2-(\psi^{*}\boldsymbol{\nabla}\psi-\boldsymbol{\nabla}\psi^{*}\psi)^2\equiv 4\rho\boldsymbol{\nabla}\psi^{*}\boldsymbol{\nabla}\psi-\rho^2\mathbf{s}^2, \tag{106}$$

$$\rho\equiv\psi^{*}\psi,\quad \mathbf{s}\equiv\psi^{*}\boldsymbol{\sigma}\psi/(2\rho),\quad \boldsymbol{\sigma}=\{\sigma_{\alpha}\},\quad \alpha=1,2,3, \tag{107}$$

where σ_{α} are Pauli matrices. By virtue of the identity (106) the action (96) reduces to the form

$$\mathcal{A}[\psi,\psi^*,\eta,S]=\int\Bigg\{\frac{1}{2}[\psi^*(ib\partial_0+A_0)\psi+(-ib\partial_0+A_0)\psi^*\psi]-\frac{1}{2}[ib\nabla\psi^*-\mathbf{A}\psi^*][-ib\nabla\psi-\mathbf{A}\psi]+\frac{b^2}{2}(\nabla s_\alpha)(\nabla s_\alpha)\rho+\frac{b^2}{8\rho}(\nabla\rho)^2-\rho E\Bigg\}d^4x, \tag{108}$$

$$\rho\equiv\psi^*\psi,\quad A_k\equiv\eta\partial_k S,\quad k=0,1,2,3$$

where s_α are defined by Eq. (107). The quantity $\mathbf{s}=\{s_\alpha\}$, $\alpha=1,2,3$ associates with the mean spin (especially, if $b=-\hbar/m$), because it is constructed on the base of the Pauli matrices. As one can see, in Eq. (108) s_α convolutes only with s_α, but not with ∇_α. As a result the action (108) is invariant with respect to space–time rotations and relabeling transformations (12) separately.

It is interesting to note in this connection that the action $\mathcal{A}_P[\psi,\psi^*]$ for the dynamical system $\mathcal{S}_P[\psi]$, described by the Pauli equation, implies the convolution between $\mathbf{s}$ and ∇. The action $\mathcal{A}_P[\psi,\psi^*]$ is invariant only with respect to the combined transformation (104) and (105), i.e., if the ψ is considered as a spinor, but it is not invariant with respect to the transformation (104), when ψ is considered as a scalar. In other words, the action $\mathcal{A}_P[\psi,\psi^*]$ is not invariant with respect to the rotation group (104), if $\mathcal{S}_P[\psi]$ is considered as a fluidlike dynamic system. The same action $\mathcal{A}_P[\psi,\psi^*]$ can be made invariant with respect to the rotation group (104) alone, provided ψ is considered as a fundamental object (not as an attribute of a dynamic system). In the last case the ψ is declared as a spinor, but the mathematical object, described by the action $\mathcal{A}_P[\psi,\psi^*]$, stops being a dynamic system. It may be regarded, for instance, as a ‘‘*dynamic system restricted by quantum axiomatics*,’’ but it is not a dynamic system in the conventional sense of this term, because a possibility of change of dynamic variables is restricted [any rotation (104) is accompanied by a proper relabeling (105)]. Of course, one may insist on the fundamental character of ψ and state that ψ is a spinor, but then $\mathcal{S}_P[\psi]$ stops being a dynamic system, and this fact may have far-reaching consequences (see the details in Ref. 28). There is a similar problem with the relativistic invariance of the dynamic system $\mathcal{S}_D[\psi]$ described by the Dirac equation.[29]

Thus, the *k*-spin is an integral property of a fluid flow, connected with kinematic properties of a dynamic system. Locally any vector field $\mathbf{g}(\boldsymbol{\xi})$ in the three-dimensional V_ξ can be written in the form

$$\mathbf{g}(\boldsymbol{\xi})=\nabla\zeta_1+\eta_2\nabla\zeta_2 \tag{109}$$

(expressed via Clebsch potentials), and one should expect that $s=1/2$ is a maximal *k*-spin of any flow in the three-dimensional space. But possible singular points of the representation (109) may lead to the circumstance that the spin of the total flow appears to be higher than $s=1/2$. It is connected with the so-called helicity of a vector field. Examples and a discussion of such a velocity field can be found in Refs. 16 and 30.

VI. CONCLUDING REMARKS

Taking into account dynamic equations for the labels $\boldsymbol{\xi}$ (Lagrangian coordinates considered as dynamic variables), one succeeds in integrating the system of hydrodynamic equations for an ideal fluid. This integration leads to the appearance of three arbitrary functions g^α, $\alpha=1,2,3$ of labels $\boldsymbol{\xi}$. The functions g^α form a vector $\mathbf{g}$ in the space V_ξ of labels $\boldsymbol{\xi}$. The vector $\mathbf{g}$ can be expressed via initial and boundary values of the fluid velocity. Dynamic equations appear to carry all essential information about the fluid motion. This form of the fluid description may appear to be important in such problems, where the character of the fluid motion depends essentially on the character of the initial and boundary conditions, and one needs to investigate dynamic equations together with boundary and initial conditions. For instance, such a necessity arises when investigating phenomena connected with a transition to an irregular motion of a fluid (turbulence).

The appearance of the field $\mathbf{g}$ activates the relabeling group. Invariant subsets of this group can be used for a classification of the fluid flows. The field $\mathbf{g}$ allows one to introduce such concepts as ψ function and k-spin which are new for the fluid dynamics. In some special cases these new constructive concepts can be identified with the wave function and the spin. Concepts of the wave function and of the spin are fundamental concepts in the sense that they cannot be defined via other more fundamental concepts. In the quantum mechanics the concepts of the wave function and of the spin are defined by their properties, i.e., by a system of axioms (quantum axiomatics).

On one hand there are derivative constructions of ψ function and k-spin, connected with stochastic electron via the construction of the statistical ensemble (ideal fluid). On the other hand, there are fundamental concepts of wave function and spin, connected with the stochastic electron via a system of axioms (quantum axiomatics). Sometimes the ψ function coincides with the wave function, but not always. Then such a question arises. Which of the two conception is valid? ψ function, or wave function?

A like problem arose in the theory of thermal phenomena. On one hand there was an axiomatic thermodynamics with its fundamental concepts of thermodynamic potentials. On the other hand there was the statistical physics, where the thermodynamic potentials were constructive quantities derived from the conception of the heat as a chaotic motion of molecules. Then the constructive theory (statistical physics) appeared to be more successful, than the axiomatic one (thermodynamics). Now the question is yet open, although there is a series of arguments in favor of the constructive approach which seems to be more reasonable and less enigmatic.

The considered general approach to the fluid dynamics is interesting from the point of view that sometimes it permits one to use advantages of the quantum technique in the dynamics of usual fluids, as well as the general technique of the fluid dynamics in application to quantum mechanics.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 1 JANUARY 1999

The Stäckel systems and algebraic curves

A. V. Tsiganov[a)]
Department of Mathematical and Computational Physics, Institute of Physics, St. Petersburg University, 198 904, St. Petersburg, Russia

(Received 15 October 1997; accepted for publication 11 May 1998)

We show how the Abel–Jacobi map provides all the principal properties of an ample family of integrable mechanical systems associated to hyperelliptic curves. We prove that derivative of the Abel–Jacobi map is just the Stäckel matrix, which determines *n*-orthogonal curvilinear coordinate systems in a flat space. The Lax pairs, *r*-matrix algebras and explicit form of the flat coordinates are constructed. An application of the Weierstrass reduction theory allows us to construct several flat coordinate systems on a common hyperelliptic curve and to connect among themselves different integrable systems on a single phase space. © *1999 American Institute of Physics.* [S0022-2488(98)02009-X]

I. INTRODUCTION

In the classical mechanics the arrow from the initial physical variables to the action-angle variables is provided by the separation of variables and then by the Arnold construction of the action-angle representation.[1] The motion in the opposite direction ought to allow us to construct various mechanical integrable systems. However, in the action-angle representation all the mechanical systems with fixed number of degrees of freedom are indistinguishable. To describe some particular integrable system one should present an explicit construction of the initial physical variables as functions on the action-angle variables. This mapping contains all the information about a given integrable system. By using a variety of these mappings the different integrable models may be connected together via the common action-angle variables. For instance, mechanical systems may be related to nonlinear equations and to gauge field theory.

As an example, investigation of the finite-gap solutions of the nonlinear problems leads to the introduction[2–4] of analytic symplectic form Ω_g on the Jacobian fibrations and to the definition of the action-angle variables on the complex space of Liouville variables. In Ref. 5 it is shown that possible obstructions to the existence of global systems of action-angle variables on symplectic vector bundles are a nontrivial first Chern class and the presence of monodromy at singularities. Introduction of the action-angle representation enables one to consider mechanical integrable systems as systems associated with these variables on a torus bundle with base $\mathscr{M}$, moduli space of complex polynomials

$$F(\lambda)=\prod_{j=1}^{2g+1}(\lambda-\lambda_j), \tag{I.1}$$

and with a fiber $J(\mathscr{C})$, the g-dimensional complex Jacobian of auxiliary curve $\mathscr{C}$ defined by the Abel–Jacobi map $\mathscr{U}$.[1,6] The fact that action-angle variables could be used for quantization of classical systems leads to the introduction of semiclassical geometric phases. This approach results, for instance, in quantum conditions on the moduli of n-dimensional Jacobi varieties.[7]

By using this Abel–Jacobi map $\mathscr{U}$ and the Jacobi problem of inversion, the so-called root variables $\{p_j,q_j\}_{j=1}^n$ (Refs. 8 and 9) on an associated Riemann surface $\mathscr{C}$ may be constructed instead of the action-angle variables. In these root variables on the level of integrals of motion the action is represented as a sum of items depending on one coordinate only, i.e., these variables are separated variables. The corresponding Riemann surface $\mathscr{C}$ depends on parameters (moduli), parameterizing the moduli space $\mathscr{M}$ of $\mathscr{C}$.[4,10] In terms of mechanical integrable systems, the curve

[a)]Electronic mail: tsiganov@mph.niif.spbu.ru

$\mathscr{C}$ is interpreted as a time-independent spectral curve, integrals of motion are some specific coordinates on the moduli space $\mathscr{M}$, and the Jacobian $J(\mathscr{C})$ is a common level of the involutive integrals of the system.[1]

In what follows, we have to describe appropriate mechanical systems together with their phase space in initial physical coordinates $\{p_j, x_j\}_{j=1}^n$. In particular, separated coordinate systems ought to be orthogonal curvilinear coordinate systems on the flat Riemannian manifold.[11,12] In this case, these separated coordinate systems are associated to some solutions to the Lamé equation.[13–15] Recently, the solutions to this equation have been obtained in an explicit form with the help of the ''dressing procedure,''[13] the Baker-Akhiezer function[14,16] and the Lie algebraic construction[15] within framework of the inverse problem method.

The main objective of this paper is to illustrate how fixed mapping from the action-angle variables[1,6,14] to separated variables completely defines all the principal properties of mechanical systems. We shall consider the uniform Stäckel models associated to the Abel–Jacobi map $\mathscr{U}$ on the hyperelliptic curve $\mathscr{C}$ and the well-known elliptic, parabolic and spherical curvilinear coordinate systems on $\mathbb{R}^n$. Also, we discuss relations of these mechanical systems with other integrable models associated to the same algebraic curve.

II. THE STÄCKEL SYSTEMS

One of the oldest problems of the Hamiltonian mechanics is to find the quadratures for the integrable Hamiltonian systems. The simplest models integrable in quadratures are the Liouville systems and the Stäckel systems[17] (the Liouville systems are a particular case of the Stäckel systems).

Before proceeding farther it is useful to recall the classical work of Stäckel.[17] The system associated with the name of Stäckel[17] is a holonomic system on the phase space $\mathbb{R}^{2n}$. Their Hamiltonian is

$$H=\sum_{j=1}^{n} g_j(q_1,\dots,q_n)(p_j^2+U_j). \tag{II.1}$$

Here $\{p_j, q_j\}_{j=1}^n$ are canonical variables in $\mathbb{R}^{2n}$ with the standard symplectic structure and with the following Poisson brackets

$$\Omega_n=\sum_{j=1}^{n} dp_j\wedge dq_j, \quad \{p_j, q_k\}=\delta_{jk}. \tag{II.2}$$

Let us recall the Stäckel theorem.

Theorem 1: For a Hamiltonian system with Hamiltonian H of the form (II.1) the following assertions are equivalent:

(i) The associated Hamilton–Jacobi equation is separable.

(ii) There exists a nondegenerate $n\times n$ Stäckel matrix $\mathbf{S}$, whose elements $\mathfrak{s}_{kj}$ depend only on q_j:

$$\det \mathbf{S}\neq 0, \quad \frac{\partial \mathfrak{s}_{kj}}{\partial q_m}=0, \quad \text{for } j\neq m, \text{ and such that } \sum_{j=1}^{n} \mathfrak{s}_{kj}(q_j) g_j(q_1,\dots,q_n)=\delta_{k1}. \tag{II.3}$$

(iii) There exist n functionally independent integrals of motion which are quadratic in momenta.

Let $C=[c_{ik}]$ denote the inverse matrix to S such that $c_{j1}=g_j$. Then the Stäckel theorem[11,17] asserts that there are n first integrals of motion, namely

$$I_k=\sum_{j=1}^{n} c_{jk}(p_j^2+U_j), \quad I_1=H. \tag{II.4}$$

The common level surface of these integrals,

$$M_\alpha=\{z\in\mathbb{R}^{2n}: I_k(z)=\alpha_k, \quad k=1,\dots,n\},$$

is diffeomorphic to the n-dimensional real torus and one immediately obtains

$$p_j^2=\left(\frac{\partial S}{\partial q_j}\right)^2=\sum_{k=1}^n \alpha_k \mathfrak{s}_{kj}(q_j)-U_j(q_j), \tag{II.5}$$

where $S(q_1,\dots,q_n)$ is an action function.[1] If this real torus is part of a complex algebraic torus, then the corresponding mechanical system is called an algebraic completely integrable system.[18]

The Stäckel theorem allows one to reduce the solution of the equations of motion to a problem in algebraic geometry. We can regard each expression (II.5) as being defined on the Riemann surface

$$\mathscr{C}_j: \quad y_j^2=F_j(\lambda), \quad F_j(\lambda)=\sum_{k=1}^n \alpha_k \mathfrak{s}_{kj}(\lambda)-U_j(\lambda), \tag{II.6}$$

which depends on the values α_k of integrals of motion. All the pairs of variables (p_j,q_j) lie on these Riemann surfaces (II.6). Considered together, they determine an n-dimensional Lagrangian submanifold in $\mathbb{R}^{2n}$:

$$\mathscr{C}^{(n)}: \quad \mathscr{C}_1(p_1,q_1)\times\mathscr{C}_2(p_2,q_2)\times\cdots\times\mathscr{C}_n(p_n,q_n). \tag{II.7}$$

The associated Hamilton–Jacobi equation,

$$\frac{\partial S}{\partial t}+H\left(t,\frac{\partial S}{\partial q_1},\dots,\frac{\partial S}{\partial q_n},q_1,\dots,q_n\right)=0\Rightarrow g^{jj}\frac{\partial S}{\partial q_j}\frac{\partial S}{\partial q_j}=E, \tag{II.8}$$

on the local manifold $\mathscr{V}_n$ with diagonal metric $g^{jj}=g_j(q_1,\dots,q_n)$ analytic in the local coordinates $\{q_j\}$ has the following additive solution:

$$S(q_1,\dots,q_n)=\sum_{j=1}^n s_j(q_j), \quad s_j(q_j)=\int \sqrt{F_j(q_j)}\,dq_j, \tag{II.9}$$

with the functions $F_j(\lambda)$ defined in (II.6). Coordinates $q_j(t,\alpha_1,\dots,\alpha_n)$ are determined from the equations

$$\begin{gathered}\sum_{j=1}^n \int_{\gamma_0(p_0,q_0)}^{\gamma_j(p_j,q_j)} \frac{\mathfrak{s}_{1j}(\lambda)d\lambda}{\sqrt{\sum_{k=1}^n\alpha_k\mathfrak{s}_{1j}(\lambda)-U_j(\lambda)}}=\beta_1=t,\\ \sum_{j=1}^n \int_{\gamma_0(p_0,q_0)}^{\gamma_j(p_j,q_j)} \frac{\mathfrak{s}_{kj}(\lambda)d\lambda}{\sqrt{\sum_{k=1}^n\alpha_k\mathfrak{s}_{kj}(\lambda)-U_j(\lambda)}}=\beta_k, \quad k=2,\dots,n,\end{gathered} \tag{II.10}$$

where points $\gamma_j(p_j,q_j)$ and $\gamma_0(p_0,q_0)$ be on the curve $\mathscr{C}_j$ of (II.6). Notice that bounded motion in this case will not be periodic in general, but only conditionally periodic.[11,17] If λ_j^0 and λ_j are the turning points determined by the conditions that functions $F_j(\lambda)$ [(II.6) and (II.9)] vanish, the periods of the motion w_{jk} are equal to

$$w_{kj}=\int_{\lambda_j^0}^{\lambda_j}\frac{\mathfrak{s}_{kj}(\lambda)d\lambda}{\sqrt{F_j(\lambda)}}. \tag{II.11}$$

Thus, Stäckel[17] showed that the orthogonal coordinates $\{q_j\}_{j=1}^n$ permit separation in the Hamilton–Jacobi equation (II.8) if the metric

$$ds^2=\sum_{j=1}^n g_{jj}(q_1,\dots,q_n)(dq^j)^2, \quad g_{jj}(q_1,\dots,q_n)\equiv g_j(q_1,\dots,q_n), \tag{II.12}$$

is in the Stäckel form

$$g_{jj}(q_1,\ldots,q_n)=\mathsf{H}_j^2(q_1,\ldots,q_n)=\frac{\det \mathbf{S}}{\mathbf{S}^{j1}}, \qquad \text{(II.13)}$$

where S^{j1} means the cofactor of $\mathfrak{s}_{j1}$ in matrix S [(II.3)]. Here g_{jj} is a diagonal metric and H_j are called the Lamé coefficients. For a modern approach to construction of the Lamé coefficients, see Refs. 13–15.

Henceforth, we shall restrict our attention to the uniform Stäckel systems, where all the potentials $U_j(q_j)=U(q_j)$ and curves $\mathscr{C}_j$ [(II.6)] are equal. Variables $\{s_k,w_k\}$ [(II.9) and (II.11)] on a single curve $\mathscr{C}$ are the action-angle variables for the uniform Stäckel systems. To construct the metric $g_j(q_1,\ldots,q_n)$ and the potentials $U(q_j)$ in an explicit form we shall identify periods w_k [(II.11)] with periods of the Abel differentials on a common hyperelliptic curve $\mathscr{C}$ [(II.5)] along the elements of a homology basis.[1,6] In this case definition of the separated variables $\{q_j\}$ [(II.10)] leads to the Jacobi inversion problem. In the next section we prove that the Stäckel matrix **S** [(II.3)] is completely defined by the derivative of the Abel–Jacobi map $\mathscr{U}$ on $\mathscr{C}$ at generic point (the so-called Brill–Noether matrix).

III. UNIFORM STÄCKEL SYSTEMS AND ALGEBRAIC CURVES

To begin with, let us briefly recall some necessary facts about the action-angle variables on the Jacobian $J(\mathscr{C})$.[1,6,4] The main ingredient of this construction is a universal configuration space, which is the moduli space[10] of all algebraic curves with fixed jets of local coordinates at a fixed number of punctures. This concept is closely related to the notion of the Baker–Akhiezer function on admissible curves[14] and to the theory of algebraic completely integrable systems.[18]

Let us consider a genus g Riemann surface $\mathscr{C}$ with N ordered punctures P_j and with two special Abelian integrals y and λ with poles of order at most $l=(l_j)_{j=1}^N$ and $m=(m_j)_{j=1}^N$ at the punctures. The universal configuration space $\mathscr{M}_g(l,m)$ can then be defined as a moduli space of $\mathscr{C}$ under certain constraints on the set of algebraic geometrical data.[14,4] In this case the space $\mathscr{M}_g(l,m)$ is a complex manifold with only orbifold singularities. To introduce the local coordinates on $\mathscr{M}_g(l,m)$ we cut apart the Riemann surface $\mathscr{C}$ along a homology basis A_i, B_j, $j=1,\ldots,g$, with canonical intersection matrix

$$A_i\circ A_j=B_i\circ B_j=0,\quad A_i\circ B_j=\delta_{ij}. \qquad \text{(III.1)}$$

By selecting cuts from P_1 to other P_j for each $2\leqslant j\geqslant N$ one gets a well-defined branch of the Abelian integrals y and λ. Among the complete set of local coordinates on $\mathscr{M}_g(l,m)$, the following moduli are distinguished:

$$s_j=\oint_{A_j} y\,d\lambda,\quad j=1,\ldots,g. \qquad \text{(III.2)}$$

The universal configuration space $\mathscr{M}_g(l,m)$ is a base space for a hierarchy of fibrations $\mathscr{C}^{(k)}(l,m)$ of particular interest to us. These are the fibrations whose fiber above each point of $\mathscr{M}_g(l,m)$ is the kth symmetric power $S^k(\mathscr{C})$ of $\mathscr{C}$. This fiber $\mathscr{C}^{(k)}(l,m)$ is the set of all effective divisors $D=\gamma_1+\cdots+\gamma_k$ (the γ_j's may not be mutually distinct) of deg k of $\mathscr{C}$, i.e., $\mathscr{C}^{(k)}(l,m)$ can be identified with the set of all unordered k-tuples $\{\gamma_1,\ldots,\gamma_k\}$, where the γ_j's are arbitrary elements of $\mathscr{C}$.

Let $\mathscr{D}$ be the open set in $\mathscr{M}_g(l,m)$, where the zero divisors of dy and $d\lambda$ do not intersect. Fixing all the local coordinates on $\mathscr{M}_g(l,m)$ except s_j [(III.2)], one can determine a smooth g-dimensional foliation of $\mathscr{D}$, independent of the choice we made to define the coordinates themselves.[4] Hereafter, by abuse of notation, one leaf of this foliation is denoted just by $\mathscr{M}$, and $\mathscr{C}^{(k)}$ means the above fibrations restricted to $\mathscr{M}$.

Let $dS=y\,d\lambda$ be a meromorphic one-form on $\mathscr{C}$ with the special Abelian integrals y and λ, which have fixed expansions near the punctures P_j.[4] It means that we have imposed certain constraints on the algebraic geometrical data (according to Ref. 14 we used admissible data). These constraints ensure the existence of a global system of action-angle variables and the presence of the corresponding symplectic form.[5] The fact that we impose some constraints provides us with additional properties of dS. Namely, generating one-form dS possesses the property

$$\frac{\partial dS}{\partial s_j}=\frac{\partial y d\lambda}{\partial s_j}=dw_j\,,\quad j=1,...,g, \tag{III.3}$$

where s_j are action coordinates of (III.2) on the moduli space $\mathscr{M}$ and differentials of the angle variables dw_j form some basis of holomorphic differentials (normally, even if the differential is holomorphic, its moduli derivative is not). Moreover, form dS gives rise to differentials spanning a whole space $\mathscr{H}_1(\mathscr{C})$ of holomorphic differentials. Hence, for any generic divisor $D=\gamma_1+\cdots\gamma_g$ on $\mathscr{C}$ the standard two-form on $\mathscr{C}^{(g)}$,

$$\Omega_g=\delta\left(\sum_{j=1}^{g} y(\gamma_j)d\lambda(\gamma_j)\right)=\sum_{j=1}^{g}\delta y(\gamma_j)\wedge d\lambda(\gamma_j)=\sum_{j=1}^{g} ds_j\wedge dw_j \tag{III.4}$$

is a desired holomorphic symplectic form Ω_g on $\mathscr{C}^{(g)}$. The set of variables $\{s_j,w_j\}_{j=1}^{g}$ is the complete set of action-angle variables on $J(\mathscr{C})$. These action-angle variables $\{s_j,w_j\}$ have been obtained by generalizing the definition of actions introduced for integrable systems on tori in the form of periods of holomorphic differentials dw_j along the elements of a homology basis in Refs. 1 and 6.

Now we turn to the uniform Stäckel systems. The corresponding algebraic curve (II.6) is a hyperelliptic curve given by an equation of the form

$$\mathscr{C}:\quad y^2=\prod_{i=1}^{2g+1}(\lambda-\lambda_i), \tag{III.5}$$

and puncture P is the point at infinity $\lambda=\infty$. Recall that the moduli λ_j of $\mathscr{C}$ are integrals of motion (II.6). Solution to the inverse Jacobi problem and associated Abel–Jacobi map on $\mathscr{C}$ relate a set of the action-angle variables and the separated variables.

Variables of separation $q_j(t)$ give the solution to the inverse Jacobi problem (II.10). The associated Abel–Jacobi map $\mathscr{U}$: Div $(\mathscr{C})\to J(\mathscr{C})$ is restricted to Lagrangian submanifold $\mathscr{C}^{(k)}$:

$$\mathscr{U}:\quad \mathscr{C}^{(k)}\to J(\mathscr{C}). \tag{III.6}$$

Note that whenever we discuss the Abel–Jacobi map, we shall tacitly assume that a base point γ_0 [(II.10)] on $\mathscr{C}$ has already been fixed in an appropriate position.

Suppose that point $D=\gamma_1+\cdots+\gamma_k$, $k\leqslant g$ belongs to $\mathscr{C}^{(k)}$. The differential of the Abel–Jacobi map (III.6) at the point D is a linear mapping from the tangent space $T_D(\mathscr{C}^{(g)})$ of $\mathscr{C}^{(g)}$ at the point D into the tangent space $T_{\mathscr{U}(D)}(J(\mathscr{C}))$ of $J(\mathscr{C})$ at the point $\mathscr{U}(D)$:

$$\mathscr{U}_D^*:\quad T_D(C^{(k)})\to T_{\mathscr{U}(D)}(J(\mathscr{C})).$$

Now suppose that D is a generic divisor, and z_j is a local coordinate on $\mathscr{C}$ near the point γ_j. Then $(z_1,\ldots,z_k)$ yields a local coordinate system near the point D in $\mathscr{C}^{(k)}$. Let dw_k $(k=1,...,g)$ be a basis for a space $\mathscr{H}_1(\mathscr{C})$ of holomorphic differentials on $\mathscr{C}$, and near γ_j

$$dw_k=\phi_{kj}(z_j)dz_j\,,$$

where $\phi_{kj}(z_j)$ is holomorphic. It follows that the Abel–Jacobi map $\mathscr{U}$ can be expressed near D as

$$\mathscr{U}(z_1,\ldots,z_k)=\left(\sum_{j=1}^{k}\int_{\gamma_0}^{z_j}\phi_{1j}(z_j)dz_j\,,\ldots,\sum_{j=1}^{k}\int_{\gamma_0}^{z_j}\phi_{gj}(z_j)dz_j\right).$$

Hence

$$\mathscr{U}_D^*=\begin{pmatrix}\phi_{11}(\gamma_1) & \cdots & \phi_{g1}(\gamma_1)\\ \vdots & \ddots & \vdots\\ \phi_{1k}(\gamma_k) & \cdots & \phi_{gk}(\gamma_k)\end{pmatrix} \tag{III.7}$$

is the so-called Brill–Noether matrix.

Theorem 2: Transpose the Brill–Noether matrix $\mathscr{U}_D^*$ on the genus $g \geqslant n$ hyperelliptic curve $\mathscr{C}$, which is the derivative of the Abel–Jacobi map $\mathscr{U}$ at generic divisor D ($\deg D = n$) is equal to the Stäckel matrix $\mathbf{S}$ for the uniform Stäckel system on $\mathbb{C}^{2n}$ with metric

$$g_{jj}(q_1,\ldots,q_n) = \frac{\det \mathbf{S}}{\mathbf{S}^{j1}}.$$

At generic point D, $\deg D = g$ matrix $\mathbf{S} = U_D^{*t}$ is a regular matrix satisfying the Stäckel theorem.

At $g > n$ we have to consider restriction of the Abel–Jacobi map (III.6) onto $\mathscr{C}^{(n)}$. In this case the symplectic form Ω_n on $\mathscr{C}^{(n)}$ is an appropriate projection of Ω_g [(III.4)] and $\mathscr{C}^{(n)}$ is a Lagrangian submanifold in the phase space $\mathbb{C}^{2n}$. The separated variables $\{p_j, q_j\}_{j=1}^n$ are constructed from the first $2n$ action-angle variables (III.9) only, and the action differential $dS = \Sigma_{j=1}^n p_j dq_j$ gives rise to an n-dimensional chart of the whole space $\mathscr{H}_1(\mathscr{C})$. The corresponding $n \times n$ Stäckel matrix is the left upper $n \times n$ block of the general matrix $\mathbf{S} = U_D^{*t}$ and, therefore, unless otherwise indicated, we assume $n = g$.

As an example, let us consider some basis for $\mathscr{H}_1(\mathscr{C})$, for instance,

$$dw_j = \frac{\lambda^{j-1}}{y(\lambda)}\, d\lambda, \quad j = 1,\ldots,g. \tag{III.8}$$

By choosing this basis we fix a basis of action-angle variables (III.2)–(III.4). To solve the Jacobi inversion problem (II.10) one obtains variables of separation

$$p_j = y(\gamma_j), \quad q_j = \lambda(\gamma_j), \quad j = 1,\ldots,g, \tag{III.9}$$

for a generic point $D = \gamma_1 + \cdots + \gamma_g$ on $\mathscr{C}$, which coincides with the divisor of simple poles of the corresponding Baker–Akhiezer function.[14] In the real case (when p_j and q_j are real), the separated variables q_j from (III.9) (so-called root variables) vary along cycles A_j [(III.1)] over basic cuts on $\mathscr{C}$ and, therefore, our problem is defined on a g-dimensional real torus. The holomorphic symplectic form Ω_g on $\mathscr{C}^{(g)}$ coincides with standard ones of (II.2) and a fiber $\mathscr{C}^{(g)}$ is a complex Lagrangian submanifold of the phase space $\mathbb{C}^{2g}$ [(II.7)]:

$$\mathscr{C}^{(n)} \equiv S^n(\mathscr{C}): \quad (\mathscr{C}(\lambda) \times \mathscr{C}(\mu) \times \cdots \times \mathscr{C}(\nu))/\sigma_n, \quad n \leqslant g, \tag{III.10}$$

where σ_n is the permutation group on n letters.

Recall that the derivative $\mathscr{U}_D^*$ bears a great resemblance to the usual Gauss mapping. The map $\mathscr{U}_D^*$ induces a canonical mapping from $\mathscr{C}$ into the $(g-1)$-dimensional projective space $\mathscr{C} \to \mathbb{P}^{g-1}$. On the other hand, the canonical mapping is defined by the derivative of the Abel–Jacobi map. For a hyperelliptic curve $\mathscr{C}$ of genus $g \geqslant 2$, the canonical map $\mathscr{C} \to \mathbb{P}^{g-1}$ is the composition of the double covering map $\mathscr{C} \to \mathbb{P}^1$, sending (y,λ) to λ, with the Veronese map $\mathbb{P}^1 \to \mathbb{P}^{g-1}$ given by a basis for the polynomial ring of degree $g-1$. With respect to the basis of $\mathscr{H}_1(\mathscr{C})$ in (III.8), the canonical map of $\mathscr{C}$ has an extremely simple expression:

$$(y,\lambda) \to \lambda \to [\lambda^{g-1}, \lambda^{g-2}, \ldots, \lambda, 1].$$

By using this map we introduce the $g \times g$ matrix

$$\mathbf{S}(\lambda,\mu,\ldots,\nu) = \begin{pmatrix} \lambda^{g-1} & \mu^{g-1} & \cdots & \nu^{g-1} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda & \mu & \cdots & \nu \\ 1 & 1 & \cdots & 1 \end{pmatrix}, \tag{III.11}$$

determined on the Lagrangian submanifold (III.10). For a generic point $D = \gamma_1 + \cdots + \gamma_g$ in (III.9), the Stäckel matrix is equal to

$$\mathbf{S}(q_1, q_2, \ldots, q_g) = \mathbf{S}(\lambda, \mu, \ldots, \nu)|_{\lambda = q_1, \mu = q_2, \ldots, \nu = q_g}, \quad \mathfrak{s}_{kj}(q_j) = \lambda^{g-k}|_{\lambda = q_j}. \tag{III.12}$$

Recall that the diagonal metric g_{jj} is completely determined by the corresponding Stäckel matrix (II.13). Nevertheless, we introduce another equivalent definition of the metric. Substituting the Stäckel matrix (III.12) in the algebraic equation (II.3) one obtain,

$$\sum_{j=1}^{g} \mathfrak{s}_{kj}(q_j) g_{jj}(q_1,q_2,\ldots,q_g) = \delta_{k1} = \sum_{j=1}^{g} \operatorname{Res}|_{\lambda=q_j} \frac{\lambda^{k-1}}{e(\lambda)} = \frac{1}{2\pi i} \oint_C \frac{\lambda^{k-1}}{e(\lambda)}, \qquad \text{(III.13)}$$

where, by definition,

$$g_{jj}(q_1,q_2,\ldots,q_n) = \operatorname{Res}|_{\lambda=q_j} \frac{1}{e(\lambda)}.$$

Here we introduced function $e(\lambda)$, which has zeroes at the points q_j giving the solution of the inverse Jacobi problem.

In general, function $e(\lambda)$ with g zeroes, which are solutions of inverse Jacobi problem, is expressed in the Riemann theta-function

$$e(\lambda) = \theta(\mathcal{U}(\gamma_1,\ldots,\gamma_g) - \beta - K), \quad \mathcal{U}(\gamma_1,\ldots,\gamma_g) = \mathcal{U}(\gamma_1) + \cdots + \mathcal{U}(\gamma_g). \qquad \text{(III.14)}$$

Here K is a vector of the Riemann constants and $\beta = (\beta_1,\ldots,\beta_g) \in \mathbb{C}^g$ is a fixed vector.[3] The principal properties of the function $e(\lambda)$ in (III.14) are considered in Ref. 3.

Proposition 1: Function $e(\lambda)$ on $\mathcal{C}$ with g zeroes (p_j, q_j) giving solution to the Jacobi inversion problem is completely defined by the metric $g_{jj}(q_1,q_2,\ldots,q_n)$ [(III.13)] for a uniform Stäckel system.

We prove this proposition in the polynomial ring only. In this case

$$e(\lambda) = \prod_{k=1}^{g} (\lambda - q_k), \qquad \text{(III.15)}$$

and

$$g_{jj}(q_1,q_2,\ldots,q_g) = \operatorname{Res}|_{\lambda=q_j} e^{-1}(\lambda) = \frac{1}{\Pi_{j\neq k}^{g}(q_j - q_k)}. \qquad \text{(III.16)}$$

To prove (III.13) for this metric, it suffices to consider the following integral:

$$\frac{1}{2\pi i} \oint_C \frac{\lambda^k}{e(\lambda)} = \sum_{j=1}^{g} \operatorname{Res}|_{\lambda=q_j} \frac{\lambda^k}{e(\lambda)} = -\operatorname{Res}|_{\lambda=\infty} \frac{\lambda^k}{e(\lambda)} = \delta_{k,g-1}, \qquad \text{(III.17)}$$

where C encloses all q_j.

The function $e(\lambda)$ is defined on the universal configuration space, i.e., it is independent on the moduli λ_j of $\mathcal{C}$ (integrals of motion) and on a choice of the basis of holomorphic differentials in $\mathcal{H}_1(\mathcal{C})$. For instance, in the polynomial ring let us consider a set of the equivalent Stäckel matrices with the following entries (III.7):

$$\mathfrak{s}_{kj}(\lambda)|_{q_j} = \phi_{kj}(\lambda)|_{q_j}, \quad \phi_{kj}(\lambda) = \lambda^{g-k} + a_1^{(j)} \lambda^{g-k-1} + \cdots + a_{g-k}^{(j)}, \qquad \text{(III.18)}$$

where polynomials ϕ_{kj} form various bases for the polynomial ring of degree $g-1$. Substituting (III.18) in (III.13) and (III.17) one obtains at once universal solution $e(\lambda)$ of (III.15). Below we shall see that the Hamiltonian H [(II.1)] with the diagonal metric g_{jj} [(III.16)] is closely related to the distinguished puncture P at infinity $\lambda = \infty$ on the hyperelliptic curve $\mathcal{C}$ [(III.5)]. The different Stäckel matrices (III.18) correspond to the distinct sets of the integrals of motion in the involution for a single Hamiltonian H. The completeness and functional independence of these integrals directly follows from the completeness and independence of the basis elements (III.18) for a polynomial ring.

Finally, we look at other fibrations $\mathcal{C}^{(n)}$ at $n \neq g$. At $g > n$, to construct the metric $g_{jj}(q_1,\ldots,q_n)$ on $\mathcal{C}^{(n)}$, we expand the initial curve $\mathcal{C}$ [(III.5)] by

$$y^2=\prod_{i=1}^{2g+1}(\lambda-\lambda_i)=U_{2g+1}(\lambda)+\prod_{i=1}^{2n+1}(\lambda-\tilde{\lambda}_i),\quad n\leqslant g. \tag{III.19}$$

Here $U_{2g+1}(\lambda)$ is an at most $2g+1$ order polynomial, which is regarded as a potential in (II.6). The $n\times n$ Stäckel matrix and the corresponding function $e(\lambda)$ may be associated to the auxiliary genus n curve

$$\tilde{\mathscr{C}}:\quad \tilde{y}^2=\prod_{i=1}^{2n+1}(\lambda-\tilde{\lambda}_i). \tag{III.20}$$

The function $e(\lambda)$ is independent on the moduli of $\mathscr{C}$ [(III.19)] and, therefore, uniform potential U_{2g+1} in (III.19) has an arbitrary form and decomposition (III.19) determines the highest power of the polynomial $U(\lambda)$ only.

At $n>g$ the above holomorphic symplectic form Ω_g on the leaves $\mathscr{M}$ is degenerate. However, a nondegenerate form on $\mathscr{C}^{(n)}$ may be obtained by restricting $\mathscr{C}^{(n)}$ to the larger leaves $\tilde{\mathscr{M}}$ of the foliation.[4] The leaves $\tilde{\mathscr{M}}$ correspond to the level sets of all the local coordinates except to holomorphic s_j [(III.2)] and to some additional $(n-g)$ coordinates associated to meromorphic differentials $d\tilde{w}_j$ in (III.3) and (III.4). In fact, to construct the action-angle variables, we have to add several meromorphic differentials to holomorphic angle variables. Thus, at $n>g$ the symplectic two-form Ω_n on $\mathscr{C}^{(n)}$ is meromorphic.[4]

As an example, at $n=g+1$, we can add one local coordinate in the neighborhood of puncture P at infinity.[4] This additional coordinate occurs in the Stäckel matrix and in the metric in the following way:

$$\begin{gathered}\mathbf{S}^{(g+1)}(\lambda,\mu,\ldots,\nu)=q_0\mathbf{S}^{(g)}(\lambda,\mu,\ldots,\nu),\\ e(\lambda)=q_0\prod_{j=1}^{n}(\lambda-q_j),\quad g_{00}=\mathrm{Res}|_{\lambda=\infty}\frac{\lambda^{g-1}}{g(\lambda)}.\end{gathered} \tag{III.21}$$

At $n>g$ these systems with meromorphic form Ω_n possess several reductions of the additional meromorphic coordinates, for instance $q_0=\text{const}$ in (III.21).[19]

The above formulas are well adjusted for generalization. If the curve $\mathscr{C}$ in (III.5) is substituted by

$$\mathscr{C}:\quad y^2=F(\lambda)=\frac{P_l(\lambda)}{Q_m(\lambda)}=\frac{\Pi_{j=1}^{2g+1}(\lambda-\lambda_j)}{\Pi_{k=1}^{m}(\lambda-\delta_k)},\quad m\leqslant 2g+1, \tag{III.22}$$

where $\{\delta_k\}$ is a set of m arbitrary constant, one obtains

$$\mathfrak{s}_{kj}(\lambda)|_{\lambda=q_j}=\left.\frac{\phi_{kj}(\lambda)}{Q_m(\lambda)}\right|_{q_j},\quad e(\lambda)=\frac{\Pi_{j=1}^{g}(\lambda-q_j)}{Q_m(\lambda)}. \tag{III.23}$$

Note that the algebraic equation (III.13) is covariant with respect to the transformations

$$\mathbf{S}\to R^{-1}(\lambda)\mathbf{S},\quad e(\lambda)\to R^{-1}(\lambda)e(\lambda),$$

which leads to the general form of the metric

$$g_{jj}(q_1,q_2,\ldots,q_n)=\mathrm{Res}|_{\lambda=q_j}\left(\frac{Q_m(\lambda)R(\lambda)}{\Pi_{j=1}^{g}(\lambda-q_j)}\right) \tag{III.24}$$

associated to the curve $\mathscr{C}$. We shall use this freedom to consider the standard curvilinear coordinate systems.[11,12,20]

So, the hyperelliptic genus g curve $\mathscr{C}$ may be associated to a family of the uniform Stäckel systems on the phase space $\mathbb{C}^{2n}$ by using the Abel–Jacobi map $\mathscr{U}$, its differential $\mathscr{U}_D^*$, and their restrictions on $\mathscr{C}^{(n)}$. Diagonal metric $g_{jj}(q_1,q_2,\dots,q_n)$ [(II.13)] in the Hamiltonian (II.1) is completely defined by number of degrees of freedom *n*, and potential $U(\lambda)$ is at most $2g+1$ order arbitrary polynomial.

On the other hand, one fixed metric $g_{jj}(q_1,\dots,q_n)$ may be associated to an infinite set of the hyperelliptic curves $\mathscr{C}$. The corresponding Hamiltonian systems differ from each other by the power and by the form of polynomial potentials $U(\lambda)$ in (III.19). Among these systems we must distinguish systems on $\mathscr{C}^{(n)}$ at $n>g$ [(III.10)] for which the number of degrees of freedom *n* is more than the genus g of the associated curve $\mathscr{C}$. In this case the corresponding symplectic two-form on $\mathscr{C}$ is meromorphic.[4] In the next section, we shall identify these systems with the degenerate or superintegrable systems.[21] Recall that for the degenerate system the number of independent integrals of motion is more than the number of degrees of freedom.

IV. THE LAX REPRESENTATIONS

Let us recall that the key idea, which has started the modern age in the study of classical integrable systems, is to bring them into the Lax form. All the properties of the uniform Stäckel systems may be recovered from the properties of the Abel map. Nevertheless, now we want to obtain the Lax representations for all the uniform Stäckel systems associated to the hyperelliptic curve $\mathscr{C}(y,\lambda)$ in (III.5). We consider construction of the Lax representation as a necessary intermediate step to study quantum counterparts of the Stäckel systems.

In the simplest case the Lax matrices $L(\lambda)$ or $L(y)$ are defined as the matrix-valued functions on bare spectral curves F_λ, $\lambda\in F_\lambda$ [(I.1)] or F_y, $y\in F_y$, while the full spectral curve $\mathscr{C}(y,\lambda)$ is given by the Lax eigenvalue equations

$$\mathscr{C}:\quad \det(L(\lambda)-y)=0,\quad \det(L(y)-\lambda)=0. \tag{IV.1}$$

As a result, $\mathscr{C}$ arises as a ramified covering over the bare spectral curve F_λ or F_y.[22]

Until now a delicate question was how to construct the Lax matrices $L(\lambda)$ or $L(y)$ for a given integrable system. The one integrable system may be associated to the different curves and one curve $\mathscr{C}$ may be associated to the different mechanical integrable system on a common phase space. As an example, the *n*-particles Toda lattice can be equivalently formulated in terms of two different Lax representations[23] associated to the single hyperelliptic curve $\mathscr{C}$.

Here we consider the equation for a general algebro-geometric symplectic structure associated to the spectral curve $\mathscr{C}$ of the given Lax representation *L*,

$$\Omega_n=-\sum_\alpha \operatorname{Res}_{P\alpha}\frac{\langle \delta\psi^+\wedge\delta L\,\psi\rangle}{\langle\psi^+\psi\rangle}, \tag{IV.2}$$

proposed in Ref. 4. Here Ω_n is the restriction of the algebro-geometrical symplectic form (III.4) on $\mathscr{C}$ generated by two differentials dy and $d\lambda$ having poles at punctures P_α. Functions ψ and ψ^+ are the Baker–Akhiezer function on $\mathscr{C}$ and its dual function. If we fix some two-form Ω_n and the Baker–Akhiezer functions ψ, ψ^+ on a given curve $\mathscr{C}$, then one can attempt to recover the associated Lax matrix *L*.

For some particular Stäckel systems the 2×2 Lax matrices[20,24] and the corresponding vector Baker–Akhiezer function $\vec{\psi}$ associated to natural vector fields on the Jacobian of any hyperelliptic curve are known. On the other hand, we know the general scalar Baker–Akhiezer function ψ on *C* defined by its analytical properties on $\mathscr{C}$, which corresponds to geodesic systems with diagonal metric.[14]

Note here we have the vector Baker–Akhiezer function $\vec{\psi}$, which is the eigenfunction of the matrix *L* associated to the curve $\mathscr{C}$, and the scalar Baker–Akhiezer ψ, which is completely defined by analytical properties on the same curve $\mathscr{C}$.

For the uniform Stäckel systems let us identify the preassigned symplectic structure Ω [(II.2)] with the symplectic structure (III.4) defined on a hyperelliptic algebraic curve $\mathscr{C}$. Next we try to recover Lame matrix for a geodesic motion under the following additional assumptions:

(1) $L(\lambda)$ is a generic 2×2 matrix associated to a spectral hyperelliptic curve $\mathscr{C}$ of genus $g=[(n-1)/2]$.

(2) The associated vector Baker–Akhiezer function $\vec{\psi}$ has a constant normalization $\vec{\alpha}$:[25]

$$\langle\vec{\alpha},\vec{\psi}\rangle=\alpha_1\psi_1+\alpha_2\psi_2=1,\quad \vec{\alpha}=(0,1).$$

(3) The first component of $\vec{\psi}$ in (IV.2) is proportional to the unique Baker–Akhiezer function ψ on $\mathscr{C}$ with fixed analytical properties.[14]

At the first assumption n is a number of integrals of motion, which are moduli of C ($n=2g+1$) and, therefore, form Ω_n in (IV.2) is a restriction of meromorphic symplectic form Ω_g in (III.4) to the minimal n-dimensional leaf $\widetilde{\mathscr{M}}$ (Ref. 4) for integrable systems on $\mathbb{C}^{2n}$. The second assumption allows us to reduce the vector Baker–Akhiezer function to a scalar one. In this case, the solution of (IV.2) is completely defined by the function ψ on $\mathscr{C}$ only. At first we present this particular solution in terms of the function $e(\lambda)$ associated to the Abel map $\mathscr{U}$. We introduce the function $e(\lambda)$ and its time derivative

$$e(\lambda)=\frac{\Pi_{j=1}^{n}(\lambda-q_j)}{\Pi_{k=1}^{m}(\lambda-\delta_k)},\quad m\leqslant n,\quad e_x(\lambda)=\{H,e(\lambda)\},\tag{IV.3}$$

where $\{\delta_k\}$ is a set of m arbitrary constant and H is a Hamiltonian of the geodesic motion

$$H=\sum_{j=1}^{n} g_{jj}(q_1,\ldots,q_n)p_j^2,\quad g_{jj}(q_1,\ldots,q_n)=\mathrm{Res}|_{\lambda=q_j}\frac{1}{e(\lambda)}.\tag{IV.4}$$

Thus, in the Lax equation for a geodesic motion

$$L_x(\lambda)=\{H,L\}=[L,A],$$

matrices L and A are given by

$$L(\lambda)=\begin{pmatrix}-e_x/2 & e\\ -e_{xx}/2 & e_x/2\end{pmatrix}(\lambda)\equiv\begin{pmatrix}h & e\\ f & -h\end{pmatrix}(\lambda),$$
$$A(\lambda)=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}.\tag{IV.5}$$

The Hamiltonian H in (IV.4) is equal to a highest residue at the distinguished Weierstrass point on $\mathscr{C}$ at infinity $\lambda=\infty$,

$$H=-\mathrm{Res}|_{\lambda=\infty}\lambda^{n-m}\det L(\lambda),\tag{IV.6}$$

where the full spectral curve $\mathscr{C}$ is equal to

$$\mathscr{C}:\quad y^2=F(\lambda)\equiv\det L(\lambda),$$
$$F(\lambda)=-h^2(\lambda)-e(\lambda)f(\lambda)=\frac{e\cdot e_{xx}}{2}-\frac{e_x^2}{4}.\tag{IV.7}$$

By definition the zeroes of $e(\lambda)$ are separation variables and conjugated variables p_j are given by

$$p_j=h(\lambda)|_{\lambda=q_j},\quad h(\lambda)=-e_x/2=e(\lambda)\sum_{j=1}^{n}\frac{g_{jj}(q_1,\ldots,q_n)p_j}{\lambda-q_j}.\tag{IV.8}$$

In accordance with Ref. 25 pairs of separation variables (q_j,p_j) lie on the spectral curve $\mathscr{C}$:

$$y^2(\gamma_j)=p_j^2=h^2(\lambda)|_{\lambda=q_j}=-F(\lambda=q_j)=-F(\lambda)|_{\gamma_j}.$$

As usual, the rational function $F(\lambda)$ admits some different representations:

$$F(\lambda)=\frac{\Sigma_{j=1}^{n}I_j\lambda^{n-j}}{\Pi_{k=1}^{m}(\lambda-\delta_k)}=\sum_{k=1}^{m}\frac{J_k}{(\lambda-\delta_k)}+\sum_{k=m+1}^{n}J_k\lambda^{n-k-1}.\tag{IV.9}$$

Here $\{I_j\}_{j=1}^n$ and $\{J_k\}_{k=1}^n$ are two sets of independent integrals of motion in the involution. The first set of integrals $\{I_j\}_{j=1}^n$ in (IV.9) corresponds to the Stäckel matrix in (III.11). The set of equivalent Stäckel matrices (III.18) relate to another decomposition of a numerator of $F(\lambda)$ in (IV.9). The second set of integrals $\{J_k\}_{k=1}^n$ in (IV.9) is associated to an expansion near punctures $\{\delta_k,\infty\}$ on $\mathscr{C}$.

The spectral curve $\mathscr{C}$ in (IV.1) is a time-independent curve and, therefore,

$$\{H,F(\lambda)\}=0\Rightarrow\partial_x^3 e(\lambda)=e_{xxx}=0. \tag{IV.10}$$

Thus, in fact,[26] we consider the polynomial solutions $e(\lambda)=\Pi(\lambda-q_j(t))$ to the equation (IV.10) and describe the Hamiltonian dynamics of their zeroes $q_j(t)$ (recall that ∂_x means derivative by time).

Substituting function $e(\lambda)$ from (IV.3) and Hamiltonian H from (IV.4) into (IV.10) one obtains the equations in the metric $g_{jj}=\mathsf{H}_j^2$ from (II.12). If we introduce so-called rotation coefficients,

$$\beta_{ij}=\frac{\partial_i\mathsf{H}_j}{\mathsf{H}_i},\quad i\neq j, \tag{IV.11}$$

these equations may be reduced to the following equations:[13]

$$\begin{gathered}\partial_k\beta_{ij}=\beta_{ik}\beta_{kj},\quad i\neq j\neq k,\\ \partial_i\beta_{ij}+\partial_j\beta_{ji}+\sum_{m\neq i,j}\beta_{mi}\beta_{mj}=0,\quad i\neq j,\end{gathered} \tag{IV.12}$$

where the notation $i\neq j\neq k$ means that indices i,j,k are distinct.

Of course, these equations may be obtained without any Lax representation by using definition (II.13) of the metric, properties of the Abel-Jacobi map, and preassigned asymptotic behavior of $e(\lambda)$ at the distinguished point $\lambda=\infty$.

The equations (IV.12) are equivalent to the vanishing conditions of all *a priori* nontrivial components of the curvature tensor.[13–15] Therefore, using (IV.12) we conclude that the local Riemannian submanifold $(\mathscr{V}_n,g|_{\mathscr{V}})$ in (II.8) of the Riemannian manifold $(\mathbb{C}^n,g)$ is a flat manifold whose metric is diagonal with respect to the coordinates $\{q_j\}$. Imposing some additional restrictions on the space of solutions to (IV.2),[19] one could get the Bourlet type equations[15] related to another Riemannian manifold of constant curvature.

To construct more general solutions to (IV.2) associated to hyperelliptic curve $\mathscr{C}$ of higher genus we begin with the calculation of the Poisson bracket relations for the initial Lax matrix $L(\lambda)$. It allows us to identify the space of solutions to Eq. (IV.2) with the loop algebra $\mathscr{L}$(sl(2)) in fundamental representation[23] and then to use the representation theory of the underlying algebra sl(2).[27]

Theorem 3: The Poisson bracket relations for the matrix $L(\lambda)$ [(IV.5)] are closed into the following r-matrix algebra at $m\leqslant n$ only:

$$\{\overset{1}{L}(\lambda),\overset{2}{L}(\mu)\}=[r_{12}(\lambda,\mu),\overset{1}{L}(\lambda)]-[r_{21}(\lambda,\mu),\overset{2}{L}(\mu)]. \tag{IV.13}$$

Here the standard notations are introduced:

$$\begin{gathered}\overset{1}{L}(\lambda)=L(\lambda)\otimes I,\quad \overset{2}{L}(\mu)=I\otimes L(\mu),\\ r_{12}(\lambda,\mu)=\frac{\Pi}{\lambda-\mu},\quad r_{21}(\lambda,\mu)=\Pi r_{12}(\mu,\lambda)\Pi,\end{gathered} \tag{IV.14}$$

and Π is the permutation operator of auxiliary spaces.[23]

The Poisson bracket relations for the Lax matrix $L(\lambda)$ in (IV.5) are preassigned by the initial symplectic structure (III.4). It is necessary to calculate two brackets only:

$$\{e(\lambda),e(\mu)\}=0 \tag{IV.15}$$

and

$$\begin{aligned}\{h(\lambda),e(\mu)\}&=\left\{e(\lambda)\sum_{j=1}^{n}\frac{g_{jj}(q_1,\ldots,q_n)p_j}{\lambda-q_j},\frac{\Pi_{j=1}^{n}(\lambda-q_j)}{\Pi_{k=1}^{m}(\lambda-\delta_k)}\right\}\\&=-e(\lambda)e(\mu)\sum_{j=1}^{n}\frac{g_{jj}}{(\lambda-q_j)(\mu-q_j)}\\&=\frac{e(\lambda)e(\mu)}{\lambda-\mu}\sum_{j=1}^{n}\left(\frac{g_{jj}}{\lambda-q_j}-\frac{g_{jj}}{\mu-q_j}\right)=\frac{1}{\lambda-\mu}[e(\mu)-e(\lambda)],\end{aligned} \tag{IV.16}$$

where we used a standard decomposition of rational function

$$e^{-1}(\lambda)=\sum_{j=1}^{n}\frac{g_{jj}}{\lambda-q_j},\quad g_{jj}=\mathrm{Res}|_{\lambda=q_j}e^{-1}(\lambda).$$

Another Poisson bracket may be directly derived from these brackets and by definition of the entries of the Lax matrix $L(\lambda)$ in (IV.5) via derivative of the single function $e(\lambda)$

$$\begin{aligned}&\{h(\lambda),h(\mu)\}=0,\\&\{f(\lambda),e(\mu)\}=\partial_x\{h(\lambda),e(\mu)\}=\frac{2}{\lambda-\mu}[h(\lambda)-h(\mu)],\\&\{f(\lambda),h(\mu)\}=-\frac{1}{2}\partial_x^2\{h(\lambda),e(\mu)\}=\frac{1}{\lambda-\mu}[f(\lambda)-f(\mu)],\\&\{f(\lambda),f(\mu)\}=-\tfrac{1}{2}\partial_x^3\{h(\lambda),e(\mu)\}=0.\end{aligned} \tag{IV.17}$$

To derive the first bracket we have to combine second and first derivatives of the brackets (IV.15) and (IV.16), respectively. At the last bracket one substitutes the equation of motion (IV.10).

If, contrary to our geometric conventions, the order of polynomial $Q_m(\lambda)$ is more than an order of polynomial P_l in (III.22), i.e., if $m>n$ in the metric (IV.5), then the rational function $e(\lambda)$ admits another representation,

$$e^{-1}(\lambda)=\sum_{j=1}^{n}\frac{g_{jj}}{\lambda-q_j}+\xi(\lambda,q_1,\ldots,q_n),$$

where remainder $\xi(\lambda)$ is a certain polynomial. Substituting this function $e(\lambda)$ into (IV.15)–(IV.17) one obtains

$$\frac{\partial\xi(\lambda,q_1,\ldots,q_n)}{\partial\lambda}=0.$$

This constraint to remainder $\xi(\lambda,q_1,\ldots,q_n)$ directly follows from the symmetry of the last Poisson bracket in (IV.17).

The r-matrix algebra (IV.13) is the so-called linear case of the r-matrix algebras corresponding to integrable systems, which are modelled on coadjoint orbits of the Lie algebra sl(2). The r-matrix in (IV.14) is a standard rational r-matrix on $\mathscr{L}$(sl(2)).[28] The general form of the function $e(\lambda)$ in (III.14) leads to the elliptic and trigonometric r-matrices.[28,29]

Thus, for a geodesic motion (IV.4), the Lax representation (IV.5) with arbitrary poles $\{\delta_k\}_{k=1}^m$ in (IV.3) may be regarded as a generic point at the loop algebra $\mathscr{L}$(sl(2)) in fundamental representation after an appropriate completion.[28] To construct the Lax representation for a potential motion with the fixed metric $g_{jj}(q_1,\dots,q_n)$ in (IV.3), we can use the outer automorphism of the space of infinite-dimensional representations of sl(2) proposed in Ref. 27.

Applying this automorphism of the underlying algebra sl(2) directly to the Lax representation $L(\lambda)$ in (IV.5) on $\mathscr{L}$(sl(2)) we obtain a family of the new Lax pairs:

$$L'(\lambda)=L(\lambda)-\sigma_-\cdot[\phi(\lambda)^{-1}(\lambda)]_N,\quad \sigma_-=\begin{pmatrix}0&0\\1&0\end{pmatrix},$$
$$A'(\lambda)=A-\sigma_-\cdot[\phi(\lambda)e^{-2}(\lambda)]_N=\begin{pmatrix}0&1\\u_N(\lambda)&0\end{pmatrix}. \tag{IV.18}$$

Here $\phi(\lambda)$ is a function on spectral parameter and $[z]_N$ means restriction of z onto the ad_R^*-invariant Poisson subspace of the initial r-bracket.[27,29,30] For the rational r-matrix (IV.14) we can use the linear combinations of the following Taylor projections

$$[z]_N=\left[\sum_{k=-\infty}^{+\infty} z_k\lambda^k\right]_N\equiv\sum_{k=0}^{N} z_k\lambda^k, \tag{IV.19}$$

or the Laurent projections.[27,29]

The mappings (IV.18) from the representation of the loop algebra $\mathscr{L}$(sl(2)) to representations of the universal enveloping algebra $U(\mathscr{L})$ play the role of a dressing procedure, allowing us to construct the Lax matrices $L_N'(\lambda)$ for an infinite set of new integrable systems starting from the single known Lax matrix $L(\lambda)$ associated to one integrable model. This mapping preserves the metric $g_j(q_1,\dots,q_n)$ in the Hamiltonian (II.1), but changes the potential $U(q_j)$ and associated curve $\mathscr{C}$.

The new Lax matrix $L'(\lambda)$ in (IV.18) obeys the linear r-bracket (IV.13), where constant r_{ij}-matrices substituted by r_{ij}'-matrices depend on dynamical variables:[27,29]

$$r_{12}(\lambda,\mu)\to r_{12}'=r_{12}-\frac{([\phi(\lambda)e^{-2}(\lambda)]_N-[\phi(\mu)e^{-2}(\mu)]_N)}{(\lambda-\mu)}\cdot\sigma_-\otimes\sigma_-\,. \tag{IV.20}$$

We have to distinguish systems on $\mathscr{C}^{(n)}$ at $n>g$ [(III.10)] for which the number of degrees of freedom n is more than genus g of the associated curve $\mathscr{C}$. According to Ref. 4 the corresponding symplectic form is meromorphic. In this case the action differential $dS=y\,d\lambda$ gives rise to a whole space $\mathscr{H}_1(\mathscr{C})$ and, in addition, several meromorphic differentials on $\mathscr{C}$. We can identify these systems with the degenerate or superintegrable systems.[21]

Theorem 4: The complete set of noncommutative integrals of motion for the degenerate uniform Stäckel systems with meromorphic symplectic form Ω_g is determined by the generalized spectral surface

$$\mathscr{C}(y,\lambda,\mu):\quad \det(yI+\Pi L'(\lambda)\otimes L'(\mu))=0.$$

Here we used the outer product of the 2×2 Lax matrices $L'(\lambda)$ with $L'(\mu)$ and Π means 4×4 permutation matrix in $\mathbb{C}^2\times\mathbb{C}^2$. The equation of motion for the matrix $L(\lambda,\mu)=\Pi L'(\lambda)\otimes L'(\mu)$ is equal to

$$\frac{d}{dt}L(\lambda,\mu)=L(\lambda,\mu)A(\lambda,\mu)-\Pi A(\lambda,\mu)\Pi^{-1}L(\lambda,\mu),$$
$$A(\lambda,\mu)=A(\lambda)\otimes I+I\otimes A(\mu), \tag{IV.21}$$

where the matrix $A(\lambda)$ is a second Lax matrix and I is a unit matrix.

It is easy to derive from (IV.18) that $n>g$ iff $n\geqslant N$, where N is a highest power in the Taylor projection (IV.19). In this case the corresponding r-matrix (IV.20) preserves the simple pole at the puncture P at $\lambda=\infty$ and the associated second Lax matrix A' remains a constant in spectral sense $\partial A(\lambda)/\partial\lambda=0$ under the mapping (IV.18).

Thus, for the degenerate systems, $A(\lambda,\mu)=\Pi A(\lambda,\mu)\Pi^{-1}$, and Eq. (IV.21) takes the standard Lax form and it proves the theorem.

As usual, spectral curve $\mathscr{C}$ [(IV.1)] of $L'(\lambda)$ is a generating function of the involutive family of integrals of motion. Substituting functions $\phi(\lambda)=\lambda^n Q_m^{-1}(\lambda)U_N(\lambda)$ into $L'(\lambda)$ [(IV.18)] one obtains their spectral curve in the form

$$\mathscr{C}:\quad y^2=F'(\lambda)=\det L'(\lambda)=U_N(\lambda)+\frac{\sum_{j=1}^{n}I'_j\lambda^{n-j}}{\Pi_{k=1}^{m}(\lambda-\delta_k)},$$

where $\{I'_j\}$ are integrals of motion. It is a time-independent curve and, therefore,

$$\frac{dF'(\lambda)}{dt}=0\Rightarrow\left[\frac{1}{4}\,\partial_x^3+u_N(\lambda)\partial_x+\frac{1}{2}\,u_{N,x}(\lambda)\right]\cdot e(\lambda)=0. \tag{IV.22}$$

Of course, this equation may be obtained directly in the framework of symplectic geometry.[31] Let us briefly explain an origin of this equation in the theory of nonlinear equations that allows us to relate the scalar Baker–Akhiezer function ψ and function $e(\lambda)$.

The same algebro-geometrical symplectic form Ω_g [(III.4)] on hyperelliptic curve $\mathscr{C}$ [(III.5)] leads directly to a Hamiltonian structure for soliton equations.[2,4] As an example, we consider the Kortewege–de Vries (KdV) equation associated to hyperelliptic curve (III.5) with one puncture $P(N=1)$ at infinity $\lambda=\infty$ and at $l=1$, $m=2$.[4] Let us select one leaf of foliation corresponding to $d\lambda$ with all zero periods

$$\oint_C d\lambda=0$$

for an arbitrary cycle C. In this case, the Abelian integral $\lambda(P)$ is a single-valued function, with only a pole of second order at $P(m=2)$. For finite-gap solutions of the KdV equations, moduli s_j from (III.2) are canonically conjugated with respect to the Gardner–Faddeev–Zakharov symplectic structure to angle variables w_j (see Ref. 32 and references within). Thus, the uniform Stäckel systems have a common set of the action-angle variables with solutions of the KdV equations.

Starting with this set of variables we consider general algebro-geometric equation (IV.2) for nonlinear systems. Solution of the equation (IV.2) in a ring of second order differential operators with the standard Baker–Akhiezer function ψ on $\mathscr{C}$ [(III.5)] is well known.[2–4,9] The associated Shrödinger operator has the form

$$\mathscr{L}(\lambda)=-\frac{\partial^2}{\partial x^2}+u(x,t,\lambda), \tag{IV.23}$$

where λ is a parameter. In some simple cases, such as the KdV equation, this parameter λ appears as an eigenvalue and one ultimately equates the potential u with a solution of the nonlinear equation itself. Let us look for a solution $\mathscr{A}(\lambda)$ of the Lax system in the ring of differential operators

$$\mathscr{L}(\lambda)\psi=0,$$
$$\left(\frac{\partial\mathscr{L}(\lambda)}{\partial t}+[\mathscr{L},\mathscr{A}]\right)\psi=0 \tag{IV.24}$$

of the form

$$\mathscr{A}(\lambda)=e(\lambda)\,\frac{\partial}{\partial x}-\frac{1}{2}\,\frac{\partial e(\lambda)}{\partial x}. \tag{IV.25}$$

Substituting the given form of $\mathscr{A}$ into the Lax system, one obtains

$$\frac{\partial u}{\partial t}=-2\left[\frac{1}{4}\,\partial_x^3+u(\lambda)\partial_x+\frac{1}{2}\,u_x(\lambda)\right]\cdot e(\lambda). \tag{IV.26}$$

Equation (IV.26) is called the generating equation. For different choices of the form of $e(\lambda)$ and $u(\lambda)$, this procedure leads to different hierarchies of integrable equations, as an example to the KdV, nonlinear Shrödinger, and sine–Gordon hierarchies[8,9] or to the Dym hierarchy.[33] If we consider the solutions of the equation (IV.26) in the form of polynomial (III.15), then the roots q_j of $e(\lambda)$ define the root variables and, as a result, finite-gap solutions of the problem of the geodesic (see Refs. 8, 9, and 33 and references within).

Substitution of the special form of second operator $\mathscr{A}(\lambda)$ [(IV.25)] into the Lax system (IV.24) allows us to eliminate the Baker–Akhiezer function ψ and to construct a 2×2 Lax matrix in $e(\lambda)$. In fact, we replace the Baker–Akhiezer function ψ on $\mathscr{C}$ to the mutually disjoint function $e(\lambda)$ on $\mathscr{C}$, which has a transparent mechanical interpretation (III.15). Recall that the function $e(\lambda)$ is defined as a function with zeroes, which gives solution to the Jacobi inversion problem[3] on the hyperelliptic curve $\mathscr{C}$.

V. THE FLAT COORDINATES

According to Ref. 14, at $n=g$ the orthogonal curvilinear coordinates $\{p_j,q_j\}_{j=1}^{g}$ form a generic divisor of the simple poles of the Baker–Akhiezer function ψ, which is defined by their analytical properties on $\mathscr{C}$. The evaluation of ψ at a set of punctures on $\mathscr{C}$ determines the flat coordinates $\{p_j,x_j\}_{j=1}^{g}$ for the diagonal metric (II.12). It turns out that, up to constant factors, the Lamé coefficients H_j are equal to the leading terms of the expansion of the same function ψ at the punctures on $\mathscr{C}$.[14]

Next we reach the same conclusions by using the function $e(\lambda)$ and the corresponding Lax representation $L(\lambda)$ on $\mathscr{C}$. As usual, we reduce the study of algebraic geometrical data to the analysis of the associated geodesic motion. The crucial observation is that the equations of motion in coordinates $\{p_j,x_j\}_{j=1}^{n}$ on the Riemannian manifolds of constant curvature have a Newtonian form and the corresponding Hamiltonian has a natural form

$$\ddot{x}_j=\xi_j(x_1,\ldots,x_n),\quad H=\sum a_{ij}p_ip_j+V(x_1,\ldots,x_n),\quad a_{ij}\in\mathbb{C}, \tag{V.1}$$

where $\xi_j(x_1,\ldots,x_n)$ and potential $V(x_1,\ldots,x_n)$ are functions on coordinates only. Let us introduce new function $\mathscr{B}(\lambda)$,

$$\mathscr{B}^2(\lambda)=e(\lambda)=\mathsf{H}^{-2}(\lambda), \tag{V.2}$$

which is "inverse" to the Lamé coefficients H_j in (II.13). One immediately obtains

$$F(\lambda)=\mathscr{B}^3\mathscr{B}_{xx},\quad F'(\lambda)=\mathscr{B}^3\mathscr{B}_{xx}+\mathscr{B}^4\left[\frac{\phi(\lambda)}{\mathscr{B}^4}\right]_N. \tag{V.3}$$

These equations have the form of Newton's equations for the function $\mathscr{B}$:

$$\mathscr{B}_{xx}=F(\lambda)\mathscr{B}^{-3},\qquad \mathscr{B}_{xx}=F'(\lambda)\mathscr{B}^{-3}-\mathscr{B}\left[\frac{\phi(\lambda)}{\mathscr{B}^4}\right]_N, \tag{V.4}$$

To expand function $\mathscr{B}(\lambda)$ at the Laurent set,

$$\mathscr{B}=\sum_{j=0}^{N}x_{N-j}\lambda^j,$$

it is easy to prove that coefficients x_j obey the Newtonian equation of motion (V.4) [see (IV.10) and references within Ref. 26]. Here we reinterpret the coefficients of the bare curves $F(\lambda)$ and $F'(\lambda)$ in (V.4) not as functions on the phase space, but rather as integration constants. In variables x_j, mapping (IV.18) affects only the potential (x dependent) part of the integrals of motion I_k. The kinetic (momentum dependent) part of I_k remains unchanged. So, the dressing mapping (IV.18) allows us to get over from a free motion on $\mathbb{C}^{2n}$ to a potential motion on $\mathbb{C}^{2n}$.

As an example, from (V.4) we get some well known orthogonal curvilinear coordinates on $\mathbb{R}^n$ (see Refs. 11, 12, and 19):

elliptic coordinates $m=n$ in (III.23):

$$e(\lambda,q_1,\dots,q_n)=\frac{\Pi_{j=1}^n(\lambda-q_j)}{\Pi_{k=1}^n(\lambda-\delta_k)}=1+\sum_{k=1}^n \frac{x_k^2}{\lambda-\delta_k}=\mathscr{B}^2(\lambda,x_1,\dots,x_n),$$

$$\delta_1<x_1<\delta_2\cdots<\delta_n<x_n\,,$$

parabolic coordinates $m=n-1$ in (III.23):

$$e(\lambda,q_1,\dots,q_n)=\frac{\Pi_{j=1}^n(\lambda-q_j)}{\Pi_{k=1}^{n-1}(\lambda-\delta_k)}=\lambda-x_n+\sum_{k=1}^{n-1} \frac{x_k^2}{\lambda-\delta_k}=\mathscr{B}^2(\lambda,x_1,\dots,x_n),$$

$$x_1<\delta_1<x_2\cdots<\delta_{n-1}<x_n\,,$$

spherical coordinates $m=n+1$ in (III.21):

$$e(\lambda,q_0,\dots,q_n)=\frac{q_0\Pi_{j=1}^n(\lambda-q_j)}{\Pi_{k=1}^{n+1}(\lambda-\delta_k)}=\sum_{k=1}^{n+1} \frac{x_k^2}{\lambda-\delta_k}=\mathscr{B}^2(\lambda,x_1,\dots,x_{n+1}).$$

Curvilinear coordinates $\{q_j\}$ are zeroes of function $e(\lambda)$ and flat coordinates $\{x_j\}$ are residues of $e(\lambda)=\mathscr{B}^2(\lambda)$ at the punctures, in accordance with the Baker–Akhiezer function approach.[14,25]

All the separable orthogonal curvilinear coordinate systems in $\mathbb{R}^n$ may be obtained from these coordinate systems.[12,19,20] According to Ref. 34, all the possible separables in these coordinates potentials, which are polynomials or rational functions of the Cartesian coordinates x_j, belong to the set of uniform Stäckel systems. Thus, we can claim that every such mechanical system is embedded into a proposed scheme.

A. Quasi-point canonical transformations

In conclusion, we discuss another parametrizations of the function $e(\lambda)$. Of course, function $e(\lambda)$ admits various representations in different variables and we can use this freedom as an example to solve equations of motion.[26] The parametrization considered above describes the point canonical transformation only. Here we discuss an application of the Weierstrass reduction theory to construct other Cartesian coordinates on $\mathscr{C}$.

It is obvious that the Lax representation,

$$\dot{L}(\lambda)=[L(\lambda),A(\lambda)],$$

is covariant with respect to the transformation of the first Lax matrix,

$$L(\lambda)\to\phi(\lambda,\lambda_1,\dots,\lambda_k)L(\lambda),$$

with an arbitrary function $\phi(\lambda,\lambda_1,\dots,\lambda_k)$ on time-independent moduli $\{\lambda_j\}$ of $\mathscr{C}$ and on spectral parameter λ. However, this transformation drastically changes the Poisson bracket relations (IV.14) and parametrization of $L(\lambda)$ in the flat coordinates $\{p_j,x_j\}$. Hence, in addition to the flat coordinates $\{p_j,x_j\}_{j=1}^n$ considered above, the same function $e(\lambda,q_1,\dots,q_n)$ may be associated to another set of flat coordinates. Now we show that to introduce these new variables $\{p_j,x_j\}$ we can use various coverings of the initial curve $\mathscr{C}$, for example, the covering listed in Ref. 35.

Let us assume that the initial torus $J(\mathscr{C})=T^{2g}$ may be decomposed in a direct product of several tori:

$$T^{2g}=T^{2g_1}\times\cdots\times T^{2g_k},\quad \sum_{j=1}^k g_j=g. \tag{V.5}$$

The corresponding Riemann matrix has a block form $B=B_1\times B_2\ldots\times B_k$, where B_j are the $g_j\times g_j$ Riemann matrices and the corresponding Baker–Akhiezer function on $\mathscr{C}$ is factorized. In this case we can consider curve $\mathscr{C}$ as a K-sheeted covering of tori T^{2g_j}. Such covers are known to exist for any $K>1$ and for arbitrary tori.[35]

First of all, we can introduce the separated variables $\{q_j\}$ associated to a whole torus T^{2g}. For dynamics on $J(\mathscr{C})=T^{2g}$, the corresponding Lax representations $L(\lambda)$ in (IV.5) are 2×2 matrices.

Second, we can introduce another set of separated variables $\{\tilde{q}_j\}$ associated to each torus T^{2g_j} in (V.5). For dynamics splitting on several tori T^{2g_j}, the Lax representations have a block form

$$L(\lambda)=\begin{pmatrix} L_1 & & \\ & \ddots & \\ & & L_k \end{pmatrix}(\lambda), \tag{V.6}$$

where $L_j(\lambda)$ are the 2×2 matrices defined by functions $e_j(\lambda)$ on each torus T^{2g_j}.[29] Two sets of variables $\{q_j\}$ and $\{\tilde{q}_j\}$ are related by canonical transformation induced by the covering, which allows us to obtain a 2×2 Lax matrix instead of matrix (V.6). This means that we have two isomorphic integrable systems with different Lax representations and the corresponding canonical transformation is a quasi-point transformation.[36]

To illustrate this construction we take as an example several systems at $n=2$. Starting with a hyperelliptic curve $\mathscr{C}$ of genus $g=n=2$ we define variables (p_1,q_1) and (p_2,q_2) on the Lagrangian submanifold $\mathscr{C}^{(2)}$ from (III.9). The Jacobi inversion problem is the problem of finding these variables from the equations (II.10) with the Stäckel matrix S given by (III.12). This problem is solved by using the Kleinian $\wp$-functions, which are second logarithmic derivatives of the Kleinian σ-function:

$$\wp_{ij}=-\frac{\partial \ln \sigma(\beta_1,\beta_2)}{\partial\beta_i\partial\beta_j}, \quad \wp_{22}=q_1+q_2, \quad \wp_{12}=-q_1q_2$$

(for details, see Refs. 35 and 37). The function $e(\lambda)$ [(III.15)] on $\mathscr{C}$ with zeroes at the points q_1,q_2 is equal to

$$e(\lambda)=\lambda^2-\wp_{22}\lambda-\wp_{12}=(\lambda-q_1)(\lambda-q_2)=\lambda^2+2\lambda x_1+(2x_2+x_1^2) \tag{V.7}$$

or

$$e(\lambda)=\frac{(\lambda-q_1)(\lambda-q_2)}{(\lambda-\delta_1)(\lambda-\delta_2)}=1+\frac{x_1'^2}{\lambda-\delta_1}+\frac{x_2'^2}{\lambda-\delta_2}. \tag{V.8}$$

Here we used the freedom (III.23), and Cartesian coordinates $\{x_j\}$ or $\{x_j'\}$ are derived from the ‘‘inverse’’ Lamé function $\mathscr{B}(\lambda)$ in (V.2). Applying the outer additive automorphism of sl(2), we can construct the Lax matrices $L'(\lambda)$ for an infinite set of integrable mechanical systems with the following Hamiltonians:

$$\begin{aligned} H&=p_1p_2+V_N(x_1,x_2),\\ H&=p_1'^2+p_2'^2+V_N'(x_1',x_2'). \end{aligned} \tag{V.9}$$

Among them, we distinguish the Hénon–Heiles systems at $N=3$ and the systems with quartic potential at $N=4$. For these systems the genus of associated curve $\mathscr{C}$ is equal to the number of degrees of freedom $g=n=2$.

The function $e(\lambda)$ in (III.13) is independent on the moduli of $\mathscr{C}$ and, therefore, the above construction of the integrable systems (V.9) readily gets over on the reducible curve $\mathscr{C}$. To construct this reducible curve, let us take two tori $T_{1,2}^2$,

$$w_\pm^2=\xi(1-\xi)(1-k_\pm^2\xi), \tag{V.10}$$

with a Jacobi moduli

$$k_{\pm}^2=-\frac{(\sqrt{\alpha}\mp\sqrt{\beta})^2}{(1-\alpha)(1-\beta)}.$$

Making the rational order two $(K=2)$ change of variables

$$w_{\pm}=-\sqrt{(1-\alpha)(1-\beta)}\,\frac{\lambda\mp\sqrt{\alpha\beta}}{(\lambda-\alpha)^2(\lambda-\beta)^2}\,y,\quad \xi=\frac{(1-\alpha)(1-\beta)}{(\lambda-\alpha)(\lambda-\beta)}\,\lambda, \tag{V.11}$$

one obtains the hyperelliptic curve

$$\mathscr{C}:\quad y^2=\lambda(\lambda-1)(\lambda-\alpha)(\lambda-\beta)(\lambda-\alpha\beta), \tag{V.12}$$

which gives a two-sheeted covering of two tori $T_{1,2}^2$ [(V.10)]. It is a well-known example of the reduction of hyperelliptic integrals to elliptic ones by using the rational change of variables proposed by Legendre and generalized by Jacobi.[35]

The complex torus T^2 is isomorphic to the curve of genus $g=1$ given by the equation $w^2=f(\xi)$. In the above, we have presented the covering for the two odd curves (V.10) at $\deg(f)=2g+1=3$. All computations concerning the even curves at $\deg(f)=2g+2=4$ give similar covering,[35] so we do not present these formulas. The odd and even curves at $g=1$ are associated to the integrable cases of the Hénon–Hailes system and the system with quartic potential, respectively.

Next we can introduce two pairs of variables $(\tilde p_1,\tilde q_1)$ and $(\tilde p_2,\tilde q_2)$ on the tori $T_{1,2}^2$. Functions $e_{1,2}(\lambda)$ on $T_{1,2}^2$ are equal to

$$e_1(\lambda)=\lambda-\tilde q_1,\quad e_2(\lambda)=\lambda-\tilde q_2. \tag{V.13}$$

Variables $\{\tilde p_j,\tilde q_j\}$ are separated Cartesian coordinates for the integrable systems on $T_1^2\times T_2^2$ with the Hamiltonians

$$H_{3,4}=\tilde p_1^2+\tilde p_2^2+V_{3,4}(\tilde q_1)+V_{3,4}(\tilde q_2), \tag{V.14}$$

which is a sum of two one-dimensional Hamiltonians on $T_{1,2}^2$. The corresponding 4×4 Lax representation has a block form (V.6), whose blocks are determined by the functions $e_{1,2}(\lambda)$ of (V.13).

The covering (V.11) induces canonical transformation of variables $\{\tilde p_j,\tilde q_j\}$ to $\{p_j,q_j\}$.[37] These pairs of variables lie on the different curves $T_{1,2}^2$ and $\mathscr{C}$, respectively. The common moduli α and β of these curves are integrals of motion. On the orbit $\mathscr{O}$ ($\alpha=$const, $\beta=$const) this canonical transformation (V.11) becomes a point transformation. It is the so-called quasi-point transformation.[36]

By using the change of variables induced by covering (V.11) one can construct the 2×2 Lax matrix for the evolution (V.14) splitting on two tori. In variables $\{\tilde q_j\}$ the matrix $L(\lambda)$ is determined by the function

$$e(\lambda)=\frac{(\lambda-\alpha)(\lambda-\beta)}{(1-\alpha)(1-\beta)}\,\tilde e(\lambda),\quad \tilde e(\lambda)=(\lambda-\tilde q_1)(\lambda-\tilde q_2). \tag{V.15}$$

In fact, we add two additional zeroes α and β into the function $e(\lambda)$ of (III.13) on the reducible curve $\mathscr{C}$ in (V.12) and, therefore, change the parametrization of the Lax matrices in flat coordinates $\{p_j,x_j\}$.

In general, to introduce new flat coordinates, we can take any tori $T_{1,2}^{2g_j}$ of arbitrary genus $g_{1,2}>1$ and consider the two-dimensional evolution (V.14) splitting on these curves with an arbitrary one-dimensional potential $V_{2g_j+1}(q_j)$. The standard change of variables,

$$\tilde q_j=\frac{\tilde x_1\pm\tilde x_2}{2}\Rightarrow\tilde e(\lambda)=\lambda^2-\tilde x_1+\frac{\tilde x_1^2-\tilde x_2^2}{4}, \tag{V.16}$$

preserves the natural form of the Hamiltonians (V.14) for arbitrary potentials $V_{2g_j+1}(q_j)$. The equations of motion remain the Newtonian equations in these variables $\{\tilde p_j,\widetilde{x_j}\}$.

In the example (V.10) considered above both independent hyperelliptic integrals are reduced to elliptic ones by using a common substitution $\xi\to\lambda$ [(V.11)]. It relates to the existence of the second order automorphism of a hyperelliptic curve (V.12):[35]

$$\tau:\quad (\lambda,y)\to\left(\frac{\alpha\beta}{\lambda},\ \frac{y}{\lambda^3}\ \sqrt{\alpha^3\beta^3}\right). \tag{V.17}$$

It allows us to introduce another parametrization of the function $\tilde{e}(\lambda)$ in Cartesian coordinates, which preserves the natural form of the Hamiltonian. Namely, in addition to (V.16), we can use the following canonical transformation of variables $\{\tilde{p}_j,\tilde{q}_j\}$ to the Cartesian coordinates $\{\hat{p}_j,\hat{x}_j\}$

$$\tilde{e}(\lambda)=\lambda^2-\frac{Q_++Q_-}{\hat{x}_1}+\frac{(Q_+-Q_-)^2}{4\hat{x}_1}. \tag{V.18}$$

Here functions $Q_\pm(\hat{p}_j,\hat{x}_j)$ are the classical counterparts of the supercharges in two-dimensional supersymmetric quantum mechanics (SUSY)[36] with the following properties:

$$\{H,Q_\pm\}=\pm f(\hat{p}_j,\hat{x}_j)Q_\pm,\quad \{H,Q_+Q_-\}=0.$$

At $g=2$ [$N=3$ or $N=4$ in (V.14)] these functions $Q_\pm$ and f on variables $\{\tilde{p}_j,\tilde{q}_j\}$ or $\{\hat{p}_j,\hat{x}_j\}$ are listed in Ref. 36. Moduli α and β in (V.17) are integrals of motion; therefore, automorphism τ induces a second quasi-point transformation associated to torus $T_1^2\times T_2^2$ [(V.10)].

Two quasi-point transformations (V.11) and (V.18) for the physical variables $\{x_j'\}$, $\{\tilde{x}_j\}$ and $\{\hat{x}_j\}$ bind together all the integrable cases of the Hénon–Hailes system at $N=3$ and three integrable cases of the system with quartic potential at $N=4$. Of course, these systems have a common set of action-angle variables. Moreover, the same variables are associated to the Kowalewski top,[3] which is a supersymmetric quantum model as well.

Thus, several supersymmetric models are related to evolution splitting on the tori, when the number of degrees of freedom is equal to the genus $g=n$ of the associated covering curve $\mathscr{C}=T_1\times T_2$. It would be interesting to get a geometrical interpretation of these supersymmetric objects arising from finite-dimensional SUSY quantum mechanics.

VI. CONCLUSION

It is known that curves $y+y^{-1}=F(\lambda)$ together with the one-forms

$$dS^{(4)}=\lambda\ \frac{dy}{y},\quad dS^{(5)}=\log\lambda\ \frac{dy}{y},$$

are implied by integrable models of the Toda chain family (standard and relativistic models). The corresponding Lax representations are defined on the Poisson–Lie groups with quadratic r-matrix algebra. The corresponding mapping from the action-angle variables to separated variables has been proposed in Ref. 32.

On the other hand, we can consider the umbilic solutions of the KdV equation.[9,33] These systems are defined on a generalized Jacobi variety of the symmetric product of n logarithmic Riemannian surfaces in place of the Liouville tori. Nevertheless, it is possible to introduce variables that linearize the corresponding Hamiltonian flows. These systems may be interpreted as counterparts of the discrete-time Stäckel systems.

Both these sets of models are associated to the change of parametrization of the hyperelliptic curve from ''plane'' parametrization to ''annulus'' ones ($\lambda\to\log\lambda$). Another possible generalization relates to the interpretation of the parameter λ as a coordinate on elliptic curve.

For all these integrable models it would be interesting to estimate the possibility of application of the usual Stäckel approach. In this way we should consider mapping between action-angle variables and separated variables, and should study the differential of this map. In the presented paper there are the Jacobi inversion problem and the differential of the Abel-Jacobi map.

Lax pairs for integrable lattice systems

R. S. Ward[a)]
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 19 August 1998; accepted for publication 4 September 1998)

This paper studies the structure of Lax pairs associated with integrable lattice systems (where space is a one-dimensional lattice, and time is continuous). It describes a procedure for generating examples of such systems, and emphasizes the features that are needed to obtain equations which are local on the spatial lattice. © *1999 American Institute of Physics.* [S0022-2488(99)02001-0]

I. INTRODUCTION

There has long been interest in integrable differential-difference equations (integrable lattice systems), especially since the discovery of the Toda lattice.[1] Such systems can have direct applications, for example, in condensed-matter physics; and also occur as spatially discrete versions of integrable partial differential equations.[2] Associated with each integrable lattice is a Lax pair, involving a matrix L that ''steps'' along the lattice, together with another matrix V that generates the time evolution. Our purpose in this paper is to investigate the structure of this Lax pair, and how it affects the nature of the associated integrable systems.

Throughout the paper, we work with functions $\varphi_n(t)$ which depend on time t, and on an integer variable n. Such a function will be written simply as φ, its dependence on t and n being understood; then φ_+ denotes $\varphi_{n+1}(t)$, and φ_- denotes $\varphi_{n-1}(t)$. The symbol Δ denotes the forward-difference operator, i.e., $\Delta\varphi=\varphi_+-\varphi$. For example, the Toda lattice equation (in first-order form) is

$$\frac{d}{dt}\varphi=\psi,\quad \frac{d}{dt}\psi=\exp\Delta\varphi-\exp\Delta\varphi_- . \tag{1}$$

We shall take the integer n to be unrestricted (i.e., the lattice is infinite). Our primary interest is in systems that are local, in the sense that the time derivative of a variable at site n equals some expression involving the variables at sites $n-1$, n and $n+1$: i.e., nearest neighbors only.

The point of view adopted here is that a lattice equation is integrable if it can be written as the consistency condition for a linear system (Lax pair) of a suitable type. This involves two $q\times q$ matrices L and V, the entries of which are functions of a ''spectral parameter'' λ, as well as of t and n. In what follows, we shall, for the sake of simplicity, restrict to the case $q=2$ (i.e., 2×2 matrices). The linear system is

$$\Psi_+=L\Psi,\qquad \frac{d}{dt}\Psi=V\Psi, \tag{2}$$

where Ψ is a column 2-vector (depending on λ, t, and n). The consistency condition for (2) is

$$\frac{d}{dt}L=V_+L-LV. \tag{3}$$

[a)]Electronic mail: Richard.Ward@durham.ac.uk

The crucial feature of (3) is that it specifies the evolution only of L, and not of V; so in order to get a meaningful equation, V has to be determined in terms of L. In the next section, we shall see how this happens. The subsequent sections illustrate how this structure can be used to generate integrable lattice systems. We shall see how known examples fit into this framework; and as a new example, construct a system that couples lattice versions of the Heisenberg ferromagnet and the derivative nonlinear Schrödinger equation.

II. HOW $L(\lambda)$ DETERMINES $V(\lambda)$

In order to analyze the structure of $L(\lambda)$ and $V(\lambda)$, one needs to impose some requirements on the way that they depend on λ. Let us assume that L, L^{-1}, and V are rational functions of λ, with poles at constant values of λ (that is, the location of the poles does not depend on t or n). This is not the only possibility: for example, there is the well-known case of the lattice Landau–Lifshitz equation,[3] which involves elliptic functions of λ. But we shall restrict to the rational case.

By making a Möbius transformation on λ, we may ensure that $V(\lambda)$ is finite at $\lambda=\infty$, i.e., that its poles occur at finite values of λ. Furthermore, since (3) is homogeneous in L, we have the freedom to multiply L by a scalar function of λ (not depending on t or n). We can use this freedom to ensure that L is a (matrix) polynomial in λ that is nonzero at each of the poles of V. Let p denote the degree of L as a polynomial in λ.

Equation (3) determines the evolution of each matrix coefficient in the polynomial $L(\lambda) = A\lambda^p + B\lambda^{p-1} + \cdots + D$; so at this stage it is a set of coupled equations for $q^2(p+1)$ functions (with $q=2$ in what follows). As was emphasized above, the matrix V has to be determined in terms of L, since (3) does not specify its evolution: let us now examine how this happens.

Assume for the time being that the poles of V are all simple. So V has the form

$$V(\lambda) = \sum_{\alpha=1}^{N} V^{(\alpha)}(\lambda-\lambda_\alpha)^{-1} + V^{(0)}, \tag{4}$$

where $V^{(0)}, V^{(1)}, \ldots, V^{(N)}$ are matrices, independent of λ. The general idea is that $V^{(0)}$ is determined by a choice of gauge, whereas each $V^{(\alpha)}$ for $1 \leqslant \alpha \leqslant N$ is determined by the residue of (3) at the pole $\lambda=\lambda_\alpha$. Note that Eqs. (2) and (3) are invariant under the gauge transformations,

$$\Psi \mapsto \Lambda\Psi, \qquad L \mapsto \Lambda_+ L \Lambda^{-1}, \qquad V \mapsto \Lambda V \Lambda^{-1} + \left(\frac{d}{dt}\Lambda\right)\Lambda^{-1}, \tag{5}$$

where Λ is a nonsingular 2×2 matrix depending on t and n (but not on λ). A choice of gauge involves the following steps.

(i) Choose a form for $L(\lambda)$ (an algebraic condition on the entries in the matrix L), such that a necessary condition for this form to be preserved under gauge transformations (5) is that $\Lambda_+ = \Lambda$.

(ii) Then choose any $V^{(0)}$ that is consistent with (i) and the evolution equation (3).

As an example to illustrate how this works, choose the coefficient of λ^p in $L(\lambda)$ (i.e., the leading term) to be the identity matrix. Then the remaining gauge freedom is (5), with Λ independent of n, as required. And the leading term in (3) gives $V_+^{(0)} = V^{(0)}$, so any choice $V^{(0)} = V^{(0)}(t)$ then fixes the gauge completely; to obtain an autonomous system of equations, one chooses $V^{(0)}$ to be a constant matrix. This is the most straightforward choice of gauge; for other gauges, $V^{(0)}$ will depend on the functions appearing in $L(\lambda)$, and this dependence is, in general, nonlocal, as we shall see below.

Consider, next, the pole at $\lambda=\lambda_\alpha$. Clearly the residue of the right-hand side of (3) at this pole must vanish, i.e.,

$$V_+^{(\alpha)} L^{(\alpha)} - L^{(\alpha)} V^{(\alpha)} = 0, \tag{6}$$

where $L^{(\alpha)}=L(\lambda_\alpha)$. The idea is that this constraint determines $V^{(\alpha)}$. Since $L^{(\alpha)}$ is a nonzero 2×2 matrix, there are two gauge-invariant possibilities: the rank of $L^{(\alpha)}$ could be either 2 or 1. In the next section we deal with the rank 2 case; thereafter, we concentrate on the rank 1 case.

III. RANK 2 CASE: NONLOCAL SYSTEMS

If $L^{(\alpha)}$ is invertible, then (6) is a difference equation,

$$V_+^{(\alpha)}=L^{(\alpha)}V^{(\alpha)}L^{(\alpha)-1},$$

which determines $V_n^{(\alpha)}$ in terms of (say) $L_{n-1}^{(\alpha)}$, $L_{n-2}^{(\alpha)},\ldots,$ and $V_{-\infty}^{(\alpha)}$. In other words, $V^{(\alpha)}$ is a nonlocal function of the entries in $L^{(\alpha)}$.

To obtain a simple example that illustrates this case, take $p=N=1$. Without loss of generality, we may set $\lambda_1=0$. Write $L=A\lambda+B$, where B is invertible; and choose a gauge by specifying

$$A=\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

and $V^{(0)}=0$. So $V(\lambda)=V^{(1)}/\lambda$, where $V^{(1)}$ is the solution of the difference equation,

$$V_+^{(1)}=BV^{(1)}B^{-1}. \tag{7}$$

In general, the 2×2 matrix B contains four functions; let us effect a reduction to one function $y_n(t)$ by taking B to have the form

$$B=\begin{pmatrix} e^y & 0 \\ 0 & e^{-y} \end{pmatrix}. \tag{8}$$

In order for the reduction to be consistent, we need $V_{-\infty}^{(1)}$ to have the form

$$V_{-\infty}^{(1)}=\begin{pmatrix} 0 & b \\ c & 0 \end{pmatrix}$$

(plus a multiple of the identity, which has no eventual effect). The resulting system of equations for y is

$$\frac{d}{dt}\,y=b\,\exp(Y)-c\,\exp(-Y), \tag{9}$$

where $Y_n(t)$ is given by the nonlocal expression

$$Y_n=y_n+2\sum_{k=-\infty}^{n-1} y_k .$$

This equation can be transformed to a form that looks local, by writing $y_n=\phi_n-\phi_{n+1}$. In terms of $\phi_n(t)$, Eq. (9) becomes

$$\frac{d}{dt}\,(\phi_+-\phi)=c\,\exp(\phi_++\phi)-b\,\exp(-\phi_+-\phi). \tag{10}$$

If (for example) $b=0$, then (10) is a differential-difference version of the Liouville equation,

$$\phi_{tx}=\exp(2\phi). \tag{11}$$

To get (11) from (10), we interpret c as the lattice spacing, put $x=nc$, and take the continuum limit $c\to 0$. Similarly, putting $b=c$ in (10) gives a differential-difference version of the sine-Gordon equation.[4] But for these lattice Liouville and sine-Gordon systems, x and t (or n and t) do not represent space and time; rather they are characteristic (null) coordinates. In particular, one cannot specify arbitrary initial data at $t=0$. In these lattice equations, one of the characteristic coordinates has become discrete, while the other (namely t) remains continuous.

This example can be generalized in several directions, as follows. If one does not make the reduction (8), then one obtains an equation for the matrix B. Choosing the slightly different gauge $A=\mathbf{I}$ (the identity matrix) and $V^{(0)}=0$, leads to

$$\frac{d}{dt}B-\Delta V^{(1)}=0, \tag{12}$$

together with (7). Now (7) and (12) ensure that there exists a matrix $R_n(t)$ with

$$B=1+R_+R^{-1}, \quad V^{(1)}=-\left(\frac{d}{dt}R\right)R^{-1}.$$

Then (12) becomes

$$\frac{d}{dt}(R_+R^{-1})+\Delta\left[\left(\frac{d}{dt}R\right)R^{-1}\right]=0. \tag{13}$$

This is a differential-difference version of the principal chiral equation,

$$(R_xR^{-1})_t+(R_tR^{-1})_x=0, \tag{14}$$

in which, as before, one of the characteristic coordinates has become discrete.

This chiral equation generalizes, of course, to larger matrices $(q>2)$. Similarly, the Liouville and sine-Gordon examples generalize to differential-difference versions of other Toda field equations.

Finally, it might be noted that there are difference-difference versions of the principal chiral[5] and Toda field[6] equations in which both characteristic coordinates (here x and t) become discrete. Another, very general, example of this type is the Hirota bilinear difference equation.[7]

So systems with $\det L^{(\alpha)}\neq 0$ may be thought of as time-evolution equations that are nonlocal on the spatial lattice, or as equations where a characteristic coordinate (neither space nor time) has become discrete. To get local evolution equations, it is necessary for each $L^{(\alpha)}$ to have rank 1. From now on, we shall concentrate on this case.

IV. RANK 1 CASE: LOCAL SYSTEMS

Given that $L^{(\alpha)}$ has rank 1 the constraint (6) may be solved as follows. Write $K^{(\alpha)}=L_-^{(\alpha)}L^{(\alpha)}$. Assuming that $\operatorname{tr} K^{(\alpha)}$ is nonzero, the general solution of (6) is

$$V^{(\alpha)}=\frac{1}{\operatorname{tr} K^{(\alpha)}}[f^{(\alpha)}K^{(\alpha)}+g^{(\alpha)} \operatorname{adj} K^{(\alpha)}], \tag{15}$$

where $\operatorname{adj} K^{(\alpha)}$ denotes the adjoint matrix of $K^{(\alpha)}$, and where $f^{(\alpha)}$ and $g^{(\alpha)}$ are scalar functions, with $f_+^{(\alpha)}=f^{(\alpha)}$. So the constraint (6) does not determine $V^{(1)},\ldots,V^{(N)}$ uniquely: in particular, one has the arbitrary functions $g^{(\alpha)}$. However, there is a further constraint, namely that the condition $\det L^{(\alpha)}=0$ has to be preserved by the evolution (3). This gives equations on the $g^{(\alpha)}$, which are precisely that they are constant on the lattice, just as the $f^{(\alpha)}$ are: $g_+^{(\alpha)}=g^{(\alpha)}$. Then (15) can be rewritten as

$$V^{(\alpha)}=\frac{c^{(\alpha)}}{\operatorname{tr} K^{(\alpha)}}\, K^{(\alpha)}+d^{(\alpha)}\mathbf{I},$$

where $c^{(\alpha)}$ and $d^{(\alpha)}$ are functions of t only. It is clear that the $d^{(\alpha)}$ term will not contribute in the evolution equations, and so only the $c^{(\alpha)}$ remain; we may as well set $d^{(\alpha)}=0$, and take

$$V^{(\alpha)}=\frac{c^{(\alpha)}}{\operatorname{tr} K^{(\alpha)}}\, K^{(\alpha)}. \tag{16}$$

At this stage, the $c^{(\alpha)}$ could still be functions of time t; for simplicity, let us take them to be constants. One point to note about (16) is that $V^{(\alpha)}$ is local: $V_n^{(\alpha)}$ is expressed in terms of L_n and L_{n-1}.

So to obtain local evolution equations with 2×2 matrix Lax pairs, one first specifies the integer p [the degree of $L(\lambda)$]; the integer N appearing in (4) equals $2p$, since the λ_α all have to be roots of $\det L(\lambda)$. The matrices $V^{(\alpha)}$ for $1\leqslant\alpha\leqslant 2p$ are given by (16), and involve the $2p$ constants $c^{(\alpha)}$. Finally, there is the choice of gauge, which determines $V^{(0)}$. In general, $V^{(0)}$ turns out to be nonlocal, and special gauge choices are needed to ensure that it is local.

One can relate all this to the r-matrix description (see, for example, Ref. 3; and also Ref. 8, which addresses the construction of an r-matrix from a given Lax pair). Suppose one has an $L(\lambda)$, a Poisson bracket and an r-matrix such that the Fundamental Poisson Bracket Relations are satisfied. Suppose also that there exist $\lambda_1,\ldots,\lambda_N$ such that $\det L(\lambda_\alpha)=0$ for each α. Let $\tau(\lambda)$ be the trace of the monodromy matrix $\ldots L_2(\lambda)L_1(\lambda)L_0(\lambda)L_{-1}(\lambda)\ldots$ (which propagates from $n=-\infty$ to $n=+\infty$). Then

$$H=\sum_{\alpha=1}^{N} c^{(\alpha)} \log\, \tau(\lambda_\alpha)$$

is a local Hamiltonian, and the corresponding Hamiltonian equations are just (3); the constants $c^{(\alpha)}$ are the same as those appearing in (16). The problem from this point of view is to choose $L(\lambda)$, in a suitable gauge, such that a compatible r-matrix structure exists.

More generally, one wants $\tau(\lambda)$ to be conserved in time, for all λ—this then gives infinitely many conserved quantities. If one has a Lax pair (2) and boundary conditions which imply that $V_{+\infty}=V_{-\infty}$, then $\tau(\lambda)$ is indeed conserved. When $V(\lambda)$ depends locally on the fields, then then it is easy to ensure that this condition is met; if, on the other hand, V is nonlocal, then the conservation of $\tau(\lambda)$ is not guaranteed. This is one reason why locality is desirable, in the present context.

If $p=1$ [in other words, $L(\lambda)$ is linear in λ], then $\det L(\lambda)$ is a quadratic polynomial in λ, the roots of which are λ_1 and λ_2. For the time being, let us assume that these roots are distinct; and by translating λ set $\lambda_1=1$ and $\lambda_2=-1$. It follows that $L(\lambda)$ has the form

$$L(\lambda)=\tfrac{1}{2}(\lambda+1)L^{(1)}-\tfrac{1}{2}(\lambda-1)L^{(2)}, \tag{17}$$

where $L^{(1)}$ and $L^{(2)}$ are 2×2 matrices each having a zero determinant. So the entries in $L^{(\alpha)}$ involve six independent functions of t and n [in effect, the requirement that λ_1 and λ_2 be constant has reduced the number of functions in $L(\lambda)$ from eight to six]. The two $L^{(\alpha)}$ satisfy evolution equations obtained by expanding (3): these are

$$\frac{d}{dt}\, L^{(\alpha)}=V_+^{(0)}L^{(\alpha)}-L^{(\alpha)}V^{(0)}-\tfrac{1}{2}\Xi, \tag{18}$$

where $\Xi=V_+^{(1)}L^{(2)}-L^{(2)}V^{(1)}-V_+^{(2)}L^{(1)}+L^{(1)}V^{(2)}$. The gauge choice reduces the number of functions by four (since Λ contains four entries), and we end up with a system involving two functions. A number of examples of this type are described in the following section.

V. SOME $p=1$ EXAMPLES

In this section we exhibit some systems of the type described in the previous section. Such examples are simple to generate; but before doing so, we should ask when two lattice equations are to be regarded as being ''the same.'' More specifically, is there an appropriate equivalence relation on the set of all such systems? Certainly such an equivalence would include gauge transformations in which Λ was constant; and strictly local redefinitions of the functions appearing in L (i.e., the new functions at lattice site n depend on the old functions at site n only). However, it is customary to allow more general transformations than just these. A well-known case is that of the Toda lattice (1). If one replaces φ by

$$r=\Delta\varphi_{-}=\varphi-\varphi_{-}, \tag{19}$$

then (1) becomes

$$\frac{d^2}{dt^2}r=e^{r_+}-2e^{r}+e^{r_-}; \tag{20}$$

and this is regarded as simply another form of the Toda lattice equation.

But any equivalence relation that admitted (1) and (20) to the same class, would also have to allow the transformations $\varphi\mapsto\Delta^k\varphi$ for all integers k (negative as well as positive). If one allows such highly nonlocal transformations, then ones ends up with rather few equivalence classes; in fact, one might as well transform to action-angle variables, and say that the ''only'' integrable lattice is linear. Clearly this is inappropriate.

The point of this argument is to conclude that there is no useful equivalence relation on integrable systems of the type that we are considering [unless we insist that (1) and (20) are to be regarded as distinct]. This means that the task of listing such systems in a systematic way is not really well defined. The best that one can do is to exhibit examples, and indicate how they are related to one another.

Example (i). Choose a gauge such that $L^{(1)}-L^{(2)}=2\mathbf{I}$. This is the gauge that was mentioned as an example in Sec. II. As was remarked there, the gauge is then fixed completely by specifying some $V^{(0)}(t)$. The simplest choice is to set $V^{(0)}=0$. Note that $L^{(1)}$ and $L^{(2)}$ must have the form

$$L^{(1)}=\mathbf{I}+M,\quad L^{(2)}=-\mathbf{I}+M,$$

where M is trace-free and det $M=-1$. So we may write $M=\mathbf{f}\cdot\sigma$, where σ_1, σ_2, and σ_3 are the Pauli matrices, and $\mathbf{f}=\mathbf{f}_n(t)$ is a unit 3-vector. The dot denotes the usual three-dimensional Euclidean scalar product (and $\wedge$ below will denote the vector product). The evolution equation for $\mathbf{f}$, derived from (18), is then

$$\frac{d}{dt}\mathbf{f}=\Delta[(1+\mathbf{f}_-\cdot\mathbf{f})^{-1}(\mu\mathbf{f}_-+\mu\mathbf{f}+\nu\mathbf{f}_-\wedge\mathbf{f})], \tag{21}$$

where $\mu=\frac{1}{2}(c^{(1)}-c^{(2)})$ and $\nu=\frac{1}{2}i(c^{(1)}+c^{(2)})$ are constants. Equation (21), then, is an integrable equation for the unit-vector function $\mathbf{f}=\mathbf{f}_n(t)$. If the parameter ν is nonzero, it can be set to unity by scaling t; so the system effectively depends on the single parameter μ. The case $\mu=0$ is the ''Lattice Heisenberg Model,'' [3,9] so called because it has the equation of the Heisenberg ferromagnet as a continuum limit. Indeed, if we set $\nu=2/h^2$, $\mu=\hat{\mu}/h$, and let $h\to0$, then (21) becomes

$$\mathbf{f}_t=\hat{\mu}\mathbf{f}_x+\mathbf{f}\wedge\mathbf{f}_{xx}; \tag{22}$$

the Heisenberg model corresponds to $\hat{\mu}=0$. A slightly different choice of gauge, namely one in which $V^{(0)}$ is a nonzero constant matrix, yields a lattice nonlinear Schrödinger equation (different from the one in the next example). This is the lattice counterpart of the well-known gauge equivalence of the nonlinear Schrödinger and Heisenberg systems.

Example (ii). Choose a gauge such that

$$L^{(1)}=\begin{pmatrix}1 & 0\\ u & 0\end{pmatrix},\quad L^{(2)}=-\begin{pmatrix}0 & v\\ 0 & 1\end{pmatrix}, \tag{23}$$

where u and v are functions of t and n. The remaining gauge freedom has Λ being a diagonal matrix function of t only. Substituting (23) into the evolution equation (18) determines $V^{(0)}$ as

$$V^{(0)}=\frac{1}{2}\begin{pmatrix}-c^{(1)}vu_- & c^{(1)}v+c^{(2)}v_-\\ c^{(2)}u+c^{(1)}u_- & -c^{(2)}uv_-\end{pmatrix},$$

plus a diagonal matrix function of t, which by the residual gauge freedom may be set to zero. In addition, (18) gives the equations for u and v, namely

$$\begin{aligned}\frac{d}{dt}u&=\frac{1}{2}\,(c^{(2)}\Delta u+c^{(1)}\Delta u_-+c^{(1)}vuu_--c^{(2)}vuu_+),\\ \frac{d}{dt}v&=\frac{1}{2}\,(c^{(1)}\Delta v+c^{(2)}\Delta v_-+c^{(2)}uvv_--c^{(1)}uvv_+).\end{aligned} \tag{24}$$

This is exactly the Ablowitz–Ladik system;[2] their L operator is slightly different from the one presented here (it is, in effect, quadratic rather than linear in λ); but it is easily seen to be equivalent. In particular, if we choose $c^{(1)}=2i=-c^{(2)}$, and impose the (consistent) reduction $v=\pm u^*$, then (24) reduces to a lattice nonlinear Schrödinger equation,

$$i\,\frac{d}{dt}u=u_+-2u+u_-\mp uu^*(u_++u_-).$$

Example (iii). Here we choose a gauge such that $L^{(1)}$ is constant. Without loss of generality, we may take $L^{(1)}$ to be

$$L^{(1)}=\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}. \tag{25}$$

The most general form for the matrix $L^{(2)}$ is

$$L^{(2)}=\begin{pmatrix}uv & uw\\ v & w\end{pmatrix}, \tag{26}$$

where u, v, and w are functions of n and t. The evolution equation (18) for $L^{(1)}$ implies that $V^{(0)}$ must have the form

$$V^{(0)}=-\frac{c^{(1)}}{2}\begin{pmatrix}0 & uw\\ v_- & 0\end{pmatrix}-\frac{c^{(2)}}{2(vu_-+w)}\begin{pmatrix}vu_- & wu_-\\ v & 0\end{pmatrix}+\begin{pmatrix}A & 0\\ 0 & D\end{pmatrix}, \tag{27}$$

where $\Delta A=0$ (i.e., A depends only on t). The residual gauge freedom, i.e., that which preserves (25), is (5) with

$$\Lambda=\begin{pmatrix}f(t) & 0\\ 0 & g(n,t)\end{pmatrix};$$

this has to be used to determine A and D, and to eliminate one of the three functions u, v, or w. In fact, the role of $f(t)$ is simply to fix A: let us choose $A=\frac{1}{2}c^{(1)}$. The remaining freedom now is

$$u \mapsto g_+^{-1} u, \qquad v \mapsto g_+ v, \qquad w \mapsto g^{-1} g_+ w. \tag{28}$$

Equation (18) for $L^{(2)}$ gives equations for u, v, and w, one form of which is

$$\begin{aligned}
&\frac{d}{d} \log v = D_+ + \frac{1}{2} c^{(1)}(wv_- / v - uv) + \frac{1}{2} c^{(2)} \frac{v_+ + vw_+}{v(uv_+ + w_+)}, \\
&\frac{d}{dt} \log w = \Delta\left(D - \frac{1}{2} c^{(2)} \frac{vu_-}{vu_- + w} \right), \\
&\frac{d}{dt}(uv) = \Delta\left(-\frac{1}{2} c^{(1)} uwv_- + \frac{1}{2} c^{(2)} \frac{vu_-}{vu_- + w} \right), \\
&\frac{d}{dt} \log(uw) = -D - \frac{1}{2} c^{(1)}(u_+ w_+ / u - uv) - \frac{1}{2} c^{(2)} \frac{uw + u_-}{u(vu_- + w)}.
\end{aligned} \tag{29}$$

(Any three of these equations implies the fourth.) We see from (28) that in order to remove the remaining gauge freedom, i.e., fix g (at least up to a function of t), there are three possibilities. Namely, we can specify either w, or uw, or v as a function of the gauge-invariant combination uv. This, in turn, will determine D, and hence $V^{(0)}$, on eliminating the relevant variable from (29). For example, specifying uw as a function of uv will give a local formula for D. Similarly, v can be specified as any function of uv. But if we impose $w = F(uv)$, then we need F to be an exponential in order to get a local expression for D. This illustrates the way in which some choices of gauge lead to a nonlocal expression for $V^{(0)}$.

As an example, let us take the gauge $w = \text{const}$. Choose $w = -1$, and write $u = -e^x$, $uv = y$. Then (29) reduces to the system

$$\begin{aligned}
&\frac{d}{dt} y = \frac{1}{2} c^{(1)} \Delta(y_- e^{\Delta x_-}) + \frac{1}{2} c^{(2)} \Delta\left(\frac{y}{y - \exp \Delta x_-} \right), \\
&\frac{d}{dt} x = \frac{1}{2} c^{(1)}(y + e^{\Delta x}) - \frac{c^{(2)}}{2(y - \exp \Delta x_-)}.
\end{aligned} \tag{30}$$

This is a version of the relativistic Toda lattice.[10–14]

Example (iv). The gauge choice,

$$L^{(1)} = \begin{pmatrix} -1 & e^x \\ 0 & 0 \end{pmatrix}, \quad L^{(2)} = \begin{pmatrix} e^y & 0 \\ -ke^{y-x} & 0 \end{pmatrix},$$

where k is a constant, gives

$$V^{(0)} = \frac{c^{(1)}}{2} \begin{pmatrix} 1 - ke^{y_- + \Delta x_-} & -e^x \\ -ke^{y_- - x_-} & 0 \end{pmatrix} + \frac{c^{(2)}}{2} \begin{pmatrix} 0 & e^{x-y} \\ ke^{-x_-} & 1 - ke^{-y + \Delta x_-} \end{pmatrix},$$

and again leads to the relativistic Toda system,[10,14,15] this time in the form

$$\begin{aligned}
&\frac{d}{dt} y = -\frac{1}{2} c^{(1)} k \Delta(e^{y_- + \Delta x_-}) - \frac{1}{2} c^{(2)} k \Delta(e^{-y + \Delta x_-}), \\
&\frac{d}{dt} x = -\frac{1}{2} c^{(1)} e^y (1 + ke^{\Delta x}) + \frac{1}{2} c^{(2)} e^{-y}(1 + ke^{\Delta x_-}).
\end{aligned} \tag{31}$$

The limit $k\rightarrow 0$ gives the Toda system (1); it is worth examining this in more detail. In order to get (1), one may replace the variables x and y by φ and ψ, where

$$e^{x}=-\sqrt{k}e^{\varphi},\quad e^{y}=-1+\sqrt{k}\psi,$$

and set $c^{(1)}=c^{(2)}=-1/\sqrt{k}$. Then the $k\rightarrow 0$ limit of (31) is indeed (1). But since $c^{(\alpha)}\rightarrow\infty$ in this limit, we need to reinterpret the associated Lax pair. The way to get a well-behaved limit is to replace λ by $2\lambda/\sqrt{k}$. The roots of det $L(\lambda)$ now occur at $\lambda=\pm\frac{1}{2}\sqrt{k}$, and so in the $k\rightarrow 0$ limit they coincide. In fact, when $k=0$ we have

$$L(\lambda)=-\begin{pmatrix} 1+\psi\lambda & e^{\varphi}\lambda \\ -e^{-\varphi}\lambda & 0 \end{pmatrix},$$

and det $L(\lambda)$ has a double zero at $\lambda=0$ (cf. Ref. 3). The corresponding expression for $V(\lambda)$ is obtained by taking the $k\rightarrow 0$ limit after first subtracting a constant multiple of the identity matrix: this yields

$$V(\lambda)=\begin{pmatrix} 0 & -e^{\varphi} \\ e^{-\varphi_{-}} & \lambda^{-1} \end{pmatrix}.$$

VI. SOME $p=2$ EXAMPLES

In the $p=2$ case, $L(\lambda)$ has the form $L(\lambda)=A\lambda^{2}+B\lambda+C$, where A, B, and C are 2×2 matrices; so to begin with, one has 12 functions of n and t. The requirement that the zeros λ_{α} of the quartic polynomial det $L(\lambda)$ be constant imposes four equations on these functions, and choice of gauge imposes a further four, so one is left with four independent functions. In other words, the generic system in this $p=2$, $q=2$ case is a system of coupled evolution equations for four lattice variables.

Reductions of such systems, so that fewer functions are involved, are, of course, possible. One example that has been known for some time is a lattice version of the sine-Gordon equation in which space is discrete and time continuous (by contrast with the version mentioned in Sec. III). Here the L operator has the form[16,3]

$$L=\begin{pmatrix} \lambda f(\varphi)e^{i\eta} & \frac{1}{4}h(e^{-i\varphi/2}-\lambda^{2}e^{i\varphi/2}) \\ \frac{1}{4}h(\lambda^{2}e^{-i\varphi/2}-e^{i\varphi/2}) & \lambda f(\varphi)e^{-i\eta} \end{pmatrix},$$

where φ and η are functions of n and t, h is a constant corresponding to the lattice spacing, and $f(\varphi)=(1+\frac{1}{8}h^{2}\cos\varphi)^{1/2}$. The resulting integrable lattice has sine-Gordon in ''laboratory coordinates'' as a continuum limit: if we replace n by $x=nh$ and let $h\rightarrow 0$, then φ satisfies $\varphi_{tt}-\varphi_{xx}+\sin\varphi=0$.

In order to obtain another example, let us choose a different gauge, namely $A=\mathbf{I}$, $V^{(0)}=0$. On B and C we impose the four constraints tr $B=0$, det $C=l$ const, $\mathrm{tr}(BC)=0$, and tr $C+\det B=-2k$ constant. It then follows that det $L(\lambda)=\lambda^{4}-2k\lambda^{2}+l$ has constant zeros. The matrices B and C now involve four independent functions, and their evolution is given by

$$\frac{d}{dt}B=\Delta Q,\qquad \frac{d}{dt}C=R_{+}C-CR, \tag{32}$$

where $Q=\Sigma_{\alpha}V^{(\alpha)}$, $R=-\Sigma_{\alpha}\lambda_{\alpha}^{-1}V^{(\alpha)}$, and the $V^{(\alpha)}$ are constructed as in (16). There are four parameters, namely the $c^{(\alpha)}$.

We can get an idea of what this system represents by looking at a continuum limit. To keep things simple, we assign particular values to the parameters, and this leads to the following continuum integrable system.

Let $\mathbf{B}$ and $\mathbf{C}$ be 3-vectors, functions of x and t, satisfying the constraints $\mathbf{B}\cdot\mathbf{C}=0$ and $\mathbf{C}\cdot\mathbf{C}=1$. Their time evolution is given by

$$\begin{aligned} \mathbf{B}_t &= (\mathbf{C}\wedge\mathbf{B}_x)_x - \{(\mathbf{C}\wedge\mathbf{C}_x\cdot\mathbf{B})\mathbf{C}\}_x + \tfrac{1}{2}\{(\mathbf{B}\cdot\mathbf{B})\mathbf{B}\}_x, \\ \mathbf{C}_t &= (\mathbf{C}\wedge\mathbf{C}_x)_x + (\mathbf{C}\wedge\mathbf{C}_x\cdot\mathbf{B})\mathbf{B}\wedge\mathbf{C} + \tfrac{1}{2}(\mathbf{B}\cdot\mathbf{B})\mathbf{C}_x. \end{aligned} \tag{33}$$

This is integrable: it has a Lax pair of the form $\Psi_x = U\Psi$, $\Psi_t = V\Psi$, where $U = -\frac{1}{2}i(\mathbf{B}\lambda^{-1} + \mathbf{C}\lambda^{-2})\cdot\sigma$ corresponds to $L(\lambda)$, and $V = \Sigma_{k=1}^{4} V_k \lambda^{-k}$ is a limiting version of the $V(\lambda)$ of the lattice system.

The equations (33) have two obvious reductions: if $\mathbf{B}=0$, then we are left with the Heisenberg ferromagnet equation for $\mathbf{C}$; while if $\mathbf{C}$ is a constant unit vector, then $\mathbf{B}$ satisfies the derivative nonlinear Schrödinger equation. So (33) may be viewed as a coupled Heisenberg–DNLS system; and (32) is a spatially discrete version of this coupled system.

VII. CONCLUDING REMARKS

It is clear that the examples given above provide only a very small sample of integrable lattice systems. One may envisage a classification involving the three integers q (the size of the matrices L and V), p [the degree of $L(\lambda)$], and r [the maximum order of the poles of $V(\lambda)$]. But in view of the remarks at the beginning of Sec. V, a complete classification would require a way of dealing with the problem of equivalence.

We conclude with a remark on higher values of r. One can take a given $L(\lambda)$ (thereby fixing q and p), and allow $r>1$: in other words, higher-order poles in $V(\lambda)$. This leads to hierarchies of lattice systems, of which the $r=1$ cases are the first members. So hierarcies also fit naturally into this framework.

(Received 21 July 1998; accepted for publication 22 September 1998)

The computational use of Killing potentials which satisfy Penrose's equation is discussed. Penrose's equation is presented as a conformal Killing–Yano equation and the class of possible solutions is analyzed. It is shown that solutions exist in space–times of Petrov type *O*, *D*, or *N*. In the particular case of the Kerr background, it is shown that there can be no Killing potential for the axial Killing vector. © *1999 American Institute of Physics.* [S0022-2488(99)03001-7]

I. INTRODUCTION

In a space–time which admits a Killing vector k^a it is straightforward to find its Killing potential. Killing potentials are real bivectors Q^{ab} whose divergence returns the Killing vector $(1/3)\nabla_b Q^{ab}=k^a$. Killing potentials attain physical importance when they are used in the Penrose–Goldberg (PG)[1] superpotential for computing conserved quantities such as mass and angular momentum. The PG superpotential is

$$U^{ab}_{\mathrm{PG}}=\sqrt{-g}\,\frac{1}{2}\,G^{ab}{}_{cd}Q^{cd}, \tag{1}$$

where $G^{ab}{}_{cd}=-{}^*R^{*ab}{}_{cd}$, the negative right and left dual of the Riemann tensor. When the Ricci tensor is zero then $G^{ab}{}_{cd}=C^{ab}{}_{cd}$, the Weyl tensor. If Q^{ab} satisfies Penrose's equation (4) then

$$\nabla_b U^{ab}_{\mathrm{PG}}=\sqrt{-g}G^{ab}k_b \tag{2}$$

for Einstein tensor G^{ab}. The current density

$$J^a=\sqrt{-g}G^{ab}k_b \tag{3}$$

is conserved independently of the left-hand side of Eq. (2). It is the PG superpotential that allows the Noether quantities to be computed by integrating over closed two-surfaces, which is Penrose's quasilocal construction.[2] If one views the Killing vector itself as a conserved current then its integral over a three-surface is identically equal to 1/3 the integral of its Killing potential over the bounding two-surface and no new information can be obtained.

The tensor version of Penrose's equation[3] is

$$P^{abc}:=\nabla^{(a}Q^{b)c}-\nabla^{(a}Q^{c)b}+g^{a[b}Q^{c]e}{}_{;e}=0. \tag{4}$$

With $j^a:=(1/3)\nabla_b Q^{*ab}$, and $k^a:=(1/3)\nabla_b Q^{ab}$, an equivalent equation[4] to $P^{abc}=0$ is

$$\nabla_c Q^{ab}=-2\,\delta_c^{[a}k^{b]}+2(\delta_c^{[a}j^{b]})^*. \tag{5}$$

If Q^{ab} is a solution of the Penrose equation then $k_{(b;c)}=-(1/2)Q_{a(b}R^a{}_{c)}$ with a similar relation connecting j^a and Q^{*ab}. For Ricci-flat space–times j^a and k^a are Killing vectors.

[a)]Permanent address: Physics Department, University of Windsor, Ontario, Canada.

For a particular space–time the number of independent Killing vectors is between zero and ten. Penrose[3] gave the complete solution to Eq. (4) in Minkowski space for ten real independent Q^{ab}.

This work discusses the existence of Killing potentials which satisfy Penrose's equation or equivalently the conformal Killing–Yano (CKY) equation for two-form $\mathcal{Q}$. The fact that such tensors only exist in space–times of Petrov type *D*, *N*, or *O* is discussed in Sec. III B and Appendices *C* and *D*.

In the Kerr background, it has previously been shown that there is no Killing potential for the axial Killing vector.[5] We show, in Sec. III C, how this can be anticipated from properties of the curvature and the fact that the axial Killing vector must vanish along the axis of symmetry.

We use both the abstract index notation familiar to relativists and some coordinate free notation for which we provide Appendix A as a reference. We use boldface characters for index free tensor notation, excepting differential forms which appear in calligraphic type. Appendix B describes some aspects of the Petrov classification in a way convenient for our purposes.

II. PREVIOUS RESULTS

An exact solution of the Penrose equation for Kerr's vacuum solution is given in Eq. (8). This solution was first used in the context of the PG superpotential construction in Ref. 6. The Kerr solution has two Killing vectors (KVs), stationary $k_{(t)}$ and axial $k_{(\varphi)}$, and the metric is

$$g^{\mathrm{Kerr}} = l\otimes n + n\otimes l - m\otimes\overline{m} - \overline{m}\otimes m, \tag{6}$$

where $\{l,n,m,\overline{m}\}$ is the Newman–Penrose principal null coframe, given in Boyer–Lindquist coordinates by

$$\begin{aligned} l &= dt - (\Sigma/\Delta)dr - a\sin^2\theta\, d\varphi, \\ n &= \frac{\Delta}{2\Sigma}[dt + (\Sigma/\Delta)dr - a\sin^2\theta\, d\varphi], \\ m &= \frac{1}{\sqrt{2}\overline{R}}[ia\sin\theta dt - \Sigma d\theta - i(r^2+a^2)\sin\theta\, d\varphi], \end{aligned} \tag{7}$$

where $R = r - ia\cos\theta$, $\Sigma = R\overline{R}$, and $\Delta = r^2 + a^2 - 2m_0 r$. The Killing potential for $k_{(t)}$ is the bivector $Q^{ab}_{(t)}$ obtained by raising the components of the two-form

$$\mathcal{Q}_{(t)} = -(R\mathcal{M} + \overline{R}\overline{\mathcal{M}}), \tag{8}$$

where $\mathcal{M} := l\wedge n - m\wedge\overline{m}$ is an anti-self-dual two-form, that is $*\mathcal{M} = -i\mathcal{M}$. We mention that $Q^{ab}_{(t)}$ is a global solution since the quasilocal PG mass, resulting from integration of the PG superpotential over two-surfaces of constant t and r, is *independent of choice of two-surface*

$$\oint_{S^2} U^{ab}_{\mathrm{PG}}\, dS_{ab} = -8\pi\, m_0 \tag{9}$$

for any r beyond the outer event horizon.

The next interesting result involves the axial Kerr symmetry. Goldberg[1] found asymptotic solutions of the Penrose equation for the Bondi–Sachs metric which includes the Kerr solution as a special case. But Glass[5] showed that the axial Killing potential could not be a solution of the Penrose equation at finite r.

The bivector $Q^{ab}_{(t)}$ generally has six independent components and so enough information to describe two Killing vectors. Since the Kerr solution has two KVs, can the dual of $Q^{ab}_{(t)}$ yield $k_{(\varphi)}$? Direct differentiation shows

$$\nabla_b Q^{*ab}_{(t)} = 0, \tag{10}$$

and so $Q^{ab}_{(t)}$ can only yield $k_{(t)}$. In fact $Q^{*ab}_{(t)}$ satisfies the Killing–Yano (KY) equation, which for an antisymmetric tensor A_{ab} can be written as

$$A_{a(b;c)} = 0. \tag{11}$$

This generalizes Killing's equation to antisymmetric tensors and can be further generalized to antisymmetric tensors of arbitrary valence. Modern usage reserves the name KY tensor for antisymmetric tensors. For the Kerr solution a symmetric tensor K_{ab} is constructed from the dual Killing potential by

$$K_{ab} = Q^{*e}_{(t)a} Q^{*(t)}_{eb} = 2\Sigma l_{(a} n_{b)} - r^2 g_{ab}. \tag{12}$$

This ''hidden'' symmetry of the Kerr solution was discovered by Carter[7] and later shown to be the ''square'' of a two-index Killing spinor,[8] or equivalently, the ''square'' of a Killing–Yano tensor. Though K_{ab} satisfies Eq. (11) it is symmetric and generally referred to as a Killing tensor.

Collinson[9] found that all vacuum metrics of Petrov type D, with the exception of Kinnersley's type $IIIB$, possess a KY tensor. He gave an explicit expression for both the KY tensor and its associated Killing tensor.

III. EXISTENCE OF SOLUTIONS

A. Conformal Killing–Yano tensors

Many of the arguments in this work depend on the conformal covariance of Penrose's equation. Penrose and Rindler[10] established the conformal covariance of its spinor form $\nabla_{A'}{}^{(A}\sigma^{BC)} = 0$ for a symmetric spinor σ^{BC}. The tensor version was previously discovered by Tachibana as the conformally covariant generalization of the KY equation.[11] In this paper it was written in the form

$$Q_{a(b;c)} = (1/3)[g_{bc} Q_{a;e}^{\;\;\;e} - g_{a(b} Q_{c)}{}^{e}{}_{;e}]. \tag{13}$$

In that same work Tachibana showed that in a Ricci-flat space, for Q_{ab} a CKY bivector satisfying Eq. (13), $(1/3)\nabla^b Q_{ab}$ is a Killing vector.

From Eq. (13) we can obtain an expression for $Q_{ab;c}$ by writing out the symmetrization brackets explicitly:

$$Q_{ab;c} = -Q_{ac;b} + \tfrac{2}{3} g_{bc} Q_{a;e}^{\;\;\;e} - \tfrac{1}{3} g_{ab} Q_{c;e}^{\;\;\;e} - \tfrac{1}{3} g_{ac} Q_{b;e}^{\;\;\;e}.$$

Now, since $Q_{ab;c}$ is antisymmetric in the first two indices, we have

$$\begin{aligned} 3Q_{ab;c} &= Q_{ab;c} + Q_{ab;c} - Q_{ba;c} \\ &= Q_{ab;c} - Q_{ac;b} + \tfrac{2}{3} g_{bc} Q_{a;e}^{\;\;\;e} - \tfrac{1}{3} g_{ab} Q_{c;e}^{\;\;\;e} - \tfrac{1}{3} g_{ac} Q_{b;e}^{\;\;\;e} \\ &\quad + Q_{bc;a} - \tfrac{2}{3} g_{ac} Q_{b;e}^{\;\;\;e} + \tfrac{1}{3} g_{ba} Q_{c;e}^{\;\;\;e} + \tfrac{1}{3} g_{bc} Q_{a;e}^{\;\;\;e} \end{aligned}$$

and so from (13) we can deduce that

$$3Q_{ab;c} = 3Q_{[ab;c]} - 2 g_{c[a} Q_{b]}{}^{e}{}_{;e}. \tag{14}$$

It is easily verified that given Eq. (14) we recover Eq. (13) and hence Eq. (14) is an alternative form of the CKY equation. Furthermore Penrose's Eq. (4) can easily be rewritten as Tachibana's Eq. (13) and so is another form of the CKY equation.

Since Q is an antisymmetric tensor, it is natural to discuss its properties in the language of differential forms. Equation (14) is manifestly antisymmetric in the first two indices, and so it is straightforward to verify that it is the abstract index equivalent of the CKY two-form equation of Benn *et al.*,[12]

$$3\nabla_z \mathcal{Q} = Z \lrcorner d\mathcal{Q} - Z^\flat \wedge \delta\mathcal{Q}, \quad \forall Z. \tag{15}$$

In this form, since $*$ commutes with ∇_Z, it is readily verified using the identities given in Appendix A, that whenever $\mathcal{Q}$ is a CKY two-form so is $*\mathcal{Q}$. Thus any solution to the CKY equation can be decomposed into self-dual and anti-self-dual CKY two-forms.

B. Existence of CKY two-forms

On a flat background the CKY equation has many solutions, while, as will be explained, in a more general space–time the curvature imposes tight consistency conditions and there can be at most two independent solutions, one self-dual and one anti-self-dual with respect to the Hodge star. This result appears to be closely tied to the four-dimensional nature of space–time and the properties of these solutions are almost universally discussed in their spinor form, where the utility of the two-component spinor formalism simplifies the calculations. A detailed discussion of this can be found in spinor form in Ref. 12 or in terms of differential forms in Ref. 13.

Since any CKY two-form can be decomposed into self-dual and anti-self-dual parts that are themselves CKY two-forms, in discussing their existence, it is sufficient to consider only two-forms of definite Hodge-duality.

In order to understand how the curvature of the underlying space–time restricts the solutions to Eq. (15) two steps are required. First, it can be shown directly from the CKY two-form equation that the real eigenvectors of (anti-) self-dual CKY two-forms are shear-free and hence principal null directions of the conformal tensor. Second, by differentiating Eq. (15) an integrability condition can be obtained that restricts the Petrov type by showing these eigenvectors to be *repeated* principal null directions.

In the case of non-null self-dual two-forms, Dietz and Rüdiger[14] used spinor methods to obtain both of these results for a scaling covariant generalization of Eq. (15). It was later shown, again using spinor methods, that similar results can be obtained for the null case.[12]

An outline of these results in the notation of differential forms is given in Appendices C and D. It is shown that apart from conformally flat space–times, non-null (anti-) self-dual CKY two-forms can only exist in space–times of Petrov type *D*, while null (anti-) self-dual CKY two-forms require a background space–time of Petrov type *N*.

C. The divergence of a CKY two-form

In order to apply the PG superpotential method using a given CKY two-form $\mathcal{Q}$, its divergence (coderivative) $\delta\mathcal{Q}$ must be dual to a Killing vector. Tachibana showed that this was always the case in a Ricci flat background[11] (the result also holds for the slightly more general case of an Einstein space–time).

In the Kerr background, there are two independent Killing vectors and two independent CKY two-forms (one of each Hodge-duality). However the divergence of either of these CKY two-forms is proportional to the timelike Killing vector, leaving the axial KV without a Killing potential. This allows a divergence free linear combination of the self-dual and anti-self-dual CKY two-forms to be found. The Hodge-dual of this two-form is known as a Killing–Yano two-form and satisfies the Killing–Yano equation (11), which can be written in a similar fashion to Eq. (15) as

$$3\nabla_X \mathcal{Q} = X \lrcorner d\mathcal{Q}. \tag{16}$$

However, this leaves open the question of why it is that the timelike rather than the axial KV possesses a Killing potential? To answer this question, we note that the axial Killing vector must vanish along the symmetry axis and we show that a Killing vector obtained as the divergence of a CKY two-form must be nowhere vanishing.

First consider a non-null anti-self-dual CKY two-form $\mathcal{Q}^-$. From Eq. (15) we can write $d(\mathcal{Q}^{-2})$ in terms of $\mathcal{Q}^-$ and $\delta\mathcal{Q}^-$:

$$d(\mathcal{Q}^{-2}) = \tfrac{4}{3}(\delta\mathcal{Q}^-)^\sharp \lrcorner \mathcal{Q}^-,$$

which after contracting with $\mathcal{Q}^-$ leads to

$$\delta\mathcal{Q}^- = -\tfrac{3}{2}(d(\mathcal{Q}^{-2}))^\sharp \lrcorner \mathcal{Q}^-.$$

Hence $\delta\mathcal{Q}^-$ vanishes if and only if $d(\mathcal{Q}^{-2})$ vanishes.

In a vacuum type D background we can deduce that $\mathcal{Q}^{-2}$ is a constant multiple of $\Psi_2{}^{-2/3}$ from the fact that $\mathcal{Q}^-$ is an eigen-two-form of $\mathbf{C}$ and both $(\mathcal{Q}^{-2})^{-3/2}\mathcal{Q}^-$ and $\mathbf{C}\mathcal{Q}^-$ are Maxwell fields. Hence if $\mathcal{Q}^-$ vanishes, then so does Ψ_2 and the background becomes conformally flat.

Further, it can be deduced from the Bianchi identities that for a type D vacuum space–time, the gradient of Ψ_2 vanishes if and only if the Ψ_2 itself vanishes. [In the Newman–Penrose (NP) formalism, using a principal null tetrad, the vacuum type D condition implies that the only nonzero curvature component is Ψ_2 and $\kappa=\sigma=\nu=\lambda=0$. Then, imposing $\nabla_{X_a}\Psi_2=0$, the Bianchi identities lead to either $\rho=\mu=\tau=\pi=0$ or $\Psi_2=0$. If we assume the former, then the NP equations for the derivatives of the spin coefficients immediately force the conclusion that Ψ_2 vanishes.] We therefore conclude that $\mathcal{Q}^{-2}$ is nowhere constant and hence $\delta\mathcal{Q}^-$ is nowhere vanishing and Kerr's axial Killing vector *cannot* have a Killing potential.

IV. SUMMARY

We have shown here that Penrose's equation for Killing potentials is equivalent to the conformal Killing–Yano equation for two-forms. With no appeal to Ricci-flatness existence of solutions was proven for space–times of Petrov type D, N or O. It was further shown, for type D vacuum backgrounds possessing a Killing–Yano two-form, that Killing vectors with zeros cannot have Killing potentials.

APPENDIX A: DIFFERENTIAL FORMS

We denote a basis for vector fields by $\{X_a\}$. The natural dual of this we denote by $\{e^a\}$, a basis for covector or one-form fields. A coordinate basis is $X_a=\partial/\partial x^a$ and $e^a=dx^a$. The metric gives a natural bijection between vector and one-form fields, which we denote by $^\sharp$ and $^\flat$; $X^\flat$ is the one-form metric dual to the vector X and $\alpha^\sharp$ is the vector field metric dual to the one-form α.

The one-forms, along with the wedge product $\wedge$, generate the algebra of differential forms. The wedge product is antisymmetric and so the differential forms of degree p can be thought of as the subset of covariant tensors of valence p that are antisymmetric in their arguments. If α and β are one-forms with components $\alpha_a=\alpha(X_a)$ and $\beta_a=\beta(X_a)$, then

$$\alpha\wedge\beta=\alpha_{[a}\beta_{a]}e^a\otimes e^b=\alpha_a\beta_b e^a\wedge e^b. \tag{A1}$$

A vector can be contracted with the p-form $\mathcal{P}$ to give a $(p-1)$-form $X\lrcorner\mathcal{P}$ so that

$$(X\lrcorner\mathcal{P})(X_{a_1},X_{a_2},\ldots,X_{a_{p-1}})=p\mathcal{P}(X,X_{a_1},X_{a_2},\ldots,X_{a_{p-1}}),$$

and so the components of a p-form can be expressed using the hook as

$$\mathcal{P}_{ab\cdots c}=\mathcal{P}(X_a,X_b,\ldots,X_c)=\frac{1}{p!}X_c\lrcorner\cdots\lrcorner X_b\lrcorner X_a\lrcorner\mathcal{P}.$$

We can define an inner product between any pair of two-forms:

$$\mathcal{P}\cdot\mathcal{Q}=\tfrac{1}{2}X_a\lrcorner X_b\lrcorner\mathcal{P}X^a\lrcorner X^b\lrcorner\mathcal{Q}=2\mathcal{P}_{ab}\mathcal{Q}^{ab}.$$

For $\mathcal{P}\cdot\mathcal{P}$ we write $\mathcal{P}^2$.

The metric defines a natural map from p-forms to $(n-p)$-forms called the Hodge star. In four dimensions, this maps two-forms to two-forms, and is defined so that

$$\mathcal{P}\wedge*\mathcal{Q}=(\mathcal{P}\cdot\mathcal{Q})*1,$$

where $*1$ is the volume four-form. For a Lorentzian metric, this map squares to -1 and so has eigenvalues, $\pm i$. Elements of the eigenspace corresponding to $(-i)+i$ are called (anti-) self-dual two-forms. Any two-form can be decomposed into self-dual and anti-self-dual parts

$$\mathcal{P}=\mathcal{P}^+ + \mathcal{P}^- \quad \text{where} \quad *\mathcal{P}^{\pm}=\pm i\mathcal{P}.$$

The Hodge star relates the hook and wedge operations by

$$X\lrcorner*\mathcal{P}=*(\mathcal{P}\wedge X^\flat). \tag{A2}$$

The two-form commutator is given by

$$[\mathcal{P},\mathcal{Q}]=-2X_a\lrcorner\mathcal{P}\wedge X^a\lrcorner\mathcal{Q} \tag{A3}$$

for two-forms $\mathcal{P}$ and $\mathcal{Q}$. The Lie algebra of two-forms under commutation is the Lie algebra of the Lorentz group.

It is often useful to work with a null coframe (basis for one-forms) $\{l,n,m,\overline{m}\}$ dual to a Newman–Penrose tetrad, that is, one for which all inner products vanish except

$$l\cdot n=-m\cdot\overline{m}=1. \tag{A4}$$

From this we can construct a basis for the anti-self-dual two-forms:

$$\mathcal{U}=-n\wedge\overline{m}, \quad \mathcal{M}=l\wedge n-m\wedge\overline{m}, \quad \mathcal{V}=l\wedge m \tag{A5}$$

with the property that all inner products vanish except

$$\mathcal{U}\cdot\mathcal{V}=1, \quad \mathcal{M}\cdot\mathcal{M}=-2. \tag{A6}$$

In this basis, the two-form commutator can be calculated from

$$[\mathcal{M},\mathcal{U}]=-4\mathcal{U}, \quad [\mathcal{M},\mathcal{V}]=4\mathcal{V}, \quad [\mathcal{U},\mathcal{V}]=-\mathcal{M}. \tag{A7}$$

The null basis elements $\mathcal{U}$ and $\mathcal{V}$ for each have one two-dimensional eigenspace, with corresponding zero eigenvalue, spanned by $\{n^\sharp,\overline{m}^\sharp\}$ and $\{l^\sharp,m^\sharp\}$, respectively. These are also the eigenspaces of $\mathcal{M}$ for which they have eigenvalues $+1$ and -1. Note that choosing $\mathcal{M}$ determines $\mathcal{U}$ and $\mathcal{V}$ up to their relative scaling or interchange.

We denote the torsion-free metric compatible covariant derivative of a two-form $\mathcal{Q}$ with respect to a vector field Z by $\nabla_Z\mathcal{Q}$. In terms of this, the exterior derivative d and coderivative $\delta=*d*$ can be expressed:

$$d\equiv e^a\wedge\nabla_{X_a}, \quad \delta\equiv-X^a\lrcorner\nabla_{X_a}.$$

APPENDIX B: THE PETROV CLASSIFICATION

In a vacuum background, the Riemann curvature tensor **R** is equal to the Weyl conformal curvature tensor **C**. The symmetries of these tensors allow them to be written as the sum of terms made of symmetric tensor products of two-forms (i.e., terms like $\mathcal{P}\otimes\mathcal{Q}+\mathcal{P}\otimes\mathcal{Q}$). So, both can be considered as self-adjoint maps on two-forms; if C_{abcd} are components of **C** and $\mathcal{P}_{ab}$ the components of a two-form, then the definition

$$(\mathbf{C}\mathcal{P})_{ab}=\tfrac{1}{2}C_{abcd}\mathcal{P}^{cd}$$

gives the components of the two-form $\mathbf{C}\mathcal{P}$. As a map on two-forms, the conformal tensor preserves the eigenspaces of $*$ and so may be decomposed into a part made from self-dual two-forms alone and a part made from anti-self-dual two-forms. That is, we can write

$$\mathbf{C}=\mathbf{C}^{(+)}+\mathbf{C}^{(-)},$$

where $\mathbf{C}^{(\pm)}\mathcal{Q}^{\mp}=0$. Note that since the conformal tensor is real, $\mathbf{C}^{(-)}$ is the complex conjugate of $\mathbf{C}^{(+)}$, and so it is sufficient to classify only one of these.

The action of $\mathbf{C}^{(-)}$ on the Newman–Penrose two-form basis described in Appendix A is the same as the action of **C** on this basis and can be written as

$$\mathbf{C}^{(-)}\begin{bmatrix}\mathcal{U}\\ \mathcal{M}\\ \mathcal{V}\end{bmatrix}=\begin{bmatrix}-\Psi_2 & \Psi_3 & -\Psi_4\\ -2\Psi_1 & 2\Psi_2 & -2\Psi_3\\ -\Psi_0 & \Psi_1 & -\Psi_2\end{bmatrix}\begin{bmatrix}\mathcal{U}\\ \mathcal{M}\\ \mathcal{V}\end{bmatrix}.$$

Note that the matrix of this transformation is trace-free and the mapping is self-adjoint (that is, $\mathcal{Q}\cdot\mathbf{C}\mathcal{P}=\mathbf{C}\mathcal{Q}\cdot\mathcal{P}$).

The Petrov classification is a classification of this mapping. The space–time is known as algebraically general when there are three distinct eigenvalues, and algebraically special otherwise. Two special cases of interest here are that of type *D* and *N*, for which a basis can be chosen so that the matrix above takes the forms,

$$\begin{bmatrix}-\Psi_2 & 0 & 0\\ 0 & 2\Psi_2 & 0\\ 0 & 0 & -\Psi_2\end{bmatrix},\quad\begin{bmatrix}0 & 0 & 0\\ 0 & 0 & 0\\ -\Psi_0 & 0 & 0\end{bmatrix},$$

respectively.

The real null direction of a null anti-self-dual two-form $\mathcal{Q}$ is said to be a *principal null direction* (PND) of the conformal tensor if $\mathcal{Q}\cdot\mathbf{C}\mathcal{Q}=0$. We will call such a $\mathcal{Q}$, a *principal null* (PN) two-form. There can be at most four independent PNDs and their number and ''multiplicities'' provide another description of the Petrov types.[3] The multiplicities can be determined in the present formulation by the following (with $\mathcal{P}$ an anti-self-dual two-form):

Multiplicity	Equivalent conditions		
1	$\mathcal{Q}\cdot\mathbf{C}\mathcal{Q}=0$		$\Psi_4=0$
2	$[\mathcal{Q},\mathbf{C}\mathcal{Q}]=0$	$\mathbf{C}\mathcal{Q}\propto\mathcal{Q}$	$\Psi_3=\Psi_4=0$
3	$\mathcal{Q}\cdot\mathbf{C}\mathcal{P}=0\ \forall\mathcal{P}$	$\mathbf{C}\mathcal{Q}=0$	$\Psi_2=\Psi_3=\Psi_4=0$
4	$[\mathcal{Q},\mathbf{C}\mathcal{P}]=0\ \forall\mathcal{P}$	$\mathbf{C}\mathcal{P}\propto\mathcal{Q}\ \forall\mathcal{P}$	$\Psi_1=\Psi_2=\Psi_3=\Psi_4=0$

APPENDIX C: CKY TWO-FORMS AND SHEAR-FREE CONGRUENCES

Defining the shear of a null geodesic vector field requires the choice of a ''screen space,'' and so is not an intrinsic property of the vector field. However, if the shear vanishes for one choice of screen space, then it does for all and hence the notion of a shear-free null vector field is well defined. For definitions and discussion of optical scalars see Ref. 3.

Robinson[15] showed that the real null eigenvector l of a (anti) self-dual null two-form ϕ is geodesic and shear-free if and only if ϕ is proportional to a source-free Maxwell field, that is $d\phi=0$. Note that the eigenspace of such a two-form is two-dimensional, isotropic and integrable. So we can use this fact or the Frobenius integrability condition, that $d\phi=\alpha\wedge\phi$ for some α, for the vanishing of the shear of l. It is convenient here to use these results interchangeably as our criterion for a shear-free null geodesic.

Note that a shear-free null geodesic is a PND of the conformal tensor.

1. Null CKY two-forms

Now, suppose that $\mathcal{Q}$ is a null anti-self-dual CKY two-form. Since the right-hand side of CKY two-form Eq. (15) is simply the anti-self-dual part of $-2Z^\flat\wedge\delta\mathcal{Q}$, we have that

$$0=\mathcal{Q}\cdot 3\nabla_Z\mathcal{Q}=-2(Z^\flat\wedge\delta\mathcal{Q})\cdot\mathcal{Q}=2Z\lrcorner(\delta\mathcal{Q})^\sharp\lrcorner\mathcal{Q}.$$

Hence we can find an α such that $\delta\mathcal{Q}=\alpha^\sharp\lrcorner\mathcal{Q}$ or equivalently $d\mathcal{Q}=-\alpha\wedge\mathcal{Q}$. So the real null eigenvector of $\mathcal{Q}$ is shear-free.

2. Non-null CKY two-forms

We wish to show that the eigenspaces of a non-null CKY two-form $\mathcal{Q}$ are integrable and hence contain a shear-free null geodesic vector field. That is, we want to show that if X and Y are elements of the same eigenspace of $\mathcal{Q}$ with eigenvalue λ ($X\lrcorner\mathcal{Q}=\lambda X^\flat$ and $Y\lrcorner\mathcal{Q}=\lambda Y^\flat$), then so is $[X,Y]$. Since $[X,Y]=\nabla_x Y-\nabla_Y X$, we will show that $\nabla_X Y\lrcorner\mathcal{Q}=\lambda\nabla_X Y^\flat$. Note that this eigenspace is isotropic, that is $g(X,Y)=0$.

Since the map $\alpha\mapsto\alpha^\sharp\lrcorner\mathcal{Q}$ is of maximal rank for non-null $\mathcal{Q}$, it can always be inverted and a one-form α found such that $\delta\mathcal{Q}=-\alpha^\sharp\lrcorner\mathcal{Q}$ and $d\mathcal{Q}=\alpha\wedge\mathcal{Q}$. Using these expressions for $\delta\mathcal{Q}$ and $d\mathcal{Q}$, and the CKY two-form Eq. (15), we have

$$\nabla_X Y\lrcorner\mathcal{Q}=\nabla_X(Y\lrcorner\mathcal{Q})-Y\lrcorner\nabla_X\mathcal{Q}=\lambda\nabla_X Y^\flat+X\lambda Y^\flat-\tfrac{1}{3}\lambda\,\alpha(X)Y^\flat.$$

Rearranging and writing the vector equation dual to this shows that

$$(\nabla_X Y\lrcorner\mathcal{Q})^\sharp-\lambda\nabla_X Y=(X\lambda-\tfrac{1}{3}\lambda\,\alpha(X))Y. \tag{C1}$$

Note that the right-hand side is a multiple of Y and hence an eigenvector of $\mathcal{Q}$ with eigenvalue λ. However, upon contracting the left-hand side with $\mathcal{Q}$, we find that it is an element of the other eigenspace, having eigenvalue $-\lambda$. Hence we must conclude that

$$\nabla_X Y\lrcorner\mathcal{Q}-\lambda\nabla_X Y^\flat=0, \tag{C2}$$

and we have the required result.

Since each eigenspace of $\mathcal{Q}$ is integrable they each give rise to a null self-dual two-form proportional to a Maxwell field, and hence the real eigenvectors of $\mathcal{Q}$ are shear-free.

APPENDIX D: INTEGRABILITY OF CKY TWO-FORMS

Apart from conformally flat space–times, CKY two-forms can only exist in space–times of Petrov type D or N. To understand this it is sufficient to consider only CKY tensors of definite Hodge-duality, for which we give an integrability condition. For an anti-self-dual CKY two-form $\mathcal{Q}$,

$$[\mathcal{Q},C\mathcal{P}]=\tfrac{1}{2}[\mathcal{P},C\mathcal{Q}], \quad \forall \text{ two-forms } \mathcal{P}. \tag{D1}$$

If we let $\mathcal{P}=\mathcal{Q}$, it follows that

$$[\mathbf{C}\mathcal{Q},\mathcal{Q}]=0.$$

Then, from the commutator algebra of anti-self-dual two-forms Eq. (A7), it can be deduced that $C\mathcal{Q}$ must be proportional to $\mathcal{Q}$, i.e.,

$$\mathbf{C}\mathcal{Q}=\mu\mathcal{Q}, \tag{D2}$$

where μ is a scalar. From this, we can deduce the Petrov type as described in Appendix B.

1. Null CKY two-forms

When $\mathcal{Q}$ is null this implies that the real null eigenvector of $\mathcal{Q}$ is a repeated principal null direction. However, if we write out Eq. (D1) in an anti-self-dual two-form basis chosen so that $\mathcal{U}=\mathcal{Q}$ and $\mathcal{V}\propto\mathcal{P}$, we find that $\mu=-\Psi_2=0$. Not only does this immediately tell us that $C\mathcal{Q}=0$, but upon substitution into Eq. (D1) we have that $[\mathcal{Q},C\mathcal{P}]=0$ for all anti-self-dual two-forms $\mathcal{P}$. Hence the real null direction defined by $\mathcal{Q}$ is a fourfold PND and the space–time is of Petrov type *N*.

2. Non-null CKY two-forms

When $\mathcal{Q}$ is non-null, we concluded in Appendix C that the real null eigenvectors of $\mathcal{Q}$ are shear-free. If we align our anti-self-dual two-form basis so that $\mathcal{M}\propto\mathcal{Q}$ then $\mathcal{U}$ and $\mathcal{V}$ have shear-free eigenvectors and hence are PN two-forms. From this we conclude that $\Psi_0=\Psi_4=0$. The integrability condition Eq. (D2) immediately requires that Ψ_1 and Ψ_3 vanish and hence the space–time is of Petrov type *D*.

This reasoning made no use of Ricci-flatness wherein the Goldberg-Sachs theorem[16] would imply the same result.

Black hole interacting with matter as a simple dynamical system

Petr Hájíček
Institute for Theoretical Physics, University of Bern, Sidlerstrasse 5, CH-3012 Bern, Switzerland

(Received 21 July 1998; accepted for publication 28 August 1998)

Recently, a variational principle has been derived from Einstein–Hilbert and a matter Lagrangian for the spherically symmetric system of a dust shell and a black hole. The so-called physical region of the phase space, which contains all physically meaningful states of the system defined by the variational principle, is specified; it has a complicated boundary. The principle is then transformed to new variables that remove some problems of the original formalism: the whole phase space is covered (in particular, the variables are regular at all horizons), the constraint has a polynomial form, and the constraint equation is uniquely solvable for two of the three conserved momenta. The solutions for the momenta are written down explicitly. The symmetry group of the system is studied. The equations of motion are derived from the transformed principle and are shown to be equivalent to the previous ones. Some lower-dimensional systems are constructed by exclusion of cyclic variables, and some of their properties are found. © *1999 American Institute of Physics.* [S0022-2488(99)03701-9]

I. INTRODUCTION

The spherically symmetric gravitating shell has been used as a simplified quantum model at many occasions. One can mention the quantum effects of domain walls in the early Universe,[1] quantum aspects of gravitational collapse,[2] quantum theory of black holes[3] or Hawking evaporation of black holes.[4]

The equations of motion for the shells has been derived by Dautcourt[5] and transformed to a geometric (i.e., ''gauge invariant'') form by Israel.[6] However, for a quantum theory, one needs a variational principle rather than dynamical equations. Such a variational principle has as yet been just guessed from the dynamical equations, Refs. 7 and 8, or from some intermediate variational principle, Refs. 4 and 9. Quite a number of different Hamiltonians have resulted and the corresponding quantum theories have not been unitarily equivalent. There are two sources of the ambiguity.

The first source of ambiguity is the invariance of the general relativity with respect to any coordinate transformations on one hand, and the property of Hamiltonians to generate dynamics with respect to a particular time coordinate on the other. For example, the choice of the proper time along the shell as such a coordinate leads to the $\cosh p$ Hamiltonian, Refs. 7 and 10, the Schwarzschild time coordinate inside the shell to the square-root Hamiltonian, Ref. 2, and the Schwarzschild time coordinate outside the shell to a merely implicitly determined Hamiltonian of Refs. 4 and 9. An attempt to work out a gauge invariant theory for at least some class of the guessed Hamiltonians is Ref. 8; based on a technical assumption that the super-Hamiltonian is quadratic in the momenta, it gives a unique action principle.

The second source of ambiguity is the fact that equations of motion do not determine the corresponding variational principle uniquely, in general. This ambiguity can be removed by a direct derivation of the variational principle for the shell from the Einstein–Hilbert and shell matter Lagrangian. Three such derivations exist: Refs. 11, 12, and 13; they all lead to the same variational principle for the same system. In Refs. 12 and 13, the reduction of the second order formalism to the spherically symmetric case is done first, followed by a reduction to dynamical variables of the shell alone and by the transformation to the second order formalism. In Ref. 11, a first and second order formalism for a general shell and gravitational field is derived (no symmetry); this second order formalism is reduced by the spherical symmetry and to shell variables in Ref. 14.

We are then left with the following dilemma. The super-Hamiltonian of Ref. 8 is simple and amenable to the existing gauge invariant quantization methods (like, e.g., Refs. 15 and 16). The super-Hamiltonian of Refs. 12, 14 and 13 follows from the Einstein–Hilbert and shell-matter Lagrangian, but it is extremely complicated: it contains nested square roots and hyperbolic functions, and for a good measure it is formulated in coordinates that diverge on horizons. It would be difficult to quantize.

A natural question then arises: what is the relation between the guessed and simple variational principle of Ref. 8 and the derived but complicated one of Refs. 12, 14 and 13? If the simple principle were equivalent to the complicated one, we could use the simple principle and forget the complicated one. However, the answer turns out to be rather surprising (see Ref. 17): the two descriptions are only locally, but not globally, equivalent. The local equivalence explains why the equations of motion are the same. For the study of the problem, a geometric approach of Ref. 18 has been applied. All gauge invariant properties of a constrained system are encoded in two objects: the constraint manifold Γ and the presymplectic form Ω on Γ. The equivalence of two such systems, (Γ_1,Ω_1) and (Γ_2,Ω_2), is then a well-defined mathematical concept independent of a choice of extended phase space, a choice of constraint functions or a choice of gauge.

In this situation, it seems natural to look for a transformation of the variational principle of Refs. 12, 14 and 13 to a better set of coordinates, and this will be the main topic of the present paper. The method will again be based on the gauge invariant description (Γ,Ω) of reparametrization invariant systems. We shall perform the transformation in three steps; to motivate the steps, we take into account the symmetry of the system, the structure of the so-called *Cartan form* Θ, which is defined by $d\Theta := \Omega$, and the topology of the space (Γ,Ω). The topological problem involved here is the existence of transversal surfaces in Γ; such surfaces are nowhere tangential to the dynamical trajectories. Functions whose levels are transversal are not only helpful, if one looks for nice coordinates, because they simplify Θ. Quite generally, they have to do with the existence of Hamiltonian and with the possibility to give the quantum dynamics the form of the Schrödinger equation (cf. Ref. 18). We shall, therefore, also look for transversal surfaces in a more systematic way. Finally, we shall find that the structure of the phase space of the spherically symmetric shell is not simple. Only a proper subset, which we call a *physical region*, contains physical states of the shell. Its nature can be roughly specified as follows. All points inside it correspond to the system consisting of a shell of positive mass and radius, interacting with a black hole. The boundary of the region is complicated; it contains shells with zero radius, shells with zero rest mass (which cannot, however, be regarded as shells made of light-like matter), as well as self-gravitating isolated shells with positive radius and mass—these are the points at the boundary that are physically meaningful. The points outside the region that describe shells with positive radius and mass correspond to systems consisting of the shell and a negative mass source. A conclusion seems to be that the system will be difficult to quantize even if the new variables have made it algebraically simple. One problem will be to keep the spectra of observables contained within the physical region. Another problem will be to construct a unitary dynamics, because the classical dynamics breaks down at the boundary of the physical region.

The plan of the paper is as follows. In Sec. II, we collect the relevant results of the previous papers, mainly Refs. 14 and 13. The variational principle that we describe allows also for an internal degree of freedom of the shell; it depends, therefore, on two additional variables in comparison with Refs. 12 and 14: the proper time along the shell trajectory and the rest mass of the shell. We determine the constraint manifold Γ and the Cartan form Θ that follow from the variational principle. We study the physical region.

In Sec. III, we introduce three new functions on the phase space that are regular at the horizons and that will replace the momentum P of the shell and the two Schwarzschild times $T^\pm$ that diverge there. We describe their physical and geometrical meaning, also using some results of previous papers. In Sec. IV, we specify a new set of coordinates on Γ, and show that the transformation from the old to the new coordinates is differentiable and invertible. We also find the ranges of these coordinates in the physical region. In Sec. V we collect and extend the results about symmetries of the system that were obtained in Ref. 17 and express the symmetry transformations in the new coordinates; the form of the transformation simplifies. The new times are cyclic coordinates, as the old have been. In Sec. VI, we transform the Cartan form into new coordinates. The square roots and hyperbolic functions disappear, and an equivalent form becomes regular at the horizons so that it can be smoothly matched across them. However, the Cartan form is still complicated and this motivates further transformations. The final result thereof can be described as follows. The extended phase space is $(\mathbf{R}^8,\bar{\Omega})$. The natural coordinates of $\mathbf{R}^8$ form a Darboux chart for $\bar{\Omega}$. The equation of the constraint surface Γ in $\mathbf{R}^8$ is polynomial in all momenta and the presymplectic form $d\Theta$ is the pull-back of $\bar{\Omega}$ to Γ.

In Sec. VII, we study the polynomial constraint. We show that it defines two disjoint submanifolds in $\mathbf{R}^8$. One, denoted by Γ_6, is six-dimensional and lies well outside the physical region. The other, denoted by Γ_7, is seven-dimensional and intersects the physical region. In the intersection of Γ_7 with the physical region, we find two different foliations by transversal surfaces. They are not globally transversal, however, because none of them is intersected by all dynamical trajectories. The problem is that each dynamical trajectory starts or finishes at the $(R=0)$-subset of the boundary of the physical region. The two different Hamiltonians corresponding to the two foliations are written down explicitly; they contain second and third roots.

In Sec. VIII, we repeat the study for some important lower-dimensional cases; they can be obtained by exclusion of cyclic coordinates from the original system. In particular, a (dynamical) black hole and the shell without its internal degree of freedom, the shell in the field of a fixed black hole external field or the isolated self-gravitating shell (with the flat spacetime inside) are considered.

II. DESCRIPTION OF THE SYSTEM

In this section, we shall collect some results of Refs. 8, 14 and 13 so that the paper becomes relatively self-consistent. We shall also describe and study the physical region.

A spherically symmetric thin-shell spacetime solution of Einstein equations can be constructed as follows. Consider two Schwarzschild spacetimes $\mathcal{M}_1$ and $\mathcal{M}_2$ with Schwarzschild masses E_1 and E_2. Let Σ_1 be a time-like hypersurface in $\mathcal{M}_1$ and Σ_2 be one in $\mathcal{M}_2$. Let Σ_1 divide $\mathcal{M}_1$ into two subspacetimes, $\mathcal{M}_{1+}$ and $\mathcal{M}_{1-}$, and similarly Σ_2 divide $\mathcal{M}_2$ into $\mathcal{M}_{2+}$ and $\mathcal{M}_{2-}$. As everything is spherically symmetric, all spacetimes are effectively two-dimensional; we chose fixed time and space orientation in the two-dimensional Schwarzschild spacetimes so that future and past as well as right and left are unambiguous; then let $\mathcal{M}_{2+}$ and $\mathcal{M}_{1+}$ be right with respect to $\mathcal{M}_{2-}$ and $\mathcal{M}_{1-}$. Let Σ_1 and Σ_2 be isometric; then the spacetime $\mathcal{M}_{1-}$ can be pasted together with the spacetime $\mathcal{M}_{2+}$ along the boundaries Σ_1 and Σ_2. The result is a shell spacetime $\mathcal{M}_s$. Given a shell spacetime, we shall leave out the indices 1 and 2, having right (left) energy E_+ (E_-), shell trajectory Σ, and the right (left) subspacetime $\mathcal{M}_+$ ($\mathcal{M}_-$). Thus, $\mathcal{M}_+=\mathcal{M}_2\cap\mathcal{M}_s$ and $\mathcal{M}_-=\mathcal{M}_1\cap\mathcal{M}_s$. In Refs. 14, 17 and 8, the Schwarzschild masses E_ϵ, $\epsilon=\pm 1$ were assumed to be *positive*.

Each subspacetime $\mathcal{M}_\epsilon$ has the metric

$$ds_\epsilon^2=-F_\epsilon(R)(dT^\epsilon)^2+F_\epsilon^{-1}(R)dR^2, \tag{1}$$

where

$$F_\epsilon(R):=1-\frac{2E_\epsilon}{R},$$

and it is split up by its horizons into four quadrants: we denote by Q_I that which is adjacent to the right infinity, Q_{II} to the left infinity, Q_{III} to the future singularity and Q_{IV} to the past singularity. Suitable notation (introduced in Ref. 14) enables us to write all formulas in a form valid in any quadrant: we define four sign functions a_ϵ and b_ϵ distinguishing the quadrants of $\mathcal{M}_\epsilon$: $a_\epsilon := \mathrm{sgn}\, F_\epsilon$, and b_ϵ equals to $+1$ (-1) in the past (future) of the event horizon in the spacetime $(\mathcal{M}_\epsilon, g_\epsilon)$. We also include the dust internal degree of freedom, M, and the proper time T along the shell trajectory using the results of Ref. 13. Then the total action for the dust and gravity can be rewritten in the form

$$S_\Sigma[\mathsf{T},\mathsf{M};T^\pm,E_\pm;R,P;\nu] = \int dt(P\dot{R} - E_+\dot{T}^+ + E_-\dot{T}^- + \mathsf{M}\dot{\mathsf{T}} - \nu\mathcal{C}), \tag{2}$$

where ν is a Lagrange multiplier,

$$\mathcal{C} = \mathsf{M} - R\sqrt{F_+ + F_- - 2a_-b_+b_-\sqrt{|F_+F_-|}\mathrm{sh}_{a_+a_-}(P/R)}, \tag{3}$$

is the super-Hamiltonian, $\mathrm{sh}_a x := (e^x + ae^{-x})/2$ for any $a = \pm 1$ and $x \in (-\infty, \infty)$. The momentum P conjugate to the radial coordinate R can be defined as follows (for more details, see Ref. 14). Let (n_ϵ, m_ϵ) be the orthonormal dyad at a shell point in the subspacetime $(\mathcal{M}_\epsilon, g_\epsilon)$, the vector n_ϵ being tangential to the shell and future oriented, m_ϵ being right oriented; we call it *shell dyad*. Further, let the so-called *Schwarzschild dyad* $(n_{S\epsilon}, m_{S\epsilon})$ be defined at each point of the shell in the spacetime $(\mathcal{M}_\epsilon, g_\epsilon)$ by the requirement that $n_{S\epsilon}$ be time-like future oriented, $m_{S\epsilon}$ be right oriented and that one of the vectors be tangential to the $(R = \text{const})$-curves. Clearly, in each quadrant, we have a different formula for the components of the Schwarzschild dyad; with respect to the Schwarzschild coordinates:

$$\text{for } F_\epsilon > 0, \quad n_{S\epsilon} = (b_\epsilon/\sqrt{F_c}, 0), \quad m_{S\epsilon} = (0, b_\epsilon\sqrt{F_\epsilon});$$

$$\text{for } F_\epsilon < 0, \quad n_{S\epsilon} = (0, b_\epsilon\sqrt{|F_\epsilon|}), \quad m_{S\epsilon} = (-b_\epsilon/\sqrt{|F_\epsilon|}, 0).$$

Then, P_ϵ/R is the hyperbolic angle between the Schwarzschild and shell dyads:

$$n_\epsilon = n_{S\epsilon} \cosh P_\epsilon/R + m_{S\epsilon} \sinh P_\epsilon/R,$$

$$m_\epsilon = n_{S\epsilon} \sinh P_\epsilon/R + m_{S\epsilon} \cosh P_\epsilon/R.$$

Finally, $P := [P]$, where we use the common short-hand for the jump $[A] := A_+ - A_-$ of a quantity A across the shell.

The extended phase space of the system is eight-dimensional, split up into 16 disjoint sectors, each sector being a pair of quadrants, one chosen from the left and one from the right subspacetimes. Each of these sectors can be covered with the coordinates P, R, E_+, T^+, E_-, T^-, M and T. The constraint surface that we call Γ is defined by the constraint equation $\mathcal{C} = 0$ in the extended phase space. It does not intersects all 16 sectors, but it is split up into at most (if $E_- > \mathsf{M}$) nonempty intersections of the sectors with it. (Observe that we admit unphysical sectors, i.e., those in which the constraint equation $\mathcal{C} = 0$ has no solutions. This simplifies the boundary of the extended phase space a great deal and does not lead to any problem: it is the very purpose of extended phase spaces to enclose also nonphysical poits, if this leads to any simplification.) These can be covered by the system of seven coordinates P, R, E_+, T^+, E_-, T^- and T. The following coordinates are assumed to have nontrivial ranges:

$$R > 0, \quad E_+ > 0, \quad E_- > 0, \quad \mathsf{M} > 0. \tag{4}$$

The pull-back of the Liouville form of the action (2) to the constraint surface Γ in these coordinates is simply

$$\Theta = P\ dR - E_+\ dT^+ + E_-\ dT^- + \mathsf{M}\ d\mathsf{T}, \tag{5}$$

where M is now a function of the seven coordinates defined by

$$\mathsf{M} = R\sqrt{F_+ + F_- - 2a_-b_+b_-\sqrt{|F_+F_-|}sh_{a_+a_-}(P/R)}. \tag{6}$$

The form (5) is called *Cartan form* of the system; it contains all information about the dynamics and about the Poisson brackets (see, e.g., Refs. 19 or 17).

In the present paper we start from these formulas and quantities. The first new observation that we make is that all these formulas remain valid also for the values $E_+ = 0$ or $E_- = 0$, if the notation and conventions are adapted a little. These cases are interesting because they describe an isolated self-gravitating shell (with the flat spacetime inside). Indeed, the metric of the flat spacetime is covered by formula (1). However, the flat spacetime does not contain any horizon and is not split into quadrants. Still, a piece of the flat spacetime can be used in four distinct ways in the construction of the shell spacetime: either it lies to the left ($E_- = 0$) or to the right ($E_+ = 0$) of the shell, and, in each case, the R coordinate can either increase to the right or to the left (R is always space-like in the flat spacetime). We can, therefore, formally define the *E-spacetime* for $E > 0$ as before to be the Kruskal spacetime of Schwarzschild mass E with four quadrants, and for $E = 0$ as consisting of two topologically separated quadrants Q_I and Q_{II}, each isometric to the flat spacetime, but with opposite time and space orientations: in Q_I, the radial (''Schwarzschild'') coordinate R increases to the right and the ''Schwarzschild'' time T to the future; in Q_{II}, R increases to the left and T to the past. It is amusing to observe that the validity of the formulas (2) and (3) can then be extended to vanishing E's, if we just use the values $a_\epsilon = 1$ everywhere, $b_\epsilon = +1$ in Q_I and $b_\epsilon = -1$ in Q_{II}. This works because the components of the Schwarzschild dyad that are crucial for the derivation of Eq. (3) in Ref. 14 retain their form in the quadrants Q_I and Q_{II} of the E-spacetime for $E = 0$, and there are no quadrants Q_{III} and Q_{IV}. Similarly, the sign relation (14) of Ref. 8, which is basic for the form of the dynamical equations, remains valid with our orientation and quadrant conventions. Observe that the presence of two topologically separated subspacetimes is not observable and does not imply any physical assertion; similarly, the orientation of coordinates is a mere coordinate convention without any physical meaning.

A very important but rather embarrassing observation is now that a formally impeccable shell spacetime can be pasted together from Schwarzschild spacetimes of any mass, even a negative one. The metric is still given by Eq. (1) and the spacetime has a similar global structure as the flat one: there are no horizons and there are two possible orientations of how it can be built in. Again, all equations remain valid, if we accept the same sign, quadrant and orientation conventions as for the flat spacetime and define the (two-quadrant) E-spacetime for $E < 0$ analogously to what we have done for $E = 0$. The corresponding shell dynamics is then again given by the action (2).

