Proposition 2.1: Let $Q = G$ and $d\alpha$ is a left-invariant Haar measure on G. If $d\nu_x = f(x,g) d\alpha(g)$, where $f: M \times G \to \mathbf{R}_+$ is a Borel function such that for every $x \in M f(x, \cdot) \in L^1(G, d\alpha)$ and $\sup_{x,g} f(x,g) \leqslant C$, then for every semispectral measure dE on G we have that $\|(\nu_x * E)(B) \leqslant C\|E(G)\|\alpha(B)$, where B is an arbitrary but α-finite Borel subset of G.

Proof: Because $(\nu_x * E)(B)$ is a positive operator we have that

$$\|(\nu_x * E)(B)\| = \|(\nu_x * E)^{1/2}(B)\|^2 = \sup_{\|\psi\|=1} \langle \psi, (\nu_x * E)(B)\psi \rangle = \sup_{\|\psi\|=1} (\nu_x * E_{\psi,\psi})(B).$$

However,

$$(\nu_x * E_{\psi,\psi})(B) = \int_G \nu_x(Bg^{-1}) dE_{\psi,\psi}(g) = \int_G \int_B f(x, hg^{-1}) d\alpha(h) dE_{\psi,\psi}(g) \leqslant C\|E(G)\|\alpha(B)\|\psi\|^2.$$

□

Proposition 2.2: Let $Q = G/K$ and $d\alpha$ is the G-invariant measure on Q. If $E(B)$ is given by $E(B) = \int_B P(q)\, d\alpha(q)$, where $P(q)$ is a projector and $q \to P(q)$ is weakly Borel measurable and weakly α-integrable, then $\|(\nu_x * E)(B)\| \leqslant C\alpha(B)$ for every $\nu_x \in M(G)$ such that $\sup_x \nu_x(G) \leqslant C$.

Proof: Now we have

$$(\nu_x * E_{\psi,\psi})(B) = \int_G E_{\psi,\psi}(g^{-1}B)\, d\nu_x(g) = \int_G \int_{g^{-1}B} \langle \psi, P(q)\psi\rangle\, d\alpha(q)\, d\nu_x(g)$$

$$\leq \|\psi\|^2 \int_G \alpha(g^{-1}B)\, d\nu_x(g) \leq C\|\psi\|^2 \alpha(B),$$

and so the assertion follows. □

In the coherent state case we can describe more precisely the influence of the classical system onto the quantum one. Let $\hat{f} = \int f(q)\, dE(q)$ be a quantum operator corresponding to a function *f*. A point $x \in M$ changes it to

$$\hat{f}_x = \int_Q f(q)\, d(\nu_x * E)(q).$$

Because

$$(\nu_x * E)(B) = \int_G E(g^{-1}B)\, d\nu_x(g)$$

and

$$E(g^{-1}B) = \int_B P_{gq}\, d\alpha(q),$$

then

$$d(\nu_x * E)(q) = \left(\int_G P_{gq}\, d\nu_x(g) \right) d\alpha(q).$$

However, $P_{gq} = \pi(g) P_q \pi(g)^*$, hence

$$\hat{f}_x = \int_G \pi(g) \hat{f} \pi(g)^* \; d\nu_x(g).$$

If ν_x is a point measure, then we get just a unitary automorphism of $\hat{f}$.

Let us begin the construction of the generator *L*. We will need the following:

Lemma 2.3: The function $x \to (\nu_x * E)(B)$ is weakly Borel measurable for every $B \in \mathcal{B}(Q)$.

Proof: Let $\psi \in \mathcal{H}_q$. Because of the polarization formula it is enough to consider the function $x \to \langle \psi, (\nu_x * E)(B)\psi\rangle$. However,

$$\langle \psi, (\nu_x * E)(B)\psi\rangle = (\nu_x * E_{\psi,\psi})(B) = \int_G E_{\psi,\psi}(g^{-1}B)\, d\nu_x(g) = \lim_{n\to\infty} \sum_{i=1}^{n} E_{\psi,\psi}(g_i^{-1}B)\, \nu_x(G_i).$$

Because G_i is a Borel subset of *G* and the function $x \to \nu_x(G_i)$ is Borel, the assertion follows. □

It is known that if a semispectral measure *dE* has the property $\|E(B)\| \leq C\alpha(B)$ for a σ-finite measure $d\alpha$, then *dE* possesses an operator-valued density.[14] Now we generalize this fact to a family of semispectral measures $d(\nu_x * E)$ and show the essential boundedness of the corresponding operator-valued density.

Theorem 2.4: There is a weakly Borel measurable function $\tilde{V}: M \times Q \to L(\mathcal{H}_q)_+$ such that $\sup_{x,q} \|\tilde{V}(x,q)\| \leq \infty$ and for every $x \in M \setminus N$, where *N* is a Borel subset of μ-measure zero,

$$(\nu_x * E)(B) = \int_B \tilde{V}(x,q)\, d\alpha(q)$$

in the weak sense. Moreover, any other such $\tilde{V}'$ agrees with $\tilde{V}$ $\mu \times \alpha$ almost everywhere.

Proof: See Appendix A.

Corollary 2.5: From the Fubini theorem there is a Borel set $Q_0 \subset Q$ such that $\alpha(Q_0) = 0$ and the map $x \to \tilde{V}_q(x) = \tilde{V}(x,q)$ is weakly Borel measurable for all $q \in Q \backslash Q_0$. Putting $\tilde{V}_q = 0$ for $q \in Q_0$ we get a well-defined map $q \to \tilde{V}_q \in \mathcal{A}_T$ for every $q \in Q$.

Proposition 2.6: $\sup_q \|\tilde{V}_q\| \leqslant \infty$ and $q \to \tilde{V}_q$ is weakly Borel measurable.

Proof: Only the second statement needs a proof. Because $\tilde{V}_q$ is uniformly bounded, it is enough to check it for simple tensors $\tilde{\Psi} = \psi \otimes \Psi$, where $\psi \in \mathcal{H}_q$ and $\Psi \in \mathcal{H}_c$. If $q \in Q \backslash Q_0$, then

$$\langle \psi \otimes \Psi, \tilde{V}_q(\psi \otimes \Psi) \rangle = \int_M d\mu(x) |\Psi(x)|^2 \langle \psi, \tilde{V}(x,q) \psi \rangle.$$

Again from the Fubini theorem, $q \to \langle \psi, \tilde{V}(x,q)\psi \rangle$ is Borel for a.e. $x \in M$, and so $q \to \int_M d\mu(x) |\Psi(x)|^2 \langle \psi, \tilde{V}(x,q)\psi \rangle$ is Borel, too. Because Q_0 is a Borel set and $\tilde{V}_q = 0$ for $q \in Q_0$, so $q \to \tilde{V}_q$ is weakly Borel measurable for all q. □

Let $\tilde{U}_q = U_q \otimes \mathbf{1}$ and let $\tilde{W}_q = \tilde{U}_q \cdot \tilde{V}_q$. Clearly $\tilde{W}_q^* \tilde{A} \tilde{W}_q \in \mathcal{A}_T$ and the map $q \to \tilde{W}_q^* \tilde{A} \tilde{W}_q$ is weakly Borel measurable.

Now let $W_n(\tilde{A})$ be defined by

$$\langle \tilde{\Psi}_1, W_n(\tilde{A}) \tilde{\Psi}_2 \rangle = \int_{Q^n} d\alpha(q) \langle \tilde{\Psi}_1, \tilde{W}_q^* \tilde{A} \tilde{W}_q \tilde{\Psi}_2 \rangle, \quad \tilde{\Psi}_1, \tilde{\Psi}_2 \in \tilde{\mathcal{H}},$$

where $Q^n := \cup_{i=1}^{i=n} Q_i$ and Q_i are α-finite sets which covers Q. Q^n is also α-finite. Because the function $q \to \langle \tilde{\Psi}_1, \tilde{W}_q^* \tilde{A} \tilde{W}_q \tilde{\Psi}_2 \rangle$ is Borel and uniformly bounded, the integral on the right-hand side exists and defines a linear and bounded operator on $\tilde{\mathcal{H}}$. As the weak limit of operators from $\mathcal{A}_T$, $W_n(\tilde{A})$ also belongs to $\mathcal{A}_T$.

Proposition 2.7: $W(\tilde{A}) = \lim_{n \to \infty} W_n(\tilde{A})$ exists and belongs to $\mathcal{A}_T$.

Proof: Let $\tilde{A}$ be a positive operator. Then

$$\tilde{W}_q^* \tilde{A} \tilde{W}_q \leqslant \|\tilde{A}\| \tilde{W}_q^* \tilde{W}_q = \|\tilde{A}\| \tilde{V}_q^2.$$

However, $\tilde{V}_q$ is positive so $\tilde{V}_q^2 \leqslant \|\tilde{V}_q\| \tilde{V}_q$ and

$$\begin{aligned}
\int_{Q^n} d\alpha(q) \langle \tilde{\Psi}, \tilde{W}_q^* \tilde{A} \tilde{W}_q \tilde{\Psi} \rangle &\leqslant \|\tilde{A}\| (\sup_q \|\tilde{V}_q\|) \int_{Q^n} d\alpha(q) \langle \tilde{\Psi}, \tilde{V}_q \tilde{\Psi} \rangle \\
&\leqslant C \|\tilde{A}\| \int_{Q^n} d\alpha(q) \int_M d\mu(x) \langle \tilde{\Psi}(x), \tilde{V}(x,q) \tilde{\Psi}(x) \rangle \\
&= C \|\tilde{A}\| \int_M d\mu(x) (\nu_x * E_{\tilde{\Psi}(x), \tilde{\Psi}(x)})(Q^n) \\
&\leqslant C \|\tilde{A}\| \int_M d\mu(x) \|(\nu_x * E)(Q)\| \cdot \|\tilde{\Psi}(x)\|^2 \\
&\leqslant C \|\tilde{A}\| (\sup_x \|(\nu_x * E)(Q)\|) \|\tilde{\Psi}\|^2.
\end{aligned}$$

However,

$$\|(\nu_x * E)(Q)\| = \sup \lim_{\|\psi\|=1} (\nu_x * E_{\psi,\psi})(Q) = \sup \lim_{\|\psi\|=1} \int_G E_{\psi,\psi}(Q)\, d\nu_x(g) = \|E(Q)\| \, \nu_x(G),$$

and $\sup_x \nu_x(G) = C_1$. Thus

$$\int_{Q^n} d\alpha(q) \langle \tilde{\Psi}, \tilde{W}_q^* \tilde{A} \tilde{W}_q \tilde{\Psi} \rangle \leqslant C C_1 \|\tilde{A}\| \cdot \|E(Q)\| \cdot \|\tilde{\Psi}\|^2.$$

So from the polarization formula we have that $\forall \tilde{\Psi}_1, \ \tilde{\Psi}_2 \in \tilde{H}$ and $\forall \tilde{A} \in \mathcal{A}_T$, $\int_Q d\alpha(q) \times \langle \tilde{\Psi}_1, \tilde{W}_q^* \tilde{A} \tilde{W}_q \tilde{\Psi}_2 \rangle$ exists. This means that $W_n(\tilde{A})$ is weakly convergent to $W(\tilde{A})$ and thus $W(\tilde{A}) \in \mathcal{A}_T$. □

Now let us consider a*-linear map $W: \mathcal{A}_T \to \mathcal{A}_T$.

Lemma 2.8: W is a completely positive and normal map.

Proof: See Appendix B.

Thus we have proved the following.

Theorem 2.9: Let $L(\tilde{A}) = W(\tilde{A}) - \frac{1}{2}\{W(\tilde{\mathbf{1}}), \tilde{A}\}$, where $\{\cdot,\cdot\}$ stands for the anticommutator. Then L is a bounded complete dissipation and $L(\tilde{\mathbf{1}}) = 0$, where $\tilde{\mathbf{1}}$ is the unit in $\mathcal{A}_T$. □

Remark: The adjoint of L is a generator of a one-parameter semigroup of completely positive and conservative maps of $\mathcal{S}_T$. Formally it can be written as

$$L_*(\tilde{\rho})(x) = \int_Q d\alpha(q) \tilde{V}_q(x) \tilde{\rho}(h_q^{-1}(x)) \tilde{V}_q(x) - \frac{1}{2} \left\{ \int_Q d\alpha(q) \tilde{V}_q^2(x), \tilde{\rho}(x) \right\}.$$

III. APPLICATIONS

In this section we present two examples of a possible classical–quantum coupling and discuss some of its properties.

Example 1: The first area of possible applications of the above formalism is the semiclassical theory of gravity, in which a classical gravitational field interacts with quantum matter. In this approach one studies the generalized Einstein's equation which is modified by regularized vacuum expectation value of the energy-momentum tensor of matter-field operators. In the so-called back-reaction problem the influence of particle creation on the dynamics of gravitational field is analyzed. In Ref. 15 the effective equation for the evolution of a Bianchi type I metric with such back reaction was derived. It was also shown there that there is the dissipation of anisotropy in the Bianchi type I universe through quantum effects. For a general discussion of the dissipation in semiclassical gravity, see Ref. 16. Here we present a simpler situation, in which a nonrelativistic classical particle moving along a geodesic line in a curved space interact with a quantum system. As the result we obtain a dissipative behavior of the quantum density matrix and the modification of the classical evolution on average through the expectation value of the quantum position operator.

At first we describe the classical system. Let us consider a classical particle moving freely on the Lobatchevsky space:

$$Q = \mathbf{R} \times \mathbf{R}_+ = \{(x_1, x_2): \quad x_2 > 0\}.$$

The phase space is the cotangent space $M = T^*Q$ with the canonical symplectic form $\omega = dp_1 \wedge dx_1 + dp_2 \wedge dx_2$. It leads to the Lebesgue'a measure $d\mu = dx_1 dx_2 dp_1 dp_2$ on M. The time evolution is governed by a complete vector field X on M:

$$X(x_i, p_i) = \sum_{k=1}^{2} \left[f_k(x_i, p_i) \frac{\partial}{\partial x_k} + g_k(x_i, p_i) \frac{\partial}{\partial p_k} \right],$$

where $f_k(x_i,p_i)=p_k$ and $g_1(x_i,p_i)=2p_1p_2/x_2$, $g_2(x_i,p_i)=(p_2^2-p_1^2)/x_2$. For simplicity we denote four parameters (x_1,x_2,p_1,p_2) by (x_i,p_i). It gives the following second-order differential equations for the position coordinates:

$$\ddot{x}_1=\frac{2}{x_2}\dot{x}_1\dot{x}_2,$$

$$\ddot{x}_2=\frac{1}{x_2}[(\dot{x}_2)^2-(\dot{x}_1)^2].$$

Hence the classical particle moves on a geodesic line with respect to the metric

$$g=\frac{1}{x_2^2}(dx_1\otimes dx_1+dx_2\otimes dx_2).$$

To describe the quantum system we use the system of generalized coherent states.[13] Let us consider a quantum particle on the Lobatchevsky space Q. It is a homogeneous space $Q=\mathrm{SL}(2,\mathbf{R})/\mathrm{U}(1)$. For simplicity we take the first representation from the series $(\mathcal{H}_k,\pi_k)$, where $k=1,\frac{3}{2},2,\ldots$. That is,

$$\mathcal{H}_q=\left\{f:\|f\|^2=\int d\mu_1(z)|f(z)|^2<\infty\right\},$$

where f is a holomorphic function in the unit complex disc $|z|<1$ and $d\mu_1=(1/\pi)dzd\overline{z}.$ For $q=(x_1,x_2)\in Q$ we have one-dimensional projectors $P_q=|\zeta\rangle\langle\zeta|$, where

$$|\zeta\rangle=\frac{1-|\zeta|^2}{(1-\overline{\zeta}z)^2}\quad\text{and}\quad\zeta=\frac{1-x_2+ix_1}{1+x_2-ix_1}.$$

The semispectral measure $E(B)$, $B\in\mathcal{B}(Q)$, is given by $E(B)=\int_B P_q\,d\alpha(q)$, where $d\alpha$ is the unique $\mathrm{SL}(2,\mathbf{R})$ invariant measure on Q normalized in such a way that $\int_Q P_q\,d\alpha(q)=I$, the identity operator. The quantum operator corresponding to a function f on Q reads

$$\hat{f}=\int_Q f(q)dE(q).$$

A self-adjoint operator H on $\mathcal{H}_q$ determines the time evolution in the standard way.

To define a generator L of the total system we assume the following:

(i) $\forall m=(q,p)\in M$ $\nu_{(q,p)}=\delta_e$, where δ_e denotes the point measure concentrated in the neutral element of the group $\mathrm{SL}(2,\mathbf{R})$, and
(ii) $\forall q\in Q$ $h_q:M\to M$ is given by $(q',p)\to(q',p+q)$.

Then $\tilde{V}(m,q)=P_q$ and so

$$L(\tilde{A})(m)=\int_Q d\alpha(q)P_q\tilde{A}(h_q(m))P_q-\tilde{A}(m),$$

$$L_*(\tilde{\rho})(m)=\int_Q d\alpha(q)P_q\tilde{\rho}(h_q^{-1}(m))P_q-\tilde{\rho}(m).$$

Let us derive the equation for the quantum density operator $\rho_t=\int_M\tilde{\rho}_t(x_i,p_i)d\mu$:

$$\dot{\rho}_t = \int_M \dot{\tilde{\rho}}_t(x_i,p_i)\,d\mu = \int_M [(\delta_c^{ad}\otimes \mathbf{1})\tilde{\rho}_t(x_i,p_i) + (\mathbf{1}\otimes \delta_q^{ad})\tilde{\rho}_t(x_i,p_i) + L_*(\tilde{\rho}_t)(x_i,p_i)]\,d\mu.$$

Here again we denote four parameters (x_1,x_2,p_1,p_2) by (x_i,p_i). Because for simple tensors $\phi \otimes \rho$, $\phi \in L^1(M,d\mu)$ and $\rho \in \mathrm{Tr}(\mathcal{H}_q)$, there is

$$\int_m (\delta_c^{ad}\otimes \mathbf{1})(\phi\otimes\rho)(x_i,p_i)\,d\mu = \rho\int_M (\delta_c^{ad}\phi)(x_i,p_i)\,d\mu = \rho\int_M \phi(x_i,p_i)\,\delta_c(id)(x_i,p_i)\,d\mu = 0$$

and

$$\int_M (\mathbf{1}\otimes \delta_q^{ad})(\phi\otimes\rho)(x_i,p_i)\,d\mu = \delta_q^{ad}\left(\rho\int_M \phi(x_i,p_i)\,d\mu\right)$$

and

$$\tilde{\rho}_t = \lim_{m\to\infty}\sum_{i=1}^{m} \phi_i(t)\otimes\rho_i(t)$$

so

$$\int_M (\delta_c^{ad}\otimes \mathbf{1})\tilde{\rho}_t(x_i,p_i)\,d\mu = 0$$

and

$$\int_M (\mathbf{1}\otimes \delta_q^{ad})\tilde{\rho}_t(x_i,p_i)\,d\mu = \delta_q^{ad}(\rho_t) = -i[H,\,\rho_t].$$

Finally

$$\int_M (L_*\tilde{\rho}_t)(x_i,p_i)\,d\mu = \int_M d\mu \int_Q d\alpha(q)\,P_q\tilde{\rho}_t(h_q^{-1}(x_i,p_i))P_q - \rho_t\,.$$

Because h_q^{-1} leaves the measure $d\mu$ invariant, by changing the order of integrals we get

$$\int_M (L_*\tilde{\rho}_t)(x_i,p_i)\,d\mu = \int_Q d\alpha(q)\,P_q\rho_t P_q - \rho_t\,.$$

Hence the time evolution equation for ρ_t is modified by a dissipative factor

$$\dot{\rho}_t = -i[H,\rho_t] + \int_Q d\alpha(q)\,P_q\rho_t P_q - \rho_t\,.$$

To see how this dissipative part acts we assume now that $H=0$. Thus

$$L_q(\rho) = \int_Q P_q\rho P_q\,d\alpha(q) - \rho.$$

Let $T_q(t)$ be the semigroup on $\mathrm{Tr}(\mathcal{H}_q)$ generated by L_q.

Theorem 3.1: Let $P_n = |n\rangle\langle n|$, where $|n\rangle(z) = \sqrt{n+1}z^n$, $n\in\mathbf{N}\cup\{0\}$, is an orthonormal base in $\mathcal{H}_q$. Then

$$T_q(t)(P_n)=\sum_{m=0}^{\infty} P(t,n,\{m\})P_m\,,$$

where

$$P(t,n,\{m\})=e^{t(\Pi-I)}=e^{-t}\sum_{k=0}^{\infty}\frac{t^k}{k!}\Pi_k(n,\{m\})$$

is the Poisson transition kernel with the probabilistic measure on $\mathbf{N}\cup\{0\}$ given by

$$\Pi(n,\{m\})=\frac{2(n+1)(m+1)}{(n+m+1)(n+m+2)(n+m+3)}.$$

Here $I(n,\{m\})=\delta_{nm}$, $\Pi_0(n,\{m\})=\delta_{nm}$, and

$$\Pi_k(n,\{m\})=\sum_{l=0}^{\infty}\Pi(n,\{l\})\Pi_{k-1}(l,\{m\})$$

for $k\geqslant 1$.

Proof: Because $T_q(t)=e^{tL_q}$, it is enough to show that

$$L_q(P_n)=\sum_{m=0}^{\infty}\Pi(n,\{m\})P_m-P_n\,.$$

To calculate the integral $\int P_qP_nP_q\,d\alpha(q)$ we use the representation of the Lobatchevski space as the Poincaré disc with SL(2,**R**) replaced by SU(1,1). Thus

$$d\alpha(q)\rightarrow d\alpha(\zeta)=\frac{1}{\pi}\frac{d\zeta d\bar{\zeta}}{(1-|\zeta|^2)^2}.$$

Let us observe that

$$P_qP_nP_q=|\langle\zeta,n\rangle|^2|\zeta\rangle\langle\zeta|=(n+1)(1-|\zeta|^2)^2|\zeta|^{2n}|\zeta\rangle\langle\zeta|.$$

In the above we use the formula $\langle\zeta,n\rangle=(1-|\zeta|^2)|n\rangle(\zeta)$.[13] We show that $\int P_qP_nP_q\,d\alpha(\zeta)$ is also diagonal in the $\{|n\rangle\}_0^\infty$ base. Indeed

$$\left\langle n_1,\int P_qP_nP_q d\alpha(\zeta)n_2\right\rangle=\int|\langle\zeta,n\rangle|^2\langle n_1,\zeta\rangle\langle\zeta,n_2\rangle d\alpha(\zeta)$$
$$=\frac{(n+1)\sqrt{(n_1+1)(n_2+1)}}{\pi}\int(1-|\zeta|^2)^2|\zeta|^{2n}\zeta^{n_2}\bar{\zeta}^{n_1}\,d\zeta d\bar{\zeta}=0.$$

On the other hand,

$$\left\langle m,\int P_qP_nP_q d\alpha(\zeta)m\right\rangle=\frac{(n+1)(m+1)}{\pi}\int(1-|\zeta|^2)^2|\zeta|^{2(n+m)}d\zeta d\bar{\zeta}$$
$$=\frac{(n+1)(m+1)}{\pi}\int_0^1\int_0^{2\pi}(1-r^2)^2r^{2(n+m)}r\,d\phi\,dr$$
$$=\frac{2(n+1)(m+1)}{(n+m+1)(n+m+2)(n+m+3)}.$$

Hence

$$\int P_q P_n P_q \, d\alpha(\zeta) = \sum_{m=0}^{\infty} \Pi(n,\{m\}) P_m ,$$

so the assertion follows. □

Now let us choose $\tilde{\rho}$ from some dense subset of $\mathcal{S}_T$ {which is compactly supported in the classical part and with the property that the commutator $[H,\tilde{\rho}(x_i,p_i)]$ belongs to the trace class}. Let us define so-called collective classical coordinates

$$\overline{x_k} = \widetilde{\mathrm{Tr}}(\tilde{\rho}(x_k \otimes \mathbf{1})) = \int_M x_k (\mathrm{Tr}\, \tilde{\rho}(x_i,p_i)) d\mu$$

and

$$\overline{p_k} = \widetilde{\mathrm{Tr}}(\tilde{\rho}(p_k \otimes \mathbf{1})) = \int_M p_k (\mathrm{Tr}\, \tilde{\rho}(x_i,p_i)) d\mu$$

for $k=1,2$. Their time evolution is given by

$$\dot{\bar{x}}_k = \int_M x_k (\mathrm{Tr}\, \dot{\tilde{\rho}}_t(x_i,p_i)) d\mu = \int_M x_k (\mathrm{Tr}(\delta_c^{ad} \otimes \mathbf{1} + \mathbf{1} \otimes \delta_q^{ad} + L_*) \tilde{\rho}_t(x_i,p_i)) d\mu.$$

However,

$$\int_M x_k \,\mathrm{Tr}(\delta_c^{ad} \otimes \mathbf{1}) \tilde{\rho}_t(x_i,p_i) d\mu = \int_M \delta_c(x_k) \mathrm{Tr}\, \tilde{\rho}_t(x_i,p_i) d\mu = \int_M p_k \,\mathrm{Tr}\, \tilde{\rho}_t(x_i,p_i) d\mu = \overline{p_k} ,$$

$$\int_M x_k \,\mathrm{Tr}(\mathbf{1} \otimes \delta_q^{ad}) \tilde{\rho}_t(x_i,p_i) d\mu = -i \int_M x_k \,\mathrm{Tr}[H, \tilde{\rho}_t(x_i,p_i)] d\mu = 0,$$

and

$$\int_M d\mu(x_i,p_i) x_k \,\mathrm{Tr}\left(\int_Q d\alpha(q) P_q \tilde{\rho}_t(x_i,p_i - q_i) P_q \right)$$
$$= \int_M d\mu(x_i,p_i') x_k \,\mathrm{Tr}\left(\int_Q d\alpha(q) P_q \right) \tilde{\rho}_t(x_i,p_i) = \overline{x_k} ,$$

so $\dot{\bar{x}}_k = \overline{p_k}$. In the same way we get that

$$\int_M p_k \,\mathrm{Tr}(\delta_c^{ad} \otimes \mathbf{1}) \tilde{\rho}_t(x_i,p_i) d\mu = \overline{\delta_c(p_k)} = \overline{g_k(x_i,p_i)},$$

$$\int_M p_k \,\mathrm{Tr}(\mathbf{1} \otimes \delta_q^{ad}) \tilde{\rho}_t(x_i,p_i) d\mu = 0,$$

and

$$\int_M d\mu(x_i,p_i)p_k \operatorname{Tr}\left(\int_Q d\alpha(q)P_q\tilde{\rho}_t(x_i,p_i-q_i)P_q\right)$$

$$=\int_M d\mu(x_i,p_i')(p_k+q_k)\operatorname{Tr}\left(\int_Q d\alpha(q)P_q\tilde{\rho}_t(x_i,p_i')\right)$$

$$=\overline{p_k}+\int_M d\mu(x_i,p_i)\operatorname{Tr}\left(\int_Q q_kP_q\,d\alpha(q)\right)\tilde{\rho}_t(x_i,p_i).$$

Let us notice that the operator $\int_Q q_kP_q\,d\alpha(q)$ is the quantum position operator $\hat{q}_k$. Thus

$$\dot{\bar{p}}_k=\overline{g_k(x_i,p_i)}+\operatorname{Tr}(\hat{q}_k\rho_t),$$

where $\rho_t=\int_M\tilde{\rho}_t(x_i,p_i)d\mu$ is the quantum density operator. Hence the classical evolution is perturbed by the expectation value of the quantum position operator.

Example 2: In this example we describe a quantum system coupled to all one-dimensional projectors considered as a classical device. Such a model was discussed in Ref. 17 in connection with the question: how do we determine the state of an individual quantum system?

Let us consider pure spin 1/2 system. Then $\mathcal{H}_q=\mathbf{C}^2$ and $\mathcal{A}_q=M_{2\times 2}(\mathbf{C})$. As the classical phase space we take the space of all one-dimensional projectors on $\mathcal{H}_q$, that is, $M=\mathbf{C}P^1=S^2$, the two-dimensional unit sphere. For any $\mathbf{n}\in S^2$, that is, $\mathbf{n}=(n_1,n_2,n_3)$, $\Sigma n_i^2=1$, let us define

$$e(\mathbf{n})=\frac{(I+\sigma\cdot\mathbf{n})}{2},$$

where $\sigma=\{\sigma_i\}$, $i=1,2,3$, denote the Pauli matrices. It is clear that $e(\mathbf{n})$ is a one-dimensional projector corresponding to a point $\mathbf{n}\in S^2$. On M there is the unique U(2) invariant measure $d\mu$ normalized to $\mu(M)=1$. Let us notice that $\mathcal{A}_q=\{e(\mathbf{n}):\mathbf{n}\in S^2\}''$ and thus a semispectral measure connected with the quantum system is given by $E(B)=\int_B e(\mathbf{n})d\mu(\mathbf{n})$ with the property $E(S^2)=I/2$. To present the coupling we assume that:

(i) $\forall\mathbf{n}\in S^2\quad \nu_{\mathbf{n}}=\delta_e$, the point measure at the neutral element of U(2), and
(ii) $\forall\mathbf{n}\in S^2\quad h_{\mathbf{n}}:S^2\to S^2$ is the geodesic symmetry on the symmetric space $S^2=\mathrm{U}(2)/\mathrm{U}(1)\times\mathrm{U}(1)$.

Then $\tilde{V}_{\mathbf{n}'}(\mathbf{n})=e(\mathbf{n}')$ and so

$$L_*(\tilde{\rho})(\mathbf{n})=\int_{S^2}d\mu(\mathbf{n}')e(\mathbf{n}')\tilde{\rho}(\mathbf{n}'(\mathbf{n}))e(\mathbf{n}')-\frac{1}{2}\tilde{\rho}(\mathbf{n}).$$

Since there is no classical evolution, the total generator reads

$$\dot{\tilde{\rho}}_t=(\mathbf{1}\otimes\delta_q^{ad})\tilde{\rho}_t+L_*(\tilde{\rho}_t).$$

Let us derive the equation for the time evolution of the quantum density operator $\rho_t=\int\tilde{\rho}_t(\mathbf{n})d\mu(\mathbf{n})$. At first we calculate the integral $\int e(\mathbf{n})e(\mathbf{n}')e(\mathbf{n})d\mu(\mathbf{n})$ for fixed projector $e(\mathbf{n}')$. Because

$$e(\mathbf{n})e(\mathbf{n}')e(\mathbf{n})=\tfrac{1}{2}(1+\mathbf{n}'\cdot\mathbf{n})e(\mathbf{n}),$$

it is enough to compute

$$\int_{S^2}n_ie(\mathbf{n})d\mu(\mathbf{n})=\int_{S^2}n_i\left(\frac{I}{2}+\frac{\sigma\cdot\mathbf{n}}{2}\right)d\mu(\mathbf{n}).$$

However, $\int n_i \, d\mu(\mathbf{n}) = 0$ for all $i = 1, 2, 3$ and $\int n_i n_j \, d\mu(\mathbf{n}) = 0$ if $i \neq j$. Thus

$$\int_{S^2} n_i e(\mathbf{n}) d\mu(\mathbf{n}) = \frac{\sigma_i}{2} \int_{S^2} n_i^2 \, d\mu(\mathbf{n}) = \frac{\sigma_i}{6},$$

and so

$$\int_{S^2} e(\mathbf{n}) e(\mathbf{n}') e(\mathbf{n}) d\mu(\mathbf{n}) = \frac{1}{6}(e(\mathbf{n}') + I).$$

By linearity, we obtain that for every $A \in M_{2\times 2}$ there is

$$\int_{S^2} e(\mathbf{n}) A e(\mathbf{n}) d\mu(\mathbf{n}) = \frac{1}{6}(A + \mathrm{Tr}(A)).$$

So,

$$\begin{aligned} &\int_{S^2} d\mu(\mathbf{n}) \int_{S^2} d\mu(\mathbf{n}') e(\mathbf{n}') \tilde{\rho}_t(\mathbf{n}'(\mathbf{n})) e(\mathbf{n}') - \frac{1}{2} \int_{S^2} d\mu(\mathbf{n}) \tilde{\rho}_t(\mathbf{n}) \\ &= \int_{S^2} d\mu(\mathbf{n}') e(\mathbf{n}') \rho_t e(\mathbf{n}') - \frac{1}{2} \rho_t \\ &= \frac{1}{6}(I - 2\rho_t). \end{aligned}$$

In the above we use the fact that $\mathbf{n}'(\mathbf{n})$ does not change the measure $d\mu$. Thus

$$\dot{\rho}_t = L_q(\rho_t) = -i[H, \rho_t] + \tfrac{1}{6}(\mathrm{Tr}\, \rho_t I - 2\rho_t).$$

We show that every density operator dissipates to the totally mixed state $I/2$. At first we describe E_r the reversible and E_o the irreversible part of the generator L_q.

Proposition 3.2: Let $A \in M_{2\times 2}$. Then

$$L_q(A) = 0 \Leftrightarrow A = zI, \quad z \in \mathbf{C},$$

$$(L_q(A) = i\lambda A, \quad \lambda \in \mathbf{R} \setminus \{0\}) \Leftrightarrow A = 0.$$

Proof: Direct calculations. □

Hence $E_r = zI$. Because $E_r \cap E_o = 0$ and $E_r \oplus E_o = M_{2\times 2}$, therefore

$$E_0 = \begin{pmatrix} z & z_1 \\ z_2 & -z \end{pmatrix}.$$

However, (see Lemma 4.2 in Ref. 18) for $A \in E_o$ there is $\lim_{t\to\infty} \|T_t A\| = 0$, where T_t denotes the semigroup generated by L_q. Thus T_∞ is the projection from $M_{2\times 2}$ onto E_r, and so for any density matrix ρ, $T_\infty(\rho) = I/2$.

IV. CONCLUDING REMARKS

The presented framework starts with a phenomenological assumption. At the very beginning we divide the world into two parts: a classical and a quantum one, which are next assumed to interact. The coupling ensures a flow of information from the quantum system to the classical system and the influence of the classics on the dynamics of the quantum system in a dissipative way. The classical evolution on average is perturbed by the expectation value of some quantum operator.

In each practical use we can guess what constitutes events and forms a classical system. Here we discuss two concrete models. However, this approach seems to be flexible enough to describe more general situations. It was shown in Ref. 19 that the spacelike asymptotic classical electromagnetic field is a superselection rule of the theory of a quantum particle carrying an electric charge, that is, each vector state from one superselection sector has the same asymptotic electromagnetic field. Also, in Ref. 20 the question of whether the radiation field can generate molecular superselection rules was discussed. Hence some classical observables can be thought of as a fundamental part of the quantum theory. Although dealing with infinite classical systems requires some elements of the scheme to be clarified, we believe that the proposed model can be also applied to such cases.

Finally, let us point out that the evolution equation for statistical states given by the dynamical semigroup encodes the behavior of individual samples. In the first example we showed that (assuming the quantum Hamiltonian is equal to zero) the evolution of a pure state is given by the Poisson probability distribution. The stochastic process describing the evolution from the second example was discussed in Ref. 17. A general construction of a piecewise deterministic process associated to a dynamical semigroup of the coupled quantum and classical continuous systems was presented in Ref. 21. Those processes can provide a practical way for calculating numbers that are needed in experiments. Such an algorithm, which generalize that of the quantum Monte Carlo method, was given in Ref. 22.

ACKNOWLEDGMENTS

I would like to thank Professor A. Jadczyk for helpful discussions and Professor Ph. Blanchard for his hospitality in Bielefeld, where the paper was finished. The financial support from A. von Humboldt Foundation is also acknowledged.

APPENDIX A: PROOF OF THEOREM 2.4

Proof. Let $\{e_k\}_1^\infty$ be an orthonormal basis in $\mathcal{H}_q$. Because for every $x\in M$

$$\alpha(B)=0 \Rightarrow (\nu_x * E_{k,l})(B)=\langle e_k,(\nu_x * E)(B)e_l\rangle=0,$$

there is a Borel and α-integrable function $f_{k,l}(x,q)$ such that $(\nu_x{}^*E_{k,l})(B)=\int_B f_{k,l}(x,q)\,d\alpha(q)$ for every $B\in\mathcal{B}(Q)$. At first we modify functions $f_{k,l}$. We have that $f_{k,l}\in L^1(Q,\mathcal{B}(Q),d\alpha)$ and from Lemma 3.5 the map $x\rightarrow\int_B f_{k,l}(x,q)\,d\alpha(q)$ is Borel for every $B\in\mathcal{B}(Q)$. Moreover, Q, as a space which satisfies the second axiom of countability, is a separable Borel space. So from the selection of representative lemma[23] there is a Borel function $f^*_{k,l}:M\times Q\rightarrow\mathbf{C}$ and a Borel set $N_{k,l}\subset M$ of μ-measure zero such that $\forall x\in M\setminus N_{k,l}$ $f^*_{k,l}(x,q)=f_{k,l}(x,q)$ α almost everywhere. Let $N=\cup_{k,l}N_{k,l}$. Then $\mu(N)=0$ and $\forall x\in M\setminus N$ $f^*_{k,l}(x,q)=f_{k,l}(x,q)$ α a.e. for every k, $l\in\mathbf{N}$.

Let U be a subspace of $\mathcal{H}_q$ generated by finite linear combinations of e_k with coefficients z_k such that $\operatorname{Re} z_k$ and $\operatorname{Im} z_k$ are rational numbers. It is clear that U is dense and countable. Let $\phi_{x,q}$ be a sesquilinear form on U defined by

$$\phi_{x,q}(v_1,v_2)=\sum_{k,l}\overline{y_k}z_l f^*_{k,l}(x,q),\quad v_1=\sum_k y_k e_k,\quad v_2=\sum_l z_l e_l.$$

Because for fixed $v\in U$ the function $(x,q)\rightarrow\phi_{x,q}(v,v)$ is Borel, sets

$$\Theta_v=\{(x,q):|\phi_{x,q}(v,v)|\leqslant C\|v\|^2\},$$

$$\Xi_v=\{(x,q):\phi_{x,q}(v,v)\geqslant 0\}$$

are Borel subsets of $M\times Q$. Thus $\Omega:=(\cap_v\Theta_v)\cap(\cap_v\Xi_v)$ is also Borel. On this set the form $\phi_{x,q}$ may be extended to a positive and bounded form $\overline{\phi}_{x,q}$ on the whole $\mathcal{H}_q$. It means that there is a function $V:\Omega\to L(\mathcal{H}_q)_+$ such that $\forall\psi_1,\psi_2\in\mathcal{H}_q\,\langle\psi_1,V(x,q)\psi_2\rangle=\overline{\phi_{x,q}}(\psi_1,\psi_2)$ when $(x,q)\in\Omega$. Now we show that Ω is big enough, i.e., that $\mu\times\alpha(M\times Q\backslash\Omega)=0$. Let $v\in U$, i.e., $v=\sum_{k=1}^{n}z_k e_k$. Then for every $x\in M\backslash N$

$$\int_Q\phi_{x,q}(v,v)d\alpha(q)=\sum_{k,l=1}^{n}\overline{z_k}z_l\int_Q f_{k,l}^{*}(x,q)d\alpha(q)$$
$$=\sum_{k,l=1}^{n}\overline{z_k}z_l\int_Q f_{k,l}(x,q)d\alpha(q)=(\nu_x*E_{v,v,})(Q)\geqslant 0.$$

So there is a Borel subset $B_{x,v}\subset Q$ such that $\alpha(B_{x,v})=0$ and $\forall q\in Q\backslash B_{x,v}\ \phi_{x,q}(v,v)\geqslant 0$. Moreover, for α-finite $B\in\mathcal{B}(Q)$ we have that

$$\int_B\phi_{x,q}(v,v)d\alpha(q)=\langle v,(\nu_x*E)(B)v\rangle\leqslant C\|v\|^2\alpha(B).$$

Thus for every Q_n $[Q=\cup_{n=1}^{\infty}Q_n$ and $\alpha(Q_n)\leqslant\infty]$ there is a Borel subset $C_{x,n,v}\subset Q_n$ such that $\alpha(C_{x,n,v})=0$ and $\forall q\in Q_n\backslash C_{x,n,v}\ \phi_{x,q}(v,v)\leqslant C\|v\|^2$. Let

$$D_x=\left(\bigcup_v B_{x,v}\right)\cup\left(\bigcup_n\bigcup_v C_{x,n,v}\right).$$

Then $\alpha(D_x)=0$ and $\forall x\in M\backslash N\forall q\in Q\backslash D_x$, $\phi_{x,q}$ is positive and bounded by constant C. Let $\Omega_0=\{(x,q):x\in M\backslash N,q\in Q\backslash D_x\}$. Because $\Omega_0\subset\Omega$, then $M\times Q\backslash\Omega\subset M\times Q\backslash\Omega_0$. However, $M\times Q\backslash\Omega$ is Borel, so from the Fubini theorem

$$\mu\times\alpha(M\times Q\backslash\Omega)=\int_M\alpha[(M\times Q\backslash\Omega)_x]d\mu(x)=\int_{M\backslash N}\alpha[(M\times Q\backslash\Omega)_x]d\mu(x).$$

Because $\forall x\in M\backslash N$

$$(M\times Q\backslash\Omega)_x=\{q\in Q:(x,q)M\times Q\backslash\Omega\}\subset D_x,$$

we have that $\alpha[(M\times Q\backslash\Omega)_x]\leqslant\alpha(D_x)=0$ and so $\mu\times\alpha(M\times Q\backslash\Omega)=0$. Let us define

$$\tilde{V}(x,q)=\begin{cases}V(x,q), & (x,q)\in\Omega,\\ 0\quad, & \text{elsewhere}\end{cases}.$$

It is clear that $(x,q)\to\tilde{V}(x,q)$ is weakly Borel measurable and $\sup_{x,q}\|\tilde{V}(x,q)\|\leqslant C$. Moreover, for every $x\in M\backslash N$, $B\in\mathcal{B}(Q)$, $\psi_1,\psi_2\in\mathcal{H}_q$,

$$\int_B\langle\psi_1,\tilde{V}(x,q)\psi_2\rangle d\alpha(q)=\int_B\overline{\phi_{x,q}}(\psi_1,\psi_2)d\alpha(q)=\langle\psi_1,(\nu_x*E)(B)\psi_2\rangle.$$

Now we check the uniqueness of $\tilde{V}$ up to a set of $\mu\times\alpha$ measure zero. Let $\tilde{V}'$ be another map which satisfies the thesis. So there is a Borel subset $N'\subset M$ such that $\mu(N')=0$ and for every $x\in M\backslash N'$

$$\langle\psi_1,(\nu_x*E)(B)\psi_2\rangle=\int_B\langle\psi_1,\tilde{V}'(x,q)\psi_2\rangle d\alpha(q).$$

Because $\tilde{V}$ and $\tilde{V}'$ are both weakly Borel measurable, a set

$$\Gamma_v=\{(x,q):\langle v,\tilde{V}(x,q)v\rangle\neq\langle v,\tilde{V}'(x,q)v\rangle\}$$

is Borel for every $v\in V$. Let $\Gamma=\cup_v\Gamma_v$. It follows that quadratic forms $v\to\langle v,\tilde V(x,q)v\rangle$ and $v\to\langle v,\tilde V'(x,q)v\rangle$ agree on $M\times Q\backslash\Gamma$. As they are both bounded the operator functions $\tilde V$ and $\tilde V'$ differ from each other only on Γ. Because $\mu(N\cup N')=0$, we have that

$$\mu\times\alpha(\Gamma)=\int_M \alpha(\Gamma_x)d\mu(x)=\int_{M\backslash(N\cup N')}\alpha(\Gamma_x)d\mu(x).$$

However, $\forall x\in M\backslash(N\cup N')$, $\tilde V(x,q)=\tilde V'(x,q)$ α a.e. so $\alpha(\Gamma_x)=0$ and $\mu\times\alpha(\Gamma)=0$. □

APPENDIX B: PROOF OF LEMMA 2.8

Proof. W_n is the weak limit of completely positive maps and W is the weak limit of W_n. Because $\forall k\in\mathbf{N}$, $W\otimes\mathbf{1}_k$, $\mathbf{1}_k\in M_{k\times k}$, is the weak limit of positive maps, for any positive operator $\hat A$ from $\mathcal{A}_T\otimes M_{k\times k}$ $W\otimes 1_k(\hat A)$ is positive. To prove that W is normal we have to show that W is an adjoint map of some bounded $T:\mathrm{Tr}(\tilde{\mathcal{H}})\to\mathrm{Tr}(\tilde{\mathcal{H}})$. Let $\tilde\rho\in\mathrm{Tr}(\tilde{\mathcal{H}})_+$. There exists a basis $\{e_m\}$ in $\tilde{\mathcal{H}}$ such that $\tilde\rho=\Sigma_{m=1}^{\infty}c_mP_m$, where P_m is a projector onto e_m. At first we show that

$$T_n(\tilde\rho)=\int_{Q^n}d\alpha(q)\tilde W_q\tilde\rho\tilde W_q^*$$

exists in $\mathrm{Tr}(\tilde{\mathcal{H}})$.

Because it exists in $L(\tilde{\mathcal{H}})_+$ and

$$S_k=\sum_{m=1}^{m=k}\langle e_m,T_n(\tilde\rho)e_m\rangle=\sum_{m=1}^{m=k}\int_{Q^n}d\alpha(q)\langle e_m,\tilde W_q\tilde\rho\tilde W_q^*e_m\rangle$$
$$\leqslant\int_{Q^n}d\alpha(q)\|\tilde W_q\tilde\rho\tilde W_q^*\|_{\mathrm{Tr}}\leqslant\alpha(Q^n)(\sup_q\|\tilde W_q\|^2)\|\tilde\rho\|_{\mathrm{Tr}},$$

so $T_n(\tilde\rho)\in\mathrm{Tr}(\tilde{\mathcal{H}})_+$. Moreover,

$$\int_Q d\alpha(q)\|\tilde W_q\tilde\rho\tilde W_q^*\|_{\mathrm{Tr}}=\int_Q d\alpha(q)\sum_{m=1}^{\infty}\langle e_m,\tilde W_q\tilde\rho\tilde W_q^*e_m\rangle$$
$$=\int_Q\sum_{m=1}^{\infty}\|\tilde\rho^{1/2}\tilde W_q^*e_m\|^2$$
$$=\int_Q d\alpha(q)\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}|\langle\tilde\rho^{1/2}\tilde W_q^*e_m,e_n\rangle|^2.$$

However, $\tilde\rho^{1/2}\tilde W_q^*\in HS(\tilde{\mathcal{H}})$. So, we get

$$\int_Q d\alpha(q)\sum_{n=1}^{\infty}\sum_{m=1}^{\infty}c_n|\langle e_m,\tilde W_qe_n\rangle|^2=\int_Q d\alpha(q)\sum_{n=1}^{\infty}c_n\|\tilde W_qe_n\|^2$$
$$=\sum_{n=1}^{\infty}c_n\int_Q d\alpha(q)\|\tilde V_qe_n\|^2$$
$$=\sum_{n=1}^{\infty}c_n\int_Q d\alpha(q)\langle e_n,\tilde V_q^2e_n\rangle$$

$$\leqslant C\sum_{n=1}^{\infty} c_n\int_Q d\alpha(q)\int_M d\mu(x)\langle e_n(x),\tilde{V}(x,q)e_n(x)\rangle$$

$$=C\sum_{n=1}^{\infty} c_n\int_M d\mu(x)\langle e_n(x),(\nu_x * E)(Q)e_n(x)\rangle$$

$$\leqslant C(\sup_x\|(\nu_x * E)(Q)\|)\|\tilde{\rho}\|_{\mathrm{Tr}}$$

$$=C\|E(q)\|(\sup_x \nu_x(G))\|\tilde{\rho}\|_{\mathrm{Tr}}=CC_1\|E(Q)\|\cdot\|\tilde{\rho}\|_{\mathrm{Tr}}.$$

Thus $T(\tilde{\rho})=\int_Q d\alpha(q)\tilde{W}_q\tilde{\rho}\tilde{W}_q^*\in \mathrm{Tr}(\tilde{\mathcal{H}})_+$ and $\mathrm{Tr}(T(\tilde{\rho})\tilde{A})=\mathrm{Tr}(\tilde{\rho}W(\tilde{A}))$ for any $\tilde{A}\in\mathcal{A}_T$. ■

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 3 MARCH 1999

Arithmetic properties of spectra produced by Farey hierarchies of approximants

O. Radulescu[a] and T. Janssen
Institute of Theoretical Physics, Nijmegen University, Postbus 9010, 6500 GL Nijmegen, The Netherlands

(Received 12 June 1998; accepted for publication 30 November 1998)

We discuss the consequences of the hierarchical nature of series of approximants of aperiodic crystals on their diffraction patterns and spectra of elementary excitations. We show how a linear form defined on $\mathbb{Z}^3$ can be used to order Bragg reflections in diffraction patterns according to their amplitudes, and gaps in spectra of elementary excitations according to their widths, for all the structures in the hierarchy. Bragg peaks amplitudes and gap widths are projective functions on $\mathbb{P}(\mathbb{Z}^3)$, recursively defined on 2D Farey sets (generalization of Farey series).
 [S0022-2488(99)00603-9]

I. INTRODUCTION

Several aperiodic ordered systems occurring in solid state physics, such as incommensurate modulated structures, composite compounds, and quasicrystals, have complex phase diagrams containing also series of commensurate structures called approximants. It is possible to pass from one approximant to another in a series, by altering the chemical nature of the building units, or by changing the thermodynamic equilibrium parameters (temperature, composition, pressure). In certain cases, approximants are dynamically selected nonequilibrium phases.

The series of approximants is hierarchical, members of this series having strong mutual structural relations. The universality of the structural relations between approximants and the consequences of these relations on their physical properties can be understood if Farey series are used to index approximants. A short summary of the properties of the Farey series is given in Appendix A. In this paper we discuss only one-dimensional (1D) structures, but our approach could in principle be generalized to higher dimension as well.

Different approximants can be embedded in a Farey hierarchy (see Appendix A for precise definitions). For each rational number p/q the corresponding approximant is called (p,q) commensurate structure and the integer numbers (p,q) are called commensurability indices. The elementary step in constructing a Farey hierarchy is the mediant construction (well known for Farey series): the unit cell of an approximant with commensurability indices (p_1+p_2,q_1+q_2) is obtained by concatenating the unit cells of two approximants with commensurability indices (p_1,q_1) and (p_2,q_2), respectively.

The periods of (p,q) commensurate structures obtained by concatenation have the general form $L_{p,q}=a(\beta p+\alpha q)$ (see Appendix A), and therefore their diffraction patterns consist of equidistant Bragg reflections with a distance $2\pi/L_{p,q}$ between consecutive reflections situated at

$$k_{p,r,q}=\frac{2\pi r}{a(\beta p+\alpha q)}. \tag{1}$$

The structure factor $h(p,r,q)$ for a reflection of wave vector $k_{p,r,q}$ is defined as the complex amplitude of the reflection divided by the total number of atoms in the unit cell, which for

[a]Present address: IRC in Polymer Science and Technology, Department of Physics, University of Leeds, Leeds LS2 9JT, UK. Electronic mail: phyor@irc.leeds.ac.uk

approximants generated by concatenation is $n_{p,q}=sp+tq$ (Appendix A). If for simplicity the atomic scattering factor is considered equal to one for all atoms, then $h(p,r,q) =(1/n_{p,q})\Sigma_{i=1}^{n_{p,q}}\exp(ikx_i)$, x_i being the atomic positions in the unit cell.

Let us define the family of complex functions $F_{p,q}(z)=\Sigma_{i=1}^{n_{p,q}}z^{x_i/a}$. It follows

$$h(p,r,q)=\frac{1}{sp+tq}F_{p,q}[\exp(ik_{p,r,q}a)],$$
$$F_{p_1+p_2,q_1+q_2}(z)=F_{p_1,q_1}(z)+z^{\beta p_1+\alpha q_1}F_{p_2,q_2}(z), \tag{2}$$

whenever $p_1/q_1,p_2/q_2$ are Farey-consecutive.

$F_{p,q}$ is uniquely defined by Eq. (2) for all p,q relatively prime and $0\leqslant p/q\leqslant 1$, once $F_{0,1}(z)$ and $F_{1,1}(z)$ are given.

At this level we may notice the occurrence of $\mathbb{Z}^3$ in the problem. Bragg peaks for all the structures in the hierarchy can be labeled with three integers, two being the commensurability indices and the third one indicating the position of the Bragg reflection along the reciprocal line. Equation (2) illustrates the special two indices recursion on Farey series satisfied by the structure factor. It is straightforward from Eq. (1) that positions of Bragg reflections are only depending on the ratios p/q, r/q. From Eq. (2) it follows that the same holds for the structure factor, i.e., for the amplitude of Bragg peaks. Thus, Bragg reflections for the entire Farey hierarchy of approximants are in correspondence with directions of $\mathbb{Z}^3$, i.e., with points in the projective module $\mathbb{P}(\mathbb{Z}^3)$.

It is known that for crystals there is a connection between Bragg reflections and gaps in the spectra of elementary excitations (electrons, phonons). This is true more generally for almost periodic structures generated by substitutions.[1] We shall show that when the structure belongs to a Farey hierarchy, then gap widths obey a recursion having the same form as the one obeyed by the structure factor [Eq. (2)], with coefficients α,β that may be different. But first of all let us clear up the relation between Bragg reflections and gaps in 1D models for phonons and electrons in crystals (periodic and aperiodic). A review of these models can be found elsewhere.[2]

Energy of electrons in a 1D periodic crystal follows from the Schrödinger equation with periodic potential:

$$(H_o+V_{p,q})\Phi=E\Phi,$$
$$H_o=-\frac{\hbar^2\nabla^2}{2m}, \tag{3}$$
$$V_{p,q}(x+L_{p,q})=V_{p,q}(x).$$

In the nearly free electron approximation the electron energy spectrum is obtained by using degenerate first-order Rayleigh–Schrödinger perturbation theory in the space spanned by the two planar waves $\exp(\pm ikx)$. A gap of width $\Delta_{p,r,q}=2\tilde{V}_{p,q}(k_{p,r,q})$ ($\tilde{V}_{p,q}$ is the Fourier transform of $V_{p,q}$) opens if $2k=k_{p,r,q}$, for some Bragg wave vector $k_{p,r,q}$. The energetic positions of the gaps are given, like the positions of the Bragg reflection, by a function of p/q and r/q, $E_{p,r,q}=\hbar^2k_{p,r,q}^2/8m$. The correspondence between Bragg reflections and gaps in the electron energy spectrum (within nearly free electron approximation) is 1–1 and, supposing that the periodic potential $V_{p,q}$ mimics the distribution of atoms, strong Bragg peaks correspond to wide gaps. The origin of gaps is the Bragg reflection of planar waves on the periodic potential $V_{p,q}$.

Furthermore, for a Farey hierarchy of structures $V_{p,q}$ obey

$$V_{p_1+p_2,q_1+q_2}(x)=\begin{cases}V_{p_1,q_1}(x), & x\in U_{p_1,q_1},\\ V_{p_2,q_2}(x-L_{p_1,q_1}), & x\in U_{p_2,q_2}+L_{p_1,q_1}.\end{cases}$$

If we define the following family of complex functions $F_{p,q}(z)=\tilde{V}_{p,q}(\log(z)/ia)$, then the absolute value of $F_{p,q}$ is half the gap width, i.e., $|F_{p,q}(\exp(ik_{p,r,q}a))|=|\tilde{V}_{p,q}(k_{p,r,q})|$. The functions $F_{p,q}(z)$ obey exactly the same recursion (with the same values of the coefficients α,β) as the similar functions giving the structure factor [Eq. (2)].

Of course, the 1–1 correspondence between Bragg reflections and gaps in the spectrum of nearly free electrons is only an approximation. Actually, for periodic structures the number of gaps is finite and the number of Bragg reflections is infinite (the correspondence can be 1–1 only for aperiodic, almost periodic structures).

A different approximation is the discretized version of Eq. (3):

$$H_o\Phi_n+V_n^{p,q}\Phi_n=E\Phi_n,$$

$$H_o\Phi_n=-\Phi_{n-1}-\Phi_{n+1}+2\Phi_n, \tag{4}$$

$$V_{n+q}^{p,q}=V_n^{p,q}.$$

This equation describes tight-binding electrons with modulated onsite potential[2] but also phonon excitations for harmonic chains under influence of a periodic substrate potential (Frenkel–Kontorova models[3]).

In this case degenerate perturbation theory applies to the Bloch waves $\exp(\pm ikn)$ and the origin of gaps is the Bragg reflection of Bloch waves on the superlattice potential $V^{p,q}$ (notice that if one defines the translation operators $T_q\Phi_n=\Phi_{n+q}$, $[H_o,T_1]=0, [V^{p,q},T_q]=0$, the above Bloch waves are eigenvectors of T_1). There are $q-1$ gaps, appearing at wave vectors obeying $k=-k+(2\pi r/q)(\mathrm{mod}\,2\pi)$. Each gap is related to an infinite family $\{2\pi r/q+2\pi n\}_{n\in\mathbb{Z}}$ of Bragg reflections. The energetic positions of the gaps are $E_{p,r,q}=4\sin^2(2\pi r/q)$, while their widths are $\Delta_{p,r,q}=(1/q)|\tilde{V}^{p,q}(2\pi r/q)|$, where $\tilde{V}^{p,q}(k)=\Sigma_{n=0}^{q-1}V_n^{p,q}\exp(ikn)$. We may notice the absence of a characteristic length a in the expression of the gap widths. The Euclidean metric occurring in the calculation of the structure factor becomes the graph metric along the chain of atomic sites. Tight-binding calculations for electrons or chain models for phonons assume instantaneous propagation of waves from one site to another. In this approximation the relation between amplitudes of Bragg peaks and widths of gaps may be nonmonotonic.

The hierarchical properties of gap widths are a consequence of

$$V_n^{p_1+p_2,q_1+q_2}=\begin{cases} V_n^{p_1,q_1}, & n=0,\ldots,q_1-1,\\ V_{n-q_1}^{p_2,q_2}, & n=q_1,\ldots,q_1+q_2.\end{cases}$$

Defining $F_{p,q}(z)=\tilde{V}^{p,q}((1/i)\log(z))$, then $\Delta_{p,r,q}=(1/q)|F_{p,q}(\exp(2\pi r/q)i)|$ and the functions $F_{p,q}(z)$ obey similar recursions as the functions giving the structure factor [Eqs. (2), with $\alpha=1$, $\beta=0$, $s=0,t=1$]. α and β are now the coefficients characterizing the linear dependence of the graph length of the unit cell (number of successive chain atoms in the unit cell) on the commensurability indices (p,q). These are generally different from the values expressing the dependence of the Euclidean length on (p,q), occurring in the structure factor problem. For Frenkel–Kontorova models the substrate is rigid with a fixed period a, therefore the length of the unit cell is pa $(\alpha=0,\beta=1)$, while the graph length scales as q $(\alpha=1,\beta=0)$.

A more complex Farey hierarchy is described by the double chain model. This model was designed[4] for the study of phonons in composite structures. The modulation is no longer diagonal because there are two interacting harmonic subsystems. The double chain infinite-dimensional dynamical matrix (second derivative of the configuration potential energy) acts as

$$D(y_n^{(1)},y_m^{(2)})=\left(-(y_{n+1}^{(1)}+y_{n-1}^{(1)})+y_n^{(1)}\left(2+\sum_m \chi_{n,m}\right)-\sum_m \chi_{n,m}y_m^{(2)},\right.$$
$$\left.-(y_{m+1}^{(2)}+y_{m-1}^{(2)})+y_m^{(2)}\left(2+\sum_n \chi_{n,m}\right)-\sum_n \chi_{n,m}y_n^{(1)}\right). \tag{5}$$

The eigenvalues of the dynamical matrix form the phonon spectrum. We have shown[4] that in the case when the interaction between the two chains is harmonic and short range represented by

$$\chi_{n,m}=\begin{cases}\chi, & m=\left\lfloor \dfrac{nq}{p}+\dfrac{1}{2}\right\rfloor,\\ 0, & \text{elsewhere},\end{cases}$$

the gap widths are given by the same type of recursion relations as in Eq. (2), but with $\alpha=1,\beta=1$. The ''effective'' graph length of the unit cell scales like $p+q$.

According to these introductory remarks, amplitudes of Bragg peaks in the diffraction spectra and widths of gaps in the spectra of the elementary excitations of approximant structures belonging to a Farey hierarchy are functions defined on the projective module $\mathbb{P}(\mathbb{Z}^3)$, i.e., on the set of fractions having common denominator $(p/q,r/q)$. These functions obey special recursion relationships, involving Farey series. The purpose of this paper is to study the properties of these kinds of functions and to analyze their consequences for the spectral properties of approximants.

The structure of this paper is the following. In the next section we introduce and discuss the properties of Farey sets that are the 2D analog of Farey series. The Farey sets were used by Kim and Oslund[5] for the problem of simultaneous approximation of pairs of real numbers by pairs of rational numbers of common denominator. We prove here a set of properties of Farey sets that are direct extensions of properties of Farey series, and that are useful for our purpose and could be also used in other applications. In the third section we discuss a representation of rational numbers that comes naturally out of the previous construction and has heuristic utility for many of the reasonings involving Farey series. In the fourth section we introduce functions that are hierarchically defined on Farey sets, and prove a theorem revealing their arithmetical structure. For Farey hierarchies of structures, widths of gaps in the spectra of elementary excitations and amplitudes of Bragg peaks are functions hierarchically defined on Farey sets. In the last section we discuss the consequences of this on the structure of spectra generated by Farey hierarchies of structures. The proofs of properties and theorems can be found in Appendix B.

II. TWO-DIMENSIONAL FAREY SETS

The Farey series $\mathcal{F}_n$ are included in the one-dimensional projective module $\mathbb{P}(\mathbb{Z}^2)$ that is composed of all directions in $\mathbb{Z}^2$. The mapping $(p,q)\rightarrow p/q$ identifies $\mathbb{P}(\mathbb{Z}^2)$ with the set of rational numbers extended by the point at infinity $\hat{\mathbb{Q}}:=\mathbb{Q}\cup\infty$.

Similarly, one may define a two-dimensional projective module $\mathbb{P}(\mathbb{Z}^3)$ consisting of all directions in $\mathbb{Z}^3$, and the mapping $(p,r,q)\rightarrow(p/q,r/q)$ allows us to identify $\mathbb{P}(\mathbb{Z}^3)$ with the set of pairs of fractions $\{(p/q,r/q)|gcd[p,q,r]=1,q\geqslant 0\}$ having a common denominator and such that q is positive and p,r,q are relatively prime. As *(p,r,q)* and *(-p,-r,-q)* represent the same direction in $\mathbb{Z}^3$ we may conventionally impose $q\geqslant 0$. The logic of this convention will show up later. The above application also maps the surface of a sphere onto the plane (Fig. 1) and is known in cartography under the name of gnomonic projection. This projection has the remarkable property of transforming geodesics (great circles) on the sphere into straight lines and proved its utility in airline navigation, meteors maps in astronomy, and indexing of the Laue diagrams in x-ray crystallography. It has the disadvantage of not being conformal (it distorts angles). The gnomonic projection embeds $\mathbb{P}(\mathbb{Z}^3)$ in a Euclidean model of the projective plane,[6] provided that the line at infinity is considered as well. For $x=(p/q,r/q)\in\mathbb{P}(\mathbb{Z}^3)$ we denote the common denominator by $\mathrm{den}(x)=q\geqslant 0$.

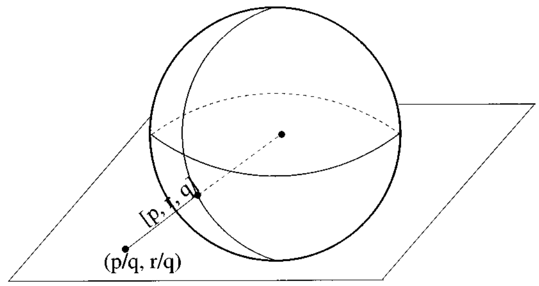

FIG. 1. Gnomonic or ''central'' projection: a direction of indices $[p,r,q]$ of the lattice with origin in the center of the sphere cuts the tangent plane in a point of coordinates $(p/q,r/q)$.

A partial projection $(p,r,q)\to(p/q,r)$ has as image $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ that can be identified to the subset $\{(p/q,r/q)|gcd[p,q]=1\}$ of $\mathbb{P}(\mathbb{Z}^3)$ via the injection $(p/q,r)\to(p/q,r/q)$. By ''abus de langage'' we shall denote this subset with $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ whenever confusion is not dangerous.

Definition 1: A direction in $\mathbb{P}(\mathbb{Z}^3)$ *is the 1D projective module* $\Delta_{h,k,l}:=\{(p/q,r/q)|ph+rk+ql=0\}$. *It is the image via the gnomonic projection of a plane of* $\mathbb{Z}^3$ *containing the origin, and whose normal has indices (h,k,l). We shall refer to the indices (h,k,l), gcd[h,k,l]=1, as the Miller indices of the direction. An orientation is conventionally chosen, by imposing* $k\geqslant 0$.

Definition 2: The mediant of two points $x_1=(p_1/q_1,r_1/q_1),x_2=(p_2/q_2,r_2/q_2)$ *is defined as* $x_1\oplus x_2:=((p_1+p_2)/(q_1+q_2),(r_1+r_2)/(q_1+q_2))$ *(see also Ref. 5).*

Example 1: In Fig. 2 $(\frac{1}{2},\frac{1}{2})=(\frac{0}{1},\frac{1}{1})\oplus(\frac{1}{1},\frac{0}{1})$, $(\frac{2}{3},\frac{1}{3})=(\frac{1}{2},\frac{1}{2})\oplus(\frac{1}{1},\frac{0}{1})$.

Definition 3: The external product of two points $x_1=(p_1/q_1,r_1/q_1),x_2=(p_2/q_2,r_2/q_2)$, $gcd[p_1,r_1,q_1]=1$, $gcd[p_2,r_2,q_2]=1$, $q_1,q_2>0$, *is defined as the following vector of* $\mathbb{Z}^3$: $x_1\wedge x_2:=(r_1q_2-q_1r_2,q_1p_2-p_1q_2,p_1r_2-r_1p_2)$.

Remark 1: The external product of two different points along the same direction is an integral multiple of (h,k,l), the set of Miller indices of the direction. This clears up the conventional choice $q\geqslant 0$ that was made in order to have $q_1p_2-p_1q_2>0$ and thus $x_1\wedge x_2$ and (h,k,l) to be in the same direction as soon as $p_1/q_1<p_2/q_2$.

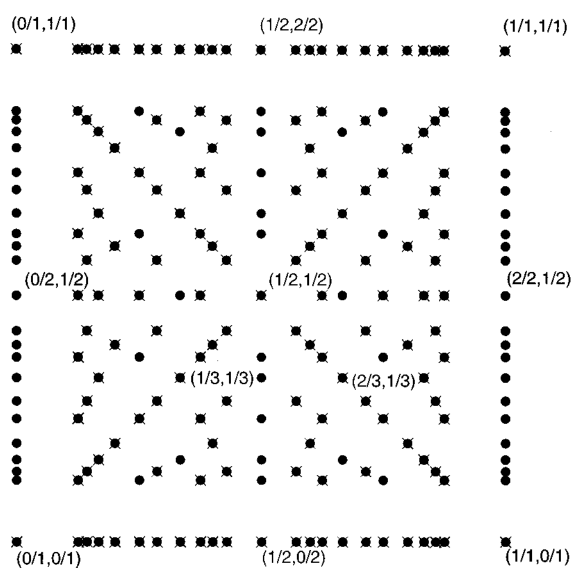

FIG. 2. The 2D Farey set of order 8 in the Euclidean plane: dots are points of $\mathcal{F}_8^{(2,0)}$, while crosses mark the subset $\mathcal{F}_8^{(1,1)}$.

The following theorem shows that the external product of two different points along the same direction of $\mathbb{P}(\mathbb{Z}^3)$ takes all values integral multiples of (h,k,l).

Theorem 4: *For any $x \in \mathbb{P}(\mathbb{Z}^3)$ along the direction $\Delta_{h,k,l}$ of Miller indices (h,k,l), there is $y \in \Delta_{h,k,l}$ such that $x \wedge y = (h,k,l)$.*

Definition 5: We call Farey set of order n in $\mathbb{P}(\mathbb{Z}^3)$ the set $\mathcal{F}_n^{(2,0)} = \{(p/q, r/q) | gcd[p,r,q] = 1, 0 \leq p/q \leq 1, 0 \leq r/q \leq 1, 0 < q \leq n\}$

Definition 6: We call Farey set of order n in $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ the set $\mathcal{F}_n^{(1,1)} := \mathcal{F}_n^{(2,0)} \cap [\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}] = \{(p/q, r/q) | gcd[p,q] = 1, 0 \leq p/q \leq 1, 0 \leq r/q \leq 1, 0 < q \leq n\}$

Remark 2: $\mathcal{F}_n^{(1,1)}$ is a subset of $\mathcal{F}_n^{(2,0)}$ (see Fig. 2). $\mathcal{F}_n^{(1,1)}$ and $\mathcal{F}_n^{(2,0)}$ coincide along some special directions, as shown by the following property.

Property 7: $\Delta_{h,k,l} = \Delta_{h,k,l} \cap [\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}]$ iff $k=1$. This is valid iff $\Delta_{h,k,l}$ contains two points $(p/q, r/q)$, $(p_1/q_1, r_1/q_1)$ such that

(i) $gcd[p,q] = 1$, $gcd[p_1,q_1] = 1$, and
(ii) *p_1/q_1 and p/q are Farey consecutive, i.e., $q_1 p - p_1 q = 1$.*

Definition 8: We call two points $x_1 = (p_1/q_1, r_1/q_1), x_2 = (p_2/q_2, r_2/q_2)$ in $\mathbb{P}(\mathbb{Z}^3) \cap [0,1]^2$ *Farey-consecutive if they belong to a direction $\Delta_{h,k,l}$, being oriented such that $x_1 \wedge x_2 = \lambda(h,k,l), \lambda > 0$, and all the points $x = (p/q, r/q)$ between them on $\Delta_{h,k,l}$ obey $q > \max(q_1, q_2)$.*

This definition is equivalent to the following:

Property 9: Two points $x_1, x_2 \in \mathbb{P}(\mathbb{Z}^3) \cap [0,1]^2$ are Farey-consecutive iff for some n and for some direction $\Delta_{h,k,l}$, $x_1, x_2 \in [\Delta_{h,k,l} \cap \mathcal{F}_n^{(2,0)}]$ and *$x_1 \wedge x_2 = \lambda(h,k,l), \lambda > 0$ and there are no other points of $\mathcal{F}_n^{(2,0)}$ between them along $\Delta_{h,k,l}$.*

The following properties are extensions of similar properties of Farey series.

Property 10: $x_1 = (p_1/q_1, r_1/q_1)$ and $x_2 = (p_2/q_2, r_2/q_2)$, $x_1, x_2 \in \mathbb{P}(\mathbb{Z}^3) \cap [0,1]^2$ are Farey-consecutive iff $x_1 \wedge x_2 = (h,k,l)$, where h,k,l are the Miller indices of the direction passing through them. In this case, $r_2/(\beta p_2 + \alpha q_2) - r_1/(\beta p_1 + \alpha q_1) = (\beta l - \alpha h)/[(\beta p_1 + \alpha q_1)(\beta p_2 + \alpha q_2)]$, where $\alpha, \beta \in \mathbb{R}$.

Remark 3: The similar property of Farey series is: $p_1/q_1 < p_2/q_2$ are Farey consecutive iff $q_1 p_2 - q_2 p_1 = 1$. (Th. 2 of Neville,[7] Th. 28 of Hardy and Wright,[8] and Th. 10.2 of Hua.[9])

Property 11: Two points $x_1 = (p_1/q_1, r_1/q_1), x_2 = (p_2/q_2, r_2/q_2)$ on a segment $\Delta_{h,k,l} \cap [0,1]^2$ with $k=1$ are Farey-consecutive iff p_1/q_1, p_2/q_2 are Farey-consecutive.

Property 12: If $x_1, x_2, x_3 \in \mathbb{P}(\mathbb{Z}^3) \cap [0,1]^2$ are three collinear, Farey-consecutive points, x_2 being between x_1, x_3 (i.e., $x_1 \wedge x_2 = \lambda(x_2 \wedge x_3), \lambda > 0$), *then $x_2 = x_1 \oplus x_3$.*

Remark 4: The similar property of Farey series is the following.

For three Farey-consecutive rationals, the one in the middle is the mediant of the other two. (Th. 29 in Hardy and Wright,[8] and Th. 10.3 in Hua.[9])

Property 13: The equation $x = x_1 \oplus x_2$ has a unique solution in $\Delta_{h,k,l} \cap [0,1]^2$, with *$x_1, x_2$ Farey-consecutive. x_1, x_2 are called right and left ascendants of x along the direction $\Delta_{h,k,l}$,* respectively, and they satisfy $x_1 \wedge x = (h,k,l)$, $x \wedge x_2 = (h,k,l)$.

Remark 5: The similar property of Farey series is the following.

The equation $p_1/q_1 \oplus p_2/q_2 = p/q$, with $p_1/q_1 < p_2/q_2$ Farey-consecutive has an unique solution. We call p_1/q_1 and p_2/q_2 left and right ascendant of p/q, respectively. (This follows from Th. 5 in Neville[7] and Remarks 3,4.)

Example 2: In Fig. 2 $(\frac{1}{2}, \frac{1}{2})$ and $(\frac{1}{1}, \frac{0}{1})$ are the ascendants of $(\frac{2}{3}, \frac{1}{3})$ along the direction $(1,1,-1)$.

III. FAREY GRAPH

Let us consider the subset $\{(p/q, 1/q) | gcd[p,q] = 1\}$ of $\mathbb{P}(\mathbb{Z}^3)$, which can be identified to $\hat{\mathbb{Q}}$ via the mapping $(p/q, 1/q) \to p/q$. This representation of rational numbers[10] has several useful properties that were the heuristic source of many of the results in this paper (see Fig. 3):

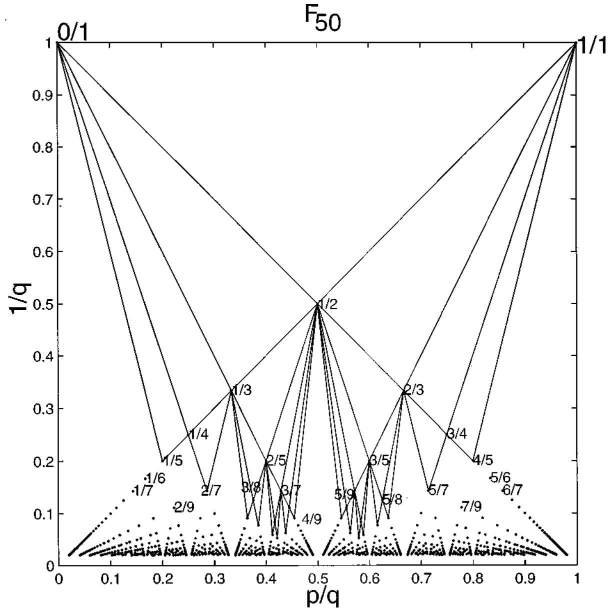

FIG. 3. Farey undirected graph (upper part of it) in the representation $(p/q,1/q)$: two vertices are connected by a segment iff one is the ascendant of the other. The triangles made by edges of the graph perform the so-called Farey-tessellation.

(i) The points representing $\mathcal{F}_n$ are all those having coordinates $y \geqslant 1/n$ in the plane of the projection. Low denominator rationals have high y coordinate.

(ii) The mediant construction has a simple geometrical interpretation. $p_1/q_1 \oplus p_2/q_2$ is represented by the intersection of two lines, one connecting the point $(p_1/q_1, 0/q_1)$ to the point $(p_2/q_2, 1/q_2)$, the second connecting the point $(p_2/q_2, 0/q_2)$ to the point $(p_1/q_1, 1/q_1)$.

(iii) There is a simple way to see if two rationals are Farey-consecutive: check if all points with x-coordinate between the x-coordinates of the two tested points have lower y-coordinate than any of the y-coordinates of the tested points.

(iv) The left and right ascendants of a rational p/q are the higher points, Farey-consecutive with p/q to its left and right, respectively. For instance, the left ascendant of 1/2, or of 1/3 is 0/1. Descendants of two Farey-consecutive rationals are all the lower points in the diagram with x-coordinate in between.

(v) If p_1/q_1 is the left ascendant of p/q, then $xl_n := p_n^l/q_n^l = (p_1+np)/(q_1+nq)$ converges to p/q in $\hat{\mathbb{Q}}$. This series is made of the left ascendant of p/q and of all rational numbers that have as right ascendant p/q, all on a straight line in the diagram. We call this the series of left low convergents of p/q in order to distinguish it from the finite series of convergents to a rational number coming from the continuous fraction expansion. Low convergents still obey the property of convergents of being best approximants (i.e., $p/q - p_n^l/q_n^l < C/(q_n^l)^2$ with lowest C), but they have denominators that can be greater than q (continuous fraction expansion convergents have all denominators smaller than q). For instance the series $0/1, 1/3, 2/5, 3/7, 4/9, \ldots$ converges to 1/2 from the left. In the same way, if p_2/q_2 is the right ascendant of p/q, the series of right low convergents $xr_n := (p_2+np)/(q_2+nq)$ converges to p/q from the right. As an example, $1/1, 2/3, 3/5, 4/7, 5/9, \ldots$ converges to 1/2 from the right. Any other series converging to p/q, and not containing p/q, are made of descendants of xl_n, xl_{n+1} or xr_n, xr_{n+1}, performing worse approximation of p/q than the low convergents.

The last remark inspired a special reasoning scheme that we shall use throughout the next sections. Let us consider $x = (p/q, r/q) \in \Delta_{h,k,l} \cap (\mathbb{P}(\mathbb{Z}^2) \times \mathbb{Z})$, thus $gcd[p,q] = 1, q > 0$. $(p_1/q_1, r_1/q_1)$ and $(p_2/q_2, r_2/q_2)$ are the unique right and left ascendants of x along the direction $\Delta_{h,k,l}$, respectively.

Let us endow $\mathbb{P}(\mathbb{Z}^3)$ with the topology induced by the gnomonic projection. i.e., the weakest topology that makes the gnomonic projection continuous from $\mathbb{P}(\mathbb{Z}^3)$ to $\mathbb{R}^2$ (with the Euclidean metric topology).

The series $xl_n^{[h,k,l]} := (p_n^l/q_n^l, r_n^l/q_n^l), p_n^l := p_1 + np, q_n^l := q_1 + nq, r_n^l := r_1 + nr$, $xr_n^{[h,k,l]} := (p_n^r/q_n^r, r_n^r/q_n^r), p_n^r := p_2 + np, q_n^r := q_2 + nq, r_n^r := r_2 + nr$, that we call series of left and right low convergents of x along $\Delta_{h,k,l}$, converge to x from the left and from the right along the direction $\Delta_{h,k,l}$, respectively. It is easy to check that all other series converging to x along $\Delta_{h,k,l}$ are made of descendants of $xl_n^{[h,k,l]}, xl_{n+1}^{[h,k,l]}$, or $xr_n^{[h,k,l]}, xr_{n+1}^{[h,k,l]}$. The following induction argument allows us to extend results valid for $xl_n^{[h,k,l]}$ and $xr_n^{[h,k,l]}$ to results valid for any series converging to x along a direction with Miller index $k=1$.

Lemma 14: Let $x_n := p_n/q_n \to p/q$ where x_n, x_{n+1} or x_{n+1}, x_n are Farey-consecutive rational numbers for any n. Define $\mathcal{I}_r := \mathcal{F}_r \cap [x_n, x_{n+1}]$. Let (P) be the property: $f(x) = y + \mathcal{O}(1/q_n)$, where f is an arbitrary real function and $y \in \mathbb{R}$. Suppose that

(i) *x_n, x_{n+1} obey (P).*
(ii) *If all $x \in \mathcal{I}_r$ obey (P), then all $x \in \mathcal{I}_{r+1}$ obey (P).*

Then all $x \in [x_n, x_{n+1}] \cap \mathbb{Q}$ obey (P).

Remark 6: We shall usually apply Lemma 14 by first checking (i), then checking the implication: if $x', x'' \in [x_n, x_{n+1}]$ *are Farey-consecutive and obey (P)*, then $x' \oplus x''$ obeys *(P)*. According to the hierarchical structure of Farey series this implies (ii).

IV. PROJECTIVE FUNCTIONS AND RECURSION ON FAREY SETS

Definition 15: We call a function $g: \mathbb{Z}^3 \to \mathbb{R}$ projective if it is constant on directions containing the origin $g(p,q,r) = g(np,nq,nr)$. A projective function induces an application $g: \mathbb{P}(\mathbb{Z}^3) \to \mathbb{R}$.

Let $\{F_{p,q}(z) | p,q \in \mathbb{Z}, gcd[p,q] = 1, 0 \leq p/q \leq 1\}$ be a family of complex functions defined as following:

$$F_{p_1+p_2,q_1+q_2}(z) = F_{p_1,q_1}(z) + z^{\beta p_1 + \alpha q_1} F_{p_2,q_2}(z), \tag{6}$$

whenever p_1/q_1, p_2/q_2 are Farey- consecutive in $\mathbb{Q}$. Equation (6) defines $F_{p,q}(z)$ for all rational numbers $0 \leq p/q \leq 1$, $gcd[p,q] = 1$, provided $F_{0,1}(z)$ and $F_{1,1}(z)$ are known.

Using this family we define the following projective function on $\mathbb{P}(\mathbb{Z}^3)$:

$$h(p,r,q) = \frac{|F_{p^*,q^*}(\exp[2\pi i r^*/(\beta p^* + \alpha q^*)]|}{sp^* + tq^*}, \tag{7}$$

where $p^* = p/gcd[p,q], q^* = q/gcd[p,q], r^* = r/gcd[p,q]$ ($r^* \in \mathbb{Q}$ is not necessarily an integer).

We have seen in the Introduction that for a Farey hierarchy of structures the structure factor at Bragg reflections and the widths of gaps in the spectra of elementary excitations are projective functions defined on $\mathbb{P}(\mathbb{Z}^2) \times \mathbb{Z}$ (see also Sec. V), and obeying relation (2) [relation (7) represents the natural extension of relation (2) to $\mathbb{P}(\mathbb{Z}^3)$].

The following theorem represents our main result, stating an important property of $h(p,r,q)$.

Theorem 16: *For any projective function h obeying Eqs. (6) and (7) and for each direction $\Delta_{h,k,l} = \{(p/q, r/q) | ph + rk + ql = 0\}$ with Miller index $k=1$, there is a projective function $\epsilon_{h,k,l}(x)$ and a projective function $f_{h,k,l}(x)$ such that.*

(i) $h(x) = (1 + \epsilon_{h,k,l}(x)) f_{h,k,l}(x), x \in \Delta_{h,k,l}$.

(ii) $f_{h,k,l}(x)$ is continuous on $\Delta_{h,k,l}$.

(iii) $\lim_{n\to\infty} \sup_{x \in [\mathbb{P}(\mathbb{Z}^2) \times \mathbb{Z} \setminus \mathcal{F}_n^{(1,1)}] \cap \Delta_{h,k,l} \cap [0,1]^2} |\epsilon_{h,k,l}(x)| = 0$.

(iv) *The limit in (iii) is more rapid for directions $\Delta_{h,k,l}$ for which $\mathcal{I} := |\beta l - \alpha h|$ is smaller. Precisely, if $|\beta l' - \alpha h'| > |\beta l - \alpha h|$, then*

$$0 \leq \lim_{n\to\infty} \frac{\sup_{x\in[\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}\setminus\mathcal{F}_n^{(1,1)}]\cap\Delta_{h,k,l}\cap[0,1]^2} \epsilon_{h,k,l}(x)}{\sup_{x\in[\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}\setminus\mathcal{F}_n^{(1,1)}]\cap\Delta_{h',k',l'}\cap[0,1]^2} \epsilon_{h',k',l'}(x)} < 1.$$

In particular, $\epsilon_{h,k,l}(x)=0$ *for directions with Miller indices satisfying* $\beta l-\alpha h=0$.

(v) *There is* $\epsilon_o>0$, *such that for any* $x=(p/q\,,r/q)\in\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$, *and for any two directions passing through x of Miller indices* (h,k,l) *and* (h',k',l'), *such that* $|\beta l-\alpha h|<|\beta l'-\alpha h'|$ *and* $\epsilon_{h,k,l}(x)<\epsilon_o$ *we have* $\epsilon_{h,k,l}(x)<\epsilon_{h',k',l'}(x)$, *i.e.,* $f_{h,k,l}(x)>f_{h',k',l'}(x)$.

The proof of Theorem 16 uses Lemma 14 and the following two lemmas:

Lemma 17: With the notations of Section III, if $xl_n^{[h,k,l]}$, $xr_n^{[h,k,l]}$ *are the series of left and right low convergents of x along* $\Delta_{h,k,l}$ *with* $k=1$, *then*

$$h(xl_n^{[h,k,l]})=h(x)/[1+\epsilon_{h,k,l}(x)]+\mathcal{O}\left(\frac{1}{q_n^l}\right),$$

$$h(xr_n^{[h,k,l]})=h(x)/[1+\epsilon_{h,k,l}(x)]+\mathcal{O}\left(\frac{1}{q_n^l}\right),$$

where

$$\epsilon_{h,k,l}(x)=\begin{cases}\left|\dfrac{\pi(\beta l-\alpha h)}{\beta p+\alpha q}\Big/\sin\left[\dfrac{\pi(\beta l-\alpha h)}{\beta p+\alpha q}\right]\right|-1, & if\ |\beta l-\alpha h|>0,\\ 0, & if\ \beta l-\alpha h=0,\end{cases}$$

and $x=(p/q\,,r/q)$ *is the unique representation of* $x\in\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ *with* $gcd[p,q]=1, q>0$.

Lemma 18: Consider the series of left and right low convergents of x along $\Delta_{h,k,l}$, $k=1$. *Consider the proposition (P1):* $h(z)=h(x)/[1+\epsilon_{h,k,l}(x)]+\mathcal{O}(1/q_n^l)$. *The following implication (and the analogous statement for left low convergents) is valid: if (P1) is satisfied when* $z=x',x''$ where x',x'' are any two Farey-consecutive points between $xl_n^{[h,k,l]},xl_{n+1}^{[h,k,l]}$ along $\Delta_{h,k,l}$, *then (P1) is also satisfied by* $z:=x'\oplus x''$.

V. EXAMPLES AND CONCLUSIONS

We have shown that the amplitudes of the structure factor at Bragg reflections and the widths of gaps (in first order of Rayleigh-Schrödinger perturbation theory) in spectra of elementary excitations of approximants forming a Farey hierarchy are given by projective functions recursively defined on $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$.

Theorem 16 states that these functions are approximated with arbitrary precision by smooth functions of the commensurability ratio p/q along special directions in $\mathbb{P}(\mathbb{Z}^3)$ [for which $k=1$, therefore common to $\mathbb{P}(\mathbb{Z}^3)$ and to $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$], when restricted to points that are ''not very rational'' i.e., they are outside $\mathcal{F}_n^{(1,1)}$, with n big enough.

Furthermore, Lemma 17 provides an analytical formula of a projective function performing the smoothing of the projective functions giving the values of gap widths (reflection amplitudes).

From point (iv) of Theorem 16 it follows that the lines with $k=1$ and smaller values of $\mathcal{I}=|\beta l-\alpha h|$ correspond to weaker fluctuations of the gap widths (amplitudes of reflections) with respect to the smooth approximating function. The smaller $\mathcal{I}$ is, the weaker the fluctuations are.

Point (v) of Theorem 16 implies that when several directions intersect, the values of the smooth approximating functions are higher for the lines with smallest value of $|\beta l-\alpha h|$ (if we ignore the tail oscillations of $\sin\Theta/\Theta$). Thus smoother lines are also thicker.

These results are very much related to what in dynamical system theory is called modular smoothing.[11] When applied to spectral properties of Farey hierarchies of structures, it reveals a simple arithmetic structure, that is, the consequence of the hierarchical construction rules.

Let us discuss here two examples:

The double-chain model.[4]

For a *(p,q)* commensurate double chain, and for small interchain coupling, the spectrum of phonon excitations has $[(p+q-1)/2]$ gaps at the positions

$$E(p,r,q)=f_1\left(\frac{p}{q},\frac{r}{q}\right),\quad r=1,2,\ldots,\left\lfloor\frac{p+q-1}{2}\right\rfloor,$$

$$f_1(x,y)=4\sin^2\left(\pi\frac{y}{x+1}\right)+\chi\frac{x}{x+1},$$

and the gap widths in first order of the interchain coupling constant χ are

$$\Delta(p,r,q)=\chi\phi_1\left(\frac{p}{q}\right)\frac{F_{p,q}(\exp[2\pi ir/(p+q)])}{p+q},$$

$$\phi_1(x)=x+1/x,$$

where $F_{p,q}$ obey Eq. (6) with $\alpha=1,\beta=1$.

The values of the projective function $\Delta(p,r,q)$ has physical meaning only for $gcd[p,q]=1$ [thus, on $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$] and for $r=1,2,\ldots,[(p+q-1)/2]$, where one has gaps.

It is customary to represent the spectra for different commensurability ratios as a plot versus p/q made of black vertical segments for bands and white vertical segments for gaps. This reveals self-similar ''Hofstadter-type'' diagrams. In Fig. 4 black and white are reversed.

Figure 4 shows first (a) the values of the function $F_{p,q}(\exp[2\pi ir/(p+q)])/(p+q)$ on $\mathcal{F}_{20}^{(1,1)}$, then (b) restricts them to the set $\{(p/q\,,\,r/q)|gcd[p,q]=1,p\leqslant q,r=1,2,\ldots,\lfloor(p+q-1)/2\rfloor\}$, and applies the continuous transformations necessary to get the real positions and widths of the gaps. The values of $\mathcal{I}=|\beta l-\alpha h|$ are represented for several directions $\Delta_{h,k,l}$ with $k=1$. As generally stated by Theorem 16 (v), when two lines of gaps intersect, the line with smaller value of n is thicker. Also, as stated at point (iv) of Theorem 16, lines with smaller values of n are smoother.

The Aubry repeated parabolas model.[2] This model corresponds to the Hamiltonian in Eq. (4) with $V_n^{p,q}=\chi\lfloor np/q+\frac{1}{2}\rfloor$.

Positions of gaps in the phonon spectrum are

$$E(p,r,q)=f_2\left(\frac{p}{q},\frac{r}{q}\right),\quad r=1,2,\ldots,q-1,$$

$$f_2(x,y)=4\sin^2(\pi y)+\chi x,$$

and the gap widths in first order of χ are

$$\Delta(p,r,q)=\omega_2^2\chi\frac{G_{p,q}(\exp[2\pi ir/q])}{q},$$

where $G_{p,q}$ obey Eq. (6) with $\alpha=1,\beta=0$.

As for the double chain model, the function $\Delta(p,r,q)$ has physical meaning only for $gcd[p,q]=1$ and for $r=1,2,\ldots,q-1$.

Figure 5 shows first (a) the values of the function $G_{p,q}(\exp[2\pi ir/q])/q$ on $\mathcal{F}_{20}^{(1,1)}$, then (b) restricts them to the set $\{(p/q\,,\,r/q)|gcd[p,q]=1,p\leqslant q,r=1,2,\ldots,q-1\}$, and applies the continuous transformations necessary to get the real positions and widths of the gaps.

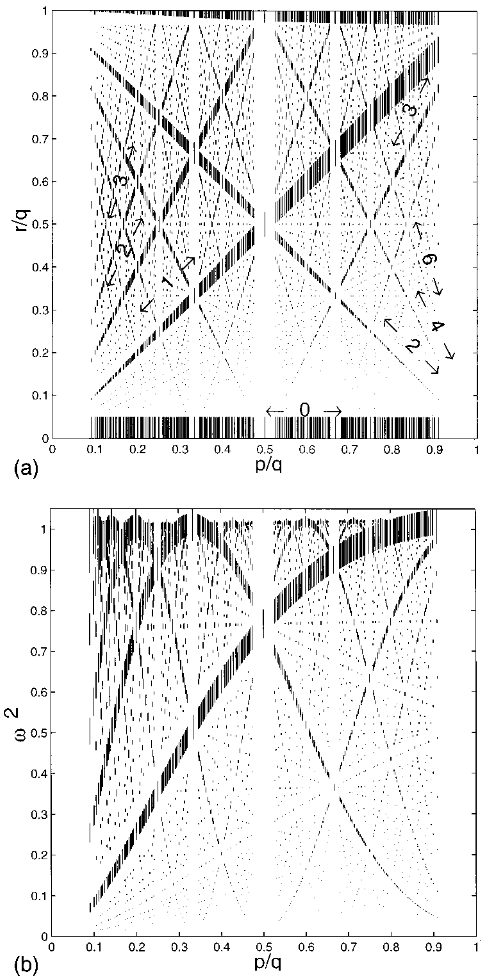

FIG. 4. Positions and widths of gaps for the DCM model: a) having $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ as support; b) real gap positions. The values of $\mathcal{I}=|\beta l-\alpha h|$ are indicated for different lines of gaps.

The properties stated at points *(iv)* and *(v)* of Theorem 16 hold in this case as well as shown by the values of $\mathcal{I}=|\beta l-\alpha h|$.

The transformation $(p/q\,,r/q)\rightarrow(1-p/q\,,r/q)$ transforms (h,k,l) to $(h,-k,-l)$ and $|\beta l-\alpha h|$ to $|\beta l+\alpha h|$. This explains the symmetrical aspect of Fig. 5 (when $\beta=0$ and $|\beta l-\alpha h|=|\beta l+\alpha h|$) and the absence of symmetry in Fig. 4 (when $\beta=1$ and $|\beta l-\alpha h|\neq|\beta l+\alpha h|$).

To summarize, here are the consequences of our results:

(i) For hierarchically defined 1D approximants, gaps in the phonon spectrum (or Bragg reflections in the diffraction pattern) are in one-to-one relation to subsets of $\mathbb{P}(\mathbb{Z}^3)$ (the set of directions in a 3D lattice). The gnomonic projection of $\mathbb{Z}^3$ onto the plane maps the directions of $\mathbb{Z}^3$ to gaps (or Bragg reflections) positions in the plot $(p/q\,,r/q)$, where r is the integer index giving the position of gaps in the spectrum at fixed commensurability ratio p/q when arranged in increasing order of energy.

(ii) The 2D planes of $\mathbb{Z}^3$ (containing the origin) with Miller indices (h,k,l) project onto lines connecting gaps (or Bragg reflections) that belong to spectra of different approximants and whose widths (amplitudes) are not very different and can be approximated by a smooth function of the commensurability ratio.

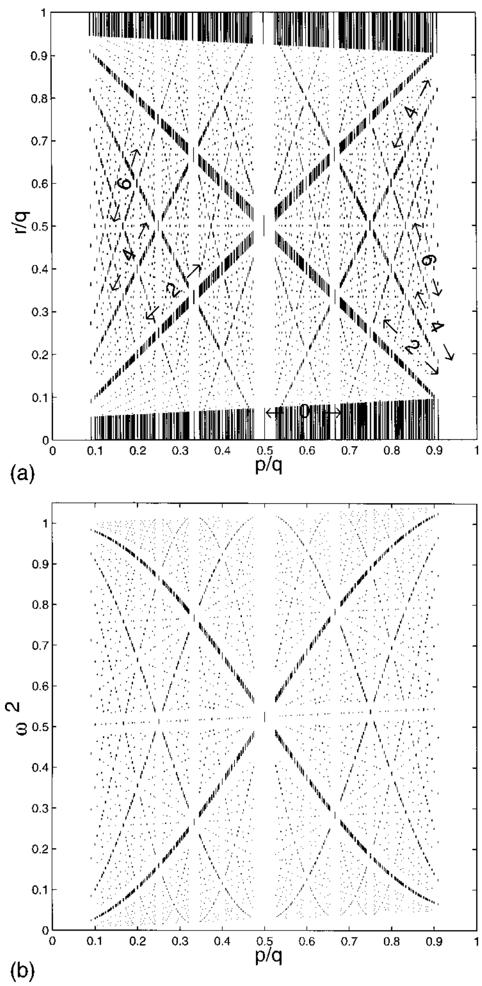

FIG. 5. Positions and widths of gaps for the Aubry model: (a) having $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ as support; (b) real gap positions. The values of $\mathcal{I}=|\beta l-\alpha h|$ are indicated for different lines of gaps.

(iii) The planes (lines in projection) with Miller indices $k=1$ and smallest values of $\mathcal{I}:=|\beta l-\alpha h|$ correspond to gaps (or Bragg reflections) whose widths (amplitudes) have weakest fluctuations with respect to the smooth approximating function.

(iv) Along a given line, the worst approximation is for the most ''rational'' points $(p/q\,,r/q)$ of $\mathbb{Z}^3$, i.e., the ones having low denominator q; the deviations relative to the smooth approximating function vanish for very irrational points $(q\rightarrow\infty)$.

(v) If we compare different lines, the smaller $\mathcal{I}$ is, the weaker the deviations with respect to the approximating smooth function are. Smoother (weakly oscillating gaps widths, or Bragg reflections amplitudes) lines are also thicker (large gaps, intense reflections).

(vi) The aspect of the ''Hofstadter-type'' diagrams is dictated by the values of α and β, that say which lines contain thicker and less fluctuating gaps (Bragg reflections), by the restriction on the possible values of r (only for the gap problem), and by the smooth function f that deforms the lines. For the diffraction problem the values of α and β are given by the way the Euclidean length of the unit cell scales with the commensurability indices p,q. For the gap problem the same values depend on the topology of the couplings between atoms and express the way the ''effective'' graph length of the unit cell scales with p,q.

The above results show the universal, simple arithmetical structure of spectra of Farey hierarchies of approximants and emphasize the importance of the geometry of numbers for spectral properties of hierarchical structures. Because the results were obtained in first order of the Rayleigh–Schrödinger perturbation theory and by using rather special recursions the range of their strict applicability is limited to 1D models of structures obtained by concatenation, in the limit of weak coupling. For strong coupling, nonlinear effects may destroy the universal structure of the spectra in the following way: lines of narrow gaps with big values of $\mathcal{I}=|\beta l-\alpha h|$ are strongly sheared and may lose their individuality each time they cross lines of wider gaps that open more rapidly with the value of the coupling. The lines of wider gaps are more robust and they preserve their individuality and structure for higher values of the coupling. Nonperturbative approaches are needed to solve the more complex details of the spectra in the case of strong coupling.

Our approach can be extended in several ways. One can imagine other types of Farey hierarchy than the one considered in this paper. For instance, approximant ground states of the Frenkel–Kontorova model can be constructed by concatenation, but continuous deformation of the unit cells should be applied at each step. In our definition of a Farey hierarchy we ignored the effect of this deformation. Also, the concatenation may be replaced by more general binary operations combining more than one copy of the unit cells. It would be also interesting to look for higher dimensional extensions of these results. The generalization of the diffraction problem to higher dimension is almost straightforward, but the spectral problem is not trivial. Already for one-dimensional models the possibility of obtaining simple recursions for the widths of the gaps relies on the topology of the couplings. It is possible to obtain these relations in all cases for diagonal tight-binding models for electrons (obtained by concatenation, therefore with a finite set of values of the onsite potential) or for the problem of phonons in the repeated parabolas Frenkel–Kontorova model, but for nondiagonal models like the double-chain model the dynamical matrix obeys simple recursions only in the special case of nearest-neighbor truncated coupling.[4]

The results presented here are also meant to be applied in material science. They provide a simple way to compare dynamical and spectral properties of approximants in homologous series. For instance, urea inclusion compounds having channels filled with different types of chainlike molecules were systematically studied for a long time.[12] It has been shown that, depending on the length of the included molecule, compounds with different host/guest ratio of periods can be produced. Because the inclusion channels are linear, 1D hierarchical models and the above analysis could be useful in the study of the variety of dynamical properties of these compounds. Another situation is represented by quasicrystalline alloys. Changing the stoichiometry or the temperature, or simply changing the nonequilibrium preparation method, produce samples that are quasiperiodic or contain a rich variety of periodic approximants having hierarchical structural relations between them. We would like to compare spectral properties of different approximants. Although quasicrystals are not 1D, 1D hierarchical models could be used to explain the very basic features of spectra.[13]

APPENDIX A: FAREY SERIES AND FAREY-HIERARCHIES OF STRUCTURES

The Farey series of order n is the set $\mathcal{F}_n=\{p/q\,|\,p,q\in\mathbb{Z},gcd[p,q]=1,0\leqslant p\leqslant q\leqslant n\}$ of fractions in their lowest terms, arranged in an increasing order. Two rationals that are consecutive in $\mathcal{F}_n$, for some order n, are called Farey-consecutive. Equivalently, two rationals $0\leqslant p_1/q_1<p_2/q_2\leqslant 1$ are Farey-consecutive iff for all p/q between them $q>\max(q_1,q_2)$.

The construction of Farey series provides an automatic way to order all rational numbers into a hierarchy of increasingly dense discrete dissections of the continuum. A nice description of this hierarchy can be found in Ref. 14. The hierarchical nature of the Farey series is emphasized by the mediant construction. The mediant of two rationals p_1/q_1 and p_2/q_2 is $p_1/q_1 \oplus p_2/q_2 := (p_1 + p_2)/(q_1+q_2)$. In order to obtain the elements of $\mathcal{F}_{n+1}$ one should add to $\mathcal{F}_n$ all the mediants of Farey-consecutive rationals (we shall call these mediants descendants) $p_1/q_1, p_2/q_2 \in \mathcal{F}_n$ in $\mathcal{F}_n$ such that $q_1+q_2=n+1$. In such a way, all rational numbers in the interval [0,1] can be obtained from the two elements of $\mathcal{F}_1$, i.e., $\frac{0}{1}$ and $\frac{1}{1}$.

The structures of different approximants are related in a similar way. The longer period and more complex unit cells of approximants that are at the bottom of the hierarchy can be obtained by concatenation of unit cells of approximants situated at previous levels of the hierarchy.

Let us call the Farey-hierarchy of structures a family $\{\mathcal{S}\}_{0 \leqslant p/q \leqslant 1}$ of sets of atomic coordinates that have the following properties:

(i) $\mathcal{S}_{p/q}$ is obtained by the periodic repeat of the primitive unit cell $U_{p,q}$. $\mathcal{S}_{p/q} = \cup_{n\in\mathbb{Z}}(U_{p,q} + nL_{p,q})$, where $L_{p,q}$ is the period. (p,q) and p/q are called commensurability indices and commensurability ratio, respectively.

(ii) The unit cells are obtained by concatenation, i.e.,

$$U_{p_1+p_2,q_1+q_2} = U_{p_1,q_1} \cup (U_{p_2,q_2} + L_{p_1,q_1}), \tag{A1}$$

where $p_1/q_1, p_2/q_2$ are Farey-consecutive.

Like the Farey series, the entire family $\mathcal{S}_{p/q}$ can be obtained by consecutive application of Eq. (A1) once $\mathcal{S}_{0/1}$ and $\mathcal{S}_{1/1}$ are known.

It is easy to check that the unit cell $U_{p,q}$ contains $n_{p,q} := \# U_{p,q} = sp + tq$ discrete atomic positions, and the period is of the form $L_{p,q} = a(\beta p + \alpha q)$, where $s = n_{1,1} - n_{0,1}, t = n_{0,1}$, $a\beta = L_{1,1} - L_{0,1}, a\alpha = L_{0,1}$.

APPENDIX B: PROOFS

Proof of Theorem 4. Consider $\{a_1,a_2\}$ a basis of the plane $\Pi_{h,k,l}$ of Miller indices (h,k,l) of $\mathbb{Z}^3$, $\Pi_{h,k,l} := \{(p,r,q) | ph + rk + ql = 0\}$. $x=(p,r,q), gcd[p,r,q]=1$ is in $\Pi_{h,k,l}$, hence $x = x_1 a_1 + x_2 a_2$, with $gcd[x_1,x_2]=1$ (because otherwise $gcd[p,r,q]>1$). Then we can choose $y = y_1 a_1 + y_2 a_2$, with y_1, y_2 solution of the equation $x_1 y_2 - y_1 x_2 = 1$. $\{x,y\}$ is obtained from $\{a_1,a_2\}$ by a unimodular transformation, therefore it is another basis of $\Pi_{h,k,l}$. Because $gcd[h,k,l]=1$ there is a vector $z=(z_1,z_2,z_3) \in \mathbb{Z}^3$ such that $z_1 h + z_2 k + z_3 l = 1$. Let us show that $\{x,y,z\}$ is a basis of $\mathbb{Z}^3$. For any vector $v=(v_1,v_2,v_3) \in \mathbb{Z}^3$ we have $v_1 h + v_2 k + v_3 l = n_3 \in \mathbb{Z}$. Let $u=(u_1,u_2,u_3) = v - n_3 z$. It is easy to check that $u_1 h + u_2 k + u_3 l = 0$, therefore $u \in \Pi_{h,k,l}$ and thus v can be expressed as $v = n_1 x + n_2 y + n_3 z$. Because $\{x,y,z\}$ is a basis of $\mathbb{Z}^3$ the determinant made of the components of the three vectors is equal to one (or can be made equal to one by changing y into $-y$). As $x \wedge y = n(h,k,l)$, one can check that this means $n=1$. ■

Proof of Property 9: If $x_1, x_2 \in \mathcal{F}_n^{(2,0)}$ and any $x=(p/q, r/q)$ between x_1, x_2 obeys $x \notin \mathcal{F}_n^{(2,0)}$, then $q > n \geqslant \max(q_1,q_2)$. Conversely, let $n = \max(q_1,q_2)$, thus $x_1, x_2 \in \mathcal{F}_n^{(2,0)}$. Then for any $x=(p/q, r/q)$ between x_1, x_2 such that $q > \max(q_1,q_2) = n$ it follows that $x \notin \mathcal{F}_n^{(2,0)}$. ■

Proof of Property 10: At least one of the indices (h,k,l) is nonzero. Without restricting generality we may suppose $k>0$ (the proof can be adapted to strictly negative indices as well). Because $\lambda, k, q_1, q_2 > 0$, $x_1 \wedge x_2 = \lambda(h,k,l)$ implies $p_1/q_1 < p_2/q_2$. From Theorem 4 there is a point $x=(p/q, r/q)$ such that $x_1 \wedge x = (h,k,l)$, and such that $n - q_1 < q \leqslant n$, i.e.,

$$\frac{p}{q} - \frac{p_1}{q_1} = \frac{k}{q_1 q}.$$

We intend to show that $x_2 = x$. Suppose that $x_2 \neq x$. Then, as x_1, x_2 are consecutive in $\mathcal{F}_n^{(2,0)}$, and $x \in \mathcal{F}_n^{(2,0)}$, $p_2/q_2 < p/q$. By adding term by term the inequalities $p/q - p_2/q_2 = (pq_2 - p_{2q})/qq_2 \geqslant k/qq_2$, and $p_2/q_2 - p_1/q_1 = (p_2 q_1 - p_1 q_2)/q_1 q_2 \geqslant k/q_1 q_2$ we obtain $k/q_1 q = p/q - p_1/q_1 \geqslant k(1/qq_2 + 1/q_1 q_2) = k(q+q_1)/qq_1 q_2 > kn/q_1 q_2 q \geqslant k/q_1 q$, contradiction. The proof of the reciprocal property is like the proof of Theorem 1 of Neville.[7]

Using $x_1\wedge x_2=(h,k,l)$, we find $r_2/(\beta p_2+\alpha q_2)-r_1/(\beta p_1+\alpha q_1)=(\beta l-\alpha h)/[(\beta p_1+\alpha q_1)(\beta p_2+\alpha q_2)]$. ■

Proof of Property 12: The equivalence between Properties 10 and 12 is entirely analogous to the known proof[8,9] for the Farey series. ■

Proof of Property 13: Using Properties 12 and 10 it follows that $x=y_1\oplus y_2$ with y_1,y_2 Farey-consecutive is equivalent to y_1,x and x,y_2 and y_1,y_2 being Farey-consecutive and therefore to having the following equations simultaneously satisfied:

$$x\wedge y_2=(h,k,l), \tag{B1}$$

$$y_1\wedge x=(h,k,l), \tag{B2}$$

$$y_1\wedge y_2=(h,k,l). \tag{B3}$$

The general solution of Eq. (B1) is of the form $y_2=y_0+nx$ where y_0 is a particular solution (its existence follows from Theorem 4), that can be chosen to satisfy (i) $0<den(y_0)\leqslant den(x)$. Also n should satisfy (ii) $den(y_0)+nden(x)>0$, otherwise the external product will have to change sign on readjusting $den(y_0+nx)$ to be positive. Similarly, Eq. (B2) has the general solution $y_1=-y_0+mx$, where m satisfies (iii) $-den(y_0)+mden(x)>0$. Then Eq. (B3) is satisfied provided $m+n=1$, which implies $n\leqslant 1$. From (i) and (ii) it follows that $n\geqslant 0$, from (iii) it follows that $m>0$, therefore $n=0,m=1$ corresponds to the unique solution we are looking for. ■

Proof of Property 7: Suppose $k=1$. Consider any p_1/q_1, p/q Farey-consecutive. Then $pq_1-p_1q=1$, hence any rational number $p_2/q_2, gcd[p_2,q_2]=1$ can be expressed as $p_2/q_2=(mp_1+np)/(mq_1+nq)$. The line $\Delta_{h,k,l}$ passes through the points $(p_1/q_1, r_1/q_1),(p/q, r/q)$ and intersects the vertical line $x=p_2/q_2$ at $((mp_1+np)/(mq_1+nq),(mr_1+nr)/(mq_1+mq))$, being made entirely of points of $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$.

Conversely, if $\Delta_{h,k,l}=\Delta_{h,k,l}\cap[\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}]$ then necessarily $k\neq 0$, because otherwise the direction would be of the form $\Delta_{-q,0,p}=\{(op/oq, r/oq)|gcd[p,q]=1\}$ with fixed p,q and arbitrary r,o and it would contain points outside $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ (those with $o\neq 1$). Let us now consider any two Farey-consecutive rationals p_1/q_1, p/q. Because $k\neq 0$, $\Delta_{h,k,l}$ intersects the lines $x=p_1/q_1$ and $x=p/q$ at points that are in $\mathbb{P}(\mathbb{Z}^2)\times\mathbb{Z}$ by hypothesis, thus of the form $(p/q, r/q)$, $(p_1/q_1, r_1/q_1)$. From Remark 3 and Property 10 it follows that $k=1$. ■

Proof of Property 11: This follows from the fact that $(p_1/q_1, r_1/q_1)\wedge(p_2/q_2, r_2/q_2)=(h,k,l)$ with $gcd[h,k,l]=1$, and $k=1$, as soon as $p_2q_1-p_1q_2=1$, i.e., $p_1/q_1, p_2/q_2$ are Farey-consecutive. ■

Proof of Lemma 17: Because p_n^l/q_n^l and p/q are Farey-consecutive for any n, then $F_{p_n^l,q_n^l}(z)=F_{p_{n-1}^l,q_{n-1}^l}(z)+z^{\beta p_{n-1}^l+\alpha q_{n-1}^l}F_{p,q}(z)$. It follows

$$F_{p_n^l,q_n^l}=F_{p_1,q_1}+z^{\beta p_1+\alpha q_1}\frac{z^{n(\beta p+\alpha q)}-1}{z^{\beta p+\alpha q}-1}F_{p,q}. \tag{B4}$$

Let $\Phi_n^l:=2\pi r_n^l/(\beta p_n^l+\alpha q_n^l)$. Using (B4) it is easy to check that

$$h(xl_n^{[h,k,l]})=\frac{|\sin n(\beta p+\alpha q)\Phi_n^l/2|}{(\beta p+\alpha q)\Phi_n^l/2}\,\frac{|F_{p,q}(\exp(i\Phi_n^l))|}{sp_n^l+tq_n^l}+\mathcal{O}\left(\frac{1}{q_n^l}\right)$$

$$=\frac{h(x)}{1+\epsilon_{h,k,l}(x)}+\mathcal{O}\left(\frac{1}{q_n^l}\right). \tag{B5}$$

For the last equality we used $(\beta p+\alpha q)\Phi_n^l/2=\pi r+\pi(\beta l-\alpha h)/(\beta p_n^l+\alpha q_n^l)$, which is a consequence of Property 10.

The part of the proof concerning $xr_n^{[h,k,l]}$ is along the same lines. ■

Proof of Lemma 18: To simplify the proof, we assumed that $\alpha,\beta\geqslant 0$, but the other situations may be analyzed in the same way.

The function $F_{p,q}$ has the following form:

$$F_{p,q}(z)=\sum_{r=1}^{\mathcal{N}_{p,q}} a_r^{(p,q)} z^{\zeta_r^{(p,q)}}, \tag{B6}$$

where $\zeta_1^{(p,q)}<\zeta_2^{(p,q)}<\cdots<\zeta_{\max}^{(p,q)}$.

Let us show that for all p'/q', $p_n^l/q_n^l<p'/q'<p_{n+1}^l/q_{n+1}^l$ we have

$$\zeta_{\max}^{(p',q')}=(\beta p'+\alpha q')\left[1+\mathcal{O}\left(\frac{1}{q_n^l}\right)\right]. \tag{B7}$$

From Eq. (B4) it follows

$$\zeta_{\max}^{(p_n^l,q_n^l)}=\max[\zeta_{\max}^{(p_1,q_1)},\zeta_{\max}^{(p,q)}+\beta(p_1-p)+\alpha(q_1-q)+n(\beta p+\alpha q)]=n(\beta p+\alpha q)+\mathcal{O}(1), \tag{B8}$$

meaning that (B7) holds for p_n^l/q_n^l ($p_n^l=p_1+np$, $q_n^l=q_1nq$).

From Eq. (6) it follows, for any $p_n^l/q_n^l\leqslant p'/q'<p''/q''\leqslant p_{n+1}^l/q_{n+1}^l$,

$$\frac{\zeta_{\max}^{(p'+p'',q'+q'')}}{\beta(p'+p'')+\alpha(q'+q'')}=\max\left[\frac{\zeta_{\max}^{(p',q')}}{\beta(p'+p'')+\alpha(q'+q'')},\chi_1\frac{\zeta_{\max}^{(p'',q'')}}{\beta p''+\alpha q''}+\chi_2\right]=1+\mathcal{O}\left(\frac{1}{q_n^l}\right),$$

where $\chi_1=(\beta p''+\alpha q'')/[\beta(p'+p'')+\alpha(q'+q'')],\chi_2=(\beta p'+\alpha q')/[\beta(p'+p'')+\alpha(q'+q'')]$, $\chi_1+\chi_2=1$.

The last equality follows if we suppose that $\zeta_{\max}^{(p',q')}$ and $\zeta_{\max}^{(p'',q'')}$ obey (B7). Lemma 14 and Remark 6 end this part of the proof.

Let $\Phi_{p',q'}:=2\pi r'/(\beta p'+\alpha q'),\Phi_{p'',q''}:=2\pi r''/(\beta p''+\alpha q'')$. From Property 10 it follows

$$\Phi_{p',q'}-\Phi_{p'',q''}=\frac{2\pi(\beta l-\alpha h)}{(\beta p'+\alpha q')(\beta p''+\alpha q'')}. \tag{B9}$$

Using Equations (B7), (B6), and (B9) it is easy to check that

$$|F_{p'',q''}(\exp i\Phi_{p',q'})-F_{p'',q''}(\exp i\Phi_{p'',q''})|\leqslant\left(\sum_{r=1}^{\mathcal{N}_{p'',q''}}|a_r^{p'',q''}|\right)\frac{2\pi(\beta l-\alpha h)}{\beta p''+\alpha q''}\left[1+\mathcal{O}\left(\frac{1}{q_n^l}\right)\right]. \tag{B10}$$

Let us show that

$$\sum_{r=1}^{\mathcal{N}_{p',q'}}|a_r^{p',q'}|<C(\beta p'+\alpha q')\left[1+\mathcal{O}\left(\frac{1}{q_n^l}\right)\right] \tag{B11}$$

for any $p_n^l/q_n^l\leqslant p'/q'\leqslant p_{n+1}^l/q_{n+1}^l$.

From Eq. (B4) it follows that all $|a_r^{p_n^l,q_n^l}|$ are less than a constant A and that $\mathcal{N}_{p_n^l,q_n^l}\leqslant\mathcal{N}_{p_1,q_1}+n\mathcal{N}_{p,q}$. It follows

$$\frac{\sum_{r=1}^{\mathcal{N}_{p_n^l,q_n^l}}|a_r^{p_n^l,q_n^l}|}{\beta p_n^l+\alpha q_n^l}<A\frac{\mathcal{N}_{p_n^l,q_n^l}}{\beta p_n^l+\alpha q_n^l}\leqslant\frac{A\mathcal{N}_{p,q}}{\beta p+\alpha q}\left[1+\mathcal{O}\left(\frac{1}{q_n^l}\right)\right]. \tag{B12}$$

In a similar way we use Eq. (6) to show that if Eq. (B11) is fulfilled by both (p',q') and (p'',q'') with $p_n^l/q_n^l \leqslant p'/q' < p''/q'' \leqslant p_{n+1}^l/q_{n+1}^l$ then it is also fulfilled by $(p'+p'',q'+q'')$. Lemma 14 and Remark 6 conclude this part of the proof.

Using Eqs. (B10) and (B11) we show that

$$|F_{p'',q''}(\exp i\Phi_{p',q'}) - F_{p'',q''}(\exp i\Phi_{p'',q''})| \leqslant C'\left[1+\mathcal{O}\left(\frac{1}{q_n^l}\right)\right] \tag{B13}$$

and, in a similar way,

$$|F_{p'+p'',q'+q''}(\exp i\Phi_{p',q'}) - F_{p'+p'',q'+q''}(\exp i\Phi_{p'+p'',q'+q''})| \leqslant C''\left[1+\mathcal{O}\left(\frac{1}{q_n^l}\right)\right]. \tag{B14}$$

From Eqs. (6), (B13), (B14) it follows that

$$h\left(\frac{p'+p''}{q'+q''},\frac{r'+r''}{q'+q''}\right) = h\left(\frac{p'}{q'},\frac{r'}{q'}\right)\eta_1 + h\left(\frac{p''}{q''},\frac{r''}{q''}\right)\eta_2 + \mathcal{O}\left(\frac{1}{q_n^l}\right), \tag{B15}$$

where $\eta_1 = (sp'+tq')/[s(p'+p'')+t(q'+q'')]$, $\eta_2 = (sp''+tq'')/[s(p'+p'')+t(q'+q'')]$, $\eta_1 + \eta_2 = 1$.

Because x',x'' satisfy (P1) from Eq. (B15) it follows that $x' \oplus x''$ satisfies (P1).

The proof for $xr_n^{[h,k,l]}$ is along the same lines. ■

Proof of Theorem 16: Along a direction $\Delta_{h,k,l}$ with $k=1$, $h(x)$ $[x=(p/q\,,r/q),gcd[p,q]=1]$ is a function of p/q only and Lemma 14 applies in this case as well, proving together with Lemmas 17 and 18 that $h(x_n) \to h(x)/[1+\epsilon_{h,k,l}(x)]$ for any series $x_n := (p_n/q_n\,,r_n/q_n)$ converging to x along $\Delta_{h,k,l}$. In this case $\epsilon_{h,k,l}(x_n) \to 0$ because $p_n\,,q_n \to \infty$. Thus, $f(x_n) \to f(x)$, where $f(x) := h(x)/[1+\epsilon_{h,k,l}(x)]$, for any series converging to x along $\Delta_{h,k,l}$, f being a continuous function along $\Delta_{h,k,l}$.

It is easy to check that $\epsilon_{h,k,l}(x)$ satisfies the conditions iii–v with $\epsilon_o = 1/y_o - 1$, y_o being the highest local maximum different from 1 of the function $|\sin\Theta/\Theta|$. ■

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 3 MARCH 1999

On a trace formula of the Buslaev–Faddeev type for a long-range potential

Alexei Rybkin[a)]
Department of Mathematics, The University of Alaska, Fairbanks, P.O. Box 6660, Fairbanks, Alaska 99775

(Received 20 February 1997; accepted for publication 14 December 1998)

We propose an approach to obtaining new trace formulas of the Gel'fand–Levitan–Buslaev–Faddeev type, valid for Hilbert–Schmidt perturbations. In this way we obtain a new trace formula for Schrödinger operators on the half-line with long-range potentials.
[S0022-2488(99)02703-6]

I. INTRODUCTION

The formulas we are concerned with first appeared in 1953 in the classic paper[1] by Gel'fand and Levitan, where the authors obtained some identities for the eigenvalues of a regular Sturm–Liouville operator. A detailed account of trace formulas on finite intervals can be found in Dikii's paper.[2] These nice formulas relating the spectrum of an operator to certain characteristics of the operator itself called trace formulas became a pattern to follow; and in 1957, Faddeev considered a generalization for the case of a singular Sturm–Liouville operator, which obtained a full exposition by Buslaev and Faddeev[3] in 1960. Namely, they studied trace formulas for a self-adjoint Schrödinger operator H in $L_2(0,\infty)$:

$$H=H_0+v(x),\quad H_0=-\frac{d^2}{dx^2},\quad u(0)=0, \tag{1.1}$$

where the real-valued potential $v(x)$ is assumed to be continuous and short range [i.e., having the first moment on $(0,\infty)$]. In particular, if, in addition, $v'(x)$ is also continuous and $v'(x)$ has a finite limit as $x\to\infty$, the following formula is valid:

$$\sum_{n\geqslant 0}\lambda_n+\int_0^\infty\left(\zeta(t)-\frac{1}{2\pi\sqrt{t}}\int_0^\infty v(x)dx\right)dt=-\frac{1}{4}v(0), \tag{1.2}$$

where $\{\lambda_n\}$ are eigenvalues of H and $\zeta(t)$ is defined by the limiting phase θ by the formula $\zeta(t)=\pi^{-1}\theta(\sqrt{t})$, $t\geqslant 0$. Formula (1.2) is, in fact, the first formula in the chain of relations that can be interpreted as expressions of regularized spectral traces of integer powers of H in terms of the potential $v(x)$, and its proof is based on Krein's trace formula that for a pair of resolvent comparable abstract operators H,H_0 reads (see, e.g., Ref. 4) as

$$\mathrm{tr}\{(H-z)^{-1}-(H_0-z)^{-1}\}=\int_{-\infty}^\infty\frac{d}{dt}(t-z)^{-1}\zeta(t)dt,\quad \mathrm{Im}\,z\neq 0. \tag{1.3}$$

The real-valued function $\zeta(t)$ is called the Krein spectral shift function of the pair H,H_0. It is summable on $(-\infty,\infty)$ with the weight $(1+t^2)^{-1}$, and for a pair (1.1) with a short-range potential $v(x)$ the following relation holds:[2]

a)Electronic mail: ffavr@uaf.edu

$$\zeta(t)=-N(t),\quad t<0;\quad \zeta(t)=\pi^{-1}\theta(\sqrt{t}),\quad t>0, \tag{1.4}$$

where $N(t)$ is the number of eigenvalues of H lying to the left from t. Note that the Gel'fand and Levitan original proof of their trace relations does not make a use of (1.3), and the connection between the Gel'fand–Levitan and Krein trace formulas was rigorously justified only quite recently in Ref. 5.

The Krein trace formula (1.3) gave a rise to a large number of papers dealing with key words: trace formulas, Krein's spectral shift function, the scattering matrix, etc.; too many to be mentioned. We refer the interested reader to the survey[4] and recent papers,[6–10] and the literature therein. Note especially only papers[6–8] by Gesztesy and Simon with coauthors, where the authors obtain new trace formulas and systematically apply them to solving the inverse problem for Schrödinger operators.

It is quite natural to ask what kind of trace formulas are available when we go over from short-range potentials to long-range ones. For such pairs H,H_0 the spectral shift function, in general, does not exist and formula (1.3) is no longer valid. However, there are quite a few substantial trace formulas[11–14] serving long-range potentials, but none of them are quite similar to (1.2). Our goal will just be finding a direct extension of (1.3) to the case of a long-range potential. We obtain such a formula basing upon a generalization of (1.3) due to L. S. Koplienko,[15] valid for self-adjoint operators H,H_0 $(H=H_0+V)$, subject to the condition $V|H_0-i|^{-1/2}$ is a Hilbert–Schmidt operator. Namely, for such a pair H,H_0, there is a unique (up to an additive constant) real-valued function $\eta(t)$ summable on $(-\infty,\infty)$ with the weight $(1+t^2)^{-\delta}$, $\delta>\frac{1}{2}$, such that $(\operatorname{Im} z\neq 0)$

$$\operatorname{tr}\{(H-z)^{-1}-(H_0-z)^{-1}+V(H_0-z)^{-2}\}=-\int_{-\infty}^{\infty}\frac{d^2}{dt^2}(t-z)^{-1}\eta(t)dt. \tag{1.5}$$

We call the function $\eta(t)$ the regularized spectral shift function. If a pair H,H_0 is defined by (1.1) with $v(x)$ twice differentiable, satisfying the condition

$$\left|\frac{d^n v(x)}{dx^n}\right|\leqslant Q(1+x)^{-\alpha-n};\quad \alpha>1/2,\quad n=0,1,2, \tag{1.6}$$

then the function $\eta(t)$ is differentiable and

$$\eta'(t)=-N(t),\quad t<0;\quad \eta'(t)=\pi^{-1}\theta(\sqrt{t}),\quad t>0, \tag{1.7}$$

where $N(t)$ is as above and θ is the modified limiting phase defined from the asymptotics $(\operatorname{Im} k=0)$:

$$\psi(x,k)=A(k)\sin\left(kx-\int_0^x\frac{\sin^2 ks}{k}v(s)ds-\theta(k)\right)+o(1),\quad x\to\infty, \tag{1.8}$$

of the solution to the following Cauchy problem:

$$H\psi=k^2\psi,\quad \psi(0,k)=0,\quad \psi'(0,k)=1.$$

II. SOME ASYMPTOTIC FORMULAS

In the sequel we will always assume that H,H_0 are defined by (1.1), and for the time being suppose that the potential $v(x)$ is four times continuously differentiable and finitely supported.

Proposition 2.1: Let R_z,R_z^0 be the resolvents of H,H_0 respectively, then

$$-\frac{1}{2\pi i}\oint_{|z|=R} z^2\,\mathrm{tr}\{R_z-R_z^0+v(R_z^0)^2\}dz=\frac{3}{8}\sqrt{R}\cdot\int_0^\infty v^2(x)dx-\frac{v^2(0)}{4}+o\left(\frac{1}{\sqrt{R}}\right),\quad R\to\infty. \tag{2.1}$$

Proof: Due to our condition on the potential, $R_z-R_z^0$ is of the trace class, and we have

$$\begin{aligned}\mathrm{tr}\{R_z-R_z^0+v(R_z^0)^2\}&=\mathrm{tr}\{R_z-R_z^0\}+\mathrm{tr}\{v(R_z^0)^2\}\\ &=-\frac{d}{dz}\log M(\sqrt{z})+\frac{d}{dz}\mathrm{tr}\{v(R_z^0)\}\\ &=\frac{d}{dz}\{\mathrm{tr}\{v(R_z^0)\}-\log M(\sqrt{z})\},\quad \mathrm{Im}\sqrt{z}\geqslant 0,\end{aligned} \tag{2.2}$$

where $M(\sqrt{z})=\det(I+vR_z^0)$ is the perturbation determinant of the pair H,H_0. Fix the branch of $\log M(\sqrt{z})$ so that $\log M(\sqrt{z})\to 1$, $|z|\to\infty$; then,[3] uniformly in z, $\mathrm{Im}\sqrt{z}\geqslant 0$, we have

$$\log M(\sqrt{z})=-\sum_{k=1}^{4}\frac{q_k}{(2i\sqrt{z})^k}+o\left(\frac{1}{|z|^2}\right),\quad |z|\to\infty, \tag{2.3}$$

where

$$q_1=\int_0^\infty v(x)dx,\quad q_2=v(0),\quad q_3=-v'(0)-\int_0^\infty v^2(x)dx,\quad q_4=v''(0)-2v^2(0).$$

Since R_z^0 is an integral operator with the kernel

$$G(x,y;z)=-\frac{1}{i\sqrt{z}}(e^{i\sqrt{z}|x-y|}-e^{i\sqrt{z}(x+y)}), \tag{2.4}$$

one can easily see that

$$\mathrm{tr}\{v(R_z^0)\}=-\frac{1}{2i\sqrt{z}}\int_0^\infty v(x)(1-e^{2i\sqrt{z}x})dx,\quad \mathrm{Im}\sqrt{z}\geqslant 0,$$

and integration by parts three times gives

$$\mathrm{tr}\{v(R_z^0)\}=-\sum_{k=1}^{4}\frac{p_k}{(2i\sqrt{z})^k}+o\left(\frac{1}{|z|^2}\right),\quad |z|\to\infty, \tag{2.5}$$

where $p_1=q_1$, $p_k=(-1)^k v^{(k-2)}(0)$, $k=2,3,4$. Asymptotics (2.5) is obviously uniform in z, $\mathrm{Im}\sqrt{z}\geqslant 0$, and, hence, plugging (2.3) and (2.5) into (2.2), we obtain

$$z^2\,\mathrm{tr}\{R_z-R_z^0+v(R_z^0)^2\}=\frac{1}{8}\sum_{k=0}^{2}\frac{(k+2)(q_{k+2}-p_{k+2})}{(2i\sqrt{z})^k}+o\left(\frac{1}{|z|^3}\right),\quad |z|\to\infty.$$

This asymptotics is uniform in z, $\mathrm{Im}\sqrt{z}\geqslant 0$, and a straightforward computation leads to (2.1).

Proposition 2.2: For the regularized spectral shift function we have

$$\eta(R)=-\frac{1}{4\pi}\int_0^\infty v^2(x)dx\cdot\frac{1}{\sqrt{R}}+O\left(\frac{1}{\sqrt{R^3}}\right),\quad R\to\infty. \tag{2.6}$$

Proof: As it follows from (1.3), (1.5),

$$\eta(R)=-\operatorname{tr}\{vE_0(R)\}+\int_{-\infty}^{R}\zeta(t)dt, \tag{2.7}$$

where E_0 is the resolution of identity for H_0 and $\zeta(t)$ is the spectral shift function of H,H_0. We calculate the asymptotics for each term of the right side of (2.7). For the kernel of E_0 we have

$$E_0(x,y;R)=\frac{1}{\pi}\left(\frac{\sin\sqrt{R}(x-y)}{(x-y)}-\frac{\sin\sqrt{R}(x+y)}{(x+y)}\right).$$

Hence,

$$\begin{aligned}\operatorname{tr}\{vE_0(R)\}&=\frac{1}{\pi}\int_0^\infty v(x)\left(\sqrt{R}-\frac{\sin 2\sqrt{R}x}{2x}\right)dx\\&=\frac{\sqrt{R}}{\pi}\int_0^\infty v(x)dx-\frac{1}{\pi}\int_0^\infty v(x)\frac{\sin 2\sqrt{R}x}{2x}dx\\&=\frac{\sqrt{R}}{\pi}\int_0^\infty v(x)dx-\frac{1}{2\pi}\int_0^\infty\frac{v(x)-v(0)}{x}\sin 2\sqrt{R}x\,dx-\frac{v(0)}{2\pi}\int_0^\infty\frac{\sin 2\sqrt{R}x}{x}dx.\end{aligned} \tag{2.8}$$

For the second integral we have

$$\int_0^\infty\frac{v(x)-v(0)}{x}\sin 2\sqrt{R}x\,dx=\frac{v'(0)}{2}\frac{1}{\sqrt{R}}+O\left(\frac{1}{\sqrt{R^3}}\right),\quad R\to\infty. \tag{2.9}$$

Taking into account that

$$\int_0^\infty\frac{\sin 2\sqrt{R}x}{x}dx=\frac{\pi}{2},$$

for (2.8) we get

$$\operatorname{tr}\{vE_0(R)\}=\frac{\sqrt{R}}{\pi}\int_0^\infty v(x)dx-\frac{v(0)}{4}-\frac{v'(0)}{4\pi}\frac{1}{\sqrt{R}}+O\left(\frac{1}{\sqrt{R^3}}\right),\quad R\to\infty.$$

Represent the second term of (2.7) as follows:

$$\int_{-\infty}^{R}\zeta(t)dt=\int_{-\infty}^{0}\zeta(t)dt+\int_0^R\zeta(t)dt. \tag{2.10}$$

Using the asymptotic expansion for $\zeta(t)$,[3]

$$\zeta(t)=\sum_{k=0}^{1}\frac{(-1)^k q_{2k+1}}{(2\sqrt{t})^k}+O\left(\frac{1}{\sqrt{t^3}}\right),\quad t\to\infty, \tag{2.11}$$

where q's are as in Proposition 2.1, and since by (1.4) $\zeta(t)=-N(t)$, $t<0$, (2.10) can be continued,

$$=\sum_n \lambda_n+\int_0^R\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}\right)dt+\frac{q_1}{\pi}\int_0^R\frac{dt}{2\sqrt{t}}$$

$$=\sum_n \lambda_n+\frac{q_1}{\pi}\sqrt{R}+\int_0^\infty\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}\right)dt-\int_R^\infty\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}\right)dt. \tag{2.12}$$

From the Buslaev–Faddeev trace formula (1.2),

$$\int_0^\infty\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}\right)dt=-\sum_n \lambda_n-\frac{v(0)}{4},$$

and (2.12) can be continued,

$$=\frac{q_1}{\pi}\sqrt{R}-\frac{v(0)}{4}-\int_R^\infty\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}\right)dt. \tag{2.13}$$

Estimate the integral in (2.13). Taking into account (2.11), we have

$$\int_R^\infty\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}\right)dt=\int_R^\infty\left(\zeta(t)-\frac{q_1}{2\pi\sqrt{t}}+\frac{q_3}{8\pi t\sqrt{t}}\right)dt-\frac{q_3}{8\pi}\int_R^\infty\frac{dt}{t\sqrt{t}}$$

$$=-\frac{q_3}{4\pi\sqrt{R}}+O\left(\frac{1}{\sqrt{R^3}}\right). \tag{2.14}$$

Therefore

$$\int_{-\infty}^R\zeta(t)dt=\frac{q_1}{\pi}\sqrt{R}-\frac{v(0)}{4}-\frac{q_3}{4\pi\sqrt{R}}+O\left(\frac{1}{\sqrt{R^3}}\right)$$

$$=\frac{\sqrt{R}}{\pi}\int_0^\infty v(x)dx-\frac{v(0)}{4}-\frac{v'(0)+\int_0^\infty v^2(x)dx}{4\pi}\frac{1}{\sqrt{R}}+O\left(\frac{1}{\sqrt{R^3}}\right),\quad R\to\infty,$$

and, combining (2.9) and (2.14), we arrive at (2.6).

III. THE TRACE FORMULA

In this section we state and prove the main result.

Theorem 3.1: *Let a potential $v(x)$ be long range, such that*

$$\left|\frac{d^n v(x)}{dx^n}\right|\leqslant Q(1+x)^{-\alpha-n};\quad \alpha>1/2,\quad n=0,1,2,3,4. \tag{3.1}$$

Then the following trace formula holds:

$$-\sum_n \lambda_n^2+2\int_0^\infty\left(\eta(t)+\frac{1}{4\pi\sqrt{t}}\cdot\int_0^\infty v^2(x)dx\right)dt=\frac{v^2(0)}{4}. \tag{3.2}$$

Proof: We prove (3.2) first for potentials as in the previous section. Multiply (1.5) by $-(1/2\pi i)z^2$ and integrate the result along the contour $C_R^\epsilon=\{z:|z|=R,\epsilon\leqslant\arg z\leqslant 2\pi-\epsilon\}$ with a sufficiently large R:

$$-\frac{1}{2\pi i}\int_{C_R^\epsilon} z^2\,\mathrm{tr}\{R_z - R_z^0 + v(R_z^0)^2\}dz = \frac{1}{2\pi i}\int_{C_R^\epsilon} dz\cdot z^2\int_{-\infty}^{\infty}\frac{d^2}{dt^2}(t-z)^{-1}\eta(t)dt. \qquad (3.3)$$

Let $\epsilon\to 0$ and apply Proposition 2.1 and Lemma 4.1 to (3.2). Taking into account (1.7), we get

$$\frac{3}{8}\sqrt{R}\int_0^\infty v^2(x)dx - \frac{v^2(0)}{4} + O\left(\frac{1}{\sqrt{R}}\right) = \sum_n \lambda_n^2 - 2\int_0^R \eta(t)dt + 2R\eta(R) - R^2\eta'(R). \qquad (3.4)$$

Apply now Proposition 2.2 to the last two terms of (3.4). Performing trivial simplifications and letting $R\to\infty$, one has

$$-\sum_n \lambda_n^2 + 2\int_0^\infty\left(\eta(t) + \frac{1}{4\pi\sqrt{t}}\cdot\int_0^\infty v^2(x)dx\right)dt = \frac{v^2(0)}{4}. \qquad (3.5)$$

Now we need to drop the requirement of boundedness of $\mathrm{supp}\, v(x)$. Following Koplienko's proof of (1.5), let $v(x)$ be subject to the condition of the theorem; we construct $v_n(x)$ such that $v_n(x)=v(x)$, $0\leqslant x\leqslant n$; $v_n(x)=0$, $x\geqslant n$, and for $n\leqslant x\leqslant n+1$ we set $v_n(x)$ subject to

$$\left|\frac{d^m v_n(x)}{dx^m}\right| \leqslant Qn^{-\alpha}; \quad m=0,1,2,3,4.$$

For such $v_n(x)$ formula (3.5) clearly holds. It can be derived from Ref. 15 that $\eta_n(t)\to\eta(t)$ in $L_1((1+x^2)^{-\alpha})$ and hence in $L_1(0,a)$ for any $a<\infty$, say $a=2\max|v(x)|$. But for $t\geqslant 2\max|v(x)|$, it follows from Lemma 4.2, Proposition 2.2, and the relation $\eta'(t)=-\pi^{-1}\theta(\sqrt{t})$, $t>0$, that

$$\left|\eta_n(t) - (4\pi)^{-1}t^{-1/2}\int_0^\infty v_n^2(x)dx\right| \leqslant C\cdot t^{-3/2},$$

with some C dependent only on Q, α in (3.1). The Lebesgue dominated convergence theorem lets us pass to the limit in (3.5) as $n\to\infty$ and the theorem is proven.

Remark 3.2: Formula (3.1) can be included into a chain of trace formulas of higher order. To obtain these formulas we need to know more terms in asymptotics (2.6). We chose to present a recipe of treating long-range potentials rather than completeness of the results.

Remark 3.3: We note that Theorem 3.1 can be proved under condition (1.6) with an additional condition on $v''(x)$ of a Lipschitz's type. This additional condition is essential and it is possible to construct a potential $v(x)$ subject to (1.6) such that the integral in (3.2) is absolutely divergent. We plan to discuss this matter in detail elsewhere.

Remark 3.4: The way we obtained trace formulas of the Buslaev–Faddeev type for long-range potentials can be easily adjusted to some other settings such as a Schrodinger operator on the whole line or the three-dimensional case. We hope to return to this point elsewhere.

APPENDIX: AUXILIARY STATEMENTS

In proving Theorem 3.1 we made a use of the following two lemmas.

Lemma 4.1: Let $\eta(t)$ be a real-valued function belonging to $L_1((1+t^2)^{-\delta}dt;(0,\infty))$, $\delta>\frac{1}{2}$, and let $C_R^\epsilon=\{z:|z|=R, \epsilon\leqslant\arg z\leqslant 2\pi-\epsilon\}$. Then, for almost all $R>0$,

$$-\frac{1}{2\pi i}\lim_{\epsilon\to 0}\int_{C_R^\epsilon} dz\cdot z^2\int_0^\infty \frac{d^2}{dt^2}(t-z)^{-1}\eta(t)dt = 2\int_0^R \eta(t)dt - 2R\eta(R) + R^2\eta'(R). \qquad (A1)$$

Proof: Let $a>R$ and consider the following expression:

$$\int_{C_R^\epsilon} dz\cdot z^2\int_a^\infty (t-z)^{-3}\cdot \eta(t)dt=\int_a^\infty dt\cdot \eta(t)\int_{C_R^\epsilon} dz\cdot z^2(t-z)^{-3}. \tag{A2}$$

Since

$$\left|\int_{C_R^\epsilon} dz\cdot z^2(t-z)^{-3}\right|\leqslant R^2\int_{C_R^\epsilon}|dz|\cdot|t-z|^{-3}\leqslant\frac{2\pi R^3}{(a-R)^3},$$

by the Lebesgue theorem, we can pass to the limit in (A2) as $\epsilon\to 0$:

$$\lim_{\epsilon\to 0}\int_{C_R^\epsilon} dz\cdot z^2\int_a^\infty (t-z)^{-3}\cdot \eta(t)dt=\int_a^\infty dt\cdot \eta(t)\int_{C_R^\epsilon} dz\cdot z^2(t-z)^{-3}=0,\quad t\in \operatorname{Ext} C_R .$$

Denote

$$F(z)=\int_0^a (t-z)^{-1}\cdot \eta(t)dt.$$

The function $F(z)$ is clearly finite, and we have

$$\int_{C_R^\epsilon} dz\cdot z^2\int_0^a \frac{d^2}{dt^2}(t-z)^{-1}\cdot \eta(t)dt=\int_{C_R^\epsilon} dz\cdot z^2F''(z)=[z^2F'(z)-2zF(z)]_{C_R^\epsilon}+2\int_{C_R^\epsilon}F(z)dz. \tag{A3}$$

Representing $F'(z)$ in the form

$$F'(z)=-\frac{\eta(a)}{a-z}-\frac{\eta(0)}{z}+\int_0^a (t-z)^{-1}\cdot \eta'(t)dt,$$

we have

$$\begin{aligned}\lim_{\epsilon\to 0}[z^2F'(z)-2zF(z)]_{C_R^\epsilon}&=R^2\left\{\int_0^a (t-z+i0)^{-1}\cdot \eta'(t)dt-\int_0^a (t-z-i0)^{-1}\cdot \eta'(t)dt\right\}\\&\quad-2R\left\{\int_0^a (t-z+i0)^{-1}\cdot \eta(t)dt-\int_0^a (t-z-i0)^{-1}\cdot \eta(t)dt\right\}\\&=-2\pi i(R^2\eta'(R)-2R\eta(R))\end{aligned} \tag{A4}$$

For the second term of the right side of (A3), we get

$$\begin{aligned}2\int_{C_R^\epsilon}F(z)dz&=2\int_{C_R^\epsilon}dz\int_0^a (t-z)^{-1}\cdot \eta(t)dt\\&=2\int_0^a dt\,\eta(t)\int_{C_R^\epsilon}(t-z)^{-1}\,dz\\&=-2\int_0^a dt\ \eta(t)[\log(\mathrm{Re}^{i\epsilon}-t)]_{C_R^\epsilon}.\end{aligned}$$

Since $|[\log(\mathrm{Re}^{i\epsilon}-t)]_{C_R^\epsilon}|=2|\arctan R\sin\epsilon/(R\cos\epsilon-1)|\leqslant\pi$ and $\lim_{\epsilon\to 0}[\log(\mathrm{Re}^{i\epsilon}-t)]_{C_R^\epsilon}=2\pi i$, if $t<R$, and 0, if $t>R$, we obtain

$$2\lim_{\epsilon\to 0}\int_{C_R^\epsilon}F(z)dz=-2\int_0^a dt\ \eta(t)\lim_{\epsilon\to 0}[\log(\mathrm{Re}^{i\epsilon}-t)]_{C_R^\epsilon}=-4\pi i\int_0^R\eta(t)dt. \tag{A5}$$

Let $\epsilon\to 0$. Plugging (A4), (A5) into (A3), we arrive at the conclusion of the lemma.

Lemma 4.2: Let a potential $v(x)$ satisfy

$$\left|\frac{d^n v(x)}{dx^n}\right|\leqslant Q(1+x)^{-\alpha-n};\quad \alpha>1/2,\quad n=0,1,2,3,4. \tag{A6}$$

Then, for the limiting phase $\theta(k)$ [defined by (1.8)], the following estimate holds:

$$\left|\theta(k)-\frac{1}{8k^3}\int v^2(x)dx\right|\leqslant Ck^{-5},\quad k\geqslant\sqrt{2\max|v(x)|}, \tag{A7}$$

where C depends only on Q and α.

Proof: Throughout the proof we agree to denote by $O(k^{-n})$ any expression whose absolute value does not exceed Ck^{-n} with some constant C depending only on Q and α in condition (4.6). It is well known,[15,16] that the equation $-y''+v(x)y=k^2y$, $x\geqslant 0$, has a solution subject to

$$\lim e^{i\tau(x,k)}f(x,k)=1,\quad x\to\infty,\quad \tau(x,k)=kx-\int_0^x\frac{\sin^2 kt}{k}v(t)dt.$$

For $k\geqslant\sqrt{2\max|v(x)|}=k_0$, $f(x,k)$ admits the representation[17]

$$f(x,k)=\frac{\sqrt{k}}{\sqrt[4]{k^2-v(x)}}e^{-\alpha(k)}g(x,k), \tag{A8}$$

where $\alpha(k)=\lim_{x\to\infty}(u(x,k)-\tau(x,k))$, $u(x,x)=\int_0^x\sqrt{k^2-v(t)}dt$, and $g(x,k)$ is the solution to the integral equation,

$$g(x,k)=e^{iu(x,k)}+\int_x^\infty\sin\{u(t,k)-u(x,k)\}R(t,k)g(t,k)dt, \tag{A9}$$

where

$$R(t,k)=-\frac{v''(t)}{4\{k^2-v(t)\}^{3/2}}-\frac{5}{16}\frac{(v'(t))^2}{\{k^2-v(t)\}^{5/2}}.$$

Under condition (A6) [even (1.6)], Eq. (A9) can be solved by iteration. We need two first iterations:

$$g_0(x,k)=e^{iu(x,k)},$$

$$g_1(x,k)=e^{iu(x,k)}+\int_x^\infty\sin\{u(t,k)-u(x,k)\}R(t,k)g_0(t,k)dt. \tag{A10}$$

Due to condition (A6), for $x\geqslant 0$, $k\geqslant k_0$, we have

$$|g(x,k)-g_1(x,k)|\leqslant\left(\int_0^\infty|R(t,k)|dt\right)^2=O(k^{-6}),$$

and, in particular, for $x=0$,

$$|g(0,k)-g_1(0,k)|=O(k^{-6}), \tag{A11}$$

$$g_1(0,k)=1+\int_0^\infty \sin u(t,k)R(t,k)e^{iu(t,k)}\,dt. \tag{A12}$$

Since (Refs. 16 and 17)

$$\theta(k)=\arg f(0,k)=\arg g(0,k)-\alpha(k), \tag{A13}$$

it is enough to take care of

$$\operatorname{Im} g_1(0,k)=\int_0^\infty \frac{1-\cos 2u(t,k)}{2}R(t)dt$$
$$=-\frac{1}{8}\int_0^\infty \frac{1-\cos 2u(t,k)}{\{k^2-v(t)\}^{3/2}}v''(t)dt-\frac{5}{16}\int_0^\infty \frac{1-\cos 2u(t,k)}{\{k^2-v(t)\}^{5/2}}(v'(t))^2\,dt.$$

The second integral is clearly $O(k^{-5})$; for the first one, we have

$$-\frac{1}{8k^3}\int_0^\infty v''(t)dt+\frac{1}{8k^3}\int_0^\infty v''(t)\cos 2u(t,k)dt+O(k^{-5})$$
$$=\frac{v'(0)}{8k^3}+\frac{1}{16k^4}\int_0^\infty \frac{v''(t)}{\sqrt{k^2-v(t)}}d\sin 2u(t,k)+O(k^{-5}).$$

Since $(1-k^{-2}v(t))^{-1/2}=O(k^{-2})$, $k\geqslant k_0$, after integration by parts twice the last equation becomes

$$\frac{v'(0)}{8k^3}-\frac{1}{16k^4}\int_0^\infty v'''(t)\cos 2u(t,k)dt+O(k^{-5})$$
$$=\frac{v'(0)}{8k^3}+\frac{v'''(0)}{32k^5}+\frac{1}{32k^5}\int_0^\infty v^{(4)}(t)\sin 2u(t,k)dt+O(k^{-5})=\frac{v'(0)}{8k^3}+O(k^{-5}).$$

Therefore

$$\arg g_1(0,k)=\operatorname{Im}\log g_1(0,k)=\frac{v'(0)}{8k^3}+O(k^{-5}). \tag{A14}$$

Let us now estimate $\alpha(k)$:

$$\alpha(k)=\lim_{x\to\infty}(u(x,k)-\tau(x,k))=\lim_{x\to\infty}\left\{\int_0^x\sqrt{k^2-v(t)}dt-kx+\int_0^x\frac{\sin^2 kt}{k}v(t)dt\right\}.$$

As one can easily observe, that for $k\geqslant k_0$,

$$\int_0^x\sqrt{k^2-v(t)}dt=kx-\frac{1}{2k}\int_0^x v(t)dt-\frac{1}{8k^3}\int_0^\infty v^2(t)dt+O(k^{-5}),$$

$$\int_0^x\frac{\sin^2 kt}{k}v(t)dt=\frac{1}{2k}\int_0^x v(t)dt+\frac{v'(0)}{8k^3}+O(k^{-5}).$$

Therefore

$$\alpha(k)=\frac{v'(0)-\int_0^x v^2(t)dt}{8k^3}+O(k^{-5}). \tag{A15}$$

Now, combining (A13), (A11), (A14), and (A15), we arrive at (A7), and the lemma is proved.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 3 MARCH 1999

Toward quantum mathematics. I. From quantum set theory to universal quantum mechanics

Karl-Georg Schlesinger[a)]
Erwin Schrödinger Institute for Mathematical Physics, Boltzmanngasse 9, 1090 Vienna, Austria

(Received 10 August 1998; accepted for publication 27 October 1998)

We develop the old idea of von Neumann of a set theory with an internal quantum logic in a modern categorical guise [i.e., taking the objects of the category **H** of (pre-)Hilbert spaces and linear maps as the sets of the basic level]. We will see that in this way it is possible to clarify the relationship between categorification and quantization and besides this to understand that in some sense a categorificational approach to quantization is a discretized version of the one taken by noncommutative geometry. The tower of higher categorifications will appear as the analog of the von Neumann hierarchy of classical set theory (where by classical set theory, we will understand the usual Zermelo–Fraenkel system). Finally, we make a suggestion of how to understand all the different categorifications as different realizations of one and the same abstract structure by viewing quantum mechanics as universal in the sense of category theory. This gives the possibility to view extended topological quantum field theories purely as involving an abstract notion of quantum mechanics plus representation theory without the need to enlarge the class of kinematic structures of quantum systems on each step of categorification. In a future part of the work we will apply the language developed here to deal especially with the question of a categorification of the manifold notion. [S0022-2488(99)03003-0]

I. INTRODUCTION

In recent years, the word *quantum*, originating from physics, has found a rapidly increasing number of occurrences in the mathematics literature. In this paper, we start from the historically first use of *quantum* to denote a mathematical structure, the quantum logic of Birkhoff and von Neumann presented in Ref. 1. But our aims are the modern quantum structures that we hope to understand in a more unified way by taking a logic-based perspective. Beyond this, our goal is to be able to extend quantization to more involved mathematical structures, especially to the nonlinear graviton construction of twistor theory (Ref. 2). Let us now be a little bit more precise about the aim and the content of the paper.

In 1936, Birkhoff and von Neumann suggested in Ref. 1 that the lattice of closed linear subspaces of a Hilbert space determines a nonclassical propositional calculus for quantum objects, in the same way the Boolean lattice on two symbols determines the propositional calculus of classical logic. Later von Neumann proposed that one should consider a quantum set theory, corresponding to quantum logic, as does conventional set theory to classical logic (see Ref. 3 and the literature cited therein). This idea is very intriguing for several reasons: First of all, set theory is the mathematical theory of the notion of pure objects. So, the question for a quantum set theory is the question for a theory of pure quantum objects. This may sound strange to some because quantum mechanics is believed to be just this theory. But there is no contradiction here. We will see that quantum set theory is in some sense just another view on quantum mechanics, albeit one where the machinery of set theory helps us to ask more refined questions on the object notion. If

[a)]Electronic mail: schles@math.uni-wuppertal.de

one is strongly convinced that there is a notion of mathematical object beyond any physical experience and that set theory captures this notion, then there is, of course, no need to change set theory on the advent of quantum mechanics. But if one is prepared to accept that even the abstract object notion of set theory might just be distilled from our experience of physical objects (as von Neumann believed), we have to ask which object notion (and therefore set theory) the fundamental theories of physics really determine. Just as we had to learn that geometry is as well a part of physics as of mathematics, it might well turn out that logic and set theory are, too (a similar standpoint is also taken by Deutsch in the closely related field of quantum computation; see Ref. 4).

Second, the idea that even set theory should be quantized—and not only geometry or topology—has been around already for quite some time in the field of quantum gravity (see, e.g., Refs. 5, 6). There is a simple argument supporting this view: In general relativity the set theoretic structure is of immediate physical relevance. The points of space–time (i.e., the elements of the underlying set) represent the physical events. In a diffeomorphism invariant theory this has no meaning in the trivial sense of a point having four coordinate values, but a point has to be identified as the intersection of the world lines of particles or by values of fields (e.g., by the null cone structure and a conformal factor, as is done in twistor theory). So, by the diffeomorphism invariance of the theory, the set theoretic structure is intimately linked to something like collision processes of particles. For this reason, we should expect that this structure might become smeared in a full fledged theory of quantum gravity.

We will use the language of category theory to deal with nonclassical set theory. In some sense categories can be thought of as generalizations of the classical set universe **Set** (the category of sets and set theoretic functions). For special categories—topoi and certain generalizations thereof—this has been made precise, i.e., they have been shown to correspond to set theories with a nonclassical internal logic (see Ref. 7, which also gives an easy introduction to general category theory). We consider the category **H** of complex (pre-)Hilbert spaces and linear maps as the (basic) quantum set universe. (Because there appear unbounded operators in quantum mechanics, we normally do not assume continuity of the maps in **H**. This sometimes causes technical problems when dealing with certain subspaces defined by linear operators, because we do not easily get closure properties then. In order to avoid these difficulties in a first approach to the general structures involved, we work with pre-Hilbert spaces instead of Hilbert spaces here.) Though **H** is not a topos, we will see that it has properties similar to one. In spite of this, in doing mathematics in quantum set theory, we are not going to follow strictly the approach of topos theory of doing everything inside **H**, i.e., in terms of objects of **H**. We will allow ourselves the freedom to consider structures in quantum set theory as objects outside of **H**, too, because this is just the way ordinary mathematics is done in practice. Of course, we can formulate classical mathematics largely in categorical language inside **Set**, but for the working mathematician this is not always the most convenient way to conceive of the structure he is dealing with (unless he wants to transport the structures to another category). The question if at least in principle a reformulation totally inside **H** is possible in quantum mathematics, too, is certainly an interesting one from the foundational viewpoint, but since our aim is to apply quantum set theory to problems in mathematical physics, we will not deal with it here (the differences of **H** to a topos should one make ready to the possibility that a reformulation might not be possible). But we will use the idea that set theory is universal in the opposite way, namely, as a requirement saying that all structures we use can also be regarded as sets. This leads to an enlargement of quantum set theory beyond **H**, i.e., we regard the objects of **H** as some kind of basic level of set theory with other levels present, too. This approach allows us to keep the universality of set theory and the possibility to stay close to the spirit of the working mathematician (and it will give some interesting results).

Remark 1: Obviously, Hilbert spaces are not the true state spaces of quantum systems but contain redundant information. To avoid this, one one would have to go over to the projective case. On the one hand, this would make some structural elements more straightforward (e.g., there would exist a true terminal object then; see below). On the other hand, Hilbert spaces have established themselves as the language of the working physicist because their linear structure is *very convenient in other respects. Since our main aim is to develop quantum set theory as a tool for mathematical physics, we stay to the convention used in this field and take the category* **H** *as our basic quantum sets.*

Besides this, a reader comparing to other approaches to nonclassical set theories, should keep in mind that—by using a categorical approach—like in topos theory, the subobject (instead of the membership) relation will become the fundamental one.

As we mentioned already at the beginning, our first aim is to understand the quantum structures appearing in the modern literature from a more unified perspective. For the modern approaches, the idea of categorification is central. (A categorification of an algebraic structure is a category with a similar structure. For example, the categorification of a module is a module category, i.e., a category with a functorially given structure satisfying the module axioms up to isomorphism. In addition, one normally needs so-called *coherence conditions* for an iterative application of the axioms. For example, for a structure with associativity up to an isomorphism, one needs an additional axiom stating that even four—not only three—factors can be rebracketed, which then suffices to guarantee that an arbitrary number of factors can be. See Ref. 8 for the details.) There is especially the idea that categorification is linked to quantization (see again Refs. 8 and 9, 10). We will see that we can make this correspondence precise in our logic-based approach.

A more advanced goal is then to quantize more involved (nonalgebraic) mathematical structures like manifolds. Especially, we are interested in a quantization of Penrose's nonlinear gravitons. In Ref. 2, Penrose suggested to consider nonlinear gravitons as the one-particle states of a future quantum theory of gravity. Since the standard symmetric Fock space construction is not applicable in this case, the proposal has not been put into a proper theory since then. It seems therefore to be natural to explore the possibility if a different approach to quantization can lead to a mathematical structure that is suitable for a second quantized (i.e., many-particle) theory of nonlinear gravitons.

This work consists of two (possibly three) parts. In this paper we deal with the fundamentals, clarifying the relationship between categorification and quantization. The more involved applications will follow in the forthcoming part(s), where we will also compare the approach presented here to the results in Ref. 11 on a quantization of the category of topological spaces and continuous injections.

As the title indicates, we consider this as an approach toward a quantum mathematics, i.e., a mathematical theory where all the ingredients (like logic and set theory) adhere to the rules of quantum mechanics. We inserted the word *toward* in the title because we surely do not consider the following results as the final word on the structure of a theory of quantum mathematics. It is only a try to explore the pathway that finally could lead to such a theory.

In closing the Introduction, let us now give a short overview of the content of the individual parts of the paper. In Sec. II, we investigate in which aspects the category **H** is similar to a topos. We will find that there is no terminal object in a technical sense, but that the one-dimensional Hilbert space $\mathbb{C}$ for several purposes takes the role of it. We have some kind of exponentiation and we have pullbacks though—if we use the tensor product to construct pullbacks (which is the favorable approach from the standpoint of quantum mechanics)—we do not get universality but a superposition of pullback structures. The same holds true for the case of the subobject classifiers. We will see that this is linked to the fact that quantum set theory may be understood as describing the observation of a quantum system by a quantum system and the iteration of this process.

In Sec. III, we go on to introduce the analogs of number systems in quantum set theory. We start with the natural numbers that can be formulated in two different ways: Either internal (as an object in **H**) as the universal infinite-dimensional Hilbert space $\mathcal{N}$ or external as the category **Hilb** of finite-dimensional Hilbert spaces and linear maps. Reals and complex numbers are then found as the self-adjoint operators, respectively, the whole operator algebra, on $\mathcal{N}$.

Having introduced number systems, in the first part of Sec. IV, we deal with the analog of module structures. We then discuss the relevance of this for the categorifications appearing in TQFTs. The rest of this section is devoted to presenting the quantum version of the von Neumann hierarchy of classical set theory up to the level of the first infinite ordinal. Actually, we will see that there are two different but related hierarchies because there are two different set concepts present in quantum set theory.

A unified view on all the different levels of quantum set theory is presented in Sec. V. By considering quantum mechanics as universal in the sense of category theory, we understand all the (higher) categorifications as different realizations of one and the same abstract structure. Section VI contains some concluding remarks. Finally, we should remark that often details of the structures presented are not worked out precisely. For example, we use the concept of weak n and weak ω category, though the existence of a single concept of this form is still in the stadium of proof (but there is hope that it will be established in the near future; see the literature cited below). We think that in a new subject like quantum set theory it is justified first to explore the general territory emerging and try to get a feeling for its general power and possible limits before sticking to the technical details.

II. THE TOPOS-LIKE STRUCTURE

In this section we will explore in which respect the category **H** of complex (pre-)Hilbert spaces and linear maps resembles a topos. Recall that a topos is a category that has a terminal object, pullbacks, exponentiation, and a subobject classifier (see Ref. 7). We will consider the existence of all of these structures in **H**, in turn, now.

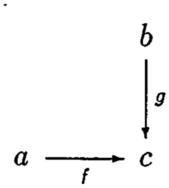
A. Terminal objects

A terminal object C of a category $\mathcal{C}$ is an object such that for any other object D of $\mathcal{C}$ there is one and only one arrow in $\mathcal{C}$ from D to C. Since there is no homomorphism set with one element in **H** (because all the homomorphism sets have a linear structure themselves), we do not have a terminal object.

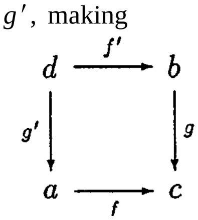
One could have the idea that maybe the question is wrongly posed. Since only the projective (i.e., subspace) structure is relevant in quantum mechanics, we should really not look for single element homomorphism sets but for one-dimensional ones. But even in this sense, we do not have a terminal object in **H**. Nevertheless, we will see below that the one-dimensional Hilbert space $\mathbb{C}$ (or, of course, any other one-dimensional Hilbert space) in some respects plays the role of a terminal object in **H**, though it is not one in a technical sense. (The reason why this works is that the true state spaces in quantum mechanics are the projective Hilbert spaces. In the category of these spaces $\mathbb{C}$ is terminal.)

B. Pullbacks

A pullback for a pair of arrows,



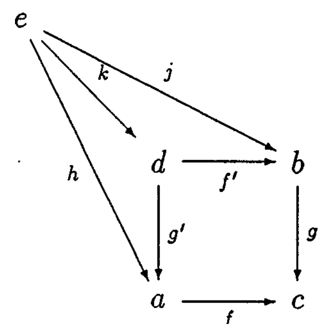
is an object d together with arrows f', g', making



commutative and satisfying that for any other object e and arrows h,j with this property there exists precisely one arrow,

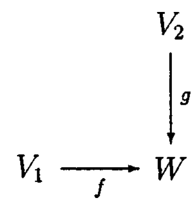
$$k : e \rightarrow d,$$

making



commutative.

Now, suppose



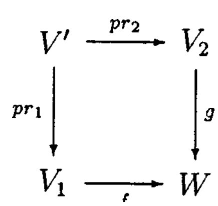
is given in **H**. Consider the direct sum and product Hilbert spaces $V_1 \oplus V_2$ and $V_1 \otimes V_2$ and denote in both cases by pr_1, pr_2 ''projections'' on the first and second component, respectively. Here, we put ''projections'' into quotation marks because in the tensor product case there exist no projections in the technical sense, of course. In this case, we mean the following: Fix a product basis in the product space and use the linear extension of the projection onto components existing for this basis. So, the construction we use is dependent on the additional structure of a fixed basis. But this dependence is not relevant from the standpoint of quantum logics, since there is redundant information in the Hilbert space structure (see above), and the remaining nonuniqueness is precisely described by the superposition structure below. Then

$$V_+ = \{ v \in V_1 \oplus V_2, \quad (f \circ \mathrm{pr}_1)(v) = (g \circ \mathrm{pr}_2)(v) \}$$

and

$$V_\times = \{ v \in V_1 \otimes V_2, \quad (f \circ \mathrm{pr}_1)(v) = (g \circ \mathrm{pr}_2)(v) \}$$

are pre-Hilbert spaces and



(where V' stands for either V_+ or $V_\times$) is commutative. For the case of V_+ the universality follows directly from the properties of the direct sum. If we use $V_\times$ instead, it is easy to show that a map k exists, too, but it is not unique. We only get uniqueness on product elements because for a general linear combination of product elements the application of pr_1 and pr_2 gives only the sum of the projections of the individual product elements. As a consequence, the pullback structure is not universal in this case—we could shift the uniqueness from the product elements to other ones by using more general projections instead of pr_1 and pr_2—but we get a kind of superposition of pullback structures. The structure of this superposition—i.e., the nonuniqueness of the pullback—is determined by the projective structure of $V_\times$. We will call such a superposition of pullback structures a *quantum pullback*.

Why do we care for these superposed structures at all and not simply restrict ourselves to the true pullbacks defined via the direct sum. The reason is that from the standpoint of quantum mechanics, of course, the tensor product is the appropriate product to be used in the category **H**. Indeed, the fact that superpositions of structures occur in this case is a fundamental feature of quantum set theory. From the standpoint of the category theorist, the pullback is one of the most fundamental structures leading to a level raising in set theory, i.e., on applying a pullback we climb up the ladder of the von Neumann hierarchy. We will understand below why this is related to an occurrence of superpositions in a set theory with an internal quantum logic.

C. Exponentiation

A category with a product $\times$ has exponentiation if for any pair of objects a and b there is an object b^a and an arrow,

$$ev: b^a \times a \to b$$

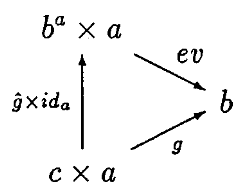
(called evaluation), such that for any object c and arrow

$$g: c \times a \to b,$$

there is a unique arrow

$$\hat{g}: c \to b^a,$$

making



commutative.

In the case of **H**, take as a product the tensor product (the direct sum works correspondingly) and define

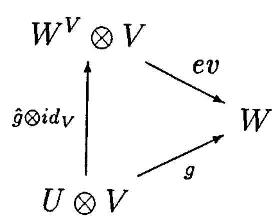
$$W^V = \mathrm{Hom}_{\mathbf{H}}(V, W)$$

and

$$ev: W^V \otimes V \to W,$$

as the evaluation map.

Now, consider the following diagram:



where U and g are supposed to be given. For $u \in U$ define $g_u: V \to W$ by

$$g_u(v) = g(u \otimes v),$$

and let $\hat{g}(u)=g_u$. Then clearly the diagram above commutes. On the other hand, commutativity of the diagram implies

$$ev(\hat{g}(u)\otimes v)=g_u(v),$$

i.e.,

$$\hat{g}(u)=g_u,$$

and therefore uniqueness of $\hat{g}$. So, **H** has a kind of exponentiation but not a true one in the technical sense of topos theory because $\mathrm{Hom}_{\mathbf{H}}(V,W)$ is not an object of **H**. [This is only true if we restrict to finite-dimensional spaces where $\mathrm{Hom}_{\mathbf{H}}(V,W)$ can be identified with $W\otimes V^*$.] But for the reason explained above, we do not consider this as a serious drawback.

D. Subobject classifier

This is the most interesting part of the topos structure since it refers to the internal logic.

In a category with a terminal object 1, a subobject classifier is an object Ω together with an arrow,

$$\mathrm{true}:1\rightarrow\Omega$$

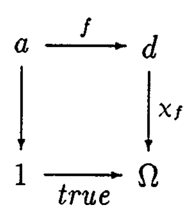
(the name refers to the fact that it represents the truth value ‘‘true’’ while Ω is the generalization of the Boolen algebra on two symbols of ordinary set theory, i.e., giving all the possible truth values) having the property that for each monomorphism,

$$f:a\rightarrowtail d,$$

there is precisely one arrow,

$$\chi_f:d\rightarrow\Omega,$$

making



into a pullback square (observe that $a\rightarrow 1$ is unique by the fact that 1 is a terminal object). Since monomorphisms define subobjects, we can regard χ_f as the characteristic function of

$$f:a\rightarrowtail d$$

in d.

Since the definition of a subobject classifier involves the terminal object in an essential way, we cannot directly use the approach of topos theory.

In a topos the object Ω has the role of representing the internal logic of the topos. Though **H** is not a topos, one suspects that the two-dimensional Hilbert space $\mathbb{C}^2$ should play a role similar to that of Ω in a topos by representing the binary quantum logic. Since the Birkhoff and von Neumann paper,[1] it has become customary to name as quantum logic every lattice of closed subspaces of a Hilbert space (and there are even more general definitions used in the literature). But considering a general Hilbert subspace lattice as some kind of logic is just the quantum counterpart to interpreting a general Boolean algebra as logic, i.e., in doing this, one mixes some kind of classically incomplete knowledge with the linear subspace structure imposed by quantum mechanics. So, the quantum analog of the classical binary logic—where one has the maximal obtainable information—is the quantum binary logic represented by the subspaces of $\mathbb{C}^2$ (physically speaking, representing a quantum bit of information). So, in considering **H** in comparison to **Set**, we should look at $\mathbb{C}^2$ as the analog of $2=\{0;1\}$.

As in **Set**, we choose a linear map,

$$\text{true}:\mathbb{C}\to\mathbb{C}^2,$$

as representing the truth value true. Let U be a subspace of V in **H** with inclusion map

$$f:U\rightarrowtail V.$$

If the following diagram gives one of the possibilities in the superpositions of a quantum pullback square,

$$\begin{array}{ccc} U & \xrightarrow{f} & V \\ \downarrow & & \downarrow \chi \\ \mathbb{C} & \longrightarrow & \mathbb{C}^2 \end{array}$$

we call χ *a quantum characteristic function (qcf)*. Here

$$\mathbb{C}\to\mathbb{C}^2$$

is the arrow true and the arrow

$$U\to\mathbb{C}$$

needs some extra comment: In a projective sense this arrow is unique, so, we may without loss of generality assume that for every space U a fixed choice of a map to $\mathbb{C}$ has been made.

As a consequence of the quantum pullback structure, we have again a superposition structure in the characteristic functions. Let us now discuss the relevance of this. Consider a quantum object described by a (pre-)Hilbert space V. The subobjects of it are then described by the linear subspaces U of V if we take an external view, i.e., if we describe the quantum object V as seen from outside by a classical observer. This is the view normally taken in quantum mechanics. The superposition structure of quantum characteristic functions means that we now do not describe the subobjects by the subspace lattice but by a kind of lattice of lattices where the structure of the outer lattice is given by the projective structure of U. This means we view the subobject question as seen from inside by the quantum object U itself. From the quantum perspective, the question of the extension of a subobject (which is the one, one asks when building a characteristic function) again has a superposition of answers. If we would apply a pullback construction twice, we would get a lattice of lattices of lattices, and so on, on iterated application. So, in this sense quantum set theory describes the observation of a quantum object by a quantum object and the iteration of this process. The higher levels of quantum set theory therefore can be seen as refining the notion of a quantum object beyond the level of description from the perspective of a classical one. To deal with questions in atomic physics, the higher levels of quantum set theory are surely not needed, but in other fields like quantum cosmology or the theory of quantum computation these structures could well be of interest. For instance, we can imagine a quantum computer observing a quantum system or the self-measurement of a quantum mechanical system. Questions of this type are beginning to be touched in the field of quantum computation (see the article[4] of Deutsch and the work mentioned there).

Finally, we should mention that the superposition structure of quantum set theory is also captured by the model theoretic approach of Takeuti (see Ref. 12), but we prefer the category theoretic approach because it makes the general scheme very transparent and allows us to connect it to results in modern mathematical physics.

In conclusion, **H** closely resembles a topos, the main difference being the appearance of superpositions of structures (if one uses the tensor product to define pullbacks). We could now use the topos-like structure to develop propositional calculus and elementary set algebra in **H**, along the lines this is done in topos theory (see Ref. 7). We refrain here from doing so explicitly because the results closely resemble the ones for set theory in the category of topological quantum field theories (though they are here often considerably more simple), which is presented in detail in Ref. 13. The only point on elementary set theory we would like shortly to mention is the question of extensionality.

The axiom of extensionality states that sets are described by their elements and nothing more, i.e., two sets are equal if and only if they have the same elements (this is maybe the most basic property of conventional set theory). Stated for functions—and in this way leading to a generalization to category theory—this means that two functions are equal if they always give the same value. Since extensionality can already be violated in topos theory (see Ref. 7), we have to ask the question if it holds true in **H**. Suppose two parallel arrows,

$$f,g:V\rightrightarrows W,$$

in **H** are given that are not equal, even in the sense of maps between projective spaces (which is surely the degree of unequalness we should require). Deciding them on an element in categorical terms means we have to give a map j from the terminal object (i.e., here $\mathbb{C}$) to V, such that

$$f\circ j\neq g\circ j.$$

But this is possible by taking j to be a map that assigns to $\mathbb{C}$ a subspace of V, where f and g differ. The other direction is trivial anyway, so we have extensionality for the basic level of quantum set theory.

III. NUMBER SYSTEMS

Having seen that **H** may be considered as a quantum set universe, it is natural next to ask if we can find analogs of the usual number systems in quantum set theory. We start by developing a concept of natural numbers.

Observe that we can equip **Set** with some additional structure: Taking the Cartesian product and the disjoint union of two sets as the product and sum on **Set**, respectively, makes **Set** into a rig category (see Ref. 8, the word *rig* is alluding to ring, the difference being that there need not be inverses with respect to the operation of addition). Then the usual arithmetic on the natural numbers is just the one induced by this category arithmetic, and the natural numbers themselves may be defined by successively taking sums of a terminal object in **Set** with itself. Especially, by taking the sum of a terminal object with itself one time, we get an object isomorphic to the subobject classifier $\{0;1\}$, determining the internal logic of **Set**.

Now, **H** may be considered a rig category, too, by equipping it with the tensor product and direct sum of (pre-)Hilbert spaces. As we noticed, in **H** the space $\mathbb{C}$ plays the role of a terminal object, i.e., we get the space $\mathbb{C}^n$ as the analog of the natural number $n\in\mathbb{N}$. In **Set**, $\mathbb{N}$ is just defined as being the target of an inclusion arrow for every natural number and by being minimal with respect to this property (minimality being defined by a factorization property for arrows). In **H** these requirements are fulfilled by an infinite-dimensional separable Hilbert space $\mathcal{N}$.

Remark 2: Since all infinite-dimensional separable Hilbert spaces are unitarily equivalent, $\mathcal{N}$ *may be considered as the universal infinite-dimensional separable Hilbert space.*

Alternatively, we could identify the natural numbers with the finite sets, i.e., taking the category **Hilb** of finite-dimensional Hilbert spaces as the analog of $\mathbb{N}$. Since finite sets are distinguished from natural numbers only by isomorphisms, it is natural to identify the two concepts in a categorical approach, i.e., to call every finite set a natural number. Both approaches—considering the universal infinite-dimensional separable Hilbert space or the category **Hilb** as the natural numbers—are fruitful, as we will see. To distinguish them, we will speak of the *internal* and *external natural numbers*, respectively, because in the latter case they are a subcategory of **H** but not an object in **H**.

Remark 3: There is still another approach to natural numbers in **H**, *namely trying to mimick the definition of a so-called natural numbers object of topos theory (see Ref. 7). We do not follow this approach explicitly here because in the case of* **H** *it is a little bit clumsy and in the end leads to considering* $\mathcal{N}$ *as the natural numbers, too.*

Let us now go on to consider an analog of the complex numbers (we use the internal natural numbers for this). Considered purely as a set, the complex numbers are isomorphic to the set of functions from $\mathbb{N}$ to $\mathbb{N}$ (because they have the same cardinality). In **H** this means that the purely set theoretic structure should be given by the space of linear operators on $\mathcal{N}$. Now, the complex numbers are, of course, not only a set but they carry an algebraic structure of addition and multiplication. On

$$\mathrm{Hom}_{\mathbf{H}}(\mathcal{N},\mathcal{N}),$$

such a structure is naturally given by the sum and product of operators, so we take this. To be able to talk sensibly of complex numbers, one more structural element is needed, namely, an operation of taking real and imaginary parts (and thereby defining an operation of complex conjugation). But this again is possible in the operator algebra on $\mathcal{N}$ by taking the self-adjoint, respectively, anti-self-adjoint, part of an operator. So, the algebra of linear operators on $\mathcal{N}$ suggests itself as the counterpart of the complex numbers. As a consequence, the self-adjoint operators on $\mathcal{N}$ take the role of the reals.

Remark 4: The fact that the self-adjoint operators take the role of the reals in quantum set theory has also been noted in Refs. 12 and 14, but here it is a direct consequence of very simple set theoretic and algebraic arguments.

That the self-adjoint operators appear as the reals of **H** gives some justification for the practice of physicists to put an overcaret on the symbols when they quantize the corresponding theory. It is therefore a first very slight confirmation to the hope that quantum set theory might be useful as a tool for the quantization of physical systems. But only a very slight one, because we do not get a prescription for which equations between real numbers translate to the corresponding ones between operators (and in which form, i.e., the factor ordering problem). That not all equations can translate is clear from the fact that quantization is proved not to be a functor (see Ref. 15).

Remark 5: We can, of course, identify the natural numbers with the projection operators and the sum of two natural numbers with the sum of disjoint projection operators. In this way, we have an embedding of the natural numbers into the real ones, as we are used to from classical mathematics.

Observe that the separability of the Hilbert space is nearly automatic in this approach.

Remark 6: We did not care for analogs of negative numbers above, but these can, of course, be gained by applying the usual algebraic construction (see Ref. 16).

Remark 7: Considering set theory as universal, we should require that numbers are sets. This is a first example, where we get an enlargement of quantum set theory beyond **H** *to operator algebras (see Ref. 17 for a reference on their theory).*

Considering the operator algebra on a separable Hilbert space as the analog of the complex numbers is just what is done in noncommutative geometry, where in this way one regards noncommutative C^* algebras as the algebras of complex-valued functions on some quantum space (see Refs. 18, 19, the latter reference really gives a representation theorem for a special class of C^* algebras in terms of operator-valued functions on some discrete space). In the spirit of algebraic geometry, one can then develop geometry on these algebras.

There is one more number concept in quantum set theory, namely, the algebraic operations on **H** inducing the ones on **Hilb**. This is the analog of Cantor's cardinal arithmetic in classical set theory.

IV. MODULES, TOPOLOGICAL QUANTUM FIELD THEORY, AND THE VON NEUMANN HIERARCHY

Having introduced analogs of the number systems, the next step is to consider modules over these. We follow the approach based on the external natural numbers in this section because it proves to be especially fruitful here. Let us start with finite-dimensional modules over the natural numbers. This is just a collection of tuples of natural numbers subject to the laws of addition and scalar multiplication, i.e., in the case of quantum set theory we get tuples of finite-dimensional Hilbert spaces subject to the mentioned laws. And since we use a categorical approach, we should only require these laws up to an isomorphism (so, we have to introduce coherence conditions, in addition, to ensure that the iterative application of the laws is possible). There immediately is a concept of a map between tuples of finite-dimensional Hilbert spaces, namely, a tuple of linear operators. So, a finite-dimensional module over the natural numbers in quantum set theory can be understood as just what is called a finite-dimensional module category over **Hilb** (or a 2-vector space in the terminology of Refs. 8 and 20). The analog of general (not necessarily finite-dimensional) modules over the natural numbers are then general module categories over **Hilb**. In the same spirit we can consider module categories over **H**.

The fact that modules over the natural numbers turn into module categories over **Hilb** gives a precise meaning to the connection between categorification and quantization discussed in Refs. 8–10. Categorification just means looking at the structure from the perspective of quantum logic. We have explicitly seen this for modules and for rings, but it extends to other algebraic structures, too. The reason is that having a module concept, we can easily discover the group (and then monoid) concept by forgetting part of the structure or, alternatively, by considering symmetry actions on the module. It turns out this way that monoids in quantum set theory are just monoidal categories. In the same way we proceed to discover other algebraic structures. There is one case that should be specially mentioned here, namely, forgetting all of the operations of an algebraic structure. This leads to the underlying sets in the classical case. Here we get general categories in this way, which is somewhat surprising because we already introduced a quantum set notion. This is a feature of quantum set theory we already encountered in the case of number systems: Starting from different classical versions of one and the same concept, we may arrive at two different and not necessarily equivalent concepts in quantum set theory. (Observe that even in topos theory this already occurs, e.g., there the Cauchy and Dedekind reals do, in general, not agree; see Ref. 7). The quantum sets as objects of **H** constitute the basic level of logically defined sets, i.e., sets are understood as realizing the logic in an extensional sense. The quantum sets as general categories give the basic level of sets understood as carriers of algebraic structures in quantum set theory. Observe that the structures in the second case followed from the logically conceived sets because quantization by categorification was a consequence of our logically minded approach. In the past, e.g., in the early works of von Neumann, quantum sets were only considered from the logical perspective. We feel that it is a decisive prerequisite for applications of quantum set theory to decide clearly between the two different set versions. In the sequel, we will term them *quantum logic sets* and *quantum algebraic sets,* respectively, if it is not clear from the context which concept we refer to. We will see below that the link between categorification and quantization carries through even to the higher levels (in the sense of the von Neumann hierarchy) of quantum set theory.

In the same way as for the case of categorifications, we see that the approach of noncommutative geometry (where one uses the operator algebra on $\mathcal{N}$ as complex numbers) again means viewing structures from the perspective of quantum logic but this time structures involving the real or complex numbers instead of the natural numbers (module categories over **Hilb**) or set algebra (module categories over **H**). So, quantum set theory clarifies the relationship between noncommutative geometry and categorifications. The latter in spirit gives a discretized version of the former one. This puts, especially, stress on the question for categorifications of manifolds because manifolds in the case of noncommutative geometry are already known.

Categorifications are of special interest in the realm of (extended) topological quantum field theories (see Ref. 8 and the literature cited therein). (Extended) n-dimensional topological quantum field theories (TQFTs) are representations of the (extended) n-dimensional cobordism category in **Hilb** (or a possibly higher categorification thereof in the extended case). In quantum mechanics, studying the quantum counterpart of a classical system means studying the Hilbert space representations of its algebraic description. TQFT shows that for very large systems—like the cobordism categories—this scheme has to be enlarged: We have to allow for representations in a module category (**Hilb** is the prototype of a module category) or even higher categorification thereof (the question of giving a Hilbert space structure on such higher modules is dealt with in Refs. 8, 16 and 21). Quantum set theory sheds new light on this enlargement of the scheme: We have to allow for modules in quantum set theory instead of simple vector space structures only, i.e., for the quantized version of the structures. We will now see that this view carries through, even to the higher levels of categorification.

We have mentioned above that quantum set theory can be seen as describing the observation of a quantum system by a quantum system and the iteration of this process. Since we have seen that categorification means quantization of a structure, one suspects that higher categorifications should be linked to iterated quantization, i.e., to higher levels in the von Neumann hierarchy of quantum set theory. This is indeed true.

Climbing up the von Neumann hierarchy in classical set theory involves the application of the power set operation. But there is another possibility of viewing the von Neumann hierarchy, namely, as incorporating the universality requirement of set theory: Higher-order structures should themselves be interpretable as sets. From a quantum perspective the most important structure is surely the module one, since it defines the superposition structure of quantum theory itself. So, the next higher level should be seen as given by quantized module structures, i.e., by module categories. Remember that in Sec. I we have seen that in an internal view of quantum set theory the subspaces of a module are given by superpositions of subspace lattices. Therefore the power set approach, too, leads to a consideration of superposed module structures, as we do in a module category. It is then obvious how to proceed. We have to consider module structures over the weak 2-category of module categories (or better 2-Hilbert spaces) in the next step, i.e., weak module 2-categories. (For the notions of higher category theory see, e.g., Ref. 22. The notion of a weak n-category for $n \geqslant 4$ has long not been precise, but there are now different approaches available, see Refs. 23–26 and there is hope that they can be proved to be equivalent. We therefore feel free to proceed as if there were a single coherent concept.) In general, sets of the next higher level correspond to the module structures of the foregoing one, i.e., the finite part of the quantum von Neumann hierarchy is given by the tower of weak n-categories (with a module and Hilbert space structure). At the ω level (i.e., the level of the first infinite ordinal of classical set theory) we then reach weak ω categories.

Remark 8: The tower of weak ω categories gives the von Neumann hierarchy of the quantum logic sets. The von Neumann hierarchy of the quantum algebraic sets is given by considering categories in **Cat** *that are (weak) double categories (see Ref. 22), and proceeding in this way,* i.e., *we get the tower of weak n-tuple categories (we term the more general cubic version of higher categories as n-tuple categories and the spherical version as n-categories). At the ω level the monoidal globular categories (MGCs) of Batanin appear (see Refs. 25 and 27). From the perspective of quantum set theory, the difference between the two types of higher categorifications is therefore due to the two different set concepts. It would therefore be interesting to see applications of the cubic version in mathematical physics.*

We could now develop analogs of number systems on each level of the von Neumann hierarchy, e.g., on the second level we could consider the weak 2-category of weak 2-Hilbert spaces as natural numbers. The module structure preserving functors on an infinite-dimensional 2-Hilbert space with a countable base are then a candidate for complex numbers, and we could go on to consider categorifications of the algebraic structures appearing in noncommutative geometry (this is highly nontrivial in detail, of course, but the general direction is clear). We see a double role for categorification here: As we remarked above, on the first level it can be seen as a discrete version of the approach of noncommutative geometry. But since it is also the operation for climbing up the von Neumann hierarchy, on the higher levels the two approaches can be mixed. Nevertheless, the whole von Neumann hierarchy of quantum logic sets is constructed in a discretized version of quantum theory because we always consider analogs of modules over discrete rigs.

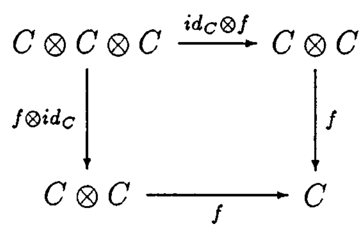
It is certainly an interesting task for future work to try to understand the analogs of the higher transfinite levels of the von Neumann hierarchy in quantum set theory. But for the moment we stop at the ω level and in the next section try to understand what we have reached so far from a still more unified perspective.

V. UNIVERSAL QUANTUM MECHANICS

We have seen in the last section that on quantizing the structure of quantum mechanics again (i.e., categorifying it), we get module categories instead of vector spaces, in the next step we come to weak module 2-categories, and so on. But the notion of a module can be given an abstract sense by formulating it in purely arrow language. For example, the notion of an object with an associative addition can be formulated in every monoidal category $\mathcal{C}$ with product $\otimes$ as an object C of $\mathcal{C}$ together with a morphism,

$$f: C\otimes C \rightarrow C,$$

making



commutative. To formulate the existence of a unit with respect to f, we have to use the unit with respect to $\otimes$. In this way we can define the notion of a ring in $\mathcal{C}$ and then a module structure over it. A module in the category **Cat** then is just a module category over some ring category while a usual module is one in **Set**. A 2-category with a module structure turns out to be a module in **2-Cat**, the category of 2-categories, and so on. There is one problem concerning this scheme: We get only the strict versions of the structures in this way (i.e., in the categorification the axioms of the algebraic structure are satisfied precisely and not only up to an isomorphism), e.g., we get a 2-category with a module structure and not a weak one. One can remedy this problem by taking the following standpoint: Together with the category $\mathcal{C}$ one should specify what commutativity of a diagram in $\mathcal{C}$ means. In the category **Cat**, which is actually a 2-category, it should mean commutativity up to natural transformations. In this way we could include the weak versions of the structures if there would not be the problem to specify the correct coherence conditions to be attached. From an abstract point of view, we can see the coherence conditions as the requirement that the laws of the structure—here the module axioms—should be iteratively applicable. The precise formulation of the conditions in a category $\mathcal{C}$ can then be a very nontrivial matter (as is known from higher-order categorifications), but it can be seen as belonging to precisely working out the concrete structure realized in $\mathcal{C}$ and not to the abstract concept of the structure (where only the existence of conditions giving coherence is required).

We can therefore subsume all the different iteratively categorified structures (i.e., all the different levels of quantum set theory) into one abstract structure concept by adding one additional postulate to conventional quantum mechanics:

Postulate (universality of quantum mechanics). Quantum mechanics is universal in the sense of category theory, i.e., we conceive of it as an abstract structure formulated in arrow language that can be concretely realized in every category $\mathcal{C}$ with a monoidal structure.

Remark 9: The work in Refs. 8, 16, and 21 on the categorification of the full Hilbert space structure shows also a way to formulate this structure in the abstract setting.

The postulate above may need some additional restriction in the sense that one has to be more specific about the ring (or rig) of scalars allowed. Certainly one should allow for the usual number systems and their categorifications, but one is less sure, e.g., concerning the p-adic numbers, though these now turn up from time to time in the physics literature.

A universality postulate for quantum mechanics frees one from the need to extend quantum mechanics to include axiomatic TQFT, i.e., we do not have to enlarge the class of kinematic structures appearing for quantum systems with each level of categorification. If we accept a universality postulate, we have once and for all one fixed abstract structure that has realizations in different categories $\mathcal{C}$. Just as we conclude from special properties of a group that we should, e.g., study its representations on an infinite-dimensional Hilbert space, we then have to conclude from the fact that we want to represent a weak n-category that we have to choose $\mathcal{C}$ as the weak $(n+1)$-category of weak n-categories in this case. We want to call the abstract structure referred to by the postulate above *universal quantum mechanics*.

Besides the concrete arguments mentioned, the postulate is certainly appealing from a principle perspective: Why should quantum mechanics be bound to the category **Set** of classical transfinite set theory? Do we not anyway believe that its principles are of an abstract algebraic nature independent of a set-theoretic base?

From the perspective of quantum set theory the universality postulate means that we can describe all levels of it in a single unified way.

VI. CONCLUSION

In this paper, we introduced the language and developed the fundamentals of a quantum set theory. We have seen that in this way we can understand the relationship between quantization and categorification and see that, indeed, categorification is quantization in the sense of shifting to a nonclassical set theory. We also understand the relationship to the view taken by noncommutative geometry in this way. Finally, we presented a suggestion of how to view the different levels of quantum set theory (i.e., the different categorifications) from a unified perspective.

In the second part of the work we will use the now established language to deal especially with the question of a categorification of the manifold notion.

ACKNOWLEDGMENTS

I want to thank Professor Dr. H. Grosse, Professor Dr. M. Reeken, and Professor Dr. E. Rosinger for discussions on the subjects involved. This work has been done during a stay at the Institute of Theoretical Physics of the University of Vienna and the Erwin Schrödinger Institute for Mathematical Physics, Vienna. The hospitality of both institutions is gratefully acknowledged. This work was made possible by a research grant under the *Gemeinsames Hochschulsonderprogramm III von Bund und Ländern* from the DAAD (German Academic Exchange Service).

(Received 8 October 1997; accepted for publication 11 December 1998)

We consider the Manev potential, given by the sum between the inverse and the inverse square of the distance, in an anisotropic space, i.e., such that the force acts differently in each direction. Using McGehee coordinates, we blow up the collision singularity, paste a collision manifold to the phase space, study the flow on and near the collision manifold, and find a positive-measure set of collision orbits. Besides *frontal homothetic*, *frontal nonhomothetic*, and *spiraling* collisions and ejections, we put into the evidence the surprising class of *oscillatory* collision and ejection orbits. Using the infinity manifold, we further tackle capture and escape solutions in the zero-energy case. By finding the connection orbits between equilibria and/or cycles at impact and at infinity, we describe a large class of capture-collision and ejection-escape solutions.
[S0022-2488(99)01903-9]

I. INTRODUCTION

The type of anisotropic problems we tackle in this paper have been defined by Gutzwiller[1] in the 1970s to find connections between classical and quantum mechanics. Gutzwiller considered the anisotropic Kepler problem, which was later extensively analyzed by Devaney[2] and by Casasayas and Llibre.[3] Here we add to these problems the anisotropic Manev two-body problem, which we call for short the *anisotropic Manev problem*. As we will see, the system of differential equations describing it has some surprising properties, unlike any kind of isotropic or anisotropic problems studied up to now.

The name Manev (or Maneff in French and German spelling) is connected to a gravitational model defined by a potential of the form $\alpha/r+\beta/r^2$, where r is the distance between particles and $\alpha,\beta>0$ are constants.[4] But this potential goes back to Newton, who first tackled it in *Principia*. In Book I, Article IX, Proposition XLIV, Theorem XIV, Corollary 2, Newton claims that it leads to a *precesionally elliptic* orbit. He introduced this potential to explain the apsidal motion of the moon, for which he found no reasonable argument in the framework of the inverse-square force law. It seems that Newton was more interested in this type of potential than it has been previously believed. The *Portsmouth Collection* of unpublished manuscripts contains several papers, written long after the publication of *Principia*, dedicated to the understanding of this attraction force.

In terms of a central-force problem, a precessionally elliptic orbit is one in which the particle moves on an ellipse that rotates in its plane of motion. The determination of this trajectory occurs as a problem in Goldstein's *Classical Mechanics* text. A formula for the solution is easy to obtain and has been known for a long time, but its complete physical picture was only recently understood[5] by using McGehee transformations and the qualitative theory of dynamical systems. The advantage of Manev's model over the Newtonian one is that it explains the perihelion advance of the inner planets with the same accuracy as relativity.[6]

Combining Gutzwiller's anisotropy with Manev's potential, we were led to the anisotropic Manev problem, described by a nonintegrable system of differential equations. In this paper, though far from obtaining a complete picture of the global flow, we settle some local and global questions and point out the main differences between this and the anisotropic Kepler problem. The object of our endeavors is to describe the flow near collision in the general case, the main features of the global flow in the zero-energy case, and to provide the physical interpretation of the solutions we encounter.

In Sec. II we define the problem and obtain the equations of motion. Then, in Sec. III, we put into the evidence the symmetries and note that they are similar to those of the anisotropic Kepler problem. In Sec. IV we blow up the singularities by using McGehee transformations and paste to the phase-space the so-called collision manifold, which is homeomorphic to a torus. Then we find out that the flow on the collision manifold is formed only by periodic orbits, except for the eight equilibria and the eight heteroclinic orbits that connect certain equilibria (see Fig. 1). This shows an important difference between this flow and that of the Kepler problems (isotropic and nonisotropic), in which the orbits are always increasing with respect to one of the variables, giving rise to heteroclinic orbits that connect the lower and upper equilibria of the collision manifold. Such transitions vanish naturally both in the isotropic and nonisotropic Manev problems.

In Sec. V we study the flow near the collision manifold and obtain the first main result that shows a sensitive difference between the physical motion in the anisotropic Manev and Kepler problems. Using a first-return-map argument we prove that for each periodic orbit belonging to the upper (lower) part of the collision manifold, there is a local two-dimensional analytic manifold of orbits ejecting from (tending to) it. The only periodic orbit for which both types of manifolds occur is the middle one, which separates the upper and lower set of periodic orbits. Physically, these manifolds correspond to *spiraling collisions*, i.e., solutions that eject from (tend to) a binary collision such that the particles spiral around each other infinitely many times after (before) contact; for these solutions the angular momentum is different from zero. This is like a ''black-whole effect'' (or an ''inverse black-whole effect'' in case of ejections), when the bodies do not simply collide in a straightforward manner, but one is absorbed by the other towards collision as in whirlpool in whose center stands one of the bodies [see Fig. 3(b)].

Other types of collision are given by those orbits that eject from (tend to) the equilibria. For each upper (lower) equilibrium there is a local one-dimensional unstable (stable) analytic manifold outside the collision manifold. Physically, these manifolds correspond to *frontal collisions*, i.e., solutions that eject from (tend to) collision such that the orbits of the two bodies have a common tangent. But even in this class of orbits we distinguish between *homothetic* and *nonhomothetic* solutions. The homothetic ones move on straight lines, whereas the nonhomothetic ones do not [see Fig. 3(a)].

But the most interesting solutions are those that eject from (tend to) the periodic orbits around the ''bumps'' of the collision manifold. Physically they correspond to *oscillatory collisions*; the orbit oscillates with smaller and smaller amplitudes when tending to collision, without tending to a definite direction, but remaining contained in a cone [see Fig. 3(c)]. This type of motion is unlike any other one encountered in the up-to-now studied two-body problems, isotropic or anisotropic. It obviously arises due to the combination between the Manev potential and the anisotropy of the space. It would be interesting to know if other types of potentials lead to such motions in an anisotropic space.

In Sec. VI we study the flow of the zero-energy level of the phase space. To determine the asymptotic behavior of the motion at infinity we define the so-called *infinity manifold*, which extends the phase space to contain infinity. Then we see that the flows on the zero-energy manifold and on the infinity manifold are *gradientlike*, which roughly means that they increase with respect to one of the variables. We find out that the infinity manifold has also eight equilibria (see Fig. 4) and show that there exist eight homothetic orbits connecting pairwise the lower and the upper equilibria of the collision manifold and the infinity manifold, respectively (see Fig. 5). Finally we describe the main features of the flow on the zero-energy manifold. We find connecting orbits between equilibria and/or cycles and give their physical interpretation in terms of capture-collision and ejection-escape orbits.

II. EQUATIONS OF MOTION

Consider the two-degrees-of-freedom Hamiltonian system of ordinary differential equations given by

$$\begin{cases} \dot{\mathbf{q}} = \mathbf{p} \\ \dot{\mathbf{p}} = \nabla W(\mathbf{q}), \end{cases} \tag{1}$$

where $\mathbf{q}=(q_1,q_2)$ and $\mathbf{p}=(p_1,p_2)$ denote the *configuration* and the *momentum* coordinates of a physical system of two particles. W is a *quasihomogeneous anisotropic potential*, given by

$$W(\mathbf{q}) = \frac{1}{\sqrt{\mu q_1^2 + q_2^2}} + \frac{b}{\mu q_1^2 + q_2^2},$$

where $\mu>0$ and $b>0$ are parameters. For example, in the astronomical applications of the classical Manev problem the parameter b is considered very small; of the order 10^{-10}. Equations (1) define the motion of two particles of unit mass in an anisotropic space, i.e., a space in which the attraction forces act differently in every direction. The above potential defines the anisotropy of the space as a function of the parameter μ. If $\mu<1$, the attraction is the weakest in the direction of the q_1-axis and the strongest in that of the q_2-axis, the situation being reversed if $\mu>1$. If $\mu=1$, the space is isotropic and we are in the case of the classical Manev problem, whose global phase-space structure was completely described in Ref. 5; therefore we will not deal with it here. Since both remaining cases have a weakest-force and a strongest-force direction, we can assume, without loss of generality, that $\mu>1$.

The Hamiltonian function of the system (1) is given by

$$H(\mathbf{p}(t),\mathbf{q}(t)) = (1/2)\|\mathbf{p}(t)\|^2 - W(\mathbf{q}(t)),$$

the sum of the kinetic and potential energies, which yields the integral of energy

$$H(\mathbf{p}(t),\mathbf{q}(t)) = h. \tag{2}$$

However, since the force ∇W is not central, the angular momentum $L(t)=\|\mathbf{p}(t)\times\mathbf{q}(t)\|$ is *not* an integral of the system, as it is in the classical (isotropic) Manev problem (see Ref. 5).

Since $W:\mathbb{R}\backslash\{\mathbf{0}\}\to\mathbb{R}$ is real analytic, standard results of differential-equation theory guarantee, for any initial data $(\mathbf{q}(0),\mathbf{p}(0))\in(\mathbb{R}\backslash\{\mathbf{0}\})\times\mathbb{R}$, the existence and uniqueness of an analytic solution defined on a maximal interval $[0,t^*)$, where $0<t^*\leqslant\infty$. If $t^*<\infty$, the solution is said to experience a *singularity*.

A particular type of singularity, called *collision*, occurs when $\mathbf{q}(t)\to\mathbf{0}$ as $t\to t^*$. In fact, by imitating the proof used in the classical Kepler problem,[7] we can show that in the anisotropic Manev problem all singularities are collisions. Solutions leading to collisions as well as those coming close to collisions are of particular interest because the whole qualitative structure of the phase space depends on their behavior. We will study these solutions starting with Sec. IV. The next section is devoted to the study of symmetries.

III. SYMMETRIES

The symmetries in the anisotropic Manev problem are the same as in the anisotropic Kepler problem (see Ref. 3). The elements of the group $\langle S_0,S_1,S_2\rangle$, generated by S_0, S_1, and S_2, map solutions of the anisotropic Manev problem into solutions. The generating elements of this group of symmetries are given by the formulas

$$S_0(q_1,q_2,p_1,p_2,t) = (q_1,q_2,-p_1,-p_2,-t),$$

$$S_1(q_1,q_2,p_1,p_2,t) = (q_1,-q_2,-p_1,p_2,-t),$$

$$S_2(q_1,q_2,p_1,p_2,t)=(-q_1,q_2,p_1,-p_2,-t).$$

Notice that the symmetry S_0 implies the reversibility of the flow.

Invariant sets are those which remain invariant under the flow, i.e., if the initial condition is in an invariant set, then the whole solution is in this set. Like in Ref. 3, we can prove that the above group of symmetries defines exactly two invariant planes for the anisotropic Manev problem. These planes are

$$\Pi_1=\{(q_1,0,p_1,0)|(q_1,p_1)\in(\mathbb{R}\backslash\{0\})\times\mathbb{R}\},$$

$$\Pi_2=\{(0,q_2,0,p_2)|(q_2,p_2)\in(\mathbb{R}\backslash\{0\})\times\mathbb{R}\}.$$

In each of these invariant planes the flow is given by a Hamiltonian system with one degree of freedom. For Π_1 the Hamiltonian function is $H_1(q_1,p_1)=p_1^2/2-1/\sqrt{\mu}|q_1|-b/\mu q_1^2$, and for Π_2 it is $H_2(q_2,p_2)=p_2^2/2-1/|q_2|-b/q_2^2$. The qualitative structure of the flow in each of these invariant planes is the same.

The phase plane is divided in two regions by the curves $p_1^2/2-1/\sqrt{\mu}|q_1|-b/\mu q_1^2=0$ and $p_2^2/2-1/|q_2|-b/q_2^2=0$, which represent the case $h=0$ for Π_1 and Π_2, respectively, where h is the energy constant. The outside region consists of solutions with $h>0$, whereas the inside region is filled with curves representing solutions with $h<0$. Each curve in the positive-energy region follows an asymptote; this is either $p_i=\sqrt{2h}$, if the curve belongs to the half-plane $p_i>0$, or $p_i=-\sqrt{2h}$, if the curve is in the half-plane $p_i<0$.

IV. THE COLLISION MANIFOLD

In the study of collision and near-collision solutions it is helpful to transform the system (1) using a method fully developed by McGehee.[8] The idea of the method is to ''blow-up'' the collision singularity, paste instead a manifold and extend the phase space to it. Of course, this manifold is fictitious, in the sense that the flow on it does not represent orbits that have correspondent in the physical reality. However, due to the continuity of the solutions with respect to initial data, knowing the flow on the collision manifold means to have information on nearby solutions, i.e., to know what the motion looks like near collision.

We first define the transformations of the dependent variables (phase space coordinates),

$$\begin{cases} r=\|\mathbf{q}\| \\ \theta=\arctan(q_2/q_1) \\ y=\dot{r}=(q_1p_1+q_2p_2)/\|\mathbf{q}\| \\ x=r\dot{\theta}=(q_1p_2-q_2p_1)/\|\mathbf{q}\|, \end{cases}$$

and

$$\begin{cases} v=ry \\ u=rx, \end{cases}$$

and then consider a transformation of the independent variable (time),

$$d\tau=r^{-2}dt.$$

Composing these transformations, which are analytic diffeomorphisms in their respective domains, the energy relation (2) becomes

$$u^2+v^2-2r\Delta^{-1/2}-2b\Delta^{-1}=2r^2h, \tag{3}$$

and the equations of motion (1) take the form

$$\begin{cases} r' = rv \\ v' = 2r^2h + r\Delta^{-1/2} \\ \theta' = u \\ u' = (1/2)(\mu-1)(r\Delta^{-3/2} + 2b\Delta^{-2})\sin 2\theta, \end{cases} \tag{4}$$

where $\Delta = \mu\cos^2\theta + \sin^2\theta$. The new variables $(r,v,\theta,u) \in (0,\infty)\times\mathbb{R}\times S^1\times\mathbb{R}$ depend on the fictitious time τ, so the prime here denotes differentiation with respect to the new independent variable τ. Note that Eqs. (4) extend analytically to $r=0$.

The symmetries S_0, S_1, S_2 in the new coordinates are changed into $\overline{S_0}$, $\overline{S_1}$, $\overline{S_2}$, where

$$\overline{S_0}(r,v,\theta,u,\tau) = (r,-v,\theta,-u,-\tau),$$

$$\overline{S_1}(r,v,\theta,u,\tau) = (r,-v,-\theta,u,-\tau),$$

$$\overline{S_2}(r,v,\theta,u,\tau) = (r,-v,\pi-\theta,u,-\tau).$$

Notice that the sets $\{(r,v,\theta,u)|r=0\}$ and $\{(r,v,\theta,u)|r>0\}$ are invariant manifolds for the Eqs. (4). The set

$$C = \{(r,v\,\theta,u)|r=0 \text{ and the energy relation (3) holds}\}$$

is called the collision-ejection manifold or simply the collision manifold. It replaces the set of singularities $\{(\mathbf{q},\mathbf{p})|\mathbf{q}=\mathbf{0}\}$ of the original system (1), with a two-dimensional manifold in the space of the new variables. This two-manifold is embedded in $\mathbb{R}^3\times S^1$ and is given by the equations

$$r=0 \quad \text{and} \quad u^2+v^2 = 2b\Delta^{-1}. \tag{5}$$

This shows that C is homeomorphic to a torus.

From now on we will work on a fixed *constant energy surface*,

$$\mathcal{E} = \{(r,v,\theta,u)|r>0 \text{ and the energy relation (3) holds}\}.$$

The system (4) does not have singularities on $\mathcal{E}_h \cup C$. The flow on C is fictitious, in the sense that it has no physical meaning, but—due to the continuity of the solutions with respect to the initial data—its structure gives information about the behavior of the nearby flow on constant energy manifolds, that is, information about collision and near-collision solutions.

The restriction of Eqs. (4) to C yields the system

$$\begin{cases} v' = 0 \\ \theta' = u \\ u' = b(\mu-1)\Delta^{-2}\sin 2\theta. \end{cases} \tag{6}$$

Since $v'=0$, the solutions of (6) lie on the level curves $v=$constant of the torus C. There are eight equilibrium points (*equilibria*) for the system (4). In the variables (r,v,θ,u), the first four of these equilibria are $A_0^{\pm} = (0,\pm\sqrt{2b/\mu},0,0)$ and $A_\pi^{\pm}(0,\pm\sqrt{2b/\mu},\pi,0)$. At these points the linearized system has the matrix

$$\begin{bmatrix} \pm\sqrt{2b/\mu} & 0 & 0 & 0 \\ 1/\sqrt{\mu} & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 2b(\mu-1)/\mu^2 & 0 \end{bmatrix},$$

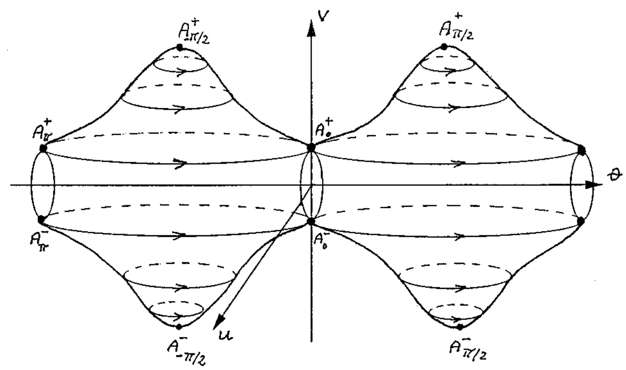

FIG. 1. The flow on the collision manifold, which shows that unlike the anisotropic Kepler problem, whose flow is gradient-like, the flow in the anisotropic Manev problem is formed by periodic orbits, four equilibria, and eight heteroclinic orbits.

the corresponding eigenvalues being real and taking the values, $\pm\sqrt{2b/\mu}$, 0, $\sqrt{2b(\mu-1)/\mu}$, and $-\sqrt{2b(\mu-1)/\mu}$. The other four equilibria are $A^{\pm}_{\pm\pi/2}=(0,\pm\sqrt{2b},\pm\pi/2,0)$ and the linearized system at these points is given by the matrix

$$\begin{bmatrix} \pm\sqrt{2b} & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 2b(1-\mu) & 0 \end{bmatrix},$$

the corresponding eigenvalues being $\pm\sqrt{2b}$, 0, $\sqrt{2b(1-\mu)}$, and $-\sqrt{2b(1-\mu)}$, where the $\pm$ sign corresponds to the upper index of *A*. Since $\mu>1$, the last two eigenvalues are purely imaginary.

There are eight *heteroclinic* orbits (i.e., orbits connecting two distinct equilibria) which lie in the level sets $v=\pm\sqrt{2b/\mu}$. All the other solutions are periodic (see Fig. 1). Hence the structure of the flow on the collision manifold is fairly simple but it differs from that of the anisotropic Kepler problem (compare with Ref. 3).

Our next goal is to understand the flow and the physical behavior of the motion near the collision manifold. We will see that the flow outside the collision manifold also differs drastically from the flow of the anisotropic Kepler problem.

V. THE FLOW NEAR THE COLLISION MANIFOLD

For a fixed value of *h*, the constant-energy surface $\mathcal{E}_h$ is a three-dimensional manifold, invariant under the flow of the system (4) and whose boundary is the two-dimensional collision manifold *C*. All of this is embedded in the four-dimensional (r,θ,u,v)-space. Let us denote by P_η the periodic orbit on *C* having $v=\eta$, i.e.,

$$P_\eta=\{(r,v,\theta,u)|r=,v=\eta\}.$$

Notice that for each $\eta\in(\sqrt{2b/\mu},\sqrt{2b})\cup(-\sqrt{2b},-\sqrt{2b/\mu})$ there are two periodic orbits whose angular coordinate θ varies in different domains (see Fig. 1). However, as long as there is no danger for confusion, we will denote each of them by the same P_η.

Using this notation we can now prove the following result which summarizes the behavior close to the total collision manifold.

Theorem 5.1: *On the collision manifold C the equilibria $A^{\pm}_0$ and $A^{\pm}_\pi$ are saddles, whereas the equilibria $A^{\pm}_{\pm\pi/2}$ are centers. Outside the collision manifold the equilibria A^+_0, $A^+_{\pm\pi/2}$, and A^+_π have a one-dimensional unstable analytic manifold, whereas the equilibria A^-_0, $A^-_{\pm\pi/2}$, and A^-_π*

have a one-dimensional stable analytic manifold. Each periodic orbit P_η on C with $v=\eta>0(v=\eta<0)$ has a two-dimensional local unstable (stable) analytic manifold, while the periodic orbit $v=0$ has both a two-dimensional local unstable and a two-dimensional local stable manifold.

Physical interpretation. Before proceeding with the proof, we will give the physical interpretation of the solutions described above. As we mentioned earlier, the orbits on the collision manifold have no physical meaning, so we will deal only with those existing outside the collision manifold. The solutions tending to (ejecting from) the equilibria represent collision (ejection) orbits which have a common tangent at collision, here the limiting angular momentum of the solution is zero; we will call them *frontal collisions (ejections)* or just *frontal collisions*, for short.

It is important to distinguish here between two types of frontal collisions (ejections): the *homothetic* and the *nonhomothetic* ones. In the physical plane (q_1,q_2), the homothetic orbits move on straight lines; on the q_1 axis for $A_\pi^\pm$ and on the q_2 axis for $A_0^\pm$. The nonhomothetic ones have a different behavior. For example, there exist orbits ending at A_π^- that will pass first close to A_0^- (see Fig. 2). In physical space such an orbit comes close to a collision [see Fig. 3(a)], departs from it, then returns to a collision from the negative part of the q_1 axis, and such that the axis is tangent to the orbit at the collision point (the origin of the q_1q_2 frame). For $h=0$ this kind of solutions form a large class of collision orbits as we will see in Sec. VI.

Let us now describe the physical interpretation of orbits tending to (ejecting from) the cycles of the collision manifold. Here we have to distinguish between two classes of solutions. First are those concerning the cycles for which $v\in(-\sqrt{2b/\mu},\sqrt{2b/\mu})$. They represent collision (ejection) orbits that spiral infinitely many times without tending to a definite direction. We will call them *spiraling collisions (ejections)*. The respective angular momentum is always different from zero. In physical space they look like Fig. 3(b).

The orbits concerning cycles on the ''bumps,'' for which $v\in(-\sqrt{2b},-\sqrt{2b/\mu})$ or $v\in(\sqrt{2b/\mu},\sqrt{2b})$, have an oscillatory behavior, therefore we will call them *oscillatory collisions (ejections)*. To understand this class of orbits, consider a cycle with $v\in(-\sqrt{2b},-\sqrt{2b/\mu})$ and $\theta>0$. In Fig. 2, the intersection of the plane $Ov\theta$ (i.e., $u=0$) with this cycle corresponds to two values of the angular momentum (say θ_1 and θ_2, symmetric with respect to the q_2 axis). The angular momentum θ of an orbit tending to this cycle will have, at $u=0$, values smaller than θ_1 and larger than θ_2. Since when the particle tends to collision, r tends to 0, the physical orbit will oscillate, as in Fig. 3(c) intersecting the lines *ON* and *OM* corresponding to θ_1 and θ_2. After infinitely many oscillations outside the cone *MON*, the particle will collide with the origin. It is remarkable to mention that oscillatory collisions do not occur in any of the Manev problem, Kepler problem, or anisotropic Kepler problem, so this unintuitive type of motion is characteristic to the anisotropic Manev problem. It would be interesting to know if any other potentials lead to such collisions in an anisotropic space.

Proof of Theorem 5.1: The part of the theorem concerning the equilibria is obvious from the

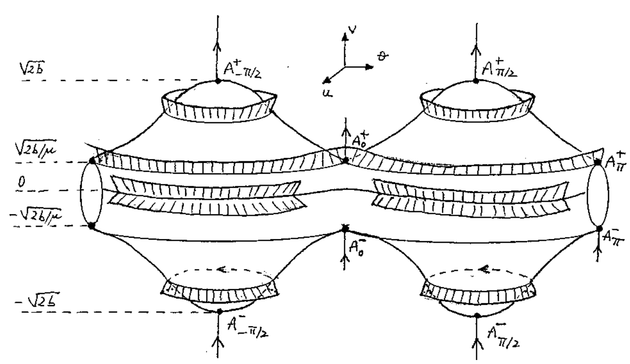

FIG. 2. The flow of the anisotropic Manev problem can reach the collision manifold at the equilibria or at any of the periodic orbits, unlike in the anisotropic Kepler problem in which the collision manifold can be reached only at equilibria.

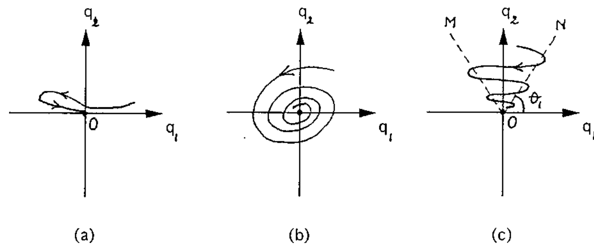

FIG. 3. Different types of collision orbits. (a) Nonhomothetic frontal collision; (b) spiralling collision; (c) oscillatory collision.

study of the eigenvalues done at the end of the previous section, so we need to deal now only with the periodic solutions P_η. For this we will distinguish between two different cases. We will first deal with the periodic orbits that go around the whole collision-manifold torus, i.e., those periodic orbits with $|\eta|<\sqrt{2b/\mu}$, and then with the orbits circling only the ''bumps'' of the collision manifold, i.e., those for which $\sqrt{2b/\mu}<|\eta|<\sqrt{2b}$. In each case we will construct the *first return map* and determine its qualitative behavior.

The first and second equations of (4) show that for small values of r the variable v is increasing. Also notice that r is decreasing in the region $v<0$ and is increasing in the region $v>0$.

We first consider the case when $0<\eta<\sqrt{2b/\mu}$. Let us fix such an η and an initial value for $\theta(0)=\theta_0$. Then, by the continuity of the flow, there is a neighborhood V of $(r,v)=(0,\eta)$ in $[0,\infty)\times\mathbb{R}$ such that every solution with initial conditions $\theta(0)=\theta_0$, $(r_0,v_0)\in V$, satisfies $\eta/2<v(t)<\frac{1}{2}(\eta+\sqrt{2b/\mu})$. For these solutions, $\theta(t)$ can be treated as the independent variable, since $\theta'=u$ and $u\neq 0$ by shrinking the neighborhood V if necessary. In this case system (4) is equivalent to the *nonautonomous* system,

$$\begin{cases} \dfrac{dr}{d\theta}=\dfrac{r'}{\theta'}=\dfrac{rv}{\sqrt{2r^2h+2r\Delta^{-1/2}+2b\Delta^{-1}-v^2}}, \\ \dfrac{dv}{d\theta}=\dfrac{v'}{\theta'}=\dfrac{2r^2h+r\Delta^{-1/2}}{\sqrt{2r^2h+2r\Delta^{-1/2}+2b\Delta^{-1}-v^2}}, \end{cases} \tag{7}$$

where $u(\theta)$ is recovered by using the energy relation (3).

The solutions to (7) form an analytic function

$$\Psi: V\times(\theta_0-\epsilon,\theta_0+2\pi+\epsilon)\to\mathbb{R}^2, \quad (r_0,v_0,\theta)\mapsto(r(\theta),v(\theta)),$$

where $r(\theta)$ and $v(\theta)$ are the solutions determined by r_0, v_0, and θ_0.

The first return map ψ is analytic and can be written as

$$\psi(r_0,v_0)=\begin{bmatrix}\psi_1(r_0,v_0)\\ \psi_2(r_0,v_0)\end{bmatrix}. \tag{8}$$

Of interest are the eigenvalues of $D\psi(r_0,v_0)$. This matrix can be calculated from the variational equations of system (7) along the periodic orbit. After some tedious computations we get the matrix

$$D\psi(0,\eta)=\begin{bmatrix}\dfrac{\partial\psi_1}{\partial r}(0,\eta) & 0\\ \dfrac{\partial\psi_2}{\partial r}(0,\eta) & 1\end{bmatrix}, \tag{9}$$

where $(\partial\psi_1/\partial r)(0,\eta)$ and $(\partial\psi_2/\partial r)(0,\eta)$ remain to be determined. The zero entry ensures that the eigenvalues of $D\psi|_{(0,\eta)}$ are 1 and $(\partial\psi_1/\partial r)(0,\eta)$. To draw the desired conclusion, we need an estimate on $(\partial\psi_1/\partial r)(0,\eta)$.

Now, the denominators in (7) are bounded on $V\times(\theta_0-\epsilon,\theta_0+2\pi+\epsilon)$, so there exists an $M>0$ such that

$$\frac{dr}{d\theta}\geqslant Mr(\theta)v(\theta)\geqslant\frac{M\eta}{2}r(\theta), \tag{10}$$

for $\theta\in[0,2\pi]$ and for all solutions $(r(\theta),v(\theta))$ starting in V. Integration with respect to θ from 0 to 2π yields the inequality

$$\psi_1(r_0,v_0)\geqslant r_0e^{M\pi v_0},$$

for all $(r_0,v_0)\in V$.

We further need the following Tauberian lemma: If $f(x)\geqslant Kx$, *where K is a constant, and* $f(0)=0$, *then* $f'(0)\geqslant K$. The proof of this lemma is obvious since $f'(0)=\lim_{h\to0^+}[f(h)-f(0)]/h=\lim_{h\to0^+}[f(h)/h]\geqslant K$.

Fix now v_0. Then, since $\psi_1(0,v_0)=0=0\cdot e^{M\pi v_0}$, by the above Tauberian lemma the slope of the curve $r_0\mapsto\psi_1(r_0,v_0)$ at $r_0=0$ is greater than that of $r_0\mapsto e^{M\pi v_0}\cdot r_0$. This is equivalent to

$$\frac{\partial}{\partial r}\psi_1\bigg|_{(0,v_0)}\geqslant e^{M\pi v_0}>1, \tag{11}$$

the last inequality being true for all $(r,v)\in V$. Thus, the periodic orbit P_η has a two-dimensional analytical unstable manifold of orbits that eject outside C. The analyticity of these invariant submanifolds follows if using a recent result by Cabré and Fontich (Theorem 4.1 in Ref. 9). This shows that the limiting behavior at collision depends analytically on the initial conditions. With a similar argument we can prove that for $-\sqrt{2b/\mu}<\eta<0$,

$$\frac{\partial\psi_1}{\partial r}(0,\eta)\leqslant e^{M\eta\pi}<1, \tag{12}$$

and so the corresponding periodic orbit P_η has a stable analytic manifold of orbits approaching it. These orbits represent solutions in which a collision (or ejection) occurs as the particles spin around each other, in contrast to the classical Newtonian case in which collisions are frontal, i.e., the particles asymptotically approach each other radially, following ultimately a definite direction.

We will now see what happens in the case $\eta=0$. For this we will apply a generalization of a theorem due to Casasayas, Fontich, and Nunes.[10]

Let $F=(F_1,F_2)$ *be an analytic function from a neighborhood of* $(0,0)$ *in* $\mathbb{R}^2$ *to* $\mathbb{R}^2$, *such that*

(*i*) $F(0,v)=(0,v)$,
(*ii*) $DF(0,0)=\begin{pmatrix}1&0\\c&1\end{pmatrix}$ *with* $c>0$,
(*iii*) $\alpha=D_rD_vF_1(0,0)>0$.

Then there exists stable and unstable manifolds of $(0,0)$ *which are, locally, graphs of analytic functions, that is,* $W^s_{loc}(\delta)=\{(\varphi^s(v),v)|v\in(-\delta,0)\}$ *and* $W^u_{loc}(\delta)=\{(\varphi^u(v),v)|v\in(0,\delta)\}$, *where* $\varphi^{s,u}\sim(\alpha/2c)v^2$. (By W^s_{loc} and W^u_{loc} we have denoted the *local stable manifold* and the *local unstable manifold*, respectively.) At $v=0$ *the functions* $\varphi^{s,u}$ *are only Lipschitz in general*.

The proof of this result follows identically the one in Ref. 10, the only difference being that in that paper the value of the constant c equals 1. This more general result is obtained by a linear transformation of coordinates. We will prove now that the conditions of this theorem are fulfilled by our first return map ψ, which is also defined by $v_0=0$ with a conveniently chosen domain.

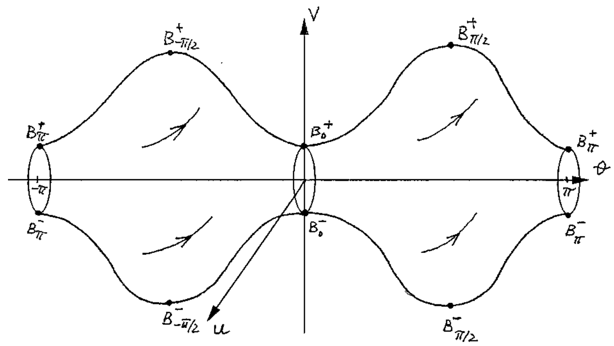

FIG. 4. The flow on the infinity manifold.

Now, the solutions starting at $(r,v)=(0,v_0)$ are periodic, so (i) is clearly satisfied. Straightforward computations in the variational equations of (7) show that

$$c=\frac{\partial}{\partial r}\psi_2\bigg|_{(0,0)}>0,$$

and from (11) and (12) we know that

$$\lim_{v_0\to 0^+}\frac{\partial}{\partial r}\psi_1\bigg|_{(0,v_0)}\geqslant 1$$

and that

$$\lim_{v_0\to 0^-}\frac{\partial}{\partial r}\psi_1\bigg|_{(0,v_0)}\leqslant 1.$$

The analyticity of ψ_1 implies that the common limit should be 1, so (ii) is fulfilled. For (iii) we have

$$\alpha=D_rD_v\psi_1(0,0)=\lim_{v_0\to 0^+}\frac{D_r\psi_1(0,v_0)-D_r\psi_1(0,-v_0)}{2v_0}\geqslant\lim_{v_0\to 0^+}\frac{e^{M\pi v_0}-e^{-M\pi v_0}}{2v_0}=M\pi>0.$$

The second equality follows again by the analyticity of ψ_1. This means that each of the two periodic orbits P_η with $\eta=0$ have both a stable manifold of approaching orbits and an unstable manifold of ejecting orbits.

To complete the proof, let us now describe the flow near a periodic solution P_η with $\sqrt{2b/\mu}<\eta<\sqrt{2b}$ and $\theta>0$. (The case with $\theta<0$ or $-\sqrt{2b}<\eta<-\sqrt{2b/\mu}$ is similar.) We start by shifting the origin of the frame from 0 to $\pi/2$ and change the variable θ to a variable ϕ. When moving from 0 to 2π, the new angular variable ϕ rotates around the v-axis, which now goes through $A^+_{\pi/2}$ instead of A_0 (see Fig. 4), such that it allows us to describe only the periodic orbits P_η with $v>\sqrt{2b/\mu}$ and $\theta>0$. This is done by defining the transformation

$$\begin{cases} u=w\sin\phi,\\ \theta=\dfrac{\pi}{2}+w\cos\phi. \end{cases}$$

With this transformation the system (4) changes to

$$\begin{cases} r' = rv, \\ v' = 2r^2 h + r\tilde{\Delta}^{-1/2}, \\ \phi' = -\sin^2\phi + (1/2)(\mu-1)w^{-1}(r\tilde{\Delta}^{-3/2} + 2b\tilde{\Delta}^{-2})\cos\phi\sin(2w\cos\phi), \\ w' = (1/2)(\mu-1)(r\tilde{\Delta}^{-3/2} + 2b\tilde{\Delta}^{-2})\sin\phi\sin(2w\cos\phi) + w\sin\phi\cos\phi, \end{cases} \tag{13}$$

and the energy relation becomes

$$w^2\sin^2\phi + v^2 - 2r\tilde{\Delta}^{-1/2} - 2b\tilde{\Delta}^{-1} = 2r^2 h, \tag{14}$$

where $\tilde{\Delta} = \mu\sin^2(w\cos\phi) + \cos^2(w\cos\phi)$.

Now, proceed as in the other case. In an appropriate neighborhood of the periodic orbit, we have $\phi' \neq 0$, so the nonautonomous system

$$\begin{cases} \dfrac{dr}{d\phi} = \dfrac{r'}{\phi'}, \\ \dfrac{dw}{d\phi} = \dfrac{v'}{\phi'}, \end{cases}$$

is analytic in that neighborhood, where the energy relation (14) is used to recover w (the positive root). Using the same methods as before, the matrix

$$D\Phi(0,\eta) = \begin{bmatrix} \dfrac{\partial\Phi_1}{\partial r}(0,\eta) & 0 \\ \dfrac{\partial\Phi_2}{\partial r}(0,\eta) & 1 \end{bmatrix} \tag{15}$$

is the derivative of the Poincaré map $\Phi(r,v)$ on the section $\phi=0$. The right column is the same as in (9) because again r' and v' are multiples of r. Since ϕ' is bounded, the same inequalities as the ones used for $(dr/d\theta)$ show that $(\partial\Phi_1/\partial r)(0,\eta) > 1$ for $\sqrt{2b} < \eta < \sqrt{2b/\mu}$. So each periodic solution with $\sqrt{2b} < \eta < \sqrt{2b/\mu}$ has an unstable manifold of ejecting solutions. Similarly each solution with $-\sqrt{2b/\mu} < \eta < -\sqrt{2b}$ has a stable manifold of approaching solutions, in which the angular momentum oscillates, and the particles stay within an acute angle from the weak axis of the force. This completes the proof of the theorem.

An obvious consequence of Theorem 5.1 is the following:

Corollary 5.2: The set of initial data leading to collisions has positive measure. More precisely, the set of initial data leading to frontal collisions has zero measure, whereas each of the sets of initial data leading to spiraling and oscillatory collisions, respectively, have positive measure.

We will further consider the zero-energy manifold and in what remains of this paper will give a qualitative description of the flow in this particular case.

VI. THE ZERO-ENERGY MANIFOLD

In this section we will study the flow on $\mathcal{E}_0$, i.e., the case of the zero energy level, $h=0$, and compare the flow on the collision manifold with the one on the so-called *infinity manifold*, which we define below. In order to understand the global flow we will analyze the invariant submanifolds associated to the equilibrium points and to the periodic orbits on the collision manifold, as well as their connection orbits.

A. Infinity manifold and homothetic orbits

Let us start by describing a characteristic property of the flow on $\mathcal{E}_0$. For this, we need the following definition:[11]

Definition 6.1: A flow is called *gradientlike* with respect to one of the coordinates, if every nonequilibrium solution increases on that coordinate.

With this definition we can now prove the following:

Lemma 6.2: The flow on $\mathcal{E}_0$ is gradientlike with respect to the v-coordinate.

Proof: For $h=0$, the second equation in (4) shows that $v'>0$ for all values of θ.

To study the asymptotic behavior at infinity, we will apply a suitable blow-up transformation. Since the potential is a *quasihomogeneous function* (i.e., the sum of homogeneous functions of different degrees[12]), this transformation is slightly different from the one used in the case of the collision. This is because the term of degree -1 predominates when $t\to\infty$.

Taking $h=0$ and $\rho=1/r$, Eqs. (4) become

$$\begin{cases} \rho' = -\rho v, \\ v' = \rho^{-1}\Delta^{-1/2}, \\ \theta' = u, \\ u' = [(\mu-1)/2](\rho^{-1}\Delta^{-3/2} + 2b\Delta^{-2})\sin 2\theta, \end{cases} \tag{16}$$

and the energy relation takes the form

$$\rho(u^2+v^2) - 2\Delta^{-1/2} - 2b\rho\Delta^{-1} = 0. \tag{17}$$

Rescaling the velocities by using the transformations $\overline{v}=\rho^{1/2}v$, $\overline{u}=\rho^{1/2}u$, and rescaling the (independent) time variable by defining the transformation $d\tau=\rho^{1/2}ds$, Eqs. (16) take the form

$$\begin{cases} \dot{\rho} = -\rho\overline{v}, \\ \dot{\overline{v}} = -(1/2)\overline{v}^2 + \Delta^{-1/2}, \\ \dot{\theta} = \overline{u}, \\ \dot{\overline{u}} = -(1/2)\overline{v}\,\overline{u} + [(\mu-1)/2](\Delta^{-3/2} + 2b\rho\Delta^{-2})\sin 2\theta, \end{cases} \tag{18}$$

where the dot denotes differentiation with respect to the new (fictitious) time variable s. In the new coordinates the energy relation becomes

$$\overline{u}^2 + \overline{v}^2 - 2\Delta^{-1/2} - 2b\rho\Delta^{-1} = 0. \tag{19}$$

Analogously to the collision manifold, we define the *infinity manifold* I,

$$I\{(\rho,\overline{v},\theta,\overline{u}) \mid \rho=0 \text{ and } \overline{u}^2+\overline{v}^2 = 2\Delta^{-1/2}\},$$

which is also homeomorphic to a torus (see Fig. 4).

The flow on I is given by

$$\begin{cases} \dot{\overline{v}} = (1/2)\overline{u}^2, \\ \dot{\theta} = \overline{u}, \\ \dot{\overline{u}} = -(1/2)\overline{v}\,\overline{u} + [(\mu-1)/2]\Delta^{-3/2}\sin 2\theta. \end{cases} \tag{20}$$

As in the case of the collision manifold, the flow on the infinity manifold is fictitious in the sense that it has no physical meaning. But once again, using the continuity of the solutions with respect to the initial data, the structure of the flow on the infinity manifold will allow us to draw conclusions about the behavior of the flow near infinity. Therefore, let us now study the flow on I.

There are eight equilibrium points on the infinity manifold I, which, in the new $(\overline{v},\theta,\overline{u})$-coordinates, have the form $B_0^{\pm}=(\pm\sqrt{2\mu^{-1/2}},0,0)$, $B_\pi^{\pm}=(\pm\sqrt{2\mu^{-1/2}},\pi,0)$, and $B_{\pm\pi/2}^{\pm}=(\pm\sqrt{2},\pm\pi/2,0)$. We can now show that the flow on I is fairly simple.

Lemma 6.3: The flow on I is gradient like with respect to the $\overline{v}$-coordinate.

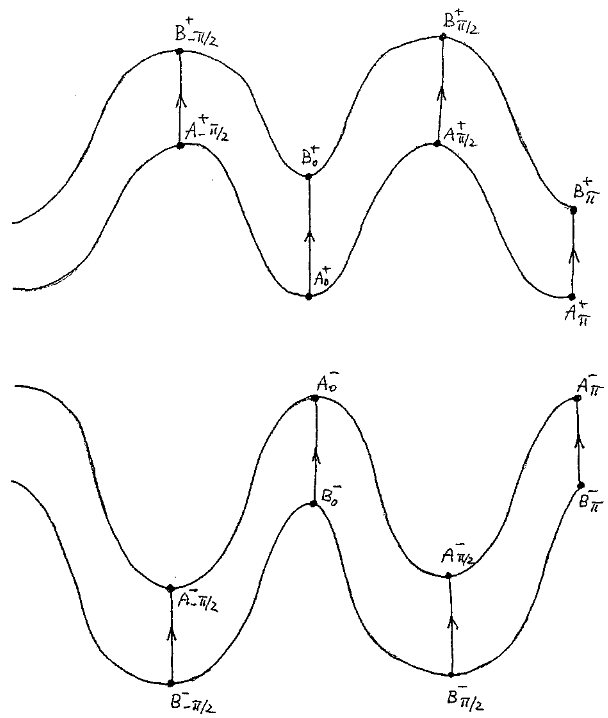

FIG. 5. Homothetic orbits connecting the collision and the infinity manifolds.

Proof: From the first equation of system (20) we see that $\dot{\bar{v}}\geqslant 0$. If $\dot{\bar{v}}=0$, then $\bar{u}=0$, so $\ddot{\bar{v}}=\bar{u}\dot{\bar{u}}=0$. But $\dddot{\bar{v}}=\dot{\bar{u}}^2+\bar{u}\ddot{\bar{u}}=\dot{\bar{u}}^2$, which is 0 only at the equilibria and is positive otherwise. This completes the proof.

We now define the notion of a *central configuration*, a concept that plays an important role both in the Newtonian case as well as in the one considered here.

Definition 6.4: The configuration q_0 is called central if $\nabla W(q_0)$ is parallel to q_0. An orbit such that the position is a homothety to q_0 is called a homothetic orbit.

The following proposition shows the existence of homothetic orbits in the anisotropic Manev problem.

Proposition 6.5: There exist eight orbits connecting the respective equilibrium points on the collision manifold C to the ones on the infinity manifold I.

Proof: Recall that the equilibrium points are defined in each of the blow-up coordinate systems, at collision and at infinity. This defines two different charts, carrying in each case the corresponding time scales for the differential equations (see Fig. 5).

In the chart containing the infinity manifold *I*, the homothetic orbits are given by the equations,

$$\dot{\rho}=-\rho\bar{v},\quad \dot{\bar{v}}=-\tfrac{1}{2}\bar{v}^2+\mu^{-(1/2)},\quad \text{if}\quad \theta=0\quad \text{or}\quad \theta=\pi,\quad \bar{u}=0,$$

$$\dot{\rho}=-\rho\bar{v},\quad \dot{\bar{v}}=-\tfrac{1}{2}\bar{v}^2+1,\quad \text{if}\quad \theta=\pm\pi/2,\quad \bar{u}=0.$$

In the chart containing the collision manifold *C*, the homothetic orbits are given by the equations

$$r'=rv,\quad v'=v^2-\mu^{-(1/2)}r-2b\mu^{-1},\quad \text{if}\quad \theta=0\quad \text{or}\quad \theta=\pi,\quad u=0,$$

$$r'=rv,\quad v'=v^2-r-2b,\quad \text{if}\quad \theta=\pm\pi/2,\quad u=0.$$

Using the energy relation and correspondingly changing the time scales, by straightforward computation we see that the set of eight orbits described in the infinity-manifold chart is identical to the eight orbits described in the collision-manifold chart. This completes the proof.

Remark: Notice that the α- and ω-limits of the four homothetic orbits described above are equilibrium points on C and I.

To describe the global flow in the zero-energy case, notice that, on $\mathcal{E}_0$, the flow is gradient-like with respect to the v coordinate, but it is gradient-like with respect to $\overline{v}$ only on the infinity manifold I, not on $\mathcal{E}_0$. Moreover, the so-called *zero velocity curve* is empty. This is easy to see, for the zero velocity curve is defined as the set of phase-space points for which the momentum coordinate p is zero in the energy relation (2). In McGehee coordinates this corresponds to taking $v=0$ and $u=0$ in the energy relation (3).

Recall from Theorem 5.1 that for each $\eta \neq \pm\sqrt{2b/\mu}$, the periodic orbit P_η has, at least locally, a two-dimensional stable (unstable) manifold if $\eta<0$ ($\eta>0$); if $\eta=0$, then P_0 has both a stable and an unstable two-dimensional submanifold. Also recall that, without loss of generality, we can take $\mu>1$.

Due to the gradient-like structure of the global flow on $\mathcal{E}_0$, the invariant manifolds corresponding to periodic orbits P_η with $\eta\leqslant 0$ cannot intersect invariant manifolds corresponding to periodic orbits P_η with $\eta\geqslant 0$.

B. The local structure

Before going deeper into the global structure of the flow on $\mathcal{E}_0$, we have to analyze the hyperbolic character of the equilibrium points. The computations are set in McGehee coordinates for the equilibrium points belonging to the total collision manifold C and in infinity-blow-up coordinates for those belonging to the infinity manifold I.

We begin with McGehee coordinates. From the energy relation (3), for $h=0$ we obtain

$$r=(1/2)(u^2+v^2)\Delta^{1/2}-b\Delta^{-1/2}.$$

Substituting r in the equations of motion (4) in McGehee coordinates, we obtain the system

$$\begin{cases} v'=(1/2)(u^2+v^2)-b\Delta^{-1}, \\ \theta'=u, \\ u'=[(\mu-1)/4][(u^2+v^2)\Delta^{-1}+2b\Delta^{-2}]\sin 2\theta. \end{cases} \tag{21}$$

The matrix of the attached linear system of variables (v,θ,u), at the equilibrium points $A_0^\pm=(\pm\sqrt{2b/\mu},0,0)$ and $A_\pi^\pm=(\pm\sqrt{2b/\mu},\pi,0)$, is

$$\begin{bmatrix} \pm\sqrt{2b/\mu} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 2b(\mu-1)/\mu^2 & 0 \end{bmatrix},$$

and has the eigenvalues $\lambda_1=\pm\sqrt{2b/\mu}$, $\lambda_2=\sqrt{2b(\mu-1)}/\mu$, $\lambda_3=-\sqrt{2b(\mu-1)}/\mu$, which, since $\mu>1$, shows that these equilibrium points are hyperbolic. The equilibria A_0^- and A_π^- have a two-dimensional stable manifold and a one-dimensional unstable manifold, whereas the equilibria A_0^+ and A_π^+ have a one-dimensional stable manifold and a two-dimensional unstable manifold.

The matrix of the attached linear system of variables (v,θ,u), at the equilibrium points $A^\pm_{\pm\pi/2}=(\pm\sqrt{2b},\pm\pi/2,0)$ is

$$\begin{bmatrix} \pm\sqrt{2b/\mu} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -2b(\mu-1) & 0 \end{bmatrix},$$

with eigenvalues $\lambda_1=\pm\sqrt{2b}$, $\lambda_2=i\sqrt{2b(\mu-1)}$, and $\lambda_3=-i\sqrt{2b(\mu-1)}$. This is in agreement with the fact that these equilibria are α- or ω-limits of the corresponding homothetic orbits and that the structure of the flow restricted to the collision manifold proves them to be centers. So these equilibrium points are *not* hyperbolic.

We pass now to the infinity-blow-up coordinates. For $h=0$, the corresponding energy relation (19) is equivalent to

$$2\rho b=(\overline{u}^2+\overline{v}^2)\Delta-2\Delta^{1/2}.$$

Substitution of ρ in Eqs. (18) gives

$$\begin{cases} \dot{\overline{v}}=-(1/2)\overline{v}^2+\Delta^{-1/2}, \\ \dot{\theta}=\overline{u}, \\ \dot{\overline{u}}=-(1/2)\overline{v}\,\overline{u}+[(\mu-1)/2][(\overline{v}^2+\overline{u}^2)\Delta^{-1}-\Delta^{-3/2}]\sin 2\theta. \end{cases} \tag{22}$$

The matrix of the attached linear system of variables $(\overline{v},\theta,\overline{u})$ at the equilibrium points $B_0^{\pm}=(\pm\sqrt{2\mu^{-1/2}},0,0)$ and $B_\pi^{\pm}=(\pm\sqrt{2\mu^{-1/2}},\pi,0)$ is

$$\begin{bmatrix} \mp\sqrt{2\mu^{-1/2}} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & (\mu-1)/\mu^{3/2} & \mp(1/2)\sqrt{2\mu^{-1/2}} \end{bmatrix}.$$

The eigenvalues of this matrix are

$$\lambda_1=\mp\sqrt{2\mu^{-1/2}},$$

$$\lambda_2=\mp(4\mu)^{-1/4}/2+(1/2)\sqrt{(4\mu)^{-1/2}+4(\mu-1)\mu^{-3/2}},$$

$$\lambda_3=\mp(4\mu)^{-1/4}/2-(1/2)\sqrt{(4\mu)^{-1/2}+4(\mu-1)\mu^{-3/2}},$$

so the equilibria are hyperbolic. The equilibria B_0^- and B_π^- have a one-dimensional stable manifold and a two-dimensional unstable manifold, whereas the equilibria B_0^+ and B_π^+ have a two-dimensional stable manifold and a one-dimensional unstable manifold.

Finally, the corresponding matrix of the linear system in variables $(\overline{v},\theta,\overline{u})$, at the equilibria $B_{\pm\pi/2}^{\pm}=(\pm\sqrt{2},\pm\pi/2,0)$, is

$$\begin{bmatrix} \mp\sqrt{2} & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1-\mu & \mp\sqrt{2}/2 \end{bmatrix},$$

with eigenvalues

$$\lambda_1=\mp\sqrt{2},$$

$$\lambda_2=\mp\sqrt{2}/4+(1/2)\sqrt{9/2-4\mu},$$

$$\lambda_3=\mp\sqrt{2}/4-(1/2)\sqrt{9/2-4\mu},$$

the sign $\mp$ being chosen with respect to the upper $\pm$ sign of B. This shows that the equilibria are also hyperbolic. In fact $B_{\pm\pi/2}^{+}$ are sinks, whereas $B_{\pm\pi/2}^{-}$ are sources. Like in the previous case, the eigenvalue λ_1 corresponds to the homothetic orbit, while the others correspond to the flow restricted to the infinity manifold.

Thus, the behavior of our flow for $\rho=0$ is in agreement with what we know about the flow on the total collision manifold for the anisotropic Kepler problem (see Ref. 3).

Now that the local structure of the flow on $\mathcal{E}_0$ at the equilibria is understood, we can go further towards enhancing the global picture of the zero-energy case.

C. Qualitative aspects of the global flow

Using all the above information, we are now in a position to state and prove the main result in this section, which describes connecting orbits on $\mathcal{E}_0$, offering the main qualitative features of the flow on the zero-energy manifold. More precisely, we find all possible connections between periodic orbits on C and equilibrium points.

Theorem 6.6: *All the orbits tending to every lower cycle of the collision manifold (including the median one), must eject from a lower equilibrium of the infinity manifold; all the orbits ejecting from every upper cycle of the collision manifold (including the median one) must tend to an upper equilibrium of the infinity manifold. There does not exist orbits in $\mathcal{E}_0$ connecting cycles, or cycles and equilibria, of the collision manifold. There does exist noncollision orbits in $\mathcal{E}_0$ connecting lower and upper equilibria of the infinity manifold*.

Physical interpretation. Any zero-energy solution tending to a lower cycle must eject from a lower equilibrium of the infinity manifold. These solutions, called *capture-collision* orbits, are unbounded at time $-\infty$ and end in a spiraling collision in finite time. Symmetrically, solutions ejecting form an upper cycle must tend to an upper equilibrium of the infinity manifold. They are called *ejection-escape* orbits, start from a spiraling ejection at a finite time and become unbounded at time $+\infty$. The next statement tells that there does not exist solutions that start from a collision (spiraling or frontal) at a finite time and end in a collision (spiraling or frontal) at a later finite time. The last sentence states the existence of collisionless orbits that are unbounded at times $-\infty$ and $+\infty$.

Proof: Recall that we have obtained a three-dimensional flow by eliminating the coordinate r from the energy relation and that the stable manifolds of the periodic orbits P_η are contained in this compact three-dimensional manifold with boundary $C\cup\mathcal{E}_0\cup I$. We will prove the existence of connecting orbits between each cycle P_η of the collision manifold and equilibria of the infinity manifold. For this let P_η, $\eta\leqslant 0$, be a cycle and take any orbit belonging to the two-dimensional local manifold of orbits tending to P_η. Since the flow is gradient-like with respect to the variable v on $\mathcal{E}_0\cup I$ (outside the collision manifold), and there are no other equilibria or cycles below P_η having an unstable manifold of positive dimension, the chosen orbit must come from one of the lower equilibria of the infinity manifold. Using the reversibility of the flow, we can prove that any orbit starting asymptotically at a cycle P_η, $\eta\geqslant 0$, connects with the upper equilibria of the infinity manifold.

The nonexistence of orbits connecting cycles of the collision manifold and of orbits connecting cycles with equilibria of the collision manifold, follows again from the gradient-like property of the flow and the nonexistence of unstable manifolds for the lower equilibria and the cycles P_η with $\eta<0$ and from the nonexistence of stable manifolds for the upper equilibria and the cycles P_η with $\eta>0$. Also, because of the gradient-like property, there are no homoclinic connections for the cycles or the equilibria.

To prove the existence of orbits connecting lower and upper equilibria of the infinity manifold, take an initial condition in the plane $v=0$ of $\mathcal{E}_0$, close to, but outside the collision manifold. Due to the gradient-like property and the fact that the upper equilibria and cycles of the collision manifold have no stable manifolds, the corresponding orbit has to end at one of the upper equilibria of the infinity manifold. Using the same arguments, we can check that this orbit starts at one of the lower equilibria at infinity. This completes the proof of the theorem.

We have thus described the main features of the flow in the zero-energy case. Unfortunately at this point we have only a vague understanding about the behavior of orbits coming from or tending to heteroclinic connections, so we still miss a complete foliation of the global flow on the zero-energy manifold.

(Received 21 July 1998; accepted for publication 20 November 1998)

The constraint reaction force of ideal nonholonomic constraints in time-dependent mechanics on a configuration bundle $Q\to\mathbf{R}$ is obtained. Using the vertical extension of Hamiltonian formalism to the vertical tangent bundle VQ of $Q\to\mathbf{R}$, the Hamiltonian of a nonholonomic constrained system is constructed. The present setting is more general than the one usually considered in the literature on nonholonomic mechanics. © *1999 American Institute of Physics.*

I. INTRODUCTION

This work addresses the geometric theory of nonholonomic constraints in time-dependent mechanics. We refer the reader to Refs. 1–7 for the autonomous case. We follow the approach based on the D'Alembert principle because the variational methods with Lagrange multipliers are not always appropriate to nonholonomic constraints (see Refs. 2, 5, 6, and 8).

Let the jet manifold J^1Q be a velocity phase space of time-dependent mechanics on a configuration bundle $Q\to\mathbf{R}$. When studying mechanical systems with constraints, one usually represents nonholonomic constraints as distributions on Q or submanifolds of the jet manifold J^1Q.[8–10] In this paper the notion of nonholonomic constraint is generalized in such a way to include codistributions $\mathbf{S}$ or, accordingly, distributions $\mathrm{Ann}(\mathbf{S})$ on the jet manifold J^1Q.[11,12] We study the following problem. Let ξ be a second-order dynamic equation on Q and $\mathbf{S}$ a codistribution on J^1Q whose annihilator $\mathrm{Ann}(\mathbf{S})$ is treated as a nonholonomic constraint. The goal is to find a decomposition,

$$\xi=\tilde{\xi}+r, \tag{1}$$

where $\tilde{\xi}$ is a second-order dynamic equation obeying the condition

$$\tilde{\xi}\subset\mathrm{Ann}(\mathbf{S}). \tag{2}$$

One can think of $\tilde{\xi}$ as describing a mechanical system subject to the nonholonomic constraint $\mathbf{S}$, while $(-r)$ is the constraint reaction acceleration. The decomposition (1), however, is not unique. In the case of Newtonian systems, including nondegenerate Lagrangian systems, we obtain the decomposition (1) which satisfies the D'Alembert principle for ideal nonholonomic constraints. We construct the Hamiltonian counterpart of the constrained equation of motion (2). We show that this can be seen as Hamilton equations in the framework of the vertical extension of Hamiltonian formalism to the configuration space VQ which is the vertical tangent bundle of $Q\to\mathbf{R}$. This may be a step towards the functional integral formulation of nonholonomic time-dependent mechanics and its further quantization.

II. GEOMETRIC INTERLUDE

All manifolds throughout the paper are real, finite dimensional, second countable (hence, paracompact), and connected.

We refer the reader to Refs. 8, 9, and 11–15 for the geometric formulation of Lagrangian and Hamiltonian time-dependent mechanics. In accordance with this formulation, a configuration space of time-dependent mechanics is an $(m+1)$-dimensional fiber bundle $Q\to\mathbf{R}$, coordinated by (t,q^i). Its base $\mathbf{R}$ is treated as a time axis provided with the Cartesian coordinate t. With this coordinate, $\mathbf{R}$ is equipped with the standard vector field ∂_t and the standard one-form dt. For the sake of convenience, we will also utilize the compact notation q^λ, where $q^0=t$. Obviously, any fiber bundle $Q\to\mathbf{R}$ is trivial, but it cannot be canonically identified to a product $\mathbf{R}\times M$ in general. Different trivializations $Q\cong\mathbf{R}\times M$ correspond to different reference frames.

The velocity phase space of time-dependent mechanics is the first-order jet manifold J^1Q of $Q\to\mathbf{R}$, coordinated by (t,q^i,q^i_t). There is the canonical imbedding,

$$\lambda: J^1Q\hookrightarrow TQ, \quad (t,q^i,q^i_t)\mapsto(t,q^i,\dot t=1,\dot q^i=q^i_t), \tag{3}$$

of J^1Q onto the affine subbundle of the tangent bundle TQ of Q which is modeled over the vertical tangent bundle VQ of $Q\to\mathbf{R}$. From now on we will identify the jet manifold J^1Q with its image in TQ.

Similarly, we have the imbeddings,

$$J^2Q\hookrightarrow J^1J^1Q\hookrightarrow TJ^1Q,$$

$$(t,q^i,q^i_t,q^i_{tt})\mapsto(t,q^i,q^i_t,\dot t=1,\dot q^i=q^i_t,\dot q^i_t=q^i_{tt}),$$

where J^2Q, coordinated by $(q^\lambda,q^i_t,q^i_{tt})$, is the second-order jet manifold of the fiber bundle $Q\to\mathbf{R}$. The affine bundle $J^2Q\to J^1Q$ is modeled over the vertical tangent bundle,

$$V_QJ^1Q\cong J^1Q\underset{Q}{\times}VQ, \tag{4}$$

of the affine jet bundle $J^1Q\to Q$.

The jet manifold J^1Q is provided with the canonical tangent-valued form,

$$\hat v=\theta^i\otimes\partial^t_i,$$

where $\theta^i=dq^i-q^i_t dt$ are the contact forms. We have the corresponding endomorphism,

$$\hat v(\partial_t)=-q^i_t\partial^t_i, \quad \hat v(\partial_i)=\partial^t_i, \quad \hat v(\partial^t_i)=0,$$

of the tangent bundle TJ^1Q and that

$$\hat v(dt)=0, \quad \hat v(dq^i)=0, \quad \hat v(dq^i_t)=\theta^i,$$

of the cotangent bundle T^*J^1Q of J^1Q. The nilpotent rule $\hat v^2=0$ holds.

Due to the imbeddings (3), any connection,

$$\Gamma=dt\otimes(\partial_t+\Gamma^i\partial_i),$$

on a fiber bundle $Q\to\mathbf{R}$ can be identified with a nowhere vanishing horizontal vector field,

$$\Gamma=\partial_t+\Gamma^i\partial_i, \tag{5}$$

on Q which is the horizontal lift of the standard vector field ∂_t on $\mathbf{R}$ by means of Γ. Conversely, any vector field Γ on Q such that $dt\rfloor\Gamma=1$ defines a connection on $Q\to\mathbf{R}$. Accordingly, the covariant differential,

$$D_\Gamma : J^1Q \underset{Q}{\to} VQ, \quad \dot{q}^i\circ D_\Gamma = q^i_t - \Gamma^i,$$

associated with a connection Γ on $Q\to\mathbf{R}$, takes its values into the vertical tangent bundle VQ of $Q\to\mathbf{R}$.

Remark: From the physical viewpoint, a connection (5) sets a reference frame. There is one-to-one correspondence between these connections and the equivalence classes of atlases of local constant trivializations of the fiber bundle $Q\to\mathbf{R}$, i.e., such that transition functions $q^i \to q'^i$ of the corresponding bundle coordinates are independent of t, and $\Gamma=\partial_t$ with respect to these coordinates.[13–15] In particular, every trivialization of Q defines a complete connection Γ on $Q\to\mathbf{R}$, and vice versa.

A connection ξ on the jet bundle $J^1Q\to\mathbf{R}$ is said to be holonomic if it is a section,

$$\begin{aligned} &\xi = \partial_t + q^i_t\partial_i + \xi^i\partial^t_i, \\ &dt\rfloor\xi = 1, \quad \xi\rfloor\hat{\upsilon} = 0, \end{aligned} \tag{6}$$

of the holonomic subbundle $J^2Q\to J^1Q$ of the affine jet bundle $J^1J^1Q\to J^1Q$. Holonomic connections (6) make up an affine space modeled over the linear space of vertical vector fields on the affine jet bundle $J^1Q\to Q$, i.e., which live in V_QJ^1Q. Every holonomic connection ξ defines the corresponding covariant differential on the jet manifold J^1Q:

$$\begin{aligned} &D_\xi : J^2Q \underset{J^1Q}{\longrightarrow} V_QJ^1Q \subset VJ^1Q, \\ &\dot{q}^i\circ D_\xi = 0, \quad \dot{q}^i_t\circ D_\xi = q^i_{tt} - \xi^i, \end{aligned} \tag{7}$$

which takes its values into the vertical tangent bundle V_QJ^1Q of the affine jet bundle $J^1Q\to Q$. Any integral section $\bar{c}:\mathbf{R}\supset(\,)\to J^1Q$ for a holonomic connection ξ is holonomic, i.e., $\bar{c}=\dot{c}$ where c is a curve in Q.

A second-order dynamic equation (or simply a dynamic equation) on a configuration bundle $Q\to\mathbf{R}$ is defined as the kernel,

$$q^i_{tt} = \xi^i(t,q^j,q^j_t), \tag{8}$$

of the covariant differential (7) for some holonomic connection ξ on the jet bundle $J^1Q\to\mathbf{R}$. Therefore, holonomic connections are also called dynamic equations. By a solution of the dynamic equation (8) is meant a curve c in Q whose second-order jet prolongation $\ddot{c}$ lives in (8). Any integral section $\bar{c}$ for the holonomic connection ξ is the jet prolongation $\dot{c}$ of a solution c of the dynamic equation (8), and vice versa.

III. NONHOLONOMIC CONSTRAINTS

Let $\mathbf{S}$ be an n-dimensional codistribution on the velocity phase space J^1Q. Its annihilator Ann$(\mathbf{S})$ is treated as a nonholonomic constraint. Let the codistribution $\mathbf{S}$ be locally spanned by the one-forms,

$$s^a = s^a_0 dt + s^a_i dq^i + \dot{s}^a_i dq^i_t,$$

on the jet manifold J^1Q. Then a dynamic equation $\tilde{\xi}$ on the configuration bundle $Q\to\mathbf{R}$ is said to be compatible with the nonholonomic constraint $\mathbf{S}$ if

$$s^a(\tilde{\xi}) = \tilde{\xi}\rfloor s^a = s^a_0 + s^a_i q^i_t + \dot{s}^a_i \tilde{\xi}^i = 0.$$

This equation is algebraically solvable for n components of $\tilde{\xi}$ iff the $n\times m$ matrix $\dot{s}^a_i(q^\lambda, q^i_t)$ has everywhere maximal rank $n \leq m$. Therefore, we restrict our consideration to the nonholonomic constraints, called admissible, such that $\dim \mathbf{S} = \dim \hat{v}(\mathbf{S})$.

If a nonholonomic constraint is admissible, there exists a local $m\times n$ matrix $\dot{s}^i_a(q^\lambda, q^i_t)$ such that

$$\dot{s}^i_a \dot{s}^b_i = \delta^b_a .$$

Then the local decomposition (1) of a dynamic equation ξ can be written in the form

$$\xi^i = \tilde{\xi}^i + \dot{s}^i_a s^a(\xi). \tag{9}$$

The global decomposition (1) exists by virtue of the following lemma.

Lemma 1: The intersection

$$W = J^2Q \cap \mathrm{Ann}(\mathbf{S})$$

is an affine bundle over J^1Q, modeled over the vector bundle

$$\overline{W} = V_Q J^1 Q \cap \mathrm{Ann}(\mathbf{S}).$$

Proof: $\overline{W}$ consists of the vertical vectors $v^i \partial^t_i \in V_Q J^1 Q$ which fulfill the conditions

$$\dot{s}^a_i(q^\lambda, q^j_t) v^i = 0.$$

Since the nonholonomic constraint $\mathbf{S}$ is admissible, every fiber of $\overline{W}$ is of dimension $m-n$, i.e., $\overline{W}$ is a vector bundle, while W is an affine bundle.

The affine structure of $W \to J^1Q$ implies that it has a global section $\tilde{\xi}$.

To construct the global decomposition (1), one usually performs a splitting of the vertical tangent bundle,

$$V_Q J^1 Q = \overline{W} \underset{J^1Q}{\oplus} \mathcal{V}, \tag{10}$$

and obtain the corresponding splitting of the second-order jet manifold,

$$J^2 Q = W \underset{J^1Q}{\oplus} \mathcal{V}. \tag{11}$$

Here $\mathcal{V} \to J^1Q$ should be interpreted as the bundle of possible constraint reaction accelerations.

If an admissible nonholonomic constraint $\mathbf{S}$ is of dimension $n = m$, a dynamic equation ξ is decomposed in a unique fashion. If $n < m$, the decomposition (1) is not unique. Different variants of this decomposition lead to different constraint reaction forces which, from the physical viewpoint, characterize different types of nonholonomic constraints. In next section, we will construct the decomposition of dynamic equations of Newtonian systems which corresponds to ideal nonholonomic constraints.

Now, let us consider some important examples of nonholonomic constraints.

Let N be a closed imbedded submanifold of the velocity phase space J^1Q, defined locally by the equations

$$f^a(q^\lambda, q^i_t) = 0, \quad a = 1,...,n < m.$$

One can treat N as a nonholonomic constraint given by the codistribution $\mathbf{S}=\mathrm{Ann}(TN)$ on $J^1Q|_N$. This codistribution is locally spanned by the one-forms

$$s^a=df^a=\partial_t f^a dt+\partial_j f^a dq^j+\partial_j^t f^a dq_t^j.$$

The nonholonomic constraint N is admissible iff the matrix $(\partial_j^t f^a)$ is of maximal rank n. It follows that N is a fibered submanifold of the affine jet bundle $J^1Q\to Q$.

A nonholonomic constraint N is said to be linear if it is an affine subbundle of the affine jet bundle $J^1Q\to Q$. Locally, a linear constraint N is given by the equations

$$f^a=f_0^a(q^\lambda)+f_i^a(q^\lambda)q_t^i=0, \tag{12}$$

where the matrix f_i^a is of maximal rank. A linear constraint is always admissible. Since N is an affine subbundle of $J^1Q\to Q$, it has a global section Γ (5) which is a connection on the configuration bundle $Q\to\mathbf{R}$, called the constraint reference frame. Then, the connection coefficients Γ^i satisfy the equations

$$f_0^a(q^\lambda)+f_i^a(q^\lambda)\Gamma^i=0,$$

and hence the constraint equations (12) take the form

$$f_i^a(q^\lambda)(q_t^i-\Gamma^i)=0. \tag{13}$$

One can think of $\dot q_\Gamma^i=q_t^i-\Gamma^i$, satisfying the equation (13), as virtual velocities relative to the linear constraint N.

Let now a configuration space Q admit a composite fibration $Q\to\Sigma\to\mathbf{R}$, where

$$\pi_{Q\Sigma}:Q\to\Sigma$$

is a fiber bundle, and let (t,σ^r,q^a) be coordinates on Q, compatible with this fibration. Given a connection,

$$B=dt\otimes(\partial_t+B^a\partial_a)+d\sigma^r\otimes(\partial_r+B_r^a\partial_a), \tag{14}$$

on the fiber bundle $Q\to\Sigma$, we have the corresponding horizontal splitting of the tangent bundle TQ. Restricted to the jet manifold $J^1Q\subset TQ$, this splitting reads

$$J^1Q=B(\pi_{Q\Sigma}^*J^1\Sigma)\underset{Q}{\oplus}V_\Sigma Q,$$

$$\partial_t+\sigma_t^r\partial_r+q_t^a\partial_a=[(\partial_t+B^a\partial_a)+\sigma_t^r(\partial_r+B_r^a\partial_a)]+[q_t^a-B^a-\sigma_t^rB_r^a]\partial_a,$$

where $\pi_{Q\Sigma}^*J^1\Sigma$ is the pull-back of the affine jet bundle $J^1\Sigma\to\Sigma$ onto Q. It is readily observed that

$$N=B(\pi_{Q\Sigma}^*J^1\Sigma)$$

is an affine subbundle of the affine jet bundle $J^1Q\to Q$, defined locally by the equations

$$q_t^a-\sigma_t^rB_r^a(q^\lambda)-B^a(q^\lambda)=0.$$

This subbundle yields a linear nonholonomic constraint.[16,17] The corresponding codistribution $\mathbf{S}=\mathrm{Ann}(TN)$ is locally spanned by the one-forms,

$$s^a=-(\partial_tB^a+\sigma_t^r\partial_tB_r^a)dt-(\partial_sB^a+\sigma_t^r\partial_sB_r^a)d\sigma^s-(\partial_bB^a+\sigma_t^r\partial_bB_r^a)dq^b+dq_t^a-B_r^a d\sigma_t^r. \tag{15}$$

With the connection (14), we also have the splitting of the vertical tangent bundle VQ of $Q\to\mathbf{R}$ and the corresponding splitting of the vertical tangent bundle V_QJ^1Q which reads

$$V_Q J^1 Q = \overline{W} \underset{J^1Q}{\oplus} \mathcal{V},$$
$$\dot\sigma^r_t \partial^t_r + \dot q^a_t \partial^t_a = \dot\sigma^r_t (\partial^t_r + B^a_r \partial^t_a) + (\dot q^a_t - B^a_r \dot\sigma^r_t)\partial^t_a . \tag{16}$$

It is readily observed that $\overline{W}|_N$ consists of vertical vectors which are the annihilators of the codistribution (15). The splitting (16) yields the corresponding splitting (11) of the second-order jet manifold J^2Q. Then we obtain the decomposition (1) of every dynamic equation ξ on J^1Q as

$$\widetilde{\xi}^r = \xi^r, \quad \widetilde{\xi}^a = \xi^a - s^a(\xi).$$

IV. NEWTONIAN SYSTEMS WITH NONHOLONOMIC CONSTRAINTS

Let $Q \to \mathbf{R}$ be a fiber bundle together with (i) a nondegenerate fiber metric,

$$\hat m : J^1Q \to V^*Q \underset{Q}{\otimes} V^*Q, \quad \hat m = \tfrac{1}{2} m_{ij} \overline{d}q^i \vee \overline{d}q^j,$$

in the fiber bundle $V_Q J^1 Q \to J^1 Q$ which satisfies the symmetry condition,

$$\partial^t_k m_{ij} = \partial^t_j m_{ik}, \tag{17}$$

and (ii) a dynamic equation ξ (6) on the jet bundle $J^1Q \to \mathbf{R}$, related to the fiber metric $\hat m$ by the compatibility condition,

$$2\xi \rfloor dm_{ij} + m_{ik}\partial^t_j \xi^k + m_{jk}\partial^t_i \xi^k = 0. \tag{18}$$

The triple $(Q, \hat m, \xi)$ is called a Newtonian system and $\hat m$ is named a mass metric.[15] A Newtonian system is said to be standard if $\hat m$ is the pull-back of a fiber metric in the vertical tangent bundle VQ in accordance with the isomorphism (4). In this case, $\hat m$ is independent of the velocity coordinates q^i_t.

There are two main reasons in order to consider Newtonian systems. From the physical viewpoint, with a mass metric, we can introduce the notion of an external force, defined as a section of the vertical cotangent bundle $V^*_Q J^1 Q \to J^1 Q$. Let $(Q, \hat m, \xi)$ be a Newtonian system and F an external force. Then

$$\xi^i_F = \xi^i + (m^{-1})^{ik} F_k$$

is a dynamic equation, but the triple $(Q, \hat m, \xi_F)$ is a Newtonian system only if F possesses the property

$$\partial^t_i F_j + \partial^t_j F_i = 0. \tag{19}$$

From the mathematical viewpoint, the equation

$$m_{ik}(q^k_{tt} - \xi^k) = 0 \tag{20}$$

is the kernel of an Euler–Lagrange-type operator. By an appropriate choice of a mass metric, one may hope to bring it into Lagrange equations. This is the well-known inverse problem in time-dependent mechanics.

Here, we consider Newtonian systems because they provide the vertical tangent bundle $V_Q J^1 Q$ with a nondegenerate fiber metric $\hat m$. Let us assume that $\hat m$ is a Riemannian metric. With this metric, we immediately obtain the splitting (10), where $\mathcal{V}$ is the orthocomplement of $\overline{W}$. Then the corresponding decomposition (9) takes the form[11]

$$\xi^i = \tilde{\xi}^i + \tilde{m}_{ab} m^{ij} \dot{s}_j^a s^b(\xi), \tag{21}$$

where $\tilde{m}_{ab}$ is the inverse matrix of

$$\tilde{m}^{ab} = \dot{s}_i^a \dot{s}_j^b m^{ij}.$$

It is readily observed that the decomposition (21) satisfies the generalized D'Alembert principle. The constraint reaction acceleration,

$$-r^i = -\tilde{m}_{ab} m^{ij} \dot{s}_j^a s^b(\xi), \tag{22}$$

is orthogonal to every element of $V_Q J^1 Q \cap \mathrm{Ann}(\mathbf{S})$ with respect to the mass metric $\hat{m}$. Since elements of $V_Q J^1 Q \cap \mathrm{Ann}(\mathbf{S})$ can be treated as the virtual accelerations relative to the nonholonomic constraint **S**, the constraint reaction acceleration (22) characterizes **S** as an ideal constraint.

The Gauss principle is also fulfilled as follows. Given a dynamic equation ξ and the abovementioned fiber metric $\hat{m}$, let us define a positive function $G(w)$ on $J^2 Q$ as

$$G(w) = \hat{m}(\xi(\pi_1^2(w)) - w, \xi(\pi_1^2(w)) - w),$$

$$G(q^\lambda, q_t^i, q_{tt}^i) = m_{ij}(q^\lambda, q_t^k)(\xi^i(q^\lambda, q_t^k) - q_{tt}^i)(\xi^j(q^\lambda, q_t^k) - q_{tt}^j).$$

We say that $\|w\| = G(w)^{1/2}$ is a norm of $w \in J^2 Q$.

Proposition 2: Among all dynamic equations compatible with a nonholonomic constraint, the dynamic equation $\tilde{\xi}$ defined by the decomposition (21) is that of least norm.

Proof: Let ζ be another dynamic equation which takes its values into W. Then $\tilde{\xi} - \zeta \subset \overline{W}$ and

$$\hat{m}(\tilde{\xi} - \zeta, \xi - \tilde{\xi}) = 0.$$

Hence, we obtain

$$\|\zeta\| = \hat{m}(\xi - \tilde{\xi} + \tilde{\xi} - \zeta, \xi - \tilde{\xi} + \tilde{\xi} - \zeta) = \|\tilde{\xi}\| + \hat{m}(\tilde{\xi} - \zeta, \tilde{\xi} - \zeta).$$

In the next section, we will show that, in the case of nondegenerate Lagrangian systems and linear nonholonomic constraints, the decomposition (21) satisfies the traditional D'Alembert principle.

V. LAGRANGIAN SYSTEMS WITH NONHOLONOMIC CONSTRAINTS

Nondegenerate Lagrangian systems are particular Newtonian systems.

A Lagrangian is defined as a horizontal density,

$$L = \mathcal{L} dt, \quad \mathcal{L}: J^1 Q \to \mathbf{R}, \tag{23}$$

on the velocity phase space $J^1 Q$. Here, we apply in a straightforward manner the first variational formula.[13,15]

Let us consider a projectable vector field

$$u = u^t \partial_t + u^i \partial_i, \quad u^t = 0,1,$$

on the configuration bundle $Q \to \mathbf{R}$ and calculate the Lie derivative of the Lagrangian (23) along the jet prolongation,

$$\overline{u} = u^t \partial_t + u^i \partial_i + d_t u^i \partial_i^t,$$

of u, where $d_t = \partial_t + q_t^i \partial_i + \cdots$ is the operator of formal derivative. We obtain

$$\mathbf{L}_{\bar{u}}L=(\overline{u}\rfloor d\mathcal{L})dt=(u^t\partial_t+u^i\partial_i+d_tu^i\partial_i^t)\mathcal{L}dt. \tag{24}$$

The first variational formula provides the following canonical decomposition of the Lie derivative (24) in accordance with the variational problem:

$$\overline{u}\rfloor d\mathcal{L}=(u^i-u^tq_t^i)\mathcal{E}_i+d_t(u\rfloor H_L), \tag{25}$$

where

$$H_L=\hat{v}(d\mathcal{L})+L=\pi_i dq^i-(\pi_i q_t^i-\mathcal{L})dt \tag{26}$$

is the Poincaré–Cartan form and

$$\mathcal{E}_L:J^2Q\to V^*Q,$$

$$\mathcal{E}_L=\mathcal{E}_i\theta^i=(\partial_i-d_t\partial_i^t)\mathcal{L}\theta^i \tag{27}$$

is the Euler–Lagrange operator for L. We will use the notation

$$\pi_i=\partial_i^t\mathcal{L},\quad \pi_{ji}=\partial_j^t\partial_i^t\mathcal{L}.$$

A Lagrangian L is called nondegenerate if det $\pi_{ji}\neq 0$ everywhere on the velocity phase space J^1Q.

The kernel $\operatorname{Ker}\mathcal{E}_L\subset J^2Q$ of the Euler–Lagrange operator (27) defines the system of second-order differential equations,

$$(\partial_i-d_t\partial_i^t)\mathcal{L}=0, \tag{28}$$

on Q, called the Lagrange equations. Their solutions are (local) section c of the fiber bundle $Q\to\mathbf{R}$ whose second-order jet prolongations $\ddot{c}$ live in (28).

A holonomic connection on the jet bundle $J^1Q\to\mathbf{R}$ is said to be a Lagrangian connection ξ_L for the Lagrangian L if it takes its values in the kernel (28) of the Euler–Lagrange operator $\mathcal{E}_L$. Every Lagrangian connection ξ_L defines a dynamic equation on the configuration space Q whose solutions are also solutions of the Lagrange equations (28). If L is nondegenerate, the Lagrange equation (28) can be algebraically solved for the second-order derivatives, and they are equivalent to the dynamic equation,

$$q_{tt}^i=\xi_L^i,\quad \xi_L^i=(\pi^{-1})^{ij}\mathcal{E}_j+q_{tt}^i, \tag{29}$$

called the Lagrange dynamic equation.

Every Lagrangian L on the jet manifold J^1Q yields the Legendre map,

$$\hat{L}:J^1Q\to V^*Q,\quad p_i\circ\hat{L}=\pi_i, \tag{30}$$

where (t,q^i,p_i) are holonomic coordinates on the vertical cotangent bundle V^*Q. As is well known, the Legendre map (30) is a local diffeomorphism iff L is nondegenerate. A Lagrangian L is called hyperregular if the Legendre map $\hat{L}$ is a diffeomorphism.

The vertical tangent map $V\hat{L}$ to the Legendre map $\hat{L}$ reads

$$V\hat{L}:V_QJ^1Q\to VV^*Q\cong V^*Q\underset{Q}{\times}V^*Q.$$

It yields the linear fibred morphism $V_QJ^1Q\to V_Q^*J^1Q$ and the corresponding mapping,

$$J^1Q\to V_Q^*J^1Q\underset{J^1Q}{\otimes}V_Q^*J^1Q,\quad m_{ij}=\pi_{ij}. \tag{31}$$

If a Lagrangian L is nondegenerate, then (31) is a mass metric which satisfies the symmetry condition (17) and the compatibility condition (18) for the Lagrange dynamic equation (29).

Thus, every nondegenerate Lagrangian L defines a Newtonian system. Moreover, a nondegenerate Lagrangian system plus an external force which fulfills the condition (19) is also a Newtonian system. Conversely, every standard Newtonian system can be seen as a Lagrangian system with the Lagrangian

$$L=\tfrac{1}{2}m_{ij}(q_t^i-\Gamma^i)(q_t^j-\Gamma^j)dt, \tag{32}$$

where Γ is a reference frame, plus an external force.

Given a nondegenerate Lagrangian L with a Riemannian mass metric $m_{ij}=\pi_{ij}$, let now $\mathbf{S}$ be an admissible nonholonomic constraint on the velocity phase space J^1Q. Since this is a particular Newtonian system, we obtain the dynamic equation

$$\begin{aligned} q_{tt}^i&=\xi_L^i-\widetilde{m}_{ab}m^{ij}\dot{s}_j^a(\dot{s}_k^b\xi_L^k+s_k^bq_t^k+s_0^b),\\ \xi_L^i&=m^{ij}(-\partial_t\pi_j-\partial_k\pi_jq_t^k+\partial_j\mathcal{L}), \end{aligned} \tag{33}$$

which is compatible with the constraint $\mathbf{S}$, treated as an ideal nonholonomic constraint. This is the Lagrange dynamic equation in the presence of the additional constraint reaction force

$$F_i=-\widetilde{m}_{ab}\dot{s}_i^a s^b(\xi_L). \tag{34}$$

Let us consider the energy conservation law in the presence of this force.

The energy conservation law in Lagrangian time-dependent mechanics is deduced from the first variational formula (25) when the vector field $u=\Gamma$ is a reference frame. On the shell $\mathcal{E}_i=0$ (28), this formula leads to the weak identity,

$$\mathbf{L}_{\bar{\Gamma}}L\approx-d_t(\pi_i\dot{q}_\Gamma^i-\mathcal{L}), \tag{35}$$

where $\dot{q}_\Gamma^i=q_t^i-\Gamma^i$ is a relative velocity and

$$T_\Gamma=\pi_i\dot{q}_\Gamma^i-\mathcal{L} \tag{36}$$

is the energy function with respect to the reference frame Γ.[14,15,18] In the presence of an external force F, i.e., on the shell $\mathcal{E}_i=-F_i$, the weak identity (35) is modified as

$$\mathbf{L}_{\bar{\Gamma}}L-\dot{q}_\Gamma^iF_i=-d_tT_\Gamma.$$

It is readily observed that, if a nonholonomic constraint is linear and Γ is a constraint reference frame, the constraint reaction force (34) does not contribute to the energy conservation law. It follows that, in this case, the standard D'Alembert principle holds, while the equation (33) describes a motion in the presence of an ideal nonholonomic constraint in the spirit of this principle.

The constrained equation of motion (33) is neither Lagrange equations nor a dynamic equation of a Newtonian system. In Sec. VI, we aim to show that it can be seen as a part of Hamilton equations in the framework of the Hamiltonian formalism extended to the configuration space VQ.

VI. VERTICAL EXTENSION OF HAMILTONIAN FORMALISM

This section provides a brief exposition of Hamiltonian formalism of time-dependent mechanics on a configuration bundle $Q\to\mathbf{R}$ and its extension to the vertical configuration space VQ. We consider this extension because any first-order dynamic equation on the momentum phase space V^*Q can be seen as a Hamilton equation in the framework of the extended Hamiltonian formalism. This extension is also of interest in the path-integral formulation of mechanics.[19,20]

Given a mechanical system on a configuration bundle $Q\to\mathbf{R}$, its momentum phase space is the vertical cotangent bundle V^*Q of $Q\to\mathbf{R}$, equipped with the holonomic coordinates $(t,q^i,p_i=\dot q_i)$.[13–15] The momentum phase space V^*Q is endowed with the canonical exterior three-form,

$$\mathbf{\Omega}=dp_i\wedge dq^i\wedge dt.$$

Let us consider the cotangent bundle T^*Q of Q with the holonomic coordinates (t,q^i,p,p_i). It admits the canonical Liouville form

$$\Xi=p\,dt+p_i dq^i. \tag{37}$$

An exterior one-form H on the momentum phase space V^*Q is called a Hamiltonian form if it is the pull-back

$$H=h^*\Xi=p_i dq^i-\mathcal{H}dt \tag{38}$$

of the Liouville form Ξ (37) by a section h of the fiber bundle

$$\zeta:T^*Q\to V^*Q. \tag{39}$$

Remark: With respect to a trivialization $Q\cong\mathbf{R}\times M$, the Hamiltonian form (38) is the well-known integral invariant of Poincaré–Cartan, where $\mathcal{H}$ is a Hamiltonian. The peculiarity of Hamiltonian time-dependent mechanics issues from the fact that Hamiltonians are not scalar functions under time-dependent transformations, but make up an affine space modeled over the linear space of functions on V^*Q.

For instance, every connection Γ on a configuration bundle $Q\to\mathbf{R}$ is an affine section.

$$p\circ\Gamma=-p_i\Gamma^i,$$

of the fiber bundle (39), and defines the Hamiltonian form

$$H_\Gamma=p_i dq^i-p_i\Gamma^i dt.$$

It follows that any Hamiltonian form on the momentum phase space V^*Q admits the splitting,

$$H=H_\Gamma-\tilde{\mathcal{H}}_\Gamma dt=p_i dq^i-(p_i\Gamma^i+\tilde{\mathcal{H}}_\Gamma)dt,$$

where Γ is a connection on $Q\to\mathbf{R}$ and $\tilde{\mathcal{H}}_\Gamma$ is a real function on V^*Q, called the Hamiltonian function. The following assertions are basic facts in the Hamiltonian formulation of time-dependent mechanics.[14,15]

Proposition 3: Every Hamiltonian form H on the momentum phase space V^*Q defines the associated Hamiltonian map,

$$\hat H:V^*Q\to J^1Q, \quad q^i_t\circ\hat H=\partial^i\mathcal{H}.$$

Proposition 4: Given a Hamiltonian form H on the momentum phase space V^*Q there exists a unique connection

$$\gamma_H=\partial_t+\partial^i\mathcal{H}\partial_i-\partial_i\mathcal{H}\partial^i \tag{40}$$

on $V^*Q\to\mathbf{R}$, called a Hamiltonian connection, such that

$$\gamma_H\rfloor\mathbf{\Omega}=dH.$$

The kernel of the covariant differential of the Hamiltonian connection (40) defines the Hamilton equations,

$$q^i_t = \partial^i \mathcal{H}, \tag{41a}$$

$$p_{ti} = -\partial_i \mathcal{H}, \tag{41b}$$

for the Hamiltonian form H. Their solutions are integral curves for the Hamiltonian connection γ_H (40).

Now let us consider the vertical tangent bundle VQ of the fiber bundle $Q \to \mathbf{R}$, coordinated by $(t,q^i,\dot{q}^i)$. It can be seen as a new configuration space, called the vertical configuration space. The corresponding vertical momentum phase space is the vertical cotangent bundle V^*VQ of $VQ \to \mathbf{R}$. The vertical momentum phase space V^*VQ is canonically isomorphic to the vertical tangent bundle VV^*Q of the ordinary momentum phase space $V^*Q \to \mathbf{R}$, coordinated by $(t,q^i,p_i,\dot{q}^i,\dot{p}_i)$. It is easily seen from the transformation laws that $(q^i,\dot{p}_i)$ and $(\dot{q}^i,p_i)$ are canonically conjugate pairs.

The vertical momentum phase space VV^*Q is endowed with the canonical three-form,

$$\mathbf{\Omega}_V = [d\dot{p}_i \wedge dq^i + dp_i \wedge d\dot{q}^i] \wedge dt.$$

For the sake of brevity, one can write $\mathbf{\Omega}_V = \partial_V \mathbf{\Omega}$, where $\partial_V = \dot{q}^i \partial_i + \dot{p}_i \partial^i$ is the vertical derivative.

The notions of a Hamiltonian connection, a Hamiltonian form, etc., on the vertical momentum phase space $VV^*Q \cong V^*VQ$ are introduced similarly to those on the ordinary momentum phase space V^*Q. In particular, a Hamiltonian form on VV^*Q reads

$$H_V = \dot{p}_i dq^i + p_i d\dot{q}^i - \mathcal{H}_V dt.$$

Since Hamiltonian forms are determined modulo exact forms and the function $p_i \dot{q}^i$ is globally defined on VV^*Q, we will write

$$H_V = \dot{p}_i dq^i - \dot{q}^i dp_i - \mathcal{H}_V dt. \tag{42}$$

The corresponding Hamilton equations read

$$\gamma^i = q^i_t = \dot{\partial}^i \mathcal{H}_V, \tag{43a}$$

$$\gamma_i = p_{ti} = -\dot{\partial}_i \mathcal{H}_V, \tag{43b}$$

$$\overline{\gamma}^i = \dot{q}^i_t = \partial^i \mathcal{H}_V, \tag{43c}$$

$$\overline{\gamma}_i = \dot{p}_{ti} = -\partial_i \mathcal{H}_V, \tag{43d}$$

where

$$\overline{\gamma} = \partial_t + \gamma^i \partial_i + \gamma_i \partial^i + \overline{\gamma}^i \dot{\partial}_i + \overline{\gamma}_i \dot{\partial}^i$$

is a Hamiltonian connection on the vertical momentum phase space $VV^*Q \to \mathbf{R}$.

There is the following relation between Hamiltonian formalisms on V^*Q and VV^*Q.[13,15] Let VT^*Q be the vertical tangent bundle of the cotangent bundle $T^*Q \to \mathbf{R}$ equipped with holonomic coordinates $(t,q^i,p_i,p,\dot{q}^i,\dot{p}_i,\dot{p})$ and endowed with the canonical form,

$$\Xi_V = \dot{p}\,dt + \dot{p}_i dq^i - \dot{q}^i dp_i.$$

Proposition 5: Let γ_H be a Hamiltonian connection on the ordinary momentum phase space $V^*Q \to \mathbf{R}$ for a Hamiltonian form,

$$H = h^* \Xi = p_i dq^i - \mathcal{H} dt. \tag{44}$$

Then the connection

$$V\gamma_H : VV^*Q \to VJ^1V^*Q \cong J^1VV^*Q,$$
$$V\gamma_H = \partial_t + \gamma^i\partial_i + \gamma_i\partial^i + \partial_V\gamma^i\dot\partial_i + \partial_V\gamma_i\dot\partial^i \tag{45}$$

on the vertical momentum phase space $VV^*Q \to \mathbf{R}$ is a Hamiltonian connection for the Hamiltonian form,

$$H_V = (Vh)^*\Xi_V = \dot p_i dq^i - \dot q^i dp_i - \partial_V\mathcal{H}dt, \tag{46}$$

$$\partial_V\mathcal{H} = (\dot q^i\partial_i + \dot p_i\partial^i)\mathcal{H}, \tag{47}$$

where $Vh: VV^*Q \to VT^*Q$ is the vertical tangent map to h.

The corresponding Hamilton equations read

$$\gamma^i = \dot\partial^i\mathcal{H}_V = \partial^i\mathcal{H}, \tag{48a}$$

$$\gamma_i = -\dot\partial_i\mathcal{H}_V = -\partial_i\mathcal{H}, \tag{48b}$$

$$\overline{\gamma}^i = \partial^i\mathcal{H}_V = \partial_V\partial^i\mathcal{H}, \tag{48c}$$

$$\overline{\gamma}_i = -\partial_i\mathcal{H}_V = -\partial_V\partial_i\mathcal{H}. \tag{48d}$$

It is easily seen that the equations (48a) and (48b) are exactly the Hamilton equations (41a) and (41b) for the Hamiltonian form H.

Remark: In order to clarify the physical meaning of the Hamilton equations (48c) and (48d) let $r(t)$ be a solution of the Hamilton equations (48a) and (48b). Let $\dot r(t)$ be a Jacobi field, i.e., $r(t) + \varepsilon\dot r(t)$ is also a solution of the same Hamilton equations modulo terms of order two in ε. Then it is readily observed that the Jacobi field $\dot r(t)$ fulfills the Hamilton equations (48c) and (48d).

The following assertion plays a prominent role in the sequel.[13,15]

Proposition 6: Any connection γ on the momentum phase space $V^*Q \to \mathbf{R}$ gives rise to the Hamiltonian connection,

$$\gamma^i = \gamma^i, \quad \gamma_i = \gamma_i, \quad \overline{\gamma}^i = \dot p_j\partial^i\gamma^j - \dot q^j\partial^i\gamma_j, \quad \overline{\gamma}_i = -\dot p_j\partial_i\gamma^j + \dot q^j\partial_i\gamma_j, \tag{49}$$

for the Hamiltonian form,

$$H_V = \dot p_i(dq^i - \gamma^i dt) - \dot q^i(dp_i - \gamma_i dt) = \dot p_i dq^i - \dot q^i dp_i - (\dot p_i\gamma^i - \dot q^i\gamma_i)dt,$$

on the vertical momentum phase space VV^*Q.

In particular, if γ is a Hamiltonian connection on the fiber bundle $V^*Q \to \mathbf{R}$, then (49) is exactly the connection $V\gamma$ (45).

It follows that every first-order dynamic equation on the momentum phase space V^*Q can be seen as the Hamilton equations (43a) and (43b) for a suitable Hamiltonian form on the vertical momentum phase space.

VII. HAMILTONIAN SYSTEMS WITH NONHOLONOMIC CONSTRAINTS

Let L be a hyperregular Lagrangian with a Riemannian mass metric $\hat m$. In this case, Hamiltonian and Lagrangian formalisms of time-dependent mechanics are equivalent. There exists a unique associated Hamiltonian form H (38) on V^*Q such that

$$\hat H = \hat L^{-1}, \quad p_i \equiv \pi_i(q^\lambda, \partial^j\mathcal{H}(q^\lambda, p_k)), \quad q^i_t \equiv \partial^i\mathcal{H}(q^\lambda, \pi_j(q^\lambda, q^k_t)), \tag{50a}$$

$$\mathcal{L}\circ\hat{H}\equiv\gamma_H\rfloor H=p_i\partial^i\mathcal{H}-\mathcal{H}. \tag{50b}$$

As an immediate consequence of (50a), we have $J^1\hat{H}=(J^1\hat{L})^{-1}$, where the jet prolongations of the Hamiltonian and Legendre maps read

$$J^1\hat{H}:J^1V^*Q\to J^1J^1Q,\quad (q^\lambda,q^i_t,q^i_{(t)},q^i_{tt})\circ J^1\hat{H}=(q^\lambda,\partial^i\mathcal{H},q^i_t,d_t\partial^i\mathcal{H}),$$

$$J^1\hat{L}:J^1J^1Q\to J^1V^*Q,\quad (q^\lambda,p_i,q^i_t,p_{ti})\circ J^1\hat{L}=(q^\lambda,\pi_i,q^i_{(t)},d_t\pi_i).$$

Then, using (50a) and (50b), we obtain

$$\gamma_H=J^1\hat{L}\circ\xi_L\circ\hat{H}.$$

Let introduce the notation $M^{ij}=\partial^i\partial^j\mathcal{H}$. There are the relations

$$M^{ik}(m_{kj}\circ\hat{H})=\delta^i_j,\quad m_{kj}(M^{ik}\circ\hat{L})=\delta^i_j,\quad m_{ij}=\pi_{ij}.$$

It follows that M is a fiber metric in the vertical tangent bundle V_QV^*Q of the fiber bundle $V^*Q\to Q$.

Given a codistribution $\mathbf{S}$ on J^1Q, let us consider the pull-back codistribution $\hat{H}^*\mathbf{S}$ on V^*Q, spanned locally by one-forms

$$\beta^a=\hat{H}^*s^a=(s^a_0+\dot{s}^a_j\partial_t\partial^j\mathcal{H})dt+(s^a_i+\dot{s}^a_j\partial_i\partial^j\mathcal{H})dq^i+\dot{s}^a_iM^{ij}dp_j=\beta^a_0dt+\beta^a_idq^i+\dot{\beta}^{ai}dp_i.$$

This codistribution defines a nonholonomic constraint on the momentum phase space V^*Q.

Given a Hamiltonian connection γ_H (40), let us find its splitting

$$\gamma_H=\tilde{\gamma}+\vartheta, \tag{51}$$

where $\tilde{\gamma}$ is a connection on $V^*Q\to\mathbf{R}$ which satisfies the condition

$$\tilde{\gamma}\subset\mathrm{Ann}(\hat{H}^*\mathbf{S}). \tag{52}$$

The connection $\tilde{\gamma}$ (52) obviously defines a first-order dynamic equation on the momentum phase space V^*Q which is compatible with the nonholonomic constraint $\hat{H}^*\mathbf{S}$. The decomposition (51) is not unique. Let us construct it as follows.

Given a Hamiltonian connection γ_H, we consider the codistribution S_H on V^*Q, spanned locally by the one-forms $dq^i-\gamma^i_Hdt$. Its annihilator $\mathrm{Ann}(S_H)$ is an affine subbundle of the affine jet bundle $J^1V^*Q\to V^*Q$, modeled over the vertical tangent bundle V_QV^*Q. The Hamiltonian connection γ_H is a section of this subbundle. Let us take the intersection

$$W=\mathrm{Ann}(S_H)\cap\mathrm{Ann}(\hat{H}^*\mathbf{S}).$$

Lemma 7: W is an affine bundle over V^*Q, modeled over the vector bundle

$$\overline{W}=V_QV^*Q\cap\mathrm{Ann}(\hat{H}^*\mathbf{S}).$$

Proof: The intersection $\overline{W}$ consists of elements $v=v_i\partial^i$ of V_QV^*Q which fulfill the conditions

$$v_i\dot{\beta}^{ai}=0.$$

Since the nonholonomic constraint $\mathbf{S}$ is admissible and the matrix M^{ij} is nondegenerate, every fiber of $\overline{W}$ is of dimension $m-n$, i.e., $\overline{W}$ is a vector bundle, while W is an affine bundle.

Then, using the fiber metric M in V_QV^*Q, we obtain the splitting

$$V_Q V^*Q = \overline{W} \oplus \mathcal{V},$$

where $\mathcal{V}$ is the orthocomplement of $\overline{W}$, and the associated splitting

$$\mathrm{Ann}(S_H) = W \oplus \mathcal{V}.$$

The corresponding decomposition (51) reads

$$\tilde{\gamma} = \gamma_H - \tilde{M}_{ab} M_{ij} \dot{\beta}^{ai} \beta^b(\gamma_H) \partial^j, \tag{53}$$

where $\tilde{M}_{ab}$ is the inverse matrix of

$$\tilde{M}^{ab} = \dot{\beta}^{ai} \dot{\beta}^{bj} M_{ij}.$$

The splitting (53) is the Hamiltonian counterpart of the splitting (21). We have the relations

$$\tilde{m}^{ab} = \tilde{M}^{ab} \circ \hat{H}, \quad \beta^a(\gamma_H) = s^a(\xi_L) \circ \hat{H},$$

and as a consequence

$$\tilde{\gamma} = J^1 L \circ \tilde{\xi} \circ \hat{H}.$$

Remark: The above procedure can be extended in a straightforward manner to any standard Newtonian system, seen as a Lagrangian system with the Lagrangian (32) and an external force. Following this procedure, one may also study a nonholonomic Hamiltonian system without appealing to its Lagrangian counterpart.

The connection (53) defines the system of first-order dynamic equations,

$$q^i_t = \partial^i \mathcal{H}, \quad p_{ti} = -\partial_i \mathcal{H} - \tilde{M}_{ab} M_{ij} \dot{\beta}^{ai} \beta^b(\gamma_H), \tag{54}$$

on the momentum phase space V^*Q, which are not Hamilton equations. Nevertheless, in accordance with Proposition 6, one can restate the constrained equations of motion (54) as the Hamilton equations (48a) and (48b) for the Hamiltonian form,

$$H_V = \dot{p}_i dq^i - \dot{q}^i dp_i - \partial_V \mathcal{H} dt - \dot{q}^i \tilde{M}_{ab} M_{ij} \dot{\beta}^{ai} \beta^b(\gamma_H) dt,$$

on the vertical momentum phase space VV^*Q, where the last term can be written in brief as $(-\partial_V \rfloor \vartheta \rfloor \mathbf{\Omega})$.

The Hamiltonian form of the constrained equations of motion may be important in connection with the following speculations.

Given a Hamiltonian form H_V (42) on the vertical momentum phase space VV^*Q, let us consider the Lagrangian

$$L_H = \dot{p}_i q^i_t - \dot{\tilde{q}}^i p_{ti} - \mathcal{H}_V \tag{55}$$

on the first-order jet manifold $J^1 VV^*Q$ of the fiber bundle $VV^*Q \to \mathbf{R}$. It is readily observed that the corresponding Lagrange equations are exactly the Hamilton equations (43a)–(43d) for the Hamiltonian form H_V. In particular, let H be a Hamiltonian form on an ordinary momentum phase space V^*Q and $\mathcal{H}_V = \partial_V \mathcal{H}$. In this case, the Lagrangian (55) reads

$$L_H = \dot{p}_i (q^i_t - \partial^i \mathcal{H}) - \dot{q}^i (p_{ti} + \partial_i \mathcal{H}).$$

It is easily seen that this Lagrangian vanishes on solutions of the Hamilton equations for the Hamiltonian form H. By this reason, it is applied to the functional integral formulation of mechanics.[19,20]

An evolutionary equation in thermoelasticity of dipolar bodies

Marin Marin[a)]
Faculty of Mathematics, University of Brasov Str. Iuliu Mariu No. 50, 2200 Brasov, Romania

(Received 6 April 1998; accepted for publication 10 December 1998)

In this paper we apply the theory of semigroups of operators in order to obtain the existence and uniqueness of solutions for the mixed initial-boundary value problems in thermoelasticity of dipolar bodies. The continuous dependence of the solutions upon initial data and supply terms is also proved. © *1999 American Institute of Physics.* [S0022-2488(99)03203-X]

I. INTRODUCTION

In recent years new continuous models of elastic bodies have been intensively studied. The departure from classical theories begins with polar theories (see Refs. 1–3, for instance).

The nonclassical (which include the theory of dipolar bodies) have found important applications in a variety of fields. Crystals, composites, polymers, suspensions, blood, grids and multibar systems can by considered as examples of media with microstructure. The domain of applicability of different non-classical theories of elastic media has been investigated in the paper.[4] Many aspects of these theories we can find in many new papers (see Refs. 5, 4, for instance).

The deformation of a dipolar medium is described by the variables

$$u_i = u_i(X,t), \varphi_{jk} = \varphi_{jk}(X,t), (X,t) \in B \times [0,t_0),$$

where u_i is the displacement field and φ_{jk} is the dipolar displacement field.

The theories of dipolar bodies are quite sufficient for a large number of solid mechanics applications. Because the system of governing equations and conditions for the thermoelasticity of dipolar bodies is more complicated, it is necessarily a new approach for the boundary value problem in this context. In this paper we establish an existence and uniqueness result for the solutions of the initial-boundary value problem in the context of the thermoelasticity of dipolar bodies. In this paper we also investigate the continuous dependence upon the initial data and supply terms of the solutions of the above problem. An inhomogeneous and anisotropic elastic material is considered and the initial-boundary value problem is transformed in an abstract temporally homogeneous evolutionary equation in a Hilbert space. By using the results of the semigroups theory of linear operators, the existence, uniqueness and continuous dependence results are derived. The proof is given for the first boundary value problem, but the results are the same if the boundary conditions are replaced by those from the second or the third problem.

II. NOTATIONS AND BASIC EQUATIONS

Let B be an open region of three-dimensional Euclidian space occupied by the reference configuration of a dipolar body. We assume that B is regular and we denote the closure of B by $\overline{B}$. The boundary ∂B of B is closed and bounded. We use a fixed system of rectangular Cartesian axes and adopt Cartesian tensor notation. Points in B are denoted by x_j and $t \in [0,\infty)$ is time. Also, the spatial argument and the time argument of a function will be omitted when there is no likelihood of confusion. The usual summation and differentiation convection are employed: Latin subscripts

[a)]Electronic mail: m.marin@unitbv.ro

are understood to range over the integers (1,2,3); a summation over repeated subscripts is implied and a subscript preceded by a comma denotes partial differentiation with respect to the corresponding Cartesian coordinate. We also use a superposed dot to denote the partial differentiation with respect to time, t. In the following we consider the theory of thermoelasticity of dipolar bodies as it is established in the paper.[6] For convention, the notations and terminology chosen are almost identical to those of Refs. 6 and 7.

The basic equations in that theory are as follows: the equations of motion:

$$(\tau_{ij}+\sigma_{ij})_{,j}+\varrho F_i=\varrho \ddot{u}_i,$$

$$\mu_{ijk,i}+\sigma_{jk}+\varrho G_{jk}=I_{kr}\ddot{\varphi}_{jr}; \tag{1}$$

the equation of energy:

$$\varrho T_0\dot{\eta}=q_{i,i}+\varrho r;(x,t)\in B\times[0,\infty) \tag{2}$$

the constitutive equations:

$$\tau_{ij}=C_{ijmn}\varepsilon_{mn}+G_{ijmn}\gamma_{mn}+F_{mnrij}\chi_{mnr}-E_{ij}\theta,$$

$$\sigma_{ij}=G_{ijmn}\varepsilon_{mn}+B_{ijmn}\gamma_{mn}+D_{ijmnr}\chi_{mnr}-D_{ij}\theta,$$

$$\mu_{ijk}=F_{ijkmn}\varepsilon_{mn}+D_{mnijk}\gamma_{mn}+A_{ijkmnr}\chi_{mnr}-F_{ijk}\theta, \tag{3}$$

$$\varrho\,\eta=a\,\theta+E_{ij}\varepsilon_{ij}+D_{ij}\gamma_{ij}+F_{ijk}\chi_{ijk},$$

$$q_i=k_{ij}\theta_{,j}(x,t)\in B\times[0,\infty)$$

the geometric equations:

$$2\varepsilon_{ij}=u_{j,i}+u_{i,j},\gamma_{ij}=u_{j,i}-\varphi_{ij},\chi_{ijk}=\varphi_{ij,k}. \tag{4}$$

In the above equations we have used the following notations: ϱ—the constant reference density; u_i—the components of displacement; φ_{jk}—the components of dipolar displacement; $\tau_{ij},\sigma_{ij},\mu_{ijk}$—the components of stress tensors; $\varepsilon_{ij},\gamma_{ij},\chi_{ijk}$—the components of strain tensors; q_i—the components of the heat conduction vector; η—the specific entropy; T_0—the constant reference temperature; θ—the temperature variation measured from the reference temperature T_0; F_i—the components of body force per unit mass; G_{jk}—the components of body couple force per unit mass; r—the heat supply per unit mass and unit time; I_{ij}—the components of inertia; $C_{ijmn},B_{ijmn},\ldots,a$—the characteristic constants of the material and they are subject to the symmetry conditions

$$C_{ijmn}=C_{mnij}=C_{ijnm},B_{ijmn}=B_{mnij},G_{ijmn}=G_{ijnm},$$

$$F_{ijkmn}=F_{ijknm},A_{ijkmnr}=A_{mnrijk},E_{ij}=E_{ji},k_{ij}=k_{ji}. \tag{5}$$

The entropy production inequality implies that

$$k_{ij}\theta_i\theta_j\geqslant 0. \tag{6}$$

To the equations (1)–(5) we adjoin the following prescribed boundary conditions:

$$u_i(x_k,t)=0,\varphi_{jk}(x_k,t)=0,\theta(x_k,t)=0,(x_k,t)\in\partial B\times[0,\infty), \tag{7}$$

and the initial conditions

$$u_i(x_k,0)=a_i(x_k),\dot{u}_i(x_k,0)=b_i(x_k),\varphi_{jk}(x_k,0)=c_{jk}(x_k),$$
$$\dot{\varphi}_{jk}(x_k,0)=d_{jk}(x_k),\theta(x_k,0)=\theta^0(x_k),(x_k)\in B, \tag{8}$$

where a_i,b_i,c_{jk},d_{jk} and θ^0 are prescribed functions. Introducing (3) and (4) in (1) and (2), we obtain the following system:

$$\varrho\ddot{u}_i=[(C_{ijmn}+G_{ijmn})u_{n,m}+(G_{mnij}+B_{ijmn})(u_{n,m}-\varphi_{mn})$$
$$+(F_{mnrij}+D_{ijmnr})\varphi_{nr,m}-(E_{ij}+D_{ij})]\theta]_{,j}+\varrho F_i,$$

$$I_{kr}\ddot{\varphi}_{jr}=[F_{ijkmn}u_{n,m}+D_{mnijk}(u_{n,m}-\varphi_{mn})+A_{ijkmnr}\varphi_{nr,m}-F_{ijk}\theta]_{,i}$$
$$+G_{jkmn}u_{m,n}+B_{jkmn}(u_{n,m}-\varphi_{mn})+D_{jkmnr}\varphi_{nr,m}-D_{jk}\theta]+\varrho G_{jk}, \tag{9}$$

$$aT_0\dot{\theta}=-T_0[E_{ij}v_{j,i}+D_{ij}(v_{j,i}-\psi_{ij})+F_{ijk}\psi_{jk,i}]+(k_{ij}\theta_{,j})_{,i}+\varrho r,$$

where $v_i=\dot{u}_i,\psi_{jk}=\dot{\varphi}_{jk}$.

By a solution of the mixed initial boundary value problem of the dipolar thermoelasticity in the cylinder $\Omega_0=B\times[0,\infty)$ we mean an ordered array $(u_i,\varphi_{jk},\theta)$ which satisfies the system (9) for all $(x,t)\in\Omega_0$, the boundary conditions (7) and the initial conditions (8).

We shall use the following assumptions on the material properties:

(i) $\varrho>0,T_0>0,I_{ij}>0,a>0;$

(ii) $k_{ij}\xi_i\xi_j\geqslant k_0\xi_i\xi_i,k_0>0,\forall\xi_i;$

(iii) $C_{ijmn}\xi_{ij}\xi_{mn}+2G_{ijmn}\xi_{ij}\eta_{mn}+2F_{mnrij}\xi_{ij}\delta_{mnr}+B_{ijmn}\eta_{ij}\eta_{mn}$
$+2D_{ijmnr}\eta_{ij}\delta_{mnr}+A_{ijkmnr}\delta_{ijk}\delta_{mnr}$
$\geqslant a_0(\xi_{ij}\xi_{ij}+\eta_{ij}\eta_{ij}+\delta_{ijk}\delta_{ijk}),\forall\eta_{ij},\forall\delta_{ijk},\forall\xi_{ij}=\xi_{ji}$, where $a_0>0$.

