C_1 and C_2 being arbitrary integration constants. For $a=4$, the same solution $u(y)$ inserted in Eq. (3.26) gives

$$f''+\left(q-\frac{3}{y}\right)f'+\left(\frac{-2q}{y}+\frac{3}{y^2}\right)f=k_1, \tag{3.31}$$

which admits the general solution

$$f(y)=qy[C_1(1-qy)+C_2e^{-qy}]-\frac{k_1y}{q}, \tag{3.32}$$

where again C_1 and C_2 are arbitrary constants.

We now turn to the case $a=-2$ which leads to the solitonic solution $u_S(y)$ of Eq. (3.24). Equation (3.26) takes the form

$$f''(y)+p_0(y)f(y)=k_1 \tag{3.33}$$

with

$$\begin{aligned} p_0(y)=\frac{1}{[(u_1+u_2)\cosh(\omega y)+2u_2]^2}\{&-(u_1^2+2u_1u_2+3u_2^2)((u_1+u_2)^2\cosh(\omega y)+2u_2)^2\\ &+6(u_2(u_1+u_2)\cosh(\omega y)+u_1^2+2u_1u_2-u_2^2)^2\\ &-6i(u_1-u_2)(u_1+u_2)(u_1+3u_2)\omega\sinh(\omega y)\}. \end{aligned} \tag{3.34}$$

Suitable changes of variables lead to a hypergeometric equation that can be solved exactly. Indeed, we first consider the homogeneous equation and use the change of variable $s=e^{\omega y}$ to get the new equation

$$f_{ss}+P(s)f_s+Q(s)f=0, \tag{3.35}$$

where

$$P(s)=\frac{1}{s},\quad Q(s)=\frac{-(s^2+10\kappa s+(\kappa)^2)}{s^2(s-\kappa)^2},$$

with $\kappa=-(2u_2-i\omega)/(u_1+u_2)$. A second change of variable will bring us to the hypergeometric equation

$$\varphi_{zz}+\frac{3(2z-1)}{z(z-1)}\varphi_z-\frac{6}{z(z-1)}\varphi=0, \tag{3.36}$$

where $z=s/(s-\kappa)$ and $\varphi=[1/z(z-1)]f$. One solution of Eq. (3.36) is easily found as $\varphi_1(z)=2z-1$, which leads us to a solution for the original homogeneous equation

$$f_1(y)=\frac{\kappa e^{\omega y}(e^{\omega y}+\kappa)}{(e^{\omega y}-\kappa)^3}. \tag{3.37}$$

The second linearly independent solution $\varphi_2(z)$ is obtained from $\varphi_1(z)$ using the formula

$$\varphi_2(z)=\varphi_1(z)\int \frac{1}{\varphi_1^2(z)}e^{-\int P(z)dz}dz, \tag{3.38}$$

or, explicitly,

$$\varphi_2(z)=32+\frac{7(2z-1)^2}{z(z-1)}-\frac{(2z-1)^2}{2z^2(z-1)^2}+30(2z-1)\ln\left(\frac{z-1}{z}\right). \tag{3.39}$$

We then get the other solution of the original homogeneous equation by replacing z in terms of y, i.e.,

$$f_2(y)=\frac{32\kappa e^{\omega y}+7(e^{\omega y}+\kappa)^2}{(e^{\omega y}-\kappa)^2}-\frac{(e^{\omega y}+\kappa)^2}{2\kappa e^{\omega y}}+30f_1(y)(-\omega y+\ln(\kappa)). \tag{3.40}$$

The corresponding solution of the inhomogeneous equation is obtained by the method of variation of constants and it is the linear combination of f_1 and f_2 and a particular solution given by

$$f_p(z(y))=\frac{k}{\omega^2}\left(-1-3z+33z^2-30z^3-6z(1-3z+2z^2)\ln\left(z-\frac{1}{z}\right)\right). \tag{3.41}$$

Finally let us take the rational solution u_R given by Eq. (3.25) and solve

$$f''+\left(\frac{48u_1^2}{(1-2iu_1y)^2}\right)f=k_1. \tag{3.42}$$

Once we put $r=1-2iu_1y$, we get an Euler type equation of the form

$$r^2f_{rr}-12f=\frac{k_1r^2}{-4u_1^2}. \tag{3.43}$$

We easily see that the general solution of Eq. (3.42) is

$$f(y)=C_1(1-2iu_1y)^4+C_2(1-2iu_1y)^{-3}+\frac{k_1}{40u_1^2}(1-2iu_1y)^2, \tag{3.44}$$

with C_1 and C_2 arbitrary integration constants.

D. Super traveling-wave solution

Returning to the original super KdV equation (2.4), let us give the expression for the solutions A which are invariant under G_1. Let us recall that we have solved Eq. (2.4) with $A=A(y,\theta)=u(y)+\theta\rho(y)$ where y is an even Grassmann variable given by Eq. (3.1). Developing u and ρ, we get (in view of the nilpotent character of θ_1 and θ_2)

$$A=u(x+ct)+i\theta_1\theta_2\frac{du}{d\xi}\bigg|_{\xi=x+ct}+(\theta_1+i\theta_2)\rho(x+ct). \tag{3.45}$$

This means that the components of A in Eq. (2.5) are not independent. Indeed we have

$$v=\frac{du}{d\xi}\bigg|_{\xi=x+ct},\quad \rho^2=i\rho^1=i\rho(\xi). \tag{3.46}$$

So we can view the solutions u and ρ as functions of $\xi=x+ct$ instead of y and $A=u(\xi)+i\theta_1\theta_2(du/d\xi)+(\theta_1+i\theta_2)\rho(\xi)$. For example, we have for $a=1$, the solutions

$$u(\xi)=\frac{i}{3}\left[q-\frac{3}{\xi}\right], \tag{3.47}$$

$$\rho(\xi)=\psi\left[C_1(6-4q\xi+q^2\xi^2)+C_2(q\xi+3)e^{-q\xi}+\frac{k_1}{2q^2}(3-2q\xi)\right]. \tag{3.48}$$

For $a=4$, we get

$$u(\xi)=\frac{i}{6}\left[q-\frac{3}{\xi}\right], \tag{3.49}$$

$$\rho(\xi)=\psi\left[q\xi[C_1(1-q\xi)+C_2e^{-q\xi}]-\frac{k_1\xi}{q}\right]. \tag{3.50}$$

Let us now develop the supersolitonic solution occurring for $a=-2$. First, we take some particular values for the constants appearing in the solution (3.24). Thus, with $u_1=1$, $u_2=0$, and $c=-1$, we get

$$u(x-t)=\frac{1}{\cosh(x-t)}, \tag{3.51}$$

the well-known solitonic solution of the mKdV equation. The first solution for the homogeneous equation in ρ becomes very simple. It takes the form $\rho_1(x-t)=\psi f_1(x-t)$ where

$$f_1(x-t)=\frac{1}{\cosh^3(x-t)}\left[\sinh(x-t)+\frac{i}{2}(1-\sinh^2(x-t))\right]. \tag{3.52}$$

In Fig. 1, we see the behavior of u, $\mathrm{Re}(f_1)$ and $\mathrm{Im}(f_1)$ as functions of $\xi=x-t$. As function of x and t, we have the graphs of $\mathrm{Re}(f_1)$ and $\mathrm{Im}(f_1)$ in Figs. 2 and 3. The solution (3.52) has a very interesting behavior, discussed earlier by Ibort *et al.*[16] for a different supersymmetric equation. They had a real solution which they called a *solitino* and its graph was similar to that of $\mathrm{Re}(f_1)$ in Fig. 2. Here we get a complex solution for which the norm of the corresponding even function $f_1(x-t)$ is $|f_1(x-t)|=\frac{1}{2}u(x-t)$. We also see that the real part of f_1 is the derivative of the usual soliton solution (up to a multiplication by a constant factor) of the KdV equation, while the imaginary part is related to u by $\mathrm{Im}\, f_1(\xi)=d^2u(\xi)/d\xi^2$.

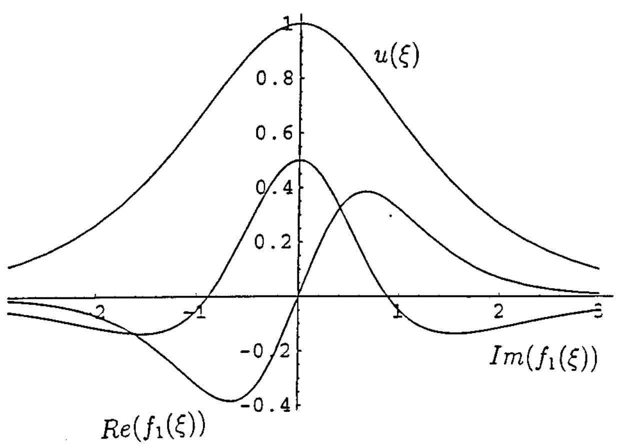

FIG. 1. The functions $u(\xi)$, $\mathrm{Re}(f_1(\xi))$, and $\mathrm{Im}(f_1(\xi))$.

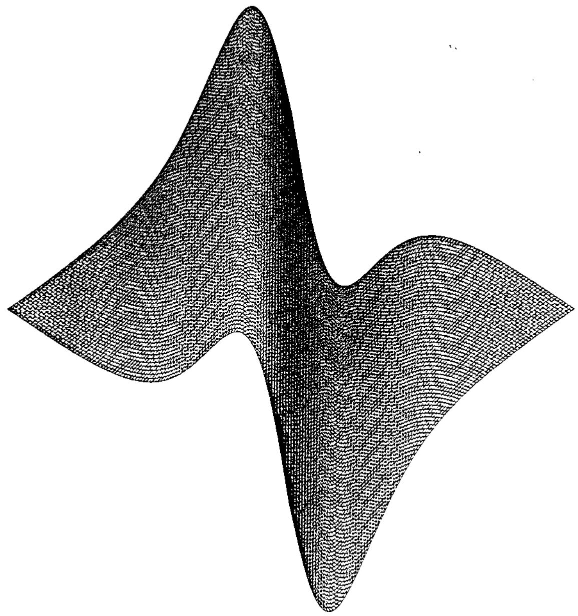

FIG. 2. The function $\mathrm{Re}(f_1(x-t))$.

Let us emphasize that our soliton type solution of the SUSY mKdV equation provides a complete solution of Eq. (2.4), since we have obtained all components of A [see Eq. (3.45)]. The behavior of the other independent solutions $\rho_2(\xi)$ and $\rho_p(\xi)$ is more complex, but we can compute it in the particular case where u is given by Eq. (3.51). They take the form

$$f_2(\xi)=\mathrm{Re}(f_2(\xi))+i\ \mathrm{Im}(f_2(\xi)) \tag{3.53}$$

with

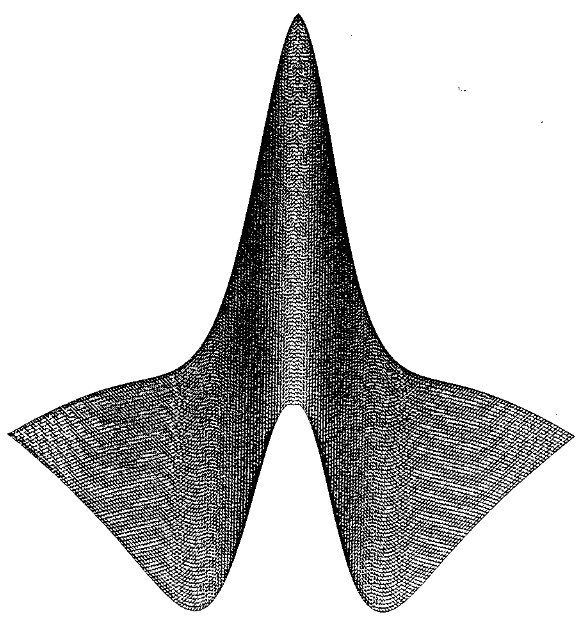

FIG. 3. The function $\mathrm{Im}(f_1(x-t))$.

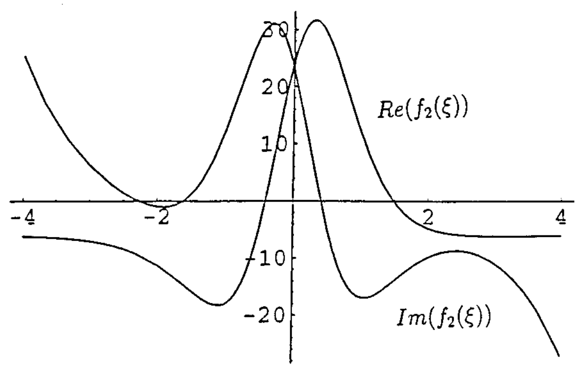

FIG. 4. The functions $\mathrm{Re}(f_2(\xi))$ and $\mathrm{Im}(f_2(\xi))$.

$$\mathrm{Re}(f_2(\xi)) = -6 + 15\pi \frac{\sinh(\xi)}{(\cosh(\xi))^3} + 30 \frac{1}{(\cosh(\xi))^2} - 30\xi \frac{\sinh(\xi)}{(\cosh(\xi))^3}, \tag{3.54}$$

$$\mathrm{Im}(f_2(\xi)) = -\sinh(\xi) + 15 \frac{\xi}{\cosh(\xi)} - 30 \frac{\xi}{(\cosh(\xi))^3} - \frac{15}{2}\pi \frac{1}{\cosh(\xi)} + 15\pi \frac{1}{(\cosh(\xi))^3} - 30 \frac{\sinh(\xi)}{(\cosh(\xi))^2}. \tag{3.55}$$

Finally, the particular solution f_p is

$$f_p(\xi) = \mathrm{Re}(f_p(\xi)) + i\,\mathrm{Im}(f_p(\xi)) \tag{3.56}$$

with

$$\mathrm{Re}(f_p(\xi)) = k_1\left(-1 - \frac{3}{2}\frac{e^{\xi}}{\cosh(\xi)} + \frac{33}{4}\frac{(-1+e^{2\xi})}{4(\cosh(\xi))^2} - \frac{15}{4}\frac{(-3e^{\xi}+e^{3\xi})}{(\cosh(\xi))^3} - 6\left(\frac{\pi}{2} - \xi\right)\left[\frac{e^{\xi}}{2\cosh(\xi)} - \frac{3}{4}\frac{(-1+e^{2\xi})}{(\cosh(\xi))^2} + \frac{(-3e^{\xi}+e^{3\xi})}{4(\cosh(\xi))^3}\right]\right), \tag{3.57}$$

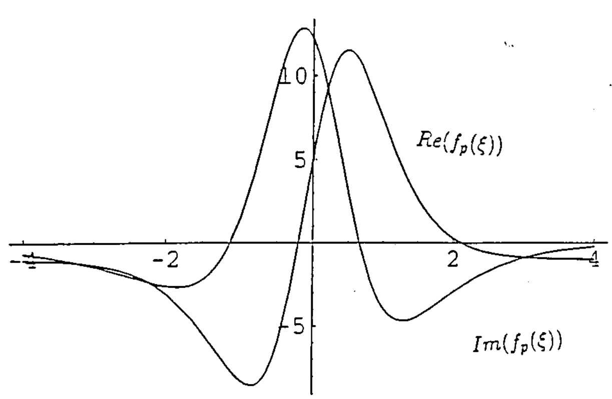

FIG. 5. The functions $\mathrm{Re}(f_p(\xi))$ and $\mathrm{Im}(f_p(\xi))$.

$$\mathrm{Im}(f_p(\xi))=k_1\left(-\frac{3}{2\cosh(\xi)}+\frac{33}{2}\frac{e^{\xi}}{(\cosh(\xi))^2}-15\frac{(-1+3e^{2\xi})}{4(\cosh(\xi))^3}\right.$$
$$\left.-6\left(\frac{\pi}{2}-\xi\right)\left[\frac{1}{2\cosh(\xi)}-\frac{3e^{\xi}}{2(\cosh(\xi))^2}+\frac{(-1+3e^{2\xi})}{4(\cosh(\xi))^3}\right]\right). \tag{3.58}$$

All these functions are represented in Figs. 4 and 5 as functions of ξ and for $k_1=1$.