Let us quickly discuss the dynamical equations following from the action (2) under these conventions. There are three conservation laws,

$$\dot{E}_+ = \dot{E}_- = \dot{\mathsf{M}} = 0, \tag{7}$$

resulting from varying the action with respect to the cyclic coordinates T^+, T^- and T. The variations with respect of the conserved momenta and P with the subsequent simplification by the constraint (6) yield

$$\dot{\mathsf{T}} = \nu, \tag{8}$$

$$\dot{T}^\epsilon = -\epsilon\nu\,\frac{R}{\mathsf{M}}\left(1 - a_-b_+b_-\,\frac{\sqrt{|F_+F_-|}}{F_\epsilon}\,\mathrm{sh}_{a_+a_-}\frac{P}{R}\right), \tag{9}$$

$$\dot{R} = \nu a_-b_+b_-\,\frac{R}{\mathsf{M}}\,\sqrt{|F_+F_-|}\mathrm{sh}_{-a_+a_-}\frac{P}{R}. \tag{10}$$

The equation determining $\dot{P}$ can be obtained either by varying the action with respect to R, or by differentiating the constraint equation $\mathcal{C}=0$ with respect to t followed by substitution for all other t-derivatives from Eqs. (7)–(10). Let us rewrite the constraint equation in the form

$$-\frac{\mathsf{M}}{2R}+\frac{R}{2\mathsf{M}}(F_+ + F_-)=a_-b_+b_-\frac{R}{\mathsf{M}}\sqrt{|F_+F_-|}\,\mathrm{sh}_{a_+a_-}\frac{P}{R}. \tag{11}$$

Equations (7)–(11) represent a complete system of dynamical equations for the shell.

We derive some important consequences from the dynamical equations. Equations (8)–(11) imply that

$$-F_\epsilon\left(\frac{dT^\epsilon}{d\mathsf{T}}\right)^2+\frac{1}{F_\epsilon}\left(\frac{dR}{d\mathsf{T}}\right)^2=-1,$$

confirming that T is the proper time along shell trajectories. Equations (8), (9) and (11) deliver the *time equation*:

$$F_\epsilon\frac{dT^\epsilon}{d\mathsf{T}}=-\epsilon\frac{\mathsf{M}}{2R}+\frac{E_+-E_-}{\mathsf{M}}. \tag{12}$$

From Eqs. (10) and (11), the *radial equation* follows:

$$\frac{dR}{d\mathsf{T}}=-\omega\sqrt{-V}, \tag{13}$$

where

$$V(R)=-\frac{\mathsf{M}^2}{4R^2}-\frac{E_++E_-}{R}-\frac{(E_+-E_-)^2}{\mathsf{M}^2}+1, \tag{14}$$

and $\omega=\pm 1$ is a suitable sign [see Eq. (2) of Ref. 17]. The square of the radial equation can be rewritten in one of the two forms

$$F_\epsilon+\left(\frac{dR}{d\mathsf{T}}\right)^2=J_\epsilon^2, \tag{15}$$

according as $\epsilon=\pm 1$, where

$$J_\epsilon:=\frac{\mathsf{M}}{2R}-\epsilon\frac{E_+-E_-}{\mathsf{M}} \tag{16}$$

(cf. Ref. 8). It follows immediately from this definition of J_ϵ that

$$J_++J_-=\frac{\mathsf{M}}{R},$$

and this can be transformed with the help of Eq. (15) to

$$\mathrm{sgn}\,J_+\sqrt{F_++\left(\frac{dR}{d\mathsf{T}}\right)^2}+\mathrm{sgn}\,J_-\sqrt{F_-+\left(\frac{dR}{d\mathsf{T}}\right)^2}=\frac{\mathsf{M}}{R}.$$

However, comparing Eqs. (12) and (16), we observe that

$$\text{sgn } J_\epsilon = -\epsilon \text{ sgn}\left(F_\epsilon \frac{dT^\epsilon}{d\mathsf{T}} \right).$$

The sign of the expression $F_\epsilon(dT^\epsilon/d\mathsf{T})$ deserves a name; let us call it τ_ϵ (cf. Ref. 8). Then, we obtain, finally,

$$-\tau_+ \sqrt{F_+ + \left(\frac{dR}{d\mathsf{T}} \right)^2} + \tau_- \sqrt{F_- + \left(\frac{dR}{d\mathsf{T}} \right)^2} = \frac{\mathsf{M}}{R}. \tag{17}$$

This is the so-called *Israel equation* for a dust shell [cf. Eqs. (14), (21) and (22) of Ref. 8].

Equations (12)–(17) are valid for all values of Schwarzschild masses $E_+ \in (-\infty, +\infty)$ and $E_- \in (-\infty, +\infty)$. Some features of the unphysical (negative E_ϵ) cases are described by the following theorem.

Theorem 1: *Let E_ϵ be nonpositive and not larger than $E_{-\epsilon}$ for some value of ϵ. Then the timelike (connected) center $(R=0)$ curve lies in the subspacetime $\mathcal{M}_\epsilon$ on the ϵ-side of the shell.* To prove the theorem, we observe that $E_\epsilon \leq E_{-\epsilon}$ implies

$$\sqrt{F_\epsilon + (dR/d\mathsf{T})^2} \geq \sqrt{F_{-\epsilon} + (dR/d\mathsf{T})^2}.$$

Thus, the left-hand side of Eq. (17) can only be positive, if $\tau_\epsilon = -\epsilon$. The assumption $E_\epsilon \leq 0$ of the theorem implies that $\mathcal{M}_\epsilon$ is the two-quadrant E-spacetime with $\tau_\epsilon > 0$ in the quadrant Q_I and $\tau_\epsilon < 0$ in the quadrant Q_{II}; this follows from the definition of τ_ϵ and from the positivity of F_ϵ (in fact, for $E_\epsilon \leq 0$, we have $F_\epsilon \geq 1$). Hence, to the right $(\mathcal{M}_+)$ of the shell, there is a part of Q_{II} with the center to the right, and to the left of the shell $(\mathcal{M}_-)$, there must be Q_I with the center to the left. Q.E.D.

An interpretation of the theorem is that the shell spacetime containing one or two negative-mass subspacetimes is unphysical: there must be at least one negative-mass source somewhere outside the shell. The theorem also says that a shell spacetime constructed from one flat and one positive-mass subspacetimes must have a regular center inside the flat subspacetime.

To summarize: The action (2) generates a regular dynamics in the enlarged phase space just defined by

$$\mathsf{M} > 0, \quad R > 0. \tag{18}$$

For $E_+ > 0$ and $E_- > 0$, it describes a shell interacting with a black hole of mass E_- (or E_+, depending on from where we observe the shell). For $E_+ > 0$ and $E_- = 0$ (or $E_+ = 0$ and $E_- > 0$), it describes a self-gravitating shell with flat spacetime inside. If any of E_+ and E_- are negative, it describes the shell interacting with a negative mass source. Only the points with

$$E_+ \geq 0, \quad E_- \geq 0, \tag{19}$$

are physically sensible; the subset specified by the inequalities (18) and (19) is the *physical region* of the phase space. There seems to be nothing about the variational principle (2) that would help us to enforce the validity of the Eqs. (19) in any natural, automatic way.

III. RADIAL AND KRUSKAL MOMENTA

From the definition of the functions $T^\pm$ and P as given in the previous section, it follows that they are singular at the horizons: T^ϵ at $R = 2E_\epsilon$ and P at $R = 2E_-$ as well as at $R = 2E_+$. In this section, we introduce three functions that are well-defined on the whole constraint surface to replace $T^\pm$ and P. Another replacement of $T^\pm$ and P with similar properties has been tried in Ref. 14. There, the functions were constructed from the Kruskal coordinates; however, the Kruskal coordinates make no sense for flat spacetime and so the important case $E_- = 0$ could not be incorporated. In this subsection, we remove this problem.

Let us define the new functions q, $[T_1]$ and $\overline{T_1}$ by

$$q:=a_-b_+b_-R\sqrt{|F_+F_-|}\mathrm{sh}_{-a_+a_-}\frac{P}{R}, \tag{20}$$

$$\overline{T_1}:=\frac{T^++T^-}{2}+E_+\ \ln\left|\frac{u_+}{v_+}\right|+E_-\ \ln\left|\frac{u_-}{v_-}\right|, \tag{21}$$

$$[T_1]:=T^+-T^-+2E_+\ \ln\left|\frac{u_+}{v_+}\right|-2E_-\ \ln\left|\frac{u_-}{v_-}\right|, \tag{22}$$

and the auxiliary functions u_ϵ and v_ϵ by

$$u_\epsilon:=-\frac{q}{\mathsf{M}}-\frac{[E]}{\mathsf{M}}+\epsilon\frac{\mathsf{M}}{2R},\quad v_\epsilon:=-\frac{q}{\mathsf{M}}+\frac{[E]}{\mathsf{M}}-\epsilon\frac{\mathsf{M}}{2R}, \tag{23}$$

in Eq. (23), the functions q and M are given by Eqs. (20), (6) and $[E]:=E_+-E_-$.

The meaning of the momentum q can be seen if it is expressed by means of velocities along dynamical trajectories. Comparing Eqs. (8), (10) and (20), we find that

$$q=\mathsf{M}\frac{dR}{d\mathsf{T}}; \tag{24}$$

hence, q is a kind of radial momentum, and it is regular everywhere along dynamical trajectories.

The meaning of the functions $\overline{T_1}$ and $[T_1]$ can be inferred from that of T_1^ϵ, which are defined by

$$T_1^\epsilon:=\overline{T_1}+\frac{\epsilon}{2}[T_1].$$

Equations (21) and (22) lead then to

$$T_1^\epsilon=T^\epsilon+2E_\epsilon\ \ln\left|\frac{u_\epsilon}{v_\epsilon}\right|,$$

for each $\epsilon=\pm1$. Let us limit ourselves to the physical region and distinguish two cases. $\underline{E_\epsilon=0}$. Then, $T_1^\epsilon=T^\epsilon$ in both quadrants of the E-spacetime, so $b_\epsilon T_1^\epsilon$ is the time coordinate of the inertial system of the Minkowski spacetime $\mathcal{M}_\epsilon$ in which the center of mass of the shell is in rest. $\underline{E_\epsilon>0}$. Then, it is possible to introduce Kruskal coordinates U_ϵ and V_ϵ in the Kruskal spacetime $\mathcal{M}_\epsilon$ by

$$R=2E_\epsilon\kappa(-U_\epsilon V_\epsilon),$$
$$T^\epsilon=2E_\epsilon\ \ln\left|\frac{V_\epsilon}{U_\epsilon}\right|, \tag{25}$$

and by the requirement that both functions U_ϵ and V_ϵ increase to the future, where κ is the well-known monotonous function defined on the interval $(-1,\infty)$ by its inverse,

$$\kappa^{-1}(x)=(x-1)e^x.$$

At each point of the shell trajectory $U_\epsilon=U_\epsilon(t)$ and $V_\epsilon=V_\epsilon(t)$, the so-called *Kruskal momentum*, P_K^ϵ, was defined in Ref. 14 by

$$P_K^\epsilon := \frac{R}{2} \ln \frac{dV_\epsilon}{dU_\epsilon}.$$

In Ref. 17, four further functions u_ϵ and v_ϵ were defined by

$$u_\epsilon := \frac{U_\epsilon e^{P_K^\epsilon/R}}{\sqrt{\kappa_\epsilon e^{\kappa_\epsilon}}}, \quad v_\epsilon := \frac{V_\epsilon e^{-P_K^\epsilon/R}}{\sqrt{\kappa_\epsilon e^{\kappa_\epsilon}}}, \tag{26}$$

where $\kappa_\epsilon := \kappa(-U_\epsilon V_\epsilon)$.

The following relation between the pairs u_ϵ, v_ϵ and R, E_ϵ was shown to hold in Ref. 17 [Eqs. (32) and (33)]:

$$u_\epsilon = -\frac{[E]}{\mathsf{M}} + \epsilon \frac{\mathsf{M}}{2R} + \omega\sqrt{-V}, \quad v_\epsilon = \frac{[E]}{\mathsf{M}} - \epsilon \frac{\mathsf{M}}{2R} + \omega\sqrt{-V}.$$

A comparison with Eqs. (13) and (14) shows that our functions u_ϵ and v_ϵ defined by Eqs. (23) coincide with the functions u_ϵ and v_ϵ of Ref. 17, if the dynamical equations are satisfied. Equation (26) then shows that u_ϵ and v_ϵ vanish at horizons and that their logarithms diverge there. It then also follows for the functions T_1^ϵ along dynamical trajectories that

$$T_1^\epsilon = \frac{4E_\epsilon P_K^\epsilon}{R}. \tag{27}$$

We can see that the functions T_1^ϵ are directly determined by the geometry of the dynamical trajectory in the spacetime $\mathcal{M}_\epsilon$ and are regular everywhere along the trajectory.

IV. A REGULAR COORDINATE SYSTEM

In this section, we describe a coordinate system that is regular at the horizons, and at the same time remains meaningful for the special values $E_\epsilon = 0$ of Schwarzschild masses.

As such coordinates on Γ, we suggest the seven functions q, R, M, T, $[E]$, $\overline{T_1}$, and $[T_1]$. Let us show that the Jacobian of the transformation from these coordinates to P, R, E_+, T^+, E_-, T^- and T is nonzero. To calculate the determinant, we observe that the four columns R, T^+, T^- and T of the Jacobian,

$$\frac{\partial(q,\ldots,[T_1])}{\partial(P,\ldots,\mathsf{T})},$$

contain each, at most, two nonzero elements; if we expand the determinant along these columns, we obtain

$$\frac{\partial(q,\ldots,[T_1])}{\partial(P,\ldots,\mathsf{T})} = -\frac{\partial q}{\partial P}\left(\frac{\partial \mathsf{M}}{\partial E_+} + \frac{\partial \mathsf{M}}{\partial E_-}\right) + \frac{\partial \mathsf{M}}{\partial P}\left(\frac{\partial q}{\partial E_+} + \frac{\partial q}{\partial E_-}\right). \tag{28}$$

For the derivatives involved here, Eqs. (6) and (20) yield immediately

$$\frac{\partial q}{\partial P} = a_- b_+ b_- \sqrt{|F_+ F_-|}\,\mathrm{sh}_{a_+ a_-} \frac{P}{R}, \quad \frac{\partial \mathsf{M}}{\partial P} = -a_- b_+ b_- \sqrt{|F_+ F_-|}\,\frac{R}{\mathsf{M}}\,\mathrm{sh}_{-a_+ a_-} \frac{P}{R},$$

$$\frac{\partial \mathsf{M}}{\partial E_+} + \frac{\partial \mathsf{M}}{\partial E_-} = \frac{R}{\mathsf{M}}\left(-2 + a_+ b_+ b_- \frac{F_+ + F_-}{\sqrt{|F_+ F_-|}}\,\mathrm{sh}_{a_+ a_-} \frac{P}{R}\right),$$

$$\frac{\partial q}{\partial E_+}+\frac{\partial q}{\partial E_-}=-a_+b_+b_-\frac{F_++F_-}{\sqrt{|F_+F_-|}}\,\mathrm{sh}_{-a_+a_-}\frac{P}{R}.$$

Substituting this in Eq. (28) and using again Eq. (6), we arrive at the simple result

$$\frac{\partial(q,..,[T_1])}{\partial(P,..,\mathsf{T})}=-\frac{\mathsf{M}}{R},$$

which holds in each sector of Γ.

It follows that the transformation is regular within each sector and can be inverted. In fact, it is not difficult to find the functions defining the inverse transformation. First, we show that

$$\overline{E}=\frac{R}{2}\left(1+\frac{q^2}{\mathsf{M}^2}-\frac{[E]^2}{\mathsf{M}^2}-\frac{\mathsf{M}^2}{4R^2}\right), \tag{29}$$

in each sector. To this aim, we substitute for q and M from Eqs. (6) and (20) into Eq. (29) and use the identities

$$F_++F_-=2\left(1-\frac{2\overline{E}}{R}\right),\quad F_+F_-=\left(1-\frac{2\overline{E}}{R}\right)^2-\frac{[E]^2}{R^2}. \tag{30}$$

In this way, we obtain

$$\frac{2\overline{E}}{R}-1=\frac{R^2}{\mathsf{M}^2}\left(-2\left(1-\frac{2\overline{E}}{R}\right)^2+2a_-b_+b_-\left(1-\frac{2\overline{E}}{R}\right)\sqrt{|F_+F_-|}\mathrm{sh}_{a_+a_-}\frac{P}{R}\right).$$

Now, the equality follows immediately from Eq. (6).

The next nontrivial part of the inverse transformation is the relation

$$P=\frac{R}{2}\ln\left|\frac{u_+v_-}{u_-v_+}\right|, \tag{31}$$

which again holds in each sector. To show Eq. (31), we use Eqs. (23) to obtain

$$\frac{u_+v_-}{u_-v_+}=\frac{(q-\mathsf{M}^2/2R)^2-[E]^2}{(q+\mathsf{M}^2/2R)^2-[E]^2}.$$

The substitution for q and M gives

$$q+\eta\frac{\mathsf{M}^2}{2R}=\eta(R-2\overline{E})-\eta a_{-\eta}b_+b_-R\sqrt{|F_+F_-|}e^{\eta P/R},$$

where $\eta=\pm 1$. After some rearrangement and applying Eqs. (30), we have

$$\left(q+\eta\frac{\mathsf{M}^2}{2R}\right)^2-[E]^2=-a_{-\eta}b_+b_-R^2\sqrt{|F_+F_-|}e^{\eta P/R}\left(F_++F_--2a_-b_+b_+\mathrm{sh}_{a_+a_-}\frac{P}{R}\right).$$

Then, Eq. (6) leads immediately to

$$\left(q+\eta\frac{\mathsf{M}^2}{2R}\right)^2-[E]^2=-a_{\eta}b_+b_-\mathsf{M}^2\sqrt{|F_+F_-|}e^{\eta P/R},$$

and this implies Eq. (31).

The rest of the inverse transformation is easy: the functions R and T are the same in both sets of variables,

$$E_\epsilon = \overline{E} + \frac{\epsilon}{2}[E] \tag{32}$$

and

$$T^\epsilon = \overline{T_1} + \frac{\epsilon}{2}[T_1] - 2E_\epsilon \ln\left|\frac{u_\epsilon}{v_\epsilon}\right|; \tag{33}$$

in the last equation, one has to substitute Eq. (32) for E_ϵ and Eqs. (23) for u_ϵ and v_ϵ.

The ranges of the variables q, R, M, T, $[E]$, $\overline{T_1}$ and $[T_1]$ in the physical region are implied by the conditions (18), (19) and Eq. (29). Let us work them out. Equation (29) together with $\overline{E}\geqslant 0$ implies that

$$[E]^2 \leqslant \mathsf{M}^2 + q^2 - \frac{\mathsf{M}^4}{4R^2}; \tag{34}$$

hence,

$$\mathsf{M}^2 + q^2 \geqslant \frac{\mathsf{M}^4}{4R^2}. \tag{35}$$

The two inequalities $E_+\geqslant 0$ and $E_-\geqslant 0$ are equivalent to $[E]^2 \leqslant 4\overline{E}^2$. Equation (29) implies that this inequality is, in turn, equivalent to

$$\left([E]^2 - \left(\mathsf{M}^2 + q^2 + \frac{\mathsf{M}^4}{4R^2}\right)\right)^2 \geqslant \left(\frac{\mathsf{M}^2}{R}\sqrt{\mathsf{M}^2+q^2}\right)^2. \tag{36}$$

From Eq. (34), it follows that

$$[E]^2 - \left(\mathsf{M}^2 + q^2 + \frac{\mathsf{M}^4}{4R^2}\right) \leqslant -\frac{\mathsf{M}^4}{2R^2} < 0.$$

Equation (36) is, therefore, equivalent to

$$[E]^2 \leqslant \left(\sqrt{\mathsf{M}^2+q^2} - \frac{\mathsf{M}^2}{2R}\right)^2. \tag{37}$$

Equation (35) shows that the inequality (37) is not weaker than (34). Hence, all information is contained in the following inequality:

$$|[E]| \leqslant \sqrt{\mathsf{M}^2+q^2} - \frac{\mathsf{M}^2}{2R}. \tag{38}$$

Inequality (38) together with $\mathsf{M}>0$ and $R>0$ define the ranges of the variables q, R, M, T, $[E]$, $\overline{T_1}$ and $[T_1]$ in the physical region.

V. SYMMETRY OF THE SYSTEM

In this section, we collect the results of Ref. 17 on the symmetry of the shell action and describe the action of the symmetry transformations on the new variables.

In Ref. 17, we have found that there is a continuous symmetry group generated by an arbitrary function of E_+ and E_-. A simple generalization of the argument given in Ref. 17 implies that the following finite transformation of the variables E_ϵ, u_ϵ, v_ϵ and $\tilde{P}_\epsilon$, which were used there, is a symmetry of the system

$$\tilde{P}_\epsilon \mapsto \tilde{P}_\epsilon - \epsilon \frac{\partial \Lambda}{4 \partial E_\epsilon}, \quad \epsilon = \pm 1,$$

the other variables being invariant, where $\Lambda(E_+, E_-)$ is an arbitrary smooth function of two variables (the factor 1/4 is introduced for convenience). In addition to this continuous infinitely dimensional group, there were two reflections, which we denote here by σ_1 and σ_2. σ_1 is a time reflection defined by

$$E_\epsilon \mapsto E_\epsilon, \quad u_\epsilon + u_\epsilon \mapsto -(u_\epsilon + v_\epsilon), \quad u_\epsilon - u_\epsilon \mapsto u_\epsilon - v_\epsilon, \quad \tilde{P}_\epsilon \mapsto -\tilde{P}_\epsilon,$$

and σ_2 is a left–right reflection defined by

$$E_+ \leftrightarrow E_-, \quad u_+ \leftrightarrow v_-, \quad u_- \leftrightarrow v_+, \quad \tilde{P}_+ \leftrightarrow -\tilde{P}_-.$$

These results can be easily expressed in our variables q, R, $[E]$, $\overline{T_1}$, $\overline{E}$ and $[T_1]$ and extended to M and T. Consider the function q; Eqs. (23) yield

$$q = -\mathsf{M}(u_\epsilon + v_\epsilon), \quad \epsilon = \pm 1.$$

It is clear that M is invariant with respect to the whole group; hence, q is invariant with respect to the Λ-transformation for any $\Lambda(E_+, E_-)$, it changes sign by the time reflection σ_1 and is invariant with respect to σ_2. The function R was written in terms of u_c and v_ϵ in Ref. 17 in the form

$$R = \frac{2E_\epsilon}{1 + u_\epsilon v_\epsilon}, \quad \epsilon = \pm 1.$$

Realizing that $4u_\epsilon v_\epsilon = (u_\epsilon + v_\epsilon)^2 - (u_\epsilon - v_\epsilon)^2$, we can see that R is an invariant of all above transformations. The function $[E]$ transforms nontrivially only by σ_2,

$$[E] \mapsto -[E],$$

and $\overline{E}$ is an invariant like R. A comparison of our Eq. (27) with Eq. (43) of Ref. 17 reveals that $T_1^\epsilon = 4\tilde{P}_\epsilon$, so that its Λ-transformation is

$$T_1^\epsilon \mapsto T_1^\epsilon - \epsilon \frac{\partial \Lambda}{\partial E_\epsilon}.$$

Using this formula, one finds easily that

$$\overline{T_1} \mapsto \overline{T_1} - \frac{\partial \Lambda}{\partial [E]}, \quad [T_1] \mapsto [T_1] - \frac{\partial \Lambda}{\partial \overline{E}}. \tag{39}$$

The time reflection σ_1 changes the signs of both times:

$$\overline{T_1} \mapsto -\overline{T_1}, \quad [T_1] \mapsto -[T_1],$$

but the left–right reflection σ_2 acts as follows:

$$\overline{T_1} \mapsto -\overline{T_1}, \quad [T_1] \mapsto [T_1].$$

From the physical meaning of M and T, it follows that they are invariant with respect to the continuous transformation for any $\Lambda(E_+,E_-)$ and of the left–right reflection σ_2, whereas the time reflection σ_1 must give

$$\mathsf{M}\mapsto\mathsf{M},\quad \mathsf{T}\mapsto-\mathsf{T}.$$

However, as T is a new cyclic coordinate, the new system has larger continuous symmetry: we can extend Λ to an arbitrary function of the three variables E_+, E_- and M, and define the action on T as follows:

$$\mathsf{T}\mapsto\mathsf{T}+\frac{\partial\Lambda}{\partial\mathsf{M}}. \tag{40}$$

Let us postpone the proof that this extended Λ-transformation is a symmetry to Sec. VI. It generates three independent constant shifts of the cyclic variables $\overline{T_1}$, $[T_1]$ and T that are different in different shell spacetimes.

We can see from these results that our new variables transform particularly simply. This was, in fact, the idea that helped to find the variables in the first place.

VI. TRANSFORMATIONS OF THE CARTAN FORM

Let us transform the Cartan form Θ in each sector of Γ to the variables q, R, M, T, $[E]$, $\overline{T_1}$ and $[T_1]$ and check that it can then be extended smoothly accross the boundaries of the sectors.

If we substitute for P, T^+, T^- and M, we obtain

$$\Theta=-\overline{E}d[T_1]-[E]d\overline{T_1}+\mathsf{M}\ d\mathsf{T}+2E_+^2d\left(\ln\left|\frac{u_+}{v_+}\right|\right)-2E_-^2d\left(\ln\left|\frac{u_-}{v_-}\right|\right)$$
$$+\ln\left|\frac{u_+v_-}{u_-v_+}\right|d\left(\frac{R^2}{4}\right)+\ln\left|\frac{u_+}{v_+}\right|d(E_+^2)-\ln\left|\frac{u_-}{v_-}\right|d(E_-^2).$$

The logarithms can be rearanged as follows:

$$\Theta=-\overline{E}d[T_1]-[E]d\overline{T_1}+\mathsf{M}\ d\mathsf{T}+d\left(\left(\frac{R^2}{4}+E_+^2\right)\ln\left|\frac{u_+}{v_+}\right|-\left(\frac{R^2}{4}+E_-^2\right)\ln\left|\frac{u_-}{v_-}\right|\right)$$
$$-\left(\frac{R^2}{4}-E_+^2\right)d\left(\ln\left|\frac{u_+}{v_+}\right|\right)+\left(\frac{R^2}{4}-E_-^2\right)d\left(\ln\left|\frac{u_-}{v_-}\right|\right).$$

The total differential of a function (that diverges badly at the horizons) can be left out. We obtain

$$\Theta=-\overline{E}d[T_1]-[E]d\overline{T_1}+\mathsf{M}\ d\mathsf{T}-\left[\left(\frac{R^2}{4}-E^2\right)d\left(\ln\left|\frac{u}{v}\right|\right)\right], \tag{41}$$

where we must substitute for E_+, E_-, $\overline{E}$, u_ϵ and v_ϵ from Eqs. (32), (29) and (23). This form of Θ has been obtained in Ref. 17 (without the matter term); there, however, u_ϵ and v_ϵ were regarded as independent variables. Observe that Eqs. (23), (29) and (32) imply

$$\frac{2E_\epsilon}{R}-1=u_\epsilon v_\epsilon, \tag{42}$$

so that u_ϵ and v_ϵ are not independent functions for $E_\epsilon=0$.

Now, we can show that the last term in Θ is regular: we just rewrite it using Eq. (42):

$$\left[\left(\frac{R^2}{4}-E^2\right)d\left(\ln\left|\frac{u}{v}\right|\right)\right]=\left[\frac{R^2}{4}\left(1+\frac{2E}{R}\right)(v\ du-u\ dv)\right]. \tag{43}$$

Thus, our new variables cover all of the constraint hypersurface Γ as promised.

Let us express Θ explicitly by means of the variables q, R, M and $[E]$. Employing Eqs. (23), we have

$$\overline{v\ du-u\ dv}=2\left(-\frac{[E]}{\mathsf{M}^2}\,dq+\frac{q}{\mathsf{M}^2}\,d[E]\right),$$

$$[v\ du-u\ dv]=2\left(\frac{1}{R}\,dq+\frac{q}{R^2}\,dR-\frac{2q}{R\mathsf{M}}\,d\mathsf{M}\right).$$

Then, applying the well-known identity $[AB]=\overline{A}[B]+\overline{B}[A]$ that holds for jumps and averages of any two functions A and B, and after using Eq. (29), we arrive at

$$\left[\left(\frac{R^2}{4}-E^2\right)d\left(\ln\left|\frac{u}{v}\right|\right)\right]=\frac{Rq[E]}{\mathsf{M}^2}\,d[E]-\left(\frac{2Rq}{\mathsf{M}}+\frac{Rq^3}{\mathsf{M}^3}-\frac{Rq[E]^2}{\mathsf{M}^3}-\frac{q\mathsf{M}}{4R}\right)d\mathsf{M}$$
$$+\left(R+\frac{Rq^2}{2\mathsf{M}^2}-\frac{3R[E]^2}{2\mathsf{M}^2}-\frac{\mathsf{M}^2}{8R}\right)dq+\left(q+\frac{q^3}{2\mathsf{M}^2}-\frac{q[E]^2}{2\mathsf{M}^2}-\frac{q\mathsf{M}^2}{8R^2}\right)dR. \tag{44}$$

This, together with Eq. (41), gives Θ as a function of new variables. It is a complicated one, so we have to transform the coordinates further in order to get a simple expression.

The following question will give some direction to this search for simplicity: is the variable $[T_1]$ suitable for the role of time? More concretely, the time levels in constraint surface should be transversal (this is shown in Ref. 10). A surface is transversal, if dynamical trajectories intersect it transversally and only once. We can see if the surface $[T_1]=\text{const}$ has this property as follows. The direction of motion on the constraint surface coincides with the direction of degeneration of the presymplectic form $d\Theta$; hence, the pull-back $d\Theta_f$ of $d\Theta$ to any transversal surface $f=\text{const}$ must be nondegenerate. If the surface is $2n$-dimensional, then the $2n$-form $d\Theta_f\wedge\cdots\wedge d\Theta_f$ must be everywhere nonzero. In our case, $n=3$. Let us calculate $d\Theta_{[T_1]}\wedge d\Theta_{[T_1]}\wedge d\Theta_{[T_1]}$. Equations (41) and (44) imply that

$$d\Theta_{[T_1]}=-d[E]\wedge d\overline{T}_1+d\mathsf{M}\wedge d\mathsf{T}+A_1dR\wedge dq+A_2dR\wedge d[E]$$
$$+A_3dR\wedge d\mathsf{M}+A_4dq\wedge d[E]+A_5dq\wedge d\mathsf{M}+A_6d[E]\wedge d\mathsf{M},$$

where A_i, $i=1,\dots,6$ are some functions of the variables R, q, $[E]$ and M. It is clear, therefore, that

$$d\Theta_{[T_1]}\wedge d\Theta_{[T_1]}\wedge d\Theta_{[T_1]}=-6A_1d[E]\wedge d\overline{T}_1\wedge d\mathsf{M}\wedge d\mathsf{T}\wedge dR\wedge dq,$$

and the points where the six-form vanishes coincide with those where A_1 vanishes. A_1 can be calculated from Eq. (44) with the result

$$A_1=\frac{q^2}{\mathsf{M}^2}+\frac{[E]^2}{\mathsf{M}^2}-\frac{\mathsf{M}^2}{4R^2}. \tag{45}$$

Thus, A_1 vanishes for

$$[E]^2=\frac{\mathsf{M}^4}{4R^2}-q^2.$$

Do these points lie in the physical region that is given by inequality (38)? Let us substitute the value of $[E]^2$ into Eq. (38) and rewrite the result in the form

$$\frac{\mathsf{M}^2}{R^2} \leqslant 4\left(1+\frac{q^2}{\mathsf{M}^2}\right)-\frac{3\mathsf{M}^2}{\mathsf{M}^2+q^2}.$$

This inequality implies inequality (35); hence, all zero points of A_1 lie in the physical region. We conclude that $[T_1]=\text{const}$ is *no* transversal surface.

Let us try to shift $[T_1]$ by a function dependent on the variables R, q, $[E]$ and M:

$$[T_1]=T_2+X(R,q,[E],\mathsf{M}).$$

Our motivation for choosing such a form is that T_2 is then transformed by the Λ-symmetry (39) in the same way as $[T_1]$ is, and that it is also a cyclic coordinate. Substitution for $[T_1]$ into $d\Theta$ changes the coefficient A_1 at $dR\wedge dq$ in $d\Theta_{T_2}$ by

$$A_1 \to A_1+\frac{\partial\overline{E}}{\partial q}\frac{\partial X}{\partial R}-\frac{\partial\overline{E}}{\partial R}\frac{\partial X}{\partial q}.$$

Comparing A_1, Eq. (45), with $\partial\overline{E}/\partial R$ calculated from Eq. (29),

$$\frac{\partial\overline{E}}{\partial R}=\frac{1}{2}+\frac{q^2}{2\mathsf{M}^2}-\frac{[E]^2}{2\mathsf{M}^2}+\frac{\mathsf{M}^2}{8R^2},$$

we observe that

$$A_1+2\frac{\partial\overline{E}}{\partial R}=2+2\frac{q^2}{\mathsf{M}^2},$$

which is always positive; thus, one possible shift is

$$[T_1]=T_2-2q. \tag{46}$$

If we perform this transformation in Θ, we find out easily that another shift,

$$\overline{T}_1=T_3+2\frac{Rq[E]}{\mathsf{M}^2}, \tag{47}$$

miraculously cancels some pesky cross terms in $d\Theta$. Indeed, shifting the ''times'' in the Cartan form, we have

$$-\overline{E}d[T_1]-[E]d\overline{T}_1+\mathsf{M}\,d\mathsf{T}=-\overline{E}\,dT_2-[E]dT_3+\mathsf{M}\,d\mathsf{T}-\left(R+\frac{Rq^2}{\mathsf{M}^2}-\frac{3R[E]^2}{\mathsf{M}^2}-\frac{\mathsf{M}^2}{4R}\right)dq$$
$$+\frac{2q[E]^2}{\mathsf{M}^2}\,dR+\frac{2qR[E]}{\mathsf{M}^2}\,d[E]-\frac{4qR[E]^2}{\mathsf{M}^3}\,d\mathsf{M}.$$

Using Eqs. (41) and (44), we obtain

$$\Theta=-\overline{E}\,dT_2-[E]dT_3+\mathsf{M}\,d\mathsf{T}-d\left(\frac{3qR[E]^2}{2\mathsf{M}^2}+\frac{q\mathsf{M}^2}{8R}\right)$$
$$+\frac{Rq^2}{2\mathsf{M}^2}\,dq-\left(q+\frac{q^3}{2\mathsf{M}^2}\right)dR+\frac{2R}{\mathsf{M}}\left(q+\frac{q^3}{2\mathsf{M}^2}\right)d\mathsf{M}.$$

The last three terms do not contain other variables than q, R and M and so the terms with $d[E]\wedge dR$, $d[E]\wedge dq$ and $d[E]\wedge d\mathsf{M}$ disappear from $d\Theta$. We have not found any simple physical or geometrical interpretation of the new times T_2 and T_3; observe that the shifts (46) and (47) ''mix the sides.''

The fact that the last three terms in Θ contain only three variables means that they can be simplified to just one term. For example,

$$\frac{Rq^2}{2\mathsf{M}^2}\,dq-\left(q+\frac{q^3}{2\mathsf{M}^2}\right)dR+\frac{2R}{\mathsf{M}}\left(q+\frac{q^3}{2\mathsf{M}^2}\right)d\mathsf{M}=d\left(\frac{Rq^3}{6\mathsf{M}^2}\right)-\left(q\mathsf{M}^2+\frac{2q^3}{3}\right)d\left(\frac{R}{\mathsf{M}^2}\right).$$

This suggests the second step of our transformation:

$$p:=q\mathsf{M}^2+\frac{2q^3}{3}, \tag{48}$$

$$x:=\frac{R}{\mathsf{M}^2}. \tag{49}$$

We arrive so at the final shape of the Cartan form,

$$\Theta=-\overline{E}\;dT_2-[E]dT_3+\mathsf{M}\;d\mathsf{T}-p\;dx, \tag{50}$$

where $\overline{E}$ is given by Eq. (29) in which q and R are expressed in terms of p and x; such expressions can be obtained by solving Eqs. (48) and (49) for q and R.

Consider Eq. (48). If we keep M fixed, p is an increasing function of q in the whole interval $(-\infty,\infty)$, for

$$\frac{\partial p}{\partial q}=\mathsf{M}^2+2q^2>0.$$

Hence, the function maps the range $(-\infty,\infty)$ of q onto the range $(-\infty,\infty)$ of p in a bijective way, and it possesses a unique inverse. One can explicitly write down this inverse using second and third roots; this will make $\overline{E}$ a complicated function of p, x, M and $[E]$ [we shall write down this function later; cf. Eq. (63)].

Equation (50) implies that

$$d\Theta_{T_2}\wedge d\Theta_{T_2}\wedge d\Theta_{T_2}=6d[E]\wedge dT_3\wedge d\mathsf{M}\wedge d\mathsf{T}\wedge dp\wedge dx,$$

$$d\Theta_{T_3}\wedge d\Theta_{T_3}\wedge d\Theta_{T_3}=6\,\frac{\partial\overline{E}}{\partial[E]}\;d[E]\wedge dT_2\wedge d\mathsf{M}\wedge d\mathsf{T}\wedge dp\wedge dx,$$

$$d\Theta_{T}\wedge d\Theta_{T}\wedge d\Theta_{T}=-6\,\frac{\partial\overline{E}}{\partial\mathsf{M}}\;d[E]\wedge dT_3\wedge d\mathsf{M}\wedge dT_2\wedge dp\wedge dx,$$

and Eq. (29) gives

$$\frac{\partial\overline{E}}{\partial[E]}=-\frac{R}{\mathsf{M}^2}\,[E],$$

$$\frac{\partial\overline{E}}{\partial\mathsf{M}}=-\frac{\mathsf{M}}{4R}.$$

Thus, the surface $T_3=\text{const}$ is not transversal at $[E]=0$, but $T_2=\text{const}$ and $\mathsf{T}=\text{const}$ are transversal everywhere.

The Cartan form (50) is not yet very simple, because $\overline{E}$ is a complicated function of p, x, $[E]$ and M. What we can still do is to extend the phase space to an eight-dimensional manifold with the coordinates $\overline{E}$, $[T_2]$, $[E]$, $\overline{T}_2$, M, T, p and x, and to express the constraint between these variables as a polynomial. Indeed, applying Eq. (49), we can rewrite Eq. (29) as follows:

$$q^2=\frac{1}{4x^2}+\frac{2\overline{E}}{x}+[E]^2-\mathsf{M}^2;$$

squaring Eq. (48) and substituting the above expression for q^2 into the result, we obtain

$$p^2=\frac{1}{9}\left(\frac{1}{4x^2}+\frac{2\overline{E}}{x}+[E]^2-\mathsf{M}^2\right)\left(\frac{1}{2x^2}+\frac{4\overline{E}}{x}+2[E]^2+\mathsf{M}^2\right)^2. \tag{51}$$

This is a constraint that is polynomial in the momenta p, $\overline{E}$, $[E]$ and M. The inequalities defining the ranges of the variables $\overline{E}$, $[T_2]$, $[E]$, $\overline{T}_2$, M, T, p and x in the physical region are also simplified:

$$[E]^2\leqslant 4\overline{E}^2,\quad \mathsf{M}>0,\quad x>0. \tag{52}$$

Let us, finally, find the transformation of the variables p, x, M, T, $\overline{E}$, T_2, $[E]$ and T_3 by the symmetry group. The results are as follows. We have for the Λ-transformation,

$$p\mapsto p,\quad x\mapsto x,\quad \mathsf{M}\mapsto\mathsf{M},\quad \mathsf{T}\mapsto\mathsf{T},\quad \overline{E}\mapsto\overline{E},\quad [E]\mapsto[E],$$

$$T_2\mapsto T_2-\frac{\partial\Lambda}{\partial\overline{E}},\quad T_3\mapsto T_3-\frac{\partial\Lambda}{\partial[E]},\quad \mathsf{T}\mapsto\mathsf{T}+\frac{\partial\Lambda}{\partial\mathsf{M}};$$

for the time reflection σ_1,

$$p\mapsto -p,\quad x\mapsto x,\quad \mathsf{M}\mapsto\mathsf{M},\quad \mathsf{T}\mapsto-\mathsf{T},\quad \overline{E}\mapsto\overline{E},\quad [E]\mapsto[E],\quad T_2\mapsto -T_2,\quad T_3\mapsto -T_3;$$

and for the left–right reflection σ_2,

$$p\mapsto p,\quad x\mapsto x,\quad \mathsf{M}\mapsto\mathsf{M},\quad \mathsf{T}\mapsto\mathsf{T},\quad \overline{E}\mapsto\overline{E},\quad [E]\mapsto-[E],\quad T_2\mapsto T_2,\quad T_3\mapsto -T_3.$$

Thus, the simple form of the symmetry transformations is preserved by the shifts (46) and (47) as well as by transformations (48) and (49). Equation (50) implies that

$$\Theta\mapsto\Theta+d\left(\frac{\partial\Lambda}{\partial\overline{E}}\,\overline{E}+\frac{\partial\Lambda}{\partial[E]}\,[E]+\frac{\partial\Lambda}{\partial\mathsf{M}}\,\mathsf{M}-\Lambda\right),$$

by a Λ-transformation, so our extended Λ-transformation is a symmetry,

$$\Theta\mapsto-\Theta,$$

by the time reflection σ_1, and

$$\Theta\mapsto\Theta,$$

by the left–right reflection σ_2. (The sign change of Θ by σ_1 is necessary, because time reflections are anti-symplectic transformations.) The constraint equation (51) is clearly invariant of the group. Thus, the action of the symmetry group is well-defined in the whole phase space and it preserves the physical region.

VII. THE CONSTRAINT SURFACE

In this section, we are going to study the properties of the constraint (51). We are interested in the topology of the constraint surface; we shall investigate the salient question of whether or not any spurious solutions have been unintentionally included during the process of transforming the constraint to the polynomial form; and we shall look for solutions of the constraint (51) with respect to some momenta.

Our new variational principle reads as follows:

$$S=\int dt(-\overline{E}\dot{T}_2-[E]\dot{T}_3+\mathsf{M}\dot{\mathsf{T}}-p\dot{x}-\nu_1\mathcal{C}_1), \tag{53}$$

where

$$\mathcal{C}_1=9p^2-\left(\frac{1}{4x^2}+\frac{2\overline{E}}{x}+[E]^2-\mathsf{M}^2\right)\left(\frac{1}{2x^2}+\frac{4\overline{E}}{x}+2[E]^2+\mathsf{M}^2\right)^2. \tag{54}$$

The constraint surface is trivial in the direction of the three times T_2, T_3 and T, so we can limit ourselves to its projection to the five-dimensional space spanned by $\overline{E}$, $[E]$, M, p and x. Let us observe that $\mathcal{C}_1$ depends on $\overline{E}$, $[E]$ and x through a function that we shall call B,

$$B:=\frac{1}{4x^2}+\frac{2\overline{E}}{x}+[E]^2, \tag{55}$$

and that the gradient of B is nonzero. It is, therefore, advantageous, to write $\mathcal{C}_1$ as a composed function,

$$\mathcal{C}_1=9p^2-(B-\mathsf{M}^2)(2B+\mathsf{M}^2)^2.$$

Let us first look for the singular points of the constraint surface (that is, where the gradient of $\mathcal{C}_1$ vanishes). We have

$$\frac{\partial\mathcal{C}_1}{\partial p}=18p, \tag{56}$$

$$\frac{\partial\mathcal{C}_1}{\partial\mathsf{M}}=6\mathsf{M}^3(2B+\mathsf{M}^2), \tag{57}$$

$$\frac{\partial\mathcal{C}_1}{\partial B}=-3(2B+\mathsf{M}^2)(2B-\mathsf{M}^2). \tag{58}$$

As all three derivatives must vanish at a singular point, all such points are determined by the equations

$$p=0,\quad 2B+\mathsf{M}^2=0. \tag{59}$$

All points satisfying Eqs. (59) are solutions of Eq. (51); however, the physical ranges (52) of the variables $\overline{E}$, $[E]$ and x do not allow B to be negative. We conclude that the constraint surface is regular (smooth) in the physical region (52).

The topology of the constraint surface can be found in the shortest way, if we consider $\mathcal{C}_1$ as a function $\mathcal{C}_1(B)$ of B keeping all other variables constant. Studying Eqs. (54) and (58) we can easily see that $\mathcal{C}_1(B)$ decreases in the interval $(-\infty,-\mathsf{M}^2/2)$ from ∞ to $9p^2$, it increases in the interval $(-\mathsf{M}^2/2),\mathsf{M}^2/2)$, from $9p^2$ to $9p^2+2\mathsf{M}^6$ and it decreases again in the interval $(\mathsf{M}^2/2,\infty)$ from $9p^2+2\mathsf{M}^6$ to $-\infty$. It follows that there is only one solution for $p\neq 0$ [because $\mathcal{C}_1(B)=9p^2$ for $B=\mathsf{M}^2$]. As $\mathcal{C}_1(\mathsf{M}^2)=9p^2>0$, the solution must satisfy the inequality $B>\mathsf{M}^2$. This solution depends smoothly on the values of all other variables. For $p=0$, there are, however, two solutions: one with $B=\mathsf{M}^2$, which is a continuous extension of the previous $p\neq 0$ case, and a new one with $B=-\mathsf{M}^2/2$, which appears when the local minimum at $-\mathsf{M}^2/2$ touches the B-axis. This shows that the constraint surface consists of two components: one is a seven-dimensional smooth manifold, let us denote it by Γ_7, that lies in the region $B\geqslant\mathsf{M}^2$, and one is a six-dimensional smooth manifold, let us denote it by Γ_6, that is defined by Eqs. (59).

Next, let us study the solvability of the constraint equation (51) with respect to the conserved momenta. The unique solution of the constraint (51) with respect to B at Γ_7 is given by

$$B=f(p,\mathsf{M}), \tag{60}$$

where

$$f(p,\mathsf{M}):=\tfrac{1}{2}\sqrt[3]{9p^2+\mathsf{M}^6+3p\sqrt{9p^2+2\mathsf{M}^6}}+\tfrac{1}{2}\sqrt[3]{9p^2+\mathsf{M}^6-3p\sqrt{9p^2+2\mathsf{M}^6}}. \tag{61}$$

The equation (51) has, in fact, three independent solutions, but only one of them is real. For $p=0$, B reaches its minimum M^2 on Γ_7; thus, at Γ_7,

$$B\geqslant\mathsf{M}^2. \tag{62}$$

Given B, one can solve uniquely for $\overline{E}$ and there is also a unique solution for $[E]^2$. The solution for $\overline{E}$ is

$$\overline{E}=-\frac{1}{8x}-\frac{x[E]^2}{2}+\frac{x}{2}f(p,\mathsf{M}). \tag{63}$$

Similarly, we can find the solution of the constraint (51) with respect to M. Consider $\mathcal{C}_1$ as a function $\mathcal{C}_1(\mathsf{M})$ of M, keeping all other variables fixed. $\mathcal{C}_1(\mathsf{M})$ is symmetric with respect to the reflection on the $\mathcal{C}_1$-axis. We have to distinguish two cases: $\underline{B<0,\ B=0:}$ $\mathcal{C}_1(\mathsf{M})$ decreases in the interval $(-\infty,2B)$ from ∞ to $9p^2$, it increases in the interval $(2B,0)$ from $9p^2$ to the local maximum $9p^2-4B^3$ at $\mathsf{M}=0$, it decreases again in the interval $(0,-2B)$ from $9p^2-4B^3$ to $9p^2$ and, finally, it increases in $(-2B,\infty)$ from $9p^2$ to ∞. A solution exists only for $p=0$, and there are two solutions; then $\mathsf{M}=\pm\sqrt{-2B}$. This is at the surface Γ_6. $\underline{B>0:}$ then, there is only one minimum, at $\mathsf{M}=0$, with the value $9p^2-4B^3$; there are no other extrema. Consider Eq. (51) as an equation for M^{-2}. There are three real solutions for M^{-2}, but all of them are negative unless

$$4B^3-9p^2\geqslant 0, \tag{64}$$

and then there is only one non-negative solution. A reasonable solution is, therefore, unique; it depends continuously of the other variables and it lies at Γ_7. We can write it in the form

$$\mathsf{M}=\pm\sqrt[4]{\frac{4B^3-9p^2}{4B}}\left(\cos\frac{1}{3}\arctan\frac{3p}{\sqrt{4B^3-9p^2}}\right)^{-1/2}.$$

This solution can, of course, be also expressed by means of square and third roots, but only if one employs complex numbers. We can see that squaring of M introduced nonphysical solutions with negative M; we have to choose the positive branch. Observe that all points at the surface Γ_7 must satisfy the inequalities (62) and (64).

The equations of motion that follow from the action (53) can be written as follows:

$$\dot{\overline{E}}=[\dot{E}]=\dot{\mathsf{M}}=0, \tag{65}$$

$$\dot{T}_2=-\nu_1\frac{\partial\mathcal{C}_1}{\partial B}\frac{\partial B}{\partial\overline{E}}, \tag{66}$$

$$\dot{T}_3=-\nu_1\frac{\partial\mathcal{C}_1}{\partial B}\frac{\partial B}{\partial[E]}, \tag{67}$$

$$\dot{\mathsf{T}}=\nu_1\frac{\partial\mathcal{C}_1}{\partial\mathsf{M}}, \tag{68}$$

$$\dot{p}=\nu_1\frac{\partial\mathcal{C}_1}{\partial B}\frac{\partial B}{\partial x}, \tag{69}$$

$$\dot{x}=-\nu_1\frac{\partial\mathcal{C}_1}{\partial p}. \tag{70}$$

It is easy to derive the radial equation from them. On Γ_6, we have only a static solution:

$$\dot{x}=\dot{T}=\dot{p}=\dot{T}_2=\dot{T}_3=0.$$

On Γ_7, $\dot{\mathsf{T}}>0$ for $\nu_1>0$ and Eqs. (57), (68) and (70) yield

$$\frac{dx}{d\mathsf{T}}=-\frac{3p}{\mathsf{M}^3(2B+\mathsf{M}^2)}.$$

Using the constraint (51) to exclude p, we obtain the radial equation on Γ_7:

$$\frac{dx}{d\mathsf{T}}=\pm\frac{1}{\mathsf{M}^2}\sqrt{\frac{B}{\mathsf{M}^2}-1}. \tag{71}$$

Let us compare it with Eq. (13). Eqs. (65) and (49) imply that

$$\frac{dx}{d\mathsf{T}}=\frac{1}{\mathsf{M}^2}\frac{dR}{d\mathsf{T}},$$

whereas Eqs. (55), (49) and (14) give

$$V=1-\frac{B}{\mathsf{M}^2}.$$

Hence, the radial equations (71) and (13) are equivalent, and the dynamics of the new action on Γ_7 coincides with that of the old action. Γ_6 consists of the unintentionally added unphysical solutions, at least on the phase space defined by Eqs. (18), but nothing is added in the physical region.

Finally, we shall study the question of the monotonicity of the time functions T_2, T_3 and T along the dynamical trajectories at Γ_7. Equations (57) and (58) show that the right-hand sides of Eqs. (66) and (68) cannot vanish, and we have for $\nu_1>0$,

$$\dot{T}_2>0, \quad \dot{\mathsf{T}}>0.$$

Hence, T_2 and T are good times and, as we have seen above, the constraint can be solved uniquely for the corresponding momenta, $\overline{E}$ and M. As for T_3, Eq. (67) implies that $\dot{T}_3>0$ for $[E]>0$, $\dot{T}_3=0$ for $[E]=0$ and $\dot{T}_3<0$ for $[E]<0$. The solvability with respect to $[E]$ is also only partial: there is a unique positive and a unique negative solution. Thus T_3 is a good time only in some special cases, as the next section will show.

VIII. SOME INTERESTING SPECIAL CASES

In this section, we shall remove some degrees of freedom and describe the resulting simpler models in terms of the new variables.

A. Dust degrees of freedom removed

Here, we remove the variables M and T and return to the system considered in Ref. 14. It has two degrees of freedom: the black hole mass E_- and the position x of the shell. To this aim, we first choose a particular value of M and demote it so to a mere parameter. In this way, a submanifold Γ_{7M} of Γ_7 emerges. Second, we take a quotient of Γ_{7M} by the T-curves (see Ref. 17 for more details of this *exclusion of a cyclic variable*). The system that results has the action

$$S_M=\int dt(-\overline{E}\dot{T}_2-[E]\dot{T}_3-p\dot{x}-\nu_1\mathcal{C}_1),$$

where $\mathcal{C}_1$ is given by Eq. (54) as before, only M is a parameter now. The equations of motion comprise Eq. (65) without $\dot{\mathsf{M}}=0$, as well as Eqs. (66), (67), (69) and (70).

The properties of this system are analogous to that of the original one. In particular, the constraint is regular everywhere on Γ_{7M} because the derivative (56) and (58) cannot both simultaneously vanish, T_2 is a good time variable and the constraint equation is uniquely solvable for $\overline{E}$.

B. Black hole degree of freedom removed

Here, we demote the variable E_- to a parameter and remove the corresponding cyclic variable $T_2/2-T_3$; the remaining two degrees of freedom are the internal energy M and the position x of the shell. The system obtained in this way will describe the dynamics of the dust shell in the field of a fixed black hole if $E_->0$ or in the Minkowski space if $E_-=0$. One returns so to the system considered in Ref. 13; the procedure, in different coordinates, has been performed in Ref. 17.

To begin with, we transform variables as follows:

$$\overline{E}=\frac{E_++E_-}{2},\quad T_2^+=T_2/2+T_3,$$

$$[E]=E_+-E_-,\quad T_2^-=T_2/2-T_3.$$

Then, we choose a particular value for E_-; this defines the black hole mass, and formally, a six-dimensional submanifold Γ_{7E} of Γ_7. Finally, we take the quotient Γ_{7E}/T_- of Γ_{7E} by the T_--curves. The result is the action

$$S_E=\int dt(-E_+\dot{T}_2^++\mathsf{M}\dot{\mathsf{T}}-p\dot{x}-\nu_1\mathcal{C}_2),$$

where

$$\mathcal{C}_2=9p^2-(B_2-\mathsf{M}^2)(2B_2+\mathsf{M}^2)^2,$$

and

$$B_2 = \frac{1}{4x^2} + \frac{E_+ + E_-}{x} + (E_+ - E_-)^2.$$

The variable T is a good time and $C_2 = 0$ is, of course, solvable for M exactly as in the general case. The variable T_2^+ is, for large values of the parameter E_-, not a good time, because it is a combination $T_2/2 + T_3$ of T_2 that increases along all dynamical trajectories and T_3 that increases along those with $E_+ > E_-$ and decreases along those with $E_+ < E_-$. One can show that $\dot{T}_2^+$ is positive for $E_+ - E_- > 0$ and negative for $E_+ - E_- < -\mathsf{M}$ and that there is no surface for $E_- > \mathsf{M}$ that would be transversal to both the dynamical trajectories and the orbits of the continuous subgroup. [Still, one can transform T_2^+ so that the resulting time levels are transversal to the dynamical trajectories, but a mere shift is not sufficient; one must screw the level to a helix form with the helix axis in the E_+-direction; this may be done by a singular ''shift'' proportional to $(E_+ - E_-)^{-1}$. We shall not go into detail.] The derivative of $\mathcal{C}_2$ with respect to E_+ changes sign somewhere if E_- is sufficiently large and so there are more than one, or no solution of the constraint with respect to E_+.

There is one prominent exception: suppose that $E_- = 0$. Then, $E_+ - E_-$ is positive if E_+ is. Hence, in the physical region (where $E_+ > 0$), T_2^+ is a good time and the constraint has a unique solution for E_+ there, namely,

$$E_+ = -\frac{1}{2x} + \sqrt{f(p, \mathsf{M})},$$

where f is defined by Eq. (61).

One can also remove all four variables T, M, E_- and T_2^- so that only one degree of freedom, the position x of the shell, remains, but it is not difficult to work out the properties of the system using the results obtained in this section, and we left it as an easy exercise to the reader.

The special case $E_- = 0$ is also interesting, because it is a part of the boundary of the physical region given by inequalities (52) on Γ_7. The variational principle (53) does not break down at the boundary, that is, it defines a regular dynamics there. From this, it must clearly follow that the action defines a regular dynamics even at those points of Γ_7 that do not satisfy the conditions (52). We have studied the meaning of this dynamics and of these points in Sec. II.

Asymptotic behavior in polarized T^2-symmetric vacuum space–times

(Received 23 March 1998; accepted for publication 20 July 1998)

We use the Fuchsian algorithm to study the behavior near the singularity of a class of solutions of Einstein's vacuum equations. These solutions admit two commuting spacelike Killing fields like the Gowdy space–times, but their twist does not vanish. The space–times are also polarized in the sense that one of the ''gravitational degrees of freedom'' is turned off. Examining an analytic family of solutions with the maximum number of arbitrary functions, we find that they are all asymptotically velocity-term dominated as one approaches the singularity. © *1999 American Institute of Physics.* [S0022-2488(99)00601-5]

I. INTRODUCTION

There is increasing evidence that cosmological solutions exhibit rather special dynamical behavior in the neighborhood of their singularities. The evidence is still essentially limited to families of solutions with at least one Killing field. However, it is quite striking that although the Hawking–Penrose singularity theorems[1] require nothing more than geodesic incompleteness in generic cosmological solutions, every study to date indicates that the solutions under investigation are either ''asymptotically velocity-term dominated'' (AVD) or show ''Mixmaster'' behavior (see Refs. 2–8).

In a space with AVD behavior, the metric tensor $g_{ab}(\mathbf{x},t)$ evolves in such a way that an observer with fixed $\mathbf{x}_0$ moving toward the singularity sees the dynamics of $g_{ab}(\mathbf{x}_0,t)$ asymptotically approach that of a Kasner space–time, with there being generally a different Kasner limit for each different $\mathbf{x}_0$ (see Refs. 9, 3, 5, and 7, and references therein). Mixmaster behavior is similar, except that this observer sees $g_{ab}(\mathbf{x}_0,t)$ move through an infinite sequence of Kasner epochs, with regular intermittent bounces from one epoch to another (see Ref. 10). Again, different observers generally see different sequences (see, for instance, Refs. 3 and 8). While neither AVD nor Mixmaster behavior as described above is trivial, the Einstein equations, even with the simplification of an assumed symmetry, are sufficiently complicated that the prevalence of these special behaviors is quite remarkable.

The earliest verifications of AVD behavior in a family of inhomogeneous solutions, the polarized Gowdy space–times, took the form of a theorem.[5,11] The techniques developed in proving that result have not, however, been readily extended to more general families. Instead, most of the recent evidence for AVD and Mixmaster behavior in cosmological space–times has been based on numerical work: Berger and Moncrief[12] provide strong numerical evidence for AVD behavior in general ($\mathbf{T}^3$) Gowdy space–times, but find that the Kasner exponents should satisfy some inequalities in generic solutions (the solutions should be ''low-velocity''); they also

have evidence in polarized $\mathbf{U}(1)$-symmetric space–times.[13] One should note that it is not always easy to be sure, in numerical computations, that the constraint equations do hold, except in the Gowdy class. Note also that Weaver, Berger, and Isenberg[8] provide similar evidence that locally $\mathbf{T}^2$-symmetric space–times with certain magnetic fields have Mixmaster behavior.

This numerical evidence motivates the search for a theoretical explanation for the prevalence of these behaviors and numerical observations such as the distinction between high- and low-velocity solutions, and, if possible, a means to predict which behavior occurs. The recent work of Kichenassamy and Rendall[7] introduces a new tool for obtaining such information. They use the Fuchsian algorithm to prove that there is a family of general (non-polarized) Gowdy space–times parametrized by the maximum number of free functions, namely four, which all exhibit AVD ''low-velocity'' behavior. If the derivative of one of these functions vanishes, ''high-velocity'' behavior is allowed. This family of solutions includes all of the previously known solutions in this class. The results also shed new light on other features of the numerical computations.

It is very likely that one can show that these new Gowdy space–times are stable under smooth perturbation of Cauchy data, by adapting the techniques described in Refs. 14 and 15. The general strategy consists in showing, using the Nash–Moser implicit function theorem, that the free functions which determine the solutions given by the Fuchsian algorithm can be used to parametrize solutions much in the same way as one uses Cauchy data on a hypersurface to label regular solutions. In a sense, one therefore generates systematically an ''asymptotic phase space'' for families of solutions, as was called for in Ref. 5.

In this work, we show that the Fuchsian algorithm is an effective tool for proving that AVD behavior occurs in a wider class of space–times: those which possess, like the Gowdy space–times, a $\mathbf{T}^2$ isometry group with spacelike generators, but in which, unlike the Gowdy case, the Killing vectors have a nonvanishing twist. The main new difficulty is that this nonvanishing twist prevents the constraint equations from decoupling from the evolution equations, resulting in a considerably more complicated partial differential equation (PDE) system than what obtains in the case of Gowdy space–times.[16–18] This difficulty is overcome by abandoning the separation of constraint and evolution equations. It is found that, combining some of the constraints with some of the ''evolution'' equations, one can form a system which is sufficient to determine the metric. One then proves directly that the remaining constraints hold everywhere if they hold asymptotically at the singularity. This latter condition can be expressed explicitly in terms of the data which determine the asymptotics at the singularity, or ''singularity data'' for short.

The Fuchsian algorithm has been extensively studied and takes a variety of forms (see Refs. 15, 19, 20, and 7). In Sec. II, we briefly review the form of the algorithm we use here, and a few relevant results we will need. Next, we describe in Sec. III the $\mathbf{T}^2$-symmetric space–times, noting some of their properties and defining the polarized subfamily. Then, in Sec. IV, we propose an AVD ansatz for the metric coefficients and show that the ''regular part'' of the field is indeed negligible in comparison with the leading terms. Finally, we discuss in Sec. V our conclusions and plans for future work.

II. THE FUCHSIAN ALGORITHM

The Fuchsian algorithm was initially developed to understand the behavior of solutions of differential equations in the neighborhood of a possible singularity of unknown location. The rationale was that if singularities are to form, it would be desirable to figure out by what mechanism they form: Which components of the solution become singular? Do singularities occur only in higher derivatives? Is the locus of the singularity arbitrary? How does it vary with Cauchy data given on a surface where the solution is smooth?

Existing results prior to Fuchsian techniques gave some information on the time of the first singularity, but did not shed light on the mechanism of singularity formation, except for special classes of singularities, such as shock waves in low dimensions, or caustic formation.

The questions asked above would be answered if it were possible to establish an expansion of the solution to relatively high order. To achieve this, one needs to establish a formal solution, and to prove that this formal expansion does characterize the solution. In practice, one is not primarily interested in the convergence or divergence of a series representation. Rather, one would like to know whether the parameters entering in a formal series representation do *determine uniquely* the solution, or whether there are infinitely many solutions differing from each other by, say, exponentially small corrections.

The Fuchsian method tackles this problem by seeking a reduction of the given system of PDEs to a Fuchsian system; that is, one which has a regular singular point with respect to one of the variables, which we call t. Using a change of coordinates if necessary, one may assume that the locus of the singularity is $t=0$. It is also possible to set things up so that one always deals with *first-order* Fuchsian systems, by the introduction of new variables. This is a familiar procedure for the Cauchy problem: for instance, if u solves the wave equation in Minkowski space, it is easy to check that the quantities $(u,\partial_a u)$ satisfy a first-order system.

Let us consider a PDE system which we write symbolically as

$$F[u]=0.$$

The exact form of the nonlinearity is not important for what follows. Generally, u can have any number of components.

Schematically, the Fuchsian algorithm has three parts:

Step 1. Identify the *leading part* of the desired expansion for u. This can be done in many cases by seeking a leading balance; that is, a leading term $a(t)$ such that, upon substitution into the equation, the most singular terms cancel each other.

Step 2. Introduce a *renormalized unknown*. This means that one writes

$$u=a(t)+t^s v(t), \tag{1}$$

where v is the new unknown. It is generally useful to compute a to relatively high order if possible, so that any arbitrary functions in the expansion are already included in a. If a is a solution up to order n, one may usually take $s=n+\varepsilon$, where ε is small.

Step 3. Obtain and solve a *Fuchsian system* for v. Indeed, one finds under rather general circumstances that the function v solves an equation of a very particular form, namely

$$(t\partial_t+A)v=t^\varepsilon f(t,x^\rho,v,\nabla_\rho v), \tag{2}$$

where ρ stands for spatial indices in this formula. The matrix A depends at most on the spatial variables, and f is, say, bounded. By taking t^ε to be a new time variable, one may always assume that ε is equal to one. Observe how spatial derivatives are effectively switched off from the equation when t goes to zero: *the Fuchsian algorithm provides a systematic procedure to guarantee AVD behavior.*

There is a variety of existence results for Fuchsian systems.[19,21,7] For our purposes, it suffices to note the following (see, Refs. 7 and 19).

Theorem 1: *There is a unique local solution which is continuous in time and analytic in space, and vanishes as t goes to zero, provided that (a) f is continuous in t and analytic in its other arguments and satisfies an estimate of the form*

$$|f(t,x^\rho,v,\nabla_\rho v)-f(t,x^\rho,w,\nabla_\rho w)|\leqslant C[|v-w|+|\nabla_\rho v-\nabla_\rho w|]$$

for some constant C provided v and w are bounded, and (b) the matrix $\sigma^A[=\exp(A\ln\sigma)]$ *is uniformly bounded for* $0<\sigma<1$.

Condition (b) is usually most conveniently checked by simply computing the matrix exponential.

We emphasize that we are not allowed to prescribe arbitrarily the initial value of v. The free data (usually called ''singularity data'') which label the solution u are already built into the choice of a in (1), and are subsequently incorporated into the function f in (2). A straightforward extension of the theorem can be made if we assume only that $v(0)$ belongs to the null space of A. By considering the equation satisfied by $v-v(0)$, one can reduce the problem to an equation to which the theorem applies. In such a case, $v(0)$ must be added to the list of singularity data.

General strategies for carrying out the algorithm can be found in Refs. 15, 20, 19, and 7, with applications to several examples. Let us simply describe here what these steps entail for the first PDE to which these ideas were applied successfully:

$$\eta^{ab}\partial_{ab}u=e^{u} \tag{3}$$

in Minkowski space, where u is a scalar field (there are similar results for power nonlinearities as well). Let $t=\psi(x)$ be the locus of the (yet unknown) singularity, and let x stand for the spatial variables. For one space dimension, Eq. (3) has a closed-form solution (''Liouville field theory''); however, we allow here the number of space dimensions to be arbitrary. Let $T=t-\psi(x)$. If we choose the leading part of u so that $\exp(u)\sim\varphi(x)T^{s}$ where s and φ are unknown, one readily finds that, to eliminate the most singular term in the expansion of (3), we need to choose $s=-2$ and $\varphi=2(1-|\nabla_x\psi|^2)$ which must therefore be positive. Hence the leading part of u takes the form

$$u\approx\ln\frac{2}{T^2}+\ln(1-|\nabla_x\psi|^2).$$

This completes the first step.

It is useful to write out the rest of the leading part $a(t)$ of u up to order two in T for two reasons: (a) this reveals that the solution contains logarithmic terms, which disappear, in fact, only if the scalar curvature of the singularity manifold vanishes identically; and (b) this shows that the coefficient of T^2 in the expansion is arbitrary. We therefore compute, by direct substitution,

$$u\approx\ln\frac{2}{T^2}+u_0(x)+u_1(x)T+u_{1,1}(x)T^2\ln T+u_2(x)T^2+\ldots,$$

where u_0, u_1, and $u_{1,1}$ are entirely determined by ψ; in particular, $u_0=\ln(1-|\nabla_x\psi|^2)$. However, u_2 remains arbitrary. One then sets

$$u=\ln\frac{2}{T^2}+u_0(x)+u_1(x)T+u_{1,1}(x)T^2\ln T+vT^2, \tag{4}$$

so that the arbitrary function u_2 appears as an 'initial value' for the renormalized unknown v. This completes the second step.

The singularity data in this case are ψ and $u_2=v(0)$. Once they are known, the formal solution is completely determined.

For the third step, we now substitute expression (4) for u into (3), and find that v solves an equation which can be thought of as a nonlinear perturbation of the Euler–Poisson–Darboux equation. One then checks that v, Tv_T, and $T\nabla_\rho v$ solve a Fuchsian system. This has the following consequences:

(a) There is a formal solution to all orders, in powers of T and $T\ln T$; for $T<0$, one replaces $T\ln T$ by $T\ln|T|$. The series are convergent if ψ and u_2 are analytic; otherwise, they are valid as far as the differentiability of the free functions allows. As already mentioned, the logarithmic terms cannot be dispensed with, except for very special solutions. The example of Gowdy space–times shows that one should even allow terms such as $T^{k(x)}$ for the application to Einstein's equations.

(b) The solution is uniquely determined by the ''singularity data'' $\{\psi,u_2\}$. In fact, the correspondence between these data and the Cauchy data on a hypersurface where the solution is regular can be inverted, using the Nash–Moser version of the inverse function theorem (see Ref. 14). From a practical viewpoint, this means that *(i)* the smoother the Cauchy data, the smoother the singularity surface; and *(ii)* there is a recipe for computing how the singularity data vary when the Cauchy data vary. The question in the opposite direction is simpler: the series representation gives explicitly the solution in terms of the singularity data.

All this makes the series representations generated by Fuchsian techniques as reliable as an exact solution in the vicinity of the singularity—a place where at present no other representation is available.

It should be stressed that the Fuchsian method applies without symmetry or integrability restrictions. For this reason, it enables one to study directly the stability of solutions furnished by generation techniques, even under fully ''inhomogeneous'' or ''asymmetric'' perturbations, and the information it provides yields concrete analytical insight into the properties of solutions.

III. POLARIZED T^2-SYMMETRIC SPACE–TIMES

While the Gowdy $\mathbf{T}^3$ space–times[22] have been extensively studied over the years,[5,16,6,12,7] and are relatively well understood, the more general $\mathbf{T}^2$-symmetric space–times have only recently begun to be considered.[16–18] The technical condition which distinguishes the Gowdy subfamily is the requirement that the Killing fields X and Y which generate the isometry group have vanishing twist constants $\kappa_x := \varepsilon^{abcd} X_a Y_b \nabla_c X_d$ and $\kappa_y := \varepsilon^{abcd} X_a Y_b \nabla_c Y_d$, where ε^{abcd} is the Levi-Civita tensor. The essential difference in practice is that, if one chooses the constant orbit area time-foliation (''Gowdy time''),[22] the constraint equations decouple from the evolution equations in the Gowdy case, and can therefore more or less be ignored in the analysis. If, however, either κ_x or κ_y is nonzero, then no such decoupling occurs.

The general form of the metric and the field equations for the $\mathbf{T}^2$-symmetric space–times is presented in Ref. 17, along with a proof that the Gowdy time always exists globally for these space–times. To write the metric, we assume that all metric components depend on two coordinates, the Gowdy time t and spatial coordinate $\theta \in S^1$ with $\partial/\partial x$ and $\partial/\partial y$ generating the $\mathbf{T}^2$ isometry. By choosing X and Y to be suitable linear combinations of the generators, we may always assume without loss of generality that $\kappa_x = 0$. We then drop the subscript from κ_y. We now focus our attention on the subclass of polarized space–times, which have $A \equiv 0$ in the notation of Ref. 17. The metric takes the form

$$ds^2 = e^{2(\nu-u)}(-\alpha dt^2 + d\theta^2) + \lambda e^{2u}(dx + G_1 d\theta + M_1 dt)^2 + \lambda e^{-2u} t^2 (dy + G_2 d\theta + M_2 dt)^2, \tag{5}$$

where λ is a positive constant and the functions u, ν, α, G_1, M_1, G_2, and M_2 depend on t and θ. The vacuum field equations take the form, writing u_t for $\partial u/\partial t$, etc., $D = t\partial_t$, $D^2 = t^2\partial_t^2 + t\partial_t$, and $m = \lambda \kappa^2$,

$$D^2 u - t^2 \alpha u_{\theta\theta} = \frac{1}{2\alpha} D\alpha D u + \frac{t^2}{2} \alpha_\theta u_\theta, \tag{6a}$$

$$D\alpha = -\frac{\alpha^2}{t^2} m e^{2\nu}, \tag{6b}$$

$$D\nu = (Du)^2 + t^2 \alpha u_\theta^2 + \frac{\alpha}{4t^2} m e^{2\nu}, \tag{6c}$$

$$\partial_\theta \nu = 2 u_\theta D u - \frac{\alpha_\theta}{2\alpha}, \tag{6d}$$

$$G_{1,t} = M_{1,\theta}, \tag{6e}$$

$$G_{2,t}=M_{2,\theta}+\frac{\kappa\alpha^{1/2}}{t^3}e^{2\nu}, \tag{6f}$$

$$\kappa_t=0, \tag{6g}$$

$$\kappa_\theta=0. \tag{6h}$$

Note that the Gowdy case is recovered if $\kappa=0$, $\alpha=1$, and $G_1=G_2=M_1=M_2=0$. Since $G_{1,t}=M_{1,\theta}$, $G_1 d\theta+M_1 dt$ is locally an exact differential $d\varphi$. Replacing x by $x+\varphi$, we may assume *locally* that $G_1=M_1=0$. Similarly, one can set $M_2=0$ by redefining y. Since these reductions are only local and may be incompatible with global requirements, we do not consider them further, even though they do make the geometric ''degrees of freedom'' more clear.

Equations (6a) constitute an initial-value problem for the polarized space–times, in which the equations (6a)–(6d) decouple from the rest. They form an independent system for $\{u,\alpha,\nu\}$. Once these three functions are known, the other equations can be solved easily.

We note that Eqs. (6b)–(6d) in particular—three of the four equations which constitute the heart of the Cauchy problem for these space–times—actually derive from the constraint equations of Einstein's theory. Unlike the Gowdy case, the wave equation (6a) does not decouple from the constraints, since it contains the function α. We therefore take (6a)–(6d) as our basic equations, treating (6a)–(6c) as evolution equations, and (6d) as the only effective constraint.

The local well-posedness of the initial-value problem away from the singularity at $t=0$ is not quite straightforward, for we must prove that Eq. (6d) propagates. This is not an immediate consequence of standard results because we are not using any of the standard setups for the initial-value problem. It nevertheless does hold, and this can be ascertained in two ways.

One approach is as follows (this is basically the argument used by Refs. 17 and 16): if we choose $\{u,u_t,\alpha,\nu,\ldots\}$ at some initial time $t_0>0$ so that they satisfy the constraint (6d), then we can view these as an initial data set for the Einstein equations without any symmetry and construct a local solution in the standard way. One then uses the results of Ref. 16 to introduce coordinates in this region so that the metric takes the form (5).

We can also give a direct argument, which will be useful later. We first deal with the analytic case, which is all we need for the results of Sec. IV. In view of its independent interest, we show in the appendix how to deal with the nonanalytic Cauchy problem as well.

Away from $t=0$, the PDE system (6a)–(6c) is of Cauchy–Kowalewska type. More precisely, we can reduce it to the following first-order system for $(z_0,z_1,z_2,\alpha,\nu):=(u,u_t,u_\theta,\alpha,\nu)$:

$$\partial_t z_0=z_1,$$

$$\partial_t z_1=\alpha\partial_\theta z_2-\frac{z_1}{t}-\frac{m}{2t^3}z_1e^{2\nu}+\tfrac{1}{2}z_2\alpha_\theta,$$

$$\partial_t z_2=\partial_\theta z_1,$$

$$\partial_t\alpha=-\frac{\alpha^2}{t^3}me^{2\nu},$$

$$\partial_t\nu=tz_1^2+t\alpha z_2^2+\frac{\alpha}{4t^3}me^{2\nu}.$$

In particular, ignoring the constraint (6d), we obtain a unique solution of the remaining equations by prescribing the data $\{u,u_t,\alpha,\nu\}$ for $t=t_0$. Now let us set

$$N:=\nu_\theta-2u_\theta Du+\frac{\alpha_\theta}{2\alpha}. \tag{7}$$

Calculating

$$0 = D\nu_\theta - \partial_\theta D\nu = DN + D\left(2u_\theta Du - \frac{\alpha_\theta}{2\alpha}\right) - \partial_\theta D\nu,$$

we find, using (6a)–(6c),

$$DN - \frac{1}{2\alpha} ND\alpha = 0. \tag{8}$$

This is a linear *ordinary* differential equation (ODE) for N (there are no θ-derivatives). Hence if we choose data $\{u, u_t, \alpha, \nu\}$ for $t = t_0$ so that $N(t_0) = 0$, the uniqueness theorem for ODEs guarantees that N is identically zero for all time.

We therefore have proved the well posedness of the initial-value problem. The results of Ref. 17 ensure that the solution remains bounded for $t > \rho$, where $\rho \geqslant 0$ is independent of θ. It is expected that $\rho > 0$ in special cases only, such as exact Kasner space–times.[23] We are interested in asymptotics near $t = 0$. Note that Fuchsian techniques may be useful for analyzing singularities for t near $\rho > 0$; however, if these solutions are nongeneric in some reasonable sense, they should not contain the full number of free parameters, and they may be nonpolarized as well. It does appear that there are consistent asymptotics of the form $u \approx u_0$, $\nu \approx 1/2 \ln(t-\rho) + \nu_0(\theta)$, and $\alpha \approx \alpha_0(\theta) \times (t-\rho)^{-2}$.

As far as the number of free functions in the metric is concerned, one might expect that there will only be two, since one of the gravitational degrees of freedom has been turned off. Indeed, while the initial data for (6a)–(6c) consist of four functions $\{u, u_t, \alpha, \nu\}$, they are constrained by one relation, *viz.* (6d), and, if we set aside the choice of the initial value for the lapse function α, we obtain two arbitrary functions in the solution.

Similarly, we will obtain a family of *singular* solutions of (6a)–(6c) depending on four arbitrary functions occurring in its singular expansion, and will show that if these ''singularity data'' are constrained by one relation, the constraint (6d) holds for all time as well.

IV. APPLICATION OF THE FUCHSIAN ALGORITHM

We are interested in generating solutions to (6) which have controlled asymptotics near $t = 0$ and which are parametrized by as many arbitrary singularity data as possible. We achieve this by following the program outlined in Sec. II.

Step 1. Leading-order asymptotics. Since we expect Kasner-like behavior at the singularity, and since u and ν appear in the metric exponentially, we choose logarithmic leading terms for u and ν:

$$u \approx k(\theta)\ln t + u_0(\theta) + \cdots; \tag{9a}$$

$$\nu \approx (1 + \sigma(\theta))\ln t + \nu_0(\theta) + \cdots; \tag{9b}$$

$$\alpha \approx \alpha_0(\theta) + \cdots. \tag{9c}$$

For Eq. (6b) to hold at leading order, it is sufficient that $\sigma > 0$. For (6c) to hold at leading order, one needs $D\nu$ and $(Du)^2$ to balance each other, which requires that

$$k^2 = 1 + \sigma, \tag{10}$$

which we assume from now on. The function α_0 should be taken to be positive, to ensure the metric has the correct signature.

Note that there are four free functions, namely (k,u_0,α_0,ν_0), in these leading term expansions, just as there were four Cauchy data in the discussion of Sec. III. These four free functions are the singularity data for this system. They are 2π-periodic; furthermore, α_0 and $\sigma=k^2-1$ are positive.

These asymptotics may be compared with those of the solutions obtained in the Gowdy case in Ref. 7. If k_G denotes the parameter called k in Ref. 7, the correspondence is $\pm k_G=2k-1$. This means that the solutions we obtain here, with $k^2>1$, are similar to the ''high-velocity'' Gowdy solutions, for which $k_G>1$. The asymptotics (9a)–(9c) are not compatible with Eqs. (6) if $0<k<1$, unless $m=0$, which is the Gowdy case. Indeed, (6b) implies that α is of the order $t^{2\sigma}$, which is singular if $\sigma=k^2-1$ is negative. This makes the term $D\alpha Du/(2\alpha)$ in (6a) more singular than all the other terms in this equation, so that (6a) cannot hold. There are two ways to circumvent this: (1) take $k=0$, so that Du vanishes to leading order, giving a consistent balance, at the expense of losing the freedom to vary k; and (2) add terms to the field equations which would compensate the most singular term in (6a)—which is possible by going over to the nonpolarized field equations. These possibilities will be addressed when we deal with nonpolarized space–times, in a forthcoming paper.

Step 2. Renormalized unknown. We now introduce new unknowns which will provide an exact form for the remainders indicated with '$\cdots$' in (9a)–(9c). Because of the $e^{2\nu}$ term, we see that it is not possible to assume that the remainder terms are of order t. We do expect them to be of order t^ε if ε is small compared to the minimum of σ. We therefore define the renormalized unknowns (v,μ,β) by

$$u(\theta,t)=k(\theta)\ln t+u_0(\theta)+t^\varepsilon v(\theta,t); \tag{11a}$$

$$\nu(\theta,t)=k^2(\theta)\ln t+\nu_0(\theta)+t^\varepsilon\mu(\theta,t); \tag{11b}$$

$$\alpha(\theta,t)=\alpha_0+t^\varepsilon\beta(\theta,t). \tag{11c}$$

Step 3. Fuchsian system. We shall now show that the renormalized field variables solve a Fuchsian problem. Consequently, once the functions (k,u_0,α_0,ν_0) have been specified, and ε has been chosen small enough, the unknowns v, μ, and β are uniquely determined via Theorem 1.

To achieve this, let us first, since we are looking for a first-order system, introduce first-order derivatives of v as new unknowns. This suggests letting

$$\vec{v}=(v_1,v_2,v_3,v_4,v_5):=(v,Dv,t^\varepsilon v_\theta,\beta,\mu).$$

Let us also introduce the abbreviation $E=m\exp(2\nu_0+2t^\varepsilon\mu)$. It is helpful to remove the t-derivatives of α in the right-hand side of (6a) by using

$$\frac{D\alpha}{\alpha}=-\alpha t^{2\sigma(\theta)}E, \tag{12}$$

which follows from (6b) and (11b). We then find the following evolution equations for $\vec{v}$:

$$Dv_1=v_2; \tag{13a}$$

$$\begin{aligned}Dv_2+2\varepsilon v_2+\varepsilon^2 v_1=&\,t^{2-\varepsilon}(\alpha_0+t^\varepsilon\beta)(k_{\theta\theta}\ln t+u_{0,\theta\theta}+v_{3,\theta})\\&-\tfrac{1}{2}E\alpha t^{2\sigma-\varepsilon}(k+t^\varepsilon(v_2+\varepsilon v_1))\\&+\tfrac{1}{2}t^{2-\varepsilon}(\alpha_0+t^\varepsilon\beta)(k_\theta\ln t+u_{0,\theta}+v_3);\end{aligned} \tag{13b}$$

$$Dv_3=t^\varepsilon\partial_\theta(\varepsilon v_1+v_2); \tag{13c}$$

$$(D+\varepsilon)v_4=-t^{2\sigma-\varepsilon}(\alpha_0+t^\varepsilon\beta)^2E; \tag{13d}$$

$$(D+\varepsilon)v_5=2k(v_2+\varepsilon v_1)+t^{\varepsilon}(v_2+\varepsilon v_1)^2+\tfrac{1}{4}Et^{2\sigma-\varepsilon}(\alpha_0+t^{\varepsilon}\beta)$$
$$+\alpha t^{2-\varepsilon}(k_\theta \ln t+u_{0,\theta}+v_3)^2. \tag{13e}$$

This system has the general form

$$(D+A)\vec{v}=t^{\varepsilon}\vec{f}(t,x,\vec{v},\partial_\theta\vec{v}),$$

where

$$A=\begin{pmatrix} 0 & -1 & 0 & 0 & 0 \\ \varepsilon^2 & 2\varepsilon & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \varepsilon & 0 \\ -2k\varepsilon & -2k & 0 & 0 & \varepsilon \end{pmatrix},$$

and $\vec{f}$ is a five-component object containing all the terms in the system that are not already included in the right-hand side.

By taking ε small (less than the smaller of 1 and any possible value of σ), we can ensure that $\vec{f}$ is continuous in t and analytic in all the remaining variables. Since the eigenvalues of A are ε and 0, of multiplicities four and one, respectively, we conclude that the boundedness condition of Theorem 1 holds. Explicitly, we have $P^{-1}AP=A_0$, hence $\sigma^A=P\sigma^{A_0}P^{-1}$, where

$$A_0=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & \varepsilon & 0 & 0 & 1 \\ 0 & 0 & \varepsilon & 0 & 0 \\ 0 & 0 & 0 & \varepsilon & 2k \\ 0 & 0 & 0 & 0 & \varepsilon \end{pmatrix} \quad \text{and} \quad P=\begin{pmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & -\varepsilon & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{pmatrix},$$

so that

$$\sigma^{A_0}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & \sigma^{\varepsilon} & 0 & 0 & \sigma^{\varepsilon}\ln\sigma \\ 0 & 0 & \sigma^{\varepsilon} & 0 & 0 \\ 0 & 0 & 0 & \sigma^{\varepsilon} & 2k\sigma^{\varepsilon}\ln\sigma \\ 0 & 0 & 0 & 0 & \sigma^{\varepsilon} \end{pmatrix}.$$

We conclude from Theorem 1 that there is a unique solution of the Fuchsian system (13) which vanishes as t tends to zero, and which is analytic in θ and continuous in time. We note in particular that if we construct u, ν, and α from (11a)–(11c) with $v=v_1$, $\mu=v_5$, and $\beta=v_4$, then (u,ν,α) is a solution of equations (6a)–(6c). To verify this, we note that equations (13a)–(13c) imply that

$$D(v_3-t^{\varepsilon}v_{1,\theta})=0,$$

so that any solution which tends to zero with t has also the property that $v_2=tv_{1,t}$ and $v_3=t^{\varepsilon}v_{1,\theta}$.

We now wish to show that, by imposing a constraint on the singularity data (k,u_0,α_0,ν_0), we can guarantee that the solution (u,ν,α) of (6a)–(6c) obtained by solving the Fuchsian system (13) will satisfy the constraint (6d) as well, in order to obtain genuine solutions of Einstein's vacuum equations. We achieve this using (8), which in turn has been derived using only (6a)–(6c).

First of all, since $\vec{f}$ is bounded, we know that $(D+A)\vec{v}$ is actually $O(t^{\varepsilon})$, which implies in particular that α and $D\alpha$ are of order 1 and t^{ε}, respectively. In particular, $D\alpha/\alpha = t\alpha_t/\alpha = O(t^{\varepsilon})$. This means, using (8), that

$$\frac{\partial_t N}{N} = \frac{\alpha_t}{2\alpha} = O(t^{\varepsilon-1}),$$

which is integrable up to $t=0$. [One could also have estimated $D\alpha/\alpha$ directly from (12).] Letting $z(t,\theta)$ be the integral of this function from 0 to t, we find that

$$N(t,\theta) \propto \exp\ z(t,\theta).$$

Thus, if we can choose the data so that $N \to 0$ as $t \to 0$ for fixed θ, we will know that N is, in fact, identically zero, and therefore that the constraint is satisfied. Now

$$N = \nu_\theta - 2u_\theta Du + \frac{\alpha_\theta}{2\alpha}$$

$$= \nu_{0,\theta} - 2ku_{0,\theta} + \frac{\alpha_{0\theta}}{2\alpha_0} + o(1),$$

where $o(1)$ is some expression which tends to zero with t. We conclude that the constraint is satisfied if and only if the singularity data satisfy

$$\nu_{0,\theta} - 2ku_{0,\theta} + \frac{\alpha_{0\theta}}{2\alpha_0} = 0. \tag{14}$$

Note also that all the considerations in this paper are, in fact, local in θ, and therefore allow in principle for other spatial topologies.

To summarize, we have proved the following result:

Theorem 2: *For any choice of the singularity data $k(\theta)$, $u_0(\theta)$, $\nu_0(\theta)$, and $\alpha_0(\theta)$, subject to condition (14), the* $\mathbf{T}^2$*-symmetric vacuum Einstein equations have a solution of the form (11) where β, v, and ν are bounded near, $t=0$. It is unique once the twist constant κ has been fixed, except for the freedom in the functions G_1, G_2, M_1, and M_2. Each of these solutions generates space–times with AVD asymptotics.*

V. CONCLUDING REMARKS

We have therefore obtained a family of singular $\mathbf{T}^2$-symmetric space–times with precise asymptotics at the singularity, which is of AVD type, and which depends on the maximum number of singularity data, that is, as many singularity data as there are Cauchy data for solutions away from the singularity. Fuchsian techniques therefore apply even if the constraints do not decouple from the ''evolution'' equations as in the Gowdy case.

We may also note the following.

First, it is likely that, as in the case of scalar fields, these singular solutions are stable in a Sobolev topology, by application of the Nash–Moser theorem, in which case these solutions form an open set in the space of all solutions. This means that this type of AVD behavior is *stable* in this class, and is therefore not a special feature of some closed-form solution.

Second, the polarized U(1)-symmetric solutions are believed to be AVD as well,[13] and work is underway to address this class by Fuchsian methods.

Third, it appears that the general (nonpolarized) $\mathbf{T}^2$-symmetric space–times may show Mixmaster behavior.[24] Numerical and analytical work to explore this possibility is being carried out.

APPENDIX: NONANALYTIC INITIAL-VALUE PROBLEM

In this appendix, we consider the nonanalytic version of the initial-value problem for $\mathbf{T}^2$-symmetric space–times. The strategy is as follows: We first promote α_θ to a new field variable $\zeta := \alpha_\theta$, and produce an evolution equation for ζ by differentiating (6b) with respect to θ. We then use (6b) to eliminate $D\alpha$ from (6a), and equation (6d) to express $\partial_\theta \nu$ in terms of the other field variables. This gives us a symmetric-hyperbolic system (A1) for $(z_0, z_1, z_2, \alpha, \zeta, \nu)$. Standard theorems then ensure that (A1) admits a unique solution, defined in a small time interval, for nonanalytic, but sufficiently smooth, initial data. We then show that the constraints $\zeta = \alpha_\theta$ and $N=0$ do propagate, by a variant of the argument used for the propagation of the constraint $N=0$. This will establish that we do obtain solutions to (6a)–(6d) with nonanalytic initial data.

We proceed with the details of this argument. The symmetric–hyperbolic system is

$$\partial_t z_0 = z_1, \tag{A1a}$$

$$\partial_t z_1 = \alpha \partial_\theta z_2 - \frac{z_1}{t} - \frac{m}{2t^3} z_1 e^{2\nu} + \frac{1}{2} z_2 \zeta, \tag{A1b}$$

$$\alpha \partial_t z_2 = \alpha \partial_\theta z_1, \tag{A1c}$$

$$\partial_t \alpha = -\frac{\alpha^2}{t^3} m e^{2\nu}, \tag{A1d}$$

$$\partial_t \nu = t z_1^2 + t \alpha z_2^2 + \frac{\alpha}{4t^3} m e^{2\nu}, \tag{A1e}$$

$$\partial_t \zeta = -\frac{2m\alpha}{t^3} e^{2\nu} \left[\zeta + \alpha \left(2t z_1 z_2 - \frac{\zeta}{2\alpha} \right) \right]. \tag{A1f}$$

One verifies by inspection that this system is symmetric–hyperbolic, so that if we prescribe sufficiently smooth initial data $\{u, u_t, \alpha, \zeta, \nu\}$ for $t = t_0$, we obtain a unique solution. The first and third equations ensure respectively that $z_1 = \partial_t z_0$ and $\partial_t (z_2 - \partial_\theta z_0) = 0$; we may thus set $z_0 = u$, $z_1 = u_t$ and $z_2 = u_\theta$. Equations (6a)–(6c) therefore hold, with α_θ replaced by ζ in (6a).

Now, let us set

$$R := \zeta - \alpha_\theta \quad \text{and} \quad N' := \nu_\theta - 2u_\theta D u + \frac{\zeta}{2\alpha}. \tag{A2}$$

We proceed to derive a first-order system of ODEs for R and N'. For the rest of this section, we write N for N', for convenience.

First of all, using Eqs. (A1d) and (A1f),

$$
\begin{aligned}
DR &= D(\zeta - \alpha_\theta) \\
&= -\frac{2m\alpha}{t^2} e^{2\nu}\left[\zeta + \alpha\left(2u_\theta Du - \frac{\zeta}{2\alpha}\right)\right] - \partial_\theta\left(-\frac{\alpha^2}{t^2} m e^{2\nu}\right) \\
&= -\frac{2m\alpha}{t^2} e^{2\nu}[R - \alpha N] \\
&= 2\frac{D\alpha}{\alpha}[R - \alpha N]. \qquad \text{(A3)}
\end{aligned}
$$

Using the expression for N from (A2), taking the relation $\zeta = \alpha_\theta + R$ into account, we have

$$DN = (D\nu)_\theta - 2DuDu_\theta - 2u_\theta D^2 u + D\left(\frac{\alpha_\theta + R}{2\alpha}\right),$$

or

$$DN - D\left(\frac{R}{2\alpha}\right) = (D\nu)_\theta - 2DuDu_\theta - 2u_\theta D^2 u + D\left(\frac{\alpha_\theta}{2\alpha}\right).$$

Then, from (A1a), (A1b), and (A1d) and the definition of R, we find

$$
\begin{aligned}
DN - D\left(\frac{R}{2\alpha}\right) &= \partial_\theta\left(-\frac{D\alpha}{4\alpha}\right) - \frac{D\alpha}{\alpha} u_\theta Du - t^2 u_\theta^2 R + D\left(\frac{\alpha_\theta}{2\alpha}\right) \\
&= -t^2 u_\theta^2 R + \partial_\theta\left(\frac{D\alpha}{4\alpha}\right) - \frac{D\alpha}{2\alpha}(2u_\theta Du).
\end{aligned}
$$

Since, from (6b), one has

$$\left(\frac{D\alpha}{4\alpha}\right)_\theta = \frac{D\alpha}{2\alpha}\left(\nu_\theta + \frac{\alpha_\theta}{2\alpha}\right),$$

it follows that

$$DN - D\left(\frac{R}{2\alpha}\right) + t^2 u_\theta^2 R = \frac{D\alpha}{2\alpha}\left(N - \frac{R}{2\alpha}\right). \qquad \text{(A4)}$$

Thus, combining (A3) and (A4), we have

$$
\begin{aligned}
DN &= N\frac{D\alpha}{2\alpha} + R\left(D\left(\frac{1}{2\alpha}\right) - t^2 u_\theta^2\right) - \frac{RD\alpha}{4\alpha^2} + \frac{D\alpha}{\alpha^2}[R - \alpha N] \\
&= R\left[\frac{D\alpha}{\alpha^2}\left(-\frac{1}{2} - \frac{1}{4} + 1\right) - t^2 u_\theta^2\right] - N\frac{D\alpha}{2\alpha} \\
&= R\left[\frac{D\alpha}{4\alpha^2} - t^2 u_\theta^2\right] - N\frac{D\alpha}{2\alpha}. \qquad \text{(A5)}
\end{aligned}
$$

Equations (A3) and (A5) constitute a linear, homogeneous system of ODEs for R and N. Therefore, if the initial data are such that these quantities are zero for $t = t_0$, they remain so for all time, QED.

(Received 14 August 1998; accepted for publication 15 September 1998)

The automorphism group and frame commutator relations in the orthonormal frame approach to Bianchi cosmology are used to construct an explicit coordinate representation of the orthonormal frame itself (and hence of the spacetime metric) which depends algebraically on the connection coefficients. This is not possible in general inhomogeneous models where differential equations must instead be solved. The shift vector field required for this procedure is intimately related to the true Smarr–York minimal strain and minimal distortion shifts. © *1999 American Institute of Physics.* [S0022-2488(99)01701-6]

I. INTRODUCTION

When studying spatially homogeneous (SH) Bianchi cosmology, two complementary approaches have been taken, one using orthonormal frames in which the metric components are fixed and the dynamics resides in the commutation functions (see references in Ref. 1) and the other using computational frames[2] in which the commutation functions are fixed and the dynamics resides in the metric components (see references in Ref. 3). The relationship between these two has been clouded by the fact that one usually uses a synchronous frame in the computational frame approach to Bianchi cosmology. By instead choosing a computational frame based on a suitable shift vector field intimately related to the true Smarr–York minimal strain and minimal distortion shifts,[4,5] one can construct an explicit coordinate representation of all the orthonormal frame vectors (and therefore a coordinate representation of the spacetime metric) using an algebraic procedure involving the commutator functions and commutator relations of the orthonormal frame approach.

For general inhomogeneous models, such an algebraic procedure is not possible and one is instead forced to solve differential equations resulting from the commutator relations in order to obtain a coordinate representation of the orthonormal frame. The closest one might come to the present SH construction in more general inhomogeneous cases would be to use a computational frame with a minimal strain or minimal distortion shift vector field. It is remarkable that the usual orthonormal frame approach to Bianchi cosmology is so closely connected to these general ideas about fixing the coordinate gauge freedom in evolving a spacetime from initial data.

Bianchi cosmology has long served as a testing ground for exploring features of general relativity both in generalizing aspects of these highly symmetric models to the broader context of more general inhomogeneous spacetimes and in specializing results from the general theory to explore them in SH models which facilitate computations. While one may not need the metric explicitly to answer questions about Bianchi models alone, an explicit representation of the metric is essential for answering many interesting questions about general inhomogeneous spacetimes.

TABLE I. Canonical structure constants for each Bianchi symmetry type. Note the special case Bianchi type III=VI_{-1} with $\hat{a}=1$.

	Class A						Class B			
Type	IX	VIII	VII_0	VI_0	II	I	VII_h	VI_h	IV	V
$\hat{n}_1$	1	1	1	1	1	0	1	1	1	0
$\hat{n}_2$	1	1	1	-1	0	0	1	-1	0	0
$\hat{n}_3$	1	-1	0	0	0	0	0	0	0	0
$\hat{a}\geqslant 0$	0	0	0	0	0	0	$\hat{a}$	$\hat{a}$	1	1

Thus relating results of Bianchi cosmology to a wider setting requires the construction of the metric.

The outline of this article is as follows. In Sec. II the symmetry group properties of this class of spacetimes are summarized. In Sec. III the essentials of the orthonormal frame approach are reviewed. In Sec. IV the general framework is described for constructing the metric in a computational frame starting from the commutation functions of an orthonormal frame and then a discussion of why it works is given. In Sec. V the metric is explicitly constructed for each Bianchi type. The last section ends with concluding remarks.

II. SYMMETRY PROPERTIES

In the present discussion we consider only those symmetry types for which the full spacetime symmetry group admits a simply transitive 3-dimensional subgroup G acting on the spatially homogeneous (SH) hypersurfaces, i.e., a Bianchi group action. Such spacetimes admit a class of spatial frames $\{\hat{\mathbf{e}}_i\}$ $(i=1,2,3)$ tangent to each hypersurface which are not only invariant under the action of the group but which have structure or commutator functions $\hat{C}^k_{ij}$ which are constants throughout the spacetime. These invariant vector fields thus themselves generate a transformation group which turns out to be isomorphic to the original Bianchi group. The constant structure functions are defined by

$$[\hat{\mathbf{e}}_i,\hat{\mathbf{e}}_j]=\hat{C}^k_{ij}\hat{\mathbf{e}}_k, \tag{2.1}$$

and may be represented in the form (see e.g., Ref. 6)

$$\hat{C}^k_{ij}=2\hat{a}_{[i}\delta^k_{j]}+\epsilon_{ijl}\hat{n}^{lk}, \tag{2.2}$$

where the Jacobi identities $\hat{C}^l{}_{m[i}\hat{C}^m{}_{jk]}=0$ require

$$0=\hat{n}^{ij}\hat{a}_j. \tag{2.3}$$

A useful parameter h may be defined by

$$\hat{a}_i\hat{a}_j=\frac{1}{2}h\epsilon_{ikl}\epsilon_{jmn}\hat{n}^{km}\hat{n}^{ln}. \tag{2.4}$$

The Bianchi symmetry types may be divided into 2 symmetry classes, A and B, depending on whether $\hat{a}_i$ is zero or not.

It is often convenient to choose a gauge in which the structure constants $\hat{n}_{ij}$ are diagonal, and the covector $\hat{a}_i$ is aligned with one of the basis directions, here chosen to be the third one,

$$\hat{n}_{ij}=\mathrm{diag}(\hat{n}_1,\hat{n}_2,\hat{n}_3), \quad \hat{a}_i=(0,0,\hat{a}). \tag{2.5}$$

This ''diagonal-alignment'' gauge will be assumed here. Canonical choices of the structure constants for each Bianchi type are given in this form in Table I.[6] The Bianchi symmetry group action

TABLE II. Dimensions of the adjoint and automorphism groups for each Bianchi symmetry type.

Type	VIII, IX	IV, VI, VII	III	V	II	I
dim(Ad)	3	3	2	3	2	0
dim(Aut)	3	4	4	6	6	9

is assumed to be a global action by a simply connected group. (The discussion of local symmetry actions which are not global is considerably more complicated.)

The automorphism matrix group of the Lie algebra with structure constants $\hat{C}^i{}_{jk}$ is the subgroup of linear transformations of its basis $\{\hat{\mathbf{e}}_i\}$ which leaves those constants invariant,

$$B^k{}_l \hat{C}^l{}_{mn} B^{-1m}{}_i B^{-1n}{}_j = \hat{C}^k{}_{ij} . \tag{2.6}$$

The Lie algebra of this matrix group consists of the matrix derivations of the original Lie algebra,

$$F^k{}_l \hat{C}^l{}_{ij} = \hat{C}^k{}_{lj} F^l{}_i + \hat{C}^k{}_{il} F^l{}_j . \tag{2.7}$$

The matrix adjoint group is the subgroup of inner automorphisms generated by the matrix Lie algebra whose basis consists of a linearly independent subset of the adjoint matrices $\hat{k}_i$ defined by $[\hat{k}_i]^j{}_k = \hat{C}^j{}_{ik}$ representing the inner derivations (Lie bracketing by elements of the original Lie algebra),

$$\pounds_{\hat{\mathbf{e}}_i} \hat{\mathbf{e}}_j = [\hat{k}_i]^l{}_j \hat{\mathbf{e}}_l . \tag{2.8}$$

These matrices satisfy the derivation property (2.7) due to the Jacobi identities. Automorphisms which are not inner are called outer automorphisms. The dimensions of the adjoint and automorphism groups are given in Table II. Their differences represent the number of independent outer automorphism generators which exist in any basis of the full matrix automorphism Lie algebra which includes a basis of the matrix adjoint Lie algebra. The automorphism structure summarized in Table II is important for the algebraic procedure for constructing the metric from the commutator functions.

III. THE ORTHONORMAL FRAME APPROACH

Let $\{\mathbf{e}_a\}$ be a SH orthonormal frame $(a=0,1,2,3)$ with dual frame $\{\boldsymbol{\omega}^a\}$ (satisfying $\langle \boldsymbol{\omega}^a, \mathbf{e}_b \rangle = \delta^a{}_b$) so that the metric takes the form

$$\mathbf{g} = \eta_{ab} \boldsymbol{\omega}^a \boldsymbol{\omega}^b , \tag{3.1}$$

where $(\eta_{ab}) = \mathrm{diag}(-1,1,1,1)$. Choose $\mathbf{e}_0 = \mathbf{n} = n^a \mathbf{e}_a$ to be the unit normal vector field of the SH hypersurfaces. The remaining frame vector fields are then tangent to the SH hypersurfaces and so are related to any set of invariant spatial frame vectors $\hat{\mathbf{e}}_i$ by a linear transformation which is constant on any given such hypersurface.

The full set of commutator functions $\gamma^a{}_{bc}$ are defined by

$$[\mathbf{e}_a , \mathbf{e}_b] = \gamma^c{}_{ab} \mathbf{e}_c , \quad \mathbf{d}\boldsymbol{\omega}^a = -\tfrac{1}{2} \gamma^a{}_{bc} \boldsymbol{\omega}^b \wedge \boldsymbol{\omega}^c . \tag{3.2}$$

As a consequence of the symmetry and hypersurface-forming condition, the normal $\mathbf{n}$ has zero acceleration and rotation. Thus, making a $3+1$ decomposition of these functions leads to[1]

$$\gamma^\alpha{}_{0\beta} = -\theta^\alpha_\beta + \epsilon^\alpha{}_{\beta\gamma} \Omega^\gamma , \qquad \gamma^\gamma{}_{\alpha\beta} = 2 a_{[\alpha} \delta^\gamma{}_{\beta]} + \epsilon_{\alpha\beta\delta} n^{\delta\gamma} , \tag{3.3}$$

where $\epsilon^{\alpha\beta\gamma}$ is the permutation symbol satisfying $\epsilon^{123}=1$ and $\alpha=1,2,3$. The quantity Ω^{α} can be interpreted as the local angular velocity of a spatial frame $\{\mathbf{e}_\alpha\}$ with respect to a second spatial frame $\{\overline{\mathbf{e}}_\alpha\}$ which is Fermi-propagated along $\mathbf{e}_0=\mathbf{n}$. The quantity θ_{ab} is the expansion tensor, which is often represented in terms of the trace-free shear tensor σ_{ab}, the expansion scalar Θ, and the spatial metric $h_{ab}=g_{ab}+n_a n_b$ as $\theta_{ab}=\sigma_{ab}+\frac{1}{3}\Theta h_{ab}$. The purely spatial components $\gamma^{\alpha}{}_{\beta\gamma}$ have been decomposed in the same way as $\hat{C}^{k}{}_{ij}$ and are assumed to have the same diagonal-alignment gauge form as the canonical structure constants for each Bianchi type, with the correspondingly defined structure functions (n_1,n_2,n_3,a) having the same signs (when nonzero) as the corresponding structure constants $(\hat{n}_1,\hat{n}_2,\hat{n}_3,\hat{a})$. The symbol n_α will be used only to designate these structure functions in the remainder of the paper, and not the covariant spatial components of the normal vector field, which are no longer needed.

The $3+1$ decomposition of the Jacobi identities,

$$[[\mathbf{e}_a,\mathbf{e}_b],\mathbf{e}_c]+[[\mathbf{e}_b,\mathbf{e}_c],\mathbf{e}_a]+[[\mathbf{e}_c,\mathbf{e}_a],\mathbf{e}_b]=0 \Leftrightarrow \mathbf{e}_{[a}(\gamma^{d}{}_{bc]})+\gamma^{e}{}_{[ab}\gamma^{d}{}_{c]e}=0, \tag{3.4}$$

leads to

$$\mathbf{e}_0(a^\alpha)=-a_\beta\theta^{\alpha\beta}-\epsilon^{\alpha\beta\gamma}a_\beta\Omega_\gamma, \tag{3.5}$$

$$\mathbf{e}_0(n^{\alpha\beta})=-\Theta n^{\alpha\beta}+2\theta^{(\alpha}{}_{\gamma}n^{\beta)\gamma}-2\epsilon^{\gamma\delta(\alpha}n^{\beta)}{}_{\gamma}\Omega_\delta, \tag{3.6}$$

$$0=a_\beta n^{\alpha\beta}. \tag{3.7}$$

The diagonal-alignment conditions imposed on the structure functions cause certain components of the first two derivative equations to have an identically zero left hand side, leading to certain relationships among components of Ω^{α} and $\theta_{\alpha\beta}$ when the right hand side is not also identically zero. Two relationships follow from the first two components of Eq. (3.5) when $a\neq 0$ and three from the off-diagonal components of (3.6), all of which must be identically zero. These restrictions are

$$a(\theta_{13}-\Omega_2)=0=a(\theta_{23}+\Omega_1), \tag{3.8}$$

and

$$(n_1+n_2)\theta_{12}+(n_1-n_2)\Omega_3=0, \tag{3.9}$$

and its two cyclic permutations.

IV. CONSTRUCTION OF THE METRIC: GENERAL FRAMEWORK

Once the commutation functions have been obtained as explicit functions of some time function t (for example, by solving the constraint and evolution equations for some metric theory with a particular choice of the lapse function N), it is possible to construct the spacetime metric explicitly in terms of local coordinates $\{t,x^i\}$ $(i=1,2,3)$ adapted to the SH hypersurfaces. This is accomplished without solving any additional differential equations, using the particular structure that is associated with the SH symmetry.

Here the orthonormal spatial frame $\{\mathbf{e}_\alpha\}$ will be expressed first in terms of an invariant spatial frame $\{\hat{\mathbf{e}}_i\}$ with canonical structure constant values for its structure functions and then in terms of local coordinates. The full orthonormal frame is related to the computational frame $\{\boldsymbol{\partial}_t,\hat{\mathbf{e}}_i\}$ by

$$\mathbf{e}_0=N(t)^{-1}(\boldsymbol{\partial}_t-\hat{N}^i(t,\mathbf{x})\hat{\mathbf{e}}_i), \quad \mathbf{e}_\alpha=\hat{e}(t)_\alpha{}^i\hat{\mathbf{e}}_i, \tag{4.1}$$

where N is the lapse function and $\vec{\mathbf{N}}=\hat{N}^i\hat{\mathbf{e}}_i$ is the shift vector field. The corresponding dual 1-forms are given by

$$\boldsymbol{\omega}^0 = N(t)\mathbf{d}t, \quad \boldsymbol{\omega}^\alpha = \hat{e}^\alpha{}_i[\hat{\boldsymbol{\omega}}^i + \hat{N}(t,\mathbf{x})^i\mathbf{d}t], \tag{4.2}$$

where $\hat{D} = (\hat{e}^\alpha{}_i)$ is the inverse matrix of $(\hat{e}_\alpha{}^j)$ (i.e., $\hat{e}^\alpha{}_i \hat{e}_\alpha{}^j = \delta^j{}_i$).

This leads to the following spacetime metric:

$$\mathbf{g} = -N(t)^2\ \mathbf{d}t^2 + \hat{g}_{ij}(t)[\hat{\boldsymbol{\omega}}^i + \hat{N}^i(t,\mathbf{x})\mathbf{d}t][\hat{\boldsymbol{\omega}}^j + \hat{N}^j(t,\mathbf{x})\mathbf{d}t], \tag{4.3}$$

where the SH components of the spatial metric tensor in the spatial frame $\{\hat{\mathbf{e}}_i\}$ are given by

$$\hat{g}_{ij} = \delta_{\alpha\beta}\hat{e}^\alpha{}_i \hat{e}^\beta{}_j\,, \tag{4.4}$$

or simply $(\hat{g}_{ij}) = \hat{D}^T\hat{D}$ in matrix notation.

The computational frame $\{\boldsymbol{\partial}_t, \hat{\mathbf{e}}_i\}$ is characterized by the Lie dragging condition $\pounds_{\boldsymbol{\partial}_t}\hat{\mathbf{e}}_i = 0$ which implies the time-independent local coordinate expression $\hat{\mathbf{e}}_i = \hat{e}_i{}^j(x^k)\boldsymbol{\partial}_j$ for the invariant spatial frame, whose constant commutator functions $\hat{C}^k{}_{ij}$ are assumed to have their canonical values given in Table I. Explicit coordinate expressions for $\hat{e}_i{}^j(x^k)$ follow from the representation of the left invariant vector fields in canonical coordinates of the second kind in Refs. 7 and 8. These spatial coordinates will be assumed throughout this article. Similarly, explicit coordinate expressions for a basis of the homogeneity Killing vector fields follow from the representation of the right invariant vector fields in these coordinates.[7,8]

The lapse function is SH, but the associated shift vector field is not necessarily SH. In fact exploiting the action of the outer automorphisms requires an inhomogeneous shift. However, the shift Lie derivative of the spatial frame $\hat{\mathbf{e}}_i$ and its dual must be SH,

$$\pounds_{\vec{\mathbf{N}}}\hat{\mathbf{e}}_i = -\hat{A}(t)^j{}_i\hat{\mathbf{e}}_j\,, \quad \pounds_{\vec{\mathbf{N}}}\hat{\boldsymbol{\omega}}^j = \hat{A}(t)^j{}_i\hat{\boldsymbol{\omega}}^i, \tag{4.5}$$

in order that the Lie derivative of the induced spatial metric be SH for any component matrix $(\hat{g}_{ij})$,

$$\pounds_{\vec{\mathbf{N}}}\hat{g}_{ij} = 2\hat{g}_{k(i}\hat{A}^k{}_{j)}\,. \tag{4.6}$$

This in turn guarantees that the extrinsic curvature (sign-reversed expansion tensor) be SH under the same condition,

$$\hat{K}_{ij} = \frac{1}{2}N^{-1}[-\dot{\hat{g}}_{ij} + \pounds_{\vec{\mathbf{N}}}\hat{g}_{ij}] = -\hat{e}_i{}^\alpha e_j{}^\beta\theta_{\alpha\beta}\,. \tag{4.7}$$

Thus, for a fixed value of t, this restricts the shift to the finite-dimensional space of derivations of the Lie algebra of invariant spatial vector fields.[7] This derivation Lie algebra (containing the homogeneity Killing vector fields which correspond to the trivial zero derivation) generates an action of the automorphism-translation group of the Bianchi homogeneity group G on each SH hypersurface which induces the action of the matrix automorphism group on the invariant spatial vector fields under Lie dragging. Given a basis for the matrix derivation Lie algebra $\{\kappa_P\}$ (so that P is an index taking values from 1 to the dimension of the automorphism group given in Table II), one can construct a corresponding basis $\{\boldsymbol{\xi}_P\}$ for the Lie algebra of derivation vector fields modulo Killing vector fields by the relation

$$\pounds_{\boldsymbol{\xi}_P}\hat{\mathbf{e}}_i = [\kappa_P]^j{}_i\hat{\mathbf{e}}_j\,. \tag{4.8}$$

One can then express the shift and its corresponding derivation matrix as time-dependent linear combinations of these respective bases with SH coefficients,

$$-\hat{A}(t) = M^P(t)\kappa_P \rightarrow \vec{\mathbf{N}} = M^P(t)\boldsymbol{\xi}_P\,. \tag{4.9}$$

This relationship may then be used to determine the shift vector field from the matrix $\hat{A}$. The basis vector fields $\boldsymbol{\xi}_P$ can be taken from a subset of invariant spatial frame vector fields $\hat{\mathbf{e}}_i$ which generate the inner automorphisms, plus some independent outer automorphism generators. Coordinate expressions for the additional independent outer automorphism vector field generators for each symmetry type, most of which may be found in Appendix 3 of Ref. 9, will be given below, while expressions for the invariant spatial vector fields themselves have already been discussed. All of these follow from known results for 3-dimensional Lie groups.

In the diagonal-alignment gauge the action of the matrix automorphism group on the spatial metric induced by the action of Lie dragging by the automorphism-translations,

$$\hat{g}_{ij} \rightarrow B^m{}_i B^n{}_j \hat{g}_{mn}, \tag{4.10}$$

has orbits which may be parametrized by a submanifold of the space of diagonal metric matrices (not unique when diagonal automorphism matrices exist). It is exactly this fact which allows one to assume a shift for which the spatial metric component matrix is confined to such a diagonal submanifold, i.e., making the matrix $\hat{D}$ diagonal. This shift generates a time-dependent matrix automorphism which transforms the orthogonal (zero shift) gauge metric matrix into the diagonal matrix $(\hat{g}_{ij})$.

One may evaluate the relationship between the structure functions of the original orthonormal frame and the computational frame by inserting the expressions (4.1) into Eqs. (3.2) and (3.3) leading to

$$\gamma^\alpha{}_{0\beta} = N^{-1}[-\dot{\hat{e}}^\alpha{}_i \hat{e}_\beta{}^i + \hat{e}^\alpha{}_i \hat{A}^i{}_j \hat{e}_\beta{}^i] = -\theta^\alpha_\beta + \epsilon^\alpha{}_{\beta\gamma}\Omega^\gamma, \tag{4.11}$$

$$\gamma^\alpha{}_{\beta\gamma} = \hat{e}^\alpha{}_i \hat{C}^i{}_{jk} \hat{e}_\beta{}^j \hat{e}_\gamma{}^k. \tag{4.12}$$

The first of these in matrix notation takes the form

$$(\gamma^\alpha{}_{0\beta}) = N^{-1}[-\dot{\hat{D}}\hat{D}^{-1} + \hat{D}\hat{A}\hat{D}^{-1}] = (-\theta^\alpha{}_\beta + \epsilon^\alpha{}_{\beta gg}\Omega^\gamma). \tag{4.13}$$

The shift may be chosen so that the matrix $\hat{D}$ is diagonal and positive-definite,

$$\hat{D} = (\hat{e}^\alpha{}_i) = \mathrm{diag}(e^{\beta^1}, e^{\beta^2}, e^{\beta^3}), \tag{4.14}$$

as will always be assumed here, with the number of independent components equal to three minus the number of independent diagonal automorphisms. This matrix represents the time-dependent rescaling of the orthogonal spatial frame $\{\hat{\mathbf{e}}_i\}$ which normalizes it to the orthonormal spatial frame $\{\mathbf{e}_\alpha\}$ and transforms the nonzero structure constants of the first frame into the corresponding nonzero time-dependent structure functions of the second frame by Eq. (4.12),

$$n_1 = e^{\beta^1 - \beta^2 - \beta^3}\hat{n}_1, \quad n_2 = e^{\beta^2 - \beta^3 - \beta^1}\hat{n}_2, \quad n_3 = e^{\beta^3 - \beta^1 - \beta^2}\hat{n}_3, \tag{4.15}$$

$$a = e^{-\beta^3}\hat{a}. \tag{4.16}$$

When $\hat{D}$ is diagonal, the (index-lowered) symmetric part of Eq. (4.13) is equivalent to the orthonormal components of the mixed form of Eq. (4.7), evaluating the extrinsic curvature or sign-reversed expansion tensor,

$$N^{-1}[-\dot{\hat{D}}\hat{D}^{-1} + \tfrac{1}{2}(\hat{D}\hat{A}\hat{D}^{-1}) + \tfrac{1}{2}(\hat{D}\hat{A}\hat{D}^{-1})^T] = \hat{D}(\hat{K}^i{}_j)\hat{D}^{-1}, \tag{4.17}$$

while the antisymmetric part of Eq. (4.13) relates the shift Lie derivative term involving the matrix $\hat{A}$ to the local angular velocity Ω^{α} of the spatial orthonormal frame [or to the off-diagonal components of the expansion tensor, due to Jacobi identities of the form (3.8) and (3.9)]. The particular way in which this diagonal matrix $\hat{D}$ is fixed when some freedom remains allows one to specialize the shift vector field either to a true minimal strain or minimal distortion shift. These shifts minimize the contribution of the diagonal time derivative term,

$$-\dot{\hat{D}}\hat{D}^{-1} = -(\ln \hat{D})^{\cdot} = \text{diag}(\dot{\beta}^1, \dot{\beta}^2, \dot{\beta}^3), \tag{4.18}$$

to the formula (4.17) for the extrinsic curvature tensor in two different ways.

A true minimal strain shift is one for which the diagonal time-derivative term $-\dot{\hat{D}}\hat{D}^{-1}$ in Eq. (4.17) is orthogonal to the remaining two $\hat{A}$ terms in that expression under the trace inner product for second rank tensors, while the true minimal distortion shift is the one for which the trace-free part of $-\dot{\hat{D}}\hat{D}^{-1}$ is instead orthogonal to the trace-free part of the remaining two $\hat{A}$ terms in that expression.[5] The assumption that $\hat{D}$ is diagonal is consistent with the generic off-diagonal part of the second term in Eq. (4.13) for all Bianchi types in the diagonal-alignment gauge, leaving only the diagonal orthogonality conditions to be analyzed. By representing the logarithm of $\hat{D}$ as an arbitrary linear combination of a set of diagonal matrices which are each orthogonal to the matrix generators of the matrix automorphism group, one obtains a true minimal strain shift vector field. By representing it instead so that the trace-free parts are orthogonal, one obtains a true minimal distortion shift vector field. Since only the true minimal strain and distortion shifts are relevant to the SH case, the modifier ''true'' will be implicitly understood below.

A. The construction procedure

The procedure for constructing a coordinate representation of the metric consists of the following steps.

(1) Represent the diagonal matrix $\hat{D}$ in terms of a minimal set of variables which parametrize the quotient space of the diagonal metric matrices under the action of the diagonal automorphisms. When 1 or 2 independent diagonal automorphism generators exist, there is no natural choice for these variables, and a parameter ζ describes the most useful variations, allowing one to specialize to a minimal strain or minimal distortion shift if desired. This is done by choosing to parametrize $\ln \hat{D}$ or its trace-free part, respectively, so that it is always orthogonal to the diagonal matrix automorphism generators.

(2) Express the minimal diagonal variables in terms of the spatial commutation functions using Eqs. (4.15) and (4.16).

(3) Construct the diagonal (κ_D) and off-diagonal (κ_O) matrix automorphism generators, so that the matrix $-\hat{A}$ can be expressed as a linear combination of them, $-\hat{A} = M^D \kappa_D + M^O \kappa_O$.

(4) Use the diagonal components of Eq. (4.13) to express the time derivatives of the minimal $\hat{D}$ variables as functions of the diagonal components of $\theta_{\alpha\beta}$ and then use these results in the solution of the same equation for the automorphism coefficients (M^D, M^O) to express the latter entirely in terms of the commutation functions. Note that some of these may be expressed in several equivalent ways due to the Jacobi identities (3.8) and (3.9).

(5) Give coordinate expressions for the basis $\{\boldsymbol{\xi}_P\}$ of the automorphism vector fields (modulo Killing vector fields). $\{\hat{\mathbf{e}}_i\}$ provide a basis of the inner automorphism generators corresponding to the adjoint matrices $\{\hat{k}_i\}$ so one only needs coordinate expressions for the remaining independent outer automorphism vector fields which may be easily found from their matrices using the condition (4.8).

(6) Re-express the automorphism matrices as a linear combination of a linearly independent subset of the adjoint matrices $\hat{k}_i$ and the remaining outer automorphisms, so that one can then re-express the shift vector field $\vec{\mathbf{N}} = M^D \boldsymbol{\xi}_D + M^O \boldsymbol{\xi}_O$ as the same linear combination of the

corresponding invariant vectors $\hat{\mathbf{e}}_i$ and the remaining inhomogeneous outer automorphism generators.

The final result then gives a coordinate representation of the orthonormal frame vectors and of the metric whose time dependence is completely determined by the commutation functions through the diagonal matrix $\hat{D}=(\hat{e}^{\alpha}{}_i)$ and the shift coefficients M^D. The spatial homogeneity determines the remaining spatial coordinate dependence.

B. Why it works

Before carrying out these steps explicitly for the various symmetry types, it is worth explaining why the symmetry allows this procedure to work. As discussed in Ref. 7, the ''minigauge group'' of symmetry compatible diffeomorphisms for Bianchi cosmology is the subgroup of the spacetime diffeomorphism group which maps into itself both the space of SH spatial vector fields and also leaves invariant the normal vector field $\mathbf{n}$ to the SH hypersurfaces. Its corresponding Lie algebra consists of vector fields of the form $\mathbf{X}=X^{\perp}\mathbf{n}+\vec{\mathbf{X}}$, where $X^{\perp}$ is SH and the spatial vector field $\vec{\mathbf{X}}$ belongs to the ''automorphism-translation'' Lie algebra on each SH hypersurface.

Since the Bianchi symmetry group G acts simply transitively on its orbits, each orbit is diffeomorphic to G with its action on the orbit corresponding to its action on itself by left translation, and one may map the semidirect product group of automorphisms and (left or right) translations $\mathrm{Aut}(G)\otimes_s L(G)=\mathrm{Aut}(G)\otimes_s R(G)$ onto each orbit, the generators of which define this ''automorphism-translation'' Lie algebra. It is characterized by the condition that the Lie derivatives of the SH spatial vector fields by its elements are themselves SH. The SH spatial vector fields correspond to the left invariant vector fields on G, while the spacetime Killing vector fields generating the action of G correspond to the right invariant vector fields. A minigauge group diffeomorphism of the spacetime is then a 1-parameter (i.e., time-dependent) family of such automorphism-translations acting on the family of SH orbits.

The subgroup of diffeomorphisms generated by the SH spatial vector fields, when acting on the space of SH spatial vector fields by Lie dragging, induces the action of the linear inner automorphism or adjoint group on that space, while the full symmetry compatible diffeomorphism subgroup of automorphism-translations induces the action of the whole linear automorphism group. When expressed in terms of a given invariant spatial frame, these groups are represented by their corresponding matrix groups, which are entirely determined by the values of the structure constants for that frame.

Associated with every computational frame $\{\boldsymbol{\partial}_t,\hat{\mathbf{e}}_i\}$ is an equivalence class of comoving coordinate systems $\{t,x^i\}$ which establish an identification of the spacetime manifold with the product manifold $R\times G$. The usual synchronous gauge frame has the time lines aligned with the unit normal vector field $\mathbf{n}$, and any other symmetry compatible computational frame with the same structure constants is related to it by the action of a time-dependent automorphism matrix induced by the action of the related shift vector field in Lie dragging the original invariant spatial frame. Conversely time-dependent changes of an invariant spatial frame by a time-dependent automorphism matrix are equivalent to the choice of a new time direction for the computational frame. Thus one can reconstruct the associated shift for a new computational frame from a knowledge of the time-dependent automorphism which relates the spatial frames, modulo spacetime Killing vector fields which commute with the spatial frame vectors and induce no change in them nor in the spatial metric or extrinsic curvature, but only change the direction of the time lines of the associated comoving coordinate system since $\boldsymbol{\partial}_t=N\mathbf{n}+\vec{\mathbf{N}}$.

Given a choice of SH spatial frame $\{\hat{\mathbf{e}}_i\}$, the action of the symmetry compatible diffeomorphism group of automorphism-translations on this frame by Lie dragging induces the action (4.10) of the matrix automorphism group on the space of SH inner product matrices. For the diagonal-alignment gauge choice of the structure constants of such a frame, the orbits of this action can be parametrized by a submanifold of the diagonal inner product matrices (corresponding to orthogonal spatial frames). Thus, starting from a frame with arbitrary inner products in synchronous gauge, one can always produce from it an orthogonal frame with minimal freedom in those diagonal inner product components by using the automorphism matrix freedom to choose an appropriate new time direction via the corresponding generating shift vector field. Conversely, given any orthogonal invariant spatial frame with constant structure functions, one can always pick a vector field to complete it to a spacetime computational frame. This is equivalent to picking the shift which generates the time-dependent automorphism matrix which transforms the synchronous gauge inner product matrix to the one of the orthogonal computational frame. Solving the key equation (4.13) for a symmetry compatible shift vector field under the assumption that $\hat{D}$ is a diagonal matrix parametrizing the orbits of the matrix automorphism group determines this desired shift.

V. CONSTRUCTION OF THE METRIC: SPECIFIC BIANCHI TYPES

The metric is simultaneously constructed for each subset of Bianchi types listed in Table II according to common adjoint and automorphism dimensions, except for Bianchi type III$=$VI$_{-1}$, which is included with the type VI and VII discussion, and type IV which is treated separately. This is an artifact of the choices of automorphism matrix parametrizations made for the convenience of calculation.

A. Bianchi types VIII and IX

In this case there are no diagonal or outer automorphisms, $\hat{a}=0=a$, and $n_1n_2n_3\neq 0 \neq \hat{n}_1\hat{n}_2\hat{n}_3$, and the equations (4.15) uniquely determine the β^α, yielding

$$e^{-2\beta^\alpha}=(n_\beta n_\gamma)/(\hat{n}_\beta\hat{n}_\gamma), \tag{5.1}$$

where (α,β,γ) is a cyclic permutation of (1,2,3). Given the canonical choice of $(\hat{n}_\alpha)$ for each symmetry type, the β^α variables are then expressed in terms of the structure functions n_α.

The relationship (4.13) may then be used to solve for the matrix automorphism generator $\hat{A}^i{}_j$. For these symmetry types, the matrix automorphism generators are off-diagonal, and consist entirely of inner automorphism generators belonging to the adjoint Lie algebra of the original Lie algebra with structure constants $\hat{C}^i{}_{jk}$, a basis for which consists of the three off-diagonal adjoint matrices,

$$[\kappa_i]^j{}_k=[\hat{k}_i]^j{}_k=\hat{C}^j{}_{ik}=\epsilon_{ikl}\hat{n}^{jl}, \tag{5.2}$$

so that

$$-\hat{A}^j{}_k=M^i[\kappa_i]^j{}_k=M^i[\hat{k}_i]^j{}_k\,. \tag{5.3}$$

Since there are no diagonal automorphisms, there is no need to examine the diagonal components of the key equation (4.13). Its off-diagonal components immediately determine the off-diagonal matrix $\hat{A}$ in terms of Ω^α and the off-diagonal components of $\theta^\alpha{}_\beta$, the latter of which are related by the off-diagonal components of the Jacobi identities (3.9). The results are

$$N^{-1}M^3=(-\theta_{12}+\Omega_3)/(n_1e^{\beta^3})=(\theta_{12}+\Omega_3)/(n_2e^{\beta^3}), \tag{5.4}$$

and its two cyclic permutations.

The shift vector field is then SH and given by

$$\vec{\mathbf{N}}=M^i\boldsymbol{\xi}_i=M^i\hat{\mathbf{e}}_i\,, \tag{5.5}$$

which is both a minimal strain and a minimal distortion shift.

B. Bianchi types VI and VII

For this category of symmetry types, both class A and B including type III$=$VI$_{-1}$, the matrix automorphism group has one independent diagonal automorphism generator so that one relationship may be imposed on the β^α, which may be parametrized as follows:

$$\ln \hat{D}=\text{diag}(\beta^1,\beta^2,\beta^3)=\beta^- \ \text{diag}(\sqrt{3},-\sqrt{3},0)+\beta^\times \ \text{diag}(\zeta,\zeta,1)$$
$$=\text{diag}(\zeta\beta^\times+\sqrt{3}\beta^-,\zeta\beta^\times-\sqrt{3}\beta^-,\beta^\times). \tag{5.6}$$

The arbitrary parameter ζ, which can be chosen to have any convenient value, reflects a freedom in the shift vector field. The β variables are determined in terms of the structure functions by the two independent components of the equation (4.15),

$$e^{-2\beta^\times}=(n_1n_2)/(\hat{n}_1\hat{n}_2), \quad e^{4\sqrt{3}\beta^-}=(n_1\hat{n}_2)/(\hat{n}_1n_2). \tag{5.7}$$

Note that in the class B case $a^2=hn^1n^2$ and $\hat{a}^2=h\hat{n}_1\hat{n}_2$ leading to an equivalent expression $e^{-2\beta^\times}=(a/\hat{a})^2$.

A basis of the matrix automorphism Lie algebra consists of the following three off-diagonal matrices whose nonzero entries are given by

$$[\kappa_i]^j{}_k=\epsilon_{ikl}\hat{n}^{jl}, \tag{5.8}$$

for each of the three cyclic permutations of (i,j,k) and the fourth diagonal automorphism generator,

$$\kappa_4=\text{diag}(1,1,0). \tag{5.9}$$

One can then express the matrix $\hat{A}$ as a linear combination of these matrices $\hat{A}=M^i\kappa_i+M^4\kappa_4$. (One could have chosen instead the basis $\{k_1,k_2,k_3-a\kappa_4,\kappa_4\}$ more closely related to the adjoint matrices but then k_1 and k_2 are linearly dependent for type III.)

The key equation (4.13) then becomes

$$N^{-1}[-\dot{\beta}^- \ \text{diag}(\sqrt{3},-\sqrt{3},0)-\dot{\beta}^\times \ \text{diag}(\zeta,\zeta,1)+\hat{D}\hat{A}\hat{D}^{-1}]=(-\theta^\alpha{}_\beta+\epsilon^\alpha{}_{\beta\gamma}\Omega^\gamma), \tag{5.10}$$

where the choice $\zeta=0$ corresponds to a minimal strain shift and the choice $\zeta=1$ corresponds to a minimal distortion shift.

The third diagonal component of this equation yields

$$N^{-1}\dot{\beta}^\times=\theta_{33}. \tag{5.11}$$

Using this in the sum of the first two diagonal components of the same equation leads to

$$N^{-1}M^4=-\tfrac{1}{2}(\theta_{11}+\theta_{22})+\zeta\theta_{33}. \tag{5.12}$$

The off-diagonal components of Eq. (5.10) may be used to determine the coefficients of the three off-diagonal automorphism generators in the same way as in the previous case of types VIII and IX,

$$N^{-1}M^1=(-\theta_{23}+\Omega_1)/(n_2e^{\beta^1}), \quad N^{-1}M^2=(\theta_{13}+\Omega_2)/(n_1e^{\beta^2}), \tag{5.13}$$

$$N^{-1}M^3=(-\theta_{12}+\Omega_3)/(n_1e^{\beta^3})=(\theta_{12}+\Omega_3)/(n_2e^{\beta^3}).$$

The shift vector field itself is then determined once a vector field generator corresponding to the diagonal automorphism is identified. Let $\boldsymbol{\xi}_4$ be the unique time-independent (inhomogeneous) spatial vector field which satisfies

$$\pounds_{\xi_4}\hat{\mathbf{e}}_i=[\mathrm{diag}(1,1,0)]^j{}_i\hat{\mathbf{e}}_j\,. \tag{5.14}$$

It has the expression $\boldsymbol{\xi}_4=-x^1\partial_1-x^2\partial_2$ in coordinates that correspond to canonical coordinates of the second kind.[9]

Except for Bianchi type III (VI_h with $h=-1$) the first three automorphism matrices may be expressed in terms of the adjoint matrices $\hat{k}_i$ and the matrix κ_4 in the following way:

$$\kappa_1=(1+h)^{-1}[\hat{k}_1+(\hat{a}/\hat{n}_1)\hat{k}_2],\quad \kappa_2=(1+h)^{-1}[\hat{k}_2-(\hat{a}/\hat{n}_2)\hat{k}_1],\quad \kappa_3=\hat{k}_3-\hat{a}\kappa_4, \tag{5.15}$$

allowing one to expand $\hat{A}$ in terms of these latter four matrices instead. The desired shift vector field is then the same linear combination of the corresponding vector fields $\hat{\mathbf{e}}_i,\boldsymbol{\xi}_4$,

$$\vec{\mathbf{N}}=(1+h)^{-1}[M^1-(\hat{a}/\hat{n}_2)M^2]\hat{\mathbf{e}}_1+(1+h)^{-1}[M^2+(\hat{a}/\hat{n}_1)M^1]\hat{\mathbf{e}}_2+M^3\hat{\mathbf{e}}_3+(M^4-\hat{a}M^3)\boldsymbol{\xi}_4. \tag{5.16}$$

In the type III case, there is one less independent adjoint matrix and one more independent outer automorphism matrix whose corresponding vector field generator must be evaluated. Introduce the combination

$$\kappa_5=\kappa_1+\kappa_2=\begin{pmatrix}0&0&1\\0&0&1\\0&0&0\end{pmatrix},\quad \boldsymbol{\xi}_5=-x^3(\partial_1+\partial_2)=-x^3(\hat{\mathbf{e}}_1+\hat{\mathbf{e}}_2). \tag{5.17}$$

Then the shift vector field can be chosen to be instead

$$\vec{\mathbf{N}}=\tfrac{1}{2}(M^1+M^2)\hat{\mathbf{e}}_1+\tfrac{1}{2}(M^1-M^2)\boldsymbol{\xi}_5+M^3\hat{\mathbf{e}}_3+(M^4-\hat{a}M^3)\boldsymbol{\xi}_4. \tag{5.18}$$

C. Bianchi type IV

Bianchi type IV is very similar to the previous case, but with slightly different algebra. One can use the same parametrization of $\hat{D}$ in terms of β^- and $\beta^\times$ but their relation to the structure functions following from Eqs. (4.15) and (4.16) is now

$$e^{-\beta^\times}=a/\hat{a},\quad e^{2\sqrt{3}\beta^-}=(n_1\hat{a})/(\hat{n}_1a). \tag{5.19}$$

A basis of the matrix automorphism Lie algebra consists of the following three off-diagonal matrices,

$$\kappa_1=\hat{k}_1,\quad \kappa_2=\hat{k}_2,\quad \kappa_3=\hat{k}_3-\hat{a}\ \mathrm{diag}(1,1,0), \tag{5.20}$$

and the fourth diagonal automorphism generator,

$$\kappa_4 = \mathrm{diag}(1,1,0). \tag{5.21}$$

One can then express the matrix $\hat{A}$ as a linear combination of these matrices $\hat{A} = M^i \kappa_i + M^4 \kappa_4$.

The key equation (5.10) and its immediate consequence (5.11) remain the same, leading to the same expression (5.12) for M^4 and to the same values of ζ for the minimal strain and minimal distortion shifts. The off-diagonal components of this equation lead to the following expressions for the remaining automorphism coefficients:

$$N^{-1}M^1 = -[(\theta_{13} + \Omega_2) - (n_1/a)(-\theta_{23} + \Omega_1)]/(ae^{\beta^1}),$$

$$N^{-1}M^2 = (\theta_{23} - \Omega_1)/(ae^{\beta^2}), \quad N^{-1}M^3 = (\theta_{12} - \Omega_3)/(n_1 e^{\beta^3}). \tag{5.22}$$

Let $\boldsymbol{\xi}_4$ be the same as in the previous case. The first three automorphism matrices may be expressed in terms of the adjoint matrices $\hat{k}_i$ and κ_4,

$$\kappa_1 = -[\hat{k}_2 + (\hat{n}_1/\hat{a})\hat{k}_1]/\hat{a}, \quad \kappa_2 = (-\hat{n}_1/\hat{a})\hat{k}_1, \kappa_3 = k_3 - \hat{a}\kappa_4, \tag{5.23}$$

allowing one to expand $-\hat{A}$ in terms of these latter four matrices instead. Then the desired shift vector field is

$$\vec{\mathbf{N}} = -[(\hat{n}_1 M^1/\hat{a}^2) + (\hat{n}_1 M^2/\hat{a})]\hat{\mathbf{e}}_1 - (M^1/\hat{a})\hat{\mathbf{e}}_2 + M^3 \hat{\mathbf{e}}_3 + (M^4 - \hat{a}M^3)\boldsymbol{\xi}_4, \tag{5.24}$$

with the same remarks about the minimal strain and distortion conditions holding as in the previous case.

D. Bianchi type V

The parametrization of $\hat{D}$ for types VI, VII, IV with $\beta^- = 0$ is appropriate here, with the one independent β variable now given by

$$e^{-\beta^\times} = a/\hat{a}, \tag{5.25}$$

as in the type IV case. In addition to the three adjoint matrices $\kappa_i = \hat{k}_i$, one must introduce three outer automorphism matrices:

$$\kappa_4 = \mathrm{diag}(1,-1,0), \quad \kappa_5 = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \kappa_6 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \tag{5.26}$$

so that one has $-\hat{A} = M^i \hat{k}_i + M^4 \kappa_4 + M^5 \kappa_5 + M^6 \kappa_6$. Note that $\hat{k}_3 = \hat{a}$ diag(1,1,0) is diagonal and $\hat{a} = 1$ by assumption. Since the diagonal matrix κ_4 is trace-free and orthogonal to ln $\hat{D}$, and $\hat{k}_3$ is the same diagonal automorphism matrix generator as in the previous two cases, the same respective values of ζ yield the minimal strain and minimal distortion shifts.

As before the third diagonal component of the key equation (4.13) yields the same result $N^{-1}\dot{\beta}^\times = \theta_{33}$, while its diagonal components together yield

$$N^{-1}M^3=[-\tfrac{1}{2}(\theta_{11}+\theta_{22})+\zeta\theta_{33}],\quad N^{-1}M^4=\tfrac{1}{2}(-\theta_{11}+\theta_{22}). \tag{5.27}$$

The off-diagonal components then give the remaining automorphism coefficients:

$$\begin{aligned} N^{-1}M^1&=(\theta_{13}+\Omega_2)/(ae^{\beta^1}),\quad N^{-1}M^2=(\theta_{23}-\Omega_1)/(ae^{\beta^2}),\\ N^{-1}M^5&=(-\theta_{12}+\Omega_3)e^{\beta^2-\beta^1},\quad N^{-1}M^6=-(\theta_{21}+\Omega_3)e^{\beta^1-\beta^2}. \end{aligned} \tag{5.28}$$

Let

$$\boldsymbol{\xi}_4=-x^1\partial_1+x^2\partial_2,\quad \boldsymbol{\xi}_5=-x^2\partial_1,\quad \boldsymbol{\xi}_6=-x^1\partial_2, \tag{5.29}$$

be the explicit expressions for the outer automorphism vector fields corresponding to $\kappa_4,\kappa_5,\kappa_6$.[9] Then the desired shift vector field is

$$\vec{\mathbf{N}}=M^i\hat{\mathbf{e}}_i+M^4\boldsymbol{\xi}_4+M^5\boldsymbol{\xi}_5+M^6\boldsymbol{\xi}_6, \tag{5.30}$$

with the same minimal distortion and strain features as in the previous Class B models.

E. Bianchi type II

For this symmetry type, the matrix automorphism group has two additional diagonal automorphism generators leading to two relationships among the β^α, which may be parametrized as follows:

$$\ln \hat{D}=\mathrm{diag}(\beta^1,\beta^2,\beta^3)=\beta^\dagger\ \mathrm{diag}((4\zeta-1)/3,\ (2\zeta+1)/3,\ (2\zeta+1)/3). \tag{5.31}$$

The arbitrary parameter ζ, which can be chosen to have any convenient value, reflects a freedom in the shift vector field. The variable $\beta^\dagger$ is determined in terms of one nonvanishing structure function by the one independent component of the equation (4.15),

$$e^{-\beta^\dagger}=n_1/\hat{n}_1. \tag{5.32}$$

A basis of the matrix automorphism Lie algebra consists of the following off-diagonal matrices:

$$\kappa_2=\hat{k}_2,\quad \kappa_3=\hat{k}_3,\qquad \kappa_1=\begin{pmatrix}0&0&0\\0&0&1\\0&0&0\end{pmatrix},\quad \kappa_4=\begin{pmatrix}0&0&0\\0&0&0\\0&1&0\end{pmatrix}, \tag{5.33}$$

plus the additional two diagonal matrices,

$$\kappa_5=\mathrm{diag}(2,1,1),\quad \kappa_6=\mathrm{diag}(0,1,-1). \tag{5.34}$$

One can then express the matrix $\hat{A}$ as a linear combination of these matrices $-\hat{A}=M^1\kappa_1+M^2\hat{k}_2+M^3\hat{k}_3+M^4\kappa_4+M^5\kappa_5+M^6\kappa_6$.

The key equation (4.13) then becomes

$$N^{-1}[-\dot{\beta}^{\dagger}\ \mathrm{diag}((4\zeta-1)/3,\ (2\zeta+1)/3,\ (2\zeta+1)/3)+\hat{D}\hat{A}\hat{D}^{-1}]=(-\theta^{\alpha}{}_{\beta}+\epsilon^{\alpha}{}_{\beta\gamma}\Omega^{\gamma}), \tag{5.35}$$

where the choice $\zeta=0$ corresponds to a minimal strain shift and the choice $\zeta=1$ corresponds to a minimal distortion shift as in the previous cases. The first diagonal component of this equation minus the sum of the last two diagonal components yields

$$N^{-1}\dot{\beta}^{\dagger}=-\theta_{11}+\theta_{22}+\theta_{33}. \tag{5.36}$$

Using this in the average of the last two diagonal components of the same equation leads to

$$N^{-1}M^{5}=-\zeta\theta_{11}+(\zeta-1)(\theta_{22}+\theta_{33}). \tag{5.37}$$

Taking half the difference of the last two diagonal components of that equation then yields the remaining diagonal automorphism coefficient,

$$N^{-1}M^{6}=-\theta_{22}+\theta_{33}. \tag{5.38}$$

The off-diagonal components yield the remaining coefficients,

$$\begin{aligned} N^{-1}M^{1}&=(-\theta_{23}+\Omega_{1})e^{\beta^{3}-\beta^{2}}, \quad N^{-1}M^{2}=-(\theta_{13}+\Omega_{2})/(n_{1}e^{\beta^{2}}),\\ N^{-1}M^{3}&=(\theta_{12}-\Omega_{3})/(n_{1}e^{\beta^{3}}), \quad N^{-1}M^{4}=-(\theta_{23}+\Omega_{1})e^{\beta^{2}-\beta^{3}}. \end{aligned} \tag{5.39}$$

The generating vector fields ξ_1,ξ_4,ξ_5,ξ_6, corresponding to outer automorphism matrices expressed in canonical coordinates of the second kind are[9]

$$\begin{aligned} \boldsymbol{\xi}_1&=-x^{3}\partial_{2}+\tfrac{1}{2}(x^{3})^{2}\partial_{1}, \quad \boldsymbol{\xi}_5=-2x^{1}\partial_{1}-x^{2}\partial_{2}-x^{3}\partial_{3},\\ \boldsymbol{\xi}_4&=-x^{2}\partial_{3}+\tfrac{1}{2}(x^{2})^{2}\partial_{1}, \quad \boldsymbol{\xi}_6=-x^{2}\partial_{2}+x^{3}\partial_{3}. \end{aligned} \tag{5.40}$$

Finally the desired shift vector field is

$$\vec{\mathbf{N}}=M^{1}\xi_{1}+M^{2}\hat{\mathbf{e}}_{2}+M^{3}\hat{\mathbf{e}}_{3}+M^{4}\xi_{4}+M^{5}\xi_{5}+M^{6}\xi_{6}. \tag{5.41}$$

F. Bianchi type I

For this symmetry type, there exist no nontrivial inner matrix automorphisms and the matrix automorphisms are just the entire general linear group, so the problem is somewhat simpler. Let

$$[E^{i}{}_{j}]^{k}{}_{l}=\delta^{i}{}_{l}\delta^{k}{}_{j} \tag{5.42}$$

be the component definition of the natural basis of 3×3 matrices. In Cartesian coordinates adapted to the translational symmetry, a basis of the corresponding vector field Lie algebra is then[9]

$$\boldsymbol{\xi}^{i}{}_{j}=-[E^{i}{}_{j}]^{k}{}_{l}x^{l}\partial_{k}. \tag{5.43}$$

One may set $\hat{D}$ equal to the identity, so that (4.13) reduces to

$$N^{-1}\hat{A}^{i}{}_{j}=\delta^{i}{}_{\beta}\delta^{\alpha}{}_{j}(-\theta^{\alpha}{}_{\beta}+\epsilon^{\alpha}{}_{\beta\gamma}\Omega^{\gamma}), \tag{5.44}$$

and the corresponding (inhomogeneous) shift vector field is

$$\vec{\mathbf{N}} = -\hat{A}^i{}_j \boldsymbol{\xi}^j{}_i\,, \tag{5.45}$$

where the entries of the matrix $\hat{A}$ themselves play the role of the automorphism coefficients M^D, M^O of the previous cases.

This is clearly both a minimal strain shift and a minimal distortion shift. However, the minimal distortion shift for all the other Bianchi types still has a time-dependent isotropic part of $\hat{D}$ present. To restore this possibility, one can relax the condition on $\hat{D}$ to allow it to have a purely isotropic time-dependent part ($\beta^1 = \beta^2 = \beta^3$) while retaining the minimal distortion condition on the shift, though not the minimal strain condition. Then the parametrization,

$$\ln \hat{D} = \beta^0 \ \mathrm{diag}(1,1,1), \tag{5.46}$$

leads to an arbitrary contribution to the pure trace part of $\hat{A}$,

$$\mathrm{Tr}\ \hat{A} = -\Theta + 3N^{-1}\dot{\beta}^0. \tag{5.47}$$

VI. CONCLUDING REMARKS

The essential ingredient of the above procedure for constructing a coordinate representation of the orthonormal frame is the hypersurface transitivity of the symmetry group. It can therefore be carried over to the temporally homogeneous case and to some extent to their corresponding hypersurface self-similar cases. While the latter are not hypersurface-homogeneous, they are conformally hypersurface-homogeneous with a particular conformal factor.

The construction procedure for SH models is valid for any choice of lapse function. However, it suggests a preferred class of lapse functions, namely those which depend only on the commutator functions through an algebraic relationship. A lapse of this type is used to produce a dimensionless time variable in the dynamical systems formulation[1] of the orthonormal frame equations.

Geometrical objects on spacetime can be assigned dimensions under constant spacetime conformal transformations. In a computational frame the lapse has dimension 1 and the shift dimension 0 provided that a dimensionless time variable is used, while the spatial metric has dimension 2 and hence $\hat{D}$ dimension 1, except for Bianchi type I where $\hat{D}$ is the identity and the spatial coordinates instead have dimension 1. By re-introducing an isotropic degree of freedom in $\hat{D}$ to carry the dimension as described above for this case, the spatial coordinates become dimensionless. In an orthonormal frame the commutation functions have dimension -1.

In the dynamical systems analysis of the orthonormal frame equations, dimensionless variables are obtained by dividing the commutation functions by a function of them which has the same dimension. Usually one chooses the expansion scalar Θ, which leads to the so-called expansion normalized variables.[1] To produce a dimensionless time variable, the lapse must be a function constructed from the commutator functions with dimension 1. In the expansion normalized approach, the associated lapse is $N \propto \Theta^{-1}$.

The minimal distortion shift choice of the present approach is naturally adapted to any such dimensionless formulation since it allows the factorization of the metric into an overall conformal factor carrying the dimension and the remaining part which is therefore automatically expressed in terms of dimensionless variables. This can be seen from the fact that by choosing the minimal distortion shift for all Bianchi types provides a purely isotropic β variable parametrizing part of $\hat{D}$ that carries the dimension, making the remaining variables, if any, dimensionless. Allowing the extra isotropic degree of freedom for Bianchi type I, one can re-express the metric for all Bianchi types in the form in which the square of the lapse is an overall conformal factor times a new unphysical metric. In the minimal distortion gauge, if the lapse is chosen to be a function of the commutation functions with dimension 1, then the new unphysical metric is then expressed entirely in terms of dimensionless combinations of the commutator functions.

In the special case of a Bianchi spacetime with an additional homothetic Killing vector not tangent to the SH hypersurfaces, all dimensionless quantities take constant values[10,11] under these conditions, and the spacetime metric in the minimal distortion gauge is explicitly stationary except for an overall conformal factor which is exponential in the dimensionless time variable. Thus one automatically obtains the standard form for a transitively self-similar spacetime metric adapted to the homothetic Killing vector field (compare Ref. 9).

(Received 29 May 1998; accepted for publication 9 July 1998)

We prove an extension of the result on the inverse Laplace transform. This extension will help toward making the applications of Borel techniques to perturbation theory in Quantum Field Theories be placed on a more rigorous foundation. © *1999 American Institute of Physics.* [S0022-2488(98)02812-6]

I. INTRODUCTION

The known elementary particle processes are very well described by the standard model,[1] which is a Quantum Field Theory (QFT) in four dimensions. No QFTs that are of direct physical interest are exactly soluble in four dimensions. Hence a recourse has to be made to the perturbation theory in the coupling constant(s) in order to evaluate testable consequences of the QFTs. However, as it turns out,[2] even for the simple $\lambda\phi^4_{[4]}$ theory, the series in powers of coupling λ is only an asymptotic series.[3] While a suitable truncation of an asymptotic series can offer a good approximation to a physical quantity $P(\lambda)$ being calculated for a given coupling λ, nonetheless, as the asymptotic series is a strictly divergent one, it cannot be regarded as a rigorous mathematical expression for $P(\lambda)$ and may miss out on some features of $P(\lambda)$. Moreover, an attempt at the evaluation of $P(\lambda)$ in a power series in λ inherently assumes the analytic nature of P at $\lambda=0$, and this will miss out contributions to $P(\lambda)$ which may be singular at $\lambda=0$. Such contributions are known to exist, say, in QCD.[4]

In view of the divergent nature of the perturbation series for $P(\lambda)$, attempts have been made to relate this perturbation series to a series with improved convergence properties, and then from this new series extract information about $P(\lambda)$ that was originally lost in its asymptotic expansion.[5] The various techniques of Borel/Laplace transforms have been utilized in these works.[6–10] In this process, results have had to be used whose mathematical validity has not been known for the class of functions to which they have been applied. Our purpose in this paper is to try to fill this gap by extending the existing results in this regard further to the set of functions that may be of interest in physical theories but not covered in the conditions that are necessary for existing results on the Borel/Laplace transform to hold.

We now summarize the plan of the paper. In Sec. II, we summarize the various methods and uses involving Borel/Laplace transforms that have been employed in QFT literature.

We summarize the known results on these in the mathematical literature.[11]

In Sec. III, we state the extended version of the theorem and prove it. In Sec. IV we make comments on the usefulness of the results and suggest further extensions of the proof.

II. PREVIOUS RESULTS

A. Uses of Borel sum, Borel transforms

First we shall review, in a nonrigorous fashion, the use of a Borel sum/transform in the literature. As mentioned in the Introduction, the perturbation expansion in powers of the coupling λ for a physical quantity $P(\lambda)$ is generally an asymptotic expansion,

$$P(\lambda)=\sum_{n=0}^{\infty} a_n\lambda^n. \tag{1}$$

[a)]Electronic mail: sdj@iitk.ernet.in

In addition, there could be nonperturbative contributions to $P(\lambda)$, singular at $\lambda=0$, say of the form $e^{A/\lambda}$, which are missed in the usual Feynman diagrammatic perturbation expansion. The series in such cases, has zero radius of convergence; yet it can give a good approximation to $P(\lambda)$ for small enough λ if one keeps a correct number of terms in (1) to get the best approximation. Now it may happen that the additional information about $P(\lambda)$ may be hidden in (1) itself but as (1) is not an expansion for $P(\lambda)$ it cannot directly be deduced from the asymptotic series. Hence, one constructs a companion series to (1); viz., the ''Borel sum,''

$$B_1(z) \equiv \sum_{n=0}^{\infty} a_n \frac{z^n}{n!}. \tag{2}$$

The series in (2) may have a finite radius of convergence (depending upon the behavior of a_n's), even though (1) had radius of convergence zero.

[Of course, if (1) has a finite radius of convergence, then it can be shown that (2) represents an entire function.[2]] Now (2) could then be, in principle, summable in the disk $|z|<R$ and could possibly be analytically continued to the entire complex plane. The function $P(\lambda)$ can be recovered formally from $B_1(z)$ via

$$\lambda P(\lambda) = \int_0^{\infty} e^{-z/\lambda} B_1(z) dz. \tag{3}$$

The reconstruction of $P(\lambda)$ from $B_1(z)$ is possible only if $B_1(z)$ has no singularities on the positive real axis. In such cases, the theory is said to be Borel summable. On the other hand, the presence of a singularity of $B_1(z)$ on the positive real axis makes (3) ill defined and any procedure of giving meaning to the right-hand side of (3) by deformation of the contour makes the process ambiguous, as the latter could be chosen in multiple ways. In such cases the theory is said to be Borel nonsummable. QCD is an example of a Borel nonsummable theory; and this is due to the presence of singularities of $B_1(z)$ called Renormalons on the positive real axis. In these latter cases, the perturbation series alone is unable to unambiguously obtain $P(\lambda)$ via (3) uniquely.[5]

Equation (3) allows one to construct, in the case of Borel summable theories, the exact analytic function $P(\lambda)$ of which (1) was only a perturbative asymptotic expansion.

Alternate forms of Borel/Laplace transforms have also been used. Here are some important ones.

First we define[7]

$$B'(s) \equiv \int_0^{\infty} e^{s/f} Z(f)\, d\left(\frac{1}{f}\right), \tag{4}$$

$$B_2(s_r) \equiv \frac{1}{2\pi} \text{disc } B'(s); \tag{5}$$

disc=discontinuity across the real axis at $s=s_r$. Then in some cases we can construct back $Z(f)$,

$$Z(f) = \int_0^{\infty} B_2(s) e^{-s/f}\, ds. \tag{6}$$

The one we shall be dealing with extensively in this work is defined as follows:
Let $P(\lambda)$ be the function we are interested in.

Define

$$F(z) = P\left(\frac{1}{z}\right), \tag{7}$$

assuming this is possible.

Now define the inverse Laplace transform,[6]

$$B_3(s)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}e^{sz}F(z)dz; \tag{8}$$

c is, at present, arbitrary. Then we can reconstruct $F(z)$ by the Laplace transform

$$F(z)=\int_0^\infty e^{-tz}B_3(t)dt. \tag{9}$$

We note that if $P(\lambda)=\Sigma_{n=1}^{\infty}c_n\lambda^n$, and the series $F(z)$ defined by (7) is substituted in (8) one would obtain (if summations and integrations could commute)

$$B_3(t)=\sum_{n=1}^{\infty} c_{n+1}\frac{t^n}{n!}, \tag{10}$$

which is very similar to $B_1(t)$ [c_n being replaced by c_{n+1}, and, in fact, by a slight modification of the definition of the Borel sum, as in Ref. 8, it may be made to coincide with $B_3(t)$].

We now make comments on the rigor of the above result. (1) is valid generally only as an asymptotic series, enabling one to estimate P to a good accuracy. $B_1(z)$ of (2) is defined only within a finite radius of convergence $|z|<R$ outside; it has to be analytically continued, and this analytic continuation is used in (3) for $|z|>R$. For small λ, and Borel summable theories, one can argue[5] that (3) yields the correct asymptotic series (1), as the region $|z|<\lambda<R$ is what contributes to the right-hand side of (3) where the uniformly convergent expansion (2) for $B_1(z)$ holds and term by term integration becomes possible. We then *assume* that $P(\lambda)$ of (3) is indeed the physical quantity we are looking for in any λ.

The expression for $F(z)$ of (7) is only valid as an asymptotic expansion and not as a uniformly convergent series. Hence on the right-hand side of (8) the interchange of summation and integration that would lead to (10) is not really justified.

In this work, we shall deal mainly with the reconstruction via $B_3(t)$ of (8). Our aim is not so much to apply it yet to the asymptotic series such as (7) but to extend and rigorously establish the sufficient conditions under which such a reconstruction is valid for a function $F(z)$. We will discuss a few applications of our extension in Sec. IV. However, we will not make the ultimate contact of establishing a rigorous procedure for reconstruction starting from asymptotic series $P(\lambda)$. We aim only at the extension of the known results in this connection, which we now recapitulate.

B. Known results on inverse Laplace transform

The Complex Laplace Inverse Theorem.[11]

Theorem: Let $F(z)$ be analytic in the whole of the Complex plane, except that it has a finite number of poles. Suppose that $F(z)$ is analytic on half-plane $\{z|\mathrm{Re}\, z>\sigma\}$ and that $|F(z)| \leqslant M/|z|^\beta$ for all $|z|\geqslant R$ for constants M, $\beta>0$. Then for $t\geqslant 0$, let

$$\tilde{F}(t)=\sum \{\text{residue of } e^{zt}F(z) \text{ at each of its pole}\}. \tag{11}$$

Then

$$\mathcal{L}_z\tilde{F}(t)=F(z), \quad \forall\ \mathrm{Re}\ z>\sigma. \tag{12}$$

A corollary to this theorem is

$$\tilde{F}(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+\infty}e^{zt}F(z)dz, \quad \forall\ \mathrm{Re}\ z>\sigma. \tag{13}$$

We have tried to extend this theorem to cover a larger class of functions. Following is the modified version.

III. EXTENSION OF THE RESULT ON LAPLACE TRANSFORM

In this section, we shall present the extension of the result on the Laplace transform.

A. The theorem

Let $F(z)$ be analytic on the half-plane $\{z|\text{Re } z>\sigma\}$. Let $c\equiv\max(\sigma,0)$. We then define, for $t\geqslant 0$,

$$\tilde{F}(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+\infty}e^{zt}F(z)dz \tag{14}$$

(whenever integral exists). Then

$$\mathcal{L}_z\tilde{F}(t)\equiv\int_0^{\infty}\tilde{F}(t)e^{-zt}\,dt=F(z), \tag{15}$$

for all Re $z>c$, if $F(z)$ satisfies the following (weaker) conditions. These require that $F(z)$ can be written as a finite sum of functions:

$$F(z)=\sum_{i=1}^{N}F_i(z), \tag{16}$$

with each $F_i(z)$ satisfying the following conditions.

(a) With some R_i, $|F_i(z)|$ can be bounded, for $|z|>R_i$, as

$$|F_i(z)|\leqslant\frac{M_i e^{-b\text{ Re }z}}{|z|^{\beta_i}}, \tag{17}$$

with $M_i,b_i,\beta_i>0$.

(b) $F_i(z)$ has only a finite number of singularities w_{ij} $(j=1,2\ldots m_i)$.

(c) $F_i(z)$ has only a finite number B of separated branch cuts, which can be chosen to be of horizontal type, extending parallel to the negative real axis.

The proof, being lengthy, is being broken up. We first prove several lemmas. In the proofs, we shall constantly refer to various contours that we shall first define.

The contours K_j $(j=1...,B)$ are around the branch point K_j. Of these k_i represents the branch point with maximum real part. $C_{21},C_{22},\ldots,C_2(B+1)$ represents a broken up vertical contour, which we shall denote collectively by C_2. Then C represents the closed contour consisting of the segments C_0,C_1,C_2,C_3 and K_j $(j=1,...,B)$. x_1,y_1,y_2,x_1' are all positive. By assumption x_1, y_1, and y_2 have been chosen to be large enough and K_j narrow enough so that C always encloses all isolated singularities of $F_k(z)$ for a given k, except those lying on the branch cut itself. The contour C_2' is always to the right of C_0 (i.e., $x_1'>c$). C_0,C_1',C_2',C_3' together constitute the contour C'. We assume that K_j's have been chosen symmetrically around the branch cut at a distance ϵ_j such that there are no singularities in the strip of width $2\epsilon_j$, except those lying on the branch cut itself.

B. The lemmas

In all the three lemmas below we shall always restrict ourselves to a function $g(z)$ satisfying the condition that there exist $R>0$ such that $|g(z)|$ can be bounded as

$$|g(z)|\leqslant\frac{Me^{-b\text{ Re }z}}{|z|^{\beta}}\quad |z|>R \tag{18}$$

with some positive real M, b, β. We shall call this condition A.

Lemma 1: Let $g(z)$ satisfy condition A. We define

$$I(\tilde{C})=\int_{\tilde{C}}g(z)e^{zt}\,dz. \tag{19}$$

Then (i) for $t<b$,

$$\lim_{\tilde{C}\to\infty} I(\tilde{C})=0, \quad \tilde{C}=C_1',C_2',C_3'; \tag{20}$$

(ii) for $t>b$,

$$\lim_{\tilde{C}\to\infty} I(\tilde{C})=0, \quad \tilde{C}=C_1,C_2,C_3; \tag{21}$$

and (iii) for $t=b$ if $\beta>1$,

$$\lim_{\tilde{C}\to\infty} I(\tilde{C})=0, \quad \tilde{C}=C_1,C_2,C_3,C_1',C_2',C_3'. \tag{22}$$

In (ii) above, the limit $\tilde{C}\to\infty$ implies, whenever applicable, that y_1 and/or $y_2\to\infty$ after x_1' or $x_1\to\infty$.

Proof: As the contour $\tilde{C}$ is tending to infinity, we can assume, without loss of generality, that all points on $\tilde{C}$ are at a distance $\geqslant R$ from the origin. Then, $y_1,y_2,x_1'-c,x_1+c\geqslant R$. (i) We note that

$$I(C_1')=\int_c^{x_1'} g(z)e^{xt+iyt}\,dx, \tag{23}$$

so that in view of the fact that $y_1>R$ and the condition A,

$$|I(C_1')|\leqslant\int_c^{x_1'}\frac{Me^{-bx}e^{xt}}{(x^2+y_1^2)^{\beta/2}}\,dx\leqslant\frac{M}{y_1^\beta}\int_c^{x_1'}e^{(t-b)x}\,dx \tag{24}$$

$$=\frac{M}{y_1^\beta}\frac{1}{t-b}\left[e^{-(b-t)x_1'}-e^{-(b-t)c}\right], \quad t\neq b$$

$$\to 0, \quad \text{as } y_1\to\infty, \tag{25}$$

for any x_1 and for $t<b$ and $I(C_1')\to 0$ for $x_1'\to\infty$, $y_1\to\infty$ in any order.

(iia) The argument also goes through with $C_1'\to C_3'$. It also works with $C_1'\to C_1$ or C_3 (with $x_1'\to -x_1$), provided $t>b$.

(ib)

$$I(C_2')=i\int_{-y_2}^{y_1} g(z)e^{x_1't+iyt}\,dy, \tag{26}$$

so that with $x_1'>R$ and the condition A on $g(z)$,

$$|I(C_2')|\leqslant\int_{-y_2}^{y_1}\frac{Me^{-bx_1'}e^{x_1't}}{(x_1'^2+y_1^2)^{\beta/2}}\,dy \tag{27}$$

$$\leqslant Me^{-(b-t)x_1'}\int_{-y_2}^{y_1}\frac{dy}{(R^2+y^2)^{\beta/2}}\to 0, \quad \text{as } x_1'\to\infty, \tag{28}$$

for $t<b$, assuming y_1,y_2 to be finite.

(iib) The argument above also goes through with $C_2'\to C_2$ and $x_1'\to -x_1$ if $t>b$.

(iii) For $t=b$ and $\beta=1+4\alpha>1$, we have from (24),

$$|I(C_1')|\leqslant\int_c^{x_1'}\frac{M}{(x^2+y_1^2)^{1/2+2\alpha}}\,dx$$

$$\leqslant M\int_c^{x_1'}\frac{dx}{(x^2+y_1^2)^{1/2+\alpha}(y_1^2)^{\alpha}}$$

$$\leqslant\frac{M}{y_1^{2\alpha}}\int_c^{x_1'}\frac{dx}{x^{1+2\alpha}}$$

$$=\frac{M}{y_1^{2\alpha}}\frac{(x_1')^{-2\alpha}-(c)^{-2\alpha}}{(-2\alpha)}\to 0,\quad \text{as } y_1\to\infty,$$

for any fixed x_1' (and also as $x_1'\to\infty$, $y_1\to\infty$ in any order). The same argument goes through if $C_1'\to C_3'$. It also goes through for $C_1'\to C_1$, with minor modifications.

Further, for $t=b$ and $\beta=1+4\alpha>1$, we have, from (27),

$$|I(C_2')|\leqslant\int_{-y_2}^{y_1}\frac{M}{(x_1'^2+y^2)^{1/2+2\alpha}}\,dy$$

$$\leqslant\int_{-y_2}^{y_1}\frac{M}{(x_1^{2\prime}+y^2)^{1/2}x_1'^{2\alpha}}\,dy$$

$$=\frac{M}{x_1'^{2\alpha}}\tilde{F}(y_1,y_2)\to 0,\quad \text{as } x_1'\to\infty,$$

for any finite y_1,y_2 [since $\tilde{F}(y_1,y_2)$ is then finite].

The same argument goes through with $C_2'\to C_2$ and $x_1'\to -x_1$.

Lemma 2: Let $g(z)$ satisfy condition A and be continuous on C_0. Then for Re $z>c$.

$$\lim_{r\to\infty} e^{-rz}\int_C\frac{dz'g(z')e^{rz'}}{z'-z}\equiv\lim_{r\to\infty} I(r)=0,$$

where C is chosen as in Fig. 1 with $x_1,y_1,y_2>R$.

Proof: On $C_1,C_3,C_{21},C_{22},\ldots,C_{2(B+1)}$; $|z'|>R$. So that condition A yields that on these,

$$|g(z')|\leqslant\frac{Me^{-b\text{ Re }z'}}{|z'|^{\beta}}\leqslant\frac{Me^{bx_1}}{R^{\beta}}\equiv g_1.\tag{29}$$

Also, $g(z)$ is continuous on the finite segment C_0 and hence bounded. Hence

$$|g(z)|\leqslant g_2,\quad \text{on } C_0.\tag{30}$$

Further, $g(z)$ is analytic on $K_j's$, $j=1,2,\ldots,B$, which are finite in length. Hence it is bounded on the set of disjoint contours $K_1+K_2+\cdots+K_B$. Let

$$|g(z)|\leqslant g_3,\quad \text{for } z\epsilon K_j,\quad \forall j.\tag{31}$$

Let $g_0\equiv\max(g_1,g_2,g_3)$. Then

$$|g(z)|\leqslant g_0,\quad \text{on } C.\tag{32}$$

Also,

$$|e^{rz'}|=e^{rx'}\leqslant e^{rc}\quad \text{on } C,\tag{33}$$

$$\frac{1}{|z-z'|}=\frac{1}{[(x'-x)^2+(y-y')^2]^{1/2}}\leqslant\frac{1}{|x-x'|}\leqslant\frac{1}{(x-c)}\quad \text{on } C.\tag{34}$$

Further, the length of the contour C [$\epsilon_{\max}\equiv\max(\epsilon_1,\ldots,\epsilon_B)$],

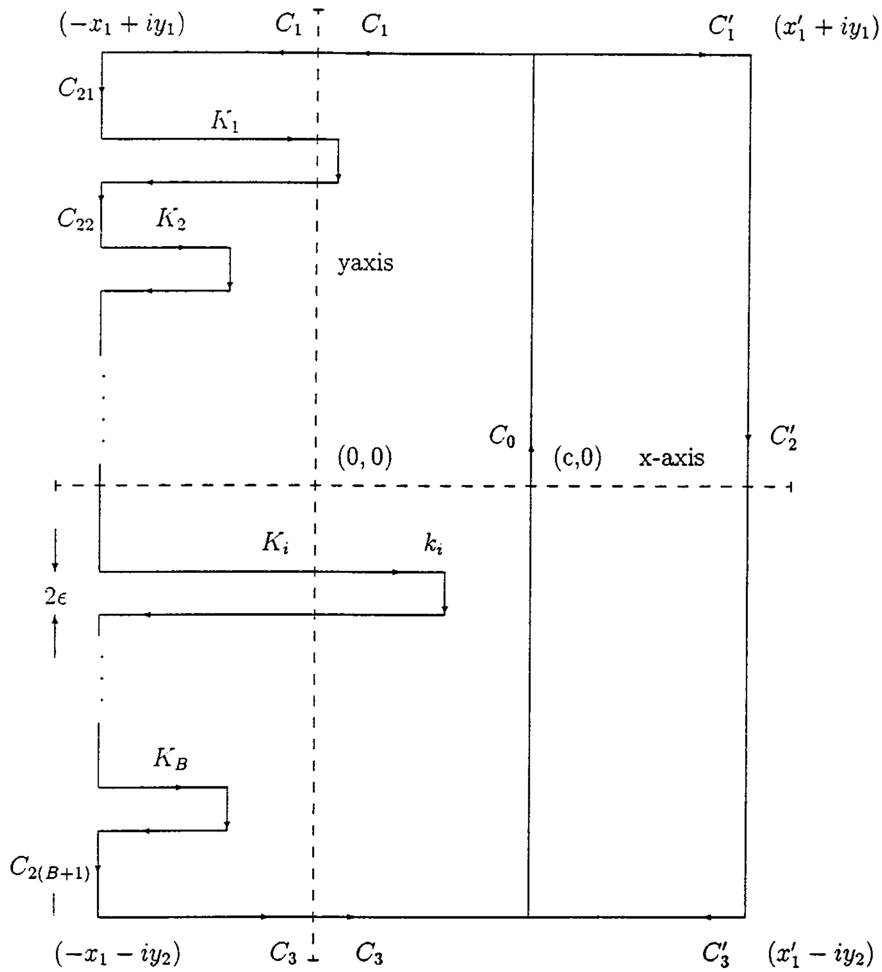

FIG. 1. The contours used in the proof of the theorem.

$$L \leqslant 2(y+y_1)+2(c+x_1)+B[2(x_1+k_i)+4\epsilon_{\max}] \equiv L_0. \tag{35}$$

Thus,

$$\left| e^{-rz}\int_C \frac{dz' g(z') e^{rz'}}{|z'-z|}\right| \leqslant L_0 g_0 \frac{1}{(x-c)} e^{rc} e^{-rx} \to 0, \quad \text{as } r\to\infty, \quad \text{for } \mathrm{Re}\, z=x>c. \tag{36}$$

Lemma 3: Let $g(z)$ satisfy the condition A. Then, for $\mathrm{Re}\, z>c$, we have

$$I=\lim_{K_j\to\infty}\int_{K_j} g(z')dz' \int_b^\infty e^{(z-z')}\, dt = \int_b^\infty dt\, e^{-zt}\int_{K_j\to\infty} e^{z't} g(z')dz' \tag{37}$$

[where K_j is the contour around the branch cut consisting of (i) a straight line parallel to the x axis: $y=y_+\equiv \mathrm{Im}\, k_j+\epsilon$; $-x_1\leqslant x\leqslant x_0\equiv \mathrm{Re}\, k_j+\epsilon$; (ii) a straight line oriented antiparallel to the y axis: $x=x_0$, $\mathrm{Im}\, k_j-\epsilon\equiv y_-\leqslant y\leqslant y_+$; (iii) A straight line antiparallel to the x axis: $y=y_-$, $x_0>x>-x_1$.]