The above assumptions are in agreement with the usual restrictions imposed in the mechanics of continua in order to obtain the existence and uniqueness of solutions. For instance, the condition (ii) represents a considerable strengthening of the consequence (6) of the entropy production inequality.

We shall use the vectorial notations

$$\mathbf{u}=(u_i),\mathbf{v}=(v_i),\varphi=(\varphi_{ij}),\psi=(\psi_{ij}),i,j=1,2,3.$$

Let us define

$$X=\{\mathbf{W}=(u,\mathbf{v},\varphi,\psi,\theta):\mathbf{u}\in\mathbf{H}_0^{1,3}(B),\mathbf{v}\in\mathbf{H}^{0,3}(B),$$
$$\varphi\in\mathbf{H}_0^{1,9}(B),\psi\in\mathbf{H}^{0,9}(B),\theta\in H^0(B)\}, \tag{10}$$

where $H_0^m(B)$ and $H^m(B)$ are the familiar Sobolev spaces, (see Ref. 8), and we used the notations $\mathbf{H}^{m,n}(B)=[H^m(B)]^n,\mathbf{H}_0^{m,n}(B)=[H_0^m(B)]^n$.

We wish to transform our initial-boundary value problem, defined by (9), (7) and (8) into a temporally homogeneous abstract equation in the Hilbert space X. Thus, we define the operators

$$
\begin{aligned}
A_i\mathbf{W}&=v_i,\\
B_i\mathbf{W}&=\frac{1}{\varrho}[(C_{ijmn}+G_{ijmn})u_{m,n}+(G_{mnij}+B_{ijmn})\gamma_{mn}\\
&\quad+(F_{mnrij}+D_{ijmnr})\varphi_{nr,m}-(E_{ij}+D_{ij})\theta]_{,j},\\
C_{ij}\mathbf{W}&=\psi_{ij},\\
D_{jk}\mathbf{W}&=(I_{ks})^{-1}[F_{ijsmn}u_{m,n}+D_{mnijs}\gamma_{mn}+A_{ijsmnr}\varphi_{nr,m}-F_{ijs}\theta]_{,i}\\
&\quad+G_{jkmn}u_{m,n}+B_{jkmn}\gamma_{mn}+D_{jkmnr}\varphi_{nr,m}-D_{jk}\theta,\\
E\mathbf{W}&=-\frac{1}{a}[E_{ij}v_{j,i}+D_{ij}(v_{j,i}-\psi_{ij})+F_{ijk}\psi_{jk,i}]+\frac{1}{aT_0}(k_{ij}\theta_{,j})_{,i}.
\end{aligned}
\tag{11}
$$

Let $\mathcal{L}$ be the operator

$$\mathcal{L}=(\mathbf{AW},\mathbf{BW},\mathbf{CW},\mathbf{DW},E\mathbf{W}) \tag{12}$$

where $\mathbf{A}=(A_i),\mathbf{B}=(B_i),\mathbf{C}=(C_{ij}),\mathbf{D}=(D_{ij}),i,j=1,2,3,$ with the domain

$$D=D(\mathcal{L})=\{\mathbf{W}\in X:\mathcal{L}\mathbf{W}\in X,\mathbf{v}=0,\psi=0 \ \text{ on } \ \partial B\}. \tag{13}$$

The closure of $D(\mathcal{L})$ is obviously the space X and hence $D(\mathcal{L})$ is dense in X. $D(\mathcal{L})$ is not empty; it contains at least $[C_0^\infty(B)]^{25}$. Thus, we reduce the initial-boundary value problem (9), (7), (8) to the abstract initial value problem on the Hilbert space X,

$$\frac{d\mathbf{W}}{dt}=\mathcal{L}\mathbf{W}+\mathcal{F}(t),\mathbf{W}(0)=\mathbf{W}_0,0\leqslant t\leqslant t_0, \tag{14}$$

where $\mathcal{F}(t)=(\mathbf{0},\mathbf{F},\mathbf{0},M,r),\mathbf{W}_0=(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d},\theta^0),\mathbf{F}=(F_i),\mathbf{G}=(G_{jk}),$ $\mathbf{a}=(a_i),\mathbf{b}=(b_i),\mathbf{c}=(c_{ij}),\mathbf{d}=(d_{ij})$.

III. BASIC RESULTS

Let X_* be the Hilbert space X equipped with the norm induced by the inner product,

$$
\begin{aligned}
\langle\mathbf{W},\overline{\mathbf{W}}\rangle_*=\int_B[&\varrho v_i\overline{v_i}+I_{ks}\psi_{js}\overline{\psi_{jk}}+a\theta\overline{\theta}+C_{ijmn}\varepsilon_{ij}\overline{\varepsilon_{mn}}\\
&+G_{ijmn}(\gamma_{ij}\overline{\varepsilon_{mn}}+\overline{\gamma_{ij}}\varepsilon_{mn})+F_{mnrij}(\varepsilon_{ij}\overline{\chi_{mnr}}+\overline{\varepsilon_{ij}}\chi_{mn})\\
&+B_{ijmn}\gamma_{ij}\overline{\gamma_{mn}}+D_{ijmnr}(\gamma_{ij}\overline{\chi_{mni}}+\overline{\gamma_{ij}}\chi_{mnr})+A_{ijkmnr}\chi_{ij}\overline{\chi_{mnr}}]dV.
\end{aligned}
\tag{15}
$$

By taking into account the hypotheses (i), (ii), (iii) we obtain

$$
\begin{aligned}
|\mathbf{W}|_*^2=\langle\mathbf{W},\mathbf{W}\rangle_*&=\int_B[\varrho v_iv_i+I_{ks}\psi_{js}\psi_{jk}+a\theta^2+C_{ijmn}\varepsilon_{ij}\varepsilon_{mn}+2G_{ijmn}\varepsilon_{ij}\gamma_{mn}\\
&\quad+2F_{mnrij}\varepsilon_{ij}\chi_{mnr}+B_{ijmn}\gamma_{ij}\gamma_{mn}+2D_{ijmnr}\gamma_{ij}\chi_{mnr}+A_{ijkmnr}\chi_{ijk}\chi_{mnr}]dV\\
&\geqslant\int_B[\varrho v_iv_i+I_{ks}\psi_{js}\psi_{jk}+a\theta^2+a_0(\varepsilon_{ij}\varepsilon_{ij}+\gamma_{ij}\gamma_{ij}+\chi_{ijk}\chi_{ijk})]dV\\
&\geqslant c_1|\mathbf{W}|_X^2.
\end{aligned}
\tag{16}
$$

On the other hand, by using the first Korn inequality, (see Ref. 2), and (15), we can prove that $|\mathbf{W}|_*^2 \leqslant c_2 |\mathbf{W}|_X^2$ such that, in view of (16), we have

$$c_1 |\mathbf{W}|_X^2 \leqslant |\mathbf{W}|_*^2 \leqslant c_2 |\mathbf{W}|_X^2;$$

hence the norm $|\cdot|_*$ is a norm equivalent to the original norm in X.

Lemma 1: The operator $\mathcal{L}$ is dissipative, that is,

$$\langle \mathcal{L}\mathbf{W}, \mathbf{W} \rangle_* \leqslant 0, \forall \mathbf{W} \in D(\mathcal{L}).$$

Proof: According to the relations (11) we have

$$\begin{aligned}\langle \mathcal{L}\mathbf{W}, \mathbf{W} \rangle_* = \int_B \Big\{ & v_i [(C_{ijmn} + G_{ijmn}) u_{m,n} + (G_{mnij} + B_{ijmn}) \gamma_{mn} \\ & + (F_{mnrij} + D_{ijmnr}) \varphi_{nr,m} - (E_{ij} + D_{ij}) \theta]_{,j} + \psi_{jk} [F_{ijkmn} u_{m,n} + D_{mnijk} \gamma_{mn} \\ & + A_{ijkmnr} \varphi_{nr,m} - F_{ijk} \theta]_{,i} + \psi_{jk} [G_{jkmn} u_{m,n} + B_{jkmn} \gamma_{mn} \\ & + D_{jkmnr} \varphi_{nr,m} - D_{jk} \theta] + \theta \left[\frac{1}{T_0} (k_{ij} \theta_{,j})_{,i} - E_{ij} v_{j,i} - D_{ij} (v_{j,i} - \psi_{ij}) - F_{ijk} \psi_{jk,i} \right] \\ & + C_{ijmn} u_{i,j} v_{m,n} + G_{ijmn} [u_{i,j} (v_{n,m} - \psi_{mn}) + v_{n,m} (u_{j,i} - \varphi_{ij})] \\ & + F_{mnrij} (u_{i,j} \psi_{nr,m} + v_{i,j} \varphi_{nr,m}) + B_{ijmn} (u_{j,i} - \varphi_{ij}) (v_{n,m} - \varphi_{mn}) \\ & + D_{ijmnr} [(u_{j,i} - \varphi_{ij}) \psi_{nr,m} + (v_{j,i} - \psi_{ij}) \varphi_{nr,m}] + A_{ijkmnr} \varphi_{jk,i} \psi_{nr,m} \Big\} dV.\end{aligned}$$

We now make use of the Green–Gauss formula and the boundary conditions (7), such that it results in

$$\langle \mathcal{L}\mathbf{W}, \mathbf{W} \rangle_* = -\frac{1}{T_0} \int_B k_{ij} \theta_{,i} \theta_{,j} \, dV. \tag{17}$$

On the basis of the inequality (iii), from (17) we obtain

$$\langle \mathcal{L}\mathbf{W}, \mathbf{W} \rangle_* \leqslant -\frac{k_0}{T_0} \int_B \theta_{,i} \theta_{,j} \, dV, \tag{18}$$

such that the proof of Lemma 1 is complete.

Lemma 2: The operator $\mathcal{L}$ satisfies the range condition, that is,

$$R(\lambda I - \mathcal{L}) = X, \lambda > 0. \tag{19}$$

Proof: Assume that $\hat{\mathbf{W}} = (\hat{\mathbf{u}}, \hat{\mathbf{v}}, \hat{\varphi}, \hat{\psi}, \hat{\theta}) \in X$. Then we must show that for all $\hat{\mathbf{W}} \in X$ the equation

$$\lambda \mathbf{W} - \mathcal{L}\mathbf{W} = \hat{\mathbf{W}} \tag{20}$$

has at least a solution $\mathbf{W}$ in $D(\mathcal{L})$. By eliminating the functions v_i and ψ_i in (20), we obtain the following system of equations in the variables u_i, v_i and θ:

$$\mathcal{L}_i\omega=\lambda^2u_i-\frac{1}{\varrho}[(C_{ijmn}+G_{ijmn})u_{m,n}+(G_{mnij}+B_{ijmn})\gamma_{mn}$$
$$+(F_{mnrij}+D_{ijmnr})\varphi_{nr,m}-(E_{ij}+D_{ij})\theta]_{,j}=g_i\,,$$
$$\mathcal{L}_{j+k+3}\omega=\lambda^2\varphi_{jk}-(I_{ks})^{-1}[F_{ijsmn}u_{m,n}+D_{mnijs}\gamma_{mn}+A_{ijsmnr}\varphi_{ns,m}-F_{ijs}\theta]_{,i}$$
$$+B_{jkmn}\gamma_{mn}+D_{jkmnr}\varphi_{nr,m}-D_{jk}\theta=g_{j+k+3}\,, \tag{21}$$
$$\mathcal{L}_{13}\omega=\lambda^2\theta-\frac{1}{aT_0}(k_{ij}\theta_{,j})_{,i}-\frac{1}{a}[E_{ij}v_{j,i}+D_{ij}(v_{j,i}-\psi_{ij})+F_{ijk}\psi_{jk,i}]=g_{13}\,,$$

where

$$\omega=(\mathbf{u},\varphi,\theta),g_i=\lambda\hat{u}_i+\hat{v}_i\,,g_{j+k+3}=\lambda\hat{\varphi}_{jk}+\hat{\psi}_{jk}\,,$$
$$g_{13}=\hat{\theta}+\frac{1}{a}[E_{ij}\hat{v}_{j,i}+D_{ij}(\hat{v}_{j,i}-\hat{\psi}_{ij})+F_{ijk}\hat{\psi}_{jk,i}]. \tag{22}$$

Let $\langle\cdot,\cdot\rangle$ denote the conveniently weighted $[L_2(B)]^{13}$ inner product and consider the bilinear form

$$Q[\omega,\overline{\omega}]=\langle\mathbf{L}\omega,\overline{\omega}\rangle=\langle(\mathcal{L}_i\omega,\mathcal{L}_{j+k+3}\omega,\mathcal{L}_{13}\omega),(\overline{u_i},\overline{\varphi_{jk}},\overline{\theta})\rangle$$
$$=\int_B\left[\varrho\overline{u_i}\mathcal{L}_i\omega+I_{ks}\overline{\psi_{js}}\mathcal{L}_{j+k+3}\omega+\frac{a}{\lambda}\overline{\theta}\mathcal{L}_{13}\omega\right]dV. \tag{23}$$

Using the Green–Gauss formula and the boundary conditions (7), it results that

$$Q[\omega,\omega]=\int_B[\varrho v_iv_i+I_{ks}\psi_{js}\psi_{jk}+a\theta^2+C_{ijmn}u_{i,j}u_{m,n}$$
$$+2G_{ijmn}(u_{j,i}-\varphi_{ij})u_{m,n}+2F_{mnrij}(u_{j,i}-\varphi_{ij})\varphi_{nr,m}$$
$$+B_{ijmn}(u_{j,i}-\varphi_{ij})(u_{n,m}-\varphi_{mn})+2D_{ijmnr}(u_{j,i}-\varphi_{ij})\varphi_{nr,m}$$
$$+A_{ijkmnr}\varphi_{jk,i}\varphi_{nr,m}]dV+\frac{1}{\lambda T_0}\int_B k_{ij}\theta_{,i}\theta_{,j}dV, \tag{24}$$

for any $\omega=(\mathbf{u},\varphi,\theta)\in Y, Y\equiv\mathbf{H}_0^{1,3}(B)\times\mathbf{H}_0^{1,9}(B)\times H_0^1(B)$.

Due to the hypotheses (i), (ii), (iii) and the first Korn inequality, it follows that

$$Q[\omega,\omega]\geqslant C_1|\omega|_Y^2,\quad \text{for all}\ \ \omega=(\mathbf{u},\varphi,\theta)\in Y, \tag{25}$$

C_1 is a positive, conveniently chosen, constant and the norm $|\omega|_Y$ is defined by

$$|\omega|_Y=|(\mathbf{u},\varphi,\theta)|_Y=|\mathbf{u}|_{\mathbf{H}^1(B)}+|\varphi|_{\mathbf{H}^1(B)}+|\theta|_{H^1(B)}\,.$$

In the usual way, we can prove that $Q[\omega,\omega]\leqslant C_1|\omega|_Y^2$, hence the bilinear form $Q[\omega,\overline{\omega}]$ determines a norm equivalent to the original norm in Y. Since the bilinear form $Q[\omega,\overline{\omega}]$ is continuous in $Y\times Y$ we deduce that there exists a linear bounded transformation T from Y into itself such that we have

$$Q[\omega,\overline{\omega}]=\langle\omega,T\omega\rangle_Y,\quad \text{for any}\ \ (\omega,\overline{\omega})\in Y\times Y. \tag{26}$$

Since

$$\langle \omega, T\omega\rangle_Y = Q[\omega,\omega] \geqslant C_1 |\omega|_Y^2, \tag{27}$$

we deduce that

$$|T\omega|_Y \geqslant C_1 |\omega|_Y, \omega \in Y. \tag{28}$$

Let $R(T)$ be the range of T. The linear transformation T is one to one. We need to prove that $T\omega = 0$ implies that $\omega = 0$. Indeed, if there is $\omega_0 \in Y$ such $T\omega_0 = 0$, then (26) implies $Q[\omega_0, \omega_0] = 0$, and then the inequality (25) proves that $\omega_0 = 0$. Therefore, there exists $T^{-1}: R(T) \to Y$. Now we prove that $R(T)$ is dense in Y. We assume to the contrary that there is $\omega_0 \in Y \backslash R(T)$, $0\omega_0 \neq 0$ such that $\langle \omega_0, T\overline{\omega}\rangle_Y = 0$ for any $\overline{\omega} \in Y$. But from (26) we deduce that $Q[\omega_0, \omega_0] = 0$ such that with the aid of (25) we deduce that $\omega_0 = 0$. This contradicts the initial assumptions and therefore we obtain that $R(T)$ is dense in Y. So we can continue T^{-1} to Y, such that

$$T^{-1}: Y \to Y \quad \text{and} \quad |T^{-1}| \leqslant C_1^{-1}.$$

Let $\mathbf{z}$ be in $R(T)$ and ω the only function in Y such that $\mathbf{z} = T\omega$. We define the functional $\mathcal{K}$ by $\mathcal{K}(\mathbf{z}) = \langle \mathbf{g}, \omega\rangle$. Obviously, we have

$$|\mathcal{K}(\mathbf{z})| \leqslant |\mathbf{g}|_{\mathbf{H}_0^{-1}(B)} |\omega|_Y \leqslant C_1^{-1} |\mathbf{g}|_{\mathbf{H}_0^{-1}(B)} |\mathbf{z}|_Y,$$

and then we deduce that $\mathcal{K}$ is a linear bounded functional defined over $R(T)$ such that

$$|\mathcal{K}| \leqslant C_1^{-1} |\mathbf{g}|_{\mathbf{H}_0^{-1}(B)}.$$

We can continue $\mathcal{K}$ in the whole space Y, in such a way that the continued functional $\mathcal{K}$ shall have the same norm. On the other hand, since Y is a Hilbert space, the Riesz–Frechet theorem, (see Ref. 8), proves that there exists a unique $\omega \in Y$ such that

$$\mathcal{K}(\tilde{\omega}) = \langle \omega, \tilde{\omega}\rangle_Y, \quad \text{for any } \tilde{\omega} \in Y; \ |\omega|_Y = |\mathcal{K}| \leqslant C_1^{-1} |\mathbf{g}|_{\mathbf{H}_0^{-1}(B)}. \tag{29}$$

If we choose $\tilde{\omega} = T\overline{\omega}$, then from (26) and (29), it follows that the unique $\omega \in Y$ satisfies the equation

$$Q[\omega, \overline{\omega}] = \langle \mathbf{g}, \tilde{\omega}\rangle, \quad \text{for all } \overline{\omega} \in Y. \tag{30}$$

From the relations $\lambda u_i - \hat{u}_i = v_i, \lambda\varphi_i - \hat{\varphi}_{jk} = \psi_{jk}$ and $\lambda\theta - \hat{\theta} = \tau$, it follows that $\mathbf{v} \in \mathbf{H}_0^{1,3}(B), \psi \in \mathbf{H}_0^{1,9}(B)$ and $\tau \in H_0^1(B)$. Therefore we deduce that $\mathbf{W} = (\mathbf{u}, \mathbf{v}, \varphi, \psi, \theta)$ is in $D(\mathcal{L})$ and the proof of Lemma 2 is complete.

Theorem 1: The operator $\mathcal{L}$ defined by the relations (12) *generates a C_0-semigroup of contractions on X.*

Proof: This result follows immediately from the Lummer–Phillips theorem, (see Ref. 9, for instance).

In order to study the existence and uniqueness of the solution for the inhomogeneous equation (14), we use the following result.

Theorem 2: Let $\mathcal{L}$ be the infinitesimal generator of a C_0-contractive semigroup $T(t)$ on X. If *$\mathcal{F}(s)$ is continuously differentiable on $[0,t_0]$, then the initial value problem* (14) *has, for every $\mathbf{W}_0 \in D(\mathcal{L})$, the unique solution*

$$\mathbf{W}(t) = T(t)\mathbf{W}_0 + \int_0^1 T(t-s)\mathcal{F}(s)\,ds, t \in [0,t_0], \tag{31}$$

such that $\mathbf{W}(t)\in C^1([0,t_0];X)\cap C^0([0,t_0];D(\mathcal{L}))$.

On the basis of the above theorem, we deduce the following.

Theorem 3: Let us assume that the thermoelastic coefficients, which are continuously differentiable, satisfy the conditions (i), (ii), (iii). Moreover, we assume that $\mathbf{F}\in C^1([0,t_0];\mathbf{L}_2(B))$, $\mathbf{M}\in C^1([0,t_0];\mathbf{L}_2(B))$, $r\in C^1([0,t_0];L_2(B))$ *and* $\mathbf{W}_0=(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d},\theta^0)\in D(\mathcal{L})$.

Then there exists an unique solution of the initial-boundary value problem (9), (7), (8) *such that*

$$(\mathbf{u},\dot{\mathbf{u}},\varphi,\dot{\varphi},\theta)\in[C^1([0,t_0];X)\cap C^0([0,t_0];D(\mathcal{L}))]^{13}.$$

The following theorem establish the continuous dependence of the solution of our problem upon the initial data and supply terms. Let (u_i,φ_i,θ) be the difference of two solutions of the problem defined by (9), (7), (8) but corresponding to the differences of the initial data and to the differences of body forces, body couples and heat supplies, $\mathbf{W}_0=(\mathbf{a},\mathbf{b},\mathbf{c},\mathbf{d},\theta^0)$, $(\mathbf{F},\mathbf{M},r)$, respectively.

Theorem 4: Let us assume that the thermoelastic coefficients, which are continuously differentiable, satisfy the conditions (i), (ii), (iii). Moreover, we assume that $\mathbf{F}\in C^1([0,t_0];\mathbf{L}_2(B))$, $\mathbf{M}\in C^1([0,t_0];\mathbf{L}_2(B))$, $r\in C^1([0,t_0];L_2(B))$ *and* $\mathbf{a}\in\mathbf{H}^1(B),\mathbf{b}\in\mathbf{H}^0(B)$, $\mathbf{c}\in\mathbf{H}^1(B),\mathbf{d}\in\mathbf{H}^0(B)\,\theta\in H^1(B)$.

If $(\mathbf{u},\varphi,\theta)$ *is the difference of two solutions of the problem* (9), (7), (8) , *then there exists a positive constant M such that*

$$|\mathbf{u}|_{\mathbf{H}^{1,3}(B)}+|\dot{\mathbf{u}}|_{\mathbf{H}^{0,3}(B)}+|\varphi|_{\mathbf{H}^{1,9}(B)}+|\bar{\varphi}|_{\mathbf{H}^{0,9}(B)}+|\theta|_{H^0(B)}$$
$$\leq M\Bigg\{|\mathbf{a}|_{\mathbf{H}^{1,3}(B)}+|\mathbf{b}|_{\mathbf{H}^{0,3}(B)}+|\mathbf{c}|_{\mathbf{H}^{1,9}(B)}+|\mathbf{d}|_{\mathbf{H}^{0,9}(B)}+|\theta^0|_{H^0(B)}$$
$$+\int_0^t[|\mathbf{F}(s)|_{\mathbf{H}^{0,3}(B)}+|\mathbf{G}(s)|_{\mathbf{H}^{0,9}(B)}+|r(s)|_{H^0(B)}]ds\Bigg\}. \tag{32}$$

Proof: On the basis of the equations (9), (7), (8) we can deduce the following identity:

$$\int_B[\varrho\dot{u}_i\dot{u}_i+I_{ks}\dot{\varphi}_{js}\dot{\varphi}_{jk}+a\theta^2+C_{ijmn}u_{i,j}u_{m,n}+2G_{ijnm}(u_{j,i}-\varphi_{ij})u_{m,n}$$
$$+F_{mnrij}(u_{j,i}-\varphi_{ij})\varphi_{nr,m}+B_{ijmn}(u_{j,i}-\varphi_{ij})(u_{n,m}-\varphi_{mn})$$
$$+2D_{ijmnr}(u_{j,i}-\varphi_{ij})\varphi_{nr,m}+A_{ijkmnr}\varphi_{jk,i}\varphi_{nr,m}]dV+\int_B\frac{1}{\lambda T_0}k_{ij}\theta_{,i}\theta_{,j}dV$$
$$=\int_B[\varrho\dot{a}_i\dot{a}_i+I_{ks}\dot{c}_{js}\dot{c}_{jk}+a(\theta^0)^2+C_{ijmn}a_{i,j}a_{m,n}+2G_{ijnm}(a_{j,i}-c_{ij})a_{m,n}$$
$$+2F_{mnrij}(a_{j,i}-c_{ij})c_{nr,m}+2B_{ijmn}(a_{j,i}-c_{ij})(a_{n,m}-c_{mn})$$
$$+2D_{ijmnr}(a_{j,i}-c_{ij})c_{nr,m}+A_{ijkmnr}c_{jk,i}c_{nr,m}]dV$$
$$+2\int_0^t\int_B\left[F_iu_i+G_{jk}\varphi_{jk}+\frac{1}{T_0}r\theta\right]dVds,s\in[0,t_0]. \tag{33}$$

By using the Schwarz's inequality, the hypotheses (i), (ii), (iii) and the first Korn's inequality, from the identity (33) we deduce a Gronwall inequality that demonstrates the estimate (32).

Remark: A similar procedure can be used in the case when the boundary conditions (7) are replaced by the other boundary conditions and the above results are still valid.

Transfer matrices for scalar fields on curved spaces

E. Prodan
University of Houston, 4800 Calhoun Road, Houston, Texas 77204-5508

(Received 13 August 1998; accepted for publication 23 November 1998)

We apply Nelson's technique of constructing Euclidean fields to the case of classical scalar fields on curved spaces. It is shown how to construct a transfer matrix and, for a class of metrics, the basic spectral properties of its generator are investigated. An application concerning the decoupling of two non-convex disjoint regions is given. © *1999 American Institute of Physics.* [S0022-2488(99)00703-3]

I. INTRODUCTION

We start our construction from the ideas comprised in Nelson's axioms[1] for scalar Euclidean–Markoff quantum fields. Here, the Markoff property of certain projectors is one of the basic ingredients in defining the transfer matrix in which the generator is identified with the Hamiltonian of Wightman quantum scalar field. We found that these ideas can be used in the same way at the nonquantum level. In the case of the scalar fields on Riemannian manifolds, for an arbitrary direction, we construct a propagator by using the Markoff property. In the stationary case it becomes a semigroup which can be considered as the transfer matrix of the system and, further, it can be used in introducing a Hamiltonian. We will show that the propagator is exponentially bounded by using Agmon's[2] results in exponential decay of solutions of second-order elliptic equations. An application concerning the decoupling (in the sense of Ref. 3) of two disjoint nonconvex regions is given.

II. INTRODUCTORY DEFINITIONS AND RESULTS

Let us consider the Riemannian manifold (R^{n+1},g) and the Laplace–Beltrami operator on it, Δ. For a point in R^{n+1} we use the notation (t,x). Let $E_m(t,x;s,y)$ be the kernel of $(\Delta+m^2)^{-1}$ on $L^2(R^{n+1},\sqrt{g}\,dt\,dx)$. As in Ref. 4, we will not consider the additional term $\frac{1}{6}\rho$. One defines the space $N\subset\mathcal{D}'(R^{n+1})$, $f\in N$ if:

$$\|f\|_N^2=\int_{R^{n+1}}\int_{R^{n+1}}\overline{f}(t,x)E_m(t,x;s,y)f(s,y)\sqrt{g(t,x)}\sqrt{g(s,y)}dt\,dx\,ds\,dy<\infty, \tag{1}$$

and, for each $\sigma\in R$, let $N_\sigma\subset D'(R^n)$ be the space: $g\in N_\sigma$ if

$$\|g\|_{N_\sigma}^2=\int_{R^n}\overline{g}(x)E_m(\sigma,x;\sigma,y)g(y)\sqrt{g(\sigma,x)}\sqrt{g(\sigma,y)}dx\,dy<\infty. \tag{2}$$

We will consider that, as in the Euclidean case, the space $L^2(R^n,d\mu_\sigma)\subset N_\sigma$, where $d\mu_\sigma(x)=\sqrt{g(\sigma,x)}\,d^nx$ and that it is dense in N_σ for each $\sigma\in R$. Now, let $\hat{E}_\sigma:N_\sigma\to L^2(R^n,d\mu_\sigma)$ be the operator corresponding to the kernel $E_m(\sigma,x;\sigma,y)$. Then $\hat{E}_\sigma^{1/2}$ defines an isometry from N_σ to $L^2(R^n,d\mu_\sigma)$ and let $(\hat{E}_\sigma^{1/2})^\dagger:L^2(R^n,d\mu_\sigma)\to N_\sigma$ be its adjoint. The following are true:

$$\hat{E}_\sigma^{1/2}\circ(\hat{E}_\sigma^{1/2})^\dagger=1_{L^2(R^n,d\mu_\sigma)}\quad\text{and}\quad(\hat{E}_\sigma^{1/2})^\dagger\circ\hat{E}_\sigma^{1/2}=1_{N_\sigma}. \tag{3}$$

With our assumptions, $\hat{E}_\sigma^{1/2}(N_\sigma)=L^2(R^n,d\mu_\sigma)\subset N_\sigma$, the operator $\hat{E}_\sigma^{1/2}$ is bounded on N_σ. Moreover, one can view $(\hat{E}_\sigma)^\dagger$ as a dense defined unbounded operator on N_σ, in fact, it is the inverse operator of $\hat{E}_\sigma$.

For $\sigma\in R$, let j_σ be the operator $j_\sigma:N_\sigma\to N$, $(j_\sigma\psi)(t,x)=\psi(x)\delta(t-\sigma)$ and j_σ^* be its adjoint. If Λ is a closed subset of R^{n+1} we denote by N_Λ the subspace of N which comprises all distributions with support in Λ. The orthogonal projection of N in N_Λ will be denoted by e_Λ. Following Ref. 5 we have:

Proposition 1: The operators j_σ are isometries and $j_\sigma^* j_\sigma=1_{N_\sigma}$, $j_\sigma j_\sigma^*=e_\sigma$, where e_σ denotes the projector corresponding to the subset of R^{n+1}, $t=\sigma$.

Then we define the operators:

$$U_{\sigma,\sigma'}:N_{\sigma'}\to N_\sigma, \quad U_{\sigma,\sigma'}=j_\sigma^*\circ j_{\sigma'}. \tag{4}$$

We will derive in the following that $U_{\sigma,\sigma'}$ are propagators in the sense of Ref. 6. This will follow from the Markoff property of the projectors e_σ.

Lemma 2: Let A, B, and C be closed subsets in R^{n+1} such that C separates A and B. Then $e_A\circ e_C\circ e_B=e_A\circ e_B$.

Solution 3: This is the consequence of the fact that E_m is the kernel of a local operator. The proof is identical with that of Ref. 5.

The basics properties of $U_{\sigma,\sigma'}$ operators are stated in the following proposition.

Proposition 4: The family of operators $U_{\sigma,\sigma'}$, $\sigma,\sigma'\in R$ has the following properties:

(1) $U_{\sigma,\sigma'}\circ U_{\sigma',\sigma''}=U_{\sigma,\sigma''}$,

(2) $U_{\sigma,\sigma}=1_{N_\sigma}$,

(3) $\|U_{\sigma,\sigma'}\|\leqslant 1$.

Solution 5: (1) *Using the Markoff property we have:*

$$e_\sigma\circ e_{\sigma'}\circ e_{\sigma''}=e_\sigma e_{\sigma''}\Leftrightarrow j_\sigma\circ j_\sigma^*\circ j_{\sigma'}\circ j_{\sigma'}^*\circ j_{\sigma''}\circ j_{\sigma''}^*=j_\sigma\circ j_\sigma^*\circ j_{\sigma''}\circ j_{\sigma''}^*. \tag{5}$$

By composition with $j_{\sigma''}$ at the right, we have

$$j_\sigma\circ(j_\sigma^*\circ j_{\sigma'}\circ j_{\sigma'}^*\circ j_{\sigma''}-j_\sigma^*\circ j_{\sigma''})=0. \tag{6}$$

From the definition of $U_{\sigma,\sigma'}$ and since j_σ are isometries, we conclude $U_{\sigma,\sigma'}U_{\sigma',\sigma''}=U_{\sigma,\sigma''}$.

(2) *It follows from proposition 1 and definition of $U_{\sigma,\sigma'}$.*

(3) *Because j_σ^* and j_σ are isometries, the property results immediately.*

III. EXPONENTIAL BOUNDS ON PROPAGATORS

To improve our estimates on the propagators $U_{\sigma,\sigma'}$ we need a supplementary condition on the metric g. We say that an application $Q:R^{n+1}\to M(n+1,n+1)$ has stable positivity if there exists $\epsilon>0$ such that for any application $\delta:R^{n+1}\to M(n+1,n+1)$ with $|\delta(x)^{ij}|\leqslant\epsilon$ the matrices $Q(x)-\delta(x)$ are positively defined for any $x\in R^{n+1}$. The following result is a direct application of Agmon theory[2] of exponentially decay of solutions of elliptic second-order operators.

Proposition 6: If the metric g has stable positivity then for any $f\in N_{\sigma'}$:

$$\int_{T_0}^\infty d\sigma\{e^{\omega\sigma}\|\hat{E}_\sigma^{1/2}\circ U_{\sigma,\sigma'}f\|_{N_\sigma}\}^2<\infty, \tag{7}$$

provided $\omega<m/\sqrt{\sup g^{11}}$.

Solution 7: Starting from

$$\begin{aligned}\langle u,U_{\sigma,\sigma'}f\rangle_{N_\sigma}&=\langle u,\hat{E}_\sigma\circ U_{\sigma,\sigma'}f\rangle_{L^2(R^n,d\mu_\sigma)}\\&=\int_{R^n}\overline{u}(x)\left[\int_{R^n}E_m(\sigma,x;\sigma',y)f(y)d\mu_{\sigma'}(y)\right]d\mu_\sigma(x)\end{aligned} \tag{8}$$

for $u\in N_\sigma$ and $f\in N_{\sigma'}$, it follows that $\varphi(\sigma,x)=(\hat{E}_\sigma\circ U_{\sigma,\sigma'}f)(x)$ is a solution of

$$(\Delta+m^2)\varphi(\sigma,x)=0 \tag{9}$$

for $\sigma>\sigma'$. *Let* $\rho_m\,(\cdot;\cdot)$ *denote the distance corresponding to the metric* $g_m=mg$. *The metric* g *has stable positivity so, there is an* $\epsilon\in R_+$ *such that* $\rho_m(\sigma_0,x_0;\sigma,x)>(\epsilon/m)|\sigma-\sigma_0|$. *For* $\Omega=\{(\sigma,x):\sigma>T_0\}$, $T_0\in R_+$ *and for some positive* λ:

$$\begin{aligned}\int_\Omega|\varphi(\sigma,x)|^2e^{-\lambda\rho_m(T_0,x_0;\sigma,x)}\sqrt{g(\sigma,x)}d\sigma\,d^nx\\
&=\int_{T_0}^\infty d\sigma\langle\hat{E}_\sigma\circ U_{\sigma,\sigma'}f,\hat{E}_\sigma\circ U_{\sigma,\sigma'}f\rangle_{L^2(R^n,d\mu_\sigma)}e^{-\lambda(\epsilon/m)(\sigma-T_0)}\\
&<ct.\int_{T_0}^\infty d\sigma\langle U_{\sigma,\sigma'}f,\hat{E}_\sigma\circ U_{\sigma,\sigma'}f\rangle_{L^2(R^n,d\mu_\sigma)}e^{-\lambda(\epsilon/m)(\sigma-T_0)}\\
&=ct.\int_{T_0}^\infty d\sigma\|U_{\sigma,\sigma'}f\|^2_{N_\sigma}e^{-\lambda(\epsilon/m)(\sigma-T_0)}<\infty.\end{aligned} \tag{10}$$

So we are in the conditions of the main theorem of Ref. 2. It follows that:

$$\begin{aligned}&\int_\Omega d\sigma\,d^nx\sqrt{g(\sigma,x)}|\varphi(\sigma,x)|^2(m^2-g(\nabla h(\sigma,x),\nabla h(\sigma,x)))e^{2h(\sigma,x)}\\
&\leqslant\frac{2(1+2d)}{d^2}m^2\int_{\Omega\backslash\Omega_d}|\varphi(\sigma,x)|^2e^{2h(\sigma,x)}\sqrt{g(\sigma,x)}dx,\end{aligned} \tag{11}$$

where d *is a positive number and* $\Omega_d=\{(\sigma,x)\in\Omega:\rho_m((\sigma,x),\{\infty\})>d\}$. *Here*

$$\rho_m((\sigma,x),\{\infty\})=\sup\{\rho_m((\sigma,x),\Omega\backslash K):K\text{ is a compact subset of }\Omega\}. \tag{12}$$

The function h *is any function which satisfies the condition* $g(\nabla h(\sigma,x),\nabla h(\sigma,x))<m^2$. *We choose* $h(\sigma,x)=\omega\sigma$ *with* $\omega<m/\sqrt{\sup g^{11}}$. *The above inequality becomes*

$$\int_\Omega d\sigma\,d^nx\sqrt{g(\sigma,x)}|\varphi(\sigma,x)|^2e^{2\omega\sigma}<\frac{2(1+2d)}{d^2}\,\frac{m^2}{m^2-g^{11}\omega^2}\int_{\Omega\backslash\Omega_d}d\sigma\,dx\sqrt{g(\sigma,x)}|\varphi(\sigma,x)|^2e^{2\omega\sigma}. \tag{13}$$

If for any point $(\sigma,x)\in\Omega$ *there is a geodesic which starts in* (σ,x) *and ends in the hyperplane* $\sigma=T_0$ *then* $\Omega\backslash\Omega_d\subset\{(\tau,x):0<\sigma\leqslant T\}$ *with* T *sufficiently large but finite. In conclusion,*

$$\int_\Omega d\sigma\,d^nx\sqrt{g(\sigma,x)}|\varphi(\tau,x)|^2e^{2\omega\sigma}=\int_{T_0}^\infty d\sigma\,e^{2\omega\sigma}\langle\hat{E}_\sigma\circ U_{\sigma,\sigma'}f,\hat{E}_\sigma\circ U_{\sigma,\sigma'}f\rangle_{L^2(R^n,\mu_\sigma)}<\infty, \tag{14}$$

or

$$\int_{T_0}^\infty d\sigma\,e^{2\omega\sigma}\langle\hat{E}_\sigma\circ U_{\sigma,\sigma'}f,\hat{E}_\sigma\circ U_{\sigma,\sigma'}f\rangle_{L^2(R^n,\mu_\sigma)}<\infty, \tag{15}$$

which implies

$$\int_{T_0}^\infty d\sigma\{e^{\omega\sigma}\|\hat{E}_\sigma^{1/2}\circ U_{\sigma,\sigma'}f\|_{N_\sigma}\}^2<\infty. \tag{16}$$

IV. THE STATIONARY CASE

We consider in this section that there is a coordinate system such that the metric g is independent of the first coordinate. In this case, the spaces N_σ and the operators $\hat{E}_\sigma^{1/2}$ are identical and will be denoted by N_0 and $\hat{E}_0^{1/2}$, respectively. Thus, the operators $U_{\sigma,\sigma'}$ are defined on the same Hilbert space and depend only on the difference $\sigma-\sigma' : U_{\sigma,\sigma'}=U_{\sigma-\sigma'}$. The family of operators $\{U_\tau\}_{\tau\in R_+}$ forms a semigroup. Using the results about existence and properties of the generators of semigroups,[7] we can obtain bounds directly on the transfer matrix U_τ.

Proposition 8: The semigroup $\{U_\tau\}_{\tau\in R_+}$ *is exponentially bounded:* $\|U_\tau\|_{N_0}<e^{-\tau\omega}$ *provided* $\omega<m/\sqrt{\sup g}$[11].

Solution 9: Because we have found estimates on $\hat{E}_0^{1/2}\circ U_\tau$, *we will consider the operators* $\tilde{U}_\tau=\hat{E}_0^{1/2}\circ U_\tau\circ(\hat{E}_0^{1/2})^\dagger$, *well defined on* $L^2(R^n,d\mu_0)$. *Using the fact that* $L^2(R^n,d\mu_0)$ *is dense in* N_0 *we can extend these operators by continuity on the space* N_0. *In this way we have built the semigroup* $\{\tilde{U}_\tau\}_{\tau\in R_+}$ *which satisfies the estimates of the precedent section:*

$$\int_{T_0}^{\infty} d\tau\{e^{\omega\tau}\|\tilde{U}_\tau\|_{N_0}\}^2<\infty, \tag{17}$$

for some $T_0>0$. *So* $\{\tilde{U}_\tau\}_{\tau\in R_+}$ *is exponentially bounded and in consequence,*[7] *if* $\tilde{K}$ *is its generator* $(\tilde{U}_\tau=e^{-\tau\tilde{K}})$ *the resolvent set of* $\tilde{K}$ *satisfies:*

$$\{z\in C|\mathrm{Re}\, z\in(-\infty,\omega)\}\subset\rho(\tilde{K}). \tag{18}$$

If K *is the generator of* $\{U_\tau\}_{\tau\in R_+}$ *then, on* $\mathcal{D}(K)$ *we have:*

$$K=(\hat{E}_0^{1/2})^\dagger\circ\tilde{K}\circ\hat{E}_0^{1/2} \tag{19}$$

by using the reciprocal formula

$$U_\tau=(\hat{E}_0^{1/2})^\dagger\circ\tilde{U}_\tau\circ\hat{E}_0^{1/2}, \tag{20}$$

valid on N_0. *If the operator*

$$(\hat{E}_0^{1/2})^\dagger\circ(\tilde{K}-z)^{-1}\circ\hat{E}_0^{1/2} \tag{21}$$

is well defined, even on a dense subset of N_0, *then* $K-z$ *is inversable.*

From (20) it follows that, if $(\tilde{K}-z)^{-1}$ exists, then

$$(\tilde{K}-z)^{-1}(L^2(R^n,d\mu_0))\subset L^2(R^n,d\mu_0), \tag{22}$$

and in consequence $(\hat{E}_0^{1/2})^\dagger\circ(\tilde{K}-z)^{-1}\circ\hat{E}_0^{1/2}$ is well defined on the entire N_0. Will follow that $\rho(\tilde{K})\subset\rho(K)$ and this ends the proof.

If the metric is symmetric at transformation $x^1\to -x^1$, the transfer matrix generator is self-adjoint and it can be considered as the Hamiltonian of the scalar field.

V. APPLICATION

Our application is for the Euclidean case. The results concerning decoupling of different regions in quantum Euclidean fields are based primarily on estimates of $\|e_{\Lambda_1}e_{\Lambda_2}\|_N$, where Λ_1,Λ_2 are two disjoint regions. Let us consider the two dimensional case. The most difficult case is when Λ_1,Λ_2 are not convex and there is no possibility of drawing a straight line between the two subsets. We can sharpen the existent estimates[5] for these cases by using the previous results. The idea is to make a change of coordinates such that for the new coordinates, lines like $\sigma=ct$.

separate the two sets and they are as close as possible to the boundaries of Λ_1,Λ_2. Then we can use the exponential bounds of the previous section to evaluate $\|e_{\Lambda_1}e_{\Lambda_2}\|_N$. More precisely:

Proposition 10: Let Λ_1,Λ_2 two regions in R^2 such that the construction of the coordinates 26 to be possible (after a rotation if necessary). Then

$$\|e_{\lambda_1}\circ e_{\Lambda_2}\|_N \leqslant e^{-m|\beta-\alpha|\min|\cos\theta|}, \tag{23}$$

where θ and $|\beta-\alpha|$ will be defined during the proof.

Solution 11: Let (t,x) denote the original coordinates in which the metric is diagonal. Let $\gamma{:}R\rightarrow R^2$ be a curve which separates Λ_1,Λ_2 and $\gamma(0)=(t=0,x=0)$. We define a new coordinate system (σ,ξ) by

$$\begin{aligned} t(\sigma,\xi)&=\sigma+\gamma^1(\xi),\\ x(\sigma,\xi)&=\gamma^2(\xi). \end{aligned} \tag{24}$$

In the new coordinates, the metric is

$$g'(\sigma,\xi)=\begin{pmatrix} 1 & \dfrac{d\gamma^1}{d\xi} \\ \dfrac{d\gamma^1}{d\xi} & \left(\dfrac{d\gamma^1}{d\xi}\right)^2+\left(\dfrac{d\gamma^2}{d\xi}\right)^2 \end{pmatrix} \tag{25}$$

so we are in the conditions of the last section. Using the Markoff property,

$$\|e_{\Lambda_1}\circ e_{\Lambda_2}\|_N=\|e_{\Lambda_1}\circ e_\alpha\circ e_\beta\circ e_{\Lambda_2}\|_N \leqslant \|e_\alpha\circ e_\beta\|_N, \tag{26}$$

where the lines $\sigma=\alpha$, $\sigma=\beta$ separate Λ_1 and Λ_2 exactly in the order they appear in the above relation (in the sense that $\sigma=\alpha$ separates Λ_1 by $\sigma=\beta$, etc.). Further,

$$\|j_\alpha\circ j_\alpha^\dagger\circ j_\beta\circ j_\beta^\dagger\|_N=\|j_\alpha\circ U_{\alpha-\beta}\circ j_\beta^\dagger\|_N=\|U_{\alpha-\beta}\|_{N_0}. \tag{27}$$

The element $(g')^{11}$ is given by $(g')^{11}=1/\cos^2\theta$, where θ is the angle between the tangent to the curve γ and the x axis. Using the bounds of the last section we have

$$\|e_{\Lambda_1}\circ e_{\Lambda_2}\|_N \leqslant e^{-m|\beta-\alpha|\min|\cos\theta|}. \tag{28}$$

Performing first a rotation, one can choose the best values for $|\beta-\alpha|$ and $\min|\cos\theta|$.

VI. CONCLUSIONS

Our primary goal was to define the transfer matrix for scalar fields on curved spaces and to investigate the basic spectral properties of its generator. Even though the generator is not self-adjoint in the general case, this approach allows us to investigate this problem by using at least two new tools besides the methods of Green's functions. One is the perturbations of hypercontractive semigroups[8] and the other is the adiabatic theorem.

Now it is straightforward to quantize the field by defining the Markoff field over the space *N*. For the stationary, symmetric at time reflection case (static), we think that one now has all elements to construct the physical field (for example that proposed in Ref. 4) by following the Nelson reconstruction method and the holomorphic continuation of the transfer matrix. Note that, according to the results of Ref. 6, the holomorphic continuation of the transfer matrix to real time is still possible in the stationary case without symmetry at time reflection, as long as the spectrum of the generator belongs to the real axis. Of course, one has to check that the results of Ref. 9 (systematized in Ref. 5), which are the core of the reconstruction theorem, are still valid. For the general case, we think that the adiabatic theorem, especially the adiabatic reduction theory,[10] may play an important role in defining the physical quantum field by following Nelson's approach.

Darboux transformation and solutions for an equation in 2+1 dimensions

P. G. Estévez[a)]
Area de Física Teórica, Facultad de Física, Universidad de Salamanca, 37008 Salamanca, Spain

(Received 5 May 1998; accepted for publication 13 October 1998)

Painlevé analysis and the singular manifold method are the tools used in this paper to perform a complete study of an equation in 2+1 dimensions. This procedure has allowed us to obtain the Lax pair, Darboux transformation and τ functions in such a way that a plethora of different solutions with solitonic behavior can be constructed iteratively. © *1999 American Institute of Physics.*

I. INTRODUCTION

Among the various approaches followed to study the behavior of nonlinear partial differential equations (PDEs), Painlevé analysis has proved to be one of the most fruitful, providing an algorithmic procedure that affords a systematic way to deal with nonlinear PDEs. Despite this, it has often been used merely as a test of integrability while other methods, as Hirota's method or inverse scattering, have been used to obtain explicit solutions.

Our aim here is to show, for an equation in 2+1, that an approach based on Painlevé techniques, such as the singular manifold method (SMM), can be successful in identifying many of the properties of nonlinear PDEs (Bäcklund and Darboux transformations, τ-functions, etc.) as well as in constructing an iterative procedure to obtain multisolitonic solutions.

The subject of our study is the 2+1 PDE

$$\begin{aligned} 0&=V_y-(u\omega)_x,\\ 0&=\lambda u_t+u_{xx}-2uV, \qquad (1.1)\\ 0&=\lambda\omega_t-\omega_{xx}+2\omega V. \end{aligned}$$

The real version of this equation was obtained in Ref. 1 as a reduction of self-dual Yang–Mills equations while the complex version appears in Ref. 2. The equation has the Painlevé property (PP) as it has been shown by Radha and Lakshmanan[3] (real version) and Porsezian[4] (complex version). The bilinear method was applied in Ref. 3 to obtain some soliton and dromion solutions.

For $\lambda=i$ and $\omega=u^*$, Eq. (1.1) is the expression proposed by Fokas in Ref. 5. This case contains the nonlinear Schrödinger equation when $x=y$.[6]

Recently,[6] the author and her co-worker have shown that there is a Miura transformation between Eq. (1.1) and the generalized dispersive long wave equation.[7,8]

The plan of this paper is as follows: In Sec. II we shall apply the singular manifold method to Eq. (1.1). Sections III, IV, and V are devoted to showing how the SMM allows us to determine algorithmically the Lax pair as well as Darboux transformations and τ-functions. In Sec. VI, several solutions are constructed explicitly. We close with a list of conclusions.

II. THE SINGULAR MANIFOLD METHOD

The equation under study in this paper is the real version of Eq. (1.1), which reads

$$
\begin{aligned}
0 &= m_y + u\omega, \\
0 &= u_t + u_{xx} + 2um_x, \qquad (2.1) \\
0 &= \omega_t - \omega_{xx} - 2\omega m_x,
\end{aligned}
$$

where we have set $\lambda = 1$ and $V = -m_x$.

A. Leading term analysis

To check the Painlevé property[9] for Eq. (2.1), we require a generalized Laurent expansion of the fields in terms of an arbitrary singularity manifold (depending on the initial data) $\chi(x,y,t) = 0$. This expansion should be of the form[10]

$$u = \sum_{j=0}^{\infty} u_j \chi^{j-a}, \quad \omega = \sum_{j=0}^{\infty} \omega_j \chi^{j-b}, \quad m = \sum_{j=0}^{\infty} m_j \chi^{j-c}. \qquad (2.2)$$

By substituting Eq. (2.2) into Eq. (2.1), we have for the leading terms

$$a = b = c = 1, \quad m_0 = \chi_x, \quad u_0 \omega_0 = \chi_x \chi_y. \qquad (2.3)$$

Leading analysis is able to determine the product of the dominant terms $u_0\omega_0$ but not each one independently, which means that u and ω are not good fields in which to apply the singularity analysis because their dominant behavior is not well defined. However, for the field m, the leading term m_0 is well defined. This suggests that the ''good field,'' from the point of view of the Painlevé analysis, is m. Accordingly, our first aim will be to write Eq. (2.1) as a partial differential equation only for m. It is not difficult to check (see Appendix) that if we identify

$$m_t = n_x, \qquad (2.4)$$

we can remove u and ω from Eq. (2.1) to obtain the PDE

$$0 = m_y^2(n_{yt} - m_{xxxy}) + m_{xy}(n_y^2 - m_{xy}^2) + 2m_y(m_{xy}m_{xxy} - n_y n_{xy}) - 4m_y^3 m_{xx}. \qquad (2.5)$$

In Ref. 6, it has been shown that there is a Miura transformation between Eq. (2.5) and the generalized long dispersive wave equation.[7,8] This is why below we shall be referring, in the next, to Eq. (2.5) as MGLDW (modified generalized long dispersive wave equation). The study of this equation for the field m will be the subject of the rest of this paper. Furthermore, u and ω can easily be obtained from m as

$$u = \sqrt{m_y} e^{\int (n_y/2m_y)dx}, \quad \omega = -\sqrt{m_y} e^{-\int (n_y/2m_y)dx}, \qquad (2.6)$$

as we show in a detailed manner in the Appendix

B. Truncated expansion: Auto-Bäcklund transformations

As stated above, the singularity manifold χ is an arbitrary function depending on the initial data. The SMM requires us to restrict ourselves to the particular cases of the singularity manifold for which the expansion (2.2) truncates at the constant level.[11] In this case the singularity manifold is not longer an arbitrary function because it is ''determined'' by the condition of truncation. We call it ''singular manifold'' and we shall use ϕ to refer to it. Thus, the truncation of Eq. (2.2) is

$$m' = m + \frac{\phi_x}{\phi} \Rightarrow n' = n + \frac{\phi_t}{\phi}, \tag{2.7}$$

where both m and m' are solutions of Eq. (2.5). Accordingly, truncation of the Painlevé series adopts the form of an auto-Bäcklund transformation between two solutions of Eq. (2.5).

C. Expression of the solutions in terms of the singular manifold

Substitution of Eq. (2.7) into Eq. (2.5) provides a polynomial in ϕ. The way to proceed in the SMM is to require that all the coefficients of this polynomial should be zero. The result should be

a) The expression of m in terms of ϕ.
b) The equations to be satisfied by ϕ.

For Eq. (2.5), the polynomial in ϕ is rather complicated. We used MAPLE V to handle the calculation. This allows us to obtain the derivatives of m in terms of the singular manifold. The result is

$$4m_x = p_t - v_x - \frac{v^2 + w^2}{2}, \tag{2.8}$$

$$4n_y = 2\frac{(q_x + qv)_x p_y - (q_x + qv)p_{xy}}{q} + 4\frac{(p_y + qp_x)}{q} m_y, \tag{2.9}$$

$$4m_y = \frac{p_y^2 - (q_x + qv)^2}{q}, \tag{2.10}$$

where p,q,wyv are defined from the singular manifold as

$$v = \frac{\phi_{xx}}{\phi_x}, \quad w = \frac{\phi_t}{\phi_x} = p_x, \quad q = \frac{\phi_y}{\phi_x}. \tag{2.11}$$

D. Singular manifold equations

The equations to be satisfied by the singular manifold ϕ are not difficult to obtain:

• On one hand, there are some generic equations arising from the compatibility of the definitions (2.11). These are

$$\begin{gathered} \phi_{xxt} = \phi_{txx} \Rightarrow v_t = (w_x + vw)_x, \\ \phi_{xxy} = \phi_{yxx} \Rightarrow v_y = (q_x + vq)_x, \\ \phi_{yt} = \phi_{ty} \Rightarrow q_t = w_y + wq_x - qw_x. \end{gathered} \tag{2.12}$$

• Also, there is an equation that is specific for Eq. (2.5) that can be determined by taking the cross derivatives in Eqs. (2.8)–(2.10). This equation is

$$p_{yt} = q_{xxx} + q(v_{xx} - vv_x) + p_x p_{xy} + \left(\frac{p_y^2 - q_x^2}{q}\right)_x. \tag{2.13}$$

The set (2.12) and (2.13) forms the singular manifold equations.

III. LAX PAIR AND SMM

It is unnecessary to talk about the importance of determining the Lax pair of a nonlinear PDE. Nevertheless, in most cases it is determined by inspection. We shall see here that a nontrivial advantage of Painlevé analysis is that it allows us to determine the Lax pair in an algorithmic way.[12,13]

A. Dominant terms in singular manifold equations

Returning to the singular manifold Eqs. (2.12) and (2.13), these can be considered to be a system of coupled nonlinear PDEs. We can, therefore, analyze their leading terms. This requires us to set

$$w \sim w_0 \chi^a, \quad v \sim v_0 \chi^b, \quad q \sim q_0 \chi^c. \tag{3.1}$$

The balance of leading powers yields:

$$a = b = -1, \quad c = 0, \tag{3.2}$$

which means that only w and v have an expansion in negative powers of χ. Thus, the Painlevé expansion is only pertinent for them but not for q. Moreover, the leading analysis provides the leading coefficients $w_0 y v_0$

$$w_0 = \pm \chi_x, \quad v_0 = \chi_x. \tag{3.3}$$

The $\pm$ sign of w_0 means that there are two possible Painlevé expansions: The problem of systems with two Painlevé branches has been extensively discussed in Refs. 12–15. The suggestion of the author and co-worker is that, for this class of systems, it is necessary to consider both branches simultaneously by using two singular manifolds; one for each branch.

B. Eigenfunctions and the singular manifold

With this idea in mind, for the dominant terms of w and v we can write

$$v = \frac{\psi_x^+}{\psi^+} + \frac{\psi_x^-}{\psi^-}, \quad w = \frac{\psi_x^+}{\psi^+} - \frac{\psi_x^-}{\psi^-}, \tag{3.4}$$

where we have used ψ^+ for the singular manifold of the positive branch and ψ^- for the negative one. As we will seen later on, ψ^+ and ψ^- will be the eigenfunctions of the Lax pair and hereafter we will designate them as eigenfunctions.

• Taking the derivatives of Eq. (3.4) with respect to t and y and using Eq. (2.12) to integrate them in x, we can write

$$w_x + wv = \frac{\psi_t^+}{\psi^+} + \frac{\psi_t^-}{\psi^-}, \quad p_t = \frac{\psi_t^+}{\psi^+} - \frac{\psi_t^-}{\psi^-} \tag{3.5}$$

and

$$q_x + qv = \frac{\psi_y^+}{\psi^+} + \frac{\psi_y^-}{\psi^-},$$

$$p_y = \frac{\psi_y^+}{\psi^+} - \frac{\psi_y^-}{\psi^-}. \tag{3.6}$$

Expressions (3.4)–(3.6) allow us *to write the logarithmic derivatives of the eigenfunctions* ψ^+ *and* ψ^- *in terms of the singular manifold as*

$$\alpha^+=\frac{\psi_x^+}{\psi^+}=\frac{v+w}{2},\quad \alpha^-=\frac{\psi_x^-}{\psi^-}=\frac{v-w}{2},\tag{3.7}$$

$$\beta^+=\frac{\psi_y^+}{\psi^+}=\frac{q_x+qv+p_y}{2},\quad \beta^-=\frac{\psi_y^-}{\psi^-}=\frac{q_x+qv-p_y}{2},\tag{3.8}$$

$$\gamma^+=\frac{\psi_t^+}{\psi^+}=\frac{w_x+wv+p_t}{2},\quad \gamma^-=\frac{\psi_t^-}{\psi^-}=\frac{w_x+wv-p_t}{2},\tag{3.9}$$

$\alpha,\beta y\,\gamma$ have been introduced with the single purpose of simplifying later calculations.

• Conversely, the determination of ϕ from $\psi^+ y\,\psi^-$ is not difficult taking into account Eq. (2.11), which allows us integrate Eq. (3.4) with respect to x, which yields

$$\phi_x=\psi^+\psi^-,\tag{3.10}$$

where the integration constant has been set at zero with no loss of generality (because the singular manifold is defined except for a multiplicative constant). The t derivative of ϕ can be obtained by combining Eqs. (2.11), (3.4), and (3.10) to obtain

$$\phi_t=\psi^-\psi_x^+-\psi^+\psi_x^-,\tag{3.11}$$

and, similarly, ϕ_y arises from Eqs. (2.10), (2.11), and (3.6) as

$$\phi_y=-\frac{\psi_y^+\psi_y^-}{m_y}.\tag{3.12}$$

Equations (3.10)–(3.12) allow us to construct ϕ from ψ^+ and ψ^-. Accordingly, *the total correspondence between singular manifolds and eigenfunctions is explicitly constructed*.

C. Linearization of the singular manifold equations: The Lax pair

We return to Eqs. (2.8)–(2.10). These equations are the expression of the seminal solution m in terms of the singular manifold. At the same time, Eqs. (3.7)–(3.12) relate the singular manifold to the eigenfunctions. The question is now: How can we express m in terms of ψ^+ and ψ^-?

• As a previous step, it is easy to see that Eq. (2.10) can be combined with Eq. (3.8), yielding

$$m_y=-\frac{\beta^+\beta^-}{q}\Rightarrow\frac{\psi_y^+\psi_y^-}{\psi^+\psi^-}=-qm_y,\tag{3.13}$$

which shows the coupling between ψ^+ and ψ^-.

• Let us return to Eq. (2.8). To write this in terms of the eigenfunctions, we need to substitute v and p_t from Eqs. (3.7) and (3.9)

$$4m_x=2\gamma^+-2\alpha_x^+-2(\alpha^+)^2,\quad \text{or}\quad 4m_x=-2\gamma^--2\alpha_x^--2(\alpha^-)^2.$$

Now, by substituting α and γ

$$0=\psi_t^+-\psi_{xx}^+-2m_x\psi^+,\quad \text{or}\quad 0=\psi_t^-+\psi_{xx}^-+2m_x\psi^-,\tag{3.14}$$

and this can be considered as the temporal part of the Lax pair.

• Finally, by combining it with Eqs. (3.7) and (3.8), Eq. (2.9) can be written as

$$qn_y=[\beta^+\beta_x^--\beta^-\beta_x^+]+m_y[(\beta^+-\beta^-)+q(\alpha^+-\alpha^-)].\tag{3.15}$$

If we use $\beta^+\beta^-=-qm_y$ and $\alpha^++\alpha^-=v$ to remove from Eq. (3.15) (β^-,α^-) or (β^+,α^+).

$$n_y = -m_{xy} + 2m_y\left(\frac{\beta_x^+}{\beta^+} + \alpha^+ + \frac{m_y}{\beta^+}\right), \quad n_y = m_{xy} - 2m_y\left(\frac{\beta_x^-}{\beta^-} + \alpha^- + \frac{m_y}{\beta^+}\right),$$

or

$$(n_y + m_{xy})\psi_y^+ = 2m_y(\psi_{xy}^+ + m_y\psi^+), \quad (-n_y + m_{xy})\psi_y^- = 2m_y(\psi_{xy}^- + m_y\psi^-), \tag{3.16}$$

and this can be considered the spatial part of the Lax pair.

Thus, the SMM allows us to define two eigenfunctions, ψ^+ and ψ^-, such that *the expression of the truncated solutions in terms of these eigenfunctions is precisely the Lax pair* Eqs. (3.15) and (3.16).

IV. DARBOUX TRANSFORMATIONS

This section will be devoted to determining an algorithmic procedure for constructing solutions.

• We shall summarize the results obtained in the previous section: Let m be a solution of Eq. (2.5), and ϕ_1 a singular manifold for it. This singular manifold can be constructed by means of two eigenfunctions ψ_1^+ and ψ_1^- through

$$\phi_{1x} = \psi_1^+\psi_1^-, \quad m_y\phi_{1y} = -\psi_{1y}^+\psi_{1y}^-, \quad \phi_{1t} = \psi_1^-\psi_{1x}^+ - \psi_1^+\psi_{1x}^-, \tag{4.1}$$

where ψ_1^+ and ψ_1^- satisfy the Lax pairs

$$0 = \psi_{1t}^+ - \psi_{1xx}^+ - 2m_x\psi_1^+, \quad 0 = \psi_{1t}^- + \psi_{1xx}^- + 2m_x\psi_1^-,$$
$$0 = 2m_y\psi_{1xy}^+ - (m_{xy} + n_y)\psi_{1y}^+ + 2m_y^2\psi_1^+, \quad 0 = 2m_y\psi_{1xy}^- - (m_{xy} - n_y)\psi_{1y}^- + 2m_y^2\psi_1^-. \tag{4.2}$$

• According to Eq. (2.7), the singular manifold ϕ_1 allows us to define a new solution m'

$$m' = m + \frac{\phi_{1x}}{\phi_1} \Rightarrow n' = n + \frac{\phi_{1t}}{\phi_1}, \tag{4.3}$$

whose Lax pairs will be

$$0 = \psi_t'^+ - \psi_{xx}'^+ - 2m_x'\psi'^+, \quad 0 = \psi_t'^- + \psi_{xx}'^- + 2m_x'\psi'^-,$$
$$0 = 2m_y'\psi_{xy}'^+ - (m_{xy}' + n_y')\psi_y'^+ + 2m_y'^2\psi'^+, \quad 0 = 2m_y'\psi_{xy}'^- - (m_{xy}' - n_y')\psi_y'^- + 2m_y'^2\psi'^-, \tag{4.4}$$

and ψ'^+ and ψ'^- can be used to construct, for m', a singular manifold ϕ' defined as

$$\phi_x' = \psi'^+\psi'^-, \quad m_y'\phi_y' = -\psi_y'^+\psi_y'^-, \quad \phi_t' = \psi'^-\psi_x'^+ - \psi'^+\psi_x'^-. \tag{4.5}$$

A. Truncated expansion in the Lax pair

A Lax pair, such as Eq. (4.4), is usually considered to be a linear system for ψ', where m' is the potential and hence the inverse scattering method can be applied.

A different interpretation[12,16] of Eq. (4.4) is to consider it as a coupled ''nonlinear'' system of PDEs for the fields m', n', ψ'^+, ψ'^-. In this case, the singular manifold method can be applied to the Lax pair itself and the truncated expansion (4.3) for m and n should be combined with a similar expansion for ψ'^+ and ψ'^-. In fact, this expansion could be written as

$$\psi'^+ = \psi_2^+ + \frac{\psi_0^+}{\phi_1}, \quad \psi'^+ = \psi_2^- + \frac{\psi_0^-}{\phi_1},$$

where ψ_0^+, ψ_0^- are the dominant terms. It is useful. For later calculations, it is useful to set $\psi_0^+ = -\psi_1^+\Omega^+$, and $\psi_0^- = -\psi_1^-\Omega^-$. Therefore

$$\psi'^+ = \psi_2^+ - \psi_1^+ \frac{\Omega^+}{\phi_1}, \quad \psi'^- = \psi_2^- - \psi_1^- \frac{\Omega^-}{\phi_1}. \tag{4.6}$$

Substitution of the truncated expansions (4.3) and (4.6) in the Lax pairs (4.4) provides the following results (we used MAPLE for the calculations):

• (1) ψ_2^+ and ψ_2^- are eigenfunctions for m. Consequently, they satisfy Lax pairs such as

$$0 = \psi_{2t}^+ - \psi_{2xx}^+ - 2m_x\psi_2^+, \quad 0 = \psi_{2t}^- + \psi_{2xx}^- + 2m_x\psi_2^-,$$

$$0 = 2m_y\psi_{2xy}^+ - (m_{xy}+n_y)\psi_{2y}^+ + 2m_y^2\psi_2^+, \quad 0 = 2m_y\psi_{2xy}^- - (m_{xy}-n_y)\psi_{2y}^- + 2m_y^2\psi_2^-. \tag{4.7}$$

• (2) Ω^+ and Ω^- are related to the eigenfunctions in the following way:

$$\Omega_x^- = \psi_1^+\psi_2^-, \quad m_y\Omega_y^- = -\psi_{1y}^+\psi_{2y}^-, \quad \Omega_t^- = \psi_{1x}^+\psi_2^- - \psi_1^+\psi_{2x}^-, \tag{4.8}$$

$$\Omega_x^+ = \psi_2^+\psi_1^-, \quad m_y\Omega_y^+ = -\psi_{2y}^+\psi_{1y}^-, \quad \Omega_t^+ = \psi_{2x}^+\psi_1^- - \psi_2^+\psi_{1x}^-. \tag{4.9}$$

• To summarize: Two pairs of eigenfunctions $(\psi_1^+, \psi_1^-), (\psi_2^+, \psi_2^-)$ for a solution (m,n) are sufficient to construct the following transformation:,

$$\begin{aligned} m' &= m + \frac{\phi_{1x}}{\phi_1}, \quad n' = n + \frac{\phi_{1t}}{\phi_1}, \\ \psi'^+ &= \psi_2^+ - \psi_1^+ \frac{\Omega^+}{\phi_1}, \quad \psi'^- = \psi_2^- - \psi_1^- \frac{\Omega^-}{\phi_1}, \end{aligned} \tag{4.10}$$

where ϕ_1, Ω^+, and Ω^- are related to the eigenfunction through Eqs. (4.1), (4.8), and (4.9).

Equation (4.10) is a transformation of potentials and eigenfunctions that leaves invariant the Lax pairs. It should, therefore, be considered a *Darboux transformation*.[17]

V. ITERATION OF THE SINGULAR MANIFOLD: τ-FUNCTIONS

A well known method for obtaining multisolitonic solutions of PDEs is the bilinear Hirota method. Indeed, some solutions of Eq. (2.1) have been identified with this method.[3] Let us address ourselves to the task of establishing, by explicit construction, the relationship between the singular manifold and the τ-functions of Hirota's method.

• Equation (4.5) could be considered as a nonlinear system among ϕ', ψ'^+ and ψ'^-. For this system we can use the same criterion used in the previous section. It requires that the expansion

$$\psi'^+ = \psi_2^+ - \psi_1^+ \frac{\Omega^+}{\phi_1}, \quad \psi'^- = \psi_2^- - \psi_1^- \frac{\Omega^-}{\phi_1}, \tag{5.1}$$

for ψ'^+ and ψ'^- should be combined with a truncated expansion for ϕ'.

$$\phi' = \phi_2 + \frac{\Delta}{\phi_1}. \tag{5.2}$$

It is not difficult to prove that the substitution of Eqs. (5.1) and (5.2) into Eq. (4.5) gives

$$\Delta = -\Omega^+\Omega^-, \tag{5.3}$$

while ϕ_2 is the singular manifold for m related to ψ_2^+ and ψ_2^-, which means

$$\phi_{2x}=\psi_2^+\psi_2^-,$$
$$m_y\phi_{2y}=-\psi_{2y}^+\psi_{2y}^-, \tag{5.4}$$
$$\phi_{2t}=\psi_2^-\psi_{2x}^+-\psi_2^+\psi_{2x}^-.$$

• As far as Eq. (5.2) defines a singular manifold for m', it can be used to obtain a new solution

$$m''=m'+\frac{\phi_x'}{\phi'},\quad n''=n'+\frac{\phi_t'}{\phi'}, \tag{5.5}$$

which, combined with Eq. (4.3), is

$$m''=m+\frac{\tau_x}{\tau},\quad n''=n+\frac{\tau_t}{\tau}, \tag{5.6}$$

where

$$\tau=\phi'\phi_1=\phi_1\phi_2-\Omega^+\Omega^-. \tag{5.7}$$

In the previous section we have shown that $\phi_1,\phi_2,\Omega^+,\Omega^-$ are obtained from the eigenfunctions $(\psi_1^+,\psi_1^-),(\psi_2^+,\psi_2^-)$. Therefore, *Eq. (5.7) affords the relationship between* τ*-functions, on one hand, and singular manifolds*, on the other hand.

VI. SOLUTIONS

From the previous results we can derive an iterative procedure to construct solutions. It can be summarized as follows:

(1) Starting with a seminal solution *m*, solve the Lax pairs (4.2) and (4.8) to obtain $\psi_1^+,\psi_1^-,\psi_2^+,\psi_2^-$.
(2) Perform the integration of Eqs. (4.1), (4.8), (4.9), and (5.4) to get ϕ_1, Ω^+, Ω^- and ϕ_2: Use Eq. (5.7) to construct τ.
(3) Use Eq. (4.3) to obtain the solution m' for the first iteration and Eq. (5.5) for the second one m''.

The easiest way to obtain explicit solutions is to apply the above explained procedure, starting with a trivial seminal solution. We shall use as seminal solutions $m=m_0y$ and $m=0$. From the dependence on y of Eqs. (4.1), (4.9), (4.10), and (5.4) it is that the behavior is totally different, depending on whether m_y is zero or not and giving rise to line-soliton or dromion behavior, respectively.

A. Line solitons $m=\omega_0 y$

• The easiest solutions of Eqs. (4.2) and (4.7) are

$$\psi_1^+=\exp\left[a_1^+x-\frac{\omega_0}{a_1^+}y+a_1^{+2}t\right],\quad \psi_2^+=\exp\left[a_2^+x-\frac{\omega_0}{a_2^+}y+a_2^{+2}t\right],$$
$$\psi_1^-=\exp\left[a_1^-x-\frac{\omega_0}{a_1^-}y-a_1^{-2}t\right],\quad \psi_2^-=\exp\left[a_2^-x-\frac{\omega_0}{a_2^-}y-a_2^{-2}t\right], \tag{6.1}$$

where $a_1^+,a_1^-,a_2^+ y a_2^-$ are arbitrary constants.
• Integration of Eqs. (4.1), (4.8), (4.9), and (5.4) affords

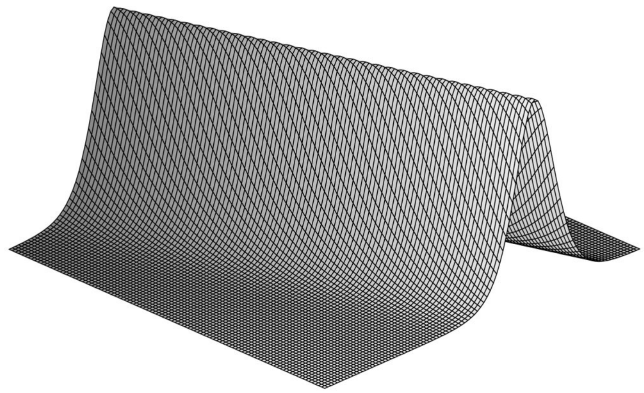

FIG. 1. Line soliton.

$$\phi_1=\frac{1}{a_1^+ + a_1^-}(b_1+\psi_1^+\psi_1^-),\quad \Omega^+=\frac{1}{a_2^+ + a_1^-}(c^+ + \psi_1^+\psi_2^-),$$
$$\phi_2=\frac{1}{a_2^+ + a_2^-}(b_2+\psi_2^+\psi_2^-),\quad \Omega^-=\frac{1}{a_1^+ + a_2^-}(c^- + \psi_2^+\psi_1^-), \tag{6.2}$$

where $b_1, b_2, c^+ y c^-$ are arbitrary constants.

• The first iteration provides the solution (Fig. 1)

$$m_y'=\psi_0+\partial_{xy}[\ln \phi_1], \tag{6.3}$$

and the second (Fig. 2)

$$m_y''=\omega_0+\partial_{xy}[\ln \tau], \tag{6.4}$$

where

$$\phi_1=\frac{b_1}{a_1^+ + a_1^-}(1+F_1). \tag{6.5}$$

$$\tau=\phi_1\phi_2-\Omega^+\Omega^-=\frac{b_1 b_2}{(a_1^+ + a_1^-)(a_2^+ + a_2^-)}[1+F_1+F_2+AF_1F_2], \tag{6.6}$$

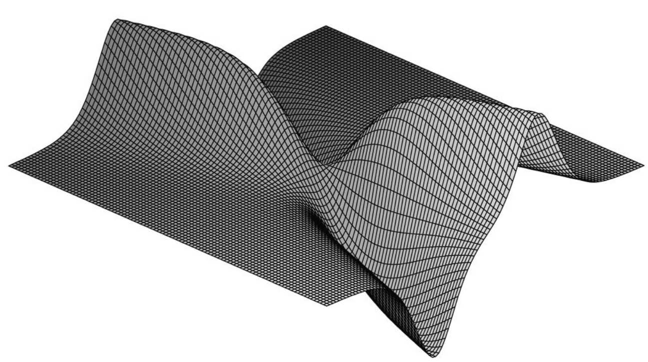

FIG. 2. Interaction of two line solitons.

and

$$F_i(x,y,t)=\exp\left[(a_i^+ + a_i^-)\left\{x-\frac{\omega_0}{a_i^+ a_i^-}y+(a_i^+ - a_i^-)t\right\}+\varphi_i\right], \tag{6.7}$$

$$A=\frac{(a_2^+ - a_1^+)(a_2^- - a_1^-)}{(a_2^+ + a_1^-)(a_2^- + a_1^+)}, \tag{6.8}$$

and b_i has been redefined as: $b_i = e^{-\varphi_i}$.

Particular case: When $a_2^+ = a_1^+$, or $a_2^- = a_1^-$, $A=0$ and this is said to be *resonant state*.[18]

B. Dromions $m=0$

In this case Eqs. (4.1), (4.8), (4.9), and (5.4) require that

$$\psi_{1y}^+\psi_{1y}^- = \psi_{2y}^+\psi_{2y}^- = \psi_{1y}^+\psi_{2y}^- = \psi_{2y}^+\psi_{1y}^- = 0.$$

Therefore, it is compulsory that $\psi_{1y}^- = \psi_{2y}^- = 0$, or $\psi_{1y}^+ = \psi_{2y}^+ = 0$.

- If we choose the possibility $\psi_{1y}^- = \psi_{2y}^- = 0$, then simple solutions of Eqs. (4.2) and (4.7) are

$$\begin{aligned}\psi_1^- &= e^{a_1^- x - a_1^{-2} t}, \quad \psi_1^+ = (e^{a_1^+ x + a_1^{+2} t})E_1(y) = Q_1^+(x,t)E_1(y),\\ \psi_2^- &= e^{a_2^- x - a_2^{-2} t}, \quad \psi_2^+ = (e^{a_2^+ x + a_2^{+2} t})E_2(y) = Q_2^+(x,t)E_2(y),\end{aligned} \tag{6.9}$$

where $a_1^+, a_1^-, a_2^+, a_2^-$ are arbitrary constants while E_i are arbitrary functions of y.

- We can now perform now the integration of Eqs. (4.1), (4.8), (4.9), and (5.4) to obtain

$$\begin{aligned}\phi_1 &= \frac{1}{a_1^+ + a_1^-}(E_1 Q_1^+ \psi_1^- + M_1(y)), \quad \Omega^+ = \frac{1}{a_2^+ + a_1^-}(E_2 \psi_1^- Q_2^+ + N^+(y)),\\ \phi_2 &= \frac{1}{a_2^+ + a_2^-}(E_2 \psi_2^- Q_2^+ + M_2(y)), \quad \Omega^- = \frac{1}{a_1^+ + a_2^-}(E_1 \psi_2^- Q_1^+ + N^-(y)).\end{aligned} \tag{6.10}$$

N^+, N^-, and M_i^+ are arbitrary functions of y. The arbitrariness of the six functions E_i, M_i, N^j, and the four constants a_i^+, a_i^- implies that there are many particular cases. We list some of them.

1. 1+1 *dromions*

These can be obtained by choosing

$$E_i(y) = 1 + b_i e^{c_i y}, \quad M_i(y) = 1 + e^{c_i y}, \quad N^* = N^- = 0, \tag{6.11}$$

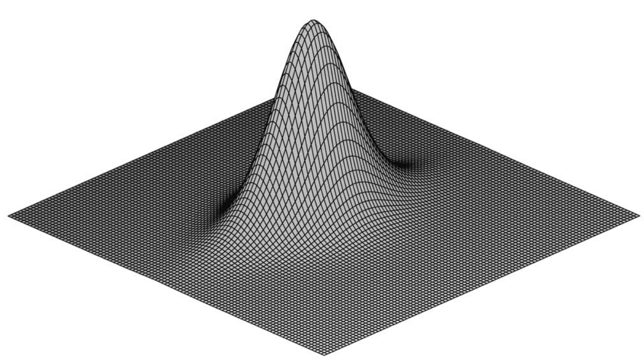

FIG. 3. One dromion.

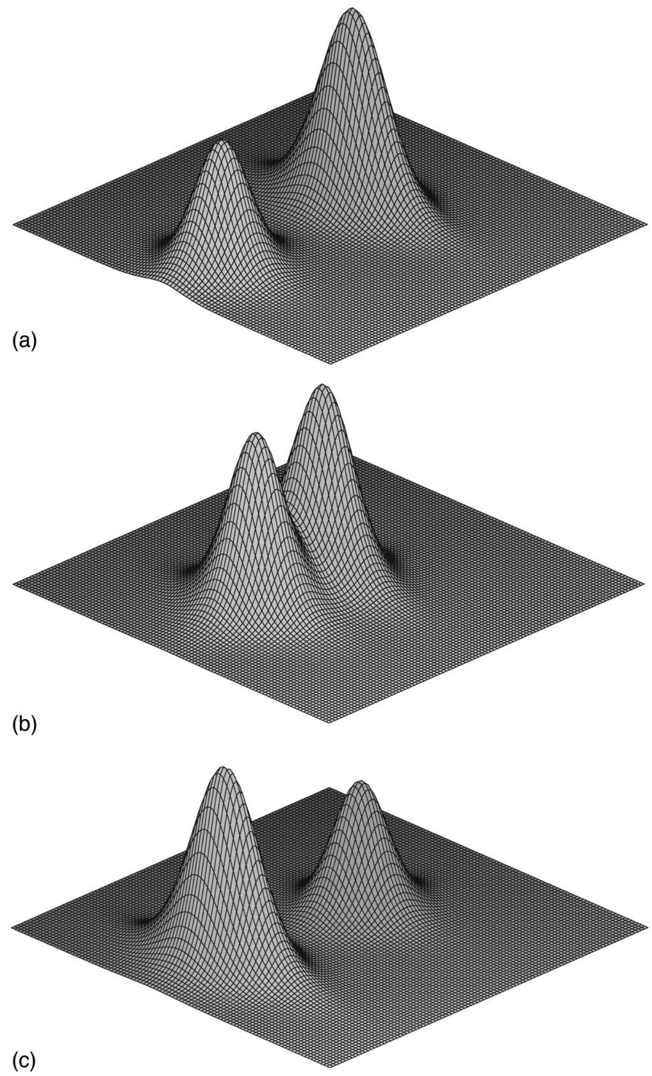

FIG. 4. (a) Interaction of two dromions, $t<0$. (b) Interaction of two dromions, $t=0$. (c) Interaction of two dromions, $t>0$.

where b_i and c_i are arbitrary constants.

• The first and second iteration yield

$$m_y' = \partial_{xy}[\ln \phi_1], \tag{6.12}$$

$$m_y'' = \partial_{xy}[\ln \tau], \tag{6.13}$$

where

$$\phi_1 = \frac{1}{a_1^+ + a_1^-}(M_1 + E_1 F_1), \tag{6.14}$$

$$\tau = \phi_1 \phi_2 - \Omega^+ \Omega^- = \frac{1}{(a_1^+ + a_1^-)(a_2^+ + a_2^-)}[M_1 M_2 + M_1 E_2 F_2 + M_2 E_1 F_1 + A E_1 E_2 F_1 F_2], \tag{6.15}$$

and

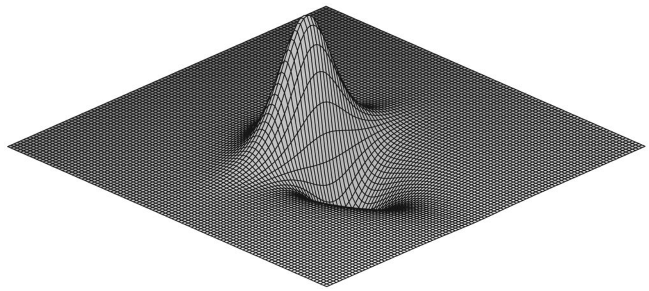

FIG. 5. $2+1$ dromion.

$$F_i(x,t)=\exp[(a_i^+ + a_i^-)\{x+(a_i^+ - a_i^-)t\}], \tag{6.16}$$

$$A=\frac{(a_2^+ - a_1^+)(a_2^- - a_1^-)}{(a_2^+ + a_1^-)(a_2^- + a_1^+)}. \tag{6.17}$$

The behavior of Eqs. (6.12) and (6.13) are represented in Figs. 3 and 4, respectively.

2. $1+n$ *dromion*

Dromions with several jumps in the y direction can be obtained by choosing

$$E_i=1+\sum_{j=1}^{n} b_{ij}e^{c_{ij}y}, \quad M_i=1+\sum_{j=1}^{n} e^{c_{ij}y}.$$

The first iteration

$$m_y'=\partial_{xy}(\ln \phi_1),$$

describes a structure with n jumps located along the y-direction, moving in the x-direction with velocity $a_1^+ - a_1^-$.

Figure 5 represents one of these structures with $n=2$ and $c_{11}>0$, $c_{12}<0$.

Figure 6 corresponds to $n=3$ and $c_{11}>0$, $c_{12}>0$, $c_{13}>0$.

The solution that we have obtained in this section generalizes the solutions found in Ref. 3 by means of the bilinear method.

VII. CONCLUSIONS

• A system of nonlinear PDEs proposed by different authors as one of the simplest equations in $2+1$ dimensions is studied from the point of view of the Painlevé property. The dominant

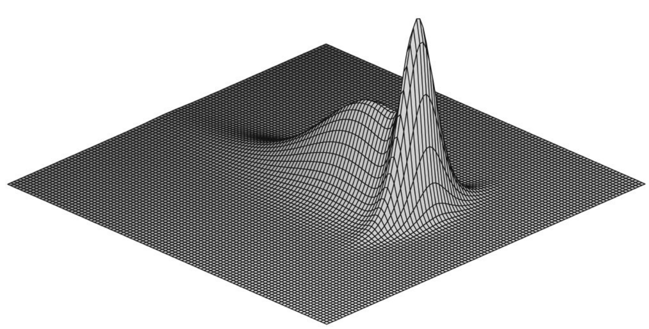

FIG. 6. $3+1$ dromion.

behavior indicates the best field to use Painlevé analysis. On this basis, we rewrite the system as a PDE [Eq. (2.5)] with only one field. This equation[6] can be considered as the modified version of the generalized long dispersive wave equation.[7] This is why we have call it MGLDW (modified generalized long dispersive wave equation).

• The singular manifold method was applied to MGLDW in Sec. II. The singular manifold equations, as well as the expression of the seminal field in terms of the singular manifold were obtained.

• In Sec. III, we linearized the singular manifold equations to obtain the Lax pair. The relation between the singular manifold and the eigenfunctions of the Lax pair is constructed explicitly.

• In Sec. IV the Lax pair was considered as a system of nonlinear coupled PDE. We applied the singular manifold method to the Lax pair itself. The bonus is the construction of Darboux transformations for MGLDW. Its transformations allow us to determine an iterative method for obtaining solutions. The relation between this method and the Hirota τ-functions is shown in Sec. V.

• Finally Sec. VI is devoted to the construction of solitonic solutions of MGLDW. A rich collection of solutions with different solitonic behavior appear depending on the seminal solution that we have chosen.

• We believe that the equation analyzed in depth in this paper is a good example of how to obtain maximum information about the equation using Painlevé analysis and the singular manifold method as the only tools.

APPENDIX: COMPLEMENTARY CALCULATION

We first attempt to write

$$0=u_t+u_{xx}+2um_x, \tag{A1}$$

$$0=\omega_t-\omega_{xx}-2\omega m_x, \tag{A2}$$

$$0=u\omega+m_y, \tag{A3}$$

as an equation for only one field

Taking u out of Eq. (A3) and substituting it into Eq. (A1), we obtain

$$0=\frac{m_{yt}+m_{xxy}}{\omega}-2m_{xy}\frac{\omega_x}{\omega^2}+m_y\left(\frac{2m_x}{\omega}-\frac{\omega_t}{\omega^2}-\frac{\omega_{xx}}{\omega^2}-2\frac{\omega_x^2}{\omega^3}\right). \tag{A4}$$

Using Eq. (A2) into Eq. (A4), we also obtain

$$0=m_{xxy}+m_{yt}-\left(2m_y\frac{\omega_x}{\omega}\right)_x, \tag{A5}$$

which can easily be integrated by setting $m_t=n_x$, which yields

$$\frac{\omega_x}{\omega}=\frac{m_{xy}+n_y}{2m_y}. \tag{A6}$$

Substituting Eq. (A6) into Eq. (A2), we obtain

$$\frac{\omega_t}{\omega}=2m_x+\frac{m_{xxy}+n_{xy}}{2m_y}-\frac{m_{xy}^2-n_y^2}{4m_y^2}. \tag{A7}$$

Next, we calculate the identity $(\omega_t/\omega)_x=(\omega_x/\omega)_t$ using Eqs. (A6) and (A7), and finally we obtain for m the equation

$$0=m_t-n_x \tag{A8}$$

$$0=m_y^2(n_{yt}-m_{xxxy})+m_{xy}(n_y^2-m_{xy}^2)+2m_y(m_{xy}m_{xxy}-n_yn_{xy})-4m_y^3m_{xx}. \tag{A9}$$

The integration of Eq. (A6) is

$$u=\sqrt{m_y}e^{\int(n_y/2m_y)dx}. \tag{A10}$$

And from Eq. (3.4) we finally obtain

$$\omega=-\sqrt{m_y}e^{\int-(n_y/2m_y)dx}. \tag{A11}$$

(Received 21 October 1998; accepted for publication 9 December 1998)

A general symmetry of the bilinear BKP hierarchy is studied in terms of tau functions. We use this symmetry to define reductions of the BKP hierarchy, among which new integrable systems can be found. The reductions are connected to constraints on the Lax operator as well as on the bilinear formulation. A class of solutions for the reduced equations is derived. © *1999 American Institute of Physics.* [S0022-2488(99)02603-1]

I. INTRODUCTION

Many integrable nonlinear partial differential equations may be obtained as dimensional reductions of hierarchies of the KP (Kadomtsev–Petviashvili) type.[1–4] In this paper, we turn our attention to symmetry reductions of the $2+1$-dimensional BKP hierarchy. Although reductions of this hierarchy were already introduced,[1,2] it is important to realize that these authors did not achieve a complete picture of those systems obtainable as reductions of the BKP hierarchy. We wish to argue that their inability to do so results from failing to identify a ''general'' symmetry of the BKP hierarchy.

Reductions may be defined in many different ways: by imposing a constraint on the Lax operator of the system, by imposing a symmetry constraint on the soliton field,... .[1,5,6,4] Here we shall reduce the BKP hierarchy by imposing a symmetry constraint on the bilinear equations, i.e., we shall implement a symmetry reduction on the level of the BKP tau function.

Typically, the KP hierarchy of $2+1$-dimensional nlpde's is defined with the help of a general (pseudodifferential) Lax operator, with which Lax equations and Zakharov–Shabat equations are written. The BKP hierarchy is obtained from this construction by imposing a certain condition on this Lax operator, while at the same time fixing a subset of the time variables.[7,8] The resulting hierarchy of integrable $2+1$-dimensional equations allows for its own tau function and for its own accompanying bilinear formulation: the BKP bilinear identity. This identity is essential in the study of this hierarchy, as it provides its most concise formulation.

An important part of this paper is devoted to the study of certain ''eigenfunction symmetries'' of the BKP bilinear equations. Eigenfunctions are defined as the fields that solve the BKP linear (Zakharov–Shabat) problem (without necessarily having to solve the Lax eigenvalue problem). Eigenfunctions are useful in the study of the BKP hierarchy, as they can be used to construct a potential closely related to the symmetries of this hierarchy. The appropriate potential for the BKP hierarchy is, however, quite different from the one used in the KP hierarchy.[9,10,4] It can, nevertheless, be defined using the KP eigenfunction potential. Making use of the BKP bilinear identity, it will be shown that any BKP eigenfunction potential generates a symmetry for the BKP hierarchy and that this potential itself can be expressed as the ratio of two BKP tau functions.

The actual symmetry reductions are defined by imposing a relation between an elementary symmetry τ_{t_k} and this eigenfunction potential symmetry. Examples of the resulting systems in-

[a)]igloris@vub.ac.be

clude equations, which, as far as the authors were able to verify, did not yet appear in the literature. In particular, as opposed to the discussion of Refs. 1, 2, in the present analysis the KdV equation is a mere special case of the 1-constrained BKP hierarchy.

Next, we investigate how such a symmetry reduction can be connected to a constraint on the Lax operator. An additional bilinear identity for the constrained BKP hierarchy is derived and an alternative identity for the *k*-constrained BKP tau function is also found.

The last section of this paper is devoted to the solutions of the reduced BKP hierarchies. First we briefly show how one may obtain the ''Pfaffian''-type tau functions[11,12] for the (unreduced) BKP hierarchy. We investigate the form of the accompanying eigenfunctions and eigenfunction potentials. Next we decide which supplementary conditions need to be imposed on the (arbitrary) functions appearing in these Pfaffian expressions in order for them to solve the constrained BKP equations. In this way solutions to these hierarchies are derived. Some examples of solitons and rational-type solutions are given.

II. BKP HIERARCHY AND EIGENFUNCTION SYMMETRIES

The Kadomtsev–Petviashvili (KP) hierarchy is defined[7,13] in terms of the pseudodifferential gauge operator $P\equiv 1+w_1\partial^{-1}+w_2\partial^{-2}+\cdots$ and the Lax operator $L\equiv P\,\partial P^{-1}\equiv\partial+u_2\partial^{-1}+u_3\partial^{-2}+\cdots$. On the gauge operator one imposes Sato's equation $P_{t_n}=-(L^n)_-P$, implying

$$L_{t_n}=[B_n,L]\quad\text{and}\quad B_{n,t_m}-B_{m,t_n}=[B_m,B_n],$$

for differential operators $B_n\equiv(L^n)_+(=\Sigma_{j=0}^n b_{n,j}\partial_x^j)$. These nonlinear partial differential equations [for the fields $u_2(t_1,t_2,\dots),u_3(t_1,t_2,\dots),\dots$] are the compatibility conditions of the linear equations

$$L\psi=\lambda\psi,\quad \psi_{t_n}=B_n\psi,$$

satisfied by the wave function $\psi(t_1,t_2,\dots;\lambda)\equiv P(\partial)\exp(\lambda t_1+\lambda^2t_2+\cdots)$.

The *BKP hierarchy*[7] is obtained from this construction by imposing the condition

$$P^*=\partial P^{-1}\partial^{-1},\quad\text{and hence}\quad L^*\partial+\partial L=0, \tag{1}$$

at the expense of having to supress the evolutions with respect to $t_2,t_4,\dots$ (i.e., fix $t_2=t_4=\cdots=0$); the condition implies that $u_3=-u_{2,x}$, $u_5=-2u_{4,x}-u_{2,3x},\dots$, and hence $b_{n,0}=0$ and $B_n1=0$ (for n odd).

The defining relation (1) implies $P\,\partial^{-1}P^*=\partial^{-1}$ and hence that one has $\mathrm{Res}_\partial[P\,\partial^{-1}P^*\,\partial^m]=\delta_{0m}$ for $m\in\{0,1,2,...\}$. Since, in general, one has (e.g., Ref. 14, p. 82)

$$\mathrm{Res}_\lambda[\lambda^{k-1}\psi(\mathbf{t},\lambda)(-\partial)^{m+1}\psi(\mathbf{t},-\lambda)]=\mathrm{Res}_\partial[P\,\partial^{k-1}P^*\,\partial^{m+1}],\quad\forall k,m; \tag{2}$$

this relation leads to the BKP bilinear identity $(\mathbf{t}=(t_1=x,t_3,t_5,\dots))$:[7]

$$\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)]=1,\quad\forall\mathbf{t},\mathbf{t}', \tag{3}$$

for BKP wave functions. This bilinear identity (3) is equivalent to the entire BKP hierarchy of nonlinear partial differential equations, and as such is an important relation for our further discussion.

One can show that there exists a ''tau function'' $\tau(\mathbf{t})$, such that[7]

$$\psi(\mathbf{t},\lambda)=\frac{\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))}{\tau(\mathbf{t})}\exp\xi(\mathbf{t},\lambda), \tag{4}$$

with $\xi(\mathbf{t},\lambda)=\Sigma_{n=0}^\infty t_{2n+1}\lambda^{2n+1}$ and $\boldsymbol{\epsilon}(\lambda)=2(\lambda^{-1},\lambda^{-3}/3,\lambda^{-5}/5,...)$. The bilinear identity (3) can now be written as

$$\mathrm{Res}_\lambda[\lambda^{-1}\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\tau(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))\exp\xi(\mathbf{t}-\mathbf{t}',\lambda)]=\tau(\mathbf{t})\tau(\mathbf{t}'). \tag{5}$$

This equation contains the Hirota bilinear equations for all the nonlinear partial differential equations in the BKP hierarchy. The lowest-order equation is

$$(9D_1D_5-5D_1^3D_3-5D_3^2+D_1^6)\tau\cdot\tau=0, \tag{6}$$

where D_i the Hirota D operator with respect to t_i.[15]

It is important to remark that the BKP tau function differs from the KP tau function:[7] $\tau_{\mathrm{BKP}}=\tau_{\mathrm{KP}}(t_2=t_4=\cdots=0)^{1/2}$.

In the rest of this section we shall concentrate on the notion of eigenfunctions and their connection to the symmetries of the BKP hierarchy. Eigenfunctions are solutions of the linear equations: $\Phi_{t_n}=B_n\Phi$ (for n:1,3,5,...). Adjoint eigenfunctions satisfy the adjoint linear equations $\Phi^*_{t_n}=-B_n^*\Phi^*$ (with n:1,3,5,...). For example,

$$\Phi_{t_3}=B_3\Phi=\Phi_{3x}+3u_2\Phi_x, \quad \Phi^*_{t_3}=\Phi^*_{3x}+3(u_2\Phi^*)_x, \tag{7}$$

with $u_2=2\partial_x^2\log\tau$. Remark that the wave functions $\psi(\mathbf{t},\lambda)$ are special instances of eigenfunctions. Furthermore, a constant is always a BKP eigenfunction.

In the BKP hierarchy, eigenfunctions and adjoint eigenfunctions are related: As $L^*=-\partial L\partial^{-1}$, we find that $B_n^*\equiv(L^{*n})_+=(-1)^n(\partial L^n\partial^{-1})_+$. Hence $B_n^*\partial=-B_n\partial-B_{n,x}$ (n: odd). This relation implies that any eigenfunction Φ gives rise to an adjoint eigenfunction $\Phi^*=\Phi_x$.

In Refs. 16, 9 a KP eigenfunction potential $S(\Phi,\Phi^*)=\int^x\Phi\Phi^*$ was introduced for any pair of eigenfunction and adjoint eigenfunction (see also Refs. 4, 10). The derivatives of this potential can be expressed as a (bilinear) differential operator working on Φ and Φ^*: $\partial_{t_n}S(\Phi,\Phi^*)=\Sigma_{j=1}^n\Sigma_{i=1}^j(-1)^{i+1}(\Phi^*b_{n,j})_{(i-1)x}\Phi_{(j-i)x}$. In the case of the KP hierarchy, this potential generates a symmetry of this hierarchy.[4] Here, we shall use it to derive some results concerning BKP eigenfunctions. The first property is the following.

Property: If Φ is a BKP eigenfunction and $\Phi^*=\Phi_x$, then one has the following relation:

$$\mathrm{Res}_\lambda[\lambda^{-1}S(\psi(\mathbf{t},\lambda),\Phi^*(\mathbf{t}))\psi(\mathbf{t}',-\lambda)]=\Phi(\mathbf{t})-\Phi(\mathbf{t}'). \tag{8}$$

Proof: Denote the residue in (8) by $I(\mathbf{t},\mathbf{t}')$. From the definition of the potential S and by using the BKP bilinear identity (3), one finds that $\partial_{t_n}\partial_{t'_m}I(\mathbf{t},\mathbf{t}')=0$. Hence $I(\mathbf{t},\mathbf{t}')=f(\mathbf{t})+g(\mathbf{t}')$. Since $S(\psi(\mathbf{t},\lambda),\Phi^*(\mathbf{t}))=\mathcal{O}(\lambda^{-1})\exp\xi(\mathbf{t},\lambda)$, we have that $I(\mathbf{t},\mathbf{t}'=\mathbf{t})=0$; hence, $I(\mathbf{t},\mathbf{t}')=f(\mathbf{t})-f(\mathbf{t}')$. As $f_x(\mathbf{t})=\partial_xI(\mathbf{t},\mathbf{t}')=\Phi^*(\mathbf{t})\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)]=\Phi^*(\mathbf{t})=\Phi_x(\mathbf{t})$ [in fact, $f_{t_n}(\mathbf{t})=\partial_{t_n}I(\mathbf{t},\mathbf{t}')=\Phi_{t_n}(\mathbf{t})$], one finds $f=\Phi$. □

Representing $S(\psi(\mathbf{t},\lambda),\Phi^*(\mathbf{t}))$ as $K(\mathbf{t},\lambda)\exp\xi(\mathbf{t},\lambda)$ [with $K(\mathbf{t},\lambda)=\mathcal{O}(\lambda^{-1})$] and choosing $\mathbf{t}-\mathbf{t}'=\boldsymbol{\epsilon}(k)$, the relation (8) becomes

$$\mathrm{Res}_\lambda\left[\lambda^{-1}K(\mathbf{t},\lambda)\frac{\tau(\mathbf{t}-\boldsymbol{\epsilon}(k)+\boldsymbol{\epsilon}(\lambda))}{\tau(\mathbf{t}-\boldsymbol{\epsilon}(k))}\left(-1+\frac{2}{1-\lambda/k}\right)\right]=\Phi(\mathbf{t})-\Phi(\mathbf{t}-\boldsymbol{\epsilon}(k)),$$

or $2K(\mathbf{t},k)\tau(\mathbf{t})/\tau(\mathbf{t}-\boldsymbol{\epsilon}(k))=\Phi(\mathbf{t})-\Phi(\mathbf{t}-\boldsymbol{\epsilon}(k))$. Hence, one finds the following expression for the eigenfunction potential $S(\psi(\mathbf{t},\lambda),\Phi^*(\mathbf{t})\equiv\Phi_x(\mathbf{t}))$:

$$S(\psi(\mathbf{t},\lambda),\Phi^*(\mathbf{t}))=\tfrac{1}{2}(\Phi(\mathbf{t})-\Phi(\mathbf{t}-\boldsymbol{\epsilon}(\lambda)))\psi(\mathbf{t},\lambda). \tag{9}$$

The x derivative of this expression yields the relation

$$\Phi_x(\mathbf{t})+\Phi_x(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))=(\Phi(\mathbf{t})-\Phi(\mathbf{t}-\boldsymbol{\epsilon}(\lambda)))\left(\partial_x\log\frac{\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))}{\tau(\mathbf{t})}+\lambda\right), \tag{10}$$

which is, in fact, another way of expressing the linear problem $\Phi_{t_n}=B_n\Phi\;\;(n:1,3,5,...)$; the reader may easily verify that relation (10) at $\mathcal{O}(\lambda^{-2})$ corresponds to the linear equation (7).

One may substitute relation (9) in Eq. (8) and use the BKP bilinear identity (3) to find

$$\mathrm{Res}_\lambda[\lambda^{-1}\Phi(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)]=2\Phi(\mathbf{t}')-\Phi(\mathbf{t}). \tag{11}$$

This identity generates bilinear equations that represent the BKP linear equations ($\Phi=\rho/\tau$):

$$\mathrm{Res}_\lambda[\lambda^{-1}\rho(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\tau(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))\exp\xi(\mathbf{t}-\mathbf{t}',\lambda)]=2\rho(\mathbf{t}')\tau(\mathbf{t})-\rho(\mathbf{t})\tau(\mathbf{t}'), \tag{12}$$

or

$$\sum_{j=0}^{\infty} p_j(-2\mathbf{y})p_j(2\tilde{D})e^{\Sigma_i y_i D_i}\tau\cdot\rho=2e^{\Sigma_i y_i D_i}\rho\cdot\tau-e^{\Sigma_i y_i D_i}\tau\cdot\rho,$$

with $\Sigma_{n=0}^{\infty}p_n(\mathbf{t})\lambda^n=\exp\xi(\mathbf{t},\lambda)$ and $\tilde{D}=(D_1,D_3/3,...)$. The simplest equation in this expression is the bilinear representation of Eq. (7):

$$(D_3-D_1^3)\rho\cdot\tau=0.$$

For the BKP hierarchy we introduce a new eigenfunction potential in terms of a pair of BKP eigenfunctions Φ_1 and Φ_2:

$$\Omega(\Phi_1,\Phi_2)=S(\Phi_2,\Phi_{1,x})-S(\Phi_1,\Phi_{2,x}), \tag{13}$$

i.e.,

$$\begin{aligned}\mathrm{d}\Omega(\Phi_1,\Phi_2)=(\Phi_{1,x}\Phi_2-\Phi_1\Phi_{2,x})\mathrm{d}x+[\Phi_{1,3x}\Phi_2-\Phi_1\Phi_{2,3x}-2\Phi_{1,2x}\Phi_{2,x}\\+2\Phi_{1,x}\Phi_{2,2x}+3u_2(\Phi_{1,x}\Phi_2-\Phi_1\Phi_{2,x})]\mathrm{d}t_3+\cdots.\end{aligned} \tag{14}$$

The potential is only defined up to a possible constant of integration. It is clear that $\Omega(\Phi_1,\Phi_2)=-\Omega(\Phi_2,\Phi_1)$ and that $\Omega(\Phi,1)=\Phi$ (remember that 1 is an eigenfunction), up to constants. In particular, all properties that will be proven for the eigenfunction potential Ω will also apply to the eigenfunctions themselves.

As wave functions are special eigenfunctions, we may compute the corresponding eigenfunction potential: from expression (9), representation (4), and definition (13), one finds

$$\Omega(\psi(\mathbf{t},\lambda),\psi(\mathbf{t},\mu))=\frac{\lambda-\mu}{\lambda+\mu}\,\frac{\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda)-\boldsymbol{\epsilon}(\mu))}{\tau}\exp\xi(\mathbf{t},\lambda)+\xi(\mathbf{t},\mu)+C \tag{15}$$

(i.e. the BKP vertex operator[7] acting on τ) and taking $\lim_{\mu\to-\lambda}$ [with an appropriate choice of integration constant $C=\tilde{C}-2\lambda/(\mu+\lambda)$], one has

$$\Omega(\psi(\mathbf{t},\lambda),\psi(\mathbf{t},-\lambda))=4\sum_{n:1,3,...}\partial_{t_n}\log\tau\lambda^{-n}+2\sum_{n:1,3,...}nt_n\lambda^n+\tilde{C}. \tag{16}$$

For further reference, it is important to consider the effect of the shift $\mathbf{t}\to\mathbf{t}\pm\boldsymbol{\epsilon}(\lambda)$ on a BKP eigenfunction potential.

Property: Let $\Omega(\mathbf{t})\equiv\Omega(\Phi_1,\Phi_2)$; then

$$\Omega(\mathbf{t}\pm\boldsymbol{\epsilon}(\lambda))=\Omega(\mathbf{t})+\Phi_1(\mathbf{t}\pm\boldsymbol{\epsilon}(\lambda))\Phi_2(\mathbf{t})-\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}\pm\boldsymbol{\epsilon}(\lambda)). \tag{17}$$

Proof: By definition (14), we have

$$\Omega_x(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))=\Phi_{1,x}(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Phi_2(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))-\Phi_1(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Phi_{2,x}(\mathbf{t}-\boldsymbol{\epsilon}(\lambda)).$$

The use of formula (10) in order to eliminate $\Phi_{1,x}(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))$ and $\Phi_{2,x}(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))$ yields

$$\left[-\Phi_{1,x}(\mathbf{t})+\Phi_1(\mathbf{t})\left(\partial_x \log\frac{\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))}{\tau(\mathbf{t})}+\lambda\right)\right]\Phi_2(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))-\Phi_1(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))$$
$$\times\left[-\Phi_{2,x}(\mathbf{t})+\Phi_2(\mathbf{t})\left(\partial_x \log\frac{\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))}{\tau(\mathbf{t})}+\lambda\right)\right].$$

Using formula (10) once more to eliminate the terms included in round brackets, we obtain

$$\Phi_{1,x}(\mathbf{t})\Phi_2(\mathbf{t})-\Phi_1(\mathbf{t})\Phi_{2,x}(\mathbf{t})+[\Phi_1(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Phi_2(\mathbf{t})-\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))]_x,$$

which proves expression (17). □

Next, we show that a BKP eigenfunction potential can always be completely expressed in terms of BKP tau functions.

Property: $\hat{\tau}\equiv\tau\Omega(\Phi_1,\Phi_2)$ is a BKP tau function:

$$\mathrm{Res}_\lambda[\lambda^{-1}\hat{\tau}(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\hat{\tau}(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))\exp\xi(\mathbf{t}-\mathbf{t}',\lambda)]=\hat{\tau}(\mathbf{t})\hat{\tau}(\mathbf{t}'). \tag{18}$$

Proof: Using representation (4), Eq. (18) is equivalent to

$$\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)\Omega(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Omega(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))]=\Omega(\mathbf{t})\Omega(\mathbf{t}'),\quad \forall \mathbf{t},\mathbf{t}'$$

This relation may be proven by making use of relation (17), the BKP bilinear identity (3), and of relation (11) and its companion ($\lambda\to-\lambda$ and $\mathbf{t}\leftrightarrow\mathbf{t}'$):

$$\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)\Phi(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))]=2\Phi(\mathbf{t})-\Phi(\mathbf{t}'),$$

and the additional relation

$$\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)\Phi_i(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Phi_j(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))]$$
$$=\Phi_i(\mathbf{t})\Phi_j(\mathbf{t}')-2\Omega(\Phi_i(\mathbf{t}),\Phi_j(\mathbf{t}))+2\Omega(\Phi_i(\mathbf{t}'),\Phi_j(\mathbf{t}')), \tag{19}$$

which is proven in the Appendix. □

This property shows that any eigenfunction potential can be written as the ratio of two tau functions, namely, $\Omega(\Phi_1,\Phi_2)=\hat{\tau}/\tau$.

As the eigenfunction potential $\Omega(\Phi_1,\Phi_2)$ is only defined up to an additive constant, we have as a consequence that $\tau\Omega(\Phi_1,\Phi_2)+C\tau$ also satisfies the BKP bilinear identity. It then follows from the above property that $\tau\Omega(\Phi_1,\Phi_2)$ is a *symmetry* for Eq. (5), meaning that $\tau+C^{-1}\tau\Omega$ satisfies the BKP bilinear identity (5) up to first order in C^{-1}. For example, the eigenfunction potential (16) generates the translation symmetries τ_{t_n} and the gauge symmetries $t_n\tau$.

Since any eigenfunction Φ can be written as the eigenfunction potential $\Omega(\Phi,1)=\Phi$, it follows from this property that the eigenfunction Φ is also expressible as $\Phi=\rho/\tau$, where ρ is a BKP tau function. It thus follows that the bilinear identity (12) constitutes a bilinear Bäcklund transformation for the bilinear BKP hierarchy. It should be clear that $\tau\Phi$ is a symmetry for the bilinear BKP equations.

III. REDUCTIONS

In this section we explore certain symmetry reductions of the BKP hierarchy. We then investigate the connection between these reductions and constraints on the BKP Lax operator L. We shall also derive a bilinear formulation of these constraints.

The k-constrained BKP hierarchy is defined by coupling the linear equations for a pair of eigenfunctions Φ_1 and Φ_2 to the nonlinear equations of the BKP hierarchy by means of the constraint

$$\tau_{t_k} = \tau\Omega(\Phi_1,\Phi_2) \tag{20}$$

(where k is a fixed odd integer). Since both the left-hand side and the right-hand side of this condition are symmetries of the BKP bilinear identity, it induces a so-called symmetry reduction on this hierarchy.

As an example, let us consider the case $k=1$. Denoting $q=\Phi_1$, $r=\Phi_2$, it follows from Eq. (7), constraint (20) and the definition (14) that (q,r) solves the system:

$$\begin{aligned} q_{t_3} &= q_{3x} + 6(q_x r - q r_x) q_x, \\ r_{t_3} &= r_{3x} + 6(q_x r - q r_x) r_x. \end{aligned} \tag{21}$$

Setting $r=\frac{1}{2}$ (a genuine eigenfunction), one finds that the field q_x satisfies the KdV equation $(q_{x,t_3} = q_{4x} + 6q_x q_{2x})$. This last equation is the result that was already derived,[1,2] but it should be clear that it is merely a special case of the 1-constrained BKP system (21). As a second example we take $k=3$ at which the constraint (20) yields the following system:

$$\begin{aligned} q_{t_3} &= q_{3x} + 3u q_x, \\ r_{t_3} &= r_{3x} + 3u r_x, \\ u_{t_3} &= 2(q_{2x} r - q r_{2x}). \end{aligned} \tag{22}$$

The special case $r=\frac{1}{2}$ $(q_{t_3} = q_{3x} + 3uq_x,\ u_{t_3} = q_{2x})$ was already given in Ref. 2. As far as the authors could verify, neither of the systems (21) or (22) has already been described in the literature.

In order to establish a connection between the symmetry reduction (20) and constraints on the Lax operator L, we consider $\Omega(\mathbf{t}) = \Omega(\Phi_1,\Phi_2)$ and $\tilde{\Omega}(\mathbf{t}) = \Omega(\psi(\mathbf{t},\lambda),\psi(\mathbf{t},-\lambda))$. By virtue of expression (16) for $\tilde{\Omega}(\mathbf{t})$, we may write the condition (20) as

$$\mathrm{Res}_\lambda[\lambda^{k-1}\tilde{\Omega}(\mathbf{t})] = 4\Omega(\mathbf{t}),$$

or, equivalently,

$$\mathrm{Res}_\lambda[\lambda^{k-1}\,\partial_{t_n}\tilde{\Omega}(\mathbf{t})] = 4\,\partial_{t_n}\Omega(\mathbf{t}), \quad \forall n{:}1,3,5,\ldots. \tag{23}$$

At $n=1$, this yields the relation

$$\mathrm{Res}_\lambda[\lambda^{k-1}(\psi_x(\mathbf{t},\lambda)\psi(\mathbf{t},-\lambda) - \psi(\mathbf{t},\lambda)\psi_x(\mathbf{t},-\lambda))] = 4(\Phi_{1,x}\Phi_2 - \Phi_1\Phi_{2,x}). \tag{24}$$

Since $\mathrm{Res}_\lambda[f(\lambda)] = \frac{1}{2}\ \mathrm{Res}_\lambda[f(\lambda) - f(-\lambda)]$, this can be written as

$$\mathrm{Res}_\lambda[\lambda^{k-1}\psi(\mathbf{t},\lambda)\psi_x(\mathbf{t},-\lambda)] = 2(\Phi_1\Phi_{2,x} - \Phi_{1,x}\Phi_2).$$

The x derivative of relation (24) similarly yields:

$$\mathrm{Res}_\lambda[\lambda^{k-1}\psi(\mathbf{t},\lambda)\psi_{2x}(\mathbf{t},-\lambda)] = 2(\Phi_1\Phi_{2,2x} - \Phi_{1,2x}\Phi_2).$$

Combining relation (23) at $n=3$ [bearing definition (14) in mind] and the second x derivative of relation (24), one finds

$$\mathrm{Res}_\lambda[\lambda^{k-1}\psi(\mathbf{t},\lambda)\psi_{3x}(\mathbf{t},-\lambda)] = 2(\Phi_1\Phi_{2,3x} - \Phi_{1,3x}\Phi_2).$$

In this way, it can be seen that (23) is equivalent to

$$\mathrm{Res}_\lambda[\lambda^{k-1}\psi(\mathbf{t},\lambda)\partial^{m+1}\psi(\mathbf{t},-\lambda)]=2(\Phi_1\Phi_{2,(m+1)x}-\Phi_2\Phi_{1,(m+1)x}), \tag{25}$$

for $m\geqslant -1$. [The case $m=-1$ follows from the definition (1): $(L^k)_+=B_k$ and $B_k 1=0$.] Keeping relations (1) and (2) in mind, one finds

$$\mathrm{Res}_\partial[L^k\partial^m]=2(-1)^m(\Phi_2\Phi_{1,(m+1)x}-\Phi_1\Phi_{2,(m+1)x}).$$

Hence, the constraint (20) is equivalent to requiring that

$$L^k=B_k+2\sum_{n\geqslant 1}(-1)^n(\Phi_1\Phi_{2,nx}-\Phi_2\Phi_{1,nx})\partial^{-n},$$

or to the following condition the BKP Lax operator:

$$L^k=B_k+2\Phi_2\,\partial^{-1}\Phi_{1,x}-2\Phi_1\,\partial^{-1}\Phi_{2,x}. \tag{26}$$

This form of reduction of the BKP hierarchy was already introduced in Refs. 1, 2. It was, however, limited to the case $\Phi_2=\frac{1}{2}$. It is our feeling that imposing a constraint on the Lax operator L to reduce the BKP equation is conceptually less clear than using a symmetry constraint. Furthermore, in the former case one must make sure that any constraints on the Lax operator do not violate the condition (1).

We may now easily derive a bilinear form for the constrained BKP hierarchies. Since wave functions and eigenfunctions obey the same evolution, $\psi_{t_n}=B_n\psi$ and $\Phi_{i,t_n}=B_n\Phi_i$ $(i:1,2)$, relation (25) implies

$$\mathrm{Res}_\lambda[\lambda^{k-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)]=2(\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}')-\Phi_1(\mathbf{t}')\Phi_2(\mathbf{t})),\quad \forall \mathbf{t},\mathbf{t}'. \tag{27}$$

If we write the eigenfunctions and the wave functions in terms of tau functions ($\Phi_1=\rho_1/\tau$ and $\Phi_2=\rho_2/\tau$), we find the following bilinear formulation of the constraint (20):

$$\mathrm{Res}_\lambda[\lambda^{k-1}\tau(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\tau(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))\exp\xi(\mathbf{t}-\mathbf{t}',\lambda)]=2(\rho_1(\mathbf{t})\rho_2(\mathbf{t}')-\rho_1(\mathbf{t}')\rho_2(\mathbf{t})).$$

In terms of Hirota operators, this yields

$$\sum_{j=0}^{\infty}p_j(2\mathbf{y})p_{j+k}(-2\tilde{D})e^{\Sigma_i y_i D_i}\tau\cdot\tau=2e^{\Sigma_i y_i D_i}(\rho_1\cdot\rho_2-\rho_2\cdot\rho_1),$$

which implies, e.g., that $D_1\,D_k\tau\cdot\tau=2D_1\rho_1\cdot\rho_2$ [the x-derivative of (20)]. Hence, the bilinear form of the system (21) is

$$(D_3-D_1^3)\rho_1\cdot\tau=0,\quad (D_3-D_1^3)\rho_2\cdot\tau=0,\quad D_1^2\tau\cdot\tau=2D_1\rho_1\cdot\rho_2,$$

with $q=\rho_1/\tau$ and $r=\rho_2/\tau$.

A last important result is the following: as the product $\tau\Omega(\Phi_1,\Phi_2)$ is a BKP tau function, the symmetry reduction (20) implies the auxiliary bilinear identity

$$\mathrm{Res}_\lambda[\lambda^{-1}\tau_{t_k}(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\tau_{t_k}(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))\exp\xi(\mathbf{t}-\mathbf{t}',\lambda)]=\tau_{t_k}(\mathbf{t})\tau_{t_k}(\mathbf{t}'),$$

for a constrained BKP tau function: i.e., the t_k derivative of a constrained BKP tau function is itself a BKP tau function.

IV. SOLUTIONS

In this section we discuss solutions of the constrained BKP hierarchies. The tau functions corresponding to these solutions are expressed as ''Pfaffians.'' A Pfaffian is defined as the square root of the determinant of an antisymmetric matrix of even order; it is a polynomial in the elements of this matrix. For example, the Pfaffians of a 2×2 and 4×4 antisymmetric matrix A (with elements $a_{ij}=-a_{ji}$) are $\mathrm{Pf}(A)=a_{12}$ and $\mathrm{Pf}(A)=a_{12}a_{34}-a_{13}a_{24}+a_{14}a_{23}$, respectively.

Solutions in Pfaffian form for the bilinear BKP equation (6) were first derived in Ref. 11. These solutions may be obtained for all the equations in the bilinear BKP hierarchy (5) by starting from the well-known Grammian determinant solutions $\tau_{\mathrm{KP}}=\det[S(\varphi_i,\varphi_j^*)]_{1\le i,j\le 2N}$ [with $\varphi_{i,t_n}=\varphi_{i,nx}$ and $\varphi^*_{i,t_n}=(-1)^{n+1}\varphi^*_{i,nx}$ for $n:1,2,3,...$] of the KP hierarchy[17,18] and by using the fact that $\tau_{\mathrm{BKP}}=\tau_{\mathrm{KP}}\ (t_2=t_4=\cdots=0)^{1/2}$: Fixing $t_2=t_4=\cdots=0$ and choosing $\varphi_i=f_i$ and $\varphi_j^*=f_{j,x}$, one finds that $S(\varphi_i,\varphi_j^*)=\frac{1}{2}[f_if_j-\Omega(f_i,f_j)]$.[12] The determinant τ_{KP} is now easily seen to equal $\det[\Omega(f_i,f_j)]_{1\le i,j\le 2N}$ (up to a multiplicative constant, which is irrelevant in our discussion). The square root of this determinant yields the following solution to the BKP bilinear hierarchy:

$$\tau_{\mathrm{BKP}}=\sqrt{\det[\Omega(f_i,f_j)]_{1\le i,j\le 2N}}\equiv \mathrm{Pf}(f_1,f_2,\ldots,f_{2N}) \tag{28}$$

(with $f_{i,t_n}=f_{i,nx}$ for $n:1,3,5,...$). The expression $\mathrm{Pf}(f_1,\ldots,f_{2N})$ has the form $\Omega(f_1,f_2)\Omega(f_3,f_4)\cdots\Omega(f_{2N-1},f_{2N})-\cdots$ [only containing potentials of the type $\Omega(f_i,f_{j>i})$]. For example, for $N=1$ one finds the BKP tau function $\tau=\Omega(f_1,f_2)$, for $N=2$ one finds the tau function $\tau=\Omega(f_1,f_2)\Omega(f_3,f_4)-\Omega(f_1,f_3)\Omega(f_2,f_4)+\Omega(f_1,f_4)\Omega(f_2,f_3)$.

The notation introduced in (28) allows us to express the properties of such Pfaffians more easily: expression (28) is multilinear [i.e., $\mathrm{Pf}(\ldots,f+g,\ldots)=\mathrm{Pf}(\ldots,f,\ldots)+\mathrm{Pf}(\ldots,g,\ldots)$] and allows for the existence of expansion rules of the form $\mathrm{Pf}(f_1,\ldots,f_{2N})=\Sigma_{i=2}^{2N}(-1)^i\times \mathrm{Pf}(f_1,f_i)\mathrm{Pf}(f_2,\ldots,\hat{f}_i,\ldots,f_{2N})$.[11]

It also follows from the multilinearity that the derivative (w.r.t. any variable) is given by

$$\frac{\partial}{\partial t}\mathrm{Pf}(f_1,\ldots,f_{2N})=\sum_{i=1}^{2N}\mathrm{Pf}\left(f_1,\ldots,\frac{\partial}{\partial t}f_i,\ldots,f_{2N}\right). \tag{29}$$

Before discussing the solutions of the constrained BKP equations, we need expressions for eigenfunctions and eigenfunction potentials that correspond to the above BKP tau functions. We start from the representation $\Phi=\rho_{\mathrm{KP}}/\tau_{\mathrm{KP}}$ of eigenfunctions in terms of KP tau functions. We use the following expression for a ρ_{KP}, which can be seen to correspond to the above τ_{KP}:[17]

$$\rho_{\mathrm{KP}}=\det\begin{bmatrix} S(\varphi_1,\varphi_1^*) & \cdots & S(\varphi_1,\varphi_{2N}^*) & \varphi_1\\ \vdots & \ddots & \vdots & \vdots\\ S(\varphi_{2N},\varphi_1^*) & & S(\varphi_{2N},\varphi_{2N}^*) & \varphi_{2N}\\ -S(\varphi,\varphi_1^*) & \cdots & -S(\varphi,\varphi_{2N}^*) & -\varphi\end{bmatrix}.$$

Let A be the antisymmetric matrix corresponding to the BKP tau function (28): $A=[\Omega(f_i,f_j)]_{1\le i,j\le 2N}$, and introduce the two column vectors $\mathbf{f}=(f_1,f_2,\ldots,f_{2N})^t$ and $\mathbf{\Omega}=(\Omega(f_1,f_{2N+1}),\ldots,\Omega(f_{2N},f_{2N+1}))^t$. Choosing again $\varphi_i=f_i$, $\varphi_j^*=f_{j,x}$ and $\varphi=f_{2N+1}$, we find

$$\rho_{\mathrm{KP}}=\det\begin{bmatrix} A & \mathbf{f}\\ \mathbf{\Omega}^t & -f_{2N+1}\end{bmatrix}=\mathrm{Pf}(A)\mathrm{Pf}\begin{bmatrix} A & \mathbf{\Omega} & \mathbf{f}\\ -\mathbf{\Omega}^t & 0 & f_{2N+1}\\ -\mathbf{f}^t & -f_{2N+1} & 0\end{bmatrix}$$

(where we have ignored an unimportant multiplicative factor and used a Jacobi determinant identity). Hence, there exist eigenfunctions of the form

$$\Phi=\frac{\rho_{\mathrm{KP}}}{\tau_{\mathrm{KP}}}=\frac{\mathrm{Pf}(f_1,f_2,\ldots,f_{2N},f_{2N+1},1)}{\mathrm{Pf}(f_1,f_2,\ldots,f_{2N})}=\frac{\rho_{\mathrm{BKP}}}{\tau_{\mathrm{BKP}}},$$

with the understanding that here $\Omega(f_i,1)\equiv f_i$ (no integration constants allowed) and $f_{i,t_n}=f_{i,nx}$ with n:1,3,5,... . With this convention of Pf(...,1) one has, e.g., at $N=1$: $\Phi=\mathrm{Pf}(f_1,f_2,f_3,1)/\mathrm{Pf}(f_1,f_2)\equiv(\Omega(f_1,f_2)f_3-\Omega(f_1,f_3)f_2+f_1\Omega(f_2,f_3))/\Omega(f_1,f_2)$.

Special choices of f_{2N+1} include $f_{2N+1}=1$, for which one recovers $\Phi=1$ and $f_{2N+1}=0$, for which one finds

$$\Phi=\frac{\mathrm{Pf}(f_1,f_2,\ldots,f_{2N-1},1)}{\mathrm{Pf}(f_1,f_2,\ldots,f_{2N})} \tag{30}$$

[in the latter case by choosing $\Omega(f_{2N},f_{2N+1}=0)=1$ and $\Omega(f_i,f_{2N+1}=0)=0$ for $1\leqslant i<2N$].

The eigenfunction potential corresponding to the eigenfunctions $\Phi_1=\mathrm{Pf}(f_1,\ldots,f_{2N},f_{2N+1},1)/\mathrm{Pf}(f_1,\ldots,f_{2N})$ and $\Phi_2=\mathrm{Pf}(f_1,\ldots,f_{2N},f_{2N+2},1)/\mathrm{Pf}(f_1,\ldots,f_{2N})$ can be shown to take on the form

$$\Omega(\Phi_1,\Phi_2)=\frac{\mathrm{Pf}(f_1,\ldots,f_{2N},f_{2N+1},f_{2N+2})}{\mathrm{Pf}(f_1,\ldots,f_{2N})}. \tag{31}$$

This expression is obtained by proving that $\Omega_x=\Phi_{1,x}\Phi_2-\Phi_1\Phi_{2,x}$, with the help of the techniques used in Ref. 11 [in particular, by using relation (2.25) of Pfaffians in this reference]. The expression (31) agrees with the fact that such a potential is always the ratio of two BKP tau functions. Specifically, the eigenfunction potential corresponding to the eigenfunction Φ_1 in (30) is

$$\Omega(\Phi_1,\Phi_2)=\frac{\mathrm{Pf}(f_1,\ldots,f_{2N-1},f_{2N+2})}{\mathrm{Pf}(f_1,\ldots,f_{2N})}. \tag{32}$$

In order to find a solution of the constrained BKP equations, we need to find a BKP tau function and two eigenfunctions such that condition (20) is satisfied. In particular, we need to find a tau function such that its t_k derivative is again a BKP tau function. From property (29), we find that

$$\frac{\partial}{\partial t_k}\mathrm{Pf}(f,f_{t_k},\ldots,f_{(2N-1)t_k})=\mathrm{Pf}(f,f_{t_k},\ldots,f_{(2N-2)t_k},f_{2Nt_k}). \tag{33}$$

In the light of formula (32) and definition (20), this formula tells us that we may choose the k-constrained tau function as $\tau=\mathrm{Pf}(f,f_{t_k},\ldots,f_{(2N-1)t_k})$ with the corresponding eigenfunctions $\Phi_1=\rho_1/\tau$ $\Phi_2=\rho_2/\tau$:

$$\begin{aligned}\Phi_1&=\frac{\rho_1}{\tau}=\frac{\mathrm{Pf}(f,f_{t_k}\cdots,f_{(2N-2)t_k},1)}{\mathrm{Pf}(f,f_{t_k}\cdots,f_{(2N-1)t_k})},\\ \Phi_2&=\frac{\rho_2}{\tau}=\frac{\mathrm{Pf}(f,f_{t_k}\cdots,f_{(2N-1)t_k},f_{2Nt_k},1)}{\mathrm{Pf}(f,f_{t_k}\cdots,f_{(2N-1)t_k})}\end{aligned} \tag{34}$$

($f_{t_n}=f_{nx}$ n:1,3,5,...). Here, some care should be taken with respect to the integration constants in the eigenfunction potentials: there are $N(2N-1)$ eigenfunction potentials $\Omega(f_{it_k},f_{jt_k})$ in the above constrained tau function τ. The potentials with $i+j$ even should contain no integration constants [as formula (33) assumes, e.g., that $f_x^2-ff_{2x}\equiv\partial_x\Omega(f,f_x)=\Omega(f,f_{2x})$]. All potentials $\Omega(f_{it_k},f_{jt_k})$ for fixed $i+j$ odd are (for the same reason) connected. Hence, there are only $2N-1$ independent integration constants in the above constrained BKP tau function τ (i

$+j$:1,3,...,$4N-3)$. In ρ_2 there is one eigenfunction potential that does not appear in τ: $\Omega(f_{(2N-1)t_k},f_{2Nt_k})$; it may contain an integration constant, but this only amounts to $\Phi_2\to\Phi_2+c\Phi_1$ [a transformation that leaves the constraint (20) invariant].

For example, for $k=1$ (i.e., $t_k=x$), one may choose $N=1$, $f=x$ and find

$$\Phi_1=\frac{x}{x+c},\quad \Phi_2=\frac{-1}{x+c},$$

as an example of rational solutions of the systems (21). Another rational solution can be found by choosing $f=x^3/6+t_3$:

$$\Phi_1=\frac{10(x^3+6t_3)}{x^5-30x^2t_3+c},\quad \Phi_2=\frac{x^6-60x^3t_3+6cx-720t_3^2}{6(x^5-30x^2t_3+c)}.$$

The one-soliton solution of this system may be obtained by choosing $N=1$ and $f=\exp\xi(\mathbf{t},p_1)+\exp\xi(\mathbf{t},p_2)$. After some straightforward manipulations one finds ($p_1=k_1+ik_2$, $p_2=k_1-ik_2$):

$$\Phi_1=\frac{-k_1}{\sqrt{k_2}}\frac{\cos\theta_2}{\cosh\theta_1},\quad \Phi_2=\frac{k_1}{\sqrt{k_2}}\frac{\sin\theta_2}{\cosh\theta_1},$$

with $\theta_1=k_1x+k_1(k_1^2-3k_2^2)t_3+\cdots$ and $\theta_2=k_2x+k_2(3k_1^2-k_2^2)t_3+\cdots$. One has $\Phi_{1,x}\Phi_2-\Phi_2\Phi_{2,x}=\partial_x^2\log\tau=k_1^2\,\mathrm{sech}^2\,\theta_1$.

V. CONCLUSIONS

In this paper we deal with a novel class of reductions of the BKP hierarchy and as such these reductions allow us to identify certain new integrable systems.

The central object in our discussion is the BKP eigenfunction potential. It was shown to be expressible as a ratio of tau functions and to correspond to a (general) symmetry of the bilinear BKP equations, i.e., for the equations the BKP tau functions satisfy.

The eigenfunction symmetry was then used to define dimensional reductions of the $2+1$-dimensional BKP equations. A link with constraints on the Lax operator was established and a simple bilinear formulation was derived. We wish to remark that in analogy to the reductions of the KP hierarchy one could consider a generalization of these reductions by using a sum of eigenfunction potential symmetries in the symmetry reduction.

Finally, we believe it is worth emphasizing that our tau-function approach to symmetry reductions has, besides a certain conceptual clarity, the additional virtue of allowing for the straightforward derivation of a class of solutions to the reduced systems. In the present case these solutions were easily expressed in terms of Pfaffians.

APPENDIX: PROOF OF RELATION (19)

To prove relation (19) (e.g., denoting Φ_i as Φ_1 and Φ_j as Φ_2), we use the formula (9) for both $S(\psi(\mathbf{t},\lambda),\Phi_1^*(\mathbf{t}))$ and $S(\psi(\mathbf{t}',-\lambda),\Phi_2^*(\mathbf{t}'))$, together with the equation (8):

$$\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)\Phi_i(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Phi_j(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))]$$
$$=4\,\mathrm{Res}_\lambda[\lambda^{-1}S(\psi(\mathbf{t},\lambda),\Phi_1^*(\mathbf{t}))S(\psi(\mathbf{t}',-\lambda),\Phi_2^*(\mathbf{t}'))]-3\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}')$$
$$+2\Phi_1(\mathbf{t})\Phi_2(\mathbf{t})+2\Phi_1(\mathbf{t}')\Phi_2(\mathbf{t}'). \tag{A1}$$

Let us denote the residue on the right-hand side by $I(\mathbf{t},\mathbf{t}')$. We shall now try to compute $\partial_{t_n}\partial_{t'_m}I(\mathbf{t},\mathbf{t}')$. As mentioned in Sec. II, the derivative of $S(\psi,\Phi^*)$ is given by $(B_n=\Sigma_{j=0}^n b_{n,j}\partial_x^j)$:

$$\partial_{t_n}S(\psi,\Phi^*)=\sum_{j=1}^{n}\sum_{i=1}^{j}(-1)^{i+1}(\Phi^* b_{n,j})_{(i-1)x}\psi_{(j-i)x}. \tag{A2}$$

Hence, $\partial_{t_n}\partial_{t'_m}I(\mathbf{t},\mathbf{t}')$ will have the form of an operator in the variables x and x' working on the residue $\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)]$. But, by virtue of the BKP bilinear identity (3), all terms will vanish except the ones without derivatives on $\psi(\mathbf{t},\lambda)$ and $\psi(\mathbf{t}',-\lambda)$. These correspond to the terms with $i=j$ in expression (A2):

$$\sum_{j=1}^{n}(-1)^{j+1}(\Phi^* b_{n,j})_{(j-1)x}\psi=\psi(B_n\partial_x^{-1})^*\Phi^*. \tag{A3}$$

As $(B_n\partial_x^{-1})^*=-\partial_x^{-1}B_n^*=\partial^{-1}(B_n+B_{n,x}\partial^{-1})$ and $\Phi^*=\Phi_x$, we find that this equals

$$\psi\partial^{-1}(B_n+B_{n,x}\partial^{-1})\partial_x\Phi=\psi B_n\Phi=\psi\Phi_{t_n}. \tag{A4}$$

In this way we find that

$$\partial_{t_n}\partial_{t'_m}I(\mathbf{t},\mathbf{t}')=\Phi_{1,t_n}(\mathbf{t})\Phi_{2,t'_m}(\mathbf{t}').$$

It follows that

$$I(\mathbf{t},\mathbf{t}')=\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}')+f(\mathbf{t})+g(\mathbf{t}'),$$

for some f and g. As $I(\mathbf{t},\mathbf{t}'=\mathbf{t})=0$ [since $S(\psi(\mathbf{t},\lambda),\Phi^*)=\mathcal{O}(\lambda^{-1})\exp\xi(\mathbf{t},\lambda)$, we have $g=-f-\Phi_1\Phi_2$ and hence $I(\mathbf{t},\mathbf{t}')=\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}')+f(\mathbf{t})-f(\mathbf{t}')-\Phi_1(\mathbf{t}')\Phi_2(\mathbf{t}')$]. To find an expression for f, we compute $\partial_{z_n}I(\mathbf{t}-\mathbf{z},\mathbf{t}+\mathbf{z})_{\mathbf{z}=\mathbf{0}}=-2f_{t_n}(\mathbf{t})-2\Phi_{1,t_n}(\mathbf{t})\Phi_2(\mathbf{t})$ or, equivalently,

$$-\mathrm{Res}_\lambda[\lambda^{-1}S_{t_n}(\psi(\mathbf{t},\lambda),\Phi_1^*(\mathbf{t}))S(\psi(\mathbf{t},-\lambda),\Phi_2^*(\mathbf{t}))]$$
$$+\mathrm{Res}_\lambda[\lambda^{-1}S(\psi(\mathbf{t},\lambda),\Phi_1^*(\mathbf{t}))S_{t_n}(\psi(\mathbf{t},-\lambda),\Phi_2^*(\mathbf{t}))].$$

Representing $\partial_{t_n}S(\psi,\Phi^*)=\Sigma_{i,j=0}^{n-1}a_{ij}\psi_{ix}\Phi_{jx}^*$, we have

$$=-\sum_{i,j=0}^{n-1}a_{ij}\Phi_{1,jx}^*(\mathbf{t})\mathrm{Res}_\lambda[\lambda^{-1}\,\partial_x^i\psi(\mathbf{t},\lambda)S(\psi(\mathbf{t},-\lambda),\Phi_2^*(\mathbf{t}))]$$
$$+\sum_{i,j=0}^{n-1}a_{ij}\Phi_{2,jx}^*(\mathbf{t})\mathrm{Res}_\lambda[\lambda^{-1}S(\psi(\mathbf{t},\lambda),\Phi_1^*(\mathbf{t}))\partial_x^i\psi(\mathbf{t},-\lambda)].$$

These last residues equal $(\partial_x^j[\Phi_2(\mathbf{t}')-\Phi_2(\mathbf{t})])_{\mathbf{t}=\mathbf{t}'}=-\Phi_{2,jx}(\mathbf{t})+\delta_{j0}\Phi_2(\mathbf{t})$ and $(\partial_{x'}^j[\Phi_1(\mathbf{t})-\Phi_1(\mathbf{t}')])_{\mathbf{t}=\mathbf{t}'}=-\Phi_{1,jx}(\mathbf{t})+\delta_{j0}\Phi_1(\mathbf{t})$, respectively, by virtue of the relation (8). Hence

$$= -\sum_{i,j=0}^{n-1} a_{ij}\Phi^*_{1,jx}(\mathbf{t})(-\Phi_{2,ix}(\mathbf{t})+\delta_{i0}\Phi_2(\mathbf{t}))+\sum_{i,j=0}^{n-1} a_{ij}\Phi^*_{2,jx}(\mathbf{t})(-\Phi_{1,ix}(\mathbf{t})+\delta_{i0}\Phi_1(\mathbf{t})),$$

which—due to the reasoning that leads from (A3) to (A4)—equals

$$S_{t_n}(\Phi_2,\Phi_1^*)-\Phi_2\Phi_{1,t_n}-S_{t_n}(\Phi_1,\Phi_2^*)+\Phi_1\Phi_{2,t_n}=\partial_{t_n}\Omega(\Phi_1,\Phi_2)-\Phi_2\Phi_{1,t_n}+\Phi_1\Phi_{2,t_n}.$$

Hence, we find that $-2f_{t_n}(\mathbf{t})-2\Phi_{1,t_n}(\mathbf{t})\Phi_2(\mathbf{t})=\partial_{t_n}\Omega(\Phi_1,\Phi_2)-\Phi_2\Phi_{1,t_n}+\Phi_1\Phi_{2,t_n}$ or

$$f=-\tfrac{1}{2}\Omega(\Phi_1,\Phi_2)-\tfrac{1}{2}\Phi_1\Phi_2.$$

It then follows that

$$I(\mathbf{t},\mathbf{t}')=\Phi_1(\mathbf{t})\Phi_2(\mathbf{t}')-\tfrac{1}{2}\Omega(\Phi_1(\mathbf{t}),\Phi_2(\mathbf{t}))+\tfrac{1}{2}\Omega(\Phi_1(\mathbf{t}'),\Phi_2(\mathbf{t}'))-\tfrac{1}{2}(\Phi_1(\mathbf{t})\Phi_2(\mathbf{t})+\Phi_1(\mathbf{t}')\Phi_2(\mathbf{t}')),$$

and thus (A1) becomes

$$\mathrm{Res}_\lambda[\lambda^{-1}\psi(\mathbf{t},\lambda)\psi(\mathbf{t}',-\lambda)\Phi_i(\mathbf{t}-\boldsymbol{\epsilon}(\lambda))\Phi_j(\mathbf{t}'+\boldsymbol{\epsilon}(\lambda))]=\Phi_i(\mathbf{t})\Phi_j(\mathbf{t}')-2\Omega(\Phi_i(\mathbf{t}),\Phi_j(\mathbf{t}))+2\Omega(\Phi_i(\mathbf{t}'),\Phi_j(\mathbf{t}')).$$

On dimension of the global attractor for damped nonlinear wave equations

Zhou Shengfan[a)]
Department of Mathematics, Sichuan Union University Chengdu, 610064, People's Republic of China

(Received 10 August 1998; accepted for publication 21 September 1998)

In this paper, we obtain a more precise estimate of upper bound of the Hausdorff dimension of the global attractor for damped nonlinear wave equations with the Dirichlet boundary condition. The obtained Hausdorff dimension decreases as the damping grows and is uniformly bounded for large damping, which conforms to physical intuition. © *1999 American Institute of Physics.*

I. INTRODUCTION

Consider the initial-boundary value problem of the damped nonlinear wave equation

$$u_{tt}+\alpha u_t-\Delta u+f(u)=g, \quad x\in\Omega, \ \ t>0,$$

$$u(x,t)|_{x\in\partial\Omega}=0, \quad t>0, \tag{1}$$

$$u(x,0)=u_0(x), \quad \frac{\partial u}{\partial t}(x,0)=u_1(x), \quad x\in\Omega,$$

where $u=u(x,t)$ is a real-valued function on $\Omega\times[0,+\infty)$, Ω is an open bounded set of R^n with a smooth boundary $\partial\Omega$, $g\in L^2(\Omega)$, $f(u)\in C^1(R;R),\alpha>0$.

Let $G(s)=\int_0^s f(r)dr$. We make the following assumptions on the functions $G(s)$ and $f(s)$:

(i)

$$\lim_{|s|\to\infty}\inf\frac{G(s)}{s^2}\geqslant 0. \tag{2}$$

(ii) There exist two positive constants $c_1>0$, $c_2>0$ such that

$$\lim_{|s|\to\infty}\inf\frac{sf(s)-c_1G(s)}{s^2}\geqslant 0, \tag{3}$$

and

$$|f'(s)|\leqslant c_2(1+|s|^\gamma) \ \text{ with } \begin{cases} 0\leqslant\gamma<\infty & \text{when } n=1,2\\ 0\leqslant\gamma<2 & \text{when } n=3, \ \forall s\in R\\ \gamma=0 & \text{when } n\geqslant 4.\end{cases} \tag{4}$$

(iii) There exists $\delta_1>0$ and for every $M>0$ there exists $c'=c'(M)$ such that

---

[a)]Electronic mail: nic2601@pop.scuu.edu.cn

$$|f'(u_1)-f'(u_2)|\leqslant c'\|u_1-u_2\|^{\delta_1},\forall u_1,u_2\in H_0^1(\Omega),\|u_1\|\leqslant M,\|u_2\|\leqslant M, \tag{5}$$

where $|\cdot|$ and $\|\cdot\|$ denote the norms of $L^2(\Omega)$, $H_0^1(\Omega)$, respectively.

Two examples of Eq. (1) are the sine-Gordon equation [i.e., $f(u)=\sin u$] and the equation of relativistic quantum mechanics ($f(u)=|u|^{\gamma}u$).

For the system (1) with conditions (2)–(5), Temam[1] showed that the continuous semigroup of mapping $S(t):\{u_0,u_1\}\mapsto\{u,u_t\}$, for $t\geqslant 0$ from $E=H_0^1(\Omega)\times L^2(\Omega)$ into itself, defined by system (1) possesses a global attractor in E and gave an upper bound of the Hausdorff dimension of attractor, but this upper bound is directly proportional to the coefficient α of damping for $\alpha\geqslant\sqrt{2\lambda_1}$ and tends to infinity as $\alpha\to+\infty$, which is obviously not precise in the physical sense, where $\lambda_1>0$ is the first eigenvalue of operator $-\Delta$.

In this paper, we obtain a more strict upper bound of the Hausdorff dimension for the global attractor by carefully estimating and splitting the positivity of the linear operator in the corresponding evolution equation of the first order in time. The obtained Hausdorff dimension decreases as the damping α grows and is uniformly bounded for large α, which conforms to physical intuition. The idea of using such a technique originates from Wang and Zhu.[2] The main result is the following theorem.

Theorem 1: *If the function $f(u)$ satisfies conditions (2)–(5), then for any $\alpha\geqslant\alpha_0>0$, the Hausdorff dimension d_H of the global attractor for system (1) satisfies:*

$$\begin{aligned} d_H&\leqslant\min\left\{l\,\middle|\,l\in N,\frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1}\leqslant\frac{2\lambda_1\alpha^2}{k^2\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}\right\}\\ &\leqslant\min\left\{l\,\middle|\,l\in N,\frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1}\leqslant\frac{2\lambda_1\alpha_0^2}{k^2\sqrt{\alpha_0^2+4\lambda_1}(\alpha_0+\sqrt{\alpha_0^2+4\lambda_1})}\right\}, \end{aligned}\tag{6}$$

where $\{\lambda_j\}_{j\in N}:0<\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\lambda_m\leqslant\cdots$, are the eigenvalues of operator $-\Delta$ with the Dirichlet boundary condition on Ω and $k=k(\alpha_0)$ is a positive constant.

Particularly, if the condition (4) is $|f'(u)|\leqslant k_0$, then for any $\alpha>0$,

$$d_H\leqslant\min\left\{l\,\middle|\,l\in N,\frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1}\leqslant\frac{2\lambda_1\alpha^2}{k_0^2\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}\right\}. \tag{7}$$

Obviously, the upper bound of d_H in (6) is a decreasing function of α and remains small for large damping α because

$$h(\alpha)=\frac{2\lambda_1\alpha^2}{k^2\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}$$

increases as α grows and

$$\lim_{l\to+\infty}\frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1}=0,\qquad \lim_{\alpha\to+\infty}\frac{2\lambda_1\alpha^2}{k^2\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}=\frac{\lambda_1}{k^2}.$$

II. PRELIMINARIES

For convenience, we omit statements of the existence and uniqueness of the solution of (1) which define a continuous semigroup of mapping

$$S(t):\{u_0,u_1\}\mapsto\{u,u_t\}\quad\text{for } t\geqslant 0 \tag{8}$$

from $H_0^1(\Omega)\times L^2(\Omega)$ (or $(H_0^1(\Omega)\cap H^2(\Omega))\times H_0^1(\Omega))$ into itself. We also omite statements of the existence of the global attractor for the semigroup $S(t)$, $t\geqslant 0$ (see, e.g., Ref. 1 for details).

It is known that the operator $A=-\Delta:D(A)=H_0^1(\Omega)\cap H^2(\Omega)\to L^2(\Omega)$ is a self-adjoint positive linear operator and its eigenvalues $\{\lambda_i\}_{i\in N}$ satisfy

$$0<\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\lambda_m\leqslant\cdots,\quad \lambda_m\to+\infty \quad \text{as} \quad m\to+\infty.$$

Let

$$E=H_0^1(\Omega)\times L^2(\Omega),\quad E_0=D(A)\times H_0^1(\Omega),$$

$$(u,v)=\int_\Omega uv\,dx,\quad |u|=(u,u)^{1/2},\quad \forall u,v\in L^2(\Omega),$$

$$((u,v))=\int_\Omega \nabla u\cdot\nabla v\,dx,\quad \|u\|=((u,u))^{1/2},\quad \forall u,v\in H_0^1(\Omega),$$

$$(y_1,y_2)_E=((u_1,u_2))+(v_1,v_2),\quad \forall y_i=(u_i,v_i)^T\in E,\quad i=1,2,$$

$$|y|_E=(y,y)_E^{1/2},\quad \forall y=(u,v)^T\in E$$

and

$$(y_1,y_2)_{E_0}=(Au_1,Au_2)+(v_1,v_2),\quad \forall y_i=(u_i,v_i)^T\in E_0,\quad i=1,2,$$

$$|y|_{E_0}=(y,y)_{E_0}^{1/2},\quad \forall y=(u,v)^T\in E_0$$

denote the usual inner products and norms in $L^2(\Omega)$, $H_0^1(\Omega)$, E, and E_0, respectively.

It is convenient to reduce (1) to an evolution equation of the first order in time. Let $\varphi=(u,v)^T$, $v=\dot{u}+\epsilon u$, where ϵ is chosen as

$$\epsilon=\frac{\lambda_1\alpha}{\alpha^2+4\lambda_1}, \tag{9}$$

then (1) can be written as

$$\dot{\varphi}+\Lambda\varphi=F(\varphi),\quad \varphi(0)=(u_0,u_1+\epsilon u_0), \tag{10}$$

where

$$F(\varphi)=\begin{pmatrix}0\\ -f(u)+g\end{pmatrix},\quad \Lambda=\begin{pmatrix}\epsilon I & -I\\ A-\epsilon(\alpha-\epsilon)I & (\alpha-\epsilon)I\end{pmatrix}. \tag{11}$$

It is easy to see that the semigroup

$$S_\epsilon(t):(u_0,u_1+\epsilon u_0)^T\to(u(t),u_t(t)+\epsilon u(t))^T,\quad E\to E(\text{or } E_0\to E_0) \tag{12}$$

defined by (10) has the following relation with $S(t)$:

$$S_\epsilon(t)=R_\epsilon S(t)R_{-\epsilon}, \tag{13}$$

where R_ϵ is an isomorphism of E (or E_0):

$$R_\epsilon:\{u,v\}\to\{u,v+\epsilon u\}.$$

Since the semigroup $\{S(t),t\geqslant 0\}$ defined by (1)–(8) possesses a global attractor $\beta_0\subset E_0\subset E$,[1] by (13), $\{S_\epsilon(t),t\geqslant 0\}$ also possesses a global attractor $\beta=R_\epsilon\beta_0$. Moreover, β and β_0 have the same dimension. So we need consider the equivalent system (10) only. First, we give a property concerning the positivity of the linear operator Λ, which plays the center role in this article.

Lemma 1: For any $\varphi=(u,v)^T\in E$,

$$(\Lambda\varphi,\varphi)_E\geqslant\sigma|\varphi|_E^2+\frac{\alpha}{2}|v|^2, \tag{14}$$

where

$$\sigma=\frac{\lambda_1\alpha}{\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}. \tag{15}$$

Proof: Since

$$\begin{aligned}(\Lambda\varphi,\varphi)_E-\sigma|\varphi|_E^2-\frac{\alpha}{2}|v|^2&=(\epsilon-\sigma)\|u\|^2+\left(\frac{\alpha}{2}-\epsilon-\sigma\right)|v|^2-\epsilon(\alpha-\epsilon)(u,v)\\&\geqslant(\epsilon-\sigma)\|u\|^2+\left(\frac{\alpha}{2}-\epsilon-\sigma\right)|v|^2-\frac{\epsilon\alpha}{\sqrt{\lambda_1}}\|u\|\cdot|v|\end{aligned}$$

and simple computation by (9) and (15) shows

$$4(\epsilon-\sigma)\left(\frac{\alpha}{2}-\epsilon-\sigma\right)=\frac{\epsilon^2\alpha^2}{\lambda_1}.$$

Thus, the proof is completed.

In this section, we suppose $\alpha\geqslant\alpha_0>0$, and we will show that the bounds of the global attractor of system (10) in the spaces E and E_0 depend on the constant α_0 only.

We write $\overline{G}(u)=\int_\Omega G(u)dx$. Taking the inner product $(\cdot,\cdot)_E$ of (10) with $\varphi=(u,v)^T$ in which $v=u_t+\epsilon u$, we find

$$\frac{1}{2}\frac{d}{dt}[|\varphi|_E^2+2\overline{G}(u)]+(\Lambda\varphi,\varphi)_E+\epsilon(f(u),u)=(g,v). \tag{16}$$

By (2), (3) and the Poincaré inequality, there exist two positive constants $k_1,k_2\geqslant 0$ such that

$$\overline{G}(u)+k_1\geqslant-\tfrac{1}{4}\|u\|^2,\quad \forall u\in H_0^1(\Omega), \tag{17}$$

$$(u,f(u))\geqslant c_1\overline{G}(u)-\tfrac{1}{4}\|u\|^2-k_2,\quad \forall u\in H_0^1(\Omega). \tag{18}$$

It is easy to see from (9) and (15) that

$$\sigma=\frac{\sqrt{\alpha^2+4\lambda_1}}{\alpha+\sqrt{\alpha^2+4\lambda_1}}\epsilon,$$

i.e.,

$$\tfrac{1}{2}\epsilon<\sigma<\epsilon. \tag{19}$$

Let

$$y = |\varphi|_E^2 + 2\overline{G}(u) + 2k_1 \geqslant \text{by } (17) \geqslant \tfrac{1}{2}|\varphi|_E^2 \geqslant 0. \tag{20}$$

By (14), (16), (17) and (18),

$$\frac{d}{dt}y + \beta_1 y \leqslant \frac{1}{\alpha}|g|^2 + 2\epsilon(c_1k_1 + k_2), \tag{21}$$

where

$$\beta_1 = \tfrac{1}{2}\epsilon\theta, \theta = \min(1,2c_1) = \begin{cases} 1 & \text{when } c_1 \geqslant \tfrac{1}{2} \\ 2c_1 & \text{when } 0 < c_1 < \tfrac{1}{2}. \end{cases} \tag{22}$$

By the Gronwall inequality, (20) and (21),

$$|\varphi|_E^2 \leqslant 2y(t) \leqslant 2y(0)\exp(-\beta_1 t) + \left(\frac{4}{\alpha\epsilon\theta}|g|^2 + \frac{8(c_1k_1+k_2)}{\theta}\right)[1 - \exp(-\beta_1 t)] \tag{23}$$

and

$$\lim_{t\to+\infty} \sup|\varphi|_E^2 \leqslant \frac{4}{\alpha\epsilon\theta}|g|^2 + \frac{8(c_1k_1+k_2)}{\theta} = M(\alpha). \tag{24}$$

By (24) and (9),

$$M(\alpha) = \frac{4}{\theta}\left(\frac{\alpha^2 + 4\lambda_1}{\lambda_1\alpha^2} + 2(c_1k_1+k_2)\right).$$

Since $M(\alpha)$ is a decreasing continuous function of α on $[\alpha_0 + \infty)$ and

$$\lim_{\alpha\to+\infty} M(\alpha) = \frac{4}{\theta}\left(\frac{1}{\lambda_1} + 2(c_1k_1+k_2)\right) < +\infty,$$

so, there exists a positive constant

$$M_0 = M_0(\alpha_0) = \frac{4}{\theta}\left(\frac{\alpha_0^2 + 4\lambda_1}{\lambda_1\alpha_0^2} + 2(c_1k_1+k_2)\right)$$

such that

$$M(\alpha) \leqslant M_0, \quad \forall \alpha \in [\alpha_0, +\infty). \tag{25}$$

We infer from (24) and (25) that the ball of E, $B_0 = B_E(0,2M_0)$, centered at 0 of radius $2M_0$, is an absorbing set in E for the semigroup $S_\epsilon(t)$, $t \geqslant 0$. So, the global attractor β is included in the bounded ball B_0. We also knew from Ref. 1 that if the set of all continuous and bounded functions from R_+ into the Hilbert space X is denoted by $C_b(R_+,X)$, then any solution $\varphi = (u,v)^T$ in $C_b(R_+,E)$ of system (10) belongs to $C_b(R_+,E_0)$, and the norm of φ in $C_b(R_+,E_0)$ is majorized by a bounded function of $|f| + |\varphi|_E$ independent of the parameter α. Hence, the global attractor β is included in a bounded ball in E_0 which depends on α_0 only, that is, there exists a constant $M_1 = M_1(\alpha_0) > 0$ such that

$$|\varphi|_{E_0} = (|Au|^2 + |v|^2)^{1/2} \leqslant M_1, \quad \forall \varphi = (u,v)^T \in \beta. \tag{26}$$

III. PROOF OF THEOREM 1

To estimate the Hausdorff dimension of the global attractor β for (10) in E, we consider the first variation equation of (10),

$$\Psi' = -\Lambda\Psi + F'(\varphi)\Psi, \quad \Psi(0) = (\xi,\eta)^T \in E, \tag{27}$$

where $\Psi = (U,V)^T \in E$, and $\varphi = (u,v)^T$ is a solution of (10) and

$$F'(\varphi) = \begin{pmatrix} 0 & 0 \\ -f'(u) & 0 \end{pmatrix}. \tag{28}$$

Lemma 2: The system (27) is a well-posed problem in E, the mapping $S_\epsilon(t)$ defined by (10) is Fréchet differentiable on E for any $t>0$, its differential at $\varphi = (u_0, u_1 + \epsilon u_0)^T$ is the linear operator on E, $(\xi,\eta)^T \mapsto (U(t),V(t))^T$, where $(U,V)^T$ is the solution of (27).

Proof: It is a direct consequence of (13) and lemma VI.6.1 in Ref. 1.

Lemma 3: For any orthonormal family of elements of E, $\{(\xi_j,\eta_j)^T\}_{j=1}^{l}$, we have

$$\sum_{j=1}^{l} |\xi_j|^2 \leq \sum_{j=1}^{l} \lambda_j^{-1}. \tag{29}$$

Proof: See lemma VI.6.3. in Ref. 1.

Lemma 4: Consider the system (10). Let Φ denote a set of l vectors $\{\Phi_1, \Phi_2, \ldots, \Phi_l\}$ which are orthonormal in E. If

$$\sup_{\Phi \subset E}\sup_{\varphi\in\beta}\sum_{i=1}^{l}((-\Lambda + F'(\varphi))\Phi_i, \Phi_i)_E \leq 0, \tag{30}$$

then the Hausdorff dimension of the global attractor β is less than or equal to l.

Proof: This is a direct consequence of theorem V.3.3, Eqs. (V.3.47)–(V.3.49) and identity (VI.6.24) of Ref. 1.

Lemma 5: If the function $f(u)$ satisfies the conditions (2), (3), (4), (5), then for any $\alpha \geq \alpha_0 > 0$, the Hausdorff dimension $d_H(\beta)$ of β for system (10) in E satisfies

$$d_H(\beta) \leq \min\left\{ l \,\middle|\, l\in N, \frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1} \leq \frac{2\alpha\sigma}{k^2}\right\}, \tag{31}$$

where $k = k(\alpha_0)$ is a positive constant depending α_0 only.

Proof: Let $l \in N$ be fixed. Consider l solutions $\Psi_1, \Psi_2, \ldots, \Psi_l$ of (27). At a given time τ, let $Q_l(\tau)$ denote the orthogonal projection in E onto the space spanned by $\Psi_1, \Psi_2, \ldots, \Psi_l$. Let $\Phi_j(\tau) = (\xi_j, \eta_j)^T \in E$, $j = 1,2,...,l$, be an orthonormal basis of

$$Q_l(\tau)E = \mathrm{span}\{\Psi_1(\tau), \Psi_2(\tau), \ldots, \Psi_l(\tau)\}.$$

From (14) and $|\Phi_j|_E = 1$, we have

$$-(\Lambda\Phi_j, \Phi_j)_E \leq -\sigma - \frac{\alpha}{2}|\eta_j|^2. \tag{32}$$

By (26),

$$|Au| \leq M_1, \quad \forall u \in D(A)\cap\beta = (H^2(\Omega)\cap H_0^1(\Omega))\cap\beta. \tag{33}$$

By (4), (33) and Sobolev embedding theorem, there exists a constant $k = k(\alpha_0) > 0$ (which is independent of α) such that

$$\sup_{u\in D(A)\cap\beta}|f'(u)|_{C(H_0^1(\Omega),L^2(\Omega))}\leqslant k<+\infty. \tag{34}$$

Thus by (28) and (34),

$$(F'(\varphi)\Phi_j,\Phi_j)_E=(-f'(u)\xi_j,\eta_j)\leqslant k|\xi_j|\cdot|\eta_j|\leqslant\frac{k^2}{2\alpha}|\xi_j|^2+\frac{\alpha}{2}|\eta_j|^2,\quad \forall\varphi=(u,v)\in\beta. \tag{35}$$

Hence,

$$\begin{aligned}\sup_{\varphi\in\beta}\sum_{i=1}^{l}((-\Lambda+F'(\varphi))\Phi_i,\Phi_i)_E&\leqslant \text{by (32) and (35)}\\ &\leqslant -l\sigma+\frac{k^2}{2\alpha}\sum_{j=1}^{l}|\xi_j|^2\\ &\leqslant \text{by (29)}\\ &\leqslant -\frac{lk^2}{2\alpha}\left(\frac{2\alpha\sigma}{k^2}-\frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1}\right).\end{aligned} \tag{36}$$

If

$$\frac{1}{l}\sum_{j=1}^{l}\lambda_j^{-1}\leqslant\frac{2\alpha\sigma}{k^2},$$

then by (36),

$$\sup_{\varphi\in\beta}\sum_{i=1}^{l}((-\Lambda+F'(\varphi))\Phi_i,\Phi_i)_E\leqslant 0.$$

By lemma 4, the proof is completed.

Combining with lemma 5 and (15), we complete the proof of theorem 1.

(Received 5 June 1998; accepted for publication 8 December 1998)

The fractionally charged solitons in a trimerized electron–phonon system are studied by both analytical and numerical methods. To make those methods possible, an effective Lagrangian is derived by diagrammatic calculations. It is found that this Lagrangian is similar to that derived by the so-called derivative expansion. Both the phase and amplitude parts of the complex order parameter are included in the Lagrangian, and here we particularly focus on the nonlinear coupling between them. When the electron–phonon coupling is very weak, the aforementioned coupling is also weak, and so the soliton is almost considered to be a pure phase soliton with a constant amplitude. While, in the intermediate electron–phonon coupling case, the two parts of the order parameter are nonlinearly coupled. As a result, the soliton changes its pattern from that of a phase soliton to a strongly amplitude-deformed one. Our both methods, i.e., the analytical and numerical ones, succeed in giving such changes as gradual ones. Moreover, the coincidence of the two results is also good at a quantitative level. © *1999 American Institute of Physics.* [S0022-2488(99)01703-X]

I. INTRODUCTION

The one-dimensional electron–phonon system is an interesting system to which many theoretical and the experimental investigations are devoted. This is one of the most ideal systems which bear nonlinear excitations such as solitons, polarons, and so on. They can be described very well, for example, by the SSH model that was proposed by Su *et al.*[1] This model contains the electron–phonon interaction in addition to electron hopping and lattice vibrations. Takayama *et al.* proposed the TLM model, which is a continuum version of the SSH model in the half-filling case and makes the analytical study of nonlinear excitations possible.[2]

A simpler model for analytical study of the one-dimensional electron–phonon system is the Fröhlich model.[3] The difference from the SSH model is in the momentum dependence of the electron–phonon coupling. While the coupling depends on both the transfer momentum and the initial momentum in the SSH model, it is simply constant in this model. The model has been analyzed by many authors. For example, Horovitz *et al.* studied the dynamical equation of both the phase and the amplitude of the complex order parameter in the commensurate case, using the self-consistent equation between electron- and phonon-degrees of freedom given by the Fröhlich model.[4] They derived an effective Lagrangian which can be considered as the sine-Gordon model, and obtained the phase soliton solution. Grabowski *et al.* solved the effective Lagrangian numerically.[5] The soliton of the sine-Gordon model was investigated in various systems.[6] The soliton appears as the spatial connection between the degenerate energy minimum points of the cosine potential. In the electron–phonon system, the local density of electron charge is represented by the spatial variation of the phase variable. The phase soliton in the trimerized system has fractionally charges $(\pm 2/3e)$.

Iwano *et al.* also investigated the Fröhlich model in the trimerized case using the Eilenberger equation which had been formulated in the study of the superconductivity in strong-coupling cases.[7] At a particular value for the coupling constant λ, the Eilenberger equation has an exact solution. They found that the coupling between the phase and the amplitude is non-negligible to cause a large distortion in the latter. Their result showed that the soliton in the commensurate and away from the half-filling system should be considered as a complex in which the two degrees of freedom are entangled rather than a simple phase soliton.

In the present paper, we study the fractionally charged soliton using the effective Lagrangian of the trimerized system. We apply another method to derive the effective Lagrangian, which has some differences from that given in Ref. 4. The solution is investigated classical mechanically using both an analytical perturbational calculation and a numerical calculation introducing a variational functional. We will show that the fractionally charged soliton has a complicated behavior which is consistent with the result given by the preceding work.

II. THE FRÖLICH MODEL

A. General formalism for a trimerized electron–phonon system

The Hamiltonian of the one-dimensional Fröhlich system of length $L=Na$ is given by

$$K=H-\mu N_e=\sum_{k,s}(\epsilon_k-\mu)C^\dagger_{k,s}C_{k,s}-\frac{\mathrm{i}}{\sqrt{N}}\sum_q\sum_{k,s}g(b_q+b^\dagger_{-q})C^\dagger_{k+q,s}C_{k,s}+\sum_q\omega_Q b^\dagger_q b_q. \quad (1)$$

The first term is the free electron part, where μ is the chemical potential, and N_e is the total number of electrons. Here we consider a tight-binding band of electrons as

$$\epsilon_k=-W\cos ka. \quad (2)$$

This band is $\frac{1}{3}$ filled with electrons. The second term represents the electron–phonon coupling. Since this is the Frölich model, the coupling factor g is now constant with no momentum dependence. The last term is the free phonon term. ω_Q is the phonon frequency for the wave number of $2k_F$, where k_F is the wave number of electron at the Fermi level.

Introducing the three component electronic field $\psi_s(x)$ and the lattice displacement operator $u(x)$ by

$$\psi_s(x)=\begin{pmatrix}\phi_s^{(1)}(x)\\ \phi_s^{(2)}(x)\\ \phi_s^{(3)}(x)\end{pmatrix}=\frac{1}{\sqrt{L}}\sum_{-k_F\leq k<k_F}\begin{pmatrix}C_{k_F+k,s}\\ C_{-k_F+k,s}\\ C_{3k_F+k,s}\end{pmatrix}e^{\mathrm{i}kx}, \quad (3)$$

and

$$u(x)=-\frac{\mathrm{i}}{\sqrt{N}}\sum_{-k_F\leq q<k_F}(b_{2k_{F+q}}+b^\dagger_{-2k_{F-q}})e^{\mathrm{i}qx}. \quad (4)$$

Equation (1) is rewritten as follows:

$$K=H_u+H_\psi-(\tfrac{1}{2}+\mu)N_e, \quad (5)$$

with

$$H_u=\frac{g^2}{2\lambda\pi v_F\omega_Q^2}\int(|\dot{u}(x)|^2+\omega_Q^2|u(x)|^2), \quad (6)$$

and

$$H_\psi=\sum_s \int \mathrm{d}x\,\psi_s^\dagger(x)H_e\psi_s(x), \tag{7}$$

where

$$H_e=\begin{pmatrix} -\mathrm{i}v_F\partial_x & 0 & 0 \\ 0 & \mathrm{i}v_F\partial_x & 0 \\ 0 & 0 & W\left(\frac{3}{2}+\frac{a^2}{2}\partial_x^2\right)\end{pmatrix}+g\begin{pmatrix} 0 & u(x) & u^*(x) \\ u^*(x) & 0 & u(x) \\ u(x) & u^*(x) & 0\end{pmatrix}. \tag{8}$$

H_u in Eq. (5) is the contribution from the lattice elastic energy given by the last term of Eq. (1). In the case of the trimerized system, the Fermi level is nearly equal to $-W/2$. We take μ as $-W/2$. The parameters are defined by

$$\lambda=\frac{ag^2}{\pi v_F\omega_Q}, \tag{9}$$

and the Fermi velocity of electron is given by

$$v_F=\frac{\sqrt{3}}{2}Wa. \tag{10}$$

In the following of this section, we concentrate our mind to obtain an effective potential of the lattice dynamics, performing renormalizations of the three component electronic field. First, introducing a two-component electronic field $\phi_s(x)$, and the amplitude $\Delta(x)$ and the phase $\theta(x)$ of the phonon field by

$$\phi_s(x)=\begin{pmatrix}\phi_s^{(1)}(x)\\ \phi_s^{(2)}(x)\end{pmatrix}, \tag{11}$$

and

$$\Delta(x)e^{\mathrm{i}\theta(x)}=gu(x), \tag{12}$$

respectively. H_ψ is rewritten as

$$\begin{aligned} H_\psi=&-\sum_s \mathrm{i}v_F\int \mathrm{d}x\,\phi_s^\dagger(x)\partial_x\sigma_3\phi_s(x)\\ &+\int \mathrm{d}x\,\phi_s^\dagger(x)\left\{\Delta(x)\begin{pmatrix}0 & e^{\mathrm{i}\theta(x)}\\ e^{-\mathrm{i}\theta(x)} & 0\end{pmatrix}-\frac{2}{3W}\Delta(x)^2\begin{pmatrix}1 & e^{-2\mathrm{i}\theta(x)}\\ e^{2\mathrm{i}\theta(x)} & 1\end{pmatrix}\right\}\phi_s(x)\\ &+\int \mathrm{d}x\left(\frac{2}{3W}\left|\frac{3W}{2}\phi_s^{(3)}(x)+\Delta(x)(\phi_s^{(1)}(x)e^{\mathrm{i}\theta(x)}+\phi_s^{(2)}(x)e^{-\mathrm{i}\theta(x)})\right|^2+\phi_s^{(3)*}\frac{Wa^2}{2}\partial_x^2\phi_s^{(3)}(x)\right). \end{aligned} \tag{13}$$

Replacing $\phi_s^{(3)}(x)$ by $\varphi_s(x)=\phi_s^{(3)}(x)-[2\Delta(x)/3W](\phi_s^{(1)}(x)e^{\mathrm{i}\theta(x)}+\phi_s^{(2)}(x)e^{-\mathrm{i}\theta(x)})$, and using that $\phi_s^{(3)}(x)$ varies slowly in the scale of the correlation length $\xi=v_F/|\Delta|$, the third and the fourth lines in the right-hand side of Eq. (13) are rewritten again as

$$\int \mathrm{d}x\,\varphi(x)\left(\frac{3W}{2}+\frac{Wa^2}{2}\partial_x^2\right)\varphi(x)+O\left(\Delta\left(\frac{\alpha}{\xi}\right)^2\left\langle\frac{\partial^2}{\partial(x/\xi)^2}\right\rangle\right). \tag{14}$$

Equation (14) means that the influence of Δ and θ on $\phi_s^{(3)}(x)$ is sufficiently small. Then, we totally neglect the contribution of $\phi_s^{(3)}(x)$ in the following.

To estimate the effective potential from the Hamiltonian in Eq. (13), we consider the partition function, which is defined by

$$Z=\int Du_r Du_i\left(\prod_s D\phi_s^\dagger D\phi_s\right)e^{-\int L\mathrm{d}\tau}, \tag{15}$$

where u_r and u_i are the real and imaginary parts of the field $u(x)$, respectively. Then, L is written as

$$L=L_\Delta^0+L_\phi, \tag{16}$$

where

$$L_\Delta^0=\frac{1}{2\pi v_F\lambda\omega_Q{}^2}\int \mathrm{d}x\left\{\left(\frac{\partial\Delta(x)}{\partial\tau}\right)^2+\Delta(x)^2\left(\frac{\partial\theta(x)}{\partial\tau}\right)^2+\omega_Q^2\Delta^2(x)\right\}, \tag{17}$$

and

$$L_\phi=\sum_s\int \mathrm{d}x\,\phi_s^\dagger(x)\frac{\partial\phi_s(x)}{\partial\tau}+\sum_s\int \mathrm{d}x\,\phi_s^\dagger(x)[-\mathrm{i}v_F\sigma_3\partial_x]\phi_s(x)$$
$$+\sum_s\int \mathrm{d}x\,\phi_s^\dagger(x)\left\{-\frac{2\Delta(x)^2}{3W}\begin{pmatrix}1&0\\0&1\end{pmatrix}+\begin{pmatrix}0&D(x)\\D^*(x)&0\end{pmatrix}\right\}\phi_s(x). \tag{18}$$

Here $\partial/(\partial\tau)$ is the derivatives with respect to the imaginary time τ. A new field $D(x)$ is introduced by

$$D(x)=\Delta(x)\mathrm{e}^{\mathrm{i}\theta(x)}-\frac{2}{3W}\Delta(x)^2\mathrm{e}^{-2\mathrm{i}\theta(x)}. \tag{19}$$

Using the phase of $D(x)$, we can introduce the chiral transformation[8]

$$\tilde{\phi}_s(x)=e^{-(\mathrm{i}/2)\chi(x)\sigma_3}\phi_s(x), \tag{20}$$

where $\chi(x)$ is the phase of the complex variable $D(x)$, namely,

$$D(x)=A(x)e^{\mathrm{i}\chi(x)}, \tag{21}$$

with

$$A(x)=|D(x)|=\sqrt{\Delta(x)^2+\left(\frac{2\Delta(x)^2}{3W}\right)^2-\frac{4}{3W}\Delta(x)^3\cos 3\theta(x)}. \tag{22}$$

Substituting Eq. (20) into Eq. (18), the Lagrangian for the scalar fields $\Delta(x)$, $\theta(x)$, and the electronic field $\tilde{\phi}_s$ is given by

$$L=L_\Delta^0+L_{\tilde{\phi}}^0+H_I, \tag{23}$$

with

$$L_{\tilde{\phi}}^0=\sum_s\int \mathrm{d}x\,\tilde{\phi}_s^\dagger(x)\frac{\partial\tilde{\phi}_s(x)}{\partial\tau}+\sum_s\int \mathrm{d}x\,\tilde{\phi}_s^\dagger(x)[-\mathrm{i}v_F\sigma_3\partial_x]\tilde{\phi}_s(x), \tag{24}$$

and

$$H_I=\sum_s \int \mathrm{d}x\,\tilde{\phi}_s^\dagger(x)\left\{\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}I+\mathrm{i}\frac{\partial\chi(x)}{\partial\tau}\frac{\sigma_3}{2}-\frac{2}{3W}\Delta(x)^2 I+A(x)\sigma_1\right\}\tilde{\phi}_s(x). \tag{25}$$

In the path integration, the Jacobian $\partial(\phi_s^\dagger,\phi_s)/\partial(\tilde{\phi}_s^\dagger,\tilde{\phi}_s)$ appears by the chiral transformation. This factor is explained physically by Fujikawa.[9] Let us consider the path integration at the zero temperature. Introducing the external electromagnetic field $(\varphi,v_F A_x)=(-\mathrm{i}A_0,A_1)$, and the Euclidian space-time $(x^0,x^1)=(\mathrm{i}t,x/v_F)$, the space and time derivatives are rewritten in the covariant forms as[10]

$$-\mathrm{i}v_F\frac{\partial}{\partial x}\to-\mathrm{i}(\partial_1+\mathrm{i}eA_1), \tag{26}$$

and

$$\mathrm{i}\frac{\partial}{\partial t}\to-(\partial_0+\mathrm{i}eA_0), \tag{27}$$

where ∂_i denotes the differentiation with respect to x^i. The Jacobian is obtained by the gauge invariant regularization of the divergent integrals.[9,11] It is given by

$$\frac{\partial(\phi_s^\dagger,\phi_s)}{\partial(\tilde{\phi}_s^\dagger,\tilde{\phi}_s)}=\exp\left(-\mathrm{i}\frac{e}{2\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\chi(x)F_{01}(x)\mathrm{d}x^1\mathrm{d}x^0\right), \tag{28}$$

where

$$F_{01}=\frac{\partial A_1}{\partial x^0}-\frac{\partial A_0}{\partial x^1}=\mathrm{i}v_F E(x), \tag{29}$$

is the electric field.

Therefore, taking care of the spin degeneracy, we should examine the partition function at finite temperatures,

$$\begin{aligned}Z&=\int Du_r Du_i D\tilde{\phi}_s^\dagger D\tilde{\phi}_s\exp\left\{\frac{e}{\pi}\int_0^\beta\int\chi(x)E(x)\mathrm{d}x\mathrm{d}\tau-\int_0^\beta L\mathrm{d}\tau\right\}\\&=Z_0\left\langle T_\tau\exp\left(\frac{e}{\pi}\int_0^\beta\int\chi(x)E(x)\mathrm{d}x\mathrm{d}\tau-\int_0^\beta H_I\mathrm{d}\tau\right)\right\rangle,\end{aligned} \tag{30}$$

where $\langle\cdots\rangle$ means a thermal average with respect to the unperturbed Lagrangian. Moreover, H_I is the perturbation term given by Eq. (25), and Z_0 is the partition function of the unperturbed Lagrangian in which the influences of the external electromagnetic field and the electron–phonon coupling are excluded.

Equation (30) suggests that $-(e/\pi)(\partial\chi/\partial x)$ corresponds to the local charge density, and the dynamics of the order parameter involves variation of the charge distribution. This result was first derived by the study of the charge- and spin-density-waves in a one-dimensional electron system.[12]

B. The effective potential

Equation (25) has some analogy with the Takayama–Lin–Liu–Maki (TLM) model. The σ_1 coupling term in Eq. (25) appears in the same manner with the electron-lattice coupling term in the TLM model, whereas the σ_3 and I coupling terms are peculiar to this model. The effective

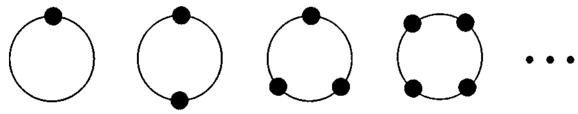

FIG. 1. The loop diagrams which contribute to the effective potential for the lattice distortion. The continuous line represents an electron Green function and the solid circle corresponds to the vertex.

potential for the TLM model was derived by the derivative expansion of the electron Green function by Horovits *et al.*[4] While, it is by our method derived by estimating the partition function of the TLM model, which comes back to the calculation of the connected loop diagrams with respect to the electron–phonon coupling.[13] By a renormalization, the effective Lagrangian at the zero temperature limit is given by

$$L_R=\frac{1}{2\pi v_F\lambda\omega_Q^2}\int dx(\dot{\Delta}(x)^2+\omega_Q^2\Delta(x)^2)+\frac{1}{2\pi v_F}\int dx\Delta(x)^2\ \ln\left(\left|\frac{\Delta(x)}{2\Lambda e^{1/2}}\right|^2\right)$$
$$+\frac{1}{\pi v_F}\int dx\Delta(x)\left(\frac{\sqrt{1+\gamma_1{}^2}}{\gamma_1}\sinh^{-1}\gamma_1-1\right)\Delta(x)$$
$$+\sum_{n=3}^{\infty}\frac{1}{n}\int dx\int dx_1\cdots\int dx_{n-1}\left(\prod_{j=1}^{n-1}\delta(x-x_j)\right)$$
$$\times D_n(x,x_1,\ldots,x_{n-1})\,\eta(x)\left(\prod_{i=1}^{n-1}\eta(x_i)\right), \tag{31}$$

where

$$\eta(x)=\Delta(x)-\Delta_0, \tag{32}$$

and

$$\gamma_1=-i\frac{v_F}{2\Delta_0}\frac{\partial}{\partial x}. \tag{33}$$

Here $D_n(x,x_1,\ldots,x_{n-1})$ is a function of derivatives with respect to $x,\ldots,x_{n-1}$, and Λ is the cut off energy of the electron band. Δ_0 is a half-width of the electron band gap at the Fermi level.

Comparing Eq. (25) and the TLM model, we find that the term $\tilde{\phi}_s^\dagger(x)A(x)\sigma_1\tilde{\phi}_s(x)$ has a similar contribution to the coupling term between the phonon field $\Delta(x)$ and the electronic one in the TLM model. Now, let us estimate the effective potential which is given by the renormalization of the electronic part Eqs. (24) and (25). The terms in which the differentials of scalar fields $\Delta(x)$ and $\theta(x)$ do not appear are given by replacing $\Delta(x)$ with $A(x)$, as

$$-\frac{1}{2\pi v_F}\int dxA(x)^2\left(2\ln\left|\frac{A(x)}{2\overline{W}}\right|-1\right), \tag{34}$$

where $\overline{W}$ is the energy cut off of the lowest electron band. The remainder in which the differentials directly appear, for example, the contribution which come from the second-order loop diagram (Figs. 1 and 2) is given by

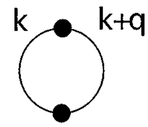

FIG. 2. The second-order loop diagram. This diagram has a momentum transfer q between the electron and the lattice.

$$-\frac{1}{\pi v_F}\int \mathrm{d}x A(x)\left(\frac{\sqrt{1+\gamma^2}}{\gamma}\sinh^{-1}\gamma-1\right)A(x)$$
$$-\frac{1}{\pi v_F}\int \mathrm{d}x\left(\frac{2\Delta(x)^2}{3W}-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right)\left(\frac{\sinh^{-1}\gamma}{\gamma\sqrt{1+\gamma^2}}\right)\left(\frac{2\Delta(x)^2}{3W}-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right), \tag{35}$$

as shown in Appendix A. In the calculation, we drop the time-dependency of the momentum transfer, which corresponds to an adiabatic approximation. We omit small terms of the order of Δ^2/W^2 and contributions which come from higher-order derivatives with respect to the space and the imaginary time than the second-order ones. Totally, the renormalized form of Lagrangian at the zero temperature limit is

$$L_{\mathrm{eff}}=L_\Delta^0-U, \tag{36}$$

where

$$U=-\frac{v_F}{4\pi}\int \mathrm{d}x\left(\frac{\partial\chi(x)}{\partial x}\right)^2+\frac{1}{\pi}\int \mathrm{d}x\,\frac{2\Delta(x)^2}{3W}\frac{\partial\chi(x)}{\partial x}$$
$$-\frac{1}{2\pi v_F}\int \mathrm{d}x A(x)^2\left(2\ln\left|\frac{A(x)}{2\overline{W}}\right|-1\right)-\frac{1}{\pi v_F}\int \mathrm{d}x A(x)\left(\frac{\gamma^2}{3}\right)A(x). \tag{37}$$

The operator γ is given by Eq. (A19). The partition function is rewritten as

$$Z=\int Du_r Du_i\,\exp\left\{\frac{e}{\pi}\int_0^\beta\int \chi(x)E(x)\mathrm{d}x\mathrm{d}\tau-\int_0^\beta L_{\mathrm{eff}}\,\mathrm{d}\tau\right\}. \tag{38}$$

In Eq. (38), we take $T\to 0$, i.e., $\beta=1/T\to\infty$.

III. CHARGE-DENSITY-WAVE STATE

First, let us consider the charge-density-wave ground state. This is the case where

$$\Delta(x)=\Delta_1=\mathrm{const}, \tag{39}$$

and

$$\theta(x)=\theta_1=\mathrm{const}. \tag{40}$$

Substituting Eqs. (39) and (40) into Eq. (37), we can see that the energy minimum point (Δ_1,θ_1) satisfies the equation

$$0=\frac{1}{\lambda}+\ln\left|\left(\frac{A_0}{W}\right)^2\right|\left[1+\frac{8\Delta_1^2}{9W^2}-\frac{2\Delta_1}{W}\cos 3\theta_1\right], \tag{41}$$

and

$$0=\sin 3\theta_1, \tag{42}$$

where

$$A_0^2=\Delta_1^2+\left(\frac{2\Delta_1^2}{3W}\right)^2-\frac{4\Delta_1^3}{3W}\cos 3\theta_1. \tag{43}$$

Then, using the solution t of the equation

$$\frac{1}{\lambda}+\left(1+2t+\frac{8}{9}t^2\right)\ln\left|t^2\left(1+\frac{2}{3}t\right)^2\right|=0, \tag{44}$$

θ_1 and Δ_1 at the minimum point are given by

$$\theta_1=\frac{n\pi}{3},\quad (n=\pm 1,\pm 3,...,\pm(2n+1),\ldots),$$

and

$$\Delta_1=Wt. \tag{45}$$

In weak coupling cases, namely, at small λ, t is much smaller than 1. For further analysis, we assume the following two conditions for the model:

(1) $\Delta(x)$ is much smaller than W.
(2) The differentiation of $\Delta(x)$ and $\theta(x)$ with respect to the space variable x are quantities of the order of $O(\Delta_1/\xi_0)$ and $O(1/\xi_0)$, respectively.

ξ_0 is a correlation length which is written as

$$\xi_0=\frac{v_F}{\Delta_1}. \tag{46}$$

Then, we can make approximations, that are,

$$A(x)^2\simeq\Delta(x)^2-\frac{4\Delta(x)^3}{3W}\cos 3\theta(x), \tag{47}$$

$$\frac{\sqrt{1+\gamma^2}}{\gamma}\sinh^{-1}\gamma-1\simeq\frac{1}{3}\gamma^2=-\frac{1}{12}\left(\frac{v_F}{\Delta_1}\right)^2\frac{\partial^2}{\partial x^2}, \tag{48}$$

$$\ln\left|\frac{A(x)}{W}\right|^2\simeq\ln\left|\frac{\Delta(x)^2}{W^2}\right|-\frac{4\Delta(x)}{3W}\cos 3\theta(x), \tag{49}$$

and

$$\frac{\partial\chi(x)}{\partial x}=\frac{\theta(x)'\left(1+\frac{2\Delta(x)}{3W}\cos 3\theta(x)-\frac{8\Delta(x)^2}{9W^2}\right)+\frac{2\Delta(x)'}{3W}\sin 3\theta(x)}{\left(1-\frac{2\Delta(x)}{3W}\right)^2-\frac{4\Delta(x)}{3W}(\cos 3\theta(x)-1)}$$

$$\simeq\theta(x)'\left(1+\frac{2\Delta(x)}{W}\cos 3\theta(x)\right)+\frac{2\Delta(x)'}{3W}\sin\theta(x). \tag{50}$$

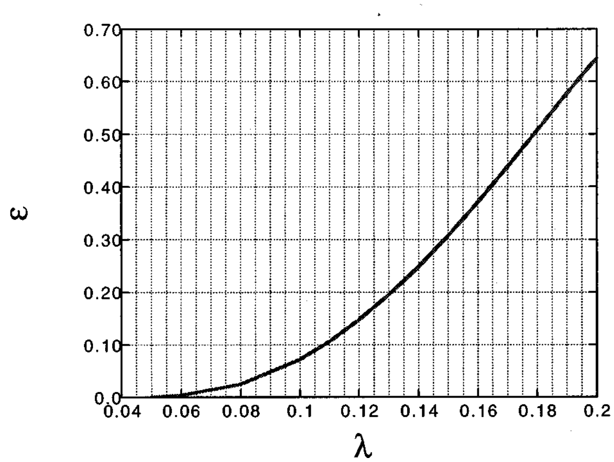

FIG. 3. The λ dependence of ϵ. It varies monotonically from 0 to 0.6 when λ changes from 0 to 0.2.

Using Eq. (45), Eq. (44) is rewritten as,

$$\ln|t| = -\frac{1}{2\lambda}\left(1+2t+\frac{8}{9}t^2\right)^{-1} - \ln\left(1+\frac{2}{3}t\right) \simeq \epsilon - \frac{1}{2\lambda} - \frac{2}{3}t + O(t^2). \tag{51}$$

Here, we introduce ϵ by

$$\epsilon = \frac{t}{\lambda} = \frac{\Delta_1}{W\lambda}. \tag{52}$$

In Fig. 3, we plot ϵ as the function of λ. In the weak coupling limit, t is nearly equal to $\exp(-1/2\lambda)$, and the parameter ϵ approaches to zero as

$$\epsilon \simeq \frac{e^{-(1/2\lambda)}}{\lambda} \to 0. \tag{53}$$

As is seen in Fig. 3, ϵ varies from 0 to 0.6 as λ changes from 0 to 0.19.

Using Eq. (37) and Eqs. (47)–(52), the total Lagrangian is given by

$$L_{\text{eff}} = L^0_{\text{eff}} + tL^1_{\text{eff}} + O(t^2), \tag{54}$$

where

$$\begin{aligned} L^0_{\text{eff}} = {} & \frac{1}{2\pi v_F \lambda \omega_Q^2} \int dx\, \dot{\Delta}(x)^2 + \frac{1}{2\pi v_F \lambda \omega_Q^2} \int dx \left\{ \Delta(x)^2 \dot{\theta}(x)^2 + \frac{\lambda \omega_Q^2 v_F^2}{2} \left(\frac{\partial \theta(x)}{\partial x} \right)^2 \right\} \\ & + \frac{1}{12\pi v_F} \left(\frac{v_F}{\Delta_1} \right)^2 \int dx \left(\frac{\partial \Delta(x)}{\partial x} \right)^2 + \frac{1}{2\pi v_F} \int dx \left[\Delta(x)^2 \left(\ln\left| \frac{\Delta(x)^2}{\Delta_1^2} \right| - 1 \right) \right] \\ & + \frac{\epsilon}{\pi v_F} \int dx\, \Delta(x)^2 \left(1 + \frac{2\Delta(x)}{3\Delta_1} \cos(3\theta(x)) \right), \end{aligned} \tag{55}$$

and

$$
\begin{aligned}
L_{\text{eff}}^{1}=&\frac{1}{2\pi v_F}\int \mathrm{d}x\left(\frac{\Delta(x)}{\Delta_1}\dot{\theta}(x)^2\cos(3\theta(x))+\frac{1}{3\Delta_1}\sin(3\theta(x))\dot{\Delta}(x)\dot{\theta}(x)\right)\\
&+\frac{1}{3\pi v_F}\left(\frac{v_F}{\Delta_1}\right)^2\int \mathrm{d}x\left\{\frac{\Delta(x)^2}{\Delta_1}\sin(3\theta(x))\left(\frac{\partial\Delta(x)}{\partial x}\right)\left(\frac{\partial\theta(x)}{\partial x}\right)-\frac{2\Delta(x)\cos(3\theta(x))}{3\Delta_1}\left(\frac{\partial\Delta(x)}{\partial x}\right)^2\right\}\\
&+\frac{v_F}{\pi}\int \mathrm{d}x\left\{\frac{\Delta(x)}{\Delta_1}\cos(3\theta(x))\left(\frac{\partial\theta(x)}{\partial x}\right)^2+\frac{\sin(3\theta(x))}{3\Delta_1}\left(\frac{\partial\theta(x)}{\partial x}\right)\left(\frac{\partial\Delta(x)}{\partial x}\right)\right\}\\
&-\frac{1}{\pi}\int \mathrm{d}x\,\frac{2\Delta(x)^2}{3\Delta_1}\left(\frac{\partial\theta(x)}{\partial x}\right)+\frac{2}{3\pi v_F}\int \mathrm{d}x\,\Delta(x)^2\\
&-\frac{2}{3\pi v_F}\int \mathrm{d}x\,\frac{\Delta(x)^3}{\Delta_1}\cos(3\theta(x))\ln\left|\frac{\Delta(x)^2}{\Delta_1^2}\right|.
\end{aligned}
\tag{56}
$$

Here it is expanded up to the first-order with respect to $t=\Delta_1/W$. The derivatives with respect to the imaginary time $\partial/\partial\tau$ are denoted by dots. The part of the second and fifth lines in Eq. (55) is the same as the sine-Gordon model. While, the first, the third, and the fourth lines in Eq. (55) give a part which is related to the dynamics of the amplitude. The whole part of L_{eff}^1 and the last line in Eq. (55) can be considered as the interaction terms between the phase $\theta(x)$ and the amplitude $\Delta(x)$. We can therefore say that Eq. (54) is an extended version of the sine-Gordon model.

Since t in Eq. (45) is much smaller than the unity, the variable $\chi(x)$, which is given by Eqs. (19) and (21), is nearly equal to $\theta(x)$. At the energy minimum point, the variable $\chi(x)$ gets the same value as $\theta(x)$.

The effective potential in Eq. (55) is also derived by Horovitz *et al.* In that derivation, they considered a self-consistent equation of the order parameter including the lattice dynamics. Our model has the same interaction term as theirs except for the difference in the multiplying factor. The other discrepancy which is found remarkably is that in the form of the derivative terms. The model of Horovitz *et al.* contained terms with the derivatives $(\partial\Delta)^2/\Delta(x)^2$, which is given by the expansion calculation of the electron Green function with respect to $(\partial\Delta(x))/\Delta(x)$. On the other hand, we have used perturbation calculation with respect to $\eta(x)/\Delta_1$, $\partial\eta(x)/\Delta_1$, $\partial^2\eta(x)/\Delta_1,\ldots,$ and so on. Then, the derivatives appear in the form of $(\partial\Delta(x))/\Delta_1$. This difference is important when $\Delta(x)$ deviates substantially from Δ_1.

IV. SOLITON IN THE TRIMERIZED SYSTEM

A. Soliton solution

The Lagrangian in Eq. (55) bears soliton solutions connecting the degenerated minimum points of the cosine potential, namely, $\theta(x)=(2n+1)\pi/3$ for integer n. This corresponds to the fractionally charged soliton. The soliton charge is determined by

$$\int_{-\infty}^{\infty}\mathrm{d}x\left(-\frac{e}{\pi}\frac{\partial\chi(x)}{\partial x}\right)=-\frac{e}{\pi}(\chi(\infty)-\chi(-\infty)). \tag{57}$$

When $\theta(x)$ varies from $-\pi/3$ to $\pi/3$, or vice versa the variable $\chi(x)$ varies by $2\pi/3$ or $-2\pi/3$. Then, these soliton carry $\mp 2/3e$ charge.

Soliton solutions in electron–phonon systems were investigated using the phase Hamiltonian.[14] The solution discussed by that Hamiltonian contained only the dynamics of the phase. However, in the numerical calculation, it was shown that the fractionally charged soliton had both the phase and amplitude degrees of freedom. For example, the soliton solution in the SSH model was numerically discussed by Ono *et al.*[15] The fractionally charged soliton in the trimerized case was analyzed, and it was found that the distortion of the amplitude was also accompanying. The soliton in the Frölich model was also investigated both analytically and numerically.[7,16] At a certain finite electron–phonon coupling, the soliton in the Frölich model showed a trajectory almost like a straight line in the complex plane of the variable $u(x)$.

In the present section, the analytical form of the fractionally charged soliton is studied for rather general values of the electron–phonon coupling. We propose the particular method to make the reductive perturbational calculation possible.

Replacing the imaginary time with the real time, the effective Lagrangian in Eq. (55) gives straightforwardly the dynamical equation

$$\frac{1}{\lambda\omega_Q^2}(\ddot{\Delta}(x)-\Delta(x)\dot{\theta}(x)^2)=\frac{\xi_0{}^2}{6}\Delta''(x)-2\Delta(x)\ln\left|\frac{\Delta(x)}{\Delta_1}\right|-2\Delta(x)\left(\frac{\Delta(x)}{\Delta_1}\cos 3\theta(x)+1\right)\epsilon, \tag{58}$$

and

$$\frac{1}{\lambda\omega_Q^2}\left(2\frac{\dot{\Delta}(x)\Delta(x)\dot{\theta}(x)}{\Delta_1^2}+\frac{\Delta(x)^2}{\Delta_1^2}\ddot{\theta}(x)\right)=\frac{\xi_0{}^2}{2}\theta''(x)+2\epsilon\left(\frac{\Delta(x)}{\Delta_1}\right)^3\sin 3\theta(x). \tag{59}$$

Equation (59) is the same as that of the sine-Gordon model, which has nonlinear excitations such as a soliton. The last term in the r.h.s. of Eq. (58) is considered as the coupling term between $\theta(x)$ and $\Delta(x)$, which causes the local distortion in $\Delta(x)$ influenced by the kink distortion in the phase mode.

We will study the effect of the interaction term for various strengths of the electron–phonon coupling. Consider the stationally case, $\dot{\Delta}(x)=0$, $\dot{\theta}(x)=0$. Introducing the space variable X instead of x as

$$X=\frac{2\sqrt{3\epsilon}}{\xi_0}x, \tag{60}$$

the equations are rewritten as follows:

$$0=-\Delta(x)\ln\left|\frac{\Delta(x)}{\Delta_1}\right|+\epsilon\left\{\frac{\partial^2\Delta(x)}{\partial X^2}-\Delta(x)\left(\frac{\Delta(x)}{\Delta_1}\cos 3\theta(x)+1\right)\right\}, \tag{61}$$

and

$$0=\frac{\partial^2(3\theta(x))}{\partial X^2}+\frac{\Delta(x)^3}{\Delta_1^3}\sin 3\theta(x). \tag{62}$$

Since $\epsilon\to 0$ as λ becomes 0, ϵ can be considered as the expansion parameter in the weak coupling case. The unperturbed equation for $\Delta(x)$ gives

$$\Delta(x)=\Delta_1=\text{const.} \tag{63}$$

Thus, the unperturbed equation for $\theta(x)$ gives the sine-Gordon equation,

$$0=\frac{\partial^2(3\theta(x))}{\partial X^2}+\sin 3\theta(x). \tag{64}$$

Equation (64) has the soliton solution,

$$3\theta_0(x)=\pi+4\tan^{-1}(e^{\pm X}). \tag{65}$$

This represents a soliton connecting the energy minimum points $\theta(x)=\pi/3$ and $\theta(x)=\pi$.

B. Perturbational expansion in the weak coupling limit

Starting from Eq. (65), we make a perturbational calculation. From now on, we take the plus sign in Eq. (65). Since $\Delta(x)>0$, we introduce $\delta(x)$ by

$$\Delta(x)=\Delta_1 e^{\delta(x)}, \tag{66}$$

the function $\delta(x)$ is zero in the weak-coupling limit, namely, $\epsilon=0$.

We introduce the deviation of $\theta(x)$ from $\theta_0(x)$ by

$$3\theta(x)=3\theta_0(x)+2\tan^{-1} v(x), \tag{67}$$

where $v(x)$ is a function which is a zero at $\epsilon=0$. Using Eq. (67), the cosine and the sine of $\theta(x)$ are given by

$$\cos 3\theta(x)=\cos 3\theta_0(x)\frac{1-v^2(x)}{1+v^2(x)}-\sin 3\theta_0(x)\frac{2v(x)}{1+v^2(x)}, \tag{68}$$

and

$$\sin 3\theta(x)=\sin 3\theta_0(x)\frac{1-v^2(x)}{1+v^2(x)}+\cos 3\theta_0(x)\frac{2v(x)}{1+v^2(x)}. \tag{69}$$

Substituting Eqs. (66)–(69) into Eqs. (61) and (62), we obtain

$$\begin{aligned}0&=\epsilon(\partial_X^2\delta(x)+(\partial_X\delta(x))^2)-\delta(x)\\&\quad-\epsilon\left(e^{\delta(x)}\cos(3\theta_0(x))\frac{1-v^2(x)}{1+v^2(x)}-e^{\delta(x)}\sin(3\theta_0(x))\frac{2v(x)}{1+v^2(x)}+1\right),\end{aligned} \tag{70}$$

and

$$\begin{aligned}0&=\partial_X^2(3\theta_0(x))+2\frac{\partial_X^2 v(x)}{1+v(x)^2}-\frac{4v(x)}{(1+v(x)^2)^2}(\partial_X v(x))^2+\cos 3\theta_0(x)\frac{2v(x)}{1+v(x)^2}e^{3\delta(x)}\\&\quad+\sin 3\theta_0(x)\frac{1-v(x)^2}{1+v(x)^2}e^{3\delta(x)},\end{aligned} \tag{71}$$

where ∂_X denotes the differential with respect to X. In the weak coupling limit, Eq. (71) becomes Eq. (64).

In the weak-coupling cases, with $\lambda<0.13$, we have

$$\epsilon<0.2. \tag{72}$$

Then, the ordinary perturbational method is applicable. We make expansions of the functions $\delta(x)$ and $v(x)$ as

$$\delta(x)=\epsilon\delta_1(x)+\epsilon^2\delta_2(x)+\cdots, \tag{73}$$

and

$$v(x)=\epsilon v_1(x)+\epsilon^2 v_2(x)+\cdots. \tag{74}$$

Comparing the first-order terms with respect to ϵ, we obtain the first-order perturbational equations,

$$0=-\delta_1(x)-(1+\cos 3\theta_0(x)), \tag{75}$$

and

$$0=2(\partial_X^2 v_1(x)+v_1(x)\cos 3\theta_0(x))+3\delta_1(x)\sin 3\theta_0(x). \tag{76}$$

The second-order terms with respect to ϵ give the second-order equations,

$$0=\partial_X^2\delta_1(x)-\delta_2(x)-(\delta_1(x)\cos 3\theta_0(x)-2v_1(x)\sin 3\theta_0(x)), \tag{77}$$

and

$$0=\sin 3\theta_0(x)(3\delta_2(x)+\tfrac{9}{2}\delta_1(x)^2-2v_1(x)^2)+2\partial_X^2 v_2(x)+2(v_2(x)+3\delta_1(x)v_1(x))\cos 3\theta_0(x). \tag{78}$$

Substituting the unperturbed solution in Eq. (65) into Eq. (75) and, using the relations

$$\cos 3\theta_0(x)=\frac{2}{\cosh^2 X}-1, \tag{79}$$

and

$$\sin 3\theta_0(x)=2\frac{\tanh X}{\cosh X}, \tag{80}$$

we obtain

$$\delta_1(x)=-\frac{2}{\cosh^2 X}. \tag{81}$$

Using Eq. (81), we can confirm from the direct substitution that the solution of Eq. (76) is given by (Appendix B)

$$v_1(x)=-\frac{3}{2}\frac{\tanh X}{\cosh X}. \tag{82}$$

Next, substituting Eqs. (79), (80), (81), and (82) into Eq. (77), $\delta_2(x)$ is given by

$$\delta_2(x)=-\frac{16}{\cosh^2 X}+\frac{22}{\cosh^4 X}. \tag{83}$$

Using Eqs. (79)–(82), we confirm from the direct substitution that the solution of Eq. (78) is given by (Appendix B)

$$v_2(x)=\frac{\tanh X}{\cosh X}\left(\frac{71}{12}\frac{1}{\cosh^2 X}-\frac{85}{24}\right). \tag{84}$$

Totally, $v(x)$ is explicitly given up to the second order with respect to ϵ by

$$\delta(x)=-\frac{2\epsilon+16\epsilon^2}{\cosh^2 X}+\frac{22\epsilon^2}{\cosh^4 X}+O(\epsilon^3), \tag{85}$$

and

$$v(x)=\frac{\tanh X}{\cosh X}\left(\left(-\frac{3}{2}\epsilon-\frac{85}{24}\epsilon^2\right)+\frac{71}{12}\epsilon^2\frac{1}{\cosh^2 X}\right)+O(\epsilon^3). \tag{86}$$

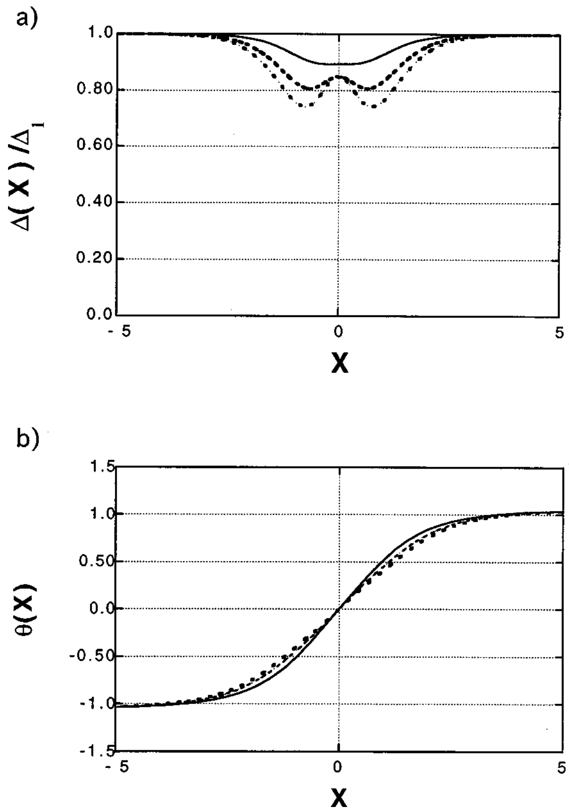

FIG. 4. The spatial change of the order parameter in the soliton configuration obtained by the reductive perturbational method. (a) is $\Delta(x)$ and (b) is $\theta(x)$. They are obtained at $\lambda=0.1$ (the solid line), $\lambda=0.12$ (the dotted line), and $\lambda=0.13$ (the rough dotted line).

In Fig. 4, we show the behaviors of $\Delta(x)$ and $\theta(x)$ as functions of the space variable X. For $\lambda \neq 0$, the amplitude is slightly deformed around the soliton center. As λ becomes larger, the distortion in the amplitude becomes larger, whereas the kink distortion of the phase $\theta(X)$ varies little. The soliton width varies as $\xi \propto 1/(t\sqrt{\epsilon})$ at small λ.

We plot trajectories of the soliton in the complex plane of $gu(x)$ in Fig. 5. When λ is 0.1, the distortion form of $u(x)$ is unusual. Since $\lambda=0.15$ corresponds to $\epsilon=0.3$, more than second-order terms give the same contribution as the first-order terms because the exponent $3\delta \simeq 3\epsilon$ in $\exp(3\delta)$ of Eq. (71) becomes the order of unity. It belongs to a case where the ordinary perturbation is not proper for analyzing a soliton.

C. Solution for $\epsilon>0.2$

Let us consider the case where

$$0.2<\epsilon<0.6, \tag{87}$$

which corresponds to

$$0.13<\lambda<0.19. \tag{88}$$

Because the ordinary reductive perturbational method is not suitable for the condition in Eq. (87), a particular analytical method is necessary.

Considering Eqs. (67) and (82), $\theta(x)$ is rewritten as follows:

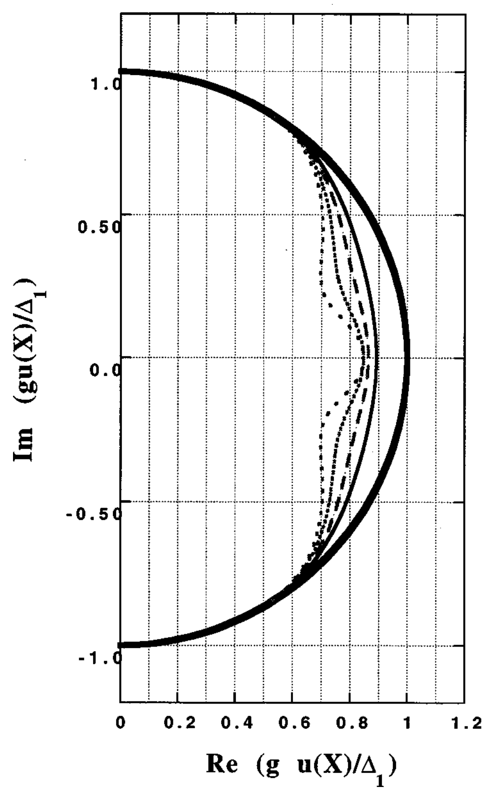

FIG. 5. The soliton configuration obtained by the reductive perturbational method. The order parameter is drawn as the trajectory in a complex plane of $\Delta(x)\exp(i\theta(x))$. The coupling constants are selected as $\lambda=0.1$ (the solid line), $\lambda=0.11$ (the broken line), $\lambda=0.12$ (the dotted line), and $\lambda=0.13$ (the rough dotted line).

$$3\theta(x)\simeq\pi+2\tan^{-1}(e^{X+c})+2\tan^{-1}(e^{X-c})+O(\epsilon^2), \tag{89}$$

where we introduce c as the parameter which satisfies the condition,

$$c^2=3\epsilon+O(\epsilon^2). \tag{90}$$

We apply a perturbational method using Eq. (89) as the unperturbed part. The deviation $t(X)$ should be introduced by

$$3\theta(x)=\frac{3\theta_0(X+c)+3\theta_0(X-c)}{2}+2\tan^{-1}t(X)=3\theta_1(X)+2\tan^{-1}t(X). \tag{91}$$

Then, the equation is rewritten as follows:

$$\begin{aligned}0=&\epsilon(\partial_X^2\delta(X)+(\partial_X\delta(X))^2)\\&-\delta(X)-\epsilon\left\{1+e^{\delta(X)}\left(\cos(3\theta_1(X))\frac{1-t^2(X)}{1+t^2(X)}-\sin(3\theta_1(X))\frac{2t(X)}{1+t^2(X)}\right)\right\}\end{aligned} \tag{92}$$

and

$$0=\partial_X^2(3\theta_1(X))+2\frac{\partial_X^2 t(X)}{1+t(X)^2}-\frac{4t(X)}{(1+t(X)^2)^2}(\partial_X t(X))^2$$
$$+\cos(3\theta_1(X))\frac{2t(X)}{1+t(X)^2}e^{3\delta(X)}+\sin 3\theta_1(X)\frac{1-t(X)^2}{1+t(X)^2}e^{3\delta(X)}. \tag{93}$$

When ϵ becomes larger than 0.3, $3\delta(X)$ in the exponential in Eq. (93) becomes larger than unity. Thus, in stead of ϵ, we introduce a new expansion parameter q by

$$q=\epsilon \mathrm{e}^{-\epsilon}. \tag{94}$$

Because $3q<1$ for $0<\lambda\leqslant 0.19$, q is suitable as an expansion parameter. The previous parameter ϵ is given by the relation,

$$\epsilon=q+q^2+O(q^3). \tag{95}$$

Consider Eq. (92), neglecting $t(X)$. The first-order terms in Eq. (92) give the relation,

$$\delta(X)\simeq-\epsilon(1+\cos 3\theta_1(X))=E. \tag{96}$$

Substituting Eq. (96) into Eq. (92), this relation is improved as

$$\delta(X)\simeq\epsilon(\partial_X^2 E)-\epsilon\{1+\mathrm{e}^E\cos 3\theta_1(X)\}. \tag{97}$$

Then, introducing a function $E(X)$ by

$$\delta(X)=-\epsilon+\epsilon e^{E(X)}(\partial_X^2 E(X)-\cos 3\theta_1(X)), \tag{98}$$

that of $\delta(X)$, i.e., Eq. (92), comes back to the equation of $E(X)$. Expanding $E(X)$ and $t(X)$ by q as

$$E(X)=qE_1(X)+q^2E_2(X)+\cdots, \tag{99}$$

and

$$t(X)=qt_1(X)+q^2t_2(X)+\cdots, \tag{100}$$

respectively. Moreover, using Eq. (98), Eq. (92) is also rewritten as follows:

$$0=q^2[-\partial_X{}^2(\cos 3\theta_1(X))+E_1(X)\cos 3\theta_1(X)-\partial_X{}^2E_1(X)+(1+\cos 3\theta_1(X))\cos 3\theta_1(X)$$
$$+2t_1(X)\cos(3\theta_1(X))\sin(3\theta_1(X))]+O(q^3). \tag{101}$$

The second-order terms with respect to q in Eq. (101) give the equation,

$$(-\partial_X{}^2+\cos 3\theta_1(X))(E_1(X)+\cos 3\theta_1(X)+1)+2t_1(X)\cos 3\theta_1(X)\sin 3\theta_1(X)=0. \tag{102}$$

Substituting Eqs. (99) and (100) into Eq. (93), and making an expansion with respect to q, the equation of $t(X)$ is rewritten as follows:

$$0=\partial_X{}^2(3\theta_1(X))+\sin 3\theta_1(X)+q(2\partial_X{}^2t_1(X)+2t_1(X)\cos 3\theta_1(X)$$
$$-3(1+\cos 3\theta_1(X))\sin 3\theta_1(X))+q^2[2\partial_X{}^2t_2(X)+2t_2(X)\cos 3\theta_1(X)$$
$$+\{-3E_1(X)\cos 3\theta_1(X)+2t_1^2(X)\partial_X{}^2(3\theta_1(X))-6t_1(X)(1+\cos 3\theta_1(X))+3\partial_X{}^2E_1(X)$$
$$+\tfrac{9}{2}(1+\cos 3\theta_1(X))^2-3(1+\cos 3\theta_1(X))\}\sin 3\theta_1(X)]+O(q^3). \tag{103}$$

On the other hand, using Eqs. (64) and (91), we can see that $\theta_1(X)$ satisfies the relations,

$$\begin{aligned}0&=\partial_X{}^2(3\theta_1(X))+\tfrac{1}{2}\sin(3\theta_0(X+c))+\tfrac{1}{2}\sin(3\theta_0(X-c))\\&=\partial_X{}^2(3\theta_1(X))+\sin 3\theta_1(X)\{1-\tanh^2 c(1+\cos(3\theta_1(X)))\}.\end{aligned}\tag{104}$$

Substituting Eq. (104) into Eq. (103), we can see that the zeroth- and the first-order terms in Eq. (103) give the equation,

$$0=q(2\partial_X{}^2 t_1(X)+2t_1(X)\cos 3\theta_1(X))+(\tanh^2 c-3q)(1+\cos 3\theta_1(X))\sin 3\theta_1(X).\tag{105}$$

To keep the consistency between Eq. (89) and Eq. (105), the first- and second-order terms with respect to $q=O(\epsilon)$ in Eq. (105) should cancel among themselves. Namely,

$$t_1(X)\equiv 0,\tag{106}$$

and

$$\tanh^2 c=3q.\tag{107}$$

Equation (107) is consistent with Eq. (90). The second-order terms with respect to q give the equation,

$$\begin{aligned}0&=2\partial_X{}^2 t_2(X)+2t_2(X)\cos(3\theta_1(X))+\{-3E_1(X)\cos(3\theta_1(X))+3\partial_X{}^2E_1(X)\\&\quad+\tfrac{9}{2}(1+\cos(3\theta_1(X)))^2-3(1+\cos(3\theta_1(X)))\}\sin(3\theta_1(X)).\end{aligned}\tag{108}$$

Using Eq. (106), Eq. (102) becomes

$$E_1(X)+\cos 3\theta_1(X)+1=0.\tag{109}$$

Then, $E_1(X)$ is given by

$$E_1(X)=-(1+\cos(3\theta_1(X)))=-\frac{2\cosh^2 c}{\cosh^2 X+\sinh^2 c}.\tag{110}$$

Using Eq. (109), Eq. (108) is rewritten as follows:

$$\begin{aligned}0&=2\partial_X^2 t_2(X)+2t_2(X)\cos(3\theta_1(X))\\&\quad+[\tfrac{33}{2}(1+\cos(3\theta_1(X)))^2-18(1+\cos(3\theta_1(X)))]\sin(3\theta_1(X)),\end{aligned}\tag{111}$$

where we use

$$\partial_X^2E_1(X)\simeq-4(1+\cos 3\theta_1(X))+3(1+\cos 3\theta_1(X))^2+O(3q).\tag{112}$$

Now we are interested in a solution that describes the soliton configuration. Therefore $t(X)$ should be odd with respect to the soliton center. Since $\sin 3\theta_1(X)$ is odd and $\cos 3\theta_1(X)$ is even, we assume that the solution takes a form of

$$t_2(X)=\sum_{n=1}^{\infty}a_n(\cos 3\theta_1(X))^n\sin 3\theta_1(X).\tag{113}$$

Substituting Eq. (113) into Eq. (111) and equating the coefficients of $(\cos(3\theta_1(X)))^n\sin(3\theta_1(X))$ on both sides, the coefficients a_n $(n=0,1,2,...)$ are determined as

$$a_0 = \tfrac{1}{12}, \quad a_1 = \tfrac{11}{12}, \tag{114}$$

and

$$a_n = 0 \quad \text{for} \quad n \geqslant 2, \tag{115}$$

where we use the relation

$$\begin{aligned}\partial_X^2[(\cos 3\theta_1(X))^n \sin 3\theta_1(X)] = (\cos 3\theta_1(X))^{n-1}[&2n(n-1) + n(2n-1)\cos 3\theta_1(X) \\ &-2(n+1)^2 \cos^2 3\theta_1(X) \\ &-(n+1)(2n+3)\cos^3 3\theta_1(X)]\sin 3\theta_1(X) + O(3q).\end{aligned} \tag{116}$$

After all, $\Delta(X)$ and $\theta(X)$ are solved correctly up to the second-order with respect to q, namely,

$$\Delta(X) = \Delta_1 e^{\delta(X)}, \tag{117}$$

and

$$3\theta(X) = 3\theta_1(X) + 2\tan^{-1} t(X). \tag{118}$$

Here

$$\delta(X) = -\epsilon e^{-q(1+\cos 3\theta_1(X))}(\cos 3\theta_1(X) + q\partial_X^2 \cos 3\theta_1(X)) - \epsilon, \tag{119}$$

and

$$t(X) = q^2\left(\tfrac{1}{12} + \tfrac{11}{12}\cos 3\theta_1(X)\right)\sin 3\theta_1(X). \tag{120}$$

The phase $\theta_1(X)$ is given by

$$3\theta_1(X) = \pi + 2\tan^{-1}(\exp(X + \sqrt{\tanh^{-1} 3q})) + 2\tan^{-1}(\exp(X - \sqrt{\tanh^{-1} 3q})). \tag{121}$$

In Fig. 6, we show the trajectory of $gu(x)$ for various values of electron–phonon coupling. At $\lambda \simeq 0.175$, trajectory is almost like a straight line, $\mathrm{Re}(g \cdot u(x)/\Delta_1) = 0.5$. The trajectory enters into the inner side of the straight line at $\lambda = 0.18$.

Lastly, let us examine the soliton width. Introducing a trial function,

$$3\theta(x) = 3\tan^{-1}(\sqrt{3}\tanh(x/\xi_1)) = 3\tan^{-1}\left(\sqrt{3}\tanh\left(\frac{\xi_0}{\xi 1}\frac{X}{2\sqrt{3\epsilon}}\right)\right), \tag{122}$$

we determine ξ_1/ξ_0 by applying the least square method to Eq. (118). Using ξ_1/ξ_0, the soliton width is given by

$$\xi_1 = \frac{\xi_1}{\xi_0} \cdot \frac{v_F}{\Delta_1} = \frac{\xi_1}{\xi_0} \cdot \frac{\sqrt{3}}{2t} a. \tag{123}$$

In Fig. 7, ξ_1/ξ_0 is plotted as a function of λ. ξ_1/ξ_0 becomes minimum nearly at $\lambda \simeq 0.18$, whereas the soliton width Eq. (123) decreases monotonically when $0 < \lambda < 0.19$. The soliton width at $\lambda = 0.175$ is about $1.45 v_F/\Delta_1$.

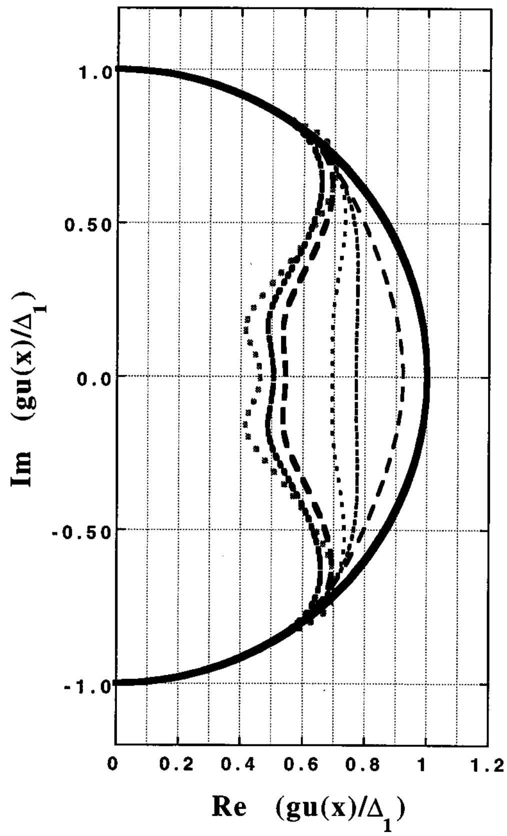

FIG. 6. The soliton configuration obtained by the perturbational calculation with Eq. (121) as the unperturbed part. The thick circular line is $\Delta(x)=\Delta_1$. The coupling constants are selected as $\lambda=0.1$ (the broken line), $\lambda=0.12$ (the dotted line), $\lambda=0.14$ (the rough dotted line), $\lambda=0.16$ (the thick broken line), $\lambda=0.175$ (the big dotted line), and $\lambda=0.19$ (the rough big dotted line).

V. NUMERICAL SOLUTIONS

In this section, we try finding numerical solutions for the effective Lagrangian derived in Sec. III. Since the space variable is continuous in this Lagrangian, we must discretize it in such a way

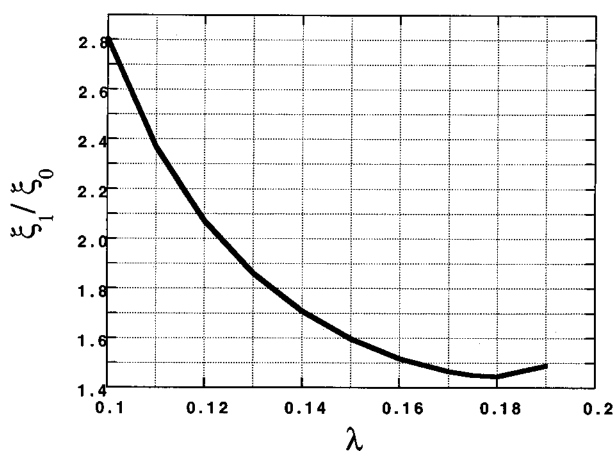

FIG. 7. The quantity ξ_1 defined by Eq. (122). It is plotted as a function of the coupling constant λ. The length ξ_0 is defined by Eq. (46).

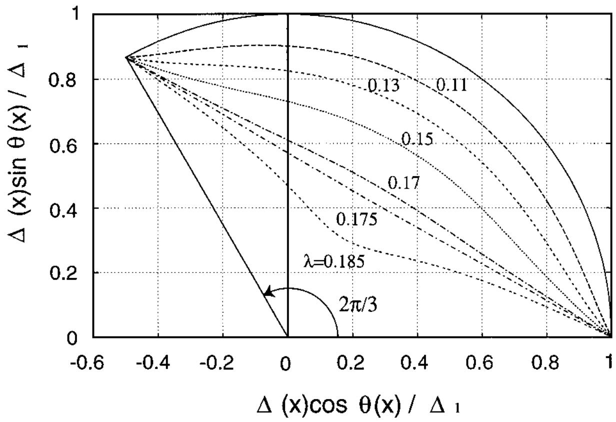

FIG. 8. The trajectories of the soliton. They are numerically obtained using the variational function Eqs. (124) and (125).

as $x=\Delta_m l$. In the following calculation, the mesh Δ_m is chosen to be small enough compared with the soliton half-width ξ. Actually, it is less than one-hundredth of ξ, even in the case with the shortest soliton width. Moreover, the system size should be large enough compared with the same length. Here we set it to be four times the largest ξ treated here.

We assume variational functional forms for the order parameters as

$$\Delta(x)=\Delta_1\sqrt{1-\tfrac{3}{4}\delta\,\mathrm{sech}(x/\xi_2)^2}, \tag{124}$$

and

$$3\theta(x)=3\tan^{-1}(\sqrt{3}\tanh(x/\xi_2))+\pi, \tag{125}$$

where ξ_2 and δ are determined so as to minimize the Hamiltonian. It should be remarked that these forms allow both types of solitons, namely, phase solitons and straight-line solitons, depending on ξ_2 and δ.

In Fig. 8, we show the optimized trajectories of the order parameter in the complex plane. As is seen clearly, the order parameter changes its shape from a phase soliton type via a straight-line to the one deformed in the inner direction. More specifically, the straight-line behavior is realized around $\lambda=0.175$, which is very close to that obtained in the exact solution.[7]

Next, we turn attention to the spatial change of the above order parameter. In Fig. 9, we plot the phase part in a weak-coupling case. Here two configurations are compared. One is the optimized solution at $\lambda=0.11$ and the other is the pure phase soliton described by a sine-Gordon solution. They are very similar, and hence this means that our variational function is correctly chosen in the weak-coupling limit.

While, beyond the weak-coupling limit, we find some discrepancy. In Fig. 10 we show the relationship between the coupling constant λ and the soliton width in the unit of v_F/Δ_1. At $\lambda=0.175$, which is the aforementioned value that gives the straight-line shape, the soliton width is about $1.54v_F/\Delta_1$. This value of λ is consistent with the result given by the analytical solution. However the width is longer than the exact value, i.e., $(2/\sqrt{3})v_F/\Delta_1\simeq 1.15v_F/\Delta_1$.[7] We think that this discrepancy comes from the neglected terms in deriving the effective potential.

In the rest of this section, we briefly check whether the above solutions are realistic. First, we discuss the straight-line soliton. At $\lambda=0.175$, the soliton width is about $1.54v_F/\Delta_1$. Since v_F is $(\sqrt{3}/2)Wa$ in the present definition and Δ_1 itself is calculated to be $0.104W$,

$$\xi_2=1.54v_F/\Delta_1=1.54(\sqrt{3}/2)Wa/0.104W=12.8a. \tag{126}$$

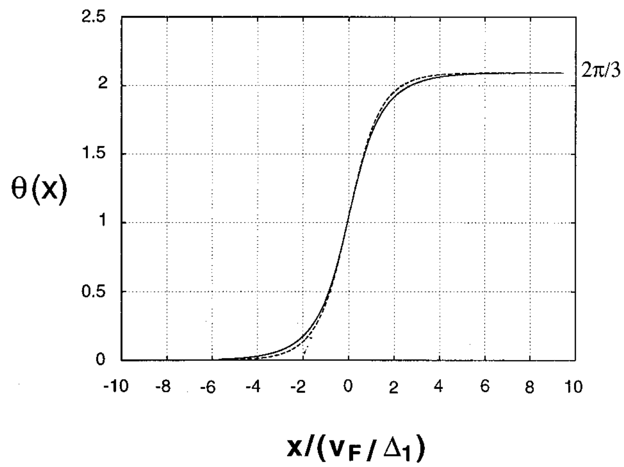

FIG. 9. The spatial pattern of the order parameter. The broken line is a pure phase soliton and the solid line is the soliton configuration at $\lambda = 0.11$.

Thus, this soliton width is much larger than the lattice constant a and is reasonable as a width. While, if the coupling is very small, the width is, for example, $2.38 v_F/\Delta_1$ at $\lambda = 0.11$. Since Δ_1 is $0.012W$ in this case, ξ_2 is calculated in the same way to be about $174a$. This value will be too large to observe such a soliton as an intrinsic object.

VI. SUMMARY

We have investigated the fractionally charged soliton in the trimerized electron–phonon system. We have found by both analytical and numerical methods that, in addition to the kink-type distortion in the phase mode, the soliton shows a peculiar distortion in the amplitude. The latter is new in the sense that the ordinary sine-Gordon model does not describe it.

We have used the Fröhlich model. Renormalizing the electronic part by the loop expansion of the partition function, we have constructed the effective Lagrangian of the order parameter. This can be applied to the investigation of the dynamics of both the amplitude and phase modes. It should be remarked that this Lagrangian is the almost same as that derived by the analysis of the

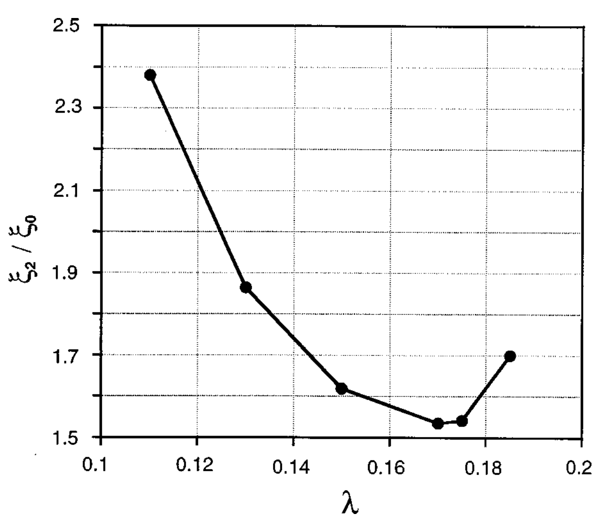

FIG. 10. The quantity ξ_2 defined by Eq. (125). It is plotted as a function of the coupling constant λ.

self-consistent equation for the Fröhlich model.[4] However, there are some discrepancies in the form of the derivative terms of the order parameter, and in the strength of the interaction term between the amplitude and phase modes.

Investigating the equations of the order parameter, we have found the analytical solution corresponding to the fractionally charged soliton. The solution is given by Eqs. (117)–(120). In the derivation, we have used the reductive perturbational method using the particular form of the unperturbed solution Eq. (121). The amplitude decreases around the soliton center. As the electron–phonon coupling becomes stronger, the distortion grows more and more. At $\lambda=0.175$, roughly speaking, the lattice distortion draws a straight-line in the complex plane. This behavior is the same with the exact solution given by Iwano *et al.*[7]

We have also analyzed the soliton solution numerically. In the calculation, the space variable is discretized and the variational functional forms are introduced. We have obtained the optimized trajectories of the order parameter. It has been shown that the order parameter changes its shape from a phase-soliton type via a straight line to the one deformed in the inner direction. Again the straight-line shape is realized nearly at $\lambda=0.175$, which is very close to that obtained in the exact solution. As for the soliton width, both the methods give similar tendencies. The width itself monotonically shortens as λ decreases. However, if it is scaled by ξ_0, it shows a saturation around $\lambda=0.17-0.18$. We think that this is characteristic of the straight-line solution.

The above results show that, in the trimerized electron-phonon system, the interaction between the phase and amplitude modes induces the distortion in the amplitude of the soliton. Thus, the spatial form of the soliton deviates substantially from that of the phase soliton when the electron–phonon coupling is not very weak.

It is important that the charge of the soliton is always the same, namely, fractional ones as $\pm\frac{2}{3}e$, irrespective of the spatial form. Thus, if we conceptually make it clear, we have two types of fractionally charged solitons, namely, a pure phase soliton and a strongly amplitude-deformed soliton, although both are related to each other by gradual changes. It of course depends on the parameter of each realistic system which type is observed experimentally. We, however, add that the former might be difficult to observed, because it has a very large width more than one hundred times the lattice constant.

ACKNOWLEDGMENT

One of the authors (R.S.) would like to express his special thanks to Professor K. Sasaki for fruitful discussions.

APPENDIX A: THE EFFECTIVE POTENTIAL

Here treat the main part of the Lagrangian concerning the lattice dynamics and study the influence of the lattice distortion on the electrons. The expression of the Lagrangian is given in Eq. (13). The partition function is given in Eq. (30).

By the path integration over $\tilde{\phi}_s$, the contribution from the electrons is renormalized to an effective potential. This estimation can be performed using a diagrammatic calculation. We take the summation over connected loop diagrams which are shown in Fig. 1.[17,18] The solid line is associated with the electron Green function. The solid circle corresponds to the vertex given by H_I. In the momentum space, the electron Green function is given by

$$G^{(0)}(k;\mathrm{i}\omega)\,\delta_{s,s'}=-\int_0^{\beta}\int\langle T_\tau\tilde{\phi}_s(x,\tau)\tilde{\phi}^{\dagger}_{s'}(x',0)\rangle e^{-\mathrm{i}k(x-x')-\mathrm{i}\omega\tau}\mathrm{d}x\,\mathrm{d}\tau=\frac{\mathrm{i}\omega I+v_F k\sigma_3}{(\mathrm{i}\omega)^2-(v_F k)^2}\,\delta_{s,s'}, \tag{A1}$$

where s denotes up or down of the spin orientation, and $\tilde{\phi}_s(x,\tau)$ is in the Heisenberg representation,

$$\tilde{\phi}_s(x,\tau)=\exp(H^0_{\tilde{\phi}}\tau)\cdot\tilde{\phi}_s(x)\cdot\exp(-H^0_{\tilde{\phi}}\tau). \tag{A2}$$

$H^0_{\tilde{\phi}}$ is the electronic part of the unperturbed Hamiltonian. The vertex is given by, in the momentum space,

$$D(q)=\frac{\mathrm{i}v_F q}{2}\chi(q)I-B(q)I+A(q)\sigma_1+\mathrm{i}\frac{1}{2}\frac{\partial\chi(q)}{\partial\tau}\sigma_3, \tag{A3}$$

where $A(q)$ and $B(q)$ are the Fourier transforms of $A(x)$ and $2\Delta(x)^2/(3W)$, respectively. Representing the summation of the diagrams in Fig. 1 as U, the partition function is approximately given by

$$\frac{Z}{Z_0}=\frac{\int(Du_rDu_i)\exp\left\{\frac{e}{\pi}\int\int\chi(x)E(x)\mathrm{d}x\mathrm{d}\tau-\int\mathrm{d}\tau(L^0_\Delta-U)\right\}}{\int(Du_rDu_i)\exp\left\{-\int\mathrm{d}\tau L^0_\Delta\right\}}. \tag{A4}$$

First, let us consider the contribution from the static lattice displacement. The lattice displacement $u(x)$ is given by

$$u_m=u_0e^{\mathrm{i}\theta_1},$$

and

$$\Delta(x)=gu_0=\Delta_1, \tag{A5}$$

where u_0 and θ_1 is constant. $D(x)$ is constant and takes the value,

$$D_0=-\frac{2\Delta_1^2}{3W}I+A_0{}^2\sigma_1,$$

with

$$A_0^2=\Delta_1^2\left(1+\frac{4\Delta_1^2}{9W^2}-\frac{4\Delta_1}{3W}\cos 3\theta_1\right). \tag{A6}$$

Contribution to the effective potential U coming from the static lattice displacement is given by the summation,

$$\frac{1}{\beta}\mathrm{Tr}\sum_{n,s,\omega}\int\mathrm{d}x\int\mathrm{d}k\frac{1}{2\pi n}[D_0G^{(0)}(k;\mathrm{i}\omega)]^n$$
$$=\frac{1}{\pi\beta}\sum_{\omega}\int\mathrm{d}x\int_{-\infty}^{\infty}\mathrm{d}k\ln\left(\frac{\left(\mathrm{i}\omega-\frac{2\Delta_1^2}{3W}\right)^2-(v_Fk)^2-A_0^2}{(\mathrm{i}\omega)^2-(v_Fk)^2}\right), \tag{A7}$$

where the summation with respect to ω is taken over the Matsubara frequencies $\omega=T(2m+1)\pi$, m being an integer. In the calculation, we use the relation,

$$\mathrm{Tr}\ln(aI-b\sigma_1-c\sigma_3)=\ln\det(aI-b\sigma_1-c\sigma_3)=\ln(a^2-b^2-c^2). \tag{A8}$$

Taking the zero-temperature limit, the summation over ω changes to the integration, i.e.,

$$\frac{1}{\beta}\sum_{\omega,\mathrm{odd}}f(\mathrm{i}\omega)\to\frac{1}{2\pi}\int\mathrm{d}zf(\mathrm{i}z), \tag{A9}$$

where $f(\alpha)$ is a function of a complex variable α. Using Eq. (A9) and the relation

$$\frac{v_F}{2\pi}\int_{-\infty}^{\infty}\mathrm{d}k\,\ln\left(\frac{\mathrm{i}v_Fk-a}{\mathrm{i}v_Fk-b}\right)=\frac{1}{2}(a-b),$$

for

$$0\leqslant \mathrm{Arg}(a),\quad \mathrm{Arg}(b)\leqslant\frac{\pi}{2}, \tag{A10}$$

Eq. (A7) is rewritten as

$$\begin{aligned}&\frac{1}{\pi}\int \mathrm{d}x\int_{-\overline{W}}^{W}\mathrm{d}z\left(\sqrt{\left(z+\mathrm{i}\frac{2\Delta_1^2}{3W}\right)^2+A_0^2}-|z|\right)\\&=-\frac{1}{2\pi v_F}\int \mathrm{d}x\left\{A_0^2\left(\ln\left|\frac{A_0^2}{(2\overline{W})^2}\right|-1\right)+\frac{1}{2}\left(\frac{4\Delta_1^2}{3W}\right)^2\right\},\end{aligned} \tag{A11}$$

where $\overline{W}$ is the energy cut off of the lowest electron band. In the trimerized case, it is $\overline{W}=W/2$.

The deviations of $\Delta(x)$ and $\theta(x)$ from $\Delta(x)=\Delta_1$ and $\theta(x)=\theta_0$, respectively, give an extra contribution to the effective potential. We define them as $\eta(x)=D(x)-D_0$ and assume that the time dependencies of $\Delta(x)$ and $\theta(x)$ are small enough. The contribution is given by,

$$\begin{aligned}-\mathrm{Tr}\frac{1}{\beta}\sum_{n=1}^{\infty}\sum_{\omega,s}\frac{1}{(2\pi)^n n}\int \mathrm{d}k\int \mathrm{d}q_1\cdots\int \mathrm{d}q_{n-1}\\ \times G(k;\mathrm{i}\omega)\,\eta(q_1)G(k+q_1;\mathrm{i}\omega)\,\eta(q_2-q_1)G(k+q_2;\mathrm{i}\omega)\,\eta(q_3-q_2)\\ \times\cdots G(k+q_{n-1};\mathrm{i}\omega)\,\eta(-q_{n-1}),\end{aligned} \tag{A12}$$

where $G(k;\mathrm{i}\omega)$ is the electron Green function in the stationary lattice distortion, which is

$$G(k;\mathrm{i}\omega)=G^{(0)}(k;\mathrm{i}\omega)[1-D_0G^{(0)}(k;\mathrm{i}\omega)]^{-1}=\frac{\left(\mathrm{i}\omega-\frac{2\Delta_1^2}{3W}\right)I+v_Fk\sigma_3+A_0\sigma_1}{\left(\mathrm{i}\omega-\frac{2\Delta_1^2}{3W}\right)^2-(v_Fk)^2-A_0^2}, \tag{A13}$$

and $\eta(q)$ is the Fourier transform of $\eta(x)$, namely,

$$\eta(q)=\int \mathrm{d}x\,\mathrm{e}^{-\mathrm{i}qx}\,\eta(x). \tag{A14}$$

The diagrams corresponding to Eq. (A12) are the same as those in Fig. 1, where the solid line and the solid circle correspond to the Green function Eq. (A13) and the vertex $\eta(q)$, respectively.

Now, we introduce the notation,

$$\eta(q)=\delta A(q)\sigma_1-\delta B(q)I+\mathrm{i}\frac{v_Fq}{2}\chi(q)I+\mathrm{i}\frac{1}{2}\frac{\partial\chi(q)}{\partial\tau}\sigma_3, \tag{A15}$$

where

$$\delta A(q)=\int \mathrm{d}x\,\mathrm{e}^{-\mathrm{i}qx}(A(x)-A_0),$$

and

$$\delta B(q)=\int \mathrm{d}x e^{-\mathrm{i}qx}\left(\frac{2\Delta(x)^2}{3W}-\frac{2\Delta_1^2}{3W}\right). \tag{A16}$$

Then, substituting Eq. (A14) into Eq. (A12), it becomes

$$\begin{aligned}
&-\sum_{n,\omega,s}\frac{1}{2\pi n\beta}\int \mathrm{d}x\int \mathrm{d}k\, \mathrm{Tr}[G(k;\mathrm{i}\omega)\eta(x)]^n\\
&=\frac{1}{\pi\beta}\sum_{\omega}\int \mathrm{d}x\int_{-\infty}^{\infty}\mathrm{d}k\\
&\quad\times\ln\left[\frac{\left(\mathrm{i}\omega+\frac{2\Delta(x)^2}{3W}-\frac{v_F}{2}\frac{\partial\chi}{\partial x}\right)^2-\left(v_F k+\mathrm{i}\frac{1}{2}\frac{\partial\chi}{\partial\tau}\right)^2-A(x)^2}{\left(\mathrm{i}\omega+\frac{2\Delta_1^2}{3W}\right)^2-(v_F k)^2-A_0^2}\right]\\
&=\frac{1}{2\pi v_F}\int \mathrm{d}x\left[\frac{1}{2}\left(\frac{4\Delta_1{}^2}{3W}\right)^2-\frac{1}{2}\left(\frac{4\Delta(x)^2}{3W}-v_F\frac{\partial\chi(x)}{\partial x}\right)^2\right.\\
&\quad\left.+A(x)^2\left(\ln\left|\frac{(2\overline{W})^2}{A(x)^2}\right|+1\right)-A_0^2\left(\ln\left|\frac{(2\overline{W})^2}{A_0^2}\right|+1\right)\right],
\end{aligned} \tag{A17}$$

where we use Eq. (A10). In the calculation of Eq. (A17), we drop the q_i dependency of the Green function $G(k+q_i;\mathrm{i}\omega)$.

We can make the calculation of the loop diagrams more exactly. Consider the second-order loop diagram with respect $\eta(q)$ that is shown in Fig. 2. The second-order term is given as follows:

$$\begin{aligned}
&-\frac{1}{2\beta(2\pi)^2}\mathrm{Tr}\sum_{\omega,s}\int_{-\infty}^{\infty}\mathrm{d}k\int_{-\infty}^{\infty}\mathrm{d}q\,G(k+q;\mathrm{i}\omega)\eta(q)G(k;\mathrm{i}\omega)\eta(-q)\\
&=-\frac{1}{4\pi^3 v_F}\int_{-\infty}^{\infty}\mathrm{d}(v_F k)\int_{-\infty}^{\infty}\mathrm{d}q\int_{-\overline{W}}^{\overline{W}}\mathrm{d}z\left\{\left(A_0^2+\left(\mathrm{i}z+\frac{2\Delta_1^2}{3W}\right)^2-v_F^2 k(k+q)\right)\delta A(q)\,\delta A(-q)\right.\\
&\quad+\left(A_0^2+\left(\mathrm{i}z+\frac{2\Delta_1^2}{3W}\right)^2+v_F^2 k(k+q)\right)\left(\delta B(q)-\frac{\mathrm{i}v_F q}{2}\chi(q)\right)\left(\delta B(-q)+\frac{\mathrm{i}v_F q}{2}\chi(-q)\right)\\
&\quad\left.+\left(-A_0^2+\left(\mathrm{i}z+\frac{2\Delta_1^2}{3W}\right)^2+v_F^2 k(k+q)\right)\left(\mathrm{i}\frac{1}{2}\frac{\partial\chi(q)}{\partial\tau}\right)\left(\mathrm{i}\frac{1}{2}\frac{\partial\chi(-q)}{\partial\tau}\right)\right\}\\
&\quad\times\left[\left(\mathrm{i}z+\frac{2\Delta_1^2}{3W}\right)^2-(v_F k)^2-A_0^2\right]^{-1}\left[\left(\mathrm{i}z+\frac{2\Delta_1^2}{3W}\right)^2-(v_F(k+q))^2-A_0^2\right]^{-1}\\
&=\frac{1}{\pi v_F}\int \mathrm{d}x\,\delta A(x)\left(\ln\left|\frac{2\overline{W}}{A_0}\right|-\frac{\sqrt{1+\gamma^2}}{\gamma}\sinh^{-1}\gamma\right)\delta A(x)\\
&\quad-\frac{1}{\pi v_F}\int \mathrm{d}x\left(\delta B(x)-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right)\frac{\sinh^{-1}\gamma}{\gamma\sqrt{1+\gamma^2}}\left(\delta B(x)-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right),
\end{aligned} \tag{A18}$$

where γ is defined by

$$\gamma=-\mathrm{i}\frac{v_F}{2\Delta_1}\frac{\partial}{\partial x}. \tag{A19}$$

In the calculation, the time dependency of the momentum transfer q is ignored. It corresponds to the adiabatic approximation. We can see easily that the contributions

$$\frac{1}{2\pi v_F}\int \mathrm{d}x(\delta A(x))^2\left(\ln\left|\frac{2\overline{W}}{A_0}\right|-1\right), \tag{A20}$$

and

$$-\frac{1}{\pi v_F}\int \mathrm{d}x\left(\delta B(x)-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right)^2, \tag{A21}$$

in the r.h.s. of Eq. (A18) are already included in Eq. (A17). Then, the difference between Eq. (A18) and Eqs. (A20)–(A21) contributes to the effective potential. Adding it to Eq. (A17), and considering the total contribution to the effective potential, U is estimated as

$$\begin{aligned} U=&-\frac{1}{2\pi v_F}\int \mathrm{d}xA^2(x)\left(\ln\left|\frac{A^2(x)}{W^2}\right|-1\right)\\ &-\frac{1}{\pi v_F}\int \mathrm{d}xA(x)\left(\frac{\sqrt{1+\gamma^2}}{\gamma}\sinh^{-1}\gamma-1\right)A(x)\\ &-\frac{1}{\pi v_F}\int \mathrm{d}x\left(B(x)-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right)\left(\frac{\sinh^{-1}\gamma}{\gamma\sqrt{1+\gamma^2}}\right)\left(B(x)-\frac{v_F}{2}\frac{\partial\chi(x)}{\partial x}\right). \end{aligned} \tag{A22}$$

Lastly, expanding $\sqrt{1+\gamma^2}$ and $\sinh^{-1}\gamma$ around $\gamma=0$ and neglecting higher-order terms with respect to γ than the second-order ones, the effective potential Eq. (37) is obtained.

APPENDIX B: SOLUTIONS OF EQS. (76) AND (78)

Substituting Eq. (79) into Eq. (76), the equation of $v_1(x)$ is rewritten as

$$\partial_X^2 v_1(x)+v_1(x)\left(\frac{2}{\cosh^2 X}-1\right)-\frac{3\tanh X}{\cosh^3 X}=0. \tag{B1}$$

Because $\tanh X/\cosh^3 X$ is the odd function, $v_1(x)$ should be odd with respect to the replacement $x\to -x$. Then we can introduce parameters $t_{1,n}$ ($n=0,1,2,...$) by

$$v_1(x)=\sum_{m=1}^{\infty} t_{1,m}\frac{\tanh X}{\cosh^{2m+1} X}. \tag{B2}$$

Substituting Eq. (B2) into Eq. (B1) and equating the coefficients of the functions $\tanh X/\cosh^{2m+1} X$ on both sides, the parameters are determined by

$$t_{1,0}=-\tfrac{3}{2}, \tag{B3}$$

and

$$t_{1,m}=0, \quad \text{for positive integer } m. \tag{B4}$$

The function $v_1(x)$ is therefore given by

$$v_1(x)=-3\tanh X/(2\cosh X). \tag{B5}$$

On the other hand, using Eqs. (81) and (B5), the equation of $v_2(x)$, namely, Eq. (78) is rewritten as,

$$\frac{\partial^2 v_2(X)}{\partial X^2}+v_2(X)\left(\frac{2}{\cosh^2 X}-1\right)+\frac{\tanh X}{2\cosh^3 X}\left(\frac{213}{\cosh^2 X}-123\right)=0. \tag{B6}$$

Introducing parameters $t_{2,m}$, we write $v_2(X)$ by

$$v_2(x)=\sum_{m=1}^{\infty} t_{2,m}\frac{\tanh X}{\cosh^{2m+1} X}. \tag{B7}$$

Substituting Eq. (B7) into Eq. (B6), and setting each coefficient of the functions $\tanh X/\cosh^{2m+1} X$ to zero, the parameters $t_{2,m}$ are determined as

$$t_{2,0}=-\tfrac{85}{24}, \tag{B8}$$

$$t_{2,1}=\tfrac{71}{12}, \tag{B9}$$

and

$$t_{2,m}=0, \quad \text{for } m\geqslant 2. \tag{B10}$$

After all, the function $v_2(x)$ is solved as

$$v_2(x)=-\frac{85}{24}\frac{\tanh X}{\cosh X}+\frac{71}{12}\frac{\tanh X}{\cosh^3 X}. \tag{B11}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 3 MARCH 1999

Classification and conformal symmetry in three-dimensional space–times

G. S. Hall[a] and M. S. Capocci[b]
Department of Mathematical Sciences, Meston Building, University of Aberdeen, Aberdeen AB24 3UE, Scotland, United Kingdom

(Received 28 August 1998; accepted for publication 26 October 1998)

Three-dimensional manifolds admitting Lorentz metrics are studied. The first part of the paper gives a classification of the Ricci and curvature tensors and also of the conformal (Schouten–Cotton–York) tensor. The second part of the paper investigates Killing and conformal symmetry and also the nature of the zeros of the associated vector fields. The maximum dimension of the Killing and conformal algebras is calculated. A theorem regarding the reduction of the conformal algebra to a Killing algebra of a conformally related metric is given. © *1999 American Institute of Physics.* [S0022-2488(99)01103-2]

I. INTRODUCTION

The recent interest in three-dimensional space–times together with the known usefulness and elegance of the various classification schemes in the four-dimensional space-time of general relativity suggest that a discussion of such schemes in the former may be useful.

Perhaps the most useful classification scheme in general relativity is the Petrov classification of the Weyl (conformal) tensor. The ''equivalent'' Weyl tensor in three-dimensions is zero and must be replaced by a tensor introduced by Schouten[1] (but often referred to as the *Cotton–York tensor*) which, like the Weyl tensor in four or more dimensions, is conformally invariant and which vanishes identically if and only if the metric is locally conformal to a flat metric. The classification of this tensor will be dealt with in Sec. IV.

The vanishing of the Weyl tensor in three dimensions leads to a close relationship between the Ricci and Riemann tensors. This link is explored in Sec. III where these tensors are classified by Segre type.

The final three sections of the paper deal with the study of conformal (including homothetic and Killing) vector fields on a three-dimensional space–time. Some results regarding the nature of zeros of such vectors fields are given and these are used to prove theorems on the maximum dimension of the conformal and related Lie algebras. A theorem concerning the reduction of the conformal algebra to a Killing algebra with respect to a conformally related metric is obtained. Section II contains some preliminary geometrical remarks about three-dimensional space–times.

II. THREE-DIMENSIONAL SPACE–TIMES

A three-dimensional space–time is a three-dimensional smooth paracompact connected manifold M admitting a global smooth Lorentz metric g of signature $(-,+,+)$. The associated Riemann and Ricci tensors are denoted by their respective components R_{abcd} and $R_{ab}(\equiv R^c_{acb})$ and a covariant derivative arising from the Levi-Civitá connection associated with g is denoted by a semicolon. Round and square brackets denote the usual symmetrization and skew symmetrization, respectively.

Let $m\in M$ and let T_mM denote the tangent space to M at m. Denote by Λ_m the three-dimensional vector space of skew symmetric tensors (bivectors) of either type (0,2) or (2,0) at m (there being no need to distinguish them for the present purposes because of the natural isomor-

[a]Electronic mail: gsh@maths.aberdeen.ac.uk
[b]Present address: 9 Victoria Street, Aylesbury, Buckinghamshire, HP20 1LZ, U.K.; electronic mail: michael@coexis.com

phism between them which arises from the metric $g(m)$ at m and in components is $F_{ab} \mapsto F^{ab}$). A triplet (l,n,x) of members of T_mM is called a *null triad* if the only nonvanishing inner products between them are $l^a n_a = x^a x_a = 1$ (so that l and n are null and x spacelike). A triplet $x,y,t \in T_mM$ is called an *orthogonal triad* if the only nonvanishing inner products between them are $x^a x_a = y^a y_a = -t^a t_a = 1$ (so that x and y are spacelike and t is timelike). If $0 \neq F \in \Lambda_m$ then its rank is even and hence equal to 2. Thus all bivectors in Λ_m are *simple*, that is, $F \in \Lambda_m$ can be written as $F^{ab} = 2p^{[a}q^{b]}$ for $p,q \in T_mM$. The two-dimensional subspace of T_mM spanned by p and q is uniquely determined by F and called the *blade* of F. A nonzero member of Λ_m can be classified as *timelike*, *null*, or *spacelike* according to whether its blade contains exactly two, exactly one, or no *null* one-dimensional subspaces (directions).

Let S be a nonzero symmetric type (0,2) tensor at m with components S_{ab}. The eigenvector–eigenvalue problem $(S_{ab} - \lambda g_{ab})k^b = 0$ at m for $k \in T_mM$ and $\lambda \in \mathbb{C}$ leads to a classification for S in terms of its Segre type. The details were given in Ref. 2 and based on the four-dimensional situation.[3,4] All four Segre types {1,11}, {21}, {3}, and $\{z\bar{z}1\}$ are possible and their canonical expressions in terms of a null triad (l,n,x) are, respectively,

$$S_{ab} = 2\alpha l_{(a}n_{b)} + \beta(l_a l_b + n_a n_b) + \gamma x_a x_b\,, \tag{1}$$

$$S_{ab} = 2\alpha l_{(a}n_{b)} + \lambda l_a l_b + \beta x_a x_b\,, \tag{2}$$

$$S_{ab} = 2\alpha l_{(a}n_{b)} + l_{(a}x_{b)} + \alpha x_a x_b\,, \tag{3}$$

$$S_{ab} = 2\alpha l_{(a}n_{b)} + \beta(l_a l_b - n_a n_b) + \gamma x_a x_b\,. \tag{4}$$

Here $\alpha,\beta,\gamma, \in \mathbb{R}$ and $\gamma = \pm 1$. In (1) the eigenvectors are $l \pm n$ and x with corresponding eigenvalues $\alpha \pm \beta$ and γ. In (2) the eigenvectors are l and x with respective eigenvalues α and β while in (3) the eigenvector is l with eigenvalue α. In (4), which is the only case to admit nonreal eigenvalues, $\beta \neq 0$ and the eigenvectors are $l \pm in$ and x with respective eigenvalues $\alpha \pm i\beta$ and γ. The type {1,11} is the only one where timelike eigenvectors can occur and the associated (unique) eigenvalue is represented by the first digit in the Segre symbol and is separated from the others by a comma. The degeneracies of these Segre types (denoted by enclosing the appropriate digits inside round brackets) are also possible. An alternative form for (1) in an orthogonal triad is

$$S_{ab} = \rho z_a z_b + \gamma x_a x_b - \delta t_a t_b\,, \tag{5}$$

where $\rho, \delta \in \mathbb{R}$, $\sqrt{2}z = l + n$, $\sqrt{2}t = l - n$ and so $\alpha + \beta = \rho$ and $\alpha - \beta = \delta$.

In (2) and (3) l spans the unique null eigendirection and in (1) there are no null eigendirections unless $\beta = 0$ (type {(1,1)1}) in which case there are exactly two independent ones spanned by l and n. There are no null eigendirections in (4).

The bivectors in Λ_m may also be classified according to Segre type. In fact in terms of an appropriate null triad a null bivector may be written as $2l_{[a}x_{b]}$ and a timelike bivector as $2l_{[a}n_{b]}$ and their respective Segre types are {3} and {111} while, in terms of an appropriate orthogonal triad a spacelike bivector may be written as $2x_{[a}y_{b]}$ and its Segre type is then $\{z\bar{z}1\}$. These canonical forms (but not the Segre types) will be required later.

There is a convenient ''duality'' between T_mM and Λ_m in a three-dimensional space–time achieved by using the alternating tensor ϵ_{abc}. Associated with $k \in T_mM$ the bivector $F \in \Lambda_m$ where $F_{ab} = \epsilon_{abc}k^c$ (and then k and F will be referred to as the *duals* of each other). Thus a bijective duality relation is established between T_mM and Λ_m. From this correspondence one finds $F_{ab}k^b = 0$ and so this duality relation may be geometrically regarded as associating a (necessarily simple) bivector with a vector (naturally scaled by ϵ) perpendicular to its blade. The vector k lies in the blade of F if and only if k (and hence F) is null. From the mathematical viewpoint it can be interpreted as a means of ''identifying'' a single tensor index with a skew symmetric pair of tensor indices. Like the duality operation in general relativity it will turn out to be rather useful algebraically and in this respect one notes the relation

$$\epsilon^{abc}\epsilon_{ade} = -(\delta^b_d\delta^c_e - \delta^c_d\delta^b_e). \tag{6}$$

It is remarked here that the above duality map between T_mM and Λ_m extends naturally to the complexification of these vector spaces taking a complex vector k^a to the complex bivector $\epsilon_{abc}k^c$. This will be required in dealing with the possible occurrence of complex eigenvectors in a later section.

The Lorentz group $\mathcal{L}$ in three-dimensions is the subgroup of GL(3,$\mathbb{R}$) given by $\mathcal{L}=\{A \in \mathrm{GL}(3,\mathbb{R}): A^T\eta A=\eta\}$ where $\eta=\mathrm{diag}(-1,1,1)$ and A^T is the transpose of A. The group $\mathcal{L}$ can, in a natural way, be given the structure of a three-dimensional Lie group which is a Lie subgroup of GL(3,$\mathbb{R}$). Let $\mathcal{L}_0$ be the identity component of $\mathcal{L}$ and let $l \in T_mM$ be null. The subgroup $N(l)$ of $\mathcal{L}_0$ of *null rotations about l* is the subgroup of $\mathcal{L}_0$ which preserves the direction of l. It is a two-dimensional Lie subgroup of $\mathcal{L}_0$ described by its effect on a null triad (l,n,x) by

$$l \mapsto l' = Al, \quad x \mapsto x' = x + bl, \quad n \mapsto n' = A^{-1}\left(n - bx - \frac{b^2}{2}l\right), \tag{7}$$

where $A,b \in \mathbb{R}$, $A>0$. Under such a null rotation n may be transformed to any other null vector at m except a null vector proportional to l.

III. THE RIEMANN AND RICCI TENSORS

The vanishing of the Weyl tensor on a three-dimensional space–time means that the Ricci and Riemann tensors are related by

$$R_{abcd} = 2R_{a[c}g_{d]b} + 2R_{b[d}g_{c]a} + Rg_{a[d}g_{c]b}, \tag{8}$$

where $R \equiv R_{ab}g^{ab}$ is the Ricci scalar. As a consequence the Ricci tensor vanishes at $m \in M$ if and only if the Riemann tensor vanishes at m.

Now construct the ''double dual'' T of the Riemann tensor where, in components,

$$T^{ef} = \epsilon^{abe}R_{abcd}\epsilon^{cdf}. \tag{9}$$

Thus T is a second order tensor and is easily seen to be symmetric. The inverse relation to (9) can be found using (6) and is

$$R_{abcd} = \tfrac{1}{4}\epsilon_{abe}T^{ef}\epsilon_{cdf}. \tag{10}$$

Theorem 1: *A vector k in T_mM (or its complexification) is an eigenvector of T with eigenvalue $\alpha \in \mathbb{C}$ if and only if the bivector $F_{ab}=\epsilon_{abc}k^c$ in Λ_m (or its complexification) is an eigenbivector of the Riemann tensor with eigenvalue $-\alpha/2 \in \mathbb{C}$.*

Proof: Suppose that $T^{ef}k_f = \alpha g^{ef}k_f = \alpha k^e$. Then (9) on premultiplying by ϵ_{emn} gives

$$\epsilon_{emn}\epsilon^{abe}R_{abcd}F^{cd} = \alpha\epsilon_{emn}k^e. \tag{11}$$

Use of (6) then reveals

$$R_{abcd}F^{cd} = -\frac{\alpha}{2}F_{ab} \tag{12}$$

and so F is an eigenbivector of the Riemann tensor with eigenvalue $-\alpha/2$. The converse result is similar and this completes the proof. □

Because of the close relationship between T and the Riemann tensor expressed in theorem 1, one is tempted to enquire about the relationship between T and the Ricci tensor. The answer is easily obtained by computing T in (9) using (8) and (6). One finds

$$T_{ab} = 4(R_{ab} - \tfrac{1}{2}Rg_{ab}) \tag{13}$$

and so T is, up to a numerical factor, the Einstein tensor. The Bianchi identities for the Riemann tensor then reappear, through duality, in the identities

$$T_a{}^b{}_{;b}=0. \tag{14}$$

It follows from (13) that $k\in T_mM$ (or its complexification) is an eigenvector of T if and only if it is an eigenvector of the Ricci tensor and that, although the eigenvalues will in general differ, any eigenvalue degeneracies will be preserved. From this remark and theorem 1 it is clear that the algebraic structure of T, of the Ricci tensor and of the Riemann tensor (regarded in the obvious way as a linear map from Λ_m to itself) are the same in the sense that their Segre type (including degeneracies) are identical.

Theorem 2: *If M is a three-dimensional space–time and $m\in M$ then M may be algebraically classified at m according to the Segre type of the Riemann tensor, the Ricci tensor, or the double dual of the Riemann tensor (the tensor T) at $m\in M$. The Segre type obtained is independent of whichever of these tensors is used and is either* $\{1,11\}$, $\{21\}$, $\{3\}$, $\{z\bar{z}1\}$, *or a degeneracy of one of these types.*

Proof: The proof follows from the preceding remarks and the material in Sec. II. □

Thus, as a corollary, one sees that every bivector in Λ_m is an eigenbivector of the Riemann tensor with the same eigenvalue if and only if every vector in T_mM is an eigenvector of the Ricci tensor with the same eigenvalue. Hence M is of constant curvature at m if and only if it is an Einstein space at m. The link between the algebraic structure of the Riemann and Ricci tensors was given earlier.[5]

Recalling the elegant and useful Bel criteria which can be used in an alternative formulation of the Petrov classification in general relativity[6,7] it is interesting to ask if one can reformulate the classification in theorem 2 in terms of ''canonical'' null directions in T_mM.

Theorem 3: *Let M be a three-dimensional space–time, let $m\in M$ and let $l\in T_mM$ be null. Then at m*:

(1) $R_{ab}l^al^b=0 \Leftrightarrow l_{[e}R_{a]bc[d}l_{f]}l^bl^c=0$.
(2) $R_{ab}l^a=\alpha l^b(\alpha\in\mathbb{R}) \Leftrightarrow R_{abcd}l^bl^c=\lambda l_al_d(\lambda\in\mathbb{R})$.
(3) $R_{abcd}l^d=F_{ab}l_c\neq 0$ *(where F is a null bivector in Λ_m satisfying $F_{ab}l^b=0$)* $\Leftrightarrow$ *the Ricci tensor has Segre type* $\{3\}$ *with eigenvector l and eigenvalue zero*.
(4) $R_{abcd}l^d=0$ $(R_{abcd}\neq 0)\Leftrightarrow$ *the Ricci tensor has Segre type* $\{(21)\}$ *with null eigenvector l and eigenvalue zero*.

Proof:

(1) If $R_{ab}l^al^b=0$ then a contraction of (8) with l^bl^c reveals the desired condition on the Riemann tensor. Conversely, this latter condition means that $R_{abcd}l^bl^c=2l_{(a}p_{d)}$ where the Riemann symmetries imply that p satisfies $l^ap_a=0$. A contraction over the indices a and b then gives $R_{ab}l^al^b=0$.
(2) If $R_{ab}l^b=\alpha l_a$ then a contraction of (8) with l^bl^c reveals the given condition on the Riemann tensor. Conversely, this latter condition implies $R_{ab}l^al^b=0$ and then the same contraction of (8) yields $R_{ab}l^b=\alpha l_a$.
(3) The condition on the Riemann tensor immediately implies that $R_{ab}l^b=0$ and that $R_{abcd}F^{cd}=0$ (since F is null). This latter condition implies that $T_{ab}l^b=0$ (theorem 1) and, since $R_{ab}l^b=0$, Eq. (13) yields $R=0$. Now construct a null triad (l,n,x) with $F_{ab}=2l_{[a}x_{b]}$ and contract (8) with l^dn^b (using $R=0$) to get $R_{ab}=2l_{(a}q_{b)}$ with $l^aq_a=0$ and $q\not\propto l$. A comparison with (3) with $\alpha=0$ reveals the stated Segre type for the Ricci tensor. Conversely, writing the Ricci tensor as in (3) with $\alpha=0$ one finds that $R=0$ and a contraction of (8) with l^d completes the proof.
(4) Using the real null triad employed in the proof of part 3 the conditions on the Riemann tensor show that $R_{abcd}F^{cd}=0$ where $F_{ab}=2l_{[a}x_{b]}$ or $F_{ab}=2l_{[a}n_{b]}$. Hence, from theorem 1, $T_{ab}l^b=0$ and $T_{ab}x^b=0$. Because $R_{abcd}\neq 0$ at m, $T\neq 0$ at m and so from (1)–(4) T must have Segre

type {(21)} with zero eigenvalue since if it had Segre type {1,11} [the only other type admitting (at least) two independent real eigenvectors] it would vanish. Thus $T_{ab}=\mu l_a l_b$ ($\mu\in\mathbb{R}$) and (13) reveals that $R_{ab}=(\mu/4)l_a l_b$ and the result follows. Conversely, the latter expression for R_{ab} used in (8) shows that $R_{abcd}l^d=0$.

It is remarked here that, from the Segre theory and Eqs. (1)–(4) in Sec. II, the null direction l in parts 3 and 4 of theorem 3 is unique and that at most two null directions could satisfy the conditions of part 2. What is less obvious is that there are at most four null directions satisfying the conditions of part 1. To see this suppose that at least one such direction exists and is spanned by l and construct a null triad (l,n,x) at m. Under a null rotation (7) n may be rotated to n' and, by a suitable choice of b, to span any null direction at m other than that spanned by l. The equation $R_{ab}n'^a n'^b=0$ is then a polynomial in b of order less than or equal to three and the result follows. There may, of course, be no null directions satisfying condition 1 of theorem 3.

IV. THE SCHOUTEN–COTTON–YORK TENSORS

For a three-dimensional space–time M consider the tensor $\bar{R}$ with components R_{abc} given in any coordinate system by

$$R_{abc}=2R_{a[b;c]}+\tfrac{1}{2}R_{;[b}g_{c]a}=R^d{}_{abc;d}+\tfrac{1}{2}R_{;[b}g_{c]a}\,. \tag{15}$$

This tensor has the properties

(1) $R_{abc}=-R_{acb}$,
(2) $R^a{}_{ac}=0$,
(3) $R_{[abc]}=0$,

and also the property that it is *conformally invariant* in the sense that it is unchanged if the metric g on M is changed to the metric $e^\sigma g$ on M for a smooth function $\sigma:M\to\mathbb{R}$. Further $\bar{R}$ vanishes on some open neighborhood U of m if and only if for some open neighborhood $V\subseteq U$ of m there exists a flat metric γ on V and a smooth function $\rho:V\to\mathbb{R}$ such that, on $V, g=e^\rho\gamma$.[1,8]

To algebraically classify $\bar{R}$ at $m\in M$ one recalls the ''duality identification'' made in Sec. II between T_mM and Λ_m. Now the tensor $\bar{R}$ may be thought of as a linear map $T_mM\to\Lambda_m$ given by $k^a\mapsto R_{abc}k^a$. Thus with the above identification $\bar{R}$ gives rise to a linear map $T_mM\to T_mM$ given by

$$k^a\mapsto R_{abc}k^a\mapsto -\tfrac{1}{2}\epsilon^{bca}(R_{dbc}k^d)=Y^a{}_d k^d, \tag{16}$$

where

$$Y^{ab}=-\tfrac{1}{2}\epsilon^{acd}R^b{}_{cd} \tag{17}$$

is the *Cotton–York tensor*.[8] The tensor Y is easily seen to be trace-free from the third property of $\bar{R}$ listed above and can also be shown to be symmetric by use of the Bianchi identity.[8] Thus $Y_{ab}=Y_{ba}$, $Y^a{}_a=0$ and (17) inverts to give

$$R^a{}_{bc}=\epsilon_{dbc}Y^{da}. \tag{18}$$

This bijective correspondence between $\bar{R}$ and Y suggests that a classification of $\bar{R}$ may be achieved by a classification of Y similar to that given in Sec. II. It is noted here that, while Y vanishes at m if and only if $\bar{R}$ does, the tensor Y is not conformally invariant. M will be called *conformally flat* if $\bar{R}\equiv 0\ (\Leftrightarrow Y\equiv 0)$ on M.

Theorem 4: *If M is a three-dimensional space–time the tensor Y may be classified at each $m\in M$ into four Segre types together with their degeneracies. They are* {1,11}, {(1,1)1}, {1,(11)}, {(1,11)}, {21}, {(21)}, {3}, *and* $\{z\bar{z}1\}$. *The trace-free condition means that if the type is* {(1,11)} *then* $Y=0$ *at m and that if the type is* {(21)} *or* {3} *the eigenvalue is zero.*

Proof: This follows immediately from (1)–(4) after imposing the trace-free condition. □

An alternative approach is to directly classify the tensor $\bar{R}$ according to its canonical null directions and in the spirit of theorem 3 for the Riemann tensor. To achieve this first note that if $k\in T_mM$ then

$$Y^a{}_b k^b=0 \Leftrightarrow R_{abc}k^a=0, \tag{19a}$$

$$Y^a{}_b k^b=\alpha k^a(\alpha\in\mathbb{R}) \Leftrightarrow R_{abc}k^ak^b=0(\Leftrightarrow R_{abc}k^ak^c=0). \tag{19b}$$

The proof of (19a) is immediate from (16). To prove (19b) let $G_{ab}=R^c{}_{ab}k_c$. Then $Y^a{}_bk^b=\alpha k^a$ and (17) imply that $\epsilon^{abc}G_{bc}\propto k^a$ and hence that $G_{ab}k^b=0$. Hence $R_{abc}k^ak^b=0$. Conversely, $R_{abc}k^ak^b=0$ implies that $G_{ab}k^b=0$ and hence that $\epsilon^{abc}G_{bc}\propto k^a$. Thus $Y^a{}_bk^b\propto k^a$. The results (19a) and (19b) are independent of whether *k* is null and are also true if *k* is complex. Hence they may be used as a reformulation of the classification in theorem 4. But it is interesting to consider the classification of $\bar{R}$ according to real *null* vectors *k* satisfying either (19a) or (19b) and to bear in mind [Eqs. (1)–(4)] that there are at most two independent real null solutions to each of Eqs. (19a) and (19b). The following theorem results directly from theorem 4.

Theorem 5: *Let M be a three-dimensional space–time, let* $m\in M$ *and suppose that* $\bar{R}(m)\neq 0$. *Then*

(1) *There are exactly two independent null solutions of (19b) if and only if Y has Segre type* {(1,1)1}.
(2) *There is exactly one independent null solution of (19b) and no non-trivial null solutions of (19a) if and only if Y has Segre type* {21}.
(3) *There is exactly one independent null solution of each of (19a) and (19b) if and only if Y has Segre type* {(21)} *or* {3} *(with eigenvalue necessarily equal to zero in each case).*
(4) *There is at most one nontrivial null solution of (19a).*

Again one sees a similarity to the well known Bel criteria for the Weyl tensor of general relativity. The number of independent *null* solutions for $\bar{R}(m)\neq 0$ of (19a) is 0 or 1 and of (19b) is 0, 1, or 2 and each can actually occur as (1)–(4) show. Also Eq. (16) and theorem 4 suggest that one thinks of the eigenvalues of the tensor Y at $m\in M$ as being the equivalent, in a three-dimensional space–time, of the well known Petrov scalars in a four-dimensional space–time. At this point one may suggest a classification scheme for $\bar{R}$ by using the same symbols as in the Petrov case but with a prime attached (and an extra distinguishing suffix needed in two of the types). The types at *m* are, from theorem 4:

Type I_1' (when $Y(m)$ has Segre type {1,11} and, recalling the trace-free condition, two independent eigenvalues),
Type I_2' ($\{z\bar{z}1\}$ and two independent eigenvalues),
Type D_1' ({(1,1)1} and one independent eigenvalue),
Type D_2' ({1,(11)} and one independent eigenvalue),
Type II' ({21} and one independent eigenvalue),
Type N' ({(21)} and all eigenvalues zero),
Type III' ({3} and all eigenvalues zero).

The relationship between each of these types and the corresponding Petrov type is clear. It is also important to note the geometry of this classification. If the type at *m* is I_1' then a unique timelike direction and a unique pair of spacelike directions are determined at *m* by the eigenvector structure. If the type at *m* is I_2' then a unique pair of null directions and a unique spacelike direction is determined at *m*. For type D_1' (respectively, D_2') a unique timelike (respectively, spacelike) two-space and a unique spacelike (respectively, timelike) direction are determined at *m*.

For types II', N', and III' a unique null and a unique spacelike direction are determined at m and they are orthogonal. A similar geometric discussion can be given for the earlier classifications of the Ricci and Riemann tensors.

V. CONFORMAL SYMMETRY ON A THREE-DIMENSIONAL SPACE–TIME

In this section conformal symmetry will be studied in the usual way by a discussion of conformal (including homothetic and Killing) vector fields on the three-dimensional space–time M. Further technical details may be found in Ref. 9.

A smooth vector field X on M is called *conformal* if in any chart of M

$$X_{a;b}=\phi g_{ab}+F_{ab}(\Leftrightarrow \mathcal{L}_X g=2\phi g), \tag{20}$$

where $F_{ab}(=-F_{ba})$ is the (conformal) bivector of X, $\phi: M\rightarrow \mathbb{R}$ is smooth and $\mathcal{L}$ denotes a Lie derivative. It is, in fact, sufficient to assume that X is C^3 for this implies that X is smooth.[10] A conformal vector field is called *homothetic* if ϕ is constant on M and *Killing* if $\phi\equiv 0$ on M. It is called *proper homothetic* if $\phi\equiv constant\neq 0$ and *proper conformal* if X is not homothetic. From (20) it follows that

$$F_{ab;c}=R_{abcd}X^d-2g_{c[b}\phi_{a]}, \tag{21}$$

$$\phi_{;ab}=2R_{c(a}F_{b)}{}^c-2\phi L_{ab}-L_{ab;c}X^c, \tag{22}$$

where $\phi_a=\phi_{;a}$ and $L_{ab}=R_{ab}-\frac{1}{4}Rg_{ab}$. The sets of all conformal (respectively, homothetic, Killing) vector fields on M will be denoted by C (respectively, H,K) so that $K\subseteq H\subseteq C$ and each of K, H, and C is a Lie algebra of smooth vector fields on M. If $m\in M$ the subset of C (respectively, H,K) consisting of vector fields which vanish at m is denoted by C_m (respectively, H_m, K_m) and is a subalgebra of C (respectively, H,K). If $X\in C$ and if the local diffeomorphisms of M associated with X in the usual way (see, e.g., Refs. 11 and 12) are denoted by ψ_t then, for each $X\in C$, $X(m)=0$ if and only if $\psi_t(m)=m$ for appropriate t and such a point m is referred to as either a *zero* or a *fixed point* of X. Such a zero of X is called *isometric* if $\phi(m)=0$ or *homothetic* if $\phi(m)\neq 0$. The subset of C_m consisting of all conformal vector fields on M for which m is an isometric zero is denoted I_m. Thus $I_m=\{X\in C_m : \phi(m)=0\}$ and is a subalgebra of C_m and C. Any conformal vector field X on M is uniquely determined by the values $X^a(m)$, $X^a_{;b}(m)$, and $X^a_{;bc}(m)$ [or equivalently by $X^a(m)$, $F_{ab}(m)$, $\phi(m)$, and $\phi_a(m)$] at any $m\in M$.

The study of conformal symmetry in the four-dimensional space–time of general relativity is facilitated by knowledge of what goes on at zeros of conformal vector fields[13–16] and a similar approach will be adopted here.

Theorem 6: *Let M be a three-dimensional space–time and X a conformal vector field on M. Then*

(1) $\mathcal{L}_X R_{abc}=0$,
(2) $\mathcal{L}_X Y^a{}_b=-3\phi Y^a{}_b$ *(or, equivalently,* $\mathcal{L}_X Y_{ab}=-\phi Y_{ab}$*)*,
(3) *If Y does not vanish over a nonempty open subset of M and l is a null eigenvector field of Y then* $\mathcal{L}_X l=\alpha l$ *for some smooth function* $\alpha: M\rightarrow\mathbb{R}$.

Proof: If one considers the smooth map ψ_t associated with X between open coordinate domains U and $\psi_t U$ then a consideration of the pullback ψ_t^{-1*} shows that this latter map preserves g up to a scalar $\lambda(t)$ (since X is conformal). The conformal invariance of $\overline{R}$ now reveals that $\psi_t^{-1*}\overline{R}=\overline{R}$ so that 1 follows. To establish 2, use of the standard Lie derivative formula together with the result that $\epsilon^{abc}_{;d}=0$ gives

$$\mathcal{L}_X \epsilon^{abc}=-3\phi\epsilon^{abc}+H^{abc}, \tag{23}$$

where H is a three-form on M satisfying $H^{abc}\epsilon_{abc}=0$. Hence $H=0$ and so

$$\mathcal{L}_X Y^a{}_b = \tfrac{1}{2}\mathcal{L}_X(\epsilon^{cad}R_{bcd}) = -3\phi Y^a{}_b\,. \tag{24}$$

For 3, if l is a null eigenvector field of Y then, from 2, so also is $\psi_t^{-1*}l$ since ψ_t^{-1*} preserves Y up to a scalar $\mu(t)$. Since Y has finitely many independent null eigenvectors at any point $m \in M$ where $Y(m)\neq 0$ it follows that $\psi_t^{-1*}l \propto l$ and 3 is proved. □

Theorem 7: *Let M be a three-dimensional space–time, $X(\not\equiv 0)$ a conformal vector field on M and let $m\in M$ be an isometric zero of X. Then*

(1) *If the conformal bivector F also vanishes at m (so that X, ϕ, and F all vanish at m) then $\overline{R}$ (and hence Y) vanishes at m.*
If on the other hand $F(m)\neq 0$ then the blade of F is, for $Y(m)\neq 0$, an eigenspace of $Y(m)$ and hence coincides with the two-space geometrically determined at m by the type of $Y(m)$ as discussed at the end of Sec. IV. In detail,
(2) *If $F(m)$ is spacelike, $Y(m)$ is either zero or of Segre type $\{1,(11)\}$ (type D_2');*
(3) *If $F(m)$ is timelike, $Y(m)$ is either zero or of Segre type $\{(1,1)1\}$ (type D_1');*
(4) *If $F(m)$ is null, $Y(m)$ is either zero or of Segre type $\{(21)\}$ with zero eigenvalue (type N').*

Proof: Under the conditions of 1, one has $X^a(m)=0$, $X^a_{;b}(m)=0$. Then if one writes out (24) in terms of covariant derivatives, covariantly differentiates, eliminates the bivector covariant derivative using (21) and evaluates at m one finds

$$\phi_b Y_{ad} - (Y_{ac}\phi^c)g_{bd} - (Y^c_b\phi_c)g_{ad} + Y_{bd}\phi_a = -3\phi Y_{ab}\,. \tag{25}$$

The skew part of (25) over the indices b and d when contracted with ϕ^a then gives $\phi^a Y_{a[d}\phi_{b]}=0$ at m. Now $\phi_a(m)\neq 0$ (otherwise the conditions of part 1 of the theorem would imply that $X\equiv 0$ on M) and so $\phi^a(M)$ is an eigenvector of $Y(m)$ with eigenvalue $\lambda\in\mathbb{R}$, $Y^a_b\phi^b = \lambda\phi^a$ at m. On substituting this into (25) and contracting with ϕ^d at m one obtains $(\phi^c\phi_c)Y_{ab}=0$ and so either $Y(m)=0$ or $\phi_a(m)$ is null. If $Y(m)\neq 0$, $\phi_a(m)$ is null and the same substitution but now followed by a contraction with ϕ^b yields $\lambda\phi_a\phi_b=0$ at m and so $\lambda=0$. Equation (25) then gives at m

$$\phi_b Y_{ad} + \phi_a Y_{bd} + 3\phi_d Y_{ab} = 0. \tag{26}$$

Now (26) implies first that $Y_{ab}=\mu\phi_a\phi_b$ at m with $\mu\in\mathbb{R}$. A final substitution into (26) then shows that $\mu=0$ and so $Y(m)=0$.

For the remainder of the proof $F(m)\neq 0$ and it is noted that (24), when evaluated at m, gives the ''commuting'' relation

$$F^a{}_c Y^c{}_b = Y^a{}_c F^c{}_b\,. \tag{27}$$

For (2) suppose that $F(m)$ is spacelike and so there exists an orthogonal triad x,y,t at m such that, at m, $F_{ab}=2\nu x_{[a}y_{b]}$ $(0\neq\nu\in\mathbb{R})$ and $F_{ab}t^b=0$. Then a contraction of (27) with t^b and using the fact that t is the unique solution, up to a scaling, of the equation $F_{ab}t^b=0$ shows that $Y^a_b t^b = \alpha t^a$ $(\alpha\in\mathbb{R})$ at m. So regarding Y as a linear map $T_mM\to T_mM$ in the usual way, this map preserves the one-dimensional subspace of T_mM spanned by t and hence preserves its orthogonal complement spanned by x and y (since $x^a t_a=0$ implies $Y^a{}_b x^b t_a - \alpha t_b x^b=0$ and similarly for y). This latter subspace is the blade of F and is positive definite. Since Y is symmetric this induced linear action is diagonalizable over $\mathbb{R}$ and one may thus assume that x and y above are eigenvectors of Y with respective eigenvalues $\beta,\gamma\in\mathbb{R}$. A contraction of (27) with x_a then reveals that $\beta=\gamma$ and so the blade of $F(m)$ is an eigenspace of Y. Thus $Y(m)$, if nonzero, had Segre type $\{1,(11)\}$ (i.e., type D_2') and canonical form $Y_{ab}=\beta(x_ax_b+y_ay_b+2t_at_b)$ at m (since $Y^a{}_a=0\Rightarrow\alpha=-2\beta$).

For (3) suppose $F(m)$ is timelike so there exists a null triad l,n,x at m such that, at m, $F_{ab}=2\nu l_{[a}n_{b]}$ $(0\neq\nu\in\mathbb{R})$ and $F_{ab}x^b=0$. A contraction of (27) with x^b then shows that $Y^a{}_b x^b = \alpha x^a$ $(\alpha\in\mathbb{R})$ at m and a contraction of (27) with l^b and use of the fact that the eigendirection of

$F(m)$ (contracted over the second index of F) spanned by l is the only one with eigenvalue ν reveals that $Y^a_b l^b = \beta l^a$ ($\beta \in \mathbb{R}$) at m. Similarly one finds $Y^a{}_b n^b = \gamma n^a$ ($\gamma \in \mathbb{R}$) at m. Finally one then sees that $\beta = Y^a{}_b l^b n_a = \gamma$ and so the blade of $F(m)$ is an eigenspace of Y. Thus if $Y(m)$ is nonzero it has Segre type {(1,1)1} (type D_1') and canonical form $Y_{ab} = \alpha(l_{(a}n_{b)} - x_a x_b)$ at m.

For (4) if $F(m)$ is null a null triad l,n,x may be chosen at m such that, at m, $F_{ab} = 2\nu l_{[a}x_{b]}$, $(0 \neq \nu \in \mathbb{R})$. A contraction of (27) with l^b shows that $Y^a_b l^b = \alpha l^a$ ($\alpha \in \mathbb{R}$). Now regarding Y as a linear map on $T_m M$ one sees that Y preserves the null direction spanned by l and hence, as before, its orthogonal subspace which is the blade of $F(m)$. Thus $Y^a{}_b x^b = \beta l^a + \gamma x^a$ for $\beta, \gamma \in \mathbb{R}$. On substituting the information so far obtained into (27) one finds $\alpha = \beta = \gamma = 0$. Hence $Y_{ab} l^b = Y_{ab} x^b = 0$ and so either $Y(m)$ is zero or of Segre type {(21)} (type N') with canonical form $Y_{ab} \propto l_a l_b$. □

This theorem together with the classification scheme given in Sec. IV is a direct analog of a similar theorem[17,14,15] in general relativity.

Theorem 8: *Let M be a three-dimensional space–time,* $X(\not\equiv 0)$ *a conformal vector field on M and* $m \in M$ *a homothetic zero of X. Then all the eigenvalues of* $Y(m)$ *vanish and either*

(1) $Y(m) = 0$; *or*
(2) $Y(m)$ *has Segre type* {(21)} *(type* N'*) and a null triad l,n,x may be chosen at m such that* $Y_{ab} = \pm l_a l_b$ *and* $F_{ab} = 3\phi(m) l_{[a}n_{b]}$; *or*
(3) $Y(m)$ *has Segre type* {3} *(type* III'*) and a null triad l,n,x may be chosen at m such that* $Y_{ab} = 2 l_{(a}x_{b)}$ *and* $F_{ab} = 6\phi(m) l_{[a}n_{b]}$.

Proof: Regarding the eigenvalues of $Y(m)$ the proof proceeds along similar lines to that in Refs. 13 and 14 (see Ref. 18). In fact, since $\mathcal{L}_X g_{ab} = 2\phi g_{ab}$ and $\mathcal{L}_X Y_{ab} = -\phi Y_{ab}$ at m, it is easily seen that if $v \in T_m M$ is an eigenvector of $Y(m)$ with eigenvalue $\alpha \in \mathbb{R}$ (so that $Y_{ab} v^b = \alpha g_{ab} v^b$ at m) then $\psi_t^* v$ is an eigenvector of $Y(m)$ with eigenvalue $\alpha \exp(3\phi(m)t)$. Since there are finitely many such eigenvalues, $\alpha = 0$. A slight modification of this argument deals with the case when $\alpha \in \mathbb{C}$ and the first result in theorem 8 follows.

Thus $Y(m)$ is either zero or has Segre type {(21)} or {3}. If $Y(m)$ has Segre type {(21)} then there exists $l \in T_m M$ with l null and $Y_{ab} = \pm l_a l_b$. Evaluating (24) at m gives

$$Y^a{}_c F^c{}_b - F^a{}_c Y^c{}_b = -3\phi(m) Y^a{}_b \tag{28}$$

and substituting for $Y^a{}_b$ at m gives $F_{ab} l^b = \alpha l_a$ ($\alpha \in \mathbb{R}$) at m. Substituting back into (28) then gives $\alpha = \frac{3}{2}\phi(m) \neq 0$. It follows that $F(m)$ is timelike and l may be extended to a null triad with the desired conditions of part 2 of the theorem. For part 3 there exists a null triad l,n,x such that, at m, $Y_{ab} = l_{(a}x_{b)}$. A substitution into (28) and contractions first with l_a and then with x_a show that $F_{ab} l^b = \mu l_a$ with $\mu = 3\phi(m) \neq 0$ so that $F(m)$ is timelike. Another back substitution and appropriate contractions show that $F_{ab} x^b = 0$ and hence that l and n span the blade of $F(m)$. This completes the proof. □

It is of interest to note that in part 3 the triad l,n,x yielding the given expression for Y_{ab} at m is easily checked to be uniquely determined by $Y(m)$. In (2), however, there is a potential freedom in the blade of $F(m)$ represented by the null rotation $l \mapsto l$, $n \mapsto n - bx - (b^2/2) l$ and hence $l_{[a}n_{b]} \mapsto l_{[a}n_{b]} - b l_{[a}x_{b]}$. This allows for the possibility (theorem 7) of taking a linear combination of X with a Killing vector field on M which vanishes at m. No such possibility exists in (3) as theorem 7 shows.

Again one notes that this theorem together with the classification scheme in Sec. IV is the direct analog of the corresponding result in general relativity.[13,14] There is one final result (again with a general relativistic analog)[13,14] which is conveniently given here.

Theorem 9: *Let M be a three-dimensional space–time,* $X(\not\equiv 0)$ *a homothetic vector field on M and* $m \in M$ *a zero of X.*

If X is proper homothetic (and so m is necessarily a homothetic zero of X) all eigenvalues of the Ricci tensor at m are zero and, at m, either

(1) *The Ricci tensor vanishes; or*
(2) *The Ricci tensor has Segre type* $\{(21)\}$ *with eigenvalue zero and a null triad l,n,x may be chosen at m such that* $R_{ab}=\pm l_a l_b$ *and* $F_{ab}=2\phi l_{[a}n_{b]}$; *or*
(3) *The Ricci tensor has Segre type* $\{3\}$ *with eigenvalue zero and a null triad l,n,x may be chosen at m such that* $R_{ab}=2l_{(a}x_{b)}$ *and* $F_{ab}=4\phi l_{a[}n_{b]}$.
If X is Killing (and so m is necessarily an isometric zero of X) then, at m, either
(4) *The Ricci tensor is a multiple of the metric tensor (possibly zero); or*
(5) *The Ricci tensor has Segre type* $\{1,(11)\}$ *and an orthogonal triad t,x,y may be chosen at m such that* $R_{ab}=\alpha(x_a x_b+y_a y_b)-\beta t_a t_b$ *and* $F_{ab}=2\mu x_{[a}y_{b]}$, $(\alpha,\beta,\mu\in\mathbb{R})$; *or*
(6) *The Ricci tensor has Segre type* $\{(1,1)1\}$ *and a null triad l,n,x may be chosen at m such that* $R_{ab}=2\alpha l_{(a}n_{b)}+\beta x_a x_b$ *and* $F_{ab}=2\mu l_{[a}n_{b]}$, $(\alpha,\beta,\mu\in\mathbb{R})$; *or*
(7) *The Ricci tensor has Segre type* $\{(21)\}$ *and a null triad l,n,x may be chosen at m such that* $R_{ab}=\alpha(2l_{(a}n_{b)}+x_a x_b)\pm l_a l_b$ *and* $F_{ab}=2\mu l_{[a}x_{b]}$, $(\alpha,\beta,\mu\in\mathbb{R})$.

Proof: The proof follows in a way sufficiently similar to those for theorems 7 and 8 for it only to be necessary to sketch it briefly. If X is homothetic then $\mathcal{L}_X R_{ab}=0$ and when computed at m this gives

$$2\phi R_{ab}+R_{ac}F^c{}_b+R_{bc}F^c{}_a=0. \tag{29}$$

If X is proper homothetic then $\phi\neq 0$ and the condition $\mathcal{L}_X R_{ab}=0$ reveals, as for Y in theorem 8, that each Ricci eigenvalue is zero at m. The proofs of parts 1–3 now follow from (29). If X is Killing, $\phi=0$, then one considers the separate cases when $F(m)$ is spacelike, timelike and null substituting the appropriate canonical forms for $F(m)$ into (29) to obtain parts 4–7. Again one notes that when X is Killing (and so m is an isometric zero of X) the blade of $F(m)$ is an eigenspace of the Ricci tensor when the latter is nonzero at m (cf. theorem 7) and hence one links the geometry of F at m with that of the canonical Ricci tensor type at m.

In the case when $X(\not\equiv 0)$ is Killing or homothetic and $X(m)=0$ the possibilities for the tensor Y at m are covered by theorems 7 (parts 2–4) and 8. □

Theorem 10: *Let M be a three-dimensional space–time, X a proper homothetic vector field on M and* $m\in M$ *a zero of X. Then either* $Y(m)$ [*and hence* $\bar{R}(m)$] *is zero or the Ricci tensor (and hence the Riemann tensor) vanishes at m.*

Proof: The proof is immediate from theorem 8 and theorem 9 parts 1–3 because of the incompatibility of the values for $F(m)$ if $Y(m)$ and the Ricci tensor at m are nonzero. □

Let X be a conformal vector field on a three-dimensional space–time M with a *homothetic* zero at m. Then if $Y(m)\neq 0$ it follows from theorem 8 that rank $X^a{}_{;b}(m)=3$. Hence, by the implicit function theorem, the zero of m at X is isolated. This result is not true for four-dimensional space–times, a counterexample being the well known plane wave metric.[19,13] It is also not true for three-dimensional space–times if the condition $Y(m)\neq 0$ is dropped. This can be seen by the following construction[20] (see also Refs. 13 and 19).

With X as above, the only possibility of m not being isolated [that is the rank of $X^a{}_{;b}(m)$ is less that 3] is, from theorems 8 and 9, when $Y(m)=0$ and when the conditions of theorem 9 (part 2) hold at m. In this case rank $X^a{}_{;b}=2$ and the condition $X^a{}_{;b}(m)n^b=0$ leads to a null geodesic of zeros of X with tangent n at m.[20] The metric, locally about m, can then be written as[20]

$$ds^2=dx^2+2\,du\,dv+f(u)x^2\,du^2 \tag{30}$$

for an arbitrary smooth function f. This metric admits the covariantly constant covector field $l_a=u_{;a}$ and the Ricci tensor satisfies $R_{ab}=-f(u)l_a l_b$. It follows from (15) that Y (and $\bar{R}$) are identically zero and the curvature tensor vanishes identically if and only if f does.[20] The vector field with components $(2v,0,x)$ is proper homothetic and its zeros are the null geodesic $x=v=0$. The bivector F and constant ϕ associated with X satisfy $F_{ab}=2\phi l_{[a}n_{b]}$ at these zeros and where n is a tangent to the corresponding null geodesic. A comparison with the four-dimensional case suggests referring to (30) as a three-dimensional plane wave and it serves as an ''example'' of theorem 10 where $Y(m)$ and $\bar{R}(m)$ vanish. Another ''example'' of this theorem arises from the metric given in a global chart v,u,x on $\mathbb{R}^3$ by[21] (see also Ref. 14)

$$ds^2 = e^{ux}\,du\,dv + dx^2. \tag{31}$$

This metric admits the proper homothetic vector field X with components $(3v,-u,x)$ and a Killing vector field $\partial/\partial v$ (and in fact $\dim C=2$). The coordinate origin is an isolated zero of X and the only nonvanishing curvature and Ricci tensor components (up to symmetries) are

$$\begin{aligned} R_{1212} &= \tfrac{1}{16}u^2 e^{2ux}, \quad R_{1223} = -\tfrac{1}{4}e^{ux}, \quad R_{1323} = -\tfrac{1}{8}u^2 e^{ux}, \\ R_{12} &= -\tfrac{1}{4}u^2 e^{ux}, \quad R_{23} = -\tfrac{1}{2}, \quad R_{33} = -\tfrac{1}{2}u^2. \end{aligned} \tag{32}$$

The Ricci tensor has Segre type {3} with zero eigenvalue at the zero (0,0,0) of X [see theorem 9 (part 3)] and it is easily checked from (15) that $\bar{R}$ (and hence Y) vanishes at this zero.

VI. THE DIMENSION OF THE CONFORMAL ALGEBRA

The Lie algebras C, H, and K of conformal, homothetic, and Killing vector fields, respectively, on M described in the last section satisfy the well known results that $\dim C \leqslant 10$, $\dim H \leqslant 7$, and $\dim K \leqslant 6$ with the optimum cases $\dim C=10$ (respectively, $\dim H=7$, $\dim K=6$) arising if $\bar{R}\equiv 0$, or equivalently $Y\equiv 0$ on M (respectively, if M is flat or M has constant curvature). In this section the values of the dimensions of these algebras will be explored under less restrictive conditions. The technique used is based on a similar one in general relativity[14,15] and depends heavily on theorems 7–9. The general idea is that when $\dim C$ exceeds the dimension of any orbit generated by C, zeros of members of C occur (in that orbit). The following theorem summarizes the present situation.

Theorem 11: *Let M be a three-dimensional space–time and let $m\in M$. Then*

(1) *If $Y(m)\neq 0 (\Leftrightarrow \bar{R}(m)\neq 0)$ then $\dim I_m \leqslant 1$ and $\dim C_m \leqslant 2$.*
(2) *If Y is of type {(21)} (N') at any point of M then $\dim C\leqslant 5$.*
(3) *If Y is of type {(1,1)1} (D_1'), type {1,(11)} (D_2') or type {3} (III') at any point of M then $\dim C \leqslant 4$.*
(4) *If Y is of type {21} (II'), type {1,11} (I_1') or type $\{z\bar{z}1\}$ (I_2') at any point of M then $\dim C \leqslant 3$.*
(5) *If Y is of type {(1,1)1} (D_1'), type {1,(11)} (D_2') or type {(21)} (N') at any point of M then $\dim K \leqslant 4$.*
(6) *If $\dim K \geqslant 5$ then M has constant curvature.*

Proof: For $Y(m)\neq 0$ the set $C(m)$, if not trivial, can (by taking appropriate linear combinations) be spanned by k independent conformal vector fields such that at least $k-1$ of them have m as an isometric zero. If $k-1>1$ then again by taking linear combinations and using theorem 7 one can find $X\in C_m$ with $\phi_m=0$ and $F(m)=0$ since all possible values of $F(m)$ are multiples of a particular bivector. The same theorem then shows that $Y(m)=0$. Thus if $Y(m)\neq 0$ then $\dim I_m \leqslant 1$ and $k=\dim C_m \leqslant 2$ since $\dim M=3$. It follows that $\dim C\leqslant 5$ or $\dim C \leqslant 4$ according as m is a homothetic zero of at least one member of C or not. Thus part 1 is proved and 2, 3, and 4 follow from theorems 7 and 8. Next, since $\dim I_m \leqslant 1$ and again taking linear combinations of members of K [and recalling that if X is Killing and $X(m)=0$, $F(m)=0$ then $X\equiv 0$ on M] part 5 follows from theorems 7 and 8. Finally if $\dim K\geqslant 5$ then theorem 7 shows that $Y\equiv 0$ on M and theorem 9 (parts 4–7) show that $R_{ab}\propto g_{ab}$ at each $m\in M$ and hence (see after theorem 2) M has constant curvature. This completes the proof. □

The above theorem shows that the conformal algebra C satisfies $\dim C \leqslant 5$ provided that Y is not identically zero on M. This result can, with a little more effort, be improved. The calculations are lengthy in places and so the proof will only be sketched with further details being available in Ref. 18.

Theorem 12: *Let M be a three-dimensional space–time which is not conformally flat. Then the conformal algebra C satisfies* $\dim C \leqslant 4$.

Proof: The previous theorem shows that $\dim C \leqslant 5$, so suppose that $\dim C = 5$. The algebra C leads to a ''generalized'' distribution Δ on M which associates with $m \in M$ the subspace $\Delta(m) = \{X(m) : X \in C\}$ of $T_p M$. Since the dimension of $\Delta(m)$ may vary with m one appeals to Hermann's generalization[22] (see also Ref. 9) of the Fröbenius theorem to obtain the existence of integral manifolds (orbits) associated with C through each $m \in M$ and whose dimension equals that of Δ_m at any m on the orbit. Now $\dim \Delta(m) + \dim C_m = \dim C = 5$ and, from theorem 10 (part 1), $\dim C_m \leqslant 2$ and so $\dim \Delta(m) = 3$ for each $m \in M$. A lengthy argument using the commutators and Jacobi relations associated with C then shows that $Y \equiv 0$ on M[18] and this contradiction completes the proof. □

The results of this section can be taken a step further. The study of the conformal algebra in any dimension possesses inherent difficulties due to its ''nonlinearity'' (see Ref. 14 for a discussion of this point). These difficulties do not arise for affine algebras (e.g., the Killing and homothetic algebras). An interesting approach to this problem was given in Ref. 23 and extended further in Ref. 24 and later in Ref. 15. These papers concerned general relativity and the essential idea, roughly speaking, was to show that under certain conditions the conformal algebra could (locally) be regarded as a Killing algebra with respect to a new metric which was conformally related to the original one. In the case of a three-dimensional space–time a similar theorem can now be stated. One interesting feature of it is the reduced number of restricting clauses compared with the corresponding four-dimensional result.[15] The proof is based on the work in the last two sections and further details can be found in Ref. 18.

Theorem 13: *Let M be a three-dimensional space–time with metric g. Suppose that the orbits associated with the conformal algebra C of M have the same dimension n at each* $m \in M$ *and, if* $n < 3$, *the same type at each* $m \in M$ [*i.e.* $\Delta(m)$ *is always spacelike, always timelike, or always null for all* $m \in M$]. *Then for* $m \in M$ *either*

(1) *There exists an open neighborhood U of m and a smooth function* $\sigma : U \to \mathbb{R}$ *such that the restrictions of members of C to U constitute a Lie algebra of Killing vector fields with respect to the metric* $e^{\sigma} g$; *or*

(2) *There exists an open neighborhood V of m on which Y vanishes; or*

(3) *The orbits are two-dimensional and null,* $C_m = I_m$, $\dim C_m = 1$, *and* $Y(m) = 0$.

(Received 9 June 1998; accepted for publication 18 November 1998)

The geodesic as well as the geodesic deviation equation for impulsive gravitational waves involve highly singular products of distributions $(\theta\delta,\theta^2\delta,\delta^2)$. A solution concept for these equations based on embedding the distributional metric into the Colombeau algebra of generalized functions is presented. Using a universal regularization procedure we prove existence and uniqueness results and calculate the distributional limits of these solutions explicitly. The obtained limits are regularization independent and display the physically expected behavior. © *1999 American Institute of Physics.* [S0022-2488(99)00903-2]

I. INTRODUCTION

Impulsive *pp*-waves (plane fronted gravitational waves with parallel rays) can be described by a metric of the form[1]

$$ds^2=\delta(u)f(x,y)du^2-du\,dv+dx^2+dy^2, \tag{1}$$

where (u,v) and (x,y) are a pair of null and (transverse) Cartesian coordinates, respectively, and f denotes the profile function subject to the field equations. Hence the space–time is flat everywhere except for the null hypersurface $u=0$, where it has a δ-like pulse modeling a gravitational shock wave. Such geometries arise most naturally as ultrarelativistic limits of boosted black hole space–times of the Kerr–Newman family (as shown by various authors[2–4]) and multipole solutions of the Weyl family.[5] Also, they play an important role in particle scattering at the Planck scale (see Ref. 6 and references therein).

There have also been intrinsic descriptions of impulsive *pp*-waves, viz. by Penrose[1] and by Dray and t'Hooft,[7] which essentially consist in glueing together two copies of Minkowski space–time with a warp across the null hypersurface $u=0$. Penrose also introduced a different coordinate system in which the components of the metric tensor are actually continuous. However, the transformation relating the coordinates used in (1) to these new ones is discontinuous (for the general form of the transformation see Ref. 8) and therefore—strictly speaking—the differential structure of the manifold is changed. In this paper we stick to the original distributional form of the metric, motivated by the fact that physically, i.e., in the ultrarelativistic limit, the space–time arises that way (cf. the approaches of Refs. 9 and 10). For recent work on *pp*-waves using the continuous form of the metric, see Ref. 11.

We describe the geometry of impulsive *pp*-waves entirely in the distributional picture using the framework of Colombeau's generalized functions, thereby generalizing previous work.[12] As discussed there in detail, the geodesic as well as the geodesic deviation equation for impulsive *pp*-waves involve formally ill-defined products of distributions, due to the nonlinearity of the equations and the presence of the Dirac δ-function in the space–time metric. However, as was also shown in Ref. 12, one can overcome these difficulties using a careful regularization procedure

[a)]Electronic mail: Michael.Kunzinger@univie.ac.at
[b)]Electronic mail: stein@doppler.thp.univie.ac.at

which, while mathematically sound, corresponds to the physical idea of viewing the impulsive wave as the limiting case of a sandwich wave of ever decreasing support but constant (integrated) strength. More precisely, regularizing the δ-distribution by a ''model δ-net'' [i.e., a net $\rho_\epsilon(x) := \epsilon^{-1}\rho(x\epsilon^{-1})$, where ρ is a smooth function with support contained in the interval $[-1,1]$ satisfying $\int\rho = 1$], it was shown that the solutions to the smoothened equations possess regularization-independent weak limits. These distributional ''solutions'' fit perfectly into the physically expected picture showing that the geometry of impulsive *pp*-waves can be described consistently using the distributional form of the metric. The reliability of the results is guaranteed by making use of regularization techniques instead of introducing ''multiplication rules'' into Schwartz linear distribution theory (cf. the discussion at the end of Sec. 2 in Ref. 12 or Ref. 13 for general remarks).