IV. CONCLUSION

Starting from the $N=2$ SUSY KdV equation (2.4), we have used a subgroup of the supersymmetry group to obtain Grassmann-valued solutions depending on one even and one odd Grassmann independent variable. Such an equation contains a lot of information, since if we decompose the bosonic superfield in terms of its components, As in Eq. (2.5), it produces a set of four partial differential equations. Our way of determining symmetries has the advantage of avoiding that decomposition, of working with the concise equation (2.4), and of producing a superalgebra (2.8) of symmetries. In the search for solutions using the method of symmetry reduction, we work with Grassmann variables until we get a PDE with one even and one odd Grassmann variable. At this stage, the nilpotency of the odd variable leads, by expansion of the dependent variable, to a set of two ODEs.

The invariant solutions that we have obtained are based on the choice of G_1 as a subgroup of the SUSY group. Let us recall that it contains a SUSY transformation and a combination of both spatial and temporal translations. It gives rise to interesting solutions such as the supersolitonic ones. Another group G_2 containing the same SUSY transformation and the dilation generated by $\mathcal{D}$ may also be considered. Here the difficulty is to solve explicitly the linear equation for the odd field ρ. Indeed, if we take the group $G_2=\{g_0'=(0,0,d;\eta,i\eta)\}$, it acts on the independent and dependent variables as

$$g_0'(x,t;\theta_1,\theta_2)=(e^d(x+\eta(\theta_1+i\theta_2)),e^{3d}t;e^{d/2}(\theta_1-\eta),e^{d/2}(\theta_2-i\eta)),$$

$$g_0'A(x,t;\theta_1,\theta_2)=e^{-d}A((g_0')^{-1}(x,t;\theta_1,\theta_2)),$$

and the invariants of this action are

$$y=t^{-1/3}(x+i\theta_1\theta_2),\quad \theta=\theta_1+i\theta_2,\quad W=t^{1/3}A. \tag{4.1}$$

It is easy to show that the reduced equation in terms of $W=W(y,\theta)$ may be developed as a set similar to Eqs. (3.4) and (3.5) where the constant c is replaced by $-y/3$. This means that the solution for u essentially follows the lines described in Sec. III. In particular, this implies the selection of the same values for a, important information for the integrability of the SUSY KdV equation. We plan to return to the study of self-similar SUSY solutions in the near future.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 4 APRIL 1999

On the integrability of nonlinear partial differential equations

H. J. S. Dorren[a)]
Department of Electrical Engineering, Eindhoven University of Technology, P.O. Box 513, 5600 MB Eindhoven, The Netherlands

(Received 31 August 1998; accepted for publication 15 January 1999)

We investigate the integrability of Nonlinear Partial Differential Equations (NPDEs). The concepts are developed by first discussing the integrability of the KdV equation. We proceed by generalizing the ideas introduced for the KdV equation to other NPDEs. The method is based upon a linearization principle that can be applied on nonlinearities that have a polynomial form. The method is further illustrated by finding solutions of the nonlinear Schrödinger equation and the vector nonlinear Schrödinger equation, which play an important role in optical fiber communication. Finally, it is shown that the method can also be generalized to higher dimensions. © *1999 American Institute of Physics.* [S0022-2488(99)01904-0]

I. INTRODUCTION

The conditions under which Nonlinear Partial Differential Equations (NPDEs) can be solved are even in one dimension not well understood.[1] Roughly speaking, the majority of the integrable systems can be classified in three main groups. In the first of these groups are those equations that can be reduced to a quadrature through the existence of an adequate number of integrals of motion. In the second class are those equations that can be mapped into a linear system by applying a number of transformations (hereafter to be called C integrable[2]). The last group consists of differential equations that can be solved by Inverse Scattering Transformations (IST). In the following, we will call equations that can be solved by inverse scattering methods ''*S* integrable.'' The discovery of the IST has led to considerable progress in understanding the topic of integrability, since this technique made it possible to investigate the integrability of large classes of NPDEs systematically.[3]

Another important consideration is that most of the work on the integrability of NPDEs has been carried out in one space dimension only. Although the inverse problem of the Schrödinger equation can be generalized to three dimensions, the method is far too complicated to solve higher-dimensional NPDEs. An alternative is the $\bar{\partial}$ approach, which is also successfully generalized to N dimensions (see, for instance, the book by Ablowitz and Clarkson[3]). Nevertheless, for both these methods the existence of the obtained solutions is difficult to prove. The concept of C integrability, however, has the potential to be generalized to dimensions higher than one. In this paper, we will demonstrate a simple method based upon linearization principles that enables us to compute solutions of large classes of NPDEs by solving a linear algebraic recursion relationship. The result suggests that the method can be generalized to higher-dimensional NPDEs.

In this paper we aim to find integrable differential equations that can be solved by linearization. The basic idea of the method goes back to Stokes,[4] and is used several times to obtain solutions of nonlinear evolution equations.[5–9] We will apply the method in a slightly different form to find conditions on the integrability of nonlinear evolution equations. Since it is not clear what integrability exactly means, we use in this paper the heuristic definition that a NPDE is integrable if given a sufficiently general initial condition, we can find analytic expressions the time evolution of the solution. For NPDEs that can be solved by inverse scattering techniques, this

[a)]Electronic mail: H.J.S.Dorren@ele.tue.nl notion is equivalent with the existence of N-soliton solutions, since it is implicitly assumed that the obtained solution can be expanded on a Fourier basis.[8] It is shown that the condition of expansion in a Fourier can be replaced by an arbitrary other infinite set of basis functions.

We present the following results. First, we derive a simple method to test NPDEs with a polynomial type of nonlinearity in the presence of N-soliton solutions. Necessary conditions that indicate whether a NPDE has N-soliton solutions includes that the nonlinearity can be expanded in the same basis functions as the linear part, and second that the dispersion relationship associated with the linearized problem can be solved. The method is demonstrated by first discussing the integrability of the KdV equation in Sec. II. In Sec. III, the concepts derived for the KdV equation are generalized to discuss the integrability of more general NPDEs. Finally, in Sec. IV, the results are applied to investigate the integrability of the coupled nonlinear Schrödinger equation. Moreover, it is indicated that the method can also be used to obtain solutions to higher-dimensional NPDEs. The paper is concluded with a discussion.

II. THE INTEGRABILITY OF THE KdV EQUATION

In order to illustrate the machinery developed throughout this paper, we first discuss the integrability of the KdV equation as an example. The integrability of the KdV equation is a well-studied problem.[3] This makes the KdV equation an ideal object to test the validity of newly developed ideas with respect to the integrability of NPDEs. We will introduce our methods on the integrability of NPDEs by discussing the existence of N-soliton solutions for the KdV equation, which is given by

$$u_t+u_{xxx}=6u_xu. \tag{1}$$

We try to find solutions of Eq. (1) by substitution of the following Fourier series:

$$u(x,t)=\sum_{n=1}^{\infty} A_n e^{in(kx-\omega t)}. \tag{2}$$

If we substitute the solution $u(x,t)$ into Eq. (2), we obtain

$$\sum_{n=1}^{\infty} (n\omega+k^3n^3)A_n e^{in(kx-\omega t)}=-6k\sum_{n=1}^{\infty}\sum_{l=1}^{n-1} lA_lA_{n-l}e^{in(kx-\omega t)}. \tag{3}$$

We can now determine the coefficients A_n by deriving a recursion relationship. This can be achieved by comparing the exponential functions in Eq. (3). If we compare all the terms for which $n=1$, we find

$$(\omega+k^3)A_1e^{i(kx-\omega t)}=0. \tag{4}$$

For a nonzero A_1, we find that Eq. (4) is satisfied if

$$\omega=-k^3. \tag{5}$$

If we put $n=2$ in Eq. (3), we can determine A_2 by solving the following relationship:

$$(2\omega+8k^3)A_2e^{2i(kx-\omega t)}=-6kA_1A_1e^{2i(kx-\omega t)}. \tag{6}$$

If we use the dispersion relationship (5), we find that A_2 is given by

$$A_2=-\frac{A_1^2}{k^2}. \tag{7}$$

By repeating this procedure, we can compute all the expansion coefficients A_n of the solutions $u(x,t)$. In general, all the coefficients A_n can be computed by solving the following linear algebraic problem:

$$L^{(n)}(k)A_n=R^{(n)}(k). \tag{8}$$

The operators $L^{(n)}(k)$ and $R^n(k)$ in Eq. (8) are given by

$$L^{(n)}(k)=n[n^2-1]k^3, \quad R^{(n)}(k)=-6k\sum_{l=1}^{n-1} lA_lA_{n-l}. \tag{9}$$

If we compute all the coefficients A_n by using Eq. (9), we then obtain the Fourier expansion of $u(x,t)$, for which the first terms are given by

$$u(x,t)=A_1e^{i(kx-\omega t)}-\frac{A_1^2}{k^2}e^{2i(kx-\omega t)}+\frac{3A_1^3}{4k^4}e^{-3i(kx-\omega t)}+\cdots. \tag{10}$$

If we substitute $k=2i\beta$ and $A_1=4\,d\beta$ into Eq. (10), we find

$$u(x,t)=4\,d\beta\,e^{-2(\beta x-4\beta^3t)}+16\,d^2e^{-4(\beta x-4\beta^3t)}+\frac{24d^3}{\beta}e^{-6(\beta x-4\beta^3t)}+\cdots. \tag{11}$$

By carrying out the summation in Eq. (11), we can formulate this equation more compactly:

$$u(x,t)=\frac{8\,d\beta\,e^{-2(\beta x-4\beta^3t)}}{\left(1+\frac{d}{\beta}e^{-2(\beta x-4\beta^3t)}\right)^2}. \tag{12}$$

Hence, if we put

$$\beta=\frac{1}{2}\sqrt{c}, \quad x_0=-\frac{1}{\sqrt{c}}\log\left(-\frac{d}{\beta}\right), \quad d<0, \tag{13}$$

we can simplify Eq. (12) one step further to

$$u(x,t)=-\frac{c}{2}\operatorname{sech}^2\left\{\frac{1}{2}\sqrt{c}(x-ct+x_0)\right\}. \tag{14}$$

Equation (14) describes the well-known KdV soliton.

What did we learn from this simple exercise? At first, the KdV equation has solutions because of the special structure of the nonlinearity. If we substitute the special solution (2) in the nonlinear part of the KdV equation, we find that we can expand the nonlinearity in the same basis functions as the linear part:

$$6u_xu=\sum_{n=1}^{\infty} D_ne^{in(kx-\omega t)}; \quad D_n=-6k\sum_{l=1}^{n-1} lA_lA_{n-l}. \tag{15}$$

This guarantees that we can find an iteration relationship for the expansion coefficients A_n. As we will see later, we do not have to restrict to a Fourier expansion of the solution only. In principle, this method works for any set of basis functions as long as we can expand the nonlinearity in the same basis functions as the linear part. In the following, we will show that the structure of the nonlinearity of the KdV equation enables us to construct the Fourier expansion of the N soliton of the KdV equation. In order to systematically solve these solutions it is illustrative to discuss also the two-soliton solutions, which are assumed to have the following series expansion:

$$u(x,t)=\sum_{\mu_1,\mu_2=1}^{\infty} C(\mu_1,\mu_2)e^{i(\mu_1 k_1 z_1+\mu_2 k_2 z_2)} \begin{cases} z_1=x-\dfrac{\omega(k_1)}{k_1}, \\ z_2=x-\dfrac{\omega(k_2)}{k_2}. \end{cases} \tag{16}$$

If we substitute Eq. (16) into the KdV equation (1), we obtain the following result:

$$\sum_{\mu_1,\mu_2=1}^{\infty} L^{(\mu_1,\mu_2)}(k_1,k_2)C(\mu_1,\mu_2)e^{i(\mu_1 k_1 z_1+\mu_2 k_2 z_2)}$$
$$=-6\sum_{\mu_1,\mu_2=1}^{\infty}\sum_{\eta_1,\eta_2=1}^{\mu_1-1,\mu_2-1} M^{(\eta_1,\eta_2)}(k_1,k_2)C(\mu_1-\eta_1,\mu_2-\eta_2)C(\eta_1,\eta_2)e^{i(\mu_1 k_1 z_1+\mu_2 k_2 z_2)}, \tag{17}$$

where

$$L^{(n_1,n_2)}(k_1,k_2)=\sum_{i=1}^{2} n_i[n_i^2-1]k_i^3, \quad M^{(n_1,n_2)}(k_1,k_2)=\sum_{i=1}^{2} n_i k_i\,. \tag{18}$$

We solve Eq. (17) by comparing equal exponential powers on both sides. This can be done by defining a parameter $\Gamma=\mu_1+\mu_2$ and subsequently comparing the powers for $\Gamma=1,2,3,\ldots$. We first discuss the case in which $\Gamma=1$ in which only the coefficients $C(1,0)$ and $C(0,1)$ contribute:

$$[\omega_1+k_1^3]C(1,0)e^{ik_1z_1}+[\omega_2+k_2^3]C(0,1)e^{ik_2z_2}=0. \tag{19}$$

If we put $C(1,0)=A_1$ and $C(0,1)=A_2$, we find that the following linear dispersion relationships must be valid:

$$\omega(k_1)=-k_1^3 \quad \text{and} \quad \omega(k_2)=-k_2^3. \tag{20}$$

Once the linear dispersion relationships are determined and if the coefficients $C(1,0)$ and $C(0,1)$ have taken their values A_1 and A_2, we can compute all the other coefficients $C(\mu,\eta)$ by applying the following linear recursion relation:

$$L^{(\mu_1,\mu_2)}(k_1,k_2)C(\mu_1,\mu_2)=R^{(\mu_1,\mu_2)}(k_1,k_2), \tag{21}$$

where

$$R^{(\mu_1,\mu_2)}(k_1,k_2)=-6\sum_{\eta_1,\eta_2=1}^{\mu_1-1,\mu_2-1} M^{(\eta_1,\eta_2)}(k_1,k_2)C(\mu_1-\eta_1,\mu_2-\eta_2)C(\eta_1,\eta_2). \tag{22}$$

Equation (21) has a similar structure as Eq. (8). In principle, Eq. (21) provides an efficient tool to compute all the coefficients $C(\mu,\eta)$. We can generalize this result to the N-soliton case by assuming that the solution $u(x,t)$ takes the following form:

$$u(x,t)=\sum_{\mu_1\cdots\mu_N=1}^{\infty} C(\mu_1\cdots\mu_N)^{i(\mu_1 k_1 z_1+\cdots+\mu_N k_N z_N)} \begin{cases} z_1=x-\dfrac{\omega(k_1)}{k_1} \\ \vdots \\ z_N=x-\dfrac{\omega(k_N)}{k_N}. \end{cases} \tag{23}$$

We can determine the nonzero coefficients $C(\mu_1\cdots\mu_N)$ by substituting Eq. (23) into the KdV equation (1):

$$\sum_{\mu_1\cdots\mu_N=1}^{\infty} L^{(\mu_1\cdots\mu_N)}(k_1\cdots k_N)C(\mu_1\cdots\mu_N)e^{i(\mu_1k_1z_1+\cdots+\mu_Nk_Nz_N)}$$
$$=-6\sum_{\mu_1\cdots\mu_N=1}^{\infty}\sum_{\eta_1\cdots\eta_N=1}^{\mu_1-1\cdots\mu_N-1} M^{(\eta_1\cdots\eta_N)}(k_1\cdots k_N)C(\mu_1-\eta_1\cdots\mu_N-\eta_N)C(\eta_1\cdots\eta_N)$$
$$\times e^{i(\mu_1k_1z_1+\cdots+\mu_Nk_Nz_N)}, \tag{24}$$

where

$$L^{(n_1\cdots n_N)}(k_1\cdots k_N)=\sum_{i=1}^{N} n_i[n_i^2-1]k_i^3;\quad M^{(n_1\cdots n_N)}(k_1\cdots k_N)=\sum_{i=1}^{N} n_ik_i. \tag{25}$$

If we use that $\omega(k_i)=-k_i^3$, $(i\in 1\cdots N)$ and $A_1=C(1,0,0,...,0), A_2=C(0,1,0,...,0),\ldots,A_N=C(0,...,0,1)$, we find that the expansion coefficients of the N-soliton solution for the KdV equation can be computed by solving the following linear relationship:

$$L^{(\mu_1\cdots\mu_N)}(k_1\cdots k_N)C(\mu_1\cdots\mu_N)=R^{(\mu_1\cdots\mu_N)}(k_1\cdots k_N), \tag{26}$$

where

$$R^{(\mu_1\cdots\mu_N)}(k_1\cdots k_N)=-6\sum_{\eta_1\cdots\eta_N=1}^{\mu_1-1\cdots\mu_N-1} M^{(\eta_1\cdots\eta_N)}(k_1\cdots k_N)C(\mu_1-\eta_1\cdots\mu_N-\eta_N)C(\eta_1\cdots\eta_N). \tag{27}$$

From the exercise performed in this section, we can conclude that general solutions of the KdV equation can be obtained by solving Eqs. (26). This implies that the KdV equation can be transformed into a simple linear algebraic equation in the coefficient space. We can conclude that the KdV equation has N-soliton solutions because the following two conditions are satisfied.