Proof: Introducing the notation

$$G(x',y',t)\equiv e^{(z'-z)t} g(z') \equiv G_R(x',y',t)+iG_I(x',y',t), \tag{38}$$

we could express I as

$$I=I_+-I_2-I_-, \tag{39}$$

with

$$I_{\pm} \equiv \int_{-\infty}^{x_0} dx' \int_b^{\infty} dt\ G_R(x',y_{\pm},t) + i \int_{-\infty}^{x_0} dx' \int_b^{\infty} dt\ G_I(x',y_{\pm},t), \tag{40}$$

$$I_2 \equiv i \int_{y_-}^{y_+} dy' \int_b^{\infty} dt\ G_R(x_0,y',t) - \int_{y_-}^{y_+} dy' \int_b^{\infty} dt\ G_I(x_0,y',t). \tag{41}$$

Equation (37) is established if the order of integration in each of the six real integrals occurring in (40)–(41) can be interchanged. According to the Tonelli–Hobson Theorem,[12] this is possible in each case if the real integral under consideration or one obtained by interchange of the order of integrations is shown to exist. Thus, (37) would be established if, in particular, the six real integrals present in (40) and (41) are (themselves) shown to exist. However, these six integrals exist iff I_+, I_-, I_2 themselves exist. We thus need to show that

$$I_{\pm} = \int_{-\infty}^{x_0} dx' \int_b^{\infty} dt\ e^{(z'-z)t} g(z') \big|_{y'=y_{\pm}} \tag{42}$$

and

$$I_2 = \int_{y_-}^{y_+} dy' \int_b^{\infty} dt\ e^{(z'-z)t} g(z') \big|_{x'=x_0} \tag{43}$$

exist. Performing the t integrals in both cases (and noting that $\mathrm{Re}\, z > c > \mathrm{Re}\, z'$), we find $[\tilde{g}(z') \equiv -g(z') e^{(z'-z)b}]$,

$$I_{\pm} = \int_{-\infty}^{x_0} dx'\ \frac{\tilde{g}(z')}{z'-z} \bigg|_{y'=y_{\pm}}, \tag{44}$$

$$I_2 = \int_{y_-}^{y_+} dy'\ \frac{\tilde{g}(z')}{z'-z} \bigg|_{x'=x_0}. \tag{45}$$

Now, as for I_2, $g(z')/(z'-z)$ is analytic on the finite interval $y_- \leqslant y' \leqslant y_+$, $x' = x_0$ and thus bounded. The range of y' is also bounded. Hence

$$|I_2| = (y_+ - y_-)\{[\tilde{g}(z')/z'-z]_{x'=x_0}\}_{\max} < \infty. \tag{46}$$

As for $I_{\pm}$,

$$I_{\pm} = \int_{-R}^{x_0} dx'\ \frac{g(z')}{z'-z} \bigg|_{y'=y_{\pm}} + \int_{-\infty}^{-R} dx'\ \frac{g(z')}{z'-z}. \tag{47}$$

The first integral on the right-hand of (46) is finite and will approach a finite limit as $R \to \infty$ if the second residual integral (I_1) goes to zero as $R \to \infty$. Now

$$|I_1| \leqslant \int_{-\infty}^{-R} dx'\ \frac{|g(z')|}{|z'-z|}. \tag{48}$$

We now note that on the contour I_1, $|z'| > R$ so that condition A then implies

$$|\tilde{g}(z')| = |e^{b(z'-z)}||g(z')| \leqslant e^{b(x'-x)}\ \frac{M e^{-bx'}}{|z'|^{\beta}} = e^{-bx}\ \frac{M}{|x'|^{\beta}}. \tag{49}$$

Further, noting that $x > 0$ while $x' < -R$,

$$\frac{1}{|z'-z|}<\frac{1}{|x'-x|}<\frac{1}{|x'|}, \tag{50}$$

so that

$$I_1 \leqslant \int_{-\infty}^{-R} dx' \, \frac{Me^{-bx}}{|x'|^{1+\beta}} = \left[\int_R^{\infty} \frac{dw}{w^{1+\beta}} \right] Me^{-bx} = \frac{Me^{-bx}}{\beta R^{\beta}} \to 0, \quad \text{as} \quad R \to \infty, \tag{51}$$

Hence, etc.

C. Proof of the theorem

As $F(z)$ is expressible as the finite sum (16): if we could prove the result for one $F_i(z)$, the result for $F(z)$ follows.

The proof proceeds as follows: We first evaluate $\tilde{F}_i(t)$ of (14) in three steps.

(1) We show that $\tilde{F}_i(t)$ vanishes for $t<b_i$.

(2) We then cast $\tilde{F}_i(t)$ for $t>b_i$ in a form amenable to the evaluation of $\mathcal{L}_z \tilde{F}_i(t)$ via (15).

(3) $\mathcal{L}_z \tilde{F}_i(t)$ is then evaluated as a limit of the integral

$$\lim_{r\to\infty} \int_0^r \tilde{F}_i(t) e^{-zt} \, dt. \tag{52}$$

This we then show indeed is $F_i(z)$, $\forall$ Re $z>c$.

In the following proof, we drop the suffix i on b_i, β_i, and M_i for convenience.

(1) Let $C' \equiv C_0 + C_1' + C_2' - C_3'$. Consider

$$\tilde{F}(t,C') \equiv \oint_{C'} F(z) e^{zt} \, dz = \int_{C_0} F(z) e^{zt} \, dz + \sum_{i=1}^{3} \int_{C_i'} F(z) e^{zt} \, dz. \tag{53}$$

By Lemma 1, for $t<b$,

$$\lim_{C_i' \to \infty} \int_{C_i'} F(z) e^{zt} \, dt \equiv 0. \tag{54}$$

Also, on account of analyticity of $F(z)e^{zt}$ on and within C', $\tilde{F}(t,C') = 0 = \lim_{C' \to \infty} \tilde{F}(t,C')$. Hence, taking the limit $C' \to \infty$ in (53) and noting (54), we obtain, for $t<b$,

$$\tilde{F}(t) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} e^{zt} F(z) dz = 0. \tag{55}$$

(2) Now consider, for $t>b$,

$$\tilde{F}(t,C) \equiv \oint_C e^{zt} F(z) dz, \tag{56}$$

where the closed contour C has been defined in Sec. III A. Since C, in particular, continues to contain the same singularities of $F(z)$ as $C \to \infty$*, we have

$$\tilde{F}(t,C) = \lim_{C\to\infty} \tilde{F}(t,C) = 2\pi i \tilde{F}(t) + \sum_{j=1}^{3} \lim_{Cj\to\infty} \int e^{zt} F(z) dz + \lim_{K_j \to \infty} \sum_{j=1}^{B} \int_{K_j} e^{zt} F(z) dz. \tag{57}$$

(The singularities lying on the branch cut (if at all) are always outside the contour C.)

Lemma 1 ensures that the second term on the right-hand side vanishes. This implies that

$$\tilde{F}(t)=\frac{1}{2\pi i}\left[\tilde{F}(t,C)-\lim_{K_j\to\infty}\sum_{j=1}^{B}\int_{K_j}e^{zt}F(z)dz\right]. \tag{58}$$

(3) Now we reexpress

$$\mathcal{L}_z\tilde{F}(t)\equiv\int_0^\infty e^{-zt}\tilde{F}(t)dt\equiv\lim_{r\to\infty}\int_0^r e^{-zt}\tilde{F}(t)dt=\lim_{r\to\infty}\int_b^r e^{-zt}\tilde{F}(t)dt\equiv\lim_{r\to\infty}F(z,r), \tag{59}$$

in view of (55). Now (56) above leads to

$$\begin{aligned}F(z,r)&=\int_b^r e^{-zt}\tilde{F}(t)dt\\&=\frac{1}{2\pi i}\int_b^r e^{-zt}\,dt\left[\tilde{F}(t,C)-\lim_{K_j\to\infty}\sum_{j=1}^{B}\int_{K_j}e^{z't}F(z')dz'\right]\\&\equiv\frac{1}{2\pi i}[J-K].\end{aligned} \tag{60}$$

Now consider the first term on the right-hand side:

$$J\equiv\int_b^r e^{-zt}\,dt\tilde{F}(t,C)=\int_b^r e^{-zt}\,dt\oint_C e^{z't}F(z')dz'. \tag{61}$$

Now the integrals over finite ranges commute. Hence

$$\begin{aligned}J=\oint_C dz'\,F(z')\int_b^r dt\,e^{(z'-z)t}&=\oint_C dz'\,F(z')\,\frac{1}{z'-z}\,[e^{r(z'-z)}-e^{b(z'-z)}]\\&=e^{-zr}\oint_C\frac{F(z')e^{rz'}\,dz'}{z'-z}-\oint_C\frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}\\&\equiv J_1-J_2.\end{aligned} \tag{62}$$

Now consider

$$J_2\equiv\oint_C\frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}\equiv\oint_C H(z')e^{tz'}dz'|_{t=b}. \tag{63}$$

Now, on C_1, C_2, and C_3, in view of the fact that $|z'|>R$, we have

$$|H(z')|=\left|\frac{F(z')}{z'-z}\right|\leqslant\frac{Me^{-b\ \mathrm{Re}\ z'}}{|z'|^\beta|z'-z|}\leqslant\frac{Me^{-b\ \mathrm{Re}\ z'}}{|z'|^{\beta+1}\left|1-\frac{z}{z'}\right|}. \tag{64}$$

For a given z, we now choose C such that on C_1, C_2, and C_3 $|1-z/z'|>1/2$, which is possible without loss of generality, as we are ultimately going to let $C\to\infty$. Then

$$|H(z')|\leqslant 2\,\frac{Me^{-b\ \mathrm{Re}\ z'}}{|z'|^{\beta'}}, \tag{65}$$

where $\beta'=1+\beta>1$. Thus on account of Lemma 1 part (iii),

$$\lim_{C\to\infty}\oint_{C_1+C_2+C_3}H(z')e^{tz'}\,dz'|_{t=b}=0. \tag{66}$$

Thus, in view of the fact that C always encloses the same singularities of $F(z')$,

$$J_2 = \oint_C \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}$$

$$= \lim_{C\to\infty} \oint_C \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}$$

$$= \lim_{C_0\to\infty} \int_{C_0} \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z} + \sum_{j=1}^{B} \lim_{K_j\to\infty} \int_{K_j} \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}. \tag{67}$$

Applying Lemma 1 part (iii) once again, we can replace $C_0 \to C'$ in the first term. Thus

$$J_2 = \lim_{C'\to\infty} \int_{C'} \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z} + \sum_{j=1}^{B} \lim_{K_j\to\infty} \int_{K_j} \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}. \tag{68}$$

The integrand in the first term on the right-hand side is analytic everywhere on and within (the clockwise contour) C', except for the simple pole at $z'=z$. Hence

$$J_2 = -2\pi i F(z) + \sum_{j=1}^{B} \lim_{K_j\to\infty} \int_C \frac{F(z')e^{b(z'-z)}\,dz'}{z'-z}. \tag{69}$$

Thus, using (60), (62), and (69), we obtain

$$F(z,r) = \frac{1}{2\pi i}[J_1 - J_2 - K] = \frac{1}{2\pi i}\left[J_1 + 2\pi i F(z) - \sum_{j=1}^{B} \lim_{K_j\to\infty} \int_{K_j} \frac{F(z')e^{b(z'-z)}dz'}{z'-z} - K\right]. \tag{70}$$

We now take the limit as $r\to\infty$ in (70) and note that Lemma 2 ensures that $\lim_{r\to\infty} J_1 = 0$ [refer to (62) for a definition]. On the other hand Lemma 3 ensures that

$$\lim_{r\to\infty} K = \sum_{j=1}^{B} \int_b^\infty e^{-zt}\,dt \int_{K_j\to\infty} F(z')e^{z't}\,dz' = \sum_{j=1}^{B} \int_{K_j\to\infty} dz'\; F(z') \int_b^\infty e^{(z'-z)t}\,dt$$

$$= \sum_{j=1}^{B} \int_{K_j\to\infty} dz'\; F(z')\,\frac{(-1)e^{b(z'-z)}}{z'-z}, \tag{71}$$

in view of Re $z > c \geqslant$ Re z' always. Thus, the last two terms on the right-hand side of (70) vanish as $r\to\infty$. Thus, as $r\to\infty$, (70) leads to

$$\mathcal{L}_z \tilde{F}(t) = \lim_{r\to\infty} F(z,r) = F(z), \quad \forall \text{ Re } z > c. \tag{72}$$

(72) is proved for a component F_i of F as in (16). The result (15) then follows from the additive nature of both sides of (15). Hence, etc.

IV. DISCUSSION AND AN APPLICATION

A. Scope of results

Having proved the extension of the Laplace Inverse Theorem, the next natural step is to investigate its utility. For this purpose let us consider a general physical quantity $P(\lambda)$. It seems reasonable to assume that there exists a continuation of $P(\lambda)$ to an entire complex plane of λ,

TABLE I. Description of functions to which the previously existing theorem and our extended version apply.

$\mathcal{F}_1$	$\mathcal{F}_2$
1. Only a finite number of poles in F are allowed, which implies only a finite number of poles in P are permissible.	Only a finite number of isolated singularities are allowed, which implies that a finite number of isolated singularities in P are permissible (these need not be only poles).
2. $\|F\|<1/\|z\|^{\beta}$, $\forall \|z\|>R$ $\Rightarrow F\to 0$ as $z\to\infty$ $\Rightarrow P\to 0$ as $\lambda\to 0$, i.e., $P(0)=0$ and hence functions singular at the origin are not covered.	$\|F\|<e^{-b\,\mathrm{Re}\,z}/\|z\|^{\beta}$, $\forall \|z\|>R$ $\Rightarrow F\to e^{-b\,\mathrm{Re}\,z}/\|z\|^{\beta}$, as $z\to\infty$ (i.e., it is not necessary that $F\to 0$ as $z\to\infty$ in all directions $\Rightarrow P\sim\lambda^{\beta}e^{-b/\lambda}$, $\lambda\to 0$, i.e., some types of essential singularities at $\lambda=0$ are allowed. (In fact, in Field Theory this is the most common type of singularity encountered at $\lambda=0$.)
3. No branch cuts are allowed.	A finite number of branch cuts are allowed.

which is analytic everywhere except possibly at some singularities and branch cuts. Thus, this class of functions (which we will refer to as $\mathcal{F}$) contains the most general physically acceptable functions.

We define

$$F(z)\equiv P\left(\frac{1}{z}\right). \tag{73}$$

We then observe the following.

(1) If there is a singularity at $z=a$ in P, then it is manifested as a singularity in F at $z=1/a$.

(2) If there is a branch cut in P, we get corresponding branch cuts in F. For example, (a) if $P\sim 1/(z-a)^{1/2}$ near $z=a$, $F\sim z^{1/2}/a^{1/2}(1/a-z)^{1/2}$, i.e., branch cuts at $z=0$ and $z=1/a$; and (b) if $P\sim\ln(a+z)$, $F\sim\ln a-\ln z+\ln(z+1/a)$, i.e., branch cuts at $z=-1/a$ and $z=0$.

(3) The behavior of P at $z=0$ is related to the behavior of F as $z\to\infty$.

We are now ready to describe the subclass of $\mathcal{F}$ for which the previously existing theorem and our extended version guarantees the existence of the Laplace Inverse. We will refer to them as $\mathcal{F}_1$ and $\mathcal{F}_2$, respectively (see Table I).

Thus we find that our extended version has definitely enlarged the subclass in $\mathcal{F}$ whose Laplace inverse exists. However, for an application to the Field Theory it is desirable to enlarge the class further, and we discuss this in some detail in Sec. IV C and also suggest how it can be achieved.

B. An application

Let us now look at a physical example where the relevent function belongs to $\mathcal{F}_2-\mathcal{F}_1$. Consider a one-dimensional (1-D) spin chain defined by the action

$$S=\sum_{i=1}^{N}(1-\hat{\phi}_i\cdot\hat{\phi}_{i+1}), \tag{74}$$

where $\hat{\phi}_i$ are unit 3-D vectors. Choosing a free boundary condition, one finds the partition function given by

$$Z_N(f)=\int\prod_i d\hat{\phi}_i\, e^{-S[\phi]/f}=\left(\frac{f}{2}\right)^N(1-e^{-2/f})^N. \tag{75}$$

For illustration purposes we take $N=1$. Then

$$Z(f)=\frac{f}{2}(1-e^{-2/f})=P_1(f)+P_2(f), \tag{76}$$

where $P_1(f)=(f/2)e^{-0/f}=f/2$ and $P_2(f)=(f/2)e^{-2/f}$. Then $F_1(z)=1/2z$ and $F_2(z)=(1/2z)e^{-2z}$. Now, though the previous theorem does not guarantee the existence of the Laplace Inverse, the extended version does; and indeed as we will see soon, the inverse exists,

$$\tilde{F}_1(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}\frac{e^{tz}}{2z}\,dz,\quad c>0. \tag{77}$$

We can close the contour from the right for $t<0$, since the integral over the right half circle vanishes, and hence the integral is zero (no pole is contained). However, for $t>0$, we have to close the contour from the left and then since the residue at $z=0$ is $-\frac{1}{2}$, we get $\tilde{F}_1(t)=\frac{1}{2}$. Hence, finally we have

$$\tilde{F}_1(t)=\tfrac{1}{2}\theta(t). \tag{78}$$

Similarly, one can compute $\tilde{F}_2(t)$, which comes out to be

$$\tilde{F}_2(t)=-\tfrac{1}{2}\theta(t-2), \tag{79}$$

$$\tilde{F}(t)=\tfrac{1}{2}[\theta(t)-\theta(t-2)]=\tfrac{1}{2}\theta(t)\theta(2-t)=B_3(t). \tag{80}$$

One can verify that by taking the Laplace Transform of B_3 we get back F and hence P,

$$\int_0^\infty e^{-zt}\,\frac{1}{2}\,\theta(t)\theta(2-t)dt=\frac{1}{2}\int_0^2 e^{-zt}\,dt=\frac{1}{2z}(1-e^{-2z}), \tag{81}$$

and we get back $Z(f)=(f/2)(1-e^{-2/f})$.

In Field Theory we also find instances where $P(\lambda)$ have branch cuts. In Ref. 8, for example, it is mentioned that in expression (1), if $a_{k+1}=(1/z_i)^k k^\gamma a_k(\gamma>0)$, then B_1 has a singularity proportional to $(z-z_i)^{-\gamma-1}$; so if γ is a positive integer we have a pole; and for noninteger γ a branch point in the z plane at $z=z_i$. It is easy to check that such a Borel transform indicates branch cuts in the original function $P(\lambda)$.

C. Possible generalization

Let us first try to find the types of functions that belong to $\mathcal{F}-\mathcal{F}_2$.

First, most functions that behave badly at $\lambda=0$, say having poles at 0, does not belong to $\mathcal{F}_2$. Here, however, we present an argument that suggests that such functions can be handled by switching to generalized functions and slightly modifying the definition of the Laplace transform that does not affect our earlier discussion. We define the Laplace transform of $\tilde{F}(t)$ (which can now be a generalized function) as

$$\mathcal{L}_z[\tilde{F}(t)]\equiv\lim_{\epsilon\to 0}\int_{-\epsilon}^{\infty}\tilde{F}(t)e^{-zt}\,dt. \tag{82}$$

Say now $P(\lambda)=a/\lambda^n$, $n\geqslant 0$, is an integer. Then $F(z)=az^n$, and we have

$$\tilde{F}(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}F(z)e^{tz}\,dz=\frac{1}{2\pi}\int_{-\infty}^{\infty}(c+iy)^n e^{ct}e^{iyt}\,dy. \tag{83}$$

Now we also have $2\pi\delta(t)=\int_{-\infty}^{\infty}e^{iyt}\,dy$ or

$$2\pi[\delta(t)e^{ct}]_n=\int_{-\infty}^{\infty}(c+iy)^n e^{ct}e^{iyt}\,dy \tag{84}$$

(the suffix n denotes differentiation with respect to t). Thus

$$\tilde{F}(t)=a[\delta(t)e^{ct}]_n=a\,\delta^n(t). \tag{85}$$

Now

$$\mathcal{L}_z[\tilde{F}(t)]=\lim_{\epsilon\to 0}\int_{-\epsilon}^{\infty}\tilde{F}(t)e^{-zt}\,dt=\lim_{\epsilon\to 0}a\int_{-\epsilon}^{\infty}\delta^n(t)e^{-zt}\,dt=a(-z)^n(-1)^n=az^n. \tag{86}$$

Thus, we see that it works and, in fact, it will now work for any polynomial in λ also.

(Received 8 June 1998; accepted for publication 3 August 1998)

The level surfaces of solutions to the eikonal equation define null or characteristic surfaces. In this paper we study, in Minkowski space, properties of these surfaces. In particular, we are interested both in the singularities of these ''surfaces'' (which can, in general, self-intersect and be only piecewise smooth) and in the decomposition of the null surfaces into a one-parameter family of two-dimensional wavefronts which can also have self-intersections and singularities. We first review a beautiful method for constructing the general solution to the flat-space eikonal equation; it allows for solutions either from arbitrary Cauchy data or for time-independent (stationary) solutions of the form $S=t-S_0(x,y,z)$. We then apply this method to obtain global, asymptotically spherical, null surfaces that are associated with shearing (''bad'') two-dimensional cuts of null infinity; the surfaces are defined from the normal rays to the cut. This is followed by a study of the caustics and singularities of these surfaces and those of their associated wavefronts. We then treat the same set of issues from an alternative point of view, namely from Arnold's theory of generating families. This treatment allows one to deal (parametrically) with the regions of self-intersection and nonsmoothness of the null surfaces, regions which are difficult to treat otherwise. Finally, we generalize the analysis of the singularities to the case of families of characteristic surfaces. © *1999 American Institute of Physics.* [S0022-2488(99)00801-4]

I. INTRODUCTION

The study of the propagation of electromagnetic wavefronts, in the high-frequency or geometric optics limit, is almost ubiquitous in physics; it is a basic staple of elementary physics courses, it arises in the practical area of optical equipment, in applied subjects, too numerable to mention in detail, involving materials with variable refractive index and in atmospheric and astrophysical studies. They have been a prime illustration of V. I. Arnold's theory of Lagrangian and Legendre maps.[1–4] In a different guise, similar problems arise in catastrophe theory. In addition to the various applications to more standard physics problems, they also play a most fundamental role in general relativity, e.g., the continuous propagation of the two-dimensional wavefronts, i.e., the one-parameter family of evolving wavefronts, form null (or characteristic) three-surfaces that are determined by the dynamics of the curved space–time in which the wavefronts propagate.[5,6] In this context it forms the basis for the theory of gravitational lensing.[7] The converse statement is also true, namely that sets of null surfaces define, up to a conformal factor, the space–time geometry itself.[8,9] In arbitrary space–times, the high-frequency limit is completely governed by the eikonal equation,

$$g^{ab}\partial_a S_b S = 0, \tag{1}$$

where $x^a = (x^i, t)$ are local space–time coordinates, $g^{ab}(x^c)$ is a given space–time metric, and $S = S(x^a)$. The level surfaces of S, i.e., $S(x^a) = \text{const}$, define the characteristic or null three-surfaces (or what Arnold calls the ''big wave fronts''[2]) and the $S(x^i, t) = \text{const}$ for const t define the two-dimensional ''small'' wavefront in the three-dimensional space of $t = \text{const}$. The vector $p^a = g^{ab}\partial_b S$ is tangent to the null geodesics that rule the characteristic surface. Though we are basically interested in Eq. (1) for arbitrary space–times, here we will confine ourselves to a study of its solutions only in flat (Minkowski) space. (A future paper, in preparation, will generalize the present material to curved space–times.) Equation (1) then becomes

$$\eta^{ab}\partial_a S \partial_b S = (\partial_t S)^2 - (\partial_x S)^2 - (\partial_y S)^2 - (\partial_z S)^2 = 0. \tag{2}$$

The level surfaces of the solutions to Eq. (1) or (2), the null surfaces, can be viewed as being generated by the evolution of two-dimensional wavefronts. Specifically, a wavefront evolves by following light rays that are normal to it, generating the null three-surface. A smooth wavefront in three-space, in general, progresses into a singular one, either to the past or the future, i.e., a generic null surface in space–time has singularities. The singular wavefronts are two-surfaces that are continuous with existing first derivatives, but where (piecewise) the second derivatives are singular, being either undefined or infinite. The structure of the singularities are generically cusp ridges and swallowtails. There are unstable exceptions.

A textbook example[2,3] of flat space singular wavefronts (and associated big wavefront) are from imploding triaxial ellipsoids, where an initially ellipsoidal wavefront is evolved inwardly, self-intersects for some finite period of time, and eventually expands out to infinity, becoming spherical in the limit.

The singularities of wavefronts are also interpreted as the location of focusing regions, where the intensity of light becomes very high. At the focusing regions, neighboring null geodesics meet, and the cross-sectional area of the bundle of light rays collapses to zero, which leads to the increase in intensity. Spherical wavefronts focus at a single point (which are unstable under small perturbations of the front) whereas generic wavefronts trace spatial curves of focusing points (cusp ridges and swallowtails).

In Sec. II we will review a beautiful method for giving the general solution to the flat-space eikonal; it allows for solutions either from arbitrary Cauchy data or for stationary solutions that arise from the ansatz, $S = t - S_0(x, y, z)$.

In Sec. III, we will apply the method of Sec. II to obtain global asymptotically spherical null surfaces that are associated with shearing (''bad'') cuts of null infinity.[10,11] They will be defined from the normal rays to a ''bad'' cut. This construction can be thought of as beginning with a deformed, initial, two-sphere in a finite region of space–time. Then, construct the future outward directed null normals to the two surface which generates a null surface and finally ''slide'' the initial two-surface along the null geodesics that generate the null surface, to future null infinity. This limit is the ''bad'' cut of null infinity.

In Sec. IV, we will study the caustics and singularities of these characteristic surfaces and their associated wavefronts.

In Sec. V, we treat the same problems of the singularities of these surfaces but now from an alternate point of view, namely from Arnold's theory of generating families.[4] This treatment allows one to handle (parametrically) the regions of self-intersection and nonsmoothness of the null surfaces.

In Sec. VI, we discuss a generalization of the ideas presented to this point. Though this generalization is primarily intended for use in nonflat Lorentzian space–times, nevertheless we believe that it is quite useful to see it in the simpler case of flat space–time; it allows for the clarification of certain points that would be difficult in more general situations. Specifically we will consider solutions of the eikonal equation that depend on two parameters—that are different from the two-parameter family of plane waves. We will see the slightly surprising result that the singularity structure of the individual characteristic surfaces can be studied via the parameter behavior of nearby solutions. More precisely, if the two-parameter set of solutions is given by $Z(x^a,\mu,\bar{\mu})$, the singularities of the level surfaces of Z for fixed values of $(\mu,\bar{\mu})$ can be studied and expressed in terms of $(\mu,\bar{\mu})$ derivatives of Z. These results become important in asymptotically flat space–times where the $Z(x^a,\mu,\bar{\mu})$ can be chosen to represent the family of past null cones from all the points of future null infinity.

II. SOLUTIONS OF THE EIKONAL EQUATION

We review a powerful method for solving the flat-space eikonal equation with arbitrary given Cauchy data. We begin with a solution S^* of the eikonal equation that depends on three arbitrary parameters, i.e.,

$$S^* = S^*(x^i,t,\alpha_i) = x^i\alpha_i - t\sqrt{\Sigma(\alpha_i)^2} \tag{3}$$

called a complete integral. A ''general integral'' (which involves an arbitrary function) can be constructed from the complete integral in the following manner: we first add to it an arbitrary function of the three α_i, i.e., we consider

$$S^{**} = S^*(x^i,t,\alpha_i) - F(\alpha_i), \tag{4}$$

with the weak condition that (aside from lower-dimensional regions)

$$\left|\frac{\partial^2 S^{**}}{\partial\alpha_i\partial\alpha_j}\right| \neq 0. \tag{5}$$

We next demand that $\partial S^{**}/\partial\alpha_i = \partial S^*/\partial\alpha_i - \partial F/\partial\alpha_i = 0$, which implies that there are three functions of the form $\alpha_i = A_i(x^i,t)$. (In general these solutions are not unique and they must be expressed on different sheets. See Sec. IV for a complete discussion of this issue.) Finally, via $\alpha_i = A_i(x^i,t)$, the α_i are eliminated in the S^{**}, yielding (perhaps multivalued)

$$S(x^i,t) = S^*(x^i,t,A_i(x^i,t)) - F(A_i(x^i,t)). \tag{6}$$

The level surfaces of this S might self-intersect and be only piecewise differentiable.

It is not difficult to show that the S so constructed satisfies the eikonal equation.[12] This follows immediately from the fact that

$$\partial_a S = \partial_a S^* + (\partial_{A_i}S^* - \partial_{A_i}F)\partial_a A_i = \partial_a S^*.$$

This solution now depends on an arbitrary function of three variables, namely the F. The task is now to determine the $F(\alpha_i)$ in terms of (appropriate) Cauchy data, $S_C(x^i)$. This is accomplished as follows; define $\alpha_i = \partial S_C/\partial x^i$ and algebraically invert it in the form of the three equations $x^i = X^i(\alpha_i)$. At $t = t_0$ we have that

$$S(x^i,t_0) = S^*(x^i,t_0,A_i(x^i,t_0)) - F(A_i(x^i,t_0)). \tag{7}$$

Replacing all the A_i by α_i and all the x_i by $X^i(\alpha_i)$, we have that

$$F(\alpha_i) = S^*(X^i,t_0,\alpha_i) - S_C(X^i), \tag{8}$$

i.e., the free $F(\alpha_i)$ is now expressed in terms of the free Cauchy data, $S_C(x^i)$.

This allows us to find (in principle, modulo algebraic inversions or parametrizations) solutions of the flat-space eikonal equation with arbitrary Cauchy data.

There exists a special class of solutions that are not studied or found easily via the Cauchy problem, namely the ''stationary'' solutions which have the form

$$S=t-S_0(x^i).$$

To generate solutions of this form we modify the complete integral, Eq. (3), making it a function of only two free parameters by imposing the condition that $\Sigma(\alpha_i)^2=\text{const}$ [for convenience chosen as $\Sigma(\alpha_i)^2=1/\sqrt{2}$].

We then write the modified complete integral as

$$S^*=x^a l_a(\zeta,\overline{\zeta}), \tag{9}$$

where

$$l_a(\zeta,\overline{\zeta})=\frac{1}{\sqrt{2}(1+\zeta\overline{\zeta})}[(1+\zeta\overline{\zeta}),-(\zeta+\overline{\zeta}),-i(\overline{\zeta}-\zeta),(1-\zeta\overline{\zeta})]. \tag{10}$$

The complex number ζ, which plays the role of two of the independent parameters among the three α_i, can be thought of as the complex stereographic coordinate on the sphere; the $l_a(\zeta,\overline{\zeta})$ is a Minkowski null vector $\eta^{ab}l_a l_b=0$ that spans the entire lightcone as ζ ranges over the sphere. Equation (9) represents a spheres worth of different families of plane waves parametrized by the direction ζ.

If we now take

$$S^{**}=x^a l_a(\zeta,\overline{\zeta})+\alpha(\zeta,\overline{\zeta}) \tag{11}$$

and construct $\eth S^{**}=\bar{\eth} S^{**}=0$, i.e.,

$$\omega\equiv x^a m_a(\zeta,\overline{\zeta})+\eth\alpha(\zeta,\overline{\zeta})=0, \tag{12}$$

$$\overline{\omega}\equiv x^a \overline{m}_a(\zeta,\overline{\zeta})+\eth\alpha(\zeta,\overline{\zeta})=0, \tag{13}$$

where

$$m_a(\zeta,\overline{\zeta})=\eth l_a(\zeta,\overline{\zeta})\equiv(1+\zeta\overline{\zeta})\,\frac{\partial l_a(\zeta,\overline{\zeta})}{\partial\zeta}, \tag{14}$$

$$\overline{m}_a(\zeta,\overline{\zeta})=\bar{\eth} l_a,(\zeta,\overline{\zeta})\equiv(1+\zeta\overline{\zeta})\,\frac{\partial l_a(\zeta,\overline{\zeta})}{\partial\overline{\zeta}}. \tag{15}$$

For generic $\alpha(\zeta,\overline{\zeta})$, Eq. (12) can be solved for

$$\zeta=\Upsilon(x,y,z), \tag{16}$$

where again these solutions need not be unique and must be expressed on different sheets. (See Sec. IV for a full treatment of this problem.) Note that Eq. (12) does not depend on the time t and hence Υ is a function only of the spatial coordinates. When the $\Upsilon(x,y,z)$ is substituted into Eq. (11), i.e.,

$$S(t,x,y,z)=\frac{t}{\sqrt{2}}-S_0(x,y,z)=\frac{t}{\sqrt{2}}+x^i l_i(\Upsilon,\overline{\Upsilon})+\alpha(\Upsilon,\overline{\Upsilon}), \tag{17}$$

we have a solution of the eikonal equation depending on an arbitrary function of two variables, $\alpha(\Upsilon,\overline{\Upsilon})$. The level surfaces of S could in general self-intersect and be only piecewise differentiable.

The procedure of beginning with a complete solution and obtaining the general solution via the two (or three) variable arbitrary function *is* geometrically equivalent to the construction of an envelope from the family of plane waves as the two (or three) constants in the complete solutions are varied.[13]

Since in this work we will only be interested in individual null surfaces and their properties, we can and will confine ourselves to the level surfaces of the solutions of the form given in Eq. (17).

III. NULL SURFACES GENERATED BY NORMALS TO TWO-SURFACES

We want to give a slightly different geometric interpretation to the method of the previous section for generating the stationary solutions of the eikonal equation. Given any (spatial) two-surface (for example, consider any two-dimensional slice of the past light cone of an arbitrary space–time point), the normal rays to the surface (either the outgoing or incoming ones) generate a null surface. In this section we will consider a particular case of this construction where this *past light cone* is taken to be the future null infinity, $\mathfrak{I}^+$, of Penrose.[10]

The future null boundary, $\mathfrak{I}^+$ (the endpoints of future directed null geodesics), of any asymptotically simple space–time is a null surface with topology $R\times S^2$. A choice of Bondi coordinates $(u,\zeta,\bar{\zeta})$ can be assigned to $\mathfrak{I}^+$, where $\zeta=\cot(\theta/2)e^{i\phi}$ for the S^2 sector. The intersection of the future lightcone $\mathfrak{C}_x$ of a point x^a with $\mathfrak{I}^+$ is a two-surface, locally imbedded in $R\times S^2$; it can generically be described locally by $u=Z(x^a,\zeta,\bar{\zeta})$. The two-surface is referred to as a light cone cut,[14] whereas the function $Z(x^a,\zeta,\bar{\zeta})$ is referred to as a light cone cut function, and is a two-point real function on the space–time and the boundary, $\mathfrak{I}^+$.

Remark 1: Though for this work it is irrelevant, we mention that the light cone cut function $Z(x^a,\zeta,\bar{\zeta})$ is one of two fundamental variables in a reformulation of general relativity via null surfaces.[8,9] It encodes all the conformal information of the space–time.

In the remainder of this work we will confine ourselves to flat space–time where (modulo Poincare transformations) a natural choice of Bondi coordinates $(u_n,\zeta,\bar{\zeta})$ exists; the $u_n=\text{const}$ is constructed from the intersection of the future light cone, $\mathfrak{C}_{(t,o,o,o)}$, of the spatial origin, at time $t=u_n$, with $\mathfrak{I}^+$; the $(\zeta,\bar{\zeta})$ are just the null directions, at the origin, carried along by the null generators of the lightcone. Using Cartesian coordinates x^a for the space–time and these natural Bondi coordinates,[15] the light cone cuts can be described as

$$u_n=x^a l_a(\zeta,\bar{\zeta}), \tag{18}$$

where l_a represents the covariant version of a null vector l^a with Cartesian components given as

$$\begin{aligned} l^a(\zeta,\bar{\zeta}) &= \frac{1}{\sqrt{2}(1+\zeta\bar{\zeta})}\,((1+\zeta\bar{\zeta}),(\zeta+\bar{\zeta}),i(\bar{\zeta}-\zeta),(\zeta\bar{\zeta}-1)) \\ &= \frac{1}{\sqrt{2}}\,(1,\sin\,\theta\,\cos\,\phi,\sin\,\theta\,\sin\,\phi,\cos\,\theta). \end{aligned} \tag{19}$$

Adding the radial coordinate r, this natural choice of Bondi coordinates is identical to the standard null polar coordinates $(u_n,r,\zeta,\bar{\zeta})$ given by

$$x^a=ut^a+rl^a(\zeta,\bar{\zeta}),\quad t^a=\sqrt{2}(1,0,0,0). \tag{20}$$

Note that Eqs. (18) and (19) are identical with Eqs. (9) and (10) though their meanings are different; Eq. (18) has the dual meaning of being, for fixed value of the x^a, the light cone cut of $\mathfrak{I}^+$ and also, for fixed values of $(u_n,\zeta,\bar{\zeta})$, it describes the plane wave (null surface) intersecting the time axis at $t=u_n$ in the direction of $(\zeta,\bar{\zeta})$.

By Eq. (18), the light cone cuts of any points $x^a=(t,0,0,0)$ along the time axis take, as we mentioned earlier, a constant value on $\mathfrak{I}^+$, namely, they are the constant-u_n slices. The natural Bondi cuts are light cone cuts as well. By following inwardly the null geodesics that leave the natural Bondi cuts orthogonally, we find no focusing other than at the apex (on the time axis) of the light cone.

By a slight modification of the above we can find other null surfaces leaving $\mathfrak{I}^+$ that have much more complicated focusing properties than that of a light cone. If we consider the one-parameter family of cuts of $\mathfrak{I}^+$ given, say by,

$$u_n=-\alpha(\zeta,\bar{\zeta})+u, \tag{21}$$

where $\alpha(\zeta,\bar{\zeta})$ is a given but arbitrary regular function on S^2, and u is a parameter on R, we can ask for the null surfaces generated by the null normals to the family of cuts.

• Note that Eq. (21) can be rewritten as $u=u_n+\alpha(\zeta,\bar{\zeta})$ and reinterpreted as a [Bondi–Metzner–Sachs (BMS)] supertranslation[11] between the coordinates u_n and u on $\mathfrak{I}^+$.

We now construct the null surface formed by the normal rays to the cuts, Eq. (21), determined by $u=$const; replacing the u_n in Eq. (21) by the null planes Eq. (18), $[u_n=x^a l_a(\zeta,\bar{\zeta})]$, we have

$$u=x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta}), \tag{22}$$

which is identical to Eq. (11). The envelope formed from all the null planes that are normal to the family of cuts are found by setting to zero the ζ and $\bar{\zeta}$ derivatives of Eq. (22) and eliminating the $(\zeta,\bar{\zeta})$ from (22), a procedure *identical* to that followed in the previous section to obtain Eq. (17), i.e., we now have the one-parameter family of null surfaces

$$S^{**}\equiv u=\frac{t}{\sqrt{2}}+x^i l_i(\Upsilon,\bar{\Upsilon})+\alpha(\Upsilon,\bar{\Upsilon}) \tag{23}$$

with $\zeta=\Upsilon(x,y,z)$, a solution of Eqs. (12) and (13). The procedure of setting to zero the ω and $\bar{\omega}$ in

$$\omega\equiv x^a m_a(\zeta,\bar{\zeta})+\bar{\eth}\alpha(\zeta,\bar{\zeta})=0, \tag{24}$$

$$\bar{\omega}\equiv x^a \bar{m}_a(\zeta,\bar{\zeta})+\bar{\eth}\alpha(\zeta,\bar{\zeta})=0 \tag{25}$$

selects the null ray at each point of $\mathfrak{I}^+$ that is orthogonal to the cut given by Eq. (21).

• Note that α can be chosen to contain only spherical harmonics of order $l\geq 2$ since any $l=0,1$ components of α could be absorbed by $x^a l_a$ with no modification other than displacing the origin of the coordinates x^a, since l_a is precisely the collection of spherical harmonics of order 0 and 1.

We can give a parametric description of the family of null surfaces, Eq. (23), by the following procedure: we consider the four functions

$$\zeta=\Upsilon(x,y,z)\Leftrightarrow x^a m_a(\zeta,\bar{\zeta})+\eth\alpha(\zeta,\bar{\zeta})=0, \tag{26}$$

$$\bar{\zeta}=\bar{\Upsilon}(x,y,z)\Leftrightarrow x^a \bar{m}_a(\zeta,\bar{\zeta})+\bar{\eth}\alpha(\zeta,\bar{\zeta})=0, \tag{27}$$

$$u=u(t,x,y,z)=\{x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta})\}|_{\Upsilon,\bar{\Upsilon}}, \tag{28}$$

$$r=r(x,y,z)=\{x^a(n_a-l_a)(\zeta,\bar{\zeta})+\eth\bar{\eth}\alpha(\zeta,\bar{\zeta})\}|_{\Upsilon,\bar{\Upsilon}}, \tag{29}$$

and consider them as a coordinate transformation between the $\{u,\zeta,\overline{\zeta},r\}$ and the $\{x^a\}$. We have used $m^a \equiv \eth l^a$, $\overline{m^a} \equiv \bar{\eth} l^a$, and $n^a \equiv \eth\bar{\eth} l^a + l^a$. From the fact that $(l^a,m^a,\overline{m^a},n^a)$ form a null tetrad for every fixed value of $(\zeta,\overline{\zeta})$, this coordinate transformation can be readily inverted into the form

$$x^a = (u-\alpha)(n^a+l^a) + (r-\eth\bar{\eth}\alpha)l^a + (\eth\alpha)\overline{m^a} + (\bar{\eth}\alpha)m^a. \tag{30}$$

This relationship can alternatively be looked on as the parametric version of the one-parameter family of null surfaces, Eq. (23) [where, for fixed u, the $(r,\zeta,\overline{\zeta})$ parametrize the surface], or as the coordinate transformation between the $\{x^a\}$ and the null-geodesic coordinates, $(u,\zeta,\overline{\zeta},r)$; u labels the null surfaces, the pair $(\zeta,\overline{\zeta})$ labels null geodesics (via their intersection with $\mathfrak{I}^+$), and r is an affine parameter along the null geodesics. That this is true can be easily seen from the parametric form, Eq. (30), by simply constructing

$$\frac{dx^a}{dr} = l^a(\zeta,\overline{\zeta}) \tag{31}$$

and observing that l^a is a null tangent vector with affine normalization.

The transformation between the x^a and the $(u,r,\zeta,\overline{\zeta})$ breaks down when the Jacobian of the transformation, Eq. (30), vanishes, i.e., when

$$D \equiv \frac{\partial(t,x,y,z)}{\partial(u,r,\zeta,\overline{\zeta})} = r^2 - \eth^2\alpha\bar{\eth}^2\alpha = 0. \tag{32}$$

Geometrically, this is where the null surface develops singularities. In the projection to the three-space (x,y,z) it is a two-surface; the ''caustic surface.'' To see this explicitly, we return to Eq. (30) where we have (for fixed u) that $(x,y,z) = x^i = X^i(r,\zeta,\overline{\zeta})$, i.e., are known functions of $(r,\zeta,\overline{\zeta})$. If the r in X^i is replaced by the r from Eq. (32) we have the parametric form of the caustic,

$$x^i = X^i(r(\zeta,\overline{\zeta}),\zeta,\overline{\zeta}) = \hat{X}^i(\zeta,\overline{\zeta}). \tag{33}$$

We will return to this in the next section.

It is interesting to note that the coordinates $(u,\zeta,\overline{\zeta},r)$ represent a type of null coordinate system that we could call *asymptotic null-polar coordinates* which are the flat space case of an *interior Bondi coordinate system*,[16,11] i.e., the extension into the interior of the space–time of the Bondi coordinates $(u,\zeta,\overline{\zeta})$ on $\mathfrak{I}^+$. They differ from the standard null polar coordinates by the fact that the null geodesics that rule these surfaces possess nonvanishing shear while for the standard ones the shear vanishes.

The complex shear is defined as $\sigma = M^aM^b\nabla_aL_b$, where L_b is tangent to the null geodesics and M^a is complex null, orthogonal to L_b, and such that $M^a\overline{M}_a = -1$. In our case, because of Eqs. (30) and (31) and the fact that $(l^a,m^a,\overline{m^a},n^a)$ forms a null tetrad, we have that $L_b = l_b$ and $M^a = m^a$. Furthermore, the gradient of l_b is $\nabla_a l_b = m_a\zeta_{,b} + \overline{m}_a\overline{\zeta}_{,b}$ and thus $\sigma = -m_a^b\overline{\zeta}_{,b}$. To obtain the derivative of $\overline{\zeta}$ along m^b we take the gradients of Eqs. (24) and (25) which yields

$$m_b(\zeta,\overline{\zeta}) + \{x^a(n_a - l_a) + \eth\bar{\eth}\alpha\}\overline{\zeta}_{,b} + \eth^2\alpha\zeta_{,b} = 0, \tag{34}$$

$$\overline{m}_b(\zeta,\overline{\zeta}) + \{x^a(n_a - l_a) + \eth\bar{\eth}\alpha\}\zeta_{,b} + \bar{\eth}^2\alpha\overline{\zeta}_{,b} = 0. \tag{35}$$

Using Eq. (29) and contracting Eqs. (34) and (35) by m^b, we obtain

$$rm^b\overline{\zeta}_{,b} + \bar{\eth}^2\alpha m^b\zeta_{,b} = 0, \tag{36}$$

$$-1+rm^b\zeta_{,b}+\bar{\eth}^2\alpha m^b\overline{\zeta_{,b}}=0. \tag{37}$$

By eliminating the $m^b\zeta_{,b}$ from these equations, we find

$$(r^2-\eth^2\alpha\bar{\eth}^2\alpha)m^b\overline{\zeta_{,b}}+\eth^2\alpha=0 \tag{38}$$

or

$$\sigma=\frac{\sigma^0}{r^2-\sigma^0\overline{\sigma^0}}, \tag{39}$$

where $\sigma^0=\eth^2\alpha$. This is also a confirmation of the Sachs theorem on the transformation of the asymptotic shear, σ^0, under a BMS transformation. Equation (39) represents a special (nontwisting) case of a more general result valid for generic null congruences in flat space.[17]

We point out that the flat-space line element, using Eq. (30), can easily be expressed in terms of these shearing Bondi coordinates as[18]

$$ds^2=\eta_{ab}dx^a dx^b=2du\left(du+dr-\bar{\eth}\eth^2\alpha\,\frac{d\zeta}{P}-\eth\bar{\eth}^2\alpha\,\frac{d\overline{\zeta}}{P}\right)-\frac{2r}{P^2}\,(\eth^2\alpha d\zeta^2+\bar{\eth}^2\alpha d\overline{\zeta}^2)$$
$$-2(r^2+\eth^2\alpha\bar{\eth}^2\alpha)\,\frac{d\zeta d\overline{\zeta}}{P^2}, \tag{40}$$

where $P=1+\zeta\overline{\zeta}$. The determinant of g_{ab} is given by $|g|=(1/P^4)\{r^2-\eth^2\alpha\bar{\eth}^2\alpha\}^2=D^2/P^4$ whose vanishing agrees with the vanishing of the Jacobian, Eq. (32).

Note that the asymptotic $r=\text{const}\Rightarrow\infty$ sections, at $u=\text{const}$, become metric spheres.

• It is perhaps interesting to speculate on the use of Eq. (40) as the Minkowski space lowest-order term, in perturbation calculations, for solutions of the Einstein equations.

We complete this section by showing how a null surface can be constructed explicitly from the normals to an arbitrary spacelike two surface, $\mathfrak{S}$, in a manner virtually identical to those constructed from a cut or slice of null infinity.

We begin from Eq. (22)

$$u=0=x^a l_a(\zeta,\overline{\zeta})+\alpha(\zeta,\overline{\zeta})$$

with Eqs. (24) and (25). The issue is, given the surface $\mathfrak{S}$, how is one to choose $\alpha(\zeta,\overline{\zeta})$?

First $\mathfrak{S}$ is defined parametrically, $x^a=x_0^a(\zeta,\overline{\zeta})$, where the parameters are chosen as follows: consider a timelike world line at the spacial origin and the family of light cones centered on the line. The null geodesics ruling these cones are labeled by their directions $(\zeta,\overline{\zeta})$ on the sphere and coincide with labeling of the generators of null infinity. The points on $\mathfrak{S}$ are now (locally) parametrized by the labels of the null geodesics passing thru those points. With this parametrization the function $\alpha(\zeta,\overline{\zeta})$ is defined by

$$\alpha(\zeta,\overline{\zeta})=-x_0^a(\zeta,\overline{\zeta})l_a(\zeta,\overline{\zeta})$$

so that Eq. (23) becomes

$$u=0=(x^a-x_0^a(\zeta,\overline{\zeta}))l_a(\zeta,\overline{\zeta})$$

and Eqs. (24) and (25) become

$$(x^a-x_0^a(\zeta,\overline{\zeta}))m_a(\zeta,\overline{\zeta})-l_a(\zeta,\overline{\zeta})\eth x_0^a=0 \quad \text{and} \quad \text{c.c.} \tag{41}$$

We see that the null surface so defined goes thru $\mathfrak{S}$, i.e., thru $x^a = x_0^a(\zeta,\bar{\zeta})$. To see that it is also normal to $\mathfrak{S}$, we notice that at $\mathfrak{S}$ the first two terms of Eq. (41) cancel out and we are left at $\mathfrak{S}$ with

$$l_a(\zeta,\bar{\zeta})\eth x_0^a = 0.$$

Thus as was claimed, the tangent vectors to $\mathfrak{S}$, namely $\eth x_0^a(\zeta,\bar{\zeta})$, are normal to the null tangent vectors to the null surface, l_a.

We see that the earlier construction of null surfaces from cuts of null infinity actually includes those constructed from finite surfaces.

IV. WAVEFRONT EVOLUTION AND SINGULARITIES

In the previous section, we mentioned that the null coordinate system broke down and the associated shearing null surfaces developed caustics at the points where $r^2 = \eth^2\alpha\bar{\eth}^2\alpha$.

Here we focus our attention on the two-dimensional wavefronts associated with these null surfaces. We show that the wavefronts develop singularities, and we locate the singularities via the standard method of singularity theory, and via our light cone cut approach. The evolution of these singularities as the wave fronts evolve become the caustics.

A wavefront is, by definition, the intersection of our null surface, $u = u_0$, with a constant-time t_0 surface. This represents an instant in the progression of a wave. In our case, this requires fixing the time coordinate $x^0 = t_0$ in Eq. (30) and solving for

$$r = \sqrt{2}t_0 - 2u_0 + 2\alpha + \eth\bar{\eth}\alpha. \tag{42}$$

The remaining coordinates (x,y,z), using Eq. (42) to eliminate r, trace a two-surface (a ''small'' wavefront) in the Euclidean three-space, parametrized by $(\zeta,\bar{\zeta})$ [or (θ,ϕ) under the transformation $\zeta = e^{i\phi}\cot\theta/2$]:

$$x = \frac{1}{\sqrt{2}}\left[(\sqrt{2}t_0 - 2u_0 + 2\alpha)\,\frac{(\zeta+\bar{\zeta})}{(1+\zeta\bar{\zeta})} + \bar{\eth}\alpha\,\frac{(1-\bar{\zeta}^2)}{(1+\zeta\bar{\zeta})} + \eth\alpha\,\frac{(1-\zeta^2)}{(1+\zeta\bar{\zeta})}\right], \tag{43}$$

$$y = \frac{i}{\sqrt{2}}\left[(\sqrt{2}t_0 - 2u_0 + 2\alpha)\,\frac{(\bar{\zeta}-\zeta)}{(1+\zeta\bar{\zeta})} - \bar{\eth}\alpha\,\frac{(1+\bar{\zeta}^2)}{(1+\zeta\bar{\zeta})} + \eth\alpha\,\frac{(1+\zeta^2)}{(1+\zeta\bar{\zeta})}\right], \tag{44}$$

$$z = \frac{1}{\sqrt{2}}\left[(\sqrt{2}t_0 - 2u_0 + 2\alpha)\,\frac{(\zeta\bar{\zeta}-1)}{(1+\zeta\bar{\zeta})} + \bar{\eth}\alpha\,\frac{2\bar{\zeta}}{(1+\zeta\bar{\zeta})} + \eth\alpha\,\frac{2\zeta}{(1+\zeta\bar{\zeta})}\right]. \tag{45}$$

The map $(\zeta,\bar{\zeta}) \to (x,y,z)$ is singular at points where the Jacobian matrix

$$\begin{pmatrix} \eth x & \bar{\eth}x \\ \eth y & \bar{\eth}y \\ \eth z & \bar{\eth}z \end{pmatrix} \tag{46}$$

drops rank, from 2 to 1 or 0. The drop in rank takes place if the three two-determinants vanish simultaneously:

$$\eth x\bar{\eth}y - \eth y\bar{\eth}x = 0, \tag{47}$$

$$\eth y\bar{\eth}z - \eth z\bar{\eth}y = 0, \tag{48}$$

$$\eth z \bar{\eth} x - \eth x \bar{\eth} z = 0. \tag{49}$$

Since

$$\eth x^a|_{u,t} = \eth^2 \alpha \overline{m}^a + r m^a, \tag{50}$$

$$\bar{\eth} x^a|_{u,t} = \bar{\eth}^2 \alpha m^a + r \overline{m}^a, \tag{51}$$

the explicit expressions of the two-determinants are as follows:

$$\eth x \bar{\eth} y - \eth y \bar{\eth} x = (r^2 - \eth^2 \alpha \bar{\eth}^2 \alpha)(m^x \overline{m}^y - \overline{m}^x m^y), \tag{52}$$

$$\eth y \bar{\eth} z - \eth z \bar{\eth} y = (r^2 - \eth^2 \alpha \bar{\eth}^2 \alpha)(m^y \overline{m}^z - \overline{m}^y m^z), \tag{53}$$

$$\eth z \bar{\eth} x - \eth x \bar{\eth} z = (r^2 - \eth^2 \alpha \bar{\eth}^2 \alpha)(m^z \overline{m}^x - \overline{m}^z m^x). \tag{54}$$

Thus, all three determinants vanish at points where

$$D \equiv r^2 - \eth^2 \alpha \bar{\eth}^2 \alpha = 0, \tag{55}$$

which, with r from Eq. (42), determines a curve, the wavefront singularities. Note that the evolution of the wavefront singularities (obtained by varying t_0) yields the caustic surface.

Since α is a regular function on the sphere, so is $\eth^2 \alpha \bar{\eth}^2 \alpha$; therefore, Eq. (55) [with r given by Eq. (42)] admits solutions ζ only within a finite interval of time t. Thus the wavefronts are singular only during a closed interval of time. On the other hand, at very long times the wavefronts become spherical, which follows from the line element Eq. (40).

The wavefront singularities (curves) are places where neighboring null geodesics meet. We have a null surface $x^a(r,\zeta,\overline{\zeta})$ foliated by null geodesics. At every fixed value of r, there are two connecting vectors $\eth x^a|_{u,r}$ and $\bar{\eth} x^a|_{u,r}$. The null geodesics in this congruence meet wherever the area orthogonal to the congruence, spanned by the connecting vectors, vanishes. The connecting vectors are, explicitly,

$$\eth x^a|_{u,r} = -\bar{\eth}\eth^2 \alpha l^a + \eth^2 \alpha \overline{m}^a + r m^a, \tag{56}$$

$$\bar{\eth} x^a|_{u,r} = -\eth\bar{\eth}^2 \alpha l^a + r \overline{m}^a + \bar{\eth}^2 \alpha m^a. \tag{57}$$

The area spanned by the connecting vectors (calculated from their skew product) is simply $D \equiv r^2 - \eth^2 \alpha \bar{\eth}^2 \alpha$. The vanishing of this area takes place at exactly the points given by Eq. (55).

We close this section with two examples.

Example 1: $\alpha = Y_{20} = 3\cos^2\theta - 1$. Due to axial symmetry, the wavefronts and their singularities for this choice of α can be completely worked out analytically, which gives insights into more general cases. The wavefronts at a given time t are given by

$$x = \frac{1}{\sqrt{2}} \sin\theta \cos\phi(\sqrt{2}t - 2u - 2 - 6\cos^2\theta), \tag{58}$$

$$y = \frac{1}{\sqrt{2}} \sin\theta \sin\phi(\sqrt{2}t - 2u - 2 - 6\cos^2\theta), \tag{59}$$

$$z = \frac{1}{\sqrt{2}} \cos\theta(\sqrt{2}t - 2u + 10 - 6\cos^2\theta). \tag{60}$$

These are axially symmetric. For a closed interval of time, all the wavefronts are singular. For early and late times, however, the wavefronts are smooth.

The singular points are located by eliminating r from Eqs. (55) and (42), yielding in this case, the two solutions or ''sheets''

$$(\sqrt{2}t-2u+10-18\cos^2\theta)(\sqrt{2}t-2u-2-6\cos^2\theta)=0. \tag{61}$$

There is a solution θ only at times $\sqrt{2}(u-5)\leqslant t\leqslant\sqrt{2}(4+u)$. This is the interval where every wavefront is singular. A smooth wavefront and its corresponding profile at a late time are shown in Fig. 1. A wavefront at a time when both the cusp ridge singularities and the z-axis singularities are occurring, and its corresponding profile, are shown in Fig. 2. In Fig. 3, we have a later wavefront and profile with only the cusp ridge singularity. In Fig. 4, we display the evolution of the singularities forming the caustic two-surface.

The high symmetry of this case is responsible for the lack of resemblance of the singular points on the z axis with standard cusps. At these points, null geodesics labeled by different, but neighboring, values of ϕ meet. This is clear from the fact that $\partial x/\partial\phi=\partial x/\partial\phi=\partial z/\partial\phi=0$ at these points, therefore the vector that connects geodesics with different values of ϕ vanishes.

In order to make a comparison, Fig. 5 shows a wavefront in the evolution of an imploding ellipsoid of revolution which is very similar to that of example 1. In this case, an ellipsoid of revolution sends an incoming wavefront, which develops singularities during a certain interval of time. The standard cuspoidal ridges are clearly visible as rings at both ends of the figure. However, the crossover points in between are also singular, of the same type of singularity as that one developed in our example. Assuming a speed of light of 1, the formulas for the imploding wavefront in this case are

$$x=a\sin\theta\cos\phi\left(1-\frac{t}{\sqrt{a^2\sin^2\theta+(a^2/c)^2\cos^2\theta}}\right), \tag{62}$$

$$y=a\sin\theta\sin\phi\left(1-\frac{t}{\sqrt{a^2\sin^2\theta+(a^2/c)^2\cos^2\theta}}\right), \tag{63}$$

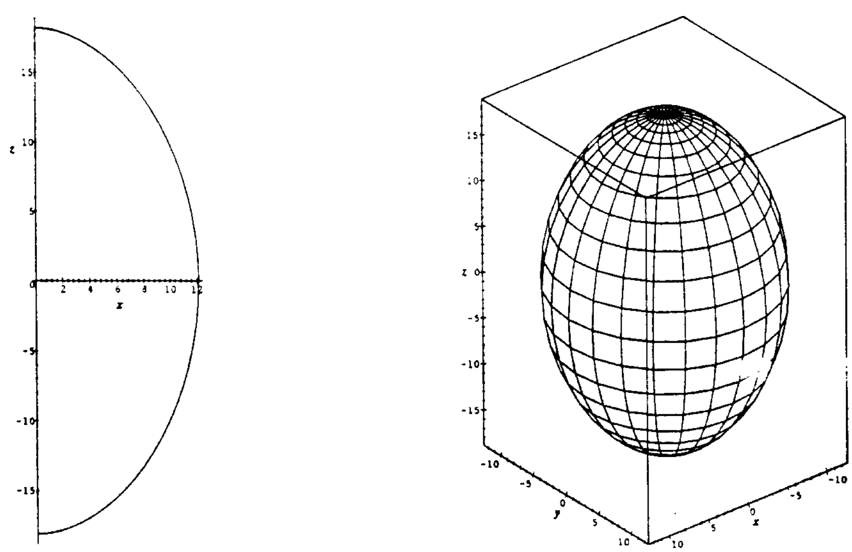

FIG. 1. The wavefront and profile ($t=10$, $u=0$) of the shearing Bondi congruence with $\alpha=Y_{20}(\theta,\phi)$.

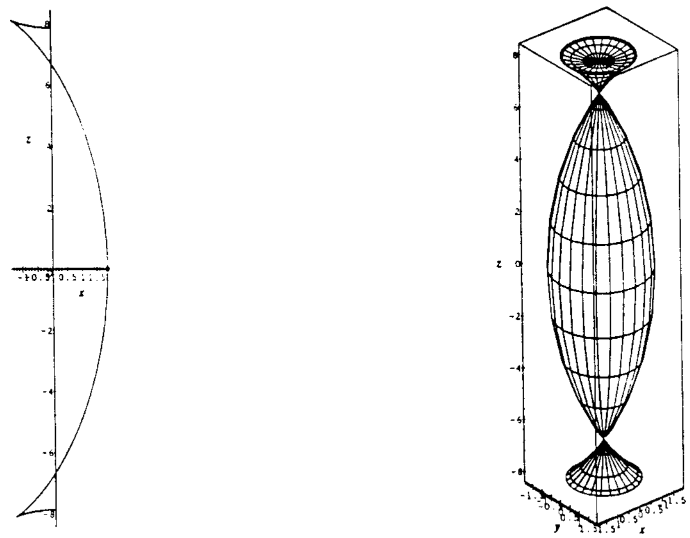

FIG. 2. The wavefront and profile ($t=2.73$, $u=0$) of the shearing Bondi congruence with $\alpha=Y_{20}(\theta,\phi)$. Notice the focusing at the crossover point.

$$z=c\,\cos\,\theta\left(1-\frac{t}{\sqrt{(c^2/a)^2\,\sin^2\,\theta+c^2\,\cos^2\,\theta}}\right). \tag{64}$$

Example 2: $\alpha=\mathrm{Real}\,(Y_{21})=(\zeta+\bar{\zeta})(\zeta\bar{\zeta}-1)/(1+\zeta\bar{\zeta})^2$. In this case, there is no advantage in writing the wavefronts explicitly. However, they can be plotted with ease, displaying the typical singularities of three-dimensional wavefronts, namely swallowtails and cusp ridges. Cusp ridges are clearly visible in Fig. 6, which represents a wavefront at $u=0$ and $t=1.5$. Swallowtails are exemplified in Fig. 7, which represents another wavefront in the same $u=0$ family, but at a later time of $t=2.35$. Locally all swallowtails have the form of Fig. 8.

Both Figs. 6 and 7 compare remarkably well with a typical wavefront in the evolution of a triaxial ellipsoid, in which case an ellipsoid $(x/a)^2+(y/b)^2+(z/c)^2=1$ emits a wavefront of light

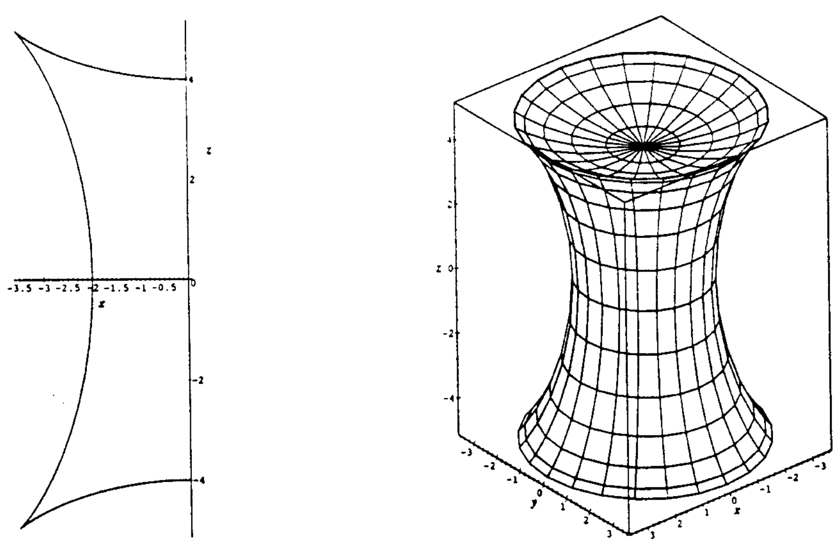

FIG. 3. The wavefront and profile ($t=0$, $u=0$) of the shearing Bondi congruence with $\alpha=Y_{20}(\theta,\phi)$. The only singularities are the standard cups, showing as rings.

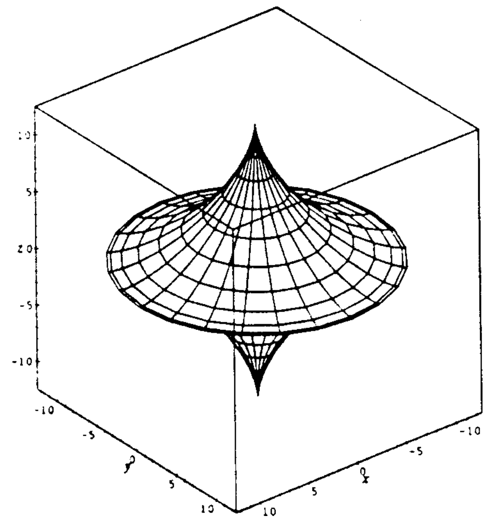

FIG. 4. The caustic surface ($u=0$) of the shearing Bondi congruence with $\alpha = Y_{20}(\theta,\phi)$. The caustic is the time evolution of the cusp ridges, projected in three-space. There is another sheet of the caustic surface, representing the time evolution of the crossover singularities, which is a line along the z axis, not visible in this picture.

inwardly, which develops singularities for a period of time. A typical singular imploding wavefront is shown in Fig. 9. The formulas for the imploding triaxial-ellipsoidal wavefront are the following:

$$x = a \sin\theta \cos\phi \left(1 - \frac{t}{a^2 \sqrt{(\sin\theta\cos\phi/a^2)^2 + (\sin\theta\sin\phi/b^2)^2 + (\cos\theta/c^2)^2}} \right),$$

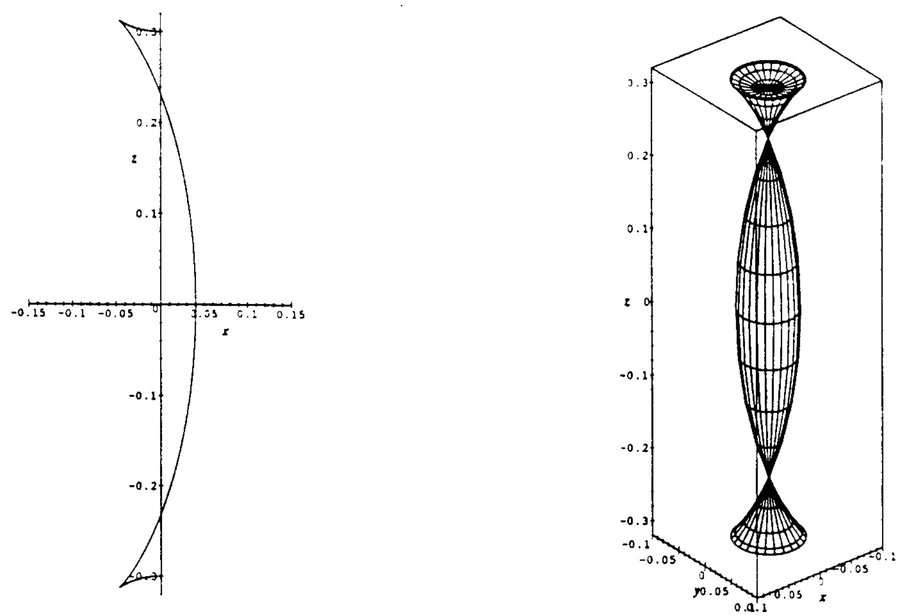

FIG. 5. A wavefront, and its profile, in the evolution of an imploding ellipsoid of revolution. The semiaxes of the initial ellipsoid $(x/a)^2+(y/b)^2+(z/c)^2=1$ have been chosen as $a=b=1$ and $c=1.2$, and the instant of time is $t=0.9$ assuming a speed of light of 1. Notice the cuspoidal ridges and the focusing at the crossover points.

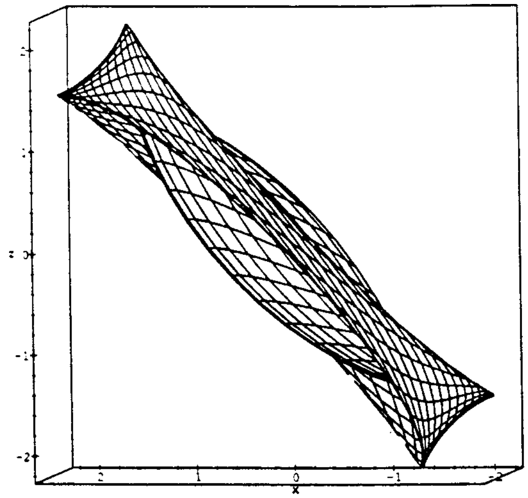

FIG. 6. A wavefront ($t=1.5$, $u=0$) of the shearing Bondi congruence with $\alpha=\Re(Y_{21}(\theta,\phi))$. Notice the cuspoidal ridges.

$$y=b\,\sin\,\theta\,\sin\,\phi\left(1-\frac{t}{b^2\sqrt{(\sin\,\theta\,\cos\,\phi/a^2)^2+(\sin\,\theta\,\sin\,\phi/b^2)^2+(\cos\,\theta/c^2)^2}}\right),\qquad(65)$$

$$z=c\,\cos\,\theta\left(1-\frac{t}{c^2\sqrt{(\sin\,\theta\,\cos\,\phi/a^2)^2+(\sin\,\theta\,\sin\,\phi/b^2)^2+(\cos\,\theta/c^2)^2}}\right).$$

V. GENERATING FAMILIES

In this section we will study the subject of the caustics of the null surfaces and the wavefront singularities via an alternative method, namely from the use of generating families for the construction of Lagrangian and Legendre submanifolds (developed by V. I. Arnold and his colleagues[1–4]) associated with cotangent and contact bundles over space–time. The value of this treatment is that it allows one to deal (via a parametric representation) with the regions of self-intersection and nondifferentiability of the null surfaces.

We first give a brief review of a special case of this theory that is adapted to the problem of null surfaces in four-dimensional space–time. Consider a four-dimensional Lorentzian manifold (with local coordinates, $\{t,x^i\}$) foliated by the constant t surfaces. Now consider the x^i as the coordinates of a configuration space M and p_i as the conjugate momentum so that we have the six-dimensional cotangent bundle T^*M, with local coordinates (x^i,p_i). We now describe the construction of a three-dimensional submanifold of T^*M (a Lagrangian submanifold—a maximal submanifold such that the symplectic form, restricted to it, vanishes) that plays a fundamental role in the discussion of the singularities of wavefronts and their associated caustics. We begin with a general description without any particular choice of dynamics, later restricting ourselves to null geodesic motion.

Choose a scalar function (determined later from the dynamics), referred to as a generating family, of the six variables

$$f=F(t,x^i,\zeta,\bar{\zeta});\qquad(66)$$

the x^i are spatial points, the $(\zeta,\bar{\zeta})$ are parametric labels (for convenience we are using a complex representation) for points on a given spatial two-surface, $\mathfrak{s}$, i.e., we have a two-point function, while t is the time for the (dynamic) particle to go from a point on $\mathfrak{s}$ to the point x^i. For a constant value of f, we consider Eq. (66) as defining t implicitly as a function of $(x^i,\zeta,\bar{\zeta})$, i.e.,

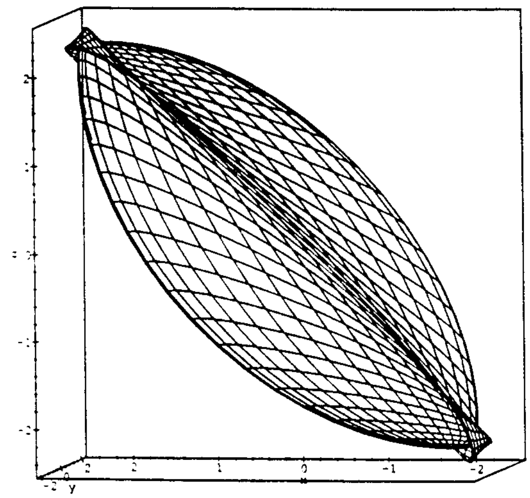

FIG. 7. A wavefront ($t=2.35$, $u=0$) of the shearing Bondi congruence with $\alpha=\Re(Y_{21}(\theta,\phi))$. Notice the swallowtails and the cuspoidal ridges.

$$t=T(f;x^i,\zeta,\overline{\zeta})$$

or simply

$$t=T(x^i,\zeta,\overline{\zeta}). \tag{67}$$

Note that T might be a multivalued function of its arguments, in which case it must be considered separately on the different sheets.

We now ask for the relationship between the $(x^i,\zeta,\overline{\zeta})$ when T is an extremal under variations of the $(\zeta,\overline{\zeta})$; i.e., we require that

$$\partial T/\partial\zeta=\partial T/\partial\overline{\zeta}=0, \tag{68}$$

which in turn forces

$$\partial F/\partial\zeta=\partial F/\partial\overline{\zeta}=0. \tag{69}$$

Finally, a rank condition is imposed on the choice of F; the following 2×5 matrix must have rank 2:

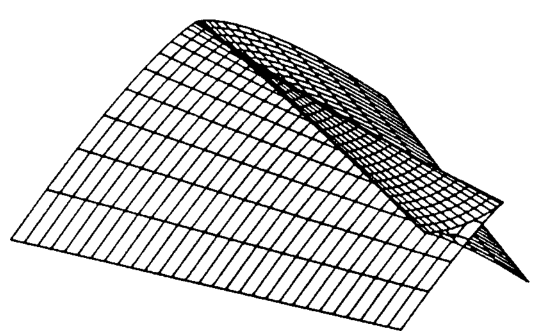

FIG. 8. The general form of a swallowtail singularity.

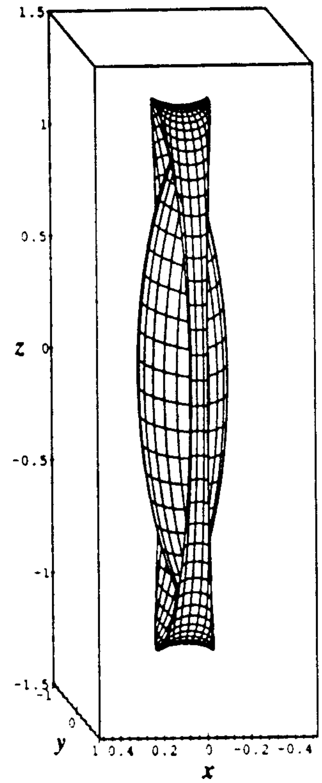

FIG. 9. An imploding triaxial-ellipsoidal wavefront, corresponding to $t=0.8$ and semiaxes $a=1$, $b=1.5$, and $c=2$ and assuming a speed of light of 1. Notice the cuspoidal ridges. Earlier instants, such as $t=0.65$, display swallowtails as well, not visible here.

$$\begin{bmatrix} \frac{\partial^2 F}{\partial \zeta^2} & \frac{\partial^2 F}{\partial \zeta \partial \overline{\zeta}} & \frac{\partial^2 F}{\partial \zeta \partial x^i} \\ \frac{\partial^2 F}{\partial \zeta \partial \overline{\zeta}} & \frac{\partial^2 F}{\partial \overline{\zeta}^2} & \frac{\partial^2 F}{\partial \overline{\zeta} \partial x^i} \end{bmatrix}. \tag{70}$$

The meaning of this condition is that the two equations [(69) or (68)] can be solved (locally) in at least one of a variety of possible ways for two of the five variables $(x^i,\zeta,\overline{\zeta})$; often it is necessary to solve them in different ways in different regions. We then have three different possible cases:

(1) $\zeta=\Upsilon(x^i)$, $\overline{\zeta}=\overline{\Upsilon}(x^i)$; the simplest of the three cases. It allows F to be treated as a function of just x^i. In the other cases F must be treated parametrically.
(2) $\zeta=\Psi(x^A,\overline{\zeta})$, $x^J=X^J(x^A,\overline{\zeta})$, where x^A are any two of the three x^i and x^J is the third one, or the conjugate version, $\overline{\zeta}=\overline{\Psi}(x^A,\zeta)$, $x^J=X^J(x^A,\zeta)$.
(3) $x^A=X^A(x^J,\zeta,\overline{\zeta})$, where again x^A are any two of the three x^i and x^J is the third one.

Case 1 can occur when the determinant

$$\hat{D}=\begin{vmatrix} \frac{\partial^2 F}{\partial \zeta^2} & \frac{\partial^2 F}{\partial \zeta \partial \overline{\zeta}} \\ \frac{\partial^2 F}{\partial \zeta \partial \overline{\zeta}} & \frac{\partial^2 F}{\partial \overline{\zeta}^2} \end{vmatrix} \neq 0; \tag{71}$$

$\hat{D}=0$ when there is a critical point of the Lagrangian map defined shortly.

The Lagrangian submanifold obtained from F is defined in the following way:

First we have $p_i=\partial F/\partial x^i$. [Note that this involves only the explicit x^i dependence in F since any implicit dependence, via the $(\zeta,\bar{\zeta})$, does not enter into the definition of p_i because of Eq. (69).] Now depending on which case, 1, 2, or 3, is relevant, we eliminate two of the five variables $(x^i,\zeta,\bar{\zeta})$, in the $p_i=(\partial F/\partial x^i)(x^i,\zeta,\bar{\zeta})$. This leaves the result that the six coordinates of T^*M can be expressed in terms of three parameters, thus defining a three-dimensional submanifold in each of the cases;

(i) In case 1, $p_i=P_i(x^i)$, $x^i=x^i$; the three parameters $\{x^i\}=\chi^\alpha$.
(ii) In case 2, $p_i=P_i(x^A,\bar{\zeta})$, $x^A=x^A$, $x^J=X^J(x^A,\bar{\zeta})$; the three parameters $\{x^A,\bar{\zeta}\}=\chi^\alpha$.
(iii) In case 3, $p_i=P_i(x^J,\zeta,\bar{\zeta})$, $x^A=X^A(x^J,\zeta,\bar{\zeta})$, $x^J=x^J$; the three parameters $\{x^J,\zeta,\bar{\zeta}\}=\chi^\alpha$.

To simplify the discussion, we have referred to the three parameters, in each of the cases, simply as χ^α. In each case we thus have

$$x^i=X^i(\chi^\alpha), \quad p_i=P_i(\chi^\alpha). \tag{72}$$

Of immediate relevance to us is the projection (Lagrange map) of the Lagrange submanifold into the configuration space which becomes in each of the cases, $x^i=X^i(\chi^\alpha)$ or

(i) in case 1, $x^i=x^i$, trivial diffeomorphism,
(ii) in case 2, $x^A=x^A$, $x^J=X^J(x^A,\bar{\zeta})$,
(iii) in case 3, $x^A=X^A(x^J,\zeta,\bar{\zeta})$, $x^J=x^J$.

The caustics of this problem are the regions in the configuration space where the mappings 1, 2, or 3 have rank 2 or 1; i.e, where the Jacobian of the mapping vanishes. They occur when the determinant $\hat{D}=0$. The inverse image to the caustics in the parameter space are referred to as the critical points of the Lagrange map. It is clear that in case 1, the Jacobian is one and rank reduction can only occur in cases 2 and 3.

This treatment of caustics can be extended into the full four-space by eliminating, in the expression for $t=T(f;x^i,\zeta,\bar{\zeta})$, or in the implicit version, $f=F(t,x^i,\zeta,\bar{\zeta})$, two of the five variables $(x^i,\zeta,\bar{\zeta})$ via the cases 1, 2, 3. This results in t now are a function of the three parameters, χ^α. Though we will not need the full theory here, this construction leads to a seven-dimensional manifold, (t,x^i,p_i) {an example of a contact manifold}, and a three-dimensional submanifold of the contact manifold (a Legendre submanifold) defined by

$$t=T(\chi^\alpha), \quad x^i=X^i(\chi^\alpha), \quad p_i=P_i(\chi^\alpha), \tag{73}$$

as well as the Legendre mapping from the Legendre submanifold, to space–time, (t,x^i),

$$\{t,x^i,p_i\}(\chi^\alpha)\Rightarrow t=T(\chi^\alpha), \quad x^i=X^i(\chi^\alpha), \tag{74}$$

a three-surface in space–time—the ''big wavefronts'' in Arnold's language—in our case a null surface. The singularities of the map (74), where the rank drops below 3, are the null surface singularities. These singularities, at fixed t, are the (''small'') wavefront singularities of the previous section.

We now return to the question of the determination of the function $f=F(t,x^i,\zeta,\bar{\zeta})$ of Eq. (66) for use in the study of null surfaces. Our choice will be, from Eq. (11),

$$F(t,x^i,\zeta,\bar{\zeta})=S^{**}(t,x^i,\zeta,\bar{\zeta})\equiv x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta}). \tag{75}$$

There are three independent reasons for this choice;

(1) It was the method of generating an arbitrary null surface from the complete solution, $x^a l_a(\zeta,\bar{\zeta})$; see Sec. II.
(2) It was the method for the construction of a null surface such that the generators were orthogonal to a given two-surface; see Sec. III.
(3) It arises from a variant of Fermat's principle of stationary time: Consider a timelike worldline, $\mathfrak{L}$ (in a Lorentzian space–time), of the form, in local coordinates, ($x^i=$const, t varies) and a two-dimensional spacelike surface, $\mathfrak{s}(\zeta,\bar{\zeta})$. Assume, locally, that from every point of $\mathfrak{s}(\zeta,\bar{\zeta})$ there is a null geodesic that reaches $\mathfrak{L}$ at a time $t=T(x^i,\zeta,\bar{\zeta})$. Then t is extremized by those curves that are normal to $\mathfrak{s}(\zeta,\bar{\zeta})$. This result (which will be described in detail elsewhere) follows from Schrödinger's derivation[19] of the gravitational frequency shift.

Note that the rank condition on the matrix, Eq. (70), is satisfied by direct calculation.

From the discussion of generating families, we see that the treatment of the null surfaces that we proposed, in Secs. II and III, namely to solve for the $\zeta=\Upsilon(x,y,z)$, was really only valid for case 1, but we actually used a version of case 3 where the additional parameter r was introduced in order not to single out any particular Cartesian coordinate. Case 1 broke down precisely on the caustic given by

$$r^2=\eth^2\alpha\bar{\eth}^2\alpha, \tag{76}$$

which is where cases 2 and 3 must be applied.

What follows is a straightforward application of case 3 of these ideas—on one patch. For completeness we repeat some of the earlier steps.

Starting with

$$u=S^{**}(x^a,\zeta,\bar{\zeta})=x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta}), \tag{77}$$

then

$$\begin{aligned}
\eth S^{**}&=\frac{1}{\sqrt{2}(1+\zeta\bar{\zeta})}\,[\bar{\zeta}^2W-\bar{W}-2z\bar{\zeta}]+\eth\alpha,\\
\bar{\eth}S^{**}&=\frac{1}{\sqrt{2}(1+\zeta\bar{\zeta})}\,[\zeta^2\bar{W}-W-2z\zeta]+\bar{\eth}\alpha,
\end{aligned} \tag{78}$$

with $W=(x+iy)$. From $\eth S^{**}=0$ and $\bar{\eth}S^{**}=0$, we obtain [from case 3, where x^A are (x,y) or $(W,\bar{W})$] that

$$\begin{aligned}
W&=\frac{\sqrt{2}(\bar{\eth}\alpha+\zeta^2\eth\alpha)-2z\zeta}{1-\zeta\bar{\zeta}},\\
\bar{W}&=\frac{\sqrt{2}(\eth\alpha+\bar{\zeta}^2\bar{\eth}\alpha)-2z\bar{\zeta}}{1-\zeta\bar{\zeta}}.
\end{aligned} \tag{79}$$

From Eq. (77) we have that

$$p_x=\frac{\partial S^{**}}{\partial x}=-\frac{\zeta+\bar{\zeta}}{\sqrt{2}(1+\zeta\bar{\zeta})},$$

$$p_y = \frac{\partial S^{**}}{\partial y} = \frac{i(\zeta - \bar{\zeta})}{\sqrt{2}(1+\zeta\bar{\zeta})}, \tag{80}$$

$$p_z = \frac{\partial S^{**}}{\partial z} = \frac{(1-\zeta\bar{\zeta})}{\sqrt{2}(1+\zeta\bar{\zeta})}.$$

Taking $p = \sqrt{2}(p_x + i p_y)$, we obtain

$$p = -\frac{2\zeta}{1+\zeta\bar{\zeta}}. \tag{81}$$

The Lagrange submanifold, parametrized by $(z, \zeta, \bar{\zeta})$, is given by

$$z = z, \tag{82}$$

$$W = \frac{\sqrt{2}(\bar{\eth}\alpha + \zeta^2 \eth\alpha) - 2z\zeta}{1-\zeta\bar{\zeta}}, \tag{83}$$

$$\bar{W} = \frac{\sqrt{2}(\eth\alpha + \bar{\zeta}^2 \bar{\eth}\alpha) - 2z\bar{\zeta}}{1-\zeta\bar{\zeta}}, \tag{84}$$

$$p = -\frac{2\zeta}{1+\zeta\bar{\zeta}}, \tag{85}$$

$$\bar{p} = -\frac{2\bar{\zeta}}{1+\zeta\bar{\zeta}}, \tag{86}$$

$$p_z = \frac{(1-\zeta\bar{\zeta})}{\sqrt{2}(1+\zeta\bar{\zeta})}. \tag{87}$$

The projection to the configuration space is given by

$$z = z,$$

$$W = \frac{\sqrt{2}(\bar{\eth}\alpha + \zeta^2 \eth\alpha) - 2z\zeta}{1-\zeta\bar{\zeta}}, \tag{88}$$

$$\bar{W} = \frac{\sqrt{2}(\eth\alpha + \bar{\zeta}^2 \bar{\eth}\alpha) - 2z\bar{\zeta}}{1-\zeta\bar{\zeta}}.$$

The critical points of the Lagrange map are obtained from the condition that the Jacobian

$$J = \frac{\partial(z, W, \bar{W})}{\partial(z, \zeta, \bar{\zeta})}. \tag{89}$$

vanishes. The vanishing of J is equivalent to $D=r^2-\eth^2\alpha\bar{\eth}^2\alpha=0$.

To construct the Legendrian submanifold [in the seven-dimensional contact space, (t,x^i,p_i)] we take the generating family $u=S^{**}(x^a,\zeta,\bar{\zeta})$ where u is constant and solve for t expressing the contact coordinate t in terms of the three parameters $(z,\zeta,\bar{\zeta})$ by

$$t=\frac{\zeta\bar{W}+\bar{\zeta}W-z(1-\zeta\bar{\zeta})}{(1+\zeta\bar{\zeta})}+\sqrt{2}[u-\alpha(\zeta,\bar{\zeta})] \tag{90}$$

with

$$W=\frac{\sqrt{2}(\bar{\eth}\alpha+\zeta^2\eth\alpha)-2z\zeta}{1-\zeta\bar{\zeta}},\qquad \bar{W}=\frac{\sqrt{2}(\eth\alpha+\bar{\zeta}^2\bar{\eth}\alpha)-2z\bar{\zeta}}{1-\zeta\bar{\zeta}}. \tag{91}$$

The full Legendre submanifold is then given by Eqs. (82)–(87) and (90).

Note that this entire construction, using Case 3, was valid where $1-\zeta\bar{\zeta}\neq 0$ (or equivalently where $p_z\neq 0$). To include the region where $p_z=0$, a different choice of parametrization would be necessary, e.g., $(x,\zeta,\bar{\zeta})$, which is valid in the region where $p_x\neq 0$ or $(y,\zeta,\bar{\zeta})$, valid where $p_y\neq 0$.

Using the example (2), from Sec. IV, given by

$$S^{**}(x^a,\zeta,\bar{\zeta})=x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta}),\quad \alpha=-\frac{(1-\zeta\bar{\zeta})(\zeta+\bar{\zeta})}{(1+\zeta\bar{\zeta})^2} \tag{92}$$

with

$$\eth S^{**}=0\Leftrightarrow\{x(-1+\bar{\zeta}^2)+iy(1+\bar{\zeta}^2)-2z\bar{\zeta}](1+\zeta\bar{\zeta})=\sqrt{2}[1+\bar{\zeta}^3\zeta-3\bar{\zeta}(\zeta+\bar{\zeta})] \tag{93}$$

and

$$\bar{\eth}S^{**}=0\Leftrightarrow\{x(-1+\zeta^2)-iy(1+\zeta^2)-2z\zeta](1+\zeta\bar{\zeta})=\sqrt{2}[1+\zeta^3\bar{\zeta}-3\zeta(\zeta+\bar{\zeta})], \tag{94}$$

one could try to solve for different pairs from the set $(x,y,z,\zeta,\bar{\zeta})$. When $D\neq 0$ one could always solve for $(\zeta,\bar{\zeta})$, though, in general, there would be more than one solution; i.e., for fixed (x,y,z) there would in general be more than one ray going thru that space-point, either at the same or at different times. Alternately one could try to solve in different regions for (x,y), (y,z), (z,x), etc. Solving for (x,y) or W we have that the Lagrange map [from the $(z,\zeta,\bar{\zeta})$ parameter space] becomes

$$W=\frac{\sqrt{2}(2\zeta^2+4\zeta\bar{\zeta}-1-\zeta^2\bar{\zeta}^2)-2z\zeta(1+\zeta\bar{\zeta})}{1-\zeta^2\bar{\zeta}^2}, \tag{95}$$

$$\bar{W}=\frac{\sqrt{2}(2\bar{\zeta}^2+4\zeta\bar{\zeta}-1-\zeta^2\bar{\zeta}^2)-2z\bar{\zeta}(1+\zeta\bar{\zeta})}{1-\zeta^2\bar{\zeta}^2}, \tag{96}$$

which in turn becomes the Legendre map when the contact coordinate t is added in:

$$t=\sqrt{2}\left\{u+\frac{1}{(1-\zeta\bar{\zeta})(1+\zeta\bar{\zeta})^2}\left[4\zeta\bar{\zeta}(\zeta+\bar{\zeta})-\frac{z}{\sqrt{2}}(1+3\zeta\bar{\zeta}+3\zeta^2\bar{\zeta}^2+\zeta^3\bar{\zeta}^3)\right]\right\}. \tag{97}$$

Though none of the details of this analysis is particularly enlightening, it nevertheless shows how in principle one constructs the Lagrange submanifold and the Lagrange map even in the presence of the caustics.

VI. FAMILIES OF FOLIATIONS

In this section we will generalize, in the following sense, the ideas of Sec. II. Recently there has been a reformulation of general relativity, referred to as the null surface formulation (NSF) where the basic idea has been to use a family (a sphere's worth) of null foliations of space–time, so that there are a spheres worth of null surfaces passing through each point of space–time. These surfaces are described as the level surfaces of the function

$$u=Z(x^a,\zeta,\bar{\zeta});$$

x^a are the local space–time coordinates and $(\zeta,\bar{\zeta})$ are the complex stereographic coordinate on the sphere which labels the family of foliations. The function Z, for every fixed value of $(\zeta,\bar{\zeta})$, satisfies the eikonal equation,

$$g^{ab}\partial_a Z\partial_b Z=0. \tag{98}$$

Knowing these families of foliations one can construct the (conformal) metric in terms of Z. The idea was then to express the Einstein equations in terms of these surfaces, i.e., in terms of Z and a conformal factor. Though this was successfully accomplished, a technical difficulty in fully understanding the equations arose due to the fact that the null surfaces developed singularities (caustics) and self-intersections. It was clear that the development of caustics was a generic feature of the equations but it was not at all clear how to see and study their existence directly in terms of the function $Z(x^a,\zeta,\bar{\zeta})$ and its derivatives. In this section, we will study, in flat space, the construction of such families and show explicitly how to calculate the structure of the null surface singularities (the caustics and wavefront singularities) directly in terms of the Z function.

Locally (up to first derivatives) there is no direct curvature involvement in the eikonal equation, so that the form of the caustics in terms of Z should apply equally in curved space as in Minkowski space. The results obtained here for Minkowski space will thus likely apply to the curved space situation.

Starting with the two-parameter family of plane waves used earlier, $Z_0(x^a,\zeta,\bar{\zeta})=x^a l_a(\zeta,\bar{\zeta})$, we will first construct a general two-parameter family of solutions to the flat-space eikonal equation, $Z(x^a,\mu,\bar{\mu})$, with $(\mu,\bar{\mu})$ parametrizing the sphere; we then study the singularities and caustics of this new family.

We begin by generalizing Eq. (11), namely

$$S^{**}=x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta}),$$

by writing α as a function on $S^2\times S^2$; i.e., as $\alpha=\alpha(\zeta,\bar{\zeta},\mu,\bar{\mu})$, and then repeating the earlier procedure of setting to zero, the ð and $\bar{ð}$ derivatives with respect to the $(\zeta,\bar{\zeta})$. Considering

$$u=Z^{**}(x,\zeta,\bar{\zeta},\mu,\bar{\mu})=x^a l_a(\zeta,\bar{\zeta})+\alpha(\zeta,\bar{\zeta},\mu,\bar{\mu}) \tag{99}$$

and

$$ð_\zeta Z^{**}=\bar{ð}_\zeta Z^{**}=0, \tag{100}$$

and then solving them (when possible) for $(\zeta,\bar{\zeta})$ obtaining

$$\zeta=\Upsilon(x,y,z,\mu,\bar{\mu}), \quad \bar{\zeta}=\bar{\Upsilon}(x,y,z,\mu,\bar{\mu}) \tag{101}$$

so that when substituted into Eq. (99), we obtain the new family which depends on the choice of $\alpha(\zeta,\bar{\zeta},\mu,\bar{\mu})$:

$$Z(x^a,\mu,\bar{\mu})=x^a l_a(\Upsilon,\bar{\Upsilon})+\alpha(\Upsilon,\bar{\Upsilon},\mu,\bar{\mu}). \tag{102}$$

[Alternatively we could use the different cases of Sec. V, when one can not solve for $(\zeta,\bar{\zeta})$.] It is obvious from the previous discussion that Eq. (102) satisfies the eikonal equation for each fixed value of $(\mu,\bar{\mu})$. All we have done so far is create a new sphere's worth of null foliations (wavefront families) of Minkowski space, different from the plane wave case of $S=x^a l_a(\zeta,\bar{\zeta})$. As in the earlier sections we could have analyzed the null surfaces for each value of $(\mu,\bar{\mu})$ separately but now in this generalization the null surfaces are smoothly connected to each other through the variable $(\mu,\bar{\mu})$ and it becomes of interest to see the development of the caustics via the variation of the $(\mu,\bar{\mu})$, or through the $(\mu,\bar{\mu})$ derivatives.

Remark 2: We will use, respectively, the notation $(\eth_\mu,\bar{\eth}_\mu)$ *for the eth and ethbar derivatives with respect to the variables* $(\mu,\bar{\mu})$ *and* $(\eth_\zeta,\bar{\eth}_\zeta)$ *for the variables* $(\zeta,\bar{\zeta})$.

We begin by defining several derivatives of Z:

$$\omega=\eth_\mu Z, \quad \bar{\omega}=\bar{\eth}_\mu Z \tag{103}$$

$$R=\bar{\eth}_\mu \eth_\mu Z, \tag{104}$$

$$\Lambda=\eth_\mu^2 Z, \quad \bar{\Lambda}=\bar{\eth}_\mu^2 Z. \tag{105}$$

A level surface of Z, with fixed $(\mu,\bar{\mu})$, is ruled by null geodesics, whose tangent vectors are given by $l_a(\Upsilon,\bar{\Upsilon})$. A pencil of rays defined from a pair of geodesic deviation vectors (from a given geodesic) has an area A that can be given[20] up to a proportionality by

$$A=K\frac{\Omega^{-2}}{\sqrt{(1-\Lambda_{,1}\bar{\Lambda}_{,1})}}, \tag{106}$$

where K is a constant determined by the initial area and

$$\Omega^2=l^a R_{,a}$$

and

$$\Lambda_{,1}=\Omega^{-2} l^a \Lambda_{,a}.$$

The derivation of Eq. (106) is lengthy and will not be given here. It will, however, be shown in this case to be proportional to the area.

We now want to see the behavior of ω, Λ, and R, as well as the area A, in the neighborhood of a caustic.

By direct calculation we have, from Eqs. (102) and (100), that

$$\omega=\eth_\mu \alpha, \quad \bar{\omega}=\bar{\eth}_\mu \alpha, \tag{107}$$

and hence is singularity free.

After a rather lengthy calculation, using Eqs. (99) and (100), we obtain

$$R=\eth_\mu\bar\eth_\mu\alpha+\frac{1}{D}\{(\eth_\zeta\eth_\mu\alpha)[(\eth_\zeta\bar\eth_\mu\alpha)(\bar\eth_\zeta^2u)-(\bar\eth_\zeta\bar\eth_\mu\alpha)(\eth_\zeta\bar\eth_\zeta u)]+(\bar\eth_\zeta\eth_\mu\alpha)[(\bar\eth_\zeta\bar\eth_\mu\alpha)(\eth_\zeta^2u) -(\eth_\zeta\bar\eth_\mu\alpha)(\eth_\zeta\bar\eth_\zeta u)]\}, \tag{108}$$

where

$$D=(\eth_\zeta\bar\eth_\zeta u)^2-\eth_\zeta^2u\bar\eth_\zeta^2u. \tag{109}$$

In a similar way we obtain

$$\Lambda=\eth_\mu^2\alpha+\frac{1}{D}\{(\eth_\zeta\eth_\mu\alpha)[(\eth_\zeta\eth_\mu\alpha)(\bar\eth_\zeta^2u)-(\bar\eth_\zeta\eth_\mu\alpha)(\eth_\zeta\bar\eth_\zeta u)] +(\bar\eth_\zeta\eth_\mu\alpha)[(\bar\eth_\zeta\eth_\mu\alpha)(\eth_\zeta^2u)-(\eth_\zeta\eth_\mu\alpha)(\eth_\zeta\bar\eth_\zeta u)]\}. \tag{110}$$

First we see that for fixed values of $(\mu,\overline{\mu})$, D from Eq. (109) is the same as in Eq. (32), namely $D=r^2-\eth_\zeta^2\alpha\bar\eth_\zeta^2\alpha$ and hence vanishes at the caustic. We can now see that ω is regular at the caustic while both R and Λ have singularities of the form D^{-1} at the caustic.

In order to find the area A we first need $R_{,a}$ and $\Lambda_{,a}$. After a lengthy calculation we obtain

$$\Omega^2\equiv l^aR_{,a}=\frac{1}{D^2}\{[(\eth_\zeta^2u)(\bar\eth_\zeta^2u)+(\eth_\zeta\bar\eth_\zeta u)^2][(\eth_\zeta\eth_\mu\alpha)(\bar\eth_\zeta\bar\eth_\mu\alpha)+(\bar\eth_\zeta\eth_\mu\alpha)(\eth_\zeta\bar\eth_\mu\alpha)] -2[(\eth_\zeta\eth_\mu\alpha)(\eth_\zeta\bar\eth_\mu\alpha)(\bar\eth_\zeta^2u)+(\bar\eth_\zeta\bar\eth_\mu\alpha)(\bar\eth_\zeta\eth_\mu\alpha)(\eth_\zeta^2u)](\eth_\zeta\bar\eth_\zeta u)\} \tag{111}$$

and

$$\Omega^2\Lambda_{,1}\equiv l^a\Lambda_{,a}=\frac{2}{D^2}\{[(\eth_\zeta^2u)(\bar\eth_\zeta^2u)+(\eth_\zeta\bar\eth_\zeta u)^2](\eth_\zeta\eth_\mu\alpha)(\bar\eth_\zeta\eth_\mu\alpha) -[(\eth_\zeta\eth_\mu\alpha)^2(\bar\eth_\zeta^2u)+(\bar\eth_\zeta\eth_\mu\alpha)^2(\eth_\zeta^2u)](\eth_\zeta\bar\eth_\zeta u)\}. \tag{112}$$

Though it is not immediately obvious, from Eqs. (111) and (112) one can show that $(1-\Lambda_{,1}\overline{\Lambda}_{,1})$ is proportional to D^2 or that $|\Lambda_{,1}|\Rightarrow 1+O(D)$ at the caustic. From these results we have that

$$A=K\frac{\Omega^{-2}}{\sqrt{(1-\Lambda_{,1}\overline{\Lambda}_{,1})}}=\frac{\pm KD}{\hat K} \tag{113}$$

with

$$\hat K=|\eth_\zeta\eth_\mu\alpha|^2-|\bar\eth_\zeta\eth_\mu\alpha|^2.$$

From Eqs. (100) and (101), we have that $\hat K=\hat K(\Upsilon,\overline{\Upsilon})$ from which it can be shown that

$$l^a\hat K_{,a}=0,$$

i.e., $\hat K$ is constant along the geodesic flow. If we chose $K=\pm\hat K$ we have that $A=D$, in agreement with the area obtained in Sec. III from geodesic deviation.

Several important observations can now be made:

(1) In our particular case of flat space, we have seen that the quantities R and Λ diverge as D^{-1} at the caustic. It appears virtually certain that this is a general result and remains true in a general curved space.
(2) As was to be expected, the area of a pencil of null geodesics vanishes at the caustic. This is clearly true in general and the result here is a confirmation that Eq. (106) really is the area formula.
(3) The quantity Ω (which plays a central role in the NSF version of GR) diverges as D^{-1} at the caustic.
(4) Though Λ diverges at the caustic, the absolute value of its weighted derivative

$$|\Lambda_{,1}|=|\Omega^{-2}\Lambda_{,a}l^a|$$

approaches one as $1-O(D)$. From this one sees that $\Lambda_{,a}l^a$ diverges as D^{-2}.

VII. DISCUSSION

Our main interest in the study of wavefronts and their associated null surfaces lies in our desire to understand and describe their singularity structure in curved Lorentzian manifolds and in particular to find the most appropriate variables and representations for their analysis. Though locally the classification of generic singularities and caustics is complete and is the same in both flat and curved spaces,[5] however, in general spaces, curvature effects are large and must eventually be taken into account for global questions. (For example, the structure of the light cone in a curved space is very different from that of a light cone in flat space.) The present work is intended to begin this study with the description of singular, global, asymptotically spherical, null surfaces in flat spaces. A follow-up second paper will be devoted to *the same* issues as here but in asymptotically flat space–times. We will see that beginning with a two-parameter family of solutions of the eikonal equation—analogous to the plane wave solutions of flat space–time—it will be possible to construct any other null surface and then analyze its singularity structure. In particular, it is possible to construct, in terms of the two-parameter family, the light cone of any space–time point. These insights are important for applications of the null surface formulation of GR.[8,9]

ACKNOWLEDGMENTS

We would like to thank Carlos Kozameh for many very useful arguments and even for some peaceful conversations. Also we want to point out that there has been a fair amount of unwitting and uncoordinated overlap between the work of the present authors (in Secs. II and III) and the group of Bishop, Gomez, Lehner, Szilagyi, and Winicour.[18] Since the motivation, notation, and final results of the work of the two groups are quite different, it has been decided to keep the work separate and publish independently. In addition, we mention that several of the issues discussed here were explored earlier in a beautiful paper by K. P. Tod.[21] We also thank the referee, Juergen Ehlers, for valuable improvements and corrections. SF and EN thank the NSF for support under Grant No. PHY 92-05109. GSO acknowledges the financial support from the Sistema Nacional de Investigadores and from the Consejo Nacional de Ciencia y Tecnología (CONACyT) México.

(Received 2 April 1998; accepted for publication 11 August 1998)

We show that a left-rigid monoidal C^* category with irreducible monoidal unit is also a sovereign and spherical category. Defining a Frobenius–Schur-type indicator we obtain selection rules for the fusion coefficients of irreducible objects. As a main result we prove S_4 invariance of $6j$ symbols in such a category. © *1999 American Institute of Physics.* [S0022-2488(99)00701-X]

I. INTRODUCTION

The quantities that are known as $6j$ *symbols* or *F coefficients* appear in various disguises in mathematics and physics, for instance, as recoupling coefficients in the theory of groups[1–3] and quantum groups,[4] as (partially gauge-fixed) fusing matrices[5–7] in conformal field theory, as the Boltzmann weights for triangulations of three-manifolds[8–11] giving rise to topological lattice field theories,[11–13] as expansion coefficients of exchange algebra relations in the algebraic theory of superselection sectors,[14] as the components of the three-cocycle in Ocneanu's non-Abelian cohomology,[15] as structure constants in the theory of three-algebras,[16] as specific endomorphisms of a von Neumann factor M in the theory of subfactors,[17] and as components of the coassociator φ of a rational Hopf algebra.[18–20] More generally, the F coefficients can be described as the projections of the associativity constraint φ of a semisimple, rigid, monoidal category onto irreducible objects, hence they map a pair of basic intertwiner spaces to another pair. The F coefficients depend on the choice of basis (gauge choices) in the basic intertwiner spaces (spaces of three-point functions).

An important property of the F coefficients is their ''tetrahedral symmetry'' or, more precisely, the fact that the gauge freedom that is present in their definition can be fixed in such a way that they are invariant under a set of transformations which form the permutation group S_4. This symmetry property is, for example, needed in three-dimensional lattice theories in order for the partition function that is defined in terms of the F coefficients to be independent of the triangulation so that the theory is topological (see, e.g., Refs. 21 and 9). Other places where this symmetry plays an important role are the derivation of identities for ''higher-order fusion coefficients''[22] and the construction of solutions to the ''big pentagon equation.''[23] Also, in pursuing a project for finding (possibly with the aid of computers) explicit solutions of the Moore–Seiberg polynomial equations for ''small'' fusion rings, the assumption of tetrahedral symmetry allows for the substantial increase in the number of accessible fusion rings. (In conformal field theory the explicit computation of fusing matrices is, e.g., required for the calculation of the operator product coefficients.)

Let us remark that in conformal field theory it seems to be common lore that the F coefficients

[a)]Electronic mail: jfuchs@x4u2.desy.de

possess S_4 invariance (see, e.g., Refs. 7 and 24); but, as a matter of fact, no complete and detailed proof has ever been published. In the theory of subfactors it was realized that the S_4 symmetry follows from Frobenius reciprocity of intertwiners between bimodules,[17] and in algebraic field theory the same aspects of the symmetry are implicit in the results of Ref. 14 (see, in particular, the appendix of that paper). The Frobenius maps between basic intertwiners generate the group S_3, and the coherent choice of bases in the orbits of this S_3 group lead to S_4-symmetric F coefficients. In Ref. 9 it was shown that in order to have S_4 symmetry one does not need a braiding—it is sufficient that the category be spherical; however, in that paper the possibility of nontrivial Frobenius–Schur (FS) indicators[25–27] was not considered.

In this paper we present a proof that in a left-rigid monoidal C^* category the F coefficients possess S_4 symmetry. We would like to emphasize two fine points. The first is that, in general, due to the possibility of having nontrivial FS indicators, the Frobenius maps provide only a $\mathbb{Z}_2$-projective representation of S_3; but nevertheless the corresponding signs cancel in the transformation of the F coefficients so that the F's are truly S_4 invariant. The second point is the following. The Frobenius transformations of order 3 map the basic intertwiners space $(p\times p,\hat{p})$ into itself; hence its eigenvalues are third roots of unity (here $\hat{p}$ is the conjugate of the irreducible object p). When considering F's that involve such intertwiner spaces, then in order to verify S_4 invariance we must calculate the different transforms of F in different bases of the space $(p\times p,\hat{p})$. If, instead, we use only a single basis in this space, then the transforms of F will possibly carry factors of third roots of unity (this is illustrated in an example in the Appendix).

Let us also briefly mention a possible application of our results to the quest of explicitly solving the polynomial equations for the braiding and fusing matrices, which constitutes, e.g., a part of the problem of classifying all rational conformal field theories. Namely, one expects that when the category is modular, then the trace of the braiding matrices $R^{pp,q}$ can be expressed completely in terms of the modular data, i.e., of the fusion rules, the modular S matrix and balancing phases (in the case of doubles of finite groups this was proved in Ref. 27). Assuming that this expectation is indeed correct, it follows that the Frobenius–Schur indicators as well as the multiplicities of the above-mentioned third roots of unity do not constitute independent data, but are already determined uniquely by the modular data. In particular, one can immediately write down all the F coefficients for which at least one line is colored by the unit object as well as the R coefficients. In fact, there are further special F coefficients that can easily be solved for. Finally, our results concerning the S_4 symmetry allow us to reduce the number of unknowns in the polynomial equations drastically, namely for generic F coefficients by a factor of 24. [Further simplifications come from the action of simple currents on the F-coefficients, which should be derivable in a way similar to the S_4-action. Moreover, one would expect the pentagon equation itself, which can be regarded as the boundary of a four-simplex, to possess S_5-symmetry, just like the tetrahedra (F-coefficients)—the boundaries of three-simplices—possess S_4-symmetry.]

II. RIGID MONOIDAL C^* CATEGORIES WITH IRREDUCIBLE MONOIDAL UNIT

Our starting point is a left-rigid monoidal C^* category $(\mathcal{C};(\varepsilon,\times,\{\lambda,\rho,\varphi\});(\hat{\ },\{e,c\});*)$ with the restriction that the monoidal unit ε is irreducible. Here $\times$ is the monoidal product and $\lambda_a,\rho_a,\varphi_{a,b,c}$ with $a,b,c\in\mathrm{Obj}\,\mathcal{C}$ are natural isomorphisms,

$$\begin{aligned}&\lambda_a:\ a\rightarrow a\times\varepsilon,\quad \rho_a:\ a\rightarrow\varepsilon\times a,\\&\varphi_{a,b,c}:\ a\times(b\times c)\rightarrow(a\times b)\times c,\end{aligned}\tag{2.1}$$

that satisfy the triangle identity

$$\varphi_{a,\varepsilon,c}=(\lambda_a\times 1_c)(1_a\times\rho_c^{-1}),\tag{2.2}$$

and the pentagon identity

$$\varphi_{a\times b,c,d}\varphi_{a,b,c\times d}=(\varphi_{a,b,c}\times 1_d)\varphi_{a,b\times c,d}(1_a\times\varphi_{b,c,d}).\tag{2.3}$$

The C^* property requires the arrows (the intertwiners)

$$(a,b)\equiv \mathrm{Hom}(a,b):=\{T:\ \ a\to b\} \tag{2.4}$$

between two objects *a,b* to form a complex Banach space. The $*$ is an involutive monoidal contravariant functor acting as identity on the objects and antilinearly on the intertwiner spaces. The norm of the intertwiners satisfies the C^* property, $\|T^*T\|=\|T\|^2$, and the natural equivalences $\{\lambda,\rho,\varphi\}$ are isometries. Irreducibility of ε implies that $(\varepsilon,\varepsilon)=\mathbb{C}\cdot 1_\varepsilon$.

The left conjugation L: $\mathcal{C}\to\mathcal{C}$ is an antimonoidal contravariant (linear) functor, which is the identity on the monoidal unit. The functor L is built up from a left rigidity structure $(\hat{\ },\{e,c\})$, where $\hat{\ }$ is the left conjugation on objects: $\hat{a}\equiv L(a)$. The left evaluation and coevaluation maps $e_a:\ \hat{a}\times a\to\varepsilon$ and $c_a:\ \varepsilon\to a\times\hat{a}$, $a\in\mathrm{Obj}\ \mathcal{C}$, satisfy the left rigidity equations

$$\lambda_a^*(1_a\times e_a)\varphi^*_{a,\hat{a},a}(c_a\times 1_a)\rho_a=1_a,\quad \rho^*_{\hat{a}}(e_a\times 1_{\hat{a}})\varphi_{\hat{a},a,\hat{a}}(1_{\hat{a}}\times c_a)\lambda_{\hat{a}}=1_{\hat{a}}, \tag{2.5}$$

and lead to the definition

$$(a,b)\ni T\mapsto L(T):=\rho^*_{\hat{a}}(e_b\times 1_{\hat{a}})((1_{\hat{b}}\times T)\times 1_{\hat{a}})\varphi_{\hat{b},a,\hat{a}}(1_{\hat{b}}\times c_a)\lambda_{\hat{b}}\in(\hat{b},\hat{a}) \tag{2.6}$$

of the conjugated intertwiners $L(T)$. Note that two left conjugations L_1 and L_2 that arise from left rigidity structures are always related by canonical natural equivalences μ: $L_1\to L_2$ given by

$$\begin{aligned}\mu_a&=\rho^*_{a^2}(e^1_a\times 1_{a^2})\varphi_{a^1,a,a^2}(1_{a^1}\times c^2_a)\lambda_{a^1}\in(a^1,a^2),\\ \mu_a^{-1}&=\rho^*_{a^1}(e^2_a\times 1_{a^1})\varphi_{a^2,a,a^1}(1_{a^2}\times c^1_a)\lambda_{a^2}\in(a^2,a^1),\end{aligned}\quad \text{for every}\ \ a\in\mathrm{Obj}\ \mathcal{C}, \tag{2.7}$$

where $a^i\equiv L_i(a)$ for $i=1,2$.

The C^* property allows us to define a right rigidity structure within $\mathcal{C}$:

$$(R(a),e^R_a,c^R_a):=(L(a),c^{L*}_a,e^{L*}_a)\equiv(\hat{a},c^*_a,e^*_a)\quad \text{for}\ \ a\in\mathrm{Obj}\ \mathcal{C}, \tag{2.8}$$

leading to a right conjugate functor R: $\mathcal{C}\to\mathcal{C}$ similarly to (2.6):

$$\begin{aligned}(a,b)\ni T\mapsto R(T)&:=\lambda^*_{R(a)}(1_{R(a)}\times e^R_b)(1_{R(a)}\times(T\times 1_{R(b)}))\varphi^*_{R(a),a,R(b)}(c^R_a\times 1_{R(b)})\rho_{R(b)}\\ &\equiv\lambda^*_{\hat{a}}(1_{\hat{a}}\times c^*_b)(1_{\hat{a}}\times(T\times 1_{\hat{b}}))\varphi^*_{\hat{a},a,\hat{b}}(e^*_a\times 1_{\hat{b}})\rho_{\hat{b}}\in(\hat{b},\hat{a}).\end{aligned} \tag{2.9}$$

Since the right and left conjugated objects are identical, $R(a)=L(a)\equiv\hat{a}$ for all $a\in\mathrm{Obj}\ \mathcal{C}$, the canonical natural isomorphisms

$$\{\kappa_a:\ \ R(L(a))\to a\},\quad \{\tilde{\kappa}_a:\ \ L(R(a))\to a\} \tag{2.10}$$

are given by

$$\begin{aligned}\kappa_a&=\lambda^*_a(1_a\times e^R_{L(a)})\varphi^*_{a,L(a),R(L(a))}(c^L_a\times 1_{R(L(a))})\rho_{R(L(a))}\equiv\lambda^*_a(1_a\times c^*_{\hat{a}})\varphi^*_{a,\hat{a},\hat{\hat{a}}}(c_a\times 1_{\hat{\hat{a}}})\rho_{\hat{\hat{a}}},\\ \tilde{\kappa}_a&=\rho^*_a(e^L_{R(a)}\times 1_a)\varphi_{L(R(a)),R(a),a}(1_{L(R(a))}\times c^R_a)\lambda_{L(R(a))}\equiv\rho^*_a(e_{\hat{a}}\times 1_a)\varphi_{\hat{\hat{a}},\hat{a},a}(1_{\hat{\hat{a}}}\times e^*_a)\lambda_{\hat{\hat{a}}},\end{aligned} \tag{2.11}$$

which satisfy

$$\begin{aligned}\kappa_a^{-1}&=\lambda^*_{\hat{\hat{a}}}(1_{\hat{\hat{a}}}\times e_a)\varphi^*_{\hat{\hat{a}},\hat{a},a}(e^*_{\hat{a}}\times 1_a)\rho_a=\tilde{\kappa}^*_a,\\ \tilde{\kappa}_a^{-1}&=\rho^*_{\hat{\hat{a}}}(c^*_a\times 1_{\hat{\hat{a}}})\varphi_{a,\hat{a},\hat{\hat{a}}}(1_a\times c_{\hat{a}})\lambda_a=\kappa^*_a.\end{aligned} \tag{2.12}$$

One can define (positive) left and right inverses for $a\in\mathrm{Obj}\ \mathcal{C}$:[28]

$$\Phi_a^L:\ (a\times b,a\times c)\rightarrow(b,c),\quad \Phi_a^R:\ (b\times a,c\times a)\rightarrow(b,c),\quad \text{for } b,c\in\text{Obj }\mathcal{C}, \tag{2.13}$$

using evaluation and coevaluation maps. In the special case $b=c=\varepsilon$ these maps,

$$\begin{aligned}(a,a)\ni T\mapsto \Phi_a^L(T)&:=e_a(1_{\hat a}\times T)e_a^*\in(\varepsilon,\varepsilon)=\mathbb{C}\cdot 1_\varepsilon,\\ (a,a)\ni T\mapsto \Phi_a^R(T)&:=c_a^*(T\times 1_{\hat a})c_a\in(\varepsilon,\varepsilon)=\mathbb{C}\cdot 1_\varepsilon,\end{aligned} \tag{2.14}$$

are faithful positive linear functionals. Since they are bounded from below,[28]

$$\begin{aligned}(a,a)\ni T^*T&\leqslant\rho_a^*(c_a^*c_a\times 1_a)\rho_a\cdot\lambda_a^*(1_a\times\Phi_a^L(T^*T))\lambda_a,\\ (a,a)\ni T^*T&\leqslant\lambda_a^*(1_a\times e_ae_a^*)\lambda_a\cdot\rho_a^*(\Phi_a^R(T^*T)\times 1_a)\rho_a,\end{aligned}\quad \text{for } T\in(a,b), \tag{2.15}$$

it follows that End $a\equiv(a,a)$ is finite dimensional for every $a\in$ Obj $\mathcal{C}$; therefore $\mathcal{C}$ is semisimple. We denote the subset of irreducible objects by $\mathcal{I}\subset$ Obj $\mathcal{C}$.

Semisimplicity allows us to construct the so-called *standard* rigidity intertwiners,[28] leading to a left conjugation functor L_s among the equivalent ones [cf. (2.7)] that obeys $L_s=R_s$ by (2.8) and (2.9). This conjugation is achieved by the following procedure.

In the case of an irreducible object $p\in\mathcal{I}$, one uses the scalar freedom $e_p\mapsto z_pe_p$, $c_p\mapsto z_p^{-1}c_p$ with $z_p\in\mathbb{C}\setminus\{0\}$ to set

$$e_pe_p^*=d_p1_\varepsilon=c_p^*c_p\quad\text{for every } p\in\mathcal{I}, \tag{2.16}$$

where d_a is the *quantum* or *statistics dimension* of an arbitrary object $a\in\mathcal{C}$, defined to be

$$d_a:=\|e_a\|\|c_a\|. \tag{2.17}$$

Then for an arbitrary object a one chooses two orthogonal and complete sets of partial isometries

$$\begin{aligned}V_a^{p\alpha}&:\ p\rightarrow a,\\ W_a^{p\alpha}&:\ \hat p\rightarrow\hat a,\end{aligned}\quad \text{for } p\in\mathcal{I},\ \ \alpha=1,...,m_a^p, \tag{2.18}$$

satisfying

$$V_a^{p\alpha*}V_a^{p'\alpha'}=\delta_{pp'}\delta_{\alpha\alpha'}1_p,\quad W_a^{p\alpha*}W_a^{p'\alpha'}=\delta_{pp'}\delta_{\alpha\alpha'}1_{\hat p}, \tag{2.19}$$

and

$$\sum_{p,\alpha}V_a^{p\alpha}V_a^{p\alpha*}=1_a,\quad \sum_{p,\alpha}W_a^{p\alpha}W_a^{p\alpha*}=1_{\hat a}, \tag{2.20}$$

to define

$$e_a:=\sum_{p,\alpha}e_p(W_a^{p\alpha*}\times V_a^{p\alpha*})\in(\hat a\times a,\varepsilon),\quad c_a:=\sum_{p,\alpha}(V_a^{p\alpha}\times W_a^{p\alpha})c_p\in(\varepsilon,a\times\hat a). \tag{2.21}$$

Then $(\hat{\ },\{e_a,c_a\})$ becomes a left rigidity structure, i.e., it satisfies (2.5) due to naturality of $\{\lambda,\rho,\varphi\}$ and (2.19) and (2.20). The rigidity intertwiners (e_a,c_a) of an object a satisfying (2.16) and (2.21) are called *standard*.

Now the corresponding right rigidity structure [cf. (2.8) and (2.9)] $(\hat{\ },\{c_a^*,e_a^*\})$ leads to a right conjugation functor R that is identical to the left conjugation L. As a matter of fact, by an explicit calculation one obtains

$$(b,a) \ni T \mapsto R(T) = L(T) = \sum_{p,\alpha,\beta} W_b^{p\beta} t_p^{\alpha\beta} 1_{\hat{p}} W_a^{p\alpha *} \in (\hat{a},\hat{b}), \tag{2.22}$$

with

$$t_p^{\alpha\beta} 1_p := V_a^{p\alpha *} T V_b^{p\beta}, \quad t_p^{\alpha\beta} \in \mathbb{C}. \tag{2.23}$$

Therefore, in the case of standard conjugation, we use the notation $\hat{T} \equiv R(T) = L(T)$ for the conjugated intertwiners.

One can also prove[28] that if (e_a, c_a) and (e'_a, c'_a) are both standard, then

$$e'_a = e_a(1_{\hat{a}} \times U_a), \quad c'_a = (U_a^* \times 1_{\hat{a}}) c_a, \tag{2.24}$$

where $U_a \in (a,a)$ is unitary. Moreover,

$$\begin{aligned} e_{(a,b)} &:= e_b(1_{\hat{b}} \times \rho_b)(1_{\hat{b}} \times (e_a \times 1_b))(1_{\hat{b}} \times \varphi_{\hat{a},a,b}) \varphi^*_{\hat{b},\hat{a},a\times b} \in ((\hat{b} \times \hat{a}) \times (a \times b), \varepsilon), \\ c_{(a,b)} &:= \varphi^*_{a\times b,\hat{b},\hat{a}}(\varphi_{a,b,\hat{b}} \times 1_{\hat{a}})((1_a \times c_b) \times 1_{\hat{a}})(\lambda_a \times 1_{\hat{a}}) c_a \in (\varepsilon, (a \times b) \times (\hat{b} \times \hat{a})) \end{aligned} \tag{2.25}$$

are standard if (e_a, c_a) and (e_b, c_b) are standard. Thus in the case of standard conjugation, $L = R$, the natural equivalence $\{\alpha_{a,b}: \widehat{a \times b} \to \hat{b} \times \hat{a}\}$ that expresses the antimonoidality of the conjugation functor is given by

$$\begin{aligned} \alpha_{a,b} &= \rho^*_{\hat{b}\times\hat{a}}(e_{a\times b} \times 1_{\hat{b}\times\hat{a}}) \varphi_{\widehat{a\times b},a\times b,\hat{b}\times\hat{a}}(1_{\widehat{a\times b}} \times c_{(a,b)}) \lambda_{a\times b} \in (\widehat{a\times b}, \hat{b}\times\hat{a}), \\ \alpha^{-1}_{a,b} &= \rho^*_{\widehat{a\times b}}(e_{(a,b)} \times 1_{\widehat{a\times b}}) \varphi_{\hat{b}\times\hat{a},a\times b,\widehat{a\times b}}(1_{\hat{b}\times\hat{a}} \times c_{a\times b}) \lambda_{\hat{b}\times\hat{a}} \in (\hat{b}\times\hat{a}, \widehat{a\times b}). \end{aligned} \tag{2.26}$$

III. SOVEREIGNTY, TRACES, AND SPHERICITY

We note that in the case of standard rigidity intertwiners the choice $\psi_a := 1_{\hat{a}}$ for every $a \in \mathrm{Obj}\,\mathcal{C}$ leads to a natural equivalence ψ: $R \to L$ and makes $\mathcal{C}$ a *sovereign* category.[29] Indeed, $\psi_\varepsilon = 1_\varepsilon$ and monoidality of ψ is clear, one has only to show the commutativity of the sovereignty diagram, which reads in this case as $\kappa_a = \tilde{\kappa}_a$. Since κ and $\tilde{\kappa}$ are natural equivalences it is enough to show this equality for $p \in \mathcal{I}$. But then one has

$$\kappa_p^* \kappa_p = x_p 1_{\hat{\hat{p}}} \quad \text{and} \quad \tilde{\kappa}_p^* \tilde{\kappa}_p = \tilde{x}_p 1_{\hat{\hat{p}}} \quad \text{for all} \quad p \in \mathcal{I}, \tag{3.1}$$

with $x_p, \tilde{x}_p \in \mathbb{R}_+$ and $x_p = \tilde{x}_p^{-1}$ due to (2.12). Using (2.16) and rigidity one obtains

$$\begin{aligned} x_p d_{\hat{p}} 1_\varepsilon &= e_{\hat{p}}(x_p 1_{\hat{\hat{p}}} \times 1_{\hat{p}}) e^*_{\hat{p}} = e_{\hat{p}}(\kappa_p^* \kappa_p \times 1_{\hat{p}}) e^*_{\hat{p}} = c_p^* c_p = d_p 1_\varepsilon, \\ \tilde{x}_p d_{\hat{p}} 1_\varepsilon &= c^*_{\hat{p}}(1_{\hat{p}} \times \tilde{x}_p 1_{\hat{\hat{p}}}) c_{\hat{p}} = c^*_{\hat{p}}(1_{\hat{p}} \times \tilde{\kappa}_p^* \tilde{\kappa}_p) c_{\hat{p}} = e_p e_p^* = d_p 1_\varepsilon, \end{aligned} \tag{3.2}$$

which imply $x_p = \tilde{x}_p$, hence $x_p = \tilde{x}_p = 1$ and $d_{\hat{p}} = d_p$. Then (3.1) and (2.12) lead to the equalities $\tilde{\kappa}_p = \kappa_p$, $p \in \mathcal{I}$, of isometries. Owing to naturality, the maps $\tilde{\kappa}_a \equiv \kappa_a : \hat{\hat{a}} \to a$, $a \in \mathrm{Obj}\,\mathcal{C}$, are isometries.

Having reached a standard conjugation, $L = R$, and sovereignty, let us consider the conjugates of standard rigidity intertwiners. Using (2.26) one obtains

$$\alpha_{\hat{\alpha},a} \hat{e}_a = c_{\hat{a}} \in (\varepsilon, \hat{a} \times \hat{\hat{a}}), \quad \hat{c}_a \alpha^{-1}_{a,\hat{a}} = e_{\hat{a}} \in (\hat{\hat{a}} \times \hat{a}, \varepsilon), \tag{3.3}$$

and the rigidity intertwiners of conjugated objects are related to the original ones as

$$e_{\hat{a}}=c_a^*(\kappa_a\times 1_{\hat{a}}),\quad c_{\hat{a}}=(1_{\hat{a}}\times\kappa_a^{-1})e_a^*,\tag{3.4}$$

as is seen by using (2.11) and (2.12). From (3.4) it follows that further specification of the rigidity intertwiners, e.g., identification of the (e_a,c_a) and $(c_{\hat{a}}^*,e_{\hat{a}}^*)$ rigidity pairs, may be achieved only in the case of involutive conjugation, which will be discussed in Sec. V.

In a sovereign monoidal category one can define left and right traces $\mathrm{tr}_a^{L/R}:(a,a)\to(\varepsilon,\varepsilon)$ for each $a\in\mathrm{Obj}\,\mathcal{C}$:

$$\begin{matrix}\mathrm{tr}_a^L(T):=e_a^L(\psi_a\times T)c_a^R,\\ \mathrm{tr}_a^R(T):=e_a^R(T\times\psi_a)c_a^L,\end{matrix}\quad\text{for}\quad\psi_a:\ R(a)\to L(a),\tag{3.5}$$

obeying the property

$$\mathrm{tr}_a^{R/L}(TS)=\mathrm{tr}_b^{R/L}(ST)\quad\text{for all}\quad T\in(b,a),\ S\in(a,b).\tag{3.6}$$

In the case of standard conjugation in a C^* category, together with the previously chosen sovereignty maps, $\{\psi_a=1_{\hat{a}}\}$, these left (right) traces become identical to left (right) inverses (2.14), hence they are positive traces. Moreover, due to standardness they are equal:

$$\mathrm{tr}_a^L(T)=\mathrm{tr}_a^R(T)=:\mathrm{tr}_a(T)\quad\text{for all}\quad T\in(a,a);\tag{3.7}$$

hence $\mathcal{C}$ is also a *spherical* category.[9]

IV. FROBENIUS–SCHUR INDICATORS

For any finite group G one defines the Frobenius–Schur element σ of the group algebra $\mathbb{C}G$ as in Ref. 25, i.e. (up to normalization),

$$\sigma:=\frac{1}{|G|}\sum_{g\in G}g^2.\tag{4.1}$$

The Frobenius–Schur element is a central self-adjoint element of $\mathbb{C}G$; its central decomposition reads

$$\sigma=\sum_{r\in\mathcal{I}}\frac{\nu_r}{d_r}e_r\quad\text{with}\quad\nu_r=\begin{cases}0 & \text{for } r\neq\hat{r},\\ \pm1 & \text{for } r=\hat{r},\end{cases}\tag{4.2}$$

where e_r, $r\in\mathcal{I}$, are the minimal central projectors and $d_r=\mathrm{tr}_r(e_r)$ is the (integral) dimension of the corresponding simple ideal of the group algebra $\mathbb{C}G$. The three-valent indicator ν_r that is defined by (4.2) is the *Frobenius–Schur indicator*, which is zero on non-self-conjugate simple ideals while on self-conjugate simple ideals the $+(-)$ sign indicates (pseudo)reality.

There is an extension of σ for C^*-Hopf[30] or weak C^*-Hopf algebras,[23] which is obtained using the Haar integral $h\in H$ of the (weak) C^*-Hopf algebra H:

$$\sigma:=\frac{1}{\epsilon(\mathbf{1})}h^{(1)}h^{(2)};\tag{4.3}$$

here we use Sweedler notation for the coproduct, i.e., $h^{(1)}\otimes h^{(2)}\equiv\Delta(h)$, and $\mathbf{1}$ and ϵ are the unit and the counit of H, respectively. Since weak C^*-Hopf algebras contain C^*-Hopf algebras as special cases, we prove the property (4.2) for σ as defined in (4.3) only for the former case.

There is a unique positive $g\in H$ (Ref. 31) that implements the square of the antipode, i.e., $gxg^{-1}=S^2(x)$ for all $x\in H$, and satisfies the normalization condition $\mathrm{tr}\,D_r(g)=\mathrm{tr}\,D_r(g^{-1})=:\tau_r\in\mathbb{R}_+$. Then $S(g)=g^{-1}$ holds, and if the unit representation is irreducible, then $\tau_r=d_r/\epsilon(\mathbf{1})$. Using the properties[32]

$$h^2=h^*=S(h)=h,\quad h^{(1)}\otimes xh^{(2)}y=S(x)h^{(1)}S^{-1}(y)\otimes h^{(2)}\quad \text{for all } x,y\in H \tag{4.4}$$

and

$$h^{(2)}\otimes h^{(1)}=h^{(1)}\otimes gh^{(2)}g,\quad S(h^{(1)})\otimes h^{(2)}=\sum_{r\in\mathcal{I}}\frac{1}{\tau_r}\sum_{i,j}e_r^{ij}g^{-1/2}\otimes g^{-1/2}e_r^{ji} \tag{4.5}$$

of the Haar integral $h\in H$, one obtains

$$\sigma^*=\frac{1}{\epsilon(\mathbf{1})}h^{(2)}h^{(1)}=\frac{1}{\epsilon(\mathbf{1})}h^{(1)}gh^{(2)}g=\frac{1}{\epsilon(\mathbf{1})}h^{(1)}S^{-1}(g)gh^{(2)}=\sigma \tag{4.6}$$

and

$$\begin{aligned}\sigma\cdot y&=\frac{1}{\epsilon(\mathbf{1})}h^{(1')}h^{(1)}h^{(2')}h^{(2)}\cdot y\\ &=\frac{1}{\epsilon(\mathbf{1})}S(h^{(1)})h^{(1')}h^{(2')}h^{(2)}\cdot y\\ &=\frac{1}{\epsilon(\mathbf{1})}S(h^{(1)}S^{-1}(y))h^{(1')}h^{(2')}h^{(2)}=y\cdot\sigma\end{aligned} \tag{4.7}$$

for all $y\in H$, i.e., σ is a central self-adjoint element of H. From the second identity in (4.5) it follows that σ vanishes on non-self-conjugate ideals, hence $\nu_r=0$ for $r\neq\hat{r}$. For a self-conjugate ideal, $e_r=e_{\hat{r}}$, one obtains

$$\epsilon(\mathbf{1})\cdot e_r\sigma=\frac{1}{\tau_r}\sum_{i,j}S^{-1}(e_r^{ij}g^{-1/2})g^{-1/2}e_r^{ji}=\frac{1}{\tau_r}\sum_{i,j}g^{1/2}S^{-1}(e_r^{ij})g^{-1/2}e_r^{ji}=\frac{1}{\tau_r}\sum_{i,j}S_0(e_r^{ij})e_r^{ji}, \tag{4.8}$$

where $S_0:=\mathrm{Ad}_{g^{1/2}}\circ S^{-1}$ is the involutive antipode: $S_0^2=id_H$, $S_0\circ *=*\circ S_0$. Since $e_r=e_{\hat{r}}$ for matrix units, it follows that $S_0(e_r^{ij})=v_re_r^{ji}v_r^*$ with $v_r\in e_rH$ unitary. Moreover,

$$e_r^{ij}=S_0^2(e_r^{ij})=S_0(v_r^*)v_re_r^{ij}v_r^*S_0(v_r) \tag{4.9}$$

implies that $S_0(v_r^*)v_r$ is a central unitary element in e_rH, hence $S_0(v_r^*)=\pm v_r^*=:\nu_rv_r^*$ for $r=\hat{r}$ due to the involutivity of S_0. But then

$$\begin{aligned}\sigma&=\sum_{\substack{r\in\mathcal{I}\\ r=\hat{r}}}\frac{1}{\epsilon(\mathbf{1})\tau_r}\sum_{i,j}S_0(e_r^{ij})e_r^{ji}\\ &=\sum_{\substack{r\in\mathcal{I}\\ r=\hat{r}}}\frac{1}{d_r}\sum_{i,j}v_re_r^{ji}v_r^*e_r^{ji}\\ &=\sum_{\substack{r\in\mathcal{I}\\ r=\hat{r}}}\frac{1}{d_r}v_rv_r^{*T}=\sum_{\substack{\tau\in\mathcal{I}\\ r=\hat{r}}}\frac{1}{d_r}v_rv_r^*S_0(v_r^*)v_r=\sum_{r\in\mathcal{I}}\frac{\nu_r}{d_r}e_r,\end{aligned} \tag{4.10}$$

proving (4.2).

There exists a purely categorical definition of the Frobenius–Schur indicator. Let $\mathcal{C}$ be a category as in Sec. II and p an irreducible object. If p is self-conjugate, then there exists an invertible intertwiner $J_p:p\rightarrow\hat{p}$. Let us define the self-intertwiner

$$\nu_p:=J_p^{-1}\hat{J}_p\kappa_p^{-1}\in(p,p), \tag{4.11}$$

which is independent of the choice of J_p due to irreducibility of p and linearity of the conjugation. Hence ν_p is an isometry, because an isometric J_p can be chosen. In order to prove that even $\nu_p = \pm 1_p$ holds, one first computes that

$$\Phi_p^R(\nu_p) := c_p^*(\nu_p \times 1_{\hat{p}}) c_p = c_p^*(J_p^{-1} \times J_p) e_p^*, \tag{4.12}$$

using (2.6) and (2.12). However, the rigidity intertwiners

$$(e_p', c_p') := (c_p^*(J_p^{-1} \times J_p), (J_p^{-1} \times J_p) e_p^*) \in ((\hat{p} \times p, \epsilon), (\epsilon, p \times \hat{p})) \tag{4.13}$$

are standard; hence, owing to (2.24) we have

$$e_p' = e_p u_p \quad \text{and} \quad c_p' = u_p^* c_p \quad \text{for some } u_p \in \mathbb{C} \text{ with } |u_p| = 1. \tag{4.14}$$

Therefore,

$$u_p d_p = u_p e_p e_p^* = e_p' e_p^* = \Phi_p^R(\nu_p) = c_p^* c_p' = u_p^* c_p^* c_p = u_p^* d_p, \tag{4.15}$$

which proves that $u_p = \pm 1$ and $\nu_p = \pm 1_p$.

Defining ν_p as the zero intertwiner for non-self-conjugate irreducible objects p, one can obtain a natural map ν between the identity functors.

Since the representation category of a (pure weak) C^*-Hopf algebra is a rigid monoidal C^* category with irreducible unit object, the consistency of the Hopf algebraic and the categorical definitions of the FS indicator requires that $\nu_p = d_p D_p(\sigma)$ for $p \in \mathcal{I}$, where $D_p : H \to \text{End } V_p$ is an irreducible representation of H. This is indeed the case: One can use the natural equivalences λ and ρ, the standard rigidity intertwiners that were given in Ref. 23, and the involutive conjugation on the objects $D \mapsto \hat{D} := D^T \circ S_0$ to arrive at $\kappa_D = 1_D$. Then for an irreducible self-conjugate object D_p the choice $J_p^{\hat{\alpha}\alpha} := D_p^{\hat{\alpha}\alpha}(S_0(v_p^*))$ for the matrix elements of the map $J_p : V_p \to \hat{V}_p$ leads to the desired result.

V. INVOLUTIVE CONJUGATION

The existence of the natural isomorphism $\{\kappa_a : \hat{\hat{a}} \to a\}$ suggests that a convenient choice $\hat{\hat{a}} = a$ can be achieved. This requires, however, a further assumption on the category $\mathcal{C}$; namely, the cardinalities of the sets of objects in any two equivalence classes that are related by conjugation must be equal. This quite harmless assumption will always hold after adjoining, if necessary, new objects to $\mathcal{C}$, and this procedure does not change the category within equivalence.

Therefore, from now on we assume that the object map $a \mapsto \hat{a}$ of our conjugation functor is involutive, $\hat{\hat{a}} = a$ for all $a \in \text{Obj } \mathcal{C}$, and that $\hat{a} = a$ whenever $\hat{a} \simeq a$. It follows that every choice of standard rigidity intertwiners leads to a conjugation functor $L \equiv R$ that is involutive on the arrows as well. As a matter of fact, for each $T \in (a,b)$ we have $T^{LL} = T^{LR} = \kappa_b^{-1} T \kappa_a = T$.

Due to the involutivity of the conjugation, for irreducible objects p the natural isomorphism $\kappa_p : \hat{\hat{p}} = p \to p$ becomes $\kappa_p = \chi_p 1_p$ with $\chi_p \sim \mathbb{C}$ and $|\chi_p| = 1$. The question arises whether the scalar χ_p that appears here has something to do with the Frobenius–Schur indicator or it can be ''gauged'' away. The relations (3.4) now read as

$$\begin{aligned} e_{\hat{p}} &= c_p^*(\kappa_p \times 1_{\hat{p}}) = \chi_p c_p^*, \\ c_{\hat{p}} &= (1_{\hat{p}} \times \kappa_p^{-1}) e_p^* = \chi_p^{-1} e_p^* \equiv \overline{\chi_p} e_p^*. \end{aligned} \tag{5.1}$$

Inserting $p = \hat{q}$ in the first equation, we obtain $\chi_{\hat{q}} e_{\hat{q}}^* = c_{\hat{q}} = \overline{\chi_q} e_q^*$, implying that $\chi_{\hat{q}} = \overline{\chi_q} \equiv \chi_q^{-1}$. For self-conjugate irreducibles $q = \hat{q}$ we obtain $\chi_q = \pm 1$. In this case by choosing the map $J_q : q \to \hat{q}$ in the definition (4.12) of the FS indicator to be 1_q, we obtain

$$\nu_q = J^{-1} \hat{J} \kappa_q^{-1} = 1_q 1_q (\chi_q^{-1} 1_q) = \chi_q^{-1} 1_q \quad \text{for all } q \in \mathcal{I} \text{ with } q = \hat{q}. \tag{5.2}$$

If $p \neq \hat{p}$ for $p \in \mathcal{I}$, then we can employ the freedom (2.24) so as to change the rigidity intertwiners of one of the irreducible objects of the pair $\{p,\hat{p}\}$, let us say of $\hat{p}$:

$$e'_{\hat{p}} := \chi_p^{-1} e_{\hat{p}}, \quad c'_{\hat{p}} := \chi_p c_{\hat{p}}, \quad e'_p := e_p, \quad c'_p := c_p. \tag{5.3}$$

Then $e'_{\hat{p}} = c'^*_p$ and $c'_{\hat{p}} = e'^*_p$, i.e., the coefficients χ that are present in (5.1) are gauged away for $p \in \mathcal{I}$, $p \neq \hat{p}$.

To summarize: after enlarging $\mathcal{C}$ appropriately, there exists a *standard conjugation functor* that is involutive both on the objects and on the arrows and has the property that for $p \in \mathcal{I}$

$$\begin{aligned} e_{\hat{p}} &= \chi_p c_p^*, \\ c_{\hat{p}} &= \chi_p^{-1} e_p^*, \end{aligned} \quad \text{with} \quad \chi_p = \begin{cases} 1 & \text{for } p \neq \hat{p}, \\ \nu_p & \text{for } p = \hat{p}. \end{cases} \tag{5.4}$$

VI. FROBENIUS MAPS ON BASIC INTERTWINER SPACES

Let us call the space $(p, q \times r)$, for $p,q,r \in \mathcal{I}$, a *basic intertwiner* space. It is a Hilbert space with scalar product determined by

$$(t_1, t_2) 1_p := t_1^* t_2 \quad \text{for} \quad t_1, t_2 \in (p, q \times r). \tag{6.1}$$

We define two antilinear maps

$$x: (p, q \times r) \to (r, \hat{q} \times p), \quad y: (p, q \times r) \to (q, p \times \hat{r}) \tag{6.2}$$

by

$$x(t) := (1_{\hat{q}} \times t^*) \varphi^*_{\hat{q},q,r} (e_q^* \times 1_r) \rho_r \sqrt{\frac{d_r}{d_p}}, \quad y(t) := (t^* \times 1_{\hat{r}}) \varphi^*_{q,r,\hat{r}} (1_q \times c_r) \lambda_r \sqrt{\frac{d_q}{d_p}} \tag{6.3}$$

and call them the Frobenius maps. These maps are antilinear isometries, i.e., for the scalar product the formula

$$\big(x(t_1), x(t_2)\big) = (t_2, t_1) = \big(y(t_1), y(t_2)\big) \tag{6.4}$$

holds due to the trace property (3.6). They generate a $\mathbb{Z}_2$-graded antilinear and projective action of S_3 on the basic intertwiner spaces. A $\mathbb{Z}_2$-graded antilinear action of a $\mathbb{Z}_2$-graded group means linear (antilinear) action for even (odd) elements of the group. A permutation group is naturally $\mathbb{Z}_2$ graded by distinguishing even and odd permutations. Moreover, the Frobenius maps generate only a projective action since using (5.4) one proves that

$$x^2 = \chi_q \cdot id_{(p,q \times r)}, \quad y^2 = \chi_r \cdot id_{(p,q \times r)}, \tag{6.5}$$

as well as

$$xyx = yxy: (p, q \times r) \to (\hat{p}, \hat{r} \times \hat{q}), \tag{6.6}$$

which constitutes just a projective version of the defining S_3 relations for the transpositions: $\sigma_{12} \leftrightarrow x$, $\sigma_{23} \leftrightarrow y$. In a generic case the Frobenius maps lead to an orbit of six different intertwiner spaces:

$$\begin{aligned} &\mathrm{Im}(id) = (p, q \times r), \quad \mathrm{Im}(xy) = (\hat{r}, \hat{p} \times q), \\ &\mathrm{Im}(x) = (r, \hat{q} \times p), \quad \mathrm{Im}(yx) = (\hat{q}, r \times \hat{p}), \\ &\mathrm{Im}(y) = (q, p \times \hat{r}), \quad \mathrm{Im}(yxy) = (\hat{p}, \hat{r} \times \hat{q}). \end{aligned} \tag{6.7}$$

It is easy to give the action of the Frobenius maps on canonical basic intertwiners $\rho_p \in (p,\varepsilon \times p)$ and $\lambda_p \in (p,p\times\varepsilon)$, namely,

$$x(\rho_p)=\rho_p\,,\quad y(\rho_p)=\frac{1}{\sqrt{d_p}}\,c_p\,,\quad xy(\rho_p)=\lambda_{\hat p}\,, \tag{6.8}$$

and

$$x(\lambda_p)=\frac{1}{\sqrt{d_p}}\,e_p^*\,,\quad y(\lambda_p)=\lambda_p\,,\quad yx(\lambda_p)=\rho_{\hat p}\,. \tag{6.9}$$

Therefore, they are not generic but length three orbits of S_3 with a possible projective $\mathbb{Z}_2$ extension by χ_p.

There are other cases, too, where the orbits are not generic. Then we have a representation of the corresponding nontrivial stabilizer subgroup of S_3 on a basic intertwiner space. In the list below we present all the possible irreducible representations of the stabilizer subgroups in the nongeneric cases. In two cases we obtain certain restrictions on fusion coefficients.

(1) $q=\hat q,\ r=p\neq q$: orbit$=\{(p,p\times q),(q,\hat p\times p),(\hat p,q\times\hat p)\}$. Therefore there is a $\mathbb{Z}_2$-graded antilinear (projective if $\chi_q=-1$) representation of $\mathbb{Z}_2$ on $(p,p\times q)$ generated by *y*. But an antilinear unitary is always of order 2, therefore this intertwiner space is the null space if $\chi_q=-1$, i.e., the corresponding fusion coefficient is $N_{pq}^{p}=0$. If $\chi_q=1$, we have a $\mathbb{Z}_2$-graded antilinear representation of $\mathbb{Z}_2$, and such irreducible representations are unique up to unitary equivalence.

(2) $q=r=\hat p\neq p$: orbit$=\{(p,\hat p\times\hat p),(\hat p,p\times p)\}$. Therefore there is a linear representation of $\mathbb{Z}_3$ on $(p,\hat p\times\hat p)$, generated by *xy*. One can use an orthonormal basis in $(p,\hat p\times\hat p)$ in which the basis elements carry one of the three possible (one-dimensional) irreducible representations of $\mathbb{Z}_3$. (A simple example is given in the Appendix.)

(3) $q=r=p=\hat p$: orbit$=\{(p,p\times p)\}$. Therefore there is a $\mathbb{Z}_2$-graded antilinear (projective if $\chi_p=-1$) representation of S_3 on $(p,p\times p)$. Similarly to the first case we have $N_{pp}^{p}=0$ if $\chi_p=-1$. If $\chi_p=1$, we get a $\mathbb{Z}_2$-graded antilinear proper representation of S_3. Such irreducible representations are one-dimensional and can be labelled by the three possible irreducible representations of $\mathbb{Z}_3$. One can use a basis in $(p,p\times p)$ where basis elements carry these irreducible representations.

VII. S_4-TRANSFORMED SIMPLICIAL MAPS OF A TETRAHEDRON

Let us consider the following Hilbert space containing certain fourfold tensor products of basic intertwiner spaces as orthogonal subspaces:

$$\begin{aligned}\mathcal{H}\equiv\bigoplus_{\mathbf{s}}\mathcal{H}_{\mathbf{s}}:=&\bigoplus_{p,q,r,t,u,v\in\mathcal{I}}(p\times q,u)\otimes(u\times r,t)\otimes(v,q\times r)\otimes(t,p\times v)\\ \equiv&\bigoplus_{p,q,r,t,u,v\in\mathcal{I}}(u,p\times q)^*\otimes(t,u\times r)^*\otimes(v,q\times r)\otimes(t,p\times v),\end{aligned} \tag{7.1}$$

where we put $(u,p\times q)^*:=\{t^*|t\in(u,p\times q)\}$. Vectors in subspaces $\mathcal{H}_{\mathbf{s}}$ of $\mathcal{H}$ that correspond to a fourfold tensor product of basic intertwiner spaces can be labeled by the two-dimensional simplicial complex of the boundary of a tetrahedron Δ^3. More precisely, there are simplicial maps

$$\nu=(\nu^0,\nu^1,\nu^2):\ \ \partial\Delta^3\rightarrow\mathcal{H}_{\mathbf{s}} \tag{7.2}$$

as follows. ν^0 maps all vertices into one point, thus the vertices of the tetrahedron remain unlabeled. (Nontrivial ν^0 is needed only in two-categories, which is out of the scope of the present paper.) ν^1 associates to each oriented edge of Δ^3 an irreducible object from the set of representants $\mathcal{I}$. Thus the edges become labeled with $\mathcal{I}$:

$$\begin{aligned} \nu^1(12)&:=p, \quad \nu^1(14):=t,\\ \nu^1(23)&:=q, \quad \nu^1(13):=u,\\ \nu^1(34)&:=r, \quad \nu^1(24):=v. \end{aligned} \tag{7.3}$$

Edges with opposite orientation carry the conjugate objects, e.g., $\nu^1(21)=\hat{p}$.

To every element of a basic intertwiner space one can associate an oriented face by a right-hand rule:

$(u,p\times q)\ni\alpha=$ 
$\longleftrightarrow$ 
$=\nu^2(123)_+$

$(u,p\times q)^*\ni\alpha^*=$ 
$\longleftrightarrow$ 
$=\nu^2(123)_-$

(In the vertex pictures, all arrows point downwards; correspondingly we can safely suppress them.)

The two possible orientations tell us whether we are in a basic intertwiner space $(u,p\times q)$ or in its adjoint $(u,p\times q)^*\equiv(p\times q,u)$. Now the images of the faces of the tetrahedron are defined to be elements of basic intertwiner spaces:

$$\begin{aligned} \nu^2(123)&:=\alpha^u_{pq}\in(u,p\times q)\equiv(\nu^1(13),\nu^1(12)\times\nu^1(23)),\\ \nu^2(134)&:=\beta^t_{ur}\in(t,u\times r)\equiv(\nu^1(14),\nu^1(13)\times\nu^1(34)),\\ \nu^2(234)&:=\gamma^v_{qr}\in(v,q\times r)\equiv(\nu^1(24),\nu^1(23)\times\nu^1(34)),\\ \nu^2(124)&:=\delta^t_{pv}\in(t,p\times v)\equiv(\nu^1(14),\nu^1(12)\times\nu^1(24)). \end{aligned} \tag{7.4}$$

Permutation of the index set $\{1,2,3,4\}$ of the points of the tetrahedron defines, using the Frobenius maps x,y, an S_4-action on the maps $\nu:\partial\Delta^3\rightarrow\mathcal{H}_s$ as follows:

$$(\nu_\tau)^0:=\nu^0\circ\tau, \quad (\nu_\tau)^1(ij):=\nu^1(\tau(i),\tau(j)) \quad \text{for all} \quad \tau\in S_4 \quad \text{and} \quad i,j\in\{1,2,3,4\}. \tag{7.5}$$

The definition of the transforms of ν^2 uses the Frobenius maps. Let τ_{12}, τ_{23}, and τ_{34} denote the generating transpositions of S_4. Then

$$\begin{aligned} (\nu_{\tau_{12}})^2(123)&:=x(\nu^2(123)), \quad (\nu_{\tau_{12}})^2(234):=\nu^2(134),\\ (\nu_{\tau_{12}})^2(134)&:=\nu^2(234), \quad (\nu_{\tau_{12}})^2(124):=x(\nu^2(124)); \end{aligned} \tag{7.6}$$

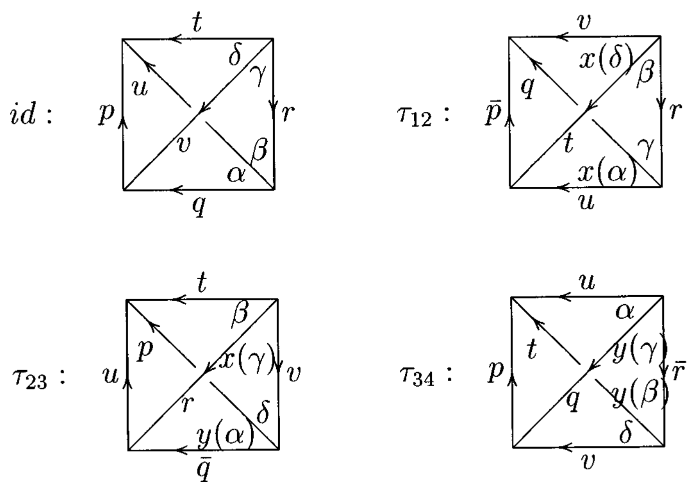
in other words, introducing the notation

$$\alpha^* \otimes \beta^* \otimes \gamma \otimes \delta = \nu^2(123)^* \otimes \nu^2(134)^* \otimes \nu^2(234) \otimes \nu^2(124) \in \mathcal{H}_s\,, \tag{7.7}$$

one has the induced transformations

$$\begin{aligned} \tau_{12}:&\;\; \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta \to x(\alpha)^* \otimes \gamma^* \otimes \beta \otimes x(\delta), \\ \tau_{23}:&\;\; \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta \to y(\alpha)^* \otimes \delta^* \otimes x(\gamma) \otimes \beta, \\ \tau_{34}:&\;\; \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta \to \delta^* \otimes y(\beta)^* \otimes y(\gamma) \otimes \alpha \end{aligned} \tag{7.8}$$

on the ν^2 images. The images of the original and the transformed maps ν, $\nu_{\tau_{12}}$, $\nu_{\tau_{23}}$, and $\nu_{\tau_{34}}$ can be pictured as



Extending the maps in (7.8) antilinearly, one obtains an action of S_4 on the Hilbert space $\mathcal{H}$ in (7.1). The important property of this S_4 action is the following:

Lemma: The above-defined action of the transpositions τ_{12}, τ_{23}, *and* τ_{34} *induces a* $\mathbb{Z}_2$*-graded antilinear representation of* S_4 *on* $\mathcal{H}$.

Proof: One has to check only the defining relations of S_4:

$$\tau_{12}^2 = \tau_{23}^2 = \tau_{34}^2 = id, \quad \tau_{12}\tau_{23}\tau_{12} = \tau_{23}\tau_{12}\tau_{23}, \quad \tau_{23}\tau_{34}\tau_{23} = \tau_{34}\tau_{23}\tau_{34}. \tag{7.9}$$

Indeed one obtains

$$\begin{aligned} \tau_{12}^2(\alpha^* \otimes \beta^* \otimes \gamma \otimes \delta) &= x^2(\alpha)^* \otimes \beta^* \otimes \gamma \otimes x^2(\delta) = \chi_p^2 \cdot \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta = \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta, \\ \tau_{23}^2(\alpha^* \otimes \beta^* \otimes \gamma \otimes \delta) &= y^2(\alpha)^* \otimes \beta^* \otimes x^2(\gamma) \otimes \delta = \chi_q^2 \cdot \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta = \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta, \\ \tau_{34}^2(\alpha^* \otimes \beta^* \otimes \gamma \otimes \delta) &= \alpha^* \otimes y^2(\beta)^* \otimes y^2(\gamma) \otimes \delta = \chi_r^2 \cdot \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta = \alpha^* \otimes \beta^* \otimes \gamma \otimes \delta, \end{aligned} \tag{7.10}$$

while

$$\begin{aligned}\tau_{12}\tau_{23}\tau_{12}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta) &= xyx(\alpha)^*\otimes x(\beta)^*\otimes x(\delta)\otimes x(\gamma)\\ &= yxy(\alpha)^*\otimes x(\beta)^*\otimes x(\delta)\otimes x(\gamma)\\ &= \tau_{23}\tau_{12}\tau_{23}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta),\\ \tau_{23}\tau_{34}\tau_{23}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta) &= y(\beta)^*\otimes y(\alpha)^*\otimes xyx(\gamma)\otimes y(\delta)\\ &= y(\beta)^*\otimes y(\alpha)^*\otimes yxy(\gamma)\otimes y(\delta)\\ &= \tau_{34}\tau_{23}\tau_{34}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta).\end{aligned} \tag{7.11}$$

■

Notice that although the Frobenius maps lead to a ($\mathbb{Z}_2$-graded antilinear) *projective* representation of S_3 on each basic intertwiner space, due to the fact that $\partial\Delta^3$ is a closed orientable surface without boundary, the action of S_4 on $\mathcal{H}$ is a *proper* (i.e., nonprojective) representation. As a matter of fact, according to (7.10), the Frobenius transformations x^2 and y^2 that lead to the signs χ are always coming in pairs.

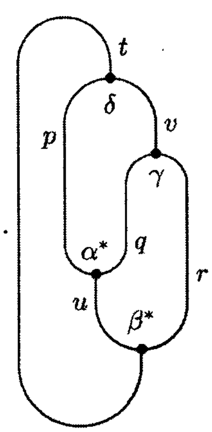
VIII. AN S_4-INVARIANT LINEAR FUNCTIONAL ON $\mathcal{H}$

Let us define a linear functional Φ: $\mathcal{H}\to\mathbb{C}$ on the Hilbert space $\mathcal{H}$ (7.1) by

$$\Phi(\alpha_{pq}^{u*}\otimes\beta_{ur}^{t*}\otimes\gamma_{qr}^{v}\otimes\delta_{pv}^{t}) := \sqrt{\frac{d_p d_q d_r}{d_t}}\cdot e_t(1_{\hat t}\times\beta_{ur}^{t*})(1_{\hat t}\times(\alpha_{pq}^{u*}))$$
$$(1_{\hat t}\times\varphi_{p,q,r})(1_{\hat t}\times(1_p\times\gamma_{qr}^{v}))(1_{\hat t}\times\delta_{pv}^{t})e_t^*. \tag{8.1}$$

Pictorially, the value is

$$\Phi(\alpha_{pq}^{u*}\otimes\beta_{ur}^{t*}\otimes\gamma_{qr}^{v}\otimes\delta_{pv}^{t}) = \sqrt{\frac{d_p d_q d_r}{d_t}}\cdot \tag{8.2}$$



(In order not to overburden the picture, we do not indicate the maps λ, ρ, and φ; due to coherence and naturality they can be put back unambiguously.)

The action of $\tau\in S_4$ on Φ is the one induced by the action on $\mathcal{H}$,

$$(\tau\Phi)(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta) := \overline{\Phi(\tau^{-1}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta))}^{\deg\tau}, \tag{8.3}$$

where the notation ''overline to the power of deg τ'' means complex conjugation for odd S_4 elements and the identity operation for even elements. This transformation property is required by the linearity of Φ and the antilinearity of S_4 on $\mathcal{H}$ to be compatible:

$$(\tau\Phi)(\lambda X)=\overline{\Phi(\tau^{-1}(\lambda X))}^{\deg\tau}=\overline{\overline{\lambda}^{\deg\tau}\Phi(\tau^{-1}(X))}^{\deg\tau}=\lambda\cdot\overline{\Phi(\tau^{-1}(X))}^{\deg\tau} \tag{8.4}$$

for $X\in\mathcal{H}$. Hence the functional Φ is S_4 invariant if

$$(\tau\Phi)(X):=\overline{\Phi(\tau^{-1}(X))}^{\deg\tau}=\Phi(X) \tag{8.5}$$

for all $\tau\in S_4$, or equivalently

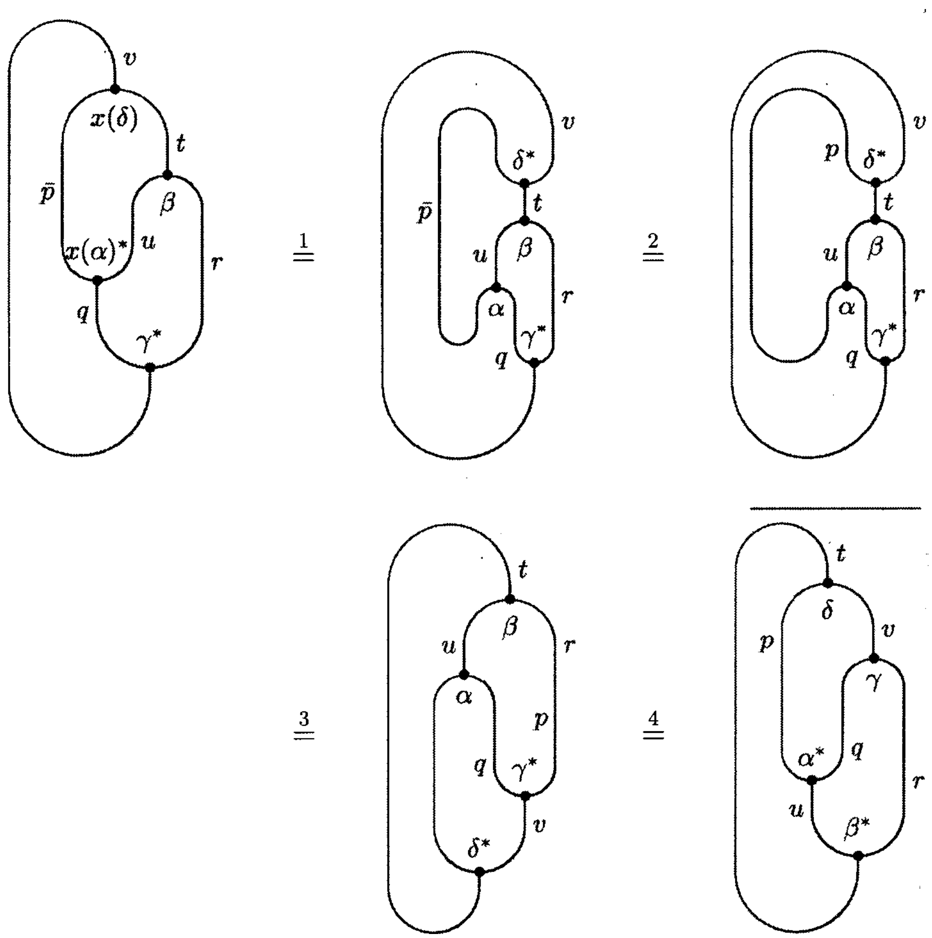
$$\Phi(\tau^{-1}(X))=\overline{\Phi(X)}^{\deg\tau} \tag{8.6}$$

for all $\tau\in S_4$.

Proposition: The functional Φ is constant on S_4 orbits.

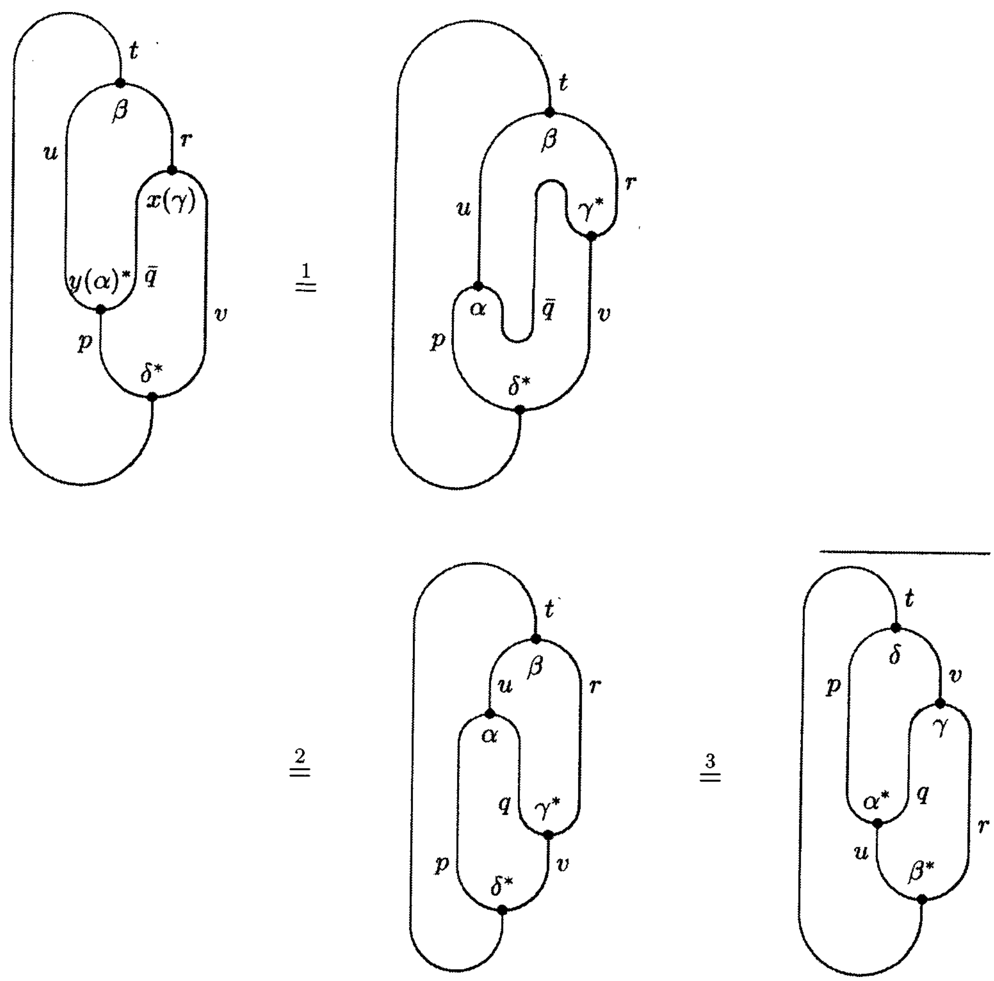
Proof: It is sufficient to show this property for the generators of S_4. Below there is a diagrammatic proof where we used the definitions of the Frobenius maps, the trace property, rigidity, the property End $\varepsilon=\mathbb{C}\cdot 1_\varepsilon$, and sphericity in the last series of pictures.

Invariance with respect to τ_{12} is shown by the following chain of equalities:



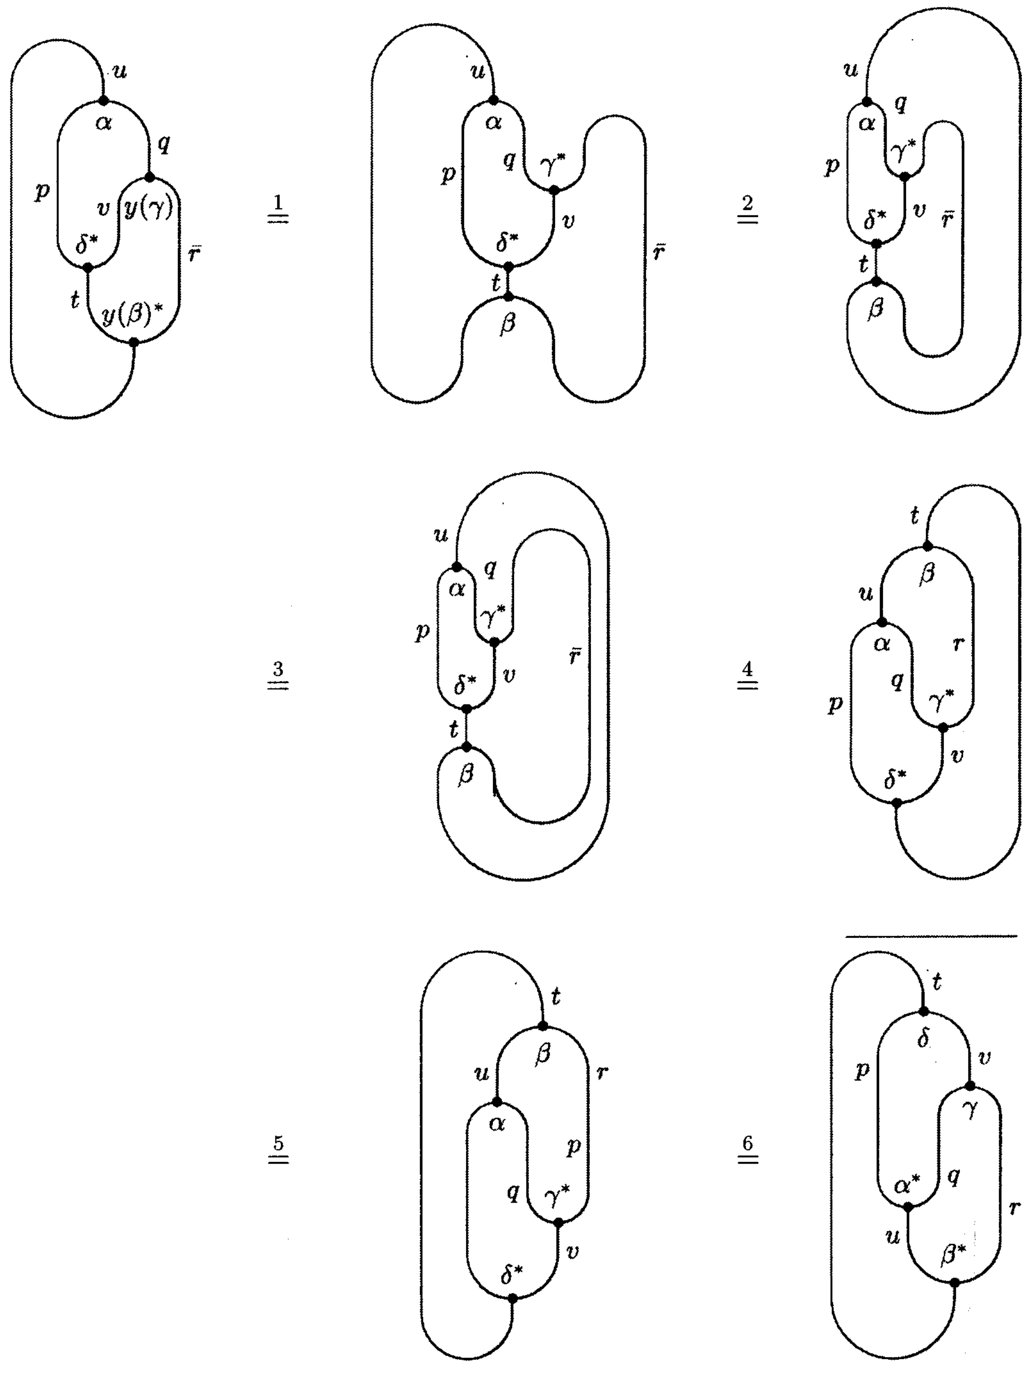
Here we have used the definition of the Frobenius map x in the first equality, the monoidality of the functor of taking duals in the second, used the trace property in the third, and the definition of ''*'' in the fourth equality.