However, the ''solutions'' obtained by this naive regularization procedure exhibit a mathematically highly unsatisfactory feature. *They do not obey the original distributional equations* (unless, again, one is willing to impose certain ''multiplication rules''), as is common to such situations. Hence—strictly speaking—this approach does not provide a reasonable solution concept for the equations under consideration. Such a notion *is* available in the nonlinear theory of generalized functions[14–16] due to J. F. Colombeau, where one has—loosely speaking—a rigorous system of bookkeeping on the regularizing sequences. Recently Hermann and Oberguggenberger[17] (see also Ref. 18) studied systems of singular, nonlinear ordinary differential equations (ODEs) in the Colombeau algebra. In this work we are going to use similar techniques to treat the geodesic and geodesic deviation equation for impulsive *pp*-waves in the Colombeau algebra. Despite the nonlinearities involved in these equations (which in principle could lead to trapping, blow-up or reflection of solutions at the shock, cf. Ref. 17), we are able to prove existence and uniqueness of geodesics crossing the shock hypersurface. We derive the (regularization independent) distributional limits of these solutions, making use of the notion of association (see Sec. II below) in the algebra, thereby significantly generalizing the results of Ref. 12. In particular, the regularization of the δ-like wave profile will no longer be restricted to a ''model δ-net'' but belong to the largest ''reasonable'' class (cf. Definition 1 below). Moreover, note that the regularization idependence of the results has the following important physical consequence: in the impulsive limit the geodesics are totally independent of the particular shape of the sandwich wave. Hence the impulsive wave ''totally forgets its seed'' (cf. also the results in Ref. 19).

Finally, we discuss the case of a nonsmooth wave profile f and give an outlook to current research which allows us to fit our previous calculations into a manifestly covariant concept of Colomebeau algebras on manifolds.

II. MATHEMATICAL FRAMEWORK

A framework that allows consistent treatment of nonlinear operations with distributions and at the same time offers a well-developed theory of (linear and nonlinear) partial differential equations is provided by Colombeau's theory of algebras of generalized functions (cf., e.g., Refs. 14–16 and 20). To begin with, we give a short description of the algebra we are going to use in the sequel. Let

$$\mathcal{A}_0(\mathbb{R}^n) = \left\{ \varphi \in \mathcal{D}(\mathbb{R}^n) : \int \varphi(x)\,dx = 1 \right\},$$

$$\mathcal{A}_q(\mathbb{R}^n) = \left\{ \varphi \in \mathcal{A}_0(\mathbb{R}^n) : \int \varphi(x) x^\alpha dx = 0, 1 \leq |\alpha| \leq q \right\} (q \in \mathbb{N}),$$

and set (for any $\Omega \subseteq \mathbb{R}^n$ open)

$$\mathcal{E}(\Omega)=\{R:\mathcal{A}_0(\mathbb{R}^n)\times\Omega\to\mathbb{C}:x\to R(\varphi,x)\in\mathcal{C}^\infty(\Omega)\forall\varphi\in\mathcal{A}_0(\mathbb{R}^n)\},$$

$$\mathcal{E}_M(\Omega)=\{u\in\mathcal{E}(\Omega):\forall K\subset\subset\Omega\forall\alpha\in\mathbb{N}_0^n\exists p\in\mathbb{N}_0\forall\varphi\in\mathcal{A}_p(\mathbb{R}^n)$$
$$\exists c>0\exists\eta>0\sup_{x\in K}|\partial^\alpha u(\varphi_\varepsilon,x)|\leqslant c\varepsilon^{-p}(0<\varepsilon<\eta)\},$$

$$\mathcal{N}(\Omega)=\{u\in\mathcal{E}(\Omega):\forall K\subset\subset\Omega\forall\alpha\in\mathbb{N}_0^n\exists p\in\mathbb{N}_0\exists\gamma\in\Gamma\forall q\geqslant p\forall\varphi\in\mathcal{A}_q(\mathbb{R}^n)$$
$$\exists c>0\exists\eta>0\sup_{x\in K}|\partial^\alpha u(\varphi_\varepsilon,x)|\leqslant c\varepsilon^{\gamma(q)-p}(0<\varepsilon<\eta)\},$$

where $\Gamma=\{\gamma:\mathbb{N}_0\to\mathbb{R}_+ : \gamma \text{ strictly increasing}, \lim_{n\to\infty}\gamma(n)=\infty\}$. Derivation ∂^α is carried out with respect to x, while the φ are treated as parameters. Also, for $\varphi\in\mathcal{D}(\mathbb{R}^n)$, $\varphi_\varepsilon(x)=\varepsilon^{-n}\varphi(x/\varepsilon)$. Note that $\varphi_\varepsilon\to\delta$ in $\mathcal{D}'(\mathbb{R}^n)$.

Elements of $\mathcal{E}_M(\Omega)$ are called of *moderate growth*. With pointwise operations $\mathcal{E}_M(\Omega)$ is a differential algebra and $\mathcal{N}(\Omega)$ is an ideal in $\mathcal{E}_M(\Omega)$. The quotient algebra

$$\mathcal{G}(\Omega)=\mathcal{E}_M(\Omega)/\mathcal{N}(\Omega)$$

is called the *Colombeau algebra* over $\Omega\subseteq\mathbb{R}^n$. Elements of $\mathcal{G}(\Omega)$ will be denoted by $R=\mathrm{cl}[(R(\varphi,.))_{\varphi\in\mathcal{A}_0}]$ where $(R(\varphi,.))_{\varphi\in\mathcal{A}_0}$ is an arbitrary representative of R (again emphasizing the fact that the φ's are viewed as parameters).

For $\Omega=\mathbb{R}^n$ the map

$$\iota:\mathcal{E}'(\Omega)\to\mathcal{G}(\Omega),$$

$$w\to\mathrm{cl}[(w*\varphi)_{\varphi\in\mathcal{A}_0}]$$

(where $*$ denotes convolution) is a linear embedding commuting with partial derivatives and coinciding with the identical embedding $f\to\mathrm{cl}[(f)_{\varphi\in\mathcal{A}_0}]$ on $\mathcal{D}(\mathbb{R}^n)$.

Here $\mathcal{G}$ is a fine sheaf of differential algebras on $\mathbb{R}^n$ and there is a unique sheaf morphism $\hat{\iota}:\mathcal{D}'\to\mathcal{G}$ coinciding with ι on every $\mathcal{E}'(\Omega)$ and rendering $\mathcal{C}^\infty(\Omega)$ a faithful subalgebra of $\mathcal{G}(\Omega)$. From the definitions it is clear that any element of $\mathcal{G}(\Omega)$ is uniquely determined by the values of any representative on φ_ε for $\varphi\in\mathcal{A}_p$ with p arbitrarily large and ε arbitrarily small (i.e., by its ''germ''), a fact that turns out to be very helpful, e.g., in constructing solutions to differential equations in $\mathcal{G}$.

Inserting points into elements of $\mathcal{G}(\mathbb{R}^n)$ gives elements of the ring of generalized numbers $\overline{\mathbb{C}}(n)$, defined as $\overline{\mathbb{C}}(n)=\mathcal{E}(n)/\mathcal{N}(n)$, where

$$\mathcal{E}(n)=\{u:\mathcal{A}_0(\mathbb{R}^n)\to\mathbb{C}:\exists p\in\mathbb{N}_0\forall\varphi\in\mathcal{A}_p(\mathbb{R}^n)\exists c>0\exists\eta>0|u(\varphi_\varepsilon)|\leqslant c\varepsilon^{-p}(0<\varepsilon<\eta)\},$$

$$\mathcal{N}(n)=\{u:\mathcal{A}_0(\mathbb{R}^n)\to\mathbb{C}:\exists p\in\mathbb{N}_0\exists\gamma\in\Gamma\forall q\geqslant p\forall\varphi\in\mathcal{A}_q(\mathbb{R}^n)$$
$$\exists c>0\exists\eta>0|u(\varphi_\varepsilon)|\leqslant c\varepsilon^{\gamma(q)-p}(0<\varepsilon<\eta)\}.$$

Thus elements of $\mathcal{G}(\mathbb{R}^n)$ take values in $\overline{\mathbb{C}}(n)$. Explicit dependence of the ring of constants on n can be avoided by a more refined construction of the sets $\mathcal{A}_q$ in the definition of $\mathcal{G}$ (see Ref. 20). Clearly, $\mathbb{C}\hookrightarrow\overline{\mathbb{C}}$ via the canonical embedding $c\to\mathrm{cl}[(c)_{\varphi\in\mathcal{A}_0}]$.

Componentwise insertion of $R\in\mathcal{G}$ into a smooth function f yields a well-defined element $f(R)$ of $\mathcal{G}$ if f is *slowly increasing*, i.e., if all derivatives of f are polynomially bounded. Moreover, if R is *locally bounded*, i.e., if it possesses a representative such that $R(\varphi_\varepsilon,.)$ is bounded uniformly in ε on compact sets [for $\varphi\in\mathcal{A}_p(\mathbb{R}^n)$, p large], then $f\circ R$ exists for any smooth f.

Finally, we mention the notion of *association* in $\mathcal{G}(\Omega)$:$R_1, R_2 \in \mathcal{G}(\Omega)$ are called associated to each other ($R_1 \approx R_2$) if there exists some $p \in \mathbb{N}$ such that $R_1(\varphi_\varepsilon,.) - R_2(\varphi_\varepsilon,.) \to 0$ in $\mathcal{D}'(\Omega)$ as $\varepsilon \to 0$ for all $\varphi \in \mathcal{A}_p(\mathbb{R}^n)$. In particular, if $R_2 \in \mathcal{D}'(\Omega)$, then R_2 is called the macroscopic aspect (or *distributional shadow*) of R_1. Equality in $\mathcal{D}'$ is reflected as equality in the sense of association in $\mathcal{G}$, while equality in $\mathcal{G}$ is a stricter concept (for example, all powers of the Heaviside function are distinct in the Colombeau algebra although they are associated with each other).

III. EXACT SOLUTIONS OF GEODESIC AND GEODESIC DEVIATION EQUATIONS

As in Ref. 12 we consider the impulsive *pp*-wave metric

$$ds^2 = f(x^i)\,\delta(u)\,du^2 - du\,dv + (dx^i)^2, \tag{2}$$

where f is a smooth function of the transverse coordinates $x^i (i=1,2)$. Our aim is to derive solutions to the corresponding geodesic and geodesic deviation equations in the Colombeau algebra.

The general strategy for solving differential equations in $\mathcal{G}$ is to embed singularities (in our case: δ) into $\mathcal{G}$ which amounts to a regularization and then solve the corresponding regularized equations. In order to obtain general results we are therefore interested in imposing as few restrictions as possible on the regularization of δ. The largest ''reasonable'' class of smooth regularizations of δ is given by nets $(\rho_\varepsilon)_{\varepsilon \in (0,1)}$ of smooth functions ρ_ε satisfying

$$\text{(a)} \quad \text{supp}(\rho_\varepsilon) \to \{0\} \quad (\varepsilon \to 0),$$

$$\text{(b)} \quad \int \rho_\varepsilon(x)\,dx \to 1 \quad (\varepsilon \to 0), \ \text{and}$$

$$\text{(c)} \quad \exists\, \eta > 0\, \exists\, C \geqslant 0 : \int |\rho_\varepsilon(x)|\,dx \leqslant C\, \forall \varepsilon \in (0,\eta)$$

(cf. the definition of *strict delta nets* in Ref. 16, Chap. 2.7). [Note that since $\mathcal{D}$ is dense in L^1 practically even discontinuous regularizations (e.g., boxes) are included.] Obviously any such net converges to δ in distributions as $\varepsilon \to 0$. To simplify notations it is often convenient to replace (a) by

$$\text{(a}'\text{)} \quad \text{supp}(\rho_\varepsilon) \subseteq [-\varepsilon, \varepsilon] \quad \forall \varepsilon \in (0,1).$$

This motivates the following (cf. Ref. 17)

Definition 1: A generalized delta function *is an element D of* $\mathcal{G}(\mathbb{R}^n)$ *possessing a representative* $(D(\varphi,.))_{\varphi \in \mathcal{A}_0}$ *such that* $\exists\, p \in \mathbb{N}_0 \forall \varphi \in \mathcal{A}_p(\mathbb{R}^n) \exists\, \eta = \eta(\varphi) > 0$:

$$\text{(i)} \quad \text{supp}(D(\varphi_\varepsilon,.)) \subseteq [-\varepsilon, \varepsilon]\, \forall \varepsilon \in (0,\eta),$$

$$\text{(ii)} \quad \int D(\varphi_\varepsilon, x)\,dx \to 1 (\varepsilon \to 0),$$

$$\text{(iii)} \quad \exists\, C = C(\varphi) > 0 \ \text{such that} \ \int |D(\varphi_\varepsilon, x)|\,dx \leqslant C\, \forall \varepsilon \in (0,\eta).$$

The canonical embedding $R = \iota(\delta)$ of course falls into this class, but clearly there are many generalized delta functions that do not correspond to any distribution via ι. Moreover, every generalized delta function is associated to δ, i.e., all generalized delta functions equal δ on the distributional level. In a sense, they may be viewed as ''delta distributions with a more refined microstructure'' (fixing the additional nonlinear properties of the singularity).

Again, condition (i) in Definition 1 has been chosen in order to avoid technicalities in the proofs of the following results, which, however, remain true if (i) is replaced by

$$(i') \quad \mathrm{supp}(R(\varphi_\varepsilon,.))\to\{0\} \quad (\varepsilon\to 0).$$

Finally, we need the following technical preparation (which is actually a generalization of appendix A of Ref. 12).

Lemma 1: Let $g:\mathbb{R}^n\to\mathbb{R}^n$, $h:\mathbb{R}\to\mathbb{R}^n$ *smooth and let* $(\rho_\varepsilon)_{\varepsilon\in(0,1)}$ *be a net of smooth functions satisfying* (a') *and (c). For any* x_0, $\dot{x}_0\in\mathbb{R}^n$ *and any* $\varepsilon\in(0,1)$ *consider the system*

$$\begin{aligned}\ddot{x}_\varepsilon(t)&=g(x_\varepsilon(t))\rho_\varepsilon(t)+h(t),\\ x_\varepsilon(-1)&=x_0,\\ \dot{x}_\varepsilon(-1)&=\dot{x}_0.\end{aligned} \tag{3}$$

Let $b>0$, $M=\int_{-1}^{1}\int_{-1}^{s}|h(r)|drds$, $I=\{x\in\mathbb{R}^n:|x-x_0|\le b+|\dot{x}_0|+M\}$ *and* $\alpha=\min\{b/(C\|g\|_{L^\infty(I)}+|\dot{x}_0|),1/2LC,1\}$ *with L a Lipschitz constant for g on I. Then (3) has a unique solution on* $J_\varepsilon=[-1,\alpha-\varepsilon]$. *Consequently, for* ε *sufficiently small,* x_ε *is globally defined and both* x_ε *and* $\dot{x}_\varepsilon$ *are bounded, uniformly in* ε, *on compact sets.*

Proof: The operator $f\to Af$,

$$Af(t)=x_0+\dot{x}_0(t+1)+\int_{-1}^{t}\int_{-1}^{s}g(f(r))\rho_\varepsilon(r)drds+\int_{-1}^{t}\int_{-1}^{s}h(r)drds,$$

is a contraction on the complete metric space

$$\{f\in C(J_\varepsilon,\mathbb{R}^n):|f(t)-x_0|\le b+M+|\dot{x}_0|\}.$$

□

Let us now turn to the geodesic equation for the *pp*-wave metric (2). Using u as an affine parameter (which excludes trivial geodesics parallel to the shock) we obtain (cf. Ref. 12)

$$\begin{aligned}\ddot{v}(u)&=f(x^i(u))\,\dot{\delta}(u)+2\,\partial_i f(x^i(u))\dot{x}^i(u)\,\delta(u),\\ \ddot{x}^i(u)&=\tfrac{1}{2}\partial_i f(x^i(u))\,\delta(u).\end{aligned} \tag{4}$$

Since all operations appearing in (4) are well defined in $\mathcal{G}$ (cf. the remarks following Theorem 1 below), we may seek solutions of the corresponding initial value problem in the Colombeau algebra by embedding $\delta(u)$ into $\mathcal{G}$. In fact, it turns out that for *any* generalized delta function there exists a unique solution. Denoting the generalized functions corresponding to x^i and v by capital letters we state the following.

Theorem 1: *Let* $D\in\mathcal{G}(\mathbb{R})$ *be a generalized delta function,* $f\in\mathcal{C}^\infty(\mathbb{R}^2)$ *and let* v_0, $\dot{v}_0$, x_0^i, $\dot{x}_0^i\in\mathbb{R}$ $(i=1,2)$. *The initial value problem,*

$$\begin{aligned}\ddot{V}(u)&=f(X^i(u))\dot{D}(u)+2\,\partial_i f(X^i(u))\dot{X}^i(u)D(u),\\ \ddot{X}^i(u)&=\tfrac{1}{2}\partial_i f(X^i(u))D(u),\\ V(-1)&=v_0, \quad X^i(-1)=x_0^i,\\ \dot{V}(-1)&=\dot{v}_0, \quad \dot{X}^i(-1)=\dot{x}_0^i,\end{aligned} \tag{5}$$

has a unique locally bounded solution $(V,X^1,X^2)\in\mathcal{G}(\mathbb{R})^3$.

Note that we impose initial conditions in $u=-1$, i.e., ''long before'' the shock. Choosing initial conditions at $u=0$ would mean to start ''at the shock,'' which inevitably leads to regularization-dependent weak limits.

Proof: Existence: Choose $p\in\mathbb{N}$ as in Definition 1, fix $\varphi\in\mathcal{A}_p(\mathbb{R}^n)$ and let $\varepsilon<\eta(\varphi)$. Then componentwise we obtain the equations

$$\begin{aligned}
\ddot{V}(\varphi_\varepsilon,u)&=f(X^i(\varphi_\varepsilon,u))\dot{D}(\varphi_\varepsilon,u)+2\partial_i f(X^i(\varphi_\varepsilon,u))\dot{X}^i(\varphi_\varepsilon,u)D(\varphi_\varepsilon,u),\\
\ddot{X}^i(\varphi_\varepsilon,u)&=\tfrac{1}{2}\partial_i f(X^i(\varphi_\varepsilon,u))D(\varphi_\varepsilon,u),\\
V(\varphi_\varepsilon,-1)&=v_0,\quad X^i(\varphi_\varepsilon,-1)=x_0^i,\\
\dot{V}(\varphi_\varepsilon,-1)&=\dot{v}_0,\quad \dot{X}^i(\varphi_\varepsilon,-1)=x_0^i.
\end{aligned}\tag{6}$$

According to Lemma 1, the second line of (6) has a unique globally defined solution $X^i(\varphi_\varepsilon,.)$ with the specified initial values. Inserting this into the first line and integrating we also obtain a solution $V(\varphi_\varepsilon,.)$. From the boundedness properties of $X^i(\varphi_\varepsilon,.)$ established in Lemma 1 and the fact that $(D(\varphi,.))_{\varphi\in\mathcal{A}_0}\in\mathcal{E}_M(\mathbb{R})$ it follows easily by induction that $(X^i(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}$ and $(V(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}$ are moderate as well. Hence their respective classes in $\mathcal{G}(\mathbb{R})$ define solutions to (5).

Uniqueness: Suppose that $V_1=\mathrm{cl}[(V_1(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}]$ and $X_1^i=\mathrm{cl}[(X^i(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}]$ are locally bounded solutions of (5) as well. On the level of representatives this means that there exist $M=\mathrm{cl}[(M(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}]$, $N^i=\mathrm{cl}[(N^i(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}]\in\mathcal{N}(\mathbb{R})$ and n_{x^i}, $n_{\dot{x}^i}$, n_v, $n_{\dot{v}}\in\mathcal{N}(1)$ with

$$\begin{aligned}
\ddot{V}_1(\varphi_\varepsilon,u)&=f(X_1^i(\varphi_\varepsilon,u))\dot{D}(\varphi_\varepsilon,u)+2\partial_i f(X_1^i(\varphi_\varepsilon,u))\dot{X}_1^i(\varphi_\varepsilon,u)D(\varphi_\varepsilon,u)+M(\varphi_\varepsilon,u),\\
\ddot{X}_1^i(\varphi_\varepsilon,u)&=\tfrac{1}{2}\partial_i f(X_1^i(\varphi_\varepsilon,u))D(\varphi_\varepsilon,u)+N^i(\varphi_\varepsilon,u),\\
V_1(\varphi_\varepsilon,-1)&=v_0+n_v(\varphi_\varepsilon),\quad X_1^i(\varphi_\varepsilon,-1)=x_0^i+n_{x^i}(\varphi_\varepsilon),\\
\dot{V}_1(\varphi_\varepsilon,-1)&=\dot{v}_0+n_{\dot{v}}(\varphi_\varepsilon),\quad \dot{X}_1^i(\varphi_\varepsilon,-1)=\dot{x}_0^i+n_{\dot{x}^i}(\varphi_\varepsilon).
\end{aligned}\tag{7}$$

We have to show that $((V-V_1)(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}$ and $((X^i-X_1^i)(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}$ belong to the ideal $\mathcal{N}(\mathbb{R})$. Since $N^i\in\mathcal{N}(\mathbb{R})$ it follows that for p sufficiently large, ε small and $\varphi\in\mathcal{A}_p(\mathbb{R})$, $N^i(\varphi_\varepsilon,.)$ is bounded on compact sets, uniformly in ε. Thus by Lemma 1 the same holds true for $X_1^i(\varphi_\varepsilon,.)$ and its first derivative. From (7) we conclude

$$\begin{aligned}
(X^i-X_1^i)(\varphi_\varepsilon,u)=&-n_{x^i}(\varphi_\varepsilon)-(u+1)n_{\dot{x}^i}(\varphi_\varepsilon)+\frac{1}{2}\int_{-1}^{u}\int_{-1}^{s}D(\varphi_\varepsilon,r)[\partial_i f(X^i(\varphi_\varepsilon,r))\\
&-\partial_i f(X_1^i(\varphi_\varepsilon,r))]drds-\int_{-1}^{u}\int_{-1}^{s}N(\varphi_\varepsilon,r)drds.
\end{aligned}$$

Hence $\forall T>0\,\exists p\in\mathbb{N}_0\,\exists\gamma\in\Gamma\,\forall q\geqslant p\,\forall\varphi\in\mathcal{A}_q(\mathbb{R})\,\exists C>0\,\exists\eta>0\,\forall\varepsilon\in(0,\eta)\,\forall u\in[-T,T]$:

$$\begin{aligned}
|(X^i-X_1^i)(\varphi_\varepsilon,u)|\leqslant C\varepsilon^{\gamma(q)-p}+\frac{1}{2}\int_{-1}^{u}\int_{-r}^{u}\int_0^1|\nabla\partial_i f(\sigma X^i(\varphi_\varepsilon,r))\\
+(1-\sigma)X_1^i(\varphi_\varepsilon,r))|d\sigma|(X^i-X_1^i)(\varphi_\varepsilon,r)||D(\varphi_\varepsilon,r)|dsdr.
\end{aligned}\tag{8}$$

By the boundedness properties of X^i and X_1^i and by (*iii*), an application of Gronwall's lemma to the above inequality yields the $\mathcal{N}$-estimates of order 0 for $(X^i-X_1^i)$. A similar argument applies to the first derivatives. The estimates of higher order then follow inductively from the differential equation, so $((X^i - X^i_1)(\varphi_\varepsilon,.))_{\varphi\in\mathcal{A}_0}\in\mathcal{N}(\mathbb{R})$. Inserting this into the integral equation for $(V - V_1)$, the $\mathcal{N}$-estimates for $(V-V_1)$ also follow inductively. □

In the proof of Theorem 1 we have only made use of properties (*i*) and (*iii*) of the generalized delta function *D*. On the other hand, property (*ii*) will be essential for the explicit calculation of distributional limits of the unique solution constructed in Theorem 1, cf. Sec. IV. Also, note that we did not have to impose any growth restrictions on *f* to obtain a well-defined element $f(X^i)$ of $\mathcal{G}$. This is of course due to the fact that any componentwise solution of the initial value problem necessarily is bounded, uniformly in ε, on compact sets (for ε small). Our next goal is an analysis of the Jacobi equation for impulsive *pp*-waves in the framework of algebras of generalized functions. As in Ref. 12 to keep formulas more transparent we make some simplifying assumptions concerning geometry (namely axisymmetry) and initial conditions. Writing $x=x^1$ and $y=x^2$ we suppose that *f* depends exclusively on the two-radius $\sqrt{x^2+y^2}$ and work within the hypersurface $y=0$ (corresponding to initial conditions $y_0=0=\dot{y}_0$). Furthermore, we demand $v_0=0=\dot{x}_0$. As was shown in Ref. 12, in this situation the Jacobi equation

$$\frac{D^2N^\alpha}{dt^2}=-R^a_{bcd}T^bT^dN^c,$$

where $N^a(u)=(N^u(u),N^v(u),N^x(u),N^y(u))$ denotes the deviation vector field, takes the form

$$\ddot{N}^v=2[N^xf'(x)\delta]^{\cdot}-N^xf'(x)\dot{\delta}+[N^uf(x)\delta]^{\cdot\cdot}-N^uf''(x)\dot{x}^2\delta-N^uf'(x)\ddot{x}\delta,$$

$$\ddot{N}^x=[\dot{N}^uf'(x)+\tfrac{1}{2}N^xf''(x)]\delta+\tfrac{1}{2}f'(x)N^u\dot{\delta}, \tag{9}$$

$$\ddot{N}^y=\ddot{N}^u=0,$$

where *x* is determined by (4). Existence and uniqueness of solutions to the corresponding initial value problem in the Colombeau algebra is established in the following result where, for the sake of brevity, we denote the $\mathcal{G}$-functions corresponding to N^a again by N^a.

Theorem 2: *Let $D\in\mathcal{G}(\mathbb{R})$ be a generalized delta function, $f\in\mathcal{C}^\infty(\mathbb{R})$, n^a, $\dot{n}^a\in\mathbb{R}^4$, and let X denote the (unique) solution to system (5) with initial conditions and simplifications as discussed above. The initial value problem*

$$\ddot{N}^v=2[N^xf'(X)D]^{\cdot}-N^xf'(X)\dot{D}+[N^uf(X)D]^{\cdot\cdot}-N^uf''(X)\dot{X}^2D-N^uf'(X)\ddot{X}D,$$

$$\ddot{N}^x=[\dot{N}^uf'(X)+\tfrac{1}{2}N^xf''(X)]D+\tfrac{1}{2}f'(X)N^u\dot{D},$$

$$\ddot{N}^y=\ddot{N}^u=0, \tag{10}$$

$$N^a(-1)=n^a,\quad \dot{N}^a(-1)=\dot{n}^a.$$

has a unique solution $N^a\in\mathcal{G}(\mathbb{R})^4$.

Proof: Since the equations are linear in the components of the deviation field we are provided with globally defined solutions on the level of representatives. The last two equations are actually trivial and so is the first one once we know that its right-hand side belongs to $\mathcal{G}(\mathbb{R})$. Hence we are left with the equation for N^x which is of the form $\ddot{N}(t)=f''(X(t))D(t)N(t)+H(t)$ with *H* in $\mathcal{G}(\mathbb{R})$. Using the boundedness properties of *X* established in Lemma 1 the $\mathcal{E}_M$-bounds for N^x easily follow from Gronwall's lemma.

Uniqueness is established along the same lines again using Gronwall-type arguments. □

In the above proof we have again only used properties (*i*) and (*iii*) of the generalized delta function *D*.

To conclude this section we remark that unique solvability of the geodesic and geodesic deviation equation for (2) is not confined to the case where the profile function *f* is smooth. Indeed, it turns out that for a large class of generalized profile functions (those that are not ''too singular'') Theorems 1 and 2 retain their validity. More precisely, we have to demand that f belongs to the algebra of *tempered* generalized functions[15] to make sure that the composition $f(X)$ is well defined and that $\nabla\nabla f$ is of L^∞-log-type[17,18] to ensure existence and uniqueness of solutions to (5) and (10). However, to include many physically interesting examples (cf. Ref. 21), one has to cut out the worldline of the ultrarelativistic particle, i.e., the v-axis from the domain of definition (cf. Ref. 22).

IV. DISTRIBUTIONAL LIMITS

In this section we are going to calculate the distributional limits (or, in the terminology of Colombeau theory, the associated distributions) of the unique solutions to the geodesic and geodesic deviation equation constructed in Theorems 1 and 2. In Ref. 12 distributional limits for regularized versions of these equations have been calculated using a model delta net regularization. Translated into our current setting this amounts to using the particular generalized delta function $D=\iota(\delta)$. Our aim is to extend the validity of the limit relations derived there to the case of solutions in the Colombeau algebra and to generalized delta functions. At the same time we will be able to prove stronger convergence results in some cases.

Theorem 3: *The unique solution* (V,X^i) *of the geodesic equation (5) satisfies the following association relations:*

$$X^i\approx x_0^i+\dot{x}_0^i(1+u)+\tfrac{1}{2}\partial_i f(x_0^i+\dot{x}_0^i)u_+\,, \tag{11}$$

$$V\approx v_0+\dot{v}_0(1+u)+f(x_0^i+\dot{x}_0^i)\,\theta(u)+\partial_i f(x_0^i+\dot{x}_0^i)(\dot{x}_0^i+\tfrac{1}{4}\partial^i f(x_0^i+\dot{x}_0^i))u_+\,. \tag{12}$$

In addition, if $X^i=\mathrm{cl}[(X^i(\varphi,.))_{\varphi\in\mathcal{A}_0}]$, *then* $\exists p\in\mathbb{N}_0$ *such that* $\forall\varphi\in\mathcal{A}_p$

$$X^i(\varphi_\varepsilon,u)\rightarrow x_0^i+\dot{x}_0^i(1+u)+\tfrac{1}{2}\partial_i f(x_0^i+\dot{x}_0^i)u_+ \tag{13}$$

for $\varepsilon\rightarrow 0$, *uniformly on compact subsets of* $\mathbb{R}$.

Proof: Choose $p\in\mathbb{N}_0$ as in Definition 1 for D. Let $\varphi\in\mathcal{A}_p$ and $\varepsilon<\eta(\varphi)$. Since integrating amounts to convolution with the Heaviside function, which is a continuous operation on the convolution algebra of distributions supported in a cone, in order to prove (11) it suffices to show that

$$\ddot{X}^i(\varphi_\varepsilon,.)=\tfrac{1}{2}\partial_i f(X^i(\varphi_\varepsilon,.))D(\varphi_\varepsilon,.)\rightarrow\tfrac{1}{2}\partial_i f(x_0^i+\dot{x}_0^i)\,\delta$$

in distributions. We first note that $X(\varphi_\varepsilon,\varepsilon t)\rightarrow x_0^i+\dot{x}_0^i$ uniformly as can be seen from the integral equation for X^i [cf. (11) in Ref. 12]. Now if $\psi\in\mathcal{D}(\mathbb{R})$, then

$$\left|\int_{-\epsilon}^{\epsilon}\psi(t)\partial_i f(X^i(\varphi_\varepsilon,t))D(\varphi_\varepsilon,t)dt-\partial_i f(x_0^i+\dot{x}_0^i)\psi(0)\right|$$

$$\leqslant\sup_{-\epsilon\leqslant t\leqslant\epsilon}|\psi(t)\partial_i f(X^i(\varphi_\epsilon,t))-\partial_i f(x_0^i+\dot{x}_0^i)\psi(0)|\int_{-\epsilon}^{\epsilon}|D(\varphi_\epsilon,t)|dt$$

$$+\int_{-\epsilon}^{\epsilon}|D(\varphi_\epsilon,t)dt-1|\partial_i f(x_0^i+\dot{x}_0^i)\psi(0).$$

So the claim follows from properties (*iii*) and (*ii*) of the generalized delta function D. Since $\dot{X}^i(\varphi_\varepsilon,t)$ is bounded on compact sets, uniformly in ε, it follows that the family $\{X^i(\varphi_\varepsilon,t):\varepsilon\in(0,1)\}$ is locally equicontinuous. Hence Ascoli's Theorem implies (13). Concerning (12), as above it suffices to calculate the limit of

$$\ddot{V}(\varphi_\varepsilon,u)=[f(X^i(\varphi_\varepsilon,u))D(\varphi_\varepsilon,u)]^{\cdot}+\partial_i f(X^i(\varphi_\varepsilon,u))\dot{X}^i(\varphi_\varepsilon,u)D(\varphi_\varepsilon,u),$$

whose first summand converges to $f(x_0^i+\dot{x}_0^i)\dot{\delta}$ by an argument similar to the one above. For the second summand we have

$$\partial_i f(X^i(\varphi_\varepsilon,u))\dot{X}^i(\varphi_\varepsilon,u)D(\varphi_\varepsilon,u)=\underbrace{\partial_i f(X^i(\varphi_\varepsilon,u))D(\varphi_\varepsilon u)\dot{x}_0^i}_{(*)}$$
$$+\frac{1}{2}\partial_i f(X^i(\varphi_\varepsilon,u))D(\varphi_\varepsilon,u)\int_{-\varepsilon}^{t}\partial_i f(X^i(\varphi_\varepsilon,s))D(\varphi_\varepsilon,s)ds$$

and $(*)\to\partial_i f(x_0^i+\dot{x}_0^i)\dot{x}_0^i\delta.$ Finally, since

$$\int_{-\varepsilon}^{\varepsilon}\psi(t)\partial_i f(X^i(\varphi_\varepsilon,t))D(\varphi_\varepsilon,t)\int_{-\varepsilon}^{t}\partial_i f(X^i(\varphi_\varepsilon,s))D(\varphi_\varepsilon,s)ds\,dt$$
$$-\frac{1}{2}\partial_i f(x_0^i+\dot{x}_0^i)^2\psi(0)\int_{-\varepsilon}^{\varepsilon}D(\varphi_\varepsilon,t)dt\to 0,$$

the claim follows. □

In calculating distributional limits for the solution of the Jacobi equation to maintain the clarity of formulas, we shall make simplifying assumptions on the initial conditions, i.e.,

$$N^a(-1)=(0,0,0,0),$$
$$\dot{N}^a(-1)=(a,b,0,0). \tag{14}$$

Then we have the following.

Theorem 4: *The unique solution of the geodesic deviation equation (10) satisfies the following association relations:*

$$N^x\approx\tfrac{1}{2}af'(x_0)(u_+ +\theta(u)), \tag{15}$$

$$N^v\approx b(1+u)+a[f(x_0)\delta(u)+\tfrac{1}{4}f'(x_0)^2(\theta(u)+u_+)]. \tag{16}$$

Proof: The general structure of this proof is ''isomorphic'' to the calculation of distributional limits for the regularized Jacobi equation in Ref. 12. The main difference is that, for representatives of generalized delta functions, dominated convergence arguments are not applicable, which makes the calculations more tedious. Nevertheless, using the uniform convergence of $X^i(\varphi_\varepsilon,.)$ established above, all steps carried out in Ref. 12 can be adapted to the present situation as demonstrated in the proof of Theorem 3. □

V. DISCUSSION AND OUTLOOK

In the previous section we have shown that the unique solutions to the geodesic and geodesic deviation equation in the Colombeau algebra possess a physically reasonable macroscopic (i.e., distributional) aspect: even within the natural maximal class of delta-regularizations (namely the class of all generalized delta functions) the regularity of the equations is sufficiently high to ensure distributional limits corresponding to physical expectations. More precisely, from the distributional point of view, the geodesics correspond to refracted, broken straight lines as suggested by the form of the metric. The scale of the jump and kink is given by the values of f and its first derivatives at the shock hypersurface, which can be traced back to the values at the initial point $(u=-1)$, thereby precisely reproducing Penrose's junction conditions.[1] The distributional limit of the Jacobi field suffers a kink and jump in the x-direction as well as an additional δ-pulse in the v-direction, which may be understood from the form of the geodesics. For a more detailed discussion, see Ref. 12.

Finally we make some comments on diffeomorphism invariance of our results. Whereas the fine sheaf of Colombeau algebras can be lifted to manifolds in a straightforward manner, the action of a diffeomorphism does not commute with the canonical embedding $\mathcal{D}' \hookrightarrow \mathcal{G}$. The reason for this is that convolution relies on the additive group structure of $\mathbb{R}^n$ and is therefore not invariant under the action of diffeomorphisms. Note, however, that our calculations did not use the embedding via convolution and therefore are not affected by this defect.

A solution to the above mentioned problem was proposed in Ref. 23 using a modified definition of the mollifier spaces $\mathcal{A}_q$. A key ingredient of this construction is that diffeomorphisms act on the φ's, introducing an implicit x dependence into the first slot of the Colombeau functions $R(\varphi,x)$. Hence, to retain smooth x dependence of R the concept of Silva differentiability was used. Future work will be concerned with a simplified concept of Colombeau algebras on manifolds using calculus in convenient vector spaces.[24] A main goal of this line of research is to provide a workable solution concept for singular differential equations on manifolds.

(Received 7 October 1997; accepted for publication 10 November 1998)

We consider Bondi's radiating metric in the context of the teleparallel equivalent of general relativity (TEGR). This metric describes the asymptotic form of a radiating solution of Einstein's equations. The total gravitational energy for this solution can be calculated by means of pseudotensors in the static case. In the nonstatic case, Bondi defines the *mass aspect* $m(u)$, which describes the mass of an isolated system. In this paper we express Bondi's solution in asymptotically spherical 3 $+1$ coordinates, not in radiation coordinates, and obtain Bondi's energy in the static limit by means of the expression for the gravitational energy in the framework of the TEGR. We can either obtain the total energy or the energy inside a large (but finite) portion of a three-dimensional spacelike hypersurface, whose boundary is far from the source. © *1999 American Institute of Physics.*

I. INTRODUCTION

The concept of energy in general relativity is considerably more intricate than in any other branch of physics. Any physical phenomena, except gravitation, is defined and described on a specific space–time, which is usually the flat space–time. For these phenomena the concept of energy can be intuitively conceived and mathematically realized. Generically, energy is an attribute of some physical system whose dynamics takes place on the space–time. Gravitation, however, acquires a distinct status because the dynamics of the gravitational field is the dynamics of the space–time itself. Consequently, the definition of the gravitational energy is not straightforward.

The several attempts at defining the gravitational energy (pseudotensors, quasilocal energy, actions, and Hamiltonians with surface terms) all agree in predicting the *total* energy of asymptotically flat gravitational fields. Moreover, there seems to exist a predominant point of view according to which the gravitational energy is not localizable, i.e., that there does not exist a gravitational energy *density*. These are probably the only two features shared by the various approaches, which are mostly based on the metric tensor. However, the very concept of a black hole lends support to the idea that gravitational energy is localizable. There is no process by means of which the gravitational mass inside a black hole can be made to vanish.

A detailed analysis of the structure of the pseudotensors shows that the (covariant) gravitational energy–momentum tensor would have to be defined by means of the first derivative of the metric tensor. But it is well known that it is not possible to write down a nontrivial covariant expression involving the first derivative of the metric, which captures the energy content of the field. However, it is possible to write down such covariant expressions with tetrads, and Møller noticed this fact long ago.[1–3]

The question of localizability of the gravitational energy can be discussed in the framework of the teleparallel equivalent of general relativity (TEGR),[3–6] which is an alternative geometrical formulation of Einstein's general relativity. The action integral of the TEGR is constructed en-

[a)]Electronic mail: wadih@fis.unb.br

tirely out of the torsion tensor. The analysis of the canonical structure of the TEGR[7] indicates the existence of a perfectly well-defined gravitational energy density. Such existence is possible, in principle, because the TEGR is defined in terms of tetrad fields. The torsion tensor allows the construction of a total divergence that transforms as a scalar (energy) density. In the $3+1$ formulation of the TEGR, the integral form of the Hamiltonian constraint equation $C=0$ can be written as an energy equation of the type[8]

$$C=H-E=0,$$

where E is the gravitational energy defined by

$$E_g=\frac{1}{8\pi G}\int_V d^3x\;\partial_i(eT^i), \tag{1}$$

where $e=\det(e_{(k)i})$, $\{e_{(k)i}\}$ are triads restricted to a three-dimensional spacelike hypersurface Σ, and T^i is the trace of the torsion tensor: $T^i=g^{ik}T_k=g^{ik}e^{(l)j}T_{(l)jk}$, $T_{(l)jk}=\partial_j e_{(l)k}-\partial_k e_{(l)j}$. V is an arbitrary three-dimensional volume of integration and G is the gravitational constant. This expression is simple and powerful. It has been successfully applied to rotating black holes,[9] de Sitter space,[10] and conical space–times.[11] The definition of gravitational energy in the TEGR may not be intuitively clear, but it is supported by its mathematical simplicity and by the applications to the space–times listed above. The use of (1) requires only the construction of the triads $\{e_{(k)i}\}$ with the appropriate boundary conditions, and that transform under the *global* SO(3) group.

The torsion tensor that appears in the Hamiltonian formulation of the TEGR is related to the antisymmetric component of the connection $\Gamma^i_{jk}=e^{(m)i}\,\partial_j e_{(m)k}$, whose curvature tensor is identically vanishing. Such a connection defines a space with teleparallelism, or absolute parallelism, or else *fernparallelismus*, according to Schouten.[12]

In this paper we investigate the energy of asymptotically flat gravitational waves, described by Bondi's radiating metric.[13] Since the metric describes an isolated system, the application of (1) is possible as it stands, provided we consider the metric in the $3+1$ spherical coordinates (t,r,θ,ϕ) at spacelike infinity, for which $t=$const defines a spacelike hypersurface. We note that the use of Cartesian (rectangular) coordinates in the asymptotic limit is necessary for the evaluation of pseudotensors out of this metric.

We recall that the Arnowitt–Deser–Misner (ADM) energy[14] is not suitable for the analysis of gravitational radiation, because it gives the *total* energy of the space–time, both from the source and from the emitted radiation, whereas the Bondi energy evaluated at null infinity furnishes only the energy of the source, from which it is possible to derive the well-known formula for the loss of mass.

The relevance of the definition (1) resides precisely in the fact that we can evaluate it on a large but *finite* volume V of the three-dimensional spacelike hypersurface, thereby not including the emitted radiation outside V. In view of the field equations (which are not considered here), the energy inside V turns out to be a decreasing function of time.

It is important to remark at this point that Bondi energy has been calculated in several geometrical frameworks, by different approaches.[15–19] A common feature of these approaches is that they yield the *total* energy of the field. In contrast, we will consider finite volumes of spacelike surfaces and obtain the energy contained within large spherical surfaces of radius r_0 up to the $1/r_0$ term.

In the next section we briefly describe the Lagrangian and Hamiltonian formulations of the TEGR. In Sec. III we compare our energy expression with Møller's expression. We show that both expressions agree for the *total* gravitational energy, but in spite of similarities they disagree when applied to finite volumes of the three-dimensional space. In Sec. IV we write Bondi's metric in (t,r,θ,ϕ) coordinates at infinity and proceed to carry out the construction of triads for the spacelike hypersurfaces Σ. There exists an infinite number of triads that lead to the metric restricted to the three-dimensional hypersurface. However, only two of them will be considered in detail. In

Sec. V we calculate both the total energy of the field and the energy contained within a large sphere of radius r_0. The total energy obtained by means of (1), in which case the integration is made over the whole Σ, agrees with the known result for the Bondi energy in the *static* case. We also obtain the expression for the energy contained within a surface of constant radius r_0 in the asymptotic region, where the metric coefficients may be determined.

Notation: spacetime indices $\mu,\nu,...$, and local Lorentz indices $a,b,...$, run from 0 to 3. In the $3+1$ decomposition Latin indices from the middle of the alphabet indicate space indices according to $\mu=0,i$, $a=(0),(i)$. The tetrad field $e^a\,_\mu$ and the spin connection $\omega_{\mu ab}$ yield the usual definitions of the torsion and curvature tensors: $R^a\,_{b\mu\nu}=\partial_\mu\omega_\nu\,^a\,_b+\omega_\mu\,^a\,_c\omega_\nu\,^c\,_b-\cdots$, $T^a\,_{\mu\nu}=\partial_\mu e^a\,_\nu+\omega_\mu\,^a\,_b e^b\,_\nu-\cdots$. The flat space–time metric is fixed by $\eta_{(0)(0)}=-1$.

II. THE TEGR

The Lagrangian density of the TEGR in empty spacetime is given by

$$L(e,\omega,\lambda)=-ke(\tfrac{1}{4}T^{abc}T_{abc}+\tfrac{1}{2}T^{abc}T_{bac}-T^aT_a)+e\lambda^{ab\mu\nu}R_{ab\mu\nu}(\omega), \tag{2}$$

where $k=1/16\pi G$, G is the gravitational constant; $e=\det(e^a\,_\mu)$, $\lambda^{ab\mu\nu}$ are Lagrange multipliers, and T_a is the trace of the torsion tensor defined by $T_a=T^b\,_{ba}$. The tetrad field $e_{a\mu}$ and the spin connection $\omega_{\mu ab}$ are completely independent field variables. The latter is enforced to satisfy the condition of zero curvature. Therefore this Lagrangian formulation is in no way similar to the usual Palatini formulation, in which the spin connection is related to the tetrad field via field equations. Later on, we will introduce the tensor Σ_{abc}, defined by

$$\tfrac{1}{4}T^{abc}T_{abc}+\tfrac{1}{2}T^{abc}T_{bac}-T^aT_a\equiv T^{abc}\Sigma_{abc}.$$

The equivalence of the TEGR with Einstein's general relativity is based on the identity

$$eR(e,\omega)=eR(e)+e(\tfrac{1}{4}T^{abc}T_{abc}+\tfrac{1}{2}T^{abc}T_{bac}-T^aT_a)-2\partial_\mu(eT^\mu), \tag{3}$$

which is obtained by just substituting the arbitrary spin connection $\omega_{\mu ab}={}^0\omega_{\mu ab}(e)+K_{\mu ab}$ in the scalar curvature tensor $R(e,\omega)$ on the left-hand side; ${}^0\omega_{\mu ab}(e)$ is the Levi-Civita connection and $K_{\mu ab}=\tfrac{1}{2}e_a\,^\lambda e_b\,^\nu(T_{\lambda\mu\nu}+T_{\nu\lambda\mu}-T_{\mu\nu\lambda})$ is the contorsion tensor. The vanishing of $R^a\,_{b\mu\nu}(\omega)$, which is one of the field equations derived from (2), implies the equivalence of the scalar curvature $R(e)$, constructed out of $e^a\,_\mu$ only, and the quadratic combination of the torsion tensor. It also ensures that the field equation arising from the variation of L with respect to $e^a\,_\mu$ is strictly equivalent to Einstein's equations in tetrad form. Let $\delta L/\delta e^{a\mu}=0$ denote the field equations satisfied by $e^{a\mu}$. It can be shown by explicit calculations that

$$\frac{\delta L}{\delta e^{a\mu}}=\frac{1}{2}e\left\{R_{a\mu}(e)-\frac{1}{2}e_{a\mu}R(e)\right\}. \tag{4}$$

We refer the reader to Refs. 7 and 8 for additional details.

Throughout this section we will be interested in asymptotically flat space–times. The Hamiltonian formulation of the TEGR can be successfully implemented if we fix the gauge $\omega_{0ab}=0$ from the outset, since in this case the constraints (to be shown below) constitute a *first class* set.[7] The condition $\omega_{0ab}=0$ is achieved by breaking the local Lorentz symmetry of (2). We still make use of the residual time-dependent gauge symmetry to fix the usual time gauge condition $e_{(k)}\,^0=e_{(0)i}=0$. Because of $\omega_{0ab}=0$, H does not depend on P^{kab}, the momentum canonically conjugated to ω_{kab}. Therefore arbitrary variations of $L=p\dot{q}-H$ with respect to P^{kab} yields $\dot{\omega}_{kab}=0$. Thus, in view of $\omega_{0ab}=0$, ω_{kab} drops out from our considerations. The above gauge fixing can be understood as the fixation of a reference frame.

As a consequence of the above gauge fixing, the canonical action integral obtained from (2) becomes[8]

$$A_{TL}=\int d^4x\{\Pi^{(j)k}\dot{e}_{(j)k}-H\}, \tag{5}$$

$$H=NC+N^iC_i+\Sigma_{mn}\Pi^{mn}+\frac{1}{8\pi G}\partial_k(NeT^k)+\partial_k(\Pi^{jk}N_j). \tag{6}$$

N and N^i are the lapse and shift functions, and $\Sigma_{mn}=-\Sigma_{nm}$ are Lagrange multipliers. The constraints are defined by

$$C=\partial_j(2keT^j)-ke\Sigma^{kij}T_{kij}-\frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji}-\frac{1}{2}\Pi^2\right), \tag{7a}$$

$$C_k=-e_{(j)k}\,\partial_i\Pi^{(j)i}-\Pi^{(j)i}T_{(j)ik}, \tag{7b}$$

with $e=\det(e_{(j)k})$ and $T^i=g^{ik}e^{(j)l}T_{(j)lk}$. We remark that (5) and (6) are invariant under global SO(3) and general coordinate transformations.

If we assume the asymptotic behavior,

$$e_{(j)k}\approx\eta_{jk}+\tfrac{1}{2}h_{jk}(\tfrac{1}{r}), \tag{8}$$

for $r\rightarrow\infty$, then, in view of the relation

$$\frac{1}{8\pi G}\int d^3x\,\partial_j(eT^j)=\frac{1}{16\pi G}\int_S dS_k(\partial_i h_{ik}-\partial_k h_{ii})\equiv E_{ADM}, \tag{9}$$

where the surface integral is evaluated for $r\rightarrow\infty$, the integral form of the Hamiltonian constraint $C=0$ may be rewritten as

$$\int d^3x\left\{ke\Sigma^{kij}T_{kij}+\frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji}-\frac{1}{2}\Pi^2\right)\right\}=E_{ADM}. \tag{10}$$

The integration is over the whole three-dimensional space. Given that $\partial_j(eT^j)$ is a scalar density, from (9) and (10) we define the gravitational energy density enclosed by a volume V of the space as

$$E=\frac{1}{8\pi G}\int_V d^3x\,\partial_j(eT^j). \tag{1}$$

It must be noted that E depends only on the triads $e_{(k)i}$ restricted to a three-dimensional spacelike hypersurface; the inverse quantities $e^{(k)i}$ can be written in terms of $e_{(k)i}$. From the identity (4) we observe that the dynamics of the triads does not depend on $\omega_{\mu ab}$. Therefore, E_g given above does not depend on the fixation of any gauge for $\omega_{\mu ab}$. We briefly remark that the reference space that defines the zero of energy has been discussed in Ref. 9.

We make now the important assumption that the general form of the canonical structure of the TEGR is the same for any class of space–times, irrespective of the peculiarities of the latter (for the de Sitter space,[10] for example, there is an *additional* term in the Hamiltonian constraint C). Therefore we assert that the integral form of the Hamiltonian constraint equation can be written as $C=H-E=0$ for *any* space–time, and that (1) represents the gravitational energy for arbitrary space–times with any topology.

Before closing this section, let us recall that Müller–Hoissen and Nitsch[20] and Kopczyński[21] have shown that, in general, the theory defined by (2) faces difficulties with respect to the Cauchy problem. They have shown that, in general, six components of the torsion tensor are not determined from the evolution of the initial data. On the other hand, the constraints of the theory constitute a first class set provided we fix the six quantities $\omega_{0ab}=0$ *before varying the action*.[7] This condition is mandatory and does not merely represent one particular gauge fixing of the theory. Since the fixing of ω_{0ab} yields a well-defined theory with first class constraints, we cannot assert that the field configurations of the latter are gauge equivalent to configurations whose time evolution is not precisely determined. The requirement of local SO(3,1) symmetry plus the addition of $\lambda^{ab\mu\nu}R_{ab\mu\nu}(\omega)$ in (2) has the ultimate effect of discarding the connection. Although we have no proof, we believe that the two properties above (the failure of the Cauchy problem and the fixation of $\omega_{0ab}=0$) are related to each other.

Constant rotations constitute a basic feature of the teleparallel geometry. According to Møller,[2] in the framework of the absolute parallelism tetrad fields, together with the boundary conditions, uniquely determine a *tetrad lattice*, apart from an arbitrary *constant rotation of the tetrads in the lattice*.

III. MØLLER'S ENERGY EXPRESSION

Møller carried out several investigations regarding the localizability of the gravitational energy. He faced difficulties in establishing a covariant expression using the metric tensor,[2] and because of this he arrived at an expression through the use of tetrads.[2,3] According to Møller, this latter expression still has a difficulty in that it is not invariant under *local* Lorentz transformations. It is very instructive to compare expression (1) with Møller's expression. For the sake of this comparison, we will put aside the difficulty regarding the noninvariance with respect to local Lorentz transformations.

Møller presents an expression for the energy–momentum of the gravitational field. However, we will only consider the energy expression. Translating into our notation, Møller's energy reads as

$$E=-\int d^3x\, \partial_\lambda U_0{}^{0\lambda}, \tag{11}$$

where the potential in the integrand is given by

$$U_\mu{}^{\nu\lambda}=\frac{1}{8\pi G}e[e^{a\nu}\nabla_\mu e_a{}^\lambda+(\delta^\nu_\mu e^{a\lambda}-\delta^\lambda_\mu e^{a\nu})\nabla_\sigma e_a{}^\sigma]. \tag{12}$$

In contrast with the notation of the previous section, all geometrical quantities in Eqs. (11)–(15) are *four-dimensional* quantities. In (12), ∇ represents the covariant derivative with respect to the Christoffel symbols $\Gamma^\lambda_{\mu\nu}$.

Møller's energy can be first rewritten as

$$E=\frac{1}{8\pi G}\int d^3x\, \partial_i(ee^{ak}\nabla_k e_a{}^i). \tag{13}$$

By means of the identity

$$\nabla_k e_{aj}=\partial_k e_{aj}-\Gamma^\sigma_{kj}e_{a\sigma}\equiv -{}^0\omega_k{}^b{}_a e_{bj}, \tag{14}$$

where ${}^0\omega_{\mu ab}$ is the Levi-Civita connection,

$${}^0\omega_{\mu ab}=-\tfrac{1}{2}e^c{}_\mu(\Omega_{abc}-\Omega_{bac}-\Omega_{cab}),$$

$$\Omega_{abc}=e_{a\nu}(e_b{}^\mu\,\partial_\mu e_c{}^\nu-e_c{}^\mu\,\partial_\mu e_b{}^\nu),$$

we can further rewrite expression (13) as

$$E=\frac{1}{8\pi G}\int d^3x\,\partial_i(ee^{ai}e^{bj}\,{}^0\omega_{jab}). \tag{15}$$

Up to this point $\{e_{a\mu}\}$ are tetrads of the four-dimensional space–time. In order to compare (15) with (1) let us impose the time gauge $e^{(0)}{}_k=e_{(j)}{}^0=0$ and establish the $3+1$ decomposition of the tetrads as in Refs. 7 and 22. Then the integrand on the right-hand side of (15) can be rewritten as

$${}^4e\,{}^4e^{ai}\,{}^4e^{bj}\,{}^0\omega_{jab}({}^4e)=Nee^{(m)i}e^{(n)j}\,{}^0\omega_{j(m)(n)}(e)-e(e^{ai}N^j-e^{aj}N^i)^0\omega_{j(0)(m)}.$$

N and N^i are the lapse and shift functions and $\{{}^4e^{a\mu}\}$ are tetrads of the four-dimensional space–time. In terms of triads restricted to a three-dimensional spacelike surface we have

$$E=\frac{1}{8\pi G}\int d^3x\,\partial_i[Nee^{(m)i}e^{(n)j}\,{}^0\omega_{j(m)(n)}-e(e^{(m)i}N^j-e^{(m)j}N^i)^0\omega_{j(0)(m)}]. \tag{16a}$$

A comparison with (1) can now be made if we make use of the *identity*[23]

$$\partial_i(ee^{(m)i}e^{(n)j}\,{}^0\omega_{j(m)(n)})\equiv\partial_i(eT^i),$$

where the right-hand side above is the same as in (1). Mǿller energy can be finally written as

$$E=\frac{1}{8\pi G}\int d^3x\,\partial_i[NeT^i-e(e^{(m)i}N^j-e^{(m)j}N^i)^0\omega_{j(0)(m)})]. \tag{16b}$$

Recall that we are ignoring *local* Lorentz transformations.

Besides the appearance of extra terms involving ${}^0\omega_{j(0)(m)}$ on the right-hand side of (16a) and (16b), there is also the crucial presence of the lapse function N multiplying eT^i. Therefore, even for configurations of the gravitational field for which the second term on the right-hand side of (16) does not contribute (if, say, $N^i=0$, as for the Schwarzschild solution) expressions (1) and (16) will lead to different results when applied to finite volumes of the three-dimensional space. Moreover, because of the presence of the lapse function, (16) is not invariant under time reparametrizations: $N'(x'^0)=(\partial x'^0/\partial x^0)N(x^0)$. Thus, for a finite volume of integration (16b) does not remain invariant under this reparametrization.

In the Einstein–Cartan theory the connection ${}^0\omega_{j(0)(m)}$ can be expressed in terms of the momenta canonically conjugated to $e_{(m)i}$. In the notation of Ref. 22 it is given by ${}^0\omega_{j(0)(m)}=(1/2e)(\pi_{(m)j}-\frac{1}{2}e_{(m)j}\pi)$ [see Eq. (12) of Ref. 22]. In this context (16b) can be rewritten as

$$E=\frac{1}{8\pi G}\int d^3x\,\partial_i\left[NeT^i-\frac{1}{2}e^{(m)i}N^j\pi_{(m)j}\right].$$

The expression above is exactly the energy expression for the Einstein–Cartan theory [see Eq. (21) of Ref. 22], assuming that the gravitational energy is obtained from the integration of surface terms of the total Hamiltonian. This expression is also very similar to (i) the integral of the surface terms in Eq. (6), and (ii) the energy expression considered by Nester[24] in the analysis of the positivity of the gravitational energy [Eq. (3.15) of Ref. 24]. All definitions of gravitational energy considered above agree for the total gravitational energy.

IV. BONDI'S RADIATING METRIC AND THE ASSOCIATED TRIADS

Bondi's metric is a not an exact solution of Einstein's equations. It describes the asymptotic form of a radiating solution. In terms of radiation coordinates (u,r,θ,ϕ), where u is the retarded time and r is the luminosity distance, Bondi's radiating metric is written as

$$ds^2=-\left(\frac{V}{r}e^{2\beta}-U^2r^2e^{2\gamma}\right)du^2-2e^{2\beta}\,du\,dr-2Ur^2e^{2\gamma}\,du\,d\theta+r^2(e^{2\gamma}\,d\theta^2+e^{-2\gamma}\sin^2\theta\,d\phi^2). \tag{17}$$

The metric above is such that the surfaces for which $u=\text{const}$ are null hypersurfaces. Each null radial (light) ray is labeled by particular values of u, θ, and ϕ. At spacelike infinity u takes the standard form $u=t-r$. The four quantities appearing in (17), V, U, β, and γ, are functions of u, r, and θ. Thus (17) displays axial symmetry. A more general form of this metric has been given by Sachs,[25] who showed that the most general metric tensor describing asymptotically flat gravitational waves depends on six functions of the coordinates.

The functions in (17) satisfy the following asymptotic behavior:

$$\beta=-\frac{c^2}{4r^2}+\cdots,\qquad \gamma=\frac{c}{r}+O\left(\frac{1}{r^3}\right)+\cdots,$$

$$\frac{V}{r}=1-\frac{2M}{r}-\frac{1}{r^2}\left[\frac{\partial d}{\partial\theta}+d\cot\theta-\left(\frac{\partial c}{\partial\theta}\right)^2-4c\left(\frac{\partial c}{\partial\theta}\right)\cot\theta-\frac{1}{2}c^2(1+8\cot^2\theta)\right]+\cdots,$$

$$U=\frac{1}{r^2}\left(\frac{\partial c}{\partial\theta}+2c\cot\theta\right)+\frac{1}{r^3}\left(2d+3c\frac{\partial c}{\partial\theta}+4c^2\cot\theta\right)+\cdots,$$

where $M=M(u,\theta)$ and $d=d(u,\theta)$ are related to the mass aspect and the dipole aspect, respectively, and from the function $c(u,\theta)$ we define the news function $\partial c(u,\theta)/\partial u$.

The application of (1) to Bondi's metric requires transforming it to coordinates t, r, θ and ϕ for which $t=\text{const}$ defines a spacelike hypersurface. Before proceeding, we recall that the analysis of (17) in t, x, y, z coordinates has already been performed by Goldberg,[26] in the investigation of the asymptotic invariants of gravitational radiation fields. Therefore, we carry out a coordinate transformation such that the new timelike coordinate is given by $t=u+r$. We arrive at

$$\begin{aligned}ds^2=&-\left(\frac{V}{r}e^{2\beta}-U^2r^2e^{2\gamma}\right)dt^2-2Ur^2e^{2\gamma}\,dt\,d\theta+2\left[e^{2\beta}\left(\frac{V}{r}-1\right)-U^2r^2e^{2\gamma}\right]dr\,dt\\&+\left[e^{2\beta}\left(2-\frac{V}{r}\right)+U^2r^2e^{2\gamma}\right]dr^2+2Ur^2e^{2\gamma}\,dr\,d\theta+r^2(e^{2\gamma}\,d\theta^2+e^{-2\gamma}\sin^2\theta\,d\phi^2).\end{aligned} \tag{18}$$

Therefore the metric restricted to a three-dimensional spacelike hypersurface is given by

$$ds^2=\left[e^{2\beta}\left(2-\frac{V}{r}\right)+U^2r^2e^{2\gamma}\right]dr^2+2Ur^2e^{2\gamma}\,dr\,d\theta+r^2(e^{2\gamma}\,d\theta^2+e^{-2\gamma}\sin^2\theta\,d\phi^2). \tag{19}$$

We must consider triads that correspond to the metric above. The construction of triads, in general, is a nontrivial step. If in a given coordinate system the metric tensor is diagonal, then the construction of triads is a relatively simple procedure. One must only make sure that the triads satisfy the appropriate boundary conditions at infinity. Recall that in order to obtain expression (9) for the ADM energy the triads must have the appropriate asymptotic behavior given by Eq. (8).

The metric tensor (19) has an off-diagonal element, and this fact adds a bit of complication in the construction of triads. Nevertheless, we can immediately write down two sets of triads that lead to this metric. They are given by

$$e_{(k)i}=\begin{pmatrix} A\sin\theta\cos\phi+B\cos\theta\cos\phi & rC\cos\theta\cos\phi & -rD\sin\theta\sin\phi \\ A\sin\theta\sin\phi+B\cos\theta\sin\phi & rC\cos\theta\sin\phi & rD\sin\theta\cos\phi \\ A\cos\theta-B\sin\theta & -rC\sin\theta & 0 \end{pmatrix}, \tag{20}$$

where

$$A=e^{\beta}\sqrt{2-\frac{V}{r}}, \tag{21a}$$

$$B=rUe^{\gamma}, \tag{21b}$$

$$C=e^{\gamma}, \tag{21c}$$

$$D=e^{-\gamma}, \tag{21d}$$

and

$$e_{(k)i}=\begin{pmatrix} A'\sin\theta\cos\phi & rB'\cos\theta\cos\phi+rC'\sin\theta\cos\phi & -rD'\sin\theta\sin\phi \\ A'\sin\theta\sin\phi & rB'\cos\theta\sin\phi+rC'\sin\theta\sin\phi & rD'\sin\theta\cos\phi \\ A'\cos\theta & -rB'\sin\theta+rC'\cos\theta & 0 \end{pmatrix}, \tag{22}$$

where

$$A'=\left[e^{2\beta}\left(2-\frac{V}{r}\right)+U^2r^2e^{2\gamma}\right]^{1/2}, \tag{23a}$$

$$B'=\frac{1}{A'}e^{\beta+\gamma}\sqrt{2-\frac{V}{r}}, \tag{23b}$$

$$C'=\frac{1}{A'}Ure^{2\gamma}, \tag{23c}$$

$$D'=e^{-\gamma}. \tag{23d}$$

It is easy to see that both (20) and (22) yield the metric tensor (19) through the relation $e_{(i)j}e_{(i)k}=g_{jk}$. They are related by a *local* SO(3) transformation.

Triads given by (20) and (22) are the *simplest* sets of triads that satisfy the two basic requirements: (i) the triads must have the asymptotic behavior given by (8); (ii) by making the physical parameters of the metric vanish we must have $T_{(k)ij}=0$ everywhere. In the present case if we make $M=d=c=0$, both (20) and (22) acquire the form

$$e_{(k)i}=\begin{pmatrix} \sin\theta\cos\phi & r\cos\theta\cos\phi & -r\sin\theta\sin\phi \\ \sin\theta\sin\phi & r\cos\theta\sin\phi & r\sin\theta\cos\phi \\ \cos\theta & -r\sin\theta & 0 \end{pmatrix}. \tag{24}$$

In Cartesian coordinates the expression above can be reduced to the diagonal form $e_{(k)i}(x,y,z)=\delta_{ik}$. The requirement (ii) above is essentially equivalent to the establishment of a reference space, as discussed in Ref. 9. Without the notion of a reference space we cannot define gravitational energy. Note that by a suitable choice of a local SO(3) rotation we can make the flat space triad (24) satisfy the requirement (i), but not (ii).

It is possible to show that (20) and (22) are particular cases of an infinite set of triads that satisfy both requirements above. It is given by

$$e_{(k)i}=\begin{pmatrix} \mathcal{A}\sin\theta\cos\phi+\mathcal{B}\cos\theta\cos\phi & r\mathcal{C}\cos\theta\cos\phi+r\mathcal{D}\sin\theta\cos\phi & -re^{-\gamma}\sin\theta\sin\phi \\ \mathcal{A}\sin\theta\sin\phi+\mathcal{B}\cos\theta\sin\phi & r\mathcal{C}\cos\theta\sin\phi+r\mathcal{D}\sin\theta\sin\phi & re^{-\gamma}\sin\theta\cos\phi \\ \mathcal{A}\cos\theta-\mathcal{B}\sin\theta & -r\mathcal{C}\sin\theta+r\mathcal{D}\cos\theta & 0 \end{pmatrix}, \tag{25}$$

with the following definitions:

$$\mathcal{A}=\sqrt{e^{2\beta}(2-V/r)+U^2r^2(e^{2\gamma}-\mathbf{b}^2)}, \quad \mathcal{B}=\mathbf{b}Ur,$$

$$\mathcal{C}=\sqrt{e^{2\gamma}-\mathbf{d}^2U^2r^2}, \quad \mathcal{D}=\mathbf{d}Ur,$$

where $\mathbf{b}$ and $\mathbf{d}$ are arbitrary, dimensionless functions that must satisfy

$$\mathbf{b}=\sqrt{e^{2\gamma}-\mathbf{d}^2U^2r^2}+\mathbf{d}e^{-\gamma+\beta}\sqrt{2-V/r}.$$

By making $\mathbf{d}=0$ we obtain (20), and $\mathbf{b}=0$ leads to (22).

From the point of view of the TEGR, triads given by (20) and (22) are physically inequivalent (that is, they are not gauge equivalent), because we have seen that the Hamiltonian formulation established by Eq. (5) is not invariant under the local SO(3) group, but rather under the global SO(3). In the TEGR, the torsion tensor describes the way in which the space–time is deformed. The latter is thus considered as a continuum with microstructure.[5] Therefore, the same space, defined uniquely by the metric tensor, may be deformed in several ways, according to the manner in which one defines the triads. This is essentially the geometrical meaning of the noninvariance of the TEGR under local SO(3) transformations.

In the Hamiltonian formulation of the TEGR, the basic geometrical field variable is the triad, not the metric tensor. Any set of triads should be ruled out on physical grounds, i.e., if they lead to incorrect physical statements concerning the energy content of the gravitational field.

In the next section we will obtain the expressions for the gravitational energy arising from (20) and (22). These expressions are quite different. Although the expression corresponding to (20) is simpler, as we will see, we have no definite experimental evidence in favor of it.

V. GRAVITATIONAL RADIATION ENERGY

In this section we will apply expression (1) both to (20) and (22). Since the two triads display distinct geometrical properties, we expect to obtain different expressions for the energy density $(1/8\pi)\partial_i(eT^i)$ (we will make the gravitational constant $G=1$). Our analysis is meaningful only in the asymptotic region of large values of the radial distance. However, we have no reason to expect (20) and (22) to yield different expressions for the *total* energy of the field. In fact, as we will see, they yield the same (expected) expression.

As we mentioned earlier, the significance of the present approach to the analysis of gravitational radiation fields resides in the fact that we can evaluate the gravitational energy inside a large but finite portion of a three-dimensional spacelike surface. In other words, by means of Gauss' law (1) can be evaluated over a surface far from the source of radiation, in the asymptotic limit where the metric components are precisely determined. Specifically, we will evaluate (1) inside a large sphere of radius r_0. The time evolution of the metric field will determine the time dependence of this energy, and consequently the energy radiated out of it.

In order to calculate $T^i=g^{ik}g^{mj}e_{(l)m}T_{(l)jk}$ we need the inverse metric g^{ij}. In terms of the definitions (21), it is given by

$$g^{ij}=\begin{pmatrix} \frac{1}{A^2} & -\frac{B}{re^{\gamma}A^2} & 0 \\ -\frac{B}{re^{\gamma}A^2} & \frac{1}{r^2e^{2\gamma}}\left(1+\frac{B^2}{A^2}\right) & 0 \\ 0 & 0 & \frac{1}{r^2e^{-2\gamma}\sin^2\theta} \end{pmatrix}. \tag{26}$$

We will initially consider the set of triads given by (20). In the following, a comma after a field quantity indicates a derivative: $A_{,1}$ and $A_{,2}$ indicative derivative of A with respect to r and θ, respectively. The torsion components for (20) are given by

$$T_{(1)12}=\cos\theta\cos\phi(C+rC_{,1}-A-B_{,2})+\sin\theta\cos\phi(-A_{,2}+B),$$

$$T_{(1)13}=\sin\theta\sin\phi(A-D-rD_{,1})+\cos\theta\sin\phi B,$$

$$T_{(1)23}=\sin\theta\sin\phi(-rD_{,2})+\cos\theta\sin\phi(rC-rD),$$

$$T_{(2)12}=\cos\theta\sin\phi(C+rC_{,1}-A-B_{,2})+\sin\theta\sin\phi(-A_{,2}+B),$$

$$T_{(2)13}=\sin\theta\cos\phi(-A+D+rD_{,1})+\cos\theta\cos\phi(-B),$$

$$T_{(2)23}=\sin\theta\cos\phi(rD_{,2})+\cos\theta\cos\phi(-rC+rD),$$

$$T_{(3)12}=\sin\theta(A+B_{,2}-C-rC_{,1})+\cos\theta(-A_{,2}+B),$$

$$T_{(3)13}=T_{(3)23}=0.$$

Since we are interested in calculating the energy inside a surface of constant radius, only T^1 will be considered. By Gauss' law, the expression of this energy is given by

$$E=\frac{1}{8\pi}\int_S d\theta\, d\phi\, eT^1, \tag{27}$$

where S is a surface of fixed radius r_0, assumed to be large as compared with the dimension of the source, and the determinant e is given by $e=r^2A\sin\theta$. After a long but otherwise straightforward calculation, we arrive at

$$E_I=\frac{r_0}{4}\int_0^{\pi}d\theta\left\{\sin\theta\left[e^{\gamma}+e^{-\gamma}-\frac{2}{A}\right]+\frac{1}{A}\frac{\partial}{\partial\theta}(Ur\sin\theta)\right\}, \tag{28}$$

with A defined by (21a). Let us note that the field quantities appearing in (28) are functions of $u=t-r$: $M=M(t-r,\theta)$, $c=c(t-r,\theta)$, etc. Therefore, once these functions are known, one can explicitly calculate the variation of E_I with respect to the time t, however, only in the limit where the metric components are precisely determined.

Unfortunately, the expansion of E_I up to terms in $1/r_0$, making use of the asymptotic behavior of U, V, β, and γ, yields no simple expression. It is given by

$$E_I=\frac{1}{2}\int_0^{\pi}d\theta\sin\theta M-\frac{1}{4r_0}\int_0^{\pi}d\theta\sin\theta\left[\left(\frac{\partial c}{\partial\theta}\right)^2+4c\left(\frac{\partial c}{\partial\theta}\right)\cot\theta+4c^2\cot^2\theta\right]$$
$$-\frac{1}{4r_0}\int_0^{\pi}d\theta\, M\frac{\partial}{\partial\theta}\left[\sin\theta\left(\frac{\partial c}{\partial\theta}+2c\cot\theta\right)\right]. \tag{29}$$

In the calculation above we have assumed that $U(\theta)\sin\theta = d(\theta)\sin\theta = 0$ when $\theta = 0$ or π.

We observe that E_I yields Bondi energy in the limit $r\to\infty$ in the *static* case (i.e., when M is a function of θ only), so that E_I is the total gravitational energy. However, in the nonstatic case an expression for the loss of mass due to gravitational radiation can be obtained from (29). This is one major result of our analysis.

Let us recall that Bondi's *mass aspect* $m(u)$,

$$m(u) = \frac{1}{2}\int_0^\pi d\theta \sin\theta M(u,\theta), \tag{30}$$

depends on the null foliation used. The mass aspect $m(u)$ can be understood as a mass associated to each null cone determined by the equation $u=$const. Since the limit $r\to\infty$ corresponds to $u\to-\infty$ for finite t, we see once again that in this limit E_I gives the total energy because it corresponds to the initial value of the Bondi energy.

We will consider next the second set of triads, Eq. (22). The components of the torsion tensor resulting from the latter are given by

$$T_{(1)12} = \cos\theta\cos\phi(B' + rB,'_1 - A') + \sin\theta\cos\phi(C' + rC,'_1 - A,'_2),$$

$$T_{(1)13} = \sin\theta\sin\phi(A' - D' - rD,'_1),$$

$$T_{(1)23} = \cos\theta\sin\phi(rB' - rD') + \sin\theta\sin\phi(rC' - rD,'_2),$$

$$T_{(2)12} = \cos\theta\sin\phi(B' + rB,'_1 - A') + \sin\theta\sin\phi(C' + rC,'_1 - A,'_2),$$

$$T_{(2)13} = -\sin\theta\cos\phi(A' - D' - rD,'_1),$$

$$T_{(2)23} = -\cos\theta\cos\phi(rB' - rD') - \sin\theta\cos\phi(rC' - rD,'_2),$$

$$T_{(3)12} = -\sin\theta(B' + rB,'_1 - A') + \cos\theta(C' + rC,'_1 - A,'_2),$$

$$T_{(3)13} = T_{(3)23} = 0.$$

As in the previous case, we are interested in calculating the energy in the interior of a surface of constant radius r_0. Therefore, only the knowledge of T^1 will be necessary. After a long calculation, we first arrive at

$$\begin{aligned} eT^1 = &-\frac{r\sin\theta}{A}\left\{ e^{-2\gamma}\left[B'\frac{\partial}{\partial r}(rB') + C'\frac{\partial}{\partial r}(rC') - A'B' - C'\frac{\partial A'}{\partial\theta}\right]\right. \\ &\left. + e^{2\gamma}\left[-A'e^{-\gamma} - r\frac{\partial\gamma}{\partial r}e^{-2\gamma} + e^{-2\gamma}\right]\right\} - \frac{rB\sin\theta}{A}\left[C' + \frac{\partial\gamma}{\partial\theta}e^{-\gamma}\right] - \frac{rB\cos\theta}{A}[B' - e^{-\gamma}], \end{aligned} \tag{31}$$

where the primed quantities are given by (23). It is not straightforward to put the expression above in a simplified form. After some rearrangements we can finally write the energy expression (27) as

$$\begin{aligned} E_{II} = \frac{r_0}{4}\int_0^\pi d\theta \frac{1}{A}&\left\{ \sin\theta\left[e^{\gamma}A' + e^{-2\gamma}A'B' - 2 + e^{-2\gamma}\frac{\partial A'}{\partial\theta}C' - BC' - Be^{-\gamma}\frac{\partial\gamma}{\partial\theta}\right]\right. \\ &\left. - B\cos\theta[B' - e^{-\gamma}]\right\}. \end{aligned} \tag{32}$$

Like Eq. (28), this expression represents the energy enclosed by a large spherical surface of radius r_0. Expanding the expression above up to the first power of $1/r_0$, we find

$$E_{II}=\frac{1}{2}\int_0^\pi d\theta\, M\sin\theta-\frac{1}{4r_0}\int_0^\pi d\theta\sin\theta\bigg[3M^2+\frac{5}{2}\left(\frac{\partial c}{\partial\theta}\right)^2+10c\left(\frac{\partial c}{\partial\theta}\right)\cot\theta+8c^2\cot^2\theta -\left(\frac{\partial M}{\partial\theta}\right)\left(\frac{\partial c}{\partial\theta}+2c\cot\theta\right)\bigg]-\frac{1}{4r_0}\int_0^\pi d\theta\cos\theta\left[2c\left(\frac{\partial c}{\partial\theta}\right)+4c^2\cot\theta\right]. \tag{33}$$

We are again assuming $U(\theta)\sin\theta=d(\theta)\sin\theta=0$ for $\theta=0,\ \pi$.

We observe that in the limit $r\to\infty$, E_{II} also gives the total energy. As before, for a finite (but sufficiently large) value of r_0 we can compute the loss of mass due to gravitational radiation, once the functions M and c are known in the asymptotic region.

VI. THE SELECTION OF TRIADS

In Sec. IV we obtained an infinite set of triads that yield the three-dimensional spacelike section of Bondi's metric, and in the previous section we considered in detail only the simplest constructions. Of course, simplicity is a major feature of physical systems, but we are really in need of experimental evidence that leads to a definite description. We need actual realizations of the quantities $M(r-t,\theta)$, $c(r-t,\theta)$, $d(r-t,\theta)$ and experimental evidence on how the energy is radiated away in order to arrive simultaneously at the correct energy expression arising from (27) and at the definite expression of $e_{(k)i}$.

However, we can envisage two possible types of conditions on the triads that associate a unique triad with the three-dimensional metric tensor.

The first condition regards the energy content of the gravitational field. If we stick to the point of view according to which physical systems in nature have a tendency to be in states of minimum energy, then the correct triad for the spacelike section of Bondi's metric is the one that minimizes expression (27) for all possible constructions of $e_{(k)i}$. By means of this criterium we consider triads given by (25), or any further construction that complies with the two conditions stated in Sec. IV, and ask which one yields the smaller value of energy contained within a surface of constant radius, in similarity with the calculations of (29) and (33). Unfortunately, this analysis cannot be carried out unless M, c, and d are known.

Certainly one can ask whether only (27) should be minimized or the energy density should be everywhere a minimum. In the context of Bondi's metric the latter possibility cannot be considered, because the metric is valid only in the asymptotic limit; but in the general case it is an open question that must be carefully addressed.

The second condition takes into account Eq. (8): we require the triads to have the asymptotic behavior determined by (8) with a *symmetric* tensor $h_{jk}=h_{kj}$. Again, one has to find out of (25), which realization of $e_{(i)k}$ in Cartesian coordinates complies with this criterium. This condition may be understood as a *rotational gauge condition*. Note that, as it stands, h_{jk} in Eq. (8) is not required to be symmetric [in Eq. (9) only the symmetrical part contributes]. By explicit calculations we observe that neither (20) nor (22) satisfy this second condition.

The two conditions above may not be mutually excluding. On the contrary, they may lead to the same triad. The determination of the correct triad is certainly an essential and crucial issue of the theory and will be further investigated elsewhere in the general case, with special attention to Bondi's metric, in light of the conditions above.

We observed that both (29) and (33) yield the same total energy. This is also the case if we carry out the calculations with a more complicated triad, whether belonging to (25) or not, which is related to (20) or (22) by a local SO(3) transformation with an appropriate asymptotic behavior. Let us consider a local SO(3) transformation, given by

$$\tilde{e}^{(k)}{}_i(x)=\Lambda^{(k)}{}_{(l)}(x)e^{(l)}{}_i(x). \tag{34}$$

Under (34) the energy expression (1) transforms as

$$\tilde{E}=E+\frac{1}{8\pi}\int_V d^3x\,\partial_i[eg^{ik}\Lambda^{(l)}{}_{(m)}e^{(m)j}(e_{(n)k}\,\partial_j\Lambda_{(l)}{}^{(n)}-e_{(n)j}\,\partial_k\Lambda_{(l)}{}^{n})]. \tag{35}$$

Expression (35) can be best analyzed if we consider an infinitesimal rotation. We assume that in the limit $r\rightarrow\infty$, the SO(3) elements have the asymptotic behavior

$$\Lambda^{(k)}{}_{(l)}\approx\delta^{(k)}_{(l)}+{}^0\omega^{(k)}{}_{(l)}+{}^1\omega^{(k)}{}_{(l)}\left(\frac{1}{r}\right),$$

such that ${}^{0,1}\omega_{(k)(l)}=-{}^{0,1}\omega_{(l)(k)}$, and $\{{}^0\omega_{(k)(l)}\}$ are constants. Taking into account (8), it is easy to see that when integrated over the whole three-dimensional space the integral on the right-hand side of (35) reduces to a vanishing expression:

$$\frac{1}{8\pi}\int_{V\rightarrow\infty}d^3x(\partial_i\,\partial_j\,{}^1\omega_{(i)(j)}-\partial_i\,\partial_i\,{}^1\omega_{(j)(j)})=0.$$

Therefore we expect to find the same result for the total energy if we evaluate (27) out of any element of the set of triads (25).

VII. DISCUSSION

The application of the energy definition (1) for a given solution of Einstein's equations requires considering a foliation of the space–time in three-dimensional spacelike surfaces. The metric for the spacelike section of Bondi's radiating metric admits an infinite set of triads related by local SO(3) transformations. In the present case, from this infinite set of triads we singled out two of them. We have considered in detail the two ones that exhibit the simplest structures in spherical coordinates, and that (i) satisfy the asymptotic conditions given by (8); (ii) reduce to the reference space ($T_{(k)ij}=0$ everywhere) if we make the physical parameters vanish: $M=c=d=0$.

The two sets of triads, (20) and (22), describe the spacelike section of Bondi's metric given by (19) and lead to the energy expressions (28) and (32), respectively. These expressions establish distinct and quite definite physical predictions. They allow us to compute the energy radiated from the interior of a spherical surface of constant radius r_0. It would be a remarkable achievement of the TEGR if, on physical grounds, we could decide for one of them or even for an arbitrary element of (25). In the TEGR the space (space–time) geometry is fundamentally described by triads (tetrads). Unfortunately, we do not dispose of experimental information for taking such a decision.

It is a very important result that the *total* energy due to both sets of triads [as well as from any element of (25)] agrees exactly with the static Bondi energy, in which case the energy arises from the integration of $M=M(\theta)$. In fact, the definition of Bondi's *mass aspect* is basically motivated by the fact that in the static case, and by investigating the asymptotic properties of the gravitational field, $M(\theta)$ arises as the mass of an isolated system.

The final expressions (29) and (33) support the consistency of the definition (1), and the relevance of the TEGR as a fundamental description of general relativity. However the present analysis, which was developed on spacelike surfaces, has to be compared with the one recently carried out on null surfaces.[27] Let us recall that in order to obtain the Hamiltonian formulation given by (5)–(7) we imposed the time gauge condition. Therefore, the resulting geometry may be understood as a *three-dimensional* teleparallel geometry, since the teleparallelism is restricted to the three-dimensional spacelike surface. On the other hand, in the Hamiltonian formulation developed in Ref. 27, we have not fixed any particular tetrad component, and consequently the teleparallel geometry is really *four dimensional*.

In Ref. 27 the constraints also contain a total divergence, in similarity with (7a), and may be taken likewise to define the gravitational energy–momentum. Although it appears that the geometrical framework of Ref. 27 is better suited to the analysis of the Bondi–Sachs metric, we note that the energy expression arising there is considerably more complicated than (1). Moreover, we do not know yet whether the constraint algebra leads to a consistent Hamiltonian formulation (either on null or spacelike surfaces). We also note that one Hamiltonian formulation cannot be reduced to the other by means of gauge fixing. Nature admits only one correct physical description, and therefore either the three-dimensional or the four-dimensional teleparallel geometry is the correct candidate for describing the energy properties of the gravitational field. All these issues will be considered in the near future.

(Received 3 June 1998; accepted for publication 9 September 1998)

A scalar field nonminimally coupled to gravity is studied in the canonical framework, using self-dual variables. The corresponding constraints are first class and polynomial. To identify the real sector of the theory, reality conditions are implemented as second class constraints, leading to three real configurational degrees of freedom per space point. Nevertheless, this realization makes nonpolynomial some of the constraints. The original complex symplectic structure reduces to the expected real one, by using the appropriate Dirac brackets. For the sake of preserving the simplicity of the constraints, an alternative method preventing the use of Dirac brackets, is discussed. It consists of converting all second class constraints into first class by adding extra variables. This strategy is implemented for the pure gravity case. © *1999 American Institute of Physics.* [S0022-2488(99)01102-0]

I. INTRODUCTION

The failure of using perturbation theory to quantize General Relativity (GR) has led to different approaches, like string theory and canonical quantization, which intend to define quantum gravity.[1] Instead of incorporating the remaining fundamental interactions as the former, the latter approach consists of just adopting standard quantum theory and classical GR. The space–time structure, on the other hand, seems to be sensible to the nonperturbative aspects modeling it.[2,3] This is in itself a major motivation for studying canonical GR. Some success has been achieved within canonical quantum gravity since the late eighties, after the introduction, by Ashtekar,[4] of a set of complex canonical variables which greatly simplify the form of the constraints to which the theory is reduced. The kernel of this algebra of constraints defines the space of physical states in the theory and some formal elements of it have been constructed.[4]

In spite of its simplicity, the constraints of GR in terms of Ashtekar variables describe complex gravity. Ashtekar himself considered reducing to the real sector, through the introduction of an inner product designed to make Hermitian the physical operators. However, this strategy has not worked up to now, except for some particular cases. Other alternatives have been presented to avoid the use of reality conditions, at the price of a more cumbersome form of the constraints. Yet, quantum mechanically, the situation seems tractable.[3]

There still remains the possibility of keeping the self-dual canonical formalism and trying to envisage how to select the real sector of the theory. Indeed this is possible, as it has been shown for pure gravity in Ref. 5, at the classical level. Reality conditions are implemented as second class constraints. The present work is devoted to show how this result is also valid in the case of a scalar field nonminimally coupled to gravity.

The strategy followed in this paper is an extension of the pure gravity analysis of Ref. 5, to incorporate a nonminimally coupled scalar field . It consists of five steps: (i) each complex canonical variable is splitted into one real and one imaginary degrees of freedom; (ii) then, every real and imaginary part is regarded as a configuration variable. An extended phase space is hence defined, where the corresponding momenta will arise directly from the action. Notice that the definition of such momenta will produce primary constraints; (iii) next, the reality conditions are implemented upon the splitting, as additional primary constraints. The criterion being to restrict to a real three-metric together with a real scalar field, during the whole evolution of the system; (iv) after imposing the conservation of the constraints, which amounts to obtaining all possible secondary constraints, a final classification of the full set into first and second class is performed. This may require the redefinition of some of them; and finally, (v) the issue of how to deal with the resulting set of second class constraints should be addressed. Since the use of Dirac brackets take the first class constraints back to its Palatini canonical form, which is highly nonpolynomial, some alternatives should be tried.

A review of how to select the real sector in phase space of pure self-dual gravity is made in Sec. II. It includes the result of converting all second class into first class constraints, by introducing extra canonical variables. Thus, Dirac brackets are not used. Next, the extension of the method to the case of the scalar field nonminimally coupled to gravity is described in Sec. III. The polynomial form of the constraints for the complex theory is exhibited, as well as the whole set of first and second class constraints describing the real sector of the theory. Finally, the last section contains some conclusions and perspectives. A possibility regarding how to avoid the use of Dirac brackets to eliminate the second class constraints for the scalar field case is briefly discussed. A point on notation: $\tilde{E}^{ai}$ is considered here as a complex density inverse triad of weight one, whilst $\tilde{e}^{ai}$ is its real part. This is just the opposite convention of Ref. 5, but it has the advantage that adjusts to the rest of the literature.[4] The number of over and under tildes represent the positive or negative density weight (± 1, ± 2, etc.) respectively, unless it is obvious from the definition of the different variables. In the case of the $\delta(\tilde{x},y)$ the tilde indicates it is a density of weight one in the argument x.

II. PURE GRAVITY

The Ashtekar complex canonical variables are: (i) $\tilde{E}^{ai} := \tilde{E} E^{ai}$, with E^{ai} being the triad ($E^{ai}E^b_i := q^{ab}$, q^{ab} is the spatial three-metric), and $a,b,\ldots = 1,2,3$ are spatial indices, whereas $i,j,\ldots = 1,2,3$ are SO(3) internal indices. Also, $\tilde{E} := \det E_{bj}$ with E_{bj} being the inverse of E^{ai}. (ii) A_{ai} is the three-dimensional projection of the self-dual connection,[4] with associated covariant derivative $\mathcal{D}_a \lambda_i = \partial_a \lambda_i + \epsilon_{ijk} A^j_a \lambda^k$ and $F^i_{ab} := \partial_a A^i_b - \partial_b A^i_a + \epsilon^i{}_{jk} A^a_j A^k_b$ is the corresponding curvature. In terms of these variables, the self-dual action of canonical GR is given by

$$S = \int dt\, d^3x \{ -i \tilde{E}^{ai} \dot{A}_{ai} - \underset{\sim}{N} \tilde{\tilde{\mathcal{S}}} - N^a \tilde{\mathcal{V}}_a - N^i \tilde{\mathcal{G}}_i \}, \tag{1}$$

where

$$\tilde{\tilde{\mathcal{S}}} := \epsilon_{ijk} \tilde{E}^{ai} \tilde{E}^{bj} F^k_{ab}, \quad \tilde{\mathcal{V}}_a := \tilde{E}^b_j F^j_{ab}, \quad \tilde{\mathcal{G}}_i := \mathcal{D}_a \tilde{E}^a_i, \tag{2}$$

are the constraints of the theory and $\underset{\sim}{N}, N^a, N^i$ are Lagrange multipliers. Such constraints are first class and polynomial in the phase space variables. Let us denote by $\mathcal{R}$ any of them and by $\{\mathcal{R}\}$ the full set.

Notice that having 18 complex phase space variables $(A_{ai},\tilde{E}^{bj})$, together with 7 complex first class constraints, $\{\mathcal{R}\}$, leaves us with 2 complex configurational degrees of freedom. Then, in order to recover the 2 real configurational degrees of freedom per point, further constraints are necessary. To this end, let us introduce the splitting

$$\tilde{E}^{ai}=\tilde{e}^{ai}+i\tilde{\mathcal{E}}^{ai}, \quad A_{bj}=\gamma_{bj}-iK_{bj}. \tag{3}$$

From now on, all the above thirty six degrees of freedom are taken as configuration variables in the action (1). Hence, the associated canonical momenta Π lead to the primary constraints $\Phi_{\mathcal{E}ai}=\Pi_{\mathcal{E}ai}, \Phi_{\gamma}^{ai}=\Pi_{\gamma}^{ai}+i\tilde{e}^{ai}$, $\Phi_K^{ai}=\Pi_K^{ai}+\tilde{e}^{ai}$, $\Phi_{eai}=\Pi_{eai}$, which as a set is denoted by $\{\Phi\}$. The coordinates of the total phase space are $Y_A=(\tilde{e}^{ai},\tilde{\mathcal{E}}_{ai},\gamma^{ai},K_{ai},\Pi_{eai},\Pi_{\mathcal{E}ai},\Pi_{\gamma}^{ai},\Pi_{ai}^{K})$.

The reduction of the complex phase space $(A_{ai},\tilde{E}^{bj})$ to a real one is achieved by means of the following reality conditions

$$\psi^{ai}:=\tilde{\mathcal{E}}^{ai}=0, \quad \chi_{ai}:=\gamma_{ai}-f_{ai}(\tilde{e})=0, \tag{4}$$

which are subsequently taken as additional primary constraints. The constraints ψ^{ai} enforces the $\tilde{E}^{ai}$ to be real, and hence the corresponding three-metric. The constraints χ_{ai} ensures that, upon evolution, $\tilde{E}^{ai}$ keeps being real. Using the compatibility condition between a real torsion-free connection and the triad, the form of f_{ai} is chosen as $f_{ai}=\frac{1}{2}[\underset{\sim}{e}_{ai}\underset{\sim}{e}_c^j\epsilon_{jrs}-2\underset{\sim}{e}_{aj}\underset{\sim}{e}_c^j\epsilon_{irs}]\tilde{e}^{dr}\partial_d\tilde{e}^{cs}$. Let us observe that χ_{ai} is not polynomial in $\tilde{e}^{bj}$.

The full set of primary constraints is $\{\{\mathcal{R}\},\ \psi,\ \chi,\{\Phi\}\}$, written in terms of the real variables Y_A. The evolution of the primary constraints does not introduce additional constraints. After redefining $\Phi_{eai}\rightarrow\Phi'_{eai}=\Phi_{eai}+\alpha_{aibj}\Phi_{\gamma}^{bj}+\beta_{ai}^{bj}\chi_{bj}+\eta_{aibj}\Phi_K^{bj}$, the Poisson brackets matrix for the subset $\{\Xi\}=\{\{\Phi'\},\ \psi,\ \chi\}$ reveals them as second class constraints. Besides having a simple form, it is a phase space independent, block diagonal matrix with non zero determinant.

To keep $\{\mathcal{R}\}$ as a first class set it is enough to redefine each element as $\mathcal{R}'=\mathcal{R}+\{\Phi_{\mathcal{E}bj},\mathcal{R}\}\psi^{bj}+\{\Phi_{\gamma}^{bj},\mathcal{R}\}\chi_{bj}+\{\Phi'_{ebj},\mathcal{R}\}\Phi_K^{bj}-\{\Phi_K^{bj},\mathcal{R}\}\Phi'_{ebj}$, so that they have zero Poisson brackets with the previous second class subset. This redefinition preserves the property $\{\mathcal{R}',\mathcal{Q}'\}\approx 0$, for any pair of constraints in $\{\mathcal{R}'\}$. In this way, there are no additional contributions to the set of primary constraints $\{\Upsilon\}:=\{\mathcal{R}'\}\cup\{\Xi\}$, which includes the reality conditions. Counting the independent variables gives 2 real configurational degrees of freedom per space point, as it should be for real GR.[5]

At this point Dirac's program calls for the elimination of the second class constraints through the use of Dirac brackets. This, however, would yield a cumbersome form for the remaining constraints. One might avoid such treatment of the second class constraints by transforming them into first class constraints. To achieve this, by means of the Batalin-Tyutin procedure,[6,7] one adds a new canonical pair, $\{Q^{ai},P_{bj}\}=\delta_a^b\delta_i^j\delta^{(3)}$, per original couple of second class constraints, i.e., the phase space is further enlarged with the new variables $\Psi_{\Xi}=(Q_{\mathcal{E}}^{ai},Q_{\gamma ai},Q_e^{ai},P_{\mathcal{E}ai},P_{\gamma}^{ai},P_{eai})$. In the present case, the set of first class constraints replacing the former second class set is

$$\overline{\psi}^{ai}:=\tilde{\mathcal{E}}^{ai}+Q_{\mathcal{E}}^{ai}, \quad \overline{\Phi}_{\mathcal{E}ai}:=\Pi_{\mathcal{E}ai}-P_{\mathcal{E}ai},$$

$$\overline{\chi}_{ai}:=\gamma_{ai}-f_{ai}(\tilde{e})+Q_{\gamma ai}, \quad \overline{\Phi}_{\gamma}^{ai}:=\Pi_{\gamma}^{ai}+i\tilde{e}^{ai}-P_{\gamma}^{ai}, \tag{5}$$

$$\overline{\Phi}_K^{ai}:=\Pi_K^{ai}+\tilde{e}^{ai}+Q_e^{ai}, \quad \overline{\Phi}'_{eai}:=\Phi_{eai}+\alpha_{aibj}\Phi_{\gamma}^{bj}+\beta_{ai}^{bj}\chi_{bj}+\eta_{aibj}\Phi_K^{bj}-P_{eai},$$

which reduces to the original set by setting $Q^{ai}=0=P_{bj}$. Let us denote any of the constraints in (5) by $\overline{\Xi}_{\Lambda}$. Any pair satisfies $\{\overline{\Xi}_{\Lambda},\overline{\Xi}_{\Lambda'}\}=0$; i.e., the set (5) is first class. Next, it is necessary to keep the set $\{\mathcal{R}'\}$ first class. This can be done by recalling that the Poisson brackets matrix among the constraints $\{\Xi\}$ is independent of the phase space variables and by following the method of Ref. 7. Thus, one redefines $\mathcal{R}'$ as

$$\overline{\mathcal{R}'} \equiv \mathcal{R}'(Y-\overline{Y}), \tag{6}$$

where

$$Y_A-\overline{Y_A} := \Bigg\{ \tilde{e}^{ai}-Q_e^{ai}, \tilde{\mathcal{E}}^{ai}+Q_{\mathcal{E}}^{ai}, \gamma_{ai}+Q_{\gamma ai}+Q_e^{bj}\frac{\delta f_{ai}}{\delta\tilde{e}^{bj}}, K_{ai}+P_{eai}+iQ_e^{bj}\frac{\delta f_{bj}}{\delta\tilde{e}^{ai}},$$
$$\Pi_{eai}-P_{eai}-iQ_{\gamma ai}+P_\gamma^{bj}\frac{\delta f_{bj}}{\delta\tilde{e}^{ai}}+Q_e^{bj}\left(\frac{\delta^2 f_{ck}}{\delta\tilde{e}^{ai}\delta\tilde{e}^{bj}}\Phi_\gamma^{ck}+i\frac{\delta^2 f_{ai}}{\delta\tilde{e}^{ck}\delta\tilde{e}^{bj}}\Phi_K^{ck}+i\frac{\delta f_{bj}}{\delta\tilde{e}^{ai}}\right),$$
$$\Pi_{\mathcal{E}ai}-P_{\mathcal{E}ai}, \Pi_\gamma^{ai}-P_\gamma^{ai}-iQ_e^{ai}, \Pi_K^{ai}\Bigg\}. \tag{7}$$

The set (6) is in involution with $\{\overline{\Xi}_\Lambda\}$, i.e., $\{\overline{\mathcal{R}'},\overline{\Xi}_\Lambda\}=0$. Hence, the final whole set of constraints is first class and contains an Abelian ideal: $\{\overline{\Xi}\}$. The non-Abelian sector is just given by $\{\overline{\mathcal{R}'}\}$. By construction, this sector preserves the structure of the first class algebra among the elements of $\{\mathcal{R}'\}$. Notice that the set $\{\mathcal{R}\}$ depends only on the configurational variables $(\tilde{e},\mathcal{E},\gamma,K)$. In this way, the most involved modifications to $\{\mathcal{R}'\}$, via Eq. (6), come from the terms that are proportional to the second class constraints. It is worth emphasizing that all the nonpolynomiality of the constraints $\{\{\overline{\mathcal{R}'}\}\cup\{\overline{\Xi}\}\}$ arises only through one function, which is $f_{ai}(\tilde{e})$, appearing in the reality conditions (4). Thus, one might think that a choice of (4) in a polynomial form would solve this undesirable feature. However, as shown in Ref. 5, this not the case and one should look for alternative approaches.

III. NONMINIMAL SELF-DUAL ECKG THEORY

The second order action with scalar field nonminimally coupled to gravity is given by

$$S[g^{ab},\phi]=\int_M d^4x\left\{\sqrt{-g}\mathcal{R}-\frac{1}{2}\sqrt{-g}(g^{ab}\partial_a\phi\partial_b\phi+(m^2+\xi\mathcal{R})\phi^2)\right\}, \tag{8}$$

where ξ is a dimensionless constant. The canonical analysis of this action has been developed in Ref. 8. In a first order formalism one can adopt instead

$$S[\omega',e,\phi]=\int_M d^4x\left\{\frac{1}{2}ee_I^ae_J^b\Omega^2R'^{IJ}_{ab}[\omega']-\frac{1}{2}e(e_I^ae^{bI}\partial_a\phi\partial_b\phi+m^2\phi^2)\right\},$$
$$\Omega^2:=1-\xi\phi^2. \tag{9}$$

As opposed to (8), action (9) gives, upon variation with respect to ω'^{IJ}_a,

$$\omega'^{IJ}_a=\omega_a^{IJ}(e)+K_a^{IJ}, \quad K_a^{IJ}=\frac{1}{2}(e_a^Ie^{bJ}-e_a^Je^{bI})\frac{1}{\Omega^2}\partial_b\Omega^2, \tag{10}$$

where $\omega_a^{IJ}(e)$ is the spin connection for pure gravity and K_a^{IJ} is the contorsion supported by the matter field.[9] To construct a first order action equivalent to the second order action in (8), it is necessary to add the term $-(3/4)(1/\Omega^2)ee_I^ae^{bI}\partial_a\Omega^2\partial_b\Omega^2$ to the action (9). The corresponding canonical analysis of the self-dual part of this modified action was studied in Ref. 10. The conclusion in that paper, at the Hamiltonian level, is that the resulting constraints are nonpolynomial in the phase space variables. In the present work, the self-dual part of the action (9) is studied. Our result is that polynomial constraints are obtained, as opposed to the case in Ref. 10.

The system to be considered is described by the so called nonminimal self-dual Einstein–Cartan–Klein–Gordon (ECKG) action

$$S[e,{}^{+4}A,\phi]=\int d^4xe\left\{\Omega^{2+}\Sigma_{IJ}^{ab+4}F_{ab}^{IJ}({}^{+4}A)+\frac{\alpha}{2}(e_I^ae^{bI}\partial_a\phi\partial_b\phi+m^2\phi^2)\right\},$$

$$\Sigma_{IJ}^{ab}:=\tfrac{1}{2}(e_I^ae_J^b-e_J^ae_I^b),\qquad \Omega^2:=1+\alpha\xi\phi^2,\tag{11}$$

where the parameter α is introduced only to allow a rescaling of the scalar field ϕ. The value $\alpha=-1$ corresponds to the case usually found in the literature.[8,10] ${}^{+4}F_{ab}^{IJ}({}^{+4}A)$ is the curvature of the self-dual connection ${}^{+4}A$.

Proceeding with the canonical analysis, the 3+1 decomposition of space-time gives

$$S=\int dt\int_\Sigma d^3x\left\{\underset{\sim}{N}\Omega^2\left[-\frac{1}{2}\epsilon^{ijk}\tilde{E}_i^a\tilde{E}_j^bF_{abk}\right]+(-i\Omega^2\tilde{E}_i^a)\mathcal{L}_tA_a^i\right\}$$

$$+\int dt\int_\Sigma d^3x\{({}^{+4}A\cdot t)^i\mathcal{D}_a(-i\Omega^2\tilde{E}_i^a)+N^b(-i\Omega^2\tilde{E}_i^a)F_{ab}^i\}$$

$$+\frac{\alpha}{2}\int dt\int_\Sigma d^3x\left\{\underset{\sim}{N}\tilde{E}_i^a\tilde{E}^{bi}\partial_a\phi\partial_b\phi-\frac{1}{\underset{\sim}{N}}[\mathcal{L}_t\phi-\mathcal{L}_N\phi]^2+\underset{\sim}{N}(\sigma)^2m^2\phi^2\right\}.\tag{12}$$

In order to get (12) one performs the usual steps.[4] $\tilde{E}_i^a$ is the densitizied inverse triad field, A_a^i is the three-dimensional projection of the self-dual full connection (gravity +matter) and F_{ab}^i is the corresponding curvature given by $F_{ab}^i=\partial_aA_b^i-\partial_bA_a^i+\epsilon_{jk}^iA_a^jA_b^k$. $(\sigma)^2$ is the determinant of the three-dimensional spatial metric q_{ab}, expressed as a function of $\tilde{E}_i^a$ and ϵ^{ijk} is the volume element of the three-dimensional internal metric $q_{ij}=\mathrm{diag}(+1,+1,+1)$. Both sets of indices run from 1 to 3.

From (12) one finds the momentum variables associated with the gravitational and scalar fields. They are given by $\tilde{\pi}_i^a$ and $\tilde{\pi}_\phi$, where

$$\tilde{\pi}_i^a:=-i\Omega^2\tilde{E}_i^a,\qquad \tilde{\pi}_\phi:=\frac{\delta S}{\delta(\mathcal{L}_t\phi)}=-\frac{\alpha}{\underset{\sim}{N}}[\mathcal{L}_t\phi-\mathcal{L}_N\phi].\tag{13}$$

Then, plugging (13) into (12), one arrives at

$$S=\int dt\int_\Sigma d^3x\{\tilde{\pi}_i^a\mathcal{L}_tA_a^i+\tilde{\pi}_\phi\mathcal{L}_t\phi-(\underset{\sim}{N}^*\tilde{\tilde{C}}+({}^{+4}A\cdot t)^i\tilde{\mathcal{G}}_i+N^a\tilde{\mathcal{V}}_a)\},\tag{14}$$

where

$$\tilde{\tilde{C}}:=-\frac{1}{2}(\Omega^2)^2\epsilon^{ijk}\tilde{\pi}_i^a\tilde{\pi}_j^bF_{abk}+\frac{\alpha}{2}\Omega^2\tilde{\pi}_i^a\tilde{\pi}^{bi}\partial_a\phi\partial_b\phi-\frac{1}{2\alpha}(\Omega^2)^3(\tilde{\pi}_\phi)^2+\frac{\alpha}{2}i(\det\tilde{\pi}_i^a)m^2\phi^2,$$

$$\tilde{\mathcal{G}}_i:=-\mathcal{D}_a\tilde{\pi}_i^a,\qquad \tilde{\mathcal{V}}_a:=-\tilde{\pi}_i^bF_{ba}^i+\tilde{\pi}_\phi\partial_a\phi,\tag{15}$$

are the scalar, vector and Gauss constraints, respectively. In (14), the Lagrange multiplier $\underset{\sim}{N}$ was redefined to $\underset{\sim}{N}^*=\underset{\sim}{N}/(\Omega^2)^3$. Note that the set of constraints (15) is *polynomial* in the phase space variables A_a^i, $\tilde{\pi}_i^a$, ϕ and $\tilde{\pi}_\phi$, where the symplectic structure is given by

$$\{A_a^i(x),\tilde{\pi}_j^b(y)\}=\delta_a^b\delta_j^i\delta^3(x,\tilde{y}),$$

$$\{\phi(x),\tilde{\pi}_\phi(y)\}=\delta^3(x,\tilde{y}).\tag{16}$$

Let us compare the actions (1) and (14). We find the same number of constraints which, nevertheless, have extra terms containing the scalar field. Besides, the new momenta have contributions arising both from the scalar field and the gravity sector.

In order to count the number of degrees of freedom of the theory it is necessary to classify the constraints in terms of their algebra. We find it convenient to use the smeared form of the constraints on Σ. If $\underset{\sim}{N}$, N^a and v^i are arbitrary tensor fields, then one defines

$$C(\underset{\sim}{N}):=\int_\Sigma d^3x\underset{\sim}{N}\tilde{\tilde{C}}(x)$$

$$=\int_\Sigma d^3x\underset{\sim}{N}\left\{-\frac{1}{2}(\Omega^2)^2\epsilon^{ijk}\tilde{\pi}^a_i\tilde{\pi}^b_jF_{abk}+\frac{\alpha}{2}\Omega^2\tilde{\pi}^a_i\tilde{\pi}^{bi}\partial_a\phi\partial_b\phi\right.$$

$$\left.-\frac{1}{2\alpha}(\Omega^2)^3(\tilde{\pi}_\phi)^2+\frac{\alpha}{2}i(\det\tilde{\pi}^a_i)m^2\phi^2\right\},$$

$$C(\mathbf{N}):=\int_\Sigma d^3xN^a\tilde{\mathcal{V}}_a(x)=\int_\Sigma d^3xN^a\{-\tilde{\pi}^b_iF^i_{ba}+\tilde{\pi}_\phi\partial_a\phi\},\tag{17}$$

$$G(v):=\int_\Sigma d^3xv^i\tilde{\mathcal{G}}_i(x)=\int_\Sigma d^3xv^i\{-\mathcal{D}_a\tilde{\pi}^a_i\}.$$

A combination of the vector and Gauss constraints yields the so called *diffeomorphisms* constraint. In terms of the vector field **N**, this constraint has the form

$$D(\mathbf{N}):=\int_\Sigma d^3xN^a[\tilde{\mathcal{V}}_a+A^i_a\tilde{\mathcal{G}}_i](x)=\int_\Sigma d^3xN^a[-\tilde{\pi}^b_iF^i_{ba}+A^i_a(-\mathcal{D}_b\tilde{\pi}^b_i)].\tag{18}$$

The following results are useful in dealing with the algebra of constraints

$$\frac{\delta C(\underset{\sim}{N})}{\delta A^l_c}=-\epsilon_l^{\ ij}\mathcal{D}_b(\underset{\sim}{N}(\Omega^2)^2\tilde{\pi}^c_i\tilde{\pi}^b_j),$$

$$\frac{\delta C(\underset{\sim}{N})}{\delta\tilde{\pi}^c_l}=\underset{\sim}{N}\left[-(\Omega^2)^2\epsilon^{ljk}\tilde{\pi}^a_jF_{cak}+\alpha\Omega^2\tilde{\pi}^{al}\partial_a\phi\partial_c\phi+\left(\frac{\alpha}{2}im^2\phi^2\right)\right.$$

$$\left.\times\left(\frac{3}{3!}\underset{\sim}{\eta}_{abc}\tilde{\pi}^a_j\tilde{\pi}^b_k\epsilon^{jkl}\right),\right]$$

$$\frac{\delta G(v)}{\delta A^l_c}=-v^i\epsilon^k_{il}\tilde{\pi}^c_k,\quad\frac{\delta G(v)}{\delta\tilde{\pi}^c_l}=\mathcal{D}_cv^l,$$

$$\frac{\delta D(\mathbf{N})}{\delta A^l_c}=-\mathcal{L}_{\mathbf{N}}\tilde{\pi}^c_l,\quad\frac{\delta D(\mathbf{N})}{\delta\tilde{\pi}^c_l}=+\mathcal{L}_{\mathbf{N}}A^l_c.\tag{19}$$

Then, by using (19), the algebra of constraints turns out to be

$$\{C(\underset{\sim}{N}),C(\underset{\sim}{M})\}=-D(\mathbf{K})+G(K^aA_a),$$

$$\{C(\underset{\sim}{N}),D(\mathbf{M})\}=-C(\mathcal{L}_{\vec{M}}\underset{\sim}{N}),$$

$$\{C(\underset{\sim}{N}),G(v)\}=0,$$

$$\{D(\mathbf{N}),D(\mathbf{M})\}=D([\mathbf{N},\mathbf{M}]),$$

$$\{D(\mathbf{N}),G(v)\}=G(\mathcal{L}_{\mathbf{N}}v),$$

$$\{G(w),G(v)\}=D(-[w,v]). \tag{20}$$

In (20), the vector field $\mathbf{K}$ is defined by $K^a:=(\Omega^2)^4(\tilde{\pi}_i^a\tilde{\pi}^{bi})(\underset{\sim}{N}\partial_b\underset{\sim}{M}-\underset{\sim}{M}\partial_b\underset{\sim}{N})$, while the commutator of internal vectors is $[w,v]^i:=\epsilon^i_{jk}w^jv^k$. Also, the commutator of spatial vectors is defined by $[\mathbf{N},\mathbf{M}]^a:=\mathcal{L}_{\mathbf{N}}M^a$, as usual.

The set of constraints (20) is *first class*. The counting of degrees of freedom leads to: $2(9)+2(1)-2(7)=6$ phase space variables per point on Σ, which implies 3 *complex* degrees of freedom: two for the gravitational field and one for the scalar field. To recover the real sector of the theory, i.e., three *real* degrees of freedom per point, one has to supply additional constraints on the phase space variables A_a^i, $\tilde{\pi}_i^a$, ϕ, $\tilde{\pi}_\phi$. This is the subject of the following section.

IV. REAL DEGREES OF FREEDOM

The real sector of the theory is recovered by extending the corresponding steps developed for pure gravity in Ref. 5. To begin with, let us consider the action (14) in the explicit form

$$S=\int dt\int_\Sigma d^3x\{(-i\Omega^2\tilde{E}_i^a)\mathcal{L}_tA_a^i+\tilde{\pi}_\phi\mathcal{L}_t\phi-(\underset{\sim}{N}^*\tilde{\tilde{C}}+({}^{+4}A\cdot t)^i\tilde{\mathcal{G}}_i+N^a\tilde{\mathcal{V}}_a)\}, \tag{21}$$

where

$$\tilde{\tilde{C}}:=(\Omega^2)^2\left(-\frac{1}{2}\epsilon^{ijk}\right)(-i\Omega^2\tilde{E}_i^a)(-i\Omega^2\tilde{E}_j^b)F_{abk}+\frac{\alpha}{2}\Omega^2(-i\Omega^2\tilde{E}_i^a)(-i\Omega^2\tilde{E}^{bi})\partial_a\phi\partial_b\phi$$
$$-\frac{1}{2\alpha}(\Omega^2)^3(\tilde{\pi}_\phi)^2+\frac{\alpha}{2}i(-i\Omega^2)^3(\det\tilde{E}_i^a)m^2\phi^2,$$
$$\tilde{\mathcal{G}}_i:=-\mathcal{D}_a(-i\Omega^2\tilde{E}_i^a), \tag{22}$$
$$\tilde{\mathcal{V}}_a:=-(-i\Omega^2\tilde{E}_i^b)F^i_{ba}+\tilde{\pi}_\phi\partial_a\phi.$$

Step (i) in the construction consists of splitting each one of the fields involved in (22) into their real and imaginary parts,

$$\tilde{E}^{ai}=\tilde{e}^{ai}+i\tilde{\mathcal{E}}^{ai},\quad A_{ai}=M_{ai}+iV_{ai},\quad \phi=\phi_1+i\phi_2,\quad \tilde{\pi}_\phi=\tilde{\pi}_1+i\tilde{\pi}_2. \tag{23}$$

Now the key point, implemented as part of step (ii), is to promote each one of the real and imaginary parts to *independent* variables, which implies that the enlarged phase space has $2[4\times9+4]=80$ degrees of freedom per point on Σ. Next, one has to determine the corresponding momenta, which results in the following constraints:

$$\Phi_{\mathcal{E}ai}:=\Pi_{\mathcal{E}ai},\quad \Phi_{eai}:=\Pi_{eai},\quad \Phi_M^{ai}:=\Pi_M^{ai}+i\Omega_1^2\tilde{e}^{ai},\quad \Phi_V^{ai}:=\Pi_V^{ai}-\Omega_1^2\tilde{e}^{ai},$$
$$\Phi_{\pi_1}:=\Pi_{\pi_1},\quad \Phi_{\pi_2}:=\Pi_{\pi_2},\quad \Phi_{\phi_1}:=\Pi_{\phi_1}-\tilde{\pi}_1,\quad \Phi_{\phi_2}:=\Pi_{\phi_2}-i\tilde{\pi}_1, \tag{24}$$

denoted generically by Π. Note that Π_M^{ai} and Π_{ϕ_2} are purely imaginary, i.e., there are 40 primary constraints arising from the definition of momenta. The corresponding symplectic structure is

$$\{\tilde{\mathcal{E}}^{ai}(x),\Pi_{\mathcal{E}bj}(y)\}:=\delta_b^a\delta_j^i\delta^3(\tilde{x},y),\quad \{\tilde{e}^{ai}(x),\Pi_{ebj}(y)\}:=\delta_b^a\delta_j^i\delta^3(\tilde{x},y),$$

$$\{M_{ai}(x),\Pi_M^{bj}(y)\}:=\delta_a^b\delta_i^j\delta^3(x,\tilde{y}),\quad \{V_{ai}(x),\Pi_V^{bj}(y)\}:=\delta_a^b\delta_i^j\delta^3(x,\tilde{y}),$$

$$\{\phi_1(x),\Pi_{\phi_1}(y)\}:=\delta^3(x,\tilde{y}),\quad \{\phi_2(x),\Pi_{\phi_2}(y)\}:=\delta^3(x,\tilde{y}),$$

$$\{\tilde{\pi}_1(x),\Pi_{\pi_1}(y)\}:=\delta^3(\tilde{x},y),\quad \{\tilde{\pi}_2(x),\Pi_{\pi_2}(y)\}:=\delta^3(\tilde{x},y). \tag{25}$$

As for step (iii), the reality conditions are chosen here as a generalization of (4), i.e.,

$$\Psi_{\mathcal{E}}^{ai}:=\tilde{\mathcal{E}}^{ai},\quad \Psi_{Mai}:=M_{ai}-\Gamma_{ai}(\tilde{e})+\frac{1}{2}\epsilon_{ij}^{k}\underset{\sim}{e}_a^j\tilde{e}_k^c\frac{1}{\Omega_1^2}\partial_c\Omega_1^2,$$

$$\Psi_{\phi_2}:=\phi_2,\quad \Psi_{\pi_2}:=\tilde{\pi}_2, \tag{26}$$

where $\Gamma_{ai}(e)$ is the three-dimensional spin connection. Again, $\Psi_{\mathcal{E}}^{ai}$ plays the role of enforcing $\tilde{E}^{ai}$ to be real and Ψ_{Mai} keeps $\tilde{E}^{ai}$ real upon evolution. The term $\frac{1}{2}\epsilon_{ij}^{k}\underset{\sim}{e}_a^j\tilde{e}_k^c(1/\Omega_1^2)\partial_c\Omega_1^2$ is the *real* contribution of matter to the full connection A_a^i: it is determined as the real term of the matter contribution to the spatial part of ${}^+A$, upon variation of (11). Also, $\Psi_{\phi_2},\Psi_{\pi_2}$ constrain the scalar field, ϕ, to the real sector. At this stage there are 60 primary constraints, 20 of which arise from the reality conditions (26).

In the next step (iv), it is necessary to preserve upon evolution the full set of primary constraints (24) and (26). Before doing so, it is convenient to redefine some of them, Φ_{eai},Φ_{ϕ_1} and Φ_{π_1}, as

$$\Phi'_{eai}(x):=\Phi_{eai}(x)+\lambda_{aibj}(x,z)\Phi_M^{bj}(z)+\varepsilon_{ai}^{bj}(x,z)\Psi_{Mbj}(z)+\vartheta_{aibj}(x,z)\Phi_V^{bj}(z),$$

$$\Phi'_{\pi_1}:=\Phi_{\pi_1}-i\Psi_{\phi_2}, \tag{27}$$

$$\Phi'_{\phi_1}(x):=\Phi_{\phi_1}(x)+\mathcal{A}_{ai}(x,z)\Phi_M^{ai}(z)+\mathcal{B}^{ai}(x,z)\Psi_{Mai}(z)+\mathcal{C}_{ai}(x,z)\Phi_V^{ai}(z),$$

where

$$\lambda_{aibj}(x,y)=-\frac{\delta\Psi_{Mbj}(y)}{\delta\tilde{e}^{ai}(x)},\quad \varepsilon_{ai}^{bj}(x,y)=i\Omega_1^2(y)\delta_a^b\delta_i^j\delta^3(x,\tilde{y}),$$

$$\vartheta_{aibj}(x,y)=-i\frac{\delta\Psi_{Mbj}(y)}{\delta\tilde{e}^{ai}(x)},$$

$$\mathcal{A}_{ai}(x,y)=-\frac{\delta\Psi_{Mai}(y)}{\delta\phi_1(x)},\quad \mathcal{B}^{ai}(x,y)=i\frac{\delta\Omega_1^2(y)}{\delta\phi_1(x)}\tilde{e}^{ai}(y),$$

$$\mathcal{C}_{ai}(x,y)=-i\frac{\delta\Psi_{Mai}(y)}{\delta\phi_1(x)}. \tag{28}$$

Here, the Einstein summation convention for dummy indices is extended to the continuous case in such a way that it includes an implicit three-dimensional integral for the repeated z variable. Thus, for instance, the term $\lambda_{aibj}(x,z)\Phi_M^{bj}(z)$ means $\int_\Sigma d^3z\lambda_{aibj}(x,z)\Phi_M^{bj}(z)$.

As the first step in classifying the constraints into first and second class one computes the Poisson brackets of the constraints $\Phi_{\mathcal{E}ai}(x)$, $\Psi^{ai}_{\mathcal{E}}(x)$, $\Phi^{ai}_{M}(x)$, $\Psi_{Mai}(x)$, $\Phi_{\phi_2}(x)$, $\Psi_{\phi_2}(x)$, $\Phi_{\pi_2}(x)$, $\Psi_{\pi_2}(x)$, $\Phi'_{\phi_1}(x)$, $\Phi^{ai}_{V}(x)$, $\Phi'_{eai}(x)$ and $\Phi'_{\pi_1}(x)$. In the standard notation, the result can be expressed as

$$D=\begin{pmatrix} A & 0 & 0 \\ 0 & B & 0 \\ 0 & 0 & C \end{pmatrix}, \tag{29}$$

where

$$A=\begin{array}{c|cccc} & \Phi_{\mathcal{E}bj}(y) & \Psi^{bj}_{\mathcal{E}}(y) & \Phi^{bj}_{M}(y) & \Psi_{Mbj}(y) \\ \Phi_{\mathcal{E}ai}(x) & 0 & -\delta^b_a\delta^j_i\delta^3(x,\tilde{y}) & 0 & 0 \\ \Psi^{ai}_{\mathcal{E}}(x) & \delta^a_b\delta^i_j\delta^3(\tilde{x},y) & 0 & 0 & 0 \\ \Phi^{ai}_{M}(x) & 0 & 0 & 0 & -\delta^a_b\delta^i_j\delta^3(\tilde{x},y) \\ \Psi_{Mai}(x) & 0 & 0 & \delta^b_a\delta^j_i\delta^3(x,\tilde{y}) & 0 \end{array}, \tag{30}$$

$$B=\begin{array}{c|cccc} & \Phi_{\phi_2}(y) & \Psi_{\phi_2}(y) & \Phi_{\pi_2}(y) & \Psi_{\pi_2}(y) \\ \Phi_{\phi_2}(x) & 0 & -\delta^3(\tilde{x},y) & 0 & 0 \\ \Psi_{\phi_2}(x) & \delta^3(x,\tilde{y}) & 0 & 0 & 0 \\ \Phi_{\pi_2}(x) & 0 & 0 & 0 & -\delta^3(x,\tilde{y}) \\ \Psi_{\pi_2}(x) & 0 & 0 & \delta^3(\tilde{x},y) & 0 \end{array}, \tag{31}$$

$$C=\begin{array}{c|cccc} & \Phi'_{\phi_1}(y) & \Phi^{bj}_{V}(y) & \Phi'_{ebj}(y) & \Phi'_{\pi_1}(y) \\ \Phi'_{\phi_1}(x) & 0 & \dfrac{\delta\Omega^2_1(y)}{\delta\phi_1(x)}\tilde{e}^{bj}(y) & 0 & -\delta^3(\tilde{x},y) \\ \Phi^{ai}_{V}(x) & -\dfrac{\delta\Omega^2_1(x)}{\delta\phi_1(y)}\tilde{e}^{ai}(x) & 0 & -\Omega^2_1(x)\,\delta^a_b\delta^i_j\delta^3(\tilde{x},y) & 0 \\ \Phi'_{eai}(x) & 0 & \Omega^2_1(y)\,\delta^b_a\delta^j_i\delta^3(x,\tilde{y}) & 0 & 0 \\ \Phi'_{\pi_1}(x) & \delta^3(x,\tilde{y}) & 0 & 0 & 0 \end{array}. \tag{32}$$

From the structure of the matrices (29)–(32) one concludes that the set of constraints arising from the definition of the momenta, together with those which come from the reality conditions are *second class*. On the other hand, the original set of constraints $\tilde{\tilde{C}}$, $\tilde{\mathcal{G}}_i$, $\tilde{\mathcal{V}}_a$, in the complex theory, were the generators of the gauge symmetry of the system. To show that this property remains so in the present real theory, one begins by redefining them in such a way that they have zero Poisson brackets with the second class constraints. Then, it should be verified that this redefinition preserves the first class character of the algebra among them. Recall that $\tilde{\tilde{C}}$, $\tilde{\mathcal{G}}_i$ and $\tilde{\mathcal{V}}_a$ depend only upon configuration variables (See (15) and (23)). Denoting any of them by $\mathcal{R}$, we find that the appropriate redefinition is

$$\mathcal{R}'(x) := \mathcal{R}(x) + I^{bj}(x,z)\Psi_{Mbj}(z) + N_{bj}(x,z)\Phi_V^{bj}(z) + O^{bj}(x,z)\Phi'_{ebj}(z) + H_{bj}(x,z)\Psi_{\mathcal{E}}^{bj}(z) + P(x,z)\Psi_{\pi_2}(z) + Q(x,z)\Psi_{\phi_2}(z) + R(x,z)\Phi'_{\phi_1}(z) + S(x,z)\Phi'_{\pi_1}(z), \tag{33}$$

where

$$I^{ai}(x,y) = \{\Phi_M^{ai}(y), \mathcal{R}(x)\}, \quad H_{ai}(x,y) = \{\Phi_{\mathcal{E}ai}(y), \mathcal{R}(x)\},$$

$$N_{ai}(x,y) = -\frac{1}{\Omega_1^2(y)}\{\Phi'_{eai}(y), \mathcal{R}(x)\}, \quad R(x,y) = -\{\Phi'_{\pi_1}(y), \mathcal{R}(x)\},$$

$$O^{ai}(x,y) = \frac{1}{\Omega_1^2(y)}\left[\{\Phi_V^{ai}(y), \mathcal{R}(x)\} + \frac{\delta\Omega_1^2(y)}{\delta\phi_1(z)}\tilde{e}^{ai}(y)\{\Phi'_{\pi_1}(z), \mathcal{R}(x)\}\right],$$

$$P(x,y) = \{\Phi_{\pi_2}(y), \mathcal{R}(x)\}, \quad Q(x,y) = \{\Phi_{\phi_2}(y), \mathcal{R}(x)\},$$

$$S(x,y) = \{\Phi'_{\phi_1}(y), \mathcal{R}(x)\} - \frac{1}{\Omega_1^2(z)} \frac{\delta\Omega_1^2(z)}{\delta\phi_1(y)}\tilde{e}^{bj}(z)\{\Phi'_{ebj}(z), \mathcal{R}(x)\}. \tag{34}$$

The Poisson brackets between any pair $\mathcal{Q}'$ and $\mathcal{R}'$ is weakly zero. This can be shown by calculating

$$\begin{aligned}\{\mathcal{Q}'(x), \mathcal{R}'(y)\} &\approx \{\mathcal{Q}'(x), \mathcal{R}(y)\} \\ &= -\frac{1}{\Omega_1^2(z)}\{\Phi'_{eai}(z), \mathcal{Q}(x)\}\{\Phi_V^{ai}(z), \mathcal{R}(y)\} + \frac{1}{\Omega_1^2(z)}\{\Phi_V^{ai}(z), \mathcal{Q}(x)\} \\ &\quad \times\{\Phi'_{eai}(z), \mathcal{R}(y)\} - \{\Phi'_{\pi_1}(z), \mathcal{Q}(x)\}\{\Phi'_{\phi_1}(z), \mathcal{R}(y)\} + \{\Phi'_{\phi_1}(z), \mathcal{Q}(x)\} \\ &\quad \times\{\Phi'_{\pi_1}(z), \mathcal{R}(y)\} + \frac{1}{\Omega_1^2(z)} \frac{\delta\Omega_1^2(z)}{\delta\phi_1(\omega)}\tilde{e}^{ai}(z)\{\Phi'_{\pi_1}(\omega), \mathcal{Q}(x)\}\{\Phi'_{eai}(z), \mathcal{R}(y)\} \\ &\quad - \frac{1}{\Omega_1^2(\omega)} \frac{\delta\Omega_1^2(\omega)}{\delta\phi_1(z)}\tilde{e}^{ai}(\omega)\{\Phi'_{eai}(\omega), \mathcal{Q}(x)\}\{\Phi'_{\pi_1}(z), \mathcal{R}(y)\}. \end{aligned} \tag{35}$$

The above result was obtained by substituting (33) together with the fact that $\mathcal{Q}(x)$, $\mathcal{R}(y)$, $\Psi_M, \Psi_{\mathcal{E}}, \Psi_{\pi_2}$ and Ψ_{ϕ_2} are independent of the momenta. Now, by using the explicit form of $\Phi'_{eai}, \Phi'_{\phi_1}$ and Φ'_{π_1} one finds, after a long (but otherwise direct) calculation

$$\begin{aligned}\{\mathcal{Q}'(x), \mathcal{R}'(y)\} \approx &-\frac{1}{\Omega_1^2(z)}\{\Phi_{eai}(z), \mathcal{Q}(x)\}\{\Phi_V^{ai}(z), \mathcal{R}(y)\} \\ &+ \frac{1}{\Omega_1^2(z)}\{\Phi_V^{ai}(z), \mathcal{Q}(x)\}\{\Phi_{eai}(z), \mathcal{R}(y)\} \\ &- \{\Phi_{\pi_1}(z), \mathcal{Q}(x)\}\{\Phi_{\phi_1}(z), \mathcal{R}(y)\} + \{\Phi_{\phi_1}(z), \mathcal{Q}(x)\}\{\Phi_{\pi_1}(z), \mathcal{R}(y)\} \\ &+ \frac{1}{\Omega_1^2(z)} \frac{\delta\Omega_1^2(z)}{\delta\phi_1(\omega)}\tilde{e}^{ai}(z)\{\Phi_{\pi_1}(\omega), \mathcal{Q}(x)\}\{\Phi_{eai}(z), \mathcal{R}(y)\}\end{aligned}$$

$$-\frac{1}{\Omega_1^2(\omega)}\frac{\delta\Omega_1^2(\omega)}{\delta\phi_1(z)}\widetilde{e}^{ai}(\omega)\{\Phi_{eai}(\omega),\mathcal{Q}(x)\}\{\Phi_{\pi_1}(z),\mathcal{R}(y)\}. \tag{36}$$

The above expression is most suitably calculated in terms of the *original* complex phase space variables. The symplectic structure (16) yields

$$\{A_a^i(x),\widetilde{E}_j^b(y)\}=\left\{A_a^i(x),\frac{i\widetilde{\pi}_j^b(y)}{\Omega^2(y)}\right\}=\frac{i}{\Omega^2(y)}\delta_a^b\delta_j^i\delta^3(x,\widetilde{y}), \tag{37}$$

$$\{\widetilde{E}_i^a(x),\widetilde{\pi}_\phi(y)\}=\left\{\frac{i\widetilde{\pi}_i^a(x)}{\Omega^2(x)},\widetilde{\pi}_\phi(y)\right\}=-\frac{1}{\Omega^2(x)}\widetilde{E}_i^a(x)\frac{\delta\Omega^2(x)}{\delta\phi(y)}. \tag{38}$$

Upon substitution of these expressions in (36) one obtains

$$\begin{aligned}\{\mathcal{Q}'(x),\mathcal{R}'(y)\}\approx&\{A_a^i(z),\widetilde{E}_j^b(\omega)\}\left(\frac{\delta\mathcal{Q}(x)}{\delta A_a^i(z)}\frac{\delta\mathcal{R}(y)}{\delta\widetilde{E}_i^b(z)}-\frac{\delta\mathcal{Q}(x)}{\delta\widetilde{E}_j^b(z)}\frac{\delta\mathcal{R}(y)}{\delta A_a^i(z)}\right)\\&+\{\phi(z),\widetilde{\pi}_\phi(\omega)\}\left(\frac{\delta\mathcal{Q}(x)}{\delta\phi(z)}\frac{\delta\mathcal{R}(y)}{\delta\widetilde{\pi}_\phi(z)}-\frac{\delta\mathcal{Q}(x)}{\delta\widetilde{\pi}_\phi(z)}\frac{\delta\mathcal{R}(y)}{\delta\phi(z)}\right)\\&+\left\{\widetilde{E}_i^a(z),\{\widetilde{\pi}_\phi(\omega)\}\left(\frac{\delta\mathcal{Q}(x)}{\delta\widetilde{E}_i^a(z)}\frac{\delta\mathcal{R}(y)}{\delta\widetilde{\pi}_\phi(\omega)}-\frac{\delta\mathcal{Q}(x)}{\delta\widetilde{\pi}_\phi(\omega)}\frac{\delta\mathcal{R}(y)}{\delta\widetilde{E}_i^a(z)}\right)\right.\\&\approx\{\mathcal{Q}(x),\mathcal{R}(y)\}_{(A,\pi),(\phi,\pi_\phi)}\approx 0.\end{aligned} \tag{39}$$

In the last line, the Poisson brackets are taken with respect to the original complex symplectic structure (16). Therefore, it has been shown that the Poisson brackets between any pair of constraints $\tilde{\tilde{\mathrm{C}}}'$, $\widetilde{\mathcal{V}}'$, $\widetilde{\mathcal{G}}'$ are weakly zero.

Thus, the system is described by the following set of primary constraints: $\Phi_{\mathcal{E}ai}(x)$, $\Psi_{\mathcal{E}}^{ai}(x)$, $\Phi_M^{ai}(x)$, $\Psi_{Mai}(x)$, $\Phi_{\phi_2}(x)$, $\Psi_{\phi_2}(x)$, $\Phi_{\pi_2}(x)$, $\Psi_{\pi_2}(x)$, $\Phi'_{\phi_1}(x)$, $\Phi_V^{ai}(x)$, $\Phi'_{eai}(x)$, $\Phi'_{\pi_1}(x)$, $\tilde{\tilde{\mathrm{C}}}'$, $\widetilde{\mathcal{V}}'$ and $\widetilde{\mathcal{G}}'$. Now, following the Dirac method, the time conservation of the constraints is imposed using the Hamiltonian density

$$\begin{aligned}\mathcal{H}=&\mu^{\mathcal{E}ai}\Phi_{\mathcal{E}ai}+\mu_{ai}^{\mathcal{E}}\Psi_{\mathcal{E}}^{ai}+\mu_{ai}^{M}\Phi_M^{ai}+\mu^{Mai}\Psi_{Mai}+\mu^{\phi_2}\Phi_{\phi_2}+\nu^{\phi_2}\Psi_{\phi_2}\\&+\mu^{\pi_2}\Phi_{\pi_2}+\nu^{\pi_2}\Psi_{\pi_2}+\mu^{\phi_1}\Phi'_{\phi_1}+\mu_{ai}^{V}\Phi_V^{ai}+\mu^{eai}\Phi'_{eai}+\mu^{\pi_1}\Phi'_{\pi_1}\\&+\underset{\sim}{N}\tilde{\tilde{C}}'+N^a\widetilde{\mathcal{V}'_a}+N^i\widetilde{\mathcal{G}'_i},\end{aligned} \tag{40}$$

where no three-dimensional integral is involved.

From Eqs. (33) and (39) one finds that the Poisson brackets between $\tilde{\tilde{\mathrm{C}}}'$, $\widetilde{\mathcal{V}'}$, $\widetilde{\mathcal{G}'}$ and $H=\int_\Sigma d^3x\mathcal{H}(x)$ are weakly zero. Finally, since the set of constraints $\Phi_{\mathcal{E}ai}(x)$, $\Psi_{\mathcal{E}}^{ai}(x)$, $\Phi_M^{ai}(x)$, $\Psi_{Mai}(x)$, $\Phi_{\phi_2}(x)$, $\Psi_{\phi_2}(x)$, $\Phi_{\pi_2}(x)$, $\Psi_{\pi_2}(x)$, $\Phi'_{\phi_1}(x)$, $\Phi_V^{ai}(x)$, $\Phi'_{eai}(x)$ and $\Phi'_{\pi_1}(x)$ is second class, the Lagrange multipliers $\mu^{\mathcal{E}^{ai}}$, $\mu_{ai}^{\mathcal{E}}$, μ_{ai}^{M}, $\mu^{M^{ai}}$, μ^{ϕ_2}, ν^{ϕ_2}, μ^{π_2}, ν^{π_2}, μ^{ϕ_1}, $\mu^{V}{}_{ai}$, μ^{eai}, μ^{π_1} are determined, and shown to be zero. In other words, there are no secondary constraints and the total Hamiltonian density is given by

$$\mathcal{H}_{\mathrm{Total}}=\underset{\sim}{N}\tilde{\tilde{C}}'+N^a\widetilde{\mathcal{V}'}_a+N^i\widetilde{\mathcal{G}'}_i, \tag{41}$$

which is a combination of the first class constraints only.

Now, let us count the physical degrees of freedom in terms of the real variables that we have introduced. Recall that the enlarged phase space, with configuration variables (23), has dimension $2\times9\times4+2\times4=80$ per space point. Since there are $6\times9+6\times1=60$ second class constraints (24) and (26), the partially reduced phase space has dimension 20. The corresponding partially reduced symplectic structure can be obtained by using Dirac brackets. To this end, the inverse of the second class constraints Poisson brackets matrix (29) is needed. Its calculation produces

$$D^{-1}=\begin{pmatrix} A^{-1} & 0 & 0 \\ 0 & B^{-1} & 0 \\ 0 & 0 & C^{-1} \end{pmatrix}, \tag{42}$$

where

$$A^{-1}=\begin{pmatrix} 0 & \delta^a_b\delta^i_j\delta^3(\tilde{x},y) & 0 & 0 \\ -\delta^b_a\delta^j_i\delta^3(x,\tilde{y}) & 0 & 0 & 0 \\ 0 & 0 & 0 & \delta^b_a\delta^j_i\delta^3(x,\tilde{y}) \\ 0 & 0 & -\delta^a_b\delta^i_j\delta^3(\tilde{x},y) & 0 \end{pmatrix}, \tag{43}$$

$$B^{-1}=\begin{pmatrix} 0 & \delta^3(x,\tilde{y}) & 0 & 0 \\ -\delta^3(\tilde{x},y) & 0 & 0 & 0 \\ 0 & 0 & 0 & \delta^3(\tilde{x},y) \\ 0 & 0 & -\delta^3(x,\tilde{y}) & 0 \end{pmatrix}, \tag{44}$$

$$C^{-1}=\begin{pmatrix} 0 & 0 & 0 & \delta^3(x,\tilde{y}) \\ 0 & 0 & \frac{1}{\Omega_1^2(y)}\delta^a_b\delta^i_j\delta^3(x,\tilde{y}) & 0 \\ 0 & -\frac{1}{\Omega_1^2(x)}\delta^b_a\delta^j_i\delta^3(\tilde{x},y) & 0 & -\frac{1}{\Omega_1^2(x)}\frac{\delta\Omega_1^2(x)}{\delta\phi_1(y)}e^{bj}(x) \\ -\delta^3(\tilde{x},y) & 0 & \frac{1}{\Omega_1^2(y)}\frac{\delta\Omega_1^2(y)}{\delta\phi_1(x)}e^{ai}(y) & 0 \end{pmatrix}. \tag{45}$$

The use of (42)–(45), leads to

$$\begin{aligned} \{f(x),g(y)\}^* = {} & +\{f(x),g(y)\} \\ & -\{f(x),\Phi_{\mathcal{E}ai}(z)\}\{\Psi^{ai}_{\mathcal{E}}(z),g(y)\}+\{f(x),\Psi^{ai}_{\mathcal{E}}(z)\}\{\Phi_{\mathcal{E}ai}(z),g(y)\} \\ & -\{f(x),\Phi^{ai}_M(z)\}\{\Psi_{Mai}(z),g(y)\}+\{f(x),\Psi_{Mai}(z)\}\{\Phi^{ai}_M(z),g(y)\} \\ & -\{f(x),\Phi_{\phi_2}(z)\}\{\Psi_{\phi_2}(z),g(y)\}+\{f(x),\Psi_{\phi_2}(z)\}\{\Phi_{\phi_2}(z),g(y)\} \\ & -\{f(x),\Phi_{\pi_2}(z)\}\{\Psi_{\pi_2}(z),g(y)\}+\{f(x),\Psi_{\pi_2}(z)\}\{\Phi_{\pi_2}(z),g(y)\} \\ & -\{f(x),\Phi'_{\phi_1}(z)\}\{\Phi'_{\pi_1}(z),g(y)\}+\{f(x),\Phi'_{\pi_1}(z)\}\{\Phi'_{\phi_1}(z),g(y)\} \end{aligned}$$

$$-\{f(x),\Phi_V^{ai}(z)\}\frac{1}{\Omega_1^2(z)}\{\Phi'_{eai}(z),g(y)\}+\{f(x),\Phi'_{eai}(z)\}\frac{1}{\Omega_1^2(z)}\{\Phi_V^{ai}(z),g(y)\}$$
$$-\{f(x),\Phi'_{\pi_1}(z)\}\left[\frac{1}{\Omega_1^2(w)}\ \frac{\delta\Omega_1^2(\omega)}{\delta\phi_1(z)}e^{ai}(w)\right]\{\Phi'_{eai}(w),g(y)\}$$
$$+\{f(x),\Phi'_{eai}(z)\}\left[\frac{1}{\Omega_1^2(z)}\ \frac{\delta\Omega_1^2(z)}{\delta\phi_1(\omega)}e^{ai}(z)\right]\{\Phi'_{\pi_1}(\omega),g(y)\}, \tag{46}$$

for the Dirac brackets of any two functions f and g on the enlarged phase space. Finally, upon partial reduction, the canonical variables are V_a^i, $\pi_j^b=-\Omega_1^2 e_j^b$, ϕ_1, π_1 and the reduced symplectic structure is just

$$\{V_a^i(x),\pi_j^b(y)\}^*=\delta_a^b\delta^i_j\delta^3(x,\tilde{y}),$$
$$\{\phi_1(x),\pi_1(y)\}^*=\delta^3(x,\tilde{y}). \tag{47}$$

In the same way as in the pure gravity case,[5] the first class constraints (15) turn out to be either purely real or purely imaginary in the above partially reduced phase space. Then, the physical phase space has dimension $20-2\times7=6$, as expected for a real scalar field coupled to real gravity.

V. CONCLUSIONS AND PERSPECTIVES

Previous results yielding the identification in phase space of the real sector of pure complex gravity[5] have been successfully extended in this work to incorporate the case of a scalar field nonminimally coupled to gravity, starting from (complex) Ashtekar variables. This provides further support for the general validity of the method proposed.

The procedure is as follows: the complex canonical variables are splitted into real and imaginary parts, each of which is taken as an independent new configuration variable. The corresponding momenta are subsequently defined from the action, leading to primary constraints. The real sector of the theory is next defined by introducing appropriate reality conditions in the form of additional primary constraints. This is possible because the original phase space has been extended. The whole set of constraints is next classified into first and second class, after imposing the conservation of the primary constraints upon evolution. Finally, one faces the problem of how to conveniently deal with the resulting second class constraints, which include the reality conditions.

The advantages of our approach are: (i) Reality conditions are incorporated as true second class constraints within the canonical description of an extended phase space, uniquely associated to each physical system. (ii) It leads to the standard Dirac's method of counting the real physical degrees of freedom arising from an originally complex theory. (iii) Although we start from a pair of reality conditions (4), only the first is truly an input, because the second condition appears as the consequence of demanding the conservation of the former upon evolution.

As opposed to Ref. 10, we have presented here a theory for a scalar field nonminimally coupled to gravity, leading to polynomial constraints, using Ashtekar variables. Unfortunately, the nonpolynomiality shows up after implementing the reality conditions, in the process of identifying the real sector of the theory. This happens either for the nonpolynomial form of the reality conditions (26), or for their polynomial realization. Recently, however, certain nonpolynomial constraints have been shown to be tractable in the quantum theory.[3,11,12] Interestingly enough, in our case the whole nonpolynomiality is encoded in the single function Γ_{ai} appearing in (26). It certainly remains an open problem to determine whether or not the results presented here may provide a tractable alternative to deal with the quantum situation.

The use of Dirac brackets, which is the standard way of eliminating the second class constraints, yields the expected real nonpolynomial form of the theory. For example, it leads to the Palatini canonical form in the case of pure gravity.[4] To explore an alternative preventing the use of Dirac brackets in the pure gravity case, we have implemented the conversion of the full set of second class constraints into a first class set, following the method of Ref. 7. Thus, we have rewritten pure real gravity as a theory involving an alternative set of first class constraints, which, for example, has not been previously done starting from the Palatini formulation with second class constraints. However, their physical meaning, together with their usefulness in a quantum theory still needs to be clarified. The method of Ref. 7 works whenever the Poisson brackets matrix of the original second class constraints is independent of the phase space variables. This is indeed the case for pure gravity, but not for the scalar field nonminimally coupled to gravity considered in this work. Hence, the application of the same strategy to the latter theory would first require an extension of the method in Ref. 7 .

(Received 16 September 1998; accepted 23 November 1998)

Within a framework of noncommutative geometry, we develop an analog of (pseudo-) Riemannian geometry on finite and discrete sets. On a finite set, there is a counterpart of the continuum metric tensor with a simple geometric interpretation. The latter is based on a correspondence between first order differential calculi and digraphs (the vertices of the latter are given by the elements of the finite set). Arrows originating from a vertex span its (co)tangent space. If the metric is to measure length and angles at some point, it has to be taken as an element of the *left-linear* tensor product of the space of 1-forms with itself, and not as an element of the (nonlocal) tensor product over the algebra of functions, as considered previously by several authors. It turns out that linear connections can always be extended to this left tensor product, so that metric compatibility can be defined in the same way as in continuum Riemannian geometry. In particular, in the case of the universal differential calculus on a finite set, the Euclidean geometry of polyhedra is recovered from conditions of metric compatibility and vanishing torsion. In our rather general framework (which also comprises structures which are far away from continuum differential geometry), there is, in general, nothing like a Ricci tensor or a curvature scalar. Because of the nonlocality of tensor products (over the algebra of functions) of forms, corresponding components (with respect to some module basis) turn out to be rather nonlocal objects. But one can make use of the parallel transport associated with a connection to ''localize'' such objects, and in certain cases there is a distinguished way to achieve this. In particular, this leads to covariant components of the curvature tensor which allow a contraction to a Ricci tensor. Several examples are worked out to illustrate the procedure. Furthermore, in the case of a differential calculus associated with a hypercubic lattice we propose a new discrete analogue of the (vacuum) Einstein equations. © *1999 American Institute of Physics.* [S0022-2488(99)00303-5]

I. INTRODUCTION

In a series of papers[1–5] we have developed a formalism of differential geometry on finite and discrete sets with applications, in particular, to lattice gauge theory[6] and discrete completely integrable models.[7]

The most basic ''differential geometric'' structure on a discrete set $\mathcal{M}$ is a *differential calculus* $(\Omega(\mathcal{M}),\mathrm{d})$, where $\Omega(\mathcal{M})=\oplus_{r\geqslant 0}\Omega^r(\mathcal{M})$ is an analog of the algebra of differential forms on a differentiable manifold and the $\mathbb{C}$-linear map $\mathrm{d}:\Omega^r(\mathcal{M})\rightarrow\Omega^{r+1}(\mathcal{M})$ generalizes the exterior derivative. Here $\mathcal{A}:=\Omega^0(\mathcal{M})$ is the algebra of $\mathbb{C}$-valued functions on $\mathcal{M}$ and noncommutativity enters the stage via nontrivial commutation relations between functions and differentials [which are elements of $\Omega^1(\mathcal{M})$]. On a discrete set there are many choices of a (first order) differential

[a)]Electronic mail: fmuelle@gwdg.de

calculus and it turned out[3] that these amount to the selection of a digraph structure and thus neighborhood relations on the discrete set.

Whereas the concept of a connection seems to be well understood in the framework of noncommutative geometry, this is not quite so for the concept of a metric. In Connes' approach to noncommutative geometry,[8] Riemannian geometry is encoded in a self-adjoint operator on a Hilbert space and recovered from it via a formula for the distance of two points. The distance formula is then generalized to a more abstract setting, including the case of discrete sets (see also Ref. 9 and references therein). A major problem with this approach is that it is bound to (generalizations of) positive definite metrics and thus at least not directly applicable to space–time geometry. The underlying philosophy of ''spectral geometry,'' namely that all geometrical data should be encoded in the spectrum of certain self-adjoint operators on a Hilbert space, is certainly very interesting but by no means compulsive.

In several papers (see Refs. 5, 10–12, for example) a metric in noncommutative geometry has been taken to be an element of the tensor product space $\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})$ with certain properties. Here $\Omega^1(\mathcal{A})$ is the space of 1-forms of a differential calculus $(\Omega(\mathcal{A}),\mathrm{d})$ over an associative algebra $\mathcal{A}$. This has just been a formal generalization of one of several, in classical differential geometry equivalent, definitions of a metric tensor field, motivated by simplicity of the mathematical structure, but without a deeper, e.g., physical, substantiation. Even on the technical level a serious problem showed up, namely, the extensibility of a (linear) connection on $\Omega^1(\mathcal{A})$ to a connection on $\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})$, which is necessary in order to define metric compatibility of a linear connection (see Refs. 5, 13 for discussions and related references).

Needless to say, generalizing another — classically equivalent — metric concept, one does not, in general, arrive at equivalent structures in the noncommutative geometric setting. In fact, motivated by previous work[6,7] we recently investigated in more detail generalizations of the Hodge $\star$-operator.[14] The metric is recovered from $(\alpha,\beta)=\star^{-1}(\alpha\star\beta)$ where α,β are differential 1-forms. For a symmetric Hodge operator on a (*non*commutative) differential calculus over a *commutative* algebra $\mathcal{A}$, contact was made with a metric defined as an element,

$$g\in\Omega^1(\mathcal{A})\otimes_L\Omega^1(\mathcal{A}), \tag{1.1}$$

and not as an element of the space $\Omega^1(\mathcal{A})\otimes_{\mathcal{A}}\Omega^1(\mathcal{A})$. The tensor product $\otimes_L$ satisfies

$$(f\alpha)\otimes_L(h\beta)=fh(\alpha\otimes_L\beta), \quad \forall f,h\in\mathcal{A},\ \alpha,\beta\in\Omega(\mathcal{A}). \tag{1.2}$$

In the following we show that it is precisely the latter metric definition which directly reproduces some familiar results in *discrete* geometry and which allows us to develop discrete noncommutative geometry to a more satisfactory level. It should be noticed, however, that the tensor product $\otimes_L$ and therefore the metric definition (1.1) does not generalize in an obvious way to *non*commutative algebras $\mathcal{A}$, at least as far as we can see. But in Ref. 14 we have generalized the associated Hodge operator to the general noncommutative framework.

In Sec. II we recall some basic definitions of noncommutative geometry. In Sec. III we concentrate on finite sets and introduce metrics and compatible linear connections on them. In Sec. IV we deal with a technical problem which has its origin in the nonlocality of the tensor product over $\mathcal{A}$. In particular, the construction of a Ricci tensor is addressed in our framework. As an example of particular interest, the geometry of a hypercubic lattice is treated in Sec. V. In Sec. VI we deal with discrete surfaces of revolution. Some conclusions are collected in Sec. VII. In particular, we propose a new discrete version of the Einstein equations on a hypercubic lattice.

II. PRELIMINARIES

In the first subsection we recall the definition of a differential calculus over an associative algebra. The second subsection contains the general definitions of linear connections, torsion and curvature in the framework of noncommutative geometry.

A. Differential calculi on associative algebras

Let $\mathcal{A}$ be an associative algebra over $\mathbb{C}$ with unit $\mathbf{1}$. A *differential calculus* over $\mathcal{A}$ is a $\mathbb{Z}$-graded associative algebra (over $\mathbb{C}$),

$$\Omega(\mathcal{A}) = \bigoplus_{r \geqslant 0} \Omega^r(\mathcal{A}), \tag{2.1}$$

where the spaces $\Omega^r(\mathcal{A})$ are $\mathcal{A}$-bimodules and $\Omega^0(\mathcal{A}) = \mathcal{A}$. There is a $\mathbb{C}$-linear map,

$$\mathrm{d}: \quad \Omega^r(\mathcal{A}) \to \Omega^{r+1}(\mathcal{A}) \tag{2.2}$$

with the following properties:

$$\mathrm{d}^2 = 0, \tag{2.3}$$

$$\mathrm{d}(ww') = (\mathrm{d}w)w' + (-1)^r w \mathrm{d}w', \tag{2.4}$$

where $w \in \Omega^r(\mathcal{A})$ and $w' \in \Omega(\mathcal{A})$. The last relation is known as the (generalized) *Leibniz rule*. One also requires $\mathbf{1}w = w\mathbf{1} = w$ for all elements $w \in \Omega(\mathcal{A})$. The identity $\mathbf{11} = \mathbf{1}$ then implies

$$\mathrm{d}\mathbf{1} = 0. \tag{2.5}$$

Furthermore, we require that d generates the spaces $\Omega^r(\mathcal{A})$ for $r > 0$ in the sense that $\Omega^r(\mathcal{A}) = \mathcal{A}\, \mathrm{d}\Omega^{r-1}(\mathcal{A})\mathcal{A}$. The space $\Omega^r(\mathcal{A})$, $r > 1$ can then be identified with a quotient of the r-fold tensor product $\Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \cdots \otimes_{\mathcal{A}} \Omega^1(\mathcal{A})$ by some sub-bimodule.

B. Linear connections, torsion and curvature

Let $(\Omega(\mathcal{A}), \mathrm{d})$ be a differential calculus over an associative algebra $\mathcal{A}$. A linear (left $\mathcal{A}$-module) connection is a $\mathbb{C}$-linear map $\boldsymbol{\nabla} : \Omega^1(\mathcal{A}) \to \Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A})$ such that

$$\boldsymbol{\nabla}(f\alpha) = \mathrm{d}f \otimes_{\mathcal{A}} \alpha + f \boldsymbol{\nabla} \alpha. \tag{2.6}$$

A linear connection extends to a map $\nabla: \Omega(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}) \to \Omega(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A})$ via

$$\boldsymbol{\nabla}(w \otimes_{\mathcal{A}} \alpha) = \mathrm{d}w \otimes_{\mathcal{A}} \alpha + (-1)^r w \boldsymbol{\nabla} \alpha, \quad \forall w \in \Omega^r(\mathcal{A}),\ \alpha \in \Omega^1(\mathcal{A}). \tag{2.7}$$

The *torsion* of a linear connection $\boldsymbol{\nabla}$ is the map $\Theta : \Omega^1(\mathcal{A}) \to \Omega^2(\mathcal{A})$, given by

$$\Theta(\alpha) := \mathrm{d}\alpha - \pi \circ \boldsymbol{\nabla} \alpha, \tag{2.8}$$

where π is the natural projection $\Omega^1(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}) \to \Omega^2(\mathcal{A})$. It satisfies

$$\Theta(f\alpha) = f\Theta(\alpha). \tag{2.9}$$

The torsion extends to a map $\Theta : \Omega(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}) \to \Omega(\mathcal{A})$ via

$$\Theta(w \otimes_{\mathcal{A}} \alpha) := \mathrm{d}(w\alpha) - \pi \circ \boldsymbol{\nabla}(w \otimes_{\mathcal{A}} \alpha), \quad \forall w \in \Omega(\mathcal{A}), \quad \alpha \in \Omega^1(\mathcal{A}), \tag{2.10}$$

where π now denotes more generally the projection $\Omega(\mathcal{A}) \otimes_{\mathcal{A}} \Omega^1(\mathcal{A}) \to \Omega(\mathcal{A})$. Then

$$\Theta(\boldsymbol{\nabla}\alpha) = \mathrm{d}\pi \circ \boldsymbol{\nabla}(\alpha) - \pi \circ \nabla^2(\alpha) = \mathrm{d}(\mathrm{d}\alpha - \Theta(\alpha)) + \pi \circ \mathfrak{R}(\alpha), \tag{2.11}$$

where we have introduced the *curvature* $\mathfrak{R}$ of $\boldsymbol{\nabla}$ as the map

$$\mathfrak{R} := -\boldsymbol{\nabla}^2, \tag{2.12}$$

which satisfies

$$\mathfrak{R}(f\alpha)=f\mathfrak{R}(\alpha). \tag{2.13}$$

We arrive at the *first Bianchi identity*,

$$\mathrm{d}\circ\Theta+\Theta\circ\boldsymbol{\nabla}=\pi\circ\mathfrak{R}. \tag{2.14}$$

The *second Bianchi identity* is

$$(\boldsymbol{\nabla}\mathfrak{R})(\alpha):=\boldsymbol{\nabla}(\mathfrak{R}(\alpha))-\mathfrak{R}(\boldsymbol{\nabla}\alpha)=-\nabla^3\alpha+\nabla^3\alpha=0. \tag{2.15}$$

Example. For the universal differential calculus, we have $\pi=\mathrm{id}$ on $\Omega^1\otimes_{\mathcal{A}}\Omega^1$ and there is a unique linear connection with vanishing torsion given by $\boldsymbol{\nabla}=\mathrm{d}$ according to (2.8). The curvature of this linear connection vanishes. ■

III. DIFFERENTIAL GEOMETRY ON FINITE SETS

In this section we collect some facts about differential calculi, vector fields and linear connections on finite sets (see also Refs. 2–5, 15, 16). We then consider metrics and elaborate on the metric compatibility condition for a linear connection.

A. First order differential calculi on a finite set

Let $\mathcal{M}$ be a finite set of N elements and $\mathcal{A}$ the algebra of all $\mathbb{C}$-valued functions on it. $\mathcal{A}$ is a complex linear space with basis e^i, $i=1,\ldots,N$, where $e^i(j)=\delta^i_j$ for $i,j\in\mathcal{M}$. These functions satisfy the two identities,

$$e^ie^j=\delta^{ij}e^j,\quad \sum_i e^i=\mathbf{1}, \tag{3.1}$$

where $\mathbf{1}$ is the constant function on $\mathcal{M}$ with value 1. In Ref. 3 it has been shown that first order differential calculi on a finite set $\mathcal{M}$ are in bijective correspondence with digraph structures on $\mathcal{M}$. Given a digraph with a set of vertices $\mathcal{M}$, we associate with an arrow from some point i to another point j, denoted as $i\to j$ in the following, an algebraic object e^{ij} and define[17]

$$\Omega^1:=\mathrm{span}_{\mathbb{C}}\{e^{ij}|i\to j\}. \tag{3.2}$$

This is turned into an $\mathcal{A}$-bimodule via

$$e^ie^{kl}=\delta^{ik}e^{kl},\quad e^{kl}e^i=\delta^{li}e^{kl}. \tag{3.3}$$

Let us introduce

$$\rho=\sum_{k,l} e^{kl}, \tag{3.4}$$

where the summation has to be restricted to those k,l for which there is an arrow from k to l in the digraph. Then

$$\mathrm{d}f=[\rho,f],\quad f\in\mathcal{A} \tag{3.5}$$

defines a $\mathbb{C}$-linear map $\mathrm{d}:\mathcal{A}\to\Omega^1$ which satisfies the Leibniz rule. If there is an arrow from i to j in the digraph, then $e^i\rho e^j=e^{ij}$, otherwise $e^i\rho e^j=0$.

The subspace

$$\Omega^1_i:=e^i\Omega^1 \tag{3.6}$$

is generated by the 1-forms e^{ij} corresponding to the arrows originating from i in the digraph. It may be regarded as the cotangent space at $i \in \mathcal{M}$. We have

$$\Omega^1 = \bigoplus_{i \in \mathcal{M}} \Omega^1_i . \tag{3.7}$$

The complete digraph where all pairs of points in $\mathcal{M}$ are connected by a pair of antiparallel arrows corresponds to the largest first order differential calculus on $\mathcal{M}$, also known as the *universal* first order differential calculus since all other calculi can be obtained from it as a quotient with respect to some sub-bimodule.

There is a canonical commutative product in Ω^1 which satisfies

$$\alpha \bullet \mathrm{d}f = [\alpha, f] \tag{3.8}$$

and

$$(f\alpha f') \bullet (h\beta h') = fh(\alpha \bullet \beta) f'h', \quad \forall f,f',h,h' \in \mathcal{A}, \quad \alpha,\beta \in \Omega^1. \tag{3.9}$$

More generally, this product exists for every first order differential calculus over a commutative algebra.[18] In the case under consideration, it is given by

$$e^{ij} \bullet e^{kl} = \delta^{ik} \delta^{jl} e^{ij}. \tag{3.10}$$

The space of 1-forms Ω^1 is free as a (left or right) $\mathcal{A}$-module. A special left $\mathcal{A}$-module basis is given by

$$\rho^i := \sum_j e^{ji}, \quad \text{if } \rho e^i \neq 0, \tag{3.11}$$

since an arbitrary 1-form A can be written as

$$A = \sum_{i,j} A_{ij}\, e^{ij} = \sum_i A_i\, \rho^i, \tag{3.12}$$

where $A_i = \Sigma_j A_{ji} e^j$. Furthermore, $\Sigma_i A_i \rho^i = 0$ implies, via multiplication with e^j from the left, that $A_{ji} = 0$ and thus $A_i = 0$.

B. Higher order differential forms on a finite set

Concatenation of the 1-forms e^{ij} leads to the r-forms

$$e^{i_0 \cdots i_r} := e^{i_0 i_1} e^{i_1 i_2} \cdots e^{i_{r-1} i_r} \quad (r>0), \tag{3.13}$$

which can also be expressed as follows:

$$e^{i_0 \cdots i_r} = e^{i_0} \rho e^{i_1} \rho \cdots \rho e^{i_r}. \tag{3.14}$$

They satisfy the simple relations

$$e^{i_0 \cdots i_r} e^{j_0 \cdots j_s} = \delta^{i_r j_0} e^{i_0 \cdots i_{r-1} j_0 \cdots j_s} \tag{3.15}$$

and span Ω^r as a vector space over $\mathbb{C}$. Using (3.3), this space is turned into an $\mathcal{A}$-bimodule. The exterior derivative d extends to higher orders via

$$\mathrm{d}e^i = \rho e^i - e^i \rho, \tag{3.16}$$

$$\mathrm{d}\rho = \rho^2 + \sum_i e^i \rho^2 e^i, \tag{3.17}$$

and the (graded) Leibniz rule (2.4). In particular, this leads to

$$\mathrm{d}e^{ij} = \rho e^i \rho e^j - e^i \rho^2 e^j + e^i \rho e^j \rho, \tag{3.18}$$

$$\mathrm{d}e^{ijk} = \rho e^i \rho e^j \rho e^k - e^i \rho^2 e^j \rho e^k + e^i \rho e^j \rho^2 e^k - e^i \rho e^j \rho e^k \rho. \tag{3.19}$$

Starting with the universal first order differential calculus on $\mathcal{M}$, these formulas generate the *universal differential calculus* (which is also known as the *universal differential envelope* of $\mathcal{A}$). A smaller first order differential calculus (where some of the e^{ij} are missing) induces restrictions on the spaces of higher order forms. A missing arrow from *i* to some other point *j* (in the complete digraph on $\mathcal{M}$) means $e^i \rho e^j = 0$. Acting with d on this equation, using (3.16) and (3.17), leads to

$$i \not\to j \;\Rightarrow\; e^i \rho^2 e^j = 0. \tag{3.20}$$

Each differential calculus is obtained from the universal one as a quotient with respect to some differential ideal. If the differential ideal is generated by ''basic forms'' (3.13) only,[19] then the differential calculus is called *basic*.[16] This class of differential calculi has been associated with polyhedral representations of simplicial complexes.[16]

C. Vector fields on a finite set

Let $\mathfrak{X}$ denote the dual of Ω^1 as a complex vector space. Let $\{\partial_{ji}\}$ be the basis of $\mathfrak{X}$ dual to $\{e^{ij}\}$. If $\langle , \rangle_0$ denotes the duality contraction, then

$$\langle e^{ij}, \partial_{kl} \rangle_0 = \delta^i_l \delta^j_k . \tag{3.21}$$

$\mathfrak{X}$ is turned into an $\mathcal{A}$-bimodule by introducing the left and right actions

$$\langle \alpha, f \cdot X \rangle_0 := \langle \alpha f, X \rangle_0 , \quad \langle \alpha, X \cdot f \rangle_0 := \langle f \alpha, X \rangle_0 . \tag{3.22}$$

As a consequence,

$$e^k \cdot \partial_{ji} = \delta^k_j \partial_{ji} , \quad \partial_{ji} \cdot e^k = \delta^k_i \partial_{ji} . \tag{3.23}$$

An element $X \in \mathfrak{X}$ can be uniquely decomposed as follows:

$$X = \sum_{i \to j} X(i)^j \partial_{ji} \tag{3.24}$$

(where the summation runs over all $i,j \in \mathcal{M}$ for which there is an arrow from *i* to *j* in the digraph associated with Ω^1). Now we introduce a duality contraction $\langle , \rangle$ of Ω^1 as a right $\mathcal{A}$-module and $\mathfrak{X}$ as a left $\mathcal{A}$-module by setting

$$\langle e^{ij}, X \rangle := e^i \langle e^{ij}, X \rangle_0 , \tag{3.25}$$

for all $X \in \mathfrak{X}$. Then we have

$$\langle f\alpha, X \cdot h \rangle = f \langle \alpha, X \rangle h, \quad \langle \alpha, f \cdot X \rangle = \langle \alpha f, X \rangle. \tag{3.26}$$

The elements of $\mathfrak{X}$ become operators on $\mathcal{A}$ via

$$X(f) := \langle \mathrm{d}f, X \rangle. \tag{3.27}$$

Using the Leibniz rule for d, one proves

$$X(fh)=fX(h)+(h\cdot X)(f), \quad \forall f,h\in\mathcal{A}. \tag{3.28}$$

Furthermore,

$$(X\cdot f)(g)=X(g)f. \tag{3.29}$$

The duality contraction extends to the pair of spaces $\Omega\otimes_{\mathcal{A}}\Omega^1$ and $\mathfrak{X}\otimes_{\mathcal{A}}\Omega$ via

$$\langle w\otimes_{\mathcal{A}}\alpha, X\otimes_{\mathcal{A}}w'\rangle=w\langle\alpha,X\rangle w'. \tag{3.30}$$

The space

$$\mathfrak{X}_i:=\mathfrak{X}e^i=\{X\cdot e^i|X\in\mathfrak{X}\} \tag{3.31}$$

may be regarded as the tangent space at $i\in\mathcal{M}$. It is dual to Ω^1_i with respect to the duality contraction $\langle,\rangle_0$. The set $\{\partial_{ji}|j\in\mathcal{M}$ such that $i\rightarrow j\}$ is a basis of $\mathfrak{X}_i$ which is dual to the basis $\{e^{ij}|j\in\mathcal{M}$ such that $i\rightarrow j\}$ of Ω^1_i.

D. Linear connections on a finite set

Let ∇: $\Omega^1\rightarrow\Omega^1\otimes_{\mathcal{A}}\Omega^1$ be a (left $\mathcal{A}$-module) linear connection. Using (2.6) and the properties of ρ, one finds that

$$\mathbb{U}(\alpha):=\rho\otimes_{\mathcal{A}}\alpha-\nabla\alpha \tag{3.32}$$

is a left $\mathcal{A}$-homomorphism $\mathbb{U}:\Omega^1\rightarrow\Omega^1\otimes_{\mathcal{A}}\Omega^1$, i.e.,

$$\mathbb{U}(f\alpha)=f\mathbb{U}(\alpha), \quad \forall f\in\mathcal{A},\ \alpha\in\Omega^1. \tag{3.33}$$

We call $\mathbb{U}$ the *parallel transport* associated with the linear connection ∇. In particular, (3.33) implies $\mathbb{U}(e^{ij})=e^i\mathbb{U}(e^{ij})$, and thus we have an expansion,

$$\mathbb{U}(e^{ij})=\sum_{k,l}U(i)^j{}_{kl}\,e^{ik}\otimes_{\mathcal{A}}e^{kl}=\sum_k e^{ik}\otimes_{\mathcal{A}}\sum_l U(i)^j{}_{kl}\,e^{kl}, \tag{3.34}$$

with constants $U(i)^j{}_{kl}$. Via

$$e^{ik}\mapsto(e^{ik})\mathbb{U}^{ij}:=\sum_l U(i)^k{}_{jl}\,e^{jl}, \tag{3.35}$$

for fixed i and j, the parallel transport defines a linear map $\Omega^1_i\rightarrow\Omega^1_j$ with associated matrix $\mathbb{U}^{ij}$. Then we have

$$\mathbb{U}(\alpha)=\sum_{i,j}e^{ij}\otimes_{\mathcal{A}}[(e^i\alpha)\mathbb{U}^{ij}]. \tag{3.36}$$

Given a linear connection on Ω^1, there is a dual connection[20] ∇: $\mathfrak{X}\rightarrow\mathfrak{X}\otimes_{\mathcal{A}}\Omega^1$, such that

$$\mathrm{d}\langle\alpha,X\rangle=\langle\nabla\alpha,X\rangle+\langle\alpha,\nabla X\rangle \tag{3.37}$$

(cf. Ref. 5, appendix B). Using $\mathrm{d}\langle\alpha,X\rangle=[\rho,\langle\alpha,X\rangle]$ one proves that the dual parallel transport defined by

$$\langle\alpha,\mathbb{U}(X)\rangle=\langle\mathbb{U}(\alpha),X\rangle, \tag{3.38}$$

acts as follows on $\mathfrak{X}$:

$$\mathbb{U}(X) := X \otimes_{\mathcal{A}} \rho + \nabla X, \tag{3.39}$$

and satisfies

$$\mathbb{U}(X \cdot f) = \mathbb{U}(X) f. \tag{3.40}$$

(3.34) leads to

$$\mathbb{U}(\partial_{ji}) = \sum_{k,l} U(k)^l{}_{ij} \; \partial_{lk} \otimes_{\mathcal{A}} e^{ki}. \tag{3.41}$$

The parallel transport (and thus also the connection) extends in an obvious way to $\Omega \otimes_{\mathcal{A}} \Omega^1$ and $\mathfrak{X} \otimes_{\mathcal{A}} \Omega$ as graded left, respectively, right Ω-homomorphisms, i.e.,

$$\mathbb{U}(w \otimes_{\mathcal{A}} \alpha) = (-1)^r w \otimes_{\mathcal{A}} \mathbb{U}(\alpha), \quad \mathbb{U}(X \otimes_{\mathcal{A}} w) = (-1)^r \mathbb{U}(X) \otimes_{\mathcal{A}} w, \tag{3.42}$$

where $w \in \Omega^r$.

The map $\mathfrak{X}_j \to \mathfrak{X}_i$ dual to the parallel transport map with matrix $\mathbb{U}^{ij}$ defined in (3.35) is given by

$$\partial_{ki} \mapsto \sum_l U(j)^l_{ik} \; \partial_{lj} = \mathbb{U}^{ij}(\partial_{ki}). \tag{3.43}$$

Now (3.41) extends to

$$\mathbb{U}(X) = \sum_{i,j} \mathbb{U}^{ij}(X \cdot e^i) \otimes_{\mathcal{A}} e^{ij}. \tag{3.44}$$

We may introduce the curvature as the right Ω-homomorphism $\mathfrak{R}' : \mathfrak{X} \otimes_{\mathcal{A}} \Omega \to \mathfrak{X} \otimes_{\mathcal{A}} \Omega$ defined by

$$\mathfrak{R}' = \nabla^2. \tag{3.45}$$

Its dual $\mathfrak{R} : \Omega \otimes_{\mathcal{A}} \Omega^1 \to \Omega \otimes_{\mathcal{A}} \Omega^1$ is then given by $\mathfrak{R} = -\nabla^2$ in accordance with our general definition (2.12). We obtain

$$\mathfrak{R}(e^{ij}) =: \sum_{k,l,m} R(i)^j{}_{klm} \; e^{ikl} \otimes_{\mathcal{A}} e^{lm} = \sum_{k,l,m} \left(\sum_n U(i)^j{}_{kn} U(k)^n{}_{lm} - U(i)^j{}_{lm} \right) e^{ikl} \otimes_{\mathcal{A}} e^{lm}, \tag{3.46}$$

where it has been convenient to set

$$U(i)^j{}_{ik} := \delta^j_k. \tag{3.47}$$

We also have the following expression for the curvature:

$$\mathfrak{R}(\alpha) = \sum_{i,j,k} e^{ijk} \otimes_{\mathcal{A}} \{(e^i \alpha)[\mathbb{U}^{ij} \mathbb{U}^{jk} - \mathbb{U}^{ik}]\}, \tag{3.48}$$

where $\mathbb{U}^{ii} := \mathrm{id}_{\Omega^1_i}$.

For the torsion we find

$$\Theta(e^{ij}) = -e^i \rho^2 e^j + e^{ij} \rho + \sum_{k,l} U(i)^j{}_{kl} \; e^{ikl} = \sum_{k,l} \left(\delta^j_k - \delta^j_l + U(i)^j{}_{kl} \right) e^{ikl}. \tag{3.49}$$

Example. In case of the universal differential calculus, the condition of vanishing torsion leads to

$$U(i)^j{}_{kl} = \delta^j_l - \delta^j_k , \tag{3.50}$$

and thus fixes the linear connection completely.[21] As mentioned in more generality in the example in Sec. II B, this connection is given by $\boldsymbol{\nabla} = \mathrm{d}$ and its curvature vanishes. ■

E. Metrics and compatible linear connections on finite sets

Using

$$e^{ij} \otimes_L e^{kl} = e^{ij} \otimes_L e^k e^{kl} = e^k e^{ij} \otimes_L e^{kl} = \delta^{ki} e^{ij} \otimes_L e^{il}, \tag{3.51}$$

one finds that an element $g \in \Omega^1 \otimes_L \Omega^1$ can be expressed as

$$g = \sum_{i,j,k} g(i)_{jk} \; e^{ij} \otimes_L e^{ik}, \tag{3.52}$$

with constants $g(i)_{jk}$. This will be our candidate for a *metric* on $\mathcal{M}$.[22]

Example 1: Consider a digraph embedded in Euclidean space such that the arrows are straight lines of Euclidean length l_{ij}. Let ϑ_{jik} denote the angle between arrows from i to j and from i to k. Define[23]

$$g(i)_{jj} = l_{ij}^2 , \quad g(i)_{jk} = l_{ij} l_{ik} \cos \vartheta_{jik} . \tag{3.53}$$

In order to describe the geometry of a polygon (without orientation of its lines) embedded in Euclidean space completely, in general, we need to associate it with a *symmetric* digraph. A line between two points i and j is then represented by a pair of antiparallel arrows, so that e^{ij} and e^{ji} are both present. Of course, we should impose $l_{ij} = l_{ji}$.[24] ■

In order to define the compatibility of a linear connection and a metric, we have to extend the connection, respectively, the map $\mathbb{U}$, to a map from $\Omega^1 \otimes_L \Omega^1$ to $\Omega^1 \otimes_{\mathcal{A}} \Omega^1 \otimes_L \Omega^1$. Let us define

$$\mathbb{U}(\alpha \otimes_L \beta) := \bullet(\mathbb{U}(\alpha) \otimes_L \mathbb{U}(\beta)), \tag{3.54}$$

where a map

$$\bullet \; : \; (\Omega^1 \otimes_{\mathcal{A}} \Omega^1) \otimes_L (\Omega^1 \otimes_{\mathcal{A}} \Omega^1) \to \Omega^1 \otimes_{\mathcal{A}} (\Omega^1 \otimes_L \Omega^1) \tag{3.55}$$

is needed. Using the canonical product (3.10) in the space of 1-forms, such a map is given by

$$\bullet((\alpha \otimes_{\mathcal{A}} \beta) \otimes_L (\alpha' \otimes_{\mathcal{A}} \beta')) := (\alpha \bullet \alpha') \otimes_{\mathcal{A}} (\beta \otimes_L \beta'), \tag{3.56}$$

and, using (3.9), we have

$$\mathbb{U}(f(\alpha \otimes_L \beta)) = f\,\mathbb{U}(\alpha \otimes_L \beta). \tag{3.57}$$

As a consequence,

$$\nabla(\alpha \otimes_L \beta) := \rho \otimes_{\mathcal{A}} (\alpha \otimes_L \beta) - \mathbb{U}(\alpha \otimes_L \beta) \tag{3.58}$$

defines a (left $\mathcal{A}$-module) connection on $\Omega^1 \otimes_L \Omega^1$. The *metric compatibility* condition $\boldsymbol{\nabla} g = 0$ now amounts to

$$\rho \otimes_{\mathcal{A}} g = \mathbb{U}(g). \tag{3.59}$$

In terms of the matrices $\mathbb{U}^{ij}$ introduced in Sec. III D, we have

$$\mathbb{U}(\alpha\otimes_L\beta)=\sum_{i,j} e^{ij}\otimes_{\mathcal{A}}\{[(e^i\alpha)\mathbb{U}^{ij}]\otimes_L(e^i\beta)\mathbb{U}^{ij}]\}. \tag{3.60}$$

Lemma: Expressed in components, $\nabla g=0$ becomes

$$g(i)_{jk}=\sum_{m,n} g(l)_{mn}U(l)^m{}_{ij}U(l)^n{}_{ik}, \tag{3.61}$$

for all $i,l\in\mathcal{M}$ such that $l\to i$ (i.e., there is an arrow from l to i in the digraph associated with Ω^1).

Proof:

$$\mathbb{U}(g)=\sum_{l,m,n} g(l)_{mn}\,\bullet(\mathbb{U}(e^{lm})\otimes_L\mathbb{U}(e^{ln}))$$

$$=\sum_{l,m,n} g(l)_{mn}\sum_{i,j,k,p} U(l)^m{}_{ij}U(l)^n{}_{pk}\,\bullet((e^{li}\otimes_{\mathcal{A}}e^{ij})\otimes_L(e^{lp}\otimes_{\mathcal{A}}e^{pk})).$$

With

$$\bullet((e^{li}\otimes_{\mathcal{A}}e^{ij})\otimes_L(e^{lp}\otimes_{\mathcal{A}}e^{pk}))=(e^{li}\bullet e^{lp})\otimes_{\mathcal{A}}(e^{ij}\otimes_L e^{pk})=\delta^{ip}e^{li}\otimes_{\mathcal{A}}(e^{ij}\otimes_L e^{pk}),$$

this becomes

$$\mathbb{U}(g)=\sum_{i,j,k,l,m,n} g(l)_{mn}U(l)^m{}_{ij}U(l)^n{}_{ik}\,e^{li}\otimes_{\mathcal{A}}(e^{ij}\otimes_L e^{ik}).$$

Using (3.59), the last expression must be equal to

$$\rho\otimes_{\mathcal{A}}g=\sum_{i,j,k,l} g(i)_{jk}\,e^{li}\otimes_{\mathcal{A}}(e^{ij}\otimes_L e^{ik}).$$

A comparison of the coefficients on both sides now leads to our formula. ■

Example 2: Again, we consider the universal differential calculus on $\mathcal{M}$. With the unique torsion-free linear connection (3.50), the metric compatibility condition reads as[25]

$$g(i)_{kl}=g(j)_{kl}+g(j)_{ii}-g(j)_{ki}-g(j)_{il},\quad i,j,k,l\in\mathcal{M}. \tag{3.62}$$

Setting $k=j$ and $l=j$, respectively, we get

$$g(i)_{jk}=g(j)_{ii}-g(j)_{ik},\quad g(i)_{kj}=g(j)_{ii}-g(j)_{ki}, \tag{3.63}$$

which, in turn, implies

$$g(i)_{jk}-g(i)_{kj}=g(j)_{ki}-g(j)_{ik} \tag{3.64}$$

and

$$g(i)_{jj}=g(j)_{ii}. \tag{3.65}$$

Furthermore, the last equation together with (3.62) leads to

$$2g(i)_{kl}-g(i)_{kj}-g(i)_{jl}=2g(j)_{kl}-g(j)_{ki}-g(j)_{il}, \tag{3.66}$$

which for $k=l$ becomes

$$2g(i)_{kk}-g(i)_{kj}-g(i)_{jk}=2g(j)_{kk}-g(j)_{ki}-g(j)_{ik}. \tag{3.67}$$

Let us now consider the special case where all the components $g(i)_{jj}$ are equal. Then (3.64) and (3.67) lead to

$$g(i)_{kj}=g(j)_{ik}. \tag{3.68}$$

With the help of (3.63) and (3.65) we now obtain

$$g(i)_{jj}=g(i)_{jk}+g(i)_{kj}. \tag{3.69}$$

Assuming in addition that the metric is symmetric [i.e., $g(i)_{jk}=g(i)_{kj}$], we have

$$g(i)_{jj}=2g(i)_{jk}, \tag{3.70}$$

and we end up with a constant metric,

$$g(i)=\begin{pmatrix} a & a/2 & \dots & a/2 \\ a/2 & \ddots & & \vdots \\ \vdots & & \ddots & \vdots \\ a/2 & \cdots & a/2 & a \end{pmatrix}, \quad \forall i\in\mathcal{M}. \tag{3.71}$$

Hence, there is a unique symmetric g for the universal differential calculus (associated with the complete digraph) on $\mathcal{M}$ which is compatible with the (unique) torsion-free linear connection and which has the property that all $g(i)_{jj}$ are equal. If $g(i)_{jj}$ is positive, we let it represent the square of the distance between i and j. The above requirement then means that all points are at equal distance $l=\sqrt{a}$ and from the metric compatibility condition we recover the Euclidean geometry of the regular polyhedron.

More generally, specializing to the ''Euclidean metric'' (3.53), our metric compatibility conditions (3.62) become

$$l_{ik}^2=l_{jk}^2+l_{ji}^2-2l_{ji}l_{jk}\cos(\vartheta_{ijk}), \tag{3.72}$$

$$l_{ik}l_{il}\cos(\vartheta_{kil})=l_{jk}l_{jl}\cos(\vartheta_{kjl})+l_{ji}^2-l_{ji}l_{jk}\cos(\vartheta_{ijk})-l_{ji}l_{jl}\cos(\vartheta_{ijl}), \tag{3.73}$$

which, in fact, reproduce well-known relations of Euclidean geometry. ■

In terms of the matrices

$$\mathbf{g}(i):=(g(i)_{jk}), \tag{3.74}$$

the metric compatibility condition takes the simple form

$$\mathbf{g}(j)=(\mathbb{U}^{ij})^t\mathbf{g}(i)\mathbb{U}^{ij}, \tag{3.75}$$

where $(\mathbb{U}^{ij})^t$ denotes the transpose of the matrix $\mathbb{U}^{ij}$. Hence, if there is an arrow from i to j in the digraph (i.e., $i\to j$), then $\mathbf{g}(i)$ determines $\mathbf{g}(j)$ via the parallel transport of a metric compatible linear connection.

The metric compatibility condition implies that, for any closed path $i_0\to i_1\to\dots\to i_r\to i_0$ in the digraph, the matrix $\mathbb{H}^{i_0\cdots i_r}:=\mathbb{U}^{i_0i_1}\mathbb{U}^{i_1i_2}\cdots\mathbb{U}^{i_ri_0}$ must be in the orthogonal group of $\mathbf{g}(i_0)$. The set of all matrices $\mathbb{H}^{i_0\cdots i_r}$, $r\geqslant 1$, forms the holonomy group $G_H(i_0)$ at $i_0\in\mathcal{M}$.

Example 3: The three point complete digraph.
Let $\mathcal{M}=\{1,2,3\}$ with $\rho=e_{12}+e_{13}+e_{21}+e_{23}+e_{31}+e_{32}$. We are dealing again with the universal differential calculus so that there are no 2-form relations. Then $\rho^2=e_{121}+e_{123}+e_{131}+e_{132}+e_{212}+e_{213}+e_{231}+e_{232}+e_{312}+e_{313}+e_{321}+e_{323}$. The condition of vanishing torsion determines the connection completely. We find

$$\mathbb{U}^{12}=\begin{pmatrix}-1 & -1\\ 0 & 1\end{pmatrix},\quad \mathbb{U}^{13}=\begin{pmatrix}0 & 1\\ -1 & -1\end{pmatrix},\quad \mathbb{U}^{23}=\begin{pmatrix}1 & 0\\ -1 & -1\end{pmatrix},$$
$$\mathbb{U}^{21}=\begin{pmatrix}-1 & -1\\ 0 & 1\end{pmatrix},\quad \mathbb{U}^{31}=\begin{pmatrix}-1 & -1\\ 1 & 0\end{pmatrix},\quad \mathbb{U}^{32}=\begin{pmatrix}1 & 0\\ -1 & -1\end{pmatrix}. \tag{3.76}$$

It follows that $\mathbb{H}^{ij}=I$, the unit matrix, for all $i\to j\to i$. Furthermore, for all permutations i,j,k of 1,2,3 we find $\mathbb{H}^{ijk}=\mathbb{U}^{ij}\mathbb{U}^{jk}\mathbb{U}^{ki}=I$. This means that parallel transport does not depend on the path which is related to the fact that the curvature vanishes. If we choose metric components at one point, then the metric components at the other points are determined via the metric compatibility condition. We find

$$g(1)=\begin{pmatrix}a & b\\ b & c\end{pmatrix},\quad g(2)=\begin{pmatrix}a & a-b\\ a-b & a-2b+c\end{pmatrix},\quad g(3)=\begin{pmatrix}c & c-b\\ c-b & a-2b+c\end{pmatrix}. \tag{3.77}$$

In particular, if $g(1)=g(2)=g(3)$ we are led to

$$g(i)=b\begin{pmatrix}2 & 1\\ 1 & 2\end{pmatrix} \tag{3.78}$$

[in accordance with (3.71)] which (for $b>0$) describes an equilateral triangle. This may be considered as a simple model of a piece of a two-dimensional surface. ■

Thinking about an inverse (or dual) of a metric tensor, as defined above, one is led to elements $h\in\mathfrak{X}\otimes_R\mathfrak{X}$ where $\otimes_R$ denotes the *right*-linear tensor product. h can be expressed as

$$h=\sum_{i,j,k} h(i)^{jk}\ \partial_{ji}\otimes_R\partial_{ki}, \tag{3.79}$$

with constants $h(i)^{jk}$. The parallel transport (and thus also the connection) extends to $\mathfrak{X}\otimes_R\mathfrak{X}$ via

$$\mathbb{U}(X\otimes_R Y):=\bullet(\mathbb{U}(X)\otimes_R\mathbb{U}(Y)) \tag{3.80}$$

and

$$\bullet((X\otimes_{\mathcal{A}}\alpha)\otimes_R(Y\otimes_{\mathcal{A}}\beta)):=(X\otimes_R Y)\otimes_{\mathcal{A}}(\alpha\bullet\beta). \tag{3.81}$$

Compatibility of h with a linear connection, i.e., $\boldsymbol{\nabla}h=0$, now reads as

$$\mathbb{U}(h)=h\otimes_{\mathcal{A}}\rho, \tag{3.82}$$

and, in components,

$$h(i)^{rs}=\sum_{j,k} h(l)^{jk}U(i)^r{}_{lj}U(i)^s{}_{lk}, \tag{3.83}$$

provided that $i\to l$. In terms of the matrices $h(i):=(h(i)^{jk})$, the metric compatibility condition reads as

$$h(i)=\mathbb{U}^{ij}h(j)(\mathbb{U}^{ij})^t. \tag{3.84}$$

Remark: Consider a differential calculus, associated with a symmetric digraph, a metric g and a compatible linear connection. If $g(i_0)$ is invertible at some point i_0, setting $h(i_0):=g(i_0)^{-1}$ defines h via (3.84) on the connected component of the digraph containing i_0. Of course, h need not be inverse to g at other points. ■

F. Metrics and compatible linear connections on a finite set with a basic differential calculus

We consider a *basic* differential calculus (cf. Sec. III B). The general torsion-free connection is then given by

$$U(i)^j{}_{kl} = \delta^j_l - \delta^j_k + u(ikl)^j, \tag{3.85}$$

where $u(ikl)^j \neq 0$ only if $e^{ikl}=0$.[26] The metric compatibility condition now becomes

$$\begin{aligned} g(j)_{kl} = {} & g(i)_{kl} - g(i)_{kj} - g(i)_{jl} + g(i)_{jj} \\ & + \sum_{m,n} g(i)_{mn} \, [\delta^m_k \, u(ijl)^n + \delta^n_l \, u(ijk)^m + u(ijk)^m \, u(ijl)^n] \\ & - \sum_m \, [g(i)_{jm} \, u(ijl)^m + g(i)_{mj} \, u(ijk)^m], \end{aligned} \tag{3.86}$$

for all i,j with $i \to j$.

Remark: Let us consider again the case of a Euclidean embedding space (cf. example 1 in Sec. III E). If all $u(ijk)^l$ vanish, then (3.72) holds which is a familiar relation between the lengths and angles of a Euclidean triangle. As shown in Ref. 27, in the triangulation of a curved space by means of geodesic segments and in Riemann normal coordinates one has

$$2 l_{ij} l_{ik} \cos \vartheta_{jik} = l^2_{ik} + l^2_{ij} - l^2_{jk} - \tfrac{1}{3} R_{\mu\alpha\nu\beta} \, \Delta x^\mu_{ij} \, \Delta x^\nu_{ij} \, \Delta x^\alpha_{ik} \, \Delta x^\beta_{ik} + \mathcal{O}(\epsilon^5), \tag{3.87}$$

where ϵ is a typical length scale of the neighborhood in which the Riemann normal coordinates are defined, and x^μ_i are the Riemann normal coordinates of the vertex i. Obviously, from (3.86) we can expect to get additional terms in (3.72), related to curvature, only if we have nonvanishing $u(ijk)^l$, that is if we have 2-form relations as in our next example. ■

Example: A refined model for a piece of a two-dimensional surface is obtained from that considered in example 3 of Sec. III E by adding a fourth point to the triangle and joining it with all the vertices of the latter, but then discard the 2-forms corresponding to the base of the resulting tetrahedron (or a pyramid with a triangle base). Hence, we consider the complete digraph on $\mathcal{M} = \{1,2,3,4\}$, but not the universal differential calculus since we impose the 2-form relations

$$e^{123} = e^{132} = e^{213} = e^{231} = e^{312} = e^{321} = 0. \tag{3.88}$$

We assume that the matrices $\mathbb{U}^{ij}$ have maximal rank and that

$$\mathbb{H}^{ij} = \mathbb{U}^{ij} \mathbb{U}^{ji} = I. \tag{3.89}$$

The condition of vanishing torsion now leads to

$$\mathbb{U}^{12} = \begin{pmatrix} -1 & -1+u_1 & -1 \\ 0 & 1+u_2 & 0 \\ 0 & u_3 & 0 \end{pmatrix}, \quad \mathbb{U}^{13} = \begin{pmatrix} 0 & 1+v_1 & 0 \\ -1 & -1+v_2 & -1 \\ 0 & v_3 & 1 \end{pmatrix},$$

$$\mathbb{U}^{23} = \begin{pmatrix} 1+w_1 & 0 & 0 \\ -1+w_2 & -1 & -1 \\ w_3 & 0 & 1 \end{pmatrix}, \quad \mathbb{U}^{14} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & -1 & -1 \end{pmatrix}, \tag{3.90}$$

$$\mathbb{U}^{24}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ -1 & -1 & -1 \end{pmatrix}, \quad \mathbb{U}^{34}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -1 & -1 & -1 \end{pmatrix},$$

and for $i<j$ we have $\mathbb{U}^{ji}=(\mathbb{U}^{ij})^{-1}$ according to (3.89). Setting

$$g(4)=l^2\begin{pmatrix} 1 & c & b \\ c & 1 & a \\ b & a & 1 \end{pmatrix} \tag{3.91}$$

means that the edges of the triangles 4-1-2, 4-1-3, 4-2-3 have equal length $l_{41}=l_{42}=l_{43}=l$ but possibly different angles $\cos\vartheta_{142}=c$, $\cos\vartheta_{143}=b$, $\cos\vartheta_{243}=a$. Via $g(i)=(\mathbb{U}^{4i})^t g(4)\,\mathbb{U}^{4i}$ for $i=1,2,3$ we obtain

$$g(1)=l^2\begin{pmatrix} 2(1-c) & 1+a-b-c & 1-c \\ 1+a-b-c & 2(1-b) & 1-b \\ 1-c & 1-b & 1 \end{pmatrix},$$

$$g(2)=l^2\begin{pmatrix} 2(1-c) & 1-a+b-c & 1-c \\ 1-a+b-c & 2(1-a) & 1-a \\ 1-c & 1-a & 1 \end{pmatrix}, \tag{3.92}$$

$$g(3)=l^2\begin{pmatrix} 2(1-b) & 1-a-b+c & 1-b \\ 1-a-b+c & 2(1-a) & 1-a \\ 1-b & 1-a & 1 \end{pmatrix}.$$

The remaining metric compatibility conditions now demand that

$$u_2=v_1=w_1=-2, \quad u_1=2\frac{bc-a}{c^2-1}, \quad v_2=2\frac{bc-a}{b^2-1}, \quad w_2=2\frac{ac-b}{a^2-1} \tag{3.93}$$

and

$$u_3=2\frac{1-a-b+c}{1+c}, \quad v_3=2\frac{1-a+b-c}{1+b}, \quad w_3=2\frac{1+a-b-c}{1+a}, \tag{3.94}$$

where we assumed that $a,b,c\neq\pm1$. We should mention here that $u_1=\cdots=w_3=0$ is also a solution. This parallel transport, which corresponds to the unique torsion-free connection on the universal differential calculus on the set of four points, has vanishing curvature. This shows that there is *a priori* no relation with the Regge curvature[28] which is given at point 4 by $2\pi-\vartheta_{142}-\vartheta_{143}-\vartheta_{243}$. We will return to this example in the next section (see example 5 there). ∎

IV. TRANSFORMATIONS TO ''LOCAL'' TENSOR PRODUCTS AND COVARIANT TENSOR COMPONENTS

As in the preceding section, we consider a finite set $\mathcal{M}$ and a differential calculus Ω (over the algebra of functions) on $\mathcal{M}$. In ordinary (continuum) differential geometry, the tensor product $\otimes_{\mathcal{A}}$ and the graded product in the space of differential forms are operations which take place over the same point. This is not so in the discrete framework under consideration. For example, in $e^{ij}\otimes_{\mathcal{A}} e^{jk}$ the first factor is an element of Ω^1_i while the second factor belongs to Ω^1_j. In contrast, in $e^{ij}\otimes_L e^{ik}$ both factors belong to the same cotangent space. As a consequence, the left components of an element of $\Omega^1\otimes_L\Omega^1$ transform covariantly under a change of module basis in Ω^1 (in contrast to the left, middle or right components of an element of $\Omega^1 \otimes_{\mathcal{A}} \Omega^1$). Covariant tensor components are of particular interest because of the possibility to construct new tensors from them via contraction. For example, we would like to build a kind of Ricci tensor from the curvature components $R(i)^j{}_{klm}$ in (3.46). The latter are not covariant, however. The indices j and l (or m) live in different (co)tangent spaces. In this section, we shall consider ways to modify or, more precisely, to ''localize'' expressions in order to provide a remedy for this problem. What we need is tensor products which act over the same point and furthermore suitable transformations from tensor products over $\mathcal{A}$ to these ''local'' tensor products. Given a connection, we have the parallel transports which enable us to move from one (co)tangent space to another and these should be expected as natural ingredients of the transformations we are looking for.

A map $\Omega^1 \otimes_L \Omega^1 \to \Omega^1 \otimes_{\mathcal{A}} \Omega^1$ is given by

$$\kappa(\alpha \otimes_L \beta) := \sum_{i,j} (e^i \alpha e^j) \otimes_{\mathcal{A}} [(e^i \beta) \mathbb{U}^{ij}]. \tag{4.1}$$

In particular,

$$\kappa(e^{ij} \otimes_L e^{ik}) = \sum_l U(i)^k{}_{jl} \, e^{ij} \otimes_{\mathcal{A}} e^{jl}. \tag{4.2}$$

κ is a left $\mathcal{A}$-homomorphism and has the property[29]

$$\kappa(\rho \otimes_L \beta) = \mathbb{U}(\beta). \tag{4.3}$$

A map,

$$\lambda_1 : \Omega^1 \otimes_{\mathcal{A}} \Omega^1 \to \Omega^1 \otimes_L \Omega^1, \tag{4.4}$$

in the opposite direction is not so easily at hand in an explicit form, except in some special cases like those listed below.

(i) If for all $i \to j$ the transport $\mathbb{U}^{ij}$ is invertible, we can define

$$\lambda_1(\alpha \otimes_{\mathcal{A}} \beta) := \sum_{i,j} (e^i \alpha e^j) \otimes_L [(e^j \beta)(\mathbb{U}^{ij})^{-1}]. \tag{4.5}$$

Then $\lambda_1 = \kappa^{-1}$. This choice is considered in case of the oriented lattice structures treated in Secs. V and VI.

(ii) If the digraph associated with Ω^1 is symmetric (i.e., a digraph where $i \to j \Leftrightarrow j \to i$) then we may define[30]

$$\lambda_1(\alpha \otimes_{\mathcal{A}} \beta) := \sum_{i,j} (e^i \alpha e^j) \otimes_L [(e^j \beta) \mathbb{U}^{ji}]. \tag{4.6}$$

In the following we assume that a map λ_1 is given, having the above examples in mind. Moreover, we will also need a similar map,

$$\lambda_2 : \Omega^2 \otimes_{\mathcal{A}} \Omega^1 \to \Omega^2 \otimes_L \Omega^1 \tag{4.7}$$

(and furthermore a way to ''localize'' 2-forms; see below). In our examples considered in Secs. V and VI, λ_1 induces such a map λ_2 in a natural way.

Example 1: Let $i \to j \to k \to l$ and $k \to i$. For $e^{ijk} \neq 0$ we may define

$$\lambda_2(e^{ijk} \otimes_{\mathcal{A}} e^{kl}) := e^{ijk} \otimes_L [(e^{kl}) \mathbb{U}^{ki}]. \tag{4.8}$$

If also $k \to j \to i$, another choice is

$$\lambda_2'(e^{ijk}\otimes_{\mathcal{A}} e^{kl}) := e^{ijk}\otimes_L[(e^{kl})\mathbb{U}^{kj}\mathbb{U}^{ji}]. \tag{4.9}$$

The two choices for λ_2 can be different as long as the holonomy of the connection is not trivial. Hence, in general, there are many different choices for λ_2. ■

Example 2: Let us now consider a differential calculus where the space of 1-forms is associated with a symmetric digraph and let us, moreover, assume that the differential calculus is basic (cf. Sec. III B). In this case, $e^{i_0\cdots i_r}\neq 0$ implies that $i_k\rightarrow i_l$ for all $0\leqslant k,l\leqslant r$ (cf. Ref. 16). A natural choice for λ_1, λ_2 and generalizations thereof is then given by

$$\lambda(e^{i_0\cdots i_r}\otimes_{\mathcal{A}} e^{i_r j}) := e^{i_0\cdots i_r}\otimes_{\mathcal{A}}[(e^{i_r j})\mathbb{U}^{i_r i_0}]. \tag{4.10}$$

■

In the following we simply write λ instead of λ_1 or λ_2.

Combining κ and π,

$$\alpha\cap\beta := \pi\circ\kappa(\alpha\otimes_L\beta) \tag{4.11}$$

determines a product $\Omega^1\otimes_L\Omega^1\rightarrow\Omega^2$ which is left $\mathcal{A}$-linear and therefore satisfies

$$e^i(\alpha\cap\beta) = (e^i\alpha)\cap(e^i\beta), \tag{4.12}$$

so that $\cap$ preserves "locality." If $(\kappa\circ\lambda)(\ker\pi)\subset\ker\pi$, the map

$$\mu := \pi\circ\kappa\circ\lambda\circ\pi^{-1}:\ \Omega^2\rightarrow\Omega^2 \tag{4.13}$$

is well-defined and can be used to transform usual products of 1-forms (i.e., elements of Ω^2) to $\cap$-products.

Example 3: Let us again consider the case of a differential calculus associated with a *symmetric* digraph. Using (4.6), we get

$$\kappa\circ\lambda_1(\alpha\otimes_{\mathcal{A}}\beta) = \sum_{i,j}(e^i\alpha e^j)\otimes_{\mathcal{A}}[(e^j\beta)\mathbb{H}^{ji}], \tag{4.14}$$

$$\lambda_1\circ\kappa(\alpha\otimes_L\beta) = \sum_{i,j}(e^i\alpha e^j)\otimes_L[(e^i\beta)\mathbb{H}^{ij}], \tag{4.15}$$

with the holonomies $\Omega^1_i\rightarrow\Omega^1_i$ given by $\mathbb{H}^{ij}$. Then

$$\mu(\alpha\beta) = \sum_{i,j}(e^i\alpha e^j)\cap[(e^j\beta)\mathbb{U}^{ji}] = \sum_{i,j}(e^i\alpha)[(e^j\beta)\mathbb{H}^{ji}]. \tag{4.16}$$

The 2-form relations are of the form

$$\sum_k e^{ikj} = 0, \quad \text{if } i\nrightarrow j \tag{4.17}$$

(where k runs over a subset of $\mathcal{M}$) and must be mapped to 0 by μ. In terms of the $\cap$-product the 2-form relations then read as

$$\sum_{k,l} U(k)^j{}_{il}\ e^{ik}\cap e^{il} = 0, \quad \text{if } i\nrightarrow j. \tag{4.18}$$

Using $(e^{kj})\mathbb{H}^{ki} =: \Sigma_l(\mathbb{H}^{ki})^j{}_l\ e^{kl}$, the condition $(\kappa\circ\lambda)(\ker\pi)\subset\ker\pi$ amounts to

$$\sum_k (\mathbb{H}^{ki})^j{}_l \, e^{ikl} = 0, \quad \forall l, \tag{4.19}$$

and thus induces restrictions on the connection, in general. ■

Lemma: For a basic differential calculus (Ω, d) and a torsion-free linear connection, we have

$$\begin{aligned} e^{ij} \cap e^{ij} &= -\sum_k e^{ijk}, \\ e^{ij} \cap e^{ik} &= e^{ijk}, \quad \text{if } j \neq k, \end{aligned} \tag{4.20}$$

and the map μ defined in (4.13) with λ from (4.6) satisfies

$$\begin{aligned} \mu(e^{iji}) &= -\sum_k e^{ij} \cap e^{ik}, \\ \mu(e^{ijk}) &= e^{ij} \cap e^{ik}, \quad \text{if } i \neq k. \end{aligned} \tag{4.21}$$

Proof: (4.20) follows from

$$e^{ij} \cap e^{ik} = \sum_m U(i)^k{}_{jm} \, e^{ijm},$$

together with (3.85). (4.21) results from

$$\mu(e^{ijk}) = e^{ij} \cap [e^{jk} \mathbb{U}^{ji}] = e^{ij} \cap \sum_m U(j)^k{}_{im} \, e^{im} = e^{ij} \cap \sum_m (\delta^k_m - \delta^k_i) e^{im},$$

using again (3.85). ■

Now we have everything at hand to ''localize'' torsion and curvature and to define corresponding covariant components as follows:

$$\mu \circ \Theta(e^{ij}) =: \sum_{k,l} Q(i)^j{}_{kl} \, e^{ik} \cap e^{il}, \tag{4.22}$$

$$(\mu \otimes_L \mathrm{id}) \circ \lambda \circ \mathfrak{R}(e^{ij}) =: \sum_{k,l,m} \hat{R}(i)^j{}_{klm} \, (e^{il} \cap e^{im}) \otimes_L e^{ik}. \tag{4.23}$$

As in ordinary differential geometry, a *Ricci tensor* can now be defined,

$$\mathrm{Ric}(i)_{jk} := \sum_l \hat{R}(i)^l{}_{jlk}, \quad \overline{\mathrm{Ric}}(i)_{jk} := \sum_l \hat{R}(i)^l{}_{jkl}. \tag{4.24}$$

There is also the contraction $\Sigma_l \hat{R}(i)^l{}_{ljk}$ which in classical Riemannian geometry vanishes identically. In the present framework its significance has still to be explored.

In order to construct a curvature scalar, we need an inverse of $g(i)$. This need not exist at all vertices of the digraph. There are examples where $g(i)$ is even degenerate at all vertices.

Example 4: We continue our example 2. With the assumptions made there, there are no conditions on the connection (cf. example 3). For the curvature we obtain

$$(\mu \otimes_L \mathrm{id}) \circ \lambda \circ \mathfrak{R}(e^{im}) = \sum_{i,j,k} e^{ij} \cap [e^{jk} \mathbb{U}^{ji}] \otimes_L \{(e^{im})[\mathbb{U}^{ij} \mathbb{U}^{jk} \mathbb{U}^{ki} - \mathbb{H}^{ik}]\}, \tag{4.25}$$

which for $e^{ij}\cap e^{ik}\neq 0$ yields

$$\hat{R}(i)^{m}{}_{njk}=\sum_{l} U(j)^{l}{}_{ik}\,[\mathbb{U}^{ij}\mathbb{U}^{jl}\mathbb{U}^{li}-\mathbb{H}^{il}]^{m}{}_{n}\,. \tag{4.26}$$

■

Example 5: We continue our example of Sec. III F and choose λ as in (4.10). The relations between the usual graded and the ∩-product are obtained from the above Lemma. In particular,

$$e^{41}\cap e^{41}=-e^{412}-e^{413}-e^{414},\quad e^{41}\cap e^{42}=e^{412} \tag{4.27}$$

and

$$e^{12}\cap e^{13}=0,\quad e^{12}\cap e^{12}=-e^{121}-e^{124},\quad e^{12}\cap e^{14}=e^{124}. \tag{4.28}$$

Since $\mathbb{H}^{ij}=I$, the map μ is well-defined. Then

$$\mu(e^{414})=-e^{41}\cap e^{41}-e^{41}\cap e^{42}-e^{41}\cap e^{43},\quad \mu(e^{412})=e^{41}\cap e^{42} \tag{4.29}$$

and

$$\mu(e^{123})=e^{12}\cap e^{13}=0,\quad \mu(e^{121})=-e^{12}\cap e^{12}-e^{12}\cap e^{14},\quad \mu(e^{124})=e^{12}\cap e^{14}. \tag{4.30}$$

The curvature $\hat{R}(i)_{jk}:=(\hat{R}(i)^{m}{}_{njk})$ at point 4 is given by

$$\hat{R}(4)_{11}=\hat{R}(4)_{22}=\hat{R}(4)_{33}=0 \tag{4.31}$$

and

$$\hat{R}(4)_{12}=\hat{R}(4)_{21}=\begin{pmatrix} 0 & 0 & 2(ac-b)/(c^2-1)\\ 0 & 0 & 2(bc-a)/(c^2-1)\\ 0 & 0 & -2\end{pmatrix},$$

$$\hat{R}(4)_{13}=\hat{R}(4)_{31}=\begin{pmatrix} 0 & 2(ab-c)/(b^2-1) & 0\\ 0 & -2 & 0\\ 0 & 2(bc-a)/(b^2-1) & 0\end{pmatrix}, \tag{4.32}$$

$$\hat{R}(4)_{23}=\hat{R}(4)_{32}=\begin{pmatrix} -2 & 0 & 0\\ 2(ab-c)/(a^2-1) & 0 & 0\\ 2(ac-b)/(a^2-1) & 0 & 0\end{pmatrix}.$$

Furthermore, we have $\hat{R}(1)_{22}=\hat{R}(1)_{33}=\hat{R}(1)_{44}=0$,

$$\hat{R}(1)_{24}=\hat{R}(1)_{42}=\begin{pmatrix} 0 & 2(bc-a)/(c^2-1) & 0\\ 0 & -2 & 0\\ 0 & 2(1-a-b+c)/(c+1) & 0\end{pmatrix}, \tag{4.33}$$

etc. and corresponding expressions for the curvature at the vertices 2 and 3. For the Ricci tensors, we find $\mathrm{Ric}(i)=\overline{\mathrm{Ric}}(i)$,

$$\mathrm{Ric}(4)=2\begin{pmatrix} 0 & (ac-b)/(a^2-1) & (ab-c)/(a^2-1)\\ (bc-a)/(b^2-1) & 0 & (ab-c)/(b^2-1)\\ (bc-a)/(c^2-1) & (ac-b)/(c^2-1) & 0\end{pmatrix}, \tag{4.34}$$

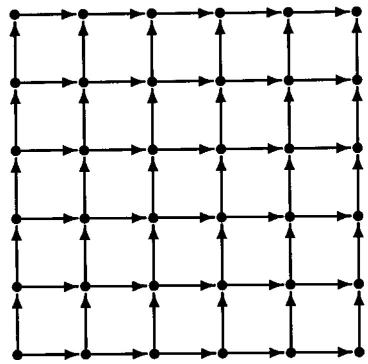

FIG. 1. A finite part of the oriented lattice graph.

$$\mathrm{Ric}(1)=2\begin{pmatrix} 0 & (1-a+b-c)/(b+1) & (bc-a)/(b^2-1) \\ (1-a-b+c)/(c+1) & 0 & (bc-a)/(c^2-1) \\ 0 & 0 & 0 \end{pmatrix}, \quad (4.35)$$

and corresponding expressions for $\mathrm{Ric}(j)$, $j=2,3$. The resulting expression for the curvature scalar turns out to be rather complicated. In the special case $a=b=c$, we obtain

$$R(4)=\sum_{i,j} g(4)^{ij}\ \mathrm{Ric}(4)_{ij}=\frac{1}{l^2}\frac{12a^2}{(a-1)(a+1)(2a+1)} \quad (4.36)$$

and

$$R(1)=R(2)=R(3)=-\frac{1}{l^2}\frac{8a}{(a+1)(2a+1)}. \quad (4.37)$$

■

The structures introduced in this section will also be exploited in the examples presented in the following two sections.

V. GEOMETRY OF THE ORIENTED LATTICE

In this section we choose $\mathcal{M}=\mathbb{Z}^n=\{a=(a^\mu)|a^\mu\in\mathbb{Z},\mu=1,\ldots,n\}$ and consider the differential calculus with

$$e^{ab}\neq 0 \Leftrightarrow b=a+\hat{\mu}, \quad \text{for some } \mu, \quad (5.1)$$

where $\hat{\mu}:=(\delta^\nu_\mu)\in\mathcal{M}$. The corresponding graph is an oriented lattice in n dimensions, a finite part of it is drawn in Fig. 1. Note that here we are dealing with an *infinite* set $\mathcal{M}$ for which in the formalism presented in the previous section in general technical problems associated with infinite sums arise. In the example under consideration we now sketch a transition to a formulation which then only makes reference to finitely generated $\mathcal{A}$-modules so that only finite sums appear and it is safe working on a purely algebraic level (see also Ref. 3).

Each $f\in\mathcal{A}$ can be written as a function of

$$x^\mu:=l_\mu\sum_a a^\mu e^a, \quad (5.2)$$

with $l_\mu\in\mathbb{R}$. Its differential is then given by

$$\mathrm{d}f = \sum_\mu \partial_{+\mu} f \ \mathrm{d}x^\mu, \tag{5.3}$$

where

$$(\partial_{+\mu} f)(x) := \frac{1}{l_\mu}[f(x+\boldsymbol{\mu}) - f(x)] \tag{5.4}$$

with $\boldsymbol{\mu} = l_\mu \hat{\mu}$. The 1-forms $\mathrm{d}x^\mu$ constitute a basis of Ω^1 as a left (or right) $\mathcal{A}$-module and satisfy the following commutation relations with a function of x^μ:

$$\mathrm{d}x^\mu \ f(x) = f(x+\boldsymbol{\mu}) \ \mathrm{d}x^\mu. \tag{5.5}$$

In particular, this implies

$$\mathrm{d}x^\nu \bullet \mathrm{d}x^\mu = [\mathrm{d}x^\mu, x^\nu] = l_\mu \delta^{\mu\nu} \mathrm{d}x^\mu \tag{5.6}$$

(cf. also Ref. 18) and, acting with d on the latter equation, leads to

$$\mathrm{d}x^\mu \ \mathrm{d}x^\nu + \mathrm{d}x^\nu \ \mathrm{d}x^\mu = 0. \tag{5.7}$$

The 1-form ρ introduced in (3.4) becomes

$$\rho = \sum_\mu \frac{1}{l_\mu} \mathrm{d}x^\mu. \tag{5.8}$$

It satisfies $\mathrm{d}\rho = 0$ and $\rho^2 = 0$. Moreover, for $w \in \Omega^r$ we have

$$\mathrm{d}w = \rho w - (-1)^r w \rho. \tag{5.9}$$

For a linear (left $\mathcal{A}$-module) connection on Ω^1 we write

$$\boldsymbol{\nabla} \mathrm{d}x^\mu = -\sum_\nu \Gamma^\mu{}_\nu \otimes_{\mathcal{A}} \mathrm{d}x^\nu, \quad \mathbb{U}(\mathrm{d}x^\mu) = \sum_\nu U^\mu{}_\nu \otimes_{\mathcal{A}} \mathrm{d}x^\nu. \tag{5.10}$$

Using (3.32), this leads to

$$U^\mu{}_\nu = \rho \delta^\mu_\nu + \Gamma^\mu{}_\nu =: \sum_\sigma \frac{1}{l_\sigma} U^\mu{}_{\sigma\nu} \ \mathrm{d}x^\sigma. \tag{5.11}$$

We shall require that $\lim_{\{l_\kappa\}\to 0} U^\mu_{\sigma\nu} = \delta^\mu_\nu$. This assumption will be used below where we work out continuum limits of curvature expressions.

The map κ introduced in Sec. IV is given by

$$\kappa(\mathrm{d}x^\mu \otimes_L \mathrm{d}x^\nu) = \sum_\sigma U^\nu{}_{\mu\sigma} \ \mathrm{d}x^\mu \otimes_{\mathcal{A}} \mathrm{d}x^\sigma. \tag{5.12}$$

For the left $\mathcal{A}$-linear $\cap$-product in Ω^2 we now obtain

$$\mathrm{d}x^\mu \cap \mathrm{d}x^\nu = \sum_\sigma U^\nu{}_{\mu\sigma} \ \mathrm{d}x^\mu \mathrm{d}x^\sigma. \tag{5.13}$$

Under a change of coordinates, $dx^\mu \cap dx^\nu$ transforms covariantly while $dx^\mu dx^\nu$ does not. Not all of the 2-forms $dx^\mu \cap dx^\nu$ are independent, in particular, as a consequence of (5.7). In the following we derive the relations which they satisfy under the assumption that κ has an inverse which means that $U^\mu{}_\nu$ has an inverse $V^\mu{}_\nu = \Sigma_\sigma (1/l_\sigma) V^\mu{}_{\sigma\nu}\, dx^\sigma$ in the sense that

$$\sum_\sigma U^\mu{}_\sigma \bullet V^\sigma{}_\nu = \rho\, \delta^\mu_\nu = \sum_\sigma V^\mu{}_\sigma \bullet U^\sigma{}_\nu . \tag{5.14}$$

In terms of components this becomes

$$\sum_\sigma U^\mu{}_{\alpha\sigma}\, V^\sigma{}_{\alpha\nu} = \delta^\mu_\nu = \sum_\sigma V^\mu{}_{\alpha\sigma}\, U^\sigma{}_{\alpha\nu}, \tag{5.15}$$

for all α. Now we have

$$dx^\mu dx^\nu = \sum_\sigma V^\nu{}_{\mu\sigma}\, dx^\mu \cap dx^\sigma. \tag{5.16}$$

We introduce

$$W^{\mu\nu}_{\rho\sigma} := U^\nu{}_{\mu\rho}\, V^\mu{}_{\rho\sigma}, \tag{5.17}$$

which satisfies $\lim_{\{l_\kappa\}\to 0} W^{\mu\nu}_{\rho\sigma} = \delta^\mu_\sigma \delta^\nu_\rho$ and

$$\sum_{\kappa,\lambda} W^{\mu\nu}_{\kappa\lambda}\, W^{\kappa\lambda}_{\rho\sigma} = \delta^\mu_\rho \delta^\nu_\sigma . \tag{5.18}$$

As a consequence,

$$(P^\pm)^{\mu\nu}_{\rho\sigma} := \frac{1}{2}(\delta^\mu_\rho \delta^\nu_\sigma \pm W^{\mu\nu}_{\rho\sigma}) \tag{5.19}$$

are projectors. In terms of the $\cap$-product, the 2-form relations (5.7) can now be expressed as follows:

$$\sum_{\kappa,\sigma} (P^+)^{\mu\nu}_{\kappa\sigma}\, dx^\kappa \cap dx^\sigma = 0. \tag{5.20}$$

This much more complicated form of the 2-form relations, as compared with (5.7), is the price we have to pay for the covariance. For a 2-form $A = \Sigma_{\mu,\nu} A_{\mu\nu}\, dx^\mu dx^\nu = \Sigma_{\mu,\nu} \hat{A}_{\mu\nu}\, dx^\mu \cap dx^\nu$ we obtain the implications

$$A = 0 \Leftrightarrow \sum_{\kappa,\sigma} (P^-)^{\kappa\sigma}_{\mu\nu}\, \hat{A}_{\kappa\sigma} = 0 \tag{5.21}$$

and

$$A_{\mu\nu} + A_{\nu\mu} = 0 \Leftrightarrow \sum_{\kappa,\sigma} (P^+)^{\kappa\sigma}_{\mu\nu}\, \hat{A}_{\kappa\sigma} = 0 \tag{5.22}$$

(since $A_{\mu\nu} = \Sigma_\rho \hat{A}_{\mu\rho} U^\rho{}_{\mu\nu}$).

With the help of (5.11), our general expression (2.8) for the torsion of a linear connection leads to

$$\Theta^\mu := \Theta(\mathrm{d}x^\mu) = \sum_{\nu,\rho} \frac{1}{l_\nu}(U^\mu{}_{\nu\rho} - \delta^\mu_\rho)\, \mathrm{d}x^\nu \mathrm{d}x^\rho = \sum_{\nu,\rho,\sigma} \frac{1}{l_\nu}(U^\mu{}_{\nu\rho} - \delta^\mu_\rho) V^\rho{}_{\nu\sigma}\, \mathrm{d}x^\nu \cap \mathrm{d}x^\sigma. \quad (5.23)$$

Writing

$$\Theta^\mu = \frac{1}{2}\sum_{\nu,\rho} Q^\mu{}_{\nu\rho}\, \mathrm{d}x^\nu \cap \mathrm{d}x^\rho, \quad (5.24)$$

where the coefficients $Q^\mu{}_{\nu\rho}$ are subject to

$$Q^\mu{}_{\nu\rho} = -\sum_{\kappa,\lambda} W^{\kappa\lambda}_{\nu\rho}\, Q^\mu{}_{\kappa\lambda}, \quad (5.25)$$

we are led to

$$Q^\mu{}_{\nu\rho} = \sum_{\kappa,\lambda,\sigma} \frac{1}{l_\kappa}(\delta^\kappa_\nu \delta^\lambda_\rho - W^{\kappa\lambda}_{\nu\rho})(U^\mu{}_{\kappa\sigma} - \delta^\mu_\sigma) V^\sigma{}_{\kappa\lambda}. \quad (5.26)$$

Example: If the torsion vanishes, we obtain

$$\frac{1}{l_\nu}(U^\mu{}_{\nu\rho} - \delta^\mu_\rho) = \frac{1}{l_\rho}(U^\mu{}_{\rho\nu} - \delta^\mu_\nu). \quad (5.27)$$

This is equivalent to the condition

$$\Gamma^\mu{}_{\nu\rho} = \Gamma^\mu{}_{\rho\nu}, \quad (5.28)$$

which is familar from continuum differential geometry. ■

A metric tensor (in the sense of Sec. III) is given by

$$g = \sum_{\mu,\nu} g_{\mu\nu}\, \mathrm{d}x^\mu \otimes_L \mathrm{d}x^\nu, \quad (5.29)$$

where $g_{\mu\nu}$ is now assumed to be a nondegenerate symmetric matrix. The metric compatibility condition $\boldsymbol{\nabla} g = 0$ with a linear connection $\boldsymbol{\nabla}$ leads to

$$g(x+\boldsymbol{\lambda})_{\mu\nu} = \sum_{\rho,\sigma} U(x)^\rho{}_{\lambda\mu}\, g(x)_{\rho\sigma}\, U(x)^\sigma{}_{\lambda\nu}, \quad (5.30)$$

for all λ. In matrix notation, this takes the form

$$g(x+\boldsymbol{\lambda}) = U(x)^t_\lambda\, g(x)\, U(x)_\lambda. \quad (5.31)$$

The continuum limit of this equation is obtained from the expansion

$$\begin{aligned} \tilde{g}_{\mu\nu} + l_\lambda(\partial_\lambda \tilde{g}_{\mu\nu} + b_{\mu\nu}) + \mathcal{O}(l^2_\mu) &= \sum_{\rho,\sigma} (\delta^\rho_\mu + l_\lambda \Gamma^\rho{}_{\lambda\mu}) g_{\rho\sigma} (\delta^\sigma_\nu + l_\lambda \Gamma^\sigma{}_{\lambda\nu}) \\ &= \tilde{g}_{\mu\nu} + l_\lambda\left(\sum_\rho (\tilde{\Gamma}^\rho{}_{\lambda\mu}\, \tilde{g}_{\rho\nu} + \tilde{g}_{\mu\rho}\, \tilde{\Gamma}^\rho{}_{\lambda\nu}) + b_{\mu\nu}\right) + \mathcal{O}(l^2_\mu), \end{aligned} \quad (5.32)$$

where

$$\tilde{\Gamma}^{\mu}{}_{\sigma\nu} := \lim_{\{l_\lambda\}\to 0} \Gamma^{\mu}{}_{\sigma\nu}, \quad \tilde{g}_{\mu\nu} := \lim_{\{l_\lambda\}\to 0} g_{\mu\nu}, \quad b_{\mu\nu} := \lim_{\{l_\lambda\}\to 0} \frac{\partial g_{\mu\nu}}{\partial l_\mu}, \tag{5.33}$$

which we assume to exist.

Remark: The vector fields $\partial_{+\mu} \in \mathfrak{X}$ are dual to the 1-forms dx^μ, i.e.,

$$\langle dx^\mu, \partial_{+\nu} \rangle = \delta^\mu_\nu. \tag{5.34}$$

The action of $X = \Sigma_\mu \partial_{+\mu} \cdot X^\mu$ on functions is given by

$$X(f) = \langle df, X \rangle = \sum_\mu X^\mu \, (\partial_{+\mu} f). \tag{5.35}$$

For the connection we have $\mathbb{U}(X) = X \otimes_{\mathcal{A}} \rho + \nabla X$, and thus

$$\mathbb{U}(\partial_{+\mu}) = \sum_\nu \partial_{+\nu} \otimes_{\mathcal{A}} U^\nu{}_\mu. \tag{5.36}$$

A dual metric tensor (cf. Sec. III) can be expressed as

$$h = \sum_{\mu,\nu} \partial_{+\mu} \otimes_R \partial_{+\nu} \cdot h^{\mu\nu}, \tag{5.37}$$

with components $h^{\mu\nu} \in \mathcal{A}$. The metric compatibility condition for a linear connection takes the form $\mathbb{U}(h) = h \otimes_{\mathcal{A}} \rho$. The latter leads to

$$h(x+\boldsymbol{\lambda})^{\mu\nu} = \sum_{\rho,\sigma} V(x)^\mu{}_{\lambda\rho} \, V(x)^\nu{}_{\lambda\sigma} \, h(x)^{\rho\sigma}. \tag{5.38}$$

With $h^{\mu\nu} = g^{\mu\nu}$, where $g^{\mu\nu}$ are the components of the matrix inverse to $(g_{\mu\nu})$, we obtain the metric tensor inverse to g. ■

Let us now turn to the calculation of the curvature of a linear connection. We have

$$\begin{aligned}
\mathfrak{R}(dx^\mu) &= \sum_\nu \left(d\Gamma^\mu{}_\nu + \sum_\rho \Gamma^\mu{}_\rho \Gamma^\rho{}_\nu \right) \otimes_{\mathcal{A}} dx^\nu \\
&= \sum_{\rho,\nu} U^\mu{}_\rho \, U^\rho{}_\nu \otimes_{\mathcal{A}} dx^\nu \\
&= \sum_{\rho,\kappa,\lambda,\nu} \frac{1}{l_\kappa l_\lambda} U(x)^\mu{}_{\kappa\rho} \, U(x+\boldsymbol{\kappa})^\rho{}_{\lambda\nu} \, dx^\kappa dx^\lambda \otimes_{\mathcal{A}} dx^\nu \\
&= \frac{1}{2} \sum_{\kappa,\lambda,\nu} \frac{1}{l_\kappa l_\lambda} [U(x)_\kappa \, U(x+\boldsymbol{\kappa})_\lambda - U(x)_\lambda \, U(x+\boldsymbol{\lambda})_\kappa]^\mu{}_\nu \, dx^\kappa dx^\lambda \otimes_{\mathcal{A}} dx^\nu.
\end{aligned} \tag{5.39}$$

With

$$\mathfrak{R}(dx^\mu) =: \frac{1}{2} \sum_{\kappa,\lambda,\nu} R^\mu{}_{\nu\kappa\lambda} \, dx^\kappa dx^\lambda \otimes_{\mathcal{A}} dx^\nu, \tag{5.40}$$

where $R^\mu{}_{\nu\kappa\lambda} = -R^\mu{}_{\nu\lambda\kappa}$, we thus have

$$R^\mu{}_{\nu\kappa\lambda} = \frac{1}{l_\kappa l_\lambda} [U(x)_\kappa \, U(x+\boldsymbol{\kappa})_\lambda - U(x)_\lambda \, U(x+\boldsymbol{\lambda})_\kappa]^\mu{}_\nu. \tag{5.41}$$

To obtain the tensorial components of the curvature, we need to transform $\otimes_{\mathcal{A}}$ into $\otimes_L$ and the $dx^\kappa dx^\lambda$ into $dx^\kappa \cap dx^\lambda$. We achieve this with $\lambda = \boldsymbol{\kappa}^{-1}$. First we note that

$$\lambda(dx^\mu \otimes_{\mathcal{A}} dx^\nu) = \sum_\rho V(x)^\nu{}_{\mu\rho}\, dx^\mu \otimes_L dx^\rho, \tag{5.42}$$

and therefore[31]

$$\begin{aligned}\lambda(dx^\mu dx^\nu \otimes_{\mathcal{A}} dx^\rho) &= \frac{1}{2}\, dx^\mu\left(\sum_\lambda V(x)^\rho{}_{\nu\lambda}\, dx^\nu \otimes_L dx^\lambda\right) - \frac{1}{2}\, dx^\nu\left(\sum_\lambda V(x)^\rho{}_{\mu\lambda}\, dx^\mu \otimes_L dx^\lambda\right)\\ &= \frac{1}{2}\sum_{\lambda,\sigma}\{V(x)^\lambda{}_{\mu\sigma}\, dx^\mu(V(x)^\rho{}_{\nu\lambda} dx^\nu) - V(x)^\lambda{}_{\nu\sigma}\, dx^\nu(V(x)^\rho{}_{\mu\lambda} dx^\mu)\}\otimes_L dx^\sigma\\ &= \frac{1}{2}\sum_\sigma [V(x+\boldsymbol{\mu})_\nu\, V(x)_\mu + V(x+\boldsymbol{\nu})_\mu\, V(x)_\nu]^\rho{}_\sigma\, (dx^\mu dx^\nu)\otimes_L dx^\sigma. \end{aligned} \tag{5.43}$$

Applying this formula, we find

$$\begin{aligned}\lambda\circ\mathfrak{R}(dx^\mu) = \frac{1}{4}\sum_{\kappa,\lambda,\nu}\frac{1}{l_\kappa l_\lambda}[(U(x)_\kappa\, U(x+\boldsymbol{\kappa})_\lambda - U(x)_\lambda\, U(x+\boldsymbol{\lambda})_\kappa)\\ \times(V(x+\boldsymbol{\kappa})_\lambda\, V(x)_\kappa + V(x+\boldsymbol{\lambda})_\kappa\, V(x)_\lambda)]^\mu{}_\nu\, dx^\kappa dx^\lambda \otimes_L dx^\nu.\end{aligned} \tag{5.44}$$

With

$$\lambda\circ\mathfrak{R}(dx^\mu) =: \sum_\nu \hat{R}^\mu{}_\nu \otimes_L dx^\nu, \tag{5.45}$$

this leads to

$$\hat{R}^\mu{}_\nu = \frac{1}{4}\sum_{\kappa,\lambda}\frac{1}{l_\kappa l_\lambda}[H(x)_{\kappa\lambda} - H(x)_{\lambda\kappa}]^\mu{}_\nu\, dx^\kappa dx^\lambda, \tag{5.46}$$

where

$$H(x)_{\kappa\lambda} := U(x)_\kappa\, U(x+\boldsymbol{\kappa})_\lambda\, V(x+\boldsymbol{\lambda})_\kappa\, V(x)_\lambda\,. \tag{5.47}$$

Expressing the 2-forms $\hat{R}^\mu{}_\nu$ as follows:

$$\hat{R}^\mu{}_\nu = \frac{1}{2}\sum_{\rho,\sigma}\hat{R}^\mu{}_{\nu\rho\sigma}\, dx^\rho \cap dx^\sigma, \tag{5.48}$$

with tensorial coefficients subject to

$$\hat{R}^\mu{}_{\nu\rho\sigma} = -\sum_{\kappa,\lambda} W^{\kappa\lambda}_{\rho\sigma}\, \hat{R}^\mu{}_{\nu\kappa\lambda}\,, \tag{5.49}$$

we get

$$\hat{R}^\mu{}_{\nu\kappa\lambda} = \frac{1}{2}\sum_\alpha \frac{1}{l_\kappa l_\alpha}[H(x)_{\kappa\alpha} - H(x)_{\alpha\kappa}]^\mu{}_\nu\, V(x)^\alpha{}_{\kappa\lambda}\,. \tag{5.50}$$

The resulting Ricci tensors are

$$\mathrm{Ric}_{\mu\nu}=\frac{1}{2}\sum_{\alpha,\beta}\frac{1}{l_\alpha l_\beta}[H(x)_{\beta\alpha}-H(x)_{\alpha\beta}]^\beta{}_\mu\ V(x)^\alpha{}_{\beta\nu}, \tag{5.51}$$

$$\overline{\mathrm{Ric}_{\mu\nu}}=\frac{1}{2}\sum_{\alpha,\beta}\frac{1}{l_\alpha l_\nu}[H(x)_{\nu\alpha}-H(x)_{\alpha\nu}]^\beta{}_\mu\ V(x)^\alpha{}_{\nu\beta}, \tag{5.52}$$

from which one obtains the curvature scalars $\hat{R}=g^{\mu\nu}\ \mathrm{Ric}_{\mu\nu}$ and $\overline{\hat{R}}=g^{\mu\nu}\ \overline{\mathrm{Ric}}_{\mu\nu}$ with the help of the inverse $g^{\mu\nu}$ of $g_{\mu\nu}$.

In order to elaborate the continuum limit of the curvature tensor, we use the expansions

$$U(x)_\kappa=I+l_\kappa\tilde{\Gamma}_\kappa+\frac{l_\kappa^2}{2}[(\tilde{\Gamma}_\kappa)^2+B_\kappa]+\mathcal{O}(l^3), \tag{5.53}$$

$$U(x+\boldsymbol{\lambda})_\kappa=I+l_\kappa\tilde{\Gamma}_\kappa+l_\kappa l_\lambda\partial_\lambda\tilde{\Gamma}_\kappa+\frac{l_\kappa^2}{2}[(\tilde{\Gamma}_\kappa)^2+B_\kappa]+\mathcal{O}(l^3), \tag{5.54}$$

$$V(x)_\kappa=I-l_\kappa\tilde{\Gamma}_\kappa+\frac{l_\kappa^2}{2}[(\tilde{\Gamma}_\kappa)^2-B_\kappa]+\mathcal{O}(l^3), \tag{5.55}$$

$$V(x+\boldsymbol{\lambda})_\kappa=I-l_\kappa\tilde{\Gamma}_\kappa-l_\kappa l_\lambda\partial_\lambda\tilde{\Gamma}_\kappa+\frac{l_\kappa^2}{2}[(\tilde{\Gamma}_\kappa)^2-B_\kappa]+\mathcal{O}(l^3). \tag{5.56}$$

This leads to

$$H(x)_{\kappa\lambda}=I+l_\kappa l_\lambda\ [\partial_\kappa\tilde{\Gamma}_\lambda+\tilde{\Gamma}_\kappa\ \tilde{\Gamma}_\lambda-\partial_\lambda\tilde{\Gamma}_\kappa+\tilde{\Gamma}_\lambda\ \tilde{\Gamma}_\kappa]+\mathcal{O}(l^3), \tag{5.57}$$

so that

$$\hat{R}^\mu{}_{\nu\kappa\lambda}=\partial_\kappa\tilde{\Gamma}^\mu{}_{\lambda\nu}-\partial_\lambda\tilde{\Gamma}^\mu{}_{\kappa\nu}+\tilde{\Gamma}^\mu{}_{\kappa\rho}\ \tilde{\Gamma}^\rho{}_{\lambda\nu}-\tilde{\Gamma}^\mu{}_{\lambda\rho}\ \tilde{\Gamma}^\rho{}_{\kappa\nu}+\mathcal{O}(l). \tag{5.58}$$

In this way we recover the continuum Riemann tensor in the limit $\{l_\alpha\}\to 0$.

We have set up a formalism which assigns geometrical notions like metric, curvature and Ricci tensor to a hypercubic lattice. In particular, one obtains a discrete counterpart of the Einstein (vacuum) equations in this way. Actually, there are several discrete Einstein equations depending on our choice of Ricci tensor. The results of the following section suggest that the difference $\mathrm{Ric}-\overline{\mathrm{Ric}}$ is the appropriate object.

Remark: The maps κ and λ extend to an arbitrary number of factors of the corresponding tensor products. We define

$$\kappa(\alpha_1\otimes_L\cdots\otimes_L\alpha_r):=(\mathrm{id}\otimes_{\mathcal{A}}\ \kappa)[\alpha_1\bullet\mathbb{U}(\alpha_2\otimes_L\cdots\otimes_L\alpha_r)], \tag{5.59}$$

and correspondingly for λ. These maps allow us to introduce covariant components of higher order forms by expressing them in terms of

$$\alpha_1\cap\cdots\cap\alpha_r:=\pi\circ\kappa(\alpha_1\otimes_L\cdots\otimes_L\alpha_r). \tag{5.60}$$

These r-forms satisfy very complicated relations which generalize (5.20) and involve the curvature, in general. ■

VI. DISCRETE SURFACES OF REVOLUTION

In terms of coordinates ϑ,φ we consider the differential calculus determined by

$$\mathrm{d}\vartheta\ f(\vartheta,\varphi)=f(\vartheta+l,\varphi)\ \mathrm{d}\vartheta,\quad \mathrm{d}\varphi\ f(\vartheta,\varphi)=f(\vartheta,\varphi+l)\ \mathrm{d}\varphi. \tag{6.1}$$

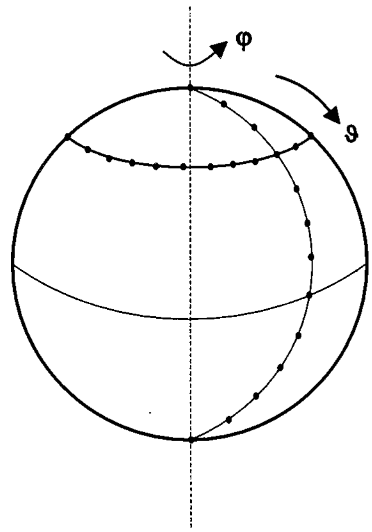

FIG. 2. Discretization of a sphere.

This is just a special case of (5.5). Via the rules of differential calculus it leads to

$$\mathrm{d}\vartheta \mathrm{d}\vartheta = 0, \quad \mathrm{d}\vartheta \mathrm{d}\varphi + \mathrm{d}\varphi \mathrm{d}\vartheta = 0, \quad \mathrm{d}\varphi \mathrm{d}\varphi = 0. \tag{6.2}$$

In contrast to the previous section, we interpret the coordinates as spherical coordinates where $\vartheta \in [0,\pi)$ and $\varphi \in [0,2\pi)$. With $l = \pi/n$, $n \in \mathbb{N}$, we obtain a discretization of the surface by fixing one point on the surface and moving in steps of coordinate length l in ϑ- and φ-directions. For the metric we make an ansatz,

$$g(\vartheta,\varphi) = \begin{pmatrix} 1 & 0 \\ 0 & b^2 \end{pmatrix}, \tag{6.3}$$

where b is a function of ϑ only. This models a surface of revolution (for example, a sphere as in Fig. 2).

Using $B := \mathrm{diag}(1,b)$, we have $g = B^t B$ and the metric compatibility condition for the parallel transport takes the form

$$(BU_\vartheta \tilde{B}^{-1})^t (BU_\vartheta \tilde{B}^{-1}) = I, \quad (BU_\varphi B^{-1})^t (BU_\varphi B^{-1}) = I, \tag{6.4}$$

where $\tilde{B} := \mathrm{diag}(1,\tilde{b})$ and $\tilde{b}(\vartheta) := b(\vartheta + l)$. As a consequence of these equations, $\tilde{B} U_\vartheta B^{-1}$ and $BU_\varphi B^{-1}$ are elements of the orthogonal group O(2). In order to obtain the correct continuum limit, we restrict them to be elements of SO(2), the component of O(2) which contains the identity. Then we have expressions

$$U_\vartheta = B^{-1} T(u) \tilde{B}, \quad U_\varphi = B^{-1} T(v) B, \tag{6.5}$$

where u,v are arbitrary functions of ϑ and φ and

$$T(\chi) = \begin{pmatrix} \cos\chi & -\sin\chi \\ \sin\chi & \cos\chi \end{pmatrix}. \tag{6.6}$$

The metric compatibility condition now leads to

$$U_\vartheta=\begin{pmatrix} \cos u & -\tilde{b}\sin u \\ (1/b)\sin u & (\tilde{b}/b)\cos u \end{pmatrix}, \quad U_\varphi=\begin{pmatrix} \cos v & -b\sin v \\ (1/b)\sin v & \cos v \end{pmatrix}, \tag{6.7}$$

and the condition of vanishing torsion becomes

$$\tilde{b}\sin u+\cos v=1, \quad \tilde{b}\cos u-\sin v=b. \tag{6.8}$$

These equations determine u and v completely in terms of b and $\tilde{b}$. We find

$$\cos u=\frac{1-p^2}{1+p^2}, \quad \sin u=\frac{2p}{1+p^2}, \quad \cos v=\frac{1+p^2-2\tilde{b}p}{1+p^2}, \quad \sin v=\frac{\tilde{b}-b-(\tilde{b}+b)p^2}{1+p^2}, \tag{6.9}$$

with

$$p=(2\tilde{b}\pm\sqrt{4\tilde{b}^2-(\tilde{b}^2-b^2)^2})/(b+\tilde{b})^2. \tag{6.10}$$

Only with the minus sign in the last expression we obtain the correct continuum limit (cf. Sec. V) where $\lim_{l\to 0}U_\vartheta=\lim_{l\to 0}U_\varphi=I$ (the unit matrix). This choice will be made in the following. The inverse parallel transport matrices are given by $V_\vartheta=\tilde{B}^{-1}T(-u)B$ and $V_\varphi=B^{-1}T(-v)B$, so that

$$V_\vartheta=\begin{pmatrix} \cos u & b\sin u \\ -(1/\tilde{b})\sin u & (b/\tilde{b})\cos u \end{pmatrix}, \quad V_\varphi=\begin{pmatrix} \cos v & b\sin v \\ -(1/b)\sin v & \cos v \end{pmatrix}. \tag{6.11}$$

With $\lambda=\kappa^{-1}$ (see Sec. IV), we obtain, for the curvature,

$$\lambda\circ\mathfrak{R}(\mathrm{d}x^\mu)=\sum_\nu r^\mu{}_\nu\,\mathrm{d}\vartheta\mathrm{d}\varphi\otimes_L\mathrm{d}x^\nu, \tag{6.12}$$

where $x^1=\vartheta, x^2=\varphi$ and

$$\begin{aligned} r&:=\frac{1}{2l^2}[U_\vartheta(\vartheta,\varphi)U_\varphi(\vartheta+l,\varphi)V_\vartheta(\vartheta,\varphi+l)V_\varphi(\vartheta,\varphi) \\ &\quad -U_\varphi(\vartheta,\varphi)U_\vartheta(\vartheta,\varphi+l)V_\varphi(\vartheta+l,\varphi)V_\vartheta(\vartheta,\varphi)] \\ &=\frac{1}{2l^2}B^{-1}[T(u)T(\tilde{v})T(-u)T(-v)-T(v)T(u)T(-\tilde{v})T(-u)]B \\ &=\frac{1}{2l^2}B^{-1}[T(\tilde{v}-v)-T(v-\tilde{v})]B=\frac{1}{l^2}\begin{pmatrix} 0 & -b\sin(\tilde{v}-v) \\ (1/b)\sin(\tilde{v}-v) & 0 \end{pmatrix}, \end{aligned} \tag{6.13}$$

with $\tilde{v}(\vartheta):=v(\vartheta+l)$. Since u and v are functions of b and $\tilde{b}$, they are functions of ϑ only. Using

$$\mathrm{d}\vartheta\mathrm{d}\varphi=V^\varphi_{\vartheta\vartheta}\,\mathrm{d}\vartheta\cap\mathrm{d}\vartheta+V^\varphi_{\vartheta\varphi}\,\mathrm{d}\vartheta\cap\mathrm{d}\varphi, \quad \mathrm{d}\varphi\mathrm{d}\vartheta=V^\vartheta_{\varphi\vartheta}\,\mathrm{d}\varphi\cap\mathrm{d}\vartheta+V^\vartheta_{\varphi\varphi}\,\mathrm{d}\vartheta\cap\mathrm{d}\varphi \tag{6.14}$$

and $r\mathrm{d}\vartheta\mathrm{d}\varphi=\frac{1}{2}r(\mathrm{d}\vartheta\mathrm{d}\varphi-\mathrm{d}\varphi\mathrm{d}\vartheta)$, we find the curvature components

$$\hat{R}_{\vartheta\vartheta}=-\frac{\sin u}{\tilde{b}}r, \quad \hat{R}_{\vartheta\varphi}=\frac{b\cos u}{\tilde{b}}r, \quad \hat{R}_{\varphi\vartheta}=-(\cos v)r, \quad \hat{R}_{\varphi\varphi}=-b(\sin v)r, \tag{6.15}$$

where $\hat{R}_{\kappa\lambda}=(\hat{R}^\mu{}_{\nu\kappa\lambda})$. We have the two Ricci tensors:

$$\mathrm{Ric} = \frac{1}{l^2}\begin{pmatrix} -(1/b)\cos v & -\sin v \\ (b/\tilde{b})\sin u & -(b^2/\tilde{b})\cos u \end{pmatrix} \sin(\tilde{v}-v), \tag{6.16}$$

$$\overline{\mathrm{Ric}} = \frac{1}{l^2}\begin{pmatrix} (1/\tilde{b})\cos u & -\sin v \\ (b/\tilde{b})\sin u & b\cos v \end{pmatrix} \sin(\tilde{v}-v), \tag{6.17}$$

and the combination

$$\widetilde{\mathrm{Ric}} := \frac{1}{2}(\mathrm{Ric} - \overline{\mathrm{Ric}}) = -\frac{1}{2l^2}\left(\frac{\cos u}{\tilde{b}} + \frac{\cos v}{b}\right)\sin(\tilde{v}-v)g, \tag{6.18}$$

from which we obtain the curvature scalars[32]

$$\hat{R} := g^{\mu\nu}\,\mathrm{Ric}_{\mu\nu} = -\frac{1}{l^2}\left(\frac{\cos u}{\tilde{b}} + \frac{\cos v}{b}\right)\sin(\tilde{v}-v), \tag{6.19}$$

$$\bar{\hat{R}} := g^{\mu\nu}\,\overline{\mathrm{Ric}}_{\mu\nu} = -\hat{R}, \tag{6.20}$$

$$\tilde{R} := g^{\mu\nu}\widetilde{\mathrm{Ric}}_{\mu\nu} = \hat{R}. \tag{6.21}$$

Now (6.18) becomes

$$\widetilde{\mathrm{Ric}}_{\mu\nu} = \frac{1}{2}\tilde{R}\, g_{\mu\nu}. \tag{6.22}$$

This result clearly distinguishes the particular linear combination (6.18) of Ricci tensors.

In the following, we present expansions in powers of l and consider the continuum limit $l \to 0$. We shall allow an explicit dependence of b on l, i.e., $b(\vartheta,l) = b_0(\vartheta) + b_1(\vartheta)l + \mathcal{O}(l^2)$. Then

$$\Gamma_\vartheta = \frac{1}{l}(U_\vartheta - I) = \begin{pmatrix} 0 & 0 \\ 0 & b_0'/b_0 \end{pmatrix} + \begin{pmatrix} 0 & -(b_0'^2/2) \\ b_0'^2/2b_0^2 & (2b_1' + b_0'')/2b_0 - b_1 b_0'/b_0^2 \end{pmatrix} l + \mathcal{O}(l^2), \tag{6.23}$$

$$\begin{aligned}\Gamma_\varphi &= \frac{1}{l}(U_\varphi - I) \\ &= \begin{pmatrix} 0 & -b_0 b_0' \\ b_0'/b_0 & 0 \end{pmatrix} + \begin{pmatrix} -b_0'^2/2 & -[b_1 b_0' + b_0 b_1' + b_0 b_0''/2] \\ (2b_1' + b_0'')/2b_0 - b_1 b_0'/b_0^2 & -b_0'^2/2 \end{pmatrix} l + \mathcal{O}(l^2),\end{aligned}$$

where b' denotes the derivative of b with respect to ϑ. For the curvature, we find $\hat{R}_{\vartheta\vartheta} = \mathcal{O}(l^2)$ and

$$\begin{aligned}\hat{R}_{\vartheta\varphi} &= \begin{pmatrix} 0 & -b_0 b_0'' \\ b_0''/b_0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & (-b_1 + b_0')b_0'' - b_0(b_1'' + b_0''') \\ -[(b_1 + b_0')b_0''/b_0^2 - (b_1'' + b_0''')/b_0] & 0 \end{pmatrix} l \\ &\quad + \mathcal{O}(l^2),\end{aligned}$$

$$\hat{R}_{\varphi\vartheta} = \begin{pmatrix} 0 & b_0 b_0' \\ -b_0''/b_0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & b_1 b_0'' + b_0(b_1'' + b_0''') \\ -[b_1 b_0'' - b_0(b_1'' + b_0''')]/b_0^2 & 0 \end{pmatrix} l + \mathcal{O}(l^2), \tag{6.24}$$

$$\hat{R}_{\varphi\varphi}=\begin{pmatrix} 0 & b_0^2 b_0' b_0'' \\ -b_0' b_0'' & 0 \end{pmatrix} l+\mathcal{O}(l^2).$$

The Ricci tensors have the following expansions:

$$\mathrm{Ric}=\begin{pmatrix} -b_0''/b_0 & 0 \\ 0 & -b_0 b_0'' \end{pmatrix}+\begin{pmatrix} [b_1 b_0''-b_0(b_1''+b_0''')]/b_0^2 & -b_0' b_0'' \\ 0 & (-b_1+b_0')b_0''-b_0(b_1''+b_0''') \end{pmatrix} l+\mathcal{O}(l^2), \tag{6.25}$$

$$\overline{\mathrm{Ric}}=\begin{pmatrix} b_0''/b_0 & 0 \\ 0 & b_0 b_0'' \end{pmatrix}+\begin{pmatrix} -(b_1+b_0')b_0''/b_0^2+(b_1''+b_0''')/b_0 & -b_0' b_0'' \\ 0 & b_1 b_0''+b_0(b_1''+b_0''') \end{pmatrix} l+\mathcal{O}(l^2), \tag{6.26}$$

$$\widetilde{\mathrm{Ric}}=\left[-\frac{b_0''}{b_0}+\frac{2b_1 b_0''+b_0' b_0''-2b_0(b_1''+b_0''')}{2b_0^2} l+\mathcal{O}(l^2)\right] g_0, \tag{6.27}$$

where $g_0:=\mathrm{diag}(1,b_0^2)$. For the curvature scalar we obtain

$$\hat{R}=-\frac{2b_0''}{b_0}+\frac{2b_1 b_0''+b_0' b_0''-2b_0(b_1''+b_0''')}{b_0^2} l+\mathcal{O}(l^2). \tag{6.28}$$

Example: In ordinary continuum differential geometry, the standard geometry of the unit sphere is obtained with $b(\vartheta)=\sin\vartheta$. With this choice, we get

$$\hat{R}=2+l\cot\vartheta+\mathcal{O}(l^2) \tag{6.29}$$

in the discrete framework and in the limit $l\to 0$ we recover the continuum result $\hat{R}=2$. To first order, there is a dependence of the curvature scalar on ϑ. With the refined choice $b(\vartheta,l)=[1+\vartheta l/4+\mathcal{O}(l^2)]\sin\vartheta$, we get

$$\hat{R}=2+\mathcal{O}(l^2). \tag{6.30}$$

■

Our discrete version of curvature describes *finite* distances on a space in contrast to infinitesimal distances as expressed by tangent vectors in continuum differential geometry. This means that the metric components in the case under consideration have to be expected to depend on the discretization (which should be regarded as a discretization of a chart), i.e., on l in the case under consideration. We still have to understand how, for example, spherical symmetry can be formulated in our framework. Then, we should be able to determine a spherically symmetric metric as a suitable discrete counterpart of the Riemannian metric of the (continuum) sphere. Furthermore, it remains to be seen how this is related to the metric with constant curvature scalar, approximated in the above example.

VII. CONCLUSIONS

Within a framework of noncommutative geometry, we have presented a formalism of discrete Riemannian geometry which is very much analogous to continuum Riemannian geometry.

Whereas the general formalism of noncommutative geometry suggests to consider a (generalized) metric tensor as an element of $\Omega^1\otimes_{\mathcal{A}}\Omega^1$, in this paper it was taken to be an element of $\Omega^1\otimes_L\Omega^1$ since a simple geometric meaning can be assigned to its components (with respect to the canonical basis e^{ij} of Ω^1; cf. Sec. III).[33]

The compatibility condition $\nabla g = 0$ for a metric and a linear connection on a finite set, when expressed in terms of parallel transport matrices, leads to relations (cf. Sec. III E) which are in complete accordance with what one should expect on the basis of a reformulation of metric compatibility in terms of parallel transport in (continuum) differential geometry.

An important role in ordinary differential geometry and especially in General Relativity is played by the Ricci tensor and the curvature scalar. There is no generalization of these tensors to the general framework of noncommutative geometry. In the case of a discrete set, we considered this problem in some detail in Sec. IV and showed that, with certain restrictions on the differential calculus (and thus the links between the points of the set), satisfactory candidates for discrete counterparts of the continuum Ricci tensor and curvature scalar do exist. The examples treated in Secs. IV–VI demonstrate how our definitions work. It should be quite evident by now that general definitions can hardly be expected since in noncommutative geometry, and already with a commutative algebra $\mathcal{A}$, we are dealing with a huge variety of structures of which only few should be expected to be close (in some sense) to continuum differential geometry.

In the last two sections we have developed discrete differential geometry on a hypercubic lattice. Since we were able to construct a Ricci tensor and a curvature scalar in this case, discrete counterparts of the (vacuum) Einstein equations are obtained. The results of the last section suggest to choose the following version:

$$\widetilde{\mathrm{Ric}}_{\mu\nu} - \tfrac{1}{2}\tilde{R} g_{\mu\nu} = 0. \tag{7.1}$$

On the left hand side we have tensor components in the sense that they transform covariantly under a change of module basis in the space of 1-forms. It is straightforward to include matter fields in this scheme. The ''discrete gravity'' theory which we propose here is very different from earlier approaches which were either based on Regge calculus,[28] other simplicial complex structures,[34] or on a certain reformulation of gravity as a gauge theory.[35] The correspondence between first order differential calculi on discrete sets and digraphs relates our formalism to the spin network approach to (quantum) gravity (see Ref. 36, in particular), at least on a basic level.

[17] Instead of $\Omega(\mathcal{A})$ we simply write Ω in the following.

[18] H. C. Baehr, A. Dimakis, and F. Müller-Hoissen, ''Differential calculi on commutative algebras,'' J. Phys. A **28**, 3197 (1995).

[19] In general, a differential ideal is generated by linear combinations of basic forms.

[20] We use the same symbol $\boldsymbol{\nabla}$ for the connection and its dual.

[21] This is no longer so when Ω^2 is smaller than $\Omega^1 \otimes_{\mathcal{A}} \Omega^1$.

[22] At this point it is worth not to impose additional conditions. Finally, we will be interested in g being *real* and *symmetric* [i.e., $g(i)_{jk} = g(i)_{kj}$], or *Hermitian*. We refer to $g(i)_{jk}$ as the components of a ''metric'' at i in order to emphasize a certain analogy with a metric tensor in continuum differential geometry. However, a better name would be *distance matrix* of the digraph at i. In general, $g(i)$ will be degenerate.

[23] More generally, let us consider a graph embedded in some affine space $\mathbb{R}^d$, $d \in \mathbb{N}$, with inner product $(,)$. Hence, there is a map $\mathbf{x}: \mathcal{M} \to \mathbb{R}^d$ with $\mathbf{x} = \sum_{i \in \mathcal{M}} \mathbf{x}_i e^i$. Given a (first order) differential calculus on $\mathcal{M}$, we have $d\mathbf{x} = \sum_{i,j} (\mathbf{x}_j - \mathbf{x}_i) e^{ij}$. The inner product then induces a metric on $\mathcal{M}$ via $g(i)_{jk} = (\mathbf{x}_j - \mathbf{x}_i, \mathbf{x}_k - \mathbf{x}_i)$. If the inner product is the Euclidean one, then we have (3.53).

[24] Our formalism admits nonstandard geometries, however. For example, measuring the (not necessarily spatial) ''distances'' from i to j and from j to i in some (in a generalized sense) anisotropic space may lead to different results. This can be taken into account by dropping the restriction $l_{ij} = l_{ji}$.

[25] Note that $g(i)_{ik}$ and $g(i)_{ki}$ do not appear in (3.52) and have to be interpreted as 0 in the following formulas.

[26] Here ''if $e^{ikl} = 0$'' should be interpreted as ''if e^{ikl} is not present in the differential calculus.'' This abuse of notation has the great advantage of being much more concise and will therefore be repeatedly used in the following.

[27] L. Brewin, ''Riemann normal coordinates, smooth lattices and numerical relativity,'' gr-qc/9701057.

[29] This shows that left $\mathcal{A}$-homomorphisms $\Omega^1 \otimes_L \Omega^1 \to \Omega^1 \otimes_{\mathcal{A}} \Omega^1$ are in one-to-one correspondence with left $\mathcal{A}$-module linear connections.

[30] If $e^i \alpha e^j \neq 0$, then $i \to j$ with which the parallel transport $\mathbb{U}^{ij}$ is associated. But instead, $\mathbb{U}^{ji}$ enters the definition (4.6) of λ_1. Therefore the symmetry condition is needed.

[31] The intermediate result in the second line is not well-defined, but helps to understand how the final formula is obtained.

[32] The geometrically interesting condition of a *constant* curvature scalar translates into a complicated difference equation for $b(\vartheta)$, $[\cos u(\vartheta)/b(\vartheta+l) + \cos v(\vartheta)/b(\vartheta)] \sin[v(\vartheta+l) - v(\vartheta)] = \text{const}$, where $b(\vartheta+l) \sin u(\vartheta) + \cos v(\vartheta) = 1$ and $b(\vartheta+l) \cos u(\vartheta) - \sin v(\vartheta) = b(\vartheta)$.

[33] In the case of a commutative algebra $\mathcal{A}$, one can think of replacing more generally $\otimes_{\mathcal{A}}$ by $\otimes_L$ in basic definitions like that of a connection. For a noncommutative differential calculus, this turns out to be inconsistent with the Leibniz rule, however. Also, it should be clear that the connection must be a nonlocal object, in contrast to something like a metric tensor.

(Received 1 April 1998; accepted for publication 24 September 1998)

Inönü–Wigner contractions from the rotation group $O(n+1)$ to the Euclidean group $E(n)$ are used to relate the separation of variables in Laplace–Beltrami operators on n-dimensional spheres and Euclidean spaces, respectively. In this article we consider all subgroup type coordinates corresponding to different chains of subgroups of $O(n+1)$ and $E(n)$, respectively. In particular, the contractions relate the graphical formalism of ''trees'' on spheres to the ''clusters'' on Euclidean spaces (introduced in this article). The contractions are considered analytically on several levels: the vector fields realizing the Lie algebras, the complete sets of commuting operators characterizing separable coordinate systems, the coordinate systems themselves and the separated eigenfunctions. © *1999 American Institute of Physics.* [S0022-2488(99)04102-X]

I. INTRODUCTION

Our purpose in this article is to use Lie algebra contractions to relate the separation of variables in Helmholtz equations on n-dimensional spheres S_n and on the Euclidean spaces E_n. An earlier article[1] was devoted to the case $n=2$. It was shown that spherical coordinates on S_2 can be contracted either to polar or Cartesian ones on E_2. Elliptic coordinates on S_2 were contracted to elliptic, parabolic and Cartesian ones on E_2.

The more complicated case of contractions from a two-dimensional Lorentzian hyperboloid H_2 to E_2 has also been studied.[2]

Here we are interested in the case of S_n for arbitrary n, but will only consider the simplest types of coordinates, the so-called subgroup type coordinates.[3–8] For S_n these are polyspherical coordinates introduced by Vilenkin[9,10] and described by the ''method of trees.''[9–13] Trees, or ''clusters'' can, of course, also be introduced to describe subgroup type coordinates in E_n, and we shall show how ''trees'' on S_n are related to ''clusters'' on E_n via the group contraction $O(n+1)\rightarrow E(n)$.

At least two definitions of Lie algebra contractions exist in the literature. The original Inönü–Wigner contractions[14–16] can be viewed as singular changes of bases. The more recent ''graded contractions''[17–23] are obtained as deformations of the original Lie algebra via modifications of the commutation relations, preserving a given grading of the Lie algebra. In many cases, though not all, the two concepts are equivalent.[23] In particular, the contractions considered in this article are simultaneously Inönü–Wigner and Z_2-graded ones.

Our main tool for dealing with contractions is the concept of ''analytic contractions,'' already introduced in Ref. 1. The generators of the original Lie algebra, in our case $o(n+1)$, are written as differential operators, involving the contraction parameters, in our case the radius R of the sphere. The parametrization must be such that in the contraction limit, in which the $o(n+1)$

[a)]Electronic mail: WINTERN@CRM.UMONTREAL.CA

algebra contracts to the $e(n)$ one, the generators themselves as differential operators, contract into generators of $e(n)$.

As a motivation for this study we mention, first of all, the theory of special functions. Indeed contractions relate two different groups and their homogeneous spaces. They relate separable coordinates in these two spaces, the separated equations and their solutions. The contractions will thus, in particular, provide asymptotic formulas and other relations between special functions.

Other applications concern the relations between integrable systems in different spaces, in particular, on spheres S_n and Euclidean spaces E_n. Indeed, each separable system can be extended by adding a potential that allows separation. The corresponding Hamiltonian systems will be integrable both on S_n and E_n, since they will also have n integrals of motion in involution. Again, the contractions relate the S_n and E_n integrable systems and their solutions.

In Sec. II we review some known results on the method of trees for S_n.[9–13] We introduce $O(n)$ subgroup diagrams and relate them to the tree diagrams. Section III is devoted to the separation of variables in Euclidean spaces E_n. We introduce $E(n)$ subgroup diagrams, E_n ''cluster'' diagrams, and relate the two. Beltrami coordinates are used in Sec. IV to introduce the radius of the sphere into the expressions for the elements of the $o(n+1)$ Lie algebras. This provides the tools for an analytical realization of the Lie algebra contraction $o(n+1)\rightarrow e(n)$. The contraction of the coordinate systems and the complete sets of commuting operators is presented in Sec. V. Finally, the asymptotic formulas representing contractions of the solutions of the Laplace–Beltrami equation on S_n to those of the Helmholtz equation on E_n are presented in Sec. VI.

II. SUBGROUP TYPE COORDINATES AND THE METHOD OF TREES

A. Subgroups of Lie groups and separable coordinates

We shall make use of an algebraic approach to separating variables in Helmholtz (and Hamilton–Jacobi) equations in Riemannian and pseudo-Riemannian spaces that are homogeneous spaces for some Lie group G.[3–8]

The equation that we are interested in can be written as

$$\Delta_{LB}\Psi = E\Psi, \quad \Delta_{LB} = \frac{1}{\sqrt{g}}\frac{\partial}{\partial \xi^i}\sqrt{g}g^{ij}\frac{\partial}{\partial \xi^j}, \quad g = |\det g_{ij}|, \tag{2.1}$$

where g_{ij} is the metric tensor written in the considered coordinates ξ_i. The space M can be identified with some factor space $M\sim G/G_0$, where G_0 is the isotropy group of the origin.

The separated solutions of Eq. (2.1) are simultaneous eigenfunctions of some complete set of n commuting operators Y_a (including the Laplace–Beltrami operator). We thus have

$$Y_a\Psi = \lambda_a\Psi, \quad \Psi = \prod_{i=1}^{n} \Psi_i(\zeta_i;\lambda_1,\lambda_2,\ldots,\lambda_n). \tag{2.2}$$

The operators Y_a are second order operators in the enveloping algebra of the Lie algebra of the isometry group G. Thus we have a Lie algebra L with basis $L\sim\{X_1,\ldots,X_N\}$ and put

$$Y_a = A^a_{ik}X_iX_k, \quad [Y_a,Y_b]=0, \quad A^a_{ik}=A^a_{ki}; \quad a=1,2,\ldots,n. \tag{2.3}$$

The commuting sets of operators $\{Y_1,\ldots,Y_n\}$ can be classified into conjugacy classes under the action of the group G. Mutually conjugate sets provide equivalent systems of coordinates, transformed amongst each other by the group G.

A classification of the sets $\{Y_a\}$ provides a classification of coordinate systems. The essential properties of the coordinate systems are related to properties of the operators Y_a. In particular, ignorable coordinates[24] ξ_j (i.e., coordinates that do not figure in the metric tensor g_{ik}) are associated with operators Y_j that are squares of elements of the Lie algebra,

$$Y_j = \left\{ \sum_{k=1}^{N} a_{jk} X_k \right\}^2 = \frac{\partial^2}{\partial \alpha_j^2}. \tag{2.4}$$

Hence, maximal Abelian subalgebras[25–31] of the algebra L will provide maximal sets of ignorable variables.

Particularly simple coordinate systems are obtained if all operators Y_a in a given set are either squares of elements in the Lie algebra L, as in Eq. (2.4), or Casimir operators of subalgebras of L. Such coordinate systems have been called *subgroup type coordinates*.[6] Thus, consider a chain of subalgebras,

$$L \supset L_1 \supset L_2 \supset \cdots \supset L_M, \tag{2.5}$$

such that each subalgebra L_j has at least one second order Casimir operator (second order operator in the center of the enveloping algebra of L_j). Subgroup type coordinates are obtained if the chain of subalgebras provides n linearly independent second order operators. They will automatically commute amongst each other.

In this article we restrict our attention to subgroup type coordinates on spheres S_n and Euclidean spaces E_n. We mention that on S_2 precisely two types of separable coordinates exist. Spherical coordinates are subgroup type, the subgroup chain being $O(3) \supset O(2)$. Elliptic coordinates are not of the subgroup type. On S_3, six separable coordinate systems exist,[6,32,33] two of them of the subgroup type, corresponding to the chain $O(4) \supset O(3) \supset O(2)$ and $O(4) \supset O(2) \otimes O(2)$, respectively. For E_3, three out of eleven separable coordinate systems are of the subgroup type: Cartesian, cylindrical and spherical.

A graphical method, called the ''method of trees,'' has been developed to treat subgroup type coordinates on real and complex spheres.[9–13] We will reproduce some of the relevant results for *real* spheres S_n in the following subsection, and then extend them to analyze subgroup type coordinates on E_n. Moreover, we will connect the tree diagrams with subgroup diagrams, introduced below.

B. Subgroup type coordinates on S_n and the method of trees

Let us consider the Lie algebra $o(n+1)$ and use the standard basis of operators on S_n:

$$L_{ik} = (u_i \partial_k - u_k \partial_i);$$

$$[L_{ij}, L_{rs}] = -g_{js} L_{ir} - g_{ir} L_{js} + g_{jr} L_{is} + g_{is} L_{jr}, \quad 0 \leqslant i,k,j,r,s \leqslant n. \tag{2.6}$$

Let us now consider the defining representation of $o(n+1)$ by matrices

$$X \in \mathcal{R}^{(n+1)(n+1)}, \quad X^T + X = 0, \tag{2.7}$$

acting on the space $\mathcal{R}^{(n+1)}$. Maximal reducibly imbedded subalgebras of $o(n+1)$ will leave some vector subspace of $\mathcal{R}^n$ invariant. All subalgebras of this type have the form

$$o(n+1) \supset o(n_1) \oplus o(n_2), \quad n_1 + n_2 = n+1, \quad n_1 \geqslant n_2 \geqslant 2, \quad \text{or} \quad o(n+1) \supset o(n). \tag{2.8}$$

Maximal irreducibly imbedded subalgebras also exist, e.g., $u(n) \subset o(2n)$ or $g_2 \subset o(7)$, but they will not be needed here.

Chains of mutually maximally imbedded subalgebras are obtained by further splitting $o(n_1)$ and $o(n_2)$ into pairs of algebras, until we end the chain with one-dimensional subalgebras $o(2)$ [we drop all the $o(1) \sim \{0\}$ algebras]. We shall describe subalgebra chains by subalgebra diagrams (or equivalently subgroup diagrams). Each $O(k)$ subgroup is represented by a circle with the corresponding number k in it. All subgroup diagrams of this type are shown in Fig. 1 for $n \leqslant 5$. Their recursive character is obvious: different subgroup diagrams for a given $O(n)$ correspond to different flags of invariant subspaces of $\mathcal{R}$.

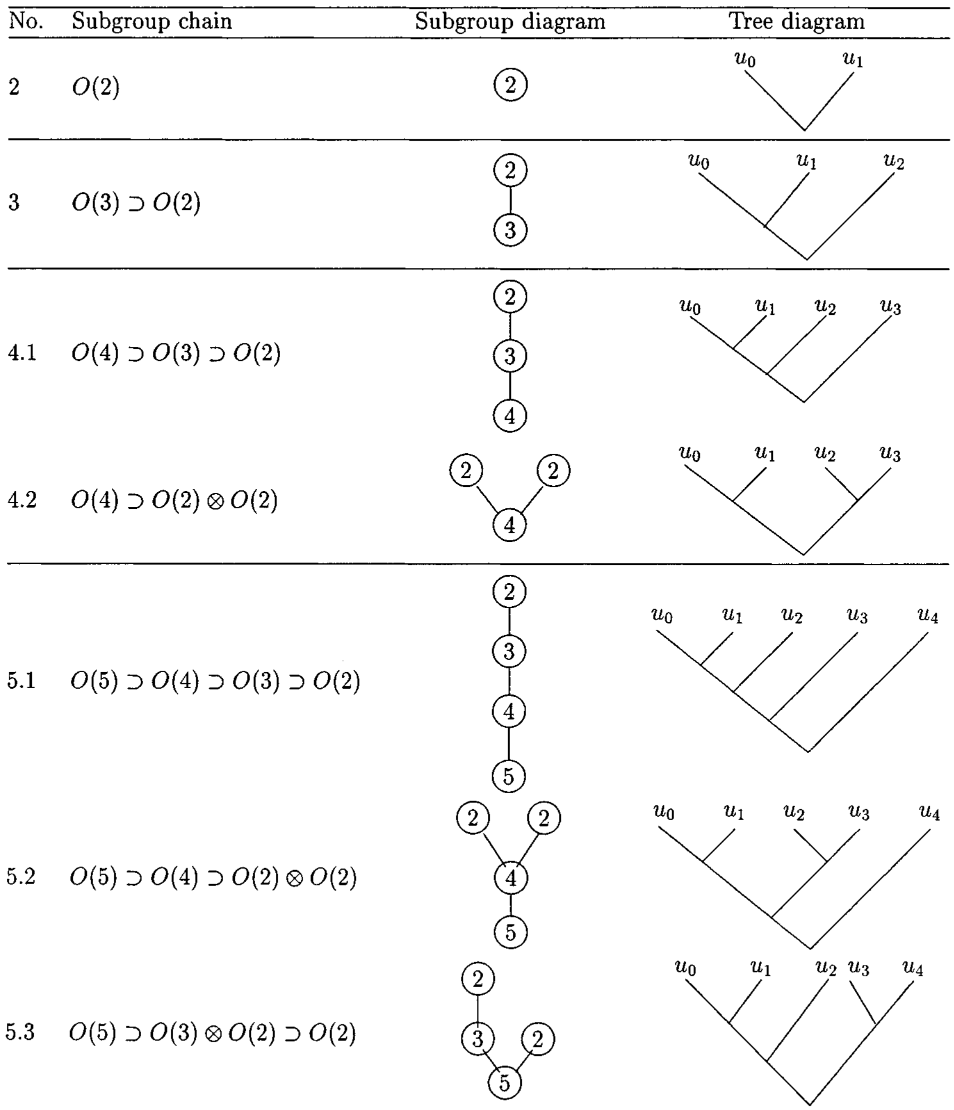

FIG. 1. Subgroup and tree diagrams for S_n.

The subgroup diagrams are closely related to the tree diagrams of Vilenkin,[9,10] describing polyspherical coordinates on S_n. In Fig. 1 we associate a tree diagram with each subgroup diagram for $2 \leqslant n \leqslant 5$. Families of different, but topologically equivalent, trees are associated with the same subgroup diagram. They are obtained either by permuting the end points, corresponding to the coordinates, or, equivalently, by rotating branches around branching points on the tree. All different trees, including equivalent ones, are shown for S_2, S_3, S_4 in Fig. 2.

The tree diagrams are best described in the original article[9] and the book.[13] Together with the subgroup diagrams described above, they provide a tool for writing coordinates on S_n, complete sets of commuting operators and their eigenvalues and separated solutions of the Helmholtz equation.

Let us recall some basic facts here, using the example of a specific tree, namely that in Fig. 3 for S_7. In Fig. 3(a) we give the corresponding $O(8)$ subgroup diagram. The actual S_7 tree is in Fig. 3(b). Figures 3(c) and 3(d) refer to the $E(7)$ group and E_7 space (after contraction) and will be used below.

Each end point on the tree of Fig. 3(b) corresponds to a Cartesian coordinate in the ambient

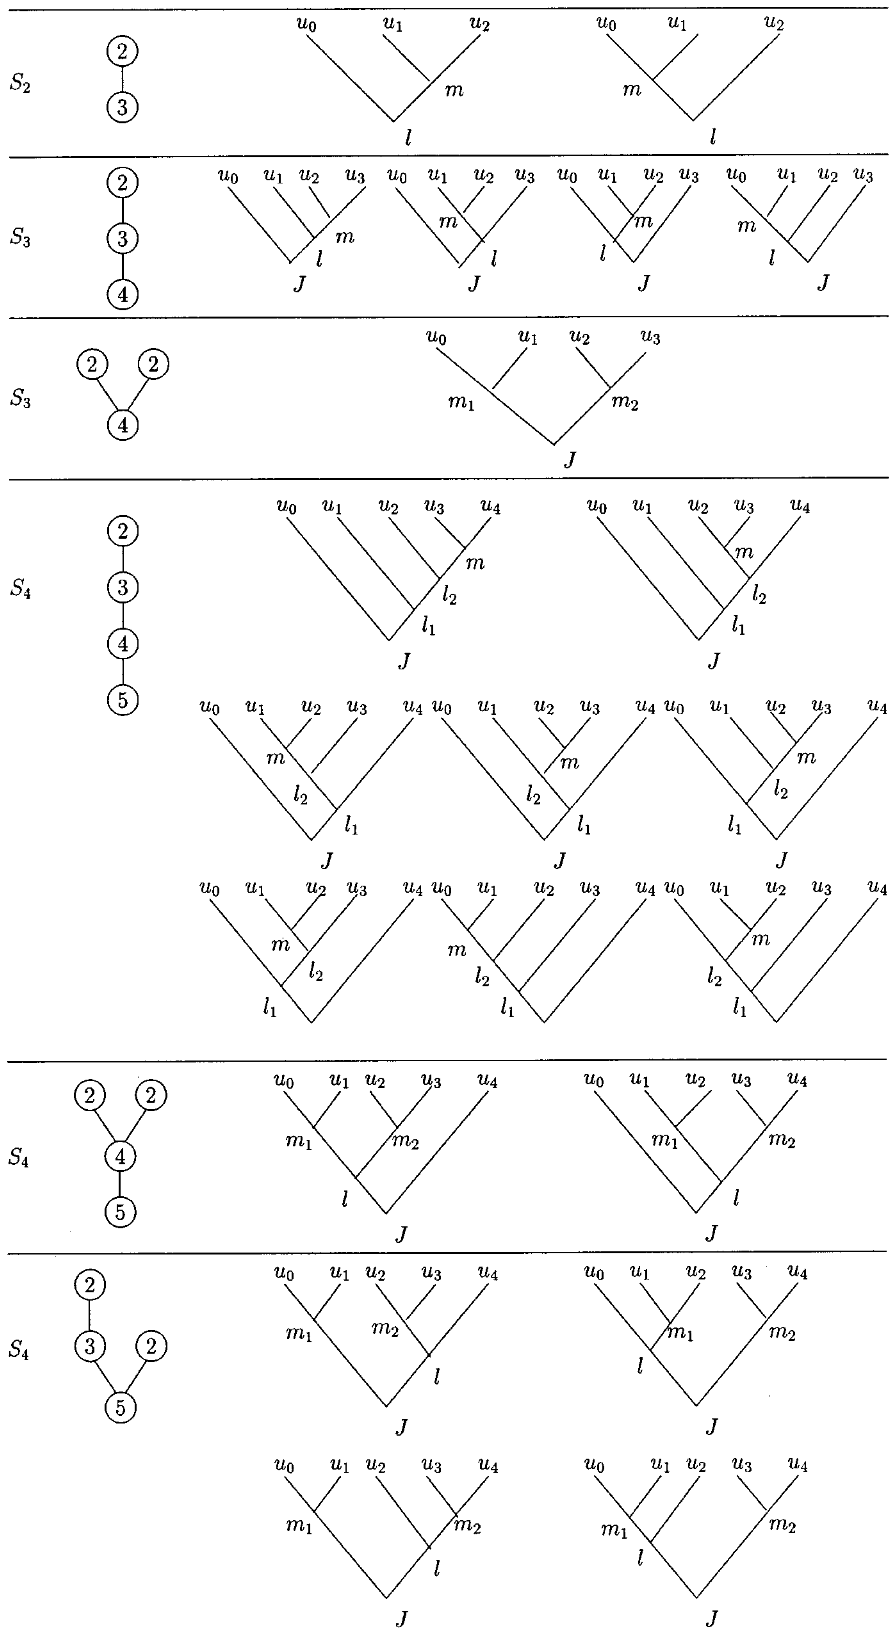

FIG. 2. Equivalent tree diagrams corresponding to one subgroup diagram for S_n.

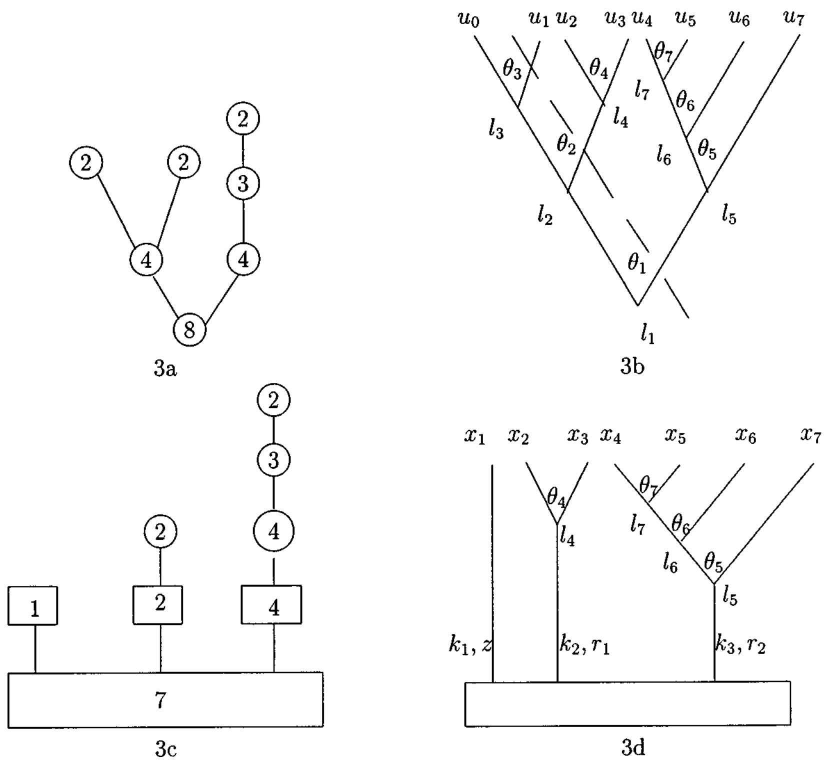

FIG. 3. Examples: An $O(8)$ subgroup diagram (3a) and the corresponding S_7 tree diagram (3b). An $E(7)$ subgroup diagram (3c) and the corresponding E_7 cluster diagram.

space $\mathcal{R}^8$. At each branching point we introduce an angle θ_i. We move along the tree from the ground upwards to a specific coordinate u_i. At each branching point we write $\cos\theta_a$ if we go to the left, $\sin\theta_a$ if we go to the right. The polyspherical coordinates corresponding to Fig. 3(b) hence are

$$\begin{aligned}
&u_0=R\cos\theta_1\cos\theta_2\cos\theta_3, \quad && u_4=R\sin\theta_1\cos\theta_5\cos\theta_6\cos\theta_7,\\
&u_1=R\cos\theta_1\cos\theta_2\sin\theta_3, \quad && u_5=R\sin\theta_1\cos\theta_5\cos\theta_6,\sin\theta_7,\\
&u_2=R\cos\theta_1\sin\theta_2\cos\theta_4, \quad && u_6=R\sin\theta_1\cos\theta_5\sin\theta_6,\\
&u_3=R\cos\theta_1\sin\theta_2\sin\theta_4, \quad && u_7=R\sin\theta_1\sin\theta_5.
\end{aligned} \tag{2.9}$$

The complete set of 7 commuting operators is also read off from the tree diagram, or from the subgroup one. We have

$$\begin{gathered}
Y_3=L_{01}^2, \quad Y_4=L_{23}^2, \quad Y_7=L_{45}^2, \quad Y_6=L_{45}^2+L_{56}^2+L_{46}^2,\\
Y_2=\sum_{0\leqslant i<k\leqslant 3} L_{ik}^2, \quad Y_5=\sum_{4\leqslant i<k\leqslant 7} L_{ik}^2, \quad Y_1=\sum_{0\leqslant i<k\leqslant 7} L_{ik}^2.
\end{gathered} \tag{2.10}$$

We see that Y_3, Y_4 and Y_7 are Casimir operators of $o(2)$ algebras, Y_6 of an $o(3)$ one, Y_2 and Y_5 correspond to $o(4)$ algebras and Y_1 is the original $o(8)$ Casimir operator. More generally, each circle in the subgroup chain provides the Casimir operator of the corresponding $o(k)$ to the set $\{Y_a\}$.

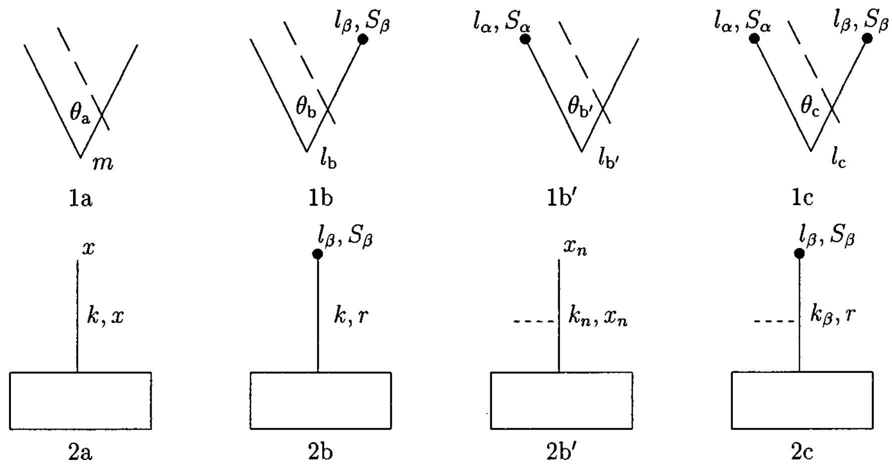

FIG. 4. Elementary cells for S_n (diagrams 1a,...,1c) and their contractions to E_n ones (diagrams 2a,...,2c).

To each branching point on the tree diagram, or each circle on the subgroup diagram, we also associate a quantum number l_j [see Fig. 3(b) for a specific case]. It will determine the eigenvalue λ of the corresponding $o(k)$ invariant operator according to the formula

$$Y_j\Psi=\Delta_{LB}\Psi=-l_j(l_j+k-2)\Psi, \tag{2.11}$$

where k is the dimension of the ambient space above the corresponding vertex on the tree [the same k as in $O(k)$]. The numbers l_j are non-negative integers, labeling irreducible representations of $O(k)$ for $k\geqslant 3$. For $k=2$, i.e., the group $O(2)$, we have $l_j=0,\pm 1,\pm 2,\ldots$.

C. The separated eigenfunctions for S_n

To specify the separated wave function,

$$\Psi=\Pi_{k=1}^{n}\Psi_k(\theta_k), \tag{2.12}$$

on S_n, we follow Refs. 9–13 and introduce four types of vertices, or ''cells'' on a tree, as illustrated in Fig. 4. The first row, diagrams 1a,...,1c, contains elementary S_n cells. The second row, 2a,...,2c contains E_n cells, obtained after a contraction, and will be discussed below in Sec. VI A. The dashed lines in row 1 will also be explained below. A circle on diagrams 1a,...1c denotes a ''closed'' end, i.e., one that leads to further branches. An open end (no circle) leads directly to a coordinate. For example, in Fig. 3 angles θ_3, θ_4 and θ_7 correspond to cells of type ''a,'' θ_5 and θ_6 to cells of type ''b′,'' and θ_1, θ_2 to cells of type ''c.'' The angles in the polyspheric coordinate systems satisfy

$$0\leqslant\theta_a<2\pi,\quad 0\leqslant\theta_b\leqslant\pi,\quad -\pi/2\leqslant\theta_{b'}\leqslant\pi/2,\quad 0\leqslant\theta_c\leqslant\pi/2. \tag{2.13}$$

The following numbers are associated with each cell: m, l, l_β, l_α are related to the separation constant corresponding to each vertex, S_α= number of vertices above vertex l_α, S_β= number of vertices above vertex l_β. The numbers m, l, l_β, l_α are all integers, labeling representations of the corresponding rotation subgroup in the chain, i.e., angular momentum type quantum numbers. We have

$$\Delta+c=n'-2, \tag{2.14}$$

where n' is the number of end points u_i connected to the vertex θ_j and c is the number of vertices above and to the left of vertex $\theta_{b'}$ or θ_c.

Each vertex and each angle θ_i provides a ''building block'' $\Psi_i(\theta_i)$ for the wave function $\Psi(\theta_1,\ldots,\theta_n)$ of Eq. (2.12). Specifically, we have the following.

(1) Cell of type a:

$$\Psi_m(\theta_a)=\frac{1}{\sqrt{2\pi}}e^{im\theta_a};\quad m=0,\pm1,\pm2,\ldots,\quad 0\leqslant\theta_a<2\pi. \tag{2.15}$$

(2) Cell of type b:

$$\Psi^{\alpha}_{n,l_\beta}(\theta_b)=N_n^{\alpha,\alpha}(\sin\theta_b)^{l_\beta}P_n^{(\alpha,\alpha)}(\cos\theta_b),$$

$$n=l-l_\beta,\quad \alpha=l_\beta+\frac{S_\beta}{2},\quad n=0,1,2,\ldots,\quad 0\leqslant\theta_b\leqslant\pi, \tag{2.16}$$

where $P_n^{(\alpha,\beta)}(x)$ is a Jacobi polynomial.

(3) Cell of type b′:

$$\Psi^{\beta}_{n,l_\alpha}(\theta_{b'})=N_n^{\beta,\beta}(\cos\theta_{b'})^{l_\alpha}P_n^{(\beta,\beta)}(\sin\theta_{b'});$$

$$n=l-l_\alpha,\quad \beta=l_\alpha+\frac{S_\alpha}{2},\quad n=0,1,2,\ldots,\quad -\pi/2\leqslant\theta_{b'}\leqslant\pi/2. \tag{2.17}$$

(4) Cell of type c:

$$\Psi^{\alpha,\beta}_{n,l_\beta,l_\alpha}(\theta_c)=2^{(\alpha+\beta)/2+1}N_n^{\alpha,\beta}(\sin\theta_c)^{l_\beta}(\cos\theta_c)^{l_\alpha}P_n^{(\alpha,\beta)}(\cos 2\theta_c);$$

$$n=\frac{l-l_\alpha-l_\beta}{2},\quad \alpha=l_\beta+\frac{S_\beta}{2},\quad \beta=l_\alpha+\frac{S_\alpha}{2},\quad n=0,1,2,\ldots,\quad 0\leqslant\theta_c\leqslant\pi/2. \tag{2.18}$$

The normalization constants are

$$N_n^{\alpha,\beta}=\sqrt{\frac{(2n+\alpha+\beta+1)\Gamma(n+\alpha+\beta+1)n!}{2^{\alpha+\beta+1}\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}}. \tag{2.19}$$

We mention that the wave functions (2.16) and (2.17) can also be expressed in terms of Gegenbauer polynomials, using the formula[34]

$$C_n^{\lambda}(x)=\frac{\Gamma(2\lambda+n)\Gamma(\lambda+1/2)}{\Gamma(2\lambda)\Gamma(\lambda+n+1/2)}P_n^{(\lambda-1/2,\lambda-1/2)}(x). \tag{2.20}$$

III. SUBGROUP TYPE COORDINATES ON E_n AND CLUSTER DIAGRAMS

Let us now consider the Euclidean Lie algebra $e(n)$, with a basis

$$L_{ik}=x_i\partial_{x_k}-x_k\partial_{x_i},\quad p_i=\partial_{x_i},\quad i,k=1,2,\ldots,n. \tag{3.1}$$

The commutation relations are, as in Eq. (2.6), together with

$$[p_j,L_{ik}]=\delta_{ji}p_k-\delta_{jk}p_i,\quad [p_i,p_k]=0. \tag{3.2}$$

Subalgebra chains (2.5) will include Euclidean subalgebras $e(k)$ and rotation subalgebras $o(k)$. A possible link in a subalgebra chain is

$$e(n)\supset e(n_1)\oplus e(n_2),\quad n_1+n_2=n,\quad n_1\geqslant n_2\geqslant 1. \tag{3.3}$$

The Casimir operator of $e(n)$ is

$$\Delta_n=p_1^2+p_2^2+\cdots+p_n^2. \tag{3.4}$$

Hence, we have $\Delta_n=\Delta_{n_1}+\Delta_{n_2}$ in the chain and only one of the Euclidean subalgebras (3.3) provides a new invariant operator, say $e(n_2)$. Alternatively, Δ_{n_1} and Δ_{n_2} can replace Δ_n. A further possible link in a chain is

$$e(n)\supset o(n),\quad n\geqslant 2, \tag{3.5}$$

where $o(n)$ will provide a new [with respect to $e(n)$] invariant operator.

As in the case of the $O(n)$ group we will introduce diagrams for the $E(n)$ group to illustrate subgroup chains and subgroup type coordinate systems on E_n Euclidean spaces. We shall use rectangles ("boxes") to denote $E(k)$ groups [or $e(k)$ algebras] and circles to denote $O(k)$ groups [or $o(k)$ algebras]. As an example, we give all subgroup chains for $E(n)$, $1\leqslant n\leqslant 4$ in Fig. 5. Maximality requires that as we go from one level to a higher one, we obey the following rules

(1) From a rectangle representing $e(n)$, we can go to two rectangles [see Eq. (3.3)], representing $e(n_1)\oplus e(n_2)$, with $n_1+n_2=n$, $n_1\geqslant n_2\geqslant 1$, or to a circle [see Eq. (3.5)], representing $o(n)$ (the same n as in the rectangle).

(2) From a circle representing $o(n)$ we can go to two circles, representing $o(n_1)\oplus o(n_2)$, $n_1+n_2=n$, $n_1\geqslant n_2\geqslant 2$, or to one circle, representing $o(n-1)$, $n\geqslant 3$.

Now let us consider subgroup type coordinates on the Euclidean space E_n and introduce diagrams to represent them. We shall call them "cluster diagrams" and they will consist of individual trees of the $O(k)$ type with a tree "trunk" added, or isolated "trunks," or of clusters of trees with trunks and isolated trunks. The E_n cluster diagrams are simpler than the $E(n)$ subgroup diagrams, since $E(k)$ subgroups that do not contribute new invariant operators will be omitted.

All clusters for E_n, $1\leqslant n\leqslant 4$, are also shown in Fig. 5. An isolated trunk corresponds to a Cartesian coordinate. A trunk with further branches above it corresponds to a radial coordinate r satisfying $0\leqslant r<\infty$. The tree above the trunk is treated exactly as in the case of polyspheric coordinates on S_n spheres.

As an example let us consider the diagrams in Fig. 3(d); the coordinates in E_7 are

$$\begin{aligned}
&x_1=z, && x_4=r_2\cos\theta_5\cos\theta_6\cos\theta_7, \\
&x_2=r_1\cos\theta_4, && x_5=r_2\cos\theta_5\cos\theta_6\sin\theta_7, \\
&x_3=r_1\sin\theta_4, && x_6=r_2\cos\theta_5\sin\theta_6, \quad x_7=r_2\sin\theta_5.
\end{aligned} \tag{3.6}$$

The prescriptions for writing the complete sets of commuting operators, eigenvalues and eigenfunctions are now quite simple.

To each tree trunk we associate an M-dimensional Laplace operator, where M is the number of end points (Cartesian coordinates) above the trunk. We also associate a number $k\in\mathbf{R}>0$ with each trunk. The corresponding radial eigenfunction [normalized to the delta function: $\delta(k'-k)$] is

$$\begin{gathered}
\Psi_{kl}(r)=\sqrt{\frac{k}{r^{M-2}}}J_{l+(M-2)/2}(kr),\quad M\geqslant 2, \\
\Psi_k(z)=\frac{e^{ikz}}{\sqrt{2\pi}},\quad M=1.
\end{gathered} \tag{3.7}$$

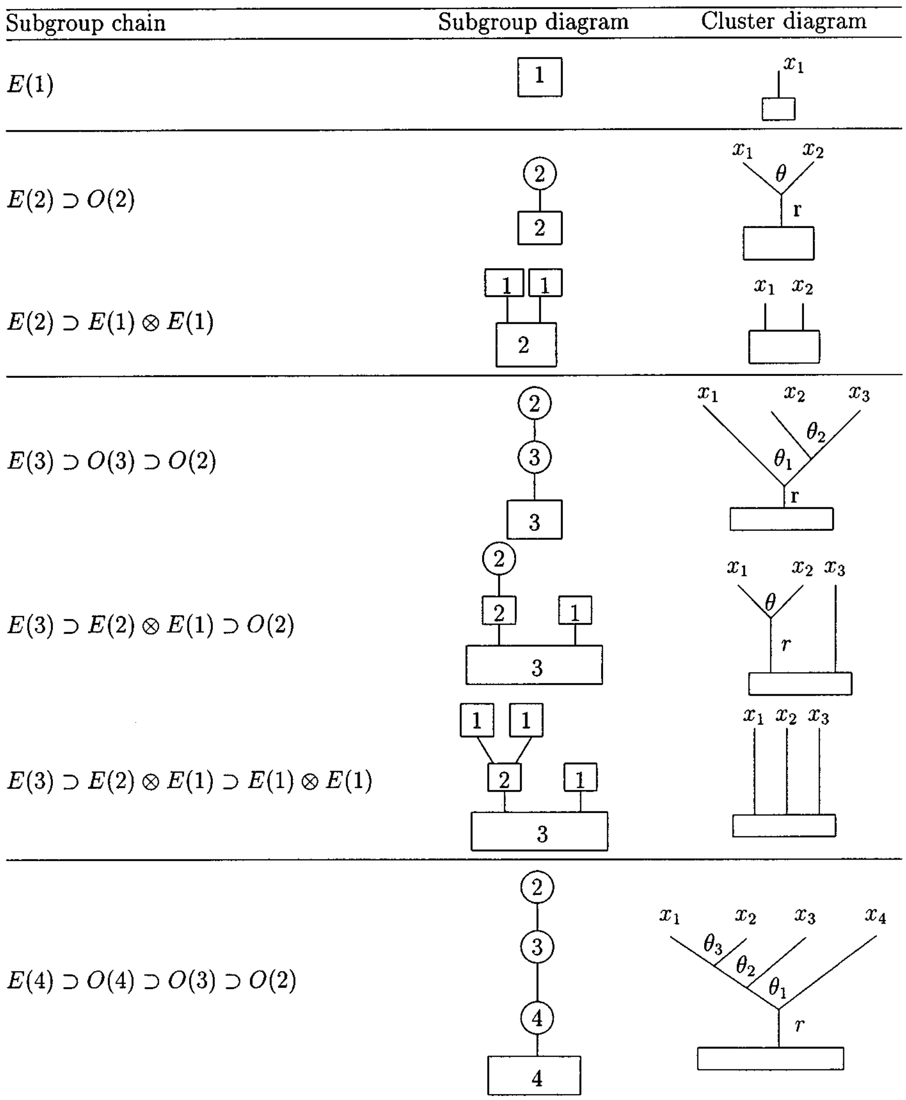

FIG. 5. Subgroup chains for $E(n)$ and cluster diagrams for E_n.

The angular part of the eigenfunctions is written following the rules for S_n spheres, as are the invariant operators and their eigenvalues.

For the example of Figs. 3(c), 3(d), the invariant operators are

$$Y_1=p_1^2,\quad Y_2=p_2^2+p_3^2,\quad Y_3=p_4^2+p_5^2+p_6^2+p_7^2,\quad Y_4=L_{23}^2,$$
$$Y_5=L_{45}^2,\quad Y_6=L_{45}^2+L_{56}^2+L_{46}^2,\quad Y_7=\sum_{4\leqslant i<k\leqslant 7} L_{ik}^2. \tag{3.8}$$

We note that the Laplace operator on E_7 does not figure explicitly; it is equal to

$$\Delta=\sum_{i=1}^{7} p_i^2=Y_1+Y_2+Y_3. \tag{3.9}$$

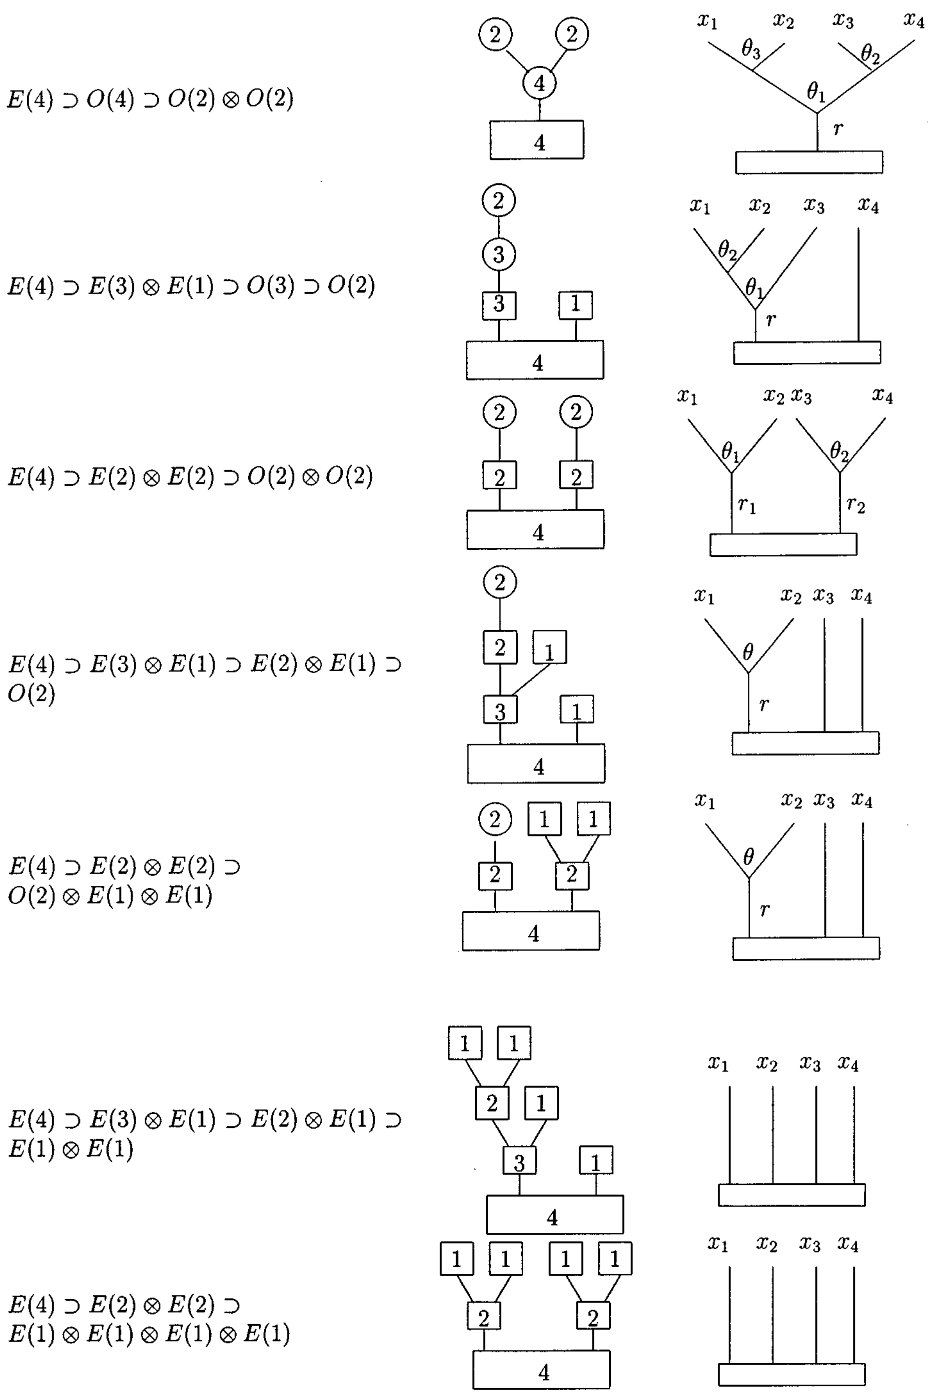

FIG. 5. (*Continued.*)

IV. CONTRACTIONS OF THE LIE ALGEBRA AND CASIMIR OPERATOR

Let us consider the n-dimensional sphere S_n:

$$u_0^2+\sum_{\nu=1}^{n} u_\nu^2=\sum_{\mu,\nu=0}^{n} g_{\mu\nu}u_\mu u_\nu=R^2, \quad R^2>0, \tag{4.1}$$

where u_μ are Cartesian coordinates in the Euclidean ambient space E_{n+1} and the metric tensor in this case has the form $g_{\mu\nu}=\mathrm{diag}(1,1,\ldots,1)$. The isometry group is $O(n+1)$. We choose a standard basis $L_{\mu,\nu}$ for the Lie algebra $o(n+1)$ as in Eq. (2.6).

The Laplace–Beltrami operator on S_n is

$$\Delta_{LB}=\frac{1}{R^2}\sum_{0\leqslant\mu<\nu\leqslant n} L^2_{\mu\nu}. \tag{4.2}$$

We shall use R^{-1} as the contraction parameter. To realize the contraction explicitly, let us introduce Beltrami coordinates on the sphere S_n, putting

$$y_i=R\frac{u_i}{u_0}=u_i\left(1-\frac{1}{R^2}\sum_{k=1}^{n} u_k^2\right)^{-1/2}, \quad i=1,2,3,\ldots,n. \tag{4.3}$$

The $O(n+1)$ generators then can be expressed as

$$\frac{L_{0i}}{R}\equiv\pi_i=p_i+\frac{y_i}{R^2}\sum_{k=1}^{n}(y_k p_k), \tag{4.4}$$

$$L_{ik}\equiv y_i p_k-y_k p_i=y_i\pi_k-y_k\pi_i; \quad i,k=1,2,\ldots,n, \tag{4.5}$$

where $p_i=\partial/\partial y_i$. The commutation relations now are

$$[L_{ik},L_{mn}]=\delta_{km}L_{in}+\delta_{in}L_{km}-\delta_{im}L_{kn}-\delta_{kn}L_{im}, \tag{4.6}$$

$$[\pi_i,L_{kj}]=\delta_{ik}\pi_j-\delta_{ij}\pi_k, \quad [\pi_i,\pi_k]=\frac{L_{ik}}{R^2}, \tag{4.7}$$

so that for $R\to\infty$ the $o(n+1)$ algebra contracts to the Euclidean $e(n)$ one. The Beltrami coordinates y_i (4.3) contract to Cartesian coordinates on E_n, and we have

$$y_i\to x_i, \quad \pi_i\to p_i=\frac{\partial}{\partial x_i}, \tag{4.8}$$

so that the rotation generators L_{0i} go into the translations p_i.

The $o(n+1)$ Laplace–Beltrami operator (2.1) contracts to the $e(n)$ one:

$$\Delta_{\mathrm{LB}}=\sum_{i=1}^{n}\pi_i^2+\sum_{i,k=1}^{n}\frac{L_{ik}^2}{2R^2}\to\Delta=p_1^2+p_2^2+\cdots+p_n^2. \tag{4.9}$$

V. CONTRACTION AND COORDINATE SYSTEMS. THE GRAPHICAL METHOD

A. General formulation

We have seen that all subgroup type coordinates on a sphere S_n can be characterized by tree diagrams. Similarly, there is a one-to-one correspondence between subgroup type coordinates in a Euclidean space E_n and the cluster diagrams of Sec. IV.

We shall now introduce a *graphical method* for connecting the subgroup type coordinate systems on S_n and E_n and give the rules relating the coordinates, invariant operators, eigenvalues and basis functions. The relations are asymptotic ones for the radius of the sphere satisfying $R\to\infty$ and one, or more, of the angles θ_i satisfying $\theta_i\to 0$.