(i) The structure of the nonlinearity of the kdV equation guarantees that the equation has solutions of the form (23). This result implies that the coefficients $R^{(\mu_1\cdots\mu_N)}(k_1\cdots k_N)$ exist.

(ii) $L^{(n_1\cdots n_N)}(k_1\cdots k_N)$ is not equal to zero if $k_1\cdots k_N\neq 0$ and $n_1\cdots n_N\neq 0$. This implies that $L^{(n_1\cdots n_N)}(k_1\cdots k_N)$ has an inverse.

In the following section we will show that a similar condition must hold for other NPDEs. In the following section it is shown that the concepts derived for the KdV equation can be generalized to large classes of NPDEs. The results obtained in this section are derived by assuming that the solution of the KdV equation can be expanded in Fourier basis functions. In the following section, it will be shown that similar principles apply for other basis functions.

III. GENERALIZATIONS

In this section we will present more general results with respect to the integrability of nonlinear evolution equations. This will be done by generalizing the results obtained for the KdV equation. In this section, we focus on NPDEs of the following type:

$$\mathcal{L}[\mathbf{u}(x,t)]=Q[\mathbf{u}(x,t)]. \tag{28}$$

In Eq. (28), the function $\mathbf{u}(x,t)$ is an M-component vector function having entries $u_i(x,t)$. The operator $\mathcal{L}[\cdot]$ is assumed to take the following form:

$$\mathcal{L}[\mathbf{u}(x,t)]=\left[i\mathbf{I}\frac{\partial}{\partial t}+\sum_{n=1}^{K}\mathbf{A}^{(n)}\frac{\partial^n}{\partial x^n}\right]\mathbf{u}(x,t). \tag{29}$$

The matrices $\mathbf{A}^{(n)}$ in Eq. (29) are $M\times M$ matrices and $\mathbf{I}$ is the identity matrix. As concluded from the previous section, integrability puts strong constraints on the nonlinearity represented by the operator Q. As a necessary condition for the integrability we require that if a solution of Eq. (28) has the following form:

$$\mathbf{u}(x,t)=\sum_{\mu_1\cdots\mu_N=1}^{\infty}\mathbf{C}(\mu_1\cdots\mu_N)\exp\left[i\sum_{r=1}^{N}\sum_{s=1}^{M}\mu_r k_{rs}z_{rs}\right];\quad z_{rs}=x-\frac{\omega(k_{rs})}{t}, \tag{30}$$

then the operator Q must satisfy the following property:

$$Q[\mathbf{u}(x,t)]=\sum_{\mu_1\cdots\mu_N=1}^{\infty}\mathbf{R}(\mu_1\cdots\mu_N)\exp\left[i\sum_{r=1}^{N}\sum_{s=1}^{M}\mu_r k_{rs}z_{rs}\right], \tag{31}$$

where $\mathbf{C}(\mu_1\cdots\mu_N)$ and $\mathbf{R}(\mu_1\cdots\mu_N)$ are M-dimensional vector functions. Similarly as for the KdV equation, the vector function $\mathbf{R}(\mu_1\cdots\mu_N)$ is specified by the nonlinearity. In other words, we require that given a solution of the form (30), the nonlinear operator $Q[\mathbf{u}(x,t)]$ can be expanded in the same set of basis functions as $\mathcal{L}[\mathbf{u}(x,t)]$. In the previous section, we have shown that the nonlinearity of the KdV equation satisfies this condition. In general, large classes of nonlinear operators will have the property (31) and among them we are especially interested in the subclass $\hat{P}$, which plays an important role in nonlinear optics:

$$\hat{P}[\mathbf{u}(x,t)]=P_N\left(\mathbf{u},\frac{\partial\mathbf{u}}{\partial x},\frac{\partial\mathbf{u}}{\partial t},\ldots,\frac{\partial^p\mathbf{u}}{\partial x^q\partial t^{p-q}}\right), \tag{32}$$

where P_N are polynomials of order N. If we let act the linear operator $\mathcal{L}$ onto the solution (30), we obtain the following relationship:

$$\mathcal{L}[\mathbf{u}(x,t)]=\left(\mathbf{I}\sum_{r=1}^{N}\sum_{s=1}^{M}\mu_r\omega(k_{rs})+\sum_{n=1}^{K}\mathbf{A}^{(n)}\left[i\sum_{r=1}^{N}\sum_{s=1}^{M}\mu_r k_{rs}\right]^n\right)\mathbf{u}(x,t). \tag{33}$$

From this result, we can identify a matrix $\mathbf{L}^{(\mu_1\cdots\mu_N)}(k_{ij})$, which is given by

$$\mathbf{L}^{(\mu_1\cdots\mu_N)}(k_{ij})=\mathbf{I}\sum_{r=1}^{N}\sum_{s=1}^{M}\mu_r\omega(k_{rs})+\sum_{n=1}^{K}\mathbf{A}^{(n)}\left[i\sum_{r=1}^{N}\sum_{s=1}^{M}\mu_r k_{rs}\right]^n. \tag{34}$$

This result implies that the coefficients $\mathbf{C}(\mu_1\cdots\mu_N)$ that determine the solution (30) can be determined by solving

$$\mathbf{L}^{(\mu_1\cdots\mu_N)}(k_{ij})\mathbf{C}(\mu_1\cdots\mu_N)=\mathbf{R}(\mu_1\cdots\mu_N). \tag{35}$$

The coefficients $\mathbf{C}(1,0,0,...,0),\mathbf{C}(0,1,0,...,0),...,\mathbf{C}(0,...,0,1)$ are determined by the initial condition.

In principle, we expand the solution $u(x,t)$ in an arbitrary set of basis functions. Suppose as an example a function $\hat{u}(x,t)$ that can be expanded in the set of basis functions $f^{(n)}(x,t|k,\omega)$:

$$\hat{u}(x,t)=\sum_{n=1}^{\infty}\alpha_n f^{(n)}(x,t|k,\omega). \tag{36}$$

We define the set $\mathcal{S}$ as the basis function:

$$\mathcal{S}=\{f^{(1)}(x,t|k,\omega),f^{(2)}(x,t|k,\omega),f^{(3)}(x,t|k,\omega),\ldots\}, \tag{37}$$

which have the following properties:

I: if $f^{(n)}(x,t|k,\omega)\in\mathcal{S}\Rightarrow\frac{\partial}{\partial t}f^{(n)}(x,t|k,\omega)=\hat{\alpha}_n(k,\omega)f^{(m)}(x,t|k,\omega)\quad(f^{(m)}(x,t)\in\mathcal{S})$,

II: if $f^{(n)}(x,t|k,\omega)\in\mathcal{S}\Rightarrow\frac{\partial}{\partial x}f^{(n)}(x,t|k,\omega)=\hat{\beta}_n(k,\omega)f^{(m)}(x,t|k,\omega)\quad(f^{(m)}(x,t)\in\mathcal{S})$,

III: if $f^{(n)}(x,t)\in\mathcal{S}$ and $f^{(m)}(x,t)\in\mathcal{S}\Rightarrow f^{(n)}(x,t)\cdot f^{(m)}(x,t)\in\mathcal{S}$. (38)

The properties I and II guarantee that $\mathcal{L}[\hat{u}(x,t)]$ can be expanded in basis functions $f^{(n)}(x,t|k,\omega)$:

$$\mathcal{L}[\hat{u}(x,t)]=\sum_{n=1}^{\infty}\hat{L}^{(n)}\alpha_n f^{(n)}(x,t|k,\omega),\tag{39}$$

where the precise structure of the operator $\hat{L}^{(n)}$ is determined by the linear differential operator $\mathcal{L}$. Property III in Eq. (38) guarantees nonlinearities of the type $\hat{P}$ can be expanded in the same basis functions $f^{(n)}(x,t|k,\omega)$. If the nonlinearity represented by the operator $\hat{P}$ can also be expanded in the same basis functions $f^{(n)}(x,t|k,\omega)$:

$$Q[\hat{u}(x,t)]=\sum_{n=1}^{\infty}\hat{R}_n f^{(n)}(x,t),\tag{40}$$

then, we can compute the expansion coefficients α_n by solving the relationship

$$\alpha_n=[\hat{L}^{(n)}]^{-1}\hat{R}_n,\tag{41}$$

where α_1 is determined by the initial condition. Of course, we can generalize this result further by replacing Eq. (30) by

$$\mathbf{u}(x,t)=\sum_{\mu_1\cdots\mu_N=1}^{\infty}\hat{\mathbf{C}}(\mu_1\cdots\mu_N)\prod_{i=1}^{N}\prod_{j=1}^{M}f^{(i)}(x,t|\hat{k}_{ij},\hat{\omega}_{ij}).\tag{42}$$

The structure of the solutions proposed in Eq. (42) is, in fact, a generalization of Eq. (30). If we replace $f^{(i)}(x,t|\hat{k}_{ij},\hat{\omega}_{ij})$ by $\exp[i\mu_i k_{ij}z_{ij}]$, the form (30) is retained. Following a similar approach as in the case of Fourier basis functions, we find that if the conditions (38) hold for the solution (42), the linear part of the differential equation acts on the solution (42) like

$$\mathcal{L}[\mathbf{u}(x,t)]=\left(i\mathbf{I}\sum_{i=1}^{N}\sum_{j=1}^{M}\hat{\omega}_{ij}+\sum_{n=1}^{K}\mathbf{A}^{(n)}\left[\sum_{i=1}^{N}\sum_{j=1}^{M}\hat{k}_{ij}\right]^n\right)\mathbf{u}(x,t),\tag{43}$$

where it is assumed that $\partial_t f^{(i)}(x,t|\hat{k}_{ij},\hat{\omega}_{ij})=\hat{\omega}_{ij}f^{(i)}(x,t|\hat{k}_{ij},\hat{\omega}_{ij})$ and $\partial_x f^{(i)}(x,t)=\hat{k}_{ij}f^{(i)}(x,t|\hat{k}_{ij},\hat{\omega}_{ij})$. This relationship enables us to identify an operator $\hat{\mathbf{L}}^{(ij)}\times(\hat{\omega}_{ij},\hat{k}_{ij})$ according to

$$\hat{\mathbf{L}}^{(ij)}(\hat{\omega}_{ij},\hat{k}_{ij})=\left(i\mathbf{I}\sum_{i=1}^{N}\sum_{j=1}^{M}\hat{\omega}_{ij}+\sum_{n=1}^{K}\mathbf{A}^{(n)}\left[\sum_{i=1}^{N}\sum_{j=1}^{M}\hat{k}_{ij}\right]^n\right).\tag{44}$$

If we, moreover, assume that the operator Q is of the class $\hat{P}$ so that

$$Q[\mathbf{u}(x,t)]=\sum_{\mu_1\cdots\mu_N=1}^{\infty}\hat{\mathbf{R}}(\mu_1\cdots\mu_N)\prod_{i=1}^{N}\prod_{j=1}^{M}f^{(i)}(x,t|\hat{k}_{ij},\hat{\omega}_{ij}),\tag{45}$$

then the expansion coefficients are determined by the following linear iteration series:

$$\hat{\mathbf{L}}^{(ij)}(\hat{\omega}_{ij},\hat{k}_{ij})\hat{\mathbf{C}}(\mu_1\cdots\mu_N)=\hat{\mathbf{R}}(\mu_1\cdots\mu_N). \tag{46}$$

From this result, we can conclude that we can transform Eq. (28) into Eq. (46). We can conclude that a NPDE of the form of Eq. (28) is integrable if the following two conditions are satisfied.

(i) The nonlinearity must have such a structure that it can be expanded in the same basis functions as the linear part. In other words, the nonlinearity must guarantee that Eq. (45) is satisfied.

(ii) The inverse matrix $\hat{\mathbf{L}}^{(ij)}(\hat{\omega}_{ij},\hat{k}_{ij})$ must exist.

From this result we can conclude that provided a solution (30) exists, the integrability of the NPDE is completely determined by the linear part of the evolution equation. These are also the conditions that guarantee the integrability of Eq. (28). In the following section, we apply these concepts to examine the integrability of some NPDEs.

IV. EXAMPLES

In this section, we will apply the machinery developed in the previous sections to investigate the integrability of various NPDEs. As a first example, we consider the nonlinear Schrödinger equation:

$$i\,\partial_t u=\partial_{xx}u+2uu^*u. \tag{47}$$

If we substitute

$$u(x,t)=e^{iax}e^{i(a^2-b^2)t}e^{i\phi}\sum_{n=1}^{\infty} A_n e^{-n(bx-2abt)}, \tag{48}$$

into Eq. (47), we obtain

$$\sum_{n=1}^{\infty}[(1-n^2)b^2]A_n e^{-n(bx-2abt)}=2\sum_{n=1}^{\infty}\sum_{l=1}^{n-2}\sum_{m=1}^{n-l-1} A_l A_m A_{n-m-l}e^{-n(bx-2abt)}. \tag{49}$$

It can be verified that for $n=1$ the linear dispersion relationship $\omega=-k^2$ $(k=a+bi)$ is satisfied. Since both the left-hand side and the right-hand side can be expanded in the same Fourier basis functions, we can determine the expansion coefficients by the following recursion relationship:

$$L^{(n)}(k)A_n=R^{(n)};\quad k=a+bi, \tag{50}$$

where

$$L^{(n)}=[1-n^2]b^2;\qquad R^{(n)}=2\sum_{l=1}^{n-2}\sum_{m=1}^{n-l-1} A_l A_m A_{n-m-l}. \tag{51}$$

If we assume that $A_1=A$, then by computing all the coefficients A_n, and carrying out the summation, similarly as in Eq. (11), we obtain the NLS soliton:

$$u(x,t)=Ae^{iax}e^{i(a^2-b^2)t}e^{i\phi}e^{\xi_0}\,\mathrm{sech}(bx-2abt+\xi_0),\qquad \xi_0=-\frac{1}{2}\log\left(\frac{A^2}{4b^2}\right). \tag{52}$$

Similarly as for the KdV equation, the two-soliton solution of the nonlinear Schrödinger equation can be computed by considering solutions:

$$u(x,t)=e^{i(a_1+a_2)x}e^{i(a_1^2+a_2^2-b_1^2-b_2^2)t}e^{i\phi}\sum_{n,m=1}^{\infty} C(n,m)e^{-n([b_1+b_2]x-2[a_1b_1+a_2b_2]t)}. \tag{53}$$

By generalizing this procedure, as presented in Sec. III, the N-soliton solution of the nonlinear Schrödinger equation can be computed.