Proof of the invariance with respect to τ_{23}:



This chain of equalities is obtained as follows. In the first equality we used the definition of the Frobenius maps x and y; in the second equality the rigidity identity is used; and in the third equality the definition of ''*'' is implemented.

Proof of the invariance with respect to τ_{34}:



In this chain of equalities we have used the definition of the Frobenius map y in the first equality; the spherical property in the second; the monoidality of the functor of taking duals in the third; used the trace property in the fourth; used the spherical property in the fifth; and used the definition of "*" in the sixth. ■

By definition the normalized F-coefficients are

$$\check{F}^{(pqr)_t}_{u,v}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta) := \Phi(\alpha^{u*}_{pq}\otimes\beta^{t*}_{ur}\otimes\gamma^{v}_{qr}\otimes\delta^{t}_{pv}), \tag{8.7}$$

where α, β, γ, and δ are elements of orthonormal bases of the corresponding basic intertwiner spaces. Their relation to the $6j$-symbols $\{F^{(pqr)_t}_{\alpha u\beta,\gamma v\delta}\}$ is given by

$$F^{(pqr)_t}_{\alpha u\beta,\gamma v\delta}=\frac{1}{\sqrt{d_pd_qd_rd_t}}\check{F}^{(pqr)_t}_{u,v}(\alpha^*\otimes\beta^*\otimes\gamma\otimes\delta). \tag{8.8}$$

Because of the isometry property of φ they are unitary matrices in the multi-labels $(\alpha u\beta,\gamma v\delta)$. The proposition leads to the possibility of computing $\check{F}$ in a single point of an S_4 orbit and determine the $6j$ symbols on all the other elements of that orbit.

APPENDIX: S_4 SYMMETRY FOR C^* CATEGORIES BASED ON $\mathbb{Z}_3$

As a simple but nevertheless nontrivial illustration of the results of the main text, let us consider the following three (degenerate) rational Hopf algebras[18,19] that can be obtained as deformations of the Hopf algebra $\mathbb{C}\mathbb{Z}_3$, i.e., of the group algebra of the cyclic group $\mathbb{Z}_3$. The structural data can be summarized as follows:

$$H=\mathbb{C}e_0\oplus\mathbb{C}e_1\oplus\mathbb{C}e_2,\quad e_p^*=e_p^2=e_p\quad\text{for } i=0,1,2, \tag{A1}$$

$$\Delta(e_p)=\sum_{\substack{q,r=0\\ q+r=p \bmod 3}}^{2} e_q\otimes e_r,\quad S(e_p)=e_{-p \bmod 3}, \tag{A2}$$

$$\lambda=\rho=\mathbf{1}\equiv e_0+e_1+e_2=l=r\in H, \tag{A3}$$

$$\varphi=\sum_{p,q,r=0}^{2}\omega_{pqr}\cdot e_p\otimes e_q\otimes e_r\in H\otimes H\otimes H. \tag{A4}$$

Here $\omega_{111}=\omega_{222}=\omega_{112}=\omega_{221}=\omega_{211}=\omega_{122}=:\omega$ is a third root of unity, $\omega^3=1$, which parametrizes the three different rational Hopf algebras, while in all three cases one has $\omega_{pqr}=1$ for all other combinations of indices.

The representation category **Rep** H is a rigid monoidal C^*-category. The irreducible representations D_p, $p=0,1,2$, are one-dimensional and obey $D_p(e_q)=\delta_{p,q}$. The basic intertwiner spaces are one-dimensional at most, and we can choose $(p,q\times r)=\mathbb{C}\cdot 1^p_{qr}$ for the nontrivial ones, where 1^p_{qr} maps the tensor product of the chosen unit vectors into the chosen unit vector of the corresponding one-dimensional representation spaces, i.e., $1^p_{qr}(v_q\otimes v_r)=v_p$. The natural isometries connected to monoidality and the standard rigidity intertwiners are given by

$$\lambda_p=1^p_{p0},\quad \rho_p=1^p_{0p},\quad \varphi_{p,q,r}=(D_p\otimes D_q\otimes D_r)(\varphi), \tag{A5}$$

$$e_p=1^{0*}_{\hat{p}p},\quad c_p=1^0_{p\hat{p}}. \tag{A6}$$

The values of χ (5.4) are all trivial: $\chi_p=1$ for $p=0,1,2$. Using the definitions (6.3) of the Frobenius maps, one obtains

$$x(1^p_{qr})=\overline{\omega}_{\hat{q}qr}1^r_{\hat{q}p},\quad y(1^p_{qr})=\omega_{qr\hat{r}}1^q_{p\hat{r}}, \tag{A7}$$

with ω_{pqr} as in (A4). In the case $(p,q\times r)=(1,2\times 2)$, this leads to

$$xy(1^1_{22}) = \omega \cdot 1^1_{22}, \tag{A8}$$

which serve as examples of a degenerate orbit of type 2 in Sec. VI with the possible third roots of unity.

The S_4 symmetry is valid in a nontrivial way in the following sense. First note that there are five S_4 orbits of normalized F-coefficients $\check{F}^{(pqr)_t}_{u,v}(\alpha^{u*}_{pq}\otimes\beta^{t*}_{ur}\otimes\gamma^{v}_{qr}\otimes\delta^{t}_{pv})$ that have the elements (only their pqr edges indicated):

$$\{000\}, \quad \{001,200,120,012\}, \quad \{002,100,210,021\},$$
$$\{010,020,102,201,121,212\}, \tag{A9}$$
$$\{101,011,110,202,022,220,111,222,112,122,221,211\},$$

respectively, together with their complex conjugated quantities. One can easily compute the first normalized F coefficient of the fifth orbit:

$$\check{F}^{(101)_2}_{1,1}(1^{1*}_{10}\otimes 1^{2*}_{11}\otimes 1^{1}_{01}\otimes 1^{2}_{11}) = 1; \tag{A10}$$

then due to the S_4 invariance one deduces that the other coefficients in the same orbit have the value 1, too. Computation of the τ_{12}-transformed quantity

$$\begin{aligned}1 = \tau_{12}(\check{F}^{(101)_2}_{1,1}(1^{1*}_{10}\otimes 1^{2*}_{11}\otimes 1^{1}_{01}\otimes 1^{2}_{11})) &= \overline{\check{F}^{(211)_1}_{0,2}(x(1^{1}_{10})^*\otimes 1^{1*}_{01}\otimes 1^{2}_{11}\otimes x(1^{2}_{11}))}\\ = \overline{\check{F}^{(211)_1}_{0,2}(\omega_{210}\overline{\omega}_{211}\cdot 1^{0*}_{21}\otimes 1^{1*}_{01}\otimes 1^{2}_{11}\otimes 1^{1}_{22})} &= \omega\cdot\overline{\check{F}^{(211)_1}_{0,2}(1^{0*}_{21}\otimes 1^{1*}_{01}\otimes 1^{2}_{11}\otimes 1^{1}_{22})} = \omega\cdot\overline{\omega}\end{aligned} \tag{A11}$$

then shows that one may not have S_4 invariance for a fixed set of basic intertwiners in general, so it is important to take the action of the Frobenius maps into account. In this example even the following stronger statement holds: in the case of $\omega\neq 1$ there is *no* such choice for the set of orthonormal basic intertwiners, $\{b^{q\times r}_{qr} := \omega_{qr}\cdot 1^{q\times r}_{qr} \mid q,\ r=0,1,2\}$ with arbitrary but fixed values of $\omega_{qr}\in\mathbb{C}$, $|\omega_{qr}|=1$, that leads to a constant value of normalized F coefficients within the chosen set of intertwiners. Indeed, the relation

$$\begin{aligned}\check{F}^{(101)_2}_{1,1}(b^{1*}_{10}\otimes b^{2*}_{11}\otimes b^{1}_{01}\otimes b^{2}_{11}) &= \tau_{13}(\check{F}^{(101)_2}_{1,1}(b^{1*}_{10}\otimes b^{2*}_{11}\otimes b^{1}_{01}\otimes b^{2}_{11}))\\ &= \overline{\check{F}^{(101)_2}_{1,1}(y(b^{1}_{10})^*\otimes b^{2*}_{11}\otimes x(b^{1}_{01})\otimes b^{2}_{11})}\end{aligned} \tag{A12}$$

implies that the common value should be ± 1, but then the product of the $\tau_{12}\tau_{34}$- and $\tau_{23}\tau_{34}\tau_{12}\tau_{23}$-transformed F-coefficients leads to the contradiction

$$\begin{aligned}1 \neq \check{F}^{(222)_0}_{1,1}&(x(b^{2}_{11})^*\otimes y(b^{1}_{01})^*\otimes y(b^{2}_{11})\otimes x(b^{1}_{10}))\\ &\times\check{F}^{(111)_0}_{2,2}(xy(b^{2}_{11})^*\otimes xy(b^{1}_{01})^*\otimes xy(b^{2}_{11})\otimes yx(b^{1}_{10})) = \omega^2.\end{aligned} \tag{A13}$$

We also note that for a nontrivial third root of unity, $\omega\neq 1$, there are no solutions of the hexagon equations, that is **Rep***H* cannot be made into a braided category in those cases.

The quantum dynamical Yang–Baxter (or Gervais–Neveu–Felder) equation defines an *R*-matrix $\hat{R}(p)$, where p stands for a set of mutually commuting variables. A family of $SL(n)$-type solutions of this equation provides a new realization of the Hecke algebra. We define quantum antisymmetrizers, introduce the notion of quantum determinant and compute the inverse quantum matrix for matrix algebras of the type $\hat{R}(p)a_1a_2=a_1a_2\hat{R}$. It is pointed out that such a quantum matrix algebra arises in the operator realization of the chiral zero modes of the WZNW model. © *1999 American Institute of Physics.* [S0022-2488(99)02801-7]

I. INTRODUCTION

Let $\{v^{(i)}, i=1,\dots,n\}$ be a "barycentric basis" in a Cartan subalgebra $\mathfrak{h}\subset \mathrm{sl}(n)$. Viewed as operators in the n-dimensional complex space $V=\mathbb{C}^n$, $v^{(i)}$ can be realized as real traceless diagonal $n\times n$ matrices:

$$(v^{(i)})^j_j=\delta_{ij}-\frac{1}{n} \quad \Rightarrow \quad \sum_{i=1}^{n} v^{(i)}=0\ . \tag{1.1}$$

Let further $\{p_i\}_{i=1}^n$ span the dual Lie algebra $\mathfrak{h}^*$. Introduce the traceless diagonal matrix

$$p=p_iv^{(i)}\left(\equiv\sum_{i=1}^{n} p_iv^{(i)}\right), \quad [p_i,p_j]=0, \quad \sum_{i=1}^{n} p_i=0. \tag{1.2}$$

We define a Hecke-type quantum dynamical R-matrix $\hat{R}(p)$ as a map from $\mathfrak{h}^*$ to End $(V\otimes V)$ satisfying the *twisted braid relation*

$$\hat{R}_{12}(p)\hat{R}_{23}(p-v_1)\hat{R}_{12}(p)=\hat{R}_{23}(p-v_1)\hat{R}_{12}(p)\hat{R}_{23}(p-v_1) \tag{1.3}$$

and the Hecke condition

$$\hat{R}(p)^2=\mathbb{I}+(q-\overline{q})\hat{R}(p)\,, \quad \overline{q}:=q^{-1}\,. \tag{1.4}$$

(Although the notation is tailored to the special case in which the parameter q takes values on the unit circle, we shall not use this property in the main body of the paper.) The subscripts in (1.3) refer to the, by now standard, tensor product notation of Faddeev *et al.* (see, e.g., Ref. 1); in particular, $\hat{R}_{23}(p-v_1)\in \mathrm{End}(V^{\otimes 3})$ has matrix elements

$$(\hat{R}_{23}(p-v_1))^{i_1 i_2 i_3}_{j_1 j_2 j_3} = \delta^{i_1}_{j_1}\hat{R}(p-v^{(i_1)})^{i_2 i_3}_{j_2 j_3}\,. \tag{1.5}$$

The twisted braid relation (1.3) is equivalent to the *quantum dynamical*[2,3] (or *deformed*[4]) *Yang–Baxter equation* (QDYBE) for the matrix $R(p)$ related to the braid operator $\hat{R}(p)$ by $\hat{R}(p)=PR(p)$, where P stands for the permutation operator $Px_1y_2=y_1x_2, x,y\in V, P^2=1$. Abusing terminology we shall also refer to Eq. (1.3) by the above abbreviation. The term ''dynamical R-matrix'' for $\hat{R}(p)$ is suggested by the fact that in the physical applications its arguments play the role of (commuting) dynamical variables and that $\hat{R}(p)$ satisfies a finite difference rather than a purely algebraic equation.

The important concept of a *quantum matrix algebra* $\mathcal{A}=\mathcal{A}(\hat{R}(p),\hat{R})$ (Sec. V) can be introduced as a (complex) associative algebra with 1 generated by rational functions of $q^{p_i}, i=1,\dots,n$, and the (noncommuting) entries of an $n\times n$ matrix $a=(a^i_\alpha)$ satisfying the quadratic exchange relations

$$\hat{R}(p)\,a_1\,a_2 = a_1\,a_2\,\hat{R}, \tag{1.6}$$

where $\hat{R}\equiv\hat{R}^{\alpha_1\alpha_2}_{\beta_1\beta_2}$ in the right-hand side is a constant (i.e., p-independent) solution of (1.3), (1.4), and all entries in a matrix row $a^i=\{a^i_\alpha\}^n_{\alpha=1}$ are acting equivalently as shift operators for p:

$$p\,a^i=a^i(p+v^{(i)})\text{or}\;\; p_{jk}a^i=a^i(p_{jk}+\delta^i_j-\delta^i_k)\;\;\text{for}\;\; p_{jk}=p_j-p_k\,. \tag{1.7}$$

Remark 1.1: It has been pointed out[4,5] that, in the su(2) case, the matrix a generates the q-Clebsh–Gordan coefficients while $\hat{R}(p)$ plays the role of a ''quantum $6j$-symbol.''[6–8]

Remark 1.2: Eq. (1.6) is related to the one with indices 1 and 2 interchanged,

$$\hat{R}(p)\,a_2\,a_1 = a_2\,a_1\,\hat{R}, \tag{1.8}$$

by the substitution $\hat{R}\rightarrow P\hat{R}P$, $\hat{R}(p)\rightarrow P\hat{R}(p)\,P$. It is, on the other hand, formally obtained from

$$\hat{R}\,\overline{a}_2\,\overline{a}_1 = \overline{a}_2\,\overline{a}_1\,\hat{R}(p) \tag{1.9}$$

by the substitution $\overline{a}=a^{-1}$; the same substitution relates (1.8) to

$$\hat{R}\,\overline{a}_1\,\overline{a}_2 = \overline{a}_1\,\overline{a}_2\,\hat{R}(p). \tag{1.10}$$

Since

$$\hat{R}(p)_{21}=P\,\hat{R}(p)P \tag{1.11}$$

satisfies conditions of the same type as $\hat{R}(p)$, we can start with either of these relations.

The QDYBE, introduced by Gervais and Neveu[2] for the exchange algebra associated with the Liouville equation and applied to the zero mode algebra[5] of the Wess–Zumino–Novikov–Witten (WZNW) model[9–11] is attracting ever more attention. Its classical counterpart, introduced in Ref. 3 (see also Ref. 12) has been displayed in Ref. 5 for the sl(2) case and in Ref. 13 for an arbitrary simple Lie algebra. The quantum $\hat{R}(p)$ is central to a continuing study[4] of q-deformed cotangent bundles on group manifolds and quantum model spaces. A quasi-Hopf-algebraic point of view is taken in Refs. 14,15, where $\hat{R}(p)$ is obtained by a Drinfeld twist of the constant R-matrix. Felder[16] explores the more general case of (classical and) QDYBE depending on a spectral parameter and finds elliptic solutions of this equation. These solutions are applied in Ref. 17 to quantize Calogero–Moser and Ruijsenaars–Schneider models. A class of $\mathrm{SL}(n|m)$-type solutions of the QDYBE (and related trigonometric solutions of the equation with spectral parameter) are described in Ref. 18. A more mathematically minded approach to the subject in terms of ''$\mathfrak{h}$-algebroids'' is being developed in Ref. 19.

The present work was motivated in part by earlier study[20–22] of the canonical quantization of the WZNW model (following Refs. 6,10,5,11,23). It was noticed, in particular, that the exchange relations[21] for the chiral zero modes a^i_α that diagonalize the $U_q(\mathrm{sl}(2))$ monodromy matrix can be written in the form (1.8). As a result, the operator realization of the chiral group valued field was understood as a quantization of the (deformed) classical Poisson bracket relations of Ref. 13 thus opening the way to its generalization for $\mathrm{SU}(n)$. Here we show that a special solution of the QDYBE (1.3) yields a new matrix representation of the Hecke algebra. We concentrate on a general study of the Hecke algebra properties of this solution and the ensuing properties of the quantum matrices satisfying (1.6) relegating applications to the WZNW model to a subsequent publication[24] which is highlighted in Sec. VI. A central result is the computation of the quantum determinant of a and the (based on it) evaluation of the inverse quantum matrix.

The paper is organized as follows. We review and extend in Sec. II results of Gurevich[25] on quantum (anti)symmetrizers and illustrate them in Sec. III on the known example of a constant $\hat{R}$. We proceed in Sec. IV to a study of a family of $\mathrm{SL}(n)$-type dynamical R-matrices and describe two types of symmetry transformations for this family: the twist transformation (a version of Drinfeld's twist for dynamical R-matrices) and the canonical shifts. In Sec. V we show that these dynamical matrices provide a new realization of the Hecke algebra. This allows us to define ''dynamical'' (p-dependent) analogs of quantum antisymmetrizers, including the Levi-Cività $\mathcal{E}$ tensor. In Sec. VI we study the quantum algebra $\mathcal{A}$, define the quantum determinant $\det(a)$, and compute the inverse matrix a^{-1}. We demonstrate that $\mathcal{A}$ provides a realization of a reflection equation algebra which is interpreted as a quantum monodromy algebra in the WZNW theory. An Appendix is devoted to deriving some useful identities for the parameters determining the solution of the QDYBE found in Ref. 18 and to computing the normalization of the dynamical Levi-Cività tensor.

II. HECKE ALGEBRAS AND *q*-ANTISYMMETRIZERS

In this section we collect some basic notions on Hecke algebras and describe the q-antisymmetrizers technique which is to be applied later on. We follow closely the approach of Gurevich.[25]

In the present context by a Hecke algebra $\mathcal{H}_k(q)$ we understand a $\mathbb{C}$-algebra with generators $1, g_1, g_2, \ldots, g_{k-1}$, a nonzero parameter $q \in \mathbb{C}$, and defining relations

$$g_i\, g_{i+1}\, g_i = g_{i+1}\, g_i\, g_{i+1} \quad \text{for } 1 \leqslant i \leqslant k-2, \tag{2.1}$$

$$g_i^2 = 1 + (q - \overline{q})\, g_i \quad \text{for } 1 \leqslant i \leqslant k-1, \tag{2.2}$$

$$g_i\, g_j = g_j\, g_i \quad \text{if } |i-j| \geqslant 2, \tag{2.3}$$

where $\overline{q} := q^{-1}$.

We shall consider the set of idempotents $A^{(j)} \in \mathcal{H}_k(q), j=1,\ldots,k$, associated with single column Young diagrams containing j nodes — the so-called q-antisymmetrizers. Their inductive definition is given by

$$A^{(1)}=1, \quad A^{(j)}=\frac{1}{[j]}A^{(j-1)}(q^{j-1}-[j-1]g_{j-1})A^{(j-1)}. \tag{2.4}$$

Here $[j]=(q^j-\overline{q}^j)/(q-\overline{q})$ and we assume $[j]\neq 0$, for $j=2,\ldots,k$. Note, that $A^{(k)}$ is a central idempotent in the algebra $\mathcal{H}_k(q)$.

Equivalently, one may write

$$A^{(j)}=\frac{1}{[j]}A^{(2,j-1)}(q^{j-1}-[j-1]g_1)A^{(2,j-1)}, \tag{2.5}$$

where we have adopted the notation $A^{(i,j)}$, $1\leqslant i\leqslant j$, for the central idempotent of the subalgebra $\mathcal{H}_{i,j}(q)\subset\mathcal{H}_j(q)$ generated by the subset $1,g_i,\ldots,g_{j-1}$. In particular, $A^{(1,j)}=A^{(j)}$, $A^{(j,j)}=1$.

Remark 2.1: All the subalgebras $\mathcal{H}_{i,r+i}(q)\subset\mathcal{H}_k(q)$, $i=1,\ldots,k-r$, are isomorphic by definition. Moreover, they are related by inner $\mathcal{H}_k(q)$-automorphisms. For example, the automorphism $\phi_i:\mathcal{H}_{i,r+i}(q)\to\mathcal{H}_{i+1,r+i+1}(q)$ is given by

$$\phi_i(t)=g_ig_{i+1}\ldots g_{r+i}\,t\,(g_ig_{i+1}\ldots g_{r+i})^{-1}, \quad \forall t\in\mathcal{H}_{i,r+i}(q). \tag{2.6}$$

The term q-antisymmetrizer for the elements $A^{(j)}$ is justified by the following properties:

$$(g_i+\overline{q})A^{(j)}=A^{(j)}(g_i+\overline{q})=0 \quad \text{for} \quad 1\leqslant i\leqslant j-1, \tag{2.7}$$

$$A^{(j)}A^{(i,l)}=A^{(i,l)}A^{(j)}=A^{(j)} \quad \text{for} \quad 1\leqslant i\leqslant l\leqslant j. \tag{2.8}$$

Remark 2.2: Replacing q by $(-q^{-1})$ in (2.4) leads to another sequence of projectors, called symmetrizers. Abstractly, inside the Hecke algebra, it is a matter of convention — which projectors one calls symmetrizers, and which — antisymmetrizers. We use the common convention. However, on the level of representations, when one can calculate the ranks of projectors and see which sequence of projectors terminates, the distinction between symmetrizers and antisymmetrizers becomes meaningful.

Consider a representation $\rho_{W,k}:\mathcal{H}_k(q)\to\mathrm{Aut}(W)$ of the algebra $\mathcal{H}_k(q)$ in a vector space W.

Definition 2.1: We shall say that $\rho_{W,k}$ is a representation of height n in one of the following two cases:

(a) $n<k$ and the conditions

$$\rho_{W,k}(A^{(n+1)})=0, \tag{2.9}$$

$$\mathrm{rank}\,\rho_{W,k}(A^{(n)})=1, \tag{2.10}$$

are fulfilled, or

(b) $n=k$ *and* $\mathrm{rank}\,\rho_{W,n}(A^{(n)})=1$.

Remark 2.3: The notion of height of a Hecke algebra representation was introduced in Ref. 25 for the special case of the representations generated by constant R-matrices. There it was named *the rank of the R-matrix*. We have changed the name here in order to avoid a possible confusion with the standard notion of rank of a matrix. Note that the use of the term ''height'' is suggested by the fact that imposing condition (2.9) for the representation $\rho_{W,k}$ results in vanishing of any central (and primitive) idempotent related to a Young diagram (standard tableaux) containing more than n boxes in one of its columns.

Remark 2.4: In view of Remark 2.1, the whole sets of q-antisymmetrizers $\{\rho_{W,k}(A^{(i,n+i)})\}_{i=1,\ldots,k-n}$ and $\{\rho_{W,k}(A^{(j,n+j-1)})\}_{j=1,\ldots,k-n+1}$ satisfy conditions (2.9) and (2.10), respectively.

Remark 2.5: Instead of using (2.9) one can impose the condition

$$A^{(n+1)}=0 \tag{2.11}$$

at the algebraic level. This is the way how generalized Temperley–Lieb–Martin algebras are defined (cf. Ref. 26). Below we present several useful equivalent forms of this condition.

Lemma 2.1: The condition (2.11) is equivalent to any of the following relations:

$$A^{(n)}g_n\cdots g_2g_1=(-1)^{n-1}q\,[n]A^{(n)}A^{(2,n+1)}, \tag{2.12a}$$

$$g_1g_2\cdots g_nA^{(n)}=(-1)^{n-1}q\,[n]A^{(2,n+1)}A^{(n)}, \tag{2.12b}$$

$$g_n\cdots g_2g_1A^{(2,n+1)}=(-1)^{n-1}q\,[n]A^{(n)}A^{(2,n+1)}, \tag{2.12c}$$

$$A^{(2,n+1)}g_1g_2\cdots g_n=(-1)^{n-1}q\,[n]A^{(2,n+1)}A^{(n)}, \tag{2.12d}$$

$$A^{(n)}A^{(2,n+1)}A^{(n)}=[n]^{-2}A^{(n)}, \tag{2.12e}$$

$$A^{(2,n+1)}A^{(n)}A^{(2,n+1)}=[n]^{-2}A^{(2,n+1)}. \tag{2.12f}$$

Proof: Applying repeatedly (2.4) for the q-antisymmetrizers that appear as last factors in the resulting products and using (2.7), (2.8) we find

$$\begin{aligned}A^{(n+1)}&=\frac{1}{[n+1]}A^{(n)}(q^n-[n]g_n)A^{(n)}\\&=\frac{1}{[n+1]}\{q^nA^{(n)}-A^{(n)}g_n(q^{n-1}-[n-1]g_{n-1})A^{(n-1)}\}\\&=\frac{1}{[n+1]}\{A^{(n)}(q^n-q^{n-1}g_n)+A^{(n)}g_ng_{n-1}(q^{n-2}-[n-2]g_{n-2})A^{(n-2)}\}\cdots\\&=\frac{1}{[n+1]}A^{(n)}(q^n-q^{n-1}g_n+\cdots+(-1)^ng_ng_{n-1}\cdots g_1).\end{aligned} \tag{2.13}$$

Next, we apply $A^{(2,n+1)}$ to the both sides of Eq. (2.13). Using again (2.7) and (2.8) we obtain

$$A^{(n+1)}=\frac{1}{[n+1]}A^{(n)}\{q[n]A^{(2,n+1)}+(-1)^ng_ng_{n-1}\cdots g_1A^{(2,n+1)}\}.$$

Taking into account the relation $(g_ng_{n-1}\cdots g_1)A^{(2,n+1)}=A^{(n)}(g_ng_{n-1}\cdots g_1)$ which is a consequence of (2.1) we end up with

$$A^{(n+1)}=\frac{1}{[n+1]}\{q[n]A^{(n)}A^{(2,n+1)}+(-1)^nA^{(n)}g_ng_{n-1}\cdots g_1\}. \tag{2.14}$$

This proves the equivalence of Eqs. (2.11) and (2.12a). A similar argument using iteratively a substitution of the first q-antisymmetrizer in the right-hand side of (2.4) implies the equivalence of (2.11) and (2.12b). Condition (2.11) is transformed to the forms (2.12c) and (2.12d) in the same manner starting from Eq. (2.5).

To show equivalence of (2.11) to (2.12e) and to (2.12f) one should employ Eqs. (2.4) and (2.5), respectively. We shall treat the case of (2.12e) here.

Consider the difference

$$[n]^2 A^{(n)} A^{(2,n+1)} A^{(n)} - A^{(n)} = A^{(n)}([n]^2 A^{(2,n+1)} - 1) A^{(n)}$$
$$= A^{(n)}\{[n] A^{(2,n)}(q^{n-1} - [n-1] g_n) A^{(2,n)} - 1\} A^{(n)}$$
$$= [n-1] A^{(n)}(q^n - g_n) A^{(n)} = [n-1][n+1] A^{(n+1)},$$

where we have again used the definition (2.4) and the relations (2.8). Comparing the first and the last lines of the calculation we deduce the equivalence of conditions (2.11) and (2.12e). ■

Equations (2.12a)–(2.12f) display properties of the rank 1 idempotents $\rho_{W,k}(A^{(n)})$ that are hidden in (2.11). In fact, they are the basic technical tools which one needs to effectively deal with the height n Hecke algebra representations.

In the rest of the paper we make use of a special type of representations of the algebras $\mathcal{H}_k(q)$ for which the representation space is given by kth tensor power of an [n-dimensional, in the case of SL(n)] vector space V: $W = V^{\otimes k}$. These representations are generated by constant or dynamical R-matrices of Hecke-type. The representations we are dealing with have the specific feature that their height, when defined (i.e., for $k \geqslant n$), coincides with the dimension of the space V.[27]

Below we first illustrate the general notions introduced above on the well known case of constant SL(n)-type R-matrices relegating the study of dynamical R-matrices to Secs. IV and V.

III. REPRESENTATIONS GENERATED BY A CONSTANT *R*-MATRIX OF THE SL(*n*) TYPE

The R-matrix corresponding to the Drinfeld–Jimbo deformation of SL(n) (Refs. 28,29) is an operator acting in a tensor square of an n-dimensional vector space V and given by

$$\hat{R}^{\alpha_1\alpha_2}_{\beta_1\beta_2} = q^{\delta_{\alpha_1\alpha_2}} \delta^{\alpha_1}_{\beta_2}\delta^{\alpha_2}_{\beta_1} + (q - \overline{q})\, \theta_{\alpha_2\alpha_1}\, \delta^{\alpha_1}_{\beta_1}\delta^{\alpha_2}_{\beta_2}, \tag{3.1}$$

(no summation in the right-hand side) where the indices α, β take values from 1 to n, and $\theta_{\alpha\beta} = \{1 \text{ if } \alpha > \beta, \ 0 \text{ if } \alpha \leqslant \beta\}$.

This R-matrix is a particular representative of a family of constant Hecke R-matrices, i.e., it satisfies the braid relation and the Hecke condition

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23}, \tag{3.2}$$

$$\hat{R}^2 = \mathbb{I} + (q - \overline{q})\, \hat{R}. \tag{3.3}$$

Equations (3.2), (3.3) imply that the matrices $\hat{R}_{12}, \hat{R}_{23}$ generate a representation of $\mathcal{H}_3(q)$ in $V^{\otimes 3}$. For an arbitrary k the representation $\rho_{\hat{R},k} : \mathcal{H}_k(q) \to \mathrm{Aut}(V^{\otimes k})$ generated by a constant Hecke R-matrix is defined by

$$\rho_{\hat{R},k}(g_i) = \hat{R}_{i\, i+1}. \tag{3.4}$$

For representations $\rho_{\hat{R},k}$ generated by the R-matrix (3.1) we have

$$\text{height}\, \rho_{\hat{R},k} = n \quad \text{if } k \geqslant n.$$

The rank 1 q-antisymmetrizers $\rho_{\hat{R},k}(A^{(i,n+i-1)})$ are most conveniently described in terms of q-analogs of (co- and contravariant) Levi-Cività tensors which are solutions of the equations

$$\hat{R}^{\alpha_i\alpha_{i+1}}_{\beta_i\beta_{i+1}} \varepsilon^{\alpha_1\cdots\beta_i\beta_{i+1}\cdots\alpha_n} = -\overline{q}\, \varepsilon^{\alpha_1\cdots\alpha_i\alpha_{i+1}\cdots\alpha_n},$$

$$\varepsilon_{\alpha_1\cdots\beta_i\beta_{i+1}\cdots\alpha_n} \hat{R}^{\beta_i\beta_{i+1}}_{\alpha_i\alpha_{i+1}} = -\overline{q}\, \varepsilon_{\alpha_1\cdots\alpha_i\alpha_{i+1}\cdots\alpha_n}, \quad i = 1,2,\ldots,n-1.$$

It is straightforward to prove that these equations have unique (up to normalization) solutions. The rank1 condition (2.10) follows as a corollary.

In the special case of representations $\rho_{\hat{R},k}$ generated by the R-matrix (3.1) the only nonvanishing components of the ε-tensors have pairwise different indices $\alpha_1,\alpha_2,\ldots,\alpha_n$, and can be chosen as

$$\varepsilon^{\alpha_1\alpha_2\cdots\alpha_n}=\overline{q}^{n(n-1)/2}(-q)^{l(\sigma)},\quad \varepsilon_{\alpha_1\alpha_2\cdots\alpha_n}=(-q)^{l(\sigma)}. \tag{3.5}$$

Here $l(\sigma)$ is the length of the permutation $\sigma=\binom{1,\ \ 2,\ \ \ldots,\ \ n}{\alpha_1,\ \alpha_2,\ \ldots,\ \alpha}$.

The rank 1 q-antisymmetrizers are expressed in terms of the ε-tensors as

$$\rho_{\hat{R},k}(A^{(i,n+i-1)})=\frac{1}{[n]!}\,\varepsilon^{|i\cdots n+i-1\rangle}\varepsilon_{\langle i\cdots n+i-1|},\quad i=1,\ldots,k-n+1. \tag{3.6}$$

Here (by analogy with the matrix notation) we substitute the vector space indices of ε-tensors by their labels: $\alpha_i\to i$. The ''bra'' and ''ket'' notation of ε-tensor indices is used in order to distinguish labels of matrix spaces from those of vector spaces. One should have in mind the following symbolic decomposition for the matrix space label: $i=|i\rangle\otimes\langle i|$. For example, the equation $A_i\,u^{|i\rangle}(\equiv A^{|i\rangle}{}_{\langle i|}\,u^{|i\rangle}=v^{|i\rangle}$ is to be understood as $\Sigma_{\beta_i}A^{\alpha_i}_{\beta_i}u^{\beta_i}=v^{\alpha_i}$.

Finally, we shall adapt for $\rho_{\hat{R},k}$ those formulas (2.12a)–(2.12f) which will be used in Sec. VI. Written in terms of the ε-tensors the relations (2.12b), (2.12c), (2.12e) and (2.12f) assume the form

$$\rho_{\hat{R},n+1}(g_1\cdots g_n)\varepsilon^{|1\cdots n\rangle}\equiv\hat{R}_{12}\cdots\hat{R}_{n\,n+1}\varepsilon^{|1\cdots n\rangle}=q\,\varepsilon^{|2\cdots n+1\rangle}\,N^{|1\rangle}{}_{\langle n+1|}, \tag{3.7}$$

$$\rho_{\hat{R},n+1}(g_n\cdots g_1)\varepsilon^{|2\cdots n+1\rangle}\equiv\hat{R}_{n\,n+1}\cdots\hat{R}_{12}\varepsilon^{|2\cdots n+1\rangle}=q\,\varepsilon^{|1\cdots n\rangle}\,K^{|n+1\rangle}{}_{\langle 1|}, \tag{3.8}$$

$$K\,N=N\,K=\mathbb{I}. \tag{3.9}$$

Here the matrices N and K are defined as

$$N^{|1\rangle}{}_{\langle n+1|}=\frac{(-1)^{n-1}}{[n-1]!}\,\varepsilon_{\langle 2\cdots n+1|}\varepsilon^{|1\cdots n\rangle}, \tag{3.10}$$

$$K^{|n+1\rangle}_{\langle 1|}=\frac{(-1)^{n-1}}{[n-1]!}\,\varepsilon_{\langle 1\cdots n|}\varepsilon^{|2\cdots n+1\rangle}, \tag{3.11}$$

and for the ε-tensors given by Eq. (3.5) we have just

$$N=K=\mathbb{I}. \tag{3.12}$$

IV. SL(n)-TYPE DYNAMICAL R-MATRICES

We now turn to the dynamical R-matrix defined in the Introduction. In order to present the QDYBE in a form suitable for our purposes we shall introduce a set of commutative variables

$$X^i,\quad i=1,\ldots,n,\quad [X^i,X^j]=0\,,\quad \prod_{i=1}^{n}X^i=1, \tag{4.1a}$$

which play the role of elementary shift operators for p_i:

$$p\,X^i=X^i\,(\,p+v^{(i)}\,)\,. \tag{4.1b}$$

The elements X^i and q^{p_i} provide a realization of (the Weyl's form of) the canonical commutation relations. Note that in concrete applications they can be naturally identified with (a subset of) dynamical variables of a model (see, e.g., Ref. 5).

Let us arrange the auxiliary variables X^i into a unimodular diagonal matrix,

$$X=\mathrm{diag}\{X^1,\ldots,X^n\},\quad \det(X)=1. \tag{4.2}$$

The *Hecke-type dynamical R-matrix* is characterized by the following set of relations:

$$\hat{R}_{12}(p)(X_1\hat{R}_{23}(p)X_1^{-1})\hat{R}_{12}(p)=(X_1\hat{R}_{23}(p)X_1^{-1})\hat{R}_{12}(p)(X_1\hat{R}_{23}(p)X_1^{-1}), \tag{4.3}$$

$$\hat{R}(p)^2=\mathbb{I}+(q-\overline{q})\hat{R}(p), \tag{4.4}$$

$$\hat{R}_{12}(p)X_1X_2=X_1X_2\hat{R}_{12}(p). \tag{4.5}$$

Here the first and second relations are the dynamical Yang–Baxter equation and the Hecke condition, respectively. A condition of type (4.5), although not always imposed on dynamical *R*-matrices, is also necessary in our treatment. As we shall see below, it ensures that conditions (2.3) for the Hecke algebra representations generated by $\hat{R}(p)$ are satisfied.

Following Ref. 18 we shall consider dynamical *R*-matrices of the form

$$\hat{R}^{i_1i_2}_{j_1j_2}(p)=a_{i_1i_2}(p)\,\delta^{i_1}_{j_2}\delta^{i_2}_{j_1}+b_{i_1i_2}(p)\,\delta^{i_1}_{j_1}\delta^{i_2}_{j_2},\quad i_{1,2},j_{1,2}=1,\ldots,n \tag{4.6}$$

(there is no summation over repeated upper and lower indices in the right-hand side); in order to have a unique decomposition in terms of the unit and the permutation matrices in the tensor square of spaces we impose the condition $b_{ii}(p)=0$. This special class of *p*-dependent Hecke *R*-matrices will be called *dynamical R-matrices of an* SL*(n)-type*.[30]

The unknown functions $a_{ij}(p)$, $b_{ij}(p)$ in the Ansatz (4.6) are to be fixed by the conditions (4.3)–(4.5). The Hecke condition (4.4) gives

$$b_{ii}=0,\ \ b_{ij}+b_{ji}=q-\overline{q},\quad \text{for}\ \ i\neq j, \tag{4.7}$$

$$a_{ij}\,a_{ji}-b_{ij}\,b_{ji}=1,\quad \text{for}\ \ i\neq j, \tag{4.8}$$

$$a_{ii}^2-(q-\overline{q})\,a_{ii}=1. \tag{4.9}$$

The last equation has two solutions: $a_{ii}=\pm\, q^{\pm 1}$ for each *i*. Below we consider only the case $a_{ii}=q,\ \forall i$ (the other cases correspond, in particular, to quantum supergroups and have been considered in Ref. 18). Finally, the dynamical Yang–Baxter equation (4.3) and Eq. (4.5) impose the constraints

$$a_{ij}(p_1,\ldots,p_n)=a_{ij}(p_{ij}),\quad b_{ij}(p_1,\ldots,p_n)=b_{ij}(p_{ij}),$$

$$b_{ij}b_{jk}b_{ki}+b_{ik}b_{kj}b_{ji}=0, \tag{4.10}$$

$$b_{ij}(p_{ij}+1)=\frac{b_{ij}(p_{ij})\,q}{\overline{q}+b_{ij}(p_{ij})}, \tag{4.11}$$

where $p_{ij}:=p_i-p_j$. For $a_{ii}=q$ the general solution of (4.7)–(4.11) can be written as[18]

$$a_{ij}(p)=\alpha_{ij}(p_{ij})\,\xi_{ij}(p_{ij}),\quad b_{ij}(p)=q-\xi_{ij}(p_{ij}), \tag{4.12}$$

where $\xi_{ij}(p)$are expressed as the following ratios:

$$\xi_{ij}(p)=\frac{f(p_{ij}-1,\beta_{ij})}{f(p_{ij},\beta_{ij})}, \quad f(p,\beta)=\overline{q^p}+[p]\beta. \tag{4.13}$$

Here $\beta_{ij}(p_{ij})=\beta_{ij}(p_{ij}+1)$. We shall consider β_{ij} as constant parameters since their functional dependence does not change any of the results below. The function $f(p,\beta)$ satisfies the finite difference equation

$$f(p+1,\beta)+f(p-1,\beta)=[2]f(p,\beta), \tag{4.14}$$

with the initial conditions

$$f(0,\beta)=1, \quad f(1,\beta)=\overline{q}+\beta. \tag{4.15}$$

Equations (4.14) can be deduced from (4.11).

Not all of the remaining in (4.12), (4.13) parameters $\alpha_{ij}(p_{ij})$ and β_{ij} are independent. The relations between them are given by

$$\alpha_{ii}=1\,, \quad \alpha_{ij}(p_{ij})\alpha_{ji}(p_{ji})=1, \tag{4.16}$$

$$\beta_{ii}=0\,, \quad \beta_{ij}+\beta_{ji}=q-\overline{q} \qquad \text{for} \qquad i\neq j, \tag{4.17a}$$

$$\beta_{ij}\beta_{jk}\beta_{ki}+\beta_{ik}\beta_{kj}\beta_{ji}=0. \tag{4.17b}$$

An easy way to solve Eqs. (4.17a), (4.17b) is to make the substitution

$$\beta_{ij}=\frac{q-\overline{q}}{1-\pi_{ij}} \quad \Leftrightarrow \quad \pi_{ij}=\frac{\beta_{ij}-q+\overline{q}}{\beta_{ij}}, \qquad \text{for } i\neq j. \tag{4.18a}$$

We stress that the parameters π_{ii} are not fixed here and can be chosen as arbitrary constants. In terms of the new variables π_{ij} Eqs. (4.17a), (4.17b) take the simple form

$$\pi_{ij}\,\pi_{ji}=1, \quad \pi_{ij}\,\pi_{jk}\,\pi_{ki}=1, \tag{4.18b}$$

and are solved by $\pi_{ij}=\Pi_{k=i}^{j-1}\pi_{k\,k+1}=\pi_{ji}^{-1}$, for $i<j$. Hence,

$$\beta_{ij}=\frac{(q-\overline{q})\Pi_{k=i}^{j-1}\beta_k}{\Pi_{k=i}^{j-1}\beta_k-\Pi_{k=i}^{j-1}(\beta_k-q+\overline{q})}, \quad \text{for } i<j, \tag{4.19}$$

where the remaining $(n-1)$ parameters $\beta_i\equiv\beta_{i\,i+1}$ are independent.

We shall describe two types of transformations on the set of SL(n)-type dynamical R-matrices.

(1) a simple version of *twisting* for dynamical R-matrices:

$$\hat{R}(p)_{21}\rightarrow{}^F\hat{R}_{21}=\hat{F}\,\hat{R}(p)\,\hat{F}^{-1},$$

where $\hat{F}(p)=F_{12}(p)P_{12}$ and

$$F_{12}\equiv F_{j_1j_2}^{i_1i_2}(p)=\delta_{j_1}^{i_1}\,\delta_{j_2}^{i_2}\,\psi_{i_1i_2}(p), \tag{4.20}$$

(an analog of Drinfeld's twist, see Ref. 31). An explanation on how this twist works is given in the two Lemmas below.

Lemma 4.1: Let F(p) be an operator acting in V⊗V. If

$$\hat{F}_{12}^{-1} X_1^{-1} \hat{F}_{23} = \hat{A}_{123} X_3^{-1} \hat{A}_{123} \tag{4.21}$$

for some operator A(p) acting in V⊗V⊗V and

$$\hat{R}(p)_{12} \hat{A}_{123} = \hat{A}_{123} \hat{R}(p)_{23} \tag{4.22}$$

then the matrix ${}^F\hat{R}_{21} = \hat{F}\hat{R}(p)\hat{F}^{-1}$ *satisfies the QDYBE (4.3).*

Proof: Substitute ${}^F\hat{R}_{21}$ in the QDYBE taking into account that the QDYBE has two equivalent forms:

$$\hat{R}(p)_{23} X_3^{-1} \hat{R}(p)_{12} X_3 \hat{R}(p)_{23} = X_3^{-1} \hat{R}(p)_{12} X_3 \hat{R}(p)_{23} X_3^{-1} \hat{R}(p)_{12} X_3 ,$$

$$\hat{R}(p)_{21} X_1^{-1} \hat{R}(p)_{32} X_1 \hat{R}(p)_{21} = X_1^{-1} \hat{R}(p)_{32} X_1 \hat{R}(p)_{21} X_1^{-1} \hat{R}(p)_{32} X_1 .$$

The first equation results from repeated application of (4.5) to (4.3). The second equation is obtained from the first one by simply permuting the subscripts 1 and 3. ■

Lemma 4.2: Let F_{12} *be the diagonal matrix (4.20) where* $\psi_{ij}\psi_{ji}=1$ *and* $\psi_{ii}=1$. *Assume that* ψ_{ij} *depends on* p_{ij} *only. Then, Eqs. (4.21), (4.22) are satisfied by* $\hat{A} = AP_{23}P_{12}$, *where the matrix A is diagonal,* $A^{ijk}_{abc} = a_{ijk}\delta^i_a \delta^j_b \delta^k_c$, *the elements* a_{ijk} *being given by*

$$a_{ijk} = \begin{cases} \psi_{ik}\psi_{jk} & \text{if } i \neq j, \\ [\psi_{ik}(p_{ik}+1)]^2 & \text{if } i = j. \end{cases} \tag{4.23}$$

Proof: The operator A_{123} is symmetric in the first two indices, $A_{123} = A_{213}$ which implies that it commutes with any *R*-matrix of the form (4.6). Therefore, (4.22) is satisfied.

Equation (4.21) can be checked directly. ■

These Lemmas demonstrate that the operator (4.20) indeed generates a twist leading to the changes $\alpha_{ij} \to \alpha_{ij}\psi_{ji}^2$, $\beta_{ij} \to \beta_{ij}$ of the parameters in (4.12), (4.13).

(2) *Canonical transformations* of the dynamical parameters $p_i \to p_i + c_i$, where c_i, $i = 1, \ldots, n$ are arbitrary constants satisfying the condition $\Sigma_{i=1}^n c_i = 0$.

We conclude the section by a brief discussion of the structure of the family of SL(n)-type dynamical *R*-matrices (4.6), (4.12), (4.13). There are two essentially different domains for the parameters β_i of this family.

(a) $\beta_i \neq 0$ and $\beta_i \neq q - \overline{q}$, for all *i*.

In this case the whole family (4.6), (4.12), (4.13) can be generated starting from any particular representative with the use of the two types of transformations described above.

Indeed, the parameters α_{ij} can be excluded with the help of a twist. Then, performing a canonical transformation of the form

$$q^{2p_{ij}} \to q^{2p_{ij}} \pi_{ij} = q^{2p_{ij}} \prod_{k=i}^{j-1} \frac{\beta_k - q + \overline{q}}{\beta_k} \quad \text{for } i<j,$$

for instance, one excludes the parameters β_{ij} from the ansatz (4.6), (4.12), (4.13) and passes to a dynamical *R*-matrix with

$$\xi_{ij}(p) = \frac{[p_{ij}-1]}{[p_{ij}]} \tag{4.24}$$

[cf. (4.13)–(4.17b)]. This *R*-matrix is the limiting case $\beta_i \to \infty$ of our family, and it is this type of dynamical *R*-matrix which is discussed in Ref. 5.

(b) Either all $\beta_i = q - \overline{q}$, or all $\beta_i = 0$.

We shall consider the first case $\beta_i = q - \overline{q}$ for which

$$\beta_{ij} = \begin{cases} q - \overline{q} & \text{for} \quad i < j \\ 0 & \text{for} \quad i \geqslant j \end{cases} \tag{4.25}$$

and put $\alpha_{ij}(p_{ij}) = \mathrm{const}_{ij}$. In this case the R-matrix (4.6), (4.12), (4.13) becomes independent on the dynamical variables p_i and is reduced to the constant R-matrix describing the multiparametric[32] deformations of $\mathrm{GL}(n)$ which are all twist-equivalent.

With the particular choice

$$\alpha_{ij} = \begin{cases} q & \text{for} \quad i < j \\ 1 & \text{for} \quad i = j \\ \overline{q} & \text{for} \quad i > j \end{cases} \tag{4.26}$$

one reproduces the standard $\mathrm{SL}(n)$-type R-matrix (3.1).

Remark 4.1: In the intermediate cases (where only a part of the parameters β_i are equal to 0 or $q - \overline{q}$) the corresponding dynamical R-matrix $\hat{R}(p)$ contains the (dynamical and constant) R-matrices described in (a) and (b) as submatrices.

V. REPRESENTATIONS GENERATED BY THE SL(n)-TYPE DYNAMICAL R-MATRICES

Now we are in a position to introduce the Hecke algebra representations associated with Hecke-type dynamical R-matrices.

Proposition 5.1: Let $\hat{R}(p)$ *be a dynamical R-matrix of the Hecke type. The matrices*

$$\rho_{\hat{R}(p),k}(g_i) = (X_1 X_2 \cdots X_{i-1}) \hat{R}_{i,i+1}(p) (X_1 X_2 \cdots X_{i-1})^{-1}, \quad i = 1, \ldots, k-1, \tag{5.1a}$$

generate a Hecke algebra representation, $\rho_{\hat{R}(p),k} : \mathcal{H}_k(q) \rightarrow \mathrm{Aut}(V^{\otimes k})$.

Proof: Obviously, Eq. (4.3) implies that the matrices $\rho_{\hat{R}(p),k}(g_i)$ and $\rho_{\hat{R}(p),k}(g_{i+1})$ satisfy the braid relations (2.1). Then, the conditions (4.5) ensure that the matrices (5.1a) satisfy (2.3) and, therefore, (5.1a) represent the generators of the braid algebra $\mathcal{B}_k$. Finally, the Hecke conditions (2.2) for the generators (5.1a) follow from the Hecke property (4.4) of the dynamical R-matrix (2.2). ∎

Remark 5.1: In contrast with the case of constant Hecke R-matrix (3.4) the representations generated by a dynamical Hecke R-matrix are nonlocal; in other words, the matrices $\rho_{\hat{R}(p),k}(g_i)$ act nontrivially as diagonal matrices on V_j with $j < i$ (and not merely on $V_i \otimes V_{i+1}$). Only the representation of the first generator with $i = 1$ has the usual ''locality'' property.

Remark 5.2: One can construct representations equivalent to $\rho_{\hat{R}(p),k}$ in which some other generator is ''localized'' instead g_1. For instance, the representation $\overline{\rho}_{\hat{R}(p),k}$ which localizes $\overline{\rho}_{\hat{R}(p),k}(g_{k-1})$ is given by

$$\overline{\rho}_{\hat{R}(p),k}(t) = (X_1 X_2 \cdots X_k)^{-1} \rho_{\hat{R}(p),k}(t) (X_1 X_2 \cdots X_k), \quad \forall t \in \mathcal{H}_k(q) \tag{5.1b}$$

so that

$$\overline{\rho}_{\hat{R}(p),k}(g_i) = (X_{i+2} \cdots X_k)^{-1} \hat{R}_{i,i+1}(p) (X_{i+2} \cdots X_k). \tag{5.1c}$$

Note that in addition to the nonlocal property the representation matrices of $\overline{\rho}_{\hat{R}(p),k}$ depend explicitly on k.

From now on we shall restrict ourselves to discussing those representations $\rho_{\hat{R}(p),k}$ which are generated by the $\mathrm{SL}(n)$-type dynamical R-matrices (4.6), (4.12), (4.13). For $k \geqslant n$ all these representations are of height *n*. The rank *1q*-antisymmetrizers are conveniently expressed in terms of dynamical $\mathcal{E}$-tensors $\mathcal{E}^{|1\cdots n\rangle}(p)$ and $\mathcal{E}_{\langle 1\ldots n|}(p)$, which are the unique (up to normalization) solutions of the equations

$$\begin{aligned}\rho_{\hat{R}(p),k}(g_i)\mathcal{E}^{|1\cdots n\rangle}(p) &= -\overline{q}\mathcal{E}^{|1\cdots n\rangle}(p),\\ \mathcal{E}_{\langle 1\ldots n|}(p)\rho_{\hat{R}(p),k}(g_i) &= \overline{q}\mathcal{E}_{\langle 1\ldots n|}(p),\end{aligned}\quad 1\leqslant i\leqslant n-1. \tag{5.2}$$

The only nonvanishing components of these $\mathcal{E}$-tensors have pairwise different indices $i_1, i_2, \ldots, i_n$ and look like

$$\mathcal{E}^{i_1 i_2\cdots i_n}(p) = (-1)^{l(\sigma)}\prod_{(j,i)\in J(\sigma)}\alpha_{ji}(p_{ji})\prod_{1\leqslant a<b\leqslant n}\xi_{i_a i_b}(p_{i_a i_b}), \tag{5.3}$$

$$\mathcal{E}_{i_1 i_2\cdots i_n}(p) = (-1)^{l(\sigma)}\prod_{(j,i)\in J(\sigma)}\alpha_{ij}(p_{ij}). \tag{5.4}$$

Here $l(\sigma)$ is the length of the permutation $\sigma = \binom{1,\ 2,\ \ldots,n}{i_1,i_2,\ldots,i_n}$, and

$$J(\sigma) = \{(i_a, i_b) : a<b, i_a>i_b\}.$$

The dynamical $\mathcal{E}$-tensors (5.3), (5.4) are normalized so that they would coincide with the constant ε-tensors (3.5) in the case (4.25), (4.26).

Now the expressions for rank 1q-antisymmetrizers in the representations $\rho_{\hat{R}(p),k}$ are given by

$$\rho_{\hat{R}(p),k}(A^{(i,n+i-1)}) = \frac{1}{[n]!}(X_1\cdots X_{i-1})\mathcal{E}^{|i\cdots n+i-1\rangle}(p)\mathcal{E}_{\langle i\cdots n+i-1|}(p)(X_1\cdots X_{i-1})^{-1}. \tag{5.5}$$

The numerical coefficient in this formula is calculated with the use of the relation

$$\mathcal{E}_{\langle 1\cdots n|}(p)\mathcal{E}^{|1\cdots n\rangle}(p) = [n]!, \tag{5.6}$$

which is proved in the Appendix.

We conclude the discussion on dynamical *R*-matrices by writing down formulas (2.12a), (2.12d), and (2.12e), (2.12f) for the representation $\rho_{\hat{R}(p),n+1}$:

$$\mathcal{E}_{\langle 1\cdots n|}(p)\,\rho_{\hat{R}(p),n+1}(g_n g_{n-1}\cdots g_1) = q\,K^{|n+1\rangle}{}_{\langle 1|}(p)\,X_1\mathcal{E}_{\langle 2\cdots n+1|}(p)X_1^{-1}, \tag{5.7}$$

$$X_1\mathcal{E}_{\langle 2\cdots n+1|}(p)X_1^{-1}\rho_{\hat{R}(p),n+1}(g_1 g_2\cdots g_n) = q\,N^{|1\rangle}{}_{\langle n+1|}(p)\,\mathcal{E}_{\langle 1\,\ldots\,n|}(p), \tag{5.8}$$

$$K(p)\,N(p) = N(p)\,K(p) = \mathbb{I}. \tag{5.9}$$

Here the matrices $N(p)$, $K(p)$ are defined as

$$N^{|1\rangle}{}_{\langle n+1|}(p) = \frac{(-1)^{n-1}}{[n-1]!}X_1\mathcal{E}_{\langle 2\cdots n+1|}(p)X_1^{-1}\mathcal{E}^{|1\cdots n\rangle}(p), \tag{5.10}$$

$$K^{|n+1\rangle}{}_{\langle 1|}(p) = \frac{(-1)^{n-1}}{[n-1]!}\mathcal{E}_{\langle 1\cdots n|}(p)X_1\mathcal{E}^{|2\cdots n+1\rangle}(p)X_1^{-1}. \tag{5.11}$$

For the SL(n)-type dynamical *R*-matrices the matrices $N(p)$, $K(p)$ are diagonal. Inserting formulas (5.3), (5.4) for the dynamical ε-tensors into (5.10), (5.11) and using (5.6), one ends up with the following expressions for their diagonal components:

$$N_i^{\,i}(p) = (K_i^{\,i}(p))^{-1} = \prod_{j \neq i} \alpha_{ij}(p_{ij} - \theta_{ji})\, \xi_{ij}(p_{ij}), \tag{5.12}$$

where $\theta_{ji} = \{1 \text{ if } j > i, 0 \text{ if } j < i\}$.

VI. QUANTUM MATRIX ALGEBRA $\mathcal{A}(\hat{R}(P),\hat{R})$: QUANTUM DETERMINANT AND INVERSION FORMULA

We shall apply the above technique to the quantum matrix algebra $\mathcal{A}$ which is defined as follows (cf. the Introduction).

Definition 6.1: Let $\mathbb{F}$ *be the field of the complex meromorphic functions of the (commuting) variables* $p_j, j = 1,\ldots,n$*. Let* $\hat{R}(p)$ *be a dynamical R-matrix of an* $\mathrm{SL}(n)$*-type and* $\hat{R}$ *be a constant* $\mathrm{SL}(m)$*-type R-matrix. Assume that both* $\hat{R}(p)$ *and* $\hat{R}$ *satisfy the Hecke condition (1.4) with the same value of q. Then* $\mathcal{A} = \mathcal{A}(\hat{R}(p),\hat{R})$ *is a complex algebra with* 1 *that is generated by* $\mathbb{F}$ *and the mn elements* a_α^i $(i = 1,\ldots,n$ *and* $\alpha = 1,\ldots,m)$*, satisfying the relations*

$$\hat{R}(p)_{12}\, a_1\, a_2 = a_1\, a_2\, \hat{R}_{12}, \tag{6.1}$$

$$a f(p) = X f(p) X^{-1} a, \quad \forall f(p) \in \mathbb{F}, \tag{6.2}$$

where X is a unimodular diagonal matrix (4.2) whose diagonal elements X^i *satisfy (4.1a), (4.1b).*

Remark 6.1: The definition above is given for arbitrary *m* and *n*. However in the sequel we shall discuss the case $m = n$ only.

Remark 6.2: For the applications envisaged here, the field $\mathbb{F}$ of meromorphic functions of p_j can be replaced by its subfield of rational functions of q^{p_j} (as stated in the Introduction). Then we should just require

$$X^k q^{p_{ij}} (X^k)^{-1} = q^{p_{ij} + \delta_{jk} - \delta_{ik}}$$

instead of (4.1b). Note that for q a root of unity, $q^{2h} = 1$ [cf. Eq. (7.8) below] p_{ij} are only determined up to an additive integer multiple of $2h$.

Remark 6.3: More general matrix algebras are of interest in which the *R*-matrices on both sides of the quadratic relations (6.1) are allowed to depend on possibly different sets of commuting variables p and p'

$$\hat{R}(p)_{12} Q_1 Q_2 = Q_1 Q_2 \hat{R}'(p')_{12}, \tag{6.3}$$

while the shift properties assume the form

$$p_{kl}\, Q_j^i = Q_j^i\, (p_{kl} + \delta_k^i - \delta_l^i), \quad p'_{kl}\, Q_j^i = Q_j^i\, (p'_{kl} + \delta_{jk} - \delta_{jl}). \tag{6.4}$$

Such $\mathcal{A}(\hat{R}(p),\hat{R}'(p'))$ can be treated in much the same way or reduced to the study of two matrix algebras of the above type setting $Q_j^i = a_\alpha^i \overline{a}_j^\alpha$, where a and $\overline{a}$ satisfy exchange relations of the type (1.6) and (1.10), respectively (see Ref. 24). Note that dynamical quantum groups (introduced in Ref. 16) are defined by relations similar to (6.3) and (6.4) but with the dynamical *R*-matrices (and momenta p,p') related to each other by some equivalence transformation $\hat{R}'(p') = X^{-1}\hat{R}(p)X$. Another desirable modification of the matrix algebra (6.1) corresponds to the case when $\hat{R}$ is an SO_q or Sp_q constant *R*-matrix. In this case $\hat{R}$ and $\hat{R}(p)$ satisfy a third order (Birman–Wenzl) condition instead of the Hecke property (2.2) and the QDYBE (4.3) have to be modified correspondingly.

Remark 6.4: The algebra $\mathcal{A}$ differs from the one considered in Ref. 33 where the counterpart of a matrix $b = X^{-1}a$ [denoted by $u_\alpha^i(\overline{\omega})$ in Eq. (11) of Ref. 33] which commutes with p is used for changing the basis of chiral vertex operators. It is assumed in Ref. 33 that the elements of b

only depend on p and hence commute among themselves while in our case this is not so. Indeed, the reflection equation subalgebra $\mathcal{M}(\hat{R})$, defined in Proposition 6.5 below, is noncommutative although its elements commute with the p's. The difference is essential: as a result, Cremmer and Gervais do not recover the standard (constant) $\mathrm{SL}_q(n) R$-matrix for $n>2$ but introduce instead new solutions of the Yang–Baxter equation. One of the authors (I.T.) would like to thank J.-L. Gervais and E. Cremmer for an enlightening discussion on this point.

The term *''matrix algebra''*[34] for the algebra $\mathcal{A} \equiv \mathcal{A}(\hat{R}(p), \hat{R})$ is justified by the fact that we shall be able to (define and) compute the determinant of a — as a function of p — and to find the inverse of a. In the case of 2×2 matrices the determinant of a was constructed in Ref. 4 (see also Ref. 36) for the special choice $\beta_i \to \infty, \alpha_{ij}=1$ of the parameters. We shall present the definition of the determinant in a general setting.

Definition 6.2: Let $a=||a^i_\alpha||$ *be the matrix of generators of the algebra* $\mathcal{A}(\hat{R}(p), \hat{R})$. *The determinant of the matrix a is given by*

$$\det(a) = \frac{1}{[n]!} \mathcal{E}_{\langle 1 \cdots n|}(p) a_1 a_2 \cdots a_n \varepsilon^{|1 \cdots n\rangle}. \tag{6.5}$$

The meaning of this definition is made clear by the following three Propositions. The first and the third of them are the quantum analogs of the basic determinant properties. The second one allows to perform an $\mathrm{SL}(n)$-reduction in the algebra $\mathcal{A}(\hat{R}(p), \hat{R})$.

Proposition 6.1: The product $(a_1 a_2 \cdots a_n)$ *intertwines between constant and dynamical* ε*-tensors:*

$$\mathcal{E}_{\langle 1 \cdots n|}(p) a_1 a_2 \cdots a_n = \det(a)\, \varepsilon_{\langle 1 \cdots n|}, \tag{6.6}$$

$$a_1 a_2 \cdots a_n \epsilon^{|1 \dots n\rangle} = \mathcal{E}^{|1 \cdots n\rangle}(p) \det(a). \tag{6.7}$$

Proof: First, observe that due to the relations (6.1), (6.2) the product of k matrices $(a_1 a_2 \cdots a_k)$ intertwines between the representations $\rho_{\hat{R},k}$ and $\rho_{\hat{R}(p),k}$ of the algebra $\mathcal{H}_k(q)$. Indeed,

$$\begin{aligned}(a_1 \cdots a_k) \rho_{\hat{R},k}(g_i) &= (a_1 \cdots a_k) \hat{R}_{i(i+1)} \\ &= a_1 \cdots a_{i-1} (\hat{R}_{i(i+1)}(p) a_i a_{i+1}) a_{i+2} \cdots a_k \\ &= (X_1 \cdots X_{i-1}) \hat{R}_{i(i+1)}(p) (X_1 \cdots X_{i-1})^{-1} (a_1 \cdots a_k) = \rho_{\hat{R}(p),k}(g_i)(a_1 \cdots a_k).\end{aligned} \tag{6.8}$$

In particular, one has

$$(a_1 \cdots a_n) \rho_{\hat{R},n}(A^{(n)}) = \rho_{\hat{R}(p),n}(A^{(n)})(a_1 \cdots a_n).$$

Multiplying both sides by $\rho_{\hat{R},n}(A^{(n)})$ from the right or by $\rho_{\hat{R}(p),n}(A^{(n)})$ from the left and using projector property of the q-antisymmetrizer one comes to the equations

$$\rho_{\hat{R}(p),n}(A^{(n)})(a_1 \cdots a_n) = \rho_{\hat{R}(p),n}(A^{(n)})(a_1 \cdots a_n) \rho_{\hat{R},n}(A^{(n)}), \tag{6.9}$$

$$(a_1 \cdots a_n) \rho_{\hat{R},n}(A^{(n)}) = \rho_{\hat{R}(p),n}(A^{(n)})(a_1 \cdots a_n) \rho_{\hat{R},n}(A^{(n)}). \tag{6.10}$$

Finally, expressing (3.6), (5.5) for constant and dynamical q-antisymmetrizers in terms of the ε-tensors, one transforms (6.9), (6.10) to the form (6.6), (6.7). ■

Proposition 6.2: The element $\det(a)$ *of the algebra* $\mathcal{A}(\hat{R}(p), \hat{R})$ *commutes with the generators* p_i *and its commutation with the generators* a^i_α *is described by*

$$\det(a)\,a = K(p)\,a\,\det(a), \tag{6.11}$$

where the diagonal matrix $K(p)$ is given in (5.11), (5.12).

Proof: Consider the permutation of $\det(a)$ with an arbitrary function $h(p)$:

$$\begin{aligned}\det(a)h(p) &= \mathcal{E}_{\langle 1\cdots n|}(p)a_1\cdots a_n\,h(p)\varepsilon^{|1\cdots n\rangle}/[n]!\\ &= \mathcal{E}_{\langle 1\cdots n|}(p)(X_n\cdots X_1)h(p)\\ &\quad\times(X_n\cdots X_1)^{-1}a_1\cdots a_n\,\varepsilon^{|1\cdots n\rangle}/[n]!.\end{aligned} \tag{6.12}$$

Since the only nonvanishing components of the tensor $\mathcal{E}_{\langle 1\cdots n|}(p)$ are those with pairwise different indices and due to the diagonal structure of the matrix X one has

$$\mathcal{E}_{\langle 1\cdots n|}(p)X_n\cdots X_1 = \mathcal{E}_{\langle 1\cdots n|}(p)\det(X) = \mathcal{E}_{\langle 1\cdots n|}(p),$$

where in the last equality the unimodularity of X [see (4.2)] is taken into account. Now we can complete the transformation of (6.12):

$$\begin{aligned}\det(a)h(p) &= \cdots\\ &= h(p)\mathcal{E}_{\langle 1\cdots n|}(p)(X_n\cdots X_1)^{-1}a_1\cdots a_n\,\varepsilon^{|1\cdots n\rangle}/[n]! = h(p)\det(a).\end{aligned}$$

This proves commutivity of $\det(a)$ and p_i.

Consider now permutation of $\det(a)$ with the matrix a. It is technically convenient to take a living in the matrix space with label $(n+1)$:

$$\begin{aligned}\det(a)\,a_{n+1} &= \mathcal{E}_{\langle 1\cdots n|}(p)\{a_1\cdots a_n\,a_{n+1}\}\varepsilon^{|1\cdots n\rangle}/[n]!\\ &= \{\mathcal{E}_{\langle 1\cdots n|}(p)\,\rho_{\hat{R}(p),n+1}(g_n\cdots g_1)\}a_1\cdots a_{n+1}\{\rho^{-1}_{\hat{R},n+1}(g_n\cdots g_1)\,\varepsilon^{|1\cdots n\rangle}\}/[n]!\\ &= K^{|n+1\rangle}{}_{\langle 1|}(p)\{X_1\mathcal{E}_{\langle 2\cdots n+1|}(p)X_1^{-1}\,a_1\}\{a_2\cdots a_{n+1}\,\varepsilon^{|2\cdots n+1\rangle}\}K^{-1|1\rangle}{}_{\langle n+1|}/[n]!\\ &= K^{|n+1\rangle}{}_{\langle 1|}(p)\,a_1\,\{\mathcal{E}_{\langle 2\cdots n+1|}(p)\mathcal{E}^{|2\cdots n+1\rangle}(p)\}\det(a)\,K^{-1|1\rangle}{}_{\langle n+1|}/[n]!\\ &= (K(p)aK^{-1})_{n+1}\det(a).\end{aligned}$$

The following formulas are used in the course of the calculation: (6.5) and (6.8) in the first line, (5.7) and (3.8) in the second line, (6.2) and (6.7) in the third line, and (5.6) in passing to the last line. For clarity we put into braces those expressions which are to be transformed in the next step.

Finally, substituting $\mathbb{I}$ for the matrix K [see (3.12)] we obtain (6.11). ■

Corollary 6.1: The element

$$\Delta = \det(a)\prod_{i<j}\frac{\varphi_{ij}(p_{ij})}{f(p_{ij})}, \tag{6.13}$$

where $f(p_{ij}) = \overline{q}^{p_{ij}} + [p_{ij}]\beta_{ij}$ and the functions φ_{ij} are defined by the relations

$$\alpha_{ij}(p_{ij}) = \frac{\varphi_{ij}(p_{ij}+1)}{\varphi_{ij}(p_{ij})} \tag{6.14}$$

belongs to the center of the algebra $\mathcal{A}(\hat{R}(p),\hat{R})$. The $\mathrm{SL}(n)$-reduction in the algebra $\mathcal{A}(\hat{R}(p),\hat{R})$ can be performed by imposing the condition $\Delta = 1$.

Proof: We shall search for the central element in $\mathcal{A}(\hat{R}(p),\hat{R})$in the form $\Delta = U(p)\det(a)$, where $U(p)$ is some function of p_i which is to be fixed. As follows from Proposition 6.2, the element Δ commutes with p_i and its commutivity with the generators a^i_α imposes the following conditions on the function U

$$X^i U(p)(X^i)^{-1} = U(p) K_i^i(p), \quad i = 1, \cdots, n. \tag{6.15}$$

Now using (4.1b), (4.13) and (5.12) it is straightforward to check that with the choice (6.13), (6.14) one satisfies conditions (6.15). ■

Proposition 6.3: Let the algebra $\mathcal{A}(\hat{R}(p), \hat{R})$ *be completed with the inverse determinant of a:* $(\det\ a)^{-1}\det(a) = \det(a)(\det a)^{-1} = 1$. *Then the left and right inverse of a is given by*

$$(a^{-1})^{|1\rangle}{}_{\langle n+1|} = \frac{(-1)^{n-1}}{[n-1]!} (\det a)^{-1}\, \mathcal{E}_{\langle 2 \cdots n+1|}(p)\, a_2 \cdots a_n\, \varepsilon^{|1 \cdots n\rangle}. \tag{6.16}$$

Proof: We first check that the expression (6.16) is a left inverse of a:

$$\begin{aligned}(a^{-1})^{|1\rangle}{}_{\langle n+1|}\, a_{n+1} &= \frac{(-1)^{n-1}}{[n-1]!} (\det a)^{-1} \{\mathcal{E}_{\langle 2 \cdots n+1|}(p) a_2 \cdots a_n\, a_{n+1}\} \varepsilon^{|1 \cdots n\rangle} \\ &= \frac{(-1)^{n-1}}{[n-1]!} (\det a)^{-1} \det(a)\, \varepsilon_{\langle 2 \cdots n+1|} \varepsilon^{|1 \cdots n\rangle} = N^{|1\rangle}{}_{\langle n+1|} = \mathbb{I}^{|1\rangle}{}_{\langle n+1|}.\end{aligned}$$

Here we have used successively Eqs. (6.6), (3.10) and (3.12).

Checking that (6.16) is also a right inverse is slightly more complicated:

$$\begin{aligned} a_1\, (a^{-1})^{|1\rangle}{}_{\langle n+1|} &= \frac{(-1)^{n-1}}{[n-1]!} \{a_1\, (\det a)^{-1}\} \mathcal{E}_{\langle 2 \cdots n+1|}(p)\, a_2 \cdots a_n\, \varepsilon^{|1 \cdots n\rangle} \\ &= \frac{(-1)^{n-1}}{[n-1]!} (\det a)^{-1} K_1(p) \{a_1\, \mathcal{E}_{\langle 2 \cdots n+1|}(p)\} a_2 \cdots a_n\, \varepsilon^{|1 \cdots n\rangle} \\ &= \frac{(-1)^{n-1}}{[n-1]!} (\det a)^{-1} K_1(p)\, X_1\, \mathcal{E}_{\langle 2 \cdots n+1|}(p) X_1^{-1} \{a_1 \cdots a_n\, \varepsilon^{|1 \cdots n\rangle} \\ &= (\det a)^{-1} K_1(p)\, N^{|1\rangle}{}_{\langle n+1|}(p)\, \det(a) = \mathbb{I}^{|1\rangle}{}_{\langle n+1|},\end{aligned}$$

where we have applied successively Eqs. (6.11), (6.2), (6.7), (5.10) and (5.9). ■

The existence of inverse matrix a^{-1} is needed in many applications of the algebra $\mathcal{A}(\hat{R}(p), \hat{R})$. As an example of such application we shall construct a realization of a reflection equation algebra $\mathcal{M}(\hat{R})$ (for definition of this algebra see, e.g., Ref. 37, and references therein) in terms of the generators of $\mathcal{A}(\hat{R}(p), \hat{R})$. We have to use here the following general property of $\mathrm{SL}(n)$-type dynamical R-matrices (which has been noticed in Ref. 5 for the $\mathrm{SL}(2)$ case, see also Refs. 4,14).

Proposition 6.4: The dynamical matrix $\hat{R}(p)$ *(4.6), (4.12), (4.13) satisfies the equation*

$$D_1\, \hat{R}(p)\, D_2^{-1} = \hat{R}(p)^{-1}\, \sigma_{12}, \tag{6.17}$$

where the diagonal matrices D and σ

$$D_j^i \equiv q^{d_i} \delta_j^i, \quad (\sigma_{12})_{j_1 j_2}^{i_1 i_2} = \delta_{j_1}^{i_1} \delta_{j_2}^{i_2}\, \sigma_{i_1 i_2} \tag{6.18}$$

are fixed by (6.17) as

$$q^{d_i - d_j} = q^{-2 p_{ij}}\, \pi_{ij} \quad (i \neq j), \tag{6.19}$$

$$\sigma_{ij} = q^{2\delta_{ij}} \tag{6.20}$$

so that d_i *are functions of* p.

Proof: First of all we note that from the Hecke condition (4.4) [and (4.7)] one can deduce

$$\hat{R}(p)^{-1}=(a_{i_1 i_2}(p)-(q-\overline{q})\,\delta_{i_1 i_2})\,\delta^{i_1}_{j_2}\delta^{i_2}_{j_1}-b_{i_2 i_1}(p)\,\delta^{i_1}_{j_1}\delta^{i_2}_{j_2}. \tag{6.21}$$

Substitution of (4.6), (6.18) and (6.21) into (6.17) gives the following equations for the parameters σ_{ij} and d_i:

$$a_{ij}=(a_{ij}-(q-\overline{q})\,\delta_{ij})\,\sigma_{ji}, \tag{6.22}$$

$$q^{d_i-d_j}\,b_{ij}=-b_{ji}\,\sigma_{ij}. \tag{6.23}$$

Equation (6.22) leads to (6.20) while (6.23) is equivalent [in view of (A7)] to (6.19). ■

Now we construct the matrix $M^{\alpha}{}_{\beta}$ which is diagonalized with the help of the matrix a^i_α and the spectrum of which is defined by the matrix D (6.18), (6.19)

$$M=a^{-1}\,D\,a. \tag{6.24}$$

It is clear that $[D_1,D_2]=0$ and therefore the spectrum of the matrix M gives a commutative set of elements.

Proposition 6.5: The elements of the matrix M (6.24) *satisfy a reflection equation of the form*

$$M_2\,\hat{R}^{-1}\,M_2\,\hat{R}^{-1}=\hat{R}^{-1}\,M_2\,\hat{R}^{-1}\,M_2, \tag{6.25}$$

and thus provide a realization of a reflection equation subalgebra $\mathcal{M}(\hat{R})$ *in* $\mathcal{A}(\hat{R}(p),\hat{R})$. *The matrix elements of M satisfy the following exchange relations with the generators of* $\mathcal{A}(\hat{R}(p),\hat{R})$:

$$[D_2,M_1]=0, \quad M_1\,a_2=q^{2/n}\,a_2\,\hat{R}^{-1}\,M_2\,\hat{R}^{-1}. \tag{6.26}$$

Proof: Using (6.2), one can bring the commutation relations of the matrix D with the elements a^i_α to the form

$$a_1\,D_2=q^{-2/n}\,\sigma_{12}\,D_2\,a_1, \tag{6.27}$$

where the diagonal matrix σ_{12} is given by (6.18), (6.20). Equations (6.24) and (6.27) imply $[D_2,M_1]=0$. Then one proves (6.25) and the second relation in (6.26) by using (6.24), (6.1), (6.27) and (6.17). ■

VII. APPLICATION TO THE SU(n) WZNW MODEL

As an application of quantum matrix algebras we briefly describe here a typical problem of the two dimensional conformal field theory in which such matrices arise (see Ref. 24 for more details).

Let G be a connected compact Lie group and $g=g(t,x)$ be a map from the cylinder $\mathbb{R}\times\mathbb{S}^1$ into G which satisfies the Wess–Zumino–Novikov–Witten (WZNW) equations of motion. The general periodic solution $g(t,x)=g(t,x+2\pi)$ of these equations factorizes into a product of group valued chiral fields

$$g^A_B(t,x)=u^A_\alpha(x-t)\,\overline{u}^\alpha_B(x+t) \quad (\text{classically, } g,u,\overline{u}\in G), \tag{7.1}$$

each of which satisfies a twisted periodicity condition; in particular,

$$u(x+2\pi)=u(x)M \quad (M\in G), \tag{7.2}$$

where M is the monodromy.

Furthermore, the quantum chiral fields obey quadratic exchange relations[5,6,10,11,20,21,23,38,39]

$$u(y)_2 u(x)_1 = u(x)_1 u(y)_2 R(x-y) \Leftrightarrow P u(y)_2 u(x)_1 = u(x)_2 u(y)_1 \hat{R}(x-y) . \tag{7.3}$$

Here the matrix $R(x)$ is a solution of the quantum Yang–Baxter equation whose x-dependence is given by a step function, while $\hat{R}(x)$ is the associated braid operator:

$$\hat{R}(x) = \hat{R}\ \theta(x) + \hat{R}^{-1}\ \theta(-x) , \quad \hat{R}(x) = P\ R(x) = \hat{R}^{\varepsilon(x)} \tag{7.4}$$

$[\varepsilon(x) = \theta(x) - \theta(-x)]$.

Since $\hat{R}$ enters Eq. (7.3) in pair with P it should be normalized to have determinant $\det \hat{R} = \det P$. For $G = \mathrm{SU}(n)$ this implies the relation

$$\hat{R}_{i i+1} = \overline{q}^{1/n}\, \rho(g_i) \quad (\text{for } g_i^2 = \mathbb{I} + (q - \overline{q}) g_i) \Rightarrow \det \hat{R} = \det P = (-1)^{\binom{n}{2}} \tag{7.5}$$

so that we have to renormalize $\hat{R}$ of (3.1) by multiplying it by $\overline{q}^{1/n}$. (The resulting $\hat{R}$ has eigenvalues $q^{1-1/n}$ and $-\overline{q}^{1+1/n}$ of multiplicities $\binom{n+1}{2}$ and $\binom{n}{2}$, respectively; thus the product of all n^2 eigenvalues of $\hat{R}$ is indeed $(-1)^{\binom{n}{2}}$.)

We expand, following Refs. 21 and 4, $u(x)$ into a basis of zero modes that diagonalizes the monodromy matrix M at least for ''physical weights'' (satisfying $p_{1n} < h$):

$$u_\alpha^A(x) = a^i_\alpha\, u_i^A(x,p) , \quad a\, M = D\, a , \quad D^i_j = q^{d_i} \delta^i_j . \tag{7.6}$$

Here $d_i = -2p_i - 1/n + 1$, $p = \{p_i\}$ are central elements of the reflection equation algebra $\mathcal{M}(\hat{R})$; in the quantum field theoretic representation at hand they form a commuting set of operators such that Eq. (1.7) takes place. The eigenvalues of the differences $p_{i i+1} (= p_i - p_{i+1})$ are natural numbers that can be identified with the extended weights, $\lambda_i + 1$ labeling the (finite dimensional) irreducible representations of $\mathrm{SU}(n)$. The labels of the $\binom{n}{j}$ dimensional fundamental representation are given by $\lambda_i^{(j)} = \delta_i^j$, $1 \leqslant i,\ j \leqslant n-1$. Under these assumptions Eq. (7.3) implies exchange relations of the type

$$\hat{R}(p)\ a_1\, a_2 = a_1\, a_2\, \hat{R}_{21} , \tag{7.7}$$

where $\hat{R}(p)$ obeys the QDYBE (1.3). Hence, the results displayed in Secs. IV and V can be applied with slight modifications. (Since $\hat{R}(p)$ and $\hat{R}_{21}$ enter (7.7) homogeneously, the factor $\overline{q}^{1/n\rangle}$ of (7.5) cancels in the two sides.) Thus we can also apply the results of Sec. VI to the (chiral zero mode) quantum matrix algebra $\mathcal{A}$ of the $\mathrm{SU}(n)$ WZNW model. It should be noted that in this case q is a root of -1 associated with the level k $\widehat{su}(n)$ Kac–Moody algebra:

$$q = e^{i(\pi/h)} , \quad [2] = q + \overline{q} = 2 \cos \frac{\pi}{h} , \quad h = n + k (\geqslant n+1) . \tag{7.8}$$

The eigenvalues q^{d_i} of the diagonal matrix D can be expressed as differences of conformal dimensions. Indeed, according to Ref. 21, the chiral vertex operators $u_j(x,p)$ satisfy

$$u_j(x + 2\pi, p) = u_j(x,p)\ e^{2\pi i (\Delta_h(p) - \Delta_h(p + v^{(j)}))} , \tag{7.9}$$

where the matrices $v^{(j)}$ and p are defined by (1.1) and (1.2). Here the conformal dimensions are expressed in terms of the $\mathrm{SU}(n)$ Casimir operator,

$$2\, h\, \Delta_h(p) = C_2(p) = \frac{1}{n} \sum_{1 \leqslant i < k \leqslant n} p_{ik}^2 - \frac{n(n^2-1)}{12} , \tag{7.10}$$

so that

$$d_j = C_2(p) - C_2(p+v^{(j)}) = -2(p|v^{(j)}) - |v^{(j)}|^2 = (1/n) - 1 - 2p_j . \tag{7.11}$$

Inserting this in (6.19), we deduce that $\pi_{ij}=1$ so that we arrive at the special solution (4.24) for $\hat{R}(p)$, allowing us to present (7.7) in the form

$$\alpha_{ij}(p)[p_{ij}-1]\, a^j_\alpha a^i_\beta = [p_{ij}]\, a^i_\beta a^j_\alpha - q^{\epsilon_{\beta\alpha} p_{ij}} a^i_\alpha a^j_\beta \tag{7.12}$$

(here $\epsilon_{\alpha\beta}$ is equal 1 for $\alpha>\beta$, 0 for $\alpha=\beta$ and -1 for $\alpha<\beta$). According to the analysis of Sec. IV we can reduce (7.12) to the case $\alpha_{ij}(p)=1$ by a suitable twist.

An important consequence of (7.8) and (7.12) is the existence of an ideal $\mathcal{I}_h$ of $\mathcal{A}$ generated by n^2 elements $(a^i_\alpha)^h$ such that the factor algebra $\mathcal{A}/\mathcal{I}_h$ is finite dimensional.[24] This allows to define a finite dimensional ''Fock space representation'' of $\mathcal{A}$ with a unique vacuum vector $|\mathrm{vac}\rangle$ corresponding to the trivial su(n) weight $\lambda_i=0$ ($p_{i\,i+1}=1$, $i=1,\ldots,n-1$) such that

$$a^i_\alpha |\mathrm{vac}\rangle = 0 \quad \text{for } i>1 , \quad \mathcal{I}_h |\mathrm{vac}\rangle = 0 . \tag{7.13}$$

ACKNOWLEDGMENTS

This work started while three of us, L.K.H., O.V.O. and I.T.T. were visiting the Bogoliubov Laboratory of Theoretical Physics of the JINR, Dubna and was completed while A.P.I., L.K.H. and I.T.T. were visiting the Department of Physics of the University of Pisa, ICTP (Trieste) and the Erwin Schrödinger Institute for Mathematical Physics, respectively. We thank all these Institutions for hospitality and support. This work was also supported in part by the RFBR (Grant No. 97-01-01041), INTAS (Grant No. 93-127-ext), by the exchange program between INFN and JINR (Dubna) and by the Bulgarian National Foundation for Scientific Research under Contract No. F-404.

APPENDIX: NORMALIZATION OF DYNAMICAL LEVI-CIVITÀ TENSORS

The definitions (5.3), (5.4) lead to the expression

$$\mathcal{E}_{i_1\cdots i_n}(p)\, \mathcal{E}^{i_1\cdots i_n}(p) = \prod_{1\leqslant a<b\leqslant n} \xi_{i_a i_b} \tag{A1}$$

(there are no summations over the indices i_k), and the normalization condition (5.6) for the dynamical $\mathcal{E}$-tensors follows from

Proposition A: Let $\xi_{ij}=d-b_{ij}$*, where d is a constant (comparing with (4.12), one gets* $d=q$*) and the elements* b_{ij} *satisfy (4.7), (4.10). Then the following identity holds:*

$$I_k \equiv \sum_{S_k} \prod_{1\leqslant a<b\leqslant k} \xi_{i_a i_b} = [k]_d! , \tag{A2}$$

where $k\leqslant n$, $[k]_d = (d^k-(d-\lambda)^k)/\lambda$ $(\lambda = q-\overline{q})$ and S_k denotes all permutations of indices $(i_1,\ldots,i_k)$ $(i_a\neq i_b$ for $a\neq b)$. Note that $[k]_d=[k]$ for $d=q$ [as it is needed in (5.6)].

Proof: We shall proceed by induction. For $k=2$ we have

$$I_2 = \xi_{i_1 i_2} + \xi_{i_2 i_1} = 2\,d - \lambda = [2]_d .$$

Let (A2) be correct for some $k(1<k<n)$, then for $k+1$ we derive

$$I_{k+1}=\sum_{S_{k+1}}\left[\left(\prod_{l=1}^{k}\xi_{i_l i_{k+1}}\right)\prod_{1\leqslant a<b\leqslant k}\xi_{i_a i_b}\right]$$
$$=\sum_{r=1}^{k+1}\left[\left(\prod_{\substack{l=1\\ l\neq r}}^{k+1}\xi_{i_l i_r}\right)\sum_{S_k}\prod_{\substack{a\neq r\neq b\\ 1\leqslant a<b\leqslant k+1}}\xi_{i_a i_b}\right]$$
$$=I_k\sum_{r=1}^{k+1}\prod_{\substack{l=1\\ l\neq r}}^{k+1}\xi_{i_l i_r}.$$

Therefore we should prove the identity

$$[k+1]_d=\sum_{r=1}^{k+1}\prod_{\substack{l=1\\ l\neq r}}^{k+1}\xi_{i_l i_r}=\sum_{r=1}^{k+1}\prod_{\substack{l=1\\ l\neq r}}^{k+1}(d-b_{i_l i_r}). \tag{A3}$$

This identity follows from the relation

$$\sum_{r=1}^{m}\prod_{\substack{l=1\\ l\neq r}}^{m}b_{i_l i_r}=\lambda^{m-1}(m\leqslant k+1), \tag{A4}$$

which can be obtained by induction. Indeed, from Eqs. (4.7), (4.10) we have for $m=2,3$,

$$b_{i_1 i_2}+b_{i_2 i_1}=\lambda,\quad b_{i_2 i_1}b_{i_3 i_1}+b_{i_1 i_2}b_{i_3 i_2}+b_{i_1 i_3}b_{i_2 i_3}=\lambda^2.$$

Then we deduce

$$\prod_{l=2}^{m}b_{i_l i_1}=b_{i_2 i_1}\left(\lambda^{m-2}-\sum_{r=3}^{m}(\lambda-b_{i_r i_1})\prod_{\substack{l=3\\ l\neq r}}b_{i_l i_r}\right)$$
$$=b_{i_2 i_1}\sum_{r=3}^{m}b_{i_r i_1}\prod_{\substack{l=3\\ l\neq r}}b_{i_l i_r}$$
$$=\sum_{r=3}^{m}(\lambda^2-b_{i_1 i_2}b_{i_r i_2}-b_{i_1 i_r}b_{i_2 i_r})\prod_{\substack{l=3\\ l\neq r}}b_{i_l i_r}$$
$$=\lambda^{m-1}-\sum_{r=2}^{m}\prod_{\substack{l=1\\ l\neq r}}b_{i_l i_r},$$

which proves (A4). Expanding the right hand side of (A3) in power series of d and taking into account (A4) we verify the relations (A3) and, thus, complete the proof. ■

One can reformulate the statement of Proposition A in more concise form (only in terms of elements ξ_{ij}).

Proposition B: Let ξ_{ij} *satisfy*

$$\xi_{ij}+\xi_{ji}=[2]=\xi_{ij}\,\xi_{jk}\,\xi_{ki}+\xi_{ik}\,\xi_{kj}\,\xi_{ji}(i\neq j\neq k\neq i).$$

We rewrite these conditions as

$$\sum_{r=1}^{k} \prod_{\substack{l=1 \\ l\neq r}}^{k} \xi_{i_l i_r} = [k] \quad \text{for } k=2,3. \tag{A5}$$

Then, Eq. (A5) is also valid for $4 \leqslant k \leqslant n$, *and the following identity holds:*

$$I_k \equiv \sum_{S_k} \prod_{1 \leqslant a < b \leqslant k} \xi_{i_a i_b} = [k]!, \tag{A6}$$

where S_k *denotes all permutations of the indices* $(i_1, \cdots, i_k)$ *and* $i_a \neq i_b$ *for* $a \neq b$.

Proof: The proof is similar to that of Proposition A. ■

Remark: There are many other interesting relations among the elements b_{ij} (4.7), (4.10) (as well as among ξ_{ij}). For example, one can easily deduce the identity

$$b_{i_1 i_2} b_{i_2 i_3} \cdots b_{i_{k-1} i_k} b_{i_k i_1} = (-1)^k b_{i_1 i_k} b_{i_k i_{k-1}} \cdots b_{i_3 i_2} b_{i_2 i_1},$$

which generalizes (4.10) and follows from the relation

$$-\frac{b_{ji}(p)}{b_{ij}(p)} q^{2p_{ij}} = \pi_{ij}. \tag{A7}$$

Note that we consider π_{ij} as constants which are independent of p_i.

Lie subalgebras of real and complex orthogonal groups in dimension four

Federico G. Lastaria[a)]
Dipartimento di Matematica, Politecnico di Milano,
Piazza Leonardo da Vinci 32, 20133 Milano, Italy

(Received 29 April 1998; accepted for publication 3 August 1998)

We give an explicit description of all Lie subalgebras of the Lie algebras $\mathfrak{so}_4\mathbb{R}$ and $\mathfrak{so}_4\mathbb{C}$ of the orthogonal groups $O(4,\mathbb{R})$ and $O(4,\mathbb{C})$. [S0022-2488(99)00501-0]

I. INTRODUCTION

In view of applications to mathematical physics as well as to differential geometry, we find it worthy to give a description, as explicit as possible, of the Lie subalgebras of the orthogonal Lie algebras $\mathfrak{so}_4\mathbb{R}$ and $\mathfrak{so}_4\mathbb{C}$.

Our approach is elementary, in the sense that we do not rely on Dynkin diagrams or general structure theorems: only some linear algebra and elementary facts about Borel subalgebras are needed.

II. LIE SUBALGEBRAS OF $\mathfrak{so}_4\mathbb{R}$

Let $\mathbb{H}$ be the skew field of quaternions and let $S^3 \subset \mathbb{H}$ be the Lie group of unit quaternions, isomorphic to the three-dimensional sphere. For each $(p,q) \in S^3 \times S^3$, let $\varphi_{p,q}$ be the $\mathbb{R}$-linear map defined by

$$\varphi_{p,q}: \quad \mathbb{H} \to \mathbb{H},$$

$$x \mapsto pxq^{-1},$$

for every $x \in \mathbb{H}$. Since $\|\varphi_{p,q}x\| = \|p\|\|x\|\|q^{-1}\| = \|x\|$, for all $p,q \in S^3$ the map $\phi_{p,q}$ belongs to $O(4,\mathbb{R})$, where we identify $\mathbb{R}^4$ with $\mathbb{H}$. Let φ be the map

$$\varphi: \quad S^3 \times S^3 \to O(4,\mathbb{R}),$$

$$(p,q) \mapsto \phi_{p,q}.$$

Since φ is continuous and $S^3 \times S^3$ is connected, the image $\varphi(S^3 \times S^3)$ of φ is in fact contained in the connected component $SO(4,\mathbb{R})$. Then we have a commutative diagram of Lie group homomorphisms:

$$\begin{array}{ccc} S^3 & \overset{\Delta}{\hookrightarrow} & S^3 \times S^3 \\ \Big\downarrow \psi & & \Big\downarrow \varphi \\ SO(3,\mathbb{R}) & \hookrightarrow & SO(4,\mathbb{R}) \end{array}$$

where Δ is the diagonal map of the Lie group S^3 and the inclusion of $SO(3,\mathbb{R})$ in $SO(4,\mathbb{R})$ is induced by the identification of $\mathbb{R}^3$ with the subspace of pure quaternions. Then the Lie group S^3,

[a)]Electronic mail: fedlas@mate.polimi.it readily seen; is the universal covering of $SO(3,\mathbb{R})$ and the Lie group $S^3\times S^3$ is the universal covering of $SO(4,\mathbb{R})$ (see, e.g., Ref. 1). As a consequence, *we have a Lie algebra isomorphism*:

$$\mathfrak{so}_4\mathbb{R}\simeq\mathfrak{so}_3\mathbb{R}\oplus\mathfrak{so}_3\mathbb{R}. \tag{II.1}$$

Henceforth, denote by $\mathfrak{so}_3E$ and $\mathfrak{so}_3F$ the first and the second summand of the direct sum (II.1):

$$\mathfrak{so}_4\mathbb{R}\simeq\mathfrak{so}_3E\oplus\mathfrak{so}_3F. \tag{II.2}$$

Given any subalgebra $\mathfrak{g}\subset\mathfrak{so}_4\mathbb{R}\simeq\mathfrak{so}_3E\oplus\mathfrak{so}_3F$, choose a linear subspace $\mathfrak{g}'$ (in general, not uniquely determined) in such a way that

$$\mathfrak{g}=(\mathfrak{g}\cap\mathfrak{so}_3E)\oplus(\mathfrak{g}\cap\mathfrak{so}_3F)\oplus\mathfrak{g}',$$

as a direct sum of vector spaces. Let

$$pr_E:\mathfrak{so}_3E\oplus\mathfrak{so}_3F\to\mathfrak{so}_3E,\quad pr_F:\mathfrak{so}_3E\oplus\mathfrak{so}_3F\to\mathfrak{so}_3F$$

be the projections, and denote by

$$\bar{\mathfrak{g}}_E=pr_E(\mathfrak{g}),\quad \bar{\mathfrak{g}}_F=pr_F(\mathfrak{g})$$

the projections of the Lie algebra $\mathfrak{g}$ on $\mathfrak{sl}E$ and $\mathfrak{sl}F$, respectively. It is easy to prove that $\mathfrak{g}\cap\mathfrak{so}_3E$ and $\mathfrak{g}\cap\mathfrak{so}_3F$ are ideal of the Lie algebras $\bar{\mathfrak{g}}_E$ and $\bar{\mathfrak{g}}_F$, respectively.

From the linear isomorphisms,

$$\frac{\mathfrak{g}}{\mathfrak{g}\cap\mathfrak{so}_3F}\simeq\bar{\mathfrak{g}}_E;\quad \frac{\mathfrak{g}}{\mathfrak{g}\cap\mathfrak{so}_3F}\simeq(\mathfrak{g}\cap\mathfrak{so}_3E)\oplus\mathfrak{g}',$$

we see that

$$\bar{\mathfrak{g}}_E\simeq(\mathfrak{g}\cap\mathfrak{so}_3E)\oplus\mathfrak{g}',$$

as vector spaces. At the same way, we see, of course, that

$$\bar{\mathfrak{g}}_F\simeq(\mathfrak{g}\cap\mathfrak{so}_3F)\oplus\mathfrak{g}'.$$

Since $\dim\mathfrak{g}'\leqslant 3$, *a priori* the following cases may occur:

(a) $\dim\mathfrak{g}'=0$.

Then $\mathfrak{g}=(\mathfrak{g}\cap\mathfrak{so}_3E)\oplus(\mathfrak{g}\cap\mathfrak{so}_3F)$ is direct sum of Lie subalgebras of $\mathfrak{so}_3E$ and $\mathfrak{so}_3F$;

(b) $\dim\mathfrak{g}'=1$.

Since there are no two-dimensional Lie subalgebras in $\mathfrak{so}_3\mathbb{R}$ (because $\mathfrak{so}_3\mathbb{R}$ is isomorphic to the Lie algebra $(\mathbb{R}^3,\wedge)$, where $\wedge$ is the ordinary vector product), we have $\mathfrak{g}\cap\mathfrak{so}_3E=\mathfrak{g}\cap\mathfrak{so}_3F=0$ and therefore $\mathfrak{g}=\mathfrak{g}'$ is one-dimensional;

(c) $\dim\mathfrak{g}'=2$.

This would imply that $\dim\bar{\mathfrak{g}}_E=2$ or 3. Either cases are impossible, because on the one hand there are no two-dimensional subalgebras of $\mathfrak{so}_3E$ and, on the other, if $\dim\bar{\mathfrak{g}}_E$ were equal to 3, then $\mathfrak{so}_3E=\bar{\mathfrak{g}}_E$ would contain a one-dimensional ideal $\mathfrak{g}_E$, which is impossible;

(d) $\dim\mathfrak{g}'=3$.

TABLE I. *Lie subalgebras of* $\mathfrak{so}_3\mathbb{R}\simeq\mathfrak{so}_3\mathbb{R}\oplus\mathfrak{so}_3\mathbb{R}$. $\mathfrak{so}_3E$ and $\mathfrak{so}_3F$ are, respectively, the first and the second summand of $\mathfrak{so}_4\mathbb{R}\simeq\mathfrak{so}_3\mathbb{R}\oplus\mathfrak{so}_3\mathbb{R}$. (e_1,e_2,e_3) is a basis of $\mathfrak{so}_3E$ for which $[e_1,e_2]=e_3$, $[e_2,e_3]=e_1$, $[e_3,e_1]=e_2$. (e_1',e_2',e_3') is a basis of $\mathfrak{so}_3F$ for which $[e_1',e_2']=e_3'$, $[e_2',e_3']=e_1'$, $[e_3',e_1']=e_2'$.

dim 1	dim 2	dim 3	dim 4	dim 5
$\mathbb{R}e_1$	$\mathbb{R}e_1+\mathbb{R}e_1'$	$\mathfrak{so}_3E$	$\mathbb{R}e_1\oplus\mathfrak{so}_3F$	
$\mathbb{R}e_1'$		$\mathfrak{so}_3F$	$\mathfrak{so}_3E\oplus\mathbb{R}e_1'$	
$\mathbb{R}(e_1+e_1')$		$\{(A,A),\ A\in\mathfrak{so}_3\mathbb{R}\}$		

If this case occurs, then $\mathfrak{g}\cap\mathfrak{so}_3E=\mathfrak{g}\cap\mathfrak{so}_3F=0$. Therefore $\mathfrak{g}\simeq\bar{\mathfrak{g}}_E\simeq\bar{\mathfrak{g}}_F\simeq\mathfrak{so}_3\mathbb{R}$ is the ''diagonal'' Lie subalgebra,

$$\mathfrak{g}=\{(A,A)\in\mathfrak{so}_3\mathbb{R}\oplus\mathfrak{so}_3\mathbb{R},\quad A\in\mathfrak{so}_3\mathbb{R}\}.$$

Results are summarized in Table I. In particular, we find the following results, already stated in Ref. 2.

(1) *The Lie algebra* $\mathfrak{so}_4\mathbb{R}$ *has no five-dimensional Lie subalgebras*.

(2) *Every subalgebra of* $\mathfrak{so}_4\mathbb{R}$ *of dimension four is a direct sum of two summands: a one-dimensional subalgebra contained either in the ideal* $\mathfrak{so}_3E$ *or in* $\mathfrak{so}_3F$, *and the ideal* $\mathfrak{so}_3F$ *or* $\mathfrak{so}_3E$, *respectively*.

III. LIE SUBALGEBRAS OF $\mathfrak{so}_4\mathbb{C}$

It is well known that $\mathfrak{so}_4\mathbb{C}\simeq\mathfrak{sl}_2\mathbb{C}\oplus\mathfrak{sl}_2\mathbb{C}$ (see, e.g., Ref. 3). We therefore begin by investigating the Lie subalgebras of $\mathfrak{sl}_2\mathbb{C}$.

Each nonzero matrix $A\in\mathfrak{sl}_2\mathbb{C}$ is $GL_2\mathbb{C}$ conjugate—and hence $SL_2\mathbb{C}$ conjugate—to one of the following matrices in Jordan canonical form:

$$\begin{vmatrix}\lambda & 0\\ 0 & -\lambda\end{vmatrix}\quad\text{or}\quad\begin{vmatrix}0 & 1\\ 0 & 0\end{vmatrix}.$$

Therefore the only one-dimensional Lie subalgebra of $\mathfrak{sl}_2\mathbb{C}$ are, up to conjugation, $\mathbb{C}H$ and $\mathbb{C}E_+$, where

$$H=\begin{vmatrix}1 & 0\\ 0 & -1\end{vmatrix}\quad\text{and}\quad E_+=\begin{vmatrix}0 & 1\\ 0 & 0\end{vmatrix}.$$

Since two-dimensional Lie algebras are solvable and it is well known that Borel subalgebras (maximal solvable Lie subalgebras) are conjugate (see Ref. 3), the only two-dimensional Lie subalgebra of $\mathfrak{sl}_2\mathbb{C}$ is

$$\left\{\begin{vmatrix}a & b\\ 0 & -a\end{vmatrix} q \quad a,b\in\mathbb{C}\right\}=\mathbb{C}H\ltimes\mathbb{C}E_+,$$

where we use the following:

Notation. $\mathfrak{g}=\mathfrak{a}\ltimes\mathfrak{h}$ means that the Lie algebra $\mathfrak{g}$ is a *semidirect sum* of the Lie subalgebra $\mathfrak{a}$ and of the *ideal* $\mathfrak{h}$.

We now go back to the problem of describing Lie subalgebras of $\mathfrak{so}_4\mathbb{C}$. Let $\mathfrak{g}$ be a Lie subalgebra of $\mathfrak{so}_4\mathbb{C}\simeq\mathfrak{sl}_2\mathbb{C}\oplus\mathfrak{sl}_2\mathbb{C}=\mathfrak{sl}E\oplus\mathfrak{sl}F$. Here we simply call $\mathfrak{sl}E$ the first summand and $\mathfrak{sl}F$ the second, with $E\simeq F\simeq\mathbb{C}^2$. Fix a linear *subspace* $\mathfrak{g}'\subseteq\mathfrak{sl}E\oplus\mathfrak{sl}F$ such that

$$\mathfrak{g}=(\mathfrak{g}\cap\mathfrak{sl}E)\oplus(\mathfrak{g}\cap\mathfrak{sl}F)\oplus\mathfrak{g}',$$

as a direct sum of *vector spaces*. (Of course, such a $\mathfrak{g}'$ is not uniquely determined.)

Set

$$\mathfrak{g}_E = \mathfrak{g} \cap \mathfrak{sl}E, \quad \mathfrak{g}_F = \mathfrak{g} \cap \mathfrak{sl}F;$$

let

$$pr_E : \mathfrak{sl}E \oplus \mathfrak{sl}F \to \mathfrak{sl}E, \quad pr_F : \mathfrak{sl}E \oplus \mathfrak{sl}F \to \mathfrak{sl}F$$

be the natural projections, and denote by

$$\bar{\mathfrak{g}}_E = pr_E(\mathfrak{g}), \quad \bar{\mathfrak{g}}_F = pr_E(\mathfrak{g})$$

the projections of $\mathfrak{g}$ on $\mathfrak{sl}E$ and $\mathfrak{sl}F$.

Remark: $\mathfrak{g}_E$ is an *ideal* of $\bar{\mathfrak{g}}_E$ (and similarly $\mathfrak{g}_F$ is an ideal of $\bar{\mathfrak{g}}_F$).

Proof: Let $x \in \mathfrak{g}_E$, $y = pr_E(y+z) \in \bar{\mathfrak{g}}_E$, with $y+z \in \mathfrak{g}$, $z \in \mathfrak{sl}F$; then $[x,y] = [x,y+z] \in \mathfrak{g}$, because both x and $y+z$ are in $\mathfrak{g}$. But $[x,y] \in \mathfrak{sl}E$, because $x,y \in \mathfrak{sl}E$; therefore $[x,y] \in \mathfrak{g} \cap \mathfrak{sl}E = \mathfrak{g}_E$.

Remark: dim $\mathfrak{g}' \leqslant 3$ (by the Grassmann formula).

Let us examine the different cases: dim $\mathfrak{g}' = 0,1,2,3$.

Case 0: dim $\mathfrak{g}' = 0$.

Then the Lie subalgebra $\mathfrak{g}$ is a direct sum, as a Lie algebra, of the two Lie subalgebras $\mathfrak{g} \cap \mathfrak{sl}E \subset \mathfrak{sl}E$ and $\mathfrak{g} \cap \mathfrak{sl}F \subset \mathfrak{sl}F$:

$$\mathfrak{g} = (\mathfrak{g} \cap \mathfrak{sl}E) \oplus (\mathfrak{g} \cap \mathfrak{sl}F).$$

Case 1: dim $\mathfrak{g}' = 1$.

From the vector space isomorphisms

$$\frac{\mathfrak{g}}{\mathfrak{g} \cap \mathfrak{sl}F} \simeq (\mathfrak{g} \cap \mathfrak{sl}E) \oplus \mathfrak{g}' \quad \text{and} \quad \frac{\mathfrak{g}}{\mathfrak{g} \cap \mathfrak{sl}F} \simeq \bar{\mathfrak{g}}_E,$$

we have $\bar{\mathfrak{g}}_E \simeq (\mathfrak{g} \cap \mathfrak{sl}E) \oplus \mathfrak{g}'$. Therefore

$$\dim \bar{\mathfrak{g}}_E + 1 \quad \text{and} \quad \dim \bar{\mathfrak{g}}_F = \dim \mathfrak{g}_F + 1.$$

Hence dim $\bar{\mathfrak{g}}_E < 3$ and dim $\bar{\mathfrak{g}}_F < 3$, because the simple Lie algebras $\mathfrak{sl}E$ and $\mathfrak{sl}F$ can not contain two-dimensional ideals. The following cases are possible: if dim $\bar{\mathfrak{g}}_E = 2$, that is $\bar{\mathfrak{g}}_E = \mathbb{C}H \ltimes \mathbb{C}E_+$, then $\mathfrak{g}_E = \mathbb{C}E_+$, because $\mathbb{C}H$ is not an ideal in $\mathbb{C}H \ltimes \mathbb{C}E_+$; if dim $\bar{\mathfrak{g}}_E = 1$ (i.e., $\bar{\mathfrak{g}}_E = \mathbb{C}E_+$), then $\mathfrak{g}_E = 0$. Analogous results hold for $\bar{\mathfrak{g}}_F$, $\mathfrak{g}_F$.

Case 2: dim $\mathfrak{g}' = 2$.

By the same argument as in Case 1, we have

$$\dim \bar{\mathfrak{g}}_E = \dim \mathfrak{g}_E + 2 \quad \text{and} \quad \dim \bar{\mathfrak{g}}_F = \dim \mathfrak{g}_F + 2;$$

since $\mathfrak{sl}_2\mathbb{C}$ is simple, dim $\bar{\mathfrak{g}}_E = $ dim $\bar{\mathfrak{g}}_F = 2$. Thus $\bar{\mathfrak{g}}_E = \mathrm{st}\ E$, $\bar{\mathfrak{g}}_F = \mathrm{st}\ F$, and therefore

$$\mathfrak{g} = \left\{ (A,A) \in \mathfrak{sl}_2\mathbb{C} \oplus \mathfrak{sl}_2\mathbb{C}, \quad A = \begin{vmatrix} a & b \\ 0 & -a \end{vmatrix} \quad a,b \in \mathbb{C} \right\} = \mathbb{C}(H+H') \ltimes \mathbb{C}(E_+ + E'_+).$$

Case 3: dim $\mathfrak{g}' = 3$.

This implies $\bar{\mathfrak{g}}_E = \mathfrak{sl}E$ and $\bar{\mathfrak{g}}_F = \mathfrak{sl}F$. Therefore $\mathfrak{g}$ is the "diagonal" Lie subalgebra,

$$\mathfrak{g} = \{ (A,A) \in \mathfrak{sl}_2\mathbb{C} \oplus \mathfrak{sl}_2\mathbb{C}, \quad A \in \mathfrak{sl}_2\mathbb{C} \}.$$

See Table II for a summary of results.

TABLE II. *Lie subalgebras of* $\mathfrak{so}_4\mathbb{C}\simeq\mathfrak{sl}_2\mathbb{C}\oplus\mathfrak{sl}_2\mathbb{C}$.

dim 1	dim 2	dim 3	dim 4	dim 5
$\mathbb{C}H$	st E	$\mathfrak{sl}E$	$\mathbb{C}H+\mathfrak{sl}F$	st $E+\mathfrak{sl}F$
$\mathbb{C}H'$	st F	$\mathfrak{sl}F$	$\mathfrak{sl}E+\mathbb{C}H'$	$\mathfrak{sl}E+$st F
$\mathbb{C}E_+$	$\mathbb{C}(H+H')\ltimes\mathbb{C}(E_++E'_+)$	$\{(A,A),A\in\mathfrak{sl}_2\mathbb{C}\}$	$\mathbb{C}E_+\oplus\mathfrak{sl}F$

String structure over the Brownian bridge

Rémi Léandre
Département de Mathématiques, Institut Elie Cartan, Faculté des Sciences, Université de Nancy I, 54000. Vandoeuvre-les-Nancy, France

(Received 22 September 1997; accepted for publication 18 September 1998)

We give the definition of a line bundle over the Brownian bridge by using its section. This allows us to define a Hilbert space of sections of a line bundle over the Brownian bridge associated to the transgression of a representative of an element of $H^3(M;Z)$. We consider the case of a string structure over the Brownian bridge: this allows us to define a Hilbert space of spinor fields over the Brownian bridge, when the first Pontryaguin class of the spin bundle over the manifold is equal to 0. [S0022-2488(99)00401-6]

I. INTRODUCTION

Let M be a compact-oriented even-dimensional manifold. A spin structure over M is a lifting of the frame bundle by the spinor group ''spin'' which is a $Z/2Z$ extension of $\mathrm{SO}(n)$ where n is the dimension of M. We choose a $Z/2Z$ cover of $\mathrm{SO}(n)$ because the spin representation in finite dimension is a projective representation of $\mathrm{SO}(n)$ with fiber $Z/2Z$.[1] There is a topological obstruction to constructing a spin structure over M,[2] which is the second Stiefel–Whitney class of M. It cannot be seen generally at the level of differential forms and of the de Rham theory over M.

Our goal is to go at the infinite-dimensional case, in order to construct spin structures over some infinite-dimensional objects. Namely in finite dimension, the Dirac operator over a manifold is related to the construction of a spin structure. In infinite dimension, the infinite-dimensional Dirac operator will be related to the construction of infinite-dimensional spin structures. Let us consider the free loop space $L_{\mathrm{fin}}(M)$ of M: it is the space of finite energy maps from the circle S^1 into M. In other words, it is the set of loops $s \to \gamma_s$ such that $\int_0^1 \| d/ds\, \gamma_s \|^2 ds < \infty$. Infinite-dimensional operators over $L_{\mathrm{fin}} M$ give topological invariants of the manifold,[3,4] if we consider their index. These are the Witten genus, the elliptic genus, and the elliptic genus of level N, which play an important role in the theory of cobordism. In order to work with these operators, we need a measure. The latter is useful for the computation of the adjoint of the operator. The index theorem is a statement at the level of Sobolev spaces. It is true at least in finite dimension. Our choice of measure is to take this Brownian bridge measure. The loops under study are only continuous.[5] A beginning of construction of these operators is given in Refs. 6–9. The case studied in Ref. 6 is related to the Witten genus of the manifold and to the Dirac operator over the free loop space.

Unfortunately, Ref. 6 gives only an approach to the construction of the Dirac operator over the free loop space, because the fiber is not what it should be. Namely, the construction of the suitable fiber is related to the theory of representations of a loop group.[1] Namely, the projective spin representation of a loop group is related to a central extension of this loop group by the circle and not by $Z/2Z$. It uses differential form unlike the finite-dimensional construction of the universal cover of $\mathrm{SO}(n)$.[10] If we consider the case of the smooth free loop space, the structure group is the loop group of $\mathrm{SO}(n)$. A spin structure is related to a lifting of the principal bundle in a loop group by a central extension of this loop group.[11,4] The obstruction is related to the first Pontryaguin class of the original bundle,[3,4,12–14] and, more precisely, to its transgression; but, of course, these considerations work only for the smooth loop space. On the other hand, the BHK measure is used in order to compute the adjoint of this type of operator and the Brownian bridge is only continuous. Let us recall the BHK measure. It is the measure over the free loop space $[p_1(x,x)dx \otimes dP_{1,x}]/[\int p_1(x,x)dx]$ where $p_t(x,y)$ is the heat kernel over the Riemannian manifold M and

$dP_{1,x}$ is the Brownian bridge measure over the based loop space of continuous loops starting from x. Gross[15] had shown that the tangent space of a continuous loop remains a Hilbert space in infinite-dimensional analysis, although the support of the measure is a Banach manifold. In this paper, we will follow the choice of Ref. 16 or 17 for the tangent space of a continuous loop.

Reference 13 has given a geometrical construction of such lifting, called a string structure, in the case of the based loop space of finite energy loops $L_{\mathrm{fin}}M$. Our goal is to construct such lifting for the Brownian bridge. The purpose of this work is to try to unify the considerations of Ref. 13 over the smooth loop space with the stochastic considerations of Refs. 17 and 18 over the continuous loop space. In order to construct a string structure, Ref. 13 introduces a commutative diagram. The holonomy over a loop plays an important role in this commutative diagram. Namely, let us consider a G principal bundle P over M. We consider the based loop space LP of P of loop starting from (x,e) in P: it is an LG principal bundle. Reference 13 constructs a U_1 bundle over LP denoted $\tilde{L}P$ which is an $\tilde{L}G$ bundle for a given central extension of LG. In order to give an explicit construction, they suppose that LP and LG are simply connected. Under this hypothesis, we can construct this bundle for a given representative of a integral cohomology class of LP of degree two. They avoid in this way all torsion phenomena: a circle bundle over a simply connected manifold is indeed determined by its curvature. So the construction of this lift is strongly related to a theory of forms and a theory of construction of a bundle by starting from a given cohomology class. The treatment is simplified, because the loop space of P is supposed simply connected.

In Ref. 17 or 18 the continuous loop space is introduced. A suitable Hilbert space which is the tangent space of a continuous loop is introduced in order to get the integration by parts formulas.[5,18,19] Reference 17 developed a theory of forms over the loop space without differential operations. In Refs. 20 and 21 a theory of stochastic cohomology of the Brownian loop is developed, where the stochastic Chen forms play a key role.

The purpose of this paper is to go one step further, by starting from elementary geometrical considerations: that is, to construct bundles by starting from a stochastic two-form. A preliminary work is Ref. 9. A closed Chen form of degree 1 is integrated by patching together its local integrals, when the path space is supposed simply connected. The key tool is the positivity theorem of Ref. 22 or 23. (The reader can find in Ref. 24 a jump version of this theorem.) Of course, we cannot integrate explicitly any closed one-form. Namely, we meet the problem that the deformation of a loop which is useful in order to integrate a form over a path in the continuous loop space does not keep the measure. Generally, the law of the deformed stochastic loop is a foreign law with respect to the Brownian bridge law. For this reason, we restrict our attention to the case where the form is a stochastic Chen form. This form is defined for a larger class of processes.

In the first part of this paper, we start from a closed Chen form of degree 2 with integral values over $L_{\mathrm{fin}}M$. An example is the transgression $\tau(\omega)$ of a representative ω of an element of $H^3(M,Z)$. A surface in the loop space is constituted by a volume in the manifold. The main property is that the integral of the transgression over a surface in the smooth loop space is equal to the integral of the underlying form over the underlying volume in M.

Let us recall[14,1] how we construct a line bundle over a simply connected manifold (of finite dimension or of infinite dimension) by starting from its curvature $\tilde{\omega}$. It is the set of couples of the shape $(l_\cdot(x),\alpha)$ [$l_\cdot(x)$ is a path starting from a point of reference and arriving at x in the manifold and α is an element of the complex line]. We say that the couple $(l_\cdot(x),\alpha)$ and $(l'_\cdot(x'),\alpha')$ are equivalent if the endpoints of the paths x and x' are equal and if

$$\alpha'=\alpha\ \exp\left[-2i\pi\int_S\tilde{\omega}\right]. \tag{1.1}$$

S is any surface bounded by the loop constituted of $l_\cdot(x)$ and $l'_\cdot(x')$ circled in the opposite sense. Such surface exists because we suppose that the manifold is simply connected. In the stochastic context, $\int_S\tau(\omega)$ leads to the study of some stochastic integrals. We have the choice of some distinguished surfaces in order to be able to integrate this transgression over a given surface in the stochastic loop space. Instead of constructing the bundle globally as in (1.1), we construct it by using a system of transition functions. However, we cannot construct the stochastic line bundle associated to this Chen form over the stochastic-based loop space. Namely, the transition functions are only almost surely defined. We request that the transition functions belong to all the Sobolev spaces, in order to give some rigidity to them. Let us recall namely that all bundles over a finite-dimensional manifold are measurably trivial. However, we construct the Hilbert space of sections of this formal line bundle, and a connection which operates over the space of sections. We hope that there are some applications to the geometric quantization of the loop space.[25] In order to do this, we suppose that the based loop space of loops with finite energy $L_{\mathrm{fin}}(M)$ is simply connected. We can determine explicitly the system of the measurable transition functions. A connection allows us to define the space of C^1 Sobolev sections of this formal line bundle. The bundle obtained is an extension in a certain sense of the underlying bundle over the finite energy loop space. Namely, if we take the polygonal approximation of a continuous loop, the transition functions are surely defined. They are, in fact, the transition functions which defined the underlying line bundle over the smooth loop space. Moreover, they tend almost surely to the transition functions which define the formal line bundle over the continuous loop space, when the length of the subdivision goes to the infinity.

We summarize the results of the second part of this work in this theorem-definition. (We refer to Ref. 20 for the theory of forms over the loop space.)

Definition I.I: Let $L_x(M)$ be the based loop space of the Riemannian manifold M endowed with the Brownian bridge measure. Let us suppose that M is two connected, and let us consider a three-form ω which is closed Z-valued. We can construct the two-form over $L_x(M)\int_0^1\omega(d\gamma_s,.,.)=\tilde{\omega}$ where γ denotes the typical continuous loop in M. There exists a system of open subsets O_i for the uniform topology which is a cover of $L_x(M)$ and a set $\rho_{i,j}$ of Brownian functionals with values in the unit circle of C, defined over $O_i\cap O_j$, which are almost surely defined and which belong to all the Sobolev spaces. Over $O_i\cap O_j$, they are such that $\rho_{i,j}\rho_{j,i}=1$ almost surely and, over a triple intersection $O_i\cap O_j\cap O_k$, they satisfy almost surely to the relation $\rho_{i,j}\rho_{j,k}\rho_{k,i}=1$. Moreover, there exists a set of one-forms over O_i denoted by A_i with values in the Lie algebra of the unit circle of C, such that almost surely over $O_i\cap O_j$ we have $A_i=A_j+\rho_{i,j}^{-1}d\rho_{i,j}$ and such that $dA_i=\sqrt{-1}2\pi\tilde{\omega}$. A section of the formal line bundle associated to the set of $\rho_{i,j}$ is a collection of random variables α_i from O_i into C such that $\alpha_j=\alpha_i\rho_{i,j}$ over $O_i\cap O_j$. The Hilbert space of sections is the set of sections ψ such that $E[|\psi|^2]<\infty$ where $|\alpha_i|=|\psi|$ is intrinsically defined.

After these elementary geometrical considerations, we consider the more complicated case of the construction of a string structure over the Brownian bridge. In the second part, we consider a G principal bundle P over M. We suppose that G is simple, simply connected. Moreover, we suppose that the based loop group of loops of finite energy $L_{\mathrm{fin}}G$ is simply connected. There exists a central extension $\tilde{L}_{\mathrm{fin}}G$ of $L_{\mathrm{fin}}G$. Let us suppose that there is a unitary representation Spin of $\tilde{L}_{\mathrm{fin}}G$, which is a Hilbert space (The reader can find references in this direction in Ref. 1 or 26). We construct over *LM*, the set of the Brownian bridge, an $L_{\mathrm{fin}}G$ bundle which extends the natural $L_{\mathrm{fin}}G$ bundle which exists over *LM*. We use the parallel transport over a loop. This bundle Q is only formal, in the sense that the transition functions are only measurable, because they belong only to all the Sobolev spaces. This allows us to construct, by using the associated transition functions, a formal linear bundle whose fiber is Spin. But we can define rigorously the space of sections of this formal linear bundle, which belong to some L^p spaces. The Dirac operator over the based loop space should act over the Hilbert space of a section of this formal bundle. We have the same topological obstructions which are involved with the first Pontryaguin class P of M as in the smooth case. This part is a mixture of the geometrical construction of Ref. 11 where the holonomy along a stochastic-based loop has a key role and of the stochastic considerations of the first part.

We can summarize the results of the third part of this work by the following theorem-definition:

Definition I.2: Let $Q\rightarrow M$ be a principal bundle over a compact Riemannian manifold with compact structural group, which is supposed simple and simply connected. We suppose that M is two connected. Let $L_{\text{fin}}G$ be the based loop group of G of loops with finite energy. Let L_eQ be the space of loops in Q of the shape $\tau_s^G g_s$ where g_s is a path in G of finite energy and τ_s^G the parallel transport over a random loop in M for the Brownian bridge measure, if the principal bundle Q is endowed by a connection. Associated to L_eQ, there exists a system of subsets V_i of L_xM such that $\cup V_i = L_xM$ almost surely. Over $V_i \cap V_j$, there exists a natural measurable application $g_{i,j}$ with values in $L_{\text{fin}}G$ such that $g_{i,j}g_{j,i} = e_.$ almost surely over $V_i \cap V_j$ and such that almost surely over $V_i \cap V_j \cap V_k$, $g_{i,j}g_{j,k}g_{k,i} = e_.$. We suppose that the Pontryagin class of the bundle is equal to 0. There exists a refinement of V_i, still denoted by V_i, and a measurable application $\rho_{i,j}$ from $V_i \cap V_j$ into $\tilde{L}_{\text{fin}}G$, the basical central extension of $L_{\text{fin}}G$, which satisfies the following conditions:

(i) Over $V_i \cap V_j$, $\rho_{i,j}\rho_{j,i} = \tilde{e}$ almost surely.
(ii) Over $V_i \cap V_j \cap V_k$, $\rho_{i,j}\rho_{j,k}\rho_{k,i} = \tilde{e}$ almost surely.
(iii) $\pi \rho_{i,j} = g_{i,j}$ almost surely, where π is the projection from $\tilde{L}_{\text{fin}}G$ into $L_{\text{fin}}G$.

Let us suppose, given a unitary representation of $\tilde{L}_{\text{fin}}G$, the space of measurable sections of the associated bundle to the system of transition functionals $\rho_{i,j}$ is given by a set of measurable functionals in the representation space called ψ_i defined over V_i, satisfying $\psi_j = \rho_{j,i}\psi_i$ almost surely over $V_i \cap V_j$. The Hilbert space of the sections is the space of sections such that $E[\|\psi\|^2] < \infty$, where the random variable $\|\psi\| = \|\psi_i\|$ over V_i is intrinsically defined.

This work is an element of a set of three papers about this construction.[27,28] We thank M. Katz for helpful discussions.

II. STOCHASTIC LINE BUNDLE

Let M be a compact Riemannian manifold. Let $L_xM = LM$ be the space of continuous loops in M starting from x and coming back in time 1 in x. Let $dP_{1,x}$ be the law of the Brownian bridge starting from x and coming back in time 1 in x: it is a probability measure over LM. Let us recall how $dP_{1,x}$ is defined. Let us introduce the heat kernel $p_t(x,y)$ associated to the Laplace–Beltrami operator over M. Let $F(\gamma_{t_1},\ldots,\gamma_{t_r})$, $0 < t_1 < \cdots < t_r < 1$, be a cylindrical functional over the based loop space. We have

$$E_{1,x}[F(\gamma_{t_1},\ldots,\gamma_{t_r})] = \frac{1}{p_1(x,x)} \int \int F(x_1,\ldots,x_r) p_{t_1}(x,x_1) p_{t_2-t_1}(x_1,x_2) \cdots p_{1-t_r}(x_r,x) dx_1 \ldots dx_r; \tag{2.1}$$

$s \to \gamma_s$ is a semi-martingale with respect to the canonical filtration associated to the canonical process $\gamma_. \to \gamma_s$.

Let us recall for that the definition of a semi-martingale. Let us introduce a filtration of σ-algebras indexed by R^+ such that $F_s \subseteq F_t s > t$ and a process X_s with values in R^d such that

(i) X_s is F_s adapted.
(ii) $s \to X_s$ is continuous almost surely for a given probability P.
(iii) X_s is in L^2.
(iv) $E[X_t | F_s] = X_s$ almost surely for $s < t$.

We say that such a random process $X_.$ is a L^2 martingale adapted to the filtration F_s. A semi-martingale is, roughly speaking, the sum of a martingale and an adapted finite variational process.

The main result is the following: if $X_.^i$, $i = 1,\ldots,d$ is a semi-martingale in R^d, $X_.^i X_.^j$ is still a semi-martingale. When we consider a family of martingales, there is an adapted finite variational process associated to each product, called the bracket of $X_.^i X_.^j$ and denoted by $\langle X^i, X^j \rangle_s$.

Let us consider a martingale X_s and Y_s a continuous ADAPTED process which is supposed to be bounded. The Itô integral $\int_0^t \langle Y_s, \delta X_s\rangle$ is the limit of the sum $\Sigma_i \langle Y_{t_i}, X_{t_{i+1}} - X_{t_i}\rangle$ for a given partition when the length of the subdivision tends to 0. It is still an L^2 martingale if the process $X_.$ is a L^2 martingale. The main ingredient in the sequel is the Itô formula.

Let $X_.$ be a semi-martingale over R^d and let f be a function from R^d into R with bounded derivatives of all orders. $f(X_.)$ is still a semi-martingale and we have

$$f(X_t) = f(X_0) + \int_0^t \langle df(X_s), \delta X_s\rangle + \frac{1}{2} \sum \int_0^t \frac{\partial^2}{\partial x_i \partial x_j} f(X_s) d\langle X^i, X^j\rangle_s . \tag{2.2}$$

We will not specify the natural different criteria of integrability which appear in these definitions.

We will say that a process $X_.$ over a manifold is a semi-martingale if, for all smooth functions with bounded derivatives with values in R, the process $f(X_.)$ is a semi-martingale with values in R. In order to specify the meaning of the sentence ''the Brownian bridge'' is a semi-martingale, we have to define a probability space. It is the space LM of continuous functions $s \to \gamma_s$ from the circle into the manifold such that $\gamma_0 = x$. The formula (2.1) gives over LM a probability measure: it is not immediately clear and is the purpose of a theorem. The σ-algebra F_s is the smallest σ-algebra such that the evaluation maps $e_u: \gamma_. \to \gamma_u$ are measurable for all $u \leqslant s$. We will not specify the technical difficulties which appear here.

Let γ_t be a loop. Let τ_t be the parallel transport from γ_0 to γ_t. In order to define it, we consider the polygonal approximation γ_t^n of a loop γ, and the parallel transport τ_t^n along the polygonal approximation of this loop: $\tau_.^n \to \tau_.$ almost surely for the topology of the uniform convergence.

In order to be more precise, we have to recall quickly the theory of stochastic differential equations. Let $X_.$ be a semi-martingale in R^d. We consider $A(y)$ a linear application from R^d into R^m which depends smoothly on y in R^m. We consider the Itô stochastic differential equation:

$$dY_t = A(Y_t)\delta Y_t . \tag{2.3}$$

This means that almost surely

$$Y_t = Y_0 + \int_0^t A(Y_s)\delta Y_s . \tag{2.4}$$

It has a unique solution. It can be given by the Picard iteration method or the Peano approximation, which converges to the solution.

There is another type of stochastic differential equation, which is simpler under a geometrical point of view. Let $Y_.$ and $X_.$ be two R-valued semi-martingales. We put

$$\int_0^t Y_s dX_s = \int_0^t Y_s \delta X_s + \frac{1}{2} \int_0^t d\langle X, Y\rangle_s . \tag{2.5}$$

It is called the Stratonovich integral. The Itô formula becomes the classical formula in the Stratonovich calculus:

$$f(X_t) = f(X_0) + \int_0^t f'(X_s) dX_s . \tag{2.6}$$

This leads to the following principle, called Malliavin's transfer principle. A formula which is true over a manifold in the deterministic context, which has a meaning in the stochastic context, is still true in the stochastic context. This leads to the theory of Stratonovich stochastic differential equations:

$$dY_t = A(Y_t) dX_t , \tag{2.7}$$

instead of (1.3) or equivalently $Y_t = Y_0 + \int_0^t A(Y_s) dX_s$. This equation can be converted into an Itô stochastic differential equation.

An important case of stochastic process is the flat Brownian motion.

We consider a set $B^i_\cdot$, $i=1,...,m$, R-valued martingales in L^2 with bracket $\langle B^i, B^j \rangle_s = \delta_{i,j} s$ starting from $(x_i) = x$ in R^m. The law of such a process is uniquely determined and is called the law of the flat Brownian motion starting from x. Let us introduce the flat Laplacian Δ over R^m:

$$\Delta = \frac{1}{2} \sum_i^m \frac{\partial^2}{\partial x_i^2}. \tag{2.8}$$

Let $\exp[t\Delta]$ be the semi-group over R^m associated to the flat Laplacian. We have a stochastic representation of it. Namely, if f is a smooth function with bounded derivatives, we get

$$\exp[t\Delta] f(x) = E[f(B_t)], \tag{2.9}$$

where $B_\cdot$ is a flat Brownian motion starting from x.

Let X_i be some vector fields over the compact manifold M. Let Δ_c be the operator $\frac{1}{2}\Sigma_1^m X_i^2 + X_0$. Let us introduce the Stratonovich differential equation,

$$dX_t = \sum_1^m X_i(X_t) dB_t^i + X_0(X_t) dt, \tag{2.10}$$

starting from x. Let us introduce the heat semi-group associated to Δ_c denoted by $\exp[-t\Delta_c]$. We have the following stochastic representation:

$$\exp[t\Delta_c] f(x) = E[f(X_t)]. \tag{2.11}$$

The equation (2.10) has a meaning in local charts, and we can patch together the local solutions, because the Itô formula in the Stratonovich context is the usual one. The equation (2.10) gives Schwartz's construction of the Brownian motion over a manifold: let us recall namely that the Laplace–Beltrami operator over a Riemannian compact manifold can be written as $\Delta = \frac{1}{2}\Sigma X_i^2 + X_0$. The semi-group associated to Δ (called the heat semi-group associated to the Riemannian manifold) has a stochastic representation in terms of the semi-martingale solution of (2.10). The law of the Brownian motion starting from x gives a probability measure over the space of continuous functions $\gamma_\cdot$ starting from x into M. Let us denote by dP_1^x this probability measure. It is characterized by

$$E_{P_1^x}[f(\gamma_{t_1}, \ldots, \gamma_{t_r})] = \int \int \cdots \int f(x_1, \ldots, x_r) p_{t_1}(x, x_1) p_{t_2 - t_1}(x_1, x_2) \ldots p_{t_r - t_{r-1}}(x_{r-1}, x_r) dx_1 \ldots dx_r. \tag{2.12}$$

Compare with (2.1). This gives another approach to the Brownian bridge measure. If we condition the Brownian motion to come back to the departure, the law of γ_t is given by the density $[p_t(x,y) p_{1-t}(y,x) / p_1(x,x)] dy$. We deduce that the law of γ_t satisfies an inhomogeneous heat equation. Equation (2.10) becomes

$$dX_t = \sum X_i(X_t)(dB_t^i + \langle X_i(X_t), \ \text{gradlog } p_{1-t}(X_t, x) \rangle dt) + X_0(t) dt. \tag{2.13}$$

Therefore, the equation of the bridge is an inhomogeneous Stratonovich differential equation. It is a nontrivial result that $X_t \to x$ when $t \to 1$ and that $X_\cdot$ is a semi-martingale. The law of X_t starting from x is the measure over the based loop space given by (2.1).

Let $Q \to M$ be a principal bundle with compact structural group. We can trivialize it locally. We endow it with a connection ∇. Let Γ be the Christoffel symbol in this trivialization. Let $X_.$ be a semi-martingale over the manifold. The following Stratonovich differential equation has a meaning

$$d\tau_t = -\Gamma_{\tau_t}(X_t)dX_t \tag{2.14}$$

if we operate in the local chart of the trivialization. Since the Itô formula in the Stratonovich calculus is the traditional one, this equation is intrinsically defined and we can patch together the local solution of it, when we change of charts. We call τ_t the parallel transport over the semi-martingale X_t. This works too if we look at a linear bundle over M. This allows us to give the notion of a semi-martingale with values in Q over the semi-martingale $X_.$: $Z_.$ is a semi-martingale over $X_.$ if and only if $\tau_t^{-1}Z_t$ is a semi-martingale over X_0.

The interest of the Stratonovich calculus is twofold: first of all, as we have seen, the Itô formula in the Stratonovich calculus is the classical one. Second, if we consider the polygonal approximation of B_t^i, we get a classical solution of (2.10) or (2.13), and we get a finite energy process $X_.^n$ which tends almost surely to the solution solution of the Stratonovoch differential equation for the uniform topology. This second property can be generalized. If in (2.14) we consider the polygonal approximation of X_t, which is defined if the length of the dyadic subdivision tends to infinity, we get the classical equation of the parallel transport over a finite energy curve. Let us denote it by $\tau_.^n$ When $n \to \infty$, $\tau_.^n \to \tau_.$ almost surely. We can consider other types of finite energy approximation of the leading semi-martingale $X_.$ (See Ref. 29, for instance).

This allows us to give the notion of the Stratonovich integral of a one-form along the trajectories of a semi-martingale X_t. Let ω be a one-form over the manifold and let X_t be a semi-martingale in the manifold M. The Stratonovich integral $\int_0^1 \langle \omega(X_s), dX_s \rangle$ is the limit of the classical integrals $\int_0^1 \langle \omega(X_s^n), dX_s^n \rangle$ for the polygonal approximation $X_.^n$ of the semi-martingale $X_.$.

The tangent space of a loop $\gamma_.$ is the space of sections X_t over γ_t of TM such that

$$X_t = \tau_t H_t, \quad H_0 = H_1 = 0, \tag{2.15}$$

where $s \to H_s$ is a process in $T_{\gamma_0}(M)$. We suppose, moreover, that H_s has finite energy and we take as the Hilbertian norm

$$\|X\|^2 = \int_0^1 |H_s'|^2 ds. \tag{2.16}$$

Let us recall the definition of a Chen form. Let $\Omega_.(M)$ be the space of forms over the manifold of degree not equal to 0. Let $\tilde{\omega}_n \in \Omega_.^{\otimes}$:

$$\tilde{\omega}_n = \omega_1 \otimes \cdots \otimes \omega_n. \tag{2.17}$$

We associate a form over the based loop space by the formula

$$\Sigma \tilde{\omega}_n = \int_{0<s_1<\cdots<s_n<1} \omega_1(d\gamma_{s_1}, .) \wedge \cdots \wedge \omega_n(d\gamma_{s_n}, .). \tag{2.18}$$

We will not repeat general considerations over the Chen forms. We will give two examples in order to show how they act. First of all, let us consider an r-form. $\Sigma\omega_1$ is an $r-1$ form over the loop space given by the formula

$$\Sigma\omega_1(X^1, \ldots, X^{r-1}) = \int \omega_1(d\gamma_s, X_s^1, \ldots, X_s^{r-1}). \tag{2.19}$$

This formula does not cause any problem if we work over the smooth loop space, because X_s is a vector over γ_s and because the differential $d\gamma_s$ is defined. If we consider continuous loops, we get $X_s=\tau_s H_s$ and $H_s=\int_0^s H'_u\,du$. We apply the Fubini theorem in (2.19) and we have

$$\Sigma\omega_1(X^1,\ldots,X^{r-1})=\int\cdots\int k(s_1,\ldots,s_{r-1})H'^{1}_{s_1}\cdots H'^{r-1}_{s_{r-1}}\,ds_1\cdots ds_{r-1}, \tag{2.20}$$

where $k(s_1,\ldots,s_{r_1})$ is a stochastic kernel given by Stratonovitch differential integral.

Let us consider the case of two-forms of degree 2, ω_1 and ω_2. Let us consider $\tilde{\omega}_2=\omega_1\otimes\omega_2$. For smooth loops,

$$\Sigma\tilde{\omega}_2(X^1,X^2)=\int_{0<s_1<s_2<1}\omega_1(d\gamma_{s_1},X^1_{s_1})\omega_2(d\gamma_{s_2},X^2_{s_2})-\int_{0<s_1<s_2<1}\omega_1(d\gamma_{s_1},X^2_{s_1})\omega_2(d\gamma_{s_2},X^1_{s_2}). \tag{2.21}$$

For continuous loops, $X^1_s=\tau_s H^1_s$, $X^2_s=\tau_s H^2_s$ where H^1 and H^2 have finite energy. We apply the Fubini theorem in the stochastic integral (2.21), and we deduce a formula analogous to (2.20) for $\Sigma\tilde{\omega}_2$.

The exterior derivative of the Chen form $\Sigma\tilde{\omega}_n$ corresponds to the Chen form associated to the Hochschild coboundary of $\tilde{\omega}_n$.[30] Let us recall that the Hochschild coboundary is given by $(b_1+b_2)\tilde{\omega}_n$. Without specifying the signs which appear in the following expressions (see Refs. 30 or 20), we have

$$b_1(\tilde{\omega}_n)=\sum \text{ sign } \omega_1\otimes\cdots\otimes d\omega_i\otimes\cdots\otimes\omega_n \tag{2.22}$$

and

$$b_2(\tilde{\omega}_n)=\sum \text{ sign } \omega_1\otimes\cdots\otimes\omega_i\wedge\omega_{i+1}\otimes\cdots\otimes\omega_n\,. \tag{2.23}$$

For the smooth loop space, the cohomology of Chen forms is equal to the cohomology of the based loop space.[31] Equivalently, the Hochschild cohomology of forms of the manifold is equal to the cohomology of the smooth loop space. A version of this theorem for the continuous loop space can be seen in Refs. 20 and 21. Especially for the continuous loop space of an homogeneous manifold, the Brownian cohomology is equal to the Hochschild cohomology of the forms of the manifold. This remains true for the finite energy loop space. In particular, the part without torsion of the Z cohomology of $L_{\text{fin}}M$ for loops of finite energy is given by Chen forms. Let us take a representative ω of a cohomology class of degree 3 with integral values. The transgression

$$\tau(\omega)=\int_0^1\omega(d\gamma_s,.,.) \tag{2.24}$$

is a Chen form over $L_{\text{fin}}M$ which is closed and with values in Z. Its integral over closed surfaces in the smooth loop space is equal to an integer. Namely, the integral over this surface of $\tau(\omega)$ is equal to the integral over the underlying volume in M of ω. If the surface in the loop space has no boundary, the underlying volume in the manifold has no boundary. This comes from the fact that the circle has no boundary.[25]

Let us recall how we produce an S^1 bundle from a Z closed form of degree 2 $\tilde{\omega}$ over a simply connected manifold V.[14] This construction works, of course, for the smooth based loop space.

We fix a base point $x_0\in V$. We consider the set of triple $(x,l_{(x_0,x)},\alpha)$ where $l_{(x_0,x)}$ is a path going from x_0 to x, and α is an element of S^1. We identify two triples $(x,l_{(x_0,x)},\alpha)$ and $(x',l'_{(x_0,x')},\alpha')$ if $x=x'$ and if $\alpha'=\exp[-2i\pi\int_B\tilde{\omega}]\alpha$. B is any surface bounded by the loop going from x_0 to x by l and going back from x to x_0 by l' circled in the opposite sense. Since ω is integral, the value of $\int_B \omega$ depends on the surface by an integer. Moreover, we can find such a surface because V is simply connected. The integral over the surface depends on the surface by an integer, because $\tilde{\omega}$ is Z valued.

We construct the connection from the parallel transport. Let $l(x,x')$ be a path in V. The parallel transport from x to x' of $(x, l_{(x,x_0)}, \alpha)$ is given by the following formula: we choose the path which goes from x_0 to x', first by going from x_0 to x by $l_{(x_0,x)}$ and, second, by going from x to x' by $l_{(x,x')}$, and we choose the same α. If we choose a loop which goes from x to $x l_{(x,x)}$, the holonomy over this loop is given by $\exp[-2\pi i \int_B \omega]$ where B is a surface bounded by the loop $l_{(x,x)}$.

This procedure for constructing an S^1 bundle is global and cannot be extended to the construction of line bundles over the Brownian bridge. However, the reader can find a solution of this problem in Ref. 32, and a definition of a stochastic curve in the stochastic loop space. We will overcome this problem in another way: $\tau(\omega)$ becomes a stochastic Chen form, and the integral over B of $\tau(\omega)$ leads to the study of some stochastic integrals. So we have to choose a distinguished surface which depends in a ''nice'' way on $\gamma_.$ in order to perform these stochastic integrals. The same remark remains true for a general Z-valued closed Chen form. We present a procedure which can be adapted to the Brownian bridge.

Let x_0 be a base point in V. Let O_i be a countable system of charts of V: there is a distinguished point x_i in each O_i such that the two following conditions are satisfied:

(i) If $x \in O_i$, there is a distinguished curve $l(x_i,x)$ going from x_i to x which depends smoothly on x.

(ii) There is a distinguished curve $l_{(x_0,x_i)}$ going from x_0 to x_i.

Therefore, there is by composition a distinguished curve going from x_0 to $x \in O_i l_i(x_0,x)$ which depends smoothly on x. This will give a system of charts which will allow us to construct our S^1 bundle by using a system of transition functions. Let $\alpha \in C$ over O_i. We identify by using $\rho_{j,i}\alpha$ with $\exp[-2\pi i \int_B \tilde{\omega}]\alpha$ over O_j. B is any surface bounded by the loop going from x_0 to x by $l_i(x_0,x)$ and coming back to x_0 by $l_j(x_0,x)$.

The system of $\rho_{i,j}$ defines a system of transition functions. Namely over $O_i \cap O_j$, we have

$$\rho_{i,j}\rho_{j,i} = Id, \tag{2.25}$$

and over $O_i \cap O_j \cap O_k$, we have

$$\rho_{i,j}\rho_{j,k}\rho_{k,i} = Id \tag{2.26}$$

because we integrate in this case $\tilde{\omega}$ over the sum of three surfaces:

(i) The first one is the surface bounded by the loop constituted by the path going from x_0 to x by l_i (orientation $+$) and coming back from x to x_0 by l_k (orientation $-$).

(ii) The second one is a surface bounded by the loop constituted by the path going from x_0 to x by l_k (orientation $+$) and coming back to x_0 by l_j (orientation $-$).

(iii) The third one is a surface bounded by the loop constituted of the path going from x_0 to x by l_j (orientation $+$) and coming back to x_0 by l_i (orientation $-$).

The sum of these three surfaces has no boundary, and the integral of $\tilde{\omega}$ over the sum of these three surfaces is an integer.

In the global construction given above, the parallel transport is given by the distinguished path $l_i(x_0,x)$ going from x_0 to x and after running from x to x' by $l(x,x')$ with $x' \in O_j$, with the same $\alpha \in C$. But if x' belongs to O_j, we have chosen a distinguished path $l_j(x_0,x')$ joining x_0 to x'. So the parallel transport is given by $\exp[-2i\pi \int_B \tilde{\omega}]$ where B is a surface bounded by $l_i(x_0,x)$,

$l(x,x')$, and $l_j(x_0,x')$ circled in the opposite sense: this means that $(l_i(x_0,x),\alpha)$ is transformed into $(l_j(x_0,x'),\exp[-2i\pi\int_B\tilde{\omega}]\alpha)$. We obtain that the connection form over O_i is given modulo the normalizing constant $2\pi i$ by

$$A_i(x)=\int_0^1\tilde{\omega}\left(l'_{i,t}(x_0,x),\ \frac{\partial}{\partial x}\ l_{i,t}(x_0,x)\right), \tag{2.27}$$

where $l'_{i,t}(x_0,x)$ is the speed of $l_i(x_0,x)$ and $\partial/\partial x$ the directional derivative in the chart O_i of $l_{i,t}(x_0,x)$. Here A_i is the restriction by the map $x\rightarrow l_i(x_0,x)$ of a Chen form. Therefore $dA_i=\tilde{\omega}$.[30]

Let us consider the Brownian bridge endowed with a closed Chen form $\tilde{\omega}$ of degree 2. We suppose that this Chen form restricted to the finite energy loop space is Z valued. Equivalently, we consider a form whose restriction to smooth loop is Z valued: namely, any surface without boundary can be approximated by a surface without boundary over the smooth loop space. In order to see this, we imbed the manifold into R^d, we regularize our loops by convolution, and, if the radius of the convolution is small, we can project the regularized loops into the manifold. By this procedure we get a surface without boundary over the smooth loop space. The surface which is obtained is an approximation of the original surface over the finite energy loop space. There is no boundary in all the surfaces which are considered. The integral of the Chen form over the approximated surface is an integer; by continuity, the integral over the surface in the finite energy loop space is still an integer, because the surface over the smooth loop space is an approximation of the original surface not only for the uniform distance, but also for the energy distance, which can be obtained by imbedding the manifold into a flat space.

We will postpone the problem of the locality of the following constructions later. We will now produce a system of charts O_i of LM: let γ_i be a countable system of finite energy paths such that the balls of radius δ for the uniform norm determines an open cover of LM. We can suppose that δ is small. The loop γ_i constitutes a distinguished point in $O_i=B(\gamma_i,\delta)$. (It is in fact the center of this ball.) Here $l(\gamma_i,\gamma)$ is constructed as follows: since δ is small, $\gamma_{i,s}$ and γ_s are joined by a unique geodesic. $l_t(\gamma_i,\gamma)$ is the loop $s\rightarrow\exp_{\gamma_{i,s}}[t(\gamma_s-\gamma_{i,s})]$ where $\gamma_s-\gamma_{i,s}$ is the vector of the unique geodesic joining $\gamma_{i,s}$ to γ_s. This allows us to define over O_i a distinguished path joining $\gamma_.$ to the center γ_i. We take a distinguished path joining γ_{base} to γ_i. We get a distinguished path going from γ_{base} to $\gamma_.$, $l_i(\gamma_{\text{base}},\gamma_.)$: we glue together the two previous pieces of paths.

The second step is to specify a distinguished surface bounded by $l_i(\gamma_{\text{base}},\gamma_.)$ and $l_j(\gamma_{\text{base}},\gamma_.)$, when $\gamma\in O_i\cap O_j$.

Since $O_i\cap O_j$ is not empty, and since δ is small, there is a path $u\rightarrow\exp_{\gamma_{i,.}}[u(\gamma_{j,.}-\gamma_{i,.})]$ joining γ_i to γ_j. Because $L_{\text{fin}}M$ is supposed simply connected, we can fill in by a surface the deterministic triangle constituted by the path joining γ_{based} to γ_i, the path joining γ_i to γ_j, and the path joining γ_j to γ_{based}. We can, moreover, fill in the small stochastic triangle constituted by $l_t(\gamma_i,\gamma)$, $l_t(\gamma_j,\gamma_.)$, and the path $\exp_{\gamma_{i,.}}u(\gamma_{j,.}-\gamma_{i,.})$ by the surface defined as follows: we join $l_t(\gamma_i,\gamma_.)$ to $l_t(\gamma_j,\gamma)$ by the curve $l_{t,u,i,j}(\gamma_.):s\rightarrow\exp_{l_t(\gamma_i,\gamma)_s}u(l_t(\gamma_j,\gamma)_s-l_t(\gamma_i,\gamma)_s)$. We produce in this way a small random surface bounded by the triangle whose the vertices are $\gamma_{i,.}$., $\gamma_.$, and $\gamma_{j,.}$. We glue together these two surfaces, and we get a surface bounded by $l_i(\gamma_{\text{base}},\gamma_.)$ and $l_j(\gamma_{\text{base}},\gamma_.)$. Let $l_{u,v}(\gamma)$ be this surface called $B_{i,j}(\gamma_.)$. We have to specify a little bit what we mean by a surface. It is a sum of smooth maps from the oriented simplex in R^2 into the continuous loop space. (See Ref. 32 for a complete theory of such stochastic surfaces.) In our case, we consider the sum of a small stochastic simplex and a deterministic simplex: (u,v) describes a square.

This surface $B_{i,j}(\gamma)$ is useful in so far as we can integrate the Chen form $\tilde{\omega}$ over it by means of the theory of stochastic integrals. Namely, $l_{u,v}(\gamma)_s$ is a semi-martingale, and $(\partial/\partial u)l_{u,v}(\gamma_.)$ is a semi-martingale over the semi-martingale $l_{u,v}(\gamma_.)$. $(\partial/\partial v)l_{u,v}(\gamma_.)$ too, is, a semi-martingale over $l_{u,v}(\gamma_.)$. We recall what is a semi-martingale over a semi-martingale $X_.$ with values in a manifold: the stochastic parallel transport τ_s along a curve with respect to the Levi-Civita connection is almost surely defined. The process Y_s is a semi-martingale if $\tau_s^{-1}Y_s$ is a semi-martingale with value in the tangent space of the starting point of $X_.$, which is supposed deterministic. We can specify what is the sense of the second term, because $(\partial/\partial u)l_{u,v}(\gamma)(s)$ is a vector over $l_{u,v}(\gamma)(s)$. We parallel transport $(\partial/\partial u)l_{u,v}(\gamma)(s)$ over the path $l_{u,v}(\gamma)(s)$ circled in the opposite sense by using the time in the reversed sense. We get a semi-martingale over the tangent space of x. Therefore the integral of $\tilde{\omega}$ over $B_{i,j}(\gamma_.)$ appears as a nonanticipative Stratonovitch integral, which is smooth in $\gamma_.$. In order to be more precise, it is $\tilde{\omega}((\partial/\partial u)l_{u,v}(\gamma_.),(\partial/\partial v)l_{u,v}(\gamma_.))$, which is a stochastic Stratonovitch integral, when $l_{u,v}$ belongs to the small stochastic triangle constituting one of the two parts of $B_{i,j}(\gamma_.)$. Let us specify a little bit what it means:

$$\tilde{\omega}\left(\frac{\partial}{\partial u}\, l_{u,v}(\gamma_.),\, \frac{\partial}{\partial v}\, l_{u,v}(\gamma_.)\right)=\int_0^1 \omega\left(d_s l_{u,v}(\gamma_.),\, \frac{\partial}{\partial u}\, l_{u,v}(\gamma_.)_s\,,\, \frac{\partial}{\partial v}\, l_{u,v}(\gamma_.)_s\right). \tag{2.28}$$

Moreover, it belongs to all the Sobolev spaces. Therefore, we can consider the system of transition functions $\rho_{i,j}(\gamma_.)=\exp[-2\pi\sqrt{-1}\int_{B_{i,j}(\gamma_.)}\tilde{\omega}]$. The transition functions belong to all the Sobolev spaces.[18] Let us recall briefly what these Sobolev spaces are: let $X_s=\tau_s H_s$, H_s deterministic, be a vector field over γ. We get the integration by parts formula:

$$E[\langle dF,X\rangle]=E[F \text{ div } X] \tag{2.29}$$

true for any cylindrical functional F. We put

$$\langle dF,X\rangle=\int_0^1 \langle k_s\,,d/dsH_s\rangle ds. \tag{2.30}$$

This allows us to define the notion of first-order Sobolev space, because this notion of derivative is intrinsically defined by using (2.29):

$$\|F\|_{W_{1,p}}=E[|F|^p]^{1/p}+E\left[\left(\int_0^1 |k_s|^2 ds\right)^{p/2}\right]^{1/p}. \tag{2.31}$$

We can iterate the notion of gradient. Namely, we introduce a connection $\nabla X_.=\tau_. DH_.$, where D is the traditional H-derivative. Let us suppose that $d_\nabla^r F$ is defined inductively. We define $d_\nabla^{r+1}F$ by

$$d_\nabla^{r+1}F(X_1,\ldots,X_{r+1})=\langle d(d_\nabla^r F(X_1,..,X_r),X_{r+1}\rangle-\sum\, d_\nabla^r F(X_1,..,\nabla_{X_{r+1}}X_i\,,..,X_r). \tag{2.32}$$

Here d_∇^r is a Hilbert–Schmidt cotensor: it is given by kernels. Let us denote it by $k^r(s_1,\ldots,s_r)$. We put

$$\|F\|_{W_{r,p}}=E[|F|p]^{1/p}+\sum_{j\leqslant r}\, E\left[\left(\int\int\, |k^j(s_1,\ldots,s_j)|^2 ds_1\cdots ds_j\right)^{1/2}\right]^{1/p}. \tag{2.33}$$

The main theorem (see Ref. 18, theorems 3.6 and 3.7 for the free loop space) is that stochastic integrals belong to all the Sobolev spaces as well as the solution of stochastic differential equations.

By using the positivity theorem of Ref. 22 or 23, we deduce that the $\rho_{i,j}$ are transition functions, in the sense that they satisfy (2.25) and (2.26) almost surely. Moreover, the $\rho_{i,j}$ are smooth functions, in the sense that they belong to all the Sobolev spaces.

The previous discussion is not completely true, because these considerations work only locally. As a first step, we regularize the indicator function of O_i. Let g be a function from $[0,\delta]$ into $[1,\infty]$, which is infinite if z is larger than $\delta-\alpha/2$, which is smooth over $[0,\delta-\alpha/2[$, and which behaves as $1/(z-\delta+\alpha/2)^{+n}$ when $z \to (\delta-\alpha/2)_-$. Moreover, $z \leqslant \delta-\alpha$ is equivalent to $g(z)=1$. Let F be an auxiliary function from $[1,\infty]$ into $[0,1]$, which is equal to 1 only in 1 and with compact support. Let G_i be the functional:

$$G_i(\gamma_.)=F\left(\int_0^1 g(d(\gamma_s,\gamma_{i,s}))ds\right). \tag{2.34}$$

The functional $G_i(\gamma_.)$ is equal to 1 if and only if $d(\gamma,\gamma_i) \leqslant \delta-\alpha$ and if $G_i(\gamma_.)>0$, $d(\gamma,\gamma_i)<\delta$.

Moreover, G_i is smooth (it belongs to all the Sobolev spaces), if n is big enough. Namely, by the exponential inequality, we have

$$P\left\{\text{Sup}\,\frac{1}{(d(\gamma_s,\gamma_{i,s})-\delta+\alpha/2)^+}>1/\epsilon;\int\frac{1}{(d(\gamma_s,\gamma_{i,s})-\delta+\alpha/2)}+<C\right\}<C(p)\epsilon^p. \tag{2.35}$$

Moreover, we can find a sequence α_i, g_i, F_i such that the sequence of the corresponding $G_i(\gamma)$ tends simply to the indicator function of O_i. The reader can see Ref. 8, p. 106, and Ref. 6, Eqs. (2.12)–(2.14), for analogous considerations.

We imbed the manifold in R^d. We can extend $(x,y) \to \exp_x[u(y-x)]$ if x and y are close to a smooth map from $R^d \times R^d$ into R^d which depends smoothly on u. This allows us to extend to the whole loop space $L(M)$ the distinguished path which was defined only over O_i, and to extend to $L(M)$ the distinguished stochastic surface $B_{i,j}(\gamma_.)$. The price to pay is that $l_{i,t}(\gamma_.)$ is a process which belongs to R^d and not to M. We can extend the forms constituting the Chen form over R^d. This gives an extension of the Chen form to the semi-martingale $l_{i,t}(\gamma_.)$ and to the semi-martingale $l_{u,v}$ over the extended surface of $B_{i,j}(\gamma_.)$. This works when $\gamma_.$ describes the whole loop space and not only O_i or $O_i \cap O_j$. This allows us to produce stochastic integrals, whose restriction over $O_i \cap O_j$ is equal to the stochastic integrals which appear in the definition of $\rho_{i,j}$. These stochastic integrals are smooth over LM.

This allows us to give the following definition:

Definition II.1: A measurable section ϕ of the line bundle associated to the Chen form $\tilde{\omega}$ is a collection of random variables α_i over O_i with value in C submitted to the rule

$$\alpha_j=\alpha_i\rho_{i,j} \tag{2.36}$$

almost surely over $O_i \cap O_j$.

Over O_i, we put the metric

$$\|\alpha(\gamma_.)\|^2=\|\alpha\|^2 \tag{2.37}$$

Since the transition functions are of modulus one, this metric is intrinsically defined.

We can give the definition:

Definition II.2: The L^p space of sections of the line bundle associated to $\tilde{\omega}$ is the space of measurable sections ϕ endowed with the norm:

$$\|\phi\|_{L^p}=\|\|\phi\|\|_{L^p}. \tag{2.38}$$

Unfortunately the random measurable sections of the line bundle do not give a lot of information about the structure of the line bundle. For this purpose, we need to study C^1 sections. We will introduce a connection.

Over O_i, the connection form is given by

$$A_i(\gamma)=\int_0^1 \tilde{\omega}_{l_{i,t}(\gamma_{\text{base}},\gamma_.)}\left(l'_{i,t}(\gamma_{\text{base}},\gamma_.),\,\frac{\partial}{\partial\gamma_.}\,l_{i,t}(\gamma_{\text{base}},\gamma_.)\right)dt. \tag{2.39}$$

We have to specify what the meaning of this expression is. $l'_{i,t}(\gamma_{\mathrm{base}},\gamma_.)$ is a semi-martingale in the tangent bundle of M over $l_{i,t}(\gamma_{\mathrm{base}},\gamma_.)$. The quantity $(\partial/\partial\gamma_.)l_{i,t}(\gamma_{\mathrm{base}},\gamma_.)$ too, is a semi-martingale over $l_{i,t}(\gamma_{\mathrm{base}},\gamma_.)$ if we describe what it is. Let us recall namely that in infinite-dimensional analysis, the tangent space is smaller than the natural tangent space of the functional space which is studied.[15] In $(\partial/\partial\gamma)l_{i,t}(\gamma_{\mathrm{base}},\gamma_.)$, we have to take the derivative of $l_{i,t}(\gamma(\mathrm{base}),\gamma)(s)$ over the tangent vector $\tau_t(\gamma_.)H_t$ ($H_0=H_1=0$, H_t of finite energy). This leads to the study of some stochastic integrals whose the structure is very similar to stochastic Chen forms.[17] Namely,

$$\frac{\partial}{\partial\gamma_.}\exp_{\gamma_{i,s}}[t(\gamma_s-\gamma_{i,s})]\tau_sH_s=\tau_s(l_{i,t}(\gamma_{\mathrm{base}},\gamma_.)A_sH_s\,, \tag{2.40}$$

where A_s is a nonanticipative process of matrices. Moreover the Ito–Stratonovitch formula of Ref. 33 shows that

$$d\ \exp_{\gamma_{i,s}}[t(gg_s-\gamma_{i,s})]=\frac{\partial}{\partial\gamma_s}\exp_{\gamma_{i,s}}[t(\gamma_s-\gamma_{i,s})]d\gamma_s+\text{finite energy}. \tag{2.41}$$

These finite energy terms are nonanticipative processes. This shows that the stochastic integral part of $A_i(\gamma)$ is

$$\tilde{A}_i(\gamma)(H)=\int_0^1\langle B_s\tau_s^{-1}d\gamma_s\,,H_s\rangle, \tag{2.42}$$

where B_s is a nonanticipative semi-martingale. Of course these manipulations are true only over O_i, but they can be extended smoothly over LM as it was done for $\rho_{i,j}$. We extend $l_{i,t}$ to the whole $L(M)$, and we extend $\tilde{\omega}$ to the new set of paths by extending the forms over M which define $\tilde{\omega}$.

For a finite energy loop, the connection forms A_i are compatible with the transition functions $\rho_{i,j}$. We deduce from the positivity theorem of Refs. 22 and 23 that this remains true in the stochastic case. This theorem tells namely that a formula which is given in terms of stochastic integrals and of the parallel transport of the Brownian bridge is true almost surely if the underlying formula which is given for the smooth loop space is true surely. Let γ^n be the polygonal approximation of $\gamma_.$. Here $\rho_{i,j}(\gamma^n)$ is surely defined and checks surely (2.25) and (2.26). Moreover, by the rules of the approximation of Stratonovitch integrals by traditional integrals, $\rho_{i,j}(\gamma^n_.)$ tends almost surely to $\rho_{i,j}(\gamma_.)$, when the length of the subdivision tends to the infinity.[33] This says that the formal bundle over $L(M)$ extends the bundle over the finite energy loop space which is deduced from $\tilde{\omega}$.

For finite energy paths, the connection preserves the metric, because the parallel transport preserves the metric. Let $\alpha(\gamma_.)$ be a scalar which depends only on a finite number of coordinates. It is a cylindrical functional. Let $G_i(\gamma_.)\alpha=\phi_i(\gamma_.)$ be the corresponding section of the line bundle which is equal to 0 outside O_i. Let us consider another section of the same structure. Since the connection preserves the metric

$$\nabla_X\langle\phi,\phi'\rangle=\langle\nabla_X\phi,\phi'\rangle+\langle\phi,\nabla_X\phi'\rangle \tag{2.43}$$

for any vector field X.

Let us suppose that the vector field X has a divergence (see Refs. 16, 5, and 19). This means that

$$E[\langle dF,X\rangle]=E[F\ \mathrm{div}\ X] \tag{2.44}$$

for all cylindrical functionals. We conclude that

$$\nabla_X^* = -\nabla_X + \operatorname{div} X. \tag{2.45}$$

If H_t is deterministic, X_t has a divergence (see Refs. 16 and 5), which is in all the L^p.

For any sum ϕ of sections ϕ_i of the previous structure, $\nabla_. \phi$ is a tensor in the tangent space in $\gamma_.$ with value in the fiber. We take its Hilbert–Schmidt norm $\|\nabla\phi\|_\gamma$. The $W_{p,1}(\tilde{\omega})$ norm of this special type of section is

$$\|\phi\|_{W_{p,1}(\tilde{\omega})} = \|\|\phi\|\|_{L^p} + \|\|\nabla_.\phi\|\|_{L^p}. \tag{2.46}$$

Since we have integration by parts formulas, the operation of covariant derivative is closable and allows us to obtain the following.

Definition II.3: The Sobolev space $W_{p,1}(\tilde{\omega})$ of a section of the formal line bundle associated to $\tilde{\omega}$ is the completion of finite combination $\Sigma\phi_i$ of local sections over O_i for the norm (2.45).

The space of C^1 sections is the intersection of the Sobolev spaces $W_{p,1}(\tilde{\omega})$. Let us recall that there is the Sobolev space $W_{p,1}$ of functionals which belong to L^p such that dF belongs in L^p. We have, obviously, the following.

Proposition II.4: The space of C^1 sections $\cap W_{p,1}(\tilde{\omega})$ is a module over $\cap W_{p,1}$.

Moreover, if F belongs to all the $W_{p,1}$, if ϕ is a C^1 section, and if X is a vector field,

$$\nabla_X(F\phi) = \langle dF, X\rangle\phi + F\nabla_X\phi. \tag{2.47}$$

Remark: Over O_i, the connection form has an exterior derivative. Namely, it is given by nonanticipative stochastic integrals and the paths $l_{i,t}(\gamma_.)$ depend smoothly on $\gamma_.$. We can apply indeed to A_i the procedure of Ref. 20 in order to define a stochastic exterior derivative, although the Lie bracket of two vector fields is not a vector field. Over the finite energy loop space,

$$dA_i = \tilde{\omega} \tag{2.48}$$

by construction. As a matter of fact, A_i is a Chen form over a set of paths over $L(M)$. The connection form A_i is a Chen form over the set of distinguished paths over $L(M)$ constructed from the form $\tilde{\omega}$ over $L(M)$. Therefore,

$$dA_i(\gamma) = \tilde{\omega}(l_{i,1}l(\gamma_{\text{base}},\gamma_.))\left(\frac{\partial}{\partial\gamma}\, l_{i,1}(\gamma_{\text{base}},\gamma_.),\ \frac{\partial}{\partial\gamma}\, l_{i,1}(\gamma_{\text{base}},\gamma_.)\right) = \tilde{\omega} \tag{2.49}$$

by the rules over the exterior derivatives of a Chen form, which are still true in infinite dimension. It remains true over the continuous loop space almost surely, by the positivity theorems of Refs. 22 and 23. The curvature of the formal line bundle is $\tilde{\omega}$. This notion of curvature has, however, only a formal meaning, because $[X,Y]$ is not a vector field.

Remark: If we suppose that the loops γ_i are smooth, which is possible, we can apply the theory of Ref. 20 to the form $A_i(\gamma)$. Namely, we imbed M into R^d and we extend ω into ω_{ext}. It is possible to extend $l_{i,t}(\gamma_.)_s$ into a function $f_t(s,\gamma_s)$ where f is a smooth application from R^d into R^d, smooth in s and piecewise smooth in t.

Here $A_i(\gamma)$ is the restriction to $B(\gamma_i;\delta)$ of the global form $\tilde{A}_i(\gamma)$ given by the following formula:

$$\tilde{A}_i(\gamma) = \int_0^1\int_0^1 \omega_{\text{ext}}(f_t(s,\gamma_s))\left(d_s f_t(s,\gamma_s),\ \frac{\partial}{\partial t}\, f_t(s,\gamma_s),\ \frac{\partial}{\partial\gamma_.}\, f_t(s,\gamma_s)\right). \tag{2.50}$$

Let us recall what is a form which belongs to all the Nualart–Pardoux spaces over the loop space (see Ref. 20). Let σ be a form of degree n over the Brownian bridge:

$$\sigma(\tau_. H^1_.,\ldots,\tau_. H^n) = \int_0^1\cdots\int_0^1 k(s_1,\ldots,s_n)H'^1_{s_1}\cdots H'^n_{s_n}\, ds_1\cdots ds_n, \tag{2.51}$$

where $k(s_1,\ldots,s_n)$ is a random variable in $T^{\otimes n}_{\gamma_0}$ (We do not specify the conditions of antisymmetry which naturally appear.) Since we have a connection over the Brownian bridge [see a little bit before (2.32) the definition of this connection], we can define the iterate covariant derivative of the form σ for this connection; let us denote them by $\nabla^r\sigma$. It is given by kernels $k(s_1,\ldots,s_n;t_1,\ldots,t_r)$. The Nualart–Pardoux Sobolev norms $N.P_{p,k}(LM)$ of the n-form σ are given by the two smallest constants $C(p;k)$ and $C'(p;k)$ such that

$$\|k(s_1,\ldots,s_n;t_1,\ldots,t_k)-k(s'_1,\ldots,s'_n;t'_1,\ldots,t'_k)\|_{L^p}\leqslant C(p;k)\left(\sum \sqrt{|s_i-s'_i|}+\sum \sqrt{|t_j-t'_j|}\right) \tag{2.52}$$

if $s_1,\ldots,s_n,t_1,\ldots,t_r$ and $s'_1,\ldots,s'_n,t'_1,\ldots t'_r$ belong to the same connected component of $[0,1]^{n+k}$. where we have removed the diagonal and such that

$$\|k(s_1,\ldots,s_n;t_1,\ldots t_k)\|_{L^p}\leqslant C'(p;k) \tag{2.53}$$

for all $s_1,\ldots,s_n,t_1,\ldots t_k$. By definition, the space of forms which belong to all the Nualart–Pardoux Sobolev spaces $N.P_{k,p}(LM)$ is the space of forms which are smooth in the Nualart–Pardoux sense, denoted by $N.P_{\infty-}(LM)$, endowed with its natural topology. The exterior derivative is continuous from $N.P_{\infty-}(LM)$ into $N.P_{\infty-}(LM)$ (see Ref. 20).

Since $s\to f_t(s,.)$ is smooth, $\tilde{A}_i(\gamma)$ is a form of degree 1 which is smooth in the Nualart–Pardoux sense. We can therefore define its exterior derivative, and define by restriction the exterior derivative of $A_i(\gamma)$.

Remark: We can specify now what is a finite-dimensional bundle over $L(M)$. Let G be a compact Lie group and let R be a representation of it over C^d or over R^d. Let O_i be a countable family of open set which constitutes a cover of $L(M)$ and let $\rho_{i,j}(\gamma)$ be a set of transition functions with values in G. In other words, we suppose that over $O_i\cap O_j$

$$\rho_{i,j}\rho_{j,i}=1 \tag{2.54}$$

almost surely, and that over $O_i\cap O_j\cap O_k$

$$\rho_{i,j}\rho_{j,k}\rho_{k,i}=1 \tag{2.55}$$

almost surely. We can define the set of measurable sections of the associated to the representation R as in the Definition I.1. But we can go one step further. We imbed G into $\mathrm{SO}(N)$. For all smooth functionals F with support in $O_i\cap O_j$, we suppose that $\gamma\to F\rho_{i,j}$ belongs to all the Sobolev spaces. We would like to say that the transition functions are in some sense continuous. For that, we define the capacity of an open set:

$$Cap_{r,p}(O)=\mathrm{Inf}\{\|F\|_{W_{r,p}},F\geqslant 1_O \text{ almost surely}\}. \tag{2.56}$$

The capacity of a Borelian subset A of $L(M)$ is the infimum of the capacities of the open subset which contain A. A slim set is a set, all of whose capacities equal 0.[34] For instance, a point is a slim set, unlike the finite-dimensional case. A functional which belongs to all the Sobolev spaces should have a redefinition which is continuous outside a slim set (see Ref. 34, Chap. IV.2). This shows us that the transition functionals $\rho_{i,j}$ should have a redefinition continuous outside a slim set and (2.54) and (2.55) should be checked outside a slim set for this redefinition. In others words, we should be able to define the topological space of the principal bundle over $L(M)$ outside a set of capacity 0. We should be able to define the linear bundle associated to the representation R outside a slim set. Under this point of view, the open set O_i should be defined modulo a slim set and they should constitute a cover modulo a slim set. We do not give more details about this point of view, because we are ultimately interested in infinite-dimensional operators, which operate about a space of sections.