A general S_n tree diagram can be represented by Fig. 6(a). One principal branch of the tree goes from the ground to the point representing the coordinate u_0. The branches growing from this one can lead directly to a coordinate u_i, or they can branch further and lead to sets of coordinates,

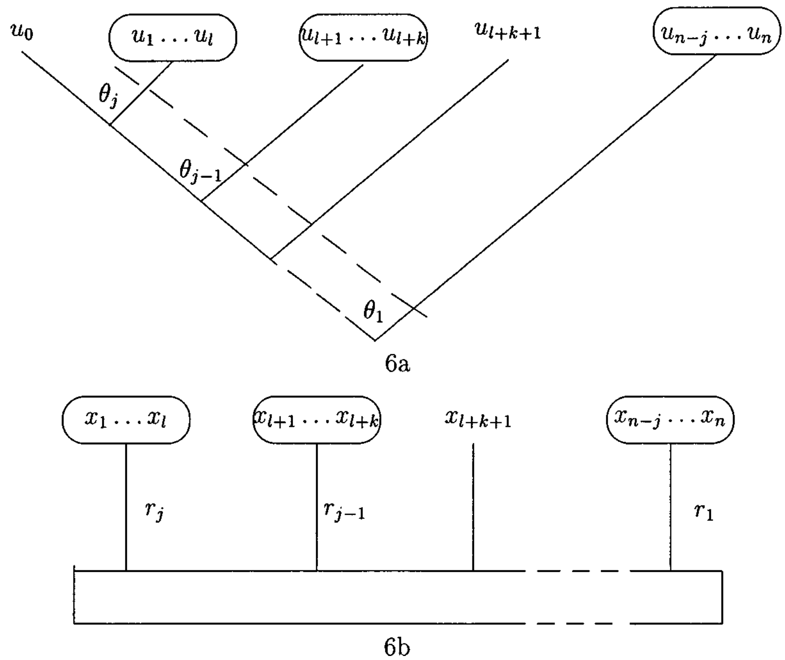

FIG. 6. Contractions of tree diagrams into cluster ones for $S_n \to E_n$.

e.g., $\{u_{l+1}, u_{l+2}, \dots, u_{l+k}\}$. Graphically the contraction $R \to \infty$ corresponds to the fact that we cut off the ground to u_0 branch by the dashed line in Fig. 6(a). The dashed line then becomes the ground for the corresponding cluster E_n diagram of Fig. 6(b) and the ambient space coordinates $(u_0, u_1, \dots, u_n)$ for S_n are replaced by the Cartesian coordinates $(x_1, x_2, \dots, x_n)$. The angles $\theta_1, \theta_2, \dots, \theta_j$ that lead to branches cut-off by the dotted line satisfy $\theta_i \to 0$ in the contraction and are replaced by radial coordinates r_i, or Cartesian coordinates x_m (if the surviving branch leads directly to a single coordinate on S_n and E_n). We have

$$R \to \infty, \quad \theta_i \to 0, \quad R \tan \theta_i \sim R \sin \theta_i \sim R \theta_i \to r_i. \tag{5.1}$$

The individual trees in an E_n cluster correspond to $O(k)$ subgroups of $O(n)$ that survive the contraction.

All contractions of coordinate systems for S_1, S_2, and S_3 are illustrated in Fig. 7. Let us run through the individual cases.

B. Contractions from S_1 to E_1

In the case of a one-dimensional sphere, i.e., a circle, we have only one diagram, namely No. 1 of Fig. 7. In the original ambient space we have polar coordinates

$$u_0 = R \cos \theta, \quad u_1 = R \sin \theta, \tag{5.2}$$

with $0 \leq \theta < 2\pi$. The Beltrami coordinate satisfies

$$y_1 = R \tan \theta \to x, \tag{5.3}$$

where x is a Cartesian coordinate on E_1.

C. Contractions from S_2 to E_2

In the case of the two-dimensional sphere S_2 we have two tree configurations and two types of coordinate contractions to consider, namely, No. 2 and No. 3 of Fig. 7.

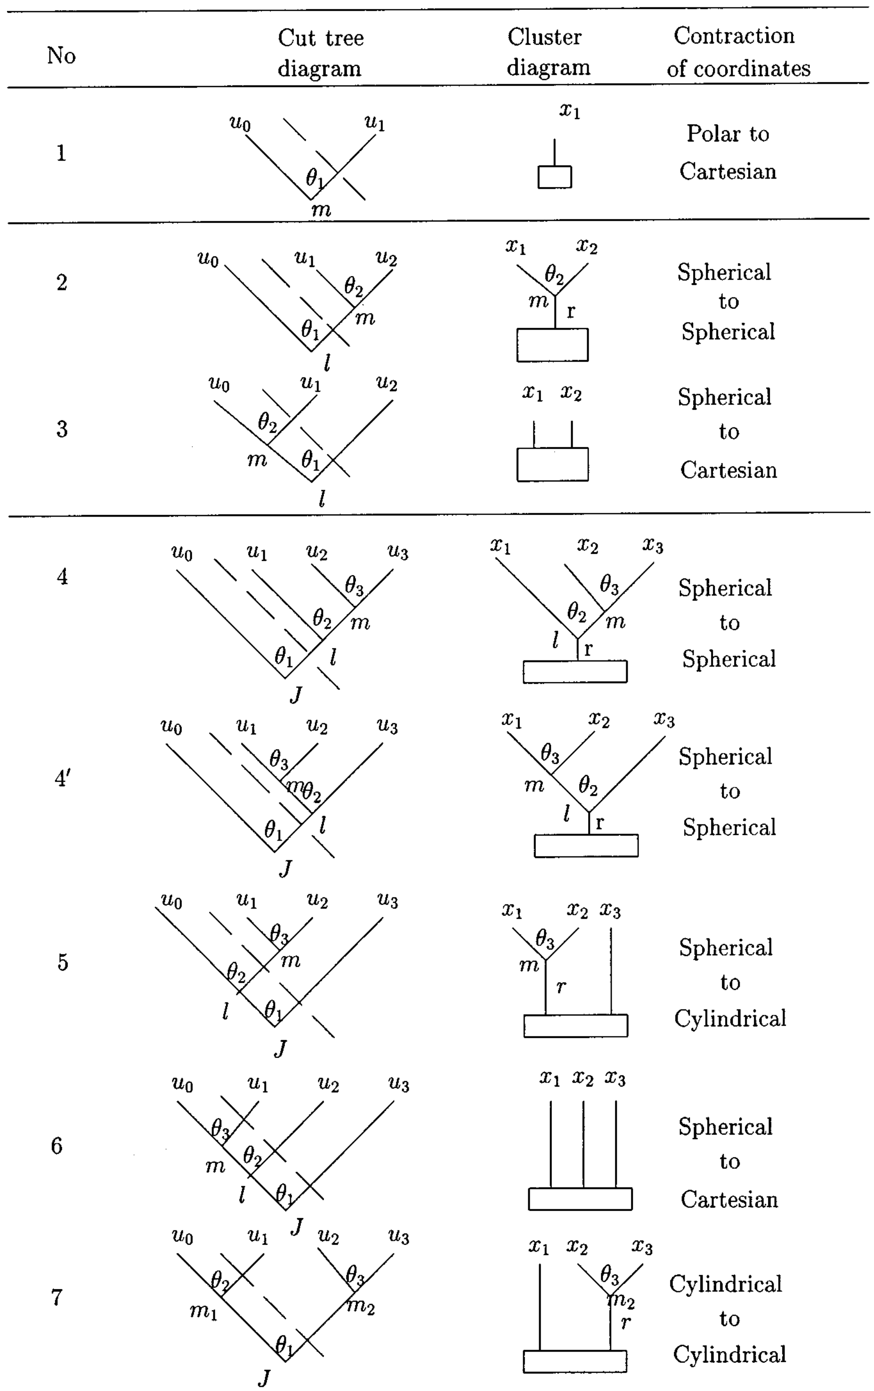

FIG. 7. Contractions of tree diagrams on S_n into cluster ones on E_n for $1 \leqslant n \leqslant 4$.

For *diagram* No. 2 we have

$$u_0 = R \cos\theta_1, \quad u_1 = R \sin\theta_1 \cos\theta_2, \quad u_2 = R \sin\theta_1 \sin\theta_2, \tag{5.4}$$

where $0 \leqslant \theta_1 < \pi$, $0 \leqslant \theta_2 < 2\pi$. Introducing Beltrami coordinates and taking the appropriate limits $R \to \infty$, $\theta_1 \sim r/R$, we have

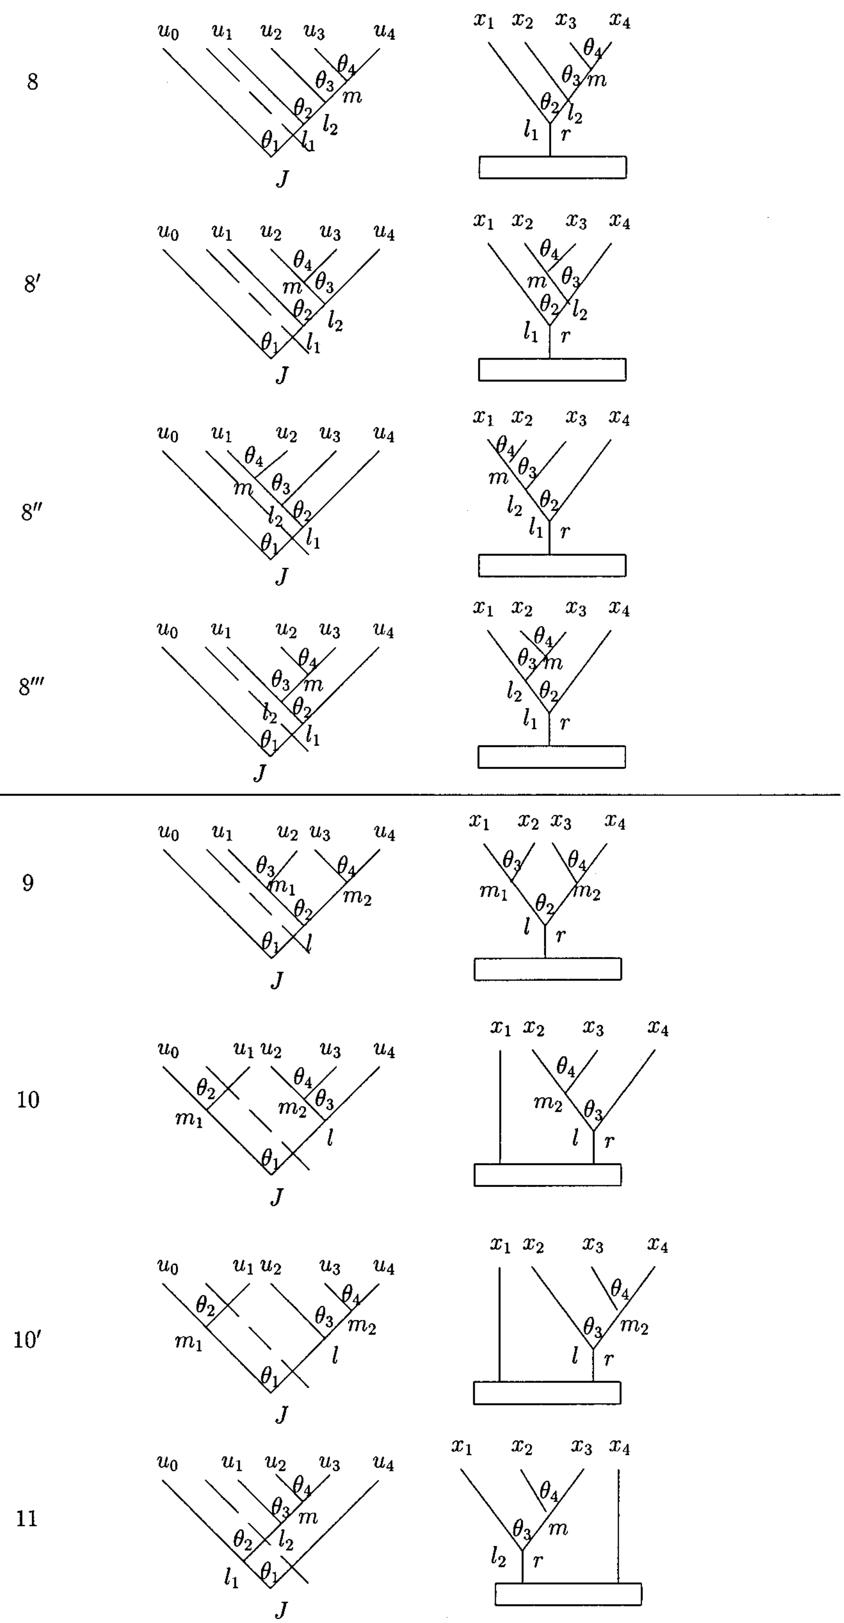

FIG. 7. (*Continued.*)

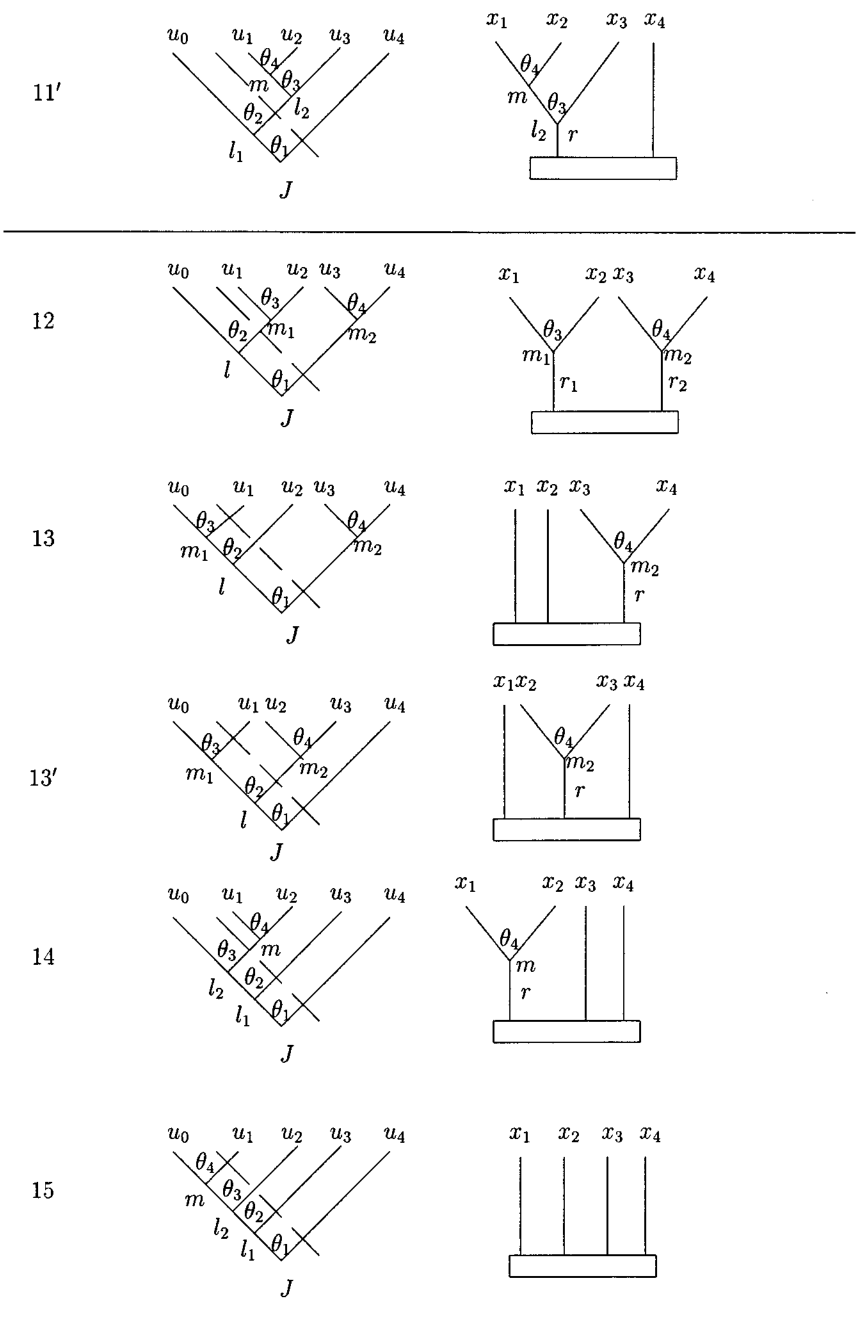

FIG. 7. (*Continued.*)

$$y_1 = R \tan\theta_1 \cos\theta_2 \rightarrow x_1 = r\cos\theta_2, \quad y_2 = R\tan\theta_1 \sin\theta_2 \rightarrow x_2 = r\sin\theta_2. \tag{5.5}$$

The subgroup chain $O(3)\supset O(2)$ contracts to the Euclidean one: $E(2)\supset O(2)$; the $O(2)$ invariant and its eigenvalues m survive the contraction $L_{12}^2 \rightarrow L_{12}^2$, $m\rightarrow m$.

For *diagram* No. 3 in Fig. 7 we have

$$u_0 = R\cos\theta_1\cos\theta_2, \quad u_1 = R\cos\theta_1 \sin\theta_2, \quad u_2 = R\sin\theta_1, \tag{5.6}$$

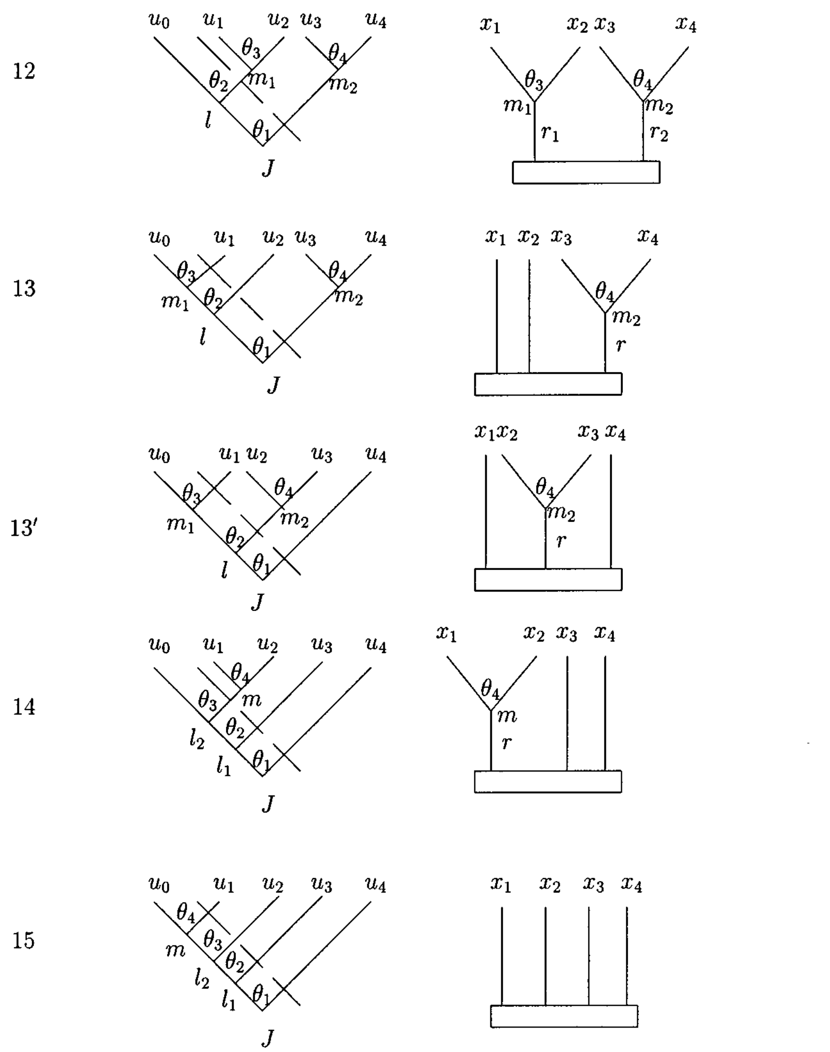

FIG. 7. (*Continued.*)

and the Beltrami coordinates satisfy ($R \to \infty$, $\theta_1 \sim x_1/R$, $\theta_2 \sim x_2/R$)

$$y_1 = R \tan \theta_2 \to x_1, \quad y_2 = R \frac{\tan \theta_1}{\cos \theta_2} \to x_2. \tag{5.7}$$

The subgroup chain $O(3) \supset O(2)$ contracts to $E(2) \supset E(1) \otimes E(1)$ and the $O(2)$ subgroup invariant undergoes a contraction,

$$\frac{Y_1}{R^2} = \frac{L_{01}^2}{R^2} = \pi_1^2 \to p_1^2. \tag{5.8}$$

D. Contractions from S_3 to E_3

Five types of $O(4)$ tree diagrams exist, but only four of them give different contractions.

The *diagrams* No. 4 and 4′ on Fig. 7 correspond to spherical coordinates on S_3 going into spherical coordinates on E_3. For No. 4 the polyspherical coordinates are

$$u_0 = R\cos\theta_1,\quad u_1 = R\sin\theta_1\cos\theta_2,$$
$$u_2 = R\sin\theta_1\sin\theta_2\cos\theta_3,\quad u_3 = R\sin\theta_1\sin\theta_2\sin\theta_3. \tag{5.9}$$

The Beltrami coordinates satisfy $(R\to\infty,\ \theta_1 \sim r/R)$

$$y_1 = R\tan\theta_1\cos\theta_2 \to x_1 = r\cos\theta_2,$$
$$y_2 = R\tan\theta_1\sin\theta_2\cos\theta_3 \to x_2 = r\sin\theta_2\cos\theta_3, \tag{5.10}$$
$$y_3 = R\tan\theta_1\sin\theta_2\sin\theta_3 \to x_3 = r\sin\theta_2\sin\theta_3.$$

We have $O(4)\supset O(3)\supset O(2)\to E(3)\supset O(3)\supset O(2)$ so that the $O(3)\supset O(2)$ subgroups and their invariants survive:

$$Y_1 = \mathbf{L}^2 = L_{12}^2 + L_{13}^2 + L_{23}^2 \to \mathbf{L}^2,\quad Y_2 = L_{23}^2 \to L_{23}^2. \tag{5.11}$$

The situation for diagram No. 4′ is quite analogous.

The case No. 5 in Fig. 7 corresponds to spherical coordinates contracting to cylindrical ones. We have

$$u_0 = R\cos\theta_1\cos\theta_2,\quad u_1 = R\cos\theta_1\sin\theta_2\cos\theta_3,$$
$$u_2 = R\cos\theta_1\sin\theta_2\sin\theta_3,\quad u_3 = R\sin\theta_1. \tag{5.12}$$

For Beltrami coordinates $(R\to\infty,\ \theta_2\sim r/R,\ \theta_1\sim x_3/R)$ we obtain

$$y_1 = R\tan\theta_2\cos\theta_3 \to x_1 = r\cos\theta_3,$$
$$y_2 = R\tan\theta_2\sin\theta_3 \to x_2 = r\sin\theta_3, \tag{5.13}$$
$$y_3 = R\frac{\tan\theta_1}{\cos\theta_2} \to x_3 = z.$$

The subgroup chain contraction is $O(4)\supset O(3)\supset O(2)\to E(3)\supset E(2)\otimes E(1)\supset O(2)$ and the subgroup invariants contract as

$$\frac{Y_1}{R^2} = \frac{1}{R^2}(L_{01}^2 + L_{02}^2 + L_{12}^2) = \pi_1^2 + \pi_2^2 + \frac{L_{12}^2}{R^2} \to p_1^2 + p_2^2,\quad Y_2 = L_{12}^2 \to L_{12}^2. \tag{5.14}$$

The diagram No. 6 in Fig. 7 corresponds to the contraction of spherical coordinates to Cartesian ones. We have

$$u_0 = R\cos\theta_1\cos\theta_2\cos\theta_3,\quad u_1 = R\cos\theta_1\cos\theta_2\sin\theta_3,$$
$$u_2 = R\cos\theta_1\sin\theta_2,\quad u_3 = R\sin\theta_1. \tag{5.15}$$

For Beltrami coordinates after the contraction $R\to\infty,\ \theta_3\sim x_1/R,\ \theta_2\sim x_2/R,\ \theta_1\sim x_3/R$, we have

$$y_1 = R\tan\theta_3 \to x_1,\quad y_2 = R\frac{\tan\theta_2}{\cos\theta_3} \to x_2,\quad y_3 = R\frac{\tan\theta_1}{\cos\theta_2\cos\theta_3} \to x_3. \tag{5.16}$$

The subgroup chain undergoes the contraction $O(4)\supset O(3)\supset O(2)\to E(3)\supset E(1)\otimes E(1)\otimes E(1)$ and the subgroup invariants satisfy

$$\frac{Y_1}{R^2}=\frac{1}{R^2}(L_{01}^2+L_{02}^2+L_{12}^2)=\pi_1^2+\pi_2^2=\frac{L_{12}^2}{R^2}\rightarrow p_1^2+p_2^2,\quad \frac{Y_2}{R^2}=\frac{L_{01}^2}{R^2}=\pi_1^2\rightarrow p_1^2. \tag{5.17}$$

Finally the diagram No. 7 of Fig. 7 corresponds to polyspherical (or cylindrical) coordinates on S_3 contracting to cylindrical ones on E_3. We have

$$\begin{aligned} u_0&=R\cos\theta_1\cos\theta_2,\quad u_1=R\cos\theta_1\sin\theta_2,\\ u_2&=R\sin\theta_1\cos\theta_3,\quad u_3=R\sin\theta_1\sin\theta_3. \end{aligned} \tag{5.18}$$

For the Beltrami coordinates after the contraction $R\rightarrow\infty$, $\theta_2\sim x_1/R$, $\theta_1\sim r/R$, we obtain

$$\begin{aligned} y_1&=R\tan\theta_2\rightarrow x_1,\\ y_2&=R\tan\theta_1\frac{\cos\theta_3}{\cos\theta_2}\rightarrow x_2=r\cos\theta_3,\\ y_3&=R\tan\theta_1\frac{\sin\theta_3}{\cos\theta_2}\rightarrow x_3=r\sin\theta_3. \end{aligned} \tag{5.19}$$

The subgroup chain satisfies $O(4)\supset O(2)\oplus O(2)\rightarrow E(3)\supset E(2)\oplus E(1)\supset O(2)$ so that for the subgroup invariants we have

$$\frac{Y_1}{R^2}=\frac{L_{01}^2}{R^2}=\pi_1^2\rightarrow p_1^2,\quad Y_2=L_{23}^2\rightarrow L_{23}^2. \tag{5.20}$$

VI. CONTRACTIONS OF BASIS FUNCTIONS

A. Contractions of functions corresponding to elementary cells

When we cut off the branches of a tree as in Fig. 6, the cutting line intersects an elementary cell (see Fig. 4) at each branch. Each elementary $O(n+1)$ cell then goes into an elementary trunk for $E(n)$, as indicated by the lower row of diagrams in Fig. 4.

Let us now discuss the four cases in Fig. 4. The limiting procedure is always the same, namely,

$$\theta_j\sim\frac{r_j}{R},\quad l_j\sim kR,\quad R\rightarrow\infty,\quad j=\mathrm{a,b,b',c}, \tag{6.1}$$

where r_j is the radius of the sphere that survives the contraction, i.e., corresponds to the circle on the right hand side of the $O(n+1)$ cell and on top of the $E(n)$ trunk. Thus, for $j=\mathrm{a}$ and $j=\mathrm{b'}$ we have $r_j=x$, a Cartesian coordinate. Similarly, we have $l_\alpha=m\in\mathbf{Z}$ and also $l_\beta=m\in\mathbf{Z}$.

Let us now run through the individual cells in Fig. 4.

1. Cell 1a to 2a

Using Eqs. (2.15) and (6.1) we have $(R\rightarrow\infty, m\sim kR, \theta\sim x/R)$

$$\lim_{R\rightarrow\infty}\frac{1}{\sqrt{2\pi}}e^{im\theta_{\mathrm{a}}}=\frac{1}{\sqrt{2\pi}}e^{ikx}. \tag{6.2}$$

2. Cell 1b to 2b

The contribution to the separated $O(n+1)$ basis function is given in Eq. (2.16). Using the formula for Jacobi polynomials in terms of the hypergeometric functions,[34] we have

$$N_{l-l_\beta}^{l_\beta+S_\beta/2,l_\beta+S_\beta/2}(\sin\theta_{\rm b})^{l_\beta}P_{l-l_\beta}^{(l_\beta+S_\beta/2,l_\beta+S_\beta/2)}(\cos\theta_{\rm b})$$
$$=\sqrt{\frac{(2l+S_\beta+1)(l+l_\beta+S_\beta)!}{2(l-l_\beta)!}}\cdot\frac{(\sin\theta_{\rm b})^{l_\beta}}{2^{l_\beta+S_\beta/2}\Gamma(l_\beta+S_\beta/2+1)}\,{}_2F_1\left(-l+l_\beta,l+l_\beta+S_\beta+1;l_\beta+\frac{S_\beta}{2}+1;\sin^2\frac{\theta_{\rm b}}{2}\right). \quad (6.3)$$

Now, using the asymptotic formulas for the hypergeometric and Γ functions ($l\sim kR,\ \theta_{\rm b}\sim r/R$),

$$\lim_{R\to\infty}{}_2F_1\left(-l+l_\beta,l+l_\beta+S_\beta+1;l_\beta+\frac{S_\beta}{2}+1;\sin^2\frac{\theta_{\rm b}}{2}\right)={}_0F_1\left(l_\beta+\frac{S_\beta}{2}+1;-\frac{k^2r^2}{4}\right), \quad (6.4)$$

$$\lim_{|z|\to\infty}\frac{\Gamma(z+\alpha)}{\Gamma(z+\beta)}=z^{\alpha-\beta}\left(1+\frac{1}{2z}(\alpha-\beta)(\alpha+\beta-1)+O(z^{-2})\right), \quad (6.5)$$

and the formula for the Bessel function,

$$J_\nu(z)=\left(\frac{z}{2}\right)^\nu\frac{1}{\Gamma(\nu+1)}\,{}_0F_1\left(\nu+1;-\frac{z^2}{4}\right), \quad (6.6)$$

we obtain

$$\lim_{R\to\infty}\frac{1}{\sqrt{R^{S_\beta+1}}}N_{l-l_\beta}^{l_\beta+S_\beta/2,l_\beta+S_\beta/2}(\sin\theta_{\rm b})^{l_\beta}P_{l-l_\beta}^{(l_\beta+S_\beta/2,l_\beta+S_\beta/2)}(\cos\theta_{\rm b})=\sqrt{\frac{k}{r^{S_\beta}}}J_{l_\beta+S_\beta/2}(kr). \quad (6.7)$$

3. Cell 1b′ to 2b′

The contribution of this cell to the $O(n+1)$ separated basis function is given in Eq. (2.17). In order to take the contraction limit (6.1) we express the Jacobi polynomials in terms of hypergeometric functions:[34]

$$P_n^{(\alpha,\alpha)}(x)=\frac{2^{2\alpha}}{\sqrt{\pi}}\frac{\Gamma(n+\alpha+1)}{\Gamma(n+2\alpha+1)}\times\begin{cases}(-1)^{n/2}\dfrac{\Gamma([n+1]/2+\alpha)}{\Gamma(n/2+1)}\,{}_2F_1\left(-\dfrac{n}{2},\dfrac{n+1}{2}+\alpha;\dfrac{1}{2};x^2\right), & n\ \text{even},\\ (-1)^{(n-1)/2}\dfrac{\Gamma(n/2+\alpha+1)}{\Gamma([n+1]/2)}2x\,{}_2F_1\left(-\dfrac{n-1}{2},\dfrac{n+2}{2}+\alpha;\dfrac{3}{2};x^2\right), & n\ \text{odd}.\end{cases} \quad (6.8)$$

In the limit $R\to\infty$ and $\theta_{\rm b'}\sim x_n/R, l\sim kR, l_\alpha\sim pR$, we have

$$\lim_{R\to\infty}(-1)^{(l-l_\alpha)/2}N_{l-l_\alpha}^{l_\alpha+S_\alpha/2,l_\alpha+S_\alpha/2}(\cos\theta_{\rm b'})^{l_\alpha}P_{l-l_\alpha}^{(l_\alpha+S_\alpha/2,l_\alpha+S_\alpha/2)}(\sin\theta_{\rm b'})$$
$$=\sqrt{\frac{2k}{\pi k_n}}\times\begin{cases}{}_0F_1\left(\dfrac{1}{2};\dfrac{-k_n^2x_n^2}{4}\right),\\ -i(k_nx_n)\,{}_0F_1\left(\dfrac{3}{2};\dfrac{-k_n^2x_n^2}{4}\right),\end{cases} \quad (6.9)$$

where $k^2 = p^2 + k_n^2$. The ${}_0F_1(x)$ hypergeometric functions in this case are expressible in terms of $\sin k_n x_n$ and $\cos k_n x_n$ functions,[34]

$$ {}_0F_1\left(\frac{1}{2}; \frac{-k_n^2 x_n^2}{4}\right) = \cos k_n x_n , \quad {}_0F_1\left(\frac{3}{2}; \frac{-k_n^2 x_n^2}{4}\right) = \sin k_n x_n , \tag{6.10} $$

and we finally have

$$ \lim_{R\to\infty} (-1)^{(l-l_\alpha)/2} N_{l-l_\alpha}^{l_\alpha + S_\alpha/2, l_\alpha + S_\alpha/2} (\cos\theta_{b'})^{l_\alpha} P_{l-l_\alpha}^{(l_\alpha + S_\alpha/2, l_\alpha + S_\alpha/2)} (\sin\theta_{b'}) = \sqrt{\frac{2k}{\pi k_n}} \begin{Bmatrix} \cos(k_n x_n) \\ -i\sin(k_n x_n) \end{Bmatrix}. \tag{6.11} $$

4. Cell 1c to 2c

The relevant basis function is given in Eq. (2.18). To take the limit (6.1), $l \sim kR$, $l_\alpha \sim k_\alpha R$ and $\theta \sim r/R$, we use the equation expressing Jacobi polynomials in terms of hypergeometric functions, and take the limit leading to Bessel functions:

$$ \begin{aligned} &\lim_{R\to\infty} \frac{\Gamma([l-l_\alpha-l_\beta]/2+1)}{\Gamma([l-l_\alpha+l_\beta+S_\beta]/2+1)} P_{(l-l_\alpha-l_\beta)/2}^{(l_\beta+S_\beta/2, l_\alpha+S_\alpha/2)}(\cos 2\theta_c) \\ &\quad = \lim_{R\to\infty} \frac{1}{\Gamma(l_\beta+S_\beta/2+1)} {}_2F_1\left(-\frac{l-l_\alpha-l_\beta}{2}, \frac{l+l_\alpha+l_\beta+S_\alpha+S_\beta}{2}+1; l_\beta+\frac{S_\beta}{2}+1; \sin^2\theta_c \right) \\ &\quad = \frac{1}{\Gamma(l_\beta+S_\beta/2+1)} {}_0F_1\left(l_\beta+\frac{S_\beta}{2}+1; -\frac{k_\beta^2 r^2}{4}\right) = \left(\frac{2}{k_\beta r}\right)^{l_\beta+S_\beta/2} J_{l_\beta+S_\beta/2}(k_\beta r), \end{aligned} \tag{6.12} $$

where $k_\alpha^2 + k_\beta^2 = k^2$. The final result is

$$ \begin{aligned} &\lim_{R\to\infty} \frac{2^{(l_\alpha+S_\alpha/2+l_\beta+S_\beta/2)/2+1}}{\sqrt{R^{S_\beta+1}}} N_{(l-l_\alpha-l_\beta)/2}^{l_\beta+S_\beta/2, l_\alpha+S_\alpha/2} (\sin\theta_c)^{l_\beta} (\cos\theta_c)^{l_\alpha} P_{(l-l_\alpha-l_\beta)/2}^{(l_\beta+S_\beta/2, l_\alpha+S_\alpha/2)}(\cos 2\theta_c) \\ &\quad = \sqrt{\frac{2k}{r^{S_\beta}}} J_{l_\beta+S_\beta/2}(k_\beta r). \end{aligned} \tag{6.13} $$

These contractions for basis functions of the elementary cells (1a,...,1c) determine the general contractions for hyperspherical functions corresponding to any tree for the sphere S_n.

B. Examples

The contraction formulas for basis functions of $O(3)$ were given in Ref. 1. Here we apply the general rules to give all different S_3 and S_4 contraction diagrams in Fig. 7.

1. The S_3 sphere

(1) Polyspherical to spherical coordinates [see Figs. 7(4)–7(4′)] ($R\to\infty$, $J\sim kR$),

$$ \lim_{R\to\infty} \frac{1}{R} \Psi_{Jlm}(\theta_1, \theta_2, \theta_3) = \sqrt{\frac{k}{r}} J_{l+1/2}(kr) Y_{lm}(\theta_2, \theta_3), \tag{6.14} $$

where $Y_{lm}(\theta_2, \theta_3)$ is a spherical function on S_2.

(2) Polyspherical to cylindrical coordinates [see Fig. 7(5)] ($R\to\infty$, $J\sim kR$, $l\sim k_3/R$),

$$ \lim_{R\to\infty} \frac{(-1)^{(J-l)/2}}{\sqrt{R}} \Psi_{Jlm}(\theta_1, \theta_2, \theta_3) = \sqrt{\frac{kp}{\pi k_3}} J_{|m|}(pr) \frac{e^{im\theta_3}}{\sqrt{2\pi}} \begin{Bmatrix} \cos k_3 z \\ -i\sin k_3 z \end{Bmatrix}, \tag{6.15} $$

where $k^2 = k_3^2 + p^2$.

(3) Polyspherical to Cartesian coordinates [see Fig. 7(6)] ($R \to \infty$, $J \sim k_1 R$, $l \sim k_2/R$, $m \sim k_3 R$)

$$\lim_{R\to\infty} (-1)^{(J-m)/2} \Psi_{Jlm}(\theta_1,\theta_2,\theta_3) = \sqrt{\frac{2}{\pi k_1 k_3}} \frac{e^{ik_1 x}}{\pi} \left\{ \begin{matrix} \cos k_2 y \cos k_3 z \\ -i \sin k_2 y \cos k_3 z \\ -i \cos k_2 y \sin k_3 z \\ -\sin k_2 y \sin k_3 z \end{matrix} \right\}, \tag{6.16}$$

where $k^2 = k_1^2 + k_2^2 + k_3^2$.

(4) Polyspherical (cylindrical) to cylindrical coordinates [see Fig. 7(7)] ($R \to \infty$, $J \sim kR$, $m \sim k_3 R$)

$$\lim_{R\to\infty} \frac{1}{\sqrt{R}} \Psi_{Jm_1m_2}(\theta_1,\theta_2,\theta_3) = \sqrt{\frac{k}{\pi}} J_{|m_2|}(pr) e^{ik_3 z} \frac{e^{im_2\theta_3}}{\sqrt{2\pi}}, \tag{6.17}$$

where $k^2 = k_3^2 + p^2$.

2. The S_4 sphere

(1) Polyspherical to polyspherical coordinates [see Figs. 7(8)–7(8‴)] ($R \to \infty$, $J \sim kR$),

$$\lim_{R\to\infty} \frac{1}{\sqrt{R^3}} \Psi_{Jl_1l_2m}(\theta_1,\theta_2,\theta_3,\theta_4) = \frac{\sqrt{k}}{r} J_{l_1+1}(kr) \Psi_{l_1l_2m}(\theta_2,\theta_3,\theta_4), \tag{6.18}$$

where $\Psi_{l_1l_2m}(\theta_2,\theta_3,\theta_4)$ is a hyperspherical function on S_3.

(2) Polyspherical to cylindrical coordinates [see Fig. 7(9)] ($R \to \infty$, $J \sim kR$),

$$\lim_{R\to\infty} \frac{1}{\sqrt{R^3}} \Psi_{Jlm_1m_2}(\theta_1,\theta_2,\theta_3,\theta_4) = \frac{\sqrt{k}}{r} J_{l+1}(kr) \Psi_{lm_1m_2}(\theta_2,\theta_3,\theta_4), \tag{6.19}$$

where $\Psi_{lm_1m_2}(\theta_2,\theta_3,\theta_4)$ is a hyperspherical function on S_3.

(3) Polyspherical to four-dimensional cylindrical coordinates in Fig. 7(10) [see also Fig. 7(10′)] ($R \to \infty$, $J \sim kR$, $m_1 \sim k_1 R$),

$$\lim_{R\to\infty} \frac{1}{R} \Psi_{Jlm_1m_2}(\theta_1,\theta_2,\theta_3,\theta_4) = \sqrt{\frac{k}{\pi r}} e^{ik_1x_1} J_{l+1/2}(pr) Y_{lm_2}(\pi/2-\theta_3,\theta_4), \tag{6.20}$$

where $Y_{lm_2}(\pi/2-\theta_3,\theta_4)$ is a spherical function on S_2 and $k^2 = k_1^2 + p^2$.

(4) Polyspherical to four-dimensional cylindrical coordinates in Fig. 7(11) [see also Fig. 7(11′)] ($R \to \infty$, $J \sim kR$, $l \sim k_4 R$),

$$\lim_{R\to\infty} \frac{(-1)^{(J-l_1)/2}}{R} \Psi_{Jl_1l_2m}(\theta_1,\theta_2,\theta_3,\theta_4) = \sqrt{\frac{2pk}{\pi k_4 r}} J_{l_2+1/2}(pr) Y_{l_2m}(\theta_3,\theta_4) \left\{ \begin{matrix} \cos(k_4x_4) \\ -i \sin(k_4x_4) \end{matrix} \right\}, \tag{6.21}$$

where $Y_{l_2m}(\theta_3,\theta_4)$ is a spherical function on S_2 and $k^2 = k_4^2 + p^2$.

(5) Polyspherical to bipolar coordinates in Fig. 7(12) ($R \to \infty$, $J \sim kR$, $l \sim k_1 R$),

$$\lim_{R\to\infty} \frac{1}{R} \Psi_{Jlm_1m_2}(\theta_1,\theta_2,\theta_3,\theta_4) = \frac{\sqrt{2kk_1}}{2\pi} J_{m_1}(k_1r_1) J_{m_2}(k_2r_2) e^{im_1\theta_3 + im_2\theta_4}, \tag{6.22}$$

where $k_1^2+k_2^2=k^2$.

(6) Polyspherical to double cylindrical coordinates in Fig. 7(13) [see also Fig. 7(13′)] ($R \to\infty$, $J\sim kR$, $l\sim k_1R$, $m\sim k_2R$),

$$\lim_{R\to\infty}\frac{(-1)^{(l-m_1)/2}}{\sqrt{R}}\Psi_{Jlm_1m_2}(\theta_1,\theta_2,\theta_3,\theta_4)=\sqrt{\frac{k\sqrt{k_1^2+k_2^2}}{\pi^3k_2}}e^{ik_1x_1}\begin{Bmatrix}\cos(k_2x_2)\\ -i\sin(k_2x_2)\end{Bmatrix}J_{|m_2|}(k_3r)\frac{e^{im_2\theta_4}}{\sqrt{2\pi}}, \tag{6.23}$$

where $k_1^2+k_2^2+k_3^2=k^2$.

(7) Polyspherical to double cylindrical coordinates in Fig. 7(14) ($R\to\infty$, $J\sim kR$, $l_1\sim k_3R$, $l_2\sim k_1R$),

$$\lim_{R\to\infty}\frac{(-1)^{(J-l_2)/2}}{\sqrt{R}}\Psi_{Jl_1l_2m}(\theta_1,\theta_2,\theta_3,\theta_4)$$
$$=\sqrt{\frac{2k_1k\sqrt{k_1^2+k_2^2}}{\pi^3k_2k_3}}J_{|m|}(k_1r)e^{im_2\theta_4}\begin{Bmatrix}\cos k_3x_3\cos k_4x_4\\ -i\sin k_3x_3\cos k_4x_4\\ -i\cos k_3x_3\sin k_4x_4\\ -\sin k_3x_3\sin k_4x_4\end{Bmatrix}, \tag{6.24}$$

where $k_1^2+k_2^2+k_3^2=k^2$.

(8) Polyspherical to Cartesian coordinates in Fig. 7(15) ($R\to\infty$, $J\sim kR$, $m\sim k_1R$, $l_2\sim k_2R$, $l_1\sim k_3R$),

$$\lim_{R\to\infty}(-1)^{(J-m)/2}\Psi_{Jl_1l_2m}(\theta_1,\theta_2,\theta_3,\theta_4)$$
$$=\sqrt{\frac{8k\sqrt{k_1^2+k_2^2}\sqrt{k_1^2+k_2^2+k_3^2}}{\pi^4k_2k_3k_4}}e^{ik_1x_1}$$
$$\times\begin{Bmatrix}\cos k_2x_2\cos k_3x_3\cos k_4x_4; & -i\sin k_2x_2\cos k_3x_3\cos k_4x_4;\\ -i\cos k_2x_2\sin k_3x_3\cos k_4x_4; & -\sin k_2x_2\sin k_3x_3\cos k_4x_4;\\ -i\cos k_2x_2\cos k_3x_3\sin k_4x_4; & -\sin k_2x_2\cos k_3x_3\sin k_4x_4;\\ -\cos k_2x_2\sin k_3x_3\sin k_4x_4; & -i\sin k_2x_2\sin k_3x_3\sin k_4x_4;\end{Bmatrix}, \tag{6.25}$$

where $k_1^2+k_2^2+k_3^2+k_4^2=k^2$.

As a final example, let us consider the contraction $O(8)\to E(7)$ for the coordinate systems of Fig. 3. The contraction of the $O(8)$ basis to the $E(7)$ one in this case is ($R\to\infty$, $l_1\sim kR$, $l_2 \sim k_2R$, $l_3\sim k_1R$):

$$\lim_{R\to\infty}\frac{1}{R^2}\Psi_{l_1l_2l_3l_4l_5l_6l_7}(\theta_1,\theta_2,\theta_3,\theta_4,\theta_5,\theta_6,\theta_7)$$
$$=\frac{\sqrt{k_2k_3}}{2\pi r_2}J_{|l_4|}(k_2r_1)J_{l_5+1}(k_3r_2)e^{ik_1x_1}e^{il_4\theta_4}Y_{l_5l_6l_7}(\theta_5,\theta_6,\theta_7). \tag{6.26}$$

VII. CONCLUSION

In our previous paper[1] we studied contractions of all (i.e., both) coordinate systems on S_2 to all (four) coordinate systems on E_2. Here we have presented all possible contractions of subgroup type coordinate systems on S_n to subgroup type ones on E_n for n arbitrary. Moreover, we have developed a graphical formalism illustrating these contractions.

Contractions of ellipsoidal and parabaloidal coordinate systems will relate more ''exotic'' special functions amongst each other. For instance, Lamé polynomials and their generalizations will go into Mathieu functions, parabolic cylinder functions, spheroidal functions, etc. Work in this direction is in progress.

ACKNOWLEDGMENTS

We thank Professor E. G. Kalnins, Professor W. Miller, Jr., and Professor V. M. Ter-Antonyan for their interest and helpful discussions. We also thank Ye. M. Hakobyan for her help in the preparation of the diagrams. Two of the authors (G.P. and P.W.) thank each others' institutions for hospitality during mutual visits that made the research leading to the present article possible.

The research of P.W. was partially supported by research grants from NSERC of Canada and FCAR du Québec, that of G.P. by the RFBI grant N98-01-00330.

(Received 27 May 1998; accepted for publication 27 August 1998)

Two classes of irreducible highest weight modules of the general linear Lie superalgebra $gl(1|\infty)$ are constructed. Within each module a basis is introduced and the transformation relations of the basis under the action of the algebra generators are written down. © *1999 American Institute of Physics.* [S0022-2488(99)04402-3]

I. INTRODUCTION

We construct two classes of irreducible representations of the infinite-dimensional general linear Lie superalgebra $gl(1|\infty)$. Both of them are classes of highest weight representations, corresponding to two different orderings of the basis in the Cartan subalgebra. Related to this it is convenient to define $gl(1|\infty)$ in two different, but certainly equivalent ways. We denote them as $gl_0(1|\infty)$ and $gl(\infty|1|\infty)$ (see the end of Sec. I for the notation that follows).

Definition 1: The Lie superalgebra $gl_0(1|\infty)$ *is a complex linear space with a basis* $\{e_{ij}\}_{i,j\in\mathbf{N}}$. *The* $\mathbf{Z}_2$*-grading on* $gl_0(1|\infty)$ *is defined from the requirement that* e_{1j}, e_{j1}, $j=2,3,...$ *are odd generators, whereas all other generators are even. The multiplication* ($\equiv$*the supercommutator*) $[\![,]\!]$ *on* $gl_0(1|\infty)$ *is a linear extension of the relations*:

$$[\![e_{ij},e_{kl}]\!]=\delta_{jk}e_{il}-(-1)^{\deg(e_{ij})\deg(e_{kl})}\delta_{il}e_{kj}, \quad i,j,k,l\in\mathbf{N}. \tag{1}$$

As a basis in the Cartan subalgebra $\mathcal{H}_0$ we choose $\{e_{ii}\}_{i\in\mathbf{N}}$ with a natural order between the generators: $e_{ii}<e_{jj}$, if $i<j$. Then $\mathcal{E}_0^+=\{e_{ij}\}_{i<j\in\mathbf{N}}$ (respectively, $\mathcal{E}_0^-=\{e_{ij}\}_{i>j\in\mathbf{N}}$) are the positive (respectively, the negative) root vectors and $\{e_{i,i+1}\}_{i\in\mathbf{N}}$ are the simple root vectors.

Definition 2: The Lie superalgebra $gl(\infty|1|\infty)$ *is a complex linear space with a basis* $\{E_{ij}\}_{i,j\in\mathbf{Z}}$. *The* $\mathbf{Z}_2$*-grading on* $gl(\infty|1|\infty)$ *is defined from the requirement that* E_{0j}, E_{j0}, $0\neq j\in\mathbf{Z}$ *are odd generators, whereas all other generators are even. The supercommutator on* $gl(\infty|1|\infty)$ *is a linear extension of the relations*:

$$[\![E_{ij},E_{kl}]\!]=\delta_{jk}E_{il}-(-1)^{\deg(E_{ij})\deg(E_{kl})}\delta_{il}E_{kj}, \quad i,j,k,l\in\mathbf{Z}. \tag{2}$$

As a basis in the Cartan subalgebra $\mathcal{H}$ we choose $\{E_{ii}\}_{i\in\mathbf{Z}}$ with a natural order between the generators: $E_{ii}<E_{jj}$, if $i<j$. $\mathcal{E}^+=\{E_{ij}\}_{i<j\in\mathbf{Z}}$ (respectively, $\mathcal{E}^-=\{E_{ij}\}_{i>j\in\mathbf{Z}}$) are the positive (respectively, the negative) root vectors in $gl(\infty|1|\infty)$ and $\{E_{i,i+1}\}_{i\in\mathbf{Z}}$ are the simple root vectors.

Both algebras are isomorphic. In order to see this let g: $\mathbf{Z}\rightarrow\mathbf{N}$ be a bijective map, defined as

$$g(z)=2|z|+\theta(z)\in\mathbf{N}, \quad \forall z\in\mathbf{Z}. \tag{3}$$

Then it is easy to verify that the map φ, which is a linear extension of the relations

$$\varphi(E_{ij})=e_{g(i),g(j)}, \quad i,j\in\mathbf{Z}, \tag{4}$$

is an isomorphism of $gl(\infty|1|\infty)$ on $gl_0(1|\infty)$. Therefore both $gl_0(1|\infty)$ and $gl(\infty|1|\infty)$ are two different realizations of one and the same algebra, namely $gl(1|\infty)$. Note that φ is a map of $\mathcal{H}$ onto $\mathcal{H}_0$; it is not however a map of $\mathcal{E}^+$ into $\mathcal{E}_0^+$. For instance take $E_{-1,0}\in\mathcal{E}^+$. Then $\varphi(E_{-1,0}) = e_{21}\in\mathcal{E}_0^-$. Hence a highest weight representation of $gl(\infty|1|\infty)$ may not be a highest weight representation of $gl_0(1|\infty)$.

The reasons for studying representations of this particular superalgebra, namely $gl(1|\infty)$, stem from physical considerations. Our motivation originates from an attempt to introduce new quantum statistics both in quantum mechanics[1,2] (in this case the superalgebras are finite-dimensional) and in quantum field theory (QFT).[3,4] In order to see where the connection to the statistics comes from, we recall shortly the origin of the Lie superstatistics.

The starting point is based on the observation that any n pairs $b_1^\pm,\ldots,b_n^\pm$ of Bose creation and annihilation operators (CAOs), namely (below and throughout $[x,y]=xy-yx$, $\{x,y\}=xy+yx$)

$$[b_i^-,b_j^+]=\delta_{ij},\quad [b_i^-,b_j^-]=[b_i^+,b_j^+]=0, \tag{5}$$

considered as odd elements, generate a representation, the Bose representation ρ, of the Lie superalgebra $osp(1|2n)\equiv B(0|n)$.[5] Denote by $B_1^\pm,\ldots,B_n^\pm$ those generators of $B(0|n)$, which in the Bose representation coincide with the Bose operators, $\rho(B_i^\pm)=b_i^\pm$. Similarly as the Chevalley generators do, the operators $B_1^\pm,\ldots,B_n^\pm$ and the relations they satisfy, namely

$$[\{B_i^\xi,B_j^\eta\},B_k^\epsilon]=(\epsilon-\xi)\delta_{ik}B_j^\eta+(\epsilon-\eta)\delta_{jk}B_i^\xi,\quad \xi,\eta,\epsilon=\pm \ \text{ or } \ \pm 1, \tag{6}$$

define uniquely the LS $B(0|n)$.[5] The operators $B_i^\pm$ are odd root vectors of $B(0|n)$, whereas $\{B_j^+,B_j^-\}$ belong to the Cartan subalgebra. The operators (6) are known in quantum field theory: these are the *para*-Bose operators, generalizing the statistics of the tensor fields.[6] The important conclusion is that the representation theory of n pairs of *para*-Bose (pB) operators is equivalent to the representation theory of the Lie superalgebra $B(0|n)$. Certainly in QFT the algebra is $B(0|\infty)$, it is infinite-dimensional.

The identification of the *para*-Bose statistics with a well-known algebraic structure provides a natural background for further generalizations. In QFT the commutation relations between the CAOs are determined from the translation invariance of the field under consideration.[7] In momentum space the translation invariance of a scalar (or tensor) field $\Psi(x)$ is expressed as a commutator between the energy–momentum P^m, $m=0,1,2,3$ and the CAOs $a_i^\pm$ of $\Psi(x)$:

$$[P^m,a_i^\pm]=\pm k_i^m a_i^\pm, \tag{7}$$

where the index i replaces all (continuous and discrete) indices of the field and

$$P^m=\frac{1}{2}\sum_j k_j^m\{a_j^+,a_j^-\}. \tag{8}$$

To quantize the field means, loosely speaking, to find solutions of Eqs. (7) and (8), where the unknowns are the CAOs $a_i^\pm$. The Bose operators (5) and their generalization, the pB operators (6), certainly satisfy (7). By no means however they do not exhaust the set of the possible solutions.

The first possibility for finding new solutions and hence for further generalization of the statistics stems from the observation that the commutation relations between the Cartan elements and the root vectors, in particular Eq. (7), remain unaltered upon q deformations. The deformations of the parastatistics along this line were studied in Refs. 8–11 and more generally in Ref. 12.

Another opportunity, closely related to the present paper, is based on the observation that $B(0|n)$ belongs to the class B superalgebras in the classification of Kac.[13] Therefore it is natural to try to satisfy the quantization equations (7) and (8) with CAOs, generating superalgebras from the classes A, C, and D or generating other superalgebras from the class B. In Refs. 3 and 4 it was shown that this is possible indeed. For charged tensor fields the main quantization condition (7) can be satisfied with CAOs, which generate the LS $gl(\infty|1|\infty)$, namely a LS from the class *A*. Up to now, however, this new statistics, the *A* superstatistics, did not achieve any further development. The reason is that so far the Fock spaces corresponding to the *A* superstatistics were not constructed. Here we come to the relation between the *A* superstatistics and the present investigation. The Fock spaces are representation spaces of $gl(1|\infty)$. In order to study the physical consequences of the *A* superstatistics in QFT one has to develop first the representation theory of $gl(\infty|1|\infty)$ (for charged scalar fields) and of $gl_0(1|\infty)$ (for neutral fields). This is what we do in the present paper. The reason to study only highest weight representations reflects the fact that there should exist a state with a lowest energy, a vacuum, which turns out to be the highest weight vector in the corresponding $gl(1|\infty)$ module.

So far the *A* superstatistics was tested only in finite-dimensional cases, namely in the frame of a (noncanonical) quantum mechanics. We have in mind the Wigner quantum systems, introduced in Refs. 1 and 2, which recently attracted some attention from different points of view.[14–16] These systems possess quite unconventional physical features, properties which cannot be achieved in the frame of the canonical quantum mechanics. The $(n+1)$-particle WQS, based on $sl(1/3n)$,[17] exhibits a quarklike structure: the composite system occupies a small volume around the center of mass and within it the geometry is noncommutative. The underlying statistics is a Haldane exclusion statistics,[18] a subject of considerable interest in condensed matter physics. The osp(3/2) WQS, studied in Ref. 19, leads to a picture where two spinless point particles, curling around each other, produce an orbital (internal angular) momentum 1/2. One can expect that also in QFT the Lie superstatistics could lead to new features.

In the literature one does not find many papers dealing with representations of infinite-dimensional simple Lie superalgebras.[20,21] Implicitly, however, such algebras and their representations were used in theoretical physics since the QFT was created. In the first place we have in mind the ordinary Fock space W_1 of infinitely many pairs of Bose CAOs $\{b_i^\pm\}_{i\in\mathbf{Z}}$. As mentioned above, the Bose operators are (representatives of) the odd generators of $B(0|\infty)$ and their Fock space W_1 is one particular irreducible $B(0|\infty)$ module. The Fock spaces W_p of *para*-Bose operators $\{B_i^\pm\}_{i\in\mathbf{Z}}$, corresponding to order of the parastatistics $p\in\mathbf{N}$,[6] are also irreducible and inequivalent to each other $B(0|\infty)$ modules. The Clifford construction in Ref. 21 is a generalization to the case when both bosons $\{b_i^\pm\}_{i\in\mathbf{Z}}$, considered as odd variables, and fermions $\{f_i^\pm\}_{i\in\mathbf{Z}}$, which are even generators, are involved. The assumption is that the bosons anticommute with the fermions. Then any *n* pairs of Bose CAOs and *m* pairs of Fermi CAOs generate (a representation of) the Lie superalgebra $B(m|n)$.[22] Therefore the Fock representation of $\{b_i^\pm, f_i^\pm\}_{i\in\mathbf{Z}}$ is an irreducible $B(\infty|\infty)$ module. Its restriction to $gl(\infty|\infty)$ leads to a set of irreducible representations of this superalgebra.

In the paper we essentially use results from the representation theory of $gl(1|n)$. The finite-dimensional irreducible modules (fidirmods) of the latter are, one can say, well understood. A character formula for all typical[13] and atypical[23] modules has been constructed. The dimensions of all fidirmods are known.[24,25] A basis, similar to the GZ basis of $gl(n)$, was defined and its transformation under the action of the Chevalley generators was written down.[26,27] The results were even generalized to the quantum algebra $U_q[gl(1|n)]$.[28] This is in contrast to the more general case of $gl(m|n)$ and $U_q[gl(m/n)]$, where most of the above problems are still waiting to be solved although partial results do exist.[29–33]

The irreducible highest weight representations of $gl_0(1|\infty)$, which we consider, are a generalization to the infinite-dimensional case of the finite-dimensional essentially typical representations of $gl(1|n)$ in the Gel'fand–Zetlin basis (GZ basis). In order to see where the possibility for a generalization comes from we recall (Sec. II A) the way the Gel'fand–Zetlin basis was introduced.[31] This basis is, however, inappropriate for a generalization to the case of highest weight $gl(\infty|1|\infty)$ modules. Therefore in Sec. II B we modify it, introducing a new basis, which we call a *C* basis. It is an analog of the *C* basis for gl_∞.[34,35] Section III is devoted to the irreducible $gl(1|\infty)$ modules. In Sec. III A we extend the Gel'fand–Zetlin basis to the infinite-dimensional case and apply it to $gl_0(1|\infty)$. The highest weight irreducible $gl(\infty|1|\infty)$ representations are defined in Sec. III B. They appear as a generalization of the essentially typical representations of $gl(1|n)$ in the C basis. The transformations of the basis under the action of the algebra generators are explicitly written down.

Throughout the paper we use the following notation:

LS, LSs	Lie superalgebra, Lie superalgebras;
CAOs	creation and annihilation operators;
fidirmod(s)	finite-dimensional irreducible module(s);
GZ basis	Gel'fand–Zetlin basis;
$\mathbf{N}$	all positive integers;
$\mathbf{Z}$	all integers;
$\mathbf{Z}_+$	all non-negative integers;
$\mathbf{Z}_2=\{0,\overline{1}\}$	the ring of all integers modulo 2;
$\mathbf{C}$	all complex numbers;

$$[p;q]=\{p,p+1,p+2,...,q-1,q\}, \text{ if } q-p\in\mathbf{Z}_+ \text{ and } [p;q]=\varnothing \text{ otherwise}; \tag{9}$$

$$[m]_k=[m_{1k},m_{2k},\dots,m_{kk}], \text{ where } m_{ik}\in\mathbf{C}; \tag{10}$$

$$[M]_{2k+\theta}=[M_{-k,2k+\theta},M_{-k+1,2k+\theta},\dots,M_{k-1+\theta,2k+\theta}], \quad \theta\in\{0,1\}, \quad k\in\mathbf{N}; \tag{11}$$

$$l_{1j}=m_{1j}+1, \quad l_{ij}=-m_{ij}+i-1, \quad i\in[2;j]; \tag{12}$$

$$\begin{aligned} &L_{0,2k+\theta}=M_{0,2k+\theta}, \quad \theta\in\{0,1\},\\ &L_{i,2k+\theta}=-M_{i,2k+\theta}+i+1, \quad \theta\in\{0,1\}, \quad i\in[-k;-1],\\ &L_{j,2k+\theta}=-M_{j,2k+\theta}+j-1, \quad \theta\in\{0,1\}, \quad j\in[1;k-1+\theta]; \end{aligned} \tag{13}$$

$$[m]\equiv[m_1,m_2,\dots,m_k,\dots]=\{m_i|m_i\in\mathbf{C},i\in\mathbf{N}\}; \tag{14}$$

$$[M]\equiv[\dots,M_{-p},\dots,M_{-1},M_0,M_1,\dots,M_q,\dots]=\{M_i|M_i\in\mathbf{C},i\in\mathbf{Z}\}; \tag{15}$$

$$P(j,l)=\begin{cases}1 & \text{for } j\geqslant l\\ -1 & \text{for } j<l\end{cases}; \tag{16}$$

$$Q(j,l)=\begin{cases}1 & \text{for } j>l\\ -1 & \text{for } j\leqslant l\end{cases}; \tag{17}$$

$$\theta(i)=\begin{cases}1 & \text{for } i\geqslant 0\\ 0 & \text{for } i<0\end{cases}. \tag{18}$$

II. FINITE-DIMENSIONAL ESSENTIALLY TYPICAL REPRESENTATIONS OF $gl(1|2n)$

As in the case of $gl(1|\infty)$ it is convenient to use two different notation for the finite-dimensional superalgebras from this class. In the first notation $gl_0(1|N)$ is the same as in Definition 1, but the indices i,j run from 1 to $N+1$.

Then $e_{11},e_{22},\dots,e_{N+1,N+1}$ is a basis in the Cartan subalgebra $\mathcal{H}_0$. Denote by $\epsilon^1,\dots,\epsilon^{N+1}$ the dual basis, $\epsilon^i(e_{jj})=\delta^i_j$. The correspondence root vector $\leftrightarrow$ root reads: $e_{ij}\leftrightarrow\epsilon^i-\epsilon^j$, $i\neq j=1,...,N+1$; $\Delta^0=\{\epsilon^i-\epsilon^j\}_{i\neq j\in[1;N+1]}$ is the root system; $\Delta^0_+=\{\epsilon^i-\epsilon^j\}_{i<j\in[1;N+1]}$ and

$$\pi^0=\{\epsilon^1-\epsilon^2,\epsilon^2-\epsilon^3,\dots,\epsilon^N-\epsilon^{N+1}\} \tag{19}$$

are the standard systems of positive roots and simple roots, respectively. The special linear superalgebra $sl_0(1|N)$ is a subalgebra of $gl_0(1|N)$ spanned by all $gl_0(1|N)$ root vectors and the Cartan elements $e_{11}+e_{ii}$ for all $i\neq 1$.

Similarly, $gl(M|1|N)$ is the same as in Definition 2, but $i,j=-M,-M+1,...,N$ and $M,N \in \mathbf{Z}_+$. In particular $\{E_{ii}\}_{i\in[-M;N]}$ is a basis in the Cartan subalgebra $\mathcal{H}$ with $\{\mathcal{E}^i\}_{i\in[-M;N]}$ its dual. The simple root vectors are $\{E_{i,i+1}\}_{i\in[-M;N-1]}$. Hence

$$\pi=\{\mathcal{E}^{-M}-\mathcal{E}^{-M+1},\mathcal{E}^{-M+1}-\mathcal{E}^{-M+2},\ldots,\mathcal{E}^{-1}-\mathcal{E}^0,\mathcal{E}^0-\mathcal{E}^1,\ldots,\mathcal{E}^{N-1}-\mathcal{E}^N\} \tag{20}$$

is the system of simple roots.

We have written explicitly the systems (19) and (20) in order to underline that they contain different number of odd roots: π^0 has only one, $\epsilon^1-\epsilon^2$, whereas the odd roots in π are $\mathcal{E}^{-1}-\mathcal{E}^0,\mathcal{E}^0-\mathcal{E}^1$. Therefore the systems of the simple roots of $sl_0(1|2n)$ and $sl(n|1|n)$ are different, despite the fact that these algebras are isomorphic. This property demonstrates one of the essential differences between the Lie algebras and the Lie superalgebras. For each simple Lie algebra there exists (up to a transformation from the Weyl group) only one system of simple roots. This is not the case for the basic Lie superalgebras, where several inequivalent simple root systems can be in general defined (for more details see Refs. 36–38). As a result one and the same irreducible $gl(1|2n)$ module can be described with different signatures. We shall have to take this into account in the definition of the C basis.

A. GZ basis (Ref. 31)

Let $V([m]_{N+1})$ be a highest weight finite-dimensional irreducible $gl_0(1|N)$ module (fidirmod) with a highest weight

$$[m]_{N+1}\equiv[m_{1,N+1},m_{2,N+1},\ldots,m_{N+1,N+1}]\equiv\sum_{i=1}^{N+1} m_{i,N+1}\epsilon^i, \tag{21}$$

where

$$m_{j,N+1}\in\mathbf{C},\quad j=1,...,N+1,\quad m_{i,N+1}-m_{i+1,N+1}\in\mathbf{Z}_+,\quad i=2,3,...,N. \tag{22}$$

If x_{N+1} is the highest weight vector in $V([m]_{N+1})$, then $e_{ii}x_{N+1}=m_{i,N+1}x_{N+1}$.

Consider the chain of subalgebras

$$gl_0(1|N)\supset gl_0(1|N-1)\supset gl_0(1|N-2)\supset\cdots\supset gl_0(1|2)\supset gl_0(1|1)\supset gl_0(1|0)\equiv gl_0(1). \tag{23}$$

Then $V([m]_{N+1})$ is said to be essentially typical, if it is completely reducible with respect to any one of the subalgebras in the chain (23). Each essentially typical module $V([m]_{N+1})$ carries a typical representation[13] of the special linear superalgebra $sl_0(1|n)$, but the inverse is in general not true.

Set

$$l_{1,N+1}=m_{1,N+1}+1,\quad l_{i,N+1}=-m_{i,N+1}+i-1,\quad i=2,3,...,N+1. \tag{24}$$

Proposition 1: (Ref. 31) The $gl_0(1|N)$ module $V([m]_{N+1})$ is essentially typical if and only if

$$l_{1,N+1}\notin[l_{2,N+1};l_{N+1,N+1}]. \tag{25}$$

Let $V([m]_{N+1})$ be an essentially typical $gl_0(1|N)$ module and let

$$V([m]_{N+1})\supset V([m]_N)\supset V([m]_{N-1})\supset\cdots\supset V([m]_{k+1})\supset\cdots V([m]_2)\supset V(m_{11}) \tag{26}$$

be a flag of $gl_0(1|k)$ fidirmods $V([m]_{k+1})$, $k=0,1,2,...,N$, where

$$[m]_{k+1}\equiv[m_{1,k+1},m_{2,k+1},\ldots,m_{k+1,k+1}]\equiv\sum_{i=1}^{k+1} m_{i,k+1}\epsilon^i \tag{27}$$

is the signature of $V([m]_{k+1})$. In the ordered basis

$$e_{11}, e_{22}, \ldots, e_{k+1,k+1} \tag{28}$$

of the Cartan subalgebra of $gl_0(1|k)$, $m_{i,k+1}$ is the eigenvalue of e_{ii} on the highest weight vector $x_{k+1} \in V([m]_{k+1})$,

$$e_{ii}x_{k+1} = m_{i,k+1}x_{k+1}, \quad i=1,...,k+1. \tag{29}$$

Since we consider only essentially typical modules and the fidirmods of $gl_0(1)$ are one dimensional, the flag (26) defines a vector $|m\rangle$ in $V([m]_{N+1})$. It turns out this vector is uniquely defined (up to, certainly, a multiplicative constant) by the signatures $[m]_{N+1}$, $[m]_N, \ldots, [m]_2, m_{11}$. Therefore one can set

$$|m\rangle \equiv \begin{bmatrix} [m]_{N+1} \\ [m]_N \\ \vdots \\ [m]_2 \\ m_{11} \end{bmatrix} \equiv \begin{bmatrix} m_{1,N+1} & m_{2,N+1} & \cdots & m_{N,N+1} & m_{N+1,N+1} \\ m_{1,N} & m_{2,N} & \cdots & m_{N,N} & \\ \cdots & \cdots & \cdots & & \\ m_{12} & m_{22} & & & \\ m_{11} & & & & \end{bmatrix}. \tag{30}$$

The vectors (30), corresponding to all possible flags (26), constitute a basis $\Gamma([m]_{N+1})$ in the $gl_0(1|N)$ fidirmod $V([m]_{N+1})$. This is the GZ basis introduced in Ref. 31 [for the more general case of $gl(M/N)$].

Proposition 2: (Ref. 31) The GZ basis $\Gamma([m]_{N+1})$ *in the essentially typical module* $V([m]_{N+1})$ *is given by all tables (30) for which*

(1) the numbers $m_{i,N+1}$, $i=1,2,...,N+1$ *are fixed for all tables and satisfy (22), (24), (25),*

$$(2) \quad m_{1i} - m_{1,i-1} \equiv \theta_{i-1} \in \{0,1\}, \quad i=2,3,...,N+1, \tag{31}$$

$$(3) \quad m_{i,j+1} - m_{ij} \in \mathbf{Z}_+, \quad m_{ij} - m_{i+1,j+1} \in \mathbf{Z}_+, \quad 2 \leqslant i \leqslant j \leqslant N. \tag{32}$$

The transformations of the basis $\Gamma([m]_{N+1})$ *under* $gl_0(1|N)$ *are completely defined from the action of the Chevalley generators*

$$e_{ii}|m\rangle = \left(\sum_{k=1}^{i} m_{ki} - \sum_{k=1}^{i-1} m_{k,i-1} \right) |m\rangle, \quad i=1,2,...,N+1, \tag{33}$$

$$e_{12}|m\rangle = \theta_1 |m\rangle_{(11)}, \quad e_{21}|m\rangle = (1-\theta_1)(l_{12}-l_{22})|m\rangle_{-(1,1)}, \tag{34}$$

$$\begin{aligned} e_{i,i+1}|m\rangle = {} & \theta_i(1-\theta_{i-1})|m\rangle_{(1i)} \\ & + \sum_{j=2}^{i} \left(- \frac{\Pi_{k=2}^{i-1}(l_{k,i-1}-l_{ji}+1)\Pi_{k=2}^{i+1}(l_{k,i+1}-l_{ji})}{\Pi_{k\neq j=2}^{i}(l_{ki}-l_{ji})(l_{ki}-l_{ji}+1)} \right)^{1/2} \\ & \times \frac{(l_{1i}-l_{ji})(l_{1i}-l_{ji}+1)}{(l_{1,i+1}-l_{ji})(l_{1,i-1}-l_{ji}+1)} |m\rangle_{(ji)}, \quad i=2,...,N, \end{aligned} \tag{35}$$

$$\begin{aligned} e_{i+1,i}|m\rangle = {} & \theta_{i-1}(1-\theta_i) \frac{\Pi_{k=2}^{i-1}(l_{1,i+1}-l_{k,i-1}-1)\Pi_{k=2}^{i+1}(l_{1,i+1}-l_{k,i+1})}{\Pi_{k=2}^{i}(l_{1,i+1}-l_{ki}-1)(l_{1,i+1}-l_{ki})} |m\rangle_{-(1,i)} \\ & + \sum_{j=2}^{i} \left(- \frac{\Pi_{k=2}^{i-1}(l_{k,i-1}-l_{ji})\Pi_{k=2}^{i+1}(l_{k,i+1}-l_{ji}-1)}{\Pi_{k\neq j=2}^{i}(l_{ki}-l_{ji}-1)(l_{ki}-l_{ji})} \right)^{1/2} |m\rangle_{-(ji)}, \quad i=2,...,N, \end{aligned} \tag{36}$$

where $l_{1j}=m_{1j}+1$, $l_{ij}=-m_{ij}+i-1$, $i\neq 1$ *and the table* $|m\rangle_{\pm(i,j)}$ *is obtained from the table* $|m\rangle$ *by the replacement* $m_{ij}\to m_{ij}\pm 1$.

If a vector from the right-hand side of (35) or (36) does not belong to the module under consideration, then the corresponding term is zero even if the coefficient in front is undefined; if an equal number of factors in numerator and denominator are simultaneously equal to zero, they should be canceled out.

The $gl_0(1|N)$ highest weight vector x_{N+1} in $V([m]_{N+1})$ is a vector from the GZ basis

$$x_{N+1}=|\hat{m}\rangle \quad \text{for which} \quad m_{ii}=m_{i,i+1}=\cdots=m_{i,N+1}, \quad i=1,2,...,N, \tag{37}$$

i.e.,

$$|\hat{m}\rangle=\left[\begin{array}{lllll} m_{1,N+1} & m_{2,N+1} & \cdots & m_{N,N+1} & m_{N+1,N+1} \\ m_{1,N+1} & m_{2,N+1} & \cdots & m_{N,N+1} & \\ \cdots & \cdots & \cdots & & \\ m_{1,N+1} & m_{2,N+1} & & & \\ m_{1,N+1} & & & & \end{array}\right]. \tag{38}$$

In this case

$$e_{ii}|\hat{m}\rangle=m_{i,N+1}|\hat{m}\rangle, \quad i=1,2,...,N+1, \quad e_{k,k+1}|\hat{m}\rangle=0, \quad k=1,2,...,N. \tag{39}$$

B. *C* basis

Let E_{ij}, $i,j=-n,-n+1,...,n$ be the generators of $gl(n|1|n)$. Define a sequence of subalgebras

$$gl(k|1|k-1+\theta)=\text{lin env}\{E_{ij}|i,j\in[-k;k-1+\theta]\}\forall\,\theta\in\{0,1\}, \quad k\in[1-\theta;n]. \tag{40}$$

As an ordered basis in the Cartan subalgebra of $gl(k|1|k-1+\theta)$ take

$$E_{-k,-k},E_{-k+1,-k+1},\ldots,E_{k-1+\theta,k-1+\theta}. \tag{41}$$

Proposition 3: The map φ, *which is a linear extension of the relations*

$$\varphi(E_{ij})=e_{g(i),g(j)}, \quad i,j=-n,-n+1,...,n, \tag{42}$$

is an isomorphism of $gl(n|1|n)$ *on* $gl_0(1|2n)$. *Its restriction on* $gl(k|1|k-1+\theta)$ *is an isomorphism of* $gl(k|1|k-1+\theta)$ *on* $gl_0(1|2k-1+\theta)$ *for each* $\theta\in\{0,1\}$ *and* $k\in[1-\theta;n]$. *The chain of subalgebras*

$$\begin{aligned} &gl(n|1|n)\supset gl(n|1|n-1)\supset gl(n-1|1|n-1)\supset gl(n-1|1|n-2)\supset\cdots \\ &\quad\supset gl(1|1|1)\supset gl(1|1)\supset gl(1), \end{aligned} \tag{43}$$

($gl(1|1|0)\equiv gl(1|1)$, $gl(0|1|0)\equiv gl(1)$) *is transformed by* φ *into the chain (23)*

$$gl_0(1|2n)\supset gl_0(1|2n-1)\supset gl_0(1|2n-2)\supset\cdots\supset gl_0(1|2)\supset gl_0(1|1)\supset gl_0(1). \tag{44}$$

The proof is straightforward.

The isomorphism φ allows one to turn any $gl_0(1|2k-1+\theta)$ irreducible module $V([m]_{2k+\theta})$ into a $gl(k|1|k-1+\theta)$ module:

$$\varphi(E_{ij})x=e_{g(i),g(j)}x, \quad \forall x\in V([m]_{2k+\theta}). \tag{45}$$

The relevant point for us is that each $V([m]_{2k+\theta})$ can be labeled also with its highest weight with respect to $gl(k|1|k-1+\theta)$. By definition it consists of the eigenvalues of the representatives of the Cartan generators (41), namely

$$\begin{gathered}\varphi(E_{-k,-k}),\quad \varphi(E_{-k+1,-k+1}),\ldots,\quad \varphi(E_{-2,-2}),\quad \varphi(E_{-1,-1}),\\ \varphi(E_{0,0}),\quad \varphi(E_{1,1}),\ldots,\quad \varphi(E_{k-1+\theta,k-1+\theta})\end{gathered} \tag{46}$$

on the $gl(k|1|k-1+\theta)$ highest weight vector $y_{2k+\theta}\in V([m]_{2k+\theta})$. The latter is defined from the requirements

$$\varphi(E_{ij})y_{2k+\theta}=0,\quad i<j=-k,-k+1,...,k-1+\theta, \tag{47}$$

$$\varphi(E_{ii})y_{2k+\theta}=M_{i,2k+\theta}y_{2k+\theta},\quad i=-k,-k+1,...,k-1+\theta. \tag{48}$$

Set

$$[M]_{2k+\theta}\equiv[M_{-k,2k+\theta},M_{-k+1,2k+\theta},\ldots,M_{k-1+\theta,2k+\theta}]. \tag{49}$$

The new signature $[M]_{2k+\theta}$ defines, as mentioned above, uniquely $V([m]_{2k+\theta})$. Hence

$$V([m]_{2k+\theta})=V([M]_{2k+\theta}). \tag{50}$$

Consider now a GZ basis vector $|m\rangle$ corresponding to the flag

$$V([m]_{2n+1})\supset V([m]_{2n})\supset V([m]_{2n-1})\supset\cdots\supset V([m]_{2k+\theta})\supset\cdots V([m]_2)\supset V(m_{11})\leftrightarrow|m\rangle, \tag{51}$$

namely the vector (30) with $N=2n$. In view of (50) the same flag can be written as

$$V([M]_{2n+1})\supset V([M]_{2n})\supset V([M]_{2n-1})\supset\cdots\supset V([M]_{2k+\theta})\supset\cdots\supset V([M]_2)\supset V(M_{11}) \tag{52}$$

and therefore the vector $|m\rangle$ is completely defined by the signatures $[M]_{2n+1},[M]_{2n},\ldots,[M]_2,M_{11}$. Therefore we can write any GZ basis vector (30) also in the form

$$|M\rangle\equiv\left[\begin{array}{cccccccc} M_{-n,2n+1} & M_{-n+1,2n+1} & \cdots & M_{-1,2n+1} & M_{0,2n+1} & M_{1,2n+1} & \cdots & M_{n-1,2n+1} & M_{n,2n+1}\\ M_{-n,2n} & M_{-n+1,2n} & \cdots & M_{-1,2n} & M_{0,2n} & M_{1,2n} & \cdots & M_{n-1,2n} & \\ & M_{-n+1,2n-1} & \cdots & M_{-1,2n-1} & M_{0,2n-1} & M_{1,2n-1} & \cdots & M_{n-1,2n-1} & \\ & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & & \\ & & \cdots & \cdots & \cdots & \cdots & \cdots & & \\ & & & M_{-1,3} & M_{03} & M_{13} & & & \\ & & & M_{-1,2} & M_{02} & & & & \\ & & & & M_{01} & & & & \end{array}\right]. \tag{53}$$

Obviously (30) (with $N=2n$) and (53) are two different labelings for one and the same vector $|m\rangle\equiv|M\rangle$. We call the basis, written in the notation (53), a C basis in $V([M]_{2n+1})\equiv V([m]_{2n+1})$ and denote it as $\Gamma([M]_{2n+1})$.

In order to use effectively the basis $\Gamma([M]_{2n+1})$ we need to determine all signatures $[M]_{2k+\theta}$, namely to find the values of the entries in (53). To this end we have to determine as a first step the highest weight vector $y_{2k+\theta}$ within each $gl(k|1|k-1+\theta)$ module $V([m]_{2k+\theta})$ in the chain (51) and subsequently, using (48), to compute its $gl(k|1|k-1+\theta)$ signature $[M]_{2k+\theta}$.

Proposition 4: The $gl(k|1|k-1+\theta)$ highest weight vector $y_{2k+\theta}$ in $V([m]_{2k+\theta})$ [from the chain (51)] is the GZ vector $|m\rangle_{2k+\theta}$, for which

$$m_{1,2r+\tau}+k-r=m_{1,2k+\theta},\quad \forall\tau\in\{0,1\},\quad r\in[1-\tau;k-\tau], \tag{54}$$

$$m_{r-j,2k-2j+\tau}=m_{r,2k+\theta}, \quad \forall r\in[3-\theta;k+1], \quad \tau\in\{0,1\}, \quad j\in[1-\theta;r-2], \tag{55a}$$

$$m_{r-j,2k-2j+\tau}=m_{r,2k+\theta}, \quad \forall r\in[k+2;2k], \quad \tau\in\{0,1\}, \quad j\in[1-\theta;2k-r+\tau]. \tag{55b}$$

Proof: It is easy to verify that the conditions (54) are equivalent to

$$\theta_{2i-1}=1, \quad i\in[1;k], \tag{56a}$$

$$\theta_{2i}=0, \quad i\in[1;k-1+\theta], \tag{56b}$$

whereas the conditions (55) can be replaced by

$$l_{s,2i+1}-l_{s,2i}=0, \quad i\in[1;k-1+\theta], \quad s\in[2;2i], \tag{57a}$$

$$l_{s+1,2i}-l_{s,2i-1}-1=0, \quad i\in[2;k], \quad s\in[2;2i-1]. \tag{57b}$$

We need to show that (47) holds for $y_{2k+\theta}=|m\rangle_{2k+\theta}$. It certainly suffices to verify it only for the $gl(k|1|k-1+\theta)$ simple root vectors, namely to prove that

$$\varphi(E_{-i,-i+1})|m\rangle_{2k+\theta}=0, \quad i\in[1;k], \tag{58}$$

$$\varphi(E_{i,i+1})|m\rangle_{2k+\theta}=0, \quad i\in[0;k-2+\theta]. \tag{59}$$

The validity of the latter follows from the observation that $\varphi(E_{-1,0})=e_{21}$, $\varphi(E_{01})=[e_{12},e_{23}]$, $\varphi(E_{-i,-i+1})=[e_{2i,2i-1},e_{2i-1,2i-2}]$, $i\in[2;k]$, $\varphi(E_{i-1,i})=[e_{2i-1,2i},e_{2i,2i+1}]$, $i\in[2;k-1+\theta]$ and Eqs. (34)–(36). This completes the proof.

We are now ready to determine the $gl(k|1|k-1+\theta)$ signature of $V([m]_{2k+\theta})$ for any $\theta\in\{0,1\}$ and $k\in[1;n]$. Taking into account (54), (55), and (45) and using the transformation relation (33), one obtains

$$\varphi(E_{ii})|m\rangle_{2k+\theta}=e_{2|i|,2|i|}|m\rangle_{2k+\theta}=(m_{i+k+2,2k+\theta}+1)|m\rangle_{2k+\theta}, \quad i\in[-k;-1], \tag{60a}$$

$$\varphi(E_{00})|m\rangle_{2k+\theta}=e_{11}|m\rangle_{2k+\theta}=(m_{1,2k+\theta}-k)|m\rangle_{2k+\theta}, \tag{60b}$$

$$\varphi(E_{ii})|m\rangle_{2k+\theta}=e_{2i+1,2i+1}|m\rangle_{2k+\theta}=m_{i+k+1,2k+\theta}|m\rangle_{2k+\theta}, \quad i\in[1;k-1+\theta]. \tag{60c}$$

Comparing (60) with the definition (48) we obtain the $gl(k|1|k-1+\theta)$ signature $[M]_{2k+\theta}$ of $V([m]_{2k+\theta})$:

$$M_{i,2k+\theta}=m_{i+k+2,2k+\theta}+1, \quad i\in[-k;-1], \tag{61a}$$

$$M_{0,2k+\theta}=m_{1,2k+\theta}-k, \tag{61b}$$

$$M_{i,2k+\theta}=m_{i+k+1,2k+\theta}, \quad i\in[1,k-1+\theta], \tag{61c}$$

$$M_{01}=m_{11}. \tag{61d}$$

We have added the evident relation (61d) for completeness, since it is not contained in (61a)–(61c). The above relations hold for any $\theta\in\{0,1\}$ and $k\in[1;n]$. In particular,

$$M_{i,2n+1}=m_{i+n+2,2n+1}+1, \quad i\in[-n;-1], \tag{62a}$$

$$M_{0,2n+1}=m_{1,2n+1}-n, \tag{62b}$$

$$M_{i,2n+1}=m_{i+n+1,2n+1}, \quad i\in[1,n]. \tag{62c}$$

The $gl(n|1|n)$ highest weight vector $y_{2n+1}\equiv|\hat{M}\rangle$ is the one from (53), for which $M_{i,j}=M_{i,2n+1}$ for any admissible i and j:

$$\left[\begin{array}{ccccccccc} M_{-n,2n+1} & M_{-n+1,2n+1} & \cdots & M_{-1,2n+1} & M_{0,2n+1} & M_{1,2n+1} & \cdots & M_{n-1,2n+1} & M_{n,2n+1} \\ M_{-n,2n+1} & M_{-n+1,2n+1} & \cdots & M_{-1,2n+1} & M_{0,2n+1} & M_{1,2n+1} & \cdots & M_{n-1,2n+1} & \\ & M_{-n+1,2n+1} & \cdots & M_{-1,2n+1} & M_{0,2n+1} & M_{1,2n+1} & \cdots & M_{n-1,2n+1} & \\ & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & & \\ & & \cdots & \cdots & \cdots & \cdots & \cdots & & \\ & & & M_{-1,2n+1} & M_{0,2n+1} & M_{1,2n+1} & & & \\ & & & M_{-1,2n+1} & M_{0,2n+1} & & & & \\ & & & & M_{0,2n+1} & & & & \end{array}\right]. \tag{63}$$

From (31) and (32) one derives the ''in-betweenness conditions,'' which define completely the new basis (53). The transformations of the C basis are most easily written in terms of the following variables:

$$\begin{aligned} &L_{0,2k+\theta}=M_{0,2k+\theta},\\ &L_{i,2k+\theta}=-M_{i,2k+\theta}+i+1, \quad i\in[-k;-1],\\ &L_{i,2k+\theta}=-M_{i,2k+\theta}+i-1, \quad i\in[1;k-1+\theta]. \end{aligned} \tag{64}$$

We formulate the result as a proposition.

Proposition 5: The $2n+1$*-tuple* $[M]_{2n+1}=[M_{-n,2n+1},M_{-n+1,2n+1},\ldots,M_{n,2n+1}]$ *is a signature of an essentially typical* $gl(n|1|n)$ *module* $V([M]_{2n+1})$ *if and only if*

$$M_{i,2n+1}\in\mathbf{C}, \quad i\in[-n;n], \tag{65a}$$

$$M_{i,2n+1}-M_{i+1,2n+1}\in\mathbf{Z}_+, \quad i\in[-n;-2]\cup[1;n-1], \tag{65b}$$

$$M_{-1,2n+1}-M_{1,2n+1}\in\mathbf{N}, \tag{65c}$$

$$M_{0,2n+1}=L_{0,2n+1}\notin[L_{-n,2n+1};L_{n,2n+1}]. \tag{65d}$$

The C basis $\Gamma([M]_{2n+1})$ *in* $V([M]_{2n+1})$ *consists of all tables (53) for which the labels*

$$M_{i,2k+\theta}, \quad \theta\in\{0,1\}, \quad k\in[1-\theta;n], \quad i\in[-k;k-1+\theta], \tag{66}$$

take all possible values consistent with the ''in-betweenness conditions''

$$M_{i,2k+1}-M_{i,2k}\in\mathbf{Z}_+, \quad k\in[1;n], \quad i\in[-k;-1]\cup[1;k-1], \tag{67a}$$

$$M_{i,2k-1}-M_{i,2k}\in\mathbf{Z}_+, \quad k\in[2;n], \quad i\in[-k+1;-1]\cup[1;k-1], \tag{67b}$$

$$M_{i-1,2k}-M_{i,2k-1}\in\mathbf{Z}_+, \quad k\in[2;n], \quad i\in[-k+1;-1]\cup[2;k-1], \tag{67c}$$

$$M_{i-1,2k}-M_{i,2k+1}\in\mathbf{Z}_+, \quad k\in[1;n], \quad i\in[-k+1;-1]\cup[2;k], \tag{67d}$$

$$M_{-1,2k}-M_{1,2k-1}\in\mathbf{N}, \quad k\in[2;n], \tag{67e}$$

$$M_{-1,2k}-M_{1,2k+1}\in\mathbf{N}, \quad k\in[1;n], \tag{67f}$$

$$M_{0,2k+1}-M_{0,2k}\equiv\psi_{2k}\in\{0,1\},\quad k\in[1;n],\tag{67g}$$

$$M_{0,2k}-M_{0,2k-1}\equiv\psi_{2k-1}\in\{0,-1\},\quad k\in[1;n].\tag{67h}$$

The transformations of the C basis under the action of the inverse images $\varphi^{-1}(e_{ii})$, $\varphi^{-1}(e_{i,i+1})$, and $\varphi^{-1}(e_{i+1,i})$ of the $gl_0(1|2n)$ Chevalley generators follow from (33) to (36) and (61), (62). The result reads [we write E_{ij} instead of $\varphi(E_{ij})$]:

$$E_{ii}|M\rangle=\left(\sum_{j=-|i|}^{|i|+\theta(i)-1}M_{j,2|i|+\theta(i)}-\sum_{j=-|i|+1-\theta(i)}^{|i|-1}M_{j,2|i|+\theta(i)-1}\right)|M\rangle,\quad i\in[-n;n],\tag{68}$$

$$E_{0,-1}|M\rangle=(1+\psi_1)|M\rangle_{(0,1)},\tag{69}$$

$$E_{-1,0}|M\rangle=-\psi_1(L_{0,2}-L_{-1,2})|M\rangle_{-(0,1)},\tag{70}$$

$$\begin{aligned}E_{i-1,-i}|M\rangle&=(1+\psi_{2i-1})(1-\psi_{2i-2})|M\rangle_{(0,2i-1)}\\&+\sum_{j\neq 0=-i+1}^{i-1}\left(-\frac{\prod_{k\neq 0=-i+1}^{i-2}(L_{k,2i-2}-L_{j,2i-1}+1)\prod_{k\neq 0=-i}^{i-1}(L_{k,2i}-L_{j,2i-1}+1)}{\prod_{k\neq 0,j;k=-i+1}^{i-1}(L_{k,2i-1}-L_{j,2i-1})(L_{k,2i-1}-L_{j,2i-1}+1)}\right)^{1/2}\\&\times\frac{(L_{0,2i-1}-L_{j,2i-1})(L_{0,2i-1}-L_{j,2i-1}+1)}{(L_{0,2i}-L_{j,2i-1}+1)(L_{0,2i-2}-L_{j,2i-1}+1)}|M\rangle_{(j,2i-1)},\quad i\in[2;n],\end{aligned}\tag{71}$$

$$\begin{aligned}E_{-i,i}|M\rangle&=-\psi_{2i}\psi_{2i-1}|M\rangle_{(0,2i)}\\&+\sum_{j\neq 0=-i}^{i-1}\left(-\frac{\prod_{k\neq 0=-i+1}^{i-1}(L_{k,2i-1}-L_{j,2i})\prod_{k\neq 0=-i}^{i}(L_{k,2i+1}-L_{j,2i})}{\prod_{k\neq 0,j;k=-i}^{i-1}(L_{k,2i}-L_{j,2i})(L_{k,2i}-L_{j,2i}+1)}\right)^{1/2}\\&\times\frac{(L_{0,2i}-L_{j,2i})(L_{0,2i}-L_{j,2i}+1)}{(L_{0,2i+1}-L_{j,2i})(L_{0,2i-1}-L_{j,2i})}|M\rangle_{(j,2i)},\quad i\in[1;n],\end{aligned}\tag{72}$$

$$\begin{aligned}E_{i,-i}|M\rangle&=(1+\psi_{2i-1})(1-\psi_{2i})\\&\times\frac{\prod_{k\neq 0=-i+1}^{i-1}(L_{0,2i+1}-L_{k,2i-1})\prod_{k\neq 0=-i}^{i}(L_{0,2i+1}-L_{k,2i+1})}{\prod_{k\neq 0=-i}^{i-1}(L_{0,2i+1}-L_{k,2i}-1)(L_{0,2i+1}-L_{k,2i})}|M\rangle_{-(0,2i)}\\&+\sum_{j\neq 0=-i}^{i-1}\left(-\frac{\prod_{k\neq 0=-i+1}^{i-1}(L_{k,2i-1}-L_{j,2i}-1)\prod_{k\neq 0=-i}^{i}(L_{k,2i+1}-L_{j,2i}-1)}{\prod_{k\neq 0,j;k=-i}^{i-1}(L_{k,2i}-L_{j,2i}-1)(L_{k,2i}-L_{j,2i})}\right)^{1/2}\\&\times|M\rangle_{-(j,2i)},\quad i\in[1;n],\end{aligned}\tag{73}$$

$$\begin{aligned}E_{-i,i-1}|M\rangle&=-\psi_{2i-2}\psi_{2i-1}\frac{\prod_{k\neq 0=-i+1}^{i-2}(L_{0,2i}-L_{k,2i-2})\prod_{k\neq 0=-i}^{i-1}(L_{0,2i}-L_{k,2i})}{\prod_{k\neq 0=-i+1}^{i-1}(L_{0,2i}-L_{k,2i-1})(L_{0,2i}-L_{k,2i-1}+1)}|M\rangle_{-(0,2i-1)}\\&+\sum_{j\neq 0=-i+1}^{i-1}\left(-\frac{\prod_{k\neq 0=-i+1}^{i-2}(L_{k,2i-2}-L_{j,2i-1})\prod_{k\neq 0=-i}^{i-1}(L_{k,2i}-L_{j,2i-1})}{\prod_{k\neq 0,j;k=-i+1}^{i-1}(L_{k,2i-1}-L_{j,2i-1}-1)(L_{k,2i-1}-L_{j,2i-1})}\right)^{1/2}\\&\times|M\rangle_{-(j,2i-1)},\quad i\in[2;n].\end{aligned}\tag{74}$$

We have written the transformation relations of the *C* basis under the action of generators, which are different from the $gl(n|1|n)$ Chevalley elements. These generators, however, define completely all other generators. In this sense Eqs. (68)–(74) are complete. We shall use them in order to derive the transformations of the $gl(\infty|1|\infty)$ irreducible modules under the action of the Chevalley generators.

Remark: We are thankful to the referee for pointing out that *Proposition 4* can be proved also without using the transformation relations (34)–(36). To this end note [see Eqs. (58) and (59)] that the $gl(k|1|k-1+\theta)$ highest weight vector $y_{2k+\theta}\equiv|m\rangle_{2k+\theta}\in V([m]_{2k+\theta})$ is determined from the requirement to be annihilated by the generators $\{\varphi(E_{-i,-i+1})|i\in[1;k]\}\cup\{\varphi(E_{i,i+1})|i\in[0;k-2+\theta]\}$, i.e., by $\{e_{2k,2k-2},e_{2k-2,2k-4},\dots,e_{42},e_{21},e_{13},e_{35},\dots,e_{2k+2\theta-3,2k+2\theta-1}\}$. The roots, corresponding to the above root vectors, namely

$$\hat{\pi}_{2k+\theta}=\{\epsilon^{2k}-\epsilon^{2k-2},\epsilon^{2k-2}-\epsilon^{2k-4},\dots,\epsilon^{4}-\epsilon^{2},\epsilon^{2}-\epsilon^{1},\epsilon^{1}-\epsilon^{3},\epsilon^{3}-\epsilon^{5},\dots,\epsilon^{2k+2\theta-3}-\epsilon^{2k+2\theta-1}\} \tag{75}$$

can be taken as a new system of simple roots of $gl(1|2k+\theta-1)$ with a system of positive roots $\hat{\Delta}_{+}^{2k+\theta}$.

Let $\Lambda_{2k+\theta}\equiv[m]_{2k+\theta}\equiv\Sigma_{i=1}^{2k+\theta}m_{i,2k+\theta}\epsilon^{i}$ be the standard signature (=the highest weight) of $V([m]_{2k+\theta})$, namely the signature corresponding to the choice of simple roots

$$\pi_{2k+\theta}=\{\epsilon^{1}-\epsilon^{2},\epsilon^{2}-\epsilon^{3},\dots,\epsilon^{2k-1+\theta}-\epsilon^{2k+\theta}\}. \tag{76}$$

Denote by $\Delta_{+}^{2k+\theta}$ the system of positive roots corresponding to it. The problem is to determine the signature (=the highest weight) $\hat{\Lambda}_{2k+\theta}$ of $V([m]_{2k+\theta})$ with respect to $\hat{\Delta}_{+}^{2k+\theta}$. This problem can be solved on the ground of results from Refs. 39 and 40. Given a subset of positive roots Δ'_{+} of $gl(1|2k+\theta-1)$ and a simple root $\alpha\in\Delta'_{+}$, one constructs a new system of positive roots Δ''_{+} by a simple α reflection $\langle\alpha\rangle$:[39,40]

$$\Delta''_{+}=\langle\alpha\rangle(\Delta'_{+})=\begin{cases} r_{\alpha}(\Delta'_{+}) & \text{if } \alpha \text{ is even}\\ (\Delta'_{+}\cup\{-\alpha\})\backslash\{\alpha\} & \text{if } \alpha \text{ is odd,}\end{cases} \tag{77}$$

where r_{α} is an element from the Weyl group of $gl(1|2k+\theta-1)$, corresponding to α.

If $V_{2k+\theta}$ is an essentially typical $gl(1|2k+\theta-1)$ module with a highest weight λ', corresponding to Δ'_{+}, then the highest weight with respect to Δ''_{+} is

$$\lambda''=r_{\alpha}(\lambda') \quad \text{if } \alpha \text{ is an even root,} \quad \lambda''=\lambda'-\alpha \quad \text{if } \alpha \text{ is an odd root.} \tag{78}$$

Let $\Pi_{i=1}^{N}\langle\alpha_i\rangle=\langle\alpha_1\rangle\langle\alpha_2\rangle\cdots\langle\alpha_N\rangle$. Then

$$\hat{\Delta}_{+}^{2k+\theta}=\prod_{i=1}^{k}\prod_{j=1}^{2i-1}\langle\epsilon_j-\epsilon_{2i}\rangle\Delta_{+}^{2k+\theta}. \tag{79}$$

From (77) to (79) one derives that

$$\hat{\Lambda}_{2k+\theta}=\sum_{j=2}^{k+1}(m_{j,2k+\theta}+1)\epsilon^{2k-2j+4}+(m_{1,2k+\theta}-k)\epsilon^{1}+\sum_{j=k+2}^{2k+\theta}m_{j,2k+\theta}\epsilon^{2j-2k-1}, \tag{80}$$

i.e.,

$$e_{2k-2i+4,2k-2i+4}|m\rangle_{2k+\theta}=(m_{i,2k+\theta}+1)|m\rangle_{2k+\theta}, \quad i\in[2;k+1], \tag{81a}$$

$$e_{11}|m\rangle_{2k+\theta}=(m_{1,2k+\theta}-k)|m\rangle_{2k+\theta}, \tag{81b}$$

$$e_{2i-2k-1,2i-2k-1}|m\rangle_{2k+\theta}=m_{i,2k+\theta}|m\rangle_{2k+\theta}, \quad i\in[k+2;2k+\theta]. \tag{81c}$$

Equations (81) are the same as (60) (written in somewhat different notation). Hence one obtains the $gl(k|1|k+\theta-1)$ signature as given in (61) and the highest weight $|m\rangle_{2k+\theta}$ corresponding to it (*Proposition 4*).

III. IRREDUCIBLE REPRESENTATIONS OF $gl(1|\infty)$

Here we construct representations of $gl_0(1|\infty)$ and $gl(\infty|1|\infty)$, which appear as a generalization to the case $n\to\infty$ of the results obtained in Sec. III. In both cases the representations (or the corresponding modules) are labeled with infinite sequences of (in general different) complex numbers. Due to the isomorphism φ [see (4)] each $gl_0(1|\infty)$ module is also a $gl(\infty|1|\infty)$ module and vice versa. Therefore we can also say that we describe below two classes of representations of the ''abstract'' Lie superalgebra $gl(1|\infty)$. For definiteness we refer to the class of representations of $gl_0(1|\infty)$ as the Gel'fand–Zetlin (GZ) representations (Sec. III A), whereas the representations of $gl(\infty|1|\infty)$ are said to be C representations.

A. Gel'fand–Zetlin representations

The extension of the results of Sec. II to the case $n\to\infty$ is rather evident. We collect the results in a proposition.

Proposition 6: To each sequence of complex numbers

$$[m]\equiv[m_1,m_2,\dots,m_k,\dots]\equiv\{m_i|m_i\in\mathbf{C},i\in\mathbf{N}\}, \tag{82}$$

such that

$$m_i-m_{i+1}\in\mathbf{Z}_+,\quad i=2,3,...,$$
$$l_1\notin\{l_2,l_2+1,l_2+2,...\}, \tag{83}$$

where

$$l_1=m_1+1,\quad l_i=-m_i+i-1,\quad i=2,3,..., \tag{84}$$

there corresponds an irreducible highest weight $gl_0(1|\infty)$ module $V([m])$ with a signature (82). The basis $\Gamma([m])$ in $V([m])$, which we call a GZ basis, consists of all tables

$$|m)\equiv\left[\begin{array}{ccccccc} m_1 & m_2 & \cdots & m_j & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \\ \cdots & \cdots & \cdots & \cdots & \cdots & & \\ m_{1j} & m_{2j} & \cdots & m_{jj} & & & \\ \cdots & \cdots & \cdots & & & & \\ \cdots & \cdots & \cdots & & & & \\ m_{12} & m_{22} & & & & & \\ m_{11} & & & & & & \end{array}\right]\equiv\left[\begin{array}{c}[m]\\ \vdots \\ [m]_j \\ \vdots \\ [m]_2 \\ m_{11}\end{array}\right], \tag{85}$$

characterized by an infinite number of coordinates

$$m_{ij},\quad \forall j\in\mathbf{N},\quad i=1,2,...,j, \tag{86}$$

which are consistent with the conditions:

(1) for each table $|m)$ there exists a positive (depending on $|m)$) integer $N[|m)]\in\mathbf{N}$ such that

$$m_{ij}=m_i,\quad \forall j>N[|m)],\quad i=1,...,j, \tag{87}$$

$$\text{(2)}\quad m_{1i}-m_{1,i-1}\equiv\theta_{i-1}\in\{0,1\},\quad i=2,3,..., \tag{88}$$

$$\text{(3)}\quad m_{i,j+1}-m_{ij}\in\mathbf{Z}_+,\quad m_{ij}-m_{i+1,j+1}\in\mathbf{Z}_+,\quad 2\le i\le j\in\mathbf{N}. \tag{89}$$

The transformation of the basis (85) is determined from the action of the Chevalley generators

$$e_{ii}|m)=\left(\sum_{k=1}^{i} m_{ki}-\sum_{k=1}^{i-1} m_{k,i-1}\right)|m), \quad i\in\mathbf{N}, \tag{90}$$

$$e_{12}|m)=\theta_1|m)_{11}, \quad e_{21}|m)=(1-\theta_1)(l_{12}-l_{22})|m)_{-(1,1)}, \tag{91}$$

$$\begin{aligned} e_{i,i+1}|m)=&\theta_i(1-\theta_{i-1})|m)_{(1i)}\\ &+\sum_{j=2}^{i}\left(-\frac{\Pi_{k=2}^{i-1}(l_{k,i-1}-l_{ji}+1)\Pi_{k=2}^{i+1}(l_{k,i+1}-l_{ji})}{\Pi_{k\neq j=2}^{i}(l_{ki}-l_{ji})(l_{ki}-l_{ji}+1)}\right)^{1/2}\\ &\times\frac{(l_{1i}-l_{ji})(l_{1i}-l_{ji}+1)}{(l_{1,i+1}-l_{ji})(l_{1,i-1}-l_{ji}+1)}|m)_{(ji)}, \quad i=2,3,..., \end{aligned} \tag{92}$$

$$\begin{aligned} e_{i+1,i}|m)=&\theta_{i-1}(1-\theta_i)\frac{\Pi_{k=2}^{i-1}(l_{1,i+1}-l_{k,i-1}-1)\Pi_{k=2}^{i+1}(l_{1,i+1}-l_{k,i+1})}{\Pi_{k=2}^{i}(l_{1,i+1}-l_{ki}-1)(l_{1,i+1}-l_{ki})}|m)_{-(1,i)}\\ &+\sum_{j=2}^{i}\left(-\frac{\Pi_{k=2}^{i-1}(l_{k,i-1}-l_{ji})\Pi_{k=2}^{i+1}(l_{k,i+1}-l_{ji}-1)}{\Pi_{k\neq j=2}^{i}(l_{ki}-l_{ji}-1)(l_{ki}-l_{ji})}\right)^{1/2}|m)_{-(ji)}, \quad i=2,3,.... \end{aligned} \tag{93}$$

The highest weight vector $|\hat{m})$ *is the one from (85) for which*

$$m_{ij}=m_i, \quad \forall j\in\mathbf{N}, \quad i\in 1,2,...,j. \tag{94}$$

Proof: Let

$$|m)\equiv\begin{bmatrix}[m]\\ \vdots\\ [m]_{N+1}\\ \vdots\\ [m]_2\\ m_{11}\end{bmatrix}\in\Gamma([m]). \tag{95}$$

Then

(i) $[m]_{N+1}\equiv[m_{1,N+1},m_{2,N+1},\dots,m_{N+1,N+1}]$, $N=1,2,...$, is said to be the $(N+1)$th signature of $|m)$;

(ii)

$$|m)^{\text{up}(N+1)}\equiv\begin{bmatrix}[m]\\ \vdots\\ [m]_j\\ \vdots\\ [m]_{N+2}\end{bmatrix}, \quad |m)^{\text{low}(N+1)}\equiv\begin{bmatrix}[m]_{N+1}\\ \vdots\\ [m]_i\\ \vdots\\ [m]_2\\ m_{11}\end{bmatrix} \tag{96}$$

are said to be the $(N+1)$th upper and the $(N+1)$th lower part of $|m)$, respectively. Consider the subalgebra

$$gl_0(1|N)=\{e_{ij}|i,j=1,...,N+1\}\subset gl_0(1|\infty). \tag{97}$$

Observation 1: Let e be a $gl_0(1|N)$ generator or any polynomial of $gl_0(1|N)$ generators. Then, for any $|m)\in\Gamma([m])$, $e|m)$ is a linear combination of vectors from $\Gamma([m])$ with one and same $(N+1)$th upper part $|m)^{\text{up}(N+1)}$.

Denote by

$$\Gamma([m]_i|i\geqslant N+1)\subset\Gamma([m]) \tag{98}$$

the set of all vectors (85), that have one and the same $[m]_i$ signatures, for all $i\geqslant N+1$. Let

$$V([m]_i|i\geqslant N+1)\subset V([m]) \tag{99}$$

be the linear span of $\Gamma([m]_i|i\geqslant N+1)$. From (90) to (93) it follows that $V([m]_i|i\geqslant N+1)$ is invariant with respect to $gl_0(1|N)$. To each vector $|m)\in\Gamma([m]_i|i\geqslant N+1)$ put in correspondence its $(N+1)$th lower part:

$$f(|m))=|m)^{\text{low}(N+1)},\quad \forall|m)\in\Gamma([m]_i|i\geqslant N+1). \tag{100}$$

Let

$$\Gamma([m]_{N+1})=\{f(|m))||m)\in\Gamma([m]_i|i\geqslant N+1)\}. \tag{101}$$

Then f maps bijectively $\Gamma([m]_i)|i\geqslant N+1)$ on $\Gamma([m]_{N+1})$. Obviously $\Gamma([m]_{N+1})$ consists of all GZ tables of an essentially typical $gl_0(1|N)$ module with a signature $[m]_{N+1}$. Define an action of $gl_0(1|N)$ on $|m)\in\Gamma([m]_{N+1})$ with the relations (33)–(36). Then the linear envelope $V([m]_{N+1})$ of $\Gamma([m]_{N+1})$ is an essentially typical $gl_0(1|N)$ module with a signature $[m]_{N+1}$. After comparing the relations (90)–(93) with (33)–(36) and having in mind *Observation 1* we have:

Observation 2: The subspace $V([m]_i|i\geqslant N+1)\subset V([m])$ is an essentially typical finite-dimensional $gl_0(1|N)$ module with a signature $[m]_{N+1}$ and a GZ basis $\Gamma([m]_i|i\geqslant N+1)$.

Let e_{ij},e_{kl} be any two generators from $gl_0(1|\infty)$ and $|m)$ be an arbitrary vector from $\Gamma([m])$. Consider e_{ij},e_{kl} as elements from $gl_0(1|N)\subset gl_0(1|\infty)$, where $N+1\geqslant\max(i,j,k,l)$. Then $|m)$ is a vector from the $gl_0(1|N)$ fidirmod $V([m]_i|i\geqslant N+1)\subset V([m])$ and therefore (*Observation 2*)

$$(e_{ij}e_{kl}-(-1)^{\deg(e_{ij})\deg(e_{kl})}e_{kl}e_{ij})|m)=(\delta_{jk}e_{il}-(-1)^{\deg(e_{ij})\deg(e_{kl})}\delta_{li}e_{kj})|m). \tag{102}$$

Therefore the linear space $V([m])$ is a $gl_0(1|\infty)$ module.

Consider any two vectors $x,y\in V([m])$,

$$x=\sum_{i=1}^{p}\alpha_i|m^i),\quad y=\sum_{i=p+1}^{q}\alpha_i|m^i),\quad |m^i)\in\Gamma([m]),$$

$$\alpha_i\in\mathbf{C},\quad i=1,...,q. \tag{103}$$

Let

$$\tilde{N}=\max\{N[|m^i)]|i=1,...,q\}. \tag{104}$$

According to (87) all vectors $|m^i)$, $i=1,...,q$, have one and the same $k-1$ signatures, for every $k-1\geqslant\tilde{N}$. Therefore $|m^i)\in V([m]_{k-1}|k-1\geqslant\tilde{N})\subset V([m])$. Hence $x,y\in V([m]_{k-1}|k-1\geqslant\tilde{N})$. The space $V([m]_{k-1}|k-1\geqslant\tilde{N})$ is a $gl_0(1|\tilde{N})$ fidirmod (*Observation 2*) and, therefore, there exist a polynomial P of the $gl_0(1|\tilde{N})$ generators such that $y=Px$. Hence $V([m])$ is an irreducible $gl_0(1|\infty)$ module.

Consider the vector $|\hat{m})\in\Gamma([m])$ [see (91)]. From Eqs. (90) to (93) we have

$$e_{ii}|\hat{m})=m_i|\hat{m}),\quad \forall i\in\mathbf{N}, \tag{105}$$

and

$$e_{k,k+1}|\hat{m})=0,\quad \forall k\in\mathbf{N}. \tag{106}$$

Therefore the irreducible $gl_0(1|\infty)$ module $V([m])$ is a highest weight module with a signature

$$[m] \equiv [m_1, m_2, \ldots, m_k, \ldots] \tag{107}$$

and a highest weight vector $|\hat{m})$. This completes the proof.

B. *C* representations

Most of the preliminary work for constructing the representations of $gl(\infty|1|\infty)$ was done in Sec. II B. It remains to give a precise definition of the C basis in the infinite-dimensional case and to write down the transformation of the basis under the action of the Chevalley generators.

Let

$$[M] \equiv [\ldots, M_{-p}, \ldots, M_{-1}, M_0, M_1, M_2, \ldots] \equiv \{M_i\}_{i\in\mathbf{Z}} \tag{108}$$

be a sequence of complex numbers such that

$$M_i - M_{i+1} \in \mathbf{Z}_+, \quad i \in [-\infty; -2] \cup [1; \infty], \tag{109a}$$

$$M_{-1} - M_1 \in \mathbf{N}, \tag{109b}$$

$$M_0 + M_1 \notin \mathbf{Z}. \tag{109c}$$

Here and throughout

$$[-\infty; a] = \{a, a-1, a-2, \ldots, a-i, \ldots\} \equiv \{a-i\}_{i\in\mathbf{Z}_+}, \tag{110}$$

$$[b; \infty] = \{b, b+1, b+2, \ldots, b+i, \ldots\} \equiv \{b+i\}_{i\in\mathbf{Z}_+}. \tag{111}$$

A table $|M)$, consisting of infinitely many complex numbers

$$M_{i,2k+\theta-1}, \quad \forall k \in \mathbf{N}, \quad \theta \in \{0,1\}, \quad i = [-k-\theta+1; k-1], \tag{112}$$

will be called a C table, provided the following conditions hold.

(1) There exists a positive, depending on $|M)$, integer $N[|M)]$ such that

$$M_{i,2k+\theta-1} = M_i, \quad \forall k > N[|M)], \quad \theta \in \{0,1\}, \quad i \in [1-\theta-k; k-1]. \tag{113}$$

(2) The coordinates $M_{i,2k+\theta-1}$, $\theta \in \{0,1\}$, take all possible values

$$M_{i,2k+1-2\theta} - M_{i,2k} \in \mathbf{Z}_+, \quad k \in [1+\theta; \infty], \quad i \in [-k+\theta; -1] \cup [1; k-1], \tag{114a}$$

$$M_{i-1,2k} - M_{i,2k+1-2\theta} \in \mathbf{Z}_+, \quad k \in [1+\theta; \infty], \quad i \in [-k+1; -1] \cup [2; k-\theta], \tag{114b}$$

$$M_{-1,2k} - M_{1,2k+1-2\theta} \in \mathbf{N}, \quad k \in [1+\theta; \infty], \tag{114c}$$

$$M_{0,2k+1-\theta} - M_{0,2k-\theta} \equiv \psi_{2k-\theta} \in \{0, 1-2\theta\}, \quad k \in [1; \infty]. \tag{114d}$$

Order the complex numbers $M_{i,2k+\theta-1}$, $k \in \mathbf{N}$, $\theta \in \{0,1\}$, as in the table below

$$|M)\equiv\left[\begin{array}{cccccccc} \cdots & M_{1-\theta-k} & \cdots & M_{-1} & M_0 & M_1 & \cdots & M_{k-1\cdots} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ & M_{1-\theta-k,2k+\theta-1} & \cdots & M_{-1,2k+\theta-1} & M_{0,2k+\theta-1} & M_{1,2k+\theta-1} & \cdots & M_{k-1,2k+\theta-1} \\ & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \\ & & & M_{-1,3} & M_{03} & M_{13} & & \\ & & & M_{-1,2} & M_{02} & & & \\ & & & & M_{01} & & & \end{array}\right]. \tag{115}$$

We are ready now to state our main and final result.

Proposition 7: To each sequence (108) [see also (109)] there corresponds an irreducible highest weight $gl(\infty|1|\infty)$ module $V([M])$ with a signature $[M]$. The basis $\Gamma([M])$ in $V([M])$ consists of all C tables (115). The transformations of the basis under the action of the $gl(\infty|1|\infty)$ Chevalley generators read:

$$E_{kk}|M)=\left(\sum_{i=-|k|}^{|k|+\theta(k)-1} M_{i,2|k|+\theta(k)}-\sum_{i=-|k|+1-\theta(k)}^{|k|-1} M_{i,2|k|+\theta(k)-1}\right)|M),\quad k\in\mathbf{Z}, \tag{116}$$

$$E_{0,-1}|M)=(1+\psi_1)|M)_{(01)}, \tag{117}$$

$$E_{-1,0}|M)=-\psi_1(L_{0,2}-L_{-1,2})|M)_{-(01)}, \tag{118}$$

$$\begin{aligned} E_{01}|M)=&-\psi_2(1+2\psi_1)|M)^{(01)}_{(0,2)}+(1+\psi_1)(-(L_{-1,3}-L_{-1,2})(L_{13}-L_{-1,2}))^{1/2}\\ &\times\frac{(L_{02}-L_{-1,2})(L_{02}-L_{-1,2}+1)}{(L_{03}-L_{-1,2})(L_{01}-L_{-1,2})(L_{01}-L_{-1,2}+1)}|M)^{(01)}_{(-1,2)}, \end{aligned} \tag{119}$$

$$\begin{aligned} E_{10}|M)=&-(-1)^{\psi_1}(1-\psi_2)\frac{(L_{02}-L_{-1,2}-\psi_1-1)(L_{03}-L_{-1,3})(L_{03}-L_{13})}{(L_{03}-L_{-1,2}-1)(L_{03}-L_{-1,2})}|M)^{-(01)}_{-(02)}\\ &-\psi_1(-(L_{-1,3}-L_{-1,2}-1)(L_{13}-L_{-1,2}-1))^{1/2}|M)^{-(01)}_{-(-1,2)}, \end{aligned} \tag{120}$$

$$\begin{aligned} E_{k,k+1}|M)=&-\psi_{2k+2}(1-\psi_{2k})(1+2\psi_{2k+1})|M)^{(0,2k+1)}_{(0,2k+2)}+\sum_{j\neq 0=-k}^{k}\psi_{2k+2}\psi_{2k+1}\\ &\times\left(-\frac{\Pi_{i\neq 0=-k}^{k-1}(L_{i,2k}-L_{j,2k+1}+1)\Pi_{i\neq 0=-k-1}^{k}(L_{i,2k+2}-L_{j,2k+1}+1)}{\Pi_{i\neq 0,j;i=-k}^{k}(L_{i,2k+1}-L_{j,2k+1})(L_{i,2k+1}-L_{j,2k+1}+1)}\right)^{1/2}\\ &\times\frac{(L_{0,2k+1}-L_{j,2k+1})(L_{0,2k+1}-L_{j,2k+1}+1)}{(L_{0,2k+2}-L_{j,2k+1}+2)(L_{0,2k+2}-L_{j,2k+1}+1)(L_{0,2k}-L_{j,2k+1}+1)}|M)^{(j,2k+1)}_{(0,2k+2)}\\ &+\sum_{j\neq 0=-k-1}^{k}(1+\psi_{2k+1})(1-\psi_{2k})\\ &\times\left(-\frac{\Pi_{i\neq 0=-k}^{k}(L_{i,2k+1}-L_{j,2k+2})\Pi_{i\neq 0=-k-1}^{k+1}(L_{i,2k+3}-L_{j,2k+2})}{\Pi_{i\neq 0,j;i=-k-1}^{k}(L_{i,2k+2}-L_{j,2k+2})(L_{i,2k+2}-L_{j,2k+2}+1)}\right)^{1/2} \end{aligned}$$

$$\times\frac{(L_{0,2k+2}-L_{j,2k+2})(L_{0,2k+2}-L_{j,2k+2}+1)}{(L_{0,2k+3}-L_{j,2k+2})(L_{0,2k+1}-L_{j,2k+2})(L_{0,2k+1}-L_{j,2k+2}+1)}|M)^{(0,2k+1)}_{(j,2k+2)}$$

$$+\sum_{l\neq 0=-k-1}^{k}\sum_{j\neq 0=-k}^{k}Q(j,l)$$

$$\times\left(-\frac{\Pi_{i\neq 0,j;i=-k}^{k}(L_{i,2k+1}-L_{l,2k+2})\Pi_{i\neq 0=-k-1}^{k+1}(L_{i,2k+3}-L_{l,2k+2})}{\Pi_{i\neq 0,l;i=-k-1}^{k}(L_{i,2k+2}-L_{l,2k+2})(L_{i,2k+2}-L_{l,2k+2}+1)}\right)^{1/2}$$

$$\times\left(\frac{\Pi_{i\neq 0=-k}^{k-1}(L_{i,2k}-L_{j,2k+1}+1)\Pi_{i\neq 0,l;i=-k-1}^{k}(L_{i,2k+2}-L_{j,2k+1}+1)}{\Pi_{i\neq 0,j;i=-k}^{k}(L_{i,2k+1}-L_{j,2k+1})(L_{i,2k+1}-L_{j,2k+1}+1)}\right)^{1/2}$$

$$\times\frac{(L_{0,2k+2}-L_{l,2k+2})(L_{0,2k+2}-L_{l,2k+2}+1)(L_{0,2k+1}-L_{j,2k+1})(L_{0,2k+1}-L_{j,2k+1}+1)}{(L_{0,2k+3}-L_{l,2k+2})(L_{0,2k+1}-L_{l,2k+2})(L_{0,2k+2}-L_{j,2k+1}+1)(L_{0,2k}-L_{j,2k+1}+1)}$$

$$\times|M)^{(j,2k+1)}_{(l,2k+2)},\quad k\in[1;\infty], \tag{121}$$

$$E_{-k+1,-k}|M)$$

$$=-(1+\psi_{2k-1})\psi_{2k-3}(1-2\psi_{2k-2})|M)^{(0,2k-2)}_{(0,2k-1)}-\sum_{j\neq 0=-k+1}^{k-2}(1+\psi_{2k-1})(1-\psi_{2k-2})$$

$$\times\left(-\frac{\Pi_{i\neq 0=-k+2}^{k-2}(L_{i,2k-3}-L_{j,2k-2})\Pi_{i\neq 0=-k+1}^{k-1}(L_{i,2k-1}-L_{j,2k-2})}{\Pi_{i\neq 0,j;i=-k+1}^{k-2}(L_{i,2k-2}-L_{j,2k-2})(L_{i,2k-2}-L_{j,2k-2}+1)}\right)^{1/2}$$

$$\times\frac{(L_{0,2k-2}-L_{j,2k-2})(L_{0,2k-2}-L_{j,2k-2}+1)}{(L_{0,2k-1}-L_{j,2k-2})(L_{0,2k-1}-L_{j,2k-2}+1)(L_{0,2k-3}-L_{j,2k-2})}|M)^{(j,2k-2)}_{(0,2k-1)}$$

$$-\sum_{j\neq 0=-k+1}^{k-1}\psi_{2k-2}\psi_{2k-3}$$

The above transformation relations (116)–(124) were derived first for $gl(n|1|n)$ from (68) to (74) and the supercommutation relations. Therefore they give a representation of $gl(n|1|n)$ for any n. An essential requirement, when passing to $n\to\infty$, is given with the condition (113). It is straightforward to check that $V([M])$ is invariant under the action of the generators. The rest of the proof, which we skip, is rather similar to that of Proposition 6, although technically it is more involved.

IV. CONCLUDING REMARKS

We have constructed two classes of highest weight irreps of the infinite-dimensional Lie superalgebra $gl(1|\infty)$. It should be noted that the GZ representations are inequivalent to the C representations. More than that: the C representations, being highest weight irreps of $gl(\infty|1|\infty)$, are not highest weight representations of $gl_0(1|\infty)$ and vice versa. Indeed, assume that the $gl_0(1|\infty)$ module $V([m])$ is also a highest weight $gl(\infty|1|\infty)$ module with a highest weight vector y. Then y has to be a highest weight vector of any of the subalgebras $gl(k|1|k-1+\theta)$. Hence Eqs. (54) and (55) have to hold for any $\theta=0,1,k\in[1-\theta;\infty]$. Therefore $y\notin V([m])$ [see (87)].

Our primary interest in the present investigation is related to its eventual applications in a generalization of the statistics in quantum field theory. From this point of view our results are, however, very preliminary. The first observation in this respect is that the algebra (for definiteness) $gl(\infty|1|\infty)$ is not large enough. It does not contain important physical observables [like the energy-momentum of the field P^m, see (8)], which are infinite linear combinations of the generators of $gl(\infty|1|\infty)$. In order to incorporate them one has to go to the completed central extension $a(\infty|1|\infty)$ of $gl(\infty|1|\infty)$ in a way similar to that for the Lie algebra gl_∞ (Ref. 41) or the Lie superalgebra $gl_{\infty|\infty}$.[20] This is only the first step. The next one will be to determine those $gl(\infty|1|\infty)$ modules $V([M])$, which can be extended to $a(\infty|1|\infty)$ modules.

The most important and perhaps the most difficult step will be to express the transformations of the $gl(\infty|1|\infty)$ modules in terms of natural for the QFT variables, namely via the creation and the annihilation operators $a_i^\pm$ of $gl(\infty|1|\infty)$, which are just its odd generators.[4] This is, however, not simple and, may not even be necessary in the general context of the representation theory. The physical state spaces, the Fock spaces, have to satisfy several additional physical requirements.[42] In particular any such space has to be generated from the vacuum (the highest weight vector) by polynomials of the creation operators, which are only a part of the negative root vectors. This imposes considerable restriction on the physically admissible modules. Hence in the applications one has to select first the Fock spaces from all $gl(\infty|1|\infty)$ modules and then study their transformation properties under the action of the physically relevant operators, in particular of the CAOs.

An additional problem is related to the circumstance that in QFT the indices of the CAOs are not elements form a countable set. Therefore as a test model one can try to consider first the $gl(\infty|1|\infty)$ statistics in the frame of a lattice quantum field theory or locking the field in a finite volume.

Generalized Lamé functions. I. The elliptic case

S. N. M. Ruijsenaars
Centre for Mathematics and Computer Science, P.O. Box 94079, 1090 GB Amsterdam, The Netherlands

(Received 24 April 1998; accepted for publication 17 September 1998)

We present and study a class of functions associated with the two-particle quantum relativistic Calogero–Moser system with elliptic interactions. The functions may be viewed as joint eigenfunctions of two independent commuting analytic difference operators, one of which is the defining quantum dynamics; The second one is obtained by interchanging the step size and the imaginary period. The functions depend on parameters that are dense in the natural parameter domain. In essence, they consist of products of Weierstrass σ-functions and plane waves. The zeros of the σ-functions satisfy a constraint system encoding both Schrödinger equations at once. © *1999 American Institute of Physics.* [S0022-2488(99)02402-0]

I. INTRODUCTION

This paper is concerned with eigenfunctions of an analytic difference operator generalizing the Lamé differential operator,

$$H_{\rm nr}=-\frac{d^2}{dx^2}+g(g-1)\wp(x), \tag{1.1}$$

where $\wp$ is the Weierstrass $\wp$-function. The pertinent analytic difference operator (henceforth AΔO) can be taken to be

$$H_{\rm rel}=\left(\frac{\sigma(x-i\beta g)}{\sigma(x)}\right)^{1/2}T_{i\beta}\left(\frac{\sigma(x+i\beta g)}{\sigma(x)}\right)^{1/2}+(\beta\to-\beta), \tag{1.2}$$

where σ is the Weierstrass σ-function. Here, the shift operator T_α is defined by

$$(T_\alpha f)(x)=f(x-\alpha),\quad \alpha\in\mathbb{C}, \tag{1.3}$$

so that one has

$$H_{\rm rel}=2+\beta^2H_{\rm nr}+O(\beta^4),\quad \beta\to 0. \tag{1.4}$$

The subscripts ''nr'' and ''rel'' in these formulas stand for ''nonrelativistic'' and ''relativistic.'' Indeed, the parameter β in the AΔO (1.2) may be viewed as $1/c$, with c the speed of light. Thus, (1.4) encodes the nonrelativistic limit $c\to\infty$; cf. Ref. 1.

In our survey paper, Ref. 2, and lecture notes, Ref. 3, we have announced and described $H_{\rm rel}$ eigenfunctions for integer coupling g. These functions generalize the $H_{\rm nr}$ eigenfunctions for integer g in the form presented on pp. 572–574 of Ref. 4. In this paper we shall not only elaborate on the $g=2,3,\ldots$ $H_{\rm rel}$ eigenfunctions from Subsection 6.3 in Ref. 3, but also obtain eigenfunctions for a dense set in the relevant parameter space. As we will detail, these functions are, in fact, *joint* eigenfunctions of *three* commuting independent AΔOs—a feature that generalizes symmetry properties of the hyperbolic specialization described in Subsection 6.3 of Ref. 3. (In the elliptic case, however, we were unable to find useful ''dual operators''—operators D acting on the spectral variable in the eigenfunctions in such a way that the latter are also D-eigenfunctions with x-dependent eigenvalues.)

In this paper we shall not dwell on the integrable system context in which the above operators arise. This setting is discussed at length in Refs. 2, 3, and is not necessary for understanding the following. On the other hand, the ancestry of the operators at issue makes itself felt in the aspects we emphasize: We are principally interested in real eigenvalues, and, more generally, in those features of the eigenfunctions that are important in promoting them to kernels of unitary operators that serve to redefine the AΔOs involved as bonafide self-adjoint Hilbert space operators. In this connection we recall that AΔOs have highly nonunique eigenfunctions (compared to differential and discrete difference operators), so that quite novel problems and features arise in their rigorous definition as quantum dynamics.

Next, we mention that a close relative S_0 of the AΔO $H_{\rm rel}$ was already introduced by Sklyanin,[5,6] together with AΔOs of a similar form. He obtained finite-dimensional representation spaces for the resulting AΔO algebra, spanned by very special eigenfunctions of S_0. General integer-g eigenfunctions of S_0 were recently presented in a related context by Krichever and Zabrodin.[7] (Roughly speaking, Sklyanin's functions correspond to eigenfunctions at the band edges in the finite-gap integration picture expounded in Ref. 7—a viewpoint that is far removed from our concerns in this paper.) For $g>2$ these functions have a rather different appearance from the eigenfunctions already detailed in Ref. 3.

Subsequent to Refs. 3 and 7, Felder and Varchenko obtained integer-g eigenfunctions in a form substantially equivalent to ours. They arrived at these eigenfunctions via their comprehensive study of representations of elliptic quantum groups, tying them in with the ''algebraic Bethe Ansatz'' of the Russian school, and with Baxter's work on the XYZ model. Their work—inasmuch as it concerns the operator $H_{\rm rel}$ and its eigenfunctions[8,9]—has a quite different perspective, emphasizing representation theoretic and algebro-geometric features. (See also a recent paper by Hasegawa[10] for yet another approach.)

Before summarizing our results, we would like to mention three forthcoming papers that are closely related to the present one. First, we point out that hyperbolic and trigonometric specializations are studied in a sequel to this paper.[11] In the latter regimes we can proceed much further, since a second, far more explicit representation of the relevant eigenfunctions exists. The results obtained in these special contexts also illuminate various issues pertaining to the elliptic regime, to which we restrict attention in this paper.

Second, the simplest nontrivial parameter choice $g=2$ will be reconsidered elsewhere.[12] This case admits an in-depth treatment that is independent of (and considerably simpler than) the present paper and its sequel. Moreover, as a striking feature of this special case we demonstrate that in a certain scaling limit its eigenfunctions give rise to the well-known eigenfunctions of the quantized nonlinear Schrödinger equation (alias the delta-function gas).

Third, our forthcoming conference contribution Ref. 13 reviews our findings regarding generalized Lamé functions and their specializations.

In order to sketch the results of the present paper, it is expedient to trade the Weierstrass σ-function $\sigma(z;\omega,\omega')$ for the function

$$s(r,a;z)\equiv\sigma\left(z;\frac{\pi}{2r},\frac{ia}{2}\right)\exp(-\eta z^2 r/\pi). \tag{1.5}$$

(Here and below, we use the elliptic function notation of Whittaker and Watson;[4] we also use some of the elliptic function lore collected in this reference.) The function $s(z)$ is an entire odd function with simple zeros in the lattice points $\mathbb{Z}\pi/r+i\mathbb{Z}a$. It is π/r-antiperiodic and obeys the analytic difference equation (henceforth AΔE)

$$\frac{s(z+ia/2)}{s(z-ia/2)}=-\exp(-2irz). \tag{1.6}$$

Moreover, it satisfies

$$\lim_{a\to\infty} s(r,a;z) = \frac{\sin rz}{r} \quad \text{(uniformly on compacts)}, \tag{1.7}$$

$$\lim_{r\to 0} s(r,a;z) = \frac{\sinh \pi z/a}{\pi/a} \quad \text{(uniformly on compacts)}, \tag{1.8}$$

and the scaling relation

$$s(r/\lambda,\lambda a;\lambda z) = \lambda s(r,a;z). \tag{1.9}$$

For later use we also note that iteration of the AΔE (1.6) yields

$$\frac{s(r,a;z+iLa)}{s(r,a;z)} = (-)^L \exp(arL^2 - 2irLz), \quad L \in \mathbb{Z}. \tag{1.10}$$

As a matter of fact, we have occasion to use two s-functions,

$$s_\delta(z) \equiv s(r,a_\delta;z), \quad \delta = +,-. \tag{1.11}$$

This is because the functions we define and study are actually joint eigenfunctions of the two AΔOs

$$H_\delta \equiv e^{-br}\left(\frac{s_\delta(x-ib)}{s_\delta(x)}\right)^{1/2} T_{ia_{-\delta}}\left(\frac{s_\delta(x+ib)}{s_\delta(x)}\right)^{1/2} + (i\to -i), \quad \delta = +,-. \tag{1.12}$$

In view of (1.5), each of these may be regarded as a multiple of the AΔO $H_{\rm rel}$ (1.2) when one sets $b = a_{-\delta}g$. The constant up front is chosen such that we have the symmetry property

$$H_\delta(a_+,a_-,b) = H_\delta(a_+,a_-,a_+ + a_- - b). \tag{1.13}$$

[Use (1.6) to verify this.] Here and below, it is understood that the parameters belong to the elliptic parameter domain

$$\mathcal{E} \equiv \{(r,a_+,a_-,b) \mid r,a_+,a_- > 0, b \in \mathbb{R}\}. \tag{1.14}$$

We begin by transforming H_δ to the form

$$A_\delta = e^{-br}\frac{s_\delta(x-ib)}{s_\delta(x)} T_{ia_{-\delta}} + (i\to -i), \quad \delta = +,-, \tag{1.15}$$

where

$$A_\delta \equiv w(x)^{-1/2} H_\delta w(x)^{1/2}. \tag{1.16}$$

The weight function $w(r,a_+,a_-,b;x)$ occurring here was introduced and studied in Ref. 14. It is a meromorphic solution to the two AΔEs

$$\frac{w(x+ia_\delta/2)}{w(x-ia_\delta/2)} = \frac{s_{-\delta}(x+ib-ia_\delta/2)}{s_{-\delta}(x-ib+ia_\delta/2)} \cdot \frac{s_{-\delta}(x+ia_\delta/2)}{s_{-\delta}(x-ia_\delta/2)}, \quad \delta = +,-, \tag{1.17}$$

which is why (1.16) entails (1.15).

The point of the similarity transformation (1.16) is that the AΔOs A_δ (1.15) have meromorphic coefficients. Thus, we may and will view them first as linear operators leaving the vector space

$$\mathcal{M} \equiv \{F(x) \mid F \ \text{meromorphic}\} \tag{1.18}$$

invariant. (We shall discuss Hilbert space aspects shortly.) In view of the AΔE (1.6), the maps $A_+, A_-: \mathcal{M} \to \mathcal{M}$ commute. Now at this point it should be emphasized that there are a great many functionally independent AΔOs commuting with A_+. (For instance, when one multiplies the two coefficients of A_- by distinct meromorphic functions with period ia_-, one obtains an AΔO that also commutes with A_+.) However, we are not aware of any general arguments guaranteeing the existence of nontrivial joint eigenspaces for A_+ and an independent AΔO in its commutant.

Even so, we have found two linearly independent joint eigenfunctions $\Psi(\pm x, y)$ of the $(a_+ \leftrightarrow a_-)$-symmetric pair (A_+, A_-), provided the parameters belong to a dense subset $\mathcal{D}$ of the parameter space $\mathcal{E}$ (1.14). (Note both AΔOs commute with parity.) The spectral variable y takes values in an interval (K, ∞), where K depends on the parameters. The eigenvalues E_+ and E_- are real-valued, real-analytic functions, satisfying

$$E_\delta(y) \sim \exp(a_{-\delta} y), \quad E'_\delta(y) \sim a_{-\delta} \exp(a_{-\delta} y), \quad \delta = +, -, \quad y \to \infty, \tag{1.19}$$

and separating points on (K, ∞):

$$K < y_1 < y_2 \Rightarrow (E_+(y_1), E_-(y_1)) \neq (E_+(y_2), E_-(y_2)). \tag{1.20}$$

The dense subset $\mathcal{D}$ is defined by (3.33)–(3.35) below. For expository simplicity, however, we shall summarize our results for a subset of $\mathcal{D}$, namely,

$$\mathcal{D}_{\text{irr}} \equiv \{(r, a_+, a_-, (N_+ + 1)a_+ - N_- a_-) \in \mathcal{E} | a_+/a_- \notin \mathbb{Q}, N_+, N_- \in \mathbb{N}\}. \tag{1.21}$$

Since the b-values allowed here are dense in $\mathbb{R}$ for a_+/a_- irrational, $\mathcal{D}_{\text{irr}}$ is already dense in $\mathcal{E}$.

Fixing $(r, a_+, a_-, b) \in \mathcal{D}_{\text{irr}}$, any joint eigenfunction of A_+ and A_- with eigenvalues $E_+(y)$ and $E_-(y)$, resp., is a linear combination of $\Psi(x, y)$ and $\Psi(-x, y)$. [More precisely, we prove that this holds true for all sufficiently large y; cf. Appendix B.] The latter are explicitly given by

$$\Psi(x, y) = \mathcal{N} \prod_{j=-N_+}^{N_+} \frac{1}{s_-(x + ija_+)} \cdot \prod_{\delta=+,-} \prod_{j=1}^{N_\delta} s_{-\delta}(x + z_j^\delta(y))$$
$$\times \exp[irx(2N_+N_- + N_+ + N_- + 1) + ixy], \quad y \in (K, \infty). \tag{1.22}$$

The normalizing factor $\mathcal{N}$ depends on the parameters, but not on x and y. The ''zero functions'' $z_1^+, \ldots, z_{N_+}^+$ and $z_1^-, \ldots, z_{N_-}^-$ are functions from (K, ∞) to $i(0, \infty)$ that are real-analytic and such that

$$\lim_{y \to \infty} z_j^\delta(y) = ija_\delta, \quad j = 1, \ldots, N_\delta, \quad \delta = +, -. \tag{1.23}$$

These functions are determined as solutions to a certain constraint system. This system depends on the parameters in a quite complicated fashion, and for brevity we do not describe it here. [It is given by (3.5), (3.10), and (3.11); cf. also Appendix A.]

In view of (1.23), the function $\Psi(x, y)$ has asymptotics

$$\Psi(x, y) \sim c(x) \exp(ixy), \quad y \to \infty. \tag{1.24}$$

Here, the c-function reads

$$c(r, a_+, a_-, (N_+ + 1)a_+ - N_- a_-; x) = \mathcal{N} \frac{\prod_{k=1}^{N_-} s_+(x + ika_-)}{\prod_{j=0}^{N_+} s_-(x - ija_+)} \exp irx(2N_+N_- + N_+ + N_- + 1). \tag{1.25}$$

It is not obvious, but true, that the normalization constant $\mathcal{N}$ can be chosen such that

$$c(r,a_+,a_-,b;x)=\frac{G(r,a_+,a_-;x-ib+i(a_++a_-)/2)}{G(r,a_+,a_-;x+i(a_++a_-)/2)}, \tag{1.26}$$

for parameters in $\mathcal{E}$ (1.14). Here, the function $G(r,a_+,a_-;z)$ is the generalized elliptic gamma function from Ref. 14, which is meromorphic in r, a_+, a_-, and z as long as a_+r and a_-r stay in the right half plane. The weight and scattering functions introduced in Ref. 14 can be written as

$$w(x)=\frac{1}{c(x)c(-x)}, \tag{1.27}$$

$$u(x)=-\exp(-2irx)\frac{c(x)}{c(-x)}. \tag{1.28}$$

[This easily follows from their definition in terms of the G-function; to check (1.28) one also needs the defining AΔEs of the latter; cf. Proposition III.8 in Ref. 14.] Thus, the joint eigenfunction

$$\mathcal{F}(x,y)=w(x)^{1/2}\Psi(x,y) \tag{1.29}$$

of the AΔOs H_+ and H_- has plane wave asymptotics

$$\mathcal{F}(x,y)\sim w(x)^{1/2}c(x)\exp(ixy)=[-\exp(2irx)u(x)]^{1/2}\exp(ixy), \quad y\to\infty. \tag{1.30}$$

The obvious question arising from these results is now the following: Are there meromorphic joint eigenfunctions $\Psi(x,y)$ for *arbitrary* parameters in $\mathcal{E}$ (1.14) that depend continuously on the parameters and are proportional to $\Psi(x,y)$ (1.22) for parameters in $\mathcal{D}_{\mathrm{irr}}$? (Since $\mathcal{D}_{\mathrm{irr}}$ is dense in $\mathcal{E}$, such an interpolation is unique up to scale factors depending on y and the parameters.) The point is that the same question has an affirmative answer for the c-function, as we have just seen.

The answer to the joint eigenfunction question, however, may well be ''No.'' To see why, one need only note that when a sequence $(r,a_{+,n},a_{-,n},b_n)\in\mathcal{D}_{\mathrm{irr}}$ converges to a point in $\mathcal{E}$, then the integers $N_{\delta,n}$ [cf. (1.21)] typically go to ∞. Thus, the poles of $\Psi(x,y)$ due to the first product in (1.22) become *dense* on the lines $\mathrm{Re}\,x=k\pi/r, k\in\mathbb{Z}$.

From this perspective our next result is quite surprising. To state it, we introduce the even function,

$$\chi(x,y)\equiv\Psi(x,y)+\Psi(-x,y). \tag{1.31}$$

Now consider a rectangle $|\mathrm{Re}\,x|<\pi/r, |\mathrm{Im}\,x|<L$. Fixing a_+, a_-, and a compact b-interval I, the number of poles of $\Psi(x,y)$ in the rectangle can be made arbitrarily large by choosing suitable $b\in I$; cf. the previous paragraph. By contrast, the number of poles of $\chi(x,y)$ in the rectangle is bounded above by a finite number that depends only on L and I!

To explain why this is true, we write

$$\chi(x,y)=\mathcal{N}\prod_{j=-N_+}^{N_+}\frac{1}{s_-(x+ija_+)}[\mathcal{H}(x,y)-\mathcal{H}(-x,y)], \tag{1.32}$$

where $\mathcal{H}$ is the holomorphic function

$$\mathcal{H}(x,y)\equiv\prod_{\delta=+,-}\prod_{j=1}^{N_\delta}s_{-\delta}(x+z_j^\delta(y))\cdot\exp[irx(2N_+N_-+N_++N_-+1)+ixy]. \tag{1.33}$$

The crux is now that one has the identities

$$\mathcal{H}(ik_+a_+ + ik_-a_-, y) = \mathcal{H}(-ik_+a_+ - ik_-a_-, y), \quad k_\delta \in \{-N_\delta, \ldots, 0, \ldots, N_\delta\}, \quad \delta = +, -. \tag{1.34}$$

Thus, poles of $\chi(x,y)$ on the imaginary axis can only occur for

$$x = ik_+a_+ + ik_-a_-, \quad k_+ \in \{-N_+, \ldots, 0, \ldots, N_+\}, \quad |k_-| > N_-, \tag{1.35}$$

and so the assertion in the previous paragraph readily follows.

Now it is clear from (1.22) that we have

$$\Psi(x \pm \pi/r, y) = \exp(\pm i\pi y/r)\Psi(x,y). \tag{1.36}$$

Thus, $\Psi(x,y)$ is π/r-periodic or π/r-antiperiodic when y/r is an integer. Defining

$$\chi_n(x) \equiv \chi(x, nr), \quad nr > K, \quad n \in \mathbb{N}, \tag{1.37}$$

we therefore obtain a function that is π/r-periodic/antiperiodic for n even/odd.

As a consequence, there is no apparent obstruction to the existence of a meromorphic interpolation for the functions $\chi_n(x)$. However, if an explicit representation for an interpolation exists, it is most likely vastly different from (1.22). Indeed, this is the case for the hyperbolic specialization, where we have found an interpolation in terms of a natural generalization of Euler's hypergeometric function; cf. Ref. 3 and papers to appear.

Before turning to orthogonality issues, we point out a consequence of the quasi-periodicity relations (1.36) that is of interest in itself, and that will be invoked later on. Recalling (1.3), we can rephrase (1.36) by saying that $\Psi(x,y)$ is an eigenfunction of the AΔOs $T_{\pm\pi/r}$. Now this is true for $\Psi(-x,y)$, too, but then we obtain different eigenvalues. On the other hand, when we introduce the ''quasi-periodicity AΔO,''

$$Q \equiv T_{\pi/r} + T_{-\pi/r}, \tag{1.38}$$

then we obtain

$$(Q\Psi)(\pm x, y) = E_Q \Psi(\pm x, y), \quad E_Q \equiv 2\cos(\pi y/r). \tag{1.39}$$

Thus, as already mentioned above, the functions $\Psi(\pm x,y)$ are, in fact, joint eigenfunctions of three commuting independent AΔOs A_+, A_-, and Q.

Next, we describe results concerning orthogonality of the functions

$$\Phi_n(x) \equiv w(x)^{1/2}\chi_n(x), \quad nr > K, \quad n \in \mathbb{N}, \quad x \in (0, \pi/r), \tag{1.40}$$

in the Hilbert space $L^2((0,\pi/r),dx)$. The weight function $w(x)$ is given by

$$w(r, a_+, a_-, (N_+ + 1)a_+ - N_-a_-; x) = (-)^{N_+ + N_- + 1}\mathcal{N}^{-2} s_-(x)^2 \frac{\prod_{\pm j=1}^{N_+} s_-(x - ija_+)}{\prod_{\pm k=1}^{N_-} s_+(x - ika_-)}; \tag{1.41}$$

cf. (1.25) and (1.27). It is non-negative for real x, and we take the positive square root in (1.40). Then the function $w(x)^{1/2}, x \in (0,\pi/r)$, has an analytic continuation to an odd, π/r-antiperiodic function that has no singularities for real x. The factor $s_-(x)$ in the latter function cancels the factor $1/s_-(x)$ in (1.22), and the remaining poles do not meet the real axis (since a_+/a_- is irrational). Hence $\Phi_n(x)$ (1.40) extends to an odd function without singularities for real x, which is π/r-periodic/-antiperiodic for n odd/even.

As a consequence, the functions $\Phi_n(x)$ are square-integrable on $(0,\pi/r)$. One of the principal results of this paper is now that these functions are *pairwise orthogonal*, provided the parameters belong to the region

$$\mathcal{C} \equiv \{(r,a_+,a_-,b) \in \mathcal{E} | 0 < b < a_+ + a_-\}. \tag{1.42}$$

To provide more perspective on this parameter restriction, we mention that $\mathcal{C}$ coincides with the parameter region for which the u-function has winding number 0 as x goes from 0 to π/r. Correspondingly, its logarithm has a rapidly convergent Fourier series. To be specific, we have [cf. Ref. 14 (4.87)]

$$u(r,a_+,a_-,b;x;.) = \exp\left(2i \sum_{j=1}^{\infty} \frac{\sinh(a_+ - b)nr \sinh(a_- - b)nr}{n \sinh a_+ nr \sinh a_- nr} \sin 2nrx \right). \tag{1.43}$$

For convergence of the series one needs $|\mathrm{Im}\, x| < d/2$, with

$$d \equiv a_+ + a_- - |a_+ - b| - |a_- - b|. \tag{1.44}$$

Thus, one gets $d > 0$ iff the parameters belong to $\mathcal{C}$ (1.42). [Note that (1.43) exhibits symmetry under $a_+ \leftrightarrow a_-$ and $b \to a_+ + a_- - b$.]

Provided the parameters belong to $\mathcal{C}$, the w-function admits a similar representation. It is expedient to write, first of all,

$$w(r,a_+,a_-,b;x) = C^2 s_-(x) s_+(x) w_r(x). \tag{1.45}$$

Here we have introduced the reduced weight function w_r, and the positive constant C reads

$$C(r,a_+,a_-) = 2r \prod_{k=1}^{\infty} [1 - \exp(-2kra_+)][a_+ \to a_-]; \tag{1.46}$$

cf. Ref. 14 (5.41). Then one has, from Ref. 14 (5.54),

$$w_r(r,a_+,a_-,b;x) = \exp\left(\sum_{j=1}^{\infty} \frac{\sinh(a_+ + a_- - 2b)nr}{n \sinh a_+ nr \sinh a_- nr} \cos 2nrx \right). \tag{1.47}$$

Just as for (1.43), the series converges in a strip containing the real axis iff the parameters belong to $\mathcal{C}$. (Note the strip width is larger than for the u-function when $a_+ < b < a_-$, say. Note also that w is symmetric under $a_+ \leftrightarrow a_-$, but not under $b \to a_+ + a_- - b$.)

Returning now to the Hilbert space $L^2((0,\pi/r),dx)$, we continue by pointing out that the restriction to $\mathcal{C}$ appears to be essential: For parameters outside $\mathcal{C}$, orthogonality is most likely violated, in general. Whenever this is the case, there exists no reinterpretation of the AΔOs H_δ (1.12) as symmetric Hilbert space operators whose domains include the eigenfunctions Φ_n and whose action equals the obvious one.

By contrast, when we restrict the parameters to $\mathcal{C}$, then we obtain self-adjoint operators (denoted again H_+, H_-) on the closed subspace

$$\mathcal{H}_1(K) \subset \mathcal{H}_1 \equiv L^2((0,\pi/r),dx), \tag{1.48}$$

spanned by the functions $\Phi_n, n > K/r$, by proceeding in the obvious way: We define

$$H_\delta \Phi_n \equiv E_\delta(nr) \Phi_n, \quad n > K/r, \quad \delta = +,-, \tag{1.49}$$

extend linearly, and then take the closure. Save for some special cases, we have not been able to prove our expectation that the orthocomplement of $\mathcal{H}_1(K)$ is spanned by joint eigenfunctions $\Phi_n, n = 0,1,\ldots,[K/r]$, of the AΔOs H_δ with real eigenvalues $E_\delta(nr)$.

The functional-analytic problems involved in the above were discussed already in Refs. 2, 3; briefly, the Hilbert space theory of analytic difference operators (as opposed to *discrete* difference operators) is virtually nonexistent. Indeed, from the concrete examples we study here and elsewhere it is likely that no straightforward generalization of the standard lore concerning self-adjointness and eigenfunction expansions for ordinary differential operators exists. Roughly speaking, our strategy is instead to exploit the properties of the explicit eigenfunctions to solve the orthogonality and self-adjointness problems simultaneously—with the above restrictions and provisos, however.

The results surveyed above are detailed in Secs. II–IV. Specifically, in Sec. II we restrict attention to the case $b=ga_+, g=2,3,\ldots,$ which we already briefly considered at the end of our lecture notes.[3] In this special case we need only appeal to the constraint system studied in Appendix A. This case has several other distinctive features compared to the general case. In particular, the ''nonrelativistic limit'' $a_+\downarrow 0$ can be handled, which gives rise to the integer g eigenfunctions of the Lamé operator (1.1).

The general case studied in Sec. III is more involved. Roughly speaking, we wind up with two constraint systems of the type studied in Appendix A: one corresponding to N_+ and the other to N_-; these two systems are coupled via the spectral variable y. In this way we can handle a dense subset $\mathcal{D}$ of $\mathcal{E}$ (1.14) [which contains (1.21)], but our knowledge about the analytic properties of the eigenfunctions neither suffices to deduce the existence of an interpolation (as discussed above) nor enables us to say anything about the eigenfunctions of the Lamé operator for g not equal to an integer. [Observe that the latter can be *formally* obtained already via sequences in $D_{\rm irr}$ (1.21). Since N_+ and/or N_- must go to ∞ in this limit, we are losing control of the eigenfunction limit, however.]

Section IV is mainly devoted to a study of self-adjointness and orthogonality questions. The principal results have already been summarized above. Here we add that we find it convenient to perform a second similarity transformation to AΔOs B_+ and B_- whose structure is quite close to those of the AΔOs A_+ and A_- given by (1.15). By contrast to the similarity (1.16), however, this second similarity does not admit an interpolation to all of the elliptic parameter domain $\mathcal{E}$ (1.14). Even so, A_δ and B_δ are sufficiently close to enable us to enlarge the parameter set for which joint (A_+,A_-)-eigenfunctions [and hence (H_+,H_-)-eigenfunctions] can be found. The pertinent enlargement is somewhat involved; furthermore, the relation between A_δ and B_δ may be quite confusing on the first acquaintance. The last part of Sec. IV, where we detail the extension, can be more easily understood for the hyperbolic specialization; cf. Ref. 11.

In Appendix A we handle the constraint system associated with the zero representation when one of the integers N_+,N_- vanishes. More precisely, we study a more general system that exhibits most (but not all) of the relevant features of the former system.

In Appendix B we first collect some results on second order analytic difference equations, associated with the notion of a Casorati determinant. These well-known results are used to prove Theorem B.1. Roughly speaking, this theorem says that the meromorphic functions $\Psi(\pm x,y)$ are a basis for the joint A_δ-eigenspace, provided the quotient a_+/a_- is irrational and the spectral variable y is large enough. [In fact, we work with the similarity transforms B_δ and their holomorphic eigenfunctions $\mathcal{H}(\pm x,y)$.]

II. EIGENFUNCTIONS FOR THE INTEGER-*g* CASE

In this section we choose

$$g=N+1=2,3,\ldots, \tag{2.1}$$

in the AΔO $H_{\rm rel}$ (1.2), and accordingly obtain eigenfunctions reducing to the Lamé functions for $\beta\to 0$. [Pushing the shifts to the right in (1.2), one sees that the $g=1$ case is trivial, just as for $H_{\rm nr}$ (1.1).] To ease the notation in this section, it is convenient to trade the parameters a_+, a_-, and b in the AΔOs (1.12)–(1.16) for

$$a_+=-iv, \quad a_-=a, \quad b=-i(N+1)v, \tag{2.2}$$

and to work with suitable positive multiples of the AΔOs (1.15).

Specifically, we start from the A_--multiple

$$A\equiv \frac{s(x-(N+1)v)}{s(x)}T_v+(v\rightarrow -v),\quad s(x)\equiv s(r,a;x), \tag{2.3}$$

and at first restrict v by requiring

$$2Nv\in i(0,a). \tag{2.4}$$

Substituting (2.2) in (1.22), we obtain (note $N_-=0$)

$$\Psi(x,y)=\mathcal{N}\prod_{j=-N}^{N}\frac{1}{s(x+jv)}\cdot\prod_{j=1}^{N}s(x+z_j(y))\cdot\exp(x\Sigma), \tag{2.5}$$

with

$$\Sigma\equiv ir(N+1)+iy. \tag{2.6}$$

In the hyperbolic case $(r=0)$ the existence of eigenfunctions of this form can be deduced for arbitrary y. This is because a second far more explicit form of the eigenfunctions exists in that case (cf. Ref. 2 and Sec. II in Ref. 11), from which the existence of the factorized representation (2.5) is readily deduced.

Staying with the elliptic case, one may view (2.5) as an Ansatz for the eigenvalue equation $A\Psi=E\Psi$. Doing so, one readily verifies the identity

$$\Psi(x,y)^{-1}(A\Psi)(x,y)=E(\Sigma,z_1,\ldots,z_N;x), \tag{2.7}$$

where

$$E\equiv\frac{1}{s(x)}\left(s(x+Nv)e^{-v\Sigma}\prod_{j=1}^{N}\frac{s(x-v+z_j)}{s(x+z_j)}+(v\rightarrow -v)\right). \tag{2.8}$$

Obviously, the function E is elliptic in x with periods $\pi/r,ia$, independently of the choice of $\Sigma,z_1,\ldots,z_N\in\mathbb{C}$. Choosing from now on the numbers $z_1,\ldots,z_N$ pairwise incongruent and incongruent to 0 (modulo the period lattice), the two summands of E have simple poles at $x\equiv 0$, $-z_1,\ldots,-z_N$.

As a consequence, we obtain an eigenfunction whenever the residues at all of these poles cancel. (Indeed, this entails that E is constant.) Now for $x=0$ we need

$$e^{-v\Sigma}\prod_{j=1}^{N}s(-v+z_j)-(v\rightarrow -v)=0, \tag{2.9}$$

so that we must have

$$\Sigma=\frac{1}{2v}\ln\left(\prod_{j=1}^{N}\frac{s(z_j-v)}{s(z_j+v)}\right). \tag{2.10}$$

Substituting this in (2.8), we now study whether the residues at $x=-z_k$ can be made to cancel. For this we clearly need

$$s(z_k-Nv)\prod_{\substack{j=1\\ j\neq k}}^{N}s(z_j-z_k-v)\prod_{j=1}^{N}s(z_j+v)-(v\rightarrow -v)=0, \tag{2.11}$$

where $k=1,\ldots,N$.

The system (2.11) of N equations for N unknowns $z_1,\dots,z_N$ is a special case of the constraint system mentioned in Sec. I. Introducing the function

$$f(w)=s(vw)/v, \quad s(z)\equiv s(r,a;z), \tag{2.12}$$

it can be rewritten as a concrete form of the system (A2)–(A3) studied in Appendix A. Thus we obtain solutions

$$z_1=v+tv, \quad z_l=lv+O(t^2), \quad dz_l/dt=O(t), \quad l=2,\dots,N, \quad t\to 0, \tag{2.13}$$

to the equations (2.11) with $k=2,\dots,N$.

Now for a general function $f(w)$ it would not follow that the solution (A8) to the system (A7) also solves the larger system (A3). Due to the ancestry of the special case (2.12) of the system, however, we may deduce that one also has $F_1(W(t))=0$. Indeed, inserting (2.13) and (2.10) in the elliptic function $E(\Sigma,z_1,\dots,z_N;x)$, we obtain vanishing residues at $x\equiv 0,-z_2,\dots,-z_N$, so the residues at $x\equiv -z_1$ must vanish, too. (Recall that a nonconstant elliptic function must have more than one pole in a period cell.)

Consequently, the system (2.11) with $k=1,\dots,N$ admits a holomorphic solution curve $z_1(t),\dots,z_N(t)$ of the form (2.13) for t near 0. Moreover, we may and will choose $\epsilon>0$ small enough so that we have

$$z_j(t)\in i(0,\infty), \quad s(z_j(t)\pm v)\neq 0, \quad s(z_j(t)+Nv)\neq 0, \quad j=1,\dots,N, \tag{2.14}$$

for all $t\in(0,\epsilon)$. This ensures that

$$y(t)=-(N+1)r-\frac{i}{2v}\ln\left(\prod_{j=1}^{N}\frac{s(z_j(t)-v)}{s(z_j(t)+v)}\right) \tag{2.15}$$

is a real-valued, real-analytic function on $(0,\epsilon)$. Moreover, since the function E (2.8) is x-independent, we may choose $x=Nv$, yielding

$$E=\mu\exp(-irv(N+1)-iyv), \quad \mu\equiv\frac{s(2Nv)}{s(Nv)}\prod_{j=1}^{N}\frac{s((N-1)v+z_j)}{s(Nv+z_j)}. \tag{2.16}$$

Clearly, $\mu(t)$ is holomorphic at $t=0$ and satisfies

$$\mu(t)=1+tv\left(\frac{s'(Nv)}{s(Nv)}-\frac{s'((N+1)v)}{s((N+1)v)}\right)+O(t^2), \quad t\to 0. \tag{2.17}$$

Next, we observe that $y'(t)$ is analytic in a neighborhood of $t=0$ but for a simple pole at the origin [cf. (2.15)]:

$$y'(t)=-\frac{i}{2vt}+O(1), \quad t\to 0. \tag{2.18}$$

Eventually decreasing ϵ, we can therefore ensure

$$y'(t)<0, \quad t\in(0,\epsilon). \tag{2.19}$$

Then y decreases monotonically from ∞ to $L_\epsilon-N-1\equiv K$ as t goes from 0 to ϵ. Thus we may and will trade the parameter t for y.

To proceed, we observe that we have

$$\frac{d}{dy}\mu(t(y))=\mu'(t)(y'(t))^{-1}\to 0, \quad y\to\infty; \tag{2.20}$$

cf. (2.17) and (2.18). In view of (2.16), this entails

$$\frac{d}{dy}E\sim -iv\exp(-irv(N+1)-iyv),\quad y\to\infty. \tag{2.21}$$

(Recall that $f\sim g$ stands for $f/g\to 1$.) To obtain the asymptotics of $E=E(y)$, we note that (2.15) yields

$$y(t)=-(N+1)r-\frac{i}{2v}\ln\left(\frac{tvs(v)}{s(Nv)s((N+1)v)}\right)+O(t),\quad t\to 0. \tag{2.22}$$

Combining this with (2.16) and (2.17), we readily deduce

$$E=\exp(-ivr(N+1)-ivy)+c_N\exp(ivr(N+1)+ivy)+O(\exp(3ivy)),\quad y\to\infty, \tag{2.23}$$

with

$$c_N\equiv[s'(Nv)s((N+1)v)-s'((N+1)v)s(Nv)]/s(v). \tag{2.24}$$

The results obtained thus far hold true when v satisfies (2.4). Indeed, this restriction guarantees first of all that the hypothesis (A6) in Theorem A.1 is satisfied; cf. (2.12). But it also enables us to ensure a well-defined eigenvalue formula (2.16).

Let us now require, more generally,

$$v\in i(0,\infty),\quad kv\notin i\mathbb{N}a,\quad k=1,\ldots,2N. \tag{2.25}$$

Then we arrive at the same results as before, but for a subtle change: To guarantee the reality of y for t near 0 we may have to choose t in an interval $(-\epsilon,0)$. This eventual sign change depends on the sign of the product in (2.15) for t near 0. In view of (2.13) this sign equals the sign of $vs(v)/s(Nv)s((N+1)v)$; cf. also the asymptotics (2.22).

Next, we introduce the AΔO

$$\tilde{A}\equiv(-)^{N+1}e^{2i(N+1)rx}T_{ia}+(i\to -i). \tag{2.26}$$

Using the iterated AΔE (1.10), one infers that $\tilde{A}$ equals a positive multiple of the AΔO A_+ (1.15); cf. (2.2). It is readily verified that $\Psi(x,y)$ (2.5) is an eigenfunction of $\tilde{A}$, with the eigenvalue

$$\tilde{E}=\exp\left(2ir\sum_{j=1}^{N}z_j(y)\right)e^{ay}+\exp\left(-2ir\sum_{j=1}^{N}z_j(y)\right)e^{-2(N+1)ar}e^{-ay}. \tag{2.27}$$

(Notice that this actually holds true for an *arbitrary* dependence of z_j on y.) Clearly, we have

$$\tilde{E}\sim\exp(iN(N+1)rv)e^{ay},\quad d\tilde{E}/dy\sim a\exp(iN(N+1)rv)e^{ay},\quad y\to\infty. \tag{2.28}$$

In summary, we have arrived at joint eigenfunctions,

$$\Psi(x,y)=\mathcal{N}\prod_{j=-N}^{N}\frac{1}{s(x+jv)}\cdot\prod_{j=1}^{N}s(x+z_j)\cdot\exp\left(\frac{x}{2v}\ln\left(\prod_{j=1}^{N}\frac{s(z_j-v)}{s(z_j+v)}\right)\right), \tag{2.29}$$

of the two AΔOs A (2.3) and $\tilde{A}$ (2.26), with eigenvalues E (2.16) and $\tilde{E}$ (2.27), respectively, and with $y\in(K,\infty)$ and parameters restricted solely by (2.25). The functions $z_1,\ldots,z_N$ are solutions to the constraint system (2.11) of the form (2.13), and the solution curve parameters t and y are related via (2.15). Since the y-derivatives of both eigenvalues are positive for y large, an eventual increase of K ensures that the eigenvalue pair $(E(y),\tilde{E}(y))$ separates points on (K,∞).

We proceed by obtaining the ''nonrelativistic limit'' $v\to 0$ of the constraints (2.10), (2.11) and eigenfunctions (2.29). First, (2.10) gives rise to

$$\Sigma=-\sum_{j=1}^{N}\frac{s'(z_j)}{s(z_j)}. \tag{2.30}$$

Second, dividing (2.11) by v and taking v to 0 yields

$$N\frac{s'(z_k)}{s(z_k)}+\sum_{\substack{j=1\\ j\neq k}}^{N}\frac{s'(z_j-z_k)}{s(z_j-z_k)}-\sum_{j=1}^{N}\frac{s'(z_j)}{s(z_j)}=0,\quad k=1,\ldots,N. \tag{2.31}$$

Proceeding formally, we can also take v to 0 in the eigenfunction (2.29), yielding the limit function

$$\Psi_0(x,y)=\mathcal{N}_0 s(x)^{-2N-1}\prod_{j=1}^{N}s(x+z_j)\exp[-xs'(z_j)/s(z_j)],\quad y=-(N+1)r+i\sum_{j=1}^{N}\frac{s'(z_j)}{s(z_j)}. \tag{2.32}$$

Now (1.5) entails

$$s'(x)/s(x)=\zeta(x)-2\eta xr/\pi, \tag{2.33}$$

where ζ is the Weierstrass ζ-function. Therefore, the functions (2.32) and constraints (2.30), (2.31) amount to the Lamé functions, and associated constraints, as specified by Whittaker and Watson; cf. p. 572 and p. 574, respectively, of Ref. 4. We do not have sufficient information on the solution curve to rigorously control the above limits, though.

Next, we derive a crucial property of the holomorphic function

$$\mathcal{H}_N(x)\equiv\prod_{j=1}^{N}s(x+z_j)\cdot\exp\left(\frac{x}{2v}\ln\left(\prod_{j=1}^{N}\frac{s(z_j-v)}{s(z_j+v)}\right)\right), \tag{2.34}$$

with $z_1,\ldots,z_N$ the above solutions to the constraint system (2.11). We have suppressed the y-dependence to prevent ambiguities in the next section. We can do so, since the property holds for arbitrary y; It reads

$$\mathcal{H}_N(kv)=\mathcal{H}_N(-kv),\quad k=1,\ldots,N. \tag{2.35}$$

(As will become clear later on, this algebraic property is a key ingredient in our orthogonality analysis.)

The only k-value for which (2.35) is immediate from (2.34) is $k=1$. Indeed, in that case it holds true for $z_1,\ldots,z_N$ having arbitrary y-dependence. In order to prove (2.35), we exploit the AΔE

$$B\mathcal{H}_N=E\mathcal{H}_N,\quad B\equiv\left(\prod_{j=-N}^{N}s(x+jv)\right)A\left(\prod_{j=-N}^{N}s(x+jv)\right)^{-1}, \tag{2.36}$$

satisfied by $\mathcal{H}_N$; cf. (2.29). Recalling (2.3), we obtain

$$B=\frac{s(x+Nv)}{s(x)}T_v+(v\to -v), \tag{2.37}$$

so this AΔE can be written as

$$s(x+Nv)\mathcal{H}_N(x-v)+s(x-Nv)\mathcal{H}_N(x+v)=Es(x)\mathcal{H}_N(x). \tag{2.38}$$

First, we put $x=0$ in (2.38). Using the oddness of $s(x)$ and the restriction (2.25), this yields $\mathcal{H}_N(-v)=\mathcal{H}_N(v)$. Now we proceed recursively. Assuming (2.35) for $k=1,\ldots,l$ with $l<N$, we first substitute $x=lv$ in (2.38) to obtain

$$s((l+N)v)\mathcal{H}_N((l-1)v)+s((l-N)v)\mathcal{H}_N((l+1)v)=Es(lv)\mathcal{H}_N(lv). \tag{2.39}$$

Next, we put $x=-lv$ and use the assumption and the oddness of $s(x)$ to get

$$s((l-N)v)\mathcal{H}_N(-(l+1)v)+s((l+N)v)\mathcal{H}_N((l-1)v)=Es(lv)\mathcal{H}_N(lv). \tag{2.40}$$

Comparing (2.39) and (2.40), we obtain $\mathcal{H}_N(kv)=\mathcal{H}_N(-kv)$ for $k=l+1$, since $s((l-N)v)\neq 0$; cf. (2.25). Thus, the asserted identities (2.35) readily follow.

Besides their use in the orthogonality problem, the identities (2.35) have two further striking consequences. First, consider the function (Casorati determinant)

$$C_N(x)\equiv\mathcal{H}_N(x+v/2)\mathcal{H}_N(-x+v/2)-\mathcal{H}_N(x-v/2)\mathcal{H}_N(-x-v/2). \tag{2.41}$$

Due to (2.35), it satisfies

$$C_N(nv)=0, \quad n=-N+1/2,-N+3/2,\ldots,N-1/2. \tag{2.42}$$

This is easily seen to entail the remarkably simple result

$$C_N(x)=\alpha_N\prod_{n=-N+1/2}^{N-1/2} s(x-nv), \tag{2.43}$$

where α_N does not depend on x. [Indeed, the quotient of $C_N(x)$ and the product on the rhs is elliptic with periods $\pi/r, ia$, and pole-free in view of (2.42).]

Second, combining (2.35) and (2.34), one deduces

$$\prod_{j=1}^{N}\frac{s(z_j-kv)}{s(z_j+kv)}=\prod_{j=1}^{N}\left(\frac{s(z_j-v)}{s(z_j+v)}\right)^k, \quad k=2,\ldots,N. \tag{2.44}$$

Thus, the asymptotics (2.13) can be rendered far more precise. Indeed, from (2.13) and (2.44) one readily obtains

$$z_l=lv+d_lvt^l+O(t^{l+2}), \quad l=2,\ldots,N, \quad t\to 0, \tag{2.45}$$

where

$$d_l\equiv v^{l-1}\prod_{j=1}^{N}\frac{s(jv+lv)}{s(jv+v)^l}\cdot\prod_{j=2}^{N}s(jv-v)^l\cdot\prod_{\substack{j=l\\ j\neq 1}}^{N}\frac{1}{s(jv-lv)}, \quad l=2,\ldots,N. \tag{2.46}$$

Note that these coefficients are real and nonzero due to (2.25). Moreover, one has

$$\lim_{v\to 0}d_l=\prod_{j=1}^{N}\frac{j+l}{(j+1)^l}\cdot\prod_{j=2}^{N}(j-1)^l\cdot\prod_{\substack{j=1\\ j\neq l}}^{N}\frac{1}{(j-l)}, \quad l=2,\ldots,N. \tag{2.47}$$

III. EIGENFUNCTIONS FOR A DENSE PARAMETER SET

In this section we take the AΔOs A_+, A_- (1.15) with

$$b=(N_+ +1)a_+ - N_- a_-, \quad N_+, N_- \in \mathbb{N}^*, \tag{3.1}$$

as our starting point. Using the AΔE (1.10), they can be rewritten as

$$A_+ = (-)^{N_+ +1} \exp[a_+ r(N_+ +1)N_+ - a_- r(2N_+ +1)N_-] \times \left(e^{2ir(N_+ +1)x} \frac{s_+(x+iN_- a_-)}{s_+(x)} T_{ia_-} + (i \to -i) \right), \tag{3.2}$$

$$A_- = (-)^{N_-} \exp[a_- r(N_- +1)N_- - a_+ r(2N_- +1)(N_+ +1)] \times \left(e^{-2irN_- x} \frac{s_-(x-i(N_+ +1)a_+)}{s_-(x)} T_{ia_+} + (i \to -i) \right). \tag{3.3}$$

In the hyperbolic case, the existence of joint eigenfunctions of the form

$$\Psi(x,y) = \mathcal{N} \prod_{j=-N_+}^{N_+} \frac{1}{s_-(x+ija_+)} \cdot \prod_{j=1}^{N_+} s_-(x+z_j^+(y)) \cdot \prod_{j=1}^{N_-} s_+(x+z_j^-(y)) \cdot e^{x\Sigma}, \tag{3.4}$$

with

$$\Sigma \equiv ir(2N_+ N_- + N_+ + N_- +1) + iy, \tag{3.5}$$

can be deduced for arbitrary y; cf. Sec. III in Ref. 11. In the elliptic case we view (3.4) as an Ansatz for solving the AΔEs

$$A_\delta \Psi = E_\delta \Psi, \quad \delta = +,-. \tag{3.6}$$

Correspondingly, we calculate the functions

$$\Psi(x,y)^{-1}(A_\delta \Psi)(x,y) = E_\delta(\Sigma, z^+, z^-; x), \quad \delta = +,-. \tag{3.7}$$

Using (1.6), this readily yields

$$E_\delta = e_\delta \frac{1}{s_\delta(x)} \left(\exp\left(2ir \sum_{j=1}^{N_\delta} z_j^\delta \right) s_\delta(x+iN_{-\delta} a_{-\delta}) \exp(-ia_{-\delta}\Sigma) \times \prod_{j=1}^{N_{-\delta}} \frac{s_\delta(x-ia_{-\delta}+z_j^{-\delta})}{s_\delta(x+z_j^{-\delta})} + (i \to -i) \right), \quad \delta = +,-, \tag{3.8}$$

with

$$e_\delta \equiv \exp[a_\delta r(N_\delta +1)N_\delta - a_{-\delta} r(2N_+ N_- + N_+ + N_- +1)]. \tag{3.9}$$

Clearly, E_δ is elliptic in x with periods $\pi/r, ia_\delta$. From now on we choose the numbers $z_1^{-\delta},\ldots,z_{N_{-\delta}}^{-\delta}$ pairwise incongruent and incongruent to 0 modulo the period lattice $\pi r^{-1}\mathbb{Z} + ia_\delta \mathbb{Z}$, so that the summands have only simple poles.

It is expedient to study first one of these two elliptic functions. To minimize signs, we concentrate on the function $E_{-\delta}$ and study if and when the residues at all of its poles can be made to vanish, so as to obtain an $A_{-\delta}$-eigenfunction with eigenvalue $E_{-\delta}$. For $x=0$ it suffices to require

$$\Sigma=\frac{2r}{a_\delta}\sum_{j=1}^{N_{-\delta}} z_j^{-\delta}+\frac{1}{2ia_\delta}\ln\left(\prod_{j=1}^{N_\delta}\frac{s_{-\delta}(z_j^\delta-ia_\delta)}{s_{-\delta}(z_j^\delta+ia_\delta)}\right). \tag{3.10}$$

Substituting this in $E_{-\delta}$, we require next

$$s_{-\delta}(z_k^\delta-iN_\delta a_\delta)\prod_{\substack{j=1\\ j\neq k}}^{N_\delta} s_{-\delta}(z_j^\delta-z_k^\delta-ia_\delta)\prod_{j=1}^{N_\delta} s_{-\delta}(z_j^\delta+ia_\delta)-(i\to -i)=0, \tag{3.11}$$

where $k=1,\ldots,N_{-\delta}$. Whenever these requirements are met, we obtain vanishing residues at all poles. Accordingly, the elliptic function $E_{-\delta}$ reduces to a constant, and so we obtain an $A_{-\delta}$-eigenfunction.

Introducing the function

$$f(w)=s_{-\delta}(ia_\delta w)/ia_\delta, \tag{3.12}$$

the constraint system (3.11) turns into a special case of the system studied in Appendix A. Now this special case arose already in the previous section. Requiring henceforth

$$ka_\delta\notin\mathbb{N}a_{-\delta},\quad k=1,\ldots,2N_\delta, \tag{3.13}$$

we can therefore deduce the existence of solutions $z_j^\delta(t_\delta)$ to (3.11) that are holomorphic at $t=0$ and satisfy

$$z_1^\delta=ia_\delta(1+t_\delta),\quad z_l^\delta=ia_\delta(l+d_{\delta,l}t_\delta^l)+O(t_\delta^{l+2}),\quad l=2,\ldots,N_\delta,\quad t_\delta\to 0, \tag{3.14}$$

where

$$d_{\delta,l}=(ia_\delta)^{l-1}\prod_{j=1}^{N_\delta}\frac{s_{-\delta}(i(j+l)a_\delta)}{s_{-\delta}(i(j+1)a_\delta)^l}\cdot\prod_{j=2}^{N_\delta}s_{-\delta}(i(j-1)a_\delta)^l\cdot\prod_{\substack{j=1\\ j\neq l}}^{N_\delta}\frac{1}{s_{-\delta}(i(j-l)a_\delta)}. \tag{3.15}$$

Substituting these solutions, we deduce as before that $E_{-\delta}$ does not depend on x. Taking, for example, $\delta=+$ in (3.10)–(3.14), we therefore obtain an A_--eigenfunction with eigenvalue E_-, independently of the choice of $z_1^-,\ldots,z_{N_-}^-$. But in order to obtain a *joint* eigenfunction of A_+ and A_-, the requirements (3.10)–(3.11) must be met *simultaneously* for $\delta=+$ and $\delta=-$.

This can be achieved as follows. Consider the functions

$$g_\delta(t_\delta)\equiv\frac{2ir}{a_{-\delta}}\sum_{j=1}^{N_\delta}z_j^\delta-\frac{1}{2a_\delta}\ln\left(\prod_{j=1}^{N_\delta}\frac{s_{-\delta}(z_j^\delta-ia_\delta)}{s_{-\delta}(z_j^\delta+ia_\delta)}\right),\quad \delta=+,-, \tag{3.16}$$

where $z^\delta=z^\delta(t_\delta)$ is the above solution to (3.11). Letting t_δ vary over $(-\epsilon_\delta,0)$ or $(0,\epsilon_\delta)$ (the choice being determined by positivity of the product), the functions $g_\delta:t_\delta\mapsto u$ are real-valued, real-analytic, and monotone for ϵ_δ small enough, and u goes to ∞ for $t_\delta\to 0$. Thus the inverse functions $h_\delta:u\mapsto t_\delta$ are well defined for u varying over an interval $I_\delta=(\rho_\delta,\infty)$, and they are real-analytic and monotone on I_δ.

Letting now $\rho=\max(\rho_+,\rho_-)$, we may view t_δ as a function $h_\delta(u)$ on (ρ,∞). Doing so, we define [cf. (3.5) and (3.10)]

$$\begin{aligned}y(u)&\equiv -r(2N_+N_-+N_++N_-+1)-\frac{2ir}{a_\delta}\sum_{j=1}^{N_{-\delta}}z_j^{-\delta}-\frac{1}{2a_\delta}\ln\left(\prod_{j=1}^{N_\delta}\frac{s_{-\delta}(z_j^\delta-ia_\delta)}{s_{-\delta}(z_j^\delta+ia_\delta)}\right)\\&=-r(2N_+N_-+N_++N_-+1)-2ir\sum_{\delta=+,-}\frac{1}{a_\delta}\sum_{j=1}^{N_{-\delta}}z_j^{-\delta}+u,\end{aligned} \tag{3.17}$$

where $z^{\delta}=z^{\delta}(h_{\delta}(u))$ and $u\in(\rho,\infty)$. Eventually increasing ρ, we deduce from (3.14) and holomorphy in t_{δ} that $y(u)$ is a real-analytic, increasing function on (ρ,∞), taking values in some interval (K,∞). Thus, we may and will view u as a real-analytic function of y on (K,∞).

The upshot is that there exist real-analytic functions

$$(K,\infty)\to i(0,\infty),\quad y\mapsto z_l^{\delta}(h_{\delta}(u(y))),\quad l=1,\ldots,N_{\delta},\quad \delta=+,- \tag{3.18}$$

[denoted once more by $z_l^{\delta}(y)$], such that (3.10) and (3.11) with $k=1,\ldots,N_{-\delta}$ are satisfied both for $\delta=+$ and for $\delta=-$. As a result, we obtain a joint eigenfunction $\Psi(x,y), y\in(K,\infty)$, of the AΔOs A_+ and A_-, as advertised. Eventually increasing K, we can ensure

$$s_{\delta}(iN_{-\delta}a_{-\delta}+z_j^{-\delta}(y))\neq 0,\quad j=1,\ldots,N_{\delta},\quad \delta=+,-, \tag{3.19}$$

for all $y\in(K,\infty)$. Then we choose $x=iN_{-\delta}a_{-\delta}$ in (3.8), yielding

$$E_{\delta}(y)=\exp\left[a_{\delta}r(N_{\delta}+1)N_{\delta}+2ir\sum_{j=1}^{N_{\delta}} z_j^{\delta}(y)+a_{-\delta}y\right]$$
$$\times\frac{s(2iN_{-\delta}a_{-\delta})}{s(iN_{-\delta}a_{-\delta})}\prod_{j=1}^{N_{-\delta}}\frac{s_{\delta}(i(N_{-\delta}-1)a_{-\delta}+z_j^{-\delta}(y))}{s_{\delta}(iN_{-\delta}a_{-\delta}+z_j^{-\delta}(y))},\quad \delta=+,-. \tag{3.20}$$

Clearly, these functions are real-valued and real-analytic on (K,∞).

The $y\to\infty$ asymptotics of E_{δ} is readily determined from the above. First, let us note that (3.5) and (3.10) entail

$$|t_{\delta}|=O(\exp(-2a_{\delta}y)),\quad y\to\infty. \tag{3.21}$$

Now from (3.14), we deduce

$$E_{\delta}=\exp(a_{-\delta}y)(1-2a_{\delta}rt_{\delta}+ia_{-\delta}d_{-\delta}t_{-\delta}+O(t_+^2)+O(t_-^2)),\quad y\to\infty, \tag{3.22}$$

$$d_{-\delta}\equiv\frac{s_{\delta}'(iN_{-\delta}a_{-\delta})}{s_{\delta}(iN_{-\delta}a_{-\delta})}-\frac{s_{\delta}'(i(N_{-\delta}+1)a_{-\delta})}{s_{\delta}(i(N_{-\delta}+1)a_{-\delta})}. \tag{3.23}$$

Thus, we conclude

$$E_{\delta}(y)=\exp(a_{-\delta}y)(1+O(\exp[-2\min(a_+,a_-)y])),\quad y\to\infty. \tag{3.24}$$

Moreover, one readily verifies that

$$\frac{d}{dy}z_l^{\delta}(y)\to 0,\quad l=1,\ldots,N_{\delta},\quad \delta=+,-,\quad y\to\infty, \tag{3.25}$$

so that (3.20) entails

$$\frac{d}{dy}E_{\delta}(y)\sim a_{-\delta}\exp(a_{-\delta}y),\quad y\to\infty. \tag{3.26}$$

From this large-y asymptotics we see that $E_{\delta}(y)$ is an increasing function of y for y sufficiently large. Thus, eventually increasing K, we may and will assume that the eigenvalue pair separates points on (K,∞). [I.e., (1.20) holds true.]

Summarizing, we have proved the existence of joint eigenfunctions when the parameter b is given by (3.1) and a_+,a_- are restricted by (3.13) with $\delta=+,-$. Whenever a_+/a_- is irrational, the restrictions (3.13) are obviously satisfied for all $N_+,N_-\in\mathbb{N}$. But (3.13) is also compatible with $a_+/a_-\in\mathbb{Q}$ and a *finite* number of $(N_+,N_-)\in\mathbb{N}^2$. To be specific, letting

$$a_+/a_-=n_-/n_+, \quad n_+,n_-\in\mathbb{N}^*, \quad n_+,n_- \text{ coprime}, \tag{3.27}$$

one easily verifies that (3.13) with $\delta=+,-$ is satisfied if and only if

$$N_\delta\in\mathbb{N}, \quad N_\delta<n_\delta/2, \quad \delta=+,-. \tag{3.28}$$

Of course, for rational a_+/a_- there are infinitely many distinct pairs $(N_+,N_-)\in\mathbb{N}^2$ yielding the same b. But the conditions (3.13) cannot be satisfied for more than one pair. (Indeed, assuming, for instance, that

$$(M+1)a_+-Na_-=(M'+1)a_+-N'a_-, \quad M>M'>0, \tag{3.29}$$

one gets $(M-M')a_+=(N-N')a_-$, so that $ka_+\in\mathbb{N}a_-$ for some $k\in\{1,\ldots,M-1\}$.) This entails, in particular, that all of the numbers $(N_++1)a_+-N_-a_-$ arising from (3.27) and (3.28) are *distinct*.

Next, we consider the case

$$b=(N_-+1)a_--N_+a_+, \quad N_+,N_-\in\mathbb{N}^*. \tag{3.30}$$

Clearly, this case can be handled in the same way as the case (3.1). Specifically, we need only interchange all subscripts $+$ and $-$ in various formulas, for example, in (3.2)–(3.4). Combining (3.4), (1.25), (1.27), and their obvious counterparts for (3.30), we obtain in both cases the *same* function $\mathcal{F}(x,y)$ (1.29), namely,

$$\mathcal{F}(x,y)=\phi(\mathcal{N})\prod_{\delta=+,-}\prod_{j=1}^{N_\delta}\frac{s_{-\delta}(x+z_j^\delta(y))}{[s_{-\delta}(x+ija_\delta)s_{-\delta}(x-ija_\delta)]^{1/2}}$$
$$\times\exp[irx(2N_+N_-+N_++N_-+1)]\exp(ixy). \tag{3.31}$$

[Here, $\phi(\mathcal{N})$ is the phase of the normalization constant $\mathcal{N}$; cf. (1.24)–(1.29); these quantities can be explicitly calculated from Ref. 14, but we do not need them in the elliptic case—by contrast to the hyperbolic case; cf. Sec. III in Ref. 11.] This coincidence is in agreement with the symmetry property (1.13) of the AΔOs H_+ and H_- (1.12). Note also that in the rational case the b-values obtained from (3.1) and (3.30) are distinct, save for one special case, viz., n_+,n_- odd; $N_+=[n_+/2],N_-=[n_-/2]$, both in (3.1) and in (3.30).

In this section we have thus far excluded the special cases $N_-=0$ and/or $N_+=0$. But these cases can be easily handled, too. Indeed, when N_+ and N_- both vanish, we may and will take

$$\Psi(x,y)=\mathcal{N}\frac{1}{s_{-\delta}(x)}\exp(irx+ixy), \quad b=a_\delta, \quad \delta=+,-, \tag{3.32}$$

and when one of N_+ and N_- equals 0, we can proceed just as in Sec. II. Clearly, the resulting function $\mathcal{F}(x,y)$ (1.29) is given by (3.31) in these special cases, too.

We now summarize and extend the above findings in the following theorem.

Theorem III.1: *Fix parameters in the set $\mathcal{D}\subset\mathcal{E}$ (1.14) defined by*

$$b=(N_\alpha+1)a_\alpha-N_{-\alpha}a_{-\alpha}, \quad \alpha\in\{+,-\}, \quad N_+,N_-\in\mathbb{N}, \tag{3.33}$$

$$ka_+\notin\mathbb{N}a_-, \quad k=1,\ldots,2N_+ \quad (N_+>0), \tag{3.34}$$

$$ka_-\notin\mathbb{N}a_+, \quad k=1,\ldots,2N_- \quad (N_->0). \tag{3.35}$$

Then there exists $K\in\mathbb{R}$ such that for all $y\in(K,\infty)$ the following holds true.

(i) *The above functions*

$$z_1^+,\ldots,z_{N_+}^+,z_1^-,\ldots,z_{N_-}^-:(K,\infty)\to i(0,\infty), \tag{3.36}$$

are real-analytic solutions to the system of equations (3.5), (3.10), and (3.11) (*where* $\delta=+,-$ *and* $k=1,\ldots,N_{-\delta}$); *they satisfy (3.19) and have large-*y *asymptotics*

$$z_l^\delta(y)=ila_\delta+O(\exp(-2la_\delta y)),\quad l=1,\ldots,N_\delta,\quad \delta=+,-,\quad y\to\infty. \tag{3.37}$$

(ii) *The A*Δ*Os* H_+ *and* H_- *(1.12) have joint eigenfunctions* $\mathcal{F}(\pm x,y)$ *given by (3.31), with eigenvalues* $E_+(y)$ *and* $E_-(y)$ *given by (3.20).*

(iii) *The eigenvalues are real-valued, real-analytic functions on* (K,∞) *satisfying (3.24), (3.26), and (1.20).*

(iv) *The A*Δ*Os* A_+ *and* A_- (1.15) *have joint eigenfunctions* $\Psi(\pm x,y)$ *with eigenvalues* $E_+(y)$ *and* $E_-(y)$; *explicitly,*

$$\Psi(x,y)=\mathcal{N}\prod_{j=-N_\alpha}^{N_\alpha}\frac{1}{s_{-\alpha}(x+ija_\alpha)}\cdot\mathcal{H}(x,y), \tag{3.38}$$

where

$$\mathcal{H}(x,y)\equiv\prod_{\delta=+,-}\prod_{j=1}^{N_\delta}s_{-\delta}(x+z_j^\delta(y))\cdot\exp[irx(2N_+N_-+N_++N_-+1)+ixy]. \tag{3.39}$$

(v) *Setting*

$$\mathcal{H}^{(\infty)}(x,y)\equiv\prod_{\delta=+,-}\prod_{j=1}^{N_\delta}s_{-\delta}(x+ija_\delta)\cdot\exp[irx(2N_+N_-+N_++N_-+1)+ixy], \tag{3.40}$$

one has

$$\mathcal{H}(x,y)=\mathcal{H}^{(\infty)}(x,y)+O(\exp(-2\min(a_+,a_-)y)),\quad y\to\infty, \tag{3.41}$$

where the bound is uniform on x*-compacts.*

(vi) *The poles on the imaginary axis of the function*

$$\chi(x,y)\equiv\Psi(x,y)+\Psi(-x,y) \tag{3.42}$$

are simple and can be located only at the points

$$x=ik_\alpha a_\alpha+ik_{-\alpha}a_{-\alpha},\quad \pm k_\alpha\in\{0,1,\ldots,N_\alpha\},\quad \pm k_{-\alpha}\in\{N_{-\alpha}+1,N_{-\alpha}+2,\ldots\}. \tag{3.43}$$

Proof: We have already proved (i)–(iv). The uniform large-y asymptotics (3.41) easily follows from (3.37). Thus, it remains to prove (vi). To this end we begin by generalizing the identities (2.35). Specifically, we claim that the function $\mathcal{H}(x,y)$ satisfies

$$\mathcal{H}(ik_+a_++ik_-a_-,y)=\mathcal{H}(-ik_+a_+-ik_-a_-,y),\quad \pm k_\delta\in\{0,\ldots,N_\delta\},\quad \delta=+,-. \tag{3.44}$$

To prove this claim, we use (1.10) and (3.10) to write

$$\mathcal{H}(ik_+a_++ik_-a_-,y)=p(k_+,k_-)\prod_{\delta=+,-}\mathcal{H}_{N_\delta}^\delta(ik_\delta a_\delta),\quad k_+,k_-\in\mathbb{Z}. \tag{3.45}$$

Here, we have introduced

$$\mathcal{H}^{\delta}_{N_\delta}(x) \equiv \prod_{j=1}^{N_\delta} s_{-\delta}(x+z_j^\delta) \cdot \exp\left(\frac{x}{2ia_\delta} \ln\left(\prod_{j=1}^{N_\delta} \frac{s_{-\delta}(z_j^\delta - ia_\delta)}{s_{-\delta}(z_j^\delta + ia_\delta)} \right) \right), \tag{3.46}$$

and the prefactor reads

$$p(k_+,k_-) = \prod_{\delta=+,-} (-)^{N_\delta k_{-\delta}} \exp rN_\delta (k_{-\delta}^2 a_{-\delta} + 2k_+k_-a_\delta). \tag{3.47}$$

Now in (3.46) the y-dependence occurs via the t_δ-dependence of z_j^δ; cf. (3.18). We may therefore invoke our previous result (2.35) to deduce that our claim (3.44) holds true. (Note that p is invariant under taking $k_+,k_- \to -k_+,-k_-$.)

We now exploit the identities (3.44) to locate the poles of $\chi(x,y)$ on the imaginary axis. The product in (3.38) gives rise to poles at

$$x = ik_\alpha a_\alpha + ik_{-\alpha} a_{-\alpha}, \quad \pm k_\alpha \in \{0,\ldots,N_\alpha\}, \quad k_{-\alpha} \in \mathbb{Z}. \tag{3.48}$$

In view of (3.34) and (3.35), all of these poles are simple. Now for $\pm k_{-\alpha} \in \{0,\ldots,N_{-\alpha}\}$, the poles are matched by zeros of $\mathcal{H}(x,y) - \mathcal{H}(-x,y)$ due to (3.44). Therefore, poles of χ on the imaginary axis must be located at (3.43). □

It is quite likely that $\chi(x,y)$ does have poles at the points (3.43), i.e., no further cancellation takes place. It is illuminating to rewrite these points as [cf. (3.33)]

$$\pm ix = b - a_+ - a_- - k_\alpha a_\alpha - k_{-\alpha} a_{-\alpha}, \quad k_\alpha \in \{0,\ldots,N_\alpha\}, \quad k_{-\alpha} \in \mathbb{N}, \tag{3.49}$$

$$\pm ix = k_\alpha a_\alpha + (N_{-\alpha} + k_{-\alpha}) a_{-\alpha}, \quad k_\alpha \in \{0,\ldots,N_\alpha\}, \quad k_{-\alpha} \in \mathbb{N}^*. \tag{3.50}$$

Indeed, from this representation it is clear that when b takes values in a bounded subset of $\mathbb{R}$, then the number of poles in a rectangle $|\mathrm{Re}\, x| < \pi/r, |\mathrm{Im}\, x| < L$ is bounded above. Moreover, assuming $a_+/a_- \notin \mathbb{Q}$, the restrictions (3.34) and (3.35) hold for arbitrary $N_+,N_- \in \mathbb{N}^*$. Thus we may let $N_+,N_- \to \infty$, whilst keeping b bounded. Doing so, the points (3.50) diverge away, whereas the points (3.49) become

$$\pm ix = b - a_+ - a_- - k_+ a_+ - k_- a_-, \quad k_+,k_- \in \mathbb{N}. \tag{3.51}$$

The latter limits illuminate the issue of arbitrary-b interpolations discussed already in Sec. I, but, of course, they do not imply that an interpolation exists. For one thing, the two summands of $\chi(x,y)$ have different Floquet multipliers $\exp(\pm i\pi y/r)$ under $x \to x + \pi/r$ unless y equals $nr, n \in \mathbb{Z}$, so that generically no pole/zero cancellation occurs on the lines $\mathrm{Re}\, x = k\pi/r, k \in \mathbb{Z}^*$. Thus poles get dense on these lines as $N_+,N_- \to \infty$, and so a meromorphic interpolation is not likely to exist for generic y.

Specializing, however, to

$$\chi_n(x) \equiv \chi(x,nr), \quad nr > K, \quad n \in \mathbb{N}, \tag{3.52}$$

we deduce

$$\chi_n(x + \pi/r) = (-)^n \chi_n(x), \tag{3.53}$$

so no such obstruction occurs for these functions. But we have neither information concerning parameter continuity nor any uniform bounds available that would help in proving the existence of a meromorphic interpolation.

Before studying orthogonality properties of the functions $\chi_n(x)$, we should consider the contingency that the functions $\Psi(x,y)$ and $\Psi(-x,y)$ are linearly dependent. Now they are manifestly not identically zero, and they have different Floquet multipliers unless y equals $nr, n \in \mathbb{Z}$, so we need only study whether one can have

$$\prod_{\delta=+,-}\prod_{j=1}^{N_\delta}\frac{s_{-\delta}(x+z_j^\delta(nr))}{s_{-\delta}(x-z_j^\delta(nr))}=C\exp[-2irx(2N_+N_-+N_++N_-+1+n)], \tag{3.54}$$

where C is a nonzero constant. Clearly, this equality can only hold if the poles and zeros on the lhs cancel. Recalling the asymptotics (3.34) and (3.35), one readily infers that no cancellation takes place for n large enough.

For arbitrary $nr\in(K,\infty)$, however, we only know that we have $z_j^\delta(nr)\in i(0,\infty)$. (Recall that we have restricted K such that this is the case.) Since the solution curve gets quite inaccessible when y moves away from ∞, it appears hard to exclude pole/zero cancellation, in general. In view of the AΔE (1.10), such a cancellation might be compatible with the rhs of (3.54).

Now, even without this difficulty, we know next to nothing about the *minimal* K compatible with the various restrictions we have imposed. Thus, we may just as well assume that K is chosen large enough so that for all $y\in(K,\infty)$ the functions $\Psi(x,y)$ and $\Psi(-x,y)$ are linearly independent, and we will do so from now on. Observe that this entails, in particular, that the functions $\chi_n(x)$ (3.52) do not vanish identically.

We conclude this section with some observations concerning parameter symmetries. To this end we fix $r,a_+,a_->0$ and $N_+,N_-\in\mathbb{N}$ such that (3.34) and (3.35) hold true. Defining $b_+\equiv(N_++1)a_+-N_-a_-$, we then obtain a point $(r,a_+,a_-,b_+)\in\mathcal{D}$. Since the representation of b_+ is unique [recall the paragraph containing (3.29)], we may define $\mathcal{F}(r,a_+,a_-,b_+;x,y)$ by the rhs of (3.31). Likewise, setting $b_-\equiv(N_-+1)a_--N_+a_+$ yields a point in $\mathcal{D}$, and we may once more define $\mathcal{F}(r,a_+,a_-,b_-;x,y)$ by the rhs of (3.31).

Proceeding in this way, we therefore obtain a well-defined function $\mathcal{F}(r,a_+,a_-,b;x,y)$ for all points in $\mathcal{D}$. A moment's thought shows that this function obeys

$$\mathcal{F}(r,a_+,a_-,b;x,y)=\mathcal{F}(r,a_+,a_-,a_++a_--b;x,y), \tag{3.55}$$

$$\mathcal{F}(r,a_+,a_-,b;x,y)=\mathcal{F}(r,a_-,a_+,b;x,y). \tag{3.56}$$

Now the w-function $w(r,a_+,a_-,b;x)$ is symmetric under $a_+\leftrightarrow a_-$, but not under $b\to a_++a_--b$. Thus, setting

$$\Psi(r,a_+,a_-,b;x,y)=w(r,a_+,a_-,b;x)^{-1/2}\mathcal{F}(r,a_+,a_-,b;x,y) \tag{3.57}$$

[cf. (1.29)], we are left with the symmetry

$$\Psi(r,a_+,a_-,b;x,y)=\Psi(r,a_-,a_+,b;x,y). \tag{3.58}$$

Note that these symmetry properties for parameters in $\mathcal{D}$ have a bearing on eventual interpolations for parameters in $\mathcal{E}$.

IV. ORTHOGONALITY AND SELF-ADJOINTNESS ISSUES

The functions χ_n (3.52) span an infinite-dimensional closed subspace

$$\mathcal{H}_w(K)\subset\mathcal{H}_w\equiv L^2((0,\pi/r),w(x)dx). \tag{4.1}$$

The AΔOs A_δ give rise to densely defined operators in $\mathcal{H}_w(K)$ (denoted again by A_δ) by setting

$$A_\delta\chi_n\equiv E_\delta(nr)\chi_n,\quad n>K/r,\quad \delta=+,-, \tag{4.2}$$

and extending linearly. The question of whether the operators thus obtained are symmetric amounts to the question of whether the functions χ_n are pairwise orthogonal. Indeed, orthogonality obviously entails symmetry, and symmetry entails orthogonality, since the eigenvalues are real and satisfy (1.20).

We are now going to prove symmetry of the operators A_δ (and hence pairwise orthogonality of the functions χ_n), assuming that the parameters belong to the convergence region $\mathcal{C}$ (1.42). This restriction is equivalent to

$$(N_\delta+1)a_\delta>N_{-\delta}a_{-\delta}, \quad \delta=+,-, \tag{4.3}$$

both when $\alpha=+$ and when $\alpha=-$ in (3.33).

Now when we work with the AΔOs A_δ (1.15), then the cases $\alpha=+$ and $\alpha=-$ cannot be simultaneously handled, since A_+ and A_- lack invariance under taking $b\to a_++a_--b$; cf. also (3.2) and (3.3). This asymmetry arises from the similarity transformation (1.16). Indeed, the AΔOs H_δ (1.12) *are* invariant; cf. (1.13), but the w-function is not; cf. (1.45)–(1.47).

On the other hand, we may just as well work with the AΔOs H_+ and H_- and eigenfunctions $\Phi_n(x)$ (1.40), since (1.48) and (1.49) are unitarily equivalent to (4.1) and (4.2). But this choice has the drawback that square root branch points occur.

We shall therefore opt for a third unitarily equivalent setting that can be associated to parameters in $\mathcal{D}$. It gives rise to economic notation and meromorphic functions, and yields the same objects for the two choices of α. Specifically, in view of (3.38) we may also consider the functions

$$\psi_n(x)\equiv\mathcal{H}(x,nr)-\mathcal{H}(-x,nr), \tag{4.4}$$

which yield a closed subspace

$$\mathcal{H}_{\hat{w}}(K)\subset\mathcal{H}_{\hat{w}}\equiv L^2((0,\pi/r),\hat{w}(x)dx), \tag{4.5}$$

with

$$\begin{aligned}\hat{w}(x)&\equiv(-)^{N_++N_-+1}\mathcal{N}^2\prod_{j=-N_\alpha}^{N_\alpha}s_{-\alpha}(x+ija_\alpha)^{-2}\cdot w((N_\alpha+1)a_\alpha-N_{-\alpha}a_{-\alpha};x)\\ &=1\Big/\prod_{\delta=+,-}\prod_{\pm k=1}^{N_\delta}s_{-\delta}(x+ika_\delta);\end{aligned} \tag{4.6}$$

cf. (1.41). The associated AΔOs/operators on $\mathcal{H}_{\hat{w}}(K)$ are then given by

$$B_\delta=p_\delta\left(\exp(-2irN_\delta x)\frac{s_\delta(x+iN_{-\delta}a_{-\delta})}{s_\delta(x)}T_{ia_{-\delta}}+(i\to-i)\right), \quad \delta=+,-, \tag{4.7}$$

where the prefactor reads

$$p_\delta\equiv(-)^{N_\delta}\exp[a_\delta r(N_\delta+1)N_\delta-a_{-\delta}r(2N_\delta+1)(N_{-\delta}+1)]. \tag{4.8}$$

[Recall that (3.2) and (3.3) hold for $\alpha=+$; cf. (3.1); the $\alpha=-$ counterparts are obtained by interchanging all subscripts $+$ and $-$.]

Though the simplicity of this choice is already apparent, it should be emphasized that the weight function $\hat{w}(x)$ does not have a continuous extension to parameters in $\mathcal{E}$ (1.14), by contrast to $w(x)$. This can be seen, e.g., as follows. Fix $N_+,N_-\in\mathbb{N}^*$, and $a_+=a\in(0,\infty)$, and choose $b=(N_++1)a-N_-a_-$. Now let $a_-\to qa$ with q a positive rational number. Then $\hat{w}(x)$ (4.6) clearly has a well-defined limit. But there are infinitely many *distinct* pairs $k,l\in\mathbb{N}^*$ yielding the *same* b for $a_-\to qa$ [i.e., such that $ka-lqa$ equals $(N_++1)a-N_-qa$]. Evidently, each of these pairs yields a different limiting $\hat{w}(x)$.

Likewise, an interpolation obstruction is present for the AΔOs B_δ. [Choose, e.g., $N_-=N_++1$ and $q=1$ in the previous paragraph. From (4.7) one then sees that the limiting $b=0$ AΔOs depend on N_+; cf. (1.10).] Of course, this leads one to expect that the joint eigenfunctions $\mathcal{H}(\pm x,y)$ cannot be interpolated either. In the hyperbolic context we show that this expectation is indeed fulfilled; cf. Sec. III in Ref. 11.

As long as we restrict attention to a *fixed* choice of parameters in $\mathcal{D}$ though, the third setting just detailed is the simplest to study. We shall also use it in Appendix B, where we prove that any meromorphic joint eigenfunction $M(x)$ with B_δ-eigenvalues $E_\delta(y), \delta=+,-$, must be a linear combination of $\mathcal{H}(x,y)$ and $\mathcal{H}(-x,y)$, provided a_+/a_- is irrational and $y\in(L,\infty)$ for some $L\geqslant K$.

Returning now to the symmetry question, we begin by observing that the functions $\psi_n(x)$ (4.4) are entire, odd, and $2\pi/r$-periodic. Moreover, provided $|k|\leqslant N_+,|l|\leqslant N_-$, they have zeros in the points

$$z_{kl}\equiv ika_+ + ila_-, \quad k,l\in\mathbb{Z}, \tag{4.9}$$

[due to (3.44)], and in the points $z_{kl}+\pi/r$ (since they are either π/r-periodic or π/r-antiperiodic).

Let us now define the vector spaces

$$\mathcal{O}_0\equiv\{F(x) \text{ entire, odd,} \quad 2\pi/r\text{-periodic}\}, \tag{4.10}$$

$$\mathcal{O}_1\equiv\{F\in\mathcal{O}_0|F(z_{kl})=0, \quad F(z_{kl}+\pi/r)=0, \quad |k|\leqslant N_+,|l|\leqslant N_-\}, \tag{4.11}$$

$$\mathcal{O}_2\equiv\{F\in\mathcal{O}_0|F(z_{kl})=0, \quad F(z_{kl}+\pi/r)=0, \quad k\in\mathbb{Z},|l|\leqslant N_-, \quad \text{and } |k|\leqslant N_+,l\in\mathbb{Z}\}. \tag{4.12}$$

Clearly, we have

$$\mathcal{O}_2\subset\mathcal{O}_1\subset\mathcal{O}_0\subset\mathcal{H}_{\hat{w}}, \tag{4.13}$$

and

$$\psi_n\in\mathcal{O}_1, \quad n>K/r. \tag{4.14}$$

Next, we fix $F\in\mathcal{O}_0$ and consider B_+F. For $N_-=0$ we have $B_+F\in\mathcal{O}_0$, but for $N_->0$ we get

$$\lim_{x\to 0} s_+(x)(B_+F)(x)=2p_+s_+(iN_-a_-)F(-ia_-), \tag{4.15}$$

where we used (4.7) and oddness of F. Now the rhs does not vanish unless $F(ia_-)=0$, so, in general, $(B_+F)(x)$ has a pole at $x=0$, entailing $B_+F\notin\mathcal{H}_{\hat{w}}$. Assuming $F\in\mathcal{O}_1$, however, we have $F(ia_-)=0$ and $F(\pi/r+ia_-)=0$, so that $B_+F\in\mathcal{H}_{\hat{w}}$. More generally, this argument yields the conclusion

$$B_\delta\mathcal{O}_1\subset\mathcal{H}_{\hat{w}}, \quad \delta=+,-. \tag{4.16}$$

Therefore, the AΔOs B_δ give rise to Hilbert space operators

$$B_\delta^{(j)}:\mathcal{O}_j\to\mathcal{H}_{\hat{w}}, \quad F(x)\mapsto(B_\delta F)(x), \tag{4.17}$$

where $\delta=+,-$ and $j=1,2$.

It is not hard to see that these operators are densely defined. Indeed, $\mathcal{O}_2$ contains the subspace

$$\mathcal{O}_\delta\equiv\frac{s_\delta(x)s_{-\delta}(x)^2}{\hat{w}(x)}\mathrm{Pol}(\cos rx), \quad \delta\in\{+,-\}, \tag{4.18}$$

where $\mathrm{Pol}(t)$ denotes the space of polynomials in t, and $\mathcal{O}_\delta$ is clearly dense in $\mathcal{H}_{\hat{w}}$. The following theorem makes clear why it is important to distinguish between the operators $B_\delta^{(1)}$ and $B_\delta^{(2)}$.

Theorem IV.1: *The operators* $B_\delta^{(2)}$ *are symmetric for all parameters in* $\mathcal{D}$; *moreover, their adjoints extend the operators* $B_\delta^{(1)}$. *The operators* $B_\delta^{(1)}$ *are not symmetric for parameters in* $\mathcal{D}\backslash\mathcal{C}$, *whereas they are symmetric for parameters in* $\mathcal{D}\cap\mathcal{C}$.

Proof: For convenience we choose $\delta=-$; the case $\delta=+$ can then be handled by interchanging the subscripts $+$ and $-$ in the following. To prove symmetry of $B_-^{(2)}$, it suffices to show $I_L=I_R$, with

$$I_L\equiv\int_0^{\pi/r}\left(\exp(2irN_-x)\frac{s_-(x-iN_+a_+)}{s_-(x)}F^*(x+ia_+)+(i\to -i)\right)G(x)\hat{w}(x)dx, \quad (4.19)$$

$$I_R\equiv\int_0^{\pi/r}F^*(x)\left(\exp(-2irN_-x)\frac{s_-(x+iN_+a_+)}{s_-(x)}G(x-ia_+)+(i\to -i)\right)\hat{w}(x)dx, \quad (4.20)$$

where we take $F,G\in\mathcal{O}_2$, and where we employ the notation

$$F^*(x)\equiv\overline{F(\overline{x})}. \quad (4.21)$$

In order to prove equality of these integrals, we introduce the function

$$I(x)\equiv\hat{w}(x-e)\exp(2irN_-(x-e))\frac{s_-(x-e-iN_+a_+)}{s_-(x-e)}F^*(x+e)G(x-e), \quad e\equiv\frac{ia_+}{2}. \quad (4.22)$$

From the definition (4.6) of $\hat{w}(x)$ we deduce that we may rewrite $I(x)$ as

$$I(x)=\hat{w}(x+e)\exp(-2irN_-(x+e))\frac{s_-(x+e+iN_+a_+)}{s_-(x+e)}F^*(x+e)G(x-e). \quad (4.23)$$

Now $\hat{w}(x)$ is even and $s_-(x),F^*(x)$ and $G(x)$ are odd, so we have

$$\begin{aligned}I_L-I_R&=\int_0^{\pi/r}(I(x+e)+I(-x+e)-I(x-e)-I(-x-e))dx\\&=\int_{-\pi/r}^{\pi/r}(I(x+e)-I(x-e))dx, \quad e\equiv ia_+/2.\end{aligned} \quad (4.24)$$

Recalling F^* and G are $2\pi/r$-periodic and noting $\hat{w}$ is π/r-periodic, it follows that $I(x)$ is $2\pi/r$-periodic. Thus the integral (4.24) vanishes (by Cauchy's theorem) whenever $I(x)$ has no poles in the strip $|\mathrm{Im}\,x|\leq a_+/2$. Now since we assumed $F,G\in\mathcal{O}_2$, the function $I(x)$ is, in fact, entire. Thus we obtain $I_L=I_R$, and so $B_-^{(2)}$ is indeed symmetric.

Choosing next $F,G\in\mathcal{O}_1$, we can proceed in the same way as before, but now $I(x)$ has poles, in general. But when one of F,G belongs to $\mathcal{O}_2$, then one easily sees that $I(x)$ is still entire. Thus, the domain of $B_-^{(2)*}$ contains $\mathcal{O}_1$, and the action of $B_-^{(2)*}$ on $\mathcal{O}_1$ coincides with the action of the AΔO B_-. A moment's thought now shows that this state of affairs holds true on a larger subspace than $\mathcal{O}_1$, so that the adjoint of $B_-^{(2)}$ is a proper extension of $B_-^{(1)}$. (One need not require entireness, for instance.)

To prove the second assertion of the theorem, we determine the location of eventual poles of $I(x)$ for $F,G\in\mathcal{O}_1$. From (4.22) and (4.6) we infer that the poles of $I(x)$ are equal to the poles of the function

$$J(x)\equiv\left(\prod_{\pm k=1}^{N_-}s_+(x-e+ika_-)\right)^{-1}\left(\prod_{n=-N_++1/2}^{N_+-1/2}s_-(x+ina_+)\right)^{-1}F^*(x+e)G(x-e). \quad (4.25)$$

Let us first analyze the poles of $J(x)$ on the imaginary axis, using the notation

$$p_{kn}\equiv ika_-+ina_+, \quad k\in\mathbb{Z}, \quad n\in\mathbb{Z}+1/2. \tag{4.26}$$

The first product yields poles at the points

$$p_{kn}, \quad \pm k\in\{1,\ldots,N_-\}, \quad n\in\mathbb{Z}+1/2, \tag{4.27}$$

and the second one at

$$p_{kn}, \quad k\in\mathbb{Z}, \quad \pm n\in\{1/2,\ldots,N_+-1/2\}. \tag{4.28}$$

Thus, the products yield double poles at

$$p_{kn}, \quad \pm k\in\{1,\ldots,N_-\}, \quad \pm n\in\{1/2,\ldots,N_+-1/2\}, \tag{4.29}$$

and simple poles at

$$p_{kn}, \quad \pm k\in\{0,N_-+1,N_-+2,\ldots\}, \quad \pm n\in\{1/2,\ldots,N_+-1/2\}, \tag{4.30}$$

$$p_{kn}, \quad \pm k\in\{1,\ldots,N_-\}, \quad \pm n\in\{N_++1/2,N_++3/2,\ldots\}. \tag{4.31}$$

Now the function $F^*(x+e)G(x-e)$ has double zeros at

$$p_{kn}, \quad \pm k\in\{0,\ldots,N_-\}, \quad \pm n\in\{1/2,\ldots,N_+-1/2\}, \tag{4.32}$$

and simple zeros at

$$p_{kn}, \quad \pm k\in\{0,\ldots,N_-\}, \quad \pm n=N_++1/2. \tag{4.33}$$

Therefore, poles of $J(x)$ can be located solely at the points

$$p_{kn}, \quad \pm k\in\{N_-+1,N_-+2,\ldots\}, \quad \pm n\in\{1/2,\ldots,N_+-1/2\}, \tag{4.34}$$

$$p_{kn}, \quad \pm k\in\{1,\ldots,N_-\}, \quad \pm n\in\{N_++3/2,N_++5/2,\ldots\}. \tag{4.35}$$

We proceed by proving that for parameters in $\mathcal{D}\cap\mathcal{C}$ the latter points lie outside the strip $|\mathrm{Im}\, x|\leqslant a_+/2$. Consider first (4.34). When k and n have the same sign, it is immediate that these points are outside the critical strip. Now let $k>0$ and $n<0$. Then we get

$$ka_-+na_+\geqslant(N_-+1)a_--(N_+-1/2)a_+>a_+/2, \tag{4.36}$$

due to (4.3). Similarly, we have $ka_-+na_+<-a_+/2$ for $k<0$ and $n>0$. Next, consider (4.35). Taking $k>0$ and $n<0$, we now have

$$ka_-+na_+\leqslant N_-a_--(N_++3/2)a_+<-a_+/2, \tag{4.37}$$

due to (4.3); the other cases are then clear.

The upshot is that eventual poles of $J(x)$ on the imaginary axis lie outside $|\mathrm{Im}\, x|\leqslant a_+/2$. The above analysis can be repeated for poles on the line $\mathrm{Re}\, x=\pi/r$, yielding the same conclusion. Since $J(x)$ is $2\pi/r$-periodic, we deduce the absence of poles in the critical strip. Thus $I(x)$ has no poles in the strip either, and so the integral (4.24) vanishes. Hence, $B_-^{(1)}$ is symmetric when (4.3) holds true.

Finally, we choose parameters in $\mathcal{D}\backslash\mathcal{C}$, so that (4.3) is violated. Thus, we either have $(N_-+1)a_-<N_+a_+$ or $(N_++1)a_+<N_-a_-$. In the first case we have

$$(N_-+1)a_--(N_+-1/2)a_+<a_+/2, \quad (N_-+1)a_--a_+/2>-a_+/2, \tag{4.38}$$

so at least one of the points $p_{N_-+1,n}$ (4.34) is in the critical strip. In the second case we have

$$N_-a_- - (N_+ + 3/2)a_+ > -a_+/2, \tag{4.39}$$

so at least one of the points $p_{N_-,n}$ (4.35) is in the strip. In either case, the integral (4.24) does not vanish, in general, since we are free to choose the values of F and G in the pertinent points. Therefore, $B_-^{(1)}$ is not symmetric for parameters outside the convergence region $\mathcal{C}$. □

Taking $F=\psi_n, G=\psi_m$ in the proof of this theorem, we clearly have

$$I_L - I_R = [E_-(nr) - E_-(mr)](\psi_n, \psi_m). \tag{4.40}$$

For parameters in $\mathcal{C}$ we therefore conclude that [using (1.20)]

$$(\psi_n, \psi_m) = 0, \quad n > m > K/r. \tag{4.41}$$

But for parameters outside $\mathcal{C}$ we cannot prove that (4.41) is violated. The point is that the relevant residue sum(s) might vanish.

We conjecture that this does not happen in general. More precisely, fixing parameters in $\mathcal{D}\backslash\mathcal{C}$, we expect that one can find a pair $n \neq m$ such that $(\psi_n, \psi_m) \neq 0$. Choosing $b = 2a_\alpha$, this conjectured orthogonality breakdown can be explicitly verified for $a_\alpha > a_{-\alpha}$ (with $a_\alpha \notin \mathbb{N}a_{-\alpha}/2$) and *all* pairs $n \neq m$ with $n-m$ even. Indeed, in this special case the integral (4.24) with $F=\psi_n, G=\psi_m$ equals a nonzero residue sum. [The resulting formula for (ψ_n, ψ_m) amounts to the formula obtained by more direct means in Ref. 12, so we skip the details.]

Since the AΔOs B_δ and domains $\mathcal{O}_j$ are invariant under complex conjugation, the operators $B_\delta^{(j)}$ admit self-adjoint extensions whenever they are symmetric. Fixing parameters in $\mathcal{C}$, the operators $B_\delta^{(1)}$ are most likely essentially self-adjoint, but the state of affairs for $B_\delta^{(2)}$ is quite opaque to us. We add one observation on the self-adjoint extensions of the latter, however. Whenever one chooses parameters outside $\mathcal{C}$ and a pair $n \neq m$ with $(\psi_n, \psi_m) \neq 0$, any self-adjoint extension of $B_\delta^{(2)}$ has a domain to which ψ_n and ψ_m may or may not belong, but if both functions belong to the domain, then the action of the extension on at least one of them cannot coincide with the B_δ-action. [If it did coincide, one would deduce $(\psi_n, \psi_m) = 0$, a contradiction.]

Let us now return to the subspace $\mathcal{H}_w(K)$ (4.1) and operators A_δ (4.2). For parameters outside $\mathcal{C}$, the operators A_δ are not symmetric whenever a pair $n \neq m$ exists for which $(\chi_n, \chi_m) \neq 0$. As mentioned above, we believe that this is always the case. Choosing parameters in $\mathcal{C}$, however, (4.41) amounts to pairwise orthogonality of the functions $\chi_n, n > K/r$, so that the operators A_δ are symmetric, as announced. We also expect that for parameters in $\mathcal{C}$ the orthocomplement of $\mathcal{H}_w(K)$ is spanned by joint eigenfunctions $\chi_0, \ldots, \chi_M, M = [K/r]$, of the AΔOs A_δ with real eigenvalues. (If so, the AΔOs A_δ are essentially self-adjoint on the linear span of $\chi_0, \chi_1, \ldots,$ of course.)

We conclude this section by exploiting the AΔOs B_δ (4.7) and their eigenfunctions $\mathcal{H}(\pm x, y)$ (3.39) in yet another way. Specifically, we use them to obtain and study joint eigenfunctions of the AΔOs $A_\delta(b)$ (1.15) for $b = -N_+a_+ - N_-a_-$ and for $b = (N_+ + 1)a_+ + (N_- + 1)a_-$. Here we have $N_+, N_- \in \mathbb{N}$, and a_+, a_- are restricted by (3.34) and (3.35).

Let us recall first that both for $b = (N_+ + 1)a_+ - N_-a_-$ and for $b = (N_- + 1)a_- - N_+a_+$ we obtain the *same* AΔOs B_δ and eigenfunctions $\mathcal{H}(\pm x, y)$. Thus, in both cases we may denote the AΔOs by $B_\delta(N_+, N_-)$, and their eigenvalues and eigenfunctions by $E_\delta(N_+, N_-; y)$ and $\mathcal{H}_{N_+,N_-}(\pm x, y)$. The key observation is now that we have the identities

$$A_\delta(-N_+a_+ - N_-a_-) = r_\delta B_\delta(N_+, N_-), \quad \delta = +, -, \tag{4.42}$$

$$A_\delta((N_+ + 1)a_+ + (N_- + 1)a_-) = P_{N_+,N_-}(x)^{-1} r_\delta B_\delta(N_+, N_-) P_{N_+,N_-}(x), \quad \delta = +, -, \tag{4.43}$$

where we have introduced

$$r_\delta \equiv \exp a_{-\delta} r(2N_+ + 1)(2N_- + 1), \quad \delta = +,-, \tag{4.44}$$

$$P_{N_+,N_-}(x) \equiv \prod_{\delta=+,-} \prod_{j=-N_\delta}^{N_\delta} s_{-\delta}(x + ija_\delta), \quad N_+, N_- \in \mathbb{N}. \tag{4.45}$$

[Indeed, this can be verified directly from (1.15) and (4.7) by using the AΔE (1.10).]

As a result, we deduce

$$A_\delta(-N_+a_+ - N_-a_-)\mathcal{H}_{N_+,N_-}(\pm x,y) = r_\delta E_\delta(N_+,N_-;y)\mathcal{H}_{N_+,N_-}(\pm x,y), \tag{4.46}$$

$$\begin{aligned} A_\delta((N_+ + 1)a_+ + (N_- + 1)a_-)P_{N_+,N_-}(x)^{-1}\mathcal{H}_{N_+,N_-}(\pm x,y) \\ = r_\delta E_\delta(N_+,N_-;y)P_{N_+,N_-}(x)^{-1}\mathcal{H}_{N_+,N_-}(\pm x,y). \end{aligned} \tag{4.47}$$

Thus, we obtain the joint eigenfunctions announced above. We claim that the $y \to \infty$ asymptotics of these new eigenfunctions and eigenvalues ties in with the asymptotics for the dense parameter set $\mathcal{D}$. (Notice that the new parameters do not belong to $\mathcal{D}$.) More precisely, we claim that this holds true when we set

$$\Psi(x,y) \equiv \mathcal{N} H_{N_+,N_-}(x,y(N_+,N_-)), \quad b = -N_+a_+ - N_-a_-, \tag{4.48}$$

$$\Psi(x,y) \equiv \mathcal{N} P_{N_+,N_-}(x)^{-1}\mathcal{H}_{N_+,N_-}(x,y(N_+,N_-)), \quad b = (N_+ + 1)a_+ + (N_- + 1)a_-, \tag{4.49}$$

where

$$y(N_+,N_-) \equiv y - (2N_+ + 1)(2N_- + 1)r, \tag{4.50}$$

so that the associated eigenvalues read

$$E_\delta(y) = r_\delta E_\delta(N_+,N_-;y(N_+,N_-)), \quad \delta = +,-. \tag{4.51}$$

To prove this claim, we recall the $\mathcal{H}$-asymptotics given by (3.40) and (3.41). It entails that $\Psi(x,y)$ as just defined satisfies (1.24), where the c-function reads

$$c(-N_+a_+ - N_-a_-;x) = \mathcal{N} \prod_{\delta=+,-} \prod_{j=1}^{N_\delta} s_{-\delta}(x + ija_\delta) \cdot \exp - irx(2N_+N_- + N_+ + N_-), \tag{4.52}$$

$$c((N_+ + 1)a_+ + (N_- + 1)a_-;x) = \mathcal{N} \prod_{\delta=+,-} \prod_{j=0}^{N_\delta} \frac{1}{s_{-\delta}(x - ija_\delta)} \cdot \exp - irx(2N_+N_- + N_+ + N_-). \tag{4.53}$$

The point is now that this agrees with the interpolation (1.26) for a suitable choice of $\mathcal{N} = \mathcal{N}(r,a_+,a_-,b)$. (This readily follows from Proposition III.8 in Ref. 14.) Similarly, the eigenvalues (4.51) have once more the y-asymptotics (1.19), as is clear from the asymptotics of $E_\delta(N_+,N_-;y)$ and the definition (4.44) of r_δ.

It is easily checked that the new eigenfunctions $\Psi(x,y)$ (4.48) and (4.49) also satisfy the quasiperiodicity relations (1.36). Thus, they are eigenfunctions of the AΔO Q (1.38) with eigenvalue $2\cos(\pi y/r)$; cf. (1.39). Furthermore, choosing a_+/a_- irrational, the uniqueness result in Appendix B applies. All of these findings are consistent with the existence of interpolating meromorphic joint (A_+,A_-,Q)-eigenfunctions $\Psi(x,y)$ for parameters in $\mathcal{E}$ (1.14), but they show once more that such an interpolation must have striking analyticity properties.

For instance, taking $N_+ = N_- = 0$ in (4.48), we obtain

$$\Psi(x,y)=\exp ixy,\quad b=0; \tag{4.54}$$

cf. (3.39), (1.24), and (1.26) with $b=0$. Now when we fix a_+ and a_- with a_+/a_- irrational, and let the number $b\equiv(N_++1)a_+-N_-a_-$ converge to 0 (by taking $N_+,N_-\to\infty$ in a suitable way), then the poles of the associated functions $\Psi(x,y)$ (1.22) become dense on the lines $\mathrm{Im}\,x=k\pi/r, k\in\mathbb{Z}$. It is fully unclear to us whether and how (suitable y-dependent multiples of) these functions converge to the entire function (4.54) as $b\to 0$. But if a continuous interpolation can be found, then the existence of this limit would be a corollary.

It should be noted that the b-values in (4.48) and (4.49) are outside the orthogonality region $\mathcal{C}$ (1.42). Of course, ''orthogonality'' refers to the Hilbert space $L^2((0,\pi/r),w(x)dx)$, with $w(x)=w(r,a_+,a_-,b;x)$. Now from (1.27), (4.52), and (4.53) we have

$$w(-N_+a_+-N_-a_-;x)=(-)^{N_++N_-}\mathcal{N}^{-2}\hat{w}_{N_+,N_-}(x), \tag{4.55}$$

$$w((N_++1)a_++(N_-+1)a_-;x)=(-)^{N_++N_-}\mathcal{N}^{-2}P_{N_+,N_-}(x)^2\hat{w}_{N_+,N_-}(x), \tag{4.56}$$

where $\hat{w}_{N_+,N_-}(x)$ is given by (4.6). Therefore, the analysis embodied in Theorem IV.1 can be applied to the *odd* linear combinations,

$$\zeta_n(x)\equiv\Psi(x,nr)-\Psi(-x,nr),\quad n\in\mathbb{N},\quad nr>K+(2N_++1)(2N_-+1)r, \tag{4.57}$$

to deduce orthogonality whenever (4.3) is satisfied.

For the even combinations $\chi_n(x)$, though, this analysis renders it quite unlikely that orthogonality holds true. In fact, for the trigonometric specialization with $b=-N_+a_+, N_+>0$, we prove in Sec. IV of Ref. 11 that orthogonality is indeed violated. Thus, in the elliptic case this must also be generically true. [Of course, the two cases where $N_+=N_-=0$, namely $b=0$ and $b=a_++a_-$, are exceptional in this regard; cf. (4.54); observe that they correspond to the boundary of $\mathcal{C}$.]

Finally, we point out that the functions $\tilde{\mathcal{F}}(x,y)$ (1.29) for the new b-values $(N_++1)a_++(N_-+1)a_-$ and $-N_+a_+-N_-a_-$ are in essence equal to the functions $\mathcal{F}(x,y)$ (3.31) for the b-values $(N_++1)a_+-N_-a_-$ and $(N_-+1)a_--N_+a_+$. More precisely, we have

$$\tilde{\mathcal{F}}(x,y)=\chi\mathcal{F}(x,y(N_+,N_-)), \tag{4.58}$$

where χ is a normalizing phase. [Indeed, this is readily verified by combining (4.48), (4.49) with (4.55), (4.56).]

This intimate relation [and also the formulas (4.42)–(4.51), for that matter] can be understood from a consideration of the AΔOs $H_\delta(b)$ given by (1.12). Indeed, it is straightforward to verify that one has the identity

$$H_\delta(-N_+a_+-N_-a_-)=r_\delta H_\delta((N_++1)a_+-N_-a_-),\quad \delta=+,-, \tag{4.59}$$

so the symmetry (1.13) also entails the identity

$$H_\delta((N_++1)a_++(N_-+1)a_-)=r_\delta H_\delta((N_++1)a_+-N_-a_-),\quad \delta=+,-. \tag{4.60}$$

This explains why (4.58) holds: the relevant AΔOs are *proportional*.

More generally, a consideration of the zeros of the coefficients of $H_\delta(b)$ shows that proportionality of $H_\delta(b_1)$ and $H_\delta(b_2)$ [for arbitrary $a_+,a_-\in(0,\infty)$] not only holds for $b_2=b_1$ (trivially) and $b_2=a_++a_--b_1$ [cf. (1.13)], but also when b_1 is of the quite special form

$$2b_1=ka_++la_-,\quad k,l\in\mathbb{Z}, \tag{4.61}$$

and b_2 satisfies

$$2b_2 \in \{ka_+ + la_-, ka_+ + (-l+2)a_-, (-k+2)a_+ + la_-, (-k+2)a_+ + (-l+2)a_-\}. \tag{4.62}$$

Thus we are dealing with the case $k,l \in 2\mathbb{Z}$ for the b-values at issue.

APPENDIX A: THE CONSTRAINT SYSTEM

Let $f(w)$ be an entire, odd function satisfying

$$f(w) = w + O(w^3), \quad w \to 0. \tag{A1}$$

Fixing $N \geqslant 2$, define functions $F_1, \ldots, F_N$ by

$$F_k : \mathbb{C}^N \to \mathbb{C}, \quad W \mapsto f(w_k - N) \prod_{\substack{j=1 \\ j \neq k}}^{N} f(w_k - w_j + 1) \prod_{j=1}^{N} f(w_j + 1) - (W \to -W). \tag{A2}$$

Then we have the following result concerning the system of N equations:

$$F_k(W) = 0, \quad k = 1, \ldots, N, \tag{A3}$$

for N unknowns $w_1, \ldots, w_N$.

Theorem A.1: *The system (A3) admits the solution*

$$W_0 \equiv (1,2,\ldots,N), \tag{A4}$$

and the determinant of the functional matrix

$$(DF)_{kl} \equiv \partial_l F_k, \quad k,l = 1,\ldots,N, \tag{A5}$$

vanishes for $W = W_0$. Assuming

$$f(k) \neq 0, \quad k = 1,2,\ldots,N+1, \tag{A6}$$

the system of $N-1$ equations

$$F_k(W) = 0, \quad k = 2,\ldots,N, \tag{A7}$$

for N unknowns $w_1, \ldots, w_N$ admits a unique solution of the form

$$W(t) = (1+t, w_2(t), \ldots, w_N(t)), \tag{A8}$$

near W_0, with $w_k(t)$ holomorphic at $t=0$ and such that

$$w_k(t) = k + O(t^2), \quad w_k'(t) = O(t), \quad t \to 0, \quad k = 2,\ldots,N. \tag{A9}$$

Moreover, assuming that $f(w)$ is real-valued for real w, the functions $w_k(t)$ are real-valued for $t \in (-\epsilon, \epsilon)$ and ϵ small enough.

Proof: Letting $W = W_0$, the second term on the rhs of (A2) vanishes, since $W_{0,1} = 1$. The first term vanishes for $k = N$, since $W_{0,N} = N$. For $k < N$ the first term vanishes too, since $f(w_k - w_j + 1)$ yields a zero when $j = k+1$. Thus, W_0 solves the system (A3).

Next, we calculate the functional matrix $(DF)(W_0)$. Due to the factor $f(-w_1+1)$ in the second term on the rhs of (A2), this term can only yield a nonvanishing contribution to $\partial_l F_k(W_0)$

for $l=1$, and then the partial ∂_1 must act on $f(-w_1+1)$. Since $f(-w_k+w_j+1)$ yields a zero for $k=2,\ldots,N$ and $j=k-1$, the second term only contributes to $(\partial_1 F_1)(W_0)$. Specifically, using $f'(0)=1$ [cf. (A1)] we get

$$(\partial_1 F_1)(W_0)=f(1-N)\prod_{j=3}^{N} f(-j+2)\prod_{j=1}^{N} f(j+1)+f(-1-N)\prod_{j=2}^{N} f(j)\prod_{j=2}^{N} f(-j+1)$$

$$=\prod_{j=2}^{N} f(-j+1)\prod_{j=2}^{N} f(j)\cdot[f(N+1)+f(-1-N)]=0, \tag{A10}$$

since f is odd.

To calculate the remaining partials, we need only take the first term into account. Taking first $k=N$, the factor $f(w_N-N)$ yields a zero unless $l=N$. Thus, we get

$$(\partial_l F_N)(W_0)=0, \quad l=1,\ldots,N-1, \tag{A11}$$

$$(\partial_N F_N)(W_0)=\prod_{j=1}^{N-1} f(N+1-j)\prod_{j=1}^{N} f(j+1)=f(N+1)\prod_{k=2}^{N} f(k)^2. \tag{A12}$$

Taking next $k<N$, we get a zero for $j=k+1$ unless the pertinent factor is differentiated. Hence, we obtain

$$(\partial_l F_k)(W_0)=0, \quad k<N, \quad l\neq k,k+1, \tag{A13}$$

$$(\partial_{k+1} F_k)(W_0)=-f(k-N)\prod_{j\neq k,k+1} f(k-j+1)\prod_{j=1}^{N} f(j+1), \quad k<N, \tag{A14}$$

$$(\partial_k F_k)(W_0)=-(\partial_{k+1} F_k)(W_0), \quad 1<k<N. \tag{A15}$$

Summarizing, the functional matrix is of the form

$$(DF)(W_0)=\begin{pmatrix} 0 & -a_1 & 0 & \cdots & 0 & 0 \\ 0 & a_2 & -a_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & a_{N-1} & -a_{N-1} \\ 0 & 0 & 0 & \cdots & 0 & a_N \end{pmatrix}, \tag{A16}$$

so its determinant vanishes.

From now on we assume (A6) holds true. Then we deduce that

$$a_2,\ldots,a_N\neq 0, \tag{A17}$$

so the principal minor with indices $2,\ldots,N$ is nonzero. Therefore, the implicit function theorem guarantees a solution to the system (A7) with the asserted properties. [Note that (A9) amounts to $w_k'(0)=0$, $k=2,\ldots,N$; these relations follow from the explicit formula (A16) via implicit differentiation.] □

For a general function f the solution $W(t)$ to (A7) need not be a solution to (A3), i.e., one has $F_1(W(t))\neq 0$ for t near 0. On the other hand, whenever f is such that $F_1(W(t))=0$ for t near 0, one readily deduces from the inverse function theorem that one must have $|DF(W(t))|=0$ for t near 0.

APPENDIX B: UNIQUENESS OF JOINT EIGENFUNCTIONS

As we have seen in Sec. IV, the joint eigenspace

$$\mathcal{V}(y) \equiv \{ M \in \mathcal{M} | B_\delta M = E_\delta(y) M, \delta = +,- \}, \tag{B1}$$

with $\mathcal{M}$ given by (1.18), the AΔOs B_δ by (4.7), and their eigenvalues $E_\delta(y)$ by (3.20), contains the holomorphic functions $\mathcal{H}(x,y)$ and $\mathcal{H}(-x,y)$, and hence all of their linear combinations. But when a_+/a_- is rational, then $\mathcal{V}(y)$ is infinite-dimensional. Indeed, letting $a_+ = pa$ and $a_- = qa$ with p and q coprime integers, all $m \in \mathcal{M}$ with period ia have periods ia_+ and ia_-, too. Thus, for any two multipliers $m_+, m_- \in \mathcal{M}$ with period ia, we have

$$m_+(x)\mathcal{H}(x,y) + m_-(x)\mathcal{H}(-x,y) \in \mathcal{V}(y). \tag{B2}$$

This entails dim $(\mathcal{V}(y)) = \infty$, as asserted.

By contrast, when a_+/a_- is irrational, then $\mathcal{V}(y)$ is 2-dimensional for y sufficiently large. This is the content of Theorem B.1 below. As a preparation for this theorem and its proof we recall some well-known general features of the second order AΔEs at issue in this paper; cf., for example, Nörlund's monograph.[15]

We start from an AΔE of the form

$$f_+(x)M(x+c) + f_-(x)M(x-c) = g(x)M(x), \quad c \in \mathbb{C}^*, \tag{B3}$$

where $f_+, f_-, g \in \mathcal{M}$ with $f_+, f_- \neq 0$, and where only solutions $M \in \mathcal{M}$ are considered. Let M_1, M_2 be two solutions to (B3). Then the Casorati determinant,

$$C(M_1, M_2; x) \equiv M_1(x+c/2)M_2(x-c/2) - M_1(x-c/2)M_2(x+c/2), \tag{B4}$$

vanishes identically iff M_1/M_2 belongs to the field F_c of c-periodic meromorphic functions. Assuming from now on $M_1/M_2 \notin F_c$, the function (B4) is a solution to the first order AΔE

$$\frac{C(x+c/2)}{C(x-c/2)} = \frac{f_-(x)}{f_+(x)}, \tag{B5}$$

as is readily verified.

Next, assume $M_3(x)$ is a third solution to (B3). Then one easily verifies the identity

$$M_3(x) = m_1(x)M_2(x) - m_2(x)M_1(x), \tag{B6}$$

with

$$m_j(x) \equiv C(M_j, M_3; x+c/2)/C(M_1, M_2; x+c/2), \quad j = 1,2. \tag{B7}$$

Now quotients of Casorati determinants are c-periodic in view of the AΔE (B5), so one has $m_1, m_2 \in F_c$. Conversely, any function of the form (B6) with $m_1, m_2 \in F_c$ solves (B3). Whenever two solutions exist whose Casorati determinant is not identically zero, the solution space is, therefore, 2-dimensional over the field F_c of c-periodic meromorphic functions.

Consider now two AΔEs of the form (B3), with shift parameters

$$c_1 = ia_+, \quad c_2 = ia_-, \quad a_+, a_- > 0. \tag{B8}$$

Assume that two joint solutions exist whose Casorati determinants w.r.t. c_1 and c_2 are nonzero. When $a_+/a_- \in \mathbb{Q}$, then the joint solution space is infinite-dimensional, as we have already seen above. (Here and from now on, the field of scalars is again $\mathbb{C}$.) It may well be that for a_+/a_- irrational one can show that the assumptions just stated imply that the joint solution space is 2-dimensional, but we are not aware of a proof.

For the concrete situation encountered in the main text, however, we have *explicit* solutions available. We shall now exploit this to prove 2-dimensionality for the case at hand.

Theorem B.1: *Assume $a_+/a_- \notin \mathbb{Q}$. Then there exists $L \geqslant K$ such that for all $y \in (L,\infty)$ the joint eigenspace $\mathcal{V}(y)$ (B1) is 2-dimensional with basis vectors $\mathcal{H}(x,y)$ and $\mathcal{H}(-x,y)$.*

Proof: Consider the quotient function

$$Q(x) \equiv \mathcal{H}(x,y)/\mathcal{H}(-x,y), \quad y \in (K,\infty). \tag{B9}$$

In view of (3.39) and (3.5), it reads

$$Q(x) = \prod_{\delta=+,-} \prod_{j=1}^{N_\delta} \frac{s_{-\delta}(x+z_j^\delta)}{s_{-\delta}(-x+z_j^\delta)} \cdot e^{2x\Sigma}, \quad \Sigma = ir(2N_+N_- + N_+ + N_- + 1) + iy. \tag{B10}$$

Since $z_j^\delta \in i(0,\infty)$, the function $Q(x)$ is analytic for $\mathrm{Re}\, x \in (0,\pi/r)$. We claim that there exists $L \geqslant K$ such that for all $y \in (L,\infty)$ we have

$$\lim_{\mathrm{Im}\, x \to \infty} Q(x) = 0, \quad \mathrm{Re}\, x \in (0,\pi/r). \tag{B11}$$

To prove this claim, we first note that the AΔE (1.10) entails the bound

$$\left| \frac{s(r,a;x+z)}{s(r,a;x-z)} \right| \leqslant C \exp\left(4r|z| \frac{\mathrm{Im}\, x}{a} \right), \quad \mathrm{Re}\, x \in (0,\pi/r), \quad z \in i(0,\infty), \quad \mathrm{Im}\, x \to \infty. \tag{B12}$$

Therefore we have

$$|Q(x)| = O(\exp[2(r\eta - y)\mathrm{Im}\, x]), \quad \mathrm{Re}\, x \in (0,\pi/r), \quad \mathrm{Im}\, x \to \infty, \tag{B13}$$

with

$$\eta \equiv 2\left(\frac{1}{a_+} \sum_{j=1}^{N_-} |z_j^-| + \frac{1}{a_-} \sum_{j=1}^{N_+} |z_j^+| \right) - 2N_+N_- - N_+ - N_- - 1. \tag{B14}$$

Now the sums have finite limits as $y \to \infty$ [recall (3.14)], so there exists $L \geqslant K$ such that $r\eta < y$ for all $y \in (L,\infty)$. Hence, our claim follows.

Fixing $y \in (L,\infty)$, it now follows from (B11) that $Q(x)$ is neither ia_+-periodic nor ia_--periodic. Therefore, the Casorati determinants of $\mathcal{H}(x,y)$ and $\mathcal{H}(-x,y)$ w.r.t. ia_+ and ia_- are nonzero. Letting $M(x) \in \mathcal{V}(y)$ (B1), we then have both

$$M(x) = \lambda_+(x)\mathcal{H}(x,y) + \lambda_-(x)\mathcal{H}(-x,y), \tag{B15}$$

with $\lambda_+, \lambda_- \in F_{ia_+}$, and

$$M(x) = \mu_+(x)\mathcal{H}(x,y) + \mu_-(x)\mathcal{H}(-x,y), \tag{B16}$$

with $\mu_+, \mu_- \in F_{ia_-}$.

Next, we combine (B15) and (B16) to obtain

$$\lambda_-(x) - \mu_-(x) = (\mu_+(x) - \lambda_+(x))Q(x). \tag{B17}$$

Since $\lambda_+(x)$ and $\lambda_-(x)$ are ia_+-periodic meromorphic functions, they are analytic on the lines $\mathrm{Re}\, x = \rho \in [0,\pi/r]$, save for finitely many ρ. Similarly, $\mu_+(x)$ and $\mu_-(x)$ have this property. Now let $\rho_0 \in (0,\pi/r)$ be such that λ_+, λ_-, μ_+, and μ_- are analytic on $\mathrm{Re}\, x = \rho_0$. By periodicity, λ_+ and μ_+ are bounded on this line, so (B11) and (B17) entail

$$\lim_{\mathrm{Im}\, x \to \infty} (\lambda_-(x) - \mu_-(x)) = 0, \quad \mathrm{Re}\, x = \rho_0 \in (0, \pi/r). \tag{B18}$$

In particular, this implies that

$$\lim_{k \to \infty} \lambda_-(\rho_0 + ika_-) = \mu_-(\rho_0), \quad k \in \mathbb{N}. \tag{B19}$$

Thus far, we have not used our assumption that a_+/a_- is irrational. But now we can combine this assumption with (B19) to deduce that $\lambda_-(x)$ equals $\mu_-(\rho_0)$ for $\mathrm{Re}\, x = \rho_0$ and so for all x. [Indeed, the numbers $\rho_0 + ika_-$, $k > N$, are dense $(\mathrm{mod}\, ia_+)$ in the interval $\rho_0 + i[0, a_+)$ for arbitrary $N \in \mathbb{N}$.] Consequently, we must have $\lambda_-(x) = \mu_-(x) = c_-$ and $\lambda_+(x) = \mu_+(x) = c_+$. □

(Received 24 April 1998; accepted for publication 17 September 1998)

In Part I [J. Math. Phys. **40**, 1595 (1999)] we studied eigenfunctions of the quantum dynamics that defines the two-particle relativistic Calogero–Moser system with elliptic interaction. In the present paper we consider the same system with hyperbolic and trigonometric interactions. In these special regimes the eigenfunctions are shown to admit an elementary representation that is far more explicit than the ''zero representation'' of Part I. In particular, the new representation can be exploited to prove that the hyperbolic eigenfunctions can be chosen to be symmetric under interchanging position and momentum variables (self-duality). In the trigonometric case duality properties are derived, too, and several orthogonality and completeness results are obtained. © *1999 American Institute of Physics.* [S0022-2488(99)02502-5]

I. INTRODUCTION

In the preceding paper[1] (henceforth denoted by I) we obtained and studied joint eigenfunctions of two commuting analytic difference operators (AΔOs) A_+ and A_- [given by Eq. (1.15) of I or I(1.15)]. The coefficients of these AΔOs are, in essence, elliptic. More precisely, both AΔOs A_δ have meromorphic coefficients with real period π/r, $r>0$, and imaginary quasi-period ia_δ, $a_\delta>0$, $\delta=+,-$. In the present paper we study hyperbolic and trigonometric specializations of the operators and functions introduced in I, referring the reader to the Introduction of I for a description of the context from which the pertinent operators arise, their connection to the Lamé operator, and literature dealing with the subject area involved.

On the one hand, the results obtained in this paper illuminate the elliptic regime, inasmuch as various questions left open in I can be answered for the hyperbolic and trigonometric regimes. On the other hand, the special cases are of independent interest, and have some remarkable features no longer present at the elliptic level. We study the hyperbolic case in Secs. II and III, the trigonometric one in Sec. IV. Though we begin each section by indicating how the zero representation of the eigenfunctions obtained in I can be adapted, we need not and will not use these results. Indeed, we reobtain the zero representation from a second one that is quite elementary and explicit. More generally, this paper is largely independent of I, especially as concerns the hyperbolic case.

We proceed by sketching our hyperbolic results, turning to trigonometric results towards the end of this Introduction. For $r=0$ the commuting AΔOs I(1.15) reduce to

$$A_\delta(b)=\frac{s_\delta(x-ib)}{s_\delta(x)}T_{ia_{-\delta}}+(i\to -i),\quad \delta=+,-, \tag{1.1}$$

where

$$(T_\alpha f)(x)=f(x-\alpha),\quad \alpha\in\mathbb{C}. \tag{1.2}$$

Here and below, we use the notation

$$s_\delta(x)=\sinh(\pi x/a_\delta),\quad c_\delta(x)=\cosh(\pi x/a_\delta),\quad e_\delta(x)=\exp(\pi x/a_\delta),\quad \delta=+,-. \tag{1.3}$$

0022-2488/99/40(3)/1627/37/$15.00

[We should point out that our hyperbolic s_δ-function differs from the hyperbolic specialization of our elliptic s_δ-function by a factor a_δ/π; cf. I(1.11) and I(1.8). Though this may give rise to confusion, we are opting for this abuse of notation in order to minimize clutter from constants.]

Unless explicitly mentioned otherwise, we choose the parameters occurring here in the hyperbolic domain

$$\mathcal{H}\equiv\{(a_+,a_-,b)|a_+,a_->0,b\in\mathbb{R}\}. \tag{1.4}$$

This ensures that the Hamiltonians

$$H_\delta(b)\equiv\left(\frac{s_\delta(x-ib)}{s_\delta(x)}\right)^{1/2}T_{ia_{-\delta}}\left(\frac{s_\delta(x+ib)}{s_\delta(x)}\right)^{1/2}+(i\to-i),\quad \delta=+,-, \tag{1.5}$$

are formally self-adjoint. The latter are related to the AΔOs A_δ by the similarity

$$H_\delta=w(x)^{1/2}A_\delta w(x)^{-1/2}. \tag{1.6}$$

Here, $w(a_+,a_-,b;x)$ is the hyperbolic weight function studied in Ref. 2; cf. also I(1.16), I(1.17).

Save for the functional-analytic results in Sec. IV of I, it is straightforward to specialize the results in I to the hyperbolic regime. As a matter of fact, considerable simplification occurs at several places, in particular, in Appendix B of I, where uniqueness of joint eigenfunctions is studied.

The latter uniqueness results are the only ones needed, however. Indeed, we start from a representation of the joint eigenfunctions that looks quite different from the zero representation obtained in I. This new representation holds true for the dense subset of $\mathcal{H}$ (1.4) given by

$$\mathcal{D}_{\text{hyp}}\equiv\{(a_+,a_-,b)|a_+,a_->0,b=ka_++la_-,k,l\in\mathbb{Z}\}. \tag{1.7}$$

Thus no (k,l)-dependent restriction on (a_+,a_-) occurs, by contrast to the dense subset $\mathcal{D}\subset\mathcal{D}_{\text{hyp}}$ that arises upon specializing the zero representation in I.

More is true: We could even allow a_+ and a_- to be arbitrary numbers in $\mathbb{C}^*$. Similarly, x and the spectral variable p may be chosen complex. Indeed, for a fixed b of the form ka_++la_-, $k,l\in\mathbb{Z}$, we obtain functions $M_{k,l}(a_+,a_-;\pm x,p)$ that are one-valued analytic functions in all of their four arguments, and that satisfy the joint eigenfunction equations

$$A_\delta M=2c_\delta(p)M,\quad \delta=+,-. \tag{1.8}$$

The variable p is related to the variable y used in I via

$$p=a_+a_-y/\pi. \tag{1.9}$$

This rescaling ensures that the eigenfunctions are symmetric under interchanging x and p (self-duality). To be sure, this property is by no means evident from the explicit formulas—it is the quantum translation of a classical self-duality property that is not manifest either, cf. Ref. 3. As it turns out, quantum self-duality boils down to some novel ''q-identities'' [viz., symmetry of the coefficients $c_{kl}^{(N)}(q)$ given by (2.2)–(2.5)].

To provide more perspective on the b-restriction in $\mathcal{D}_{\text{hyp}}$ (1.7), we would like to mention that the even linear combination,

$$R_{k,l}(a_+,a_-;x,p)=M_{k,l}(a_+,a_-;x,p)+(x\to-x), \tag{1.10}$$

admits an interpolation to all parameters in $\mathcal{H}$ (1.4). To be specific, there exists a joint A_δ-eigenfunction $R(a_+,a_-,b;x,p)$ that reduces to $R_{k,l}$ for $b=ka_++la_-$; it is meromorphic in x and p for fixed $(a_+,a_-,b)\in\mathcal{H}$ and real-analytic on $\mathcal{H}$ for fixed x,p with $\operatorname{Re}x$, $\operatorname{Re}p\neq0$. We already detailed this function in Subsection 6.3 of our lecture notes, Ref. 4, and it will be further studied elsewhere. It is quite unclear whether the odd combination admits interpolation, too. (If so, it presumably has a quite different structure and weaker analyticity properties; cf. the pertinent discussion in I.)

Let us now describe the contents of Secs. II and III in some more detail. In Sec. II we study the special case where the coupling constant

$$g \equiv b/a_+ \tag{1.11}$$

takes integer values. More precisely, we only study the choices

$$b = (N+1)a_+, \quad N \in \mathbb{N}. \tag{1.12}$$

For this special case the hyperbolic eigenfunctions and several salient features thereof were already presented in our survey, Ref. 5, but detailed proofs were not given there. In Sec. II we demonstrate various properties of an algebraic nature, but we relegate an account of orthogonality and completeness properties to another occasion.

Specifically, the joint A_δ-eigenfunctions read

$$M_{N+1,0}(a_+,a_-;x,p) \equiv (-i)^{N+1}[P_N(x)P_N(p)]^{-1}K_N(x,p), \tag{1.13}$$

with

$$P_N(x) \equiv \prod_{j=-N}^{N} [2s_-(x+ija_+)], \tag{1.14}$$

$$K_N(x,p) \equiv \exp(i\pi xp/a_+a_-) \sum_{k,l=0}^{N} c_{kl}^{(N)}(q) e_-((N-2k)x+(N-2l)p). \tag{1.15}$$

Here, the coefficients c_{kl} depend only on N and the phase factor

$$q \equiv \exp(i\pi a_+/a_-). \tag{1.16}$$

Explicitly, they are Laurent polynomials in q with integer coefficients, given by (2.2)–(2.5).

Equivalently, the function $K_N(x,p)$ is a joint eigenfunction of the auxiliary AΔOs

$$B_- = \frac{s_-(x+iNa_+)}{s_-(x)} T_{ia_+} + (i \to -i), \tag{1.17}$$

$$B_+ = (-)^N T_{ia_-} + (i \to -i), \tag{1.18}$$

obtained by similarity transforming the AΔOs $A_\delta((N+1)a_+)$ with $P_N(x)$. Observe that one of the two eigenvalue equations, viz.,

$$B_+K_N(x,p) = 2c_+(p)K_N(x,p), \tag{1.19}$$

is immediate from the structure (1.15) of K_N, independently of the choice of c_{kl}. With (2.2)–(2.5) in force, the second one (2.1) is proved in Theorem II.1, together with various other features of $K_N(x,p)$.

With these results at our disposal, we are in the position to make the connection to the seemingly different joint eigenfunctions arising upon hyperbolic specialization of Sec. II in I. Moreover, several uniqueness aspects can be clarified by adapting Theorem B.1 in I to the case at hand. Subsequently, we study the even combination $R_{N+1,0}(a_+,a_-;x,p)$ (1.10) in Theorem II.2. [It is denoted $R_N(x,p)$ for brevity.] In particular, we show that this joint A_δ-eigenfunction specializes to a polynomial in $c_-(x)$ for certain values of p. These results will be exploited for the trigonometric regime (Sec. IV).

The third and last theorem of Sec. II concerns the case of a rational quotient a_+/a_-. It throws new light on the zero representation, and is also a crucial input for Sec. III.

In the latter section we obtain joint A_δ- and H_δ-eigenfunctions for arbitrary parameters in $\mathcal{D}_{\rm hyp}$ (1.7), but just as in Sec. II it is convenient to use an auxiliary pair of AΔOs B_+,B_- as a starting point. These AΔOs are defined for b of the form

$$b_{+-}\equiv(N_++1)a_+-N_-a_-,\quad N_+,N_-\in\mathbb{N},\tag{1.20}$$

by similarity transforming A_+,A_- (1.1) with $P_{N_+}(x)$ (1.14). Explicitly, this yields

$$B_\delta=(-)^{N_\delta}\frac{s_\delta(x+iN_{-\delta}a_{-\delta})}{s_\delta(x)}T_{ia_{-\delta}}+(i\to -i),\quad \delta=+,-.\tag{1.21}$$

[Note this reduces to (1.17), (1.18) for $N_+=N$, $N_-=0$, and $\delta=-,+$, as should be the case, of course.]

Using the functions $K_N(x,p)$ from Sec. II as building blocks, joint B_δ-eigenfunctions are readily constructed. By virtue of (the hyperbolic specialization of) Theorem B.1 in I, the joint B_δ-eigenspace associated with eigenvalues $2c_\delta(p)$ is two-dimensional for a_+/a_- *irrational*. Now it is clear that the b-values (1.20) with a_+/a_- irrational already give rise to a dense subset of the hyperbolic parameter domain $\mathcal{H}$ (1.4). Moreover, the AΔOs B_δ (1.21) may be reinterpreted as specializations of the AΔOs

$$B_\delta(b)=\frac{s_\delta(x-i\delta(b-a_+))}{s_\delta(x)}T_{ia_{-\delta}}+(i\to -i),\quad \delta=+,-,\tag{1.22}$$

which are defined for all of $\mathcal{H}$. [By contrast, the elliptic generalizations I(4.7) do not admit a continuous interpolation to the whole elliptic parameter domain.]

On the other hand, the joint B_δ-eigenfunctions exhibit an infinite-dimensional ambiguity already for the b-values b_{+-} (1.20) and *rational* a_+/a_-. This provides an example demonstrating that the absence of interpolation ambiguities cannot follow from general arguments (as one might believe). But the ambiguity exhibited by the joint B_δ-eigenfunctions does not occur for the joint H_δ- and A_δ-eigenfunctions. Indeed, we show that for rational a_+/a_- the infinity of distinct $(k,l)\in\mathbb{Z}^2$ yielding the same $b=ka_++la_-$ gives rise to an infinity of distinct representations for the *same* function.

In order to arrive at the latter conclusions, we need as technical input Theorem III.1, which deals with the case of rational a_+/a_-. The joint H_δ- and A_δ-eigenfunctions $F(\Xi;x,p)$ and $M(\Xi;x,p)$ for arbitrary $\Xi\in\mathcal{D}_{\rm hyp}$ (1.7) are further studied in Theorems III.2 and III.3, respectively; the meromorphic functions $M_{k,l}(a_+,a_-;\pm x,p)$ mentioned above are equal to $M(a_+,a_-,b;\pm x,p)$ for $b=ka_++la_-$.

Let us now turn to the trigonometric regime, studied in Sec. IV. This arises from the elliptic regime by sending one of the two imaginary periods ia_+,ia_- [cf. I(1.11)] to $i\infty$. We will take a_- to ∞ and trade a_+ for a new parameter β. Of course, the real period π/r is kept fixed. Thus, we arrive at the trigonometric parameter domain

$$\mathcal{T}\equiv\{(r,\beta,b)\,|\,r,\beta>0,b\in\mathbb{R}\}.\tag{1.23}$$

Obviously, the elliptic AΔOs H_+ and A_+ have no limits for $a_-\to\infty$. Therefore we are left with

$$A(b)=\frac{\sin r(x-ib)}{\sin rx}T_{i\beta}+(i\to -i)\tag{1.24}$$

and

$$H(b)=\left(\frac{\sin r(x-ib)}{\sin rx}\right)^{1/2}T_{i\beta}\left(\frac{\sin r(x+ib)}{\sin rx}\right)^{1/2}+(i\to -i). \tag{1.25}$$

These AΔOs are related by the similarity

$$A=w(x)^{-1/2}Hw(x)^{1/2}, \tag{1.26}$$

with $w(r,\beta,b;x)$ the trigonometric weight function from Ref. 2. Now the parameter b is of the form $ka_+ + la_-$, $k,l\in\mathbb{Z}$, for all of the eigenfunctions in I. Thus, we need to choose $l=0$ for b to remain finite as $a_-\to\infty$. Accordingly, we only obtain eigenfunctions for the $\mathcal{T}$-subset

$$\mathcal{D}_{\mathrm{trig}}\equiv\{(r,\beta,b)\,|\,r,\beta>0, b=k\beta, k\in\mathbb{Z}\}, \tag{1.27}$$

which is no longer dense. Just as in I, all of the pertinent functions are also eigenfunctions of the quasi-periodicity AΔO

$$Q\equiv T_{\pi/r}+T_{-\pi/r}. \tag{1.28}$$

Our trigonometric joint (A,Q)-eigenfunctions are obtained via analytic continuation of their hyperbolic counterparts from Sec. II. Besides the zero representation obtained by specializing Sec. II in paper I to the trigonometric regime, we therefore get a second, far more accessible, representation.

We begin Sec. IV by detailing the latter, and then clarify its relation to the zero representation. In the remainder of Sec. IV we deal with various functional-analytic aspects. Correspondingly, the spectral variable is discretized, and we wind up with Hilbert space eigenfunctions that are essentially q-Gegenbauer polynomials, with $q=\exp(-2\beta r)$. To our knowledge, our two representations are new even in this well-studied case.

By contrast to Secs. II, III, and the first part of Sec. IV, which are largely self-contained, the remainder of Sec. IV involves various features and issues already encountered in Sec. IV of I. In particular, the drastic simplification arising in the trigonometric case allows us to answer some questions that we left open in the elliptic setting. These questions can be studied by choosing k negative in (1.27).

II. THE HYPERBOLIC INTEGER-*g* CASE

The results of this section have already been summarized in some detail in the Introduction, and we will freely use the notation and operators introduced there.

We begin by recalling that in Sec. II of I we also restricted attention to the integer g case (1.12). Now when one replaces the function $s(r,a;x)$ from I by its hyperbolic counterpart $(a/\pi)\sinh(\pi x/a)$, then it is straightforward to adapt the arguments and results that can be found in Sec. II of I. There is only one minor snag in the reasoning below I(2.13): A nonconstant hyperbolic function may have one or no pole in a period strip; cf. the functions cotanh(x) and cosh(x). The pertinent hyperbolic function $E(x)$ I(2.8), however, has *finite* and *equal* limits for $\mathrm{Re}\, x\to\pm\infty$. Therefore, the usual residue argument for elliptic functions can be easily adapted to exclude the presence of only one pole in the period strip.

The results of this section go far beyond those of Sec. II in I, however. The crux is that the eigenfunctions and eigenvalues admit a simpler and much more explicit form in the hyperbolic setting, without restrictions on the spectral variable y and the pertinent parameters. In particular, this enables us to shed more light on the "zero representation" I(2.34) of the eigenfunctions. As will be shown, the latter structure of the eigenfunctions is a consequence of the eigenfunction representation employed in this section, but various features obtained below are invisible from I(2.34). For example, the spectral variable y appears to be on a very different footing from the variable x, whereas it will turn out that x and the rescaled spectral variable p (1.9) play symmetric roles.

We proceed by detailing the joint eigenfunctions $K_N(x,p)$ (1.15) of the AΔOs B_- (1.17) and B_+ (1.18) with eigenvalues $2c_\delta(p)$, $\delta=+,-$. As already pointed out, the eigenvalue equation (1.19) is satisfied irrespective of the choice of c_{kl}. It will be shown later on, however, that the coefficients are uniquely determined up to an overall q-dependent scale factor by requiring

$$B_-K_N(x,p)=2c_-(p)K_N(x,p), \tag{2.1}$$

and continuity in q.

In order to specify c_{kl}, we introduce N-element subsets $I_k^{(N)}$ of the $2N$-element set $\{-N,\ldots,-1,1,\ldots,N\}$, as follows:

$$I_k^{(N)}\equiv\{-N,\ldots,-N+k-1,\ldots,k+1,\ldots,N\},\quad k=0,\ldots,N. \tag{2.2}$$

Now we put

$$s_{kl}^{(N)}(w)\equiv\sum_{\substack{i_1<\ldots<i_k\\ i_m\in I_l^{(N)}}} w^{i_1+\cdots+i_k}, \tag{2.3}$$

$$c_l^{(N)}(w)\equiv\sum_{\substack{i_1<\ldots<i_l\\ i_m\in I_0^{(N)}}} w^{i_1+\cdots+i_l}, \tag{2.4}$$

$$c_{kl}^{(N)}(q)\equiv(-)^{k+l}q^{N(N+1)/2}s_{kl}^{(N)}(q^{-2})c_l^{(N)}(q^{-2}). \tag{2.5}$$

(Here, empty sums equal 1 by definition.) For later use we also introduce polynomials

$$Q_l^{(N)}(u)\equiv\sum_{k=0}^{N}(-)^k s_{kl}^{(N)}(w)u^k=\prod_{i\in I_l^{(N)}}(1-w^iu). \tag{2.6}$$

With these definitions in place, we are going to prove that (2.1) holds true. Before doing so, however, we specify the cases $N=0,\ldots,3$, exemplifying the above notation:

$$(N=0)\quad c_{00}=1, \tag{2.7}$$

$$(N=1)\quad c_{00}=c_{11}=q,\quad c_{01}=c_{10}=-q^{-1}, \tag{2.8}$$

$$\begin{gathered}(N=2)\quad c_{00}=c_{22}=q^3,\quad c_{02}=c_{20}=q^{-3},\\ c_{01}=c_{10}=c_{12}=c_{21}=-q-q^{-1},\quad c_{11}=q^5+q^3+q^{-3}+q^{-5},\end{gathered} \tag{2.9}$$

$$\begin{gathered}(N=3)\quad c_{00}=c_{33}=q^6,\quad c_{03}=c_{30}=-q^{-6},\\ c_{02}=c_{20}=c_{13}=c_{31}=-\overline{c_{32}}=-\overline{c_{23}}=-\overline{c_{01}}=-\overline{c_{10}}=1+q^{-2}+q^{-4},\\ c_{11}=c_{22}=-\overline{c_{12}}=-\overline{c_{21}}=q^{10}+q^8+q^6+1+2q^{-2}+2q^{-4}+q^{-6}.\end{gathered} \tag{2.10}$$

Note that, more generally, the coefficients are Laurent polynomials in q with integer coefficients for arbitrary $N\in\mathbb{N}$. The symmetry properties

$$c_{kl}=c_{lk}=c_{N-k,N-l}=(-)^N\overline{c_{N-k,l}},\quad k,l=0,\ldots,N, \tag{2.11}$$

exhibited by these special cases are, in fact, valid for arbitrary N; they are equivalent to the symmetry properties (2.13)–(2.15) in the following theorem.

Theorem II.1: *With c_{kl} defined by (2.2)–(2.5), the function $K_N(x,p)$ (1.15) satisfies the AΔE*

$$s_-(x+iNa_+)F(x-ia_+)+s_-(x-iNa_+)F(x+ia_+)=2s_-(x)c_-(p)F(x). \tag{2.12}$$

It has the symmetry properties

$$K_N(x,p)=K_N(p,x), \tag{2.13}$$

$$K_N(x,p)=K_N(-x,-p), \tag{2.14}$$

$$K_N(x,p)=(-)^N\overline{K_N}(-x,p), \quad x,p\in\mathbb{R}, \tag{2.15}$$

and satisfies

$$K_N(x,i\delta Na_+)=(2i)^N\prod_{k=N+1}^{2N}\sin(\pi ka_+/a_-), \quad \delta=+,-. \tag{2.16}$$

Now assume

$$ka_+\notin\mathbb{N}a_-, \quad k=1,\ldots,2N. \tag{2.17}$$

Then one has

$$K_N(x,i\delta(N-l)a_+)=i^NB_l^{(N)}(c_-(x)), \quad l=0,\ldots,N, \quad \delta=+,-, \tag{2.18}$$

where $B_l^{(N)}(u)$ is a polynomial of degree l and parity $(-)^l$ with real coefficients.

Proof: For $N=0$ we have

$$K_0(x,p)=\exp(i\pi xp/a_+a_-), \tag{2.19}$$

and all assertions are immediate. Assuming $N\in\mathbb{N}^*$ from now on, we find it convenient to rewrite $K_N(x,p)$ as

$$K_N(x,p)=K_0(x,p)e_-(Nx+Np)S_N(q;e_-(-2x),e_-(-2p)), \tag{2.20}$$

with

$$S_N(q;r,t)=\sum_{k,l=0}^{N}c_{kl}^{(N)}(q)r^kt^l. \tag{2.21}$$

Now we fix $N\in\mathbb{N}^*$ and suppress the dependence on N wherever this does not give rise to confusion.

We first view the general form (2.20)–(2.21) of $K(x,p)$ as an Ansatz for solving the AΔE (2.12), so as to arrive at a system of equations for the coefficients c_{kl}. We then study this system in its own right before proving that it is satisfied by the above coefficients (2.5). The general insights thus obtained will be crucial for later purposes.

Accordingly, we plug (2.20) into (2.12), and cancel factors to obtain

$$\begin{aligned}&[q^Ne_-(x)-q^{-N}e_-(-x)]e_-(p)q^{-N}S(q^2e_-(-2x),e_-(-2p))\\&\quad+[q^{-N}e_-(x)-q^Ne_-(-x)]e_-(-p)q^NS(q^{-2}e_-(-2x),e_-(-2p))\\&\quad=[e_-(x)-e_-(-x)][e_-(p)+e_-(-p)]S(e_-(-2x),e_-(-2p)).\end{aligned} \tag{2.22}$$

Multiplying by $e_-(-x-p)$ and using (2.21), this can be rewritten as

$$(1-w^N r)\sum_{k,l=0}^{N} c_{kl}w^{-k}r^k t^l+(1-w^{-N}r)t\sum_{k,l=0}^{N} c_{kl}w^k r^k t^l-(1-r)(1+t)\sum_{k,l=0}^{N} c_{kl}r^k t^l=0,$$
$$w\equiv q^{-2}=\exp(-2i\pi a_+/a_-). \tag{2.23}$$

Clearly, this is satisfied iff the coefficients d_{mn} of the monomials $r^m t^n$, $m,n=0,\ldots,N+1$, vanish. The latter read

$$d_{mn}=(1-w^{-N+m-1})c_{m-1,n-1}+(1-w^{N-m+1})c_{m-1,n}-(1-w^m)c_{m,n-1}-(1-w^{-m})c_{mn}. \tag{2.24}$$

We now study the system of equations $d_{mn}=0$ for the unknowns c_{kl} under the side conditions

$$c_{kl}=0,\quad k<0,\quad k>N,\quad l<0. \tag{2.25}$$

These conditions are obviously satisfied for the above coefficients, and they entail $d_{mn}=0$ for $m\leqslant 0$, $m\geqslant N+1$, and $n\leqslant -1$. (This is because the first two terms in brackets vanish for $m=N+1$ and the last two for $m=0$.) Thus, we wind up with the system $d_{mn}=0$, where $m=1,\ldots,N$, $n\in\mathbb{N}$, for unknowns c_{kl} in the vertical half-strip $k=0,\ldots,N$, $l\in\mathbb{N}$.

To avoid degeneracies, we now fix $a_+,a_-\in(0,\infty)$ such that $a_+/a_-\notin\mathbb{Q}$. We claim that the solution to the system is then uniquely determined, provided we prescribe the numbers $c_{0n}\equiv b_n$, $n\in\mathbb{N}$, at the left boundary of the half-strip. To explain this, we observe that the system involves four lattice points on a plaquette. Thus, we can calculate successively $c_{mn}=c_{10},c_{20},\ldots,c_{N0},c_{11},\ldots c_{N1},c_{21},\ldots$, etc. [Indeed, since $w^m\neq 1$ for $m\in\mathbb{Z}^*$, the term $(1-w^{-m})$ in (2.24) is nonzero.] Hence our claim follows. In particular, there exists a uniquely determined solution to the system when we choose boundary coefficients

$$b_n\equiv\begin{cases}(-)^n w^{-N(N+1)/4}\displaystyle\sum_{1\leqslant i_1<\cdots<i_n\leqslant N} w^{i_1+\cdots+i_n}, & n=0,\ldots,N,\\ 0, \quad n>N, & \end{cases} \tag{2.26}$$

in accordance with (2.2)–(2.5).

The unicity of this solution will be crucial shortly, but we first prove that the unique solution is actually given by (2.5). Though this can be seen directly, it is somewhat simpler to recall that the solution property is equivalent to (2.23), and to observe that (2.23) holds iff the coefficients of the monomials t^n, $n=0,\ldots,N+1$, vanish. With c_{kl} given by (2.5), the latter conditions can be written as

$$(1-w^N r)b_n Q_n(w^{-1}r)+(1-w^{-N}r)b_{n-1}Q_{n-1}(wr)-(1-r)[b_n Q_n(r)+b_{n-1}Q_{n-1}(r)]=0,$$
$$n=0,\ldots,N+1, \tag{2.27}$$

since we have

$$b_n Q_n(r)=\sum_{m=0}^{N} c_{mn}r^m,\quad b_n=c_{0n}; \tag{2.28}$$

cf. (2.6). The crux is that we may now cancel common factors in (2.27), which yields a recurrence relation for the boundary coefficients.

Specifically, taking first $n=0$ in (2.27) and noting

$$Q_0(r)=\prod_{j=1}^{N}(1-w^j r), \tag{2.29}$$

we deduce that (2.27) is satisfied. Similarly, (2.27) is satisfied for $n=N+1$. For $n\in\{1,\ldots,N\}$ we can cancel factors to obtain

$$b_n(1-w^n r)(1-w^{-N-1}r)+b_{n-1}(1-w^{N+1}r)(1-w^{-N+n-1}r)$$
$$-b_n(1-r)(1-w^{-N+n-1}r)-b_{n-1}(1-r)(1-w^n r)=0. \tag{2.30}$$

Simplifying this, we can divide by $w^{-N+n-1}-w^n$ to obtain

$$(1-w^{-n})b_n=(1-w^{N-n+1})b_{n-1}. \tag{2.31}$$

Thus, it remains to show that the boundary coefficients (2.26) satisfy this recurrence relation.

In order to prove this, we write the recurrence as

$$(1-w^{-n})\sum_{1\le i_1<\cdots<i_n\le N} w^{i_1+\cdots+i_n}+(1-w^{N-n+1})\sum_{1\le i_1<\cdots<i_{n-1}\le N} w^{i_1+\cdots+i_{n-1}}=0,$$
$$n=1,\ldots,N. \tag{2.32}$$

Now we first handle the special case $n=N$. Then (2.32) reads

$$(1-w^{-N})w^{1+\cdots+N}+(1-w)w^{1+\cdots+N}(w^{-1}+w^{-2}+\cdots+w^{-N})=0, \tag{2.33}$$

which is clearly true. Next, we use induction on N. Thus we assume (2.32) holds when N is replaced by $N-1$. Then we need only prove (2.32) for $n\in\{1,\ldots,N-1\}$. To this end we rewrite the first term on the lhs, using the induction hypothesis:

$$(1-w^{-n})\left(\sum_{1\le i_1<\cdots<i_n\le N-1} w^{i_1+\cdots+i_n}+w^N\sum_{1\le i_1<\cdots<i_{n-1}\le N-1} w^{i_1+\cdots+i_{n-1}}\right)$$
$$=-(1-w^{N-n})\sum_{1\le i_1<\cdots<i_{n-1}\le N-1} w^{i_1+\cdots+i_{n-1}}+(w^N-w^{N-n})$$
$$\times\sum_{1\le i_1<\cdots<i_{n-1}\le N-1} w^{i_1+\cdots+i_{n-1}}$$
$$=(w^N-1)\sum_{1\le i_1<\cdots<i_{n-1}\le N-1} w^{i_1+\cdots+i_{n-1}}. \tag{2.34}$$

Adding the second term, we obtain

$$w^N\left(\sum_{1\le i_1<\cdots<i_{n-1}\le N-1}-\sum_{0\le i_1<\cdots<i_{n-1}\le N-1}\right)w^{i_1+\cdots+i_{n-1}}$$
$$+\left(\sum_{1\le i_1<\cdots<i_{n-1}\le N}-\sum_{1\le i_1<\cdots<i_{n-1}\le N-1}\right)w^{i_1+\cdots+i_{n-1}}$$
$$=-w^N\sum_{1\le i_2<\cdots<i_{n-1}\le N-1} w^{i_2+\cdots+i_{n-1}}+w^N\sum_{1\le i_1<\cdots<i_{n-2}\le N-1} w^{i_1+\cdots+i_{n-2}}=0, \tag{2.35}$$

and so (2.32) follows.

The upshot is that $K(x,p)$ satisfies the AΔE (2.12). To prove the symmetry properties (2.13)–(2.15), we exploit the uniqueness of the solution to the system $d_{mn}=0$ with side conditions (2.25) and boundary condition (2.26). First, let us note that (2.13) is equivalent to symmetry of the coefficient matrix; cf. (1.15). Now it is clear from (2.2)–(2.5) that we have $c_{m0}=c_{0m}$ for $m=0,\ldots,N$, so by uniqueness it suffices to show that the transposed matrix solves the system $d_{mn}=0$, too.

In order to prove this, we use (2.26) to write the pertinent numbers d_{mn} as

$$b_{m-1}((-)^{n-1}s_{n-1,m-1}(1-w^{-N+m-1})+(-)^n s_{n,m-1}(1-w^{N-m+1}))$$
$$-b_m((-)^{n-1}s_{n-1,m}(1-w^m)+(-)^n s_{nm}(1-w^{-m})). \tag{2.36}$$

Now we deduce from the recurrence relation (2.31) that this expression vanishes iff

$$w^{-N+m-1}s_{n-1,m-1}+s_{n,m-1}=s_{nm}+w^m s_{n-1,m}. \tag{2.37}$$

From (2.3) we see that this amounts to

$$w^{-N+m-1}\sum_{\substack{i_1<\ldots<i_{n-1}\\ i_l\in I_{m-1}}} w^{i_1+\cdots+i_{n-1}}+\sum_{\substack{i_1<\ldots<i_n\\ i_l\in I_{m-1}}} w^{i_1+\cdots+i_n}$$
$$=\sum_{\substack{i_1<\ldots<i_n\\ i_l\in I_m}} w^{i_1+\cdots+i_n}+w^m\sum_{\substack{i_1<\ldots<i_{n-1}\\ i_l\in I_m}} w^{i_1+\cdots+i_{n-1}}. \tag{2.38}$$

A moment's thought reveals that this is indeed true: both the lhs and rhs are equal to the sum

$$\sum_{\substack{i_1<\ldots<i_n\\ i_l\in\{-N,\ldots,-N+m-1,m,\ldots,N\}}} w^{i_1+\cdots+i_n}. \tag{2.39}$$

Therefore, the self-duality relation (2.13) is now proved.

Next, we demonstrate (2.14) and (2.15). Since (2.14) follows by combining (2.15) with the already proved symmetry property (2.13), it suffices to show (2.15). In view of (1.15) this amounts to c_{kl} being equal to $(-)^N\overline{c_{N-k,l}}$, and since the coefficient matrix is symmetric we need only show

$$c_{kl}=(-)^N\overline{c_{k,N-l}}. \tag{2.40}$$

Now from (2.3) we deduce $\overline{s_{k,N-l}}=s_{kl}$, and from (2.4) we have

$$\overline{c_{N-l}}=\sum_{1\le i_1<\cdots<i_{N-l}\le N} w^{-(i_1+\cdots+i_{N-l})}=w^{-(1+2+\cdots+N)}\sum_{1\le j_1<\cdots<j_l\le N} w^{j_1+\cdots j_l}=q^{N(N+1)}c_l. \tag{2.41}$$

Therefore, (2.40) is clear from (2.5).

In summary, we have now proved that $K(x,p)$ (1.15) satisfies (2.12)–(2.15), provided $a_+/a_-\notin\mathbb{Q}$. (Recall that the restriction was needed to ensure uniqueness of the solution to the coefficient system. To see why uniqueness breaks down otherwise, one need only inspect the special case $a_+=a_-$.) Since the coefficients $c_{kl}(q)$ are Laurent polynomials in $q=\exp(i\pi a_+/a_-)$, the function $K(x,p)$ is well defined and continuous for all $a_+,a_-\in(0,\infty)$. Hence, it satisfies (2.12)–(2.15) for rational a_+/a_-, too.

We continue by proving (2.16). From (2.19)–(2.21) we have

$$K(x,-iNa_+)=e_-(Nx)e_-(Nx)q^{-N^2}\sum_{k,l=0}^{N} c_{kl}e_-(-2kx)q^{2lN}. \tag{2.42}$$

Using $c_{kl}=c_{lk}$ and recalling (2.2)–(2.6), this can be rewritten as

$$K(x,-iNa_+)=e_-(2Nx)q^{-N^2+N(N+1)/2}\sum_{k=0}^{N}(-)^k c_k e_-(-2kx)Q_k(q^{2N}). \quad (2.43)$$

The key point is now that $Q_k(u)$ vanishes for $u=q^{2N}=w^{-N}$, unless $k=N$. [Indeed, N belongs to $I_k^{(N)}$, save for $k=N$; cf. (2.2).] Hence we get

$$K(x,-iNa_+)=(-)^N q^{-N^2-N(N+1)/2}Q_N(q^{2N})=\prod_{k=N+1}^{2N}(q^k-q^{-k}). \quad (2.44)$$

This amounts to (2.16) with $\delta=-$. For $\delta=+$ we use (2.14) to obtain

$$K(x,iNa_+)=K(-x,-iNa_+)=K(x,-iNa_+). \quad (2.45)$$

To prove the last assertion of the theorem, we note that by virtue of (2.13), $K(x,p)$ satisfies the dual AΔE

$$s_-(p+iNa_+)K(x,p-ia_+)+s_-(p-iNa_+)K(x,p+ia_+)=2s_-(p)c_-(x)K(x,p). \quad (2.46)$$

Substituting $p=iNa_+$, this yields

$$s_-(2iNa_+)K(x,i(N-1)a_+)=2s_-(iNa_+)c_-(x)K(x,iNa_+). \quad (2.47)$$

Assuming (2.17) from now on, we have $s_-(ika_+)\neq 0$ for $k=1,\ldots,2N$. From (2.16) we then deduce that $K(x,i(N-1)a_+)$ is a nonzero multiple of $c_-(x)$. Putting next $p=i(N-1)a_+$ in the dual AΔE, we infer that $K(x,i(N-2)a_+)$ is of the form $Ac_-(x)^2+B$, with $A\neq 0$, etc. This yields (2.18) for $\delta=-$, and then the $\delta=+$ case follows from the evenness relation (2.14). □

It should be noted that the self-duality property (2.13) entails that we have

$$\hat{B}_\delta K_N(x,p)=2c_\delta(x)K_N(x,p), \quad \delta=+,-, \quad (2.48)$$

where $\hat{B}_\delta$ are the dual AΔOs

$$\hat{B}_-\equiv\frac{s_-(p+iNa_+)}{s_-(p)}\hat{T}_{ia_+}+(i\to -i), \quad (2.49)$$

$$\hat{B}_+\equiv(-)^N\hat{T}_{ia_-}+(i\to -i), \quad (2.50)$$

with

$$(\hat{T}_\alpha G)(p)\equiv G(p-\alpha), \quad \alpha\in\mathbb{C}. \quad (2.51)$$

Thus $K_N(x,p)$ is a joint eigenfunction of four independent AΔOs. [In fact, we already exploited (2.48) with $\delta=-$ in the above proof; cf. (2.46).]

We continue by detailing the relation between $K_N(x,p)$ and the function $\mathcal{H}_N(x,y)$ from Sec. II in I [cf. I(2.34)], specialized to the hyperbolic context. Consider the two-variable polynomial $S_N(r,t)$ (2.21). The coefficient of t^N reads

$$\sum_{k=0}^{N}c_{kN}r^k=(-)^N q^{-N(N+1)/2}Q_N(r)=(-)^N q^{-N(N+1)/2}\prod_{j=1}^{N}(1-q^{2j}r); \quad (2.52)$$

cf. (2.6). Similarly, the coefficient of t^0 reads

$$S(r,0)=q^{N(N+1)/2}Q_0(r)=q^{N(N+1)/2}\prod_{j=1}^{N}(1-q^{-2j}r). \tag{2.53}$$

Now we view $S(r,t)$ as a polynomial in r with t-dependent coefficients, recalling $S(r,t)=S(t,r)$. The coefficient of r^N is therefore given by the rhs of (2.52) with $r\to t$. Assuming $t\neq q^{-2j}$, $j=1,\ldots,N$, from now on, it follows that $S(r,t)$ is of degree N in r and can be written as

$$S(r,t)=q^{-N(N+1)/2}\prod_{j=1}^{N}(1-q^{2j}t)(\rho_j-r), \tag{2.54}$$

where the roots ρ_j depend on q and t. Likewise, (2.53) entails

$$S(0,t)=q^{N(N+1)/2}\prod_{j=1}^{N}(1-q^{-2j}t). \tag{2.55}$$

Hence, putting $r=0$ in (2.54), we deduce

$$\prod_{j=1}^{N}\rho_j=q^{N(N+1)}\prod_{j=1}^{N}\frac{1-q^{-2j}t}{1-q^{2j}t}. \tag{2.56}$$

In particular, none of the roots vanishes, provided $t\neq q^{2j}$, $j=1,\ldots,N$. Moreover, from (2.53) we infer that the root ρ_j may be chosen equal to q^{2j} for $t=0$.

We now rewrite t as $e_-(-2p)$, so that (2.56) becomes

$$\prod_{j=1}^{N}\rho_j=\prod_{j=1}^{N}\frac{s_-(p+ija_+)}{s_-(p-ija_+)}. \tag{2.57}$$

Restricting attention to $\{\mathrm{Re}\, p>0\}$, we may introduce (continuous) functions $z_j(p)$ by requiring

$$\rho_j=e_-(2z_j),\quad z_j(p)\to ija_+,\quad p\to\infty,\quad j=1,\ldots,N. \tag{2.58}$$

Then a routine calculation [using (2.54)] yields

$$e_-(Nx+Np)S(e_-(-2x),e_-(-2p))=2^{2N}\prod_{j=1}^{N}[s_-(p+ija_+)s_-(p-ija_+)]^{1/2}s_-(x+z_j(p)). \tag{2.59}$$

It should be emphasized that the above holds true for all positive a_+,a_-. To establish contact with Sec. II in I, however, we should require (2.17); cf. I(2.25). Then it easily follows that the zeros $z_j(p)$ may be identified with the zeros $z_j(y)$ in *loc. cit.*, with p and y related via (1.9), and that the relation to $\mathcal{H}_N$ I(2.34), reads

$$K_N(x,p)=(4\pi/a_-)^N\prod_{j=1}^{N}[s_-(p+ija_+)s_-(p-ija_+)]^{1/2}\cdot\mathcal{H}_N(x,\pi p/a_+a_-). \tag{2.60}$$

Moreover, (2.17) entails *nonconstancy* in p for all of the zeros $z_j(p)$. [Indeed, the coefficients d_l I(2.46) in the asymptotics I(2.45) are nonzero.] We will show later on that p-independent zeros do occur when (2.17) is violated; equivalently, the polynomial $S_N(r,t)$ is not irreducible in that case.

It is a remarkable consequence of (the hyperbolic specialization of) Sec. II in I that all of the roots ρ_j lie on the unit circle for $t\in(0,\epsilon)$ and ϵ small enough. For $N=1$ this remains true for all $t\in(0,1]$ and all $a_+,a_-\in(0,\infty)$; cf. (2.56). But already for $N=2,3$ and suitable a_+,a_-, the roots do not stay on the unit circle as t goes to 1. Hence, the functions $z_j(p)$ move off the imaginary axis as p decreases from ∞ to 0. This entails that the parameter K is indispensable when one requires the z_j to belong to $i(0,\infty)$—as we do in *loc. cit.*

To see the roots move off the unit circle for $N=2$, one need only use (2.9) to calculate

$$S_2(r,1)=(q^3-q-q^{-1}+q^{-3})(1+C_2r+r^2), \quad C_2\equiv q^2+2+q^{-2}. \tag{2.61}$$

Since we have $C_2=4\cos^2(\pi a_+/a_-)$, we get $C_2\in(2,4)$ for $a_+\in(0,a_-/4)$ (say). Thus, the roots $[-C_2\pm(C_2^2-4)^{1/2}]/2$ do not lie on the unit circle for $a_+/a_-<1/4$. Likewise, for $N=3$ one readily calculates from (2.10),

$$S_3(r,1)=[q^6-q^4-q^2-(q\to q^{-1})][1+C_3(r+r^2)+r^3], \quad C_3\equiv q^4+2q^2+3+2q^{-2}+q^{-4}. \tag{2.62}$$

For $q\to 1$ the roots therefore converge to those of the polynomial $(1+r)(1+8r+r^2)$. From this it easily follows that for a_+/a_- small enough (at least) two roots move off the unit circle as $p\downarrow 0$.

Next, we reconsider the formula I(2.43) for the Casorati determinant I(2.41). In view of (2.60) and (2.14) we may as well study

$$D_N^+(x)\equiv K_N(x+ia_+/2,p)K_N(x-ia_+/2,-p)-(i\to -i). \tag{2.63}$$

Adapting the reasoning in *loc. cit.* to the present context, we obtain

$$D_N^+(x)=\beta_N(p)\prod_{n=-N+1/2}^{N-1/2} s_-(x-ina_+). \tag{2.64}$$

Indeed, the quotient of $D_N^+(x)$ and the product on the rhs is hyperbolic with period ia_- and pole-free. Since the quotient has finite limits for $\mathrm{Re}\,x\to\pm\infty$, it is x-independent.

Now the limit $\beta_N(p)$ of the quotient for $\mathrm{Re}\,x\to\infty$ (say) can be determined explicitly from (1.15); it reads

$$\beta_N(p)=2^{2N}[e_-(-p)-e_-(p)]\left(\sum_{l=0}^{N} c_{0l}e_-((N-2l)p)\right)(p\to -p). \tag{2.65}$$

Using $c_{0l}=c_{l0}$ and (2.4)–(2.6), this can be rewritten as

$$\begin{aligned}\beta_N(p)&=2^{2N+1}s_-(-p)q^{N(N+1)}Q_0(e_-(-2p))Q_0(e_-(2p))\\&=(-)^{N+1}2^{4N+1}\prod_{j=-N}^{N} s_-(p+ija_+).\end{aligned} \tag{2.66}$$

Recalling (2.60), we deduce that α_N in I(2.43) specializes to

$$\alpha_N=(-)^{N+1}2\sinh(a_+y), \quad y=\pi p/a_+a_-. \tag{2.67}$$

From (2.66) we read off that the Casorati determinant of the solutions $K_N(x,p)$ and $K_N(x,-p)$ to the AΔE (2.12) vanishes identically iff p equals $p_{jk}\equiv ija_++ika_-$ with $j=-N,\ldots,N$ and $k\in\mathbb{Z}$. For other p-values it then follows that the meromorphic quotient function $K_N(x,p)/K_N(x,-p)$ is not ia_+-periodic (cf. Appendix B in I). Moreover, from (2.18) we obtain

$$K_N(x,p_{jk})=e_+(-2kx)K_N(x,-p_{jk}), \quad j=-N,\ldots,N, \quad k\in\mathbb{Z}. \tag{2.68}$$

As should be the case, this yields an ia_+-periodic quotient $e_+(-2kx)$ whenever the lhs does not vanish identically.

Consider next the Casorati determinant

$$D_N^-(x) \equiv K_N(x+ia_-/2,p)K_N(x-ia_-/2,-p)-(i\to -i), \tag{2.69}$$

corresponding to the AΔE (1.19). From (2.19)–(2.21), we obtain

$$D_N^-(x) = -2s_+(p)e_-(2Nx)S_N(q;-e_-(-2x),e_-(-2p))S_N(q;-e_-(-2x),e_-(2p)). \tag{2.70}$$

Thus, $D_N^-(x)$ vanishes for $p=ija_+$, $j\in\mathbb{Z}$, and for p such that $K_N(x,p)=0$ identically, while for other p-values the quotient $K_N(x,p)/K_N(x,-p)$ is not ia_--periodic. [Note that the functions $K_N(x,\pm ija_+)$ are manifestly either ia_--periodic or ia_--antiperiodic, depending on the parity of j.]

Restricting attention to $\mathrm{Re}\, p\neq 0$, both $D_N^+(x)$ and $D_N^-(x)$ are nonzero. Then the reasoning in the proof of Theorem B.1 in I applies with various simplifications. It leads to the conclusion that for $a_+/a_-\notin\mathbb{Q}$ and $\mathrm{Re}\, p>0$ the joint eigenspace of the AΔO pair (B_+,B_-) corresponding to eigenvalues $(2c_+(p),2c_-(p))$ is two-dimensional, and spanned by the functions $K_N(\pm x,p)$.

The result just arrived at amounts to a sharpening of Theorem B.1 in I for the hyperbolic integer g case. It entails, in particular, that for a_+/a_- irrational the coefficients in (2.21) must be proportional to (2.5) whenever (2.1) holds true. Hence, the assertion in the sentence containing (2.1) easily follows.

It is of interest to point out a second, closely related corollary. Recall that we showed in the proof of Theorem II.1 that the system $d_{mn}=0$ with side conditions (2.25) and irrational a_+/a_- has a unique solution c_{kl} for *arbitrary* boundary coefficients c_{0n}. We are now in the position to deduce that this solution does not vanish for all $l>N$ *unless* the boundary coefficients are proportional to b_n (2.26)—a surprising fact that we are unable to establish directly.

We continue by deriving some features of the joint eigenfunction

$$R_N(x,p) \equiv (-i)^{N+1}[K_N(x,p)-K_N(x,-p)][P_N(x)P_N(p)]^{-1}, \tag{2.71}$$

of the AΔOs A_+ and A_-. Notice that this definition entails, in particular,

$$R_0(x,p) = \frac{\sin(\pi xp/a_+a_-)}{2s_-(x)s_-(p)}; \tag{2.72}$$

cf. (2.19).

Theorem II.2: *The function $R_N(x,p)$ satisfies the AΔE*

$$s_-(x-i(N+1)a_+)F(x-ia_+)+s_-(x+i(N+1)a_+)F(x+ia_+) = 2s_-(x)c_-(p)F(x). \tag{2.73}$$

It has the symmetry properties

$$R_N(x,p)=R_N(p,x), \tag{2.74}$$

$$R_N(x,p)=R_N(-x,p)=R_N(x,-p), \tag{2.75}$$

$$R_N(x,p)=\overline{R_N}(x,p), \quad x,p\in\mathbb{R}. \tag{2.76}$$

Now assume

$$a_+/a_-\notin\mathbb{Q}. \tag{2.77}$$

Then one has

$$R_N(x,\pm i(N+1)a_+) = \prod_{k=N+1}^{2N+1}[2\sin(\pi ka_+/a_-)]^{-1}. \tag{2.78}$$

Moreover, one has

$$R_N(x,i\delta(N+1+l)a_+)=G_l^{(N)}(c_-(x)),\quad l\in\mathbb{N},\quad \delta=+,-,\tag{2.79}$$

where $G_l^{(N)}(u)$ is a polynomial of degree l and parity $(-)^l$ with real coefficients.

Proof: The features (2.73)–(2.76) readily follow from Theorem II.1. Combining (2.73) and (2.74) yields the dual AΔE

$$s_-(p-i(N+1)a_+)R_N(x,p-ia_+)+(i\to -i)=2s_-(p)c_-(x)R_N(x,p).\tag{2.80}$$

Substituting $p=i(N+1)a_+$, this reads

$$s_-(2i(N+1)a_+)R_N(x,i(N+2)a_+)=2s_-(i(N+1)a_+)c_-(x)R_N(x,i(N+1)a_+).\tag{2.81}$$

Assuming (2.77) from now on, let us first take (2.78) for granted. Then (2.81) entails that $R_N(x,i(N+2)a_+)$ is a nonzero real multiple of $c_-(x)$. Taking next $p=i(N+2)a_+$ in (2.80), we infer that $R_N(x,i(N+3)a_+)$ is of the form $Cc_-(x)^2+D$, with $C\in\mathbb{R}^*$, $D\in\mathbb{R}$. More generally, putting $p=i(N+l)a_+$, $l\in\mathbb{N}^*$, yields a three-term recurrence relation with coefficients in $i\mathbb{R}^*$, and so the last assertion of the theorem easily follows.

It remains to prove (2.78). Due to (2.71) this identity amounts to

$$K_N(x,-i(N+1)a_+)-K_N(x,i(N+1)a_+)=(-)^N\prod_{j=-N}^{N}(q^je_-(x)-q^{-j}e_-(-x))\prod_{l=1}^{N}(q^l-q^{-l}).\tag{2.82}$$

In view of (1.15) and (2.14), the lhs can be written as

$$2\sum_{k=0}^{N}L_ks_-((2k+1)x),\tag{2.83}$$

with

$$\begin{aligned}L_k&\equiv q^{N(N+1)}\sum_{l=0}^{N}c_{kl}^{(N)}(q)q^{-2l(N+1)}\\&=(-)^kq^{3N(N+1)/2}c_k^{(N)}(q^{-2})\prod_{j\in I_k}(1-q^{-2j}\cdot q^{-2(N+1)}),\quad k=0,\dots,N.\end{aligned}\tag{2.84}$$

[Here we used $c_{kl}=c_{lk}$, (2.5) and (2.6).]

On the other hand, we have

$$\begin{aligned}\prod_{j=-N}^{N}(q^je_-(x)-q^{-j}e_-(-x))&=e_-((2N+1)x)\prod_{j=-N}^{N}(1-q^{-2j}e_-(-2x))\\&=e_-((2N+1)x)\sum_{m=0}^{2N+1}(-)^ms_me_-(-2mx),\end{aligned}\tag{2.85}$$

where

$$s_m\equiv\sum_{-N\le j_1<\cdots<j_m\le N}q^{-2(j_1+\cdots+j_m)},\quad m=0,\dots,2N+1.\tag{2.86}$$

Now one easily sees that $s_{2N+1-m}=s_m$, so the rhs of (2.85) can be written as

$$2\sum_{k=0}^{N} R_k s_-((2k+1)x), \quad R_k \equiv (-)^{N-k} s_{N-k}, \quad k=0,\ldots,N. \tag{2.87}$$

Comparing, we deduce that (2.82) is equivalent to the identities

$$L_k = (-)^N R_k \prod_{l=1}^{N} (q^l - q^{-l}), \quad k=0,\ldots,N. \tag{2.88}$$

We proceed by proving (2.88). First, we take $k=N$. Then (2.84) yields [cf. (2.2) and (2.4)]

$$L_N = (-)^N q^{N(N+1)/2} \prod_{l=1}^{N} (1-q^{-2l}), \tag{2.89}$$

whereas (2.87) and (2.86) imply $R_N=1$. Hence (2.88) holds true for $k=N$.

Next, we note that the recurrence relation (2.31) obtained in the proof of Theorem II.1 can be rewritten as

$$(1-w^{-k}) c_k^{(N)}(w) = (w^{N-k+1}-1) c_{k-1}^{(N)}(w), \quad k=1,\ldots,N; \tag{2.90}$$

cf. (2.26) and (2.4). In view of (2.84) and (2.2), this entails

$$\frac{L_k}{L_{k-1}} = \frac{1-w^{N-k+1}}{1-w^{-k}} \cdot \frac{1-w^{-N+k-1}\cdot w^{N+1}}{1-w^{k}\cdot w^{N+1}} = \frac{w^k - w^{N+1}}{w^{k+N+1}-1}, \quad k=1,\ldots,N. \tag{2.91}$$

To conclude the proof of the theorem, it is therefore sufficient to show that the coefficients R_k satisfy the recurrence relation (2.91), too. Due to (2.87) this amounts to the recurrence

$$\frac{s_{N-k}}{s_{N-k+1}} = \frac{w^k - w^{N+1}}{1-w^{k+N+1}}, \quad k=1,\ldots,N. \tag{2.92}$$

To prove that (2.92) indeed holds, we observe that we may write (2.86) as

$$s_m = w^{-m(N+1)} \sum_{1\leqslant i_1<\cdots<i_m\leqslant 2N+1} w^{i_1+\cdots+i_m} = w^{-m(N+1)} c_m^{(2N+1)}(w). \tag{2.93}$$

Using (2.90) with $N \to 2N+1$, we therefore have

$$\frac{s_{m-1}}{s_m} = w^{N+1} \frac{1-w^{-m}}{w^{2N-m+2}-1}, \quad m=1,\ldots,2N+1. \tag{2.94}$$

Putting $m=N-k+1$, this yields (2.92), completing the proof. □

The polynomials $G_l^{(N)}$ (2.79) may be viewed as analytic continuations of q_t^2-Gegenbauer polynomials with $q_t \in (0,1)$ to q on the unit circle; cf. (1.16). This will become clear from our study of the trigonometric setting, which we undertake in Sec. IV. Indeed, the results embodied in Theorems II.1 and II.2 have trigonometric corollaries that can be obtained rather easily.

Our next and last theorem in this section has no bearing on the trigonometric case. Rather, it throws new light on the zero representation (2.59) and the restriction (2.17) corresponding to I(2.25). Moreover, the theorem plays a crucial role in Sec. III, where we handle the general hyperbolic case. It concerns the case of rational a_+/a_-, which we encode here as

$$a_+/a_- = s/r, \quad s,r \in \mathbb{N}^*, \quad s,r \text{ coprime}. \tag{2.95}$$

Assuming (2.95), the restriction (2.17) is satisfied iff $N<r/2$. Hence for $N<r/2$ all of the zeros $z_j(p)$ on the rhs of (2.59) are p-dependent. [Recall the paragraph containing (2.60).] Now (2.59) was derived without restrictions on a_+, a_-, and N. In particular, it holds true for

$$L=M+mr, \quad M\in\mathbb{N}, \quad M\leq r-1, \quad m\in\mathbb{N}^*. \tag{2.96}$$

Our next result entails that in (2.59) we then have

$$z_j(p)=ija_+, \quad j=M+1,\ldots,L. \tag{2.97}$$

That is, these zeros are p-independent and therefore equal to their limits for $p\to\infty$; cf. (2.58). Moreover, for $r>1$ and $M\in[r/2,r-1]$, one also has

$$z_j(p)=ija_+, \quad j=r-M,\ldots,M. \tag{2.98}$$

The following theorem contains far more information than its easy corollaries just mentioned. Note, however, that the prefactors in the formulas (2.99) and (2.100) can be independently checked when one takes (2.97) and (2.98) for granted and uses (2.59).

Theorem II.3: *Fix $a_+,a_->0$ such that (2.95) holds true, and assume (2.96). Then one has*

$$K_L(x,p)=q^{L(L+1)/2}q^{-M(M+1)/2}[4s_-(rx)s_-(rp)]^m K_M(x,p). \tag{2.99}$$

Next, assume $r>1$ and $M\in[r/2,r-1]$. Then one has

$$K_M(x,p)=\prod_{j=r-M}^{M}[4q^{-j}s_-(x+ija_+)s_-(p+ija_+)]\cdot K_N(x,p), \quad N\equiv r-1-M. \tag{2.100}$$

Proof: Since the variables

$$q=\exp(i\pi s/r), \quad w=\exp(-2i\pi s/r) \tag{2.101}$$

are fixed, we may as well suppress them. Our starting point is the identity

$$S_N(u,t)=q^{N(N+1)/2}\sum_{n=0}^{N}(-t)^n c_n^{(N)}Q_n^{(N)}(u), \tag{2.102}$$

which easily follows from the above definitions [cf. (2.21) and (2.2)–(2.6)]. It entails that (2.99) is equivalent to the relation

$$\sum_{l=0}^{L}(-t)^l c_l^{(L)}Q_l^{(L)}(u)=(1-u^r)^m(1-t^r)^m\sum_{k=0}^{M}(-t)^k c_k^{(M)}Q_k^{(M)}(u). \tag{2.103}$$

We prove (2.103) in several steps. First, we note the identity

$$\prod_{l=\rho+1}^{\rho+r}(1-w^l u)=1-u^r, \quad \rho\in\mathbb{Z}. \tag{2.104}$$

Indeed, since s and r are coprime, the numbers ls, with r consecutive integers l, are distinct $\bmod\, r$. Thus (2.104) is a consequence of the identity

$$\prod_{j=1}^{r}(1-\zeta^j u)=1-u^r, \quad \zeta\equiv\exp(-2i\pi/r), \tag{2.105}$$

whose proof is immediate.