As a second example we consider the coupled nonlinear Schrödinger equation:

$$\begin{aligned} iu_{1t}&=u_{1xx}+(|u_1|^2+|u_2|^2)u_1=0,\\ iu_{2t}&=u_{2xx}+(|u_2|^2+|u_1|^2)u_2=0. \end{aligned} \tag{54}$$

If we make the following substitution for the solution $\mathbf{u}(x,t)=[u_1(x,t),u_2(x,t)]^T$:

$$\mathbf{u}(x,t)=e^{iax}e^{i(a^2-b^2)t}\sum_{n=1}^{\infty} \mathbf{A}_n e^{-n(bx-2abt)}, \quad \mathbf{A}^{(n)}=(A_1^{(n)},A_2^{(n)})^T, \tag{55}$$

into Eq. (54), it can be verified that both the left-hand side and the right-hand side of Eq. (54) can be expanded in the same basis functions. This is due to the fact that both $u_1(x,t)$ and $u_2(x,t)$ have the same dispersion relation $\omega(k)=-k^2$. As a result, we can determine the expansion coefficients $\mathbf{A}^{(n)}$ by solving the following recursion relation:

$$\mathbf{L}^{(n)}(k)\mathbf{A}^{(n)}=\mathbf{R}^{(n)}, \quad k=a+bi, \tag{56}$$

where

$$\mathbf{L}^{(n)}=\mathbf{I}[1-n^2]b^2; \quad \mathbf{R}^{(n)}=\sum_{l=1}^{n-2}\sum_{m=1}^{n-l-1}\begin{pmatrix} A_1^{(l)}A_1^{(m)}A_1^{(n-m-l)}+A_2^{(l)}A_2^{(m)}A_1^{(n-m-l)}\\ A_1^{(l)}A_1^{(m)}A_2^{(n-m-l)}+A_2^{(l)}A_2^{(m)}A_2^{(n-m-l)}\end{pmatrix}. \tag{57}$$

As a last example, we consider the three-dimensional nonlinear Schrödinger equation:

$$i\,\partial_t u=\sum_{n=1}^{3}\partial_{x_n}^2 u+2uu^*u. \tag{58}$$

If we substitute

$$u(\mathbf{x},t)=e^{i\mathbf{a}\cdot\mathbf{x}}e^{i(\mathbf{a}\cdot\mathbf{a}-\mathbf{b}\cdot\mathbf{b})t}e^{i\phi}\sum_{n=1}^{\infty} A_n e^{-n(\mathbf{b}\cdot\mathbf{x}-2\mathbf{a}\cdot\mathbf{b}t)}, \tag{59}$$

into Eq. (47), we obtain

$$\sum_{n=1}^{\infty}[(1-n^2)\mathbf{b}\cdot\mathbf{b}]A_n e^{-n(\mathbf{b}\cdot\mathbf{x}-2\mathbf{a}\cdot\mathbf{b}t)}=2\sum_{n=1}^{\infty}\sum_{l=1}^{n-2}\sum_{m=1}^{n-l-1} A_lA_mA_{n-m-l}e^{-n(\mathbf{b}\cdot\mathbf{x}-2\mathbf{a}\cdot\mathbf{b}t)}. \tag{60}$$

In Eq. (59) and Eq. (60), it is used that $\mathbf{x}=(x_1,x_2,x_3)^T$, $\mathbf{a}=(a_1,a_2,a_3)^T$, and $\mathbf{b}=(b_1,b_2,b_3)^T$. It can be verified that for $n=1$ the linear dispersion relationship $\omega^2=-\mathbf{k}\cdot\mathbf{k}(\mathbf{k}=\mathbf{a}+\mathbf{b}i)$ is satisfied. Since both the left-hand side and the right-hand side can be expanded in the same Fourier basis functions, we can determine the expansion coefficients by the following recursion relationship:

$$L^{(n)}(\mathbf{k})A_n=R^{(n)}; \quad \mathbf{k}=\mathbf{a}+\mathbf{b}i, \tag{61}$$

where

$$L^{(n)}(\mathbf{k})=[1-n^2]\mathbf{b}\cdot\mathbf{b};\quad R^{(n)}=2\sum_{l=1}^{n-2}\sum_{m=1}^{n-l-1}A_lA_mA_{n-m-l}. \tag{62}$$

Similarly as in the one-dimensional case, explicit solutions of the three-dimensional nonlinear Schrödinger equation can be obtained by carrying out the summation of the expansion coefficients. The discussion can be made more general by using other expansion functions, similarly as in Eq. (53).

V. DISCUSSION AND CONCLUSIONS

We have presented a method to investigate the integrability for NPDEs having a polynomial type of nonlinearity. It has to be remarked that we have assumed throughout this paper that integrability is equivalent with the existence of N solitons. It is shown that two conditions play an important role. The first condition is that the nonlinearity can be expanded in the same basis functions as the linear part. The second condition is that the linearized part of the NPDE has nontrivial solutions. The method is presented by investigating the integrability of the KdV equation as an example. In Sec. III the method is first generalized for NPDEs having solutions that can be expanded in an infinite set of Fourier basis functions. Later on, it is shown that we do not have to restrict ourselves to Fourier basis functions only. Moreover, it is likely that the method also works for nonpolynomial types of nonlinearity, at least if the nonlinearity can be expanded in polynomial form. The paper is concluded by applying the method on the nonlinear Schrödinger equation, the coupled nonlinear Schrödinger equation, and a three-dimensional example. It is shown that we can derive special solutions of the three-dimensional nonlinear Schrödinger equation.

There is an interesting link between the work carried out in this paper and Hirota's method[5,9] in which it is shown for the KdV equation that by applying the transformation

$$u=2(\log F)_{xx}, \tag{63}$$

the solution F can be written as

$$F(x,t)=\det|M|, \tag{64}$$

where the $N\times N$ matrix M has the entries

$$M_{ij}(x,t)=\delta_{ij}+\frac{2(P_iP_j)^{1/2}}{P_i+P_j}e^{(1/2)(\xi_i+\xi_j)};\quad \xi_i=P_ix-P_i^3t-\xi_i^0, \tag{65}$$

and P_i and ξ_i^0 are arbitrary constants. The result presented above was obtained by assuming that the solution $F(x,t)$ can be expanded in a similar series that formed the starting point in this paper:

$$F(x,t)=1+F^{(1)}(x,t)+F^{(2)}(x,t)+\cdots. \tag{66}$$

The major difference between the method presented in this paper and Hirota's method is that the latter succeeded to formulate solutions of the KdV equation by using a finite number of functions $F^{(N)}(x,t)$, whereas our method needs an infinite number of basis functions. It is also interesting to mention that the solutions obtained by Hirota have a similar structure as inverse scattering solutions for rational reflection coefficients as obtained by Sabatier.[10] Moreover, in Ref. 11 it is shown for the KdV equation that Fourier expansion of the inverse scattering solutions as derived by Sabatier is equal to the series (11). The solutions derived in this paper can therefore be regarded as a Fourier expansion of Hirota's solution.

Isospectral problem for Schrödinger operator: Evolutional viewpoint

V. M. Eleonsky and V. G. Korolev[a)]
Lukin Research Institute of Physical Problems, Zelenograd, Moscow, Russia, 103460

(Received 15 May 1998; accepted for publication 7 December 1998)

An isospectral transform of the Schrödinger operator is considered as an evolutional problem. For a transform defined by the McKean–Trubowitz flows associated evolutional equations are derived. It is shown that for one-level and two-level flows these equations can be split into integrable Liouville equations. A relationship between the Liouville equations and the Darboux transforms is discussed; this analysis suggests that the evolutional equations can be split into the Liouville equations in the general case. A Hamiltonian formulation of the isospectral transform defined by the McKean–Trubowitz flows is presented. It is shown that this transform is performed by a canonical change of variables, which is related to the Darboux transform. © *1999 American Institute of Physics.*

I. INTRODUCTION

Any progress in a study of isospectral transforms for the Schrödinger operator always gives rise to particular interest. On the one hand, such transforms provide a tool to extend a class of models for which the Schrödinger equation can be solved exactly; this explains the special interest of isospectral transforms among physicists. For mathematicians, to develop a theory of the Sturm–Liouville operator (and for them, the Schrödinger operator is nothing but its particular case) always was a generous classical challenge. In some branches of mathematics (i.e., in the theory of the Korteweg–de Vries equation) the Schrödinger operator plays an auxiliary role; its isospectral properties are related with an existence of soliton solutions to evolutional equations.[1]

The Darboux transform[2] is known as the most popular isospectral transform of the Schrödinger operator. Since Darboux's earliest papers,[3] this method was extensively developed;[4,5] it is mostly used in building new operators whose spectrum differs from the spectrum of the initial Schrödinger operator by one eigenvalue.

The Darboux transform of the Schrödinger operator is closely related with a number of modern approaches, such as the factorization method[6–8] (which, in its turn, is a basis for the theory of supersymmetry in physics[9,10]); the method of dressing chains;[11] the method of nonlinear spectrum shift operators,[12] etc.

There exists another approach to the isospectral problem; it involves an investigation of isospectral phase flows. This branch of the problem goes back to the theory of integrable ''soliton'' equations and is related with a Hamiltonian description of the evolution that is governed by such equations. Comparatively recently, an important step was made in this direction: there appeared the paper by McKean and Trubowitz;[13] the authors studied phase flows of the form

$$U_t=\sum_n \tau_n[\psi_n^2]_x; \quad \tau_n\in\mathcal{R} \tag{1}$$

(ψ_n are eigenfunctions of discrete states); it was shown that in this case the deformation of the potential as well as of the eigenfunctions is isospectral; the flows (1) were analyzed from the

[a)]Electronic mail: korolev@nonlin.msk.ru viewpoint of symplectic geometry in associated function spaces. Later, the results exposed in this paper were made more strict, generalized and extended by Levitan in Ref. 14.

Note that in both the Darboux transform and the McKean and Trubowitz approach *closed evolutional equations* (i.e., partial differential equations where one of the partial derivatives is in the deformation parameter t) for eigenfunctions as well as for a potential are not derived. So the solutions for the isospectral deformation of eigenfunctions and a potential were not looked for as a result of the integration of such evolutional equations. This (quite natural) problem was formulated and solved in our paper.[15] There we derived coupled evolutional equations of the Liouville type that govern the isospectral deformation defined by the flows (1). In the simplest case, when the sum in (1) contains the only term, those equations degenerate into an integrable Liouville equation for the evolutions both of the eigenfunction that ''specifies'' the flow and of the potential itself; and into d'Alembert equations for the other eigenfunctions. The simple asymptotical analysis performed in Ref. 15 showed that such an evolution is accompanied by splitting off a local potential well, which asymptotically gains the form of the soliton reflectionless potential $\gamma^2/\cosh^2[\gamma\xi]$; and this scenario holds for a wide class of potentials, including scattering potentials as well as the potential of the harmonic (and anharmonic) oscillator.

In the present paper we develop the ''evolutional approach'' to the isospectral problem using the flow (1) in the following directions.

(i) We consider a generalization of this flow in the form

$$U_t=\sum_k \tau_k[\psi_k\tilde{\psi}_k]_x, \tag{2}$$

where $\psi_k(x,t)$ and $\tilde{\psi}_k(x,t)$ are a pair of solutions to the Schrödinger equation with the parameter E_k, but only ψ_k must be an eigenfunction. For this case we derive proper PDEs for an evolution of the eigenfunctions of the Schrödinger operator.

(ii) Returning to the original McKean–Trubowitz flows we study a ''two-level'' flow [in the expression (1) two constants τ_n are nonzero] in detail. It is found out that an associated pair of evolutional equations splits into *two integrable Liouville equations* for certain combinations of the eigenfunctions for those states and of their derivatives in x. The integration of the evolutional equation for the potential provides a solution, which can be rewritten as the well-known formula for the isospectral deformation of the potential that arises in the Gelfand–Levitan–Marchenko theory. It seems likely that the conclusion about the splitting of the coupled evolutional equation into independent integrable Liouville equations can be extended to the general case of arbitrary multi-level flows (1).

(iii) We show that the Darboux transform is also directly related with the integrable Liouville equations and the McKean and Trubowitz ''flow'' approach.

(iv) Finally, in the case of two-level flow, we present a Hamiltonian formulation of the isospectral evolution that obeys the Liouville equations; we show that splitting of the initial coupled equations into the Liouville equations is performed by a canonical change of variables.

The paper is arranged as follows: in Sec. II we discuss the role of the McKean–Trubowitz flows in the isospectral problem; in Sec. III we derive evolutional equations for the generalization of the McKean–Trubowitz flows. In Sec. IV we present a brief review of the results related to the simplest flow (''individual,'' in the terminology of Ref. 13). In Sec. V we study evolutional equations for the two-level flow; we discuss relations between the Darboux transform and the Liouville equations and between them both and the McKean–Trubowitz flows. Finally, in Sec. VI we develop a Hamiltonian description for the two-level case.

II. ON A NOTION OF ISOSPECTRAL FLOWS. THE McKEAN–TRUBOWITZ FLOWS

To begin with, we would like to say a few common words concerning the ''flow'' approach to the Schrödinger isospectral problem; this will help us in clearing up a role of the flows studied by McKean and Trubowitz in the general context of the isospectral problem.

Consider the Sturm–Liouville problem for the 1D Schrödinger operator in $\mathcal{R}^1$:

$$-\tfrac{1}{2}(\psi_n)_{xx}+U\psi_n=E_n\psi_n, \quad n\geqslant 0, \quad \lim_{x\to\pm\infty}\psi_n=0. \tag{3}$$

Let U and ψ_n be functions of parameter t (it is a deformation parameter and should not be confused with the physical time: we deal with a *stationary* Schrödinger equation). A dependence of the eigenelements of the problem (3) on the parameter t will be specified by the following relation:

$$U_t=F(U,U_x,\ldots;\{\psi_k\},\{(\psi_k)_x\},\ldots). \tag{4}$$

If the right-hand side of this relation can be represented as a gradient (in x) of a variational derivative for a certain functional of the potential U, then such a relation has a meaning of *a phase flow*. Since we will mostly deal with relations (4) that admit of this representation, we will say that relation (4) specifies a phase flow.

Demand that the eigenvalues E_n do not vary as the potential deforms. As follows from (3), the conditions,

$$(E_n)_t=0, \quad \forall t; \quad n\geqslant 0, \tag{5}$$

lead to the system of equations,

$$\int_{-\infty}^{+\infty} U_t\psi_n^2=0, \quad n\geqslant 0. \tag{6}$$

Hence, we get a *necessary* condition for a flow of type (4) to be *isospectral* (to preserve the spectrum of the Schrödinger operator):

$$\int_{-\infty}^{+\infty} F\psi_n^2=0, \quad n\geqslant 0. \tag{7}$$

In the other words, for any isospectral flow the functional F is to belong to the orthogonal complement to the set $\{\psi_n^2\}$.

Return to the Schrödinger equation (3). Differentiating it in x gives us the following equations:

$$\tfrac{1}{8}(\psi_n)^2_{xxx}-\tfrac{1}{2}U_x\psi_n^2-(U-E_n)(\psi_n^2)_x=0, \quad n\geqslant 0, \tag{8}$$

which can be rewritten in the form

$$\mathbf{L}[\psi_n^2]_x=E_n[\psi_n^2]_x, \quad n\geqslant 0, \tag{9}$$

if one introduces the integro-differential operator,

$$\mathbf{L}\equiv -\tfrac{1}{8}D^2-\tfrac{1}{2}U_xD^{-1}+U, \tag{10}$$

where $Dg(x)\equiv dg/dx$, $D^{-1}g(x)\equiv\int_x^{+\infty}g(x')dx'$ (this remark is usually assigned to Hermite; see, for instance, the monograph[16]).

The operator $\mathbf{L}$ has two important properties (quite a large number of them is listed in the book[17]).

(1) The functions $[\psi_n^2]_x$ are its eigenfunctions, which correspond to the eigenvalues E_n; this fact is expressed by formula (9). So, if the set of pairs $\{(E_m,\psi_m)\}$ is a set of eigenelements for the operator $H=-(1/2)D^2+U$, then the set $\{(E_m,[\psi_m^2]_x)\}$ is a set of eigenelements for the operator $\mathbf{L}$. Note that $\mathbf{L}$ is not a Hermitian operator, so the set $[\psi_n^2]_x$ is not to be complete.

(2)

$$\int_{-\infty}^{+\infty} \psi_n^2 \mathbf{L} f(x)\, dx = E_n \int_{-\infty}^{+\infty} \psi_n^2 f(x)\, dx, \quad n \geqslant 0, \tag{11}$$

for quite a wide class of functions $f(x)$ (this class includes functions that grow at infinity slower than the exponential). This property implies that if some relation $U_t = F$ determines an isospectral flow, then all the flows $U_t = \mathbf{L}^k F$, $k > 0$ are also isospectral: each of them satisfies the condition (6). The last feature of the operator $\mathbf{L}$ is widely used when one builds hierarchies of integrable evolutional equations, and is the reason to call it *a recursion operator*.

Note that the operator $\mathbf{L}$ can be written in the following symmetric form:

$$\mathbf{L} = -\tfrac{1}{8} D^2 - \sqrt{U} D \sqrt{U} D^{-1} \tag{12}$$

(here U is assumed to be non-negative; but, obviously, the formula can be generalized).