Remark: The system of sections of the line bundle depends apparently on the systems of curve $\gamma_{i,.}$ chosen. Let us consider another countable system of finite energy loops γ_i' such that the balls of radius δ' for δ' small enough and of center γ_i' constitute an open cover of $L(M)$ for the uniform distance. The set of $B(\gamma_j', \delta') \cap B(\gamma_i, \delta)$ constitutes still an open cover of $L(M)$. Let us call this open cover by O_i. There exists two distinguished curves going from γ_{base} to γ: the first one, $l_i(\gamma_{\text{base}}, \gamma)$, is constructed as before and is passing by γ_i. The second one, $l'(\gamma_{\text{base}}, \gamma)$, is passing by γ_i'. There exists two distinguished surfaces $B_{i,j}(\gamma)$ and $B_{i,j}'(\gamma)$ constructed as before over $O_i \cap O_j$, by choosing the system of γ_i or the system of γ_i'. Let us denote

$$\rho_{i,j}(\gamma) = \exp\left[-2\pi\sqrt{-1}\int_{B_{i,j}(\gamma)} \tilde{\omega}\right] \tag{2.57}$$

and

$$\rho_{i,j}'(\gamma) = \exp\left[-2\pi\sqrt{-1}\int_{B_{i,j}'(\gamma)} \tilde{\omega}\right]. \tag{2.58}$$

We choose a small stochastic surface as it was done before whose boundary is the small circle constructed from $l_i(\gamma_{\text{base}}, \gamma)$ and $l_i'(\gamma_{\text{base}}, \gamma)$ circled in the opposite sense. Let us call it $S_i(\gamma)$. We put

$$\chi_i(\gamma) = \exp\left[-2\pi\sqrt{-1}\int_{S_i(\gamma)} \tilde{\omega}\right]. \tag{2.59}$$

We get, since $\tilde{\omega}$ is Z valued, almost surely

$$\rho_{i,j}(\gamma) = \chi_i(\gamma)\chi_j^{-1}(\gamma)\rho_{i,j}'(\gamma). \tag{2.60}$$

Let us define the section of the line bundle by its local section α_i for $\rho_{i,j}$ and α_i' for $\rho_{i,j}'$. Let us consider the transformation:

$$\alpha_i' \to \alpha_i' \chi_i^{-1} = \alpha_i. \tag{2.61}$$

It defines an isomorphism of the measurable sections of the line bundle and of the space of L^p sections of the line bundle, since the complex number χ_i is of modulus 1. Namely the relation $\alpha_i' = \alpha_j' \rho_{j,i}'$ is equivalent to the relation $\alpha_i = \alpha_j \rho_{j,i}$ over $O_i \cap O_j$, because we have the relation (2.61).

III. STOCHASTIC STRING STRUCTURE

Let us introduce a compact, simple, simply connected Lie group G. Since G is simple, all the invariant bilinear forms on Lie G are proportional. We can find a Killing form such that

$$\omega(X,Y,Z) = \frac{1}{8\pi^2}\langle X,[Y,Z]\rangle \tag{3.1}$$

defines a G-invariant form with integral values,[1,14] since G is simple.

In all this part, we will identify a form invariant under the group action over the Lie algebra with the corresponding form over the Lie group.

Let $P_{\text{fin}}G$ be the space of the finite energy path over G starting from e. Let π be the projection from $P_{\text{fin}}G$ to G which to a path g_s associates its end point g_1. Let $L_{\text{fin}}G$ be the based loop group of loops of finite energy in G starting from e. Here π determines a $L_{\text{fin}}G$ fibration. If g_1 is in a small neighborhood $O_i(G)$ of G, we get a trivialization of this principal bundle. We introduce the local slice of $O_i(G)$ into $P_{\text{fin}}G$: $g_1 \to g_s^i(g_1)$ where the path $g_s^i(g)$ depends smoothly of g in $O_i(G)$ and joins e to g. The transition functions $\rho_{i,j}$ are equal to $(g_s^j)(g)^{-1}g_s^i(g)$ and satisfy the rule of a system of transition functions. Since G is compact, there exists ∇^G an $L_{\mathrm{fin}}G$ connection over $P_{\mathrm{fin}}G$.[35] Moreover, $L_{\mathrm{fin}}G$ is a Hilbertian Lie group. Its Lie algebra is the space of finite energy loops L_{fin} Lie G going from 0 and arriving at 0 at time 1 in the Lie algebra of G. We introduce over it the energy Hilbert norm.

In the local chart given over $O_i(G)$ by the slice $g \to g^i(g)$, the connection form is a one-form A_i with values in L_{fin} Lie G. This one-form is compatible with the transition function in $O_i(G) \cap O_j(G)$.[35]

Let $X_s \in L_{\mathrm{fin}}$ Lie G. We choose a two cocycle

$$c(X,Y) = \frac{1}{8\pi^2}\left(\int_0^1 \langle X_s, dX_s\rangle - \langle Y_s, dX_s\rangle\right). \tag{3.2}$$

This gives an invariant closed form of degree 2 over $L_{\mathrm{fin}}G$. It has integral values. Namely c is equal to the transgression of ω modulo an exact form.[1] The transgression of ω is the Chen form over $L_{\mathrm{fin}}G$:

$$\int_0^1 \omega(dg_{\mathrm{fin},s}, X_s, Y_s), \tag{3.3}$$

which is closed over $L_{\mathrm{fin}}G$. Namely $X_0 = Y_0 = 0$ and $d\omega = 0$. This transgression is integral because the circle has no boundary. The reader can see the first part for analogous considerations. The integrability condition holds classically for the smooth loop space[25] and not for the finite energy loop space: we can approximate any surface without boundary in the finite energy loop space by a surface without boundary in the smooth loop space, as it was done in the first chapter. Therefore the integrability condition holds for the finite energy loop space.

The formula (3.2) gives a form over P_{fin} Lie G, the Lie algebra of $P_{\mathrm{fin}}G$. The difference is that we do not have $X_0 = X_1 = 0$. The main property of this form is the following;[11] when we consider its version over $P_{\mathrm{fin}}G$:

$$dc = \pi^*(\omega). \tag{3.4}$$

Let us remark that in the previous considerations, we have always worked with finite energy paths.

Let LM be the space of continuous based loop endowed with the Brownian bridge measure. Let us suppose that there is principal bundle P over M with structure group G. We introduce a connection over P. Let τ_s^G be the parallel transport starting from e in G over $x = \gamma_0$. (γ_s, τ_s^G) is the horizontal lift of γ_s starting from e and is almost surely defined. Q is the set of paths g_s over γ_s such that $g_s = \tau_s^G l_s$ where l_s is of finite energy and such that $g_0 = g_1 = e$. We can give a description of Q in a more algebraic way.[13]

We have a map f from LM into G which to a stochastic loop γ associates $(\tau_1^G)^{-1}$. Q is the pullback of $P_{\mathrm{fin}}G$ by f. We have the following commutative diagram:

$$\begin{array}{ccc} Q & \rightarrow & P_{\mathrm{fin}}G \\ \downarrow & & \downarrow \\ LM & \rightarrow & G \end{array} \tag{3.5}$$

The first vertical map is the projection map p. The second vertical map is the projection map π. The lower horizontal map is f and the upper horizontal map is f^*. f is an application from $L(M)$ into G which belongs to all the Sobolev spaces, because the parallel transport is a solution of a stochastic differential equation.[18]

A system of trivializations of Q is given by the pullback of a system of trivializations of $P_{\mathrm{fin}}G$. If $(\tau_1^G)^{-1} \in O_i(G)$, Q is trivialized by the slice $\gamma \to g^i((\tau_1^G)^{-1})$, and the fiber is isomorphic to $L_{\mathrm{fin}}G$. The transition functions are $g^j((\tau_1^G)^{-1})^{-1} g^i((\tau_1^G)^{-1})$ and belong to all the Sobolev spaces from LM into the Hilbertian Lie group $L_{\mathrm{fin}}G$. They are smooth in the sense that they are restrictions of smooth functions in $L_{\mathrm{fin}}R^d$, after imbedding G into R^d, and after extending $g^j_{\cdot}(g)$ over R^d. This is possible because R^d is contractible.

Over the principal bundle $Q \to LM$ with projection p, we choose the pullback connection ∇^G. If $(\tau_1^G)^{-1} \in O_i(G)$, the pullback connection form is the one-form:

$$A_i(d(\tau_1^G)^{-1}) = A_i^{f^*}. \tag{3.6}$$

We can take the derivative of τ_1^G, because τ_1^G belongs to all the Sobolev spaces.

Let us introduce the Pontryagin class of the G bundle P. Let F^G be the curvature of the G bundle P for the connection ∇ determining the horizontal lift τ_s^G over the Brownian loop. We have

$$\mathrm{Pont}(F^G) = \frac{1}{8\pi^2} \langle F^G \wedge F^G \rangle. \tag{3.7}$$

It is a closed form over M. The transgression of $\mathrm{Pont}(F^G)$ is the closed form of degree 3 over $LM \int_0^1 \mathrm{Pont}(F^G)(d\gamma_s,.)$.

It is a stochastic Chen form.[17]

We have[13] the following.

Lemma III.1: $f^{*-1}\omega$ is cohomologuous to the transgression of the Pontryagin class.

Proof: Let us consider over LM the principal bundle P_s which is the pullback by the evaluation map $\gamma_\cdot \to \gamma_s$ of the principal bundle P over M. Let ∇_s be the pullback connection of the connection ∇ by this evaluation map. Its curvature F_s^G is given by

$$F_s^G(X,Y) = F_{\gamma_s}^G(X_s, Y_s). \tag{3.8}$$

Moreover, P_s is a trivial bundle: a trivialization is given by $\tau_s^G g$ where g belongs to the fiber of P over $x = \gamma_0$. In this system of trivializations, the connection form is given by the heuristic notation:

$$(\tau_s^G)^{-1} \nabla_\cdot \tau_s^G = \hat{A}_s. \tag{3.9}$$

In order to give a rigorous meaning to this notation, let us introduce ω_1^G, the canonical connection form associated to the connection ∇ over the G bundle P. U_s is the derivative of the couple (γ_s, τ_s^G) in P over the vector field $X_\cdot$. We transform $\gamma_\cdot$ in $\exp_{\gamma_\cdot}(lX)$, we compute the associated lift $\tau_s^G(l)$, and we take its derivative in $l=0$. We get a vector U_s over (γ_s, τ_s^G) in P and we apply ω_1^G to U_s.

Since the curvature is intrinsically defined, and since the bundle P_s is trivial, we have the important relation:

$$d\hat{A}_s + [\hat{A}_s, \hat{A}_s] = (\tau_s^G)^{-1} F_{\gamma_s}^G(\tau_s^G), \tag{3.10}$$

where we take the exterior derivative of $\hat{A}_s$ over LM. This exterior derivative has not only a formal sense. Namely, we can use the matrix notation for the group. The computations of Refs. 36 and 16 show that

$$\hat{A}_s(X) = \int_0^s (\tau_t^G)^{-1} F_{\gamma_t}^G(d\gamma_t, X_t) \tau_t^G, \tag{3.11}$$

which takes its values in the Lie algebra of G. Moreover, $X_s = \tau_s H_s$ where τ_s is the parallel transport for the Levi-Civita connection for the tangent space. We have the obvious relations

$H_0 = H_1 = 0$ and H_s is of finite energy.[16,17] $X_.$ is a vector over $\gamma_.$. Let us recall that it is the parallel transport τ which has a key role in the definition of Sobolev calculus over loop spaces[5,18] and not τ_s^G.

Let us suppose that H and H^1 are deterministic. Since the Levi-Civita connection is without torsion, we have[16,36]

$$[X,Y]_t = (\nabla_Y \tau_t) H_t - (\nabla_X \tau_t) H_t^1, \tag{3.12}$$

if $Y_t = \tau_t H_t^1$. Moreover, we have

$$\nabla_Y \tau_t = \tau_t^{-1} \int_0^t \tau_s^{-1} R(d\gamma_s, Y_s) \tau_s. \tag{3.13}$$

Moreover, we have

$$d\hat{A}_s(X,Y) = X\hat{A}_s(Y) - Y\hat{A}_s(X) - \hat{A}_s[X,Y]. \tag{3.14}$$

From (3.12)–(3.14), we deduce that $d\hat{A}_s$ exists and is a stochastic nonanticipative integral in the way described in Ref. 17.

Let us compute now $\hat{A}_1$. We consider the based loop space, such that $X_0 = X_1 = 0$. Therefore the counterterm which appears when we consider $\omega_1^G(U_1)$ which depends linearly from x_1 and from the Christoffel symbols of the connection ∇ disappears.[18] This shows us that

$$\hat{A}_1 = (\tau_1^G)^{-1} d\tau_1^G. \tag{3.15}$$

From the formula (2.12), we deduce the analogous formula then (5.7) in Ref. 13:

$$d_s \hat{A}_s(X) = (\tau_s^G)^{-1} F_{\gamma_s}(d\gamma_s, X_s) \tau_s^G. \tag{3.16}$$

Moreover, we have

$$F^G \wedge F^G(d\gamma_s, X_s, Y_s, Z_s) = F^G(d\gamma_s, X_s) F^G(Y_s, Z_s) + \text{antisymmetry}. \tag{3.17}$$

We have

$$(F^G \wedge F^G)(d\gamma_s, .) = F^G(d\gamma_s, .) \wedge F^G + F^G \wedge F^G(d\gamma_s, .). \tag{3.18}$$

Since the Killing form is symmetric, we have

$$\langle (F^G \wedge F^G)(d\gamma_s, .) \rangle = 2 \langle F^G(d\gamma_s, .) \wedge F^G \rangle. \tag{3.19}$$

We use the fact that the Killing form is invariant under the group action. We find, after using (3.10) and (3.11),

$$8\pi^2 \int_0^1 \text{Pont}(F^G)(d\gamma_t, .) = 2\int_0^1 \langle d_t \hat{A}_t \wedge d\hat{A}_t \rangle + 2\int_0^1 \langle d_t \hat{A}_t \wedge [\hat{A}_t, \hat{A}_t] \rangle = B + C. \tag{3.20}$$

In $\int_0^1 \langle d_t d\hat{A}_t \wedge \hat{A}_t(X,Y,Z) \rangle$, there are three expressions which occur of the type $\int_0^1 \langle d_t d\hat{A}_t(X,Y,Z) \hat{A}_t(Z) \rangle$. When we sum these expressions after performing an integration by parts, we find, since $d_t d = d_t d$,

$$\int_0^1 \langle d d_t \hat{A}_t \wedge \hat{A}_t \rangle (X,Y,Z) = -\left(\int_0^1 d_t A_t \wedge dA_t \right)(X,Y,Z). \tag{3.21}$$

We have used the symmetry of the Killing form. It remains to consider the integrated term. However, we have

$$\langle \hat{A}_1(Y)\hat{A}_1(X)-\hat{A}_1(X)\hat{A}_1(Y),\hat{A}_1(Z)\rangle=-\langle \hat{A}_1(X),\hat{A}_1(Y)\hat{A}_1(Z)-\hat{A}_1(Z)\hat{A}_1(Y)\rangle$$
$$=\langle \hat{A}_1(X),\hat{A}_1(Z)\hat{A}_1(Y)-\hat{A}_1(Y)\hat{A}_1(Z)\rangle. \tag{3.22}$$

because the form $\langle . \rangle$ is invariant under the G action. This shows that, by using (3.10),

$$\int_0^1 \langle d_t d\hat{A}_t \wedge \hat{A}_t\rangle = -8\pi^2 f^*\omega - \int_0^1 \langle d_t\hat{A}_t \wedge d\hat{A}_t\rangle. \tag{3.23}$$

This shows us that

$$dc(\hat{A},\hat{A}) = -8\pi^2 f^*\omega - 2\int_0^1 \langle d_t\hat{A}\wedge d\hat{A}_t\rangle, \tag{3.24}$$

or, equivalently, we have

$$2\int_0^1 d_t\hat{A}_t\wedge d\hat{A}_t = -8\pi^2 f^*\omega - dc(\hat{A},\hat{A}). \tag{3.25}$$

Let us study now

$$\int_0^1 \langle d_t\hat{A}_t(X),\hat{A}_t(Y)\hat{A}_t(Z)-\hat{A}_t(Z)-\hat{A}_t(Z)\hat{A}_t(Y)\rangle. \tag{3.26}$$

We integrate by parts. We find

$$\langle \hat{A}_1(X),\hat{A}_1(Y)\hat{A}_1(Z)-\hat{A}_1(Z)\hat{A}_1(Y)\rangle - \int_0^1 \langle \hat{A}_t(X),d_t\hat{A}_t(Y)\hat{A}_t(Z)-\hat{A}_t(Z)d_t\hat{A}_t(Y)\rangle$$
$$-\int_0^1 \langle \hat{A}_t(X),\hat{A}_t(Y)d_t\hat{A}_t(Z)-d_t\hat{A}_t(Z)\hat{A}_t(Y)\rangle$$
$$=\langle \hat{A}_1(X),\hat{A}_1(Y)\hat{A}_1(Z)-\hat{A}_1(Z)\hat{A}_1(Y)\rangle + \int_0^1 \langle d_t\hat{A}_t(Y),\hat{A}_t(X)\hat{A}_t(Z)-\hat{A}_t(Z)\hat{A}_t(X)\rangle$$
$$-\int_0^1 \langle d_t\hat{A}_t(Z),\hat{A}_t(X)\hat{A}_t(Y)-\hat{A}_t(Y)\hat{A}_t(X)\rangle. \tag{3.27}$$

Because the form $\langle . \rangle$ is invariant under the G action, the two last integrals cancel with the two others which appear in $\int_0^1 \langle d_t\hat{A}_t,[\hat{A}_t,\hat{A}_t]\rangle(X,Y,Z)$. These two other terms are in fact $-\int_0^1 \langle d_t\hat{A}_t(Y),\hat{A}_t(X)\hat{A}_t(Z)-\hat{A}_t(Z)\hat{A}_t(X)\rangle$ and $\int_0^1 \langle d_t\hat{A}_t(Z),\hat{A}_t(X)\hat{A}_t(Y)-\hat{A}_t(Y)\hat{A}_t(X)\rangle$. Namely in the first case, we deduce (Y,X,Z) from (X,Y,Z) by one permutation and (Z,X,Y) from (X,Y,Z) by two permutations.

In order to summarize,

$$2\int_0^1 \langle d_t\hat{A}_t,[\hat{A}_t,\hat{A}_t]\rangle = 8\pi^2 2\, f^*\omega. \tag{3.28}$$

We deduce by (3.20) that

$$f^*(\omega)=\int_0^1 \text{Pont } F^G(d\gamma_t,.)+dc(\hat{A},\hat{A}). \tag{3.29}$$

This proves the lemma. ◇

Let us recall how we construct a central extension of $L_{\text{fin}}G$ from the cocycle c.[37,14]

We will make in this paper the following hypothesis:

Hypothesis H.1: $L_{\text{fin}}G$ is simply connected.

We consider the set of path starting from the unit path in $L_{\text{fin}}G$. Let l_t be such a path. We consider a product of $(l_.,\alpha)$ where $\alpha\in S^1$. We endow the set of (l,α) with the group structure:

$$(l_.,\alpha)(l',\beta)=(ll',c(l,l')\alpha\beta), \tag{3.30}$$

where $c(l,l')=\exp[2\pi i\int_B c]$. The integral of c is taken over any surface bounded by the triangle in $L_{\text{fin}}G$ with vertices $(1,1l'_1,l_1l'_1)$ and edges $(l'_t,l_tl'_1)$ and $l_tl'_t$, the last one being circled in the opposite direction. Under the hypothesis H.1, we can find such surface. We identify $(l_.,\alpha)$ and $(l'_.,\alpha')$ modulo a normal subgroup. This one is constituted of (l,α) where l is a loop in $L_{\text{fin}}G$ and $\alpha=\exp[-2\pi i\int_B c]$ where B is a surface bounded by l. c being integral valued, the integral over the surface depends only on its boundary modulo an integer. We get by this procedure a central extension $\tilde{L}_{\text{fin}}G$ of $L_{\text{fin}}G$.

If we consider the diagram (3.5) for the finite energy loop, we get a bundle Q_{fin} over $L_{\text{fin}}M$, the based loop space of loops of finite energy in M. We make the following hypothesis:

Hypothesis H.2: Q_{fin} is simply connected.

This will allow us to construct a formal S^1 bundle over Q by starting from a given closed form of degree 2 with integral values over Q_{fin}.

The last hypothesis we will give is the following:

Hypothesis H.3: Pont F^G gives a trivial cohomology class.

This will allow us to construct a closed form with integral value over Q_{fin} (see Ref. 13). Namely, if Pont F^G gives a trivial cohomology class, we have

$$\text{Pont } F^G=d\mu. \tag{3.31}$$

Over the finite energy based loop space $L_{\text{fin}}G$,

$$f^*\omega=d\int_0^1 \mu(d\gamma_s,.)+dc(\hat{A},\hat{A})=d\nu. \tag{3.32}$$

Namely, we have

$$d\int_0^1 \mu(d\gamma_s,.)=\int_0^1 d\mu(d\gamma_s,.), \tag{3.33}$$

since we work over the based loop space (We refer to Ref. 30 for the rules of derivation of Chen forms). Equation (3.32) remains true for the stochastic loop space.

We follow Ref. 13. Let us put

$$F_{Q_{\text{fin}}}=f^*c-p^*\nu. \tag{3.34}$$

Over Q_{fin}, $dF_{Q_{\text{fin}}}=0$, but $F_{Q_{\text{fin}}}$ has no integral values. The Z homology of $L_{\text{fin}}M$ is finitely generated. Since $L_{\text{fin}}G$ is simply connected, we can find a lifting of the finite numbers of cycle which generate the Z homology of $L_{\text{fin}}M$. Moreover, the Hochschild cohomology is equal to the cohomology of the based loop space.[31] We can perturb ν in (3.34) by a finite combination of Chen forms of degree 2 such that $F_{Q_{\text{fin}}}$ in (3.34) has integral values over Q_{fin}. The number of string structures is related to the number of deformations by Chen forms of $F_{Q_{\text{fin}}}$. A perturbation by a

Chen form instead of a general form as in Ref. 13 is useful in so far as we can integrate Chen forms over random surfaces as it was done in the first part. We will still call F_Q the perturbated Z-valued form.

Let us recall what Ref. 13 does in order to construct the lift $\tilde{Q}_{\text{fin}}$ of Q_{fin}: they consider the space of path PQ_{fin} starting from a based point in Q_{fin}. Over $PQ_{\text{fin}} \times S^1$ [a typical element is denoted by $(q_{.}, \alpha)$], there is an action of $PL_{\text{fin}}G \times S^1$, where $PL_{\text{fin}}G$ is the set of path in $L_{\text{fin}}G$ starting from the unit path. A typical element of this last one is denoted by $(l_{.}, \alpha)$. The action is defined as follows:

$$(q_{.}, \alpha_{.})(l_{.}, \alpha') = (ql, c(q,l)\alpha\alpha'). \tag{3.35}$$

The expression $c(q,l)$ is defined as follows:

$$c(q,l) = \exp\left[2i\pi \int F_Q\right]. \tag{3.36}$$

We omit writing the distinction between F_Q and $F_{Q_{\text{fin}}}$. The integral is taken over any surface B filling in the triangle with vertices $(q_0, q_o l_1, q_1 l_1)$ and edges $(q_0 l_t, q_t l_1)$ and $(q_t l_t)$, the edge $q_t l_t$ being circled in the opposite sense. We identify (q,α) and (q', α') if q and q' have the same point and if

$$\alpha' = c(q,q')\alpha, \tag{3.37}$$

where $c(q,q') = \exp[2\pi i \int F_Q]$. (see Refs. 14 and 37 for analogous considerations). The integral is taken over a surface B whose boundary is the loop constituted from q' circled in the positive direction and q circled in the negative direction. We use the fact that F_Q is invariant under the $L_{\text{fin}}G$ action. We construct an S^1 bundle $\tilde{Q}_{\text{fin}}$ over Q_{fin} which is an $\tilde{L}_{\text{fin}}G$ principal bundle. The bundle $\tilde{Q}_{\text{fin}}$ over Q_{fin} is an S^1 bundle with a connection whose curvature is F_Q modulo the normalizing term $2\pi i$. There is a tower of bundles: $\tilde{Q}_{\text{fin}}$ which is an S^1 bundle over Q_{fin}. Q_{fin} which is an $L_{\text{fin}}G$ bundle over $L_{\text{fin}}(M)$ and $\tilde{Q}_{\text{fin}}$ which is an $\tilde{L}_{\text{fin}}G$ bundle over $L_{\text{fin}}(M)$.

The purpose of the remaining part of this paper is to construct a formal $\tilde{L}_{\text{fin}}G$ bundle over the stochastic loop space $L(M)$ which extends in some sense the bundle $\tilde{Q}_{\text{fin}}$ over $L_{\text{fin}}(M)$. For that, we have to construct over Q the analogous parts of the distinguished curves and of the distinguished surfaces of the first part. It is the purpose of a connection to lift curves over a bundle. By introducing a suitable connection over Q, we will produce a system of transition functions with values in $\tilde{L}_{\text{fin}}G$, which satisfy almost surely (2.25) and (2.26). But these transition functions cannot be defined over a system of open sets for the uniform distance over $L(M)$, because they depend on τ_1^G which is only almost surely defined.

Let γ_i be a countable set of finite energy loops such that the union of the open balls of radius δ for the uniform norm $B(\gamma_i, \delta)$ is equal to LM. If $\gamma_{.}$ belongs to $B(\gamma_i, \delta)$, there is a curve $l_t(\gamma_i, \gamma_{.})$ joining γ_i to $\gamma_{.}$. The parallel transport $\tau_1^G(l_t(\gamma_i, \gamma_{.}))$ depends almost surely on t on this curve. Therefore, starting from an element $q(\gamma_{.})$ over $\gamma_{.}$ in Q, we use the parallel transport for the connection ∇^G and we deduce a curve $q_t(\gamma)$ over $l_t(\gamma_i, \gamma_{.})$.

Let us introduce another condition over $\gamma_{.}$. It is $(\tau_1^G)^{-1} \in O_j(G)$, a small neighborhood of G. If this condition is satisfied, we have a slice $g^j(\gamma_{.})$ of Q which depends smoothly on $\gamma_{.}$. Of course this dependance is only local. However, it is the restriction of a smooth application which takes its values in the smooth manifold $P_{\text{fin}}R^{d'}$, by imbedding M into R^d and G into $R^{d'}$. As in the first part, we can regularize the indicator function of $B(\gamma_i, \delta) \cap \{(\tau_1^G)^{-1} \in O_j(G)\}$. The indicator function of the first event is regularized as in the first part. The indicator function of the second event can be easily regularized, because it depends only on (τ_1^G). In particular, we can find a sequence of smooth functions $G_{i,j}$ with support in the event $B(\gamma_i, \delta) \cap \{(\tau_1^G)^{-1} \in O_j(G)\}$ which tends simply to the indicator function of this event and with support in this event.

Let g_k be a family of elements of $L_{\mathrm{fin}}G$ such that the set of open balls $B(g_k,\delta)$ for the uniform distance constitutes a cover of $L_{\mathrm{fin}}G$. We have a cover of Q by the set of $g^j(\gamma_.)g$ for $\gamma \in B(\gamma_i,\delta)\cap\{(\tau_1^G)^{-1}\in O_j(G)\}$ and $g\in B(g_k,\delta)$.

In order to simplify the exposure, we will call only by one parameter i this family of subsets Q_i of Q.

We will define a set of transition functions $\rho_{i,j}$ which will define a formal circle bundle $\tilde{Q}$ over Q.

This means that almost surely in $\gamma\in B(\gamma_i,\delta)\cap\{(\tau_1^G)^{-1}\in O_i\}$, for all $g\in B(g_i,\delta)$, we have almost surely the following properties:

$$\rho_{i,j}\rho_{j,i}=1 \tag{3.38}$$

over $Q_i\cap Q_j$ and over $Q_i\cap Q_j\cap Q_k$

$$\rho_{i,j}\rho_{j,k}\rho_{k,i}=1. \tag{3.39}$$

The topological space $\tilde{Q}$ is not defined, because these transition functions are only almost surely defined over the basis LM. But this system will allow us to define another system of transition functions $\rho_{i,j}$ over $O_i\cap O_j$ for a suitable cover O_i of LM. It is a cover of $L(M)$ modulo a set of measure 0 and it satisfies almost surely

$$\rho_{i,j}\in\tilde{L}_{\mathrm{fin}}G, \tag{3.40}$$

$$\rho_{i,j}\rho_{j,i}=1 \tag{3.41}$$

over $O_i\cap O_j$ and

$$\rho_{i,j}\rho_{j,k}\rho_{k,i}=1 \tag{3.42}$$

over $O_i\cap O_j\cap O_k$.

Let us suppose that this last point is satisfied. Let us suppose that there is a unitary representation Spin of $\tilde{L}_{\mathrm{fin}}G$, which is a Hilbert space (see Ref. 26 and 1). The transition functions allow to define the space of measurable sections of the bundle Spin.

Definition III.2: Let ψ_i be a system of random variables over O_i with value in Spin. This system defines a section of the formal bundle Spin over LM if over $O_i\cap O_j$:

$$\psi_j=\rho_{j,i}\psi_i. \tag{3.43}$$

If ψ_i is an element of Spin over O_i, we will define its norm $\|\psi_i\|^2$, which is compatible with the transition functions. Namely the representation of $\tilde{L}_{\mathrm{fin}}G$ over Spin is supposed unitary.

Definition III.3: The space of L^p sections of Spin is the space of measurable sections ψ such that

$$\|\|\psi\|\|_{L^p}<\infty. \tag{3.44}$$

Let $(\gamma_.,g^i(\gamma_.)g)$ be in Q_i. There is a distinguished path joining g to g_j, the center of the ball for the uniform distance in $L_{\mathrm{fin}}G$ which constitutes the vertical part of Q_i. After this, there is a distinguished path joining $\gamma_.$ to γ_i, the center of the ball in the basis LM which constitutes the basical part of Q_i. We parallel transport by $\nabla^G g^i(\gamma_.)g_i$ to $\tilde{g}^i(\gamma_.)g_i$, which is over γ_i. The element $\tilde{g}^i(\gamma_.)g_i$ depends smoothly on $\gamma_.$. The main problem is that $\tilde{g}^i(\gamma_.)g_i$ is not $g^i(\gamma_i)g_i$. In order to be able to choose a nice distinguished curve joining these two elements over γ_i, we have to impose another condition over Q_i. The element $\tilde{g}^i(\gamma_.)g_i$ in the fiber of γ_i remains in a small tubular neighborhood of $P_{\mathrm{fin}}G$. This can be done if we assume, for instance, that the process of the holonomy τ_1^G over the distinguished path joining γ to γ_i remains in a small tubular neighborhood of $P_{\mathrm{fin}}G$. We use the fact that Q is simply connected. There is a distinguished path $l_{i,Q}(q)$ joining

q in Q_i to q_{base} in Q, a reference element of Q. When we have arrived at $g^i(\gamma_i)g_i$, we go by a deterministic path to q_{base}, a reference element in Q. This path depends smoothly on q. In the fiber direction, it depends smoothly on q in the traditional sense. In the basis direction, it depends smoothly on q in the generalized sense of Ref. 5 or 18.

Let us choose a distinguished surface bounded by the loop constituted of $l_{i,Q}(q)$ and of $l_{j,Q}(q)$ if $q \in Q_i \cap Q_j$. We should be able to integrate F_Q over this distinguished surface by using the theory of stochastic integrals.

Let us recall some results of the first part. There is a distinguished path joining $p(l_{i,Q,t}(q))$ to $p(l_{j,Q,t}(q))$ for t smaller than the time which is used in order to join $\tilde{g}^i(\gamma_\cdot)(g_i)$ to $g^i(\gamma_i)(g_i)$. We parallel transport $l_{i,Q,t}(q)$ over this distinguished path, and we find at the end over $p(l_{j,Q,t}(q))$ a curve $\tilde{l}_{j,Q,t}(q)$. Moreover, there is a deterministic path joining $(\gamma_i, g^i(\gamma_i)(g_i))$ to $(\gamma_j, g^j(\gamma_j) \times (g_j))$. Namely, Q_{fin} is supposed simply connected. Therefore, we get a surface whose boundary differs of the $l_{j,Q,t}(q)$ and the path joining $(\gamma_i, g^i(\gamma_i)g_i)$ and $(\gamma_j, g^j(\gamma_j)g_j)$ by a loop in $L_{\text{fin}}G$. We take any vertical surface $l_{u,v}(\gamma_\cdot)$ in $L_{\text{fin}}(G)$ bounded by this loop. We get a surface $B_{i,j}(q)$ in Q bounded by the loop constituted of $l_{i,Q,t}(q)$ and of $l_{j,Q,t}(q)$. Namely we can fill in the triangle constituted of the path joining q_{base} to γ_i, $g^i(\gamma_i)g_i$, the path joining $(\gamma_i, g^i(\gamma_i)(g_i))$ to $(\gamma_j, g^j(\gamma_j)g_j)$ by a surface, because Q_{fin} is simply connected.

In the integral of F_Q over $B_{i,j}(q)$, there are two parts:

(i) The part involved with integral in the basis. Since $c(\hat{A},\hat{A})$ is a stochastic integral, and since we have perturbed ν by a Chen form, this contribution can be treated as in the first part.

(ii) The part which is involved with the fiber integration, which is a traditional integration, does not involve any stochastic integration. In particular, we can take $l_{u,v}(\gamma_\cdot)$ arbitrary: since F_Q is integral, it does not change the value of the transition function.

Since we can take $l_{u,v}(\gamma)$ arbitrary, this shows us that $(\gamma,g) \to \rho_{i,j}$ is smooth in $(\gamma_\cdot, g)$. The transition function $\rho_{i,j}$ has a similar shape as in the first part. As a matter of fact, we are working over Q instead of over $L(M)$. The derivative in g is in the normal sense for the Hilbert manifold $L_{\text{fin}}G$, and the derivative in γ is in the general sense of Ref. 18. In particular, for almost all $\gamma_\cdot$, $g \to \rho_{i,j}(\gamma,g)$ is smooth. We localize the smoothness assumption by using a regularized version of the indicator function of Q_i. It is a regularization in the Sobolev sense in $\gamma_\cdot$, and a regularization in the normal sense in $g \in L_{\text{fin}}(G)$. In order to do this operation, we have chosen the slice $\gamma \to g^i(\gamma_\cdot)$. The regularization of a tubular neighborhood of $P_{\text{fin}}G$ is performed as in the first part. It is not clear that we get a smooth function when we compose with $\tilde{g}^i(\gamma_\cdot)$, but it has a derivative in the generalized sense which is locally integrable.

In particular, if $(\gamma, g^i(\gamma_\cdot)) \in Q_i$, and if we consider a polygonal approximation $\gamma^n_\cdot$ of $\gamma_\cdot$, $(\gamma^n, g^i(\gamma^n)g) \in Q_i$ for n big enough. We get a transition function $\rho_{i,j}(\gamma^n, g)$ which tends to $\rho_{i,j}(\gamma_\cdot, g)$ (see Ref. 31) almost surely.

But over finite energy path, we have (3.38) and (3.39) surely, if we do the same procedure to construct the transition functions. In particular, it is true for $\rho_{i,j}(\gamma^n)$. We deduce that (3.38) and (3.39) are almost surely true when we consider a fixed g. But $\rho_{i,j}$ depends in a smooth way of g in the fiber. The topological space $L_{\text{fin}}G$ has a countable dense set of elements. We deduce that (3.38) and (3.39) are almost surely true in the following sense: it is almost surely in $\gamma_\cdot$ over $p(Q_i) \cap p(Q_j)$, for all $q \in p^{-1}(\gamma)$ in $Q_i \cap Q_j$, that we have (3.38). There is the same statement for (3.39).

Let us now state (3.40)–(3.42). We are working over $\tilde{Q}_{\text{fin}}$. Since there is an action of $\tilde{L}_{\text{fin}}G$ which preserves the projection $\tilde{p}$, it is enough to find local slices of $\tilde{Q}_{\text{fin}}$ over $L_{\text{fin}}M$.

It is possible to find such slices for the continuous loop space.

The chart $O_i \subset LM$ is defined by the three following conditions:

(i) $\gamma_\cdot$ is closed of a given energy curve γ_i.

(ii) $(\tau_1^G)^{-1}(\gamma)$ is in a small neighborhood of G.

(iii) The parallel transport for ∇^G of $g^i(\gamma_\cdot)$ over the distinguished curve given in the first part which joins $\gamma_\cdot$ to γ_i is in a small tubular neighborhood of $L_{\text{fin}}G$ for the uniform distance.

Over O_i, we can find a formal slice $\tilde{q}_i(\gamma_\cdot)$ of the formal line bundle $\tilde{Q}$. Namely the parallel transport of $g^i(\gamma)$ over the distinguished curve joining γ_i to γ remains in a small neighborhood of $L_{\text{fin}}G$. There is, since Q_{fin} is simply connected, a distinguished curve joining $q_{\text{base}} \in Q$ to $(\gamma, g^i(\gamma))$. We will denote it by $q_{i,\cdot}(\gamma)$ and we put $\tilde{q}_i(\gamma) = (q_i, (\gamma), 1)$.

Let us work over $O_i \cap O_j$. Let us show that almost surely

$$(q_i, .(\gamma_\cdot), 1) = (q_j, .(\gamma_\cdot), 1)\rho_{j,i}(\gamma_\cdot). \tag{3.45}$$

The quantity $\rho_{j,i} \in \tilde{L}_{\text{fin}}G$ has an action given by (3.35).

The quantity $q_{i,1}(\gamma)$ is the path $g_t^i((\tau_1^G))$ over $\gamma_\cdot$ and $q_{j,1}(\gamma)$ is the path $g_t^j((\tau_1^G)^{-1})$ over $\gamma_\cdot$. Moreover, τ_1^G over O_i remains in a small neighborhood of G and τ_1^G over O_j remains in a small ball of G. There is, therefore, a distinguished path in $L_{\text{fin}}G$, smooth in τ_1^G joining $g_t^i((\tau_1^G)^{-1})$ to $g_t^i((\tau_1^G)^{-1})$ by right multiplication. Moreover, this path remains in a small tubular neighborhood of $L_{\text{fin}}G$. Let us call it $l_{j,i,1}(\gamma_\cdot)$. Since it remains in a small neighborhood of $L_{\text{fin}}G$, we can find a path $l_{j,i,t}(\gamma_\cdot)$ joining the unit path in $L_{\text{fin}}G$ to $l_{j,i,1}(\gamma_\cdot)$, and which is smooth in γ. Let us compute by the rule (3.35) and (3.36) the quantity

$$(q_{j,\cdot}(\gamma), 1)(l_{j,i,\cdot}(\gamma), 1) = (q_{j,\cdot}(\gamma) l_{j,i,\cdot}(\gamma), \alpha_{j,i}). \tag{3.46}$$

We have to find a distinguished suitable surface which depends on a nice way of $\gamma_\cdot$. Its vertices are given by $(q_{j,0}(\gamma), q_{j,0}(\gamma) l_{j,i,1}(\gamma), q_{j,1}(\gamma) l_{j,i,1}(\gamma))$. Its edges are given by $(q_{j,0}(\gamma) l_{j,i,s}(\gamma), q_{j,s}(\gamma) l_{j,i,1}(\gamma), q_{j,s}(\gamma) l_{j,i,s}(\gamma))$, the last one being circled in the opposite sense. We do as before in order to produce this surface by filling in first the loop over the basis LM as it was done in the first part, and afterwards by using the connection ∇^G and using the third condition in the definition of O_i. We use the parallel transport over the natural path joining $pq_{j,0}(\gamma_\cdot) l_{j,i,s}(\gamma_\cdot)$ to $pq_{j,s}(\gamma_\cdot) l_{j,i,s}(\gamma_\cdot)$. An extra loop in $L_{\text{fin}}G$ appears. We find an arbitrary surface in $L_{\text{fin}}G$ whose boundary is this extra loop. Two parts in the integral of F_Q over the global surface are obtained. The basic part leads to a nonanticipative stochastic integral. The fiber part is a traditional integral and is smooth. Namely, the surface filling in the extra loop which appears in $L_{\text{fin}}G$ can be chosen arbitrarily. We deduce that $\alpha_{j,i}$ is smooth. More precisely, $G_i G_j \alpha_{j,i}$ belongs locally to all the Sobolev spaces, where G_i is a regularization of the indicator function of the same type of the previous regularizations.

We conclude that

$$(q_{j,\cdot}, 1)(l_{j,i,\cdot}, \beta_{j,i}) \equiv (q_{i,\cdot}, 1), \tag{3.47}$$

where the $\beta_{j,i}$ are smooth in the previous sense. Namely, we have to identify $(q_{i,\cdot}(\gamma_\cdot), 1)$ to $(q_{j,\cdot} l_{j,i}, (\gamma_\cdot), \beta_{i,j})$. We have to find a nice surface which joins $q_{i,\cdot}(\gamma_\cdot)$ to $q_{j,\cdot}(\gamma_\cdot) l_{j,i,\cdot}(\gamma_\cdot)$ where we can integrate F_Q by using the theory of stochastic integrals. As in the first part, there is a distinguished surface bounded by the loop $p(q_{i,\cdot}(\gamma)$ to $p(q_{j,\cdot}(\gamma_\cdot) l_{j,i,\cdot}(\gamma_\cdot))$. We parallel transport $q_{i,t}(\gamma_\cdot)$ over the path joining $p(q_{i,t}(\gamma_\cdot))$ to $p(q_{j,t}(\gamma_\cdot))$. We find $\tilde{q}_{j,t}(\gamma_\cdot)$. But $\tilde{q}_{j,1}(\gamma_\cdot)$ is different from $q_j(\gamma_\cdot)$, but it differs by a loop in $L_{\text{fin}}G$. An arbitrary surface in $L_{\text{fin}}G$ is bounded by this loop, because the third condition is checked in the definition of O_i.

We get a global random surface over Q. They are two parts in the integral of F_Q over this surface. The basic part leads to a nonanticipative stochastic integral. The fiber part is a traditional integral, which is smooth. Namely, the surface bounded by the extra loop which arises in $L_{\text{fin}}G$ can be chosen arbitrarily.

Moreover, if $\gamma \in O_i$, $\gamma^n \in O_i$ for a polygonal approximation of γ. $\rho_{i,j}(\gamma^n)$ tends almost surely to $\rho_{i,j}(\gamma)$. Since over $\tilde{Q}_{\text{fin}}$ the $\rho_{i,j}$ are transition functions, we have (3.41) and (3.42) surely for $\rho_{i,j}(\gamma^n)$; (3.41) and (3.42) are true almost surely for $\rho_{i,j}(\gamma_\cdot)$.

Remark: If we look at the formalism of the Definition I.2, we have immediately $g_{j,i} = (g^j_{\cdot}((\tau_1 G)^{-1}))^{-1} g^i_{\cdot}((\tau_1^G)^{-1})$, and $\rho_{j,i} = (l_{j,i}, \beta_{j,i})$ checks clearly the condition of Definition I.2.

A canonical realization of the BMS algebra

G. Longhi[a)] and M. Materasso
Department of Physics, University of Firenze, 50125 Firenze, Italy

(Received 8 December 1997; accepted for publication 18 August 1998)

A canonical realization of the BMS (Bondi–Metzner–Sachs) algebra is given on the phase space of the classical real Klein–Gordon field. By assuming the finiteness of the generators of the Poincaré group, it is shown that a countable set of conserved quantities exists (supertranslations); this set transforms under a particular Lorentz representation, which is uniquely determined by the requirement of having an invariant four-dimensional subspace, which corresponds to the Poincaré translations. This Lorentz representation is infinite-dimensional, nonunitary, reducible and indecomposable. Its representation space is studied in some detail. It determines the structure constants of the infinite-dimensional canonical algebra of the Poincaré generators together with the infinite set of the new conserved quantities. It is shown that this algebra is isomorphic with that of the BMS group. © *1999 American Institute of Physics.* [S0022-2488(99)00301-1]

I. INTRODUCTION

Our purpose in this paper is to give a canonical realization of the algebra of the Bondi–Metzner–Sachs (BMS) group[1] on the phase space of the real classical Klein–Gordon field.

The BMS group arises in general relativity as the asymptotic symmetry at null infinity of a space–time describing an isolated (radiating) gravitational source. Such space–time is expected to become flat at null infinity,[2] and to exhibit the Poincaré group as the group of asymptotic symmetry.

While an asymptotic symmetry exists, its group is not the Poincaré group. It is a larger group containing the Poincaré group as a subgroup, and is a semidirect product of the homogeneous Lorentz group with an infinite-dimensional Abelian group. Among the infinitely many generators of this Abelian group there are the generators of translations; the remaining are the so-called supertranslations.

The idea of asymptotic flatness was formalized by Penrose by a process of conformal compactification;[3] by means of this process a boundary (scri) was added to space–time, consisting of end points of null geodesics. In this way the notion of flatness acquired an intrinsic meaning.

The asymptotic symmetry at null infinity has been studied by several authors. Apart from the classic papers[1] we also quote some review articles.[4] Here we only mention some points discussed in the literature on this argument.

One problem with the BMS group is due to the presence of infinitely many copies of the homogeneous Lorentz group, obtained from one another by conjugation with a supertranslation. This happens even in the case of the Poincaré group, but the spin Casimir of the Poincaré group is not invariant under such a conjugation.[5] This causes difficulties in the definition of a unique Poincaré group, and, by consequence, in the definition of the angular momentum of the system[6] (see, however, Ref. 7).

The unitary and irreducible representations of the BMS group have been studied in Ref. 8 to give a possible interpretation of this group as a fundamental group of elementary particles, a line of research no longer pursued.

There is a situation analogous to that of null infinity in the case of spatial infinity, where a similar (bigger) asymptotic symmetry arises.[9]

[a)]Electronic mail: longhi@fi.infn.it

More recently the classical approach to null infinity was criticized,[10] and it was shown that a more general asymptotic expansion for the metric should be used (polyhomogeneous expansion). Nevertheless, the group of asymptotic symmetry at null infinity is still the BMS group.

In view of the role played by the BMS group in general relativity it seems of interest to show that its algebra can be canonically realized in terms of conserved quantities of a real classical Klein–Gordon field. While this field has been chosen for its simplicity we expect that a similar analysis could be done for any other classical field. In particular, we will give explicitly the underlying infinite-dimensional representation of the Lorentz algebra, which determines the structure constants of the BMS algebra. Indeed we will show that, besides the total energy-momentum P^μ of the Klein–Gordon field, it is possible to define a countable set of other conserved quantities, with vanishing Poisson brackets with P^μ and among themselves. This new set of conserved quantities is given in terms of a countable set of functions on momentum space, which are the basis for an infinite-dimensional representation of the Lorentz group, which is nonunitary, reducible and indecomposable.

The structure of this representation function space is the same as that of the translations and supertranslations of the BMS group. We show that the Poisson algebra of the conserved quantities built from these functions and the generators of the Lorentz group is the same as that of the BMS group. So we call these conserved quantities the generators of supertranslations.

The action of the Lorentz generators on the supertranslations defines a set of structure constants of the BMS algebra, *which are the matrix elements* of the infinite-dimensional representation of the Lorentz group. The action of the supertranslations on the field is nonlocal. Nevertheless it defines, as in the case of P^μ, a canonical transformation on the field.

In Sec. II we recall some definitions about the Klein–Gordon field and define the Laplace–Beltrami operator on the mass hyperboloid. The eigenfunctions of this operator are studied in Sec. III and, in Sec. IV, the infinite representation of the Lorentz algebra is studied in some detail. In Sec. V the Poisson algebra of the generators of supertranslations is given and it is shown that it is isomorphic with the algebra of the BMS group.

The definitions and notations for the Klein–Gordon field are given in Appendix A. In Appendix B we discuss the eigenfunction problem for the Laplace–Beltrami operator on the mass hyperboloid. Moreover, we study in some detail the representation of the Lorentz group, which is the basis for the definition of the supertranslation generators.

II. THE KLEIN–GORDON FIELD AND THE LAPLACE–BELTRAMI OPERATOR

The notations and definitions for the real Klein–Gordon field $\Phi(\mathbf{x},t)$ are given in Appendix A. For each $t\in R$ the field $\Phi(\mathbf{x},t)$ will be supposed to belong, together with its spatial and temporal derivatives, to $L^2(R^3)$, that is

$$(\Phi(\cdot,t),\dot{\Phi}(\cdot,t))\in H^1(R^3)\times L^2(R^3), \tag{2.1}$$

where $\dot{\Phi}=\partial\Phi/\partial t$ and where $H^1(R^3)$ is the $W_2^1(R^3)$ Sobolev space.[11] This implies the existence of the total energy–momentum,

$$P^\mu=\int d^3x\left[\dot{\Phi}(\mathbf{x},t)\partial^\mu\Phi(\mathbf{x},t)-\frac{1}{2}\eta^{\mu 0}(\partial_\nu\Phi(\mathbf{x},t)\partial^\nu\Phi(\mathbf{x},t)-m^2\Phi^2(\mathbf{x},t))\right], \tag{2.2}$$

or, in terms of the Fourier coefficients of the field Φ,

$$P^\mu=\int \widetilde{d}k\, k^\mu\overline{a}(\mathbf{k})a(\mathbf{k}), \tag{2.3}$$

where the measure $\widetilde{d}k$ is defined in Appendix A and $k^0=\omega(\mathbf{k})$. The energy–momentum P^μ is time-like and future oriented.

Apart from the existence of a well defined total momentum P^{μ}, we require the existence of the generators of the Lorentz group. This implies a more stringent condition on Φ, or on $a(\mathbf{k})$. We require the additional condition: $\nabla a(\mathbf{k}) \in L^2(R^3)$. From Eq. (2.3), with $\mu=0$, we have that $a(\mathbf{k}) \in L^2(R^3)$; with this additional condition we have that $a(\mathbf{k})$ is continuous and that has a vanishing limit when $|\mathbf{k}| \to \infty$.[12]

The scalar field $\Phi(x)$, where $x \equiv (\mathbf{x},t)$, transforms under a Poincaré transformation $U(\Lambda,\alpha)$ as

$$(U(\Lambda,\alpha)\Phi)(x)=\Phi(\Lambda^{-1}(x-\alpha)). \tag{2.4}$$

This induces the transformation on $a(\mathbf{k})$,

$$(U(\Lambda,\alpha)a)(\mathbf{k})=a(\Lambda^{-1}\mathbf{k})e^{i(k\cdot\alpha)}. \tag{2.5}$$

In this last equation the notation $\Lambda^{-1}\mathbf{k}$ has the meaning $\Lambda^{i}{}_{\cdot\nu}k^{\nu}, i=1,2,3$, where $k^0 = \sqrt{m^2+\mathbf{k}^2}$.

The canonical action of the Poincaré generators on $a(\mathbf{k})$ is given by (see Ref. 11)

$$\{P^{\mu},a(\mathbf{k})\}=ik^{\mu}a(\mathbf{k}), \tag{2.6}$$

$$\{M'^{\mu\nu},a(\mathbf{k})\}=D_{\mu\nu}a(\mathbf{k}), \quad \{M'^{\mu\nu},\overline{\mathbf{a}}(\mathbf{k})\}=D_{\mu\nu}\overline{\mathbf{a}}(\mathbf{k}), \tag{2.7}$$

where $M'^{\mu\nu}$ is defined in Eq. (A21) and

$$D_{\mu\nu}=(\eta^{i}_{\mu}k_{\nu}-\eta^{i}_{\nu}k_{\mu})\frac{\partial}{\partial k^{i}}. \tag{2.8}$$

The differential operators $D_{\mu\nu}$ satisfy the algebra

$$[D_{\mu\nu},D_{\rho\lambda}]=\eta_{\mu\rho}D_{\nu\lambda}+\eta_{\nu\lambda}D_{\mu\rho}-\eta_{\mu\lambda}D_{\nu\rho}-\eta_{\nu\rho}D_{\mu\lambda}. \tag{2.9}$$

We can now work with the field $a(\mathbf{k})$ and its complex conjugate $\overline{a}(\mathbf{k})$, which are defined on the mass hyperboloid. This is a Riemannian manifold which will be called H^1_3, following the notations of Ref. 13, where such manifolds are studied.

Indeed, if we define H^1_3 as the inclusion f of the submanifold $q^2-m^2=0$ with $q^0>0$ in the Minkowski space M^4 (with coordinates q^{μ}), with f defined by

$$f:\{k^i\}\to\{q^{\mu}\}, \tag{2.10}$$

with

$$q^0=\sqrt{m^2+\mathbf{k}^2} \quad \text{and} \quad q^i=k^i \quad (i=1,2,3), \tag{2.11}$$

we get for the induced metric $\hat{\eta}$,

$$\hat{\eta}=f^*\eta, \tag{2.12}$$

the following expression:

$$\hat{\eta}=\hat{\eta}_{ij}\,dk^i\,dk^j, \tag{2.13}$$

with

$$\hat{\eta}_{ij}=\frac{1}{\omega^2(k)}k_ik_j-\delta_{ij} \quad (i,j=1,2,3). \tag{2.14}$$

The inverse of the matrix $\{\hat{\eta}_{ij}\}$ is

$$\hat{\eta}^{ij}=-\left(\delta^{ij}+\frac{k^i k^j}{m^2}\right); \tag{2.15}$$

its determinant is

$$|\hat{\eta}|=\det\{\hat{\eta}_{ij}\}=-\frac{m^2}{\omega^2(\mathbf{k})}; \tag{2.16}$$

and its eigenvalues are $-1,-1,-1+\mathbf{k}^2/\omega^2(\mathbf{k})$.

So the metric $\hat{\eta}$ is proper Riemannian. The manifold H_3^1 is a space-like surface since its normal is

$$n^\mu\equiv\left(\frac{\omega(\mathbf{k})}{m},\frac{\mathbf{k}}{m}\right)\equiv\frac{k^\mu}{m},\quad n^2=1, \tag{2.17}$$

and has constant negative scalar curvature, as can be shown by explicit calculation.

The only invariant second order differential operator on H_3^1 is the Laplace–Beltrami operator Δ (no invariant differential operator of first order exists):

$$\Delta=-\frac{1}{\sqrt{|\hat{\eta}|}}\frac{\partial}{\partial k^i}\hat{\eta}^{ij}\sqrt{|\hat{\eta}|}\frac{\partial}{\partial k^j}, \tag{2.18}$$

where $|\hat{\eta}|=\det\{\hat{\eta}_{ij}\}$.

Explicitly, this operator is

$$\Delta=\frac{\omega(\mathbf{k})}{m}\frac{\partial}{\partial k^i}\left(\delta^{ij}+\frac{k^i k^j}{m^2}\right)\frac{m}{\omega(\mathbf{k})}\frac{\partial}{\partial k^j}, \tag{2.19}$$

or

$$\Delta=\left[\boldsymbol{\nabla}^2+\frac{2}{m^2}\mathbf{k}\cdot\nabla+\frac{1}{m^2}(\mathbf{k}\cdot\nabla)^2\right]. \tag{2.20}$$

This operator is invariant under a Lorentz transformation Λ,

$$k^i\rightarrow k'^i=\Lambda^i_j k^j+\Lambda^i_0\sqrt{m^2+\mathbf{k}^2}. \tag{2.21}$$

The operator Δ is formally self-adjoint with respect to the invariant measure $\widetilde{d}k$. It is an elliptic operator and has the property

$$\Delta k^\mu=\frac{3}{m^2}k^\mu. \tag{2.22}$$

Let us define

$$D=-m^2\Delta+3, \tag{2.23}$$

so that

$$Dk^\mu=0. \tag{2.24}$$

When explicitly written (see the following Section) the equation

$$Df(\mathbf{k})=0, \tag{2.25}$$

is an equation which can be separated in spherical coordinates. The radial equation has three regular singularities in the complex plane of $z=-\mathbf{k}^2/m^2$, which are in $-1,0,\infty$, so it is a hypergeometric equation. The four functions k^μ are a subset of the solutions of Eq. (2.25), with the characteristic exponents $l=0,1$ in the neighborhood of the point 0 $[k^0=\omega(\mathbf{k})$ has the exponent $l=0$ and $\mathbf{k}$ has the exponent $l=1]$. In the neighborhood of the point at infinity the characteristic exponents are $+1$ and -3. So we may expect that an infinite set of solutions could have the same asymptotic behavior like k^μ, when $|\mathbf{k}|\to\infty$; we will see in the next Section that this is indeed the case and that there is an infinite set of solutions of Eq. (2.25) which gives a set of well defined integrals, when we put them in place of k^μ in Eq. (2.3).

III. THE EIGENFUNCTIONS OF THE LAPLACE–BELTRAMI OPERATOR

The Laplace–Beltrami operator Δ of Eqs. (2.18) and (2.20) was studied in a series of papers by Raczka, Limic, and Niederle,[13] where it is called $\Delta(H_3^1)$ [see Eq. (5.10) in the first reference of Ref. 13]. There it is shown that Δ has no discrete spectrum, but only a continuous one, and the basis of its generalized eigenfunctions is determined.

Δ can be identified with one of the Casimir operators of the Lorentz group, whose Lie algebra is defined in terms of the differential operators

$$l_{\mu\nu}=iD_{\mu\nu}, \tag{3.1}$$

with $D_{\mu\nu}$ as in Eq. (2.8).

To make contact with the notations used by Naimark in his book[14] we put

$$L_i=l_i,\quad K_i=-l_{0i}, \tag{3.2}$$

$$l_i=-\tfrac{1}{2}\epsilon_{ijk}l_{jk}\quad (i,j,k=1,2,3) \tag{3.2}$$

(in Naimark's notations:

$$H_3=L_3;\quad H_\pm=L_\pm=L_1\pm iL_2; \tag{3.3}$$

$$F_3=K_3;\quad F_\pm=K_\pm=K_1\pm iK_2). \tag{3.3}$$

These operators satisfy the Lorentz algebra

$$[L_i,L_j]=i\epsilon_{ijk}L_k,\quad [K_i,L_j]=i\epsilon_{ijk}K_k,\quad [K_i,K_j]=-i\epsilon_{ijk}L_k. \tag{3.4}$$

Two invariant operators can be defined using $\mathbf{L}$ and $\mathbf{K}$,

$$\Xi_1=\mathbf{L}\cdot\mathbf{K},\quad \Xi_2=|\mathbf{K}|^2-|\mathbf{L}|^2, \tag{3.5}$$

and these are the two Casimir operators of the Lorentz group.

The operators $\mathbf{L}$ and $\mathbf{K}$ can be written as

$$\mathbf{L}=-i\mathbf{k}\wedge\boldsymbol{\nabla},\quad \mathbf{K}=i\omega(\mathbf{k})\boldsymbol{\nabla}, \tag{3.6}$$

so

$$\Xi_1=-[\mathbf{k}\wedge\boldsymbol{\nabla}\omega(\mathbf{k})]\cdot\boldsymbol{\nabla},\quad \Xi_2=m^2\nabla^2+2(\mathbf{k}\cdot\boldsymbol{\nabla})+(\mathbf{k}\cdot\boldsymbol{\nabla})^2. \tag{3.7}$$

$\omega(\mathbf{k})$ has a gradient which is parallel to $\mathbf{k}$, so $\Xi_1=0$. We are left with one Casimir only,

$$\Xi_2 = m^2\Delta. \tag{3.8}$$

In terms of $l_{\mu\nu}$ we have

$$\Delta = \tfrac{1}{2} l_{\mu\nu} l^{\mu\nu}, \quad \epsilon_{\mu\nu\rho\lambda} l^{\mu\nu} l^{\rho\lambda} = 0, \tag{3.9}$$

and of course we have

$$[D, D_{\mu\nu}] = 0, \tag{3.10}$$

where the operator D is defined in Eq. (2.23).

If we denote λ the eigenvalue of $-m^2\Delta$, the relation with Naimark's notations[14] is given by

$$\lambda = -(k_o^2 + c^2 - 1), \quad k_o c = 0, \tag{3.11}$$

where k_o and c are the eigenvalues of two operators Δ and Δ' defined in the quoted reference,

$$\Delta|_{\text{eigenvalue}} = -2(k_o^2 + c^2 - 1), \qquad \Delta'|_{\text{eigenvalue}} = -4ik_o c. \tag{3.12}$$

If we choose

$$k_o = 0, \quad c = i\Lambda, \tag{3.13}$$

we get

$$\lambda = 1 + \Lambda^2 \in [1, +\infty), \tag{3.14}$$

corresponding to the representations of the Lorentz group of the principal series, with $k_o = 0$, which are unitary; see Ref. 14.

The zero modes of the operator D of Eq. (2.23) correspond to

$$\lambda = -3. \tag{3.15}$$

This value of λ corresponds to a nonunitary representation of the Lorentz group, which is reducible but not completely reducible (indecomposable) as it will be shown later. In Appendix B we give the details of the determination of this representation. Let us show here the expression of the boost K_3 and its action on the representation $\lambda = -3$. From Eqs. (3.1), (3.2) and (2.8) we get

$$l_{ij} = -\epsilon_{ijk} L_k = i(x^i \partial_j - x^j \partial_i), \quad l_{0j} = -K_j = -i\sqrt{1 + \mathbf{x}^2}\,\partial_j, \tag{3.16}$$

where

$$\mathbf{x} = \frac{\mathbf{k}}{m}. \tag{3.17}$$

From these expressions we get

$$K_3 = i\sqrt{1 + r^2}\left(\cos\theta \frac{\partial}{\partial r} - \frac{\sin\theta}{r}\frac{\partial}{\partial\theta}\right), \tag{3.18}$$

in the spherical coordinates (r, θ, ϕ) of $\mathbf{x}$.

D becomes

$$D=-m^2\Delta+3=-\Delta|_x+3, \tag{3.19}$$

where

$$\Delta|_x=\left[(1+r^2)\frac{\partial^2}{\partial r^2}+\left(\frac{2}{r}+3r\right)\frac{\partial}{\partial r}-\frac{J^2}{r^2}\right], \tag{3.20}$$

and $J^2=\mathbf{L}^2$ as usual.

The eigenfunctions of $-\Delta|_x$ correspond to $\lambda\in[1,+\infty)$, or $\Lambda\in[0,+\infty)$ as a limit from the upper half-plane of the complex plane of Λ. They are given in Ref. 13 [also see Eqs. (B2) and (B3)]

$$u_{\lambda,l,m}(r,\theta,\phi)=N_{\lambda l}v^{(o)}_{1,\lambda,l,m}=N_{\lambda l}r^lF\left(\frac{l+1+i\Lambda}{2},\frac{l+1-i\Lambda}{2};l+\frac{3}{2};-r^2\right)Y_{l,m}(\theta,\phi), \tag{3.21}$$

where F is the hypergeometric function, with the three parameters of $F(\alpha,\beta;\gamma;-r^2)$ satisfying the relation

$$\alpha+\beta+\tfrac{1}{2}=\gamma, \tag{3.22}$$

and where $l=0,1,2,\ldots,$ and $|m|\leqslant l$.

The normalization factor $N_{\lambda l}$ is

$$N_{\lambda l}=\frac{2\pi}{m\sqrt{\Lambda}}\left|\frac{\Gamma((l+2-i\Lambda)/2)\Gamma((l+1-i\Lambda)/2)}{\Gamma(i\Lambda)\Gamma(l+(3/2))}\right|, \tag{3.23}$$

for $\Lambda\in[0,\infty)$.

With this normalization $u_{\lambda,l,m}$ is an orthonormal set with respect to the scalar product of $L_2(\tilde{d}k)$,

$$\int \tilde{d}k\,\overline{u}_{\lambda lm}(r,\theta,\phi)u_{\lambda',l',m'}(r,\theta,\phi)=\delta_{ll'}\delta_{mm'}\delta(\Lambda-\Lambda'). \tag{3.24}$$

This basis is complete in $L_2(\tilde{d}k)$, that is

$$\sum_{l\geqslant 0}\sum_{|m|\leqslant l}\int_1^\infty d\lambda\, u_{\lambda,l,m}(r,\theta,\phi)\overline{u}_{\lambda,l,m}(r',\theta',\phi')=\Omega(k)\delta^3(k-k'). \tag{3.25}$$

The action of the Lorentz generators on the basis $\{v^{(o)}_{1,\lambda,l,m}\}$ is given in Appendix B, subsection 2.

For $\lambda\in[1,+\infty)$, as shown in Ref. 13, the representation of the Lorentz group on these bases is unitary. This interval for λ corresponds to the continuous spectrum of Δ.

We are interested in the case $\lambda=-3$, which corresponds to a pure imaginary Λ [see Eq. (3.14)], with $\mathrm{Im}\,\Lambda>0$. In this case the normalization factor $N_{\lambda,l}$ becomes meaningless, and the functions $\{v^{(o)}_{1,\lambda,l,m}\}$ are no more normalizable.

Following the discussion of Appendix B the only set of solutions of Eq. (2.25) which we will take into account in the following is the set $\{v^{(o)}_{1,\lambda,l,m}\}$, with $\lambda=-3$.

The action of K_3 on $v^{(o)}_{1,\lambda,l,m}$ is

$$K_3v^{(o)}_{1,\lambda,l,m}=-i\frac{(l+1+i\Lambda)(l+1-i\Lambda)}{2l+3}C_{l+1,m}v^{(o)}_{1,\lambda,l+1,m}++i(2l+1)C_{l,m}v^{(o)}_{1,\lambda,l-1,m}, \tag{3.26}$$

as given in Eq. (B32).

The action of $K_{\pm}$ is given in Eq. (B33), where the dependence on l of the coefficients in the r.h.s. is determined by the action of K_3 in Eq. (3.26) through Eq. (4.8).

From this equation we see that, for complex values of Λ in the upper half-plane, the first term in the r.h.s. of Eq. (3.26) vanishes for

$$\Lambda = i(l+1). \tag{3.27}$$

We may conclude that the *only representation* with an invariant subspace of dimension 4 is the representation with

$$\Lambda = 2i, \quad \text{or} \quad \lambda = -3. \tag{3.28}$$

In the next section we will study in more detail this representation.

IV. THE REPRESENTATION $\lambda = -3$

In this section we will study in some detail the representation $\lambda = -3$. For $\Lambda = 2i$ let us define

$$w_{l,m}(r,\theta,\phi) = v^{(o)}_{-3,l,m}(r,\theta,\phi). \tag{4.1}$$

From Eq. (3.26) we have the action of K_3 on $w_{l,m}$:

$$K_3 w_{l,m} = -i\frac{(l-1)(l+3)}{(2l+3)} C_{l+1,m} w_{l+1,m} + +i(2l+1) C_{l,m} w_{l-1,m}, \tag{4.2}$$

where the coefficients $C_{l,m}$ are defined in Eq. (B30), and where the values of $|m|$ in the right hand side are always limited by l in the first term and by $l-1$ in the second term.

Explicitly $w_{l,m}(\mathbf{x})$ is given by

$$w_{l,m}(r,\theta,\phi) = r^l F\left(\frac{l-1}{2}, \frac{l+3}{2}; l+\frac{3}{2}; -r^2\right) Y_{l,m}(\theta,\phi), \tag{4.3}$$

where r, θ, and ϕ are the spherical coordinates of $\mathbf{x} = \mathbf{k}/m$.

Observe that for $l=0,1$,

$$w_{0,0} = \sqrt{1+r^2} Y_{0,0} = \frac{\omega(\mathbf{k})}{m} Y_{0,0}, \quad w_{1,m} = r Y_{1,m} = \frac{|\mathbf{k}|}{m} Y_{1,m}, \tag{4.4}$$

which are the components of the 4-vector k^μ/m in the spherical basis, with the Minkowski diagonal metric given by

$$\tilde{\eta} = \frac{4\pi m^2}{3}(3,-1,-1,-1), \tag{4.5}$$

where $(l,m) = (0,0),(1,-1),(1,0),(1,-1)$ and

$$\sum_{l=0,1} \sum_{|m|\leq l} \overline{w}_{l,m} \tilde{\eta}_{lm,lm} w_{l,m} \equiv \overline{w} \cdot \tilde{\eta} \cdot w = m^2. \tag{4.6}$$

It is important to observe that all the functions $w_{l,m}$ have the same asymptotic behavior as $|\mathbf{k}| \to \infty$. In other words we have an infinite sequence of zero modes of the operator D, all with the same asymptotic behavior as k^μ. This fact is explicitly shown by Eq. (B14).

The subspace spanned by the components $l=0,1$ of $w_{l,m}$ is *invariant* under the action of the generators of the Lorentz group. Indeed, from Eq. (4.2), we have

$$K_3 w_{0,0} = \frac{i}{\sqrt{3}} w_{1,0}, \quad K_3 w_{1,m} = i\sqrt{3}\,\delta_{m,0} w_{0,0}. \tag{4.7}$$

Moreover, since

$$K_{\pm} = \pm [K_3, L_{\pm}], \tag{4.8}$$

and since $L_{\pm}$ does not modify the value of l, even the action of $K_{\pm}$ leaves the subspace $l=0,1$ invariant.

It is the factor $l-1$ in the r.h.s. of Eq. (4.2) which is responsible for this fact. There are no other values of Λ, in the upper half of its complex plane, which could provide an invariant subspace of the same dimension. If we choose $\Lambda = in$, as in Eq. (3.27), with an n integer >0, we have an invariant subspace with a dimension which is determined by the maximum value of l, which is equal to $n-1$, as we can see from Eq. (3.26). In conclusion, the value $\lambda = -3$, or $\Lambda = 2i$, is determined by the requirement of the existence of an invariant subspace of dimension 4.

The representation whose basis is $\{w_{l,m}\}$ is reducible, but not decomposable (not completely reducible). That it is reducible is clear, since the matrix of K_3, determined by Eq. (3.26), is block triangular. Indeed, if we define

$$K_3 w_{l,m} = w_{l',m} (K_3)_{l',l}, \tag{4.9}$$

we have

$$(K_3)_{2,1} = 0, \tag{4.10}$$

but

$$(K_3)_{1,2} \neq 0. \tag{4.11}$$

Now, a representation like this is decomposable if there exists a similarity transformation defined by a matrix S of the form

$$\begin{pmatrix} 1 & Y \\ 0 & 1 \end{pmatrix}, \tag{4.12}$$

transforming all the generators of the Lorentz group $l_{\mu\nu}$ in a block diagonal form; see Ref. 15.

The matrix Y has four rows and infinitely many columns and, of course, it must be nonzero. It should similarly transform in a block diagonal form also the matrix of $\mathbf{L}^2$, which is already in block diagonal form. This is clearly impossible. So the representation is indecomposable.

V. THE SUPERTRANSLATIONS

The presence of a whole series of zero modes of the operator D, with the same asymptotic behavior as $|\mathbf{k}| \to \infty$, allows us to define the following set of integrals:

$$P_{l,m} = \int \tilde{d}k\, w_{l,m}(\mathbf{k}) \overline{a(\mathbf{k})} a(\mathbf{k}), \tag{5.1}$$

where

$$\overline{P}_{l,m} = (-1)^m P_{l,-m}, \tag{5.2}$$

and where the functions $w_{l,m}$ are given in Eq. (4.3).

As shown in Appendix B [see Eqs. (B14) and (B22)] all these integrals are well defined.

The canonical action of the generators of the Lorentz group $M^{\mu\nu}$ on the $P_{l,m}$ can be obtained from Eqs. (2.6) and (2.7); since from Eq. (2.8) we have

$$D^{ij}=\left(k^i\frac{\partial}{\partial k^j}-k^j\frac{\partial}{\partial k^i}\right)=i\epsilon_{ijk}L_k,\quad D^{0j}=\omega(k)\frac{\partial}{\partial k^j}=-iK_j,\tag{5.3}$$

with the definitions (3.1) and (3.2), we get

$$\{M^{i,j},P_{l,m}\}=-i\epsilon_{ijk}P_{l',m'}(L_k)_{l',m';l,m},\tag{5.4}$$

$$\{M^{0,j},P_{l,m}\}=iP_{l',m'}(K_j)_{l',m';l,m}.\tag{5.5}$$

In these equations the matrices $\|L_k\|$ and $\|K_j\|$ are those given in Eqs. (B25), (B37) and (B38), and correspond to the representation $\lambda=-3$ of the Lorentz algebra.

Moreover, we have

$$\{P_{l,m},P_{l',m'}\}=0.\tag{5.6}$$

For $l=0,1$ the $P_{l,m}$ are the spherical components of P^{μ}.

Equations (5.4), (5.5) and (5.6) show that this algebra is infinite-dimensional, that the Abelian subalgebra of the $\{P_{l,m}\}$ is a normal subalgebra, and that the factor algebra is isomorphic to the Lorentz algebra.

In order to show that this algebra is the same as that of the BMS group, we simply redefine the $P_{l,m}$ with

$$\hat{P}_{l,m}=\nu_l P_{l,m},\tag{5.7}$$

with ν_l satisfying the recurrence relation

$$\nu_{l+1}=\frac{2l+3}{l+3}\nu_l,\tag{5.8}$$

or

$$\nu_l=\frac{(2l+1)!!}{(l+2)!}2\nu_0.\tag{5.9}$$

By defining

$$R_z=iK_3,\quad R_{\pm}=iK_{\pm},\quad L'_z=iL_z,\tag{5.10}$$

we get exactly the algebra given by Sachs[5] [see in this reference Eqs. (IV.19) and (IV.20)].

As shown by Sachs,[5] the four-dimensional subgroup of translations ($P_{l,m}$ with $l=0,1$) is unique. On the other hand the homogeneous Lorentz group is not similarly unique. This is due to the fact that copies of the Lorentz group can be obtained by a conjugation with an arbitrary supertranslation, whose role is here played by the quantities $P_{l,m}, l\geqslant 2$.

Indeed, let us define the following transformation of the Lorentz generators:

$$M'^{i,j}\to M'^{i,j}+\alpha\{P_{l,m},M'^{i,j}\}=M'^{i,j}+i\alpha\epsilon_{ijk}P_{l',m'}(L_k)_{l',m';l,m},\tag{5.11}$$

$$M'^{0,j}\to M'^{0,j}+\alpha\{P_{l,m},M'^{0,j}\}=M'^{0,j}-i\alpha P_{l',m'}(L_j)_{l',m';l,m},\tag{5.12}$$

where α is an arbitrary real parameter, and Eqs. (5.4), (5.5) were used.

For a fixed infinitesimal transformation (5.11), (5.12), getting the same r.h.s. terms:

$$e^{\alpha P_{l,m}}*M'^{i,j}=M'^{i,j}+i\alpha\epsilon_{ijk}P_{l',m'}(L_k)_{l',m';l,m},\tag{5.13}$$

$$e^{\alpha P_{l,m}}*M'^{0,j}=M'^{0,j}-i\alpha P_{l',m'}(L_j)_{l',m';l,m}.\tag{5.14}$$

In these equations the $*$ operation is defined by

$$e^{A}*B=\sum_{n\geqslant 0}\frac{1}{n!}D_A^n B,\quad D_A=\{A,\cdot\}. \tag{5.15}$$

This transformation corresponds to a conjugation of the Lorentz algebra with an arbitrary fixed supertranslation. It can be verified that the transformed algebra is again the Lorentz algebra.

As a consequence, the Casimir operator of the Poincaré group given by the square of the Pauli–Lubanski four-vector, which is invariant under the transformation (5.13) and (5.14) when $l=0,1$, will in general, change.[5]

The canonical action of a fixed supertranslation on the field is determined by

$$\{P_{l,m},a(\mathbf{k})\}=iw_{l,m}(\mathbf{k})a(\mathbf{k}),\quad \{P_{l,m},\overline{a}(\mathbf{k})\}=-iw_{l,m}(\mathbf{k})\overline{a}(\mathbf{k}), \tag{5.16}$$

which, for $l=0,1$, reduces to (2.6), written in spherical coordinates.

Since $P_{l,m}$ is not real ($\overline{P}_{l,m}=(-1)^m P_{l,-m}$), it induces two different canonical transformations on the field Φ, determined by its real and its imaginary part,

$$P_{l,m}=R_{l,m}+iI_{l,m}, \tag{5.17}$$

where

$$\{R_{l,m},a(\mathbf{k})\}=i\,\mathrm{Re}(w_{l,m}(\mathbf{k}))a(\mathbf{k}),\quad \{R_{l,m},\overline{a}(\mathbf{k})\}=-i\,\mathrm{Re}(w_{l,m}(\mathbf{k}))\overline{a}(\mathbf{k}), \tag{5.18}$$

and

$$\{I_{l,m},a(\mathbf{k})\}=i\,\mathrm{Im}(w_{l,m}(\mathbf{k}))a(\mathbf{k}),\quad \{I_{l,m},\overline{a}(\mathbf{k})\}=-i\,\mathrm{Im}(w_{l,m}(\mathbf{k}))\overline{a}(\mathbf{k}). \tag{5.19}$$

Again these can be exponentiated for a fixed supertranslation, for instance,

$$e^{\alpha R_{l,m}}a(\mathbf{k})=e^{i\alpha\,\mathrm{Re}\,w_{l,m}(\mathbf{k})}a(\mathbf{k}),\quad e^{\alpha R_{l,m}}\overline{a}(\mathbf{k})=e^{-i\alpha\,\mathrm{Re}\,w_{l,m}(\mathbf{k})}\overline{a}(\mathbf{k}), \tag{5.20}$$

and the analogous expressions for $I_{l,m}$.

Equation (5.20) defines a canonical transformation of the field, since the canonical Poisson brackets (A16) are invariant under such a transformation.

This transformation is nonlocal in the field $\Phi(\mathbf{x},t)$. It is a particular case of a linear transformation,

$$(\Phi,\Pi)\rightarrow(\Phi',\Pi'), \tag{5.21}$$

realized as an integral transformation of the convolution type. Indeed, $a(\mathbf{k})$ belongs to $L^2(R^3)$, and so is a tempered distribution, and the exponentials $\exp(i\,\mathrm{Re}\,w_{l,m})$ and $\exp(i\,\mathrm{Im}\,w_{l,m})$ are tempered distributions too. Moreover, the convolution product between their Fourier transforms is well defined. Indeed, the functions $w_{l,m}(\mathbf{k})$, being the solutions of a homogeneous elliptic equation, are infinitely differentiable.[16] They and all their derivatives are polynomially bounded, due to the bound (B14). So, the functions $w_{l,m}(\mathbf{k})$ and their exponential $\exp(i\,\mathrm{Re}\,w_{l,m})$, $\exp(i\,\mathrm{Im}\,w_{l,m})$, are multipliers in $S'(R^3)$, the space of tempered distributions on R^3.[17] This implies that their Fourier transforms are convolutes,[18] that is, their convolution exists with any tempered distribution. In conclusion, we may write the relation among (Φ,Π) and (Φ',Π') as

$$\begin{aligned}\Phi'(\mathbf{x},t)&=\int d^3x'[f(\mathbf{x}-\mathbf{x}')\Phi(\mathbf{x}',t)+g(\mathbf{x}-\mathbf{x}')\Pi(\mathbf{x}',t)],\\ \Pi'(\mathbf{x},t)&=\int d^3x'[h(\mathbf{x}-\mathbf{x}')\Phi(\mathbf{x}',t)+k(\mathbf{x}-\mathbf{x}')\Pi(\mathbf{x}',t)],\end{aligned} \tag{5.22}$$

where the distributions f, g and h are defined by

$$f(\mathbf{x})=\int \tilde{d}k\,\omega(\mathbf{k})(e^{i\alpha\,\mathrm{Re}\,w_{l,m}(\mathbf{k})+i\mathbf{k}\cdot\mathbf{x}}+\mathrm{c.c.}),\quad g(\mathbf{x})=i\int \tilde{d}k(e^{i\alpha\,\mathrm{Re}\,w_{l,m}(\mathbf{k})+i\mathbf{k}\cdot\mathbf{x}}-\mathrm{c.c.}),$$
$$h(\mathbf{x})=-i\int \tilde{d}k\,\omega^2(\mathbf{k})(e^{i\alpha\,\mathrm{Re}\,w_{l,m}(\mathbf{k})+i\mathbf{k}\cdot\mathbf{x}}-\mathrm{c.c.}),\quad k(\mathbf{x})=f(\mathbf{x}),\tag{5.23}$$

where c.c. means the complex conjugated. It is easily seen that the condition

$$\int d^3y[f(\mathbf{x}-\mathbf{y})k(\mathbf{x}'-\mathbf{y})-g(\mathbf{x}-\mathbf{y})h(\mathbf{x}'-\mathbf{y})]=\delta^3(\mathbf{x}-\mathbf{x}'),\tag{5.24}$$

which must be satisfied if the transformation (5.22) has to be canonical, holds.

The transformation induced by $I_{l,m}$ is the same with the replacement $\mathrm{Re}\,w_{l,m}\rightarrow\mathrm{Im}\,w_{l,m}$.

The transformation (5.22) changes the initial configuration of the field determined by the functions $a(\mathbf{k})$, to a new one, determined by the functions $a'(\mathbf{k})=\exp(i\alpha\,\mathrm{Re}(w_{l,m}(\mathbf{k})))a(\mathbf{k})$. As we have seen, this transformation can change the spin content of the field, when $l\geqslant 2$.

As a conclusion we collect Eqs. (5.4), (5.5) and (5.6), which give the Poisson algebra of the BMS group,

$$\{M'^{\mu\nu},P_{l,m}\}=P_{l',m'}(M'^{\mu\nu})_{l',m';l,m},\quad \{P_{l,m},P_{l',m'}\}=0,\tag{5.25}$$

where, as given by Eqs. (5.4) and (5.5),

$$(M'^{ij})_{l',m';l,m}=-i\epsilon_{ijk}(L_k)_{l',m';l,m},\quad (M'^{0j})_{l',m';l,m}=i(K_j)_{l',m';l,m},\tag{5.26}$$

with the matrix elements of L_k and of K_j given in Eqs. (B25), (B37) and (B38).

VI. CONCLUSIONS

Following our initial purpose, we have found a Poisson algebra isomorphic to the BMS algebra, realized on the phase space of a real classical Klein–Gordon field.

The structure constants of this algebra are given by the matrix elements of an infinite-dimensional representation of the Lorentz group, which is nonunitary, reducible and indecomposable. We have given an explicit basis of functions for this representation, which are not normalizable in the sense of an L_2 space with Lorentz invariant measure, but for which we give an asymptotic bound.

The requirement of the existence of a four-dimensional invariant subspace selects this representation almost uniquely among all the possible representations of the Lorentz group.

Thus, we have shown that it is possible to realize the BMS algebra outside the general relativity context, in which it was originally discovered. This fact suggests a more general role of the BMS group.

As it is well known, the BMS group is the semidirect product of the Lorentz group with the finite set of translations and the infinite set of supertranslations. In the general relativity case, on the basis of physical arguments, the vanishing of the supertranslations is required.[5,4] In the case of the same algebra realized in terms of the Klein–Gordon field this requirement should be a strong restriction on the possible field configurations, which could not have a clear justification.

As we have observed in the Introduction, we may expect that a similar analysis could be worked out for other classical massive fields. Something similar should also happen for a zero mass field, by performing a harmonic analysis on the $k_\mu k^\mu=0$ cone, where the Laplace–Beltrami operator changes significantly.[19]

The existence of the supertranslations in the context of the Klein–Gordon field theory is a byproduct of a larger study on the search of a canonical set of collective and relative variables for a classical relativistic field, playing a role analogous to the center of mass and relative variables of a nonrelativistic system of particles. This study will be the argument of a forthcoming paper.

ACKNOWLEDGMENTS

The authors wish to thank L. Lusanna for many suggestions and enlightening discussions on the subject of this paper, for his useful criticism and for reading the manuscript. The authors are also indebted to K. Marathe for many suggestions and for reading the manuscript.

APPENDIX A: NOTATIONS FOR THE CLASSICAL REAL KLEIN–GORDON FIELD

We list in this appendix the various definitions concerning the real Klein–Gordon field. We will put $c=\hbar=1$, and the metric signature is $(+;-,-,-)$.

The Lagrangian and the Lagrangian density are

$$L=\int dt\,\mathcal{L},\quad \mathcal{L}=\frac{1}{2}(\partial_\mu\Phi\,\partial^\mu\Phi-m^2\Phi^2), \tag{A1}$$

where $\mu=0,1,2,3$, and

$$\overline{\Phi}=\Phi. \tag{A2}$$

The conjugate momentum and the equation of motion are

$$\Pi(x)=\dot{\Phi}(x)\equiv\partial_o\Phi(x),\quad (\Box+m^2)\Phi(x)=0, \tag{A3}$$

and the generators of the Poincaré group are

$$P^\mu=\int d^3x\, j^{0\mu}(x),$$

$$M^{\mu\nu}=\int d^3x(x^\mu j^{0\nu}-x^\nu j^{0\mu}). \tag{A4}$$

The canonical Poisson brackets are (see Ref. 11)

$$\{\Phi(\mathbf{x},x^0),\Pi(\mathbf{x}',x^0)\}=\delta^3(\mathbf{x}-\mathbf{x}'), \tag{A5}$$

with the other Poisson brackets vanishing.

The Poincaré algebra is

$$\{P^\mu,P^\nu\}=0, \tag{A6}$$

$$\{M^{\mu\nu},P^\rho\}=P^\mu\eta^{\nu\rho}-P^\nu\eta^{\mu\rho}, \tag{A7}$$

$$\{M^{\mu\nu},M^{\rho\lambda}\}=M^{\mu\lambda}\eta^{\nu\rho}+\eta^{\mu\lambda}M^{\nu\rho}-M^{\mu\rho}\eta^{\nu\lambda}-\eta^{\mu\rho}M^{\nu\lambda}. \tag{A8}$$

The Fourier expansion of the field is

$$\Phi(\mathbf{x},t)=\int \tilde{d}k[a(\mathbf{k})e^{-i(k\cdot x)}+\overline{a(\mathbf{k})}e^{i(k\cdot x)}], \tag{A9}$$

where c.c. means the complex conjugate, and $(\cdot)$ is the usual Lorentz invariant scalar product between four-vectors, and (we use the notations of Ref. 20)

$$\tilde{d}k = \frac{d^3k}{\Omega(k)}, \quad \Omega(\mathbf{k}) = (2\pi)^3 2\omega(\mathbf{k}),$$

$$\mathbf{k} \equiv \{k^i\} \quad (i=1,2,3), \quad k_i = -k^i, \tag{A10}$$

$$\omega(\mathbf{k}) = k_o = \sqrt{\mathbf{k}^2 + m^2}.$$

If we denote with $\hat{\Phi}(\mathbf{k},t)$ the Fourier transform of the field, with respect to the measure d^3k, then

$$\Phi(\mathbf{x},t) = \int d^3k\, \hat{\Phi}(\mathbf{k},t) e^{i\mathbf{k}\cdot\mathbf{x}}, \tag{A11}$$

with

$$\overline{\hat{\Phi}}(\mathbf{k},t) = \hat{\Phi}(-\mathbf{k},t), \tag{A12}$$

and

$$a(\mathbf{k}) = \frac{1}{2}\Omega(\mathbf{k}) e^{i\omega(\mathbf{k})t}\left[\hat{\Phi}(\mathbf{k},t) + \frac{i}{\omega(\mathbf{k})}\dot{\hat{\Phi}}(\mathbf{k},t)\right]. \tag{A13}$$

From this we have the bound

$$|a(\mathbf{k})|^2 \leqslant (2\pi)^6 [\mathbf{k}^2 |\hat{\Phi}(\mathbf{k},t)|^2 + |\dot{\hat{\Phi}}(\mathbf{k},t)|^2]. \tag{A14}$$

Since we have assumed that $\Phi(\mathbf{x},\cdot)$, $\dot{\Phi}(\mathbf{x},\cdot)$ and $\boldsymbol{\nabla}\Phi(\mathbf{x},\cdot)$ are functions in $L^2(R^3)$, from the Parseval identity we get that $a(\mathbf{k}) \in L^2(R^3)$.

This implies the existence of P^μ, but not of $M^{\mu\nu}$. This last will be assured if we assume $\boldsymbol{\nabla} a(\mathbf{k}) \in L^2(R^3)$. So $a(\mathbf{k})$ will go to zero as $|\mathbf{k}| \to \infty$.

The conjugate momentum is

$$\Pi(x) = -i \int \tilde{d}k\, \omega(\mathbf{k}) [a(\mathbf{k}) e^{-i(k\cdot x)} - \overline{a}(\mathbf{k}) e^{i(k\cdot x)}]. \tag{A15}$$

The Poisson brackets for the Fourier coefficients are

$$\{a(\mathbf{k}), \overline{a}(\mathbf{k}')\} = -i\Omega(\mathbf{k}) \delta^3(\mathbf{k} - \mathbf{k}'), \tag{A16}$$

with the other Poisson brackets vanishing.

The Fourier coefficients in terms of the field are given by

$$a(\mathbf{k}) = \int d^3x\, e^{i(k\cdot x)} [\omega(\mathbf{k})\Phi(x) + i\Pi(x)]. \tag{A17}$$

In terms of the Fourier coefficients the Poincaré generators are the following:

$$P^\mu = \int \tilde{d}k\, k^\mu \overline{a}(\mathbf{k}) a(\mathbf{k}), \tag{A18}$$

$$M^{ij} = -i \int \tilde{d}k\, \overline{a}(\mathbf{k}) \left(k^i \frac{\partial}{\partial k^j} - k^j \frac{\partial}{\partial k^i} \right) a(\mathbf{k}) = \overline{M}^{ij}, \tag{A19}$$

$$M_{0j}=tP_j-i\int \tilde{d}k\,\overline{a(\mathbf{k})}\,\omega(\mathbf{k})\,\frac{\partial}{\partial k^j}a(\mathbf{k})=-M^{jo}=\overline{M}^{0j}. \tag{A20}$$

We define

$$M'^{0j}=-i\int \tilde{d}k\,\overline{a(\mathbf{k})}\,\omega(\mathbf{k})\,\frac{\partial}{\partial k^j}a(\mathbf{k}),\quad M'^{ij}=M^{ij}, \tag{A21}$$

where M'^{ij} and M'^{0j} have the same Poisson algebra as M^{ij} and M^{0j}, and will be used as the Lorentz generators.

APPENDIX B: THE EIGENFUNCTIONS OF THE LAPLACE–BELTRAMI OPERATOR AND THE ACTION OF THE LORENTZ GENERATORS

1. The eigenfunctions of the Laplace–Beltrami operator

The eigenfunctions of the continuous spectrum of the Laplace–Beltrami operator, corresponding to $\lambda\in[1,\infty)$, have been studied in Ref. 13. However, we are also interested in the non-normalizable solutions of the equation,

$$(-\Delta|_x-\lambda)v_{\lambda,l,m}=0, \tag{B1}$$

for other values of λ.

A fundamental system of solutions, in the neighborhood of the origin, that is for $r\simeq 0$, of Eq. (B1) in spherical coordinates, is

$$v^{(o)}_{1,\lambda,l,m}(\mathbf{r})=u^{(o)}_{1,\lambda,l}(r)Y_{l,m}(\theta,\phi),\quad v^{(o)}_{2,\lambda,l,m}(\mathbf{r})=u^{(o)}_{2,\lambda,l}(r)Y_{l,m}(\theta,\phi), \tag{B2}$$

where $r=|\mathbf{k}|/m$, $Y_{l,m}$ are the spherical harmonics as defined in Ref. 21, and

$$\begin{aligned} u^{(o)}_{1,\lambda,l}(r)&=r^lF\left(\frac{l+1+i\Lambda}{2},\frac{l+1-i\Lambda}{2};l+\frac{3}{2};-r^2\right),\\ u^{(o)}_{2,\lambda,l}(r)&=r^{-l-1}F\left(-\frac{l+i\Lambda}{2},-\frac{l-i\Lambda}{2};\frac{1}{2}-l;-r^2\right),\end{aligned} \tag{B3}$$

$$(u^{(o)}_{2,\lambda,l}(r)=u^{(o)}_{1,\lambda,-l-1}(r)), \tag{B4}$$

where F is the hypergeometric function.

The relation between λ and Λ is given by $\lambda=1+\Lambda^2$, with $\operatorname{Im}\Lambda\geqslant 0$, as in Sec. III.

A fundamental system in the neighborhood of the point at infinite $r\simeq\infty$ is

$$v^{(\infty)}_{1,\lambda,l,m}(\mathbf{r})=u^{(\infty)}_{1,\lambda,l}(r)Y_{l,m}(\theta,\phi),\quad v^{(\infty)}_{2,\lambda,l,m}(\mathbf{r})=u^{(\infty)}_{2,\lambda,l}(r)Y_{l,m}(\theta,\phi), \tag{B5}$$

where

$$\begin{aligned} u^{(\infty)}_{1,\lambda,l}(r)&=r^{-1-i\Lambda}F\left(\frac{l+1+i\Lambda}{2},-\frac{l-i\Lambda}{2};1+i\Lambda;-\frac{1}{r^2}\right),\\ u^{(\infty)}_{2,\lambda,l}(r)&=r^{-1+i\Lambda}F\left(\frac{l+1-i\Lambda}{2},-\frac{l+i\Lambda}{2};1-i\Lambda;-\frac{1}{r^2}\right).\end{aligned} \tag{B6}$$

For $r \geqslant 0$ no other singular points are met. For the argument $z=-1$, the hypergeometric series is absolutely convergent, since the coefficients of $F(\alpha,\beta;\gamma;z)$ satisfy the condition [see Eq. (3.22)]

$$\alpha+\beta-\gamma=-\tfrac{1}{2}. \tag{B7}$$

If $i\Lambda$ is a positive integer, the solution $u^{(\infty)}_{1,\lambda,l}(r)$ requires a modification of the expression given in Eq. (B6). However, since we are only interested in the solution $u^{(o)}_{1,\lambda,l}(r)$ for $\mathrm{Im}\,\Lambda \geqslant 0$, here we do not give the necessary modification.

We are interested in the normalization properties of these solutions in the neighborhood of the points 0 and ∞, with respect to the invariant measure,

$$\tilde{d}r=\frac{d^3r}{\sqrt{1+r^2}}. \tag{B8}$$

The solution $v^{(o)}_{1,\lambda,l,m}$ is regular and normalizable in the neighborhood of the origin. The solution $v^{(o)}_{2,\lambda,l,m}$ on the other hand is normalizable in the neighborhood of origin for $l=0,1$ only. We will discard this solution, even in the case $l=0,1$, since under the action of the Lorentz generators it will be transformed into a solution with a different value of l, thus becoming non-normalizable in the neighborhood of origin. See also the discussion at the end of subsection 2.

The solution $u^{(o)}_{1,\lambda,l}$ can be analytically continued to $r\simeq\infty$, and, for a generic value of Λ, has an asymptotic expansion which is a linear combination of the two powers of r [see Eq. 2.10(2) of Ref. 22],

$$r^{-1-i\Lambda}, \quad r^{-1+i\Lambda}, \tag{B9}$$

and, for a real Λ, is normalizable in the sense of the continuous spectrum.

For real values of $\Lambda\in[0,\infty)$, $v^{(o)}_{1,\lambda,l,m}$ is an eigenfunction of the operator Δ, see Ref. 13, belonging to the continuous spectrum.

In the case $\lambda=-3$, that is $\Lambda=2i$, we must use another asymptotic expansion. In general, for $\Lambda=ni$, with an n integer, we must use the expansion given in Eq. 2.10(7) of Ref. 22; for $\Lambda=2i$ and for $r\to\infty$ we get

$$u^{(o)}_{1,-3,l}\simeq r+O(r^{-1}). \tag{B10}$$

So, this solution is no more normalizable at ∞, but only at 0.

The other solution at $r\simeq\infty$ has the behavior

$$u^{(o)}_{2,-3,l}\simeq r+O(r^{-1}), \quad \text{for } l=0,1; \tag{B11}$$

$$u^{(o)}_{2,-3,l}\simeq r+O(r^{-3}), \quad \text{for } l\geqslant 2, \tag{B12}$$

and is singular at the origin for $l>0$. So it is not normalizable at $r\simeq\infty$.

As for the second fundamental system given in Eqs. (B5) and (B6) they are linear combinations of the first set, since they can be obtained by analytic continuation using well known relations. The solution $u^{(\infty)}_{1,\lambda,l}$ has, for $r\simeq\infty$, the asymptotic behavior

$$r^{-1+\mathrm{Im}\,\Lambda-i\,\mathrm{Re}\,\Lambda}, \tag{B13}$$

and, for $\mathrm{Im}\,\Lambda\geqslant 0$, is not normalizable.

The second solution $u^{(\infty)}_{2,\lambda,l,m}$ is instead normalizable for $r\simeq\infty$.

The solutions $w_{l,m}=v^{(o)}_{1,-3,l,m}$ satisfy the following inequality:

$$|w_{l,m}(\mathbf{k})|\leqslant\sqrt{\frac{2l+1}{4\pi}}\sqrt{1+r^2}M_l\,, \tag{B14}$$

where

$$M_l=\frac{\Gamma(l+(3/2))\Gamma(2)}{\Gamma((l/2)+2)\Gamma(l/2)},\quad \text{if } l\geqslant 2,$$
$$M_l=1,\quad \text{if } l=0,1. \tag{B15}$$

Indeed, since

$$|Y_{l,m}(\theta,\phi)|\leqslant\sqrt{\frac{2l+1}{4\pi}}, \tag{B16}$$

and

$$u_l(r)=r^lF\left(\frac{l-1}{2},\frac{l+3}{2};l+\frac{3}{2};-r^2\right)=r^l(1+r^2)^{(1-l)/2}F\left(\frac{l-1}{2},\frac{l}{2};l+\frac{3}{2};\frac{r^2}{1+r^2}\right), \tag{B17}$$

using Eq. 2.9(3) of Ref. 22, and the bounds

$$0\leqslant\frac{r^2}{1+r^2}<1, \tag{B18}$$

$$|F(\alpha,\beta;\gamma;x)|\leqslant F(\alpha,\beta;\gamma;1)=\frac{\Gamma(\gamma-\alpha-\beta)\Gamma(\gamma)}{\Gamma(\gamma-\alpha)\Gamma(\gamma-\beta)}, \tag{B19}$$

where the last holds if $\alpha,\beta,\gamma>0$ and $\gamma-\alpha-\beta>0$, we have from Eq. (B17),

$$|u_l(r)|\leqslant r^l(1+r^2)^{(1-l)/2)}\frac{\Gamma(2)\Gamma(l+(3/2))}{\Gamma((l/2)+2)\Gamma((l+3)/2)}. \tag{B20}$$

Now

$$r^l(1+r^2)^{(1-l)/2}\leqslant\sqrt{1+r^2}, \tag{B21}$$

and collecting the results we get the inequality (B14) for $l\geqslant 2$.

For $l=0,1$ the last hypergeometric function in Eq. (B17) is equal to 1, and we get the inequality (B14) for $l=0,1$.

The inequality (B14) for $w_{l,m}$ implies the existence of the integrals $P_{l,m}$ defined in Eq. (5.1). Indeed,

$$|P_{l,m}|\leqslant\int\tilde{d}k|w_{l,m}(\mathbf{k})|\overline{a}(\mathbf{k})a(\mathbf{k})\leqslant\sqrt{\frac{2l+1}{4\pi}}M_l\frac{P_0}{m}. \tag{B22}$$

So, if P_0 exists, all the integrals $P_{l,m}$ will similarly exist.

2. The action of the Lorentz generators

Let us determine the action of the generators of the Lorentz group on the solutions $v^{(o)}$. The explicit expression of the generators is

$$L_3=-i\frac{\partial}{\partial\phi},\quad L_\pm=L_1\pm iL_2=e^{\pm i\phi}\left(\pm\frac{\partial}{\partial\theta}+i\cot\theta\frac{\partial}{\partial\phi}\right),$$

$$K_3=i\sqrt{1+r^2}\left(\cos\theta\frac{\partial}{\partial r}-\frac{\sin\theta}{r}\frac{\partial}{\partial\theta}\right), \tag{B23}$$

$$K_\pm=i\sqrt{1+r^2}e^{\pm i\phi}\left(\sin\theta\frac{\partial}{\partial r}+\frac{\cos\theta}{r}\frac{\partial}{\partial\theta}\pm\frac{i}{r\sin\theta}\frac{\partial}{\partial\phi}\right).$$

They satisfy the algebra

$$\begin{aligned}
&[L_+,L_-]=2L_3,\quad [L_3,L_\pm]=\pm L_\pm,\\
&[K_+,K_-]=-2L_3,\quad [K_3,K_\pm]=\mp L_\pm,\\
&[K_3,L_3]=0,\quad [K_3,L_\pm]=\pm K_\pm,\\
&[L_3,K_\pm]=\pm K_\pm,\quad [K_\pm,L_\pm]=0.
\end{aligned} \tag{B24}$$

The action of L_3 and $L_\pm$ is the usual one,

$$\begin{aligned}
&L_3 v_{..,\lambda,l,m}=m v_{..,\lambda,l,m},\\
&L_\pm v_{..,\lambda,l,m}=\sqrt{l(l+1)-m(m\pm 1)}\;v_{..,\lambda,l,m\pm 1}.
\end{aligned} \tag{B25}$$

For the action of K_3 and $K_\pm$ we will use the following formulas:

$$\frac{d}{dr}F(a_l,b_l;c_l;-r^2)=-\frac{r}{2\sqrt{1+r^2}}\frac{(2a_l)(2b_l)}{c_l}F(a_{l+1},b_{l+1};c_{l+1};-r^2), \tag{B26}$$

$$\begin{aligned}
\frac{d}{dr}[r^lF(a_l,b_l;c_l;-r^2)]=(2l+1)\frac{r^{l-1}}{\sqrt{1+r^2}}F(a_{l-1},b_{l-1};c_{l-1};-r^2)\\
-(l+1)r^{l-1}F(a_l,b_l;c_l;-r^2),
\end{aligned} \tag{B27}$$

where $F(a_l,b_l;c_l;-r^2)$ is the hypergeometric function and where, see Eq. (3.22),

$$a_l+b_l+\tfrac{1}{2}=c_l. \tag{B28}$$

Equation (B26) can be obtained by using Eqs. 2.11(10) and 2.8(20) of Ref. 22, and Eq. (B27) using Eqs. 2.8(27) and 2.11(10) of the same reference.

Moreover, we will use the properties of the spherical harmonics,[21]

$$\cos\theta\;Y_{l,m}(\theta,\phi)=C_{l+1,m}Y_{l+1,m}(\theta,\phi)+C_{l,m}Y_{l-1,m}(\theta,\phi), \tag{B29}$$

where

$$C_{l,m}=\sqrt{\frac{(l-m)(l+m)}{(2l-1)(2l+1)}}, \tag{B30}$$

and

$$\sin\theta\frac{\partial}{\partial\theta}Y_{l,m}(\theta,\phi)=l\cos\theta\;\; Y_{l,m}(\theta,\phi)-\sqrt{\frac{(2l+1)(l^2-m^2)}{(2l-1)}}Y_{l-1,m}(\theta,\phi). \tag{B31}$$

With these relations we get

$$K_3 v^{(o)}_{1,\lambda,l,m}=-i\frac{(l+1+i\Lambda)(l+1-i\Lambda)}{(2l+3)}C_{l+1,m}v^{(o)}_{1,\lambda,l+1,m}+i(2l+1)C_{l,m}v^{(o)}_{1,\lambda,l-1,m}, \tag{B32}$$

and

$$K_\pm v^{(o)}_{1,\lambda,l,m}=\pm i\Bigg[\frac{(l+1+i\Lambda)(l+1-i\Lambda)}{(2l+3)}\sqrt{\frac{(l+1\pm m)(l+2\pm m)}{(2l+1)(2l+3)}}v^{(o)}_{1,\lambda,l+1,m\pm1}$$
$$+(2l+1)\sqrt{\frac{(l\mp m)(l\mp m-1)}{(2l-1)(2l+1)}}v^{(o)}_{1,\lambda,l-1,m\pm1}\Bigg]. \tag{B33}$$

For the solution $v_{2,\lambda,l,m}$ we get similarly

$$K_3 v^{(o)}_{2,\lambda,l,m}=+i\frac{(l+i\Lambda)(l-i\Lambda)}{(2l-1)}C_{l,m}v^{(o)}_{2,\lambda,l-1,m}-i(2l+1)C_{l+1,m}v^{(o)}_{2,\lambda,l+1,m}, \tag{B34}$$

and

$$K_\pm v^{(o)}_{2,\lambda,l,m}=\pm i\Bigg[\frac{(l+i\Lambda)(l-i\Lambda)}{(2l-1)}\sqrt{\frac{(l\mp m)(l-1\mp m)}{(2l-1)(2l+1)}}v^{(o)}_{2,\lambda,l-1,m\pm1}$$
$$+(2l+1)\sqrt{\frac{(l+1\pm m)(l+2\pm m)}{(2l+1)(2l+3)}}v^{(o)}_{2,\lambda,l+1,m\pm1}\Bigg]. \tag{B35}$$

If we put $\Lambda=2i$ we get for

$$w_{l,m}=v^{(o)}_{1,-3,l,m},\qquad w'_{l,m}=v^{(o)}_{2,-3,l,m}, \tag{B36}$$

$$K_3 w_{l,m}=-i\frac{(l-1)(l+3)}{(2l+3)}C_{l+1,m}w_{l+1,m}+i(2l+1)C_{l,m}w_{l-1,m}, \tag{B37}$$

$$K_\pm w_{l,m}=\pm i\Bigg[\frac{(l-1)(l+3)}{(2l+3)}\sqrt{\frac{(l+1\pm m)(l+2\pm m)}{(2l+1)(2l+3)}}w_{l+1,m\pm1}$$
$$+(2l+1)\sqrt{\frac{(l\mp m)(l\mp m-1)}{(2l-1)(2l+1)}}w_{l-1,m\pm1}\Bigg]. \tag{B38}$$

$$K_3 w'_{l,m}=+i\frac{(l-2)(l+2)}{(2l-1)}C_{l,m}w'_{l-1,m}-i(2l+1)C_{l+1,m}w'_{l+1,m}, \tag{B39}$$

$$K_\pm w'_{l,m}=\pm i\Bigg[\frac{(l-2)(l+2)}{(2l-1)}\sqrt{\frac{(l\mp m)(l-1\mp m)}{(2l-1)(2l+1)}}w'_{l-1,m\pm1}$$
$$+(2l+1)\sqrt{\frac{(l+1\pm m)(l+2\pm m)}{(2l+1)(2l+3)}}w'_{l+1,m\pm1}\Bigg]. \tag{B40}$$

In the previous formulas, the terms on the right hand side with the function $w_{l,m}$ with l negative or with $|m|>l$ are to be considered zero.

Referring to Eq. (B37) and (B38), observe that the representation subspace corresponding to the values of $l=0,1$ is an invariant subspace. This is due to the factor $(l-1)$.

Similarly, looking at Eq. (B39) and (B40), we see that the subspace corresponding to the values $l\geqslant 2$ is invariant.

Let us define the matrices corresponding to the representations $w_{l,m}$ and $w'_{l,m}$,

$$Mw_{l,m}=w_{l',m'}(M)_{l',m';l,m}, \quad Mw'_{l,m}=w'_{l',m'}(M')_{l',m';l,m}, \tag{B41}$$

where M is any one of the Lorentz generators.

If we define the new bases,

$$\hat{w}_{l,m}=N_l w_{l,m}, \quad \text{and} \quad \hat{w}'_{l,m}=N'_l w'_{l,m}, \tag{B42}$$

with

$$N_l=N'_l=\frac{1}{\sqrt{2l+1}}, \tag{B43}$$

we get for the new matrices

$$(\hat{M})_{l',m';l,m}=\frac{N_l}{N_{l'}}(M)_{l',m';l,m}, \tag{B44}$$

$$(\hat{M}')_{l',m';l,m}=\frac{N_l}{N_{l'}}(M')_{l',m';l,m}, \tag{B45}$$

the relation

$$(\hat{M}')^{\dagger}=\hat{M}. \tag{B46}$$

That is, the representation $\hat{w}'_{l,m}$ is the adjoint of the representation $\hat{w}_{l,m}$.[14]

Involutive automorphisms and Iwasawa decomposition of some hyperbolic Kac–Moody algebras

K. C. Pati, D. Parashar, and R. S. Kaushal[a]
Department of Physics and Astrophysics, University of Delhi, Delhi-110 007, India

(Received 13 July 1998; accepted for publication 11 August 1998)

The involutive automorphisms of hyperbolic Kac–Moody algebras are computed from Satake diagrams of these algebras which are then used to furnish a general procedure of their Iwasawa decomposition. In particular $\hat{A}_1^{(1)}$ and $\hat{A}_2^{(1)}$ are considered as representative examples to illustrate the efficacy of the underlying treatment. © *1999 American Institute of Physics.* [S0022-2488(99)01501-7]

I. INTRODUCTION

It is now widely accepted that the study of infinite dimensional Lie algebras[1,2] and more particularly the hyperbolic version of Kac–Moody algebras[3,4] has played an outstanding role in the realms of string theory (with special reference to the over extended exceptional algebra E_{10}), duality properties of supersymmetric gauge theories,[5] and two-dimensional field theories.[6] This lends sufficient credence to the desirability of studying the classification theory and representations of hyperbolic Kac–Moody algebras. While the Dynkin diagrams[7] and root spaces[8–12] of such algebras have already been exhaustively investigated and classified, a complete analysis of their representations has not yet been achieved to that extent. We shall, therefore, make a modest attempt to address this problem in the present communication.

Here we carry out the Iwasawa decomposition[9] of the hyperbolic Kac–Moody algebras. The involutive automorphisms required for such a decomposition are determined from the Satake diagrams of these algebras. In addition, these diagrams are capable of providing the real forms of Lie algebras[13–15] and their supersymmetric extensions.[16] In a recent work, this technique has been exploited to obtain the involutive automorphisms of affine Kac–Moody algebras[17–19] and superalgebras.[20] Here we shall expound that the same technique can be employed to generate involutive automorphisms of hyperbolic Kac–Moody algebras once their Satake diagrams have been constructed. The essential ingredients entering the method comprise the root system and the associated Dynkin diagrams which eventually lead to the construction of Satake diagrams within the framework of a standard prescription outlined earlier.

Before embarking on a systematic analysis, it is prudent to emphasize that the generalized Kac–Moody algebras (GKMA) differ from the finite simple Lie algebras (FSLA) or the affine Kac–Moody algebras (AKMA) in terms of their Cartan matrices. While the determinant of the Cartan matrix is positive for FSLA and zero for AKMA, it can be anything for the GKMA. The hyperbolic Kac–Moody algebras are those types of GKMA which fall back to the case of AKMA or FSLA on deletion of any one simple root from their Dynkin diagrams. Fortunately, the Dynkin diagrams[7] of all such algebras are known. It is instructive to distinguish between two types of hyperbolic Kac–Moody algebras, namely, (i) the strictly hyperbolic one which yields only FSLA Dynkin diagrams on deletion of any one vertex, with maximum allowed rank being 4 and (ii) the hyperbolic one whose Dynkin diagram reverts to those of FSLA or AKMA on deletion of any vertex, with the maximum allowed rank being 10 in this case. However, note must be taken of the fact that there is no hyperbolic Kac–Moody algebra of rank larger than 10. Furthermore, though there are infinitely many hyperbolic Kac–Moody algebras of rank 2, the number of these algebras of rank from 3 to 10 is necessarily finite. However, for Iwasawa decomposition[19] we restrict ourselves to only those types of hyperbolic Kac–Moody algebras which are extensions of the

[a]UGC Research Scientist.

affine algebras by a basic representation, since the root system of these types of algebras is less complicated than their other counterparts.

The outline for the construction of Satake diagrams of the hyperbolic Kac–Moody algebras are briefly delineated in Sec. II. All possible Satake diagrams of $\hat{A}_1^{(1)}$ and $\hat{A}_2^{(1)}$ along with their root automorphisms are computed in detail and listed in Tables I and II, respectively. Section III is devoted to a quick resume of the procedure for obtaining the Iwasawa decomposition within the present context. The explicit construction of this decomposition is then carried out for the hyperbolic Kac–Moody algebras $\hat{A}_1^{(1)}$ and $\hat{A}_2^{(1)}$. Section IV contains a few concluding remarks.

II. HYPERBOLIC KAC–MOODY ALGEBRAS AND SATAKE DIAGRAMS

We commence this section by taking a look at the hyperbolic Kac–Moody algebras $\hat{G}$ which are extensions of affine algebras G by a basic representation and the construction of the Satake diagrams. Let (a_{ij}), $i,j=0,1,...,r$, be the Cartan matrix of G and e_{α_i}, $e_{-\alpha_i}$, h_{α_i} be the generators associated with the simple roots α_i. By convention, the root α_0 is the extended root of the affine algebra G and the remaining roots α_j, $(j=1,...,r)$ are those of the associated finite simple Lie algebra. We can extend G by a derivation d which commutes with Cartan generators h_{α_i} and $[d,e_{\alpha_i}]=-\delta_{i,0}e_{\alpha_i}$, $[d,e_{-\alpha_i}]=\delta_{i,0}e_{-\alpha_i}$. The Cartan matrix $\hat{a}$ of the extension of G is defined by $\hat{a}_{ij}=a_{ij}$ for $i,j=0,1,...,r$, $\hat{a}_{i,-1}=\hat{a}_{-1,i}=-\delta_{i,0}$. The algebra $\hat{G}$ is thus of rank $(r+1)$. The root α_{-1} is usually referred to as the overextended root. The algebra $\hat{G}$ can be defined as the algebra generated by the elements $\{e_{\alpha_i}, e_{-\alpha_i}, h_{\alpha_i}, i=-1,0,1,...,r\}$ with relations

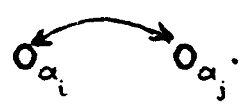
$$\begin{gathered}[h_{\alpha_i},h_{\alpha_j}]=0, \quad [e_{\alpha_i},e_{-\alpha_j}]=\delta_{ij}h_{\alpha_i}, \quad [e_{\pm\alpha_j},h_i]=a_{ij}e_{\pm\alpha_j}, \\ (ad\ e_{\alpha_i})^{1-\alpha_{ij}}e_{\alpha_j}=(ad\ e_{-\alpha_i})^{1-a_{ij}}e_{-\alpha_i}=0, \quad i\neq j.\end{gathered} \tag{2.1}$$

We can now associate to each simple root system a Dynkin diagram, the details of which can be found in Ref. 7. The construction of Satake diagrams for hyperbolic Kac–Moody algebra is achieved with the help of the following prescription.

Let R be a root system of hyperbolic Kac–Moody algebra. For $\alpha\in R$, let $\overline{\alpha}=\alpha-\sigma(\alpha)$, where σ is the involutive automorphisms of root α. Let us introduce $R_-=\{\overline{\alpha}|\overline{\alpha}\neq 0,\alpha\in R\}$ and $R_0=\{\alpha\in R|\overline{\alpha}=0\}$. If B_- (resp. B) denotes the basis of R_- (resp. R) and B_0 a basis of R_0 then $B=B\cap R_0$. If $B_-=B\setminus B_0=\{\alpha_i\}$ and $B_0=\{\beta_l\}$, then it can be shown that

$$-\sigma(\alpha_i)=\alpha_{\pi(i)}+\sum_l \eta_{il}\beta_l, \tag{2.2}$$

where π is the involutive permutation of $\{-1,0,1,...,r\}$ and η_{il} are non-negative integers. We should note that $\sigma(\beta_l)=\beta_l$ and $\alpha+\sigma(\alpha)\notin R\forall\alpha\in R$. We can now associate with B its Satake diagrams. In the Dynkin diagram of B denote the roots α_i by the usual white circles ○ and roots β_l by the black circles ●. If $\pi(i)=j$, then it is indicated by



Satake diagrams determine the involution of R uniquely. As an illustration, we restrict ourselves to the consideration of two examples $\hat{A}_1^{(1)}$ and $\hat{A}_2^{(1)}$.

A. Satake diagrams of $\hat{A}_1^{(1)}$

The Cartan matrix of $\hat{A}_1^{(1)}$ is

$$\begin{bmatrix} 2 & -2 & 0 \\ -2 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix}.$$

The three simple roots of $\hat{A}_1^{(1)}$ are α_1, α_0, and α_{-1}. The possible Satake diagrams of $\hat{A}_1^{(1)}$ along with their root automorphisms are represented in Table I.

B. Satake diagrams of $\hat{A}_2^{(1)}$

The Cartan matrix of $\hat{A}_2^{(1)}$ is

$$\begin{bmatrix} 2 & -1 & -1 & 0 \\ -1 & 2 & -1 & 0 \\ -1 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{bmatrix}$$

and the four simple roots of $\hat{A}_2^{(1)}$ are α_1, α_2, α_0, and α_{-1}, where $\alpha_0 = \delta - (\alpha_1 + \alpha_2)$. The possible Satake diagrams of $\hat{A}_2^{(1)}$ along with their root automorphisms can be read from Table II.

III. IWASAWA DECOMPOSITION OF HYPERBOLIC KAC–MOODY ALGEBRAS

The notion of direct determination of Iwasawa decomposition of Lie algebras is now extended to the case of hyperbolic Kac–Moody algebras. Let $\mathbf{G}$ be a real hyperbolic Kac–Moody algebra generated from its compact real form $\hat{\mathbf{G}}_k$ by an involutive automorphism defined with respect to the Cartan subalgebra $\mathbf{h}$ of $\hat{\mathbf{G}}_c$, where $\hat{\mathbf{G}}_c$ is the complexification of $\hat{\mathbf{G}}$. The following commutation relations are satisfied by the elements of $\hat{\mathbf{G}}_c$:

$$[e_\alpha, h] = \alpha(h) e_\alpha, \quad h \in \mathbf{h}, \quad \alpha \in \Delta,$$

$$[e_\alpha, e_\beta] = \begin{cases} N_{\alpha\beta} e_{\alpha+\beta} & \text{if } \alpha+\beta \text{ is a root} \\ 0 & \text{otherwise,} \end{cases} \tag{3.1}$$

$$[e_\alpha, e_{-\alpha}] = h_\alpha, h_\alpha \in \mathbf{h}.$$

Here Δ denotes the set of roots of $\hat{\mathbf{G}}_c$ w.r.t. $\mathbf{h}$ and the Killing form is defined by $B(e_\alpha, e_{-\alpha}) = -1$. Here $\alpha(h) = B(h, h_\alpha)$. The compact real form $\hat{\mathbf{G}}_k$ may be taken to consist of ih_α, $\alpha = \alpha_{-1}, \alpha_0, \alpha_1, \ldots, \alpha_r$ and $(e_\alpha + e_{-\alpha})$, $i(e_\alpha - e_{-\alpha}) \forall \alpha \in \Delta$. Let $\mathbf{k}$ be the maximal compact subalgebra of $\hat{\mathbf{G}}$ defined in such a way that $a \in \mathbf{k}$ if $a \in \hat{\mathbf{G}}$ and $\sigma a = a$. Let $\mathbf{p}$ be the subspace such that $a \in \mathbf{p}$ if $a \in \hat{\mathbf{G}}_c$ and $\sigma a = -a$. Thus, $\mathbf{k}$ and $\mathbf{p}$ are given by

$$\mathbf{k} = \{ih_\alpha, \alpha = \alpha_{-1}, \alpha_0, \alpha_1, \ldots, \alpha_r \text{ and } (e_\alpha + e_{-\alpha}), i(e_\alpha - e_{-\alpha}) \forall \alpha | \exp \alpha(h) = +1\}, \tag{3.2}$$

(ii) 	$-\sigma(\alpha_1)=\alpha_2$ $-\sigma(\alpha_2)=\alpha_1$ $-\sigma(\alpha_0)=\alpha_0$ $-\sigma(\alpha_{-1})=\alpha_{-1}$
(iii) 	$\sigma(\alpha_1)=\alpha_i$ $-\sigma(\alpha_1)=\alpha_0+\alpha_2$ $-\sigma(\alpha_2)=\alpha_0+\alpha_1$ $\sigma(\alpha_2)=\alpha_2$ $-\sigma(\alpha_0)=\alpha_1+\alpha_2$ $-\sigma(\alpha_0)=\alpha_1+\alpha_2$ $-\sigma(\alpha_{-1})=\alpha_{-1}$ $-\sigma(\alpha_{-1})=\alpha_{-1}$
(iv) 	$\sigma(\alpha_1)=\alpha_1$ $\sigma(\alpha_2)=\alpha_2$ $-\sigma(\alpha_0)=\alpha_0+2\alpha_1+2\alpha_2$ $-\sigma(\alpha_0)=\alpha_{-1}$

$$\mathbf{p}=\{i(e_\alpha+e_{-\alpha}),(e_\alpha-e_{-\alpha})\forall\alpha|\exp\ \alpha(h)=-1\}. \tag{3.3}$$

Let $\mathbf{a}$ be the maximal Abelian subalgebra of $\mathbf{p}$ with dimension $|m_i|$ and $\mathbf{m}$ be the centralizer of $\mathbf{a}$ in $\mathbf{k}$. Thus, $\mathbf{a}$ may be taken to have a basis consisting of the elements of the form $i(e_\alpha+e_{-\alpha})$. Let R_A denote the set of positive roots α that appear in this way in $\mathbf{a}$. Similarly, $\mathbf{m}$ may be taken to have a basis consisting of the elements of the form $(e_\alpha+e_{-\alpha})$, with a set of positive roots α appearing this way in $\mathbf{m}$, being denoted by R_M, together possibly with some elements of $\mathbf{h}\cap\hat{\mathbf{G}}$. If $h''\in\mathbf{h}\cap\hat{\mathbf{G}}$ is a member of $\mathbf{m}$, then $\alpha(h'')=0\forall\alpha\in R_A\cup R_M$. Complexification of $\mathbf{a}\oplus\mathbf{m}$ together with the derivation d' gives a Cartan subalgebra $\mathbf{h}'$ of $\hat{\mathbf{G}}_c$ with basis $H'_{-1},H'_0,H'_1,\ldots,d'$. Now there exists an inner automorphism V: $\mathbf{h}'\rightarrow\mathbf{h}$, i.e.,

$$H_j=VH'_j,\ \ \text{where}\ \ V=\prod_\alpha V_\alpha,\ \ \alpha\in\Delta. \tag{3.4}$$

Let Δ^+ be the set of positive roots, then

$$h_\alpha=\sum_{j=-1}^{r} b_j(\alpha)H_j. \tag{3.5}$$

Thus, $\alpha\in\Delta^+$ iff $b_j(\alpha)>0$, where j is the least index such that $b_j(\alpha)\neq 0$. The positive roots can be again divided into the following classes:

$$\text{(i)}\ \ \Delta_+^+=\{\alpha|\alpha\in\Delta^+,\ \ \alpha(h)\neq\alpha(V\sigma V^{-1}h)\forall h\in\mathbf{h}\}, \tag{3.6}$$

$$\text{(ii)}\quad \Delta_{-}^{+}=\{\alpha|\alpha\in\Delta^{+},\ \ \alpha(h)=\alpha(V\sigma V^{-1}h)\forall h\in\mathbf{h}\}. \tag{3.7}$$

Let the subalgebra $\tilde{\mathbf{n}}$ be spanned by the elements $V^{-1}e_{\alpha}$ for $\alpha\in\Delta_{+}^{+}$ and $\mathbf{n}=\tilde{\mathbf{n}}\cap\hat{\mathbf{G}}_{c}$, where $\tilde{\mathbf{n}}$ and $\mathbf{n}$ are the nilpotent subalgebras of $\hat{\mathbf{G}}_{c}$ and $\hat{\mathbf{G}}$, respectively. Thus the Iwasawa decomposition of $\hat{\mathbf{G}}$ is given by

$$\hat{\mathbf{G}}=\mathbf{k}\oplus\mathbf{a}\oplus\mathbf{n}. \tag{3.8}$$

A. Iwasawa decomposition of $\hat{A}_{1}^{(1)}$

Let us consider the involutive automorphisms of $\hat{A}_{1}^{(1)}$ determined by any one of the Satake diagrams, say (ii), of Table I. The simple root automorphisms are given by

$$\alpha(\alpha_{1})=\alpha_{1},\quad -\sigma(\alpha_{0})=\alpha_{0}+2\alpha_{1},\quad -\sigma(\alpha_{-1})=\alpha_{-1}. \tag{3.9}$$

The positive roots of $\hat{A}_{1}^{(1)}$ are given by

$$\begin{aligned}\Delta=\{&n_{1}\alpha_{-1}+n_{2}\alpha_{1}+(n_{2}-1)\alpha_{0},\ \ \text{where}\ \ n_{1}=0,1,...,(n_{2}-1);\ \ n_{1}\alpha_{-1}+(n_{2}-1)\alpha_{1}\\ &+n_{2}\alpha_{0},n_{1}\alpha_{-1}+n_{2}(\alpha_{1}+\alpha_{0}),\ \ \text{where}\ \ n_{1}=0,1,...,n_{2}\ \ \text{and}\ \ n_{2}\in Z\}.\end{aligned} \tag{3.10}$$

We can apply the simple root automorphisms to find out the automorphisms of other roots and we see that the positive roots can be separated into categories, i.e.,

$$\exp\ \alpha(h)=+1\quad\text{for}\quad \alpha=n_{1}\alpha_{-1}+n_{2}\alpha_{1}+(n_{2}-1)\alpha_{0}, \tag{3.11}$$

$$\exp\ \alpha(h)=-1\quad\text{for}\quad \alpha=\begin{cases}n_{1}\alpha_{-1}+(n_{2}-1)\alpha_{1}+n_{2}\alpha_{0}\\ n_{1}\alpha_{-1}+n_{2}(\alpha_{1}+\alpha_{0})\end{cases}. \tag{3.12}$$

Thus, for $\hat{A}_{1}^{(1)}$, $\mathbf{k}$ and $\mathbf{p}$ are given by

$$\mathbf{k}=\{ih_{\alpha}\ \ \text{for}\ \ \alpha=\alpha_{-1},\alpha_{0},\alpha_{1}\ \ \text{and}\ \ (e_{\alpha}+e_{-\alpha}),\ \ i(e_{\alpha}-e_{-\alpha})\ \ \text{for}\ \ \alpha\ \ \text{given by Eq. (3.11)}\}, \tag{3.13}$$

$$\mathbf{p}=\{i(e_{\alpha}+e_{-\alpha}),(e_{\alpha}-e_{-\alpha})\ \ \text{for}\ \ \alpha\ \ \text{given by Eq. (3.12)}\}. \tag{3.14}$$

We now select a maximal Abelian subalgebra $\mathbf{a}$ which is one-dimensional and may be chosen to have a basis element

$$H_{-1}'=i(e_{\alpha_{0}}-e_{-\alpha_{0}}). \tag{3.15}$$

In fact, we may also choose $i(e_{\alpha_{-1}}-e_{-\alpha_{-1}})$ as a basis element of $\mathbf{a}$. But we shall see that later on it will pose a problem while calculating the elements of nilpotent subalgebra $\tilde{\mathbf{n}}$ because of the fact that the α_{-1} string containing $n_{1}\alpha_{-1}+(n_{2}-1)\alpha_{1}+n_{2}\alpha_{0}$ or $n_{1}\alpha_{-1}+n_{2}(\alpha_{1}+\alpha_{0})$ or $n_{1}\alpha_{-1}+n_{2}\alpha_{1}+(n_{2}-1)\alpha_{0}$ can have a large number of roots up to infinity. So, now we have $R_{A}=\{\alpha_{0}\}$ and R_{M} is empty. $\mathbf{m}$ is two-dimensional and its basis elements are given by

$$-iH_{0}'=ih_{\alpha_{1}+\alpha_{0}},\quad -iH_{1}'=ih_{2\alpha_{-1}+2\alpha_{0}+\alpha_{1}}. \tag{3.16}$$

Note that H_{-1}',H_{0}',H_{1}' together with scaling element d' are the elements of the Cartan subalgebra $\mathbf{h}'$. The inner automorphism of $\hat{A}_{1}^{(1)}$ is given by the expression

$$V_{\alpha_{0}}=\exp[ad\{ia_{\alpha_{0}}(e_{\alpha_{0}}-e_{-\alpha_{0}})\}], \tag{3.17}$$

where

$$a_{\alpha_0}=\frac{\pi}{[8(\alpha_0,\alpha_0)]^{1/2}}. \tag{3.18}$$

Applying this to the Cartan subalgebra $\mathbf{h}'$ of $\hat{A}_1^{(1)}$ we obtain

$$H_{-1}=-2^{-1/2}h_{\alpha_0},\quad H_0=-(h_{\alpha_1}+h_{\alpha_0}),\qquad H_1=-(2h_{\alpha_{-1}}+2h_{\alpha_0}+h_{\alpha_1}). \tag{3.19}$$

With respect to this Cartan subalgebra, the set of positive roots is given by

$$\begin{aligned}\Delta^+=\{&n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0\forall n_1,n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0 \text{ for } n_1>2,\\ &-(n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0) \text{ for } n_1\leqslant 2,\\ &n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0) \text{ for } n_1\neq 0,\\ &-(n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0)) \text{ for } n_1=0\}.\end{aligned} \tag{3.20}$$

Now Δ_+^+ and Δ_-^+ can be written down as

$$\Delta_-^+=\{n_2+(\alpha_1+\alpha_0),2\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0\}. \tag{3.21}$$

$$\begin{aligned}\Delta_+^+=\{&n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0,n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0 \text{ for } n_1>2,\\ &-(n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0) \text{ for } n_1<2,\\ &n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0) \quad \text{ for } n_1\neq 0\}.\end{aligned} \tag{3.22}$$

The elements of $\tilde{\mathbf{n}}$ are determined by the structures $V_{\alpha_0}^{-1}e_\alpha$, where $\alpha\in\Delta_+^+$. These are given by

$$\begin{aligned}V_{\alpha_0}^{-1}e_{n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0)}&=-i2^{-1/2}Ae_{n_1\alpha_{-1}+n_2\alpha_1+(n_2+1)\alpha_0}+i2^{-1/2}Be_{n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)a_0},\\ V_{\alpha_0}^{-1}e_{n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0}&=\tfrac{1}{2}e_{n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0}+i2^{-1/2}Be_{n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0)}\\ &\quad+\tfrac{1}{2}ABe_{n_1\alpha_{-1}+n_2\alpha_1+(n_2+1)\alpha_0},\\ V_{\alpha_0}^{-1}e_{n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0}&=\tfrac{1}{2}e_{n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0}-i2^{-1/2}Ce_{n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0)}\\ &\quad+\tfrac{1}{2}CDe_{n_1\alpha_{-1}+(n_2-1)\alpha_1+(n_2-2)\alpha_0},\\ V_{\alpha_0}^{-1}e_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0)}&=\tfrac{1}{2}e_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0)}+i2^{-1/2}Ee_{-(n_1\alpha_{-1}+(n_2-1)(\alpha_1+a_0))}\\ &\quad+\tfrac{1}{2}EFe_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+(n_2-2)\alpha_0)},\end{aligned} \tag{3.23}$$

where

$$A=\operatorname{sgn} N_{\alpha_0,n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0)},$$

$$B=\operatorname{sgn} N_{-\alpha_0,n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0)},$$

$$C=\operatorname{sgn} N_{\alpha_0,n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0)},$$

$$D=\operatorname{sgn} N_{-\alpha_0,n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0)},$$

$$E = \text{sgn } N_{-\alpha_0', -(n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0))},$$
$$F = \text{sgn } N_{\alpha_0', -(n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0))}. \tag{3.24}$$

Now $\mathbf{n}$ can be calculated from $\tilde{\mathbf{n}}$ and its elements are given by

$$-i2^{-1/2}A[e_{n_1\alpha_{-1}+n_2\alpha_1+(n_2+1)\alpha_0}+e_{-(n_1\alpha_{-1}+n_2\alpha_1+(n_2+1)\alpha_0)}]$$
$$+i2^{-1/2}B[e_{n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0}+e_{-(n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0)}],$$

$$\tfrac{1}{2}[e_{n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0}+e_{-(n_1\alpha_{-1}+n_2\alpha_1+(n_2-1)\alpha_0)}]$$
$$+i2^{-1/2}B[e_{n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0)}+e_{-(n_1\alpha_{-1}+n_2(\alpha_1+\alpha_0))}]$$
$$+\tfrac{1}{2}AB[e_{n_1\alpha_{-1}+n_2\alpha_1+(n_2+1)\alpha_0}+e_{-(n_1\alpha_{-1}+n_2\alpha_1+(n_2+1)\alpha_0)}],$$

$$\tfrac{1}{2}[e_{n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0}+e_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0)}]$$
$$-i2^{-1/2}C[e_{n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0)}+e_{-(n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0))}]$$
$$+\tfrac{1}{2}CD[e_{n_1\alpha_{-1}+(n_2-1)\alpha_1+(n_2-2)\alpha_0}+e_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+(n_2-2)\alpha_0)}],$$

$$\frac{i}{2}[e_{n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0}-e_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+n_2\alpha_0)}]$$
$$-2^{-1/2}E[e_{n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0)}-e_{-(n_1\alpha_{-1}+(n_2-1)(\alpha_1+\alpha_0))}]$$
$$+\tfrac{1}{2}EF[e_{n_1\alpha_{-1}+(n_2-1)\alpha_1+(n_2-2)\alpha_0}-e_{-(n_1\alpha_{-1}+(n_2-1)\alpha_1+(n_2-2)\alpha_0)}]. \tag{3.25}$$

The required Iwasawa decomposition is then written as

$$\hat{A}_1^{(1)} = \mathbf{k} \oplus \mathbf{a} \oplus \mathbf{n}, \tag{3.26}$$

where $\mathbf{k}$, $\mathbf{a}$, and $\mathbf{n}$ are given by Eqs. (3.13), (3.15), and (3.25), respectively.

B. Iwasawa decomposition of $\hat{A}_2^{(1)}$

As a second example, we consider the involutive automorphism of $\hat{A}_2^{(1)}$ determined by the Satake diagrams, say (iv), of Table II. The basic root automorphisms are given by

$$\sigma(\alpha_1)=\alpha_1, \qquad \sigma(\alpha_2)=\alpha_2,$$
$$-\sigma(\alpha_0)=\alpha_0+2\alpha_1+2\alpha_2, \qquad -\sigma(\alpha_{-1})=\alpha_{-1}. \tag{3.27}$$

The above equations can be written as

$$\sigma(\alpha_1)=\alpha_1, \qquad \sigma(\alpha_2)=\alpha_2,$$
$$-\sigma(\delta-\alpha_1-\alpha_2)=\delta+\alpha_1+\alpha_2, \qquad -\sigma(\alpha_{-1})=\alpha_{-1}. \tag{3.28}$$

The positive roots of $\hat{A}_2^{(1)}$ are given by

$$\Delta = \{n_1\alpha_{-1}\pm a_1+n_2\delta,\ n_1\alpha_{-1}\pm\alpha_2+n_2\delta,\ n_1\alpha_{-1}\pm(\alpha_1+\alpha_2)+n_2\delta,$$
$$n_1\alpha_{-1}+n_2\delta, \text{ where } n_1=0,1,\ldots,n_2 \text{ and } n_2\in Z^+\}. \tag{3.29}$$

We can apply the simple root automorphisms to find out the automorphisms of other roots and it is easy to see that

$$\exp\ \alpha(h)=+1 \quad \text{for} \quad \alpha=\alpha_1,\alpha_2,\ n_1\alpha_{-1}+\alpha_1+n_2\delta,\ n_1\alpha_{-1}+\alpha_2+n_2\delta,$$
$$n_1\alpha_{-1}+(\alpha_1+\alpha_2)+n_2\delta, \tag{3.30}$$

$$\exp\ \alpha(h)=-1 \quad \text{for} \quad \alpha=\alpha_{-1},\alpha_0,\ n_1\alpha_{-1}-\alpha_1+n_2\delta,$$
$$n_1\alpha_{-1}-\alpha_2+n_2\delta,\ n_1\alpha_{-1}-(\alpha_1+\alpha_2)+n_2\delta, n_2\delta+n_1\alpha_{-1}. \tag{3.31}$$

Thus, for $\hat{A}_2^{(1)}$, **k** and **p** are given by

$$\mathbf{k}=\{ih_\alpha \ \text{for} \ a=\alpha_{-1},\alpha_0,\alpha_1,\alpha_2 \ \text{and} \ (e_\alpha+e_{-\alpha}),i(e_\alpha-e_{-\alpha}) \ \text{for} \ \alpha \ \text{given by Eq. (3.30)}\}, \tag{3.32}$$

$$\mathbf{p}=\{i(e_\alpha+e_{-\alpha}),(e_\alpha-e_{-\alpha}) \ \text{for} \ \alpha \ \text{given by Eq. (3.31)}\}. \tag{3.33}$$

Again in an analogous manner, we select a maximal Abelian subalgebra **a** and we see that **a** is one-dimensional. Its basis element is given by

$$H'_{-1}=i(e_\alpha+e_{-\alpha}) \quad \text{for} \quad \alpha=-\alpha_2+m\delta. \tag{3.34}$$

So, we have $R_A=\{-\alpha_2+m\delta\}$ and R_M is empty, **m** is three-dimensional and its basis elements are given by

$$\begin{gathered} -iH'_0=i[h_{\alpha_2+(m+n)\delta}+2h_{\alpha_1+(m+n)\delta}], \\ -iH'_1=ih_{(m+n)\delta}, \qquad -iH'_2=i(h_{\alpha_{-1}}+mh_{\alpha_2}). \end{gathered} \tag{3.35}$$

The elements H'_{-1},H'_0,H'_1,H'_2 together with scaling element d' form the Cartan subalgebra $\mathbf{h}'$. Defining the inner automorphism of $\hat{A}_2^{(1)}$ as

$$V=V_{-\alpha_2+n\delta}=\exp[ad\{\alpha_{-\alpha_2+n\delta}(e_{-\alpha_2+n\delta}-e_{\alpha_2+n\delta})\}], \tag{3.36}$$

where

$$a_{-\alpha_2+n\delta}=\frac{\pi}{t^n[8(\alpha_2,\alpha_2)]^{1/2}}, \tag{3.37}$$

and applying to the Cartan subalgebra $\mathbf{h}'$, we obtain

$$\begin{aligned} H_{-1}&=2^{1/2}h_{-\alpha_2+(m+n)\delta}, \\ H_0&=-(h_{\alpha_2+(m+n)\delta}+2h_{\alpha_1+(m+n)\delta}), \\ H_1&=-h_{(m+n)\delta}, \\ H_2&=-h_{\alpha_{-1}}-\frac{m}{2}\,h_{\alpha_2}. \end{aligned} \tag{3.38}$$

The set of positive roots w.r.t. this Cartan subalgebra is given by

$$\Delta^{+}=\{(n_1\alpha_{-1}+\alpha_1+(m+n)\delta),(n_1\alpha_{-1}-\alpha_1+(m+n)\delta) \quad \text{for} \quad mn_1\neq 0,$$
$$-(n_1\alpha_{-1}-\alpha_1+(m+n)\delta) \quad \text{for} \quad mn_1=0,$$
$$(n_1\alpha_{-1}+\alpha_2+(m+n)\delta) \quad \text{for} \quad mn_1\geqslant 2,$$
$$-(n_1\alpha_{-1}+\alpha_2+(m+n)\delta) \quad \text{for} \quad mn_1=0,1,$$
$$(n_1\alpha_{-1}-\alpha_2+(m+n)\delta),(n_1\alpha_{-1}+\alpha_1+\alpha_2+(m+n)\delta) \quad \text{for} \quad mn_1\geqslant 2,$$
$$-(n_1\alpha_{-1}+\alpha_1+\alpha_2+(m+n)\delta) \quad \text{for} \quad mn_1=0,1,$$
$$(n_1\alpha_{-1}-\alpha_1-\alpha_2+(m+n)\delta),(n_1\alpha_{-1}+(m+n)\delta) \quad \text{for} \quad mn_1\neq 0,$$
$$-(n_1\alpha_{-1}+(m+n)\delta) \quad \text{for} \quad mn_1=0\}. \tag{3.39}$$

The sets Δ_{+}^{+} and Δ_{-}^{+} can similarly be written as

$$\Delta_{-}^{+}=\{(n_1\alpha_{-1}+\alpha_1+(m+n)\delta) \quad \text{for } mn_1=1,$$
$$(n_1\alpha_{-1}-\alpha_2+(m+n)\delta) \quad \text{for } mn_1=2,$$
$$(n_1\alpha_{-1}-\alpha_1-\alpha_2+(m+n)\delta) \quad \text{for } mn_1=2,$$
$$-(n_1\alpha_{-1}+(m+n)\delta) \quad \text{for } mn_1=0\}, \tag{3.40}$$

and

$$\Delta_{+}^{+}=\Delta^{+}/\Delta_{-}^{+}. \tag{3.41}$$

As before, for $\hat{A}_2^{(1)}$ the elements of $\tilde{\mathbf{n}}$ are given by $V^{-1}e_{\alpha}$, where $\alpha\in\Delta_{+}^{+}$. These structures can be calculated explicitly by applying the properties of inner automorphisms. For example, the element $V^{-1}e_{n_1\alpha_{-1}+\alpha_1+(m+n)\delta}$ is given by

$$V^{-1}e_{n_1\alpha_{-1}+\alpha_1+(m+n)\delta}=\frac{1}{1+t^{2n}}\,e_{n_1\alpha_{-1}+\alpha_1+(m+n)\delta}$$
$$+\frac{1}{1+t^{2n}}\,[\operatorname{sgn} N_{-\alpha_2,n_1\alpha_{-1}+\alpha_1+\alpha_2}]e_{n_1\alpha_{-1}+\alpha_1+\alpha_2+(m+2n)\delta}. \tag{3.42}$$

The elements of $\mathbf{n}$ can be known by considering the elements $\tilde{\mathbf{n}}\cap\tilde{\mathbf{G}}$ as before. The required Iwasawa decomposition is then written as

$$\hat{A}_2^{(1)}=\mathbf{k}\oplus\mathbf{a}\oplus\mathbf{n}. \tag{3.43}$$

IV. CONCLUDING REMARKS

The present work has concerned itself with the application of the powerful techniques of Satake diagrams to the case of hyperbolic Kac–Moody algebras with special emphasis on the Iwasawa decomposition of these algebras. The involutive automorphisms for the corresponding Satake diagrams of these algebras are determined in a rather unambiguous manner. It is pertinent to stress that the Iwasawa decomposition readily leads to Langlands decomposition from which it is straightforward to obtain parabolic subalgebras necessary for constructing induced representations. Since the Satake diagrams have been previously exploited to classify the real forms of Lie algebras,[13–15] Lie superalgebras,[16] and Z graded semisimple algebras,[21] it would indeed be possible to extend the method to classify the real forms of all hyperbolic Kac–Moody algebras. We have, however, not endeavored to discuss this aspect in this communication but expect to delve into it in the future.

TABLE III. Satake diagrams and involutive automorphisms of $G(3)$.

Satake diagrams of $G(3)$	Involutive automorphisms
(*i*) 	$-\sigma(\alpha_1)=\alpha_1$ $-\sigma(\alpha_2)=\alpha_2$
(*ii*) 	$-\sigma(\alpha_1)=\alpha_2$ $-\sigma(\alpha_2)=\alpha_1$
(*iii*) 	$-\sigma(\alpha_1)=\alpha_1+3\alpha_2$ $\sigma(\alpha_2)=\alpha_2$
(*iv*) 	$\sigma(\alpha_1)=\alpha_1$ $-\sigma(\alpha_2)=\alpha_2+3\alpha_1$

The two examples $\hat{A}_1^{(1)}$ and $\hat{A}_2^{(1)}$ of the hyperbolic Kac–Moody algebras are typical illustrations of the working scheme and the general framework of the Satake diagrams. In principle, however, one can construct Satake diagrams for all hyperbolic Kac–Moody algebras which would indeed be a stupendous effort. We take the example of $G(3)$, which is not an extension of the affine Kac–Moody algebras and compute the Satake diagrams and the corresponding root automorphisms displayed in Table III so as to have a glimpse into the pragmatic way in which the technique has been appropriately tailored for these algebras.

Propagation estimates for dispersive wave equations: Application to the stratified wave equation

David W. Pravica
Department of Mathematics, East Carolina University, Greenville, North Carolina 27858

(Received 14 March 1997; accepted for publication 19 September 1998)

The plane-stratified wave equation $(\partial_t^2+H)\psi=0$ with $H=-c(y)^2\nabla_z^2$ is studied, where $z=x\oplus y$, $x\in\mathbf{R}^k$, $y\in\mathbf{R}^1$ and $|c(y)-c_\infty|\to 0$ as $|y|\to\infty$. Solutions to such an equation are solved for the propagation of waves through a layered medium and can include waves which propagate in the x-directions only (i.e., trapped modes). This leads to a consideration of the pseudo-differential wave equation $(\partial_t^2+\omega(-\Delta_x))\psi=0$ such that the dispersion relation $\omega(\xi^2)$ is analytic and satisfies $c_1\leqslant\omega'(\xi^2)\leqslant c_2$ for $c_*>0$. Uniform propagation estimates like $\int_{|x|\leqslant|t|^\alpha}\mathcal{E}(U_t\mathcal{P}_\pm\boldsymbol{\phi}_0)d^kx\leqslant C_{\alpha,\beta}(1+|t|)^{-\beta}\int\mathcal{E}(\boldsymbol{\phi}_0)d^kx$ are obtained where U_t is the evolution group, $\mathcal{P}_\pm$ are projection operators onto the Hilbert space of initial conditions $\boldsymbol{\phi}\in\boldsymbol{\mathcal{H}}$ and $\mathcal{E}(\cdot)$ is the local energy density. In special cases scattering of trapped modes off a local perturbation satisfies the causality estimate $\|\mathcal{P}^j_{+\rho\Lambda}S\mathcal{P}^k_{-\rho\Lambda}\|\leqslant C_\nu\rho^{-\nu}$ for each $\nu<1/2$. Here $\mathcal{P}^j_{+\rho\Lambda}$ $(\mathcal{P}^k_{-\rho\Lambda})$ are remote outgoing/detector (incoming/transmitter) projections for the jth (kth) trapped mode. Also $\Lambda\Subset\mathbf{R}^+$ is compact, so the projections localize onto formally-incoming (eventually-outgoing) states. © *1999 American Institute of Physics.*

I. INTRODUCTION

The inhomogeneous-media wave equation[1] (in symmetric form[2,3]) in $\mathbf{R}^n$ is,

$$-\partial_t^2\psi=K^p\psi,\quad K^p\equiv-c_p(z)\nabla_z^2c_p(z)+V_p(z),\qquad(1)$$

$$\psi(z,t=0)=\psi_1(z),\quad \partial_t\psi(z,t=0)=\psi_2(z),$$

where the dependent variables are bounded above and below, i.e.,

$$0<\epsilon_p\leqslant c_p(z)\leqslant c_p^M,\quad 0\leqslant V_p(z)\leqslant V_p^M.\qquad(2)$$

Since K^p is a positive self-adjoint operator, we can rewrite (1) as a Schrödinger equation,

$$i\partial_t\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}=i\begin{pmatrix}0 & \sqrt{K^p}\\ -\sqrt{K^p} & 0\end{pmatrix}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\quad \begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}_{t=0}=\begin{pmatrix}\sqrt{K^p}\psi_1\\ \psi_2\end{pmatrix},\qquad(3)$$

where the solution to the corresponding wave equation is $\psi=(1/\sqrt{K^p})\phi_1$. This form allows us to work on a vector-Hilbert space $\boldsymbol{\mathcal{H}}=\mathcal{L}^2(\mathbf{R}^n,d^nz)\oplus\mathcal{L}^2(\mathbf{R}^n,d^nz)$. By Stone's Theorem, Eq. (3) defines a unitary evolution group U_t^p on $\boldsymbol{\mathcal{H}}$ and this solves the wave equation (1) under conditions (2).

Now suppose that the space variables decompose as $z=x\oplus y\in\mathbf{R}^k\oplus\mathbf{R}^1$ and that there are bounded functions of the y-variable $c(y)\geqslant\epsilon>0, V(y)\geqslant 0$ so that,

$$\max\{|c(y)-c_p(z)|,\ |V(y)-V_p(z)|\}\to 0,\ \text{as}\ |z|\to\infty.$$

Then Eq. (1) is a perturbation of the plane-stratified wave equation,

$$-\partial_t^2\psi = K\psi, \quad K \equiv -c(y)\nabla_z^2 c(y) + V(y). \tag{4}$$

By writing Eq. (4) in the form of (3) we can define the *free* evolution group U_t which is also defined on $\boldsymbol{\mathcal{H}}$ as a family of unitary operators. Taking the Fourier transform of Eq. (4) in the x-variable gives the reduced wave equation,

$$-\partial_t^2\hat{\psi}_\xi = K_y^\xi\hat{\psi}_\xi, \quad K_y^\xi \equiv -c(y)\partial_y^2 c(y) + \xi^2 c^2(y) + V(y), \tag{5}$$

which operates on functions in $\mathcal{L}^2(\mathbf{R}^k, d^k\xi)\otimes\mathcal{L}^2(\mathbf{R}^1, dy)$. The corresponding wave equation decomposes into a *free part* associated with $\sigma_{\mathrm{cont}}(K_y^\xi)$, the continuous spectrum of K_y^ξ, and a *trapped part* associated with $\sigma_{pp}(K_y^\xi)$, the pure point spectrum of K_y^ξ. This latter set is defined by the eigenvalue equation,

$$K_y^\xi\hat{\psi}_\xi = \omega(\xi^2)\hat{\psi}_\xi, \quad \int_{\mathbf{R}^1}|\hat{\psi}_\xi(y)|^2 dy = 1. \tag{6}$$

Here $\hat{\psi}_\xi(y)\in\mathcal{L}^2(\mathbf{R}^1, dy)$ are normalized eigenmodes of the reduced stratified system. From (6) a family of eigenvalues are obtained $\{\omega_j(\xi^2)\}$ along with associated *thresholds* $\{\xi_j\}$ and eigenfunctions $\{\hat{\psi}_\xi^j\}$ so that $\omega_j(\xi^2)$ and $\hat{\psi}_\xi^j$ are locally analytic for $|\xi|>\xi_j$. We can now define the jth-*mode subspace* as,

$$\mathcal{H}_j \equiv \mathrm{closure}\left\{ \psi(x,y) = \int_{|\xi|>\xi_j} e^{ix\cdot\xi} f(\xi)\hat{\psi}_\xi^j(y)\, d^k\xi \,\middle|\, f\in\mathcal{L}^2(\mathbf{R}^k)\right\}.$$

On initial states $\psi_1, \psi_2 \in \mathcal{H}_j$ the stratified wave equation (4) becomes,

$$-\partial_t^2\psi^j = \omega_j(-\Delta_x)\psi^j, \quad \psi^j(x,y,0) = \psi_1(x,y), \quad \partial_t\psi^j(x,y,0) = \psi_2(x,y), \tag{7}$$

which is a pseudo-differential wave equation on $\mathbf{R}^k$. Solutions to (7) $\psi^j(x,y,t)$ can be expressed using Fourier transforms. We will call them *trapped* or *channeled modes* since they propagate in the x-directions only.[4]

To study (1) using the asymptotics of (4) we construct the scattering operator,

$$S \equiv \Omega_-^*\Omega_+, \quad \Omega_\pm \equiv s-\lim_{t\to\pm\infty} U_t^p U_{-t}. \tag{8}$$

Next, we introduce a class of projection operators $\mathcal{P}_\Lambda$ for $\Lambda \Subset \mathbf{R}^+$, so that $\forall\,\boldsymbol{\phi}\in\boldsymbol{\mathcal{H}}$,

$$\|\chi_+(|\rho|^\alpha - |x|)\mathcal{P}_{\rho\Lambda}\boldsymbol{\phi}\| \leqslant C_\Lambda|\rho|^{-\beta}\|\boldsymbol{\phi}\|, \tag{9}$$

for $0<\alpha\leqslant 1$ and some $\beta>0$. Here $\chi_+(s)=1$ for $s>0$ and 0 otherwise. Property (9) implies that $\mathcal{P}_{\rho\Lambda}$ localizes states outside a ball of radius $|\rho|^\alpha$, leaving a small polynomial tail inside the ball. For each modal subspace $\mathcal{H}_j$ it is possible to define orthogonal projections $\mathcal{P}_\Lambda^j$ satisfying (9). By taking the perspective that $\mathcal{P}_\Lambda$ projects onto outgoing scattering states (and $\mathcal{P}_{-\Lambda}$ onto incoming states) we can ask whether perturbations cause a leakage of incoming into outgoing modes during the scattering process. In particular, *causality estimates* of the form,

$$\|\mathcal{P}_{+\rho\Lambda}^j S\mathcal{P}_{-\rho\Lambda}^k\| \leqslant C_\nu/\rho^\nu, \tag{10}$$

are obtained, for each $\nu\in(0,1/2)$. We say that ''asymptotically, incoming channeled modes do not effect outgoing states.'' Here $\Lambda\Subset\mathbf{R}^+\equiv(0,\infty)$ is a compact set, so for $\rho>0$, $\mathcal{P}_{+\rho\Lambda}^k$ projects onto outgoing states which are formally-incoming and similarly $\mathcal{P}_{-\rho\Lambda}^j$ projects onto incoming states which are eventually-outgoing. Also, due to the difficulty of this problem, we only consider strictly positive thresholds $\xi_j>0$ in a media with a single layer. Extensions are possible to all thresholds $\xi_j\geqslant 0$ and to many cases of multi-layered media.

Inequality (10) is a type of cluster property in time, which was introduced by Taylor.[5] Our analysis uses $x\cdot\hat{\nabla}_x$ the *formal-time operator* originally used by Lavine[6] and expanded upon by Mourre.[7] For further history on this approach see the work of Perry.[8] Though the phase space techniques which we use are standard,[9] there has been little work on the behavior near thresholds. For stratified media problems, restrictions on energy-decay are due mainly to thresholds and not due to dispersion. Hence our main goal is to obtain uniform-energy-propagation estimates and then to use these estimates to obtain properties like (10). We refer to Ref. 10 for a discussion of other properties of S which are obtainable through phase space analysis.

In this paper we have chosen to study the wave equation because working with a vector-Hilbert space allows us to define a *global* time operator. In the special case that the threshold vanishes $\xi_j=0$, that there is no dispersion $\omega_j''=0$, that the dimension is odd and the perturbation is compactly supported, Lax and Phillips have shown that $\mathcal{P}_{+\rho}S\mathcal{P}_{-\rho}=0$, i.e., the system is *completely causal*.[11] Our analysis applies to noncompact perturbations in any dimension so we can only show that the scattering operator is *weakly* causal. For further discussion about the effects of dispersion on causality, we suggest consulting the work of Nussenzveig.[12]

The paper is organized as follows. In the next section we review the theory of wave equations as needed for this work. Section III then begins with an explicit definition of the projection operators $\mathcal{P}_\Lambda$ and a presentation of important properties. The section ends with a series of Propositions intended to justify the terminology incoming/outgoing. Finally in Sec. IV we consider the scattering operator for the stratified wave equation and obtain causality estimates of the form (10). Some calculations are left for the Appendix.

II. PRELIMINARIES

We begin with a discussion of the wave equation which also applies to the dispersive case. Let us rewrite (7) as a system,

$$i\partial_t\begin{pmatrix}\psi\\ \partial_t\psi\end{pmatrix}=i\begin{pmatrix}0 & 1\\ -\omega_j(-\Delta_x) & 0\end{pmatrix}\begin{pmatrix}\psi\\ \partial_t\psi\end{pmatrix},\qquad \begin{pmatrix}\psi\\ \partial_t\psi\end{pmatrix}_{(t=0)}=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}. \tag{11}$$

For each channel define the *spectral thresholds* $\tau_j\geqslant 0$, where $\tau_j^2=\omega_j(\xi_j^2)$. Then,

$$\text{Domain}(\omega_j)=[\xi_j^2,\infty),\qquad \text{Range}(\omega_j)=[\tau_j^2,\infty).$$

Energy of the solution to (11) is, for $h=\omega^2$

$$E(\psi_0,\psi_1;t)\equiv\int_{\mathbf{R}^k}(|h(|\nabla_x|)\psi|^2+|\partial_t\psi|^2)d^kx=\int_{\mathbf{R}^k}\mathcal{E}(\psi)d^kx, \tag{12}$$

where the *local-energy density* at time t is defined,

$$\mathcal{E}(\psi)=\left|\left(\frac{1}{-\Delta_x}\omega(-\Delta_x)\right)^{1/2}\nabla_x\psi\right|^2+|\partial_t\psi|^2. \tag{13}$$

This agrees with the usual notion of local-energy density when $\omega(\cdot)$ is a homogeneous function of degree one. The total energy E is a conserved quantity and functions with finite energy define the Hilbert space on which we will work.

In this paper we suppose that $c(y)$ and $V(y)$ satisfy one of the following conditions:

(C1) (a) $V,c\in\mathcal{C}^\infty$ and $\exists\,\gamma_b>0$ so that $\|e^{\gamma_b|y|}V(y)\|_\infty+\|e^{\gamma_b|y|}(c(y)-c_\infty)\|_\infty<\infty$;

(b) $V(y)$ and $c(y)$ are finitely-piecewise constant, with $V(y)$ and $c(y)-c_\infty$ compactly supported.

Then we have the following important result due to the work of Klaus and Simon.[13]

Theorem 2.1: Suppose that (C1) (a) or (b) hold. Then $\exists\{\omega_j(\xi^2)\}$ a sequence of nondegenerate negative eigenvalues of (6) which are locally analytic for $|\xi|>\xi_j$ and continuous for $|\xi|\geqslant\xi_j$. Furthermore, $\exists c_*,\epsilon_*,l_*$ strictly positive constants, so that,

(i) $c_1\leqslant\omega'(\xi^2)\leqslant c_2$ for all $|\xi|\geqslant\xi_j$;
(ii) $|\xi^{2(l-1)}\omega_j^{(l)}(\xi^2)|\leqslant c_3$ for all $\xi^2>\xi_j^2+\epsilon_\infty$ and $l\leqslant l_\infty$;
(iii) If $\tau_j>0$ and $\xi_j>0$, then $\lim_{\xi\to\xi_{\tau_j}^+}|(\xi^2-\xi_j^2)^{\epsilon_j}\omega^{(l)}(\xi^2)|\leqslant c_4$ for all $l\leqslant_j$;
otherwise, if $\tau_j=\xi_j=0$ then $\lim_{\xi\to 0^+}|\xi^{2(l-1)}\omega^{(l)}(\xi^2)|\leqslant c_5$ for all $l\leqslant l_j$.

Now define $h(\xi)\equiv(\omega(\xi^2))^{1/2}$ where we abuse notation by writing $\xi=|\xi|$ and by ignoring the j-index, i.e., $\omega\equiv\omega_j, h\equiv h_j, \xi_\tau\equiv\xi_j$, etc. Then, to generalize our results, suppose that $h(\xi)$ has the following properties, which are weaker than actually required,

(P1) Domain$(h)=[\xi_\tau,\infty)$, Range$(h)=[\tau,\infty)$, $\tau=h(\xi_\tau)$;
(P2) $\exists c_*,\epsilon_\infty,l_\infty>0$, so that
 (a) $c_1\leqslant h'(\xi)\leqslant c_2$ for all $\xi\geqslant\xi_\tau$;
 (b) $h\in\mathcal{C}^{l_\infty}(\xi_\tau+\epsilon_\infty,\infty)$ and $|\xi^{(l-1)}h^{(l)}(\xi)|\leqslant c_3$ for all $\xi>\xi_\tau+\epsilon_\infty$ and $l\leqslant l_\infty$;
(P3) $\exists\epsilon_\tau,l_\tau>0$, so that
 if $\tau>0$ and $\xi_\tau>0$ then $\lim_{\xi\to\xi_\tau^+}|(\xi-\xi_\tau)^{\epsilon_\tau}h^{(l)}(\xi)|\leqslant c_4$ for all $l\leqslant l_\tau$;
 otherwise, if $\tau=\xi_\tau=0$ then $\lim_{\xi\to 0^+}|\xi^{l-1}h^{(l)}(\xi)|\leqslant c_4$ for all $l\leqslant l_\tau$.

Now denote $\phi_1=h\psi$, $\phi_2=\partial_t\psi$. Then the wave equation (11) has the alternate form,

$$i\partial_t\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}=i\begin{pmatrix}0 & h(|\nabla_x|)\\ -h(|\nabla_x|) & 0\end{pmatrix}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\qquad \begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}_{(t=0)}=\begin{pmatrix}h(|\nabla_x|)\psi_1\\ \psi_2\end{pmatrix}. \tag{14}$$

Evolution is unitary on the Hilbert space,

$$\boldsymbol{\mathcal{H}}_\tau\equiv\mathcal{H}_\tau\oplus\mathcal{H}_\tau,$$

$$\mathcal{H}_\tau\equiv E^{-\Delta_x}_{[\tau^2,\infty)}\mathcal{L}^2(\mathbf{R}^k,d^kx)=\text{closure}\left\{\psi(x)=\int_{|\xi|>\xi_\tau}e^{ix\cdot\xi}f(\xi)d^k\xi\,\middle|\,f\in\mathcal{L}^2(\mathbf{R}^k)\right\},$$

where E^K_Λ is the spectral measure of a self-adjoint operator K on the set Λ. The norm of $\boldsymbol{\mathcal{H}}_\tau$ is the sum of $\mathcal{L}^2$-norms which is equivalent to the energy in (12). Furthermore, the system in (14) can be diagonalized by defining,

$$\phi_\pm=(1/2)^{1/2}(\phi_1\mp i\phi_2)=(1/2)^{1/2}(h(|\nabla_x|)\psi\mp i\partial_t\psi). \tag{15}$$

Then it is clear that,

$$E(\psi_0,\psi_1)=\|\phi_1\|^2+\|\phi_2\|^2=\|\phi_+\|^2+\|\phi_-\|^2.$$

To solve the dispersive wave equation (14) we introduce the Fourier transform on $\mathbf{R}^k$,

$$\mathcal{F}_x\psi(\xi\mu)=\Omega_k\int_{\mathbf{R}^k}e^{i(x\cdot\mu)\xi}\psi(x)d^kx,$$

for $\mu\in S^{k-1}$ and $\Omega_k\equiv(2\pi)^{-k/2}$. Making the extension,

$$h(-\xi)=-h(\xi),\qquad \mathcal{D}_\tau\equiv\text{Domain}(h)=(-\infty,-\xi_\tau]\cup[\xi_\tau,\infty),$$

allows (14) to be rewritten as,

$$i\partial_t f(\xi,\mu;t)=-h(\xi)f(\xi,\mu;t),\quad\text{on}\quad\mathcal{L}^2(\mathcal{D}_\tau\otimes S^{k-1},|\xi|^{k-1}d\xi d\mu),$$

where, in terms of solutions to (14) and the notation of (15), we define,

$$f(\xi,\mu;t)\equiv(\mathcal{F}_x\phi_\pm)(\xi,\mu;t), \quad \text{for } \xi\in\mathcal{D}_\tau \quad \text{and } \pm\xi\geqslant 0.$$

In this way the wave equation becomes first order. A study of this equation in the case that $h(\xi)$ is a homogeneous function of degree 1 with $\xi_\tau=0$ was carried out in Ref. 11, Sec. VI. We also refer to Ref. 14 for a detailed discussion of *domains of definition*.

In this paper, instead of using $\mathcal{F}_x$, we work with the transformation,

$$\mathcal{F}^h\psi(q,\mu)=\Omega_k H_k(q)\int_{\mathbf{R}^k} e^{i(x\cdot\mu)h^{-1}(q)}\psi(x)d^kx,$$

where the dispersion weight factor is defined as,

$$H_k(q)=\frac{|h^{-1}(q)|^{(k-1)/2}}{\sqrt{h'(h^{-1}(q))}},$$

for $q\in\sigma_\tau$. Here $\sigma_\tau\equiv(-\infty,-\tau]\cup[\tau,\infty)$ and in this case Eq. (14) becomes,

$$i\partial_t g(q,\mu;t)=-qg(q,\mu;t), \quad \text{on} \quad \mathcal{L}^2(\sigma_\tau\otimes S^{k-1},dq\,d\mu),$$

where $g(q,\mu;t)\equiv(\mathcal{F}^h\phi_{\mathrm{sgn}(q)})(q,\mu;t)$. Finally, applying the inverse 1-d Fourier transform,

$$(\mathcal{F}_1^{-1}g)(s)\equiv\Omega_1\int_{\sigma_\tau} e^{-isq}g(q)dq, \quad s\in\mathbf{R},$$

gives the one-dimensional wave equation,

$$\partial_t k(s,\mu,t)=-\partial_s k(s,\mu,t), \quad \text{on} \quad \mathcal{L}^2(\mathbf{R},ds;\mathcal{N}), \quad \mathcal{N}\equiv\mathcal{L}^2(S^{k-1},d\mu). \tag{16}$$

The s-variable is conjugate to $-i\partial_s$, (i.e., $i[-i\partial_s,s]=1$) and the solution of (16) is $k(s,\mu,t)=k_0(s-t,\mu)$, which is just translation to the right in the s-variable for some initial condition function $k_0(\cdot,\cdot)$. The solution to (11) is $\psi(x,t)=[h(|\nabla_x|)]^{-1}\phi(x,t)$, which can be an equivalence class of functions if $\tau=0$ (see discussions in Refs. 1 and Ref. 15). Here,

$$\phi(x,t)=\Omega_{k+1}\int_{\sigma_\tau\otimes S^{k-1}} e^{-ix\cdot\mu h^{-1}(q)}H_k(q)\left(\int_{-\infty}^{\infty} e^{isq}k_0(s-t,\mu)ds\right)dq\,d\mu,$$

and the Lax–Phillips transformation of the initial data are,

$$\begin{aligned} k_0(s,\mu)&\equiv\mathcal{LP}(\psi_0,\psi_1)(s,\mu)\\ &=\partial_s\mathcal{R}(\psi_0)(s,\mu)-\mathcal{R}(\psi_1)(s,\mu)\\ &=\Omega_{k+1}\int_{\sigma_\tau} e^{-is\overline{q}}H_k(\overline{q})\left(\int_{\mathbf{R}^k} e^{i\overline{x}\cdot\mu h^{-1}(\overline{q})}\mathrm{sgn}(\overline{q})[\overline{q}\psi_0(\overline{x})-i\psi_1(\overline{x})]d^k\overline{x}\right)d\overline{q}. \end{aligned}$$

$\mathcal{R}(\cdot)$ is called the Radon transformation and it is used to define the projection operators $\mathcal{P}_\pm^{LP}$ on $\boldsymbol{\mathcal{H}}$ so that,

$$\mathcal{LP}(\mathcal{P}_\pm^{LP}(\psi_0,\psi_1))(s,\mu)=\chi_\pm(s)\mathcal{LP}(\psi_0,\psi_1)(s,\mu).$$

Here $\chi_\pm(s)=1$ for $s\gtrless 0$ respectively and 0 otherwise. The spaces $\boldsymbol{\mathcal{D}}_\pm^{LP}\equiv\mathcal{P}_\pm^{LP}\boldsymbol{\mathcal{H}}$ are called *outgoing/incoming* in the sense of Lax–Phillips. Let U_t be the unitary group which solves (14) on $\boldsymbol{\mathcal{H}}_\tau$. Then $\boldsymbol{\mathcal{D}}_\pm^{LP}$ have the well known properties,

$$\text{(i)}\quad U_t\boldsymbol{\mathcal{D}}_{\pm}^{LP}\subset\boldsymbol{\mathcal{D}}_{\pm}^{LP},\quad t\gtrless 0;\quad \text{(ii)}\quad \bigcap_{t\in\mathbf{R}} U_t\boldsymbol{\mathcal{D}}_{\pm}^{LP}=\{\mathbf{0}\};\quad \text{(iii)}\quad \overline{\bigcap_{t\in\mathbf{R}} U_t\boldsymbol{\mathcal{D}}_{\pm}^{LP}}=\boldsymbol{\mathcal{H}},\tag{17}$$

which follow from the Weyl relations, which hold due to the translation representation of (16). The difficulty in studying the wave equation in this form is that if $\tau\neq 0$ then the variable s does not act like simple differentiation under Fourier transform. In fact,

$$\mathcal{F}_1(sk_0(\cdot,\mu))(q)=\Omega_1\int_{-\infty}^{\infty}e^{isq}sk_0(s,\mu)ds=(i\partial_q+\delta(q-\tau)-\delta(q+\tau))\mathcal{F}_1(sk_0(\cdot,\mu))(q),$$

so $\mathcal{P}_{\pm}^{LP}$ are t-dependent. However if $\tau=0$ then $\mathcal{F}_1: s\to i\partial_q$ as operators. Thus Lax–Phillips theory only applies to the $\tau=0$ case, i.e., systems with uniform multiplicity.[11,15]

III. ENERGY REPRESENTATION

In this section we introduce projection operators $\mathcal{P}_{\pm}$ for the dispersive wave equation without using the Radon transform. This leads to a decomposition of the initial condition space into $\boldsymbol{\mathcal{D}}_{\pm}=\mathcal{P}_{\pm}\boldsymbol{\mathcal{H}}_{\tau}$. These outgoing and incoming spaces agree with the Lax–Phillips definition only if $\tau=0$ and k is odd. Propagation estimates are obtained for elements in $\boldsymbol{\mathcal{D}}_{+}$. Corresponding results hold for $\boldsymbol{\mathcal{D}}_{-}$.