Second, we exploit (2.104) to relate $Q_l^{(L)}$ for l of the form $k+jr$ with $k=0,\ldots,M$ and $j=0,\ldots,m$ to $Q_k^{(M)}$. Specifically, from the definitions (2.6) and (2.2), we obtain

$$\begin{aligned} Q_{k+jr}^{(L)}(u) &= \prod_{l=-L}^{-L+k+jr-1} (1-w^l u)\cdot \prod_{l=k+jr+1}^{L} (1-w^l u) \\ &= (1-u^r)^j \prod_{l=-M}^{-M+k-1} (1-w^l u)\cdot (1-u^r)^{m-j} \prod_{l=k+1}^{M} (1-w^l u) \\ &= (1-u^r)^m Q_k^{(M)}(u), \quad k=0,\ldots,M, \quad j=0,\ldots,m. \end{aligned} \tag{2.106}$$

Third, we combine the special case $k,j=0$ of (2.106), which we rewrite as

$$Q_0^{(L)}(u) = Q_0^{(M)}(u) \sum_{j=0}^{m} (-)^j \binom{m}{j} u^{jr}, \tag{2.107}$$

with the expansions

$$Q_0^{(L)}(u) = \sum_{l=0}^{L} c_l^{(L)} (-u)^l, \quad Q_0^{(M)}(u) = \sum_{k=0}^{M} c_k^{(M)} (-u)^k, \tag{2.108}$$

which follow from (2.3)–(2.6). Since $Q_0^{(M)}(u)$ has degree $M<r$, this yields

$$c_l^{(L)} = 0, \quad l = M+1,\ldots,r-1 \pmod r, \tag{2.109}$$

$$c_{k+jr}^{(L)} = (-)^{jr+j} \binom{m}{j} c_k^{(M)}, \quad k=0,\ldots,M, \quad j=0,\ldots,m. \tag{2.110}$$

Fourth, we use (2.109), (2.110), and (2.106) to write

$$\begin{aligned} \sum_{l=0}^{L} (-t)^l c_l^{(L)} Q_l^{(L)}(u) &= \sum_{k=0}^{M} \sum_{j=0}^{m} (-t)^{k+jr} c_{k+jr}^{(L)} Q_{k+jr}^{(L)}(u) \\ &= (1-u^r)^m \sum_{k=0}^{M} (-t)^k c_k^{(M)} Q_k^{(M)}(u) \sum_{j=0}^{m} (-t^r)^j \binom{m}{j} \\ &= (1-u^r)^m (1-t^r)^m \sum_{k=0}^{M} (-t)^k c_k^{(M)} Q_k^{(M)}(u). \end{aligned} \tag{2.111}$$

This equals (2.103), so (2.99) follows.

To prove (2.100), we begin by noting that when we write

$$Q_j^{(M)}(u) = P^{(M)}(u) R_j^{(M)}(u), \quad P^{(M)}(u) \equiv \prod_{k=r-M}^{M} (1-w^k u), \tag{2.112}$$

then $R_j^{(M)}(u)$ is a polynomial of degree N. Of course, this is plain from (2.6) for $j=0,\ldots,N$, independently of the value of w. Since we have $w^r=1$ in the present case however, the remainder term $R_j^{(M)}(u)$ is still a polynomial for $j=r-M,\ldots,M$.

From (2.102) with $N\to M$ we now deduce that $S_M(u,t)$ is the product of $P^{(M)}(u)$ and a polynomial in u and t. By self-duality (symmetry under $u\leftrightarrow t$) we then must have

$$S_M(u,t) = P^{(M)}(u) P^{(M)}(t) P_N(u,t), \tag{2.113}$$

where $P_N(u,t)$ is a polynomial of degree N in u and t, symmetric under the interchange of u and t. Using (2.113) to rewrite the lhs of (2.100), it now follows from a straightforward calculation that (2.100) amounts to

$$P_N(u,t)=\prod_{j=r-M}^{M} q^j \cdot S_N(u,t). \tag{2.114}$$

Next, we observe that (2.114) holds true for $u=t=0$. [To check this, use $S_K(0,0)=q^{K(K+1)/2}$ and $P^{(M)}(0)=1$.] Thus, we need only show that the polynomials P_N and S_N are proportional. Switching back, this amounts to the quotient function

$$Q_N(x,p)\equiv K_M(x,p) \Big/ \prod_{j=r-M}^{M} [s_-(x+ija_+)s_-(p+ija_+)] \tag{2.115}$$

being proportional to $K_N(x,p)$. We proceed by proving this, making suitable use of the first part of the proof of Theorem II.1.

First, we note that since $K_M(x,p)$ satisfies the AΔE (2.12) with $N\to M$, we must have

$$\begin{aligned} s_-(x+iMa_+)&\prod_{j=r-M}^{M} s_-(x+i(j-1)a_+)\cdot Q_N(x-ia_+,p)\\ &+s_-(x-iMa_+)\prod_{j=r-M}^{M} s_-(x+i(j+1)a_+)\cdot Q_N(x-ia_+,p)\\ &=2s_-(x)c_-(p)\prod_{j=r-M}^{M} s_-(x+ija_+)\cdot Q_N(x,p). \end{aligned} \tag{2.116}$$

When we now divide this by the product on the rhs and use the identity

$$s_-(x-iMa_+)s_-(x+i(M+1)a_+)=s_-(x+i(r-M)a_+)s_-(x+i(M+1-r)a_+), \tag{2.117}$$

then we obtain

$$s_-(x+iNa_+)Q_N(x-ia_+,p)+(i\to -i)=2s_-(x)c_-(p)Q_N(x,p). \tag{2.118}$$

Second, we recall that $K_N(x,p)$ also satisfies the AΔE (2.118). Indeed, we used the general form (2.20)–(2.21) of $K_N(x,p)$ as an Ansatz to arrive at the system of equations $d_{mn}=0$ with side conditions (2.25), and then showed that the coefficients (2.5) solve this system. Now in view of (2.113) $Q_N(x,p)$ has the same general form as $K_N(x,p)$, except that the coefficients of the monomials in $P_N(u,t)$ are as yet unknown. We do know, however, that the coefficient matrix is *symmetric*.

Third, we reconsider the paragraph containing (2.26). Choosing a_+/a_- irrational guaranteed a unique solution for each set of boundary coefficients b_n, $n\in\mathbb{N}$. In the present case, however, a_+/a_- is rational, and we have a symmetric solution $\tilde{c}_{kl}$ arising from $Q_N(x,p)$ on hand. The remaining problem, then, is to show that the latter coefficients equal the symmetric coefficients $c_{kl}^{(N)}$ occurring in $K_N(x,p)$, up to a common factor.

It is not hard to see that this is true. The key point is that we still have $w^m\neq 1$ for $m=1,\ldots,N$. Hence a *symmetric* solution to the system is uniquely determined up to an overall factor. Indeed, starting from a given c_{00}, we can calculate successively $c_{10},c_{20},\ldots,c_{N0}$, since $w^m\neq 1$. But then the boundary coefficients c_{0n} are determined by symmetry. Therefore, the remaining coefficients can be successively calculated (again because $w^m\neq 1$), entailing uniqueness. □

III. THE GENERAL HYPERBOLIC CASE

Just as in the special integer g case studied in Sec. II, it is easy to adapt our results for the general elliptic case (cf. Sec. III in I) to the hyperbolic regime. But the results from Sec. II can actually be exploited to proceed considerably beyond the hyperbolic specialization of Sec. III in I. Indeed, we are going to obtain joint eigenfunctions for all parameters in the space $\mathcal{D}_{\rm hyp}$ (1.7) and for all $p\in\mathbb{C}$. Moreover, for parameters in the subset $\mathcal{D}$ [defined by I(3.33)–I(3.35)], the representation derived below is far more explicit than the zero representation I(3.39).

We have occasion to make extensive use of the results obtained in Sec. II. To prevent ambiguous notation, the function $K_N(x,p)$ (2.20) is henceforth denoted by $K_N(a_+,a_-;x,p)$. We also need *two* ''q-variables,'' viz.,

$$q_+\equiv\exp(i\pi a_+/a_-),\quad q_-\equiv\exp(i\pi a_-/a_+). \tag{3.1}$$

Thus q (1.16) is, from now on, denoted by q_+.

To ease the exposition, we restrict attention to b-values of the form (1.20) until further notice, and, accordingly, study the auxiliary AΔOs B_δ (1.21). We now claim that the functions

$$K_{N_+,N_-}(a_+,a_-;x,p)\equiv\exp(i\pi xp/a_+a_-)\prod_{\delta=+,-}e_\delta(N_\delta[x+p])S_{N_\delta}(q_\delta;e_{-\delta}(-2x),e_{-\delta}(-2p)) \tag{3.2}$$

are joint B_δ-eigenfunctions with eigenvalues $2c_\delta(p)$. Given Theorem II.1, this is quite easily verified: For B_- we can use the identity

$$K_{N_+,N_-}(a_+,a_-;x,p)=K_{N_+}(a_+,a_-;x,p)e_+(N_-[x+p])S_{N_-}(q_-;e_+(-2x),e_+(-2p)), \tag{3.3}$$

whereas for B_+ we can use

$$K_{N_+,N_-}(a_+,a_-;x,p)=K_{N_-}(a_-,a_+;x,p)e_-(N_+[x+p])S_{N_+}(q_+;e_-(-2x),e_-(-2p)). \tag{3.4}$$

The joint eigenfunction property just demonstrated holds true for arbitrary $a_+,a_->0$. Restricting a_+ and a_- by I(3.34) and I(3.35), respectively, we also obtain a joint B_δ-eigenfunction $\mathcal{H}(x,y)$ I(3.39) in a quite different guise. Again, from Sec. II the connection between the two representations is easily established: One has

$$K_{N_+,N_-}(a_+,a_-;x,p)=\prod_{\delta=+,-}\left(\prod_{\pm j=1}^{N_\delta}\frac{4\pi}{a_{-\delta}}\sinh\frac{\pi}{a_{-\delta}}(p+ija_\delta)\right)^{1/2}\cdot\mathcal{H}(x,\pi p/a_+a_-). \tag{3.5}$$

[To see this, note first of all that I(3.17) becomes $y=u$ in the hyperbolic case. Canceling the plane wave $K_0(x,p)$ in the relation (2.60), the resulting formula readily yields (3.5).]

Next, we observe that the Casorati determinants

$$D^\delta_{N_+,N_-}(x)\equiv K_{N_+,N_-}(a_+,a_-;x+ia_\delta/2,p)K_{N_+,N_-}(a_+,a_-;x-ia_\delta/2,-p)-(i\to -i) \tag{3.6}$$

can be explicitly determined from (2.63)–(2.66) by using (3.3)/(3.4) for $\delta=+/-$. This yields

$$D^\delta_{N_+,N_-}(x)=(-)^{N_\delta+1}\prod_{k=-N_\delta}^{N_\delta}2s_{-\delta}(p-ika_\delta)\cdot\prod_{l=-N_\delta+1/2}^{N_\delta-1/2}2s_{-\delta}(x-ila_\delta)$$
$$\cdot e_\delta(2N_{-\delta}x)\prod_{\alpha=+,-}S_{N_{-\delta}}(q_{-\delta};-e_\delta(-2x),e_\delta(2\alpha p)),\quad \delta=+,-. \tag{3.7}$$

Furthermore, it follows as before that the determinants do not vanish identically for $\mathrm{Re}\, p \neq 0$. Adapting Theorem B.1 in I, we infer that for a_+/a_- irrational and $\mathrm{Re}\, p > 0$ the functions $K_{N_+,N_-}(a_+,a_-;x,\pm p)$ form a basis for the joint eigenspace of B_+ and B_- corresponding to eigenvalues $2c_+(p)$ and $2c_-(p)$, respectively.

Next, we recall from Sec. III in I that for points $(a_+,a_-,b) \in \mathcal{D}$ there is at most one way to write b as $(N_+ + 1)a_+ - N_- a_-$ with $N_+, N_- \in \mathbb{N}$ [cf. the paragraph containing I(3.29)]. Returning to the general case $a_+,a_- > 0$, this is no longer true, of course. In particular, let us choose

$$\frac{a_+}{a_-} = \frac{n_-}{n_+}, \quad n_+, n_- \in \mathbb{N}^*, \quad n_+, n_- \text{ coprime.} \tag{3.8}$$

Then we may rewrite (1.20) as

$$b_{+-} = (N_+ + 1 + m n_+)a_+ - (N_- + m n_-)a_-, \tag{3.9}$$

where m is an arbitrary integer.

Choosing $m \in \mathbb{N}$, we now deduce from the identity (2.99) that we have

$$K_{N_+ + mn_+, N_- + mn_-}(a_+,a_-;x,p) = \eta_{N_+,N_-}(m) \prod_{\delta=+,-} [4 s_{-\delta}(n_\delta x) s_{-\delta}(n_\delta p)]^m \cdot K_{N_+,N_-}(a_+,a_-;x,p), \tag{3.10}$$

where $\eta \in \{\pm 1, \pm i\}$ is given by

$$\eta_{N_+,N_-}(m) \equiv (-)^{mN_+n_- + mN_-n_+ + m^2 n_+ n_-} \cdot i^{mn_- + mn_+}. \tag{3.11}$$

All of the functions on the rhs of (3.10) are manifestly independent, so we wind up with an infinity of joint eigenfunctions for the same b-value!

We proceed by connecting the ambiguity just uncovered to the interpolation question discussed below I(4.8). As we have seen there, we get distinct weight functions $\hat{w}(x)$ for distinct $m \in \mathbb{N}$; cf. I(4.6). Moreover, in the elliptic case the AΔOs B_δ also depend on the choice of m. But as we have already detailed in the Introduction, the hyperbolic counterparts (1.21) do admit the continuous interpolation $B_\delta(b)$ (1.22). [A caveat is in order at this point: For b of the form $(N_- + 1)a_- - N_+ a_+$ one would need a *different* interpolation. Specifically, one must take $b \to a_+ + a_- - b$ on the rhs of (1.22) in that case.]

This fact leads to a remarkable conclusion of a general character that we wish to emphasize before we discard the auxiliary AΔOs B_δ in favor of the AΔOs $A_\delta(b)$ (1.1) and $H_\delta(b)$ (1.5), which are defined for arbitrary real b to begin with. Indeed, since the functions (3.10) are independent for different $m \in \mathbb{N}$, we may deduce that the commuting AΔO pair $B_\delta(b)$ (1.22) *does not admit* joint eigenfunctions depending continuously on the parameters, already for parameters $a_+,a_- > 0$ and b of the form (1.20). [In virtue of the specialization of Theorem B.1 in I, the ambiguity (3.10) is inescapable.]

This shows by example that the existence of interpolations cannot follow from general arguments. It is all the more remarkable that for the AΔOs $H_\delta(b)$ (1.5) [and hence for $A_\delta(b)$ (1.1), too] the interpolation ambiguity disappears: The ambiguity in the joint B_δ-eigenfunctions is canceled by the ambiguity in the auxiliary weight function $\hat{w}(x)$.

To detail this, we first introduce the renormalized weight function

$$\hat{w}_{N_+,N_-}(a_+,a_-;x) \equiv 1 \Big/ \prod_{\delta=+,-} \prod_{\pm j=1}^{N_\delta} \left[2 \sinh \frac{\pi}{a_{-\delta}}(x + i j a_\delta) \right]. \tag{3.12}$$

[It differs from the hyperbolic specialization of $\hat{w}(x)$ I(4.6) by a multiplicative constant.] With the rationality assumption (3.8) in effect, it satisfies

$$\hat{w}_{N_++mn_+,N_-+mn_-}(a_+,a_-;x)=\prod_{\delta=+,-}[2s_{-\delta}(n_\delta x)]^{-2m}\cdot\hat{w}_{N_+,N_-}(a_+,a_-;x). \tag{3.13}$$

[Indeed, this comes down to the identity (2.104).]

Consider now the functions

$$F_{N_+,N_-}(a_+,a_-;x,p)$$
$$\equiv\phi_{N_+,N_-}[\hat{w}_{N_+,N_-}(a_+,a_-;x)\hat{w}_{N_+,N_-}(a_+,a_-;p)]^{1/2}K_{N_+,N_-}(a_+,a_-;x,p), \tag{3.14}$$

where ϕ is the phase

$$\phi_{N_+,N_-}\equiv(-i)^{2N_+N_-+N_++N_-+1}. \tag{3.15}$$

By construction, they are joint eigenfunctions of the AΔOs $H_\delta((N_++1)a_+-N_-a_-)$ with eigenvalues $2c_\delta(p)$. The phase satisfies

$$\phi_{N_++mn_+,N_-+mn_-}=\phi_{N_+,N_-}\overline{\eta}_{N_+,N_-}(m), \tag{3.16}$$

so with (3.8) in force one deduces the equality

$$F_{N_++mn_+,N_-+mn_-}(a_+,a_-;x,p)=F_{N_+,N_-}(a_+,a_-;x,p),\quad m\in\mathbb{N}. \tag{3.17}$$

Hence the ambiguities cancel out, as announced.

It should be noted that the definition (3.14) preserves the symmetry under $x\leftrightarrow p$. Moreover, it entails that we have

$$F_{N_+,N_-}(a_+,a_-;x,p)=\mathcal{F}(x,\pi p/a_+a_-), \tag{3.18}$$

where $\mathcal{F}(x,y)$ is the hyperbolic specialization of I(3.31). Indeed, equality up to phase follows via (3.5), so we need only verify that the phase of the normalization constant $\mathcal{N}$ in the c-function I(1.25) equals ϕ_{N_+,N_-} (3.15). Now from Proposition III.8 in Ref. 2 we easily calculate

$$c(a_+,a_-,(N_++1)a_+-N_-a_-;x)=\phi_{N_+,N_-}\frac{\Pi_{k=1}^{N_-}2s_+(x+ika_-)}{\Pi_{j=0}^{N_+}2s_-(x-ija_+)}. \tag{3.19}$$

Hence the phase $\phi(\mathcal{N})$ in I(3.31) indeed equals (3.15) in the hyperbolic case. (In fact, it is not hard to see that this is still true in the elliptic case.)

Thus far we have assumed b-values of the form (1.20). Let us next assume b-values of the form

$$b_{-+}=-N_+a_++(N_-+1)a_-,\quad N_+,N_-\in\mathbb{N}. \tag{3.20}$$

Rewriting $H_\delta(b)$ (1.5) as

$$H_\delta(b)=\left(\frac{s_\delta(x-ib)s_\delta(x+ib-ia_{-\delta})}{s_\delta(x)s_\delta(x-ia_{-\delta})}\right)^{1/2}T_{ia_{-\delta}}+(i\rightarrow-i),\quad\delta=+,-, \tag{3.21}$$

we read off the symmetry property

$$H_\delta(b)=H_\delta(a_++a_--b). \tag{3.22}$$

Thus, we may and will choose as joint eigenfunctions of $H_+(b_{-+})$ and $H_-(b_{-+})$ the functions $F_{N_+,N_-}(a_+,a_-;x,p)$ just defined.

More generally, we obtain the same AΔO pair $H_\delta(b)$ for the four b-values in the set

$$B_{N_+,N_-}\equiv\{b_{+-},b_{-+},b_{--},b_{++}\}, \tag{3.23}$$

where we use the notation (1.20), (3.20), and

$$b_{--}\equiv -N_+a_+-N_-a_-, \quad b_{++}\equiv(N_++1)a_++(N_-+1)a_-. \tag{3.24}$$

[Once more, this can be read off from (3.21).] But then we have

$$H_\delta(b)F_{N_+,N_-}(a_+,a_-;x,p)=2c_\delta(p)F_{N_+,N_-}(a_+,a_-;x,p), \quad b\in B_{N_+,N_-}. \tag{3.25}$$

Hence, we have now constructed joint eigenfunctions for all parameters in $\mathcal{D}_{\mathrm{hyp}}$ (1.7), as advertised in the Introduction.

But more can and should be said. In particular, for the rational case (3.8) we have shown the absence of ambiguity for positive m in (1.20), but, of course, we can just as well choose m equal to a negative integer. As long as N_++mn_+ and N_-+mn_- are non-negative, it is clear one still obtains (3.17). But when one of these integers becomes negative, the state of affairs is quite unclear at this stage. The next theorem supplies, in particular, the information that will enable us to unambiguously define a joint H_δ-eigenfunction $F(a_+,a_-,b;x,p)$ for all (a_+,a_-,b) in $\mathcal{D}_{\mathrm{hyp}}$. But it also yields additional information about the rational case (3.8) that is of interest in itself.

Theorem III.1: *The function* $F_{N_+,N_-}(a_+,a_-;x,p)$ *(3.14) satisfies*

$$F_{N_+,N_-}(a_+,a_-;x,p)=F_{N_-,N_+}(a_-,a_+;x,p). \tag{3.26}$$

Now assume (3.8). Fixing $N_+,N_-\in\mathbb{N}$, *one has*

$$F_{N_++m_+n_+,N_-+m_-n_-}(a_+,a_-;x,p)=\zeta_{N_+,N_-}(m_+,m_-)F_{N_+,N_-}(a_+,a_-;x,p), \tag{3.27}$$

$$\zeta_{N_+,N_-}(m_+,m_-)\equiv(-)^{(m_+-m_-)(N_-n_+-N_+n_-)}\cdot i^{(m_+-m_-)[n_--n_++(m_+-m_-)n_+n_-]}, \tag{3.28}$$

where m_+ *and* m_- *are integers such that* $N_\delta+m_\delta n_\delta\geqslant 0$, $\delta=+,-$. *Moreover, choosing* $N_+\in[0,n_+/2)$, *one has*

$$F_{M_+,N_-}(a_+,a_-;x,p)=\xi_{N_+,N_-}F_{N_+,N_-}(a_+,a_-;x,p), \quad M_+\equiv n_+-1-N_+, \tag{3.29}$$

$$\xi_{N_+,N_-}\equiv(-)^{(n_+-1)N_-+(n_--1)N_+}\cdot i^{n_+n_--n_--n_++1}. \tag{3.30}$$

Proof: The symmetry property (3.26) can be read off from the definitions (3.14), (3.15), (3.12), and (3.2). To prove (3.27), we first note that (3.13) generalizes as

$$\hat{w}_{N_++m_+n_+,N_-+m_-n_-}(a_+,a_-;x)=\prod_{\delta=+,-}[2s_{-\delta}(n_\delta x)]^{-2m_\delta}\cdot\hat{w}_{N_+,N_-}(a_+,a_-;x). \tag{3.31}$$

Second, we can use the identity (2.99) once more to generalize (3.10). A straightforward calculation yields

$$K_{N_++m_+n_+,N_-+m_-n_-}(a_+,a_-;x,p)$$
$$=\eta_{N_+,N_-}(m_+,m_-)\prod_{\delta=+,-}[4s_{-\delta}(n_\delta x)s_{-\delta}(n_\delta p)]^{m_\delta}\cdot K_{N_+,N_-}(a_+,a_-;x,p), \tag{3.32}$$

$$\eta_{N_+,N_-}(m_+,m_-)\equiv(-)^{m_+N_+n_-+m_-N_-n_+}\cdot i^{[m_+n_-+m_-n_++(m_+^2+m_-^2)n_+n_-]}. \tag{3.33}$$

Third, (3.16) generalizes to

$$\phi_{N_++m_+n_+,N_-+m_-n_-}=\phi_{N_+,N_-}\zeta_{N_+,N_-}(m_+,m_-)\overline{\eta}_{N_+,N_-}(m_+,m_-). \tag{3.34}$$

Combining these relations, we obtain (3.27).

In order to prove (3.29), we note first

$$\hat{w}_{M_+,N_-}(a_+,a_-;x)=\prod_{\pm j=N_++1}^{n_+-1-N_+}[2s_-(x+ija_+)]^{-1}\cdot\hat{w}_{N_+,N_-}(a_+,a_-;x). \tag{3.35}$$

Second, we exploit (2.100) to write

$$K_{M_+,N_-}(a_+,a_-;x,p)=\prod_{j=N_++1}^{n_+-1-N_+}[4q_+^{-j}s_-(x+ija_+)s_-(p+ija_+)]\cdot K_{N_+,N_-}(a_+,a_-;x,p). \tag{3.36}$$

Consider now the function

$$Q(x)\equiv\frac{\Pi_{j=N_++1}^{n_+-1-N_+}q_+^{-j}s_-(x+ija_+)}{[\Pi_{\pm j=N_++1}^{n_+-1-N_+}s_-(x+ija_+)]^{1/2}}. \tag{3.37}$$

From the identity

$$s_-(x-ija_+)=(-)^{n_-}s_-(x+i(n_+-j)a_+), \tag{3.38}$$

we deduce that $Q(x)$ equals a phase, so taking $x\to\infty$ we obtain $Q(x)=1$. Hence (3.14) yields

$$F_{M_+,N_-}(a_+,a_-;x,p)=\phi_{M_+,N_-}\overline{\phi}_{N_+,N_-}\prod_{j=N_++1}^{n_+-1-N_+}q_+^j\cdot F_{N_+,N_-}(a_+,a_-;x,p). \tag{3.39}$$

Calculating the phase yields the rhs of (3.30), so (3.29) follows. □

Still assuming (3.8), this theorem shows that the vector space spanned by the functions F_{M_+,M_-}, $M_+,M_-\in\mathbb{N}$, is finite-dimensional: It is already spanned by the functions F_{N_+,N_-} with $N_\delta\in[0,n_\delta/2)$, $\delta=+,-$. Indeed, all of the former functions are phase multiples of the latter, as follows by combining (3.27), (3.29), and (3.26). This fact is in accordance with (but not implied by) the relation

$$H_\delta(b+mn_+a_+)=H_\delta(b+mn_-a_-)=H_\delta(b),\quad m\in\mathbb{Z},\quad \delta=+,-, \tag{3.40}$$

whose validity is clear from (3.21).

More importantly, the theorem enables us to dispose of the $m\in\mathbb{Z}$ ambiguity in (3.9) and its b_{-+}-analog. Specifically, taking $N_+,N_-\in\mathbb{N}$, we set [recall (1.20), (3.20), and (3.24)]

$$F(a_+,a_-,b_{+-};x,p)\equiv F_{N_+,N_-}(a_+,a_-;x,p), \tag{3.41}$$

$$F(a_+,a_-,b_{-+};x,p)\equiv F_{N_+,N_-}(a_+,a_-;x,p), \tag{3.42}$$

$$F(a_+,a_-,b_{--};x,p)\equiv\tilde{F}_{N_+,N_-}(a_+,a_-;x,p), \tag{3.43}$$

$$F(a_+,a_-,b_{++};x,p)\equiv\tilde{F}_{N_+,N_-}(a_+,a_-;x,p), \tag{3.44}$$

where

$$\tilde{F}_{N_+,N_-}(a_+,a_-;x,p) \equiv \chi_{N_+,N_-} F_{N_+,N_-}(a_+,a_-;x,p), \tag{3.45}$$

$$\chi_{N_+,N_-} \equiv (-)^{N_+ + N_-} \cdot i. \tag{3.46}$$

Of course, we are free to do so for $a_+/a_- \notin \mathbb{Q}$, since then all b-values $ka_+ + la_-$, $k,l \in \mathbb{Z}$, are distinct. But our task is now to show that for the rational case (3.8) the function $F(a_+,a_-,b;x,p)$ is still well defined.

Now we have already seen that (3.41) by itself is a legitimate definition; cf. (3.17). In view of the symmetry property (3.26), this is true for (3.42) as well. For (3.43) and (3.44) to be well defined by themselves, we should have

$$\tilde{F}_{N_+ + mn_+,N_-}(a_+,a_-;x,p) = \tilde{F}_{N_+,N_- + mn_-}(a_+,a_-;x,p), \quad m \in \mathbb{N}. \tag{3.47}$$

Recalling (3.27), we see that this amounts to

$$\zeta_{N_+,N_-}(m,0)\chi_{N_+ + mn_+,N_-} = \zeta_{N_+,N_-}(0,m)\chi_{N_+,N_- + mn_-}, \tag{3.48}$$

which is easily verified. To prove the compatibility of (3.41) and (3.43), we need to show that when $M_+ \in [n_+/2, n_+ - 1]$, then we have

$$F_{M_+,N_- + n_-}(a_+,a_-;x,p) = \tilde{F}_{N_+,N_-}(a_+,a_-;x,p), \quad N_+ \equiv n_+ - 1 - M_+. \tag{3.49}$$

Combining (3.27) and (3.29), we deduce that this amounts to the relation

$$\zeta_{M_+,N_-}(0,1)\xi_{N_+,N_-} = \chi_{N_+,N_-}, \quad M_+ = n_+ - 1 - N_+. \tag{3.50}$$

The phase χ_{N_+,N_-} obeys this relation (indeed, it is defined such that it does), so (3.49) follows. The remaining compatibilities can now be handled by using (3.26). Thus, the function $F(\Xi;x,p)$ is well defined for all parameters $\Xi = (a_+,a_-,b)$ in $\mathcal{D}_{\text{hyp}}$ (1.7).

We proceed by summarizing some salient features of the function $F(\Xi;x,p)$.

Theorem III.2: *For all $\Xi \in \mathcal{D}_{hyp}$ the definition (3.41)–(3.44) gives rise to a well-defined, generically two-valued, analytic function $F(\Xi;x,p)$ with a meromorphic square. It satisfies*

$$H_\delta F(\Xi;x,p) = 2c_\delta(p)F(\Xi;x,p), \quad \delta = +,-, \tag{3.51}$$

and has parameter and variable symmetries

$$F(a_+,a_-,b;x,p) = F(a_+,a_-,a_+ + a_- - b;x,p), \tag{3.52}$$

$$F(a_+,a_-,b;x,p) = F(a_-,a_+,b;x,p), \tag{3.53}$$

$$F(\Xi;x,p) = F(\Xi;p,x), \tag{3.54}$$

$$F(\Xi;x,p) = F(\Xi;-x,-p). \tag{3.55}$$

Now denote by F_r the function defined for $x,p > 0$ by taking positive square roots in (3.14). For $a_+/a_- \notin \mathbb{Q}$ this function has a real-analytic extension F_r to $x,p \in \mathbb{R}$, which satisfies

$$F_r(a_+,a_-,b;x,p) = -\overline{F_r}(a_+,a_-,b;-x,p), \quad b = b_{+-}, b_{-+}, \tag{3.56}$$

$$F_r(a_+,a_-,b;x,p) = \overline{F_r}(a_+,a_-,b;-x,p), \quad b = b_{--}, b_{++}. \tag{3.57}$$

Proof: It remains to prove (3.54)–(3.57). By virtue of (3.3) and (3.4), the holomorphic function (3.2) satisfies

$$K_{N_+,N_-}(a_+,a_-;x,p)=K_{N_+,N_-}(a_+,a_-;p,x), \tag{3.58}$$

$$K_{N_+,N_-}(a_+,a_-;x,p)=K_{N_+,N_-}(a_+,a_-;-x,-p), \tag{3.59}$$

$$K_{N_+,N_-}(a_+,a_-;x,p)=(-)^{N_++N_-}\overline{K}_{N_+,N_-}(a_+,a_-;-x,p), \quad x,p\in\mathbb{R}. \tag{3.60}$$

[Recall (2.13)–(2.15).] In view of (3.14), this entails

$$F_{N_+,N_-}(a_+,a_-;x,p)=F_{N_+,N_-}(a_+,a_-;p,x), \tag{3.61}$$

$$F_{N_+,N_-}(a_+,a_-;x,p)=F_{N_+,N_-}(a_+,a_-;-x,-p), \tag{3.62}$$

so (3.54) and (3.55) follow. For a_+/a_- irrational, the auxiliary weight function (3.12) has a real-analytic, positive, and even restriction to $\mathbb{R}$, so (3.56) and (3.57) follow from (3.60) and the phase definitions (3.15) and (3.46). □

Of course, for a_+/a_- rational, the restriction F_r is still real-analytic for $x,p>0$. But in that case the weight function (3.12) may have poles at the origin, so that ambiguities can arise for $x<0$. (Taking a real-analytic restriction to $\mathbb{R}$ and taking parameter limits need not commute; we mention the function $x\mapsto(x^2+\epsilon^2)^{-1/2}$ to exemplify this difficulty.)

Such square-root subtleties are not present for the meromorphic joint A_δ-eigenfunction

$$M(\Xi;x,p)\equiv[w(\Xi;x)w(\Xi;p)]^{-1/2}F(\Xi;x,p), \quad \Xi\in\mathcal{D}_{\text{hyp}}, \tag{3.63}$$

which we study next. From Ref. 2 Eq. (5.21), we have

$$w(a_+,a_-,k_+a_++k_-a_-;x)$$
$$=\prod_{\delta=+,-}\prod_{j=1}^{|k_\delta|}\left(\left[2\sinh\frac{\pi}{a_{-\delta}}(x+ia_\delta(j_\delta-\theta(k_\delta)))\right][i\to -i]\right)^{k_\delta/|k_\delta|}, \quad k_\delta\in\mathbb{Z}. \tag{3.64}$$

[Here, $\theta(k)=1$ for $k>0$ and $\theta(k)=0$ for $k<0$.] Using (3.14) and (3.41)–(3.46), this yields the explicit formulas

$$M(a_+,a_-,b_{\alpha,-\alpha};x,p)=(-i)^{2N_+N_-+N_++N_-+1}[P_{N_\alpha}(a_\alpha,a_{-\alpha};x)P_{N_\alpha}(a_\alpha,a_{-\alpha};p)]^{-1}$$
$$\cdot K_{N_+,N_-}(a_+,a_-;x,p), \quad \alpha=+,-, \tag{3.65}$$

$$M(a_+,a_-,b_{--};x,p)=i^{2N_+N_-+N_++N_-}K_{N_+,N_-}(a_+,a_-;x,p), \tag{3.66}$$

$$M(a_+,a_-,b_{++};x,p)=i^{2N_+N_-+N_++N_-}\left[\prod_{\alpha=+,-}P_{N_\alpha}(a_\alpha,a_{-\alpha};x)P_{N_\alpha}(a_\alpha,a_{-\alpha};p)\right]^{-1}$$
$$\cdot K_{N_+,N_-}(a_+,a_-;x,p), \tag{3.67}$$

where

$$P_N(a_+,a_-;x)\equiv\prod_{j=-N}^{N}\left[2\sinh\frac{\pi}{a_-}(x+ija_+)\right]. \tag{3.68}$$

Theorem III.3: *The meromorphic function* $M(\Xi;x,p)$, $\Xi\in\mathcal{D}_{\text{hyp}}$ (1.7), *satisfies*

$$A_\delta M(\Xi;x,p)=2c_\delta(p)M(\Xi;x,p), \quad \delta=+,-, \tag{3.69}$$

and has parameter and variable symmetries

$$M(a_+,a_-,b;x,p)=M(a_-,a_+,b;x,p), \tag{3.70}$$

$$M(\Xi;x,p)=M(\Xi;p,x), \tag{3.71}$$

$$M(\Xi;x,p)=M(\Xi;-x,-p), \tag{3.72}$$

$$M(\Xi;x,p)=\overline{M}(\Xi;-x,p), \quad x,p\in\mathbb{R}. \tag{3.73}$$

Proof: The asserted properties are clear from the definition of M and from (3.58)–(3.60). [Recall that $w(a_+,a_-,b;x)$ is symmetric under $a_+\leftrightarrow a_-$.] □

We do not know whether the function $M(\Xi;x,p)$ admits an interpolation to all of the hyperbolic parameter domain $\mathcal{H}$ (1.4). But for the even joint A_δ-eigenfunction,

$$R(\Xi;x,p)\equiv M(\Xi;x,p)+M(\Xi;-x,p), \quad \Xi\in\mathcal{D}_{\rm hyp}, \tag{3.74}$$

this is the case (see Ref. 4 and papers to appear). Observe that the latter function already appeared in the integer g case: One has

$$R(a_+,a_-,(N+1)a_+;x,p)=R_N(x,p), \tag{3.75}$$

where $R_N(x,p)$ is given by (2.71). [To check this, use (3.65) with $\alpha=+$, $N_+=N$ and $N_-=0$.]

To conclude this section, let us add one more observation on the auxiliary AΔOs B_δ (1.21). Since they are only defined for b of the form (1.20), we may specify their b-dependence by writing $B_\delta(N_+,N_-)$. Comparing (1.21) and (1.1), we now deduce

$$B_\delta(N_+,N_-)=A_\delta(-N_+a_+-N_-a_-), \quad \delta=+,-. \tag{3.76}$$

This coincidence agrees with (3.66). Indeed, the latter formula says that the joint $A_\delta(b)$-eigenfunction M for $b=-N_+a_+-N_-a_-$ is proportional to the joint $B_\delta(N_+,N_-)$-eigenfunction K_{N_+,N_-}. (See also the remarks at the end of Sec. IV in I, specialized to the hyperbolic case.)

IV. THE TRIGONOMETRIC SPECIALIZATION

At the end of the Introduction we have already delineated how various objects from the elliptic regime studied in I give rise to trigonometric counterparts. We will use the corresponding formulas (1.23)–(1.28) without further comment.

Until further notice, we restrict attention to the special choice $k=N+1\in\mathbb{N}^*$ in (1.27). Then the results in Sec. II of I can be readily specialized, giving rise to functions $\Psi(\pm x,y)$ that are joint eigenfunctions of

$$A=\frac{\sin r(x-i(N+1)\beta)}{\sin rx}T_{i\beta}+(i\rightarrow -i) \tag{4.1}$$

[the AΔO (1.24) for $b=(N+1)\beta$)] and Q (1.28). [Indeed, the relevant trigonometric function $E(x)$ I(2.8) has finite and equal limits for $\mathrm{Im}\,x\rightarrow\pm\infty$, entailing constancy.]

Comparing the trigonometric AΔO A (4.1) to its hyperbolic counterpart $A_-((N+1)a_+)$ (1.1), one sees they are related via the substitutions

$$a_+\rightarrow\beta, \quad a_-\rightarrow\pi/ir. \tag{4.2}$$

Moreover, these substitutions turn the second hyperbolic AΔO $A_+((N+1)a_+)$ (1.1) into $(-)^{N+1}Q$. Therefore, the joint $A_\delta((N+1)a_+)$-eigenfunctions from Sec. II can be exploited to obtain (A,Q)-eigenfunctions. (The latter will be shown to be essentially equal to those arising from the trigonometric specialization of Sec. II in I.)

Once more, we find it expedient to study first the pertinent eigenfunctions of the similarity transformed AΔO

$$B \equiv \prod_{j=-N}^{N} \sin r(x+ij\beta) \cdot A \cdot \prod_{j=-N}^{N} \sin r(x+ij\beta)^{-1} = \frac{\sin r(x+iN\beta)}{\sin rx} T_{i\beta} + (i \to -i). \quad (4.3)$$

While translating our results from Sec. II to trigonometric analogs, we retain the spectral variable y from Sec. II in I. As will soon become clear, this can be achieved by combining the substitutions (4.2) with

$$\pi p/a_- \to \beta(y+(N+1)r). \quad (4.4)$$

Equivalently, we can anticipate the relation to *loc. cit.* by taking

$$p \to \beta y_N/ir, \quad (4.5)$$

where we have set

$$y_N \equiv y+(N+1)r. \quad (4.6)$$

With the above substitutions in the hyperbolic (B_+, B_-)-eigenfunctions $K_N(a_+, a_-; x, p)$ (1.15), we obtain the trigonometric counterparts

$$L_N(r,\beta;x,y) \equiv K_N(\beta, \pi/ir; x, \beta y_N/ir). \quad (4.7)$$

More specifically, this yields

$$L_N(x,y) = \exp(ixy_N) \sum_{k,l=0}^{N} c_{kl}^{(N)}(q_t) \exp[i(N-2k)rx + (N-2l)\beta y_N]. \quad (4.8)$$

Here, we are using

$$q_t \equiv \exp(-\beta r), \quad (4.9)$$

to avoid confusion with the phase factor q (1.16), and the coefficients are defined by (2.2)–(2.5). Notice that in the present case all of the coefficients are real numbers, so that (4.8) entails

$$\overline{L_N}(x,y) = L_N(-x,y), \quad x,y \in \mathbb{R}. \quad (4.10)$$

In view of our hyperbolic result (2.1) (proved in Theorem II.1), we have

$$BL_N(x,y) = 2\cosh(\beta[y+(N+1)r])L_N(x,y). \quad (4.11)$$

Also, (1.19) translates into

$$QL_N(x,y) = -2\cos(\pi y/r)L_N(x,y). \quad (4.12)$$

[Just as (1.19), this is immediate from (4.8), of course.] Likewise, the dual eigenfunction properties (2.48)–(2.51) become

$$\tilde{B}L_N(x,y) = 2\cos(rx)L_N(x,y), \quad (4.13)$$

$$\tilde{Q}L_N(x,y)=(-)^N 2\cosh(\pi x/\beta)L_N(x,y), \tag{4.14}$$

where

$$\tilde{B}\equiv\frac{\sinh(\beta[y+(2N+1)r])}{\sinh(\beta[y+(N+1)r])}\tilde{T}_r+\frac{\sinh(\beta[y+r])}{\sinh(\beta[y+(N+1)r])}\tilde{T}_{-r}, \tag{4.15}$$

$$\tilde{Q}\equiv\tilde{T}_{i\pi/\beta}+\tilde{T}_{-i\pi/\beta}, \tag{4.16}$$

with

$$(\tilde{T}_\alpha G)(y)\equiv G(y-\alpha), \quad \alpha\in\mathbb{C}. \tag{4.17}$$

[Again, (4.14) is plain from (4.8).]

We can deduce a few more salient features from Theorem II.1. First, combining (4.7) with (2.14) and (4.10), we obtain

$$L_N(x,-y-2(N+1)r)=\overline{L_N}(x,y), \quad x,y\in\mathbb{R}. \tag{4.18}$$

Second, from (4.7) and (2.16) we infer

$$L_N(x,-r)=L_N(x,-(2N+1)r)=(-2)^N\prod_{k=N+1}^{2N}\sinh(k\beta r). \tag{4.19}$$

Finally, (4.7) and (2.18) entail

$$L_N(x,-(l+1)r)=L_N(x,-(2N+1-l)r)=C_l^{(N)}(\cos(rx)), \quad l=0,\ldots,N. \tag{4.20}$$

Here, $C_l^{(N)}(u)$ is a polynomial of degree l and parity $(-)^l$. Moreover, this polynomial has real coefficients in view of (4.18), and one has

$$BC_l^{(N)}(\cos(rx))=2\cosh((N-l)\beta r)C_l^{(N)}(\cos(rx)), \quad l=0,\ldots,N, \tag{4.21}$$

due to (4.11).

We proceed by obtaining the relation between $L_N(x,y)$ and the function $\mathcal{H}_N(x,y)$ I(2.34), specialized to the trigonometric context. To this end we exploit the arguments leading from (2.52) to (2.60). Specifically, (2.52) and (2.53) remain true when q is replaced by q_t. Assuming $t\neq q_t^{-2j}$, $j=1,\ldots,N$, one obtains (2.54)–(2.56). Hence the roots $\rho_j(q_t,t)$ are nonzero for $t\neq q_t^{2j}$, $j=1,\ldots,N$, and ρ_j can be chosen equal to q_t^{2j} for $t=0$.

In the case at hand, we need $t=\exp(-2\beta y_N)$, which entails

$$\prod_{j=1}^{N}\rho_j=\prod_{j=1}^{N}\frac{\sinh(\beta[y+jr])}{\sinh(\beta[y+(N+1+j)r])}. \tag{4.22}$$

Therefore, restricting attention to $\{\mathrm{Re}\, y>-r\}$, we may set

$$\rho_j=\exp(2irz_j), \quad z_j(y)\to ij\beta, \quad y\to\infty, \quad j=1,\ldots,N. \tag{4.23}$$

Now I(2.25) yields no restriction on $\beta=-iv$, since $a=\infty$ in the trigonometric regime. Hence it follows that the functions $z_j(y)$ thus defined may be identified with the zero functions $z_j(y)$ from Sec. II of I and that the desired relation reads

$$L_N(x,y)=(4ir)^N\prod_{j=1}^{N}[\sinh(\beta[y+jr])\sinh(\beta[y+(N+1+j)r])]^{1/2}\cdot\mathcal{H}_N(x,y),\quad y\in(K,\infty).\tag{4.24}$$

From the trigonometric specialization of I(2.45)–I(2.46) we also deduce that all of the zeros $z_j(y)$ are nonconstant.

It follows from Sec. II of I that all of the zeros $z_1(y),\ldots,z_N(y)$ belong to $i(0,\infty)$ for $y\in(R,\infty)$ and R large. For $N=1$ this is easily seen to be true for all $y\in(-r,\infty)$; cf. (4.22). But just as in the hyperbolic case, already for $N=2$ and a suitable choice of βr, the zeros move off the imaginary axis as y decreases from ∞ to 0, showing once more that the parameter K is necessary.

To see this phenomenon happen, we use (2.9) to calculate (note $y=0$ corresponds to $t=q_t^6$ for $N=2$)

$$S_2(q;s,q^6)=(q^9-q^7-q^5+q^3)P_2(q;s),\tag{4.25}$$

$$P_2(q;s)\equiv 1-(q^4+q^2+1+q^{-2}+q^{-4})s+(q^6+q^4+2q^2+2+2q^{-2}+q^{-4}+q^{-6})s^2.\tag{4.26}$$

Taking $q\to q_t$ and letting $q_t\uparrow 1$, one gets $P_2\to 1-5s+10s^2$. Since the limit polynomial has nonreal roots, it follows that the numbers $z_1(0),z_2(0)$ are not purely imaginary for βr small enough. [Recall that we need $s=\exp(-2irx)$ in the present case.]

Next, we calculate the Casorati determinant

$$D_N(x)\equiv L_N(x+i\beta/2,y)L_N(-x+i\beta/2,y)-(\beta\to-\beta).\tag{4.27}$$

The argument in Sec. II of I leading to I(2.43) is easily adapted, yielding

$$D_N(x)=\gamma_N(y)\prod_{n=-N+1/2}^{N-1/2}\sin r(x+in\beta).\tag{4.28}$$

Using (4.8) with $\operatorname{Im}x\to\infty$, we now obtain

$$\gamma_N(y)=(-2i)^{2N}[\exp(-\beta y_N)-\exp(\beta y_N)]\cdot\left(\sum_{l=0}^{N}c_{Nl}^{(N)}(q_t)\exp[(N-2l)\beta y_N]\right)\left(\sum_{l=0}^{N}c_{0l}^{(N)}(q_t)\exp[(N-2l)\beta y_N]\right).\tag{4.29}$$

From symmetry of the coefficients and (2.4)–(2.6) we then infer

$$\begin{aligned}\gamma_N(y)&=(-)^{N+1}2^{2N+1}\sinh(\beta y_N)\exp(2N\beta y_N)(-)^N Q_N(e^{-2\beta y_N})Q_0(e^{-2\beta y_N})\\&=-2^{4N+1}\prod_{j=1}^{2N+1}\sinh(\beta y+j\beta r).\end{aligned}\tag{4.30}$$

In view of the relation (4.24), it follows that in the trigonometric case the quantity α_N in I(2.43) becomes

$$\alpha_N=(-)^{N+1}2\sinh(\beta y+(N+1)\beta r).\tag{4.31}$$

From (4.30) we read off that $L_N(x,y)/L_N(-x,y)$ is not $i\beta$-periodic in x, unless y equals $y_{jk}\equiv -jr+i\pi k/\beta$ with $j=1,\ldots,2N+1$ and $k\in\mathbb{Z}$; in the latter case we readily obtain

$$L_N(x,y_{jk})/L_N(-x,y_{jk})=\exp(-2\pi kx/\beta),\quad j=1,\ldots,2N+1,\quad k\in\mathbb{Z}.\tag{4.32}$$

[The formulas (4.27)–(4.32) should be compared to their hyperbolic counterparts (2.63)–(2.68).]

Restricting attention to meromorphic B-eigenfunctions, it follows that the eigenspace corresponding to the eigenvalue $2\cosh(\beta[y+(N+1)r])$ is two-dimensional over the field of $i\beta$-periodic meromorphic functions, provided $y\neq y_{jk}$; cf. Appendix B in I. (It is not hard to see that for $y=y_{jk}$ this is still true; note in this connection that one need only handle the case $k=0$.) When we insist on joint (B,Q)-eigenfunctions with eigenvalues $(2\cosh(\beta[y+(N+1)r]),-2\cos(\pi y/r))$, we still obtain an infinite-dimensional eigenspace, since we can allow multipliers from the field of elliptic functions with periods $(\pi/r,i\beta)$.

Next, we turn to quantum-mechanical/functional-analytic properties of the operator B and its eigenfunctions. We begin by observing that the relation (4.24) can be used to define $\mathcal{H}_N(x,y)$ for complex y with $\mathrm{Re}\, y>-r$ (say), and, in particular, for $y=nr$, $n\in\mathbb{N}$. (We have already seen that $K>0$, in general, so this is a genuine extension.) We now study the functions

$$\psi_n(x)\equiv\mathcal{H}(x,nr)-\mathcal{H}(-x,nr),\quad n\in\mathbb{N}, \tag{4.33}$$

in relation to the Hilbert space

$$\mathcal{H}_{\hat{w}}\equiv L^2((0,\pi/r),\hat{w}(x)dx), \tag{4.34}$$

where

$$\hat{w}(x)\equiv\prod_{\pm n=1}^{N}\frac{r}{\sin r(x+in\beta)}. \tag{4.35}$$

First, let us note that all of the functions $\psi_n(x)$ belong to the dense subspace $\mathcal{O}_1$ I(4.11) (with $N_+=N,N_-=0$, of course). Indeed, from Sec. II of I we have

$$\mathcal{H}(ik\beta,y)=\mathcal{H}(-ik\beta,y),\quad |k|\leqslant N. \tag{4.36}$$

[See the paragraph containing I(2.39).] Moreover, $\psi_n(x)$ is π/r-periodic (π/r-antiperiodic) for n odd (even). Hence $\psi_n\in\mathcal{O}_1$, as asserted.

Second, it is easily checked that the operator B (4.3) is symmetric on $\mathcal{O}_1$. (One need only adapt the proof of Theorem IV.1 in I, which simplifies considerably in this case.) Now from (4.11) and (4.24) one gets

$$B\psi_n=2\cosh([n+N+1]\beta r)\psi_n,\quad n\in\mathbb{N}, \tag{4.37}$$

so the functions ψ_n are pairwise orthogonal.

Third, we combine (4.13), (4.15), and (4.24) to deduce that $\psi_n(x)$ satisfies the recurrence relation

$$C_n\psi_{n-1}(x)+C_{n+1}\psi_{n+1}(x)=2\cos(rx)\psi_n(x),\quad n\in\mathbb{N}, \tag{4.38}$$

where

$$C_n\equiv\left(\frac{\sinh([n+2N+1]\beta r)}{\sinh([n+N+1]\beta r)}\cdot\frac{\sinh(n\beta r)}{\sinh([n+N]\beta r)}\right)^{1/2},\quad n\in\mathbb{N}. \tag{4.39}$$

Now for $N=0$ we have

$$\mathcal{H}_0(x,y)=\exp ix(y+r),\quad \psi_n(x)=2i\sin(n+1)rx,\quad C_n=1,\quad n\in\mathbb{N}. \tag{4.40}$$

For $N>0$ we have $C_0=0$, so we deduce from (4.38) that $\psi_0(x)$ cannot vanish identically. [Indeed, $\psi_0=0$ would entail successively $\psi_1=0,\psi_2=0,\ldots$, contradicting the $y\to\infty$ asymptotics of $\mathcal{H}_N(x,y)$; cf. the specialization (4.46) of I(3.41).] In fact, using the hyperbolic result (2.78), the function $\psi_0(x)$ will be explicitly determined below.

Fourth, we use (4.38) with $N>0$ to infer

$$\psi_n(x)/\psi_0(x)=G_n(\cos rx),\quad n\in\mathbb{N},\tag{4.41}$$

where the functions $G_n(u)$ are polynomials of degree n and parity $(-)^n$ with real coefficients. As a consequence, the functions ψ_n, $n\in\mathbb{N}$, are an orthogonal base for the Hilbert space $\mathcal{H}_{\hat{w}}$ (4.34). Of course, this entails that the operator B is essentially self-adjoint on the linear span of $\psi_0,\psi_1,\ldots,$ and hence on $\mathcal{O}_1$, too. [For $N=0$ the analogous conclusions are immediate from (4.40).]

In the following theorem we summarize some of the above findings and add some new ones. In particular, we reinterpret the three-term recurrence (4.38) in terms of the *discrete* difference operator

$$D=\left(\frac{\sinh([n+2N+1]\beta r)}{\sinh([n+N+1]\beta r)}\right)^{1/2}S\left(\frac{\sinh([n+1]\beta r)}{\sinh([n+N+1]\beta r)}\right)^{1/2}+\text{h.c.},\tag{4.42}$$

on the Hilbert space $l^2(\mathbb{N})$. Here, S is the right shift,

$$(Sf)_n\equiv\begin{cases}0, & n=0,\\ f_{n-1}, & n>0,\end{cases}\tag{4.43}$$

with $f=(f_0,f_1,\ldots)\in l^2(\mathbb{N})$, and h.c. stands for hermitean conjugate. Clearly, D is a bounded self-adjoint operator on $l^2(\mathbb{N})$.

Theorem IV.1: *The B-eigenfunctions* $\{(r/2\pi)^{1/2}\psi_n(x)\}_{n=0}^{\infty}$ *are an orthonormal base for* $\mathcal{H}_{\hat{w}}$ *(4.34). The self-adjoint operator* D *on* $l^2(\mathbb{N})$ *has a purely absolutely continuous spectrum* $[-2,2]$ *with multiplicity one.*

Proof: Setting

$$N_n\equiv(\psi_n,\psi_n)^{1/2},\quad n\in\mathbb{N},\tag{4.44}$$

it follows from the above that the functions $\psi_0/N_0,\psi_1/N_1,\ldots,$ give rise to an isometric linear map U from $\mathcal{H}_{\hat{w}}$ onto $l^2(\mathbb{N})$. To prove that the normalization constants equal $(2\pi/r)^{1/2}$, we first show that they do not depend on n. Indeed, consider the inner product of the recurrence relation (4.38) with ψ_{n+1}. By virtue of orthogonality, this yields

$$C_{n+1}N_{n+1}^2=(\psi_{n+1}(x),\quad 2\cos(rx)\psi_n(x)).\tag{4.45}$$

Now when we rewrite 2 $\cos(rx)\psi_{n+1}(x)$ by using (4.38) with $n\to n+1$, then we deduce that the rhs of (4.45) equals $C_{n+1}N_n^2$. Hence we get $N_{n+1}=N_n$, and so our assertion follows. (This argument is probably not new, but we do not know a reference.)

Next, specializing I(3.41) to the trigonometric case, we obtain

$$\mathcal{H}(x,y)=\mathcal{H}^{(\infty)}(x,y)+O(e^{-2\beta y}),\quad y\to\infty,\tag{4.46}$$

uniformly on x-compacts, with

$$\mathcal{H}^{(\infty)}(x,y)=\prod_{j=1}^{N}\frac{\sin r(x+ij\beta)}{r}\cdot e^{irx(N+1)}e^{ixy}.\tag{4.47}$$

[This asymptotics can also be derived directly from (4.24) and (4.8).] In view of (4.33), this entails

$$\psi_n(x)=\prod_{j=1}^{N}\frac{\sin r(x+ij\beta)}{r}\cdot e^{irx(N+1+n)}-(x\to -x)+O(e^{-2n\beta r}),\quad n\to\infty,\tag{4.48}$$

the bound being uniform for $x\in[0,\pi/r]$. Since the inner product (ψ_n,ψ_n) does not depend on n, we can now calculate it by using (4.48) and taking $n\to\infty$. Thus we obtain the norm formula [recall (4.35)]

$$(\psi_n,\psi_n)=2\pi/r,\quad n\in\mathbb{N}, \tag{4.49}$$

and so the first assertion of the theorem follows.

Now (4.38) says that $(\psi_0(x),\psi_1(x),\ldots)$ is an improper D-eigenfunction with eigenvalue $2\cos rx$. More precisely, the unitary operator $U^{-1}:l^2(\mathbb{N})\to\mathcal{H}_{\hat{w}}$ sets up a spectral representation for D as multiplication by $2\cos rx$ on $\mathcal{H}_{\hat{w}}$:

$$(U^{-1}DUf)(x)=2\cos(rx)f(x),\quad f\in\mathcal{H}_{\hat{w}}. \tag{4.50}$$

Thus the second assertion is plain. □

We continue by determining $\psi_0(x)$ explicitly. To this end we note that (4.24) and (4.7) entail

$$\psi_0(x)=(4ir)^{-N}\Delta_N(x)\prod_{j=1}^{N}[\sinh(j\beta r)\sinh([N+1+j]\beta r)]^{-1/2}, \tag{4.51}$$

where

$$\Delta_N(x)\equiv K_N(\beta,\pi/ir;x,-i(N+1)\beta)-K_N(\beta,\pi/ir;-x,-i(N+1)\beta). \tag{4.52}$$

Now we use (2.14), (2.71), and (2.78) to calculate $\Delta_N(x)$. This yields

$$\Delta_N(x)=(-)^N2^{3N+1}i\prod_{n=-N}^{N}\sin r(x+in\beta)\cdot\prod_{j=1}^{N}\sinh(j\beta r), \tag{4.53}$$

so that

$$\psi_0(x)=r(2i/r)^{N+1}\prod_{j=1}^{N}\left(\frac{\sinh(j\beta r)}{\sinh([N+1+j]\beta r)}\right)^{1/2}\cdot\prod_{n=-N}^{N}\sin r(x+in\beta). \tag{4.54}$$

Comparing this explicit formula to (4.3), we deduce

$$B=\psi_0(x)^{-1}A\psi_0(x). \tag{4.55}$$

In view of (4.41), this entails that A (4.1) can be viewed as a self-adjoint operator on the Hilbert space

$$\mathcal{H}_A\equiv L^2((0,\pi/r),|\psi_0(x)|^2\hat{w}(x)dx), \tag{4.56}$$

yielding an orthonormal base of polynomials $(r/2\pi)^{1/2}G_n(\cos rx)$; the A-eigenvalues read $2\cosh([n+N+1]\beta r)$ [cf. (4.37)], and the polynomials are uniquely determined by the recurrence (4.38) and $G_0(u)=1$ (save for $N=0$; cf. below).

As already pointed out in Ref. 5 [cf. the paragraph in Ref. 5 containing Eq. (3.84)], the orthogonal polynomials thus obtained are not new: They are q-Gegenbauer polynomials generalizing the integer g Gegenbauer polynomials arising from the trigonometric specialization of the Lamé operator I(1.1). These q-Gegenbauer polynomials were studied in considerable detail by Askey and Ismail;[6] their parameters are related to ours via

$$q_{\mathrm{AI}}=q_t^2=\exp(-2\beta r),\quad \beta_{\mathrm{AI}}=\exp(-2g\beta r),\quad \lambda_{\mathrm{AI}}=g. \tag{4.57}$$

As far as we know, the two representations we have exploited to derive some important features of the integer g polynomials *are* new. In this connection we should also point out that the pertinent weight function integral is immediate from the above. Indeed, from (4.49) we have, in particular, $(\psi_0,\psi_0)=2\pi/r$. Hence (4.54) and (4.35) yield the integral

$$\frac{1}{2\pi}\int_0^\pi dy\,\sin y\prod_{n=-N}^{N}\sin(y+in\alpha)=\frac{1}{4^{N+1}}\prod_{j=1}^{N}\frac{\sinh([N+1+j]\alpha)}{\sinh(j\alpha)},\quad N\in\mathbb{N},\quad \alpha>0, \tag{4.58}$$

as a corollary.

In the remainder of this section we study the case $b=k\beta$ with $-k\in\mathbb{N}$. Since we intend to compare the insights obtained for these parameters to the state of affairs at the elliptic level, we follow the relevant part of Sec. IV in I [starting with the paragraph containing I(4.42)] to a large extent. We first need some preparations, however.

First, in keeping with the notation adopted for the elliptic case, we denote the $A((N+1)\beta)$-eigenfunctions corresponding to $\mathcal{H}_N(x,y)$ by $\Psi(x,y)$. Thus, we have

$$\Psi(x,y)=\mathcal{N}\prod_{j=-N}^{N}\sin r(x+ij\beta)^{-1}\cdot\mathcal{H}_N(x,y),\quad b=(N+1)\beta, \tag{4.59}$$

so that we get the asymptotics

$$\Psi(x,y)\sim c(x)\exp(ixy),\quad y\to\infty, \tag{4.60}$$

with

$$c(r,\beta,(N+1)\beta;x)=\mathcal{N}\prod_{j=0}^{N}\sin r(x-ij\beta)^{-1}\cdot\exp i(N+1)rx. \tag{4.61}$$

(As before, the symbol $\mathcal{N}$ is used to denote normalization constants.)

Second, the trigonometric c-function occurring here equals, more generally,

$$c(r,\beta,b;x)=\frac{G(r,\beta;-x-i\beta/2)}{G(r,\beta;-x+ib-i\beta/2)}, \tag{4.62}$$

where $G(r,\beta;z)$ is the generalized trigonometric gamma function from Ref. 2; just as in the elliptic case, the weight and scattering functions are then given by I(1.27) and I(1.28). [Compare also I(1.24)–I(1.26) with (4.60)–(4.62).]

We are now prepared to follow our elliptic reasoning. Denoting B (4.3) by $B(N)$, and comparing this AΔO to $A(b)$ (1.24), we obtain

$$A(-N\beta)=B(N),\quad N\in\mathbb{N}. \tag{4.63}$$

This equality is the trigonometric counterpart of the elliptic relation I(4.42) with $N_-=0$ and $\delta=-$; the prefactor r_- is absent here, since we omitted the prefactor $\exp(-br)$ occurring in I(1.15); cf. (1.24). (As will be explained at the end of this section, in the trigonometric case this omission is not motivated solely by a desire to avoid clutter from constants.)

Due to (4.63), (4.11), and (4.24) we now have

$$A(-N\beta)\mathcal{H}_N(\pm x,y)=2\cosh(\beta[y+(N+1)r])\mathcal{H}_N(\pm x,y), \tag{4.64}$$

which is the analog of I(4.46) with $N_-=0,\delta=-$. Similarly, I(4.48) and I(4.50) specialize to

$$\Psi(x,y)=\mathcal{N}\mathcal{H}_N(x,y-(2N+1)r),\quad b=-N\beta,\quad \mathrm{Re}\,y>2Nr. \tag{4.65}$$

[Note that (4.24) and (4.20) entail that $\Psi(x,y)$ becomes *singular* for $y=(N+j)r$ with $\pm j=1,\dots,N$.] This guarantees that (4.60) holds true, with

$$c(-N\beta;x)=\mathcal{N}\prod_{j=1}^{N}\sin r(x+ij\beta)\cdot\exp -iNrx. \tag{4.66}$$

[This formula agrees with the pertinent specializations of I(4.52) and (4.62); cf. also Proposition III.14 in Ref. 2.]

The upshot is that we have now obtained eigenfunctions $\Psi(b;\pm x,y)$ of $A(b)$ [and of Q (1.28), of course] for $b=k\beta$, $k\in\mathbb{Z}$. Denoting the eigenvalues by $E(y)$, they have asymptotics

$$E(y)\sim e^{br}e^{\beta y},\quad y\to\infty,\quad b=k\beta,\quad k\in\mathbb{Z}, \tag{4.67}$$

in accord with I(1.19) for $\delta=-$. [Recall that we omitted the factor exp($-br$) in I(1.15) for the trigonometric AΔO (1.24).]

In contrast to the elliptic and hyperbolic cases, the subset $\mathcal{D}_{\text{trig}}$ (1.27) is not dense in the trigonometric parameter domain $\mathcal{T}$(1.23). Therefore, our results have no direct implications for the existence and properties of joint $(A(b),Q)$-eigenfunctions $\Psi(x,y)$ for arbitrary $b\in\mathbb{R}$. But we can shed more light on the orthogonality question for the elliptic case by specializing to the b-values $-N\beta$, $N\in\mathbb{N}$, and studying the analogous trigonometric question. Then we are dealing with the Hilbert space of square-integrable functions on $(0,\pi/r)$ w.r.t. the measure $w(r,\beta,-N\beta;x)dx$; due to (4.66) and the relation $w(x)=1/c(x)c(-x)$, the weight function is proportional to $\hat{w}(x)$ (4.35), so we may as well use $\mathcal{H}_{\hat{w}}$ to study orthogonality.

First, we observe that due to (4.65) the functions

$$\zeta_k(x)\equiv\Psi(x,kr)-\Psi(-x,kr),\quad k\geqslant 2N+1,\quad b=-N\beta, \tag{4.68}$$

are proportional to the functions ψ_{k-2N-1} given by (4.33). Thus they yield an orthogonal base of eigenvectors of $A(-N\beta)$. But in this case we can actually rule out that for $N>0$ the even combinations

$$\chi_k(x)\equiv\Psi(x,kr)+\Psi(-x,kr),\quad k\geqslant 2N+1,\quad b=-N\beta, \tag{4.69}$$

are orthogonal in $\mathcal{H}_{\hat{w}}$. This entails that the elliptic generalizations for $b=-N_\delta a_\delta, N_\delta>0$, are not orthogonal as well [as announced below I(4.57)]. In the following theorem we prove not only nonorthogonality, but also an unexpected completeness property.

Theorem IV.2: *For all $N\in\mathbb{N}$ the functions $\chi_k(x)$ (4.69) satisfy*

$$A(-N\beta)\chi_k(x)=2\cosh([k-N]\beta r)\chi_k(x),\quad k\geqslant 2N+1. \tag{4.70}$$

Now let $N\in\mathbb{N}^*$. Then the functions $\{\chi_k(x)\}_{k=2N+1}^{\infty}$ are total, but not pairwise orthogonal in the Hilbert space $\mathcal{H}_{\hat{w}}$ (4.34).

Proof: The first statement follows from (4.64) and (4.65). In order to prove the second one, we begin by noting that the functions $\chi_k(x)$ satisfy the recurrence relation

$$C_n\chi_{2N+n}(x)+C_{n+1}\chi_{2N+n+2}(x)=2\cos(rx)\chi_{2N+n+1}(x),\quad n\in\mathbb{N}, \tag{4.71}$$

with C_n given by (4.39). [Indeed, this follows in the same way as (4.38).] Since $C_0=0$ and $C_n>0$ for all $n\in\mathbb{N}^*$, this entails as before that $\chi_{2N+1}(x)$ is not identically 0 and that

$$\chi_{2N+n+1}(x)/\chi_{2N+1}(x)=G_n(\cos rx),\quad n\in\mathbb{N}; \tag{4.72}$$

cf. (4.41).

Since $G_n(\cos rx)$ is a polynomial of degree n in $\cos rx$, it now follows from (4.72) that the linear span of the functions $\chi_{2N+1},\chi_{2N+2},\ldots,$ is dense in $\mathcal{H}_{\hat{w}}$. Thus, it remains to show that they are not pairwise orthogonal. We now prove this by deriving a contradiction from the assumption of pairwise orthogonality.

Indeed, this assumption entails (by virtue of the reasoning in the proof of Theorem IV.1) that the polynomials $(r/2\pi)^{1/2}G_n(\cos rx)$ are an orthonormal base for the Hilbert space

$$\tilde{\mathcal{H}}_A \equiv L^2((0,\pi/r),|\eta_0(x)|^2\hat{w}(x)dx), \tag{4.73}$$

where

$$\eta_0(x)\equiv \mathcal{H}_N(x,0)+\mathcal{H}_N(-x,0). \tag{4.74}$$

Since we have already proved that these polynomials have this property w.r.t. the Hilbert space $\mathcal{H}_A$ (4.56), it easily follows that $|\psi_0(x)|^2$ and $|\eta_0(x)|^2$ are equal for $x\in[0,\pi/r]$. Now this amounts to the real part of $\overline{\mathcal{H}_N}(x,0)\mathcal{H}_N(-x,0)$ being 0 for $x\in[0,\pi/r]$, so using (4.24) we infer $\mathrm{Re}\,\overline{L_N}(x,0)L_N(-x,0)$ vanishes for $x\in[0,\pi/r]$. Recalling (4.10), this entails $\mathrm{Re}(L_N(x,0)^2)=0$ for real x. But an inspection of (4.8) reveals that the function $L_N(x,0)^2$ is of the form $\Sigma_{m=2}^{4N+2}a_m \exp imrx$, with $a_m\in\mathbb{R}$. Thus, we infer $L_N(x,0)$ vanishes identically. Since this entails $\psi_0(x)=0$, we finally arrive at the desired contradiction. □

The alert reader will have noted that we excluded the choice $N=0$ from consideration. Indeed, from (4.65) and the $N=0$ formula (4.40), we have $\Psi(x,y)=\mathcal{N}\exp ixy$. Thus, the functions $\zeta_k(x)$ (4.68) and $\chi_k(x)$ (4.69) are proportional to $\sin krx$ and $\cos krx$, respectively, with $k=1,2,\ldots$. Moreover, $\mathcal{H}_{\hat{w}}$ reduces to $L^2((0,\pi/r),dx)$. Now, as before, the functions $\zeta_1,\zeta_2,\ldots,$ are an orthogonal base. But clearly the functions $\chi_1,\chi_2,\ldots,$ are *also* pairwise orthogonal, and they are *not* complete in $\mathcal{H}_{\hat{w}}$, since they are all orthogonal to the constant functions!

At first sight, this seems to contradict our previous reasoning. In fact, however, there is a subtle, but decisive difference with the case $N>0$: The pertinent recurrence coefficients C_n, $n\in\mathbb{N}$, are equal to 1 *including* C_0, whereas C_0 vanishes for $N>0$ [cf. (4.39)]. Hence it does not follow that (4.72) yields polynomials, and indeed the functions $\cos(n+1)rx/\cos rx$ are not polynomials in $\cos rx$.

We also observe that the $N=0$ recurrence is obeyed both by the second-kind Tchebichev polynomials $\sin(n+1)rx/\sin rx$ and by the first-kind ones $\cos nrx$, $n\in\mathbb{N}$. The latter *can* be used to define $A(0)$ as a self-adjoint operator on $L^2((0,\pi/r),dx)$, whereas the former are equal to the above q_t^2-Gegenbauer polynomials for $b=\beta$ [and as such were used to turn $A(\beta)$ into a self-adjoint operator on $L^2((0,\pi/r),\sin^2(rx)dx)$].

To conclude this section, we present some more observations on the relation between the cases $b=(N+1)\beta$ and $b=-N\beta$. When we transform the $A(b)$-eigenfunctions $\Psi(x,y)$ to functions $\mathcal{F}(x,y)$ by using I(1.29) [with $w(x)$ the trigonometric w-function $w(r,\beta,b;x)$], then the functions $\tilde{\mathcal{F}}(x,y)$ for the b-values $-N\beta$ are related to the functions $\mathcal{F}(x,y)$ for the b-values $(N+1)\beta$ via

$$\tilde{\mathcal{F}}(x,y)=\chi\mathcal{F}(x,y-(2N+1)r), \quad \mathrm{Re}\, y>2Nr, \tag{4.75}$$

with χ a phase. [This follows by combining (4.59) and (4.65) with the c-function formulas (4.61) and (4.66).]

This relation is in agreement with the identity

$$H(-b)=H(b+\beta), \tag{4.76}$$

satisfied by the Hamiltonian $H(b)$ (1.25). We have omitted the factor $\exp(-br)$ present in the elliptic counterpart H_- I(1.12), since the symmetry property I(1.13) does not admit a trigonometric specialization. Because we have done so, the symmetry property (4.76) appears instead. Note that this invariance property at the relativistic level turns into $g \to 1-g$ invariance at the nonrelativistic level; cf. I(1.1). By contrast, the invariance property I(1.13) has no nonrelativistic counterpart.

Let us observe finally that—again in contrast to the elliptic case—the AΔOs $H(b_1)$ and $H(b_2)$ are proportional (in fact, equal) only when $b_2 = b_1$ and $b_2 = -b_1 + \beta$. Of course, this easily verified assertion assumes that we restrict attention to $\mathcal{T}$ (1.23), as we have done throughout this section.

(Received 22 July 1998; accepted for publication 29 October 1998)

This article revolves around the properties on the L^p scale of spaces of the integral kernel operator K whose kernel function is the reproducing kernel of the Segal-Bargmann space. We find sufficient conditions on p and q for K to be a Hille-Tamarkin (and hence compact) operator from L^p to L^q with respect to the standard Gaussian measure as well as with respect to a weighted measure on the codomain space. We also find sufficient conditions for K to be unbounded with respect to the standard Gaussian measure. Finally we give sufficent conditions for a Toeplitz operator to be Hille-Tamarkin on the L^p scale of spaces with respect to both the standard Gaussian measure and a weighted measure on the codomain space. © *1999 American Institute of Physics.* [S0022-2488(99)02702-4]

I. INTRODUCTION

The Segal-Bargmann space has enjoyed a long history in mathematics and mathematical physics. Originally introduced by Fischer,[1] it found its first use in physics in the early days of quantum mechanics by Fock[2] and has since come to be recognized as a quantum mechanical version of the phase space of classical mechanics (see Ref. 3). The aspects of this structure relevant to mathematical physics were put on a rigorous basis by Segal (see Refs. 4 and 5) in the infinite dimensional case, and by Bargmann[6] in the finite dimensional case. This last article describes a transform, often call the Segal-Bargmann transform, associated with the Segal-Bargmann space and with another space, sometimes called the configuration space or the Schrödinger space. The reader should be warned that unfortunately the Segal-Bargmann space has been given a wide variety of appellations, including all combinations and permutations of the names Bargmann, Fock, and Segal as well as the ''complex wave representation.'' Of course, the Segal-Bargmann transform has suffered a similar fate, all of which makes literature searches problematical even in an age of computerized data bases. Moreover, in the field of white noise analysis, the S-transform is closely related to the Segal-Bargmann transform (see Ref. 7, p. 337).

In this article, the role of the Segal-Bargmann transform is replaced completely by another structure, the reproducing kernel function, or more precisely, its associated integral kernel transform. (See Ref. 8 for a related analysis of the Segal-Bargmann transform itself.) Consequently, the theory here is developed in the Segal-Bargmann space and other related Banach spaces, without reference to the configuration space. Moreover, only the finite dimensional case is discussed here. The reproducing kernel integral transform is a principal ingredient in the quantization scheme which assigns to a function ϕ, which can be thought of as a classical observable (if it is real valued), a corresponding operator $T(\phi)$ (called a Toeplitz operator), which can be thought of as the corresponding quantum observable.

We now give a summary of this article. Precise definitions will be given in the next section. We work with the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$ (see Refs. 4–6) of holomorphic functions on $\mathbf{C}^n$ that are square integrable with respect to a Gaussian measure μ_n. This space has a reproducing kernel function $K(w,z)$, which in turn defines an integral kernel operator

$$Kf(w) := \int_{\mathbf{C}^n} d\mu_n(z) K(w,z) f(z),$$

[a)]Electronic mail: sontz@xanum.uam.mx

where $f:\mathbf{C}^n \rightarrow \mathbf{C}$ and $w \in \mathbf{C}^n$. This integral operator is well defined for all f in $L^p(\mathbf{C}^n,\mu_n)$ with $1<p\leqslant\infty$. It is proved in Theorem 3.1 that K is a compact (actually, Hille-Tamarkin) operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ for $p'q<4$ and that in this case

$$||K||_{p\rightarrow q}\leqslant\min((1-p'q/4)^{-n/q},(1-p'q/4)^{-n/p'}),$$

where p' is the dual index of p. Note $p'q<4$ implies $p>q$. Next, calculations with test functions demonstrate that $||K||_{p\rightarrow q}=\infty$ if $p'q>4$. Note $p<q$ implies $p'q>4$. Also, $p=q\neq 2$ implies $p'q>4$. In Theorem 3.2 it is shown that K is a compact (actually, again Hille-Tamarkin) operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\nu_{ab})$ given only that $1<p\leqslant\infty$ and $1\leqslant q<\infty$ where ν_{ab} is the probability measure given by $d\nu_{ab}(z)=c_{ab}\exp(-ax^2-by^2)d\mu_n(z)$ and a and b are constants which depend only on p and q. Here c_{ab} is a normalization constant. Some of the results of Theorem 3.1 can be derived as special cases of Theorem 3.2, but it is hoped that the present exposition shows better how the ideas of Theorem 3.2 were formed. As is usual in L^p analysis, most of the results of this article depend in one way or other on Hölder's inequality, though interpolation theorems are used as well.

The results presented in this article are applied in two ways. First, they are used in Theorem 3.3 to prove a sufficient condition for a Toeplitz operator to be Hille-Tamarkin from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ or to $L^q(\mathbf{C}^n,\nu_{ab})$. A second application is a demonstration of a reverse log-Sobolev inequality in the Segal-Bargmann space, which is proved in a subsequent article[9] by the author.

The organization of the paper is as follows. The next section introduces the requisite definitions and notation. Section III gives the statements of the theorems, while their proofs are given in Sec. IV. Section V concludes with some comments and remaining open questions.

II. NOTATION AND DEFINITIONS

This section contains a review of notation and definitions. A reference for most of the notation used here for the Segal-Bargmann space is Bargmann's article.[6] For each integer $n\geqslant 1$, the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$ (see Refs. 4–6) is the Hilbert space of holomorphic functions $f:\mathbf{C}^n\rightarrow\mathbf{C}$ which are square integrable with respect to a Gaussian measure given by

$$d\mu_n(z):=\pi^{-n}\exp(-z^*\cdot z)d^nxd^ny,$$

where for each $z=(z_1,\ldots,z_n)\in\mathbf{C}^n$ and $w=(w_1,\ldots,w_n)\in\mathbf{C}^n$ we define $z^*:=(z_1^*,\ldots,z_n^*)$ and $z\cdot w:=z_1w_1+\cdots+z_nw_n$. Here d^nxd^ny is Lebesgue measure on $\mathbf{C}^n$ and λ^* is the complex conjugate of the complex number λ. Also, we write $z^2:=z\cdot z$ for $z\in\mathbf{C}^n$; this specializes to $x^2:=x\cdot x$ for $x\in\mathbf{R}^n$. Notice that

$$HL^2(\mathbf{C}^n,\mu_n)=L^2(\mathbf{C}^n,\mu_n)\cap\mathcal{H}_n,$$

where $L^2(\mathbf{C}^n,\mu_n)$ is the space of all functions $f:\mathbf{C}^n\rightarrow\mathbf{C}$ that are square integrable with respect to μ_n and where $\mathcal{H}_n$ is the space of all holomorphic functions from $\mathbf{C}^n$ to $\mathbf{C}$. The reproducing kernel K for the Segal-Bargmann space is given by

$$K(w,z)=\exp(w\cdot z^*),$$

where $w,z\in\mathbf{C}^n$. It is then well known (see Ref. 6) that K does indeed satisfy the reproducing kernel property, namely, that

$$f(w)=\int_{\mathbf{C}^n}d\mu_n(z)K(w,z)f(z) \tag{2.1}$$

holds for all w in $\mathbf{C}^n$ and for all f in the Segal-Bargmann space. We can also define an integral kernel operator, also denoted by K, associated with the reproducing kernel. Explicitly, we define

$$Kf(w) := \int_{\mathbf{C}^n} d\mu_n(z) K(w,z) f(z), \tag{2.2}$$

where $f:\mathbf{C}^n \to \mathbf{C}$ is measurable and $w \in \mathbf{C}^n$, provided that the integral exists. An application of Hölder's inequality shows that $Kf(w)$ is well defined for all w in $\mathbf{C}^n$ and for all f in $L^p(\mathbf{C}^n, \mu_n)$ when $1 < p \leqslant \infty$; Kf is also a holomorphic function in this case. Then formula (2.1) says that $Kf = f$ for all f in the Segal-Bargmann space $HL^2(\mathbf{C}^n, \mu_n)$. Moreover, it is well known that K as an operator defined in all of $L^2(\mathbf{C}^n, \mu_n)$ is the orthogonal projection operator whose range is precisely the Segal-Bargmann space $HL^2(\mathbf{C}^n, \mu_n)$, which is a closed subspace of $L^2(\mathbf{C}^n, \mu_n)$.

Some of the usual notation for Lebesgue spaces has already been used in the previous paragraph. Here we review this. Whenever (X, μ) is a measure space and $1 \leqslant p \leqslant \infty$, we denote the usual L^p norm of a measurable function $f:X \to \mathbf{C}$ by $\|f\|_p$ or sometimes by $\|f\|_{L^p(\mu)}$ if we need to be more explicit. Also $L^p(X, \mu)$, or simply L^p, denotes the corresponding Banach space. If B is a linear map defined on a dense subspace D of $L^p(X, \mu)$ for $1 \leqslant p \leqslant \infty$ such that $Bf:Y \to \mathbf{C}$ is measurable for every f in D, where (Y, ν) is also a measure space, then we define the operator norm from $L^p(X, \mu)$ to $L^q(Y, \nu)$ where $1 \leqslant q \leqslant \infty$ by

$$\|B\|_{p \to q} := \sup\{\|Bf\|_{L^q(\nu)} : f \in D \text{ and } \|f\|_{L^p(\mu)} = 1\}.$$

It should be noted that this defines an element in $[0, \infty]$. Moreover, if this operator norm is a finite number, then B can be extended uniquely to a continuous linear map defined on all of $L^p(X, \mu)$ and with codomain $L^q(Y, \nu)$. Even though it is standard, the notation $\|\cdot\|_{p \to q}$ is ambiguous because it suppresses reference to the measure spaces as well as to their measures. As usual, context should resolve this ambiguity, though sometimes clarifying comments will be added in the text.

Suppose that (X, μ) and (Y, ν) are σ-finite measure spaces. We say that any measurable function $B:X \times Y \to \mathbf{C}$ is a kernel function. Given such a kernel function, we define its associated integral operator

$$Bf(x) := \int_Y d\nu(y) B(x,y) f(y),$$

where $x \in X$ and $f:Y \to \mathbf{C}$ is measurable, provided that the integral exists. Here we follow the common convention, already used above, of using the same symbol B for the kernel function and for its associated operator. We define the transpose kernel function $B^T:Y \times X \to \mathbf{C}$ by $B^T(y,x) := B(x,y)$ for all $(y,x) \in Y \times X$. For given indices p and q in $[1, \infty]$, we define the Hille-Tamarkin norm (see Refs. 10 and 11) of a kernel function B by

$$|||B|||_{p,q} := \|B_p\|_{L^q(\mu)}, \tag{2.3}$$

where $B_p:X \to \mathbf{C}$ is defined by

$$B_p(x) := \|B(x, \cdot)\|_{L^{p'}(\nu)},$$

where $x \in X$ and p' is the usual dual index of p. As in the case of the operator norm, the notation $|||\cdot|||_{p,q}$ is ambiguous and precisely for the same reason, namely that the notation suppresses reference to the measure spaces and to their measures. Context, sometimes including explicit comments, should again clarify the precise meaning. In the special case $1 < p \leqslant \infty$ and $1 \leqslant q < \infty$, the Hille-Tamarkin norm is given by the formula

$$|||B|||_{p,q} = \left\{ \int_X d\mu(x) \left(\int_Y d\nu(y) |B(x,y)|^{p'} \right)^{q/p'} \right\}^{1/q}.$$

Furthermore, when $p=q=2$, this norm becomes the Hilbert-Schmidt norm. Also one says that the associated operator is a Hille-Tamarkin operator with respect to p,q if its kernel function has a finite Hille-Tamarkin norm for p,q. Here are some facts about the Hille-Tamarkin norm. (See Ref. 11 for proofs of these and other properties.) The notation and hypotheses continue to be those already used in this section.

Proposition 2.1: $||B||_{p\to q}\leqslant|||B|||_{p,q}$ and $||B||_{p\to q}\leqslant|||B^T|||_{q',p'}$.

Proposition 2.2: If $|||B|||_{p,q}$ is finite and $1<p\leqslant\infty$ and $1\leqslant q<\infty$, then the associated integral operator B is a compact operator from $L^p(Y,\nu)$ to $L^q(X,\mu)$.

Proposition 2.3: If $p\geqslant q'$, then $|||B|||_{p,q}\leqslant|||B^T|||_{q',p'}$. If $p\leqslant q'$, then $|||B|||_{p,q}\geqslant|||B^T|||_{q',p'}$.

The proof of the first proposition is an application of Hölder's inequality, while the second is proved by a limiting argument similar to that which shows that the Hilbert-Schmidt operators are compact. Since the set of all Hille-Tamarkin operators with respect to p,q is a Banach space with the Hille-Tamarkin norm, the first part of the first proposition implies that this Banach space is contractively contained in the space of all bounded linear operators, while the second proposition says that this Banach space is a subspace of the space of all compact operators when $p\neq 1$ and $q\neq\infty$. The third proposition is proved by Minkowski's inequality for integrals. It tells us which of the two estimates in the first proposition is better. While this is an easy matter to decide in the applications given here, this proposition shows what is happening in its full generality.

Finally, we define the Toeplitz operator $T(\phi)$ associated to a measurable function $\phi:\mathbf{C}^n\to\mathbf{C}$ by

$$(T(\phi)f)(w):=K(\phi f)(w)=\int_{\mathbf{C}^n}d\mu_n(z)K(w,z)\phi(z)f(z), \tag{2.4}$$

where $w\in\mathbf{C}^n$ and $f:\mathbf{C}^n\to\mathbf{C}$ is measurable provided that the integral exists. This differs from the usual definition in that there are no requirements that f belong to a space of holomorphic functions nor that ϕ be bounded. When ϕ is real valued, it can be interpreted as a physical observable defined on the classical phase space $\mathbf{C}^n$, or equivalently, $\mathbf{R}^{2n}$. More details can be found in Refs. 3 and 12, and references therein.

III. STATEMENT OF THEOREMS

Now we can state the results of this article. The first theorem describes some of the L^p mapping properties of the integral kernel operator K.

Theorem 3.1: Let K denote the integral kernel operator associated to the reproducing kernel function of the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$, as defined in (2.2). Let p, p_1, q, and q_1 be indices in $[1,\infty]$.

(i) If $p\geqslant p_1$ and $q\leqslant q_1$, then $||K||_{p\to q}\leqslant||K||_{p_1\to q_1}$.

(ii) $||K||_{p\to q}\geqslant 1$.

(iii) $||K||_{2\to 2}=1$.

(iv) If $p\geqslant 2$ and $q\leqslant 2$, then $||K||_{p\to q}=1$.

(v) K is a Hille-Tamarkin operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ if and only if $p'q<4$ where p' is the dual index of p. In this case,

$$1<|||K|||_{p,q}=(1-p'q/4)^{-n/q}.$$

In particular, $|||K|||_{2,2}=\infty$. (Notice that $p'q<4$ implies $p>q$.)

(vi) If $p'q<4$, then K is a compact operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ with $||K||_{p\to q}\leqslant A_{pq}$, where $A_{pq}:=\min((1-p'q/4)^{-n/q},(1-p'q/4)^{-n/p'})$.

(vii) If $p'q<4$, then $||K||_{p_t\to q_t}\leq A^t_{pq}$ for all $0\leq t\leq 1$, where p_t and q_t are defined implicitly by

$$p_t^{-1}=(1-t)2^{-1}+tp^{-1} \quad \text{and} \quad q_t^{-1}=(1-t)2^{-1}+tq^{-1}. \tag{3.1}$$

(viii) If $p'q>4$, then $||K||_{p\to q}=\infty$. (Notice that $p<q$ implies $p'q>4$. Also $p=q\neq 2$ implies $p'q>4$.)
(ix) If $p'q\neq 4$, then $||K||_{p\to q}=||K||_{q'\to p'}$.

It seems reasonable to conjecture that $||K||_{p\to q}=||K||_{q'\to p'}$ for the remaining case $p'q=4$ as well. The next theorem also concerns L^p mapping properties of the integral kernel operator K, except that now a different measure (which implies a different norm) is used in the codomain space.

Theorem 3.2: Let K denote the integral kernel operator associated to the reproducing kernel function of the Segal-Bargmann space, as defined in (2.2).
(i) If $1<p\leq\infty$ and $1\leq q<\infty$, then there exist real numbers a and b such that K is a Hille-Tamarkin and compact operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\nu_{ab})$ where ν_{ab} is the probability measure $d\nu_{ab}(z):=c_{ab}\exp(-ax^2-by^2)d\mu_n(z)$. Here $z=x+iy\in\mathbf{C}^n$ where $x,y\in\mathbf{R}^n$ and where the normalization constant is $c_{ab}=(1+a)^{n/2}(1+b)^{n/2}$. Explicitly, we have $||K||_{p\to q}\leq|||K|||_{p,q}<\infty$ and $||K||_{p\to q}\leq|||K^T|||_{q',p'}<\infty$, where

$$1<|||K|||_{p,q}=((1+a)(1+b)(a+1-p'q/4)^{-1}(b+1-p'q/4)^{-1})^{n/2q}$$

and

$$1<|||K^T|||_{q',p'}=((1+a)(1+b)(a+1-p'q/4)^{-1}(b+1-p'q/4)^{-1})^{n/2p'},$$

and where a and b satisfy

$$a>p'q/4-1 \quad \text{and} \quad b>p'q/4-1. \tag{3.2}$$

Notice that the operator norm as well as the Hille-Tamarkin norms are with respect to the measure μ_n in the domain space and the measure ν_{ab} in the codomain space. Also, notice that the inequalities (3.2) imply $a>-1$ and $b>-1$ so that c_{ab} and hence ν_{ab} are well-defined.
(ii) If $1<p\leq\infty$ and $1\leq q<\infty$, then K is a bounded linear operator from $L^{p_t}(\mathbf{C}^n,\mu_n)$ to $L^{q_t}(\mathbf{C}^n,\nu^t_{ab})$, where $0\leq t\leq 1$ and

$$d\nu^t_{ab}(z):=c_{ab}^{tq_t/q}\exp\left(-\frac{tq_t}{q}(ax^2+by^2)\right)d\mu_n(z)$$

and p_t and q_t are defined above in (3.1) and a and b satisfy the inequalities (3.2) in part (i). Explicitly, we have the estimate

$$||K||_{p_t\to q_t}\leq(\min(|||K|||_{p,q},|||K^T|||_{q',p'}))^t,$$

where $|||K|||_{p,q}$ and $|||K^T|||_{q',p'}$ are given in part (i). Here the operator norm is with respect to the measure μ_n in the domain space and ν^t_{ab} in the codomain space. However, the Hille-Tamarkin norms are with respect to μ_n in the domain space and ν_{ab} in the codomain space.

As a particular case, we have the estimate

$$||f||_{L^{q_t}(\nu^t_{ab})}\leq M^t||f||_{L^{p_t}(\mu_n)} \tag{3.3}$$

for all f in the Segal-Bargmann space and $M=\min(|||K|||_{p,q},|||K^T|||_{q',p'})$.

Moreover, K is actually a Hille-Tamarkin operator with respect to μ_n in the domain space and ν^t_{ab} in the codomain space for $0<t\leq 1$.

The division of $\mathbf{C}^n$ into two copies of $\mathbf{R}^n$ (via the representation $z=x+iy$) and the corresponding introduction of the two constants a and b is somewhat arbitrary. One could have divided $\mathbf{C}^n$ into $2n$ summands with the introduction of $2n$ constants and have an analogous result.

The final theorem gives some sufficient conditions for a Toeplitz operator to be Hille-Tamarkin with respect to the L^p scale of spaces. This is done with both the standard measure and the weighted measure in the codomain space.

Theorem 3.3: (i) Suppose that $\phi\in L^r(\mathbf{C}^n,\mu_n)$ for some $r>4/3$. Suppose p satisfies $p^{-1}+r^{-1}<3/4$. Define s by $s^{-1}=p^{-1}+r^{-1}$. Suppose q satisfies $s'q<4$. Then the Toeplitz operator $T(\phi)$ is a Hille-Tamarkin and hence compact operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ with

$$||T(\phi)||_{p\to q}\leq|||T(\phi)|||_{p,q}\leq|||K|||_{s,q}||\phi||_r=(1-s'q/4)^{-n/q}||\phi||_r<\infty.$$

(ii) Suppose $\phi\in L^r(\mathbf{C}^n,\mu_n)$ for some $r>1$. Suppose p satisfies $p^{-1}+r^{-1}<1$. Define s by $s^{-1}=p^{-1}+r^{-1}$. Suppose q satisfies $1\leq q<\infty$. Then the Toeplitz operator $T(\phi)$ is a Hille-Tamarkin and hence compact operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\nu_{ab})$, where ν_{ab} is the probability measure given in part (i) of Theorem 3.2 (where s replaces p). Moreover,

$$\begin{aligned}||T(\phi)||_{p\to q}&\leq|||T(\phi)|||_{p,q}\leq|||K|||_{s,q}||\phi||_r\\&=(1+a)^{n/2q}(1+b)^{n/2q}(a+1-s'q/4)^{-n/2q}(b+1-s'q/4)^{-n/2q}||\phi||_r<\infty,\end{aligned}$$

where a and b satisfy inequality (3.2), again with s replacing p.

It is an immediate consequence of this theorem that one obtains a compact operator with the same operator norm estimate when one restricts $T(\phi)$ to the holomorphic (or any other) subspace of L^p.

IV. PROOFS OF THEOREMS

In this section the theorems are proved and some additional commentary on them is given.

Proof of Theorem 3.1:

(i) If $||K||_{p_1\to q_1}=\infty$, the result is trivial. Otherwise, one uses Hölder's inequality to demonstrate that we have contractive inclusions

$$i_1:L^p(\mathbf{C}^n,\mu_n)\to L^{p_1}(\mathbf{C}^n,\mu_n)$$

and

$$i_2:L^{q_1}(\mathbf{C}^n,\mu_n)\to L^q(\mathbf{C}^n,\mu_n)$$

for $p\geq p_1$ and $q_1\geq q$, where $i_1(f):=f$ and $i_2(f):=f$ for f in the respective space. Since we can factor K, we obtain

$$||K||_{p\to q}=||i_2Ki_1||_{p\to q}\leq||i_2||_{q_1\to q}||K||_{p_1\to q_1}||i_1||_{p\to p_1}=||K||_{p_1\to q_1}.$$

Remark: I call this property of $||K||_{p\to q}$ the *northwest property* since the ordered pair (p^{-1},q^{-1}) is located to the upper left of the pair (p_1^{-1},q_1^{-1}) in the unit square $[0,1]\times[0,1]$. Here one sets $\infty^{-1}=0$. The pair (p^{-1},q^{-1}) is more convenient to use than the corresponding pair (p,q) because of interpolation theory, as we will see below. Obviously, this property also holds in general for integral kernel operators defined between probability (and even finite) measure spaces. In fact, only after completing a preliminary version of this article, did I become aware that this property is also known in the literature as *extrapolation*. (See Ref. 13, page 14.) It is also convenient to name the four quadrants of the unit square by their compass directions (northwest, southwest, northeast, and southeast). Each quadrant is understood to include the appropriate part of the boundary of the unit square, but to exclude the lines $p^{-1}=2^{-1}$ and $q^{-1}=2^{-1}$.

(ii) $K1=1$ where 1 denotes the function that is the constant 1. Since $\|1\|_p=1$ for all $1\leqslant p\leqslant\infty$, the result follows.
(iii) With the domain $L^2(\mathbf{C}^n,\mu_n)$, K is the orthogonal projection operator with range equal to the Segal-Bargmann space. Consequently, $\|K\|_{2\to 2}=1$.
(iv) This follows immediately from parts (i), (ii), and (iii).
(v) We have $|||K|||_{p,q}=\|K_p\|_q$, where $K_p(w)=\|K(w,\cdot)\|_{p'}$ for all $w\in\mathbf{C}^n$. If $p=1$, then

$$K_p(w)=K_1(w)=\|K(w,\cdot)\|_\infty=\sup_{z\in\mathbf{C}^n}|\exp(w\cdot z^*)|=\infty$$

if $w\neq 0$. So, $|||K|||_{1,q}=\|K_1\|_q=\infty$ for all $1\leqslant q\leqslant\infty$. For $1<p\leqslant\infty$ and $w=u+iv$ with u,v in $\mathbf{R}^n$, we have

$$K_p(w)=\left\{\int_{\mathbf{C}^n} d^nx\,d^ny\,\pi^{-n}e^{-x^2-y^2}|e^{w\cdot z^*}|^{p'}\right\}^{1/p'}=\exp(p'(u^2+v^2)/4) \tag{4.1}$$

by doing the Gaussian integral explicitly. If $q=\infty$, then

$$|||K|||_{p,q}=\|K_p\|_\infty=\sup_{w\in\mathbf{C}^n}\exp(p'(u^2+v^2)/4)=\infty.$$

If $1\leqslant q<\infty$, then by doing the Gaussian integral we have

$$|||K|||_{p,q}=\|K_p\|_q=\left\{\int_{\mathbf{C}^n} d^nu\,d^nv\,\pi^{-n}e^{-u^2-v^2}e^{p'q(u^2+v^2)/4}\right\}^{1/q}=(1-p'q/4)^{-n/q}$$

if $1-p'q/4>0$. Moreover, $|||K|||_{p,q}=\|K_p\|_q=\infty$ if $1-p'q/4\leqslant 0$. Finally, since $1-p'q/4<1$, we have that $(1-p'q/4)^{-n/q}>1$. This shows (v).

Remark: Notice that $|||K|||_{2,2}=\infty$ follows as a special case of (v). This says that K is not a Hilbert-Schmidt operator in $L^2(\mathbf{C}^n,\mu_n)$ even though it is bounded. Of course, we already know that K is an orthogonal projection operator in $L^2(\mathbf{C}^n,\mu_n)$ with infinite dimensional range, and so it is not a compact operator, and hence not Hilbert-Schmidt.
(vi) This follows immediately from part (v) and Propositions 2.1 and 2.2 and from a calculation, similar to that given in part (v), which shows that for $p'q<4$ we have

$$\|K\|_{p\to q}\leqslant|||K^T|||_{q',p'}=(1-p'q/4)^{-n/p'}.$$

Remarks: Part (iv) says that the situation for the norm $\|K\|_{p\to q}$ is trivial for all (p^{-1},q^{-1}) that are northwest of $(2^{-1},2^{-1})$. The condition $p'q<4$ includes all of those cases, but also allows other values of (p^{-1},q^{-1}). For instance, $\|K\|_{4\to q}$ is finite for all $2<q<3$ and $(4^{-1},q^{-1})$ lies southwest of $(2^{-1},2^{-1})$. Also, $\|K\|_{8/5\to q}$ is finite for $1\leqslant q<3/2$ and $(5/8,q^{-1})$ lies northeast of $(2^{-1},2^{-1})$. We can find pairs (p^{-1},q^{-1}) as near as we like to $(2^{-1},2^{-1})$ in the southwest or in the northeast and such that $p'q<4$. For example, $p^{-1}=2.01^{-1}$ and $q^{-1}=2.001^{-1}$ is one such pair in the southwest. An example in the northeast is $p^{-1}=1.9905^{-1}$ and $q^{-1}=1.99^{-1}$. Notice that in all of these cases $p>q$ and that the operator is compact. If we define the set

$$G:=\{(p^{-1},q^{-1})\in[0,1]\times[0,1]\ :\ p'q<4\}, \tag{4.2}$$

then the reflection S in the diagonal line $p^{-1}+q^{-1}=1$ leaves G invariant as the following shows. Explicitly, $S(x,y)=(1-y,1-x)$ for any (x,y) in $\mathbf{R}^2$ is the reflection in the line $x+y=1$. The transformation of Lebesgue indices corresponding to S sends (p,q) to (q',p') and so G is clearly invariant under S. However, the Hille-Tamarkin norm is *not* invariant under this transformation. Nonetheless, the estimate of the operator norm that we get in part (vi) from *two* Hille-Tamarkin norms indeed is invariant under S. This result should be compared with that of part (ix).
(vii) This follows immediately from parts (iii) and (vi) and the Riesz-Thorin interpolation theorem (see Ref. 14) applied to the pairs (p,q) and (2,2). Notice that the estimate in (vi) behaves

badly as (p^{-1},q^{-1}) approaches $(2^{-1},2^{-1})$, namely it approaches infinity. However, the estimate in part (vii) behaves well as t approaches zero (which implies that (p_t^{-1},q_t^{-1}) approaches $(2^{-1},2^{-1})$ along a line segment), namely it approaches 1, which is the value of $||K||_{2\to 2}$.

(viii) The idea is to use a family of trial functions to estimate $||K||_{p\to q}$ from below. Define

$$g(z)=\exp((a+bi)\cdot x+(c+di)\cdot y), \tag{4.3}$$

where x, y, a, b, c, and d are in $\mathbf{R}^n$ and $z=x+iy$ is in $\mathbf{C}^n$. The following three computations then consist of nothing more than evaluations of Gaussian integrals. We do these computations in the case $1\leqslant p<\infty$ and $1\leqslant q<\infty$. First, we have

$$||g||_p=\exp(p(a^2+c^2)/4).$$

Next, for w in $\mathbf{C}^n$, we obtain

$$Kg(w)=\exp\{\tfrac{1}{4}[2w\cdot(a+bi-ci+d)+(a+bi)^2+(c+di)^2]\}.$$

And finally, we compute

$$||Kg||_q=\exp\left\{\frac{1}{4}\left(a^2-b^2+c^2-d^2+q\left[\left(\frac{(a+d)}{2}\right)^2+\left(\frac{(b-c)}{2}\right)^2\right]\right)\right\}.$$

Then a lower bound on the norm $||K||_{p\to q}$ is given by

$$\frac{||Kg||_q}{||g||_p}=\exp\left\{\frac{1}{16}[\alpha a^2+\beta b^2+\alpha c^2+\beta d^2+2q(ad-bc)]\right\},$$

where $\alpha=4+q-4p$ and $\beta=q-4$. The quadratic form in the square brackets on the right hand side here can be diagonalized in the pair of variables a,d and separately in the pair of variables b,c. The result is that the quadratic form has two distinct eigenvalues, each of multiplicity two. They are denoted λ_+ and λ_- where

$$\lambda_\pm=(q-2p)\pm(q^2+4(p-2)^2)^{1/2}.$$

Since $\lambda_+>\lambda_-$, the quadratic form has at least one positive eigenvalue if and only if $\lambda_+>0$. Moreover, $\lambda_+>0$ implies

$$\sup_g\frac{||Kg||_q}{||g||_p}=\infty,$$

where g in the supremum ranges over all functions of the above form (4.3). It is straightforward to show that $p'q>4$ implies $\lambda_+>0$. Hence, $p'q>4$ implies $||K||_{p\to q}=\infty$ if both $1\leqslant p<\infty$ and $1\leqslant q<\infty$. The case $q=\infty$ and $1\leqslant p<\infty$ is proved using the northwest property and the previous result. The case $p=\infty$ and $1\leqslant q<\infty$ is handled by taking $a=c=0$ in the definition of g so that

$$\frac{||Kg||_q}{||g||_\infty}=\exp\left\{\frac{1}{16}((q-4)b^2+(q-4)d^2)\right\}.$$

Then $p'q=q>4$ implies $||K||_{\infty\to q}=\infty$. Finally, the case $p=q=\infty$ is demonstrated with the northwest property and the previous case. And so all cases of (viii) have been shown.

(ix) By part (viii), this result is trivial if $p'q>4$. So, we assume that $p'q<4$. In this case $|||K|||_{p,q}$ is finite by part (v). We will use the characterization of the operator norm given by

$$||K||_{p\to q}=\sup\{|(g,Kf)|\ :\ ||f||_p=1 \quad\text{and}\quad ||g||_{q'}=1\}, \tag{4.4}$$

where (g,Kf) denotes the usual duality pairing (without complex conjugation). So, for $||f||_p=1$ and $||g||_{q'}=1$, we have

$$(g,Kf)=\int_{\mathbf{C}^n} d\mu_n(w)g(w)Kf(w)=\int_{\mathbf{C}^n} d\mu_n(w)g(w)\int_{\mathbf{C}^n} d\mu_n(z)K(w,z)f(z)$$

$$=\int_{\mathbf{C}^n} d\mu_n(z)f(z)\int_{\mathbf{C}^n} d\mu_n(w)e^{w\cdot z^*}g(w). \tag{4.5}$$

The interchange of integrals is justified by Fubini's theorem for functions that are integrable in the product space, since by two applications of Hölder's inequality and by Fubini's theorem for non-negative functions we have

$$\int_{\mathbf{C}^n\times\mathbf{C}^n} d\mu_n(z)d\mu_n(w)|g(w)K(w,z)f(z)|\leqslant||f||_p||g||_{q'}|||K|||_{p,q}=|||K|||_{p,q}<\infty.$$

(As an aside, the reader should note that a calculation of the sort in the last line is the way one proves Proposition 2.1.) But similarly

$$||K||_{q'\to p'}=\sup\{|(f,Kg)|\ :\ ||g||_{q'}=1 \quad \text{and} \quad ||f||_p=1\} \tag{4.6}$$

and

$$(f,Kg)=\int_{\mathbf{C}^n} d\mu_n(w)f(w)Kg(w)=\int_{\mathbf{C}^n} d\mu_n(w)f(w)\int_{\mathbf{C}^n} d\mu_n(z)e^{w\cdot z^*}g(z)$$

$$=\int_{\mathbf{C}^n} d\mu_n(z^*)f(z^*)\int_{\mathbf{C}^n} d\mu_n(w^*)e^{w\cdot z^*}g(w^*) \tag{4.7}$$

by a simple change of variables. But this change of variables leaves invariant the measure μ_n and the classes of functions f (respectively, g) such that $||f||_p=1$ (respectively, $||g||_{q'}=1$). So the numbers which appear in Eq. (4.7) as f and g vary are the same as appear in (4.5). So the result follows from Eqs. (4.4) and (4.6). This completes the proof of part (ix) and of Theorem 3.1. □

We proceed next to the proof of the second theorem.

Proof of Theorem 3.2:

(i) We need to compute the Hille-Tamarkin norm of K much as in part (v) of Theorem 3.1. Only now we use a different measure in the codomain space, namely ν_{ab}. However, the definition and hence computation of $K_p(w)$ in formula (4.1) does not change. So, for $1<p\leqslant\infty$ and $1\leqslant q<\infty$, we have

$$|||K|||_{p,q}=||K_p||_q=\left\{\int_{\mathbf{C}^n} d^nu\,d^nv\,\pi^{-n}c_{ab}e^{-au^2-bv^2}e^{-u^2-v^2}e^{p'q(u^2+v^2)/4}\right\}^{1/q}$$

$$=((1+a)(1+b)(a+1-p'q/4)^{-1}(b+1-p'q/4)^{-1})^{n/2q} \tag{4.8}$$

provided that $a>p'q/4-1$ and $b>p'q/4-1$. Also, since $p'q>0$, it follows that $|||K|||_{p,q}>1$. Together with Propositions 2.1 and 2.2, this shows that the operator is compact and that the first formula in part (i) holds. The second formula follows by a similar calculation.

Remark: Notice that when $p'q/4-1<0$ we can take $a=b=0$ and so we recover one implication in part (v) of Theorem 3.1 as a special case. Notice also that we can always select a and b so that $a=b$. In this case, we can think of the codomain space as being a Banach space associated with a Segal-Bargmann space endowed with a Planck's constant distinct from that of the domain space. See Ref. 15, pp. 138 and 168, for a presentation of the Segal-Bargmann space with explicit use of Planck's constant. Actually, in the case $a\neq b$, we can think of the codomain as arising from a generalized type of Segal-Bargmann space with *two* distinct values for Planck's ''constant.'' Also, in the case $p=1$ or $q=\infty$ it is straightforward to show that there is no Gaussian weight factor for the codomain space such that K is Hille-Tamarkin.

To prove part (ii) of Theorem 3.2, we will again use interpolation theory, except that now the relevant result is a theorem due to Stein.[16] Since it is not as well known as the Riesz-Thorin theorem, here is a statement of Stein's theorem taken from Ref. 16 and transcribed into the notation of this article. First, recall that a simple function is a measurable function f with a finite range I such that $f^{-1}(i)$ has finite measure for every nonzero $i \in I$.

Theorem 4.1 (Stein): Let (M,ν) and (N,μ) be σ-finite measure spaces. Let T be a linear transformation defined on simple functions of M to measurable functions on N. Suppose that p_0, p_1, q_0, and q_1 are in $[1,\infty]$ and define p_t and q_t implicitly by

$$p_t^{-1}=(1-t)p_0^{-1}+tp_1^{-1} \quad \text{and} \quad q_t^{-1}=(1-t)q_0^{-1}+tq_1^{-1}$$

for $0 \leqslant t \leqslant 1$. Suppose that for some measurable functions $k_0,k_1:N \to [0,\infty)$ and $u_0,u_1:M \to [0,\infty)$ and for all simple $f:M \to \mathbf{C}$ one has

$$||(Tf)k_0||_{L^{q_0}(\mu)} \leqslant M_0||fu_0||_{L^{p_0}(\nu)} \tag{4.9}$$

and

$$||(Tf)k_1||_{L^{q_1}(\mu)} \leqslant M_1||fu_1||_{L^{p_1}(\nu)} \tag{4.10}$$

for some M_0 and M_1 in $\mathbf{R}$. (The right hand side of either of these inequalities may be infinite for some f.) Define new functions $k_t := k_0^{1-t}k_1^t$ on N and $u_t := u_0^{1-t}u_1^t$ on M for $0 \leqslant t \leqslant 1$. Then T can be extended uniquely to a linear transformation on all functions f satisfying $||fu_t||_{L^{p_t}(\nu)} < \infty$ so that

$$||(Tf)k_t||_{L^{q_t}(\mu)} \leqslant M_0^{1-t}M_1^t||fu_t||_{L^{p_t}(\nu)}. \tag{4.11}$$

To apply Stein's theorem, we take the measure spaces (M,ν) and (N,μ) to be $(\mathbf{C}^n,\mu_n)$. Also, we take the Lebesgue indices to be $p_1=p$, $q_1=q$ and $p_0=q_0=2$. Finally, we take the weight functions to be $k_0=u_0=u_1=1$ and

$$k_1(z)=c_{ab}^{1/q}\exp\left(-\frac{1}{q}(ax^2+by^2)\right), \tag{4.12}$$

where a and b satisfy (3.2). Then it is easy to show that

$$||(Kf)k_1||_{L^q(\mu_n)}=||Kf||_{L^q(\nu_{ab})}.$$

So, it follows from part (i) that

$$||(Kf)k_1||_{L^q(\mu_n)} \leqslant M_1||fu_1||_{L^p(\mu_n)},$$

where $M_1=\min(|||K|||_{p,q},|||K^T|||_{q',p'})$. This shows that inequality (4.10) of Stein's theorem holds. But we have

$$||(Kf)k_0||_{L^2(\mu_n)} \leqslant ||fu_0||_{L^2(\mu_n)}$$

since K is an orthogonal projection. This shows that inequality (4.9) of Stein's theorem holds with $M_0=1$. So we conclude that inequality (4.11) of Stein's theorem holds, that is to say, that for $0 \leqslant t \leqslant 1$

$$||(Kf)k_t||_{L^{q_t}(\mu_n)} \leqslant M_1^t||fu_t||_{L^{p_t}(\mu_n)}.$$

But $u_t = 1$ and

$$k_t(z) = k_0^{1-t}(z) k_1^t(z) = k_1^t(z) = c_{ab}^{t/q} \exp\left(-\frac{t}{q}(ax^2 + by^2) \right) \tag{4.13}$$

for all $0 \leqslant t \leqslant 1$. Since it is easy to see that

$$||(Kf)k_t||_{L^{q_t}(\mu_n)} = ||Kf||_{L^{q_t}(\nu_{ab}^t)}$$

we have that

$$||Kf||_{L^{q_t}(\nu_{ab}^t)} \leqslant M_1^t ||f||_{L^{p_t}(\mu_n)} \tag{4.14}$$

or in the notation of operator norms,

$$||K||_{p_t \to q_t} \leqslant M_1^t$$

which is the estimate we had to show.

The particular case (3.3) follows immediately from (4.14) since $Kf = f$ for f in the Segal-Bargmann space.

To show that K is Hille-Tamarkin with respect to μ_n and ν_{ab}^t we have to show, according to part (i), that

$$\frac{tq_t}{q} a > p_t' q_t /4 - 1 \text{ and } \frac{tq_t}{q} b > p_t' q_t /4 - 1$$

hold for $0 < t \leqslant 1$ given that a and b satisfy (3.2). (Notice that ν_{ab}^t is in general a finite measure, but not a probability measure. Nonetheless, the criterion of part (i) applies.) To do this, it suffices to show that

$$\frac{q}{tq_t}(p_t' q_t/4 - 1) \leqslant p' q/4 - 1, \tag{4.15}$$

since the right hand side of (4.15) is $< \min(a,b)$ by (3.2) and $t > 0$. But a computation for the case $1 < p < \infty$ shows that

$$\frac{q}{tq_t}(p_t' q_t/4 - 1) = \frac{q}{4} \frac{2(2 + pt - 2t)}{(p + pt - 2t)} - 1$$

and so it suffices to show that for $0 < t \leqslant 1$ we have

$$\frac{2(2 + pt - 2t)}{p + pt - 2t} \leqslant p' = \frac{p}{p-1}.$$

But this last inequality is trivial to verify. Since $p > 1$ by hypothesis, the remaining case is $p = \infty$, which is also straightforward. This concludes the proof of Theorem 3.2. □

Remark: Notice that in part (ii), the measure in the codomain space depends on the interpolating parameter t. Again, in the special case $a = b$, we can think of these interpolating measures as being given by a continuous deformation of Planck's constant between two extreme values. The behavior of the estimate of the operator norm $||K||_{p \to q}$ in part (i) is highly erratic as (p,q) approaches (2,2) because the parameters a and b depend on p and q, but only via the inequalities (3.2) rather than in a functional manner. Worse yet, at $(p,q) = (2,2)$, part (i) tells us that K is a Hille-Tamarkin operator but only if we pick $a > 0$ and $b > 0$. Of course, we know that K is actually a bounded operator at $(p,q) = (2,2)$ with $a = b = 0$, though *not* a Hille-Tamarkin operator with

$a=b=0$. So the interpolation in part (ii) gives us a better behaved estimate of $||K||_{p_t\to q_t}$ as $t\to 0$ (which implies that (p_t^{-1},q_t^{-1}) approaches $(2^{-1},2^{-1})$ along a line segment) since only one choice of parameters a and b is used, namely that at the endpoint corresponding to $t=1$.

Proof of Theorem 3.3: The two parts will be proved simultaneously. First notice that the hypotheses on r, p and q ensure that the rest of the assertions are non-vacuous and that $|||K|||_{s,q}$ is finite. Next notice that according to its definition in (2.4), $T(\phi)$ is an integral kernel operator with kernel function $K(w,z)\phi(z)$ for w,z in $\mathbf{C}^n$. Since the relation $s^{-1}=p^{-1}+r^{-1}$ implies $p'^{-1}=s'^{-1}+r^{-1}$, we have for all w in $\mathbf{C}^n$ that

$$||K(w,\cdot)\phi(\cdot)||_{p'}\leq||K(w,\cdot)||_{s'}||\phi||_r,$$

where the norms are with respect to $d\mu_n(z)$. Next, we take the L^q norm of both sides of the previous inequality. We do this with respect to $d\mu_n(w)$ for the first part of the theorem and correspondingly with respect to $d\nu_{a,b}(w)$ for the second part. Using the definition (2.3) of the Hille-Tamarkin norm, we obtain $|||T(\phi)|||_{p,q}\leq|||K|||_{s,q}||\phi||_r$. Together with Propositions 2.1 and 2.2 and the formulas for the Hille-Tamarkin norms in Theorems 3.1 and 3.2, this gives all the results. This concludes the proof of Theorem 3.3. □

V. CONCLUDING REMARKS

The results of this article depend critically on the estimates that come from the Hille-Tamarkin norm. However, this norm is usually much stronger than the operator norm, which is to say the estimates of Proposition 2.1 are often far from optimal. Despite this, the general situation of the transform K with respect to the L^p scale of spaces is revealed by this method. Specifically, if we define

$$E:=\{(p^{-1},q^{-1})\ :\ p'q=4\},$$

then for every (p^{-1},q^{-1}) that is not in E, we have either that K is compact (actually, Hille-Tamarkin) from L^p to L^q or that $||K||_{p\to q}=\infty$. For pairs (p^{-1},q^{-1}) in E, it remains an open problem to determine $||K||_{p\to q}$, except in the case $p=q=2$. It follows that K, as a transform from $L^2(\mathbf{C}^n,\mu_n)$ to itself is not the generic case on the L^p scale of spaces (i.e., is neither Hille-Tamarkin nor unbounded). The Segal-Bargmann transform is also generically either Hille-Tamarkin or unbounded (see Ref. 8) and, in fact, this is a general property of a Gaussian integral kernel operator G defined between two Euclidean spaces, each endowed with a Gaussian measure.

Of course, the lack of sharpness in the operator norm estimate is a question of finding best constants and this is an open problem for all of the estimates given of operator norms by Hille-Tamarkin norms in this article. It is perhaps interesting, in its own right, to know the value of the operator norm of K restricted to the subspace of holomorphic functions of $L^p(\mathbf{C}^n,\mu_n)$ with codomain $L^q(\mathbf{C}^n,\mu_n)$ or $L^q(\mathbf{C}^n,\nu_{ab})$. Moreover, the operator norm of K from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ may obey a ''one-infinity'' law. This means that for every pair of indices p and q in $[1,\infty]$ one would have either $||K||_{p\to q}=1$ or $||K||_{p\to q}=\infty$. All of the results of this paper are consistent with this possibility. Also, various calculations with Gaussian trial functions failed to contradict this possibility. But it remains an open question.

Some comments are in order about the rather nice paper by Lieb[17] on Gaussian kernel integral transforms, especially since his results have not been used here. At first reading, it might appear that there is little overlap with the cases presented here and those found in Ref. 17, but the situation is more complicated. The fact that Lieb's results are presented with respect to Lebesgue measure (instead of Gaussian measure as is done in this article) is no obstacle; it is well known that there are Banach space isomorphisms (i.e., one-to-one, onto isometries) between $L^p(\mathbf{C}^n,\mu_n)$ and $L^p(\mathbf{C}^n,d^nxd^ny)$ for all p in $[1,\infty]$. Using these isomorphisms, one can easily translate the results of Lieb to the case of Gaussian measures. For example, using the lemma on p. 185 of Ref. 17, one can show that K is a compact operator from $L^p(\mathbf{C}^n,\mu_n)$ to $L^q(\mathbf{C}^n,\mu_n)$ provided that $p'q<4$. And one can even directly read off the estimate $||K||_{p\to q}\leq(1-p'q/4)^{-n/q}$ from the proof of this lemma, since Lieb uses implicitly the estimate $||B||_{p\to q}\le|||B|||_{p,q}$ of Proposition 2.1. (It should be remarked that the above Banach space isomorphisms preserve Hille-Tamarkin norm.) But the most interesting part of Ref. 17 is the determination of the maximizers, which in the context of Theorem 3.1 are those nonzero f in $L^p(\mathbf{C}^n,\mu_n)$ such that $||Kf||_q=||K||_{p\to q}||f||_p$, if indeed such f exist. However, Lieb's results for maximizers apply only under certain hypotheses. Either the situations described here do not fall directly under one of Lieb's conditions or, when they do as in Theorem 3.2, the resulting algebraic calculations are quite complicated.

It should be commented that the technique of the Hille-Tamarkin norm works here because these norms become Gaussian integrals, which can therefore be evaluated explicitly. This happens because the measures and the reproducing kernel function are Gaussian; consequently this analysis works as well in a more general Gaussian situation. See, for example, Ref. 8 where a similar analysis of the Segal-Bargmann transform is given. It seems that the Hille-Tamarkin norm has not seen much use in classical analysis because for many commonly occurring integral operators, such as convolutions with respect to Lebesgue measure or oscillatory integrals (for example, the Fourier transform $\mathcal{F}$), the Hille-Tamarkin norm is typically infinite. However, in this regard, note that $|||\mathcal{F}|||_{1,\infty}$ is finite and that the standard argument that $||\mathcal{F}||_{1\to\infty}$ is finite can be expressed in this terminology as $||\mathcal{F}||_{1\to\infty}\le|||\mathcal{F}|||_{1,\infty}<\infty$.

The results of Theorem 3.3 depend on the fact that the Toeplitz operator $T(\phi)$ has a factorization as a Hille-Tamarkin operator, namely K, multiplied by a bounded operator, namely multiplication by ϕ which we denote M_ϕ. It would be interesting to know what happens in contexts where M_ϕ is more singular since it may be possible that $T(\phi)$ is bounded or compact, though not Hille-Tamarkin, in such a case. Also it would be interesting to know whether the mapping properties of $T(\phi)$ are stronger when its domain of definition is taken to be the subspace of holomorphic functions of $L^p(\mathbf{C}^n,\mu_n)$.

Finally, the results of this article are exclusively for the case when n, the dimension, is finite and so it would be interesting to know what happens in the case of infinitely many dimensions.

ACKNOWLEDGMENTS

I wish to thank Lawrence Thomas for stimulating my interest in the Segal-Bargmann space as well as for much encouragement and support. I also thank Brian Hall for conversations about Segal-Bargmann analysis and for providing me with a preprint of his article (Ref. 3).

A reverse log-Sobolev inequality in the Segal-Bargmann space

Stephen Bruce Sontz[a)]
Universidad Autónoma Metropolitana-Iztapalapa, Col. Vicentina, México DF 09340, México

(Received 5 October 1998; accepted for publication 2 November 1998)

This article is based on recent results of the author on the properties of the reproducing kernel of the Segal-Bargmann space. Those results are used here to demonstrate a family of energy-entropy inequalities in the Segal-Bargmann space. In some cases this is a log-Sobolev inequality while in other cases this is actually a *reverse* log-Sobolev inequality, which means that the energy term is bounded above by the entropy term, plus a norm term. This implies that in the Segal-Bargmann space the entropy is finite if and only if the energy is finite. Applications of this result to the Segal-Bargmann transform are given as well as a discussion of its possible relation with reverse hypercontractivity. It should be noted that all of the results of this article are proved without using hypercontractivity estimates.

I. INTRODUCTION

Suppose that (X,μ) is a probability measure space and that we have a distinguished non-negative quadratic form (say, a Dirichlet form) $Q(f)$ defined for all $f\in\mathcal{H}$ where $\mathcal{H}$ is a closed subspace of $L^2(X,\mu)$. One calls $Q(f)$ the energy of f. Then a log-Sobolev inequality in $\mathcal{H}$ is an inequality of the form

$$S(f)\leqslant a_1Q(f)+a_2||f||_2^2$$

for constants $a_1>0$ and $a_2\geqslant 0$ for all f in $\mathcal{H}$. Here $S(f)$ is the entropy of f, to be defined later. Such an inequality says that finite energy implies finite entropy. Such inequalities and their variants have played an important role in various fields of mathematics. The article[1] by Gross is the first systematic discussion of these inequalities. A later review article[2] of his has references to the literature before the date of that publication. One of the many recent references is Ref. 3. This gives a far from complete guide to the extensive literature on log-Sobolev inequalities.

On the other hand, we have a related situation in the following definition which says that finite entropy implies finite energy. We continue to use the hypotheses and notation introduced above.

Definition 1.1: An inequality of the form

$$Q(f)\leqslant b_1S(f)+b_2||f||_2^2$$

with $b_1>0$ and $b_2\geqslant 0$ and f in $\mathcal{H}$ is called a reverse log-Sobolev inequality.

In this article, I prove a parameterized family of inequalities involving energy and entropy for f in the Segal-Bargmann space of the form

$$(p^{-1}-q^{-1})S(f)\leqslant \frac{n}{q}(a-\log(a+1-p'q/4))||f||_2^2+\frac{a}{q}\langle f,Nf\rangle,$$

[a)]Electronic mail: sontz@xanum.uam.mx

where $1<p\leqslant\infty$, $1\leqslant q<\infty$, $a>p'q/4-1$, $\langle f,Nf\rangle$ is the Dirichlet form associated to the energy operator N in the Segal-Bargmann space, and p' is the dual index of p. (The parameter n is a dimension and will be specified later.) For some choices of the parameters, one gets a (regular) log-Sobolev inequality. This is a result that has been established already various times in the literature. (It was originally shown in Ref. 1, but also follows from a complex hypercontractivity inequality shown in Refs. 4–8.) For other choices of the parameters, one gets a trivial inequality that says that a non-positive quantity is bounded above by a positive quantity. But for other choices still, one gets a reverse log-Sobolev inequality in the Segal-Bargmann space. The best form (given by the method of this article) of the reverse log-Sobolev inequality is

$$\langle f,Nf\rangle\leqslant cS(f)+n\left(-1+c\log\left(\frac{4c^2}{(2c-1)(c-1)}\right)\right)||f||_2^2$$

for any $c>1$. This result is based on an earlier work of the author in Ref. 9 which in turn depends on an analysis of the reproducing kernel in the Segal-Bargmann space. Surprisingly, we obtain that finite entropy $S(f)$ implies finite energy $\langle f,Nf\rangle$, for all f in the Segal-Bargmann space. That finite energy implies finite entropy in the Segal-Bargmann space was already known by the above cited works.

The article is organized as follows. The next section reviews definitions and notation. Section III gives the statement of the theorem and its proof. In Secs. IV and V there are discussions of the question of best possible constants and of the relation to reverse hypercontractivity. In Sec. VI some applications of the reverse log-Sobolev inequality to the Segal-Bargmann transform are presented. In Sec. VII we conclude with comments and open questions.

II. NOTATION AND DEFINITIONS

We continue with the notation introduced in Ref. 9. We define the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$ (see Refs. 10–12) for each integer $n\geqslant 1$ as the Hilbert space of holomorphic functions $f:\mathbf{C}^n\to\mathbf{C}$ which are square integrable with respect to the Gaussian probability measure

$$d\mu_n(z):=\pi^{-n}\exp(-z^*\cdot z)d^nxd^ny.$$

Here for every $z=(z_1,\ \dots\ ,z_n)\in\mathbf{C}^n$ and $w=(w_1,\ \dots\ ,w_n)\in\mathbf{C}^n$ we define $z^*:=(z_1^*,\ \dots\ ,z_n^*)$ and $z\cdot w:=z_1w_1+\ \dots\ +z_nw_n$, where ω^* is the complex conjugate of the complex number ω. Also, d^nxd^ny denotes Lebesgue measure on $\mathbf{C}^n$. We write $z^2:=z\cdot z$ for $z\in\mathbf{C}^n$ as well. A special case of this notation is $x^2=x\cdot x$ for $x\in\mathbf{R}^n$. Moreover, we put $|z|^2:=z^*\cdot z$. We have

$$HL^2(\mathbf{C}^n,\mu_n)=L^2(\mathbf{C}^n,\mu_n)\cap\mathcal{H}_n$$

where $L^2(\mathbf{C}^n,\mu_n)$ is the space of all functions $f:\mathbf{C}^n\to\mathbf{C}$ that are square integrable with respect to μ_n and where $\mathcal{H}_n$ is the space of all holomorphic functions from $\mathbf{C}^n$ to $\mathbf{C}$.

Suppose (X,μ) is a measure space and that $1\leqslant p\leqslant\infty$. For a measurable function $f:X\to\mathbf{C}$ we denote the usual L^p norm of f by $||f||_{L^p(\mu)}$ or sometimes by $||f||_p$ if we do not need to be so explicit. Also $L^p(X,\mu)$ or simply L^p denotes the corresponding Banach space. We also write

$$HL^p(\mathbf{C}^n,\mu_n)=L^p(\mathbf{C}^n,\mu_n)\cap\mathcal{H}_n$$

for the space of holomorphic L^p functions. Moreover p' is the dual index of p, namely, $p^{-1}+p'^{-1}=1$.

Let (X,μ) be a probability measure space. Then for any function f in $L^2(X,\mu)$ define its entropy by

$$S(f):=\int_X d\mu|f|^2\log|f|^2-||f||_2^2\log||f||_2^2, \tag{2.1}$$

where $\log r$ denotes the natural logarithm (base e) of the real number $r>0$. We shall always use the usual convention that $0\log 0=0$. Then by Jensen's inequality, one has that $S(f)\geqslant 0$ though $S(f)=\infty$ is a possibility. The entropy, like the standard deviation, is a measure of the degree of concentration of a function. It was first introduced by Shannon[13] in information theory.

Next, $\langle f,Nf\rangle$ is the Dirichlet form in the Segal-Bargmann space associated to the non-negative operator N, known as the energy or number operator, which is given by

$$N:=z_1\frac{\partial}{\partial z_1}+\cdots+z_n\frac{\partial}{\partial z_n}.$$

The spectrum of N is the set of all non-negative integers. The Dirichlet form $\langle f,Nf\rangle$ is explicitly defined for *all* functions f in the Segal-Bargmann space by

$$\langle f,Nf\rangle:=\sum_{k=1}^{n}\left\|\frac{\partial f}{\partial z_k}\right\|_2^2, \tag{2.2}$$

where, as usual,

$$\frac{\partial}{\partial z_k}=\frac{1}{2}\left(\frac{\partial}{\partial x_k}-i\frac{\partial}{\partial y_k}\right).$$

Here we write the coordinate $z_k=x_k+iy_k$ where $x_k,y_k\in\mathbf{R}$ and i is the imaginary unit.

III. THE MAIN RESULT

Now we can state the result of this article which gives a parameterized family of energy-entropy inequalities in the Segal-Bargmann space. Under some conditions these are log-Sobolev inequalities but under others they are reverse log-Sobolev inequalities.

Theorem 3.1: For all f in the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$ satisfying $f\in HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$ we have the inequality

$$(p^{-1}-q^{-1})S(f)\leqslant\frac{n}{q}(a-\log(a+1-p'q/4))\|f\|_2^2+\frac{a}{q}\langle f,Nf\rangle \tag{3.1}$$

for $1<p\leqslant\infty$, $1\leqslant q<\infty$ and $a>p'q/4-1$ where $S(f)$ is the entropy defined in Eq. (2.1) and $\langle f,Nf\rangle$ is the Dirichlet form defined in Eq. (2.2). Moreover, this energy-entropy inequality (3.1) holds for all $f\in HL^2(\mathbf{C}^n,\mu_n)$ provided that $S(f)$ is finite and $1<p\leqslant 2$ and $1\leqslant q\leqslant 2$ and $a>p'q/4-1$.

In particular, $S(f)<\infty$ if and only if $\langle f,Nf\rangle<\infty$ for all f in the Segal-Bargmann space.

The coefficient of $\|f\|_2^2$ in (3.1) is always strictly positive. There are three qualitatively different cases for the other two coefficients in (3.1).

Case 1: $p^{-1}>q^{-1}$. It follows that $p'q/4-1>0$ and so $a>0$. The coefficients of $S(f)$ and $\langle f,Nf\rangle$ are positive, and so (3.1) is a (regular) log-Sobolev inequality.

Case 2: $p^{-1}\leqslant q^{-1}$ and $p'q/4-1\geqslant 0$. It follows that $a>0$ and so the coefficient of $S(f)$ is non-positive while the coefficient of $\langle f,Nf\rangle$ is positive. So, (3.1) is trivially true.

Case 3: $p'q/4-1<0$. It follows that $p^{-1}<q^{-1}$ so that the coefficient of $S(f)$ is negative. In this case we can take a with $0>a>p'q/4-1$ so that the coefficient of $\langle f,Nf\rangle$ is negative and so (3.1) is a reverse log-Sobolev inequality. (Taking $a\geqslant 0$, while valid, only yields a trivial inequality.)

Proof of Theorem 3.1: The proof of this theorem will be given in two passes. In the first pass some formulas will be derived in a nonrigorous way, but all the main ideas will be presented. Then in the second pass, the gaps in the first pass will be filled in.

To start the first pass, we first recall some results proved in Ref. 9. There it is shown that for every f in the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$ one has the inequality

$$||f||_{L^{q_t}(\nu_a^t)} \leqslant M^t ||f||_{L^{p_t}(\mu_n)} \tag{3.2}$$

for $0 \leqslant t \leqslant 1$, $1 < p \leqslant \infty$ and $1 \leqslant q < \infty$ with the following notation. First, p_t and q_t are defined implicitly by

$$p_t^{-1} = (1-t)2^{-1} + tp^{-1} \quad \text{and} \quad q_t^{-1} = (1-t)2^{-1} + tq^{-1} \tag{3.3}$$

for each $0 \leqslant t \leqslant 1$. The measure ν_a^t on $\mathbf{C}^n$ is defined by

$$d\nu_a^t(z) := c_a^{tq_t/q} \exp\left(-\frac{taq_t}{q} |z|^2 \right) d\mu_n(z) \tag{3.4}$$

for $z \in \mathbf{C}^n$ and $0 \leqslant t \leqslant 1$ where $c_a := (1+a)^n$ and a satisfies

$$a > p'q/4 - 1. \tag{3.5}$$

Finally, M can be taken to be the smaller of $D^{n/q}$ and $D^{n/p'}$ where

$$D := (a+1)(a+1-p'q/4)^{-1}. \tag{3.6}$$

The results in this paragraph are obtained from part (ii) of Theorem 3.2 of Ref. 9 by taking $a = b$ in the notation of that article. Notice that none of the results of Ref. 9 (nor of the present article) use hypercontractivity results. Rather the result (3.2) is based on interpolation theory.

Notice that for $t=0$, the above inequality (3.2) becomes an *equality* with both sides being $||f||_{L^2(\mu_n)}$. This allows us to use a technique of Hirschman.[14] This starts by fixing an element f in the Segal-Bargmann space as well as fixing the indices p and q such that $1 < p \leqslant \infty$ and $1 \leqslant q < \infty$. Then one takes the derivative of both sides of the inequality (3.2) at $t=0$ in order to generate the new inequality

$$\left.\frac{d}{dt}\right|_{t=0^+} ||f||_{q_t} \leqslant \left.\frac{d}{dt}\right|_{t=0^+} (M^t ||f||_{p_t})$$

which is to say

$$\left.\frac{d}{dt}\right|_{t=0^+} ||f||_{q_t} \leqslant (\log M) ||f||_2 + \left.\frac{d}{dt}\right|_{t=0^+} ||f||_{p_t}, \tag{3.7}$$

where we are only using the right hand derivative, since each side of the inequality (3.2) is a real valued function of t where $0 \leqslant t \leqslant 1$. Of course, in general the derivative is not an order preserving operator; however, in this situation the right hand derivative at $t=0$ is order preserving because of the *equality* in (3.2) at $t=0$.

Naturally, this discussion is still at a formal level, since one must show that the relevant derivatives indeed exist. However, it is also clear at a formal level that the derivative of

$$\psi(r) := \int_{\mathbf{C}^n} d\mu_n(z) |f(z)|^r \tag{3.8}$$

at $r=2$ is given by

$$\psi'(2) = \int_{\mathbf{C}^n} d\mu_n(z) |f(z)|^2 \log|f(z)| \tag{3.9}$$

since this is just differentiation under the integral sign. Using this formal result and the rules of elementary calculus, we get

$$\left.\frac{d}{dt}\right|_{t=0^+}||f||_{p_t}=\frac{p'(0)S(f)}{4||f||_2} \tag{3.10}$$

where $S(f)$ is the entropy of f, given in Eq. (2.1), and $p'(0)=4(2^{-1}-p^{-1})$ is the derivative at $t=0$ of $p(t):=p_t$. We do not intend to make (3.10) rigorous if $||f||_2=0$. However, the inequality (3.1) which we wish to prove is trivially true if $f=0$. So, hereafter, we consider only the case $f\neq 0$.

The derivative of $||f||_{q_t}$ is more complicated because the measure used to compute this norm also depends on t. Using the definition

$$k_t(z):=c_a^{t/q}\exp\left(-\frac{ta}{q}|z|^2\right) \tag{3.11}$$

for $z\in\mathbf{C}^n$ and $0\leqslant t\leqslant 1$ we have more specifically that

$$||f||_{q_t}=||f||_{L^{q_t}(\nu_a^t)}=||fk_t||_{L^{q_t}(\mu_n)}=\left\{\int_{\mathbf{C}^n}d\mu_n(z)(k_t(z)|f(z)|)^{q_t}\right\}^{1/q_t}.$$

It follows that

$$\left.\frac{d}{dt}\right|_{t=0^+}||f||_{q_t}=\frac{q'(0)S(f)}{4||f||_2}+\frac{1}{||f||_2}\int_{\mathbf{C}^n}d\mu_n(z)\left.\frac{dk_t}{dt}\right|_{t=0^+}|f(z)|^2 \tag{3.12}$$

by the rules of calculus again, a differentiation under the integral sign, and the seemingly innocuous, but sometimes false, statement that an integral of a sum of functions is the sum of the integrals. Here $q'(0)=4(2^{-1}-q^{-1})$ is the derivative at $t=0$ of $q(t):=q_t$. (The notation $q'(0)$ introduced here, as well as $p'(0)$ used earlier, has nothing to do with the dual index.) Substituting in the derivative of k_t,

$$\left.\frac{d}{dt}\right|_{t=0^+}k_t(z)=\left.\frac{d}{dt}\right|_{t=0^+}k_1(z)^t=\log k_1(z)=\frac{1}{q}\log c_a-\frac{1}{q}a|z|^2$$

which comes from Eq. (3.11), one gets

$$\left.\frac{d}{dt}\right|_{t=0^+}||f||_{q_t}=\frac{q'(0)S(f)}{4||f||_2}+\frac{n}{q}||f||_2\log(1+a)-\frac{a}{q||f||_2}\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2|z|^2 \tag{3.13}$$

since $c_a=(1+a)^n$. Now we can use the formula

$$\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2|z|^2=n||f||_2^2+\langle f,Nf\rangle \tag{3.14}$$

which comes from formula (3.17) of Bargmann's article,[14] and is proved there by using the Taylor series expansion of f. I will refer to (3.14) as Bargmann's identity. Here $\langle f,Nf\rangle$ is the Dirichlet form defined in Eq. (2.2). The formula (3.14) is valid for all f in the Segal-Bargmann space. In particular, one side of Eq. (3.14) is infinite if and only if the other side is infinite. One can think of (3.14) as a consequence of the canonical commutation relations. In this regard, see part (vii) of Theorem 13.7 in Ref. 15. Using Bargmann's identity (3.14) in Eq. (3.13), we get

$$\left.\frac{d}{dt}\right|_{t=0^+}||f||_{q_t}=\frac{q'(0)S(f)}{4||f||_2}+\frac{n}{q}||f||_2\log(1+a)-\frac{an}{q}||f||_2-\frac{a}{q||f||_2}\langle f,Nf\rangle. \tag{3.15}$$

Substituting the value $M=D^{n/q}$ and the Eqs. (3.6), (3.10) and (3.15) into inequality (3.7) and rearranging terms, some of which may possibly be infinite, we have

$$\left(\frac{q'(0)-p'(0)}{4}\right)S(f)\leqslant\frac{n}{q}(a-\log(a+1-p'q/4))||f||_2^2+\frac{a}{q}\langle f,Nf\rangle \tag{3.16}$$

for any $1<p\leqslant\infty$ and $1\leqslant q<\infty$ and $a>p'q/4-1$. Substituting the formulas for the derivatives $p'(0)$ and $q'(0)$ into (3.16) gives us precisely (3.1). Of course, we could have taken M to be $D^{n/p'}$ or simply equal to the optimal constant in the inequality (3.2). The value $M=D^{n/q}$ was used just to get a specific value for the coefficient of the norm term in (3.16). The proof of the assertion that the coefficient of the norm term is strictly positive is an exercise in elementary calculus. Using the value $M=D^{n/p'}$ gives a better bound if and only if $p^{-1}+q^{-1}>1$. But the resulting coefficient of the norm term is still strictly positive by another elementary exercise.

Before starting the second pass of the proof, here are some results which will be useful.

Lemma 3.2: For the left side derivative at $r=2$ of $\psi(r)$, as defined in Eq. (3.8), we have

$$\psi'(2^-):=\lim_{h<0,\,h\to 0}\frac{\psi(2+h)-\psi(2)}{h}=\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2\log|f(z)| \tag{3.17}$$

for all $f\in L^2(\mathbf{C}^n,\mu_n)$, where the equality includes the case where both sides are $+\infty$. For the right side derivative we have

$$\psi'(2^+):=\lim_{h>0,\,h\to 0}\frac{\psi(2+h)-\psi(2)}{h}=\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2\log|f(z)| \tag{3.18}$$

for all $f\in L^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$ where the equality is between finite real numbers.

The proof of this lemma is an exercise using convexity arguments and the monotone convergence theorem, and so will be left to the reader. Let us notice that this lemma implies that $S(f)$ is finite throughout the argument of the theorem. This is because we either have the hypothesis that $f\in L^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$ (in which case we have (3.18) which implies that $S(f)$ is finite) or we have $S(f)$ finite by explicit hypothesis. This justifies the interchange of integral and sum used to derive (3.12), since the first term on the right hand side of (3.12) is finite. Moreover, this implies that (3.10) is an equality between finite real numbers, provided that it is a valid equation, of course. But Lemma 3.2 also justifies (3.10). To show this we note that $||f||_{p_t}=[\psi(p_t)]^{1/p_t}$, where ψ is defined in (3.8) and that p_t approaches 2 monotonically as t decreases to zero by the definition (3.3) of p_t. If $1<p<2$, then p_t increases monotonically to 2 and we use (3.17). If $2<p\leqslant\infty$, then p_t decreases monotonically to 2, and we apply (3.18), which is applicable since we assume that f is in $HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$ when $2<p\leqslant\infty$. In either case we have (3.10) as a simple consequence. If $p=2$, then $p_t=2$ for all $0\leqslant t\leqslant 1$ implying $p'(0)=0$ so that (3.10) follows since each side is zero. This completes the justification of (3.10). Notice that the assumptions on f are what one expects from an examination of (3.2). Specifically, (3.2) is trivial for any f in the Segal-Bargmann space for which $||f||_{p_t}$ is infinite for all $0<t\leqslant 1$, and so one can not calculate a useful (i.e., finite) derivative in such a case. To have a finite derivative, it is necessary that $||f||_{p_t}<\infty$ for all $t\in(0,\delta]$ for some $0<\delta\leqslant 1$. If $1<p\leqslant 2$, then $||f||_{p_t}\leqslant||f||_2<\infty$ since $1<p_t\leqslant 2$. So we can take $\delta=1$ in this case and f arbitrary in the Segal-Bargmann space. If $2<p\leqslant\infty$, then we use the hypothesis that $f\in L^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$ which implies that $||f||_{p_t}\leqslant||f||_{2+\epsilon}<\infty$ whenever $2\leqslant p_t\leqslant 2+\epsilon$, which holds for all $t\in(0,\delta]$ for some $\delta>0$ sufficiently small. So the above argument based on Lemma 3.2 shows that this necessary condition on f for $||f||_{p_t}$ to have a finite derivative is also sufficient if $2<p\leqslant\infty$. If $1<p\leqslant 2$, we simply assume that the derivative is finite, or equivalently that $S(f)$ is finite. In the next lemma we find another consequence of the condition that f is in $HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$.

Lemma 3.3: The Dirichlet form $\langle f,Nf\rangle$ is finite if f is in $HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$.

To show this we note that

$$n\|f\|_2^2+\langle f,Nf\rangle=\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2|z|^2\leq\|f\|_{2s}^2\|z\|_{2s'}^2, \tag{3.19}$$

for any $1\leq s\leq\infty$, by an application of Bargmann's identity (3.14) and Hölder's inequality. Here by $\|z\|_{2s'}$ we mean the $L^{2s'}$ norm of the function that maps z in $\mathbf{C}^n$ to $|z|$. By taking $s=1+\epsilon/2$ where f is in $L^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$, we have $s>1$ and so $s'<\infty$. But $\|z\|_{2s'}$ is then finite and so is $\|f\|_{2s}=\|f\|_{2+\epsilon}$. So the right hand side of (3.19) is finite, implying that $\langle f,Nf\rangle$ is finite. The inequality (3.19) shows the importance of the analyticity of the elements of the Segal-Bargmann space; it says that if a function in the Segal-Bargmann space has a bit more integrability than just square integrability, then the function has finite energy. So (3.19) is a *reverse* Sobolev inequality. This result appears to be basically new, though the author has used it previously in Ref. 16. This concludes the proof of Lemma 3.3.

Another basic result relating the quantities that we use in this theorem is the following lemma.

Lemma 3.4: Finite energy $\langle f,Nf\rangle$ implies finite entropy $S(f)$ for all f in the Segal-Bargmann space.

This can be derived from the log-Sobolev inequality $S(f)\leq\langle f,Nf\rangle$ which follows from a hypercontractivity result for the semigroup $\{e^{-tN}\}_{t\geq 0}$ (see Refs. 4–8). (A general reference for log-Sobolev inequalities and hypercontractivity is the article[1] by Gross.) Also, this lemma can be derived directly from the log-Sobolev inequality proved in Ref. 1 for Euclidean space. One then only gets $S(f)\leq 2\langle f,Nf\rangle$, but this is still sufficient to prove this lemma. However, hypercontractivity will not be used to derive any of the results of this article. So here is an elementary proof of the lemma.

First, for any f in the Segal-Bargmann space, one has the well known point-wise estimate $|f(z)|\leq\|f\|_2\exp(|z|^2/2)$ for all $z\in\mathbf{C}^n$. This follows from the fundamental property of the reproducing kernel function and the Cauchy-Schwarz inequality (see Ref. 10). Using this and Bargmann's identity (3.14), we then have for any f in the Segal-Bargmann space that

$$S(f)=\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2\log\left(\frac{|f(z)|^2}{\|f\|_2^2}\right)\leq\int_{\mathbf{C}^n}d\mu_n(z)|f(z)|^2|z|^2=n\|f\|_2^2+\langle f,Nf\rangle \tag{3.20}$$

which shows that $\langle f,Nf\rangle<\infty$ implies that $S(f)<\infty$. Notice that the log-Sobolev inequality (3.20) is not as sharp as the log-Sobolev inequality given by the theory of hypercontractivity, but that it serves our purpose here. This ends the proof of Lemma 3.4.

We now start the second pass of the proof of the theorem. The formula (3.12) now has to be justified rigorously. We still must establish the interchange of integral and derivative

$$\left.\frac{d}{dt}\right|_{t=0^+}\int_{\mathbf{C}^n}d\mu_n(z)(k_t(z)|f(z)|)^{q_t}=\int_{\mathbf{C}^n}d\mu_n(z)\left(2|f(z)|^2\left.\frac{dk_t}{dt}\right|_{t=0^+}+q'(0)|f(z)|^2\log|f(z)|\right), \tag{3.21}$$

which is the only remaining step needed to justify (3.12). Inverting the defining relation given in Eq. (3.3) for q_t, we have that

$$t=\frac{q_t^{-1}-2^{-1}}{q^{-1}-2^{-1}}$$

provided that $q\neq 2$. (The case $q=2$ will be considered later.) Using this, and the relation $k_t(z)=(k_1(z))^t$, one can write the integrand on the left hand side of Eq. (3.21) as

$$(k_t(z)|f(z)|)^{q_t}=(k_1(z)^t|f(z)|)^{q_t}=(k_1(z)^{((q_t^{-1}-2^{-1})/(q^{-1}-2^{-1}))}|f(z)|)^{q_t}$$

which leads us to define the function

$$\eta(r) := \int_{\mathbf{C}^n} d\mu_n(z) (k_1(z)^{((r^{-1}-2^{-1})/(q^{-1}-2^{-1}))} |f(z)|)^r \tag{3.22}$$

for $r \in [1,\infty)$. Notice that $\eta(r) \in [0,\infty]$. So the left hand side of Eq. (3.21) is equal to

$$\left.\frac{d}{dt}\right|_{t=0^+} \eta(q(t)) = \eta'(2^{\pm}) q'(0), \tag{3.23}$$

where the right side (respectively, left side) derivative of $\eta(r)$ at $r=2$ is used if $q(t)$ is decreasing (respectively, increasing) to 2 as t decreases to 0. (Because of its definition in (3.3), the convergence of $q(t)$ to 2 is monotone as t decreases to 0.) Notice that the integrand of the expression (3.22) is a convex function of r, so that we may use standard measure theory arguments as before. However, the details are a bit more complicated and so will be presented in full. But before entering into the details of computing $\eta'(2^{\pm})$, notice that η itself depends on q, a and f. So the following argument will be by cases which depend on the hypotheses satisfied by q, a and f.

Also, notice that we will prove the two sides of (3.21) are equal without yet knowing that they are finite. On the right hand side there is no problem with the second term; it is integrable since $S(f)$ is finite. However, the first term, which includes an energy term when it is expanded out, may well be $+\infty$ or $-\infty$ as far as we know in this part of the argument. Similarly, the left hand side of (3.21), which is given again in (3.23), may be $+\infty$ or $-\infty$. Thus as far as we know $\eta'(2^{\pm})$ may be $+\infty$ or $-\infty$ as well. Only after completing this part of the argument will we be able to establish that in fact (3.21) is an equality between finite real numbers.

Before starting the cases, notice that since f is always in the Segal-Bargmann space, $\eta(2) = ||f||_2^2$ is finite. To compute the one-sided derivatives of $\eta(r)$ at $r=2$, we start with the difference quotient

$$\frac{\eta(2+h)-\eta(2)}{h} = \int_{\mathbf{C}^n} d\mu_n(z) k_1(z)^{\alpha} \left[\frac{(k_1(z)^{\beta}|f(z)|)^{2+h} - (k_1(z)^{\beta}|f(z)|)^2}{h} \right] \tag{3.24}$$

for $h \neq 0$, where $\alpha = 1/(q^{-1}-2^{-1})$ and $\beta = -2^{-1}/(q^{-1}-2^{-1})$. The pointwise limit of the integrand on the right hand side of (3.24), as $h \to 0$, is

$$\gamma(z) := |f(z)|^2 \log|f(z)| + \beta |f(z)|^2 \log k_1(z). \tag{3.25}$$

The goal is to prove that $\eta'(2^{\pm}) = \int_{\mathbf{C}^n} d\mu_n(z) \gamma(z)$, and then use (3.23) to show (3.21), since $q'(0)\gamma(z)$ is the integrand on the right hand side of (3.21). Since $k_1(z) > 0$, the convergence of the integrand of (3.24) to $\gamma(z)$ is monotone increasing as $h \nearrow 0$ (i.e., $h<0$, $h \to 0$), and it is monotone decreasing as $h \searrow 0$ (i.e., $h>0$, $h \to 0$). The difference quotient in (3.24) is a finite number if and only if the integrand on the right hand side of (3.24) is integrable if and only if $\eta(2+h)$ is a finite number. But by Hölder's inequality, we have

$$\begin{aligned} \eta(2+h) &= \int_{\mathbf{C}^n} d\mu_n(z) k_1(z)^{hq/(q-2)} |f(z)|^{2+h} \\ &\leq ||k_1^{hq/(q-2)}||_{s'} \, || \, |f|^{2+h} ||_s \\ &= (||k_1||_{hqs'/(q-2)})^{hq/(q-2)} (||f||_{(2+h)s})^{2+h} \end{aligned} \tag{3.26}$$

for any $1 \leq s \leq \infty$.

Now we are ready to argue by cases. The reader should be aware that these cases are not the same as the three cases in the statement of the theorem. First, let us consider the case of the left side derivative of $\eta(r)$ at $r=2$. Notice that this arises in the argument when we have $q_t \nearrow 2$, which itself occurs exactly when $q<2$. The idea is to use (3.26) to show $\eta(2+h)<\infty$ for some $-1 \leqslant h<0$ and apply the monotone convergence theorem, since the monotone increasing integrands in (3.24) will then be uniformly bounded below by an integrable function for all $h_0 \in [h,0)$. For each case, the condition imposed on a must be combined with the overall condition given in (3.5).

Case A: $q<2$, $a \geqslant 0$, $a>p'q/4-1$, $f \in HL^2(\mathbf{C}^n,\mu_n)$.

We take $s=1$. Then the first factor in (3.26) is finite since $a \geqslant 0$ while the second factor is finite for all $-1 \leqslant h<0$.

Case B: $q<2$, $a>p'q/4-1$, $f \in HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$.

Now we take $s>1$ and we use (3.26) for some h satisfying

$$2<(2+h)s \leqslant 2+\epsilon. \tag{3.27}$$

It follows that $\|f\|_{(2+h)s} \leqslant \|f\|_{2+\epsilon}$ and this makes the second factor on right hand side of (3.26) finite. Therefore the right hand side of (3.26) will be finite if and only if $\|k_1\|_{hqs'/(q-2)}$ is finite. So it remains to show that

$$\int_{\mathbf{C}^n} d\mu_n(z) k_1(z)^{hqs'/(q-2)}<\infty \tag{3.28}$$

for some $h<0$ which also satisfies (3.27). But by the definition (3.11) of $k_1(z)$, this last integral is finite if and only if

$$1+hs'a/(q-2)>0 \tag{3.29}$$

which is equivalent to

$$a>(2-q)/hs' \tag{3.30}$$

since $h<0$ and $q-2<0$. The lower bound here, namely $(2-q)/hs'$, is negative and decreases to $-\infty$ as $h \nearrow 0$ for *any* fixed $s>1$. So for $|h|$ sufficiently small, this new lower bound on a is less restrictive than (3.5) for any fixed $s>1$. Moreover, if s is fixed so that $1<s \leqslant 1+\epsilon/2$ (say $s=1+\epsilon/2$), then the inequality (3.27) is also satisfied for all $h<0$ with $|h|$ sufficiently small.

Case C: $q<2$, $a>q/2-1$, $a>p'q/4-1$, $f \in HL^2(\mathbf{C}^n,\mu_n)$.

Notice that the condition (3.27) can be weakened to $(2+h)s=2$. This still makes the second factor on the right hand side of (3.26) finite. The difference here is that now s is not fixed as h approaches zero. However, the argument works for any $f \in HL^2(\mathbf{C}^n,\mu_n)$. Moreover, it turns out that since $s'=-2/h$ the condition on a to make the first factor finite is then

$$a>q/2-1$$

which is independent of h and is more restrictive than (3.5) if $p>2$. Under this new condition on a, we then have Eq. (3.31), which is now an equality between finite real numbers, or both sides are $+\infty$. Weakening (3.27) further to $1 \leqslant (2+h)s<2$ leads to nothing new since the smaller value of s implies a larger value of s', thereby making larger the first factor on the right hand side of (3.26).

So it follows under Case A, B or C that

$$\eta'(2^-)=\int_{\mathbf{C}^n} d\mu_n(z)\gamma(z) \tag{3.31}$$

which is *a priori* either an equality of real numbers, or both sides are $+\infty$. [Recall that $\gamma(z)$ is defined in (3.25).]

Next, let us consider the right side derivative of $\eta(r)$ at $r=2$. Notice that this case occurs in the argument when $q_t \searrow 2$, which happens precisely when $q>2$. Now we want $\eta(2+h)$ to be finite for some $h>0$ so that we can use the monotone convergence theorem for the monotone decreasing integrands in (3.24), which will then be uniformly bounded above by an integrable function for all $h_0 \in (0,h]$. Of course, we can not solve $(2+h)s=2$ for $s \geqslant 1$ and $h>0$, so we need a bit more integrebility of f to make the right hand side of (3.26) finite. Now we want to satisfy $(2+h)s \leqslant 2+\epsilon$ for some $h>0$ and $s \geqslant 1$, so that the second factor on the right hand side of (3.26) is finite.

Case D: $q>2$, $a \geqslant 0$, $a>p'q/4-1$, $f \in HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$.

We take $s=1$ so that the first factor on the right hand side of (3.26) is finite since $a \geqslant 0$, which may be more restrictive than (3.5).

Case E: $q>2$, $a>p'q/4-1$, $f \in HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$.

Now we choose $s>1$ so the first factor is finite on the right hand side of (3.26) if and only if (3.29) holds as before, and this is again equivalent to (3.30), except now because $h>0$ and $q-2>0$. Again, the lower bound $(2-q)/hs'$ in (3.30) is negative and decreases to $-\infty$ as $h \searrow 0$, and the resulting condition on a is weaker than (3.5) for all $h>0$ with h sufficiently small. Also, by fixing s with $1<s<1+\epsilon/2$, we can satisfy (3.27) for all $h>0$ with h sufficiently small.

So it follows for Cases D and E that

$$\eta'(2^+) = \int_{\mathbf{C}^n} d\mu(z)\,\gamma(z)$$

which is an equality between real numbers or both sides are $-\infty$.

The formula (3.21) must still be justified in the case $q=2$. But then $q_t=2$ for all $0 \leqslant t \leqslant 1$, and so the integrand of the left hand side of (3.21) is

$$(k_t(z)|f(z)|)^{q_t} = k_1(z)^{2t}|f(z)|^2.$$

So the difference quotient used to compute the derivative on the left hand side of (3.21) is

$$\int_{\mathbf{C}^n} d\mu_n(z)\left(\frac{k_1(z)^{2h}-1}{h}\right)|f(z)|^2 \tag{3.32}$$

for $h>0$. The pointwise limit of the integrand here as $h \searrow 0$ is

$$(2\log k_1(z))|f(z)|^2 = 2|f(z)|^2 \left.\frac{dk_t}{dt}\right|_{t=0^+}$$

and the convergence is monotone decreasing. This is the integrand on the right hand side of (3.21) since $q'(0)=0$ in this case. So to interchange the limit and the integral using the monotone convergence theorem, we need the integral in (3.32) to be finite for some $h>0$. This is equivalent to the integrability of $k_1(z)^{2h}|f(z)|^2$. However, by Hölder's inequality

$$\int_{\mathbf{C}^n} d\mu_n(z) k_1(z)^{2h}|f(z)|^2 \leqslant \|k_1^{2h}\|_{s'} \| \, |f|^2 \|_s = (\|k_1\|_{2hs'})^{2h}(\|f\|_{2s})^2 \tag{3.33}$$

for any $1 \leqslant s \leqslant \infty$.

Case F: $q=2$, $a \geqslant 0$, $a>p'q/4-1$, $f \in HL^2(\mathbf{C}^n,\mu_n)$.

Since $a \geqslant 0$, we take $s=1$ in (3.33) since k_1 is then bounded and f is in $L^2(\mathbf{C}^n,\mu_n)$.

Case G: $q=2$, $a>p'q/4-1$, $f \in HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$.

Now we take $s>1$ satisfying $2s \leqslant 2+\epsilon$. So $\|f\|_{2s} \leqslant \|f\|_{2+\epsilon} < \infty$. To show the other factor in (3.33) is finite is equivalent to showing

$$\int_{\mathbf{C}^n} d\mu_n(z) k_1(z)^{2hs'} < \infty$$

and this is equivalent to $a>-q/2hs'$. But for s fixed (and satisfying $1<s<1+\epsilon/2$), the limit of the lower bound $-q/2hs'$ as $h\searrow 0$ is $-\infty$. So for all $h>0$ sufficiently small, this new restriction on a is weaker than (3.5) and so we have $\|k_1\|_{2hs'}<\infty$ in this case, and it follows that (3.21) holds in the case $q=2$, provided a satisfies (3.5).

So it follows for Cases F and G that

$$\eta'(2^+)=\int_{\mathbf{C}^n} d\mu(z)\,\gamma(z)$$

which is an equality between real numbers or both sides are $-\infty$.

At this point of the argument, we have established (3.21) in the seven cases A through G described above, but with the possibility that the expression in (3.21) could be infinite. And (3.21) in turn implies (3.12), but again with the understanding that both sides of (3.12) could be $+\infty$ or $-\infty$.

Now we will show that $S(f)$ finite implies that $\langle f,Nf\rangle$ is finite for any f in the Segal-Bargmann space. We take any p and q satisfying $1<p\leqslant 2$, $1\leqslant q<2$, and $p'q<4$. (These conditions are consistent and imply $q^{-1}>p^{-1}$.) Now we can apply Case C above, which is valid for all f in the Segal-Bargmann space, provided that a satisfies the two conditions specified in that case. But $p'q/4-1\geqslant q/2-1$ since $p'\geqslant 2$ so that a must satisfy merely the one condition $a>p'q/4-1$. This means we can (and do) pick a with $a<0$, this being possible since $p'q<4$. Then the inequality (3.7) says

$$\frac{q'(0)S(f)}{4\|f\|_2}+\frac{1}{\|f\|_2}\int_{\mathbf{C}^n} d\mu_n(z)|f(z)|^2\log k_1(z)\leqslant(\log M)\|f\|_2+\frac{p'(0)S(f)}{4\|f\|_2} \tag{3.34}$$

using (3.10) and (3.12). Since we are assuming that $S(f)$ is finite this can be rewritten as

$$\int_{\mathbf{C}^n} d\mu_n(z)|f(z)|^2\log k_1(z)\leqslant(\log M)\|f\|_2^2+(q^{-1}-p^{-1})S(f) \tag{3.35}$$

using the formulas for the derivatives $p'(0)$ and $q'(0)$. Now,

$$\log k_1(z)=\frac{n}{q}\log(1+a)-\frac{a}{q}|z|^2$$

so that (3.35) becomes

$$\left(\frac{n}{q}\log(1+a)-\frac{na}{q}\right)\|f\|_2^2-\frac{a}{q}\langle f,Nf\rangle\leqslant(\log M)\|f\|_2^2+(q^{-1}-p^{-1})S(f)$$

by an application of Bargmann's identity (3.14), and this is true even if $\langle f,Nf\rangle$ is not assumed to be finite, that is, even if (3.12) happened to be an equality between infinite quantities. In the last inequality the coefficient of $\langle f,Nf\rangle$ is positive since $a<0$ while the coefficient of $S(f)$ is positive since $q^{-1}>p^{-1}$. So $S(f)$ finite does imply $\langle f,Nf\rangle$ finite for all f in the Segal-Bargmann space, as claimed.

The result of the last paragraph together with Lemma 3.4 establishes that the entropy $S(f)$ is finite if and only if the energy $\langle f,Nf\rangle$ is finite, this being the third assertion of the theorem.

We are now ready to prove the first assertion in the theorem. So we have by hypothesis that $f\in HL^{2+\epsilon}(\mathbf{C}^n,\mu_n)$ for some $\epsilon>0$ and $1<p\leqslant\infty$ and $1\leqslant q<\infty$ and $a>p'q/4-1$. The assumption on f implies that $\langle f,Nf\rangle$ is finite as proved in Lemma 3.3. And this in turn implies that $S(f)$ is finite. We now apply Case B, Case E or Case G depending on the value of q. This gives us (3.21) and hence (3.12). To arrive at (3.16) from (3.12) now comes from simple substitution and the rearrangement of terms, all of which are now known to be finite. This concludes the demonstration of the first assertion of the theorem.

We proceed to the second assertion in the theorem. Now the hypotheses are that f is in the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$, $S(f)$ is finite, $a>p'q/4-1$, $1<p\leqslant 2$ and $1\leqslant q\leqslant 2$. If $1\leqslant q<2$, we use Case C. If $q=2$, we use Case F, which requires that $a\geqslant 0$. But $1<p\leqslant 2$ and $q=2$ imply $p'q/4-1=p'/2-1\geqslant 0$. So the hypothesis $a>p'q/4-1$ implies $a\geqslant 0$ and so Case F does apply. This gives us (3.12). Since $S(f)$ is finite by hypothesis, we have that $\langle f,Nf\rangle$ is finite by the above argument. So we can rearrange terms to arrive at (3.16).

Finally, the three cases in the statement of the theorem follow immediately from an elementary analysis of the coefficients of the energy and entropy terms. And this concludes the proof of the theorem. □

Cases A and D of the proof of this theorem were never used subsequently in that argument. They are included only for the sake of giving a complete analysis of all the possible cases. They do not imply the inequality (3.1) in any case not already established.

The inequality (3.1) has two limiting cases, one when the coefficient of the entropy term is zero and the other when the coefficient of the energy term is zero. The coefficient of the entropy being zero means that $p^{-1}=q^{-1}$ and (3.1) becomes trivial, as was already noted in Case 2 of the statement of the theorem. The coefficient of the energy being zero means $a=0$, and this implies that $p'q/4-1<a=0$ which in turn implies $p^{-1}<q^{-1}$. So again (3.1) becomes trivial since the left hand side is a non-positive quantity while the right hand side is non-negative. However, this leads one to ask if an inequality of the form $BS(f)\leqslant ||f||_2^2$ holds for all f in the Segal-Bargmann space with $B>0$. The negative answer to this question is provided by considering the holomorphic functions f_λ defined by

$$f_\lambda(z):=\exp\left(\frac{\sqrt{2}\lambda\cdot z}{2}-\frac{\lambda^2}{4}\right)$$

where $\lambda\in\mathbf{R}^n$ and $z\in\mathbf{C}^n$. These functions are in the Segal-Bargmann space. They also satisfy $||f_\lambda||_2=1$ and $S(f_\lambda)=|\lambda|^2/2$ by direct evaluation of the relevant Gaussian integrals. These functions also show that no inequality of the form $C||f||_2^2\leqslant S(f)$ with $C>0$ holds for all f in the Segal-Bargmann space. Essentially, this says that $S(f)$ and $||f||_2^2$ are inequivalent ways to gauge the size of f. This is to be expected; $S(f)$ measures the concentration of a state (that is, f satisfying $||f||_2=1$), and this concentration should be independent of the normalization of f. The analogous result in $L^2(\mathbf{C}^n,\mu_n)$ can be shown with characteristic functions, and so holds in quite great generality. The above example shows that the result still holds in the rather ''small'' subspace $HL^2(\mathbf{C}^n,\mu_n)$. The exponential functions f_λ also saturate the log-Sobolev inequality $S(f)\leqslant\langle f,Nf\rangle$ in the Segal-Bargmann space, and I conjecture that modulo a multiplicative constant these are the only functions to do so.

IV. BEST CONSTANTS

While the best constants for the reverse log-Sobolev inequality are not yet known, some partial results are given in this section. These have the effect of showing what the best constants *cannot* be, as well as what are the best constants given by the method of this article. First, we define

$$g_\lambda(z):=(1-\lambda^2)^{n/4}\exp(\lambda z^2/2) \tag{4.1}$$

for $-1<\lambda<1$ and $z\in\mathbf{C}^n$. Then g_λ is holomorphic with $||g_\lambda||_2=1$. So g_λ is in the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$. Moreover, we can calculate

$$\langle g_\lambda,Ng_\lambda\rangle=\frac{n\lambda^2}{1-\lambda^2}$$

and

$$S(g_\lambda)=\frac{n}{2}\log(1-\lambda^2)+\frac{n\lambda^2}{1-\lambda^2}.$$

But we can also write this in the form

$$\langle g_\lambda, Ng_\lambda\rangle = S(g_\lambda)-\frac{n}{2}(\log(1-\lambda^2))||g_\lambda||_2^2. \tag{4.2}$$

However, $-\log(1-\lambda^2)\to+\infty$ as $|\lambda|$ increases to 1 so that there is no reverse log-Sobolev inequality of the form

$$\langle f,Nf\rangle \leqslant cS(f)+n\beta||f||_2^2 \tag{4.3}$$

with $c\leqslant 1$. Also, let us note in passing that the functions g_λ show that the relation $S(f)=\langle f,Nf\rangle$ does not hold for all f in the Segal-Bargmann space.

Moreover, the reverse log-Sobolev inequality proved here can be brought into the form of (4.3) for any $c>1$ as the following argument shows. In this discussion we assume that $p'q<4$ and $0>a>p'q/4-1$, which is precisely the case of the reverse log-Sobolev inequality for (3.1). However, instead of analyzing (3.1), this analysis will start from

$$(p^{-1}-q^{-1})S(f)\leqslant \frac{a}{q}\langle f,Nf\rangle + n\left(\frac{a}{q}+\left(\frac{1}{p'}-\frac{1}{q}\right)\log(a+1)-\frac{1}{p'}\log(a+1-p'q/4)\right)||f||_2^2$$

which follows from (3.7) by using the value $M=D^{n/p'}$ instead of $M=D^{n/q}$ which was used to derive (3.1). This amounts to nothing more than a change in the coefficient of the norm term, but this will give a better constant than (3.1). First, write this in the form

$$\langle f,Nf\rangle \leqslant \left(\frac{q}{a}\right)(p^{-1}-q^{-1})S(f)+n\left(-1+\frac{q}{a}\left(\frac{1}{q}-\frac{1}{p'}\right)\log(a+1)+\frac{q}{ap'}\log(a+1-p'q/4)\right)||f||_2^2$$

by rearranging terms and multiplying by $-q/a$, which is positive. For fixed p and q, the coefficient of $S(f)$ is bounded below by

$$\inf_{0>a>p'q/4-1}\left(\frac{q}{a}\right)(p^{-1}-q^{-1})=\frac{4p^2-4p-4pq+4q}{4p^2-4p-p^2q} \tag{4.4}$$

though the infimum is not achieved as a runs over its allowed interval. Next, it is easy to show that the right hand side of (4.4) being $\geqslant 1$ is equivalent to $(p-2)^2\geqslant 0$, with the right hand side being equal to 1 if and only if $p=2$. So the coefficient of $S(f)$ is bounded below by 1, and it can be made to approach 1 precisely in the case $p=2$. So we now take $p=2$ and keep q fixed so that the standing assumptions become $q<2$ and $0>a>q/2-1$. We then get

$$\langle f,Nf\rangle \leqslant a^{-1}(q/2-1)S(f)+n\left(-1+\left(\frac{2-q}{2a}\right)\log(a+1)+\frac{q}{2a}\log(a+1-q/2)\right)||f||_2^2,$$

where the coefficient $a^{-1}(q/2-1)$ is greater than 1 and approaches 1 as a decreases to $q/2-1$ and approaches $+\infty$ as a increases to 0. This means that we can realize (4.3) for any $c>1$ as claimed. In fact, in (4.3) we can take

$$\beta=-1+\left(\frac{2-q}{2a}\right)\log(a+1)+\frac{q}{2a}\log(a+1-q/2).$$

Notice that then $\beta \to +\infty$ as a decreases to $q/2-1$. Now one would like to know the dependence of the coefficient $n\beta$ of the norm term as a function of the coefficient $c := a^{-1}(q/2-1)$ of the entropy term. Substituting $a = c^{-1}(q/2-1)$ we find that

$$\beta(q) = -1 - c \log(q/2 - 1 + c) + c \log c - \left(\frac{cq}{2-q}\right) \log\left(\frac{(2-q)(c-1)}{2c}\right)$$

for $c>1$ and $1 \leqslant q < 2$. By calculus, one verifies that $\beta(q)$ is a strictly increasing function for each fixed $c>1$ and for $1 \leqslant q < 2$. [Hint: Show $\beta''(q)>0$ and $\beta'(1)>0$. This implies that $\beta'(q)>0$ for $q \geqslant 1$.] So $q=1$ minimizes $\beta(q)$ and the minimum value is

$$\beta(1) = -1 + c \log\left(\frac{4c^2}{(2c-1)(c-1)}\right).$$

The appearance of the non-zero norm term in (4.3) is a bit troublesome. For example, the optimal form of the regular log-Sobolev inequality in the Segal-Bargmann space does not have such a term. Anyway, the best form obtainable by the method of this article is

$$\langle f, Nf \rangle \leqslant cS(f) + n\left(-1 + c \log\left(\frac{4c^2}{(2c-1)(c-1)}\right)\right) ||f||_2^2$$

for any $c>1$.

There is no point in optimizing (3.1) in the case that it is a log-Sobolev inequality, since the coefficient of the norm term in (3.1) is positive, while the optimal log-Sobolev inequality in the Segal-Bargmann space is $S(f) \leqslant \langle f, Nf \rangle$.

V. REVERSE HYPERCONTRACTIVITY

In Ref. 4, Carlen proves the hypercontractivity for the semigroup $\{e^{-tN}\}$ from $HL^p(\mathbf{C}^n, \mu_n)$ to $HL^q(\mathbf{C}^n, \mu_n)$ for $0<p<q$ and $t \geqslant 0$ provided that $t \geqslant \frac{1}{2}\log(q/p)$. Here one defines $e^{-tN}f(z) := f(e^{-t}z)$ for z in $\mathbf{C}^n$ and f in $HL^p(\mathbf{C}^n, \mu_n)$ using the motivation that this formula for the semigroup can be proved in the case $p=2$ where one uses spectral theory to define the semigroup. As remarked earlier, similar results are to be found in Refs. 5–8. However, Carlen also proves a result for e^{-tN} when t is negative, using the same defining formula for e^{-tN}. He shows that if $0<q<p$ and $t>\frac{1}{2}\log(q/p)$, then e^{-tN} is bounded from $HL^p(\mathbf{C}^n, \mu_n)$ to $HL^q(\mathbf{C}^n, \mu_n)$ with norm bounded above by $(1-e^{-2t}q/p)^{-n/q}$. This result is trivially true if $t \geqslant 0$, since it is easy to show that e^{-tN} has norm 1 in that case. But for $\frac{1}{2}\log(q/p)<t<0$, this is a new and interesting result. The question which we will address here is the relation of this reverse hypercontractivity result due to Carlen to the reverse log-Sobolev inequality of this article. Before proceeding, let us note that Carlen's results include Lebesgue indices between 0 and 1, but in this article we only have used Lebesgue indices between 1 and $+\infty$ due to the limitations of interpolation theory. The following discussion will be limited to the latter case.

Define $C(t,q,p,n)$ to be the supremum of $||e^{-tN}f||_q$ where $f:\mathbf{C}^n \to \mathbf{C}$ is holomorphic and $||f||_p = 1$. Then $C(t,q,p,n)$ could be infinite, though when it is finite it is just the above operator norm. Using this notation Carlen's result says that for $1<q \leqslant p$

$$||e^{-tN}f||_q \leqslant C(t,q,p,n) ||f||_p, \tag{5.1}$$

where $C(t,q,p,n)$ is finite, $t>\frac{1}{2}\log(q/p)$ and f is in $HL^p(\mathbf{C}^n, \mu_n)$. We use $C(t,q,p,n)$ here and not the estimate which Carlen derives, since his bound is not optimal. It remains an open problem to find a formula for $C(t,q,p,n)$ when $q<p$. Suppose that $p>1$ and $\epsilon>0$ are fixed. Suppose that s is a function mapping $(-\epsilon, 0]$ to $(1, +\infty)$. Suppose that s satisfies these conditions:

$$\text{(a)} \quad s(t) < pe^{2t} \quad \text{for} \quad -\epsilon < t < 0;$$

$$\text{(b)} \quad s(0)=p; \tag{5.2}$$

$$\text{(c)} \quad s'(0^-) \text{ exists.}$$

Here $s'(0^-)$ denotes the left side derivative of $s(t)$ at $t=0$. Then by condition (a) we can apply (5.1) to get

$$\|e^{-tN}f\|_{s(t)} \leqslant C(t,s(t),p,n)\|f\|_p \tag{5.3}$$

for all $t\in(-\epsilon,0)$. Moreover, (5.3) is valid also for $t=0$. In fact, it reduces to an equality for $t=0$, since $C(0,s(0),p,n)=1$ by condition (b). Notice that it is in this step that one uses the optimality of the constant $C(t,q,p,n)$. If we use Carlen's bound $M(t,q,p,n):=(1-e^{-2t}q/p)^{-n/q}$ instead, we find that $M(t,s(t),p,n)$ is undefined at $t=0$. Since the inequality (5.3) becomes an equality at the right end-point of its interval of validity (namely at $t=0$), the operation of taking the one-sided derivative at that end-point reverses the sense of the inequality, giving

$$\left.\frac{d}{dt}\right|_{t=0^-}\|e^{-tN}f\|_{s(t)} \geqslant \left.\frac{d}{dt}\right|_{t=0^-} C(t,s(t),p,n)\|f\|_p .$$

Proceeding here formally, we have

$$\left.\frac{d}{dt}\right|_{t=0^-}\|e^{-tN}f\|_{s(t)}=(p^{-2}s'(0^-)S_p(f)-\mathrm{Re}\langle f_p,Nf\rangle)\|f\|_p^{p-1},$$

where $f_p:=f|f|^{p-2}=\mathrm{sgn}(f)|f|^{p-1}$ and $S_p(f):=S(|f|^{p/2})$. One can find sufficient conditions for this interchange of derivative and integral in Refs. 1 and 2. Since $C(t,s(t),p,n)\geqslant 1$ (because $e^{-tN}1=1$ where 1 is the constant function) and $C(0,s(0),p,n)=1$, we see that $\kappa:=(d/dt)|_{t=0^-}C(t,s(t),p,n)\leqslant 0$. Moreover by conditions (a) and (b) of (5.2), $s'(0^-)\geqslant 2p$, which is positive. So we have shown

$$p^{-2}s'(0^-)S_p(f)-\mathrm{Re}\langle f_p,Nf\rangle \geqslant \kappa\|f\|_p^p,$$

which rearranges to

$$\mathrm{Re}\langle f_p,Nf\rangle \leqslant p^{-2}s'(0^-)S_p(f)-\kappa\|f\|_p^p. \tag{5.4}$$

For $p=2$, (5.4) becomes the following reverse log-Sobolev inequality

$$\langle f,Nf\rangle \leqslant \tfrac{1}{4}s'(0^-)S(f)-\kappa\|f\|_2^2, \tag{5.5}$$

which motivates calling (5.4) an index p reverse log-Sobolev inequality.

It seems now to be just a matter of arguing a bit more carefully to show that Carlen's reverse hypercontractivity result implies the reverse log-Sobolev inequality. But unfortunately this is not the case. First, note that there is an apparent contradiction between (5.5) and a result of Sec. IV. This is because the above formal argument should work for *any* function $s(t)$ satisfying the three conditions in (5.2). Let us consider the case $p=2$. We can take $s(t)$ so that it has first order contact at $t=0$ with the function $\phi(t):=2e^{2t}$ that majorizes $s(t)$. That is, we can pick $s(t)$ such that $s'(0^-)=\phi'(0^-)=4$. But then the coefficient of $S(f)$ in (5.5) is 1, and this seems to contradict what we have already shown in Sec. IV. This would indeed be a contradiction if the norm term in (5.5) were finite. So, we can conclude that the coefficient of the norm term is not finite or, equivalently, that $C(t,s(t),2,n)$ is not differentable from the left at $t=0$. This lack of smoothness must be inherited from a lack of smoothness in the operator norm $C(t,q,2,n)$ since $s(t)$ is by construction differentiable from the left at $t=0$. This means that at least one of the partial derivatives $\partial C/\partial t$ or $\partial C/\partial q$ does not exist when evaluated at the appropriate point. And this lack of smoothness in the operator norm then aborts any attempt to make rigorous the argument leading to (5.5), even in the ''good'' case when $s'(0^-)>4$. One can actually see directly from spectral theory that $C(t,2,2,n)=1$ for $t\geqslant 0$ and $C(t,2,2,n)=+\infty$ for $t<0$. And this shows that $(\partial C/\partial t)\times(t,2,2,n)$ evaluated at $t=0^-$ does not exist.

The above argument also can not be made rigorous for $p>2$. Using the functions g_λ from (4.1) we have in general for real λ satisfying $|\lambda|<\min(2/p,1)$

$$||g_\lambda||_p=(1-\lambda^2)^{n/4}(1-p^2\lambda^2/4)^{-n/2p},$$

$$\mathrm{Re}\langle (g_\lambda)_p, Ng_\lambda\rangle = np\lambda^2 2^{n+1}(1-\lambda^2)^{np/4}(4-p^2\lambda^2)^{-1-n/2},$$

$$S_p(g_\lambda)=np^2\lambda^2 2^n(1-\lambda^2)^{np/4}(4-p^2\lambda^2)^{-1-n/2} + (n/2)(1-\lambda^2)^{np/4}(1-p^2\lambda^2/4)^{-n/2}\log(1-p^2\lambda^2/4),$$

so that

$$\mathrm{Re}\langle (g_\lambda)_p, Ng_\lambda\rangle=(2/p)S_p(f)-(n/p)(\log(1-p^2\lambda^2/4))||g_\lambda||_p^p.$$

But $-(n/p)\log(1-p^2\lambda^2/4)\to+\infty$ as $|\lambda|$ increases to $2/p$, which is less than 1 for $p>2$. This shows that an index p reverse log-Sobolev inequality of the form

$$\mathrm{Re}\langle f, Nf\rangle \leqslant c_p S_p(f)+n\beta_p||f||_p^p \tag{5.6}$$

cannot hold for $c_p\leqslant 2/p$. But by picking $s(t)$ so that it has first order contact with $\psi(t):=pe^{2t}$ at $t=0$, one sees that the coefficient of the entropy term in (5.4) can be made equal to $2/p$. And so we observe the same sort of near contradiction as in the case $p=2$, and consequently the derivation of (5.4) fails.

However, it may be possible to make this argument rigorous in the case $p<2$. The above construction does not invalidate (5.4) in this case, since $|\lambda|$ can only increase to $1<2/p$. So it seems reasonable to conjecture that (5.4) holds for $p<2$ and that the above argument will establish this provided one can show that $C(t,q,p,n)$ is differentiable in this case. If this is so, it might be possible then to prove the index 2 reverse log-Sobolev inequality by taking the limit as p increases to 2 of the index p reverse log-Sobolev inequality.

The results of this section are a bit disappointing, since what at first looked like a straightforward way of relating reverse hypercontractivity to the reverse log-Sobolev inequality has not given us a positive result. Unfortunately, the usual method of smoothing out estimates by using interpolation theory is not available here in spaces of holomorphic functions. So, it still remains an open question whether an index p reverse log-Sobolev inequality (5.6) holds in the Segal-Bargmann space when $p\neq 2$.

VI. APPLICATIONS

The result of this article can be used to derive in a new way some results in Ref. 16. This makes the nature of those results more transparent. Let us recall in this paragraph some basic results from Refs. 10–12 expressed in the formulation of Ref. 16. One defines the configuration space (in the ground state representation) to be $L^2(\mathbf{R}^n,\nu_n)$ where ν_n is the Gaussian probability measure given by

$$d\nu_n(x):=\pi^{-n/2}\exp(-x^2)d^n x$$

for $x\in\mathbf{R}^n$ where $d^n x$ is Lebesgue measure on $\mathbf{R}^n$. Then the Segal-Bargmann transform A is defined by

$$Af(z):=\int_{\mathbf{R}^n} d\nu_n(x) A(z,x) f(x)$$

for $z\in\mathbf{C}^n$ and $f:\mathbf{R}^n\rightarrow\mathbf{C}^n$ measurable, provided that the integral converges absolutely. The kernel function is defined by $A(z,x):=\exp(-z^2/2+\sqrt{2}z\cdot x)$ for $z\in\mathbf{C}^n$ and $x\in\mathbf{R}^n$. Then by Hölder's inequality $Af(z)$ is well-defined for every z in $\mathbf{C}^n$ and for every element f of $L^p(\mathbf{R}^n,\nu_n)$ if $1<p\leqslant\infty$. Moreover, A maps $L^2(\mathbf{R}^n,\nu_n)$ unitarily onto the Segal-Bargmann space $HL^2(\mathbf{C}^n,\mu_n)$, and it furthermore intertwines the standard representations of the Heisenberg-Weyl group (exponentiated canonical commutation relations) on the spaces $L^2(\mathbf{R}^n,\nu_n)$ and $HL^2(\mathbf{C}^n,\mu_n)$. In particular, A preserves the energy, which can be expressed in terms of the Dirichlet forms as

$$\langle\psi,N_1\psi\rangle=\langle A\psi,NA\psi\rangle \tag{6.1}$$

for *all* $\psi\in L^2(\mathbf{R}^n,\nu_n)$ where

$$\langle\psi,N_1\psi\rangle:=\frac{1}{2}\sum_{j=1}^{n}\left|\left|\frac{\partial\psi}{\partial x_k}\right|\right|^2_{L^2(\nu_n)}$$

defines the Dirichlet form for *all* $\psi\in L^2(\mathbf{R}^n,\nu_n)$. (The factor of one-half in the previous definition corrects an error in Ref. 16.) Notice that one side of (6.1) is infinite if and only if the other side is infinite.

Entropy also enters in the analysis of the Segal-Bargmann space via the Segal-Bargmann transform, since that transform does not preserve entropy. One of the results from Ref. 16 which restricts how the Segal-Bargmann transform A can change entropy is a Hirschman type inequality (see Ref. 14) of the form

$$S(\psi)\leqslant c_1 S(A\psi)+c_2||\psi||_2^2 \tag{6.2}$$

with c_1 and c_2 being non-negative constants and ψ being in $L^2(\mathbf{R}^n,\nu_n)$. This inequality was derived by studying the L^p to L^q mapping properties of A for (p,q) close to $(2,2)$. Now it can be proved simply by noting

$$S(\psi)\leqslant 2\langle\psi,N_1\psi\rangle=2\langle A\psi,NA\psi\rangle\leqslant 2(a_1S(A\psi)+a_2||A\psi||_2^2)=2a_1S(A\psi)+2a_2||\psi||_2^2,$$

where the first step is the log-Sobolev inequality in $L^2(\mathbf{R}^n,\nu_n)$ originally proved in Ref. 1, the next step is just (6.1), the next step is the reverse log-Sobolev inequality in the Segal-Bargmann space and the last step is the unitarity of A. In this proof, one still uses mapping properties of A (preservation of norm and energy), but the energy-entropy properties pertain now to each space separately.

Another related fact about entropy in the Segal-Bargmann space is that there is no Hirschman type inequality of the form

$$S(A\psi)\leqslant b_1S(\psi)+b_2||\psi||_2^2 \tag{6.3}$$

for all $\psi\in L^2(\mathbf{R}^n,\nu_n)$ with b_1,b_2 non-negative constants. First, we can explicitly construct elements ψ in $L^2(\mathbf{R}^n,\nu_n)$ with finite entropy and infinite energy. I claim that any such ψ violates (6.3). This is because the right hand side of (6.3) is finite by construction. However, the left hand side of (6.3) must be infinite. Otherwise we would have $S(A\psi)<\infty$ implying $\langle A\psi,NA\psi\rangle<\infty$ by the reverse log-Sobolev inequality in the Segal-Bargmann space, and so $\langle\psi,N_1\psi\rangle<\infty$ because A preserves energy. But this contradicts the construction of ψ with infinite energy. So $S(A\psi)=\infty$ follows and (6.3) fails. Notice again the failure of (6.3) follows from energy-entropy properties of the individual spaces themselves plus the elementary properties that A preserves norm and energy. If one is inclined to think in categorical terms, one can formulate the result that (6.3) is false as saying that a certain commutative diagram cannot be constructed. This formulation is left to the interested reader. Also, using the functions f_λ introduced at the very end of Sec. III, one can show that none of the other possible non-trivial forms of a Hirschman type inequality in the Segal-Bargmann space can be valid.

VII. CONCLUSION

The result of this article shows a remarkable relation between entropy and energy in the Segal-Bargmann space. It seems reasonable to suppose that this comes about because the elements in the Segal-Bargmann space are holomorphic functions, rather than just merely square-integrable functions. For example, the proof here depends on the analysis of the reproducing kernel in Ref. 9, and the existence of a reproducing kernel is a hallmark of Hilbert spaces of holomorphic functions. It would be interesting therefore to investigate other Hilbert spaces of holomorphic functions to see if a natural reverse log-Sobolev inequality can be demonstrated even though a regular log-Sobolev inequality might not hold.

The presence of the norm term in the reverse log-Sobolev inequality proved here may not be optimal. It seems natural to conjecture that this term can be eliminated, and with it the only dependence on dimension in the coefficients of the inequality. This would then lead to an infinite dimensional version of the reverse log-Sobolev inequality. In any event, it would be interesting to know what is the exact relation of energy and entropy in the case of infinitely many dimensions.

Despite the results of Sec. V, there still might be another way of relating reverse hypercontractivity to the reverse log-Sobolev inequality. One might try to use the usual method of generating (regular) hypercontractivity inequalities from (regular) log-Sobolev inequalities. That method originated in Ref. 1 and has been modified in Ref. 5 for the holomorphic case. It is an open problem whether one can ''turn around'' the inequalities in that method to produce an argument for the reverse inequalities. As noted before, it remains an open problem if there is an index p reverse log-Sobolev inequality in the Segal-Bargmann space for $p \neq 2$. Another open problem from Sec. V is to determine the exact value of the operator norm $C(t,q,p,n)$ and hence whether it is differentiable at $t=0^-$ when $q<p$.

The failure of the Hirschman type inequality (6.3) is due to the fact that the Segal-Bargmann transform of a function with finite entropy can be a function with infinite entropy. It remains an open problem to identify the image of the finite entropy functions under the Segal-Bargmann transform.

Finally, the question of what are the best constants in the reverse log-Sobolev inequality remains an open problem. Let me just note that this question is independent of whether the norm term is really present or not.

ACKNOWLEDGMENTS

It is a great pleasure to thank Lawrence Thomas for initiating my interest in the Segal-Bargmann analysis. I thank Leonard Gross for bringing to my attention the reverse hypercontractivity result of Carlen and for various useful comments. I also thank Brian Hall for many stimulating discussions.

New approach to semiclassical analysis in mechanics

M. A. Alonso[a] and G. W. Forbes[b]
Department of Physics, Macquarie University, Sydney, New South Wales 2109, Australia

(Received 8 June 1998; accepted for publication 16 December 1998)

A new method is proposed for constructing approximate solutions to the Schrödinger equation. In place of the wave function, its Gaussian-windowed Fourier transform is used as the fundamental entity. This allows an intuitively attractive connection to be made with a family of classical trajectories and, at all times, the wave function is inferred from the present state of these trajectories. The fact that the connection between the wave function and the classical trajectories is consistently constructed in phase space allows this method to be free of the limitations of other methods. © *1999 American Institute of Physics.* [S0022-2488(99)02803-0]

I. INTRODUCTION

While classical mechanics models the motion of a particle in terms of a well-defined trajectory, quantum mechanics characterizes its evolution in a probabilistic fashion by means of a wave function $\Psi(\mathbf{x},t)$ that satisfies the Schrödinger equation:

$$i\hbar \frac{\partial\Psi}{\partial t}(\mathbf{x},t) = -\frac{\hbar^2}{2m}\nabla^2\Psi(\mathbf{x},t) + V(\mathbf{x},t)\Psi(\mathbf{x},t). \tag{1.1}$$

Here, m is the particle's mass, $V(\mathbf{x},t)$ is the potential, and $\hbar$ is Planck's constant. The spatial probability density for the location of the particle at time t is then $|\Psi(\mathbf{x},t)|^2$.

Except for some simple potentials, the determination of an exact solution of Eq. (1.1) given some initial condition, say $\Psi(\mathbf{x},t_0)$, is generally a formidable task. Schemes to construct approximate solutions are therefore important. The so-called *semiclassical* or *quasiclassical* methods offer one such option that is essentially expressed in terms of the classical description of the problem. These methods are direct analogs of ray optics, and allow intuition of the classical macroscopic world to be applied to quantum mechanics. An invaluable review of hundreds of key papers in this area was recently presented by Gutzwiller.[1]

In several of these methods, the wave function is associated with an n-parameter family of classical trajectories, where n is the number of spatial dimensions. Each of these trajectories carries an associated weight or amplitude. At any given time, the position and momentum of each trajectory identify a point in phase space, and the locus of all these points is known as the *Lagrange manifold*. For simplicity, the methods described in this work are presented for the one-dimensional case $(n=1)$. The Lagrange manifold or *phase space curve* is then composed of the points $(x,p)=[X(\xi,t),P(\xi,t)]$, where ξ is the parameter that labels the trajectories. Each trajectory, and hence the phase space curve itself, evolves in time according to the classical laws:

$$\frac{\partial X}{\partial t}(\xi,t) = \frac{P(\xi,t)}{m}, \tag{1.2a}$$

$$\frac{\partial P}{\partial t}(\xi,t) = -\frac{\partial V}{\partial x}[X(\xi,t),t]. \tag{1.2b}$$

[a]Electronic mail: alonso@physics.mq.edu.au
[b]Electronic mail: forbes@physics.mq.edu.au

There are several alternative prescriptions for estimating the wave function from the classical framework given by $[X(\xi,t),P(\xi,t)]$ once it is supplemented by the relative weight of each trajectory, say $D(\xi)$ (assumed for the moment to be independent of t). Some of the well-known methods are revisited in Sec. IX. The most direct of these estimates couples the spatial probability density to the spatial density of the trajectories, that is, $|\Psi[X(\xi,t),t]|^2 \propto D(\xi)/X'(\xi,t)$, where the prime denotes derivative with respect to ξ. This relation holds only while the phase space curve corresponds to a single-valued function of x [i.e., provided $X'(\xi,t)\neq 0$ for all ξ]. However, as X and P evolve according to Eqs. (1.2), this condition is eventually violated in most cases, and the estimate then diverges at the so-called *caustics* [where $X'(\xi,t)=0$].

Another possibility is first to estimate the *momentum distribution*, which is just the Fourier transform of $\Psi(x,t)$:

$$\tilde{\Psi}(p,t)=\frac{1}{\sqrt{2\pi\hbar}}\int \Psi(x,t)\exp\left(-i\frac{xp}{\hbar}\right)dx, \tag{1.3a}$$

$$\Psi(x,t)=\frac{1}{\sqrt{2\pi\hbar}}\int \tilde{\Psi}(p,t)\exp\left(i\frac{xp}{\hbar}\right)dp. \tag{1.3b}$$

Now, the probability density in momentum is coupled to the trajectory density in momentum, i.e., $|\tilde{\Psi}[P(\xi,t),t]|^2 \propto D(\xi)/P'(\xi,t)$. In this case, the phase space curve must be single valued in p, i.e., $P'(\xi,t)\neq 0$ for all ξ. Again, in most applications, this condition is ultimately violated.

These conditions on the form of the phase space curve are evidently tied to the representation that is used. Our aim is to state the connection between a wave function and an associated phase space curve in a way that is not inherently coupled to a particular representation. This is shown to lead to a more robust semiclassical method that is based upon the concept of representing the wave function as a phase space distribution by means of the *Gaussian-windowed Fourier transformation* (GWFT) defined in Sec. II. The evolution equation for this phase space distribution is derived in Sec. III. A form for the GWFT of a wave function is devised in Sec. IV so that the result is localized around a prescribed curve in phase space. The properties of this construction are studied in Sec. V and, in Sec. VI, it is shown that the result can readily be made to satisfy the evolution equation presented in Sec. III. The new estimate for the wave function is stated in Sec. VII, and some criteria for its use are given in Sec. VIII. Section IX gives a comparison with related methods. Finally, a summary of the new semiclassical method is given in Sec. X.

II. GAUSSIAN-WINDOWED FOURIER TRANSFORM

The GWFT of $\Psi(x,t)$ is defined here as

$$G(x,p;t)=\text{GWFT}\{\Psi(x,t)\}:=\frac{1}{\sqrt{2\pi\hbar}}l^{-1/4}\int \Psi(x',t)\exp\left[-\frac{(x'-x)^2}{2l\hbar}-\frac{ip}{\hbar}\left(x'-\frac{x}{2}\right)\right]dx', \tag{2.1a}$$

where ''$:=$'' means ''is defined to be equal to'' and l determines the width of the Gaussian window. The GWFT preserves its general form when expressed in terms of $\tilde{\Psi}(p,t)$, as can be seen upon substituting Eq. (1.3b) into (2.1a):

$$G(x,p;t)=\frac{1}{\sqrt{2\pi\hbar}}l^{1/4}\int \tilde{\Psi}(p',t)\exp\left[-\frac{l}{2\hbar}(p'-p)^2+\frac{ix}{\hbar}\left(p'-\frac{p}{2}\right)\right]dp'. \tag{2.1b}$$

The GWFT is linear in the wave function and, for the purposes to be considered here, this gives it several advantages over other phase space distributions. For example, it is straightforward to fully recover $\Psi(x,t)$ or $\tilde{\Psi}(p,t)$ from $G(x,p;t)$:

$$\Psi(x,t)=\frac{1}{\sqrt{2\pi\hbar}}l^{1/4}\int G(x,p;t)\exp\left(i\frac{px}{2\hbar}\right)dp, \tag{2.2a}$$

$$\tilde{\Psi}(p,t)=\frac{1}{\sqrt{2\pi\hbar}}l^{-1/4}\int G(x,p;t)\exp\left(-i\frac{px}{2\hbar}\right)dx. \tag{2.2b}$$

It is easily seen from either of Eqs. (2.1) that $G(x,p;t)$ satisfies

$$\left(l\frac{\partial}{\partial x}-i\frac{\partial}{\partial p}\right)G(x,p;t)=-\frac{1}{2\hbar}(x-ilp)G(x,p;t). \tag{2.3}$$

Notice that, given Eq. (2.3), the specification of G along a curve is sufficient in principle to infer its value over all of phase space. As a result, Ψ itself is fully determined once G is prescribed on a curve. While this option turns out to be unworkable, in general, Eq. (2.3) has implications in any work with the GWFT.

A useful insight into the structure of $|G|$ follows upon writing

$$G(x,p;t)=\exp[\gamma(x,p;t)+i\phi(x,p;t)], \tag{2.4}$$

where γ and ϕ are real functions. Two real-valued equations follow upon substituting Eq. (2.4) into Eq. (2.3):

$$\frac{\partial\gamma}{\partial x}+\frac{1}{l}\frac{\partial\phi}{\partial p}+\frac{x}{2\hbar l}=0, \tag{2.5a}$$

$$\frac{\partial\phi}{\partial x}-\frac{1}{l}\frac{\partial\gamma}{\partial p}-\frac{p}{2\hbar}=0. \tag{2.5b}$$

Equations (2.5) can now be decoupled by taking both the x and p derivatives of each of them, and then eliminating the cross-derivative terms to find

$$\left(\frac{\partial^2}{\partial x^2}+\frac{1}{l^2}\frac{\partial^2}{\partial p^2}\right)\gamma(x,p;t)=-\frac{1}{\hbar l}, \tag{2.6a}$$

$$\left(\frac{\partial^2}{\partial x^2}+\frac{1}{l^2}\frac{\partial^2}{\partial p^2}\right)\phi(x,p;t)=0. \tag{2.6b}$$

Notice that Eqs. (2.6) involve the Laplacian operator in the scaled phase space with coordinates (x,lp). From Eqs. (2.5) [especially through Eq. (2.6a)] it follows that if $|G|$ is localized along a curve—i.e., it has a ridge along which the first and second derivatives of γ are small—then the transverse profile of the ridge in this scaled phase space is approximately a Gaussian of width $\sqrt{\hbar l}$.

III. TIME EVOLUTION EQUATION FOR THE GWFT

The time evolution equation for G can be found by taking the GWFT of both sides of Eq. (1.1). From the p derivative of Eq. (2.1a), it is easy to show that

$$\mathrm{GWFT}\{x\Psi(x,t)\}=\hat{X}G(x,p;t):=\left(\frac{x}{2}+i\hbar\frac{\partial}{\partial p}\right)G(x,p;t), \tag{3.1}$$

where $\hat{X}$ is then the position operator for G and, more generally,

$$\mathrm{GWFT}\{x^n\Psi(x,t)\}=\hat{X}^n G(x,p;t). \tag{3.2}$$

By using integration by parts, it can be seen that

$$\mathrm{GWFT}\left\{\frac{\partial\Psi}{\partial x}(x,t)\right\}=\frac{-1}{\sqrt{2\pi\hbar}}l^{-1/4}\int \Psi(x',t)\frac{\partial}{\partial x'}\exp\left[-\frac{(x'-x)^2}{2l\hbar}-\frac{ip}{\hbar}\left(x'-\frac{x}{2}\right)\right]dx'$$
$$=\left(-\frac{x}{2l\hbar}+\frac{ip}{\hbar}+\frac{i}{l}\frac{\partial}{\partial p}\right)G(x,p;t), \tag{3.3}$$

where Eq. (3.1) has been used in the last step. This result can be written in a more suggestive form by using Eq. (2.3) to eliminate the p derivative and multiplying both sides by $-i\hbar$:

$$\mathrm{GWFT}\left\{-i\hbar\frac{\partial\Psi}{\partial x}(x,t)\right\}=\hat{P}G(x,p;t):=\left(\frac{p}{2}-i\hbar\frac{\partial}{\partial x}\right)G(x,p;t), \tag{3.4}$$

and, therefore,

$$\mathrm{GWFT}\left\{\left(-i\hbar\frac{\partial}{\partial x}\right)^n\Psi(x,t)\right\}=\hat{P}^nG(x,p;t). \tag{3.5}$$

By using Eqs. (3.2) and (3.5), the result of taking the GWFT of both sides of Eq. (1.1) can be written as

$$i\hbar\frac{\partial G}{\partial t}(x,p;t)=\frac{1}{2m}\hat{P}^2G(x,p;t)+V(\hat{X},t)G(x,p;t), \tag{3.6}$$

where V has been assumed to be analytic. This form of the Schrödinger equation turns out to be ideally suited for semiclassical analysis, and enables a robust connection to the classical domain.

IV. CONSTRUCTING *G* BY USING A PHASE SPACE CURVE

As mentioned in the Introduction, several semiclassical methods have been derived for cases where $\Psi(x,t)$ can be associated with a one-parameter family of classical trajectories, which, at any given time, is represented by a curve in phase space. However, this association is straightforward only when the curve corresponds to a single-valued function of x or p. This is a significant limitation, and the objective of this section is to give a form for a wave function that can be associated with a more general family of classical trajectories.

To begin, consider the GWFT of a Gaussian that has width $\sqrt{\hbar\Lambda}$ and a linear phase proportional to P:

$$\mathrm{GWFT}\left\{\exp\left[-\frac{(x-X)^2}{2\hbar\Lambda}+i\frac{P}{\hbar}\left(x-\frac{X}{2}\right)\right]\right\}=\frac{l^{1/4}\sqrt{\Lambda}}{\sqrt{l+\Lambda}}\exp\left[-\frac{(x-X)^2}{2\hbar(l+\Lambda)}-\frac{l\Lambda(p-P)^2}{2\hbar(l+\Lambda)}\right.$$
$$\left.+i\frac{2(\Lambda xP-lXp)+(l-\Lambda)(xp+XP)}{2\hbar(l+\Lambda)}\right]$$
$$=\frac{l^{1/4}\sqrt{\Lambda}}{\sqrt{l+\Lambda}}\exp\left[-\frac{z_{-l}(z_\Lambda-Z_\Lambda)-Z_\Lambda(z_{-l}-Z_{-l})}{2\hbar(l+\Lambda)}\right], \tag{4.1}$$

where the expression was simplified in the last step by using

$$z_\eta:=x+i\eta p, \tag{4.2a}$$

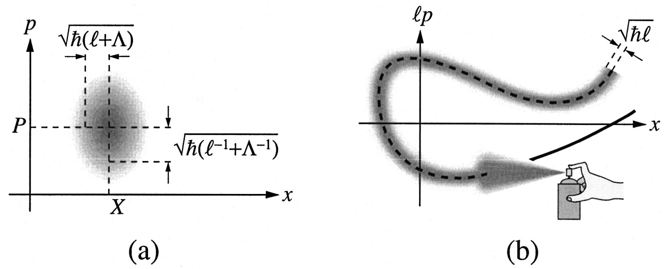

FIG. 1. (a) Dimensions in phase space of the Gaussian given in Eq. (4.1). (b) Construction of a wave function based on painting its GWFT over a curve in phase space. The grey level in both (a) and (b) represents $|G(x,p)|$. This process uses the Gaussian shown in (a) as the footprint of the notional spray can. Notice that the resulting ridge in $|G|$ has a transverse width that is essentially independent of the dimensions of the footprint.

$$Z_\eta := X + i\eta P, \tag{4.2b}$$

for η either $-l$ or Λ. The phase space distribution given in Eq. (4.1) is a Gaussian localized around (X,P), as shown in Fig. 1(a).

A form of G that is localized around a curve in phase space described by $[X(\xi),P(\xi)]$ can be built by superimposing a weighted sequence of Gaussians of the form given in Eq. (4.1):

$$G_\Lambda(x,p) = \frac{1}{\sqrt{2\pi\hbar}} \int w_\Lambda(\xi) g_\Lambda(x,p;\xi)\, d\xi, \tag{4.3}$$

where $w_\Lambda(\xi)$ is a weighting factor, and

$$g_\Lambda(x,p;\xi) = \frac{l^{1/4}\sqrt{\Lambda}}{\sqrt{l+\Lambda}} \exp\left\{ i\frac{\varphi(\xi)}{\hbar} - \frac{z_{-l}[z_\Lambda - Z_\Lambda(\xi)] - Z_\Lambda(\xi)[z_{-l} - Z_{-l}(\xi)]}{2\hbar(l+\Lambda)} \right\}. \tag{4.4}$$

The extra phase $\varphi(\xi)/\hbar$ in Eq. (4.4) could have been incorporated into $w_\Lambda(\xi)$, but it is included separately here for convenience.

The properties of $G_\Lambda(x,p)$ can be discussed more easily in terms of the picture presented in Fig. 1(b). With this, Eq. (4.3) associates a wave function to a curve in phase space by painting the GWFT of the wave function using something analogous to a spray can that is traced over the curve. The footprint of the spray can corresponds to $g_\Lambda(x,p;\xi)$. Increasing Λ gives a footprint that is wider in x and narrower in p. One might then think that the form of $G_\Lambda(x,p)$ would depend strongly on Λ. However, it is possible to choose $w_\Lambda(\xi)$ to ensure that G_Λ is insensitive to variations in Λ. This can be realized asymptotically when certain quantities turn out to be much larger than $\hbar$. The signature of the footprint then becomes effectively irrelevant in the continuous superposition. The weak dependence of G_Λ on Λ is of central importance, since it means that the corresponding wavefunction depends on just the essential elements of the classical framework, namely the phase space curve and its weighting factor, $w_\Lambda(\xi)$.

In the construction proposed in Eq. (4.3), $|G_\Lambda|$ is expected to take its largest values near the phase space curve. [Remember that g_Λ is largest at $z_{-l} = Z_{-l}$.] It is therefore required that this superposition of Gaussians is constructive in the neighborhood of the curve. From Eq. (4.4), the ξ derivative of g_Λ is seen to be given by

$$\begin{aligned}\frac{\partial g_\Lambda}{\partial \xi} &= \left[\frac{(z_{-l} - Z_{-l})}{\hbar(l+\Lambda)} \frac{\partial Z_\Lambda}{\partial \xi} + \frac{1}{2\hbar(l+\Lambda)} \left(\frac{\partial Z_\Lambda}{\partial \xi} Z_{-l} - Z_\Lambda \frac{\partial Z_{-l}}{\partial \xi} \right) + \frac{i}{\hbar} \frac{\partial \varphi}{\partial \xi} \right] g_\Lambda \\ &= \left[\frac{(z_{-l} - Z_{-l})}{\hbar(l+\Lambda)} \frac{\partial Z_\Lambda}{\partial \xi} + \frac{i}{\hbar} \left(\frac{\partial \varphi}{\partial \xi} - \frac{P}{2}\frac{\partial X}{\partial \xi} + \frac{X}{2}\frac{\partial P}{\partial \xi} \right) \right] g_\Lambda .\end{aligned} \tag{4.5}$$

Under the assumption that $w_\Lambda(\xi)$ does not vary significantly over the spread of g_Λ, constructive interference occurs along the curve if $\partial g_\Lambda/\partial\xi=0$ at $z_{-l}=Z_{-l}$. It then follows from Eq. (4.5) that $\varphi(\xi)$ must satisfy

$$\frac{\partial\varphi}{\partial\xi}(\xi)=\frac{1}{2}\left[P(\xi)\frac{\partial X}{\partial\xi}(\xi)-X(\xi)\frac{\partial P}{\partial\xi}(\xi)\right], \tag{4.6}$$

and Eq. (4.5) then reduces to

$$\frac{\partial g_\Lambda}{\partial\xi}=\frac{Z'_\Lambda\Delta}{\hbar}g_\Lambda, \tag{4.7}$$

where $\Delta:=(z_{-l}-Z_{-l})/(l+\Lambda)$, and the prime denotes a derivative with respect to ξ. Notice that the right-hand side of Eq. (4.6) is independent of Λ. Therefore, φ could depend on Λ only through an additive term that is independent of ξ. This term is now taken to be absorbed by w_Λ, so that φ is then independent of Λ.

It follows from Eqs. (4.3) and (4.4) that

$$\frac{\partial G_\Lambda}{\partial\Lambda}(x,p)=\frac{1}{\sqrt{2\pi\hbar}}\int\left\{\frac{\partial w_\Lambda}{\partial\Lambda}+w_\Lambda\left[\frac{l}{2\Lambda(l+\Lambda)}+\frac{\Delta^2}{2\hbar}\right]\right\}g_\Lambda(x,p;\xi)d\xi. \tag{4.8}$$

Notice that the second term inside the brackets on the right-hand side of Eq. (4.8) depends not only on ξ but also on x and p, due to the factor of Δ^2. This dependence can be eliminated by repeatedly using Eq. (4.7) and integrating by parts:

$$\frac{\partial G_\Lambda}{\partial\Lambda}=\frac{1}{\sqrt{2\pi\hbar}}\left\{\int\left[\frac{\partial w_\Lambda}{\partial\Lambda}+\frac{lw_\Lambda}{2\Lambda(l+\Lambda)}\right]g_\Lambda\,d\xi-\int\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda\Delta}{2Z'_\Lambda}\right)g_\Lambda\,d\xi\right\}$$

$$=\frac{1}{\sqrt{2\pi\hbar}}\int\left\{\frac{\partial w_\Lambda}{\partial\Lambda}+\frac{w_\Lambda}{2\Lambda}\frac{X'}{Z'_\Lambda}+\frac{\hbar}{2}\frac{\partial}{\partial\xi}\left[\frac{1}{Z'_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)\right]\right\}g_\Lambda\,d\xi. \tag{4.9}$$

The only dependence on x and p in the final integrand of Eq. (4.9) is now within $g_\Lambda(x,p;\xi)$, so like Eq. (4.3), Eq. (4.9) is simply a superposition of Gaussians in phase space. More importantly, integration by parts has now clarified the asymptotic significance of each of the terms; this device is also used repeatedly below. Given the factor of $\hbar$ on the third term inside the braces of Eq. (4.9), w_Λ is now chosen to make the first two terms cancel in order to achieve the desired insensitivity. This condition fixes the dependence of $w_\Lambda(\xi)$ on Λ:

$$w_\Lambda(\xi)=\sqrt{D(\xi)Z'_\Lambda(\xi)/\Lambda}, \tag{4.10}$$

where D is an arbitrary function of ξ.

With this form for $w_\Lambda(\xi)$, G_Λ can be estimated at the phase space curve by using the saddle point method:[2]

$$G_\Lambda[X(\xi_0),P(\xi_0)]\sim l^{1/4}\sqrt{\frac{D(\xi_0)}{Z'_{-l}(\xi_0)}}\exp\left[i\frac{\varphi(\xi_0)}{\hbar}\right]. \tag{4.11}$$

As desired, this result is independent of Λ and does not vanish as long as $D(\xi_0)$ is nonzero. The asymptotic estimate of G_Λ can be found to decay as a Gaussian in any section that is transverse to the curve. (The saddle point then corresponds to a complex value of ξ.) Alternatively, it follows from the discussion at the end of Sec. II that, since $|G_\Lambda|$ evidently has a ridge along the phase space curve, it therefore has a transverse profile that is approximately Gaussian of width $\sqrt{\hbar l}$ in the scaled phase space with coordinates (x,lp).

By using Eqs. (4.10) and Eq. (4.9), it is found that

$$G_{\Lambda+\delta\Lambda}(x,p)\approx G_\Lambda(x,p)+\delta\Lambda\,\frac{\partial G_\Lambda}{\partial\Lambda}(x,p)=\frac{1}{\sqrt{2\pi\hbar}}\int\left\{w_\Lambda(\xi)+\delta\Lambda\,\frac{\hbar}{2}\,\delta w_\Lambda(\xi)\right\}g_\Lambda(x,p;\xi)d\xi, \tag{4.12}$$

where

$$\delta w_\Lambda(\xi):=\frac{1}{\sqrt{\Lambda}}\,\frac{\partial}{\partial\xi}\left(\frac{1}{Z'_\Lambda}\,\frac{\partial}{\partial\xi}\,\sqrt{\frac{D}{Z'_\Lambda}}\right). \tag{4.13}$$

Equation (4.12) states that, to first order, a change in Λ is equivalent to a change in the weighting. Given Eq. (4.11), it now follows that G_Λ is not significantly affected by a change $\delta\Lambda$ in Λ, provided $\delta\Lambda\ll|2w_\Lambda/(\hbar\,\delta w_\Lambda)|$ for all ξ. If we require G_Λ to be insensitive to changes in Λ that are of the order of Λ itself, this condition becomes

$$\left|\frac{\delta w_\Lambda(\xi)}{w_\Lambda(\xi)}\right|=\left|\frac{1}{\sqrt{DZ'_\Lambda}}\,\frac{\partial}{\partial\xi}\left(\frac{1}{Z'_\Lambda}\,\frac{\partial}{\partial\xi}\,\sqrt{\frac{D}{Z'_\Lambda}}\right)\right|\ll\frac{1}{\hbar\Lambda},\quad\text{for all}\quad\xi. \tag{4.14}$$

That is, as anticipated, G_Λ is insensitive to changes in Λ provided $\hbar^{-1}$ is sufficiently large compared to the value of a particular expression involving the curve and its weight function.

V. INTERPRETATION OF THE INSENSITIVITY CONDITION

Condition (4.14) can be used to delineate an acceptable interval for the value of Λ. Expanding the derivatives and multiplying both sides by $\hbar\Lambda$ leads to

$$\left|\left[5Z''^2_\Lambda-2Z'_\Lambda Z'''_\Lambda-4\,\frac{D'}{D}\,Z'_\Lambda Z''_\Lambda+\left(2\,\frac{D''}{D}-\frac{D'^2}{D^2}\right)Z'^2_\Lambda\right]\frac{\hbar\Lambda}{4Z'^4_\Lambda}\right|\ll 1,\quad\text{for all}\quad\xi. \tag{5.1}$$

[Remember that $Z_\Lambda(\xi)=X(\xi)+i\Lambda P(\xi)$.] Notice that, as $\Lambda\to 0$, condition (5.1) is satisfied for all ξ, except in the neighborhood of the values of ξ for which $X'(\xi)=0$. At these values, the left-hand side of condition (5.1) diverges—it is $O(\Lambda^{-3})$. Therefore, the points in the phase space curve where the local tangent is parallel to the p axis [that is, where $X'(\xi)=0$], fix a lower bound on Λ. Alternatively, for large Λ, condition (5.1) is satisfied everywhere except in the neighborhood of the points where the local tangent to the phase space curve is parallel to the x axis, that is, where $P'(\xi)=0$. At these points the left-hand side of condition (5.1) diverges—it is $O(\Lambda^3)$. This then fixes an upper bound for Λ. Since most phase space curves will have both vertical and horizontal segments, finite, nonzero values of Λ must be used and the allowed interval evidently follows from condition (5.1).

The functions $X(\xi)$, $P(\xi)$, $\varphi(\xi)$, and $D(\xi)$, can be reparametrized without affecting Eq. (4.3) or condition (4.14), provided the parametrization monotonically describes the phase space curve. If the relationship between the old and new parameters is $\xi=R(\check{\xi})$, then the reparametrized quantities are $\check{X}(\check{\xi}):=X[R(\check{\xi})]$, $\check{P}(\check{\xi}):=P[R(\check{\xi})]$, $\check{\varphi}(\check{\xi}):=\varphi[R(\check{\xi})]$, and $\check{D}(\check{\xi}):=R'(\check{\xi})D[R(\check{\xi})]$. A simple geometrical interpretation of condition (4.14) follows upon choosing the special parametrization where $|\check{Z}'_\Lambda(\check{\xi})|\equiv\sqrt{\Lambda}$ for all $\check{\xi}$. In this case, $\check{Z}'_\Lambda$ reduces to $\sqrt{\Lambda}\exp[i\alpha(\check{\xi})]$, where

$$\alpha(\check{\xi})=\arctan\left[\frac{\Lambda\check{P}'(\check{\xi})}{\check{X}'(\check{\xi})}\right]. \tag{5.2}$$

Now, consider the scaled phase space $(\Lambda^{-1/2}x,\Lambda^{1/2}p)$, where both axes again have the same dimensions. Here, $\alpha(\check{\xi})$ corresponds to the angle between the $\Lambda^{-1/2}x$ axis and the local tangent to the scaled phase space curve (see Fig. 2), and $\check{\xi}$ corresponds to the arclength along the curve. With this, condition (4.14) becomes

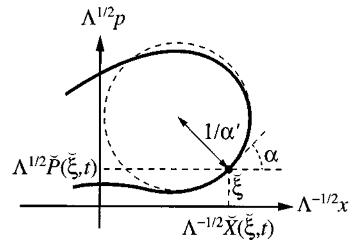

FIG. 2. At any point, labeled by $\check{\xi}$, along the scaled phase space curve, α is the angle between the $\Lambda^{-1/2}x$ axis and the local tangent to the curve, and α' is the local curvature.

$$\frac{1}{4}\left|2\frac{\check{D}''}{\check{D}}-\frac{\check{D}'^2}{\check{D}^2}-3\alpha'^2-2i\left(\alpha''+2\alpha'\frac{\check{D}'}{\check{D}}\right)\right|\ll\frac{1}{\hbar},\quad \text{for all } \check{\xi}, \tag{5.3}$$

where α' and α'' correspond, respectively, to the local curvature and the rate of change of the curvature of the scaled phase space curve.

Condition (5.3) is satisfied when any segment of length $\sqrt{\hbar}$ of the scaled phase space curve is sufficiently straight, and the relative variation in $\check{D}$ is small over the segment. That is, it is sufficient to require each term in condition (5.3) to be small, and this leads to

$$|\alpha'|\ll\frac{1}{\sqrt{\hbar}}, \tag{5.4a}$$

$$|\alpha''|\ll\frac{1}{\hbar}, \tag{5.4b}$$

$$\left|\frac{\check{D}'}{\check{D}}\right|\ll\frac{1}{\sqrt{\hbar}}, \tag{5.4c}$$

$$\left|\frac{\check{D}''}{\check{D}}\right|\ll\frac{1}{\hbar},\quad \text{for all } \check{\xi}. \tag{5.4d}$$

Notice that condition (5.4a) is consistent with what was said at the outset of this section: at points where $P'=0$, the curvature is given by $\Lambda^{3/2}P''/X'^2$, so Λ must satisfy $\Lambda\ll|X'^4/\hbar P''^2|^{1/3}$, while at points where $X'=0$, the curvature is $X''/(\Lambda^{3/2}P'^2)$ so Λ must be chosen such that $\Lambda\gg|\hbar X''^2/P'^4|^{1/3}$. It is clear that, when the curvature of the phase space curve is sufficiently tight, these two inequalities can be incompatible. Nevertheless, this limitation of the semiclassical method developed here turns out to be insignificant compared to the analogous limitations of other existing methods.

VI. TIME EVOLUTION

Each of X, P, φ, and D is now taken to be a function, not only of ξ, but also of time. The goal of this section is to show that G_Λ approximately satisfies the propagation equation given in Eq. (3.6) when X and P are, respectively, the parametric position and momentum for a classical trajectory, and φ is simply related to the classical action for that trajectory.

From Eqs. (4.4), (4.6), and (4.10), the time derivatives of g_Λ and w_Λ are

$$\frac{\partial g_\Lambda}{\partial t}=\frac{i}{\hbar}\left(\dot{\varphi}+\frac{X\dot{P}-\dot{X}P}{2}-i\dot{Z}_\Lambda\Delta\right)g_\Lambda, \tag{6.1a}$$

$$\frac{\partial w_\Lambda}{\partial t}=\left(\frac{\dot{D}}{D}+\frac{\dot{Z}'_\Lambda}{Z'_\Lambda}\right)\frac{w_\Lambda}{2}, \tag{6.1b}$$

where the overdot denotes a derivative with respect to t and Δ is defined after Eq. (4.7). It now follows from Eq. (4.3) that

$$i\hbar\frac{\partial G_\Lambda}{\partial t}=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda g_\Lambda\left(-\dot{\varphi}+\frac{\dot{X}P-X\dot{P}}{2}+i\dot{Z}_\Lambda\Delta+\frac{i\hbar}{2}\frac{\dot{D}}{D}+\frac{i\hbar}{2}\frac{\dot{Z}'_\Lambda}{Z'_\Lambda}\right)d\xi. \tag{6.2}$$

Notice that the third term inside the parentheses on the right-hand side of Eq. (6.2) contains a Δ, and therefore it depends on x and p. This dependence can be removed by using Eq. (4.7) and integrating by parts as in Eq. (4.9):

$$\int w_\Lambda\dot{Z}_\Lambda\,\Delta g_\Lambda\,d\xi=-\hbar\int g_\Lambda\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda\dot{Z}_\Lambda}{Z'_\Lambda}\right)d\xi=-\hbar\int w_\Lambda g_\Lambda\left[\frac{\dot{Z}_\Lambda}{w_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)+\frac{\dot{Z}'_\Lambda}{Z'_\Lambda}\right]d\xi, \tag{6.3}$$

so Eq. (6.2) becomes

$$i\hbar\frac{\partial G_\Lambda}{\partial t}=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda g_\Lambda\left[-\dot{\varphi}+\frac{\dot{X}P-X\dot{P}}{2}-i\hbar\frac{\dot{Z}_\Lambda}{w_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)-\frac{i\hbar}{2}\frac{\dot{Z}'_\Lambda}{Z'_\Lambda}+\frac{i\hbar}{2}\frac{\dot{D}}{D}\right]d\xi. \tag{6.4}$$

From the definition of $\hat{P}$ in Eq. (3.4), it follows that

$$\frac{\hat{P}^2}{2m}G_\Lambda=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda g_\Lambda\left(\frac{P^2}{2m}+\frac{\hbar}{2m(l+\Lambda)}+\frac{iP\Delta}{2}-\frac{\Delta^2}{2m}\right)d\xi. \tag{6.5}$$

Again, the Δ's are now eliminated by using Eq. (4.7) and integrating by parts, giving

$$\frac{\hat{P}^2}{2m}G_\Lambda=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda g_\Lambda\left\{\frac{P^2}{2m}-i\hbar\frac{P}{m}\frac{1}{w_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)-\frac{i\hbar}{2}\frac{P'}{mZ'_\Lambda}-\frac{\hbar^2}{2m}\frac{1}{w_\Lambda}\frac{\partial}{\partial\xi}\left[\frac{1}{Z'_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)\right]\right\}d\xi. \tag{6.6}$$

Following similar steps, it is shown in Appendix A that

$$\begin{aligned}V(\hat{X},t)G_\Lambda=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda g_\Lambda\Bigg\{&V_0-\hbar\Lambda\left[V_1\frac{1}{w_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)+\frac{V_2}{2}\frac{X'}{Z'_\Lambda}\right]\\&+(\hbar\Lambda)^2\frac{Z'_\Lambda}{w_\Lambda}\left[\frac{V_2}{2}\hat{\partial}^2_{Z_\Lambda}+\frac{V_3}{6}(2\hat{\beta}\hat{\partial}_{Z_\Lambda}+\hat{\partial}_{Z_\Lambda}\hat{\beta})+\frac{V_4}{8}\hat{\beta}^2\right]\frac{w_\Lambda}{Z'_\Lambda}\\&+\sum_{n=3}^{\infty}(\hbar\Lambda)^n\sum_{j=0}^{n}V_{2n-j}\sum_{k=0}^{\binom{n}{j}}c_k^{n,j}\frac{Z'_\Lambda}{w_\Lambda}\Pi_k^{n,j}(\hat{\partial}_{Z_\Lambda},\hat{\beta})\frac{w_\Lambda}{Z'_\Lambda}\Bigg\}d\xi,\end{aligned} \tag{6.7}$$

where $V_n=\partial^nV/\partial x^n$ evaluated at $X(\xi,t)$, $\hat{\partial}_{Z_\Lambda}:=Z'^{-1}_\Lambda\partial/\partial\xi$, $\hat{\beta}:=X'/Z'_\Lambda$, $\Pi_k^{n,j}(\hat{\partial}_{Z_\Lambda},\hat{\beta})$ corresponds to the kth permutation of the product of j factors of $\hat{\partial}_{Z_\Lambda}$ and $n-j$ factors of $\hat{\beta}$, and $c_k^{n,j}$ is a numerical coefficient.

By substituting Eqs. (6.4), (6.6), and (6.7) into Eq. (3.6), the Schrödinger equation is found to take the form

$$\int w_\Lambda(\xi) g_\Lambda(x,p;\xi)\Bigg\{\left(\dot\varphi-\frac{\dot X P - X\dot P}{2}+\frac{P^2}{2m}+V_0\right)$$
$$-i\hbar\left[\frac{1}{w_\Lambda}\left(\frac{P}{m}-i\Lambda V_1-\dot Z_\Lambda\right)\frac{\partial}{\partial\xi}\left(\frac{w_\Lambda}{Z'_\Lambda}\right)+\frac{1}{2Z'_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{P}{m}-i\Lambda V_1-\dot Z_\Lambda\right)+\frac{1}{2}\frac{\dot D}{D}\right]$$
$$+(\hbar\Lambda)^2\frac{Z'_\Lambda}{w_\Lambda}\left[\frac{V_2-(m\Lambda^2)^{-1}}{2}\hat\partial^2_{Z_\Lambda}+\frac{V_3}{6}(2\hat\beta\hat\partial_{Z_\Lambda}+\hat\partial_{Z_\Lambda}\hat\beta)+\frac{V_4}{8}\hat\beta^2\right]\frac{w_\Lambda}{Z'_\Lambda}$$
$$+\sum_{n=3}^{\infty}(\hbar\Lambda)^n\sum_{j=0}^{n}V_{2n-j}\sum_{k=0}^{\binom{n}{j}}c_k^{n,j}\frac{Z'_\Lambda}{w_\Lambda}\Pi_k^{n,j}(\hat\partial_{Z_\Lambda},\hat\beta)\frac{w_\Lambda}{Z'_\Lambda}\Bigg\}d\xi=0. \tag{6.8}$$

The integral on the left-hand side of Eq. (6.8) must vanish for all x and p, and for any l. Notice that the only dependence on these parameters comes from g_Λ, and that, like Eqs. (4.3) and (4.9), Eq. (6.8) is just a weighted sum of the Gaussians. Equation (6.8) can evidently be satisfied by requiring the expression inside the braces to vanish. This is now realized by introducing three constraints:

$$-\dot\varphi+\frac{\dot X P-X\dot P}{2}=\frac{P^2}{2m}+V(X,t), \tag{6.9a}$$

$$\dot Z_\Lambda=\dot X+i\Lambda\dot P=\frac{P}{m}-i\Lambda\frac{\partial V}{\partial x}(X,t), \tag{6.9b}$$

$$\frac{\dot D}{D}=-i\hbar\Lambda^2\sqrt{\frac{Z'_\Lambda}{D}}\left\{[V_2-(m\Lambda^2)^{-1}]\hat\partial^2_{Z_\Lambda}+\frac{V_3}{3}(2\hat\beta\hat\partial_{Z_\Lambda}+\hat\partial_{Z_\Lambda}\hat\beta)+\frac{V_4}{4}\hat\beta^2\right\}\sqrt{\frac{D}{Z'_\Lambda}}$$
$$-2i\sum_{n=3}^{\infty}\hbar^{n-1}\Lambda^n\sum_{j=0}^{n}V_{2n-j}\sum_{k=0}^{\binom{n}{j}}c_k^{n,j}\sqrt{\frac{Z'_\Lambda}{D}}\Pi_k^{n,j}(\hat\partial_{Z_\Lambda},\hat\beta)\sqrt{\frac{D}{Z'_\Lambda}}, \tag{6.9c}$$

where Eq. (4.10) was used in Eq. (6.9c).

Notice that Eq. (6.9b) was chosen such that its real and imaginary parts correspond to the classical laws of motion [see Eqs. (1.2)], so $X(\xi,t)$ and $P(\xi,t)$ can be identified as the position and momentum of the classical trajectory labeled by ξ. Also, Eq. (6.9a) was chosen to be compatible with Eq. (4.6), since these two equations can be shown to lead to the same expression for $\partial^2\varphi/\partial\xi\,\partial t$. Further, if we write φ as

$$\varphi(\xi,t)=S(\xi,t)-\frac{X(\xi,t)P(\xi,t)}{2}, \tag{6.10}$$

then Eq. (6.9a) becomes

$$\dot S(\xi,t)=\frac{P^2(\xi,t)}{2m}-V[X(\xi,t),t], \tag{6.11}$$

where Eq. (1.2a) was used to eliminate $\dot X$. The right-hand side of Eq. (6.11) is equal to the Lagrangian for the trajectory, so S can be identified as the classical action. Upon substituting Eq. (6.10) into Eq. (4.6), it follows that S satisfies

$$\frac{\partial S}{\partial\xi}(\xi,t)=P(\xi,t)\frac{\partial X}{\partial\xi}(\xi,t), \tag{6.12}$$

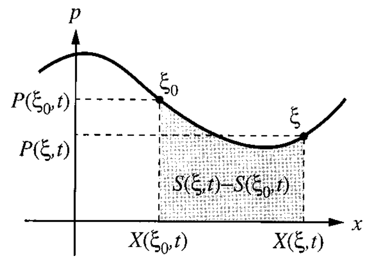

FIG. 3. $S(\xi,t)$ corresponds to an area under the phase space curve.

so S is also related to the area under the phase space curve, as shown in Fig. 3.

VII. SEMICLASSICAL ESTIMATE

Equation (6.9c) corresponds to the transport equation, which gives the time rate of change of the weighting D along a trajectory. While Eqs. (6.9a) and (6.9b) do not contain $\hbar$, Eq. (6.9c) has the form of a series in positive powers of $\hbar$. Unless V is a polynomial in x, this series is infinite. In conventional semiclassical methods, $\hbar$ is effectively regarded as a variable and $\hbar\to 0$ then underlies the asymptotic analysis. In this limit, Eq. (6.9c) states that D is conserved for each trajectory (i.e., $\dot{D}=0$), while Eqs. (6.9a) and (6.9b) remain unchanged. The form of the resulting semiclassical estimate follows from Eqs. (4.3) and (4.10):

$$G_\Lambda(x,p)=\frac{1}{\sqrt{2\pi\hbar\Lambda}}\int\sqrt{D(\xi,t_0)Z'_\Lambda(\xi,t)}\,g_\Lambda(x,p;\xi,t)\,d\xi, \tag{7.1}$$

where D has been frozen at the initial time t_0. The time interval over which this expression is valid can be estimated by using Eq. (6.9c): after a time given by the inverse of the absolute value of the right-hand side of Eq. (6.9c), the local estimate of $G(x,p)$ around the phase space point $[X(\xi,t),P(\xi,t)]$ is no longer expected to be accurate. In fact, Eq. (6.9c) gives a simple measure of the local deterioration of $G_\Lambda(x,p)$. It turns out that a suitable choice of Λ can help extend the validity of this estimate, and this is considered in Sec. VIII.

This approach allows a direct asymptotic estimate for any representation of the wave function. For example, by substituting Eq. (7.1) into Eq. (2.2a), and using Eqs. (4.2), (4.4), and (6.10), the associated estimate for $\Psi(x,t)$ is found to be

$$\Psi_\Lambda(x,t)=\frac{1}{\sqrt{2\pi\hbar\Lambda}}\int\sqrt{D(\xi,t_0)[X'(\xi,t)+i\Lambda P'(\xi,t)]}\times\exp\left\{-\frac{[x-X(\xi,t)]^2}{2\hbar\Lambda}\right\}\exp\left\{i\,\frac{S(\xi,t)+[x-X(\xi,t)]P(\xi,t)}{\hbar}\right\}d\xi. \tag{7.2}$$

Notice that the superfluous parameter l is entirely absent from Eq. (7.2). Also, provided condition (4.14) is satisfied, $\Psi_\Lambda(x,t)$ depends weakly on Λ. Alternatively, if Eq. (2.2b) is used in place of Eq. (2.2a) here, it is found that

$$\tilde{\Psi}_\Lambda(p,t)=\frac{1}{\sqrt{2\pi\hbar}}\int\sqrt{D(\xi,t_0)[X'(\xi,t)+i\Lambda P'(\xi,t)]}\times\exp\left\{-\Lambda\,\frac{[p-P(\xi,t)]^2}{2\hbar}\right\}\exp\left\{i\,\frac{S(\xi,t)-pX(\xi,t)}{\hbar}\right\}d\xi. \tag{7.3}$$

Again, this estimate does not depend on l, and has a weak dependence on Λ provided that condition (4.14) is satisfied. Further, $\tilde{\Psi}_\Lambda(p,t)$ is precisely the Fourier transform of $\Psi_\Lambda(x,t)$. As a result, it is easily shown that the mean square error is the same for these two estimates.

An important consideration for $\Psi_\Lambda(x,t)$ is that its norm is preserved in time. It is shown in Appendix B that $\int|\Psi_\Lambda(x,t)|^2\,dx \approx \int|D(\xi,t_0)|d\xi$. The weighting is therefore chosen to be normalized by

$$\int |D(\xi,t_0)|d\xi = 1. \tag{7.4}$$

VIII. CHOOSING Λ

It was mentioned in Sec. V that, for phase space curves that are multivalued in both x or p, a finite and nonzero value must be used for Λ. It was also anticipated in Sec. VII that a suitable choice for Λ may extend the validity of the estimate. To see this, consider rewriting Eq. (6.9c) in the form

$$\frac{\dot{D}}{D} = -i\hbar\left\{[\Lambda^2 V_2 - m^{-1}]\frac{1}{\sqrt{DZ'_\Lambda}}\frac{\partial}{\partial\xi}\left(\frac{1}{Z'_\Lambda}\frac{\partial}{\partial\xi}\sqrt{\frac{D}{Z'_\Lambda}}\right)\right.$$
$$\left.+\Lambda^2 V_3\left[\frac{X'}{Z'_\Lambda}\frac{1}{\sqrt{DZ'_\Lambda}}\frac{\partial}{\partial\xi}\sqrt{\frac{D}{Z'_\Lambda}} + \frac{1}{3Z'_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{X'}{Z'_\Lambda}\right)\right] + \frac{\Lambda^2 V_4}{4}\left(\frac{X'}{Z'_\Lambda}\right)^2\right\} + O(\hbar^2), \tag{8.1}$$

where we have concentrated on the terms that are first order in $\hbar$. The expected time of validity of the estimate is simply coupled to the modulus of the expression on the right-hand side of Eq. (8.1). Notice that the first term inside the braces in Eq. (8.1) has a factor that precisely corresponds to $\delta w_\Lambda / w_\Lambda$ [see Eqs. (4.10) and (4.13)], which was required to be small in order to achieve insensitivity to Λ. When this factor is expanded in the form shown in condition (5.1), one can see that the first term inside the braces in Eq. (8.1) is $O(\Lambda^{-4})$ for $\Lambda \to 0$ at points where $X'=0$, and it is $O(\Lambda^4)$ for $\Lambda \to \infty$ at points where $P'=0$. The rest of the expression in Eq. (8.1) is $O(\Lambda^0)$ and $O(\Lambda^3)$, respectively. Therefore, for both extreme cases, the first term dominates the expression inside the braces in Eq. (8.1). The insensitivity condition is then useful for enhancing the validity of the estimate. [In fact, the higher-order terms in Eq. (6.9c) are also kept from diverging by choosing Λ to make the scaled phase space curve satisfy conditions analogous to conditions (5.4) over all derivatives.]

So far, Λ has been treated as a constant. It is important, however, to see how the equations change when Λ is a function of time. [It is also natural to consider $\Lambda(\xi,t)$, but this is beyond the scope of this work.] In fact, by using Eq. (4.12) it follows that the only change is the appearance of an extra term of the form $i\hbar^2\,\delta w_\Lambda\,\dot{\Lambda}/(2w_\Lambda)$ inside the brackets in Eq. (6.4), and Eq. (8.1) then becomes

$$\frac{\dot{D}}{D} = -i\hbar\left\{[\Lambda^2 V_2 - m^{-1} - i\dot{\Lambda}]\frac{1}{\sqrt{DZ'_\Lambda}}\frac{\partial}{\partial\xi}\left(\frac{1}{Z'_\Lambda}\frac{\partial}{\partial\xi}\sqrt{\frac{D}{Z'_\Lambda}}\right)\right.$$
$$\left.+\Lambda^2 V_3\left[\frac{X'}{Z'_\Lambda}\frac{1}{\sqrt{DZ'_\Lambda}}\frac{\partial}{\partial\xi}\sqrt{\frac{D}{Z'_\Lambda}} + \frac{1}{3Z'_\Lambda}\frac{\partial}{\partial\xi}\left(\frac{X'}{Z'_\Lambda}\right)\right] + \frac{\Lambda^2 V_4}{4}\left(\frac{X'}{Z'_\Lambda}\right)^2\right\} + O(\hbar^2). \tag{8.2}$$

Since Eqs. (6.9a) and (6.9b) remain unchanged, the form of the estimates given in Eqs. (7.1)–(7.3) is preserved and they depend on Λ evaluated at the final time alone. That is, the history of Λ between the initial and final times turns out to be of no relevance for the estimates. The local deterioration of $\Psi_\Lambda(x,t)$ is now measured by Eq. (8.2). It follows that, for the purposes of arriving at a validity measure, the value of Λ should be chosen at all times by ensuring insensitivity for just the current form of the phase space curve.

Finally, also notice that Λ can be taken to be complex provided its real part is positive [so the Gaussian in Eq. (4.1) remains localized]. The imaginary part of Λ causes a shear in the footprint. Let $\Lambda^{-1}=\lambda^{-1}+i\nu^{-1}$, where both λ and ν are real, and $\lambda>0$. Equation (7.2) can now be rewritten as

$$\Psi_\Lambda(x,t)=\frac{1}{\sqrt{2\pi\hbar\lambda}}\exp\left(-i\frac{x^2}{2\hbar\nu}\right)\int\sqrt{D(\xi,t_0)[X'(\xi,t)+i\lambda\mathcal{P}'(\xi,t)]}$$
$$\times\exp\left\{-\frac{[x-X(\xi,t)]^2}{2\hbar\lambda}\right\}\exp\left\{i\frac{\mathcal{S}(\xi,t)+[x-X(\xi,t)]\mathcal{P}(\xi,t)}{\hbar}\right\}d\xi, \tag{8.3}$$

where

$$\mathcal{P}(\xi,t):=P(\xi,t)+\nu^{-1}X(\xi,t), \tag{8.4a}$$

$$\mathcal{S}(\xi,t):=S(\xi,t)+\nu^{-1}\frac{X^2(\xi,t)}{2}. \tag{8.4b}$$

Other than the chirp factor outside the integral, Eq. (8.3) has exactly the same form as Eq. (7.2), with Λ replaced by λ. Notice from Eq. (8.4a) that the parametric plot of $[X(\xi,t),\mathcal{P}(\xi,t)]$ corresponds to a sheared version of the phase space curve, where the degree of shearing is given by ν^{-1}. Also, it is easy to show from Eqs. (6.12) and (8.4b) that

$$\frac{\partial\mathcal{S}}{\partial\xi}(\xi,t)=\mathcal{P}(\xi,t)\frac{\partial X}{\partial\xi}(\xi,t), \tag{8.5}$$

so $\mathcal{S}$ corresponds to the area under the sheared phase space curve.

The condition for insensitivity on Λ can now be stated as follows: the real and imaginary parts of Λ must be chosen such that the scaled and sheared phase space curve described by $[\lambda^{-1/2}X(\xi,t),\lambda^{1/2}\mathcal{P}(\xi,t)]$ must have, for all ξ, a curvature much smaller than $\hbar^{-1/2}$, a rate of change of curvature much smaller than $\hbar^{-1}$, and first- and second-order rates of relative change in weighting that are negligible within any segment of the curve of length $\hbar^{1/2}$. Complex Λ therefore gives an extra degree of freedom that can be used to satisfy the validity condition for the semiclassical estimate given here.

IX. CONNECTION WITH OTHER SEMICLASSICAL ESTIMATES

As mentioned in Sec. V, when $X'(\xi,t)\neq 0$ for all ξ, condition (5.1) is satisfied for $\Lambda\to 0$. When this limit is taken, the spread in p of the footprint shown in Fig. 1(a) grows as $\Lambda^{-1/2}$, and the Gaussian in Eq. (7.2) together with the $\Lambda^{-1/2}$ factor approach a delta function. Therefore, the integral, evaluated at $x=X(\xi_0,t)$, gives

$$\Psi_{\Lambda\to 0}[X(\xi_0,t),t]=\sqrt{D(\xi_0,t_0)}\left|\frac{\partial X}{\partial\xi}(\xi_0,t)\right|^{-1/2}\exp\left[i\frac{S(\xi_0,t)}{\hbar}-i\frac{\pi}{2}M\right]. \tag{9.1}$$

Here, M is an integer known as the Maslov index, which accounts for the phase accumulated by the $\sqrt{Z'_\Lambda}$ factor in the integrand of Eq. (7.2) during propagation. [Notice that, since $\Lambda\to 0$, the phase of Z'_Λ is an integer multiple of π.] Equation (9.1) is precisely the conventional estimate mentioned in Sec. I, which is valid when the phase space curve is single valued in x. (Notice that the phase is now explicit.)

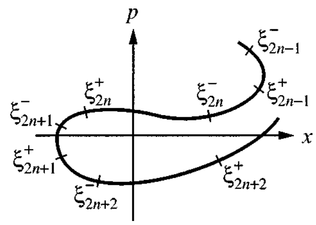

FIG. 4. Segmentation of the phase space curve for Maslov's method, where $X'(\xi,t)\neq 0$ for all $\xi\in[\xi_{2n}^-,\xi_{2n}^+]$, $P'(\xi,t)\neq 0$ for all $\xi\in[\xi_{2n+1}^-,\xi_{2n+1}^+]$, and $X'(\xi,t)P'(\xi,t)\neq 0$ for all $\xi\in[\xi_j^+,\xi_{j+1}^-]$.

Equivalently, when $P'(\xi,t)\neq 0$ for all ξ, condition (5.1) is satisfied as $\Lambda\to\infty$, which causes the footprint's spread in x to diverge as $\Lambda^{1/2}$. This limit leads to a delta function inside the integral in Eq. (7.3), which then gives

$$\tilde{\Psi}_{\Lambda\to\infty}[P(\xi_0,t),t]=\sqrt{D(\xi_0,t_0)}\left|\frac{\partial P}{\partial \xi}(\xi_0,t)\right|^{-1/2}\exp\left[i\,\frac{S(\xi_0,t)-X(\xi_0,t)P(\xi_0,t)}{\hbar}+i\,\frac{\pi}{4}-i\,\frac{\pi}{2}\tilde{M}\right],\tag{9.2}$$

where $\tilde{M}$ is the Maslov index for the momentum representation. Equation (9.2) corresponds to the estimate of the momentum distribution also mentioned in Sec. I, and is valid for phase space curves that are single valued in p.

The estimate given in Eq. (7.2) is significantly more general and robust than the conventional ones given in Eqs. (9.1) and (9.2). This follows from the fact that Λ can be chosen to reduce the deterioration of the estimate, as measured by $\dot{D}$. In particular, when the real part of Λ is finite and greater than zero, $\dot{D}$ remains finite since Z'_Λ [whose inverse appears repeatedly in Eq. (8.1)] never vanishes. For the two conventional estimates mentioned above, the corresponding measures of deterioration follow from the limits $\Lambda\to 0$ and $\Lambda\to\infty$ of Eq. (8.1), respectively. It is easily seen than that the time derivative of the weighting function then diverges at the caustics of the corresponding representation.

Another conventional semiclassical estimate that follows directly as a special case of Eq. (7.1) is Maslov's canonical operator method,[3,4] which is used at times when the phase space curve is multivalued in both x and p. [In such a case, neither Eq. (9.1) nor Eq. (9.2) can be used on their own.] To obtain this estimate, first define a series of switching functions $e_j(\xi)$, such that (i) $e_j(\xi)=1$ for ξ inside the interval $[\xi_j^-,\xi_j^+]$, which corresponds to a segment of the phase space curve that is single valued in either x (say, when j is even) or p (say, when j is odd), as shown in Fig. 4; (ii) $e_j(\xi)$ switches smoothly from 0 to 1 inside the interval (ξ_{j-1}^+,ξ_j^-) and from 1 to 0 inside the interval (ξ_j^+,ξ_{j+1}^-), where the phase space curve must be single valued in both x and p for both these intervals; (iii) $e_j(\xi)=0$ for all other ξ; and (iv) $\Sigma_j e_j(\xi)\equiv 1$ for all ξ. By inserting $\Sigma_j e_j(\xi)$ into Eq. (7.1), this expression can then be written as

$$G_\Lambda(x,p)=\sum_j \frac{1}{\sqrt{2\pi\hbar\Lambda}}\int \sqrt{D_j(\xi)Z'_\Lambda(\xi,t)}\,g_\Lambda(x,p;\xi,t)\,d\xi,\tag{9.3}$$

where $D_j(\xi):=e_j^2(\xi)D(\xi,t_0)$, and Λ is such that Eq. (7.1) satisfies the insensitivity condition (4.14).

Each of the terms in the sum in Eq. (9.3) is now effectively an independent estimate of the form given in Eq. (7.1). In fact, the value of Λ can now be varied independently for each term, provided the associated $D_j(\xi)$ satisfies condition (4.14). It follows from conditions (5.4c) and (5.4d) then, that the switching functions must themselves satisfy

$$\left|\frac{\check{e}_j'}{\check{e}_j}\right| \ll \frac{1}{\sqrt{\hbar}}, \tag{9.4a}$$

$$\left|\frac{\check{e}_j''}{\check{e}_j}\right| \ll \frac{1}{\hbar}, \quad \text{for } \check{\xi} \in (\check{\xi}_{j-1}^{+}, \check{\xi}_{j+1}^{-}), \tag{9.4b}$$

where $\check{e}_j(\check{\xi}) := e_j[R(\check{\xi})]$ and $R(\check{\xi}_j^{\pm}) = \xi_j^{\pm}$. The switching intervals should therefore be made as wide as possible given the restriction that they are necessarily constrained between two adjacent caustics—$X'(\xi,t)=0$ at one and $P'(\xi,t)=0$ at the other. These requirements impose added constraints on the validity of Maslov's method. This has been studied quantitatively (within the optics context) elsewhere,[5] where it is established that these are, in fact, the dominant limiting factors for this approach. [Of course, conditions (9.4) are necessarily violated within a neighborhood of ξ_{j-1}^{+} and ξ_{j+1}^{-}, where $e_j(\xi)$ vanishes, but since the weighting is small there, any associated errors are insignificant.]

To obtain an estimate for $\Psi(x,t)$, the even terms in Eq. (9.3) are substituted into Eq. (2.2a), and the odd ones are inserted into Eq. (2.2b) and inverse Fourier transformed according to Eq. (1.3b). Since the even terms correspond to segments of the phase space curve that are single valued in x, the associated integrals can be estimated, as in Eq. (9.1), by letting $\Lambda \to 0$. The resulting expressions (which are given in parametric form) are expressed explicitly as functions of x by evaluating them at $\xi = \Xi_j(x,t) \in (\xi_{j-1}^{+}, \xi_{j+1}^{-})$, which is the solution of $X[\Xi_j(x,t),t] = x$ for $x \in [X(\xi_{j-1}^{+},t), X(\xi_{j+1}^{-},t)]$. Similarly, the integral over ξ for the odd terms can be estimated by letting $\Lambda \to \infty$ as in Eq. (9.2), since they correspond to segments that are single valued in p. The result takes the form

$$\begin{aligned}\Psi_{\mathrm{M}}(x,t) = &\sum_n e_{2n}[\Xi_{2n}(x,t)]\sqrt{D[\Xi_{2n}(x,t),t_0]}\left|\frac{\partial \Xi_{2n}}{\partial x}(x,t)\right|^{1/2} \exp\left\{ i\,\frac{S[\Xi_{2n}(x,t),t]}{\hbar} - i\,\frac{\pi}{2} M_{2n}\right\}\\ &+ \frac{1}{\sqrt{2\pi\hbar}}\sum_n \int_{\xi_{2n}^{+}}^{\xi_{2n+2}^{-}} e_{2n+1}(\xi)\sqrt{D(\xi,t_0)}\left|\frac{\partial P}{\partial \xi}(\xi,t)\right|^{1/2}\\ &\times \exp\left\{ i\,\frac{S(\xi,t)+[x-X(\xi,t)]P(\xi,t)}{\hbar} + i\,\frac{\pi}{4} - i\,\frac{\pi}{2}\tilde{M}_{2n+1}\right\} d\xi,\end{aligned} \tag{9.5}$$

where M_{2n} and $\tilde{M}_{2n+1}$ are the Maslov indices for the corresponding segments. This is the standard result from Maslov's method and it is now seen to follow as a special case of Eq. (7.2). It is important to appreciate, however, that the dominant limitations on the validity of Ψ_{M} (i.e., the switching errors) are avoided altogether by the new method.

The form of Eq. (7.2) also suggests a clear link to propagation schemes based on summing Gaussian wave packets.[6] The basic idea is that the initial wave function is decomposed into a sum of Gaussians, and each of these is propagated independently. Similar ideas were considered in a different context by Daubechies,[7] who points out the clear link with the coherent states[8] of quantum electrodynamics. In these works, however, phase space acts only as a mathematical domain for field decomposition at a fixed time. This stands in contrast to the method developed here, where the field is explicitly propagated in phase space itself. Further, as shown in Sec. V, for Λ within a certain interval, the sum of Gaussians in Eq. (7.2) is effectively independent of Λ. It follows that the evolution of the individual Gaussians is irrelevant: Λ can simply be chosen such that it satisfies condition (4.14) at the final time alone.

This property of a sum of Gaussians was first noted by Heller,[9] who realized that a sum of propagated Gaussian beam elements may lead to a cancellation of the dominant errors within each element when their widths are frozen (i.e., there is then no beam waist). This is precisely what we have now derived directly from Eq. (1.1) and, as a result, arrived at explicit validity conditions. Further, we have shown in Sec. VIII that the beamwidths must actually be varied in time to determine the validity of the final results.

Herman and Kluk[10] justified Heller's heuristic approach quite differently and, just as in the Gabor method[11] that was further developed by Bastiaans,[12] they end up with a sum over all of phase space—not just over a curve. Kay recently introduced both an ansatz to generalize these integral approaches[13] and an empirical means to deal with the onset of chaos.[14] Walton and Manolopoulos[15] have recently combined some of the strengths of these ideas. However, the foundation of all this work is the conventional asymptotic propagator as developed by Van Vleck.[16] This propagator takes the form of Eq. (9.1), whose glaring limitations motivated this work. That is, unlike earlier semiclassical methods, the results developed here are derived directly from the Schrödinger equation and not from the fundamentally limited result given in Eq. (9.1). Nevertheless, these important contributions are clearly relevant to the method developed here.

X. SUMMARY OF THE METHOD

Our semiclassical method for estimating $\Psi(x,t)$ given the initial condition $\Psi(x,t_0)$ can be summarized in the following three steps.

(I) Find a phase space curve and an associated weighting—i.e., $X(\xi,t_0)$, $P(\xi,t_0)$, and $D(\xi,t_0)$, so that the right-hand side of Eq. (7.2) matches this prescribed initial condition. [Recall that $S(\xi,t_0)$ can be constructed from Eq. (6.12) evaluated at t_0.]

(II) Propagate the family of classical trajectories by using Eqs. (1.2), and construct $S(\xi,t)$ by integrating Eq. (6.11):

$$S(\xi,t)=S(\xi,t_0)+\int_{t_0}^{t}\left\{\frac{P^2(\xi,t')}{2m}-V[X(\xi,t'),t']\right\}dt'. \tag{10.1}$$

[Alternatively, $S(\xi,t)$ can be found, to within a constant, directly from X and P at t from the ξ integral of Eq. (6.12).]

(III) Find the estimate for $\Psi(x,t)$, namely, $\Psi_\Lambda(x,t)$, by using Eq. (7.2), where Λ is chosen to satisfy condition (4.14) at t.

For a significant set of wave functions, the solution to Step (I) is straightforward. For example, when the amplitude of $\Psi(x,t_0)$ is slowly varying, a prescription for determining $X(\xi,t_0)$, $P(\xi,t_0)$, and $D(\xi,t_0)$ is given by

$$X(\xi,t_0)=\xi, \tag{10.2a}$$

$$P(\xi,t_0)=\hbar\,\mathrm{Im}\left\{\frac{\Psi'(\xi,t_0)}{\Psi(\xi,t_0)}\right\}, \tag{10.2b}$$

$$D(\xi,t_0)=|\Psi(\xi,t_0)|^2. \tag{10.2c}$$

Alternatively, when the amplitude of $\tilde{\Psi}(p,t_0)$ varies slowly, one can use

$$X(\xi,t_0)=-\hbar\,\mathrm{Im}\left\{\frac{\tilde{\Psi}'(\xi,t_0)}{\tilde{\Psi}(\xi,t_0)}\right\}, \tag{10.3a}$$

$$P(\xi,t_0)=\xi, \tag{10.3b}$$

$$D(\xi,t_0)=|\tilde{\Psi}(\xi,t_0)|^2. \tag{10.3c}$$

Of course, $\Psi_\Lambda(x,t)$ may also accurately model wave functions for which the initial conditions do not fall into the categories considered above. A more general solution to the task outlined in Step (I) is clearly a natural next step.

Finally, we comment that the simplicity of Eq. (7.2) means that the generalization to higher dimensions is straightforward. The estimate for a wave function $\Psi(\mathbf{x},t)$, where $\mathbf{x}=(x_1,x_2,\ldots,x_n)$, is given in terms of an associated n-parameter family of trajectories by

$$\Psi_{\mathbb{L}^{-1}}(\mathbf{x},t)=(2\pi\hbar)^{-n/2}\int\left\{D(\boldsymbol{\xi},t_0)\,\frac{\partial[\mathbb{L}\cdot\mathbf{X}(\boldsymbol{\xi},t)+i\mathbf{P}(\boldsymbol{\xi},t)]}{\partial(\boldsymbol{\xi})}\right\}^{1/2} \times\exp\left\{-\frac{[\mathbf{x}-\mathbf{X}(\boldsymbol{\xi},t)]\cdot\mathbb{L}\cdot[\mathbf{x}-\mathbf{X}(\xi,t)]}{2\hbar}+i\,\frac{S(\boldsymbol{\xi},t)+[\mathbf{x}-\mathbf{X}(\boldsymbol{\xi},t)]\cdot\mathbf{P}(\boldsymbol{\xi},t)}{\hbar}\right\}d^n\xi, \tag{10.4}$$

where $\boldsymbol{\xi}=(\xi_1,\xi_2,\ldots,\xi_n)$, $\mathbb{L}$ is a real, symmetric $n\times n$ matrix with positive eigenvalues, and $\partial(\mathbf{Y})/\partial(\boldsymbol{\xi})$ is a Jacobian determinant. This estimate is insensitive to changes in $\mathbb{L}$ when any patch of radius $\hbar^{1/2}$ of the n-dimensional, scaled Lagrange manifold described by $[\mathbb{L}^{1/2}\cdot\mathbf{X}(\boldsymbol{\xi},t),\ \mathbb{L}^{-1/2}\cdot\mathbf{P}(\boldsymbol{\xi},t)]$ is sufficiently flat, and the relative variations of $D(\boldsymbol{\xi},t_0)$ over the patch are insignificant.

APPENDIX A: THE APPLICATION OF $V(\hat{X},t)$ TO G_Λ

From Eq. (4.3), it follows that

$$\begin{aligned}V(\hat{X},t)G_\Lambda&=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda(\xi,t)V(\hat{X},t)g_\Lambda(x,p;\xi,t)d\xi\\&=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda\sum_{n=0}^{\infty}\frac{V_n}{n!}(\hat{X}-X)^n g_\Lambda\,d\xi,\end{aligned}\tag{A1}$$

where $V_n=\partial^n V/\partial x^n$ evaluated at $X(\xi,t)$. Our goal in this appendix is to rewrite Eq. (A1) in a form where all of the dependence on x and p (as well as on l) is contained within g_Λ, and the remaining weighting expression takes the form of a series in powers of $\hbar$ that is consistent with an asymptotic treatment.

From Eqs. (3.1), (4.4), and (4.7), it follows that

$$(\hat{X}-X)g_\Lambda=\Lambda\,\Delta g_\Lambda=\hbar\Lambda Z_\Lambda'^{-1}\frac{\partial g_\Lambda}{\partial\xi}=\hbar\Lambda\,\hat{\partial}_{Z_\Lambda}g_\Lambda\,, \tag{A2}$$

where $\Delta:=(z_{-l}-Z_{-l})/(l+\Lambda)$ and $\hat{\partial}_{Z_\Lambda}:=Z_\Lambda'^{-1}\partial/\partial\xi$. Equation (A2) is now used to eliminate the powers of $(\hat{X}-X)$ progressively from Eq. (A1):

$$\sum_{n=0}^{\infty}\frac{V_n}{n!}(\hat{X}-X)^n g_\Lambda=V_0 g_\Lambda+\hbar\Lambda V_1\,\hat{\partial}_{Z_\Lambda}g_\Lambda+\hbar\Lambda\sum_{n=2}^{\infty}\frac{V_n}{n!}(\hat{X}-X)^{n-1}\,\hat{\partial}_{Z_\Lambda}g_\Lambda\,. \tag{A3}$$

The commutator between $(\hat{X}-X)$ and $\hat{\partial}_{Z_\Lambda}$ follows from

$$(\hat{X}-X)\hat{\partial}_{Z_\Lambda}=\frac{X'}{Z_\Lambda'}+\hat{\partial}_{Z_\Lambda}(\hat{X}-X)=\hat{\beta}+\hat{\partial}_{Z_\Lambda}(\hat{X}-X), \tag{A4}$$

where $\hat{\beta}:=X'/Z_\Lambda'$. Since $\hat{\beta}$ commutes with $(\hat{X}-X)$ (but not with $\hat{\partial}_{Z_\Lambda}$), it follows that

$$(\hat{X}-X)^{\mu}\hat{\partial}_{Z_\Lambda}=\mu\hat{\beta}(\hat{X}-X)^{\mu-1}+\hat{\partial}_{Z_\Lambda}(\hat{X}-X)^{\mu}. \tag{A5}$$

Equations (A2) and (A5) are used repeatedly in Eq. (A3) to find

$$\begin{aligned}\sum_{n=0}^{\infty}\frac{V_n}{n!}(\hat{X}-X)^n g_\Lambda &= V_0 g_\Lambda+\hbar\Lambda V_1\,\hat{\partial}_{Z_\Lambda}g_\Lambda \\ &\quad+\hbar\Lambda\sum_{n=2}^{\infty}\frac{V_n}{n!}[(n-1)\hat{\beta}(\hat{X}-X)^{n-2}+\hat{\partial}_{Z_\Lambda}(\hat{X}-X)^{n-1}]g_\Lambda \\ &= V_0 g_\Lambda+\hbar\Lambda V_1\,\hat{\partial}_{Z_\Lambda}g_\Lambda+\hbar\Lambda\frac{V_2}{2}\hat{\beta}g_\Lambda+(\hbar\Lambda)^2\frac{V_2}{2}\hat{\partial}^2_{Z_\Lambda}g_\Lambda \\ &\quad+(\hbar\Lambda)^2\sum_{n=3}^{\infty}\frac{V_n}{n!}[(n-1)\hat{\beta}(\hat{X}-X)^{n-3}+\hat{\partial}_{Z_\Lambda}(\hat{X}-X)^{n-2}]\hat{\partial}_{Z_\Lambda}g_\Lambda\,. \end{aligned}\tag{A6}$$

By repeating these steps, we ultimately obtain an expression of the form

$$\begin{aligned}\sum_{n=0}^{\infty}\frac{V_n}{n!}(\hat{X}-X)^n g_\Lambda &= V_0 g_\Lambda+\hbar\lambda\left[V_1\hat{\partial}_{Z_\Lambda}+\frac{V_2}{2}\hat{\beta}\right]g_\Lambda \\ &\quad+(\hbar\Lambda)^2\left[\frac{V_2}{2}\hat{\partial}^2_{Z_\Lambda}+\frac{V_3}{6}(2\hat{\beta}\hat{\partial}_{Z_\Lambda}+\hat{\partial}_{Z_\Lambda}\hat{\beta})+\frac{V_4}{8}\hat{\beta}^2\right]g_\Lambda \\ &\quad+\sum_{n=3}^{\infty}(\hbar\Lambda)^n\sum_{j=0}^{n}V_{2n-j}\sum_{k=0}^{\binom{n}{j}}a_k^{n,j}\Pi_k^{n,j}(\hat{\partial}_{Z_\Lambda},\hat{\beta})g_\Lambda\,, \end{aligned}\tag{A7}$$

where $\Pi_k^{n,j}(\hat{\partial}_{Z_\Lambda},\hat{\beta})$ corresponds to the kth permutation of the product of j factors of $\hat{\partial}_{Z_\Lambda}$ and $n-j$ factors of $\hat{\beta}$, and $a_k^{n,j}$ is a numerical coefficient. The terms for $n\leqslant 2$ have been written out explicitly here.

Remember that $\hat{\partial}_{Z_\Lambda}$ contains a ξ derivative that acts over the whole expression to its right. When Eq. (A7) is substituted into Eq. (A1), these derivatives can be removed from g_Λ by repeatedly integrating by parts in the form

$$\begin{aligned}\int BV_\mu\hat{\beta}^\eta\,\hat{\partial}_{Z_\Lambda}\hat{A}\,g_\Lambda\,d\xi &= \int\hat{\beta}^\eta\frac{B}{Z'_\Lambda}V_\mu\frac{\partial}{\partial\xi}(\hat{A}g_\Lambda)d\xi \\ &= -\int\frac{\partial}{\partial\xi}\left[\hat{\beta}^\eta\frac{B}{Z'_\Lambda}V_\mu\right]\hat{A}g_\Lambda\,d\xi \\ &= -\int\left[V_\mu\hat{\partial}_{Z_\Lambda}\left(\hat{\beta}^\eta\frac{B}{Z'_\Lambda}\right)+V_{\mu+1}\hat{\beta}^{\eta+1}\frac{B}{Z'_\Lambda}\right](Z'_\Lambda\hat{A}g_\Lambda)d\xi. \end{aligned}\tag{A8}$$

By substituting Eq. (A7) into Eq. (A1) and using Eq. (A8) repeatedly, the desired result is found to be

$$V(\hat{X},t)G_\Lambda=\frac{1}{\sqrt{2\pi\hbar}}\int w_\Lambda g_\Lambda\Bigg\{V_0-\hbar\Lambda\frac{Z'_\Lambda}{w_\Lambda}\left[V_1\hat{\partial}_{Z_\Lambda}+\frac{V_2}{2}\hat{\beta}\right]\frac{w_\Lambda}{Z'_\Lambda}$$
$$+(\hbar\Lambda)^2\frac{Z'_\Lambda}{w_\Lambda}\left[\frac{V_2}{2}\hat{\partial}^2_{Z_\Lambda}+\frac{V_3}{6}(2\hat{\beta}\hat{\partial}_{Z_\Lambda}+\hat{\partial}_{Z_\Lambda}\hat{\beta})+\frac{V_4}{8}\hat{\beta}^2\right]\frac{w_\Lambda}{Z'_\Lambda}$$
$$+\sum_{n=3}^{\infty}(\hbar\Lambda)^n\sum_{j=0}^{n}V_{2n-j}\sum_{k=0}^{\binom{n}{j}}c_k^{n,j}\frac{Z'_\Lambda}{w_\Lambda}\Pi_k^{n,j}(\hat{\partial}_{Z_\Lambda},\hat{\beta})\frac{w_\Lambda}{Z'_\Lambda}\Bigg\}d\xi. \tag{A9}$$

Notice that, as required, the term in braces is now a series in $\hbar$, with all terms given explicitly through $O(\hbar^2)$.

APPENDIX B: NORMALIZATION OF Ψ_Λ

By using Eq. (7.2), the integral of $|\Psi_\Lambda(x,t)|^2$ over all x can be carried out in closed form, leaving

$$\int |\Psi_\Lambda(x,t)|^2\,dx$$
$$=\frac{1}{2\sqrt{\pi\hbar\Lambda}}\int\int\sqrt{D(\xi,t_0)D^*(\tau,t_0)[X'(\xi,t)+i\Lambda P'(\xi,t)][X'(\tau,t)-i\Lambda P'(\tau,t)]}$$
$$\times\exp\left\{i\,\frac{S(\xi,t)-S(\tau,t)}{\hbar}+i\,\frac{[P(\xi,t)+P(\tau,t)][X(\xi,t)-X(\tau,t)]}{2\hbar}\right\}$$
$$\times\exp\left\{-\frac{[X(\xi,t)-X(\tau,t)]^2}{4\hbar\Lambda}-\Lambda\,\frac{[P(\xi,t)-P(\tau,t)]^2}{4\hbar}\right\}d\xi\,d\tau. \tag{B1}$$

Notice that the integrand of the right-hand side of Eq. (B1) is most significant when $\xi\approx\tau$. The integral over τ is now approximated by using the saddle point method: the exponent of Eq. (B1) is expanded in τ around ξ up to second order, and the local variation of the amplitude factor in the square root is neglected. This leads to

$$\int |\Psi_\Lambda(x,t)|^2\,dx\approx\frac{1}{2\sqrt{\pi\hbar\Lambda}}\int\int|D(\xi,t_0)Z'_\Lambda(\xi,t)|\exp\left[-\frac{|Z'_\Lambda(\xi,t)|^2(\tau-\xi)^2}{4\hbar\Lambda}\right]d\xi\,d\tau$$
$$=\int|D(\xi,t_0)|\,d\xi. \tag{B2}$$

Bounded Bose fields in 1+1 dimensions commuting for space- and timelike distances

Klaus Baumann[a)]
Institut für Theoretische Physik, Universität Göttingen, Bunsenstraße 9, D-37073 Göttingen, Germany

Shortly after submission of this article, Klaus Baumann died at a much too young age. His scientific work was devoted to the foundations of relativistic quantum field theory and consists of masterly pieces of mathematical physics. He settled pertinent structural questions and helped to open our view for the subtle features of quantum field theory beyond perturbation theory.
Collegues and friends in Göttingen

(Received 29 August 1998; accepted for publication 29 October 1998)

We consider scalar Bose fields Φ in 1+1 dimensions which are bounded [i.e., $\Phi(F)$ is a bounded operator], commute for space- and timelike distances, and are dilation covariant with scaling dimension $d=1,3,5,\ldots$. We show that their truncated n-point-functions W_n^T are related to the truncated functions V_n^T of $\varphi(x)=\psi_{d/2}(x_+)\otimes\psi_{d/2}(x_-)$ via $W_n^T=c_nV_n^T$ with $c_n>0$. $\psi_{d/2}(x_\pm)$ is a free chiral real Fermi field of dimension $d/2$ depending on the light cone coordinates $x_\pm=t\pm x$. This comes close to the conjecture that under the above assumptions Φ is nothing but a weighted s-product of $\varphi=\psi_{d/2}\otimes\psi_{d/2}$. © *1999 American Institute of Physics.* [S0022-2488(99)00104-8]

INTRODUCTION

From ordinary quantum mechanics on $\mathbf{R}^d$ we are used to expecting that position and momentum operators are unbounded because of the Heisenberg commutation relations. The same is true for a relativistic quantum field theory in $d+1$-dimensional space–time fulfilling canonical commutation relations. But the Wightman axioms[1] for Bose fields do not ask explicitly for unbounded field operators and, furthermore, in two-dimensional space–time there exist examples of Bose fields, such that the smeared field operators $\Phi(F)$ are bounded operators (''bounded Bose fields'').[2] An especially simple class is constructed by tensor products of free chiral Fermi fields depending on the light cone coordinates $x_+=x_0+x_1$, respectively $x_-=x_0-x_1$, i.e., $\Phi(x)=\psi_+(x_+)\otimes\psi_-(x_-)$. Because of this construction they have the peculiar property to commute not only for spacelike but also for timelike distances. More complicated and therefore more interesting examples have been given by Rehren[3] based on tensor products of vertex operators. Starting with a scalar bounded Bose field Φ which commutes for space- and timelike distances and which is scale covariant, we try to prove the converse, namely we want to show that Φ looks like an s-product[4]—or a generalization thereof—of the above example given by Buchholz. In the case of chiral field theories we were able to show[5] that Bose fields are unbounded with the exception of c-number fields and that only free Fermi fields are bounded. The vertex operators considered by Rehren[3] fulfill more general commutation relations and he characterized which of them are bounded.

I. ASSUMPTIONS AND RESULTS

We want to do relativistic quantum field theory in the framework given by Wightman.[1] Our assumptions are as follows:

[a)]Deceased.

(A1) Φ is a scalar, neutral Bose field in $1+1$-dimensional space–time.

(A2) Φ commutes not only for spacelike, but also for timelike distances. Written in light cone coordinates $x_+ = t+x$ and $x_- = t-x$ we have

$$[\Phi(x),\Phi(y)]=0 \quad \text{if } (y_+-x_+)(y_--x_-)\neq 0. \tag{1.1}$$

(A3) Φ is scale covariant.

Remark: Lorentz invariance together with scale covariance imply the existence of unitary operators $U_{\lambda,\mu}$ such that

$$\Phi\begin{pmatrix}\lambda x_+\\ \mu x_-\end{pmatrix}=\frac{1}{(\lambda\mu)^{d/2}}U_{\lambda,\mu}\Phi\begin{pmatrix}x_+\\ x_-\end{pmatrix}U^\dagger_{\lambda,\mu} \quad \text{for all } \lambda,\mu>0, \tag{1.2}$$

and $U_{\lambda,\mu}\Omega=\Omega$ where Ω denotes the vacuum vector. Written with test functions this means

$$\Phi\begin{pmatrix}(f_+)_\lambda\\ (f_-)_\mu\end{pmatrix}=\frac{1}{(\lambda\mu)^{d/2-1}}U_{\lambda,\mu}\Phi\begin{pmatrix}f_+\\ f_-\end{pmatrix}U^\dagger_{\lambda,\mu} \quad \text{for all } \lambda,\mu>0, \tag{1.3}$$

if we define $(f)_\lambda(x):=f(x/\lambda)$ for $\lambda>0$. To fulfill space- and timelike commutativity, the allowed scaling dimensions d have to be integers from $\mathbf{N}_0$.

(A4) Φ is a bounded field, i.e., for every test function $F\in\mathcal{S}(\mathbf{R}^2)$ we have

$$\Phi(F) \text{ is a bounded operator with norm } \|\Phi(F)\|<\infty, \tag{1.4}$$

and because the operators $U_{\lambda,\mu}$ are unitary we get

$$\|\Phi(F_{\lambda,\mu})\|=\frac{1}{(\lambda\mu)^{d/2-1}}\|\Phi(F)\| \quad \text{for all } \lambda,\mu>0. \tag{1.5}$$

Remark: A nontrivial field which obviously fulfills the above assumptions **A** is given by $\varphi(x):=\psi(x_+)\otimes\psi(x_-)$ where ψ is a free neutral chiral Fermi field of (half-integer!) scaling dimension $d/2$. We shall discuss this example given by Buchholz in the next section.

Now we can formulate our main result:

Theorem: Let Φ fulfill the assumptions **A** with scaling dimension $d\in\mathbf{N}$, d odd. Then the truncated n-point functions $\mathcal{W}_n^T$ of the field Φ are proportional to the truncated n-point functions $\mathcal{V}_n^T$ of the just introduced field $\varphi=\psi\otimes\psi$, i.e., there exist positive numbers c_{2n} such that

$$\mathcal{W}_{2n}^T(F_1,\ldots,F_{2n})=c_{2n}\mathcal{V}_{2n}^T(F_1,\ldots,F_{2n}) \quad \text{and} \quad \mathcal{W}_{2n+1}^T\equiv 0. \tag{1.6}$$

Remark: If the sequence $(c_{2n}|n\in\mathbf{N})$ is of the form $c_{2n}=\Sigma_i\alpha_i^{2n}$ (a property which can be tested by an infinite set of inequalities such as $c_2^2\geqslant c_4$, and so on), we can write the field Φ as a weighted s-product of the field φ.

Remark: We can slightly generalize our theorem by relaxing Lorentz invariance and scale covariance in the following way:

$$\Phi\begin{pmatrix}\lambda x_+\\ \mu x_-\end{pmatrix}=\frac{1}{\lambda^{d_+/2}\mu^{d_-/2}}U_{\lambda,\mu}\Phi\begin{pmatrix}x_+\\ x_-\end{pmatrix}U^\dagger_{\lambda,\mu} \quad \text{for all } \lambda,\mu>0, \tag{1.7}$$

where d_+ and d_- are both half-integer numbers. If $d_+>d_-$, the field $\hat{\phi}:=\partial_-^{d_+-d_-}\phi$ fulfills the assumptions of our theorem. Therefore we have a candidate for all truncated functions and it is easy to show their uniqueness.

II. THE EXAMPLE GIVEN BY BUCHHOLZ

As remarked by Buchholz,[2] a simple method to construct a bounded Bose field in $1+1$-dimensional space–time is the following:

Take two bounded chiral Fermi fields in the light cone coordinates x_+, resp x_-. Their tensor product will define a bounded Bose field! But the class of bounded chiral Fermi fields coincides with free fields,[5] i.e., their anticommutator is a c-number. Therefore let ψ denote a neutral chiral Fermi field with scaling dimension $d_\psi = \frac{1}{2}$ fulfilling canonical anticommutation relations

$$\{\psi(u),\psi(v)\} = \delta(v-u)\mathbf{1} \quad \text{for all } u,v \in \mathbf{R}, \tag{2.1}$$

and bounded by

$$\|\psi(f)\| \leqslant \|f\|_2 \quad \text{for all } f \in \mathcal{S}(\mathbf{R}). \tag{2.2}$$

The field $\varphi(x) := \psi(x_+) \otimes \psi(x_-)$ defines a bounded scalar Bose field of scaling dimension $d=1$ and its commutation relations are

$$[\varphi(x),\, \varphi(y)] = \tfrac{1}{2}[\psi(x_+),\, \psi(y_+)] \otimes \{\psi(x_-),\psi(y_-)\} + \{\psi(x_+),\psi(y_+)\} \otimes \tfrac{1}{2}[\psi(x_-),\psi(y_-)] \tag{2.3}$$

$$= b(x_+,y_+)\,\delta(y_- - x_-) + b(x_-,y_-)\,\delta(y_+ - x_+) = 0$$

$$\text{if } (y_+ - x_+)(y_- - x_-) \neq 0 \tag{2.4}$$

i.e., φ commutes not only for spacelike but also for timelike distances.

As a pedagogical exercise let us calculate the double commutator.

$$\left[\left[\varphi\begin{pmatrix} x_+ \\ x_- \end{pmatrix},\varphi\begin{pmatrix} y_+ \\ y_- \end{pmatrix}\right]\varphi\begin{pmatrix} z_+ \\ z_- \end{pmatrix}\right] = \delta(y_- - x_-)\left\{\delta(z_+ - y_+)\,\varphi\begin{pmatrix} x_+ \\ z_- \end{pmatrix} - \delta(z_+ - x_+)\,\varphi\begin{pmatrix} y_+ \\ z_- \end{pmatrix}\right\}$$
$$+ \delta(y_+ - x_+)\left\{\delta(z_- - y_-)\,\varphi\begin{pmatrix} z_+ \\ x_- \end{pmatrix} - \delta(z_- - x_-)\,\varphi\begin{pmatrix} z_+ \\ y_- \end{pmatrix}\right\}. \tag{2.5}$$

To get a scalar bounded Bose field with scaling dimension d odd we start with a free neutral chiral Fermi field of scaling dimension $d/2$ given uniquely up to a constant by $\psi_{d/2}(u) = \partial^{(d-1)/2}\psi(u)$.

In the following we fix d odd and denote the corresponding bounded Bose field by φ, i.e., $\varphi = \psi_{d/2} \otimes \psi_{d/2}$. Many expressions can be written elegantly if we define

$$\langle fg \rangle := \int_{\mathbf{R}} f^{((d-1)/2)}(u)\, g^{((d-1)/2)}(u)\, du \quad \text{for all } f,g \in \mathcal{S}(\mathbf{R}), \tag{2.6}$$

for example, $\{\psi_{d/2}(f),\psi_{d/2}(g)\} = \langle fg \rangle \mathbf{1}$. The commutator and the double commutator of φ written with test functions are given by

$$\left[\varphi\begin{pmatrix} f_+ \\ f_- \end{pmatrix},\varphi\begin{pmatrix} g_+ \\ g_- \end{pmatrix}\right] = \langle f_- g_- \rangle b(f_+,g_+) + \langle f_+ g_+ \rangle b(f_-,g_-) \tag{2.7}$$

where

$$b(f,g) = \tfrac{1}{2}[\psi(f),\psi(g)], \tag{2.8}$$

respectively,

$$\left[\left[\varphi\begin{pmatrix}f_+\\f_-\end{pmatrix},\varphi\begin{pmatrix}g_+\\g_-\end{pmatrix}\right]\varphi\begin{pmatrix}h_+\\h_-\end{pmatrix}\right]=\langle f_-g_-\rangle\left\{\langle g_+h_+\rangle\varphi\begin{pmatrix}f_+\\h_-\end{pmatrix}-\langle f_+h_+\rangle\varphi\begin{pmatrix}g_+\\h_-\end{pmatrix}\right\}$$
$$+\langle f_+g_+\rangle\left\{\langle g_-h_-\rangle\varphi\begin{pmatrix}h_+\\f_-\end{pmatrix}-\langle f_-g_-\rangle\varphi\begin{pmatrix}h_+\\g_-\end{pmatrix}\right\}. \qquad (2.9)$$

Next we want to consider s-products of $\varphi=\psi\otimes\psi$, because with their help it is easy to outline and exemplify the proof of our theorem.

For fixed $K\in\mathbf{N}$ and given sequence $\underset{\sim}{\alpha}=(\alpha_1,\ldots,\alpha_K)$, let $\varphi_{\underset{\sim}{\alpha}}$ be the K-fold s-product of the fields $\varphi_i:=\alpha_i\varphi$, i.e., $\varphi_{\underset{\sim}{\alpha}}=(\alpha_1\varphi)s(\alpha_2\varphi)s\cdots s(\alpha_K\varphi)$ (see Ref. 4 for details).

From the very rules of s-products we get immediately for a commutator

$$[\varphi_{\underset{\sim}{\alpha}}(x),\varphi_{\underset{\sim}{\beta}}(y)]=(\alpha_1\beta_1[\varphi(x),\varphi(y)])s\cdots s(\alpha_K\beta_K[\varphi(x),\varphi(y)])$$
$$=[\varphi(x),\varphi(y)]_{\underline{\alpha\beta}}\quad\text{with}\quad\underline{\alpha\beta}=(\alpha_1\beta_1,\ldots,\alpha_K\beta_K), \qquad (2.10)$$

respectively for a double commutator

$$\left[\left[\varphi_{\underset{\sim}{\alpha}}\begin{pmatrix}f_+\\f_-\end{pmatrix},\varphi_{\underset{\sim}{\beta}}\begin{pmatrix}g_+\\g_-\end{pmatrix}\right]\varphi_{\underset{\sim}{\gamma}}\begin{pmatrix}h_+\\h_-\end{pmatrix}\right]=\langle f_-g_-\rangle\left\{\langle g_+h_+\rangle\varphi_{\underset{\sim}{\delta}}\begin{pmatrix}f_+\\h_-\end{pmatrix}-\langle f_+h_+\rangle\varphi_{\underset{\sim}{\delta}}\begin{pmatrix}g_+\\h_-\end{pmatrix}\right\}$$
$$+\langle f_+g_+\rangle\left\{\langle g_-h_-\rangle\varphi_{\underset{\sim}{\delta}}\begin{pmatrix}h_+\\f_-\end{pmatrix}-\langle f_-g_-\rangle\varphi_{\underset{\sim}{\delta}}\begin{pmatrix}h_+\\g_-\end{pmatrix}\right\}, \qquad (2.11)$$

with $\underset{\sim}{\delta}=\overline{\alpha\beta\gamma}$

Later on we shall show in a general setting the analoga to these two equations as a starting point of our proof!

Starting from $\Phi_1:=\Phi:=\varphi_{\underset{\sim}{\alpha}}$, respectively $\Delta_2(x,y):=[\varphi_{\underset{\sim}{\alpha}}(x),\varphi_{\underset{\sim}{\alpha}}(y)]=[\varphi(x),\varphi(y)]_{\overline{\alpha^2}}$, we define a sequence of field operators $\Phi_{2k-1}=\varphi_{\overline{\alpha^{2k-1}}}$, resp. commutator functions $\Delta_{2k}(x,y):=[\Phi_{2k-1}(x),\Phi_1(y)]$ for all $k\in\mathbf{N}$. Obviously we have

$$[\Phi_{2k-1}(x),\Phi_{2l-1}(y)]=\Delta_{2(k+l-1)}(x,y) \qquad (2.12)$$

and

$$\left[\left[\Phi_{2k-1}\begin{pmatrix}f_+\\f_-\end{pmatrix},\Phi_{2l-1}\begin{pmatrix}g_+\\g_-\end{pmatrix}\right]\Phi_{2m-1}\begin{pmatrix}h_+\\h_-\end{pmatrix}\right]=\langle f_-g_-\rangle\left\{\langle g_+h_+\rangle\Phi_n\begin{pmatrix}f_+\\h_-\end{pmatrix}-\langle f_+h_+\rangle\Phi_n\begin{pmatrix}g_+\\h_-\end{pmatrix}\right\}$$
$$+\langle f_+g_+\rangle\left\{\langle g_-h_-\rangle\Phi_n\begin{pmatrix}h_+\\f_-\end{pmatrix}-\langle f_-g_-\rangle\Phi_n\begin{pmatrix}h_+\\g_-\end{pmatrix}\right\} \qquad (2.13)$$

with $n=2(k+l+m)-3$.

Let V_n, resp. W_n, denote the n-point functions of φ, resp. of the s-product $\varphi_{\underset{\sim}{\alpha}}$. Because the underlying chiral Fermi field is a free field, all odd n-point functions have to vanish, i.e., $V_{2k-1}\equiv 0\equiv W_{2k-1}$ and by the governing rules of s-products we have for the even truncated n-point functions the relation $W_{2n}^T=c_{2n}V_{2n}^T$ with $c_{2n}=\Sigma_i\alpha_i^{2n}$. From the sequence $\{\Phi_{2k-1}|k\in\mathbf{N}\}$ we can reconstruct the c_n without referring to $\underset{\sim}{\alpha}$ as follows:

By using Eqs. (2.13) and (2.12) we get for any $(2n-1)$-fold commutator

$$[[\cdots[\Phi(x_1),\Phi(x_2)]\cdots]\Phi(x_{2n})]\sim\Delta_{2n}\quad(\text{sum of }2^{2n-2}\text{ terms!}). \qquad (2.14)$$

By scaling covariance we have for the vacuum expectation values

$$(\Omega,\Delta_{2n}(x,y)\Omega)=c_{2n}\langle[\varphi(x),\varphi(y)]\rangle. \qquad (2.15)$$

Because the algebraic relations (2.12), (2.13) and (2.7), (2.9) have an identical structure we get

$$(\Omega,[[\cdots[\Phi(x_1),\Phi(x_2)]\cdots]\Phi(x_{2n})]\Omega)=c_{2n}\langle[[\cdots[\varphi(x_1),\varphi(x_2)]\cdots]\varphi(x_{2n})]\rangle. \tag{2.16}$$

and this implies $W^T_{2n}=c_{2n}V^T_{2n}$! It is another task to reconstruct $\underset{\sim}{\alpha}$, but in Sec. VI we shall describe a very effective method for this job.

III. LEMMATA ON COMMUTATORS

In this section we want to exhibit the structure of commutators and double commutators. But in the course of our proof we shall encounter not only the field Φ, but also new fields which live in the same Hilbert space, are relatively local to Φ, and fulfill the assumptions **A**.

Lemma 1: Let A_1 and A_2 be two fields with scaling dimension d, relatively local to Φ, and fulfilling the assumptions **A**. For the commutator we have

$$\begin{aligned}[A_1(x),A_2(y)]&=(-1)^{(d-1)/2}\delta^{(d-1)}(y_- - x_-)B^{(+)}_{12}(x_+,y_+)\\&\quad+(-1)^{(d-1)/2}\delta^{(d-1)}(y_+ - x_+)B^{(-)}_{12}(x_-,y_-).\end{aligned} \tag{3.1}$$

Proof: (a) From space- and timelike commutativity $[A_1(x),A_2(y)]=0$ if $(y-x)^2\neq 0$ and scale covariance with dimension d we get

$$[A_1(x),A_2(y)]\Omega(y_+-x_+)^d(y_- - x_-)^d\equiv 0. \tag{3.2}$$

By the Reeh–Schlieder theorem this implies

$$\begin{aligned}[A_1(x),A_2(y)]&=\delta^{(d-1)}(y_- - x_-)B^{(+)}_{12}(x_+,y_+)+\delta^{(d-1)}(y_+-x_+)B^{(-)}_{12}(x_-,y_-)\\&\quad+\sum_{k=0}^{d-2}\left\{\delta^{(k)}(y_- - x_-)B^{(+)}_k\left(x_+,y_+,\frac{x_-+y_-}{2}\right)\right.\\&\quad\left.+\delta^{(k)}(y_+-x_+)B^{(-)}_k\left(x_-,y_-,\frac{x_++y_+}{2}\right)\right\}\end{aligned} \tag{3.3}$$

and because of scale covariance the coefficients $B^{(+)}_k$, resp. $B^{(-)}_k$, have to depend on $(x_- + y_-)/2$, resp. $(x_+ + y_+)/2$, too. The corresponding scaling dimension is $d-k-1$.

(b) To prove Lemma 1 we have to get rid of the terms $\Sigma_{k=0}^{d-2}\{\cdots\}$! These terms show up only if $d\geqslant 2$.

Let $F(x)=f_+(x_+)f_-(x_-)$ and $G(y)=g_+(y_+)g_-(y_-)$ with

(i) supp $f_+\cap$ supp $g_+=\varnothing$ [This eliminates all terms with an upper index $(-)$!]
(ii) supp $g_-\subseteq[-1,1]$.
(iii) $f_-\in\mathcal{S}(\mathbf{R})$ such that $f_-(x_-)\equiv 1$ on $[-1,1]$.

To evaluate integrals of the form $\int\int B((x_-+y_-)/2)\delta^{(k)}(y_- - x_-)f_-(x_-)g_-(y_-)dx_-dy_-$ we introduce new variables $u=(x_-+y_-)/2$ and $\xi=y_- - x_-$:

$$\begin{aligned}&\int\int B\left(\frac{x_-+y_-}{2}\right)\delta^{(k)}(y_- - x_-)f_-(x_-)g_-(y_-)dx_-dy_-\\&=\int B(u)\int\delta^{(k)}(\xi)f_-(u-\xi/2)g_-(u+\xi/2)d\xi\,du\\&=\int B(u)(-\partial_\xi)^k f_-(u-\xi/2)g_-(u+\xi/2)\Big|_{\xi=0}du\\&=(-\tfrac{1}{2})^k B(\partial^k g_-)\end{aligned} \tag{3.4}$$

because $f_- \equiv 1$ on the support of g_-. Therefore, we have

$$[A_1(F),A_2(G)] = \sum_{k=0}^{d-2} \left(-\frac{1}{2}\right)^k B_k^{(+)}(f_+,g_+,\partial^k g_-). \tag{3.5}$$

We remark that space- and timelike commutativity acts as a cutoff for f_-. Therefore we can replace f_- by $(f_-)_\mu(x_-) = f_-(x_-/\mu)$ with $\mu \geqslant 1$. This does not change the commutator because we still have $(f_-)_\mu(x_-) \equiv 1$ if $|x_-| \leqslant 1$, i.e.,

$$[A_1(F),A_2(G)] = [A_1(F_{(1,\mu)}),A_2(G)] \quad \text{if } \mu \geqslant 1, \tag{3.6}$$

but for $d>2$ we know by our assumption (**A4**)

$$\|A_i(F_{(1,\mu)})\| = \frac{1}{(\mu)^{d/2-1}} \|A_i(F)\| \to 0 \quad \text{as } \mu \to \infty \quad \text{for } i=1,2. \tag{3.7}$$

As a result of our assumptions we get

$$0 = \sum_{k=0}^{d-2} \left(-\frac{1}{2}\right)^k B_k^{(+)}(f_+,g_+,\partial^k g_-). \tag{3.8}$$

We can also interchange the roles of f_- and g_-, i.e., we put $\hat{F}(x) = f_+(x_+)g_-(x_-)$ and $\hat{G}(y) = g_+(y_+)f_-(y_-)$. Then as before we get for all $\mu \geqslant 1$

$$[A_1(\hat{F}),A_2(\hat{G})] = \sum_{k=0}^{d-2} \left(\frac{1}{2}\right)^k B_k^{(+)}(f_+,g_+,\partial^k g_-) = [A_1(\hat{F}),A_2(\hat{G}_{(1,\mu)})], \tag{3.9}$$

and therefore the additional equation

$$0 = \sum_{k=0}^{d-2} \left(\frac{1}{2}\right)^k B_k^{(+)}(f_+,g_+,\partial^k g_-). \tag{3.10}$$

Therefore, in the case $d=3$ we have

$$B_0^{(+)}(f_+,g_+,g_-) = 0 = B_1^{(+)}(f_+,g_+,\partial g_-), \tag{3.11}$$

which solves our task and for $d=5$ we get the two equations

$$B_0^{(+)}(f_+,g_+,g_-) + \tfrac{1}{4} B_2^{(+)}(f_+,g_+,\partial^2 g_-) = 0, \tag{3.12}$$

$$B_1^{(+)}(f_+,g_+,\partial g_-) + \tfrac{1}{4} B_3^{(+)}(f_+,g_+,\partial^3 g_-) = 0. \tag{3.13}$$

To get more (and, in fact, sufficiently many) equations, we consider the modified commutators $[A_1(x),A_2(y)](y_- - x_-)^l$.

Let $(\mathbf{X}^m f_-)(x_-) := x_-^m f_-(x_-)$. Then

$$\int\int \left[A_1\begin{pmatrix} f_+ \\ x_- \end{pmatrix}, A_2\begin{pmatrix} g_+ \\ y_- \end{pmatrix}\right](y_- - x_-)^l f_-(x_-) g_-(y_-) dx_- dy_-$$

$$= \sum_{m=0}^{l} \binom{l}{m} (-1)^m \left[A_1\begin{pmatrix} f_+ \\ \mathbf{X}^m f_- \end{pmatrix}, A_2\begin{pmatrix} g_+ \\ \mathbf{X}^{l-m} g_- \end{pmatrix}\right] \tag{3.14}$$

but

$$\left\| A_i\begin{pmatrix} f_+ \\ \mathbf{X}^m(f_-)_\mu \end{pmatrix}\right\| = \mu^m \left\| A_i\begin{pmatrix} f_+ \\ (\mathbf{X}^m f_-)_\mu \end{pmatrix}\right\| = \frac{1}{\mu^{d/2-1-m}}\left\| A_i\begin{pmatrix} f_+ \\ \mathbf{X}^m f_- \end{pmatrix}\right\| \xrightarrow{\mu\to\infty} 0 \quad \text{if } 0 \leqslant m < d/2-1, \tag{3.15}$$

and, therefore, as long as $l<d/2-1$, all the commutators (3.14) vanish. Evaluating the corresponding rhs we get

$$0=\sum_{k=l\geqslant 0}^{d-2}\left(-\frac{1}{2}\right)^k \frac{k!}{(k-l)!} B_k^{(+)}(f_+,g_+,\partial^{k-l}g_-), \tag{3.16}$$

where we have used

$$\partial_\xi^k \xi^l h(\xi)|_{\xi=0} = \begin{cases} 0, & \text{if } l>k, \\ \dfrac{k!}{(k-l)!}\partial_\xi^{k-l}h(0), & \text{if } l\leqslant k, \end{cases} \tag{3.17}$$

and h is of the form $h(\xi)=f_-(u-\xi/2)g_-(u+\xi/2)$. As before we can interchange f_- and g_- and end up with

$$0=\sum_{k=l\geqslant 0}^{d-2}\left(\frac{1}{2}\right)^k \frac{k!}{(k-l)!} B_k^{(+)}(f_+,g_+,\partial^{k-1}g_-), \tag{3.18}$$

i.e., we get separate equations for even and odd k's. For d odd we have $l=0,1,...,(d-3)/2$, and therefore $d-1$ independent equations for the coefficients $B_0^{(+)},\dots,B_{d-2}^{(+)}$. In the case $d=5$ the possible values of l are 0 and 1. So beside (3.12) and (3.13) we get the two further equations,

$$B_1^{(+)}(f_+,g_+,g_-)+\tfrac{3}{4}B_3^{(+)}(f_+,g_+,\partial^2 g_-)=0, \tag{3.19}$$

$$B_2^{(+)}(f_+,g_+,\partial g_-)=0, \tag{3.20}$$

which altogether imply $B_k^{(+)}(f_+,g_+,\partial^k g_-)=0,\ k=0,1,2,3,4.$

Remark: Because the operators $B_k^{(+)}(f_+,g_+,g_-),\ k=0,...,d-2$, have scaling dimension $d-k-1$ wrt u, an equation like $B_k^{(+)}(f_+,g_+,\partial^m g_-)=0$ implies $B_k^{(+)}(f_+,g_+,g_-)=0$ as can be seen from the two-point function.

Now we interchange the coordinates x_+,y_+ with x_-,y_-. By analogous reasoning we get $B_k^{(-)}(f_-,g_-,\partial^k g_+)=0$, $k=0,1,2,3,4$, as long as $\operatorname{supp} f_-\cap\ \operatorname{supp} g_-=\varnothing$.

(c) Up to now we have shown

$$[A_1(x),A_2(y)]=\delta^{(d-1)}(y_--x_-)B_{12}^{(+)}(x_+,y_+)+\delta^{(d-1)}(y_+-x_+)B_{12}^{(-)}(x_-,y_-) + \sum_{k,l=0}^{d-2}\underbrace{\delta^{(k)}(y_+-x_+)\delta^{(l)}(y_--x_-)}_{\text{contact terms!}}B_{kl}\left(\frac{x_++y_+}{2},\frac{x_-+y_-}{2}\right), \tag{3.21}$$

because part (b) of our proof relied heavily on the fact that either f_+ and g_+, or f_- and g_-, have disjoint supports!

In a first step we show for $m=0,...,(d-3)/2$

$$\lim_{\lambda\to\infty} B_{12}^{(\pm)}(\mathbf{X}^m(f)_\lambda,g)=0=\lim_{\lambda\to\infty} B_{12}^{(\pm)}(f,\mathbf{X}^m(g)_\lambda). \tag{3.22}$$

To prove this statement we start with

$$[A_1(x), A_2(y)](y_- - x_-)^{d-1} = (d-1)!\,\delta(y_- - x_-)B_{12}^{(+)}(x_+, y_+) + \delta^{(d-1)}(y_+ - x_+)B_{12}^{(-)}(x_-, y_-)(y_- - x_-)^{d-1} = \sum_{l=0}^{d-1}\binom{d-1}{l}(-1)^l[x_-^{d-1-l}A_1(x), y_-^l A_2(y)], \tag{3.23}$$

or, written with test functions,

$$\int\int\left[A_1\binom{f_+}{x_-}, A_2\binom{g_+}{y_-}\right](y_- - x_-)^{d-1} f_-(x_-)g_-(y_-)\,dx_-\,dy_- = \sum_{l=0}^{d-1}\binom{d-1}{l}(-1)^l\left[A_1\binom{f_+}{\mathbf{X}^{d-1-l}f_-}, A_2\binom{g_+}{\mathbf{X}^l g_-}\right] = (d-1)!\int f_-g_-(u)\,du\,B_{12}^{(+)}(f_+, g_+) + (-1)^{(d-1)/2}\int f_+^{((d-1)/2)}g_+^{((d-1)/2)}(u)\,du \times\int\int B_{12}^{(-)}(x,y)(y-x)^{d-1}f_-(x)g_-(y)\,dx\,dy. \tag{3.24}$$

Therefore we have the bound

$$\|B_{12}^{(+)}(f_+, g_+)\|(d-1)!\left|\int f_-g_-(u)du\right| \leq \sum_{l=0}^{d-1}\binom{d-1}{l}\left\|\left[A_1\binom{f_+}{\mathbf{X}^{d-1-l}f_-}, A_2\binom{g_+}{\mathbf{X}^l g_-}\right]\right\| + \left|\int f_+^{((d-1)/2)}g_+^{((d-1)/2)}(u)du\right| \times\left\|\int\int B_{12}^{(-)}(x,y)(y-x)^{d-1}f_-(x)g_-(y)\,dx\,dy\right\|. \tag{3.25}$$

Inserting $\mathbf{X}^m(f_+)_\lambda$ with $m = 1,...,(d-3)/2$ instead of f_+, using bounds similar to (3.15), and doing the limit $\lambda\to\infty$ gives

$$\lim_{\lambda\to\infty} B_{12}^{(+)}(\mathbf{X}^m(f_+)_\lambda, g_+) = 0.$$

The other equations of the statement (3.22) can be proven in an analogous way.

To show that all contact terms

$$B_{kl}\left(\frac{x_+ + y_+}{2}, \frac{x_- + y_-}{2}\right) \quad \text{for } k,l = 0,...,d-2$$

have to vanish, we start from

$$[A_1(x), A_2(y)](y_+ - x_+)^{m_+}(y_- - x_-)^{m_-}$$

for suitably chosen exponents m_+, resp. m_-. Let us demonstrate this for the simplest case $d = 3$:

$$\int\int \left[A_1\begin{pmatrix} f_+ \\ x\end{pmatrix}, A_2\begin{pmatrix} g_+ \\ y\end{pmatrix}\right](y-x)f_-(x)g_-(y)dxdy$$

$$=\left[A_1\begin{pmatrix} f_+ \\ f_-\end{pmatrix}, A_2\begin{pmatrix} g_+ \\ \mathbf{X}g_-\end{pmatrix}\right]-\left[A_1\begin{pmatrix} f_+ \\ \mathbf{X}f_-\end{pmatrix}, A_2\begin{pmatrix} g_+ \\ g_-\end{pmatrix}\right]$$

$$=B_{12}^{(+)}(f_+,g_+)\int (f_-g'_- - f'_-g_-)(u)du-\{B_{12}^{(-)}(f_-,\mathbf{X}g_-)-B_{12}^{(-)}(\mathbf{X}f_-,g_-)\}$$

$$\times\int f'_+g'_+(u)\,du \quad -B_{01}(f_+g_+,f_-g_-)+\frac{1}{2}B_{11}(f_+g'_+-f'_+g_+,f_-g_-).$$

By choosing $g_\pm\in\mathcal{D}([-1,1]$ and $f_\pm\in\mathcal{S}(\mathbf{R})$ with $f(x)\equiv 1$ on $[-1,1]$ we get

$$=-B_{01}(g_+,g_-)+\tfrac{1}{2}B_{11}(g'_+,g_-). \tag{3.26}$$

Now we replace f_+ by $(f_+)_\lambda$. For $\lambda\to\infty$, the lhs of (3.26) goes to zero and we have

$$0=-B_{01}(g_+,g_-)+\tfrac{1}{2}B_{11}(g'_+,g_-), \tag{3.27}$$

but by interchanging f_+ with g_+ we have also

$$0=-B_{01}(g_+,g_-)-\tfrac{1}{2}B_{11}(g'_+,g_-), \tag{3.28}$$

and therefore

$$B_{01}(g_+,g_-)=0=B_{11}(g'_+,g_-). \tag{3.29}$$

Interchanging the $+$ and $-$ coordinates we get

$$B_{10}(g_+,g_-)=0=B_{11}(g_+,g'_-). \tag{3.30}$$

Finally starting from

$$\left[A_1\begin{pmatrix} f_+ \\ f_-\end{pmatrix}, A_2\begin{pmatrix} g_+ \\ g_-\end{pmatrix}\right]=-B_{12}^{(+)}(f_+,g_+)\int f'_-g'_-(u)du-B_{12}^{(-)}(f_-,g_-)\int f'_+g'_+(u)\,du$$

$$+B_{00}(f_+g_+,f_-g_-)+\tfrac{1}{2}B_{01}(f_+g_+,f'_-g_- - f_-g'_-)$$

$$+\tfrac{1}{2}B_{10}(f'_+g_+-f_+g'_+,f_-g_-)+\tfrac{1}{4}B_{11}(f'_+g_+-f_+g'_+,f'_-g_- - f_-g'_-),$$

using the above methods, we end up with

$$B_{00}(g_+,g_-)=0. \tag{3.31}$$

For higher scaling dimensions d the calculations are a little bit cumbersome but not difficult. This finishes the proof of Lemma 1.

For the sequel it is convenient to write Lemma 1 in the form

$$[A_1(F),A_2(G)]=\langle f_-g_-\rangle B_{12}^{(+)}(f_+,g_+)+\langle f_+g_+\rangle B_{12}^{(-)}(f_-,g_-) \tag{3.32}$$

with $F=f_+\otimes f_-$, $G=g_+\otimes g_-$ and $\langle fg\rangle$ is given by definition (2.6).

Lemma 2: Let A_i, $i=1,2,3$, be three fields with scaling dimension d, relatively local to Φ, and fulfilling the assumptions **A**. For the double commutator we have

$$[[A_1(F),A_2(G)]A_3(H)]=\langle f_-g_-\rangle\left\{\langle g_+h_+\rangle C_1\begin{pmatrix} f_+\\ h_-\end{pmatrix}-\langle f_+h_+\rangle C_2\begin{pmatrix} g_+\\ h_-\end{pmatrix}\right\}$$
$$+\langle f_+g_+\rangle\left\{\langle g_-h_-\rangle C_3\begin{pmatrix} h_+\\ f_-\end{pmatrix}-\langle f_-h_-\rangle C_4\begin{pmatrix} h_+\\ g_-\end{pmatrix}\right\}, \qquad (3.33)$$

and the local fields C_j fulfill the same assumptions as the A_i.

Proof: (a) From Lemma 1 we know

$$[[A_1(F),A_2(G)]A_3(H)]=\langle f_-g_-\rangle[B_{12}^{(+)}(f_+,g_+),A_3(H)]+\langle f_+g_+\rangle[B_{12}^{(-)}(f_-,g_-),A_3(H)], \qquad (3.34)$$

and by the Jacobi identity

$$=[[A_1(F),A_3(H)]A_2(G)]+[[A_3(H),A_2(G)]A_1(F)]$$
$$=\langle f_-h_-\rangle[B_{13}^{(+)}(f_+,h_+),A_2(G)]+\langle f_+h_+\rangle[B_{13}^{(-)}(f_-,h_-),A_2(G)]+\langle h_-g_-\rangle$$
$$\times[B_{32}^{(+)}(h_+,g_+),A_1(F)]+\langle h_+g_+\rangle[B_{32}^{(-)}(h_-,g_-),A_1(F)].$$

Therefore each term on the rhs of (3.34) does contain a factor $\langle f_-g_-\rangle$, resp. $\langle f_+g_+\rangle$, combined with a factor out of the set $\{\langle f_-h_-\rangle,\langle f_+h_+\rangle,\langle g_-h_-\rangle,\langle g_+h_+\rangle\}$. On the other hand, $[B_{12}^{(+)}(f_+,g_+),A_3(H)]$ no longer depends on f_- and g_-! So only the combinations $\langle f_-g_-\rangle\langle f_+h_+\rangle$ and $\langle f_-g_-\rangle\langle g_+h_+\rangle$ can show up. Therefore

$$[[A_1(F),A_2(G)]A_3(H)]=\langle f_-g_-\rangle\left\{\langle g_+h_+\rangle C_1\begin{pmatrix} f_+\\ h_-\end{pmatrix}-\langle f_+h_+\rangle C_2\begin{pmatrix} g_+\\ h_-\end{pmatrix}\right\}$$
$$+\langle f_+g_+\rangle\left\{\langle g_-h_-\rangle C_3\begin{pmatrix} h_+\\ f_-\end{pmatrix}-\langle f_-h_-\rangle C_4\begin{pmatrix} h_+\\ g_-\end{pmatrix}\right\}. \qquad (3.35)$$

(b) We can prepare $C_1\binom{f_+}{h_-}$ in the following way:

We shift the test functions f_-, g_-, g_+, and h_+ by a and in the limit $a\to\infty$ we get

$$C_1\begin{pmatrix} f_+\\ h_-\end{pmatrix}=\lim_{a\to\infty}\left[\left[A_1\begin{pmatrix} f_+\\ \{h_-\}_a\end{pmatrix},\quad A_2\begin{pmatrix} \{g_+\}_a\\ \{g_-\}_a\end{pmatrix}\right]A_3\begin{pmatrix} \{h_+\}_a\\ h_-\end{pmatrix}\right] \qquad (3.36)$$

because for fixed f_+ and h_-

$$\lim_{a\to\infty}\langle f_+\{h_+\}_a\rangle=\lim_{a\to\infty}\int f_+^{((d-1)/2)}(u)h_+^{((d-1)/2)}(u-a)\,du=0,$$

and so on. The other operators C_i can be prepared in an analogous manner. From this explicit representation it is easy to see that all $C_i(x)$ are local fields and fulfill assumption **A** again. This proves Lemma 2.