Now let us return to the isospectral problem and compare two simple isospectral flows. The first of them is a so-called ''shift flow:''

$$U_t = c U_x = \frac{c}{2} \frac{\partial}{\partial x} \frac{\delta \Lambda}{\delta U}; \quad \Lambda = \int dx U^2. \tag{13}$$

Really,

$$\int_{-\infty}^{+\infty} U_x \psi_n^2\, dx = 0, \tag{14}$$

in the same class of potentials that grow at infinity slower than the exponential; this simple result immediately follows from Eq. (3). Usually, however, to avoid a singularity in t, one demands a ''good behavior'' of U_x at infinity (in particular, for scattering potentials $U_x \to 0$ as $x \to \pm\infty$).

Sequentially applying the recursion operator $\mathbf{L}$ to the shift flow (13), one builds a hierarchy of KdV flows:

$$\begin{gathered} k=0: \quad U_t = c_0 U_x, \\ k=1: \quad U_t = c_1 (U_{xxx} + 6(U^2)_x), \\ \cdots \\ k=m: \quad U_t = c_m \mathbf{L}^m U_x. \\ \cdots \end{gathered}$$

Let us stress again that all these flows lie in the orthogonal complement to the set $\{\psi_n^2\}$.

The second elementary type of isospectral flows is given by the expression

$$U_t = \sum_n \tau_n [\psi_n^2]_x; \quad \tau_n \in \mathcal{R}; \tag{15}$$

actually, it can be shown that

$$\int_{-\infty}^{+\infty} \psi_n^2 [\psi_m^2]_x\, dx = 0, \quad \forall n,m \geqslant 0, \tag{16}$$

by virtue of Eq. (3); in the other words, the sets $\{\psi_n^2\}$ and $\{[\psi_n^2]_x\}$ lie in orthogonal complements. The flows (15) and their isospectral property were studied in detail in Ref. 13; in what follows they will be referred to as ''the McKean–Trubowitz flows'' or simply ''MKT flows.''

What sets off the MKT flows among other isospectral flows? Note two their important properties.

(a) The functional F that determines the MKT flow does not depend on the potential (only on the eigenfunctions, which always behave well). So these flows exist both for scattering potentials and for potentials *growing at infinity* (e.g., for the potential of the harmonic oscillator).

(b) As it follows from the first property of the recursion operator $\mathbf{L}$, the functions $[\psi_n^2]_x$ are its eigenfunctions. It means that it is impossible to build an $\mathbf{L}$-hierarchy starting with the MKT flow:

$$\mathbf{L}\sum_n \tau_n[\psi_n^2]_x=\sum_n \tau_n\mathbf{L}[\psi_n^2]_x=\sum_n \tau_n'[\psi_n^2]_x. \tag{17}$$

Thus, the operator $\mathbf{L}$ simply changes the weights τ_n, but the flow is related with the linear envelope of the set $\{[\psi_n^2]_x\}$, as before. On the contrary, the elements of a functional space that are associated with different flows of the KdV hierarchy, are sequentially mapped onto each other by the operator $\mathbf{L}$. One can say loosely that the MKT flows are ''eigenflows'' of the recursion operator $\mathbf{L}$; this, in particular, explains an interest in a deeper study of their features.

Note that these two elementary isospectral flows can coincide: as is well known (see, for example, Ref. 17), the reflectionless soliton potentials can be represented in the form

$$U=2\sqrt{2}\sum_{n=0}^{N} \sqrt{-E_n}\psi_n^2, \tag{18}$$

where the sum is taken over all the discrete states of the Schrödinger operator. So, if we specify the weights τ_n by the relations $\tau_n=c\sqrt{-E_n}$, then the MKT flow with these weights reduces to the simplest shift flow (the first flow of the KdV hierarchy) for those potentials; hence, each of the higher k-th flows of the KdV hierarchy coincides with the MKT flow with properly changed weights:

$$\tau_n^{(k)}=c\sqrt{-E_n}E_n^k. \tag{19}$$

It is clear that the expressions for the KdV flows are evolutional equations for the potential U themselves. The situation with the MKT flows is more complex. In the paper[15] we showed that in the case of ''individual'' MKT flow (all $\tau_n=0$ but one) the deformation both of the potential and of the eigenfunctions is related to the integrable Liouville equation $S_{x\tau}=\exp 2S$. In the present paper we show that an analogous statement holds for more complex MKT flows; moreover, everything indicates that this is true for any McKean–Trubowitz flow.

III. EQUATIONS OF ISOSPECTRAL DEFORMATION FOR SCHRÖDINGER OPERATORS: GENERAL CASE

Let us supplement the Schrödinger problem (3) by the relation

$$U_t=\sum_k \tau_k(\psi_k\tilde{\psi}_k)_x, \tag{20}$$

where $\psi_k(x,t)$ and $\tilde{\psi}_k(x,t)$ are a pair of solutions to the Schrödinger equation with the parameter E_k and $\{\psi_k,E_k\}$ is an eigenelement:

$$\int_{-\infty}^{+\infty}\psi_k^2(x',t)dx'<\infty, \quad \forall t. \tag{21}$$

Evidently, relation (20) is an analog and a generalization of Eq. (15), which determines MKT flows.

Linear independence of the functions ψ_k and $\tilde{\psi}_k$ is characterized by the Wronskian,

$$w_k(t)=[\psi_k,\tilde{\psi}_k]\equiv\psi_k(\tilde{\psi}_k)_x-(\psi_k)_x\tilde{\psi}_k. \tag{22}$$

In the case $w_k(t)\neq 0$ we do not know a representation of the relation (20) in the form of a phase flow (with a gradient of a variational derivative on the right-hand side).

Let us derive equations that determine an evolution of the eigenelements $\{\psi_m,E_m\}$, $m=0,1,...$, of the Schrödinger operator under the condition (20). Differentiating Eq. (3) in t and substituting the right-hand side of Eq. (20) for U_t, we obtain the system of equations:

$$\psi_m^2(E_m)_t+\frac{1}{2}[\psi_m(\psi_m)_{xt}-(\psi_m)_x(\psi_m)_t]_x=\sum_k \tau_k(\psi_k\tilde{\psi}_k)_x, \quad m=0,1,\dots . \tag{23}$$

Now we take into account the following identities:

$$\psi_m^2(\psi_k\tilde{\psi}_k)_x\equiv\tfrac{1}{2}(\psi_m^2\psi_k\tilde{\psi}_k)_x+\tfrac{1}{2}\{\psi_m^2(\psi_k\tilde{\psi}_k)_x-(\psi_m^2)_x\psi_k\tilde{\psi}_k\}, \tag{24}$$

and

$$\psi_m^2(\psi_m\tilde{\psi}_m)_x-(\psi_m^2)_x\psi_m\tilde{\psi}_m\equiv\psi_m^2 w_m(t),$$

$$\psi_m^2(\psi_k\tilde{\psi}_k)_x-(\psi_m^2)_x\psi_k\tilde{\psi}_k\equiv\frac{\{[\psi_m,\psi_k]\cdot[\psi_m,\tilde{\psi}_k]\}_x}{2(E_m-E_k)}, \quad k\neq m.$$

Then the system (23) can be written as follows:

$$\left\{(E_m)_t-\frac{1}{2}\tau_m w_m(t)\right\}\psi_m^2=-\frac{1}{2}[\psi_m(\psi_m)_{xt}-(\psi_m)_x(\psi_m)_t]_x+\frac{1}{2}\sum_k \tau_k[\psi_m\psi_k\tilde{\psi}_k]_x$$
$$+\frac{1}{2}\sum_{k\neq m}\frac{\tau_k}{2(E_m-E_k)}[\psi_m,\psi_k][\psi_m,\tilde{\psi}_k]. \tag{25}$$

Integrating Eqs. (25) in $x\in\mathcal{R}$, we eventually find that the evolution of the eigenvalues E_m and the eigenfunctions ψ_m obeys the following equations:

$$(E_m)_t=\tfrac{1}{2}\tau_m w_m(t), \quad m=0,1,..., \tag{26}$$

$$\left[\frac{(\psi_m)_x}{\psi_m}\right]_t=\sum_k \tau_k\psi_k\tilde{\psi}_k+\sum_{k\neq m}\frac{\tau_k}{2\psi_m^2(E_m-E_k)}[\psi_m,\psi_k][\psi_m,\tilde{\psi}_k]. \tag{27}$$

Thus, for all the states with ''weights'' $\tau_m\neq 0$ the evolution of the eigenvalues $E_m(t)$ is described by the simple formula:

$$E_m(t)=E_m^0+\frac{\tau_m}{2}\int_0^t w_m(t')dt'. \tag{28}$$

In the other words, only those eigenvalues move, for which $w_m(t)\neq 0$ [i.e., the relation (20) contains a corresponding pair of linearly *independent* functions]. Eigenvalues are constant if $w_m(t)=0$. All the other eigenvalues (for which $\tau_m=0$) are also invariant [regardless of $w_m(t)$, naturally].

IV. ONE-LEVEL ISOSPECTRAL DEFORMATION

Let us present a brief review of results for the simplest case: the relation (20) contains only one product of the functions ψ_m, $\tilde{\psi}_m$; the detailed analysis, including a study of asymptotical behavior both of the eigenfunctions and of the potential, together with a description of the one-level isospectral deformation in terms of explicit unitary operators, was presented in our paper.[15]

Let all $\tau_m=0$ except for the only $\tau_n=1$. In this case the general equations (26), (27) split into separate equations for the evolution of the eigenelement (ψ_n, E_n) and for the evolution of the other eigenelements $\{(\psi_m, E_m), m\neq n\}$:

$$(E_n)_t=\tfrac{1}{2}w_n(t),\quad (E_m)_t=0,\quad m\neq n;\quad (\mathrm{D}_{\log}\psi_n)_t=\psi_n\tilde{\psi}_n,$$

$$(\mathrm{D}_{\log}\psi_m)_t=\psi_n\tilde{\psi}_n+\frac{[\psi_m,\psi_n][\psi_m,\tilde{\psi}_n]}{2\psi_m^2(E_m-E_n)},\quad m\neq n$$

[for brevity, hereafter we use the operator of ''logarithmic derivative'' $\mathrm{D}_{\log}$: $\mathrm{D}_{\log}G(x)\equiv G_x/G \equiv(\ln|G|)_x$].

In the case $\tilde{\psi}_n=\psi_n$ (''individual'' MKT flow) we have $w_n(t)=0$, and the above equations take the form

$$(E_n)_t=(E_m)_t=0,\quad (\mathrm{D}_{\log}\psi_n)_t=\psi_n^2, \tag{29}$$

$$(\mathrm{D}_{\log}\psi_m)_t=\psi_n^2+\frac{[\psi_m,\psi_n]^2}{2\psi_m^2(E_m-E_n)},\quad m\neq n. \tag{30}$$

Equation (29), which determines evolution (in the parameter t) of the ''specifying'' eigenfunction ψ_n can be rewritten in the classical form of the *integrable Liouville equation* after the substitution $\psi_n\rightarrow\exp S_n$. It has the following solution:

$$\psi_n(x,t)=\frac{\psi_n^0}{1+(e^t-1)\int_x^{+\infty}[\psi_n^0]^2dx'}. \tag{31}$$

Here the t-function, which is arbitrary in the general case, is chosen exponential to keep the norm of the eigenfunction.

After a few transforms, the equations (30) for the other eigenfunctions can be written in the simple form

$$\frac{\partial}{\partial t}\mathrm{D}_{\log}\frac{\psi_m}{[\psi_n,\psi_m]}=0. \tag{32}$$

They are integrated in an obvious way; this allows us to write down the evolution of any function $\psi_m(x,t)$ if we know a solution for the ''main'' eigenfunction $\psi_n(x,t)$.

Note that by virtue of the Schrödinger operator the Wronskian of these functions can always be expressed through the integral of their product, and *vice versa*:

$$[\psi_n,\psi_m]=(E_n-E_m)\int_x^{\infty}\psi_n\psi_m dx'; \tag{33}$$

this relation can be used if convenient.

Of course, formula (31) as well as the solutions for the other eigenfunctions ψ_m, $m\neq n$ are known in the literature for quite a long time; they were also presented by McKean and Trubowitz in Ref. 13; we have obtained these results in the framework of the evolutional approach, considering the isospectral deformation as an evolution in the parameter t; deriving associated PDEs and integrating them.

Return to the generalization of the individual flow. Let $\tilde{\psi}_n \neq \psi_n$ $[w_n(t) \neq 0]$. Expressing $\tilde{\psi}_n$ from Eq. (20) and substituting it into the equation for the evolution of ψ_n, we get

$$(\mathrm{D}\log\psi_n)_t = \psi_n^2\left(1 + w_n(t)\int^x \frac{dx'}{\psi_n^2(x',t)}\right). \tag{34}$$

On the other hand, expressing $\tilde{\psi}_n$ from the equation for the evolution of ψ_n and substituting it into the formula for the flow (20), we obtain an equation, which is convenient to rewrite introducing the function $\phi_n \equiv 1/\psi_n$:

$$\left[\frac{(\phi_n)_{xx}}{\phi_n}\right]_t = -w_n(t); \tag{35}$$

it can be integrated in t; as a result we find

$$\frac{(\phi_n)_{xx}}{\phi_n} - \frac{(\phi_n^0)_{xx}}{\phi_n^0} = -2(E_n - E_n^0). \tag{36}$$

If ψ_n^0 is given, then this is the Schrödinger equation for ϕ_n. Taking into account that $(\psi_n^0)_{xx}/\psi_n^0 = 2(U^0 - E_n^0)$, we can rewrite it in the form

$$-\frac{1}{2}(\phi_n)_{xx} + \left\{U^0 - \frac{d^2}{dx^2}\ln|\psi_n^0|\right\}\phi_n = E_n\phi_n. \tag{37}$$

This formula clearly witnesses that in the case of individual flow defined by a pair of linearly independent functions, the integration of the associated evolutional equations leads to the same results as does the Darboux transform.

Note also that the functions $\psi_n(x,t)$ can be expressed through solutions of the Schrödinger equations at $t=0$ (this is especially important if those solutions are known explicitly):

$$\psi_n(x,t) = \frac{\psi_n^0}{[\psi_n^0, \chi^0]}; \tag{38}$$

here χ^0 is a solution of the following Schrödinger equation:

$$-\tfrac{1}{2}(\chi^0)_{xx} + U^0\chi^0 = E_n(t)\chi^0 \tag{39}$$

[with the initial potential U^0, but for the value $E_n(t)$ already shifted].

We stress that all the formulas related to the case $w_n(t) \neq 0$ directly transform to the corresponding formulas for the case $w_n(t) = 0$; except for expressions (38), (39): when they are derived, the assumption $E_n(t) - E_n^0 \neq 0$ is used. Note also that the above formulas for the generalized MKT flow were also obtained by McKean and Trubowitz in their approach.[13]

Up to this point we dealt with equations that describe a deformation of *eigenfunctions* of the Schrödinger operator. Using them, one can derive an equation that governs a deformation of *the potential* $U(x,t)$ for the generalization of the individual flow:

$$\frac{\partial}{\partial t}\left[\mathrm{D}_{\log} Y - \frac{w_n(t)}{Y}\right] = 2Y, \tag{40}$$

where

$$Y=\frac{\partial}{\partial t}\int^{x}U(x',t)dx'. \tag{41}$$

If $w_n(t)=0$ it also degenerates into the Liouville equation. In this case the analysis of the asymptotical behavior for $U(x,t)$ shows,[15] that for a wide class of potentials, such a deformation involves the formation of moving local wells in the potential relief; their form is asymptotically close to the reflectionless soliton potential:

$$\Delta U(x\sim x_0(t);t\to\infty)\approx-\frac{2(U^0(x_0)-E_n)}{\cosh^2\sqrt{2(U^0(x_0)-E_n)}(x-x_0(t))}, \tag{42}$$

where the ''center'' $x_0(t)$ of the moving soliton well is determined by the equation

$$\int^{x_0}\sqrt{2(U^0(x')-E_n)}dx'=\frac{t}{2}. \tag{43}$$

The eigenfunction that defines the flow (for which $\tau_n\neq 0$) is localized in this well; as $t\to\infty$ the domains of localization move to infinity, which is related with disappearance of the corresponding state from the spectrum. This process is accompanied by a deformation of all the other functions in such a way that the number of nodes and zeros for the other eigenfunctions corresponds to the new spectrum after the ''governing'' state is removed.