Define $\phi_{*0}=\phi_*(t=0)\in\mathcal{H}_{\tau}$. We also use the notations, for $q\in\mathbf{R}$,[1]

$$\hat{q}\equiv\operatorname{sgn}(q),\quad \langle q\rangle\equiv(1+q^2)^{1/2},$$

$$\hat{v}_q=\frac{1}{\sqrt{2}}\begin{pmatrix}1\\ i\hat{q}\end{pmatrix},\quad \phi_{\hat{q}}=\frac{1}{\sqrt{2}}(\phi_1-i\hat{q}\phi_2)=\hat{v}_q^T\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},$$

[see (15)]. Then returning to (14), the solution of the wave equation is given by,

$$\begin{aligned}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}(t)&=U_t\begin{pmatrix}\phi_{10}\\ \phi_{20}\end{pmatrix}\\ &\equiv\begin{pmatrix}\cos ht & \sin ht\\ -\sin ht & \cos ht\end{pmatrix}\begin{pmatrix}\phi_{10}\\ \phi_{20}\end{pmatrix}\\ &=\frac{1}{\sqrt{2}}\begin{pmatrix}e^{iht}\phi_{+0}+e^{-iht}\phi_{-0}\\ ie^{iht}\phi_{+0}-ie^{-iht}\phi_{-0}\end{pmatrix}\\ &=\frac{\Omega_k^2}{\sqrt{2}}\int_{\sigma_\tau\otimes\mathcal{S}^{k-1}}e^{i(qt-x\cdot\mu h^{-1}(q))}H_k^2(q)\left(\int_{\mathbf{R}^k}e^{i\overline{x}\cdot\mu h^{-1}(q)}\begin{pmatrix}\phi_{\hat{q}0}\\ i\hat{q}\phi_{\hat{q}0}\end{pmatrix}d^k\overline{x}\right)dq\,d\mu.\end{aligned}\tag{18}$$

Let $\chi_\Lambda(s)$ be the characteristic function of the set $\Lambda\subset\mathbf{R}$ and denote $\chi_{\pm}(s)\equiv\chi_{\mathbf{R}^+}(\pm s)$. Then with $\gamma\equiv\hat{q}^{(k+1)/2}$ for k odd and $\tau=0$, and $\gamma=1$ otherwise, define $\mathcal{P}_\Lambda$ so that,

$$\begin{aligned}\mathcal{P}_\Lambda\begin{pmatrix}\phi_{10}\\ \phi_{20}\end{pmatrix}&=\Omega_k\int_{\sigma_\tau\otimes\mathcal{S}^{k-1}}e^{-ix\cdot\mu h^{-1}(q)}H_k(q)\mathcal{F}^h\left[\mathcal{P}_\Lambda\begin{pmatrix}\phi_{10}\\ \phi_{20}\end{pmatrix}\right]dq\,d\mu\\ &\equiv\Omega_k\int_{\mathbf{R}\otimes\mathcal{S}^{k-1}}e^{-ix\cdot\mu h^{-1}(q_p)}H_k(q_p)\hat{v}_p(\gamma\chi_\Lambda(-i\partial_p)\gamma)\hat{v}_p^T\begin{pmatrix}\mathcal{F}^h\phi_{10}\\ \mathcal{F}^h\phi_{20}\end{pmatrix}dp\,d\mu,\end{aligned}\tag{19}$$

where we use the change of variables $p=q-\tau\hat{q}\in(-\infty,\infty)$ and define the quantity $q_p\equiv p+\tau\hat{p}\in\sigma_\tau$. Here $\mathcal{P}_\Lambda\equiv\chi_\Lambda(\mathcal{A}^h)$ where $\mathcal{A}^h$ is a self-adjoint extension (see the work of Nagy[16]) of the following symmetric operator:

$$\mathcal{A}^h\equiv i\begin{pmatrix}0 & A_h\\ -A_h & 0\end{pmatrix},\quad \text{on}\quad \boldsymbol{\mathcal{D}}(\mathcal{A}^h)=\{\boldsymbol{\phi}\in\mathcal{D}^2(A_h)\subset\boldsymbol{\mathcal{H}}_\tau|\mathcal{F}^h\boldsymbol{\phi}(\pm\tau)=\mathbf{0}\},$$

$$A_h\equiv\frac{1}{4i}\frac{1}{\sqrt{h'(|\nabla_x|)}}(\hat{\nabla}_x\cdot x+x\cdot\hat{\nabla}_x)\frac{1}{\sqrt{h'(|\nabla_x|)}}.$$

For $\Lambda=(a,b)\subset\mathbf{R}^+$, $\rho>0$, we use the notations,

$$\mathcal{P}_{+\rho\Lambda}\equiv\mathcal{P}_{(\rho a,\rho b)},\quad \mathcal{P}_{-\rho\Lambda}\equiv\mathcal{P}_{(-\rho b,-\rho a)},\quad \mathcal{P}_{\pm\rho}\equiv\mathcal{P}_{\pm[\rho,\infty)},\quad \mathcal{P}_\pm=\mathcal{P}_{\pm 0}\equiv\mathcal{P}_{\pm\mathbf{R}^+}.$$

To demonstrate that $\boldsymbol{\mathcal{D}}_\pm\equiv\mathcal{P}_\pm\boldsymbol{\mathcal{H}}_\tau$ are orthogonal spaces, we prove in the Appendix,

Lemma 3.1: The operators $\mathcal{P}_\pm$ are complementary-orthogonal projections. In particular $\mathcal{P}_+\mathcal{P}_-=0$, $\mathcal{P}_++\mathcal{P}_-=1$, $\mathcal{P}_\pm^*=\mathcal{P}_\pm$.

We also consider the following in the Appendix:

Claim 3.2: Let U_t be the unitary group defined in (18) on $\boldsymbol{\mathcal{H}}_\tau$. Then for any $\tau\geqslant 0$ properties (ii) and (iii) of Lax–Phillips hold. Furthermore,

(i)′ (a) $\mathcal{P}_\mp U_t\overset{s}{\rightarrow}0$ and $U_t\mathcal{P}_\pm\overset{w}{\rightarrow}0$ as $t\rightarrow\pm\infty$;

(b) $(1-\mathcal{P}_{+t})U_t\mathcal{P}_+=0$ for $t=(n\pi/\tau)$ if $\tau>0, n\in\mathbf{N}$ and $\forall t>0$ if $\tau=0$.

Remark: Property (i) in (17) can be restated as $\mathcal{P}_\mp U_t\mathcal{P}_\pm=0, \forall t\gtrless 0$. Lax and Phillips also discuss the operator $Z(t)\equiv(1-\mathcal{P}_{+\rho})U_t^p(1-\mathcal{P}_{-\rho})$, where U_t^p is the evolution group of a compactly perturbed system. If $\|Z(t)\|\rightarrow 0$ as $t\rightarrow\infty$ then the perturbed system will have uniform energy-decay properties. For the problem studied here, property (i)′ only says that $Z(t)$ vanishes strongly, even if there is no perturbation.

The claim is established from estimates of the form,

$$\|\chi_+(c_m'|t\pm\rho|^\alpha-|x|)U_t\mathcal{P}_{\pm\rho\Lambda}\boldsymbol{\phi}_0\|^2\leqslant\frac{C(\alpha,\beta,\Lambda)}{(1+|t\pm\rho|)^\beta}\|\boldsymbol{\phi}_0\|^2,\quad t\gtrless 0,\quad \rho>0. \tag{20}$$

If $\exists\,\alpha\geqslant 0,\beta>0,\Lambda\subseteq\mathbf{R}^+$ so that (20) holds $\forall\,\boldsymbol{\phi}_0\in\boldsymbol{\mathcal{H}}_\tau$ then it is called a *uniform-energy-propagation estimate*. Note that uniformity refers to the absence of momentum cutoff functions on either $\boldsymbol{\phi}_0$ or U_t.

Discussion: Equation (20) is not just a propagation estimate. For $t=0$ and Λ compact, it shows that $\mathcal{P}_{+\rho\Lambda}\boldsymbol{\mathcal{H}}_\tau$ are outgoing states, which were once incoming. Similarly $\mathcal{P}_{-\rho\Lambda}\boldsymbol{\mathcal{H}}_\tau$ consists of incoming states which are eventually outgoing. These propagation estimates allow us to replace strict notions of incoming/outgoing with an energy-density estimate. If $\tau=0$ and the dimension is odd, then localization is nearly exponential, but if $\tau>0$ one can only localize the energy in space in terms of inverse powers of ρ.

We now present our main results for system (14) under conditions (P1)-(P3), concentrating on the $\Lambda=\mathbf{R}^+$ case and considering only outgoing projections.

Proposition 3.3: Suppose that k is odd, $\tau=0$, $N\equiv\min\{l_\infty,l_\tau\}-1>(k+1)/2$ and $\alpha<1$. Then for $\beta\equiv 2N-\alpha k-1$ and $t,\rho>0$ the estimate,

$$\int\chi_+(c_m'|t+\rho|^\alpha-|x|)\mathcal{E}(U_t\mathcal{P}_{+\rho}\boldsymbol{\phi}_0)d^kx\leqslant C_{\alpha,\beta}(1+|t+\rho|)^{-\beta}E(\boldsymbol{\phi}_0), \tag{21}$$

holds for any $\boldsymbol{\phi}_0 \in \boldsymbol{\mathcal{H}}_\tau$. If $\alpha=1$ then for each $c_m' < c_m$ there is a $C>0$ so that (21) holds. Furthermore, if $h(\xi)=c_m\xi$ (i.e., homogeneous of degree one) then we can take $C=0$ for any $\alpha \leqslant 1$, $c_m' < c_m$.

Remark: The last statement is Huygen's (energy) principle which holds for odd $k \geqslant 1$.

Proof: We extend the methods of Theorem 2.6.1 in Ref. 8 by introducing a scaling argument. For any $B \gg 1$ define the symmetric functions,

$$\mathcal{G}(q)=1-G(q/B), \quad \text{where} \quad G(q)=\begin{cases} 0, & |q|\leqslant 1 \\ 1, & |q|\geqslant 2 \end{cases}, \quad qG'(q)\geqslant 0, \quad G\in\mathcal{C}^\infty(\mathbf{R}).$$

Then the left-hand side of (21), can be written, for $\rho=0$, $c_m'=1$, $\alpha<1$ and each $t>0$,

$$\int_{|x|\leqslant t^\alpha} \mathcal{E}(U_t\mathcal{P}_+\boldsymbol{\phi}_0)d^kx \leqslant 2\|G(|\nabla_x|/B)\mathcal{P}_+\boldsymbol{\phi}_0\|^2 + 2t^{\alpha k}\mathrm{Vol}(\mathcal{S}^{k-1}) \sup_{|x|\leqslant t^\alpha} \mathcal{E}(U_t\mathcal{G}(|\nabla_x|)\mathcal{P}_+\boldsymbol{\phi}_0).$$

The first term on the right-hand side vanishes as $B\to\infty$. As for the last term, first note that $-i\partial_q$ is a self-adjoint operator on $\mathcal{L}^2(\mathbf{R}^1,dq)$. Thus the Weyl relations hold,

$$e^{iqt}e^{s\partial_q}=e^{-ist}e^{s\partial_q}e^{iqt} \Leftrightarrow e^{iqt}\chi_\Lambda(-i\partial_q)=\chi_{\Lambda+t}(-i\partial_q)e^{iqt}. \tag{22}$$

Now, applying expression (19), then (18) and definition (13), gives,

$$\begin{aligned}
&\mathcal{E}(U_t\mathcal{G}(|\nabla_x|)\mathcal{P}_+\boldsymbol{\phi}_0) \\
&\equiv \mathcal{E}\left(U_t\Omega_k \int_{\mathbf{R}\otimes\mathcal{S}^{k-1}} e^{-ix\cdot\mu h^{-1}(q_p)}\mathcal{G}(h^{-1}(q_p))H_k(q_p)\hat{v}_p(\gamma\chi_+(-i\partial_p)\gamma)\hat{v}_p^T\mathcal{F}^h\boldsymbol{\phi}_0 dp\, d\mu \right) \\
&\equiv \frac{\Omega_k^2}{\sqrt{2}}\left| \begin{pmatrix} \hat{\nabla}_x & 0 \\ 0 & 1 \end{pmatrix} \int_{\sigma_\tau\otimes\mathcal{S}^{k-1}} e^{i(qt-x\cdot\mu h^{-1}(q))}\mathcal{G}(h^{-1}(q))H_k(q)\hat{v}_q \right. \\
&\qquad \left. \times(\gamma\chi_+(-i\partial_q)\gamma)\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}_0 dq\, d\mu \right|^2 \\
&\equiv \frac{\Omega_k^2}{2}\left| \int dq\, d\mu e^{i(qt-x\cdot\mu h^{-1})}\mathcal{G}\circ h^{-1}H_k\begin{pmatrix} -i\hat{q} \\ i\hat{q} \end{pmatrix}(\gamma\chi_+\gamma)\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}_0 \right|^2.
\end{aligned} \tag{23}$$

Consider the linear case where $q=h(\xi)=c_m\xi$ and $\tau=0$. We then use self-adjointness of $i\partial_q$ on $\mathcal{L}^2(\mathbf{R},dq)$, relation (22) and the Schwartz inequality to bound (23) by,

$$\Omega_k^2\int dq\, d\mu |\chi_{(-\infty,-t)}(-i\partial_q)e^{-ix\cdot\mu q/c_m}\mathcal{G}(q/c_m)\gamma\hat{q}|q|^{(k-1)/2}|^2 \times \int dq\, d\mu|\gamma e^{iqt}\mathcal{F}^h\boldsymbol{\phi}_0|^2.$$

Next, by the Parseval equality we obtain an upper bound of,

$$\mathrm{Vol}(S^{k-1})\sup_\mu \int_{-\infty}^{-t}\left| \int_{-2B}^{2B} e^{-iq(s+x\cdot\mu/c_m)}\mathcal{G}(q/c_m)q^{(k-1)/2}dq\right|^2 ds \times 2E(\boldsymbol{\phi}_0).$$

Hence $\exists C_*>0$ so that applying integration by parts M-times gives a larger upper bound,

$$\begin{aligned}
&C_kE(\boldsymbol{\phi}_0)\sup_\mu\int_{-\infty}^{-t}\left|\int_{-2B}^{2B}\left(\frac{i}{s+x\cdot\mu/c_m}\right)^M[\partial_q^M e^{-iq(s+x\cdot\mu/c_m)}]\mathcal{G}(q/c_m)q^{(k-1)/2}dq\right|^2 ds \\
&\leqslant C_{k,M}E(\boldsymbol{\phi}_0)\int_{-\infty}^{-t}(|s|-|x|/c_m)^{-2M}ds\left(\int_{-2B}^{2B}|\partial_q^M\mathcal{G}(q/c_m)q^{(k-1)/2}|dq\right)^2,
\end{aligned} \tag{24}$$

from which we can easily conclude that,

$$\sup_{|x|\leqslant t^{\alpha}} \mathcal{E}(U_t\mathcal{G}(|\nabla_x|)\mathcal{P}_+\boldsymbol{\phi}_0)\leqslant C_{k,M,\alpha}t^{-2M+1}(2B)^{-2M+k+1}E(\boldsymbol{\phi}_0). \tag{25}$$

Hence as $B\to\infty$ (for M sufficiently large) the right-hand side of (25) vanishes for each fixed t. Replacing t with $t+\rho$ at appropriate points verifies the last statement of Proposition 3.3.

Remark: All remaining computations required in this section are modifications of the steps in (23)–(25). Repetitions will be kept to a minimum.

Next, in case that $h(\xi)=q$ is nonlinear and $\tau=0$, let us define the phase function,

$$\varphi_0(q)=sq+x\cdot\mu h^{-1}(q)=sh(\xi)+x\cdot\mu\xi,$$

and the operators,

$$L\equiv\frac{i}{\varphi_0'(q)}\partial_q,\quad L^*\equiv-i\frac{\varphi_0''(q)}{(\varphi_0'(q))^2}+\frac{i}{\varphi_0'(q)}\partial_q,$$

or, using the change of variables identities $1=h'(\xi)\partial_q h^{-1}(q)$ and $\partial_q=(h')^{-1}\partial_\xi$,

$$L^*\equiv i\frac{x\cdot\mu h''/h'}{(sh'+x\cdot\mu)^2}+\frac{i}{sh'+x\cdot\mu}\partial_\xi.$$

For $s\leqslant -t$ and $|x|\leqslant(c_m'/c_m)t$, (24) gives,

$$\left|\int_{-2B}^{2B}e^{-i\varphi_0(q)}(L^*)^N\mathcal{G}(h^{-1}(q))\gamma\hat{q}H_k(q)dq\right|\leqslant\frac{C_N}{(|s|-c_m't/c_m)^N}\int_{-2B}^{2B}\langle q\rangle^{-N+(k-1)/2}dq, \tag{26}$$

where C_N is finite due to the smoothness conditions (P2) and (P3). The right-hand side of (26) has a finite limit as $B\to\infty$ if $N-(k-1)/2>1$. Integrating for $s\in(-\infty,-t)$ completes the proof for $\rho=0$. The $\rho>0$ cases are similarly obtained. □

For the remaining results of this section, consider $\Lambda=(a,b)$ with $0\leqslant a<b$ and define $\delta=2$ if $b<\infty$ or $\delta=1$ if $b=\infty$.

Proposition 3.4: Suppose that $k\geqslant1$ (even or odd), $\tau>0$ and $\min\{l_\infty,l_\tau\}\geqslant2$. For each $\alpha<\delta/k$ with $\alpha\leqslant1$ and $\beta\equiv\delta-\alpha k>0$, $\exists C>0$ so that (20) holds for all $\boldsymbol{\phi}_0\in\boldsymbol{\mathcal{H}}$.

Proof: We change the previous proof by defining, for $A>\tau$ and $B\geqslant A$,

$$\mathcal{G}(q)=\mathcal{G}_A(q)+\mathcal{G}_\infty(q),$$

$$\mathcal{G}_A(q)=G(q_\tau/A_\tau)(1-G(q/c_\tau)),\quad \mathcal{G}_\infty(q)=(1-G(q/B))G(q/c_\tau), \tag{27}$$

$$q_\tau\equiv q-\tau,\quad A_\tau\equiv A-\tau,\quad c_\tau\equiv1+\tau.$$

Using the $\mathcal{G}(q)$ partition on the left-hand side of (20) gives, for $t>0$ and $h\equiv h(|\nabla_x|)$,

$$\int_{|x|\leqslant t^\alpha}|U_t\mathcal{P}_\Lambda\boldsymbol{\phi}_0|^2d^kx\leqslant2\|(1-G((h-\tau)/A_\tau))\mathcal{P}_\Lambda\boldsymbol{\phi}_0\|^2+2\|G(h/B)\mathcal{P}_\Lambda\boldsymbol{\phi}_0\|^2$$
$$+Ct^{\alpha k}\sup_{|x|\leqslant t^\alpha}|U_t\mathcal{G}_A(h)\mathcal{P}_\Lambda\boldsymbol{\phi}_0|^2+C't^{\alpha k}\sup_{|x|\leqslant t^\alpha}|U_t\mathcal{G}_\infty(h)\mathcal{P}_\Lambda\boldsymbol{\phi}_0|^2. \tag{28}$$

The $\mathcal{G}_\infty(h)$ and $G(h/B)$ terms can be handled as in the previous Proposition. However, since $\tau>0$, we cannot use (22). Define the time-dependent phase function and operator,

$$\varphi_t(q) \equiv (s-t)q + x\cdot\mu h^{-1}(q) = (s-t)h(\xi) + x\cdot\mu\xi, \quad L_t \equiv \frac{i}{\varphi_t'(q)}\partial_q .$$

For the $\mathcal{G}_A$ term in (28) use integration by parts only once, i.e., $M=1$ in (24). Then,

$$\chi_\Lambda(s)\int_A^{2c_\tau} |L_t^* \mathcal{G}_A(q) H_k(q)| dq \leq \frac{C_{k,\tau}\chi_\Lambda(s)}{c_m|s-t|-|x|} + \frac{C'_{k,\tau}\chi_\Lambda(s)\|(\xi^2-\xi_\tau^2)h''\|_\infty}{(c_m|s-t|-|x|)^2}. \tag{29}$$

Thus, integrating in $s\in\mathbf{R}$, gives the following estimate, analogous to (25):

$$\sup_{|x|\leq t^\alpha} |U_t \mathcal{G}_A(|\nabla_x|)\mathcal{P}_{+\Lambda}\boldsymbol{\phi}_0|^2 \leq C_{k,\tau,\Lambda}\frac{1}{(c_m t - t^\alpha)^\delta}\|\boldsymbol{\phi}_0\|^2.$$

Returning to (28) it is clear that for $\alpha k<\delta$ one obtains an estimate independent of A, except for the first term on the right-hand side. This term vanishes as $A\to\tau^+$. The same computations hold if we replace t^α with $|t+\rho|^\alpha$ and Λ with $\rho\Lambda$. The result is complete. □

Proposition 3.5: Suppose that $k\geq 1$, $\tau=0$ and $\min\{l_\infty, l_\tau\}\geq 2+k/2$. Then, for any $\alpha\leq 1$ with $\beta>0$, where $\beta(\alpha)\equiv(1-\alpha)k+(\delta-1)-(1+(-1)^k)/2$, $\exists C>0$ so that (20) holds.

Proof: The difficulty in these cases is that even when $l_\tau=\infty$ integration by parts can be used only $M\equiv\lceil k/2\rceil$ (least integer greater than $k/2$) times, due to the singularity of $q^{(k-1)/2}$. To prove this, return to (29) with $\tau=0$ and $q=h(\xi)=c_m\xi$. Then given $N\leq\lceil k/2\rceil$, $\exists C_N$ so that,

$$\left|\int_A^{2c_\tau}(L^*)^N\mathcal{G}_A(q)q^{(k-1)/2}dq\right|^2 \leq \frac{C_N}{(c_m|s-t|-|x|)^{2N}}.$$

Now we may proceed as in the proof of Proposition 3.4. The case of nonlinear $h(\xi)$ is handled similarly. We omit the details. □

Remark: The difference between (20) and (21) is unimportant for our study of the scattering matrix since the energy norms are equivalent if $\tau>0$. It will be convenient in the next section to use the estimates in (20).

IV. SCATTERING THEORY FOR TRAPPED WAVES

A. Plane stratified media

We now apply the results of Sec. III to the study of time-asymptotic solutions for the plane-stratified wave equation. Recall that $z=x\oplus y\in\mathbf{R}^k\times\mathbf{R}^1$.

A typical trapped mode for system (4) has initial conditions of the form,

$$\phi_*(x,y) = \Omega_k\int_{\mathbf{R}^k} e^{-ix\cdot\xi} f(\xi)\hat{\psi}_\xi^j(y)d^k\xi, \tag{30}$$

for appropriate $f\in\mathcal{L}^2(\mathbf{R}^k)$ and with $\hat{\psi}_\xi^j$ defined in (6). Using the $\mathcal{F}^h$-transform on (6) gives the new eigenvalue equation,

$$\begin{gathered} H_y^q\tilde{\psi}_j(q,y) = q^2\tilde{\psi}_j(q,y), \quad \tilde{\psi}_j(q,y)\equiv\mathcal{F}^h\mathcal{F}_x^{-1}\hat{\psi}_\xi^j, \\ H_y^q \equiv \mathcal{F}^h K(\mathcal{F}^h)^{-1} = \mathcal{F}^h(\mathcal{F}_x)^{-1}K_y^\xi\mathcal{F}_x(\mathcal{F}^h)^{-1}. \end{gathered} \tag{31}$$

In this case the initial conditions will take the form,

$$\phi_*(x,y) = \Omega_k\int_{\sigma_\tau\otimes S^{k-1}} e^{-ix\cdot\mu h^{-1}(q)} g(q,\mu)\tilde{\psi}_j(q,y)H_k(q)dq\, d\mu, \tag{32}$$

for appropriate $g\in\mathcal{L}^2(\sigma_\tau\times\mathcal{S}^{k-1})$. Now, for any Borel set $\Sigma\subseteq[\tau_j^2,\infty)$, we define $P^j[\Sigma]$ to be the projection onto the ω_j eigenspace of Σ. Explicitly, if $E^K_{\{\lambda\}}$ is the spectral projection of K onto the eigenvalue λ, we have,

$$P^j[\Sigma]\phi(x,y)\equiv\int_{|\xi|^2\in\omega_j^{-1}(\Sigma)}\left(E^{K_y^\xi}_{\{\omega_j(\xi^2)\}}\phi\right)(x,y)d^k\xi$$

$$=\Omega_k\int_{|\xi|^2\in\omega_j^{-1}(\Sigma)}e^{-ix\cdot\xi}\hat{\psi}^j_\xi(y)\left(\int_{\mathbf{R}^1}\hat{\psi}^j_\xi(\overline{y})\mathcal{F}_x\phi(\xi,\overline{y})d\overline{y}\right)d^k\xi.$$

We use the notations $P^j\equiv P^j[\tau_j,\infty)$ and $\mathbf{P}^t\equiv\oplus_j P^j$. Then the *trapped space* is defined,

$$\boldsymbol{\mathcal{H}}^t\equiv\mathbf{P}^t\mathcal{H}\oplus\mathbf{P}^t\mathcal{H}\equiv\mathbf{P}^t\boldsymbol{\mathcal{H}},\tag{33}$$

where $\boldsymbol{\mathcal{H}}\equiv\mathcal{H}\oplus\mathcal{H}$ and $\mathcal{H}\equiv\mathcal{L}^2(\mathbf{R}^{k+1},d^kxdy)$. The *space of free states* is,

$$\boldsymbol{\mathcal{H}}^f\equiv\mathbf{P}^f\mathcal{H}\oplus\mathbf{P}^f\mathcal{H}\equiv\mathbf{P}^f\boldsymbol{\mathcal{H}},\tag{34}$$

where $\mathbf{P}^f=(1-\mathbf{P}^t)$. The *full Hilbert space of initial conditions* for the *stratified wave equation* is thus $\boldsymbol{\mathcal{H}}=\boldsymbol{\mathcal{H}}^f\oplus\boldsymbol{\mathcal{H}}^t$, which is the standard decomposition.[2,4]

The theory of Sec. III is now used to further decompose $\boldsymbol{\mathcal{H}}^t$ by introducing,

$$\mathcal{P}^j_\Lambda\boldsymbol{\phi}(x,y)\equiv\Omega_k\int_{\sigma_\tau\otimes S^{k-1}}e^{-ix\cdot\mu h_j^{-1}(q)}\tilde{\psi}_j(q,y)H_k(q)\hat{v}_q\chi_\Lambda(-i\partial_q)$$

$$\times\left(\int_{\mathbf{R}^1}\tilde{\psi}_j(q,\overline{y})\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}(q,\overline{y})d\overline{y}\right)dq\,d\mu.\tag{35}$$

Lemma 4.1: For each $j\in\mathbf{N}$, $\mathcal{P}^j_\pm$ are complementary-orthogonal projections on $\boldsymbol{\mathcal{H}}_j$.

The proof is similar to that of Lemma 3.1 so the details are not repeated.

Now to proceed, detailed properties of $\tilde{\psi}(q,y)$ are needed. Thus we consider the special case of a stratified operator with single layer, which is an example of (C1)(b) in Sec. II;

(C2) Assume that $V(y)=0$. Furthermore, suppose $\exists c_*,R_*$ with $0<c_m<c_\infty$ so that $c(y)=c_m$ for $R_1<y<R_2$ and $c(y)=c_\infty$ otherwise.

If $R_1=-R_2=-R$ for $R>0$ and j is even, the normalized eigenstates of (31) are,

$$\tilde{\psi}_j(q,y)=N_j(q)\begin{cases}(1/c_\infty)\cos(g_jR)\exp[-f_j(|y|-R)], & |y|>R\\ (1/c_m)\cos(g_jy), & |y|<R\end{cases},\tag{36}$$

where the q-dependent quantities are,

$$f_j\equiv\sqrt{\omega_j^{-1}(q^2)-q^2/c_\infty^2},\quad g_j\equiv\sqrt{q^2/c_m^2-\omega_j^{-1}(q^2)},$$
$$N_j(q)\equiv\left[(f_jc_\infty^2)^{-1}\cos^2(g_jR)+2(g_jc_m^2)^{-1}\int_0^{g_jR}\cos^2u\,du\right]^{-1/2},\tag{37}$$

and the thresholds are $\tau_j=j\pi/R\sqrt{c_m^{-2}-c_\infty^{-2}}$. The dispersion relations satisfy,

$$c_mf_j=c_\infty g_j\tan(g_jR),\quad f_j^2+g_j^2=q^2(c_m^{-2}-c_\infty^{-2}),$$

which ensure the existence of analytic neighborhoods for $\omega_j^{-1}(q^2)$ around τ_j and ∞ so that,

$$f_j=\sum_{k=1}^\infty a_k(q^2-\tau_j^2)^k,\quad g_j=(j+1)\pi/2R+\sum_{k=1}^\infty b_kq^{-k},$$

respectively. Similar expressions hold for the odd j modes. Using these explicit expressions we now obtain propagation estimates for outgoing trapped states with $\Lambda=(a,b)$, where $0<a<b$ and with $\delta=2$ for $b<\infty$, or with $\delta=1$ for $b=\infty$ (as defined in Sec. III). The corresponding result holds for incoming states.

Proposition 4.2: Let (C2) hold and suppose that $\tau_j>0$. Then for each $\alpha<\delta/k$ with $\alpha<1$ and $\beta\equiv\delta-\alpha k>0$, $\exists C$ so that $\forall\,\boldsymbol{\psi}_0\in\boldsymbol{\mathcal{H}}$,

$$\|\chi_+(|t+\rho|^\alpha-|z|)U_t\mathcal{P}^j_{+\rho\Lambda}\boldsymbol{\psi}_0\|^2\leqslant C(1+|t+\rho|)^{-\beta}\|\boldsymbol{\psi}_0\|^2,\quad t>0. \tag{38}$$

If $\tau_j=0$ then for each $\alpha<1$, $\beta\equiv\delta-\alpha$, $\exists C>0$ so that (38) holds.

Proof: We sketch the essential details. Set $\rho=1$. Then, proceeding as in (27) and (28), we can bound the left-hand side of (38) with,

$$\begin{aligned}\int_{y=-t^\alpha}^{t^\alpha}\int_{|x|\leqslant|t|^\alpha}|U_t\mathcal{P}^j_{+\Lambda}\boldsymbol{\psi}_0|^2d^kx\,dy&\leqslant 2\int_{\mathbf{R}^{k+1}}|(1-\mathcal{G}(h(|\nabla_x|)))\mathcal{P}^j_{+\Lambda}\boldsymbol{\psi}_0|^2d^kx\,dy\\&\quad+2\int_{y=-t^\alpha}^{t^\alpha}\int_{|x|\leqslant|t|^\alpha}|U_t\mathcal{G}(h(|\nabla_x|))\mathcal{P}^j_{+\Lambda}\boldsymbol{\psi}_0|^2d^kx\,dy.\end{aligned} \tag{39}$$

The first term on the right-hand side vanishes as $A\to\tau_j^+$, $B\to\infty$. For the second term we decompose the y-integration into oscillatory and exponential parts as defined in (36). In the oscillatory region $|y|<R$ integration by parts gives,

$$\begin{aligned}\int_{-R}^{R}\sup_{\mu}\sup_{|x|\leqslant t^\alpha}\int_{-b}^{-a}\Bigg\{&\left|\int_A^{2c_\tau}e^{i\psi_t}(\psi_t''(\psi_t')^{-2}+(\psi_t')^{-1}\partial_q)\mathcal{G}_AH_kN(q)dq\right|^2\\&+\left|\int_{c_\tau}^{2B}e^{i\psi_t}(\psi_t''(\psi_t')^{-2}+(\psi_t')^{-1}\partial_q)^{\lceil k/2\rceil}\mathcal{G}_BH_kN(q)dq\right|^2\Bigg\}ds\,dy,\end{aligned} \tag{40}$$

where the phase function is defined, suppressing the j index,

$$\varphi_t\equiv tq-sq-x\cdot\mu h^{-1}(q)\pm g(q)y,\quad \varphi_t'=t-s-x\cdot\mu(h^{-1})'\pm g'y. \tag{41}$$

By analyticity of f, g, and N, the integral in (40) is bounded by $Ct^{-\delta}$.

In the exponential region $R<|y|<t^\alpha$ we modify the previous expression by integrating $|y|$ from $R\to t^\alpha$ and replacing $N(q)$ with $N(q)\exp(-f(|y|-R))$. In the phase function (41) set $y=R$. We may now proceed as above except for terms of the form,

$$\int_R^{t^\alpha}\left|\int_{c_\tau}^{2B}e^{i\varphi_t}\mathcal{G}^{(k_1)}H_k^{(k_2)}N^{(k_3)}\partial_q^{k_4}e^{-f(y-R)}dq\right|^2dy\leqslant\sum_{l=1}^{k_4}\left(\int_0^{f(t^\alpha-R)}u^{2l}e^{-2u}du\right)C_l,$$

which are clearly bounded. Here $\Sigma k_i=\lceil k/2\rceil$. This leads to a $t^{-\delta}$ bound. When $\tau_j=0$ then the H_k function improves the bounds for $k\geqslant 2$ near A. We omit the details. □

B. Perturbed stratified media

As an application to scattering theory, consider the perturbed system (1), where the dependent variables satisfy, in addition to (2),

(C3) $V_p, c_p\in\mathcal{C}^4$ and $\exists\,\gamma_p>1/2$ so that for $\langle z\rangle\equiv(1+|z|^2)^{1/2}$,

$$\|\langle z\rangle^{2\gamma_p}(V_p(z)-V(y))\|_\infty+\|\langle z\rangle^{2\gamma_p}(c_p(z)-c(y))\|_\infty<\infty.$$

Let $F \equiv F_{(u,v)} \in C^{\infty}(\mathbf{R}^1)$ be a uniformly bounded positive function with support on (u,v), $0 < u < v < \infty$. The following is a consequence of the work in Ref. 2. See also Ref. 15 for further discussion of operator-smoothness and Ref. 3 for similar energy estimates.

Lemma 4.3: Suppose the systems in (4) and (1) satisfy (C1) and (C3), respectively. Then the following energy-decay estimate holds:

$$\int_{-\infty}^{\infty} \|\langle z\rangle^{-\gamma\#} U_t^{\#} F(K^{\#}) \boldsymbol{\psi}_0\|_{\mathcal{H}}^2 dt \leq C \|\boldsymbol{\psi}_0\|_{\mathcal{H}}^2, \tag{42}$$

for $\gamma_{\#} > 1/2$ and $\gamma_{\#} = \gamma_0$ or γ_p, $U_t^{\#} = U_t$ or U_t^p and $K^{\#} = K$ or K^p, respectively.

The scattering operator S in (8) is defined in terms of the wave operators $\Omega_{\pm}$ which, by Cook's method, have the alternative representations,

$$\Omega_{\pm} = 1 + i \int_0^{\pm\infty} U_t^p \mathcal{V} U_{-t} dt. \tag{43}$$

Here $\mathcal{V}$ is a matrix operator with localness properties (shown in the Appendix),

Lemma 4.4: Under conditions (C1) and (C3), with $F \equiv F_{(u,v)}$, the operators,

$$\mathcal{V} F(K) \langle z\rangle^{\mu}, \quad \langle z\rangle^{\mu} F(K^p) \mathcal{V},$$

$$\langle z\rangle^{2\gamma} F(K^p) \mathcal{V} F(K) \langle z\rangle^{2(\gamma_p - \gamma)}, \quad \langle z\rangle^{2\gamma} (F(K^p) - F(K)) \langle z\rangle^{2(\gamma - \gamma_p)},$$

are bounded for each $0 < u < v < \infty$ and $\mu \leq \gamma_p$ and $0 \leq \gamma \leq \gamma_p$. If $c_p(z) = c(y)$, i.e., $K^p - K = V_p - V$, then the same holds for $v = \infty$.

Using the $\mathcal{H}$-decomposition into free and trapped states, we obtain, with obvious interpretation,

$$S = \mathbf{P}^f S \mathbf{P}^f + \mathbf{P}^f S \mathbf{P}^t + \mathbf{P}^t S \mathbf{P}^f + \mathbf{P}^t S \mathbf{P}^t.$$

The paper is completed with the following:

Main Theorem 4.5: The scattering operator S exists, given conditions (C1) and (C3). Furthermore, for nondegenerate trapped modes with positive thresholds $\tau_j, \tau_k > 0$ and any finite $u > \max\{\tau_j, \tau_k\}$, $v > u$, $\exists\, \nu, C_\nu > 0$ so that,

$$\|P_{+\rho}^j S F_{(u,v)}(K) P_{-\rho}^k\| \leq C_\nu / \rho^\nu. \tag{44}$$

If (C2) and $c_p(z) = c(y)$ hold, i.e., $K^p - K = V_p$, then the uniform causality estimate in (10) holds. Furthermore, if condition (C3) holds for all $\gamma_p > 1/2$, then for each $\nu < 1/2$ a finite constant C_ν exists so that (10) holds.

Proof: The existence of S follows directly from completeness of the wave operators $\Omega_{\pm}$. The latter holds by observing that for any $\boldsymbol{\phi} \in F(K^p)\mathcal{H}$, $\boldsymbol{\psi} \in F(K)\mathcal{H}$, with $F \equiv F_{(u,v)}$,

$$\left| \left\langle \boldsymbol{\phi}, \int_0^{\infty} U_t^p \mathcal{V} U_{-t} dt\, \boldsymbol{\psi} \right\rangle \right| \leq C_F \|\boldsymbol{\phi}\| \|\boldsymbol{\psi}\|,$$

using Lemmas 4.3 and 4.4. Thus $\Omega_{\pm}$ in (43) are densely defined on $\mathcal{H}$. By a similar argument the adjoints are densely defined. Since the wave operators are all bounded linear operators, a standard $\epsilon/3$ argument verifies completeness for $u = 0$, $v = \infty$.

Inequality (44) requires propagation estimates like those in (38). Due to the momentum cutoff function $F_{(u,v)}$ we can proceed as in Proposition 4.2 and use local analyticity of eigenstates[17] to show that for each $M > 0$ and $c_m' < c_m$, $\exists C_M$ so that,

$$\|\chi_+(c_m'|t+\rho| - |z|) U_t F(K) \mathcal{P}_{+\rho}^j \boldsymbol{\psi}_0\|^2 \leq C_M (1 + |t+\rho|)^{-M} \|\boldsymbol{\psi}_0\|^2, \quad t > 0. \tag{45}$$

Choose any $\phi,\psi\in\mathcal{H}$ and let $G^3=F(K)$. Also define $G_0\equiv G(K)$ and $G_p\equiv G(K^p)$. Then (44) is obtained by considering,

$$\langle\boldsymbol{\phi},\mathcal{P}^j_{+\rho}G_0\Omega^*_-G_p\Omega_+G_0\mathcal{P}^k_{-\rho}\boldsymbol{\psi}\rangle=\langle\boldsymbol{\phi},\mathcal{P}^j_{+\rho}G_0G_pG_0\mathcal{P}^k_{-\rho}\boldsymbol{\psi}\rangle+C_1\|\boldsymbol{\phi}\|\int_0^\infty\|\langle z\rangle^{-\gamma_p}U_{-t}G_0\mathcal{P}^k_{-\rho}\boldsymbol{\psi}\|dt$$

$$+C_2\int_0^\infty\|\langle z\rangle^{-\gamma_p}U^p_tG_0\mathcal{P}^j_{+\rho}\boldsymbol{\phi}\|dt\|\boldsymbol{\psi}\|.$$

The last two terms are bounded by inverse powers of ρ due to (45). For the first term on the right-hand side, write $G_p=(G_p-G_0)+G_0$, and note that Lemma 4.4 and Eq. (45) combine to handle the difference of operators. If $j\neq k$ then the G_0 term vanishes. Else, we need to establish the following causality estimate (in the Appendix),

Lemma 4.6: Let $\mathcal{P}^j_*$ be the projections defined in (35) on $\mathcal{H}$. Then for any $F\in\mathcal{C}_0^\infty(\mathbf{R}^+)$ and $\forall M>0,\exists C_*>0$, so that,

$$\|\mathcal{P}^j_\pm F(K)\mathcal{P}^j_{\mp\rho}\|\leq C_{M,F}/\rho^M.$$

Finally we show (10), assuming that (C3) holds for all $\gamma_p>1/(2\alpha)$. Remaining results are obtained similarly. For $\tau_j\leq\tau_k$ consider the decomposition of $P^j_{+\rho\Lambda}SP^k_{-\rho\Lambda}$,

$$P^j_{+\rho\Lambda}\chi_k\Omega^*_+[(1-P^k_-)\Omega_-P^k_{-\rho\Lambda}]+[P^j_{+\rho\Lambda}\chi_k\Omega^*_+P^k_-]\Omega_-P^k_{-\rho\Lambda}, \tag{46}$$

for $\chi_k\equiv\chi_{[\tau_k,\infty)}(K)$. Write the $[\cdots]$ factor in the first term as,

$$(1-P^k_-)\Omega_-P^k_{-\rho\Lambda}=(1-P^k_-)P^k_{-\rho\Lambda}+i\int_0^{-\infty}(1-P^k_-)U^p_t\mathcal{V}U_{-t}P^k_{-\rho\Lambda}\,dt.$$

The first term on the right-hand side is clearly 0. As for the second term, we use Lemmas 4.3 and 4.4 and consider, for any $\boldsymbol{\psi}\in\mathcal{H}$,

$$\int_0^{-\infty}\|\langle z\rangle^{-\gamma_p}U_{-t}P^k_{-\rho\Lambda}\boldsymbol{\psi}\|^2dt\leq\|\boldsymbol{\psi}\|^2\int_0^{-\infty}\|\langle z\rangle^{-\gamma_p}\chi_+(|z|-|t-\rho|^\alpha)\|^2_\infty dt$$

$$+\int_0^{-\infty}\|\chi_+(|t-\rho|^\alpha-|z|)U_{-t}P^k_{-\rho\Lambda}\boldsymbol{\psi}\|^2dt$$

$$\leq\|\boldsymbol{\psi}\|^2(C_1/\rho^{(2\alpha\gamma_p)-1}+C_2/\rho^{\delta-\alpha k-1}).$$

Since $\Lambda\Subset\mathbf{R}^+$ is compact, $\delta=2$. Hence for α arbitrarily small and γ_p large we obtain a nearly $\rho^{-1/2}$ bound for the norm of the first term in (46).

Finally, if $\tau_j<\tau_k$ then the term $P^j_{+\rho\Lambda}\chi_k\Omega^*_+P^k_-$ in (46) has a stronger bound than the one above, even for $\Lambda=(a,\infty)$, $a>0$. This completes the Theorem. □

V. CONCLUSION

In this paper we introduced incoming/outgoing projection operators and obtained uniform decay estimates for solutions of the wave equation with initial conditions in the corresponding subspaces. These estimates allowed us to study the scattering operator for the perturbed-stratified wave equation. The concept of strict causality for the system is replaced by a causality estimate.

ACKNOWLEDGMENT

This is dedicated to the memory of Sanjaya Baratham.

APPENDIX

Proof of Lemma 3.1: Due to the details involved, we only consider the special case $h(\xi)=\xi$ and $\gamma=1$. However we allow $\tau\geqslant 0$ in order to demonstrate how one can *bridge the energy gap*. Let $\phi_*,\psi_*\in\mathcal{H}_\tau$ be arbitrary.

Idempotentcy: We show $\mathcal{P}_+^2=\mathcal{P}_+$ using definition (3.2). That $\mathcal{P}_-^2=\mathcal{P}_-$ follows similarly. Compute,

$$\begin{aligned}\mathcal{P}_+^2\boldsymbol{\phi}&=\mathcal{P}_+(\mathcal{F}^h)^{-1}\hat{v}_q(\chi_+(-i\partial_q))\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}\\&=(\mathcal{F}^h)^{-1}\hat{v}_r\chi_+(1/2)(\mathcal{F}^h(\mathcal{F}^h)^{-1}-i\hat{r}\mathcal{F}^h(\mathcal{F}^h)^{-1}i\hat{q})\chi_+\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}\\&=(\mathcal{F}^h)^{-1}\hat{v}_r\chi_+^2\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}=\mathcal{P}_+\boldsymbol{\phi},\end{aligned}$$

where we use the fact that $\mathcal{F}^h(\mathcal{F}^h)^{-1}=\delta(r-q)$ and $\chi_+^2=\chi_+$.

Self-adjointness: Since $\mathcal{P}_\pm$ are bounded operators, we need only show the symmetric property. Using Fubini's theorem and the δ-function properties we calculate,

$$\langle\boldsymbol{\psi},\mathcal{P}_+\boldsymbol{\phi}\rangle=\Omega_k\int_{\sigma_\tau\otimes S^{k-1}}(\mathcal{F}^h\boldsymbol{\psi})^*\hat{v}_q(\gamma\chi_+(-i\partial_q)\gamma)\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}\,dq\,d\mu.$$

Then, since $-i\partial_q$ is a self-adjoint operator on $\mathcal{L}^2(\sigma_\tau\otimes\mathcal{S}^{k-1},dq\,d\mu)$, so is $\chi_+(-i\partial_q)$.

To complete the Lemma note that $\chi_+(-s)=\chi_-(s)$, $\chi_+\chi_-=0$, $\chi_++\chi_-=1$, etc. □

Proof of Claim 3.2: From (3.3) it is clear that for each $R>0$, as $t\to\infty$, $\|\chi_+(R-|x|)U_t\mathcal{P}_+\|\to 0$ and this, along with its corresponding adjoint expression, verifies (i)′(a). For (i)′ (b), choose any $\boldsymbol{\phi}\in\boldsymbol{\mathcal{H}}$ and observe that using (3.5) gives,

$$\begin{aligned}(1-\mathcal{P}_{+t})U_t\mathcal{P}_+\boldsymbol{\phi}&=\int dq\,d\mu\, e^{-ix\cdot\mu h^{-1}(q)}H_k(q)\hat{v}_q(1-\chi_{+t})e^{iqt}\chi_+(\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi})\\&=\int dq\,d\mu\, e^{i((q+\tau\hat{q})t-x\cdot\mu h^{-1}(q))}H_k(q)\hat{v}_q[\chi_-e^{i\tau\hat{q}t}\chi_+](\hat{v}_q^T\mathcal{F}^h\boldsymbol{\phi}).\end{aligned}$$

The factor in $[\cdots]$ vanishes identically if $\tau t=n\pi$ for $t\geqslant 0$, $n\in\mathbf{N}$.

Property (ii) follows immediately from (i)′(b). For (iii) we approximate any $\boldsymbol{\phi}\in\boldsymbol{\mathcal{H}}$ by a state in $\cup U_t\mathcal{D}_+$. In particular, consider,

$$\|\boldsymbol{\phi}-U_t\mathcal{P}_+U_{-t}\boldsymbol{\phi}\|=\|(1-\mathcal{P}_+)U_{-t}\boldsymbol{\phi}\|=\|\mathcal{P}_-U_{-t}\boldsymbol{\phi}\|.$$

The right-hand side vanishes as $t\to-\infty$ by (i)′(a). □

Proof of Lemma 4.4: The perturbed matrix operator is,

$$\mathcal{V}\equiv\begin{pmatrix}0&\sqrt{K}-\sqrt{K^p}\\\sqrt{K^p}-\sqrt{K}&0\end{pmatrix}.$$

To study this quantity, we use Kato's square root formula,

$$\sqrt{K}-\sqrt{K^p}=\int_0^\infty\sqrt{\omega}\frac{1}{K^p+\omega}(K-K^p)\frac{1}{K+\omega}\,d\omega.\tag{A1}$$

Similarly we can reduce the study of $F(K)-F(K^p)$ to that of $K-K^p$ (see the discussion in Sec. VI of Ref. 2). Here we only consider the integrand on the right-hand side of (A1). A simple computation gives,

$$K-K^p=(1-c_p/c)K-K^p(1-c/c_p)-Vc_p/c+V_pc/c_p.$$

Now, for $L=K$ or K^p denote $F\equiv F_{(u,v)}(L)$ where $0\leqslant F\leqslant 1$. In the case $c_p\neq c$ we have the obvious bounds,

$$\left\|\frac{K}{K+\omega}F(K)\right\|_\infty=\left\|\frac{K^p}{K^p+\omega}F(K^p)\right\|_\infty\leqslant\frac{v}{u+\omega}.$$

If $c_p=c$ (but $V_p\neq V$) then these bounds will not be required, hence $v=\infty$ is allowed.

To verify the first two bounds in Lemma 4.4, we seek to prove,

$$\left\|\langle z\rangle^{-\mu}F(L)\frac{L^\delta}{L+\omega}\langle z\rangle^\mu\right\|\leqslant\frac{C_\mu}{\omega+1},\quad \delta=0,1,$$

where $\delta=1$ requires $v<\infty$. Here $\mu\geqslant 0$ but we consider only the $\mu=1$ case. The result is clear for $\mu=0$ and the following techniques apply for any integer μ. Interpolation obtains this bound for all $\mu\in\mathbf{R}$. The remaining bounds in Lemma 4.4 are obtained similarly.

Define the smooth cutoff functions $\{G_i\}$ so that $F=G_0=G_1^2=G_2^4=$etc. Then using a partition of $\mathbf{R}^n$, homogeneous of degree 0 in $|z|$ near ∞, it is sufficient to consider, for any $z_j\in\mathbf{R}$, $1\leqslant j\leqslant k+1$, $n\in\mathbf{N}$ with $G_*=G_*(L)$ and $i=\sqrt{-1}$,

$$\begin{aligned}G_{n-1}(L+\omega)^{-1}(z_j+i)-(z_j+i)G_{n-1}(L+\omega)^{-1}\\=G_n(L+\omega)^{-1}[G_n,z_j]-G_n(L+\omega)^{-1}[L,z_j](L+\omega)^{-1}G_n\\+[G_n,z_j](L+\omega)^{-1}G_n.\end{aligned}\tag{A2}$$

For the middle term on the right-hand side of (A2), we evaluate for $1\leqslant l\leqslant k$,

$$[K,x_l]=-2c^2(y)\partial_{x_l},\quad [K^p,x_l]=-2c^p(z)\partial_{x_l}c^p(z),$$

$$[K,y]=-2c\partial_y c,\quad [K^p,y]=-2c^p\partial_y c^p.$$

Thus for any $\phi\in\mathcal{H}$, using the Schwartz inequality,

$$\|[L,z_j](L+\omega)^{-1}G_i\phi\|^2\leqslant 4(c_p^M)^2\|(L+\omega)^{-1}G_i\|\|\phi\|^2\leqslant C(\omega+1)^{-1}\|\phi\|^2.$$

We are left to consider the remaining terms in (A2). Define $R\equiv(L+1)^{-1}$ and $J_n=(L+1)^2G_n$ if $v<\infty$ or $J_n=(L+1)^2(1-G_n)$ if $v=\infty$. Then,

$$[G_n,z_j]=RJ_n[R,z_j]+R[J_n,z_j]R+[R,z_j]J_nR.$$

To bound the middle term on the right-hand side it is standard to use the Fourier transform $\hat{J}_n$ of J_n and write,

$$R[J_n,z_j]R=\int_0^\infty\hat{J}_n(s)\int_0^s e^{iL(s-r)}R[L,z_j]Re^{-iLr}dr\,ds.$$

This is clearly a bounded operator. Iteration of these techniques verifies the result. □

Proof of Lemma 4.6: For brevity we only consider the $h(q)=c_mq,\tau=0$ case. Compute,

$$\begin{aligned}\|\mathcal{P}_+^j F(K)\mathcal{P}_{-\rho}^j \boldsymbol{\phi}\|^2 &= \int_{\mathbf{R}^k} (\mathcal{P}_+^j F \mathcal{P}_{-\rho}^j \boldsymbol{\phi})^* (\mathcal{P}_+^j F \mathcal{P}_{-\rho}^j \boldsymbol{\phi}) d^k x \\ &= \int_{\mathbf{R}^{k+1}} \left[\int_{\mathbf{R}\times\mathcal{S}^{k-1}} e^{i(x\cdot\omega/c_m)r} \tilde{\psi}_j(r,y) |r|^{(k-1)/2} \hat{v}_r^* \right. \\ &\quad \times (\gamma\chi_-(-i\partial_r) F(r^2)\chi_\rho(-i\partial_r)\gamma^*) \\ &\quad \times \left. \left(\int_{\mathbf{R}^1} \tilde{\psi}_j(r,\overline{y})(\hat{v}_r^T)^* \overline{(\mathcal{F}^h \boldsymbol{\phi})^* dy} \right) dr\, d\omega \right] (\text{c.c.}) d^k x\, dy \\ &= \int_{\mathbf{R}\times\mathcal{S}^{k-1}} |r|^{k-1} [\hat{v}_r^* (\gamma\chi_- F \chi_\rho \gamma^*)(\hat{v}_r^T)^* (\mathcal{F}^h \boldsymbol{\phi})^*] (\text{c.c.}) dr\, d\omega \\ &\leqslant 2\|\chi_- F \chi_\rho\|_{op}^2 \|\boldsymbol{\phi}\|^2,\end{aligned}$$

where c.c. means complex conjugate of the previously bracketed factor. Now, since $F \in C_0^\infty(\mathbf{R}^+)$, we can write $F(r^2) = \int_{-\infty}^{\infty} e^{-irs}\hat{G}(s)ds$ for some $\hat{G} \in \mathcal{S}(\mathbf{R})$. Then, using (3.5),

$$\begin{aligned}\|\chi_- F \chi_\rho \psi\|^2 &= \int_{\mathbf{R}\times\mathcal{S}^{k-1}} \left| \int_{-\infty}^{-\rho} e^{-irs}\hat{G}(s)\chi_{(\rho,-s)}(-i\partial_r)\psi(r,\omega)ds \right|^2 |r|^{k-1} dr\, d\omega \\ &\leqslant \int |r|^{k-1} dr d\omega \left[\int_{-\infty}^{-\rho} \langle s\rangle^{M+1} |\hat{G}(s)|^2 ds \int_{-\infty}^{-\rho} \langle t\rangle^{-(M+1)} |\chi_{(\rho,-t)}\psi(r,\omega)|^2 dt \right] \\ &\leqslant C \int_{-\infty}^{-\rho} \langle t\rangle^{-(M+1)} \left(\int |r|^{k-1} dr\, d\omega |\chi_{(\rho,-t)}\psi(r,\omega)|^2 \right) dt \leqslant C' \rho^{-M} \|\psi\|^2.\end{aligned}$$

These details easily extend to the case of nonlinear $h(q)$. □

Poisson–Lie structures on infinite-dimensional jet groups and quantum groups related to them

Ognyan Stoyanov[a)]
Department of Mathematics, Rutgers University, New Brunswick, New Jersey 08903

(Received 22 December 1997; accepted for publication 17 September 1998)

We study the problem of classifying all Poisson–Lie structures on the group G_∞ of formal diffeomorphisms of the real line $\mathbb{R}^1$ which leave the origin fixed, as well as the extended group of diffeomorphisms $G_{0\infty}\supset G_\infty$ whose action on $\mathbb{R}^1$ does not necessarily fix the origin. A complete local classification of all Poisson–Lie structures on the groups G_∞ and $G_{0\infty}$ is given. This includes a classification of all Lie-bialgebra structures on the Lie algebra $\mathcal{G}_\infty$ of G_∞, which we prove to be all of the coboundary type, and a classification of all Lie-bialgebra strucutures on the Lie algebra $\mathcal{G}_{0\infty}$ (the Witt algebra) of $G_{0\infty}$ which also turned out to be all of the coboundary type. A large class of Poisson structures on the space V_λ of λ-densities on the real line is found such that V_λ becomes a homogeneous Poisson space under the action of the Poisson–Lie group G_∞. We construct a series of quantum semigroups whose quasiclassical limits are finite-dimensional Poisson–Lie quotient groups of G_∞ and $G_{0\infty}$.
[S0022-2488(99)00201-7]

I. INTRODUCTION

Quantum groups have been introduced in Refs. 1,2 as deformations of universal enveloping algebras of Lie groups and of the algebra of functions on Poisson–Lie groups.[3] The latter are Lie groups equipped with Poisson structures compatible with the group structure (from where the term Poisson–Lie group originates). In this approach to constructing quantum groups the first step is to analyze the existence of Poisson–Lie structures on the corresponding Lie group. The question of classifying all Poisson–Lie structures on a given Lie group (provided any exist) has been posed originally by Drinfel'd and Belavin.[4–6] In the same paper they give a complete solution for the case of finite-dimensional complex (semi)simple Lie groups. The problem, in general, is very difficult. It has been solved for some other groups in low dimensions. Let us give a list of groups for which the solution of the classification problem is known to us at present: (a) Finite dimensional complex (semi)simple Lie groups;[4] (b) the groups $GL(2,\mathbb{R})$, $SL(2,\mathbb{R})$, $GL(1|1)$;[7,8] (c) the 3-dimensional Heisenberg group,[9] and some unipotent subgroups of $GL(n,\mathbb{R})$ in various dimensions;[10] (d) the group of affine transformations of the line $Aff(1)$; (e) the group of motions of $\mathbb{R}^1\times\mathbb{R}^1$; (f) the Lorentz group considered as a realification of $SL(2,\mathbb{C})$.[11]

Note that all the groups mentioned above are *finite-dimensional*, and the only infinite *series* for which the classification has been completed are *complex* not *real* groups.

With this paper we initiate a program of study of Poisson–Lie structures for the important case of the group of (formal) diffeomorphisms $FDiff(\mathbb{R}^n)$. One of our principal results is the complete solution of the classification problem for the case $n=1$. Namely, in the work presented here we study the problem of local classification (up to a local change of coordinates) of all the Poisson–Lie structures on the group $G_\infty=FDiff(\mathbb{R}^1)$ of formal diffeomorphisms of the real line $\mathbb{R}^1$ which leave the origin fixed, as well as the full group of diffeomorphisms $G_{0\infty}=FDiff_0(\mathbb{R}^1)\supset G_\infty$ (considered as a formal group) whose action on $\mathbb{R}^1$ does not necessarily fix the origin.

The existence of Poisson–Lie structures on G_∞ and $G_{0\infty}$ is far from being obvious. For instance, since G_∞ is a projective limit of groups of finite jets (cf. Sec. III), if we consider the group of 3-jets leaving the origin fixed, then there exists a Poisson–Lie structure on this group,[12] which can not be extended to G_∞. Even though the above groups are infinite-dimensional, surprisingly, the classification problem has a complete solution. There exist countably many isomorphism classes of Poisson–Lie structures on G_∞ and $G_{0\infty}$, labeled by integers $d\in\mathbb{N}\rightarrow\mathbb{Z}_+$ and $d\in\mathbb{N}\rightarrow\mathbb{Z}_+\cup\{-1\}$, respectively. The isomorphism classes under the actions of $G_{0\infty}$ and G_∞ are explicitly described.

Let $[u\mapsto x(u)=x_0+x_1u+x_2u^2+\cdots]\in G_{0\infty}$ be a formal diffeomorphism. The coordinate ring $\mathbb{R}[[x]]$ of $G_{0\infty}$ is countably generated. Let $x=(x_0,x_1,\ldots)$ be a formal point of $G_{0\infty}$, where x_1 is assumed to be invertible. For any $f,g\in\mathbb{R}[[x]]$ a Poisson–Lie bracket, $\{,\}:\mathbb{R}[[x]]\otimes\mathbb{R}[[x]]\rightarrow\mathbb{R}[[x]]$, is defined as

$$\{f,g\}(x):=\omega_{ij}(x)\frac{\partial f}{\partial x_i}\frac{\partial g}{\partial x_j}, \tag{1}$$

where summation over repeated indices is understood. Here $\omega_{ij}=\{x_i,x_j\}\in\mathbb{R}[[x]]$, $i,j\in\mathbb{Z}_+$ are the components of a (formal) tensor that satisfy the infinite system of differential equations (the Jacobi identities):

$$\omega_{ij}\frac{\partial\omega_{kl}}{\partial x_i}+\omega_{ik}\frac{\partial\omega_{lj}}{\partial x_i}+\omega_{il}\frac{\partial\omega_{jk}}{\partial x_i}=0, \tag{2}$$

and the infinite system of functional equations [ω is required to be a (group) 1-cocycle)],

$$\omega_{ij}(z)=\omega_{kl}(x)\frac{\partial z_i}{\partial x_k}\frac{\partial z_j}{\partial x_l}+\omega_{kl}(y)\frac{\partial z_i}{\partial y_k}\frac{\partial z_j}{\partial y_l}, \tag{3}$$

where $z_i=F_i(x,y)$, $i=0,1,2,\ldots$, describe the formal group law[24] induced by the substitution of formal power series $z(u)=x(y(u))$. We introduce $\Omega(u,v;x):=\sum_{i,j=1}^{\infty}\omega_{ij}(x)u^iv^j$, a generating series for the brackets ω_{ij}. The multiplicativity (3) of the Poisson brackets is equivalent to $\Omega(u,v;x)$ satisfying the following functional equation (Lemma IV.1):

$$\Omega(u,v;xy)=\Omega(y(u),y(v);x)+\Omega(u,v;y)x'(y(u))x'(y(v)). \tag{4}$$

Here x' denotes the derivative of x with respect to its argument. The general solution of this equation is (Theorem IV.1)

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)-\varphi(x(u),x(v)), \tag{5}$$

where $\varphi(u,v)=-\varphi(v,u)\in\mathbb{R}[[u,v]]$ is a formal series in u,v, and satisfies the following functional partial differential equation (Lemma IV.2):

$$\begin{aligned}\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]+\varphi(v,w)[\partial_v\varphi(u,v)+\partial_w\varphi(u,w)]\\+\varphi(w,u)[\partial_w\varphi(v,w)+\partial_u\varphi(v,u)]=0.\end{aligned} \tag{6}$$

This equation is equivalent to the Jacobi identities (2) and is a functional realization of the Classical Yang–Baxter Equation (Sec. VI). We show that G_∞ acts on the space of solutions of (6). Further, we explicitly describe the moduli space of solutions and show that it is isomorphic to $\mathbb{Z}_+\cup\{-1\}$. By choosing the representative $\tilde{\varphi}(u,v)=uv(v^d-u^d)$, $d\in\mathbb{Z}_+\cup\{-1\}$, of each isomorphism class of solutions we obtain explicit formulas for the Poisson–Lie brackets. For each $d\in\mathbb{N}$ this gives rise to the Poisson–Lie tensor,

$$\omega_{ij}(x)=(i-d)jx_jx_{i-d}-i(j-d)x_ix_{j-d}+x_i\sum_{\Sigma_{k=1}^{d+1}s_k=j}x_{s_1}\ldots x_{s_{d+1}}-x_j\sum_{\Sigma_{k=1}^{d+1}s_k=i}x_{s_1}\ldots x_{s_{d+1}},\tag{7}$$

where $i,j\in\mathbb{Z}_+$. When $d=-1$ we have the tensor

$$\omega_{ij}(x)=i(j+1)x_ix_{j+1}-(i+1)jx_{i+1}x_j-x_i\delta_j^0+x_j\delta_i^0,\quad i,j\in\mathbb{Z}_+.\tag{8}$$

The class of the trivial Poisson–Lie bracket corresponds to $d=0$.

As we can see from the above formulas, the Poisson structures on $G_{0\infty}$ and G_∞ are given by polynomials of arbitrary degree, extending the existing list of known linear (Kirillov–Kostant brackets on the dual of a Lie algebra), quadratic (coming from solutions of CYBE for finite-dimensional groups),[13] and cubic (Toda lattice)[14] Poisson brackets. They give a series of nontrivial examples of infinite-dimensional Poisson manifolds.

The classification problem can be studied also on the level of Lie algebras. The Lie algebras of the groups $G_{0\infty}$ and G_∞ are the Witt algebra,

$$\mathcal{G}_{0\infty}=\mathrm{span}_k\{e_i|[e_i,e_j]=(i-j)e_{i+j},i,j\geqslant -1\},\quad \text{where } k=\mathbb{R}\text{ or }\mathbb{C},$$

and its principal subalgebra $\mathcal{G}_\infty=\mathrm{span}_k\{e_i|[e_i,e_j]=(i-j)e_{i+j},i\geqslant 0\}$. We prove that there is a one-to-one correspondence between the Poisson–Lie structures on G_∞ and the Lie-bialgebra structures on $\mathcal{G}_\infty$ (Sec. VI). The latter are shown to be *all* of the coboundary type (Theorem V.2). *All* Lie-bialgebra structures on $\mathcal{G}_{0\infty}$ are also of the coboundary type (Theorem V.1), they are all classified, and there is a one-to-one correspondence between them and an explicitly listed family of the Poisson–Lie structures on $G_{0\infty}$. Thus, a complete classification of all Lie-bialgebra structures on the Witt algebra $\mathcal{G}_{0\infty}$ and its principal subalgebra $\mathcal{G}_\infty$ is obtained. The result is that every Lie-bialgebra structure on $\mathcal{G}_\infty$ and $\mathcal{G}_{0\infty}$ is induced by a Lie-bialgebra structure on a 2-dimensional subalgebra generated by $\{e_0,e_d\}$ where $d\in\mathbb{N}$ and $d\in\mathbb{N}\cup\{-1\}$, respectively.

The study of Poisson homogeneous spaces under the action of Poisson–Lie groups is a subject of its own right. In this paper we construct a class of Poisson homogeneous spaces for the group G_∞. With a fixed Poisson–Lie structure the group G_∞ acts naturally (by substitution) on the modules $V_\lambda=\mathbb{R}[[u]](du)^\lambda$ of λ-densities on the line. Each Poisson–Lie structure on the group G_∞ induces a family of Poisson structures on V_λ such that V_λ becomes a homogeneous Poisson G_∞-space. Namely, the following theorem holds.

Theorem I.1: *For every $\lambda\in\mathbb{R}$ and $y(u)(du)^\lambda\in V_\lambda$ the following family of Poisson structures on V_λ:*

$$\{y(u),y(v)\}=\phi(u,v)y'(u)y'(v)+\lambda\partial_u\phi(u,v)y(u)y'(v)$$
$$+\lambda\partial_v\phi(u,v)y'(u)y(v)+\lambda^2\frac{\partial^2}{\partial u\,\partial v}\phi(u,v)y(u)y(v),\tag{9}$$

makes the action $G_\infty\times V_\lambda\to V_\lambda$ Poisson. Here $\phi(u,v)=-\phi(v,u)$, and $\phi(u,v)$ satisfies the functional partial differential equation (6).

Finally, we address the quantization problem for the Poisson–Lie brackets. We construct a series of finitely generated noncommutative noncocommutative bialgebras (quantum semigroups) whose quasi-classical limits are finite-dimensional Poisson–Lie quotient groups of G_∞ and $G_{0\infty}$. These are constructed by a formal deformation of the product of the coordinate ring of G_∞. The Poisson–Lie structures on these finite-dimensional groups are restrictions of the Poisson-Lie structures on G_∞ and $G_{0\infty}$, that is, restrictions of the families of brackets (7) to the finite-dimensional quotient groups $G_n=G_\infty \bmod u^{n+1}$ of n-jets. It is easy to show that the restriction is a well defined Poisson map. All such finite-dimensional Poisson–Lie groups for $d\leqslant 5$ and $n\leqslant 7$ have been quantized. Below we give an example of such quantization for the case $d=1$ and $n=4$. The corresponding Poisson brackets on G_4 are

$$\{x_1,x_2\}=x_1^3-x_1^2,$$

$$\{x_1,x_3\}=2x_2(x_1^2-x_1),$$

$$\{x_2,x_3\}=(3x_1-x_1^2)x_3+x_2^2(2x_1-4),$$

$$\{x_1,x_4\}=x_3(2x_1^2-3x_1)+x_2^2x_1,$$

$$\{x_2,x_4\}=x_4(4x_1-x_1^2)+x_3x_2(2x_1-6),$$

$$\{x_3,x_4\}=x_4x_2(8-2x_1)+x_3x_2^2+x_3^2(2x_1-9).$$

Their quantization is described by the following theorem.

Theorem I.2: *Let $X=\{x_1,x_2,x_3,x_4\}$ be a set of four generators and let $\langle X\rangle$ be the associative semigroup with an identity generated by X. Consider an ideal $\mathcal{I}_h$ generated by the following set of relations in $\mathbb{C}[[h]]\langle X\rangle$:*

$$x_1x_2=x_2x_1+h(x_1^3-x_1^2),$$

$$x_1x_3=x_3x_1+h(2x_2x_1^2-2x_2x_1)+h^2(2x_1^4-3x_1^3+x_1^2),$$

$$x_2x_3=x_3x_2+h(3x_3x_1-x_3x_1^2+2x_2^2x_1-4x_2^2)+h^2(3x_2x_1^2-3x_2x_1)+h^3(2-2C_3)(x_1^5-x_1^2),$$

$$\begin{aligned}x_1x_4=&x_4x_1+h(-3x_3x_1+2x_3x_1^2+x_2^2x_1)\\&+h^2x_2(3x_1-8x_1^2+5x_1^3)+h^3[(5x_1^5-12x_1^4+7x_1^3)+C_3(x_1^5-x_1^2)],\end{aligned}$$

$$\begin{aligned}x_2x_4=&x_4x_2+h(4x_4x_1-x_4x_1^2+2x_3x_2x_1-6x_3x_2+x_2^3)+h^2(3x_2^2x_1^2-10x_2^2x_1\\&+12x_2^2+12x_3x_1^2-2x_3x_1^3-15x_3x_1)+h^3x_2[(9+2C_3)x_1-17x_1^2+6x_1^3+(5-5C_3)x_1^4]\\&+h^4[(22-22C_3)x_1^2+(-4+4C_3)x_1^3+(-18+18C_3)x_1^5+C_4(x_1^6-x_1^2)],\end{aligned}$$

$$\begin{aligned}x_3x_4=&x_4x_3+h(8x_4x_2-2x_4x_2x_1+x_3x_2^2-9x_3^2+2x_3^2x_1)\\&+h^2[x_3x_2(-x_1^2+16x_1-24)+x_4(-7x_1^2+16x_1)]\\&+h^3[(10-10C_3)x_2^2x_1^3+(-9+8C_3)x_2^2+(-5+5C_3)x_3x_1^4+16x_3x_1^2-(6+9C_3)x_3x_1]\\&+h^4[(8-9C_3-2C_4)x_2x_1+(-8C_3+9)x_2x_1^2\\&+(10-10C_3)x_2x_1^4+(2C_4-18+18C_3)x_2x_1^5]\\&+h^5[(C_4+2C_3-2)x_1^2+(4-4C_3-C_4)x_1^6+(2C_3-2)x_1^5+C_5(x_1^7-x_1^2)],\end{aligned}$$

where $C_3,C_4,C_5\in\mathbb{C}$ are arbitrary parameters. Then the semigroup quotient algebra $\mathbb{C}[[h]]\langle X\rangle/\mathcal{I}_h$ is a bialgebra (quantum semigroup), denoted $G^1_{4|h}$, with a comultiplication (induced by the group multiplication) defined by

$$\Delta x_1 = x_1 \otimes x_1,$$

$$\Delta x_2 = x_1 \otimes x_2 + x_2 \otimes x_1^2,$$

$$\Delta x_3 = x_1 \otimes x_3 + x_2 \otimes x_1 x_2 + x_2 \otimes x_2 x_1 + x_3 \otimes x_1^3,$$

$$\Delta x_4 = x_1 \otimes x_4 + x_2 \otimes x_1 x_3 + x_2 \otimes x_2^2 + x_2 \otimes x_3 x_1 + x_3 \otimes x_1^2 x_2 + x_3 \otimes x_1 x_2 x_1 + x_3 \otimes x_2 x_1^2 + x_4 \otimes x_1^4.$$

Moreover, the algebra $\mathbb{C}[[h]]\langle X\rangle/\mathcal{I}_h$ has a Poincaré–Birkhoff–Witt basis.

This is a 3-parameter family of quantum semigroups and *the quantization is exact*. That is, it is *not a quantization modulo* h^6. Simply, no terms of higher order in h arise. This is due to the fact that the algebras under consideration are graded. On the generators the degree is defined by $\deg(x_i) = i-1$ and h has degree $\deg(h) = d$ ($d=1$ in the above case). Quantizations of other brackets are described in Sec. IX. The combinatorial nature of the coefficients of the noncommutative polynomials in the above relations remains a mystery.

The paper is organized as follows. In Sec. II we recall the basic concepts related to the Poisson–Lie theory and formulate the fundamental theorem of Drinfel'd relating Poisson–Lie groups and Lie-bialgebras. In Sec. III we introduce the infinite-dimensional group G_∞ and a smooth structure on it. In Sec. IV we find a class of Poisson–Lie structures on G_∞. In Sec. V we find all bialgebra structures on the Lie algebras $\mathcal{G}_{0\infty}$ and $\mathcal{G}_\infty$ and show that they are all coboundaries. In Sec. VI we show that there is a one-to-one correspondence between the Lie-bialgebra structures on $\mathcal{G}_\infty$ and the Poisson–Lie structures found on G_∞, and prove that the latter give a complete list of all Poisson–Lie structures on G_∞. In Sec. VII we classify all Poisson–Lie structures on $G_{0\infty}$. Section VIII is devoted to elements of representation theory for the Poisson–Lie group G_∞ on the homogeneous spaces V_λ. In Sec. IX we describe a series of finitely generated quantum semigroups. These we believe to be precursors of quantizations of G_∞ and $G_{0\infty}$ which are presently unknown.

II. POISSON–LIE THEORY

In this section we review the basic objects to be studied: Poisson manifolds, Poisson–Lie groups, Lie bialgebras, and some basic results about them.

Let $\mathcal{M}$ be a finite-dimensional smooth manifold. A Poisson structure (bracket) on $\mathcal{M}$ is a bilinear map $\{,\}: C^\infty(\mathcal{M}) \times C^\infty(\mathcal{M}) \to C^\infty(\mathcal{M})$, which makes $C^\infty(\mathcal{M})$ a Lie algebra, and is a derivation with respect to each argument. That is, there exists a section $\omega \in \wedge^2 T_{\mathcal{M}}$, where $T_{\mathcal{M}}$ is the tangent bundle of $\mathcal{M}$, such that for any $f,g,h \in C^\infty(\mathcal{M})$ we have $(f,g) \mapsto \{f,g\} = \langle \omega, df \wedge dg\rangle$, and

(i) $\{\{f,g\},h\} + \{\{g,h\},f\} + \{\{h,f\},g\} = 0$ (Jacobi identity);

(ii) $\{f,gh\} = \{f,g\}h + \{f,h\}g$ (derivation property);

(iii) $\{f,g\} = -\{g,f\}$ (antisymmetry),

where $\langle,\rangle$ denotes the natural pairing between $\wedge^2 T_{\mathcal{M}}$ and $\wedge^2 T^*_{\mathcal{M}}$, where $T^*_{\mathcal{M}}$ is the tangent bundle of $\mathcal{M}$. The second property, (ii), amounts to compatibility between the Lie algebra structure defined by $\{,\}$ and the multiplication in $C^\infty(\mathcal{M})$. In local coordinates,

$$\{f,g\}(x) = \omega_{ij}(x) \frac{\partial f}{\partial x_i} \frac{\partial g}{\partial x_j},$$

where $\omega_x = \omega_{ij}(x)(\partial/\partial x_i) \wedge \partial/\partial x_j \in \wedge^2 T_x$ is a bi-vector field at the point $x \in \mathcal{M}$, and $\{\partial/\partial x_i\}$ is a basis of the tangent space T_x at $x \in \mathcal{M}$ in the local coordinates (x_i).

Here and throughout this text a summation is understood over repeated nonfixed indices unless stated otherwise. Note also that our convention about the position of indices of tensors is the opposite to the standard one. Namely, all contravariant(covariant) tensors have lower(upper) indices. We found this notation more convenient when working with power series, and hope that it will not create confusion.

The Jacobi identity (i) is equivalent to the following system of equations for the components $\omega_{ij}(x) = -\omega_{ji}(x)$:

$$\omega_{ij}\frac{\partial \omega_{kl}}{\partial x_i} + \omega_{ik}\frac{\partial \omega_{lj}}{\partial x_i} + \omega_{il}\frac{\partial \omega_{jk}}{\partial x_i} = 0. \tag{10}$$

Definition II.1 (Poisson Manifold):[15] *A Poisson manifold is a smooth manifold with a Poisson structure.*

A smooth map $F:\mathcal{M}_1 \to \mathcal{M}_2$, of two Poisson manifolds $\mathcal{M}_1$ and $\mathcal{M}_2$, is said to be *Poisson* if $F^*(\{g,h\}_{\mathcal{M}_2}) = \{F^*(g),F^*(h)\}_{\mathcal{M}_1}$, for all $g,h \in C^\infty(\mathcal{M}_2)$, where $(F^*(g))(x) := g(F(x))$, for any $x \in \mathcal{M}_1$, and $\{,\}_{\mathcal{M}_1}$, $\{,\}_{\mathcal{M}_2}$ are the Poisson brackets on $\mathcal{M}_1$ and $\mathcal{M}_2$, respectively. Thus, the above condition is equivalent to $\{g,h\}_{\mathcal{M}_2} \circ F = \{g\circ F, h\circ F\}_{\mathcal{M}_1}$.

If $\mathcal{M}_1$ and $\mathcal{M}_2$ are two Poisson manifolds with Poisson structures $\omega_1 \in \wedge^2 T_{\mathcal{M}_1}$ and $\omega_2 \in \wedge^2 T_{\mathcal{M}_2}$, respectively, we define the direct product Poisson structure on $\mathcal{M}_1 \times \mathcal{M}_2$ as

$$\omega_1 \times \omega_2 := \omega_1 \times 1 + 1 \times \omega_2, \tag{11}$$

which is a map $:\wedge^2 T_{\mathcal{M}_1} \oplus \wedge^2 T_{\mathcal{M}_2} \hookrightarrow \wedge^2 T_{\mathcal{M}_1 \times \mathcal{M}_2}$. Here the space $C^\infty(\mathcal{M}_1 \times \mathcal{M}_2)$ is identified with the space $C^\infty(\mathcal{M}_1) \otimes C^\infty(\mathcal{M}_2)$ [the reason being that a Poisson structure on $C^\infty(\mathcal{M}_1 \times \mathcal{M}_2)$ is uniquely defined by the one on $C^\infty(\mathcal{M}_1) \otimes C^\infty(\mathcal{M}_2)$] under appropriate completion of the tensor product. In more detail, for any function $f \in C^\infty(\mathcal{M}_1 \times \mathcal{M}_2)$, and for each $x \in \mathcal{M}_1$ and $y \in \mathcal{M}_2$ let us define the functions f^x on $\mathcal{M}_2$ and f^y on $\mathcal{M}_1$ as follows:

$$f^x(y) = f(x,y) \quad \text{and} \quad f^y(x) = f(x,y).$$

Then (11) means

$$\{f_1,f_2\}_{\mathcal{M}_1 \times \mathcal{M}_2}(x,y) = \{f_1^x, f_2^x\}_{\mathcal{M}_2}(y) + \{f_1^y, f_2^y\}_{\mathcal{M}_1}(x),$$

for any two functions $f_1, f_2 \in C^\infty(\mathcal{M}_1 \times \mathcal{M}_2)$.

Definition II.2 (Poisson–Lie group):[16] *Let G be a Lie group. Let ω be a Poisson structure on G. The pair (G,ω) is said to be a Poisson–Lie group if the multiplication map $m:G\times G \to G$ is Poisson, where the manifold $G\times G$ is equipped with the direct product Poisson structure $\omega \times \omega$.*

Let $L_x:G\to G$ and $R_x:G\to G$ be the left and right actions of G on itself defined by $y \mapsto xy$ and $y \mapsto yx$, respectively, where $x,y \in G$. Then for any two functions $f_1,f_2 \in C^\infty(G)$ the compatibility between the product Poisson structure on $G\times G$ introduced by (11) and the Poisson structure on G can be written as

$$\begin{aligned}
\{f_1,f_2\}_G(xy) &= m^*(\{f_1,f_2\}_G)(x,y)\\
&= \{m^*f_1, m^*f_2\}_{G\times G}(x,y)\\
&= \{(m^*f_1)^x,(m^*f_2)^x\}_G(y) + \{(m^*f_1)^y,(m^*f_2)^y\}_G(x)\\
&= \{f_1\circ L_x, f_2\circ L_x\}_G(y) + \{f_1\circ R_y, f_2\circ R_y\}_G(x).
\end{aligned}$$

If $(L_x)_{*y}$ and $(R_y)_{*x}$ are the tangent maps to L_x and R_y evaluated at the points y and x, respectively, we deduce

$$\omega_{xy} = (L_x)_{*y}\omega_y + (R_y)_{*x}\omega_x. \tag{12}$$

In local coordinates,

$$\omega_{ij}(z)=\omega_{kl}(x)\frac{\partial z_i}{\partial x_k}\frac{\partial z_j}{\partial x_l}+\omega_{kl}(y)\frac{\partial z_i}{\partial y_k}\frac{\partial z_j}{\partial y_l}, \tag{13}$$

where $z=xy$.

If $e\in G$ is the identity of G, then (12) yields $2\omega_e=\omega_e$. Therefore $\omega_e=0$. This implies that ω is not a symplectic structure since the rank of ω at the identity of G is zero, and we are dealing with more general Poisson manifolds.

Locally, (10) and (13) are the defining equations of a Poisson–Lie group.

Remark II.1: In the definitions above all manifolds were finite-dimensional ($\mathcal{M}$, *respectively, the group* G). *To extend these to the infinite-dimensional case, one needs two objects:* $T_{\mathcal{M}}$ *and* $C^\infty(\mathcal{M})$. *Since we shall study infinite-dimensional groups in this text, the infinite-dimensional aspects will be addressed at the moment they are introduced.*

We now proceed with the definition of a Lie-bialgebra and formulate a theorem (again due to Drinfel'd) relating the concept of a Lie-bialgebra to the concept of a Poisson–Lie group.

Definition II.3: A Lie-bialgebra $\mathcal{G}$ *is a Lie algebra* $\mathcal{G}$ *equipped with a coalgebra map* $\alpha:\mathcal{G}\to\mathcal{G}\wedge\mathcal{G}$ *such that* α *is a 1-cocycle of* $\mathcal{G}$ *with values in the* $\mathcal{G}$*-module* $\wedge^2\mathcal{G}$*, where* $\mathcal{G}$ *acts on* $\wedge^2\mathcal{G}$ *by means of the adjoint representation, and* α *satisfies the co-Jacobi identity. Thus,* $(\mathcal{G},\alpha)$ *is a Lie bialgebra iff*

$$(i)\quad \tau\circ\alpha=-\alpha,$$

$$(ii)\quad \alpha([X,Y])=\mathrm{ad}_X\alpha(Y)-\mathrm{ad}_Y\alpha(X),\qquad X,Y\in\mathcal{G},$$

$$(iii)\quad [1\otimes 1\otimes 1+(\tau\otimes 1)(1\otimes\tau)+(1\otimes\tau)(\tau\otimes 1)](1\otimes\alpha)\circ\alpha=0,$$

where τ *is the transposition map* $\tau:\mathcal{G}\otimes\mathcal{G}\to\mathcal{G}\otimes\mathcal{G}$ *defined by* $\tau(a\otimes b)=b\otimes a$*, for any* $a,b\in\mathcal{G}$.

This definition encompasses the case when $\mathcal{G}$ is infinite-dimensional. Condition (ii) means that α is a 1-cocycle in the Chevalley–Eilenberg cohomology of Lie algebras. Therefore we will refer to (ii) as the 1-cocycle condition in the sequel. In the case when $\alpha=\delta\alpha^0$ is a 1-coboundary, $\alpha(X)=ad_X r$, where $r\in\mathcal{G}\wedge\mathcal{G}$ is a 0-cochain, which is referred to as the classical r-matrix.[17]

Let $\{e_i\}$ be a basis of $\mathcal{G}$ and let us write α in this basis as $\alpha(e_n)=\alpha_{ij}^n e_i\wedge e_j$. Let C_n^{ij} be the structure constants of $\mathcal{G}$ defining the Lie structure on $\mathcal{G}$ by $[e_i,e_j]=C_n^{ij}e_n$. Property (i) in the definition of α implies that $\alpha_{ij}^n=-\alpha_{ji}^n$. Then the equation (iii) written in terms of α_{ij}^n becomes

$$\alpha_{ij}^n\alpha^{\ j}_{sp}+\alpha_{pj}^n\alpha^{\ j}_{is}+\alpha_{sj}^n\alpha_{pi}^j=0. \tag{14}$$

Similarly, equation (ii) expressed in terms of α_{ij}^n and the structure constants C_n^{ij} of $\mathcal{G}$ becomes

$$C_n^{ij}\alpha_{kl}^n=\alpha_{ml}^jC_k^{im}+\alpha_{km}^jC_l^{im}-\alpha_{ml}^iC_k^{jm}-\alpha_{km}^iC_l^{jm}. \tag{15}$$

Thus, these two systems of equations, (14) and (15), plus the Jacobi identity for the structure constants of the Lie algebra $\mathcal{G}$,

$$C_m^{ij}C_n^{mk}+C_m^{jk}C_n^{mi}+C_m^{ki}C_n^{mj}=0, \tag{16}$$

define a Lie-bialgebra structure on $\mathcal{G}$. We have the following result.

Theorem II.1:[16] *The category of connected, simply connected finite dimensional Poisson–Lie groups is equivalent to the category of finite-dimensional Lie-bialgebras.*

For a proof see, for example, Refs. 18,19. We complete this section by proving a property of (finite-dimensional) Poisson–Lie groups, which is usually assumed to be part of the definition.

Theorem II.2: *Let* G *be a Poisson–Lie group. Then the map* $\varphi:G\to G$ *defined by* $\varphi(x)=x^{-1}$ *is an anti-Poisson map.*

Proof: We prove the statement in a neighborhood of the identity element of G. Let $z_i=z_i(x,y)$, for $i=1,\dots,n$, be the coordinate functions of $z=xy$. After solving $z_i=z_i(x,y)$ with respect to the coordinates of y we have $y_i = y_i(x,z)$. We differentiate the identities $y_i \equiv y_i(x,z(x,y))$, for $i=1,\dots,n$, with respect to y_k for each $k=1,\dots,n$ to obtain

$$\delta_i^k = \left.\frac{\partial y_i}{\partial z_l}\right|_{(x,z)} \left.\frac{\partial z_l}{\partial y_k}\right|_{(x,y)}. \tag{17}$$

Let $\varphi: G \to G$ be the map defined by $\varphi(x) = x^{-1}$, which is given in coordinates by the functions $\varphi_i = \varphi_i(x)$. Then we have $0 = z_i(x,\varphi(x))$, for $i=1,\dots,n$. We differentiate this identity with respect to x_k to obtain

$$0 = \left.\frac{\partial z_l}{\partial x_k}\right|_{(x,\varphi(x))} + \left.\frac{\partial z_i}{\partial y_l}\right|_{(x,\varphi(x))} \frac{\partial \varphi_l}{\partial x_k}. \tag{18}$$

After multiplying both sides of (13) by $\partial y_m/\partial z_i|_{(x,z)}\ \partial y_n/\partial z_j|_{(x,z)}$ and summing over i,j we get

$$\left.\frac{\partial y_m}{\partial z_i}\right|_{(x,z)} \left.\frac{\partial y_n}{\partial z_j}\right|_{(x,z)} \omega_{ij}(z) = \left.\frac{\partial y_m}{\partial z_i}\right|_{(x,z)} \left.\frac{\partial y_n}{\partial z_j}\right|_{(x,z)} \omega_{kl}(x) \frac{\partial z_i}{\partial x_k} \frac{\partial z_j}{\partial x_l} + \omega_{mn}(y), \tag{19}$$

where we have used (17).

We now set $z = e = x\varphi(x)$ in (19), and obtain

$$0 = \left.\frac{\partial y_m}{\partial z_i}\right|_{(x,e)} \left.\frac{\partial y_n}{\partial z_j}\right|_{(x,e)} \omega_{kl}(x) \left.\frac{\partial z_i}{\partial x_k}\right|_{(x,\varphi(x))} \left.\frac{\partial z_j}{\partial x_l}\right|_{(x,\varphi(x))} + \omega_{mn}(\varphi(x)).$$

After using (18) the above equality becomes equivalent to

$$0 = \left.\frac{\partial y_m}{\partial z_i}\right|_{(x,e)} \left.\frac{\partial y_n}{\partial z_j}\right|_{(x,e)} \omega_{kl}(x) \left.\frac{\partial z_i}{\partial y_p}\right|_{(x,\varphi(x))} \frac{\partial \varphi_p}{\partial x_k} \left.\frac{\partial z_j}{\partial y_s}\right|_{(x,\varphi(x))} \frac{\partial \varphi_s}{\partial x_l} + \omega_{mn}(\varphi(x)).$$

Now using again (17) as

$$\delta_i^k = \left.\frac{\partial y_i}{\partial z_l}\right|_{(x,e)} \left.\frac{\partial z_l}{\partial y_k}\right|_{(x,\varphi(x))},$$

we finally conclude that

$$\omega_{mn}(\varphi(x)) = -\omega_{kl}(x) \frac{\partial \varphi_m}{\partial x_k} \frac{\partial \varphi_n}{\partial x_l}. \qquad \square$$

In the following sections we will adapt the above given definitions for the case where G will stand for the infinite-dimensional groups $FDiff(\mathbb{R}^1)$ and $FDiff_0(\mathbb{R}^1)$. We will show that theorems analogous to Theorem II.1 and Theorem II.2 above also hold in this case.

III. THE GROUP OF INFINITE-JETS G_∞ AND ITS LIE ALGEBRA

Let $G_\infty = \{x = (x_1, x_2, \dots) \in \mathbb{R}^\infty | x \neq 0\} \subset \mathbb{R}^\infty$ be a subset of the set of infinite sequences of real numbers. (We may adopt a purely formal point of view and take sequences of letters (indeterminates) which we interpret as generators of an algebra of ''functions'' on the group. This is done in Sec. VI where the group of diffeomorphisms of the line is treated as a formal group. For the group of diffeomorphisms fixing a point, discussed in this section, both points of view are possible, and they lead to the same results, since our treatment is mostly algebraic in nature.) For each $x \in G_\infty$ consider the formal power series, $x(u) = \sum_{i=1}^\infty x_i u^i$, in the variable u. This defines a bijective map from G_∞ into the group of ∞-jets, maps from $\mathbb{R}^1 \to \mathbb{R}^1$ at $0 \in \mathbb{R}^1$, as follows. Define a multiplication $m_\infty : G_\infty \times G_\infty \to G_\infty$ on G_∞ induced by the substitution of formal power series. For any $x,y \in G_\infty$ define $xy \in G_\infty$ by $(xy)(u) := x(y(u))$. The induced multiplication makes G_∞ a group with an identity $e=(1,0,0,\ldots)$. That is, $e:\mathbb{R}^1 \to \mathbb{R}^1$ is the identity map, $e(u)=u$. The associativity of multiplication is implied by the associativity of substitution of power series. In coordinates $z(u)=(xy)(u)=\Sigma_{i=1}^{\infty} z_i u^i$ gives

$$z_k = \sum_{i=1}^{k} x_i \sum_{(\Sigma_{\alpha=1}^{i} j_\alpha)=k} y_{j_1} \ldots y_{j_i}. \tag{20}$$

The first several formulas are given below:

$$z_1 = x_1 y_1,$$

$$z_2 = x_1 y_2 + x_2 y_1^2,$$

$$z_3 = x_1 y_3 + x_2 2 y_1 y_2 + x_3 y_1^3,$$

$$z_4 = x_1 y_4 + x_2 (y_2^2 + 2 y_1 y_3) + x_3 3 y_1^2 y_2 + x_4 y_1^4,$$

$$\vdots$$

$$z_n = x_1 y_n + x_n y_1^n + y_{n-1} 2 y_1 x_2 + x_{n-1}(n-1) y_1^{n-2} y_2 + O(<n-1), \quad n>3,$$

$$\vdots$$

The group so obtained is the group of formal diffeomorphisms (∞-jets) of the line, leaving the origin fixed. It can be viewed as a projective limit of a family of finite-dimensional Lie groups with a smooth structure introduced as follows. Consider the family of Lie groups and maps $(G_n, \pi_{n+1,n})_{n\in\mathbb{N}}$, where $G_n = \mathbb{R}^n \backslash M_n$ and $M_n = \{(x_1,\ldots,x_n) \in \mathbb{R}^n | x_1 = 0\}$. The multiplication $m_n : G_n \times G_n \to G_n$ is induced by substitution $(\mathcal{X}_n \mathcal{Y}_n)(u) = \mathcal{X}_n(\mathcal{Y}_n(u)) \bmod u^{n+1}$, where $\mathcal{X}_n$ and $\mathcal{Y}_n$ are polynomials in u of degree n. That is, the group G_n is an open subset of $\mathbb{R}^n$, that carries the structure of a finite-dimensional C^∞ manifold modeled on $\mathbb{R}^n$. The maps $\pi_{n+1,n} : G_{n+1} \to G_n$ defined by $\pi_{n+1,n}(x_1,\ldots,x_{n+1}) = (x_1,\ldots,x_n)$ are homomorphisms, i.e., $\pi_{n+1,n} \circ m_{n+1} = m_n \circ (\pi_{n+1,n} \times \pi_{n+1,n})$.[20] This follows from the definition of $\pi_{n+1,n}$ and (20). The family $(G_n, \pi_{n+1,n})_{n\in\mathbb{N}}$ has a projective limit $(G_\infty, (\pi_{\infty,n})_{n\in\mathbb{N}})$, where $G_\infty = \{x \in \mathbb{R}^\infty | x_1 \neq 0\}$ is an open subset of $\mathbb{R}^\infty$. The maps $\pi_{\infty,n} : G_\infty \to G_n$ are defined by $\pi_{\infty,n}(x_1,\ldots,x_n,x_{n+1},\ldots) = (x_1,\ldots,x_n)$. Obviously, these maps satisfy $\pi_{\infty,n} = \pi_{n+1,n} \circ \pi_{\infty,n+1}$, and are homomorphisms, $\pi_{\infty,n} \circ m_\infty = m_n \circ (\pi_{\infty,n} \times \pi_{\infty,n})$, where $m_\infty : G_\infty \times G_\infty \to G_\infty$ is defined by (20).

Let us consider now the family of spaces and maps $(C^\infty(G_n), \pi^*_{n,n+1})_{n\in\mathbb{N}}$, where the maps $\pi^*_{n,n+1} : C^\infty(G_n) \to C^\infty(G_{n+1})$ are defined by $(\pi^*_{n,n+1}(f))(x_1,\ldots,x_n,x_{n+1}) = f(x_1,\ldots,x_n)$, for any $f \in C^\infty(G_n)$. Then the above family has an inductive limit $(C^\infty(G_\infty), \pi^*_{n,\infty})$, where $\pi^*_{n,\infty} : C^\infty(G_n) \to C^\infty(G_\infty)$ is defined by $((\pi^*_{n,\infty})(f))(x) = f(x_1,\ldots,x_n)$ for any $x \in G_\infty$ and $f \in C^\infty(G_n)$. Thus, by definition, the space $C^\infty(G_\infty)$ of smooth functions on G_∞ is the space of smooth functions (of *finite* number of variables) on $\mathbb{R}^\infty$, restricted to $\mathbb{R}^\infty \backslash M$, where $M = \{x \in \mathbb{R}^\infty | x_1 = 0\}$.

One can define the Lie algebra of G_∞ in different ways. Probably the most efficient one is as the Lie algebra of derivations (smooth vector fields) of the algebra $C^\infty(G_\infty)$. These are of the form

$$X = \sum_{i=1}^{\infty} v_i \frac{\partial}{\partial x_i}, \quad v_i \in C^\infty(G_\infty). \tag{21}$$

Note that if $f\in C^\infty(G_\infty)$, then $X(f)=\Sigma_{i=1}^n v_i(\partial f/\partial x_i)$ is a finite sum, for some $n\in\mathbb{N}$, since f depends only upon a finite number of variables. We also have $X(f)\in C^\infty(G_\infty)$. Every automorphism $\varphi: G_\infty\to G_\infty$ acts on the space of derivations by $(\varphi_* X)=(\varphi_*^{-1})X\varphi^*$, and on $C^\infty(G_\infty)$ it acts by $(\varphi^* f)(x)=f(\varphi(x))$. Since the functions $f\in C^\infty(G_\infty)$ are functions of a finite number of variables it is enough to describe the map φ_* on vector fields restricted to $C^\infty(G_n)$ for each $n\in\mathbb{N}$.

Lemma III.1: The set $\{X_n\}_{n\geqslant 1}$ of left-invariant vector fields on G_∞ is given by

$$X_n=\sum_{i=1}^{\infty} ix_i\frac{\partial}{\partial x_{i+n-1}}. \tag{22}$$

Proof: From (20) the map $y\mapsto xy$ is given by

$$z_n=(xy)_n=x_1y_n+y_1^n x_n+\sum_{i=2}^{n-1} x_i\sum_{(\Sigma_{\alpha=1}^i j_\alpha)=n} y_{j_1}\ldots y_{j_i},\quad \text{for each}\quad n\geqslant 1. \tag{23}$$

The matrix of the tangent to the map defined by (23) is $\partial z_n/\partial y_m|_{y=e}$. The only terms in

$$\sum_{i=2}^{n-1} x_i\sum_{(\Sigma_{\alpha=1}^i j_\alpha)=n} y_{j_1}\ldots y_{j_i},\quad \text{for each}\quad n\geqslant 1,$$

that will contribute to the tangent map are the ones for which the product $y_{j_1}\cdots y_{j_i}$ has exactly $(i-1)$ multiples equal to y_1 and the one remaining equal to y_{j_α} for some α, $2\leqslant\alpha\leqslant i$. There are exactly $\binom{i}{i-1}=i$ terms of this form. Therefore we rewrite (23) as

$$z_n=\sum_{i=1}^{n} ix_i y_1^{i-1}y_{n-i+1}+\ \ldots,$$

where the dots indicate terms that do not contribute to $\partial z_n/\partial y_m|_{y=e}$. Hence,

$$\left.\frac{\partial z_n}{\partial y_m}\right|_{y=e}=\sum_{i=1}^{n} ix_i\delta_{n-i+1}^m=(n-m+1)x_{n-m+1}.$$

If $\{\partial/\partial y_i\}$ is a basis of vector fields at the identity, then

$$\left(\varphi_*\frac{\partial}{\partial y_m}\right)_x=\sum_{i=1}^{n}\left.\frac{\partial z_i}{\partial y_m}\right|_{y=e}\frac{\partial}{\partial x_i}=\sum_{i=m}^{n}(i-m+1)x_{i-m+1}\frac{\partial}{\partial x_i}=\sum_{i=1}^{n-m+1} ix_i\frac{\partial}{\partial x_{i+m-1}}.$$

Therefore for each $n\in\mathbb{N}$, the set of vector fields $\{X_k\}_{k=1}^n$, where $X_k=\Sigma_{i=1}^{n-k+1}ix_i(\partial/\partial x_{i+k-1})$, for $1\leqslant k\leqslant n$, forms a basis of left-invariant vector fields on G_n. The set $\{X_n\}_{n\geqslant 1}$, where $X_n=\Sigma_{i=1}^{\infty}ix_i(\partial/\partial x_{i+n-1})$, forms a basis of left-invariant vector fields on G_∞. □

Lemma III.2: Every smooth vector field on G_∞ is generated by the set $\{X_n\}_{n\geqslant 1}$ of left-invariant vector fields (22) on G_∞.

Proof: Let $Y=\Sigma_{i=1}^{\infty}v_i(\partial/\partial x_i)$ be a smooth vector field on G_∞. We define inductively the following sequence of smooth vector fields. Let

$$Y_1=Y-\frac{v_1}{x_1}X_1=Y-\psi_1X_1,\quad \text{where}\quad \psi_1:=\frac{v_1}{x_1},$$

$$Y_2=Y_1-\psi_2X_2,\quad \text{where}\quad \psi_2:=\frac{1}{x_1}(v_2-2x_2\psi_1),$$

$$\vdots \tag{24}$$

$$Y_n = Y_{n-1} - \psi_n X_n, \quad \text{where} \quad \psi_n := \frac{1}{x_1}\left(v_n - \sum_{i=2}^{n} i x_i \psi_{n-i+1} \right),$$

$$\vdots$$

Summing up the first n equalities in (24) we get $Y = \Sigma_{i=1}^{n} \psi_i X_i + Y_n$. By construction Y_n is such that $Y_n|_{C^\infty(G_n)} = 0$, for any $n \in \mathbb{N}$. Hence, $Y = \Sigma_{i=1}^{\infty} \psi_i X_i$. □

We now show that $\{X_n\}_{n \geqslant 1}$ forms a Lie subalgebra of the Lie algebra of vector fields on G_∞ with a Lie bracket given by

$$[X_n, X_m] = (n-m) X_{n+m-1}. \tag{25}$$

For that we compute the commutator of two left-invariant vector fields $X_n = \Sigma_{i=1}^{\infty} i x_i (\partial/\partial x_{i+n-1})$ and $X_m = \Sigma_{j=1}^{\infty} j x_j (\partial/\partial x_{j+m-1})$:

$$\begin{aligned} [X_n, X_m] &= \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} i x_i j \delta^j_{i+n-1} \frac{\partial}{\partial x_{j+m-1}} - \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} j x_j i \delta^i_{j+n-1} \frac{\partial}{\partial x_{i+n-1}} \\ &= \sum_{i=1}^{\infty} i x_i (i+n-1) \frac{\partial}{\partial x_{i+n+m-2}} - \sum_{j=1}^{\infty} j x_j (j+m-1) \frac{\partial}{\partial x_{j+n+m-2}} \\ &= (n-m) \sum_{i=1}^{\infty} i x_i \frac{\partial}{\partial x_{i+n+m-2}} = (n-m) X_{n+m-1}. \end{aligned} \tag{26}$$

To make correspondence with the more familiar notation we shift the indices by 1, and introduce $e_n := X_{n+1}$. Then $[e_n, e_m] = (n-m) e_{n+m}$, for all $n,m \geqslant 0$. The algebra so obtained is the maximal subalgebra of the Witt algebra.

Let us assume now that G_n are equipped with Poisson–Lie structures $\{,\}_n : C^\infty(G_n) \times C^\infty(G_n) \to C^\infty(G_n)$. It is natural to require that the projection maps $\pi_{n+1,n} : G_{n+1} \to G_n$ are Poisson, i.e., $\pi^*_{n+1,n}(\{f,g\}_n) = \{\pi^*_{n+1,n}(f), \pi^*_{n+1,n}(g)\}_{n+1}$, where, as above, $(\pi^*_{n+1,n}(f))(x) := f(\pi_{n+1,n}(x))$ for every $f \in C^\infty(G_n)$ and $x \in G_{n+1}$.

For a smooth bivector field ω on G_∞ [that is, a rank 2 skew-symmetric tensor such that $\omega_{ij} \in C^\infty(G_\infty)$ and $\omega_x = \omega_{ij}(x) (\partial/\partial x_i) \wedge (\partial/\partial x_j)$] let us assume that a map $\{,\} : C^\infty(G_\infty) \times C^\infty(G_\infty) \to C^\infty(G_\infty)$ gives a Poisson–Lie structure on G_∞ defined by $\{f,g\}(x) = \omega_{ij}(x)(\partial f/\partial x_i)(\partial g/\partial x_j)$ for any $f,g \in C^\infty(G_\infty)$. Then it is also natural to require that the maps $\pi_{\infty,n}$ are Poisson. That is, we want the condition $\pi^*_{n,\infty}(\{f,g\}_n) = \{\pi^*_{n,\infty}(f), \pi^*_{n,\infty}(g)\}$ to be satisfied, for any $f,g \in C^\infty(G_n)$. One defines $(G_\infty, \{,\}, (\pi_{\infty,n})_{n \in \mathbb{N}})$ to be the projective limit of the family of Poisson–Lie groups and maps $(G_n, \{,\}_n, \pi_{n+1,n})_{n \in \mathbb{N}}$. Later it will be clear that for the Poisson–Lie groups studied in this text these conditions are automatically satisfied.

Are there any Poisson–Lie structures on G_∞? If such structures exist, can they be classified? Also, since for any finite n there is a one-to-one correspondence between the Poisson–Lie structures on G_n and the Lie-bialgebra structures on the Lie algebra $\mathcal{G}_n$ of G_n, one is led to inquire if there are any Lie-bialgebra structures on the Lie algebra $\mathcal{G}_\infty$ of G_∞. The same questions exist for the group $G_{0\infty}$ of formal diffeomorphisms of the line without fixed points and its Lie algebra $\mathcal{G}_{0\infty}$, which is the Witt algebra. It turns out that all these questions can be fully answered. Let us turn our attention to the group G_∞ first.

IV. POISSON–LIE STRUCTURES ON G_∞

In this section we study Poisson–Lie structures on the group G_∞. It turns out that there exists a large class of such structures, which can be described explicitly. In the next two sections we prove that, in fact, this class exhausts all Poisson–Lie structures on G_∞.

We recall the definition of a Poisson–Lie structure on the group G_∞. It is defined as a skew-symmetric map $\{,\}:C^\infty(G_\infty)\times C^\infty(G_\infty)\to C^\infty(G_\infty)$ which is multiplicative, is a derivation in both arguments, and satisfies the Jacobi identity. The derivation property implies that there is a bi-vector field $\omega\in\wedge^2 TG_\infty$ given locally by $\omega_x=\omega_{ij}(x)(\partial/\partial x_i)\wedge\partial/\partial x_j$, where $\omega_{ij}\in C^\infty(G_\infty)$ are smooth functions on G_∞. Then for every $f,g\in C^\infty(G_\infty)$ we have $\{f,g\}(x)=\omega_{ij}(x)(\partial f/\partial x_i)\times(\partial g/\partial x_j)$. Note that on the right-hand side (r.h.s.) we have in effect a finite sum since the functions f and g depend only upon a finite number of arguments. In particular, $\{\mathcal{X}_i,\mathcal{X}_j\}=\omega_{ij}$, where $\mathcal{X}_i$, $i\in\mathbb{N}$, are the coordinate functions of $x\in G_\infty$, i.e., $\mathcal{X}_i(x)=x_i$. Similarly, the 1-cocycle equation (13) for ω_{ij} is given by

$$\omega_{ij}(xy)=\omega_{kl}(x)\frac{\partial z_i}{\partial x_k}\frac{\partial z_j}{\partial x_l}+\omega_{kl}(y)\frac{\partial z_i}{\partial y_k}\frac{\partial z_j}{\partial y_l}. \tag{27}$$

Here again the sums on the right-hand-side are finite, since for every $n\in\mathbb{N}$ we have $z_n=z_n(x_1,\ldots,x_n;y_1,\ldots,y_n)$. The same is true for the sums in the Jacobi identity (10) in terms of the functions ω_{ij}.

Let us introduce the formal series $\mathcal{X}(u):=\Sigma_{i=1}^{\infty}\mathcal{X}_i u^i$. Then $x(u)=\mathcal{X}(u)(x)=\Sigma_{i=1}^{\infty}x_i u^i$. Define the formal series $\Omega(u,v;\mathcal{X}):=\Sigma_{i,j=1}^{\infty}\omega_{ij}u^i v^j$. Thus $\Omega(u,v;\mathcal{X})$ is a generating series for the brackets ω_{ij}. Evaluating at $x\in G_\infty$ we have $\Omega(u,v;x)=\Sigma_{i,j=1}^{\infty}\omega_{ij}(x)u^i v^j$.

Lemma IV.1: In terms of Ω the cocycle condition (27) assumes the form

$$\Omega(u,v;z)=\Omega(y(u),y(v);x)+\Omega(u,v;y)x'(y(u))x'(y(v)),\quad z(u)=x(y(u)). \tag{28}$$

Proof: Recall that $z(u)=x(y(u))=\Sigma_{i=1}^{\infty}x_i[y(u)]^i=\Sigma_{i=1}^{\infty}z_i u^i$, where $z_i=(xy)_i$. From the last formula we obtain that

$$\frac{\partial z(u)}{\partial x_k}=[y(u)]^k\quad\left(=\sum_{i=1}^{\infty}\frac{\partial z_i}{\partial x_k}u^i\right),$$

and

$$\frac{\partial z(u)}{\partial y_k}=\sum_{i=1}^{\infty}ix_i u^k[y(u)]^{i-1}=u^k\sum_{i=1}^{\infty}ix_i[y(u)]^{i-1}=u^k x'(y(u))\quad\left(=\sum_{i=1}^{\infty}\frac{\partial z_i}{\partial y_k}u^i\right).$$

Here $x'(u)$ denotes the derivative of $x(u)$ with respect to its argument u. If we multiply both sides of Eq. (27) by $u^i v^j$ and sum over i and j we obtain

$$\begin{aligned}\sum_{i,j=1}^{\infty}\omega_{ij}(z)u^i v^j&=\sum_{k,l=1}^{\infty}\omega_{kl}(x)\sum_{i=1}^{\infty}\frac{\partial z_i}{\partial x_k}u^i\sum_{j=1}^{\infty}\frac{\partial z_j}{\partial x_l}v^j+\sum_{k,l=1}^{\infty}\omega_{kl}(y)\sum_{i=1}^{\infty}\frac{\partial z_i}{\partial y_k}u^i\sum_{j=1}^{\infty}\frac{\partial z_j}{\partial y_l}v^j\\&=\sum_{k,l=1}^{\infty}\omega_{kl}(x)[y(u)]^k[y(v)]^l+x'(y(u))x'(y(v))\sum_{k,l=1}^{\infty}\omega_{kl}(y)u^k v^l.\end{aligned}$$

Now, using the definition of Ω we finally obtain that

$$\Omega(u,v;z)=\Omega(y(u),y(v);x)+\Omega(u,v;y)x'(y(u))x'(y(v)).$$

Notice also that both sides of the above equation are divisible by uv. □

Equation (28) has a large class of solutions $\Omega(u,v;x)$. Namely, we have the following theorem.

Theorem IV.1: *For any* $\varphi=\varphi(u,v)$ *with the properties*
(i) $\varphi(u,v)$ *is divisible by* u *and* v;
(ii) $\varphi(u,v)=-\varphi(v,u)$,
we have the following solution of (28)*:*

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)-\varphi(x(u),x(v)). \tag{29}$$

Proof: Indeed, in terms of (29), the left-hand side of Eq. (28) reads as

$$\begin{aligned}\Omega(u,v;z)&=\varphi(u,v)z'(u)z'(v)-\varphi(z(u),z(v))\\&=\varphi(u,v)x'(y(u))y'(u)x'(y(v))y'(v)-\varphi(z(u),z(v)).\end{aligned}$$

The right-hand side of (28) gives

$$\begin{aligned}&\Omega(y(u),y(v);x)+\Omega(u,v;y)x'(y(u))x'(y(v))\\&\quad=\varphi(y(u),y(v))x'(y(u))x'(y(v))-\varphi(z(u),z(v))\\&\qquad+\varphi(u,v)x'(y(u))y'(u)x'(y(v))y'(v)-\varphi(y(u),y(v))x'(y(u))x'(y(v)).\end{aligned}$$

Comparing both sides we obtain an identity.

The condition (ii) is equivalent to $\Omega(u,v;\mathcal{X})=-\Omega(v,u;\mathcal{X})$ which on the other hand is equivalent to the skew-symmetry of the ω_{ij}'s.

The condition (i) is needed since, as noticed above, $\Omega(u,v;x)$ is divisible by uv. This requires that the r.h.s. of (29) is divisible by uv. From the definition of $x(u)$ it is clear that $x'(u)x'(v)$ is not divisible by uv. It begins with a term $x_1^2+2x_1x_2(u+v)+\cdots$. Suppose that $\varphi(u,v)$ is not divisible by uv. Then $\varphi(x(u),x(v))$ is also not divisible by uv, and so is the difference $\varphi(u,v)z'(u)z'(v)-\varphi(z(u),z(v))$, as an easy analysis shows. □

Next, we would like to find out for which classes of φ's the Jacobi identity is satisfied. This will be an important step in the solution of the problem of classifying all possible Lie–Poisson structures on G_∞. For this we use the following technical tool.

Let $\mathcal{U}=\{u_1,u_2,\ldots\}$ be a countably infinite set of indeterminates. Consider the ring of formal power series $C^\infty(G_\infty)[[\mathcal{U}]]$ in $\mathcal{U}$ over the algebra $C^\infty(G_\infty)$ defined as the inductive limit of the rings $\{C^\infty(G_\infty)[[u_1,\ldots,u_n]]\}_{n\in\mathbb{N}}$. Then the map $\{,\}:C^\infty(G_\infty)\times C^\infty(G_\infty)\to C^\infty(G_\infty)$ induces a map $\{,\}:C^\infty(G_\infty)[[\mathcal{U}]]\times C^\infty(G_\infty)[[\mathcal{U}]]\to C^\infty(G_\infty)[[\mathcal{U}]]$. In particular, we have

$$\{\mathcal{X}(u),\mathcal{X}(v)\}=\sum_{i,j=1}^{\infty}\{\mathcal{X}_i,\mathcal{X}_j\}u^iv^j=\Omega(u,v;\mathcal{X}),$$

where $u=u_i$ and $v=u_j$ for some $u_i,u_j\in\mathcal{U}$. Then the Jacobi identities (10), in terms of generating series, can be put together in a single equation,

$$\{\mathcal{X}(w),\{\mathcal{X}(u),\mathcal{X}(v)\}\}+\{\mathcal{X}(u),\{\mathcal{X}(v),\mathcal{X}(w)\}\}+\{\mathcal{X}(v),\{\mathcal{X}(w),\mathcal{X}(u)\}\}=0, \tag{30}$$

for any $u,v,w\in\mathcal{U}$. On the other hand, we have

$$\{\mathcal{X}(w),\{\mathcal{X}(u),\mathcal{X}(v)\}\}=\{\mathcal{X}(w),\varphi(u,v)\mathcal{X}'(u)\mathcal{X}'(v)-\varphi(\mathcal{X}(u),\mathcal{X}(v)\}$$
$$=\varphi(u,v)[\{\mathcal{X}(w),\mathcal{X}'(u)\}\mathcal{X}'(v)+\{\mathcal{X}(w),\mathcal{X}'(v)\}\mathcal{X}'(u)]$$
$$-\partial_1\varphi(\mathcal{X}(u),\mathcal{X}(v))\{\mathcal{X}(w),\mathcal{X}(u)\}$$
$$-\partial_2\varphi(\mathcal{X}(u),\mathcal{X}(v))\{\mathcal{X}(w),\mathcal{X}(v)\},$$

where ∂_1 denotes the derivative with respect to the first argument and ∂_2 is the derivative with respect to the second argument. Also

$$\{\mathcal{X}(w),\mathcal{X}'(u)\}=\partial_u\{\mathcal{X}(w),\mathcal{X}(u)\}$$
$$=\partial_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}'(u)+\varphi(w,u)\mathcal{X}'(w)\mathcal{X}''(u)+\partial_2\varphi(\mathcal{X}(w),\mathcal{X}(u))\mathcal{X}'(u),$$

and we have similar formulas coming from the remaining two terms in (30) with w,u,v cyclicly permuted.

Lemma IV.2: The solution (29) satisfies the Jacobi identity (30) iff $\varphi(u,v)$ satisfies the following functional partial differential equation:

$$\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]+\varphi(v,w)[\partial_v\varphi(u,v)+\partial_w\varphi(u,w)]$$
$$+\varphi(w,u)[\partial_w\varphi(v,w)+\partial_u\varphi(v,u)]=0. \tag{31}$$

Proof: After substituting (29) into (30), using the formulas derived above, and collecting terms we obtain

$$(\varphi(u,v)[\partial_u\varphi(w,v)+\partial_v\varphi(w,v)]+\text{cyclic}(u,v,w))\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)$$
$$+(\varphi(\mathcal{X}(v),\mathcal{X}(u))[\partial_2\varphi(\mathcal{X}(w),\mathcal{X}(v))+\partial_2\varphi(\mathcal{X}(w),\mathcal{X}(u))]+\text{cyclic}(u,v,w))=0. \tag{32}$$

Let us define $\Phi(w,u,v)$ by

$$\Phi(w,u,v):=\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]$$
$$+\varphi(v,w)[\partial_v\varphi(u,v)+\partial_w\varphi(u,w)]+\varphi(w,u)[\partial_w\varphi(v,w)+\partial_u\varphi(v,u)].$$

It is easily verified that $\Phi(w,u,v)$ is antisymmetric with respect to each pair of its arguments. For example $\Phi(w,u,v)=-\Phi(u,w,v)$. After evaluation at x (32) becomes

$$\Phi(x(w),x(u),x(v))=x'(w)x'(u)x'(v)\Phi(w,u,v).$$

This equation is satisfied for every $x(u)$. In particular, it is true for $x(u)=\lambda u$, where $\lambda\neq 0$. In this case the above equation is equivalent to $\Phi(\lambda w,\lambda u,\lambda v)=\lambda^3\Phi(w,u,v)$. In other words Φ is homogeneous of degree 3. But the only homogeneous function $\Phi(w,u,v)$ of degree 3 which is also antisymmetric with respect to each pair of its arguments is $\Phi=0$. Therefore the statement of the Lemma follows. Note that the last equation shows that the group of formal diffeomorphism acts on the space of solutions of (31), since it is invariant under this action. □

Theorem IV.2: *The map $x\mapsto x^{-1}$ is an anti-Poisson map.*

Proof: Let $\bar{\mathcal{X}}(u)$ denote the inverse of $\mathcal{X}(u)$. Then we have the identities

$$\bar{\mathcal{X}}(\mathcal{X}(u))=u,\quad \text{and}\quad \mathcal{X}(\bar{\mathcal{X}}(u))=u,$$

as well as (following from them)

$$\bar{\mathcal{X}}'(\mathcal{X}(u))\mathcal{X}'(u)=1,\quad \text{and}\quad \mathcal{X}'(\bar{\mathcal{X}}(u))\bar{\mathcal{X}}'(u)=1.$$

On the other hand we have

$$0=\{u,\mathcal{X}(v)\}=\{\overline{\mathcal{X}}(\mathcal{X}(u)),\mathcal{X}(v)\}=\{\overline{\mathcal{X}}(w),\mathcal{X}(v)\}|_{w=\mathcal{X}(u)}+\overline{\mathcal{X}}'(w)|_{w=\mathcal{X}(u)}\{\mathcal{X}(u),\mathcal{X}(v)\}.$$

Therefore,

$$\{\mathcal{X}(v),\overline{\mathcal{X}}(w)\}|_{w=\mathcal{X}(u)}=\overline{\mathcal{X}}'(w)|_{w=\mathcal{X}(u)}\{\mathcal{X}(u),\mathcal{X}(v)\}. \tag{33}$$

Also, we have the following chain of identities:

$$\begin{aligned}0=\{v,\overline{\mathcal{X}}(w)\}|_{w=\mathcal{X}(u)}&=\{\overline{\mathcal{X}}(\mathcal{X}(v)),\overline{\mathcal{X}}(w)\}|_{w=\mathcal{X}(u)}\\&=\{\overline{\mathcal{X}}(s),\overline{\mathcal{X}}(w)\}|_{s=\mathcal{X}(v),w=\mathcal{X}(u)}\\&\quad+\overline{\mathcal{X}}'(s)|_{s=\mathcal{X}(v)}\{\mathcal{X}(v),\overline{\mathcal{X}}(w)\}|_{w=\mathcal{X}(u)}.\end{aligned}$$

Using (29) and (33), the last identity can be rewritten as

$$\begin{aligned}0&=\varphi(\mathcal{X}(v),\mathcal{X}(u))\overline{\mathcal{X}}'(\mathcal{X}(v))\overline{\mathcal{X}}'(\mathcal{X}(u))-\varphi(v,u)\\&\quad+\overline{\mathcal{X}}'(\mathcal{X}(v))\overline{\mathcal{X}}'(\mathcal{X}(u))[\varphi(u,v)\mathcal{X}'(u)\mathcal{X}'(v)-\varphi(\mathcal{X}(u),\mathcal{X}(v))]\\&=\{\overline{\mathcal{X}}(s),\overline{\mathcal{X}}(w)\}|_{s=\mathcal{X}(v),w=\mathcal{X}(u)}+\varphi(u,v)-\overline{\mathcal{X}}'(w)\overline{\mathcal{X}}'(s)\varphi(w,s).\end{aligned}$$

Thus,

$$\{\overline{\mathcal{X}}(w),\overline{\mathcal{X}}(s)\}=-[\overline{\mathcal{X}}'(w)\overline{\mathcal{X}}'(s)\varphi(w,s)-\varphi(\overline{\mathcal{X}}(w),\overline{\mathcal{X}}(s))],$$

and the proof is finished. □

In order to classify *all* Poisson–Lie structures on G_∞ one has, in particular, to classify all solutions of the functional partial differential equation (31). The main result of this section is formulated below.

Theorem IV.3: *The moduli space of solutions of (31) is parametrized by* $\mathbb{N}$, *that is, the space of isomorphism classes of solutions of (31) under the action of the formal group of diffeomorphisms of the line is isomorphic to the set of natural numbers.*

Proof: Let $\Phi(u,v,w)$ be the left-hand side of (31) as defined above. For $w=v+\epsilon$ we expand $\Phi(u,v,v+\epsilon)$ near the diagonal,

$$\Phi(u,v,v+\epsilon)=\left.\frac{\partial\Phi}{\partial w}\right|_{w=v}\epsilon+\frac{1}{2}\left.\frac{\partial^2\Phi}{\partial w^2}\right|_{w=v}\epsilon^2+\cdots .$$

Thus $\Phi(u,v,w)=0$ is equivalent to the infinite system $\partial\Phi/\partial w|_{w=v}=0$, $\partial^2\Phi/\partial w^2|_{w=v}=0, \ldots$. However, using the fact that the equation $\Phi(u,v,w)=0$ is gauge invariant under the action of G_∞ to find all of its solutions, it is enough to find all gauge invariant solutions of $\partial\Phi/\partial w|_{w=v}=0$. Indeed, let S be the space of solutions of $\Phi(u,v,w)=0$ and S' be the space of solutions of $\partial\Phi/\partial w|_{w=v}=0$. Clearly, $S\subset S'$. Thus, restricting S' to the subspace S'_{inv} of gauge invariant solutions we can recover the space S of solutions of the original equation. As we shall see below $S'_{inv}\subset S$ and since we also have $S\subset S'_{inv}$ we shall obtain that $S=S'_{inv}$. We now set out to find S'_{inv}. We have

$$\left.\frac{\partial\Phi}{\partial w}\right|_{w=v}=\varphi(u,v)\partial_v\partial_u\varphi(v,u)+2f(v)\partial_v\varphi(u,v)+\partial_v\varphi(v,u)[f(v)+\partial_u\varphi(v,u)]+\varphi(v,u)g(v)=0,$$

where $f(v) := \partial_2 \varphi(v,v)$, $g(v) = \partial_2^2 \varphi(v,v)$ and we used the fact that $\partial_1 \partial_2 \varphi(v,v) = 0$. Here ∂_1 and ∂_2 denote the derivatives with respect of the first and second arguments. This equation is equivalent to

$$f(v)\partial_v \varphi(u,v) - g(v)\varphi(u,v) = \varphi(u,v)\partial_u \partial_v \varphi(u,v) - \partial_v \varphi(u,v)\partial_u \varphi(u,v). \tag{34}$$

We note that the right-hand side is symmetric with respect to u and v. This implies that

$$f(v)\partial_v \varphi(u,v) - g(v)\varphi(u,v) = -f(u)\partial_u \varphi(u,v) + g(u)\varphi(u,v). \tag{35}$$

Since $\varphi(u,v) = -\varphi(v,u)$, this also implies that $\varphi(u,v) = (u-v)^n \psi(u,v)$, where $\psi(u,v) = \psi(v,u)$, and some odd $n \in \mathbb{N}$. From

$$\partial_v \varphi(u,v) = (u-v)^{n-1}[-n\partial_v \psi(u,v) - (u-v)\partial_v \psi(u,v)],$$

and the definition of $f(v) = \partial_v \varphi(u,v)|_{u=v}$ we obtain that

$$f(v) = \begin{cases} -\psi(v,v), & \text{if } n=1, \\ 0, & \text{if } n>1. \end{cases} \tag{36}$$

Further, from

$$\partial_v^2 \varphi(u,v) = (u-v)^{n-2}[-n(n-1)\psi(u,v) - 2(u-v)\partial_v \psi(u,v) + (u-v)^2 \partial_v^2 \psi(u,v)],$$

and the definition of $g(v) = \partial_v^2 \varphi(u,v)|_{u=v}$ follows that $g=0$, if $n>2$. If $n=2$ we have $g(v) = -2\psi(v,v)$ but then Eq. (35) together with (36) imply that $g(u) = -g(v)$, which implies $g = 0$. If $n=1$ we have $g(v) = -2\partial_2 \psi(v,v) = -\partial_1 \psi(v,v) - \partial_2 \psi(v,v) = f'(v)$. Thus,

$$g(v) = \begin{cases} f'(v), & \text{if } n=1, \\ 0, & \text{if } n>1. \end{cases} \tag{37}$$

Let us assume that $n>1$. Then Eq. (34) implies that

$$\varphi(u,v)\partial_u \partial_v \varphi(u,v) = \partial_v \varphi(u,v)\partial_u \varphi(u,v),$$

which after integration leads to $\varphi(u,v) = \exp(\int C_1(v)dv + C_2(u))$, where $C_1(v) \in k[[v]]$ and $C_2(u) \in k[[u]]$ are formal power series. This is in clear contradiction with $\varphi(u,v) = -\varphi(v,u)$. Therefore $n=1$ and $\varphi(u,v)$ has a zero of order 1 on the diagonal. Thus, from (35) we have

$$-[f'(v)\varphi - f(v)\partial_v \varphi] = [f'(u)\varphi - f(u)\partial_u \varphi],$$

or equivalently,

$$-\partial_v \left(\frac{f(v)}{\varphi} \right) = \partial_u \left(\frac{f(u)}{\varphi} \right).$$

This implies that there is a formal Laurent series $\theta(u,v)$ such that

$$\frac{f(u)}{\varphi(u,v)} = \partial_v \theta(u,v),$$

$$\frac{f(v)}{\varphi(u,v)} = -\partial_u \theta(u,v),$$

from where we obtain

$$f(v)\frac{\partial\theta}{\partial v}+f(u)\frac{\partial\theta}{\partial u}=0. \tag{38}$$

The general solution of (38) is given by $\theta(u,v)=\zeta(F(u)-F(v))$, where $F(u)=\int du/f(u)$ is a formal Laurent series and $\zeta(t)$ is a formal Laurent series in one variable. Thus,

$$\varphi(u,v)=-\frac{1}{F'(u)F'(v)\zeta'(F(u)-F(v))}=-\frac{\eta(F(u)-F(v))}{F'(u)F'(v)}, \tag{39}$$

where $\eta(u)=1/\zeta'(u)$. Let $u\mapsto x(u)$ be a formal diffeomorphism such that $F(x(u))=u$. Then the general solution (39) of $\partial_w\Phi(u,v,w)|_{w=v}=0$ transforms to $\varphi(u,v)=-\eta(u-v)$. To find the space S'_{inv} of invariant solutions of $\partial_w\Phi(u,v,w)|_{w=v}=0$ we substitute back into (34) which leads to

$$-\eta(u-v)\eta''(u-v)+\eta'(0)\eta'(u-v)-\eta'(u-v)^2=0, \tag{40}$$

where we used the fact that $\eta(-u)=-\eta(u)$, which, in particular, implies that $\eta(0)=0=\eta''(0)$. The only nontrivial solution of (40) is $\eta(u)=\eta'(0)u$. Thus, the space S'_{inv} is described by all

$$\varphi(u,v)=\frac{F(v)-F(u)}{F'(u)F'(v)}. \tag{41}$$

By direct substitution one checks that this solution satisfies (31) and thus we have also $S'_{inv}\subset S$. Therefore all solutions of (31) are described by (41). Let

$$F(u)=\sum_{n=-d}^{\infty}C_nu^n=C_{-d}\frac{1}{u^d}+C_{-d+1}\frac{1}{u^{d-1}}+\cdots,$$

where $d>0$ or $d<0$. (By a formal diffeomorphism we can always remove the constant term.) From $F'(u)=1/f(u)$ and that $\varphi(u,v)$ is divisible by uv it follows that $d>0$ for the group G_∞. Let $x(u)$ be a formal diffeomorphism, such that $F(u)=x(u)^{-d}$. Then the solution (41) transforms to

$$\tilde{\varphi}(u,v)=\frac{1}{d^2}u^{d+1}v^{d+1}(v^{-d}-u^{-d})=\frac{1}{d^2}uv(v^d-u^d). \tag{42}$$

For each $d\in\mathbb{Z}_+$ this gives a representative of an isomorphism class of solutions of (31). For each $d\in\mathbb{N}$ formula (29) gives rise to the Poisson–Lie tensor,

$$\omega_{ij}(x)=(i-d)jx_jx_{i-d}-i(j-d)x_ix_{j-d}+x_i\sum_{\Sigma_{k=1}^{d+1}s_k=j}x_{s_1}\ldots x_{s_{d+1}}-x_j\sum_{\Sigma_{k=1}^{d+1}s_k=i}x_{s_1}\ldots x_{s_{d+1}}, \tag{43}$$

where $i,j\in\mathbb{Z}_+$, describing a class of Poisson–Lie structures on G_∞. □

We shall give a more detailed description of the Poisson–Lie structures on G_∞ in the general position. For this, we use the following equivalent formulation of the last theorem.[19]

Theorem IV.4: *For each $d\in\mathbb{N}$, and any formal power series $f_d(u),g_d(u)$ such that $f'_d(u)g_d(u)-f_d(u)g'_d(u)=-d\lambda_{1,d+1}f_d(u)$, where $\lambda_{1,d+1}\neq 0$ is an arbitrary parameter, and f_d has a zero of order $d+1$ at $u=0$, there is a solution of (31) given by the series*

$$\varphi_d(u,v)=\frac{1}{\lambda_{1,d+1}}[f_d(u)g_d(v)-f_d(v)g_d(u)].$$

The set of all solutions of (31) is described in this way.

In more detail this means the following. Let us write $\varphi(u,v)=\Sigma\lambda_{mn}u^m v^n\in k[[u,v]]$. Let

$$M=\{(\mu_1,\mu_2,\ldots)|\mu_i\in k,i\in\mathbb{N}\}$$

be the set of all sequences with elements in the field k.

Then *all* Poisson–Lie structures on G_∞ are described as follows. For each $d\in\mathbb{N}$ and

$$M_d=\{(\underbrace{0,0,\ldots,0}_{d},\mu_{d+1},\mu_{d+2},\ldots)|\mu_{d+1}\neq 0\}\subset M,$$

there is a Poisson–Lie structure on G_∞ given by

$$\{x_i,x_j\}=\sum_{p=1}^{i}\sum_{q=1}^{j}px_pqx_q\lambda_{i-p+1,j-q+1}-\sum_{p=1}^{i}\sum_{q=1}^{j}\lambda_{pq}\sum_{\Sigma_{k=1}^{p}r_k=i}x_{r_1}\ldots x_{r_p}\sum_{\Sigma_{l=1}^{q}s_l=j}x_{s_1}\ldots x_{s_q}, \tag{44}$$

where

$$\lambda_{mn}=\frac{1}{\mu_{d+1}}[\mu_m\lambda_{d+1,n}-\mu_n\lambda_{d+1,m}],\forall_{m,n\geqslant 1}.$$

Clearly $\lambda_{mn}=-\lambda_{nm}$ and we implicitly assume the convention that $\lambda_{mn}=0$ whenever $m<1$ or $n<1$. Here, $\lambda_{d+1,n}$ are given by rational functions $\lambda_{d+1,n}=f_n(\mu_{d+1},\ldots,\mu_{d+n})$ for $n\geqslant 1$, which are computed by the following recursive formula:

$$\lambda_{d+1,n}=-\frac{1}{(d-n+1)\mu_{d+1}}\left[d\mu_{d+1}\mu_{n+d}-\sum_{s=1}^{n-1}(n+d-2s+1)\mu_{n+d-s+1}\lambda_{s,d+1}\right], \tag{45}$$

where $\lambda_{1,d+1}=\mu_{d+1}$. The sequences from M_d are ''almost arbitrary'' in the sense that there is *precisely one* relation between the numbers μ_n:

$$d\mu_{d+1}\mu_{2d+1}+2(d-1)\mu_{2d}\lambda_{1,d+1}+2(d-2)\mu_{2d-1}\lambda_{2,d+1}+\cdots+2\mu_{d+2}\lambda_{d,d+1}=0, \tag{46}$$

which are otherwise subject to no other restrictions. Here

$$\lambda_{1,d+1}=\mu_{d+1},$$

$$\lambda_{2,d+1}=f_2(\mu_{d+1},\mu_{d+2})=\frac{1}{1-d}\mu_{d+2},$$

$$\lambda_{3,d+1}=f_3(\mu_{d+1},\mu_{d+2},\mu_{d+3})=\frac{2}{2-d}\mu_{d+3}+\frac{d}{(d-1)(d-2)}\frac{(\mu_{d+2})^2}{\mu_{d+1}},$$

$$\vdots$$

$$\lambda_{d-1,d+1}=f_{d-1}(\mu_{d+1},\mu_{d+2},\ldots,\mu_{2d-1}),$$

$$\lambda_{d,d+1}=f_d(\mu_{d+1},\mu_{d+2},\ldots,\mu_{2d}),$$

where the functions $f_2, f_3, \ldots, f_d$ are rational in μ_{d+1} and polynomial in $\mu_{d+2}, \ldots, \mu_{2d}$. Thus, the above relation involves only $d+1$ elements of the sequence M_d. Namely, the elements $\mu_{d+1}, \mu_{d+2}, \ldots, \mu_{2d+1}$.

For example, to each sequence,

$$M_d = \{(\underbrace{0,0,\ldots,0}_{d},1,0,0,\ldots), \quad d \in \mathbb{N},$$

there correspond the Poisson–Lie brackets (43). We compute below a set of solutions obtained by an appropriate diffeomorphism from (42). The elements of this set are labeled by the sequences

$$M_d = \{(\underbrace{0,0,\ldots,0}_{d},1,\lambda,\lambda^2,\lambda^3,\ldots), \quad d \in \mathbb{N}, \quad \text{and } \lambda \in k. \tag{47}$$

Lemma IV.3: For each $d \in \mathbb{N}\backslash\{1\}$, *if* $\lambda_{1n} = (\lambda_{1,d+2})^{n-d-1}/(\lambda_{1,d+1})^{n-d-2}$, *for every* $n \geqslant d+1$, *it follows that* $\lambda_{n,d+1} = 0$, *for every* $n \geqslant d+1$, *and* $\lambda_{n,d+1} = -[1/(d-1)][(\lambda_{1,d+2})^{n-1}/(\lambda_{1,d+1})^{n-2}]$, *for all n such that* $2 \leqslant n \leqslant d$.

Proof: From (45) we have

$$\lambda_{n,d+1} = \frac{1}{(d-n+1)\lambda_{1,d+1}}\left[d\frac{(\lambda_{1,d+1})^{n-1}}{(\lambda_{1,d+1})^{n-3}} - \sum_{s=1}^{n-1}(n+d-2s+1)\frac{(\lambda_{1,d+2})^{n-s}}{(\lambda_{1,d+1})^{n-s-1}}\lambda_{s,d+1}\right]. \tag{48}$$

For $n=2$ we obtain

$$\lambda_{2,d+1} = \frac{1}{(d-n+1)\lambda_{1,d+1}}[d\lambda_{1,d+1}\lambda_{1,\,d+2} - (d+1)\lambda_{1,d+2}\lambda_{1,d+1}] = -\frac{1}{d-1}\lambda_{1,d+2}.$$

Let as assume now that $\lambda_{k,d+1} = -[1/(d-1)][(\lambda_{1,d+2})^{k-1}/(\lambda_{1,d+1})^{k-2}]$ for all k, such that $2 \leqslant k \leqslant n-1 < d$. We will now prove that this relation is true for $k=n \leqslant d$. Indeed, we have

$$\begin{aligned}\lambda_{n,d+1} &= \frac{1}{(d-n+1)\lambda_{1,d+1}}\left[d\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-3}} + \frac{1}{d-1}\sum_{s=1}^{n-1}(n+d-2s+1)\frac{(\lambda_{1,d+2})^{n-s}}{(\lambda_{1,d+1})^{n-s-1}}\lambda_{s,d+1}\right] \\ &= \frac{1}{(d-n+1)}\left[-(n-1) + \frac{1}{d-1}(n-2)(n+d+1) - \frac{2}{d-1}\left(\frac{n(n-1)}{2} - 1\right)\right]\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}} \\ &= -\frac{1}{d-1}\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}}.\end{aligned}$$

This proves the second part of the lemma. If $n=d+1$, then the l.h.s. of (48) is zero. We check for the consistency of whether the r.h.s. is zero. Indeed, the expression in the brackets reads as

$$-d + \frac{1}{d-1}\sum_{s=2}^{d}2(d-s+1) = \frac{1}{d-1}\left[-d^2 + d + 2(d+1)(d-1) - 2\left(\frac{d(d+1)}{2} - 1\right)\right] = 0.$$

Now, we check whether the statement is true for $\lambda_{d+2,d+1}$. From (48) one has

$$\begin{aligned}\lambda_{d+2,d+1} &= -\left[-(d+1) + \frac{1}{d-1}\sum_{s=2}^{d}(2d+3-2s)\right]\frac{(\lambda_{1,d+2})^{d+1}}{(\lambda_{1,d+1})^{d}} \\ &= -\frac{1}{d-1}\left[-d^2 + 1 + (d-1)(2d+3) - 2\left(\frac{d(d+1)}{2} - 1\right)\right]\frac{(\lambda_{1,d+2})^{d+1}}{(\lambda_{1,d+1})^{d}} = 0.\end{aligned}$$

We use again an inductive argument. We assume that $\lambda_{k,d+1}=0$ for all k such that $d+1\leqslant k\leqslant n-1$, and we aim to show that this implies $\lambda_{n,d+1}=0$. With these assumptions from (48) we have

$$\lambda_{n,d+1}=\frac{1}{(d-n+)}\left[d\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}}-\sum_{s=1}^{d}(n+d-2s+1)\frac{(\lambda_{1,d+2})^{n-s}}{(\lambda_{1,d+1})^{n-2}}\lambda_{s,d+1}\right]$$
$$=\frac{1}{(d-n+1)}\left[-(n-1)+\frac{1}{d-1}\sum_{s=2}^{d}(n+d-2s+1)\right]\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}}$$
$$=\frac{1}{(d-n+1)(d-1)}\left[-(n-1)(d-1)+(d-1)(n+d+1)\right.$$
$$\left.-2\left(\frac{d(d+1)}{2}-1\right)\right]\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}}=0.$$

This concludes the proof of the lemma. □

Theorem IV.5: *For every $d\geqslant 2$ and $\lambda:=\lambda_{1,d+2}/\lambda_{1,d+1}$ the formal power series,*

$$\varphi_{d,\lambda}(u,v)=\frac{1}{(d-1)(1-\lambda u)(1-\lambda v)}\{(d-1)uv(v^{d}-u^{d})+\lambda\, du^{2}\, v^{2}(u^{d-1}-v^{d-1})\},\qquad(49)$$

is a solution of (31). It is a one-parameter extension of the solution $\varphi(u,v)=uv(v^{d}-u^{d})$, for every $d\geqslant 2$, which we obtain back from (49) by setting $\lambda=0$.

Proof: With the assumptions of Lemma IV.3 we have

$$f_{d}(u)=\sum_{n=d+1}^{\infty}\lambda_{1n}u^{n}=\sum_{n=d+1}^{\infty}\frac{(\lambda_{1,d+2})^{n-d-1}}{(\lambda_{1,d+1})^{n-d-2}}u^{n}=\lambda_{1,d+1}u^{d+1}\sum_{n=0}^{\infty}\left(\frac{\lambda_{1,d+2}}{\lambda_{1,d+1}}u\right)^{n}=\frac{\lambda_{1,d+1}}{1-\lambda u}u^{d+1},$$

and

$$g_{d}(u,v)=-\sum_{n=1}^{d}\lambda_{n,d+1}u^{n}=-\lambda_{1,d+1}u+\frac{1}{d-1}\sum_{n=2}^{d}\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}}u^{n}$$
$$=-\lambda_{1,d+1}u+\frac{1}{d-1}\lambda_{1,d+2}u^{2}\left[\frac{1-(\lambda u)^{d-1}}{1-\lambda u}\right]$$
$$=\frac{\lambda_{1,d+1}}{(d-1)(1-\lambda u)}[d\lambda u^{2}-u(d-1+(\lambda u)^{d})].$$

By Theorem IV.4 we obtain

$$\varphi_{d,\lambda}(u,v)=\frac{1}{\lambda_{1,d+1}}[f_{d}(u)g_{d}(v)-f_{d}(v)g_{d}(u)]$$
$$=\frac{1}{(d-1)(1-\lambda u)(1-\lambda v)}\{v^{d+1}[-\lambda du^{2}+u(d-1+(\lambda u)^{d})]$$
$$-u^{d+1}[-\lambda dv^{2}+v(d-1+(\lambda v)^{d})]\}$$
$$=\frac{1}{(d-1)(1-\lambda u)(1-\lambda v)}\{(d-1)uv(v^{d}-u^{d})+\lambda du^{2}v^{2}(u^{d-1}-v^{d-1})\}$$
$$=\frac{F(v)-F(u)}{F'(u)F'(v)},$$

where $F(u)=-(1/d)u^{-d}+[\lambda/(d-1)]u^{-d+1}$. □

Remark IV.1: One can obtain the solution $\varphi(u,v)=uv(v-u)$, *which gives the Poisson–Lie structure for* $d=1$ *in Theorem IV.3, from (49) in the following way. Rewriting (49) as*

$$\varphi_{d,\lambda}(u,v)=\frac{uv(v^d-u^d)}{(1-\lambda u)(1-\lambda v)}+\frac{\lambda\ du^2\ v^2}{(1-\lambda u)(1-\lambda v)}\frac{u^{d-1}-v^{d-1}}{d-1},$$

we pass to the limit $d\to 1$ *and then set* $\lambda=0$.

Summarizing, we showed the existence of countably infinite classes of Poisson–Lie structures on the group G_∞. In the following two sections we shall show that this family of classes exhausts all such possible structures on G_∞.

V. BIALGEBRA STRUCTURES ON THE WITT ALGEBRA $\mathcal{G}_{0\infty}$ AND ITS PRINCIPAL SUBALGEBRA $\mathcal{G}_\infty$

In this section we use completely elementary methods to compute the Shevalley–Eilenberg cohomology groups $H^1(\mathcal{G}_{0\infty},\mathcal{G}_{0\infty}\hat{\wedge}\mathcal{G}_{0\infty})$ and $H^1(\mathcal{G}_\infty,\mathcal{G}_\infty\hat{\wedge}\mathcal{G}_\infty)$ with coefficients in the completion of the tensor product under the natural grading induced from the gradings on $\mathcal{G}_{0\infty}$ and $\mathcal{G}_\infty$. We show that both groups are trivial. Thus, we find all 1-cocycles on the Lie algebra $\mathcal{G}_{0\infty}$ (the Witt algebra), and all 1-cocycles on the Lie algebra $\mathcal{G}_\infty$ of the group G_∞. All of them are coboundaries, and they are all explicitly enumerated. The algebras $\mathcal{G}_{0\infty}$ and $\mathcal{G}_\infty$ are taken over $\mathbb{R}$ (or $\mathbb{C}$).

Let $\{e_i=u^{i+1}(d/du)\}_{i\geqslant -1}$ be the canonical basis of the Lie algebra $\mathcal{G}_{0\infty}$ (the Witt algebra). We recall that the Lie algebra structure on $\mathcal{G}_{0\infty}$ is defined by

$$[e_n,e_m]=(n-m)e_{n+m},\quad n,m\geqslant -1.$$

To find the 1-cocycles we turn to the 1-cocycle equation,

$$\alpha([e_n,e_m])=e_n.\alpha(e_m)-e_m.\alpha(e_n),$$

which we rewrite as

$$(n-m)\alpha(e_{n+m})=e_n.\alpha(e_m)-e_m.\alpha(e_n),\quad n,m\geqslant -1. \tag{50}$$

Let $\alpha(e_n)=\Sigma_{i,j=-1}^{\infty}\alpha_{ij}^n e_i\wedge e_j\in\mathcal{G}_{0\infty}\hat{\wedge}\mathcal{G}_{0\infty}=\oplus_k\oplus_{i+j=k}\mathcal{G}_{0i}\wedge\mathcal{G}_{0j}$, where $\mathcal{G}_{0i}$ is the 1-dimensional subspace of $\mathcal{G}_{0\infty}$ generated by e_i. Then (50) is equivalent to the following infinite system of linear equations:

$$(n-m)\alpha_{ij}^{n+m}=(2n-i)\alpha_{i-n,j}^m+(2n-j)\alpha_{i,j-n}^m-(2m-i)\alpha_{i-m,j}^n-(2m-j)\alpha_{i,j-m}^n, \tag{51}$$

where $n,m,i,j\geqslant -1$. Therefore, to find all 1-cocycles, one has to describe all solutions of this system.

Theorem V.1: *All 1-cocycles on the Lie algebra* $\mathcal{G}_{0\infty}$ *are coboundaries.*

Proof: We observe that (51) consists of two independent subsystems. Namely, one for α_{ij}^n's with $n\neq i+j$ and the other for α_{ij}^n's with $n=i+j$.

Set $m=0$ in (51). [Note that (51) is invariant with respect to $m\to n$, $n\to m$.] Then from (51) we deduce that

$$(n-i-j)\alpha_{ij}^n=(2n-i)\alpha_{i-n,j}^0+(2n-j)\alpha_{i,j-n}^0,\quad \text{for every}\quad n,i,j\geqslant -1. \tag{52}$$

(a) In case $n\neq i+j$ we obtain from (52) immediately the solution of the first subsystem,

$$\alpha_{ij}^n=\frac{(2n-i)}{(n-i-j)}\alpha_{i-n,j}^0+\frac{(2n-j)}{(n-i-j)}\alpha_{i,j-n}^0.$$

This means that the coalgebra structure constants α_{ij}^{n}, where $n\neq i+j$, are given in terms of α_{ij}^{0}, $i,j\in\mathbb{Z}_{+}$, which are arbitrary.

(b) The case $n=i+j$ requires a more thorough analysis. Set $j=n+m-i$ in (51). Then we have

$$(n-m)\alpha_{i,n+m-i}^{n+m}=(2n-i)\alpha_{i-n,m+n-i}^{m}+(n-m+i)\alpha_{i,m-i}^{m} \\ -(2m-i)\alpha_{i-m,n+m-i}^{n}-(m-n+i)\alpha_{i,n-i}^{n}, \tag{53}$$

where $n,m,i\geqslant -1$. It turns out that it is enough to investigate (53) for a few values of m and i in order to obtain a complete set of reccurence relations sufficient to find the general solution for $\alpha_{i,n-i}^{n}$. First we set $m=0$ in (53). This implies that $0=(2n-i)\alpha_{i-n,n-i}^{0}+(n+i)\alpha_{i,-i}^{0}$, for every $i,n\geqslant -1$. In particular, if $n=i$ we obtain $0=i\alpha_{-i,i}^{0}$, for every $i\geqslant -1$, since $\alpha_{0,0}^{0}=0$ by the antisymmetry of $\alpha_{ij}^{n}(=-\alpha_{ji}^{n})$. Therefore $\alpha_{-i,i}^{0}=0$, for every $i\geqslant -1$. Set $m=-1=i$ in (53) to obtain

$$(n+1)\alpha_{-1,n}^{n-1}=(2n+1)\alpha_{-1-n,n}^{-1}+n\alpha_{-1,0}^{-1}+\alpha_{0,n}^{n}+(n+2)\alpha_{-1,n+1}^{n}. \tag{54}$$

Then we have the following lemma.

Lemma V.1: One has $\alpha_{-1,n+1}^{n}=[1/(n+2)([n(n+1)/2]\alpha_{0,-1}^{-1}-\Sigma_{i=1}^{n}\alpha_{0,i}^{i})$, *for every* $n\geqslant 1$.

Proof: For $n=-1,0$, (54) is identically satisfied. For $n=1$ we have from (54): $2\alpha_{-1,1}^{0}=\alpha_{-1,0}^{-1}+\alpha_{0,1}^{1}+3\alpha_{-1,2}^{1}$, where we used that $\alpha_{-2,1}^{-1}=0$. From this it follows that $\alpha_{-1,2}^{1}=\frac{1}{3}[\alpha_{0,-1}^{-1}-\alpha_{0,1}^{1}]$, Assume that $\alpha_{-1,k+1}^{k}=[1/(k+2)]([k(k+1)/2]\alpha_{0,-1}^{-1}-\Sigma_{i=1}^{k}\alpha_{0,i}^{i})$, for all k, such that $1\leqslant k\leqslant n-1$. Then from (54), using the induction hypothesis we have

$$\begin{aligned}\alpha_{-1,n+1}^{n}&=\frac{1}{(n+2)}[n\alpha_{0,-1}^{-1}-\alpha_{0,n}^{n}+(n+1)\alpha_{-1,n}^{n-1}]\\ &=\frac{1}{(n+2)}\left[n\alpha_{0,-1}^{-1}-\alpha_{0,n}^{n}+\frac{n(n-1)}{2}\alpha_{0,-1}^{-1}-\sum_{i=1}^{n-1}\alpha_{0,i}^{i}\right]\\ &=\frac{1}{(n+2)}\left[\frac{n(n+1)}{2}\alpha_{0,-1}^{-1}-\sum_{i=1}^{n}\alpha_{0,i}^{i}\right].\end{aligned}$$

□

Lemma V.2: One has $\alpha_{0,2}^{2}=\alpha_{0,1}^{1}-\alpha_{0,-1}^{-1}$, *and* $\alpha_{1,n-1}^{n}=[(n+1)/2][-\alpha_{0,-1}^{-1}+\alpha_{0,n-1}^{n-1}-\alpha_{0,n}^{n}]$, *for every* $n\geqslant 3$.

Proof: From (53), after setting $m=-1,i=0$, we obtain

$$(n+1)\alpha_{0,n-1}^{n-1}=2n\alpha_{-n,n-1}^{-1}+(n+1)\alpha_{0,-1}^{-1}+2\alpha_{1,n-1}^{n}+(n+1)\alpha_{0,n}^{n}. \tag{55}$$

For $n=-1,0,1$, (55) is identically satisfied. Next, for $n=2$ we obtain from (55) that

$$\alpha_{0,2}^{2}=\alpha_{0,1}^{1}-\alpha_{0,-1}^{-1}, \tag{56}$$

since $\alpha_{-2,1}^{-1}=0$. Finally, since $\alpha_{-n,n-1}^{-1}=0$ for $n\geqslant 2$, we obtain from (55) the second assertion of the Lemma. □

Lemma V.3: The formula $\alpha_{2,n-2}^{n}=[n(n+1)/6][\alpha_{0,n-2}^{n-2}-2\alpha_{0,n-1}^{n-1}+\alpha_{0,n}^{n}]$ *is valid for every* $n\geqslant 5$.

Proof: In (53) set $m=-1$, $i=1$. Then we have

$$(n+1)\alpha_{1,n-2}^{n-1}=(2n-1)\alpha_{1-n,n-2}^{-1}+3\alpha_{2,n-2}^{n}+n\alpha_{1,n-1}^{n}.$$

For $n=-1,0$ this formula yields trivial identitites. For $n=1$ we obtain that $3\alpha^{1}_{-1,2}=\alpha^{-1}_{0,-1}-\alpha^{1}_{0,1}(=-\alpha^{2}_{0,2})$. The case $n=2$ reduces to formula (56), and $n=3$ yields the identity $0=3\alpha^{3}_{2,1}+3\alpha^{3}_{1,2}$. For $n=4$ we obtain the relation

$$5\alpha^{3}_{1,2}=4\alpha^{4}_{1,3}. \tag{57}$$

If $n\geqslant 5$, then $\alpha^{-1}_{1-n,n-2}=0$, and using Lemma V.2 we obtain that

$$\begin{aligned}\alpha^{n}_{2,n-2}&=\frac{1}{3}[(n+1)\alpha^{n-1}_{1,n-2}-n\alpha^{n}_{1,n-1}]\\&=\frac{1}{3}\left[\frac{n(n+1)}{2}(-\alpha^{-1}_{0,-1}+\alpha^{n-2}_{0,n-2}-\alpha^{n-1}_{0,n-1})-\frac{n(n+1)}{2}(-\alpha^{-1}_{0,-1}+\alpha^{n-1}_{0,n-1}-\alpha^{n}_{0,n})\right]\\&=\frac{n(n+1)}{6}[\alpha^{n-2}_{0,n-2}-2\alpha^{n-1}_{0,n-1}+\alpha^{n}_{0,n}].\end{aligned}$$

□

The result obtained in Lemma V.3 is suggestive in finding a general formula for $\alpha^{n}_{i,n-i}$ (that is, α^{n}_{ij} with $n=i+j$) in terms of $\alpha^{n}_{0,n},\ldots,\alpha^{n-i}_{0,n-i}$, for every $i\geqslant 2$ and $n\geqslant i+3$.

Lemma V.4: For every $i\geqslant 2$ and $n\geqslant i+3$ the following formula is valid:

$$\alpha^{n}_{i,n-i}=\frac{1}{i+1}\binom{n+1}{i}\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k}\alpha^{n-k}_{0,n-k}. \tag{58}$$

Proof: We use an induction in i. For $i=2$ the statetment is true by Lemma V.3. Assume that (58) is true for all $\alpha^{n}_{j,n-j}$, where $2\leqslant j\leqslant i$. We now proceed in proving that it is true for $j=i+1$ and all $n\geqslant i+4$. Setting $m=-1$ in (53) and using that $i\geqslant 2$ and $n\geqslant i+3$ we obtain

$$(n+1)\alpha^{n-1}_{i,n-i-1}-(n+1-i)\alpha^{n}_{i,n-i}=(i+2)\alpha^{n}_{i+1,n-i-1}. \tag{59}$$

Then we use the induction hypothesis in the left-hand side of (59) and deduce that

$$\begin{aligned}\alpha^{n}_{i+1,n-i-1}&=\frac{1}{i+2}\left[\frac{(n+1)}{i+1}\binom{n}{i}\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k}\alpha^{n-k-1}_{0,n-k-1}\right.\\&\qquad\left.-\frac{(n+1-i)}{i+1}\binom{n+1}{i}\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k}\alpha^{n-k}_{0,n-k}\right]\\&=\frac{1}{i+2}\binom{n+1}{i+1}\left[\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k}\alpha^{n-k-1}_{0,n-k-1}-\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k}\alpha^{n-k}_{0,n-k}\right]\\&=\frac{1}{i+2}\binom{n+1}{i+1}\left[\sum_{k=1}^{i+1}\binom{i}{k-1}(-1)^{i-k+1}\alpha^{n-k}_{0,n-k}+\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k+1}\alpha^{n-k}_{0,n-k}\right]\\&=\frac{1}{i+2}\binom{n+1}{i+1}\left[\sum_{k=1}^{i}\left[\binom{i}{k-1}+\binom{i}{k}\right](-1)^{i-k+1}\alpha^{n-k}_{0,n-k}+\alpha^{n-i-1}_{0,n-i-1}+(-1)^{i+1}\alpha^{n}_{0,n}\right]\\&=\frac{1}{i+2}\binom{n+1}{i+1}\sum_{k=0}^{i+1}\binom{i+1}{k}(-1)^{i+1-k}\alpha^{n-k}_{0,n-k},\end{aligned}$$

which concludes the proof. It is also an immediate corollary that the relation (57) is identically satisfied. □

Let $m=1,i=-1$ in (53). Then we have

$$(n-1)\alpha^{n+1}_{-1,n+2}=(2n+1)\alpha^{1}_{-1-n,n+2}+(n-2)\alpha^{1}_{-1,2}+n\alpha^{n}_{-1,n+1}. \tag{60}$$

For $n=-1$ (60) yields $\alpha^{1}_{-1,2}=\frac{1}{3}(\alpha^{-1}_{0,-1}-\alpha^{1}_{0,1})$. For $n=0,1$, it is identically satisfied. For $n=2$, we obtain the relation

$$\alpha^{3}_{-1,4}=2\alpha^{2}_{-1,3}. \tag{61}$$

Continuing further we have

$$2\alpha^{4}_{-1,5}=\alpha^{1}_{-1,2}+3\alpha^{3}_{-1,4} \quad (n=3),$$

$$3\alpha^{5}_{-1,6}=2\alpha^{1}_{-1,2}+4\alpha^{4}_{-1,5} \quad (n=4),$$

$$\vdots$$

which, as we shall see later, are all identically satisfied.

Lemma V.5: The following formula is valid for every $n\geqslant 2$*:*

$$\alpha^{n}_{0,n}=a_n(\alpha^{1}_{0,1}-\alpha^{-1}_{0,-1}),$$

where $a_2=1$, $a_3=3$, *and the coefficients* a_n, $(n\geqslant 4)$ *are computed by the recursive formula*

$$a_{n+1}=\frac{2n}{(n-1)(n+2)}+\frac{2(n+1)}{(n+2)}a_n-\frac{(n+1)(n-2)}{(n-1)(n+2)}a_{n-1},$$

which is valid for all $n\geqslant 3$.

Proof: For $n=2$ the statement is true according to formula (56). In order to compute a_3 we use the relation (61) and Lemma V.2. From Lemma V.1 we have

$$\alpha^{2}_{-1,3}=\tfrac{1}{2}[2\alpha^{-1}_{0,-1}-\alpha^{1}_{0,1}], \quad \text{and} \quad \alpha^{3}_{-1,4}=\tfrac{1}{5}[7\alpha^{-1}_{0,-1}-2\alpha^{1}_{0,1}-\alpha^{3}_{0,3}].$$

Then from (61) it follows that $\alpha^{3}_{0,3}=3(\alpha^{1}_{0,1}-\alpha^{-1}_{0,-1})$. After setting $m=1,i=1$ in (53) one obtains

$$(n-1)\alpha^{n+1}_{1,n}=-n\alpha^{1}_{0,1}-\alpha^{n}_{0,n}+(n-2)\alpha^{n}_{1,n-1}, \quad \text{for } n\geqslant 3, \tag{62}$$

since $\alpha^{1}_{1-n,n}=0$, for $n\geqslant 3$. Next, we use Lemma V.2 to write formulas for

$$\alpha^{n}_{1,n-1}=\frac{(n+1)}{2}[-\alpha^{-1}_{0,-1}+\alpha^{n+1}_{0,n+1}-\alpha^{n}_{0,n}] \quad \text{and} \quad \alpha^{n+1}_{1,n}=\frac{(n+2)}{2}[-\alpha^{-1}_{0,-1}+\alpha^{n}_{0,n}-\alpha^{n+1}_{0,n+1}].$$

Substituting the above formulas into (62) we obtain, after some algebra, that

$$\alpha^{n+1}_{0,n+1}=\frac{2n}{(n-1)(n+2)}(\alpha^{1}_{0,1}-\alpha^{-1}_{0,-1})+\frac{2(n+1)}{(n+2)}\alpha^{n}_{0,n}-\frac{(n+1)(n-2)}{(n-1)(n+2)}\alpha^{n-1}_{0,n-1}, \quad \text{for all } n\geqslant 3. \tag{63}$$

Now, we make an induction hypothesis. Namely, we assume that for all k, $2\leqslant k\leqslant n$, it is true that $\alpha^{k}_{0,k}=a_k(\alpha^{1}_{0,1}-\alpha^{-1}_{0,-1})$, for some a_k. Then from (63) it follows that $\alpha^{n+1}_{0,n+1}=a_{n+1}(\alpha^{1}_{0,1}-\alpha^{-1}_{0,-1})$, where

$$a_{n+1}=\frac{2n}{(n-1)(n+2)}+\frac{2(n+1)}{(n+2)}a_n-\frac{(n+1)(n-2)}{(n-1)(n+2)}a_{n-1}.$$

The first several coefficients are: $a_2=1$, $a_3=3$, $a_4=5$, $a_5=\frac{64}{9}$, $a_6=\frac{28}{3}$, $a_7=\frac{451}{45}$, ... This concludes the proof. □

Corollary V.1: From Lemma V.4 *and Lemma* V.5 *it follows that*

$$\alpha^n_{i,n-i} = \frac{1}{i+1}\binom{n+1}{i}\sum_{k=0}^{i}\binom{i}{k}(-1)^{i-k}a_{n-k}(\alpha^1_{0,1}-\alpha^{-1}_{0,-1}),$$

for every $i \geqslant 2$ *and* $n \geqslant i+3$.

Lemma V.6: One has the following relation: $\alpha^{-1}_{0,-1}=\alpha^1_{0,1}$.

Proof: In (53) set $m=0, i=-1$. Then one has

$$(n-2)\alpha^{n+2}_{-1,n+3}=(2n+1)\alpha^2_{-1-n,n+3}+(n-3)\alpha^2_{-1,3}+(n-1)\alpha^n_{-1,n+1}. \tag{64}$$

For $n=-1$ we obtain from (64) that $-3\alpha^1_{-1,2}=-\alpha^2_{0,2}-4\alpha^2_{-1,3}-2\alpha^{-1}_{-1,0}$, which, after using Lemma V.1, turns into an identity. For $n=0$ we have an identity. For $n=1$ we obtain $-\alpha^3_{-1,4} = -2\alpha^2_{-1,3}$, which leads to an identity after using Lemma V.1 and Lemma V.5. The case $n=2$ leads to an identity. For $n=3$ we obtain the nontrivial relation

$$\alpha^5_{-1,6}=2\alpha^3_{-1,4}. \tag{65}$$

We use now Lemma V.1 and Lemma V.5 to reduce both sides of the relation (65) which leads to

$$\frac{1}{7}\left[15\alpha^{-1}_{0,-1}-\sum_{i=1}^{5}\alpha^i_{0,i}\right]=\frac{2}{5}\left[6\alpha^{-1}_{0,-1}-\sum_{i=1}^{3}\alpha^i_{0,i}\right],$$

$$\frac{1}{7}\left[15\alpha^{-1}_{0,-1}-\alpha^1_{0,1}-\left(1+3+5+\frac{64}{9}\right)(\alpha^1_{0,1}-\alpha^{-1}_{0,-1})\right]=\frac{2}{5}[6\alpha^{-1}_{0,-1}-\alpha^1_{0,1}-(1+3)(\alpha^1_{0,1}-\alpha^{-1}_{0,-1})],$$

$$\frac{40}{9}\alpha^{-1}_{0,-1}-\frac{22}{9}\alpha^1_{0,1}=4\alpha^{-1}_{0,-1}-2\alpha^1_{0,1},$$

$$\alpha^{-1}_{0,-1}=\alpha^1_{0,1}.$$

This concludes the proof. □

Immediately several corollaries follow.

Corollary V.2: One has $\alpha^n_{0,n}=0$, *for all* $n \geqslant 2$.

Corollary V.3: One obtains that $\alpha^n_{-1,n+1}=[1/(n+2)]([n(n+1)/2]\alpha^{-1}_{0,-1}-\alpha^1_{0,1})=[(n-1)/2]\alpha^1_{0,1}$, *for all* $n \geqslant -1$.

Corollary V.4: One has $\alpha^n_{i,n-i}=0$, *for all* $i \geqslant 2$ *and* $n \geqslant i+3$.

Corollary V.5: One has $\alpha^n_{1,n-1}=-[(n+1)/2]\alpha^1_{0,1}$, *for all* $n \geqslant 3$.

In the above formulas $\alpha^1_{0,1}$ is arbitrary. As a result we are now able to write a formula for the general solution of (50). Namely,

$$\begin{aligned}
\alpha(e_n) &= \sum_{i,j=-1}^{\infty}\alpha^n_{ij}e_i\wedge e_j \\
&= \sum_{i,j=-1, i+j\neq n}^{\infty}\alpha^n_{ij}e_i\wedge e_j+\sum_{i,j=-1,i+j=n}^{\infty}\alpha^n_{ij}e_i\wedge e_j \\
&= \sum_{i,j=-1,i+j\neq n}^{\infty}\left[\frac{(2n-i)}{(n-i-j)}\alpha^0_{i-n,j}+\frac{(2n-j)}{(n-i-j)}\alpha^0_{i,j-n}\right]e_i\wedge e_j+\sum_{i=-1}^{\infty}\alpha^n_{i,n-i}e_i\wedge e_{n-i} \\
&= e_n\cdot\left(-\sum_{i,j=-1,i+j\neq 0}^{\infty}\frac{1}{(i+j)}\alpha^0_{ij}e_i\wedge e_j\right)+\alpha^n_{-1,n+1}e_{-1}\wedge e_{n+1} \\
&\quad +\alpha^n_{0,n}e_0\wedge e_n+\alpha^n_{1,n-1}e_1\wedge e_{n-1}
\end{aligned}$$

$$=e_n.\left(-\sum_{i,j=-1,i+j\neq 0}^{\infty}\frac{1}{(i+j)}\alpha_{ij}^0 e_i\wedge e_j+\frac{1}{2}\alpha_{0,1}^1(1+\delta_{n,\pm 1})e_{-1}\wedge e_1\right),\quad \text{for all } n\geqslant -1.$$

This shows that the general solution of (50) is a coboundary. The proof of Theorem V.1 is completed. □

With a different technique it has been obtained in Ref. 21 that the first cohomology of $\mathcal{G}_{0\infty}$ with coefficients in the ordinary tensor product is trivial. This result follows from Theorem V.1 of which it is a special case.

We now proceed with describing all bialgebra structures on the Lie algebra $\mathcal{G}_\infty$ of the group G_∞. The problem now is to describe all solutions of

$$(n-m)\alpha(e_{n+m})=e_n.\alpha(e_m)-e_m.\alpha(e_n),\qquad \text{for all } n,m\geqslant 0. \tag{66}$$

Equation (66) is now equivalent to the following infinite system of equations for the coalgebra structure constants α_{ij}^n:

$$(n-m)\alpha_{ij}^{n+m}=(2n-i)\alpha_{i-n,j}^m+(2n-j)\alpha_{i,j-n}^m-(2m-i)\alpha_{i-m,j}^n-(2m-j)\alpha_{i,j-m}^n, \tag{67}$$

where $n,m,i,j\geqslant 0$.

Theorem V.2: *All 1-cocycles on the Lie algebra $\mathcal{G}_\infty$ are coboundaries.*

Proof: The begining of the argument is similar to the one in the proof of Theorem V.1. Namely, the system of equations (67) is split into two completely independent systems. One for the structure constants α_{ij}^n with $n\neq i+j$, and one for the structure constants α_{ij}^n with $n=i+j$. In the first case, after setting $m=0$ in (67) we obtain

$$(n-i-j)\alpha_{ij}^n=(2n-i)\alpha_{i-n,j}^0+(2n-j)\alpha_{i,j-n}^0,\quad \text{for every}\quad n,i,j\geqslant 0.$$

Since $n\neq i+j$ we obtain that

$$\alpha_{ij}^n=\frac{(2n-i)}{(n-i-j)}\alpha_{i-n,j}^0+\frac{(2n-j)}{(n-i-j)}\alpha_{i,j-n}^0,$$

i.e., the coalgebra structure constants α_{ij}^n, where $n\neq i+j$, are expressed in terms of α_{ij}^0, $i,j\geqslant 0$, which are arbitrary.

We now turn to the second case, which requires a more detailed analysis. The system of equations for the coalgebra structure constants α_{ij}^n with $n=i+j$ is obtained from (67) by setting $j=n+m-i$:

$$(n-m)\alpha_{i,n+m-i}^{n+m}=(2n-i)\alpha_{i-n,m+n-i}^m+(n-m+i)\alpha_{i,m-i}^m$$
$$-(2m-i)\alpha_{i-m,n+m-i}^n-(m-n+i)\alpha_{i,n-i}^n, \tag{68}$$

where $n,m,i\geqslant 0$.

Again we split the rest of the proof into lemmas.

Lemma V.7: One has $\alpha_{0,n}^n=n\alpha_{0,1}^1$, for all $n\geqslant 0$.

Proof: After setting $m=1,i=0$ in (68) one obtains $\alpha_{0,n+1}^{n+1}=\alpha_{0,1}^1+\alpha_{0,n}^n$, since $n\alpha_{-n,n+1}^1=0$ for all $n\geqslant 0$. A simple inductive argument now leads to $\alpha_{0,n}^n=n\alpha_{0,1}^1$, for all $n\geqslant 0$. □

Lemma V.8: One has $\alpha_{1,n}^{n+1}=-(n+2)\alpha_{0,1}^1$ for all $n\geqslant 2$.

Proof: Set $m=1,i=1$ in (68). Then one has

$$(n-1)\alpha_{1,n}^{n+1}=(2n-1)\alpha_{1-n,n}^1-2n\alpha_{0,1}^1+(n-2)\alpha_{1,n-1}^n. \tag{69}$$

We investigate (69) for small values of n. For $n=0,1$ one obtains identities. For $n=2$ we obtain the first nontrivial relation. Namely, $\alpha_{1,2}^3=-4\alpha_{0,1}^1$. Clearly, since $\alpha_{1-n,n}^1=0$ for all $n\geqslant 2$, (69) is equivalent to

$$(n-1)\alpha_{1,n}^{n+1}=-2n\alpha_{0,1}^{1}+(n-2)\alpha_{1,n-1}^{n},$$

for all $n\geqslant 2$. Again, an induction argument leads to $\alpha_{1,n}^{n+1}=-(n+2)\alpha_{0,1}^{1}$, for all $n\geqslant 2$. □

Lemma V.9: One has $\alpha_{i,n}^{n+i}=-(n+2i)\alpha_{0,1}^{1}+[3(1-i^2)/(n-i)]\alpha_{0,1}^{1}$ *for all* $n\geqslant 1$, *and all* $i\geqslant 1$, *and* $n\neq i$.

Proof: Set $m=i$ in (68) to obtain

$$(n-i)\alpha_{i,n}^{n+i}=(2n-i)\alpha_{i-n,n}^{i}+n\alpha_{i,0}^{i}-i\alpha_{0,n}^{n}+(n-2i)\alpha_{i,n-i}^{n}. \tag{70}$$

After using Lemma V.7, (70) reduces to

$$(n-i)\alpha_{i,n}^{n+i}=-2ni\alpha_{0,1}^{1}+(n-2i)\alpha_{i,n-i}^{n}. \tag{71}$$

If we set $n=i$ in (71) it reduces further to $2i\alpha_{0,i}^{i}=2i^2\alpha_{0,1}^{1}$, from where for $i\neq 0$ it is equivalent to the assertion of Lemma V.7. Let $n\neq i$. Then the general solution of (71) is given by

$$\alpha_{i,n}^{n+i}=-(n+2i)\alpha_{0,1}^{1}+f(n,i), \tag{72}$$

where $f(n,i)$ satisfies the equation $(n-i)f(n,i)=(n-2i)f(n-i,i)$. If we define $\alpha(n,i):=(n-i)f(n,i)$ then this equation is equivalent to $\alpha(n,i)=\alpha(n-i,i)$. From here it follows that $\alpha(n,i)=\alpha(i)$, that is, α is independent of n. Therefore the general solution (72) is given by

$$\alpha_{i,n}^{n+i}=-(n+2i)\alpha_{0,1}^{1}+\frac{\alpha(i)}{(n-i)}. \tag{73}$$

Our next goal is to determine the parameters $\alpha(i)$, for all $i\geqslant 2$. From the conclusion of Lemma V.7 we know that $\alpha(1)=0$. Set $n=1$ in (73). This yields $\alpha_{i,1}^{i+1}=-(1+2i)\alpha_{0,1}^{1}+\alpha(i)/(1-i)$. Using the result of Lemma V.7, this leads to the equations $-(1+2i)\alpha_{0,1}^{1}+\alpha(i)/(1-i)=(i+2)\alpha_{0,1}^{1}$, for all $i\geqslant 2$, from where, solving for $\alpha(i)$, we obtain $\alpha(i)=3(1-i^2)\alpha_{0,1}^{1}$, for all $i\geqslant 2$. Therefore, $\alpha_{i,n}^{n+i}=-(n+2i)\alpha_{0,1}^{1}+[3(1-i^2)/(n-i)]\alpha_{0,1}^{1}$, for all $n\geqslant 1$, and all $i\geqslant 1$, and $n\neq i$. □

Quite similarly as in the case of the Witt algebra the following observation helps to complete the argument.

Lemma V.10: One has $\alpha_{0,1}^{1}=0$.

Proof: Set $m=2,i=1$ in (68) to obtain

$$(n-2)\alpha_{1,n+1}^{n+2}=(2n-1)\alpha_{1-n,n+1}^{2}+(n-3)\alpha_{1,n-1}^{n}. \tag{74}$$

We investigate (74) for small values of n. For $n=0$ it yields an identity. For $n=1$ it gives $-\alpha_{1,2}^{3}=\alpha_{0,2}^{2}-2\alpha_{1,0}^{1}=4\alpha_{0,1}^{1}$, a fact we learned from Lemma V.9. For $n=2$ it yields a trivial identity. For $n=3$ it gives $\alpha_{1,4}^{5}=0$. But from Lemma V.8 we have $\alpha_{1,4}^{5}=-6\alpha_{0,1}^{1}$, a clear contradiction. Therefore we conclude that $\alpha_{0,1}^{1}=0$, which is what we set out to show. □

The following two corollaries are direct consequences of the last result and the preceding lemmas.

Corollary V.6: One has $\alpha_{0,n}^{n}=0$, *for all* $n\geqslant 1$.

Corollary V.7: One has $\alpha_{i,n}^{n+i}=0$ *for all* $n,i\geqslant 1$.