Corollary 3: If in Lemma 2 all three fields A_i are equal, then the four fields C_j are equal, too.

Proof: By Lemma 2 and the Jacobi identity we have

$$0=[[A(F),A(G)]A(H)]+[[A(G),A(H)]A(F)]+[[A(H),A(F)]A(G)]$$
$$=\langle f_-g_-\rangle\langle g_+h_+\rangle\{C_1-C_4\}\begin{pmatrix} f_+\\ h_-\end{pmatrix}-\langle f_-g_-\rangle\langle f_+h_+\rangle\{C_2-C_3\}\begin{pmatrix} g_+\\ h_-\end{pmatrix}$$
$$+\langle f_+g_+\rangle\langle g_-h_-\rangle\{C_3-C_2\}\begin{pmatrix} h_+\\ f_-\end{pmatrix}-\langle f_+g_+\rangle\langle f_-h_-\rangle\{C_4-C_3\}\begin{pmatrix} h_+\\ g_-\end{pmatrix}$$

$$+\langle g_+h_+\rangle\langle f_-h_-\rangle\{C_3-C_2\}\binom{f_+}{g_-}+\langle g_-h_-\rangle\langle f_+h_+\rangle\{C_1-C_4\}\binom{g_+}{f_-}.$$

By a suitable limit procedure we can pick out every one of the six terms in curly brackets and therefore $C_1=C_2=C_3=C_4$.

IV. THE DEFINING SEQUENCE FOR MULTIPLE COMMUTATORS

Lemmas 1 and 2 together with the corollary enable us to calculate higher commutators of the field Φ we started with.

Lemma 4: Let Φ fulfill the assumptions (**A**). Then there exists a sequence of field operators

$$\Phi_1,\Phi_3,\Phi_5,\dots,\Phi_{2k-1},\dots,$$

and a sequence of commutator functions (bilocal operators)

$$\Delta_2,\Delta_4,\Delta_6,\dots,\Delta_{2k},\dots,$$

such that

(i) all $\Phi_{2k-1},k\in\mathbf{N}$, fulfill (**A**) again and are relatively local to Φ;

(ii) all $\Delta_{2k},k\in\mathbf{N}$, are of the form

$$\Delta_{2k}(F,G)=\langle f_-g_-\rangle B_{2k}^{(+)}(f_+,g_+)+\langle f_+g_+\rangle B_{2k}^{(-)}(f_-,g_-), \tag{4.1}$$

and the Δ_{2k} are antisymmetric, i.e., $\Delta_{2k}(F,G)=-\Delta_{2k}(G,F)$;

(iii)

$$[\Phi_{2k-1}(F),\Phi_{2l-1}(G)]=\Delta_{2(k+l-1)}(F,G); \tag{4.2}$$

(iv)

$$[\Delta_{2k}(F,G),\Phi_{2l-1}(H)]=\langle f_-g_-\rangle\langle g_+h_+\rangle\Phi_{2(k+l)-1}\binom{f_+}{h_-}-\langle f_-g_-\rangle\langle f_+h_+\rangle\Phi_{2(k+l)-1}\binom{g_+}{h_-}$$
$$+\langle f_+g_+\rangle\langle g_-h_-\rangle\Phi_{2(k+l)-1}\binom{h_+}{f_-}-\langle f_+g_+\rangle\langle f_-h_-\rangle\Phi_{2(k+l)-1}\binom{h_+}{g_-}. \tag{4.3}$$

Proof: We want to prove the lemma by an inductive definition of the two sequences.

(1) Let $\Phi_1:=\Phi$ and let $\Delta_2(F,G):=[\Phi(F),\Phi(G)]$. The antisymmetry of Δ_2 is obvious.

(2) Assume we have defined up to $n\in\mathbf{N}$ field operators $\Phi_1,\Phi_3,\dots,\Phi_{2n-1}$ relatively local to Φ and antisymmetric commutator functions $\Delta_2,\Delta_4,\dots,\Delta_{2n}$ with the following two properties:

(a)

$$[\Delta_{2(m-k)}(F,G),\Phi_{2k-1}(H)]=\langle f_-g_-\rangle\langle g_+h_+\rangle\Phi_{2m-1}\binom{f_+}{h_-}-\langle f_-g_-\rangle\langle f_+h_+\rangle\Phi_{2m-1}\binom{g_+}{h_-}$$
$$+\langle f_+g_+\rangle\langle g_-h_-\rangle\Phi_{2m-1}\binom{h_+}{f_-}-\langle f_+g_+\rangle\langle f_-h_-\rangle\Phi_{2m-1}\binom{h_+}{g_-}, \tag{4.4}$$

(b)

$$[\Phi_{2(m-k)-1}(F),\Phi_{2k-1}(G)]=\Delta_{2m}(F,G) \tag{4.5}$$

valid for all $m\leqslant n$ and $k=1,\dots,m$.

(3) To define Φ_{2n+1} we proceed as follows.

(α) By Lemma 2 we know

$$[\Delta_{2n}(F,G),\,\Phi_1(H)]=[[\Phi_{2(n-k)}(F),\Phi_{2k-1}(G)]\Phi_1(H)]$$
$$=\langle f_-g_-\rangle\langle g_+h_+\rangle C_1\binom{f_+}{h_-}-\langle f_-g_-\rangle\langle f_+h_+\rangle C_2\binom{g_+}{h_-}$$
$$+\langle f_+g_+\rangle\langle g_-h_-\rangle C_3\binom{h_+}{f_-}-\langle f_+g_+\rangle\langle f_-h_-\rangle C_4\binom{h_+}{g_-}, \tag{4.6}$$

but the antisymmetry $\Delta_{2n}(F,G)=-\Delta_{2n}(G,F)$ implies $C_1=C_2$ and $C_3=C_4$.

(β) Now we use the Jacobi identity

$$0=[[\Phi_{2(n-k)+1}(F),\,\Phi_{2k-1}(G)]\Phi_1(H)]+[[\Phi_{2k-1}(G),\,\Phi_1(H)]\Phi_{2(n-k)+1}(F)]$$
$$+[[\Phi_1(H),\,\Phi_{2(n-k)+1}(F)]\Phi_{2k-1}(G)]$$
$$=[\Delta_{2n}(F,G),\,\Phi_1(H)]+[\Delta_{2k}(G,H),\,\Phi_{2(n-k)+1}(F)]+[\Delta_{2(n-k+1)}(H,F),\,\Phi_{2k-1}(G)]$$

(Δ_{2n},Δ_{2k}, and $\Delta_{2(n-k+1)}$ are antisymmetric by assumption)

$$=\langle f_-g_-\rangle\langle g_+h_+\rangle\{C_1-D_3\}\binom{f_+}{h_-}-\langle f_-g_-\rangle\langle f_+h_+\rangle\{C_1-E_3\}\binom{g_+}{h_-}$$
$$+\langle f_+g_+\rangle\langle g_-h_-\rangle\{C_3-D_1\}\binom{h_+}{f_-}-\langle f_+g_+\rangle\langle f_-h_-\rangle\{C_3-E_1\}\binom{h_+}{g_-}$$
$$+\langle g_+h_+\rangle\langle f_-h_-\rangle\{D_3-E_1\}\binom{f_+}{g_-}+\langle g_-h_-\rangle\langle f_+h_+\rangle\{D_1-E_3\}\binom{g_+}{f_-},$$

where C_i, D_i, and E_i are the field operators corresponding to the three commutators. As in the proof of Corollary 3 we must have $C_1=C_3=D_1=D_3=E_1=E_3=:\Phi_{2n+1}$, and we take this as definition of Φ_{2n+1}. This proves (a) for the case $m=n+1$.

(4) As the definition of Δ_{2n+2} we take

$$\Delta_{2n+2}(F,G)=[\Phi_{2n+1}(F),\Phi_1(G)] \tag{4.7}$$

and, because of Lemma 1, this is meaningful and guarantees the right structure as given in (4.1). We still have to show the antisymmetry of Δ_{2n+2} and the relation

$$\Delta_{2n+2}(F,G)=[\Phi_{2(n-k)+3}(F),\,\Phi_{2k-1}(G)]\quad\text{for all}\quad k=1,2,\ldots,2n+1.$$

From part (3) we know already

$$[\Delta_{2k}(F,G),\,\Phi_{2(n-k)+1}(H)]=\langle f_-g_-\rangle\langle g_+h_+\rangle\Phi_{2n+1}\binom{f_+}{h_-}-\langle f_-g_-\rangle\langle f_+h_+\rangle\Phi_{2n+1}\binom{g_+}{h_-}$$
$$+\langle f_+g_+\rangle\langle g_-h_-\rangle\Phi_{2n+1}\binom{h_+}{f_-}-\langle f_+g_+\rangle\langle f_-h_-\rangle\Phi_{2n+1}\binom{h_+}{g_-},$$

and therefore

$$
\begin{aligned}
&[[\Delta_{2k}(F,G),\,\Phi_{2(n-k)+1}(U)]\Phi_1(V)]\\
&=\langle f_-g_-\rangle\langle g_+u_+\rangle\left[\Phi_{2n+1}\begin{pmatrix}f_+\\u_-\end{pmatrix},\,\Phi_1(V)\right]-\langle f_-g_-\rangle\langle f_+u_+\rangle\left[\Phi_{2n+1}\begin{pmatrix}g_+\\u_-\end{pmatrix},\,\Phi_1(V)\right]\\
&\quad+\langle f_+g_+\rangle\langle g_-u_-\rangle\left[\Phi_{2n+1}\begin{pmatrix}u_+\\f_-\end{pmatrix},\,\Phi_1(V)\right]-\langle f_+g_+\rangle\langle f_-u_-\rangle\left[\Phi_{2n+1}\begin{pmatrix}u_+\\g_-\end{pmatrix},\,\Phi_1(V)\right]\\
&=\langle f_-g_-\rangle\langle g_+u_+\rangle\Delta_{2n+2}\left(\begin{pmatrix}f_+\\u_-\end{pmatrix},V\right)-\langle f_-g_-\rangle\langle f_+u_+\rangle\Delta_{2n+2}\left(\begin{pmatrix}g_+\\u_-\end{pmatrix},V\right)\\
&\quad+\langle f_+g_+\rangle\langle g_-u_-\rangle\Delta_{2n+2}\left(\begin{pmatrix}u_+\\f_-\end{pmatrix},V\right)-\langle f_+g_+\rangle\langle f_-u_-\rangle\Delta_{2n+2}\left(\begin{pmatrix}u_+\\g_-\end{pmatrix},V\right)
\end{aligned}\tag{4.8}
$$

and by the Jacobi identity

$$
\begin{aligned}
&=[[\Delta_{2k}(F,G),\,\Phi_1(V)]\Phi_{2(n-k)+1}(U)]+\underbrace{[[\Phi_1(V),\,\Phi_{2(n-k)+1}(U)]}_{\Delta_{2(n-k+1)}(V,U)},\Delta_{2k}(F,G)]\\
&=\langle f_-g_-\rangle\langle g_+v_+\rangle\left[\Phi_{2k+1}\begin{pmatrix}f_+\\v_-\end{pmatrix},\,\Phi_{2(n-k)+1}(U)\right]-\langle f_-g_-\rangle\langle f_+v_+\rangle\left[\Phi_{2k+1}\begin{pmatrix}g_+\\v_-\end{pmatrix},\,\Phi_{2(n-k)+1}(U)\right]\\
&\quad+\langle f_+g_+\rangle\langle g_-v_-\rangle\left[\Phi_{2k+1}\begin{pmatrix}v_+\\f_-\end{pmatrix},\,\Phi_{2(n-k)+1}(U)\right]-\langle f_+g_+\rangle\langle f_-v_-\rangle\\
&\quad\times\left[\Phi_{2k+1}\begin{pmatrix}v_+\\g_-\end{pmatrix},\,\Phi_{2(n-k)+1}(U)\right]+[\Delta_{2(n-k+1)}(V,U),\Delta_{2k}(F,G)].
\end{aligned}
$$

Let us denote $[\Phi_{2k+1}(F),\,\Phi_{2(n-k)+1}(G)]=:\hat{\Delta}(F,G)$ for the moment. Then we can rewrite Eq. (4.8) as

$$
\begin{aligned}
[\Delta_{2(n-k+1)}(V,U),\Delta_{2k}(F,G)]=\langle f_-g_-\rangle\Bigg\{&\langle g_+u_+\rangle\Delta_{2n+2}\left(\begin{pmatrix}f_+\\u_-\end{pmatrix},V\right)-\langle g_+v_+\rangle\hat{\Delta}\left(\begin{pmatrix}f_+\\v_-\end{pmatrix},U\right)\\
&-\langle f_+u_+\rangle\Delta_{2n+2}\left(\begin{pmatrix}g_+\\u_-\end{pmatrix},V\right)+\langle f_+v_+\rangle\hat{\Delta}\left(\begin{pmatrix}g_+\\v_-\end{pmatrix},U\right)\Bigg\}\\
+\langle f_+g_+\rangle\Bigg\{&\langle g_-u_-\rangle\Delta_{2n+2}\left(\begin{pmatrix}u_+\\f_-\end{pmatrix},V\right)-\langle g_-v_-\rangle\hat{\Delta}\left(\begin{pmatrix}v_+\\f_-\end{pmatrix},U\right)\\
&-\langle f_-u_-\rangle\Delta_{2n+2}\left(\begin{pmatrix}u_+\\g_-\end{pmatrix},V\right)+\langle f_-v_-\rangle\hat{\Delta}\left(\begin{pmatrix}v_+\\g_-\end{pmatrix},U\right)\Bigg\}.
\end{aligned}\tag{4.9}
$$

Interchanging U and V on the lhs of Eq. (4.9) gives an additional $(-)$sign, whereas on the rhs we get

$$
\begin{aligned}
&\langle f_-g_-\rangle\Bigg\{\langle g_+v_+\rangle\Delta_{2n+2}\left(\begin{pmatrix}f_+\\v_-\end{pmatrix},U\right)-\langle g_+u_+\rangle\hat{\Delta}\left(\begin{pmatrix}f_+\\u_-\end{pmatrix},V\right)-\langle f_+v_+\rangle\Delta_{2n+2}\left(\begin{pmatrix}g_+\\v_-\end{pmatrix},U\right)\\
&\quad+\langle f_+u_+\rangle\hat{\Delta}\left(\begin{pmatrix}g_+\\u_-\end{pmatrix},V\right)\Bigg\}+\langle f_+g_+\rangle\Bigg\{\langle g_-v_-\rangle\Delta_{2n+2}\left(\begin{pmatrix}v_+\\f_-\end{pmatrix},U\right)-\langle g_-u_-\rangle\hat{\Delta}\left(\begin{pmatrix}u_+\\f_-\end{pmatrix},V\right)\\
&\quad-\langle f_-v_-\rangle\Delta_{2n+2}\left(\begin{pmatrix}v_+\\g_-\end{pmatrix},U\right)+\langle f_-u_-\rangle\hat{\Delta}\left(\begin{pmatrix}u_+\\g_-\end{pmatrix},V\right)\Bigg\}.
\end{aligned}
$$

This can only be true if

$$\hat{\Delta}(F,G)\equiv\Delta_{2n+2}(F,G). \tag{4.10}$$

This proves (b) for the case $m=n+1$. The antisymmetry of Δ_{2n+2} is a consequence of (b) and can be seen as follows:

$$\begin{aligned}\Delta_{2n+2}(F,G)&=[\Phi_{2(n-k)+1}(F),\,\Phi_{2k+1}(G)]\\ \text{but because of (b) we also have}&=[\Phi_{2k+1}(F),\Phi_{2(n-k)+1}(G)]\\ &=-[\Phi_{2(n-k)+1}(G),\,\Phi_{2k+1}(F)]\\ &=-\Delta_{2n+2}(G,F).\end{aligned} \tag{4.11}$$

This shows that the inductive definition of the two sequences Φ_{2k-1}, resp. Δ_{2k}, $k\in\mathbf{N}$, works and gives all the properties as stated in Lemma 4.

Remark: In proving Eq. (4.9) we have shown as a side result

$$\begin{aligned}[\Delta_{2k}(V,U),\Delta_{2l}(F,G)]=\langle f_-g_-\rangle\Big\{&\langle g_+u_+\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}f_+\\u_-\end{pmatrix},V\right)-\langle g_+v_+\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}f_+\\v_-\end{pmatrix},U\right)\\ &-\langle f_+u_+\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}g_+\\u_-\end{pmatrix},V\right)+\langle f_+v_+\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}g_+\\v_-\end{pmatrix},U\right)\Big\}\\ &+\langle f_+g_+\rangle\Big\{\langle g_-u_-\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}u_+\\f_-\end{pmatrix},V\right)-\langle g_-v_-\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}v_+\\f_-\end{pmatrix},U\right)\\ &-\langle f_-u_-\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}u_+\\g_-\end{pmatrix},V\right)+\langle f_-v_-\rangle\Delta_{2(k+l)}\left(\begin{pmatrix}v_+\\g_-\end{pmatrix},U\right)\Big\}.\end{aligned} \tag{4.12}$$

At first glance this looks quite asymmetric with respect to an interchange of (V,U) and (F,G). But this asymmetry disappears if we express everything in the bilocal operators $B_{2i}^{(\pm)}$

$$\begin{aligned}[B_{2k}^{(+)}(V,U),\,B_{2l}^{(+)}(F,G)]=&\langle g_+u_+\rangle B_{2(k+l)}^{(+)}(f_+,v_+)-\langle g_+v_+\rangle B_{2(k+l)}^{(+)}(f_+,u_+)\\ &-\langle f_+u_+\rangle B_{2(k+l)}^{(+)}(g_+,v_+)+\langle f_+v_+\rangle B_{2(k+l)}^{(+)}(g_+,u_+),\end{aligned} \tag{4.13}$$

and a similar relation for $B_{2i}^{(-)}$.

Remark: From the definitions of the bilocal operators $B_{2k}^{(\pm)}$ and the field operators ϕ_{2k+1} it is clear that all multiple commutators containing $2k$, resp. $2k+1$, $k\in\mathbf{N}$, fields Φ are linear in $B_{2k}^{(\pm)}$, resp. Φ_{2k+1}, e.g.,

$$[\Phi(F),\,\Phi(G)]=\langle f_-g_-\rangle B_2^{(+)}(f_+,g_+)+\langle f_+g_+\rangle B_2^{(-)}(f_-,g_-)$$

$$[[\Phi(F),\,\Phi(G)]\Phi(U)]=\langle f_-g_-\rangle\langle g_+u_+\rangle\Phi_3\begin{pmatrix}f_+\\u_-\end{pmatrix}+\cdots\quad\text{(another 3 terms)}$$

$$[[[\Phi(F),\,\Phi(G)]\Phi(U)]\Phi(V)]=\langle f_-g_-\rangle\langle g_+u_+\rangle\langle u_-v_-\rangle B_4^{(+)}(f_+,v_+)+\cdots\quad\text{(another 7 terms)}$$

$$\begin{aligned}[[\Phi(F),\,\Phi(G)]\cdots\Phi(W)]=&\langle f_-g_-\rangle\langle g_+u_+\rangle\langle u_-v_-\rangle\langle v_+w_+\rangle\Phi_5\begin{pmatrix}f_+\\w_-\end{pmatrix}\\ &+\cdots\quad\text{(another 15 terms)}.\end{aligned}$$

V. THE TRUNCATED *n*-POINT FUNCTIONS

In this section we shall show that all truncated *n*-point functions are fixed already by the sequences of field operators Φ_{2k-1} and of commutator functions Δ_{2k}. The idea is the following:

Let d be the scaling dimension of the field Φ under consideration. By assumption (**A**) d is an odd number. Let $\varphi(x)=\psi_{d/2}(x_+)\otimes\psi_{d/2}(x_-)$ as defined in Sec. II (Buchholz' example).

Up to a factor, Lorentz invariance and scaling covariance together determine the one- and two-point functions uniquely. But the scalar fields Φ_{2k-1}, $k\in\mathbf{R}$, and φ all have the scaling dimension d and therefore it is clear that for all $k\in\mathbf{N}$ we have

$$(\Omega,\Phi_{2k-1}(F)\Omega)=0 \quad \text{(one-point function)}, \tag{5.1}$$

$$(\Omega,\Delta_{2k}(F,G)\Omega)=c_{2k}(\Omega_0,[\varphi(F),\varphi(G)]\Omega_0) \quad \text{(two-point function)}, \tag{5.2}$$

and because of the special form of Δ_{2k} as given by (4.1), Eq. (5.2) is equivalent to

$$(\Omega,B_{2k}^{(\pm)}(f,g)\Omega)=c_{2k}(\Omega_0,\tfrac{1}{2}[\psi_{d/2}(f),\psi_{d/2}(g)]\Omega_0). \tag{5.3}$$

This fixes a sequence c_{2k}, $k\in\mathbf{N}$, of real numbers.

Let W_n, resp. V_n, denote the n-point functions of the fields Φ, resp. φ.

Lemma 5: For the truncated n-point functions we have

$$W_{2n-1}^T\equiv 0 \quad \text{and} \quad W_{2n}^T=c_{2n}V_{2n}^T, \tag{5.4}$$

and all c_{2n} are positive.

Proof: (a) The vacuum expectation value of a $2n$-fold commutator vanishes because, as shown in the last section, this multiple commutator is linear in the field Φ_{2n-1} and $(\Omega,\Phi_{2n-1}(F)\Omega)=0$.

On the other hand, the vacuum expectation value of a multiple commutator containing an even number of fields is given by

$$\begin{aligned}(\Omega,&\underbrace{[\ldots[}_{2n-1}\Phi(F^{(1)}),\Phi(F^{(2)})],\ldots,\Phi(F^{(2n)})]\Omega)\\ &=\langle f_-^{(1)}f_-^{(2)}\rangle\langle f_+^{(2)}f_+^{(3)}\rangle\cdots\langle f_-^{(2n-1)}f_-^{(2n)}\rangle(\Omega,B_{2n}^{(+)}(f_+^{(1)},f_+^{(2n)})\Omega)+\cdots(2^n-1)\ \text{further terms}\\ &=\langle f_-^{(1)}f_-^{(2)}\rangle\cdots\langle f_-^{(2n-1)}f_-^{(2n)}\rangle c_{2n}\left(\Omega,\frac{1}{2}[\psi_{d/2}(f_+^{(1)}),\psi_{d/2}(f_+^{(2n)})]\Omega\right)+\cdots(2^n-1)\ \text{further terms}\\ &=c_{2n}(\Omega_0,[\cdots[\varphi(F^{(1)}),\varphi(F^{(2)})],\cdots,\varphi(F^{(2n)})]\Omega_0),\end{aligned} \tag{5.5}$$

i.e., all the n-fold commutators of the fields Φ and $\varphi=\psi_{d/2}\otimes\psi_{d/2}$ are linearly related.

(b) By the very definition of the truncated n-point functions this implies

$$W_{2n}^T([\cdots[F^{(1)},F^{(2)}],\cdots,F^{(2n)}])=c_{2n}V_{2n}^T([\cdots[F^{(1)},F^{(2)}],\cdots,F^{(2n)}]). \tag{5.6}$$

As a consequence of the spectrum condition this linear relationship, valid for all $(2n-1)$-fold commutators, can be extended to $W_{2n}^T=c_{2n}V_{2n}^T$. To do this in a systematic way we write

$$W_{2n}^T(F_1,\ldots,F_{2n})=c_{2n}V_{2n}^T(F_1,\ldots,F_{2n})+R_{2n}^T(F_1,\ldots,F_{2n}) \tag{5.7}$$

and R_{2n}^T fulfills again the spectrum condition. From Eq. (5.6) we already know

$$R_{2n}^T([\ldots[F_1,F_2],\ldots,F_{2n}])=0 \tag{5.8}$$

and we have to show

$$R_{2n}^T(F_1,\ldots,F_{2n})\equiv 0. \tag{5.9}$$

We shall exemplify this for the case of the truncated two- and four-point functions:

For the test function $F\in\mathcal{S}(\mathbf{R}^2)$ we denote by F^+ the part of F which in momentum space is supported in $\overline{V^+}\backslash\{0\}$, i.e., ''closed forward cone with the origin exempted.'' F^- is defined analogously as the part of F which in momentum space is supported in $\overline{V^-}\backslash\{0\}$, i.e., ''closed backward cone with the origin exempted.'' By the spectrum condition we have $\Phi(F)\Omega=\Phi(F^+)\Omega$ and $\Phi(F^-)\Omega=0$.

We begin with the two-point function. We know $R_2^T([F,G])=0$:

$$R_2^T(F,G) \overset{sp.c.}{=} R_2^T(F,G^+)=R_2^T([F,G^+])+\underbrace{R_2^T(G^+,F)}_{=0}=0 \tag{5.10}$$

Next we consider the four-point function. We know

$$R_4^T([[[F_1,F_2]F_3]F_4])=0 \quad \text{and} \quad R_4^T([[F_1,F_2][F_3,F_4]])=0. \tag{5.11}$$

where the second equation follows from the Jacobi identity.

(i)

$$\begin{aligned} R_4^T([[F_1,F_2]F_3]F_4) &\overset{sp.c.}{=} R_4^T([[F_1,F_2]F_3]F_4^+) \\ &= R_4^T([[[F_1,F_2]F_3]F_4^+])+R_4^T(F_4^+[[F_1,F_2]F_3]) \\ &= 0 \text{ by Eq. (5.11) and spectrum condition,} \end{aligned} \tag{5.12}$$

and similarly also $R_4^T(F_1[[F_2,F_3]F_4])=0$.

(ii)

$$\begin{aligned} R_4^T([F_1,F_2][F_3,F_4]) &\overset{sp.c.}{=} R_4^T([F_1,F_2][F_3,F_4]^+) \\ &= R_4^T([[F_1,F_2],[F_3,F_4]^+])+R_4^T([F_3,F_4]^+[F_1,F_2]) \\ &= 0 \text{ by Eq. (5.11) and spectrum condition.} \end{aligned} \tag{5.13}$$

(iii)

$$\begin{aligned} R_4^T([F_1,F_2]F_3F_4) &\overset{sp.c.}{=} R_4^T([F_1,F_2]F_3F_4^+) \\ &= \underbrace{R_4^T([F_1,F_2][F_3,F_4^+])}_{=0 \text{ by Eq. (5.13)}}+R_4^T([F_1,F_2]F_4^+F_3) \\ &= R_4^T([[F_1,F_2]F_4^+]F_3)+R_4^T(F_4^+[F_1,F_2]F_3) \\ &= 0 \text{ by Eq. (5.12) and spectrum condition} \end{aligned} \tag{5.14}$$

and similarly also $R_4^T(F_1F_2[F_3,F_4])=0$.

(iv)

$$\begin{aligned} R_4^T(F_1[F_2,F_3]F_4) &\overset{sp.c.}{=} R_4^T(F_1[F_2,F_3]F_4^+) \\ &= R_4^T(F_1[[F_2,F_3]F_4^+])+R_4^T(F_1F_4^+[F_2,F_3]) \text{ by Eq. (5.12)} \\ &= R_4^T([F_1F_4^+][F_2,F_3])+R_4^T(F_4^+F_1[F_2,F_3]) \\ &= 0 \quad \text{by Eq. (5.13) and spectrum condition.} \end{aligned} \tag{5.15}$$

(v) From (iii) and (iv) it follows

$$R_4^T(F_1F_2F_3F_4) \overset{sp.c.}{=} R_4^T(F_1F_2F_3F_4^+)$$
$$=R_4^T(F_1F_2[F_3,F_4^+])+R_4^T(F_1[F_2F_4^+]F_3)+R_4^T([F_1,F_4^+]F_2F_3)$$
$$+R_4^T(F_4^+F_1F_2F_3)$$
$$=0 \text{ which proves our claim.} \tag{5.16}$$

The proof of $R_{2n}^T(F_1,\ldots,F_{2n})\equiv 0$ for $n>2$ is tedious but by no means more complicated!

From $W_{2n}^T=c_{2n}V_{2n}^T$ we get immediately $c_{2n}\geqslant 0$ because of positivity. If for some $n>1$ we have $c_{2n}=0$, then all $c_{2n}\equiv 0$ except possibly c_2 as well known. But then c_2 has to be 0, too, because otherwise Φ is a free field and this contradicts the assumption of boundedness! So we have shown Lemma 5.

VI. REDUCTION TO *s*-PRODUCTS?

Up to now we have shown that our field Φ with scaling dimension $d\in\mathbf{N}$, d odd is related to $\varphi=\psi_{d/2}\otimes\psi_{d/2}$ via

$$W_{2n}^T=c_{2n}V_{2n}^T, \quad W_{2n-1}^T\equiv 0\equiv V_{2n-1}^T,$$

where W_n, resp. V_n, denote the Wightman functions corresponding to Φ, resp. φ. This looks quite similar to an s-product of φ, but up to now we are not able to prove this conjecture. If Φ were an s-product of φ, then we would have

$$c_{2n}=\sum_{k=1}^{K}\alpha_k^{2n} \quad \text{if } \Phi=\varphi_{\underset{\sim}{\alpha}}=(\alpha_1\varphi)s\cdots s(\alpha_K\varphi). \tag{6.1}$$

We are not able to determine a sequence $\underset{\sim}{\alpha}$ such that $\Phi=\varphi_{\underset{\sim}{\alpha}}$ but at least we can find a function $\rho(\alpha)$ such that $c_{2n}=\int_{\mathbf{R}}\alpha^{2n-1}\rho(\alpha)\,d\alpha$.

The construction goes as follows:

For the special real test functions $F=f_+\otimes f_-$ and $G=g_+\otimes g_-$ s.t. $g_-\equiv f_-$, $\langle f_+g_+\rangle=0$ and $\langle f_-^2\rangle=1=\langle g_+^2\rangle$, we get

$$e^{-i\gamma\Phi(G)}\Phi(F)e^{i\gamma\Phi(G)}=\Phi(F)+\sum_{n=1}^{\infty}\frac{(i\gamma)^n}{n!}[\ldots[\Phi(F),\underbrace{\Phi(G)]\ldots,\Phi(G)}_{n}]$$
$$=\sum_{n=0}^{\infty}(-1)^n\frac{\gamma^{2n}}{(2n)!}\Phi_{2n+1}(F)$$
$$+i\sum_{n=0}^{\infty}(-1)^n\frac{\gamma^{2n+1}}{(2n+1)}B_{2n+2}^{(+)}(f_+,g_+). \tag{6.2}$$

Taking the vacuum expectation value

$$(\Omega, e^{-i\gamma\Phi(G)}\Phi(F)e^{i\gamma\Phi(G)}\Omega) = i\sum_{n=0}^{\infty}(-1)^n\frac{\gamma^{2n+1}}{(2n+1)!}(\Omega, B_{2n+2}^{(+)}(f_+,g_+)\Omega)$$

$$= \underbrace{i\sum_{n=0}^{\infty}(-1)^n\frac{\gamma^{2n+1}}{(2n+1)!}c_{2n+2}}_{\sigma(\gamma)}\left\langle\frac{1}{2}[\psi_{d/2}(f_+),\psi_{d/2}(g_+)]\right\rangle$$

$$= \sigma(\gamma)\left\langle\frac{1}{2}[\psi_{d/2}(f_+),\psi_{d/2}(g_+)]\right\rangle \tag{6.3}$$

defines the function $\sigma(\gamma)$.

Its Fourier transformed $\rho(\alpha) = \int_{\mathbf{R}} e^{-i\alpha\gamma}\sigma(\gamma)d\gamma/2\pi$ has the property

$$\int_{-\infty}^{\infty}\alpha^{2n-1}\rho(\alpha)\,d\alpha = \int_{-\infty}^{\infty}\alpha^{2n-1}\left(\int_{-\infty}^{\infty}e^{-i\alpha\gamma}\sigma(\gamma)\frac{d\gamma}{2\pi}\right)d\alpha$$

interchanging $d\alpha$ and $d\gamma$

$$= \int_{-\infty}^{\infty}\sigma(\gamma)\underbrace{\int_{-\infty}^{\infty}\alpha^{2n-1}e^{-i\alpha\gamma}\frac{d\alpha}{2\pi}}_{(i\partial_\gamma)^{2n-1}\delta(\gamma)}d\gamma$$

$$= i(-1)^n\sigma^{(2n-1)}(0) = c_{2n}. \tag{6.4}$$

For the s-product $\Phi = \varphi_{\underline{\alpha}}$ and the above special test functions F and G we get

$$e^{-i\gamma\Phi(G)}\Phi(F)e^{i\gamma\Phi(G)} = \varphi_{\underline{\alpha\cos(\gamma\alpha)}}(F) + i[\varphi(F),\varphi(G)]_{\underline{\alpha\sin(\gamma\alpha)}}, \tag{6.5}$$

the vacuum expectation value of which defines the function

$$\sigma(\gamma) = i\sum_{k=1}^{K}\alpha_k\sin(\gamma\alpha_k) \tag{6.6}$$

and obviously its Fourier transformed

$$\rho(\alpha) = \sum_{k=1}^{K}\frac{\alpha_k}{2}[\delta(\alpha-\alpha_k) - \delta(\alpha+\alpha_k)] \tag{6.7}$$

fulfills Eq. (6.1) for the c_{2n} and allows us to reconstruct the sequence $\underline{\alpha}$. Each α_k is determined up to a factor ± 1. This nonuniqueness corresponds to a unitary transformation. Positivity imposes strong restrictions on the weight functions $\rho(\alpha)$, e.g., there are convincing arguments that $\rho(\alpha)$ cannot have a continuous part.

VII. OUTLOOK

Let us make some comments on the work we have done:

(1) We can only conjecture, but we have not fully succeeded in proving it, that every field Φ fulfilling our assumptions **A** with scaling dimension $d \in \mathbf{N}$, d odd, is an s-product, eventually with infinitely many components, of the corresponding Buchholz field $\phi = \psi_{d/2} \otimes \psi_{d/2}$.

(2) What happens if the scaling dimension of Φ is an even natural number? We expect, in this case, that bounded fields do not exist.

For the simplest case, $d = 2$, the commutator looks like

$$[\Phi(x),\Phi(y)]=\delta'(y_- - x_-)B^{(+)}(x_+,y_+)+\delta'(y_+ - x_+)B^{(-)}(x_-,y_-)$$
$$+\delta(y_- - x_-)B_0^{(+)}\left(x_+,y_+,\frac{x_-+y_-}{2}\right)+\delta(y_+ - x_+)B_0^{(-)}\left(x_-,y_-,\frac{x_++y_+}{2}\right), \tag{7.1}$$

and we are not able to get rid of the second line, at least not with the methods used in Sec. III. The same difficulty appears for higher even d's. There are always two equations missing!

Nevertheless, let us explain why we think there is no bounded Bose field of dimension $d=2$ fulfilling our assumptions. Assume the second line in Eq. (7.1) to be absent. As in Sec. III we get

$$[[\Phi(x),\Phi(y)]\Phi(z)]=\delta'(y_- - x_-)\left\{\delta'(z_+ - y_+)\Phi_3\begin{pmatrix}x_+\\ z_-\end{pmatrix}+\delta'(z_+ - x_+)\Phi_3\begin{pmatrix}y_+\\ z_-\end{pmatrix}\right\}$$
$$+\delta'(y_+ - x_+)\left\{\delta'(z_- - y_-)\Phi_3\begin{pmatrix}z_+\\ x_-\end{pmatrix}+\delta'(z_- - x_-)\Phi_3\begin{pmatrix}z_+\\ y_-\end{pmatrix}\right\} \tag{7.2}$$

and so on. As a consequence, the Wightman functions have the following structure,

$$W^T_{2n-1}\equiv 0 \quad \text{and} \quad W^T_{2n}=c_{2n}V^T_{2n},$$

and all the c_{2n} are positive. The Wightman functions V_n correspond now to the field $\varphi(x)=\varphi_1(x_+)\otimes\varphi_1(x_-)$, where φ_1 is the free chiral Bose field of scaling dimension 1. But for a real factorized test function $f=f_+\otimes f_-$ we have

$$V^T_{2n}(f,\ldots,f)=(2n-1)!\,V_2(f,f)>0 \quad \text{and therefore} \quad W^T_{2n}(f,\ldots,f)>0,$$

too. This is incompatible with the boundedness of $\Phi(f)$ as can be easily seen from the characteristic functional

$$E(f)=(\Omega,e^{i\Phi(f)}\Omega)=\exp\sum_{n\geqslant 1}\frac{(-1)^n}{2n!}W^T_{2n}(f,\ldots,f), \tag{7.3}$$

because $|E(i\lambda f)|$ is not bounded by $\exp\{|\lambda|\cdot\|\Phi(f)\|\}$. This is no proof, but just a strong and plausible hint because we have neglected the second line in Eq. (7.1)! But perhaps these additional terms do not disturb the behavior too much.

(3) An important generalization in our opinion would be to give up strict covariance under dilations. But this step requires new ideas to prove an analogon to our theorem.

ACKNOWLEDGMENTS

Many thanks to Heide Narnhofer and Jakob Yngvason for inviting me to the Erwin Schrödinger Institut at Vienna and their hospitality. Most of the work has been done there. J. Yngvason and K.-H. Rehren contributed good ideas and I had interesting and helpful discussions with them. B. Lütge-Hampe gave many useful hints for typesetting the LATEX manuscript.

(Received 7 July 1998; accepted for publication 10 December 1998)

We consider here the exact solution of a nonrelativistic quantum system composed of a two-level atom interacting with a laser with arbitrary large frequency and intensity. We use the analogy of this system and a $\hbar/2$-spin particle interacting with a time-dependent magnetic field. A systematic use of the dynamical symmetry underlying the physical system is made. Actually the Hamiltonian is a Hermitian element of the SU(2) Lie Algebra. The exact Temporal Evolution Operator in terms of a Generalized Displacement Operator of the group is constructed. It is possible to develop a nonperturbative method that allows us to solve exactly the model for any value of the relevant frequencies (Rabi, Laser, and Atom Frequencies) and in so doing the usual Rotating Wave and Small Interaction approximations are unnecessary. The properties of periodicity of this model and the phenomenon of harmonic generation are considered by using Floquet Analysis. We find that in addition to the so far well-known spectrum composed by odd harmonics, this model generates another type of noninteger harmonics whose frequencies and amplitudes are determined for any value of the relevant parameters of the system. © *1999 American Institute of Physics.* [S0022-2488(99)02704-8]

I. INTRODUCTION

The monochromatic electric field of a very intense laser is the source of a variety of nonlinear responses as it interacts with the matter fields, usually two- or three-level atoms. A particular area of interest in the last ten years has been the so-called higher harmonics generation: the appearance of optical harmonics of various frequencies close to that of the laser pump. These harmonics usually manifest themselves as radiation of the atoms with frequencies that are integer multiples of the incident field. This effect has been thought to be extremely useful to generate further laser beams of a shorter wavelength.[1] The spectrum of such outgoing radiation is given by the Fourier transform of the atom dipole moment, which encompasses the available dipolar oscillations among which the energy can be interchanged. The ultimate reason for the appearance of these harmonics is obviously the nonlinear response of the individual atoms to a strong pumping field. An adequate theoretical understanding requires *the description of the interaction of the atom with the strong external field*. This has been usually achieved by solving the Schrödinger Equation (2), with a time-dependent oscillating potential. When the pumping field is not very strong one can use safely conventional perturbation theory. However, as the intensity of the laser increases, perturbative methods are no longer reliable and a large body of literature has appeared to deal with the problem of interaction of the atom with very strong fields. The paper by Shirley[3] has always been considered the first step toward a reliable theory of atom–laser interaction for arbitrary large electric and magnetic fields. This approach was followed shortly after by Zel'dovich.[4] A recent paper by

[a)]Electronic mail: cervero@rs6000.usal.es

Compagno, Dietz, and Persico[5] contains a set of recent references in the subject and we address the interested reader to this paper for a complete account of the current literature on the field of strongly driven atoms. As a consequence of this interaction, a large variety of methods has been used to actually solve the equations leading to a more or less accurate prediction of higher harmonics generation. Numerical solutions of the Schrödinger Equation,[2] time-dependent (Hartree–Fock) iterative methods[1,6] and treatments involving the analysis of two-level atoms.[7,8] As we shall heavily rely in this paper on various aspects of Floquet Analysis it is necessary to mention that Floquet Theory has also been recently applied to high-order harmonic generation with the same aim than ours but with different perspective. (See Refs. 9–11.)

However, without leaving the paradigm of the two-level atom, the properties of the SU(2) dynamical symmetry of the system can be used to build the exact Temporal Evolution Operator (TEO),[12] that in our opinion becomes the core of the problem, as this operator determines with the appropriated initial conditions on the state vector the instantaneous state of the atom and all its relevant physical properties. Moreover, this method has an additional advantage, namely, that it does not require any kind of approximate treatment such as the Rotating Wave, Weak Field, or Adiabatical Approximations.

This paper is organized as follows: In Sec. II we describe in detail the main features of the model: the relevant mathematical properties of its dynamical symmetry and the specific application of the method to this physical problem in order to build the exact Temporal Evolution Operator. To identify this operator among the elements of the group one has to solve a first-order Riccati differential equation that can easily be linearized. Some transformations are considered in Sec. III, where an Invariant for the system is built and an exact solution in terms of a Taylor series is also found. In Sec. IV the relevant physical properties of the atom are described and compared to those of the Rotating Wave Approximation. We discuss in Secs. V and VI the properties of periodicity of this system by using Floquet Analysis. With these results in hand we can justify in Sec. VII the composition of the harmonic spectrum of the instantaneous electric dipole moment of the atom that is described completely, and both the resulting frequencies and amplitudes of the generated harmonics are discussed. Finally, Sec. VIII is one of conclusions and future prospects in pursuing this line of research.

II. THE PHYSICAL SYSTEM AND ITS DYNAMICAL SYMMETRY

Let us consider the physical system containing a *two-level atom* and its electric dipole interaction with the coherent field of a laser. The external monochromatic field of frequency ω will be treated classically and the possible amplification effects of the laser or spontaneous emission of the atom will be ignored. The system can be described by the Hamiltonian,[13]

$$H(t)=\hbar\omega_0|b\rangle\langle b|+\hbar\Omega_0 s(t)\cos(\omega t)[|a\rangle\langle b|+|b\rangle\langle a|], \tag{2.1}$$

where $|a\rangle$ and $|b\rangle$ are the atomic states whose energy is 0 and $\hbar\omega_0$. Also, $\hbar\Omega_0$ is the energy of the interaction and Ω_0 the *Rabi frequency*. Here $s(t)$ denotes a dimensionless function of time that describes a laser pulse. The introduction of the operators $J_0=J_0^+$ and $J_+^+=J_-$,

$$J_0=\tfrac{1}{2}\{|b\rangle\langle b|-|a\rangle\langle a|\},\quad J_-=|a\rangle\langle b|,\quad J_+=|b\rangle\langle a|, \tag{2.2}$$

with the commutation relations $[J_0,J_\pm]=\pm J_\pm$ and $[J_+,J_-]=2J_0$ allows the Hamiltonian to be expressed as

$$H(t)=\hbar\omega_0[\tfrac{1}{2}+J_0]+\hbar\Omega_0 s(t)\cos(\omega t)[J_+ + J_-], \tag{2.3}$$

and one can identify this system with a j-spin particle interacting with a time-dependent magnetic field. When the dynamical symmetry of this Hamiltonian is considered, $H(t)$ can be seen as a Hermitian element of the triparametric Lie-Algebra SU(2), whose properties[14] will be considered in the full solution of the problem. The physical states (rays) of the atom can be obtained by acting on the eigenstates of J_0 with the *Unitary Displacement Operator* $S(\beta)$ or $S(\eta)$ whose fragmentation properties are[15]

$$S(\beta)=\exp\{\beta J_+-\beta^* J_-\}=\exp\{\eta J_+\}\exp\{\delta J_0\}\exp\{-\eta^* J_-\}=S(\eta), \tag{2.4}$$

$$\beta=re^{i\phi}, \quad \eta=\tan re^{i\phi}, \quad \delta=\log\{1+|\eta|^2\}. \tag{2.5}$$

Every Displacement Operator generates a unitary transformation of the algebra,

$$S(\eta)J_+S^+(\eta)=\frac{1}{1+|\eta|^2}[J_++2\eta^* J_0-\eta^{*2}J_-], \tag{2.6}$$

$$S(\eta)J_0S^+(\eta)=\frac{1}{1+|\eta|^2}[-\eta J_++(1-|\eta|^2)J_0-\eta^* J_-], \tag{2.7}$$

$$S(\eta)J_-S^+(\eta)=\frac{1}{1+|\eta|^2}[-\eta^2 J_++2\eta J_0+J_-], \tag{2.8}$$

and a measure of the change with time of this operator can be given by the quantity

$$\dot{S}(\eta)S^+(\eta)=\frac{1}{1+|\eta|^2}[\dot{\eta}J_++(\dot{\eta}\eta^*-\eta\dot{\eta}^*)J_0-\dot{\eta}^* J_-]. \tag{2.9}$$

The explicit form of the $H(t)$ makes no reference to any specific representation of the algebra, and therefore all properties of the physical system determined by the dynamical symmetry can be extended to any representation. In particular, we can generalize the treatment of the problem to describe an *m-level-atom* interaction with either Equidistant Levels or with an Electric Dipole moment operator connecting only contiguous levels.

III. THE TEMPORAL EVOLUTION OPERATOR

The Temporal Evolution Operator that satisfies the Schrödinger equation,

$$i\hbar\dot{U}(t)U^+(t)=H(t), \quad U(0)=1, \tag{3.1}$$

can be obtained by mapping exponentially a Hermitian element of the algebra. We express this element by a Displacement Operator with arbitrary factorization as

$$U(t)=\exp\left\{-i\frac{\omega_0}{2}t\right\}S[\eta(t)]\exp\{ih(t)J_0\}, \tag{3.2}$$

and as a consequence of (3.1) and the properties of the algebra the following system of equations must hold:

$$-i\Omega_0 s(t)\cos(\omega t)(1+|\eta|^2)=\dot{\eta}-i\dot{h}\eta, \tag{3.3}$$

$$-i\omega_0(1+|\eta|^2)=\dot{\eta}\eta^*-\eta\dot{\eta}^*+i\dot{h}(1-|\eta|^2). \tag{3.4}$$

Finally, it is easy to see that the explicit identification of the TEO requires the knowledge of two functions: $h(t)$ real and $\eta(t)$ complex, whose evolution imposed by the Schrödinger equation is governed by the system of ordinary differential equations:

$$\dot{\eta}=-i\Omega_0 s(t)\cos(\omega t)(1-\eta^2)-i\omega_0\eta, \quad \eta(0)=0, \tag{3.5}$$

$$h(t) = -\omega_0 t + 2\Omega_0 \int_0^t s(u)\cos(\omega u)\mathrm{Re}[\eta(u)]du. \tag{3.6}$$

The nonlinear first-order Riccati equation is the heart of the problem. If we know the complex function $\eta(t)$, the solution of this Riccati equation, we can obtain the real function $h(t)$ by a quadrature, and in terms of these functions all the remaining relevant properties of the system. This equation is exactly solvable in the following particular cases: (i) $\eta = -i\tan\{(\Omega_0/\omega)\sin(\omega t)\}$ if the energy of the atom is negligible compared to the energy of the interaction ($\omega_0 \to 0$); (ii) $\eta = 0$ in the reciprocal case ($\Omega_0 \to 0$); and (iii) in the rotating wave approximation that will be considered later.
In the general case and with $\omega_0 \neq 0$ we consider the following transformations

(i) Conformal transformation:

$$\eta = \frac{1-\xi(t)}{1+\xi(t)}, \tag{3.7}$$

$$\dot{\xi} = 2i\Omega_0 s(t)\cos(\omega t)\xi + i\frac{\omega_0}{2}(1-\xi^2), \quad \xi(0) = 1. \tag{3.8}$$

The evolution of the new function $\xi(t)$ is governed by another Riccati equation with a constant coefficient for the nonlinear term. Therefore our system is equivalent to an atom with a time-dependent oscillating *energy*, interacting with an external stationary electric field.

(ii) Linearization of the Riccati equation: The new nonlinear Riccati equation can be linearized by introducing a new complex function $q(t)$:

$$\xi = -\frac{2i}{\omega_0}\frac{\dot{q}}{q}, \tag{3.9}$$

which must be a solution of the *second-order linear differential equation*,

$$\ddot{q} - 2i\Omega_0 s(t)\cos(\omega t)\dot{q} + \frac{\omega_0^2}{4}q = 0, \tag{3.10}$$

$$q(0) = 1, \quad \dot{q}(0) = i\frac{\omega_0}{2}. \tag{3.11}$$

This last differential equation shows the equivalence between our system and a harmonic oscillator subjected to viscous damping with an imaginary time-dependent coefficient. Introducing new variables given by $q = re^{i\phi}$ and $p = r^2\dot{\phi}$, we can construct an *invariant* of this system in the form

$$\dot{r}^2 + \frac{p^2}{r^2} + \frac{\omega_0^2}{4}r^2 = \frac{\omega_0^2}{2}, \tag{3.12}$$

$$\dot{p} = 2s(t)\frac{\Omega_0}{\omega_0}\cos(\omega t)r\dot{r}. \tag{3.13}$$

This invariant is reminiscent of the total energy of an isotropic two-dimensional oscillator. One should emphasize that the existence of the invariant (3.12) is independent of the function $s(t)$ that governs the shape of the incident pulse of the external field. The analogy cannot be pushed too far because in this system the ''angular momentum'' is not a conserved quantity.

If we introduce $\gamma = \Omega_0/\omega$, $\epsilon = \omega_0/\omega$, $x = \omega t$, and we use *primes* to denote d/dx, the new form of the linear equation (3.10) is

$$q(0)=1, \quad q'(0)=i\frac{\epsilon}{2}, \tag{3.15}$$

which can be solved by applying the *Frobenius Theory* in terms of a *power series*,

$$u(x)=\sum_{k=0}^{\infty} A_k x^k, \quad v(x)=\sum_{k=0}^{\infty} B_k x^k, \quad A_0=B_1=1, \quad A_1=B_0=0, \tag{3.16}$$

whose coefficients A_k and B_k must satisfy the same following recurrence law:

$$A_{k+2}=\frac{1}{(k+2)(k+1)}\left[2i\gamma\sum_{r=0}^{k+1} a_{k+1-r}A_r r-\frac{\epsilon^2}{4}A_k\right], \tag{3.17a}$$

$$B_{k+2}=\frac{1}{(k+2)(k+1)}\left[2i\gamma\sum_{r=0}^{k+1} a_{k+1-r}B_r r-\frac{\epsilon^2}{4}B_k\right], \tag{3.17b}$$

where the a_j are the coefficients of the de Taylor series of the damping function $s(x)\cos x$ that in the case of a square pulse $s(x)=1$ are $a_{2k}=(-1)^k/(2k)!$, $a_{2k+1}=0$. Explicitly, the first terms of these series are collected in Tables I and II. An important consequence of this procedure is that all points of the real line are regular for the linear equation (3.14) that fully determines all physical properties of the model, and according to the Frobenius theorem the functions $u(x)$ and $v(x)$ satisfying $u(0)=\dot{v}(0)=1$ and $\dot{u}(0)=v(0)=0$ are *a fundamental system of solutions* of the linear differential equation. They *converge in the real line for all values of the parameters*,[16] although,

in general, this convergence could be very slow. The method reveals itself as an intrinsically nonperturbative one, and it is valid regardless of the magnitude of the intensity of the coupling atom laser. In other words, the procedure is also applicable for arbitrarily intense strong fields. We can use these series to obtain $q(t)$ and $\eta(t)$ in the form

$$q(\omega t)=u(\omega t)+i\frac{\omega_0}{2}v(\omega t), \tag{3.18}$$

$$\eta(\omega t)=\frac{\omega_0 q(\omega t)+2i\dot{q}(\omega t)}{\omega_0 q(\omega t)-2i\dot{q}(\omega t)}, \tag{3.19}$$

which define the general solution.

IV. THE PHYSICAL OBSERVABLES AND THE ROTATING WAVE APPROXIMATION

Once both previous equations have been solved we immediately know $\eta(t)$, and we can obtain $h(t)$ through a quadrature as well as all other physical quantities of interest. For instance, the natural evolution of the eigenstates of the free atom is given by

$$U(t)|a\rangle=\frac{e^{-(i/2)[h+\omega_0 t]}}{\sqrt{1+|\eta|^2}}\{|a\rangle+\eta|b\rangle\}, \tag{4.1}$$

$$U(t)|b\rangle=\frac{e^{(i/2)[h-\omega_0 t]}}{\sqrt{1+|\eta|^2}}\{-\eta^*|a\rangle+|b\rangle\}. \tag{4.2}$$

The normalized transition probabilities between states is also given by

$$P_{ab}=P_{ba}=\frac{|\eta|^2}{1+|\eta|^2}=\sin^2|\beta|, \tag{4.3}$$

$$P_{aa}=P_{bb}=\frac{1}{1+|\eta|^2}=\cos^2|\beta|. \tag{4.4}$$

The instantaneous population inversion ($q=re^{i\phi}$) is

$$W(t)=P_{ab}-P_{aa}=-\frac{\xi+\xi^*}{1+|\xi|^2}=-\frac{2}{\omega_0}r^2\dot{\phi}. \tag{4.5}$$

The instantaneous electric dipole moment takes the form

$$d(t)=-\frac{\hbar\Omega_0}{E_0}\frac{\eta+\eta^*}{1+|\eta|^2}=-\frac{\hbar\Omega_0}{E_0}\{r^2-1\}, \tag{4.6}$$

and so we can identify the ''angular moment'' introduced above with the population inversion and conclude that the invariant describes the temporal evolution of the rescaled dipole moment $D(t)=r^2-1$,

$$\dot{D}^2+\omega_0^2D^2+\omega_0^2W^2=\omega_0^2. \tag{4.7}$$

In the tridimensional subspace of the phase space of the system labeled by the coordinates $\{\dot{D},D,W\}$, this equation of the invariant describes an ellipsoid with semiaxis $\{\omega_0,1,1\}$ and guarantees a bounded evolution of both the dipole moment and the population inversion for any value of the parameters. In particular, the dipole moment cannot be greater than $\hbar\Omega_0/E_0$ and the function $q(t)$ must be bound as it verifies $0\leqslant r=|q|\leqslant\sqrt{2}$.

Let us now consider the previous system in the traditional Rotating Wave Approximation just by ignoring fast oscillations of frequency $\{\omega+\omega_0\}$ that are much larger than $\{\omega-\omega_0\}$. The Hamiltonian of the system can now be written as

$$H(t)=\hbar\omega_0(\tfrac{1}{2}+J_0)+\tfrac{1}{2}\hbar\Omega_0(e^{-i\omega t}J_++e^{i\omega t}J_-), \tag{4.8}$$

and the Riccati equation is now simplified to read as

$$\dot{\eta}=-i\frac{\Omega_0}{2}(e^{-i\omega t}-\eta^2e^{i\omega t})-i\omega_0\eta, \quad \eta(0)=0, \tag{4.9}$$

whose exact solution is

$$\eta(t)=-i\frac{e^{-i\omega t}\sin(\Delta T)}{\sqrt{1+\kappa^2}\cos(\Delta t)+i\kappa\sin(\Delta t)}, \tag{4.10}$$

$$h(t)=-\omega t-2\arctan\left\{\frac{\kappa}{\sqrt{1+\kappa^2}}\tan(\Delta t)\right\}, \tag{4.11}$$

$$\kappa=\frac{\omega_0-\omega}{\Omega_0}, \quad \Delta=\frac{\Omega_0}{2}\sqrt{1+\kappa^2}. \tag{4.12}$$

When the frequencies ω and Δ are commensurable, (i.e., $\omega/\Delta = p/q$, a rational number), all the physical states of the atom are cyclic. They return to the $t=0$ situation after an evolution time equal to $T=(2\Pi/\Delta)q=(2\Pi/\omega)p$ plus a phase $\exp\{-ip\pi(1+\omega_0/\omega)\}$. In this approximation, the transition probabilities are expressed by the well-known formula:

$$P_{ab}=P_{ba}=\frac{\sin^2(\Delta t)}{1+\kappa^2}, \quad P_{\max}=\frac{1}{1+\kappa^2}, \quad t=\frac{l\pi}{2\Delta}, \tag{4.13}$$

with a maximum value just in resonance. The population inversion can be written as

$$W(t)=-\frac{\kappa^2+\cos(2\Delta t)}{1+\kappa^2}. \tag{4.14}$$

The quantity $W(t)$ oscillates between its maximum and minimum values with frequency 2Δ. The dipole moment is (ignoring spontaneous emission)

$$d(t)=-2\frac{\hbar\Omega_0}{E_0}\frac{\sin(\Delta t)}{1+\kappa^2}\{\sqrt{1+\kappa^2}\cos(\Delta t)\sin(\omega t)+\kappa\sin(\Delta t)\cos(\omega t)\}, \tag{4.15}$$

and thus the Fourier transform of the dipole moment contains just oscillations of frequencies $\pm\omega$ and $\pm(2\Delta\pm\omega)$. Only these frequencies can, in fact, be generated.

V. THE FLOQUET THEORY AND THE ATOM–LASER SYSTEM

The equivalent linear equation (3.14) with $s(x)=1$ has periodic coefficients of period 2π and *Floquet analysis (Bloch Theorem)*[16,17] can be applied. Note, however, that this analysis can also be applied to the case of nonconstant but periodic $s(x)$. Hereafter we shall concentrate just in the $s(x)=1$ case. Suppose that a pair of independent solutions $u(x)$ and $v(x)$ of the equation have been already built. The periodicity property of the coefficients leads to the fact that the translated functions $u(x+2\pi)$ and $v(x+2\pi)$ must be new solutions of the equation themselves and must be expressed as a linear combination of the previous ones. Explicitly,

$$u(x+2\pi)=u(2\pi)u(x)+u'(2\pi)v(x), \tag{5.1}$$

$$v(x+2\pi)=v(2\pi)u(x)+v'(2\pi)v(x). \tag{5.2}$$

There exist solutions—the *Floquet–Bloch functions* $q(x)$—verifying the *Floquet condition*

$$q(x+2\pi)=\lambda q(x), \tag{5.3}$$

where $\lambda(\gamma,\epsilon)$ is a complex number that depends on the specific values of the parameters of the system and must be a solution of the algebraic *characteristic equation*:

$$\lambda^2-[u(2\pi)+v'(2\pi)]\lambda+1=0. \tag{5.4}$$

The allowed values of $\lambda(\gamma,\epsilon)$ must be constrained by the the invariariant (3.12), which must be a C number of unit modulus. Therefore $\lambda=e^{2i\pi\nu}$, and its argument is not single-valued, since all physical situations can be described as we restrict their values to the interval $0\leqslant\nu\leqslant\frac{1}{2}$.

The most general form of the Floquet function $q(x)$ is

$$q(x)=e^{i\nu x}F(x), \quad F(x+2\pi)=F(x) \tag{5.5}$$

being $F(x)$ a 2π-*periodic* function. The Floquet solution $q(x)$ must be bound for all values of the parameters and for all x according to the condition obtained in the previous analysis. We can consider now two different cases.

(a) *Nondegenerate characteristic equation*. When the characteristic equation has two different roots, two independent Floquet functions $q_1(x)$ and $q_2(x)$ exist:

$$q_1(x)=e^{i\nu x}F^+(x), \quad q_2(x)=e^{-i\nu x}F^-(x), \tag{5.6}$$

where $F^\pm(x+2\pi)=F^\pm(x)$ are two linearly independent 2π-periodic functions, and the general solution can be expressed as

$$q(x)=Ae^{i\nu x}F^+(x)+Be^{-i\nu x}F^-(x), \tag{5.7}$$

with constants A and B depending on the initial conditions. It must pointed out that the general solution will not be itself a Floquet function if $AB\neq 0$. Thus, we can conclude that if $\nu\neq 0$ there are no 2π-periodic solutions. The general solution is not a Floquet function, but we can find particular Floquet solutions (quasiperiodic with period 2π) and those systems whose parameter is of the form $\nu=m_1/m_2$ (a rational number) are periodic. Its general solution is $2m_2\pi$ periodic.

(b) *Degenerate characteristic equation*. When $[u(2\pi)+v'(2\pi)]=\pm 2$, the characteristic equation has only one double solution $\lambda=\pm 1$, and there exists only one Floquet solution. However, a pair of functions $q_1(x)$ and $q_2(x)$ can be found, verifying Refs. 16 and 17:

$$q_1(x+2\pi)=\pm q_1(x), \quad q_2(x+2\pi)=\pm[q_1(x)+q_2(x)], \tag{5.8}$$

whose general form is

$$q_1(x)=e^{i\nu x}F_1(x), \quad q_2(x)=e^{i\nu x}\left[\frac{x}{2\pi}F_1(x)+F_2(x)\right], \tag{5.9}$$

with $\nu=0$ or $\frac{1}{2}$ and $F_1(x)$ and $F_2(x)$ 2π periodic. The general solution must now be of the form

$$q(x)=e^{i\nu x}\left\{AF_1(x)+B\left[\frac{x}{2\pi}F_1(x)+F_2(x)\right]\right\}, \tag{5.10}$$

and we can conclude in this case that there will be *particular solutions* of periodic character ($\nu=0$) and of antiperiodic ($\nu=\frac{1}{2}$) character, but the general solution is *neither bound nor periodic*.

VI. THE CONSTRUCTION OF THE FLOQUET FUNCTIONS

The explicit construction of the Floquet functions requires the previous knowledge of the characteristic exponent ν. In order to find ν we have to solve the *characteristic equation* plus the values of $u(2\pi)$ and $v'(2\pi)$. Nevertheless, the symmetry of Eq. (3.14) allows us to write the following set of conditions:

$$u(x+\pi)=u(\pi)u^*(x)+u'(\pi)v^*(x), \tag{6.1}$$

$$v(x+\pi)=v(\pi)u^*(x)+v'(\pi)v^*(x), \tag{6.2}$$

since $q(x+\pi)$ is a solution of the conjugate equation of (3.14), provided that $q(x)$ is a solution of (3.14) as well. One can reproduce the complete solution with the help of these functions $u(x)$ and $v'(x)$ defined in the closed neighbor $[0,\pi]$ and then to obtain the Floquet exponent as

$$2\cos(2\pi\nu)=u(\pi)u^*(\pi)+u'(\pi)v^*(\pi)+v(\pi)u'^*(\pi)+v'(\pi)v'^*(\pi). \tag{6.3}$$

These values, represented in Fig. 1, can be found either by numerical simulation of the equation (3.14) or using the Taylor series (3.16) for these functions. In order to obtain the correspondent 2π-*periodic function* we have to solve the Ordinary Differential Equation:

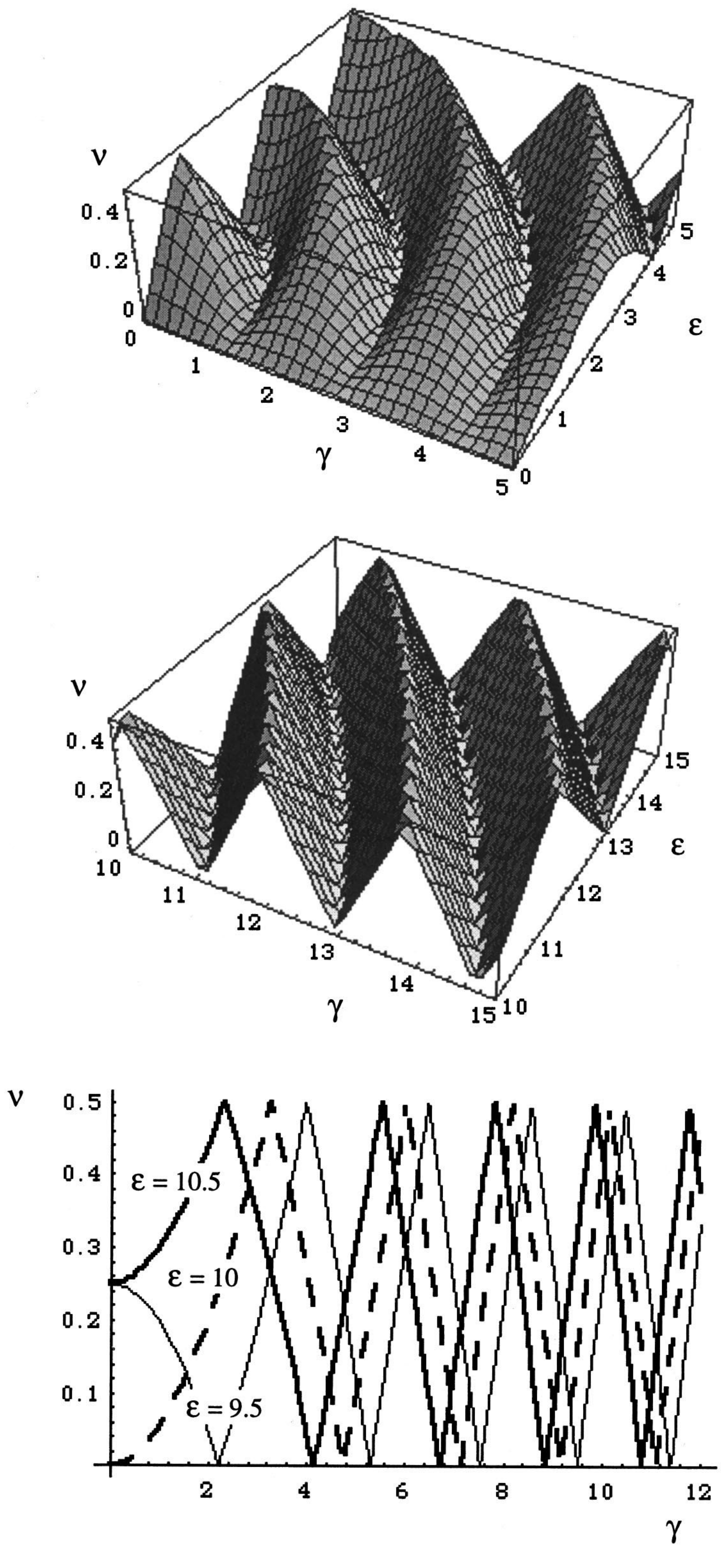

FIG. 1. Floquet exponents as a function of the γ,ϵ parameters.

$$F''+2i(\nu-\gamma\cos x)F'+\left(\frac{\epsilon^2}{4}-\nu^2+2\gamma\nu\cos x\right)F=0. \tag{6.4}$$

Just for the nondegenerate case, we have to find the solutions $F^{\pm}(x)$ corresponding to the two possible values of the Floquet exponents $\pm\nu$. As the periodicity is actually guaranteed, these functions can, in fact, be expressed as a usual Fourier superposition of harmonic components with a frequency multiple of that laser:

$$F^{\pm}(x)=\sum_{p=-\infty}^{\infty} F_p^{\pm}e^{ipx}, \quad F_0^{\pm}=1. \tag{6.5}$$

When we introduce this superposition in the ODE, we find the following relationship between three consecutive coefficients:

$$-\left\{\frac{\epsilon^2}{4\gamma}-\frac{(p\pm\nu)^2}{\gamma}\right\}F_p^{\pm}=(p\pm\nu-1)F_{p-1}^{\pm}+(p\pm\nu+1)F_{p+1}^{\pm}, \tag{6.6}$$

whose resolution requires the introduction of the relative amplitudes between contiguous harmonics,

$$G_p^{\pm}=\frac{F_p^{\pm}}{F_{p-1}^{\pm}}, \quad H_{-p}^{\pm}=\frac{F_{-p}^{\pm}}{F_{-p+1}^{\pm}}, \quad p\geqslant 1, \tag{6.7}$$

that must verify

$$G_p^{\pm}=-\frac{p\pm\nu-1}{V_p^{\pm}+(p\pm\nu+1)G_{p+1}^{\pm}}, \quad p\geqslant 1, \tag{6.8}$$

$$H_{-p}^{\pm}=\frac{p\mp\nu-1}{V_{-p}^{\pm}-(p\mp\nu+1)H_{-p-1}^{\pm}}, \quad p\geqslant 1, \tag{6.9}$$

$$V_l^{\pm}=\frac{\epsilon^2}{4\gamma}-\frac{(l\pm\nu)^2}{\gamma}. \tag{6.10}$$

These relationships determine every coefficient by a *continued fraction*.[7] The way to proceed is the following. If the series G_p and H_{-p} have a finite limit, this must be zero. Therefore, if we consider a value of $p=p_{\max}$ sufficiently high, we can also assume that the correspondent terms G_{p+1} and H_{-p-1} vanish. More precisely, what would vanish is the quantity $\pm\gamma/(p+1)$. Thus, all the previous terms can be calculated hereafter by using the recurrence relationship (6.5)–(6.7). Hence, all the coefficients are given by the quantities

$$F_p^{\pm}=G_p^{\pm}G_{p-1}^{\pm}C_{p-2}^{\pm},\ldots,G_3^{\pm}G_2^{\pm}G_1^{\pm}, \tag{6.11}$$

$$F_{-q}^{\pm}=H_{-q}^{\pm}H_{-q+1}^{\pm}H_{-q+2}^{\pm},\ldots,H_{-3}^{\pm}H_{-2}^{\pm}H_{-1}^{\pm}, \tag{6.12}$$

except the first one that remains undetermined and can be made equal to one $(F_0^{\pm}=1)$.

There exists an additional condition that so far has not been used, namely, the characteristic equation among the coefficients for the value $p=0$:

$$-\left\{\frac{\epsilon^2}{4\gamma}-\frac{\nu^2}{\gamma}\right\}=(\pm\nu-1)H_{-1}^{\pm}+(\pm\nu+1)G_1^{\pm}, \tag{6.13}$$

that must be considered a *compatibility condition*,[18] that connects all the relevant parameters of the system:

$$F(\gamma,\epsilon,\nu)=0, \tag{6.14}$$

and can be used to find through an iterative process the characteristic exponent if it is still unknown[18] or to classify all systems with a fixed exponent. The results coincide with those of Fig. 1. In particular, when $\nu=0$ or $\frac{1}{2}$, the equation (6.14) selects the parameters of those particular systems that have a general periodic or antiperiodic solution and forces the physical system described by our Hamiltonian to a truly periodical behavior.

All these properties allow us to establish an important relationship between the functions $F^{+}(x)$ and $F^{-}(x)$. It is easy to see that the following relations hold:

$$G_p^{+}=-H_{-p}^{-},\quad G_p^{-}=-H_{-p}^{+}. \tag{6.15}$$

As a consequence of these symmetries, one has to find the amplitudes of only one of the two functions because these coefficients verify

$$F_p^{-}=(-1)^p F_{-p}^{+}, \tag{6.16}$$

and $F^{\pm}(x)$ can be expressed by series of *even harmonics* and *odd harmonics* of the laser according to the expression

$$F^{+}(x)=E(x)+O(x),\quad F^{-}(x)=E^{*}(x)-O^{*}(x), \tag{6.17}$$

where

$$E(x)=\sum_{p=-\infty}^{\infty} F_{2p}e^{i2px},\quad O(x)=\sum_{p=-\infty}^{\infty} F_{2p+1}e^{i(2p+1)x}, \tag{6.18}$$

and we have redefined $F_j^{+}=F_j$ in order to simplify the notation. As soon as the *Floquet functions* have been constructed, the function $q(x)$ is totally determined by using the physical initial conditions of the problem. The result is

$$q(x)=Ae^{i\nu x}[E(x)+O(x)]+Be^{-i\nu x}[E^{*}(x)-O^{*}(x)], \tag{6.19}$$

$$A=\frac{1}{\Sigma}\left\{(c-d)\left(\nu+\frac{\epsilon}{2}\right)+e-f\right\}, \tag{6.20}$$

$$B=\frac{1}{\Sigma}\left\{(c+d)\left(\nu-\frac{\epsilon}{2}\right)+e+f\right\}, \tag{6.21}$$

$$\Sigma=2(ec-df)+2\nu(c^2-d^2), \tag{6.22}$$

where *c*, *d*, *e*, and *f* are constants depending on the initial values of the Floquet functions and their derivatives,

$$c=\sum_{p=-\infty}^{\infty} F_{2p},\quad d=\sum_{p=-\infty}^{\infty} F_{2p+1}, \tag{6.23}$$

$$e=2\sum_{p=-\infty}^{\infty} pF_{2p},\quad f=\sum_{p=-\infty}^{\infty} (2p+1)F_{2p+1}. \tag{6.24}$$

We would like to emphasize at this point that these series are always convergent as they correspond to Fourier coefficients of regular periodic functions.

VII. FLOQUET ANALYSIS AND THE HARMONIC GENERATION

The interaction between the atom and the coherent field forces the atomic dipole to oscillate with frequencies that can be different of the external field. Thus, one can analyze the phenomenon of higher harmonic generation, starting with the Fourier Transform of the instantaneous dipole moment of the atom. One has just to remember the relationship between this physical observable and the complex function $q(x)$. It is quite clear that we can obtain its harmonic spectrum with the help of $q(x)$. Alternatively, we can consider the equivalent system of equations, obtained from (3.12)–(3.13) and (4.5)–(4.7):

$$D''+\epsilon^2 D=2\gamma\epsilon\cos x W,\quad D(0)=0,\quad D'(0)=0, \tag{7.1}$$

$$W'+2\frac{\gamma}{\epsilon}\cos x D'=0,\quad W(0)=-1, \tag{7.2}$$

which describes the dipole moment forced by the population inversion. This is the treatment used in Ref. 7, where a stationary approximation of the problem is made and the instantaneous dipole moment of the atom is found in terms of a Fourier series built with a superposition of *only odd harmonics* of the frequency of the coherent field. The amplitude of the different harmonics is obtained using a *continued fraction*[7] totally equivalent to the one we have described above. However, the stationary approximation becomes unnecessary if we can describe in an analytical form the exact instantaneous dipole moment of the atom represented by its Fourier Transform whose frequencies and amplitudes are totally known, as we have just done. An exact expression would be

$$\begin{aligned} D(x)=(A^2+B^2)\sum_{s=0}^{\infty} P_s\cos(2sx)-1+2(A^2-B^2)\sum_{s=0}^{\infty} I_s\cos[(2s+1)x] \\ +2AB\sum_{s=0}^{\infty}\{T_s^+\cos[2(s+\nu)x]+T_s^-\cos[2(s-\nu)x]\}, \end{aligned} \tag{7.3}$$

whose coefficients are expressed in terms of the constants that we have just found:

$$P_0=\sum_{p=-\infty}^{\infty} F_pF_p,\quad T_0^{\pm}=\frac{1}{2}\sum_{p=-\infty}^{\infty}(F_{2p}F_{-2p}-F_{2p+1}F_{-2p-1}), \tag{7.4}$$

$$P_s=2\sum_{p=-\infty}^{\infty} F_pF_{p+2s},\quad s\geqslant 1, \tag{7.5}$$

$$I_s=\sum_{p=-\infty}^{\infty} F_{2p}(F_{2p+2s+1}+F_{2p-2s-1}),\quad s\geqslant 0, \tag{7.6}$$

$$T_s^{\pm}=\sum_{p=-\infty}^{\infty}(F_{2p}F_{\pm 2s-2p}-F_{2p+1}F_{\pm 2s-2p-1}),\quad s\geqslant 1. \tag{7.7}$$

One could, in principle, work directly with the system (7.1)–(7.2), basically because the convergence of the series appearing in $D(x)$ is faster than the series of $q(x)$. However, the periodic character of the functions $D(x)$ and $W(x)$ is still unknown as *there is no reason to assume that the solution of a linear system of first-order differential equations with periodic* *time-dependent coefficients is actually periodic*. In fact, only an adequate Floquet analysis (Bloch) of the type that has been performed in Ref. 3 can give us a clear cut answer to this question. According to our results the dipole moment must be described by a real function that must contain a purely 2π-periodic real function and another periodic function modulated by an exponential factor that contains the contribution due to the Floquet exponent. Let the primed coefficients be the Fourier coefficients of the Dipole Moment $D(x)$ that we have found using Eqs. (7.1) and (7.2). This function $D(x)$ can be expressed in this notation as $(T_0'^{-}=0)$

$$D(x)=\sum_{s=0}^{\infty}\{I_s'\cos((2s+1)x)+T_s'^{+}\cos(2(s+\nu)x)+T_s'^{-}\cos(2(s-\nu)x)\}. \tag{7.8}$$

This ansatz already contains the initial condition $D'(0)=0$ and the mathematical property concerning the fact that the system of equations itself cancels the even harmonics in $D(x)$. Also, the ansatz must yield the complete solution when the initial state has a good energy quantum number of the noninteracting atom. This is due to the property $D(t)=|q|^2-1$ that shifts just the even harmonics in an amount 2ν (instead of ν, as one might have initially expected). The same effect could be interpreted as a split of the odd harmonics followed by a shift of one of these in an amount $\pm(1-2\nu)$, giving rise to a sort of *triplet associated to each odd harmonic*, as can be seen in Fig. 2.

The relationships between contiguous harmonics $\Lambda_s=I_s'/I_{s-1}'$, $\Lambda_s^{\pm}=T_s'^{\pm}/T_{s-1}'^{\pm}$ must now verify

$$\Lambda_s=-\frac{2s-1}{2s}\left\{\frac{\epsilon^2-(2s+1)^2}{\gamma^2}+\frac{(2s+1)^2}{2s(s+1)}+\frac{2s+3}{2(s+1)}\Lambda_{s+1}\right\}^{-1},\quad s\geqslant 1, \tag{7.9}$$

$$\Lambda_s^{\pm}=-\frac{s-1\pm\nu}{2s-1\pm2\nu}\left\{\frac{\epsilon^2-4(s\pm\nu)^2}{2\gamma^2}+\frac{4(s\pm\nu)^2}{4(s\pm\nu)^2-1}+\frac{s+1\pm\nu}{2s+1\pm2\nu}\Lambda_{s+1}^{\pm}\right\}^{-1}, \tag{7.10}$$

and all these coefficients go over $\gamma^2/4s^2$ for large values of s and verifying the compatibility condition,

$$\frac{\epsilon^2-4\nu^2}{2\gamma^2}+\frac{4\nu^2}{4\nu^2-1}+\frac{1+\nu}{1+2\nu}\Lambda_1^{+}+\frac{1-\nu}{1-2\nu}\Lambda_1^{-}=0, \tag{7.11}$$

that can be used to adjust the value of ν. Therefore, starting with a sufficiently high value of s we can calculate the ratios $\Lambda_s=\Lambda_s^{\pm}=\gamma^2/4s^2$, and using (7.9)–(7.10) we can go backward and calculate all the others. With all these ratios we find the coefficients:

$$I_s'=\Lambda_s\Lambda_{s-1}\Lambda_{s-2}\Lambda_{s-3},\ldots,\Lambda_3\Lambda_2\Lambda_1I_0'=\Delta_sI_0',\quad s\geqslant 1, \tag{7.12}$$

$$\Lambda_s^{\pm}=\Lambda_s^{\pm}\Lambda_{s-1}^{\pm}\Lambda_{s-2}^{\pm}\Lambda_{s-3}^{\pm},\ldots,\Lambda_3^{\pm}\Lambda_2^{\pm}\Lambda_1^{\pm}T_0'^{+}=\Delta_s^{\pm}T_0'^{+}, \tag{7.13}$$

in terms of two of these I_0' and $T_0'^{+}$ that can be considered as integration constants. These integration constants are fixed by using the initial conditions $D(0)=0$ and $W(0)=-1$. This leads to the following set of algebraic equations:

$$C'I_0'+D'T_0'^{+}=0, \tag{7.14}$$

$$\left(\frac{\epsilon^2-1}{\gamma^2}-\frac{1}{2}-E'+\frac{3}{2}\Lambda_1\right)I_0'-4F'T_0'^{+}=-\frac{2\epsilon}{\gamma}, \tag{7.15}$$

where

TABLE III. The Fourier spectrum of the electric dipole moment. The symbol* means amplitudes less than 10^{-3}. The oscillations with a negative amplitude have an extra phase of $\exp\{i\pi\}$.

$$C'=\sum_{s=0}^{\infty}\Delta_s,\quad F'=\sum_{s=0}^{\infty}\left\{\frac{4(s+\nu)^2}{4(s+\nu)^2-1}\Delta_s^{+}+\frac{4(s-\nu)^2}{4(s-\nu)^2-1}\Delta_s^{-}\right\},\tag{7.16}$$

$$E'=\sum_{s=1}^{\infty}\frac{(2s+1)^2}{s(s+1)}\Delta_s,\quad D'=\sum_{s=0}^{\infty}\{\Delta_s^{+}+\Delta_s^{-}\}.\tag{7.17}$$

Finally, we identify

$$P_s=0,\quad I_s=I'_s,\quad T_s^{+}=T_s'^{+},\quad T_s^{-}=T_s'^{-},\tag{7.18}$$

as can easily be seen for any particular set of values of the parameters. The amplitude of every harmonic can be calculated either by (7.4)–(7.7) or (7.8)–(7.17).

The *Fourier Spectrum* so far described in the literature includes only *odd* harmonics. According to the results developed in this paper, the following composition of the *Fourier Spectrum* both in frequencies and amplitudes emerges. Indeed, *odd integer harmonics* must necessarily be an

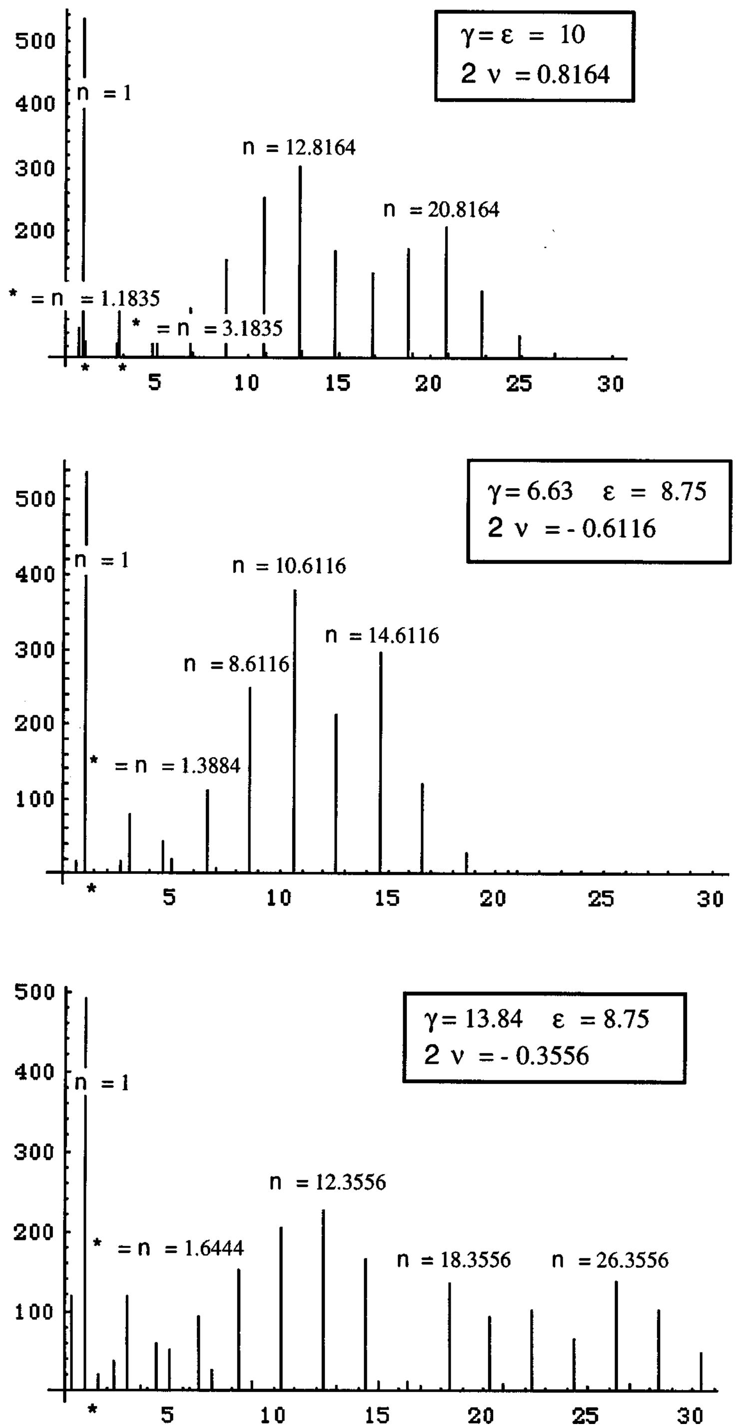

FIG. 2. Fourier spectra for different values of the ϵ,γ parameters.

unavoidable ingredient of the spectrum, but it must also contain *noninteger harmonics* that can be interpreted as the *odd harmonics displaced an amount* $\pm(1-2\nu)$ fixed by the *Floquet exponents* of the system. In both cases (integer and noninteger) the amplitude can be calculated by the expressions (7.4)–(7.7) or alternatively (7.8)–(7.17). We would like to emphasize that this result has arisen directly from the systematic use of the Floquet Analysis. An interesting question for further research is whether a shift in the physical initial conditions may change this Fourier Spectrum that we have just described. Some preliminary calculations show us that if the initial state of the atom is not an eigenstate of the energy, the formalism can be equally applied to the prediction of the Spectrum, but the results show nontrivial changes, both in the amplitudes and in the role played by the phases of the harmonics. Note that the formalism and hence the spectrum, depends only upon the full knowledge of $q(x)$.

A remaining question deals with the behavior of the spectrum in the limiting cases $\omega_0 \to 0$ and $\omega \to 0$. In the first case, any of the equations (3.5) or (3.10) lead to the same result. If the initial state of the atom is an eigenstate of energy, the Dipole Moment vanishes and no outgoing emission would be present. In the latter case, using Eq. (3.10) we obtain in this limit,

$$q(t)=\exp\{i\Omega_0 t\}\left\{ \cos\left(\sqrt{\Omega_0^2+\frac{\omega_0^2}{4}}\,t\right) - i\,\frac{\Omega_0-\frac{\omega_0}{2}}{\sqrt{\Omega_0^2+\frac{\omega_0^2}{4}}}\sin\left(\sqrt{\Omega_0^2+\frac{\omega_0^2}{4}}\,t\right)\right\}, \quad (7.19)$$

and the Dipole Moment takes the form in this case

$$D(t)=|q|^2-1=-\frac{\omega_0\Omega_0}{2\left(\Omega_0^2+\frac{\omega_0^2}{4}\right)}\left\{1-\cos\left(2\sqrt{\Omega_0^2+\frac{\omega_0^2}{4}}\,t\right)\right\}, \quad (7.20)$$

that describes a spectrum given by a constant contribution and just one frequency of value,

$$2\sqrt{\Omega_0^2+\frac{\omega_0^2}{4}}, \quad (7.21)$$

which is the standard result.

In Table III and Fig. 2 we give the results obtained in a *calculation of the Fourier Spectrum* of the atomic dipole moment based on the equations (7.4)–(7.8) and (7.8)–(7.17) for some values of the parameters. Only the Fourier components with an amplitude larger than 10^{-3} have been included. In the case $\epsilon=\gamma=10$, the energy of the atom–laser interaction equals the energy of the atomic transition, and one needs ten photons of the laser to produce the transition. A first estimation of the *Floquet exponent* was made, starting from the values of $u(\pi)$, $u'(\pi)$, $v(\pi)$, $v'(\pi)$ arising from a simulation of the ODE (3.14). The value $\nu=0.408\,202$ was obtained. This value was improved in the above described iterative process, yielding finally a value of $\nu=0.408\,238\,570\,386\,171\,53$. For this last numerical value the *compatibility conditions* (6.13) and (7.11), are zero with numerical precision of one part in 10^{14}. The values of the parameters do not have to be integers, as it is also shown in Table III for the cases $\epsilon=8.75$, $\gamma=6.63$, and $\epsilon=8.75$, $\gamma=13.84$. The theoretically calculated Floquet exponents are $-0.305\,808\,224\,854\,750\,90$ and $-0.177\,814\,603\,653\,674\,38$, respectively, fulfilling the compatibility conditions (6.13) and (7.11) also with an accuracy of one part in 10^{14}.

VIII. CONCLUSIONS

The physical system composed by a two-level atom interacting with a coherent external electromagnetic field has an *exact solution for all ratios between the relevant frequencies of the problem: Transition, Laser, and Rabi frequencies. It is possible to* make use of the dynamical symmetry of the Hamiltonian to develop a *nonperturbative method that allows us to solve exactly the model*. No approximations at all such as the Rotating Wave or Weak Field Approximations have been made. The Schrödinger equation is equivalent to a Riccati differential equation whose solution yields all the physical observables of the system. This Riccati equation can be linearized and becomes a linear second-order differential equation with periodic coefficients. This periodic character allows us to apply Floquet Theory for differential equations with periodic coefficients in order to describe the periodicity properties of the interacting atom. In particular, when the Fourier transform of the electric dipole moment of the atom is calculated and the problem of the Higher Harmonics Generation is considered, qualitatively new and rather surprising conclusions are found. To the usual harmonic spectrum composed by harmonics labeled just by *odd* integers, one should add a series of noninteger harmonics that heavily depend on the Floquet exponent. This Fourier Spectrum was implicit in other contributions on the two-level model (see Ref. 5 and references therein), but is not yet fully understood. Finally, the present authors claim that the new harmonics need to be more carefully analyzed experimentally, as they seem to arise naturally from a model that describes quite accurately the important effect of Higher Harmonic Generation. At any rate the Exact Solution for Strong Field Laser–Atom Interaction hereby presented is relevant in its own right, since the Two-State Model can also be used for a large variety of Physical Applications.

Note added in proof: A more detailed account of the numerical results hereby presented, including a general study for a wide range of the physical parameters as well as a careful numerical analysis dealing with the limiting cases, will be the subject of a forthcoming publication.

ACKNOWLEDGMENTS

We acknowledge with thanks Professor Joseph H. Eberly for his advice and support as well as for a careful reading of a previous version of this manuscript. We would also like to thank both Professor L. Roso-Franco for bringing Ref. 7 to our attention and to an anonymous referee whose suggestions greatly improved various technical aspects of the paper as well as the set of references. This research has been supported in part by the DGICYT under Contract No. PB95-0947.

(Received 22 October 1998; accepted for publication 11 December 1998)

We generalize the Birman–Schwinger method, and derive a general upper bound on the number of bound states in the *S* wave for a spherically symmetric potential. This general bound includes, of course, the Bargmann bound, but also leads, for increasing (negative) potentials, to a Calogero–Cohn-type bound. Finally, we show that for a large class among these potentials, one can obtain further improvements.
 [S0022-2488(99)00804-X]

I. INTRODUCTION

The Birman–Schwinger method[1,2] was invented in order to put the Lippmann–Schwinger equation of scattering theory[3,4] on a firm basis within the framework of the Fredholm theory of integral equation in L^2 spaces. Among many important results, it led to a general proof of the Bargmann bound on the number of bound states,[5] without using the nodal theorem, which asserts that the number of bound states in each angular momentum state of a spherically symmetric potential is equal to the number of nodes (zeros) of the regular solution of the reduced radial Schrödinger equation at zero energy. The nodal theorem was used by Bargmann in his original proof.[5]

The reduced radial Schrödinger equation at zero energy for the lth angular momentum state reads

$$\varphi_l''(r)=\left[\frac{l(l+1)}{r^2}+V(r)\right]\varphi_l(r), \quad \varphi_l(0)=0. \tag{1}$$

The potential is assumed here to satisfy the integrability condition

$$\int_0^\infty r|V(r)|dr<\infty, \tag{2}$$

which entails the self-adjointness of the Hamiltonian $-(d^2/dr^2)+l(l+1)/r^2+V(r)$ in $L^2(0,\infty)$, and other good properties for a well-defined scattering theory.[3,4] Combining the Schrödinger equation and the boundary condition at the origin, one can write (1) as the Fredholm integral equation[3]

$$\varphi_l(r)=r^{l+1}-\frac{1}{(2l+1)}\int_0^\infty r_<^{l+1}r_>^{-l}V(r')\varphi_l(r')dr', \tag{3}$$

[a]Laboratoires associés au Centre National de la Recherche Scientifique.

where the symbols $r_<$ and $r_>$ mean, respectively, minimum (r,r') and maximum (r,r'). Here, the Birman–Schwinger method is to multiply both sides of (3) by $|V(r)|^{1/2}$, and write $\psi_l=|V(r)|^{1/2}\varphi_l$. The equation for ψ_l then has the kernel given by

$$K_l(r,r')=-\frac{r_<^{l+1}r_>^{-l}}{(2l+1)}|V(r)|^{1/2}|V(r')|^{1/2}\frac{V(r')}{|V(r')|}, \tag{4}$$

and it is easily seen that this kernel is indeed of Hilbert–Schmidt type, and has the trace

$$\text{Trace}\,K_l(r,r')=-\frac{1}{2l+1}\int_0^\infty r|V(r)|\text{sign}\,V(r)dr, \tag{5}$$

which, by (2), is finite.

Now, if we write $V=V_++V_-$, where V_+ is the positive part of $V:V_+=V(r)\theta[V(r)]$, and V_- its negative part defined similarly, we have, for the number of bound states n[1–4]

$$n(V)\leqslant n(V_-).$$

An upper bound for $n(V)$ is therefore given by $n(V_-)$. For V_-, the corresponding kernel (4) and its trace (5) are now positive. K_l becomes a symmetric positive kernel, and its characteristic values $\lambda_j^{(-)}$ (inverse of its eigenvalues) are all positive, and accumulate at infinity as $j\rightarrow\infty$ (remember that, for Hilbert–Schmidt kernels, the eigenvalues accumulate at the origin as $j\rightarrow\infty$). With V_-, these characteristic values are defined by

$$\psi_{l,j}(r)=\lambda_j^{(-)}\int_0^\infty\frac{r_<^{l+1}r_>^{-l}}{(2l+1)}|V_-(r)|^{1/2}|V_-(r')|^{1/2}\psi_{l,j}(r')dr'. \tag{6}$$

That there are an infinity of eigenvalues comes from the fact that the kernel is not of finite rank, unless V_- is a finite sum of δ potentials. Looking differently, if we multiply V_- by λ, and increase λ from $\lambda=0$, the characteristic values $\lambda_j^{(-)}$ are the values for which new bound states appear one by one at zero energy, the bottom of the continuum, and then move to the left to become real bound states with negative energy as we increase λ. That this is so follows from the Feynman–Hellmann theorem for bound states (V is negative here!)[4,6]

$$\frac{\partial E_j^{(-)}(\lambda)}{\partial\lambda}\leqslant 0,\quad \lambda\geqslant\lambda_j,\quad E_j^{(-)}(\lambda_j)=0. \tag{7}$$

In all rigor, one must first consider the bound states below some negative energy, $E\leqslant-\epsilon^2$, $\epsilon>0$, consider the number $n_\epsilon(V)$ of these bound states, and then make $\epsilon\downarrow 0$ in order to find the total number of bound states. As shown in Refs. 1, 4, and 6, one uses here the continuity theorem, which shows that one can take this limit for a large class of potentials. In the radial case, this class includes potentials satisfying (2).

We are interested now in those characteristic values $\lambda_j^{(-)}$ for V_- which are in the interval [0, 1] because they give the total number of bound states of V_-. Obviously

$$n(V_-)\leqslant\sum_{\lambda_j^{(-)}\leqslant 1}\frac{1}{\lambda_j^{(-)}}. \tag{8}$$

Therefore

$$n_l(V)\leqslant n_l(V_-)\leqslant\sum_{\lambda_j^{(-)}\leqslant 1}\frac{1}{\lambda_j^{(-)}}\leqslant\sum_{j=1}^{\infty}\frac{1}{\lambda_j^{(-)}}=\text{Trace}\,K_l(V_-)=\frac{1}{(2l+1)}\int_0^\infty r|V_-|dr, \tag{9}$$

which is the Bargmann bound. One can, of course, replace V_- by V inside the integral in (9), but this makes the upper bound bigger, and is unnecessary. Notice that, in (9), the finite sum is less than the infinite sum if all $\lambda_j^{(-)}$ are positive, which is the case here. The potential V_- is negative, and therefore λV_- cannot have bound states if λ also is negative.

The upper bound (9), while it can be saturated by sums of delta-function potentials[1–3]

$$V(r) = -\sum_{1}^{n} g_j \delta(r - r_j), \quad g_j > 0, \tag{10}$$

by adjusting g_j and r_j in order to get equality between the two sides of (9), has several weak points. The first is its bad behavior for strong attractive potentials. Indeed, if we replace V_- by λV_-, and make $\lambda \to \infty$, (9) would suggest that $n(\lambda V_-)$ should grow like λ, whereas we know that it actually grows like $\lambda^{1/2}$, as was shown some years ago.[7,8] This weak point was improved by a new bound by Calogero[9] and Cohn,[10] who showed that, at least for the class of purely attractive and increasing potentials, one has the bound, assuming of course the integral to be finite,

$$n_0(V) \leqslant \frac{2}{\pi} \int_0^\infty |V(r)|^{1/2} dr, \tag{11a}$$

$$V < 0, \quad V' \geqslant 0, \quad V(\infty) = 0. \tag{11b}$$

Here also, one can show that one can make the left-hand side of (11a) as close to the right-hand side as one wishes, with appropriate square-well potentials. The above bound, valid for the S wave $(l=0)$, and therefore for all higher angular momenta, has itself the defect of having, contrary to (9), no l dependence, and also contains the condition $V' \geqslant 0$. It has been shown recently that the condition $V' \geqslant 0$ can be relaxed to a large extent,[11] and also that (11a) can be generalized to $l > 0$ with appropriate l dependence.[12] Let us emphasize here that the proofs of Calogero and Cohn are both based on the nodal theorem mentioned earlier.

The second weak point of (9) is that it is not good for potentials having a strong repulsive (positive) part for, in such cases, the left-hand side of (9) may be much smaller than the right-hand side.

In the present paper, generalizing the Birman–Schwinger method, we are going to show that, first, for potentials satisfying (11b), one can get a bound of the Calogero–Cohn type by the trace method given above, though with a slightly larger constant than $2/\pi$ as in (11a), without using the nodal theorem; and second, generalize this same bound, with an extra term, for a large class of negative potentials which may oscillate (no condition on V'). Finally, we shall show that, for a large class of potentials, one can also improve these new bounds further.

II. CALOGERO–COHN-TYPE BOUND

We consider here purely negative potentials satisfying (2). As mentioned before, we are going to generalize the Birman–Schwinger method to obtain a more general bound than (9), which would contain, as a particular case, a Calogero–Cohn-type bound, of the form (11a), but with the constant 1 instead of $2/\pi$ in front of the integral. For the simplicity of algebra, we restrict ourselves to the case $l=0$ (S wave), and leave the case $l>0$ for a forthcoming paper. In essence, the Birman–Schwinger method relies on the Lippmann–Schwinger integral equation (3) in which the inhomogeneous term is the regular solution for the free case, i.e., without the potential V. However, this is not the only way of writing an integral equation for the full solution. One can write a more general integral equation by writing the Hamiltonian as (remember that we consider $l=0$)

$$H \equiv H_0 + V = -\frac{d^2}{dr^2} + V = \left(\frac{-d^2}{dr^2} + V_0 \right) + (V - V_0) \equiv \overline{H}_0 + \overline{V}, \tag{12}$$

where we assume that V_0 satisfies also (2). If we denote by φ_0 and χ_0 the regular and irregular solutions of $\overline{H}_0\psi=0$, such that $\varphi_0(0)=0$, $\varphi_0'(0)=1$, $\chi_0(0)=1$, $\lim_{r\to 0} r\chi_0'(r) = \lim_{r\to 0}\varphi_0(r)\chi_0'(r)=0$, and Wronskian $(\varphi_0,\chi_0)\equiv\varphi_0'\chi_0-\varphi_0\chi_0'=1$, we have the integral equation[3]

$$\varphi(r)=\varphi_0(r)-\int_0^\infty \varphi_0(r_<)\chi_0(r_>)\overline{V}(r')\varphi(r')dr', \tag{13}$$

as can be verified easily. Also, since we assume V_0 to satisfy (2), the above equation is, as for (3), a good equation of the Fredholm type, with well-defined Fredholm determinants (numerator as well as denominator).[3] One can again use the Birman–Schwinger method by multiplying both sides of (13) by $|\overline{V}|^{1/2}$ in order to obtain an L^2 kernel of Hilbert–Schmidt type with finite trace. Indeed, since V_0 is supposed to satisfy (2), we have the general bound[3]

$$|\varphi_0\chi_0|\leqslant Ar \tag{14}$$

for all values of r, with an appropriate finite constant $A(>0)$. When $V_0=0$, we get back, of course, (3) for $l=0$. *We shall assume henceforth that* $V_0(r)\geqslant 0$. Let us now look at the homogeneous integral equation which defines the characteristic values $\overline{\lambda}_j$ which correspond to the thresholds in $\overline{\lambda}$ for having new bound states appearing at zero energy ($\overline{V}=V-V_0$, $V\leqslant 0$, $V_0\geqslant 0$, $\overline{V}\leqslant 0$):

$$\overline{\varphi}(r)=-\overline{\lambda}\int_0^\infty \varphi_0(r_<)\chi_0(r_>)\overline{V}(r')\overline{\varphi}(r')dr' \tag{15}$$

and its corresponding differential equation

$$\overline{\varphi}''(r)=V_0\overline{\varphi}(r)+\overline{\lambda V}\overline{\varphi}(r). \tag{16}$$

We have to compare this equation with the original Schrödinger equation

$$\varphi''(r)=\lambda V(r)\varphi(r). \tag{17}$$

Since $\overline{V}=V-V_0$, we see that (16) and (17) are identical for $\overline{\lambda}=\lambda=1$, as it should be. Now, if $V(r)$ has n bound states, this means that there are n characteristic values λ_j in the interval (0, 1]. Therefore, there should exist also n values of $\overline{\lambda}_j$ in (0, 1] since for $\overline{\lambda}=1$, $V_0+\overline{\lambda V}$ has n bound states. There is a one-to-one correspondence between λ_j and $\overline{\lambda}_j$ for $j=1,2,...,n$. Also, since V_0 in (16) was assumed to be positive, it is obvious, by comparing $\varphi_j''=\lambda_j V\varphi_j$ with $\overline{\varphi}_j''=V_0\overline{\varphi}_j+\overline{\lambda}_j\overline{V}\overline{\varphi}_j=\overline{\lambda}_j V\overline{\varphi}_j+(1-\overline{\lambda}_j)V_0\overline{\varphi}_j$, that we should have $\overline{\lambda}_j>\lambda_j$ for $j=1,2,...,n$. This is simply because, for $j\leqslant n$, the potential $(1-\overline{\lambda}_j)V_0$ in the last equation is repulsive. For $j>n$, the reverse is true: $\lambda_j>\overline{\lambda}_j$. These are all simple consequences of Sturm-type comparison theorems.[15] Also, it is obvious that we cannot have any negative characteristic values $\overline{\lambda}$ for (16) since, for $\overline{\lambda}<0$, the total potential there is positive. In any case, for getting an upper bound for the number of bound states of $V(r)$, we can, as well, look at (15), and use

$$n(V)\leqslant\sum_{\overline{\lambda}_j\leqslant 1}\frac{1}{\overline{\lambda}_j}. \tag{18}$$

Proceeding as before, and remembering that, by hypotheses on V and V_0, we are dealing with positive definite kernels, we get the general bound

$$n(V) \leqslant -\int_0^\infty \varphi_0(r)\chi_0(r)[V-V_0]dr, \quad V\leqslant 0, \quad V_0 \geqslant 0, \tag{19}$$

which we are going now to exploit by making appropriate choices for V_0. Note that, if we take $V_0=0$, we have $\varphi_0=r$, $\chi_0=1$, and we get back the Bargmann bound.

Calogero–Cohn-type bound: Since V is assumed to be purely attractive, and we wish to obtain a Calogero–Cohn-type bound, we have also to assume, as they did, that $V'\geqslant 0$. The appropriate choice of V_0 would here be

$$V_0 = -V - \frac{d}{dr}\sqrt{-V(r)}, \quad \bar{V} = 2V + \frac{d}{dr}\sqrt{-V}, \tag{20}$$

in V_0 both parts are positive, and in $\bar{V}$ both parts are negative. The Schrödinger equation for this V_0 reads now

$$\left(-\frac{d}{dr}+\sqrt{-V(r)}\right)\left(\frac{d}{dr}+\sqrt{-V(r)}\right)\psi_0 = 0. \tag{21}$$

It is easily seen that its solutions φ_0 and χ_0 are given by

$$\chi_0(r) = \exp\left(-\int_0^r \sqrt{-V(t)}dt\right), \tag{22a}$$

$$\varphi_0(r) = \exp\left(-\int_0^r \sqrt{-V(u)}du\right)\int_0^r \exp\left(+2\int_0^t \sqrt{-V(u)}du\right)dt, \tag{22b}$$

so that

$$\varphi_0(r)\chi_0(r) = \int_0^r \exp\left[-2\int_t^r \sqrt{-V(u)}du\right]dt. \tag{23}$$

Using this in (19), and integrating by parts the term containing $\varphi_0\chi_0 d\sqrt{-V(r)}$, we get

$$n \leqslant \int_0^\infty (-V(r))^{1/2}dr, \quad V\leqslant 0, \quad V'\geqslant 0, \tag{24}$$

which is the desired result. Although (24) is not as good as (11a), it contains its main feature, which is that, for the Calogero–Cohn type potentials, the upper bound of $n(\lambda V)$ grows as $\lambda^{1/2}$ in the limit of λ becoming very large. But we did not use the nodal theorem.

More general bound: We can take, more generally,

$$V_0 = W_0^2 - W_0', \tag{25}$$

where W_0 is assumed to be positive and decreasing (non-increasing). Proceeding as before, we would then get

$$n \leqslant \int_0^\infty [W_0 - (V+W_0^2)\varphi_0\chi_0]dr, \tag{26}$$

where φ_0, χ_0, and $\varphi_0\chi_0$ are given by formulas identical to (22a), (22b), and (23) in which $\sqrt{-V}$ is replaced by W_0. Here, we have a formula in which V is given, and W_0 is arbitrary. One may think of setting up a variational principle for finding W_0 such that the integral in (26) is minimum. Unfortunately, the Euler equation one gets has no solution.

Oscillating negative potentials: Let us now first assume that the potential is of bounded variation. It is then known that such a function can be written as the difference of two positive and monotone functions.[13,14] Saying it differently,

$$V(r)=\tilde{V}_{+}(r)+\tilde{V}_{-}(r), \tag{27}$$

where $\tilde{V}_{+}$ is positive, $\tilde{V}_{-}$ is negative, and we have $\tilde{V}'_{+}\leqslant 0$ and $\tilde{V}'_{-}\geqslant 0$. Since $V(\infty)=0$, we also have $\tilde{V}_{\pm}(\infty)=0$. We can now choose our previous V_0 in (25) to be

$$\tilde{V}_0=-\tilde{V}_{-}-\frac{d}{dr}\sqrt{-\tilde{V}_{-}}(\geqslant 0). \tag{28}$$

We would then get

$$n(V)\leqslant\int_0^\infty[|\tilde{V}_{-}|^{1/2}-(\tilde{V}_{+})\tilde{\varphi}_{-}\tilde{\chi}_{-}]dr, \tag{29}$$

where $\tilde{\varphi}_{-}$ and $\tilde{\chi}_{-}$ are given by formulas similar to (22a) and (22b). *Remember that here* $\tilde{V}_{+}$ *and* $\tilde{V}_{-}$ *are not just simply the positive and negative parts of the potential*.

The bound (29) is somehow a generalization of (24) to the case of oscillating potentials. See also Ref. 11 for the generalization of (11a) for another class of oscillating potentials, as we mentioned earlier.

Remark: When the potential is not of bounded variation (too many oscillations around some points, going to $-\infty$ at $r=0$, etc.), it can often be the limit of such functions. If this is the case, and the limits $\tilde{V}_{-}$ and $\tilde{V}_{+}$ are such that the integrals on the right-hand side of (29) are finite, then (29) is valid. Note also that $\tilde{\varphi}_{-}$ and $\tilde{\chi}_{-}$ are explicitly given by (22a) and (22b). In conclusion, we have

Theorem: For negative potentials of total bounded variation on $[0, \infty)$, the number of bound states in the S wave satisfies the inequality (29). For negative potentials which satisfy (2), and are appropriate limits of potentials of bounded variation such that the two integrals on the right-hand side of (29) are each finite, the bound also holds.

III. IMPROVING THE BOUND (24)

So far, we have been writing

$$n\leqslant\sum_{\Lambda_j\geqslant 1}\bar{\Lambda}_j\leqslant\sum_{\text{all } j}\bar{\Lambda}_j, \tag{30}$$

where $\Lambda_j=1/\lambda_j$ are the eigenvalues of the positive kernels of our various integral equations, and then have calculated the last sum by the trace of the kernels. One way to improve on this is to stop at the middle sum. More specifically, to write

$$n\leqslant\sum_{\text{all } j}\bar{\Lambda}_j-\sum_{\Lambda_j<1}\bar{\Lambda}_j \tag{31}$$

and then try to find a lower bound for the second sum in (31), and use it there. If this can be done, one would then get an improvement of (30).

We are going to show that this can be done, at least for a class of potentials defined as follows. First, we have to remember that we had two sets of characteristic values, $\{\lambda_j\}$ for the original Schrödinger equation, and $\{\bar{\lambda}_j\}$ for the modified equation. And we had $\bar{\lambda}_j<\lambda_j$ for $j>n$, that is,

$$\Lambda_j<\bar{\Lambda}_j<1,\quad j>n. \tag{32}$$

Therefore, we can replace the second sum on the right-hand side of (31) by $\Sigma_{n+1}^{\infty}\Lambda_j$, and get still an upper bound for n. Now, assume that the potential V, which is purely attractive, satisfies $V'\geqslant 0$. We make now the Liouville transformation[15]

$$r\to Z=Z(r)=\int_0^r\sqrt{-V(t)}dt,$$

$$\overline{\varphi}(r)\to\psi(Z)=[-V(r)]^{1/4}\overline{\varphi}(r)|_{r=r(Z)}, \tag{33a}$$

in the Schrödinger equation (16) with (20):

$$\overline{\varphi}''=\left[(2\overline{\lambda}-1)V+(\overline{\lambda}-1)\frac{d}{dr}\sqrt{-V}\right]\overline{\varphi}. \tag{33b}$$

The change of variable $r\to Z$ is a good one-to-one and C^2 mapping from $[0,\infty)$ to $[0,I=\int_0^\infty\sqrt{-V(r)}dr<\infty]$. It is easily seen that the Schrödinger equation (33b), with $\overline{\varphi}(0)=0$, is transformed to[15]

$$\ddot{\psi}(Z)+(2\overline{\lambda}-1)\psi(Z)=\tilde{V}(Z)\psi(Z)+(\overline{\lambda}-1)\left[\frac{(\sqrt{-V})'}{-V}\right]\psi(Z),$$

$$\tilde{V}(Z)=\frac{\ddot{F}(Z)}{F(Z)},\quad F(Z)=[-V(r)]^{1/4}|_{r=r(Z)}, \tag{34}$$

$$Z\in[0,I],\quad \psi(0)=0,\quad I=\int_0^\infty\sqrt{-V(r)}dr.$$

The Liouville transformation does not change, of course, anything essential: self-adjointness of the new Hamiltonian is secured, and the characteristic values $\overline{\lambda}_j$, corresponding now to the eigenvalues $2\overline{\lambda}_j-1$, remain the same. As for the boundary condition at $Z=I$, we have to remember that for bound states in the r variable, the boundary condition at $r=\infty$ is $\overline{\varphi}'+\gamma\overline{\varphi}=0$, where $-\gamma^2$ is the energy of the bound state.[3] At zero energy, that is, at the thresholds $\overline{\lambda}_j$, the condition becomes simply[3]

$$\overline{\varphi}_j'(\infty)=0,\quad \overline{\varphi}_j(\infty)=\text{finite constant}. \tag{35}$$

Since $V(\infty)=0$, the boundary condition for $\psi(Z)$ is then

$$\psi(I)=0. \tag{36}$$

We have therefore the Dirichlet boundary condition at both ends of the interval for $\psi(Z)$.

For $\overline{\lambda}>1$, the second potential on the right-hand side of the differential equation (34) is negative. Now, assume that $\tilde{V}(Z)$ in (34) is also negative (attractive) everywhere in $[0,I]$. In the presence of both potentials, we have the eigenvalues of (34), $0<(2\overline{\lambda}_1-1)<(2\overline{\lambda}_2-1)<\cdots$. If we neglect these negative potentials, we get the ''free'' eigenvalues

$$2\overline{\lambda}_j^{(0)}-1=\frac{j^2\pi^2}{I^2},\quad j=1,2,... \tag{37}$$

and we know that $2\overline{\lambda}_j^{(0)}-1>2\overline{\lambda}_j-1$ for $j=n+1,...$. Therefore, we have the bound

$$\sum_{j=n+1}^{\infty} \frac{1}{\overline{\lambda_j^{(0)}}} \leqslant \sum_{j=n+1}^{\infty} \frac{1}{\overline{\lambda_j}}. \tag{38}$$

Using (37) on the left-hand side here, we get the sum (and its minorant integral)

$$2I^2 \sum_{n+1}^{\infty} \frac{1}{I^2 + j^2\pi^2} \geqslant 2I^2 \int_{n+1}^{\infty} \frac{dx}{I^2 + \pi^2 x^2}. \tag{39}$$

Using this to minorize the left-hand side of (38), we get ($\overline{\Lambda}_j = \overline{\lambda}_j^{-1}$)

$$\sum_{j=n+1}^{\infty} \overline{\Lambda}_j \geqslant \frac{2I}{\pi}\left[\frac{\pi}{2} - \mathrm{Arctg}\,\frac{\pi}{I}(n+1)\right]. \tag{40}$$

Using this now in (31), and remembering the trace (24), we get finally

$$n \leqslant \frac{2I}{\pi}\,\mathrm{Arctg}\left[\frac{\pi}{I}(n+1)\right], \tag{41}$$

which we have to solve to get a bound for n. Starting with $n \leqslant I$, and iterating (41), we end up, in fact, with an upper bound n_0 given by the solution of the equation

$$n \leqslant n_0 = \frac{2I}{\pi}\,\mathrm{Arctg}\left[\frac{\pi}{I}(n_0+1)\right], \tag{42}$$

which we have to solve for n_0. It can easily be seen that this bound is better than (24), but yet not as good as the Calogero–Cohn bound (11a).

It is also easily seen that a sufficient condition for $\tilde{V}(Z)$ to be purely attractive ($\leqslant 0$) is that $[-V(r)]^{-1/4}$ be a concave function of r (concave upward!). Of course, for such potentials, we can also improve the Bargmann bound. In any case, we have

Theorem: For any negative potential which satisfies (2), and is such that $G(r) = [-V(r)]^{-1/4}$ is a concave function (upward) of r, we have the upper bound $n \leqslant n_0$, where n_0 is given by (42). Note that, if $(-V)^{-1/4}$ is concave, we have $V' \geqslant 0$.

Energy levels of a quantal particle enclosed in *N* identical, mirror symmetric wells of a periodic potential. Numerical test of phase-integral formulas

Per Olof Fröman, Kilian Larsson, and Anders Hökback
Department of Theoretical Physics, University of Uppsala, Box 803, S-751 08 Uppsala, Sweden

(Received 24 March 1998; accepted for publication 2 December 1998)

An interesting structure prevails for the energy levels of a quantal particle in a periodic potential with N ($\geqslant 2$) mirror symmetric wells separated by $N-1$ mirror symmetric barriers, when the logarithmic derivative of the wave function is given at corresponding (periodically and mirror symmetrically situated) points in the barrier to the left of the first well and in the barrier to the right of the Nth well. It is shown that the quantization conditions that one obtains for these energy levels by means of a careful and rigorous phase-integral treatment are capable of giving extremely accurate results. The accuracy obtainable is demonstrated for $N=3$ by comparison with numerically exact results, which were obtained by means of the extended version of the phase-amplitude method presented in an Appendix. In the concluding section we summarize the results and point out unexpected features of the energy spectrum and the wave functions. Two different boundary conditions, commonly used in the theory of crystals, and closely related to the present investigation, are also discussed there. © *1999 American Institute of Physics.* [S0022-2488(99)02303-8]

I. INTRODUCTION

During several decades the solution of the one-dimensional Schrödinger equation has been the subject of numerous studies, both analytical and numerical. In spite of this fact, there are still problems of that kind, the solutions of which can give rise to new physical insight. One such problem concerns the energy levels of a quantal particle in a periodic potential subject to varying boundary conditions. Phase-integral formulas for the solution of this problem, derived by Fröman and Fröman (unpublished) on the basis of results in Chaps. 1 and 5 of Ref. 1, reveal an interesting structure of the energy spectrum and unexpected properties of the wave functions. Since it is the question of subtle effects, it seemed desirable to confirm the correctness of the phase-integral formulas and to test their accuracy by numerical calculations. It thereby turned out that the numerical phase-amplitude method,[2–6] though very powerful, had to be further extended as described in an Appendix. It is the purpose of this paper to present the phase-integral formulas along with results of numerical calculations for checking their accuracy, and to draw attention to the unexpected, and to our knowledge hitherto unknown, features of energy spectrum and wave functions that are revealed by the formulas.

II. PHASE-INTEGRAL QUANTIZATION CONDITIONS

Consider the one-dimensional Schrödinger equation

$$\frac{d^2\psi}{dx^2}+R(x)\psi=0, \tag{2.1}$$

where, with obvious notations,

0022-2488/99/40(4)/1764/16/$15.00

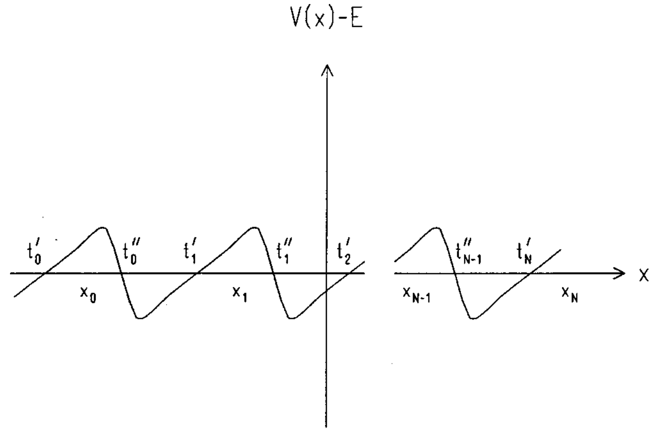

FIG. 1. The figure shows $V(x)-E$ as a function of x, where E is the energy of a quantal particle in a periodic potential $V(x)$ with N wells separated by $N-1$ barriers. The points x_0 and x_N are the points where the boundary conditions (2.3a) and (2.3b) are imposed on the wave function, and the points $x_1,\ldots,x_{N-1}$ correspond to the auxiliary points $z_1,\ldots,z_{N-1}$ that are used in the numerical phase-amplitude method described in Appendix B of the present paper. In the figure the wells and barriers are not mirror symmetric, although the treatment in this paper (except in the appendices) is restricted to the mirror symmetric case.

$$R(x)=\frac{2m}{\hbar^2}[E-V(x)]. \tag{2.2}$$

The potential $V(x)$ is assumed to be periodic and to consist of broad wells separated by barriers that are assumed to be mirror symmetric. Let x_0 be a point in a barrier, and let x_N ($N\geqslant 2$, $x_0<x_N$) be a point in another barrier such that between x_0 and x_N there are N wells separated by $N-1$ barriers; see Fig. 1. The points x_0 and x_N are assumed to be situated at the barrier maxima. Considering the wave function $\psi(x)$ in the interval $x_0\leqslant x\leqslant x_N$, we impose the boundary conditions

$$\psi'(x_0)/\psi(x_0)=k_0, \tag{2.3a}$$

$$\psi'(x_N)/\psi(x_N)=k_N. \tag{2.3b}$$

With the aid of the phase-integral approximation generated from an unspecified base function, described by Fröman and Fröman in Chap. 1 of Ref. 1, and also presented briefly in our Appendix A, Fröman and Fröman (unpublished) have derived quantization conditions for the problem described above.

For the case that $k_0=k_N=k$ the energy levels are obtained from the two quantization conditions

$$L=(s+1/2)\pi-\tilde{\phi}-\arcsin\frac{\cos(\nu\pi/N)}{[\exp(2K)+1]^{1/2}},$$

$$s=0,1,2,\ldots;\quad \nu=1,\ldots,N-1, \tag{2.4a}$$

$$L=(s+1/2)\pi-\tilde{\phi}+\arctan\left(\frac{k^2[1+\exp(-2K)]+|q(x_0)|^2}{k^2[1+\exp(-2K)]-|q(x_0)|^2}\exp(-K)\right),$$

$$s=0,1,2,\ldots, \tag{2.4b}$$

where (see Fig. 1)

$$L=\left|\int_{(t''_{n-1})}^{(t'_n)} q(z)dz\right|, \quad 1\leqslant n\leqslant N, \tag{2.5}$$

$$K=\left|\int_{(t'_n)}^{(t''_n)} q(z)dz\right|, \quad 1\leqslant n\leqslant N-1, \tag{2.6}$$

and $\tilde{\phi}$ is the function given by eq. (5.5.30), with ϕ replaced by $\tilde{\phi}$, $\lambda=1$ and $\ln(\overline{K_0}/\lambda)$ replaced by $\ln|\overline{K_0}|$, along with eqs. (5.5.25a–g), (5.4.21), and (5.4.23) in Chap. 5 of Ref. 1. In (2.5), as well as in (2.6), the integral, with the limits of integration within parentheses, is a simplified notation for half of the corresponding contour integral along a closed contour encircling the two limits of integration; see pp. 90–91 in Ref. 1. For the first order of the phase-integral approximation it is equal to an ordinary integral between the two limits of integration. The quantization condition (2.4a) has been derived under the assumption that the barriers are superdense, while the quantization condition (2.4b) has been derived under the assumption that the barriers are not only superdense but also thick. The accuracy of (2.4a) is expected to be greater than that of (2.4b) except when k approaches 0 or ∞. When $K(>0)$ is sufficiently large compared to unity, one can neglect $\exp(-2K)$ in (2.4b), getting

$$L=(s+1/2)\pi-\tilde{\phi}+\arctan\left(\frac{k^2+|q(x_0)|^2}{k^2-|q(x_0)|^2}\exp(-K)\right). \tag{2.4b$'$}$$

Numerical checks show that the accuracy of (2.4b′) is almost the same as that of (2.4b) even when K is as small as 2.7. When k is equal to zero or infinity, one can unify the two quantization conditions (2.4a) and (2.4b) into the single quantization condition

$$L=(s+1/2)\pi-\tilde{\phi}-\arcsin\frac{\cos(\nu\pi/N)}{[\exp(2K)+1]^{1/2}},$$
$$s=0,1,2,\ldots,\nu=0,\ldots,N-1 \ \text{ when } \ k=0, \quad \nu=1,\ldots,N \ \text{ when } \ k=\infty, \tag{2.7}$$

and for the validity of this quantization condition it is sufficient that the barriers are superdense. Since the potential is mirror symmetric, and the points x_0 and x_N are situated in a mirror symmetric way, the exact energy levels must be independent of the sign of k in the case when $k_0=k_N=k$. The approximate energy levels obtained from the quantization conditions (2.4a) and (2.4b), as well as (2.4a) and (2.4b′), also possess this property. These quantization conditions reveal an unexpected property of the energy spectrum and the corresponding eigenfunctions. For a given value of the quantum number s, the condition (2.4a) yields $N-1$ fine structure levels that depend on N but not on k, while the condition (2.4b), as well as (2.4b′), yields one *particular* level that depends on k but not on N. For each one of the $N-1$ *nonparticular* energy levels any solution of the differential equation (2.1) is an eigenfunction corresponding to a certain value of k. For the *particular* energy level there is a uniquely determined eigenfunction (except for a constant factor); it has the periodicity of the potential. When the absolute value of k increases from zero to infinity, one sees from (2.4b) or (2.4b′) that $L-(s+1/2)\pi+\tilde{\phi}$ decreases monotonically, and assumes for $|k|=0$ the approximate value $\pi-\exp(-K)$, then decreases slightly until $|k|$ approaches $|q(x_0)|[1+\exp(-2K)]^{-1/2}$, then decreases rapidly and assumes the value $\pi/2$ when $|k|$ is equal to $|q(x_0)|[1+\exp(-2K)]^{-1/2}$, then continues to decrease rapidly, and finally decreases slowly until $L-(s+1/2)\pi+\tilde{\phi}$ assumes the approximate value $\exp(-K)$ for $|k|=\infty$. The decrease of $L-(s+1/2)\pi+\tilde{\phi}$ from values slightly below π to values slightly above 0 takes place in an interval of $|k|$ values around $|q(x_0)|[1+\exp(-2K)]^{-1/2}$ that is small compared to $|q(x_0)|$.

For the case that $k_0=-k_N=k(>0)$ and $N\geqslant 3$, and the barriers are superdense and thick, the energy levels are obtained from the quantization condition

$$L=(s+1/2)\pi-\tilde{\phi}-\arcsin\Delta,\quad N\geqslant 3, \tag{2.8}$$

where Δ (small to its absolute value) is obtained from the equation (Fröman and Fröman, unpublished)

$$\left(\Delta+\frac{\kappa}{[\exp(2K)+1]^{1/2}}\right)\prod_{\mu=1}^{N-1}\left(\Delta-(-1)^s\frac{\cos(\mu\pi/N)}{[\exp(2K)+1]^{1/2}}\right)$$
$$-\frac{1-\kappa^2}{4[\exp(2K)+1]}\prod_{\mu=1}^{N-2}\left(\Delta-(-1)^s\frac{\cos[\mu\pi/(N-1)]}{[\exp(2K)+1]^{1/2}}\right)=0,\quad N\geqslant 3, \tag{2.9}$$

where

$$\kappa=\frac{k-|q(x_0)|}{k+|q(x_0)|}. \tag{2.10}$$

In the limit when $k\to 0$ or $k\to\infty$ one obtains the quantization condition (2.7) from (2.8), (2.9), and (2.10) by replacing in (2.9) μ by ν when s is even but by $N-\nu$ when s is odd. In these limits (2.9) is expected to give more accurate values of Δ than for other values of k. In the particular case when $N=3$ the quantum number s disappears from (2.9), and this equation has the three roots:

$$\Delta_1=\frac{(\kappa^2+8)^{1/2}-\kappa}{4[\exp(2K)+1]^{1/2}}\quad(>0), \tag{2.11a}$$

$$\Delta_2=-\frac{\kappa}{2[\exp(2K)+1]^{1/2}}, \tag{2.11b}$$

$$\Delta_3=-\frac{(\kappa^2+8)^{1/2}+\kappa}{4[\exp(2K)+1]^{1/2}}\quad(<0). \tag{2.11c}$$

It is easily seen that

$$\Delta_1>\Delta_2>\Delta_3. \tag{2.12}$$

When $k=0$ the root Δ_1, when inserted into (2.8), gives the particular state that one obtains from (2.7) for $\nu=0$. When $k=\infty$ the root Δ_3, when inserted into (2.8), gives the particular state that one obtains from (2.7) for $\nu=N=3$.

III. CHOICE OF POTENTIAL

To get information on the capability of the phase-integral quantization conditions presented in Sec. II to give accurate results it is convenient to choose the analytical expression for the potential $V(x)$ to be physically reasonable and to contain some parameters, so that the shape of the potential can be changed. By solving then the eigenvalue problem numerically as well as by means of the quantization conditions in Sec. II, and comparing the results thus obtained, one can get some information on the accuracy of the phase-integral eigenvalues associated with potentials of various shapes.

Our choice of potential is

$$V(x)=E_0\sum_{n=-\infty}^{+\infty}\exp\left[-\left(\frac{x-na}{b}\right)^2\right]. \tag{3.1}$$

When we introduce the dimensionless variable

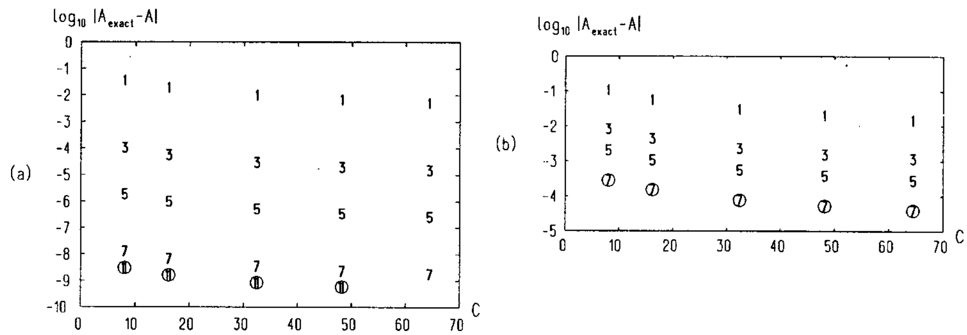

FIG. 2. In this figure $N=3$, $k_0=k_3=\infty$, $B=50$, $\nu=1$, and $K\approx 2.7$. In (a), where $\tilde{\phi}$ in (2.7) is retained, one obtains in the ninth-order approximation errors that are almost the same as those of the seventh-order approximation but of opposite sign. In (b), where $\tilde{\phi}$ in (2.7) is replaced by zero, one obtains in the ninth-order approximation errors that are almost the same as those of the fifth-order approximation but of opposite sign. In both (a) and (b) the quantum number s in (2.7) is $s=12$, 28, 60, 91, and 123 (corresponding to five different values of C).

$$z=\frac{x}{b} \tag{3.2}$$

and the dimensionless parameters

$$A=\frac{2mE_0b^2}{\hbar^2}, \tag{3.3a}$$

$$B=\frac{2mE_0b^2}{\hbar^2}, \tag{3.3b}$$

$$C=\frac{a}{b}, \tag{3.3c}$$

the Schrödinger equation (2.1) along with (2.2) and (3.1) becomes

$$\frac{d^2\psi}{dz^2}+\left\{A-B\sum_{n=-\infty}^{+\infty}\exp[-(z-nC)^2]\right\}\psi=0, \tag{3.4}$$

where we shall assume that

$$0<A<B, \tag{3.5a}$$

$$0<C. \tag{3.5b}$$

IV. NUMERICAL RESULTS

For a fixed value of B and various values of C we have calculated the eigenvalues A of the Schrödinger equation (3.4) by means of the quantization condition (2.7) with $N=3$ and $k=\infty$ for such values of s that K, defined by (2.6), remains approximately constant. In the present section the variable x in Sec. II is, of course, replaced by z; cf. (3.2). We have made the calculations with $\tilde{\phi}$ in (2.7) retained as well as replaced by zero. We have also calculated the corresponding exact eigenvalues A_{exact} by means of the phase-amplitude method described in Appendix B of the present paper. The values of $\log_{10}|A_{\text{exact}}-A|$ are shown for a fixed value of B and for various values of C in each one of Figs. 2 and 3. The digits in these figures indicate the orders of the phase-integral approximation. When there is a circle around such a digit, the quantity $A_{\text{exact}}-A$ is

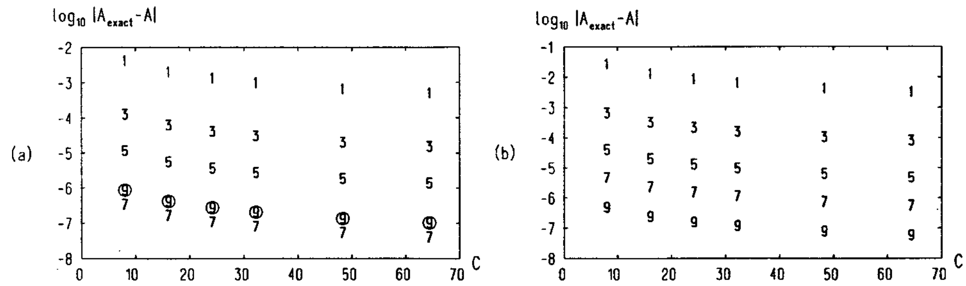

FIG. 3. In this figure $N=3$, $k_0=k_3=\infty$, $B=50$, $\nu=1$, and $K\approx 7.1$. In (a), where $\tilde{\phi}$ in (2.7) is retained, one obtains in the eleventh- and thirteenth-orders approximation errors that are almost the same as those of the ninth-order approximation and of the same sign. In (b), where $\tilde{\phi}$ in (2.7) is replaced by zero, one obtains in the 11th-order approximation errors that are only slightly smaller than those of the ninth-order approximation but of opposite sign, and in the 13th-order approximation one obtains errors that are almost the same as those of the ninth-order approximation but of opposite sign. In both (a) and (b) the quantum number s in (2.7) is $s=8$, 20, 32, 44, 68, and 92 (corresponding to six different values of C).

positive; otherwise $A_{\text{exact}}-A$ is negative. Each one of Figs. 2(a) and 3(a) shows the error when, in (2.7), $\tilde{\phi}$ is retained, while each one of Figs. 2(b) and 3(b) shows the error when, in (2.7), $\tilde{\phi}$ is replaced by zero. Since it is instructive to know how the wave function behaves for different values of ν, we have in Figs. 4 and 5 plotted the wave function (without caring about its normalization) for two different sets of values of B, C, s and the different possible values of ν. Note that, although $s=0$, the wave function in Fig. 4(b), as well as in Fig. 5(b), has a node in the middle potential well and is to its absolute value much smaller in this well than in the two adjacent wells.

For fixed values of B and C and values of $k_0=k_3=k$ ranging from -10 to $+10$ we have calculated energy eigenvalues A of the Schrödinger equation (3.4) by means of the numerically exact phase-amplitude method presented in Appendix B. The results are presented in Fig. 6.

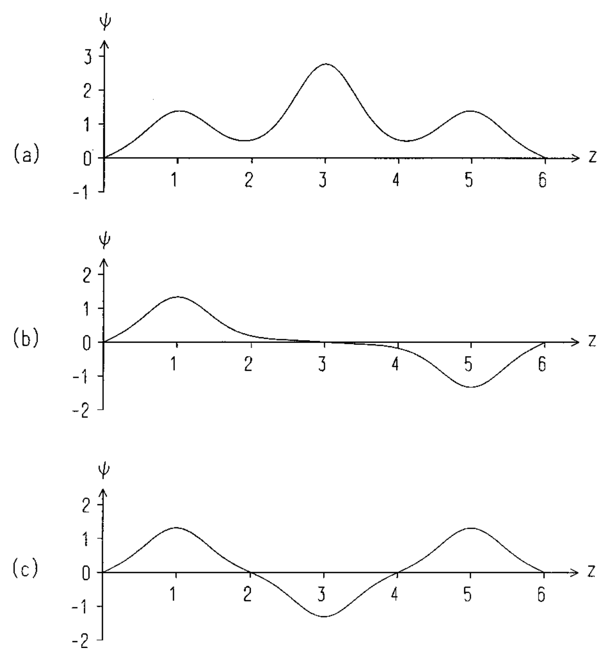

FIG. 4. In this figure $N=3$, $k_0=k_3=\infty$, $B=50$, $C=2.0034$, $s=0$, and $K=2.697$ in the fifth order of the phase-integral approximation. The classically allowed regions are $0.6<z<1.4$, $2.6<z<3.4$, and $4.6<z<5.4$. In (a) $\nu=1$ and $A_{\text{exact}}=41.939\,237\,827\,890$. In (b) $\nu=2$ and $A_{\text{exact}}=42.178\,416\,065\,134$. In (c) $\nu=3$ and $A_{\text{exact}}=42.312\,438\,121\,360$.

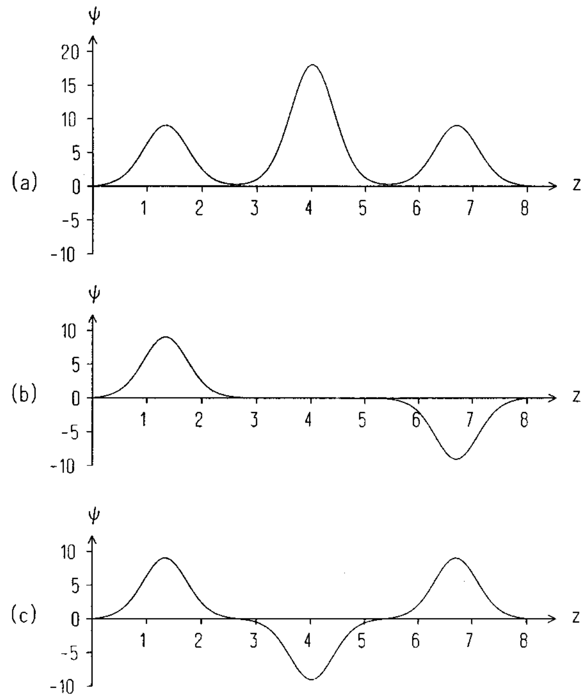

FIG. 5. In this figure $N=3$, $k_0=k_3=\infty$, $B=50$, $C=2.68055$, $s=0$, and $K=7.099$ in the fifth order of the phase-integral approximation. The classically allowed regions are $0.9<z<1.7$, $3.6<z<4.4$, and $6.3<z<7.1$. In (a) $\nu=1$ and $A_{\text{exact}}=22.845\,113\,870\,188$. In (b) $\nu=2$ and $A_{\text{exact}}=22.848\,428\,923\,516$. In (c) $\nu=3$ and $A_{\text{exact}}=22.850\,090\,112\,763$.

When $N=3$ and $k_0=-k_3=k>0$ we have for a fixed value of B and various values of C and k calculated the eigenvalues A of the Schrödinger equation (3.4) by means of the quantization condition (2.8) with $\tilde{\phi}$ retained and with Δ given by (2.11a) and (2.10) for such values of s that K, defined by (2.6), remains approximately constant. The phase-integral results thus obtained for the lowest fine structure level associated with the quantum number s under consideration have been compared with the corresponding exact energy levels obtained by means of the numerically exact phase-amplitude method presented in Appendix B. The absolute errors of the phase-integral values for the energy levels are presented graphically in Figs. 7 and 8. The digits in these figures indicate the orders of the phase-integral approximation. When there is a circle around such a digit, the quantity $A_{\text{exact}}-A$ is positive; otherwise $A_{\text{exact}}-A$ is negative. By recalling that the quantization conditions pertaining to $k=k_1=k_3$ and to $k=k_1=-k_3$ are the same in the limit $k\to\infty$, and by comparing Fig. 2(a) with Fig. 7 and Fig. 3(a) with Fig. 8, and by comparing also a number of figures analogous to these figures, but not presented in the present paper, we have found that even for very large values of k the figures may look quite different from those obtained in the limit $k\to\infty$.

V. CONCLUSIONS

For every quantum number s there are, in the case of $N(\geq 2)$ wells and $k_0=k_N=k$, in general N fine structure levels. Among these levels there is a *particular* one for which the energy is affected by the value of the logarithmic derivative k, but not by the number N of wells. The eigenfunction of this level is uniquely determined (except for a constant factor), and this eigenfunction has the same form in every well; only the amplitude is in general changed from one well to another. For the other $N-1$ *nonparticular* levels the energies are not affected by the value of the logarithmic derivative k, but by the number N of wells. For each one of these levels every solution of the Schrödinger equation is periodic (except sometimes for a change of sign) over the N wells. This unexpected behavior of the fine structure levels and the wave functions, which we have verified for $N=3$ (see Fig. 6), is to the best of our knowledge hitherto unknown. In certain

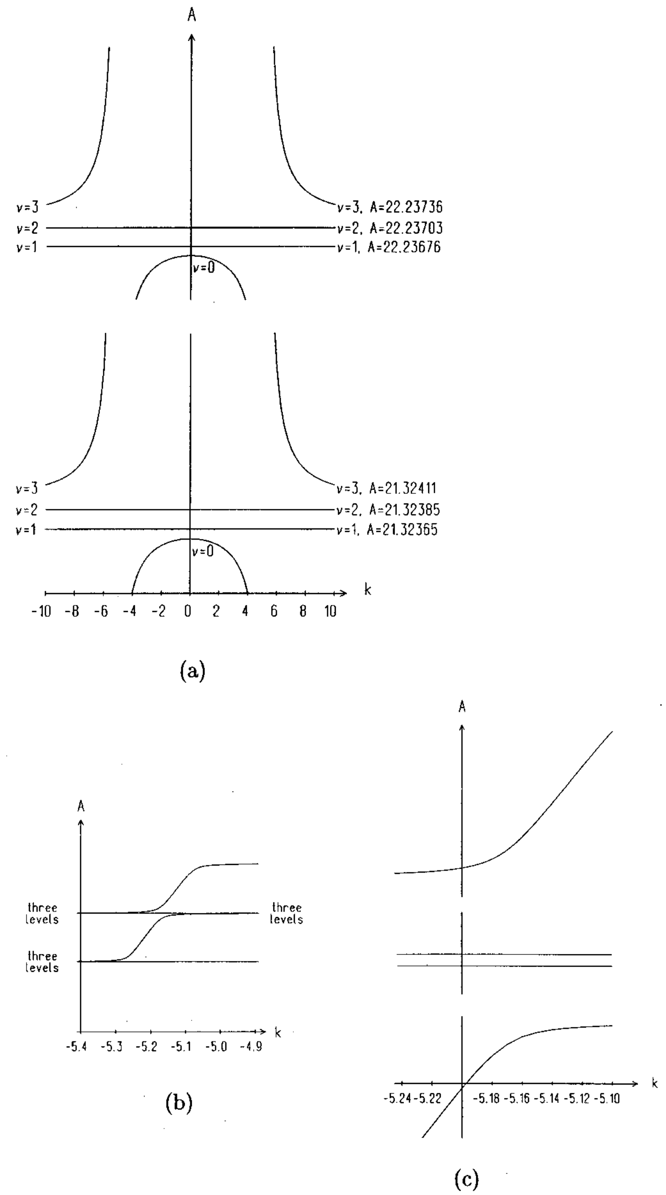

FIG. 6. In this figure $N=3$, $k=k_0=k_3$, $B=50$, and $C=32.6206$. The figure shows the dependence on k of the energy levels in two groups of fine structure levels which for $k=\infty$ have the quantum numbers $s=44$ and $s=45$ according to the phase-integral quantization condition (2.7) with $\nu=1$, 2, or 3. One more energy level is shown at the bottom of (a). The calculations have been performed by means of the numerically exact phase-amplitude method presented in Appendix B, but for $k=0$ and $k=\pm\infty$ the energy levels can be characterized by the quantum number ν in (2.7). In (a) the logarithmic derivative k assumes values in a large interval (in principle from $-\infty$ to $+\infty$). As mentioned above, the values of ν refer to $k=\pm\infty$ or $k=0$, but the values of A in the figure refer to $k=\pm 10$. Note that the vertical axis in (a) is interrupted. In (b) it is shown that A changes rapidly in a comparatively small interval of k-values. Note that the same eigenvalues A for two groups of fine structure levels are shown in (a) and (b) but that the scales of both horizontal and vertical axes differ strongly in (a) and (b). In (c), which is a magnification of a certain part of (b), we show the four highest-lying energy levels of (a) in a small interval of k values around $k=-5.17$. These energy levels form in this interval of k values a group of *four* close-lying levels (two of which are extremely close lying), which for $k=-5.17\,175$ have the energies $A=22.35\,084$, 22.23 703, 22.23 676, and 22.12 295. Note that the vertical axis in (c) is interrupted twice. The other energy levels of (a) form for $k=-5.17\,175$ a group of *three* still more close-lying levels (two of which are extremely close lying) with the energies $A=21.32\,385$, 21.32 365, and 21.31 252. The two groups of energy levels are clearly separated from each other.

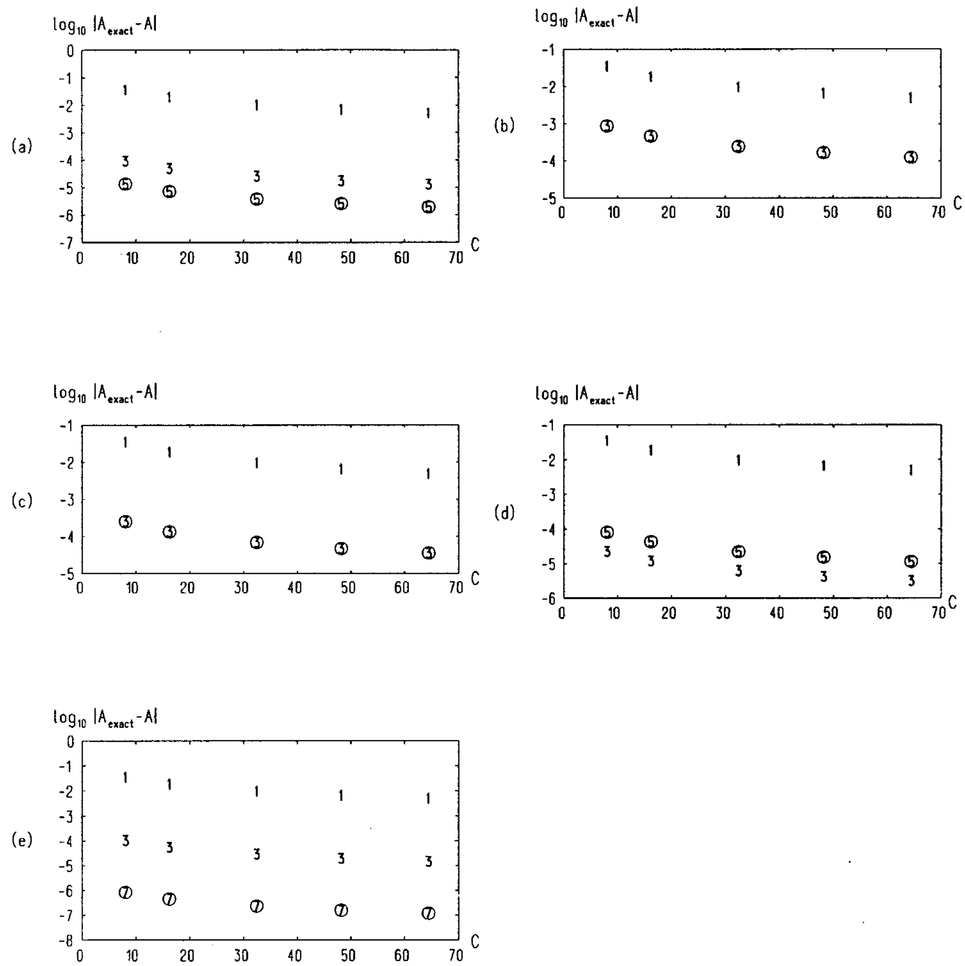

FIG. 7. This figure has reference to the lowest fine structure level associated with the quantum number s under consideration and the case when $N=3$, $k_0=-k_3$, $B=50$, and $K\approx 2.7$. The eigenvalues A have been obtained from (2.8) with $\tilde{\phi}$ retained and $s=12$, 28, 60, 91, and 123 (corresponding to five different values of C) along with (2.11a) and (2.10). In (a) $k_0=-k_3=10^{-2}$. In (b) $k_0=-k_3=2$. The errors of the fifth-order approximation are almost the same and of the same sign as those of the third-order approximation. In (c) $k_0=-k_3=20$. The third order of the phase-integral approximation is optimal, the fifth order being only slightly less accurate than the third order. In (d) $k_0=-k_3=100$. The errors of the seventh-order approximation are almost the same and of the same sign as those of the fifth-order approximation. In (e) $k_0=-k_3=10^4$. The seventh order of the phase-integral approximation is optimal. The errors of the fifth order are almost the same, but of opposite sign as those of the seventh-order approximation.

small intervals for the value of the logarithmic derivative in the boundary conditions there may be $N+1$ instead of, in general, N close-lying energy levels. We have also verified this, at a cursory glance unexpected, feature of the energy spectrum; see Fig. 6. In a single-well potential the wave function has s nodes in the well. It is, however, not common knowledge that in a multi-well potential there may exceptionally be a well in which there are $s+1$ nodes, if the absolute value of the wave function is much smaller in that well than in the two adjacent wells. We have verified this conclusion numerically for $N=3$ and $s=0$; see Figs. 4 and 5.

In the theory of crystals one uses boundary conditions implying either that the crystal is enclosed in a potential box with infinitely high walls or (according to Born and von Kármán) that the wave function (defined in the whole infinitely large space) has the periodicity of the whole crystal. For a one-dimensional crystal with N potential wells both these boundary conditions imply that the quantization condition is [cf. (2.7)]

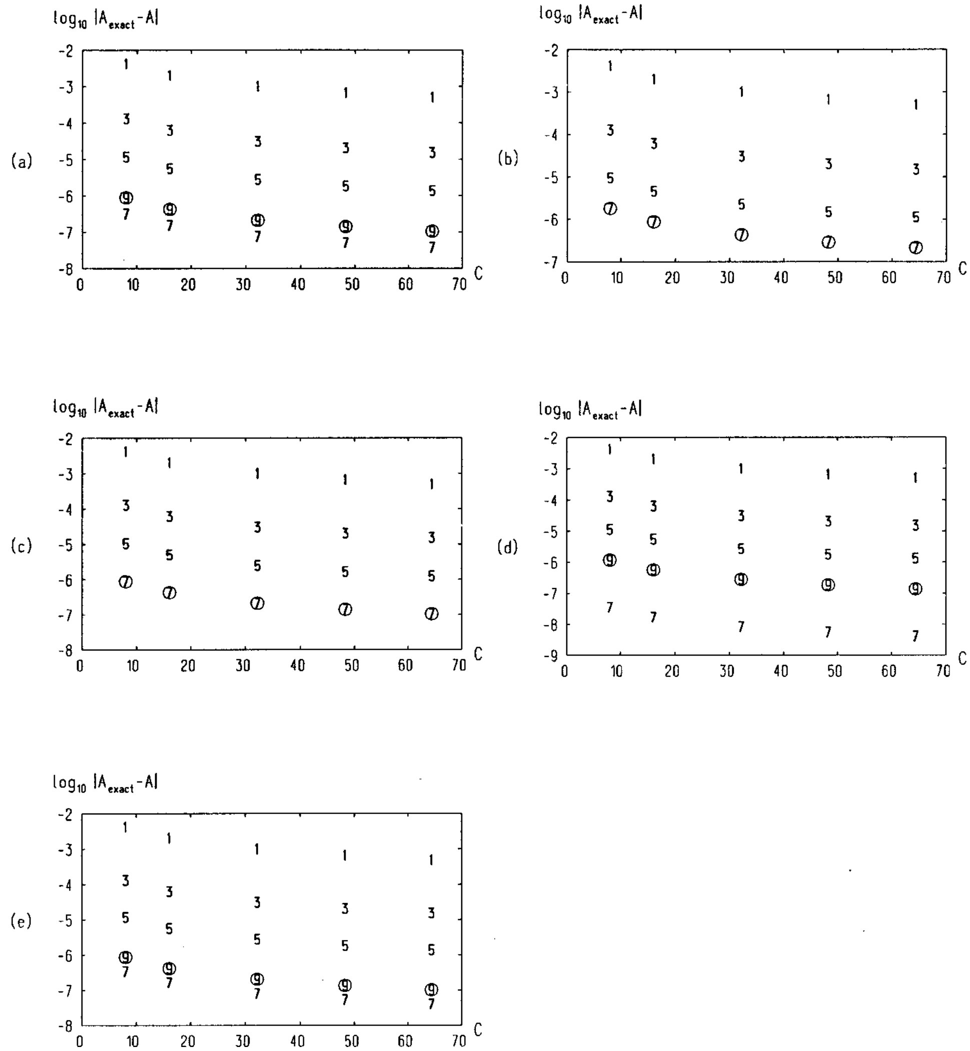

FIG. 8. This figure has reference to the lowest fine structure level associated with the quantum number s under consideration and the case when $N=3$, $k_0=-k_3$, $B=50$, and $K\approx 7.1$. The eigenvalues A have been obtained from (2.8) with $\tilde{\phi}$ retained and $s=8$, 20, 44, 68, and 92 (corresponding to five different values of C) along with (2.11a) and (2.10). In (a) $k_0=-k_3=10^{-2}$. In (b) $k_0=-k_3=2$. The seventh order of the phase-integral approximation is optimal. The errors of the ninth order are only slightly larger than and of the same sign as those of the seventh order. In (c) $k_0=-k_3=20$. The seventh order of the phase-integral approximation is optimal, and the errors of the ninth order are slightly larger than and of the same sign as those of the seventh order. In (d) $k_0=-k_3=100$. In (e) $k_0=-k_3=10^4$. The seventh order of the phase-integral approximation is optimal, and the errors of the 11th-order approximation are almost the same and of the same sign as those of the ninth-order approximation. As one should expect, this figure looks rather similar to Fig. 3(a); see, however, the comment at the end of Sec. IV.

$$L=(s+1/2)\pi-\tilde{\phi}-\arcsin\frac{\cos(\nu\pi/N)}{[\exp(2K)+1]^{1/2}}, \tag{5.1}$$

where for the boundary conditions associated with the potential box with infinitely high walls ν is *any* integer such that $1\leqslant\nu\leqslant N$, while for the boundary conditions of Born and von Kármán $0\leqslant\nu\leqslant N$ with ν even when s is even and $N-\nu$ even when s is odd. This shows the difference between the energy spectra associated with the two different boundary conditions in question. When the crystal is enclosed in a potential box with infinitely high walls, the wave function is uniquely determined (except for a constant normalization factor). When the Born–von Kármán boundary condition is imposed, the wave function is *uniquely* determined (except for a constant normalization factor) only for $\nu=0$ and $\nu=N$, while *every* solution of the Schrödinger equation has the periodicity of the whole crystal when $1\leqslant\nu\leqslant N-1$. For both boundary conditions now under consideration one finds, by comparing (2.4b) with (5.1), that the logarithmic derivative of the wave function at the center of each barrier is equal to zero when $\nu=0$ but equal to infinity when $\nu=N$. The discussion in the beginning of the present section of the particular and nonparticular energy levels applies, of course, also when one imposes the two boundary conditions now considered.

ACKNOWLEDGMENT

We are indebted to Professor Nanny Fröman who has read the manuscript and suggested improvements in the presentation.

APPENDIX A: PHASE-INTEGRAL APPROXIMATION GENERATED FROM AN UNSPECIFIED BASE FUNCTION

For a detailed description of the phase-integral approximation generated from an unspecified base function we refer to Chap. 1 in Ref. 1. A brief description is given below.

Approximate, but often very accurate, solutions of the differential equation

$$\frac{d^2\psi}{dz^2}+R(z)\psi=0, \tag{A1}$$

where $R(z)$ is an analytic function, can be obtained by means of the arbitrary-order phase-integral approximation generated from an unspecified base function. In this approximation there appears an unspecified function $Q(z)$ called the *base function*. This function is often chosen to be equal to $R^{1/2}(z)$, but in many physical problems it is important to use the possibility of choosing $Q(z)$ differently in order to achieve the result that the phase-integral approximation be valid close to certain exceptional points (e.g., the origin in connection with the radial Schrödinger equation), where the approximation would fail, if $Q(z)$ were chosen to be equal to $R^{1/2}(z)$. The function $Q(z)$ is in general chosen such that it is approximately equal to $R^{1/2}(z)$ except possibly in the neighborhood of the exceptional points.

To be able to write the phase-integral approximation in question in condensed form one introduces the new independent variable

$$\zeta=\int^{z}Q(z)\,dz \tag{A2}$$

and the function

$$\epsilon_0=Q^{-3/2}(z)\,\frac{d^2}{dz^2}\,Q^{-1/2}(z)+\frac{R(z)-Q^2(z)}{Q^2(z)}. \tag{A3}$$

It can be shown that in a local region of the complex z plane where the absolute value of ϵ_0 is small, the differential equation (A1) has the approximate solutions

$$\psi(z)=q^{-1/2}(z)\exp[\pm iw(z)], \tag{A4a}$$

$$w(z)=\int_{Z}^{z}q(z)\,dz, \tag{A4b}$$

where the lower limit of integration Z is an unspecified constant, and the function $q(z)$, pertaining to the phase-integral approximation of the order $2N+1$, is

$$q(z)=\sum_{n=0}^{N} q^{(2n+1)}(z), \tag{A5a}$$

$$q^{(2n+1)}(z)=Q(z)Y_{2n}, \tag{A5b}$$

with the first few functions Y_{2n} given by

$$Y_0=1, \tag{A6a}$$

$$Y_2=\tfrac{1}{2}\epsilon_0, \tag{A6b}$$

$$Y_4=-\frac{1}{8}\epsilon_0^2-\frac{1}{8}\frac{d^2\epsilon_0}{d\zeta^2}. \tag{A6c}$$

The choice of the function $Q(z)$ does not affect the expressions for Y_{2n} in terms of ϵ_0 and derivatives of ϵ_0 with respect to ζ, but only the expressions for ϵ_0 and ζ as functions of z.

It is an essential advantage of the phase-integral approximation, briefly described above, versus the Carlini (JWKB) approximation in higher order that the former approximation contains the unspecified base function $Q(z)$, which one can take advantage of in several ways. A criterion for the determination of the base function is that the function ϵ_0 be in some sense small in the region of the complex z plane relevant for the problem under consideration. However, this criterion does not determine the base function $Q(z)$ uniquely; it turns out that, within certain limits, the results are not very sensitive to the choice of $Q(z)$, when the approximation is used in higher orders. An inconvenient, but possible, choice of $Q(z)$ introduces in the first-order approximation an unnecessarily large error that is, however, in general corrected already in the third-order approximation. In many important cases the function $Q^2(z)$ can be chosen to be identical to $R(z)$. In other important cases, for instance when one wants to include the immediate neighborhood of a first- or second-order pole of $R(z)$ in the region of validity of the phase-integral approximation, the function $Q^2(z)$ is in general chosen to be similar to $R(z)$ except in the neighborhood of the pole. As regards a rather detailed discussion of the freedom that one has in the choice of the base function $Q(z)$, we refer to Chap. 1 in Ref. 1.

APPENDIX B: EXTENSION OF THE PHASE-AMPLITUDE METHOD FOR ACCURATE NUMERICAL SOLUTION OF THE ONE-DIMENSIONAL SCHRÖDINGER EQUATION

In this Appendix we present an extended version of the numerically exact phase-amplitude method, initiated by Milne,[2] Wilson,[3] Young,[4,5] and Wheeler,[6] to apply to the accurate numerical solution of the one-dimensional Schrödinger equation for a quantal particle in a potential consisting of N wells separated by $N-1$ superdense barriers.

Consider the differential equation

$$\frac{d^2\psi}{dz^2}+R(z)\psi=0, \tag{B1}$$

where, for real z values, $R(z)$ is positive in N regions that are separated by $N-1$ regions in which $R(z)$ is negative. The boundary conditions are assumed to be

$$\psi'(z_0)/\psi(z_0)=k_0, \tag{B2a}$$

$$\psi'(z_N)/\psi(z_N)=k_N, \tag{B2b}$$

where z_0 and $z_N(>z_0)$ lie in regions where $R(z)$ is negative and are separated by N regions where $R(z)$ is positive and $N-1$ regions where $R(z)$ is negative. We introduce in the regions where

$R(z)$ is negative further points $z_1,\ldots,z_{N-1}$ such that $z_0<z_1<\cdots<z_{N-1}<z_N$. These points correspond to the points $x_0,x_1,\ldots,x_{N-1}$, x_N in Fig. 1. For the eigenvalue problem considered in the present paper, the potential is periodic in the region to the right of x_0 (or z_0) and to the left of x_N (or z_N), but for the numerical phase-amplitude method to be described here this assumption need not be introduced, nor need we here introduce any assumption concerning symmetry.

To solve the differential equation (B1) numerically we put

$$\psi=F_n\hat{q}_n^{-1/2}(z)\sin\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)dz\right)+G_n\hat{q}_n^{-1/2}(z)\cos\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)dz\right),$$
$$z_{n-1}\leqslant z\leqslant z_n,\quad n=1,\ldots,N, \tag{B3}$$

where F_n and G_n are constants, and $\hat{q}_n(z)$ is to be determined numerically as a nonoscillating solution of the q equation

$$\frac{d^2}{dz^2}\hat{q}_n^{-1/2}+R(z)\hat{q}_n^{-1/2}=\hat{q}_n^{+3/2}, \tag{B4}$$

which one obtains by inserting (B3) into (B1) and requiring that the resulting equation be satisfied for all constant values of F_n and G_n. In passing we remark that the q equation appears not only in the phase-amplitude method[2–6] but also in connection with the Ermakov–Lewis invariant,[7,8] which is discussed in Chap. 1 of Ref. 1; see also Ref. 9. The continuity of $\psi(z)$ and $\psi'(z)$ at $z=z_n$, where $1\leqslant n\leqslant N-1$, gives the conditions

$$F_n\left[\hat{q}_n^{-1/2}(z)\sin\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)dz\right)\right]_{z=z_n}+G_n\left[\hat{q}_n^{-1/2}(z)\cos\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)dz\right)\right]_{z=z_n}$$
$$=F_{n+1}\left[\hat{q}_{n+1}^{-1/2}(z)\sin\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)dz\right)\right]_{z=z_n}+G_{n+1}\left[\hat{q}_{n+1}^{-1/2}(z)\cos\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)dz\right)\right]_{z=z_n} \tag{B5a}$$

and

$$F_n\left\{\frac{d}{dz}\left[\hat{q}_n^{-1/2}(z)\sin\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)dz\right)\right]\right\}_{z=z_n}+G_n\left\{\frac{d}{dz}\left[\hat{q}_n^{-1/2}(z)\cos\left(\int_{z_{n-1}}^{z}\hat{q}_n(z)dz\right)\right]\right\}_{z=z_n}$$
$$=F_{n+1}\left\{\frac{d}{dz}\left[\hat{q}_{n+1}^{-1/2}(z)\sin\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)dz\right)\right]\right\}_{z=z_n}$$
$$+G_{n+1}\left\{\frac{d}{dz}\left[\hat{q}_{n+1}^{-1/2}(z)\cos\left(\int_{z_n}^{z}\hat{q}_{n+1}(z)dz\right)\right]\right\}_{z=z_n}, \tag{B5b}$$

from which we obtain

$$F_{n+1}=\frac{\hat{q}'_{n+1}(z_n)/\hat{q}^2_{n+1}(z_n)-\hat{q}'_n(z_n)/\hat{q}^2_n(z_n)}{2\hat{q}^{1/2}_{n+1}(z_n)\hat{q}^{1/2}_n(z_n)}\left[F_n\sin\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)dz\right)+G_n\cos\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)dz\right)\right]$$
$$+\frac{\hat{q}^{1/2}_n(z_n)}{\hat{q}^{1/2}_{n+1}(z_n)}\left[F_n\cos\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)dz\right)-G_n\sin\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)dz\right)\right],\quad n=1,\ldots,N-1, \tag{B6a}$$

and

$$G_{n+1}=\frac{\hat{q}_{n+1}^{1/2}(z_n)}{\hat{q}_n^{1/2}(z_n)}\left[F_n \sin\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)dz\right)+G_n \cos\left(\int_{z_{n-1}}^{z_n}\hat{q}_n(z)dz\right)\right],\quad n=1,...,N-1. \tag{B6b}$$

The boundary conditions (B2a) and (B2b) give

$$F_1\left\{\frac{d}{dz}\left[\hat{q}_1^{-1/2}(z)\sin\left(\int_{z_0}^{z}\hat{q}_1(z)dz\right)\right]\right\}_{z=z_0}+G_1\left\{\frac{d}{dz}\left[\hat{q}_1^{-1/2}(z)\cos\left(\int_{z_0}^{z}\hat{q}_1(z)dz\right)\right]\right\}_{z=z_0}$$
$$=k_0\left\{F_1\left[\hat{q}_1^{-1/2}(z)\sin\left(\int_{z_0}^{z}\hat{q}_1(z)dz\right)\right]_{z=z_0}+G_1\left[\hat{q}_1^{-1/2}(z)\cos\left(\int_{z_0}^{z}\hat{q}_1(z)dz\right)\right]_{z=z_0}\right\} \tag{B7a}$$

and

$$F_N\left\{\frac{d}{dz}\left[\hat{q}_N^{-1/2}(z)\sin\left(\int_{z_{N-1}}^{z}\hat{q}_N(z)dz\right)\right]\right\}_{z=z_N}+G_N\left\{\frac{d}{dz}\left[\hat{q}_N^{-1/2}(z)\cos\left(\int_{z_{N-1}}^{z}\hat{q}_N(z)dz\right)\right]\right\}_{z=z_N}$$
$$=k_N\left\{F_N\left[\hat{q}_N^{-1/2}(z)\sin\left(\int_{z_{N-1}}^{z}\hat{q}_N(z)dz\right)\right]_{z=z_N}+G_N\left[\hat{q}_N^{-1/2}(z)\cos\left(\int_{z_{N-1}}^{z}\hat{q}_N(z)dz\right)\right]_{z=z_N}\right\}. \tag{B7b}$$

From (B7a) and (B7b) we obtain

$$F_1=\left(\frac{k_0}{\hat{q}_1(z_0)}+\frac{\hat{q}_1'(z_0)}{2[\hat{q}_1(z_0)]^2}\right)G_1 \tag{B8a}$$

and

$$\int_{z_{N-1}}^{z_N}\hat{q}_N(z)dz=\hat{s}\pi+\arctan\frac{F_N-G_N(k_N/\hat{q}_N(z_N)+\hat{q}_N'(z_N)/2[\hat{q}_N(z_N)]^2)}{F_N(k_N/\hat{q}_N(z_N)+\hat{q}_N'(z_N)/2[\hat{q}_N(z_N)]^2)+G_N}, \tag{B8b}$$

where $\hat{s}$ is an integer.

To determine the functions $\hat{q}_n(z)$ one starts the integration of the differential equation (B4) in the middle of the actual potential well by using for $\hat{q}_n(z)$ a phase-integral expression of convenient order. When the functions $\hat{q}_n(z)$, $n=1,...,N$, have been calculated, we obtain from (B8a) F_1 expressed in terms of G_1 or G_1 expressed in terms of F_1, and from (B6a) and (B6b) we successively obtain $F_2,G_2;\ldots;F_N,G_N$. By inserting the values of F_N and G_N thus obtained into (B8b), we obtain a quantization condition from which the energy eigenvalues can be calculated by iteration.

There occur numerical difficulties when the potential is periodic and one tries to treat the *particular* fine structure level (corresponding to a given value of $\hat{s}$) by means of the general formulas that we have so far presented in this Appendix. One can overcome these difficulties by noting that the wave function of the *particular* fine structure level has the period of the potential and thus can be obtained if one puts $N=1$. Therefore we shall now give formulas that apply to $N=1$.

Particularization to the case when $N=1$

When $N=1$ we obtain from (B8a) and (B8b)

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\hat{s}\pi+\arctan\frac{(k_0/\hat{q}_1(z_0)+\hat{q}_1'(z_0)/2[\hat{q}_1(z_0)]^2)-(k_1/\hat{q}_1(z_1)+\hat{q}_1'(z_1)/2[\hat{q}_1(z_1)]^2)}{(k_0/\hat{q}_1(z_0)+\hat{q}_1'(z_0)/2[\hat{q}_1(z_0)]^2)(k_1/\hat{q}_1(z_1)+\hat{q}_1'(z_1)/2[\hat{q}_1(z_1)]^2)+1}. \tag{B9}$$

For the further particularization that the function $R(z)$ is mirror symmetric, that the points z_0 and z_1 lie mirror symmetrically, and that the function $\hat{q}_1(z)$ is mirror symmetric [and hence $\hat{q}_1(z_0)=\hat{q}_1(z_1)$ and $\hat{q}_1'(z_0)=-\hat{q}_1'(z_1)$], the quantization condition (B9) simplifies to

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\hat{s}\pi+\arctan\frac{(k_0-k_1)\hat{q}_1(z_0)+\hat{q}_1'(z_0)}{(k_0+\hat{q}_1'(z_0)/2\hat{q}_1(z_0))(k_1-\hat{q}_1'(z_0)/2\hat{q}_1(z_0))+[\hat{q}_1(z_0)]^2}. \tag{B10}$$

From (B10) we obtain when $k_1=k_0$

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\hat{s}\pi+\arctan\frac{\hat{q}_1'(z_0)}{k_0^2-(\hat{q}_1'(z_0)/2\hat{q}_1(z_0))^2+[\hat{q}_1(z_0)]^2}, \tag{B11a}$$

and when $k_1=-k_0$

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\hat{s}\pi+\arctan\frac{2k_0\hat{q}_1(z_0)+\hat{q}_1'(z_0)}{[\hat{q}_1(z_0)]^2-(k_0+\hat{q}_1'(z_0)/2\hat{q}_1(z_0))^2}. \tag{B11b}$$

We shall now show how approximate phase-integral quantization conditions can be obtained from the numerically exact phase-amplitude quantization conditions (B11a) and (B11b). When the barriers are thick, and the phase of the base function is chosen conveniently, we have approximately

$$\hat{q}_1(z_0)=-iq_1(z_0)\exp[-2iw_1(z_0)], \tag{B12}$$

where $q_1(z_0)$ is the asymptotic phase integrand given by (A5a) and (A5b), and $w_1(z_0)$ is the corresponding asymptotic phase integral (A4b) with the constant lower limit of integration for the first-order approximation chosen to lie at the right-hand turning point t_0'' of the barrier in which z_0 is situated. When a higher-order approximation is used, $w_1(z_0)$ is a related contour integral; see Eq. (4.3.3) in Ref. 1. Since the barrier in question is assumed to be mirror symmetric, with z_0 lying at its center, (B12) can be written as

$$\hat{q}_1(z_0)=|q_1(z_0)|\exp(-K), \tag{B12$'$}$$

with K given by (2.6). From (B12) we obtain approximately

$$\begin{aligned}\hat{q}_1'(z_0)&=-iq_1'(z_0)\exp[-2iw_1(z_0)]+2[-iq_1(z_0)]^2\exp[-2iw_1(z_0)]\\&=2[-iq_1(z_0)]^2\exp[-2iw_1(z_0)]\left[1+\frac{iq_1'(z_0)}{2[q_1(z_0)]^2}\right]\\&\approx 2[-iq_1(z_0)]^2\exp[-2iw_1(z_0)]\\&=2|q_1(z_0)|^2\exp(-K)\end{aligned} \tag{B13}$$

and hence, with the aid of (B12$'$),

$$\frac{\hat{q}_1'(z_0)}{2\hat{q}_1(z_0)}\approx|q_1(z_0)|. \tag{B14}$$

Inserting (B12′), (B13), and (B14) into (B11a) and (B11b), respectively, and noting that the barriers are assumed to be thick $[\exp(-2K)\ll 1]$, we obtain the *approximate* quantization conditions

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\hat{s}\pi+\arctan\frac{2\exp(-K)}{|k_0/q_1(z_0)|^2-1+\exp(-2K)}$$

$$\approx\hat{s}\pi+\arctan\frac{2\exp(-K)}{|k_0/q_1(z_0)|^2-1},\quad k_1=k_0, \tag{B15a}$$

and

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\hat{s}\pi-\arctan\frac{2\exp(-K)[k_0/|q_1(z_0)|+1]}{[k_0/|q_1(z_0)|+1]^2-\exp(-2K)}$$

$$\approx\hat{s}\pi-\arctan\frac{2\exp(-K)}{|k_0/q_1(z_0)|+1},\quad k_1=-k_0, \tag{B15b}$$

respectively. The numerically exact function $\hat{q}_1(z)$ is approximately the same as the asymptotic function $q_1(z)$ in the interior of the classically allowed region, but $\hat{q}_1(z)$ differs essentially from $q_1(z)$ in the classically forbidden regions; see (B12′). Putting

$$\int_{z_0}^{z_1}\hat{q}_1(z)dz=\int_{(t_0'')}^{(t_1')}q_1(z)dz+\pi/2+\tilde{\phi}-\exp(-K), \tag{B16a}$$

$$\hat{s}=s+1, \tag{B16b}$$

one can from (B15a) approximately obtain the phase-integral quantization condition (2.4b′), which is valid for $N=1$ when $k_1=k_0=k$, and one can from (B15b) approximately obtain

$$\int_{(t_0'')}^{(t_1')}q_1(z)dz=\left(s+\frac{1}{2}\right)\pi-\tilde{\phi}+\frac{k_0/|q_1(z_0)|-1}{k_0/|q_1(z_0)|+1}\exp(-K), \tag{B17}$$

which is the correct approximate phase-integral quantization condition when the barriers are thick and $N=1$ and $k_1=-k_0$. Because of the one-directional nature of the connection formulas, (B17) is expected to be valid only when $k_0\geqslant 0$.

Instability of a pseudo-relativistic model of matter with self-generated magnetic field

Marcel Griesemer[a),b)] and Christian Tix
Mathematik, Universität Regensburg, D-93040 Regensburg, Germany

(Received 23 November 1998; accepted for publication 23 November 1998)

For a pseudo-relativistic model of matter, based on the no-pair Hamiltonian, we prove that the inclusion of the interaction with the self-generated magnetic field leads to instability for all positive values of the fine structure constant. This is true no matter whether this interaction is accounted for by the Breit potential, by an external magnetic field which is chosen to minimize the energy, or by the quantized radiation field. © *1999 American Institute of Physics.* [S0022-2488(99)01203-7]

I. INTRODUCTION

The stability of matter problem concerns the questions whether the minimal energy of a system of particles is bounded from below (stability of the first kind), and whether it is bounded from below by a constant times the number of particles (stability of the second kind). Stability of the second kind for nonrelativistic quantum-mechanical electrons and nuclei was first proved in 1967 by Dyson and Lenard.[1,2] Since the new proofs of Lieb and Thirring, and Federbush in 1975 stability of matter is a subject of ongoing interest dealing with more and more realistic models of matter such as systems with a classical or quantized magnetic field included or with relativistic electrons (see Ref. 3 and the references therein). Stability with relativistic electrons is more subtle because of the uniform 1/length scaling behavior of the energy, which holds for massless particles (high particle–energy limit). Then the minimal energy is either non-negative or equal $-\infty$, so that stability of the second kind becomes equivalent to the statement that stability of the first kind holds for any given number of particles. We simply call this stability henceforth.

This paper is about a pseudo-relativistic model of matter which is stable, but which becomes unstable when the electrons are allowed to interact with the self-generated magnetic field. The self-generated magnetic field may be described using either an effective potential (the Breit-potential), an external magnetic field over which the energy is minimized, or the quantized radiation field. In all these cases we find instability for all positive values of the fine-structure constant. In contrast to most other models, where the collapse of the system, if it occurs, is due to the attraction of electrons and nuclei[4–7] (there would be no collapse without this interaction), the instability here is due to the attraction of parallel currents.

The model we study is based on a pseudo-relativistic Hamiltonian sometimes called the no-pair or Brown–Ravenhall Hamiltonian describing N relativistic electrons and K fixed nuclei interacting via Coulomb potentials. The electrons are vectors in the positive energy subspace of the free Dirac operator and their kinetic energy is described by this operator. For a physical justification of this model see the papers of Sucher,[8,9] for applications of the model in computational atomic physics and quantum chemistry; see Ishikawa and Koc[10,11] and Pyykkö.[12] The Brown–Ravenhall Hamiltonian yields stability for sufficiently small values of the fine-structure constant and the charge of the nuclei,[13–16,3] there are further rigorous results concerning the virial theorem[17] and eigenvalue estimates.[18]

We are interested in the minimal energy of this model when it is corrected to account for the interaction of the electrons with the self-generated magnetic field. This correction may be done,

for instance, by introducing a external magnetic field $\nabla\times\mathbf{A}$ to which the electrons are then minimally coupled and whose field energy is added to the energy of the system. The field **A** is now considered part of the system and hence the energy is to be minimized w.r.t. **A** as well. The minimizing **A** for a given electronic state is the self-generated one (to avoid instability for trivial reasons the gauge of **A** has to be fixed). The energy of this system is unbounded from below if $N\alpha^{3/2}$ is large, α being the fine structure constant, even if the vector potential is restricted to lie in a two parameter class $\{\gamma\mathbf{A}_0(\delta x):\gamma,\delta\in\mathbb{R}_+\}$ where $\mathbf{A}_0$ is fixed and obeys a weak condition requiring not much more than $\mathbf{A}_0\not\equiv 0$. This is our first main result. It extends a previous result of Lieb *et al.*[3] and is reminiscent of the fact that a static nonvanishing classical magnetic field in QED is not regular, in the sense that the dressed electron–positron emission and absorption operators do not realize a representation of the CAR on the Fock space of the free field.[19]

Alternatively the energy-shift due to the self-generated magnetic field may approximately be taken into account by including the Breit-potential in the energy. The resulting model is unstable as well. That is, the energy is unbounded from below if $N\alpha^{3/2}$ is large, no matter how small α is. This is our second main result. It concerns a Hamiltonian that is closely related the Dirac–Coulomb–Breit or Dirac–Breit Hamiltonian, which is the bases for most calculations of relativistic effects in many electron atoms.[8,12] We mention that for $\alpha=1/137$ the energy is bounded below if $N\leqslant 39$ and unbounded below if $N\geqslant 3.4\times 10^7$ (Theorem 4 and Theorem 3).

A third way of accounting for the self-generated field is to couple the electrons to the quantized radiation field. From a simple argument using coherent states (Lemma 5) it follows that the instability of this model is rather worse than the instability of the model first discussed.

As mentioned above the instability with the external magnetic field was previously found by Lieb *et al.*[3] Our result extends their result and our proof is simpler. The model with the Breit interaction corresponds to the classical system described by the Darwin Hamiltonian, which has been studied in the plasma physics literature (see Ref. 20 and the references therein). This classical model is thermodynamically unstable as well.[21]

In Secs. II, III, and IV we introduce the models with an external magnetic field, with the Breit-potential, and with quantized radiation field, and prove their instability (Theorem 1, Theorem 3, and Lemma 5). In Sec. III we also discuss dynamic nuclei for the model with Breit-potential. There is an appendix where numerical values for stability bounds on $N\alpha^{3/2}$ given in the main text are computed.

II. INSTABILITY WITH CLASSICAL MAGNETIC FIELD

We begin with the model of matter with an external magnetic field. For simplicity, the electrons are assumed to be noninteracting, and no nuclei are present. We could just as well treat a system of interacting electrons and static nuclei and would obtain essentially the same result (see Remark 4 below).

Consider a system of N noninteracting electrons in the external magnetic field $\nabla\times\mathbf{A}$. The energy of this system is

$$\mathcal{E}_N(\psi,\mathbf{A})=\left\langle \psi,\sum_{\mu=1}^{N} D_\mu(\mathbf{A})\psi\right\rangle+\frac{1}{8\pi}\int|\nabla\times\mathbf{A}(\mathbf{x})|^2d\mathbf{x},$$

where $D_\mu(\mathbf{A})$ is the Dirac operator $D(\mathbf{A})=\boldsymbol{\alpha}\cdot(-i\nabla+\alpha^{1/2}\mathbf{A}(\mathbf{x}))+\beta m$ acting on the μ-th particle, and the vector ψ, describing the state of the electrons, belongs to the Hilbert space,

$$\mathcal{H}_N=\bigwedge_{\mu=1}^{N}\Lambda_+L^2(\mathbb{R}^3,\mathbb{C}^4),$$

$$\Lambda_+=\chi_{(0,\infty)}(D(\mathbf{A}\equiv 0)),$$

or rather the dense subspace $\mathfrak{D}_N=\mathcal{H}_N\cap H^1[(\mathbb{R}^3\times\{1,...,4\})^N]$. That is, an electron is, by definition, a vector in the positive energy subspace of the free Dirac operator. We will always assume that the vector potential $\mathbf{A}$ belongs to the class $\mathcal{A}$ defined by the properties

$$(i)\quad \nabla\cdot\mathbf{A}=0,$$

$$(ii)\quad \mathbf{A}(\mathbf{x})\to 0,\quad \text{as } |\mathbf{x}|\to\infty,$$

$$(iii)\quad \int_{\mathbb{R}^3}|\nabla\times\mathbf{A}|^2<\infty.$$

Notice that $\mathcal{H}_N$ is not invariant under multiplication with smooth functions, in particular, it is not invariant under gauge transformations of the states. It follows that the minimal energy for fixed $\mathbf{A}$ is gauge-dependent. It can actually be driven to $-\infty$ by a pure gauge transformation (see Remark 3 below). To avoid this trivial instability we fixed the gauge of $\mathbf{A}$ by imposing conditions (i) and (ii).

The constants $\alpha>0$ and $m\geqslant 0$ in the definition of $D(\mathbf{A})$ are the fine-structure constant and the mass of the electron, respectively. In our units $\hbar=1=c$, so that $\alpha=e^2$ which is about 1/137 experimentally. We denote the Fourier transform of a function f by $\hat{f}$ or $\mathfrak{F}(f)$ and use $\mathbf{p}$ or $\mathbf{k}$ for its argument rather than $\mathbf{x}$ or $\mathbf{y}$. Our first result is the following.

Theorem 1: *Suppose $\mathbf{A}\in\mathcal{A}$ is such that $Re[\mathbf{e}\cdot\hat{\mathbf{A}}(\mathbf{p})]<0$ in $B(0,\epsilon)$ for some $\mathbf{e}\in\mathbb{R}^3$ and $\epsilon>0$. Then there exist a constant $C_\mathbf{A}$ such that for all $\alpha>0$, $m\geqslant 0$ and $N\geqslant C_\mathbf{A}\alpha^{-3/2}$,*

$$\inf_{\psi\in\mathfrak{D}_N,\|\psi\|=1,\gamma,\delta\in\mathbb{R}_+}\mathcal{E}_N(\psi,\gamma\mathbf{A}(\delta\mathbf{x}))=-\infty.$$

Remarks:

1. It is sufficient that $\mathbf{A}\in\mathcal{A}\cap L^1$ and $\int_{R^3}\mathbf{A}(\mathbf{x})d\mathbf{x}\neq 0$, since $\hat{\mathbf{A}}$ is then continuous and $\hat{\mathbf{A}}(0)\neq 0$. Thus, we have instability for virtually all nonvanishing $\mathbf{A}\in\mathcal{A}$.
2. The smallness of $N\alpha^{3/2}$ is not only necessary but also sufficient for stability (see Ref. 3, Sec. 4).
3. If the condition (ii) that $\mathbf{A}$ vanishes at infinity (and thus the gauge fixing) is dropped there is instability even for $N=1$ and the theorem becomes trivial. In fact, for $N=1$ and $\mathbf{A}(\mathbf{x})\equiv\mathbf{a}\neq 0$, $\mathcal{E}_{N=1}(\psi,\gamma\mathbf{A})=\langle\psi,D(0)\psi\rangle+\gamma\alpha^{1/2}\mathbf{a}\int\psi^+(\mathbf{x})\boldsymbol{\alpha}\psi(x)d\mathbf{x}$ which, as a function of γ, is unbounded from below for suitable $\psi\in\Lambda_+L^2(\mathbb{R}^3,\mathbb{C}^4)$.
4. The statement of the theorem also holds for the system of electrons and static nuclei with energy $\mathcal{E}_N(\psi,\mathbf{A})+\alpha\langle\psi,V_c\psi\rangle$ where
$$V_c:=-\sum_{\mu=1}^{N}\sum_{\kappa=1}^{K}\frac{Z_\kappa}{|\mathbf{x}_\mu-\mathbf{R}_\kappa|}+\sum_{\mu<\nu}^{N}\frac{1}{|\mathbf{x}_\mu-\mathbf{x}_\nu|}+\sum_{\kappa<\sigma}^{K}\frac{Z_\kappa Z_\sigma}{|\mathbf{R}_\kappa-\mathbf{R}_\sigma|},\tag{1}$$
if both N and $\Sigma_{\kappa=1}^K Z_\kappa$ are bigger than $C_\mathbf{A}\alpha^{-3/2}$ and if the energy is, in addition, minimized with respect to the pairwise distinct nuclear positions $\mathbf{R}_\kappa$. (See the proof of Theorem 3.)
5. Quantizing the radiation field does not improve the stability of the system (see Sec. IV).

The only way to restore stability we know is to replace $\mathcal{H}_N$ by the $\mathbf{A}$-dependent Hilbert space,

$$\mathcal{H}_{N,\mathbf{A}}=\bigwedge_{\mu=1}^{N}\chi_{(0,\infty)}(D(\mathbf{A}))L^2(\mathbb{R}^3,\mathbb{C}^4).$$

Obviously $\mathcal{E}_N(\psi,\mathbf{A})\geqslant 0$ for $\psi\in\mathcal{H}_{N,\mathbf{A}}$. In fact, even $\mathcal{E}_N(\psi,\mathbf{A})+\alpha\langle\psi,V_c\psi\rangle$ is non-negative for Z_κ and α small enough.[3]

Proof of Theorem 1: We will only work with Slater determinants and the following representation of one-particle orbitals. If $u\in L^2(\mathbb{R}^3;\mathbb{C}^2)$ then

$$\hat{\psi}(\mathbf{p})=\left(\frac{E(\mathbf{p})+m}{2E(\mathbf{p})}\right)^{1/2}\begin{pmatrix} u(\mathbf{p}) \\ \dfrac{\boldsymbol{\sigma}\cdot\mathbf{p}}{E(\mathbf{p})+m}u(\mathbf{p})\end{pmatrix}, \tag{2}$$

with $E(\mathbf{p})=\sqrt{\mathbf{p}^2+m^2}$, is the Fourier transform of a vector $\psi\in\Lambda_+L^2$, and the map $u\mapsto\psi$, $L^2(\mathbb{R}^3;\mathbb{C}^2)\to\Lambda_+L^2(\mathbb{R}^3;\mathbb{C}^4)$ is unitary.

It suffices to consider the case $m=0$ and find a Slater determinant $\psi=\psi_1\wedge\cdots\wedge\psi_N$ and γ, $\delta\in\mathbb{R}_+$ such that $\mathcal{E}_N(\psi,\gamma\mathbf{A}(\delta\mathbf{x}))<0$. In fact, by the scaling $\psi\mapsto\psi_\delta$, $\mathbf{A}\mapsto\mathbf{A}_\delta$ defined by $u_{\mu,\delta}=\delta^{-3/2}u_\mu(\delta^{-1}\mathbf{p})$ and $\mathbf{A}_\delta(\mathbf{x})=\delta\mathbf{A}(\delta\mathbf{x})$ we can then drive the energy with $m>0$ to $-\infty$ because $\mathcal{E}(\psi_\delta,\mathbf{A}_\delta,m)=\delta\mathcal{E}(\psi,\mathbf{A},m/\delta)$ and $\mathcal{E}(\psi,\mathbf{A},m/\delta)\to\mathcal{E}(\psi,\mathbf{A},m=0)$ for $\delta\to\infty$.

Choice of ψ: Let Q be the unit cube $\{\mathbf{p}\in\mathbb{R}^3|0\leq p_i\leq 1\}$, $u(\mathbf{p})=(\chi_Q(\mathbf{p}),0)^T$, and $\mathbf{e}\in\mathbb{R}^3$ an arbitrary unit vector. Set

$$u_\mu(\mathbf{p})=u(\mathbf{p}-\lambda N^{1/3}\mathbf{e}-\mathbf{n}_\mu),\quad \mu=1,...,N, \tag{3}$$

where λ is a positive constant to be chosen sufficiently large later on, and $(\mathbf{n}_\mu)_{\mu=1,\ldots,N}\subset\mathbb{Z}^3$ are the N lattice sites nearest to the origin, i.e., $\max_{\mu=1,\ldots,N}|\mathbf{n}_\mu|$ is minimal. We define $\psi=\psi_1\wedge\cdots\wedge\psi_N$ by

$$\hat{\psi}_\mu(\mathbf{p})=\frac{1}{\sqrt{2}}\begin{pmatrix} u_\mu(\mathbf{p}) \\ \boldsymbol{\sigma}\cdot\boldsymbol{\omega}_{\mathbf{p}}u_\mu(\mathbf{p})\end{pmatrix},\quad \boldsymbol{\omega}_{\mathbf{p}}=\frac{\mathbf{p}}{|\mathbf{p}|}, \tag{4}$$

which is (2) for $m=0$. Then $\psi\in\mathcal{H}_N$ and $\langle\psi_\mu,\psi_\nu\rangle=\langle u_\mu,u_\nu\rangle=\delta_{\mu\nu}$. Notice that

$$|\mathbf{p}-\lambda N^{1/3}\mathbf{e}|\leq N^{1/3},\quad \text{for all}\ \ \mathbf{p}\in\operatorname{supp}(u_\mu), \tag{5}$$

at least for large N (see the Appendix), i.e., in Fourier space all electrons are localized in a ball with radius $N^{1/3}$ and a distance from the origin which is large compared to the radius (since λ will be large).

Since $\psi=\psi_1\wedge\cdots\wedge\psi_N$ and $m=0$ we have

$$\mathcal{E}_N(\psi,\mathbf{A})=\sum_{\mu=1}^N\langle\psi_\mu,|\boldsymbol{\nabla}|\psi_\mu\rangle+\alpha^{1/2}\sum_{\mu=1}^N\int\mathbf{J}_\mu(x)\mathbf{A}(\mathbf{x})d\mathbf{x}+\frac{1}{8\pi}\int|\boldsymbol{\nabla}\times\mathbf{A}(\mathbf{x})|^2d\mathbf{x}, \tag{6}$$

where $\mathbf{J}_\mu(\mathbf{x})=\psi_\mu^*(x)\boldsymbol{\alpha}\psi_\mu(x)$. By definition of ψ_μ,

$$\hat{\mathbf{J}}_\mu(\mathbf{p})=\frac{1}{2}(2\pi)^{-3/2}\int u_\mu^*(\mathbf{k}-\mathbf{p})[\boldsymbol{\sigma}(\boldsymbol{\omega}_{\mathbf{k}}\cdot\boldsymbol{\sigma})+(\boldsymbol{\omega}_{\mathbf{k}-\mathbf{p}}\cdot\boldsymbol{\sigma})\boldsymbol{\sigma}]u_\mu(\mathbf{k})d\mathbf{k}. \tag{7}$$

Replace here u_μ by its defining expression and substitute $(\mathbf{k}-\lambda N^{1/3}\mathbf{e}-\mathbf{n}_\mu)\mapsto\mathbf{k}$. Since $\boldsymbol{\omega}_{\mathbf{k}+\lambda N^{1/3}\mathbf{e}+\mathbf{n}_\mu}\to\mathbf{e}$ as $\lambda\to\infty$, and since u has compact support, it follows that $\hat{\mathbf{J}}_\mu(\mathbf{p})$ converges to the current

$$\hat{\mathbf{J}}_0(\mathbf{p})=\mathbf{e}(2\pi)^{-2/3}\int u^*(\mathbf{k}-\mathbf{p})u(\mathbf{k})d\mathbf{k}, \tag{8}$$

as $\lambda\to\infty$. More precisely, $|\hat{\mathbf{J}}_\mu(\mathbf{p})-\hat{\mathbf{J}}_0(\mathbf{p})|\leq C\lambda^{-1}|\hat{\mathbf{J}}_0(\mathbf{p})|$ for $\lambda\geq\lambda_0$ where λ_0 and C are independent of μ and N. From $\hat{\mathbf{J}}_0(\mathbf{p})|\mathbf{p}|^{-1}$, $\hat{\mathbf{A}}(\mathbf{p})|\mathbf{p}|\in L^2$, it follows that

$$\int\hat{\mathbf{J}}_\mu^*(\mathbf{p})\hat{\mathbf{A}}(\mathbf{p})d\mathbf{p}=\int\hat{\mathbf{J}}_0^*(\mathbf{p})\hat{\mathbf{A}}(\mathbf{p})d\mathbf{p}+O(\lambda^{-1}),\quad \lambda\to\infty. \tag{9}$$

After a scaling $\mathbf{A}\mapsto\mathbf{A}_\delta$ we may assume that $\mathrm{Re}[\mathbf{e}\cdot\hat{\mathbf{A}}(\mathbf{p})]<0$ in the support of $\hat{\mathbf{J}}_0$ rather than in $B(0,\epsilon)$, so that (9) is bounded from above by some $-c_1<0$ for $\lambda\geqslant\lambda_0$ where c_1 and λ_0 are independent of μ and N. Observing finally that

$$\langle\psi_\mu,|\nabla|\psi_\mu\rangle=\int|\hat{\psi}_\mu(\mathbf{p})|^2|\mathbf{p}|d\mathbf{p}\leqslant(\lambda+1)N^{1/3}, \tag{10}$$

for all μ, we conclude that

$$\mathcal{E}_N(\psi,\gamma\mathbf{A})\leqslant(\lambda_0+1)N^{4/3}-\alpha^{1/2}\gamma Nc_1+\gamma^2c_2=(\lambda_0+1)N^{4/3}-\alpha\frac{c_1^2}{4c_2}N^2,$$

which is negative for $N\alpha^{3/2}$ large enough. At the end we inserted the optimal γ. □

The theorem has the obvious corollary.

Corollary 2: There is a constant C such that for all $\alpha>0$, $m\geqslant0$ and $N\geqslant C\alpha^{-3/2}$,

$$\inf_{\psi\in\mathfrak{D}_N,\|\psi\|=1;\mathbf{A}\in\mathcal{A}}\mathcal{E}_N(\psi,\mathbf{A})=-\infty.$$

This result is due to Lieb, Siedentop, and Solovej.[3]

Remark: It is sufficient that $C=1.4\times10^5$ or that $N\geqslant3.4\times10^7$ for $\alpha^{-1}=137$; see the Appendix.

To conclude this section we compute $\min_{\mathbf{A}\in\mathcal{A}}\mathcal{E}_N(\psi,\mathbf{A})$. This will provide a link to the instability with Breit-potential discussed in the next section. To exhibit the $\mathbf{A}$-dependence, we write the energy as

$$\mathcal{E}_N(\psi,\mathbf{A})=\mathcal{E}_N(\psi,\mathbf{A}\equiv0)+\alpha^{1/2}\int\mathbf{J}(\mathbf{x})\mathbf{A}(\mathbf{x})+\frac{1}{8\pi}\int|\nabla\times\mathbf{A}(\mathbf{x})|^2d\mathbf{x},$$

where $\mathbf{J}(\mathbf{x})$ is the probability current density associated with ψ. Its functional dependence on ψ is not crucial here. A straightforward computation shows that the Euler–Lagrange equation for $\mathbf{A}$ is $-\Delta\mathbf{A}=4\pi\alpha^{1/2}\mathbf{J}_T$ where $\mathbf{J}_T$ is the divergence-free—or transversal—part of $\mathbf{J}$. Comparing this equation with the Maxwell-equation for $\mathbf{A}$ in Coulomb gauge, which is $\Box\mathbf{A}=4\pi\alpha^{1/2}\mathbf{J}_T$, we find that the minimizing magnetic field is the self-generated one up to effects of retardation. Solving the Euler–Lagrange equation gives

$$\min_{\mathbf{A}\in\mathcal{A}}\mathcal{E}_N(\psi,\mathbf{A})=\mathcal{E}_N(\psi,\mathbf{A}\equiv0)-\frac{\alpha}{2}\int\frac{\mathbf{J}_T(\mathbf{x})\mathbf{J}_T(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|}d\mathbf{x}\,d\mathbf{y}. \tag{11}$$

III. INSTABILITY WITH BREIT-POTENTIAL

A. Static nuclei

We now consider a system of N (interacting) electrons in the external electric field of K static nuclei. There is no external magnetic field but a self-generated one which is approximately accounted for by the Breit-potential. The energy is now

$$\mathcal{E}_N(\psi,\mathbf{R})=\left\langle\psi,\left(\sum_{\mu=1}^{N}D_\mu+\alpha(V_c-B)\right)\psi\right\rangle, \tag{12}$$

where

$$B=\sum_{\mu<\nu}^{N}\frac{1}{2|\mathbf{x}_\mu-\mathbf{x}_\nu|}\left(\sum_i\alpha_{i,\mu}\otimes\alpha_{i,\nu}+\frac{\boldsymbol{\alpha}_\mu\cdot(\mathbf{x}_\mu-\mathbf{x}_\nu)\otimes\boldsymbol{\alpha}_\nu\cdot(\mathbf{x}_\mu-\mathbf{x}_\nu)}{|\mathbf{x}_\mu-\mathbf{x}_\nu|^2}\right), \tag{13}$$

and V_c is the Coulomb potential defined in (1). $\mathbf{R}$ denotes the K-tuple $(\mathbf{R}_1,\ldots,\mathbf{R}_K)$ of pairwise different nuclear positions, and $D_\mu = D_\mu(\mathbf{A}\equiv 0)$. As before, ψ belongs to $\mathfrak{D}_N \subset \mathcal{H}_N$. The interaction $-\alpha B$ is usually derived from the corresponding interaction in the Darwin Hamiltonian by the quantization $\mathbf{p}/m \mapsto \boldsymbol{\alpha}$[22] or from QED: treating the interactions of the electrons with the quantized radiation field in second order perturbation theory leads to a shift of the bound state energy levels approximately given by $-\alpha\langle\psi,B\psi\rangle$.[23] Important for our purpose is that

$$\langle\psi,B\psi\rangle + \begin{pmatrix}\text{self-energy \&}\\ \text{exchange terms}\end{pmatrix} = \frac{1}{2}\int \frac{\mathbf{J}_T(\mathbf{x})\mathbf{J}_T(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|}\, d\mathbf{x}\, d\mathbf{y}, \tag{14}$$

for any Slater determinant $\psi = \psi_1 \wedge \cdots \wedge \psi_N$ of orthonormal functions ψ_μ (see the proof of Theorem 3).

We are interested in the lowest possible energy,

$$E_{N,K} = \inf \mathcal{E}_N(\psi,\mathbf{R}),$$

where the infimum is taken over all $\psi \in \mathfrak{D}_N$ with $\|\psi\| = 1$ and all K-tuples $(\mathbf{R}_1,\ldots,\mathbf{R}_K)$ with $\mathbf{R}_j \neq \mathbf{R}_k$ for $j \neq k$. Our second main result is the following.

Theorem 3: There exists a constant C such that for all $\alpha > 0$, $m \geqslant 0$, $K \in \mathbb{N}$ and $Z_1,\ldots,Z_K \in \mathbb{R}_+$,

$$E_{N,K} = -\infty,$$

whenever N, $\sum_{\kappa=1}^K Z_\kappa \geqslant C \max(\alpha^{-3/2},1)$. *If* $\sum Z_\kappa^2 \geqslant 1$ it suffices that $C = 5\times 10^4$ or—when $\alpha^{-1} = 137$—that $N = \sum_{\kappa=1}^K Z_\kappa \geqslant 3.4\times 10^7$.

Remarks:

1. Similar to Section I, V_c and hence the condition on $\sum_{\kappa=1}^K Z_\kappa$ may be dropped. Then there is instability for $N \geqslant C \max(\alpha^{-3/2},1)$. It is for completeness of the model that we keep V_c in this section.
2. Without B the energy is proven to be non-negative if $\alpha Z_\kappa \leqslant 2/\pi$ for all κ and if $\alpha \leqslant 1/94$[6] (see also Ref. 3). One expects, however, stability, even for $\alpha Z_\kappa \leqslant 2(2/\pi + \pi/2)^{-1}, \alpha \leqslant 0.12$,[13,16] which would cover the atomic numbers of all known elements.

At least partly, this theorem can be understood from Corollary 2, Eq. (11) and Eq. (14).

Proof of Theorem 3: To begin with, we prove (14). Let $\psi = \psi_1 \wedge \cdots \wedge \psi_N$ with $\langle\psi_\mu,\psi_\nu\rangle = \delta_{\mu\nu}$ and let $\mathbf{J}(\mathbf{x}) = \sum_{\mu=1}^N \psi_\mu^+(x)\boldsymbol{\alpha}\psi_\mu(x)$ be the current density of ψ. Note that $\hat{J}_{T,i}(\mathbf{p}) = \sum_{j=1}^3 (\delta_{ij} - p_i p_j/p^2)\hat{J}_j(\mathbf{p})$ and that

$$\mathfrak{F}\frac{4\pi}{p^2}\left(\delta_{ij} - \frac{p_i p_j}{p^2}\right) = \frac{1}{2|x|}\left(\delta_{ij} + \frac{x_i x_j}{x^2}\right).$$

With $B(\mathbf{x})$ defined by

$$B(x) = \frac{1}{2|x|}\sum_{i,j} \alpha_i \left(\delta_{ij} + \frac{x_i x_j}{x^2}\right)\alpha_j = \frac{1}{2|x|}\left(\sum_i \alpha_i \otimes \alpha_i + \frac{\boldsymbol{\alpha}\cdot\mathbf{x} \otimes \boldsymbol{\alpha}\cdot\mathbf{x}}{|x|^2}\right),$$

it follows that

$$\frac{1}{2}\int \frac{\mathbf{J}_T(x)\mathbf{J}_T(y)}{|\mathbf{x}-\mathbf{y}|}\, d\mathbf{x}\, d\mathbf{y} = \frac{1}{2}\sum_{\mu,\nu} \langle\psi_\mu\otimes\psi_\nu, B(x-y)\psi_\mu\otimes\psi_\nu\rangle = \langle\psi,B\psi\rangle$$

$$+ \frac{1}{2}\sum_{\mu,\nu} \langle\psi_\mu\otimes\psi_\nu, B(x-y)\psi_\nu\otimes\psi_\mu\rangle, \tag{15}$$

which is Eq. (14). Similar as in the proof of Theorem 1 it suffices to consider the case $m=0$ and to find a Slater determinant $\psi=\psi_1\wedge\cdots\wedge\psi_N$ and nuclear positions $\mathbf{R}_1,\ldots,\mathbf{R}_K$ such that $\mathcal{E}_N(\psi,\mathbf{R})<0$.

Choice of the nuclear positions: A beautiful argument given in Ref. 3 shows that, after moving some electrons or nuclei far away from all others,

$$\langle\psi,V_c\psi\rangle\leqslant\epsilon+\frac{1}{2N^2}\sum_{\mu,\nu}\int\frac{|\psi_\mu(\mathbf{x})|^2|\psi_\nu(\mathbf{y})|^2}{|\mathbf{x}-\mathbf{y}|}\,d\mathbf{x}\,d\mathbf{y},$$

for suitably chosen nuclear positions. Here $\varepsilon>0$ is the (arbitrary small) contribution of the particles moved away. The second term can be dropped if $\Sigma_{\kappa=1}^K Z_\kappa^2\geqslant 1$. We use the inequality obtained in Ref. 14 to estimate it from above, and find

$$\langle\psi,V_c\psi\rangle\leqslant\epsilon+\mathrm{const}\frac{1}{N}\sum_{\mu=1}^N\langle\psi_\mu,D\psi_\mu\rangle. \tag{16}$$

The number N of remaining electrons obeys $N<\Sigma Z_\kappa+1$ which is the reason for the assumption on ΣZ_κ. Of course, the choice of the nuclear positions depends on ψ, which has not been specified yet.

Define one-particle orbitals ψ_μ and currents $\mathbf{J}_\mu$ and $\mathbf{J}_0$ exactly as in the proof of Theorem 1 with $\mathbf{e}$ being an arbitrary unit vector in $\mathbb{R}^3$. The convergence $\hat{\mathbf{J}}_\mu(\mathbf{p})\to\hat{\mathbf{J}}_0(\mathbf{p})$ as $\lambda\to\infty$ now implies that

$$\frac{1}{2}\int\frac{\mathbf{J}_T(\mathbf{x})\mathbf{J}_T(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|}\,d\mathbf{x}\,d\mathbf{y}=N^2\left[\frac{1}{2}\int\frac{\mathbf{J}_{0,T}(\mathbf{x})\mathbf{J}_{0,T}(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|}\,d\mathbf{x}\,d\mathbf{y}+O(\lambda^{-1})\right]\geqslant c_2N^2, \tag{17}$$

for $\lambda\geqslant\lambda_0$, where λ_0 and $c_2>0$ are independent of N.

To estimate the sum of exchange- and self-energy terms in (15), notice that

$$\langle\psi_\mu\otimes\psi_\nu,B(x-y)\psi_\nu\otimes\psi_\mu\rangle=\int\frac{4\pi}{p^2}|\hat{\mathbf{J}}_{\mu\nu,T}(\mathbf{p})|^2\,d\mathbf{p}, \tag{18}$$

where $\mathbf{J}_{\mu\nu}(\mathbf{x})=\psi_\mu^*(x)\boldsymbol{\alpha}\psi_\nu(x)$. After writing $\hat{\mathbf{J}}_{\mu\nu}(\mathbf{p})$ as an integral in Fourier space in terms of u_μ and u_ν similar as in (7), it is easily seen, using the support properties of u_μ and u_ν, that

$$|\hat{\mathbf{J}}_{\mu\nu,T}(\mathbf{p})|^2\leqslant|\hat{\mathbf{J}}_{\mu\nu}(\mathbf{p})|^2\leqslant 3(2\pi)^{-3}\chi(|\mathbf{p}+\mathbf{n}_\mu-\mathbf{n}_\nu|\leqslant\sqrt{3}). \tag{19}$$

The N balls $B(n_\nu,\sqrt{3})$, $\nu=1,\ldots,N$ all lie in the ball $B(0,N^{1/3})$ and cover a given point, at most, say, $4^3=64$ times (replace the balls by cubes with side $2\sqrt{3}$). Therefore (19) implies that

$$\sum_{\nu=1}^N|\hat{\mathbf{J}}_{\mu\nu}(\mathbf{p})|^2\leqslant 192(2\pi)^{-3}\chi(|\mathbf{p}+\mathbf{n}_\mu|<N^{1/3})\leqslant\frac{24}{\pi^3}\chi(|\mathbf{p}|<2N^{1/3}),$$

which, in conjunction with (18), gives

$$\frac{1}{2}\sum_{\mu,\nu}\langle\psi_\mu\otimes\psi_\nu,B(x-y)\psi_\nu\otimes\psi_\mu\rangle\leqslant\frac{384}{\pi}N^{4/3}. \tag{20}$$

Rewriting the energy using (15) and inserting the estimates (16), (10), (17), and (20) we arrive at

$$\mathcal{E}_N(\psi,\mathbf{R})\leqslant c_1(1+\alpha)N^{4/3}-c_2\alpha N^2,\quad c_2>0,$$

which is negative for $N>\mathrm{const}\max(\alpha^{-3/2},1)$. This proves the theorem.

For small N and small α there is stability. A similar result for the energy in Sec. I was proved in Ref. 3.

Theorem 4: Suppose $\tilde{\alpha}\leqslant 1/94$, $\max_\kappa Z_\kappa \leqslant 2/\pi\tilde{\alpha}^{-1}$ and $N-1\leqslant 2(2/\pi+\pi/2)(\alpha^{-1}-\tilde{\alpha}^{-1})$. Then $E_{N,K}\geqslant 0$. Inserting $\tilde{\alpha}=1/94$ and $\alpha=1/137$ we find stability for $N\leqslant 39$ and $\max Z_\kappa \leqslant 59$.

Proof: Since $B(x)\leqslant 2/|x|$ on $\mathbb{C}^4\otimes\mathbb{C}^4$ and $1/|x|\leqslant\delta^{-1}D$ on $\Lambda_+L^2(\mathbb{R}^3;\mathbb{C}^4)$ where $\delta=2(2/\pi+\pi/2)$,[14] one has, by the symmetry property of the states in $\mathcal{H}_N$,

$$B\leqslant\frac{N-1}{\delta}\sum_{\mu=1}^{N} D_\mu, \quad \text{on } \mathcal{H}_N. \tag{21}$$

Furthermore,

$$V_c\geqslant-\frac{1}{\tilde{\alpha}}\sum_{\mu=1}^{N} D_\mu, \quad \text{on } \mathcal{H}_N, \tag{22}$$

for all $\tilde{\alpha}>0$ with $\tilde{\alpha}\max Z_\kappa\leqslant 2/\pi$ and $\tilde{\alpha}q\leqslant 1/47$ by Ref. 6, where the number q of spin states may be set equal to 2.[3] Inserting (21) and (22) in the energy proves the theorem. □

B. Dynamic nuclei

Making the nuclei dynamical would improve stability if their kinetic energy were the only term we added to (12). However, if the nuclei are relativistic spin 1/2 particles like the electrons and if the Breit-potential couples all pairs of particles, taking their charges into account, then the instability will actually become worse.

Let us illustrate this for a system of N electrons and K identical nuclei of spin 1/2 and atomic number $Z>0$. These nuclei are described by vectors in the positive energy subspace of the free Dirac operator with the mass $M>0$ of the nuclei. To prove instability we adopt the strategy of the proof of Theorem 3 and thus assume $M=0$ and $m=0$. As a trial-wave function we take

$$\psi=(\psi_1\wedge\cdots\wedge\psi_N)\otimes(\phi_1\wedge\cdots\wedge\phi_K),$$

where ψ_μ is defined by Eqs. (3) and (4) and ϕ_κ is defined like ψ_κ, except that $\mathbf{e}$ and N are replaced by $-\mathbf{e}$ and K, respectively. It follows that in the limit $\lambda\to\infty$ we get $N+K$ (charge-) currents, the nuclear ones being larger than the electronic ones by a factor of Z but otherwise identical. The Breit interaction thus gives a negative contribution to the energy of order $\alpha(N+ZK)^2$. While the parallel currents of the $N+K$ particles add up, the opposite charges of the electrons and nuclei cancel themselves. In fact, for ψ defined as above,

$$\begin{aligned}\langle\psi,V_c\psi\rangle&\leqslant\sum_{\mu<\nu}^{N}\int d\mathbf{x}\,d\mathbf{y}\frac{|\psi_\mu(\mathbf{x})|^2|\psi_\nu(\mathbf{y})|^2}{|\mathbf{x}-\mathbf{y}|}+Z^2\sum_{\kappa<\sigma}^{K}\int d\mathbf{R}_1\,d\mathbf{R}_2\frac{|\phi_\kappa(\mathbf{R}_1)|^2|\phi_\sigma(\mathbf{R}_2)|^2}{|\mathbf{R}_1-\mathbf{R}_2|}\\&\quad-Z\sum_{\kappa=1}^{K}\sum_{\mu=1}^{N}\int d\mathbf{x}\,d\mathbf{R}\frac{|\psi_\mu(\mathbf{x})|^2|\phi_\kappa(\mathbf{R})|^2}{|\mathbf{x}-\mathbf{R}|}\\&=\left[\frac{N(N-1)}{2}+Z^2\frac{K(K-1)}{2}-NKZ\right](I+O(\lambda^{-1}))\\&=[(KZ-N)^2-KZ^2-N](I/2+O(\lambda^{-1})),\end{aligned}\tag{23}$$

where I is the limit of the above double integrals as $\lambda\to\infty$. Hence, $\langle\psi,V_c\psi\rangle$ is negative, e.g., if $KZ=N$ and λ is large. To achieve this in the static case we had to choose the nuclear positions properly. It is instructive to recall how this was done. The total energy is bounded from above by $c_1(N^{4/3}+K^{4/3})-c_2\alpha(N+KZ)^2$, $c_2>0$, for $N=KZ$ and λ large, and is therefore negative for $N=KZ$ large enough.

IV. STABILITY AND INSTABILITY WITH QUANTIZED RADIATION FIELD

Instability for the model with a classical magnetic field implies instability for the model with a quantized radiation field without UV-cutoff. In fact, for each classical magnetic field there is a coherent state of photons which reproduces the classical field as far as the energy is concerned. If an UV-cutoff is introduced the relativistic scale invariance of the energy is broken and stability of the first kind is restored. The lower bound depends on the cutoff and goes to $-\infty$ as the cutoff is removed.

The state of the system is now described by a vector $\Psi \in \mathcal{H}_N \otimes \mathcal{F}$ where $\mathcal{F}$ denotes the bosonic Fock-space over $L^2(\mathbb{R}^3)\otimes\mathbb{C}^2$, the factor $\mathbb{C}^2$ accounting for the two possible polarizations of the transversal photons, and the total energy of Ψ is

$$\mathcal{E}_N^{\mathrm{qed}}(\Psi) = \left\langle \Psi, \sum_{\mu=1}^{N} [\boldsymbol{\alpha}_\mu \cdot (-i\boldsymbol{\nabla}_\mu + \alpha^{1/2}\mathbf{A}(\mathbf{x}_\mu)) + \beta_\mu m]\Psi \right\rangle + \langle \Psi, (1\otimes H_f)\Psi\rangle,$$

$$H_f = \sum_{\lambda=1}^{2} \int d\mathbf{k}|\mathbf{k}| a_\lambda^\dagger(\mathbf{k}) a_\lambda(\mathbf{k}),$$

where

$$\mathbf{A}(\mathbf{x}) := \sum_{\lambda=1}^{2} \int dk [e_\lambda(\mathbf{k}) e^{i\mathbf{kx}} \otimes a_\lambda(\mathbf{k}) + \mathbf{e}_\lambda(\mathbf{k}) e^{-i\mathbf{kx}} \otimes a_\lambda^\dagger(\mathbf{k})] =: \mathbf{A}^+(\mathbf{x}) + \mathbf{A}^+(\mathbf{x})^*$$

is the quantized vector potential in the Coulomb gauge. The operators $a_\lambda(\mathbf{k})$ and $a_\lambda^\dagger(\mathbf{k})$ are creation and annihilation operators acting on $\mathcal{F}$ and obeying the CCR,

$$[a_\lambda(\mathbf{k}_1), a_\mu^\dagger(\mathbf{k}_2)] = \delta_{\lambda\mu}\delta(\mathbf{k}_1 - \mathbf{k}_2), \quad [a_\lambda^\#(\mathbf{k}_1), a_\mu^\#(\mathbf{k}_2)] = 0,$$

where $a_\lambda^\sharp = a_\lambda$ or $a_\lambda^\dagger$, and the two polarization vectors $\mathbf{e}_\lambda(\mathbf{k})$ are orthonormal and perpendicular to $\mathbf{k}$ for each $\mathbf{k}\in\mathbb{R}^3$. We use dk as a short hand for $(2\pi)^{-3/2}(2|\mathbf{k}|)^{-1/2} d\mathbf{k}$, and the subindex of $\boldsymbol{\alpha}_\mu$, $\boldsymbol{\nabla}_\mu$ and β_μ indicates that these one-particle operators act on the μ-th particle. While we used Gaussian units in Secs. II and III we now work with Heaviside Lorenz units.

Lemma 5: For each $\mathbf{A}_{cl} \in \mathcal{A}\cap L^2(\mathbb{R}^3)$ there exists a vector $\theta\in\mathcal{F}$ (coherent state) such that

$$\mathcal{E}_N^{\mathrm{qed}}(\psi\otimes\theta) = \mathcal{E}_N(\psi, \mathbf{A}_{cl}),$$

for all $\psi \in \mathfrak{D}_N$.

Proof: Pick $\mathbf{A}_{cl}\in\mathcal{A}\cap L^2(\mathbb{R}^3)$ and define $\eta_\lambda(\mathbf{k}) = (|\mathbf{k}|/2)^{1/2}\mathbf{e}_\lambda(\mathbf{k})\cdot\hat{\mathbf{A}}_{cl}(\mathbf{k})$ so that $\mathbf{A}_{cl}(\mathbf{x}) = \mathbf{A}_{cl}^+(\mathbf{x}) + \mathbf{A}_{cl}^+(\mathbf{x})^*$ with

$$\mathbf{A}_{cl}^+(\mathbf{x}) = \sum_{\lambda=1}^{2} \int dk\ \eta_\lambda(\mathbf{k})\mathbf{e}_\lambda(\mathbf{k}) e^{i\mathbf{kx}}. \tag{24}$$

Next, set

$$\Pi(\eta) := i\sum_{\lambda=1}^{2} \int d\mathbf{k}[\eta_\lambda(\mathbf{k}) a_\lambda^\dagger(\mathbf{k}) - \overline{\eta_\lambda(\mathbf{k})} a_\lambda(\mathbf{k})],$$

and $\Theta = e^{-i\Pi(\eta)}\Omega \in \mathcal{F}$. Θ is called a coherent state, it is normalized, and, most importantly, it is an eigenvector of all annihilation operators,

$$a_\lambda(\mathbf{k})\Theta = \eta_\lambda(\mathbf{k})\Theta. \tag{25}$$

From (24), (25), and the definition of $\eta_\lambda(\mathbf{k})$ it follows that

$$\boldsymbol{\alpha}_\mu \mathbf{A}^+(\mathbf{x}_\mu)\psi\otimes\Theta=(\boldsymbol{\alpha}_\mu \mathbf{A}^+_{cl}(\mathbf{x}_\mu)\otimes\mathbf{1})\psi\otimes\Theta$$

and

$$\langle\Theta,H_f\Theta\rangle=\int d\mathbf{k}|\mathbf{k}|\sum_\lambda |\eta_\lambda(\mathbf{k})|^2=\frac{1}{2}\int d\mathbf{k}\,k^2|\hat{\mathbf{A}}_{cl}(\mathbf{k})|^2.$$

Inserting this in the energy proves the theorem. □

If an ultraviolet cutoff is introduced in the field operator $\mathbf{A}(\mathbf{x})$ then stability of the first kind is restored for all N and a certain range of values for α and Z_κ. This follows from Ref. 24, Lemma I.5 and Ref. 3, Theorem 1.

ACKNOWLEDGMENTS

It is a pleasure to thank Heinz Siedentop for many discussions, and Arne Jensen, Jan Philip Solovej, and Erik Skibsted for the hospitality at Aarhus University in August 97, where this work was begun. M. G. also thanks Michael Loss for clarifying discussions. This work was partially supported by the European Union under Grant No. ERB4001GT950214 and under the TMR-network Grant No. FMRX-CT 96-0001.

APPENDIX: NUMERICAL ESTIMATES

To obtain the numerical values for the constants in Corollary 2 and Theorem 3 we follow the proof of Theorem 3 up to a few modifications, and explicitly evaluate the constants in this proof.

The main modifications are that the two-spinor u is now defined in terms of the (normalized) characteristic function of the ball with radius 1/2 contained in the unit cube $\{\mathbf{p}|0\leqslant p_i\leqslant 1\}$ and that the 4-spinors $\psi_{2\mu-1}$ are defined in terms of the $\psi_{2\mu}$'s by interchanging the components of u, while $\mathbf{n}_{2\mu-1}$ runs over the $N/2$ or—if N is odd—the $(N+1)/2$ lattice sites of $\mathbb{Z}^3$ closest to the origin. The balls simplify the computation of $\hat{\mathbf{J}}_0(\mathbf{p})$ and the double occupation $\mathbf{n}_{2\mu-1}=\mathbf{n}_{2\mu}$ reduces the kinetic energy. To begin with, we note that the n unit cubes of the lattice $\mathbb{Z}^3$ which are closest to the origin, all fit in a ball of radius

$$n^{1/3}\left(\frac{3}{4\pi}\right)^{1/3}+\sqrt{3}.$$

In particular, the $N/2$ or $(N+1)/2$ unit cubes containing the supports of the spinors ψ_μ, $\mu=1,...,N$ all lie in the ball of radius $bN^{1/3}$ centered at $\lambda N^{1/3}\mathbf{e}$ where $b=1/2$ if $N\geqslant 1.2\times 10^7$, $b=3/5$ if $N\geqslant 5\times 10^3$ and $b=\sqrt{3}$ if $N\geqslant 1$ (the ball of radius $\sqrt{3}n^{1/3}$ contains never less than n lattice cubes). This replaces Eq. (4) and implies, together with Eqs. (7) and (8), that

$$|\hat{\mathbf{J}}_\mu(\mathbf{p})-\hat{\mathbf{J}}_0(\mathbf{p})|\leqslant\frac{6b}{\lambda-b}|\hat{\mathbf{J}}_0(\mathbf{p})|,\quad \lambda>b.$$

Using this and $|\hat{\mathbf{J}}_0(\mathbf{p})|=1/2(2\pi)^{-3/2}(1-p)^2(2+p)$ one finds

$$\begin{aligned}\int\frac{\mathbf{J}_T(\mathbf{x})\mathbf{J}_T(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|}d\mathbf{x}\,d\mathbf{y}&=\sum_{\mu,\nu=1}^N\int d\mathbf{p}\frac{4\pi}{\mathbf{p}^2}\hat{\mathbf{J}}^*_\mu(\mathbf{p})T\hat{\mathbf{J}}_\nu(\mathbf{p})\\&\geqslant N^2\left[\int d\mathbf{p}\frac{4\pi}{p^2}\hat{\mathbf{J}}^*_0(\mathbf{p})T\hat{\mathbf{J}}_0(\mathbf{p})-\frac{12b}{\lambda-b}\int d\mathbf{p}\frac{4\pi}{p^2}|\hat{\mathbf{J}}_0(\mathbf{p})|^2\right]\\&=N^2\left[1-\frac{18b}{\lambda-b}\right]\frac{11}{35\pi},\end{aligned}\tag{A1}$$

where T is the 3×3 matrix with the components $T_{ij}=\delta_{ij}-p_ip_j/p^2$. This replaces (17). We proceed to bound the self-energy and exchange terms. Inequality (19) becomes

$$|\hat{\mathbf{J}}_{\mu\nu}(\mathbf{p})|^2\leqslant 3(2\pi)^{-3}\chi(|\mathbf{p}+\mathbf{n}_\mu-\mathbf{n}_\nu|\leqslant 1), \tag{A2}$$

because the support of u now has diameter 1 not $\sqrt{3}$. Since the N balls $B(\mathbf{n}_\nu,1)$ cover a given point, at most, 8 times (recall that now $\mathbf{n}_{2\nu-1}=\mathbf{n}_{2\nu}$) inequality (A2) leads to the bound

$$\frac{1}{2}\sum_{\mu,\nu}\langle\psi_\mu\otimes\psi_\nu,B(x-y)\psi_\nu\otimes\psi_\mu\rangle\leqslant\frac{48}{\pi}bN^{4/3}, \tag{A3}$$

improving (20). The kinetic energy is bounded by $(\lambda+b)N^{4/3}$ and $\langle\psi,V_c\psi\rangle\leqslant 0$ since $\Sigma Z_\kappa=N$ and $\Sigma Z_\kappa^2\geqslant 1$. In conjunction with (A1) and (A3) this gives

$$\mathcal{E}_N(\psi)\leqslant N^{4/3}\left[\lambda+b+\frac{48}{\pi}b\alpha-\alpha N^{2/3}\frac{11}{70\pi}\left(1-\frac{18b}{\lambda-b}\right)\right]. \tag{A4}$$

For $b=1/2$, $\alpha^{-1}=137$ and the optimal λ this is negative for $N\geqslant 3.4\times 10^7$. For $b=3/5$ and $\alpha>0$ arbitrary this is negative for $N\geqslant C\max(\alpha^{-3/2},1)$ with $C=43859$ where λ was chosen to minimize C. This explains the numbers in Theorem 3.

Now drop the term $(48/\pi)b\alpha$ in Eq. (A4) which was due to the exchange- and self-energy terms. By Eq. (11) what we are left with is a upper bound for $\inf_{\psi,\mathbf{A}\in\mathcal{A}}\mathcal{E}_N(\psi,\mathbf{A})$. It is negative for $b=\sqrt{3}$, the optimal λ and $\alpha^{3/2}N\geqslant 134'863$, or for $b=1/2$ the optimal λ, $\alpha^{-1}=137$, and $N\geqslant 3.4\times 10^7$. This explains the numbers in the remark after Corollary 2.

We study the geometry of the Lagrangian Batalin–Vilkovisky (BV) theory on an antisymplectic manifold. We show that gauge symmetries of the BV theory are essentially the symmetries of an even symplectic structure on the stationary surface of the master action.
[S0022-2488(99)01803-4]

I. INTRODUCTION

In this paper, we investigate gauge symmetries in the Lagrangian Batalin–Vilkovisky (BV) formalism,[1,2] which is the most universal approach to the quantization of general gauge theories. The version of the BV quantization in which the coordinates are not explicitly separated into fields and antifields is known as the covariant approach.[3–9] The partition function is then given by a path integral of the exponential of the master action over a gauge-fixing surface $\mathcal{L}$ that is a Lagrangian submanifold of an odd-symplectic manifold $\mathcal{M}$. The gauge independence is realized as the independence from the choice of $\mathcal{L}$ and is ensured by the master equation imposed on the master action.

While the gauge symmetries of the original action are no longer symmetries of the formalism, the covariant formulation itself has its own ''gauge'' transformations. Each observable [a Becchi–Rouet–Stora–Tyutin- (BRST-) closed function] determines a gauge symmetry. Studied in Ref. 10 were the gauge symmetries corresponding to the trivial observables (BRST-exact functions). It was shown there that the space of functions modulo the BRST-exact ones, called *the space of gauge parameters*,[10] is endowed with a Lie algebra structure induced by the Lie algebra structure on the space of BRST-trivial gauge symmetries.

In this paper, we study symmetries of the BV formalism using the geometrical setting where the BV data are viewed as a QP-manifold.[7,11] This is a supermanifold equipped with an antisymplectic structure (the P-structure) and an odd nilpotent Hamiltonian vector field (the Q-structure); in the BV setting, the vector field is given by the antibracket with the master action.

An important characteristic of the Q-structure is the *zero locus* $\mathcal{Z}_{\mathbf{Q}}$ of the odd vector field. The most interesting case in applications is where $\mathcal{Z}_{\mathbf{Q}}$ is a smooth $(n|N-n)$-dimensional submanifold (assuming the antisymplectic supermanifold $\mathcal{M}$ to be $(N|N)$-dimensional). We call such QP-manifolds the proper QP-manifolds; then the QP-structure induces a symplectic structure on the zero locus of $\mathbf{Q}$ [see (II.8)]. [The existence of a symplectic structure on the zero locus can also be inferred from Ref. 11; the Poisson bracket on (,)-Lagrangian submanifolds was described in Ref. 12; see also Ref. 13.]

It turns out that symmetries of the BV ''master system'' are to a considerable degree determined by Hamiltonian vector fields on the stationary surface of the master action (the vector fields being Hamiltonian with respect to the *Poisson bracket*). We will explicitly define a nondegenerate Poisson bracket on the quotient algebra of all smooth functions modulo the functions vanishing on $\mathcal{Z}_{\mathbf{Q}}$; this generalizes the bilinear operation of Ref. 10, which is not a Poisson bracket since it fails to satisfy the Leibniz rule (in fact, it defined on the space that is not an algebra under the associative multiplication).

We show that each symmetry of a proper QP-manifold, i.e., a vector field preserving the QP-structure, can be restricted to $\mathcal{Z}_{\mathbf{Q}}$ and, moreover, this restriction is a locally Hamiltonian vector field with respect to the Poisson bracket on $\mathcal{Z}_{\mathbf{Q}}$. Conversely, locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ can be lifted to vector fields on $\mathcal{M}$, into symmetries of the proper QP-manifold. At the same time, the *globally* Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ lift to BRST-trivial symmetries. In this way, we obtain a ''translation table'' between the objects pertaining to the antisymplectic geometry on $\mathcal{M}$ and those of the symplectic geometry on $\mathcal{Z}_{\mathbf{Q}}$.

We further select the *on-shell symmetries*, i.e., symmetries modulo those vanishing on the stationary surface. We show that the Lie algebra $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ of the on-shell gauge symmetries is isomorphic to the Lie algebra of locally Hamiltonian vector fields on the stationary surface $\mathcal{Z}_{\mathbf{Q}}$. The Lie algebras of the on-shell gauge symmetries ($\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$), of gauge parameters[10] ($\tilde{\mathcal{O}}^c_{\text{triv}}$), and of gauge symmetries of the master action ($\tilde{\mathcal{O}}^c$), as well as their quantum counterparts, are related to each other as shown in (III.11) and to the cohomology, as shown in (III.16), (III.18), and (III.19).

We consider two examples of the general construction. We explicitly calculate the Lie algebras $\mathcal{O}^c$ and $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ in the Abelianized[14] gauge theory. It is not difficult to see then that the algebra of gauge symmetries of the original classical theory is embedded into the Lie algebra $\mathcal{O}^c$ as a subalgebra in such a way that the algebra of the on-shell gauge symmetries of the original theory is embedded into the Lie algebra $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$. As another example, we consider the theory with the vanishing action on a Lie group. Not surprisingly, the Poisson structure on the ''stationary surface'' is then related to the Kirillov bracket[15] on the coalgebra.

In Sec. II, we study the geometry of QP-manifolds. In Sec. III, we give a short reminder on the BV-quantization and then study the quantum and classical gauge symmetries. In Sec. IV, we demonstrate the main points of our construction in two characteristic examples.

II. GEOMETRY OF PROPER QP-MANIFOLDS

In this section, we study geometry of the QP-manifolds and define proper QP-manifolds by simply reformulating the condition from Ref. 1 for a solution of the master equation to be proper. We then show that the zero locus $\mathcal{Z}_{\mathbf{Q}}$ of the vector field $\mathbf{Q}$ on a proper QP-manifold is a symplectic manifold. Moreover, the vector fields that are *symmetries* of a proper QP-manifold correspond to locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$; the *BRST-trivial* symmetries then correspond to globally Hamiltonian vector fields.

A. A poisson structure

Let $\mathcal{M}$ be an $(N|N)$-dimensional supermanifold and let $\mathbb{C}_{\mathcal{M}}$ denote the algebra of smooth functions on $\mathcal{M}$. Let $(\cdot,\cdot)$: $\mathbb{C}_{\mathcal{M}}\times\mathbb{C}_{\mathcal{M}}\to\mathbb{C}_{\mathcal{M}}$ be an antibracket on $\mathcal{M}$. It satisfies

$$\epsilon((F,G))=\epsilon(F)+\epsilon(G)+1, \tag{II.1}$$

$$(F,G)=-(-1)^{(\epsilon(F)+1)(\epsilon(G)+1)}(G,F), \tag{II.2}$$

$$(F,GH)=(F,G)H+(-1)^{\epsilon(G)(\epsilon(F)+1)}G(F,H), \tag{II.3}$$

$$0=\underset{F,G,H}{\text{cycle}}(-1)^{(\epsilon(F)+1)(\epsilon(H)+1)}(F,(G,H)). \tag{II.4}$$

In a local coordinate system Γ^A, $A=1,...,2N$, we have the matrix $E^{AB}=(\Gamma^A,\Gamma^B)$ that defines a bivector E such that $(F,G)=E(dF,dG)$. We assume the antibracket to be nondegenerate.

Consider an odd vector field $\mathbf{Q}:\mathbb{C}_{\mathcal{M}}\to\mathbb{C}_{\mathcal{M}}$ on $\mathcal{M}$ satisfying the following conditions:

(1) $\mathbf{Q}$ preserves the antibracket, i.e., $\pounds_{\mathbf{Q}}E=0$, where $\pounds_{\mathbf{Q}}$ is the Lie derivative along $\mathbf{Q}$; equivalently, $\mathbf{Q}$ differentiates the antibracket:

$$\mathbf{Q}(F,G)-(\mathbf{Q}F,G)-(-1)^{\epsilon(F)+1}(F,\mathbf{Q}G)=0,\quad F,G\in\mathbb{C}_M; \tag{II.5}$$

(2) $\mathbf{Q}$ is nilpotent: $\mathbf{Q}(\mathbf{Q}F)=0$, $F\in\mathbb{C}_{\mathcal{M}}$, $\Leftrightarrow[\mathbf{Q},\mathbf{Q}]=0$.

Definition II.1[7,11]*: A supermanifold $\mathcal{M}$ equipped with a nondegenerate antibracket $(\cdot,\cdot)$ and an odd nilpotent vector field* **Q** *that satisfies condition (II.5) is called the* QP*-manifold.*

The main object of our analysis is the set $\mathcal{Z}_{\mathbf{Q}}$ of zeroes of **Q**, i.e., the set defined by the equations $Q^A=0$, where $\mathbf{Q}=Q^A\partial_A$ in a local coordinate system Γ^A. We assume $\mathcal{Z}_{\mathbf{Q}}$ to be a submanifold in $\mathcal{M}$. Denote by $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}\subset\mathbb{C}_{\mathcal{M}}$ the ideal of all smooth functions vanishing on $\mathcal{Z}_{\mathbf{Q}}$. We also assume the ''regularity condition,'' i.e., that **Q**-exact functions *generate* $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$, which means that any function $f\in\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ admits a representation $f=(\mathbf{Q}h)g$ with some $g,h\in\mathbb{C}_{\mathcal{M}}$. The quotient $\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}=\mathbb{C}_{\mathcal{M}}/\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ is the algebra of smooth functions on $\mathcal{Z}_{\mathbf{Q}}$. Obviously, $\mathbf{Q}\mathbb{C}_{\mathcal{M}}\subset\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$.

An additional requirement imposed on **Q** is that its local cohomology (that is, the cohomology evaluated in a sufficiently small neighborhood of a point) is trivial (constants only) at every point $p\in\mathcal{Z}_{\mathbf{Q}}$. In local coordinates, then, the nilpotent operator $\partial Q^A/\partial\Gamma^B|_{Q^A=0}$ has the vanishing cohomology on the tangent space to every $p\in\mathcal{Z}_{\mathbf{Q}}$.[7,11] This in turn implies the condition from Ref. 1:

$$\mathrm{rank}\left|\left(\frac{\partial Q^A}{\partial\Gamma^B}\right)\right|_{Q^A=0}=N. \tag{II.6}$$

In particular, it follows from (II.6) that $\mathcal{Z}_{\mathbf{Q}}$ is an $(n|N-n)$-dimensional submanifold.

Definition II.2: A proper QP*-manifold is a* QP*-manifold on which the local cohomology of* **Q** *is trivial at every point of* $\mathcal{Z}_{\mathbf{Q}}$.

Lemma II.3: The submanifold $\mathcal{Z}_{\mathbf{Q}}$ of a proper QP*-manifold is Lagrangian with respect to the antibracket. In particular, the ideal $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ is closed under the antibracket:*

$$(\mathbb{I}_{\mathcal{Z}_Q},\mathbb{I}_{Z_{\mathbf{Q}}})\subset\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}. \tag{II.7}$$

Proof: Since any function from $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ can be represented as the product $(\mathbf{Q}f)h$ with some $h\in\mathbb{C}_{\mathcal{M}}$, it suffices to check that the antibracket of **Q**-exact functions is **Q**-exact, which is obvious in view of $(\mathbf{Q}g,\mathbf{Q}h)=\mathbf{Q}(g,\mathbf{Q}h)$.

In fact, the submanifold $\mathcal{Z}_{\mathbf{Q}}$ is endowed with a natural Poisson structure. This is given by a construction of the type of those used, with some variations, in Refs. 10, 12, 13, and 16, namely,

$$\{F,G\}=(F,\mathbf{Q}G),\quad F,G\in\mathbb{C}_{\mathcal{M}}. \tag{II.8}$$

We interpret this structure as a bilinear mapping on the quotient algebra $\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}$. Functions from $\mathbb{C}_{\mathcal{M}}$ considered modulo $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ represent functions on $\mathcal{Z}_{\mathbf{Q}}$. We then have the following.

Theorem II.4: *For any proper* QP*-manifold,*

(1) *Equation (II.8) defines a Poisson bracket $\{\cdot,\cdot\}$: $\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}\times\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}\to\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}$ on the submanifold $\mathcal{Z}_{\mathbf{Q}}$.*
(2) *Moreover, the Poisson bracket $\{\cdot,\cdot\}$ is nondegenerate (thus, $\mathcal{Z}_{\mathbf{Q}}$ is symplectic).*

Proof: First of all, we must prove that definition (II.8) does not depend on the choice of representatives of the equivalence classes, i.e., $\{F+f,G+g\}-\{F,G\}\in\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ whenever $f,g\in\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$. Since **Q** differentiates the antibracket, we can check that

$$\{F+f,G+g\}-\{F,G\}=(-1)^{\epsilon(F)}(\mathbf{Q}F,g)+(-1)^{\epsilon(F)+1}\mathbf{Q}(F,g)+(f,\mathbf{Q}(G+g)).$$

The first and the third terms belong to $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ by Lemma (II.3) and the second term is in $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ because it is **Q**-exact. Thus (II.8) defines a mapping $\{\cdot,\cdot\}$: $\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}\times\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}\to\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}$. It is antisymmetric because

$$\{F,G\}+(-1)^{\epsilon(F)\epsilon(G)}\{G,F\}=(F,\mathbf{Q}G)+(-1)^{\epsilon(F)\epsilon(G)}(G,\mathbf{Q}F)=(-1)^{\epsilon(F)+1}\mathbf{Q}(F,G)\in\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}},$$

where we used (II.5) again. Next, to prove the Leibnitz rule, we evaluate

$$\{F,GH\}-\{F,G\}H-(-1)^{\epsilon(F)\epsilon(G)}G\{F,H\}$$
$$=(-1)^{(\epsilon(F)+1)(\epsilon(G)+1)}(\mathbf{Q}G)(F,H)+(-1)^{\epsilon(G)}(F,G)(\mathbf{Q}H), \quad \text{(II.9)}$$

which evidently vanishes modulo terms from $\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}$. Finally, to prove the Jacobi identity we have to show that

$$\underset{F,G,H}{\text{cycle}}(-1)^{\epsilon(F)\epsilon(H)}\{F,\{G,H\}\}=\underset{F,G,H}{\text{cycle}}(-1)^{\epsilon(F)\epsilon(H)}(F,\mathbf{Q}(G,\mathbf{Q}H))\equiv 0 \bmod \mathbb{I}_\mathbf{Q}.$$

In view of the Leibniz rule and the nilpotency condition this rewrites, modulo terms from $\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}$ as

$$\underset{\mathbf{Q}F,G,\mathbf{Q}H}{\text{cycle}}(-1)^{(\epsilon(\mathbf{Q}F)+1)(\epsilon(\mathbf{Q}H)+1)}(\mathbf{Q}F,(G,\mathbf{Q}H)),$$

which vanishes by virtue of the Jacobi identity for the antibracket.

To prove that the Poisson bracket is nondegenerate on $\mathcal{Z}_\mathbf{Q}$, we recall a standard fact from symplectic geometry, namely that in some neighborhood of $\mathcal{Z}_\mathbf{Q}$ there exists a coordinate system x^i, ξ_i such that the antibracket takes the canonical form $(x^i,\xi_j)=\delta^i_j$ and $\mathcal{Z}_\mathbf{Q}$ is determined by $\xi_i=0$. Locally, the vector field $\mathbf{Q}$ can be written in the form $\mathbf{Q}=(S,\cdot)$ with some function $S\in\mathbb{C}_\mathcal{M}$ [since a vector field preserving a nondegenerate (anti)bracket is locally Hamiltonian]. Expanding S as

$$S=S_0(x)+\xi_iS^i(x)+\xi_iS^{ij}(x)\xi_j+\xi_i\xi_j\xi_kS^{ijk}(x)+\cdots,$$

we see that $S_0(x)=\text{const}$ and $S^i(x)=0$, because $\mathbf{Q}=(S,\cdot)$ vanishes as $\xi=0$. Then condition (II.6) means that the matrix $S^{ij}(x)$ is nondegenerate at each point of $\mathcal{Z}_\mathbf{Q}$. On the other hand, $S^{ij}(x)|_{\xi=0}=-\frac{1}{2}\{x^i,x^j\}|_{\xi=0}$, which shows the theorem. ■

Note that the symbol $\{\cdot,\cdot\}$ is used for the formal operation (II.8) on the manifold $\mathcal{M}$ and also for the Poisson bracket on the submanifold $\mathcal{Z}_\mathbf{Q}$. We do not introduce two different symbols and hope that this will not lead to confusion.

B. Symmetries of QP-manifolds

For applications to the BV quantization in the subsequent sections, we will need some facts about symmetries of QP-manifolds.

Definition II.5: A vector field $\mathbf{X}$ *on a* QP-*manifold* $\mathcal{M}$ *is called a symmetry of* $\mathcal{M}$ *if*

(1) $\mathbf{X}$ *preserves the antibracket* $(\cdot,\cdot)$:

$$\mathbf{X}(F,G)-(\mathbf{X}F,G)-(-1)^{(\epsilon(F)+1)\epsilon(\mathbf{X})}(F,\mathbf{X}G)=0, \quad F,G\in\mathbb{C}_\mathcal{M}, \quad \text{(II.10)}$$

and

(2) $\mathbf{X}$ *preserves the odd vector field* $\mathbf{Q}$: $[\mathbf{Q},\mathbf{X}]=0$.

Our aim is to demonstrate that symmetries of a proper QP-manifold restrict to the zero locus of $\mathbf{Q}$, and to study the properties of such restrictions. We begin with characterizing, in the standard way, those vector fields on $\mathcal{M}$ that restrict to $\mathcal{Z}_\mathbf{Q}$:

Lemma II.6: A vector field $\mathbf{X}$ *on a proper* QP-*manifold* $\mathcal{M}$ *restricts to* $\mathcal{Z}_\mathbf{Q}$ *if and only if*

$$[\mathbf{X},\mathbf{Q}]|_{\mathcal{Z}_\mathbf{Q}}=0. \quad \text{(II.11)}$$

Proof: A vector field restricts to $\mathcal{Z}_\mathbf{Q}$ if and only if it preserves the ideal of functions vanishing on $\mathcal{Z}_\mathbf{Q}$: $\mathbf{X}\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}\subset\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}$. Now, $[\mathbf{X},\mathbf{Q}]|_{\mathcal{Z}_\mathbf{Q}}=0\Leftrightarrow[\mathbf{X},\mathbf{Q}]f\in\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}\forall f\in\mathbb{C}_\mathcal{M}$, which rewrites as $\mathbf{XQ}f\in\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}$. Since $\mathbf{Q}$-exact functions generate the ideal, we conclude that $\mathbf{X}\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}\subset\mathbb{I}_{\mathcal{Z}_\mathbf{Q}}$. The converse is now obvious. ■

It follows from this Lemma that any vector field $\mathbf{X}$ that is a symmetry of a proper QP-manifold can be restricted to $\mathcal{Z}_{\mathbf{Q}}$. We now recall that the zero locus of $\mathbf{Q}$ is endowed with a Poisson structure.

Theorem II.7: *If a vector field* $\mathbf{X}$ *is a symmetry of a proper* QP-*manifold* $\mathcal{M}$, *its restriction* $\mathbf{X}|_{\mathcal{Z}_{\mathbf{Q}}}$ *to the zero locus of* $\mathbf{Q}$ *preserves the Poisson bracket from Theorem II.4:*

$$\mathbf{X}|_{\mathcal{Z}_{\mathbf{Q}}}\{F,G\}-\{\mathbf{X}|_{\mathcal{Z}_{\mathbf{Q}}}F,G\}-(-1)^{\epsilon(F)\epsilon(\mathbf{X})}\{F,\mathbf{X}|_{\mathcal{Z}_{\mathbf{Q}}}G\}=0,\quad F,G\in\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}. \tag{II.12}$$

Proof: Let us choose two representatives $F,G\in\mathbb{C}_{\mathcal{M}}$ of the equivalence classes of functions on $\mathcal{Z}_{\mathbf{Q}}$. Using the properties stated in Definition (II.5), we have

$$\mathbf{X}\{F,G\}=\mathbf{X}(F,\mathbf{Q}G)=(\mathbf{X}F,\mathbf{Q}G)+(-1)^{(\epsilon(F)+1)\epsilon(\mathbf{X})}(F,\mathbf{X}\mathbf{Q}G)=\{\mathbf{X}F,G\}+(-1)^{\epsilon(F)\epsilon(\mathbf{X})}\{F,\mathbf{X}G\}.$$

■

It follows from the nondegeneracy of the Poisson bracket (II.8) that any vector field $\mathbf{x}$ on $\mathcal{Z}_{\mathbf{Q}}$ that preserves the Poisson bracket can be written as $\mathbf{x}=\{H,\cdot\}$ with some (locally) defined function H. We will refer to this as a *locally Hamiltonian* vector field. Every $\mathbf{x}=\{H,\cdot\}$ with a globally defined H will be called *globally Hamiltonian*. It is well known that globally Hamiltonian vector fields form an ideal in the Lie algebra of locally Hamiltonian vector fields.

C. Lifts and restrictions of vector fields

In this section, we are interested in relations between Hamiltonian vector fields on the symplectic manifold $\mathcal{Z}_{\mathbf{Q}}$ and the Hamiltonian vector fields on $\mathcal{M}$, in particular, the symmetries of the proper QP-manifold $\mathcal{M}$. (Thus, whenever we speak about Hamiltonian vector fields on $\mathcal{M}$, these are Hamiltonian with respect to the *anti*bracket, while the Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ are Hamiltonian with respect to the Poisson bracket.)

To explain why there exists a correspondence between symmetries of a proper QP-manifold $\mathcal{M}$ and symmetries of its symplectic submanifold $\mathcal{Z}_{\mathbf{Q}}$, we begin with an example.[16] Consider an N-dimensional symplectic manifold $\mathcal{K}$ with the symplectic form $\hat{\omega}$ which defines the nondegenerate Poisson bracket $\{\cdot,\cdot\}$ (in general, $\mathcal{K}$ can be a supermanifold, but we assume for simplicity that it is an even manifold). In a local coordinate system x^i, we have the invertible matrix $\omega^{ij}=\{x^i,x^j\}$. Let $\Pi T^*\mathcal{K}$ be the cotangent bundle with the flipped parity. In the canonical coordinates x^i, ξ_i [with the antibracket $(x^i,\xi_j)=\delta^i_j$], the manifold $\mathcal{K}$ can be identified with the zero section $\xi_i=0$ of $\Pi T^*\mathcal{K}$. The function $S=\frac{1}{2}\xi_i\omega^{ij}\xi_j$ satisfies $(S,S)=0$ because ω^{ij} is the matrix of a Poisson bracket. Then the submanifold $\mathcal{K}$ is the zero locus of the vector field

$$\mathbf{Q}=(S,\cdot)=\frac{1}{2}\xi_i\left(\frac{\vec{\partial}}{\partial x^k}\omega^{ij}\right)\xi_j\frac{\vec{\partial}}{\partial\xi_k}-\xi_i\omega^{ij}\frac{\vec{\partial}}{\partial x^j}. \tag{II.13}$$

It is easy to see that $\mathbf{Q}$ satisfies the conditions of Definition II.1. In addition, condition (II.6) is satisfied because the dimension of $\mathcal{K}$ is N. Thus $\Pi T^*\mathcal{K}$ is a QP-manifold and, in fact, a proper QP-manifold (because ω^{ij} is nondegenerate). With the help of the symplectic form, we can identify $\Pi T^*\mathcal{K}$ with the tangent bundle $\Pi T\mathcal{K}$ (with $\xi^i=\omega^{ij}\xi_j$ being the coordinates on the fibers). Then we can rewrite $\mathbf{Q}$ as

$$\mathbf{Q}=\xi^i\frac{\vec{\partial}}{\partial x^i}. \tag{II.14}$$

Upon the identification of functions on $\Pi T\mathcal{K}$ with differential forms on $\mathcal{K}$, $\mathbf{Q}$ becomes the De Rham differential on $\mathcal{K}$.[11]

Further, every locally Hamiltonian vector field $\mathbf{x}$ on $\mathcal{K}$ can be lifted to a globally Hamiltonian vector field $\mathbf{X}$ on $\Pi T^*\mathcal{K}$. Namely, if $\mathbf{x}=\{H,\cdot\}$ (where we allow H to be multivalued), we take

$F=(-1)^{\epsilon(H)}\mathbf{Q}(\pi^*H)$, where π^* is the pullback with respect to the canonical projection $\pi:\Pi T^*\mathcal{K}\rightarrow\mathcal{K}$. Then the vector field $\mathbf{X}=(F,\cdot)$ *is well-defined* (independent of the multivaluedness of H) and satisfies

$$\mathbf{X}|_{\mathcal{K}}=\mathbf{x} \tag{II.15}$$

and is also a symmetry of $\Pi T^*\mathcal{K}$ in the sense of Definition II.5. Conversely, any symmetry of $\Pi T^*\mathcal{K}$ determines a locally Hamiltonian vector field on $\mathcal{K}$ (see Theorem II.7), which is obviously a symmetry of this symplectic manifold.

The above is a particular case of a more general construction, where $\mathcal{M}$ can be an arbitrary proper QP-manifold. There still exists a correspondence between symmetries of $\mathcal{M}$ and symmetries of its symplectic submanifold $\mathcal{Z}_{\mathbf{Q}}$.

We have seen in Theorem II.7 that every symmetry of a proper QP-manifold restricts to $\mathcal{Z}_{\mathbf{Q}}$ as a locally Hamiltonian vector field. Consider now the converse problem. We say that a symmetry $\mathbf{X}$ of a proper QP-manifold $\mathcal{M}$ is a lift from $\mathcal{Z}_{\mathbf{Q}}$ of a locally Hamiltonian vector field $\mathbf{x}$ if $\mathbf{X}$ restricts to $\mathcal{Z}_{\mathbf{Q}}$ and $\mathbf{X}|_{\mathcal{Z}_{\mathbf{Q}}}=\mathbf{x}$.

Theorem II.8: *Every locally Hamiltonian vector field* $\mathbf{x}$ *on* $\mathcal{Z}_{\mathbf{Q}}$ *admits a lift to a symmetry of* $\mathcal{M}$ *that is a globally Hamiltonian vector field on* $\mathcal{M}$ *with a* $\mathbf{Q}$*-closed Hamiltonian. If* $\mathbf{x}$ *is globally Hamiltonian on* $\mathcal{Z}_{\mathbf{Q}}$*, it is lifted to a globally Hamiltonian vector field with a* $\mathbf{Q}$*-exact Hamiltonian.*

In what follows, symmetries of $\mathcal{M}$ of the form $\mathbf{X}=(F,\cdot)$ with a $\mathbf{Q}$-exact Hamiltonian F are called the *BRST-trivial symmetries*.

Proof: For a (locally) Hamiltonian vector field $\mathbf{x}$ on $\mathcal{Z}_{\mathbf{Q}}$, the equation $\mathbf{x}=\{H,\cdot\}$ can be solved for H in a sufficiently small neighborhood of every point $p\in\mathcal{Z}_{\mathbf{Q}}$. Different such solutions can be considered as a multivalued Hamiltonian H. This can be extended to a multivalued function $\tilde{H}$ on $\mathcal{M}$ that restricts to H on $\mathcal{Z}_{\mathbf{Q}}$ (for example, consider a neighborhood U of $\mathcal{Z}_{\mathbf{Q}}$ in $\mathcal{M}$ and identify it with a neighborhood of the zero section of a vector bundle over $\mathcal{Z}_{\mathbf{Q}}$; if $\tilde{h}$ is the pullback of the multivalued function H to the bundle, we can choose a function $\alpha\in\mathbb{C}_{\mathcal{M}}$ such that $\alpha|_{\mathcal{Z}_{\mathbf{Q}}}=1$ and $\alpha=0$ outside U, which yields the lifting $\tilde{H}=\alpha\tilde{h}$ of the multivalued Hamiltonian H).

Then consider the function $F=(-1)^{\epsilon(H)}\mathbf{Q}\tilde{H}$ on $\mathcal{M}$; F is *single-valued,* is $\mathbf{Q}$-closed by construction, but in general is not $\mathbf{Q}$-exact (because its $\mathbf{Q}$-primitive is not necessarily single-valued). Now, let $\mathbf{X}=(F,\cdot)$. For any function $\tilde{G}\in\mathbb{C}_{\mathcal{M}}$, we have

$$(F,\tilde{G})|_{\mathcal{Z}_{\mathbf{Q}}}=(\tilde{H},\mathbf{Q}\tilde{G})|_{\mathcal{Z}_{\mathbf{Q}}},$$

which coincides with $\{\tilde{H}|_{\mathcal{Z}_{\mathbf{Q}}},\tilde{G}|_{\mathcal{Z}_{\mathbf{Q}}}\}=\mathbf{x}\tilde{G}|_{\mathcal{Z}_{\mathbf{Q}}}$ [see (II.8)]. Thus $\mathbf{X}$ is a lift of $\mathbf{x}$ to a symmetry of $\mathcal{M}$.

Whenever the Hamiltonian H of $\mathbf{x}$ on $\mathcal{Z}_{\mathbf{Q}}$ is globally defined on $\mathcal{Z}_{\mathbf{Q}}$, the function F is obviously $\mathbf{Q}$-exact and thus $\mathbf{X}=(F,\cdot)$ is a BRST-trivial symmetry of $\mathcal{M}$. ■

This theorem can also be seen by noticing that the cohomology of $\mathbf{Q}$ evaluated on an appropriately chosen neighborhood U of $\mathcal{Z}_{\mathbf{Q}}$ in $\mathcal{M}$ coincides with the De Rham cohomology of $\mathcal{Z}_{\mathbf{Q}}$.[11] Namely, one can identify the neighborhood U of $\mathcal{Z}_{\mathbf{Q}}$ with some neighborhood of the zero section of $\Pi T\mathcal{Z}_{\mathbf{Q}}$. Then we can write $\mathbf{Q}=\xi^i\vec{\partial}/\partial x^i$, where x^i and ξ^i are coordinates on $\mathcal{Z}_{\mathbf{Q}}$ and on the fibers, respectively. Thus $\mathbf{Q}$ coincides with the De Rham differential of $\mathcal{Z}_{\mathbf{Q}}$ if one identifies functions on U that are homogeneous in ξ with the differential forms on $\mathcal{Z}_{\mathbf{Q}}$. In particular, every closed but not exact one-form $f=dx^if_i$ gives rise to the function $F=\xi^if_i$ on U that is obviously in the cohomology of $\mathbf{Q}$. At the same time, the one-form $f=dx^if_i$ gives rise to the locally Hamiltonian vector field $\mathbf{x}=(-1)^{\epsilon(x^i)\epsilon(f_i)}f_i\omega^{ij}\vec{\partial}/\partial x^j$ on $\mathcal{Z}_{\mathbf{Q}}$ (where $\omega^{ij}=\{x^i,x^j\}$). Therefore, $\mathbf{x}$ lifts to the vector field $(-1)^{\epsilon(F)+1}(F,\cdot)$ on U whose Hamiltonian is the same function $F=\xi^if_i$.

We see, in particular, that a locally Hamiltonian vector field representing the first cohomology of $\mathcal{Z}_{\mathbf{Q}}$ corresponds to an element of the $\mathbf{Q}$-cohomology on $\mathcal{M}$. We now single out those $(\cdot,\cdot)$-Hamiltonian vector fields on $\mathcal{M}$ that restrict to $\{\cdot,\cdot\}$-Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$, and describe the full arbitrariness of the lifts of Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ to Hamiltonian vector fields on $\mathcal{M}$. The following is proved by directly generalizing the proof of Theorem II.8.

Theorem II.9:

(1) *Let* $\mathbf{X}=(F,\cdot)$ *be a globally Hamiltonian vector field on a proper* QP*-manifold* $\mathcal{M}$ *with the Hamiltonian satisfying* $\mathbf{Q}F\in\mathbb{I}^3_{\mathcal{Z}_{\mathbf{Q}}}$ *(i.e.,* $\mathbf{Q}F=Q^AQ^BQ^CY_{ABC}$ *with some* $Y_{ABC}\in\mathbb{C}_{\mathcal{M}}$*). Then* $\mathbf{X}$ *restricts to a locally Hamiltonian vector field on* $\mathcal{Z}_{\mathbf{Q}}$.

(2) *Every locally Hamiltonian vector field* $\mathbf{x}$ *on* $\mathcal{Z}_{\mathbf{Q}}$ *admits a lift to a globally Hamiltonian vector field on* $\mathcal{M}$ *with the Hamiltonian F satisfying* $\mathbf{Q}F=0$. *If* $\mathbf{x}$ *is globally Hamiltonian on* $\mathcal{Z}_{\mathbf{Q}}$ *with the Hamiltonian H, the Hamiltonians of all its lifts to* $\mathcal{M}$ *are of the form*

$$F=(-1)^{\epsilon(\tilde{H})}\mathbf{Q}\tilde{H}+K+\text{const},\quad K\in\mathbb{I}^2_{\mathcal{Z}_{\mathbf{Q}}},\tag{II.16}$$

where $\tilde{H}$ *is any function on* $\mathcal{M}$ *such that* $\tilde{H}|_{\mathcal{Z}_{\mathbf{Q}}}=H$.

III. GAUGE SYMMETRIES OF THE MASTER ACTION

We now interpret the classical gauge symmetries in the covariant BV formalism as symmetries of the corresponding proper QP-manifold. Using the results of the previous section, we then show that the Lie algebra of locally Hamiltonian vector fields on the stationary surface of the master action coincides with the algebra of *on-shell gauge symmetries*. Section III A contains a brief reminder on the BV formalism, so the reader may wish to go directly to Sec. III B.

A. Batalin–Vilkovisky quantization

The geometrical background of the covariant formulation of the BV quantization is an $(N|N)$-dimensional supermanifold $\mathcal{M}$ equipped with a nondegenerate antibracket $(\cdot,\cdot)$ and a volume form $d\mu=\rho d\Gamma$, where $\rho=\rho(\Gamma)$ is a density (and Γ^A, $A=1,...2N$, are some local coordinates). The density should be compatible with the antibracket in such a way that the BV Δ operator

$$\Delta_\rho H=\tfrac{1}{2}\,\mathrm{div}_\rho(\mathbf{V}_H)\tag{III.1}$$

be nilpotent, $\Delta_\rho^2=\frac{1}{2}[\Delta_\rho,\Delta_\rho]=0$. Here, div_ρ denotes the divergence of a vector field with respect to the density ρ and $\mathbf{V}_H=(H,\cdot)$ is the globally Hamiltonian vector field with the Hamiltonian H.

The physics is determined by the quantum master action $W\in\mathbb{C}_{\mathcal{M}}[[\hbar]]$ (a formal power series in $\hbar$ with coefficients in $\mathbb{C}_{\mathcal{M}}$) that satisfies the quantum master equation

$$\Delta_\rho e^{(i/\hbar)W}=0\Leftrightarrow\tfrac{1}{2}(W,W)=i\hbar\Delta_\rho W.\tag{III.2}$$

Writing $W=S+i\hbar W_1+(i\hbar)^2W_2+\cdots$, we rewrite (III.2) as

$$(S,S)=0,\tag{III.3}$$

$$(S,W_1)=\Delta_\rho S,\tag{III.4}$$

and so on. Equation (III.3) is the classical master equation and the function $S=W|_{\hbar=0}$ is called the classical master action.

In addition to the master equation, one should impose boundary conditions on W. This requires fixing a Lagrangian submanifold $\mathcal{L}_0$ in $\mathcal{M}$ (in the canonical coordinates, the manifold of fields, with the antifields set to zero) and a function $\mathcal{S}$ on $\mathcal{L}_0$, which is the *original (''bare'') action* of the classical theory that is being quantized. Then one requires $W(\Gamma,\hbar)$ to be such that $W(\cdot,0)|_{\mathcal{L}_0}=\mathcal{S}$.

By definition, a quantum observable is a function $A\in\mathbb{C}_{\mathcal{M}}[[\hbar]]$ satisfying $\delta_WA=0$, where

$$\delta_WA=(W,A)-i\hbar\Delta_\rho A.\tag{III.5}$$

It follows from (III.2) that $\delta_W^2=0$, and, therefore, any function A of the form $A=\delta_W B$ is an observable; these are called *trivial observables*. Expanding $A=A_0+i\hbar A_1+(i\hbar)^2A_2+\cdots$, we rewrite the equation $\delta_W A=0$ as

$$(S,A_0)=0, \tag{III.6}$$

$$(S,A_1)+(W_1,A_0)=\Delta_\rho A_0, \tag{III.7}$$

and so on. An $\hbar$-independent function A_0 satisfying (III.6) is called a *classical observable*. It is easy to see that if $A=\delta_W B$, then $A_0=(S,B_0)$, where $B_0=B|_{\hbar=0}$. Any classical observable A_0 of the form $A_0=(S,B_0)$ with some $\hbar$-independent function B_0 is called a *trivial classical observable*.

The quantum expectation of an observable is defined via the path-integral over a Lagrangian submanifold $\mathcal{L}$,

$$\langle A\rangle=\int_{\mathcal{L}} d\lambda_\rho\, A e^{(i/\hbar)W}, \tag{III.8}$$

where $d\lambda_\rho$ is the volume form on $\mathcal{L}$ determined by the volume form $d\mu=\rho d\Gamma$ on $\mathcal{M}$ and by the antisymplectic structure as follows:[4,3,8]

$$d\lambda_\rho(e^1,\ldots,e^N)=(d\mu(e^1,\ldots,e^N,f_1,\ldots,f_N))^{1/2}, \tag{III.9}$$

where $e^i\in T\mathcal{L}$ and $f_j\in T\mathcal{M}$ are any vectors that satisfy $\hat{E}(e^i,f_j)=\delta^i_j$ and $\hat{E}$ is the antisymplectic two-form on $\mathcal{M}$. It follows from (III.9) that the volume form $d\lambda_{\rho'}$ corresponding to the density function $\rho'=\rho e^H$ is related to $d\lambda_\rho$ as $d\lambda_{\rho'}=d\lambda_\rho e^{(1/2)H}$ (this is the origin of the exponent in Definition III.1). If the submanifold $\mathcal{L}$ is determined by the equations $G_\alpha=0$, $\alpha=1,...,N$, it is Lagrangian whenever $(G_\alpha,G_\beta)=U^\gamma_{\alpha\beta}G_\gamma$.

An important part of the BV axioms is the nondegeneracy conditions. The submanifold $\mathcal{L}$ in (III.8) must be such that the restriction of $S=W|_{\hbar=0}$ to $\mathcal{L}$ be nondegenerate. In terms of the equations $G_\alpha=0$, the matrix $\partial_A G_\alpha$ and the Hessian matrix $\partial_A\partial_B S$ should have no common null vectors at the points where $\partial_A S=0$ and $G_\alpha=0$.[1–3] Whenever the set $\mathcal{Z}_{(S,\cdot)}$ defined by equations $\partial_A S=0$ is a submanifold, this requirement means that $\mathcal{Z}_{(S,\cdot)}$ intersects $\mathcal{L}$ transversely. It also follows that the rank of the Hessian matrix $H_{AB}=(\partial_A\partial_B S)|_{\partial_A S=0}$ satisfies $\mathrm{rank}(H_{AB})\geqslant N$. At the same time, the classical master equation (III.3) implies that $\mathrm{rank}(H_{AB})\leqslant N$, whence we have[1–3]

$$\mathrm{rank}\left(\frac{\partial^2 S}{\partial\Gamma^A\partial\Gamma^B}\right)\Bigg|_{\partial_A S=0}=N. \tag{III.10}$$

The solution of classical master equation (III.3) that satisfies (III.10) is called a *proper solution*.

The key statement of the BV formalism is that the path integral constructed as in (III.8) is invariant under infinitesimal deformations of the Lagrangian submanifold $\mathcal{L}$[1–4] for every quantum observable A. In the case where $A=1$, this is often called the gauge independence of the partition function.

B. Lie algebras of gauge symmetries

We now study Lie algebras of gauge symmetries in the BV quantization scheme. These are Lie algebras $\mathcal{O}^q$ and $\mathcal{O}^c$ of *quantum and classical gauge symmetries*, respectively. In addition to these two basic algebras, it is useful to consider several more Lie algebras, which we define in what follows and which can be arranged into the following commutative diagram of Lie algebra homomorphisms:

$$\begin{array}{ccccc} \tilde{\mathcal{O}}^q_{\mathrm{triv}} & \longrightarrow & \mathcal{O}^q_{\mathrm{triv}} & \longrightarrow & \mathcal{O}^q \\ \downarrow{\scriptstyle \hbar=0} & & \downarrow{\scriptstyle \hbar=0} & & \downarrow{\scriptstyle \hbar=0} \\ \tilde{\mathcal{O}}^c_{\mathrm{triv}} & \longrightarrow & \mathcal{O}^c_{\mathrm{triv}} & \longrightarrow & \mathcal{O}^c \\ & \searrow & \downarrow & \swarrow & \\ & & \mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}} & & \end{array} \tag{III.11}$$

In addition, we have homomorphisms (III.16), (III.18), and (III.19), whose constructions will also be explained in what follows. Here $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ is the Lie algebra of the *on-shell gauge symmetries* (which, as we show, is the algebra of locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$), $\mathcal{O}^q_{\mathrm{triv}}$ is the Lie algebra *of BRST-trivial quantum gauge symmetries*, and $\tilde{\mathcal{O}}^q_{\mathrm{triv}}$ is the Lie algebra *of quantum gauge parameters*.[10,6] The Lie algebras $\mathcal{O}^c$, $\mathcal{O}^c_{\mathrm{triv}}$, and $\tilde{\mathcal{O}}^c_{\mathrm{triv}}$ are the classical counterparts of $\mathcal{O}^q$, $\mathcal{O}^q_{\mathrm{triv}}$, and $\tilde{\mathcal{O}}^q_{\mathrm{triv}}$, respectively. We now proceed to the exact definitions.

Definition III.1:[10,17] *A vector field* $\mathbf{X}(\hbar)$ *is called a quantum gauge symmetry if it preserves the antibracket and the measure* $\rho e^{(2i/\hbar)W} d\Gamma$ *(viewed as formal power series in* $\hbar$*). The Lie algebra* $\mathcal{O}^q$ *of these vector fields is called the Lie algebra of quantum gauge symmetries.*

It follows from this definition that a quantum gauge symmetry $\mathbf{X}(\hbar)$ satisfies

$$\mathrm{div}_\rho(\mathbf{X}(\hbar)) + \frac{2i}{\hbar}\mathbf{X}(\hbar)W = 0, \tag{III.12}$$

$$\mathbf{X}(F,G) - (\mathbf{X}F,G) - (-1)^{(\epsilon(F)+1)\epsilon(\mathbf{X})}(F,\mathbf{X}G) = 0, \quad F,G \in \mathbb{C}_{\mathcal{M}}. \tag{III.13}$$

Equation (III.13) implies that there exists, at least locally, a function $A(\hbar)$ such that $\mathbf{X}(\hbar) = (A(\hbar),\cdot)$. Then Eq. (III.12) implies that $(W,A(\hbar)) - i\hbar\Delta_\rho A(\hbar) = 0$. Whenever $A(\hbar)$ is globally defined, it is a quantum observable. We explicitly indicate the $\hbar$ dependence of $\mathbf{X}(\hbar)$ because $\rho e^{(2i/\hbar)W}$ should be preserved for any value of $\hbar$; we assume $\mathbf{X}(\hbar)$ to be a formal power series in $\hbar$ with coefficients in the vector fields on $\mathcal{M}$.

Although $\mathbf{X}(\hbar)$ is not a symmetry of any classical system (in particular, it preserves neither the quantum master action nor the measure $d\mu$), we call it a quantum gauge symmetry because its classical counterpart, obtained by taking the $\hbar \to 0$ limit, does preserve the classical master action S. (This action can be considered as the action of some classical system defined on $\mathcal{M}$. Then the classical master equation can be viewed as an additional constraint imposed on the system with the action S. One can naturally identify gauge symmetries of this system with the transformations preserving both S and the master equation imposed on S.)

To make contact with the literature, we consider the Lie algebra $\mathcal{O}^q_{\mathrm{triv}}$ of quantum *BRST-trivial gauge symmetries*.[10] These are quantum gauge symmetries $\mathbf{X}_B(\hbar) = (\delta_W B(\hbar),\cdot)$ whose Hamiltonians are trivial observables [see (III.5)], which span an ideal in $\mathcal{O}^q$.

Now, the (Hamiltonian) mapping $\mathbb{C}_{\mathcal{M}}[[\hbar]] \to \mathcal{O}^q_{\mathrm{triv}}$ allows us to pull back the Lie bracket from $\mathcal{O}^q_{\mathrm{triv}}$ to the space of $\hbar$-dependent functions. Namely,

$$[B^1(\hbar), B^2(\hbar)]^q = (B^1(\hbar), \delta_W B^2(\hbar)), \tag{III.14}$$

which implies

$$[\mathbf{X}_{B^1}(\hbar), \mathbf{X}_{B^2}(\hbar)] = (\delta_W(B^1(\hbar), \delta_W B^2(\hbar)),\cdot) = \mathbf{X}_{[B^1(\hbar), B^2(\hbar)]^q}. \tag{III.15}$$

The bracket (III.14) was shown in Refs. 10 and 6 to determine a Lie algebra structure on the quotient space

$$\tilde{O}^q_{\mathrm{triv}} = \mathbb{C}_{\mathcal{M}}[[\hbar]]/\delta_W \mathbb{C}_{\mathcal{M}}[[\hbar]]$$

of all $\hbar$-dependent functions modulo the δ_W-exact ones. $\mathcal{O}^q_{\text{triv}}$ was called the *Lie algebra of quantum gauge parameters* in Refs. 10 and 6. [This is not an algebra under the *associative* multiplication because the multiplication does not preserve the equivalence classes $B(\hbar)\sim B(\hbar)+\delta_W C(\hbar)$; in particular, (III.14) is not a Poisson bracket.]

There is a nice way to ''measure'' how much $\mathcal{O}^q_{\text{triv}}$ differs from $\tilde{\mathcal{O}}^q_{\text{triv}}$. The (Hamiltonian) mapping $\mathbb{C}_{\mathcal{M}}[[\hbar]]\to\mathcal{O}^q_{\text{triv}}$ induces a homomorphism $\tilde{\mathcal{O}}^q_{\text{triv}}\to\mathcal{O}^q_{\text{triv}}$ [see diagram (III.11)], whose kernel consists of functions (modulo δ_W-exact ones) satisfying $\delta_W B(\hbar)=\text{const}(\hbar)$. However, the fact that a function F satisfies $\delta_W F(\hbar)=\text{const}(\hbar)$ implies $\delta_W F(\hbar)=0$. [In order to see this, consider first a function F_0 satisfying $\mathbf{Q}F_0=(S,F_0)=\text{const}$. Since (as we see in the next subsection) $\mathcal{M}$ is a proper QP-manifold, the function $\mathbf{Q}F_0$ vanishes on the zero locus of $\mathbf{Q}$, and therefore, $\mathbf{Q}F_0=0$. Now, to see that equation $\delta_W F(\hbar)=\text{const}(\hbar)$ leads to $\delta_W F(\hbar)=0$, we rewrite δ_W and $F(\hbar)$ as a power series in $\hbar$: $\delta_W=\delta^0_W+i\hbar\,\delta^1_W+(i\hbar)^2\delta^2_W+\cdots$, where in particular $\delta^0_W=\mathbf{Q}$, and $F=F_0+i\hbar F_1+(i\hbar)^2F_2+\cdots$. Since $\mathcal{M}$ is a proper QP-manifold, the equation $\mathbf{Q}F_0=(S,F_0)=0$ implies that in some neighborhood, we have $F_0=\mathbf{Q}\phi_0+\text{const}$ with some function ϕ_0. Then in the first order in $\hbar$, the equation $\delta^1_W F_0+\delta^0_W F_1=\text{const}$ implies that $\delta^1_W F_0+\delta^0_W F_1=0$ because $\delta^1_W F_0=-\delta^0_W\delta^1_W\phi_0$. A similar argument applies to higher orders in $\hbar$. Thus, the kernel of the homomorphism $\tilde{\mathcal{O}}^q_{\text{triv}}\to\mathcal{O}^q_{\text{triv}}$ coincides with the cohomology of δ_W evaluated on the space of formal power series in $\hbar$ with the coefficients in smooth function on $\mathcal{M}$.] We thus conclude that the homomorphism $\tilde{\mathcal{O}}^q_{\text{triv}}\to\mathcal{O}^q_{\text{triv}}$ is included into the exact sequence that involves the cohomology of δ_W:

$$0\to\mathcal{H}^q\to\tilde{\mathcal{O}}^q_{\text{triv}}\to\mathcal{O}^q_{\text{triv}}\to 0,\quad \mathcal{H}^q=\text{Ker}\,\delta_W/\text{Im}\,\delta_W. \tag{III.16}$$

The classical versions of these constructions are as follows.

Definition III.2: A vector field $\mathbf{X}_0$ *is called a classical gauge symmetry if* $\mathbf{X}_0 S=0$ *and* $\mathbf{X}_0$ *preserves the antibracket. The Lie algebra* $\mathcal{O}^c$ *of these vector fields is called the Lie algebra of classical gauge symmetries*.

The classical *BRST-trivial gauge symmetries* are the vector fields $\mathbf{X}_0=((S,B_0),\cdot)$ whose Hamiltonians are trivial classical observables [see (III.6)]. These vector fields span the ideal $\mathcal{O}^c_{\text{triv}}\subset\mathcal{O}^c$, which is called the *classical BRST-trivial gauge symmetries*.

We have the obvious homomorphism $\mathcal{O}^q\xrightarrow{\hbar\to 0}\mathcal{O}^c$. This induces a homomorphism from the ideal $\mathcal{O}^q_{\text{triv}}\subset\mathcal{O}^q$ into the ideal $\mathcal{O}^c_{\text{triv}}\subset\mathcal{O}^c$ [which are shown in (III.11)].

The classical counterpart of $\tilde{\mathcal{O}}^q_{\text{triv}}$ is the space $\tilde{\mathcal{O}}^c_{\text{triv}}$ of all functions on $\mathcal{M}$ modulo the functions of the form (S,C), where S is the classical master action satisfying $(S,S)=0$. One can see that the space $\tilde{\mathcal{O}}^c_{\text{triv}}$ is endowed with a Lie algebra structure with respect to the ''classical'' bracket

$$[B^1_0,B^2_0]^c=(B^1_0,(S,B^2_0)). \tag{III.17}$$

Thus, we have the Lie algebra homomorphism $\tilde{\mathcal{O}}^c_{\text{triv}}\to\mathcal{O}^c_{\text{triv}}$ shown in (III.11). The kernel of the homomorphism coincides with the cohomology of $\mathbf{Q}$; therefore, we have the following exact sequence involving the cohomology of $\mathbf{Q}$:

$$0\to\mathcal{H}^c\to\tilde{\mathcal{O}}^c_{\text{triv}}\to\mathcal{O}^c_{\text{triv}}\to 0,\quad \mathcal{H}^c=\text{Ker}\,\mathbf{Q}/\text{Im}\,\mathbf{Q}. \tag{III.18}$$

We also observe that the relation between the quantum and the classical bracket is given by $[B^1_0,B^2_0]^c=[B^1(\hbar),B^2(\hbar)]^q|_{\hbar=0}$, where $B^i_0=B^i|_{\hbar=0}$. Therefore, there exists a Lie algebra homomorphism $\tilde{\mathcal{O}}^q_{\text{triv}}\xrightarrow{\hbar\to 0}\tilde{\mathcal{O}}^c_{\text{triv}}$. Following Refs. 10 and 6 we call $\tilde{\mathcal{O}}^c_{\text{triv}}$ the *Lie algebra of classical gauge parameters*. We thus see how it is related to the other algebras in (III.11).

Of the algebras entering (III.11), it only remains to construct $\mathbb{H}_{\mathcal{Z}_\mathbf{Q}}$, which we now do in the BV setting.

C. The Hamiltonian algebra of on-shell gauge symmetries

The BV field–antifield manifold $\mathcal{M}$ and the classical master action S satisfying the BV quantization axioms are such that $\mathcal{M}$ is a proper QP-manifold. Indeed, the odd vector field $\mathbf{Q} = (S,\cdot)$ on the $(N|N)$-dimensional antisymplectic manifold $\mathcal{M}$ preserves the antibracket, and therefore, satisfies condition (II.5); the master equation imposed on S implies that $\mathbf{Q}$ is nilpotent; finally, the fact that S is a proper solution of the master equation implies the rank condition (II.6).

The zero locus $\mathcal{Z}_{\mathbf{Q}}$ of $\mathbf{Q}$ determined by the equations $\partial_A S = 0$ will be referred to as the *stationary surface* of the action S. As before, we assume $\mathcal{Z}_{\mathbf{Q}}$ to be a smooth submanifold. (Although in realistic examples the structure of the zero locus of $\mathbf{Q}$ can be very involved, we treat $\mathcal{Z}_{\mathbf{Q}}$ as a submanifold. Note in passing that the finite-dimensional models of gauge systems should be considered with some caution also in view of the results of Ref. 18). Then, according to Theorem II.4, $\mathcal{Z}_{\mathbf{Q}}$ has a natural symplectic structure. Further, the classical gauge symmetries (see Definition III.2) are in fact symmetries of the proper QP-manifold $\mathcal{M}$.

Theorem III.3: *Every classical gauge symmetry $\mathbf{X}_0$ determines a vector field $\mathbf{x} = \mathbf{X}_{0|_{\mathcal{Z}_{\mathbf{Q}}}}$ on $\mathcal{Z}_{\mathbf{Q}}$ that preserves the Poisson bracket on $\mathcal{Z}_{\mathbf{Q}}$.*

Proof: Indeed, any vector field $\mathbf{X}_0$ preserving the master action S and the antibracket commutes with $\mathbf{Q} = (S,\cdot)$ and is therefore a symmetry of $\mathcal{M}$ (Definition II.5). As we saw in Sec. II B, any vector field $\mathbf{X}_0$ that is a symmetry of $\mathcal{M}$ restricts to $\mathcal{Z}_{\mathbf{Q}}$, and $\mathbf{X}_{0|_{\mathcal{Z}_{\mathbf{Q}}}}$ is locally Hamiltonian on $\mathcal{Z}_{\mathbf{Q}}$. ■

We denote the Lie algebra of locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ by $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$. As we are going to see, this is the algebra of the on-shell gauge symmetries.

Definition III.4: A classical gauge symmetry $\mathbf{X}_0$ is called on-shell trivial if it vanishes on the stationary surface $\mathcal{Z}_{\mathbf{Q}}$.

We now show that the Lie algebra of locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ is isomorphic to the algebra of the on-shell gauge symmetries.

Theorem III.5: *The algebra $\mathcal{I}_0$ of the on-shell trivial symmetries is an ideal in the Lie algebra $\mathcal{O}^c$ of gauge symmetries and the quotient algebra $\mathcal{O}^c/\mathcal{I}_0$ is isomorphic to the Lie algebra $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ of locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$.*

Proof: Let $\mathbf{Y}_0 \in \mathcal{I}_0$ and $\mathbf{X}_0 \in \mathcal{O}^c$. For any function $F \in \mathbb{C}_{\mathcal{M}}$, we have $\mathbf{Y}_0 F \in \mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$. Since $\mathbf{X}_0 \mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}} \subset \mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ and $\mathbf{Y}_0 F \in \mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$, we have $[\mathbf{X}_0,\mathbf{Y}_0]F = \mathbf{X}_0\mathbf{Y}_0 F - (-1)^{\epsilon(\mathbf{X}_0)\epsilon(\mathbf{Y}_0)}\mathbf{Y}_0\mathbf{X}_0 F \in \mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$. Therefore, $\mathcal{I}_0$ is an ideal in the Lie algebra $\mathcal{O}^c$. Further, we have seen in Theorem II.8 that any locally Hamiltonian vector field $\mathbf{x}$ on $\mathcal{Z}_{\mathbf{Q}}$ is a restriction of some vector field $\mathbf{X} \in \mathcal{O}^c$. Thus we can identify the quotient algebra $\mathcal{O}^c/\mathcal{I}_0$ with the Lie algebra of locally Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$. ■

It follows from the theorem that the homomorphism $\mathcal{O}^c \to \mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ is included into the exact sequence

$$0 \to \mathcal{I}_0 \to \mathcal{O}^c \to \mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}} \to 0. \tag{III.19}$$

Note that we cannot replace $\mathcal{O}^c$ with $\mathcal{O}^c_{\mathrm{triv}}$ here, because the homomorphism $\mathcal{O}^c_{\mathrm{triv}} \to \mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ is *not* surjective whenever there exists the first cohomology of $\mathcal{Z}_{\mathbf{Q}}$. Indeed, a nonvanishing first cohomology implies that there exist locally Hamiltonian vector fields that are not globally Hamiltonian on $\mathcal{Z}_{\mathbf{Q}}$, which we have seen in Theorem II.8 to correspond to *BRST-nontrivial* gauge symmetries. Due to the existence of the latter, the mapping $\mathcal{O}^c_{\mathrm{triv}} \to \mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ is not surjective in general.

Looking at diagram (III.11), it is natural to ask the following question: What is the analog of $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ for the upper line of the diagram, i.e. what is the *quantum* analog of the on-shell gauge symmetries? We propose one possible answer to this question.

Note that Poisson bracket (II.8) on $\mathcal{Z}_{\mathbf{Q}}$ and Lie bracket (III.17) on the space of gauge parameters are defined by the same bilinear operation $(\cdot, \mathbf{Q}\ \cdot)$ on $\mathbb{C}_{\mathcal{M}}$. The difference between these two brackets is that (III.17) is defined on the quotient space $\mathbb{C}_{\mathcal{M}}/\mathrm{Im}\,\mathbf{Q}$, while the Poisson bracket is defined on $\mathbb{C}_{\mathcal{M}}/\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$. For a proper QP-manifold, $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}}$ is the ideal generated by $\mathrm{Im}\,\mathbf{Q}$, i.e., $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}} = \mathbb{C}_{\mathcal{M}} \cdot \mathrm{Im}\,\mathbf{Q}$. At the same time, (III.17) is the limit as $\hbar \to 0$ of the quantum construction (III.14) defined on $\mathbb{C}_{\mathcal{M}}[[\hbar]]$. Therefore, in the quantum case one can construct a Poisson bracket as a direct generalization of (II.8), as $\{\cdot,\cdot\}^q = (\cdot, \delta_W \cdot)$. The bracket $\{\cdot,\cdot\}^q$ would be well defined only on the quotient algebra of $\mathbb{C}_{\mathcal{M}}[[\hbar]]$ modulo the ideal $\mathbb{I}_{\delta_W}$ generated by $\mathrm{Im}\,\delta_W$. Obviously, $\mathrm{Im}\,\delta_W$ is generated by all series of the form $\delta_W f(\hbar)$, where $f(\hbar) = f_0 + f_1\hbar + f_2\hbar^2 + \cdots$ with the coefficients f_i taking independently each value 1, Γ^A, and $\Gamma^A\Gamma^B$. Since the matrix $E^{AB} = (\Gamma^A, \Gamma^B)$ is invertible, we thus see that $\mathbb{I}_{\delta_W}$ consists of the series of the form $\mathbb{I}_{\mathcal{Z}_{\mathbf{Q}}} + \mathbb{C}_{\mathcal{M}}\hbar + \mathbb{C}_{\mathcal{M}}\hbar^2 + \cdots$. Thus, the quotient algebra $\mathbb{C}_{\mathcal{M}}[[\hbar]]/\mathbb{I}_{\delta_W}$ coincides with the algebra $\mathbb{C}_{\mathcal{Z}_{\mathbf{Q}}}$ of functions on the zero locus of $\mathbf{Q}$. This means that the algebra $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ is in a certain sense the most general algebra of the on-shell symmetries not only of the classical but also of the quantum, master action.

IV. EXAMPLES

A. Abelianized gauge theory

We now consider the field–antifield space and the master action corresponding to the simplest gauge theory, the Abelianized gauge theory, which we choose as an instructive example that is free of additional complications because gauge symmetries are explicitly separated from the physical ones. We then explicitly construct the Poisson bracket and the Lie algebras $\mathcal{O}^c$ and $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$. Moreover, this example shows that the classical gauge symmetries $\mathcal{O}^c$ contain the Lie algebra of gauge symmetries of the *original* theory as a subalgebra and that, similarly, the on-shell gauge symmetries $\mathbb{H}_{\mathcal{Z}_{\mathbf{Q}}}$ contain the on-shell symmetries of the Abelianized gauge theory.

Let $S_0(X,x)$ be a polynomial action such that

$$\partial_\alpha S_0 = 0, \quad \det(\partial_i \partial_j S_0)\big|_{\partial_i S_0 = 0} \neq 0, \tag{IV.1}$$

where we denote $\partial_\alpha = \partial/\partial x^\alpha$ and $\partial_i = \partial/\partial X^i$ and assume X^i and x^α to be bosonic for simplicity. Due to rank condition (IV.1), the equations $\partial_i S_0 = 0$ admit only a finite set of solutions $\mathfrak{M}$. Thus, the stationary surface of this theory is the direct product of $\mathfrak{M}$ with the space parametrized by x^α. The gauge transformations preserving the action S_0 are of the form

$$\mathbf{Y}_0 = Y_0^\alpha(X,x)\partial_\alpha + \mu^{ij}(X,x)\partial_i S_0 \partial_j, \tag{IV.2}$$

where $\mu^{ij}(X,x)$ is an antisymmetric matrix. These vector fields span a Lie algebra $\mathcal{A}$ with respect to the commutator of vector fields; those vanishing on the stationary surface span the ideal $\mathcal{A}_{\mathrm{triv}}$ in $\mathcal{A}$. Then $\tilde{\mathcal{A}} = \mathcal{A}/\mathcal{A}_{\mathrm{triv}}$ is the algebra of the on-shell gauge symmetries, which can be identified with the Lie algebra of vector fields on the stationary surface.

To implement the BV scheme, we choose the gauge generators in the form $R^\alpha_\beta = \delta^\alpha_\beta$ and introduce the ghosts c^α and the antifields x^*_α, X^*_i, and c^*_α. The canonical antibracket is $(\phi^A, \phi^*_B) = \delta^A_B$, where $\phi^A = (X^i, x^\alpha, c^\alpha)$ and $\phi^*_A = (X^*_i, x^*_\alpha, c^*_\alpha)$. Then the master action

$$S = S_0 + x^*_\alpha c^\alpha \tag{IV.3}$$

is a proper solution of the master equation $(S,S) = 0$. This action gives rise to the vector field

$$\mathbf{Q} = (S,\cdot) = \partial_i S_0 \frac{\vec{\partial}}{\partial X^*_i} + c^\alpha \frac{\vec{\partial}}{\partial x^\alpha} + x^*_\alpha \frac{\vec{\partial}}{\partial c^*_\alpha}, \tag{IV.4}$$

whose stationary surface $\mathcal{Z}_{\mathbf{Q}}$ is determined by $\partial_i S_0 = 0$, $x^*_\alpha = 0$, $c^\alpha = 0$. Thus $\mathcal{Z}_{\mathbf{Q}}$ is the direct product of $\mathfrak{M}$ (the set of solutions to the system of equations $\partial_i S_0 = 0$) with the space parametrized by $Y^A = \{X^*_i, x^\alpha, c^*_\alpha\}$. The Poisson bracket (II.8) on $\mathcal{Z}_{\mathbf{Q}}$ is then represented by the matrix

$$\Omega^{AB}=\{Y^A,\, Y^B\}=\begin{pmatrix} \partial_i\partial_j S_0 & 0 & 0 \\ 0 & 0 & \delta_\alpha^\beta \\ 0 & -\delta_\gamma^\nu & 0 \end{pmatrix}. \tag{IV.5}$$

We now want to show that the Lie algebras $\mathcal{A}$ and $\tilde{\mathcal{A}}$ of the original theory are subalgebras in the Lie algebras $\mathcal{O}^c$ and $\mathbb{H}_{\mathcal{Z}_\mathbf{Q}}$, respectively. To do so, we calculate $\mathcal{O}^c$ in the master theory with the master action (IV.3). Note that for the Abelianized gauge theory, the first cohomology group of the field–antifield space vanishes, and, therefore, each Hamiltonian vector field has a globally defined Hamiltonian. Thus, in order to find $\mathcal{O}^c$, it suffices to find the kernel of $\mathbf{Q}$ evaluated on the space of globally defined functions. Any element $A\in \mathrm{Ker}\,\mathbf{Q}$ can be written in the form $A=\mathbf{Q}F+G$, where F is an arbitrary smooth function on the field–antifield space and G is a representative of the cohomology class of $\mathbf{Q}$. To calculate the cohomology of $\mathbf{Q}$, we write $\mathbf{Q}=\mathbf{Q}_1+\mathbf{Q}_2$, where

$$\mathbf{Q}_1=\partial_i S_0\frac{\vec{\partial}}{\partial X_i^*},\quad \mathbf{Q}_2=c^\alpha\frac{\vec{\partial}}{\partial x^\alpha}+x_\alpha^*\frac{\vec{\partial}}{\partial c_\alpha^*}\quad\text{and}\quad \mathbf{Q}_1^2=\mathbf{Q}_2^2=[\mathbf{Q}_1,\mathbf{Q}_2]=0. \tag{IV.6}$$

(Note that in the case where $S_0=\frac{1}{2}\delta_{ij}X^iX^j$, the vector field $\mathbf{Q}$ is nothing but the De Rham differential of $\mathcal{Z}_\mathbf{Q}$. In this case the cohomology of $\mathbf{Q}$ consists of constants only and $\mathcal{O}^c$ coincides with $\mathcal{O}^c_{\mathrm{triv}}$.)

By the Poincaré lemma, the cohomology of $\mathbf{Q}_2$ consists of constants only. Thus the cohomology of $\mathbf{Q}$ is determined by the cohomology of $\mathbf{Q}_1$ on the space of functions $F(X,X^*)$. A function $F(X,X^*)$ belongs to the image of $\mathbf{Q}_1$ whenever $F(X,X^*)=\partial_i S_0 f^i(X,X^*)$, i.e., $F(X,X^*)$ vanishes at each point where $\partial_i S_0=0$. Thus, any element A from $\mathrm{Ker}\,\mathbf{Q}$ is of the form

$$A(X,X^*)=\mathbf{Q}F(X,X^*)+G(X), \tag{IV.7}$$

where F is an arbitrary function and $G(X)$ is a function that does not vanish at least at one point of $\mathfrak{M}$. Whenever $\mathfrak{M}$ is an n-point set, the cohomology of $\mathbf{Q}$ is an n-dimensional vector space. (In this example, the group of ''physical'' symmetries is the group of permutations of these n points. This group obviously acts on the cohomology of $\mathbf{Q}$.)

We thus see that $\mathcal{O}^c$ and $\mathcal{O}^c_{\mathrm{triv}}$ are spanned by the vector fields of the form $(\mathbf{Q}F+G(X),\cdot)$ and $(\mathbf{Q}F,\cdot)$ respectively. The algebra $\mathbb{H}_{\mathcal{Z}_\mathbf{Q}}$ of the on-shell symmetries consists of Hamiltonian vector fields $\{H(\mathfrak{m},X^*,x,c^*),\cdot\}$ on $\mathcal{Z}_\mathbf{Q}$ (where we label the Hamiltonian by $\mathfrak{m}\in\mathfrak{M}$ enumerating the different components of $\mathfrak{M}$).

To see that the algebra $\mathcal{A}$ of gauge transformations of the original theory is embedded into the Lie algebra $\mathcal{O}^c$ of the classical gauge symmetries, we note that vector fields of the form

$$\mathbf{Y}=(Y_0^\alpha(X,x)x_\alpha^*+\mu^{ij}(X,x)\partial_i S_0 X_j^*,\cdot) \tag{IV.8}$$

form a subalgebra in $\mathcal{O}^c$. Moreover, these fields restrict to the subspace $c^\alpha=c_\alpha^*=x_\alpha^*=X_i^*=0$ as elements of $\mathcal{A}$ [see (IV.2)]. Thus, we have an embedding of $\mathcal{A}$ into $\mathcal{O}^c$ (obviously, the embedding is not unique).

As regards the on-shell gauge symmetries, observe that the vector fields on $\mathcal{Z}_\mathbf{Q}$ of the form

$$\mathbf{y}=\{y^\alpha(\mathfrak{m},x)c_\alpha^*,\cdot\} \tag{IV.9}$$

(which define a subalgebra in $\mathbb{H}_{\mathcal{Z}_\mathbf{Q}}$) restrict to the stationary surface of the original theory (which is a submanifold of $\mathcal{Z}_\mathbf{Q}$ determined by the equations $c_\alpha^*=0$ and $X_i^*=0$) and span $\tilde{\mathcal{A}}$. Thus the algebra of the on-shell gauge symmetries $\tilde{\mathcal{A}}$ of the original theory is embedded into the Lie algebra $\mathbb{H}_{\mathcal{Z}_\mathbf{Q}}$ of the on-shell gauge symmetries.

B. A ''topological'' field theory

We now apply Theorem II.4 to the ''topological'' theory with the vanishing action on a Lie group $\mathcal{G}$. We show that in this case, bracket (II.8) is related to the Kirillov bracket on the coalgebra. Denote by x^i a coordinate system in the neighborhood of $1 \in \mathcal{G}$. Let $\mathcal{R}_\alpha = \mathcal{R}^i_\alpha \partial_i$ (where the Greek indices have the same cardinality as the Latin ones) be the basis of the left invariant vector fields on $\mathcal{G}$. We have $[\mathcal{R}_\alpha, \mathcal{R}_\beta] = \mathcal{F}^\gamma_{\alpha\beta}\mathcal{R}_\gamma$, where $\mathcal{F}^\gamma_{\alpha\beta}$ are the structure constants.

In accordance with the BV prescription we introduce the ghosts c^α and the antifields x^*_i and c^*_α such that $(x^i, x^*_j) = \delta^i_j$ and $(c^\alpha, c^*_\beta) = \delta^\alpha_\beta$. The master action $S = x^*_i R^i_\alpha c^\alpha - \frac{1}{2} c^*_\gamma \mathcal{F}^\gamma_{\alpha\beta} c^\beta c^\alpha$ is a proper solution of $(S,S)=0$. Then

$$\mathbf{Q} = (S,\cdot) = c^\alpha R^i_\alpha \frac{\vec{\partial}}{\partial x^i} + \frac{1}{2}\mathcal{F}^\gamma_{\alpha\beta} c^\beta c^\alpha \frac{\vec{\partial}}{\partial c^\gamma} + (x^*_i R^i_\alpha - c^*_\gamma \mathcal{F}^\gamma_{\alpha\beta} c^\beta)\frac{\vec{\partial}}{\partial c^*_\alpha}, \tag{IV.10}$$

and therefore the zero locus $\mathcal{Z}_{\mathbf{Q}}$ of $\mathbf{Q}$ is determined by the equations $c^\alpha = 0$ and $x^*_i = 0$ and is coordinatized by $Y^A = \{x^i, c^*_\alpha\}$. In this case $\mathcal{Z}_{\mathbf{Q}} = T^*\mathcal{G} = \mathcal{G} \times \mathfrak{g}^*$ is the cotangent bundle to $\mathcal{G}$, where $\mathfrak{g}^*$ is the coalgebra. The matrix of Poisson bracket (II.8) takes the form

$$\Omega^{AB} = \{Y^A, Y^B\} = \begin{pmatrix} \{x^i, x^j\} & \{x^i, c^*_\beta\} \\ \{c^*_\alpha, x^j\} & \{c^*_\alpha, c^*_\beta\} \end{pmatrix} = \begin{pmatrix} 0 & R^i_\beta \\ -R^j_\alpha & -c^*_\gamma \mathcal{F}^\gamma_{\alpha\beta} \end{pmatrix}. \tag{IV.11}$$

It is nondegenerate because R^i_α are nondegenerate everywhere on $\mathcal{Z}_{\mathbf{Q}}$, since R^i_α are the coefficients of the left invariant vector fields on a Lie group. The cotangent bundle to a Lie group is trivial, therefore we have the embedding $\mathfrak{g}^* \to T^*\mathcal{G}$, which induces a Poisson bracket on $\mathfrak{g}^*$. This gives us the Kirillov bracket[15] on the coalgebra $\mathfrak{g}^*$ parametrized by the coordinates c^*.

V. CONCLUSIONS

We have seen that a number of objects of the antisymplectic BV geometry are essentially determined by objects of the symplectic geometry on the stationary surface of the master action, where the nondegenerate Poisson bracket is given by (II.8). In particular, every observable determines a symmetry of the master action, which in turn restricts to a locally Hamiltonian vector field on $\mathcal{Z}_{\mathbf{Q}}$; at the same time, every trivial observable determines a symmetry of the master action such that the corresponding vector field on $\mathcal{Z}_{\mathbf{Q}}$ is globally Hamiltonian. Those Hamiltonian vector fields on $\mathcal{Z}_{\mathbf{Q}}$ that are not globally Hamiltonian correspond then to the BRST-nontrivial observables.

Recalling how the master theory is constructed in terms of the bare classical action $\mathcal{S}$, we were able to explicitly see, in the Abelianized setting, that the gauge symmetries of $\mathcal{S}$ are dressed into master theory symmetries, i.e., into (,)-Hamiltonian vector fields; at the same time, the on-shell gauge symmetries of $\mathcal{S}$ are dressed into { , }-Hamiltonian vector fields on the symplectic manifold $\mathcal{Z}_{\mathbf{Q}}$. This would be interesting to extend to the general gauge theory setting.

Our analysis was performed in the framework of a finite-dimensional model; such models should be viewed with caution precisely for the reasons related to the existence of the BRST cohomology.[18] It would be interesting to see how our results can be reformulated in local field theory, where the gauge symmetries have been discussed in Ref. 19, and, possibly, also in application to string field theory,[5,6] which has been one of the motivations behind the geometrically covariant reformulation of the BV quantization.

ACKNOWLEDGMENTS

We are grateful to I. Batalin and I. Tyutin for many illuminating discussions on various aspects of the field–antifield quantization and the related problems. A.M.S. wishes to thank P. H. Damgaard for helpful discussions and for kind hospitality at the Niels Bohr Institute where a part of this paper was written. We also appreciated discussions with O. Khudaverdyan, A. Nersessian, and B. Voronov.

On path integral localization and the Laplacian

Topi Kärki[a)]
Institut Mittag-Leffler, Auravagen 17, S-18262 Djursholm, Sweden

(Received 10 August 1998; accepted for publication 15 January 1999)

We introduce a new localization principle, which is a generalized canonical transformation. It unifies BRST localization, the non-Abelian localization principle and a special case of the conformal Duistermaat–Heckman integration formula of Paniak, Semenoff, and Szabo. The heat kernel on compact Lie groups is localized in two ways. First, using a non-Abelian generalization of the derivative expansion localization of Palo and Niemi and second, using the BRST localization principle and a configuration space path integral. In addition, we present some new formulas on homogeneous spaces, which might be useful in a possible localization of Selberg's trace formula on locally homogeneous spaces. © *1999 American Institute of Physics.* [S0022-2488(99)01804-6]

I. INTRODUCTION

Integral localization is a method to calculate path integrals. It conventionally involves a BRST symmetry and a one-parameter localization deformation of the action, which in the limit that the localization parameter is put to infinity evaluates the integral.[1–3] The result is usually a sum over the critical points of the action or an integral over a finite-dimensional subspace of the original infinite-dimensional integration domain. The method has been effective in topological field theories.[4]

A special case of it is the Duistermaat–Heckman integration formula[5] and its loop space version,[6] where the BRST symmetry is another way of writing the definition of the Hamiltonian vector field. A more technical introduction to the Hamiltonian BRST symmetry is given in Sec. II.

Recently there has emerged localizations that cannot be understood from the conventional BRST point of view: the non-Abelian localization principle[7] and the conformal Duistermaat–Heckman formula of Paniak, Semenoff, and Szabo.[8] In Secs. III, IV, and V they are unified in a new localization principle.

The two main questions behind this article are ''why is the heat kernel of the Laplacian on compact Lie groups semiclassically exact?''[9,10] and ''why are there Selberg's trace formulae?''[11–14] The new localization principle was also discovered in studying these questions. We review shortly the facts that motivated them. The heat kernel on Lie groups has been proved to be semiclassically exact[9,10] by direct comparison. On the other hand, the loop space Duistermaat–Heckman theorem[6] explains semiclassical exactness, in the case that the Hamiltonian vector field is also a Killing vector field, using a path integral localization proof. It is not, however, the case (in the obvious way) on Lie groups. In addition, there is Selberg's trace formula on constant negative curvature Riemann surfaces,

$$\operatorname{tr} e^{-\beta\Delta_0}=F+(4\pi\beta)^{-1/2}e^{-\beta/4}\sum_{n=1}^{\infty}\sum_{p}\frac{l(p)/2}{\sin l(p^n)/2}e^{-l^2(p^n)/4\beta}, \tag{1}$$

where F is the fixed point contribution.[13] p means a primitive geodesic and $l(p)$ the length of it. The formula is similar to the semiclassical approximation because it holds that $S=\frac{1}{4}\int_0^\beta g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu=l^2(p^n)/4\beta$ at the critical points of the action S. The negative constant curvature Riemann sur-

[a)]Electronic mail: karki@ml.kva.se

faces can be obtained as quotient spaces $\Gamma\backslash[\mathrm{SU}(1,1)/\mathrm{U}(1)]$, where Γ is a discrete subgroup.[12] This, together with the semiclassical exactness on Lie groups and the fact that there are also generalizations of Selberg's trace formula on some symmetric spaces,[14] leads to the speculation of a localization of the Laplacian on locally homogeneous manifolds $\Gamma\backslash(G/H)$.

The answers that we provide to the questions above are organized as follows.

A localization deformation of the Laplacian on homogeneous spaces is given in Sec. VI. The formulas and notations are presented in Appendices A and B because most of them are not needed in the rest of the discussion. They involve some new formulas: the use of a degenerate basis for vector fields is new as well as the Maurer–Cartan connection on the tangent bundle and the phase space metric. In Appendix D the scalar curvature is calculated. In addition, a formula is presented that might appear in the hypothetical localization on locally homogeneous manifolds.

The question about the heat kernel on Lie groups is answered partially in Sec. VII using a non-Abelian derivative expansion localization. The localization principle is even more interesting because it formally seems to apply to homogeneous manifolds as well, and because it may even apply to integrable models (Sec. IX). The final answer to the question is given in Sec. VIII using a configuration space path integral and the symplectic form pointed out by Picken in Ref. 10.

The question about Selberg's trace formulas is left open, despite the negative result, that it is not the deformation in Sec. VI, and the speculations in Sec. IX.

In addition, a new bound for the geodesic action is presented in Appendix C.

II. BRST LOCALIZATION PRINCIPLE

We review the (Hamiltonian) BRST localization principle, introducing some notations.