It is important that such a scenario (a splitting off of local potential wells of soliton form) is realized not only for the scattering potentials but also for the potential of *the harmonic oscillator*.

V. ANALYSIS OF ISOSPECTRAL EVOLUTION FOR TWO-LEVEL FLOW

Now consider a case of the ''two-level'' MKT flow. Assume that in the relation (20) τ_n, $\tau_l\neq 0$ for two states, and for all the other states $\tau_m=0$, $m\neq n,l$; let also $w_m=0$, $m=0,1,\ldots$. Since $w_n=w_l=0$, the evolution of the system is not accompanied by a shift of the eigenvalues E_n, E_l (as we know, for the other states eigenvalues do not change in any case). Then Eqs. (26), (27), which describe a deformation of the eigenfunctions of the Schrödinger problem, take the form

$$(\mathrm{D}_{\log}\psi_l)_t=\tau_n(\psi_n)^2+\tau_l(\psi_l)^2-\frac{\tau_n}{2\Delta_{nl}}\left\{\frac{[\psi_l,\psi_n]}{\psi_l^2}\right\}^2, \tag{44}$$

$$(\mathrm{D}_{\log}\psi_n)_t=\tau_n(\psi_n)^2+\tau_l(\psi_l)^2+\frac{\tau_l}{2\Delta_{nl}}\left\{\frac{[\psi_l,\psi_n]}{\psi_n^2}\right\}^2, \tag{45}$$

where $\Delta_{nl}=E_n-E_l$.

For the convenience of the further analysis, rewrite this pair of coupled evolutional equations as follows:

$$(\mathrm{D}_{\log}\psi_l)_t=\Sigma-\frac{\tau_n}{2\Delta_{nl}}\left(\psi_n\,\mathrm{D}_{\log}\left[\frac{\psi_n}{\psi_l}\right]\right)^2, \tag{46}$$

$$(\mathrm{D}_{\log}\psi_n)_t=\Sigma+\frac{\tau_l}{2\Delta_{nl}}\left(\psi_l\,\mathrm{D}_{\log}\left[\frac{\psi_n}{\psi_l}\right]\right)^2; \tag{47}$$

here we denoted $\Sigma\equiv\tau_n\psi_n^2+\tau_l\psi_l^2$.

Subtracting these equations, we get

$$\left(\mathrm{D}_{\log}\left[\frac{\psi_n}{\psi_l}\right]\right)_t=\frac{\Sigma}{2\Delta_{nl}}\left(\mathrm{D}_{\log}\left[\frac{\psi_n}{\psi_l}\right]\right)^2, \tag{48}$$

so

$$\Sigma=-\frac{\partial}{\partial t}\left\{\frac{2\Delta_{nl}}{\mathrm{D}_{\log}\left[\frac{\psi_n}{\psi_l}\right]}\right\}. \tag{49}$$

Furthermore, from a pair of Schrödinger equations for the functions ψ_n, ψ_l for some potential U follows:

$$\frac{1}{2}\frac{(\psi_n)_{xx}}{\psi_n}+E_n=\frac{1}{2}\frac{(\psi_l)_{xx}}{\psi_l}+E_l, \tag{50}$$

which we rewrite in the form

$$[\psi_n,\psi_l]_x=2\Delta_{nl}\psi_n\psi_l. \tag{51}$$

Note that this relation must be satisfied by any pair of eigenfunctions of the Schrödinger operator for which the difference between eigenvalues equals Δ_{nl}. In the other words, for the equations that determine the evolution in t the expression (51) is an additional condition, which is to hold at any t; *a priori* it is not known whether this condition is substantial or holds always by virtue of the equations themselves (i.e., in some sense, it is a *a local integral* of those equations).

Dividing both sides of Eq. (51) by $[\psi_n,\psi_l]$, and comparing the result with Eq. (49), we find that

$$\Sigma=\frac{\partial}{\partial t}\mathrm{D}_{\log}[\psi_n,\psi_l]\equiv a(x,t). \tag{52}$$

If we return to a definition of the flow ($U_t=\Sigma_x$), we notice that the function $a(x,t)$ that denotes the right-hand side of the relation (52) coincides with the antiderivative of the potential $V(x,t)$: $V_x=U$ up to an arbitrary term depending on x only.

Substituting the expression for Σ from (52) into the coupled equations (44)–(45), we obtain two *separated* equations for the functions $\{[\psi_n,\psi_l]/\psi_l\}^2$ and $\{[\psi_n,\psi_l]/\psi_n\}^2$:

$$\frac{\partial}{\partial t}\mathrm{D}_{\log}\left\{\frac{[\psi_n,\psi_l]}{\psi_l}\right\}^2=+\frac{\tau_n}{\Delta_{nl}}\left\{\frac{[\psi_n,\psi_l]}{\psi_l}\right\}^2, \tag{53}$$

$$\frac{\partial}{\partial t}\mathrm{D}_{\log}\left\{\frac{[\psi_n,\psi_l]}{\psi_n}\right\}^2=-\frac{\tau_l}{\Delta_{nl}}\left\{\frac{[\psi_n,\psi_l]}{\psi_n}\right\}^2. \tag{54}$$

Thus, for the McKean–Trubowitz flow defined at two eigenfunctions of the Schrödinger operator, the evolution of these combinations obeys two *independent* integrable equations that reduce to classical Liouville equations after substitutions of the kind $[\psi_n,\psi_l]/\psi_{n,l}\rightarrow\exp S_{n,l}$.

It can be proved that expression (51) is *a local integral* for that pair of independent equations (for any choice of two arbitrary functions of t in their solutions). In terms of Dirac's description of Hamiltonian systems with constraints (see the next section) this expression is classified as ''a complementary condition that is not substantial by virtue of a dynamics of the system'' (this means that such a condition does not violate an integrability of the dynamical system).

Consider the ''diagonalizing'' transform

$$\{\psi_n,\psi_l\}\Rightarrow\left\{\Phi_n=+\frac{\psi_l}{[\psi_n,\psi_l]},\quad \Phi_l=-\frac{\psi_n}{[\psi_n,\psi_l]}\right\} \tag{55}$$

in more detail. This transform is antisymmetric:

$$\Phi_n=+\frac{\psi_l}{[\psi_n,\psi_l]},\quad \psi_n=-\frac{\Phi_l}{[\Phi_n,\Phi_l]},$$
$$\Phi_l=-\frac{\psi_n}{[\psi_n,\psi_l]},\quad \psi_l=+\frac{\Phi_n}{[\Phi_n,\Phi_l]}; \tag{56}$$

since

$$[\Phi_n,\Phi_l]\cdot[\psi_n,\psi_l]=-1. \tag{57}$$

The condition (50) or (51) (which was written as a condition for the functions ψ_n and ψ_l to be solutions of the Schrödinger equation for the same potential but for different values E_n and E_l) can be rewritten in the form

$$\frac{1}{2}\frac{(\Phi_n)_{xx}}{\Phi_n}+E_n=\frac{1}{2}\frac{(\Phi_l)_{xx}}{\Phi_l}+E_l. \tag{58}$$

It means that the functions $\psi_l/[\psi_n,\psi_l]$, $\psi_n/[\psi_n,\psi_l]$ are also solutions of the Schrödinger equation for a potential, which differs from the potential for the functions ψ_n,ψ_l, but for the same values of the parameters E_n,E_l. Indeed, it is not difficult to prove that the transform (55) can be represented as a product of two Darboux transforms defined at the states with eigenvalues E_n and E_l, respectively.

The explicit formula for the change of the potential by the transform (55) is as follows:

$$U'=U+\frac{d}{dx}\mathrm{D}_{\log}[\psi_n,\psi_l]. \tag{59}$$

Let us try to understand the following: why it is after the transform to the functions Φ_n^{-2},Φ_l^{-2} that the initial coupled evolutional equations for the functions ψ_n,ψ_l are diagonalized in our problem? The answer is related to the following simple observation: if some function $F(x,t)$ is a solution to the equation

$$(\mathrm{D}_{\log}F)_t=F \tag{60}$$

(which reduces to the Liouville equation $S_{xt}=\exp S$), then the function $\Phi=F^{-1/2}$ is a solution to the equation

$$\left\{\frac{\Phi_{xx}}{\Phi}\right\}_t=0, \tag{61}$$

and *vice versa* (generically, in the latter case the ''times'' t in these equations are not the same, but they are related by a simple scaling).

It is easy to see that Eq. (61) is satisfied by a family of solutions to the Schrödinger equation with a fixed potential and a fixed parameter E, if we identify t with a substantial parameter of that family (the parameter that cannot be removed by scaling). In the other words, if we continuously change the parameter t and thus move over solutions $\Phi^{(t)}$ of the Schrödinger equation with a fixed potential and fixed parameter E, then the functions $F^{(t)}=(\Phi^{(t)})^{-2}$ ''evolve'' in accordance with the Liouville equations (60); it is important that E is constant.

Thus, the Liouville equations for the functions Φ^{-2} arise in the problem on the isospectral deformation quite naturally. A switch from the set of eigenfunctions ψ_k to the set of functions Φ_k is performed by transforms of the Darboux type: in the case of ''individual'' MKT flows it is a simple Darboux transform; in the case of ''two-level'' MKT flow, which we study, it is the transform (55) that can be represented as an analogous double (consecutive) transform.

Now return to the separated equations for the functions $\Phi_n^{-2}=([\psi_n,\psi_l]/\psi$ and $\Phi_l^{-2}=([\psi_n,\psi_l]/\psi_n)^2$ (53), (54). They can be written in the form

$$\frac{\partial}{\partial t_1}\mathrm{D}_{\log}\frac{1}{\Phi_n^2}=+\frac{1}{\Phi_n^2}, \tag{62}$$

$$\frac{\partial}{\partial t_2}\mathrm{D}_{\log}\frac{1}{\Phi_l^2}=-\frac{1}{\Phi_l^2}, \tag{63}$$

where $t_1=\tau_n/\Delta_{nl}t,\ t_2=\tau_l/\Delta_{nl}t$. Solutions of these equations are as follows:

$$\frac{1}{\Phi_n^2}=+2\frac{\partial}{\partial t_1}\mathrm{D}_{\log}\left[1-\frac{1}{2}\int_0^{t_1}\exp g_1(t')dt'\int_x^\infty \frac{1}{\Phi_n^2}\bigg|_{t=0}dx'\right], \tag{64}$$

$$\frac{1}{\Phi_l^2}=-2\frac{\partial}{\partial t_2}\mathrm{D}_{\log}\left[1+\frac{1}{2}\int_0^{t_2}\exp g_2(t')dt'\int_x^\infty \frac{1}{\Phi_l^2}\bigg|_{t=0}dx'\right]. \tag{65}$$

Denote the right-hand sides of these solutions by F_1 and F_2, respectively. Then final formulas for the isospectral deformation of the eigenfunctions in the case of two-level flow will be given in the form

$$\psi_l=1\bigg/\sqrt{F_2}\int_x^\infty\frac{dx'}{\sqrt{F_1F_2}},\quad \psi_n=1\bigg/\sqrt{F_1}\int_x^\infty\frac{dx'}{\sqrt{F_1F_2}}. \tag{66}$$

Equations (53), (54) can also be rewritten as a pair of separated equations for certain functions $Z^\pm$, which are only expressed through the function $a(x,t)$ [see Eq. (52)] and its derivative; i.e., in fact, we can obtain equations that describe the isospectral deformation of the *potential* in closed form for the case of two-level McKean–Trubowitz flow. Define the functions $Z^\pm$ as follows:

$$Z^+=\frac{a_x}{a}-a+\frac{2\Delta_{nl}}{a}, \tag{67}$$

$$Z^-=\frac{a_x}{a}-a-\frac{2\Delta_{nl}}{a}; \tag{68}$$

and use, together with Eq. (3), the identity

$$\frac{a_x}{a}-a=\mathrm{D}_{\log}\left[\frac{a^2}{\psi_n\psi_l}\right]. \tag{69}$$

It can be shown that Eqs. (53), (54) and relations (3), (69) lead to the separated equations for the functions $Z^\pm(x,t)$:

$$\frac{\partial}{\partial t}\mathrm{D}_{\log}Z_t^\pm=-Z_t^\pm. \tag{70}$$

Any of them can be used to determine the evolution of the potential, since the compatibility condition for their solutions (i.e., a condition under which they give the same potential),

$$2(Z^+)_x+(Z^+)^2+4\Delta_{nl}=2(Z^-)_x+(Z^-)^2-4\Delta_{nl}, \tag{71}$$

is nothing but the condition (51) rewritten in the new variables.

The solutions of Eqs. (70) have the form

$$Z^{\pm}=Z^{\pm}+2\mathrm{D}_{\log}\,\theta^{\pm}(x,t),$$

$$\theta\equiv 1-\frac{1}{2}\int_0^t \exp g^{\pm}(t')dt'\int_x^{\infty}|Z_t^{\pm}|_{t=0}dx'. \tag{72}$$

Using these expressions, we can write down a solution for the function $a(x,t)$ (an antiderivative of the potential); the same solution can be obtained from formulas (64), (65):

$$\frac{1}{a(x,t)}=\frac{1}{a^0(x)}+\frac{1}{2\Delta_{nl}}\mathrm{D}_{\log}\frac{1-2\tau_l\Delta_{nl}\alpha(t)\int_x^{\infty}(\psi_l/a)^2|_{t=0}dx'}{1+2\tau_n\Delta_{nl}\beta(t)\int_x^{\infty}(\psi_n/a)^2|_{t=0}dx'}, \tag{73}$$

where $\alpha(t)=\int_0^t \exp g_1(t')dt'$, $\beta(t)=\int_0^t \exp g_2(t')dt'$.

It can be proved that this expression can be transformed to a particular case of a well-known formula for the isospectral deformation of the potential in the Schrödinger operator,

$$a(x,t)=a^0-\mathrm{D}_{\log}\begin{vmatrix} 1+\alpha(t)\int_x^{\infty}(\psi_n^0)^2dx' & \alpha(t)\int_x^{\infty}\psi_n^0\psi_l^0dx' \\ \beta(t)\int_x^{\infty}\psi_n^0\psi_l^0dx' & 1+\beta(t)\int_x^{\infty}(\psi_l^0)^2dx' \end{vmatrix}, \tag{74}$$

which is derived both in the method related to the integral equations of the Gelfand–Levitan and Marchenko types, and in the McKean and Trubowitz approach. The transformation from formula (73) to (74) is not obvious; but it is not difficult to check, as an intermediate step, that Eqs. (73) and (74) can be rewritten as follows:

$$\frac{1}{a(x,t)}=\frac{1}{a^0}-\frac{1}{(a^0)^2}\frac{-R_x}{R-R_x[a^0]^{-1}} \tag{75}$$

and

$$a(x,t)=a^0-\mathrm{D}_{\log}R, \tag{76}$$

respectively.

Thus, we have shown that the known formulas for the isospectral deformation of the potential and of the eigenfunctions can also be obtained as solutions of PDEs (reducible to the Liouville equations), which we derived using the ‘‘evolutional’’ approach to the description of the isospectral deformation of the Schrödinger operator together with the formulas for the McKean–Trubowitz flow.