Thus, all coalgebra structure constants $\alpha_{ij}^{n}=0$, whenever $n=i+j$. Therefore the general solution of (66) is described by

$$\alpha(e_n)=\sum_{i,j=0}^{\infty}\alpha_{ij}^n e_i\wedge e_j=\sum_{i,j=0,i+j\neq n}^{\infty}\alpha_{ij}^n e_i\wedge e_j$$

$$=\sum_{i,j=0,i+j\neq n}^{\infty}\left[\frac{(2n-i)}{(n-i-j)}\alpha_{i-n,j}^0+\frac{(2n-j)}{(n-i-j)}\alpha_{i,j-n}^0\right]e_i\wedge e_j$$

$$=e_n.\left(-\sum_{i,j=0,i+j\neq 0}^{\infty}\frac{1}{(i+j)}\alpha_{ij}^0 e_i\wedge e_j\right).$$

This shows that for $\mathcal{G}_\infty$ all 1-cocycles are coboundaries. □

VI. THE GROUP G_∞ AND THE R-MATRIX

In this section we describe the correspondence between the solution

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)-\varphi(x(u),x(v)) \tag{75}$$

of the cocycle equation and the classical r-matrix on $\mathcal{G}_\infty$.[17] We prove that there is a one-to-one correspondence between the Poisson–Lie structures on G_∞ and the r-matrices on $\mathcal{G}_\infty$. This establishes the classification of Poisson–Lie (Lie-bialgebra) structures for the group G_∞ and its Lie algebra $\mathcal{G}_\infty$. In the next section we extend this result to the group $G_{0\infty}$ and its Lie algebra $\mathcal{G}_{0\infty}$. Let $e_n=u^{n+1}(d/du)$, $n=0,1,2,\ldots$, be the canonical basis of $\mathcal{G}_\infty$. We write the classical r-matrix (taking values in the completed tensor product) as

$$\lambda=\sum_{m,n=0}^{\infty}\lambda_{m+1,n+1}u^{m+1}\frac{d}{du}\wedge v^{n+1}\frac{d}{dv}=\varphi(u,v)\frac{d}{du}\wedge\frac{d}{dv}\in\bar{\wedge}^2\mathcal{G}_\infty,$$

where $\varphi(u,v)=\sum_{m,n=1}^{\infty}\lambda_{mn}u^m v^n$, and $\lambda_{mn}=-\lambda_{nm}$. If α is a 1-cocycle, then

$$(\delta\alpha)(e_l,e_m)=e_l.\alpha(e_m)-e_m\cdot\alpha(e_l)-\alpha([e_l,e_m])=0,$$

where δ is the coboundary operator in the Chevalley–Eilenberg cohomology of Lie algebras.

In Sec. V we proved that all 1-cocycles α are coboundaries. Thus, $\alpha=\delta\lambda$. Let us define $\langle\lambda,\lambda\rangle:=\Phi(u,v,w)(d/du)\wedge d/dv\wedge d/dw\in\bar{\wedge}^3\mathcal{G}$ as

$$\langle\lambda,\lambda\rangle:=[\lambda^{12},\lambda^{13}]+[\lambda^{12},\lambda^{23}]+[\lambda^{13},\lambda^{23}],$$

where

$$[\lambda^{12},\lambda^{13}]:=[\varphi(u,v)\partial_u\varphi(u,w)-\varphi(u,w)\partial_u\varphi(u,v)]\frac{d}{du}\wedge\frac{d}{dv}\wedge\frac{d}{dw},$$

$$[\lambda^{12},\lambda^{23}]:=[\varphi(u,v)\partial_v\varphi(v,w)-\varphi(v,w)\partial_v\varphi(u,v)]\frac{d}{du}\wedge\frac{d}{dv}\wedge\frac{d}{dw},$$

$$[\lambda^{13},\lambda^{23}]:=[\varphi(u,w)\partial_w\varphi(v,w)-\varphi(v,w)\partial_w\varphi(u,w)]\frac{d}{du}\wedge\frac{d}{dv}\wedge\frac{d}{dw}.$$

Therefore, we have

$$\langle\lambda,\lambda\rangle=\{\varphi(u,v)[\partial_u\varphi(u,w)+\partial_v\varphi(v,w)]+\text{cyclic}(u,v,w)\}\frac{d}{du}\wedge\frac{d}{dv}\wedge\frac{d}{dw}.$$

Then α satisfies the co-Jacobi identity, that is, α defines a Lie-bialgebra structure on $\mathcal{G}$, if and only if $\langle\lambda,\lambda\rangle$ is $\mathcal{G}_\infty$-invariant with respect to the adjoint action of $\mathcal{G}_\infty$ on itself.[1] Let $f(u)(d/du)\in\mathcal{G}_\infty$ be an arbitrary element, where $f(u)\in\mathbb{C}[[u]]$ is a formal power series. Then ad$\mathcal{G}_\infty$-invariance implies that $f(u)\frac{d}{du}.\langle\lambda,\lambda\rangle=0$. This is equivalent to the following equation:

$$f(u)\frac{\partial\Phi}{\partial u}+f(v)\frac{\partial\Phi}{\partial v}+f(w)\frac{\partial\Phi}{\partial w}=(f'(u)+f'(v)+f'(w))\Phi(u,v,w)\,. \tag{76}$$

Lemma VI.1: The subspace of ad$\mathcal{G}_\infty$-invariants in $\widetilde{\bigwedge}^3\mathcal{G}_\infty$ is empty.

Proof: Let $e_0=u(d/du)$. Then from (76) it follows that $e_0.\langle\lambda,\lambda\rangle=0$ is equivalent to

$$u\frac{\partial\Phi}{\partial u}+v\frac{\partial\Phi}{\partial v}+w\frac{\partial\Phi}{\partial w}=3\Phi(u,v,w). \tag{77}$$

Thus, $\Phi(u,v,w)$ is homogeneous of degree 3. But $\Phi(u,v,w)$ is antisymmetric with respect of all of its arguments. The only $\Phi(u,v,w)$ with both of the above properties is $\Phi(u,v,w)=0$. We conclude that all Lie-bialgebra structures on $\mathcal{G}_\infty$ are given by solutions of the classical Yang–Baxter equation. □

Remark VI.1: It is immediately clear that the above argument can be extended to the case of the Witt algebra $\mathcal{G}_{0\infty}$ with basis $u^{n+1}(d/du)$, where $n=-1,0,2,\ldots$, and the double-sided Witt algebra with basis $u^{n+1}(d/du)$, $n\in\mathbb{Z}$. Therefore, all bialgebra structures for these algebras are also obtained as solutions of the Classical Yang–Baxter equation.

Now, we turn our attention to the Poisson brackets on the group, written in local coordinates, by writing $\Omega(u,v;x)$ in components. In order to do this we shall need the formula

$$x(u)^n=\sum_{s_1=1}^{\infty}x_{s_1}u^{s_1}\ldots\sum_{s_n=1}^{\infty}x_{s_n}u^{s_n}=\sum_{s_1=1}^{\infty}\ldots\sum_{s_n=1}^{\infty}x_{s_1}\ldots x_{s_n}u^{s_1+\cdots+s_n}$$
$$=\sum_{i=n}^{\infty}\left(\sum_{(\Sigma_{k=1}^{n}s_k)=i}x_{s_1}\ldots x_{s_n}\right)u^i.$$

Then we have

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)-\varphi(x(u),x(v))$$
$$=\sum_{p,q=1}^{\infty}\lambda_{pq}u^pv^q\sum_{i=1}^{\infty}ix_iu^{i-1}\sum_{j=1}^{\infty}jx_jv^{j-1}$$
$$-\sum_{p,q=1}^{\infty}\lambda_{pq}\sum_{i=p}^{\infty}\left(\sum_{(\Sigma_{k=1}^{p}r_k)=i}x_{r_1}\ldots x_{r_p}\right)u^i\sum_{j=q}^{\infty}\left(\sum_{(\Sigma_{l=1}^{q}s_l)=j}x_{s_1}\ldots x_{s_q}\right)v^j$$
$$=\sum_{p,q=1}^{\infty}\sum_{i=p}^{\infty}\sum_{j=q}^{\infty}\Bigg(\lambda_{i-p+1,j-q+1}px_pqx_q$$
$$-\lambda_{pq}\sum_{(\Sigma_{k=1}^{p}r_k)=i}x_{r_1}\ldots x_{r_p}\sum_{(\Sigma_{l=1}^{q}s_l)=j}x_{s_1}\ldots x_{s_q}\Bigg)u^iv^j$$
$$=\sum_{i,j=1}^{\infty}\Bigg[\sum_{p=1}^{i}\sum_{q=1}^{j}\Bigg(\lambda_{i-p+1,j-q+1}px_pqx_q$$

$$-\lambda_{pq}\sum_{(\Sigma_{k=1}^{p} r_k)=i} x_{r_1}\ldots x_{r_p}\sum_{(\Sigma_{l=1}^{q} s_l)=j} x_{s_1}\ldots x_{s_q}\Bigg)\Bigg] u^i v^j.$$

Therefore for $\{x_i, x_j\}=\omega_{ij}(x)$ we obtain

$$\omega_{ij}(x)=\sum_{p=1}^{i}\sum_{q=1}^{j} p x_p q x_q \lambda_{i-p+1,j-q+1} - \sum_{p=1}^{i}\sum_{q=1}^{j}\lambda_{pq}\left(\sum_{(\Sigma_{k=1}^{p} r_k)=i} x_{r_1}\ldots x_{r_p}\sum_{(\Sigma_{l=1}^{q} s_l)=j} x_{s_1}\ldots x_{s_q}\right). \tag{78}$$

Before we continue further, let us deduce the following useful formulas:

$$\frac{\partial}{\partial x_n}\sum_{(\Sigma_{k=1}^{p} r_k)=i} x_{r_1}\ldots x_{r_p}=\sum_{(\Sigma_{k=1}^{p} r_k)=i}\left(\sum_{l=1}^{p} x_{r_1}\ldots\delta_{r_l}^{n}\ldots x_{r_p}\right) =\sum_{l=1}^{p}\left(\sum_{(\Sigma_{k=1}^{p} r_k)=i} x_{r_1}\ldots\delta_{r_l}^{n}\ldots x_{r_p}\right) =p\sum_{(\Sigma_{k=1}^{p-1} r_k)=i-n} x_{r_1}\ldots x_{r_{p-1}},$$

as well as

$$\sum_{(\Sigma_{k=1}^{p-1} r_k)=i-n} x_{r_1}\ldots x_{r_{p-1}}\big|_e=\sum_{(\Sigma_{k=1}^{p-1} r_k)=i-n}\delta_{r_1}^{1}\ldots\delta_{r_{p-1}}^{1}=\delta_{i-n}^{p-1},$$

$$\left(\frac{\partial}{\partial x_n}\sum_{(\Sigma_{k=1}^{p} r_k)=i} x_{r_1}\ldots x_{r_p}\right)\Bigg|_e=p\,\delta_{i-n}^{p-1}. \tag{79}$$

Differentiating (78) with respect to x_n we obtain

$$\frac{\partial\omega_{ij}}{\partial x_n}\bigg|_x=\sum_{p=1}^{i}\sum_{q=1}^{j}(p\,\delta_p^n q x_q\lambda_{i-p+1,j-q+1}+p x_p\delta_q^n q\lambda_{i-p+1,j-q+1}) -\sum_{p=1}^{i}\sum_{q=1}^{j}\left[p\sum_{(\Sigma_{k=1}^{p-1} r_k)=i-n} x_{r_1}\ldots x_{r_{p-1}}\sum_{(\Sigma_{l=1}^{q} s_l)=j} x_{s_1}\ldots x_{s_q}\right]\lambda_{pq} -\sum_{p=1}^{i}\sum_{q=1}^{j}\left[q\sum_{(\Sigma_{k=1}^{p} r_k)=i} x_{r_1}\ldots x_{r_p}\sum_{(\Sigma_{l=1}^{q-1} s_k)=j-n} x_{s_1}\ldots x_{s_{q-1}}\right]\lambda_{pq}.$$

From the above formula we have (keeping in mind that $x_p|_e=\delta_p^1$)

$$\beta_{ij}^{n}:=\frac{\partial\omega_{ij}}{\partial x_n}\bigg|_e=\sum_{p=1}^{i} p\,\delta_p^n\lambda_{i-p+1,j}+\sum_{q=1}^{j} q\,\delta_q^n\lambda_{i,j-q+1}-\sum_{p=1}^{i}\sum_{q=1}^{j}\lambda_{pq}[p\,\delta_{i-n+1}^{p}\delta_j^q+q\,\delta_i^p\delta_{j-n+1}^{q}] =(2n-i-1)\lambda_{i-n+1,j}+(2n-j-1)\lambda_{i,j-n+1}. \tag{80}$$

Using this correspondence we can now prove the following theorem.

Theorem VI.1: *There is a one-to-one correspondence between the coboundary Lie-bialgebra structures on $\mathcal{G}_\infty$ given by λ and the Poisson–Lie structures of the type (75) on G_∞. Since all Lie bialgebra structures on $\mathcal{G}_\infty$ are given by λ (cf. Theorem V.1), Theorem IV.3 gives a classification of all solutions of the classical Yang–Baxter equation for $\mathcal{G}_\infty$.*

Proof: Recall that ω_{mn} satisfy the infinite system of functional equations (13):

$$\omega_{mn}(z)=\omega_{kl}(x)\frac{\partial z_m}{\partial x_k}\frac{\partial z_n}{\partial x_l}+\omega_{kl}(y)\frac{\partial z_m}{\partial y_k}\frac{\partial z_n}{\partial y_l}, \quad \text{where } x,y\in G_\infty, \tag{81}$$

and $z_n=z_n(x,y)$ is given by

$$z_n=\sum_{i=1}^{n} x_i \sum_{(\Sigma_{\alpha=1}^{i} j_\alpha)=n} y_{j_1}\dots y_{j_i}. \tag{82}$$

From (82) it follows that

$$\left.\frac{\partial z_i}{\partial y_k}\right|_{y=e}=(i-k+1)x_{i-k+1} \quad \text{and} \quad \left.\frac{\partial z_i}{\partial x_k}\right|_{y=e}=\delta_i^k.$$

Let us fix $n\in\mathbb{N}$ and consider a subsystem of the system of equations (81) for all ω_{ij} with $1\leqslant i<j\leqslant n$. After differentiating (81) with respect to y_j, for each j such that $1\leqslant j\leqslant n$, and setting $y=e$ we deduce that ω_{mn} satisfy the following inhomogeneous system of linear partial differential equations:

$$\sum_{i=j}^{n}(i+1-j)x_{i+1-j}\frac{\partial\omega_{mn}}{\partial x_i}=\omega_{m+1-j,n}(x)(m+1-j)+\omega_{m,n+1-j}(x)(n+1-j)$$
$$+\sum_{k=1}^{m}\sum_{l=1}^{n}\beta_{kl}^{j}(m+1-k)(n+1-l)x_{m+1-k}x_{n+1-l}, \tag{83}$$

for $1\leqslant j\leqslant n$, and where $\beta_{kl}^{j}=\partial\omega_{kl}/\partial y_j|_{y=e}$.

The method of proof is as follows. Let β_{kl}^{j} be given by (80). For each $n\in\mathbb{N}$ the general solution of (83) is a linear combination of the general solution of the homogeneous system of equations,

$$\sum_{i=j}^{n}(i+1-j)x_{i+1-j}\frac{\partial\omega_{mn}}{\partial x_i}=\omega_{m+1-j,n}(x)(m+1-j)+\omega_{m,n+1-j}(x)(n+1-j), \tag{84}$$

and a particular solution of the inhomogeneous system (83). We now show that for each $n\in\mathbb{N}$ and $1\leqslant m<n$ the system (83) has a unique solution by demonstrating that the only solution of the homogeneous system is the zero solution. Therefore, since every solution of the system of functional equations (81) is a solution of the system of partial differential equations (83) it follows that the class of solutions of (81) found in Sec. IV exhausts all its possible solutions. We shall prove this by induction applied in several steps. Recall that

$$\omega_{mn}(e)=0, \quad \text{for every } n,m\in\mathbb{N}, \tag{85}$$

and that $\omega_{mn}=0$ whenever $n<1$ or $m<1$.

(i) For $n=1$ there is nothing to prove. Let $n=2$. Then from (84) we obtain

$$x_1\frac{\partial\omega_{12}}{\partial x_1}=3\omega_{12}. \tag{86}$$

The general solution of this equation is $\omega_{12}(x)=Cx_1^3$, where C is an arbitrary constant. From (85) it follows that $C=0$. Therefore $\omega_{12}(x)=0$ is the only solution of (86). Let $n=3$. Then from (84) we obtain

$$x_1\frac{\partial\omega_{13}}{\partial x_1}+2x_2\frac{\partial\omega_{13}}{\partial x_2}=4\omega_{13},\qquad x_1\frac{\partial\omega_{13}}{\partial x_2}=0. \tag{87}$$

From (87) it follows that $\omega_{13}(x)=\omega_{13}(x_1)$. We deduce that $\omega_{13}(x)=Cx_1^5$, and from (85) it follows that $C=0$, and thus $\omega_{13}(x)=0$. Let us assume now that $\omega_{1k}(x)=0$ for $2\leqslant k\leqslant n-1$. From (84) we have

$$\sum_{i=j}^{n}(i+1-j)x_{i+1-j}\frac{\partial\omega_{1n}}{\partial x_i}=\omega_{2-j,n}(x)(2-j)+\omega_{1,n+1-j}(x)(n+1-j),\quad \text{for}\ \ 1\leqslant j\leqslant n,$$

which implies

$$\sum_{i=1}^{n}ix_i\frac{\partial\omega_{1n}}{\partial x_i}=(n+1)\omega_{1n}(x), \tag{88}$$

$$\sum_{i=j}^{n}(i+1-j)x_{i+1-j}\frac{\partial\omega_{1n}}{\partial x_i}=0,\quad \text{for}\ \ 2\leqslant j\leqslant n, \tag{89}$$

after using the induction hypothesis: $\omega_{1k}(x)=0$ for $2\leqslant k\leqslant n-1$. Then from (88) follows that $\omega_{1n}(x_1)$ satisfies

$$x_1\frac{\partial\omega_{1n}}{\partial x_1}=(n+1)\omega_{1n}. \tag{90}$$

From (90) we have that $\omega_{1n}(x)=Cx_1^{n+1}$ for an arbitrary constant C. Applying again (85) we conclude that $\omega_{1n}(x)=0$. Therefore $\omega_{1n}(x)=0$ for every $n\in\mathbb{N}$.

(ii) Let $m=2$ and $n=3$. Then from (84) we have the following homogeneous system of partial differential equations for ω_{23}:

$$x_1\frac{\partial\omega_{23}}{\partial x_1}+2x_2\frac{\partial\omega_{23}}{\partial x_2}+3x_3\frac{\partial\omega_{23}}{\partial x_3}=5\omega_{23},$$

$$x_1\frac{\partial\omega_{23}}{\partial x_2}+2x_2\frac{\partial\omega_{23}}{\partial x_3}=\omega_{13}=0,$$

$$x_1\frac{\partial\omega_{23}}{\partial x_3}=-\omega_{12}=0.$$

Arguing in a similar manner as above we obtain that $\omega_{23}(x)=0$. Let us assume that $\omega_{2k}(x)=0$ for all k such that $3\leqslant k\leqslant n-1$. We now prove that $\omega_{2n}(x)=0$. From (84) we have

$$\sum_{i=j}^{n}(i+1-j)x_{i+1-j}\frac{\partial\omega_{2n}}{\partial x_i}=\omega_{3-j,n}(x)(3-j)+\omega_{2,n+1-j}(x)(n+1-j),\quad \text{for}\ \ 1\leqslant j\leqslant n. \tag{91}$$

After using the induction hypothesis and the already proved fact that $\omega_{1n}=0$, for every $n\in\mathbb{N}$, (91) yields

$$\sum_{i=1}^{n} i x_i \frac{\partial \omega_{2n}}{\partial x_i} = (n+2)\,\omega_{2n}(x), \tag{92}$$

$$\sum_{i=j}^{n} (i+1-j) x_{i+1-j} \frac{\partial \omega_{2n}}{\partial x_i} = 0, \quad \text{for } 2 \leqslant j \leqslant n. \tag{93}$$

Therefore from (93) and (92) it follows that $\omega_{2n}(x) = \omega_{2n}(x_1) = C x_1^{n+2}$, and imposing (85) again we obtain that $\omega_{2n}(x_1) = 0$. Thus $\omega_{2n}(x) = 0$ for every $n \in \mathbb{N}$.

(iii) Assume now that $\omega_{sn} = 0$ for all s such that $1 \leqslant s \leqslant m-1$, for some $m \geqslant 2$ and all $n > s$. We will prove that $\omega_{mn} = 0$ for all $n \geqslant m$. Let $n = m+1$. From (84) we have

$$\sum_{i=j}^{m+1} (i+1-j) x_{i+1-j} \frac{\partial \omega_{m,m+1}}{\partial x_i} = \omega_{m+1-j,n}(x)(m+1-j) + \omega_{m,m+2-j}(x)(m+2-j),$$
$$\text{for } 1 \leqslant j \leqslant m+1. \tag{94}$$

We apply now the induction hypothesis and deduce from (94) the following system of equations:

$$\sum_{i=1}^{m+1} i x_i \frac{\partial \omega_{m,m+1}}{\partial x_i} = (2m+1)\,\omega_{m,m+1}(x), \tag{95}$$

$$\sum_{i=j}^{m+1} (i+1-j) x_{i+1-j} \frac{\partial \omega_{m,m+1}}{\partial x_i} = 0, \quad \text{for } 2 \leqslant j \leqslant m+1. \tag{96}$$

From (96) it follows that $\omega_{m,m+1}(x) = \omega_{m,m+1}(x_1)$, and from (95) we deduce that $\omega_{m,m+1}(x)$ must satisfy

$$x_1 \frac{\partial \omega_{m,m+1}}{\partial x_1} = (2m+1)\,\omega_{m,m+1}.$$

The solution of the above equation is $\omega_{m,m+1}(x) = C x_1^{2m+1}$, where C is an arbitrary constant. Then from $\omega_{m,m+1}(e) = C = 0$ we obtain that $\omega_{m,m+1}(x) = 0$. Finally, we assume that $\omega_{mk} = 0$ for all k such that $m+1 \leqslant k \leqslant n-1$, and we prove it for $k = n$. Indeed, from (84), after applying the induction hypothesis, we obtain

$$\sum_{i=1}^{n} i x_i \frac{\partial \omega_{mn}}{\partial x_i} = (m+n)\,\omega_{mn}(x), \tag{97}$$

$$\sum_{i=j}^{n} (i+1-j) x_{i+1-j} \frac{\partial \omega_{mn}}{\partial x_i} = 0, \quad \text{for } 2 \leqslant j \leqslant n. \tag{98}$$

Again, from (98) it follows that $\omega_{mn}(x) = \omega_{mn}(x_1)$, and that $\omega_{mn}(x)$ must satisfy

$$x_1 \frac{\partial \omega_{mn}}{\partial x_1} = (m+n)\,\omega_{mn}.$$

From here we conclude that $\omega_{mn}(x) = C x_1^{m+n}$ for an arbitrary constant C. But the requirement $\omega_{mn}(e) = 0$ fixes the value of this constant to be $C = 0$. Therefore $\omega_{mn}(x) = 0$.

Thus, we showed that for every $m, n \in \mathbb{N}$ the only solution of (84) is the zero solution. Therefore the system of partial differential equations (83) has a unique solution. The existence of the solution follows from the existence of the solution of the system of functional equations (81) of which (83) is a consequence. Thus, the structure constants β_{kl}^{j} of the Lie-bialgebra $\mathcal{G}_\infty$, as given by (80), determine uniquely all Poisson–Lie structures on the group G_∞. The proof of Theorem VI.1 is completed. □

We conclude this section by writing an explicit formula for the family of Lie-bialgebra structures arising from the family of Poisson–Lie structures obtained in Theorem IV.3, as well as the more general one-parameter family, obtained from it by an action of a formal diffeomorphism group element, for $d \geqslant 1$. An elegant way to do this is by deriving a formula for the Lie-bialgebra structures on $\mathcal{G}_\infty$ in terms of generating series and solutions of

$$\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]+\text{cyclic}(u,v,w)=0.$$

Let us define $\mathcal{A}_n(u,v)$ as

$$\mathcal{A}_n(u,v) := \frac{\partial}{\partial x_n}\Omega(u,v;\mathcal{X})\bigg|_e = \sum_{i,j=1}^{\infty} \alpha_{ij}^n u^i v^j.$$

Then we have the following lemma.

Lemma IV.2: The generating series $\mathcal{A}_n(u,v)$ is given by

$$\mathcal{A}_n(u,v)=n\varphi(u,v)(u^{n-1}+v^{n-1})-[u^n\partial_u\varphi(u,v)+v^n\partial_v\varphi(u,v)].$$

Proof: We use formula (75) and the following facts. If $x(u)=\Sigma_{i=1}^{\infty}x_iu^i$ then $\mathcal{X}'(u)|_x=\Sigma_{i=1}^{\infty}ix_iu^{i-1}\Rightarrow\mathcal{X}'(u)|_e=1$, and also $(\partial/\partial x_n)\mathcal{X}'(u)|_x=\Sigma_{i=1}^{\infty}i\,\delta_i^n u^{i-1}=nu^{n-1}$. From this it follows that

$$\frac{\partial}{\partial x_n}[\mathcal{X}'(u)\mathcal{X}'(v)]|_x=nu^{n-1}x'(v)+nv^{n-1}x'(u)\Rightarrow\frac{\partial}{\partial x_n}[\mathcal{X}'(u)\mathcal{X}'(v)]|_e=n(u^{n-1}+v^{n-1}).$$

Finally we have

$$\begin{aligned}\frac{\partial}{\partial x_n}\varphi(\mathcal{X}(u),\mathcal{X}(v))\bigg|_e &= \frac{\partial\mathcal{X}(u)}{\partial x_n}\partial_1\varphi(\mathcal{X}(u),\mathcal{X}(v))\bigg|_e+\frac{\partial\mathcal{X}(v)}{\partial x_n}\partial_2\varphi(\mathcal{X}(u),\mathcal{X}(v))\bigg|_e\\ &= u^n\partial_u\varphi(u,v)+v^n\partial_v\varphi(u,v).\end{aligned}$$

In the above equality we used that $\partial\mathcal{X}(u)/\partial x_n|_e=u^n$. □

Proposition VI.1: (Michaelis,[22] Taft[23]): For each $d\in\mathbb{N}$ the family of Poisson–Lie structures (75) given by $\varphi_d(u,v)=uv(v^d-u^d)$ gives rise to the following family of Lie-bialgebra structures on $\mathcal{G}_\infty$:

$$\alpha(e_n)=2ne_d\wedge e_n-2(n-d)e_0\wedge e_{d+n}\quad(n\geqslant 0),$$

where $\{e_n=u^{n+1}(d/du)\}_{n\in\mathbb{Z}_+}$ is a canonical basis for $\mathcal{G}_\infty$.

Proof: The generating series $\mathcal{A}_{n,d}$ in this case is

$$\begin{aligned}\mathcal{A}_{n,d}(u,v)&=n[uv^{d+1}-vu^{d+1}](u^{n-1}+v^{n-1})-\{u^n[v^{d+1}-(d+1)vu^d]+v^n[(d+1)uv^d-u^{d+1}]\}\\ &=(n-1)u^nv^{d+1}-(n-1)v^nu^{d+1}+(n-d-1)uv^{n+d}-(n-d-1)vu^{n+d}\\ &=\{(n-1)[\delta_i^n\delta_j^{d+1}-\delta_j^n\delta_i^{d+1}]+(n-d-1)[\delta_i^1\delta_j^{d+n}-\delta_j^1\delta_i^{d+n}]\}u^iv^j\\ &=\sum_{i,j=1}^{\infty}\alpha_{ij|d}^n u^iv^j,\end{aligned}$$

where

$$\alpha^n_{ij|d}=\{(n-1)[\delta^n_i\delta^{d+1}_j-\delta^n_j\delta^{d+1}_i]+(n-d-1)[\delta^1_i\delta^{d+n}_j-\delta^1_j\delta^{d+n}_i]\}.$$

Therefore

$$\begin{aligned}\alpha_d(e_n)=\alpha^n_{ij|d}e_i\wedge e_j&=(n-1)[e_n\wedge e_{d+1}-e_{d+1}\wedge e_n]+(n-d-1)[e_1\wedge e_{d+n}-e_{d+n}\wedge e_1]\\&=2(n-1)e_n\wedge e_{d+1}+2(n-d-1)e_1\wedge e_{n+d},\end{aligned}$$

and after shifting indices by 1 we obtain

$$\alpha_d(e_n)=-2ne_d\wedge e_n+2(n-d)e_0\wedge e_{n+d},\quad \text{for every}\quad n\in\mathbb{Z}_+.$$

This concludes the proof. □

Proposition VI.2: For every $d\geqslant 2$ the family of Poisson–Lie structures described by (49) gives rise to the following family of Lie-bialgebra structures on $\mathcal{G}_\infty$:

$$\begin{aligned}\alpha_{d,\lambda}(e_n)=&\,2\sum_{i=d+n}^{\infty}(2n-i)\lambda^{i-(n+d)}e_0\wedge e_i-2n\sum_{i=d}^{\infty}\lambda^{i-d}e_i\wedge e_n\\&+\frac{2}{d-1}\sum_{i=d+n}^{\infty}\sum_{j=1}^{d-1}(2n-i)\lambda^{i+j-(n+d)}e_i\wedge e_j\\&+\frac{2}{d-1}\sum_{i=d}^{\infty}\sum_{j=n+1}^{d+n-1}(2n-j)\lambda^{i+j-(n+d)}e_i\wedge e_j,\end{aligned}\tag{99}$$

for every $n\in\mathbb{Z}_+$.

Proof: Let $\alpha_{d,\lambda}(e_n)=\alpha^n_{ij|d}e_i\wedge e_j$, where $\{e_n\}_{n\geqslant 1}$ is a basis of $\mathcal{G}_\infty$, and

$$\alpha^n_{ij|d}=(2n-i-1)\lambda_{i-n+1,j}+(2n-j-1)\lambda_{i,j-n+1},\quad \text{for every}\ \ n,i,j\in\mathbb{N}.$$

With the assumptions of Lemma IV.3 and Theorem VI.5 we have

$$\lambda_{ij}=\frac{1}{\lambda_{1,d+1}}[\lambda_{1i}\lambda_{d+1,j}-\lambda_{1j}\lambda_{d+1,i}],$$

where

$$\begin{aligned}&\lambda_{n,d+1}=0,\quad \text{for every}\ \ n\geqslant d+1,\\&\lambda_{n,d+1}=-\frac{1}{d-1}\frac{(\lambda_{1,d+2})^{n-1}}{(\lambda_{1,d+1})^{n-2}}=-\frac{1}{d-1}\lambda_{1,d+1}\lambda^{n-1},\ \ \text{for}\ \ 2\leqslant n\leqslant d,\\&\lambda_{1n}=\frac{(\lambda_{1,d+2})^{n-d-1}}{(\lambda_{1,d+1})^{n-d-2}}=\lambda_{1,d+1}\lambda^{n-d-1},\quad \text{for every}\ \ n\geqslant d+1,\end{aligned}\tag{100}$$

and where we have introduced $\lambda:=\lambda_{1,d+2}/\lambda_{1,d+1}$. Then

$$\begin{aligned}\alpha_{d,\lambda}(e_n)&=[(2n-i-1)\lambda_{i-n+1,j}+(2n-j-1)\lambda_{i,j-n+1}]e_i\wedge e_j\\&=\frac{1}{\lambda_{1,d+1}}\{(2n-i-1)[\lambda_{1,i-n+1}\lambda_{d+1,j}-\lambda_{1j}\lambda_{d+1,i-n+1}]\\&\quad+(2n-j-1)[\lambda_{1i}\lambda_{d+1,j-n+1}-\lambda_{1,j-n+1}\lambda_{d+1,i}]\}e_i\wedge e_j\end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{\lambda_{1,d+1}} \left\{ \sum_{i=d+n}^{\infty} \sum_{j=1}^{d} (2n-i-1)\lambda_{1,i-n+1}\lambda_{d+1,j} e_i \wedge e_j \right. \\
&\quad - \sum_{i=n}^{d+n-1} \sum_{j=d+1}^{\infty} (2n-i-1)\lambda_{1j}\lambda_{d+1,i-n+1} e_i \wedge e_j \\
&\quad + \sum_{i=d+1}^{\infty} \sum_{j=n}^{d+n-1} (2n-j-1)\lambda_{1i}\lambda_{d+1,j-n+1} e_i \wedge e_j \\
&\quad \left. - \sum_{i=1}^{d} \sum_{j=d+n}^{\infty} (2n-j-1)\lambda_{1,j-n+1}\lambda_{d+1,i} e_i \wedge e_j \right\} \\
&= \frac{1}{\lambda_{1,d+1}} \left\{ \sum_{i=d+n}^{\infty} \sum_{j=2}^{d} (2n-i-1)\lambda_{1,i-n+1}\lambda_{d+1,j} e_i \wedge e_j \right. \\
&\quad + \lambda_{d+1,1} \sum_{i=d+n}^{\infty} (2n-i-1)\lambda_{1,i-n+1} e_i \wedge e_1 \\
&\quad - \sum_{i=n+1}^{d+n-1} \sum_{j=d+1}^{\infty} (2n-i-1)\lambda_{1j}\lambda_{d+1,i-n+1} e_i \wedge e_j \\
&\quad - \lambda_{d+1,1} \sum_{j=d+1}^{\infty} (n-1)\lambda_{1j} e_n \wedge e_j + \sum_{i=d+1}^{\infty} \sum_{j=n+1}^{d+n-1} (2n-j-1)\lambda_{1i}\lambda_{d+1,j-n+1} e_i \wedge e_j \\
&\quad + \lambda_{d+1,1} \sum_{i=d+1}^{\infty} (n-1)\lambda_{1i} e_i \wedge e_n - \sum_{i=2}^{d} \sum_{j=d+n}^{\infty} (2n-j-1)\lambda_{1,j-n+1}\lambda_{d+1,i} e_i \wedge e_j \\
&\quad \left. - \lambda_{d+1,1} \sum_{j=d+n}^{\infty} (2n-j-1)\lambda_{1,j-n+1} e_1 \wedge e_j \right\} \\
&= \frac{1}{\lambda_{1,d+1}} \left\{ 2 \sum_{i=d+n}^{\infty} \sum_{j=2}^{d} (2n-i-1)\lambda_{1,i-n+1}\lambda_{d+1,j} e_i \wedge e_j \right. \\
&\quad + 2 \sum_{i=d+1}^{\infty} \sum_{j=n+1}^{d+n-1} (2n-j-1)\lambda_{1i}\lambda_{d+1,j-n+1} e_i \wedge e_j \\
&\quad \left. + 2\lambda_{1,d+1} \sum_{i=d+n}^{\infty} (2n-i-1)\lambda_{1,i-n+1} e_1 \wedge e_i - 2\lambda_{1,d+1} \sum_{i=d+1}^{\infty} (n-1)\lambda_{1i} e_i \wedge e_n \right\} \\
&= \lambda_{1,d+1} \left\{ \frac{2}{d-1} \sum_{i=d+n}^{\infty} \sum_{j=2}^{d} (2n-i-1)\lambda^{i+j-(n+d+1)} e_i \wedge e_j \right. \\
&\quad + \frac{2}{d-1} \sum_{i=d+1}^{\infty} \sum_{j=n+1}^{d+n-1} (2n-j-1)\lambda^{i+j-(n+d+1)} e_i \wedge e_j \\
&\quad \left. + 2 \sum_{i=d+n}^{\infty} (2n-i-1)\lambda^{i-(n+d)} e_1 \wedge e_i - 2 \sum_{i=d+1}^{\infty} (n-1)\lambda^{i-(d+1)} e_i \wedge e_n \right\},
\end{aligned}
$$

where we used formulas (100) to obtain the last equality. Hence, after normalizing by the quotient $\lambda_{1,d+1} \neq 0$ and shifting indices by 1 we obtain (99). □

Remark VI.2: One can show directly that $\alpha_{d,\lambda}$ satisfies the co-Jacobi identity. The r.h.s. of (99) is an element of the completed tensor product $\mathcal{G}_\infty \hat{\otimes} \mathcal{G}_\infty$.[24]

VII. THE GROUP $G_{0\infty}$ AND POISSON–LIE STRUCTURES ON IT

In this section we study the group $G_{0\infty}$ of which G_∞ is a subgroup. We classify all Poisson–Lie structures on $G_{0\infty}$.

Let $X=\{x_i\}_{i\in\mathbb{Z}_+}$ be a countable set of indeterminates. Let $k[[X]]$ be the ring of formal power series over X without a constant term with the standard multiplication. Here k is a commutative field assumed to be of characteristic zero. Let $Y=\{y_i\}_{i\in\mathbb{Z}_+}$ be a second set of indeterminates, and $k[[Y]]$ be the corresponding ring of formal power series over Y. Consider the formal group $G_{0\infty}$ defined by a formal group law $F=(F_i)_{i\in\mathbb{Z}_+}$[25,24] in a countably infinite number of variables, where $F_i\in k[[X,Y]]$ for every $i\in\mathbb{Z}_+$, induced by a substitution of formal power series in one variable. Let $x(u)=\Sigma_{i=0}^{\infty}x_iu^i\in k[[X]][[u]]$ and $y(u)=\Sigma_{i=0}^{\infty}y_iu^i\in k[[Y]][[u]]$ be elements in the rings of formal power series with a constant term in the variable u over the rings $k[[X]]$ and $k[[Y]]$, respectively. The multiplication of formal power series in the variable u is defined again as the substitution:

$$\begin{aligned}(xy)(u)=x(y(u))=\sum_{i=0}^{\infty} x_i(y(u))^i&=\sum_{i=0}^{\infty} x_i\left[y_0^i+\sum_{j=1}^{\infty}\left(\sum_{(\Sigma_{\alpha=1}^{i}s_\alpha)=j} y_{s_1}\dots y_{s_i}\right)u^j\right]\\ &=\sum_{i=0}^{\infty} x_iy_0^i+\sum_{i=1}^{\infty} x_i\sum_{j=1}^{\infty}\left(\sum_{(\Sigma_{\alpha=1}^{i}s_\alpha)=j} y_{s_1}\dots y_{s_i}\right)u^j\\ &=\sum_{i=0}^{\infty} x_iy_0^i+\sum_{j=1}^{\infty}\left(\sum_{i=1}^{\infty} x_i\sum_{(\Sigma_{\alpha=1}^{i}s_\alpha)=j} y_{s_1}\dots y_{s_i}\right)u^j. \quad (101)\end{aligned}$$

Therefore from (101) we obtain

$$F_0(X,Y)=\sum_{i=0}^{\infty} x_iy_0^i, \quad (102)$$

$$F_j(X,Y)=\sum_{i=1}^{\infty} x_i\sum_{(\Sigma_{\alpha=1}^{i}s_\alpha)=j} y_{s_1}\dots y_{s_i},\quad \text{for every } j\geq 1. \quad (103)$$

This is a model of the group of diffeomorphisms of $\mathbb{R}^1$ not necessarily leaving the point $u=0$ fixed. The identity here is $e=(0,1,0,0,\dots)$. Formulas (102) and (103) have the following interpretation. The ring $k[[X]]$ is naturally graded. Namely, let us introduce a degree $|\,|:X\rightarrow\mathbb{Z}_+$ defined on the generators by $|x_i|:=i$. We extend it to monomials as $|x_{i_1}\dots x_{i_n}|=i_1+\dots+i_n$. The grading on $k[[X]]$ and $k[[Y]]$ induces a grading on $k[[X,Y]]$ in an obvious way. Then $F_i(X,Y)=\Sigma_n f_n(X,Y)$, where each $f_n(X,Y)$ is a finite linear combination of monomials of degree n. Clearly G_∞, if viewed as a formal group, is a subgroup of $G_{0\infty}$. We define a Poisson structure $\omega_x=\omega_{ij}(x)\partial/\partial x_i\wedge\partial/\partial x_j$ on the group $G_{0\infty}$ as a bi-derivation $\omega_x:k[[X]]\otimes k[[X]]\rightarrow k[[X]]$, where $\omega_{ij}(x)=-\omega_{ji}(x)\in k[[X]]$, satisfying the Jacobi identity. The methods developed in analyzing the Poisson–Lie structures on G_∞ apply without major changes to the case of $G_{0\infty}$, but with two important differences. Namely, Theorem IV.1 still holds with $\Omega(u,v;\mathcal{X})$ defined as $\Omega(u,v;\mathcal{X}):=\Sigma_{i,j=0}^{\infty}\omega_{ij}u^iv^j$, but in the solution of the cocycle equation,

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)-\varphi(x(u),x(v)), \quad (104)$$

$\varphi(u,v)$ does not have to be divisible by uv. Thus, this condition is dropped. This change affects the analysis of the space of solutions of the equation

$$\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]+\text{cyclic}(u,v,w)=0. \tag{105}$$

Namely, the general solution of (105) is given by

$$\varphi(u,v)=\frac{F(v)-F(u)}{F'(u)F'(v)}, \tag{106}$$

where

$$F(u)=\sum_{n=-d}^{\infty} C_n u^n = C_{-d}\frac{1}{u^d}+C_{-d+1}\frac{1}{u^{d-1}}+\cdots,$$

is a formal Laurent series and $d>0$ or $d<0$. Since on the other hand $F'(u)=1/f(u)$, where $f(u)\in\mathbb{R}[[u]]$ is a formal power series, the only negative value of d can be $d=-1$.

We found that the solution (104) corresponds to a cocycle $\mathcal{G}_{0\infty}\to\mathcal{G}_{0\infty}\hat{\wedge}\mathcal{G}_{0\infty}$ that is a coboundary. We showed that all cocycles on $\mathcal{G}_{0\infty}$ are coboundaries. This allows us to complete their classification.

Theorem VII.1: *The moduli space of solutions of (105) is parametrized by $\mathbb{N}\cup\{-1\}$, that is, the space of isomorphism classes of solutions of (105) under the action of the formal group of diffeomorphisms of the line is isomorphic to the countable set $\mathbb{N}\cup\{-1\}$.*

For $d=-1$ formula (42) yields $\varphi(u,v)=u-v$. This solution yields in coordinates the Poisson–Lie tensor,

$$\omega_{ij}(x)=i(j+1)x_i x_{j+1}-(i+1)jx_{i+1}x_j-x_i\delta_j^0+x_j\delta_i^0,\quad i,j\in\mathbb{Z}_+. \tag{107}$$

Proposition VII.1: The functions
(i) $\varphi(u,v)=u-v$, and
(ii) $\varphi(u,v)=e^{\lambda u}-e^{\lambda v}$, where λ is an arbitrary parameter,
are the only solutions of (105) of the form $\varphi(u,v)=a(u)-a(v)$.

The proof is straightforward. The Poisson–Lie tensor that corresponds to (ii) is

$$\omega_{ij}(x)=(j+1)x_{j+1}\sum_{p=0}^{i+1}\frac{px_p}{(i-p+1)!}-(i+1)x_{i+1}\sum_{q=0}^{j+1}\frac{qx_q}{(j-q+1)!}$$
$$-\delta_j^0\sum_{p=0}^{i}\frac{1}{p!}\sum_{r_1+\cdots+r_p=i}x_{r_1}\ldots x_{r_p}+\delta_i^0\sum_{q=0}^{j}\frac{1}{q!}\sum_{r_1+\cdots+r_q=j}x_{r_1}\ldots x_{r_q}.$$

We conclude this section with a useful reformulation of Theorem VII.1.[19]

Theorem VII.2: *All solutions of (105) fall into the following two classes:*
(a) The first class is given by Theorem IV.4.
(b) The second class is given by

$$\varphi(u,v)=\frac{1}{\lambda_{01}}[f(u)g(v)-f(v)g(u)], \tag{108}$$

where $\lambda_{01}\neq 0$, for any formal power series $f(u)$ and $g(u)$ satisfying the relation

$$f'(u)g(u)-f(u)g'(u)=\lambda_{01}g(u)-2\lambda_{02}f(u). \tag{109}$$

Here, λ_{01} *and* λ_{02} *are arbitrary parameters with* λ_{01} *being subject to the above restriction:* $\lambda_{01} \neq 0$.

VIII. ELEMENTS OF REPRESENTATION THEORY

Let G be a Poisson–Lie group and $\overline{\omega}$ be a Poisson–Lie structure on G. Let V be a space on which G acts, that is, there is a map $G\times V\rightarrow V$. Such a space is called a G-space. Assume that V is equipped with a Poisson structure ω. Recall the following definition.[26]

Definition VIII.1: The action of G *on* V *is called Poisson if the map* $G\times V\rightarrow V$ *is Poisson. Here* $G\times V$ *is equipped with the product Poisson structure.*

In this section we study the following problem. Suppose that we are given the Poisson–Lie group G_∞. Consider the space $V_\lambda=\{x(u)(du)^\lambda | x(u)=\Sigma_{i=0}^\infty x_i u^i\}$, $\lambda\in\mathbb{R}$. The space V_λ is the space of λ-densities (Jacobians) over the real line. The group G_∞ acts naturally on V_λ. Let $y\in G_\infty$ and $x(u)(du)^\lambda\in V_\lambda$. Then the action of G_∞ on V_λ is defined by

$$x(u)(du)^\lambda \mapsto x(y(u))(y'(u))^\lambda (du)^\lambda,$$

where $y(u)=\Sigma_{i=1}^\infty y_i u^i$, and

$$\begin{aligned}(y'(u))^\lambda &= \left(\sum_{i=1}^\infty i y_i u^{i-1}\right)^\lambda = \left(y_1+\sum_{i=2}^\infty i y_i u^{i-1}\right)^\lambda \\ &= y_1^\lambda\left(1+\sum_{i=2}^\infty i\frac{y_i}{y_1}u^{i-1}\right)^\lambda \\ &= y_1^\lambda\left[1+\frac{\lambda}{1!}\sum_{i=2}^\infty i\frac{y_i}{y_1}u^{i-1}+\frac{\lambda(\lambda-1)}{2!}\left(\sum_{i=2}^\infty i\frac{y_i}{y_1}u^{i-1}\right)^2+\ldots\right].\end{aligned}$$

Are there Poisson structures on the space V_λ such that the above action of G_∞ on V_λ is a Poisson action? In other words, is there a Poisson strucuture ω on V_λ such that the map $G_\infty\times V_\lambda\rightarrow V_\lambda$ is a Poisson map? Here again $G_\infty\times V_\lambda$ is equipped with the product Poisson structure.

Let $y(u)=\Sigma_{i=1}^\infty y_i u^i\in G_\infty$, and $x(u)(du)^\lambda\in V_\lambda$. Let us define $z_\lambda(u)\coloneqq x(y(u))[y'(u)]^\lambda=\Sigma_{i=0}^\infty z_i u^i$, where $z_i=z_i(x,y;\lambda)$ are the coordinates of z_λ. If we also introduce the notation $J(u)\coloneqq y'(u)=\Sigma_{i=1}^\infty i y_i u^{i-1}$, we have

$$\begin{aligned}x(u)(du)^\lambda \mapsto x(y(u))(y'(u))^\lambda(du)^\lambda &= x(y(u))(J(u))^\lambda(du)^\lambda \\ &= z_\lambda(u)(du)^\lambda=\sum_{i=0}^\infty x_i(y(u))^i\left(\sum_{i=1}^\infty i y_i u^{i-1}\right)^\lambda (du)^\lambda.\end{aligned}$$

Defining $z(u)\coloneqq x(y(u))$ and using the definition $z_\lambda(u)=x(y(u))[J(u)]^\lambda$ we deduce that $z_\lambda'(u)=z'(u)(J(u))^\lambda+z(u)[(J(u))^\lambda]'$, where $'$ stands for the derivative with respect to u.

An argument analogous to the argument given in Sec. I implies that the map $G_\infty\times V_\lambda\rightarrow V_\lambda$ is Poisson if and only if

$$\omega_{ij}(z)=\omega_{kl}(x)\frac{\partial z_i}{\partial x_k}\frac{\partial z_j}{\partial x_l}+\overline{\omega}_{kl}(y)\frac{\partial z_i}{\partial y_k}\frac{\partial z_j}{\partial y_l}. \tag{110}$$

Here $\omega_{ij}(x)=\{x_i,x_j\}$ and $\overline{\omega}_{ij}(y)=\{y_i,y_j\}$, where $\{x_i\}_{i\in\mathbb{Z}_+}$ and $\{y_i\}_{i\in\mathbb{Z}_+}$ are the coordinates on V_λ and G_∞, respectively. Also, let us introduce in a manner similar to the one used in Sec. IV a generating series for the Poisson strucutures on V_λ as $\Omega(u,v;\mathcal{X})\coloneqq\Sigma_{i,j=0}^\infty \omega_{ij}u^i v^j$.

Lemma VIII.1: The multiplicativity condition (110) is equivalent to the following functional equation:

$$\Omega(u,v;z_\lambda)=\Omega(y(u),y(v);x)(J(u))^\lambda(J(v))^\lambda+\overline{\Omega}(u,v;y)z'(u)(J(u))^{\lambda-1}z'(v)(J(v))^{\lambda-1}$$
$$+\lambda\ \partial_u\overline{\Omega}(u,v;y)z(u)(J(u))^{\lambda-1}z'(v)(J(v))^{\lambda-1}$$
$$+\lambda\ \partial_v\overline{\Omega}(u,v;y)z'(u)(J(u))^{\lambda-1}z(v)(J(v))^{\lambda-1}$$
$$+\lambda^2\ \partial^2_{u,v}\overline{\Omega}(u,v;y)z(u)(J(u))^{\lambda-1}z(v)(J(v))^{\lambda-1}. \tag{111}$$

Here $\overline{\Omega}$ stands for the generating series of the Poisson–Lie strucutures on G_∞.

Proof: Multiplying both sides of Eq. (110) by u^iv^j, summing over i and j, and using the definition of Ω we obtain

$$\Omega(u,v;z_\lambda)=\omega_{kl}(x)\frac{\partial z_\lambda}{\partial x_k}\frac{\partial z_\lambda}{\partial x_l}+\overline{\omega}_{kl}(y)\frac{\partial z_\lambda}{\partial y_k}\frac{\partial z_\lambda}{\partial y_l}. \tag{112}$$

On the other hand, the following formulas are valid:

$$\frac{\partial z_\lambda}{\partial x_k}=\left(\sum_{j=1}^{\infty} y_ju^j\right)^k\left(\sum_{i=1}^{\infty} iy_iu^{i-1}\right)^\lambda=[y(u)]^k[J(u)]^\lambda,$$

$$\frac{\partial z_\lambda}{\partial y_k}=\left[\sum_{i=0}^{\infty} ix_i\left(\sum_{j=1}^{\infty} y_ju^j\right)^{i-1}u^k\right]\left(\sum_{i=1}^{\infty} iy_iu^{i-1}\right)^\lambda$$
$$+\left[\sum_{i=0}^{\infty} x_i\left(\sum_{j=1}^{\infty} y_ju^j\right)^{i}\right]\lambda\left(\sum_{i=1}^{\infty} iy_iu^{i-1}\right)^{\lambda-1}ku^{k-1}$$
$$=x'(y(u))(J(u))^\lambda u^k+\lambda x(y(u))[J(u)]^{\lambda-1}ku^{k-1}$$
$$=z'(u)[J(u)]^{\lambda-1}u^k+\lambda z_\lambda(u)[J(u)]^{-1}ku^{k-1}.$$

Therefore Eq. (112) takes the form

$$\Omega(u,v;z_\lambda)=\Omega(y(u),y(v);x)(J(u))^\lambda(J(v))^\lambda+\overline{\omega}_{kl}(y)[z'(u)(J(u))^{\lambda-1}u^k$$
$$+\lambda z(u)(J(u))^{\lambda-1}ku^{k-1}]$$
$$\times[z'(v)(J(v))^{\lambda-1}v^l+\lambda z(v)(J(v))^{\lambda-1}lv^{l-1}]$$

$$=\Omega(y(u),y(v);x)(J(u))^\lambda(J(v))^\lambda$$
$$+\overline{\omega}_{kl}(y)z'(u)(J(u))^{\lambda-1}u^kz'(v)(J(v))^{\lambda-1}v^l$$
$$+\overline{\omega}_{kl}(y)\lambda z(u)(J(u))^{\lambda-1}ku^{k-1}z'(v)(J(v))^{\lambda-1}v^l$$
$$+\overline{\omega}_{kl}(y)z'(u)(J(u))^{\lambda-1}u^k\lambda z(v)(J(v))^{\lambda-1}lv^{l-1}$$
$$+\lambda^2\overline{\omega}_{kl}(y)z(u)(J(u))^{\lambda-1}ku^{k-1}z(v)(J(v))^{\lambda-1}lv^{l-1}$$

$$=\Omega(y(u),y(v);x)(J(u))^\lambda(J(v))^\lambda$$
$$+\overline{\Omega}(u,v;y)z'(u)(J(u))^{\lambda-1}z'(v)(J(v))^{\lambda-1}$$
$$+\lambda\partial_u\overline{\Omega}(u,v;y)z(u)(J(u))^{\lambda-1}z'(v)(J(v))^{\lambda-1}$$
$$+\lambda\partial_v\overline{\Omega}(u,v;y)z'(u)(J(u))^{\lambda-1}z(v)(J(v))^{\lambda-1}$$

$$+\lambda^2\partial^2_{u,v}\overline{\Omega}(u,v;y)z(u)(J(u))^{\lambda-1}z(v)(J(v))^{\lambda-1}.$$

This concludes the proof of the Lemma. □

In the above formulas $\overline{\Omega}$ is given by (cf. Sec. IV)

$$\overline{\Omega}(u,v;y)=\varphi(u,v)y'(u)y'(v)-\varphi(y(u),y(v)), \tag{113}$$

where $\varphi(u,v)$ satisfies the equation

$$\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]+\text{cyclic}(u,v,w)=0. \tag{114}$$

In other words, $\varphi(u,v)$ is given by $\varphi(u,v)=f(u)g(v)-f(v)g(u)$ (cf. Sec. IV), where the functions f and g satisfy the relation

$$f'(u)g(u)-f(u)g'(u)=\alpha f'(u)+\beta g'(u)(\Rightarrow f''(u)g(u)-f(u)g''(u)=\alpha f''(u)+\beta g''(u)). \tag{115}$$

Here, α and β are arbitrary constants.

Theorem VIII.1: *If $\varphi(u,v)$ satisfies Eq. (114) and $\overline{\Omega}$ is defined by (113) one has the following solution of (111):*

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)+\lambda\ \partial_u\varphi(u,v)x(u)x'(v)+\lambda\ \partial_v\varphi(u,v)x'(u)x(v)$$
$$+\lambda^2\ \partial^2_{u,v}\varphi(u,v)x(u)x(v). \tag{116}$$

Proof: Using formula (113) in the r.h.s. of Eq. (111) we obtain

$$\begin{aligned}\text{r.h.s.}=&\Omega(y(u),y(v);x)(J(u))^{\lambda}(J(v))^{\lambda}+\varphi(u,v)z'(u)z'(v)(J(u))^{\lambda}(J(v))^{\lambda}\\&-\varphi(y(u),y(v))z'(u)z'(v)(J(u))^{\lambda-1}(J(v))^{\lambda-1}+\lambda\ \partial_u\varphi(u,v)z_\lambda(u)z'(v)(J(v))^{\lambda}\\&+\varphi(u,v)z(u)z'(v)[(J(u))^{\lambda}]'(J(v))^{\lambda}-\lambda\ \partial_1\varphi(y(u),y(v))z_\lambda(u)z'(v)(J(v))^{\lambda-1}\\&+\lambda\ \partial_v\varphi(u,v)z_\lambda(v)z'(u)(J(u))^{\lambda}+\varphi(u,v)z'(u)z(v)[(J(v))^{\lambda}]'(J(u))^{\lambda}\\&-\lambda\ \partial_2\varphi(y(u),y(v))z_\lambda(v)z'(u)(J(u))^{\lambda-1}+\lambda^2\ \partial^2_{u,v}\varphi(u,v)z_\lambda(u)z_\lambda(v)\\&+\lambda\ \partial_u\varphi(u,v)z_\lambda(u)z(v)[(J(v))^{\lambda}]'+\lambda\ \partial_v\varphi(u,v)z_\lambda(v)z(u)[(J(u))^{\lambda}]'\\&+\varphi(u,v)z(u)z(v)[(J(u))^{\lambda}]'[(J(v))^{\lambda}]'-\lambda^2\ \partial^2_{1,2}\varphi(y(u),y(v))z_\lambda(u)z_\lambda(v).\end{aligned}$$

Above we used the formulas

$$\partial_u\overline{\Omega}(u,v;y)=\partial_u\varphi(u,v)J(u)J(v)+\varphi(u,v)J'(u)J(v)-\partial_1\varphi(y(u),y(v))J(u),$$

$$\partial_v\overline{\Omega}(u,v;y)=\partial_v\varphi(u,v)J(u)J(v)+\varphi(u,v)J(u)J'(v)-\partial_2\varphi(y(u),y(v))J(v).$$

For the l.h.s. of Eq. (111) we have

$$\begin{aligned}\text{l.h.s.}=&\varphi(u,v)z'_\lambda(u)z'_\lambda(v)+\lambda\ \partial_u\varphi(u,v)z_\lambda(u)z'_\lambda(v)+\lambda\ \partial_v\varphi(u,v)z'_\lambda(u)z_\lambda(v)\\&+\lambda^2\ \partial^2_{u,v}\varphi(u,v)z_\lambda(u)z_\lambda(v)\\=&\varphi(u,v)\{z'(u)(J(u))^{\lambda}+z(u)[(J(u))^{\lambda}]'\}\{z'(v)(J(v))^{\lambda}+z(v)[(J(v))^{\lambda}]'\}\\&+\text{remaining terms}\\=&\varphi(u,v)z'(u)z'(v)(J(u))^{\lambda}(J(v))^{\lambda}+\varphi(u,v)z'(u)z(v)(J(u))^{\lambda}[(J(v))^{\lambda}]'\end{aligned}$$

$$+\varphi(u,v)z(u)z'(v)(J(v))^{\lambda}[(J(u))^{\lambda}]'+\varphi(u,v)z(u)z(v)[(J(u))^{\lambda}]'[(J(v))^{\lambda}]'$$
$$+\lambda\ \partial_u\varphi(u,v)z_{\lambda}(u)z'(v)(J(v))^{\lambda}+\lambda\ \partial_u\varphi(u,v)z_{\lambda}(u)z(v)[(J(v))^{\lambda}]'$$
$$+\lambda\ \partial_v\varphi(u,v)z_{\lambda}(v)z'(u)(J(u))^{\lambda}+\lambda\ \partial_v\varphi(u,v)z_{\lambda}(v)z(u)[(J(u))^{\lambda}]'$$
$$+\lambda^2\ \partial^2_{u,v}\varphi(u,v)z_{\lambda}(u)z_{\lambda}(v).$$

On the other hand, we also have

$$\begin{aligned}\Omega(y(u),y(v);x)(J(u))^{\lambda}(J(v))^{\lambda}=&\varphi(y(u),y(v))z'(u)z'(v)(J(u))^{\lambda-1}(J(v))^{\lambda-1}\\&+\lambda\ \partial_1\varphi(y(u),y(v))z_{\lambda}(u)z'(v)(J(v))^{\lambda-1}\\&+\lambda\ \partial_2\varphi(y(u),y(v))z_{\lambda}(v)z'(u)(J(u))^{\lambda-1}\\&+\lambda^2\ \partial^2_{1,2}\varphi(y(u),y(v))z_{\lambda}(u)z_{\lambda}(v).\end{aligned}$$

After comparing the terms on the l.h.s. and the r.h.s. of Eq. (111) we obtain an identity. This concludes the proof of the Theorem. □

Remark VIII.1: Notice that for $\lambda\neq 0$ *we can not have an inhomogeneous term of the form* $\overline{\varphi}(x(u),x(v))$ *in (116). Had it been the case it would impose on* $\overline{\varphi}(u,v)$ *the condition of being a homogeneous function of degree 1 in both arguments. In order to satisfy the equation (111)* $\overline{\varphi}(u,v)$ *must have the property* $\overline{\varphi}(z_{\lambda}(u),z_{\lambda}(v))=\overline{\varphi}(z(u)(J(u))^{\lambda},z(v)(J(v))^{\lambda})=\overline{\varphi}(z(u),z(v))\times((J(u))^{\lambda}(J(v))^{\lambda})$. *But since* $\overline{\varphi}(u,v)$ *must be also antisymmetric it follows that the only function with these properties is* $\overline{\varphi}=0$. *On the contrary, for* $\lambda=0$ *we have a solution of (111) of the form*

$$\Omega(u,v;x)=\varphi(u,v)x'(u)x'(v)-\overline{\varphi}(x(u),x(v)),$$

where the function $\overline{\varphi}$ *has the property* $\overline{\varphi}(u,v)=-\overline{\varphi}(v,u)$. *The Jacobi identity for* Ω *then implies that* $\overline{\varphi}$ *must satisfy (114).*

Next, we come to the following fact.

Theorem VIII.2: *If* $\varphi(u,v)$ *satisfies (114) then the solution (116) satisfies the Jacobi identity, thus yielding a class of Poisson structures on* V_{λ} *for which the action of* G_{∞} *on* V_{λ} *is a Poisson action.*

Proof: We shall use again the bracket $\{\mathcal{X}(u),\mathcal{X}(v)\}:=\Sigma_{i,j=0}^{\infty}\{\mathcal{X}_i,\mathcal{X}_j\}u^iv^j$ introduced in Sec. IV. Then we have

$$\begin{aligned}\{\mathcal{X}(u),\mathcal{X}(v)\}=&\varphi(u,v)\mathcal{X}'(u)\mathcal{X}'(v)+\lambda\ \partial_u\varphi(u,v)\mathcal{X}(u)\mathcal{X}'(v)\\&+\lambda\ \partial_v\varphi(u,v)\mathcal{X}'(u)\mathcal{X}(v)+\lambda^2\ \partial^2_{u,v}\varphi(u,v)\mathcal{X}(u)\mathcal{X}(v),\end{aligned}$$

as well as

$$\begin{aligned}\partial_u\{\mathcal{X}(u),\mathcal{X}(v)\}=&\partial_v\varphi(u,v)\mathcal{X}''(u)\mathcal{X}'(v)+\varphi(u,v)\mathcal{X}'(u)\mathcal{X}''(v)+\lambda^2\ \partial^2_{u,v}\varphi(u,v)\mathcal{X}(u)\mathcal{X}'(v)\\&+\lambda\ \partial_u\varphi(u,v)\mathcal{X}(u)\mathcal{X}''(v)+\lambda\ \partial^2_v\varphi(u,v)\mathcal{X}'(u)\mathcal{X}(v)+\lambda\ \partial_v\varphi(u,v)\mathcal{X}'(u)\mathcal{X}'(v)\\&+\lambda^2\ \partial^3_{u,v^2}\varphi(u,v)\mathcal{X}(u)\mathcal{X}(v)+\lambda^2\ \partial^2_{u,v}\varphi(u,v)\mathcal{X}(u)\mathcal{X}'(v).\end{aligned}$$

The Jacobi identity $\{\mathcal{X}(w),\{\mathcal{X}(u),\mathcal{X}(v)\}\}+\text{cyclic}(u,v,w)=0$ is equivalent to the following equation: $\mathcal{A}+\mathcal{B}+\mathcal{C}+\mathcal{D}=0$. Here,

$$\mathcal{A}=\varphi(u,v)\{\mathcal{X}(w),\mathcal{X}'(u)\mathcal{X}'(v)\}+\text{cyclic}(u,v,w)$$
$$=\varphi(u,v)[\partial_u\{\mathcal{X}(w),\mathcal{X}(u)\}\mathcal{X}'(v)+\partial_v\{\mathcal{X}(w),\mathcal{X}(v)\}\mathcal{X}'(u)]+\text{cyclic}(u,v,w),$$

$$\mathcal{B}=\lambda\ \partial_u\varphi(u,v)\{\mathcal{X}(w),\mathcal{X}(u)\mathcal{X}'(v)\}+\text{cyclic}(u,v,w)$$
$$=\lambda\ \partial_u\varphi(u,v)[\{\mathcal{X}(w),\mathcal{X}(u)\}\mathcal{X}'(v)+\partial_v\{\mathcal{X}(w),\mathcal{X}(v)\}\mathcal{X}(u)]+\text{cyclic}(u,v,w),$$

$$\mathcal{C}=\lambda\ \partial_v\varphi(u,v)\{\mathcal{X}(w),\mathcal{X}'(u)\mathcal{X}(v)\}+\text{cyclic}(u,v,w)$$
$$=\lambda\ \partial_v\varphi(u,v)[\partial_u\{\mathcal{X}(w),\mathcal{X}(u)\}\mathcal{X}(v)+\{\mathcal{X}(w),\mathcal{X}(v)\}\mathcal{X}'(u)]+\text{cyclic}(u,v,w),$$

$$\mathcal{D}=\lambda^2\ \partial^2_{u,v}\varphi(u,v)\{\mathcal{X}(w),\mathcal{X}(u)\mathcal{X}(v)\}+\text{cyclic}(u,v,w)$$
$$=\lambda^2\ \partial^2_{u,v}\varphi(u,v)[\{\mathcal{X}(w),\mathcal{X}(u)\}\mathcal{X}(v)+\{\mathcal{X}(w),\mathcal{X}(v)\}\mathcal{X}(u)]+\text{cyclic}(u,v,w).$$

For the expressions in the square brackets for each term we therefore obtain

$$\begin{aligned}\mathcal{A}'=&\partial_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)+\varphi(w,u)\mathcal{X}'(w)\mathcal{X}''(u)\mathcal{X}'(v)\\
&+\lambda\ \partial^2_{w,u}\varphi(w,u)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)+\lambda\ \partial_w\varphi(w,u)\mathcal{X}(w)\mathcal{X}''(u)\mathcal{X}'(v)\\
&+\lambda\ \partial^2_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}'(v)+\lambda\ \partial_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)\\
&+\lambda^2\ \partial^3_{w,u^2}\varphi(w,u)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}'(v)+\lambda^2\ \partial^2_{w,u}\varphi(w,u)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)\\
&+\partial_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)+\varphi(w,v)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}''(v)\\
&+\lambda\ \partial^2_{w,v}\varphi(w,v)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)+\lambda\ \partial_w\varphi(w,v)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}''(v)\\
&+\lambda\ \partial^2_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}(v)+\lambda\ \partial_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)\\
&+\lambda^2\ \partial^3_{w,v^2}\varphi(w,v)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}(v)+\lambda^2\ \partial^2_{w,v}\varphi(w,v)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v),\end{aligned}$$

$$\begin{aligned}\mathcal{B}'=&\varphi(w,u)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)+\lambda\ \partial_w\varphi(w,u)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)\\
&+\lambda\ \partial_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}'(v)+\lambda^2\ \partial^2_{w,u}\varphi(w,u)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}'(v)\\
&+\partial_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}'(v)+\varphi(w,v)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}''(v)\\
&+\lambda\ \partial^2_{w,v}\varphi(w,v)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}'(v)+\lambda\ \partial_w\varphi(w,v)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}''(v)\\
&+\lambda\ \partial^2_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}(v)+\lambda\ \partial_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}'(v)\\
&+\lambda^2\ \partial^3_{w,v^2}\varphi(w,v)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v)+\lambda^2\ \partial^2_{w,v}\varphi(w,v)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}'(v),\end{aligned}$$

$$\begin{aligned}\mathcal{C}'=&\partial_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}(v)+\varphi(w,u)\mathcal{X}'(w)\mathcal{X}''(u)\mathcal{X}(v)+\lambda\ \partial^2_{w,u}\varphi(w,u)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}(v)\\
&+\lambda\ \partial_w\varphi(w,u)\mathcal{X}(w)\mathcal{X}''(u)\mathcal{X}(v)+\lambda\ \partial^2_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}(u)\mathcal{X}(v)\\
&+\lambda\ \partial_u\varphi(w,u)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}(v)+\lambda^2\ \partial^3_{w,u^2}\varphi(w,u)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v)\\
&+\lambda^2\ \partial^2_{w,u}\varphi(w,u)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}(v)+\varphi(w,v)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}'(v)\\
&+\lambda\ \partial_w\varphi(w,v)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)+\lambda\ \partial^2_{w,v}\varphi(w,v)\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}(v)\\
&+\lambda\ \partial_v\varphi(w,v)\mathcal{X}'(w)\mathcal{X}'(u)\mathcal{X}(v),\end{aligned}$$

$$\mathcal{D}'=\varphi(w,u)\mathcal{X}''(w)\mathcal{X}''(u)\mathcal{X}(v)+\lambda\ \partial_w\varphi(w,u)\mathcal{X}(w)\mathcal{X}''(u)\mathcal{X}(v)+\lambda\ \partial_u\varphi(w,u)\mathcal{X}''(w)\mathcal{X}(u)\mathcal{X}(v)$$
$$+\lambda^2\ \partial^2_{w,u}\varphi(w,u)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v)+\varphi(w,v)\mathcal{X}''(w)\mathcal{X}(u)\mathcal{X}''(v)$$
$$+\lambda\ \partial_w\varphi(w,v)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}''(v)+\lambda\ \partial_v\varphi(w,v)\mathcal{X}''(w)\mathcal{X}(u)\mathcal{X}(v)$$
$$+\lambda^2\ \partial^2_{w,v}\varphi(w,u)\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v).$$

In what follows, we shall study the four terms in the Jacobi identity written as

$$\mathcal{A}=\varphi(u,v)\mathcal{A}'+\text{cyclic}(u,v,w),\quad \mathcal{B}=\lambda\partial_u\varphi(u,v)\mathcal{B}'+\text{cyclic}(u,v,w),$$

$$\mathcal{C}=\lambda\partial_v\varphi(u,v)\mathcal{C}'+\text{cyclic}(u,v,w),\quad \mathcal{D}=\lambda^2\partial^2_{u,v}\varphi(u,v)\mathcal{D}'+\text{cyclic}(u,v,w).$$

We split the analysis of the Jacobi identity into seven steps (A)–(G).

(A) Terms proportional to $\mathcal{X}''\mathcal{X}''\mathcal{X}''$. From them we obtain (after cyclicly permuting the arguments of some of them):

$$\{\varphi(u,v)[\partial_u\varphi(w,u)+\partial_v\varphi(w,v)]+\text{cyclic}(u,v,w)\}\mathcal{X}''(w)\mathcal{X}''(u)\mathcal{X}''(v).$$

But from (114) it follows that the above term is zero.

(B) Terms proportional to $\mathcal{X}\mathcal{X}''\mathcal{X}''$ cancel each other out after cyclic permutation.

(C) Terms proportional to $\mathcal{X}\mathcal{X}''\mathcal{X}$ cancel each other out after cyclic permutation.

(D) Terms proportional to $\mathcal{X}\mathcal{X}\mathcal{X}$ give

$$\lambda^3[\partial_u\varphi(u,v)\partial^3_{w,v^2}\varphi(w,v)+\partial_v\varphi(u,v)\partial^3_{w,u^2}\varphi(w,u)+\text{cyclic}(u,v,w)]\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v)$$
$$+\lambda^4[\partial^2_{u,v}\varphi(u,v)(\partial^2_{w,u}\varphi(w,u)+\partial^2_{w,v}\varphi(w,v))+\text{cyclic}(u,v,w)]\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v).$$

Since $\varphi(u,v)$ is a solution of (114) the results obtained in Sec. IV showed that $\varphi(u,v)=f(u)g(v)-f(v)g(u)$, where f and g satisfy (115). Therefore the λ^3-term becomes

$$\lambda^3\{[f'(u)g(v)-f(v)g'(u)][f'(w)g''(v)-f''(v)g'(w)]+[f(u)g'(v)-f'(v)g(u)]$$
$$\times[f'(w)g''(u)-f''(u)g'(w)]+\text{cyclic}(u,v,w)\}\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v),$$

and the λ^4-term assumes the form

$$\lambda^4\{[f'(u)g'(v)-f'(v)g'(u)][f'(w)g'(u)-f'(u)g'(w)$$
$$+f'(w)g'(v)-f'(v)g'(w)]+\text{cyclic}(u,v,w)\}\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}(v).$$

Using the identities $f'(u)g(u)-f(u)g'(u)=\alpha f'(u)+\beta g'(u)(\Rightarrow f''(u)g(u)-f(u)g''(u)=\alpha f''(u)+\beta g''(u))$ one easily shows that both terms proportional to λ^3 and λ^4, respectively, are identically zero.

(E) Terms proportional to $\mathcal{X}\mathcal{X}\mathcal{X}''$ give

$$\lambda^2[\varphi(u,v)\partial^3_{w,u^2}\varphi(w,u)+\varphi(v,w)\partial^3_{u,w^2}\varphi(u,w)+\partial_u\varphi(u,v)\partial^2_{w,v}\varphi(w,v)+\partial_w\varphi(w,u)\partial^2_u\varphi(v,u)$$
$$+\partial_u\varphi(w,u)\partial^2_w\varphi(v,w)+\partial_w\varphi(v,w)\partial^2_{u,v}\varphi(u,v)]\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}''(v)+\text{cyclic}(u,v,w).$$

The expression in the square brackets becomes identically zero after using (115) in a similar way as in (D). Also we have a term proportional to λ^3 which reads as

$$\lambda^3[\partial_u\varphi(u,v)\partial^2_{w,u}\varphi(w,u)+\partial_u\varphi(u,v)\partial^2_{w,v}\varphi(w,v)+\partial_w\varphi(v,w)\partial^2_{u,v}\varphi(u,v)$$
$$+\partial_w\varphi(v,w)\partial^2_{u,w}\varphi(u,w)+\partial_w\varphi(v,w)\partial^2_{w,u}\varphi(w,u)+\partial_u\varphi(u,v)\partial^2_{v,w}\varphi(v,w)$$
$$+\partial_w\varphi(w,v)\partial^2_{u,v}\varphi(u,v)+\partial_u\varphi(v,u)\partial^2_{w,u}\varphi(w,u)]\mathcal{X}(w)\mathcal{X}(u)\mathcal{X}'(v)+\text{cyclic}(u,v,w),$$

which is identically zero.

(F) Terms proportional to $\mathcal{X}\mathcal{X}'\mathcal{X}'$ give

$$\lambda[\varphi(u,v)\partial^2_{w,u}\varphi(w,u)+\varphi(w,u)\partial^2_{w}\varphi(v,w)+\varphi(u,v)\partial^2_{w,v}\varphi(w,v)+\varphi(v,w)\partial^2_{w}\varphi(u,w)$$
$$+\partial_w\varphi(w,u)\partial_u\varphi(v,u)+\partial_w\varphi(v,w)\partial_v\varphi(u,v)]\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)+\text{cyclic}(u,v,w).$$

The expression in the square brackets can be shown to be identically zero after using (115) in a similar way as in (D) and (E).

The other two terms of the same form are

$$\lambda^2[\varphi(u,v)\partial^2_{w,u}\varphi(w,u)+\varphi(u,v)\partial^2_{w,v}\varphi(w,v)$$
$$+\varphi(v,u)\partial^2_{w,u}\varphi(w,u)+\varphi(u,v)\partial^2_{w,v}\varphi(v,w)]\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)+\text{cyclic}(u,v,w),$$

which is identically zero, and

$$\lambda^2[\partial_w\varphi(w,u)\partial_u\varphi(u,v)+\partial_w\varphi(w,u)\partial_w\varphi(v,w)+\partial_w\varphi(w,u)\partial_u\varphi(v,u)+\partial_w\varphi(v,w)\partial_v\varphi(u,v)$$
$$+\partial_v\varphi(u,v)\partial_w\varphi(w,v)+\partial_w\varphi(v,w)\partial_w\varphi(u,w)]\mathcal{X}(w)\mathcal{X}'(u)\mathcal{X}'(v)+\text{cyclic}(u,v,w),$$

which is again identically zero.

(G) Terms proportional to $\mathcal{X}'\mathcal{X}''\mathcal{X}'$ cancel each other.

Thus all terms have been covered and the proof of Theorem VIII.2 is completed. □

As a result of Theorem VIII.1 and Theorem VIII.2 for each Poisson–Lie structure on G_∞ defined by a function φ satisfying the equation (114) there exists a Poisson structure on V_λ for which the action of G_∞ is Poisson. Thus we obtain a series of representations $\mathcal{V}_{\varphi,\lambda}$ of the Poisson–Lie group G_∞ in the Poisson spaces V_λ.

IX. QUANTIZATION

This section is devoted to the quantization of some of the Poisson–Lie structures on the group G_∞ when restricted to the finite-dimensional quotient-groups $G_n=G_\infty \bmod u^{n+1}$. We shall construct explicitly families of finitely generated quantum (semi)groups. Their quasi-classical limits are the finite-dimensional Poisson–Lie groups endowed with Poisson–Lie structures, which are restrictions of the Poisson–Lie structures on the group G_∞, and belong to the countable family obtained in Theorem IV.3. We shall consider quotient-groups G_n, for $n\geqslant 4$ (cf. Sec. III). In this aproach to quantization we shall start from the quasi-classical limits, that is, the corresponding Poisson–Lie groups, and reconstruct from this data their quantum counterparts. This quantization procedure amounts to deformation quantization of the Poisson algebra $\mathcal{A}$ of C^∞ functions on the corresponding finite-dimensional Poisson–Lie groups to a noncommutative noncocommutative bialgebra $\mathcal{A}_h$ such that $\mathcal{A}_h/h\mathcal{A}_h\cong\mathcal{A}$. The second postulate of quantization requires that the deformation be ‘‘flat,’’ that is, the dimension of $\mathcal{A}_h$ as a $k[[h]]$-module, for a field k of characteristic zero, be the same as the dimension of $\mathcal{A}$ as a k-module. For the general philosophy underlying the method we refer the reader to Refs. 1 and 27.

(i) Let $X=\{x_i\}_{i\in\mathbb{N}}$ be a set of indeterminates. Let us introduce a grading on the algebra $k[X]$, where k denotes the ground field (assumed to be of characteristic zero), by assigning a degree (denoted $||$) to each of the generators x_i of $k[X]$ by the following definition: $|x_i|=i-1$, for every $i\in\mathbb{N}$. We extend it on monomials by $|AB|=|A|+|B|$, for every two monomials A,B.

As we have mentioned above, in this section we shall be concerned with the quantization problem for the countable family of Poisson–Lie structures on the group G_∞, found in Sec. IV, the formulas for which we now recall:

$$\{x_i,x_j\}=(i-d)jx_jx_{i-d}-i(j-d)x_ix_{j-d}+x_i\sum_{(\Sigma_{k=1}^{d+1}s_k)=j}x_{s_1}\ldots x_{s_{d+1}}-x_j\sum_{(\Sigma_{k=1}^{d+1}s_k)=i}x_{s_1}\ldots x_{s_{d+1}}, \tag{117}$$

for all $d\in\mathbb{N}$. It is clear from the right-hand side of (117) that for each $d\in\mathbb{N}$ the degree of the bracket $\{x_i,x_j\}$ is given by

$$|\{x_i,x_j\}|=|x_i|+|x_j|-d=i+j-d-2.$$

(ii) Let $X=\{x_i\}_{i\in\mathbb{N}}$ be a set of indeterminates and let $\langle X\rangle$ be a free associative semigroup with identity on X. Let $k[[h]]\langle X\rangle$ be the semigroup algebra of $\langle X\rangle$ over the ring of formal power series $k[[h]]$ in the parameter h. Here k is assumed to be a field of characteristic zero. Consider the set of relations

$$\mathcal{R}_h=\{x_ix_j-x_jx_i=f_{ij|h}(x)|i,j\in\mathbb{N}\},$$

where $f_{ij|h}(x)$ are polynomials in x_i with coefficients in $k[[h]]$, such that $f_{ij|0}=0$. Let $\mathcal{I}_h$ be the ideal generated by $\mathcal{R}_h$. Define $\mathcal{A}_h:=k[[h]]\langle X\rangle/\mathcal{I}_h$, and define a grading on $k\langle X\rangle$ as was done in (i).

The following is the first postulate of quantization. As explained earlier we require that $\mathcal{A}_h/h\mathcal{A}_h\cong k\langle X\rangle$, that is,

$$[x_i,x_j]=h\{x_i,x_j\}+O(h^2).$$

Here $[x_i,x_j]=x_ix_j-x_jx_i$, and the product is the product in $\mathcal{A}_h$. In other words, we would like to recover the Poisson–Lie bracket on G_∞ (or the quotient groups $G_n=G_\infty \bmod u^{n+1}$) in the quasi-classical limit $h\to 0$. This also means that for $h\to 0$ we should have

$$f_{ij|h}(x)=h\{x_i,x_j\}+O(h^2).$$

After computing the degree of the right-hand side of the above equality $|h\{x_i,x_j\}|=|h|+|\{x_i,x_j\}|=|h|+i+j-d-2$, we deduce that for each $d\in\mathbb{N}$ the parameter h must have degree $|h|=d$, since $|[x_i,x_j]|=i+j-2$.

(iii) Consider the semigroup algebra $k[[h]]\langle X\rangle$ of $\langle X\rangle$ over the ring $k[[h]]$. For each $d\in\mathbb{N}$ consider the set of relations

$$\mathcal{R}_h^d=\{x_ix_j=x_jx_i+f_{ij|h}^d(x)|i<j,\quad \text{for } i,j\in\mathbb{N}\}, \tag{118}$$

where $f_{ij|h}^d(x)\in k[[h]]\langle X\rangle$ are linear combinations of monomials $h^nx_{i_1}^{n_1}\ldots x_{i_k}^{n_k}$ such that $i_1>\ldots>i_k$ and $nd+\Sigma_{s=1}^k n_s(i_s-1)=i+j-d-2$. We shall say that these monomials are in canonical form. Thus $f_{ij|h}^d(x)$ are linear combinations of monomials in canonical form. Recall the following definition.

Definition IX.1: The semigroup algebra $k[[h]]\langle X\rangle$ has a Poincaré–Birkhoff–Witt (PBW) property if every monomial $A\in\langle X\rangle$ can be reduced to a unique expression as a linear combination of monomials in canonical form using the set of relations (118) independently of the choice of a reduction procedure.

We shall use a version of the result known as the Diamond Lemma,[28,29] applicable here, which allows us to prove the PBW property, by only proving it for the monomials with so called ‘‘overlap’’ ambiguities.[28]

Definition IX.2: For each $d \in \mathbb{N}$ *a quantum semigroup* $G^d_{\infty|h}$ *is defined as follows. As a ''quantum space''* $G^d_{\infty|h}$ *is defined by its quotient semigroup algebra* $\mathcal{A}^d_h := k[[h]]\langle X\rangle/\mathcal{I}^d_h$*, where* $\mathcal{I}^d_h \subset k[[h]]\langle X\rangle$ *is the ideal generated by the set of relations (118), and we require that in the quasi-classical limit* $[x_i, x_j] = h\{x_i, x_j\} + O(h^2)$*, one obtains the Poisson algebra of functions on the Poisson-Lie group* G^d_∞ *defined by (117). The multiplication of formal power series in one variable under the operation of substitution* $(xy)(u) = x(y(u))$*, where* $x(u) = \Sigma_{i=1}^\infty x_i u^i$*, and* $y(u) = \Sigma_{i=1}^\infty y_i u^i$*, induces a comultiplication map* $\Delta: \mathcal{A}^d_h \to \mathcal{A}^d_h \otimes \mathcal{A}^d_h$*, which is defined on the generators by*

$$\Delta(x_n) = \sum_{i=1}^n x_i \otimes \sum_{\Sigma_{\alpha=1}^i j_\alpha = n} x_{j_1} \ldots x_{j_i}, \quad n \in \mathbb{N}, \tag{119}$$

and is required to be an algebra homomorphism. Also, one defines a counit map $c: \mathcal{A}^d_h \to k[[h]]$ *by*

$$c(x_i) = \delta_i^1, \quad i \in \mathbb{N}. \tag{120}$$

All tensor products are over $k[[h]]$*. This endows* $\mathcal{A}^d_h$ *with a structure of a bialgebra and the quantum semigroup* $G^d_{\infty|h}$ *is defined to be the bialgebra* $\mathcal{A}^d_h$*, if, in addition,* $k[[h]]\langle X\rangle$ *has the PBW basis described above.*

Does such an object exist? We do not know yet. However, if we consider the Poisson–Lie quotient groups $G^d_n = G^d_\infty \bmod u^{n+1}$, for $n \leqslant 7$, then there exist quantum objects that satisfy the above definition for small values of d, $d \leqslant 5$, and whose quasi-classical limits are the Poisson–Lie groups G^d_n. The definition of the finitely generated quantum semigroups $G^d_{n|h}$ is the same as the definition above with $\mathcal{I}^d_h$ being an ideal generated by a finite set of relations $\mathcal{R}^d_h$. Their defining semigroup algebras turn out to have other interesting properties. We shall describe in more detail the construction of the quantum semigroup $G^2_{5|h}$, while omitting parts of the construction that consist of lengthy and tedious calculations, and we shall state the results for the quantum semigroups $G^1_{4|h}$ and $G^3_{5|h}$ without entering into the details of the calculations. The construction of the last two mimics exactly the construction of $G^2_{5|h}$.

Let $G^2_5 = G^2_\infty \bmod u^{n+1}$, for $n \geqslant 5$, be the finite-dimensional (dim = 5, $d=2$) Poisson–Lie group with a Poisson–Lie structure defined by

$$\{x_i, x_j\} = (i-2) j x_j x_{i-2} - i(j-2) x_i x_{j-2} + x_i \sum_{s_1+s_2+s_3=j} x_{s_1} x_{s_2} x_{s_3} - x_j \sum_{s_1+s_2+s_3=i} x_{s_1} x_{s_2} x_{s_3}.$$

The above formulas are obtained from (117) with $d=2$, and we adopt the convention that $x_i = 0$ whenever $i < 1$. In more detail, we have

$$\{x_1, x_2\} = 0,$$

$$\{x_1, x_3\} = -x_1^2 + x_1^4,$$

$$\{x_2, x_3\} = x_2(x_1^3 - 2x_1),$$

$$\{x_1, x_4\} = x_2(3x_1^3 - 2x_1),$$

$$\{x_2, x_4\} = x_2^2(3x_1^3 - 4),$$

$$\{x_3, x_4\} = x_4(4x_1 - x_1^3) + x_3 x_2(3x_1^2 - 6),$$

$$\{x_1, x_5\} = x_3(3x_1^3 - 3x_1) + 3x_2^2 x_1^2,$$

$$\{x_2,x_5\}=3x_2^3x_1+x_3x_2(3x_1^2-6),$$

$$\{x_3,x_5\}=x_5(5x_1-x_1^3)+x_3^2(3x_1^2-9)+3x_3x_2^2x_1,$$

$$\{x_4,x_5\}=x_5x_2(10-3x_1^2)+x_4x_3(3x_1^2-12)+3x_4x_2^2x_1.$$

Theorem IX.1: *Let $X=\{x_i\}_{1\leqslant i\leqslant 5}$ be a set of indeterminates and let $\langle X\rangle$ be the associative semigroup with identity generated by X. Consider an ideal $\mathcal{I}_h^2$ generated by the set of relations $\mathcal{R}_h^2$ in $k[[h]]\langle X\rangle$:*

$$x_1x_2=x_2x_1,$$

$$x_1x_3=x_3x_1+h(-x_1^2+x_1^4),$$

$$x_2x_3=x_3x_2+hx_2(x_1^3-2x_1),$$

$$x_1x_4=x_4x_1+hx_2(3x_1^3-2x_1),$$

$$x_2x_4=x_4x_2+hx_2^2(3x_1^3-4),$$

$$x_3x_4=x_4x_3+h[x_4(4x_1-x_1^3)+x_3x_2(3x_1^2-6)]+2h^2x_2x_1,$$

$$x_1x_5=x_5x_1+h[x_3(3x_1^3-3x_1)+3x_2^2x_1^2]+h^2\left(-6x_1^4+\frac{9}{2}x_1^6+\frac{3}{2}x_1^2\right),$$

$$x_2x_5=x_5x_2+h[3x_2^3x_1+x_3x_2(3x_1^2-6)]+h^2x_2\left(6x_1-9x_1^3+\frac{9}{2}x_1^5\right),$$

$$x_3x_5=x_5x_3+h[x_5(5x_1-x_1^3)+x_3^2(3x_1^2-9)+3x_3x_2^2x_1]+h^2x_3\left(-\frac{15}{2}x_1+6x_1^3+\frac{3}{2}x_1^5\right)$$
$$+h^3C(x_1^8-x_1^2),$$

$$x_4x_5=x_5x_4+h[x_5x_2(10-3x_1^2)+x_4x_3(3x_1^2-12)+3x_4x_2^2x_1]$$
$$+h^2\left[x_4\left(-24x_1+9x_1^3+\frac{3}{2}x_1^5\right)+6x_3x_2\right]+h^3x_2[-(6+2C)x_1+3Cx_1^7],$$

where $C\in k$ is an arbitrary parameter. Then the semigroup quotient algebra $k[[h]]\langle\rangle/\mathcal{I}_h^2$ defines a quantum semigroup $G_{5|h}^2$ in the sense of Definition IX.2 with a comultiplication defined by (119). Namely,

$$\Delta x_1=x_1\otimes x_1,$$

$$\Delta x_2=x_1\otimes x_2+x_2\otimes x_1^2,$$

$$\Delta x_3=x_1\otimes x_3+x_2\otimes x_1x_2+x_2\otimes x_2x_1+x_3\otimes x_1^3, \tag{121}$$

$$\Delta x_4=x_1\otimes x_4+x_2\otimes x_1x_3+x_2\otimes x_2^2+x_2\otimes x_3x_1+x_3\otimes x_1^2x_2+x_3\otimes x_1x_2x_1+x_3\otimes x_2x_1^2+x_4\otimes x_1^4,$$

$$\Delta x_5 = x_1 \otimes x_5 + x_2 \otimes x_1 x_4 + x_2 \otimes x_2 x_3 + x_2 \otimes x_3 x_2 + x_2 x_4 x_1 + x_3 x_1^2 x_3 + x_3 \otimes x_1 x_2^2$$
$$+ x_3 \otimes x_1 x_3 x_1 + x_3 \otimes x_2 x_1 x_2 + x_3 \otimes x_2^2 x_1 + x_3 \otimes x_3 x_1^2 + x_4 \otimes x_1^3 x_2$$
$$+ x_4 \otimes x_1^2 x_2 x_1 + x_4 \otimes x_1 x_2 x_1^2 + x_4 \otimes x_2 x_1^3 + x_5 \otimes x_1^4.$$

Moreover, the semigroup algebra $k[[h]]\langle X \rangle$ *has the Poincaré–Birkhoff–Witt property.*

Proof: The proof is constructive. We look for a set of relations $\mathcal{R}_h^2$ in $k[[h]]\langle X \rangle$ in the following form:

$$x_1 x_2 = x_2 x_1,$$

$$x_1 x_3 = x_3 x_1 + h(-x_1^2 + x_1^4),$$

$$x_2 x_3 = x_3 x_2 + h x_2 (x_1^3 - 2x_1),$$

$$x_1 x_4 = x_4 x_1 + h x_2 (3x_1^3 - 2x_1),$$

$$x_2 x_4 = x_4 x_2 + h x_2^2 (3x_1^3 - 4) + h^2 f_1(x_1),$$

$$x_3 x_4 = x_4 x_3 + h[x_4(4x_1 - x_1^3) + x_3 x_2 (3x_1^2 - 6)] + h^2 x_2 f_2(x_1),$$

$$x_1 x_5 = x_5 x_1 + h[x_3(3x_1^3 - 3x_1) + 3x_2^2 x_1^2] + h^2 f_3(x_1),$$

$$x_2 x_5 = x_5 x_2 + h[x_3 x_2 (3x_1^2 - 6) + 3x_2^3 x_1] + h^2 x_2 f_4(x_1),$$

$$x_3 x_5 = x_5 x_3 + h[x_5(5x_1 - x_1^3) + x_3^2(3x_1^2 - 9) + 3x_3 x_2^2 x_1] + h^2[x_3 f_5(x_1) + x_2^2 f_6(x_1)] + h^3 f_7(x_1),$$

$$x_4 x_5 = x_5 x_4 + h[x_5 x_2 (10 - 3x_1^2) + x_4 x_3 (3x_1^2 - 12) + 3x_4 x_2^2 x_1]$$
$$+ h^2[x_4 f_8(x_1) + x_3 x_2 f_9(x_1) + x_2^3 f_{10}(x_1)] + h^3 x_2 f_{11}(x_1), \tag{122}$$

where $\{f_i(x)\}_{1 \leqslant i \leqslant 11}$ is a set of arbitrary polynomials. Since the degree of h is $|h| = 2$ and the degree of x_1 is $|x_1| = 0$ this is the most general form of the set of relations that one can have, such that their quasi-classical limit gives the Poisson–Lie structure on G_5^2.

We now require $k[[h]]\langle X \rangle / \mathcal{I}_h^2$ to be a bialgebra, that is, that Δ be an algebra homomorphism. This leads to some restrictions on the polynomials $f_i(x)$. Using the formulas for comultiplication (121) one can see that the first four relations are compatible with the coalgebra structure. One obtains functional equations for $f_i(x)$ from the remaining six relations after a reduction to a canonical form. We shall analyze first the equations that arise from terms of order h^2.

(a) The compatibility with comultiplication induces that

$$\Delta(x_2 x_4) = \Delta(x_4 x_2) + h(-4\Delta x_2^2 + 3\Delta(x_2^2 x_1^2)) + h^2 f_1(\Delta x_1).$$

After reducing both sides of this relation to a canonical form, using the comultiplication formulas (121), we obtain the following linear functional equation for $f_1(x)$: $-f_1(x_1 \otimes x_1) + x_1^2 \otimes f_1(x_1) + x_1^6 \otimes f_1(x_1) = 0$. From now on since all equations for the unknowns f_i will depend only on the variable x_1 we shall use the notation $x := x_1$. Therefore we have

$$-f_1(x \otimes x) + x^2 \otimes f_1(x) + x^6 \otimes f_1(x) = 0.$$

The most general solution of the above equation is

$$f_1(x) = C_1(x^6 - x^2),$$

where $C_1 \in k$ is an arbitrary constant. There are no terms of higher order in h that arise in the analysis of this relation. We move on to the next.

(b) Again after reducing to a canonical form both sides of

$$\Delta(x_3x_4)=\Delta(x_4x_3)+h(\Delta(4x_4x_1)-\Delta(x_4x_1^3)-\Delta(6x_3x_2)+\Delta(3x_3x_2x_1^2))+h^2\Delta(x_2f_2(x_1)),$$

we obtain two equations. One of them arises from a term proportional to $x_2\otimes 1$, that is, we have a term of the form

$$(x_2\otimes 1)[-f_2(x_1\otimes x_1)+(2-2C_1)x_1\otimes x_1+f_2(x_1)\otimes x_1^5+(-2+2C_1)x_1\otimes x_1^5],$$

which does not cancel. It leads to the equation

$$-f_2(x\otimes x)+(2-2C_1)x\otimes x+f_2(x)\otimes x^5+(-2+2C_1)x\otimes x^5=0. \tag{123}$$

The term proportional to $1\otimes x_2$ leads to

$$-f_2(x\otimes x)+x\otimes f_2(x)-2C_1x\otimes x^5+2C_1x^5\otimes x^5=0. \tag{124}$$

Solving (123) and (124) together we obtain

$$f_2(x)=(2-2C_1)x+2C_1x^5.$$

There are no terms of higher order in h arising from this relation.

At this stage of the calculation we check whether the PBW property is satisfied in the subalgebra of $k[[h]]\langle X\rangle$ generated by the set $\{x_1,x_2,x_3,x_4\}$ and subject to the first six relations of (122). By direct calculation, using the Diamond Lemma, one shows that the monomial $x_2x_3x_4$ can be reduced to a unique canonical form if and only if $C_1=0$. The other possible monomials of three variables have a unique canonical form. Therefore we obtain that

$$f_1(x)=0 \quad \text{and} \quad f_2(x)=2x.$$

(c) From the next relation one has

$$\Delta(x_1x_5)=\Delta(x_5x_1)+h(-3\Delta(x_3x_1)+3\Delta(x_2^2x_1^2)+3\Delta(x_3x_1^3))+h^2f_3(\Delta x_1);$$

after a reduction to a canonical form one is lead to the equation

$$-f_3(x\otimes x)+x^2\otimes f_3(x)+6x^2\otimes x^4+x^6\otimes f_3(x)-6x^4\otimes x^4-6x^2\otimes x^6+6x^4\otimes x^6=0.$$

The most general solution of the above equation is given by

$$f_3(x)=6x^2-6x^4+C_2(x^6-x^2),$$

where $C_2\in k$ is an arbitrary constant. There are no terms of order h^3 or higher that arise after the reduction to a canonical form of thisabove relation.

(d) The analysis of the next relation,

$$\Delta(x_2x_5)=\Delta(x_5x_2)+h(-6\Delta(x_3x_2)+3\Delta(x_2^3x_1)+3\Delta(x_3x_2x_1^2))+h^2\Delta(x_2f_4(x_1)),$$

leads to two equations. The first one is

$$-f_4(x\otimes x)+(15-2C_2)x\otimes x+f_4(x)\otimes x^5-9x^3\otimes x^3+(-15+2C_2)x\otimes x^5+9x^3\otimes x^5=0, \tag{125}$$

and comes from a term proportional to $h^2x_2\otimes 1$. The second equation comes from a term proportional to $h^2(1\otimes x_2)$ and reads as

$$-f_4(x\otimes x)+x\otimes f_4(x)+9x\otimes x^3-9x^3\otimes x^3-C_2x\otimes x^5+C_2x^5\otimes x^5=0. \tag{126}$$

Solving together (125) and (126) one obtains

$$f_4(x)=(15-2C_2)x-9x^3+C_2x^5. \tag{127}$$

There are no terms of higher order in h that do not cancel after the reduction to a canonical form.

(e) We move on to the next relation which gives

$$\Delta(x_3x_5)=\Delta(x_5x_3)+h\Delta(5x_5x_1-9x_3^2+3x_3x_2^2x_1+3x_3^2x_1^2-x_5x_1^3)$$
$$+h^2\Delta[x_3f_5(x_1)+x_2^2f_6(x_1)]+h^3\Delta f_7(x_1).$$

Terms of order h^2 give rise to five functional equations which we now describe.

(i) A term proportional to $x_3\otimes 1$ gives rise to

$$-f_5(x\otimes x)+(6-3C_2)x\otimes x+f_5(x)\otimes x^5+6x^3\otimes x^3-6x^3\otimes x^5+(-6+3C_2)x\otimes x^5=0, \tag{128}$$

and a term prortional to $1\otimes x_3$ gives rise to the equation

$$-f_5(x\otimes x)+x\otimes f_5(x)-6x\otimes x^3+6x^3\otimes x^3+(3-C_2)x\otimes x^5+(-3+C_2)x^5\otimes x^5=0. \tag{129}$$

Solving (128) and (129) together we obtain for f_5,

$$f_5(x)=(6-3C_2)x+6x^3+(-3+C_2)x^5.$$

(ii) Terms proportional to $x_2^2\otimes 1$ and $1\otimes x_2^2$ give rise to another two functional equations:

$$-f_6(x\otimes x)+x^4\otimes f_6(x)=0, \tag{130}$$

and

$$-f_6(x\otimes x)+1\otimes f_6(x)=0, \tag{131}$$

respectively. The only solution that satisfies both (130) and (131) is

$$f_6(x)=0. \tag{132}$$

(iii) The last term from the terms of order h^2 is a term proportional to $x_2\otimes x_2$ which gives rise to the following equation for f_5 and f_6:

$$-2f_5(x\otimes x)+(12-6C_2)x\otimes x-2(x\otimes x)f_6(x\otimes x)+12x^3\otimes x^3+(-6+2C_2)x^5\otimes x^5=0. \tag{133}$$

After substituting the solutions $f_5(x)$ and (132) into (133) we obtain that it is satisfied identically. There is one term of order h^3 that arises which gives rise to

$$x^2\otimes f_7(x)+f_7(x)\otimes x^8-f_7(x\otimes x)=0. \tag{134}$$

The most general solution of (134) is given by

$$f_7(x)=C_3(x^8-x^2),$$

where $C_3\in k$ is an arbitrary constant. No terms of higher order in h arise.

(f) The last relation to be analyzed is

$$\Delta(x_4x_5)=\Delta(x_5x_4)+h\Delta(10x_5x_2-12x_4x_3+3x_4x_2^2x_1+3x_4x_3x_1^2-3x_5x_2x_1^2)$$
$$+h^2\Delta[x_4f_8(x_1)+x_3x_2f_9(x_1)+x_2^3f_{10}(x_1)]+h^3\Delta(x_2f_{11}(x_1)).$$

After reducing to a canonical form both sides of the above relation we obtain ten terms of order h^2 that do not cancel and two terms of order h^3. We analyze first the terms of order h^2.

(i) Two terms proportional to $x_4\otimes 1$ and $1\otimes x_4$ give rise to the following two equations:

$$-f_8(x\otimes x)+(-6-4C_2)x\otimes x+f_8(x)\otimes x^5+9x^3\otimes x^3+(6+4C_2)x\otimes x^5-9x^3\otimes x^5=0, \tag{135}$$

$$-f_8(x\otimes x)+x\otimes f_8(x)-9x\otimes x^3+9x^3\otimes x^3+(3-C_2)x\otimes x^5+(-3+C_2)x^5\otimes x^5=0. \tag{136}$$

The most general solution of (135) and (136) is

$$f_8(x)=(-6-4C_2)x+9x^3+(-3+C_2)x^5. \tag{137}$$

(ii) Terms proportional to $x_3x_2\otimes 1$ and $1\otimes x_3x_2$ give rise to the equations

$$6(1\otimes 1)-f_9(x\otimes x)-6(1\otimes x^4)+f_9(x)\otimes x^4=0, \tag{138}$$

$$-f_9(x\otimes x)+1\otimes f_9(x)=0. \tag{139}$$

The solution of the system (138) and (139) is

$$f_9(x)=6. \tag{140}$$

(iii) A term proportional to $x_3\otimes x_2$ gives rise to

$$-3f_8(x\otimes x)+(-12-12C_2)x\otimes x-(x\otimes x)f_9(x\otimes x)+27x^3\otimes x^3+(-9+3C_2)x^5\otimes x^5=0. \tag{141}$$

After substituting (137) and (140) into (141) it yields an identity. Similarly the term proportional to $x_2\otimes x_3$ leads to an identity.

(iv) Two terms proportional to $x_2^3\otimes 1$ and $1\otimes x_2^3$ lead to the equations

$$-f_{10}(x\otimes x)+f_{10}(x)\otimes x^3=0, \tag{142}$$

$$1\otimes f_{10}(x)-(x\otimes 1)f_{10}(x\otimes x)=0. \tag{143}$$

The only solution of (142) and (143) solved together is

$$f_{10}(x)=0. \tag{144}$$

(v) The terms proportional to $x_2\otimes x_2^2$ and $x_2^2\otimes x_2$ give rise to

$$-f_8(x\otimes x)+(6-4C_2)x\otimes x-2(x\otimes x)f_9(x\otimes x)$$
$$-3(x^2\otimes x^2)f_{10}(x\otimes x)+9x^3\otimes x^3+(-3+C_2)x^5\otimes x^5=0, \tag{145}$$

and

$$12(1\otimes 1)-2f_9(x\otimes x)-3(x\otimes x)f_{10}(x\otimes x)=0, \tag{146}$$

which are identically satisfied. This becomes obvious after substituting (137), (140), and (144) into (145) and (146). The two terms of order h^3 are proportional to $x_2\otimes 1$ and $1\otimes x_2$ and give rise to

$$-f_{11}(x\otimes x)+(3-2C_2-2C_3)x\otimes x+f_{11}(x)\otimes x+(-3+2C_2+2C_3)x\otimes x^7=0, \tag{147}$$

$$-f_{11}(x\otimes x)+x\otimes f_{11}(x)-3C_3x\otimes x^7+3C_3x^7\otimes x^7=0, \tag{148}$$

respectively. The most general solution of (147) and (148) is

$$f_{11}(x)=(3-2C_2-2C_3)x+3C_3x^7.$$

We need one last step in order to complete the construction. We would like to find whether the so obtained set of relations define an algebra with the PBW property. After lengthy and tedious calculation one shows that the requirement that the monomials $x_1x_3x_5$, $x_1x_4x_5$, $x_2x_4x_5$, and $x_3x_4x_5$ can be reduced to a unique canonical form imposes the following single equation on the arbitrary constant C_2:

$$-9+2C_2=0.$$

The monomial $x_1x_2x_5$ is reducible to a canonical form without imposing any conditions. Thus $C_2=\frac{9}{2}$. If we introduce $C:=C_3$ we obtain the statement of the Theorem. This concludes the proof. □

Remark IX.1: Notice that our construction yields a one-parameter family of quantum semigroups $G_{5}^{2}\big|_{h}^{C}$ *parametrized by* C. *Theorem I.2 describes a family of quantum semigroups parametrized by even more parameters.*

Let $G_4^1=G_\infty^1 \bmod u^{n+1}$, for $n\geqslant 4$, be the finite-dimensional (dim = 4, $d=1$) Poisson–Lie group with a Poisson–Lie structure defined by

$$\{x_i,x_j\}=(i-1)jx_jx_{i-1}-i(j-1)x_ix_{j-1}+x_i\sum_{s_1+s_2=j}x_{s_1}x_{s_2}-x_j\sum_{s_1+s_2=i}x_{s_1}x_{s_2}.$$

The explicit formulas for the Poisson brackets were given in the Introduction and their quantization was described by Theorem I.2.

Remark IX.2: The proof of Theorem I.2 goes along the same lines as the proof of Theorem IX.1, that is, it is constructive. In the course of the construction five arbitrary constants C_1,C_2,C_3,C_4,C_5 *appear in solving the corresponding functional equations. The requirement for the existence of a PBW basis fixes two of them. Namely,* $C_1=1$ *and* $C_2=2-2C_3$. *Thus we obtain a 3-parameter family of quantum semigroups* $G_{4|h}^{1|C_3,C_4,C_5}$.

Finally we describe a third quantum semigroup arising after the quantization of the Poisson algebra of functions on the finite-dimensional (dim = 5, $d=3$) Poisson–Lie group G_5^3. The Poisson–Lie structure on G_5^3 is given by

$$\{x_i,x_j\}=(i-3)jx_jx_{i-3}-i(j-3)x_ix_{j-3}+x_i\sum_{s_1+s_2+s_3+s_4=j}x_{s_1}x_{s_2}x_{s_3}x_{s_4}$$
$$-x_j\sum_{s_1+s_2+s_3+s_4=i}x_{s_1}x_{s_2}x_{s_3}x_{s_4}.$$

The above formulas are obtained again from (117) with $d=3$. Writing them explicitly we have

$$\{x_1,x_2\}=0,$$

$$\{x_1,x_3\}=0,$$

$$\{x_2,x_3\}=0,$$

$$\{x_1,x_4\}=x_1^5-x_1^2,$$

$$\{x_2,x_4\}=x_2(x_1^4-2x_1),$$

$$\{x_3,x_4\}=x_3(x_1^4-3x_1),$$

$$\{x_1,x_5\}=x_2(4x_1^4-2x_1),$$

$$\{x_2,x_5\}=x_2^2(4x_1^4-4),$$

$$\{x_3,x_5\}=x_3x_2(4x_1^3-6),$$

$$\{x_4,x_5\}=x_4x_2(4x_1^3-8)+x_5(5x_1-x_1^4).$$

Then we have our last theorem.

Theorem IX.2: *Let $X=\{x_i\}_{1\leqslant i\leqslant 5}$ be a set and let $\langle X\rangle$ be the associative semigroup with identity generated by X. Consider an ideal $\mathcal{I}_h^3$ generated by the set of relations $\mathcal{R}_h^3$ in $k[[h]]\langle X\rangle$:*

$$x_1x_2=x_2x_1,$$

$$x_1x_3=x_3x_1,$$

$$x_2x_3=x_3x_2,$$

$$x_1x_4=x_4x_1+h(x_1^5-x_1^2),$$

$$x_2x_4=x_4x_2+hx_2(x_1^4-2x_1),$$

$$x_3x_4=x_4x_3+hx_3(x_1^4-3x_1),$$

$$x_1x_5=x_5x_1+hx_2(4x_1^4-2x_1),$$

$$x_2x_5=x_5x_2+hx_2^2(4x_1^4-4),$$

$$x_3x_5=x_5x_3+hx_3x_2(4x_1^3-6),$$

$$x_4x_5=x_5x_4+h[x_4x_2(4x_1^3-8)+x_5(5x_1-x_1^4)]+h^23x_2x_1.$$

Then the semigroup quotient algebra $k[[h]]\langle X\rangle/\mathcal{I}_h^3$ defines a quantum semigroup $G_{5|h}^3$ in the sense of Definition IX.2 with a comultiplication defined by (121), and the semigroup algebra $k[[h]]\langle X\rangle$ has the Poincaré–Birkhoff–Witt property.

Remark IX.3: The proof is again constructive. Note that no arbitrary parameters arise in dimension 5 for $d=3$. Arbitrary parameters arise in higher dimensions though. We have been able to construct all quantum semigroups $G_{n|h}^d$ for $n\leqslant 7$ and $d\leqslant 5$. However, we refrain from describing more examples here.

Functional versus canonical quantization of a nonlocal massive vector-gauge theory

R. Amorim[a] and J. Barcelos-Neto[b]

(Received 5 May 1998; accepted for publication 26 August 1998)

It has been shown in literature that a possible mechanism of mass generation for gauge fields is through a topological coupling of vector and tensor fields. After integrating over the tensor degrees of freedom, one arrives at an effective massive theory that, although gauge invariant, is nonlocal. Here we quantize this nonlocal resulting theory both by path integral and canonical procedures. This system can be considered as equivalent to one with an infinite number of time derivatives and consequently an infinite number of momenta. This means that the use of the canonical formalism deserves some care. We show the consistency of the formalism we use in the canonical procedure by showing that the obtained propagators are the same as those of the (Lagrangian) path integral approach. The problem of nonlocality appears in the obtainment of the spectrum of the theory. This fact becomes very transparent when we list the infinite number of commutators involving the fields and their velocities.

I. INTRODUCTION

It is widely accepted that the forces of nature are described by gauge theories. These theories are characterized by the gauge symmetries which are related to massless fields. However, sometimes it is necessary that these fields become massful, as occurs, for instance, in the case of the Salam–Weinberg theory. Nowadays, it has also been widely accepted that spontaneous symmetry breaking together with the Higgs mechanism is the most probable explanation for the origin of the acquisition of mass by gauge fields. However, if this is actually true, the Higgs bosons must exist in nature. The point is that there is no precise theoretical prediction on the mass scale where these fields could be found and experiments until now have shown no evidence about them.

In this way, alternative mechanisms of mass generation for gauge fields that do not spoil what is well established and that do not contain Higgs bosons are welcome. This might be the case of vector–tensor gauge theories,[1] where vector and tensor fields are coupled in a topological way by means of a kind of Chern–Simons term. The general idea of this mechanism resides in the following: Tensor gauge fields[2] are antisymmetric quantities and consequently in $D=4$ they exhibit six degrees of freedom. By virtue of the massless condition, the number of degrees of freedom goes down to four. Since the gauge parameter is a vector quantity, this number would be zero if all of its components were independent. This is nonetheless the case because the system is reducible (which means that the gauge transformations are not all independent) and we mention that the final number of physical degrees of freedom is one. It is precisely this degree of freedom that can be absorbed by the vector gauge field in the vector–tensor gauge theory in order to acquire mass.[1,3] This peculiar structure of constraints involving tensor gauge theories implies that quantization as well as its non-Abelian formulation deserve some care and a reasonable amount of work has been done on these subjects.[4–7]

[b]Electronic mail: barcelos@if.ufrj.br

Usually, the treatment of the vector–tensor gauge theory is carried out with both vector and tensor fields placed together and just at the end the integration over the tensor field is done in order to obtain the effective result for the vector theory. This procedure usually hides an important aspect of this effective theory, that is, its nonlocality. We mention that it is equivalent to a theory with an infinite number of higher derivative terms and, consequently, an infinite number of momenta also.

It is not our purpose here to advocate if a vector–tensor gauge theory with topological coupling is more suitable to explain the mass generation than the usual spontaneous symmetry breaking together with the Higgs mechanism. Our intention in the present paper is to study the quantization of a massive vector gauge field directly by means of the nonlocal effective Lagrangian.[8] We do it both by path integral, where we use a Lagrangian formulation, as well as by the canonical approach. This is the subject of Secs. II and III, respectively. We would like also to add that the non-Abelian formulation for the vector tensor gauge theory is not a simple task. This is so because the non-Abelian version loses the reducibility condition unless we consider that the Maxwell stress tensor is zero.[6] Another possibility is to introduce a kind of Stuckelberg field, that disappears in the Abelian limit, in order to keep the same number of degrees of freedom in both sectors (Abelian and non-Abelian) of the theory.[7] We shall consider only the Abelian case in this paper. We left Sec. IV for some concluding remarks and include four appendices to present details of some calculations.

II. BRIEF REVIEW OF THE VECTOR–TENSOR GAUGE THEORY AND THE PATH INTEGRAL QUANTIZATION OF THE EFFECTIVE VECTOR THEORY

The Abelian theory for vector and tensor fields coupled in a topological way is described by the Lagrangian density:[1]

$$\mathcal{L}=-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}+\frac{1}{12}H_{\mu\nu\rho}H^{\mu\nu\rho}+\frac{m}{2}\epsilon^{\mu\nu\rho\lambda}B_{\mu\nu}F_{\rho\lambda}, \tag{2.1}$$

where $F_{\mu\nu}$ and $H_{\mu\nu\rho}$ are totally antisymmetric tensors written in terms of the potentials A_μ and $B_{\mu\nu}$ (also antisymmetric) through the stress tensors

$$F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu, \tag{2.2}$$

$$H_{\mu\nu\rho}=\partial_\mu B_{\nu\rho}+\partial_\rho B_{\mu\nu}+\partial_\nu B_{\rho\mu}. \tag{2.3}$$

In expression (2.1), $\epsilon^{\mu\nu\rho\lambda}$ is the totally antisymmetric symbol and m is a mass parameter. It is easy to see, by using the (coupled) Euler–Lagrange equations for A^μ and $B^{\mu\nu}$, as well as the Jacobi identity, that $F_{\mu\nu}$ satisfy a massive Klein–Gordon equation, with a mass parameter m.[1]

We observe that the Lagrangian (2.1) is invariant under the gauge transformations

$$\delta A^\mu=\partial^\mu\Lambda, \tag{2.4}$$

$$\delta B^{\mu\nu}=\partial^\mu\Lambda^\nu-\partial^\nu\Lambda^\mu, \tag{2.5}$$

where Λ and Λ^μ are (before fixing the gauge) generic functions of space–time. This is a reducible theory, which means that not all the gauge transformations above are independent. In fact, if we choose the gauge parameter Λ^μ as the gradient of some scalar Ω we have that $B^{\mu\nu}$ does not change under the gauge transformation (2.5).

Functionally integrating over the antisymmetric tensor field $B_{\mu\nu}$ we get, after a convenient gauge fixing procedure, the effective action[3]

$$S_0[A_\mu]=-\frac{1}{4}\int d^4x\, F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)F^{\mu\nu}. \tag{2.6}$$

The action (2.6), although nonlocal, is gauge invariant. It is important to emphasize that this theory is renormalizable, a characteristic that is lost when a mass term is directly put by hand as in the Proca theory.

Let us calculate the (covariant) propagator for the field A_μ. We opt to use a Lagrangian formulation in order to avoid the problem of the infinite number of momenta. Let us use the Batalin–Vilkovisky (BV) formalism.[5,9] The nonminimum BV action can be written as

$$S = S_0 + \int dx (A^*_\mu \partial^\mu c + b\overline{c^*}), \tag{2.7}$$

where the A^*_μ and the pair $(c^*, \overline{c^*})$ are, respectively, the antifields of the gauge field A^μ and of the ghosts $(c, \bar{c})$. The auxiliary field b was introduced in order to fix the gauge in a covariant way. This can be done, for instance, with the aid of the gauge-fixing fermion functional

$$\Psi = \int dx \; \bar{c}(-\alpha b + \partial^\mu A_\mu), \tag{2.8}$$

with α being a parameter. The vacuum functional is defined by[5,9]

$$Z_\Psi = \int [dA_\mu][d\bar{c}][dc][db][dA^*_\mu][d\overline{c^*}][dc^*] \delta\left[\phi^* - \frac{\delta\Psi}{\delta\phi}\right] \exp\{iS\}. \tag{2.9}$$

The action S is given by (2.7) and ϕ is generically referring to gauge and ghost fields. After functionally integrating over the antifields as well as over the auxiliary field b, we arrive at

$$\bar{S}[J] = \int d^4x \left[-\frac{1}{4} F_{\mu\nu}\left(1 + \frac{m^2}{\Box}\right) F^{\mu\nu} - \partial_\mu \bar{c} \partial^\mu c + \frac{1}{2\alpha} (\partial^\mu A_\mu)^2 + J_\mu A^\mu \right], \tag{2.10}$$

where we have introduced an external source J^μ in order to calculate the propagator. This can be directly obtained by a straightforward calculation. The result, written in momentum space, is

$$K^{\mu\nu} = -\frac{1}{k^2 + m^2} \left[\eta^{\mu\nu} + \left(\frac{\alpha - 1}{k^2} + \frac{m^2}{k^4} \right) k^\mu k^\nu \right]. \tag{2.11}$$

We notice that there is actually a mass pole at $k_0^2 = \vec{k}^2 + m^2$.

In Sec. III we are going to see how this and other features appear in terms of a canonical quantization procedure.

III. CANONICAL QUANTIZATION

Let us consider the Lagrangian for vector fields of Eq. (2.10),

$$\mathcal{L} = -\frac{1}{4} F_{\mu\nu}\left(1 + \frac{m^2}{\Box}\right) F^{\mu\nu} - \frac{1}{2\alpha} (\partial^\mu A_\mu)^2. \tag{3.1}$$

To implement the process of canonical quantization for such system, it is necessary to obtain the canonical momenta. So, we have to isolate the time derivatives from the nonlocal operator $\Box^{-1}$. We then conveniently write

$$\frac{1}{\Box} = -(\nabla^2 - \partial_t^2)^{-1} = -\frac{1}{\nabla^2} - \frac{\partial_t^2}{\nabla^4} - \frac{\partial_t^4}{\nabla^6} - \cdots . \tag{3.2}$$

As one observes, the system described by (3.1) is effectively a system with an infinite number of time derivatives and consequently it contains an infinite number of momenta.[10,11] A practical way of obtaining the momentum expressions is to consider the variation of the action by fixing the fields and their velocities at just one of the extreme times, say, $\delta A_\mu(\vec{x},t_0)=0=\delta\dot{A}_\mu(\vec{x},t_0)=\delta\ddot{A}_\mu(\vec{x},t_0)=\cdots$. After some algebraic calculation, we get (please, see Appendix A)

$$\begin{aligned}\delta\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\mathcal{L}=&\int_{t_0}^{t}d\tau\int d^3\vec{x}\left[\left(1+\frac{m^2}{\Box}\right)\partial^\mu F_{\mu\nu}+\frac{1}{\alpha}\,\partial_\mu\partial_\nu A^\mu\right]\delta A^\nu-\int d^3\vec{x}\left[\left(1+\frac{m^2}{\Box}\right)F_{0\nu}\right.\\&\left.+\frac{m^2}{2\Box}\,\frac{\partial^i}{\nabla^2}\,\dot{F}_{i\nu}+\frac{1}{\alpha}\,\partial_\mu A^\mu\eta_{0\nu}\right]\delta A^\nu+\frac{m^2}{2}\int d^3\vec{x}\,\frac{1}{\Box}\,\frac{\partial^\mu}{\nabla^2}\,F_{\mu\nu}\delta\dot{A}^\nu\\&-\frac{m^2}{2}\int d^3\vec{x}\,\frac{1}{\Box}\left(\frac{1}{\nabla^2}\,F_{0\nu}+\frac{\partial^i}{\nabla^4}\,\dot{F}_{i\nu}\right)\delta\ddot{A}^\nu+\frac{m^2}{2}\int d^3\vec{x}\,\frac{1}{\Box}\,\frac{\partial^\mu}{\nabla^4}\,F_{\mu\nu}\delta\dddot{A}^\nu+\cdots\;.\end{aligned}\tag{3.3}$$

The coefficient of δA^ν in the first term is the equation of motion, namely,

$$\left(1+\frac{m^2}{\Box}\right)\partial^\mu F_{\mu\nu}+\frac{1}{\alpha}\,\partial_\mu\partial_\nu A^\mu=0.\tag{3.4}$$

In the remaining terms, the coefficients of δA^ν, $\delta\dot{A}^\nu$, $\delta\ddot{A}^\nu$, etc., are the canonical momentum conjugate to A^ν, $\dot{A}^\nu$, $\ddot{A}^\nu$, etc. Denoting these momenta by π_ν, $\pi_\nu^{(1)}$, $\pi_\nu^{(2)}$, etc., we have

$$\begin{aligned}\pi_\nu&=-\left(1+\frac{m^2}{\Box}\right)F_{0\nu}-\frac{m^2}{2\Box}\,\frac{\partial^i}{\nabla^2}\,\dot{F}_{i\nu}-\frac{1}{\alpha}\,\partial_\mu A^\mu\eta_{0\nu},\\ \pi_\nu^{(1)}&=\frac{m^2}{2\Box}\,\frac{\partial^\mu}{\nabla^2}\,F_{\mu\nu},\\ \pi_\nu^{(2)}&=-\frac{m^2}{2\Box}\,\frac{1}{\nabla^2}\left(F_{0\nu}+\frac{\partial^i}{\nabla^2}\,\dot{F}_{i\nu}\right),\\ \pi_\nu^{(3)}&=\frac{m^2}{2\Box}\,\frac{\partial^\mu}{\nabla^4}\,F_{\mu\nu},\\ \pi_\nu^{(4)}&=-\frac{m^2}{2\Box}\,\frac{1}{\nabla^4}\left(F_{0\nu}+\frac{\partial^i}{\nabla^2}\,\dot{F}_{i\nu}\right),\\ &\;\vdots\,.\end{aligned}\tag{3.5}$$

Systems with higher derivatives have fields and their velocities as independent coordinates. For example, a system with two derivatives has its fields (denoting them generically by ϕ) and their velocities $\dot{\phi}$ as independent coordinates. If there are no constraints in the theory, the Poisson brackets (PB) are the bridge to the quantum commutator. Thus, we must have $[\phi,\dot{\phi}]=0$. The commutators that might not be zero are those (in this example with two derivatives) involving ϕ and $\dot{\phi}$ with the higher derivatives $\ddot{\phi}$ and $\dddot{\phi}$.[11]

The problem that comes out in the system we are studying is that there is an infinite number of time derivatives and it is not clear *a priori* which commutators are not zero. In order to try to figure them out we take the Lagrangian (3.1), expanded in t derivatives, until a certain limit order n and at the end we let n go to infinity. Let us then consider the expansion (3.2) until ∂_t^2, which is the first nontrivial order,

$$\mathcal{L}_3=-\frac{1}{4}\,F_{\mu\nu}F^{\mu\nu}+\frac{m^2}{4}\,F_{\mu\nu}\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{1}{\nabla^2}\,F^{\mu\nu}-\frac{1}{2\alpha}\,(\partial_\mu A^\mu)^2.\tag{3.6}$$

The equation of motion and the momenta are given by

$$\partial^\mu F_{\mu\nu} - m^2\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{\partial^\mu}{\nabla^2}F_{\mu\nu} + \frac{1}{\alpha}\,\partial_\mu\partial_\nu A^\mu = 0, \tag{3.7}$$

$$\pi_\nu = -F_{0\nu} + m^2\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{1}{\nabla^2}F_{0\nu} + \frac{m^2}{2}\,\frac{\partial^i\partial_t}{\nabla^4}F_{i\nu} - \frac{1}{\alpha}\,\eta_{0\nu}\partial_\mu A^\mu, \tag{3.8}$$

$$\pi_\nu^{(1)} = -\frac{m^2}{2}\,\frac{\partial^\mu}{\nabla^4}F_{\mu\nu}, \tag{3.9}$$

$$\pi_\nu^{(2)} = \frac{m^2}{2}\,\frac{1}{\nabla^4}F_{0\nu}. \tag{3.10}$$

In this order, the phase-space coordinate is given by $(A_\mu, \pi^\nu)\oplus(\dot{A}_\mu, \pi^{(1)\nu})\oplus(\ddot{A}_\mu, \pi^{(2)\nu})$. We thus observe that relations (3.9) and (3.10) are constraints, as well as the zero component of π_ν. The fundamental nonvanishing PB are

$$\begin{aligned}
&\{A_\mu(\vec{x},t), \pi^\nu(\vec{y},t)\} = \delta_\mu^\nu\,\delta(\vec{x}-\vec{y}),\\
&\{\dot{A}_\mu(\vec{x},t), \pi^{(1)\nu}(\vec{y},t)\} = \delta_\mu^\nu\,\delta(\vec{x}-\vec{y}),\\
&\{\ddot{A}_\mu(\vec{x},t), \pi^{(2)\nu}(\vec{y},t)\} = \delta_\mu^\nu\,\delta(\vec{x}-\vec{y}).
\end{aligned} \tag{3.11}$$

In order to calculate the PB matrix of the constraints, it is convenient to develop them separating all the velocities. The result is

$$T_0 = \pi_0 + \left(\frac{1}{\alpha} + \frac{m^2}{2\nabla^2}\right)\dot{A}_0 + \frac{m^2}{2\nabla^4}\,\partial^i\ddot{A}_i + \frac{1}{\alpha}\,\partial_i A^i, \tag{3.12}$$

$$T_\nu^{(1)} = \pi_\nu^{(1)} - \frac{m^2}{2\nabla^4}\,[\nabla^2 A_\nu + \delta_\nu^0\partial_i\dot{A}^i - \delta_\nu^i(\ddot{A}_i - \partial_i\dot{A}_0 - \partial_i\partial_j A^j)], \tag{3.13}$$

$$T_\nu^{(2)} = \pi_\nu^{(2)} + \delta_\nu^i\,\frac{m^2}{2\nabla^4}\,(\partial_i A_0 - \dot{A}_i). \tag{3.14}$$

We observe that the last constraint for $\nu=0$ becomes $T_0^{(2)} = \pi_0^{(2)}$. We also observe that the other constraints do not contain $\ddot{A}_0$ and consequently the PB matrix for the constraints above will be singular (in fact, $\ddot{A}_0$ does not play any role in the theory). Thus, instead of the constraint (3.14), we take

$$T_i^{(2)} = \pi_i^{(2)} + \frac{m^2}{2\nabla^4}\,(\partial_i A_0 - \dot{A}_i). \tag{3.15}$$

The PB matrix of the constraints reads

$$S=\begin{pmatrix} 0 & m^2\delta_0^\nu\left(\frac{1}{\alpha}+\frac{1}{\nabla^2}\right) & m^2\,\frac{\partial^j}{\nabla^4} \\ -m^2\delta_\mu^0\left(\frac{1}{\alpha}+\frac{1}{\nabla^2}\right) & -m^2(\delta_\mu^0\eta^{k\nu}+\delta_\mu^k\eta^{0\nu})\,\frac{\partial_k}{\nabla^4} & m^2\delta_\mu^j\,\frac{1}{\nabla^4} \\ m^2\,\frac{\partial_1}{\nabla^4} & -m^2\delta_i^\nu\,\frac{1}{\nabla^4} & 0 \end{pmatrix}\delta(\vec{x}-\vec{y}). \tag{3.16}$$

Since this matrix involves space and time indices separately, the calculation of its inverse requires some care. The details of the calculation are presented in Appendix B. The result reads

$$S^{-1}=\begin{pmatrix} 0 & -\alpha\delta_0^\nu & \alpha\partial^j \\ \alpha\delta_\mu^0 & -\alpha(\delta_\mu^0\delta_k^\nu\partial^k+\delta_\mu^k\delta_0^\nu\partial_k) & -\delta_\mu^k\left(\delta_k^j\,\frac{\nabla^4}{m^2}-\alpha\partial_k\partial^j\right) \\ \alpha\partial_i & \delta_k^\nu\left(\delta_i^k\,\frac{\nabla^4}{m^2}-\alpha\partial^k\partial_i\right) & 0 \end{pmatrix}\delta(\vec{x}-\vec{y}). \tag{3.17}$$

With this inverse, we directly obtain the following Dirac brackets (DB):[12]

$$\begin{aligned} \{\dot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)\}_D&=\alpha\delta_\mu^0\delta_0^\nu\delta(\vec{x}-\vec{y}),\\ \{\ddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)\}_D&=\alpha\delta_\mu^i\delta_0^\nu\partial_i\delta(\vec{x}-\vec{y}). \end{aligned} \tag{3.18}$$

The bracket $\{\dddot{A}_\mu,A^\nu\}$ is obtained from $\{\pi_\mu,A^\nu\}$. The result is

$$\{\dddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)\}=-\delta_\mu^\nu\,\frac{\nabla^4}{m^2}\,\delta(\vec{x}-\vec{y}). \tag{3.19}$$

The commutators follow directly from expressions (3.18) and (3.19), i.e.,

$$\begin{aligned} [\dot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]&=i\alpha\delta_\mu^0\delta_0^\nu\delta(\vec{x}-\vec{y}),\\ [\ddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]&=i\alpha\delta_\mu^i\delta_0^\nu\partial_i\delta(\vec{x}-\vec{y}),\\ [\dddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]&=-i\delta_\mu^\nu\,\frac{\nabla^4}{m^2}\,\delta(\vec{x}-\vec{y}). \end{aligned} \tag{3.20}$$

It might be opportune and instructive to call our attention to the following fact. We notice that from the first commutator above we get $[\dot{A}_i(\vec{x},t),A^j(\vec{y},t)]=0$. Since there is no dependence of this result with the mass parameter m, it may appear that there is a conflict with the limit case when $m\to 0$, where the Maxwell theory is obtained. We know that this commutator is not zero in the Maxwell theory. What happens is that in the limit of $m\to 0$, the structure of constraints is not the same as in the massful case, and consequently, the results we obtain in one sector cannot be kept in the other. We find it important to explain this point with detail in order to reinforce the formalism we are using. We use Appendix C to do this.

Let us now consider the propagator calculation. One can directly show by using the path integral formalism that the propagator corresponds to the inverse of the operator that appears in the equation of motion. Considering (3.7), we have

$$\left\{\eta_{\mu\nu}\left[1-\left(1+\frac{\partial_t^2}{\nabla^2}\right)\,\frac{m^2}{\nabla^2}\right]\Box+\left[\frac{1}{\alpha}-1+\left(1+\frac{\partial_t^2}{\nabla^2}\right)\,\frac{m^2}{\nabla^2}\right]\partial_\mu\partial_\nu\right\}A^\nu=0. \tag{3.21}$$

This means that the propagator must satisfy the equation

$$\left\{ \eta_{\mu\nu}\left[1-\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{m^2}{\nabla^2}\right]\Box+\left[\frac{1}{\alpha}-1+\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{m^2}{\nabla^2}\right]\partial_\mu\partial_\nu\right\} T(A^\nu(x)A^\rho(x'))=i\,\delta^\rho_\mu\,\delta(\vec{x}-\vec{x}\,'). \tag{3.22}$$

If what we have done until now is consistent, that is to say, if the quantization is embodied in the commutators (3.20), the expression (3.22) ought to be verified. In fact, after a hard algebraic calculation, we show that this actually occurs (see Appendix D for some details).

Let us now consider the Lagrangian with the next term of the expansion of $\Box^{-1}$,

$$\mathcal{L}_4=-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}+\frac{m^2}{4}F_{\mu\nu}\left(1+\frac{\partial_t^2}{\nabla^2}+\frac{\partial_t^4}{\nabla^4}\right)\frac{1}{\nabla^2}F^{\mu\nu}-\frac{1}{2\alpha}(\partial_\mu A^\mu)^2. \tag{3.23}$$

Proceeding as before we obtain the equation of motion

$$\partial^\mu F_{\mu\nu}-m^2\left(1+\frac{\partial_t^2}{\nabla^2}+\frac{\partial_t^4}{\nabla^4}\right)\frac{\partial^\mu}{\nabla^2}F_{\mu\nu}+\frac{1}{\alpha}\partial_\mu\partial_\nu A^\mu=0 \tag{3.24}$$

and the momentum expressions

$$\pi_\nu=-F_{0\nu}+m^2\left(1+\frac{\partial_t^2}{\nabla^2}+\frac{\partial_t^4}{\nabla^4}\right)\frac{1}{\nabla^2}F_{0\nu}+\frac{m^2}{2}\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{\partial^i\partial_t}{\nabla^4}F_{i\nu}-\frac{1}{\alpha}\eta_{0\nu}\partial_\mu A^\mu,$$

$$\pi^{(1)}_\nu=-\frac{m^2}{2}\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{\partial^\mu}{\nabla^4}F_{\mu\nu},\qquad \pi^{(2)}_\nu=\frac{m^2}{2}\left(1+\frac{\partial_t^2}{\nabla^2}\right)\frac{1}{\nabla^4}F_{0\nu}+\frac{m^2}{2}\frac{\partial_t\partial^i}{\nabla^6}F_{i\nu}, \tag{3.25}$$

$$\pi^{(3)}_\nu=-\frac{m^2}{2\nabla^6}\partial^\mu F_{\mu\nu},\qquad \pi^{(4)}_\nu=\frac{m^2}{2\nabla^6}F_{0\nu}.$$

The set of independent constraints is now given by

$$T_0=\pi_0+\frac{1}{\alpha}\partial_i A^i+\left(\frac{m^2}{2\nabla^2}+\frac{1}{\alpha}\right)\dot{A}_0+\frac{m^2}{2}\frac{\partial^i}{\nabla^4}\ddot{A}_i+\frac{m^2}{2\nabla^4}\dddot{A}_0+\frac{m^2}{2}\frac{\partial^i}{\nabla^6}\ddddot{A}_i,$$

$$T^{(1)}_\mu=\pi^{(1)}_\mu-\frac{m^2}{2\nabla^2}\left(A_\mu+\delta^i_\mu\frac{\partial_i\partial_j}{\nabla^2}A^j\right)-\frac{m^2}{2}\delta^0_\mu\frac{\partial^i}{\nabla^4}\dot{A}_i-\frac{m^2}{2}\delta^i_\mu\frac{\partial_i}{\nabla^4}\dot{A}_0-\frac{m^2}{2}\delta^0_\mu\frac{1}{\nabla^4}\ddot{A}_0$$
$$-\frac{m^2}{2}\delta^i_\mu\frac{\partial_i\partial_j}{\nabla^6}\ddot{A}^j-\frac{m^2}{2}\delta^0_\mu\frac{\partial^i}{\nabla^6}\dddot{A}_i-\frac{m^2}{2}\delta^i_\mu\frac{\partial_i}{\nabla^6}\dddot{A}_0+\frac{m^2}{2}\delta^i_\mu\frac{1}{\nabla^6}\ddddot{A}_i,$$

$$T^{(2)}_i=\pi^{(2)}_i+\frac{m^2}{2}\frac{\partial_i}{\nabla^4}A_0+\frac{m^2}{2}\frac{\partial_i\partial_j}{\nabla^6}\dot{A}^j+\frac{m^2}{2}\frac{\partial_i}{\nabla^4}\ddot{A}_0-\frac{m^2}{2\nabla^6}\dddot{A}_i, \tag{3.26}$$

$$T^{(3)}_i=\pi^{(3)}_i-\frac{m^2}{2\nabla^4}A_i-\frac{m^2}{2}\frac{\partial_i\partial_j}{\nabla^6}A^j-\frac{m^2}{2}\frac{\partial_i}{\nabla^6}\dot{A}_0+\frac{m^2}{2\nabla^6}\ddot{A}_i,$$

$$T^{(4)}_i=\pi^{(4)}_i+\frac{m^2}{2}\frac{\partial_i}{\nabla^6}A_0-\frac{m^2}{2\nabla^6}\dot{A}^i,$$

where, as before, velocities were conveniently separated. In the last constraint, we have not considered the index $\mu=0$ because there is no other term involving $\ddot{\ddot{A}}_0$. We have not also considered the zero components of $T_\mu^{(2)}$ and $T_\mu^{(3)}$ because these components do not constitute independent constraints.

With these constraints, we calculate the DB involving fields and their velocities, in the same way we have done in the previous approximation. The quantization of the present approximation is expressed by the following commutators:

$$\begin{gathered}
[\dot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=i\alpha\delta_\mu^0\delta_0^\nu\delta(\vec{x}-\vec{y}),\\
[\ddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=i\alpha\delta_\mu^k\delta_0^\nu\partial_k\delta(\vec{x}-\vec{y}),\\
[\dddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=0,\quad [\ddot{\ddot{A}}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=0,\\
[\overset{(v)}{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=-i\delta_\mu^\nu\frac{\nabla^6}{m^2}\,\delta(\vec{x}-\vec{y}),
\end{gathered}\tag{3.27}$$

where $\overset{(v)}{A}_\mu$ stands for five time derivatives over A_μ. Using the commutators above, one can also show that the propagator satisfies a similar relation like (3.23) with the operator that appears in the equation of motion (3.25). This shows that the commutators above are also consistent relations.

Now it is not difficult to infer the commutator relations when all the terms of the operator $\Box^{-1}$ are taken into account. These are given by

$$\begin{gathered}
[\dot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=i\alpha\delta_\mu^0\delta_0^\nu\delta(\vec{x}-\vec{y}),\\
[\ddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=i\alpha\delta_\mu^k\delta_0^\nu\partial_k\delta(\vec{x}-\vec{y}),\\
[\dddot{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=0,\\
[\ddot{\ddot{A}}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=0,\\
[\overset{(v)}{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)]=0,\\
\vdots\\
\lim_{n\to\infty}([\overset{(2n-1)}{A}_\mu(\vec{x},t),A^\nu(\vec{y},t)])=-i\delta_\mu^\nu\frac{\nabla^{2n}}{m^2}\,\delta(\vec{x}-\vec{y}).
\end{gathered}\tag{3.28}$$

We see in this way that the canonical structure, despite its nonlocality, is perfectly consistent with the functional procedure, generating propagators for the vectorial theory which display the presence of a massive field. To develop the theory furthermore, trying to construct the Fock space by introducing creation and annihilation operators for the vectorial fields, this seems to be nontrivial. This is so because there is no way, if m does not vanish, to avoid a canonical dependence between the vectorial field and its derivative of order $2n-1$, in the limit when n goes to infinity. We may say that the set of equations (3.28) shows us where the nonlocability problem appears in the process of quantization of these theories.

IV. CONCLUSION

In this work we have considered the quantization of a nonlocal massive vector gauge invariant field theory, which can be effectively obtained from a vector–tensor theory with topological coupling. We have quantized this nonlocal system first by using the BV Lagrangian functional formalism, where the propagator could be obtained without major problems. After that, we have considered its canonical quantization, where the nonlocalibility becomes a more difficult problem to be circumvented. The nonlocalibility manifests itself through the canonical independence, at commutator level, between the gauge field and its derivative of order n, in the limit when n goes to infinity. We have shown, however, that a systematic use of the canonical quantization procedure order by order permitted us to generate the same Greens functions as those obtained from the functional formalism. On the other hand, the Fock space structure seems difficult to be displayed, due to the odd canonical structure generated by the system. As it would be expected, when the mass parameter goes to zero, the tensor and vector sector of the theory decouple, and in the effective vector theory new constraints arise as a consequence of this limit. We have also shown in the Appendix C that a careful analysis of these constraints leads to a canonical structure that is identical to the usual massless gauge theory.

We could argue about the functional Hamiltonian quantization, due to Batalin, Fradkin, and Vilkovisky (BFV),[13] of this nonlocal system. The use of this formalism here appears to be a nontrivial task. Even with the procedure of how to circumvent the infinity number of momenta, we still have an additional problem because velocities have to be considered as independent canonical coordinates in higher derivative systems. Consequently, it is necessary to distinguish in the Hamiltonian path integral formalism what is a time derivative of a coordinate and what is an independent coordinate itself.[14] This problem is presently under study and possible results shall be reported elsewhere.[15]

APPENDIX A: OBTAINMENT OF EQ. (3.3)

Considering the Lagrangian (3.1), we have for a general variation of the corresponding action,

$$\delta\int_{t_0}^{t} d\tau \int d^3\vec{x}\ \mathcal{L} = -\int_{t_0}^{t} d\tau \int d^3\vec{x}\bigg[\frac{1}{2}\,\partial_\mu \delta A_\nu\left(1+\frac{m^2}{\Box}\right)F^{\mu\nu} + \frac{1}{2}\,F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\partial^\mu \delta A^\nu + \frac{1}{\alpha}\,(\partial_\mu A^\mu)\partial_\nu \delta A^\nu\bigg]. \tag{A1}$$

Let us consider each term of the above expression in a separate way. The development of the first term leads to

$$\begin{aligned} -\frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}\ \partial_\mu \delta A_\nu\left(1+\frac{m^2}{\Box}\right)F^{\mu\nu} &= -\frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}\left\{\partial_\mu\left[\delta A_\nu\left(1+\frac{m^2}{\Box}\right)F^{\mu\nu}\right] - \delta A_\nu\left(1+\frac{m^2}{\Box}\right)\partial_\mu F^{\mu\nu}\right\} \\ &= -\frac{1}{2}\int d^3\vec{x}\ \delta A_\nu\left(1+\frac{m^2}{\Box}\right)F^{0\nu} + \frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}\ \delta A_\nu\left(1+\frac{m^2}{\Box}\right)\partial_\mu F^{\mu\nu}. \end{aligned} \tag{A2}$$

For the second term, we have

$$
\begin{aligned}
-\frac{1}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\; F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\partial^\mu\delta A^\nu
&=-\frac{1}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\left\{\partial^\mu\left[F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\delta A^\nu\right]-\partial^\mu F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\delta A^\nu\right\}\\
&=-\frac{1}{2}\int d^3\vec{x}\; F_{0\nu}\left(1+\frac{m^2}{\Box}\right)\delta A^\nu+\frac{1}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\partial^\mu F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\delta A_\nu\\
&=-\frac{1}{2}\int d^3\vec{x}\; F_{0\nu}\delta A^\nu+\frac{1}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\partial^\mu F_{\mu\nu}\delta A^\nu+\frac{m^2}{2}\int d^3\vec{x}\; F_{0\nu}\left(\frac{1}{\nabla^2}+\frac{\partial_t^2}{\nabla^4}+\cdots\right)\delta A^\nu\\
&\quad-\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\,\partial^\mu F_{\mu\nu}\left(\frac{1}{\nabla^2}+\frac{\partial_t^2}{\nabla^4}+\cdots\right)\delta A^\nu, \qquad \text{(A3)}
\end{aligned}
$$

where we have used the expansion (3.2). We observe that in the last term of Eq. (A3), there is an integration over time and an infinite number of time derivatives acting over δA^ν. It is necessary to use some care to deal with these terms. Let us consider some of them separately,

$$
\begin{aligned}
-\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\partial^\mu F_{\mu\nu}\frac{\partial_t^2}{\nabla^4}\,\delta A^\nu
&=-\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\left\{\partial_t\left[\frac{\partial^\mu}{\nabla^4}F_{\mu\nu}\partial_t\partial A^\nu\right]-\frac{\partial_t\partial^\mu}{\nabla^4}F_{\mu\nu}\partial_t\delta A^\nu\right\}\\
&=-\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^4}F_{\mu\nu}\delta\dot{A}^\nu+\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\left\{\partial_t\left[\frac{\partial_t\partial^\mu}{\nabla^4}F_{\mu\nu}\delta A^\nu\right]-\frac{\partial_t^2\partial^\mu}{\nabla^4}F_{\mu\nu}\delta A^\nu\right\}\\
&=-\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^4}F_{\mu\nu}\delta\dot{A}^\nu+\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^4}\dot{F}_{\mu\nu}\delta A^\nu-\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^4}\ddot{F}_{\mu\nu}\delta A^\nu.
\end{aligned}
\qquad \text{(A4)}
$$

In a similar way, we would have for the next term

$$
\begin{aligned}
-\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\partial^\mu F_{\mu\nu}\frac{\partial_t^4}{\nabla^6}\,\delta A^\nu
&=-\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^6}F_{\mu\nu}\delta\dddot{A}^\nu+\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^6}\dot{F}_{\mu\nu}\delta\ddot{A}^\nu-\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^6}\ddot{F}_{\mu\nu}\delta\dot{A}^\nu\\
&\quad+\frac{m^2}{2}\int d^3\vec{x}\;\frac{\partial^\mu}{\nabla^6}\dddot{F}_{\mu\nu}\delta A^\nu-\frac{m^2}{2}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\frac{\partial_t^4}{\nabla^6}\,\partial^\mu F_{\mu\nu}\delta A^\nu, \qquad \text{(A5)}
\end{aligned}
$$

and so on. Introducing these results into the initial expression (A3), we obtain

$$
\begin{aligned}
&-\frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}\, F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\partial^\mu \delta A^\nu \\
&\quad=\frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}\left(1+\frac{m^2}{\Box}\right)\partial^\mu F_{\mu\nu}\delta A^\nu \\
&\qquad+\frac{1}{2}\int d^3\vec{x}\left(-F_{0\nu}+m^2\frac{1}{\nabla^2}F_{0\nu}+m^2\frac{\partial^\mu}{\nabla^4}\dot{F}_{\mu\nu}+\cdots\right)\delta A^\nu \\
&\qquad-\frac{m^2}{2}\int d^3\vec{x}\left(\frac{\partial^\mu}{\nabla^4}F_{\mu\nu}+\frac{\partial^\mu}{\nabla^6}\ddot{F}_{\mu\nu}+\frac{\partial^\mu}{\nabla^8}\ddot{\ddot{F}}_{\mu\nu}+\cdots\right)\delta\dot{A}^\nu \\
&\qquad+\frac{m^2}{2}\int d^3\vec{x}\left(\frac{1}{\nabla^4}F_{0\nu}+\frac{\partial^\mu}{\nabla^6}\dot{F}_{\mu\nu}+\frac{\partial^\mu}{\nabla^8}\dddot{F}_{\mu\nu}+\cdots\right)\delta\ddot{A}^\nu \\
&\qquad-\frac{m^2}{2}\int d^3\vec{x}\left(\frac{\partial^\mu}{\nabla^6}F_{\mu\nu}+\frac{\partial^\mu}{\nabla^8}\ddot{F}_{\mu\nu}+\frac{\partial^\mu}{\nabla^{10}}\ddot{\ddot{F}}_{\mu\nu}+\cdots\right)\delta\dddot{A}^\nu+\cdots. \qquad \text{(A6)}
\end{aligned}
$$

We notice in the expression above that some terms can be put together to reobtain the nonlocal operator $\Box^{-1}$. For example,

$$
\begin{aligned}
\frac{1}{\nabla^2}F_{0\nu}+\frac{\partial^\mu}{\nabla^4}\dot{F}_{\mu\nu}+\frac{\partial^\mu}{\nabla^6}\dddot{F}_{\mu\nu}+\cdots&=\left(\frac{1}{\nabla^2}+\frac{\partial_t^2}{\nabla^4}+\cdots\right)F_{0\nu}+\left(\frac{1}{\nabla^4}+\frac{\partial_t^2}{\nabla^6}+\cdots\right)\partial^i\dot{F}_{i\nu} \\
&=-\frac{1}{\Box}F_{0\nu}-\frac{1}{\nabla^2}\frac{\partial^i}{\Box}\dot{F}_{i\nu}, \qquad \text{(A7)}
\end{aligned}
$$

$$
\frac{\partial^\mu}{\nabla^4}F_{\mu\nu}+\frac{\partial^\mu}{\nabla^6}\ddot{F}_{\mu\nu}+\frac{\partial^\mu}{\nabla^8}\ddot{\ddot{F}}_{\mu\nu}+\cdots=-\frac{1}{\nabla^2}\frac{\partial^\mu}{\Box}F_{\mu\nu} \qquad \text{(A8)}
$$

and so on. Using these results into (A6), we obtain the final form of the second term of (A1),

$$
\begin{aligned}
&-\frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}F_{\mu\nu}\left(1+\frac{m^2}{\Box}\right)\partial^\mu \delta A^\nu \\
&\quad=\frac{1}{2}\int_{t_0}^{t} d\tau \int d^3\vec{x}\left(1+\frac{m^2}{\Box}\right)\partial^\mu F_{\mu\nu}\delta A^\nu \\
&\qquad-\frac{1}{2}\int d^3\vec{x}\left[\left(1+\frac{m^2}{\Box}\right)F_{0\nu}+\frac{m^2}{\nabla^2}\frac{\partial^i}{\Box}F_{i\nu}\right]\delta A^\nu+\frac{m^2}{2}\int d^3\vec{x}\,\frac{1}{\nabla^2}\frac{\partial^\mu}{\Box}F_{\mu\nu}\delta\dot{A}^\nu \\
&\qquad-\frac{m^2}{2}\int d^3\vec{x}\left(\frac{1}{\nabla^2}\frac{1}{\Box}F_{0\nu}+\frac{1}{\nabla^4}\frac{\partial^i}{\Box}\dot{F}_{i\nu}\right)\delta\ddot{A}^\nu \\
&\qquad+\frac{m^2}{2}\int d^3\vec{x}\,\frac{1}{\nabla^4}\frac{\partial^\mu}{\Box}F_{\mu\nu}\delta\dddot{A}^\nu+\cdots. \qquad \text{(A9)}
\end{aligned}
$$

We finally consider the last term of expression (A1),

$$-\frac{1}{\alpha}\int_{t_0}^{t}d\tau\int d^3\vec{x}\;\partial_\mu A^\mu\partial_\nu\delta A^\nu=-\frac{1}{\alpha}\int_{t_0}^{t}d\tau\int d^3\vec{x}[\partial_\nu(\partial_\mu A^\mu\delta A^\nu)-\partial_\nu\partial_\mu A^\mu A^\nu]$$
$$=-\frac{1}{\alpha}\int d^3\vec{x}\;\partial_\mu A^\mu\delta A^0+\frac{1}{\alpha}\int_{t_0}^{t}d\tau\int d^3\vec{x}\partial_\nu\partial_\mu A^\mu\delta A^\nu. \tag{A10}$$

Introducing the results given by expressions (A2), (A9) and (A10) into the initial expression (A1), Eq. (3.3) is obtained.

APPENDIX B: CALCULATION OF THE INVERSE OF THE MATRIX (3.16)

First we notice that matrix (3.16) has the following block structure:

$$S=\begin{pmatrix}(1\times1) & (1\times4) & (1\times3)\\ (4\times1) & (4\times4) & (4\times3)\\ (3\times1) & (3\times4) & (3\times3)\end{pmatrix}. \tag{B1}$$

Of course, since the inverse S^{-1} has the same block structure, we consider it is generically given by

$$S^{-1}=\begin{pmatrix}A & B^\rho & C^k\\ D_\nu & E^\rho_\nu & F^k_\nu\\ G_j & H^\rho_j & I^k_j\end{pmatrix}. \tag{B2}$$

We then must have

$$\int d^3\vec{y}\;S(\vec{x},\vec{y})S^{-1}(\vec{y}-\vec{z})=\begin{pmatrix}1 & 0 & 0\\ 0 & \delta^\rho_\mu & 0\\ 0 & 0 & \delta^k_j\end{pmatrix}\delta(\vec{x}-\vec{z}). \tag{B3}$$

The combination of Eqs. (3.16), (B2), and (B3) gives us the following set of equations (after integrating over the intermediary variable $\vec{y}$ and summing on mudding indices):

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)D_0+\frac{m^2}{\nabla^4}\;\partial^jG_j=\delta(\vec{x}-\vec{z}),$$

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)E^\rho_0+\frac{m^2}{\nabla^4}\;\partial^jH^\rho_j=0, \tag{B4}$$

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)F^k_0+\frac{m^2}{\nabla^4}\;\partial^jI^k_j=0,$$

$$\delta^0_\mu\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)A+\delta^0_\mu\,\frac{m^2}{\nabla^4}\,\partial_jD^j+\delta^j_\mu\,\frac{m^2}{\nabla^4}\,\partial_jD^0-\delta^j_\mu\,\frac{m^2}{\nabla^4}\,G_j=0,$$

$$\delta^0_\mu\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)B^\rho+\delta^0_\mu\,\frac{m^2}{\nabla^4}\,\partial_jE^\rho_j+\delta^j_\mu\,\frac{m^2}{\nabla^4}\,\partial_jE^\rho_0-\delta^j_\mu\,\frac{m^2}{\nabla^4}\,H^\rho_j=\delta^\rho_\mu\delta(\vec{x}-\overline{y}), \tag{B5}$$

$$\delta^0_\mu\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)C^k+\delta^0_\mu\,\frac{m^2}{\nabla^4}\,\partial_jF^k_j+\delta^j_\mu\,\frac{m^2}{\nabla^4}\,\partial_jF^k_0-\delta^j_\mu\,\frac{m^2}{\nabla^4}\,I^k_j=0,$$

$$\partial_iA-D_i=0,$$

$$\partial_iB^\rho-E^\rho_i=0, \tag{B6}$$

$$\partial_iC^k-F^k_i=\frac{\nabla^4}{m^2}\,\delta^k_i\,\delta(\vec{x}-\vec{z}),$$

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)A+\frac{m^2}{\nabla^4}\,\partial^jD_j=0,$$

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)B^0+\frac{m^2}{\nabla^4}\,\partial^jE^0_j=-\,\delta(\vec{x}-\vec{z}),$$

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)B^k+\frac{m^2}{\nabla^4}\,\partial^jE^k_j=0,$$

$$\left(\frac{m^2}{\nabla^2}+\frac{1}{\alpha}\right)C^k+\frac{m^2}{\nabla^4}\,\partial^jF^k_j=0,$$

$$\partial_iE^0_0-H^0_i=0, \tag{B7}$$

$$\partial_iE^k_0-H^k_i=-\,\frac{\nabla^4}{m^2}\,\delta^k_i\,\delta(\vec{x}-\vec{z}),$$

$$\partial_iD_0-G_i=0,$$

$$\partial_iF^k_0-I^k_i=0.$$

The inverse S^{-1} is obtained by solving these equations. This is just a matter of algebraic work and the solution is

$$A=0,$$

$$B^0=-\,\alpha\,\delta(\vec{x}-\vec{z}),$$

$$B^k=0,$$

$$C^k=\alpha\,\partial^k\,\delta(\vec{x}-\vec{z}),$$

$$D_0=\alpha\,\delta(\vec{x}-\vec{z}),$$

$$D_i=0,$$

$$
\begin{aligned}
&E_0^0=0,\\
&E_i^0=-\alpha\partial_i\delta(\vec{x}-\vec{z}),\\
&E_0^k=-\alpha\partial^k\delta(\vec{x}-\vec{z}),\\
&E_i^k=0,\\
&F_0^k=0,\\
&F_i^k=\left(\alpha\partial_i\partial^k-\delta_i^k\,\frac{\nabla^4}{m^2}\right)\delta(\vec{x}-\vec{z}),\\
&G_j=\alpha\partial_j\delta(\vec{x}-\vec{z}),\\
&H_j^0=0,\\
&H_j^k=-\left(\alpha\partial_j\partial^k-\delta_j^k\,\frac{\nabla^4}{m^2}\right)\delta(\vec{x}-\vec{z}),\\
&I_j^k=0.
\end{aligned}
\tag{B8}
$$

These are the elements of the matrix S^{-1} given by (3.17).

APPENDIX C: LIMIT $m\to 0$ OF EXPRESSION (3.5)

When we take the limit $m\to 0$ in expressions (3.5), we get the following expressions for the momenta:

$$
\begin{aligned}
&\pi_\nu=-F_{0\nu}-\frac{1}{\alpha}\,\eta_{0\nu}\partial_\mu A^\mu,\\
&\pi_\nu^{(1)}=0.
\end{aligned}
\tag{C1}
$$

The remaining momenta (which are all zero) do not make sense to be considered because in the limit $m\to 0$ the system does not have infinite derivatives anymore. We observe that relations (C1) are constraints. So, the commutators cannot come from the PB of A_μ and $\dot{A}^\nu$, that is actually zero, but from the Dirac one. Let us calculate the DB of A_μ and $\dot{A}_\nu$. First, we need the PB matrix of the constraints. We denote these constraints by

$$
\begin{aligned}
&T_{1\mu}=\pi_\mu+F_{0\mu}+\frac{1}{\alpha}\,\eta_{0\mu}\partial_\nu A^\nu,\\
&T_{2\mu}=\pi_\mu^{(1)}.
\end{aligned}
\tag{C2}
$$

Thus,

$$
(S^{\mu\nu})=\begin{pmatrix}\{T_1^\mu,T_1^\nu\} & \{T_1^\mu,T_2^\nu\}\\ \{T_2^\mu,T_1^\nu\} & \{T_2^\mu,T_2^\nu\}\end{pmatrix}=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\left(\eta^{\mu\nu}+\frac{1-\alpha}{\alpha}\,\eta^{0\mu}\eta^{0\nu}\right)\delta(\vec{x}-\vec{y}). \tag{C3}
$$

To calculate the DB we need the inverse of the matrix above. This is given by

$$(S_{\mu\nu})^{-1}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}(\eta_{\mu\nu}+(\alpha-1)\eta_{0\mu}\eta_{0\nu})\,\delta(\vec{x}-\vec{y}). \tag{C4}$$

Now, the DB can be directly calculated. The result is

$$\{A_\mu(\vec{x},t),\dot{A}^\nu(\vec{y},t)\}=-(\delta_\mu^\nu+(\alpha-1)\eta_{0\mu}\delta_0^\nu)\,\delta(\vec{x}-\vec{y}). \tag{C5}$$

The commutator between A_i and $\dot{A}^j$ can be directly obtained from the DB above and it is actually nonzero when $m\to 0$, which makes consistent the procedure we are developing.

APPENDIX D: VERIFICATION OF THE IDENTITY (3.22)

Considering that

$$T(A^\nu(x)A^\rho(x'))=\theta(t-t')A^\nu(x)A^\rho(x')+\theta(t'-t)A^\rho(x')A^\nu(x) \tag{D1}$$

and using the commutators given by expression (3.20) we can obtain the following relations:

$$\begin{gathered}
\frac{\partial^2}{\partial t^2}\,T(A^\nu(x)A^\rho(x'))=i\alpha\delta_0^\nu\eta^{0\rho}\delta(x-x')+T(\ddot{A}^\nu(x)A^\rho(x')),\\
\nabla^2T(A^\nu(x)A^\rho(x'))=T(\nabla^2A^\nu(x)A^\rho(x')),\\
\Box T(A^\nu(x)A^\rho(x'))=i\alpha\delta_0^\nu\eta^{0\rho}\delta(x-x')+T(\Box A^\nu(x)A^\rho(x')),\\
\frac{1}{\nabla^2}\,\Box T(A^\nu(x)A^\rho(x'))=i\alpha\delta_0^\nu\eta^{0\rho}\,\frac{1}{\nabla^2}\,\delta(x-x')+T\left(\frac{1}{\nabla^2}\,\Box A^\nu(x)A^\rho(x')\right),\\
\frac{\partial_t^2}{\nabla^2}\,\Box T(A^\nu(x)A^\rho(x'))=i\left[\alpha\delta_0^\nu\eta^{0\rho}\,\frac{1}{\nabla^2}\,\Box+\alpha\eta^{\nu i}\delta_0^\rho\,\frac{\partial_t\partial_i}{\nabla^2}-\eta^{\nu\rho}\,\frac{\nabla^2}{m^2}\right]\delta(x-x')\\
+T\left(\frac{\partial_t^2}{\nabla^2}\,\Box A^\nu(x)A^\rho(x')\right),\\
\partial_\mu\partial_\nu T(A^\nu(x)A^\rho(x'))=i\alpha\delta_\mu^0\delta_0^\rho\delta(x-x')+T(\partial_\mu\partial_\nu A^\nu(x)A^\rho(x')),\\
\frac{\partial_\mu\partial_\nu\partial_t^2}{\nabla^4}\,T(A^\nu(x)A^\rho(x'))=i\left[\alpha\delta_\mu^0\delta_0^\rho\,\frac{\partial_t^2}{\nabla^4}+\alpha\delta_\mu^i\delta_0^\rho\,\frac{\partial_i\partial_t}{\nabla^4}-\delta_\mu^0\delta_0^\rho\,\frac{1}{m^2}-\alpha\delta_\mu^0\delta_0^\rho\,\frac{1}{\nabla^2}\right]\delta(x-x')\\
+T\left(\frac{\partial_\mu\partial_\nu\partial_t^2}{\nabla^4}\,A^\nu(x)A^\rho(x')\right).
\end{gathered} \tag{D2}$$

Using the relations above in the left-hand side of Eq. (3.22) we can show that the identity is actually satisfied.

(Received 10 August 1998; accepted for publication 28 August 1998)

For a quantum field in a thermal equilibrium state we discuss the group generated by time translations and the modular action associated with an algebra invariant under half-sided translations. The modular flows corresponding to the algebras of the forward light cone and a space-like wedge admit a simple geometric description in two-dimensional models that factorize in light-cone coordinates. At large distances from the domain boundary compared to the inverse temperature, the flow pattern is essentially the same as time translations, whereas the zero temperature results are approximately reproduced close to the edge of the wedge and the apex of the cone. For each domain there is also a one-parameter group with a positive generator, for which the thermal state is a ground state. Formally, this may be regarded as a certain converse of the Unruh effect. © *1999 American Institute of Physics.* [S0022-2488(99)01002-6]

I. INTRODUCTION

Algebraic quantum field theory in the sense of Araki, Haag, and Kastler[1] is concerned with von Neumann algebras $\mathcal{M}(\mathcal{O})$ of observables localized in space time domains $\mathcal{O}$, together with states ω on these algebras satisfying some physical selection criterion. Due to the Reeh–Schlieder property of quantum field theory,[2] one may associate with certain regions $\mathcal{O}$ and states ω the Tomita–Takesaki modular objects $\Delta_{\mathcal{O},\omega}$ and $J_{\mathcal{O},\omega}$.[3,4] The positive operator $\Delta_{\mathcal{O},\omega}$ generates a one-parameter group ad $\Delta^{it}_{\mathcal{O},\omega}$ of automorphisms of $\mathcal{M}(\mathcal{O})$, and the conjugation ad $J_{\mathcal{O},\omega}$ defined by the antiunitary $J_{\mathcal{O},\omega}$ maps $\mathcal{M}(\mathcal{O})$ onto its commutant on the GNS Hilbert space corresponding to ω.

Important structural properties of the theory are encoded in the modular objects (see, e.g., Refs. 5, 6) but an explicit description of $\Delta^{it}_{\mathcal{O},\omega}$ and $J_{\mathcal{O},\omega}$ has so far only been obtained in the following cases with ω a vacuum state.

(a) $\mathcal{O}$ is a space-like wedge and the local algebras are generated by Wightman fields that transform covariantly with a finite-dimensional representation of the Lorentz group.[7,8]
(b) $\mathcal{O}$ is a forward light cone and $\mathcal{M}(\mathcal{O})$ is generated by a massless, noninteracting field.[9]
(c) $\mathcal{O}$ is a double cone and $\mathcal{M}(\mathcal{O})$ is generated by conformally covariant fields.[10]
(d) $\mathcal{O}$ is a space-like wedge and the local algebras are generated by generalized free fields of a certain type that break Lorentz covariance.[11]

In case (a), the modular group is the group of Lorentz boosts that leave the wedge invariant, and the conjugation is the PCT operator (combined with a rotation). Cases (b) and (c) can be reduced to case (a) by a conformal mapping onto the wedge of the forward light cone and the double cone, respectively. In (b) the modular group is the dilation group, and in (c) it consists of the conformal transformations that leave the double cone invariant. In the examples considered in

[a)]Electronic mail: yngvason@Thor.thp.univie.ac.at

(d), the action of the modular group is, in general, nonlocal, i.e., an algebra $\mathcal{M}(\mathcal{O}_1)$ with $\mathcal{O}_1$ a bounded subset of the wedge need not be mapped into an $\mathcal{M}(\mathcal{O}_2)$ with $\mathcal{O}_2$ bounded.

A key to a general understanding of possible geometric interpretations of modular groups is the interplay between the modular action and certain subgroups of the space–time translations. In Ref. 12 it was shown that the modular group of a space-like wedge in a vacuum state acts on the translation group like the Lorentz boosts that leave the wedge invariant. Subsequently, Wiesbrock[13] introduced the concept of a half-sided modular inclusion and proved a certain converse of the results of Ref. 12, namely, that the two-dimensional translation group can be recovered from the modular groups of the wedge and some of its translates.

In this paper we want to investigate the modular groups when ω is a thermodynamic equilibrium state (KMS state) rather than a vacuum state. In Sec. II we discuss the generalizations of the results of Ref. 12 to KMS states. We investigate the commutation relations between the time translations and the modular group in a KMS state for any domain that is mapped into itself under half-sided time translations. Using the results of Ref. 6 we prove that the time translations and modular action together give rise to a representation of the abstract Lie group generated by one-dimensional dilations and translations. The important observation that half-sided modular actions always lead to a representation of this group was first made by Wiesbrock.[13,14] We express all its one-parameter subgroups in terms of the translations and the modular group. Of particular interest is a subgroup with a positive generator. This group acts on the global observable algebra for positive values of the group parameter.

The group relations alone do not determine the modular action and the group with a positive generator, but they put definite restrictions on the possible disclocalization of observables by the group actions. More precisely, if $\mathcal{N}$ denotes the observable algebra of a domain invariant under half-sided translations and $\mathcal{N}(t)$ its time translate by t, then the modular group $\Delta_{\mathcal{N}}^{iu}$ of $\mathcal{N}$ transforms $\mathcal{N}(t)$ into $\mathcal{N}(\varphi(u,t))$ with a certain function $\varphi(u,t)$. Likewise, the group with a positive generator transforms $\mathcal{N}(t)$ into $\mathcal{N}(\psi(\tau,t))$, where ψ is another function of t and the group parameter τ. The precise statements are given in Theorem 2.1. We also discuss the action of $\Delta_{\mathcal{N}}^{iu}$ on individual observables in $\mathcal{N}(t)$ for t large and show that, in a sense made precise in Theorems 2.2 and 2.3, this action approximates a time translation by $-\beta u$ as $t/\beta \to \infty$.

In Sec. III we consider two-dimensional (2-D) models that factorize in the light-cone coordinates. Applying the results of the previous section to the algebras on each of the light rays, one obtains a geometric description of the actions of the groups associated with the forward light cone and a space-like wedge. In the case of the forward light cone, the algebra of a translated light cone is mapped into another such algebra. An analogous statement holds for the wedge. The flow patterns are illustrated in Figs. 1 and 2. Close to the apex of the light cone and the edge of the wedge the action of the modular flow is essentially the same as for the zero temperature case, i.e., dilations for the forward light cone and Lorentz boosts for the wedge. On the other hand, at large distances from the domain boundary compared to the inverse temperature the modular flow approaches the dynamical flow, i.e., the time translations.

The one-parameter unitary group with a positive generator associated with the forward light cone, which in the limiting case of zero temperature reduces to time translations, approximates the dynamical flow close to the apex of the light cone. It corresponds everywhere to a decelerated movement toward the origin in the space variable (Fig. 3). Formally at least, this may be regarded as a reverse Unruh effect:[15–17] In the latter the vacuum appears as a KMS state with respect to a dynamics that accelerates points toward light-like infinity; here a KMS state appears as a vacuum state with respect to a dynamics that moves points from light-like infinity toward the origin of space.

For the wedge there is also a unitary group with a positive generator, which has the KMS state as a ground state. This group operates on the observables for a restricted parameter range. It approximates the time translations close to the space axis and light-like translations far away from the space axis. The action of this group is illustrated in Fig. 4. This action may also be interpreted as a kind of reverse Unruh effect, because here the acceleration is away from the wedge, whereas in the usual Unruh effect the acceleration points in the direction of the wedge.

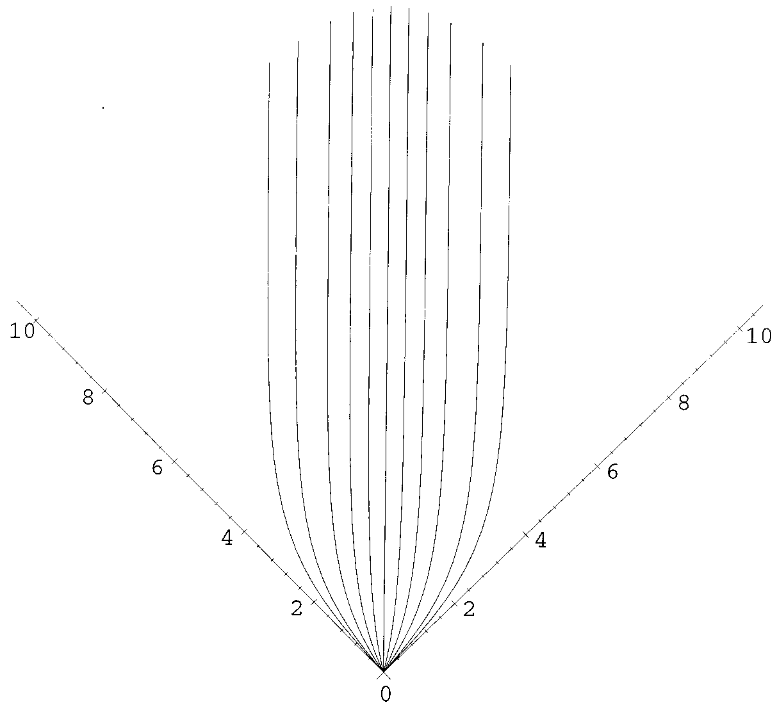

FIG. 1. The modular flow in the forward light cone. The unit is inverse temperature, β.

In Sec. IV we compute explicitly the modular groups and the groups with a positive generator for a quasifree KMS state on the Weyl algebra of a generalized free field in 2-D space time that factorizes in light-cone coordinates. For a field of minimal scaling dimension one obtains a strengthening of the general results of the previous section on the group actions: A local algebra $\mathcal{M}(\mathcal{O})$ with $\mathcal{O}$ a double cone is transformed into an algebra of the same kind. For fields of higher scaling dimension, however, double cone localization may get lost under the group action, and only a localization in a translated light cone or wedge remains.

II. THE GROUP GENERATED BY TRANSLATIONS AND THE MODULAR ACTION

Let $(\mathcal{A},\alpha_t)$ be a C^*-dynamical system and $\mathcal{B}$ a subalgebra, such that

$$\alpha_t\mathcal{B}\subset\mathcal{B}, \quad \text{for } t\geqslant 0. \tag{2.1}$$

Suppose, furthermore, that the algebra $\cup_{t\in\mathbf{R}}\alpha_t\mathcal{B}$ is norm dense in $\mathcal{A}$. Let ω be a KMS state[18] for the dynamical system $(\mathcal{A},\alpha_t)$ at inverse temperature β and denote by π the corresponding GNS representation of $\mathcal{A}$ with cyclic vector Ω, and by $T(t)$ the unitary implementation of α_t on the GNS Hilbert space $\mathcal{H}$. Put $\mathcal{M}=\pi(\mathcal{A})''$ and $\mathcal{N}=\pi(\mathcal{B})''$.