We assume that Γ is a $2D$-dimensional phase space, ω a symplectic form, and H a Hamiltonian. The classical partition function of the Hamiltonian system is

$$Z=\int_\Gamma \omega^D e^{-\beta H}, \tag{2}$$

and it is calculated using the BRST localization principle. The definition of the Hamiltonian vector field χ can be written as

$$(d+i\chi)(H+\omega)=0, \tag{3}$$

where d is the exterior derivative and i_χ is a contraction operator. The equivariant derivative,

$$d+i_\chi=d_\chi=Q,$$

is a BRST symmetry with the exception that it is closed only in the invariant subspace,

$$Q^2\alpha=L_\chi\alpha=0,$$

where L_χ is the Lie derivative and α is a differential form on the phase space. The BRST localization principle can be formulated as follows: Analogously to the Fradkin–Vilkovisky theorem, the partition function (see the explanation of notations below),

$$Z_\lambda=\int d\phi^\mu\, d\psi^\mu\, e^{-\beta(H+\omega)+\lambda\, d_\chi\psi}, \tag{4}$$

is independent of λ, provided that the arbitrary one-form ψ satisfies the Lie derivative condition

$$L_\chi\psi=0. \tag{5}$$

In (4), ϕ^μ are the coordinates on the phase space Γ and the Grassmann variables ψ^μ are associated with the one-forms $d\phi^\mu$ on the phase space. In particular, the symplectic form has been replaced by a bilinear in the fermionic variables $\omega_{\mu\nu}\, d\phi^\mu\wedge d\phi^\nu\to\omega_{\mu\nu}\psi^\mu\psi^\nu$. When λ vanishes the integral reduces to the partition function (2) modulo an irrelevant factor of $(-\beta)^D$. (We use throughout the paper the convention that such normalization factors are neglected, which is usual with path integrals.) If one makes a clever choice of the one-form ψ and takes the localization parameter λ to infinity, one is able to evaluate the integral.

One can also give a loop space version of the localization principle. The path integral describing the quantum partition function is

$$Z_\lambda(\beta)=\int [d\phi^\mu\, d\psi^\mu]\exp\int_0^\beta \theta_\mu\dot{\phi}^\mu - H+\omega+\lambda\, d_S\psi, \tag{6}$$

where ω is the loop space symplectic form, θ is the symplectic potential, and d_S is the loop space equivariant derivative,

$$d_S=d+i_{\dot{\phi}-\chi}=d+i_{\chi_S}. \tag{7}$$

(We use the convention that the imaginary unit i is missing.) In addition, χ_S is called the loop space Hamiltonian vector field and $\dot{\phi}=\dot{\phi}^\mu(\partial/\partial\phi^\mu)\equiv\int_0^\beta dt\, \dot{\phi}^\mu(t)[\delta/\delta\phi^\mu(t)]$ is a vector field on the loop space. We use the notation that the integral sign is not written and the functional derivatives are written as ordinary derivatives.[6] The loop space one-form ψ must also satisfy the Lie derivative condition,

$$L_{\chi_S}\psi=0.$$

Various applications of the principle can be found in Refs. 6, 15, 16 and 17, which, however, is not an exhaustive list.

III. NEW LOCALIZATION PRINCIPLE

We discuss the new localization principle and give the first example of a localization deformation that is obtained using it.

We define that

$$[S(\lambda),\chi(\lambda),\psi] \tag{8}$$

is a triple of the new localization principle (or triple) if the following occurs.

(1) $S(\lambda)=H(\lambda)+\omega(\lambda)$ is a one-parameter family of Hamiltonian structures, with the exception that the symplectic form can be degenerate except when λ is zero,

(2) $\chi(\lambda)$ is a one-parameter family of vector fields satisfying

$$d_{\chi(\lambda)}S(\lambda)=0. \tag{9}$$

(3) ψ is such a one-form that

$$\frac{dS}{d\lambda}=d_{\chi(\lambda)}\psi. \tag{10}$$

Theorem 1: *If* $[S(\lambda),\chi(\lambda),\psi]$ *is a triple, then the partition function,*

$$Z_\lambda=\int d\phi^\mu\, d\psi^\mu\, e^{S(\lambda)}, \tag{11}$$

is independent of λ.

Proof: If one makes an infinitesimal change of variables in the direction of the supervector field $V=\psi d_{\chi(\lambda)}$, the integrand is invariant, and the Jacobian is $1+\epsilon S\text{div}\, V=1+\epsilon\, d_{\chi(\lambda)}\psi$ which proves that $Z(\lambda+\epsilon)=Z(\lambda)$. □

We make few remarks on the theorem that is the new localization principle.

Remark 1: The definition of the principle is complicated due to the fact that one cannot assume that $\omega(\lambda)$ is nondegenerate for all λ. If one could neglect the complication, taking any point $H+\omega$ in the space of Hamiltonian structures and any one-form ψ on the phase space would give a one-parameter flow of Hamiltonian structures, because then $\chi(\lambda)$ is uniquely determined as

$$\chi(\lambda)=\omega(\lambda)^{-1}\, dH(\lambda). \tag{12}$$

Remark 2: There are some interesting special cases of the localization principle. If the one-form is exact, $\psi=dF$, it reduces to a canonical transformation generated by the function F. On the other hand, if $L_\chi\psi=0$ and $\chi(\lambda)=\chi$, it is the BRST localization principle.

Remark 3: The one-form ψ is in many examples of the principle associated with a phase space metric g that is contracted with some vector field, for example, $\psi=i_{\chi(0)}g$.

Remark 4: The loop space version of the principle is obtained by thinking that the phase space is the infinite-dimensional loop space.

Remark 5: If $\omega(\lambda)=\omega(0)+\lambda\, d\psi$ is nondegenerate for all λ, the localization principle further simplifies. We define another vector field,

$$u(\lambda)=\omega(\lambda)^{-1}\psi, \tag{13}$$

and write the flow equation (10) in the alternative form

$$\frac{dS}{d\lambda}=-L_{u(\lambda)}S, \tag{14}$$

which is a diffeomorphism of the phase space. It is then possible to transport any tensor T along the flow (14) according to the equation

$$\frac{dT}{d\lambda}=-L_{u(\lambda)}T. \tag{15}$$

One should not think that the invertibility of $\psi(\lambda)$ is generic, for example, the Duistermaat–Heckman theorem on a compact phase space[5] gives a counterexample, which can be deduced as follows: On a compact phase space the Hamiltonian function has a maximum and minimum, which cannot change under any diffeomorphism flow. (We thank Losev for this observation.) But in the Duistermaat–Heckman case the maximum of the Hamiltonian function goes to infinity under the localization flow because $H(\lambda)=H(0)+\lambda g(\chi(0),\chi(0))$, where g is a phase space metric. Thus, the flow cannot be a diffeomorphism and therefore $\omega(\lambda)$ must be degenerate for some λ.

Finally, we give the first example of the localization principle. Suppose that the phase space admits a metric g such that

$$\nabla_\chi\chi=0. \tag{16}$$

Then $[\frac{1}{2}g((1+\lambda)\chi,(1+\lambda)\chi)+d(i_{(1+\lambda)\chi}g),(1+\lambda)\chi,i_\chi g]$ is a triple of the new localization principle, provided that the two-form $d(i_\chi g)$ is nondegenerate. For example, the geodesic motion on homogeneous manifolds has this structure; there is actually a one-parameter family of metrics (B13) satisfying the condition (16). As a triple, it is a very special case because λ can be actually any function that satisfies $L_\chi\lambda=0$ and the partition function is still independent of λ. The conditions of a triple can be proved using the identity[5]

$$\nabla_\chi\chi=0\Leftrightarrow d_\chi[\tfrac{1}{2}g(\chi,\chi)+d(i_\chi g)]=0.$$

IV. NON-ABELIAN LOCALIZATION PRINCIPLE

We review the non-Abelian localization principle, making some additions to the original discussion in Ref. 7. In the end of the section it is interpreted using the new localization principle.

The partition function for two-dimensional gauge theories is

$$Z=\int [dA_\mu^B]e^{-(1/e)\int \mathrm{tr}\, F_{\mu\nu}F^{\mu\nu}}. \tag{17}$$

The configuration space $\mathcal{A}$ of gauge potentials that is integrated over has a symplectic form,

$$\omega=\int dx^\mu\wedge dx^\nu\ \delta A_\mu^B\wedge\delta A_\nu^B=\frac{1}{2}\int \sqrt{g}d^2x\sqrt{g}\epsilon^{\mu\nu}\ \delta A_\mu^B\wedge\delta A_\nu^B, \tag{18}$$

a metric,

$$g=\int \sqrt{g}d^2x\, g^{\mu\nu}\ \delta A_\mu^B\otimes\delta A_\nu^B, \tag{19}$$

and an almost complex structure,

$$J=\omega^{-1}g,\quad J^2=-\mathbf{1}. \tag{20}$$

The partition function (17) is actually an integration over the Liouville measure of the symplectic form (18). In addition, the ''Hamiltonian'' in the partition function (17) is the quadratic Casimir of the group of gauge transformations: The gauge transformations act symplectically and the momentum map is μ: $\mathcal{A}\to g^*$ (g is the Lie algebra of gauge transformations),

$$\mu(A)=F=dA+A\wedge A. \tag{21}$$

In other words,

$$\mu_\epsilon=\int F_{\mu\nu}^B\epsilon^B\, dx^\mu\wedge dx^\nu=\int \sqrt{g}d^2x(\sqrt{g}\epsilon^{\mu\nu}F_{\mu\nu}^B)\epsilon^B \tag{22}$$

generates the gauge transformation

$$\{\mu_\epsilon,A_\mu^B\}=D_\mu\epsilon^B. \tag{23}$$

The associated Hamiltonian vector fields are

$$v_\epsilon=\omega^{-1}\, d\mu_\epsilon=\int \sqrt{g}d^2x\, D_\mu^B\epsilon\frac{\delta}{\delta A_\mu^B}, \tag{24}$$

which generate isometries of the metric,

$$L_{v_\epsilon}g=0. \tag{25}$$

Using the Hamiltonian generators of the Lie algebra of gauge transformations,

$$\mu^{Bx}=\mu_{\epsilon=\delta^{BC}\delta(x-y)}=\sqrt{g}\epsilon^{\mu\nu}F_{\mu\nu}^B, \tag{26}$$

one can write the Hamiltonian in (17) as the quadratic Casimir,

$$S=\int \sqrt{g}d^2x\, \mu^{Bx}\mu^{Bx}=\int \sqrt{g}d^2x\, F_{\mu\nu}^BF_B^{\mu\nu}. \tag{27}$$

The discussion above is analogous to the following finite-dimensional situation: We assume that $C=\Sigma_i\mu_i^2$ is the quadratic Casimir of a group that acts symplectically on the phase space and that there is a metric g that is invariant. The partition function is

$$Z=\int \omega^n e^{-\Sigma\mu_i^2}=\int dx^\mu\, dc^\mu\, e^{-\Sigma\mu_i^2+\omega} \tag{28}$$

$$=\int d\phi_i e^{(1/4)\Sigma\phi_i^2}\int dx^\mu\, dc^\mu\, e^{\Sigma\phi_i\mu_i+\omega}, \tag{29}$$

where $\Sigma\phi^i\mu_i+\omega$ is closed by the equivariant derivative

$$d+i_{\phi^i v_i}, \tag{30}$$

and v_i is the Hamiltonian vector field of μ_i. (See Ref. 7 for the correct reinsertion of the imaginary unit.) We choose a one-form ψ on the phase space that is invariant under the action of the group,

$$L_{v_i}\psi=0, \tag{31}$$

for all v_i. One can use the BRST localization principle to prove that

$$Z=\int d\phi_i e^{(1/4)\Sigma\phi_i^2}\int dx^\mu\, dc^\mu\, e^{\Sigma\phi_i\mu_i+\omega+\lambda(d+i_{\phi^i v_i})\psi}, \tag{32}$$

$$=\int dx^\mu\, dc^\mu\, e^{-\Sigma_i(\mu_i+\lambda i_{v_i}\psi)^2+\omega+\lambda\, d\psi}, \tag{33}$$

is independent of λ. The limit $\lambda\to\infty$ yields a localization on

$$i_{v_i}\psi=0. \tag{34}$$

We choose more specifically $\psi=i_\chi g$ $(\chi=\{\Sigma\mu_i^2,\}=2\Sigma\mu_i v_i)$, which is equivalent to the one-form in Ref. 7, and get a localization on the critical points of $\Sigma\mu_i^2$, which is the non-Abelian localization principle.

Equation (33) can be interpreted as a consequence of the new localization principle because $[-\Sigma_i(\mu_i+\lambda i_{v_i}\psi)^2+\omega+\lambda\, d\psi, 2\Sigma(\mu_i+\lambda i_{v_i}\psi)v_i, i_\chi g]$ is a triple. The conditions of a triple can be proved using the identity $(d+i_{v_i})(\mu_i+\omega+\lambda\, d_{v_i}\psi)=0$. We are reminded that, neglecting possible complications due to the degeneracy of $\omega(\lambda)$, one deforms the action $S=-\Sigma_i\mu_i^2+\omega$ using the flow (10), where the one-form is $\psi=i_\chi g$.

V. CONFORMAL DUISTERMAAT–HECKMAN FORMULA

We derive the conformal Duistermaat–Heckman formula using the new localization principle. We have to impose, however, a restriction that is not present in the original approach in Ref. 8.

In the following it is assumed that the phase space admits a metric g such that the Hamiltonian vector field χ is a conformal Killing vector,

$$L_\chi g=\Lambda g. \tag{35}$$

Λ is a function on the phase space. In addition, the following is assumed.

(1) There is a one-parameter family of vector fields $\chi(\lambda)$, such that

$$d_{\chi(\lambda)}[H+\omega+\lambda d_\chi(i_\chi g)]=0. \tag{36}$$

(2) Here

$$g(\chi(\lambda),\chi)=g(\chi,\chi) \text{ at the points } p, \text{ where } \Lambda \text{ vanishes,} \tag{37}$$

which follows if $\chi(\lambda)=\chi$ at the points p or if $\omega(\lambda)=\omega+\lambda d(i_\chi g)$ is nondegenerate for all λ.

Lemma 1: $[H+\omega+\lambda d_\chi(i_\chi g),\chi(\lambda),i_\chi g]$ *is a triple of the new localization principle.*

Proof: We prove only the condition (10) of a triple because the other two conditions are evident. If λ is zero, (10) is trivially true, and we can assume that it is nonzero. A conformal Killing vector satisfies the equation

$$dg(\chi,\chi)=\Lambda i_\chi g-i_\chi d(i_\chi g),$$

and using the condition (36) we get the identity

$$i_{\chi(\lambda)}\omega(\lambda)=-d[H+\lambda g(\chi,\chi)]=i_\chi\omega(\lambda)-\lambda\Lambda i_\chi g.$$

If $\Lambda\neq 0$, we get that

$$i_{\chi(\lambda)}i_\chi g=\frac{1}{\lambda\Lambda}i_{\chi(\lambda)}i_\chi\omega(\lambda)=\frac{1}{\lambda\Lambda}i_\chi\, dH(\lambda)=g(\chi,\chi),$$

which is enough to prove (10). If Λ vanishes then (10) follows directly from the restriction (37).□

Because of the new localization principle, the partition function,

$$Z_\lambda=\int d\phi^\mu\, d\psi^\mu\, e^{S(\lambda)}, \tag{38}$$

is independent of λ, and in the limit $\lambda\to-\infty$ the action produces a delta function $\delta(\chi)$, which localizes the integral to the critical points of the Hamiltonian H. Calculation of the integral gives the Duistermaat–Heckman formula

$$Z=\sum_{dH=0}\frac{\sqrt{\det\omega_{\mu\nu}}}{\sqrt{\det\dfrac{\partial^2 H}{\partial\phi^\mu\partial\phi^\nu}}}e^{-\beta H}. \tag{39}$$

We have used the fact that $\Lambda=0$ at the critical points that follows from the formula[8]

$$\Lambda=\frac{1}{2D}\nabla_\lambda\chi^\lambda=\frac{1}{2D}(\nabla_\lambda\omega^{\lambda\rho})\partial_\rho H.$$

The details of the calculation can be found in Ref. 5.

VI. LOCALIZATION DEFORMATION OF THE LAPLACIAN ON HOMOGENEOUS SPACES

We derive a localization deformation (51) of the Laplacian (40), (43) on homogeneous spaces using the new localization principle. It is demonstrated that the deformation does not give the desired localization to the geodesics. However, it is worth presenting as a nontrivial solvable example of the triple, or more accurately a combination of the two of them. We mention also another flow that might localize, but it seems to be nonsolvable in closed form, and it is not clear if the conditions of a triple are satisfied (we conjecture that they are satisfied). See Appendices A and B for notations.

We consider the partition function

$$Z=\operatorname{tr} e^{-\beta[(1/2)\Delta_0-J^i v_i]}, \tag{40}$$

where β, J^i are constants and Δ_0 is the zero-form part of the Laplacian $\Delta = dd^* + d^*d$ on homogeneous manifolds. $e^{\beta J^i v_i}$ is the translation operator in the direction of the isometry $J^i v_i$. The partition function (40) coincides with the heat kernel that is integrated over the manifold:

$$Z = \int \sqrt{g} dx \langle x | e^{-\beta[(1/2)\Delta_0 - J^i v_i]} | x \rangle = \int \sqrt{g} dx \langle x | e^{-(1/2)\beta\Delta_0} | e^{\beta J^i v_i} x \rangle, \tag{41}$$

$$= \int \sqrt{g} dx\, k_\beta(x, e^{\beta J^i v_i} x). \tag{42}$$

The path integral presentation of (40) is

$$Z = \int [dx^\mu\, dp_\mu\, d\psi^\mu\, d\overline{\psi}_\mu] \exp \int_0^\beta I_i \omega^i(\dot{x}) - \frac{1}{2} K^{ij} I_i I_j + J^i I_i + d(I_i \omega^i), \tag{43}$$

where $\frac{1}{2}K^{ij}I_iI_j = \frac{1}{2}g^{\mu\nu}p_\mu p_\nu$ is the Hamiltonian of the geodesic motion and the Grassmann variables are associated with the one-forms, $\psi^\mu \sim dx^\mu$, $\overline{\psi}_\mu \sim dp_\mu$. In addition, there is DeWitt's term;[18] we assume that it is proportional to the scalar curvature. (There has been some controversy about this term; see Ref. 18 for a recent discussion and the speculation at the end of Sec. VIII.) We have neglected it because homogeneous manifolds are of constant scalar curvature and it yields only a shift in the energy levels.

The straightforward way to derive a localization deformation of the action in Eq. (43) would be to choose the loop space one-form,

$$\psi = i_{\chi_S} g,$$

where g is the phase space metric (B13) (lifted[6] on the loop space) and χ_S is the loop space Hamiltonian vector field,[6]

$$\chi_S = \dot{\phi} - \chi + J^i v_i^H, \quad \chi = \tfrac{1}{2} K^{ij} I_i v_j^H,$$

and apply the flow equation (10), neglecting the degeneracy problem. One can think (hopefully) that the inverse of the symplectic form becomes singular at some points of the phase space but $\chi_S(\lambda) = \omega(\lambda)^{-1} dH(\lambda)$ stays finite, we conjecture that this is the case. However, we have not been able to solve the flow equation. A power series solution experiment seems to give an infinity of different terms, which probably indicates that the flow is not solvable in closed form. However, this flow might localize to the geodesics if one could extract its asymptotic behavior somehow.

The following refined approach gives a localization deformation that is solvable and does not suffer from the degeneracy problem of the symplectic form; the latter is argued afterward for reasons of pedagogy. We use two one-forms [g_1 and g_2 are the two components of the metric (B13)],

$$\psi_i = i_{\chi_S} g_i, \quad i = 1,2,$$

both of which give a flow that is exactly solvable and localizes half of the degrees of freedom. In addition, ψ_2 satisfies

$$L_{\chi_S} \psi_2 = 0, \tag{44}$$

so that the flow in the direction of it is just a BRST flow,

$$S \to S + \alpha\, d_{\chi_S} \psi_2.$$

We combine the flows as follows:

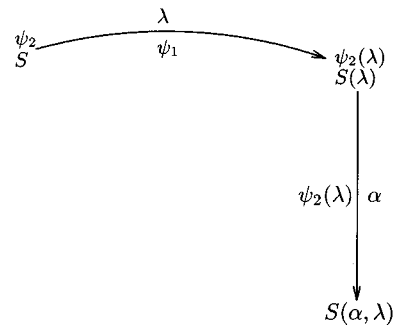

FIG. 1. Localization principle.

First, the action and the one-form ψ_2 are evolved by the flow of the one-form ψ_1, the localization parameter of the flow is λ. Second, the resulting action is evolved by the flow of the transported one-form $\psi_2(\lambda)$ and the localization parameter is α. The principle is described graphically in Fig. 1; by the arrows there is the localization parameter and the one-form that generates the flow. It is important to note that the first flow turns out to be such that $\omega(\lambda)$ is nondegenerate for all λ. It can be seen using the formulas in Appendices A and B. Thus, one can transport the one-form ψ_2 along it according to Eq. (15). In addition, the flow preserves the Lie derivative condition (44) in the form

$$L_{\chi_S(\lambda)}\psi_2(\lambda)=0.$$

Consequently, the flow along the transported one-form $\psi_2(\lambda)$ is again a BRST flow. The conditions of a triple are trivially satisfied because both the flows are familiar special cases: a diffeomorphism and a BRST flow. In the former the vector field $\chi_S(\lambda)$ is obtained from $\chi_S(0)$ by letting the diffeomorphism flow it according to Eq. (15). In the latter $\chi_S(\alpha,\lambda)=\chi_S(\lambda)$.

We get the total two-parameter localization deformation,

$$S(\alpha,\lambda)=S-S_B(\alpha,\lambda)-S_F(\alpha,\lambda), \tag{45}$$

$$S_B=(\lambda+\tfrac{1}{2}\lambda^2)K_{ij}\tilde{\chi}_x^i\tilde{\chi}_x^j+\alpha K^{ij}\,\partial_t^J I_i(\lambda)\partial_t^J I_j(\lambda), \tag{46}$$

$$S_F=\lambda d(K_{ij}\tilde{\chi}_x^i\omega^j)+\alpha K^{ij}d[\partial_t^J I_i(\lambda)dI_j(\lambda)], \tag{47}$$

where

$$\tilde{\chi}_x^i=\omega^i(\dot{x})-K^{ij}I_j+g_j^iJ^j, \tag{48}$$

$$I_i(\lambda)=I_i-\lambda K_{ij}\tilde{\chi}_x^j, \tag{49}$$

$$\partial_t^J=\delta_i^j\partial_t+J^kC_{ki}^j. \tag{50}$$

The partition function,

$$Z(\alpha,\lambda)=\int[dx\,dp\,d\psi\,d\bar{\psi}]e^{S(\alpha,\lambda)}, \tag{51}$$

is independent of the parameters α and λ and coincides with (43) when they vanish. The limit that the localization parameters are put to infinity localizes only half of the degrees of freedom, namely,

$$\tilde{\chi}_x^i=0, \tag{52}$$

leaving an infinite-dimensional integral. The full localization on the equations of motion (the geodesics) would be

$$\partial_t^J I_i = 0, \quad \tilde{\chi}_x^i = 0.$$

The fact that the localization deformation localizes only half of the degrees of freedom can be proved as follows: As λ and α are large there is exponential damping in the path integral due to the bosonic part (46), unless

$$\tilde{\chi}_x^i \sim \frac{1}{\lambda} f^i, \quad \partial_t^J I_i \sim \partial_t^J K_{ij} f^j + \frac{1}{\sqrt{\alpha}} g_i, \tag{53}$$

where f^i and g^i are finite. The fermionic part does not change the situation because the zeta function scaling of the fermionic determinant shows that it can only give a polynomial dependence. We see from the equations (53) that we get localization only on (52). However, it might be that taking first λ to infinity and then α would localize, or although there is no exponential damping, there might be a rational delta function $\delta(x) \sim \alpha/[1+(\alpha x)^2]$. Neither occurs, as can be proved in the case $J=0$ by integrating the fermions and expanding the bosonic action around $\tilde{\chi}_x^i = 0$ using the coordinate system x^μ, $\phi_S^\mu = v_i^\mu \tilde{\chi}_x^i$. One sees that the residual α and λ dependence cannot localize further. In addition, if there would be localization in the case that $J \neq 0$, there would also be localization in the limit that J vanishes.

VII. NON-ABELIAN DERIVATIVE EXPANSION LOCALIZATION

We localize the heat kernel on compact Lie groups using a derivative expansion localization. In the end of the section it is commented how it might be possible to obtain new localization formulas using the principle. Many of the equations in this section are formal; they involve distributions or possess singularities that cancel. We do not address the difficult mathematical problem of how to treat them rigorously.

We begin by studying the shifted heat kernel,

$$\langle x | e^{-\beta[(1/2)K^{ij}v_i v_j - J^i v_i]} | y \rangle, \tag{54}$$

on homogeneous manifolds $M = G/H$. If one puts the points $x,y \in M$ equal and integrates over x one gets the partition function (40).

Theorem 2: *Provided that the series* (57) *converges in the sense of distribution theory,*[19] *the following formal identity holds:*

$$\langle x | e^{-\beta[(1/2)K^{ij}v_i v_j - J^i v_i]} | y \rangle = e^{-(1/2)\beta K^{ij} u_i u_j} \langle x | e^{\varphi^i v_i} | y \rangle |_{\varphi = \beta J}, \tag{55}$$

where

$$u_i = \left(\frac{-\varphi^k C_k}{e^{-\varphi^k C_k} - 1} \right)_i^j \frac{\partial}{\partial \varphi^j}. \tag{56}$$

$[(C_i)_k^j = C_{ik}^j$ are the structure constants; see Appendix A.$]$

Proof: We expand the exponential function on the left-hand side as

$$\langle x | e^{-\beta[(1/2)K^{ij}v_i v_j - J^i v_i]} | y \rangle = \sum_{n=0}^{\infty} \langle x | e^{\varphi^i v_i} \left(-\frac{1}{2} \beta K^{ij} v_i v_j \right)^n | y \rangle \Big/ n!, \tag{57}$$

and by definition the right-hand side is

$$e^{-(1/2)\beta K^{ij}u_iu_j}\langle x|e^{\varphi^i v_i}|y\rangle=\sum_{n=0}^{\infty}\frac{1}{n!}\left(-\frac{1}{2}\beta K^{ij}u_iu_j\right)^n\langle x|e^{\varphi^i v_i}|y\rangle. \tag{58}$$

The terms in the series on the right-hand side are actually distributions: the $n=0$ term is

$$\langle x|e^{\varphi^i v_i}|y\rangle=\delta(x-e^{\varphi^i v_i}y), \tag{59}$$

and higher terms are obtained by differentiating it (it may occur that the terms diverge because of the singularities of u_i but then the series does not converge). Moreover, the terms on both sides are equal in each order (which suffices to prove the theorem because the series converge) because of the formal identity

$$u_i e^{\varphi^k v_k}=e^{\varphi^k v_k}v_i\,, \tag{60}$$

which can be proved as follows: Using Duhamel's formula[20]

$$\frac{\partial}{\partial\varphi^i}e^{\varphi^k v_k}=e^{\varphi^k v_k}\omega(\varphi)_i^j v_j\,, \tag{61}$$

where

$$\omega(\varphi)_i^j\,d\varphi^i=\left(\frac{e^{-\varphi^k C_k}-1}{-\varphi^k C_k}\right)_i^j d\varphi^i \tag{62}$$

can be understood as the left-invariant one-form of the Lie group G in exponential coordinates. It is, however, continued on the whole Lie algebra, including the points where the coordinate system is singular. The equation (60) follows, inverting it, which is possible, except at the singular points of the exponential coordinate system. However, formally the equation (60) holds also at these points, then u_i is singular, but the singularity cancels in the whole expression (60). □

One can turn the derivative expansion in Theorem 2 formally into an integral using the kernel

$$K_\beta(\varphi',\varphi)=\langle\varphi'|e^{-(1/2)\beta K^{ij}u_iu_j}|\varphi\rangle \tag{63}$$

as follows:

$$e^{-(1/2)\beta K^{ij}u_iu_j}\langle x|e^{\varphi^i v_i}|y\rangle=\int\sqrt{g'(\varphi')}d\varphi'\,K_\beta(\varphi,\varphi')\langle x|e^{\varphi'^i v_i}|y\rangle, \tag{64}$$

where g' is the degenerate metric,

$$g'(\varphi)_{kl}=K_{ij}\omega(\varphi)_k^i\omega(\varphi)_l^j\,, \tag{65}$$

on the Lie algebra.

In addition, one can formally calculate the kernel as follows:

$$K_\beta(\varphi',\varphi)=\langle 0|e^{-(1/2)\beta K^{ij}u_iu_j}|\xi(\varphi',\varphi)\rangle=K_\beta(0,\xi),$$

where ξ is defined as

$$e^{-\varphi'^k v_k}e^{\varphi^k v_k}=e^{\xi(\varphi',\varphi)^k v_k}. \tag{66}$$

An explicit expression for ξ can be obtained using the Campbell–Baker–Hausdorff theorem[21] in a neighborhood that φ' and φ are close to zero. The kernel $K_\beta(0,\xi)$ has been calculated in Ref. 9,

$$K_\beta(0,\varphi) = \frac{M}{(2\pi\beta)^{D/2}} \hat{A}(\varphi^i C_i) e^{-(1/2\beta)K_{ij}\varphi^i\varphi^j + (D/48)\beta}, \tag{67}$$

where $\hat{A}(X) = \Pi_{x_k>0}(x_k/2/\sin x_k/2)$ (ix_k are the eigenvalues of the antisymmetric real matrix X) and M is a normalization constant.[9,10]

We localize the Laplacian on Lie groups, assuming that the condition of Theorem 2 holds and one can transform the derivative operator into an integral as in Eq. (64), which is plausible because the singularities cancel. We calculate

$$k_\beta(\mathbf{1},g) = \langle \mathbf{1} | e^{-(1/2)\beta\Delta_0} | g \rangle, \tag{68}$$

$$= \int \sqrt{g'} d\varphi \, K_\beta(0,\varphi) \, \delta(\mathbf{1} - g e^{\varphi^i T_i}) = \sum_{\varphi \in L} K_\beta(\sigma), \tag{69}$$

where $\mathbf{1}$, $g \in G$ and we use the notation of matrix groups. T_i are the generators of the Lie algebra. One should notice that the delta function is normalized with respect to the volume on the Lie group whereas the integral is over φ, however, because one can associate φ as the exponential coordinate we get agreement. The lattice L is

$$L = \{\varphi | g = e^{\varphi^i T_i}\}. \tag{70}$$

[We have used the symmetry $K_\beta(\varphi) = K_\beta(-\varphi)$ to fix the sign convention for the lattice L.] It is in one to one correspondence with the geodesics starting at $\mathbf{1}$ and ending at g because one can associate with $\varphi \in L$ a geodesic $e^{t/\beta \varphi^i T_i}$, $t \in [0,\beta]$. The expression (69) coincides with the semi-classical approximation and it is studied in more detail in the next section.

Finally, we comment on how it might be possible to obtain new localization formulas using Theorem 2. Putting $y = x$ in Theorem 2 and integrating over x gives

$$\operatorname{tr} e^{-\beta[(1/2)K^{ij}v_i v_j - J^i v_i]} = e^{-(1/2)\beta K^{ij} u_i u_j} \operatorname{tr} e^{\varphi^i v_i}\big|_{\varphi = \beta J}. \tag{71}$$

There is, however, a minor subtlety: the condition of Theorem 2 does not necessarily hold. In the Lie group case the terms in the series (57) are not in the space of distributions because the delta functions restrict the vector field u_i to its singular points, hence, the series does not converge in the sense of distributions. The problem can be circumvented by replacing y instead by $e^{\varphi_0^i v_i} x$ and continuing analytically φ_0 to zero (or modifying the formulas by φ_0).

The linear partition function,

$$Z = \operatorname{tr} e^{\varphi^k v_k}, \tag{72}$$

is in the path integral form ($\varphi = \beta J$),

$$Z = \int [dx \, dp \, d\psi \, d\bar{\psi}] \exp \int_0^\beta I_i \omega^i(\dot{x}) + J^i I_i + d(I_i \omega^i). \tag{73}$$

It can be localized using the BRST localization principle because the Hamiltonian vector field of the Hamiltonian $J^i I_i$ generates an isometry of the phase space metric (B13). Consequently, we should get a localization for the partition function (71) that is a derivative expansion of ordinary localization formulas. (This principle appeared first in the Abelian form in Ref. 16. There is also a path integral derivation of it which lacks for the non-Abelian case; see also Ref. 22.) However, one has to be careful because the linear partition function (72) is a distribution, therefore the path integral (73) must diverge (for example, the divergent integral $\int_{-\infty}^{\infty} e^{ipx} \, dx$ can be associated with the delta function).

One can formally add a BRST exact term to the action in the path integral (73) with any of the following gauge fermions or their linear combinations, multiplied by the localization parameter λ:

$$\psi_1 = i_{J^i v_i^H} g, \tag{74}$$

$$\psi_2 = i_{\dot\phi} g, \tag{75}$$

$$\psi_3 = i_{\dot\phi - K^{ij} I_i v_j^H} g, \tag{76}$$

where g is the phase space metric (B13).

For example, the gauge fermion (75) should give a localization formula that is an integral over the phase space[15] of an equivariant characteristic class. (The Dirac genus should possibly be replaced by the Todd class[23] in Ref. 15.) The integral must be divergent, but if one would be able to differentiate the derivative expansion in the full formula (71) one would perhaps get a convergent integral over the phase space and a novel localization formula.

Moreover the gauge fermion $\psi_2 - \psi_1$ should give the loop space Duistermaat–Heckman formula[6] or its degenerate version, but it turns out to be singular because there are no critical points, except at fixed values of β. The localization by the gauge fermion (75) seems to be even more singular; it should localize to the nonexisting critical points of the Hamiltonian.[22] The gauge fermion (76) can possibly give a localization only if one first sums the derivative expansion and then takes the limit, which we have not been able to do.

VIII. CONFIGURATION SPACE LOCALIZATION

We localize the Laplacian on a Lie group using a configuration space path integral.

On the space ΩG of based loops (loops that start and end at the unit element **1** of the Lie group), there is a natural symplectic form that is right invariant,

$$\omega = \tfrac{1}{2} K_{ij} \omega_R^i \wedge \partial_t \omega_R^j, \quad d\omega = 0. \tag{77}$$

(The left- and right-invariant forms have changed places compared to Ref. 24.) The notation is that v_i, v_i^R are the left- and right-invariant vector fields and the dual one-forms are

$$\omega^i = K^{ij} g(v_j), \quad \omega_R^i = K^{ij} g(v_j^R),$$

where g is the bi-invariant metric and the vector fields coincide at **1**, $v_i|_{\mathbf{1}} = v_i^R|_{\mathbf{1}}$.

The configuration space path integral is

$$Z = \int [dx^\mu \, d\psi^\mu]_{\text{vbc}} \exp \int_0^\beta \frac{1}{2} K_{ij} [\omega^i(\dot x) + J^i][\omega^j(\dot x) + J^j] + \frac{1}{2} K_{ij} \omega_R^i \wedge \partial_t \omega_R^j, \tag{78}$$

where vbc means vanishing boundary conditions for both bosons and fermions, $x^\mu(\beta) = x^\mu(0) = 0$, $\psi^\mu(\beta) = \psi^\mu(0) = 0$, and the coordinates x^μ are chosen so that $x^\mu = 0$ corresponds to the unit element **1** of the Lie group.

Integration of the fermionic part of the integral gives a Pfaffian,

$$\sqrt{\det(\omega_{R\mu}^i K_{ij} \, \partial_t \omega_{R\nu}^j)} = \sqrt{\det g_{\mu\nu}} \sqrt{\det(\delta_j^i \partial_t)_{\text{vbc}}}, \tag{79}$$

where we have used the product rule for the determinant and the determinants obey vanishing boundary conditions. The equation (79) can be justified using the change of variables,

$$\psi^\mu = v_i^\mu M_{ij}^{-1} \theta^j, \quad K_{ij} = (M^T M)_{ij}, \tag{80}$$

writing the measure as $[d\theta^j]_{\text{vbc}} = [d\theta^j]_{\text{pbc}} \delta[\theta^j(0)]$ and expanding θ^j in Fourier modes (pbc means periodic boundary conditions). The procedure also evaluates the determinant,

$$\det(\delta^i_j\partial_t)_{\rm vbc}=\det{}'(\beta\partial_t)^D=1,$$

in terms of the standard determinant

$$\det{}'(\partial_t+\mu)_{\rm pbc}=\prod_{n\neq 0}\left(\mu+\frac{2\pi n i}{\beta}\right)=\beta\frac{\sinh\beta\mu/2}{\beta\mu/2}. \tag{81}$$

(We have chosen a regularization that preserves the ''charge conjugation'' symmetry[25,23] $\mu\leftrightarrow-\mu$.)

The result, after the integration of fermions, is

$$\int [\sqrt{g}dx^\mu]_{\rm vbc}\exp\int\frac{1}{2}K_{ij}[\omega^i(\dot x)+J^i][\omega^j(\dot x)+J^j],$$

which, using the change of variables,

$$x^\mu\to e^{-tJ^iv_i}x^\mu, \tag{82}$$

gives the equivalent path integral

$$\int [\sqrt{g}dx]_{\rm bc}\exp\frac{1}{2}\int_0^\beta K_{ij}\omega^i(\dot x)\omega^j(\dot x),$$

with the boundary conditions (bc)

$$x^\mu(\beta)=(e^{\beta J^iv_i}x^\mu)|_{x=0}\sim e^{\beta J^iT_i}=g,\quad x^\mu(0)=0\sim\mathbf{1}.$$

Thus, the configuration space path integral (78) coincides with the heat kernel $k_\beta(\mathbf{1},g)$.

We proceed to localize the integral (78) using the Hamiltonian BRST localization principle. The Hamiltonian vector field for the action,[24]

$$S=\int_0^\beta\frac{1}{2}K_{ij}[\omega^i(\dot x)+J^i][\omega^j(\dot x)+J^j], \tag{83}$$

is

$$\chi_S=\chi+J^iu_i, \tag{84}$$

where

$$\chi=\dot x-\omega^i(\dot x)|_{t=0}v_i^R, \tag{85}$$

$$u_i=v_i-v_i^R, \tag{86}$$

and one can use the Hamiltonian BRST symmetry with the equivariant derivative d_{χ_S}.

We construct the gauge fermion ψ starting with an invariant tensor,

$$g'=\int_0^\beta K_{ij}\,d\omega^i(\dot x)\otimes d\omega^j(\dot x),\quad L_{\chi_S}g'=0, \tag{87}$$

and contracting it with the loop space Hamiltonian vector field,

$$\psi=i_{\chi_S}g'. \tag{88}$$

This is analogous to the localization in Ref. 6. Adding the gauge fermion gives the action

$$S(\lambda)=S+\omega+\lambda d_{\chi_S}(i_{\chi_S}g'), \tag{89}$$

$$=S+\omega+\lambda K_{ij}\,\partial_t^J\omega^i(\dot{x})\partial_t^J\omega^j(\dot{x})+\lambda K_{ij}d[\partial_t^J\omega^i(\dot{x})d\omega^j(\dot{x})], \tag{90}$$

where $\partial_t^J=\delta_j^i\partial_t-J^kC_{kj}^i$.

The path integral,

$$Z=\int [dx^\mu\, d\psi^\mu]_{\rm vbc}e^{S(\lambda)}, \tag{91}$$

coincides with (78) when λ vanishes and localizes in the limit $\lambda\to-\infty$ on $\partial_t^J\omega^i(\dot{x})=0$, which are the classical geodesics $\partial_t\omega^i(\dot{x})=0$ before the change of variables in Eq. (82).

One can write the geodesics starting at **1** and ending at $g=e^{\beta J^iT_i}$ (in matrix group notation) as[9,10]

$$\gamma_\nu(t)=e^{(t/\beta)(\varphi^i+2\pi\nu^i)T_i},\quad \nu^i\in L,$$

where $\varphi^i=\beta J^i$ and

$$L=\{\nu^i|[\nu^iT_i,\varphi^jT_j]=0,\quad e^{2\pi\nu^iT_i}=\mathbf{1}\},$$

and we assume that φ^iT_i is in the generic position that its annihilator is a conjugated Cartan subalgebra. One can also write the lattice L in terms of the roots of the algebra; see Refs. 9 and 10. The solutions of the equation $\partial_t^J\omega^i(\dot{x})=0$ are obtained from these by inverting the change of variables in Eq. (82) [which is translated into matrix group notation as $x^\mu(t)\sim g(t)\to e^{-tJ^iv_i}x^\mu\sim g(t)e^{-tJ^iT_i}$], giving

$$\tilde{\gamma}(t)=e^{(t/\beta)2\pi\nu^iT_i}. \tag{92}$$

Then we calculate the limit $\lambda\to-\infty$ in the path integral (91).

First we make the change of variables,

$$[dx^\mu\, d\psi^\mu]_{\rm vbc}\to[dX^i\, d\eta^i],$$

where $X^i=\omega^i(\dot{x})$ and $\eta^i=dX^i=[\delta\omega^i(\dot{x})/\delta x^\mu]\psi^\mu$. It changes the vanishing boundary conditions into something more complicated. Fortunately it is enough to study what occurs near the critical points because of the localization and the fact that the first variation of the bosonic part in $S(\lambda)$ vanishes. In first order the bosonic coordinates are related by the identity

$$x^\mu=x^\mu_{\rm cr}+\delta x^\mu,\quad \delta\omega^i(\dot{x})=\left.\frac{\delta\omega^i(\dot{x})}{\delta x^\mu}\right|_{x_{\rm cr}}\delta x^\mu=(\tilde{D}_t^{M-C})^i_j(\omega^j_\mu\,\delta x^\mu),$$

where we have the Maurer–Cartan differential operator (A20). The critical points are given in equation (92) so that the Maurer–Cartan operator is

$$\tilde{D}_t^{M-C}=e^{-(t/\beta)2\pi\nu^iC_i}\,\partial_te^{(t/\beta)2\pi\nu^iC_i}.$$

We get that the vanishing boundary condition results in the condition

$$\int_0^\beta e^{(t/\beta)2\pi\nu^iC_i}\,\delta X^i=0, \tag{93}$$

for the coordinate $X^i = X^i_{\rm cr} + \delta X^i$ near the critical point. The fermionic coordinates η^i also obey the same condition (93).

Integrating the fermions and putting the localization parameter to infinity yields

$$Z = \sum_\nu \frac{1}{\mathrm{Pf}(\partial_t^J)} e^{-(1/2\beta)K_{ij}(\varphi^i + 2\pi\nu^i)(\varphi^j + 2\pi\nu_j)},$$

where the Pfaffian obeys the boundary condition (93). It is calculated conjugating the Hilbert space by the operator $e^{-(t/\beta)2\pi\nu^i v_i}$, which turns the boundary condition (93) into $\int_0^\beta \delta X^i = 0$ and the operator ∂_t^J into $\partial_t^{J+2\pi\nu}$. Furthermore, the diagonalization of $(\varphi^i + 2\pi\nu^i)C_i$ gives the eigenvalues μ_j,

$$\mu_j = \begin{cases} 0; & j = 1,...,r, \\ i\langle \varphi + 2\pi\nu, \alpha_j \rangle; & j = r+1,...,D, \end{cases} \tag{94}$$

where r is the rank of the group, α_i are the roots (they are in the annihilator of $\varphi^i T_i$, which is isomorphic to the Cartan subalgebra), and $\langle , \rangle$ is the contraction by the Killing tensor K_{ij}. The Pfaffian reduces into a product of usual determinants (81) and the final result is

$$k_\beta(\mathbf{1}, e^{\varphi^i T_i}) = \frac{M}{(2\pi\beta)^{D/2}} \sum_\nu \prod_{\alpha>0} \frac{\langle \varphi + 2\pi\nu, \alpha \rangle /2}{\sin\langle \varphi + 2\pi\nu, \alpha \rangle /2} e^{-(1/2\beta)\langle \varphi + 2\pi\nu, \varphi + 2\pi\nu \rangle}, \tag{95}$$

which, however, has to be corrected with DeWitt's term, which gives the extra factor exp $[-\beta(D/48)]$. It is consistent with DeWitt's original[26] proportionality constant $\frac{1}{12}$ in front of the scalar curvature $D/4$. The result coincides with the expression (69) and has been calculated using the different methods in Refs. 9 and 10. This is, however, disturbing because the natural value[18] of DeWitt's constant should be $\frac{1}{8}$. We hope that further research solves this puzzle. We speculate that both values may be correct, they just correspond to different path integral measures, and that this trivial looking problem may reveal deep insights in how to make the path integral rigorous and what the quantization is all about.

IX. CONCLUSIONS, SPECULATIONS, AND FUTURE PROSPECTS

We have developed two new localization methods: the new localization principle and the non-Abelian derivative expansion localization. We emphasize that both the principles are universal and probably have many other applications that are not yet known. For example, the non-Abelian derivative expansion localization may apply to integrable models: Many integrable models can be embedded in Poisson–Lie algebras.[27] The integrable hierarchy is the sequence of Casimirs with respect to the r-deformed Poisson bracket. The linear generators generate the coadjoint action and are therefore isometries of the Killing metric on the algebra. However, the algebra in many cases is noncompact and the metric that is pulled back on the phase space may be indefinite. There may also be anomalous problems associated with the quantization and the derivative expansion in Theorem 2 may be singular, so that before concrete examples are worked out we cannot say if the principle eventually works or not.

Another direction of research is to generalize the configuration space localization on Lie groups in Sec. VIII to homogeneous or locally homogeneous manifolds and try to understand Selberg's trace formulas. However, it may be that the existence of Selberg's trace formulas is a separate phenomenon; see the remarks below. Yet another direction of research would be to study if there would be an analog of the configuration space localization for two-dimensional sigma models, for example, the Laplacian on loop groups might be such. In addition, it and the derivative expansion localization in Sec. VII may have supersymmetric versions; the starting point would be the grand canonical partition function that was introduced in Ref. 18.

Finally, we collect few remarks on Selberg's trace formula on constant negative curvature Riemann surfaces, which might be helpful in a possible path integral localization.

Remark 6: Selberg's trace formula is the exact Gutzwiller's trace formula,[28] which suggests that the path integral should perhaps be enlarged by one degree of freedom,

$$Z(\beta)=\mathrm{tr}\, e^{-\beta\Delta_0}\rightarrow\int_0^\infty e^{-\beta E}Z(\beta). \tag{96}$$

Remark 7: The Riemannian surfaces have a natural symplectic form, the volume form $\sqrt{g}\epsilon_{\mu\nu}\,dx^\mu\wedge dx^\nu$, which makes it possible to write the path integral as follows:

$$Z(\beta)=\int [\sqrt{g}dx]\exp\int g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu=\int [dx^\mu\, d\psi^\mu]\exp\int g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu+\sqrt{g}\epsilon_{\mu\nu}\psi^\mu\psi^\nu. \tag{97}$$

Perhaps it should be taken to be the starting point for localization.

Remark 8: We have assumed in *Remark 7* that the path integral takes implicit care of the fact that the Riemann surfaces are not simply connected. It can be made explicit (it may even be that it is necessary) by integrating on the Poincaré upper half-plane and splitting the integral into a sum of path integrals with different boundary conditions. It is possible to transform the boundary conditions into periodic using an analogous change of variables that was used in Sec. VIII in Eq. (82), which allows one to use localization deformations. Furthermore, in order to replace the sum as an integral, one can perhaps make an analogous trick,[29] as in the case of the material particle on U(1):

$$\mathrm{tr}\, e^{\beta\partial_x^2}=\sum_{n=-\infty}^{\infty}\int_0^L dx(0)\int [dx]_{x(\beta)=x(0)+nL}e^{\int\dot{x}^2}=\int [dx]_{\mathrm{pbc}}\exp\int\left[\dot{x}+\left(\frac{x(0)}{L}\right)L\right]^2,$$

where $x(t)\in\mathbf{R}^1$ and $[x]$ is the greatest integer smaller than x. U(1) is associated with $\mathbf{R}^1 \bmod L$.

ACKNOWLEDGMENTS

We thank A. Niemi for pointing out the Ref. 8 and the connection with Selberg's trace formula. We thank him also for the problem of finding a non-Abelian derivative expansion localization in connection with integrable models. We thank O. Tirkkonen for pointing out the possibility of a configuration space localization. We thank K. Palo for giving his beautiful calculations in the degenerate Duistermaat–Heckman localization. In addition, we thank A. Alekseev, Cheeqer, B. S. DeWitt, L. D. Faddeev, J. Kalkkinen, A. Losev, M. Miettinen, T. Nassar, A. Niemi, K. Palo, P. Pasanen, V. Rubtsov, R. J. Szabo, and O. Tirkkonen for discussions.

APPENDIX A: FORMULAS ON HOMOGENEOUS SPACES

We introduce formulas on homogeneous spaces that use a degenerate basis for vector fields. In addition, we define a Maurer–Cartan connection on the tangent bundle.

A homogeneous space is, in this article, the quotient space $M=G/H$ (G and H are Lie groups) with the metric that is inherited from the unique bi-invariant metric on the Lie group G. Technically, one inverts the metric on G and pushes it on M using the canonical projection.[30] We require, in addition, that G is compact, although the formulas are valid also in the noncompact case, with the exception that the metric tensors are not necessarily positive definite.

As the quotient is taken by the right action we get the standard left action of G on M that is generated by the vector fields,

$$v_i,\quad i=1,\ldots,N, \tag{A1}$$

on the D-dimensional manifold M. They are isometries of the metric and satisfy the Lie algebra of G,

$$[v_i,v_j]=C_{ij}^k v_k. \tag{A2}$$

We define the Killing tensor,

$$K_{ij} = -\mathrm{tr}\, C_i C_j = -C_{il}^k C_{jk}^l, \tag{A3}$$

which is positive definite because G is compact. The inverse of K is K^{ij} and it is used to raise indices $i,j,k\cdots \in \{1,...,N\}$ as Greek indices $\alpha,\beta\cdots \in \{1,...,D\}$ are raised and lowered by the metric $g_{\mu\nu}$. For example, the tensor

$$C_{ijk} = K_{im} C_{jk}^m$$

is antisymmetric in all the three indices when the upper index is lowered.

We define the one-forms,

$$\omega^i = K^{ij} g(v_j), \tag{A4}$$

that are dual to the vector fields (A1). If x^μ are coordinates on M one can write the vector fields and their dual one-forms in the coordinate basis as $v_i = v_i^\mu \partial_\mu$ and $\omega^i = \omega_\mu^i dx^\mu$ that satisfy the relation

$$\omega_\mu^i v_i^\nu = \delta_\mu^\nu. \tag{A5}$$

The metric can be written as

$$g = K_{ij} \omega^i \otimes \omega^j, \quad g^{-1} = K^{ij} v_i \otimes v_j. \tag{A6}$$

We define a tensor g_j^i,

$$g_j^i = \omega^i \cdot v_j, \tag{A7}$$

which has the properties

$$g_{ij} = g_{ji}, \quad g_j^i g_k^j = g_k^i, \quad g_j^i \omega^j = \omega^i, \quad g_j^i v_i = v_j. \tag{A8}$$

Using it, we can associate the Lie algebra of the local isotropy group

$$H_p = \{g \in G | gp = p\}, \quad p \in M,$$

with

$$h_p = \{X^i v_i | X^i \in \mathbf{R}, g_j^i(p) X^j = 0\},$$

and the orthogonal complement of it, which is isomorphic to the tangent space at p, with

$$m_p = \{X^i v_i | X^i \in \mathbf{R}, [\delta_j^i - g_j^i(p)] X^j = 0\}.$$

The key observation is that $X^i v_i$ vanishes at p if and only if $g_j^i(p) X^j = 0$. Using the association the standard commutation relations on homogeneous spaces,[30]

$$[h_p, m_p] \subset m_p, \quad [h_p, h_p] \subset h_p,$$

give the identity

$$(\delta_n^m - g_n^m) C_{nk}^i g_j^k = (\delta_n^m - g_n^m) g_k^i C_{mj}^k. \tag{A9}$$

The dual of the algebra (A2) is

$$d\omega^i = -\tfrac{1}{2}(2\delta_m^i - g_m^i) C_{kl}^m \omega^k \wedge \omega^l, \tag{A10}$$

and we obtain the formulas for the connection,

$$\nabla_{v_i} v_j = \Gamma^k_{ij} v_k , \tag{A11}$$

$$\Gamma^k_{ij} = \tfrac{1}{2} K^{kl} (C^n_{ij} g_{ln} - C^n_{li} g_{jn} + C^n_{jl} g_{il}), \tag{A12}$$

and the curvature

$$R(v_i , v_j) v_k = R^l_{kij} v_l , \tag{A13}$$

$$R^l_{kij} = C^m_{ij} \Gamma^l_{mk} + C^m_{ik} \Gamma^l_{jm} - C^m_{jk} \Gamma^l_{im} + \Gamma^m_{jk} \Gamma^l_{mi} - \Gamma^m_{ik} \Gamma^l_{mj} . \tag{A14}$$

The formula for the connection can be checked using the formula[20]

$$2(\nabla_X Y \cdot Z) = X(Y \cdot Z) - Z(X \cdot Y) + Y(Z \cdot X) + [X,Y] \cdot Z - [Y,Z] \cdot X - [Z,X] \cdot Y,$$

where $\cdot$ means contraction with respect to the metric g. The Laplacian on zero-forms is actually the Casimir,

$$\Delta_0 = K^{ij} v_i v_j . \tag{A15}$$

One can also check that these manifolds are of constant scalar curvature by calculating

$$R = R^i_{jkl} g^j_i g^{kl},$$

and checking that

$$L_{v_i} R = 0$$

(Appendix D).

We make few comments on the connection and the curvature. First, we have on TM the usual Levi-Civita connection (A12), which is denoted as

$$D = D_{\mathrm{L-C}} = \delta^\alpha_\beta d + dx^\gamma \Gamma^\alpha_{\gamma\beta} . \tag{A16}$$

Since

$$\Gamma^\gamma_{\alpha\beta} = (\partial_\alpha \omega^j_\beta) v^\gamma_j + \omega^i_\alpha \omega^j_\beta \Gamma^k_{ij} v^\gamma_k = (\partial_\alpha \omega^j_\beta) v^\gamma_j + \tfrac{1}{2} \omega^i_\alpha \omega^j_\beta C^k_{ij} v^\gamma_k ,$$

we can write

$$D^\mu_\nu = v^\mu_i (\delta^i_j d + \tfrac{1}{2} \omega^k C^i_{kj}) \omega^j_\nu , \tag{A17}$$

$$= v^\mu_i \tilde{D}^i_j \omega^j_\nu , \tag{A18}$$

where $\tilde{D}$ is a differential operator. There is also another interesting connection on TM, which we call the Maurer–Cartan connection:

$$(D_{\mathrm{M-C}})^\mu_\nu = v^\mu_i (\tilde{D}_{\mathrm{M-C}})^i_j \omega^j_\nu , \tag{A19}$$

where

$$(\tilde{D}_{\mathrm{M-C}})^i_j = \delta^i_j d + \omega^k C^i_{kj} . \tag{A20}$$

The differential operator associated with it has the property

$$(\tilde{D}_{\mathrm{M-C}})^i_j g^j_k = g^i_j (\tilde{D}_{\mathrm{M-C}})^j_k . \quad \text{(A21)}$$

The fact that it really is a connection is checked by calculating the difference of it and the Levi-Civita connection that yields the tensor,

$$C_{\kappa\mu\nu} = \omega^i_\mu \omega^j_\nu C^k_{ij} K_{kl} \omega^l_\kappa . \quad \text{(A22)}$$

Then one can check easily that the axioms of a connection are satisfied, except the torsion-free axiom.[31] The definition of the tensor (A22) is invariant under rotations that take v_i into their linear combinations but may depend on the particular way that M is quotiented, $M = G/H$. In addition, it is antisymmetric in all the three indices. Consequently, on any two-dimensional homogeneous manifold D and $D_{\mathrm{M-C}}$ coincide.

Then we calculate the curvature of the Maurer–Cartan tensor, but first the Levi-Civita curvature:

$$D^2 = \tfrac{1}{2} R^\alpha_{\beta\gamma\delta}\, dx^\gamma \wedge dx^\delta ,$$

where the curvature tensor is easily expressed in terms of the tensor (A14) as $R^\alpha_{\beta\gamma\delta} = v_i^\alpha R^i_{jkl} \omega^j_\beta \omega^k_\gamma \omega^l_\delta$. One can calculate the Maurer–Cartan curvature,

$$F^\alpha_{\beta\gamma\delta} = v_i^\alpha F^i_{jkl} \omega^j_\beta \omega^k_\gamma \omega^l_\delta ; \quad \text{(A23)}$$

similarly,

$$D^2_{\mathrm{M-C}} = v_i^\mu \tilde{D}_{\mathrm{M-C}}\, g^i_j \tilde{D}_{\mathrm{M-C}} \omega^j_\nu = v_i^\mu \tilde{D}^2_{\mathrm{M-C}} \omega^j_\nu = \tfrac{1}{2} F^i_{jkl} v_i^\mu \omega^j_\nu \omega^k_\kappa \omega^l_\lambda\, dx^\kappa \wedge dx^\lambda ,$$

where

$$F^i_{jkl} = C^i_{jn} (\delta^n_m - g^n_m) C^m_{kl} . \quad \text{(A24)}$$

In the Lie group case $g^n_m = \delta^n_m$ and $F = 0$, which is very natural because on a Lie group,

$$D_{\mathrm{M-C}} = g^{-1}\, dg = d + \Omega ,$$

where $\Omega = g^{-1}\, dg$ is the Maurer–Cartan form (g is now exceptionally a group element $g \in G$, $g = e^{\theta^i T_i}$, where θ are the exponential coordinates on the Lie group and T_i are the generators of the Lie algebra), and the connection is zero-curvature by the Maurer–Cartan equation,[21]

$$D^2_{\mathrm{M-C}} = d\Omega + \Omega \wedge \Omega = g^{-1}\, d^2 g = 0.$$

APPENDIX B: FORMULAS ON THE COTANGENT BUNDLE

We introduce some formulas and a one-parameter family of invariant metrics on the cotangent bundle of homogeneous manifolds.

The phase space of the geodesic motion on a manifold is the cotangent bundle. If x^μ, p_μ are the standard coordinates on it,

$$p_\mu\, dx^\mu|_p \in T^*M, \quad p \in M,$$

the standard symplectic potential is

$$\theta = p_\mu\, dx^\mu ,$$

and the Hamiltonian of the geodesic motion is

$$H = \tfrac{1}{2}\, g^{\mu\nu} p_\mu p_\nu .$$

The G action on M has a Hamiltonian lift;[7] the Hamiltonians that generate it are

$$I_i = v_i^{\mu} p_{\mu}, \tag{B1}$$

and they satisfy the Poisson brackets

$$\{I_i, I_j\} = C_{ij}^k I_k. \tag{B2}$$

The associated Hamiltonian vector fields are

$$v_i^H = \{I_i, \ \} = v_i - \frac{\partial I_i}{\partial x^{\mu}} \frac{\partial}{\partial p_{\mu}}. \tag{B3}$$

The symplectic form[7] can be written as

$$\omega = d\theta = d(I_i \omega^i) = dI_i \wedge \omega^i - \tfrac{1}{2} I_i C_{jk}^i \omega^j \wedge \omega^k, \tag{B4}$$

where ω^i is actually the pull-back of the familiar form on M onto the cotangent bundle by the canonical projection.

The dual vector fields to the forms ω^i, dI_i are

$$u_i = v_i^H - C_{ij}^k I_k w^j, \quad w^i = \omega_{\mu}^i \frac{\partial}{\partial p_{\mu}},$$

and the word ''dual'' means that the identity tensor in the fiber of the tangent bundle can be written as

$$\mathbf{1}_{2D} = u_i \otimes \omega^i + w^i \otimes dI_i = v_i^H \otimes \omega^i + w^i \otimes (dI_i + C_{ij}^k I_k \omega^j). \tag{B5}$$

However, we prefer the vector fields v_i^H, w^i, whose contractions are

$$v_i^H \cdot dI_j = C_{ij}^k I_k, \tag{B6}$$

$$v_i^H \cdot \omega^j = g_i^j, \tag{B7}$$

$$w^i \cdot dI_j = g_j^i, \tag{B8}$$

$$w^i \cdot \omega^j = 0, \tag{B9}$$

and commutators,

$$[w^i, w^j] = 0, \quad [w^i, v_i^H] = C_{jk}^i w^k, \quad [v_i^H, v_j^H] = C_{jk}^i v_i^H.$$

The inverse of the symplectic form can be written using these vector fields as

$$\omega^{-1} = v_i^H \wedge w^i + \tfrac{1}{2} I_i C_{jk}^i w^j \wedge w^k. \tag{B10}$$

Finally, we describe a natural invariant metric on the cotangent bundle. Observing that

$$L_{v_i^H} \omega_j = C_{ij}^k \omega_k, \quad L_{v_i^H} dI_j = C_{ij}^k dI_k,$$

the following tensors are invariant under the action of the group G because of the Casimir structure:

$$g_1 = K_{ij} \omega^i \otimes \omega^j, \tag{B11}$$

$$g_2 = K^{ij}\, dI_i \otimes dI_j\,. \tag{B12}$$

From these two one can combine a metric,

$$g = \alpha g_1 + \beta g_2\,, \tag{B13}$$

provided that α and β are positive.

Proof: The combination is positive semidefinite because K_{ij} is positive definite. One needs to check that it is nondegenerate, which can be done by calculating the determinant of it,

$$\det g = \beta \det g_1^{\mu\nu} \det\,[\alpha g^1_{\mu\nu} + \beta (K^{ij} - g^{ij})\partial_\mu I_i\, \partial_\nu I_j],$$

using the block matrix formula, and proving that it is nonzero, which is not difficult because the last term in the latter determinant is positive semidefinite. □

The invariance property of the metric can be written explicitly as

$$L_{v_i^H} g = 0;$$

see also Ref. 7 for a different metric.

APPENDIX C: BOUND FOR THE GEODESIC ACTION

We derive a bound for the geodesic action,

$$S = \int_0^\beta g_{\mu\nu} \dot{x}^\mu \dot{x}^\nu, \tag{C1}$$

starting from the expression[32]

$$S(t) = \int g_{\mu\nu}(\dot{x}^\mu + t g^{\mu\kappa}\theta_\kappa)(\dot{x}^\nu + t g^{\nu\lambda}\theta_\lambda) \geqslant 0, \tag{C2}$$

where θ is an arbitrary one-form. The inequality holds for all t, especially at the minimum,

$$t = -\frac{\int \theta_\mu \dot{x}^\mu}{\int g^{\mu\nu}\theta_\mu \theta_\nu}, \tag{C3}$$

where it gives the bound

$$\int g_{\mu\nu}\, \dot{x}^\mu\, \dot{x}^\nu \geqslant \frac{(\int \theta_\mu \dot{x}^\mu)^2}{\int g^{\mu\nu}\theta_\mu \theta_\nu}. \tag{C4}$$

For BRST quantization of the winding number action that appears in the bound, see Ref. 33.

APPENDIX D: CALCULATION OF THE SCALAR CURVATURE AND A FORMULA

We calculate the scalar curvature on homogeneous manifolds, but first we calculate

$$g^a_n g^k_b g^i_c g^j_d R^n_{kij} \tag{D1}$$

using the missing identity,

$$\Gamma^k_{ij} g^l_k g^i_a = \Gamma^k_{aj} g^l_k\,; \tag{D2}$$

the torsion,

$$\Gamma^k_{ij}-\Gamma^k_{ji}=g^k_l C^l_{ij}; \tag{D3}$$

and the following property of the connection coefficient:

$$g^i_a g^j_b \Gamma^k_{ij} g^c_k=\tfrac{1}{2} g^i_a g^j_b C^k_{ij} g^c_k. \tag{D4}$$

The point is to use (D2) to eliminate the Γ's using (D4) when one substitutes the expression (A14) in (D1). Another way is just hard work, but it requires perhaps the introduction of Feynman rules for the terms. The result is

$$=g^a_n g^k_b g^i_c g^j_d[-C^m_{ij}C^n_{mk}+\tfrac{1}{2}C^m_{ij}g^p_m C^n_{pk} \tag{D5}$$

$$+\tfrac{1}{4}(C^m_{ik}g^p_m C^n_{pj}-C^m_{jk}g^p_m C^n_{pi})], \tag{D6}$$

which is also useful in calculating the equation (D14). The scalar curvature is

$$R=R^i_{jkl}g^i_j g^{kl}, \tag{D7}$$

$$=K^{ij}C^m_{ik}g^k_l C^l_{jm}-\tfrac{3}{4}K^{ij}C^m_{ik}g^k_l C^l_{jn}g^n_m, \tag{D8}$$

$$=K^{ij}\,\mathrm{tr}(C_i g C_j)-\tfrac{3}{4}K^{ij}\,\mathrm{tr}(C_i g C_j g). \tag{D9}$$

Using the equation

$$L_{v_a}g^k_l=[g,C_a]^k_l=g^k_p C^p_{al}-C^k_{ap}g^p_l, \tag{D10}$$

it is easy to see that $L_{v_a}R=0$. If one puts $g^i_j=\delta^i_j$ one recovers the Lie group formula

$$=\frac{1}{4}K^{ij}\,\mathrm{tr}\,C_i C_j=\frac{D}{4}, \tag{D11}$$

where D is the dimension of the Lie group.

Finally we mention a formula. We define first

$$D_-=D_t-\tfrac{1}{2}\omega^i(\dot{x})C^l_{ik}v^\lambda_l\omega^k_\kappa=v^\lambda_i\,\partial_t\omega^i_\kappa, \tag{D12}$$

$$D_+=D_t+\tfrac{1}{2}\omega^i(\dot{x})C^l_{ik}v^\lambda_l\omega^k_\kappa=D^{\mathrm{M-C}}_t, \tag{D13}$$

where the operators are considered on classical trajectories of the geodesic motion which means that $\omega^i(\dot{x})$ is constant. The formula reads as

$$D_+D_-=D_-D_+=D^2_t+R^\alpha_{\beta\gamma\delta}\,\dot{x}^\beta\dot{x}^\gamma+F^\alpha_{\beta\gamma\delta}\,\dot{x}^\beta\dot{x}^\gamma, \tag{D14}$$

where F is the curvature of the Maurer–Cartan connection. In the Lie group case it reduces to the factorization of the geodesic deviation operator,

$$g^{\mu\kappa}\frac{\delta S}{\delta x^\kappa\,\delta x^\nu}\bigg|_{\delta S=0}=D_+D_-=D_-D_+=D^2_t+R^\alpha_{\beta\gamma\delta}\,\dot{x}^\beta\dot{x}^\gamma,$$

where $S=\tfrac{1}{2}\int g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu$.

(Received 22 September 1998; accepted for publication 23 October 1998)

We consider potential scattering theory of a nonrelativistic quantum mechanical 2-particle system in $\mathbb{R}^2$ with anyon statistics. Sufficient conditions are given which guarantee the existence of Møller operators and the unitarity of the *S*-matrix. As examples the rotationally invariant potential well and the δ-function potential are discussed in detail. In case of a general rotationally invariant potential the angular momentum decomposition leads to a theory of Jost functions. The anyon statistics parameter gives rise to an interpolation for angular momenta analogous to the Regge trajectories for complex angular momenta. Levinson's theorem is adapted to the present context. In particular we find that in case of a zero energy resonance the statistics parameter can be determined from the scattering phase. [S0022-2488(99)01504-2]

I. INTRODUCTION

In recent years the theory of identical quantum mechanical particles with braid group statistics has received increasing attention (for a recent review and references on anyon physics (see, e.g., Refs. 1, 2). The original observation that in two-dimensional configuration space $\mathbb{R}^2$ identical particles may obey statistics different from Bose or Fermi statistics is due to Leinaas and Myrheim.[3] They based the notion of quantum statistics on the topological structure of the classical configuration space for identical particles. The relevant symmetry group is then shown to be the braid group which replaces the permutation group. Models for particles with a one-dimensional representation of the braid group were first discussed by Wilczek, who coined the name anyons for particles with these new statistics[4] (see also Refs. 5–7). Wilczek suggested the following physical picture of anyons: Magnetic flux tubes (vortices) are attached to either charged bosons or fermions. The latter then give rise to arbitrary Aharonov–Bohm phases when transported along paths exchanging the particle positions. The magnetic flux tubes are described by long range gauge potentials whose curvature vanishes and can be related to Chern–Simons theory.[4,8] This point of view was taken up by several authors (e.g., Refs. 9, 10) leading to a second quantized version of anyons obtained by coupling a Chern–Simons U(1)-gauge potential to a matter field.[11]

Also, the general case, where the finite-dimensional representation of the braid group is not one-dimensional, has been considered. The corresponding particles are called ''plektons.''[12,13] The relevance of braid group statistics in conformal quantum field theory was realized by Tsuchiya and Kanie[14] and in algebraic quantum field theory by Fröhlich[15] and Fredenhagen, Rehren and Schroer.[12,13]

However, in the discussion of particles with braid group statistics the main focus is on anyons (Abelian statistics), since in many particle theory they might provide an explanation for the fractional quantum Hall effect and for high T_c superconductivity (for a review see, e.g., Refs. 16, 17 and 18, 19).

In this article we want to discuss nonrelativistic two-particle potential scattering theory for anyons. This is done in the framework of ordinary quantum mechanics, i.e., we insert a gauge potential of the Aharonov–Bohm type in the center of mass Hamiltonian. Emphasis is then put on showing how well known techniques of scattering theory extend to the case of anyon statistics. The motivation is twofold. On the one hand scattering theory is a powerful tool in spectral analysis and thus might be helpful for a better understanding of fractional statistics. On the other hand, scattering data can be used to compute the virial coefficients of an *interacting* anyon gas.[20] Hence, it is possible to infer bulk properties from scattering theory. The latter are of main interest in the investigation of the above mentioned phenomena.

The first calculation of the second virial coefficient for the two-particle anyon system was done by Arovas *et al.*[9] They considered the case when only the statistics is present corresponding to the case of Aharonov–Bohm scattering.[21,22] See Ref. 23 and references therein for recent articles on the second virial coefficient of interacting anyon systems. In a forthcoming publication we intend to apply the results of this article to the calculation of the second virial coefficient.

The case of non-Abelian vortex–vortex scattering has been investigated in Refs. 24–26. By looking at the irreducible components (which are then one-dimensional Abelian) our discussion then also applies.

The article is organized as follows. In Sec. II we review the quantum mechanics of two ''free'' anyons in order to introduce our notation and to keep the paper self-contained. In particular, we give the energy eigenfunctions, the resolvent (Green's function) and the propagator. We also recapitulate the relation of the free anyon system and Aharonov–Bohm scattering which will be used in our discussion of the differential cross-section in Sec. IV. In Appendix A we recall the equivalent differential geometric formulation in terms of vector bundles, which in the case of anyons are line bundles. In particular, we recall that there exists a canonical Hermitian connection encoding the statistics such that the ''free'' Hamiltonian is the canonically associated Bochner Laplacian.

In Sec. III we consider scattering theory for the interacting anyon system obtained by adding a potential to the center of mass Hamiltonian. We give sufficient conditions for the existence of the Møller operators, which also cover the nonspherical symmetric case. Applying the Kuroda–Birman theorem[27] we derive the unitarity of the resulting S-matrix.

In Sec. IV we discuss the differential cross-section with the modifications necessary to accommodate anyon statistics. We show that the scattering amplitude splits into two parts: one describing the effects of the statistics the other the interaction represented by the potential.

In Sec. V, Jost functions are introduced which depend on the statistics parameter for anyons. The latter enters in the form of continuous angular momentum. This establishes a connection with Regge trajectories in the theory of complex angular momenta. We conclude Sec. V by showing how Levinson's theorem, which relates the scattering phase shift to the number of bound states, carries over to the present situation. In case the Jost function vanishes at zero energy, we derive an explicit formula giving the statistics parameter in terms of the scattering phase shift.

Sections VI and VII are devoted to explicitly solvable examples. In Sec. VI we examine the δ-potential. This case also figures under the name of anyons without a hard-core condition. The corresponding resolvent is calculated in closed form in Appendix D and the bound state problem is then considered. We also remark on the modification of Levinson's theorem and find an additional formula relating the statistics parameter to the scattering phase. In Sec. VII we discuss the square well potential. The Jost function is calculated and Regge trajectories are plotted which show the dependence of the point spectrum on angular momentum and the statistics parameter. In Secs. VI and VII we provide numerical examples for the differential cross-section which display the interpolation between Bose and Fermi statistics when the statistics parameter for anyons is varied.

The results presented here are based in part on the diploma thesis of two of the authors (Korff[28] and Lang[29]).

Throughout the article we will work in atomic units, $\hbar = e = m = 1$, where m denotes the mass of the particles. In particular, this sets the reduced mass of a two-particle system equal to 1/2. In estimates we make the convention that C, $C(\epsilon)$, etc. denote generic constants depending on ϵ, etc.

II. QUANTUM MECHANICS OF TWO ANYONS

The theory of identical particles with statistics differing from Bose or Fermi statistics may show up when the configuration (or momentum) space of one particle is the two-dimensional Euclidean space. Henceforth we will often use the complex plane $\mathbb{C}$ to describe such a space. For the configuration space $\mathbb{C}\times\mathbb{C}$ of two nonidentical particles with points labeled by (z_1,z_2), the relative coordinate $z=z_1-z_2$ changes into $-z$ if the coordinates z_1 and z_2 of the two particles are interchanged. The basic observation of Leinaas and Myrheim was, that by leaving out the case where the two particles are at the same point, i.e., where $z=0$, the configuration space in the center of mass frame of two identical particles should be the space obtained from $\mathbb{C}^\star=\mathbb{C}\setminus\{0\}$ by identifying the points z and $-z$. This space is therefore the orbit space $\mathbb{C}^\star/\mathbb{Z}_2$, where $\mathbb{Z}_2=\{+1,-1\}$ acts in the obvious way as a transformation group on $\mathbb{C}^\star$. This space is also obtained from the closed upper half-plane $\mathbb{H}$ in $\mathbb{C}$ minus the origin, i.e., the set $\mathbb{H}\setminus\{0\}$, by identifying the points x and $-x$ on the real axis. Geometrically this leads to a cone with removed apex as configuration space. The obvious choice of polar coordinates $(r,\theta)\in\mathbb{R}^+\times[0,\pi)$ on $\mathbb{H}$ carries over to the cone $\mathbb{C}^\star/\mathbb{Z}_2$. We take the state vectors of the system to be the square integrable functions on the cone $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)$ or equivalently the π-periodic functions on the punctured plane $\mathbb{C}^\star$. The fact that the cone's apex or, respectively, the plane's origin is removed, allows for the particles to carry flux-tubes. This corresponds to the physical picture introduced by Wilczek (see, e.g., Refs. 4, 18), who named such particles *anyons*. The flux-tubes are taken into account by inserting a gauge potential of the Aharonov–Bohm type,

$$A_\alpha=\frac{\alpha}{r}e_\theta, \quad \alpha\in[0,1], \tag{II.1}$$

into the center of mass Hamiltonian. Here α is the so called statistics parameter and e_θ denotes the unit vector corresponding to the polar angle. Choosing units in such a way that $\hbar=1$ and setting the mass of the particles to one, the resulting Hamiltonian has the form

$$H_0(\alpha)=-(\nabla+iA_\alpha)^2=-\frac{\partial^2}{\partial r^2}-\frac{1}{r}\frac{\partial}{\partial r}-\frac{1}{r^2}\left(\frac{\partial}{\partial\theta}+i\alpha\right)^2,$$

in polar coordinates. This operator will be considered to be the free Hamiltonian in the center of mass frame for a two-particle anyon system with statistics parameter $\alpha\in[0,1]$. If $\alpha=0$ the particles actually behave like bosons, while for $\alpha=1$ they behave like fermions. In Appendix A we give a short review of a mathematically precise formulation of this model in terms of vector bundles, following Refs. 30, 31 (see also Refs. 32, 33). There we also argue why $\alpha=0,1$ corresponds to bosons and fermions, respectively, and why we may restrict the parameter α to the interval [0, 1].

We now determine the spectrum and the eigenfunctions of $H_0(\alpha)$. We start with the decomposition

$$\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)\cong\mathcal{L}^2(\mathbb{R}^+,r\,dr)\otimes\mathcal{L}^2(S^1,d\theta),$$

where the points in S^1, the unit circle in $\mathbb{C}$, are parameterized as $\exp(2i\theta)$ with $0\leq\theta<\pi$. This leads to the decomposition

$$\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)\cong \bigoplus_{m\in\mathbb{Z}} \mathfrak{h}_{2m}, \quad \mathfrak{h}_{2m}=\mathcal{L}^2(\mathbb{R}^+,r\,dr)\otimes\left\{\frac{e^{2im\theta}}{\sqrt{\pi}}\right\}. \tag{II.2}$$

This decomposition is of course related to the following fact. The rotation group SO/(2)≅U(1) maps $\mathbb{C}^\star$ into itself and commutes with the action of $\mathbb{Z}_2$, thus acts on $\mathbb{C}^\star/\mathbb{Z}_2$ and defines a unitary action on $L^2(\mathbb{C}^\star/\mathbb{Z}_2)$. Also $H_0(\alpha)$ commutes with this action of U(1); it is diagonal w.r.t. the decomposition, i.e.,

$$H_0(\alpha)=\bigoplus_{m\in\mathbb{Z}} H_{0,2m}(\alpha),$$

with

$$H_{0,2m}(\alpha)=-\left\{\frac{d^2}{dr^2}+\frac{1}{r}\frac{d}{dr}-\frac{(2m+\alpha)^2}{r^2}\right\},$$

on $\mathcal{L}^2(\mathbb{R}^+,r\,dr)\cong\mathfrak{h}_{2m}$. To find all solutions of the stationary Schrödinger equation for $H_0(\alpha)$ it therefore suffices to find the solutions of the Bessel equation for each $m\in\mathbb{Z}$,

$$\left\{\frac{d^2}{dr}+\frac{1}{r}\frac{d}{dr}-\frac{(2m+\alpha)^2}{r^2}+E\right\}R(r)=0. \tag{II.3}$$

For definiteness we choose those solutions of Eqs. (II.3) which are regular near $r=0$.

This gives the following improper eigenfunctions:

$$\phi_{\alpha;m,E}(r,\theta)=\frac{e^{2im\theta}}{\sqrt{2\pi}}\cdot J_{|2m+\alpha|}(\sqrt{E}r).$$

In what follows we will use the notations

$$k:=\sqrt{E}, \quad \mu:=|2m+\alpha|.$$

The identity

$$\int_0^\infty J_\mu(at)J_\mu(bt)t\,dt=\frac{1}{\sqrt{ab}}\delta(a-b), \quad \text{for } a,b>0,$$

gives the following orthogonality and completeness relations:

$$\langle\phi_{\alpha;m,E}|\phi_{\alpha;m',E'}\rangle=\delta_{m,m'}\delta(E-E'), \tag{II.4}$$

$$\sum_{m=-\infty}^{+\infty}\int_0^\infty dE\,\phi_{\alpha;m,E}(r,\theta)\overline{\phi_{\alpha;m,E}(r',E')}=\frac{1}{r}\delta(r-r')\delta(\theta-\theta'). \tag{II.5}$$

We will also need the integral kernel for the resolvent $R_{0,\alpha}(z):=(H_0(\alpha)-z)^{-1}$, also called the Green's function, given by

$$\langle r,\theta|R_{0,\alpha}(k\pm i\epsilon)|r',\theta'\rangle=\pm\frac{i}{2}\sum_{m=-\infty}^{+\infty}e^{2im(\theta-\theta')}J_\mu(kr_<)H_\mu^\pm(kr_>). \tag{II.6}$$

Here we have used the standard convention $r_>:=\max(r,r')$ and $r_<:=\min(r,r')$. To abbreviate the notation we will sometimes make the convention that $H_\mu^\pm$ denotes the first and second Hankel function $H_\mu^{(1)}$ and $H_\mu^{(2)}$, respectively. I_μ is the modified Bessel function and K_μ is the MacDonald function (see, e.g., Ref. 34). To establish (II.6) one uses the well-known formula (see, e.g., Ref. 35).

$$\int_0^\infty kdk\,\frac{J_\mu(kr)J_\mu(kr')}{k^2+c^2}=I_\mu(cr_<)K_\mu(cr_>)[\mathrm{Re}\,\mu>-1,\mathrm{Re}\,c>0].$$

Finally we give the kernel of the unitary time evolution $\exp(-itH_0(\alpha))$:

$$\mathfrak{k}_\alpha(r,\theta;r',\theta';t):=\langle r,\theta|e^{-itH_0(\alpha)}|r',\theta'\rangle. \tag{II.7}$$

We can make this explicit by adapting a calculation, which is quite standard in the context of the Aharonov–Bohm effect.[21] Along the lines of Refs. 36, 37 we obtain the following result:

$$\mathfrak{k}_\alpha(r,\theta;r',\theta';t)=\mathfrak{k}_{\alpha,0}(r,\theta;r',\theta';t)+\hat{\mathfrak{k}}_\alpha(r,\theta;r',\theta';t). \tag{II.8}$$

Here the two subexpressions $\mathfrak{k}_{\alpha,0}$ and $\hat{\mathfrak{k}}_\alpha$ are given as

$$\mathfrak{k}_{\alpha,0}(r,\theta;r',\theta';t)=\frac{1}{2\pi it}e^{-(1/4it)(r^2+r'^2)}e^{i\alpha(\theta-\theta'-(\pi/2)\mathrm{sgn}(\theta-\theta'))}\times\cos\left(-\frac{\alpha\pi}{2}\mathrm{sgn}(\theta-\theta')+\frac{rr'}{2t}\cos(\theta-\theta')\right), \tag{II.9}$$

$$\hat{\mathfrak{k}}_\alpha(r,\theta;r',\theta';t)=\frac{i}{2\pi t}\cdot\frac{\sin(\pi\alpha)}{\pi}e^{-(1/4it)(r^2+r'^2)}I_\alpha(rr'/2t,\theta-\theta'), \tag{II.10}$$

where we have introduced

$$I_\alpha(\rho,\chi)=\int_{-\infty}^{+\infty}dy\,e^{i\rho\cosh y}\frac{e^{-y\alpha}}{1-e^{-2y-2i\chi}}. \tag{II.11}$$

The formal relation to the Aharonov–Bohm effect used in the derivation of (II.9) and (II.10) does not come by accident. In fact, the Hamiltonian of the two-anyon system coincides with the Hamiltonian of the Aharonov–Bohm effect when restricted to the subspace of symmetric wave functions. As has been realized before (see, e.g., Ref. 18) one can exploit this by describing the anyonic dynamics with the help of Aharonov–Bohm scattering and thus demonstrate the nontrivial character of the statistical interaction. The description of the Aharonov–Bohm effect in terms of scattering theory was first given by Aharonov and Bohm themselves and later taken up by several authors, among others, Refs. 22, 38, 39. We will mostly follow the discussion presented in Ref. 22 because there the time-dependent as well as the time-independent scattering formalism are considered. The wave operators and the scattering operator of the Aharonov–Bohm effect are formally defined by

$$\Omega_{AB}^{\pm}:=\underset{t\to\pm\infty}{\text{s-lim}}\,e^{itH_0(\alpha)}e^{-itH_0}\quad\text{and}\quad S_{AB}:=(\Omega_{AB}^{+})^*\Omega_{AB}^{-}, \tag{II.12}$$

respectively. Here and henceforth H_0 denotes the bosonic Hamiltonian $H_0(\alpha=0)$ and the symbol s-lim stands for the strong operator limit. Furthermore, by writing (II.12) we have implied the restriction of the Aharonov–Bohm scattering to the subspace of symmetric functions or equivalently to the space $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)$. It has been shown[22] that the wave operators exist and are complete, whence the scattering operator is unitary. For later use we give the explicit form of the integral kernels of $\Omega_{AB}^{\pm}$, i.e., the stationary scattering states, which can be obtained by symmetrizing the results given in Refs. 22, 39,

$$\langle r,\theta|\Omega^{\pm}_{AB}|k,\theta'\rangle=\frac{1}{\pi}\sum_{m\in\mathbb{Z}}(\pm i)^{|2m+\alpha|}J_{|2m+\alpha|}(kr)e^{i2m(\theta-\theta')},\tag{II.13}$$

where $|k,\theta'\rangle$ denotes the symmetric plane wave, i.e.,

$$\langle r,\theta|k,\theta'\rangle=\frac{1}{\pi}\cos(kr\cos(\theta-\theta')).$$

The scattering phase shift corresponding to S_{AB} was first derived by Henneberger.[38] Using his result we can rewrite the scattering operator in the compact form

$$S_{AB}=e^{i\pi\alpha}P_{\geqslant}+e^{-i\pi\alpha}P_{<},\tag{II.14}$$

with $P_{\geqslant}$ and $P_{<}$ denoting the spectral projections onto the subspaces of positive, respectively, negative angular momentum. Equation (II.14) serves physical intuition by clarifying the effect of the gauge potential A_α defined in (II.1).

However, of practical importance is the integral kernel of the *S*-matrix in momentum space which was first given in Ref. 22. After symmetrization we obtain for $\alpha\in[0,1]$,

$$\langle k,\theta|S_{AB}|k',\theta'\rangle=4\,\delta(k^2-k'^2)\left[\cos\pi\alpha\,\delta(\Theta)+\frac{\sin\pi\alpha}{2\pi i}PV(1+i\cot\Theta)\right].\tag{II.15}$$

Here, $\Theta=\theta-\theta'$ and *PV* stands for the principal value prescription. From (II.15) one immediately derives the scattering amplitude,

$$f_{AB}(k,\Theta)=\left(\frac{\pi}{ik}\right)^{1/2}\langle\theta|T_{AB}(E=k^2)|\theta'\rangle=\left(\frac{\pi}{ik}\right)^{1/2}2\left[(\cos\pi\alpha-1)\,\delta(\Theta)+\frac{\sin\pi\alpha}{2\pi i}PV(1+i\cot\Theta)\right],\tag{II.16}$$

where $\langle\theta|T_{AB}(E)|\theta'\rangle$ denotes the on-shell matrix element of $T_{AB}:=S_{AB}-\mathbf{1}$ defined by the equation

$$\langle k,\theta|T_{AB}|k',\theta'\rangle=2\,\delta(E-E')\langle\theta|T_{AB}(E)|\theta'\rangle,$$

with $E=k^2$ and $E'=k'^2$. Note that Eq. (II.16) differs from what one would get when symmetrizing the amplitude in the way calculated by Aharonov and Bohm.[21] In their result the contribution of the δ-function was left out. This violates the unitarity of the *S*-matrix, as was pointed out by Ruijsenaars.[22] Thus, away from the forward direction we end up with the following expression for the differential cross-section:

$$\frac{d\sigma_{AB}}{d\theta}=|f_{AB}(k,\theta)|^2=\frac{\sin^2\pi\alpha}{\pi k}(1+\cot^2\theta),\quad\theta\neq 0,\tag{II.17}$$

which has a nontrivial angular dependence. Note that the total cross-section is infinite if $\alpha\notin\mathbb{Z}$ because of the singular contribution in the forward direction, as displayed in (II.16). The latter has been interpreted to be characteristic of anyon statistics reflecting the long range nature of the statistical interaction (Ref. 18, p. 23). For $\alpha=0,1$, i.e., for bosons and fermions, the cross-section vanishes. This is obvious from Eq. (II.14) which shows that bosons are not scattered at all while fermions pick up a factor minus one.

III. POTENTIAL SCATTERING

In this section we discuss two-particle potential scattering for anyons. Time-dependent scattering theory involves the comparison between two dynamics, one of which is considered to be ''free'' in an appropriate sense. Here, we shall consider the ''free'' dynamics to be the one defined by $H_0(\alpha)$. This appears to be a natural choice, if one views statistics to be an inherent property of the particles. It is a generalization of the fermionic picture, where usually the free time evolution acts on the space of antisymmetric functions. Note, however, that this ''free'' dynamics contains an interaction given by the long range gauge forces encoding the statistics. In particular, noninteger values of α lead to a highly nontrivial ''free'' time evolution similar to the Aharonov–Bohm effect (see our discussion at the end of Sec. II). As a consequence not all methods used in potential scattering theory may be applied. For example, we do not know how to adopt Enss'[40] method, which makes use of the Fourier transformation and is therefore not suitable in the present context. Thus, in order to prove the existence of the wave operators and the unitarity of the *S*-matrix, we will rely on Cook's method (see, e.g., Ref. 41) and the Kuroda–Birman theorem,[27] respectively.

Following our discussion in Sec. II we will formulate the two-particle scattering theory in the center of mass system using the Hilbert space $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)$ with $H_0(\alpha)=-\Delta_\alpha$ being the free Hamiltonian. Let V, the potential, be a measurable function on $\mathbb{C}^\star/\mathbb{Z}_2$. For example, V may result from a function, also denoted by $V(z)$, on $\mathbb{C}$ with $V(-z)=V(z)$ and which acts as a multiplication operator. We set

$$H(\alpha):=H_0(\alpha)+V=-\Delta_\alpha+V$$

as an operator on $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)$. At this point we are not concerned with giving a criterium for self-adjointness of $H_0(\alpha)$; below we specify a certain class of spherically symmetric potentials for which this operator is self-adjoint. The wave operators $\Omega_\alpha^\pm$ for the pair $(H(\alpha),H_0(\alpha))$ are defined as follows:

$$\Omega_\alpha^\pm:=\operatorname*{s-lim}_{t\to\pm\infty} e^{itH(\alpha)}e^{-itH_0(\alpha)},$$

provided the strong operator limit, denoted by s-lim, exists. Note that in the present context the absolute continuous spectrum of $H_0(\alpha)$ is the positive real axis including the origin and the associated space is all of $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)$. The *S*-matrix is then defined as

$$S_\alpha:=(\Omega_\alpha^+)^*\Omega_\alpha^-.$$

Now we have the following theorem.

Theorem III.1: *Let $(1+r)V$ be in $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2)$. Then the wave operators $\Omega_\alpha^\pm$ for the pair $(H(\alpha),H_0(\alpha))$ exist for all α.*

According to Cook's theorem (see, e.g., Ref. 41) it suffices to prove the following lemma.

Lemma III.1: Under the conditions on V stated in the Theorem one has

$$\int_t^\infty \|Ve^{-isH_0(\alpha)}\phi\|ds<\infty,$$

for a dense set of ϕ's and for some $t=t(\phi)<\infty$.

We will provide two proofs of this lemma. The first one will use the explicit form of the integral kernel of $e^{-itH_0(\alpha)}$ given in expressions (II.9), (II.10) and (II.11). The second proof will make use of the asymptotic form of Bessel functions near the origin and at infinity.

1. Proof of lemma III.1: It suffices to consider the case $\alpha\in(0,1)$ since the cases $\alpha=0$ and $\alpha=1$ are the already well known bosonic and fermionic situation, respectively. We will choose ϕ to be of the form $r\phi(r,\theta)=(\partial/\partial r)\Phi(r,\theta)$ with $\Phi\in C_0^\infty(\mathbb{C}^\star/\mathbb{Z}_2)$. It is easy to see that such ϕ's form a dense set.

Using (II.8), we write

$$|(e^{-itH(\alpha)}\phi)(r,\theta)|\leq F_{\alpha,0}(r,\theta;t)+\hat{F}_\alpha(r,\theta;t),$$

with

$$F_{\alpha,0}(r,\theta;t)=\left|\int_0^\infty\int_0^\pi \mathfrak{k}_{\alpha,0}(r,\theta;r',\theta';t)\phi(r',\theta')r'\,dr'\,d\theta'\right|,$$

$$\hat{F}_{\alpha}(r,\theta;t)=\left|\int_0^\infty\int_0^\pi \hat{\mathfrak{k}}_{\alpha}(r,\theta;r',\theta';t)\phi(r',\theta')r'\,dr'\,d\theta'\right|.$$

We start with an estimate of $F_{\alpha,0}$. Partial integration w.r.t. r' gives

$$F_{\alpha,0}(r,\theta;t)\leqslant\frac{1}{t^2}\int_0^\infty\int_0^\pi G_0(r,\theta;r',\theta';t)|\Phi(r',\theta')|dr'\,d\theta',$$

where G_0 satisfies an estimate of the form

$$0\leqslant G_0(r,\theta;r',\theta';t)\leqslant(1+r)C,$$

uniformly in $r,\theta,t,\alpha\in(0,1)$ and (r',θ') in the support of Φ. This gives

$$F_{\alpha,0}(r,\theta;t)\leqslant C\frac{(1+r)}{t^2},$$

and hence

$$\int_0^\infty\int_0^\pi|V(r,\theta)F_{\alpha,0}(r,\theta;t)|^2r\,dr\,d\theta\leqslant\frac{C}{t^4}\int_0^\infty\int_0^\pi|(1+r)V(r,\theta)|^2r\,dr\,d\theta, \tag{III.1}$$

uniformly in $\alpha\in(0,1)$. We turn to an estimate of $\hat{F}_\alpha$. By (II.10),

$$0\leqslant\hat{F}_\alpha(r,\theta;t)\leqslant\frac{C}{t}\cdot\left|\int_0^\infty\int_0^\pi e^{-(1/4it)(r^2+r'^2)}I_\alpha(\rho,\chi)\phi(r',\theta')r\,dr'\,d\theta'\right|,$$

with the notation

$$\rho=\frac{rr'}{2t},\quad \chi=\theta-\theta'.$$

Adding and subtracting $I_\alpha(0,\chi)$ gives

$$0\leqslant\hat{F}_\alpha(r,\theta;t), \tag{III.2}$$

$$\leqslant\frac{C}{t}\int_0^\infty\int_0^\pi|I_\alpha(\rho,\chi)-I_\alpha(0,\chi)||\phi(r',\theta')|r'\,dr'\,d\theta'$$

$$+\frac{C}{t}\left|\int_0^\infty\int_0^\pi e^{-(1/4it)(r^2+r'^2)}I_\alpha(0,\chi)\frac{\partial}{\partial r'}\Phi(r',\theta')dr'\,d\theta'\right|. \tag{III.3}$$

We need the following lemma which will be proved in Appendix B.

Lemma III.2: The quantity $I_\alpha(\rho,\chi)$ satisfies the estimates

$$|I_\alpha(\rho,\chi)|\leqslant C,$$

$$|I_\alpha(\rho,\chi)-I_\alpha(0,\chi)|\leqslant C(\epsilon)\rho^\epsilon,$$

uniformly in ρ and χ for all $0\leqslant\epsilon<\min(\alpha,1-\alpha)$.

We use this lemma combined with a partial integration w.r.t. r' in the second term of the r.h.s of (III.2) to obtain

$$|\hat{F}_\alpha(r,\theta;t)| \leq C(\epsilon)\left(\frac{r^\epsilon}{t^{1+\epsilon}}+\frac{1}{t^2}\right).$$

Therefore, since $r^\epsilon \leq 1+r$ we finally arrive at

$$\int_0^\infty \int_0^\pi |V(r,\theta)|^2 |\hat{F}_\alpha(r,\theta;t)|^2 r\,dr\,d\theta \leq C(\epsilon)\left(\frac{1}{t^2}+\frac{1}{t^{1+\epsilon}}\right)^2 \int_0^\infty \int_0^\pi (1+r)^2 |V(r,\theta)|^2 r\,dr\,d\theta. \tag{III.4}$$

Combining (III.1) and (III.4) shows that $\|Ve^{-itH_0(\alpha)}\|$ is integrable in t on the interval $[1,\infty)$, say, concluding the first Proof of lemma III.1. □

2. Proof of lemma III.1: For fixed and given $\alpha \in (0,1)$ we use the spectral decomposition of $H_0(\alpha)$ to obtain an α-dependent unitary equivalence,

$$\hat{V}_\alpha : \mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2) \to \hat{\mathcal{L}} = \bigoplus_{m\in\mathbb{Z}} \mathcal{L}^2(\mathbb{R}^+,dE), \tag{III.5}$$

defined by

$$\psi \mapsto \hat{\psi} \equiv \{\hat{\psi}_m\}_{m\in\mathbb{Z}}, \quad \hat{\psi}_m(E) = \langle \phi_{\alpha;m,E} | \psi \rangle,$$

such that $H_0(\alpha)$ just turns into a multiplication operator $\widehat{H_0(\alpha)}$:

$$(\widehat{H_0(\alpha)\psi})_m(E) = (\widehat{H_0(\alpha)}\hat{\psi})_m(E) = E\hat{\psi}_m(E).$$

Via this isomorphism we have

$$\|Ve^{-itH_0(\alpha)}\|^2 = \sum_{m,m'\in\mathbb{Z}} \int_0^\infty dE \int_0^\infty dE'\, e^{-it(E'-E)} \overline{\hat{\psi}_m(E)} v_\alpha^{m,m'}(E,E') \hat{\psi}_{m'}(E'), \tag{III.6}$$

where

$$v_\alpha^{m,m'}(E,E') = \langle \phi_{\alpha;m,E} | V^2 \phi_{\alpha;m',E'} \rangle.$$

We now choose the following dense subspace $\hat{\mathcal{D}} \subset \mathcal{D}(\widehat{H_0(\alpha)})$ in $\hat{\mathcal{L}}$:

$$\hat{\mathcal{D}} = \{\hat{\psi} \in \hat{\mathcal{L}} \,|\, \hat{\psi}_m \in C_0^\infty(\mathbb{R}^+) \text{ and } \hat{\psi}_m \equiv 0 \text{ for almost every } m\}.$$

Correspondingly, we set $\mathcal{D} = (\hat{V}_\alpha)^{-1}\hat{\mathcal{D}}$. We need the following lemma, which will be proved in Appendix B.

Lemma III.3: Let V satisfy the conditions of the Theorem. For arbitrary m and m' the functions $v_\alpha^{m,m'}(E,E')$ have measurable partial derivatives up to order 3 in E and E' on $(0,\infty)$, which are essentially bounded on compact sets.

With this lemma at hand we now proceed as follows. We use the identity

$$e^{itE} = \left(\frac{1}{it}\frac{\partial}{\partial E}\right)^n e^{itE}$$

to perform 3 partial integrations w.r.t. E in (III.6). This gives for $\psi \in \mathcal{D}$,

$$\|Ve^{-itH_0(\alpha)}\psi\|^2 \leq \frac{1}{t^3}\sum_{m,m'}\int dE\int dE'|\partial_E^3\{\overline{\hat{\psi}_m(E)}v_\alpha^{m,m'}(E,E')\}||\hat{\psi}_{m'}(E')| \leq C\frac{1}{t^3},$$

which again shows that $\|Ve^{-itH_0(\alpha)}\psi\|$ is integrable in t in the interval $[1,\infty)$ say. This concludes the second proof of lemma III.1. □

Now we turn to the situation, where the potential is centrally symmetric, i.e., where $V = V(r)$. According to Ref. 42 it is possible to define $H(\alpha)=H_0(\alpha)+V$ as a self-adjoint operator, if the potential is of the form $\gamma/r+\beta/r^b+W(r)$ say, where γ and β are arbitrary reals, $b \in [0,2)$ and W is a bounded function on $\mathbb{R}^+$. In general, $H(\alpha)$ is obviously diagonal w.r.t. the decomposition (II.2) such that

$$H(\alpha)=\bigoplus_{m\in\mathbb{Z}} H_{2m}(\alpha) \quad \text{with} \quad H_{2m}(\alpha)=H_{0,2m}(\alpha)+V,$$

acting on $\mathcal{L}^2(\mathbb{R}^+,r\,dr)$. This leads to a corresponding decomposition for the wave operators and the S-matrix,

$$\Omega_\alpha^\pm=\bigoplus_{m\in\mathbb{Z}}\Omega_{\alpha,2m}^\pm, \quad \text{where} \quad \Omega_{\alpha,2m}^\pm=\operatorname*{s-lim}_{t\to\pm\infty} e^{itH_{2m}(\alpha)}e^{-itH_{0,2m}(\alpha)} \tag{III.7}$$

and

$$S_\alpha=\bigoplus_{m\in\mathbb{Z}} S_{\alpha,2m}, \quad \text{with} \quad S_{\alpha,2m}=(\Omega_{\alpha,2m}^+)^*\Omega_{\alpha,2m}^-.$$

The Kuroda–Birman theorem[27] now leads to the following result.

Theorem III.2: *Let the centrally symmetric potential V satisfy*

$$\int_0^1|V(r)|r\,dr+\int_1^\infty|V(r)|dr<\infty.$$

Then the wave operators $\Omega_{\alpha,2m}^\pm$ exist and are complete. In particular, the S-matrices $S_{\alpha,2m}$ are unitary and so are the S_α.

We recall that the wave operators for an arbitrary pair (H,H_0) are called complete if they are unitary when considered as operators from the absolutely continuous subspace of H_0 to the absolutely continuous subspace of H. Note that these conditions on V in the central symmetric case are weaker than the conditions used in theorem III.1.

Proof: We have to show that the operator

$$|V|^{1/2}(H_{0,2m}(\alpha)+k^2)^{-1}V^{1/2}$$

in $\mathcal{L}^2(\mathbb{R}^+,r\,dr)$ has finite trace class norm $\|\cdot\|_1$, where $V^{1/2}(r)=\text{sgn}(V(r))\cdot|V(r)|^{1/2}$. Here it suffices to choose any $k^2>0$. By (II.6) we have

$$\langle r|(H_{0,2m}(\alpha)+k^2)^{-1}|r'\rangle=I_\mu(kr_<)K_\mu(kr_>),$$

with $\mu=|2m+\alpha|$. Therefore we obtain the following *a priori* estimate:

$$\||V|^{1/2}(H_{0,2m}(\alpha)+k^2)^{-1}V^{1/2}\|_1\leq\int_0^\infty|V(r)||I_\mu(kr)||K_\mu(kr)|r\,dr. \tag{III.8}$$

The following estimates for I_μ,K_μ can be derived from the asymptotic behavior near the origin and at infinity (see, e.g., Refs. 34, 35)

$$\text{for } kr\leq 1: \quad |I_\mu(kr)|\leq C(\mu)(kr)^\mu, \quad |K_\mu(kr)|\leq C(\mu)(kr)^{-\mu};$$

$$\text{for } kr \geqslant 1: \quad |I_\mu(kr)| \leqslant C(\mu)\frac{e^{kr}}{\sqrt{kr}}, \quad |K_\mu(kr)| \leqslant C(\mu)\frac{e^{-kr}}{\sqrt{kr}}.$$

Now we choose $k=1$. For this choice of k the right hand side of (III.8) is bounded by

$$C(\mu)\left\{\int_0^1 |V(r)| r dr + \int_1^\infty |V(r)| dr\right\},$$

concluding the proof of the theorem. □

IV. THE DIFFERENTIAL CROSS-SECTION

We now turn to the discussion of the two-particle scattering cross-section. The conventional approach when dealing with identical particles is to compute first the cross-section for *distinguishable* particles and in a second step to symmetrize or anti-symmetrize it in order to describe boson or fermion scattering. This is allowed because all observables commute with the projection operators onto the subspaces of symmetric and antisymmetric wave functions, respectively (see, e.g., Ref. 43 for a detailed account on this issue). In the context of anyon statistics this procedure is not applicable since no corresponding projection operators on the anyonic Hilbert spaces are available. Hence, we will investigate the two-particle cross-section in the center of mass system in a way similar to the single particle case. Doing this one encounters an additional difficulty, namely, the presence of the gauge potential A_α encoding the statistics. The latter gives rise to a nontrivial differential cross-section, even if no *dynamical* potential is present, i.e., $V\equiv 0$. This should not come as a surprise since the ''free'' dynamics generated by $H_0(\alpha)$ is described by Aharonov–Bohm scattering in the infinite time limit (see our discussion in Sec. II). Thus, the cross-section will display both the statistical as well as the dynamical interaction represented by A_α and V, respectively.

Let us first consider the simplest case where $\alpha=0$, i.e., the particles are bosons. Then the natural choice of a basis for describing the scattering is given by the *symmetric* plane waves $|k,\theta\rangle$, because the incoming asymptote is usually taken to have a sharply peaked momentum distribution. Moreover, we recall that the localization of some state ψ at large times can be determined by means of its Fourier transform,

$$\lim_{t\to\pm\infty}\int_{\mathcal{C}} |e^{-itH_0}\psi|^2 = \int_{\mathcal{C}} d\theta k dk |\langle k,\theta|\psi\rangle|^2, \tag{IV.1}$$

where $\mathcal{C} := \{(k,\theta): k\in\mathbb{R}_+, \theta\in(a,b)\subset[0,\pi]\}$ denotes a cone in real space on the left hand side and in momentum space on the right hand side. The above identity can be found in several text books on scattering theory; see, e.g., Ref. 44.

If $\alpha\notin\mathbb{Z}$ the flux-tube destroys translation invariance, whence the plane waves are not eigenstates of $H_0(\alpha)$. Thus, we have to look for an appropriate replacement such that the new basis diagonalizes $H_0(\alpha)$ and we still can form an incident wave packet with a sharply peaked momentum distribution. It turns out that this can be achieved by making use of Aharonov–Bohm scattering theory. We assign to each symmetric plane wave denoted by $|k,\theta\rangle$ the corresponding stationary Aharonov–Bohm scattering state, that is,

$$|k,\theta\rangle^{in} := \Omega_{AB}^{-}|k,\theta\rangle \quad \text{and} \quad |k,\theta\rangle^{out} := \Omega_{AB}^{+}|k,\theta\rangle. \tag{IV.2}$$

The symbols $\Omega_{AB}^{\pm}$ stand for the Aharonov–Bohm wave operators, as defined in (II.12). Note that each of the sets $\{|k,\theta\rangle^{in}\}$ and $\{|k,\theta\rangle^{out}\}$ forms a complete orthonormal system since the Aharonov–Bohm wave operators are unitary.[22] Moreover, the basis elements are (improper) eigenstates of $H_0(\alpha)$ due to the intertwining relation

$$H_0(\alpha)\Omega^{\pm}_{AB}=\Omega^{\pm}_{AB}H_0.$$

Their explicit form was given in Sec. II, Eq. (II.13). Now, by construction every wave packet in the $|k,\theta\rangle^{in}_{out}$ basis under the ''free'' anyonic time evolution $\exp(-itH_0(\alpha))$ approaches the corresponding wave packet in the plane wave basis $|k,\theta\rangle$ as $t\to\mp\infty$. Therefore, we shall refer to $|k,\theta\rangle^{in}_{out}$ as the anyonic state with incoming, respectively, outgoing (relative) momentum (k,θ). Note that according to their definition the ''in'' states are transformed into the ''out'' states by the Aharonov–Bohm S-matrix,

$$^{out}\langle k,\theta|k',\theta'\rangle^{in}=\langle k,\theta|S_{AB}|k',\theta'\rangle.$$

An additional argument for the usefulness of the two bases $|k,\theta\rangle^{in}_{out}$ is the following generalization of Dollard's theorem to anyonic dynamics:

$$\lim_{t\to\pm\infty}\int_{\mathcal{C}}|e^{-itH_0(\alpha)}\psi|^2=\int_{\mathcal{C}}d\theta k dk|^{in}_{out}\langle k,\theta|\psi\rangle|^2. \tag{IV.3}$$

The proof is immediate. By construction, the state $e^{-itH_0}(\Omega^{\pm}_{AB})^*\psi$ approaches the anyonic state $e^{-itH_0(\alpha)}\psi$ in the norm as $t\to\pm\infty$. Applying (IV.1) yields the desired relation.

We are now prepared to consider a single scattering event of two anyons when a potential V is present. Denote now by ψ the incoming wave function. According to (IV.3) the probability that the particles are scattered into $\mathcal{C}$ is given by

$$\lim_{t\to\infty}\int_{\mathcal{C}}|e^{-itH_0(\alpha)}S_\alpha\psi|^2=\int_{\mathcal{C}}d\theta\, k dk|^{out}\langle k,\theta|S_\alpha\psi\rangle|^2, \tag{IV.4}$$

where S_α is the scattering operator introduced in Sec. III. On physical grounds ψ is assumed to have a sharply peaked momentum distribution at $t=-\infty$, whence it will be given in the basis $|k,\theta\rangle^{in}$. Therefore, we perform the following transformation:

$$\begin{aligned} ^{out}\langle k,\theta|S_\alpha\psi\rangle &= \int d\theta'\, k'\, dk'\ ^{out}\langle k,\theta|S_\alpha|k',\theta'\rangle^{in\ in}\langle k,',\theta'|\psi\rangle \\ &= \int d\theta'\, k'\, dk' \langle k,\theta|(\Omega^{+}_{AB})^* S_\alpha \Omega^{-}_{AB}|k',\theta'\rangle\ ^{in}\langle k',\theta'|\psi\rangle, \end{aligned} \tag{IV.5}$$

where in the second step we have used the defining relation (IV.2). Thus, we are lead to consider the operator

$$S^{tot}_\alpha := (\Omega^{+}_{AB})^* S_\alpha \Omega^{-}_{AB},$$

which can be identified with the S-matrix resulting from the wave operators

$$\Omega^{\pm}(H(\alpha),H_0)=\operatorname*{s-lim}_{t\to\pm\infty} e^{itH(\alpha)}e^{-itH_0}.$$

This can be easily verified by using the well known chain rule for wave operators (see, e.g., Ref. 41)

$$\Omega^{\pm}(H(\alpha),H_0)=\Omega^{\pm}(H(\alpha),H_0(\alpha))\Omega^{\pm}(H_0(\alpha),H_0)=\Omega^{\pm}_\alpha\Omega^{\pm}_{AB}. \tag{IV.6}$$

Notice that the scattering operator S^{tot}_α incorporates the statistical as well as the dynamical interaction while S_α only takes care of the latter. This is best displayed by setting the potential equal to zero,

$$V \equiv 0 \Rightarrow S_\alpha = \mathbf{1}, \quad S_\alpha^{tot} = S_{AB}.$$

Therefore, in order to accommodate the anyon statistics of the particles we shall define the scattering amplitude f_α, referring to the dynamical interaction V as follows. Denote by T_α^{tot} the operator

$$T_\alpha^{tot} := (\Omega_{AB}^+)^* (S_\alpha - \mathbf{1}) \Omega_{AB}^- = S_\alpha^{tot} - S_{AB}.$$

Then the scattering amplitude is given by

$$f_\alpha(k,\theta-\theta') := \left(\frac{\pi}{ik}\right)^{1/2} \langle \theta | T_\alpha^{tot}(E=k^2) | \theta' \rangle, \tag{IV.7}$$

where $\langle \theta | T_\alpha^{tot}(E) | \theta' \rangle$ denotes the on-shell matrix element defined by the relation

$$\langle k,\theta | T_\alpha^{tot} | k',\theta' \rangle = 2\,\delta(E-E') \langle \theta | T_\alpha^{tot}(E) | \theta' \rangle,$$

with $E=k^2$ and $E'=k'^2$. From (IV.4) and (IV.5) one can now derive the differential cross-section analogously to the single-particle case, e.g., Refs. 43, 44. Away from the forward direction one ends up with the expression

$$\begin{aligned} \frac{d\sigma}{d\theta}(E_0,\theta_0) &= \pi E_0^{-1/2} |\langle \theta | T_\alpha^{tot}(E_0) + T_{AB}(E_0) | \theta_0 \rangle|^2 \\ &= |f_\alpha(k_0,\theta-\theta_0) + f_{AB}(k_0,\theta-\theta_0)|^2, \end{aligned} \tag{IV.8}$$

with $\theta \neq \theta_0$. Here, $E_0 = k_0^2, \theta_0$ determine the energy and direction of the incident particle beam and $\langle \theta | T_{AB}(E) | \theta' \rangle$ denotes the on-shell matrix element of the operator $T_{AB} = S_{AB} - \mathbf{1}$ [see Sec. II, Eq. (II.17) for the explicit expression of the Aharonov–Bohm scattering amplitude f_{AB}]. Note that we have a normalization factor π instead of 2π in (IV.8) because the polar angle is restricted to the interval $[0,\pi]$. As mentioned in Sec. II the total Aharonov–Bohm cross-section is infinite for $\alpha \notin \mathbb{Z}$, whence the total cross-section corresponding to (IV.8) is infinite as well. However, the above differential cross-section coincides with the usual one for bosons or fermions if we set $\alpha=0$ and $\alpha=1$, respectively. This can be most easily seen by use of the defining relation (IV.2) for the ''in'' and ''out'' states which for the values $\alpha=0,1$ become symmetric and antisymmetric plane waves, respectively [compare (II.13)]. In case $\alpha=1$, however, this is only true up to an angular-dependent phase factor which comes in by representing fermions as bosons with attached flux-tubes. This does not influence the outcome since the differential cross-section is given by the square modulus of the scattering amplitude. Thus, as special cases we obtain the familiar result that the differential cross-section for bosons and fermions is given by the square modulus of the symmetrized and anti-symmetrized scattering amplitude, respectively. In particular, f_{AB} vanishes and the total cross-section becomes finite for suitable short range interactions V.

V. JOST FUNCTIONS AND LEVINSON'S THEOREM

In this section we will introduce Jost functions[45] indexed by a continuous angular momentum and discuss their properties. This continuous parameter leads to an alternative formulation of the generalized Levinson theorem. We start by adapting the standard theory and results of Jost functions to the present situation (see e.g., Refs. 41, 43, 46–48). Conditions on the spherically symmetric potential will be presented at the appropriate places.

Consider the unitary map $U:\mathcal{L}^2(\mathbb{R}^+, r\,dr) \to \mathcal{L}^2(\mathbb{R}^+, dr)$, given by

$$\psi(r) \mapsto \sqrt{r}\,\psi(r). \tag{V.1}$$

Under this map the Hamiltonian $H_{2m}(\alpha) = H_{0,2m}(\alpha) + V$ turns into the operator

$$h_\mu = h_{0,\mu} + V, \tag{V.2}$$

with $\mu = |2m+\alpha| > 0$, where

$$h_{0,\mu} = -\left(\frac{d^2}{dr^2} - \frac{\mu^2 - \frac{1}{4}}{r^2}\right). \tag{V.3}$$

In this section μ will be allowed to be any positive number. Also in this section the notation $\phi_0(r;k,\mu)$ will be reserved for the regular solutions (so called because of their behavior near $r=0$) of the free Schrödinger equation $(h_{0,\mu}-k^2)\psi=0$ given as

$$\phi_0(r;k,\mu) = \sqrt{\frac{\pi k r}{2}}\, J_\mu(kr). \tag{V.4}$$

With the help of these solutions the orthogonality and completeness relations (II.4) and (II.5) are now reformulated as

$$\int_0^\infty \phi_0(r;k,\mu)\phi_0(r';k,\mu)\,dk = \frac{\pi}{2}\,\delta(r-r'), \tag{V.5a}$$

$$\int_0^\infty \phi_0(r;k,\mu)\phi_0(r;k',\mu)\,dr = \frac{\pi}{2}\,\delta(k-k'). \tag{V.5b}$$

We will also need the irregular, free solutions $\chi_0^\pm$ given as

$$\chi_0^\pm(r;k,\mu) = \pm i\sqrt{\frac{\pi k r}{2}}\, H_\mu^\pm(kr).$$

With help of these solutions the free Green's functions read [compare (II.6)] as

$$G_0^\pm(r,r';k,\mu) = \langle r|(h_{0,\mu}-k^2 \mp i\epsilon)^{-1}|r'\rangle = \frac{1}{k}\,\phi_0(r_<;k,\mu)\chi_0^\pm(r_>;k,\mu). \tag{V.6}$$

Definition V.1: For given V the function $\phi=\phi(r;k,\mu)$ is the regular solution of the equation $(h_\mu - k^2)\psi=0$ which for $r\to 0$ approximates the free, regular solution ϕ_0:

$$\lim_{r\to 0}\left(\frac{2}{kr}\right)^{\mu+1/2}\frac{\Gamma(\mu+1)}{\sqrt{\pi}}\,\phi(r;k,\mu) = 1.$$

As in the standard theory (see, e.g., Refs. 46, 47) one establishes the following facts.

(A0) ϕ is the solution to the integral equation

$$\psi = \phi_0 - G_0^< V\psi, \quad \text{with} \quad G_0^<(r,r';k,\mu) = \Theta(r-r')g_0(r,r';k,\mu). \tag{V.7}$$

Here Θ denotes the Heaviside step function and g_0 is given as

$$g_0(r,r';k,\mu) = \frac{1}{k}[\phi_0(r;k,\mu)\chi_0^-(r';k,\mu) - \chi_0^-(r;k,\mu)\phi_0(r';k,\mu)]. \tag{V.8}$$

(B0) If the potential V satisfies the condition

$$\int_0^\infty r\,dr|V(r)|<\infty,$$

then the regular solution ϕ to the eigenvalue problem $(h_{0,\mu}+\lambda V-k^2)\psi=0$ has a convergent power series expansion in λ of the form

$$\phi=\sum_{n=0}^\infty \lambda^n\phi_n, \quad \text{with} \quad \phi_{n=0}=\phi_0 \quad \text{and} \quad \phi_n=-G_0^< V\phi_{n-1}, \quad n\geqslant 1. \tag{V.9}$$

(C0) For fixed $\mu>0$, $r>0$ and real V the solution ϕ has an analytic continuation in k into the complex plane with a cut along the negative imaginary axis. There one has the relation $(k>0)$

$$\phi(r;-ik-0,\mu)=e^{i\pi(\mu+1/2)}\phi(r;ik,\mu)=e^{2i\pi(\mu+1/2)}\phi(r;-ik+0,\mu). \tag{V.10}$$

The proofs of (A0), (B0) and (C0) are as in ordinary 3-dimensional Schrödinger theory (see, e.g., Ref. 47). As a byproduct of the proof one also has the two estimates:

$$|\phi_n(r;k,\mu)|<e^{|\mathrm{Im}\,k|r}\left(\frac{|k|r}{1+|k|r}\right)^{\mu+1/2}\frac{C(\mu)^{n+1}}{n!}\left[\int_0^r dr'\frac{r'|V(r')|}{1+|k|r'}\right]^n, \tag{V.11a}$$

$$|\phi(r;k,\mu)|<C(\mu)e^{|\mathrm{Im}\,k|r}\left(\frac{|k|r}{1+|k|r}\right)^{\mu+1/2}. \tag{V.11b}$$

We will prove these estimates in Appendix C. Relation (V.10) is a consequence of the relation

$$J_\mu(e^{in\pi})=e^{in\pi\mu}J_\mu(z).$$

We now introduce the irregular solutions of the eigenvalue equation with potential as those solutions $\chi^\pm$ which approximate the free irregular solutions $\chi_0^\pm$ at $r=\infty$.

Definition V.2: The functions $\chi^\pm=\chi^\pm(r;k,\mu)$ are the solutions of the eigenvalue problem $(h_\mu-k^2)\psi=0$ satisfying the boundary conditions at infinity of the form

$$\lim_{r\to\infty} e^{\mp i(kr-(\pi/2)\mu+\pi/4)}\chi^\pm(r;k,\mu)=1.$$

These solutions will be called Jost solutions. With the help of these solutions ϕ and $\chi^\pm$ the Green's function for the full Hamiltonian h_μ now takes a form analogous to the free case [see (V.6)],

$$G^\pm(r,r';k,\mu)=\langle r|(h_\mu-k^2\mp i\epsilon)^{-1}|r'\rangle=\frac{\phi(r_<;k,\mu)\chi^\pm(r_>;k,\mu)}{W(\chi^\pm,\phi)}, \tag{V.12}$$

where W is the Wronskian, i.e.,

$$W(\psi_1,\psi_2)(r)=\psi_1(r)\partial_r\psi_2(r)-\psi_2(r)\partial_r\psi_1(r).$$

We recall that since ϕ and $\chi^\pm$ are solutions of the same eigenvalue equation, the Wronskian in (V.12) is actually independent of r, whence the notation.

Again one may establish the following facts (see, e.g., Ref. 47).

(A$\pm$) The functions $\chi^\pm$ are the solutions to the integral equations,

$$\psi=\chi_0^\pm-G_0^> V\psi, \quad G_0^>(r,r';k,\mu):=\Theta(r'-r)g_0(r,r';k,\mu). \tag{V.13}$$

Here, g_0 denotes the function defined in (V.8) which can be rewritten as

$$g_0(r,r';k,\mu)=\frac{i}{2k}[\chi_0^+(r;k,\mu)\chi_0^-(r';k,\mu)-\chi_0^-(r;k,\mu)\chi_0^+(r';k,\mu)].$$

(B±) If the potential V satisfies the condition

$$\int_0^\infty r\,dr(1+r)|V(r)|<\infty, \tag{V.14}$$

the irregular solutions $\chi^\pm$ to the eigenvalue problem $(h_{0,\mu}+\lambda V-k^2)\psi=0$ with $\pm\operatorname{Im} k\geqslant 0$, $k\neq 0$ have a convergent power series expansion in λ of the form

$$\chi^\pm=\sum_{n=0}^\infty \lambda^n\chi_n^\pm, \quad \text{with} \quad \chi_{n=0}^\pm=\chi_0^\pm \quad \text{and} \quad \chi_n^\pm=-G_0^> V\chi_{n-1}^\pm, \quad n\geqslant 1.$$

(C±) For V real and $\mu>0$, $r>0$ the functions $\chi^\pm$ are analytic in k for $\pm\operatorname{Im} k>0$ with continuous extensions to the real axis, except possibly for a singularity of order $\mu-1/2$ at $k=0$. In case V satisfies

$$\int_0^\infty r\,dr|V(r)|e^{\eta r}<\infty, \quad \eta>0, \tag{V.15}$$

then the functions $\chi^\pm$ have an analytic continuation into the domains given by $\pm\operatorname{Im} k>-\eta/2$ for all $\mu>0$, $r>0$, with the exception of a branch cut from $k=0$ to $k=\mp i(\eta/2)$. There one has the relation $(k>0)$

$$\chi^\pm(r;\mp(ik+0),\mu)=\chi^\pm(r;\mp(ik-0),\mu)+2i\cos\pi\mu\;\chi^\pm(r;\pm ik,\mu).$$

The proof of these statements is similar to the one in the regular case and involves a proof of the bounds,

$$|\chi_n^\pm(r;k,\mu)|<e^{\mp\operatorname{Im}(k)r}\left(\frac{|k|r}{1+|k|r}\right)^{-\mu+1/2}\frac{C(\mu)^{n+1}}{n!}\left[\int_r^\infty dr'\,e^{|\operatorname{Im} k|r'\mp\operatorname{Im}(k)r}\frac{r'|V(r')|}{1+|k|r'}\right]^n \tag{V.16}$$

and

$$|\chi^\pm(r;k,\mu)|<C(\mu)e^{\mp\operatorname{Im}(k)r}\left(\frac{|k|r}{1+|k|r}\right)^{-\mu+1/2}, \tag{V.17}$$

for all $\mu>0$ and $r>0$. We will establish these bounds in Appendix C. Due to the uniqueness of the solutions $\chi^\pm$ and the multivaluedness of the Hankel functions (see, e.g., Ref. 35) one has the relation

$$\overline{\chi^\pm(r;k,\mu)}=\chi^\mp(r;\bar{k},\mu)=\mp i e^{\pm i\pi\mu}\chi^\pm(r,-\bar{k},\mu).$$

We are now in the position to introduce the Jost functions in the present context and establish their properties. Since χ^+ and χ^- form a basis of solutions, ϕ is a linear combination of these two solutions. As in the standard theory (see, e.g., Ref. 47) it turns out that this linear combination is of the form

$$\phi(r;k,\mu)=\frac{i}{2}[F(k,\mu)\chi^-(r;k,\mu)-F(-k,\mu)\chi^+(r;k,\mu)],$$

where the coefficient function $F=F(k,\mu)$ is called the Jost function given by the Wronskian

$$F=\frac{1}{k}W(\chi^{+},\phi). \tag{V.18}$$

The Jost function was first introduced by and named after R. Jost. Note, however, that our definition of F follows the convention introduced by Newton,[47] which differs from the original one given in Ref. 49. We have the first main result concerning these Jost functions.

Theorem V.1: *Let the potential V satisfy the condition (V.14). Then for fixed $\mu>0$ $F(k,\mu)$ extends to an analytic function in k in the open upper half plane, which is continuous up to the real axis with the exception of the origin.*

In case the potential satisfies the stronger condition (V.15), $F(k,\mu)$ is analytic in k in $\{k|\mathrm{Im}\,k>-\eta/2\}$, except for a cut on the negative imaginary axis. Then F also satisfies the relation $(k>0)$

$$F(-ik-0,\mu)=-e^{2i\pi\mu}F(-ik+0,\mu)+2\cos\pi\mu F(ik,\mu).$$

The proof follows from the representation for F:

$$F(k,\mu)=1+\frac{1}{k}\langle\chi_0^{-}(\cdot;k,\mu)|V\phi(\cdot;k,\mu)\rangle, \tag{V.19}$$

the estimate (V.11b) for ϕ and the estimate (V.17), which is also valid for χ_0^{+}. To establish this relation we use the integral equation (V.7) for ϕ, which for large r gives

$$\phi(r;k,\mu)\xrightarrow{r\to\infty}\frac{i}{2}\left[\chi_0^{-}(r;k,\mu)\left\{1+\frac{1}{k}\langle\chi_0^{-}(\cdot;k,\mu)|V\phi(\cdot;k,\mu)\rangle\right\}\right.$$
$$\left.-\chi_0^{+}(r;k,\mu)\left\{1+\frac{1}{k}\langle\chi_0^{+}(\cdot;k,\mu)|V\phi(\cdot;k,\mu)\rangle\right\}\right]. \tag{V.20}$$

Since $\chi^{\pm}(r;k,\mu)$ approaches $\chi_0^{\pm}(r;k,\mu)$ for $r\to\infty$, relation (V.19) follows from this behavior.

Note that making use of the analytic properties just proven there is an equivalent definition of the Jost function in terms of Fredholm theory, see, e.g., Refs. 47, 50. Consider the operator $G_0^{+}(k,\mu)V$ with G_0^{+} the free Green's operator and V satisfying relation (V.14). Then for k positive imaginary $(k\in i\mathbb{R}^{+})$ the operator $G_0^{+}(k,\mu)V$ is trace class, whence its Fredholm determinant $\det(\mathbf{1}+G_0^{+}(k,\mu)V)$ is well defined. It turns out that the Jost function is just the analytic continuation of this determinant to the upper half complex plane.

We note that the series expansion (V.9) for the regular solution ϕ gives the series expansion

$$F=1+\frac{1}{k}\sum_0^{\infty}F^{n},\quad\text{with}\quad F^{n}(k,\mu)=\langle\chi_0^{-}(\cdot;k,\mu)|V\phi^{n}(\cdot;k,\mu)\rangle.$$

The bound (V.11a) for ϕ_n combined with the bound (V.17) for χ_0^{+} gives the bound

$$|F^{n}(k,\mu)|<C(\mu)\frac{C^{n}}{n!}\int_0^{\infty}dr\ e^{(|\mathrm{Im}\,k|-\mathrm{Im}\,k)r}\frac{|k|r}{1+|k|r}|V(r)|,$$

while the bound (V.11b) gives

$$|F(k,\mu)-1|\leqslant C(\mu)\int_0^{\infty}dr\ e^{(|\mathrm{Im}\,k|-\mathrm{Im}\,k)r}\frac{r|V(r)|}{1+|k|r}.$$

The importance of the Jost function stems from its role in the discussion of the S-matrix. Let $\Omega_{\mu}^{\pm}$ be the wave operators for the pair $(h_{\mu},h_{0,\mu})$ such that one has [see (III.7) and (V.1)]

$$\Omega_\mu^\pm = U\Omega_{\alpha,2m}^\pm U^{-1} \quad \text{and} \quad S_\mu = (\Omega_\mu^+)^* \Omega_\mu^- = US_{\alpha,2m}U^{-1}.$$

Since S_μ commutes with $h_{0,\mu}$ there is a decomposition of S_μ in the form

$$S_\mu = \int_\oplus dk S(k,\mu),$$

with respect to the spectral decomposition of $h_{0,\mu}$. Since the spectrum of $h_{0,\mu}$ is not degenerate, $S(k,\mu)$ acts in a one-dimensional Hilbert space and therefore is a complex number of absolute value one, i.e.,

$$S(k,\mu) = e^{2i\delta(k,\mu)}, \quad k \geqslant 0, \quad \mu \geqslant 0,$$

with $\delta(k,\mu)$ being the phase shift. We define by

$$f(k,\mu) := \frac{e^{2i\delta(k,\mu)} - 1}{\sqrt{\pi i k}}$$

the partial wave amplitude for the angular momentum $\pm\mu$, such that we obtain the following partial wave decomposition of the scattering amplitude given in (IV.7):

$$\begin{aligned} f_\alpha(k,\theta-\theta') &= \left(\frac{\pi}{ik}\right)^{1/2} \langle \theta | T_\alpha^{tot}(k^2) | \theta' \rangle \\ &= \left(\frac{\pi}{ik}\right)^{1/2} \frac{1}{\pi} \sum_{m\in\mathbb{Z}} e^{-i\pi|2m+\alpha|}(e^{2i\delta(k,|2m+\alpha|)} - 1) e^{i2m(\theta-\theta')} \\ &= \sum_{m\in\mathbb{Z}} e^{-i\pi|2m+\alpha|} f(k,|2m+\alpha|) e^{i2m(\theta-\theta')}. \end{aligned} \tag{V.21}$$

Here we have used the relation $\langle k,\theta | T_\alpha^{tot} | k',\theta' \rangle = {}^{out}\langle k,\theta | S_\alpha - \mathbf{1} | k',\theta' \rangle^{in}$ as well as the identities

$$\langle r,\theta | k,\theta' \rangle_{out}^{in} = \sqrt{2\pi}\, \frac{1}{\pi} \sum_{m\in\mathbb{Z}} (\mp i)^{|2m+\alpha|} \phi_{\alpha;m,E}(r,\theta) e^{-i2m\theta'},$$

$$\langle \phi_{\alpha;m,E} | S_\alpha \phi_{\alpha;m',E'} \rangle = \delta_{mm'} \delta(E-E') e^{2i\delta(k,|2m+\alpha|)}.$$

Now set

$$\phi^\pm(r;k,\mu) = (\Omega_\mu^\pm \phi_0)(r;k,\mu).$$

By construction one has a solution of the eigenvalue equation $(h_\mu - k^2)\psi = 0$ and $\phi^\pm$ satisfies the Lippmann–Schwinger equation,

$$\phi^\pm(\cdot;k,\mu) = \phi_0(\cdot;k,\mu) - (h_\mu - k^2 \pm i0)^{-1} V \phi^\pm(\cdot;k,\mu).$$

With the help of $\phi^\pm$ one may express the partial wave amplitude as

$$f(k,\mu) = -\frac{2}{k^2}\left(\frac{ik}{\pi}\right)^{1/2} \langle \phi_0(\cdot;k,\mu) | V\phi^+(\cdot;k,\mu) \rangle.$$

The solution ϕ^+ of the Lippmann–Schwinger equation has the following asymptotic behavior for $r \to \infty$:

$$\phi^{+}(r;k,\mu) \xrightarrow[r\to\infty]{} \phi_0(r;k,\mu)+\tfrac{1}{2}\sqrt{\pi k}f(k,\mu)e^{i(kr-(\pi/2)\mu)},$$

where we have used $\chi_0^{+}(r;k,\mu) \xrightarrow[r\to\infty]{} e^{i(kr-(\pi/2)\mu+\pi/4)}$. Alternatively, using the relation $\phi_0 = i/2(\chi_0^{-}-\chi_0^{+})$ one gets

$$\phi^{+}(r;k,\mu) \xrightarrow[r\to\infty]{} \frac{i}{2}(\chi_0^{-}(r;k,\mu)-e^{2i\delta(k,\mu)}\chi_0^{+}(r;k,\mu)).$$

With the same arguments as in the standard theory (see, e.g., Refs. 41, 46, 47) one proves the following.

Lemma V.1: Let $\mu>0$ be fixed and assume that V satisfies the condition (V.14). Then one has the following.

(i) For k on the real axis ($k\in\mathbb{R}^{+}$), the following identities are valid:

$$\phi(r;k,\mu)=F(k,\mu)\phi^{+}(r;k,\mu), \tag{V.22}$$

$$S(k,\mu)=e^{2i\delta(k\mu)}=\frac{\overline{F}(k,\mu)}{F(k,\mu)}=\frac{F(-k,\mu)}{F(k,\mu)}. \tag{V.23}$$

Furthermore, $F(k,\mu)$ can only vanish at the origin.

(ii) The zeros of $F(k,\mu)$ in the upper half plane $\mathrm{Im}\,k>0$ all lie on the positive imaginary axis and are simple. In particular, $k\in i\mathbb{R}^{+}$ is a zero of $F(k,\mu)$ *iff* k^2 is the energy of a bound state of h_μ with angular momentum $\pm\mu$.

(iii) The following limit relation is valid in the closed upper half plane:

$$\lim_{k\to\infty} F(k,\mu)=1.$$

Since the proof is analogous to the one given in three-dimensional Schrödinger theory[41,46,47] we omit it here. Now, the famous Levinson's theorem follows as a corollary by use of the residue theorem. Only the so called resonance case, i.e., $F(k=0,\mu)=0$, requires some more work.

Theorem V.2: *Let $\mu>0$ and V satisfy* (V.14). *If $F(k=0,\mu)\neq 0$ one has the following relation between the phase shift $\delta(k,\mu)$ and the number n_μ of bound states with angular momentum $\pm\mu$,*

$$\delta(k=0,\mu)-\delta(k=\infty,\mu)=\pi n_\mu. \tag{V.24}$$

Proof: The proof of Eq. (V.24) is standard and can be found in, e.g., Refs. 41, 43, 46, 47. For the sake of completeness we recall the main arguments. Integrate the logarithmic derivative of F with respect to k over a closed semi-circle in the complex upper half plane centered at the origin. According to the preceding lemma the integrand has simple poles on the positive imaginary axis, each of which corresponds to a bound state of h_μ. While the contribution of the semi-circle vanishes in the limit of infinite radius [see (III.4)] the integration over the real axis yields the phase difference by Eq. (V.23). Applying the residue theorem completes the proof. □

We comment on the results of the above theorem. Equation (III.5) generalizes Levinson's theorem to continuous angular momentum μ. One might wonder what happens when μ varies. On physical grounds one expects that for higher angular momentum μ there are fewer bound states since then the centrifugal barrier is stronger. Thus, when μ is steadily increased the zeros of the Jost function F move along the positive imaginary axis towards the origin. Every time a zero moves out of the upper half plane we get a discontinuous jump in the phase shift indicating the disappearance of a bound state.

Theorem V.3: *Let $\mu\notin\mathbb{Z}$, $\mu>0$ and assume V satisfies* (V.15). *In case $F(k=0,\mu)=0$ the above form of Levinson's theorem remains valid when $\mu>1$ and is modified as*

$$\delta(k=0,\mu)-\delta(k=\infty,\mu)=\pi(n_\mu+\mu), \tag{V.25}$$

when $\mu<1$.

So far we have not been able to settle the case $\mu \in \mathbb{Z}$ corresponding to boson and fermion statistics. For real anyons, however, note that in case of positive angular momentum we have $\mu=\alpha$ when $\mu<1$. Thus, Eq. (V.25) then specializes to

$$\delta(k=0,\alpha)-\delta(k=\infty,\alpha)=\pi(n_\mu+\alpha), \tag{V.26}$$

showing that one can determine the statistics parameter from the scattering phase independently of the detailed form of the short range potential V. Below we will find a similar formula for the delta potential. Setting $\alpha=1/2$ (i.e., for semions) in (V.25) we obtain the well known resonance case of three-dimensional Schrödinger theory,[46] since then the radial Schrödinger equation is formally identical to the one in three dimensions [compare (V.2) and (V.3)].

Proof: The strategy for proving (V.25) is similar to the one used for (V.24). The techniques used are analogous to those in three-dimensional Schrödinger theory (see Refs. 43, 46) but the line of argument is slightly changed.

Because $F(k=0,\mu)=0$ we change the integration contour as follows. We cut the semi-circle at the origin and insert a small semi-circle C_ρ of radius $\rho \ll 1$ centered at the origin. Then there is an additional contribution to Eq. (V.24), namely,

$$\pi n'_\mu=\delta(k=0,\mu)-\delta(k=\infty,\mu)+\lim_{\rho\to 0}\frac{1}{2i}\oint_{C_\rho} d\ln F, \tag{V.27}$$

where n'_μ is the number of bound states with the exception of a possible zero energy eigenstate. In order to compute the second term of the right hand side in the above equation we only need to know the small energy behavior of F. Since we have assumed that the potential is decaying exponentially we can continue F in the lower half plane and expand it into a convergent power series around the origin for suitably small k. We start by rewriting expression (V.19),

$$\begin{aligned} F(k,\mu)&=1+\frac{1}{k}\langle \chi_0^-(\cdot;k,\mu)|V\phi(\cdot;k,\mu)\rangle \\ &=1+\frac{1}{k\sin\pi\mu}[\langle \phi_0(\cdot;k,-\mu)|V\phi(\cdot;k,\mu)\rangle - e^{-i\pi\mu}\langle\phi_0(\cdot;k,\mu)|V\phi(\cdot;k,\mu)\rangle]. \end{aligned} \tag{V.28}$$

Here we have used the identity $H_\mu^{(1)}(z)=(1/i\sin\pi\mu)[J_{-\mu}(z)-e^{-i\pi\mu}J_\mu(z)]$ which can be found in, e.g., Refs. 34, 35. Note that in case of integer μ the Hankel function is defined by the limit of the r.h.s. of the last equation. Then the above decomposition (V.28) is no longer valid, whence we restrict ourselves to the noninteger case. Both integrals in (V.28) converge uniformly as can be shown by use of the estimates

$$|\phi_0(r;k,\mu)\phi(r;k,\mu)|\le C(\mu)e^{2|\mathrm{Im}\,k|r}\left(\frac{|k|r}{1+|k|r}\right)^{2\mu+1},$$

$$|\phi_0(r;k,-\mu)\phi(r;k,\mu)|\le C(\mu)e^{2|\mathrm{Im}\,k|r}\left(\frac{|k|r}{1+|k|r}\right),$$

which follow from (V.11a) and (V.11b). The functions $\phi_0(r;k,-\mu)$ and $\phi_0(r;k,\mu)$ can be written as a convergent power series in k^2 times a factor $k^{-\mu+1/2}$ and $k^{\mu+1/2}$, respectively. This follows from their definition (V.4) and the series expansions of the Bessel functions $J_{-\mu}(kr),J_\mu(kr)$; see, e.g., Refs. 34, 35. From (V.9) we see that also $\phi(r;k,\mu)$ can be written as a convergent power series in k^2 times $k^{\mu+1/2}$, since the Green's function is an even function in k. Therefore, in a suitably small chosen neighborhood of $k=0$ the Jost function can be expanded in a convergent series of the form

$$F(k,\mu)=\sum_{n=0}^{\infty} a_n(\mu)k^{2n}+k^{2\mu}\sum_{n=0}^{\infty} b_n(\mu)k^{2n}, \quad |k|\ll 1. \tag{V.29}$$

Recall our convention to place the branch cut of F along the negative imaginary axis. The assumption $F(0,\mu)=0$ gives $a_0=0$. In order to deduce from this expansion the small energy behavior of F, we need to know the first nonvanishing coefficient in (V.29). We claim $a_1(\mu)\neq 0$ for $\mu>1$ and $b_0(\mu)\neq 0$ for $\mu<1$. But then we have

$$F(k,\mu)=\begin{cases}\mathcal{O}(k^{2\mu}), & \text{if } \mu<1,\\ \mathcal{O}(k^2), & \text{if } \mu>1.\end{cases}$$

Thus, evaluating the integral over the semi-circle C_ρ yields

$$\lim_{\rho\to 0}\frac{1}{2i}\oint_{C_\rho} d\ln F=\begin{cases}-\pi\mu, & \text{if } \mu<1,\\ -\pi, & \text{if } \mu>1.\end{cases} \tag{V.30}$$

In order to prove the claim we consider the limit $\lim_{k\to 0}k^{-1}(\partial/\partial k)F$. If we can show that

$$\lim_{k\to 0}k^{-1}\frac{\partial}{\partial k}F(k,\mu)=\begin{cases}\infty, & \text{if } \mu<1,\\ C(\mu)\neq 0, & \text{if } \mu>1,\end{cases}$$

then the claim follows, as can be inferred directly from (V.29). We calculate the expression $(\partial/\partial k)F$ by making use of the identity (V.18). Since the solutions χ^+, ϕ are ill defined for $k\to 0$ we consider instead the modified solutions

$$\Psi(r;k,\mu):=k^{\mu-1/2}\chi^+(r;k,\mu) \quad \text{and} \quad \Phi(r;k,\mu):=k^{-\mu-1/2}\phi(r;k,\mu),$$

which are both finite and nonvanishing at $k=0$. This can be seen by taking the limit $k\to 0$ in the defining integral equations (V.7) and (V.13), respectively. In particular, one then derives that $\Phi(r;0,\mu)$ behaves like $r^{\mu+1/2}$ for $r\to 0$ and $\Psi(r;0,\mu)$ like $r^{-\mu+1/2}$ for $r\to\infty$. In terms of Φ, Ψ the Jost function and its derivative w.r.t. k (denoted by a dot) then read as

$$F=W(\Psi,\Phi) \quad \text{and} \quad \dot F=W(\dot\Psi,\Phi)+W(\Psi,\dot\Phi).$$

Since Ψ is a solution of the radial equation one easily verifies the identity

$$\frac{\partial}{\partial r}W[\Psi(r;k,\mu),\Psi(r;k',\mu)]=(k^2-k'^2)\Psi(r;k,\mu)\Psi(r;k',\mu).$$

Differentiating w.r.t. k and setting subsequently $k=k'$ one obtains from this the relation

$$W[\dot\Psi(r;k,\mu),\Psi(r;k,\mu)]=-2k\int_r^\infty dr'\,\Psi(r';k,\mu)^2, \tag{V.31}$$

where the r.h.s. is finite for $\operatorname{Im}k>0$. The assumption $F(0,\mu)=0$ implies that the regular and the irregular solution are proportional when $k=0$, i.e., $\Psi(r;0,\mu)=\kappa(\mu)\Phi(r;0,\mu)$ holds. Note that the proportionality factor $\kappa(\mu)$ is nonzero and finite because both solutions are nonvanishing. Thus, in the limit $k\to 0$ we have

$$\dot F(0,\mu)=\kappa(\mu)^{-1}W(\dot\Psi(r;0,\mu),\Psi(r;0,\mu))+\kappa(\mu)W(\Phi(r;0,\mu),\dot\Phi(r;0,\mu)).$$

However, $\dot{F}(0,\mu)$ does not depend on r whence we can set $r=0$ in the last equation. Since the regular solution Φ vanishes at $r=0$ we obtain from (V.31),

$$\lim_{k\to\infty} k^{-1}\frac{\partial}{\partial k}F(k,\mu)=\lim_{k\to 0} k^{-1}\kappa(\mu)^{-1}W[\dot{\Psi}(0;k,\mu),\Psi(0;k,\mu)]$$

$$=-2\kappa(\mu)^{-1}\int_0^\infty dr\Psi(r;0,\mu)^2$$

$$=-2\kappa(\mu)\int_0^\infty dr\Phi(r;0,\mu)^2. \tag{V.32}$$

The irregular solution Ψ falls off like $r^{-\mu+1/2}$ for large r and is proportional to the regular solution Φ at $k=0$, therefore the r.h.s. of (V.32) is finite for $\mu>1$. This means that the regular solution is square integrable and hence a proper eigensolution of the full Hamiltonian h_μ. The number of bound states is thus $n_\mu=n'_\mu+1$, whence we read off from (V.27) and (V.30) that Levinson's theorem also holds in case $F(0,\mu)=0$ when $\mu>1$.

For $\mu<1$, however, the regular solution is no longer square integrable and the expression (V.32) is divergent. Hence the number of bound states is given by $n_\mu=n'_\mu$ and from (V.27) and (V.30) we infer the modified equation (V.25). This completes the proof. □

VI. THE δ-POTENTIAL

In this section we will introduce and discuss the δ-potential, often also called the contact potential or zero-range interaction potential because it describes an interaction which is ''nonvanishing'' only if the two particles are at the same place, i.e., if $z_{rel}=0$. In the literature this figures also under the notion of anyons without a hard-core condition.[23] See, e.g., Refs. 51–53 for previous articles on this subject also in connection with field theoretic considerations.

To introduce the δ-potential we follow a standard strategy (see, e.g., Ref. 54), i.e., we consider the free Hamiltonian (in the center of mass system) restricted to a definition domain of wave functions which vanish at $z_{rel}=0$. The resulting operator has deficiency indices (1,1) and so there is a one-parameter family of self-adjoint extensions, one of which is of course the ordinary free Hamiltonian given as the Friedrich's extension. We discuss the bound state problem and the resulting scattering theory. We also check the validity of Levinson's theorem.

Note that Aharonov–Bohm scattering on $\mathbb{R}^2$ with δ-type interactions have been discussed in Refs. 55, 56. On $\mathbb{R}^2$ deficiency indices are (2, 2), leading to a four-parameter family of self-adjoint extensions. By specializing to symmetric functions one can obtain some of the results below.

For a start, consider the operator

$$h_{0,\mu}=-\partial_r^2+\frac{\mu^2-4^{-1}}{r^2},$$

on $\mathcal{L}^2(\mathbb{R}^+,dr)$ [recall (V.1)] with domain of definition $\mathcal{D}(h_{0,\mu})$ consisting of wave functions $\psi(r)$ having compact support away from the origin such that ψ and $\partial_r\psi$ are locally absolutely continuous and such that $h_{0,\mu}\psi$ (defined in the sense of distributions) is an element of $\mathcal{L}^2(\mathbb{R}^+,dr)$. Recall that locally absolutely continuous functions are such that their derivatives in the sense of distributions are locally integrable functions (see, e.g., Ref. 57).

Let us now investigate the most general solution of the equation $h_{0,\mu}\psi=0$, given by

$$c_1\cdot r^{1/2+\mu}+c_2\cdot r^{1/2-\mu}.$$

Using Weyl's terminology (consult, e.g., Ref. 58), one has the limit point case at $r=\infty$. At $r=0$ one also has the limit point case if and only if $\mu\geqslant 1$, otherwise one has the limit circle case. If now $0\leqslant\mu<1$, by Weyl's alternative there is exactly one solution of $h_{0,\mu}\psi=0$, which is $\mathcal{L}^2$ near infinity. By construction this solution must be $\mathcal{L}^2$ at both infinity and at zero, and thus it follows that $\dim(\ker(h_{0,\mu}\pm i))=1$ by Weyl's alternative. Therefore the deficiency indices are (1,1) and there is a one-parameter family of s.a. extensions (see e.g. Ref. 50).

In terms of the statistics parameter α we have the following situation: If one chooses $\alpha=1$, then $\mu=|2m+\alpha|\geqslant 1$ for all $m\in\mathbb{Z}$ and all the $\{h_{0,\mu}\}$ are essentially self-adjoint. Now, if $\alpha\in[0,1)$ we have $\mu<1$ if and only if $m=0$. In this case, just as in the three-dimensional case, the δ-potential affects only one of the angular momentum channels, namely, the one associated with the smallest eigenvalue in the sense of the modulus (in three dimensions called the *s*-channel).

Let α be in $[0,1)$. To construct the s.a. extensions of the operators $h_{0,\alpha}$ with domain $\mathcal{D}(h_{0,\alpha})$ given above, following Refs. 42, 54 we define the regular and irregular solutions of $h_{0,\alpha}\psi=0$:

$$F_\alpha(r):=r^{1/2+\alpha}\quad\text{(regular)},$$

$$G_\alpha(r):=F_\alpha(r)\int_r^{r_0}dr'(F_\alpha(r'))^{-2}\quad\text{(irregular)},$$

where $r_0\in\mathbb{R}^+$ may be chosen arbitrary. The choice $r_0=1$ gives

$$G_\alpha(r)=\begin{cases}\dfrac{1}{2\alpha}(r^{1/2-\alpha}-r^{1/2+\alpha}), & \alpha>0,\\ -\sqrt{r}\ln r, & \alpha=0.\end{cases}$$

In order to explicitly construct the s.a. extensions of the $\{h_{0,\alpha}\}$ we take recourse to the following theorem, to be found in, e.g., Ref. 58.

Theorem VI.1: *For $\alpha<1$ the operator $h_{0,\alpha}$ with domain $\mathcal{D}(h_{0,\alpha})$ has a one-parameter family of s.a. extensions $\{h_{0,\alpha}(s)\}_{s\in\mathbf{R}}$ which are essentially s.a. on the domains*

$$\mathcal{D}(h_{0,\alpha}(s))=\{\psi\in\mathcal{D}(h_{0,\alpha}^*)|\lim_{r\downarrow 0}W(\psi_{\alpha,s},\psi)(r)=0\}.\tag{VI.1}$$

Here again W is the Wronskian and

$$\psi_{\alpha,s}:=G_\alpha+sF_\alpha.$$

The choice $s=\infty$ gives the Friedrich's extension.

In Appendix D we will prove the following.

Theorem VI.2: *The integral kernel of the resolvent of $h_{0,\alpha}(s)$ for $\alpha<1$ is given as*

$$\frac{1}{h_{0,\alpha}(s)-k^2}(r,r')=\frac{i\pi}{2}\sqrt{rr'}J_\alpha(kr_<)H_\alpha^{(1)}(kr_>)-A(k,\alpha;s)\cdot\sqrt{rr'}H_\alpha^{(1)}(kr)H_\alpha^{(1)}(kr'),\tag{VI.2}$$

where k satisfies $0<\arg(k)<\pi$. $A(k,\alpha;s)$ is given as

$$A(k,\alpha;s)=\frac{\pi}{2}\left[\left(\frac{k}{2}\right)^{-2\alpha}(2s\alpha-1)\frac{1}{\sin\pi\alpha}\frac{\Gamma(1+\alpha)}{\Gamma(1-\alpha)}+\cot\pi\alpha-i\right]^{-1}.\tag{VI.3}$$

Note that $\lim_{s\to\infty}A(k,\alpha;s)=0$ such that with (VI.2) in the limit $s\to\infty$ we indeed recover the kernel of the resolvent of the Friedrich's extension (V.6). Taking the ''bosonic limit'' $\alpha\to 0$ one arrives at the expression

$$A(k,0;s)=\frac{\pi^2}{4}\left[\ln\frac{k}{2i}+\gamma+s\right]^{-1}\quad(\gamma:\ \text{Euler's constant}).$$

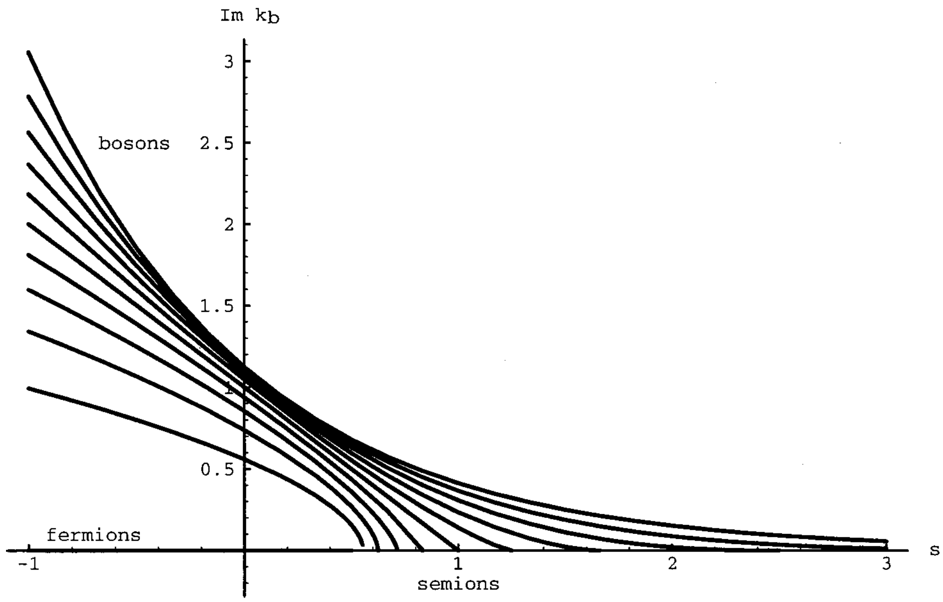

FIG. 1. Bound state energies.

Combined with (VI.2) we have arrived at an expression for the resolvent of the δ-potential in the bosonic case, which agrees with Ref. 54.

We turn to the discussion of the bound states. It can be shown that the essential spectrum as a set is equal to $\mathbb{R}_0^+$ and that $\mathbb{R}^+$ is the purely absolutely continuous spectrum. We therefore have to look for poles of the resolvent at energies $E_b=k_b^2<0$. By (VI.2) we have to search for the poles of $A(k,\alpha;s)$ as a function of k, and by (VI.3) this gives the condition

$$k_b^{2\alpha}=2^{2\alpha}e^{i\pi\alpha \bmod 2\pi i}\frac{\Gamma(1+\alpha)}{\Gamma(1-\alpha)}(1-2\alpha s). \tag{VI.4}$$

The restriction $0<\arg(k)<\pi$ now implies $0<\arg(k^{2\alpha})<2\pi\alpha$. Applying this condition to (VI.4) leads to three different cases.

(i) $1-2\alpha s>0$: Then (VI.4) may be solved to give

$$k_b=k_b(\alpha,s)=2i\left(\frac{\Gamma(1+\alpha)}{\Gamma(1-\alpha)}(1-2\alpha s)\right)^{1/2\alpha},$$

i.e., k_b is purely imaginary. The case $k_b=0$ occurs when $\alpha\uparrow 1$. Note that this requires $0\leqslant s<\frac{1}{2}$. Hence there is exactly one bound state.

(ii) $1-2\alpha s<0$: Since by definition $0\leqslant\alpha<1$, it is easy to see that in this case there is no solution to Eq. (VI.4), only in the limit $\alpha\uparrow 1$ one obtains $k_b=0$. This means that there is no bound state.

(iii) $1-2\alpha s=0$: This immediately gives $k_b=0$, which implies that there is no bound state.

For comparison we recall that in the three-dimensional case the attractive δ-potential supports, at most, one bound state. A bound state exists if the particles obey bosonic statistics. For fermions there is none. In the present context a bound state always exists for $\alpha=0$ (bosons) and disappears at the latest when $\alpha=1$ (fermions). The fact that for $\alpha=0$ there is always a bound state suggests that in two dimensions there is no such thing as a repulsive δ-potential.

Below we argue that case (iii) corresponds to a zero energy resonance in three-dimensional Schrödinger theory. Figure 1 gives a plot of $|k_b(\alpha,s)|$ as a function of s for various values of α in case (i), i.e., when $1-2\alpha s>0$. To calculate the bound state wave function ψ_b when $1-2\alpha s<0$, we note that

$$\frac{1}{h_{0,\alpha}(s)-k^2}\approx\frac{1}{k_b^2-k^2}P_b,$$

for $k\approx k_b$ where P_b is the orthogonal projector onto the eigenspace of energy $E_b=k_b^2<0$. Since this pole of the resolvent is isolated, P_b may be calculated as a residue. The calculation is easy and shows that P_b is indeed one-dimensional and that the associated (normalized) eigenfunction ψ_b is given as

$$\psi_b(r;\alpha)=\left(\frac{2\sin\pi\alpha}{\pi\alpha}\right)^{1/2}\sqrt{r|E_b|}K_\alpha(|k_b|r),$$

for $\alpha<1$ and hence $|k_b(\alpha,s)|>0$. For any fixed $\alpha<1$ the wave function decays exponentially for large r, which guarantees square-integrability. In the limit $\alpha\uparrow 1$ the bound state wave function approaches $r^{-1/2}$ times a normalization constant, which is not square integrable. The case $\alpha=1$ should therefore be considered as a resonance at $E=0$.

We turn to a discussion of the resulting scattering theory. First we note that due to relation (VI.2) the difference of the resolvents for $h_{0,\alpha}(s)$ and the free Hamiltonian $h_{0,\alpha}(s=\infty)$ is a rank-one operator and therefore in particular trace class. Therefore the S-matrix exists and is unitary by the Kuroda–Birman theorem (see, e.g., Ref. 27).

Theorem VI.3: *For given α and $E=k^2>0$ the outgoing states for the Hamiltonian $h_{0,\alpha}(s)$ are given as*

$$\phi^+(r;k,\alpha)=\phi_0(r;k,\alpha)+\frac{2i}{\pi}A(k,\alpha;s)\cdot\chi_0^+(r;k,\alpha).$$

In particular, the resulting partial wave amplitude and the phase shift take the form

$$f(k,\alpha;s)=\frac{4i}{\pi}\frac{A(k,\alpha;s)}{\sqrt{\pi ik}},\tag{VI.5a}$$

$$e^{2i\delta(k,\alpha;s)}=1+\frac{4i}{\pi}A(k,\alpha;s).\tag{VI.5b}$$

Proof: We start by rewriting the resolvent (VI.2) as

$$\frac{1}{h_{0,\alpha}(s)-k^2}(r,r')=\left(\phi_0(r_<;k,\alpha)+\frac{2i}{\pi}A(k,\alpha;s)\chi_0^+(r_<;k,\alpha)\right)\frac{i}{k}\chi_0^+(r_>;k,\alpha).\tag{VI.6}$$

Now we observe that (see, e.g., Ref. 54, p. 37)

$$\lim_{\epsilon\downarrow 0}\lim_{r'\to\infty}e^{-i(k+i\epsilon)r'}\frac{1}{h_{0,\alpha}(s)-(k+i\epsilon)^2}(r,r')\tag{VI.7}$$

must be proportional to the outgoing solution $\phi^+(r;k,\alpha)$. The claim now follows by applying (VI.7) to (VI.6). □

In view of Levinson's theorem we would like to make the following comments on this last result: The limiting values of $\delta(k,\alpha;s)$ at $k\to 0^+$ and $k\to\infty$ are *a priori* determined up to an additive constant in $\pi\cdot\mathbb{Z}$, only. We shall choose these constants in such a way, that $\delta(k,\alpha;s)$ as a function of $k \in \mathbb{R}^+$ can be defined as a continuous function of k. Now, $\exp(i2\delta(k,\alpha;s))$ is of the form $(a(k;\alpha;s)+i)(a(k,\alpha;s)-i)^{-1}$. Here $a(k,\alpha;s)$ is a real-valued, continuous function of k. Explicitly,

$$a(k,\alpha;s)=\frac{\pi}{2}A(k,\alpha;s)^{-1}+i.$$

[This observation also shows that the right hand side of (VI.5b) is indeed unimodular.] Hence

$$\delta(k,\alpha;s)=\arg(a(k,\alpha;s)+i).$$

Here the branch of $\arg(\cdot)$ is chosen such that $\delta(k,\alpha;s)$ is a continuous function of all its arguments. In particular, we can achieve $\delta(k,\alpha;s)\in(0,\pi)$, for any k and fixed $\alpha<1$ and s. For the cases, where there is a bound state, this is consistent with the attractive nature of the interaction. By the explicit form of $a(k,\alpha;s)$, it is easily seen that

$$\delta(k,\alpha;s)\xrightarrow{k\to 0^+}\pi\frac{1-\mathrm{sgn}(2\alpha s-1)}{2},$$

$$\delta(k,\alpha;s)\xrightarrow{k\to\infty}\pi\alpha.$$

The fraction $n:=[1-\mathrm{sgn}(2\alpha s-1)]/2$ takes values in $\{0, 1\}$ and is, in fact, nothing but the number of bound states given by (VI.4). We therefore have the following relation:

$$\delta(0^+,\alpha;s)-\delta(\infty,\alpha;s)=\pi(n-\alpha), \tag{VI.8}$$

which is *not* of the form one would naively expect in view of Levinson's theorem V.2. In this context we note that the statement of Levinson's theorem also fails in the nonanyonic three-dimensional case, if a δ-interaction is considered. However, we obtain a formula similar to (V.26) relating the phase shift to the statistics parameter α.

By relations (IV.8) and (V.21), we obtain the following expression for the differential cross-section:

$$\frac{d\sigma}{d\theta}=|f(k,\alpha;s)\cdot e^{-i\pi\alpha}+f_{AB}(k,\theta)|^2,$$

where f_{AB} and f are given by expressions (II.16) and (VI.5a), respectively. Inserting these explicit expressions, one obtains—away from the forward direction—the following relation:

$$\frac{d\sigma}{d\theta}=\frac{1}{\pi k}\left|\sin\pi\alpha(\cot\theta-i)+e^{-i\pi\alpha}\frac{4i}{\pi}A(k,\alpha;s)\right|^2.$$

So far, we have been unable to analyze this in a non-numerical way. Figures 2 and 3 show some numerical results of the differential cross-section as a function of the scattering angle θ. Displayed is the deviation from pure Aharonov–Bohm scattering, which is asymptotically reached when $s\to\pm\infty$. Note the simultaneous cross over at $\theta=\pi\alpha$ for varying s in each of the plots with $s\neq\pm\infty$. In particular, the point corresponding to the cross over always lies on the graph ($s=\pm\infty$) associated with the Aharonov–Bohm cross-section. We like to point out that in both Figs. 2 and 3 only for $s=0,2$ and $\alpha=0.5$ (semions) the differential cross-section actually vanishes for some scattering angle θ. In the other cases the cross-section becomes very small but is nonvanishing for all θ.

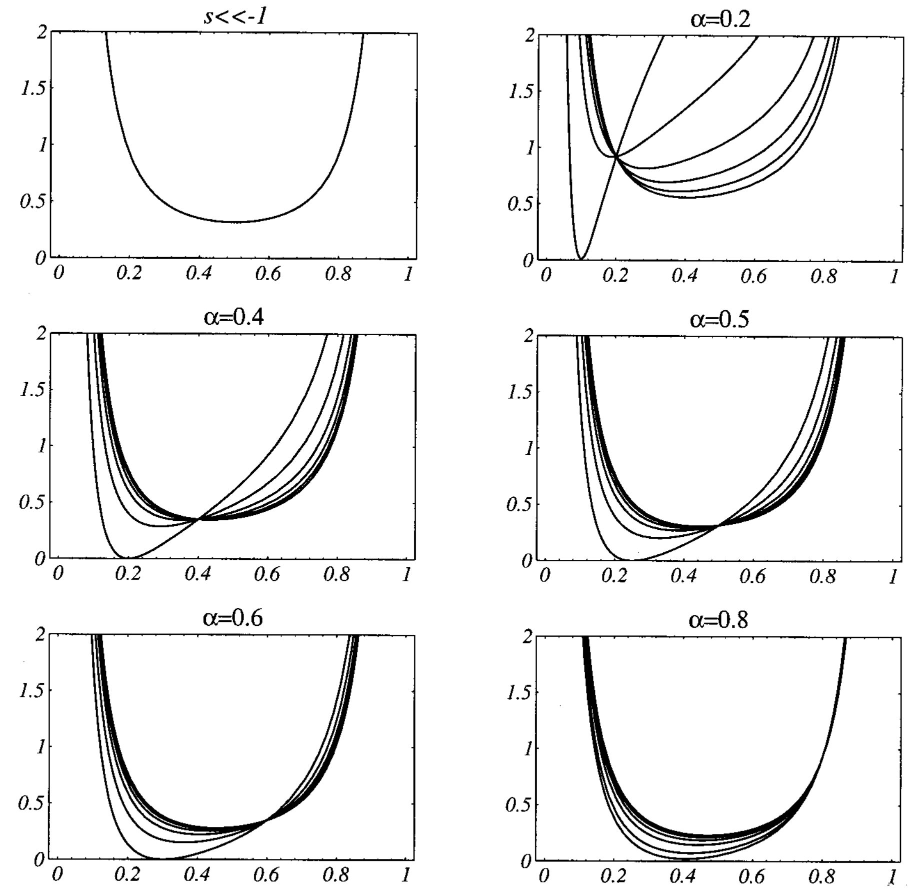

FIG. 2. Cross-sections for contact interaction 1.

VII. THE SQUARE WELL POTENTIAL

Another explicitly solvable problem in scattering theory is given by the square well,

$$V(r)=\begin{cases}-V_0, & r\leqslant d,\\ 0, & r>d,\end{cases} \quad \text{with} \quad V_0>0.$$

The regular solution of the eigenvalue problem $(h_\mu-k^2)\psi=0$ in the interval $0<r\leqslant d$ is given by

$$\phi(r;k,\mu)=\left(\frac{k}{q}\right)^{\mu+1/2}\phi_0(r;q,\mu), \quad \text{where} \quad q=\sqrt{k^2+V_0}.$$

For $r>d$ the eigensolutions of h_μ obey the free radial equation and hence the Jost solutions in this interval are just given by the free solutions,

$$\chi^{\pm}(r;k,\mu)=\chi_0^{\pm}(r;k,\mu), \quad r>d.$$

Making the usual requirement that all solutions are continuously differentiable we can evaluate the Wronskian $W(\chi^{\pm},\phi)$ at $r=d$ and obtain the following expression for the Jost function:

$$F(k,\mu)=\left(\frac{k}{q}\right)^{\mu-1/2}\left[\chi_0^{+}(d;k,\mu)\phi_0(d;q,\mu-1)-\frac{k}{q}\chi_0^{+}(d;k,\mu-1)\phi_0(d;q,\mu)\right].$$

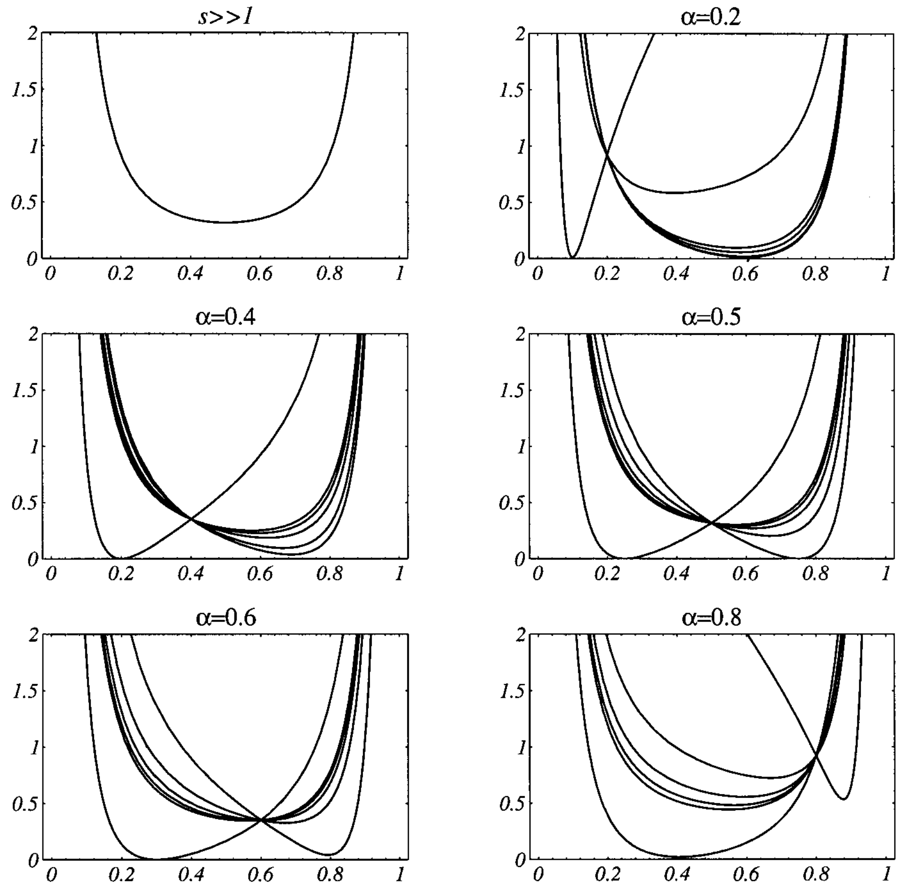

FIG. 3. Cross-sections for contact interaction 2.

Here, we have used the common differentiation rules for Bessel and Hankel functions (see, e.g., Refs. 34, 35). With the help of the Jost function we can now calculate the phase shift and the partial wave amplitude. We find

$$\tan \delta(k,\mu) = i\,\frac{F-\overline{F}}{F+\overline{F}} = \frac{qJ_\mu(kd)J_{\mu-1}(qd) - kJ_{\mu-1}(kd)J_\mu(qd)}{qY_\mu(kd)J_{\mu-1}(qd) - kY_{\mu-1}(kd)J_\mu(qd)},$$

$$f(k,\mu) = \frac{\overline{F}-F}{\sqrt{\pi ik}F} = \frac{-2}{\sqrt{\pi ik}}\,\frac{qJ_\mu(kd)J_{\mu-1}(qd) - kJ_{\mu-1}(kd)J_\mu(qd)}{qH_\mu^{(1)}(kd)J_{\mu-1}(pd) - kH_{\mu-1}^{(1)}(kd)J_\mu(qd)}.$$

Inserting the last expression into the formula (V.21) for the partial wave decomposition of the scattering amplitude we can calculate the differential cross-sections for various parameters α. Note that for small momenta we can make use of the small energy behavior of the partial wave amplitude, which is given by

$$k \to 0: \quad f(k,\mu) = \mathcal{O}(k^{2\mu-1}).$$

Thus, when calculating the scattering amplitude in the partial wave decomposition the partial wave amplitudes for higher angular momentum hardly contribute to the infinite sum in (V.21). According to our discussion in Sec. IV we have to add the Aharonov–Bohm scattering amplitude f_{AB} in order to obtain the differential cross-section [see (IV.8)]. A numerical example is displayed in Fig.

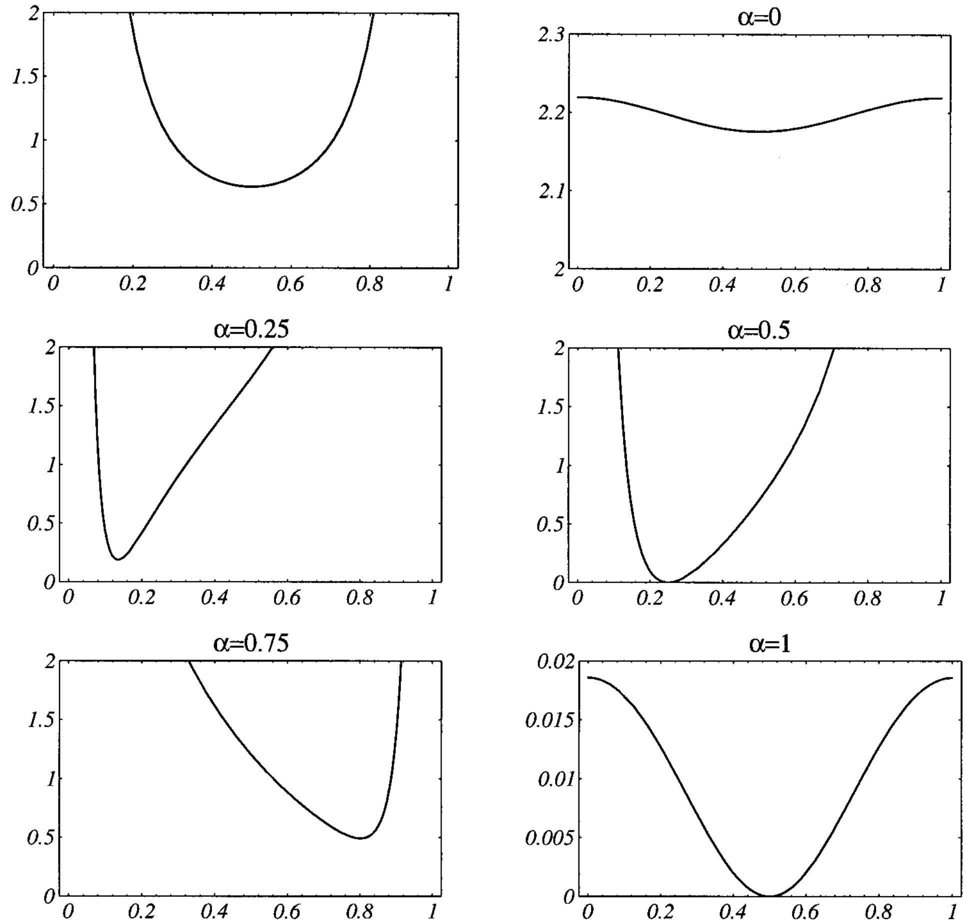

FIG. 4. Square well cross-sections.

4. For different values of the statistics parameter α one obtains very different angular distributions of the scattered particles. One observes the interpolation between the bosonic ($\alpha=0$) and the fermionic ($\alpha=1$) cross-section at energy $E=k^2=0.25$. Note that the singularities at the scattering angles $\theta=0$ and $\theta=\pi$ for $\alpha\notin\mathbb{Z}$ enter due to the long range nature of the statistics. In fact, according to (IV.8) they result from adding the Aharonov–Bohm amplitude given in (II.16). For fermions ($\alpha=1$) there is no scattering under an angle of $\theta=\pi/2$, as is well known. The figure for $\alpha=0.5$ shows that a similar effect can take place for fractional statistics.

According to our discussion in Sec. V the zeros of the Jost function F lie on the positive imaginary axis and determine the bound states. Thus, plotting the solutions of

$$F(ik,\mu)=0, \quad k>0,$$

we get so called (real) Regge trajectories (see, e.g., Ref. 47) displaying the μ dependence of the discrete spectrum of h_μ. Figure 5 provides a numerical example. In contrast to three-dimensional scattering theory here every point on the Regge trajectories has a specific physical meaning because the statistics parameter α interpolates between the integer-valued angular momentum channels.

VIII. CONCLUSION

We have demonstrated that it is possible to formulate nonrelativistic quantum scattering theories for two particles obeying anyon statistics. In particular, we have proven the existence of

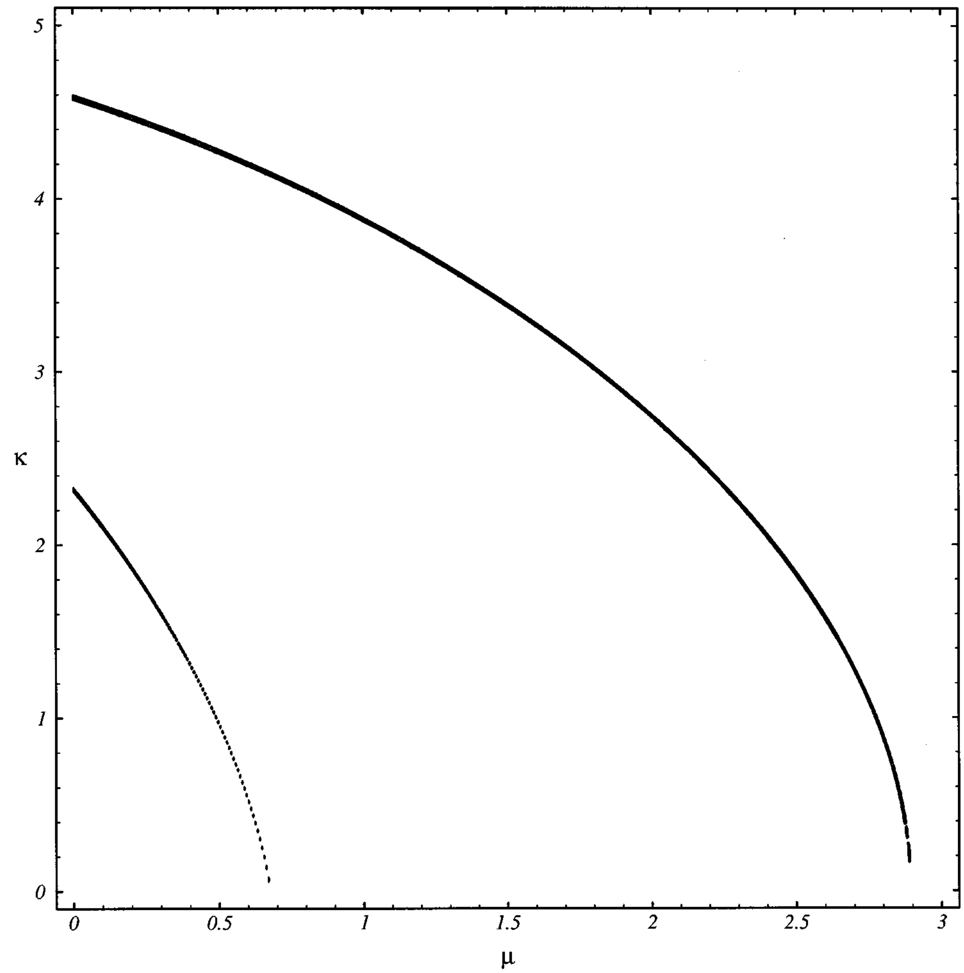

FIG. 5. Regge trajectories for the square well.

the wave operators under certain assumptions concerning the interaction. For spherically symmetric potentials we gave the criteria for completeness, i.e., unitarity of the *S*-matrix. These criteria turned out to be the same as in three-dimensional Schrödinger theory. It remains an open problem to show completeness in the general case in a way comparable to Enss' method. To generalize the latter, we believe it is crucial to obtain a better analytic control of the propagator. (There is an extensive literature on a similar problem, namely, to obtain a closed form of the Aharonov–Bohm propagator, see, e.g., Ref. 37.) We extended the notion of a differential cross-section to two dimensions and showed that in case of anyon statistics, the corresponding scattering amplitude consists of two parts. The first encodes the anyon statistics and resembles the Aharonov–Bohm amplitude, while the second is relevant to spectral analysis of the perturbed Hamiltonian. For spherically symmetric potentials we carried out this analysis by introducing Jost functions and showed how fractional statistics is equivalent to fractional angular momentum. We also showed that Levinson's theorem holds in the conventional case and gave the modifications necessary in the presence of a zero energy resonance. In the latter case we found that for positive angular momentum $\mu<1$ the statistics parameter—independently of the detailed form of the short range potential—can be determined from the scattering phase, namely [compare (V.26)]

$$\alpha \equiv \frac{1}{\pi}(\delta(k=0,\alpha)-\delta(k=\infty,\alpha)) \bmod \mathbb{Z}.$$

We then applied our results to the following two examples. First we considered the δ-potential, where we extracted information regarding the point spectrum of the perturbed Hamiltonian from its resolvent and showed that the above relation between the statistics parameter and scattering phase is also valid in this context [compare (VI.8)]. Second, we considered the square well potential, where we obtained similar information from the corresponding Jost function. In both situations we numerically evaluated the differential cross-section for noninteger values of the statistics parameter. It then became evident that fractional statistics is fundamentally different from Bose and Fermi statistics: The statistical gauge forces produce singularities of the differential cross-section in the forward direction, showing the long range nature of these forces. Due to this fact the angular dependence of the statistical interaction will invariably show up in the scattering data. In particular, this might cause a differential cross-section which is constant for bosons or fermions, but which becomes angular-dependent for intermediate statistics. Our discussion of the δ-potential provides an example.

The results presented in this paper may also be relevant to the investigation of bulk properties of anyon matter, via the relation between the virial coefficients and the scattering data.[20] This we intend to discuss in a forthcoming publication.

ACKNOWLEDGMENTS

The authors would like to thank Jens Mund for numerous discussions concerning the differential geometric formulation of fractional statistics and valuable comments on the results of this paper. This work was supported in part by DFG Sfb 288 ''Differentialgeometrie und Quantenphysik.''

APPENDIX A: THE BUNDLE THEORETIC FORMULATION

In Sec. II we used the physical picture of particles carrying flux-tubes in order to describe the anyon model. Anyons, however, are but a special case in a more general class of particles, called plektons, obeying neither Bose nor Fermi statistics. In this appendix we give a short review of plektonic systems, i.e., systems of n particles whose statistics are determined by a finite-dimensional unitary representation of the braid group B_n. The appropriate mathematical tool to describe such particles is the concept of vector bundles. This will, in particular, provide the Hilbert space and a canonical ''free'' dynamics described by a certain Laplace operator. Our presentation will closely follow the one given in Refs. 30, 31, where, however, emphasis was mainly given to relativistic formulations using momentum space considerations. For other references on the bundle theoretic formulation see, e.g., Refs. 32, 33. We continue to use $\mathbb{C}$ to describe the one-particle configuration space. Let $\mathbb{C}^{\times n}$ denote the n-fold product, viewed as the configuration space for n distinguishable particles. The set D_n in $\mathbb{C}^{\times n}$ is the set of all points $z=(z_1,z_2,\ldots,z_n)$ with $z_i=z_j$ for at least one pair of different indices. Any element σ of the permutation group S_n acts in an obvious way on $\mathbb{C}^{\times n}$ via $(z\sigma)_i=z_{\sigma(i)}$. We define the configuration space of n identical particles in two dimensions to be

$$^{n}\mathbb{C}:=(\mathbb{C}^{\times n}\setminus D_n)/S_n,$$

with points in it denoted by $\underline{z}$. Let $^{n}\tilde{\mathbb{C}}$ denote the universal covering space of $^{n}\mathbb{C}$ with points there being written as $\tilde{z}$ and let π: $^{n}\tilde{\mathbb{C}}\to {}^{n}\mathbb{C},\tilde{z}\mapsto\pi(\tilde{z})=\underline{z}$ be the associated projection mapping.

It is well-known that the fundamental group of $^{n}\mathbb{C}$, denoted by $\pi_1(^{n}\mathbb{C})$, is isomorphic to the braid group B_n and that any element $b\in B_n$ acts in a standard way from the right $\tilde{z}\mapsto\tilde{z}b$ on the manifold $^{n}\tilde{\mathbb{C}}$. Furthermore, the universal covering $^{n}\tilde{\mathbb{C}}\mapsto{}^{n}\mathbb{C}$ can be viewed as a principal fiber bundle over $^{n}\mathbb{C}$ with structure group $\pi_1(^{n}\mathbb{C})$ and fiber $\pi^{-1}(\underline{z})$ for any $\underline{z}\in{}^{n}\mathbb{C}$. Given any finite-dimensional unitary representation $b\mapsto\rho(b)$ of B_n in a Hilbert space F with scalar product $\langle\cdot|\cdot\rangle$ there is an associated Hermitian vector bundle. This vector bundle $\mathcal{F}$ with base space $^{n}\mathbb{C}$ is given by $^{n}\tilde{\mathbb{C}}\times_{\rho,B_n}F$, which by definition is the set of orbits in $^{n}\tilde{\mathbb{C}}\times F$ under the following action of B_n on this space:

$$b:(\tilde{z},f)\mapsto(\tilde{z}b,\rho(b^{-1})f),\quad \tilde{z}\in{}^{n}\tilde{\mathbb{C}},\ \ f\in F. \tag{A1}$$

$\mathcal{F}$ is a smooth fibered space with base ${}^{n}\mathbb{C}$ and fibers isomorphic to F. On the fiber over $\underline{z}$ there is a natural scalar product denoted by $\langle\cdot|\cdot\rangle_{\underline{z}}$. Furthermore, there is a canonical measure $d\mu(\underline{z})$ on ${}^{n}\mathbb{C}$ inherited from the Lebesgue measure on $\mathbb{C}^{\times n}$. This defines a scalar product on the space $\Gamma_c(\mathcal{F})$ of smooth sections in $\mathcal{F}$ with compact support via

$$\langle\psi|\phi\rangle:=\int_{{}^{n}\mathbb{C}}\langle\psi(\underline{z})|\phi(\underline{z})\rangle_{\underline{z}}d\mu(\underline{z}). \tag{A2}$$

By $\mathcal{L}^2(\mathcal{F})$ we denote the resulting Hilbert space completion. There is another Hilbert space equally well suited and canonically isomorphic to this space. Consider the set of maps Ψ: ${}^{n}\tilde{\mathbb{C}}\mapsto F$ which are smooth with $\pi(\mathrm{supp}\Psi)\subset{}^{n}\mathbb{C}$ being compact and which satisfy the equivariance property

$$\Psi(\tilde{z}b)=\rho(b^{-1})\Psi(\tilde{z}),\quad \forall\tilde{z}\in{}^{n}\tilde{\mathbb{C}},\ \ b\in B_n. \tag{A3}$$

For any two such functions Φ and Ψ we therefore have

$$\langle\Psi(\tilde{z}b)|\Phi(\tilde{z}b)\rangle=\langle\Psi(\tilde{z})|\Phi(\tilde{z})\rangle,\quad \forall\tilde{z}\in{}^{n}\tilde{\mathbb{C}},\ \ b\in B_n. \tag{A4}$$

Hence this expression depends on $\underline{z}=\pi(\tilde{z})$ only and so the integral over the base space makes sense and we may define a scalar product by

$$\langle\Psi|\Phi\rangle:=\int_{{}^{n}\mathbb{C}}\langle\Psi(\tilde{z})|\Phi(\tilde{z})\rangle d\mu(\underline{z}). \tag{A5}$$

The resulting Hilbert space obtained again by completion is denoted by $\mathcal{L}^2_{eq}({}^{n}\tilde{\mathbb{C}},F)$ and there is a canonical isomorphism between $\mathcal{L}^2(\mathcal{F})$ and $\mathcal{L}^2_{eq}({}^{n}\tilde{\mathbb{C}},F)$ (see, e.g., Refs. 30, 31). Furthermore the canonical (flat) Levi-Civita connection on $\mathbb{C}^{\times n}$ induces a (flat) connection on ${}^{n}\mathbb{C}$ which in turn defines a Hermitian connection $\boldsymbol{\nabla}$ on $\mathcal{F}$. The associated Bochner or generalized Laplacian (see, e.g., Ref. 59) $\Delta=\boldsymbol{\nabla}\circ\boldsymbol{\nabla}$ on $\mathcal{L}^2(\mathcal{F})$ is what defines a free Hamiltonian $H_0=-\Delta/2m$ for a system of n plektons, if $m>0$ is taken to be the mass of one particle.

When the unitary representation ρ of B_n is one-dimensional one speaks of anyons. Any such representation is obviously Abelian and can be shown to be of the form $b_k\mapsto\exp(i\alpha\pi)$ in terms of the generators $b_1,\dots,b_{n-1}\in B_n$ for a fixed $\alpha\in[0,2)$. This follows easily from the observation that all the b_k's are conjugate to each other. We denote the resulting line bundle by $\mathcal{F}_\alpha$. Another consequence of F being one-dimensional is that all anyonic line bundles are actually trivial. This observation was first made by Dowker,[60] based on Arnold's result that $H^2({}^{n}\mathbb{C},\mathbb{Z})=0$[61] and the classification theorem of Cartan, Kostant, Souriau and Isham. It was rediscovered by Gaberdiel[62] and is implicitly contained in Refs. 63 and 64. Another proof is given in Refs. 30, 31.

Let us now consider in more detail the Hilbert spaces constructed above when $n=2$. We first introduce relative coordinates by considering the following transformation of $\mathbb{C}^{\times 2}$:

$$(z_1,z_2)\mapsto(2^{-1}(z_1+z_1),z_1-z_2)=(z_{cen},z_{rel}). \tag{A6}$$

The transposition in $S_2\cong\mathbb{Z}_2$ obviously maps (z_{cen},z_{rel}) into $(z_{cen},-z_{rel})$. Therefore ${}^{2}\mathbb{C}$ is diffeomorphic to $\mathbb{C}\times\mathbb{C}^\star/\mathbb{Z}_2$. The first factor is the configuration space for the center of mass motion. The corresponding quantum mechanical discussion is analogous to ordinary multi-particle systems, since it is not affected by the statistics. Therefore we will concentrate on the second factor and the associated quantum mechanical description. In the same way as $\mathbb{R}$ is the universal covering space of S^1; the universal covering space of $\mathbb{C}^\star/\mathbb{Z}_2\cong\mathbb{R}^+\times S^1$ is given by $\mathbb{R}^+\times\mathbb{R}$ with the projection mapping

$$\pi:\mathbb{R}^+\times\mathbb{R}\to\mathbb{R}^+\times S^1,\quad \text{with}\quad (r,\theta)\mapsto(r,e^{2i\theta}). \tag{A7}$$

The action of B_2 on the universal covering is given in terms of its only generator b_1 as

$$(r,\theta)\mapsto(r,\theta)b_1:=(r,\theta+\pi). \tag{A8}$$

Choosing the representation $b_1\mapsto\exp(-i\pi\alpha)$ for a fixed $\alpha\in[0,1]$ we are prepared to construct the line bundle $\mathcal{F}_\alpha$ and the Hilbert space $\mathcal{L}^2(\mathcal{F}_\alpha)$, or equivalently $\mathcal{L}^2_{eq}({}^n\tilde{\mathbb{C}},F)$. The fact that the bundle $\mathcal{F}_\alpha$ is trivial is now reflected in the possibility to ''pull-down'' the theory from either of those $\mathcal{L}^2$ spaces onto the space of square integrable functions on ${}^n\mathbb{C}$ itself, denoted by $\mathcal{L}^2({}^n\mathbb{C})$. Explicitly there is the following unitary map from $\mathcal{L}^2({}^n\mathbb{C})$ onto $\mathcal{L}^2_{eq}({}^n\tilde{\mathbb{C}})$ given as

$$\psi\in\mathcal{L}^2({}^n\mathbb{C})\mapsto\Psi\in\mathcal{L}^2_{eq}({}^n\tilde{\mathbb{C}}),\quad\text{with}\quad\Psi(\tilde z)=e^{i\pi\alpha\cdot\theta(\tilde z)}\cdot\psi(\pi(\tilde z)),$$

where $\theta(\tilde z)$ is a real-valued, continuous function of $\tilde z$ induced by the polar angle. With the help of this unitary mapping, we can pull-down the Bochner Laplacean from $\mathcal{L}^2(\mathcal{F}_\alpha)$ to obtain an expression for the free Hamiltonian on $\mathcal{L}^2({}^n\mathbb{C})$. The result of this procedure is precisely the Hamiltonian we introduced in Sec. II on physical grounds.

Let it be noted that α was introduced as a parameter fixing the representation $B_2\ni b_1\mapsto\exp(-i\pi\alpha)$ and is hence determined up to an additive even integer, only. Therefore we lose no generality if we restrict α to the interval $[0, 2)$. In fact, we have $H_0(\alpha+2)=\exp(-i2\theta)H_0(\alpha)\exp(i2\theta)$, which is a gauge transformation reflecting the arbitrariness we have. On the other hand, time inversion causes α to change sign, i.e., if T denotes the anti-unitary operator of time inversion, we have $H_0(-\alpha)=TH_0(\alpha)T$. However, $H_0(-\alpha)$ is, in turn, equivalent to $H_0(2-\alpha)$ and consequently the anyon models with $\alpha\in[0,1]$ are connected to those with $\alpha\in[1,2]$ by time reversal. This justifies the restriction of α to the interval $[0, 1]$.

Furthermore, we remark that $\mathcal{L}^2(\mathbb{C}^\star/\mathbb{Z}_2,r\,dr\,d\theta)$ is unitary equivalent to the square integrable symmetric functions on the punctured plane $P_+\mathcal{L}^2(\mathbb{C}^\star,1/2r\,dr\,d\theta)$ and therefore the case $\alpha=0$ corresponds to the bosonic case [since $H_0(\alpha=0)=-\Delta$]. If $\alpha=1$ our model is equivalent to $H_0(\alpha=1)$ acting on $P_+\mathcal{L}^2(\mathbb{C}^\star)$, which is, in turn, unitary equivalent to $-\Delta$ on $P_-\mathcal{L}^2(\mathbb{C}^\star,1/2r\,dr\,d\theta)$, the Hilbert space of square integrable, anti-symmetric functions on the punctured plane. Hence we call anyons obeying statistics corresponding to $\alpha=1$ fermions.

APPENDIX B: SOME ESTIMATES

This appendix is devoted to a proof of the lemmas III.2 and III.3.

Proof of lemma III.2: For the moment let $0<\epsilon<1$ be arbitrary. Since $|e^{ix}-1|\le\min(2,|x|)$, we have $|e^{ix}-1|<2|x|^\epsilon$ for all $x\in\mathbb{R}$. This gives

$$|I_\alpha(\rho,\chi)-I_\alpha(0,\chi)|\le\left|\int_{-\infty}^{+\infty}dy(e^{i\rho\cosh y}-1)\,\frac{e^{-\alpha y}}{1-e^{-2y-2i\chi}}\right|$$

$$\le2\rho^\epsilon\int_0^\infty dy\,\cosh^\epsilon y\left|\frac{e^{-\alpha y}}{1-e^{-2y-2i\chi}}+\frac{e^{\alpha y}}{1-e^{2y-2i\chi}}\right|.$$

To proceed further, we split the integral into a part from 0 to 1 and the rest. This gives

$$|I_\alpha(\rho,\chi)-I_\alpha(0,\chi)|\le2\rho^\epsilon(\cosh(1)\cdot I_1(\chi)+I_2(\chi)).$$

For I_1 we have an expression involving the sum of three integrals $I_{1,1}$, $I_{1,2}$ and $I_{1,3}$, given by

$$I_1(\chi)=I_{1,1}(\chi)+I_{1,2}(\chi)+I_{1,3}(\chi)=\int_0^1dy\left|\frac{e^{-\alpha y}-1}{1-e^{-2y-2i\chi}}\right|+\int_0^1dy\left|\frac{e^{\alpha y}-1}{1-e^{2y-2i\chi}}\right|$$

$$+\int_0^1dy\left|\frac{1}{1-e^{-2y-2i\chi}}+\frac{1}{1-e^{2y-2i\chi}}\right|.$$

For I_2 we have the expression

$$I_2(\chi)=\int_1^\infty dy\,\cosh^\epsilon y\left(\left|\frac{e^{-\alpha y}}{1-e^{-2y-2i\chi}}\right|+\left|\frac{e^{\alpha y}}{1-e^{2y-2i\chi}}\right|\right).$$

The aim is to estimate these quantities for $\chi\in[-\pi,+\pi]$. To estimate $I_{1,1}(\chi)$ we use the following estimates:

$$2|1-e^{-\alpha y}|\leqslant 2y,\quad \text{for } y>0 \text{ and } \alpha\in(0,1); \tag{B1}$$

$$|1-e^{-2y-2i\chi}|\geqslant|1-e^{-2y}|,\quad \text{for } y\in\mathbb{R}. \tag{B2}$$

This gives

$$I_{1,1}(\chi)\leqslant\int_0^1 dy\,\frac{\alpha y}{1-e^{-2y}}<C.$$

$I_{1,2}(\chi)$ is estimated similarly, if one replaces the estimate (B1) by

$$0\leqslant e^{\alpha y}-1\leqslant 2e^2 y,\quad \text{for } 0\leqslant y\leqslant 1 \text{ and } \alpha\in(0,1).$$

To estimate $I_{1,3}(\chi)$ for $\chi\in[-\pi,+\pi]$ we first observe that for $\min(|\chi|,\pi-\chi,\pi+\chi)\geqslant\pi/4$ it is obviously bounded. Hence, it suffices to estimate the three remaining cases $|\chi|\leqslant\pi/4$, $3/4\pi\leqslant\chi\leqslant\pi$ or $-\pi\leqslant\chi\leqslant-3/4\pi$. We only consider the first case, since the other two cases may be discussed with similar arguments. So let $|\chi|\leqslant 1/4\pi$ and add and subtract $(\pm 2y+2i\chi)^{-1}$ in the integrand of $I_{1,3}(\chi)$. This way we can estimate $I_{1,3}$ by a sum of three integrals, which we will denote by $\hat{I}_i$,

$$I_{1,3}(\chi)\leqslant\hat{I}_1(\chi)+\hat{I}_2(\chi)+\hat{I}_3(\chi)=\int_0^1 dy\left|\frac{1}{1-e^{-2y-2i\chi}}-\frac{1}{2y+2i\chi}\right|+\int_0^1 dy\left|\frac{1}{1-e^{2y-2i\chi}}-\frac{1}{-2y+2i\chi}\right|+\int_0^1 dy\left|\frac{1}{2y+2i\chi}+\frac{1}{-2y+2i\chi}\right|.$$

To estimate $\hat{I}_1(\chi)$ and $\hat{I}_2(\chi)$ we note that the function

$$G(\zeta)=\frac{1}{1-e^{-\zeta}}-\frac{1}{\zeta},$$

is obviously analytic in $\{\zeta\in\mathbb{C}\,|\,|\mathrm{Im}(\zeta)|\leqslant\pi/2\}$, except possibly at the origin $\zeta=0$. However, $G(\zeta=0)=1$ and hence by Riemann's theorem, $G(\zeta)$ is an analytic function in that domain. In particular, $G(\zeta)$ is bounded on every compact subset, and this gives the boundedness of $\hat{I}_1(\chi)$ and $\hat{I}_2(\chi)$ for $\chi\in[-1/4\pi,1/4\pi]$. $\hat{I}_3(\chi)$ can be estimated as follows:

$$\hat{I}_3(\chi)\leqslant\int_0^1 dy\,\frac{|\chi|}{\chi^2+y^2}\leqslant\int_0^\infty d\eta\,\frac{1}{1+\eta^2}<\infty.$$

This concludes the estimate for $I_1(\chi)$ and it remains to estimate $I_2(\chi)$. By (B2) we have

$$I_2(\chi)\leqslant\int_1^\infty dy\,2e^{\epsilon y}\left(\frac{e^{-\alpha y}}{1-e^{-2y}}+\frac{e^{\alpha y}}{e^{2y}-1}\right).$$

Now this integral is finite whenever $\epsilon<\min(\alpha,1-\alpha)$. □

Proof of lemma III.3: We will consider the third partial derivatives w.r.t. E only, since this is actually the case we will need and since the other cases may be discussed similarly. By interchanging integration and differentiation we formally have

$$\frac{\partial^n}{\partial E^n} v_\alpha^{m,m'}(E,E') = \int_{\mathbb{H}\setminus\{0\}} \frac{\partial^n}{\partial E^n} [\overline{\phi_{\alpha;m,E}(z)} V(z)^2 \phi_{\alpha;m',E'}(z)] d\mu(z), \tag{B3}$$

for $n=1,2,3$. This is permitted provided the integrand is a measurable function in z, E and E', bounded in the sense of the modulus by a function which is in $\mathcal{L}^1$ w.r.t. z and with uniform bounds in E and E' in compact sets in $(0, \infty)$. To prove this claim it obviously suffices to replace $\partial/\partial E$ by $\partial/\partial k$ with $E=k^2$ in (B3). By the explicit form of $\phi_{\alpha;m,E}$ given in Sec. II, for fixed α, m and m' we therefore have to estimate the product

$$|\partial_k^n J_\mu(kr)| \cdot |J_\mu(k'r)| \cdot |V(r,\theta)|^2, \quad \text{for } n=1,2,3.$$

Using the formula to be found in Refs. 34 or 35,

$$\frac{d}{dk} J_\sigma(kr) = \frac{r}{2}(J_{\sigma-1}(kr) - J_{\sigma+1}(kr)), \tag{B4}$$

it follows by iteration that it suffices to estimate

$$r^n |J_{\mu+l}(kr)| \cdot |J_{\mu'}(k'r)| \cdot |V(r,\theta)|^2, \tag{B5}$$

for $-n \leqslant l \leqslant n$ with $0 \leqslant n \leqslant 3$. Let the compact set in question be given by $E_1 \leqslant E$, $E' \leqslant E_2$ such that $k_1 \leqslant k$, $k' \leqslant k_2$. Using the well known estimates

$$(a) \quad |J_\sigma(kr)| \leqslant C(\sigma), \quad \text{for } |kr| \leqslant 1,$$

$$(b) \quad |J_\sigma(kr)| \leqslant C(\sigma)(kr)^{-1/2}, \quad \text{for } |kr| \geqslant 1,$$

we see that (B5) with $k_1 \leqslant k$, $k' \leqslant k_2$ is bounded by

$$C(\mu,\mu') \cdot r^n |V(r,\theta)|^2 \leqslant C(\mu,\mu') \cdot \max(1,k_2^{-1})^3 |V(r,\theta)|^2,$$

for $r \leqslant k_2^{-1}$ and by

$$C(\mu,\mu') \cdot r^{n-1} k_1^{-1} |V(r,\theta)|^2 \leqslant C(\mu,\mu') \cdot \max(k_1^2, k_1^{-1}) \cdot r^2 |V(r,\theta)|^2,$$

for $r \geqslant k_1^{-1}$. Obviously (B5) is bounded for r in the interval (k_2^{-1}, k_1^{-1}) uniformly for $k_1 \leqslant k$, $k' \leqslant k_2$. This proves the claim and by our previous remark this concludes the proof. □

APPENDIX C: BOUNDS FOR JOST FUNCTIONS

In this section we will prove the estimates (V.11b), (V.17), (V.11a) and (V.16) for the functions ϕ and $\chi^\pm$ and their power series coefficients ϕ^n and $\chi^{\pm,n}$. Also, we will show that the analyticity properties for ϕ and $\chi^\pm$ also extend to their derivatives with respect to r. We start with two preparations. Observe first that (V.11b) and (V.17) hold when $V=0$, i.e., for $\phi=\phi_0$ and $\chi^\pm=\chi_0^\pm$, respectively. Indeed, for ϕ_0 (V.11b) follows from the relations (see, e.g., Refs. 34, 35)

$$J_\mu(z) \xrightarrow[z\to 0]{} C(\mu) z^\mu \quad \text{and} \quad J_\mu(z) \xrightarrow[|z|\to\infty]{} \frac{\cos\left(z - \frac{\pi}{2}(2\mu+1)\right)}{\sqrt{\frac{\pi}{2} z}}.$$

For $\chi_0^{\pm}$ the equation (V.17) follows from the following asymptotic behavior:

$$H_\mu^{\pm}(z) \xrightarrow[z\to 0]{} C(\mu) z^\mu \quad \text{and} \quad H_\mu^{\pm}(z) \xrightarrow[|z|\to\infty]{} \frac{e^{\pm i(z-(\pi/2)\mu-1/4)}}{\sqrt{\frac{\pi}{2}z}}.$$

Second, for g_0 [see (V.7)] one establishes analogously

$$0 \leqslant r' \leqslant r: \ |g_0(r,r';k,\mu)| \leqslant C(\mu) e^{|\mathrm{Im}(k)|(r-r')} \left(\frac{r}{1+|k|r}\right)^{\mu+1/2} \left(\frac{r'}{1+|k|r'}\right)^{-\mu+1/2}, \tag{C1}$$

$$0 \leqslant r \leqslant r': \ |g_0(r,r';k,\mu)| \leqslant C(\mu) e^{|\mathrm{Im}(k)|r-\mathrm{Im}(kr')} \left(\frac{r}{1+|k|r}\right)^{\mu+1/2} \left(\frac{r'}{1+|k|r'}\right)^{-\mu+1/2}. \tag{C2}$$

Now (V.11a) is proved by induction on n as follows. Define A_n by

$$|\phi_n(r;k,\mu)| = e^{|\mathrm{Im}(k)|r} \left(\frac{r}{1+|k|r}\right)^{\mu+1/2} A_n(r;k,\mu),$$

and it suffices to show that

$$A_n(r;k,\mu) \leqslant |k|^{\mu+1/2} \frac{C(\mu)^{n+1}}{n!} \left[\int_0^r dr' \frac{r'|V(r')|}{1+|k|r'}\right]^n,$$

where $C(\mu)$ is the maximum of the $C(\mu)$ in (V.11b) and the one in (C1). By the preparatory remarks (V.11a) holds for $n=0$, i.e., for $\phi_0 = \phi_{n=0}$. To perform the induction step, by construction we have

$$\phi_n(r;k,\mu) = \int_0^r dr' g_0(r,r';k,\mu) V(r') \phi_{n-1}(r';k,\mu),$$

which gives the inequality

$$A_n(r;k,\mu) \leqslant C(\mu) \int_0^r dr' \frac{r'|V(r')|}{1+|k|r'} A_{n-1}(r';k,\mu),$$

from which the induction step follows easily. This completes the proof of (V.11a) and (V.11b) follows from it by summation.

The proof of the bounds (V.16) and (V.17) is similar and we will consider the case χ^- only. Now write

$$|\chi_n^-(r;k,\mu)| = e^{\mathrm{Im}(kr)} \left(\frac{r}{1+|k|r}\right)^{-\mu+1/2} B_n(r;k,\mu),$$

such that it suffices to prove

$$B_n(r;k,\mu) \leqslant \frac{C(\mu)^{n+1}}{n!} |k|^{-\mu+1/2} \left(\int_r^\infty dr' \frac{r'|V(r')|}{1+|k|r'}\right)^n.$$

By the preparatory remarks, this inequality is valid for $n=0$. To make the induction step, we note that by construction

$$\chi_n^-(r;k,\mu)=\int_r^\infty dr' g_0(r,r';k,\mu)\chi_{n-1}^-(r';k,\mu).$$

Hence one has the estimate

$$B_n(r;k,\mu)\leqslant C(\mu)\int_r^\infty dr' \frac{r'|V(r')|}{1+|k|r'} B_{n-1}(r';k,\mu),$$

from which the induction step easily follows. This completes the proof of (V.16) and (V.17) follows by summation.

APPENDIX D: THE RESOLVENT OF THE δ-POTENTIAL

Proof of theorem VI.2: For any $\eta\in\mathcal{L}^2(\mathbb{R}^+)$ define

$$\psi:=\frac{1}{h_{0,\alpha}(s)-k^2}\,\eta,$$

using the integral kernel given by (VI.2). It is easily seen that ψ is well-defined. In order to prove the theorem we shall show that (VI.2) formally defines a resolvent, i.e., we have

$$\left(-\frac{\partial^2}{\partial r}-\frac{\alpha^2-\frac{1}{4}}{r^2}\right)\psi-k^2\psi=\eta. \tag{D1}$$

That this ''resolvent property'' is formally satisfied can easily be verified with the aid of the well-known formulas for the first derivatives of Bessel functions. In particular, one uses the relations

$$C'_\alpha=\frac{\alpha}{z}C_\alpha-C_{\alpha+1},\quad C'_{\alpha+1}=C_\alpha-\frac{\alpha+1}{z}C_{\alpha+1},\quad \text{for } C_\alpha=J_\alpha \text{ or } H_\alpha.$$

Furthermore, we shall show that ψ satisfies the boundary condition in (VI.1), i.e.,

$$\lim_{r\downarrow 0} W(\psi_{\alpha,s},\psi)(r)=0. \tag{D2}$$

For convenience we introduce the following notation:

$$I_<(r):=\int_0^r dr'\,\sqrt{r'}J_\alpha(kr')\,\eta(r'),\quad I:=\int_0^\infty dr'\,\sqrt{r'}H_\alpha^{(1)}(kr')\,\eta(r'),$$

$$I_>(r):=\int_r^\infty dr'\,\sqrt{r'}H_\alpha^{(1)}(kr')\,\eta(r').$$

ψ can now be cast into the form

$$\psi(r)=\sqrt{r}\left[\frac{i\pi}{2}H_\alpha^{(1)}(kr)I_<(r)+\frac{i\pi}{2}J_\alpha(kr)I_>(r)-A(k,\alpha;s)H^{(1)}(kr)I\right]. \tag{D3}$$

To verify the boundary condition (D2), we note that

$$\psi_{\alpha,s}(r)=\frac{1}{2\alpha}\cdot r^{1/2-\alpha}+\tilde{s}\cdot r^{1/2+\alpha},\quad \text{with}\quad \tilde{s}=s-\frac{1}{2\alpha},$$

giving

$$\psi'_{\alpha,s}(r)=\left(\frac{1}{4\alpha}-\frac{1}{2}\right)\cdot r^{1/2-\alpha}+\left(\frac{\tilde{s}}{2}+\tilde{s}\alpha\right)r^{-1/2+\alpha},$$

and hence

$$W(\psi_{\alpha,s},\psi)(r)=B'(r)\left(\frac{1}{2\alpha}\cdot r^{1-\alpha}+\tilde{s}r^{1+\alpha}\right)+B(r)\left(\frac{1}{2}\cdot r^{-\alpha}-\alpha\tilde{s}r^{\alpha}\right),$$

where $B(r)$ denotes the quantity in the square brackets in (D3). In order to take the limit, we remark that $z^{-\alpha}J_\alpha(z)$ is an analytic function for any value of $\alpha\in\mathbb{R}$. From its power series expansion at $z=0$ (see, e.g., Ref. 35) one obtains the following asymptotic relations when $\alpha>0$:

$$\lim_{r\downarrow 0} r^{-\alpha}J_\alpha(kr)=\iota_\alpha(k):=\left(\frac{k}{2}\right)^{\alpha}\frac{1}{\Gamma(1+\alpha)},$$

$$\lim_{r\downarrow 0} r^{\alpha}Y_\alpha(kr)=\gamma_\alpha(k):=-\left(\frac{2}{k}\right)^{\alpha}\frac{1}{\sin\pi\alpha}\,\frac{1}{\Gamma(1-\alpha)},$$

$$\lim_{r\downarrow 0} r^{\alpha}Y_{-\alpha}(kr)=\gamma_{-\alpha}(k):=-\left(\frac{k}{2}\right)^{-\alpha}\frac{1}{\tan\pi\alpha}\,\frac{1}{\Gamma(1-\alpha)}.$$

For the definition of the integral kernel (VI.2) we restricted the Bessel functions to the sheet given by $0<\arg(k)<\pi$. Since the irrational powers of k in the above expressions stem from the asymptotic behavior of the Bessel functions, they have to be evaluated on the same sheet. Bearing this in mind, we are prepared to take the limit $r\to 0^+$, which will make most of the terms in (D3) disappear. Since $|I_<(r)|\sim C\cdot r^{\alpha+1}$ and $I_>\sim I$ for $r\ll 1$, the remaining terms are

$$\lim_{r\downarrow 0} W(\psi_{\alpha,s},\psi)(r)=I\cdot\lim_{r\downarrow 0}\left[\frac{i\pi}{2}r^{-\alpha}J_\alpha(kr)+\tilde{s}\cdot k\cdot A(k,\alpha;s)r^{1+\alpha}H^{(1)}_{\alpha+1}(kr)+\frac{k}{2\alpha}A(k,\alpha;s)r^{1-\alpha}\left(H^{(1)}_{\alpha+1}(kr)-\frac{2\alpha}{kr}H^{(1)}_{\alpha}(kr)\right)\right].$$

Now, by a standard theorem for Bessel functions, we have $H^{(1)}_{\alpha+1}(kr)-(2\alpha/kr)H^{(1)}_\alpha(kr)=-H^{(1)}_{\alpha-1}(kr)$. The boundary condition (D2) therefore implies

$$A(k,\alpha;s)=\frac{i\pi}{2}\iota_\alpha(k)\left[\iota_\alpha(k)-2i\tilde{s}\alpha\cdot\gamma_\alpha+\frac{ik}{2\alpha}\gamma_{\alpha-1}\right]^{-1}.$$

Substituting $\tilde{s}=s-1/2\alpha$ and the expressions for ι_α, γ_α and $\gamma_{\alpha-1}$ we see that $A(k,\alpha;s)$ is given by (VI.3), thus completing the proof of theorem (VI.2). □

Poisson brackets of normal-ordered Wilson loops

C.-W. H. Lee and S. G. Rajeev
Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627

(Received 2 November 1998; accepted for publication 2 December 1998)

We formulate Yang–Mills theory in terms of the large-N limit, viewed as a classical limit, of gauge-invariant dynamical variables, which are closely related to Wilson loops, via deformation quantization. We obtain a Poisson algebra of these dynamical variables corresponding to normal-ordered quantum (at a finite value of $\hbar$) operators. Comparing with a Poisson algebra one of us introduced in the past for Weyl-ordered quantum operators, we find, using ideas closely related to topological graph theory, that these two Poisson algebras are, roughly speaking, the same. More precisely speaking, there exists an invertible Poisson morphism between them. © *1999 American Institute of Physics.* [S0022-2488(99)02204-5]

I. INTRODUCTION

Among the many different approaches to Yang–Mills theory, one of the most widely studied is the large-N limit.[1] The large-N limit can be formulated as a classical limit,[2] with a well-defined phase space and a Poisson bracket between dynamical variables which are functions of the phase space. The hallmark of Yang–Mills theory is the gauge invariance of physical observables, and it is natural for us to think that the dynamical variables should also be gauge-invariant functions. Next comes naturally this question: Is there a sensible Poisson bracket between these gauge-invariant functions? If so, this will be a major step towards the classical formulation of Yang–Mills theory in the large-N limit.

One of us, together with Turgut, introduced in a previous article[3] such a Poisson bracket. Consider a Yang–Mills theory with matter fields z^i, where different matter fields are distinguished by different values of the index i, in the adjoint representation. Such a theory can be obtained, for example, by dimensionally reducing a D-dimensional Yang–Mills theory to a two-dimensional one. The two color indices carried by the adjoint matter field can be regarded as matrix entries. In this sense, the adjoint matter fields are Hermitian matrices. Consider the trace of a product of these matrices. Under a gauge transformation characterized by a unitary matrix g, the adjoint matter fields are changed in the following manner:

$$z^i \to g z^i g^\dagger. \tag{1}$$

Hence the trace remains unchanged, and is thus a gauge-invariant function, and a dynamical variable of the theory. We call this gauge-invariant function a loop variable, as this was originally motivated from the study of Wilson loops.[4]

A convenient way to quantize such loop variables is via deformation quantization. (Deformation quantization was proposed by Flato, Lichnerowicz and Sternheimer.[5] See also Ref. 6. Reference 7 gives a pedagogical introduction. A more comprehensive list of references can be found in Ref. 8.) The essential idea is that the commutative product of these loop variables is deformed in such a way that when we multiply two loop variables, it is as if we are multiplying the two operators they represent. (We say that the loop variables are the symbols of these operators.) As there are different ways to order a product of operators, there are also different schemes of deformation quantization. In Ref. 3, the operators are Weyl-ordered. Then the Poisson bracket of two loop variables can be defined as the large-N limit of the commutator of them. We will review the precise definition of this Poisson bracket at the beginning of Sec. III. In a sense, we have obtained a classical limit not by setting $\hbar$ to 0 but by letting N go to infinity. This Poisson bracket dictates the classical dynamics of a system in which the dynamical variables are expressed in terms of these loop variables.

However, as most finite-$\hbar$ quantum theory are formulated in terms of normal-ordered operators, it should be interesting to find another Poisson bracket which corresponds to normal-ordered operators, i.e., the loop variables should be multiplied in such a way that it is as if we are multiplying normal-ordered operators. This is the goal in Sec. II.

This Poisson algebra is closely related to the Lie algebras we presented in previous papers,[9–11] though we derived those Lie algebras in a manner thoroughly independent of this Poisson algebra. We believe that the loop variables have a meaning in noncommutative geometry, and, in some sense, the Lie algebras are linear approximations of this Poisson algebra. We have not yet precisely identified the nature of this approximation, and this is a subject worthy of being pursued in the future. Nevertheless, at the end of Sec. II, we will indicate in a crude manner how the Poisson algebra can be truncated to obtain these Lie algebras.

The next interesting question which comes to mind is: what is the relationship between these two seemingly different Poisson algebras? It turns out that when there are only a finite number of distinct Hermitian matrices z^i, i.e., when i can take on a finite number of distinct values only, these two Poisson brackets are, roughly speaking, the same. More precisely speaking, there exists an invertible Poisson morphism between the two Poisson algebras. We are going to show the existence of this Poisson morphism in Sec. III. The astute reader will notice that many of the lemmas in the proof have simple interpretations in terms of topological graph theory. (For an introductory account on topological graph theory, see, e.g., Ref. 12. However, we will not use any of the results there because of the difference between the underlying topologies discussed in that reference and the topologies here.) Indeed, we will derive from first principles some properties of topological graphs which, we hope, will be of interest to topological graph theorists.

II. DEFORMATION QUANTIZATION

We are going to derive a Poisson algebra pertinent to gauge theory via deformation quantization in this section. Deformation quantization refers to the procedure of defining an algebra of smooth functions in such a way that when the functions are multiplied, it is as if we are multiplying suitably ordered operators these smooth functions represent. To be more specific, consider the set of all smooth functions on a one-dimensional complex Euclidean space. Let z be a coordinate of this one-dimensional space. Then we can associate a smooth function $f(z,\bar{z})$ on it with a Weyl-ordered operator in the way described by Chari and Pressley.[7] The way to associate $f(z,\bar{z})$ with a normal-ordered operator is similar. Indeed, the first step is to obtain the Fourier transform $\hat{f}(\xi,\eta)$ of $f(z,\bar{z})$ first,

$$\hat{f}(\xi,\eta)=\frac{1}{(2\pi)^2}\int dz\,d\bar{z}\,f(z,\bar{z})e^{-(i/\hbar)(\xi z+\eta\bar{z})}. \tag{2}$$

Here ξ and η are still complex variables and $\hbar$ is a quantization parameter. Then the associated normal-ordered operator $\Phi(f)$ is defined as

$$\Phi(f)=\int d\xi\,d\eta\,\hat{f}(\xi,\eta)e^{i\hbar\xi a^\dagger}e^{i\hbar\eta a}, \tag{3}$$

where a and $a^\dagger$ are the annihilation and creation operators satisfying $[a,a^\dagger]=1$, respectively. We then define a noncommutative associative product $*_\hbar$ such that

$$\Phi(f_1 *_\hbar f_2)=\Phi(f_1)\Phi(f_2). \tag{4}$$

Equation (4) is satisfied if this product is defined as follows:

$$f_1 *_\hbar f_2 \equiv e^{\hbar(\partial/\partial\bar{z})(\partial/\partial z')} f_1(z,\bar{z}) f_2(z',\bar{z'})|_{z=z',\bar{z}=\bar{z}'}. \tag{5}$$

Then this operation $*_\hbar$ is a deformation of the algebra of functions on a one-dimensional complex Euclidean space.

In the physical systems we are interested, the dynamical variables are represented by loop variables. Mathematically these loop variables are traces of $N\times N$ matrices. Thus we would like to generalize the above formulation of deformation quantization from ordinary complex variables to $N\times N$ matrices. Furthermore, physically each matrix corresponds to a state with a particular set of quantum numbers other than color (e.g., momentum). There are, of course, more than one possible set of quantum numbers and so we would also generalize the quantization scheme from a one-dimensional space to a multidimensional space. For the sake of simplicity, this dimension is still finite though in the actual physical context it should be infinite.

Having said this, let us generalize the formulation of deformation quantization to a system of bosons. Consider a complex Euclidean space of dimension $2\Lambda N^2$, where Λ is an arbitrary positive integer. Let z^i, where $i=-\Lambda, -\Lambda+1, \ldots, -1, 1, 2, \ldots$, or Λ, be a Hermitian $N\times N$ matrix. An entry of z^i is denoted by z_b^{ia}, a and b being the row and column indices, respectively. Denote z^{-i} by $\overline{z^i}$. A *normal-ordered loop variable* is a function of the form

$$\tilde{\phi}^I(z,\bar{z}) = \operatorname{Tr} z^{i_1}\cdots z^{i_m}. \tag{6}$$

Here I represents the sequence of nonzero integers $i_1, \ldots, i_m$ between $-\Lambda$ and Λ inclusive. $\tilde{\phi}^I(z,\bar{z})$ is gauge-invariant since it remains unchanged under the gauge transformation given by Eq. (1). Linear combinations of products of normal-ordered loop variables form a function space $\mathcal{N}$. Equation (5) can be generalized to

$$\tilde{\phi}^I * \tilde{\phi}^J(z,\bar{z}) = e^{\hbar\gamma^{\mu\nu}(\partial/\partial z_b^{\mu a})(\partial/\partial z'^{\nu b}_a)} \tilde{\phi}^I(z,\bar{z})\tilde{\phi}^J(z',\bar{z'})|_{z=z',z^\dagger=z'^\dagger} \tag{7}$$

with $\gamma^{\mu\nu}=0$ unless $\mu<0$ and $\nu>0$. In the limit $\hbar\to\infty$, Eq. (7) produces the ordinary Poisson bracket.

Let us derive from Eq. (7) a Poisson bracket for a finite value of $\hbar$. This is done by expanding Eq. (7) as a power series of $\hbar$. Indeed, we obtain

$$\tilde{\phi}^I *_\hbar \tilde{\phi}^J = \tilde{\phi}^I\tilde{\phi}^J + \sum_{r=1}^{\infty} \frac{\hbar^r}{r!} \gamma^{i_{\mu_1} j_{\nu_1}} \cdots \gamma^{i_{\mu_r} j_{\nu_r}} \frac{\partial^r \tilde{\phi}^I}{\partial z_{b_1}^{i_{\mu_1} a_1} \cdots z_{b_r}^{i_{\mu_r} a_r}} \frac{\partial^r \tilde{\phi}^J}{\partial z_{a_1}^{j_{\nu_1} b_1} \cdots z_{a_r}^{j_{\nu_r} b_r}}, \tag{8}$$

where $i_{\mu_1}, i_{\mu_2}, \ldots, i_{\mu_r} < 0$ and $j_{\nu_1}, j_{\nu_2}, \ldots, j_{\nu_r} > 0$. We can always bring the first set of indices to the order $\mu_1 < \mu_2 < \cdots < \mu_r$ by relabeling the indices. Then the set of indices $\nu_1, \nu_2, \ldots, \nu_r$ will be rearranged in one of all $r!$ possible permutations. We note that

$$\frac{\partial \tilde{\phi}^I}{\partial z_b^{ka}} = 0 \tag{9}$$

unless k is equal to one of the elements of the loop $(i_1, \ldots, i_m)$. If $k=i_\mu$ for some $\mu = 1, \ldots, m$, then

$$\frac{\partial \tilde{\phi}^I}{\partial z_b^{ka}} = [z^{i_{\mu+1}} z^{i_{\mu+2}} \cdots z^{i_m} z^{i_1} \cdots z^{i_{\mu-1}}]_a^b. \tag{10}$$

More generally, when $\mu_1 < \mu_2 < \cdots < \mu_r$,

$$\frac{\partial^r \tilde{\phi}^I}{\partial z^{i_{\mu_1} a_1}_{b_1} \partial z^{i_{\mu_2} a_2}_{b_2} \cdots \partial z^{i_{\mu_r} a_r}_{b_r}} = P^{b_1}_{a_2}(I(\mu_1,\mu_2)) P^{b_2}_{a_3}(I(\mu_2,\mu 3)) \cdots P^{b_r}_{a_1}(I(\mu_r,\mu_1)), \tag{11}$$

where

$$P^{b_1}_{a_2}(I(\mu_1,\mu_2)) = \begin{cases} [z^{i_{\mu_1+1}} z^{i_{\mu_1+2}} \cdots z^{i_{\mu_2-1}}]^{b_1}_{a_2} & \text{if } \mu_2 > \mu_1 \\ [z^{i_{\mu_1+1}} z^{i_{\mu_1+2}} \cdots z^{i_m} z^{i_1} \ldots z^{i_{\mu_2-1}}]^{b_1}_{a_2} & \text{if } \mu_2 < \mu_1 \end{cases} \tag{12}$$

and so on for the other P's. Hence, we can substitute Eq. (11) into Eq. (8) to get

$$\begin{aligned} \sum_{\{\sigma\}} \frac{\hbar^r}{r!} \gamma^{i_{\mu_1} j_{\nu_{\sigma(1)}}} \cdots \gamma^{i_{\mu_r} j_{\nu_{\sigma(r)}}} \\ \cdot P^{b_1}_{a_2}(I(\mu_1,\mu_2)) P^{b_2}_{a_3}(I(\mu_2,\mu_3)) \cdots \\ \cdot P^{b_r}_{a_1}(I(\mu_r,\mu_1)) P^{a_{\sigma(1)}}_{b_{\sigma(2)}}(J(\nu_{\sigma(1)},\nu_{\sigma(2)})) P^{a_{\sigma(2)}}_{b_{\sigma(3)}}(J(\nu_{\sigma(2)},\nu_{\sigma(3)})) \cdots \\ \cdot P^{a_{\sigma(r)}}_{b_{\sigma(1)}}(J(\nu_{\sigma(r)},\nu_{\sigma(1)})) \end{aligned} \tag{13}$$

for the rth order term. Here σ is any possible permutation of $\nu_1, \ldots, \nu_r$.

In the large-N limit, the term with the largest number of traces will dominate. This occurs if the ν indices are in decreasing order up to a cyclic permutation, e.g., $\nu_2 > \nu_3 > \cdots > \nu_r > \nu_1$, etc. Then to the first two orders in the large-N limit,

$$\begin{aligned} \tilde{\phi}^I *_\hbar \tilde{\phi}^J \simeq \tilde{\phi}^I \tilde{\phi}^J \\ + \sum_{r=1}^{\infty} \sum_{\substack{\mu_1 < \mu_2 < \cdots < \mu_r \\ (\nu_1 > \nu_2 > \cdots > \nu_r)}} \hbar^r \gamma^{i_{\mu_1} j_{\nu_1}} \cdots \gamma^{i_{\mu_r} j_{\nu_r}} \\ \cdot \tilde{\phi}^{I(\mu_1,\mu_2) J(\nu_2,\nu_1)} \tilde{\phi}^{I(\mu_2,\mu_3) J(\nu_3,\nu_2)} \ldots \tilde{\phi}^{I(\mu_r,\mu_1) J(\nu_1,\nu_r)}, \end{aligned} \tag{14}$$

where

$$\tilde{\phi}^{I(\mu_1,\mu_2) J(\nu_2,\nu_1)} = P^b_a(I(\mu_1,\mu_2)) P^a_b(J(\nu_2,\nu_1)). \tag{15}$$

To ensure that the large-N limit is well defined, we need to normalize the functions ϕ^I by some N-dependent factor. The normalization is such that the vacuum expectation value of ϕ^I remains finite as $N \to \infty$. Consider the vacuum state of the Hamiltonian $g_{ij} \operatorname{Tr} z^i \overline{z^j}$, where $i,j = 1, \ldots, \Lambda$. Then the vacuum expectation value of $z^{ia}_b z^{jc}_d$ is $\langle z^{ia}_b z^{jc}_d \rangle = \gamma^{ij} \delta^a_d \delta^c_b$. Thus the vacuum expectation value of the product of an odd number of z's will vanish whereas that of an even number of z's will be given by Wick's theorem. A short calculation reveals that the $\langle \tilde{\phi}^I \rangle$ for the ϕ^I defined in Eq. (6) with m even is of order $N^{(m/2)+1}$. This can further be shown to be independent of the particular form of the Hamiltonian. Consequently, we define the normalized functions

$$\phi^I = \frac{1}{N^{(m/2)+1}} \tilde{\phi}^I. \tag{16}$$

Combining Eqs. (14) and (15), we get

$$\phi^I *_\hbar \phi^J = \phi^I \phi^J + \frac{1}{N_c^2} \sum_{r=1}^{\infty} \sum_{\substack{\mu_1<\mu_2<\cdots<\mu_r \\ (\nu_1>\nu_2>\cdots>\nu_r)}} \hbar^r \gamma^{i_{\mu_1} j_{\nu_1}} \cdots \gamma^{i_{\mu_r} j_{\nu_r}} \cdot \phi^{I(\mu_1,\mu_2)J(\nu_2,\nu_1)} \phi^{I(\mu_2,\mu_3)J(\nu_3,\nu_2)} \cdots \phi^{I(\mu_r,\mu_1)J(\nu_1,\nu_r)} + O\left(\frac{1}{N^3}\right). \tag{17}$$

Let us define the Poisson bracket by

$$\{\phi^I, \phi^J\}_N \equiv \lim_{N\to\infty} N^2 (\phi^I * \phi^J - \phi^J * \phi^I). \tag{18}$$

We then finally obtain

$$\{\phi^I, \phi^J\}_N = a \sum_{r=1}^{\infty} \sum_{\substack{\mu_1<\mu_2<\cdots<\mu_r \\ (\nu_1>\nu_2>\cdots>\nu_r)}} \hbar^r \gamma^{i_{\mu_1} j_{\nu_1}} \cdots \gamma^{i_{\mu_r} j_{\nu_r}} \cdot \phi^{I(\mu_1,\mu_2)J(\nu_2,\nu_1)} \phi^{I(\mu_2,\mu_3)J(\nu_3,\nu_2)} \cdots \phi^{I(\mu_r,\mu_1)J(\nu_1,\nu_r)} - (I \leftrightarrow J). \tag{19}$$

We can visualize Eq. (19) by the diagrammatic representations in Fig. 1.

Equation (19) characterizes the Poisson algebra of loop variables corresponding to normal-ordered operators, and we call this the *normal-ordered Poisson algebra*. In comparison with the Poisson algebra found in a previous paper,[3] where the loop variables correspond to Weyl-ordered operators, we notice that the antisymmetric tensors ω^{ij} in the last equation of Ref. 3 are here replaced by γ^{ij}, which are nonzero only if $i<0$ and $j>0$. In addition, terms of order $\hbar^1, \hbar^3, \hbar^5, \ldots$, etc. vanish in the last equation of Ref. 3 but they are nonzero here in general.

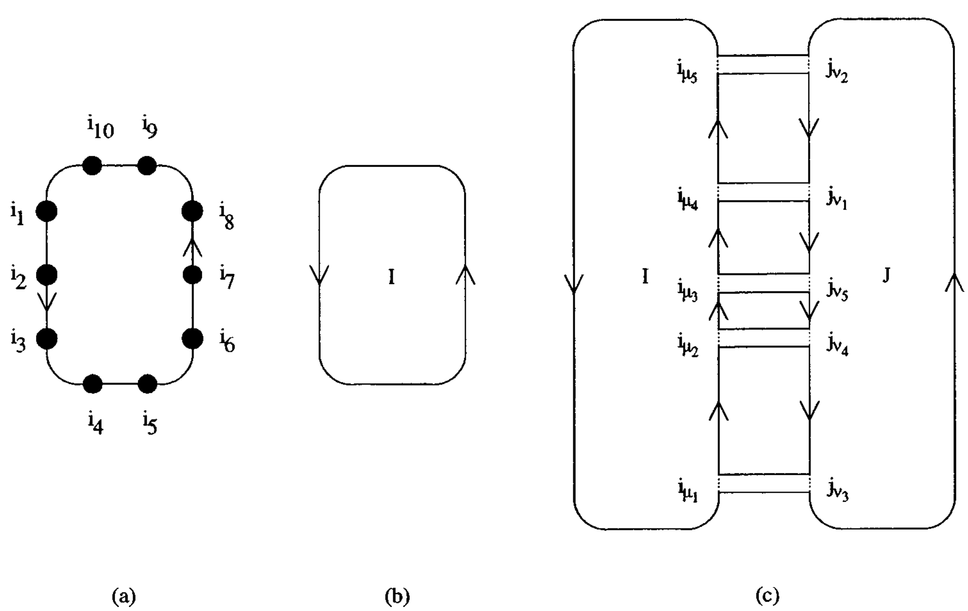

FIG. 1. (a) A typical loop variable ϕ^I. Each solid circle represents a z^i. Notice the cyclic symmetry of the figure. (b) A simplified diagrammatic representation of ϕ^I. We use the capital letter I to denote the whole sequence $i_1, i_2, \ldots, i_m$. (c) A typical term in $\{\phi^I, \phi^J\}_N$. This is a product of the loop variables $\phi^{I(\mu_1,\mu_2)J(\nu_4,\nu_3)}$, $\phi^{I(\mu_2,\mu_3)J(\nu_5,\nu_4)}$, $\phi^{I(\mu_3,\mu_4)J(\nu_1,\nu_5)}$, $\phi^{I(\mu_4,\mu_5)J(\nu_2,\nu_1)}$, and $\phi^{I(\mu_5,\mu_1)J(\nu_3,\nu_2)}$.

Nevertheless, these two Poisson algebras have a deep relationship — there is an invertible Poisson morphism between the Poisson algebra of Weyl-ordered operators and that of normal-ordered operators, whose proof will be given in the next section.

In previous papers, we defined and discussed a number of Lie algebras like the cyclix algebra,[9] the centrix algebra,[10] and the heterix algebra.[11] These Lie algebras arise from taking the planar large-N limit of gauge theory. We can actually think of them as various approximations of the Poisson algebra given by Eq. (19). For example, to get the centrix algebra from this Poisson algebra, we choose $\hbar=1$ and $\gamma^{ij}=\delta^{-i,j}$ and restrict ourselves to loop variables of the form $\sigma_J^I \equiv \phi^{IJ^*}=\mathrm{Tr}\, z^{i_1}z^{i_2}\cdots z^{i_{\#(I)}}\overline{z^{j_{\#(J)}}}\,\overline{z^{j_{\#(J)-1}}}\cdots\overline{z^{j_1}}$, where $\#(I)$ and $\#(J)$ are the numbers of integers in I and J, respectively, and all the indices $i_1, i_2, \ldots, i_{\#(I)}, j_1, j_2, \ldots,$ and $j_{\#(J)}$ are positive integers between 1 and Λ inclusive. (J^* is defined as the reverse sequence of J.) If we now compute the Poisson bracket between two loop variables of this form using Eq. (19), we should obtain

$$\{\sigma_J^I,\sigma_L^K\}_N=\sum_{r=1}^{\infty}\sum_{\substack{\mu_1>\mu_2>\cdots>\mu_r\\(\nu_1>\nu_2>\cdots>\nu_r)}}\phi^{J^*(\mu_1,\mu_2)K(\nu_2,\nu_1)}\cdot\phi^{J^*(\mu_2,\mu_3)K(\nu_3,\nu_2)}\cdots\phi^{J^*(\mu_{r-1},\mu_r)K(\nu_r,\nu_{r-1})}$$
$$\cdot\,\phi^{J^*(\mu_r,0)I(0,\#(I)+1)J^*(\#(J)+1,\mu_1)K(\nu_r,\#(K)+1)L^*(\#(L)+1,0)K(0,\nu_1)}-(I\leftrightarrow K,J\leftrightarrow L). \quad (20)$$

If we now retain only those terms in which $\mu_1, \mu_2, \ldots, \mu_r$ are consecutive integers in the reverse order, i.e., $\mu_2=\mu_1-1, \mu_3=\mu_2-1, \ldots,$ and $\mu_r=\mu_{r-1}-1$, and in which $\nu_1, \nu_2, \ldots, \nu_r$ are also consecutive integers in the reverse order, we will get precisely the Lie bracket of the centrix algebra. If we retain some more terms, we will obtain the heterix algebra. The cyclix algebra is obtained from the heterix algebra by identifying certain products of loop variables as a linear combination of single loop variables. We believe that the loop variables have a geometrical meaning in a noncommutative space, and thus there should be a geometrical meaning of these truncating approximations. We hope to understand the geometry better in the future.

III. A POISSON MORPHISM

We are going to show that there exists an invertible Poisson morphism between the Poisson algebra of Weyl-ordered loop variables described in Ref. 3 and the Poisson algebra of normal-ordered loop variables given in Eq. (19). It should be interesting for the reader to discern, with the help of the accompanying diagrams, the meanings of many of the following lemmas in topological graph theory.

Let us remind ourselves the definition of the Weyl-ordered Poisson algebra here. Consider 2Λ distinct $N\times N$ Hermitian matrices $\eta^{-\Lambda}, \eta^{-\Lambda+1}, \ldots, \eta^{-1}, \eta^1, \eta^2, \ldots,$ and η^Λ. A *Weyl-ordered loop variable* is a trace of an arbitrary sequence of these matrices $f^I=\mathrm{Tr}\,\eta^{i_1}\eta^{i_2}\cdots\eta^{i_m}$, where m is a positive integer called the *degree of* f^I, $i_k\in\{-M,-M+1,\ldots,-1,1,2,\ldots,M\}\forall k=1,2,\ldots,m,$ and I denotes the integer sequence $i_1,i_2,\ldots,i_m$. Linear combinations of products of Weyl loops form a function space $\mathcal{W}$. The Poisson bracket between two Weyl-ordered loop variables f^I and $f^J=\mathrm{Tr}\,\eta^{j_1}\eta^{j_2}\cdots\eta^{j_n}$, where n, j_k, and J have analogous definitions as m, i_k, and I, is given by the following formula:

$$\{f^I,f^J\}_W=2i\sum_{r=1,\mathrm{odd}}^{\infty}\sum_{\substack{\mu_1<\mu_2<\cdots<\mu_r\\(\nu_1>\nu_2>\cdots>\nu_r)}}\left(-\frac{i\hbar}{2}\right)^r\tilde{\omega}^{i_{\mu_1}j_{\nu_1}}\cdots\tilde{\omega}^{i_{\mu_r}j_{\nu_r}}$$
$$\cdot\, f^{I(\mu_1,\mu_2)J(\nu_2,\nu_1)}f^{I(\mu_2,\mu_3)J(\nu_3,\nu_2)}\cdots f^{I(\mu_r,\mu_1)J(\nu_1,\nu_r)}. \quad (21)$$

In this equation, for every value of r, we sum over all possible sets of integers $\mu_1,\mu_2,\ldots,\mu_r \in\{1,2,\ldots,m\}$ such that $\mu_1<\mu_2<\ldots<\mu_r$, and all sets of integers $\nu_1,\nu_2,\ldots,\nu_r$

$\in\{1,2,\ldots,m\}$ such that $\nu_1,\nu_2,\ldots,\nu_r$ form a decreasing sequence up to a cyclic permutation. $\tilde{\omega}^{ij}$ is an antisymmetric tensor. Equation (21) defines the *Weyl-ordered Poisson algebra* for the space $\mathcal{W}$.

Now we are going to define a linear transformation $F:\mathcal{W}\to\mathcal{N}$. Nevertheless, we need a number of lemmas first in order to show that F is well defined. Introduce two matrices S and J as follows:

$$S=2\begin{pmatrix} I & 0 \\ 0 & -iI \end{pmatrix}; \tag{22}$$

and

$$J=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \tag{23}$$

where I is the $\Lambda\times\Lambda$ unit matrix. The index of each row and column of S and J runs from 1 to Λ, then from -1 to $-\Lambda$. From Eq. (22), we see that

$$S^{-1}=\frac{1}{2}\begin{pmatrix} I & 0 \\ 0 & iI \end{pmatrix}. \tag{24}$$

Let η'^{i}, where $i\in\{-\Lambda,-\Lambda+1,\ldots,-1,1,2,\ldots,\Lambda\}$, be defined as

$$\eta'^{i}=(S^{-1})^{i}(z^{i}+J^{i\bar{i}}z^{\bar{i}}), \tag{25}$$

where

$$(S^{-1})^{i}=(S^{-1})^{ii} \tag{26}$$

and

$$\bar{i}=-i. \tag{27}$$

Moreover, let

$$C^{ij}=\gamma^{ij}+J^{i\bar{i}}\gamma^{\bar{i}j}+J^{j\bar{j}}\gamma^{i\bar{j}}+J^{i\bar{i}}J^{j\bar{j}}\gamma^{\bar{i}\bar{j}} \tag{28}$$

and

$$T^{ij}=\frac{\hbar}{2}(S^{-1})^{i}(S^{-1})^{j}(C^{ij}+C^{ji}). \tag{29}$$

We will need these formulas in the definition of $F(f^{I})$.

Next we want to introduce the concepts of an allowable set of contracted indices, a forbidden set of contracted indices and leftover indices. Choose an ordered sequence I_a of $2k$ integers, where k is a non-negative integer with $2k\leqslant m$, from $i_1,\ldots,i_m$ with distinct subscripts. Let us call the integers $i_{a(-1)},i_{a(1)},i_{a(-2)},i_{a(2)},\ldots,i_{a(-k)}$ and $i_{a(k)}$, respectively, where $a(-1),a(1)$, $a(-2),a(2),\ldots,a(-k),a(k)\in\{1,2,\ldots,m\}$ and $a(r)\neq a(s)$ if $r\neq s$ for integers r and s such that $1\leqslant|r|\leqslant k$ and $1\leqslant|s|\leqslant k$. Then $I_a=(i_{a(-1)},i_{a(1)},i_{a(-2)},i_{a(2)},i_{a(-k)},i_{a(k)})$ will be called *an allowable set of contracted indices* (or in short I_a is *allowable*) if any arbitrary integers r and s such that $1\leqslant r<s\leqslant k$,

Condition 1: either $i_{a(\pm s)}\in I(a(-r),a(r))$ *or* $i_{a(\pm s)}\in I(a(r),a(-r))$.

Otherwise, I_a will be a *forbidden set of contracted indices* (or in short I_a is *forbidden*). We illustrate in Fig. 2 examples of an allowable set of contracted indices, and one of a forbidden set of contracted indices.

We have the following lemmas characterizing an allowable set of contracted indices.

Lemma 1: Let I_a be an allowable set of $2k$ contracted indices, and r any integer between 1 and k inclusive. Let $b(-1),b(1),b(-2),b(2),\ldots,b(-k),b(k)$ be an ordered sequence of integers such that for each r, either $b(\pm r)=a(\pm r)$ or $b(\pm r)=a(\mp r)$. Then $I_b=(i_{b(-1)},i_{b(1)},i_{b(-2)},i_{b(2)},\ldots,i_{b(-k)},i_{b(k)})$ is also an allowable set of contracted indices. If I_a is forbidden, then I_b is also forbidden.

Proof: Trivial.

Lemma 2: Let $I_a=(i_{a(-1)},i_{a(1)},i_{a(-2)},i_{a(2)},\ldots,i_{a(-k)},i_{a(k)})$ be an allowable set of contracted indices, p an arbitrary integer between 1 and $k-1$ inclusive, r any integer between 1 and k inclusive, and $(b(-1),b(1),b(-2),b(2),\ldots,b(-k),b(k))$ a sequence of integers such that

$$\begin{cases} b(\pm r)=a(\pm r) \text{ if } r\neq p \text{ and } r\neq p+1; \\ b(\pm p)=a(\pm(p+1)); \text{ and} \\ b(\pm(p+1))=a(\pm p). \end{cases} \tag{30}$$

Then $I_b=(i_{b(-1)},i_{b(1)},i_{b(-2)},i_{b(2)},\ldots,i_{b(-k)},i_{b(k)})$ is also an allowable set of contracted indices. If I_a is forbidden, then I_b is also forbidden.

Proof: Assume that I_a is allowable. From Lemma 1, we can assume without loss of generality that $a(-p)<a(p)$. It is clear that the set of integers $(i_{b(-1)},i_{b(1)},i_{b(-2)},i_{b(2)},\ldots,i_{b(-p)},i_{b(p)})$ satisfies Condition 1. Consider $i_{b(-p-1)}$ and $i_{(p+1)}$. Since I_a is allowable, we have from Condition 1 that either $i_{b(\pm(p+1))}=i_{a(\pm p)}\in I(a(-s),a(s))=I(b(-s),b(s))$ or $i_{b(\pm(p+1))}\in I(b(s),b(-s))\forall s=1,2,\ldots,p-1$. Moreover, we have either case (1) that $i_{b(\pm p)}=i_{a(\pm(p+1))}\in I(a(-p),a(p))=I(b(-p-1),b(p+1))$; case (2) that $i_{b(\pm p)}<i_{b(-p-1)}$; case (3) that $i_{b(\pm p)}>i_{b(p+1)}$; or case (4) that $i_{b(-p)}<i_{b(-p-1)}$ and $i_{b(p)}>i_{b(p+1)}$. If one of the first 3 cases holds, then $i_{b(\pm(p+1))}\in I(b(p),b(-p))$. If case (4) holds, then $i_{b(\pm(p+1))}\in I(b(-p),b(p))$. Hence in all cases, the set of integers $(i_{b(-1)},i_{b(1)},i_{b(-2)},i_{b(2)},\ldots,i_{b(-p-1)},i_{b(p+1)})$ satisfies Condition 1. It is now easy to deduce that the whole set $(i_{b(-1)},i_{b(1)},i_{b(-2)},i_{b(2)},\ldots,i_{b(-k)},i_{b(k)})$ satisfies Condition 1. Hence I_b is also allowable. The proof that I_b is forbidden if I_a is forbidden is similar. Q.E.D.

Lemma 3: Consider an allowable set of contracted indices

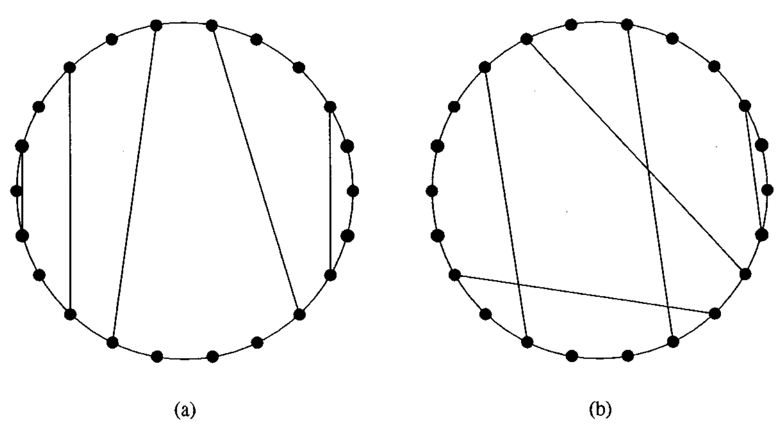

FIG. 2. (a) An allowable set of contracted indices in a loop variable (Weyl-ordered or normal-ordered). Each straight line joins $i_{a(-r)}$ and $i_{a(r)}$ together. Note that no two straight lines cross each other. (b) A forbidden set of contracted indices. Note that some straight lines cross one other.

$$I_a=(i_{a(-1)},i_{a(1)},i_{a(-2)},i_{a(2)},\ldots,i_{a(-k)},i_{a(k)}).$$

Let $\sigma:\{1,2,\ldots,k\}\rightarrow\{1,2,\ldots,k\}$ *be a permutation of the set of integers 1, 2, ..., and k. Then*

$$I_{\sigma(a)}=(i_{a(-\sigma(1))},i_{a(\sigma(1))},i_{a(-\sigma(2))},i_{a(\sigma(2))},\ldots,i_{a(-\sigma(k))},i_{a(\sigma(k))})$$

is also allowable. If I_a *is forbidden, then* $I_{\sigma(a)}$ *is also forbidden.*

Proof: This can be easily deduced from Lemma 2. Q.E.D.

In short, we see from Lemma 3 that whether a set of contracted indices I_a is allowable or not is independent of the order of the pairs of indices $i_{a(s)},i_{a(-s)}$'s. Each of these pairs will be called a *contraction pair*.

Let us concentrate on an allowable set of contracted indices I_a. For the i_l's such that $l\in\{1,2,\ldots,m\}$ but that $l\neq a(s)\in I_a\forall s=\pm1,\ldots,\pm k$ (these i_l's are called the *leftover indices*), form *subloops* by defining an integer-valued auxiliary function L of some positive integers as below. Let $L(1)=l$. If $L(v)$ is defined for an integer v, then we define $L^{(i)}(v+1)$ for some integers i by the following:

Algorithm 1: (cf. Fig. 3 below) In the following, $L(v)+_m1$ *means precisely* $L(v)+1$ *if* $L(v)\neq m$, *and it means 1 if* $L(v)=m$. *Similarly,* $L(v-_m1)$ *means* $L(v)-1$ if $L(v)\neq1$, *and it means m if* $L(v)=1$.

Step 1: Set $i=1$.

Step 2: $L^{(i)}(v+1)=L(v)+_m1$.

Step 3: If $L^{(i)}(v+1)\neq a(s)\forall s=\pm1,\ldots,\pm k$, *then end this algorithm.*

Step 4: Let s_i *be such that* $a(s_i)=L^{(i)}(v+1)$.

Step 5: Increment the value of i by 1.

Step 6: Set $L^{(i)}(v+1)=a(-s_i)+_m1$.

Step 7: Go back to Step 3.

If $L^{(i)}(v+1)\neq L(1)$, where i is the maximum integer such that $L^{(i)}(v+1)$ is defined, then define $L(v+1)=L^{(i)}(v+1)$; otherwise, $L(v+1)$ and thus $L(v+2)$, $L(v+3)$, ..., etc. are all left undefined.

Before proceeding on using the auxiliary function L to define a subloop, we need to show that the above algorithm is well defined by

Lemma 4: In the notations of Algorithm 1, if $L(v)$ *is well defined, then there is an i such that* $L^{(i)}(v+1)\neq a(s)\forall s=\pm1,\ldots,\pm k$.

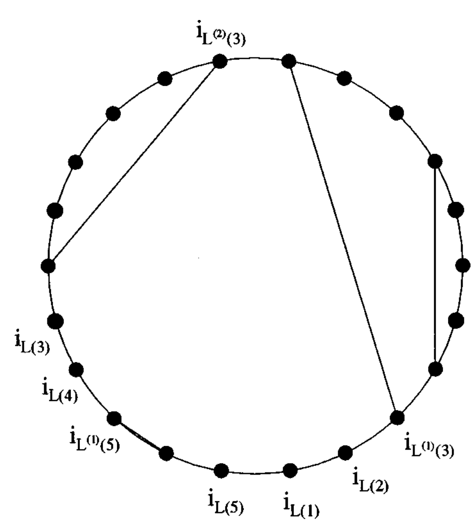

FIG. 3. A typical subloop with 5 numbers in the integer sequence L.

Proof: Assume on the contrary that such an i does not exist. Then we have an infinite sequence $L^{(1)}(v+1), L^{(2)}(v+1), \ldots$ and so on. Since there are a finite number of $a(s)$'s for $s = \pm 1, \ldots, \pm k$ only, there is an integer i_2 such that $L^{(i_2)}(v+1) = L^{(i_1)}(v+1) \exists i_1 \in \{1,2,\ldots,i_2 - 1\}$. Consider the case $i_1 \neq 1$. Let $L^{(i_1-1)}(v+1) = a(s_1)$ and $L^{(i_2-1)} = a(s_2)$ for some integers s_1 and s_2. Then $L^{(i_1)}(v+1) = a(-s_1) +_m 1$ and $L^{(i_2)}(v+1) = a(-s_2) +_m 1$. Hence $a(-s_1) +_m 1 = a(-s_2) +_m 1$ and thus $a(s_1) = a(s_2)$, i.e., $L^{(i_1-1)}(v+1) = L^{(i_2-1)}(v+1)$, contradicting the assumption that $L^{(i_2)}(v+1)$ is the first integer that repeats one of the previous numbers in the sequence. Now consider the case $i_1 = 1$. Then $L^{(i_1)}(v+1) = L(v) +_m 1$ and $L^{(i_2)}(v+1) = a(-s_2) +_m 1$. Hence $L(v) = a(-s_2)$. However, $L(v)$ does not belong to I_a and this equation is impossible. Consequently, there is an i such that $L^{(i)}(v+1) \neq a(s)$ for all $s = \pm 1, \ldots, \pm k$. Q.E.D.

Let u be the maximum integer such that $L(u)$ is defined. Then the *subloop of f^I with respect to I_a* including i_l is given by $\phi^L = \mathrm{Tr}\, \eta'^{i_{L(1)}} \eta'^{i_{L(2)}} \cdots \eta'^{i_{L(u)}}$, where η'^{i} is defined in Eq. (25). Obviously any one of the leftover indices belongs to at least one of these subloops. Moreover, no two distinct subloops ϕ^{L_1} and ϕ^{L_2} of f^I with respect to I_a share even one common η'^{i_l} for an arbitrary leftover index i_l because of the following two lemmas.

Lemma 5: Consider a subloop $\phi^L = \mathrm{Tr}\, \eta'^{i_{L(1)}} \cdots \eta'^{i_{L(u)}}$ of f^I with respect to I_a. Let r and s be integers between 1 and u inclusive. Then $L(r) \neq L(s)$ if $r \neq s$.

Proof: Assume on the contrary that there exist some integers $\tilde{r}$ and $\tilde{s}$ such that $\tilde{r} \neq \tilde{s}$ but $L(\tilde{r}) = L(\tilde{s})$. Choose the smallest integer r out of these $\tilde{r}$ and $\tilde{s}$'s. Then $r > 1$ from the statement immediately after Algorithm 1. Let s be the smallest integer distinct from r such that $L(s) = L(r)$. Then $s > r > 1$. Again from the statement immediately after Algorithm 1, there exists an unknown integer x such that $L(r) = L^{(x)}(r)$. Consider the following reverse of Algorithm 1:

Algorithm 2: Here is the procedure of this algorithm.

Step 1: Set $i = 0$.

Step 2: Let an integer y be such that it satisfies the equation $L^{(x-i)}(r) = y +_m 1$.

Step 3: If y does not belong to I_a, then $y = L(r-1)$ from Step 2 of Algorithm 1 (or else $L^{(x-i)}(r) = y +_m 1$, where $y \in I_a$ because of Step 6 of Algorithm 1, which is impossible). Hence $x - i = 1 \Rightarrow x = i + 1$. End the algorithm.

Step 4: Since $y \in I_a$, $L^{(x-i)}(r) = a(-s_{i+1}) +_m 1 \exists$ integer s_{i+1}.

Step 5: Increment the value of i by 1.

Step 6: From Steps 6 and 4 of Algorithm 1, $L^{(x-i)}(r) = a(s_i)$.

Step 7: Go back to Step 2.

Hence $L(r-1)$ can be uniquely determined just from the value of $L(r)$ by Algorithm 2. Moreover, $L(s-1)$ can be uniquely determined just from the value of $L(s)$ by the same algorithm. Since $L(r) = L(s)$, we must have $L(r-1) = L(s-1)$, contradicting the assumption that r is the smallest number such that $L(r) = L(s)$ for a number $s > r$. Q.E.D.

Corollary 1: The degree of a subloop is a finite positive integer.

Proof: Since the degree of a loop is a finite number only, a subloop of it also has a finite degree by Lemma 5.

Lemma 6: For each distinct $l \in \{1,2,\ldots,m\}$ such that i_l is a leftover index, η'^{i_l} is contained in at most one of the distinct subloops produced from all the leftover indices.

Proof: Let $\eta'^{i_l} \in \phi^L = \mathrm{Tr}\, \eta'^{i_{L(1)}} \cdots \eta'^{i_{L(u)}}$, where $L(1) = l$. Consider another subloop $\phi^{\tilde{L}} = \mathrm{Tr}\, \eta'^{i_{\tilde{L}(1)}} \cdots \eta'^{i_{\tilde{L}(v)}} \cdots \eta'^{i_{\tilde{L}(\tilde{u})}}$, where $\tilde{L}(v) = l$. From Algorithm 1, it is clear that $\tilde{L}(v+1) = L(2)$, $\tilde{L}(v+2) = L(3)$, $\ldots$, and $\tilde{L}(\tilde{u}) = L(\tilde{u} - v + 1)$. Then $\tilde{L}^{(i)}(\tilde{u}+1) = \tilde{L}(1)$ for the maximum integer i such that $\tilde{L}^{(i)}(\tilde{u}+1)$ is defined. On the other hand, $\tilde{L}^{(i)}(\tilde{u}+1) = L^{(i)}(\tilde{u} - v + 2) = L(\tilde{u} - v + 2)$. Hence $\tilde{L}(1) = L(\tilde{u} - v + 2)$. Then $\tilde{L}(2) = L(\tilde{u} - v + 3)$, $\ldots$, and $\tilde{L}(u - \tilde{u} + v - 1) = L(u)$. $L^{(j)}(u+1) = L(1)$ for the maximum integer j such that $L^{(j)}(u+1)$ is defined. However, $L^{(j)}(u+1) = \tilde{L}^{(j)}(u - \tilde{u} + v) = \tilde{L}(u - \tilde{u} + v)$. As a result, $\tilde{L}(u - \tilde{u} + v) = L(1) = \tilde{L}(v)$. By Lemma 5, $\tilde{L}(u - \tilde{u} + v) = \tilde{L}(v)$ only if $u = \tilde{u}$. Now it is clear that $\phi^L = \phi^{\tilde{L}}$. Q.E.D.

Figure 3 shows a typical subloop.

The following lemmas and corollary pertaining to subloops will be found useful later.

Lemma 7: Let us consider a particular pair of indices $a(-s_0)$ and $a(s_0)$, where $1 \leqslant |s_0|$

$\leqslant k$, and the sequence L^{ext} of the numbers $L(1), L^{(1)}(2), L^{(2)}(2), \ldots, L^{(\iota_2)}(2) = L(2), L^{(1)} \times(3), L^{(2)}(3), \ldots, L^{(\iota_3)}(3) = L(3), \ldots, L^{(1)}(u), L^{(2)}(u), \ldots, L^{(\iota_u)}(u) = L(u), L^{(1)}(u+1), L^{(2)}(u+1), \ldots$, and $L^{(\iota_{u+1}-1)}(u+1)$, where $\iota_2, \iota_3, \ldots, \iota_{u+1}$ are the maximum integers such that $L^{(\iota)}(x)$ is defined for $2 \leqslant x \leqslant u+1$ and $\iota \leqslant \iota_x$. Moreover, $L^{(\iota_{u+1})}(u+1) = L(1)$ by the definition of u. Then either all numbers in $L^{ext} \in I(a(-s_0), a(s_0)) \cup \{a(s_0)\}$ or all numbers in $L^{ext} \in I(a(s_0), a(-s_0)) \cup \{a(-s_0)\}$.

Proof: Let $L(1) \in I(a(s_0), a(-s_0)) \cup \{a(-s_0)\}$. Note that in the sequence L^{ext}, the immediately succeeding number $\lambda^{(s)}$ of a preceding number $\lambda^{(p)}$ is always obtained either by (1) $\lambda^{(s)} = \lambda^{(p)} +_m 1$ if $\lambda^{(p)}$ does not belong to I_a, or by (2) $\lambda^{(s)} = a(-s^{(p)}) +_m 1$ for an integer $s^{(p)}$ such that $\lambda^{(p)} = a(s^{(p)})$ if $\lambda^{(p)} \in I_a$. Assume that $\lambda^{(p)} \in I(a(s_0), a(-s_0)) \cup \{a(-s_0)\}$. In Case (1), $\lambda^{(p)} \in I(a(s_0), a(-s_0))$ and so $\lambda^{(s)} \in I(a(s_0), a(-s_0))$ or $\lambda^{(s)} = a(-s_0)$. Hence $\lambda^{(s)} \in I(a(s_0), a(-s_0)) \cup \{a(-s_0)\}$. In Case (2), if $a(s^{(p)}) \neq a(-s_0)$, then $a(s^{(p)}) \in I(a(s_0), a(-s_0))$ and so $a(-s^{(p)}) \in I(a(s_0), a(-s_0))$ (because I_a is allowable and because of Lemma 3). This implies $a(-s^{(p)}) +_m 1 \in I(a(s_0), a(-(s_0)) \cup \{a(-s_0)\}$. If, on the other hand, $a(s^{(p)}) = a(-s_0)$, then $a(-s^{(p)}) = a(s_0)$ and so $a(-s^{(p)}) +_m 1 \in I(a(s), a(-s_0)) \cup \{a(-s_0)\}$. By induction, all numbers in $L^{ext} \in I(a(s_0), a(-s_0)) \cup \{a(-s_0)\}$. The case for $L(1) \cup I(a(-s_0), a(s_0)) \cup \{a(s_0)\}$ is similar. Q.E.D.

Lemma 8: Consider a subloop $\phi^L = \mathrm{Tr}\, \eta'^{i_{L(1)}} \cdots \eta'^{i_{L(u)}}$ of f^I with respect to I_a. Without loss of generality, $L(1)$ can be chosen to be the smallest among $L(1), L(2), \ldots, L(u)$ by a cyclic permutation of the η' matrices. Then using the notations of Lemma 5, we have $L(1) < L^{(1)}(2) < L^{(2)}(2) < \cdots < L^{(\iota_2)}(2) < L^{(1)}(3) < L^{(2)}(3) < \cdots < L^{(\iota_3)}(3) < \cdots < L^{(1)}(u) < L^{(2)}(u) < \cdots < L^{(\iota_u)}(u)$.

Proof: Consider the numbers $\lambda^{(p)}$ and $\lambda^{(s)}$ defined in the proof of Lemma 7. Assume that $L(1) < L^{(1)}(2) < \cdots < L^{(\iota_2)}(2) < \cdots < \lambda^{(p)}$. If $\lambda^{(p)} = L^{(\iota_u)}(u)$, the lemma is proved. If $\lambda^{(p)}$ is a number before $L^{(\iota_u)}(u)$ in the sequence L^{ext}, then $\lambda^{(s)}$ is obtained by the two alternatives described in the proof of Lemma 7. For the case $\lambda^{(p)}$ does not belong to I_a, we have $\lambda^{(s)} = \lambda^{(p)} +_m 1$. Thus either $\lambda^{(s)} = 1 \leqslant L(1)$ or $\lambda^{(s)} > \lambda^{(p)}$. For the case $\lambda^{(p)} \in I_a$, we have $\lambda^{(s)} = a(-s^{(p)}) +_m 1$ where $s^{(p)}$ is defined in the proof of the Lemma 7. If $a(s^{(p)}) < a(-s^{(p)})$, then either $\lambda^{(s)} \leqslant L(1)$ or $\lambda^{(s)} > \lambda^{(p)}$. If $a(s^{(p)}) > a(-s^{(p)})$, then we deduce from $\lambda^{(p)} \in I(a(-s^{(p)}), a(s^{(p)})) \cup \{a(s^{(p)})\}$ and Lemma 7 that $L(1) \in I(a(-s^{(p)}), a(s^{(p)}))$. Then $\lambda^{(s)} = a(-s^{(p)}) +_m 1 \leqslant L(1)$. Hence this lemma is proved if we can show that $\lambda^{(s)} \leqslant L(1)$ is impossible.

Clearly, $\lambda^{(s)} = L(1)$ is impossible by Lemma 5. Let $\lambda^{(s)} < L(1)$, and let $\lambda^{(s)} = L^{(\iota)}(x)$ for some numbers ι and x. Consider the numbers $L^{(\iota)}(x), L^{(\iota+1)}(x), \ldots$, and $L^{(\iota_x)}(x) = L(x)$. Since $L(x) > L(1)$, there is a smallest integer ι_c such that $L^{(\iota_c)}(x) < L(1)$ but $L^{(\iota_c+1)}(x) > L(1)$. Let $L^{(\iota_c)}(x) = a(s_c)$. Then $L^{(\iota_c+1)}(x) = a(-s_c) +_m 1 > L(1)$ and so $a(-s_c) > L(1)$. This, together with $a(s_c) < L(1)$, implies $L(1) \in I(a(s_c), a(-s_c)) \cup \{a(-s_c)\}$. By Lemma 7, $a(s_c) = L^{(\iota_c)}(x) \in I(a(s_c), a(-s_c)) \cup \{a(-s_c)\}$, and this is clearly impossible. Q.E.D.

Corollary 2: Consider a subloop $\phi^L = \mathrm{Tr}\, \eta'^{i_{L(1)}} \cdots \eta'^{i_{L(u)}}$ of f^I with respect to I_a. $L(1)$ can be chosen to be the smallest among $L(1), L(2), \ldots, L(u)$ without loss of generality. Then $L(1) < L(2) < \cdots < L(u)$.

Proof: This follows directly from Lemmas 6 and 8. Q.E.D.

We are now ready to define $F: \mathcal{W} \to \mathcal{N}$. Let $f^I = \mathrm{Tr}\, \eta^{i_1} \cdots \eta^{i_m} \in \mathcal{W}$. Then,

$$F(f^I) = \sum_{\substack{\text{all distinct allowable sets} \\ \text{of contracted indices } I_a}} T^{i_{a(-1)} i_{a(1)}} T^{i_{a(-2)} i_{a(2)}} \ldots T^{i_{a(-k)} i_{a(k)}} \cdot \prod_{\substack{\text{all distinct subloops } L \\ \text{of } f^I \text{ w.r.t. } I_a.}} \mathrm{Tr}\, \eta'^{i_{L(1)}} \eta'^{i_{L(2)}} \cdots \eta'^{i_{L(u)}}. \tag{31}$$

For instance,

$$F(\text{Tr } \eta^{i_1}\eta^{i_2}\eta^{i_3}\eta^{i_4}) = \text{Tr } \eta'^{i_1}\eta'^{i_2}\eta'^{i_3}\eta'^{i_4} + T^{i_1i_2}\text{ Tr } \eta'^{i_3}\eta'^{i_4} + T^{i_1i_3}\text{ Tr } \eta'^{i_2}\text{ Tr } \eta'^{i_4} + T^{i_1i_4}\text{ Tr } \eta'^{i_2}\eta'^{i_3} + T^{i_2i_3}\text{ Tr } \eta'^{i_1}\eta'^{i_4} + T^{i_2i_4}\text{ Tr } \eta'^{i_1}\text{ Tr } \eta'^{i_3} + T^{i_3i_4}\text{ Tr } \eta'^{i_1}\eta'^{i_2} + T^{i_1i_2}T^{i_3i_4} + T^{i_1i_4}T^{i_2i_3}. \tag{32}$$

Let us give another example. In $F(\text{Tr } \eta^{i_1}\eta^{i_2}\eta^{i_3}\eta^{i_4}\eta^{i_5}\eta^{i_6})$, there are terms like $T^{i_2i_3}T^{i_5i_6}\text{ Tr } \eta'^{i_1}\eta'^{i_4}$, $T^{i_1i_6}T^{i_3i_4}\text{ Tr } \eta'^{i_2}\eta'^{i_5}$ and $T^{i_1i_2}T^{i_4i_5}\text{ Tr } \eta'^{i_3}\eta'^{i_6}$. Moreover, we define $F(f^I f^J) = F(f^I)F(f^J)$ for some $f^I, f^J \in \mathcal{W}$. The following lemma shows that F is invertible.

Lemma 9: Consider the mapping $F:\mathcal{W}\rightarrow\mathcal{N}$ defined in Eq. (32). Then F is invertible.

Proof: Let $P(n)$ be the proposition that for every normal-ordered loop variable ϕ^I in $\mathcal{N}$ of degree n, there is a unique element in $\mathcal{W}$ such that F maps this element to ϕ^I. From Eq. (25), we see that

$$\begin{cases} z^j = \eta'^j + i\,\eta'^{-j} \\ z^{-j} = \eta'^j - i\,\eta'^{-j} \end{cases} \tag{33}$$

for $j \in \{1, \ldots, M\}$. Hence

$$\begin{cases} \text{Tr } z^j = \text{Tr } \eta'^j + i\text{ Tr } \eta'^{-j} \\ \text{Tr } z^{-j} = \text{Tr } \eta'^j - i\text{ Tr } \eta'^{-j} \end{cases} \tag{34}$$

for each j. Hence $P(1)$ is true. Assume that $P(k)$ is true. Consider $\phi^J = \text{Tr } z^{j_1}\cdots z^{j_{k+1}}$. From Eq. (33), ϕ^J is a linear combination of $\text{Tr } \eta'^{j'_1}\eta'^{j'_2}\cdots\eta'^{j'_{k+1}}$, where $j'_1 = j_1$ or $-j_1$, $j'_2 = j_2$ or $-j_2$, ..., and $j'_{k+1} = j_{k+1}$ or $-j_{k+1}$. Each of these in turn differs from $F(\text{Tr } \eta^{j'_1}\eta^{j'_2}\cdots\eta^{j'_{k+1}})$ by normal-ordered loop variables of degrees less than $k+1$. By the induction hypothesis, there is an element f' in W which is mapped by F to the sum of these normal-ordered loop variables of lower degree. Hence $\text{Tr } \eta'^{j'_1}\eta'^{j'_2}\cdots\eta'^{j'_{k+1}} = F(\text{Tr } \eta^{j'_1}\eta^{j'_2}\cdots\eta^{j'_{k+1}} + f')$. Therefore, $P(k+1)$ is true and there is an element $f^I \in \mathcal{W}$ such that $F(f^I) = \phi^J$. If there is another element $f^{I'} \neq f^I$ such that $F(f^{I'}) = \phi^J$, then $F(f^{I'} - f^I) = 0$ for $f^{I'} - f^I \neq 0$. However, this is impossible from Eq. (31). Q.E.D.

Having defined a mapping $F:\mathcal{W}\rightarrow\mathcal{N}$, we are going to prove that this is a Poisson morphism. Let f^I and $f^J \in \mathcal{W}$. F is a Poisson morphism if (1) every term in $\{F(f^I), F(f^J)\}_N$ is also a term in $F(\{f^I, f^J\}_W)$, which is a product of normal-ordered loop variables, and (2) every term in $F(\{f^I, f^J\}_W)$ is also a term in $\{F(f^I), F(f^J)\}_N$.

Let us derive expressions for $\{F(f^I), F(f^J)\}_N$ and $F(\{f^I, f^J\}_W)$ first before proving these two statements. From Eq. (31) and the Leibniz property of a Poisson bracket,

$$\begin{aligned} \{F(f^I), F(f^J)\}_N = & \sum_{\substack{\text{distinct} \\ \text{allowable } I_a}} T^{i_{a(-1)}i_{a(1)}}T^{i_{a(-2)}i_{a(2)}}\cdots T^{i_{a(-k)}i_{a(k)}} \\ & \cdot \sum_{\substack{\text{distinct} \\ \text{allowable } J_b}} T^{j_{b(-1)}j_{b(1)}}T^{j_{b(-2)}j_{b(2)}}\cdots T^{j_{b(-l)}j_{b(l)}} \\ & \cdot \prod_{\substack{\text{distinct subloops } L \text{ of } f^I \\ \text{w.r.t. } I_a \text{ except subloop } A}} \text{Tr } \eta'^{i_{L(1)}}\eta'^{i_{L(2)}}\cdots\eta'^{i_{L(u)}} \\ & \cdot \prod_{\substack{\text{distinct subloops } M \text{ of } f^J \\ \text{w.r.t. } J_b \text{ except subloop } B}} \text{Tr } \eta'^{j_{M(1)}}\eta'^{j_{M(2)}}\cdots\eta'^{j_{M(v)}} \\ & \cdot \{\text{Tr } \eta'^{i_{A(1)}}\cdots\eta'^{i_{A(\alpha)}},\ \text{Tr } \eta'^{j_{B(1)}}\cdots\eta'^{j_{B(\beta)}}\}_N, \end{aligned} \tag{35}$$

where $J_b=(j_{b(-1)},j_{b(1)},j_{b(-2)},j_{b(2)},\ldots,j_{b(-l)},j_{b(l)})$ is an allowable set of contracted indices in J for a positive integer l, u, and v are the degrees of the subloops L and M, respectively, and α and β are the degrees of the subloops A and B. Furthermore, from Eqs. (25) and (19),

$$\begin{aligned}&\{\mathrm{Tr}\,\eta'^{i_{A(1)}}\cdots\eta'^{i_{A(\alpha)}},\ \mathrm{Tr}\,\eta'^{j_{B(1)}}\cdots\eta'^{j_{B(\beta)}}\}_N\\ &=\sum_{r'=1}^{\infty}\sum_{\substack{\mu_1<\mu_2<\cdots<\mu_{r'}\\(\nu_1>\nu_2>\cdots>\nu_{r'})}}\hbar^{r'}(S^{-1})^{i_{A(\mu_1)}}(S^{-1})^{i_{A(\mu_2)}}\cdots(S^{-1})^{i_{A(\mu_{r'})}}\\ &\quad\cdot(S^{-1})^{j_{B(\nu_1)}}(S^{-1})^{j_{B(\nu_2)}}\cdots(S^{-1})^{j_{B(\nu_{r'})}}\\ &\quad\cdot(C^{i_{A(\mu_1)}j_{B(\nu_1)}}C^{i_{A(\mu_2)}j_{B(\nu_2)}}\cdots C^{i_{A(\mu_{r'})}j_{B(\nu_{r'})}}-C^{j_{B(\nu_1)}i_{A(\mu_1)}}C^{j_{B(\nu_2)}i_{A(\mu_2)}}\cdots C^{j_{B(\nu_{r'})}i_{A(\mu_{r'})}})\\ &\quad\cdot H^{I_A(\mu_1,\mu_2)J_B(\nu_2,\nu_1)}H^{I_A(\mu_2,\mu_3)J_B(\nu_3,\nu_2)}\cdots H^{I_A(\mu_{r'},\mu_1)J_B(\nu_1,\nu_{r'})}.\end{aligned}\tag{36}$$

In this equation, if $\mu_1<\mu_2$, then

$$I_A(\mu_1,\mu_2)=i_{A(\mu_1+1)},i_{A(\mu_1+2)},\ldots,i_{A(\nu_2-1)}.\tag{37}$$

If, instead, $\mu_1\geqslant\mu_2$, then

$$I_A(\mu_1,\mu_2)=i_{A(\mu_1+1)},i_{A(\mu_1+2)},\ldots,i_{A(\alpha)},i_{A(1)},i_{A(2)},\ldots,i_{A(\nu_2-1)}.\tag{38}$$

We have a similar definition for $J_B(\nu_2,\nu_1)$. In addition,

$$H^{I_A(\mu_1,\mu_2)J_B(\nu_2,\nu_1)}=\mathrm{Tr}\,\eta'^{i_{A(\mu_1+1)}}\cdots\eta'^{i_{A(\mu_2-1)}}\eta'^{j_{B(\nu_2+1)}}\cdots\eta'^{j_{B(\nu_1-1)}}\tag{39}$$

if $\mu_1<\mu_2$ and $\nu_1>\nu_2$, and so on for $H^{I_A(\mu_2,\mu_3)J_B(\nu_3,\nu_2)}$, …, etc.

Let us define,

$$\omega^{ij}=\mathrm{i}(S^{-1})^i(S^{-1})^j(C^{ij}-C^{ji}).\tag{40}$$

Then Eq. (36) can be simplified by the following lemma:

Lemma 10: (Within the statements and proofs of Lemmas 10 and 11, $i_{A(\mu_k)}$ and $j_{B(\nu_k)}$ will be abbreviated as i_k and j_k, respectively.) The following identity holds true:

$$\begin{aligned}&(S^{-1})^{i_1}(S^{-1})^{i_2}\cdots(S^{-1})^{i_{r'}}(S^{-1})^{j_1}(S^{-1})^{j_2}\cdots(S^{-1})^{j_{r'}}\\ &\quad\cdot(C^{i_1j_1}C^{i_2j_2}\cdots C^{i_{r'}j_{r'}}-C^{j_1i_1}C^{j_2i_2}\cdots C^{j_{r'}i_{r'}})\\ &=2\sum_{\substack{\text{distinct sets of choices for}\\ \Delta\text{ with an odd number of }\omega'\text{s}}}(\Delta)^{i_1j_1}(\Delta)^{i_2j_2}\cdots(\Delta)^{i_{r'}j_{r'}}\end{aligned}\tag{41}$$

where each $(\Delta)^{ij}$ can be chosen as either $-(i/2)\omega^{ij}$ or $(1/\hbar)T^{ij}$.

In order to prove Lemma 10, we need to state and prove Lemma 11 simultaneously.

Lemma 11: The following identity holds true:

$$\begin{aligned}&(S^{-1})^{i_1}(S^{-1})^{i_2}\cdots(S^{-1})^{i_{r'}}(S^{-1})^{j_1}(S^{-1})^{j_2}\cdots(S^{-1})^{j_{r'}}\\ &\quad\cdot(C^{i_1j_1}C^{i_2j_2}\cdots C^{i_{r'}j_{r'}}+C^{j_1i_1}C^{j_2i_2}\cdots C^{j_{r'}i_{r'}})\\ &=2\sum_{\substack{\text{distinct sets of choices of}\\ \Delta\text{ with an even number of }\omega'\text{s}}}(\Delta)^{i_1j_1}(\Delta)^{i_2j_2}\cdots(\Delta)^{i_{r'}j_{r'}}\end{aligned}\tag{42}$$

Proof of Lemmas 10 and 11: Let us calculate the coefficient of the term

$$(S^{-1})^{i_1}(S^{-1})^{i_2}\cdots(S^{-1})^{i_{r'}}(S^{-1})^{j_1}(S^{-1})^{j_2}\cdots(S^{-1})^{j_{r'}}C^{i_1j_1}C^{i_2j_2}\cdots C^{i_{r'}j_{r'}} \tag{43}$$

on the right-hand sides of Eqs. (41) and (42) first. This is $(1/2^{r-1})$ the number of summands on the right-hand sides of these two equations because each summand contributes to Formula (43) whatever set of choices of Δ's we choose. Since the number of distinct choices is $C_1^{r'}+C_3^{r'}+\cdots+C_{r'-1}^{r'}$ or $C_1^{r'}+C_3^{r'}+\cdots+C_{r'}^{r'}=2^{r'-1}$ for Eq. (41) and $C_0^{r'}+C_2^{r'}+\cdots+C_{r'-1}^{r'}$ or $C_0^{r'}+C_2^{r'}+\cdots+C_{r'}^{r'}=2^{r'-1}$ for Eq. (42), this coefficient is 1. Similarly, the numerical coefficient of the expression

$$(S^{-1})^{i_1}(S^{-1})^{i_2}\cdots(S^{-1})^{i_{r'}}(S^{-1})^{j_1}(S^{-1})^{j_2}\cdots(S^{-1})^{j_{r'}}C^{j_1i_1}C^{j_2i_2}\cdots C^{j_{r'}i_{r'}} \tag{44}$$

is -1 on the R.H.S. of Eq. (41) and 1 on that of Eq. (42), the negative sign in Eq. (41) being due to the fact that we choose an odd number of the Δ's to be ω's, whereas in Eq. (42) we choose an even number. Hence, every term on the left-hand sides of Eq. (41) and Eq. (42) are contained in the right-hand sides of the same equations with the same coefficient. We are going to show that there are no other terms on the R.H.S.'s besides the terms present on the left-hand sides.

Indeed, let $C^{\langle ij\rangle}=C^{ij}$ or C^{ji}, and let $P(r',k,-)$ be the proposition that the coefficient of $C^{\langle i_1j_1\rangle}C^{\langle i_2j_2\rangle}\cdots C^{\langle i_{r'}j_{r'}\rangle}$, where k of the $C^{\langle ij\rangle}$'s are C^{ji}'s and $r'-k$ of them are C^{ij}'s vanishes on the R.H.S. of Eq. (41) for $1\leqslant k\leqslant r'-1$. Similarly, let $P(r',k,+)$ be the proposition that this coefficient vanishes on the R.H.S. of Eq. (42) for $1\leqslant k\leqslant r'-1$. Consider $P(2,1,-)$ and $P(2,1,+)$. The R.H.S. of Eq. (41) is

$$-i\frac{T^{i_1j_1}\omega^{i_2j_2}}{\hbar}-i\frac{\omega^{i_1j_1}T^{i_2j_2}}{\hbar}=(S^{-1})^{i_1}(S^{-1})^{i_2}(S^{-1})^{j_1}(S^{-1})^{j_2}(C^{i_1j_1}C^{i_2j_2}-C^{j_1i_1}C^{j_2i_2}). \tag{45}$$

Therefore, $P(2,1,-)$ is true. Similarly, the R.H.S. of Eq. (42) is

$$2\frac{T^{i_1j_1}T^{i_2j_2}}{\hbar^2}-\frac{1}{2}\omega^{i_1j_1}\omega^{i_2j_2}=(S^{-1})^{i_1}(S^{-1})^{i_2}(S^{-1})^{j_1}(S^{-1})^{j_2}(C^{i_1j_1}C^{i_2j_2}+C^{j_1i_1}C^{j_2i_2}). \tag{46}$$

Hence $P(2,1,+)$ is also true.

Now assume that $P(r'',k,-)$ and $P(r'',k,+)$ are true for a positive integer $r''\geqslant 2$ and $1\leqslant k\leqslant r''-1$. Consider $P(r''+1,k,-)$. There are 2 types of summands on the R.H.S. of Eq. (41) which contributes to $t=C^{\langle i_1j_1\rangle}\cdots C^{\langle i_{r''}j_{r''}\rangle}C^{\langle i_{r''+1}j_{r''+1}\rangle}$. One type (*type 1 summands*) is of the general form $(\Delta)^{i_1j_1}\cdots(\Delta)^{i_{r''}j_{r''}}T^{i_{r''+1}j_{r''+1}}$. Here an odd number of the Δ's are ω's, and the rest are T's. The other type (*type 2 summands*) is of the general form $(\Delta)^{i_1j_1}\cdots(\Delta)^{i_{r''}j_{r''}}\omega^{i_{r''+1}j_{r''+1}}$. Here an even number of the Δ's are ω's. There are several different cases.

- *Case 1*: $2\leqslant k\leqslant r''-1$.

Subcase a: $t=C^{\langle i_1j_1\rangle}\cdots C^{\langle i_{r''}j_{r''}\rangle}C^{i_{r''+1}j_{r''+1}}$.

Since $P(r'',k,-)$ is true, the coefficient of t derived from type 1 summands, where the first r'' $C^{\langle ij\rangle}$'s come from $(\Delta)^{ij}$'s and $C^{i_{r''+1}j_{r''+1}}$ comes from $T^{i_{r''+1}j_{r''+1}}$, is 0. Since $P(r'',k,+)$ is also true, the coefficient of t derived from type 2 summands, where $C^{i_{r''+1}j_{r''+1}}$ comes from $\omega^{i_{r''+1}j_{r''+1}}$ instead, is also 0. As a result, $P(r''+1,k,-)$ is true in this subcase.

Subcase b: $t=C^{\langle i_1j_1\rangle}\cdots C^{\langle i_{r''}j_{r''}\rangle}C^{j_{r''+1}i_{r''+1}}$.

Since $P(r'',k-1,-)$ is true, the coefficient of t derived from type 1 summands is 0. Since $P(r'',k-1,+)$ is also true, the coefficient of t from type 2 summands is also 0. Hence $P(r''+1,k,-)$ is also true in this subcase.

- *Case 2:* $k=1$.

Subcase a: $t=C^{\langle i_1j_1\rangle}\cdots C^{\langle i_{r''}j_{r''}\rangle}C^{i_{r''+1}j_{r''+1}}$.

This is exactly the same as Subcase 1a.

Subcase b: $t=C^{i_1j_1}\cdots C^{i_{r''}j_{r''}}C^{j_{r''+1}i_{r''+1}}$.

The coefficient of t derived from type 1 summands is $\frac{1}{2}$ (this $\frac{1}{2}$ comes from the term $\frac{1}{2}C^{j_{r''+1}i_{r''+1}}$ in $T^{i_{r''+1}j_{r''+1}}$), and the coefficient of t derived from type 2 summands is $-\frac{1}{2}$ (because of the term $-\frac{1}{2}C^{j_{r''+1}i_{r''+1}}$ in $\omega^{j_{r''+1}i_{r''+1}}$). Hence the total coefficient is $\frac{1}{2}-\frac{1}{2}=0$, i.e., $P(r''+1,1,-)$ is true in this case.

• *Case 3:* $k=r''$

Subcase a: $t=C^{j_1 i_1}\cdots C^{j_{r''}i_{r''}}C^{i_{r''+1}j_{r''+1}}$.

The coefficient of t derived from type 1 summands is $-\frac{1}{2}$, whereas that derived from type 2 summands is $\frac{1}{2}$. Hence the total coefficient vanishes and $P(r''+1,r'',-)$ is true in this case.

Subcase b: $t=C^{\langle i_1 j_1\rangle}\cdots C^{\langle i_{r''}j_{r''}\rangle}C^{j_{r''+1}i_{r''+1}}$.

This is the same as Subcase 1b.

Thus $P(r''+1,k,-)$ is true for all cases for $1\leqslant k\leqslant r''$. With the same induction hypothesis, $P(r''+1,k,+)$ is also true by a similar analysis. By induction, $P(r',k,-)$ and $P(r',k,+)$ are always true for $r'\geqslant 2$ and $1\leqslant k\leqslant r'-1$. Q.E.D.

With the help of Lemma 10, we can derive from Eqs. (35) and (36) that $\{F(f^I),F(f^J)\}_N$ is a linear combination of all terms of the form

$$
\begin{aligned}
&T^{i_{a(-1)}i_{a(1)}}T^{i_{a(-2)}i_{a(2)}}\cdots T^{i_{a(-k)}i_{a(k)}}T^{j_{b(-1)}j_{b(1)}}T^{j_{b(-2)}j_{b(2)}}\cdots T^{j_{b(-l)}j_{b(l)}}\\
&\cdot\prod_{\substack{\text{distinct subloops } L \text{ of } f^I\\ \text{w.r.t. } I_a \text{ except subloop } A}}\operatorname{Tr}\eta'^{i_{L(1)}}\eta'^{i_{L(2)}}\cdots\eta'^{i_{L(u)}}\\
&\cdot\prod_{\substack{\text{distinct subloops } M \text{ of } f^J\\ \text{w.r.t. } J_b \text{ except subloop } B}}\operatorname{Tr}\eta'^{j_{M(1)}}\eta'^{j_{M(2)}}\cdots\eta'^{j_{M(v)}}\\
&\cdot 2\hbar^{r'}(\Delta)^{i_{A(\mu_1)}j_{B(\nu_1)}}(\Delta)^{i_{A(\mu_2)}j_{B(\nu_2)}}\cdots(\Delta)^{i_{A(\mu_{r'})}j_{B(\nu_{r'})}}\\
&\cdot H^{I_{A(\mu_1,\mu_2)}J_{B(\nu_2,\nu_1)}}H^{I_{A(\mu_2,\mu_3)}J_{B(\nu_3,\nu_2)}}\cdots H^{I_{A(\mu_{r'},\mu_1)}J_{B(\nu_1,\nu_{r'})}}
\end{aligned}
\tag{47}
$$

with an arbitrary allowable I_a, an arbitrary allowable J_b, an arbitrary positive integer r', arbitrary sets of μ's and ν's such that $\mu_1<\mu_2<\cdots<\mu_{r'}$ and $(\nu_1>\nu_2>\cdots>\nu_{r'})$, and an arbitrary set $\mathcal{C}$ of choices of Δ's with an odd number of ω's. On the other hand, from Eqs. (21) and (31), $F(\{f^I,f^J\}_W)$ is a linear combination of all terms of the form

$$
\begin{aligned}
&2\mathrm{i}\left(-\frac{\mathrm{i}\hbar}{2}\right)^r\omega^{i_{\rho_1}j_{\sigma_1}}\cdots\omega^{i_{\rho_r}j_{\sigma_r}}\cdot\prod_{p=1}^{r}T^{\kappa^{(p)}_{a(-1)}\kappa^{(p)}_{a(1)}}T^{\kappa^{(p)}_{a(-2)}\kappa^{(p)}_{a(2)}}\cdots T^{\kappa^{(p)}_{a(-k)}\kappa^{(p)}_{a(k)}}\\
&\cdot\prod_{\substack{\text{distinct subloops } L\\ \text{of } f^K \text{ w.r.t. } K^{(p)}_a}}\operatorname{Tr}\eta'^{\kappa^{(p)}_{L(1)}}\eta'^{\kappa^{(p)}_{L(2)}}\cdots\eta'^{\kappa^{(p)}_{L(u)}}
\end{aligned}
\tag{48}
$$

with an arbitrary positive odd integer r, arbitrary sets of ρ's and σ's such that $\rho_1<\rho_2<\cdots<\rho_r$ and $(\sigma_1>\sigma_2>\cdots>\sigma_r)$, and an arbitrary allowable set of contracted indices $K^{(p)}_a$ in

$$
K^{(p)}=\begin{cases} I(\rho_p,\rho_{p+1})J(\sigma_{p+1},\sigma_p) & \text{for } 1\leqslant p\leqslant r-1\\ I(\rho_r,\rho_1)J(\sigma_1,\sigma_r) & \text{for } p=r.\end{cases}
\tag{49}
$$

Moreover, the indices of $K^{(p)}$ are $\kappa^{(p)}_1,\kappa^{(p)}_2,\ldots,$ etc.

It is possible to rewrite Eqs. (47) and (48) in the same form. Because of the emergence of a large number of new parameters, before writing out the new expression (Eq. (52) below), we would like to introduce these parameters first with the help of Fig. 4.

In Fig. 4, the oval object on the left, which is delineated by a thick closed line with an arrow, is the Weyl-ordered loop variable f^I. The oval object on the right is f^J. If we map them to

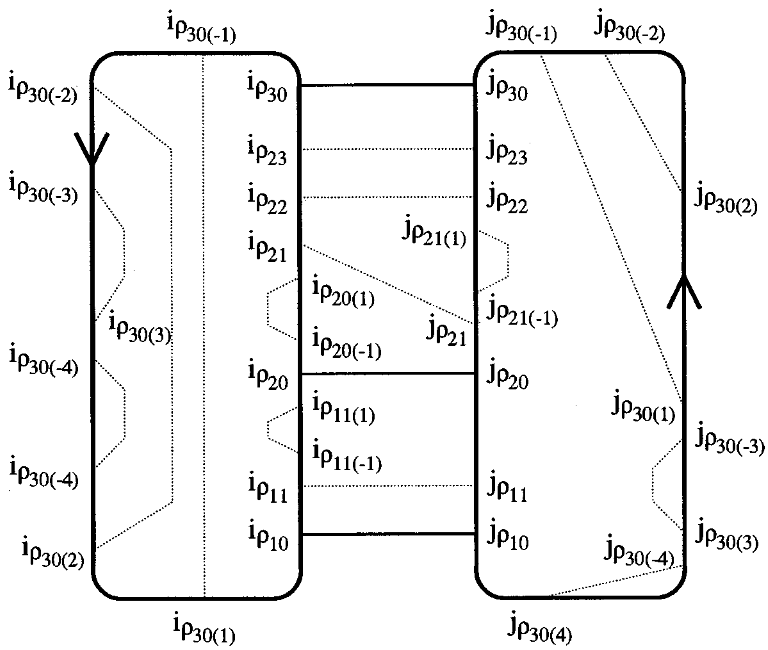

FIG. 4. An illustration for a typical term in Eq. (52). See the text for the legend of this figure.

normal-ordered loop variables and then take the Poisson bracket, we will obtain Eq. (47); if we take the Poisson bracket first and map the resultant expression to the space of normal-ordered loop variables later, we will obtain Eq. (48) instead. There are a number of ω^{ij}'s in both Eqs. (47) and (48). They will be labeled as $\omega^{i_{\rho_{10}}j_{\sigma_{10}}}$, $\omega^{i_{\rho_{20}}j_{\sigma_{20}}}$, $\ldots$, and $\omega^{i_{\rho_{r0}}j_{\sigma_{r0}}}$, where r is a positive *odd* integer. Moreover, it is always possible to arrange the indices in such a way that $i_{\rho_{10}}<i_{\rho_{20}}<\cdots<i_{\rho_{r0}}$ and $(j_{\sigma_{10}}>j_{\sigma_{20}}>\cdots>j_{\sigma_{r0}})$. We represent these ω's as solid lines joining the two oval objects in Fig. 4.

There are also a number of T^{ij}'s, where the index i comes from I and j comes from J, in both Eqs. (47) and (48). We will show in the following two lemmas that if they are generically labeled as $T^{i_{\rho_{x_1x_2}}j_{\sigma_{x_1x_2}}}$, where $1\leq x_1\leq r$ and x_2 is an integer between 1 and a certain positive integer s_{x_1}, in such a way that

$$(\rho_{10}<\rho_{11}<\cdots<\rho_{1s_1}<\rho_{20}<\rho_{21}<\cdots<\rho_{2s_2}<\cdots<\rho_{r0}<\rho_{r1}<\cdots<\rho_{rs_r}), \tag{50}$$

then

$$(\sigma_{10}>\sigma_{11}>\cdots>\sigma_{1s_1}>\sigma_{20}>\sigma_{21}>\cdots>\sigma_{2s_2}>\cdots>\sigma_{r0}>\sigma_{r1}>\cdots>\sigma_{rs_r}). \tag{51}$$

These T's are depicted as broken lines joining the two oval objects in Fig. 4.

There are other T^{ij} in both Eqs. (47) and (48) such that both i and j come from I. We will also show in the following two lemmas that they can be generically labeled as $T^{i_{a_{x_1x_2(-x_3)}}i_{a_{x_1x_2(x_3)}}}$, where x_3 is an integer between 1 and a certain positive integer $k_{x_1x_2}$ in such a way that $i_{a_{x_1x_2}(\pm x_3)}\in I(\rho_{x_1x_2},\rho_{x_1x_2+1})$ for $x_2<s_{x_1}$ or $i_{a_{x_1x_2}(\pm x_3)}\in I(\rho_{x_1x_2},\rho_{x_1+_m1,0})$ for $x_2=s_{x_1}$. These T's are depicted as broken lines within the left oval object in Fig. 4. There are still other T^{ij} in both equations such that both i and j come from J. Likewise, we will show that they can be generically labeled $T^{j_{b_{x_1x_2(-x_3)}}j_{b_{x_1x_2(x_3)}}}$, where x_3 is an integer between 1 and a certain positive integer $l_{x_1x_2}$ in such a way that $j_{b_{x_1x_2}(\pm y_3)}\in I(\sigma_{x_1x_2},\sigma_{x_1x_2+1})$ for $x_2<s_{x_1}$ or $j_{b_{x_1x_2}(\pm y_3)}\in I(\sigma_{x_1x_2},\sigma_{x_1+_m1,0})$ for $x_2=s_{x_1}$. These T's are depicted as broken lines within the right oval object in Fig. 4.

We are now ready to introduce the following lemmas.

Lemma 12: $i\{F(f^I),F(f^J)\}_N$ *is equal to a linear combination of all terms of the form*

$$2i\prod_{x_1=1}^{r}\left(-\frac{i\hbar}{2}\right)\omega^{i_{\rho_{x_1 0}}j_{\sigma_{x_1 0}}}\prod_{x_2=1}^{s_{x_1}}T^{i_{\rho_{x_1x_2}}j_{\sigma_{x_1x_2}}}\cdot\prod_{x_3=1}^{k_{x_1x_2}}T^{i_{a_{x_1x_2}(-x_3)}i_{a_{x_1x_2}(x_3)}}\prod_{y_3=1}^{l_{x_1x_2}}T^{\sigma_{b_{x_1x_2}(-y_3)}j_{b_{x_1x_2}(y_3)}}$$
$$\cdot\prod_{\substack{\text{distinct subloops } L \text{ within } I\\ \text{w.r.t. all contracted indices in } I}}\operatorname{Tr}\eta'^{i_{L(1)}}\eta'^{i_{L(2)}}\cdots\eta'^{i_{L(u)}}$$
$$\cdot\prod_{\substack{\text{distinct subloops } M \text{ within } J\\ \text{w.r.t. all contracted indices in } J}}\operatorname{Tr}\eta'^{j_{M(1)}}\eta'^{j_{M(2)}}\cdots\eta'^{j_{M(v)}}$$
$$\cdot\prod_{\substack{\text{distinct subloops } QR \text{ between } I \text{ and } J\\ \text{w.r.t. all contracted indices in } I \text{ and } J}}\operatorname{Tr}\eta'^{i_{Q(1)}}\eta'^{i_{Q(2)}}\cdots\eta'^{i_{Q(w_1)}}\cdot\eta'^{j_{R(1)}}\eta'^{j_{R(2)}}\cdots\eta'^{j_{R(w_2)}},\tag{52}$$

where

(1) *r is an arbitrary odd positive integer;*
(2) *the set of indices $\rho_{x_1x_2}$ is arbitrary except that these indices have to satisfy Eq. (50). Similarly, the set of indices $\sigma_{x_1x_2}$ is arbitrary except that these indices have to satisfy Eq. (51).*
(3) *the set of all $i_{a_{x_1x_2}(\pm x_3)}$'s is an arbitrary allowable set of contracted indices in I satisfying the stipulations in a paragraph on p. 42, and with $i_{a_{x_1x_2}(-x_3)}$ and $i_{a_{x_1x_2}(x_3)}$ forming a contraction pair. Similarly, the set of all $j_{b_{x_1x_2}(\pm y_3)}$'s is an arbitrary allowable set of contracted indices in J also satisfying the stipulations in the same paragraph, and with $j_{b_{x_1x_2}(-y_3)}$ and $j_{b_{x_1x_2}(y_3)}$ forming a contraction pair;*
(4) *u and v are the degrees of the subloops L and M, respectively. w_1 and w_2 are integers such that w_1+w_2 is the degree of the subloop QR; and*
(5) *the set of all indices in I belonging to any subloop QR comes from one subloop in I with respect to the set of all $i_{a_{x_1x_2}(\pm x_3)}$'s. Similarly, the set of all indices in J belonging to any subloop QR comes from one subloop in J with respect to the set of all $J_{b_{x_1x_2}(\pm y_3)}$'s.*

Proof: First of all, let us prove that any expression of the form shown in Eq. (47) can be rewritten in the manner shown in Eq. (52). Indeed, let r be the number of Δ's in Eq. (47) which are ω's. r is then a positive odd number (Statement (1)). By Corollary 2, $\mu_1<\mu_2<\cdots<\mu_{r'}$ implies $A(\mu_1)<A(\mu_2)<\cdots<A(\mu_{r'})$ and $(\nu_1<\nu_2<\cdots<\nu_{r'})$ implies $(B(\nu_1)<B(\nu_2)<\cdots<B(\nu_{r'}))$. Let us rename the indices $A(\mu_1),A(\mu_2),\ldots,A(\mu_{r'})$ and $B(\nu_1)<B(\nu_2),\ldots,B(\nu_{r'})$ by the following:

Algorithm 3: Here is the procedure of this algorithm.

Step 1: Set $x_1=0$ and $x_2=0$.

Step 2: Set $y=1$.

Step 3: If $(\Delta)^{i_{A(\mu_y)}j_{B(\nu_y)}}=T^{i_{A(\mu_y)}j_{B(\nu_y)}}$, then increment the value of x_2 by 1. Put $\rho_{x_1x_2}=A(\mu_y)$ and $\sigma_{x_1x_2}=B(\nu_y)$.

Step 4: If $(\Delta)^{i_{A(\mu_y)}j_{B(\nu_y)}}=\omega^{i_{A(\mu_y)}j_{B(\nu_y)}}$, then put $s_{x_1}=x_2$. Increment the value of x_1 by 1 and set the value of x_2 to 0. Put $\rho_{x_10}=A(\mu_y)$ and $\sigma_{x_10}=B(\nu_y)$.

Step 5: If $y\neq r'$, then increment the value of y by 1. Go back to Step 3.

Step 6: Put $s_r=x_2+s_0$.

Step 7: Set $x_2'=1$.

Step 8: If $x_2'>s_0$, then end the algorithm.

Step 9: Put $\rho_{r,x_2+x_2'}=\rho_{0,x_2'}$ *and* $\sigma_{r,x_2+x_2'}=\sigma_{0,x_2'}$.
Step 10: Increment the value of x_2' *by 1.*
Step 11: Go back to Step 8.

It is now clear that Eqs. (50) and (51) are true (Statement (2)). Consider $i_{a(-s)}$ and $i_{a(s)}$ in Eq. (47), where $1\le|s|\le k$. If $i_{a(-s)}\in I(\rho_{x_1x_2},\rho_{x_1,x_2+1})$ where $x_2<s_{x_1}$ but $i_{a(s)}\in I(\rho_{x_1,x_2+1},\rho_{x_1x_2})$, then $i_{\rho_{x_1x_2}}\in I(a(s),a(-s))$ and $i_{\rho_{x_1,x_2+1}}\in I(a(-s),a(s))$. Thus two subloops of f^I are involved to produce the γ's by Lemma 7 and then the Δ's in the Poisson bracket with f^J. However, only one subloop of f^I, namely A in Eq. (47), should be involved and this leads to a contradiction. Hence, if $i_{a(-s)}\in I(\rho_{x_1x_2},\rho_{x_1,x_2+1})$, then $i_{a(s)}\in I(\rho_{x_1x_2},\rho_{x_1,x_2+1})$ also. Similarly, if $i_{a(-s)}\in I(\rho_{x_1,x_2+1},\rho_{x_1x_2})$, then $i_{a(s)}\in I(\rho_{x_1,x_2+1},\rho_{x_1x_2})$ also. In addition, $i_{a(-s)}$ and $i_{a(s)}\in I(\rho_{x_1s_{x_1}},\rho_{x_1+_r1,0})$ or $i_{a(-s)}$ and $i_{a(s)}\in I(\rho_{x_1+_r1,0},\rho_{x_1s_{x_1}})$. Let $a_{x_1x_2}(\pm 1),a_{x_1x_2}(\pm 2),\ldots,a_{x_1x_2}(\pm k_{x_1x_2})$ be those $a(\pm s)$'s such that $a(\pm s)\in I(\rho_{x_1x_2},\rho_{x_1,x_2+1})$ for $x_2<s_{x_1}$ or $a(\pm s)\in I(\rho_{x_1s_{x_1}},\rho_{x_1+_r1,0})$ for $x_2=s_{x_1}$, and let the $b_{x_1x_2}(\pm x_3)$'s have analogous definitions. These definitions of $a_{x_1x_2}(x_3)$'s and $b_{x_1x_2}(y_3)$'s are consistent with the ones given in the paragraph preceding this Lemma. Furthermore, Statement (3) should be clear. Statements (4) and (5) are direct consequences of Eq. (47).

The subloops L and M are still defined by using Algorithm 1. From Eqs. (47) and (52), every QR lies within $I(\rho_{x_1x_2},\rho_{x_1x_2+1})$ and $J(\sigma_{x_1x_2+1},\sigma_{x_1x_2})$ for $x_2<s_{x_1}$ or within $I(\rho_{x_1s_{x_1}},\rho_{x_1+_r1,0})$ and $J(\sigma_{x_1s_{x_1}},\sigma_{x_1+_r1,0})$. Let $Q(0)=\rho_{x_1x_2}$. If $Q(v)$ is defined for an integer v, then we define $Q^{(i)}(v+1)$ for some integers i as follows:

Algorithm 4: Here is the procedure of this algorithm.
Step 1: Set $i=1$.
Step 2: $Q^{(i)}(v+1)=Q(v)+_m1$.
Step 3: If $Q^{(i)}(v+1)=\rho_{x_1x_2}\exists x_1$ *and* x_2, *then jump to Step 9.*
Step 4: If $Q^{(i)}(v+1)\neq a_{x_1x_2}(x_3)\forall x_1,x_2,x_3$ *(where* x_3 *can be positive or negative), then end the algorithm.*
Step 5: Let $\{x_1,x_2,x_3\}$ *be a set of numbers such that* $a_{x_1x_2}(x_3)=Q^{(i)}(v+1)$.
Step 6: Increment the value of i by 1.
Step 7: Set $Q^{(i)}(v+1)=a_{x_1x_2}(-x_3)+_m1$.
Step 8: Go back to Step 3.
Step 9: Let $\{x_1,x_2\}$ *be a set of numbers such that* $\rho_{x_1x_2}=Q^{(i)}(v+1)$.
Step 10: Increment the value of i by 1.
Step 11: Set $Q^{(i)}(v+1)=\sigma_{x_1x_2}$.
Step 12: End the algorithm.

If the algorithm was ended in Step 4, then define $Q(v+1)=Q^{(i)}(v+1)$; if the algorithm was ended in Step 12, then define $R(0)=Q^{(i)}(v+1)$. If $R(v)$ is defined for an integer v, then we define $R^{(i)}(v+1)$ for some integers i by *Algorithm 5*, which is the same as Algorithm 4 except that $Q^{(i)}(v+1)$ is changed to $R^{(i)}(v+1)$, $+_m$ to $+_n$, $\rho_{x_1x_2}$ to $\sigma_{x_1x_2}$, $a_{x_1x_2}(x_3)$ to $b_{x_1x_2}(y_3)$, and $\sigma_{x_1x_2}$ to $\rho_{x_1x_2}$. Then, if Algorithm 5 was ended in Step 4, we will define $R(v+1)=R^{(i)}(v+1)$; if it was ended in Step 12, then this $R^{(i)}(v+1)$ should be exactly $Q(0)$.