VI. ON HAMILTONIAN DESCRIPTION OF TWO-LEVEL ISOSPECTRAL DEFORMATION

Performing the scaling $x/\sqrt{\Delta_{nl}}\Rightarrow\xi$, $\sqrt{\Delta_{nl}}t\Rightarrow\tau$, $\sqrt{\tau_n}\psi_n\Rightarrow\Psi_n$, $\sqrt{\tau_l}\psi_l\Rightarrow\Psi_l$, and defining the variables Γ_n, Γ_l, Γ_{nl} by the relations

$$\Gamma_n\equiv\frac{(\Psi_n)_\xi}{\Psi_n},\quad \Gamma_l\equiv\frac{(\Psi_l)_\xi}{\Psi_l},\quad \Gamma_{nl}\equiv\Gamma_n-\Gamma_l, \tag{77}$$

rewrite the initial system of two coupled evolutional equations in the form

$$(\Gamma_n)_\tau-(\Psi_n^2+\Psi_l^2)=+\tfrac{1}{2}(\Gamma_{nl}\Psi_l)^2, \tag{78}$$

$$(\Gamma_l)_\tau-(\Psi_n^2+\Psi_l^2)=-\tfrac{1}{2}(\Gamma_{nl}\Psi_n)^2. \tag{79}$$

In the new variables the relation (50) (the condition for the functions ψ_n, ψ_l to be solutions of the Schrödinger equation with one and the same potential for E_n and E_l) takes the form of a relation between the logarithmic derivatives Γ_n and Γ_l:

$$\tfrac{1}{2}(\Gamma_{nl})_\xi = -1 - \tfrac{1}{2}\Gamma_n^2 + \tfrac{1}{2}\Gamma_l^2. \tag{80}$$

Note that Eqs. (78), (79) and the relation (80) do not contain any parameters.

The evolutional equations (78), (79) can be written as Hamiltonian equations with respect to the dynamical variables Γ_n, Γ_l:

$$(\Gamma_n)_\tau = -\frac{\partial}{\partial\xi}\frac{\delta\mathbf{H}}{\delta\Gamma_n}, \quad (\Gamma_l)_\tau = +\frac{\partial}{\partial\xi}\frac{\delta\mathbf{H}}{\delta\Gamma_l}; \tag{81}$$

these equations are generated by the functional

$$\mathbf{H} = \frac{1}{4}\int_{-\infty}^{+\infty} d\xi\,\Gamma_{nl}^2(\xi,\tau)\left[\exp\left(2\int_{-\infty}^{\xi} d\xi'\,\Gamma_n(\xi',\tau)\right) + \exp\left(2\int_{-\infty}^{\xi} d\xi'\,\Gamma_l(\xi',\tau)\right)\right]. \tag{82}$$

In fact, one can prove that Eqs. (81) together with the condition (80) and the definitions (77) lead to the initial system of evolutional equations (78), (79).

Thus, the evolutional formulation of the problem on isospectral deformations of the Schrödinger operator is related with dynamical systems of the Hamiltonian type with constraints. The Hamiltonian formalism for such a class of dynamical systems was first studied by Dirac.[18]

Now pass from the variables $\{\Psi_{n,l}, \Gamma_{n,l} = \mathrm{D}_{\log}\Psi_{n,l}\}$ to the variables $\{\zeta_{n,l}, \gamma_{n,l} = \mathrm{D}_{\log}\zeta_{n,l}\}$ by the relations

$$\gamma_n = \Gamma_n + \frac{(\Gamma_{nl})_\xi}{\Gamma_{nl}}, \quad \gamma_l = \Gamma_l + \frac{(\Gamma_{nl})_\xi}{\Gamma_{nl}},$$

$$\zeta_n = \Psi_n\Gamma_{nl}, \quad \zeta_l = \Psi_l\Gamma_{nl}.$$

In these variables the evolutional equations (78), (79) and the constraint (80) take the form

$$(\gamma_n)_\tau = -\tfrac{1}{2}\zeta_n^2, \quad (\gamma_l)_\tau = +\tfrac{1}{2}\zeta_l^2, \tag{83}$$

$$-\tfrac{1}{2}(\gamma_{nl})_\xi + \tfrac{1}{2}(\gamma_n^2 - \gamma_l^2) = -1. \tag{84}$$

Thus, the transform $(\Gamma_i, \Psi_i) \Rightarrow (\gamma_i, \zeta_i)$ leads to a system of two *separated* equations. Moreover, this transform *preserves a Hamiltonian structure* of the dynamical system: the equations

$$(\gamma_n)_\tau = -\frac{\partial}{\partial\xi}\frac{\delta\mathbf{h}}{\delta\gamma_n}, \quad (\gamma_l)_\tau = +\frac{\partial}{\partial\xi}\frac{\delta\mathbf{h}}{\delta\gamma_l}, \tag{85}$$

generated by the functional

$$\mathbf{h} = \frac{1}{4}\int_{-\infty}^{+\infty} d\xi\left[\exp\left(2\int_{-\infty}^{\xi} d\xi'\,\gamma_n(\xi',\tau)\right) + \exp\left(2\int_{-\infty}^{\xi} d\xi'\,\gamma_l(\xi',\tau)\right)\right] \tag{86}$$

provide the evolutional equations (83); note that $\mathbf{h} = \mathbf{H}$.

Furthermore, the transform $(\Gamma_i, \Psi_i) \Rightarrow (\gamma_i, \zeta_i)$ preserves ‘‘naive’’ (in terms of Ref. 16) Poisson brackets. For example, if they are defined as follows:

$$\{a,b\}_{P(\Gamma)} \equiv \int_{-\infty}^{+\infty} d\xi\,\frac{\delta a}{\delta\Gamma(\xi)}\frac{\partial}{\partial\xi}\frac{\delta b}{\delta\Gamma(\xi)}, \tag{87}$$

then we find that

$$\{\gamma_m,\gamma_{m'}\}_{P(\gamma)}=\{\gamma_m,\gamma_{m'}\}_{P(\Gamma)}, \tag{88}$$

since the variational derivative of a logarithmic derivative always vanishes.

Thus, the transform $(\Gamma_i,\Psi_i)\Rightarrow(\gamma_i,\zeta_i)$ is *a canonical transform* for the Hamiltonian dynamical system with the Hamiltonian function $\mathbf{h}=\mathbf{H}$.

Note also that the constraint (84) is *a local integral* of the system (83). This means that the expression on the right-hand side of Eq. (84) (denote it by J_{nl}) satisfies the equation $(J_{nl})_\tau=0$ by virtue of Eqs. (83). Hence, the equations give us $J_{nl}=C(\xi)$; and only choosing the ''level'' $C(\xi)=-1$ we can satisfy the condition (84).

Now let us formulate principal results of this section.

(i) The above-considered system of two coupled evolutional equations can be written as Hamiltonian equations generated by the functional (82) (where ''logarithmic derivatives'' of the eigenfunctions are canonical variables).

(ii) The switch from the system of two coupled evolutional equations to the pair of split evolutional equations of Liouville form is performed by a canonical change of variables.

APPENDIX: SEQUENCE OF CANONICAL TRANSFORMS

Consider the following sequence of transforms, each of which preserves a Hamiltonian structure of the equations (78), (79).

(i): $(\Gamma_i,\Psi_i)\Rightarrow(\gamma_i,\zeta_i)$. The initial system of evolutional equations (78), (79) and the constraint (80) are transformed to (83), (84).

(ii): $(\gamma_i,\zeta_i)\Rightarrow(\tilde{\gamma}_i,\tilde{\zeta}_i)$: $\tilde{\gamma}_n=-\gamma_n$, $\tilde{\gamma}_l=-\gamma_l$, $\tilde{\zeta}_n=\zeta_n^{-1}$, $\tilde{\zeta}_l=\zeta_l^{-1}$. Now the system of equations (83), (84) is transformed to the form

$$(\tilde{\gamma}_n)_\tau=-\tfrac{1}{2}\tilde{\zeta}_n^{-2},\quad (\tilde{\gamma}_l)_\tau=+\tfrac{1}{2}\tilde{\zeta}_l^{-2}, \tag{A1}$$

$$+\tfrac{1}{2}(\tilde{\gamma}_{nl})_\xi-\tfrac{1}{2}\tilde{\gamma}_{nl}(\tilde{\gamma}_n+\tilde{\gamma}_l)=-1. \tag{A2}$$

(iii): $(\tilde{\gamma}_i,\tilde{\zeta}_i)\Rightarrow(\tilde{\Gamma}_i,\tilde{\Psi}_i)$:

$$\tilde{\Gamma}_n=\tilde{\gamma}_n+\frac{(\tilde{\gamma}_{nl})_\xi}{\tilde{\gamma}_{nl}},\quad \tilde{\Gamma}_l=\tilde{\gamma}_l+\frac{(\tilde{\gamma}_{nl})_\xi}{\tilde{\gamma}_{nl}},$$

$$\tilde{\Psi}_n=\tilde{\Gamma}_{nl}\tilde{\zeta}_n,\quad \tilde{\Psi}_l=\tilde{\Gamma}_{nl}\tilde{\zeta}_l.$$

Here the system (A1), (A2) takes the form

$$\left(\tilde{\Gamma}_n+\frac{2}{\tilde{\Gamma}_{nl}}\right)_\tau=+\frac{\tilde{\Gamma}_{nl}^2}{2\tilde{\Psi}_n^2},\quad \left(\tilde{\Gamma}_l+\frac{2}{\tilde{\Gamma}_{nl}}\right)_\tau=-\frac{\tilde{\Gamma}_{nl}^2}{2\tilde{\Psi}_l^2}, \tag{A3}$$

$$-\tfrac{1}{2}(\tilde{\Gamma}_{nl})_\xi+\tfrac{1}{2}\tilde{\Gamma}_{nl}(\tilde{\Gamma}_n+\tilde{\Gamma}_l)=-1. \tag{A4}$$

(iv): $(\tilde{\Gamma}_i,\tilde{\Psi}_i)\Rightarrow(\bar{\Gamma}_i,\bar{\Psi}_i)$: $\bar{\Gamma}_n=-\tilde{\Gamma}_n$, $\bar{\Gamma}_l=-\tilde{\Gamma}_l$, $\bar{\Psi}_n=\tilde{\Psi}_n^{-1}$, $\bar{\Psi}_l=\tilde{\Psi}_l^{-1}$.
After this (last) step the system (A3), (A4) is written as follows:

$$\left(\bar{\Gamma}_n+\frac{2}{\bar{\Gamma}_{nl}}\right)_\tau=-\frac{1}{2}(\bar{\Gamma}_{nl}\bar{\Psi}_n)^2, \tag{A5}$$

$$\left(\overline{\Gamma}_l+\frac{2}{\overline{\Gamma}_{nl}}\right)_\tau=-\tfrac{1}{2}(\overline{\Gamma}_{nl}\overline{\Psi}_l)^2, \tag{A6}$$

$$+\tfrac{1}{2}(\overline{\Gamma}_{nl})_\xi+\tfrac{1}{2}\overline{\Gamma}_{nl}(\overline{\Gamma}_n+\overline{\Gamma}_l)=-1. \tag{A7}$$

It is not difficult to prove that

$$\overline{\Gamma}_n=\Gamma_n,\quad \overline{\Gamma}_l=\Gamma_l,\quad \overline{\Psi}_n=-\Psi_n,\quad \overline{\Psi}_l=-\Psi_l, \tag{A8}$$

whereas Eqs. (A5), (A7) coincide with the initial system of evolutional equations (78), (79) and the constraint (80).

Thus, the chain of transforms $(\Gamma_i,\Psi_i)\Rightarrow(\gamma_i,\zeta_i)\Rightarrow(\tilde{\gamma}_i,\tilde{\zeta}_i)\Rightarrow(\tilde{\Gamma}_i,\tilde{\Psi}_i)\Rightarrow(\overline{\Gamma}_i,\overline{\Psi}_i)$ maps the initial Hamiltonian system with constraints into itself (up to change of signs of the solutions Ψ_i).

Note that links of this chain coincide, principally, with links of the double Darboux transform. This points to a possibility to define a correspondence between the Darboux approach in the theory of integrable evolutional equations of the isospectral deformation in the Schrödinger problem and canonical transforms of an associated Hamiltonian system with constraints. This statement should be made more formal by a strict analysis of the multi-flow case and a more correct definition of Poisson–Dirac brackets.[16]

(Received 5 October 1998; accepted for publication 14 December 1998)

Exact integrability of the Sasa Satsuma equation (SSE) in the Liouville sense is established by showing the existence of an infinite set of conservation laws. The explicit form of the conserved quantities in terms of the fields are obtained by solving the Riccati equation for the associated 3×3 Lax operator. The soliton solutions, in particular, one and two soliton solutions, are constructed by the Hirota's bilinear method. The one soliton solution is also compared with that found through the inverse scattering method. The gauge equivalence of the SSE with a generalized Landau Lifshitz equation is established with the explicit construction of the new equivalent Lax pair.
[S0022-2488(99)00204-2]

I. INTRODUCTION

Nonlinear Schrödinger equation and its various generalized versions (higher order nonlinear Schrödinger equation) is well known in describing various physical phenomenas.[1] A common property in all these physical systems is the appearance of solitons, as a result of a balance between the nonlinear and dispersive terms of the wave equations. With the advancement of experimental accuracy, solitons having more complicated dynamics can also be detected and observed now.[2] The Sasa Satsuma equation[3]

$$iQ_T+\frac{1}{2}Q_{XX}+|Q|^2Q+\frac{i}{6\epsilon}(Q_{XXX}+6|Q|^2Q_X+3|Q|^2_XQ)=0 \tag{1}$$

describing the evolution of a complex scalar field, is an example of such a system, whose soliton solutions have been obtained through inverse scattering method (ISM) in Ref. 3.

A limited class of soliton bearing equations exhibits further interesting properties and belongs to the exclusive club of integrable systems. The most prominent definition of integrability is the integrability in the Liouville sense, i.e., the existence of a set of infinite numbers of conserved quantities in involution,[4] which can be considered as the action variables. This criterion of integrability is extendable also to the quantum case. The Lax pair associated with the model is usually a sign of such integrability, while the Painlevé singularity analysis[5] is supposed to be a direct test of integrability for the given equation.

[a)]Electronic mail: sasanka@iitg.ernet.in
[b)]Electronic mail: anjan@tnp.saha.ernet.in
[c)]Electronic mail: sudipta@iitg.ernet.in

It should be mentioned that the Lax pair for the SSE as well as its one soliton through ISM were found in Ref. 3, while the Painleve analysis for the equation was carried out in Ref. 6. However, extraction of the higher conserved quantities for the Sasa Satsuma system and thus establishing the integrability of the whole hierarchy in the Liouville sense remained unexplored. A possible reason of this may be the difficulty involved due to the unusual 3×3 matrix form of the Lax operator, associated with the SSE.

Our objective is, therefore, to find the Riccati equation for the 3×3 Lax operator, associated with the SSE and consequently, to obtain the whole hierarchy of conserved charges in a systematic way. This construction will be somewhat involved due to the extended form of the Lax operator.

For investigating SSE from a different view point, we further find the explicit soliton solutions of the equation through Hirota's bilinear method. This is a direct and much more effective method compared to ISM for obtaining the soliton solutions, since it does not require the knowledge of the Lax pair. Moreover, the construction of the τ function becomes straightforward in this method.

One should recall in this context another interesting fact about the NLS equation that it is gauge related to the well known Landau Lifshitz equation (LLE).[7] This equivalence can also be established through the space curve method.[8] It is, therefore, natural to ask what is the gauge equivalent equation to the SSE. Though such an equivalent system has been discovered by the space curve method in Ref. 6, we complete the investigation for SSE by showing the equivalence of it through an explicit gauge transformation, which not only reproduces the generalized LLE (GLLE), but also constructs the associated Lax pair for the GLLE.

The organization of this paper is as follows. In Sec. II we study the soliton solutions of SSE by Hirota's bilinear method. We compute explicitly the one and two soliton solutions and compare our result of one soliton solution with the known one.[3] In Sec. III, we construct the related Riccati equation using the 3×3 Lax operator of the SSE and subsequently find the infinite number of conserved quantities through the recursion relation. The time invariance of the conserved quantities is checked directly by using the evolution equation. This proves the Liouville integrability of the SSE. Section IV provides the gauge equivalent generalized LLE and gives the associated new Lax operators in the explicit form. Section V is the concluding one.