Because of the analyticity properties of the time translations in a KMS state, the vector Ω is separating for $\mathcal{M}$ and hence also for $\mathcal{N}$. Moreover, Ω is cyclic for $\mathcal{M}$ (by definition), and since $\cup_{t\in\mathbf{R}}\alpha_t\mathcal{B}$ is dense in $\mathcal{A}$ it follows by a Reeh–Schlieder-type argument that Ω is also cyclic for $\mathcal{N}$.

Let $\Delta_{\mathcal{M}}$ and $J_{\mathcal{M}}$ be the modular objects corresponding to Ω and $\mathcal{M}$. We have

$$\Delta_{\mathcal{M}}^{\mathrm{is}}=T(-\beta s), \tag{2.2}$$

where the sign is a consequence of different conventions in physics and mathematics: For $A\in\mathcal{M}$ the expression $T(t)A\Omega$ has an analytic continuation into the strip $S(0,\beta/2)$, where

$$S(a,b):=\{z\in\mathbb{C}:a<\mathrm{Im}\, z<b\}, \tag{2.3}$$

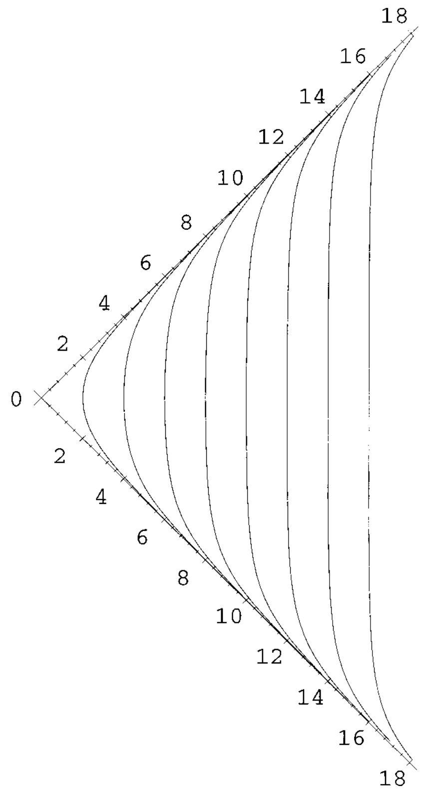

FIG. 2. The modular flow in a space-like wedge.

while $\Delta_{\mathcal{M}}^{is}A\Omega$ has an analytic continuation into $S(-1/2,0)$, by the sign convention in modular theory. Since $J_{\mathcal{M}}\Delta_{\mathcal{M}}^{1/2}A\Omega = A^*\Omega$, it follows from (2.2) that

$$T(t+i\beta)A\Omega = J_{\mathcal{M}}T(t)A^*\Omega. \tag{2.4}$$

By assumption (2.1), we have

$$T(t)\mathcal{N}T(-t)\subset\mathcal{N}, \quad \text{for } t\geqslant 0, \tag{2.5}$$

i.e., we are in the situation of a half-sided translation in the sense of Ref. 12. Because of (2.2) we are also in the situation of a half-sided modular inclusion in the sense of Wiesbrock,[13] i.e.,

$$\Delta_{\mathcal{M}}^{is}\mathcal{N}\Delta_{\mathcal{M}}^{-is}\subset\mathcal{N}, \quad \text{for } s\leqslant 0. \tag{2.6}$$

If $T(t)$ had a positive generator, then (2.5) would imply the well-known relations[12] between $T(t)$ and the modular group $\Delta_{\mathcal{N}}^{iu}$. In a KMS state, however, the spectrum of the Hamiltonian is the whole real axis and the analysis of Ref. 12 has to be generalized. The main results of this generalization are stated in Eqs. (2.20), (2.29), and (2.31) below.

We start with a heuristic discussion of the consequences of (2.6), similar to that in Ref. 13. This discussion disregards questions of domains of unbounded operators, but it leads quickly to the commutation relations between $\Delta_{\mathcal{M}}^{is}$ and $\Delta_{\mathcal{N}}^{iu}$ stated in Ref. 14. A rigorous proof of these relations follows from the results of Ref. 6 and will be given after the discussion.

Since $\mathcal{N}\subset\mathcal{M}$, it follows by standard arguments that $\Delta_{\mathcal{N}}\geqslant\Delta_{\mathcal{M}}$, and this, domain questions aside, implies that

$$G := \log\Delta_{\mathcal{N}} - \log\Delta_{\mathcal{M}} \tag{2.7}$$

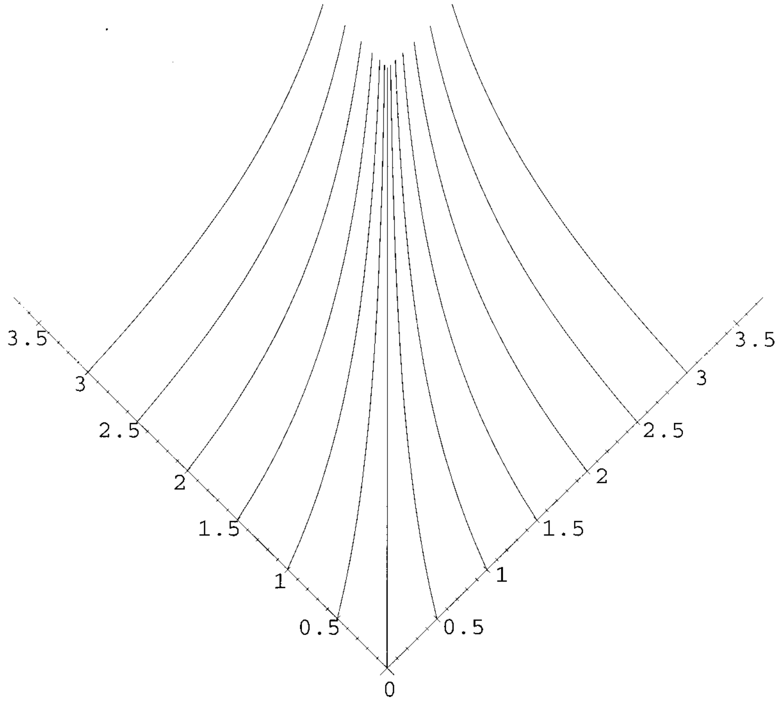

FIG. 3. The flow of $\Gamma_{V^+}(\tau)$ within the forward light cone. The whole pattern is invariant under translations in the x^0 direction.

is a non-negative operator, because log is an operator monotone function. Equations (2.1), (2.2), (2.6), and the Trotter product formula now lead to

$$e^{i\tau G}\mathcal{N}e^{-i\tau G}\subset\mathcal{N}, \quad \text{for} \ \ \tau\geqslant 0. \tag{2.8}$$

Putting $U(\tau):=\exp(i\tau G)$, Eq. (2.8) and $G\geqslant 0$ imply[12]

$$\Delta_{\mathcal{N}}^{iu}U(\tau)\Delta_{\mathcal{N}}^{-iu}=U(e^{-2\pi u}\tau), \tag{2.9}$$

for all τ, $u\in\mathbf{R}$. Hence, we obtain a unitary representation of the two-parameter Lie group $\mathcal{G}$ with elements $(\tau,u)\in\mathbf{R}^2$ and the composition law

$$(\tau,u)\circ(\tau',u')=(\tau+e^{-2\pi u}\tau',u+u'). \tag{2.10}$$

The representation $U(\tau,u)$ corresponding to (2.9) is

$$U(\tau,u):=e^{i\tau G}\Delta_{\mathcal{N}}^{iu}. \tag{2.11}$$

The group $\mathcal{G}$ defined by (2.10) is the semidirect product of $\mathbf{R}$ with itself and is the unique two-dimensional non-Abelian Lie group (''$ax+b$ group''). Some of its properties are discussed in Ref. 19.

For a discussion of the one-parameter subgroups and the Lie algebra of $\mathcal{G}$, it is convenient to realize the group in terms of 2×2 matrices:

$$(\tau,u)\leftrightarrow\begin{pmatrix}1 & \tau\\ 0 & 1\end{pmatrix}\cdot\begin{pmatrix}e^{-2\pi u} & 0\\ 0 & 1\end{pmatrix}=\begin{pmatrix}e^{-2\pi u} & \tau\\ 0 & 1\end{pmatrix}. \tag{2.12}$$

It is straightforward to determine the one-parameter subgroups, $r\mapsto g(r)$ of $\mathcal{G}$. These have the form

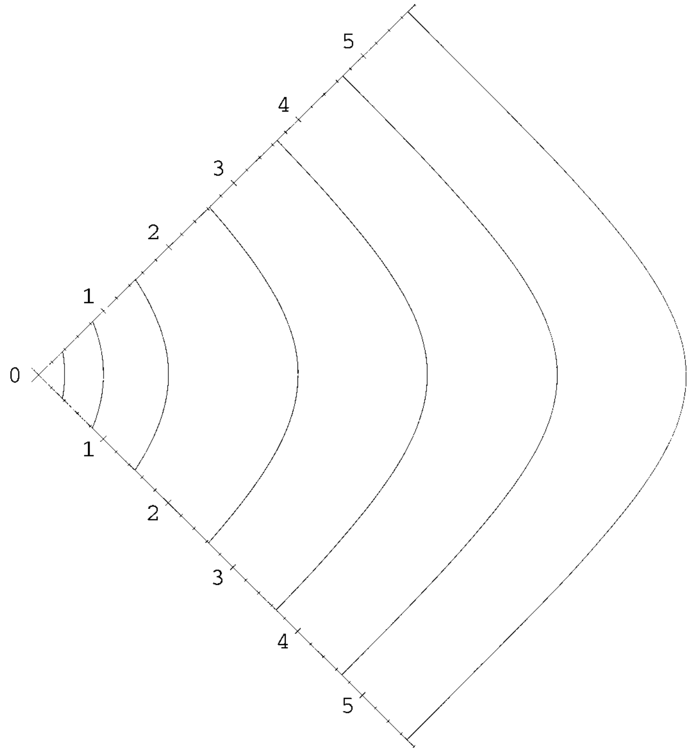

FIG. 4. The flow of $\Gamma_W(\tau)$ in a space-like wedge. The whole pattern is invariant under translations in the x^1 direction.

$$g_{a,b}(r)=\begin{pmatrix} e^{ar} & \frac{b}{a}(e^{ar}-1) \\ 0 & 1 \end{pmatrix}, \tag{2.13}$$

with $a,b\in\mathbf{R}$. In the half-plane $(\tau,e^{-2\pi u})\in\mathbf{R}\times\mathbf{R}_+$, these correspond to straight lines through (0,1). The infinitesimal generator of $g_{a,b}(r)$ is

$$\hat{g}_{a,b}=\frac{d}{dr}\, g_{a,b}(r)\bigg|_{r=0}=\begin{pmatrix} a & b \\ 0 & 0 \end{pmatrix}. \tag{2.14}$$

The group $\Delta_{\mathcal{N}}^{iu}$ corresponds to $a=-2\pi$, $b=0$; the group $\exp(i\tau G)$ to $a=0$, $b=1$. Since the generator of $\Delta_{\mathcal{M}}^{is}$ is $\log\Delta_{\mathcal{N}}-G$, this one-parameter group corresponds to $a=-2\pi$, $b=-1$. Denoting for short the one-parameter subgroups of $\mathcal{G}$ in these three cases by $g_{\mathcal{N}}(u)$, $g_{\text{pos}}(\tau)$, and $g_{\mathcal{M}}(s)$, respectively, we have

$$g_{\mathcal{N}}(u)=\begin{pmatrix} e^{-2\pi u} & 0 \\ 0 & 1 \end{pmatrix},\quad g_{\text{pos}}(\tau)=\begin{pmatrix} 1 & \tau \\ 0 & 1 \end{pmatrix},\quad g_{\mathcal{M}}(s)=\begin{pmatrix} e^{-2\pi s} & \frac{1}{2\pi}(e^{-2\pi s}-1) \\ 0 & 1 \end{pmatrix}. \tag{2.15}$$

One verifies the relation

$$g_{\mathcal{N}}(u)\cdot g_{\mathcal{M}}(s)=g_{\mathcal{M}}(F(u,s))\cdot g_{\mathcal{N}}(-F(u,s)+s+u), \tag{2.16}$$

with

$$F(u,s) = -\frac{1}{2\pi}\log\{1+e^{-2\pi u}(e^{-2\pi s}-1)\}, \tag{2.17}$$

provided

$$1+e^{-2\pi u}(e^{-2\pi s}-1)>0, \tag{2.18}$$

which is always fulfilled for $s\leqslant 0$. The relation corresponding to (2.16) for the modular groups $\Delta_{\mathcal{N}}^{\mathrm{i}u}$ and $\Delta_{\mathcal{M}}^{\mathrm{i}s}$ is

$$\Delta_{\mathcal{N}}^{\mathrm{i}u}\cdot\Delta_{\mathcal{M}}^{\mathrm{i}s} = \Delta_{\mathcal{M}}^{\mathrm{i}F(u,s)}\cdot\Delta_{\mathcal{N}}^{\mathrm{i}(-F(u,s)+s+u)}. \tag{2.19}$$

This relation also appears in Ref. 14; our heuristic discussion has brought its group theoretical origin into focus.

In terms of the original translation group $T(t)$ we can, because of (2.2), write (2.19), as

$$\Delta_{\mathcal{N}}^{\mathrm{i}u}\cdot T(t)\cdot\Delta_{\mathcal{N}}^{-\mathrm{i}u} = T\left(\frac{\beta}{2\pi}\log\{1+e^{-2\pi u}(e^{2\pi t/\beta}-1)\}\right)\cdot\Delta_{\mathcal{N}}^{\mathrm{i}(1/2\pi)\log\{1+e^{-2\pi u}(e^{2\pi t/\beta}-1)\}-\mathrm{i}(t/\beta)}. \tag{2.20}$$

In the limit $\beta\to\infty$ we recover the Bisognano–Wichmann result,

$$\Delta_{\mathcal{N}}^{\mathrm{i}u}\cdot T(t)\cdot\Delta_{\mathcal{N}}^{-\mathrm{i}u} = T(e^{-2\pi u}t). \tag{2.21}$$

The one-parameter groups $g_{a,b}(r)$ can be expressed in terms of $g_{\mathcal{M}}(s)$ and $g_{\mathcal{N}}(u)$:

$$g_{a,b}(r) = g_{\mathcal{M}}(s(r))\cdot g_{\mathcal{N}}(u(r)) = g_{\mathcal{N}}(u(-r))\cdot g_{\mathcal{M}}(s(-r)), \tag{2.22}$$

with

$$s(r) = -\frac{1}{2\pi}\log\left\{1+\frac{2\pi b}{a}(e^{ar}-1)\right\},$$

$$u(r) = -s(r)-\frac{a}{2\pi}r. \tag{2.23}$$

Specializing to $a=0$, $b=1$ we obtain, for $r>-1/(2\pi)$,

$$g_{\mathrm{pos}}(\tau) = g_{\mathcal{M}}(-(2\pi)^{-1}\log(1+2\pi\tau))\cdot g_{\mathcal{N}}((2\pi)^{-1}\log(1+2\pi\tau)), \tag{2.24}$$

and hence

$$U(\tau) = \Delta_{\mathcal{M}}^{-(\mathrm{i}/2\pi)\log(1+2\pi r)}\cdot\Delta_{\mathcal{N}}^{(\mathrm{i}/2\pi)\log(1+2\pi r)} = \Delta_{\mathcal{N}}^{-(\mathrm{i}/2\pi)\log(1-2\pi\tau)}\cdot\Delta_{\mathcal{M}}^{(\mathrm{i}/2\pi)\log(1-2\pi\tau)}. \tag{2.25}$$

The first representation can be used for $\tau>-1/(2\pi)$, the second one for $\tau<1/(2\pi)$.

The group $g_{\mathcal{N}}(u)$ operates on $g_{\mathrm{pos}}(\tau)$ according to

$$g_{\mathcal{N}}(u)g_{\mathrm{pos}}(\tau)g_{\mathcal{N}}(-u) = g_{\mathrm{pos}}(\exp(-2\pi u)\tau), \tag{2.26}$$

which is just the abstract form of the basic relation (2.9). This is a special case of the general relation

$$g_{a,b}(r)g_{\mathrm{pos}}(\tau)g_{a,b}(-r) = g_{\mathrm{pos}}(\exp(ar)\tau). \tag{2.27}$$

For $a=-2\pi$, $b=-1$, i.e., $g_{\mathcal{M}}$, the corresponding relation for the unitary groups on Hilbert space is

$$\Delta_{\mathcal{M}}^{is}U(\tau)\Delta_{\mathcal{M}}^{-is}=U(\exp(-2\pi s)\tau), \tag{2.28}$$

which also follows directly from (2.25) and (2.19). We note in passing that (2.28) may be interpreted as an ''Anosov relation'' that leads to exponential clustering of matrix elements of the time translations $T(t)=\Delta_{\mathcal{M}}^{-it/\beta}$ in states of the form $A\Omega$ with A in a dense subalgebra of $\mathcal{M}$.[20]

Defining $\Gamma(\tau):=U(\tau/\beta)$ we have, by (2.25),

$$\Gamma(\tau)=T\left(\frac{\beta}{2\pi}\log\{1+(2\pi\tau/\beta)\}\right)\cdot\Delta_{\mathcal{N}}^{(i/2\pi)\log\{1+(2\pi\tau/\beta)\}}$$
$$=\Delta_{\mathcal{N}}^{-(i/2\pi)\log\{1-(2\pi\tau/\beta)\}}\cdot T\left(-\frac{\beta}{2\pi}\log\{1-(2\pi\tau/\beta)\}\right), \tag{2.29}$$

where the first equality is valid for $\tau>-\beta/(2\pi)$ and the second for $\tau<\beta/(2\pi)$. Evidently, $\Gamma(\tau)\rightarrow T(\tau)$ for $\beta\rightarrow\infty$, and

$$G/\beta=H+\frac{1}{\beta}\log\Delta_{\mathcal{N}}, \tag{2.30}$$

tends in this limit to the Hamiltonian H, which in the vacuum representation is $\geqslant 0$.

The relation (2.28) means that

$$T(t)\Gamma(\tau)T(-t)=\Gamma(\exp(2\pi t/\beta)\tau). \tag{2.31}$$

By (2.8) and our assumption that $\cup_t\alpha_t\mathcal{B}$ is norm dense in $\mathcal{A}$ (and hence $\cup$ ad $T(t)\mathcal{N}$ weakly dense in $\mathcal{M}$), we may thus conclude that

$$\text{ad }\Gamma(\tau)\mathcal{M}\subset\mathcal{M},\quad \text{for all}\quad \tau\geqslant 0. \tag{2.32}$$

A rigorous proof of the relations (2.19) and (2.25) [and hence of (2.20), (2.29), and (2.31)] can be obtained by applying Theorems A and B in Ref. 6 to the operator-valued functions,

$$V(v)=\Delta_{\mathcal{M}}^{-iv}\Delta_{\mathcal{N}}^{iv}, \tag{2.33}$$

and $W(w)=V(v(w))$, where

$$v(w)=\frac{1}{2\pi}\log(1+e^{2\pi w}). \tag{2.34}$$

The function $V(v)$ has a bounded analytic continuation into the strip $S(0,1/2)$ with continuous boundary values, and satisfies the relation

$$V\left(v+\frac{i}{2}\right)=J_{\mathcal{M}}V(v)J_{\mathcal{N}}, \tag{2.35}$$

for $v\in\mathbf{R}$. Moreover, ad $V(v)$ maps $\mathcal{N}$ into $\mathcal{N}$ for $v\geqslant 0$ and the commutant $\mathcal{N}'$ into $\mathcal{N}'$ for $v\leqslant 0$. By (2.35) it follows that ad $V(v+i/2)$ maps $\mathcal{N}'$ into $\mathcal{N}'$ for all v.

In order to apply Theorem B in Ref. 6 we have to map the strip $S(0,1/2)$ biholomorphically onto itself in such a way that $\mathbf{R}$ is mapped onto $\mathbf{R}_+$ and $\mathbf{R}+i/2$ onto $(\mathbf{R}+i/2)\cup\mathbf{R}_-$. The map (2.34) accomplishes this. It has a singularity at $w=i/2$, but as remarked in Ref. 6 such a singularity is harmless.

[The reason is as follows: Theorem B in Ref. 6 is based on the edge-of-the-wedge theorem, applied to matrix elements of the operator-valued function,

$$(u,w)\mapsto\Delta_{\mathcal{N}}^{iu}W(w)\Delta_{\mathcal{N}}^{-iu}. \tag{2.36}$$

These matrix elements have bounded analytic continuations, which are continuous at the boundary of their domain with the possible exception of points with $w = \mathrm{i}/2$. By the dominated convergence theorem and the boundedness of (2.36) this piecewise continuity is sufficient to ensure coincidence of boundary values in the sense of distributions. The edge-of-the-wedge theorem then implies analyticity in the coincidence region, so continuity in the points with $w = \mathrm{i}/2$ holds *a fortiori*.]

Theorem B in Ref. 6 leads to the general relations

$$\Delta_{\mathcal{N}}^{\mathrm{i}u} W(w) \Delta_{\mathcal{N}}^{-\mathrm{i}u} = W(w-u) \tag{2.37}$$

and

$$J_{\mathcal{N}} W(w) J_{\mathcal{N}} = W\left(w + \frac{\mathrm{i}}{2}\right). \tag{2.38}$$

Eq. (2.37) is precisely (2.19) in case (2.18) holds, but note that (2.37) is true for all $u, w \in \mathbf{R}$. As noted by Wiesbrock (Refs. 13, 14) these relations imply that $\Delta_{\mathcal{N}}^{\mathrm{i}u}$ and $\Delta_{\mathcal{M}}^{\mathrm{i}s}$ generate a unitary representation of the Lie group $\mathcal{G}$. The infinitesimal generators $\log \Delta_{\mathcal{N}}$ and $\log \Delta_{\mathcal{M}}$, together with their real linear combinations, are thus essentially self adjoint on a common core. The representation $U(\tau)$ of the one-parameter subgroup $g_{\mathrm{pos}}(\tau)$ fulfills, together with $\Delta_{\mathcal{N}}^{\mathrm{i}u}$, the relation (2.9) (because of the corresponding relation in $\mathcal{G}$), and this implies, by Ref. 21, that $U(\tau) = \exp(\mathrm{i}\tau G)$ with $G \geqslant 0$. Hence, the starting point of the heuristic discussion is rigorously justified.

The following theorem summarizes the main conclusions of the preceding discussion and states, in addition, the most important consequence of the relations (2.20), (2.29), and (2.31) for the present investigation, namely the action of the group $\mathcal{G}$ on translates of $\mathcal{N}$.

Theorem 2.1: *Let $(\mathcal{A}, \alpha_t)$ be a C^*-dynamical system and $\mathcal{B}$ a subalgebra such that $\alpha_t \mathcal{B} \subset \mathcal{B}$ for $t \geqslant 0$ and $\cup_t \alpha_t \mathcal{B}$ is norm dense in $\mathcal{A}$. In the GNS representation defined by a KMS state on $\mathcal{A}$ at inverse temperature β let $\mathcal{M}$ and $\mathcal{N}$ denote the weak closures of $\pi(\mathcal{A})$ and $\pi(\mathcal{B})$, respectively, and $T(t) = \exp(\mathrm{i}tH)$ the unitary group implementing α_t. Denote* ad $T(t)\mathcal{N} = \mathcal{N}(t)$. *Then*

(i) The translations $T(t)$ and the modular group $\Delta_{\mathcal{N}}^{\mathrm{i}u}$, defined by $\mathcal{N}$ and the KMS state vector, fulfill the relation (2.20). We have

$$\mathrm{ad}\ \Delta_{\mathcal{N}}^{\mathrm{i}u} \mathcal{N}(t) = \mathcal{N}(\varphi(u,t)), \tag{2.39}$$

with

$$\varphi(u,t) = \frac{\beta}{2\pi} \log\{1 + e^{-2\pi u}(e^{2\pi t/\beta} - 1)\}, \tag{2.40}$$

for all u, t, satisfying

$$1 + e^{-2\pi u}(e^{2\pi t/\beta} - 1) > 0. \tag{2.41}$$

In particular,

$$\mathrm{ad}\ \Delta_{\mathcal{N}}^{\mathrm{i}u} \mathcal{M} \subset \mathcal{M}, \tag{2.42}$$

for all $u \geqslant 0$, and

$$\mathcal{N} = \bigcap_{u \geqslant 0} \mathrm{ad}\ \Delta_{\mathcal{N}}^{\mathrm{i}u} \mathcal{M}. \tag{2.43}$$

(ii) The operator $G = \beta H + \log \Delta_{\mathcal{N}}$ is non-negative and essentially self-adjoint on a common core of H and $\log \Delta_{\mathcal{N}}$. The one parameter group $\Gamma(\tau) = \exp(i\tau G/\beta)$ is given by (2.29) and the groups $\Gamma(\tau)$ and $T(t)$ satisfy (2.31). We have

$$\text{ad } \Gamma(\tau)\mathcal{N}(t)=\mathcal{N}(\psi(u,t)), \tag{2.44}$$

with

$$\psi(\tau,t)=t+\frac{\beta}{2\pi}\log\left\{1+\frac{2\pi\tau}{\beta}e^{-2\pi t/\beta}\right\}, \tag{2.45}$$

for all τ, t *satisfying*

$$1+\frac{2\pi\tau}{\beta}e^{-2\pi t/\beta}<0. \tag{2.46}$$

In particular,

$$\text{ad } \Gamma(\tau)\mathcal{M}\subset\mathcal{M} \quad \text{and} \quad \text{ad } \Gamma(\tau)\mathcal{N}\subset\mathcal{N}, \tag{2.47}$$

for $\tau\geqslant 0$, *and*

$$\mathcal{N}=\text{ad } \Gamma(\beta/2\pi)\mathcal{M}. \tag{2.48}$$

Proof: As already noted, the key relations (2.20), (2.29), and (2.31), and the self-adjointness and positivity of G are a rigorous consequence of the Theorems in Refs. 6, 21, 13, and 14. Equations (2.39) and (2.44) follow directly from (2.20) and (2.29) and the fact that $\varphi(-u,\varphi(u,t))=t$, $\psi(-\tau,\psi(\tau,t))=t$ for (u,t) and (τ,t), satisfying (2.41) and (2.46), respectively. Equations (2.42), (2.43), (2.47), and (2.48) are simple consequences of (2.39) and (2.44), since $\cup_t$ ad $T(t)\mathcal{N}$ is dense in $\mathcal{M}$.

As a last topic in this section we discuss the relation between the translation group $T(t)$ and the modular group $\Delta_{\mathcal{N}}^{iu}$. Since $T(-\beta u)=\Delta_{\mathcal{M}}^{iu}$, one may expect that the actions of $T(-\beta u)$ and $\Delta_{\mathcal{N}}^{iu}$ approximately coincide on elements that have been translated far into $\mathcal{N}$, so that ''boundary effects'' are negligible. That this intuition is indeed solidly founded is the content of the next two theorems. The first concerns certain matrix elements of the unitary groups, and gives an estimate for the rate of the convergence. The second is about strong convergence of Hilbert space vectors and operators, but the error estimates are less explicit.

Theorem 2.2: *If* $A\in\mathcal{N}(t)$ *and* $B\in\mathcal{N}'$, *the following estimate holds for* $t>0$ *and all* u*:*

$$|(B\Omega,\Delta_{\mathcal{N}}^{iu}A\Omega)-(B\Omega,T(-\beta u)A\Omega)|\leqslant 2M\,\min\left\{\frac{|\exp(2\pi u)-1|}{\exp(2\pi t/\beta)-1},1\right\}, \tag{2.49}$$

with

$$M=\max\{\|A\Omega\|\|B\Omega\|,\|A^*\Omega\|\|B^*\Omega\|\}. \tag{2.50}$$

Proof: Consider the two functions

$$F^+(u)=(B\Omega,\Delta_{\mathcal{N}}^{-iu}T(-\beta u)A\Omega) \quad \text{and} \quad F^-(u)=(A^*\Omega,T(\beta u)\Delta_{\mathcal{N}}^{iu}B^*\Omega). \tag{2.51}$$

Theorem A in Ref. 6 implies that $\Delta_{\mathcal{N}}^{-iu}T(-\beta u)$ has a bounded analytic continuation into the strip $S(-\frac{1}{2},0)$. It follows that F^+ has an analytic continuation into $S(-\frac{1}{2},0)$, and F^- into $S(0,\frac{1}{2})$. Moreover, by continuity of the unitary groups, $F^\pm$ is continuous on the real axis.

Denoting $j_{\mathcal{M}}=\text{ad } J_{\mathcal{M}}$, $j_{\mathcal{N}}=\text{ad } J_{\mathcal{N}}$ we obtain

$$F^+\left(u-\frac{i}{2}\right)=(B\Omega,J_{\mathcal{N}}\,\Delta_{\mathcal{N}}^{-iu}T(-\beta u)J_{\mathcal{M}}A\Omega)=(\Delta_{\mathcal{N}}^{-iu}T(-\beta u)j_{\mathcal{M}}(A)\Omega,j_{\mathcal{N}}(B)\Omega),$$

$$F^{-}\left(u+\frac{\mathrm{i}}{2}\right)=(A^{*}\Omega,J_{\mathcal{M}}T(\beta u)\Delta_{\mathcal{N}}^{\mathrm{i}u}J_{\mathcal{N}}\,B^{*}\Omega)=(T(\beta u)\Delta_{\mathcal{N}}^{\mathrm{i}u}j_{\mathcal{N}}(B^{*})\Omega,j_{\mathcal{M}}(A^{*})\Omega).$$

In particular, $F^{\pm}$ is continuous at $u\pm \mathrm{i}/2$, $u\in\mathbf{R}$, and $j_{\mathcal{N}}(B^{*})\in\mathcal{N}$ and $j_{\mathcal{M}}(A^{*})\in\mathcal{M}'$ implies

$$F^{+}\left(u-\frac{\mathrm{i}}{2}\right)=F^{-}\left(u+\frac{\mathrm{i}}{2}\right). \tag{2.52}$$

Moreover, since $T(-s)AT(s)\in\mathcal{N}$ for $s<t$, we have

$$F^{+}(u)=F^{-}(u),\quad \text{for } u<t/\beta. \tag{2.53}$$

Hence, F^{+} and F^{-} have a common analytic continuation to a periodic function, F, with the period i and cuts $[t/\beta,\infty)+\mathrm{i}n$, $n\in\mathbf{Z}$. This function is majorized by

$$M=\max\{\|A\Omega\|\|B\Omega\|,\|A^{*}\Omega\|\|B^{*}\Omega\|\}. \tag{2.54}$$

The function $F(z)-F(0)$ vanishes at $z=\mathrm{i}n$, $n\in\mathbf{Z}$, and is bounded by $2M$. Therefore,

$$G(z)=\frac{F(z)-F(0)}{\exp(2\pi z)-1}$$

is analytic and bounded in the same domain as F. Along the cuts we have $|G(z)|\leq 2M(\exp(2\pi t/\beta)-1)^{-1}$. By the maximum modulus principle this estimate holds everywhere, and thus

$$|(B\Omega,\Delta_{\mathcal{N}}^{-\mathrm{i}u}T(-\beta u)A\Omega)-(B\Omega,A\Omega)|\leq 2M\,\frac{|\exp(2\pi u)-1|}{\exp(2\pi t/\beta)-1}. \tag{2.55}$$

This estimate blows up for $t\to 0$, but the left-hand side is trivially bounded by $2M$ for all real u and t. Replacing $B\in\mathcal{N}'$ by ad $\Delta_{\mathcal{N}}^{-\mathrm{i}u}B\in\mathcal{N}'$ does not change M, so (2.55) gives the desired estimate (2.49).

Theorem 2.3: *(i) For every $A\in\mathcal{M}$ and Hilbert space vector Ψ,*

$$\lim_{t\to\infty}\|\Delta_{\mathcal{N}}^{\mathrm{i}u}A(t)\Psi-T(-\beta u)A(t)\Psi\|=0, \tag{2.56}$$

with $A(t)=\mathrm{ad}\;T(t)A$. The convergence is uniform on half-sided u intervals $I=(-\infty,u_0]$, $u_0<\infty$.

(ii) For every A in a dense subalgebra of $\mathcal{M}$,

$$\lim_{t\to\infty}\|\mathrm{ad}\;\Delta_{\mathcal{N}}^{\mathrm{i}u}A(t)-\mathrm{ad}\;T(-\beta u)A(t)\|=0, \tag{2.57}$$

with uniform convergence on half-sided u intervals.

Proof: From (2.48), (2.2), and (2.31), it follows that

$$\Delta_{\mathcal{N}}^{\mathrm{i}u}=\Gamma(\beta/2\pi)T(-\beta u)\Gamma(-\beta/2\pi)=T(-\beta u)\Gamma((\exp(2\pi u)-1)\beta/2\pi). \tag{2.58}$$

Hence, using (2.31) again,

$$\mathrm{ad}\;\Delta_{\mathcal{N}}^{\mathrm{i}u}A(t)-\mathrm{ad}\;T(-\beta u)A(t)=\mathrm{ad}\;T(t-\beta u)[\mathrm{ad}\;\Gamma(\exp(-2\pi t/\beta)(u))A-A], \tag{2.59}$$

with $h(u)=(\exp(2\pi u)-1)\beta/2\pi$. Now (i) follows from the strong convergence of $\Gamma(\tau)$ to 1 as $\tau\to 0$, because $\sup_{u\in I}|h(u)|<\infty$ for $I=(-\infty,u_0]$.

For general $A\in\mathcal{M}$, $\|\mathrm{ad}\,\Gamma(\tau)A-A\|$ need not converge to zero as $\tau\to 0$. However, on elements of the form $A_g=\int g(\tau)\mathrm{ad}\,\Gamma(\tau)A\,d\tau$ with g continuous of compact support, this convergence holds. Moreover, if g is continuously differentiable, then (2.59) implies

$$\|\mathrm{ad}\,\Delta_{\mathcal{N}}^{\mathrm{i}u}A_g(t)-\mathrm{ad}\,T(-\beta u)A_g(t)\|\leqslant\|A\|\cdot\|dg/d\tau\|_1\sup_{u\in I}|h(u)|\cdot e^{-2\pi t/\beta}. \tag{2.60}$$

By (2.44) such regularized elements are dense in $\mathcal{M}$ if the support of g is sufficiently small, and $A_g\to A$ weakly if g tends to a delta function.

III. TWO-DIMENSIONAL MODELS

The general results of the preceding setting were formulated for a C^*-dynamical system $(\mathcal{A},\alpha_t)$ and a subalgebra $\mathcal{B}$, invariant under half-sided shifts by α_t. We shall now be more specific and consider a quasilocal algebra $\mathcal{A}$ generated by a local net $\mathcal{O}\mapsto\mathcal{A}(\mathcal{O})$ of C^*-algebras and $\mathcal{B}=\mathcal{A}(\mathcal{O}_0)$ with $\mathcal{O}_0$ a domain invariant under half-sided translations in the t direction. In the representation π generated by a KMS state ω, we denote $\pi(\mathcal{A}(\mathcal{O}))''$ by $\mathcal{M}(\mathcal{O})$ and $\pi(\mathcal{A})''$ by $\mathcal{M}$, as before.

Equations (2.39) and (2.44) describe the action of the modular and Γ groups associated with $\mathcal{N}=\mathcal{M}(\mathcal{O}_0)$ on the translated algebras $\mathcal{M}(\mathcal{O}_0+t\mathbf{e})$, where $\mathbf{e}$ is the unit vector in the t direction. We now want to investigate how the groups associated with $\mathcal{M}(\mathcal{O}_0)$ act on the algebras of more general domains than $\mathcal{O}_0+t\mathbf{e}$, in particular, $\mathcal{O}_0+\mathbf{x}$, with $\mathbf{x}$ an arbitrary vector in space–time. While a general answer to this question appears difficult, the previous results lead directly to a description of the action in the case of two-dimensional theories that factorize in the light-cone variables.

We start by considering local nets in two-dimensional space time depending only on one light-cone variable, i.e., nets on a light ray. With x^0 the time and x^1 the space coordinate of $\mathbf{x}\in\mathbf{R}^2$, the light-cone variables are $x^R=x^0+x^1$ and $x^L=x^0-x^1$. We consider either one of them and denote it simply by x. Note that translations in time $t=x^0$ are equivalent to translations in x. A local algebra corresponding to an x interval $I\subset\mathbf{R}$ is denoted by $\mathcal{M}(I)$. Local commutativity means that $\mathcal{M}(I_1)$ and $\mathcal{M}(I_2)$ commute if $I_1\cap I_2=\emptyset$.

We denote the modular group for the algebra $\mathcal{M}(\mathbf{R}_+)$ by $\Delta_+^{\mathrm{i}u}$ and the corresponding group with the positive generator $G_+/\beta=H+(1/\beta)\log\Delta_+$ by $\Gamma_+(\tau)$. We shall also consider the algebra of the negative half-axis, $\mathcal{M}(\mathbf{R}_-)$, with modular group $\Delta_-^{\mathrm{i}u}$ and the positive operator $G_-/\beta=H+(1/\beta)\log\Delta_-$, which generates the group $\Gamma_-(\tau)=\exp(\mathrm{i}\tau G_-/\beta)$. Note that $\mathrm{ad}\,\Gamma_-(\tau)$ maps $\mathcal{M}(\mathbf{R}_-)$ into itself for $\tau\leqslant 0$.

By Eq. (2.39), we have

$$\mathrm{ad}\,\Delta_+^{\mathrm{i}u}\mathcal{M}([x,\infty[)=\mathcal{M}([\varphi_+(u,x),\infty[), \tag{3.1}$$

with

$$\varphi_+(u,x)=\frac{\beta}{2\pi}\log\{1+e^{-2\pi u}(e^{2\pi x/\beta}-1)\}, \tag{3.2}$$

for all x, $u\in\mathbf{R}$, such that

$$1+\exp(-2\pi u)[\exp(2\pi x/\beta)-1]>0. \tag{3.3}$$

Note that (3.2) is just the function (2.40). We denote it here by φ_+ because there is an analogous result for $\mathcal{M}(\mathbf{R}_-)$:

$$\mathrm{ad}\,\Delta_-^{\mathrm{i}u}\mathcal{M}(]-\infty,x])=\mathcal{M}(]-\infty,\varphi_-(u,x)]), \tag{3.4}$$

with

$$\varphi_-(u,x) = -\varphi_+(-u,-x), \tag{3.5}$$

for

$$1+\exp(2\pi u)[\exp(-2\pi x/\beta)-1]>0. \tag{3.6}$$

Likewise, from Eq. (2.44),

$$\mathrm{ad}\ \Gamma_+(\tau)\mathcal{M}([x,\infty[) = \mathcal{M}([\psi_+(\tau,x),\infty[), \tag{3.7}$$

with

$$\psi_+(\tau,x) = x + \frac{\beta}{2\pi}\log\left\{1+\frac{2\pi\tau}{\beta}e^{-2\pi x/\beta}\right\}, \tag{3.8}$$

for

$$1+(2\pi\tau/\beta)\exp(-2\pi x/\beta)>0, \tag{3.9}$$

and

$$\mathrm{ad}\ \Gamma_-(\tau)\mathcal{M}(]-\infty,x]) = \mathcal{M}(]-\infty,\psi_-(u,x)]), \tag{3.10}$$

with

$$\psi_-(\tau,x) = -\psi_+(-\tau,-x), \tag{3.11}$$

for

$$1-(2\pi\tau/\beta)\exp(2\pi x/\beta)>0. \tag{3.12}$$

We now turn to models in two space–time dimensions that can be written as a tensor product of one-dimensional models in the light-cone variables, $x^R = x^0 + x^1$ and $x^L = x^0 - x^1$. For a domain $I_L \times I_R \subset \mathbf{R}^2$ with I_L and I_R intervals on the x_L and x_R axis, respectively, the local algebra is thus

$$\mathcal{M}(I_L\times I_R) = \mathcal{M}(I_L)\otimes\mathcal{M}(I_R). \tag{3.13}$$

Here $\otimes$ is the von Neumann tensor product, and $I \mapsto \mathcal{M}(I)$ is a local net of von Neumann algebras over $\mathbf{R}$. (For simplicity of notation we take identical nets on both axes.) In particular, we are interested in the algebras of the forward light cone,

$$\mathcal{M}(V^+) = \mathcal{M}(\mathbf{R}_+)\otimes\mathcal{M}(\mathbf{R}_+), \tag{3.14}$$

and the right wedge

$$\mathcal{M}(W) = \mathcal{M}(\mathbf{R}_-)\otimes\mathcal{M}(\mathbf{R}_+). \tag{3.15}$$

The modular groups for these algebras and a factorizing KMS state $\omega\otimes\omega$, where ω is a KMS state for the algebra on a light ray, are

$$\Delta_{V^+}^{\mathrm{i}u} = \Delta_+^{\mathrm{i}u}\otimes\Delta_+^{\mathrm{i}u} \tag{3.16}$$

and

$$\Delta_W^{\mathrm{i}u} = \Delta_-^{\mathrm{i}u}\otimes\Delta_+^{\mathrm{i}u}. \tag{3.17}$$

If $\mathbf{x}\in\mathbf{R}^2$, we denote the translated light cone $V^+ +\mathbf{x}$ by $V_{\mathbf{x}}^+$ and the translated wedge $W+\mathbf{x}$ by $W_{\mathbf{x}}$. From Eqs. (3.1) and (3.5), we obtain

Theorem 3.1:

$$\text{ad}\ \Delta_{V^+}^{\mathrm{i}u}\mathcal{M}(V_{\mathbf{x}}^+)=\mathcal{M}(V^+_{\varphi_{V^+(u,\mathbf{x})}}),\tag{3.18}$$

with

$$\varphi_{V^+}(u,\mathbf{x})=(\varphi_+(u,x^L),\varphi_+(u,x^R)),\tag{3.19}$$

for $u\in\mathbf{R}$ *and* $\mathbf{x}\in\mathbf{R}^2$ *such that (3.3) holds for* $x=x^L$ *and* $x=x^R$*. If* $u\geqslant 0$*, then* ad $\Delta_{V^+}^{\mathrm{i}u}\mathcal{M}(V_{\mathbf{x}}^+)\subset\mathcal{M}$ *for all* $\mathbf{x}\in\mathbf{R}^2$*, and if* $\mathbf{x}\in V^+$*, then* ad $\Delta_{V^+}^{\mathrm{i}u}\mathcal{M}(V_{\mathbf{x}}^+)\subset\mathcal{M}(V^+)$ *for all u.*

Likewise,

$$\text{ad}\ \Delta_W^{\mathrm{i}u}\mathcal{M}(W_{\mathbf{x}})=\mathcal{M}(W_{\varphi_W(u,\mathbf{x})}),\tag{3.20}$$

with

$$\varphi_W(u,\mathbf{x})=(\varphi_-(u,x^L),\varphi_+(u,x^R)),\tag{3.21}$$

for $u\in\mathbf{R}$ *and* $\mathbf{x}\in\mathbf{R}^2$ *such that (3.3) holds for* $x=x^R$ *and (3.6) for* $x=x^L$*. If* $\mathbf{x}\in W$*, then* ad $\Delta_W^{\mathrm{i}u}\mathcal{M}(W_x)\subset\mathcal{M}(W)$ *for all u.*

The flow lines of φ_{V^+} and φ_W within the respective domains are shown in Figs. 1–2.

It is evident from the figures that the character of the modular flow depends of the distance from the boundary of the domain considered (forward light cone or wedge). The natural unit of length is here the reciprocal temperature, β. Consider first the modular group of the forward light cone V^+. In terms of the original space time coordinates $x^0=(x^R+x^L)/2$ and $x^1=(x^R-x^L)/2$ the map (3.19) takes (x_0,x^1) to (x'^0,x'^1) with

$$x'^0=x^0-\beta u+R_{V^+}^0(x,u),\quad x'^1=x^1+R_{V^+}^1(x,u),\tag{3.22}$$

where

$$R_{V^+}^0(x,u)=(\beta/4\pi)\log\{(1+e^{-2\pi(x^R-\beta u)/\beta}-e^{-2\pi x^R/\beta})(1+e^{-2\pi(x^L-\beta u)/\beta}-e^{-2\pi x^L/\beta})\}\tag{3.23}$$

and

$$R_{V^+}^1(x,u)=(\beta/4\pi)\log\left\{\frac{1+e^{-2\pi(x^R-\beta u)/\beta}-e^{-2\pi x^R/\beta}}{1+e^{-2\pi(x^L-\beta u)/\beta}-e^{-2\pi x^L/\beta}}\right\}.\tag{3.24}$$

Far from the domain boundary, i.e., for x^R, x^L, $x^R-\beta u$, and $x^L-\beta u$ large compared to β, the terms $R_{V^+}^0$ and $R_{V^+}^1$ are exponentially small, and $\psi_{V^+}(\cdot,u)$ is essentially the same as translation in time by $-\beta u$ in accord with Theorems 2.2 and 2.3. On the other hand, close to the apex of the light cone (compared to β), the action is essentially the same as for $\beta=\infty$, i.e., dilation by the factor $\exp(-2\pi u)$. The deviation from a dilation is of the order $(|x|/\beta)^2$.

For the wedge W the formulas corresponding to (3.22)–(3.24) are

$$x'^0=x^0-\beta u+R_W^0(x,u),\quad x'^1=x^1+R_W^1(x,u),\tag{3.25}$$

with

$$R_W^0(x,u)=(\beta/4\pi)\log\left\{\frac{1+e^{-2\pi(x^R-\beta u)}-e^{-2\pi x^R/\beta}}{1+e^{2\pi(x^L-\beta u)/\beta}-e^{2\pi x^L/\beta}}\right\}\tag{3.26}$$

and

$$R_W^1(x,u)=(\beta/4\pi)\log\{(1+e^{-2\pi(x^R-\beta u)}-e^{-2\pi x^R/\beta})(1+e^{2\pi(x^L-\beta u)/\beta}-e^{2\pi x^L/\beta})\}. \quad (3.27)$$

Note that the wedge is characterized by $x^R \geqslant 0$ and $x^L \leqslant 0$. Again, the modular action coincides essentially with time translations far from the domain boundary. Near the edge of the wedge, the coordinate x^R is scaled by $\exp(-2\pi u)$ and x^L is scaled by $\exp(2\pi u)$, up to terms of order $(|x|/\beta)^2$. This corresponds to a Lorentz boost, i.e., the modular action at temperature zero.

From $\Gamma_\pm(\tau)$ we can form the one-parameter unitary groups,

$$\tau \mapsto \Gamma_\pm(\tau) \otimes \Gamma_\pm(\tau), \quad (3.28)$$

on the tensor product Hilbert space. These groups have the positive generators $H + (1/\beta)\log \Delta_{\pm,\pm}$, where $\Delta_{\pm,\pm} = \Delta_\pm \otimes 1 + 1 \otimes \Delta_\pm$ is the modular operator of $\mathcal{M}(\mathbf{R}_\pm \times \mathbf{R}_\pm)$. They correspond, respectively, to the forward and backward light cone ($++$ and $--$) and the left and the right wedge ($+-$ and $-+$). All four groups converge to the time translations as $\beta \to \infty$.

The group associated with the forward light cone is

$$\Gamma_{V^+}(\tau) = \Gamma_+(\tau) \otimes \Gamma_+(\tau). \quad (3.29)$$

By (2.44) we have the following theorem.

Theorem 3.2: *If* $\mathbf{x} \in \mathbf{R}^2$ *and*

$$\tau > -\beta(2\pi)^{-1} \min\{e^{2\pi x^L/\beta}, e^{2\pi x^R/\beta}\}, \quad (3.30)$$

then

$$\text{ad } \Gamma_{V^+}(\tau)\mathcal{M}(V_{\mathbf{x}}^+) = \mathcal{M}(V_{\psi_{V^+}(\tau,\mathbf{x})}^+), \quad (3.31)$$

with

$$\psi_{V^+}(\tau,\mathbf{x}) = (\psi_+(\tau,x^L), \psi_+(\tau,x^R)). \quad (3.32)$$

If

$$\tau > -\beta(2\pi)^{-1}(\min\{e^{2\pi x^L/\beta}, e^{2\pi x^R/\beta}\} - 1), \quad (3.33)$$

then

$$\text{ad } \Gamma_{V^+}(\tau)\mathcal{M}(V_{\mathbf{x}}^+) \subset \mathcal{M}(V^+). \quad (3.34)$$

The group associated with the right wedge,

$$\Gamma_W(\tau) = \Gamma_-(\tau) \otimes \Gamma_+(\tau), \quad (3.35)$$

does not induce half-sided translations on the wedge algebra, but it nevertheless acts geometrically for a restricted parameter range. In fact, by Eqs. (3.7) and (3.10) we have the following theorem.

Theorem 3.3: *If* $\mathbf{x} \in \mathbf{R}^2$ *and*

$$-\beta(2\pi)^{-1} e^{2\pi x^R/\beta} < \tau < \beta(2\pi)^{-1} e^{-2\pi x^L/\beta}, \quad (3.36)$$

then

$$\text{ad } \Gamma_W(\tau)\mathcal{M}(W_{\mathbf{x}}) = \mathcal{M}(W_{\psi_W(\tau,\mathbf{x})}), \quad (3.37)$$

with

$$\psi_W(\tau,\mathbf{x})=(\psi_-(\tau,x^L),\psi_+(\tau,x^R)). \tag{3.38}$$

If

$$-\beta(2\pi)^{-1}(e^{2\pi x^R/\beta}-1)<\tau<\beta(2\pi)^{-1}(e^{-2\pi x^L/\beta}-1), \tag{3.39}$$

then

$$\mathrm{ad}\;\Gamma_W(\tau)\mathcal{M}(W_{\mathbf{x}})\subset\mathcal{M}(W). \tag{3.40}$$

The flows of ψ_{V+} and ψ_W are shown in Figs. 3 and 4. The groups $\Gamma_{V+}(\tau)$ and $\Gamma_W(\tau)$, approximate the time translations close to the tip of the light cone and the edge of the wedge, respectively. Indeed, ψ_{V+} maps (x^0,x^1) to (x'^0,x'^1) with

$$x'^0=x^0+\tau[\exp(-2\pi x^R)+\exp(-2\pi x^L)]/2+O(\tau^2/\beta) \tag{3.41}$$

and

$$x'^1=x^1+\tau[\exp(-2\pi x^R)-\exp(-2\pi x^L)]/2+O(\tau^2/\beta). \tag{3.42}$$

For x^R and x^L both close to zero, this is close to $x'^0=x^0+\tau$, $x'^1=x^1$. More interesting, however, is the behavior of $\Gamma_{V+}(\tau)$ far from the apex of the cone. From Fig. 3 one sees clearly that the flow corresponds to a decelerated motion toward the origin of space. More quantitatively, the velocity $v=dx'^1/dx'^0$ is

$$v=-\tanh(2\pi x'^1/\beta), \tag{3.43}$$

and this differential equation has the general solution

$$x'^0(x'^1)=-(\beta/2\pi)\log(\sinh(2\pi x'^1/\beta))+C, \tag{3.44}$$

where C is an arbitrary constant. The path through the origin, $x'^1=0$, corresponds formally to $C=-\infty$. The flow pattern is invariant under a shift in the time direction, in accord with (2.31).

As already mentioned in the Introduction, this flow brings points that start out with the velocity of light at infinity gradually to rest. Formally we have the reverse of an Unruh effect for the generator of the flow of the observables is positive, with the KMS state vector as a ground state. Measured in terms of the parameter τ, it takes $\beta/2\pi$ τ units for points to reach the forward light cone from infinity. The τ parameter along the path through the origin is related to the real time t by

$$t=(\beta/2\pi)\log(1+2\pi\tau/\beta),\quad \text{i.e.,}\quad \tau=(\beta/2\pi)(\exp(2\pi t/\beta)-1). \tag{3.45}$$

The τ unit is calibrated in such a way that the t and τ scales coincide precisely where the path hits the apex of the light cone. According to Eq. (2.31), a different calibration corresponds simply to a shift of the cone in the time direction. It is clear from (3.45) that the τ parameter is ''slower'' than t, in the sense that $d\tau/dt<1$, for a point on the path outside the light cone ($\tau<0$), and ''faster'' than t, i.e., $d\tau/dt>1$, inside the light cone ($\tau>0$).

For ψ_W the equations corresponding to (3.41) and (3.42) are

$$x'^0=x^0+\tau[\exp(-2\pi x^R)+\exp(2\pi x^L)]/2+O(\tau^2/\beta) \tag{3.46}$$

and

$$x'^1=x^1+\tau[\exp(-2\pi x^R)-\exp(2\pi x^L)]/2+O(\tau^2/\beta), \tag{3.47}$$

and the velocity is

$$v = -\tanh(2\pi x'^0/\beta). \tag{3.48}$$

Thus, the velocity is small close to the space axis, but approaches ± 1 far away from the space axis. The explicit solution of (3.48) is

$$x'^1(x'^0) = -(\beta/2\pi)\log(\cosh(2\pi x'^0/\beta)) + C. \tag{3.49}$$

This flow is invariant under a translation in the x^1 direction. Here the situation is different from the light cone, since not all paths pass through the wedge, and those who do stay in the wedge only for a finite τ interval; cf. Eq. (3.39). The group even moves localized observables out of the global observable algebra in finite ''τ time,'' cf. Eq. (3.36). The direction of acceleration is in the opposite wedge here, whereas in the usual Unruh effect it points in the direction of the wedge. In this sense, here we also have a kind of reverse of the situation in the Unruh effect.

For the path passing through the origin, the τ parameter is related to $t = x^0$ by

$$t = \frac{\beta}{4\pi}\log\frac{1+(2\pi\tau/\beta)}{1-(2\pi\tau/\beta)}, \quad \text{i.e.} \quad \tau = \frac{\beta}{2\pi}\tanh\frac{2\pi t}{\beta}. \tag{3.50}$$

The relation to the proper time t_p along the path is

$$\tau = \frac{\beta}{2\pi}\sin\frac{2\pi t_p}{\beta}, \tag{3.51}$$

i.e., up to a slight deformation τ is essentially the proper time. We have

$$d\tau/dt_p = \cos\frac{2\pi t_p}{\beta} = (1-(2\pi\tau/\beta)^2)^{1/2}, \tag{3.52}$$

so ''τ time'' is everywhere slower than t_p except at the origin (calibration point), where both scales coincide with t. A change of scale corresponds to a translation of the wedge along the x^1 axis because of (2.31).

Above, we have described the actions of the modular- and Γ groups in terms of the space time coordinates (x^L, x^R) and also in terms of (x^0, x^1). The simplest description is obtained in yet another coordinate system, which is related to the others by a nonlinear transformation. For $x \in \mathbf{R}$ define

$$\xi_\pm = \pm(\beta/2\pi)(\exp(\pm 2\pi x/\beta) - 1). \tag{3.53}$$

The range of ξ_+ is $]-\beta/2\pi, \infty[$ and the range of ξ_- is $]-\infty, \beta/2\pi[$. With $x = x^L$ and $x = x^R$, respectively, we thus obtain the four coordinates, ξ_+^L, ξ_-^L, ξ_+^R, and ξ_-^R. In the case of the forward light cone we pick (ξ_+^L, ξ_+^R) and in the case of the right wedge (ξ_-^L, ξ_+^R) as a curvilinear coordinate system on Minkowski space. In these coordinates the transformations (3.19), (3.21) for the groups associated with the forward light cone V^+ become

$$(\xi_+^L, \xi_+^R) \mapsto e^{-2\pi u}(\xi_+^L, \xi_+^R), \quad (\xi_+^L, \xi_+^R) \mapsto (\xi_+^L, \xi_+^R) + \tau(1,1), \tag{3.54}$$

and the corresponding transformations (3.32) and (3.38) for the right wedge W are

$$(\xi_-^L, \xi_+^R) \mapsto (e^{2\pi u}\xi_-^L, e^{-2\pi u}\xi_+^R), \quad (\xi_-^L, \xi_+^R) \mapsto (\xi_-^L, \xi_+^R) + \tau(1,1). \tag{3.55}$$

Analogous formulas hold for the backward cone and the left wedge. Hence, in the ξ coordinates the transformations have exactly the same form for all β, including the vacuum case, $\beta = \infty$.

The four coordinate systems $(\xi_\pm^L, \xi_\pm^R)$ can be put together by defining

$$(\tilde{\xi}^L, \tilde{\xi}^R) = (\beta/2\pi)(\epsilon(x^L)(\exp(\epsilon(x^L)2\pi x^L/\beta) - 1), \epsilon(x^R)(\exp(\epsilon(x^R)2\pi x^R/\beta) - 1), \tag{3.56}$$

with $\epsilon(x)=1$ for $x\geqslant 0$ and -1 for $x<0$. This transformation is once continuously differentiable, but second derivatives have a discontinuity on the light cone. The lines corresponding to the flow of the Γ groups of the four domains (the forward and backward cones and the two wedges) pass continuously through the boundaries between the domains, although the groups themselves do *not* merge to a single one-parameter unitary group on the Hilbert space.

The transformation (3.56) is of the form $(x^L,x^R)\mapsto(f(x^L),f(x^R))$ with f an order preserving bijective map $\mathbf{R}\to\mathbf{R}$. Hence, it is a causal transformation on two-dimensional space–time, i.e., it takes light cones into light cones. Such nonlinear causal maps on Minkowski space exist only in two space–time dimensions.

Finally, we remark that all results of this section hold for general 2-D theories, provided the state satisfies a KMS condition with respect to both light-cone coordinates, x^L and x^R. For factorizing states, this holds automatically as a consequence of the KMS condition with respect to the time direction. A general proof of a KMS condition with respect to light-like translations seems out of reach, however, even if one involves the relativistic KMS condition.[22]

IV. EXPLICIT REALIZATIONS OF MODULAR GROUPS

In this section we compute explicitly the modular and Γ groups for generalized free fields on a light ray and the corresponding tensor product models on $\mathbf{R}^2$. In these examples it is possible to discuss the action of the groups on the algebras of double cones and not only of translated forward cones and wedges.

The Weyl algebra of a generalized free Bose field on a light ray is generated by elements $W(f)$, with f a real-valued Schwartz test function on $\mathbf{R}$, satisfying the following relations:

$$W(f)^*=W(-f) \tag{4.1}$$

and

$$W(f)W(g)=e^{-K(f,g)/2}W(f+g), \tag{4.2}$$

with

$$K(f,g)=\int_{-\infty}^{\infty} pQ(p^2)\tilde{f}(-p),\tilde{g}(p)dp, \tag{4.3}$$

where $Q(p^2)$ is a non-negative polynomial that characterizes the field (see Ref. 11). Here $\tilde{f}(p)=(1/2\pi)\int\exp(-ipx)f(x)dx$ is the Fourier transform of f. The kernel of $\mathcal{K}$ of K, defined by $K(f,g)=\int\mathcal{K}(y-x)f(x)g(y)dx\,dy$, is

$$\mathcal{K}(y-x)=M(-id/dy)\,\delta(y-x), \tag{4.4}$$

with $M(p)=pQ(p^2)$, so $W(f)$ and $W(g)$ commute if f and g have disjoint supports.

Translations in time are equivalent to translations along the light ray and are represented by automorphisms of the Weyl algebra,

$$\alpha_t(W(f))=W(f(\cdot-t)). \tag{4.5}$$

A quasifree KMS state ω at inverse temperature β is defined on the Weyl algebra by

$$\omega(W(f))=\exp(-\omega_2(f,f)), \tag{4.6}$$

where ω_2 is given by a positive definite kernel $\mathcal{W}_2(y-x)$ (two-point function) that is analytic in the strip $S(0,\beta)$, and satisfies

$$\mathcal{W}_2(\xi)-\mathcal{W}_2(-\xi)=\mathcal{K}(\xi), \tag{4.7}$$

for real ξ, together with the KMS condition

$$\mathcal{W}_2(\xi+\mathrm{i}\beta)=\mathcal{W}_2(-\xi). \tag{4.8}$$

It is straightforward to show that these conditions fix $\mathcal{W}_2$ (up to normalization); its Fourier transform is

$$\tilde{\mathcal{W}}_2(p)=\frac{pQ(p^2)}{1-e^{-\beta p}}. \tag{4.9}$$

The Fourier transform of the meromorphic function $(1-\exp(-\beta p))^{-1}$ is seen to be $\lim_{\varepsilon\to 0_+}(2\pi i\beta)^{-1}(\exp(\beta^{-1}2\pi\xi+\mathrm{i}\varepsilon)-1)^{-1}$ by contour integration. The Fourier transform of (4.9) for general Q follows by differentiation. In particular, we have for $Q\equiv 1$, i.e., a field of scaling dimension 1,

$$\mathcal{W}_2(\xi)=\lim_{\varepsilon\to 0_+}\frac{1}{\beta^2}\frac{1}{\left(\sinh\dfrac{\pi(\xi+i\varepsilon)}{\beta}\right)^2}, \tag{4.10}$$

and for Q a polynomial of degree n,

$$\mathcal{W}_2(\xi)=\lim_{\varepsilon\to 0_+}\frac{P\left(\cosh\dfrac{\pi\xi}{\beta},\sinh\dfrac{\pi\xi}{\beta}\right)}{\left(\sinh\dfrac{\pi(\xi+\mathrm{i}\varepsilon)}{\beta}\right)^{2n+2}}, \tag{4.11}$$

where P is a polynomial in two variables. We shall restrict ourselves to the case that $Q(p^2)=p^{2n}$, i.e., a field of a definite scaling dimension $(n+1)$, in order not to mix the effects coming from the nonzero temperature with those due to inhomogeneous polynomials Q (see Ref. 11 for the latter).

Denoting the Weyl operators corresponding to $Q(p^2)=p^{2n}$ by $W^{(n)}(f)$, it is clear from (4.3) that we may identify

$$W^{(n)}(f)=W^{(0)}(\mathrm{i}^n f^{(n)}), \tag{4.12}$$

where $f^{(n)}$ is the nth derivative of f, and from (4.9) we see also that a KMS state for any n is the same as the KMS state for $n=0$ restricted to the operators $W^{(0)}(\mathrm{i}^n f^{(n)})$. This will allow us to reduce everything to the simplest case, $n=0$.

Let π be the GNS representation defined by the KMS state (4.6) on the Weyl algebra of the $W^{(0)}(f)$'s. If $I\subset\mathbf{R}$ is an interval, bounded or unbounded, we define $\mathcal{M}^{(n)}(I)$ to be the von Neumann algebra generated by $\pi(W^{(n)}(f))$ with supp $f\subset I$. Because of the identification discussed above, these algebras are for all n realized on the same Hilbert space.

By exactly the same arguments as in Ref. 11, Sec. III, one proves the following.

4.1 Lemma: *If I is an unbounded interval, then $\mathcal{M}^{(n)}(I)\equiv\mathcal{M}(I)$ is independent of n. If I is bounded with a nonempty interior, then $\mathcal{M}^{(m)}(I)$ is a proper subalgebra of $\mathcal{M}^{(n)}(I)$ for $m>n$.*

This lemma implies, in particular, that the modular operator Δ_+ corresponding to the half-line $\mathbf{R}_+$ is the same for all n.

The main result about the modular action is the following

Theorem 4.2: *Let ω be the quasifree KMS state (4.6) and π the corresponding representation of the Weyl algebra for $n=0$. The modular group of $\mathcal{M}(\mathbf{R}_+)$ defined by ω has the form*

$$\Delta_+^{\mathrm{i}u}\pi(W^{(0)}(f))\Delta_+^{-\mathrm{i}u}=\pi(W^{(0)}(\delta_u^{(0)}f)), \tag{4.13}$$

with

$$\delta_u^{(0)}f(x)=f\left(\frac{\beta}{2\pi}\log\{1+e^{2\pi u}(e^{2\pi x/\beta}-1)\}\right), \tag{4.14}$$

for supp $f\subset\mathbf{R}_+$.

Remark 1: It is understood that if supp $f\subset\mathbf{R}_+$, then also $\delta_u^{(0)}f(x)=0$ for all $x<0$.

Remark 2: The cyclic vector Ω corresponding to ω has the Reeh–Schlieder property, in particular, it is cyclic for $\mathcal{M}(\mathbf{R}_+)$. Hence, (4.13) with supp $f\subset\mathbf{R}_+$, together with $\Delta_+^{it}\Omega=\Omega$, already fixes Δ_+^{it} as a unitary group on the GNS Hilbert space. But $\Delta_+^{iu}\pi(W^{(0)}(f))\Delta_+^{-iu}$ is, of course, a well-defined operator on the Hilbert space for all f of compact support, and, in fact, if $u\geqslant 0$, then (4.13) and (4.14) hold for functions with support outside of $\mathbf{R}_+$ with the understanding that (4.14) is zero when the argument of the logarithm is $\leqslant 0$. This is a simple consequence of (3.1)–(3.3). If $u<0$, however, the transformed operator only belongs to the observable algebra if condition (3.3) holds on the support of f.

Proof of Theorem 4.2: The formula (4.14) is motivated by Eq. (2.20). In order to show that it is the correct formula for the modular action, we have to check the following properties of $\delta_u^{(0)}$: (i) $\delta_u^{(0)}$ maps the space of test functions with support in $\mathbf{R}_+$ into itself; (ii) the group property, i.e., $\delta_u^{(0)}\circ\delta_{u'}^{0}=\delta_{u+u'}^{(0)}$; (iii) the unitary of $\delta_u^{(0)}$ in the scalar product defined by the two point function (4.10); (iv) the KMS condition: For real test functions f and g with support in $\mathbf{R}_+$ the function $u\mapsto\omega_2(f,\delta_u^{(0)}g)$ has an analytic continuation into the strip $S(-1,0)$ and

$$\omega_2(f,\delta_{u-i}^{(0)}g)=\omega_2(\delta_u^{(0)}g,f).$$

Property (i) is obvious from the definition, and (ii) and (iii) are straightforward calculations. We now check the KMS condition. Put

$$L(u,x):=\frac{\beta}{2\pi}\log\{1+e^{2\pi u}(e^{2\pi x/\beta}-1)\}. \tag{4.15}$$

Since $L(u,L(-u,y))=y$ (group property), we have

$$\omega_2(f,\delta_u^{(0)}g)=\int\int\mathcal{W}_2(L(-u,y)-x)\,\frac{\partial L(-u,y)}{\partial y}\,f(x)g(y)dx\,dy. \tag{4.16}$$

Using the addition formula for hyperbolic functions, we compute, for the two-point function, (4.10):

$$\begin{aligned}
&\mathcal{W}_2(L(-u,y)-x)\partial L(-u,y)/\partial y\\
&\quad=\frac{1}{4\beta^2}[\sinh(\pi L(-u,y)/\beta)\cosh(\pi x/\beta)-\cosh(\pi L(-u,y)/\beta)\\
&\qquad\times\sinh(\pi x/\beta)+i\varepsilon]^{-2}\,\frac{\partial L(-u,y)}{\partial y}\\
&\quad=\frac{1}{16\beta^2}[\{(1+e^{-2\pi u}(e^{2\pi y/\beta}-1))^{1/2}+(1+e^{-2\pi u}(e^{2\pi y/\beta}-1))^{-1/2}\}\cosh(\pi x/\beta)\\
&\qquad-\{(1+e^{-2\pi u}(e^{2\pi y/\beta}-1))^{1/2}+(1+e^{-2\pi u}(e^{2\pi y/\beta}-1))^{-1/2}\}\\
&\qquad\times\sinh(\pi x/\beta)+i\varepsilon]^{-2}\,\frac{e^{-2\pi u}e^{2\pi y/\beta}}{e^{-2\pi u}(e^{2\pi y/\beta}-1)+1}\\
&\quad=\frac{1}{16\beta^2}[\{e^{-2\pi u}(e^{2\pi y/\beta}-1)\}\cosh(\pi x/\beta)-\{2+e^{-2\pi u}(e^{2\pi y/\beta}-1)\}\\
&\qquad\times\sinh(\pi x/\beta)+i\varepsilon]^{-2}e^{-2\pi u}e^{2\pi y/\beta}\\
&\quad=\frac{e^{2\pi y/\beta}}{16\beta^2}[e^{-\pi u}(e^{2\pi y/\beta}-1)[\cosh(\pi x/\beta)-\sinh(\pi x/\beta)]-e^{\pi u}2\sinh(\pi x/\beta)+i\varepsilon]^{-2}.
\end{aligned}$$

For $x,y>0$, $e^{-\pi u}$ comes with a positive factor and $e^{\pi u}$ with a negative one. For $\varepsilon>0$, the total expression is therefore analytic in u in the strip $S(-1,0)$, and this analyticity is preserved in the limit $\varepsilon\rightarrow 0_+$ after smearing in x and y, with test functions with support in $\mathbf{R}_+$. The boundary value at $u-i$, $u\in\mathbf{R}$ is

$$\frac{e^{2\pi y/\beta}}{16\beta^2}\,[e^{\pi u}2\sinh(\pi x/\beta)-e^{-\pi u}(e^{2\pi y/\beta}-1)[\cosh(\pi x/\beta)-\sinh(\pi x/\beta)]+\mathrm{i}\varepsilon]^{-2}.$$

This is precisely $\mathcal{W}_2(x-L(-u,y))\partial L(-u,y)/\partial y$ (by the same computation). Hence, the KMS condition is verified.

The representation of the group $\Gamma_+(\tau)=\exp(\mathrm{i}\tau G_+/\beta)$ with the positive generator $G_+/\beta=H+(1/\beta)\log\Delta_+$ now follows immediately from Eqs. (2.25) and (4.13)–(4.14):

Theorem 4.3: *For* $\tau\geqslant 0$ *and all* f

$$\Gamma_+(\tau)\pi(W^{(0)}(f))\Gamma_+(-\tau)=\pi(W^{(0)}(\gamma_\tau^{(0)}f)) \tag{4.17}$$

with

$$\gamma_\tau^{(0)}f(x)=f\left(x+\frac{\beta}{2\pi}\log\left\{1-\frac{2\pi\tau}{\beta}e^{-2\pi x/\beta}\right\}\right). \tag{4.18}$$

Remark: It is understood that $\gamma_\tau^{(0)}f(x)=0$ if the argument of the logarithm is $\leqslant 0$, i.e., if $x\leqslant-\beta/(2\pi)\log(2\pi\tau/\beta)$. Note that if $\tau\geqslant\beta/(2\pi)$, then supp $\gamma_\tau^{(0)}f\subset\mathbf{R}_+$ for any f of compact support.

By (4.12) we obtain as a corollary of Theorems 4.2 and 4.3, the following.

Theorem 4.4: *For* $n>0$ *the action of* ad $\Delta_+^{\mathrm{i}u}$ *and* ad $\Gamma_+(\tau)$ *on* $W^{(n)}(f)$ *with* supp $f\subset\mathbf{R}_+$ *is*

$$\Delta_+^{\mathrm{i}u}\pi(W^{(n)}(f))\Delta_+^{-\mathrm{i}u}=\pi(W^{(n)}(\delta_u^{(n)}f)), \tag{4.19}$$

with

$$\delta_u^{(n)}f(x)=\int_0^x dx_1\int_0^{x_1}\cdots\int_0^{x_{n-1}}dx_n\;\delta_u^{(0)}f^{(n)}(x_n), \tag{4.20}$$

and, for $\tau\geqslant 0$,

$$\Gamma_+(\tau)\pi(W^{(n)}(f))\Gamma_+(-\tau)=\pi(W^{(n)}(\gamma_\tau^{(n)}f)), \tag{4.21}$$

with

$$\gamma_\tau^{(n)}f(x)=\int_0^x dx_1\int_0^{x_1}\cdots\int_0^{x_{n-1}}dx_n\;\gamma_\tau^{(0)}f^{(n)}(x_n). \tag{4.22}$$

Remark. It should be noted that $\delta_u^{(n)}f$ is, in general, no longer a test function if $n>0$, for it may behave like x^{n-1} for $x\rightarrow\infty$. However, it belongs to the Hilbert space defined by the two-point function, and hence the Weyl operators are well defined. The same applies to $\gamma_\tau^{(n)}f$.

Next, we investigate the localization properties of the modular groups. We recall from Lemma 4.1 that for an unbounded interval $[x,\infty[$ the algebras $\mathcal{M}^{(n)}([x,\infty[)\equiv\mathcal{M}([x,\infty[)$ are independent of n. Hence, the general result (3.1) applies. For the algebras corresponding to bounded intervals, we have the following theorem.

Theorem 4.5: *For* $-\infty<x<y<\infty$ *and* u *and* τ *restricted according to (3.3), (3.5) (3.9), (3.12),*

$$\mathrm{ad}\,\Delta_+^{\mathrm{i}u}\mathcal{M}^{(0)}([x,y])=\mathcal{M}^{(0)}([\varphi_+(u,x),\varphi_+(u,y)]), \tag{4.23}$$

and

$$\mathrm{ad}\,\Gamma_+(\tau)\mathcal{M}^{(0)}([x,y])=\mathcal{M}^{(0)}([\psi_+(\tau,x),\psi_+(\tau,y)]). \tag{4.24}$$

For $n>0$ a local algebra $\mathcal{M}^{(n)}([x,y])$ is not mapped into an $\mathcal{M}^{(n)}(I)$ with bounded I.

Proof: For fixed u and τ the maps $x\mapsto\varphi_+(u,x)$ and $x\mapsto\psi_+(\tau,x)$ are one to one for x satisfying (3.3) and (3.9), respectively, and the inverse maps correspond to $u\to-u$ and $\tau\to-\tau$. From (3.14) it is clear that f has its support in $[x,y]$, iff $\delta_u^{(0)}f$ has its support in $[\varphi_+(u,x),\varphi_+(u,y)]$ iff $\gamma_\tau^{(0)}f$ has its support in $[\psi_+(\tau,x),\psi_+(\tau,y)]$. Hence (4.23) and (4.24) follows directly from Theorems 4.2 and 4.3.

To show the dislocalization for $n>0$ we note first that neither $\delta_u^{(0)}f^{(n)}$ nor $\gamma_\tau^{(0)}f^{(n)}$ is a derivative of a function with compact support (except for $f\equiv0$). This is easily seen by considering the Fourier transforms of these functions, divided by p; the $1/p$ singularity is not compensated by the derivatives because of the nonlinear variable transformations, and analyticity is lost. Consider now a bounded interval I and a function g such that $g^{(n+1)}$ vanishes on I. Then $W^{(0)}(g)$ belongs to the commutant of $\mathcal{M}^{(n)}(I)$. If $W^{(n)}(\delta_u^{(n)}f)=W^{(0)}(\delta_u^{(0)}f^{(n)})$ would belong to $\mathcal{M}^{(n)}(I)$, then it would commute with $W^{(0)}(g)$, which means that

$$\int\delta_u^{(0)}f^{(n)}(x)g'(x)dx=0.$$

This must, in particular, hold for all g with $g'\equiv1$ on I because such g fulfill $g^{(n+1)}=0$ on I for $n>0$. Hence

$$\int_I\delta_u^{(0)}f^{(n)}(x)dx=0. \tag{4.25}$$

By isotony this should also hold for all larger intervals, and hence $\delta_u^{(0)}f^{(n)}$ would be a derivative of a function of compact support. As remarked above, this is not the case, and we have a contradiction to the assumption that $W^{(n)}(\delta_u^{(n)}f)$ belongs to $\mathcal{M}^{(n)}(I)$ with I bounded. By the same argument $W^{(n)}(\gamma_\tau^{(n)}f)$ does not belong to $\mathcal{M}^{(n)}(I)$.

Remark 1: In terms of the field operators $\Phi^{(n)}(x)$, defined by

$$\pi(W^{(n)}(f))=\exp\left(\mathrm{i}\int\Phi^{(n)}(x)f(x)dx\right), \tag{4.26}$$

Eqs. (3.13) and (3.17) say that

$$\Delta_+^{\mathrm{i}u}\Phi^{(0)}(x)\Delta_+^{-\mathrm{i}u}=\Phi^{(0)}(\varphi_+(u,x))\,\frac{\partial\varphi_+(u,x)}{\partial x} \tag{4.27}$$

and

$$\Gamma_+(\tau)\Phi^{(0)}(x)\Gamma_+(-\tau)=\Phi^{(0)}(\psi_+(\tau,x))\,\frac{\partial\psi_+(\tau,x)}{\partial x}. \tag{4.28}$$

In particular, we have

$$\Delta_+^{\mathrm{i}u}\Phi^{(0)}(0)\Delta_+^{-\mathrm{i}u}=e^{-2\pi u}\Phi^{(0)}(0) \tag{4.29}$$

and

$$\Gamma_+(\tau)\Phi^{(0)}(0)\Gamma_+(-\tau)=(1+(2\pi\tau/\beta))^{-1}\Phi^{(0)}((\beta/2\pi)\log(1+(2\pi\tau/\beta))). \tag{4.30}$$

(Although the field is only an operator-valued distribution, these equations have a rigorous meaning in terms of quadratic forms.) Conversely, (3.33) and (3.34), together with Eqs. (2.20) and (2.26), imply (3.31) and (3.32). For $n>0$, however, ad Δ_+^{iu} is a nonlocal transformation of the field operators by Theorem 4.4. For instance, we have

$$\Delta_+^{iu}\Phi^{(1)}(0)\Delta_+^{-iu}=e^{-2\pi u}\Phi^{(1)}(0)-(2\pi/\beta)e^{-4\pi u}\int_0^\infty \Phi^{(1)}(x)dx. \tag{4.31}$$

This shows clearly that there is more to the transformation law for the fields than Eqs. (2.20) and (2.29) alone.

If $\mathcal{M}(\mathbf{R}_+)$ is replaced by $\mathcal{M}(\mathbf{R}_-)$, the previous results apply with appropriate changes of signs; cf. (3.5).

Forming tensor product algebras as in (3.13), we obtain generalized free fields on two-dimensional space–time and KMS states that factorize in the light-cone variables. In the case of the field with lowest scaling dimension, i.e., $n=0$, the double cone algebras $\mathcal{M}^{(0)}(I_L\times I_R)$, with I_L, I_R bounded intervals, are again mapped into algebras of double cones. The flow lines of Figs. 1–4 describe in this case not only the movement of the apex of a forward light cone or the edge of a wedge, but also the movement of the double cones.

For fields of higher scaling dimension, i.e., $n>0$, however, double cone algebras are after the transformation no longer localized in double cones within the net $\mathcal{M}^{(n)}$. They are still localized in double cones within the net $\mathcal{M}^{(0)}(\cdot)$, because $\mathcal{M}^{(n)}(\cdot)$ is a subnet of $\mathcal{M}^{(0)}(\cdot)$.

V. CONCLUSIONS

In a KMS state at inverse temperature β the time translations coincide (up to a sign and scaling by β) with the modular group of the global observable algebra. From this fact, and the general theory of half-sided modular inclusions, algebraic relations between time translations and the modular groups for certain domains of space–time can be derived. The action of the modular groups on observables localized inside these domains far from the boundary is approximately given by the time translations. In two-dimensional models and states that satisfy a KMS condition with respect to light-like translations (in particular, models that factorize in the light-cone coordinates), a geometric interpretation can be given of the action of the modular groups of the forward light cone and a space-like wedge on observable algebras localized in translated domains of the same type. This action can be studied in detail in simple free field models. Besides the modular groups, the theory also leads to one-parameter groups with positive generators, for which the KMS state is a ground state. The actions of these groups for the forward cone and the wedge can also be described geometrically and interpreted, at least formally, as a kind of a reverse Unruh effect.

(Received 23 July 1998; accepted for publication 19 October 1998)

The Schrödinger equation in higher dimensions is considered. It consists of the kinetic energy part given by the corresponding Laplace operator, and a term describing the interaction with the electrostatic field of a point charge. From Rutherford-type scattering experiments one can conclude that the potential of a point charge is $\sim 1/r$ irrespective of the dimension of the space where the experiment is carried through. Also the structure of the kinetic energy is unchanged in higher dimensions so that one is lead to the result that there exist stable atoms in higher spatial dimensions $d \geqslant 4$. The solutions and energy eigenvalues to this Schrödinger equation in higher dimensions are presented. As a consequence, the dimensionality of space can be read off from the spectral scheme of atoms: The three-dimensionality of space is a consequence of the existence of the Lyman series. Another consequence is that the Maxwell equations in higher dimensions must be modified in order to have the $1/r$-potential as solution for a point charge.

I. INTRODUCTION

The idea of extra space–time dimensions continues to pervade current attempts to unify the fundamental forces, but in ways somewhat different from that originally envisaged. A modern perspective on the role of internal dimensions in physics comes mainly from the superstring theory, which is the most promising candidate for a unified field theory. The appearance of extra space–time dimensions at high energy scales is a generic feature of string theory. Typically these extra dimensions remain compactified at the Planck scale, but it is possible for new dimensions to have an effect below the Planck scale. In particular, large-radius compactification schemes have recently been discussed in a number of theoretical and phenomenological contexts.[1,2] Similarly, the effects of extra dimensions below the Planck scale have played a role in understanding the strong-coupling behavior of string theory.[3] Even the old pioneer Kaluza–Klein theory is embedded in a super-string theory; their states persist as a subset of the full string spectrum. However, string theory comes to rescue and ensures correct high-energy behavior.[4] Then, we can regard this theory as an effective ''medium'' energy model coming from finite string field theories. Therefore, the study of different higher-dimensional models is of importance for the understanding of more general theories.

One of the most interesting questions addressed to the higher-dimensional approaches concerns the stability of atoms in higher spatial dimensions, i.e., $d > 3$. These investigations started

with the well-known paper of Ehrenfest[5] and has inspired many additional interesting investigations. For reviews see Refs. 6 and 7, and for a recent paper on this problem see Ref. 8 where the dimensionality of space–time has been related to physical phenomena which are accessible to experiment.

According to the analysis of Ehrenfest, see also Ref. 9, there are statements in all papers that in higher dimensions it is not possible to have stable atoms. It is one of our purposes in this paper to show that it is indeed possible to have *stable atoms in higher dimensions*. The main point is that first the kinetic energy in the Schrödinger has the usual form described by the d-dimensional Laplacian and that the electrostatic interaction in the Schrödinger equation has the same form irrespective of the spatial dimension. This of course leads to modified Maxwell equations in higher dimensions. While the main characteristics of these new Maxwell equations in higher dimensions remains the same as compared with the Maxwell equations in three dimensions (the solutions have the same structure and the force between charges is the same as in three dimensions), these modified Maxwell equations do not lead to a Gaussian law for charges. This may sound strange but the results of scattering experiments, the stability of atoms in higher dimensions, and the structure of the force between charges is certainly of more basic physical content.

A second point in our paper is that the spectra of atoms are influenced by the spatial dimension. That means, as we shall show, that we *can decide from a spectroscopic experiment the dimension of our configuration space*. To be more concrete, the ratio of the frequencies of two distinguished spectral lines leads to a number from which we uniquely infer the three-dimensionality of our space. If this ratio gives a different number we would be led to four or another number of spatial dimensions.

The most important starting point of our investigation is the structure of the Schrödinger equation in higher dimensions. One way which fixes the kinetic part of the Schrödinger equation is the quantization scheme arising from the Hamilton–Jacobi equation of a point mass which also in higher dimensions has the usual form $E=p^2/2m+V$, where V is some potential energy. In addition, also from a constructive axiomatic scheme (see, for example, Refs. 8 or 10) one gets a Dirac equation in higher dimensions which nonrelativistic limit[11] necessarily possesses a kinetic term which is proportional to the Laplace operator. Therefore, any modification of this term would need a modification of the quantization scheme as well as a violation of fundamental properties (like unique evolution, superposition principle, finite propagation speed, etc., see, for example, Ref. 10) of single particle quantum systems. Since these modifications obviously changes physics drastically we do not change the structure of the usual kinetic term.

As far as the potential energy term is concerned we use results from scattering experiments to fix its form. Indeed, since the results of Rutherford-type scattering experiments are independent of the spatial dimension, we can unambiguously conclude from the experimental data, that in any dimension d the potential must be of the form $\sim 1/r$. This is of course consistent with the analysis of Ref. 5 that atoms with the usual kinetic energy coupled to a modified potential of the form $\sim/r^{d-2}$ are not stable (the exponent $d-2$ is due to the requirement that Gauss' law should be still valid in higher dimensions). Since our result for the electrostatic potential is not compatible with a Gaussian law for electrostatics, we conclude that we have to modify the structure of Maxwell's equations in higher dimensions.

Consequently, we take as general ansatz for the Hamilton operator for the hydrogen atom in higher dimensions,

$$H=\frac{p^2}{2m}+V(r), \tag{1}$$

where $V(r)$ is the spherically symmetric potential given by

$$V(r)=\frac{\alpha}{r}. \tag{2}$$

In comparison to other work on the problem of physics in higher dimensions, we do not consider the usual physical laws like the Maxwell equations (see, for example, Refs. 12 and 13) or the Schrödinger equation or Newton's field equations (see Ref. 5), or the Einstein equations (see Refs. 14–16) to be valid in higher dimensions and discuss physical implications of the solutions. Instead, we start with general *physical* properties of the class of phenomena under consideration and then try to get information of the structure of the physical laws. In general, these equations in higher dimensions are very different from the equations in three dimensions describing the same effects. An interesting approach,[17] which is in the line of our reasoning, is based on the causal structure of space–time events. It deduces the four-dimensionality of space–time from a set of axioms which do not use the notion of a differentiable manifold or of the dimensionality. Another approach having some similarities to our reasoning is given in Ref. 18 where it is shown that for a gravitational theory based on a quadratic Lagrangian the usual Newtonian limit and Huygens' principle is valid only if this theory if formulated in six space–time dimensions. In Ref. 8, a very general approach to a generalized Dirac equation in arbitrary dimensions has been used and the dimensions of space–time has been inferred from the propagation of helicity states and from the validity of Huygen's principle. In this work we do not consider the fractal dimension; see, for example, Ref. 19.

In earlier work[5–7] it has been shown that there are no stable hydrogen atoms in higher dimensions. Essential for that was the assumption that also in higher dimensions Maxwell's equations were assumed to be valid leading to a potential of a point charge of the form $\sim 1/r^{d-2}$ where d is the spatial dimension. In our approach we do not assume the usual Maxwell equations to be valid. We only use the results of scattering experiments to get information about the potential of a point charge. We use this potential in Sec. III in order to solve the hydrogen atom and then show that even in higher dimensions there are stable atoms. However, from the comparison of the calculated spectrum with the observational data we are able to determine in Sec. IV the dimensionality of our space. In Sec. V we present the full set of modified Maxwell equations in order to show that even our potential violating Gauss' law is part of a consistent set of equations governing electrodynamical phenomena in a higher dimension. Though being nonlocal in general, they are still Lorentz-covariant.

II. THE POTENTIAL OF A POINT CHARGE IN HIGHER DIMENSIONS

The electrostatic potential of the atomic nucleus which we assume to be pointlike, can be determined by means of scattering processes. Indeed, using the scattering of α-particles at gold atoms, Rutherford was able to deduce that the electrostatic potential within an atom is the Coulomb potential. We will show that this procedure and this result is true independent of the underlying spatial dimensions. This can be seen already from the fact that the classical trajectory of a point charge in a $1/r$ potential does not depend on the spatial dimension so that the relation between the deflection angle and the potential also remains the same.

Starting with (1,2), conventional quantum mechanics gives the asymptotics of scattered waves according to

$$u^{+}(\vec{r}) = \frac{1}{(2\pi)^{d/2}} \left(e^{i\vec{k}\vec{r}} + f_{\vec{k}}(\vec{e})\, \frac{e^{ikr}}{r^{(d-1)/2}} \right), \tag{3}$$

with $\vec{e} = \vec{r}/r$. This can be shown by calculating the Green's function in the energy representation

$$G(\vec{r},\vec{r}\,') = \frac{1}{(2\pi\hbar)^d} \lim_{\epsilon\to 0^+} \int \frac{e^{(i/\hbar)(\vec{r}-\vec{r}\,')\cdot\vec{p}}}{E_0 + i\epsilon - p^2/2m}\, d^d p$$

which results in a position dependence of the form $\sim |\vec{r}-\vec{r}\,'|^{-(d-2)}$ with factors depending on the dimension d and an integration over a spherical Bessel function. The scattering amplitude is then given by

$$f_{\vec{k}}(\vec{e}) \sim \int e^{-ik\vec{e}\vec{r}\,'} V(\vec{r}\,') u^{+}(\vec{r}\,') d^d x', \tag{4}$$

where $\vec{e}=\vec{r}/r$. In the Born approximation we have

$$f_{\vec{k}}(\vec{e}) \sim \int e^{i(\vec{k}-\vec{q})\vec{r}} V(\vec{r}) d^d x. \tag{5}$$

In a scattering experiment the measured quantity is the differential cross section $\sigma(\vec{e},\vec{k}_0)$ which is related to the scattering amplitude by

$$\sigma(\vec{e},\vec{k}_0) = |f_{\vec{k}_0}(\vec{e})|^2. \tag{6}$$

This is a relation which is independent of the dimension of the underlying space. In the Born approximation there is a one-to-one correspondence between the differential cross section and the potential $V(\vec{r})$. Therefore, by analyzing the standard Rutherford-type experiments we can uniquely conclude that a point charge, or the nucleus of a hydrogen atom, possess a potential of the form $\sim r^{-1}$, independent of the spatial dimension.

III. THE HYDROGEN ATOM IN HIGHER DIMENSIONS

We start with the Hamilton operator (1) in the external spherically symmetric potential (2) which gives, in position representation,

$$[\Delta - \phi + \epsilon]\psi = \psi, \tag{7}$$

where we introduced the abbreviations

$$\phi(r) = \frac{2m}{\hbar^2} V(r), \tag{8}$$

$$\epsilon = \frac{2m}{\hbar^2} E. \tag{9}$$

The following calculations are analogous to that in three dimensions. Also, in a higher dimension we can separate the Laplace operator into a radial and an angular part:

$$\Delta = \hat{R} - \frac{1}{r^2} \hat{L}, \tag{10}$$

where we introduced

$$\begin{aligned} \hat{R} &= \frac{\partial^2}{\partial r^2} + \frac{d-1}{r} \frac{\partial}{\partial r}, \\ \hat{L} &= \hat{L}(\Theta_2, \ldots, \Theta_n). \end{aligned} \tag{11}$$

With the corresponding ansatz,

$$\psi = R(r) Y(\Theta_2, \ldots, \Theta_d), \tag{12}$$

we get from the Schrödinger equation in d dimensions,

$$\frac{r^2}{R}\hat{R}R+r^2(\epsilon-\phi)=\frac{1}{Y}\hat{L}Y=l(l+d-2). \tag{13}$$

$Y(\Theta_2,\ldots,\Theta_d)$ represents the spherical harmonics in d dimensions. They are eigenstates of the angular momentum operator $\hat{L}$ with the eigenvalues $l(l+d-2)$. Thus we get for the radial part of the wave function,

$$\left[\frac{\partial^2}{\partial r^2}+\frac{d-1}{r}\frac{\partial}{\partial r}+\epsilon-\phi-\frac{l(l+d-2)}{r^2}\right]R=0. \tag{14}$$

We introduce

$$r'=\frac{r}{r_0},\quad -\epsilon=\frac{1}{r_0^2},\quad \alpha'=\frac{2m\alpha}{\hbar^2}\frac{r_0}{2}, \tag{15}$$

and assume for the potential the form

$$\phi(r')r_0^2=-\frac{\alpha'}{r'}. \tag{16}$$

We also introduce a new variable $f(r')$ through

$$R=e^{-(1/2)r'}r'^{\gamma}f(r'), \tag{17}$$

and get an equation for the function f:

$$\begin{aligned}0=r\frac{d^2f(r')}{dr'^2}+[2\gamma+d-1-r]\frac{df(r')}{dr'}\\+\left[\frac{\gamma(\gamma+d-2)-l(l+d-2)}{r'}+\frac{\alpha'}{r'}-\frac{2\gamma+d-1}{2}\right]f(r').\end{aligned} \tag{18}$$

This equation is valid for arbitrary d. In order to solve this equation we specify the value of γ by the requirement that the term $\sim 1/r'$ should vanish:

$$\gamma(\gamma+d-2)-l(l+d-2)=0. \tag{19}$$

This gives the two possibilities

$$\gamma_+=l, \tag{20}$$

$$\gamma_-=-(l+d-2), \tag{21}$$

and from (18),

$$zf''-[\vartheta-z]f'-\beta f=0, \tag{22}$$

with

$$\vartheta:=\pm(2l+d-2)+1,\quad \beta:=\frac{\pm(2l+d-2)+1}{2}-\alpha'. \tag{23}$$

Equation (22) is the confluent hypergeometric differential equation with the solution[20]

$$f(\beta,\vartheta,z)=\sum_{\nu=0}^{\infty}\frac{(\beta+\nu)!\,\vartheta!}{\beta!(\vartheta+\nu)!}\frac{z^{\nu}}{\nu!}, \tag{24}$$

which is appropriate for our problem.

It is clear that, in order to get no infinite terms, ϑ is not allowed to be a negative integer: $\vartheta\neq-1,-2,\ldots$. Therefore we cannot use the solution (21). In addition, if the sum does not terminate, then the solution diverges for large r faster than $\exp(\frac{1}{2}r')$ which leads to non-normalizable solutions. The condition for a termination of the sum is $\beta\in\mathbb{Z}^{-}$, or

$$\beta=l+\frac{d-1}{2}-\alpha'=-k, \quad k\in\mathbb{N}. \tag{25}$$

Here α' is connected with the energy eigenvalues (1,8,15). Therefore we get for the energy eigenvalues E,

$$E=\frac{2m\alpha^2}{\hbar^2}\frac{1}{\alpha'^2}=-\frac{2m\alpha^2}{\hbar^2}\frac{1}{(l+[(d-1)/2]+k)^2}=-Ry\frac{1}{n^2}=:E_n, \tag{26}$$

where the principal quantum number n is given by the series

$$n=\frac{d-1}{2},\ \frac{d-1}{2}+1,\ \frac{d-1}{2}+2,\ \frac{d-1}{2}+3,\ldots . \tag{27}$$

We also introduced the Rydberg constant Ry which, in general, may depend through α on the dimension d. In the case $d=3$ we recover the usual expressions. Note that, in general, the principal quantum number n must not be an integer.

Consequently, we have shown that for a potential of the form $\sim 1/r$ even in higher dimensions there is a lowest energy level, that is, there are stable atoms.

IV. THE INFLUENCE OF THE DIMENSION ON THE SPECTRUM

We discuss now the spectrum of stable hydrogen atoms in higher dimensions. It is clear that the spectrum depends on the dimension d. An interesting question is whether this dependence is accessible to observations. In an experiment only the difference of two energy eigenvalues,

$$\Delta E_{n',n}=E_{n'}-E_n, \quad n'>n, \tag{28}$$

can be measured. For a fixed n one gets an atomic series which now depends on the dimension d. In three dimensions $d=3$ one gets for $n=1$ the Lyman series, for $n=2$ the Balmer series, for $n=3$ the Paschen series, etc. In 4 dimension, for example, according to (27) it is not possible to have $n=1$, so that in this case there is no Lyman series. In $d=6$ dimensions there is also no Balmer series.

However, since the Rydberg constant Ry may depend on the dimension d in an unknown way, we are not able to draw any conclusions about the dimensionality of space from testing the atomic spectral series. Therefore we are forced to restrict ourselves to the ratio of two energy differences which is also independent of any unit conventions. In our case it is enough to take the ratio of the difference between the three lowest energy levels of one series characterized by n:

$$D(n)=\frac{\Delta E_{n+2,n}}{\Delta E_{n+1,n}}=\frac{4(1+n)^3}{(2+n)^2(1+2n)}. \tag{29}$$

Because this function $D(n)$ is one-to-one, the value of $D(n)$ uniquely characterizes the corresponding series. For the first few values we get $D(0)=1$, $D(\frac{1}{2})=\frac{27}{25}=1.08$, $D(1)=\frac{32}{27}=1.18519$, $D(\frac{3}{2})=\frac{125}{98}=1.275$, $D(2)=\frac{27}{20}=1.35$, $D(\frac{5}{2})=\frac{343}{243}=1.41152$, etc.

Therefore we have the following experimental method at hand in order to determine the dimensionality of our space: We consider that series which belongs to the lowest energy state. From this series we take the two highest frequency spectral lines and calculate the ratio. This gives the value $D(n_{\min})$. From this value we can calculate the corresponding $n_{\min}$ and, using (27), the dimension $d=2n_{\min}+1$ of our space. Here we used that in each dimension the lowest series contains only transitions with $l=k=0$.

We know from spectroscopy of the hydrogen atom that the two spectral lines coming from transitions to the lowest energy level have (see, for example, Ref. 21) 1215.67 Å and 1025.73 Å, so that $D(n_{\min})=1216/1026=1.18518$. A comparison with the values of $D(n)$ shows that this implies $n_{\min}=1$, and from Eq. (27) that $d=3$. Therefore we have *proven by a spectroscopic experiment that our space is three-dimensional*. In other words, because we know the spectrum of the hydrogen atom we are able to determine the dimensionality of space.

We want to stress once more that it is not the stability of the atom which one may use as argument in favor of three spatial dimensions. In our approach the stability of atoms is secured in any dimension. It is only the structure of the spectral series which leads us to the conclusion that space is three-dimensional.

V. MAXWELL EQUATIONS IN HIGHER DIMENSIONS

We have seen that the electric potential of a point charge in the Schrödinger equation in higher dimensions must be of the form $U\sim 1/r$ independent of the dimension d. Since the usual Laplacian has the same form in any dimension, the above potential cannot be a solution of the Poisson equation in $d>3$ dimensions. However, we show that it is indeed possible to present a consistent set of equations governing the electromagnetic phenomena in higher dimensions which violates no fundamental principle of electrodynamics and, in addition, possesses the above electrostatic solutions for a point charge. Of course, the structure of the Maxwell equations will be not the same as in three dimensions.

In order to determine the structure of the stationary Maxwell equation for the electric field, we use results of Riesz distributions, see, for example, Refs. 22, 23. In doing so we first define the distribution

$$G_\lambda := \frac{e^{-i\pi\lambda}\Gamma[(d/2)-\lambda]r^{2\lambda-d}}{4^\lambda \pi^{d/2}\Gamma(\lambda)}, \tag{30}$$

where r as usual is the distance $r^2=\Sigma_{i=1}^d x_i^2$. The properties of these distributions G_λ are given by the composition law

$$G_\mu * G_\lambda = G_{\lambda+\mu}, \tag{31}$$

and an explicit representation in the case of negative integers,

$$G_k = \Delta^{-k}\delta, \quad k=0,-1,-2,..., \tag{32}$$

where Δ is again the Laplace operator in an arbitrary dimension, δ the usual Dirac delta distribution, and the star $*$ the convolution operation.

We formally introduce operators $\overline{\Delta}^\lambda$ by

$$\overline{\Delta}^\lambda := G_{-\lambda}, \tag{33}$$

so that the following composition law holds:

$$\overline{\Delta}^{\mu} * G_{\lambda} = G_{\lambda-\mu}. \tag{34}$$

An important special case is given by $\mu=\lambda$:

$$\overline{\Delta}^{\mu} * G_{\mu} = \delta. \tag{35}$$

This means that G_{μ} is a Green's function corresponding to the operator $\overline{\Delta}^{\mu} *$.

Now we come back to our problem of finding the field equations which are required to possess the solution $\sim r^{-1}$ in any dimension d. That means that we require in any dimension $G_{\mu} \sim 1/r$ which implies $\mu=(d-1)/2$. Consequently,

$$\overline{\Delta}^{(d-1)/2} * G_{(d-1)/2} = \delta, \tag{36}$$

or

$$\overline{\Delta}^{(d-1)/2} * \frac{1}{r} = (4\pi)^{(d-1)/2} e^{[i\pi(d-1)/2]} \Gamma\left(\frac{d-1}{2}\right) \delta. \tag{37}$$

This means that the equation for the electric potential, or the generalized Poisson equation, reads as

$$(\overline{\Delta}^{(d-1)/2} * \phi)(x) = (4\pi)^{(d-1)/2} e^{[i\pi(d-1)/2]} \Gamma\left(\frac{d-1}{2}\right) \rho(x), \tag{38}$$

where $\rho(x)$ is the charge density in d dimensions. The operator $\overline{\Delta}^{(d-1)/2}$ replaces the Laplacian in three dimensions. In general, this operator is no differential operator.

We briefly discuss this new form of the Poisson equation in electrostatics.

(1) It is possible to reformulate the field equation for the potential ϕ in terms of the electric field strength $\mathbf{E}=-\nabla\phi$. For doing so we use (31) and (32):

$$\overline{\Delta}^{(d-1)/2} * \phi = (\overline{\Delta} * \overline{\Delta}^{(d-3)/2}) * \phi = \Delta\delta * (\overline{\Delta}^{(d-3)/2} * \phi) = \delta * (\overline{\Delta}^{(d-3)/2} * \delta\phi) = (\overline{\Delta}^{(d-3)/2} * \nabla \cdot \mathbf{E}), \tag{39}$$

so that we get as field equation for the electric field strength,

$$((\overline{\Delta}^{(d-3)/2} * \nabla) \cdot \mathbf{E})(x) = (4\pi)^{(d-1)/2} e^{[i\pi(d-1)/2]} \Gamma\left(\frac{d-1}{2}\right) \rho(x). \tag{40}$$

(2) The force between two charges still has the same form as in 3 dimensions, namely $f \sim q_1 q_2 / r^2$.

(3) For all charge densities $\rho(x)$ the solution for the potential looks as usual, i.e., $1/r * \rho$.

(4) In odd dimensions $d=1,3,5,...$, the above equation reduces via (31) and (32) to a differential equation:

$$\overline{\Delta}^{(d-1)/2} * \frac{1}{r} = \delta * \Delta^{(d-1)/2} \frac{1}{r} = \Delta^{(d-1)/2} \frac{1}{r} = (4\pi)^{(d-1)/2} e^{[i\pi(d-1)/2]} \Gamma\left(\frac{d-1}{2}\right) \delta. \tag{41}$$

For a three-dimensional space, $d=3$, we get the usual Laplace equation $\Delta\phi(x) = -4\pi\rho(x)$ and in a five-dimensional space we get $\Delta^2 \phi(x) = (4\pi)^2 \rho(x)$.

(5) In even dimensions, the operator $\overline{\Delta}^{(d-1)/2}$ is no differential operator but instead a pseudo-differential operator. Therefore the corresponding field equations are pseudo-differential operator equations. These operators are nonlocal. (Indeed, differential operators are the only local operators acting linearly and surjective on C^{∞}; see Ref. 24. For a physical discussion, see, for example, Ref. 25.)

(6) An essential difference to the usual properties of the electric field in 3 dimensions is that now the Gauss' law is no longer valid. This is easy to see by integrating the fundamental solution r^{-1} in an arbitrary dimension over the surface of a sphere with radius R:

$$\int \mathbf{E} \cdot d\mathbf{A} = \int_R \nabla \frac{1}{r} \cdot \hat{\mathbf{r}} R^{d-1} d\Omega = (4\pi)^{(d-1)/2} e^{[i\pi(d-1)/2]} \Gamma\left(\frac{d-1}{2}\right) R^{d-3}, \tag{42}$$

where $\hat{\mathbf{r}}$ is the unit vector in radial direction and $d\Omega$ is the surface element in d dimensions. The result depends on the radius of the sphere so that indeed Gauss' law does not hold. It is only in three spatial dimensions that the quantity $\mathbf{E}$ which plays the role of a force on a charged particle, is also that quantity which integral over the area enclosing a volume gives the total charge which acts as source of $\mathbf{E}$ (the field strength $\mathbf{E}$ is defined by means of the force acting on a charged particle; whether this quantity obeys a law like Gauss' law is a deduced property which holds in three dimensions).

However, Gauss' law is valid for a quantity deduced from $\mathbf{E}$, namely for $\mathfrak{E}=\overline{\Delta}^{(d-3)/2}\mathbf{E}$:

$$\nabla\cdot\mathfrak{E}=(4\pi)^{(d-1)/2}e^{i\pi[(d-1)/2]}\Gamma\left(\frac{d-1}{2}\right)\rho(x)\Leftrightarrow\oint\mathfrak{E}\cdot d\mathbf{A}=(4\pi)^{(d-1)/2}e^{i\pi[(d-1)/2]}Q, \tag{43}$$

where $Q=\int_V\rho(x)d^dx$ is the charge contained in the volume V.

It is also straightforward to give the full set of Maxwell's equations such that their static limit give the Poisson equation discussed above: Since the covariant generalization of the Laplace operator Δ is given by the d'Alambert operator $\Box$, the covariant generalization of Poisson's equation is $\bar{\Box}^{(d-1)/2}*\phi=(4\pi)^{(d-1)/2}e^{i\pi[(d-1)/2]}\Gamma((d-1)/2)\rho$. We complete the quantities to covariant 4-vectors, namely the 4-potential A^a and the 4-current j^a. Then we have, using the same methods as above,

$$\begin{aligned} j^a&=\bar{\Box}^{(d-1)/2}*A^a=(\bar{\Box}*\bar{\Box}^{(d-3)/2})*A^a=\Box\,\delta*(\bar{\Box}^{(d-3)/2}*A^a)=\delta*(\bar{\Box}^{(d-3)/2}*\Box A^a)\\ &=\bar{\Box}^{(d-3)/2}*\partial_bF^{ba}=:\overline{\partial_b}F^{ba}, \end{aligned} \tag{44}$$

where we defined a generalized partial derivative $\overline{\partial_b}:=\bar{\Box}^{(d-3)/2}*\partial_b$ and, as usual, the Maxwell field strength $F_{ab}=\partial_aA_b-\partial_bA_a$. We also used the Lorentz condition $\partial_aA^a=0$. By construction, these generalization of Maxwell's equations is covariant. Also current conservation is fulfilled. For even spatial dimensions these equations are nonlocal.

To sum up: despite the fact that the mathematical structure of the equation determining the electric potential from a given charge density changes dramatically when compared with the three-dimensional case, the physical content does not change. The solution has the same form and the force between charges is the same as in three dimensions. Only Gauss' law loses its meaning. However, we think that the specific expression for the force between charged particles and the stability of atoms are of more basic physical importance than the validity of Gauss' law.

VI. SUMMARY AND DISCUSSION

To sum up, we have shown the following.

(1) From Rutherford-type experiments we can conclude that the potential of the point charge in any spatial dimension must be $\sim 1/r$.
(2) This potential leads to stable atoms in higher dimensions.
(3) The dimensionality enters the atomic spectra thus making it possible to infer uniquely from atomic spectra the three dimensionality of space.
(4) That the Maxwell equations have to be modified in higher dimensions in order to allow solutions of the form $1/r$, leading to nonlocal equations in even spatial dimensions.

In the case that one uses the usual Maxwell equations in higher dimensions the hydrogen atom is proven to be not stable. This has been related to the fact that orbits of classical bodies in a potential derived from the usual Poisson equation in higher dimensions are not stable, as well: small perturbations of the circular orbit leads the body to fall into the central body or to leave the system. Consequently, if one wants to enlarge the above reasoning to the case of Newtonian mechanics, one has to require stable orbits, which gives the $1/r$ potential for gravity also in higher dimensions. This forces one to modify the Poisson equation for the Newtonian potential in the same way as the Poisson equation for the electrostatic potential in Sec. V. That means, in higher dimension d the field equation for the Newtonian potential $U(x)$ must be of the form $(\overline{\Delta}^{(d-1)/2} * U)(x) = (4\pi)^{(d-1)/2} e^{i\pi(d-1)/2} \Gamma((d-1)/2)\rho(x)$, where $\rho(x)$ is the mass density. As a consequence, also Einstein's equations should be modified in higher dimensions.

In conclusion, we want to say that our or similar considerations do not rule out the possibility of unifying physics in higher dimensions; we just restrict, from observations, the direct physical applicability of dynamical equations to three spatial dimensions.

Implementation of an iterative map in the construction of (quasi)periodic instantons: Chaotic aspects and discontinuous rotation numbers

A. Chakrabarti[a)]
Centre de Physique Théorique, Ecole Polytechnique 91128 Palaiseau, France

(Received 4 March 1998; accepted for publication 15 October 1998)

An iterative map of the unit disk in the complex plane is used to explore certain aspects of self-dual, four-dimensional gauge fields (quasi)periodic in the Euclidean time. These fields are characterized by two topological numbers and contain standard instantons and monopoles as different limits. The iterations do not correspond directly to a discretized time evolution of the gauge fields. They are implemented in an indirect fashion. First, (t,r,θ,ϕ) being the standard coordinates, the (r,t) half-plane is mapped on the unit disk in an appropriate way. This provides an (r,t) parametrization of Z_0, the starting point of the iterations and makes the iterates increasingly complex functions of r and t. These are then incorporated as building blocks in the generating function of the fields. We explain in what sense and to what extent some remarkable features of our map (indicated in the title) are thus carried over into the *continuous* time development of the fields. Special features for quasiperiodicity are studied. Spinor solutions and propagators are discussed from the point of view of the mapping. Several possible generalizations are indicated. Some broader topics are also discussed.
[S0022-2488(99)03802-5]

I. INTRODUCTION

An iterative map of the unit disk centered at the origin of the complex plane is studied in the Appendix. The motivation is that it can be implemented fruitfully in the study of a hierarchy of four-dimensional, self-dual, (quasi)periodic gauge fields. Fields with spherical symmetry in R^3 are mostly used to illustrate our approach. More general possibilities are indicated at the end (Sec. VI). Such fields have been studied previously in a series of papers[1–8] which contains references to other sources. Here we reformulate them from the point of view of the iterative map. This brings remarkable new aspects to light.

Our gauge fields are (quasi)periodic in Euclidean time. The basic ingredient (one may say the generating function) for the spherically symmetric fields is a holomorphic function $g(r+it)$ satisfying certain constraints (Sec. II) in the (r,t) half-plane $(r\geqslant 0)$. Here (t,r,θ,ϕ) are the standard coordinates. The function g can have several factors (or nonfactorized terms) each with its own period in t. When all the periods are mutually commensurable the lowest common multiple of the component periods is the overall one. This is the periodic case. When at least one of the component periods is incommensurable with some others, one has, by definition, quasiperiodicity.

As is well known, fields periodic in Euclidean time provide one possible approach to field theory at finite temperature. Our explicit constructions are such that even an infinitesimal change in one single parameter (determining one of the component periods) can make a periodic solution quasiperiodic and vice versa. So they are considered in a parallel fashion.

The map studied in the Appendix is

[a)]Electronic mail: chakra@cpth.polytechnique.fr; also at: Laboratoire Propre du CNRS UPR A.0014.

$$Z_{p+1}=\frac{a_p+Z_p}{\bar{a}_p+Z_p^{-1}}, \quad |Z_0|\leq 1, \quad 0<|a_p|<1. \tag{1}$$

Note the inverse (Z_p^{-1}) in the denominator. Possible choices of a_p are discussed in the Appendix. *For implementing the map in the construction of the gauge fields the crucial step is a suitable* (r,t) *parametrization of* Z_0. The two choices considered are

$$Z_0=e^{-k(r+it)} \quad (k>0), \tag{2}$$

and

$$Z_0=\frac{\Sigma_{l=1}^{n}\lambda_l^2(e^{k_l(r+it-ic_l)}-1)^{-1}}{\Sigma_{l=1}^{n}\lambda_l^2(1-e^{-k_l(r+it-ic_l)})^{-1}} \tag{3}$$

with real parameters (λ,k,c) and

$$k_n>k_{(n-1)}>\cdots>k_2>k_1>0.$$

The uses of (2) will be amply illustrated (Secs. II, III, and the Appendix). The choice (3) is particularly suited to the construction of spinor solutions (Sec. IV). It can be shown to satisfy all the necessary constraints.

With Z_0 thus chosen one can set (Sec. II) the generating function of the gauge fields to be

$$g=\left(\prod_{j=1}^{n} Z_{p_j}^{(j)}\right), \tag{4}$$

where different sets of parameters are associated with each factor.

The iterations do not correspond to a discretized time evolution of the fields. At each step one has a different action (Sec. II), a different system. But the (r,t) parametrization of $Z_0^{(j)}$ will provide the key to the usefulness of the iterations. As p_j increases, g becomes a more and more complicated function of (r,t). But the fact that such complications are introduced in a very specific fashion stepwise makes some remarkable properties readily accessible. Some crucial properties of each block $Z_{p_j}^{(j)}$ as a whole are delivered directly. To give this statement explicit content let us look at the two most striking features of our map. [Up to Sec. IV, (2) will usually be referred to directly for simplicity. This is not an essential restriction.]

(1) For $r=0$ (the circumference of the unit disk) Z_p for any p, is a phase, the angle denoted by ψ_p, and (1) becomes a circle map. This map (see the Appendix) satisfies all the criteria for being chaotic (Ref. 9, Def.8.5, p. 50). These are as follows:

(a) a sensitive dependence on initial data, encoded by a positive characteristic index;

(b) a dense set of periodic points;

(c) transitivity.

Moreover this phase and its derivatives provide the coefficients of a series expansion in r of Z or g (the Appendix).

Suppose now, that as a consequence of (a), namely the positive index, at a certain level l of iterations the difference

$$\psi_l(\psi_0+\delta\psi_0)-\psi_l(\psi_0)$$

is appreciably large even for a small $\delta\psi_0$ (considering ψ_l as a function of its initial datum ψ_0). Due to our parametrization this means

$$\psi_l(t+\delta t)-\psi_l(t)$$

is large even for small δt.

Through (4), the result above, for each factor j, is injected into the time evolution of the fields. *This leads to sensitive time dependence.* (See, however, the remarks in Sec. VII.)

The overall phase of g (for any r) does not contribute directly to the action density, expressible in terms of $g\bar{g}$ and its derivatives (Sec. II). But the amplitude at each order of iteration involves the phases of the lower ones (the Appendix). Moreover the phase *is* directly involved in the power series expansion in r.

The phase can be studied directly and analogously for any value of r (inside the disk). The emphasis on the phase at $r=0$ is due to two factors.

(a) The relative simplicity for $r=0$ permits a transparent derivation of the crucial properties.
(b) For spherical symmetry, in our ansatz, the time dependence is damped exponentially with increasing r (going toward the center of the disk). Hence a small sphere around the origin in R^3 is the most suitable domain for studying the time evolution. The leading term of the action density for small r is given explicitly (Sec. II) to display the role of the iterated phases.

(2) We do not ignore, however, other remarkable features associated with certain values of r away from the spatial origin (the choice of the parameters a and k determines how far away or how close). These are the domains on which the $Z^{(j)}$'s can vanish and hence also g. They lead to discontinuous rotation numbers associated to the phases (the Appendix). So far as the zeros of g can be located their cumulative effects lead to staircaselike patterns. An example is given in Sec. II.

The rotation numbers are *asymptotic* quantities $[n\rightarrow\infty$ in (A58)]. Hence, discontinuities can arise even if we are dealing with well-behaved, integrable action densities.

In Ref. 10 it is emphasized (p. 20), in the context of standard circle maps, that *discontinuous* rotation numbers can arise for *smooth* maps. Here they arise in the context of "annular" maps (the Appendix) when the annulus can become a disk. It is also closely related to the central property of our map that after each iteration "on the average" the phase turns twice as fast (the Appendix).

In Sec. II the construction of the periodic fields is reformulated, with respect to our previous papers, in order to display prominently the role of the iterative map. The self-dual solutions are characterized by *two* topological integers. One is "instantonlike" (P_T) and the other is "monopolelike" (q). Their remarkable combined role in index theorems with $R^3\times S^1$ as the base manifold for periodic fields[2,4,6,7] are recapitulated in the context of explicit construction of spinor solutions (Sec. IV).

Some special features of quasiperiodic fields are studied in Sec. III. For periodic backgrounds a finite number of normalizable, zero-mass spinor solutions are obtained by imposing on them (anti)periodic boundary conditions in t (Sec. IV). For quasiperiodic backgrounds the number cannot thus be limited, unless rational approximations of the component periods are considered. Nevertheless, the spinor solutions are constructed in a way that works for both classes. The aim (not realized here) is to study the effect on the spinors of *several* mutually incommensurable periods in the background field.

For some particularly simple systems the possible effects of quasiperiodic kicks have been studied by several authors with different conclusions. (See Ref. 11, and sources cited therein.)

In a more general context (quasiperiodic state with k frequencies and a quasiperiodic attractor for the value $\mu=\mu_0$ of a continuous bifurcation parameter) the situation has been summed up as follows (Ref. 12, p. 631):

"For $k\geqslant 3$, strange attractors and positive characteristic exponent may be present for μ arbitrarily close to μ_0."

We provide (though only for zero mass and Euclidean signature) exact, explicit solutions for spinors in four dimensions in a gauge field background that can bring into play an arbitrary number of mutually incommensurable periods. This can provide an interesting starting point for further investigations.

Our iterations can also be implemented in propagators (Sec. V). This can lead to a systematic semiclassical development for our classes of background.

Several directions are indicated (Sec. VI) for possible generalizations of our study. The possibilities mentioned are—breaking spherical symmetry, magnetic charge $q \geqslant 1$, gauge group SU(N) with $N > 2$ and the use of hyperbolic coordinates.

After presenting our formalism in full, certain general questions are taken up in the concluding remarks (Sec. VII).

II. A CLASS OF PERIODIC SELF-DUAL GAUGE FIELDS

The class we consider, to start with, has spherical symmetry in R^3 and periodicity in Euclidean time. The gauge group is SU(2). Let (t, r, θ, ϕ) be the standard time and radial coordinates with

$$ds^2 = dt^2 + dr^2 + r^2(d\theta^2 + (\sin\theta)^2 d\phi^2).$$

Let $(\sigma_r, \sigma_\theta, \sigma_\phi)$ denote the projections of the Pauli matrices, respectively, on the directions indicated. The gauge potentials are given by

$$A_r \pm iA_t = \pm i(\partial_r \pm i\partial_t)\zeta \frac{\sigma_r}{2}, \tag{5}$$

$$A_\theta \pm i(\sin\theta)^{-1}A_\phi = \pm i(e^\zeta - 1)\left(\frac{\sigma_\theta \pm i\sigma_\phi}{2}\right), \tag{6}$$

where

$$e^\zeta = \frac{r}{(1 - g\bar{g})}((\partial_r^2 + \partial_t^2)(g\bar{g}))^{1/2}. \tag{7}$$

Here g is a holomorphic function $g(r+it)$ in the (r,t) half-plane $(r \geqslant 0)$, postulated to satisfy the following properties:

(1) $g\bar{g} = 1 + O(r)$ for $r \to 0$,
(2) g has no poles for $r \geqslant 0$,
(3) g falls exponentially as $r \to \infty$ (giving a constant logarithmic derivative),
(4) g is periodic in t.

We start with strict periodicity. Quasiperiodicity will be defined and studied in Sec. III. Our previous studies of periodic instantons (Refs. 1–8) will be reformulated below to display at each stage the role of the iterative map (the Appendix).

A. First iteration: From monopoles to periodic instantons

The simplest choice satisfying all the constraints is evidently

$$g = e^{-k(r+it)} \quad (k > 0). \tag{8}$$

But now $g\bar{g}$ has no time dependence and from (7)

$$e^\zeta = \frac{kr}{\sinh kr}.$$

One obtains the famous self-dual BPS monopole with the magnetic topological winding number

$$q = 1.$$

Here we have, of course, the Euclidean version, A_t replacing the Higgs field.

In (8) g is precisely Z_0, the initial point of the iterative map studied in the Appendix. Apply one iteration. Then

$$g=\frac{a_0+e^{-k(r+it)}}{\overline{a_0}+e^{k(r+it)}}. \tag{9}$$

There is a spectacular change. One now has an authentic periodic solution characterized by *two* topological integers.

(1) The magnetic number remains unchanged since as $r\to\infty$ there is no essential change in the configuration. One has still the (monopolelike) number

$$q=1.$$

(2) A second (instantonlike) topological integer P_T is now given by the total action S_T over one period $(T=2\pi k^{-1})$ divided by $8\pi^2$. One defines

$$8\pi^2 P_T=4\pi\int_0^T dt\int_0^\infty dr(\partial_r^2+\partial_t^2)\omega, \tag{10}$$

where

$$\omega=\frac{1}{2}e^{2\zeta}+\ln\left(\frac{1-g\overline{g}}{r}\right),$$

$$(\partial_r^2+\partial_t^2)\omega=\frac{1}{2}(\partial_r^2+\partial_t^2)(e^{2\zeta}-2\zeta)=\frac{1}{2}(\partial_r^2+\partial_t^2)e^{2\zeta}+\frac{1}{r^2}(1-e^{2\zeta}). \tag{11}$$

For (9) one obtains

$$P_T=2.$$

The computation of the action will be given below in a form particularly suited to our purpose. But first let us introduce a more general form of g.

In (8) set, assuming k to be sufficiently large,

$$k=\sum_{j=1}^{n} k_j \quad (k_j>0).$$

At this stage the k_j's are supposed to be mutually commensurate. Thus, in evident notations,

$$g=\prod_{j=1}^{n} g_j^{(0)}=\prod_{j=1}^{n} e^{-k_j(r+it)}.$$

Now apply one iteration to each factor giving

$$g=\prod_{j=1}^{n} g_j^{(1)}=\prod_{j=1}^{n}\left(\frac{a_0^{(j)}+e^{-k_j(r+it)}}{\overline{a_0^{(j)}}+e^{k_j(r+it)}}\right). \tag{12}$$

In the notation of the Appendix,

$$g_j^{(1)}=Z_1^{(j)}.$$

Each factor now has its own period,

$$T_j = 2\pi k_j^{-1}. \tag{13}$$

Since the k_j's are mutually commensurate one can set

$$k_j = \hat{k}\frac{P_j}{Q_j}, \tag{14}$$

where P_j, Q_j are integers without common factor. Thus there is an overall period

$$T = \frac{2\pi}{\hat{k}}\left(\prod_j Q_j\right). \tag{15}$$

We now compute the total action over T. Using (10) and Stokes' theorem with the boundary indicated by the limits, one obtains

$$S_T = 4\pi\int_\delta^R dr[\partial_t\omega]_0^T + 4\pi\int_0^T dt[\partial_r\omega]_\delta^R \quad (\delta\to 0, R\to\infty). \tag{16}$$

The first integral vanishes due to periodicity. In the second one, nonzero contributions come only from the limit $r\to 0$. These can be evaluated by using standard integrals.[3,4] *But the very first step* $(p=0)$ *of our study (the Appendix) of the circle map and the small-r expansion furnishes the result directly.*

From (12) and (A38) as $r\to 0$,

$$g\bar{g} = 1 + 2\left(\sum_j \frac{d\psi_1^{(j)}}{dt}\right)r + 2\left(\sum_j \frac{d\psi_1^{(j)}}{dt}\right)^2 r^2 + O(r^3), \tag{17}$$

where

$$e^{-i\psi_1^{(j)}} = \left(\frac{a_0^{(j)} + e^{-ik_jt}}{\bar{a}_0^{(j)} + e^{ik_jt}}\right). \tag{18}$$

From (A19) as

$$k_jt = \psi_0^{(j)} \to \psi_0^{(j)} + 2\pi, \qquad \psi_1^{(j)} \to \psi_1^{(j)} + 4\pi. \tag{19}$$

Inserting ω of (10) in (16) and using (17), the only nonzero contributions are seen to come from

$$\lim_{r\to 0}\left(\partial_r \ln\left(\frac{1-g\bar{g}}{r}\right)\right) = \sum_j \frac{d\psi_1^{(j)}}{dt}. \tag{20}$$

Hence, in terms of the previous definitions, one obtains quite simply

$$S_T = 4\pi\left(4\pi\sum_{j=1}^n \frac{T}{T_j}\right) = 8\pi T\left(\sum_{j=1}^n k_j\right) = 8\pi^2 2\left(\prod_j Q_j\right)\left(\sum_{j=1}^n \frac{P_j}{Q_j}\right). \tag{21}$$

Hence,

$$P_T = 2\left(\sum_{j=1}^n \frac{T}{T_j}\right). \tag{22}$$

Since each (T/T_j) is an integer, P_T is an even integer. Odd indices can be obtained through a simple modification described below.

B. Comments on the limiting values $a_0^{(j)}=0,\ \pm 1$

In general, the parameters a will be assumed to satisfy $0<|a|<1$. The limits indicated are associated with monopoles and standard aperiodic instantons. The following points are to be noted.

(1) For

$$a_0^{(j)}=0, \quad \psi_1^{(j)}=2k_j t. \tag{23}$$

This limit, consistent with (19), can be taken smoothly. For all $a_0^{(j)}=0$ one has a static monopole. But having determined beforehand each T_j and T, if this limit is taken *a posteriori* one obtains (formally) (22) in the simplest fashion.

(2) For

$$a_0^{(j)}=1, \quad \psi_1^{(j)}=k_j t. \tag{24}$$

As compared to (23) there is a rescaling by $\frac{1}{2}$. [The choice -1 in (24) implies no essential change.] If say, only

$$a_0^{(1)}=1$$

one obtains, instead of (22),

$$P_T=\frac{T}{T_1}+2\left(\sum_{j=2}^{n}\frac{T}{T_j}\right). \tag{25}$$

Now P_T can be odd. Consider, for example,

$$g=\left(\frac{\frac{1}{2}(1+\epsilon)+e^{-k(r+it)}}{\frac{1}{2}(1+\epsilon)+e^{k(r+it)}}\right)\prod_{j=1}^{n}\left(\frac{a_j+e^{-k(r+it)}}{\overline{a_j}+e^{k(r+it)}}\right). \tag{26}$$

For

$$\epsilon=-1, \quad P_T=2n+2; \quad \epsilon=1, \quad P_T=2n+1. \tag{27}$$

(3) For each j, taking the combined limit

$$k_j\to 0, \quad a_0^{(j)}=-1+k_j b_j \quad (b_j+\overline{b_j}>0), \tag{28}$$

one obtains from (12)

$$g=\prod_{j=1}^{n}\left(\frac{b_j-(r+it)}{\overline{b_j}+(r+it)}\right). \tag{29}$$

This is Witten's multi-instanton solution[13] with centers on the time axis and total action on R^4,

$$S=8\pi^2(n-1). \tag{30}$$

The magnetic charge is lost in this limit.

To sum up, g as given by (12), combines instantonlike and monopolelike aspects. It is a more general construction containing them as limits. As an expression of this double role such periodic self-dual configurations are characterized by the presence of *two* topological integers: one instantonlike (P^T) and one monopolelike (q). The combined role of these two in the index theorems will be discussed later (Sec. VI). So far, though, P_T can range through the entire spectrum of integers, q is restricted to unity. This restriction can be removed (Sec. VI).

Finally, we just mention that concerning the rotation numbers defined in the Appendix, the result (A59) implies for (12), which has n factors, a staircaselike pattern with n steps. It was pointed in Sec. I that jumps in the rotation numbers can arise though the action density remains smooth. We illustrate this explicitly for the simplest nontrivial case. Let

$$g=\left(\frac{a+e^{-k(r+it)}}{\overline{a}+e^{k(r+it)}}\right). \tag{31}$$

Here the crucial value of r corresponding to (A59) is

$$e^{-kr}=a. \tag{32}$$

But now from (7),

$$e^{2\zeta}=(kr)^2((\sinh kr)^{-2}-(1-a^2)(\cosh kr+a\cos t)^{-2}). \tag{33}$$

Inserting (33) in (10) one obtains a smooth action density.

The results (A39) and (A40) can be used to study the time dependence of the action density in a small sphere around $r=0$. We defer the discussion to be able to include higher iterations and quasiperiodicity.

C. Higher iterations

For higher iterations one stays within the class of (quasi)periodic instantons with unit magnetic charge. But various interesting properties arise or are accentuated as the configuration becomes more complex. Some crucial features are presented below.

A generalization of the ansatz (12) is *automatically* implemented. One more iteration on (9) gives [see (A62)]

$$g=Z_2=Z_0^{-2}\left(\frac{a_0+Z_0}{\overline{a}_0+Z_0^{-1}}\right)\left(\frac{\mu_++Z_0}{\overline{\mu}_++Z_0^{-1}}\right)\left(\frac{\mu_-+Z_0}{\overline{\mu}_-+Z_0^{-1}}\right), \tag{34}$$

where

$$\mu_\pm=\tfrac{1}{2}((a_0+\overline{a}_0a_1)\pm((a_0+\overline{a}_0a_1)^2-4a_1)^{1/2}).$$

The factor Z_0^{-2} (i.e., $e^{2k(r+it)}$) is an *increasing* exponential in r, though Z_2 as a whole falls as e^{-kr}. This aspect is generalized by setting [compare (12)]

$$g=e^{l(r+it)}\prod_{j=1}^{n}\left(\frac{a_0^{(j)}+e^{-k_j(r+it)}}{\overline{a}_0^{(j)}+e^{k_j(r+it)}}\right) \tag{35}$$

with

$$l<\left(\sum_{j=1}^{n}k_j\right).$$

The total action, instead of (21), is now (assuming l is so chosen that the overall period is still T)

$$S_T=4\pi T\left(2\sum_{j=1}^{n}k_j-l\right). \tag{36}$$

Thus one has a lower action with the same number of parameters a. In (34) the factor Z_0^{-2} lowers S_T (and P_T) to give

$$(8\pi^2)^{-1}S_T = P_T = 2(3-1) = 4. \tag{37}$$

D. Effect on rotation numbers

The rotation numbers are defined and discussed in the Appendix [(A58)–(A65)]. In the course of time evolution of the gauge field generated by (34), g can vanish for

$$e^{-kr} = |a_0|, |\mu_+|, |\mu_-|, \tag{38}$$

though $|\mu_+|$ and $|\mu_-|$ may coincide to $|a_1|^{1/2}$. Thus though S_T is doubled, the number of zeros are here (generically) tripled.

Let $r_1 < r_2 < r_3$ be the three distinct roots of (38) in r and let Ω_2 denote the rotation number after the second iteration. Then (A59) is generalized as follows:

$$\frac{\Omega_2}{\Omega_0} = 4, \frac{7}{2}, 3, \frac{5}{2}, 2, \frac{3}{2}, 1, \tag{39}$$

respectively, for

$$r < r_1, \quad r = r_1, \quad r_1 < r < r_2, \quad r = r_2, \quad r_2 < r < r_3, \quad r = r_3, \quad r > r_3.$$

Cumulative effects of higher iterations will increase the number of steps. One can factorize Z_{p+2} in terms of Z_p analogously to (34). But rather than repeating such steps our aim is to show how the results of the Appendix can lead directly to remarkable properties. An example, in a different direction, follows.

E. Action density near the spatial origin

Let us explore the role of the iterations in the action density in a small sphere about the origin where the intricate interplay of (quasi)periodic pulsations are least affected by exponential damping with increasing r. We generalize (12) by setting

$$g = \prod_{j=1}^{n} Z_{p_j}^{(j)}, \tag{40}$$

where $Z_{p_j}^{(j)}$ is $e^{-k_j(r+it)}$ iterated p_j times. For each $p_j = 1$ one obtains (12). The doubling after each iteration of the contribution of each factor to the total action has to be taken into account. A simple particular case is given by (37). The general result is evident on noting how (A19) generalizes (19) and hence the derivation of (21). For (40) one obtains, instead of (21),

$$S_T = 8\pi T\left(\sum_{j=1}^{n} 2^{(p_j-1)}k_j\right). \tag{41}$$

As the action increases, the ''weight'' of that particular field configuration in path integrals diminishes. Hence the interest of an extra factor, as in (35), bringing down the action as far as possible for a given period, as in (36). Having obtained the total action let us now take a close look at a small sphere around $r=0$. Using the results obtained in (A38), (A39), and (A40) one obtains after simplifications for (40),

$$e^{2\zeta} = \frac{r^2}{(1-g\bar{g})^2}((\partial_r^2 + \partial_t^2)(g\bar{g})) = 1 - \frac{2}{3}\Gamma_t r^2 + O(r^3), \tag{42}$$

where

$$\Gamma_t = \tfrac{1}{2}C^2 + (\ddot{C}/C) - \tfrac{3}{2}(\dot{C}/C)^2, \tag{43}$$

$$C = \sum_{j=1}^{n} \dot{\psi}_{p_j}^{(j)} \equiv \dot{\Psi}. \tag{44}$$

Here the dots denote time derivatives and $\psi_{p_j}^{(j)}$ is the phase of the jth factor (for $r=0$) in (40). This leads, for ω given by (10), to

$$(\partial_r^2 + \partial_t^2)\omega = \tfrac{4}{3}\Gamma_t r^2 + O(r^3). \tag{45}$$

The total action over R^3 and a period T is given by (41). Let $S(r)$ denote the action, at any instant t, integrated over a small sphere of radius r about the origin. Then

$$S(r) = 4\pi \int_0^r dr(\partial_r^2 + \partial_t^2)\omega = \left(\frac{4}{3}\Gamma_t^2\right)V_r + \cdots, \tag{46}$$

where (the dots indicating higher powers of r)

$$V_r = \tfrac{4}{3}\pi r^3.$$

The leading term, logically, is proportional to the volume of the sphere. [This is rendered possible by the zero coefficient of the term linear in r in (42).]

In (43) Γ_t has an interesting structure. There is a ''kinetic'' term,

$$\tfrac{1}{2}C^2 = \tfrac{1}{2}\dot{\Psi}^2$$

and the *Schwarzian derivative* of Ψ. For the simplest case [one factor with $p=1$ in (40)] using (A17), with

$$a = |a_0|, \quad \chi = \psi_0 - \alpha_0, \quad \psi_0 = kt,$$

$$C = \dot{\Psi} = 2k\frac{1 + a\cos\chi}{1 + a^2 + 2a\cos\chi} \equiv 2k\frac{X}{Y}.$$

Hence

$$\frac{\ddot{C}}{C} - \frac{3}{2}\left(\frac{\dot{C}}{C}\right)^2 = k^2 a(1-a^2)\left(\cos\chi + a(\sin\chi)^2\left(\frac{3}{2}X^{-1} + Y^{-1}\right)\right)(XY)^{-1}. \tag{47}$$

This changes sign at points determined by the choice of a_0. But for all a_0, it is positive (negative) for $\chi = 0(\pi)$, respectively. For the general case (40) the very complex structure implied by (43) determines the time dependence.

III. QUASIPERIODICITY

So far we have been considering strict periodicity, having just mentioned that the component periods T_j need not necessarily be commensurate. We now take a closer look at this possibility.

As an example let $(k_2, k_3, \ldots, k_n)$ in (12) be all mutually commensurate as in (14) but not with k_1. [This relatively simple case will suffice to exhibit some remarkable features. It is possible to consider several incommensurate periods. One can also start with Z_0 given by (3) rather than by (2).]

Let $\hat{T}$ be the common overall period for $(T_2, T_3, \ldots, T_n)$, but *not* for T_1. One can take successive rational approximations of $(\hat{T}/T_1)$,

$$\left(\frac{\hat{T}}{T_1}\right)_{(\text{appr})} = \frac{N_1}{N_2}, \tag{48}$$

N_1, N_2 being integers without common factors. Then

$$T = N_2 \hat{T}$$

is the overall period at that approximation. As the approximation is improved, N_1, N_2, T all increase without limit. (Since there is no exact period, improving the approximation one tends to cover the entire time axis.) One can keep in mind the famous example of successive rational approximations of the ''golden mean''

$$G = \tfrac{1}{2}(\sqrt{5} - 1)$$

using the Fibonacci sequence. But our considerations will not be limited to any such particular case. For the lth approximation, in evident notations, the action over the period $T^{(l)}$ is

$$S_l = 16\pi^2 \left(\frac{T^{(l)}}{T_1} + \sum_{j=2}^{n} \frac{T^{(l)}}{T_j} \right). \tag{49}$$

As $l \to \infty$ so do $T^{(l)}$ and S_l. One can now consider the limiting form of the action per unit time or the ''normalized'' action

$$S_N = \left(\frac{S_l}{T^{(l)}} \right)_{l \to \infty}. \tag{50}$$

This gives a *continuous index*, a positive real number, not an integer. The possible mathematical significance of S_N has been discussed elsewhere.[4,7] The magnetic index q does *not* vary in the successive stages described above. As one approaches the asymptotic S_2 in R^3 the exponential damping of time dependences give the same static configuration at each stage, namely that of the monopole. Hence our *quasiperiodic instantons are characterized, not by two topological integers, but by one positive real number* (S_N) *and one integer* (q). For the class of solutions under consideration $q = 1$. More general possibilities are indicated in Sec. VI.

So far we have been looking at quasiperiodic solutions from the point of view of successive approximations. Let us now look at some *exact* consequences of the postulated incommensurability.

In the case considered before, consider the Poincaré sections of the factor g_1 (corresponding to the period T_1) for

$$t = t_0 + nT \quad (n = 0,1,2,\ldots).$$

One obtains

$$g_1(n) = e^{-i2\alpha_1} \frac{|a_1| + e^{-k_1(r + i(t_0 + nT)) + i\alpha_1}}{|a_1| + e^{k_1(r + i(t_0 + nT)) - i\alpha_1}}. \tag{51}$$

We simplify notations by setting

$$a = |a_1| = a_1 e^{i\alpha_1}, \quad k_1 = k, \quad k\omega = kt_0 - \alpha_1,$$

$$X^{(n)}=e^{i2\alpha_1}g_1(n)=\frac{a+F_n}{a+F_n^{-1}},$$

where

$$F_n=e^{-k(r+i\omega+inT)}=e^{-k(r+i\omega)-i2\pi n\delta},\quad \delta\neq\frac{N_1}{N_2}\quad (N_1,N_2\ \text{integers}).$$

The irrationality of δ *is the basic quasiperiodicity postulate.* Now

$$X^{(n+p)}=\frac{a+F_{n+p}}{a+F_{n+p}^{-1}}=\frac{a+F_ne^{-i2\pi p\delta}}{a+F_n^{-1}e^{i2\pi p\delta}}. \tag{52}$$

We show that if the parameters $(r,t_0,k,\alpha,n,p,\delta)$ are fine-tuned, X may come back *just once* to an initial value but no more (*not even twice*). From (52),

$$F_n^2+e^{i2\pi p\delta}a(1-X^{(n+p)})F_n-e^{i4\pi p\delta}X^{(n+p)}=0. \tag{53}$$

Eliminating F_n from the equations for three *distinct* integer values of p say,

$$p=p_1,p_2,p_3,$$

one of which may be zero, one has as a necessary constraint the vanishing determinant

$$\det\begin{vmatrix}1 & a(1-X^{n+p_1})e^{i2\pi p_1\delta} & -X^{n+p_1}e^{i4\pi p_1\delta}\\ 1 & a(1-X^{n+p_2})e^{i2\pi p_2\delta} & -X^{n+p_2}e^{i4\pi p_2\delta}\\ 1 & a(1-X^{n+p_3})e^{i2\pi p_3\delta} & -X^{n+p_3}e^{i4\pi p_3\delta}\end{vmatrix}=0. \tag{54}$$

For, say,

$$X^{(n+p_1)}=X^{(n+p_2)}=X^{(n+p_3)}=X \tag{55}$$

this reduces to

$$X(1-X)e^{i(p_1+p_2+p_3)2\pi\delta}((1-e^{i(p_1-p_2)2\pi\delta})(1-e^{i(p_2-p_3)2\pi\delta})(1-e^{i(p_3-p_1)2\pi\delta}))=0. \tag{56}$$

The coefficient of $X(1-X)$ cannot vanish due to our quasiperiodicity postulate. Neither can $X^{(n+p)}$ be zero or unity for three distinct values of p. That would imply, for example for $X=1$,

$$F_n^2=e^{i4\pi p_j\delta}$$

for three different values of p_j and so on. Hence the constraint (55) cannot be satisfied. So $X^{(n)}$ cannot come back twice *exactly* to a previous value. There is, however, no restriction concerning repeated very close approaches.

Let us now look at the conditions necessary for a *single* return, namely,

$$X^{(n+p)}=X^{(n)}.$$

From (52) this is seen to imply

$$(F_ne^{-i\pi p\delta})^2+2\lambda(F_ne^{-i\pi p\delta})+1=0, \tag{57}$$

where

$$\lambda=a^{-1}\cos\pi p\delta.$$

Hence,

$$F_n = e^{i\pi p\delta}(-\lambda \pm \sqrt{\lambda^2 - 1}). \tag{58}$$

Case (1): $(|\lambda| \leqslant 1)$

Let $\lambda = \cos\eta$ (η real). Then

$$F_n = e^{-k(r+i\omega)-i2\pi n\delta} = -e^{i(\pi p\delta \pm \eta)}. \tag{59}$$

This implies $r=0$ and

$$e^{-i(kt_0 - \alpha_1 + \pi(2n+p)\delta \pm \eta)} = -1. \tag{60}$$

(The $\pm$ sign implies one or the other. They do not hold simultaneously.)

Case (2): $(|\lambda| > 1)$

Let $\lambda = \coth\zeta$ (ζ real). Then, retaining the solution leading to a real value of r,

$$F_n = -(\tanh(\zeta/2))e^{i\pi p\delta} \tag{61}$$

and

$$e^{-kr} = |\tanh(\zeta/2)|, \quad e^{-i(kt_0 - \alpha_1 + \pi(2n+p)\delta)} = \pm 1. \tag{62}$$

It should be noted that $X^{(n+p)} = X^{(n)}$ does not imply a periodic situation. In the solutions above n is not arbitrary for a given p. One can indeed show that given the foregoing situation

$$X^{(n+2p)} \neq X^{(n+p)} = X^{(n)}$$

consistently with the impossibility of (55). In this context the ambiguity of sign of the inverse map (expressing F_n in terms of X_n) plays an interesting role. But we will not present such details here.

Let us note one more point. *The action density and the rotation numbers now involve mutually incommensurable numbers.* It would be interesting to study in detail the time evolution of the coefficient (43)

$$\Gamma_t = \tfrac{1}{2}C^2 + (\ddot{C}/C) - \tfrac{3}{2}(\dot{C}/C)^2, \tag{63}$$

$$C = \sum_{j=1}^{n} \dot{\psi}_{p_j}^{(j)} \equiv \dot{\Psi} \tag{64}$$

with three or more incommensurable periods (namely, k_j's at the origin of the ψ_j's) varying the parameters a. Our purpose in leaving the period T and Ω_0 in (A58) is now evident. In general one will have, to start with, incommensurable $\Omega_0^{(j)}$'s corresponding to different factors of g. For the simple case considered above (only k_1 incommensurable with the rest and with F_n corresponding to a section of $Z_0^{(1)}$) one has

$$\Omega_0^{(1)} = 2\pi\delta,$$

δ being irrational. The cumulative effects of several irrational numbers have to be taken into account in a more general case.

The different roles of rational and irrational rotation numbers are well known.[9,10] Here the rotations of the phases are considered in the context of annular maps (the Appendix). The ''average'' doubling of the phase (sufficiently near the origin) for each iteration is also specific to our case. Though we have demonstrated the existence of striking discontinuities, the role of the rotation number remains to be explored.

IV. INDEX THEOREMS AND SPINOR SOLUTIONS

Again we start with the periodic case, deferring a discussion of quasiperiodicity. For periodic gauge fields the base manifold is $R^3 \times S^1$ rather than R^4 or S^4. The index theorems have to take into account the boundary effects induced by S^1. This has been discussed elsewhere.[4,6,7] Here we just mention that the number of zero modes of spinors in periodic backgrounds characterized by two topological integers (P_T, q). $= P_T - q$ for periodic spinors of isospin $\frac{1}{2}$ (see Refs. 2 and 4), $= 4P_T - 2q$ for periodic spinors of isospin 1 (see Ref. 7), $= P_T$ for antiperiodic spinors of isospin $\frac{1}{2}$ (see Ref. 6).

(The background is, of course, still periodic for antiperiodic spinors.) We construct below the spinor solutions in a more general and systematic fashion than in the previous papers. This is facilitated by introducing a gauge transformation leading from the Witten-type gauge introduced in (5) and (6) to a (quasi)periodic generalization of 't Hooft or Jackiw–Nohl–Rebbi (JNR) type solutions.[2,4,6,7] Two historical references for the standard (aperiodic) solutions are Refs. 13 and 14.

A. Gauge transformation

We start with A_μ given by (5) and (6) and gauge transform by

$$G(r,t) = e^{-id(r,t)\sigma_r/2},$$

where

$$e^{id} = \left(\frac{1-g}{1-\bar{g}}\right)\left(\frac{(\partial_r - i\partial_t)g}{(\partial_r + i\partial_t)\bar{g}}\right)^{1/2}. \tag{65}$$

One obtains

$$A'_\mu = G^{-1}A_\mu G - iG^{-1}\partial_\mu G = \sigma_{\mu\nu}\partial_\nu \ln \Sigma,$$

where $\sigma_{10} = \sigma_{23} = \sigma_1$ (cyclic), and

$$\Sigma = \frac{1}{2r}\left(\frac{1+g}{1-g} + \frac{1+\bar{g}}{1-\bar{g}}\right) = \frac{1}{r}\,\frac{(1-g\bar{g})}{(1-g)(1-\bar{g})} \tag{66}$$

satisfying, since $(\partial_r + i\partial_t)g = 0 = (\partial_r - i\partial_t)\bar{g}$,

$$\Box\Sigma = \left(\partial_t^2 + \partial_r^2 + \frac{2}{r}\partial_r\right)\Sigma = 0. \tag{67}$$

Thus we have obtained the famous ansatz leading to 't Hooft or JNR solutions. But here it is being implemented in the context of magnetically charged (quasi)periodic solutions rather than that of standard aperiodic instantons.

The poles of Σ play an essential role in the construction of spinor solutions. *The passage from g to Σ maintains contact with the iterative map implemented for g*. But this raises the problem of displaying in an additive form the poles of Σ. The roots of $g=1$ are not, in general, explicitly available. Generally there are $2n$ roots for (12), all for $r=0$. The particular case, with $(0<a<1)$ and

$$g = \left(\frac{a+e^{-(r+it)}}{a+e^{(r+it)}}\right)^n$$

is fully treated in Ref. 7. We display some typical features of the passage from g to Σ through simple examples, motivating the generalization to follow.

(1) For $g = e^{-k(rit)}$,

$$\frac{1+g}{1-g} = \coth\frac{1}{2}k(r+it),$$
$$\Sigma = \frac{1}{2r}\left(\coth\frac{1}{2}k(r+it) + \coth\frac{1}{2}k(r-it)\right) = \sum_{l=-\infty}^{\infty}\frac{1}{k^2}\frac{1}{r^2+(t-k^{-1}2\pi l)^2}. \tag{68}$$

This is the periodic form of the BPS monopole, gauge equivalent with the still better-known static form. The action over one period $(T=2\pi/k)$ can be considered, quite formally, to be $8\pi^2$ (or $P_T=1$). [See the comments following (8) and (23).]

(2) For, with $(0<a<1)$,

$$g = \left(\frac{a+e^{-k(r+it)}}{a+e^{k(r+it)}}\right), \quad P_T=2,$$

and

$$\frac{1+g}{1-g} = \frac{1+a}{2}\coth\frac{1}{2}k(r+it) + \frac{1-a}{2}\coth\frac{1}{2}k(r+it-i\pi k^{-1}). \tag{69}$$

(3) For

$$g = e^{-k(r+it)}\left(\frac{a+e^{-k(r+it)}}{a+e^{k(r+it)}}\right),$$

$$P_T=3 \quad [\text{the simplest case of (26) and (27)}]$$

and

$$\frac{1+g}{1-g} = \lambda_1^2\coth\frac{1}{2}k(r+it) + \lambda_2^2\coth\frac{1}{2}k(r+it-ick^{-1}) + \lambda_3^2\coth\frac{1}{2}k(r+it+ick^{-1}), \tag{70}$$

where

$$\cos c = -\frac{1+a}{2}, \quad \lambda_1^2 = \frac{1+a}{3+a}, \quad \lambda_2^2 = \lambda_3^2 = \frac{1}{3+a}.$$

For our normalization a general consequence is

$$\sum_i \lambda_i^2 = 1.$$

The number of coth terms in $(1+g)/(1-g)$ gives P_T if each one has the same period, say T and *distinct singularities*. A term with period (T/m) contributes m units to P_T.

(4) Once the roots of $g=1$ are obtained the residues at the poles give the λ's. But this is not strictly necessary for constructing the spinor solutions.

Consider a case with two different periods $(2\pi k^{-1}, \pi k^{-1})$, namely $(0<a<1)$ and

$$g = \left(\frac{a+e^{-k(r+it)}}{a+e^{k(r+it)}}\right)\left(\frac{a+e^{-2k(r+it)}}{a+e^{2k(r+it)}}\right).$$

Now

$$P_T = 2 + 2.2 = 6, \quad q = 1. \tag{71}$$

The zeros of g (and hence the jumps in rotation numbers) correspond to

$$e^{-kr} = a, \sqrt{a}.$$

It is sufficient to note that $g=1$ for

$$r=0, \quad e^{it} = \pm 1, \left(-\frac{1}{2} \pm i\frac{\sqrt{3}}{2}\right), \left(\frac{1-a}{2} \pm i\sqrt{1-\left(\frac{1-a}{2}\right)^2}\right).$$

One can then construct $(P_T - q) = 5$ periodic and $P_T = 6$ antiperiodic spinor solutions. The explicit solutions will follow.

More generally, using real parameters a_p at each iteration one obtains some simplifications. Thus, for example, iterating g as a whole (with $0 < a_p < 1$).

$$g_{p+1} = \frac{a_p + g_p}{a_p + g_p^{-1}}, \tag{72}$$

and

$$\frac{1+g_{p+1}}{1-g_{p+1}} = -\left(\frac{1+a_p}{2}\left(\frac{1+g_p}{1-g_p}\right) + \frac{1-a_p}{2}\left(\frac{1-g_p}{1+g_p}\right)\right). \tag{73}$$

Hence $g_{p+1} = 1$ for $g_p = \pm 1$, consistently with the doubling of the periodic action. For real a_0, a_1, and

$$g_0 = e^{-k(r+it)},$$

$$g_2 = 1 \quad \text{for } r=0; \quad \sin\frac{kt}{2} = 0, \quad \cos\frac{kt}{2} = 0, \quad \pm\sqrt{\frac{1-a_0}{2}}.$$

B. Generalization of Z_0 and g

Having noted the relation between the structures of g and Σ one can now invert the procedure. Start with

$$\Sigma = \frac{1}{2r}\sum_{l=1}^{n} \lambda_l^2 \left(\coth\frac{1}{2}k_l(r+it-ic_l) + \coth\frac{1}{2}k_l(r-it+ic_l)\right) \tag{74}$$

$$= \frac{1}{2r}\left(\frac{1+g}{1-g} + \frac{1+\bar{g}}{1-\bar{g}}\right), \tag{75}$$

where convenient conventions are

$$\sum_{l=1}^{n} \lambda_l^2 = 1, \quad k_n > k_{n-1} > \cdots > k_2 > k_1 > 0.$$

Now

$$g = \frac{\Sigma_{l=1}^{n} \lambda_l^2 (e^{k_l(r+it-ic_l)} - 1)^{-1}}{\Sigma_{l=1}^{n} \lambda_l^2 (1 - e^{-k_l(r+it-ic_l)})^{-1}}. \tag{76}$$

Thus we have motivated the parametrization (3) of Z_0 (here g). One can verify that (76) satisfies all the constraints listed below (7). In particular, g is a phase for $r=0$ and drops as $e^{-k_1 r}$ as r becomes large. *The major interest is that now, even in presence of an arbitrary number of different periods (different k's) g is directly adapted to the construction of spinor solutions to follow.* The Σ of (74) can easily be generalized to break spherical symmetry. But we defer such considerations to Sec. VI.

To give a better idea of the relation of (76) to the previous factorized form we consider again some simple examples. Different subclasses of the previous form will be found already in the simplest examples of (76).

We set $n=2$; $c_1=c_2=0$ and we use below often $\lambda_1^2+\lambda_2^2=1$.

(1) For $k_1=k_2=k$,

$$g=e^{-k(r+it)}.$$

More generally, for all k's and all c's equal one has the monopole solution.

(2) For $k_1=k,\ k_2=2k$,

$$g=\frac{\lambda_1^2+e^{-k(r+it)}}{\lambda_1^2+e^{k(r+it)}}.$$

(3) For $k_1=k,\ k_2=3k$,

$$g=e^{k(r+it)}\left(\frac{a+e^{-k(r+it)}}{\bar{a}+e^{k(r+it)}}\right)\left(\frac{\bar{a}+e^{-k(r+it)}}{a+e^{k(r+it)}}\right),$$

where $a=\frac{1}{2}(\lambda_1^2+i\lambda_1\sqrt{4-\lambda_1^2})\quad (a\bar{a}=\lambda_1^2<1)$.

(4) For $k_1=2k,\ k_2=3k$,

$$g=\left(\frac{a_1+e^{-k(r+it)}}{\bar{a}_1+e^{k(r+it)}}\right)\left(\frac{a_2+e^{-k(r+it)}}{\bar{a}_2+e^{k(r+it)}}\right),$$

where, respectively, for

$$1>\lambda_1^2>\tfrac{1}{4},\quad a_1=\bar{a}_2=\tfrac{1}{2}(1+i\sqrt{4\lambda_1^2-1});$$

$$\tfrac{1}{4}>\lambda_1^2>0,\quad a_1=\bar{a}_1=\tfrac{1}{2}(1+\sqrt{1-4\lambda_1^2});$$

$$a_2=\bar{a}_2=\tfrac{1}{2}(1-\sqrt{1-4\lambda_1^2});$$

$$\lambda_1^2=\tfrac{1}{4},\quad a_1=a_2=\tfrac{1}{2}.$$

For special values of the k's and the c's in (76) some poles can coincide, diminishing P_T accordingly. The preceding examples, apart from leading to simple factorized expressions for g also illustrate this point. One degeneracy (the common pole for $r=0$, $\sin kt=0$) diminishes P_T by 1 in each case. This is consistently incorporated in the factorized forms of g. Thus for $k_1=2k$, $k_2=3k$ one obtains $P_T=4$ instead of 5. We will assume, in general, that the choice of parameters in Σ imply distinct poles.

Spinor solutions for zero mass were constructed[2] directly in Witten-type gauge. But since the counting of the number of zero modes (and hence comparison with the index theorems) is more transparent in the 't Hooft- or JNR-type gauge, we start by generalizing (74) as follows. Let

$$A_\mu=\sigma_{\mu\nu}\partial_\nu\ln\Sigma,$$

where, with $\epsilon=\pm1$,

$$\Sigma=\frac{1}{2}(1+\epsilon)+\frac{1}{2r}\sum_{j=1}^{n}\lambda_j^2\left(\coth\frac{1}{2}k_j(r+it-ic_j)+\coth\frac{1}{2}k_j(r-it+ic_j)\right)$$
$$=\frac{1}{2}(1+\epsilon)+\sum_{j=1}^{n}\sum_{l=-\infty}^{\infty}\frac{\lambda_j^2}{k_j^2}\frac{1}{r^2+(t-k_j^{-1}2\pi l)^2}. \tag{77}$$

The role of ϵ is interesting concerning the index theorems. For $\epsilon=1$, one has a 't Hooft-like form. It can be shown that on the asymptotic sphere in R^3 one now has a dipole like configuration rather than a monopole. (See the discussion in Ref. 6 and the sources cited there.) Hence for

$$\epsilon=1, \quad q=0,$$

while for

$$\epsilon=-1, \quad q=1.$$

However, for *both* values $(\epsilon=\pm 1)$, the periodic action is the same. For an overall period T and integers n_j such that

$$T_j=2\pi k_j^{-1}, \quad T=2\pi k^{-1}, \quad k_j=n_jk, \quad S_T=8\pi^2\sum_j n_j. \tag{78}$$

This can be seen as a limiting case of the familiar ('t Hooft and JNR) solutions as follows. Start by retaining in (77) the poles covering an interval *NT*. Define, in evident notations,

$$S_T=(N^{-1}S_{NT})_{N\to\infty}.$$

The value of S_{NT} is given by the very well-known results for the 't Hooft and JNR solutions leading to

$$S_T=\frac{8\pi^2}{N}\left(N\sum_j n_j-(1-\epsilon)/2\right)_{N\to\infty}=8\pi^2\sum_{j=1}^{n}n_j.$$

Thus for the periodic case, in contrast with the aperiodic one, the change from $\epsilon=-1$ *to* $\epsilon=1$ *does not increase* P_T *by* 1 *but diminishes* q *by* 1. For $n=1$, one has quite a special case. Then for $\epsilon=-1$, one has a static monopole gauge transformed to a periodic form, whereas for $\epsilon=1$ the periodicity is authentic but $q=0$.

C. Spinor solutions

Having thoroughly prepared the ground, we at last introduce the spinors. Here we consider[2,6] only isospin

$$I=\tfrac{1}{2}$$

(see Ref. 7 for $I=1$). We consider only zero mass spinors.

For our conventions only upper (positive) helicity spinors have normalizable solution. Separating this helicity (Ψ_U) the Dirac equation reduces to

$$\overline{\alpha_\mu}(i\partial_\mu-A_\mu)\Psi_U=0,$$

where

$$\overline{\alpha_\mu}=(\tau_0,i\vec{\tau}), \quad \alpha_\mu=(\tau_0,-i\vec{\tau}).$$

(We denote space–time Pauli matrices by τ_μ and those in the isospace by σ_μ.) The isospin components are separated as

$$\Psi_U = \begin{vmatrix} \Psi_U^{(+)} \\ \Psi_U^{(-)} \end{vmatrix}, \quad I_3 \Psi_U^{(\pm)} = \pm \frac{1}{2} \Psi_U^{(\pm)}.$$

Set

$$\Psi_U^{(\pm)} = \Sigma^{1/2} \begin{vmatrix} a_\pm \\ b_\pm \end{vmatrix}$$

and define

$$u = \tfrac{1}{2}(x_3 + i x_0), \quad \overline{u} = \tfrac{1}{2}(x_3 - i x_0),$$

$$v = \tfrac{1}{2}(x_1 + i x_2), \quad \overline{v} = \tfrac{1}{2}(x_1 - i x_2).$$

Formally, the solutions are given (see Ref. 6 and the sources cited therein) by

$$a_+ = \partial_v (\Sigma^{-1} H), \quad b_+ = -\partial_u (\Sigma^{-1} H),$$

$$a_- = -\partial_{\overline{u}} (\Sigma^{-1} H), \quad b_- = -\partial_{\overline{v}} (\Sigma^{-1} H),$$

where

$$\Box H = (\partial_u \partial_{\overline{u}} + \partial_v \partial_{\overline{v}}) H = 0.$$

Normalizable solutions are obtained by matching the poles of H with the zeros of Σ^{-1}. From (77) it is evident that there are an infinite number of such possible choices of H. A finite number is obtained by imposing suitable boundary conditions relating $\Psi_U(t)$ and $\Psi_U(t+T)$, $T = 2\pi K^{-1}$ being the period.

For *periodic* spinors satisfying

$$\Psi_U(t) = \Psi_U(t+T)$$

set

$$H_{m_j} = \frac{1}{2r} \left(\coth \frac{1}{2} K(r + i(t - c_j) - i 2\pi k_j^{-1} m_j) + \coth \frac{1}{2} K(r - i(t - c_j) + i 2\pi k_j^{-1} m_j) \right) \tag{79}$$

with $T_j = 2\pi k_j^{-1}$ and

$$m_j = 1,2,\ldots,n_j, \quad k_j = n_j K \quad (j = 1,2,\ldots,n).$$

These provide all the normalizable zero modes. The total number is

$$\left(\sum_{j=1}^{n} n_j \right). \tag{80}$$

But they are not all necessarily independent since

$$\frac{1}{n_j} \sum_{m_j=1}^{n_j} \coth \frac{1}{2} K(r \pm i(t - c_j - 2\pi k_j^{-1} m_j)) = \coth \frac{1}{2} k_j (r \pm i(t - c_j)). \tag{81}$$

(This is probably most easily derived via the logarithmic derivative of the well-known product formula for $\sinh nx$.) Hence

$$\sum_j n_j^{-1}\lambda_j^2\left(\sum_{m_j} H_{m_j}\right)=\Sigma-\frac{1}{2}(1+\epsilon). \tag{82}$$

Thus for $\epsilon=-1$, in an evident notation,

$$\sum_j n_j^{-1}\lambda_j^2\left(\sum_{m_j} \Psi_U^{(m_j)}\right)=0. \tag{83}$$

There is no such constraint for $\epsilon=1$. Moreover, for *both* cases $(\epsilon=\pm 1)$, as explained before

$$P_T=\left(\sum_{j=1}^{n} n_j\right).$$

Thus in both cases, consistent with the index theorems stated at the beginning of this section, the number of zero modes $=P_T-q$.

Here q is limited to zero and one. But, on the other hand, we have done much more than counting the number of possible solutions. They have been obtained explicitly. One can now study, to take only one example, the time evolution of such spinor densities.

For *antiperiodic* spinors (in periodic backgrounds)

$$\Psi_U(t)=-\Psi_U(t+T)$$

and the correct choice[6] for H turns out to be

$$H_{m_j}=\frac{1}{2r}\left(\operatorname{cosech}\frac{1}{2}K(r+i(t-c_j)-i2\pi k_j^{-1}m_j)+\operatorname{cosech}\frac{1}{2}K(r-i(t-c_j)+i2\pi k_j^{-1}m_j)\right). \tag{84}$$

The linear constraint (83) is now absent even for $q=1$ $(\epsilon=-1)$. *There is no "magnetic defect,"* no subtraction of q, and one obtains (consistently with the result stated at the beginning of this section but now via explicit constructions)

$$\text{number of zero modes}=P_T.$$

Static configurations can be considered as a limiting case of periodic ones (infinite period) but not of antiperiodic ones. The Dirac modes in a monopole background that introduce the q subtraction as a boundary effect are not relevant for antiperiodic spinors.

D. Spinors in quasiperiodic backgrounds

Consider now the case where in (77) the k's are *not* all mutually commensurable. Generalizing the approximation (48) to several component irrational ratios one may construct (anti)periodic spinor solutions at each level of rational approximation. As this approximation is improved P_T (approx) and hence the number of spinor modes will diverge. There being no exact period for the gauge field one cannot limit the number of spinor modes by imposing (anti)periodic boundary conditions as before. *But our previous solutions provide a subset of "typical" ones which permit a comparative study of time* evolution of spinors in periodic and quasiperiodic backgrounds respectively. Consider, for example, the subset (periodic and antiperiodic, respectively, for a periodic background) corresponding to

$$H_j^{(+)}=\frac{1}{2r}\left(\coth\frac{1}{2}k_j(r+it-ic_j)+\coth\frac{1}{2}k_j(r-it+ic_j)\right), \tag{85}$$

$$H_j^{(-)}=\frac{1}{2r}\left(\operatorname{cosech}\frac{1}{2}k_j(r+it-ic_j)+\operatorname{cosech}\frac{1}{2}k_j(r-it+ic_j)\right). \tag{86}$$

Suppose we start with mutually commensurable k's and then vary some of them (infinitesimally or more) to introduce incommensurability and quasiperiodicity. $H_j^{(\pm)}$ will continue to give solutions, normalizable over any rationally approximated period or over unit time [analogously to (50)]. One can express the spinor densities

$$(\Psi_U^{(\pm)})^\dagger\Psi_U^{(\pm)}, \quad (\Psi_U^{(\pm)})^\dagger\vec{\tau}\Psi_U^{(\pm)}$$

in terms of $a_\pm$, $b_\pm$, and Σ. One can implement the constraints due to the harmonic property of Σ and the H's and (for our present case) those due to spherical symmetry. Then it might be rewarding to follow the time evolution of the densities for different values (small or some other crucial ones) of r, particularly when there are three or more incommensurable k's. Such a study is, however, entirely beyond the scope of this paper.

Let us finally note that starting with (76) as g_0 and iterating with real parameters as in (72), namely,

$$g_{p+1}=\frac{a_p+g_p}{a_p+g_p^{-1}},$$

the roots of $g_0=1$ will form a subset of those of $g_p=1$. Hence defining

$$\Sigma_p=\frac{1}{2r}\left(\frac{1+g_p}{1-g_p}+\frac{1+\overline{g_p}}{1-\overline{g_p}}\right) \tag{87}$$

and still retaining the explicit expressions (85), (86) for $H_j^{(\pm)}$ obtained for Σ_0, one obtains an interesting subset of spinor modes for the background corresponding to Σ_p, for both cases (periodic and quasiperiodic). At the level of g_0 the space–time dependence can already be quite complex. With iterations this will become much more so. But we will still have explicit solutions whose evolutions can be studied.

Note that our spinor solutions (except periodic ones for $q=0$) fall off exponentially for large r. For antiperiodic ones this is more evident. But though the leading term (for $q=1$) in (H_j/Σ) is constant for periodic spinors, the presence of derivatives introduce again exponential damping. For $q=0$ periodic spinor densities fall off as r^{-4}. We have already studied the action density of the gauge fields near the origin (Sec. II). One can now study our ''exponentially confined'' fermion densities near the origin in such backgrounds.

V. PROPAGATORS

For the gauge field backgrounds considered in the preceding sections the propagators for massless, isospin $\frac{1}{2}$ fields were given in Ref. 3. For periodic backgrounds the (anti)periodic propagators were presented in explicitly summed up, closed forms. *Our iterative map can be implemented in them* through the functions $g(\overline{g})$ corresponding to the points x and y of the propagator $\Delta(x,y)$. We recapitulate briefly the results of Ref. 3, where other sources are cited.

Define

$$t=x_0, t'=y_0, \quad r=\sqrt{\vec{x}^2}, \quad r'=\sqrt{\vec{y}^2},$$

$$\sigma_r=\frac{\vec{\sigma}\cdot\vec{x}}{r}, \quad \sigma_{r'}=\frac{\vec{\sigma}\cdot\vec{y}}{r'},$$

$$G=\frac{1+g(r+it)}{1-g(r+it)}, \quad G'=\frac{1+g(r'+it')}{1-g(r'+it')},$$

$$\Sigma=\frac{1}{2r}(G+\overline{G}),\quad \Sigma'=\frac{1}{2r'}(G'+\overline{G'}),$$

and

$$-i2F(r,t;r',t')=\frac{(1-\sigma_r)(1+\sigma_{r'})}{(t-t')+i(r-r')}(G-G')-\frac{(1+\sigma_r)(1-\sigma_{r'})}{(t-t')-i(r-r')}(\overline{G}-\overline{G'})$$
$$+\frac{(1-\sigma_r)(1-\sigma_{r'})}{(t-t')+i(r+r')}(G+\overline{G'})-\frac{(1+\sigma_r)(1+\sigma_{r'})}{(t-t')-i(r+r')}(\overline{G}+G'). \tag{88}$$

Let unprimed fields (A_μ) correspond to x and primed ones (A'_μ) to y. Let

$$\tilde{\Delta}(x,y)=\Sigma^{-1/2}\frac{F}{4\pi^2(x-y)^2}\Sigma'^{-1/2} \tag{89}$$

and

$$D_\mu=(\partial_\mu+iA_\mu)(\partial_\mu+iA_\mu).$$

Then

$$-D^2\tilde{\Delta}(x,y)=\delta^4(x-y). \tag{90}$$

Thus $\tilde{\Delta}$ gives the *aperiodic* propagator for massless scalar fields. For $G(G')$ periodic in $t(t')$ with a period T, say, the *periodic* and the *antiperiodic* propagators are, respectively, defined to be

$$\Delta_+(x,y)=\sum_{n=-\infty}^{\infty}\tilde{\Delta}(x_0+nT,\vec{x};y_0,\vec{y}), \tag{91}$$

$$\Delta_-(x,y)=\sum_{n=-\infty}^{\infty}(-1)^n\tilde{\Delta}(x_0+nT,\vec{x};y_0,\vec{y}). \tag{92}$$

Define

$$V_1=(t-t')+i|\vec{x}-\vec{y}|,\quad V_2=(t-t')-i|\vec{x}-\vec{y}|,$$
$$V_3(\epsilon,\epsilon')=(t-t')+i(\epsilon r+\epsilon' r'),\quad (\epsilon,\epsilon'=\pm 1), \tag{93}$$

and

$$S_+(\epsilon,\epsilon')=\frac{\pi}{T}\frac{\left((V_2-V_3)\cot\left(\frac{\pi}{T}V_1\right)+\text{cyclic}\right)}{(V_1-V_2)(V_2-V_3)(V_3-V_1)},$$
$$S_-(\epsilon,\epsilon')=\frac{\pi}{T}\frac{\left((V_2-V_3)\operatorname{cosec}\left(\frac{\pi}{T}V_1\right)+\text{cyclic}\right)}{(V_1-V_2)(V_2-V_3)(V_3-V_1)}. \tag{94}$$

[The indices (ϵ,ϵ') are implicit in V_3 on the right-hand sides.] Then one obtains[3]

$$\Delta_{\pm}(x,y)=\frac{i(\Sigma\Sigma')^{-1/2}}{8\pi^2}\begin{pmatrix}(G-G')S_{\pm}(1,-1)(1-\sigma_r)(1+\sigma_{r'})\\ -(\bar{G}-\bar{G}')S_{\pm}(-1,1)(1+\sigma_r)(1-\sigma_{r'})\\ +(G+\bar{G}')S_{\pm}(1,1)(1-\sigma_r)(1-\sigma_{r'})\\ -(\bar{G}+G')S_{\pm}(-1,-1)(1+\sigma_r)(1+\sigma_{r'})\end{pmatrix}. \tag{95}$$

The propagator for spinors is obtained now through a standard prescription[15] as

$$(\gamma\cdot D(x)\Delta(x,y)(1+\gamma_5)/2+\Delta(x,y)\gamma\cdot\overleftarrow{D}(y)(1-\gamma_5)/2),$$

where Δ can be $\tilde{\Delta},\Delta_+$, or Δ_-.

All that has been assumed is that g (at x,y or at any other point) satisfies the properties listed under (7). Thus g can involve an arbitrary number of iterations. When x and y are both close to the origin, G and G' will exhibit strongly and simultaneously the consequences of the chaotic aspects studied in the Appendix. (See the remarks in Sec. VII). For a quasiperiodic background one can consider the aperiodic $\tilde{\Delta}$ or $\Delta_{\pm}$ for some adequate rational approximation.

VI. GENERALIZATIONS

Only brief indications will be given below concerning some possible generalizations.

A. Beyond spherical symmetry for $q=0,1$

One can generalize (66) and (77) as follows. Let

$$A_\mu=\sigma_{\mu\nu}\partial_\nu\ln\Sigma,$$

where, with $\epsilon=\pm1$,

$$\Sigma=\frac{1}{2}(1+\epsilon)+\sum_{m=1}^{M}\frac{1}{2r_m}(G_m+\bar{G}_m) \tag{96}$$

and $G_m(r_m+it)$ is a holomorphic function with

$$r_m=|\vec{x}-\vec{x}_m|.$$

Choosing

$$G_m=\frac{1+g_m}{1-g_m}, \tag{97}$$

where g_m is now given by (40) with the origin translated to $\vec{x}_m$, iterations can be introduced independently for each center. One can have a ''gas'' (dilute or dense) of (quasi)periodic instantons. In Ref. 7 spinors were studied in such a background without iterations. One can also start by generalizing (76) including shifts of origin, starting for the mth term with

$$g_m^{(0)}=\frac{\Sigma_{l=1}^{n_m}\lambda_{l,m}^2(e^{k_{l,m}(r_m+it-ic_{l,m})}-1)^{-1}}{\Sigma_{l=1}^{n_m}\lambda_{l,m}^2(1-e^{-k_{l,m}(r_m+it-ic_{l,m})})^{-1}}. \tag{98}$$

Then one may apply iterations independently for each m. As explained in Sec. IV a subset of spinor solutions can readily be obtained.

B. $q>1$; spherical symmetry necessarily broken