Conversely, now let us prove that any expression in the form shown in Eq. (52) and satisfying the five ensuing statements can be rewritten in the way shown in Eq. (47). It should be clear by a reversal of the procedure described earlier in this proof that we can rewrite the $-\mathrm{i}\omega^{i_{\rho_{x_10}}j_{\sigma_{x_10}}}/2$'s and $T^{i_{\rho_{x_1x_2}}j_{\sigma_{x_1x_2}}}/\hbar$'s as $(\Delta)^{i_{A(\mu_x)}j_{B(\nu_x)}}$'s with $\mu_1<\mu_2<\cdots<\mu_{r'}$ and $(\nu_1>\nu_2>\cdots>\nu_{r'})$. Moreover, the $T^{i_{a_{x_1x_2}(-x_3)}i_{a_{x_1x_2}(x_3)}}$'s can be rewritten as $T^{i_{a(-x)}i_{a(x)}}$'s, and the $T^{j_{b_{x_1x_2}(-y_3)}j_{b_{x_1x_2}(y_3)}}$'s can be rewritten as $T^{j_{b(-y)}j_{b(y)}}$'s. If we can show that the set of all $i_{\rho_{x_1x_2}}$'s come from one subloop with respect to the set of $i_{a_{x_1x_2}(x_3)}$'s in I, and the set of all $j_{\sigma_{x_1x_2}}$'s come from one subloop with respect to the set of $j_{b_{x_1x_2}(y_3)}$'s in J, then the subloops QR can be rewritten as those H's in Eq. (47).

To show that all $i_{\rho_{x_1x_2}}$'s come from one subloop, we need to show that if $L(v')=\rho_{x_1x_2}$ for some values of x_1 and x_2, then there exists an integer v such $L(v)=\rho_{x_1x_2+1}$ for $x_2<s_{x_1}$ or $L(v)=\rho_{x_1+_r1,0}$ for $x_2=s_{x_1}$. We will write $L(v)=\rho_{x_1x_2+1}$ generically. We can set $v'=1$ without loss of generality by Lemma 6. Obviously $(L(1)<\rho_{x_1x_2+1})$. Assume that $(L(1)<L(2)<\cdots L(v-1)<\rho_{x_1x_2+1})$ for an integer $v>1$, and assume that $L(v)$ does not exist. Then there should be an $L^{\iota'}(v)$ for an integer $\iota'\geqslant 1$ such that $L^{(\iota')}(v)=a_{\tilde{x}_1\tilde{x}_2}(-\tilde{x}_3)$ for some integers $\tilde{x}_1,\tilde{x}_2,\tilde{x}_3$ and $a_{\tilde{x}_1\tilde{x}_2}(\tilde{x}_3)+_m1=L(1)$. Thus $(a_{\tilde{x}_1\tilde{x}_2}(\tilde{x}_3)<L(1)<L^{(1)}(v)<\rho_{x_1x_2+1})$. Hence there exists a smallest integer ι such that $(a_{x_1x_2}(x_3)<L(1)<L^{(\iota)}(v)<\rho_{x_1x_2+1})$, where $a_{x_1x_2}(-x_3)=L^{(\iota)}(v)$. However, this is impossible and so $L(v)$ exists. Assume $(\rho_{x_1x_2+1}<L(v)<L(1))$. Then there should be an $L^{(\iota')}(v)$ for an integer $\iota'\geqslant 1$ such that $L^{(\iota')}(v)=a_{\tilde{x}_1\tilde{x}_2}(-\tilde{x}_3)$ for some integers $\tilde{x}_1,\tilde{x}_2,\tilde{x}_3$ and $a_{\tilde{x}_1\tilde{x}_2}(\tilde{x}_3)+_m1=L(v)$. Hence $(L^{(1)}(v)<\rho_{x_1x_2+1}<a_{\tilde{x}_1\tilde{x}_2}(x_3)<L(1))$. This implies the existence of a smallest integer ι such that $L^{(\iota)}(v)=a_{x_1x_2}(-x_3)$ for an integer x_3 and $(L^{(\iota)}\times(v)<\rho_{x_1x_2+1}<a_{x_1x_2}(x_3)<L(1))$. Again this is impossible. Hence $(L(1)<L(v)\leqslant\rho_{x_1x_2+1})$. By Corollary 2, $(L(1)<L(2)<\cdots<L(v)\leqslant\rho_{x_1x_2+1})$. Since there are only a finite number of indices between $L(1)$ and $\rho_{x_1x_2+1}$, there exists a number $\tilde{v}$ such that $L(\tilde{v})=\rho_{x_1x_2+1}$. Hence $i_{\rho_{x_1x_2}}$ and $i_{\rho_{x_1x_2+1}}$ belong to the same subloop of I. Consequently, the set of all $i_{\rho_{x_1x_2}}$'s for $1\leqslant x_1\leqslant r$ and $0\leqslant x_2\leqslant s_{x_1}$ belongs to one subloop of I. Similarly, the set of all $j_{\sigma_{x_1x_2}}$'s belongs to one subloop of J. Q.E.D.

Before we prove Lemma 13, we remark that in the following, by $I(\rho_{x_10},\rho_{x_1+_r1,0})J(\sigma_{x_1+_r1,0},\sigma_{x_10})(\rho_{x_1x_2},\sigma_{x_1x_2})$ we mean the sequence $i_{\rho_{x_1x_2}+1},i_{\rho_{x_1x_2}+2},\ \ldots,i_{\rho_{x_1+_r1,0}},j_{\sigma_{x_1+_r1,0}},\ldots,j_{\sigma_{x_1x_2}}$.

Lemma 13: $F(\{f^I,f^j\}_W)$ can also be written as a linear combination of all terms of the form shown in Eq. (52) with the five accompanying statements.

Proof: First of all, let us show that any expression of the form given in Eq. (48) can be rewritten as shown in Eq. (52) with the accompanying five statements being satisfied. Indeed, Statement (1) is obvious. Let us rename the indices $\rho_1,\rho_2,\ \ldots,\rho_r,\sigma_1,\sigma_2,\ \ldots,\sigma_r$ in Eq. (48) as $\rho_{10},\rho_{20},\ \ldots,\rho_{r0},\sigma_{10},\sigma_{20},\ \ldots,\sigma_{r0}$. Moreover, within the loop $f^{I(\rho_{x_10},\rho_{x_1+_r1,0})J(\sigma_{x_1+_r1,0},\sigma_{x_10})}$, for those contraction pairs with one index coming from I and the other one from J, call these indices $i_{\rho_{x_1x_2}}$ and $j_{\sigma_{x_1x_2}}$ in such a way that $\rho_{x_10}<\rho_{x_11}<\cdots<\rho_{x_1s_{x_1}}<\rho_{x_1+1,0}$ if there are s_{x_1} such pairs for $x_1<r$, or $(\rho_{r0}<\rho_{r1}<\cdots<\rho_{rs_r}<\rho_{10})$ if $x_1=r$. Thus Eq. (50) is true. Obviously $(\sigma_{x_1+_r1,0}>\sigma_{x_11}>\sigma_{x_10})$. Assume that $(\sigma_{x_1+_r1,0}>\sigma_{x_1x_2}>\sigma_{x_1x_2-1}>\cdots>\sigma_{x_10})$. If $x_2\neq s_{x_1}$, consider σ_{x_1,x_2+1}. Since $i_{\rho_{x_1x_2+1}}\in I(\rho_{x_10},\rho_{x_1+_r1,0})J(\sigma_{x_1+_r1,0},\sigma_{x_10})(\rho_{x_1x_2},\sigma_{x_1x_2})$, we get $j_{\sigma_{x_1,x_2+1}}\in I(\rho_{x_10},\rho_{x_1+_r1,0})J(\sigma_{x_1+_r1,0},\sigma_{x_10})(\rho_{x_1x_2},\sigma_{x_1x_2})$ also. Hence $(\sigma_{x_1+_r1,0}>\sigma_{x_1,x_2+1}>\sigma_{x_1x_2}>\sigma_{x_1,x_2-1}>\cdots>\sigma_{x_10})$. Thus $\sigma_{x_1+_r1,0}>\sigma_{x_1s_{x_1}}>\sigma_{x_1,s_{x_1}-1}>\cdots>\sigma_{x_10}$. Therefore Statement (2) is true. Statements (3) and (4) are obvious.

Now let us fix the values of x_1 and x_2, and consider those contraction pairs with both indices coming from I, and one of them, say i_c, belonging to $I(\rho_{x_1x_2},\rho_{x_1,x_2+1})$ for $x_2<s_{x_1}$ or $I(\rho_{x_1x_2},\rho_{x_1+_r1,0})$ for $x_2=s_{x_1}$. Let $i_{c'}$ be the other index of this contraction pair. Clearly $i_{c'}\in I(\rho_{x_10},\rho_{x_1+_r1,0})$. If i'_c does not belong to $I(\rho_{x_1x_2},\rho_{x_1,x_2+1})$ for $x_2<s_{x_1}$ or $I(\rho_{x_1x_2},\rho_{x_1+_r1,0})$ for $x_2=s_{x_1}$, then $i_c\in I(\rho_{x_10},\rho_{x_1+_r1,0})J(\sigma_{x_1+_r1,0},\sigma_{x_10})(\rho_{x_1x_2},\sigma_{x_1x_2})$ but $i_{c'}\in J(\sigma_{x_1+_r1,0},\sigma_{x_10})I(\rho_{x_10},\rho_{x_1+_r1,0})(\sigma_{x_1x_2},\rho_{x_1x_2})$, which is impossible. Thus any contraction pairs coming only from I can be written as $i_{a_{x_1x_2}(\pm x_3)}$ because both of them must belong to a sequence $I(\rho_{x_1x_2},\rho_{x_1x_2+1})$ with $x_2<s_{x_1}$, or belong to a sequence $I(\rho_{x_1x_2},\rho_{x_1+_m1,0})$ with $x_2=s_{x_1}$.

We can now say that for a fixed value of x_1, the set of all $i_{\rho_{x_1x_2}}$, $j_{\sigma_{x_1x_2}}$, $i_{a_{x_1x_2}(\pm x_3)}$ and $j_{b_{x_1x_2}(\pm y_3)}$, where $1\leqslant x_2\leqslant s_{x_1}$, $1\leqslant x_3\leqslant k_{x_1x_2}$ and $1\leqslant y_3\leqslant l_{x_1x_2}$, together form an allowable set of contracted indices in the loop $I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})$ with $i_{\rho_{x_1 x_2}}$ and $j_{\sigma_{x_1 x_2}}$ being contraction pairs, $i_{a_{x_1 x_2}(x_3)}$ and $i_{a_{x_1 x_2}(-x_3)}$ being contraction pairs, and $j_{b_{x_1 x_2}(y_3)}$ and $j_{b_{x_1 x_2}(-y_3)}$ being contraction pairs.

The remaining thing to do to prove that Statement (5) is satisfied is to show that the set of all $i_{a_{x_1 x_2}(\pm x_3)}$'s for $1 \leqslant x_1 \leqslant r$, $0 \leqslant x_2 \leqslant s_{x_1}$ and $1 \leqslant x_3 \leqslant k_{x_1 x_2}$ is allowable in I, and the set of all $j_{b_{x_1 x_2}(\pm y_3)}$'s for $1 \leqslant x_1 \leqslant r$, $0 \leqslant x_2 \leqslant s_{x_1}$ and $1 \leqslant y_3 \leqslant l_{x_1 x_2}$ is allowable in J. Indeed, since for each fixed x_1, the set of all $i_{a_{x_1 x_2}(\pm x_3)}$'s is allowable in $I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})$, this set alone is allowable in I also. Now let us choose a fixed set of values for x_1, x_2 and x_3. Consider two integers $\tilde{x}_1$ and $\tilde{x}_2$ such that $1 \leqslant \tilde{x}_1 \leqslant r$ and $1 \leqslant \tilde{x}_2 \leqslant s_{\tilde{x}_1}$. In addition, either $\tilde{x}_1 \neq x_1$ or $\tilde{x}_2 \neq x_2$, or both. Then $i_{a_{x_1 x_2}(\pm x_3)} \in I(a_{\tilde{x}_1 \tilde{x}_2}(\tilde{x}_3), a_{\tilde{x}_1 \tilde{x}_2}(-\tilde{x}_3))$ for $1 \leqslant \tilde{x}_3 \leqslant k_{\tilde{x}_1 \tilde{x}_2}$ if $a_{\tilde{x}_1 \tilde{x}_2}(\tilde{x}_3) \geqslant a_{\tilde{x}_1 \tilde{x}_2}(-\tilde{x}_3)$ and $\rho_{\tilde{x}_1 0} < \rho_{\tilde{x}_1+_r 1,0}$, or if $a_{\tilde{x}_1 \tilde{x}_2}(\tilde{x}_3) > a_{\tilde{x}_1 \tilde{x}_2}(-\tilde{x}_3) > \rho_{\tilde{x}_1 0} > \rho_{\tilde{x}_1+_r 1,0}$, or if $\rho_{\tilde{x}_1 0} > \rho_{\tilde{x}_1+_r 1,0} > a_{\tilde{x}_1 \tilde{x}_2}(\tilde{x}_3) > a_{\tilde{x}_1 \tilde{x}_2}(-\tilde{x}_3)$. Similarly, $i_{a x_1 x_2(\pm x_3)} \in I(a_{\tilde{x}_1 \tilde{x}_2}(-\tilde{x}_3), a_{\tilde{x}_1 \tilde{x}_2}(\tilde{x}_3))$ if $a_{\tilde{x}_1 \tilde{x}_2}(\tilde{x}_3) > \rho_{\tilde{x}_1 0} > \rho_{\tilde{x}_1+_r 1,0} > a_{\tilde{x}_1 \tilde{x}_2}(-\tilde{x}_3)$. As a result, the set of all $i_{a_{x_1 x_2}(\pm x_3)}$'s is allowable in I. A similar argument holds for all $j_{b_{x_1 x_2}(\pm y_3)}$'s in J.

The subloops L and M are found by using Algorithm 1, and the subloops QR can again be determined by Algorithms 4 and 5.

Let us consider the converse, i.e., whether any expression of the form shown in Eq. (52) and satisfying the five accompanying statements is a term in Eq. (48). The only thing we need to do to substantiate this converse statement is to prove that if the set of all $i_{a_{x_1 x_2}(\pm x_3)}$'s is allowable in I, the set of all $j_{b_{x_1 x_2}(\pm y_3)}$'s is allowable in J, the set of all $i_{\rho_{x_1 x_2}}$'s satisfies Eq. (50) and the set of all $j_{\sigma_{x_1 x_2}}$'s satisfies Eq. (51), then for each fixed x_1, the set of all $i_{a_{x_1 x_2}(\pm x_3)}$'s and $j_{b_{x_1 x_2}(\pm y_3)}$'s together with $i_{\rho_{x_1 x_2}}$ and $j_{\sigma_{x_1 x_2}}$ is allowable in $f^{I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})}$.

Indeed, let all the five statements accompanying Eq. (52) be satisfied. Obviously the pair $i_{\rho_{x_1 1}}$ and $j_{\sigma_{x_1 1}}$ forms an allowable set of contraction pairs in the loop $I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})$. Assume that $(i_{\rho_{x_1 1}}, j_{\sigma_{x_1 1}}, i_{\rho_{x_1 2}}, j_{\sigma_{x_1 2}}, \ldots, i_{\rho_{x_1 x_2}}, j_{\sigma_{x_1 x_2}})$ is allowable. If $x_2 < s_{x_1}$, consider the set $(i_{\rho_{x_1 1}}, j_{\sigma_{x_1 1}}, i_{\rho_{x_1 2}}, j_{\sigma_{x_1 2}}, \ldots, i_{\rho_{x_1 x_2+1}}, j_{\sigma_{x_1 x_2+1}})$. It is clear that $i_{\rho_{x_1 x_2+1}} \in I(\rho_{x_1 x_2},\rho_{x_1+_r 1,0})$ and $j_{\sigma_{x_1 x_2+1}} \in J(\sigma_{x_1+_r 1,0},\sigma_{x_1 x_2})$ from Eqs. (50) and (51). Hence both $i_{\rho_{x_1 x_2+1}}$ and $j_{\sigma_{x_1 x_2+1}} \in I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})(\rho_{x_1 \tilde{x}_2},\sigma_{x_1 \tilde{x}_2}) \forall \tilde{x}_2 = 1, 2, \ldots,$ and x_2. As a result, $(i_{\rho_{x_1 1}}, j_{\sigma_{x_1 1}}, i_{\rho_{x_1 2}}, j_{\sigma_{x_1 2}}, \ldots, i_{\rho_{x_1 s_{x_1}}}, j_{\sigma_{x_1 s_{x_1}}})$ is allowable in $I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})$.

Let us turn to $i_{a_{x_1 x_2}(\pm x_3)}$'s for the fixed x_1 we are considering. Since $i_{a_{x_1 x_2}(\pm x_3)} \in I(\rho_{x_1 x_2},\rho_{x_1, x_2+1})$ for $x_2 < s_{x_1}$ or $I(\rho_{x_1 x_2},\rho_{x_1+_r 1,0})$ for $x_2 = s_{x_1}$, we have $i_{a_{x_1 x_2}(\pm x_3)} \in I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})(\rho_{x_1 \tilde{x}_2},\sigma_{x_1 \tilde{x}_2})$ for $\tilde{x}_2 \leqslant x_2$, or $i_{a_{x_1 x_2}(\pm x_3)} \in I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})(\sigma_{x_1 \tilde{x}_2},\rho_{x_1 \tilde{x}_2})$ for $\tilde{x}_2 > x_2$. Moreover, the set of all $i_{a_{x_1 x_2}(\pm x_3)}$'s for the fixed x_1 is allowable in I, so this set of $i_{a_{x_1 x_2}(\pm x_3)}$'s alone is also allowable in $I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})$. Furthermore, $i_{a_{x_1 x_2}(\pm x_3)} \in I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0}) \times (b_{x_1 \tilde{x}_2(-y_3)}, b_{x_1 \tilde{x}_2(y_3)})$ for $0 \leqslant \tilde{x}_2 \leqslant s_{x_r}$ and $(\sigma_{x_1+_r 1,0} < b_{x_1 \tilde{x}_2(-y_3)} < b_{x_1 \tilde{x}_2(y_3)} < \sigma_{x_1 0})$. A similar argument applies to the set of all $j_{b_{x_1 x_2}(\pm y_3)}$'s for the fixed x_1. Consequently, for each fixed x_1, the set of all $i_{a_{x_1 x_2}(\pm x_3)}, j_{b_{x_1 x_2}(\pm y_3)}, i_{\rho_{x_1 x_2}}, j_{\sigma_{x_1 x_2}}$'s is allowable in $I(\rho_{x_1 0},\rho_{x_1+_r 1,0})J(\sigma_{x_1+_r 1,0},\sigma_{x_1 0})$. Q.E.D.

Theorem 1: *There exists an invertible Poisson morphism between the Poisson algebra of Weyl-ordered loop variables and the Poisson algebra of normal-ordered loop variables.*

Proof: This is a direct consequence of Lemmas 9, 12 and 13. Q.E.D.

Differential equations for scaling relation in $N=2$ supersymmetric SU(2) Yang–Mills theory coupled with massive hypermultiplet

Yűji Ohta
Research Institute for Mathematical Sciences, Kyoto University, Sakyoku, Kyoto 606, Japan

(Received 7 October 1998; accepted for publication 12 January 1999)

Differential equations for the scaling relation of prepotential in $N=2$ supersymmetric SU(2) Yang–Mills theory coupled with massive matter hypermultiplet are proposed and are explicitly demonstrated in one flavor ($N_f=1$) theory. By applying Whitham dynamics, the first-order derivative of the prepotential over the T_0 variable corresponding to the mass of the hypermultiplet, which has a line integral representation, is found to satisfy a differential equation. As a result, the closed form of this derivative can be obtained by solving this equation. In this way, the scaling relation of massive prepotential is established. Furthermore, as an application of another differential equation for the massive scaling relation, the massive prepotential in a strong coupling region is derived. © *1999 American Institute of Physics.* [S0022-2488(99)01704-1]

I. INTRODUCTION

It is well-known that the low energy effective action of $N=2$ supersymmetric Yang–Mills theory is described in terms of the holomorphic prepotential $\mathcal{F}$.[1] In this case, the perturbative part of the prepotential is not modified beyond one-loop order according to the nonrenormalization theorem,[2–5] but is known to be affected by instantons. In the case of the SU(2) gauge group, Seiberg and Witten[6,7] proposed a general prescription to determine the nonperturbative prepotential with the aid of Riemann surface of genus one. Based on their observation, Klemm *et al.*[8] determined the instanton corrected prepotential by adopting a method of Picard–Fuchs equation, which was often used in the mirror symmetry of Calabi–Yau manifold.[9–11] On the other hand, Matone[12] derived a recurrence formula of the instanton expansion coefficients of the prepotential by noticing a modularity. As a bonus, he obtained a quite simple relation between prepotential and moduli often referred as a scaling relation. After this discovery, the existence of such relation in $N=2$ supersymmetric Yang–Mills theory coupled with or without massive quark hypermultiplets was pointed out independently by two groups.[13,14] Sonnenschein *et al.*[13] proved it by noticing the homogeneity of the prepotential, while Eguchi and Yang[14] established the same result (2.17) in the language of Whitham dynamics.[15,16] However, in the framework of Whitham dynamics, we always encounter the problem of evaluating the derivative of $\mathcal{F}$ over the T_0 variable in order to establish a scaling relation when the mass of the hypermultiplets is not ignored. In the Whitham theory, this quantity is represented by a line integral interpolating two coverings of Riemann surface and therefore its evaluation is quite complicated, especially, in a massive case. In fact, explicit calculation of this integral is not found in the literature.

One of the aims of the paper is to give a solution to this problem. However, since the calculation in the case of a theory with N_f massive flavors is very complicated even for SU(2), we treat only SU(2) $N_f=1$ case. In addition, extension to $N_f>1$ is straightforward, so it is recommended that the reader try to proceed to other cases. Our construction starts from comparing the Wronskian of a massive Picard–Fuchs equation with the modular invariant of Matone.[12] These two are shown to be related by a Fuchsian differential equation. Applying the Whitham theory of soliton to this equation, we can obtain a differential equation for $\partial\mathcal{F}/\partial T_0$. In this way, it is determined as a solution to this equation. The details are discussed in Sec. II. On the other hand, in the course of the calculus used in the derivation of this differential equation, we can find another simple differential equation, which indicates a relation between prepotential and moduli like that in five dimensions.[17] This equation is also a consequence of scaling relation in the massive theory. As an application, the prepotential in the strong coupling region (dual prepotential) is derived in Sec. III. At first sight, the dual prepotential looks very complicated, but the massless limit coincides with that in the massless theory obtained by Ito and Yang.[18] Section IV is a brief summary.

II. SCALING RELATION AND THE WHITHAM HIERARCHY

A. The Picard–Fuchs equation

First of all, let us recall the basics of the massive $N_f=1$ theory in the Seiberg–Witten approach.[7] In the case of SU(2), we can take two kinds of curves, one of which is elliptic type[7] and the other is hyperelliptic type.[19] Though an elliptic curve is used in the next section, here we take the hyperelliptic curve. In this case, it is given by

$$y^2=(x^2-u)^2-\Lambda^3(x+m), \tag{2.1}$$

where $u=\langle \mathrm{tr}\,\phi^2\rangle$ is the moduli (ϕ is the complex scalar field of $N=2$ chiral superfield), m is the mass of the hypermultiplet, and Λ is the mass scale parameter of this $N_f=1$ theory. For this curve, the Seiberg–Witten differential 1-form λ is determined from the basic relation $d\lambda/du \propto dx/y$. Taking into account the numerical normalization factor, we find[19,20]

$$\lambda=\frac{\sqrt{2}}{4\pi i}\frac{x\,dx}{y}\left[\frac{x^2-u}{2(x+m)}-2x\right]. \tag{2.2}$$

In general, the Seiberg–Witten 1-form in a theory involving massive matter hypermultiplets in the fundamental representation of the gauge group is endowed with a pole structure whose residue is linearly proportional to the masses of the hypermultiplets.[7,19]

The Seiberg–Witten ansatz requires that the vacuum expectation value of ϕ and its dual are quantum mechanically given by the two periods

$$a=\oint_\alpha \lambda, \quad a_D=\oint_\beta \lambda, \tag{2.3}$$

respectively, along the canonical basis ($\alpha\cap\beta=+1$) of 1-cycles on (2.1). Then the periods satisfy the Picard–Fuchs equation

$$\frac{d^3\Pi}{du^3}+X\frac{d^2\Pi}{du^2}+Y\frac{d\Pi}{du}=0, \tag{2.4}$$

where

$$X=\frac{d}{du}\ln\frac{\Delta}{4m^2-3u},\qquad Y=-\frac{8}{\Delta}\left[4(2m^2-3u)+3\,\frac{3m\Lambda^3-4u^2}{4m^2-3u}\right]. \tag{2.5}$$

Here,

$$\Delta(u)=256u^3-256m^2u^2-288m\Lambda^3u+256m^3\Lambda^3+27\Lambda^6 \tag{2.6}$$

is the discriminant of the curve (2.1).

B. Differential equations for scaling relation

Differential equations for the Wronskian can be used to make a relation to prepotential. The reader might know the example in the context of mirror symmetry presented by Candelas *et al.*,[10,11] who used the ''Wronskian'' in order to make contact with Yukawa coupling in a complex structure moduli space. A similar presentation is possible also in $N=2$ supersymmetric Yang–Mills theory coupled with or without massless matter hypermultiplets. In the case of SU(2), the integral of Wronskian of Picard–Fuchs equation yields the scaling relation of the prepotential.[14] However, when hypermultiplets are massive, it is not easy to see such a simple relation connecting prepotential and moduli. We encountered a similar problem in the five-dimensional gauge theory.[17] Since we did not know a five-dimensional analog of the scaling relation in four-dimensional gauge theory, we proposed a differential relation between prepotential and the Wronskian. The method used in the course of this calculation reveals further aspects of the scaling relation, provided it is applied to four-dimensional gauge theory.

For this, let us prepare the following two quantities:

$$W=a'a_D''-a''a_D', \quad w=aa_D'-a'a_D, \tag{2.7}$$

where $'=d/du$. The first equation is precisely the Wronskian for the third-order Picard–Fuchs equation (2.4), while the integration of the second one produces the modular invariant of Matone[12]

$$\int_0 w\,du=aa_D-2\mathcal{F}. \tag{2.8}$$

Remark: The Modular invariance mentioned here is the sense of pure SU(2) theory.

Here, the integral symbol indicates that it is an integration constant free integral, namely, the integration constant is set to zero. What we would like to clarify is a relation between (2.8) and (integration of) W, so the first task is to try to connect W and w.

Fortunately, this is simply done by differentiating w over u repeatedly modulo the Picard–Fuchs equation (2.4), and we can find

$$w''+Xw'+Yw=W. \tag{2.9}$$

It is interesting to notice that w satisfies a Picard–Fuchs equation with W as a source term. On the other hand, for W we can easily obtain

$$W'+XW=0, \tag{2.10}$$

which implies

$$W=c\,\frac{4m^2-3u}{\Delta}, \tag{2.11}$$

where c is an integration constant. Note that the discriminant of the curve appears in the denominator and a similar relation was noticed in five dimensions.[17] In order to fix c, we may use a massless or double scaling limit as a boundary condition. For example, in the massless limit, it is well-known that $w=i3/(4\pi)$,[21] therefore, from (2.9)

$$c=-i\,\frac{16}{\pi}. \tag{2.12}$$

Of course, c must be uniquely fixed, and the same value is obtained from double scaling limit. (2.11) with (2.12) plays an important role in the next section.

In this way, we arrive at

$$w''+Xw'+Yw=-i\frac{16}{\pi}\frac{4m^2-3u}{\Delta}. \tag{2.13}$$

Since the solution to this equation gives w and must be related to (2.8), w obtained from (2.13) is expected to give a scaling relation in this massive theory[13]

$$a\frac{\partial\mathcal{F}}{\partial a}-2\mathcal{F}=-m\frac{\partial\mathcal{F}}{\partial m}-\Lambda\frac{\partial\mathcal{F}}{\partial\Lambda}, \tag{2.14}$$

where $\mathcal{F}$ is regarded here as a homogeneous function $\mathcal{F}=\mathcal{F}(a,\Lambda,m)$ in variables. Specifically, the solution of (2.13) will include information on the right-hand side of (2.14) and what we would like to do next is extract such information from (2.13). The best way to accomplish this is to introduce the Whitham theory.[15,16]

C. Relation to Whitham dynamics

Let us consider a consequence of (2.13) in view of Whitham dynamics in $N=2$ Yang–Mills theory. For details of Whitham dynamics in the context of Yang–Mills theory, see Refs. 14–16.

Let T_n $(n\in\mathbf{N}\cup\{0\})$ be time variables coupled to $(n+1)$th order pole of the Seiberg–Witten differential 1-form. In the SU(2) $N_f=1$ theory, the prepotential is available from the relation

$$\frac{\partial\mathcal{F}}{\partial a}=\oint_\beta\lambda,\quad \frac{\partial\mathcal{F}}{\partial T_n}=-2\pi i\,\mathrm{res}(z^{-n}\lambda),\quad \frac{\partial\mathcal{F}}{\partial T_0}=-2\pi i\int_{z_*=-m}^{z=-m}\lambda, \tag{2.15}$$

where residue is evaluated at $x=1/z=\infty$ and $z_*(=1/x)$ is the coordinate on the other sheet of the curve. At $x=\infty$, λ is expanded as

$$\lambda=\left[-\sum_{n>0}^{\infty}nT_nz^{-n-1}+T_0z^{-1}-\frac{1}{2\pi i}\sum_{n>0}^{\infty}\frac{\partial\mathcal{F}}{\partial T_n}z^{n-1}\right]dz. \tag{2.16}$$

Then, Whitham dynamics in $N=2$ Yang–Mills theory implies the homogeneity relation of the prepotential[14]

$$a\frac{\partial\mathcal{F}}{\partial a}-2\mathcal{F}=-T_0\frac{\partial\mathcal{F}}{\partial T_0}-T_1\frac{\partial\mathcal{F}}{\partial T_1}. \tag{2.17}$$

Note that the right-hand side of (2.17) should be identified with that in (2.14).

In the framework of Whitham hierarchy, T_0, T_1, and $\partial\mathcal{F}/\partial T_1$ are read from (2.16) as

$$T_0=-i\frac{m}{4\sqrt{2}\pi},\quad T_1=i\frac{3}{4\sqrt{2}\pi},\quad \frac{\partial\mathcal{F}}{\partial T_1}=\sqrt{2}\left(\frac{m^2}{4}-u\right). \tag{2.18}$$

Due to our normalization, the numerical factors are different from those used by Eguchi and Yang.[14] Note that T_0 vanishes when $m=0$. This simplifies (2.17) and because of this, the scaling relation in the massless theory is easily determined by using the Whitham hierarchy. In this case, it is not necessary to know $\partial\mathcal{F}/\partial T_0$, but in a massive case it must be known. However, in a massive theory the calculation of $\partial\mathcal{F}/\partial T_0$ requires care because the third equation in (2.15) is a line integral from one covering of the Riemann surface to the other. In the case at hand, this integral consists of two pieces of integral from $-m$ to ∞ on one sheet and a copy of it on the other sheet (when the mass vanishes, it reduces to a familiar integral[14]). Due to the pole of λ at $x=-m$, the evaluation of it is not easy and it is therefore still at a challenging stage. However, we can develop another method and show that $\partial\mathcal{F}/\partial T_0$ satisfies a differential equation with the aid of (2.13). Then $\partial\mathcal{F}/\partial T_0$ is obtained as a solution to this equation.

Differentiation of (the left-hand side of) (2.17) gives w, so a differential equation for $\partial\mathcal{F}/\partial T_0$ can be obtained by substituting w calculated from (2.17) with (2.18) into (2.13)

$$\Theta''' + X\Theta'' + Y\Theta' = \frac{4\sqrt{2}}{m}\left[i\frac{\pi}{2}W + \frac{6}{\Delta}\left(-8m^2 + 3\frac{3m\Lambda^3 - 4u^2}{4m^2 - 3u}\right)\right], \tag{2.19}$$

where $\Theta = \partial\mathcal{F}/\partial T_0$. It is easy to get a solution to this equation

$$\Theta' = c_1 a' + c_2 a_D' + i\frac{2\sqrt{2}\pi}{m}w + i\frac{3\sqrt{2}\pi}{2m}\left[a_D'\int_0 \frac{a'Z}{4m^2-3u}du - a'\int_0 \frac{a_D'Z}{4m^2-3u}du\right], \tag{2.20}$$

where c_i are integration constants and

$$Z = -8m^2 + 3\frac{3m\Lambda^3 - 4u^2}{4m^2-3u}. \tag{2.21}$$

In the derivation of (2.20), we have used the fact that a second-order differential equation

$$\frac{d^2y}{dx^2} + P(x)\frac{dy}{dx} + Q(x)y = R(x) \tag{2.22}$$

with any function $P(x)$, $Q(x)$ and $R(x)$ has a general solution in the form

$$y = c_1 y_1 + c_2 y_2 - y_1\int_0 \frac{y_2 R(x)}{W(y_1,y_2)}dx + y_2\int_0 \frac{y_1 R(x)}{W(y_1,y_2)}dx, \tag{2.23}$$

where y_i are two independent solutions in the case of $R(x)=0$ and $W(y_1,y_2)$ is its Wronskian. Since (2.19) without the right-hand side is nothing but the massive Picard–Fuchs equation, the above y_i may be chosen as a' and a_D'. Then $W(y_1,y_2)$ is identified with W defined in (2.7). Furthermore, (2.11) is used to arrive at the final expression (2.20).

Let us see the massless limit of (2.20). In this limit, naively, the factor $1/m$ diverges, but we leave it for the moment. When m vanishes, the integrals can be easily evaluated and the resulting terms cancel out the third term in (2.20). Therefore, it follows that

$$\left.\frac{\partial\mathcal{F}}{\partial T_0}\right|_{m\to 0} = c_1 a + c_2 a_D + \text{const.} \tag{2.24}$$

This result reflects the fact that (2.19) reduces to the total differentiation of the massless Picard–Fuchs equation because of vanishing of the right-hand side of (2.19) for $m\to 0$. Actually, $\partial\mathcal{F}/\partial T_0$ corresponds to $\partial\mathcal{F}/\partial m$, so all constants in (2.24) should be zero for $m\to 0$.

On the other hand, integrating (2.20) for $m\neq 0$, we obtain

$$aa_D - 2\mathcal{F} = i\frac{m}{6\sqrt{2}\pi}(c_1 a + c_2 a_D) + c_3 - \frac{1}{4}\int_0\left[a_D'\int_0 \frac{a'Z}{4m^2-3u}du - a'\int_0 \frac{a_D'Z}{4m^2-3u}du\right]du, \tag{2.25}$$

where c_3 is an integration constant, with the aid of (2.17) and (2.18). This is the general form of the massive scaling relation.

Remark: If the prepotential is known,[20] c_i *are easily determined as*

$$c_1 = -3\pi i n', \quad c_2 = 3\pi i n, \quad c_3 = -\frac{m^2}{16}(i + 4i\ln 2 - 2\pi n n'), \tag{2.26}$$

where $n,n' \in \mathbf{Z}$ are the winding numbers of 1-cycles around the pole corresponding to $x=-m$ of λ. These constants support the massless limit behavior of $\partial\mathcal{F}/\partial T_0$. However, precisely, these integration constants must be determined by comparing them with the result of lower order expansion of the third equation in (2.15).

III. MASSIVE PREPOTENTIAL IN STRONG COUPLING REGIME

Next, let us study the prepotential in the strong coupling region following the technology recently developed in the five-dimensional gauge theory.[17] The basic tool in our case is (2.11).

For later convenience, we take the elliptic curve[7]

$$y^2=x^2(x-u)+\frac{1}{4}m\Lambda^3x-\frac{\Lambda^6}{64}, \tag{3.1}$$

whose discriminant coincides with (2.6). The Seiberg–Witten differential 1-form is given by

$$\lambda=\frac{\sqrt{2}}{8\pi}\frac{dx}{y}\left[2u-3x-\frac{m\Lambda^3}{4x}\right]. \tag{3.2}$$

For this curve, we choose the 1-cycles on the surface (3.1) as Ito-Yang cycles,[18] which reduce for large u with vanishing mass

$$\alpha:\quad -i\frac{\Lambda^3}{8\sqrt{u}}\rightarrow +i\frac{\Lambda^3}{8\sqrt{u}},\qquad \beta:\quad u\rightarrow -i\frac{\Lambda^3}{8\sqrt{u}}. \tag{3.3}$$

Also in this case, the periods are defined by (2.3) and satisfy (2.4).

To find strong coupling regime, let us decompose the discriminant as

$$\Delta(u)=256\prod_{i=1}^{3}(u-e_i), \tag{3.4}$$

where e_i are given by the vanishing points of $\Delta(u)=0$, which correspond to the strong coupling regime. e_i can be easily obtained by solving $\Delta(u)=0$ for u, but we should take care of the derivation. In general, any cubic equation in x,

$$x^3+ax^2+bx+c=0, \tag{3.5}$$

where a, b, and c are some constants independent of x, has three independent solutions. One of them is

$$x=-\frac{2^{1/3}(-a^2+3b)}{3[-2a^3+9ab-27c+\sqrt{4(-a^2+3b)^3+(-2a^3+9ab-27c)^2}]^{1/3}}+\cdots, \tag{3.6}$$

where the ellipsis $(\cdots)$ means omission of the remaining terms. However, if the denominator vanishes

$$-2a^3+9ab-27c+\sqrt{4(-a^2+3b)^3+(-2a^3+9ab-27c)^2}=0, \tag{3.7}$$

i.e.,

$$(a^2-3b)^3=0, \tag{3.8}$$

formula (3.6) is not valid any more. In this case, one must start again from (3.5) under condition (3.8).

In the case at hand, the condition (3.8) for (2.6) corresponds to

$$m^3(2m+3\Lambda)^3(4m^2-6m\Lambda+9\Lambda^2)^3=0, \tag{3.9}$$

which implies that the directly obtained location under $m\neq 0$ [cf. (3.6)], does not reflect the precise massless limit of the massive discriminant. To understand more illustratively, let us set $u=x+iy$, where $x,y\in\mathbf{R}$. Then the equation $\Delta(u)=0$ produces $3(x-m^2/3)^2-y^2=m(8m^3+27)/24$. For a nonzero m, this is nothing but hyperbolic curves, but for $m=0$ it becomes crossing lines. Clearly, the zeros of the discriminant at $m=0$ behave singularly because transition from the hyperbolic curve to lines is always suppressed.

In fact, though the correct massless location in the strong coupling regime must be

$$e_1^{(0)}=-\frac{3\Lambda^2}{2^{8/3}},\quad e_2^{(0)}=\frac{3(1-i\sqrt{3})\Lambda^2}{2^{11/3}},\quad e_3^{(0)}=\frac{3(1+i\sqrt{3})\Lambda^2}{2^{11/3}}, \tag{3.10}$$

these cannot be obtained from (3.6) with $m=0$. Therefore, (3.9) distinguishes regions in quantum moduli space at $m=0$ and $m\neq 0$. To see a connection with massless theory, for example, we realize the zero locus of the massive discriminant as a small mass perturbation in the form $e_i=e_i^{(0)}+(\text{series in } m)$, where this series converges for $|m|<1$. Substituting this into the equation $\Delta=0$ and equating coefficient of powers in m to zero, one finds

$$\begin{aligned}
e_1&=e_1^{(0)}-\frac{m}{2^{1/3}}\Lambda+\frac{m^2}{3}-\frac{4}{27}\frac{2^{1/3}m^3}{\Lambda}+\frac{4}{81}\frac{2^{2/3}m^4}{\Lambda^2}+\cdots,\\
e_2&=e_2^{(0)}-\frac{(1+i\sqrt{3})}{2^{4/3}}m\Lambda+\frac{m^2}{3}+\frac{2^{4/3}(1-i\sqrt{3})m^3}{27\Lambda}+\cdots,\\
e_3&=e_3^{(0)}+\frac{(1-i\sqrt{3})}{2^{4/3}}m\Lambda+\frac{m^2}{3}+\frac{2^{4/3}(1+i\sqrt{3})m^3}{27\Lambda}+\cdots.
\end{aligned} \tag{3.11}$$

As a final check, (3.4) must be satisfied, but this can be easily confirmed by order in m greater than m^3. Note that (3.11) coincides with the massless strong coupling points for $m=0$ and thus the above e_i are the expected ones for small but finite mass. Below, to make a contact with the result of Ito and Yang,[18] e_1 is chosen as a representative of the strong coupling regime. On the other hand, for m greater than or equal to 1, (3.6) is available to derive zeros of the discriminant.

Remark: In the case of the SU(2) *gauge group, this situation is characteristic of the* $N_f=1$ *theory. For* $N_f=2$ *and* 3 *theories' discriminants, we do not encounter such a sensitive problem in the determination of the strong coupling region.*

Performing differential calculation between periods and dual prepotential

$$\begin{aligned}
\frac{da}{du}&=\frac{\mathcal{F}_D''}{u'},\\
\frac{d^2a}{du^2}&=\frac{1}{u'^3}(\mathcal{F}_D'''u'-\mathcal{F}_D''u''),\\
\frac{da^3}{du^3}&=\frac{1}{u'^5}[(\mathcal{F}_D^{(4)}u'-\mathcal{F}_D'''u''')u'-3u''(\mathcal{F}_D'''u'-\mathcal{F}_D''u'')],
\end{aligned} \tag{3.12}$$

where $'=d/da_D$ and $\mathcal{F}_D$ is the prepotential defined by

$$a=\frac{d\mathcal{F}_D}{da_D}, \tag{3.13}$$

and using (2.4) for $\Pi = a$ with inverse relation du/da_D (see also Ref. 17), we can arrive at the differential equation for $\mathcal{F}_D$,

$$\mathcal{F}_D^{(4)} + u'\left(X - \frac{3u''}{u'^2}\right)\mathcal{F}'''_D = 0. \tag{3.14}$$

This equation is integrated to give

$$\mathcal{F}'''_D = c\,\frac{4m^2 - 3u}{\Delta}\,u'^3, \tag{3.15}$$

where c is an integration constant to be determined later. The factor $(4m^2 - 3u)/\Delta$ corresponds to the Wronskian W defined in (2.7).

Since $\mathcal{F}'''_D$ manifestly vanishes at $u = 4m^2/3$, $\mathcal{F}_D$ is represented by a linear combination of a_D^2, a_D, and 1, although $O(a_D)$ terms can be neglected, thus it follows immediately from (3.13) that $a \propto a_D$. This induces the trivial monodromy

$$\begin{pmatrix} a \\ a_D \end{pmatrix} \to \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} a \\ a_D \end{pmatrix}, \tag{3.16}$$

which indicates that the indicial indices of the Picard–Fuchs equation at $u = 4m^2/3$ are integers and the BPS spectrum is unchanged at this point.

Remark: The same monodromy can be seen from a version of (3.15) in the weak coupling region.

As is easy to find, all we need to determine $\mathcal{F}_D$ is a function $u = u(a_D)$, which is obtainable from inverting the solution of the Picard–Fuchs equation. Therefore, substituting these data into (3.15) and triply integrating it, we will be able to determine $\mathcal{F}_D$. On the other hand, it would be sufficient to once determine c at a representative point in the moduli space. Since c has mass dimension zero, it can be regarded as a pure number. In fact, c can be determined at the massless point and the result

$$c = \frac{i}{16\pi} \tag{3.17}$$

follows from comparing (3.15) with the massless prepotential.[21]

Next we calculate u', but this is an easy task. Since $u' = (da_D/du)^{-1}$, it is sufficient to obtain the solution to the Picard–Fuchs equation at $u = e_1$. With the help of (3.4), it is found by a linear combination

$$\frac{da_D}{du} = \rho_1\varphi_1 + \rho_2\varphi_2, \tag{3.18}$$

where

$$\begin{aligned} \varphi_1 &= 1 - \frac{6u}{4m^2 - 3e_1} - \frac{u^2}{e_1(2e_1 - e_2)(2e_1 - e_3)(3e_1 - 4m^2)^2}[9e_1^2(36e_1 - e_2 - e_3) - 12(112e_1^2 \\ &\quad - 3e_1e_2 - 3e_1e_3 + e_2e_3)m^2 + 512(3e_1 - m^2)m^4 + 36m(3e_1 - 4m^2)\Lambda^3] - \cdots, \\ \varphi_2 &= u - \frac{3e_1^2(4e_1 - e_2 - e_3) - 4(8e_1^2 - 3e_1e_2 - 3e_1e_3 + e_2e_3)m^2}{2e_1(2e_1 - e_2)(2e_1 - e_3)(3e_1 - 4m^2)}u^2 - \cdots. \end{aligned} \tag{3.19}$$

Since these φ_i are extremely complicated functions in the language of explicit e_i, i.e., the right-hand sides of e_i in (3.11), we do not try to express φ_i by using them. The constants ρ_i are determined from an asymptotic expansion of the period integral of a_D, i.e.,

$$\rho_1 = -\frac{1}{2^{1/6}\sqrt{3}\Lambda}, \quad \rho_2 = -\frac{25}{9\Lambda^3}\sqrt{\frac{2}{3}}. \tag{3.20}$$

Integration produces a_D itself with an integration constant, but from dimensional analysis, it is found that it has a unit mass dimension. Since all dependence of the scale parameter (instanton correction) should be entered on the right-hand side of (3.18), the integration constant must be proportional to m. In addition, since the massless theory does not have this term, it can be regarded as a characteristic feature in massive theory. Actually, it is a residue contribution from the massive meromorphic 1-form, and this is the case. Thus,

$$a_D = 2\pi i n \operatorname{res}(\lambda) + \int_0 (\rho_1\varphi_1 + \rho_2\varphi_2)du, \tag{3.21}$$

where $n \in \mathbf{Z}$ is the winding number of the β-cycle which loops around the pole of the massive meromorphic 1-form and the residue is evaluated at $x=0$. Denoting $\tilde{a}_D = a_D - 2\pi i n \operatorname{res}(\lambda)$ and repeatedly solving (3.21), one can arrive at the inverse relation $u = u(a_D)$.

In this way, the result

$$\mathcal{F}_D = \frac{1}{2}c_1\tilde{a}_D^2 + c_2\tilde{a}_D + c_3 - i\frac{\Lambda^2}{\pi}\frac{\tilde{a}_D^2}{(e_1-e_2)(e_1-e_3)}\Bigg[\frac{3}{2^{17/3}}(3e_1-4m^2)(\ln\tilde{a}_D^2 - 3)$$
$$+ \frac{1}{2^{29/6}3^{2/3}(e_1-e_2)(e_1-e_3)}[125(e_1-e_2)(e_1-e_3)(3e_1-4m^2) + 9\cdot 2^{7/3}(e_2+e_3-2e_1)$$
$$\times m^2\Lambda^2 + 27\cdot 2^{1/3}(6e_1^2 + 4e_2e_3 - 5e_1(e_2+e_3))\Lambda^2]\frac{\tilde{a}_D}{\Lambda} + \cdots\Bigg], \tag{3.22}$$

where c_i are integration constants, follows from expanding (3.15). $c_2\tilde{a}_D + c_3$ may be neglected because this term does not change the effective coupling constant, but c_1 is nontrivial. Dimensional analysis shows that c_1 is a pure number. Therefore, it is sufficient to choose it as a constant such that $\mathcal{F}_D$ for $m \to 0$ coincides with that in the massless theory. As a check, one can see that this $\mathcal{F}_D$ reduces to that of massless theory for $m \to 0$, provided

$$c_1 = -\frac{i}{4\pi}\ln\Lambda^2. \tag{3.23}$$

The reader might already have noticed that actually this prepotential was obtained without regard to the details of e_1, although it was calculated under the assumption of small mass to see a connection with the massless theory. For general m in the strong coupling regime, only the differences of the final form of the prepotential are explicit values of e_i, c_i and c. For instance, for a large mass case, it is enough to simply expand (3.6) near $m = \infty$ to get the zeros of Δ and replace e_i by, e.g.,

$$e_1 = m^2 + \frac{\Lambda^3}{8m} + \cdots, \quad e_2 = \Lambda^{3/2}\sqrt{m} - \frac{\Lambda^3}{16m} + \cdots, \quad e_3 = -\Lambda^{3/2}\sqrt{m} - \frac{\Lambda^3}{16m} + \cdots. \tag{3.24}$$

The period a_D can be obtained by simply substituting (3.24) into (3.18). In this way, the dual prepotential for a large mass is calculated, but its form is not so attractive for us because it is again written by a complicated function in e_i. For this reason, it would not be necessary to write down the dual prepotential for $|m| \geqq 1$, and for other N_f cases.

IV. SUMMARY

In this paper, it has been shown that the Wronskian of the Picard–Fuchs equation in massive theory is related to (differentiation of) Matone's modular invariant through a differential equation. By comparing the solution to this equation with the Whitham dynamics, we have found a closed form of $\partial\mathcal{F}/\partial T_0$, which has not been evaluated so far. In this way, we have found a general form of the massive scaling relation. In the pure SU(2) theory, the scaling relation of the prepotential is known to also be obtained as an anomalous superconformal Ward identity,[22] therefore, it would be a natural question to ask whether (2.25) can be obtained as ''an anomalous superconformal Ward identity'' in this $N_f=1$ massive theory.

On the other hand, we have also found that the differential equation for the Wronskian gives a differential relation between prepotential and moduli, which is quite reminiscent of the one presented in the five-dimensional gauge theory[17] and the dual prepotential is calculated from this equation.

A more detailed study of the relation between the Wronskian and modular invariant of Matone will provide us with more useful information on the massive prepotentials in the future.

(Received 24 June 1998; accepted for publication 5 January 1999)

The quantum probability flux of a particle integrated over time and a distant surface gives the probability for the particle crossing that surface at some time. The relation between these crossing probabilities and the usual formula for the scattering cross section is provided by the flux-across-surfaces theorem, which was conjectured by Combes, Newton, and Shtokhamer [Phys. Rev. D **11**, 366–372 (1975)]. We prove the flux-across-surfaces theorem for short range potentials and wave functions without energy cutoffs. The proof is based on the free flux-across-surfaces theorem (Daumer *et al.*) [Lett. Math. Phys. **38**, 103–116 (1996)], and on smoothness properties of generalized eigenfunctions: It is shown that if the potential $V(x)$ decays like $|x|^{-\gamma}$ at infinity with $\gamma > n \in \mathbb{N}$ then the generalized eigenfunctions of the corresponding Hamiltonian $-1/2\Delta + V$ are $n-2$ times continuously differentiable with respect to the momentum variable. © *1999 American Institute of Physics.* [S0022-2488(99)00604-0]

I. INTRODUCTION

Potential scattering theory is concerned with the long-time behavior of wave functions Ψ_t. Its relation to experiment, i.e., to the definition of the scattering cross section, is, however, only rarely discussed. One such relation is provided by Dollard's scattering-into-cones theorem.[1] It asserts that, assuming asymptotic completeness of the wave operators, the probability of finding a particle with a wave function $\Psi_t = e^{-iHt}\Psi_0 \in \mathcal{H}_{ac}(H)$, the absolutely continuous subspace for the Hamiltonian H, in the far future in a given cone $C \subset \mathbb{R}^3$ (with a vertex at the origin) equals the probability that the quantum mechanical momentum of the asymptotic outgoing wave $W_+^{-1}\Psi_0$ lies in the same cone,

$$\lim_{t\to\infty} \int_C |\Psi_t(x)|^2\, dx = \int_C |\widehat{W_+^{-1}\Psi_0}(k)|^2\, dk, \tag{1}$$

where $\widehat{\ }$ denotes the Fourier transform, $W_+ := s-\lim_{t-\infty} e^{iHt}e^{-iH_0 t}$ is the wave operator, and $H = H_0 + V$ with the free Hamiltonian $H_0 = -\frac{1}{2}\Delta$ (we choose units such that $\hbar = m = 1$) and the potential V. The scattering-into-cones theorem is regarded as fundamental for quantum mechanical scattering theory. The expression for the differential cross section $d\sigma/d\Omega = |f(\theta,\phi)|^2$ from the time-independent scattering theory can be derived from the right-hand side of (1).

Combes, Newton, and Shtokhamer[3] observed, however, that what is relevant for scattering theory is a formula for the probability that the particle crosses some distant surface at some time during the scattering process. Heuristically, this probability should be given by integrating the

[a]Electronic mail: teufel@rz.mathematik.uni-muenchen.de
[b]Electronic mail: kmb@amath.unizh.ch

quantum mechanical probability flux $j^{\Psi_t} := \mathrm{Im}(\Psi_t^* \nabla \Psi_t)$ over the relevant time interval and this surface.[4–6] Combes, Newton, and Shtokhamer hence conjectured the flux-across-surfaces theorem,

$$\lim_{R\to\infty} \int_0^\infty dt \int_{R\Sigma} j^{\Psi_t} \cdot n \, d\sigma = \int_{C_\Sigma} |\widehat{W_+^{-1}\Psi_0}(k)|^2 \, dk, \tag{2}$$

where Σ is a measurable subset of S_1, the sphere with radius 1, $R\Sigma := \{Rx \in \mathbb{R}^3 : x \in \Sigma\}$ and $C_\Sigma := \{\lambda x \in \mathbb{R}^3 : x \in \Sigma, \lambda \geq 0\}$ is the cone spanned by Σ. The free flux-across-surfaces theorem (2) was proven by Daumer, Dürr, Goldstein, and Zanghi[4] for the case $V=0$. Recently (2) has been established for a large class of short range potentials by Amrein and Zuleta.[7] For long range potentials Amrein and Pearson[8] showed that the left-hand side of (2) equals the left-hand side of (1). [In this case, modified wave operators have to be introduced to define the right-hand side of (1) and (2).] However, since the proofs in Refs. 7 and 8 apply the usual time-dependent methods, they have to assume that $\widehat{W_+^{-1}\Psi_0}$ has compact support not containing the origin. Although this condition is a natural idealization of the experimental situation often encountered in scattering theory, and these wave functions form a dense set in L^2, there are no physical or mathematical reasons that (2) should hold only for this restricted class of wave functions. Furthermore, there are situations, i.e., the decay of an unstable system, where the physically interesting wave functions do have momentum support at zero. But the set of wave functions for which (2) holds cannot be enlarged by a simple limiting procedure in L^2, since the expression

$$\int_0^\infty dt \int_{R\Sigma} j^{\Psi_t} \cdot n \, d\sigma$$

is an unbounded sesquilinear form. Therefore the essential propagation estimates have to be proven directly for wave functions without energy cutoffs. Some results in this direction, so-called L^p estimates, have been established under rather restrictive conditions on the potential.[9,10] However, these estimates alone are not sufficient to prove (2).

In this paper we will give an elementary proof of (2) for a class of wave functions without energy cutoffs. We must assume, however, that the potential is short range with decay of order $|x|^{-4-\epsilon}$, $\epsilon>0$, at infinity, and that it does not have a zero energy resonance or eigenvalue. Our proof as well as the proof in Ref. 7 are based on the results of the free case $(V=0)$ established in Ref. 4. We employ stationary phase methods and the so-called generalized eigenfunctions $\Phi(x,k)$, which are certain solutions of the stationary Schrödinger equation $(-\frac{1}{2}\Delta + V(x))\Phi(x,k) = k^2\Phi(x,k)$, $k \in \mathbb{R}^3$, not belonging to $L^2(\mathbb{R}^3)$. This strategy of proof has been put forward in Ref. 5. We need $\Phi(x,k)$ to be differentiable with respect to k as well as to be uniformly bounded in both variables. Furthermore, we need that $\sup_{k\in\mathbb{R}\setminus\{0\}} |\partial_{k_l}\Phi(x,k)| \leq c(1+|x|)$ for some constant c and $l=1,2,3$.

In Sec. II, the flux-across-surfaces theorem will be established under suitable conditions on the generalized eigenfunctions. In Sec. III we will prove a theorem on the regularity of the generalized eigenfunctions, which will, among other things, justify the assumptions made in Sec. II: $\Phi(x,k)$ is n times partially differentiable with respect to k if $V(x) = O(|x|^{-n-2-\epsilon})$ for $|x| \to \infty$ and some $\epsilon>0$. Moreover, consider a family of Hamiltonians $H_c := H_0 + cV$, $c \in \mathbb{R}$. Then, if $V(x) = O(|x|^{-3-\epsilon})$,[11] the eigenfunctions corresponding to H_c are uniformly bounded and their partial derivatives of order n with respect to k grow not faster than $(1+|x|)^n$, except for a discrete set of constants, $c \in \mathbb{R}$.

II. THE FLUX-ACROSS-SURFACES THEOREM

We start with notation. Points in position space will be denoted by $x \in \mathbb{R}^3$; points in momentum space by $k \in \mathbb{R}^3$. By dx and dk integration with respect to the Lebesgue measure on $\mathbb{R}^3$ is understood. For $n \geqslant 2$, the following conditions on the potential V will be denoted by $(\mathbf{V})_n$:$(\mathbf{V})_n$ $V:\mathbb{R}^3 \to \mathbb{R}$ and (i) V is locally Hölder continuous except at a finite number of singularities;[12] (ii) $V \in L^2(\mathbb{R}^3)$; and (iii) $|V(x)| = O(|x|^{-n-\epsilon})$ for $|x| \to \infty$ and some $\epsilon > 0$.

For $n=2$ these are the conditions of Ikebe.[13] Under these conditions H is self-adjoint on the domain of H_0. The absolutely continuous part of the spectrum is $[0, \infty)$. Furthermore, H has neither positive eigenvalues nor a singular continuous spectrum. The wave operators $W_\pm = s-\lim_{t\to\pm\infty} e^{-iHt}e^{iH_0t}$ exist and are complete, i.e., Ran $W_\pm = \mathcal{H}_{\mathrm{ac}}(H)$.

The time-dependent wave function will be denoted by $\Psi_t := e^{-iHt}\Psi_0$, $\Psi_0 \in L^2(\mathbb{R}^3)$. To simplify notation we will abbreviate $\Psi_{\mathrm{out}} := W_+^{-1}\Psi_0$ for the outgoing asymptotic wave. By S we denote the set of Schwartz functions.

Zero is said to be a resonance of H if there exists a solution f of $-1/2\Delta f(x) + V(x)f(x) = 0$ such that $(1+|x|)^{-\gamma} f(x) \in L^2(\mathbb{R}^3)$ for any $\gamma > \frac{1}{2}$ and not for $\gamma = 0$.[14] The appearance of zero-energy resonances or eigenvalues is an exceptional event: $H_c = H_0 + cV$ can have a zero-energy resonance or eigenvalue only for c in discrete subset of $\mathbb{R}$.[14]

Theorem 2.1: Let the potential satisfy the condition $(\mathbf{V})_4$ and let zero be neither a resonance nor an eigenvalue of H. Let $\Psi_{\mathrm{out}} \in S$. Then $\Psi_t = e^{-iHt}W_+\Psi_{\mathrm{out}}$ is continuously differentiable, except at the singularities of V and for any measurable $\Sigma \subset S_1$ and any $T \in \mathbb{R}$,

$$\lim_{R\to\infty} \int_T^\infty dt \int_{R\Sigma} j^{\Psi_t}(x)\cdot n \, d\sigma = \lim_{R\to\infty} \int_T^\infty dt \int_{R\Sigma} |j^{\Psi_t}(x)\cdot n| d\sigma = \int_{C_\Sigma} |\hat{\Psi}_{\mathrm{out}}(k)|^2 \, dk. \tag{3}$$

Remark 2.2: The first equality in (3) shows that far away from the scattering center the flux is essentially outgoing, i.e., that there the particles cross spherical surfaces only once and do not return. Thus (3) yields the crossing probability of interest.

Remark 2.3: It would be, of course, more satisfactory if we could prove (3) under a suitably general condition on Ψ_0, not on Ψ_{out}. However, the set of wave functions $\Psi_0 = W_+\Psi_{\mathrm{out}}$ for which Theorem 2.1 holds is dense in $\mathcal{H}_{\mathrm{ac}}(H)$, since S is dense in L^2 and $W_+ : L^2 \to \mathcal{H}_{\mathrm{ac}}(H)$ is unitary. For an explicit characterization of the domain W_+S one would need suitable mapping properties of the wave operators. Some mapping properties for wave functions without energy cutoffs have been established by Yajima,[10] however, they are not sufficient for our purpose.

Remark 2.4: Due to the so-called intertwining property of the wave operators, $W_\pm e^{-iH_0t} = e^{-iHt}W_\pm$, and the fact that S is left invariant under the free time evolution, the condition imposed on Ψ in Theorem 2.1 is invariant under the full time evolution: $e^{-iHt}W_+S = W_+e^{-iH_0t}S = W_+S$.

As already mentioned, we will make use of the generalized eigenfunctions $\Phi(x,k)$ that diagonalize H in the same sense as the ordinary plane waves $\{e^{ik\cdot x}, k \in \mathbb{R}^3\}$ diagonalize H_0. We define $\Phi(x,k)$ and state the properties that we will use in the proof of Theorem 2.1 in a proposition.

Proposition 2.5: Let V satisfy $(\mathbf{V})_2$. Then for any $k \in \mathbb{R}^3 \backslash \{0\}$ there are unique continuous solutions $\Phi_\pm(\cdot,k):\mathbb{R}^3 \to \mathbb{C}$ of the Lippmann–Schwinger equations,

$$\Phi_\pm(x,k) = e^{ik\cdot x} - \frac{1}{2\pi} \int \frac{e^{\mp i|k||x-y|}}{|x-y|} V(y)\Phi_\pm(y,k)dy, \tag{4}$$

with the boundary conditions $\lim_{|x|\to\infty}[\Phi_\pm(x,k) - e^{ik\cdot x}] = 0$, which are also classical solutions of the stationary Schrödinger equation,

$$\left[-\frac{1}{2}\Delta + V(x)\right]\Phi_\pm(x,k) = \frac{k^2}{2}\Phi_\pm(x,k), \tag{5}$$

such that the following holds.

(i) For any compact $D \subset \mathbb{R}^3 \backslash \{0\}$ the functions $\Phi_\pm(\cdot,\cdot):\mathbb{R}^3 \times D \to \mathbb{C}$ are uniformly continuous.

(ii) For any $f \in L^2(\mathbb{R}^3)$ the generalized Fourier transforms,

$$(\mathcal{F}_{\pm} f)(k) = \frac{1}{(2\pi)^{3/2}} \text{l.i.m.} \int \Phi^{*}_{\pm}(x,k) f(x) dx,$$

exist in $L^2(\mathbb{R}^3)$.[15]

(iii) Ran $\mathcal{F}_{\pm} = L^2(\mathbb{R}^3)$ and $\mathcal{F}_{\pm} : \mathcal{H}_{\text{ac}}(H) \to L^2(\mathbb{R}^3)$ are unitary and the inverse of $\mathcal{F}_{\pm}$ is given by

$$(\mathcal{F}^{-1}_{\pm} f)(x) = \frac{1}{(2\pi)^{3/2}} \text{l.i.m.} \int \Phi_{\pm}(x,k) f(k) dk.$$

(iv) For any $f \in D(H) \cap \mathcal{H}_{\text{ac}}(H)$, we have

$$Hf(x) = \left(\mathcal{F}^{-1}_{\pm} \frac{k^2}{2} \mathcal{F}_{\pm} f \right)(x) = \frac{1}{(2\pi)^{3/2}} \text{l.i.m.} \int \frac{k^2}{2} \Phi_{\pm}(x,k) (\mathcal{F}_{\pm} f)(k) dk, \tag{6}$$

and therefore for any $f \in \mathcal{H}_{\text{ac}}(H)$,

$$e^{-iHt} f(x) = (\mathcal{F}^{-1}_{\pm} e^{-i(k^2/2)t} \mathcal{F}_{\pm} f)(x) = \frac{1}{(2\pi)^{3/2}} \text{l.i.m.} \int e^{-i(k^2 t/2)} \Phi_{\pm}(x,k) (\mathcal{F}_{\pm} f)(k) dk. \tag{7}$$

(v) For any $f \in \mathcal{H}_{\text{ac}}(H)$ the relations $W_{\pm} f = \mathcal{F}^{-1}_{\pm} \mathcal{F} f$ hold, where $\mathcal{F}$ denotes the ordinary Fourier transform.

(vi) If V satisfies $(\mathbf{V})_3$, then $\Phi_{\pm}(x,k)$ are continuously differentiable with respect to k for all $x \in \mathbb{R}^3$, except at $k=0$. The partial derivatives $\partial_{k_l} \Phi_{\pm}(x,k)$ are continuous in x and k. If, in addition, zero is not an eigenvalue or resonance of H, then $\Phi_{\pm}(x,k)$ is well defined and continuous for $x,k \in \mathbb{R}^3$,

$$\sup_{x \in \mathbb{R}^3, k \in \mathbb{R}^3} |\Phi_{\pm}(x,k)| < \infty,$$

and there is a $c < \infty$ such that

$$\sup_{k \in \mathbb{R}^3 \setminus \{0\}} \left| \frac{\partial}{\partial k_l} \Phi_{\pm}(x,k) \right| < c(1 + |x|),$$

for $l = 1,2,3$.

The proof of (i)–(v) of Proposition 2.5 is due to Ikebe.[13] (vi) is a special case of Theorem 3.1 on the regularity of generalized eigenfunctions that we shall state and prove in Sec. III.

Remark 2.6: Similar eigenfunction expansions can be obtained also for potentials with slower decay, but then, in general, the continuity in k will not hold anymore.[16]

Proof (of Theorem 2.1): Let $\Psi_t = e^{-iHt} W_+ \Psi_{\text{out}}$, $\Psi_{\text{out}} \in S$. Using Proposition 2.5.(iv), (v) and $\eta(x,k) := \Phi_+(x,k) - e^{ik \cdot x}$, we have that

$$\begin{aligned}
\Psi_t(x) &= \frac{1}{(2\pi)^{3/2}} \int e^{-i(k^2 t/2)} \hat{\Psi}_{\text{out}}(k) \Phi_+(x,k) dk \\
&= \frac{1}{(2\pi)^{3/2}} \int e^{-i(k^2 t/2)} \hat{\Psi}_{\text{out}}(k) e^{ik \cdot x} dk + \frac{1}{(2\pi)^{3/2}} \int e^{-i(k^2 t/2)} \hat{\Psi}_{\text{out}}(k) \eta(x,k) dk \\
&=: \alpha(x,t) + \beta(x,t).
\end{aligned} \tag{8}$$

The flux generated by this wave function is

$$j^{\Psi_t}(x) = \text{Im}(\alpha^* \nabla \alpha + \alpha^* \nabla \beta + \beta^* \nabla \alpha + \beta^* \nabla \beta), \tag{9}$$

where the differentiability of α is obvious and that of β will be established later.

The first part $j_0 = \mathrm{Im}(\alpha^* \nabla \alpha)$ is the flux generated by the free time evolution of Ψ_{out} and according to the free flux-across-surfaces theorem,[2]

$$\lim_{R\to\infty} \int_T^\infty dt \int_{R\Sigma} j_0(x,t)\cdot n\, d\sigma = \lim_{R\to\infty} \int_T^\infty dt \int_{R\Sigma} |j_0(x,t)\cdot n|\, d\sigma = \int_{C_\Sigma} |\hat{\Psi}_{\mathrm{out}}(k)|^2\, dk.$$

Therefore to prove (3) we need only show that the last three terms in (9) do not contribute to the flux across distant surfaces, i.e., that for $j_1 := \mathrm{Im}(\alpha^* \nabla \beta + \beta^* \nabla \alpha + \beta^* \nabla \beta)$,

$$\lim_{R\to\infty} \int_T^\infty dt \int_{S_R} |j_1(x,t)\cdot n|\, d\sigma = 0. \tag{10}$$

For some fixed $T>0$ this will follow from the estimates (which we shall prove below)

$$\sup_{x\in S_R} |\alpha(x,t)| \leqslant t^{-3/2} f_1(R,t), \quad \forall t \geqslant T \tag{11}$$

$$\sup_{x\in S_R} |\nabla \alpha(x,t)| \leqslant t^{-3/2} f_2(R,t), \quad \forall t \geqslant T, \tag{12}$$

where there exists a $c<\infty$ such that $f_i(R,t)$ satisfy

$$\lim_{R\to\infty} f_i(R,t) = 0, \quad \forall t \geqslant T \tag{13}$$

and

$$\sup_{R\in[0,\infty),t\geqslant T} f_i(R,t) < c, \tag{14}$$

for $i=1,2$, and there is $R_0 \geqslant 0$ such that

$$\sup_{x\in S_R} |\beta(x,t)| \leqslant c\, \frac{1}{R(t+R)}, \quad \forall R>0, \tag{15}$$

$$\sup_{x\in S_R} |\nabla \beta(x,t)| \leqslant c\, \frac{1}{R(t+R)}, \quad \forall R>R_0, \tag{16}$$

for $t \geqslant T$. Note that the constants in these estimates depend on T.

Using (11) and (16) we obtain by dominated convergence

$$\begin{aligned} \lim_{R\to\infty} \int_T^\infty \int_{S_R} |\mathrm{Im}(\alpha^* \nabla \beta)\cdot n|\, d\sigma\, dt &\leqslant \lim_{R\to\infty} 4\pi \int_T^\infty \sup_{x\in S_R} R^2 |\alpha||\nabla \beta|\, dt \\ &\leqslant c \lim_{R\to\infty} \int_T^\infty \frac{R^2 f_1(R,t)}{t^{3/2} R(t+R)}\, dt = c \int_T^\infty \lim_{R\to\infty} \frac{R f_1(R,t)}{t^{3/2}(t+R)}\, dt = 0, \end{aligned} \tag{17}$$

for $T>0$, where we observed that the integrand in (17) is bounded by an integrable function uniformly in R,

$$\frac{R f_1(R,t)}{t^{3/2}(t+R)} \leqslant c t^{-3/2}.$$

The terms $|\beta^* \nabla \alpha|$ and $|\beta^* \nabla \beta|$ can be treated analogously and thus (10) holds for positive times T.

According to Remark 2.4, the set of wave functions for which (3) holds as well as the right-hand side of (3) are invariant under finite time shifts:

$$\lim_{R\to\infty} \int_T^\infty dt \int_{R\Sigma} j^{\Psi_t}(x)\cdot n\, d\sigma = \lim_{R\to\infty} \int_{\tilde{T}}^\infty dt \int_{R\Sigma} j^{\Psi_{t+T-\tilde{T}}}(x)\cdot n\, d\sigma$$

$$= \int_{C_\Sigma} |e^{-i(k^2/2)(T-\tilde{T})}\hat{\Psi}_{\text{out}}(k)|^2\, dk = \int_{C_\Sigma} |\hat{\Psi}_{\text{out}}(k)|^2\, dk.$$

Therefore if (3) holds (for all $\Psi_{\text{out}} \in S$) for some fixed T, then (3) will hold for all T; hence (3) is proved for all T.

We turn now to the proof of the estimates (11)–(16). Recalling that $\alpha(x,t) = (e^{-iH_0 t}\Psi_{\text{out}})(x)$ and, since ∇ commutes with the free time evolution, $\nabla\alpha(x,t) = (e^{-iH_0 t}\nabla\Psi_{\text{out}})(x)$, we can write

$$\alpha(x,t) = \frac{1}{(2\pi i t)^{3/2}} \int e^{i(|x-y|^2/2t)}\Psi_{\text{out}}(y)\,dy \tag{18}$$

and

$$\nabla\alpha(x,t) = \frac{1}{(2\pi i t)^{3/2}} \int e^{i(|x-y|^2/2t)}\nabla\Psi_{\text{out}}(y)\,dy. \tag{19}$$

Now (11)–(14) are immediate consequences of (18) and (19) and the fact that, for every fixed $t \geqslant T$, $\alpha(x,t)$, and $\nabla\alpha(x,t)$ are Schwartz functions.

By (4) $\eta(x,k) = \Phi_+(x,k) - e^{ik\cdot x} = -1/2\pi \int (e^{i|k||x-y|}/|x-y|)V(y)\Phi_+(y,k)\,dy$, and therefore

$$\beta(x,t) = \frac{1}{(2\pi)^{3/2}} \int e^{-i(k^2 t/2)}\hat{\Psi}_{\text{out}}(k)\,\eta(x,k)\,dk$$

$$= -\frac{1}{(2\pi)^{5/2}} \int e^{-i(k^2 t/2)}\hat{\Psi}_{\text{out}}(k)\left[\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y)\Phi_+(y,k)\,dy\right]dk$$

$$= -\frac{1}{(2\pi)^{5/2}} \int \frac{V(y)}{|x-y|} \int e^{-i(k^2 t/2+|k||x-y|)}\hat{\Psi}_{\text{out}}(k)\Phi_+(y,k)\,dk\,dy$$

$$=: -\frac{1}{(2\pi)^{5/2}} \int \frac{V(y)}{|x-y|} f(x,y,t)\,dy, \tag{20}$$

where

$$f(x,y,t) := \int e^{-i(k^2 t/2+|k||x-y|)}\hat{\Psi}_{\text{out}}(k)\Phi_+(y,k)\,dk. \tag{21}$$

The change of order of integration in (20) is justified by Fubini's theorem. We shall now apply ''stationary phase'' methods to estimate (21). We set

$$\chi := \frac{\frac{k^2 t}{2} + |k||x-y|}{\frac{t}{2} + |x-y|},$$

$$\chi' = \frac{d}{d|k|}\chi = \frac{|k|t + |x-y|}{\frac{t}{2} + |x-y|} = \frac{|k| + |x-y|t^{-1}}{\frac{1}{2} + |x-y|t^{-1}} \geqslant \min(1, 2|k|),$$

$$\omega := \frac{t}{2} + |x-y|.$$

In the following, $'$ will denote differentiation with respect to $|k|$. Introducing spherical coordinates, with $d\Omega$ denoting the Lebesgue measure on the unit sphere, we estimate (21):

$$\begin{aligned} |f(x,y,t)| &= \left| \int \frac{1}{\omega \chi'} \left[\frac{d}{d|k|} e^{-i\omega\chi} \right] \hat{\Psi}_{\text{out}}(k) \Phi_+(y,k) |k|^2 d|k| d\Omega(k) \right| \\ &= \left| \frac{1}{\omega} \int e^{-i\omega\chi} \frac{d}{d|k|} \left[\frac{1}{\chi'} \hat{\Psi}_{\text{out}}(k) \Phi_+(y,k) |k|^2 \right] d|k| d\Omega(k) \right| \\ &\leqslant \frac{1}{\omega} \int \left| \frac{d}{d|k|} \left[\frac{1}{\chi'} \hat{\Psi}_{\text{out}}(k) \Phi_+(y,k) |k|^2 \right] \right| d|k| d\Omega(k). \end{aligned} \tag{22}$$

For the second equality in (22), the boundary term from the partial integration at $|k| = \infty$ vanishes since $\chi'^{-1} \leqslant \max(1, 1/2|k|)$, $\lim_{|k|\to\infty} |k|^2 \hat{\Psi}_{\text{out}}(k) = 0$, and Ψ_+ is bounded according to Proposition 2.5 (vi). The boundary term at $|k| = 0$ vanishes since $\hat{\Psi}_{\text{out}}$ and Φ_+ are bounded and $\chi'^{-1}|k|^2 \leqslant \max(|k|^2, |k|/2)$. Note that the differentiability of Φ_+ is ensured by Proposition 2.5 (vi). Next, observe that

$$\begin{aligned} \left| \frac{d}{d|k|} \left[\frac{1}{\chi'} \hat{\Psi}_{\text{out}} \Phi_+ |k|^2 \right] \right| \leqslant & \left| \frac{1}{\chi'^2} \chi'' \hat{\Psi}_{\text{out}} \Phi_+ |k|^2 \right| + \left| \frac{1}{\chi'} \hat{\Psi}'_{\text{out}} \Phi_+ |k|^2 \right| + \left| \frac{1}{\chi'} \hat{\Psi}_{\text{out}} \Phi'_+ |k|^2 \right| \\ & + \left| \frac{1}{\chi'} \hat{\Psi}_{\text{out}} \Phi_+ 2|k| \right|. \end{aligned} \tag{23}$$

Since $\chi'' = (\frac{1}{2} + |x-y|t^{-1})^{-1} \leqslant 2$, we obtain for the first term

$$\int \left| \frac{1}{\chi'^2} \chi'' \hat{\Psi}_{\text{out}} \Phi_+ \right| dk \leqslant \sup_{y,k \in \mathbb{R}^3} |\Phi_+(y,k)| \left(\int_{|k|<1/2} \frac{|\hat{\Psi}_{\text{out}}(k)|}{2|k|^2} dk + \int_{|k|\geqslant 1/2} 2|\hat{\Psi}_{\text{out}}(k)| dk \right) \leqslant c_1. \tag{24}$$

Analogously we get for the second and fourth term in (23),

$$\int \left| \frac{1}{\chi'} \hat{\Psi}'_{\text{out}} \Phi_+ \right| dk \leqslant c_2 \quad \text{and} \quad \int \left| \frac{2}{\chi'|k|} \hat{\Psi}_{\text{out}} \Phi_+ \right| dk \leqslant c_4.$$

By Proposition 2.5 (vi), the third term satisfies a bound linear in $|y|$:

$$\int \left| \frac{1}{\chi'} \hat{\Psi}_{\text{out}} \Phi'_+ \right| dk \leqslant \tilde{c}_3 \sup_{k \in \mathbb{R}^3 \setminus \{0\}} |\Phi'_+(y,k)| \leqslant c_3(1+|y|).$$

Combining the four estimates, we arrive at

$$|f(x,y,t)| \leqslant c\,\frac{1}{\omega}(1+|y|) = c\,\frac{1+|y|}{\frac{t}{2}+|x-y|}, \tag{25}$$

which inserted into (20) yields

$$\sup_{x\in S_R}|\beta(x,t)| = \sup_{x\in S_R}\left|\frac{1}{(2\pi)^{5/2}}\int \frac{V(y)}{|x-y|} f(x,y,t)\,dy\right| \leqslant c\,\sup_{x\in S_R}\int \frac{|V(y)|(1+|y|)}{|x-y|\left(\frac{t}{2}+|x-y|\right)}\,dy. \tag{26}$$

Now, substituting $z=x-y$,

$$\begin{aligned}\int \frac{|V(y)|(1+|y|)}{|x-y|\left(\frac{t}{2}+|x-y|\right)}\,dy &= \int_{|z|<|x|/2} \frac{|V(x-z)|(1+|x-z|)}{|z|\left(\frac{t}{2}+|z|\right)}\,dz \\ &\quad + \int_{|x-y|\geqslant|x|/2} \frac{|V(y)|(1+|y|)}{|x-y|\left(\frac{t}{2}+|x-y|\right)}\,dy \\ &\leqslant \sup_{z\in B_{|x|/2}} |V(x-z)|(1+|x-z|)\int_0^{|x|/2} \frac{4\pi|z|^2}{|z|\left(\frac{t}{2}+|z|\right)}\,d|z| \\ &\quad + \frac{1}{\frac{|x|}{2}\left(\frac{t}{2}+\frac{|x|}{2}\right)}\int |V(y)|(1+|y|)\,dy,\end{aligned}$$

where B_r denotes the ball with radius r in $\mathbb{R}^3$ centered at the origin. Since $V(x)=O(|x|^{-4-\epsilon})$ for some $\epsilon>0$,

$$\sup_{z\in B_{|x|/2}} |V(x-z)|(1+|x-z|) \leqslant c|x|^{-3},$$

for $|x|$ sufficiently large. Using

$$\int_0^{\delta} \frac{z}{t+z}\,dz = \delta + t\ln\left(\frac{t}{t+\delta}\right) \leqslant \delta + t\left(\frac{t}{t+\delta}-1\right) = \frac{\delta^2}{t+\delta},$$

we compute

$$\int_0^{|x|/2} \frac{|z|^2}{|z|\left(\frac{t}{2}+|z|\right)}\,d|z| \leqslant \frac{1}{2}\,\frac{|x|^2}{t+|x|}.$$

Finally, $\int |V(y)|(1+|y|)\,dy<\infty$, so that altogether

$$\sup_{x\in S_R}|\beta(x,t)| \leqslant c\,\sup_{x\in S_R}\left(|x|^{-3}\frac{|x|^2}{t+|x|} + \frac{1}{|x|(t+|x|)}\right) = \frac{c}{R(t+R)}. \tag{27}$$

We now show that the same bound holds for $\sup_{x\in S_R}|\nabla\beta(x,t)|$ and $R>R_0$, where R_0 is chosen such that all singularities of V lie in the ball with radius R_0. Then

$$|\nabla\beta(x,t)|\leqslant\frac{1}{(2\pi)^{5/2}}\left|\int\frac{V(y)}{|x-y|^2}\int e^{-i(k^2t/2+|k||x-y|)}\hat{\Psi}_{\text{out}}(k)\Phi_+(y,k)dk\,dy\right|$$
$$+\frac{1}{(2\pi)^{5/2}}\left|\int\frac{V(y)}{|x-y|}\int e^{-i(k^2/2+|k||x-y|)}|k|\hat{\Psi}_{\text{out}}(k)\Phi_+(y,k)dk\,dy\right|,\tag{28}$$

where the exchange of differentiation and integration will be justified below. The second term can be treated analogously to $|\beta(x,t)|$, since also $|k|\hat{\Psi}_{\text{out}}(k)\in S$. The first term can as well be estimated along the same lines: in Eq. (26) $|x-y|^2$ will appear in the denominator instead of $|x-y|$, which leads to a stronger bound than (27).

To get (28) from (20) we note that, according to Proposition 2.5, $\Phi(\cdot,k)$ is a classical solution of the stationary Schrödinger equation. Thus, $\Phi(\cdot,k)$ as well as $\eta(\cdot,k)$ are differentiable with respect to *x*, except at the singularities of V. We will show that

$$\nabla_x\eta(x,k)=\nabla_x\left(-\frac{1}{2\pi}\int\frac{e^{-i|k||x-y|}}{|x-y|}V(y)\Phi_+(y,k)dy\right)$$
$$=-\frac{1}{2\pi}\int\nabla_x\left(\frac{e^{-i|k||x-y|}}{|x-y|}\right)V(y)\Phi_+(y,k)dy,\tag{29}$$

and that therefore

$$|\nabla_x\eta(x,k)|\leqslant c_1+c_2|k|,\tag{30}$$

for some $c_1,c_2<\infty$. Then, changing the order of differentiation and integration in the first line of (20) is justified by dominated convergence and (28) follows for all *x* which are not singularities of V.

To get (29) for some $x_0\in\mathbb{R}^3$ that is no singularity of V, we split the domain of integration into $B_{2R}(x_0):=\{y\in\mathbb{R}^3:|x_0-y|\leqslant 2R\}$ and its complement $B^c_{2R}(x_0)$, where R is chosen such that $B_{2R}(x_0)$ contains no singularity of V. Then one can change the order of integration and differentiation in the $B^c_{2R}(x_0)$ term, since there the integrand is bounded by an integrable function uniformly in x for $x\in B_R(x_0)$. To see that the $B_{2R}(x_0)$ term can be made arbitrarily small by appropriately choosing R, we write down the difference quotient for this term. Using that $\sup_{y\in B_{2R}(x_0)}(V(y)\Phi+(y,k))\leqslant c_k<\infty$ and that $|re^{i\theta}-(r+\Delta r)e^{i(\theta+\Delta\theta)}|\leqslant|r\Delta\theta|+|\Delta r|$, we compute

$$\lim_{|\epsilon|\to 0}\frac{1}{|\epsilon|}\left|\int_{B_{2R}(x_0)}\left(\frac{e^{-i|k||x+\epsilon-y|}}{|x+\epsilon-y|}-\frac{e^{-i|k||x-y|}}{|x-y|}\right)V(y)\Phi_+(y,k)dy\right|$$
$$\leqslant\lim_{|\epsilon|\to 0}\frac{1}{|\epsilon|}c_k\int_{B_{2R}(x_0)}\left|\frac{e^{i|k||x+\epsilon-y|}|x-y|-e^{-i|k||x-y|}|x+\epsilon-y|}{|x+\epsilon-y||x-y|}\right|dy$$
$$\leqslant\lim_{|\epsilon|\to 0}\frac{1}{|\epsilon|}c_k\int_{B_{2R}(x_0)}\frac{|x-y||k||\epsilon|+|\epsilon|}{|x+\epsilon-y||x-y|}dy$$
$$\leqslant\lim_{|\epsilon|\to 0}c_k\int_{B_{2R}(x_0)}\left(\frac{|k|}{|x+\epsilon-y|}+\frac{1}{|x+\epsilon-y||x-y|}\right)dy\leqslant c_k12\pi R,$$

where the last inequality is justified by elementary integrations. The bound (30) can be obtained by a simple calculation.

From that we also conclude that $\Psi_t(x)$ is differentiable outside the singularities of $V(x)$ since α and β are. □

Remark 2.7: We used the domain $\Psi_{\text{out}} \in S$ to simplify the proof and avoid tedious estimates. A more detailed analysis of the proof shows that Theorem 2.1 also holds for $\Psi_{\text{out}} \in L^2$ such that $(1+k^2)^{(q+p)/2}(1+\Delta)^{p/2}\hat{\Psi}_{\text{out}} \in L^2$ for some $p > \frac{7}{2}$ and $q > \frac{9}{2}$. Then $(1+k^2)^{q/2}(1+\Delta)^{p/2}e^{-i(k^2/2)t}\hat{\Psi}_{\text{out}} \in L^2$ for all $t \in \mathbb{R}$, and this is enough regularity to prove the free theorem as well as our estimates.

III. REGULARITY OF THE GENERALIZED EIGENFUNCTIONS

In this section we will prove a theorem about the generalized eigenfunctions that connects the differentiability of $\Phi(x,k)$ with respect to k with the behavior of the potential at infinity and gives uniform bounds on $\Phi(x,k)$ and its partial derivatives. At the end of the section we state two simple corollaries that show other applications of our results.

Theorem 3.1: Let the potential satisfy the condition $(\mathbf{V})_{\mathbf{n}}$ for some $n \geqslant 3$, $n \in \mathbb{N}$. Then we have the following.

(i) $\Phi_{\pm}(x,\cdot) \in C^{n-2}(\mathbb{R}^3 \backslash \{0\})$ for all $x \in \mathbb{R}^3$ and the partial derivatives $\partial_k^{\alpha}\Phi_{\pm}(x,k)$, $|\alpha| \leqslant n-2$, are continuous with respect to x and k.[17]

(ii) If, in addition, zero is not an eigenvalue or a resonance of H, then

$$\sup_{x \in \mathbb{R}^3, k \in \mathbb{R}^3} |\Phi_{\pm}(x,k)| < \infty,$$

and for any α with $|\alpha| \leqslant n-2$ there is a $c_{\alpha} < \infty$ such that

$$\sup_{k \in \mathbb{R}^3 \backslash \{0\}} |\partial_k^{\alpha}\Phi_{\pm}(x,k)| < c_{\alpha}(1+|x|)^{|\alpha|}.$$

Remark 3.2: Proposition 2.5 (vi) follows from Theorem 3.1 by taking $n=3$.

Proof (of Theorem 3.1): To simplify notation we will give the proof for $\Phi_{+}(x,k) =: \Phi(x,k)$ since the proof for $\Phi_{-}(x,k)$ is exactly the same apart from the change of some signs.

The structure of the proof will be as follows: First we introduce some notation and results from Ikebe and Povzner that we will use frequently. Then part (i) of Theorem 3.1 is shown for $|\alpha|=1$ involving several lemmas and results proven in the appendix. The generalization to $|\alpha| \geqslant 1$ will be sketched afterward.

In the proof of part (ii) of Theorem 3.1 we will establish boundedness of $\Phi(x,k)$ for k near zero and for $|k| \to \infty$ separately in two propositions.

We start with an investigation of Eq. (4). If $\Phi(x,k) = e^{ik\cdot x} + \eta(x,k)$ is a continuous solution of the Lippmann–Schwinger equation (4) with $\lim_{|x|\to\infty} \eta(x,k) = 0$ for $k \in \mathbb{R}^3$, then $\eta(x,k)$ is a solution of the integral equation

$$\eta(x,k) = -\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y)[e^{ik\cdot y} + \eta(y,k)]dy, \tag{31}$$

and $\eta(\cdot,k) \in C_{\infty}(\mathbb{R}^3)$. Therefore Eq. (31) is examined on the Banach space $B = C_{\infty}(\mathbb{R}^3)$; the set of continuous functions vanishing at infinity, equipped with the norm $\|f\|_B = \sup_{x \in \mathbb{R}^3}|f(x)|$. $\mathcal{L}(B)$ denotes the space of bounded linear operators mapping B into itself, equipped with the operator norm. Following Ikebe,[13] we define the linear operators $T_k \in \mathcal{L}(B)$, $k \in \mathbb{R}^3$, by

$$(T_k f)(x) = -\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y) f(y) dy. \tag{32}$$

Since we will make use of some results of Ikebe and Povzner, we state them as a lemma.

Lemma 3.3: Let the potential satisfy the condition $(\mathbf{V})_{\mathbf{3}}$. Then the following holds.

(i) The operator $T_k \in \mathcal{L}(B)$ defined in (32) is compact for all $k \in \mathbb{R}^3$.

(ii) Let $f(x)$ be a bounded continuous function on $\mathbb{R}^3$; then

$$h(x) := -\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y) f(y) dy$$

is an element of B for all $k \in \mathbb{R}^3$ and $h(x) = O(|x|^{-1})$ for $|x| \to \infty$.

(iii) Let

$$g(x,k) := -\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y) e^{ik\cdot y}\, dy = (T_k e^{ik\cdot\cdot})(x);$$

then $g(\cdot,k) \in B$ for all $k \in \mathbb{R}^3$ and $g(\cdot,k)$ is continuous with respect to k.

(iv) Let $f(\cdot,k) \in B$ be a solution of the homogeneous equation $f(\cdot,k) = T_k f(\cdot,k)$ for $k \in \mathbb{R}^3$. If $|k|>0$, then $f=0$, and if $k=0$ then $(-\frac{1}{2}\Delta + V(x)) f(x,0) = 0$.

(v) The map $T:\mathbb{R}^3 \to \mathcal{L}(B)$, $k \mapsto T_k$ is continuous.

For the proofs of (i), (ii), (iii), and (iv) see Ikebe;[13] for the proof of (v) see Povzner.[18]

Since we will use similar reasoning, we will briefly repeat Ikebe's proof of the existence of continuous solutions of Eq. (31), starting from Lemma 3.3. Equation (31) now reads as

$$\eta(\cdot,k) = g(\cdot,k) + T_k \eta(\cdot,k). \tag{33}$$

According to Lemma 3.3 (iv) the homogeneous equation $\eta(\cdot,k) = T_k\eta(\cdot,k)$ has only the trivial solution $\eta(x,k)=0$ if $k\neq 0$. Thus 1 is not an eigenvalue of T_k and therefore 1 is in the resolvent set since T_k is compact,[19] i.e., $(1-T_k)^{-1} \in \mathcal{L}(B)$ exists. The unique solution of (31) for $|k|>0$ is then given by

$$\eta(\cdot,k) = (1-T_k)^{-1} g(\cdot,k). \tag{34}$$

Since $\mathcal{L}(B)$ is a Banach algebra in which the map $A \mapsto A^{-1}$ is continuous,[19] from Lemma 3.3 (v) it follows that $(1-T_k)^{-1}$ is continuous in k. Thus, since according to Lemma 3.3 (iii) $g(\cdot,k)$ is continuous with respect to k, we have that $\eta(x,k)$ is continuous with respect to k.

We will now prove part (i) of Theorem 3.1 for $|\alpha|=1$ and assume $(\mathbf{V})_3$. The generalization to $|\alpha|>1$ will then be immediate. Consider arbitrary $l \in \{1,2,3\}$ and $k^0 \in \mathbb{R}^3 \setminus \{0\}$. We use the following notation: k_l denotes the lth Cartesian coordinate of a vector $k \in \mathbb{R}^3$ and $k_{\bar{l}}$ the tuple of the other coordinates. Symbolically we will write $k = (k_l, k_{\bar{l}})$.

By (formally) differentiating (31) we obtain

$$\frac{\partial}{\partial k_l}\eta(x,k) = \frac{\partial}{\partial k_l} g(x,k) + \frac{i}{2\pi}\frac{k_l}{|k|}\int e^{-i|k||x-y|} V(y)\,\eta(y,k) dy - \frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y) \frac{\partial}{\partial k_l}\eta(y,k) dy. \tag{35}$$

Assume that for $k_l \in I_l := [k_l^0 - \delta_l, k_l^0 + \delta_l]$ and $k_{\bar{l}} \in I_{\bar{l}} := [k_{\bar{l}}^0 - \delta_{\bar{l}}, k_{\bar{l}}^0 + \delta_{\bar{l}}]$, where δ_l and $\delta_{\bar{l}}$ are chosen such that, in particular, $0 \notin I := I_l \times I_{\bar{l}}$, the equation

$$\xi(x,k) = \frac{\partial}{\partial k_l} g(x,k) + \frac{i}{2\pi}\frac{k_l}{|k|}\int e^{-i|k||x-y|} V(y) \left[\int_{k_l^0}^{k_l} \xi(y,(k_l', k_{\bar{l}})) dk_l' + \eta(y,(k_l^0, k_{\bar{l}}))\right] dy - \frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|} V(y)\xi(y,k) dy, \tag{36}$$

which arises from (35) by substituting $\eta(x,k) = \int_{k_l^0}^{k_l} \xi(x,(k_l', k_{\bar{l}})) dk_l' + \eta(x,(k_l^0, k_{\bar{l}}))$, has a continuous solution $\xi(x,k)$. Integrating (36) with respect to k_l and using Fubini's theorem we get

$$
\begin{aligned}
\int_{k_l^0}^{k_l}\xi(x,(k_l',k_{\bar{l}}))dk_l' &= g(x,k)-g(x,(k_l^0,k_{\bar{l}}))\\
&\quad -\frac{1}{2\pi}\int V(y)\left[\frac{e^{-i|k||x-y|}}{|x-y|}\left(\int_{k_l^0}^{k_l'}\xi(y,(k_l'',k_{\bar{l}}))dk_l''+\eta(y,(k_l^0,k_{\bar{l}}))\right)\right]_{k_l^0}^{k_l}dy\\
&= g(x,k)-g(x,(k_l^0,k_{\bar{l}}))+\frac{1}{2\pi}\int\frac{e^{-i|(k_l^0,k_{\bar{l}})||x-y|}}{|x-y|}V(y)\,\eta(y,(k_l^0,k_{\bar{l}}))dy\\
&\quad -\frac{1}{2\pi}\int\frac{e^{-i|k||x-y|}}{|x-y|}V(y)\left(\int_{k_l^0}^{k_l}\xi(y,(k_l',k_{\bar{l}}))dk_l'+\eta(y,(k_l^0,k_{\bar{l}}))\right)dy. \qquad (37)
\end{aligned}
$$

Since $\eta(x,(k_l^0,k_{\bar{l}}))$ is a solution of (31), the second and third term of the right-hand side of (37) combine to $-\eta(x,(k_l^0,k_{\bar{l}}))$. Therefore (37) simply reads as

$$
\begin{aligned}
&\eta(x,(k_l^0,k_{\bar{l}}))+\int_{k_l^0}^{k_l}\xi(x,(k_l',k_{\bar{l}}))dk_l'\\
&\quad = g(x,k)-\frac{1}{2\pi}\int\frac{e^{-i|k||x-y|}}{|x-y|}V(y)\left(\eta(y,(k_l^0,k_{\bar{l}}))+\int_{k_l^0}^{k_l}\xi(y,(k_l',k_{\bar{l}}))dk_l'\right)dy.
\end{aligned}
$$

In other words, if $\xi(x,k)$ is a continuous solution of (36), then the function $f(x,k) = \eta(x,(k_l^0,k_{\bar{l}}))+\int_{k_l^0}^{k_l}\xi(x,(k_l',k_{\bar{l}}))dk_l'$ is a solution of Eq. (31). Since (31) has a unique solution in B, we may conclude that $f(x,k)=\eta(x,k)$, i.e., that $\partial_{k_l}\eta(x,k)=\xi(x,k)$ for $x\in\mathbb{R}^3$ and $k\in I$ once we have shown that $f(\cdot,k)\in B$.

We show now that Eq. (36) has a solution $\xi(x,k)$ that is continuous with respect to $x\in\mathbb{R}^3$ and $k\in I$, such that $\eta(\cdot,(k_l^0,k_{\bar{l}}))+\int_{k_l^0}^{k_l}\xi(\cdot,(k_l',k_{\bar{l}}))dk_l'\in B$. From the physical argument that $\Phi(x,k) \sim e^{ik\cdot x}+e^{i|k||x|}/|x|$ for $|x|\to\infty$, we expect $|\nabla_k\eta(x,k)|\sim e^{i|k||x|}$, $|x|\to\infty$, to be a uniformly bounded function, but we will only show that $|\nabla_k\eta(x,k)|\leq c(1+|x|)^s$ for any $s>0$. We start by multiplying Eq. (36) by $\langle x\rangle^{-s}:=(1+|x|)^{-s}$, $s>0$:

$$
\begin{aligned}
\tilde{\xi}(x,k) &= \langle x\rangle^{-s}\,\partial_{k_l}g(x,k)-\frac{1}{2\pi}\int\frac{e^{-i|k||x-y|}}{\langle x\rangle^s|x-y|}\langle y\rangle^s V(y)\tilde{\xi}(y,k)dy\\
&\quad +\frac{i}{2\pi}\frac{k_l}{|k|}\int\frac{e^{-i|k||x-y|}}{\langle x\rangle^s}\langle y\rangle^s V(y)\left[\int_{k_l^0}^{k_l}\tilde{\xi}(y,(k_l',k_{\bar{l}}))dk_l'+\langle y\rangle^{-s}\eta(y,(k_l^0,k_{\bar{l}}))\right]dy.
\end{aligned}
\qquad (38)
$$

To see that $\xi(x,k)=\langle x\rangle^s\tilde{\xi}(x,k)\leq c(1+|x|)^s$, we show that (38) has a unique solution in

$$\tilde{B}:=\{f(x,k)\in C(\mathbb{R}^3\times I):\ \lim_{|x|\to\infty}\sup_{k\in I}|f(x,k)|=0\}.$$

In the appendix we prove that $\tilde{B}$ equipped with the norm $\|f\|_{\tilde{B}}=\sup_{x\in\mathbb{R}^3,k\in I}|f(x,k)|$ is a Banach space (see Lemma A.1); and that for $f\in\tilde{B}$ the operators,

$$(\tilde{T}f)(x,k) := -\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s|x-y|}\langle y\rangle^s V(y)f(y,k)dy,$$

$$(\tilde{T}'f)(x,k) := \frac{i}{2\pi}\frac{k_l}{|k|}\int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s}\langle y\rangle^s V(y)f(y,k)dy,$$

and

$$(\tilde{K}f)(x,k) := \int_{k_l^0}^{k_l} f(x,(k_l',k_{\bar{l}}))dk_l',$$

belong to $\mathcal{L}(\tilde{B})$ if $s>0$ is chosen, such that $\langle x\rangle^s V(x)$ still satisfies $(\mathbf{V})_3$ (see Lemma A.2).

Noting that $\langle x\rangle^{-s}\,\partial_{k_l}g(x,k)$ and $\langle x\rangle^{-s}\,\eta(x,(k_l^0,k_{\bar{l}}))$ belong to $\tilde{B}$ (see Lemma A.2), Eq. (38) can be written as

$$\tilde{\xi} = \langle\cdot\rangle^{-s}\,\partial_{k_l}g + \tilde{T}'\tilde{K}\tilde{\xi} + \tilde{T}'\langle\cdot\rangle^{-s}\,\eta(\cdot,(k_l^0,k_{\bar{l}})) + \tilde{T}\tilde{\xi},$$

where $\langle\cdot\rangle^{-s}$ denotes the operator of multiplication with $\langle x\rangle^{-s}$ in $\tilde{B}$. To prove that this equation has a unique solution in $\tilde{B}$, we show that $(1-\tilde{T})^{-1}\in\mathcal{L}(\tilde{B})$ exists, and that

$$\tilde{\xi} = (1-\tilde{T})^{-1}(\langle\cdot\rangle^{-s}\partial_{k_l}g + \tilde{T}'\langle\cdot\rangle^{-s}\,\eta(\cdot,(k_l^0,k_{\bar{l}}))) + (1-\tilde{T})^{-1}\tilde{T}'\tilde{K}\tilde{\xi} \tag{39}$$

has a unique solution. The former will be the content of Lemma 3.4, and to see the latter note that, according to Lemma A.2.(i),

$$\|(1-\tilde{T})^{-1}\tilde{T}'\tilde{K}\|_{\mathcal{L}(\tilde{B})} \le \|(1-\tilde{T})^{-1}\tilde{T}'\|_{\mathcal{L}(\tilde{B})} 2\delta_l .$$

Also $\|(1-\tilde{T})^{-1}\|_{\mathcal{L}(\tilde{B})}$ and $\|\tilde{T}\|_{\mathcal{L}(\tilde{B})}$ depend on δ_l since be space $\tilde{B}$ itself depends on δ_l. But the norm of these operators decreases as δ_l decreases, since according to Lemma A.1.(ii) and the constructions in the proofs of Lemma A.2 and Lemma 3.4, $\|\tilde{T}'\|_{\mathcal{L}(\tilde{B})} \le \sup_{k\in I}\|T_k'^s\|_{\mathcal{L}(B)}$ and $\|(1-\tilde{T})^{-1}\|_{\mathcal{L}(\tilde{B})} \le \sup_{k\in I}\|(1-T_k^s)^{-1}\|_{\mathcal{L}(B)}$. Thus, one can choose δ_l such that

$$\|(1-\tilde{T})^{-1}\tilde{T}'\tilde{K}\|_{\mathcal{L}(\tilde{B})} < 1.$$

Then (39) has a unique solution $\tilde{\xi}\in\tilde{B}$ since $(1-\tilde{T})^{-1}\tilde{T}'\tilde{K}$ is a contraction in a complete metric space.

Now $\xi(x,k) = \langle x\rangle^s\tilde{\xi}(x,k)$ is a solution of (36) and $f(x,k) = \eta(x,(k_l^0,k_{\bar{l}})) + \int_{k_l^0}^{k_l}\xi(x,(k_l',k_{\bar{l}}))dk_l'$ is a solution of (31). Recall that to conclude $f(x,k) = \eta(x,k)$, i.e., that ξ is the partial derivative of η with respect to k_l, we need to show $f(\cdot,k)\in B$. By construction, $\sup_{k\in I}|\xi(x,k)| = O(|x|^s)$ for $|x|\to\infty$ and therefore also $|f(x,k)| = O(|x|^s)$ for any $k\in I$. Thus, writing $V(x)f(x,k) = \langle x\rangle^s V(x)\langle x\rangle^{-s}f(x,k)$ and observing that $\langle x\rangle^s V(x)$ satisfies $(\mathbf{V})_3$ and $\langle x\rangle^{-s}f(x,k)$ is bounded we use Lemma 3.3 (ii) to conclude that $f(\cdot,k)\in B$.

To complete the proof of part (i) for $|\alpha|=1$ we need to show the following lemma.

Lemma 3.4: $(1-\tilde{T})^{-1}\in\mathcal{L}(\tilde{B})$ exists.

Proof: First we show that $(1-T_k^s)^{-1}\in\mathcal{L}(B)$ exists, where $T_k^s := \langle\cdot\rangle^{-s}T_k\langle\cdot\rangle^s\in\mathcal{L}(B)$. Since $\langle x\rangle^s V(x)$ meets the requirements of Lemma 3.3 and multiplication by $\langle x\rangle^{-s}$ is a bounded operation on B,T_k^s is compact. Therefore $(1-T_k^s)^{-1}$ exists if the homogeneous equation $(1-T_k^s)f_s = 0$ has only the trivial solution $f_s=0$. Now let $f_s\in B$ be a solution of the homogeneous equation, which explicitly reads as

$$f_s(x)=(T_k^s f_s)(x)=-\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s|x-y|}V(y)\langle y\rangle^s f_s(y)dy.$$

Then $f(x):=\langle x\rangle^s f_s(x)$ is a solution of

$$f(x)=-\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|}V(y)f(y)dy,$$

and Lemma 3.3 (ii) implies $f\in B$ since $\langle x\rangle^s V(x)$ satisfies $(\mathbf{V})_\mathbf{3}$ and $\langle x\rangle^{-s}f(x)$ is bounded. Using Lemma 3.3 (iv), we conclude that $f(x)=f_s(x)=0$ for $k\neq 0$. Therefore $(1-T_k^s)^{-1}$ exists for any $k\in I$. The continuity of $(1-T_k^s)^{-1}$ with respect to k follows again from the continuity of $(1-T_k^s)$.

Using Lemma A.1 (ii), we define the operator $(1-\tilde{T})^{-1}\in\mathcal{L}(\tilde{B})$. Since $(1-T_k^s)(1-T_k^s)^{-1}=(1-T_k^s)^{-1}(1-T_k^s)=1$ holds for all $k\in I$, also $(1-\tilde{T})(1-\tilde{T})^{-1}=(1-\tilde{T})^{-1}(1-\tilde{T})=1$ holds. □

It is now easy to prove the existence of higher-order derivatives by induction. From the proof for $|\alpha|=1$ we conclude that if $\eta(x,k)\in B$ is a solution of (31) then $\langle x\rangle^{-s}\,\partial_{k_l}\eta(x,k)$ is given by the unique solution $\xi(x,k)$ in B of

$$\xi(x,k)=\langle x\rangle^{-s}\,\partial_{k_l}g(x,k)+\frac{i}{2\pi}\frac{k_l}{|k|}\int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s}V(y)\,\eta(y,k)dy$$
$$-\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s|x-y|}\langle y\rangle^s V(y)\,\xi(y,k)dy,$$

for any $k\in\mathbb{R}^3\backslash\{0\}$. In general, assume that $\eta(x,\cdot)\in C^p(\mathbb{R}^3\backslash\{0\})$ for some $p<n-2$ and that $\langle x\rangle^{-s-p+1}\partial_k^\alpha\eta(x,k)$, $|\alpha|=p$, is given by the unique solution $\xi(x,k)$ of

$$\xi(x,k)=\langle x\rangle^{-s-p+1}[\partial_k^\alpha g(x,k)+\partial_k^\alpha(T_k\eta)(x,k)-(T_k\partial_k^\alpha\eta)(x,k)]+(T_k^{s+p-1}\xi)(x,k), \quad (40)$$

in B, where T_k^{s+p-1} is given by

$$(T_k^{s+p-1}f)(x):=-\frac{1}{2\pi}\int \frac{e^{-i|k||x-y|}}{\langle x\rangle^{s+p-1}|x-y|}V(y)\langle y\rangle^{s+p-1}f(y)dy.$$

Then one can prove by exactly the same method as in the case $|\alpha|=1$ that $\partial_{k_l}\xi(x,k)$ exists: Equation (40) is analogous to (33), where g is replaced by $\langle x\rangle^{-s-p+1}[\partial_k^\alpha g(x,k)+\partial_k^\alpha(T_k\eta)(x,k)-(T_k\,\partial_k^\alpha\eta)(x,k)]\in B$ and T_k by T_k^{s+p-1}. As long as $\langle y\rangle^{s+p-1}V(y)$ satisfies $(\mathbf{V})_\mathbf{3}$, the proof of differentiability of the solution of (40) can be done along the same lines as for $|\alpha|=1$.

Proof [of part (ii) of Theorem 3.1]: From the continuity of Φ and the fact that $\lim_{|x|\to\infty}(\Phi(x,k)-e^{ik\cdot x})=0$ for all $k\neq 0$, Ikebe already concluded that for compact $D\subset\mathbb{R}^3\backslash\{0\}$,

$$\sup_{x\in\mathbb{R}^3,k\in D}|\Phi(x,k)|<\infty,$$

holds. It remains to examine the cases $k\to 0$ and $|k|\to\infty$. If H has a zero-energy resonance or eigenvalue, according to Jensen and Kato,[14] the spectral density is singular at $E=0$. Since the spectral density and the generalized eigenfunctions are closely related,[20] we expect that in this case also the generalized eigenfunctions become singular at $k=0$.

But assuming that H has neither a resonance nor an eigenvalue at $E=0$, the eigenfunctions are uniformly bounded near $k=0$:

Proposition 3.5: Let the potential satisfy $(\mathbf{V})_\mathbf{n}$ for some $n\geqslant 3$. If H has no zero-energy resonance or eigenvalue, then for any compact $D\subset\mathbb{R}^3$,

$$\sup_{x\in\mathbb{R}^3,k\in D}|\Phi(x,k)|<\infty,$$

and, for any α with $|\alpha|<n-2$, there is a $c_\alpha<\infty$ such that

$$\sup_{k\in D\setminus\{0\}}|\partial_k^\alpha\Phi(x,k)|<c_\alpha(1+|x|)^{|\alpha|}.$$

Proof: If H has no zero-energy resonance or eigenvalue, the homogeneous equation $f=T_0f$ has no solution in B since, according to Lemma 3.3, under the conditions $(\mathbf{V})_\mathbf{3}$ any solution of $f=T_0f$ is a solution of $(-\frac{1}{2}\Delta+V(x))f(x)=0$ with $f(x)=O(|x|^{-1})$. And a solution $f\in B$ of $Hf=0$ with $f(x)=O(|x|^{-1})$ is, in particular, a resonance. Thus, either $f\in L^2$, i.e., zero is an eigenvalue, or $f\notin L^2$, but then zero is a resonance.

Thus $(1-T_k)^{-1}$ exists for all $k\in D$ and, recalling $\eta(x,k)=((1-T_k)^{-1}g)(x,k)$,

$$\sup_{x\in\mathbb{R}^3,k\in D}|\eta(x,k)|=\sup_{k\in D}\|\eta_k\|_B\leqslant\sup_{k\in D}\|(1-T_k)^{-1}\|_{\mathcal{L}(B)}\|g_k\|_B<\infty,$$

since $\|(1-T_k)^{-1}\|_{\mathcal{L}(B)}$ is a continuous function on a compact set and therefore bounded. Recalling $\Phi(x,k)=e^{ik\cdot x}+\eta(x,k)$, the proof of the first statement is complete.

The bounds for the partial derivatives near zero also follow from the fact that $(1-T_0)^{-1}$ exists if zero is neither a resonance nor an eigenvalue of H. To see this we introduce spherical coordinates $(|k|,\omega)$, $|k|\in(0,\infty)$ and $\omega\in S^2$ for k. If we replace $\partial_{k_i}|k|=k_i/|k|=\omega\cdot e_i$ in Eq. (40), it has a unique solution $\xi(\cdot,|k|,\omega)\in B$ also for $|k|=0$. Thus, $\lim_{|k|\to 0}\partial_k^\alpha\eta(x,|k|,\omega)$ exists for all $\omega\in S^2$. As in the first part of this proof,

$$\sup_{x\in\mathbb{R}^3,k\in D\setminus\{0\}}\frac{\partial_k^\alpha\eta(x,k)}{\langle x\rangle^{s+|\alpha|-1}}\leqslant\sup_{x\in\mathbb{R}^3,|k|\in[0,R],\omega\in S^2}|\xi(x,|k|,\omega)|<\infty,$$

for some R such that $D\subset K_R$, follows from the fact that $\xi(\cdot,|k|,\omega)\in B$ depends continuously on k. Noting $|\partial_k^\alpha e^{ik\cdot x}|=|x_1^{\alpha_1}x_2^{\alpha_2}x_3^{\alpha_3}e^{ik\cdot x}|<\langle x\rangle_{|\alpha|}$ completes the proof. □

To prove the uniform bound on Φ and its derivatives, it remains to examine their behavior for large k. This can be done using the Born series. As expected on physical grounds, the generalized eigenfunctions for large momentum are essentially plane waves.

Proposition 3.6: Let the potential V satisfy $(\mathbf{V})_\mathbf{n}$ for some $n\geqslant 3$. Then

$$\lim_{|k|\to\infty}\sup_{x\in\mathbb{R}^3}\langle x\rangle^{-|\alpha|}|\partial_k^\alpha\Phi(x,k)-\partial_k^\alpha e^{ik\cdot x}|=0,$$

for every $|\alpha|\leqslant n-2$.

Proof: First we will show that the function $\eta(x,k)=\Phi(x,k)-e^{ik\cdot x}$ converges uniformly to zero for $|k|\to\infty$. Recall (34):

$$\eta(\cdot,k)=(1-T_k)^{-1}g(\cdot,k).$$

We shall show that $\lim_{|k|\to\infty}\|g(\cdot,k)\|_B=0$, but we have no simple control of the norm of $(1-T_k)^{-1}$, for example, in terms of the Born series, since

$$\|T_k\|_{\mathcal{L}(B)}=\sup_{x\in\mathbb{R}^3}\int\frac{|V(y)|}{|x-y|}dy=\text{const},$$

does not depend on $|k|$. Following Zemach and Klein[21] we iterate Eq. (33) once and obtain

$$\eta(\cdot,k)=g(\cdot,k)+T_kg(\cdot,k)+T_k^2\eta(\cdot,k), \tag{41}$$

with the formal solution

$$\eta(\cdot,k)=(1-T_k^2)^{-1}(g(\cdot,k)+T_k g(\cdot,k)). \tag{42}$$

If Eq. (41) has a unique solution, it must equal the unique solution of (33), since any solution of (33) is clearly also a solution of (41). We shall now first establish that (a) $(1-T_k^2)^{-1}\to 1$ for $|k|\to\infty$ and then that (b) $\|g(\cdot,k)+T_k g(\cdot,k)\|_B\to 0$ for $|k|\to\infty$, since then

$$\lim_{|k|\to\infty}\|\eta(\cdot,k)\|_B \leqslant \lim_{|k|\to\infty}\|(1-T_k^2)^{-1}\|_{\mathcal{L}(B)}\|(g(\cdot,k)+T_k g(\cdot,k)\|_B=0.$$

(a) follows from the following.

Lemma 3.7: Let $V\in L^1\cap L^2$; then

$$\lim_{|k|\to\infty}\|T_k^2\|_{\mathcal{L}(B)}=0. \tag{43}$$

Here (43) also holds, if T_k^2 is understood as an operator on bounded continuous functions.

Now $|k|$ can be chosen such that $\|T_k^2\|_{\mathcal{L}(B)}<1$, and then $(1-T_k^2)^{-1}$ is given as the norm convergent Born series:

$$(1-T_k^2)^{-1}=\sum_{n=0}^{\infty}(T_k^2)^n.$$

Thus, $\lim_{|k|\to\infty}\|(1-T_k^2)^{-1}-1\|_{\mathcal{L}(B)}=0.$

Proof (of Lemma 3.7): We compute for $f\in B$,

$$\begin{aligned}(T_k^2 f)(x)&=\frac{1}{4\pi^2}\int\frac{e^{-i|k||x-y|}}{|x-y|}V(y)\int\frac{e^{-i|k||y-z|}}{|y-z|}V(z)f(z)dz\,dy\\&=\frac{1}{4\pi^2}\int V(z)f(z)\int\frac{e^{-i|k|(|x-y|+|y-z|)}}{|x-y||y-z|}V(y)dy\,dz\\&=\frac{1}{4\pi^2}\int\frac{V(z)}{|x-z|}f(z)\left[|x-z|\int\frac{e^{-i|k|(|x-y|+|y-z|)}}{|x-y||y-z|}V(y)dy\right]dz\\&=:\frac{1}{4\pi^2}\int\frac{V(z)}{|x-z|}f(z)I^V(x,z,|k|)dz.\end{aligned}$$

Zemach and Klein[21] showed that, for $V\in C_0^1(\mathbb{R}^3)$,

$$\lim_{|k|\to\infty}\sup_{x,z\in\mathbb{R}^3}|I^V(x,z,|k|)|=0,$$

i.e., that $\lim_{|k|\to\infty}\|T_k^2\|_{\mathcal{L}(B)}=0$ holds for $V\in C_0^1(\mathbb{R}^3)$.

Potentials $V\in L^1\cap L^2$ will be approximated in the following norm:

$$|||V|||=\sup_{x\in\mathbb{R}^3}\int\frac{|V(y)|}{|x-y|}dy.$$

Observing that

$$|||V|||\leqslant\sup_{x\in\mathbb{R}^3}\int_{|x-y|<1}\frac{|V(y)|}{|x-y|}dy+\sup_{x\in\mathbb{R}^3}\int_{|x-y|\geqslant 1}\frac{|V(y)|}{|x-y|}dy\leqslant c(\|V\|_{L^2}+\|V\|_{L^1})<\infty, \tag{44}$$

where we used Schwarz's inequality for the $\|V\|_{L^2}$ term, we conclude that, since any $V \in L^1 \cap L^2$ can be approximated by a function $U \in C_0^1$ simultaneously in the L^1 and L^2 norm, this is also true for the $\||\cdot\||$ norm. Thus we get the following bound for the norm of T_k^2:

$$\|T_k^2 f\|_B = \sup_{x\in\mathbb{R}^3}\left|\frac{1}{(2\pi)^2}\int \frac{e^{-i|k||x-y|}}{|x-y|}(V(y)-U(y)+U(y))\int \frac{e^{-i|k||y-z|}}{|y-z|}V(z)f(z)dz\,dy\right|$$
$$\leqslant \|f\|_B \||V\||(\||V-U\||+\sup_{x,z\in\mathbb{R}^3}|I^U(x,z,|k|)|).$$

The first term in the brackets becomes small for appropriately chosen $U \in C_0^1$ while the second one converges to zero for $|k|\to\infty$. □

We now proceed to (b), namely, that $\lim_{|k|\to\infty}\|g(\cdot,k)+T_k g(\cdot,k)\|_B=0$. By $T_k g(x,k) = T_k^2 e^{ik\cdot x}$ and Lemma 3.7, $\lim_{|k|\to\infty}\|T_k g(\cdot,k)\|_B=0$ follows immediately. To get the analogous statement for $g(\cdot,k)$ we assume first again $V\in C_0^1(\mathbb{R}^3)$. Then

$$|g(x,k)| = \frac{1}{2\pi}\left|\int \frac{e^{-i|k||x-y|}}{|x-y|}V(y)e^{-ik\cdot(x-y)}\,dy\right|$$
$$\leqslant \frac{1}{2\pi}\left|\int_{\theta<\theta_0}\frac{e^{-i|k||z|(1+\cos\theta)}}{|z|}V(x-z)dz\right| + \frac{1}{2\pi}\int_{\theta\geqslant\theta_0}\frac{|V(x-z)|}{|z|}dz \tag{45}$$

holds. Herein θ denotes the angle between $z=(x-y)$ and k. Stationary phase methods on the first term yields

$$\frac{1}{2\pi}\left|\int_{\theta<\theta_0}\frac{1}{i|k|(1+\cos\theta)}\left(\frac{d}{d|z|}e^{-i|k||z|(1+\cos\theta)}\right)V(x-z)|z|d|z|d\Omega(z)\right|$$
$$=\frac{1}{2\pi}\left|\int_{\theta<\theta_0}\frac{1}{i|k|(1+\cos\theta)}e^{-i|k||z|(1+\cos\theta)}\left(\frac{d}{d|z|}V(x-z)|z|\right)d|z|d\Omega(z)\right|$$
$$\leqslant\frac{1}{2\pi}\frac{1}{|k|(1+\cos\theta_0)}\int\left|\frac{d}{d|z|}V(x-z)|z|\right|d|z|d\Omega(z)\leqslant\frac{c}{|k|(1+\cos\theta_0)}\xrightarrow{|k|\to\infty}0,$$

where

$$\sup_{x\in\mathbb{R}^3}\int\left|\frac{\frac{d}{d|z|}V(x-z)|z|}{|z|^2}\right|dz=c<\infty$$

was used. This follows directly from $V\in C_0^1$.

The second term in (45) is an integration over a cone with opening angle θ_0, where the potential in the integrand has compact support, is bounded and displaced by $-x$. Thus

$$\lim_{\theta_0\to\pi}\sup_{x\in\mathbb{R}^3}\int_{\theta\geqslant\theta_0}\frac{|V(x-z)|}{|z|}dz\leqslant c\lim_{\theta_0\to\pi}\int_{\theta_0}^{\pi}|\sin\theta|d\theta=0,$$

and $\lim_{|k|\to\infty}\sup_{x\in\mathbb{R}^3}|g(x,k)|=0$ follows. To get this for $V\in L^1\cap L^2$, we approximate V by $U \in C_0^1$, as in Lemma 3.7.

Analogously we show that $\langle x\rangle^{-|\alpha|}|\partial_k^\alpha\Phi(x,k)-\partial_k^\alpha e^{ik\cdot x}|$ vanish uniformly for $|k|\to\infty$. According to the proof of part (i) of Theorem 3.1, $\partial_k^\alpha\eta(x,k)$ is obtained as the unique solution of (40) in B. For large $|k|$ the operator $(1-(T_k^{s+p-1})^2)^{-1}$ with $p=|\alpha|$ can be expanded in terms of the Born series, and the solution of the modified equation is given by

$$\xi=(1-(T_k^{s+p-1})^2)^{-1}(\langle\cdot\rangle^{-s-p+1}[\partial_k^\alpha g+\partial_k^\alpha T_k\,\eta-T_k\,\partial_k^\alpha\eta]$$
$$+T_k^{s+p-1}\langle\cdot\rangle^{-s-p+1}[\partial_k^\alpha g+\partial_k^\alpha T_k\,\eta-T_k\,\partial_k^\alpha\eta]).$$

It can be shown by the same methods as in the case of $g(x,k)$ that the term, on which $(1-(T_k^{s+p-1})^2)^{-1}$ acts, uniformly approaches zero for $|k|\to\infty$, which completes the proof of the proposition. □

The uniform boundedness of Φ as well as the bounds on its partial derivatives with respect to k now follow from Proposition 3.5 and Proposition 3.6. □

We will conclude this section with two corollaries to Theorem 3.1 and Proposition 3.6: The first one states that the Riemann–Lebesgue lemma holds also for the generalized Fourier transformation and its inverse. Furthermore, the differentiability of the generalized Fourier transform of a function is connected to its decay as in the case of the ordinary Fourier transform. Related results can be found in a work by Isozaki.[22]

Corollary 3.8: Let V satisfy $(\mathbf{V})_{\mathbf{n}}$ with some $n\geqslant 3$ and let zero not be an eigenvalue or resonance of H. Then, for any $N\leqslant n-2$ and any f such that $\langle x\rangle^N f\in L^1(\mathbb{R}^3)\mathcal{F}_\pm f$ and $\mathcal{F}_\pm^{-1}f$ are in $C^N(\mathbb{R}^3)$ and $\partial_k^\alpha\mathcal{F}_\pm f\in C_\infty(\mathbb{R}^3)$ and $\partial_k^\alpha\mathcal{F}_\pm^{-1}f\in C_\infty(\mathbb{R}^3)$ for all α with $|\alpha|\leqslant N$.

Proof: Let $\langle x\rangle^N f\in L^1$, $0\leqslant|\alpha|\leqslant N$, then, e.g.,

$$\partial_k^\alpha(\mathcal{F}_+f)(k)=\partial_k^\alpha\frac{1}{(2\pi)^{3/2}}\int\Phi_+^*(x,k)f(x)dx$$
$$=\frac{1}{(2\pi)^{3/2}}\int\partial_k^\alpha\Phi_+^*(x,k)f(x)dx$$
$$=\frac{1}{(2\pi)^{3/2}}\int\partial_k^\alpha e^{-ik\cdot x}f(x)dx+\frac{1}{(2\pi)^{3/2}}\int\partial_k^\alpha\eta_+^*(x,k)f(x)dx \tag{46}$$

is bounded and continuous since $|\partial_k^\alpha\Phi_+^*(x,k)|$ is bounded by $c_\alpha\langle x\rangle^{|\alpha|}$ according to Theorem 3.1 and $\langle x\rangle^{|\alpha|}f\in L^1$. Furthermore, the first term in the second line belongs to C_∞ by the ordinary Riemann–Lebesgue lemma and the second term belongs to C_∞ since $\langle x\rangle^{-|\alpha|}|\partial_k^\alpha\eta_+^*(x,k)|$ tends uniformly to zero for $|k|\to\infty$ according to Proposition 3.6. □

The second corollary concerns the so-called T matrix, an object widely discussed in quantum mechanical scattering theory. Let V satisfy $(\mathbf{V})_{\mathbf{3}}$; then the T matrix $\mathbf{T}(\cdot,\cdot)$ is defined by

$$\mathbf{T}(k,k')=(2\pi)^{-3}\int e^{-ik\cdot x}V(x)\Phi_-(x,k')dx. \tag{47}$$

There are several results about the analyticity of the T matrix for potentials with exponential decay.[23] The following corollary gives sufficient conditions for $\mathbf{T}(k,k')$ to be continuously differentiable.

Corollary 3.9: Let V satisfy $(\mathbf{V})_{\mathbf{n}}$ for some $n\geqslant 3$ and let zero be neither a resonance nor an eigenvalue of H. Then (i) $\mathbf{T}(\cdot,\cdot)\in C^{n-3}(\mathbb{R}^3\times(\mathbb{R}^3\setminus\{0\}))$; (ii) for every multi-index α with $|\alpha|\leqslant n-3$,

$$\sup_{k\in\mathbb{R}^3,k'\in\mathbb{R}^3\setminus\{0\}}|\partial_{k'}^\alpha\mathbf{T}(k,k')|<\infty.$$

ACKNOWLEDGMENTS

This work was supported by the DFG. We thank W. Amrein for very helpful correspondence, for Reference 14 and for sending us his preprints 7 and 8 prior to publication. Very helpful discussions with S. Goldstein, A. Soffer and N. Zanghi are gratefully acknowledged.

APPENDIX

In this appendix we prove two lemmas used in Sec. III.

Lemma A.1: (i) The space $\tilde{B}$ equipped with the norm

$$\|f\|_{\tilde{B}} = \sup_{x\in\mathbb{R}^3, k\in I} |f(x,k)|$$

is a Banach space.

(ii) Let $\{A_k\}_{k\in I}\subset\mathcal{L}(B)$ be a family of bounded operators on B such that A_k depends continuously on k with respect to the operator norm. Then

$$(Af)(x,k) := (A_k f(\cdot,k))(x)$$

defines an operator $A\in\mathcal{L}(\tilde{B})$ and $\|A\|_{\mathcal{L}(\tilde{B})}\leqslant \sup_{k\in I}\|A_k\|_{\mathcal{L}(B)}$.

Proof [of part (i)]: Let $\{f_n\}_{n\in\mathbb{N}}$ be a Cauchy sequence in $\tilde{B}\subset C(\mathbb{R}^3\times I)$. Then there exists $f\in C(\mathbb{R}^3\times I)$ such that $\lim_{n\to\infty}\|f-f_n\|_{\tilde{B}}=0$. It remains to show that $f\in\tilde{B}$, i.e., that $\lim_{|x|\to\infty}\sup_{k\in I}|f(x,k)|=0$. But

$$\sup_{k\in I}|f(x,k)|\leqslant \sup_{k\in I}|f(x,k)-f_n(x,k)| + \sup_{k\in I}|f_n(x,k)| \leqslant \|f-f_n\|_{\tilde{B}} + \sup_{k\in I}|f_n(x,k)|.$$

The first term can be made arbitrarily small by appropriately choosing n, and the second term vanishes for $|x|\to\infty$.

Proof [of part (ii)]: Let $f\in\tilde{B}$. Then for any fixed $k\in I$, $f(\cdot,k)\in B$ and therefore $A_k f(\cdot,k)\in B$. First we show that $Af(\cdot,\cdot)\in C(\mathbb{R}^3\times I)$:

$$\begin{aligned}|(Af)(x,k)-(Af)(x',k')| &= |(A_k f(\cdot,k))(x)-(A_{k'}f(\cdot,k'))(x')|\\ &\leqslant |(A_k f(\cdot,k))(x)-(A_k f(\cdot,k))(x')| + |((A_k-A_{k'})f(\cdot,k))(x')|\\ &\quad + |(A_{k'}(f(\cdot,k)-f(\cdot,k')))(x')|. \end{aligned} \tag{A1}$$

Since $A_k f(\cdot,k)\in B$, the first term can be made arbitrarily small by choosing $|x-x'|$ small enough. The second term becomes small uniformly in x' by choosing $|k-k'|$ small enough, since

$$\sup_{x'\in\mathbb{R}^3}|((A_k-A_{k'})f(\cdot,k))(x')| = \|(A_k-A_{k'})f(\cdot,k)\|_B \leqslant \|A_k-A_{k'}\|_{\mathcal{L}(B)}\|f\|_{\tilde{B}},$$

and A_k depends continuously on k. The third term in (A1) yields

$$\begin{aligned}\sup_{x'\in\mathbb{R}^3}|(A_{k'}(f(\cdot,k)-f(\cdot,k')))(x')| &\leqslant \|A_{k'}\|_{\mathcal{L}(B)}\|f(\cdot,k)-f(\cdot,k')\|_B\\ &\leqslant c\max\left(\sup_{|x'|>R}|f(x',k)-f(x',k')|,\ \sup_{|x'|\leqslant R}|f(x',k)-f(x',k')|\right),\end{aligned}$$

where we used $\sup_{k\in I}\|A_k\|_{\mathcal{L}(B)}\leqslant c<\infty$. This holds because $\|A_k\|_{\mathcal{L}(B)}$ is a continuous function of k on a compact set. The first term in $\max(\cdots)$ can be made arbitrarily small by choosing R large since $f\in\tilde{B}$. The second term vanishes for $|k-k'|\to 0$ since a continuous function on a compact domain is uniformly continuous.

We now show that

$$\lim_{|x|\to\infty}\sup_{k\in I}(Af)(x,k) = \lim_{|x|\to\infty}\sup_{k\in I}(A_k f(\cdot,k))(x)=0.$$

Suppose that this is wrong; then there exists an $\epsilon > 0$ and a sequence $\{x_n, k_n\}_{n\in\mathbb{N}} \subset \mathbb{R}^3 \times I$ with $\lim_{n\to\infty} x_n = \infty$, such that $|(A_{k_n} f(\cdot, k_n))(x_n)| > \epsilon, \forall n \in \mathbb{N}$. Since I is compact, $\{k_n\}$ contains a convergent subsequence (for simplicity also denoted by $\{k_n\}$) with $\lim_{n\to\infty} k_n = k \in I$. Now

$$|A_{k_n} f(x_n, k_n)| \leqslant |A_{k_n}(f(x_n, k_n) - f(x_n, k))| + |(A_{k_n} - A_k) f(x_n, k)| + |A_k f(x_n, k)|,$$

where the first two terms get arbitrarily small as $n \to \infty$, as has just been shown, and the third term gets arbitrarily small as $n \to \infty$ since $A_k f(\cdot, k) \in B$. Thus, we have a contradiction and $Af \in \tilde{B}$ follows.

The estimate for the norm follows directly from

$$\|Af\|_{\tilde{B}} = \sup_{x\in\mathbb{R}^3, k\in I} |(A_k f(\cdot, k))(x)| \leqslant \sup_{k\in I} \|A_k\|_{\mathcal{L}(B)} \|f(\cdot, k)\|_B \leqslant \sup_{k\in I} \|A_k\|_{\mathcal{L}(B)} \|f\|_{\tilde{B}}.$$

□

Lemma A.2: Let V satisfy $\mathbf{(V)_3}$ and let $s > 0$ such that $\langle x\rangle^s V(x)$ still satisfies $\mathbf{(V)_3}$. For $f \in \tilde{B}$ let

$$(\tilde{T} f)(x,k) := -\frac{1}{2\pi} \int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s |x-y|} \langle y\rangle^s V(y) f(y,k) dy,$$

$$(\tilde{T}' f)(x,k) := \frac{i}{2\pi} \frac{k_l}{|k|} \int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s} \langle y\rangle^s V(y) f(y,k) dy,$$

and

$$(\tilde{K} f)(x,k) := \int_{k_l^0}^{k_l} f(x, (k_l', k_{\bar{l}})) dk_l';$$

then (i) the operators $\tilde{T}$, $\tilde{T}'$, and $\tilde{K}$ belong to $\mathcal{L}(\tilde{B})$ and $\|\tilde{K}\|_{\mathcal{L}(\tilde{B})} \leqslant 2\delta_l$, where $2\delta_l$ is the length of the interval I_l; (ii) the functions $\langle x\rangle^{-s} \partial_{k_l} g(x,k)$ and $\langle x\rangle^{-s} \eta(x, (k_l^0, k_{\bar{l}}))$ belong to $\tilde{B}$.

Proof [of part (i)]: Let $f \in B$ and define

$$(T_k^s f)(x) = -\frac{1}{2\pi} \int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s |x-y|} \langle y\rangle^s V(y) f(y) dy,$$

$$(T_k'^s f)(x) = \frac{i}{2\pi} \frac{k_l}{|k|} \int \frac{e^{-i|k||x-y|}}{\langle x\rangle^s} \langle y\rangle^s V(y) f(y) dy;$$

then for $\tilde{f} \in B$ we have $(\tilde{T}\tilde{f})(x,k) = (T_k^s \tilde{f}(\cdot, k))(x)$ and analogously for $\tilde{T}'$. We shall use Lemma A.1 (ii) to prove that $\tilde{T}$ and $\tilde{T}'$ are in $\mathcal{L}(\tilde{B})$. We have to show that $(T_k^s)_{k\in I}$ and $(T_k'^s)_{k\in I}$ are families of operators in $\mathcal{L}(B)$ continuously depending on k.

Now $\langle y\rangle^s V(y)$ still satisfies the conditions $\mathbf{(V)_3}$. According to Lemma 3.3 (i) and (v) $\langle x\rangle^s T_k^s$ satisfies the conditions of Lemma A.1 (ii). Multiplication by $\langle x\rangle^{-s}$ is a bounded operation in B, and thus also $(T_k^s)_{k\in I}$ satisfies the conditions of Lemma A.1 (ii). Hence $\tilde{T} \in \mathcal{L}(\tilde{B})$.

Next consider $T_k'^s$. From $\langle y\rangle^s V(y) \in L^1$ and

$$|(T_k'^s f)(x)| \leqslant \langle x\rangle^{-s} \frac{1}{2\pi} \int |\langle y\rangle^s V(y)| dy \|f\|_B,$$

$\lim_{|x|\to\infty} |(T_k'^s f)(x)| = 0$ follows. With $|e^{i\alpha} - e^{i\alpha'}| \leqslant |\alpha - \alpha'|$ for $\alpha, \alpha' \in \mathbb{R}$ we estimate

$$|\langle x\rangle^s(T_k'^s f)(x)-\langle x'\rangle^s(T_k'^s f)(x')| \leq \frac{1}{2\pi}\int |e^{-i|k||x-y|}-e^{-i|k||x'-y|}||\langle y\rangle^s V(y)||f(y)|dy$$

$$\leq \frac{1}{2\pi}\int |k|||x-y|-|x'-y|||\langle y\rangle^s V(y)|dy\|f\|_B$$

$$\leq |x-x'||k|\frac{1}{2\pi}\int |\langle y\rangle^s V(y)|dy\|f\|_B,$$

which proves the continuity of $\langle x\rangle^s(T_k'^s f)(x)$ in x and thus that of $(T_k'^s f)(x)$ itself. Therefore $T_k'^s \in \mathcal{L}(B)$. It remains to show that $T_k'^s$ is norm continuous with respect to k:

$$\|(T_k'^s - T_{k'}'^s)f\|_B = \sup_{x\in\mathbb{R}^3}\left|\frac{1}{2\pi}\int \frac{\langle y\rangle^s V(y)f(y)}{\langle x\rangle^s}\left(\frac{k_l}{|k|}e^{-i|k||x-y|}-\frac{k_l'}{|k'|}e^{-i|k'||x-y|}\right)\right|$$

$$\leq \sup_{x\in\mathbb{R}^3}\left|\frac{1}{2\pi}\int \frac{\langle y\rangle^s V(y)f(y)}{\langle x\rangle^s}e^{-i|k||x-y|}\left(\frac{k_l}{|k|}-\frac{k_l'}{|k'|}\right)\right|$$

$$+\sup_{x\in\mathbb{R}^3}\left|\frac{1}{2\pi}\int \frac{\langle y\rangle^s V(y)f(y)}{\langle x\rangle^s}\frac{k_l'}{|k'|}(e^{-i|k||x-y|}-e^{-i|k'||x-y|})\right|$$

$$\leq c\left|\frac{k_l}{|k|}-\frac{k_l'}{|k'|}\right|\|f\|_B+\sup_{x\in\mathbb{R}^3}\frac{1}{2\pi}\int \frac{|\langle y\rangle^s V(y)|}{\langle x\rangle^s}|e^{-i|k||x-y|}-e^{-i|k'||x-y|}|dy\|f\|_B.$$

Since we can achieve $c|k_l/|k|-k_l'/|k'||<\epsilon/2$ for any $\epsilon>0$ by choosing $|k-k'|$ small, it remains to show that also

$$\sup_{x\in\mathbb{R}^3}\frac{1}{2\pi}\int \frac{|\langle y\rangle^s V(y)|}{\langle x\rangle^s}|e^{-i|k||x-y|}-e^{-i|k'||x-y|}|dy<\frac{\epsilon}{2},$$

for $|k-k'|$ small. Since $\langle x\rangle^s V(x)\in L^1$ and $|e^{-i|k||x-y|}-e^{-i|k'||x-y|}|\leq 2$, there exists R_1 such that

$$\sup_{|x|>R_1}\frac{1}{2\pi}\int \frac{|\langle y\rangle^s V(y)|}{\langle x\rangle^s}|e^{-i|k||x-y|}-e^{-i|k'||x-y|}|dy \leq \sup_{|x|>R_1}\frac{1}{\langle x\rangle^s}\frac{1}{2\pi}\int 2|\langle y\rangle^s V(y)|dy<\frac{\epsilon}{2}.$$

Similarly, there is R_2 such that

$$\sup_{x\in\mathbb{R}^3}\frac{1}{2\pi}\int_{y>R_2}\frac{|\langle y\rangle^s V(y)|}{\langle x\rangle^s}|e^{-i|k||x-y|}-e^{-i|k'||x-y|}|dy \leq \sup_{x\in\mathbb{R}^3}\frac{1}{\langle x\rangle^s}\frac{1}{2\pi}\int_{y>R_2}2|\langle y\rangle^s V(y)|dy<\frac{\epsilon}{4},$$

holds. Observing that from $|x|<R_1$ and $|y|<R_2|x-y|<R_1+R_2$ follows, we obtain for the remaining part,

$$\sup_{|x|<R_1}\frac{1}{2\pi}\int_{|y|<R_2}\frac{|\langle y\rangle^s V(y)|}{\langle x\rangle^s}|e^{-i|k||x-y|}-e^{-i|k'||x-y|}|dy$$

$$\leq ||k|-|k'||\frac{1}{2\pi}(R_1+R_2)\int |\langle y\rangle^s V(y)|dy \leq C|k-k'|<\frac{\epsilon}{4},$$

for $|k-k'|$ sufficiently small. Combining these results, we get that, for any $\epsilon>0$,

$$\|(T_k'^s - T_{k'}'^s)f\|_B<\epsilon\|f\|_B,$$

for $|k-k'|$ small enough, which proves the norm continuity of $T_k'^s$. Therefore $T_k'^s$ meets the requirements of Lemma A.1 (ii), and we conclude that $\tilde{T}' \in \mathcal{L}(\tilde{B})$.

Finally, consider $\tilde{K}$. For $f \in \tilde{B}$ the continuity of $(\tilde{K}f)(x,k) = \int_{k_l^0}^{k_l} f(x,(k_l',k_{\bar{l}}))dk_l'$ in x and k is clear. Furthermore,

$$\lim_{|x|\to\infty} \sup_{k\in I} |(\tilde{K}f)(x,k)| \leq \lim_{|x|\to\infty} 2\delta_l \sup_{k\in I} |f(x,k)| = 0,$$

so that $\tilde{K} \in \mathcal{L}(\tilde{B})$ and

$$\|\tilde{K}f\|_{\tilde{B}} = \sup_{x\in\mathbb{R}^3, k\in I} \left| \int_{k_l^0}^{k_l} f(x,(k_l',k_{\bar{l}}))dk_l' \right| \leq 2\delta_l \|f\|_{\tilde{B}}.$$

Proof [of part (ii)]: Since $\eta(x,k) \in B$ for all $k \neq 0$ and I is compact, $\langle x\rangle^{-s}\eta(x,(k_l^0,k_{\bar{l}}))$ $\in \tilde{B}$ is obvious. Observing

$$\partial_{k_l} g(x,k) = \frac{i}{2\pi}\frac{k_l}{|k|}\int e^{-i|k||x-y|}V(y)e^{ik\cdot y}\,dy - \frac{i}{2\pi}\int \frac{e^{-i|k||x-y|}}{|x-y|}V(y)y_l e^{ik\cdot y}\,dy,$$

$\langle x\rangle^{-s}\partial_{k_l} g(x,k) \in \tilde{B}$ can be shown using the same types of estimates as in the proof of part (i) of this lemma. □

On conserved quantities at spatial infinity

Shyan-Ming Perng[a]
Enrico Fermi Institute, University of Chicago, Chicago, Illinois 60637

(Received 31 July 1998; accepted for publication 20 November 1998)

There is a well-known short list of asymptotic conserved quantities for a physical system at spatial infinity. We search for new ones. This is carried out within the asymptotic framework of Ashtekar and Romano, in which spatial infinity is represented as a smooth boundary of space–time. We first introduce, for physical fields on space–time, a characterization of their asymptotic behavior as certain fields on this boundary. Conserved quantities at spatial infinity, in turn, are constructed from these fields. We find, in Minkowski space–time, that each of a Klein–Gordon field, a Maxwell field, and a linearized gravitational field yields an entire hierarchy of conserved quantities. Only certain quantities in this hierarchy survive into curved space–time. © *1999 American Institute of Physics.* [S0022-2488(99)00504-6]

I. INTRODUCTION

In the description of isolated systems in flat space–time, conserved quantities have often been found to be useful. Examples of such conserved quantities include electric charge, energy–momentum, angular momentum, and, in certain circumstances, various multipole moments. These conserved quantities are usually expressed as surface integrals in the limit as the surface approaches infinity. In general relativity, by contrast, the construction of such conserved quantities is more complicated. Not the least of these complications is that ''infinity'' is so much more difficult to pin down in the presence of curvature.

The study of isolated systems in general relativity was pioneered by Arnowitt, Deser, and Misner.[1] They defined asymptotic flatness of a space–time in terms of the existence of an initial data set, which, expressed in suitable coordinates, has the initial data approach the flat values at suitable rates. Conserved quantities, such as energy–momentum and angular momentum, were then expressed as limits of certain surface integrals.

One unfortunate aspect of the approach of Arnowitt, Deser, and Misner is that their asymptotic conditions are tied so closely to coordinates. Their approach was subsequently geometrized and extended by Geroch[2] via a conformal completion by a single point ''at spatial infinity.'' Multipole moments for certain fields in flat space–time were generalized to static asymptotically flat space–times within this framework.[3] An alternative geometrical framework, which unifies spatial and null infinity and is thus adapted to the relation between these two asymptotic regimes, was introduced by Ashtekar and Hansen.[4] This framework involves a conformal completion of the entire space–time, null infinity becoming a null cone with spatial infinity its vertex. This framework is used, for example, both to formulate and to prove the assertion that the ADM mass is the past limit of the future Bondi mass.[5]

In both of the geometrical frameworks outlined above spatial infinity is squeezed into a point, and there smoothness of the completed manifold fails. So, inevitably, one is forced to deal with complicated differentiable structures there. This circumstance is less satisfactory than that of null infinity, which is formulated as a smooth boundary of space–time. Early attempts to restore smoothness to spatial infinity include those of Sommers[6] and Persides.[7] Beig and Schmidt,[8,9] using a coordinate-dependent treatment similar to that of Bondi *et al.*,[10] obtained fields on the surface at spatial infinity order by order, and noticed that these fields there satisfy hyperbolic equations. This

[a]Electronic mail: sperng@rainbow.uchicago.edu

work culminates in that of Ashtekar and Romano,[11] who introduced a new geometrical framework for asymptotic flatness in which spatial infinity was indeed expressed as a smooth boundary of space–time. Their definition also provided a natural geometrical setting for the results of Beig and Schmidt. The Ashtekar and Romano framework is somewhat of a hybrid, in that it involves both the conformal and projective structure. By their definition, a space–time is asymptotically flat at spatial infinity, provided one can attach to it a smooth boundary $\mathcal{H}$ and introduce a smooth function Ω vanishing at $\mathcal{H}$ such that the induced metric on and the normal to the constant-Ω surfaces are, after rescaling by suitable powers of Ω, smoothly extendible to $\mathcal{H}$. This new definition has proven to be useful in the study of asymptotic properties of space–time at spatial infinity, since various physical fields turn out to be smooth there.

We return now to conserved quantities. It is natural to ask the following: Do, in some sense, the well-known conserved quantities—energy–momentum, angular momentum, electric charge—at spatial infinity exhaust all conserved quantities that could possibly be defined there? To settle this question would clearly provide insights into the asymptotic properties of the physical fields and of the space–time. The framework introduced by Ashtekar and Romano is perfectly suited to addressing this question. One has a simple, universal smooth structure at spatial infinity, enabling one to investigate fields at spatial infinity order by order. The notion of a conserved quantity had already been formulated by Ashtekar and Romano: Each conserved quantity is to be expressed as an integral over a two-sphere section of spatial infinity, where the value of the integral is independent of section. In particular, the well-known conserved quantities are so expressed. We seek others.

This paper is organized as follows. Section II contains the basic framework, which underlies the rest of the paper. We first review briefly (a slight modification of) the Ashtekar–Romano definition of asymptotic flatness. We then formulate within this framework the asymptotic structure of the physical fields. In particular, we introduce the notion of a conserved quantity, and give some familiar examples. In Sec. III, we consider the special but important case of fields in Minkowski space–time. We construct all linear conserved quantities associated with a Klein–Gordon field, with a Maxwell field, and with a linearized gravitational field and having a certain ''polynomial dependence'' on asymptotic translations. We then study the symmetry properties and the ''gauge behavior'' (the dependence on a certain freedom in the formulation of an asymptotic structure) of these quantities. In Sec. IV, we consider fields in a curved, asymptotically flat space–time. We first derive the equations, at spatial infinity, satisfied by the asymptotic fields. We then show that—at least in the Klein–Gordon and Maxwell cases—certain of the conserved quantities found in Sec. III for Minkowski space–time can be generalized to these curved space–times. In Sec. V, we discuss various related issues. In particular, we formulate two conjectures. One asserts that a certain conserved quantity for linearized gravity in Minkowski space–time can be generalized to curved space–time. The other asserts that we have here found all conserved quantities in curved space–time for Klein–Gordon, Maxwell, and gravitational fields.

II. PRELIMINARIES

A. Asymptotic flatness

Fix a space–time $(\tilde{M},\tilde{g}_{ab})$.

Definition 1: By a completion of $(\tilde{M},\tilde{g}_{ab})$, *we mean (cf. Ashtekar and Romano in Ref. 11): A manifold M with boundary* $\mathcal{H}$, *a smooth function* Ω *defined on M vanishing on* $\mathcal{H}$, *and a diffeomorphism from* $\tilde{M}$ *to* $M-\mathcal{H}$ *(by means of which we identify* $\tilde{M}$ *with its image in M) satisfying the following three classes of conditions.*

(1) The combinations (i) $\nabla_a\Omega$, *(ii)* $\Omega^{-4}\tilde{g}^{ab}\nabla_b\Omega(\equiv n^a)$, *and (iii)* $\Omega^2[\tilde{g}_{ab}-(\tilde{g}^{cd}\nabla_c\Omega\,\nabla_d\Omega)^{-1}\nabla_a\Omega\,\nabla_b\Omega](\equiv q_{ab})$ *admit smooth, nowhere-vanishing extensions to* $\mathcal{H}$ *such that (iv)* $n^a\nabla_a\Omega(\equiv\lambda^{-2})|_{\mathcal{H}}=1$ *and (v)* $\mathcal{L}_n[(n^m\nabla_m\Omega)^{-1}q_{ab}]|_{\mathcal{H}}=0$.

(2) $(\mathcal{H},q_{ab}|_{\mathcal{H}})$ *is a standard timelike hyperboloid, i.e.,* $\mathcal{H}$ *has topology* $S^2\times\mathbb{R}$, $q_{ab}|_{\mathcal{H}}\equiv\overset{0}{q}_{ab}$ *is of constant positive curvature and is geodesically complete.*

(3) The combinations (i) $n^k n^l \tilde{G}_{kl}$, *(ii)* $\Omega^{-1} q_a{}^k n^l \tilde{G}_{kl}$, *and (iii)* $\Omega^{-2} q_a{}^k q_b^l \tilde{G}_{kl}$, *are smoothly extendible to* $\mathcal{H}$, *where* $\tilde{G}_{ab}$ *is the Einstein tensor of* $\tilde{g}_{ab}$.

The boundary $\mathcal{H}$ represents spatial infinity. Conditions (1) describe the falloff behavior of the metric $\tilde{g}_{ab}$ and conditions (3) that of its second derivative. Conditions (2) ensure, among other things, that we are dealing with (all of) spatial infinity. There is some redundancy in the above conditions. Specifically, the constancy both of the left side of (1) (iv) and of the curvature of q_{ab} already follow from the other conditions. In light of this, the choice of the constant ''1'' in condition (i) (iv) (which is equivalent to the demand that $\overset{0}{q}_{ab}$ be the metric of a unit hyperboloid) serves only to restrict the freedom of multiplying Ω by a constant factor. Condition (1)(v) is essentially the condition, $\overset{0}{B}_{ab}=0$ [cf. Eq. (3)], introduced by Ashtekar and Hansen[4] in order to define angular momentum. More precisely, when $\overset{0}{B}_{ab}=0$, condition (1)(v) can always be achieved without affecting the other conditions by choosing a suitable Ω.

Definition 1 is essentially the same as the definition, given by Ashtekar and Romano,[11] of what they call an asymptotically Minkowskian space–time. However, there are three differences. First, our conditions on the Einstein tensor are weaker than the corresponding condition, namely, $\lim_{\Omega\to 0} \Omega^{-1}\tilde{G}_{ab}=0$, in their definition. Their condition, expressed in the present language, is equivalent to the smooth extendibility to $\mathcal{H}$ of $\Omega^{-2} n^k n^l \tilde{G}_{kl}$, $\Omega^{-2} q_a{}^k n^l \tilde{G}_{kl}$, and $\Omega^{-2} q_a{}^k q_b^l \tilde{G}_{kl}$. Indeed, our condition holds while theirs fails (for $n^k n^l \tilde{G}_{kl}|_{\mathcal{H}} \neq 0$) in the Reissner–Nordstrom solution. Second, we impose condition (1)(iv), which, as mentioned above, is effectively a gauge restriction on the conformal factor Ω, a restriction that is absent in the definition of Ashtekar and Romano. Finally, we impose condition (1)(v), which Ashtekar and Romano omit from the general definition of asymptotic Minkowskian space–times, but subsequently impose for their discussion of angular momentum.

We give a few simple examples of completion. As a first example, let $(\tilde{M},\tilde{g}_{ab})$ be Minkowski space–time, and let (t,r,θ,ϕ) be ordinary spherical polar coordinates. Set $\Omega=(r^2-t^2)^{-1/2}$ and $\tanh \chi = t/r$. Let M be $\tilde{M}$ together with the boundary $\mathcal{H}$ consisting of the points labeled by $\Omega=0$ in the (hyperbolic coordinate) chart $(\Omega,\chi,\theta,\phi)$, with a differentiable structure given by that chart. Then this (M,Ω) is a completion of Minkowski space–time. As a second example, let $(\tilde{M},\tilde{g}_{ab})$ be Reissner–Nordstrom solution, and let (t,r,θ,ϕ) be the usual Schwarzschild-like coordinates therein. Repeat the same construction as in Minkowski space–time to obtain a manifold with boundary (M,Ω). Then this choice of Ω satisfies all conditions in definition 1, except condition (1)(v). Condition (1)(v), in turn, can be achieved, without violating other conditions, by choosing a new conformal factor Ω' of the form $\Omega'=\Omega(1+\omega\Omega)$ with a suitable smooth function ω. In general, all stationary vacuum space–times asymptotically flat by the usual definition[3] admit completions in the present sense.[12]

Two completions, (M,Ω), (M',Ω') of $(\tilde{M},\tilde{g}_{ab})$, are said to be equivalent if the identity map of $\tilde{M}$ extends to a diffeomorphism from M to M'. It turns out that a space–time may admit inequivalent completions.[13] Minkowski space–time, for instance, has a four-parameter family of inequivalent completions related to each other by what are called ''logarithmic translations.''[14] Indeed, let x^μ be a usual Minkowskian coordinate system in Minkowski space–time $\tilde{M}$, and c^μ any constant vector. Then the hyperbolic coordinates associated with x'^μ given by $x^\mu = x'^\mu - c^\mu \log \Omega'$ yield a new completion of $\tilde{M}$ inequivalent to that arising from x^μ. In this case we can single out the usual completion to be the preferred one among this four-parameter family since it is the only one in which all Killing fields are smoothly extendible to the boundary at spatial infinity. Similarly, any stationary asymptotically flat space–time admits at least a one-parameter family of inequivalent completions, arising from logarithmic time translations. There is also a sort of converse to this: the existence of two inequivalent completions related by such a logarithmic translation implies that the space–time admits an asymptotic translational Killing field—a vector field $\tilde{\xi}^a$ with the properties that $\Omega^{-1}\tilde{\xi}^a$ is smoothly extendible to, and vanishes nowhere on, $\mathcal{H}$; and that $\tilde{\nabla}_{(a}\tilde{\xi}_{b)}$ and all its derivatives vanishes on $\mathcal{H}$. In the spatial-infinity framework of Geroch and Ashtekar–Hansen, it has been shown by Chrusciel[15] that these logarithmic translations are the only kind of inequivalent completions that may arise. We conjecture the following in the present framework: Any two inequivalent completions are related by such a logarithmic translation. If this conjecture is true, then our work will not be affected by the possible existence of inequivalent completions. In what follows, we will always fix a specific completion and only consider completions smoothly related (i.e., equivalent) to the fixed one.

B. Physical fields and their remnants

We now set up the framework for dealing with the asymptotic structure of physical fields. Let $(\tilde{M},\tilde{g}_{ab})$ be a space–time, with (M,Ω) a completion. Let $\tilde{v}_{a_1\cdots a_m}$ be a smooth, covariant, mth rank tensor field on $\tilde{M}$, and consider the 2^m tensor fields that result from contracting each index of $\tilde{v}$ with either $\Omega^2 n^a$ or $\Omega q^a{}_b$. We say $\tilde{v}$ is *asymptotically regular of order s*, provided each of these 2^m tensor fields, multiplied by Ω^{-s}, is smoothly extendible to $\mathcal{H}$. Asymptotic regularity of a general tensor field is defined by lowering any contravariant indices with $\tilde{g}_{ab}$ and applying the definition above to the resulting covariant field. Note that conditions (1)(*ii*), (*iii*) above are precisely the statement that $\tilde{g}_{ab}$ is asymptotically regular of order 0; and conditions (3)(*i*)–(*iii*) are precisely the statement that $\tilde{G}_{ab}$ is asymptotically regular of order 4. The outer product of two asymptotically regular fields, of respective orders s and s', is asymptotically regular, of order $s+s'$. Contractions using $\tilde{g}^{ab}$ preserve asymptotic regularity, and order.

Thus, an asymptotically regular physical field gives rise, on M, to 2^m smooth fields, with ranks ranging from m down to zero, whose behavior near $\mathcal{H}$ reflects the asymptotic behavior of the physical field. Let $u_{a_1\cdots a_m}$ denote any one of these fields. Then set, for k any non-negative integer,

$$\overset{k}{u}_{a_1\cdots a_m} \equiv \underset{\leftarrow}{\psi}[(\mathcal{L}_{(n\cdot\nabla\Omega)^{-1}n})^k u_{a_1\cdots a_m}], \tag{1}$$

where $\underset{\leftarrow}{\psi}$ stands for the pull-back to $\mathcal{H}$ via the natural embedding map $\mathcal{H}\overset{\psi}{\rightarrow}M$. Note the right side of Eq. (1) exists since $u_{a_1\cdots a_m}$ (and therefore each of its derivatives) is smoothly extendible to $\mathcal{H}$. The $\overset{k}{u}_{a_1\ldots a_m}$ so defined will be called the kth-*order remnant* of $u_{a_1\cdots a_m}$. These remnants, ($k=0,1,\ldots$), clearly carry, order by order, the asymptotic information contained in $u_{a_1\cdots a_m}$, and, therefore, the asymptotic information in the original physical field $\tilde{v}$. Suppose, next, that the physical field $\tilde{v}$ satisfies various field equations. Then these field equations yield partial differential equations on M on the u's that arise via asymptotic regularity from $\tilde{v}$, and so partial differential equations on $\mathcal{H}$ on the remnants $\overset{k}{u}$ that arise via Eq. (1) from the u's. We will refer to these as the *remnant field equations*.

We give some examples of asymptotically regular fields and their associated remnants. Fix a space–time $(\tilde{M},\tilde{g}_{ab})$ with a completion (M,Ω). For the first example, consider the space–time metric $\tilde{g}_{ab}$. Then, as we mentioned above, this field is asymptotically regular of order 0. The corresponding u's are $q_{ab}(\equiv\Omega^2 q_a{}^k q_b{}^l \tilde{g}_{kl})$, $0(\equiv\Omega^3 q_a{}^k n^l \tilde{g}_{kl})$, and $\lambda^{-2}(\equiv[\Omega^4 n^a n^b \tilde{g}_{ab}])$. Their corresponding remnants, $\overset{k}{q}_{ab}$ and $\overset{k}{\lambda}$, carry the asymptotic information contained in the space–time geometry. We note that conditions $(1)(iv)$ and $(1)(v)$ in the definition of a completion are actually conditions on these remnants: namely, $\overset{0}{\lambda}=1$, and $\overset{1}{q}_{ab}=-2\overset{1}{\lambda}\overset{0}{q}_{ab}$, respectively. For the second example, consider the Einstein tensor $\tilde{G}_{ab}$. Then, as we mentioned above, this field is asymptotically regular of order 4. The corresponding u's, written in terms of the stress–energy tensor $\tilde{T}_{ab}$ $(=\tilde{G}_{ab}/\kappa$, with $\kappa=8\pi G/c^4)$ are

$$T\equiv\lambda^2 n^a n^b(\kappa\tilde{T}_{ab}),\quad T_a\equiv\lambda\Omega^{-1}q_a{}^k n^l(\kappa\tilde{T}_{kl}),\quad \text{and}\quad T_{ab}\equiv\Omega^{-2}q_a{}^k q_b{}^l\kappa(\tilde{T}_{kl}-\tfrac{1}{2}\tilde{T}\tilde{g}_{kl}),\tag{2}$$

where we have introduced certain powers of λ and have used the trace-reversed version of $\tilde{T}_{ab}$ in defining T_{ab} for later convenience. We denote by $\overset{k}{T},\overset{k}{T}_a,\overset{k}{T}_{ab}$, the remnants of T, T_a, and T_{ab}, respectively. For the third example, consider the Weyl tensor, $\tilde{C}_{abcd}$, of this space–time. It is shown in Appendix C [cf. the discussion around Eq. (C14)] that this field is asymptotically regular of order 3. The u's in this case may be taken to be

$$E_{ab}\equiv\Omega^3\lambda^2 q_a{}^j q_b{}^l n^k n^m\tilde{C}_{jklm}\quad\text{and}\quad B_{ab}\equiv\Omega^3\lambda^2 q_a{}^j q_b{}^l n^k n^m{}^*\tilde{C}_{jklm}.\tag{3}$$

Denote their remnants $\overset{k}{E}_{ab}$ and $\overset{k}{B}_{ab}$. Note that condition $(1)(v)$ in the definition of a completion is actually a condition on one of these remnants, namely, $\overset{0}{B}_{ab}=0$ [cf. Eq. (C17)]. For the final example, consider a Maxwell field $\tilde{F}_{ab}$ in this space–time. We demand that it be asymptotically regular of order 2,[16] i.e., that each of

$$E_a\equiv\Omega\lambda n^b\tilde{F}_{ab}\quad\text{and}\quad B_a\equiv\Omega\lambda n^b{}^*\tilde{F}_{ab}\tag{4}$$

be smoothly extendible to $\mathcal{H}$. These are effectively the u's. This demand reflects the idea that a physically reasonable Maxwell field must fall off like $1/r^2$ near spatial infinity. We denote by $\overset{k}{E}_a,\overset{k}{B}_a$ the remnants of E_a,B_a, respectively. Note that it follows that the stress–energy tensor of this Maxwell field has the fall-off rate consistent with that of Eq. (2). Indeed, from $\tilde{T}_{ab}=\tfrac{1}{2}(\tilde{F}_{am}\tilde{F}_b{}^m-\tfrac{1}{4}\tilde{F}^2\tilde{g}_{ab})$ we have

$$T=\tfrac{1}{2}\kappa(E^2+B^2),\quad T_a=-\kappa\epsilon_{amn}E^m B^n,\quad T_{ab}=\kappa[E_aE_b+B_aB_b-\tfrac{1}{2}(E^2+B^2)q_{ab}].\tag{5}$$

There remains, as it turns out, some gauge freedom in the present framework. Fix a space–time $(\tilde{M},\tilde{g}_{ab})$, and let (M,Ω) and (M,Ω'), be two completions of $(\tilde{M},\tilde{g}_{ab})$. It then follows that $\Omega'=\Omega(1+\omega\Omega)$, for some smooth function ω on M such that $\overset{0}{\omega}\equiv\omega|_{\mathcal{H}}$ satisfies Eq. (7) below (i.e., $\overset{0}{\omega}$ is an ''asymptotic translation''); and, conversely, for (M,Ω) any completion and ω and Ω' as above, then (M,Ω') is also a completion. Thus, the gauge freedom consists precisely of such ω fields. The asymptotic gauge freedom, then, is described by the remnants, $\overset{k}{\omega}$, of ω. It turns out[8] that one can, utilizing this gauge freedom, always achieve

$$\overset{k}{\lambda}=0,\quad k\geqslant 2,\tag{6}$$

and that this exhausts the gauge freedom associated with the remnants $\overset{k}{\omega}$, for $k\geqslant 1$. Thus, making this gauge choice, the remaining gauge freedom is represented by a single $\overset{0}{\omega}$ satisfying Eq. (7).

C. Asymptotic translations

In order to construct conserved quantities, it will be convenient to have on hand some facts about asymptotic translations. Denote by $\mathcal{T}$ the set of functions v on $\mathcal{H}$ satisfying the differential equation,

$$D_a D_b v + v \overset{0}{q}_{ab} = 0, \tag{7}$$

where D_a denotes the derivative operator of $\overset{0}{q}_{ab}$. This $\mathcal{T}$ is a four-dimensional vector space [since, by virtue of the fact that the curl of Eq. (7) is an identity, v is completely determined by its value and derivative at any one point] equipped with a Lorentz metric $\langle v,w\rangle \equiv \overset{0}{q}{}^{ab} D_a v D_b w + vw$ [since, by virtue of Eq. (7), the right side is a constant]. Elements of $\mathcal{T}$ can be interpreted[11] as asymptotic translations on M in the following sense: For $\tilde{\xi}^a$ a vector field on $\tilde{M}$ asymptotically regular of order 0 such that $\mathcal{L}_{\tilde{\xi}} \tilde{g}_{ab}$ is asymptotically regular of order 2, then $\Omega^{-2} \mathcal{L}_{\tilde{\xi}} \Omega|_{\mathcal{H}} \in \mathcal{T}$.

It is convenient to introduce an index notation for tensors over $\mathcal{T}$: Greek superscripts and subscripts denote, respectively, elements of $\mathcal{T}$ and its dual $\mathcal{T}^*$. Thus, a solution v of Eq. (7) might be denoted v^μ, while a linear map $\mathcal{T} \overset{w}{\mapsto} \mathbb{R}$ might be denoted w_μ. The action of w on v would be expressed by contraction: $w(v) = w_\mu v^\mu$. We denote by $\eta_{\mu\nu}$ the above Lorentz metric on $\mathcal{T}$, i.e., we set $\eta_{\mu\nu} v^\mu w^\nu = \langle v,w \rangle$. We shall use $\eta_{\mu\nu}$ (and its inverse) to lower and raise indices of tensors over $\mathcal{T}$. The objects with which we shall be concerned are fields on $\mathcal{H}$ that may have Latin indices (indicating tensor character over the manifold $\mathcal{H}$) and Greek indices (indicating tensor character over the vector space $\mathcal{T}$). Thus, for example, ζ_α would denote a $\mathcal{T}^*$-valued function on $\mathcal{H}$, ζ^a would denote an ordinary tangent vector field on $\mathcal{H}$, and $\zeta^a{}_\alpha$ would denote a $\mathcal{T}^*$-valued tangent vector field on $\mathcal{H}$. In particular, an element v^μ in $\mathcal{T}$ is now viewed as a $\mathcal{T}$-valued constant function on $\mathcal{H}$. We lower and raise Greek indices of such fields with $\eta_{\alpha\beta}$ and its inverse, and lower and raise Latin indices with $\overset{0}{q}_{ab}$ and its inverse. There is a natural field, α_μ, defined by the property that, for any $v^\mu \in \mathcal{T}$, $\alpha_\mu v^\mu$ is the corresponding solution of Eq. (7).[17] Then, e.g., $\alpha_\mu \alpha^\mu = 1$. The derivative operator D_a on $\mathcal{H}$ associated with $\overset{0}{q}_{ab}$ extends to a derivative operator on our indexed fields by demanding that $D_a v^\alpha = 0$, for v^α any constant field. There now follows $D_a \overset{0}{q}_{bc} = 0$, $D_a \eta_{\alpha\beta} = 0$,

$$D_a D_b \alpha_\mu + \alpha_\mu \overset{0}{q}_{ab} = 0 \tag{8}$$

[from Eq. (7)],

$$D_a \alpha_\mu D^a \alpha_\nu + \alpha_\mu \alpha_\nu = \eta_{\mu\nu} \tag{9}$$

(from the definition of $\eta_{\mu\nu}$), and $\eta^{\mu\nu} D_a \alpha_\mu D_b \alpha_\nu = \overset{0}{q}_{ab}$.[18]

D. Conserved quantities

Now imagine that we were somehow able to find a divergence-free vector field, constructed from (the remnants of) some physical fields and the background geometry of $\mathcal{H}$. Integrating (the dual of) this vector field over a two-sphere cut (i.e., a noncontractible two-sphere submanifold) of $\mathcal{H}$, we obtain a number—one clearly independent of the choice of cut. Think of such an integral as being the limit of an integral over a spacelike 2-sphere in space–time, as the 2-sphere approaches the cut at spatial infinity. These integrals we call conserved quantities. In each of the examples we shall consider, the divergence-free vector field is multilinear in α_μ,[19] and so the conserved quantities may be viewed as a tensor over $\mathcal{T}$.

We now give three well-known[1,2,4,11] examples of conserved quantities. Some of the computations are relegated to Sec. IV and Appendix C. Fix a space–time $(\tilde{M},\tilde{g}_{ab})$, a completion (M,Ω) thereof, and a cut C of $\mathcal{H}$.

For the first example, let $\tilde{F}_{ab}$ be a Maxwell field on $\tilde{M}$, regular of order 2. Consider the right side of

$$Q=\frac{1}{4\pi}\int_C \overset{0}{E}{}^a\, dS_a, \tag{10}$$

where $\overset{0}{E}{}^a$ is the (zeroth-order) remnant of E_a given by Eq. (4). Maxwell's equations imply the integrand above is divergence-free [cf. Eq. (51)]. Thus, Eq. (10) defines a conserved quantity. This Q is precisely the electric charge, for the right side of Eq. (10) is the limit of the integral of $^*F_{ab}$ over a large spacelike 2-sphere in the space–time as that 2-sphere approaches the cut C. For the second example, consider the right side of

$$\mathcal{P}^\mu=\frac{1}{8\pi}\int_C \overset{0}{E}{}^{ab} D_b \alpha^\mu\, dS_a, \tag{11}$$

where $\overset{0}{E}_{ab}$ is the remnant of E_{ab}, a portion of the Weyl tensor, given in Eq. (3). The remnant field equation [Eq. (C20)] together with Eq. (8) on α_μ, imply that the integrand above is divergence-free. Thus, Eq. (11) defines a conserved quantity, which is a vector over $\mathcal{T}$. This $\mathcal{P}^\mu$ is precisely[1,2] the total mass momentum of the space–time. For the third example, consider the right side of

$$\mathcal{M}_{\mu\nu}=-\frac{1}{16\pi}\epsilon_{\mu\nu}{}^{\tau\sigma}\int_C \overset{1}{B}{}^{ab}\alpha_\tau D_b \alpha_\sigma\, dS_a, \tag{12}$$

where $\epsilon_{\mu\nu\tau\sigma}$ denotes the η-alternating tensor on $\mathcal{T}$. In order for the integrand above to be divergence-free, we must impose on the space–time the additional condition[20] that

$$D_{[a}\overset{0}{T}_{b]}=0. \tag{13}$$

Under this additional condition, Eq. (12) defines a conserved quantity, which is a two-form over $\mathcal{T}$. This $\mathcal{M}_{\mu\nu}$ is precisely[4] the total angular momentum of the space–time.

Finally, we revisit the issue of gauge. Fix a space–time $(\tilde{M},\tilde{g}_{ab})$, and a completion (M,Ω) thereof. Demand further that the completion satisfy the gauge condition (6), so the remaining gauge freedom is represented by the choice of some $\overset{0}{\omega}\in\mathcal{T}$. Applying such a gauge transformation, the remnants of any physical field, and thus also of any conserved quantities associated with that field, will, in general, change. Specifically, let Q_A be any conserved quantity or any remnant field, where the subscript A is an abbreviation for all the indices of Q. Then, for each translation $\overset{0}{\omega}\in\mathcal{T}$, there corresponds a ''gauge-transformed'' quantity—$Q_A[\overset{0}{\omega}]$. Thus, we may regard our quantity Q_A as a tensor field on the 4-manifold $\mathcal{T}$ so defined that its value at $\overset{0}{\omega}\in\mathcal{T}$ is $Q_A[\overset{0}{\omega}]$. In short, the gauge behavior of our original quantity Q_A is coded in the position dependence of this tensor field on $\mathcal{T}$. The derivative of this tensor field reflects the behavior of the quantity under ‘‘infinitesimal gauge transformation.’’ Indeed, from

$$Q_A[\overset{0}{\omega}+\delta\overset{0}{\omega}]=Q_A[\overset{0}{\omega}]+(\delta\overset{0}{\omega})^{\mu}Q^{(1)}{}_{\mu A}[\overset{0}{\omega}]+O((\delta\overset{0}{\omega})^2), \tag{14}$$

we have

$$\nabla_{\mu}Q_A=Q^{(1)}{}_{\mu A}, \tag{15}$$

where ∇_{μ} denote the natural derivative operator on the 4-manifold $\mathcal{T}$. As examples, consider the conserved quantities (10)–(12). Under a gauge transformation, $\Omega'=\Omega(1+\omega\Omega)$ with $\overset{0}{\omega}\in\mathcal{T}$ the remnants $\overset{0}{E}_a,\overset{0}{E}_{ab}$ remain unchanged, while $\overset{1}{B}_{ab}$ changes to $\overset{1}{B'}_{ab}=\overset{1}{B}_{ab}-2\epsilon_{(a}{}^{kl}\overset{0}{E}_{b)k}D_l\overset{0}{\omega}$. In terms of the corresponding tensor fields on the 4-manifold $\mathcal{T}$, these become $\nabla_{\mu}\overset{0}{E}_a=0$, $\nabla_{\mu}\overset{0}{E}_{ab}=0$, and $\nabla_{\mu}\overset{1}{B}_{ab}=-2\epsilon_{(a}{}^{kl}\overset{0}{E}_{b)k}D_l\alpha_{\mu}$. It follows that the total electric charge Q (10) and the 4-momentum $\mathcal{P}^{\mu}$ (11) are gauge invariant, and that[11] the angular momentum $\mathcal{M}_{\mu\nu}$ (12) changes via[21]

$$\mathcal{M}'_{\mu\nu}=\mathcal{M}_{\mu\nu}-\overset{0}{\omega}_{[\mu}\mathcal{P}_{\nu]}. \tag{16}$$

In terms of the corresponding tensor fields on the 4-manifold $\mathcal{T}$, these become, respectively, $\nabla_{\lambda}Q=0$, $\nabla_{\lambda}\mathcal{P}^{\mu}=0$, and

$$\nabla_{\lambda}\mathcal{M}_{\mu\nu}=-\eta_{\lambda[\mu}\mathcal{P}_{\nu]}. \tag{17}$$

III. MINKOWSKI SPACE–TIME

We now apply the framework developed in the previous section to the study of conserved quantities associated with physical fields in Minkowski space–time. Minkowski space–time is a good starting point: It is simple and suggestive of what might happen in the presence of curvature. We shall take as the physical field successively a Klein–Gordon field, a Maxwell field, and a linearized gravitational field. We will write down, for each of these cases, all conserved quantities linear in the physical fields and multilinear in asymptotic translations.

Let $(\tilde{M},\tilde{\eta}_{ab})$ be Minkowski space–time. Fix a point $p\in\tilde{M}$; let Ω be the inverse geodesic distance from p. Then this Ω yields a completion (M,Ω) of Minkowski space–time that we call the *standard completion*. In this completion, we have $\overset{n}{\lambda}=0$ and $\overset{n}{q}_{ab}=0$, for $n\geqslant 1$.

A. Remnant field equations

Here we derive the remnant field equations for Klein–Gordon, Maxwell, and linearized gravitational fields for later use in constructing conserved quantities. For what follows we fix a standard completion of Minkowski space–time $\tilde{M}$ and denote by D_a the derivative operator associated with q_{ab} on constant-Ω surfaces.

Let $\tilde{\phi}$ be a Klein–Gordon field on $\tilde{M}$ asymptotically regular of order 1. Setting $\phi=\Omega^{-1}\tilde{\phi}$, we have

$$0=\tilde{\nabla}^2\tilde{\phi}=\Omega^3[(D^2-1)\phi+\Omega\mathcal{L}_n\phi+\Omega^2(\mathcal{L}_n)^2\phi]. \tag{18}$$

Taking the remnants of the above equation, we obtain

$$D^2 \overset{n}{\phi} = (-n^2+1)\overset{n}{\phi}, \tag{19}$$

for $n=0,1,2,\ldots$.

Let $\tilde{F}_{ab}$ be a Maxwell field on $\tilde{M}$ asymptotically regular of order 2, with remnants $\overset{n}{E}_a$ and $\overset{n}{B}_a$. Using Eq. (4), Maxwell's equation can be written as

$$0 = \tilde{\nabla}^m \tilde{F}_{ma} = \Omega D^m E_m \nabla_a \Omega - \Omega^2 (\Omega \mathcal{L}_n E_a - \epsilon_{akl} D^k B^l), \tag{20}$$

$$0 = \tilde{\nabla}^m {}^*\tilde{F}_{ma} = \Omega D^m B_m \nabla_a \Omega - \Omega^2 (\Omega \mathcal{L}_n B_a + \epsilon_{akl} D^k E^l). \tag{21}$$

Taking the remnants of the above equations, we obtain

$$D_a \overset{0}{E}{}^a = 0, \quad D_a \overset{0}{B}{}^a = 0, \tag{22}$$

$$\epsilon^{abc} D_b \overset{n}{B}_c = n \overset{n}{E}{}^a, \quad -\epsilon^{abc} D_b \overset{n}{E}_c = n \overset{n}{B}{}^a, \tag{23}$$

for $n=0,1,2,\ldots$. Note that Eqs. (23) imply

$$D^2 \overset{n}{E}_a = (-n^2+2)\overset{n}{E}_a, \quad D^2 \overset{n}{B}_a = (-n^2+2)\overset{n}{B}_a, \tag{24}$$

for $n=0,1,2,\ldots$.

Let $\tilde{K}_{abcd}$ be a linearized gravitational field on $\tilde{M}$, i.e., a tensor field on $\tilde{M}$ having the same symmetry and contractions as the Weyl tensor and satisfying the linearized Bianchi identity:

$$\tilde{\nabla}_{[a} \tilde{K}_{bc]de} = 0. \tag{25}$$

Let $\tilde{K}_{abcd}$ be asymptotically regular of order 3, so $E_{ab} \equiv \Omega^3 \tilde{K}_{akbl} n^k n^l$ and $B_{ab} \equiv \Omega^3 {}^*\tilde{K}_{akbl} n^k n^l$ are smoothly extendible to $\mathcal{H}$. Their remnants, denoted $\overset{n}{E}_{ab}$ and $\overset{n}{B}_{ab}$, are symmetric and trace-free. The linearized Bianchi identity can be written as

$$\begin{aligned} 0 &= \tilde{\nabla}^m \tilde{K}^*_{mabc} \\ &= [\Omega^{-1} \nabla_a \Omega \, D^m B_{m[b} - (\Omega \mathcal{L}_n B_{a[b} + \epsilon_{akl} D^k E^l{}_{[b]})] \nabla_{c]} \Omega \\ &\quad + \tfrac{1}{2} [\nabla_a \Omega \, D^k E_{km} - \Omega (\Omega \mathcal{L}_n E_{ma} - \epsilon_{mkl} D^k B^l{}_a)] \epsilon^m{}_{bc}. \end{aligned} \tag{26}$$

Taking the remnants of the above equation, we obtain

$$\epsilon^{lma} D_l \overset{n}{B}_m{}^b = n \overset{n}{E}{}^{ab}, \quad -\epsilon^{lma} D_l \overset{n}{E}_m{}^b = n \overset{n}{B}{}^{ab}, \tag{27}$$

for $n=0,1,2,\ldots$. Note that Eqs. (27) imply

$$D^2 \overset{n}{E}_{ab} = (-n^2+3)\overset{n}{E}_{ab}, \quad D^2 \overset{n}{B}_{ab} = (-n^2+3)\overset{n}{B}_{ab}, \tag{28}$$

for $n=0,1,2,\ldots$.

Recall that the present framework is subject to a class of restricted gauge transformations [namely, replacements of Ω by $\Omega' = \Omega(1+\omega\Omega)$], which preserve the gauge conditions $\overset{n}{\lambda} = 0$, n

$\geqslant 2$, and that each such gauge transformation is completely characterized by an $\overset{0}{\omega}\in\mathcal{T}$. For completeness, we summarize the behavior of the remnants above under such a gauge transformation:

$$\nabla_\mu \overset{n}{\phi} = n(\mathcal{L}_{D\alpha_\mu} \overset{n-1}{\phi} - n\alpha_\mu \overset{n-1}{\phi}), \tag{29}$$

$$\nabla_\mu \overset{n}{E}_a = n(\mathcal{L}_{D\alpha_\mu} \overset{n-1}{E}_a - n\alpha_\mu \overset{n-1}{E}_a + \epsilon_a{}^{kl} \overset{n-1}{B}_k D_l\alpha_\mu), \tag{30}$$

$$\nabla_\mu \overset{n}{B}_a = n(\mathcal{L}_{D\alpha_\mu} \overset{n-1}{B}_a - n\alpha_\mu \overset{n-1}{B}_a - \epsilon_a{}^{kl} \overset{n-1}{E}_k D_l\alpha_\mu), \tag{31}$$

$$\nabla_\mu \overset{n}{E}_{ab} = n(\mathcal{L}_{D\alpha_\mu} \overset{n-1}{E}_{ab} - n\alpha_\mu \overset{n-1}{E}_{ab} + 2\epsilon^{kl}{}_{(a} \overset{n-1}{B}_{b)k} D_l\alpha_\mu), \tag{32}$$

$$\nabla_\mu \overset{n}{B}_{ab} = n(\mathcal{L}_{D\alpha_\mu} \overset{n-1}{B}_{ab} - n\alpha_\mu \overset{n-1}{B}_{ab} - 2\epsilon^{kl}{}_{(a} \overset{n-1}{E}_{b)k} D_l\alpha_\mu), \tag{33}$$

for $n=0,1,2,\ldots$. Note that $\overset{0}{\phi}$, $\overset{0}{E}_a$, $\overset{0}{B}_a$, $\overset{0}{E}_{ab}$, and $\overset{0}{B}_{ab}$ are gauge invariant. As a consistency check, we note also that the ∇_μ curl of the right side of each of the above equations vanishes, by virtue of $\nabla_\mu \alpha_\nu = 0$, as it must. Of course, these gauge-transformed fields satisfy the same equations as the original fields.

B. Remnant radiation multipoles

It is perhaps most natural to seek conserved quantities that are linear in the remnants, since, e.g., this category includes all well-known conserved quantities.[22] In this section we shall find all such conserved quantities for a Klein–Gordon field, a Maxwell field, and a linearized gravitational field in Minkowski space–time $\tilde{M}$. Again, we fix the standard completion of $\tilde{M}$.

We begin with the Klein–Gordon field. Let $\tilde{\phi}$ be a Klein–Gordon field asymptotically regular of order 1, with remnants $\overset{n}{\phi}$.

Theorem 1: *(i) The conserved quantities linear in this Klein–Gordon field consist precisely of the family*

$$\mathcal{K}_{\mu_1\cdots\mu_{n-1}}[\overset{n}{\phi}] \equiv \int_C [\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}}) D^a \overset{n}{\phi} - \overset{n}{\phi} D^a \mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})] dS_a, \quad n \geqslant 1, \tag{34}$$

where $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$ denotes the symmetric, trace-free part of $\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}}$.[23]

(ii) The $\mathcal{K}_{\mu_1\cdots\mu_{n-1}}$ are totally symmetric and trace-free.

(iii) The behavior of $\mathcal{K}_{\mu_1\cdots\mu_{n-1}}$ under restricted gauge transformations is given by

$$\nabla_\mu \mathcal{K}_{\mu_1\cdots\mu_{n-1}} = \tfrac{1}{2} n(n-2)\, \eta_{(\mu_1\mu_2} \mathcal{K}_{\mu_3\cdots\mu_{n-1})\mu} - n(n-1)\, \eta_{\mu(\mu_1} \mathcal{K}_{\mu_2\cdots\mu_{n-1})}\,. \tag{35}$$

We will refer to these $\mathcal{K}$'s as the remnant radiation multipoles of a Klein–Gordon field.

To see that Eq. (34) indeed defines a conserved quantity, take the divergence of the integrand, and use that both $\overset{n}{\phi}$ and $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$ satisfy Eq. (19). To prove *(iii)*, use Eq. (29), the definition of $\mathcal{K}$, and a certain identity on $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$. See Appendix B for details. Note the right side of Eq. (35) is, up to an overall factor, the only $(n-1)$th rank, symmetric, trace-free tensor linear in $\overset{n-2}{\mathcal{K}}$. Equation (35) states that the dependence of the $\mathcal{K}$'s on position in $\mathcal{T}$ is exactly that of ordinary multipole moments. The proof that the family given by Eq. (34) exhausts the linear conserved quantities in the Klein–Gordon case is outlined in Appendix B. As an example of these remnant radiation multipoles, let $\tilde{\phi}=(f(t+r)-f(t-r))/r$. Then, provided $k_{\pm}(x)\equiv f(\pm 1/x)$, $x>0$, are both smoothly extendible to zero, this $\tilde{\phi}$ will be asymptotically regular of order 1. Then the remnants of $\tilde{\phi}$ are given by $\overset{n}{\phi}=(1+\zeta^2)^{-1/2}\{k_+^{(n)}(0)[(1+\zeta^2)^{1/2}-\zeta]^n-k_-^{(n)}(0)[(1+\zeta^2)^{1/2}+\zeta]^n\}$, where we have set $\zeta=-\Omega^{-2}(\partial\Omega/\partial t)|_{\mathcal{H}}\in\mathcal{T}$. The $\mathcal{K}$'s in this example involve various derivatives of $k_{\pm}$ at zero. Explicitly, the first two are given by $\mathcal{K}=4\pi[k_+'(0)+k_-'(0)]$, $\mathcal{K}_\mu=4\pi[k_-''(0)+k_-''(0)]\langle\alpha_\mu,\zeta\rangle$. Thus, the $\mathcal{K}$'s in this example describe radiation emanating from future and past timelike infinity.

We turn next to the Maxwell case. Let $\tilde{F}_{ab}$ be a Maxwell field asymptotically regular of order 2, with remnants $\overset{n}{E}_a$ and $\overset{n}{B}_a$.

Theorem 2: *(i) The conserved quantities linear in this Maxwell field consist precisely of the electric charge [given by Eq. (10)], the magnetic charge [obtained by replacing $\overset{0}{E}_a$ by $\overset{0}{B}_a$ in Eq. (10)], and the family*

$$\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}\equiv\mathcal{K}_{\mu_1\cdots\mu_{n-1}}[\overset{n}{E}{}^m D_m\alpha_\mu]$$
$$=\int[D^a(\overset{n}{E}{}^m D_m\alpha_\mu)\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})-\overset{n}{E}{}^m D_m\alpha_\mu D^a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})]dS_a, \quad (36)$$

for $n=1,2,3,\ldots$.

(ii) The $\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}$ are trace-free in all indices, totally symmetric in the indices $\mu_1\cdots\mu_{n-1}$, and satisfy

$$\mathcal{E}_{(\mu\mu_1\cdots\mu_{n-1})}=0. \quad (37)$$

(iii) The gauge behavior of $\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}$ is given by

$$\nabla^\mu\mathcal{E}^\nu{}_{\mu_1\cdots\mu_{n-1}}=\tfrac{1}{2}n(n-2)\,\eta_{(\mu_1\mu_2}\mathcal{E}^{\nu\mu}{}_{\mu_3\cdots\mu_{n-1})}-n(n-1)\,\delta^\mu{}_{(\mu_1}\mathcal{E}^\nu{}_{\mu_2\cdots\mu_{n-1})}$$
$$+\frac{n(n-2)}{n-1}\,\eta_{(\mu_1\mu_2}\mathcal{E}^{[\nu\mu]}{}_{\mu_3\cdots\mu_{n-1})}-2n\,\delta^{[\mu}{}_{(\mu_1}\mathcal{E}^{\nu]}{}_{\mu_2\cdots\mu_{n-1})}. \quad (38)$$

We will refer to the $\mathcal{E}$'s as the remnant radiation multipoles of a Maxwell field.

To see that Eq. (36) indeed defines a conserved quantity, take the divergence of the integrand and use that $\overset{n}{E}{}^m D_m\alpha_\mu$ (and $\overset{n}{B}{}^m D_m\alpha_\mu$) satisfy Eq. (19). To prove Eq. (37), we note that its integrand is the divergence of an antisymmetric tensor.[24] Equation (37) implies, in particular, that $\mathcal{E}_\mu$ is zero, and that $\mathcal{E}_{\mu\nu}$ is antisymmetric. While a second family of conserved quantities, $*\mathcal{E}$, associated similarly with $\overset{n}{B}_a$ could be defined, they yield nothing new, for we have[25]

$$*\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}=\frac{n-1}{n}\,\epsilon_{\mu(\mu_1}{}^{\nu\nu_1}\mathcal{E}_{|\nu\nu_1|\mu_2\cdots\mu_{n-1})}. \quad (39)$$

Note that $*\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}$ has the symmetries *(ii)* in Theorem 2 above and that $**\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}=-\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}$. The gauge behavior, Eq. (38), is proved in Appendix B. Note that Eq. (38) yields, in particular, that $\mathcal{E}_{\mu\nu}$ is gauge invariant. The proof that the quantities given by Eq. (36) exhaust the linear, Maxwell conserved quantities is outlined in Appendix B. Here is an example of these electromagnetic conserved quantities. Let $\tilde{\phi}$ be a Klein–Gordon field asymptotically regular of order 1, $\tilde{w}^{ab}$ a constant antisymmetric tensor field on $\tilde{M}$, and set $\tilde{F}_{ab}=\tilde{\boldsymbol{\nabla}}_{[a}(\tilde{w}_{b]m}\tilde{\boldsymbol{\nabla}}^m\tilde{\phi})$. Then this $\tilde{F}_{ab}$ is a solution of Maxwell's equations, asymptotically regular of order 2. Its remnants are given in terms of those of $\tilde{\phi}$ by

$$\overset{n}{E}_a=D_a D_b \overset{n-1}{\phi}\ \xi^b-(n+1)D_m\xi_a D^m \overset{n-1}{\phi}+n^2\overset{n-1}{\phi}\ \xi_a, \tag{40}$$

where we have set $\xi^a=\tilde{w}^{ab}x_b$. Then, the remnant radiation multipoles of $\tilde{F}_{ab}$ can be expressed in terms of those of $\tilde{\phi}$. For instance, we have $\mathcal{E}_{\mu\nu}=\mathcal{K}w_{\mu\nu}$, where we have set $w_{\mu\nu}\equiv 2\xi_a\alpha_{[\mu}D^a\alpha_{\nu]}+D_a\xi_b D^a\alpha_\mu D^b\alpha_\nu$.

We turn finally to linearized gravity. Let $\tilde{K}_{abcd}$ be a linearized gravitational field asymptotically regular of order 3, with remnants $\overset{n}{E}_{ab}$ and $\overset{n}{B}_{ab}$.

Theorem 3: *(i) The conserved quantities linear in this linearized gravitational field consist precisely of the mass–momentum [given by Eq. (11)], the angular momentum [given by Eq. (12)], and*

$$\begin{aligned}\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}&\equiv\mathcal{K}_{\mu_1\cdots\mu_{n-1}}[\overset{n}{E}{}^{kl}D_k\alpha_\mu D_l\alpha_\nu]\\&=\mathcal{E}_{\nu\mu_1\cdots\mu_{n-1}}[\overset{n}{E}_{ab}D^b\alpha_\mu]\\&=\int[D^a(\overset{n}{E}{}^{kl}D_k\alpha_\mu D_l\alpha_\mu)\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})\\&\quad-\overset{n}{E}{}^{kl}D_k\alpha_\mu D_l\alpha_\mu D^a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})]dS_a,\end{aligned} \tag{41}$$

for $n=1,2,3,\ldots$.

(ii) The $\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}$ are trace-free in all indices, totally symmetric in the indices $\mu_1\cdots\mu_{n-1}$, symmetric in indices μ, ν, and satisfy

$$\mathcal{G}_{\mu(\nu\mu_1\cdots\mu_{n-1})}=0. \tag{42}$$

(iii) The gauge behavior of $\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}$ is given by

$$\begin{aligned}\boldsymbol{\nabla}^\sigma\mathcal{G}^{\mu\nu}{}_{\mu_1\cdots\mu_{n-1}}&=\tfrac{1}{2}n(n-2)\,\eta_{(\mu_1\mu_2}\mathcal{G}^{\mu\nu\sigma}{}_{\mu_3\cdots\mu_{n-1})}-n(n-1)\,\delta^\sigma{}_{(\mu_1}\mathcal{G}^{\mu\nu}{}_{\mu_2\cdots\mu_{n-1})}\\&\quad+\frac{n(n-2)}{n-1}\,\eta_{(\mu_1\mu_2}(\mathcal{G}^{\mu[\nu\sigma]}{}_{\mu_3\cdots\mu_{n-1})}+\mathcal{G}^{\nu[\mu\sigma]}{}_{\mu_3\cdots\mu_{n-1})})\\&\quad-2n\,\delta^{[\sigma}{}_{(\mu_1}(\mathcal{G}^{\mu]\nu}{}_{\mu_2\cdots\mu_{n-1})}+\mathcal{G}^{\nu]\mu}{}_{\mu_2\cdots\mu_{n-1})}).\end{aligned} \tag{43}$$

We will refer to the $\mathcal{G}$'s as the remnant radiation multipoles of a linearized gravitational field.

To see that Eq. (41) indeed defines a conserved quantity, take the divergence of the integrand, and use that $\overset{n}{E}{}^{kl}D_k\alpha_\mu D_l\alpha_\nu$ (and $\overset{n}{B}{}^{kl}D_k\alpha_\mu D_l\alpha_\nu$) satisfy Eq. (19). Equation (42), which is actually equivalent to $\mathcal{E}_{(\nu\mu_1\cdots\mu_{n-1})}=0$, implies, in particular, that $\mathcal{G}_{\mu\nu}=\mathcal{G}_{\mu\nu\sigma}=0$. While a second family of conserved quantities, $*\mathcal{G}$, associated similarly with $\overset{n}{B}_{ab}$ could be defined, they yield nothing new, for we have[26]

$$*\mathcal{G}^{\mu\nu}{}_{\mu_1\cdots\mu_{n-1}}=\frac{n-1}{n}\,\epsilon^{\sigma(\mu}{}_{\lambda(\mu_1}\mathcal{G}^{\nu)\lambda}{}_{|\sigma|\mu_2\cdots\mu_{n-1})}\,. \tag{44}$$

Note that $*\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}$ also satisfies *(ii)* in Theorem 3 and that $**\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}=-\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}$. The proof that the quantities given by Eq. (41) exhaust the linear, gravitational conserved quantities is outlined in Appendix B. We omit the proof of the gauge behavior [Eq. (43)], which is similar to the Maxwell case. Examples of linearized gravitational fields, their remnants, and their remnant radiation multipoles can be constructed in a manner similar to that of the Maxwell case.[27]

One might expect, on physical grounds, that a static field would be characterized completely by its static multipole moments and that its remnant radiation multipoles would all vanish identically. This indeed turns out to be the case. See Appendix A.

IV. CURVED SPACE–TIME

It is natural to ask whether the remnant radiation multipoles constructed above for various fields in Minkowski space–time can be generalized to curved space–time. To address this issue, we first obtain the remnant equations. Let $\tilde{\phi}$ be a Klein–Gordon field asymptotically regular of order 1, so, $\phi(\equiv\Omega^{-1}\tilde{\phi})$ is smoothly extendible to $\mathcal{H}$. Then the Klein–Gordon equation on $\tilde{\phi}$ yields

$$\begin{aligned}0=\tilde{\nabla}^2\tilde{\phi}=\Omega^3[D^2\phi+\lambda^{-1}D^a\lambda\,D_a\phi+\Omega\lambda^{-2}(2\overset{1}{\phi}+\Omega\overset{2}{\phi})\\ +(\phi+\Omega\overset{1}{\phi})(-\lambda^{-2}-\Omega\lambda^{-3}\overset{1}{\lambda}+\tfrac{1}{2}\Omega\lambda^{-2}q^{ab}\overset{1}{q}_{ab})],\end{aligned} \tag{45}$$

where D_a is, as before, the derivative operator on constant-Ω surfaces induced from $\tilde{\boldsymbol{\nabla}}_a$. Evaluating (45) and its first two normal derivatives on $\mathcal{H}$, we obtain, respectively,

$$0=(D^2-1)\overset{0}{\phi}, \tag{46}$$

$$0=D^2\overset{1}{\phi}, \tag{47}$$

$$\begin{aligned}0=D^2\overset{2}{\phi}+3\overset{2}{\phi}-\overset{2}{q}{}^{ab}D_aD_b\overset{0}{\phi}-16\overset{1}{\lambda}\overset{1}{\phi}-14\overset{1}{\lambda}\,D^a\overset{1}{\lambda}\,D_a\overset{0}{\phi}\\ -2(D_aD_b\overset{1}{\lambda})D^a\overset{1}{\lambda}\,D^b\overset{0}{\phi}+32\overset{1}{\lambda}{}^2\overset{0}{\phi}+2(D\overset{1}{\lambda})^2\overset{0}{\phi}.\end{aligned} \tag{48}$$

For the nth derivative, the equation that results has the form

$$0=(D^2+n^2-1)\overset{n}{\phi}-4n^2(n-1)\overset{1}{\lambda}\,\overset{n-1}{\phi}+\cdots, \tag{49}$$

where $\cdots$ involves only remnants of ϕ of order $\leqslant n-2$.

Next, let $\tilde{F}_{ab}$ be a Maxwell field asymptotically regular of order 2. Then Maxwell's equations yield

$$0=\tilde{\boldsymbol{\nabla}}^m\tilde{F}_{ma}=-\lambda\Omega\, D^m E_m\, \boldsymbol{\nabla}_a\Omega-\lambda^{-1}\Omega^2\epsilon_a{}^{bc}[D_b(\lambda B_c)+\tfrac{1}{2}\Omega\mathcal{L}_{\lambda^2 n}(E^m\epsilon_{mbc})]. \tag{50}$$

Evaluating (50) and its first two normal derivatives on $\mathcal{H}$, we obtain, respectively,

$$D_a\overset{0}{E}{}^a=0, \quad D_a\overset{0}{B}{}^a=0, \tag{51}$$

$$D_{[a}\overset{0}{E}_{b]}=0, \quad D_{[a}\overset{0}{B}_{b]}=0, \tag{52}$$

$$D_{[a}\overset{1}{\mathcal{B}}_{b]}=-\tfrac{1}{2}\epsilon_{ab}{}^c(\overset{1}{\mathcal{E}}_c-2\overset{1}{\lambda}\overset{0}{E}_c), \tag{53}$$

$$D_{[a}\overset{1}{\mathcal{E}}_{b]}=\tfrac{1}{2}\epsilon_{ab}{}^c(\overset{1}{\mathcal{B}}_c-2\overset{1}{\lambda}\overset{0}{B}_c), \tag{54}$$

$$D_{[a}\overset{2}{\mathcal{B}}_{b]}=-\epsilon_{ab}{}^c[\overset{2}{\mathcal{E}}_c-4\overset{1}{\lambda}\overset{1}{\mathcal{E}}_c+w_{cd}\overset{0}{E}{}^d], \tag{55}$$

$$D_{[a}\overset{2}{\mathcal{E}}_{b]}=\epsilon_{ab}{}^c[\overset{2}{\mathcal{B}}_c-4\overset{1}{\lambda}\overset{1}{\mathcal{B}}_c+w_{cd}\overset{0}{B}{}^d], \tag{56}$$

where we have set $\overset{1}{\mathcal{E}}_a=\overset{1}{E}_a+\overset{1}{\lambda}\overset{0}{E}_a$, $\overset{2}{\mathcal{E}}_a=\overset{2}{E}_a+2\overset{1}{\lambda}\overset{1}{E}_a+\overset{2}{\lambda}\overset{0}{E}_a$, $\overset{1}{\mathcal{B}}_a=\overset{1}{B}_a+\overset{1}{\lambda}\overset{0}{B}_a$, $\overset{2}{\mathcal{B}}_a=\overset{2}{B}_a+2\overset{1}{\lambda}\overset{1}{B}_a+\overset{2}{\lambda}\overset{0}{B}_a$, and $w_{ab}=-\overset{2}{q}_{ab}+(\tfrac{1}{2}q^2+3\overset{1}{\lambda}{}^2-\overset{2}{\lambda})\overset{0}{q}_{ab}$. For the nth derivative, the equations that result have the form

$$D_{[a}(\overset{n}{B}_{b]}+n\overset{1}{\lambda}\overset{n-1}{B}_{b]})=-\frac{n}{2}\epsilon_{ab}{}^c(\overset{n}{E}_c-n\overset{1}{\lambda}\overset{n-1}{E}_c+\cdots), \tag{57}$$

$$D_{[a}(\overset{n}{E}_{b]}+n\overset{1}{\lambda}\overset{n-1}{E}_{b]})=\frac{n}{2}\epsilon_{ab}{}^c(\overset{n}{B}_c-n\overset{1}{\lambda}\overset{n-1}{B}_c+\cdots), \tag{58}$$

where $\cdots$ involves only remnants of E_a, B_a of order $\leqslant n-2$.

We turn finally to the gravitational field. The remnant field equations of order $\leqslant 2$ were obtained by Beig and Schmidt[8,9] in the vacuum case under the gauge conditions (6). We here drop the assumption of the vacuum and the gauge condition. See Appendix C for an outline of our derivation. The zeroth-order equations are satisfied identically. The first-order equations are

$$\overset{1}{q}_{ab}=-2\overset{1}{\lambda}\overset{0}{q}_{ab}, \tag{59}$$

$$(D^2+3)\overset{1}{\lambda}=0. \tag{60}$$

The second-order equations are

$$\overset{2}{q}=2(D\overset{1}{\lambda})^2+24\overset{1}{\lambda}{}^2-D^2\overset{2}{\lambda}-6\overset{2}{\lambda}-D^m\overset{0}{T}_m-2\overset{0}{T}, \tag{61}$$

$$D_b\overset{2}{q}_a{}^b=32\overset{1}{\lambda}\,D_a\overset{1}{\lambda}+4\,D^b\overset{1}{\lambda}\,D_a\,D_b\overset{1}{\lambda}-4\,D_a\overset{2}{\lambda}-6D_a(D^2\overset{2}{\lambda})+D_a(-D^m\overset{0}{T}_m-2\overset{0}{T})+2\overset{0}{T}_a, \tag{62}$$

$$(D^2-2)\overset{2}{q}_{ab}=8(D\overset{1}{\lambda})^2\overset{0}{q}_{ab}+20\,D_a\overset{1}{\lambda}\,D_b\overset{1}{\lambda}+28\overset{1}{\lambda}D_a\,D_b\overset{1}{\lambda}-36\overset{1}{\lambda}{}^2\overset{0}{q}_{ab}+4D_a\,D^c\overset{1}{\lambda}\,D_b\,D_c\overset{1}{\lambda}$$
$$+4D^c\overset{1}{\lambda}D_aD_b\,D_c\overset{1}{\lambda}-4D_a\,D_b\overset{2}{\lambda}+4\overset{2}{\lambda}\overset{0}{q}_{ab}-D_aD_b(D^2\overset{2}{\lambda})$$
$$-4\overset{0}{T}_{ab}+D_aD_b(-D^m\overset{0}{T}_m-2\overset{0}{T})+4D_{(a}\overset{0}{T}_{b)}\,. \tag{63}$$

The third- and fourth-order equations are not used in what follows and are collected in Appendix C, where we also rewrite the second-order equations in terms of the remnants of the Weyl tensor.

We turn now to the issue of whether or not the various conserved quantities that we defined in flat space–time can be generalized to curved space–time. Recall that a conserved quantity is given by the integral over a cut of $\mathcal{H}$ of a vector field $v^a{}_\Gamma$ on $\mathcal{H}$, where that field is expressed as an algebraic function of the preferred field α_μ of the universal background geometry of $\mathcal{H}$, the remnants of the physical field, the remnants of the geometry, and their derivatives. The divergence of this $v^a{}_\Gamma$ must, for independence of cut, vanish by virtue of the equations satisfied by α_μ and the various remnants. In the special case of flat space–time, we have (or, at least, achieved via gauge) $\overset{k}{\lambda}=0$, $\overset{k}{q}_{ab}=0$, for $k\geqslant 1$, i.e., we have effectively no "remnants of the geometry." Clearly, every conserved quantity, in general, remains a conserved quantity in the special case of flat space–time. But the converse need not hold. Given a conserved quantity in flat space–time—i.e., given a divergence-free field $v^a{}_\Gamma$ constructed from the preferred field α_μ, the remnants of the physical field, and their derivatives—then it may or may not be the case that it is the specialization to flat space–time of some conserved quantity in curved space–time. When it is, we say we have produced a *generalization* of our given flat-space conserved quantity.

Consider first the Klein–Gordon case. We have immediately from Eq. (47), the following.

Theorem 4: *The conserved quantity $\mathcal{K}$ [$n=1$ in Eq. (34)] for the Klein–Gordon field in flat space–time admits a generalization, in the sense described above, to a conserved quantity in curved space–time, namely, that given by*

$$\mathcal{K}=\int D^a\overset{1}{\phi}\,dS_a\,. \tag{64}$$

For the higher-order Klein–Gordon remnant radiation multipoles, we have the following.

Theorem 5: *Fix $n\geqslant 2$. Then the conserved quantity $\mathcal{K}_{\mu_1\cdots\mu_{n-1}}$ for the Klein–Gordon field in flat space–time, given by Eq. (34), does not admit generalization to curved space–time.*

Proof: Let, for contradiction, $v^a{}_{\mu_1\cdots\mu_{n-1}}$ be a generalization to curved space–time. By a simple scaling argument (using, respectively, linearity of the Klein–Gordon remnant field equations in the $\overset{k}{\phi}$ and homogeneity of all remnant field equations in order), we may assume that $v^a{}_{\mu_1\cdots\mu_{n-1}}$ is linear in the $\overset{k}{\phi}$, and of total order n in all remnants. Thus, $v^a{}_{\mu_1\cdots\mu_{n-1}}$ contains no $\overset{k}{\phi}$, for $k>n$, and the term involving $\overset{n}{\phi}$ is, because $v^a{}_{\mu_1\cdots\mu_{n-1}}$ must reduce to the integrand of $\mathcal{K}_{\mu_1\cdots\mu_{n-1}}$ in flat space–time, precisely $\psi_{\mu_1\cdots\mu_{n-1}}D^a\overset{n}{\phi}-\overset{n}{\phi}D^a\psi_{\mu_1\cdots\mu_{n-1}}$, where we have set $\psi_{\mu_1\cdots\mu_{n-1}}=\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$. Denote by $u^a{}_{\mu_1\cdots\mu_{n-1}}$ the term of $v^a{}_{\mu_1\cdots\mu_{n-1}}$ involving $\overset{n-1}{\phi}$. Then, the vanishing of divergence of $v^a{}_{\mu_1\cdots\mu_{n-1}}$ implies

$$D_au^a{}_{\mu_1\cdots\mu_{n-1}}\hat{=}-4n^2(n-1)\overset{1}{\lambda}\psi_{\mu_1\cdots\mu_{n-1}}\overset{n-1}{\phi}\,, \tag{65}$$

where $\hat{=}$ stands for equality modulo Klein–Gordon remnants of order $\leqslant n-2$. But there exists no such $u^a{}_{\mu_1\cdots\mu_{n-1}}$, as one sees by the following steps. First, add to $v^a{}_{\mu_1\cdots\mu_{n-1}}$ a divergence of an antisymmetric tensor field to achieve the form

$$u^a{}_{\mu_1\cdots\mu_{n-1}}=w_{\mu_1\cdots\mu_{n-1}}D^a\overset{n-1}{\phi}-\overset{n-1}{\phi}D^a w_{\mu_1\cdots\mu_{n-1}}, \tag{66}$$

with $w_{\mu_1\cdots\mu_{n-1}}$ linear in $\overset{1}{\lambda}$ and $\psi_{\mu_1\cdots\mu_{n-1}}$, and from Eqs. (65) and (49), satisfying

$$(D^2+n^2-2n)w_{\mu_1\cdots\mu_{n-1}}=4n^2(n-1)\overset{1}{\lambda}\psi_{\mu_1\cdots\mu_{n-1}}. \tag{67}$$

Second, replace every occurrence of $\overset{1}{\lambda}$ in Eq. (67) by α_μ. Then, under this substitution, $w_{\mu_1\cdots\mu_{n-1}}$ reduces to the form $w_{\mu_1\cdots\mu_{n-1}}=c\,D_a\alpha_\mu D^a\psi_{\mu_1\cdots\mu_{n-1}}+c'\alpha_\mu\psi_{\mu_1\cdots\mu_{n-1}}$, for some constants c,c'. Since α_μ satisfies Eq. (60), which is the only property of $\overset{1}{\lambda}$ that may be used in establishing (67), it follows that Eq. (67) must continue to hold after replacing $\overset{1}{\lambda}$ therein by α_μ. However, under this substitution, Eq. (67) becomes

$$2[(n+1)c+c'][D_a\alpha_\mu D^a\psi_{\mu_1\cdots\mu_{n-1}}+(n-1)\alpha_\mu\psi_{\mu_1\cdots\mu_{n-1}}]=4n^2(n-1)\alpha_\mu\psi_{\mu_1\cdots\mu_{n-1}}, \tag{68}$$

which can never hold. □

We turn next to Maxwell fields. We have the following.

Theorem 6: *Let* $\overset{0}{B}_a=0$, *and let the stress–energy tensor* T_{ab} *satisfy*

$$\overset{0}{T}_a=0,\quad \overset{0}{T}_{ab}\overset{0}{E}{}^b-\overset{0}{T}\overset{0}{E}_a=0. \tag{69}$$

Then the conserved quantity $\mathcal{E}_{\mu\nu}$ *[of Eq. (36)] for the Maxwell field in flat space–time admits a generalization to a conserved quantity in curved space–time, namely, that given by*

$$\mathcal{E}_{\mu\nu}=\int s^{ab}\alpha_{[\nu}D_{|b|}\alpha_{\mu]}\,dS_a, \tag{70}$$

where we have set

$$\begin{aligned}s_{ab}={}&2D_{(a}\overset{2}{\mathcal{E}}_{b)}-2D^c\overset{2}{\mathcal{E}}_c\overset{0}{q}_{ab}+16\overset{1}{\mathcal{E}}_{(a}D_{b)}\overset{1}{\lambda}-8\overset{1}{\mathcal{E}}{}^cD_c\overset{1}{\lambda}\overset{0}{q}_{ab}+16\psi\overset{1}{\lambda}D_aD_b\overset{1}{\lambda}+8\overset{1}{\lambda}\overset{0}{E}_{(a}D_{b)}\overset{1}{\lambda}\\&+8\overset{1}{\lambda}{}^2D_a\overset{0}{E}_b+[12\psi\overset{1}{\lambda}{}^2-20\overset{1}{\lambda}\overset{0}{E}{}^cD_c\overset{1}{\lambda}-4\psi(D\overset{1}{\lambda})^2]\overset{0}{q}_{ab}+4\psi w_{ab}+4\psi\overset{0}{T}_{ab}-4\psi\overset{0}{T}\overset{0}{q}_{ab}\\&-11(\psi D_aD_b\overset{2}{\lambda}+\overset{2}{\lambda}D_aD_b\psi-2D_{(a}\psi D_{b)}\overset{2}{\lambda})-\psi(11D^2\overset{2}{\lambda}+22\overset{2}{\lambda})\overset{0}{q}_{ab},\end{aligned} \tag{71}$$

where ψ *is so chosen to satisfy* $D_a\psi=\overset{0}{E}_a$.[28]

The integrand reduces, in flat space–time, to the integrand of $\mathcal{E}_{\mu\nu}$ therein plus a divergence, namely, $D_b(\overset{2}{E}{}^{[a}\alpha_{[\mu}D^{b]}\alpha_{\nu]})$, of an antisymmetric tensor field. The demonstration of $D_bs^{ab}=0$ is given in Appendix B. The above conditions, (69), on T_{ab} are satisfied when the space–time is vacuum, and also when the source is the Maxwell field itself. But the condition (69) need not be satisfied in the presence of other matter sources. It is readily verified that this generalized $\mathcal{E}_{\mu\nu}$ is again gauge invariant.

For higher-order Maxwell remnant radiation multipoles, we have the following theorem.

Theorem 7: *Fix* $n \geqslant 3$. *Then the conserved quantity* $\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}$ *for the Maxwell field in flat space–time, given by Eq. (36), does not admit generalization to curved space–time.*

The proof of Theorem 7 is similar to that of Theorem 5, and is therefore omitted.

V. CONCLUSION

We have constructed, for each of a Klein–Gordon field, a Maxwell field, and a linearized gravitational field in Minkowski space–time, a hierarchy of conserved quantities that we call the remnant radiation multipoles. In the cases of Klein–Gordon and Maxwell, we have generalized the remnant radiation monopoles to curved space–time. There follows a discussion of some outstanding issues.

Does the remnant gravitational monopole admit generalization to curved space–time? We conjecture that the answer is yes. In Appendix C we give the remnant field equations necessary for addressing this question. There we also display a candidate for a curved-space gravitational remnant monopole. This candidate has the attractive feature that its divergence, which could, in principle, have contained remnants of order as high as 3, contains only remnants of order $\leqslant 2$. Although the existence of this candidate lends some support to the conjecture, it is, of course, far from a proof of it. Work is in progress to settle this conjecture. We further conjecture that none of the higher-order remnant radiation multipoles for linearized gravitational fields admit generalization to curved space–time.

The way we introduced the Klein–Gordon and Maxwell remnant radiation monopoles in a curved space–time involves a quite strong falloff condition, namely, $\overset{0}{B}_{ab}=0$, on the gravitation remnants. In the Klein–Gordon case, this restriction is, in fact, unnecessary. Indeed, in the absence of this condition, the first-order remnant field equation on $\overset{1}{\phi}$ becomes $D_a v^a = 0$, with $v^a = D^a \overset{1}{\phi} - \overset{1}{q}{}^{ab} D_b \overset{0}{\phi} + \frac{1}{2} \overset{2}{q} D^a \overset{0}{\phi} + \overset{1}{\lambda} D^a \overset{0}{\phi}$. Thus, $\mathcal{K} \equiv \int_C v^a \, dS_a$ remain conserved in asymptotic conditions weaker than the ones presently imposed. Can other conserved quantities be defined with such weaker asymptotic conditions?

Do there exist conserved quantities analogous to our remnant radiation multipoles, but defined at null rather than spatial infinity? And if so, are there any simple relations between the values of corresponding quantities at spatial and null infinity? In Minkowski space–time, it should not be too difficult to answer these two questions. A relevant observation[29] is that, in the case of Minkowski space–time corresponding conserved quantities, in general, take different values at spatial and null infinity. This result suggests that ''remnant radiation'' is capable of escaping between spatial infinity and null infinity. Recall that Newman, Penrose, and Exton[30,31] have introduced certain conserved quantities at null infinity in curved space–time. Are these quantities analogs, in any sense, of the remnant radiation monopoles?

It is unfortunate that the present treatment of asymptotic quantities involves such complicated algebra. It is not entirely clear whether these complications are inherent in the subject itself, or merely a reflection of the present techniques. One case in which we know that these techniques are the culprit is that of stationary space–times. It is not hard to convince oneself that the present framework, in the case of stationary space–times, is essentially equivalent to the usual formalism involving a three-dimensional manifold of trajectories. Since the stationary gravitational multipole moments of all order can be defined within this three-dimensional formalism, it should also be possible, in principle, to define these very same moments within the present framework. However, it already seems difficult to define even the first few stationary multipoles in the present framework. Unlike the three-dimensional formalism, the present framework is not well adapted to the presence of Killing fields. For example, to treat Killing's equation order by order yields a complicated set of remnant equations. Finding a more natural way of dealing with stationary space–times within the present framework may give some clue as to how to tame its algebraic complexity. Indeed, it may further lead to a generalization of the stationary multipoles to more general asymptotically flat space–times.

Here we have restricted our consideration to conserved quantities that are linear in (the highest-order part of the remnants of) the physical fields. More generally, one might allow polynomial dependence on the remnants. A candidate for a conserved quantity quadratic in the remnants has been given by Beig:[9] $\int \epsilon^{kl(a} D_k \overset{1}{\lambda} \overset{0}{E}_l{}^{b)} \alpha_{[\mu} D_{|b|} \alpha_{\nu]} \, dS_a$, where ξ^a is any Killing field in $\mathcal{H}$. However, as shown in Ref. 9, this quantity vanishes identically by virtue of the second-order gravitational remnant equations. It would be of interest to carry out a systematic search for polynomial conserved quantities. One might even search for conserved quantities with nonpolynomial dependence on the remnant fields, but the fact that these remnant fields have complicated gauge behavior rather suggests that no such quantities will exist.

APPENDIX A: STATIONARY FIELDS IN MINKOWSKI SPACE–TIME

Consider in Minkowski space–time a physical field that is static, i.e., that is invariant under a time translation in the space–time. In this appendix, we do two things: Express within the present framework the ordinary static multipole moments of such a field; and show that, in this static case, all the remnant radiation multipoles vanish. We will only discuss linearized gravity here since the treatment of Klein–Gordon and Maxwell fields is similar and simpler.

Let $\tilde{K}_{abcd}$ be a linearized gravitational field in Minkowski space–time $\tilde{M}$, asymptotically regular of order 3. Further, let $\tilde{K}_{abcd}$ be static, i.e., let

$$\mathcal{L}_{\tilde{t}} \tilde{K}_{abcd} = 0, \tag{A1}$$

where $\tilde{t}^a$ is a (unit) timelike Killing field in $\tilde{M}$. Denote by $\zeta\ (=\Omega^{-2}\mathcal{L}_{\tilde{t}}\Omega)$ the corresponding unit time translation on $\mathcal{H}$. Taking the remnants of Eq. (A1), we obtain the following equations on the remnant fields:[32]

$$\mathcal{L}_{D\zeta} \overset{n}{E}_{ab} - (n+1)\zeta \overset{n}{E}_{ab} + 2\epsilon^{lm}{}_{(a} \overset{n}{B}_{b)l} D_m \zeta = 0, \tag{A2}$$

for $n=0,1,2,\ldots$. Set $\overset{n}{\phi}_E = \overset{n}{E}_{ab} D^a\zeta D^b\zeta$. Then this $\overset{n}{\phi}_E$ satisfies Eq. (19), and, from Eq. (A2), also

$$\mathcal{L}_{D\zeta} \overset{n}{\phi}_E - (n+1)\zeta \overset{n}{\phi}_E = 0. \tag{A3}$$

Under a gauge transformation $\overset{n}{\phi}_E$ changes according to Eq. (29). The same equations hold, similarly, on $\overset{n}{\phi}_B = \overset{n}{B}_{ab} D^a\zeta D^b\zeta$, $n=0,1,\ldots$. We note that the $\overset{n}{E}_{ab}$ and $\overset{n}{B}_{ab}$ for this static linearized gravitational field can be expressed in terms of $\overset{n}{\phi}_E$ and $\overset{n}{\phi}_B$. Indeed, we have, from Eq. (A2) and Eq. (27), that

$$\overset{n}{E}_{ab}=\frac{2\zeta^2+1}{(n+1)(n+2)}D_a D_b \overset{n}{\phi}_E+\frac{3D_{(a}\zeta D_{b)} D_m \overset{n}{\phi}_E D^m\zeta}{2(n+1)(n+2)}-\frac{D^k D^l \overset{n}{\phi}_E D_k\zeta D_l\zeta \overset{0}{q}_{ab}}{2(n+1)(n+2)}$$
$$+\frac{5\zeta D_{(a}\zeta D_{b)}\overset{n}{\phi}_E}{2(n+1)}+\frac{4n+5}{2(n+2)}\overset{n}{\phi}_E D_a\zeta D_b\zeta+\frac{(n-3)\zeta^2+2n+1}{2(n+2)}\overset{n}{\phi}_E \overset{0}{q}_{ab}$$
$$+\frac{2\zeta\epsilon^{kl}{}_{(a}D_{b)} D_k\overset{n}{\phi}_B D_l\zeta}{(n+1)(n+2)}+\frac{2\epsilon^{kl}{}_{(a}D_{b)}\zeta D_k\overset{n}{\phi}_B D_l\zeta}{n+1}, \tag{A4}$$

and similarly for $\overset{n}{B}_{ab}$.

Now consider, for $n=0,1,2,...$,

$$M_{\mu_1\cdots\mu_n}[\overset{n}{\phi}_E]\equiv\frac{(2n+1)!}{2^{n+1}(n!)^3}\int_C[\overset{n}{\phi}_E(\alpha_{\mu_1}+\langle\alpha_{\mu_1},\zeta\rangle\zeta)\cdots(\alpha_{\mu_n}+\langle\alpha_{\mu_n},\zeta\rangle\zeta)(1+\zeta^2)^{-1}D^a\zeta]dS_a. \tag{A5}$$

The integrand on the right above is divergence-free, by Eq. (A3), and so Eq. (A5) defines, for each n, a conserved quantity, $M_{\mu_1\cdots\mu_n}[\overset{n}{\phi}_E]$. These are precisely the ordinary static electric multipole moments of the linearized gravitational field.[33] They are totally symmetric, and satisfy

$$0=\zeta^{\mu_1}M_{\mu_1\mu_2\mu_3\cdots\mu_n}, \tag{A6}$$

$$0=\eta^{\mu_1\mu_2}M_{\mu_1\mu_2\mu_3\cdots\mu_n}, \tag{A7}$$

$$\boldsymbol{\nabla}_\mu M_{\mu_1\cdots\mu_n}=-(2n-1)h_{\mu(\mu_1}M_{\mu_2\cdots\mu_n)}+(n-1)h_{(\mu_1\mu_2}M_{\mu_3\cdots\mu_n)\mu}, \tag{A8}$$

where we have set $h_{\mu\nu}=\eta_{\mu\nu}+\zeta_\mu\zeta_\nu$. To prove Eq. (A7), use that $\overset{n}{\phi}_E$ satisfies Eq. (19); to prove Eq. (A8), use the gauge behavior (29) of $\overset{n}{\phi}_E$. Similarly, we obtain the magnetic multipole moments, $M_{\mu_1\cdots\mu_n}[\overset{n}{\phi}_B]$. These two sets of moments are the linearized versions of Hansen's mass and angular momentum multipole moments, respectively.

Finally, we show that all of the gravitational remnant radiation multipoles [the $\mathcal{G}$'s introduced in Eq. (41), Sec. III], vanish for a static linearized gravitational field in Minkowski space–time. To see this, substitute Eq. (A4) into the integrand of $\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}$, to obtain

$$\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}=\mathcal{K}[c_1\eta_{0\mu}\eta_{0\nu}\overset{n}{\phi}_E+c_2\eta_{\mu\nu}\overset{n}{\phi}_E+c_3\eta_{0(\mu}\mathcal{L}_{\xi^*_{\nu)}}\overset{n}{\phi}_B+c_4\mathcal{L}_{\xi^*_{(\mu}}\mathcal{L}_{\xi^*_{\nu)}}\overset{n}{\phi}_E$$
$$+c_5\eta_{0(\mu}\mathcal{L}_{\xi_{\nu)}}\overset{n}{\phi}_E+c_6\mathcal{L}_{\xi_{(\mu}}\mathcal{L}_{\xi^*_{\nu)}}\overset{n}{\phi}_B+c_7\mathcal{L}_{\xi_{(\mu}}\mathcal{L}_{\xi_{\nu)}}\overset{n}{\phi}_E]_{\mu_1\cdots\mu_{n-1}}, \tag{A9}$$

where $c_1,...,c_7$ are certain constants, and $\xi^a{}_\mu$ and $\xi^{*a}{}_\mu$ are the Killing fields given by $\xi^a{}_\mu=\zeta D^a\alpha_\mu-\alpha_\mu D^a\zeta$ and $\xi^{*a}{}_\mu=\epsilon^{abc}D_b\zeta D_c\alpha_\mu$. Let C denote the $\zeta=0$ 2-sphere section of $\mathcal{H}$. We show that each term on the right in eqn. (A9) contributes zero by evaluating the integral over C. The first four terms contribute zero by virtue of the fact that each of the terms satisfies the same equations as a static nth-order Klein–Gordon remnant field $\overset{n}{\phi}$, and that, for any such $\overset{n}{\phi}$,

$\int_C \overset{n}{\phi}\alpha_{\mu_1}\cdots\alpha_{\mu_k}D^a\zeta\, dS_a=0$, for $0\leqslant k<n$. The fifth and sixth terms contribute zero because for any $\overset{n}{\phi}$ as above, $\mathcal{L}_{\xi_\mu}\overset{n}{\phi}$ vanishes on C, and $\mathcal{L}_{D\zeta}(\mathcal{L}_{\xi_\mu}\overset{n}{\phi})$ is a sum of two terms, one of which [namely $(n+1)\zeta\mathcal{L}_{\xi_\mu}\overset{n}{\phi}$] vanishes on C and the other [namely $-(\overset{n}{\phi})_\mu\equiv -D^a\alpha_\mu D_a\overset{n}{\phi}+(n+1)\alpha_\mu\overset{n}{\phi}$] satisfies the $(n+1)$th remnant field equation and is static. Finally, the last term contributes zero because $(\mathcal{L}_{\xi_\mu}\mathcal{L}_{\xi_\nu}\overset{n}{\phi}_E)$ is a translation times a term that satisfies the $(n+1)$th remnant field equation and is static, and because $\mathcal{L}_{D\zeta}(\mathcal{L}_{\xi_\mu}\mathcal{L}_{\xi_\nu}\overset{n}{\phi}_E)$ is a sum of two terms, one of which [namely, $(n+1)\zeta\mathcal{L}_{\xi_\mu}\mathcal{L}_{\xi_\nu}\overset{n}{\phi}_E-\mathcal{L}_{\xi_{(\mu}}(\overset{n}{\phi}_E)_{\nu)}$] vanishes on C and the other (namely, $-[\mathcal{L}_{\xi_{(\mu}}\overset{n}{\phi}_E]_{\nu)}$) satisfies the $(n+1)$th remnant field equation and is equal to a static field $\overset{n+1}{\phi}$ on C. □

APPENDIX B: MISCELLANEOUS RESULTS

Appendix B 1 contains the proofs of item *(i)* of each of Theorems 1–3. Appendix B 2 contains the proofs of item *(iii)* of each of Theorems 1–2. Appendix B 3 completes the proof that the $\mathcal{E}_{\mu\nu}$ we introduced in Theorem 6 is indeed conserved.

1. The remnant radiation multipoles exhaust the conserved quantities in Minkowski space–time

We first show that, in the Klein–Gordon case, the $\mathcal{K}$'s of Eq. (34) exhaust all conserved quantities in Minkowski space–time linear in $\overset{n}{\phi}$ and multilinear in $\mathcal{T}$. Sketch of proof: Let $v^a{}_\Gamma$ be a divergence-free vector field on $\mathcal{H}$, constructed linearly in the $\overset{n}{\phi}$, and multilinearly in $\mathcal{T}$. (We introduce the subscript Γ to stand for any Greek indices that may be attached to v^a.) Since the various $\overset{n}{\phi}$ are uncoupled in (19), we may take $v^a{}_\Gamma$ to depend on just a single remnant field, say $\overset{n}{\phi}$. Then $v^a{}_\Gamma$ takes the form

$$v^a{}_\Gamma=\sum_{k=0}^{s} w^{aa_1\cdots a_k}{}_\Gamma D_{a_1}\cdots D_{a_k}\overset{n}{\phi}, \tag{B1}$$

where s is the order of the highest derivative in $v^a{}_\Gamma$. We may assume $w^{aa_1\cdots a_s}{}_\Gamma=w^{(aa_1\cdots a_s)}{}_\Gamma$, since any parts of $w^{aa_1\cdots a_s}{}_\Gamma$ antisymmetric between "a" and another index can be eliminated by adding to $v^a{}_\Gamma$ the divergence of an antisymmetric second-rank tensor field, and any parts antisymmetric between two indices neither "a" can be eliminated using the definition of the Riemann tensor. It now follows, from $D_a v^a{}_\Gamma=0$, that $w^{aa_1\cdots a_s}{}_\Gamma=q^{(aa_1}u^{a_2\cdots a_s)}{}_\Gamma$, for some tensor field $u^{a_2\cdots a_4}{}_\Gamma$. Were $s\geqslant 2$, then this term could now be eliminated in its entirety by adding to $v^a{}_\Gamma$ a divergence, namely $D_{a_2}[2(D^{[a}D_{a_3}\cdots D_{a_s}\overset{n}{\phi})u^{a_2]a_3\cdots a_4}{}_\Gamma]$, of an antisymmetric tensor. So we may assume $s=1$ in Eq. (B1), i.e., we may set $v^a=w_\Gamma D^a\overset{n}{\phi}-\overset{n}{\phi}w^a{}_\Gamma$. It now follows, again from $D_a v^a{}_\Gamma=0$, that $w^a{}_\Gamma=D^a w_\Gamma$, where w_Γ is some solution of Eq. (19). But this w_Γ must be multilinear in $\mathcal{T}$, and the only[34] such solution of Eq. (19) is $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$.[35]

We next show that, in the Maxwell case, the $\mathcal{E}$'s of Eq. (36), together with the electric and magnetic charges, exhaust all conserved quantities in Minkowski space–time linear in the remnants of the Maxwell field and multilinear in $\mathcal{T}$. Sketch of proof: Let $v^a{}_\Gamma$ be a divergence-free vector field on $\mathcal{H}$, constructed linearly in the $\overset{n}{E}_a$ and multilinearly in $\mathcal{T}$. As before, we may take $v^a{}_\Gamma$ to depend on a single remnant field, $\overset{n}{E}_a$. If $n=0$, the result, that $v^a = \overset{0}{E}{}^a$ follows by setting $\overset{0}{E}_a = D_a\psi$ with $D^2\psi=0$, and using the Klein–Gordon result. So, let $n\geqslant 1$. Then $v^a{}_\Gamma$ takes the form

$$v^a{}_\Gamma = \sum_{k=0}^{s} w^{aa_1\cdots a_{k+1}}{}_\Gamma D_{a_1}\cdots D_{a_k}\overset{n}{E}_{a_{k+1}}, \quad n\geqslant 1, \tag{B2}$$

where s is the order of the highest derivative in $v^a{}_\Gamma$. An argument similar to the Klein–Gordon case shows that $v^a{}_\Gamma$ can be brought to the form

$$v^a{}_\Gamma = w_{b\Gamma}\, D^a\overset{n}{E}{}^b - \overset{n}{E}_b\, D^a w^b{}_\Gamma + \mu_\Gamma \overset{n}{E}{}^a, \tag{B3}$$

where $(D^2+n^2-2)w_{a\Gamma} = D_a\mu_\Gamma$. We may achieve $\mu_\Gamma=0$ in (B2) by adding to $v^a{}_\Gamma$ a divergence of an antisymmetric tensor field, namely, $D_b(2\overset{n}{E}{}^{[a}\, D^{b]}w_\Gamma + 2w_\Gamma\, D^{[a}\overset{n}{E}{}^{b]} + (2/n^2)c_\Gamma\, D^{[a}\overset{n}{E}{}^{b]})$, where c_Γ is a certain constant and where we have set $w_\Gamma = (1/n^2)(-\mu_\Gamma + D_a w^a{}_\Gamma)$. Now $w^a{}_\Gamma$ satisfies precisely the same equations as $\overset{n}{E}{}^a$. The conserved quantity thus arises from the ''symplectic product'' between $\overset{n}{E}_a$ and $w_{a\Gamma}$. But this $w^a{}_\Gamma$ must be multilinear in $\mathcal{T}$, and the only such solution of Eq. (23) is $w^a{}_{\mu\mu_1\cdots\mu_{n-1}} = \mathcal{C}(\alpha_\mu\cdots\alpha_{\mu_{n-1}})D^a\alpha_\mu + (1/n^2)D^a(D^b\alpha_\mu\, D_b\mathcal{C}(\alpha_\mu\cdots\alpha_{\mu_{n-1}})) - \alpha_\mu\mathcal{C}(\alpha_\mu\cdots\alpha_{\mu_{n-1}})$.

Finally, we show that, in the case of linearized gravity, the $\mathcal{G}$'s [of Eq. (41)], together with the mass–momentum and angular momentum exhaust all conserved quantities in Minkowski space–time linear in remnants of the linearized gravitational field and multilinear in $\mathcal{T}$. Sketch of proof: Let $v^a{}_\Gamma$ be a divergence-free vector field on $\mathcal{H}$, constructed linearly in the $\overset{n}{E}_{ab}$ and multilinearly in $\mathcal{T}$. As before, we may take $v^a{}_\Gamma$ to depend on a single remnant field, $\overset{n}{E}_{ab}$. If $n=0$, the result, that $v^a{}_\mu = \overset{0}{E}{}^{ab}D_b\alpha_\mu$, follows by setting $\overset{0}{E}_{ab} = D_a\, D_b\psi + \psi \overset{0}{q}_{ab}$ with $D^2\psi = -3\psi$, and using the Klein–Gordon result. If $n=1$, the result, that $v^a{}_{\mu\nu} = \overset{1}{E}{}^{ab}\alpha_{[\mu}\, D_b\alpha_{\nu]}$, follows by setting $\overset{1}{E}_{ab} = D_{(a}u_{b)}$ with $D^2u_a = -2u_a$, $D_a u^a = 0$, and using the Maxwell result. So, let $n\geqslant 2$. Then $v^a{}_\Gamma$ takes the form

$$v^a{}_\Gamma = \sum_{k=0}^{s} w^{aa_1\cdots a_{k+2}}{}_\Gamma D_{a_1}\cdots D_{a_k}\overset{n}{E}_{a_{k+1}a_{k+2}}, \quad n\geqslant 2, \tag{B4}$$

where s is the order of the highest derivative in $v^a{}_\Gamma$. An argument similar to the Klein–Gordon case shows that $v^a{}_\Gamma$ can be brought to the form

$$v^a{}_\Gamma = w_{bc\Gamma}D^a\overset{n}{E}{}^{bc} - \overset{n}{E}_{bc}D^a w^{bc}{}_\Gamma + \overset{n}{E}{}^{ab}u_{b\Gamma}, \tag{B5}$$

where $w_{ab\Gamma}$ is symmetric and trace-free, and satisfies $(D^2+n^2-3)w_{ab\Gamma} = D_{(a}u_{b)\Gamma} - \frac{1}{3}\overset{0}{q}_{ab}D_m u^m{}_\Gamma$. We may achieve $u_{a\Gamma}=0$ in (B5) by adding to $v^a{}_\Gamma$ a divergence of an antisymmetric tensor field. The result now follows from an argument similar to the Maxwell case.

2. Gauge behavior of remnant radiation multipoles

Here we prove that the gauge behavior of the Klein–Gordon and Maxwell remnant radiation multipoles is that given, respectively, by Eqs. (35) and (38).

For the Klein–Gordon case, denote by $k^a{}_{\mu_1\cdots\mu_{n-1}}$ the integrand of Eq. (34). Then we have

$$\begin{aligned}\nabla_\mu k^a{}_{\mu_1\cdots\mu_{n-1}} &= nD^a(\mathcal{L}_{D\alpha_\mu}\overset{n-1}{\phi} - n\alpha_\mu \overset{n-1}{\phi})\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})\\ &\quad - n(\mathcal{L}_{D\alpha_\mu}\overset{n-1}{\phi} - n\alpha_\mu\overset{n-1}{\phi})D^a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}}).\\ &= \tfrac{1}{2}n(n-2)\,\eta_{(\mu_1\mu_2}k^a_{\mu_3\cdots\mu_{n-1})\mu} - n(n-1)\,\eta_{\mu(\mu_1}k^a_{\mu_2\cdots\mu_{n-1})}\\ &\quad + D_m[2n\,D^{[a}\overset{n-1}{\phi}\,D^{m]}\alpha_\mu\,\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})\\ &\quad + 2n\overset{n-1}{\phi}\,D^{[a}\alpha_\mu D^{m]}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})],\end{aligned} \tag{B6}$$

where we used, in the first step, Eqs. (34) and (29), and, in the second, the identity[36]

$$\begin{aligned}D^m\alpha_\mu D_m\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}}) &= -(n-1)\,\alpha_\mu\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}}) + (n-1)\,\eta_{\mu(\mu_1}\mathcal{C}(\alpha_{\mu_2}\cdots\alpha_{\mu_{n-1})})\\ &\quad - \frac{n-2}{2}\,\eta_{(\mu_1\mu_2}\mathcal{C}(\alpha_{\mu_3}\cdots\alpha_{\mu_{n-1})}\alpha_\mu).\end{aligned} \tag{B7}$$

Integrate over a cut of $\mathcal{H}$.

For the Maxwell case, denote by $(e^E)^a_{\nu\mu_1\cdots\mu_{n-2}}$ the integrand of Eq. (36), and set $\xi^a{}_{\mu\nu} = 2\alpha_{[\mu}D^a\alpha_{\nu]}$. Then we have

$$\begin{aligned}\nabla^\mu[(e^E)^a]^\nu{}_{\mu_1\cdots\mu_{n-1}} &= nD^a[(\mathcal{L}_{D\alpha_\mu}\overset{n-1}{E}{}_m - n\alpha_\mu\overset{n-1}{E}{}_m + \epsilon_{mkl}\overset{n-1}{B}{}^k D^l\alpha_\mu)D^m\alpha_\nu]\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})\\ &\quad - n[(\mathcal{L}_{D\alpha_\mu}\overset{n-1}{E}{}_m - n\alpha_\mu\overset{n-1}{E}{}_m + \epsilon_{mkl}\overset{n-1}{B}{}^k D^l\alpha_\mu)D^m\alpha_\nu]D^a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})\\ &= \nabla_\mu k^a_{\mu_1\cdots\mu_{n-1}}[\overset{n-1}{E}{}_m D^m\alpha_\nu] + \frac{n(n-2)}{n-1}\,\eta_{(\mu_1\mu_2}[(e^E)^a]^{[\nu\mu]}{}_{\mu_3\cdots\mu_{n-1})}\\ &\quad - 2n\,\delta^{[\mu}{}_{(\mu_1}[(e^E)^a]^{\nu]}{}_{\mu_2\cdots\mu_{n-1})} - \frac{n}{n-1}D_m[2(D^{[a}\overset{n-1}{E}{}_k D^{m]}\xi^k{}_{\mu\nu}\\ &\quad + \overset{n-1}{E}{}^{[a}\xi^{m]}{}_{\mu\nu})\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}}) + 2\overset{n-1}{E}{}^k D^{[a}\xi_{k\mu\nu}D^{m]}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})],\end{aligned} \tag{B8}$$

where we used, in the first step, Eqs. (30) and (36), and, in the second, the identity, Eq. (B7), again. Integrate over a cut of $\mathcal{H}$.

3. Completion of proof of Theorem 6

In our proof of Theorem 6, we omitted one step: The demonstration the the s_{ab} of Eq. (71) is indeed divergence-free. Here we supply that step. We have

$$D^b s_{ab} = -2\epsilon_{abc} D^b(w^{cd}\overset{0}{B}_d) + 16\overset{1}{\lambda}\epsilon_{abc} D^b\overset{1}{\lambda}\overset{0}{B}{}^c - 8\psi\overset{0}{T}_a + 4(\overset{0}{T}_{ab}\overset{0}{E}{}^b - \overset{0}{T}\overset{0}{E}_a) = 0, \tag{B9}$$

where, in the first step, we used the following six equations:

$$D^b(2D_{(a}\overset{2}{\mathcal{E}}_{b)} - 2D^c\overset{2}{\mathcal{E}}_c\overset{0}{q}_{ab}) = 16(D_{[a}\overset{1}{\mathcal{E}}_{b]})\, D^b\overset{1}{\lambda} + 24\overset{1}{\lambda}\overset{1}{\mathcal{E}}_a - 16\overset{1}{\lambda}{}^2\overset{0}{E}_a - 4w_{ab}\overset{0}{E}{}^b - 2\epsilon_{abc}D^b(w^{cd}\overset{0}{B}_d)$$
$$+16\overset{1}{\lambda}\epsilon_{abc}\, D^b\overset{1}{\lambda}\overset{0}{B}{}^c, \tag{B10}$$

$$D^b(16\overset{1}{\mathcal{E}}_{(a}\, D_{b)}\overset{1}{\lambda} - 8\overset{1}{\mathcal{E}}{}^c\, D_c\overset{1}{\lambda}\,\overset{0}{q}_{ab}) = -16(D_{[a}\overset{1}{\mathcal{E}}_{b]})D^b\overset{1}{\lambda} - 24\overset{1}{\lambda}\overset{1}{\mathcal{E}}_a + 16(\overset{0}{E}{}^c\, D_c\overset{1}{\lambda})D_\alpha\overset{1}{\lambda}, \tag{B11}$$

$$D^b(4\psi w_{ab}) = 4w_{ab}\overset{0}{E}{}^b - 8\psi\overset{1}{\lambda}\, D_a\overset{1}{\lambda} - 8\psi D_a\, D_b\overset{1}{\lambda}\, D^b\overset{1}{\lambda} + 22\psi D_a(D^2\overset{2}{\lambda})$$
$$+\psi D_a(2\, D_b T^b + 4T) - 8\psi T_a, \tag{B12}$$

$$D^b[16\psi\overset{1}{\lambda}D_a\, D_b\overset{1}{\lambda} + 8\overset{1}{\lambda}\overset{0}{E}_{(a}\, D_{b)}\overset{1}{\lambda} + 8\overset{1}{\lambda}{}^2\, D_a\overset{0}{E}_b + (12\psi\overset{1}{\lambda}{}^2 - 20\overset{1}{\lambda}\overset{0}{E}{}^c\, D_c\overset{1}{\lambda} - 4\psi(D\overset{1}{\lambda})^2)\overset{0}{q}_{ab}]$$
$$= 16\overset{1}{\lambda}\overset{0}{E}_a - 16(\overset{0}{E}{}^b D_b\overset{1}{\lambda})D_a\overset{1}{\lambda} + 8\psi\overset{1}{\lambda}\, D_a\overset{1}{\lambda} + 8\psi D_a\, D_b\overset{1}{\lambda}\, D^b\overset{1}{\lambda}, \tag{B13}$$

$$D^b[-11(\psi D_a\, D_b\overset{2}{\lambda} + \overset{2}{\lambda}D_a\, D_b\psi - 2D_{(a}\psi\, D_{b)}\overset{2}{\lambda}) + \psi(-11\, D^2\overset{2}{\lambda} + 22\overset{2}{\lambda})\overset{0}{q}_{ab}\,,] = -22\psi D_a(D^2\overset{2}{\lambda}), \tag{B14}$$

$$D^b(4\psi\overset{0}{T}_{ab} - 4\psi\overset{0}{T}\overset{0}{q}_{ab}) = 4(\overset{0}{T}_{ab}\overset{0}{E}{}^b - \overset{0}{T}\overset{0}{E}_a) + 4\psi(D^b\overset{0}{T}_{ab} - D_a\overset{0}{T}) \tag{B15}$$

(themselves consequences of the remnant field equations [(50)–(56), (60)–(63), (C12), (C13)], and, in the second step, $\overset{0}{B}_a = 0$ and Eq. (69) of the theorem.

APPENDIX C: GRAVITATIONAL REMNANT EQUATIONS

In Appendix C 1 we discuss the issue of generalizing the remnant radiation multipoles from linearized to full gravitation. In Appendix C 2, we outline the derivation of gravitational remnant field equations. In Appendix C 3 we present an alternative version of the second-order gravitational remnant field equations, involving the remnants of the Weyl tensor.

1. Generalization of gravitational remnant radiation monopole

In Sec. IV, we generalized the flat-space Klein–Gordon and Maxwell remnant radiation monopoles to curved space–time. However, we have been unable to determine whether there exists a similar generalization for linearized gravity. Here is how far we have gotten.

The remnant equations for gravitation were given, up to second order, in (60)–(63). We shall need the next two orders. The third-order remnant equations are

$$\overset{3}{q} = \overset{2}{q}{}^{ab}D_a\, D_b\overset{1}{\lambda} + 2D^a\, D^b\overset{1}{\lambda}\, D_a\overset{1}{\lambda}\, D_b\overset{1}{\lambda} + 12\overset{1}{\lambda}(D\overset{1}{\lambda})^2 - 24\overset{1}{\lambda}{}^3, \tag{C1}$$

$$D^b\overset{3}{q}_{ab} = D_a\overset{3}{q} + 2\overset{2}{q}_{ab}\, D^b\overset{1}{\lambda} + 4(D\overset{1}{\lambda})^2\, D_a\overset{1}{\lambda} + 64\overset{1}{\lambda}{}^2\, D_a\overset{1}{\lambda}, \tag{C2}$$

$$
\begin{aligned}
D^2\overset{3}{q}_{ab}={}&-\overset{3}{q}_{ab}+D_a D_b\overset{3}{q}-12\,D\overset{1}{\lambda}\cdot D\overset{2}{q}_{ab}+24\overset{1}{\lambda}\overset{2}{q}_{ab}+16D_{(a}(\overset{2}{q}_{b)m}D^m\overset{1}{\lambda})+16D_{(a}\overset{1}{\lambda}\,D_{b)}D_c\overset{1}{\lambda}\,D^c\overset{1}{\lambda}\\
&-4(D\overset{1}{\lambda})^2D_aD_b\overset{1}{\lambda}+160\overset{1}{\lambda}\,D_a\overset{1}{\lambda}\,D_b\overset{1}{\lambda}-52\overset{1}{\lambda}^2D_aD_b\overset{1}{\lambda}-[5\overset{3}{q}-12\overset{1}{\lambda}(D\overset{1}{\lambda})^2+372\overset{1}{\lambda}^3]\overset{0}{q}_{ab}.
\end{aligned}
\tag{C3}
$$

The fourth-order remnant equations are

$$
\begin{aligned}
\overset{4}{q}={}&\tfrac{2}{3}\overset{3}{q}{}^{ab}D_aD_b\overset{1}{\lambda}+\tfrac{1}{3}D\overset{1}{\lambda}\cdot D\overset{3}{q}+\tfrac{10}{3}\overset{2}{q}{}^{ab}D_a\overset{1}{\lambda}\,D_b\overset{1}{\lambda}+5\overset{1}{\lambda}\overset{2}{q}{}^{ab}D_aD_b\overset{1}{\lambda}+2\overset{2}{q}{}^{ab}\overset{2}{q}_{ab}\\
&-\tfrac{4}{3}(D\overset{1}{\lambda})^2(D\overset{1}{\lambda})^2+\tfrac{92}{3}\overset{1}{\lambda}^2(D\overset{1}{\lambda})^2+10\overset{1}{\lambda}D^aD^b\overset{1}{\lambda}\,D_a\overset{1}{\lambda}\,D_b\overset{1}{\lambda}-192\overset{1}{\lambda}^4,
\end{aligned}
\tag{C4}
$$

$$
\begin{aligned}
D^b\overset{4}{q}_{ab}={}&D_a\overset{4}{q}+4\overset{3}{q}_{ab}D^b\overset{1}{\lambda}+2\overset{3}{q}\,D_a\overset{1}{\lambda}+3D^b(\overset{2}{q}_{ac}\overset{2}{q}{}^c{}_b)-\tfrac{9}{4}D_a(\overset{2}{q}_{bc}\overset{2}{q}{}^{bc})\\
&-\tfrac{3}{2}\overset{2}{q}_{ab}D^b\overset{2}{q}-10\overset{1}{\lambda}\overset{2}{q}_{ab}D^b\overset{1}{\lambda}+76\overset{1}{\lambda}(D\overset{1}{\lambda})^2D_a\overset{1}{\lambda}+832\overset{1}{\lambda}^3D_a\overset{1}{\lambda},
\end{aligned}
\tag{C5}
$$

$$
\begin{aligned}
D^2\overset{4}{q}_{ab}={}&-6\overset{4}{q}_{ab}+2D_{(a}D^m\overset{4}{q}_{b)m}+2\overset{4}{q}\overset{0}{q}_{ab}+16\overset{1}{\lambda}D_{(a}D^m\overset{3}{q}_{b)m}+16D_{(a}\overset{3}{q}_{b)m}D^m\overset{1}{\lambda}+72\overset{1}{\lambda}\overset{3}{q}_{ab}-20\overset{1}{\lambda}\overset{3}{q}\overset{0}{q}_{ab}\\
&-8\lambda\,D^2\overset{3}{q}_{ab}-16D\overset{1}{\lambda}\cdot D\overset{3}{q}_{ab}+96\overset{1}{\lambda}^2D_{(a}D^m\overset{2}{q}_{b)m}+96\overset{1}{\lambda}^2\overset{2}{q}_{ab}-96\overset{1}{\lambda}^2\overset{2}{q}\overset{0}{q}_{ab}\\
&+120\overset{1}{\lambda}\,D_{(a}\overset{2}{q}_{b)m}D^m\overset{1}{\lambda}-48\overset{1}{\lambda}^2D^2\overset{2}{q}_{ab}-156\overset{1}{\lambda}\,D\overset{1}{\lambda}\cdot D\overset{2}{q}_{ab}+16D^cD_{(a}\overset{1}{\lambda}\overset{3}{q}_{b)c}+16\,D^c\overset{3}{q}_{c(a}D_{b)}\overset{1}{\lambda}\\
&-8\overset{3}{q}{}^{cd}D_cD_d\overset{1}{\lambda}\,\overset{0}{q}_{ab}-8\,D^c\overset{3}{q}_{cd}D^d\overset{1}{\lambda}\,\overset{0}{q}_{ab}-12\,D_c\overset{2}{q}{}^{cd}D_{(a}\overset{2}{q}_{b)d}-12\overset{2}{q}{}^{cd}D_cD_{(a}\overset{2}{q}_{b)d}\\
&+6\,D_c\overset{2}{q}{}^{cd}D_d\overset{2}{q}_{ab}+6\overset{2}{q}{}^{cd}D_cD_d\overset{2}{q}_{ab}+192\overset{1}{\lambda}\,D_{(a}\overset{1}{\lambda}\,D^c\overset{2}{q}_{b)c}+192\overset{1}{\lambda}D^cD_{(a}\overset{1}{\lambda}\overset{2}{q}_{b)c}\\
&+192\,D_{(a}\overset{1}{\lambda}\,\overset{2}{q}_{b)c}D^c\overset{1}{\lambda}-96\overset{1}{\lambda}\,D_c\overset{2}{q}{}^{cd}D_d\overset{1}{\lambda}\,\overset{0}{q}_{ab}-96\overset{1}{\lambda}\overset{2}{q}{}^{cd}D_cD_d\overset{1}{\lambda}\,\overset{0}{q}_{ab}-96\overset{2}{q}{}^{cd}D_c\overset{1}{\lambda}\,D_d\overset{1}{\lambda}\,\overset{0}{q}_{ab}\\
&+432\overset{1}{\lambda}^3D_aD_b\overset{1}{\lambda}+1440\overset{1}{\lambda}^2D_a\overset{1}{\lambda}\,D_b\overset{1}{\lambda}+1488\overset{1}{\lambda}^2(D\overset{1}{\lambda})^2\overset{0}{q}_{ab}+1296\overset{1}{\lambda}^4\overset{0}{q}_{ab}+48\overset{1}{\lambda}\,D\overset{1}{\lambda}\cdot D\overset{2}{q}\,\overset{0}{q}_{ab}\\
&-3\,D\overset{2}{q}\cdot D\overset{2}{q}_{ab}+6\,D_{(a}\overset{2}{q}_{b)c}D^c\overset{2}{q}+4\,D\overset{1}{\lambda}\cdot D\overset{3}{q}\,\overset{0}{q}_{ab}+48(D\overset{1}{\lambda})^2(D\overset{1}{\lambda})^2\overset{0}{q}_{ab}+24\overset{2}{q}_{ac}\overset{2}{q}{}^c{}_b\\
&-12\overset{2}{q}_{cd}\overset{2}{q}{}^{cd}\overset{0}{q}_{ab}-48(D\overset{1}{\lambda})^2\overset{2}{q}_{ab}-6\,D_c\overset{2}{q}_{d(a}D^d\overset{2}{q}_{b)}{}^c-3\,D_a\overset{2}{q}_{cd}D_b\overset{2}{q}{}^{cd}+6\,D_c\overset{2}{q}_{da}D^c\overset{2}{q}_b{}^d\\
&-D_cD_b\overset{4}{q}-8D_aD_b(\overset{1}{\lambda}\overset{3}{q})+3D_aD_b(\overset{2}{q}{}^{cd}\overset{2}{q}_{cd})-48D_aD_b(\overset{1}{\lambda}^2\overset{2}{q}).
\end{aligned}
\tag{C6}
$$

We begin by noting that, introducing a potential h_{ab} for the linearized gravitational field, the integrand of $\mathcal{G}_{\mu\nu\lambda\sigma}$ in flat space–time in Eq. (41) is a multiple of $D_{(a}\overset{4}{h}_{bc)}\xi^b{}_{(\mu|(\lambda}\xi^c{}_{\sigma)|\nu)}$, where we have set $\xi^a{}_{\mu\nu}=\alpha_{[\mu}D^a\alpha_{\nu]}$. Note also that $D_{(a}\overset{4}{h}_{bc)}$ is divergence-free, by virtue of the remnant field equations on $\overset{k}{h}_{ab}$. Thus, the problem of generalizing to curved space–time the $\mathcal{G}_{\mu\nu\lambda\sigma}$ of flat space–time is equivalent to that of finding a third-rank, totally symmetric, divergence-free tensor field s_{abc} on $\mathcal{H}$, constructed from the gravitational remnants, such that s_{abc} reduces, in the case of linearized gravity, to $D_{(a}\overset{4}{h}_{bc)}$. Consider, in this connection, the candidate $\hat{s}_{abc}$ given by

$$\begin{aligned}\hat{s}_{abc}=&D_{(a}\overset{4}{q}_{bc)}+(\tfrac{82}{3}+4c)\lambda_{(a}\overset{3}{q}_{bc)}-(24+4c)\overset{0}{q}_{(ab}\overset{3}{q}_{c)d}\lambda^{d}+(\tfrac{20}{3}+2c)\overset{1}{\lambda}\,D_{(a}\overset{3}{q}_{bc)}\\&-\left(\tfrac{10}{3}+c\right)\lambda^{d}{}_{(ab}\overset{3}{q}_{c)d}+\left(\tfrac{2}{3}+\tfrac{c}{2}\right)\overset{0}{q}_{(ab}\lambda_{c)de}\overset{3}{q}^{de}+\tfrac{4}{3}\lambda^{d}{}_{(a}D_{b}\overset{3}{q}_{c)d}-\left(\tfrac{10}{3}+\tfrac{c}{2}\right)\overset{0}{q}_{(ab}D_{c)}\overset{3}{q}_{de}\lambda^{de}\\&+\tfrac{8}{3}\overset{0}{q}_{(ab}D^{d}\overset{3}{q}^{e}{}_{c)}\lambda_{de}+(2+c)\lambda^{d}D_{(a}D_{b}\overset{3}{q}_{c)d}-(\tfrac{8}{3}+c)\lambda^{d}D_{d}D_{(a}\overset{3}{q}_{bc)}+c\lambda_{d(a}D^{d}\overset{3}{q}_{bc)},\end{aligned}\tag{C7}$$

where c is any constant, and where we have set $\lambda_a\equiv D_a\overset{1}{\lambda}$, $\lambda_{ab}\equiv D_a D_b\overset{1}{\lambda}+\overset{1}{\lambda}\overset{0}{q}_{ab}$, and $\lambda_{abc}\equiv D_a\lambda_{bc}$. This $\hat{s}_{abc}$ has all the required properties, except that its divergence, instead of vanishing, includes remnants of order not exceeding 2. The issue, then, is whether one can add to this $\hat{s}_{abc}$ terms of order not exceeding two to achieve vanishing divergence. In any case, the mere existence of this field $\hat{s}_{abc}$ lends support to the conjecture that $\mathcal{G}_{\mu\nu\lambda\sigma}$ admits a generalization to curved space–time. Work is in progress to settle this conjecture.

2. Derivation of gravitational remnant field equations

The Einstein equation gives rise to certain differential equations on the gravitational remnants, $\overset{k}{\lambda}_{ab}, \overset{k}{q}_{ab}$. These equations for a vacuum space–time were first systematically studied by Beig and Schmidt.[8,9] We have here utilized the nonvacuum equations, of order one (59)–(60), two (61)–(63), and vacuum equations of order three (C1)–(C3), and four (C4)–(C6). We summarize how these were derived. First write Einstein's equation in a $3+1$ form, adapted to the surfaces $\Omega=\text{const}$:

$$\Omega^2 T=-\tfrac{1}{2}[\mathcal{R}+p^{mn}p_{mn}-p^2],\tag{C8}$$

$$\Omega^2 T_a=D^m(p_{am}-pq_{am}),\tag{C9}$$

$$\Omega^2 T_{ab}=\mathcal{R}_{ab}+2p_a{}^{m}p_{mb}-pp_{ab}-\lambda^{-1}D_a D_b\lambda+\lambda^{-1}p_{ab}-\Omega\mathcal{L}_{\lambda n}p_{ab},\tag{C10}$$

where D_a denotes the derivative operator of the metric q_{ab} of these surfaces, $\mathcal{R}_{ab}$ its Ricci curvature, and p_{ab} the rescaled extrinsic curvature of these surfaces, defined by

$$p_{ab}\equiv\Omega q_a{}^{k}q_b{}^{l}\tilde{\nabla}_k(\Omega^{-2}\lambda\,\tilde{\nabla}_l\Omega)=-\lambda^{-1}q_{ab}+\tfrac{1}{2}\Omega\mathcal{L}_{\lambda n}q_{ab}.\tag{C11}$$

Taking the remnants of Eqs. (C8)–(C10) through fourth order, we obtain Eqs. (59)–(60), (60)–(63), (C1)–(C3), and (C4)–(C6).

We remark, finally, that the conservation equation of the stress–energy tensor, $\tilde{\nabla}^a\tilde{T}_{ab}=0$, yields, for the zeroth-order remnants of $\tilde{T}_{ab}$, the following equations:

$$0=D^a\overset{0}{T}_a+2\overset{0}{T}+2\overset{0}{T}{}^{m}{}_{m},\tag{C12}$$

$$0=D^b\overset{0}{T}_{ab}-D_a(\overset{0}{T}+\overset{0}{T}{}^{m}{}_{m}).\tag{C13}$$

3. Second-order equations in Weyl remnants

We first remark that, for any space–time with completion, the Weyl tensor is asymptotically regular of order 3. To see this, rewrite $2\tilde{\nabla}_{[a}\tilde{\nabla}_{b]}n_c=\tilde{R}_{abc}{}^d n_d$ as

$$E_{ab}=\Omega^{-1}(-\overset{q}{\mathcal{R}}_{ab}-p_a{}^m p_{bm}+pp_{ab})+\Omega[\tfrac{1}{2}(T_{ab}-\tfrac{1}{3}q_{ab}T^m{}_m)-\tfrac{2}{3}q_{ab}T], \tag{C14}$$

$$B_{ab}=\Omega^{-1}\epsilon_{mn(a}\overset{q}{D}{}^m p^n{}_{b)}, \tag{C15}$$

with E_{ab} and B_{ab} given by Eq. (3), p_{ab} given by Eq. (C11), and T_{ab} given by Eq. (2). But, by the conditions in Definition 1, the right sides are smooth on M.

We next remark that the gravitational remnant equations, (60)–(63), can be written in terms of the Weyl remnants, $\overset{k}{E}_{ab}, \overset{k}{B}_{ab}$. To see this, first take the zeroth-order remnants of Eqs. (C14), (C15) above, to obtain

$$\overset{0}{E}_{ab}=-(D_a D_b\overset{1}{\lambda}+\overset{1}{\lambda}\overset{0}{q}_{ab}), \tag{C16}$$

$$\overset{0}{B}_{ab}=\epsilon_{kl(a}D^k(\overset{1}{q}{}^l{}_{b)}+2\overset{1}{\lambda}\overset{0}{q}{}^l{}_{b)})=0, \tag{C17}$$

and the first-order remnants, to obtain

$$\overset{1}{E}_{ab}=-\tfrac{1}{2}\overset{2}{q}_{ab}+[(D\overset{1}{\lambda})^2+5\overset{1}{\lambda}{}^2]\overset{0}{q}_{ab}+\overset{1}{\lambda}D_a D_b\overset{1}{\lambda}-2D_a\overset{1}{\lambda}\, D_b\overset{1}{\lambda}-\tfrac{1}{2}\overset{0}{T}_{ab}-(\tfrac{2}{3}\overset{0}{T}+\tfrac{1}{6}\overset{0}{T}{}^m{}_m)\overset{0}{q}_{ab}, \tag{C18}$$

$$\overset{1}{B}_{ab}=\tfrac{1}{2}\epsilon_{mn(a}D^m\overset{2}{q}{}^n{}_{b)}. \tag{C19}$$

These Weyl remnants satisfy, by virtue of Eqs. (60)–(63), the equations

$$D_{[a}\overset{0}{E}_{b]c}=0, \tag{C20}$$

$$D_{[a}\overset{1}{\mathcal{E}}_{b]c}=\tfrac{1}{2}\epsilon_{ab}{}^m[\overset{1}{B}_{mc}+4\epsilon_{kl(m}(D^k\overset{1}{\lambda})\overset{0}{E}{}^l{}_{c)}+\tfrac{1}{2}\epsilon_{mc}{}^n\overset{0}{T}_n], \tag{C21}$$

$$D_{[a}\overset{1}{B}_{b]c}=-\tfrac{1}{2}\epsilon_{ab}{}^m[\overset{1}{\mathcal{E}}_{mc}-2\overset{0}{T}_{mc}-\overset{0}{T}\overset{0}{q}_{mc}+D_c\overset{0}{T}_m], \tag{C22}$$

where we have set

$$\overset{1}{\mathcal{E}}_{ab}=\overset{1}{E}_{ab}-\overset{1}{\lambda}\overset{0}{E}_{ab}+\tfrac{1}{2}\overset{0}{T}_{ab}+(\tfrac{1}{6}\overset{0}{T}{}^m{}_m-\tfrac{2}{3}\overset{0}{T})\overset{0}{q}_{ab}. \tag{C23}$$

Now fix a space–time with completion, and define $\overset{0}{E}_{ab}$, $\overset{1}{E}_{ab}$, and $\overset{1}{B}_{ab}$ by Eqs. (C16)–(C19). Then Eqs. (60)–(63) are equivalent to the statements that the $\overset{0}{E}_{ab}$, $\overset{1}{E}_{ab}$, $\overset{1}{B}_{ab}$, so defined are trace-free and satisfy (C20)–(C22).

[12] Sketch of proof: Let $(\tilde{M},\tilde{g}_{ab})$ be a stationary asymptotically flat vacuum space–time with Killing field ξ^a. Denote by μ and ω the norm and twist of the Killing field, respectively. Let $(\tilde{V},\tilde{h}_{ab})$ denote the (Riemannian) manifold of orbits of the Killing field, (V,Λ) its completion, Ω_G a conformal factor, and $h_{ab}=\Omega_G^2\tilde{h}_{ab}$ (see Ref. 3). It follows[37] that each of $\Omega_G^{-1/2}\mu^{1/4}(\mu-\mu^{-1}+\mu^{-1}\omega^2)$, $\Omega_G^{-1/2}\mu^{1/4}(\mu^{-1}\omega)$, and $\mu+\mu^{-1}+\mu^{-1}\omega^2$ is smooth on V. Fix any smooth coordinates x^i on V near Λ such that $h_{ij}|_\Lambda=\delta_{ij}$, and Lie drag them into $\tilde{M}$ by ξ^a. Perform an inversion on these coordinates to obtain $\tilde{x}^i$ on $\tilde{M}$. Pick a τ'_a on V satisfying $D_{[a}\tau'_{b]}=-\frac{1}{2}\mu^{-3/2}\epsilon_{abc}D^c\omega$ and such that τ'_a is smooth in y' and vanishes at Λ (See, e.g., the appendix of Ref. 37 for motivation). Let τ_a be the pull-back of τ'_a to $\tilde{M}$. Define $\tilde{x}^0$ on $\tilde{M}$ such that $\boldsymbol{\nabla}_a\tilde{x}^0=\mu^{-1}\xi_a-\tau_a$ (note the right side is curl-free and yields 1 when contracted with $\tilde{\xi}^a$). Then the hyperbolic coordinates associated with the $\tilde{x}^\mu$ coordinates yield a completion of $\tilde{M}$ in the sense above.
[13] Such freedom in choices of (inequivalent) completion are known to exist also for other frameworks such as that of Geroch and that of Ashtekar-Hansen.
[14] P. G. Bergmann, Phys. Rev. **124**, 274 (1961).
[15] P. T. Chrusciel, J. Math. Phys. **30**, 2094 (1989).
[16] More generally, for a spin-s field, we would demand asymptotic regularity of order $s+1$.
[17] In essence, one may view α_μ as a choice of an orthonormal basis of $\mathcal{T}$, and $v=v^\mu\alpha_\mu$ as the expansion of an element $v\in\mathcal{T}$ in the basis α_μ with constant coefficients v^μ. Our presentation serves the same purpose without committing ourselves to a particular choice of basis. Thus, the α_μ might be better viewed as an ''abstract orthonormal basis.''
[18] To see this, evaluate $D_{[a}D_{b]}(\eta^{\mu\nu}D_c\alpha_\mu D_d\alpha_\nu)$ using Eq. (8) and equate the result to $2R_{ab(c}{}^m(\eta^{\mu\nu}D_{d)}\alpha_\mu D_m\alpha_\nu)$, to obtain $\eta^{\mu\nu}D_a\alpha_\mu D_b\alpha_\nu=\eta^{\mu\nu}\alpha_\mu\alpha_\nu \overset{0}{q}_{ab}$. Now contract with $\overset{0}{q}{}^{ab}$ using Eq. (9).
[19] One might be tempted to consider, in addition, those divergence-free vector fields that are multilinear in the Killing fields on $\mathcal{H}$. However, this adds nothing new, since every antisymmetric second rank tensor $F^{\mu\nu}$ in $\mathcal{T}$ yields a Killing field in $\mathcal{H}$ when contracted with $\alpha_{[\mu}D^a\alpha_{\nu]}$ and, conversely, for every Killing field ξ^a in $\mathcal{H}$, there exists an antisymmetric second rank tensor over $\mathcal{T}$ (namely, $F_{\mu\nu}\equiv 2\xi_a\alpha_{[\mu}D^a\alpha_{\nu]}+D_a\xi_b D^a\alpha_\mu D^b\alpha_\nu$) that gives rise to it. Similarly, multilinearity in conformal Killing fields yields nothing new, for every vector v^μ in $\mathcal{T}$ yields a curl-free conformal Killing field in $\mathcal{H}$ when contracted with $D^a\alpha_\mu$ and conversely, for every curl-free conformal Killing field ζ^a in $\mathcal{H}$, there exists a vector over $\mathcal{T}$ [namely, $v^\mu=\zeta^a D_a\alpha^\mu-\frac{1}{3}(D_a\zeta^a)\alpha^\mu$] that gives rise to it.
[20] In Ref. 11, Ashtekar and Romano used instead the condition $\lim_{\Omega\to 0}\Omega^{-1}\tilde{G}_{ab}=0$ to show that the angular momentum is conserved. As we have noted earlier, their condition is too strong. The condition we are imposing is the necessary and sufficient condition for $\overset{1}{B}_{ab}$ to be divergence-free on $\mathcal{H}$ [cf. Eq. (C22)]. An example of a space–time satisfying our additional condition is the Kerr–Newman solution. In fact, the Kerr–Newman solution satisfies a stronger condition: $\overset{0}{T}_a=0$. In general, it is not clear how restrictive is the condition given by Eq. (13). However, the condition is presumably satisfied for all stationary asymptotically flat space–times since in that case one expects the angular momentum is well defined and equal to Hansen's angular-momentum dipole moment.[38]
[21] To see this, note that $\mathcal{M}'_{\mu\nu}-\mathcal{M}_{\mu\nu}=-(1/16\pi)\epsilon_{\mu\nu}{}^{\tau\sigma}\int_C\{(-2\epsilon^{mn(a}\overset{0}{E}{}^{b)}{}_m D_n\overset{0}{\omega})\alpha_\tau D_b\alpha_\sigma\}dS_a=-(1/8\pi)\overset{0}{\omega}_{[\mu}\int_C\overset{0}{E}{}^{ab}D_{|b|}\alpha_{\nu]}\,dS_a=-\overset{0}{\omega}_{[\mu}\mathcal{P}_{\nu]}$.
[22] The linearity is clear for electric charge. For total energy–momentum and angular momentum, we have in mind the linearized gravity in Minkowski space–time in which these quantities are linear in the gravitational field and are expressible as surface integrals.[39]
[23] That is, $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})\equiv\Sigma_{m=0}^{[n/2]}(-1/4)^m\binom{n-m-1}{m}\eta_{(\mu_1\mu_2}\cdots\eta_{\mu_{2m-1}\mu_{2m}}\alpha_{\mu_{2m+1}}\cdots\alpha_{\mu_{n-1})}$, with $[n/2]$ denoting the largest integer not exceeding $n/2$.
[24] Indeed, we have $D^a(\overset{n}{E}{}^m D_m\alpha_{(\mu})\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1})})-\overset{n}{E}{}^m D_m\alpha_{(\mu}D^a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1})})=D_b\{2\overset{n}{E}{}^{[a}D^{b]}\alpha_{(\mu}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1})})+\epsilon^{abc}\overset{n}{B}_c[\alpha_{(\mu}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1})})-(1/2)\eta_{(\mu\mu_1}\mathcal{C}(\alpha_{\mu_2}\cdots\alpha_{\mu_{n-1})})]\}$, which can be seen by using Eq. (B7) and the identity $\alpha_{(\mu}D^a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1})})=(n-1)\mathcal{C}(\alpha_{(\mu_1}\cdots\alpha_{\mu_{n-1}})D^a\alpha_{\mu)}+(1/2)\eta_{(\mu\mu_1}D^a\mathcal{C}(\alpha_{\mu_2}\cdots\alpha_{\mu_{n-1})})$.
[25] To see this, note that the difference between the integrands of $*\mathcal{E}_{\mu\mu_1\cdots\mu_{n-1}}$ and that of the right of Eq. (39) is given by $D_k\{(2/n)D_m\alpha_\mu\,\epsilon^{lm[a}[(D^{k]}\overset{n}{E}_l)\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})-\overset{n}{E}_l D^{k]}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})]\}$. Integrate over a cut of $\mathcal{H}$.

[26]To see this, note that the difference between the integrands of $*\mathcal{G}_{\mu\nu\mu_1\cdots\mu_{n-1}}$ and the right side of Eq. (44) is given by $D_k\{(1/n)\epsilon^{akl}\overset{n}{E}_{lm}\alpha_{(\mu}D^m\alpha_{\nu)}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})+(2/n)D_m\alpha_{(\mu}D^s\alpha_{\nu)}\epsilon^{lm[a}[(D^{k]}\overset{n}{E}_{ls})\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})-\overset{n}{E}_{ls}D^{k]}\mathcal{C}$ $\times(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})]\}$. Integrate over a cut of $\mathcal{H}$.

[27]Indeed, we have the following. Let $\overset{n-2}{\phi}$ satisfy the $n-2$th remnant equation for a Klein–Gordon field, ξ^a any Killing field. Denote by $\overset{n-2}{\psi}_{a_1\cdots a_s}$ the symmetric and trace-free part of $D_{a_1}\cdots D_{a_s}\overset{n-2}{\phi}$. Then $\overset{n}{E}_{ab}\equiv\overset{n-2}{\psi}_{abcd}\xi^c\xi^{*d}+\frac{12}{7}(n+1)$ $\times(n+2)[\xi^{*m}\overset{n-2}{\psi}_{m(a}\xi_{b)}+\xi^m\overset{n-2}{\psi}_{m(a}\xi^*_{b)}-\frac{2}{3}\overset{0}{q}_{ab}\overset{n-2}{\psi}_{cd}\xi^c\xi^{*d}]-\frac{4}{5}n(n+1)(n+2)\overset{n-2}{\psi}{}^m D_m(\xi_{(a}\xi^*_{b)})+\frac{4}{5}n(n-1)(n+1)(n+2)$ $\times\overset{n-2}{\psi}\xi_{(a}\xi^*_{b)}+(n+2)\overset{n-2}{\psi}_{cd(a}D_{b)}(\xi^{(c}\xi^{*d)})$, satisfies the nth remnant equations for a linearized gravitational field.

[28]Adding to ψ a constant changes the integrand of $\mathcal{E}_{\mu\nu}$ in Eq. (70) by a divergence of an antisymmetric tensor.

[29]Let $\tilde{\phi}$ be a Klein–Gordon field in Minkowski space–time asymptotically regular of order 1. Consider $I=\int_{S_\infty}$ $-\tilde{\epsilon}_{abcd}x^c\tilde{\nabla}^d[(x^e\tilde{\nabla}_e+1)\tilde{\phi}]$, where S_∞ denotes a two-sphere at infinity, and x^a a position vector field. When S_∞ is any two-sphere cut at spatial infinity, the above integral reproduces the remnant radiation monopole $\mathcal{K}$ associated with $\tilde{\phi}$. However, in general, the integral evaluates to a different value when the two-sphere S_∞ is at null infinity. For example, let $\tilde{\phi}=(f(t+r)-f(t-r))/r$, with $k_\pm(x)\equiv f(\pm 1/x)$, $x>0$, both smoothly extendible to zero. Then, when S_∞ is at spatial infinity, we have $I=\mathcal{K}=4\pi[k'_+(0)+k'_-(0)]$, while for S_∞ any cut at future null infinity, $I=4\pi k'_+(0)$, and for S_∞ any cut at past null infinity, $I=4\pi k'_-(0)$.

[31]A. R. Exton, E. T. Newman, and R. Penrose, J. Math. Phys. **10**, 1566 (1969).

[32]The analogous equation for $\overset{n}{B}_{ab}$,

$$\mathcal{L}_{D\zeta}\overset{n}{B}_{ab}-(n+1)\zeta\overset{n}{B}_{ab}-2\epsilon^{lm}{}_{(a}\overset{n}{E}_{b)}D_m\zeta=0,$$

follows from Eq. (A2) and the remnant field equations. For a Maxwell field the corresponding equation is $\mathcal{L}_{D\zeta}\overset{n}{E}_a-(n+1)\zeta\overset{n}{E}_a+\epsilon_a{}^{kl}\overset{n}{B}_k D_l\zeta=0$, and for a Klein–Gordon field, Eq. (A3).

[33]We remark that the multipole moment M defined here is related to the Q defined by Geroch in Ref. 40 by a normalization factor: $Q_{i_1\cdots i_n}=(-\frac{1}{3})^n n!M_{i_1\cdots i_n}$.

[34]We are concerned only with ''irreducible'' solutions. Thus, for example, $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$ and $\eta_{\mu\nu}\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$ are viewed as equivalent solutions to Eq. (19).

[35]To see this, embed $\mathcal{H}$ as the unit hyperboloid in Minkowski space–time M'. Let x^a denote the position vector field from some origin. Then $\nabla_a x^b=\delta_a{}^b$ and $\mathcal{H}$ is specified by $x^a x_a=1$. Let k^a be a constant vector field in M'. Then $k^a x_a$ is a translation on $\mathcal{H}$. Thus, the most general function multilinear in translations is a sum of terms of the form $w(s)$ $\equiv w^{a_1\cdots a_s}x_{a_1}\cdots x_{a_s}$, with $w_{a_1\cdots a_s}$ some symmetric, trace-free constant tensor. This $w(s)$ satisfies the Klein–Gordon equation in M'. Using $\nabla^2 w=[D^2+(x\cdot x)^{-1}((x\cdot\nabla)^2+2x\cdot\nabla)]w$, we see that $w(n-1)$ satisfies Eq. (19) on $\mathcal{H}$. Such $w(n-1)$'s clearly exhaust all solutions of Eq. (19), which are multilinear in translations. But each such $w(n-1)$'s on $\mathcal{H}$ is the contraction of $\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$ with some tensor over $\mathcal{T}$.

[36]One way to prove the identity is to note the following: $D^a\alpha_\mu D_a\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})+(n-1)\alpha_\mu\mathcal{C}(\alpha_{\mu_1}\cdots\alpha_{\mu_{n-1}})$ satisfies Eq. (19) with n replaced by $n-1$ and is trace-free in $\mu_1\cdots\mu_{n-1}$. The overall normalization factor can be fixed by comparing, say, the coefficients of the term $\eta_{(\mu\mu_1}\mathcal{C}(\alpha_{\mu_2}\cdots\alpha_{\mu_{n-1})})$ on both sides.

Group invariant solutions for the $N=2$ super Korteweg–de Vries equation

M. A. Ayari,[a] V. Hussin,[b] and P. Winternitz[c]
Centre de Recherches Mathématiques, Université de Montréal, C.P. 6128, Succ. Centre-ville, Montreal, Quebec H3C 3J7, Canada

(Received 3 August 1998; accepted for publication 9 November 1998)

The method of symmetry reduction is used to solve Grassmann-valued differential equations. The $(N=2)$ supersymmetric Korteweg–de Vries equation is considered. It admits a Lie superalgebra of symmetries of dimension 5. A two-dimensional subsuperalgebra is chosen to reduce the number of independent variables in this equation. We are then able to give different types of exact solutions, in particular soliton solutions.
[S0022-2488(99)02903-5]

I. INTRODUCTION

The study of integrability and conservation laws for systems of Grassmann-valued differential equations (SGVDEs) has known a wide expansion in the area of supersymmetry.[1–13] Many of these equations have been constructed[2–6] in order to combine bosonic and fermionic degrees of freedom in such a way that these equations are invariant under supersymmetry transformations. This means that in these cases, there exists a symmetry relating bosonic and fermionic fields.

Many authors have proven integrability by finding Lax pairs and conservation laws. For example, Yung[12] has studied the supersymmetric Boussinesq hierarchies and his results were confirmed later by Bellucci *et al.*[13] Mathieu[3,4] has investigated the supersymmetric (SUSY) Korteweg–de Vries (KdV) equation for $N=1,2$ odd independent variables and has found that integrability occurs for special values of a parameter figuring in the superequations.

These SUSY KdV equations are the starting point of our approach and more particularly the case[4] $N=2$. These equations contain both the KdV and modified KdV equations in the limit where odd Grassmann dependent variables are set equal to zero. Moreover, the supersymmetry group is richer in the $N=2$ case than for $N=1$ and it contains significant subgroups.[14] We will use the technique of symmetry reduction adapted to the super case to give some solutions of this $(N=2)$ SUSY KdV equation. This technique does not depend on the integrability of the equation and consists of a systematic application of group theory to reduce the SGVDE to a system of ordinary differential equations (ODEs).

The problem of computing solutions for SGVDEs has recently received a large amount of attention.[15–19] In these approaches, the SGVDEs are decomposed and give rise to systems of classical partial differential equations (PDEs) which can be solved. Our approach is based on symmetries and supersymmetries and does not require that we start with such a decomposition.

The Lie-point symmetries of a SGVDE have been obtained using an extension to Grassmann variables of the procedure described, e.g., by Olver.[20] The $N=2$ SUSY KdV admits a symmetry superalgebra with three even and two odd generators.[14] The equation, its invariance superalgebra, and the corresponding group will be given in Sec. II. The technique of symmetry reduction allows us to consider solutions which are invariant under subsuperalgebras with at least one supersymmetric (or odd) generator. In Sec. III, a subsuperalgebra of dimension 2 will be used to derive the

[a]Electronic mail: ayaria@dms.umontreal.ca
[b]Electronic mail: hussin@dms.umontreal.ca
[c]Electronic mail: wintern@crm.umontreal.ca

reduced equations and the solutions of the bosonic and fermionic part of the superfield. Some conclusions are drawn in Sec. IV.

II. THE SUPERSYMMETRY GROUPS OF THE $N=2$ SUSY KdV EQUATION

Let us recall that a SGVDE is a system of s partial differential equations of order $k=(k_1;k_2)$ of the form

$$\Delta_\nu(\mathbf{X},\Theta;\mathbf{A}^{(k_1)},\mathbf{\Gamma}^{(k_2)})=0, \quad \nu=1,...,s \tag{2.1}$$

with m independent even variables $\mathbf{X}=\{x_1,\ldots,x_m\}$, n independent odd variables $\mathbf{\Theta}=\{\theta_1,\ldots,\theta_n\}$, q dependent even variables $\mathbf{A}=\{A^1,A^2,\ldots,A^q\}$, and p dependent odd variables $\mathbf{\Gamma}=\{\Gamma^1,\Gamma^2,\ldots,\Gamma^p\}$. Note that odd variables η_i must satisfy

$$\eta_i\eta_j=-\eta_j\eta_i, \quad \eta_i^2=0, \quad 1\leqslant i,j\leqslant r.$$

The equation we are interested in is precisely of this type. It takes the form:[4]

$$A_t=-A_{xxx}+3(AD_1D_2A)_x+\frac{(a-1)}{2}(D_1D_2A^2)_x+3aA^2A_x, \tag{2.2}$$

where D_1,D_2 are the covariant superderivatives

$$D_i=\theta_i\partial_x+\partial_{\theta_i}, \quad i=1,2. \tag{2.3}$$

Equation (2.2) thus represents a one-parameter ($a\in\mathbb{R}$) family of Grassmann-valued partial differential equations having four (two even and two odd) independent variables $(x,t;\theta_1,\theta_2)$ and one dependent variable A which is supposed to be a bosonic (or even) superfield. It has been constructed by Mathieu *et al.*[4] as a nontrivial SUSY equation which contains both the KdV and the modified KdV as nonSUSY limits.

A more suitable form of Eq. (2.2) is given using partial derivatives, i.e.,

$$\begin{aligned}
&A_t+A_{xxx}-3a\,\theta_1\theta_2A_xA_{xx}-(a+2)\,\theta_1AA_{xx\theta_2}-(a+2)\{\theta_1\theta_2AA_{xxx}-\theta_2AA_{xx\theta_1}\}\\
&\quad+(2a+1)\,\theta_2A_xA_{x\theta_1}+(a+2)\{A_xA_{\theta_1\theta_2}+AA_{x\theta_1\theta_2}\}-(2a+1)\,\theta_1A_xA_{x\theta_2}\\
&\quad-(a-1)\{\theta_1A_{\theta_2}A_{xx}-\theta_2A_{\theta_1}A_{xx}+A_{\theta_1}A_{x\theta_2}-A_{\theta_2}A_{x\theta_1}\}-3aA^2A_x=0.
\end{aligned} \tag{2.4}$$

Since the superfield A is bosonic, it can be decomposed into

$$A(x,t;\theta_1,\theta_2)=u(x,t)+\theta_1\rho^1(x,t)+\theta_2\rho^2(x,t)+\theta_1\theta_2v(x,t), \tag{2.5}$$

where u and v are even functions of (x,t) while ρ^1 and ρ^2 are odd functions of the same independent even variables. It is then easy to see that the superequation (2.4) reduces to the following system of two bosonic and two fermionic equations:

$$\begin{gathered}
u_t+u_{xxx}-3au^2u_x+(a+2)(uv)_x-(a-1)(\rho^1\rho^2)_x=0,\\
v_t+v_{xxx}+6vv_x-3au_xu_{xx}-(a+2)uu_{xxx}-3\rho^2\rho^2_{xx}-(a+2)\rho^1\rho^1_{xx}\\
-3a(u^2v_x+2uu_xv-2u\rho^1\rho^2_x+2u\rho^2\rho^1_x-2u_x\rho^1\rho^2)=0,
\end{gathered} \tag{2.6}$$

and

TABLE I. The supercommutator table of the SUSY KdV equation ($N=2$).

	$\mathcal{P}_1$	$\mathcal{P}_0$	$\mathcal{D}$	$\mathcal{Q}_1$	$\mathcal{Q}_2$
$\mathcal{P}_1$	0	0	$\mathcal{P}_1$	0	0
$\mathcal{P}_0$	0	0	$3\mathcal{P}_0$	0	0
$\mathcal{D}$	$-\mathcal{P}_1$	$-3\mathcal{P}_0$	0	$(-1/2)\mathcal{Q}_1$	$(-1/2)\mathcal{Q}_2$
$\mathcal{Q}_1$	0	0	$(1/2)\mathcal{Q}_1$	$-2\mathcal{P}_1$	0
$\mathcal{Q}_2$	0	0	$(1/2)\mathcal{Q}_2$	0	$-2\mathcal{P}_1$

$$\begin{aligned}
&\rho_t^1+\rho_{xxx}^1+(a+2)(\rho^1 v)_x-(a-1)(\rho^1 v)_x-(a+2)u\rho_{xx}^2-(2a+1)u_x\rho_x^2\\
&\quad-(a-1)\rho^2 u_{xx}-3a(u^2\rho_x^1+2uu_x\rho^1)=0,\\
&\rho_t^2+\rho_{xxx}^2+(a+2)(\rho^2 v)_x+(a+2)u\rho_{xx}^1+(2a+1)u_x\rho_x^1+(a-1)\rho^1 u_{xx}\\
&\quad-(a-1)(\rho^2 v)_x-3a(u^2\rho_x^2+2uu_x\rho^2)=0.
\end{aligned}\tag{2.7}$$

We see that the first bosonic equation reduces to the mKdV equation when $v=0$ and $\rho^1=\rho^2=0$. The second one reduces to the KdV equation when $u=0$ and $\rho^1=\rho^2=0$. So we expect to find, for example, supersolitonic solutions for the complete supersymmetric system. Concerning the fermionic equations, they form a system of coupled linear equations in ρ^1 and ρ^2 once u and v are known. We will see later that the method of symmetry reduction will decouple these equations and will help in its resolution.

The Lie superalgebra of symmetries for Eq. (2.4) has been computed making use of a MAPLE program GLIE.[21] It is a $(3|2)$-dimensional superalgebra with basis

$$\begin{gathered}
\mathcal{P}_1=\partial_x,\quad \mathcal{P}_0=\partial_t,\\
\mathcal{D}=x\partial_x+3t\partial_t+\tfrac{1}{2}\theta_1\partial_{\theta_1}+\tfrac{1}{2}\theta_2\partial_{\theta_2}-A\partial_A,\\
\mathcal{Q}_1=\theta_1\partial_x-\partial_{\theta_1},\quad \mathcal{Q}_2=\theta_2\partial_x-\partial_{\theta_2},
\end{gathered}\tag{2.8}$$

where $\mathcal{P}_0,\mathcal{P}_1,\mathcal{D}$ are the three even generators and $\mathcal{Q}_1$ and $\mathcal{Q}_2$ are the two odd ones. This result is true independent of the value of the parameter a entering in the superequation. The supercommutator table of the Lie superalgebra is given in Table I, where, as usual, commutation relations are satisfied for even–even and even–odd products while anticommutation relations are satisfied for odd–odd products.

As usual in super Lie group theory, starting with a Lie superalgebra, we obtain the corresponding Lie group by exponentiation. The group G of Lie-point symmetries for Eq. (2.4) is generated by the elements $g=(x_0,t_0,d;\eta_1,\eta_2)$ where x_0,t_0,d are even Grassmann numbers and η_1,η_2 odd ones. They satisfy the composition law

$$g\equiv(x_0,t_0,d;\eta_1,\eta_2)=(x_0^2,t_0^2,d_2;\eta_1^2,\eta_2^2)(x_0^1,t_0^1,d_1;\eta_1^1,\eta_2^1)=g_2g_1\tag{2.9}$$

with

$$\begin{gathered}
d=d_2+d_1,\quad t_0=t_0^2+e^{3d_2}t_0^1,\\
x_0=x_0^2+e^{d_2}x_0^1+\exp\left[\left(d_2+\frac{d_1}{2}\right)\right](\eta_1^2\eta_1^1+\eta_2^2\eta_2^1),\\
\eta_1=\eta_1^1+e^{-d_1/2}\eta_1^2,\quad \eta_2=\eta_2^1+e^{-d_1/2}\eta_2^2.
\end{gathered}\tag{2.10}$$

The identity element is $e=(0,0,0;0,0)$ and the inverse g^{-1} of g is

$$g^{-1}=(-e^{-3d}t_0,-e^{-d}x_0,-d;-e^{-d/2}\eta_1,-e^{-d/2}\eta_2). \tag{2.11}$$

This group acts on the superspace $(x,t;\theta_1,\theta_2)$ and on the superfield A as

$$g(x,t;\theta_1,\theta_2)=(e^d(x+\eta_1\theta_1+\eta_2\theta_2)-x_0,e^{3d}t-t_0;e^{d/2}(\theta_1-\eta_1),e^{d/2}(\theta_2-\eta_2)) \tag{2.12}$$

and

$$gA(x,t;\theta_1,\theta_2)=e^{-d}A(g^{-1}(x,t;\theta_1,\theta_2)). \tag{2.13}$$

The even parameters x_0 and t_0 correspond to space and time translations, respectively, while d corresponds to a dilatation. The two odd parameters η_1 and η_2 correspond to supersymmetric transformations mixing even and odd variables.

III. INVARIANT SOLUTIONS

Different subgroups may be chosen to get invariant solutions of the SUSY KdV equation (2.4). The more interesting ones contain at least one SUSY transformation. In fact, since both $\mathcal{Q}_1$ and $\mathcal{Q}_2$ are like square roots of the translation generator $\mathcal{P}_1$, they come together in a subgroup structure and lead to invariant solutions constant in the variable x. We are not interested in such trivial solutions. Nevertheless, a combination like $\mathcal{Q}_+=\mathcal{Q}_1+i\mathcal{Q}_2$ is allowed giving $(\mathcal{Q}_+)^2=0$. The subgroup $G_1=\{g_0=(cb,b,0;\eta,i\eta)\}$ will be considered since it has the superalgebra $\mathcal{G}_1=\{\mathcal{P}_0-c\mathcal{P}_1,\mathcal{Q}_+\}$ and will give rise to traveling-wave solutions of Eq. (2.4). In order to perform the symmetry reduction using such a subgroup of the symmetry group G, we have first to find the invariants of the action of this subgroup on the independent and dependent variables and then rewrite the equations in terms of them. This will reduce the number of independent variables and we will get superequations with one even and one odd variables.

A. The reduced superequations

From Eqs. (2.12) and (2.13), we see that the subgroup G_1 acts on the independent and dependent variables as follows:

$$g_0(x,t;\theta_1,\theta_2)=(x+\eta(\theta_1+i\theta_2)-cb,t-b;\theta_1-\eta,\theta_2-i\eta),$$

$$g_0A(x,t;\theta_1,\theta_2)=A(g_0^{-1}(x,t;\theta_1,\theta_2)).$$

It is then easy to compute the invariants of this action. They are

$$y=x+ct+i\theta_1\theta_2,\quad \theta=\theta_1+i\theta_2. \tag{3.1}$$

Now, if we take $A=A(y,\theta)$, we get, from Eq. (2.4) and the fact that $D_1=\partial_\theta+\theta\partial_y$, $D_2=i(\partial_\theta-\theta\partial_y)$, the reduced superequation

$$\begin{aligned}cA_y={}&-A_{yyy}+3aA^2A_y-i(a+2)(A_y)^2-i(a+2)AA_{yy}\\&+2i(2a+1)\theta A_yA_{y\theta}+2i(a+2)\theta AA_{yy\theta}+2i(a-1)\theta A_\theta A_{yy}.\end{aligned} \tag{3.2}$$

Such an equation may be integrated once with respect to y and gives

$$A_{yy}-aA^3+i(a+2)AA_y-2i(a+2)\theta AA_{y\theta}-2i(a-1)\theta A_\theta A_y+cA+c_1-\theta k=0, \tag{3.3}$$

where c_1 and k are even and odd integration constants, respectively. In fact, it is again a PDE but much simpler than the original one. Indeed, expanding now the bosonic superfield A as

$$A(y,\theta)=u(y)+\theta\rho(y),$$

we finally get the system of ODEs:

$$u'' - au^3 + i(a+2)uu' + cu + c_1 = 0, \tag{3.4}$$

$$\rho'' - i(a+2)u\rho' + (c - 3au^2 + i(4-a)u')\rho = k. \tag{3.5}$$

The prime ($'$) means that we differentiate with respect to y. We notice that Eq. (3.4) is a second-order nonlinear differential equation in u which does not depend on ρ. For $a=-2$, we recover a reduction of the mKdV equation. Since u is an even function in y, the method of resolution of Eq. (3.4) is a standard one and we will use the classification given in Ince's book[22] to get explicit solutions. We will see that this will give a selection of admissible values for the parameter a. Equation (3.5) is linear in ρ once u is known and it can be solved by the usual techniques for linear equations, once we take $\rho(y) = \psi f(y)$, where ψ is an odd constant parameter and $f(y)$ an even function.

B. Solution of the equation for *u*

It has been noted that Eq. (3.4) reduces to the mKdV equation for the special value $a=-2$ and then has well-known solutions such as the soliton solution $u = 1/\cosh y$. Requiring that all solutions of Eq. (3.4) be free of movable critical points, we will see that this value of a appears in a list of only five admissible values, namely $a=-4$, -2, -1, 1, and 4. Here let us mention that the complete integrability of Eq. (2.2), in terms of the existence of Lax pairs, has been proven by Mathieu *et al.*[4] only for $a=-2$ and 4. Conservation laws have been found for $a=1$ but not a Lax pair.

To make use of the classification of second-order ODEs without movable critical points given in Ince's book,[22] we first make the following change of variables:

$$u(y) = \alpha(y)w(z(y)) + \beta(y), \quad \alpha(y) \neq 0, \quad z'(y) \neq 0, \tag{3.6}$$

in order to take Eq. (3.4) to one of the canonical forms of the equation

$$w_{zz} = (A(z)w + B(z))w_z + C(z)w^3 + D(z)w^2 + E(z)w + F(z). \tag{3.7}$$

This corresponds to the case 14.31 i) listed by Ince. The functions *A,B,C,D,E,F* are written as follows:

$$A(z) = -i(a+2)\frac{\alpha}{z'}, \quad B(z) = -\frac{1}{\alpha(z')^2}(2\alpha'z' + \alpha z'' + i(a+2)\beta\alpha z'),$$

$$C(z) = \frac{a\alpha^2}{(z')^2}, \quad D(z) = \frac{1}{(z')^2}(3a\alpha\beta - i(a+2)\alpha'),$$

$$E(z) = \frac{1}{\alpha(z')^2}(3a\alpha\beta^2 - i(a+2)(\alpha'\beta + \alpha\beta') - \alpha'' - \alpha c),$$

$$F(z) = \frac{1}{\alpha(z')^2}(a\beta^3 - c\beta - c_1 - i(a+2)\beta'\beta - \beta'').$$

In order to obtain an equation with solutions free from movable critical points, the pair of functions A and C must belong to the following list (after a suitable choice of the functions α, β and z):

$$\text{(i.a)} \quad A=0, \quad C=0; \quad \text{(i.b)} \quad A=-2, \quad C=0;$$

$$\text{(i.c)} \quad A=-3, \quad C=-1; \quad \text{(i.d)} \quad A=-1, \quad C=1;$$

$$\text{(i.e)}\quad A=0,\quad C=2.$$

The first two cases cannot occur in our context. Indeed, no value of a satisfies (i.a). For the case (i.b), a must be zero and $\alpha=-iz'$. Continuing with the classification,[23] we have to satisfy at least one of the following conditions:

$$\text{(i)}\quad B=D,\quad E=0;\quad \text{(ii)}\quad D=F=0,\quad E=B',$$

to get an integrable equation. This is impossible for $c\neq 0$.

The three other cases effectively occur and give rise to a selection of the admissible values for a. This leads to $a=1$ or $a=4$ for the case (i.c), $a=-4$ or $a=-1$ for the case (i.d) and finally $a=-2$ for the case (i.e). Let us now specify the classification process and exhibit the solutions for all these cases.

1. Case (i.c): a=1, or a=4

We have to take $\alpha=-3iz'/(a+2)$ and the functions B, D, E, and F must verify $B=D$ and $E=F=0$. The first equality is trivially satisfied when $a=1$ or $a=4$ and the other constraints lead to the following equations on β and z':

$$\beta''-a\beta^3+i(a+2)\beta\beta'+c\beta+c_1=0, \tag{3.8}$$

$$z'''+i(a+2)(z'\beta)'-3a\beta^2z'+cz'=0. \tag{3.9}$$

Equation (3.8) is the same as the original Eq. (3.4) but now we only need one particular solution. It is obtained as the constant solution

$$\beta=\left(\frac{-c_1}{2a}\right)^{1/3}=\left(\frac{c}{3a}\right)^{1/2}, \tag{3.10}$$

which gives a relation between c and the integration constant c_1. With such a solution β, the function z satisfying Eq. (3.9) can be simply taken as $z(y)=y$.

Thus, Eq. (3.7) reduces to the canonical form

$$w_{yy}=-3ww_y-w^3+q(w_y+w^2), \tag{3.11}$$

where the constant q is given by

$$q=-i(a+2)\left(\frac{c}{3a}\right)^{1/2}=-i(3c)^{1/2}, \tag{3.12}$$

which is the same for $a=1$ and $a=4$. The solution of Eq. (3.11) is easily computed using the substitution $w=v_y/v$, where v satisfies the linear equation $v'''=qv''$, i.e.,

$$v(y)=c_2e^{qy}+c_3y+c_4. \tag{3.13}$$

Finally, since $u(y)=(-3i/(a+2))w(y)+\beta$, we get

$$u(y)=\frac{i}{a+2}\left[q-3\,\frac{v_y}{v}\right]. \tag{3.14}$$

We see that v given by Eq. (3.13) depends on three integration constants but u depends only on two independent constants. Indeed for $c_2\neq 0$, we get

$$u(y)=\frac{i}{a+2}\left[q-3\,\frac{qe^{qy}+c_3}{e^{qy}+c_3y+c_4}\right]. \tag{3.15}$$

For $c_2=0, c_3\neq 0$, the solution is

$$u(y)=\frac{i}{a+2}\left[q-\frac{3}{y+c_4}\right], \tag{3.16}$$

and finally for $c_2=c_3=0$, we get the constant solution $u(y)=\beta$. Thus we have obtained the general solution of Eq. (3.4) with $a=1$, or $a=4$ subject to the constraint (3.10) on c and c_1.

2. Case (i.d): a=−4, or a=−1

We choose $\alpha=-iz'/(a+2)$ and all solutions of Eq. (3.7) will be free from movable critical points if $B=D=0$ and $F=-E'$. These conditions are satisfied for $\beta=0$, $z''=0$ and this implies that the integration constant c_1 must be zero. Hence Eq. (3.7) reduces to the canonical form

$$w_{zz}=-ww_z+w^3-pw, \tag{3.17}$$

where $p=-c/(z')^2$ is a constant. The standard way of solving Eq. (3.17) is to introduce a new function $v(z)$ that satisfies

$$v_z^2=p_3v^3+p_2v^2+p_1v+p_0, \tag{3.18}$$

for some constants p_i $(i=0,1,2,3)$ and to write $w=v_z/(v-1)$. From Eq. (3.18), we immediately get

$$v_{zz}=\tfrac{1}{2}(3p_3v^2+2p_2v+p_1), \quad v_{zzz}=(3p_3v+p_2)v_z. \tag{3.19}$$

Inserting now the new expression of w in Eq. (3.17) and using the expressions (3.19), we get the admissible values for the constants p_1, p_2, and p_3. A canonical choice gives

$$p_3=\frac{p}{3}, \quad p_2=0, \quad p_1=-p.$$

The solution of Eq. (3.18) is expressed in terms of the P-Weierstrass elliptic function, $\mathcal{P}(z,g_2,g_3)$, (see, e.g., Byrd and Friedman[23]) and is written as follows:

$$v(z)=\left(\frac{12}{p}\right)^{1/3}\mathcal{P}(z), \tag{3.20}$$

where

$$g_2=(12p^2)^{1/3}, \quad g_3=-p_0.$$

Finally, for the simplest choice $z(y)=y$, we obtain the solution of Eq. (2.4) as

$$u(y)=-\frac{i}{(a+2)}\left(\frac{v'(y)}{v(y)-1}\right)=-\frac{i}{(a+2)}\left(\frac{\mathcal{P}'(y)}{\mathcal{P}(y)-(p/12)^{1/3}}\right), \tag{3.21}$$

where $\mathcal{P}'(y)=-\sqrt{4\mathcal{P}^3(y)-g_2\mathcal{P}(y)+p_0}$.

3. Case (i.e): a=−2

This corresponds to the mKdV equation and all solutions are free from movable critical points. We set $\alpha^2=-(z')^2$ and have $B=D=0$. We choose the auxiliary quantities to be $\alpha=i$, $\beta=0$, and $z=y$ so that from Eq. (3.6), we see that $u(y)=iw(y)$. Hence, we can solve directly Eq. (3.4), which reduces to

$$u''+2u^3+cu+c_1=0. \tag{3.22}$$

Multiplying it by u' and integrating once, we get

$$(u')^2 = -(u^4 + cu^2 + 2c_1 u - c_2) = H(u), \tag{3.23}$$

where c_2 is an integration constant. This is a well-known equation solvable in terms of elliptic functions and their degenerate cases. Let us give some particular solutions.

We first consider the solitonic solution

$$u_S(y) = u_2 + \frac{\omega^2}{2u_2 + (u_1 + u_2)\cosh(\omega y)}, \tag{3.24}$$

where $\omega = \sqrt{(u_1 - u_2)(u_1 + 3u_2)}$, u_1, u_2 being roots of the polynomial $H(u)$ in Eq. (3.23). Indeed, if we denote by u_1, u_2, u_3 and u_4 the four roots of $H(u)$, the solution u_S corresponds to the case where $u_1 \geqslant u_S > u_2 = u_3 > u_4$ (note that $u_4 = -u_1 - u_2 - u_3$). The constants c and c_1 (written now as c_S and c_{1S}) are then given by

$$c_S = -(u_1^2 + 2u_1u_2 + 3u_2^2), \quad c_{1S} = -2u_2(u_1^2 + u_1u_2 + u_2^2).$$

The second solution we are interested in, is the rational one

$$u_R(y) = u_1 - \frac{4u_1}{4u_1^2 y^2 + 1}. \tag{3.25}$$

It corresponds to the case where three roots of $H(u)$ are equal and such that $u_1 = u_2 = u_3 > u_R > u_4$. Again the constants c and c_1 in Eq. (3.23) may be written as

$$c_R = -6u_1^2, \quad c_{1R} = -8u_1^3.$$

C. Solutions of the equation for ρ

Now we will use the solutions u of the PDE (3.4) to solve Eq. (3.5) that is linear in ρ. We can take $\rho(y) = \psi f(y)$ and $k = \psi k_1$, where ψ is an odd constant. We get a linear equation satisfied by the even function f:

$$f''(y) + p_1 f'(y) + p_0 f(y) = k_1, \tag{3.26}$$

where

$$p_1(y) = -i(a+2)u, \quad p_0(y) = c - 3au^2 + i(4-a)u' \tag{3.27}$$

and u is a solution of Eq. (3.4). For general solutions $u(y)$, Eq. (3.26) cannot be solved in terms of elementary functions, nor the standard special functions. Some particular solutions for u lead to simple forms of Eq. (3.26) that can be solved explicitly.

For the case $a=1$, or $a=4$, the general solution $u(y)$ was given by Eq. (3.14) with v satisfying the expression (3.13). It is easy to see that p_1 and p_0 in Eq. (3.27) are now given by

$$p_1(y) = \left(q - 3\frac{v_y}{v}\right), \quad p_0(y) = -2q\frac{v_y}{v} + (a-1)\left(\frac{v_y}{v}\right)^2. \tag{3.28}$$

We see that $p_1(y)$ does not depend on a and that $p_0(y)$ has been simplified taking into account the admissible values of a. We now distinguish the two values of a. For $a=1$, we use the particular solution (3.16) which leads to the linear equation

$$f'' + \left(q - \frac{3}{y}\right)f' - \frac{2q}{y}f = k_1, \tag{3.29}$$

where without loss of generality we put the constant c_4 equal to zero. The general solution is

$$f(y)=C_1(6-4qy+q^2y^2)+C_2(qy+3)e^{-qy}+\frac{k_1}{2q^2}(3-2qy), \tag{3.30}$$