II. SOLITON SOLUTIONS THROUGH HIROTA'S METHOD

Let us begin with the SSE (1), which through a change of variable and a Galelian transformation:

$$Q(X,T)=u(x,t)\exp\left\{i\epsilon\left(x+\frac{\epsilon t}{6}\right)\right\},$$

$$T=t,$$

$$X=x+\frac{\epsilon}{2}t, \tag{2}$$

may be simplified to the form

$$u_t+\frac{1}{6\epsilon}(u_{xxx}+6|u|^2u_x+3(|u|^2)_xu)=0. \tag{3}$$

This is an example of a complex modified KdV type equation and goes to mKdV for the real valued field. The associated spectral problem can be studied through the pair of linear equations

$$\Psi_x=\mathbf{U}(x,t,\lambda)\Psi, \tag{4a}$$

$$\Psi_t=\mathbf{V}(x,t,\lambda)\Psi, \tag{4b}$$

where $\mathbf{U}(x,t,\lambda)$ and $\mathbf{V}(x,t,\lambda)$ are 3×3 matrices and λ is the spectral parameter. The explicit form of $\mathbf{U}$ and $\mathbf{V}$ may be given using the result of Ref. 3 as

$$\mathbf{U}=-i\lambda\Sigma+\mathbf{A}, \tag{5a}$$

$$\mathbf{V}=-i4\epsilon\lambda^3\Sigma+4\epsilon(\lambda^2-|u|^2)\mathbf{A}-i2\lambda\epsilon\Sigma(\mathbf{A}^2-\mathbf{A}_x)-\epsilon\mathbf{A}_{xx}+\epsilon(\mathbf{A}_x\mathbf{A}-\mathbf{A}\mathbf{A}_x), \tag{5b}$$

with

$$\Sigma=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix},$$

$$A=\begin{pmatrix} 0 & 0 & u \\ 0 & 0 & u^* \\ -u^* & -u & 0 \end{pmatrix}.$$

Compatibility of (4a) and (4b) leads to SSE (3), which can be shown easily by using the following properties of Σ and $\mathbf{A}$ matrices:

$$\{\Sigma,\mathbf{A}\}=0,$$

$$\Sigma^2=1,$$

$$\mathbf{A}^3+2|u|^2\mathbf{A}=0.$$

Note that SSE in the form (3), though suitable for studying inverse scattering technique, is not convenient for casting it into Hirota's bilinear form. On the other hand, the higher order nonlinear Schrödinger equation form (1) for SSE is more suitable for this purpose. Now, in order to write (1) in the bilinear form, we make the transformation

$$Q(X,T)=G(X,T)/F(X,T), \tag{6}$$

where, G is complex and F is real. Consequently, in these new variables, we have the following set of equations:

$$\left(iD_T+\frac{1}{2}D_X^2+\frac{i}{6\epsilon}D_X^3\right)G\cdot F=0, \tag{7a}$$

$$D_X^2F\cdot F=4G^*\cdot G, \tag{7b}$$

$$\left(1-\frac{2i}{\epsilon}D_X\right)G^*\cdot G=0, \tag{7c}$$

which follow from (1). D_T, D_X, D_{XX} etc. in (7) are Hirota derivatives.[9] Equation (7) belongs to a new class of bilinear equations, whose general form would be of the type

$$\mathcal{B}(D_X,D_T,\ldots)G\cdot F=0, \tag{8a}$$

$$\mathcal{A}(D_X,D_T,\ldots)F\cdot F=\mathcal{C}(D_X,D_T,\ldots)G^*\cdot G, \tag{8b}$$

$$\mathcal{E}(1-D_X,D_T,\ldots)G^*\cdot G=0. \tag{8c}$$

The additional bilinear equation (7c) involving G^*G imposes one further condition on the complex parameter P (shown below), which is absent in other examples of higher order nonlinear Schrödinger equations.[10]

For obtaining one soliton solution of SSE (1), we choose G and F in the following form

$$G = L\exp(\eta), \tag{9a}$$

$$F = 1 + K\exp(\eta+\eta^*), \tag{9b}$$

where, L is a complex c-number parameter and

$$\eta = PX + \Omega T + \cdots, \tag{10}$$

with P, Ω are in general complex parameters. Substituting the expressions (9) for G and F in (7), we see that G and F are the solutions of (7) provided the following relations hold:

$$i\Omega + \frac{1}{2}P^2 + i\frac{P^3}{6\epsilon} = 0, \tag{11a}$$

$$K = \frac{LL^*}{2\mu^2}, \tag{11b}$$

$$P - P^* = 2i\epsilon, \tag{11c}$$

where the complex parameter, P is of the form

$$P = \mu + i\epsilon. \tag{12a}$$

Equation (11a) is nothing but the dispersion relation and (11b) determines K. In the above solution, so far, L is an arbitrary complex parameter. We will see shortly that in order to compare our result with the one obtained through the ISM,[3] the parameter L is to be chosen in a specific form. It follows from the dispersion relation (11a) and the expression of P (12a) that Ω should be of the form

$$\Omega = -\mu\left(\frac{\mu^2}{6\epsilon} + \frac{\epsilon}{2}\right) - i\frac{\epsilon^2}{3}. \tag{12b}$$

Substituting (12a) and (12b) in (10) and using (11b) the one soliton solution in the explicit form becomes

$$Q(X,T) = \frac{L\exp\eta}{1+K\exp(\eta+\eta^*)} = \frac{L\exp\left\{(\mu+i\epsilon)X - \left(\frac{\mu^3}{6\epsilon} + \frac{\mu\epsilon}{2} + i\frac{\epsilon^2}{3}\right)T\right\}}{1 + \frac{|L|^2}{2\mu^2}\exp\left\{2\mu X - \left(\frac{\mu^3}{3\epsilon} + \mu\epsilon\right)T\right\}}. \tag{13}$$

To compare (13) with that of ISM, we choose L as

$$L = 2\mu\exp(-i\epsilon X^{(1)} - \mu X^{(0)}), \tag{14}$$

which reduces (13) to the form

$$Q(X,T)=\frac{\frac{\mu}{\sqrt{2}}\exp\left\{i\epsilon\left(X-\frac{\epsilon}{3}T-X^{(1)}\right)\right\}}{\cosh\left(\mu X-\mu\left(\frac{\mu^2}{6\epsilon}+\frac{\epsilon}{2}\right)T-\mu X^{(0)}+\log\sqrt{2}\right)} \tag{15}$$

and this is in agreement with the ISM result of Ref. 3.

Two soliton solutions of the Sasa Satsuma equation may be obtained, following Ref. 10, by choosing G and F of the form

$$G=L(\exp\eta_1+M\exp(\eta_1+\eta_A)), \tag{16a}$$

$$F=1+k\exp(\eta_1+\eta_1^*)+\exp(\eta_A)+kMM^*\exp(\eta_1+\eta_1^*+\eta_A), \tag{16b}$$

where, η_1 is complex as in the case of one solition, but η_A is chosen to be real. Substituting F and G (16) in the bilinear forms (7), we observe that η_1 soliton satisfies the same dispersion relation as (11a), whereas the dispersion relation for η_A becomes $P_A^2=0$. The degree 2 term in (7a) determines the parameter M to be unity. Once again following Ref. 10, we define the degree of a term by the number of η's present in the exponent. Now the degree 2 and 4 terms in (7b), yield the value of k as in (11b). However, because of the additional bilinear form (7c) in our case, we obtain one more relation, $\epsilon(P_1^*-P_1)=2i$. Note that, in general for complex bosonic systems having complex parameters, the two soliton solutions may have some relation, which is analogous to the three soliton conditions.[10] But, the choice of the real parameter η_A, makes the three soliton condition trivial in our case. A more general choice of F and G for two soliton solutions will give such a nontrivial condition.

III. RICCATI EQUATION AND THE CONSERVED QUANTITIES

To show the Liouville integrability, i.e., the existence of an infinite number of conserved quantities related to SSE (3), we first write the associated Riccati equation. Since the Lax operators in this case are 3×3 matrices, the Riccati equation becomes more complicated, though tactable. Let us write the auxiliary field Ψ in the component form as

$$\Psi=\begin{pmatrix}\chi_1\\ \chi_2\\ \chi_3\end{pmatrix}. \tag{17}$$

Substituting (17) in (4a), we get a set of three coupled equations:

$$\chi_{1x}=-i\lambda\chi_1+u\chi_3, \tag{18a}$$

$$\chi_{2x}=-i\lambda\chi_2+u^*\chi_3, \tag{18b}$$

$$\chi_{3x}=i\lambda\chi_3-u^*\chi_1-u\chi_2. \tag{18c}$$

Now expressing (18) in terms of $\Gamma_1=(\chi_1/\chi_3)$ and $\Gamma_2=(\chi_2/\chi_3)$, and eliminating χ_1, χ_2, and χ_3, one obtains

$$\Gamma_{1x}=u-2i\lambda_1+u^*\Gamma_1^2+u\Gamma_1\Gamma_2, \tag{19a}$$

$$\Gamma_{2x}=u^*-2i\lambda_2+u\Gamma_2^2+u^*\Gamma_1\Gamma_2. \tag{19b}$$

The first order nonlinear coupled equations (19) for Γ_1 and Γ_2 are the Riccati equations in our case. Notice that neither the integral of Γ_1 nor of Γ_2, plays the role of generating functions for conserved quantities, but a suitable combination of them does. The infinite number of conserved quantities (Hamiltonians), H_{2n+1}; $n=0,1,2,\ldots$ can be obtained from (19) by identifying

$$a(\lambda)=\exp(-i\lambda x)|_{x\to\infty}\Psi_3(\infty,\lambda)=\exp\left\{-\int_{-\infty}^{\infty}(u^*\Gamma_1+u\Gamma_2)dx\right\}, \tag{20a}$$

where H_{2n+1} are related to $a(\lambda)$ as

$$\ln a(\lambda)=-2\sum_{n=0}^{\infty}(2i)^{-2n-1}H_{2n+1}\lambda^{-2n-1}. \tag{20b}$$

We will see that Hamiltonians with odd indices only survive, while the terms with even indices become trivial. This property is similar to that of the real KdV or the modified KdV equation.

We may look for series solutions of (19) by assuming Γ_1 and Γ_2 in the form

$$\Gamma_1=\sum_{n=0}^{\infty}C_n^1\lambda^{-n}, \tag{21a}$$

$$\Gamma_2=\sum_{n=0}^{\infty}C_n^2\lambda^{-n}, \tag{21b}$$

which yield the following recursion relations from (19a) and (21):

$$C_0^1=0,\quad C_1^1=\frac{u}{2i},$$

$$2iC_{n+2}^1=-(C_{n+1}^1)_x+\sum_{m=0}^{n+1}(u^*C_m^1C_{n-m+1}^1+uC_m^1C_{n-m+1}^2). \tag{22}$$

Similarly (19b) and (21) determine another, though quite similar, set of recursion relations given as

$$C_0^2=0,\quad C_1^2=\frac{u^*}{2i},$$

$$2iC_{n+2}^2=-(C_{n+1}^2)_x+\sum_{m=0}^{n+1}(uC_m^2C_{n-m+1}^2+u^*C_m^2C_{n-m+1}^1). \tag{23}$$

Inserting the expressions of C_n^1 and C_n^2, thus obtained through the recursion relations (22), (23) in (21), we get from (20a) and (20b) the explicit form of all conserved quantities, H_{2n+1}. These expressions are the integrals taken over the functions of the fields u and u^* and their derivatives. The first few conserved quantities of the infinite set of the SSE hierarchies are given by

$$H_1=\int u^*u\,dx, \tag{24}$$

$$H_3=\int(-u_x^*u_x+2|u|^4)dx, \tag{25}$$

$$H_5=\int(u_{xx}^*u_{xx}-8|u|^2u_x^*u_x-3((|u|^2)_x)^2+8|u|^6)dx. \tag{26}$$

We have checked explicitly by using equations of motion (3) that H_1, H_3, and H_5 are, indeed, the constants of motion.

IV. GENERALIZED LANDAU LIFSHITZ TYPE EQUATION AS THE GAUGE EQUIVALENT SYSTEM

We now show an interesting connection between the SSE in the form (3) and the generalized Landau Lifshitz type equation, by exploiting the gauge equivalence of the Lax pairs of these two dynamical systems. The procedure is similar to that between the NLS and the standard Landau Lifshitz equation.[7] Under a local gauge transformation, the Jost function, $\Psi(x,t,\lambda)$ changes as

$$\tilde{\Psi}(x,t,\lambda)=g^{-1}(x,t)\Psi(x,t,\lambda), \tag{27}$$

where $g(x,t)=\Psi(x,t,\lambda)|_{\lambda=0}$, may be taken as an element of the gauge group. Consequently, the Lax equations (4) under this gauge transformation (27) become

$$\tilde{\Psi}_x=\tilde{\mathbf{U}}(x,t,\lambda)\tilde{\Psi}, \tag{28a}$$

$$\tilde{\Psi}_t=\tilde{\mathbf{V}}(x,t,\lambda)\tilde{\Psi}, \tag{28b}$$

where $\tilde{\mathbf{U}}$ and $\tilde{\mathbf{V}}$ are the new gauge transformed Lax pair, given by

$$\tilde{\mathbf{U}}(x,t,\lambda)=g^{-1}(\mathbf{U}-\mathbf{U}_0)g, \tag{29a}$$

$$\tilde{\mathbf{V}}(x,t,\lambda)=g^{-1}(\mathbf{V}-\mathbf{V}_0)g, \tag{29b}$$

with $\mathbf{U}_0=\mathbf{U}|_{\lambda=0}=g^{-1}(x,t)g_x(x,t)$ and $\mathbf{V}_0=\mathbf{V}|_{\lambda=0}=g^{-1}(x,t)g_t(x,t)$.

We may identify the spin field of the Landau Lifshitz type equation as

$$S=g(x,t)^{-1}\Sigma g(x,t), \quad S^2=1. \tag{30}$$

With this identification, the gauge transformed Lax pair (29) can be expressed in terms of the spin field S (30) and its derivatives only, yielding

$$\tilde{\mathbf{U}}=-i\lambda S, \tag{31a}$$

$$\tilde{\mathbf{V}}=-4i\epsilon\lambda^3S+2\epsilon\lambda^2SS_x+i\epsilon\lambda(S_{xx}+\tfrac{3}{2}SS_x^2). \tag{31b}$$

In deriving (31) one has to use the following important identities:

$$SS_x=2g^{-1}\mathbf{A}g, \quad SS_x^2=-4g^{-1}\Sigma\mathbf{A}^2g \quad \text{and} \quad S_{xx}+SS_x^2=2g^{-1}\Sigma\mathbf{A}_xg.$$

The zero curvature condition of (31);

$$\tilde{\mathbf{U}}_t-\tilde{\mathbf{V}}_x+[\tilde{\mathbf{U}},\tilde{\mathbf{V}}]=0 \tag{32}$$

leads to the generalized Landau Lifshitz type equation

$$S_t+\epsilon S_{xxx}+\tfrac{3}{2}\epsilon(S_x^3+SS_{xx}S_x+SS_xS_{xx})=0 \tag{33}$$

with $S\in SU(3)/SU(2)$.

V. CONCLUSION

In this paper, we have bilinearized the higher order nonlinear Schrödinger equation via the SSE following Hirota's method. Hirota's method is an effective and important method to obtain multisoliton solutions. We have found explicitly one and two soliton solutions and recovered the ISM result of one soliton solution from that of Hirota's method after a specific choice of the parameter involved. The result related to higher soliton solutions are more complicated and will be given elsewhere. It is found that the SSE falls under a new class of bilinear forms.

The linear problem of SSE is a nontrivial one in the sense that the Lax operator corresponding to this dynamical equation is a 3×3 matrix, which makes the related Riccati equation more involved. However, by solving such coupled Riccati equations we are able to compute explicitly the infinite number of conserved quantities through the recursion relations and to show that terms with odd indices only contribute to the conserved charges like KdV and mKdV systems. This result establishes explicitly the integrability of the SSE in the Liouville sense. Finding out the Poisson bracket structures among the dynamical fields and consequently revealing the explicit form of the hierarchy of SSE from the conserved charges obtained here will be an interesting future problem.

The gauge equivalence of the GLLE with the SSE has been established here. This equivalence not only gives a direct relationship between the fields, which would help to find the soliton solutions of the GLLE using those of the SSE, but also yields explicit Lax operators for GLLE from which one would be able to extract the related higher conserved quantities in the similar way following the present results of SSE.

(Received 19 May 1998; accepted for publication 9 November 1998)

A new integrable differential-difference system is proposed. By the dependent variable transformation, the system is transformed into multilinear form. By introducing an auxiliary variable, we further transform it into the bilinear form. A corresponding Bäcklund transformation for it is obtained. Furthermore a nonlinear superposition formula is presented. As an application of the obtained results, soliton solutions to the system are derived. © *1999 American Institute of Physics.* [S0022-2488(99)03202-8]

I. INTRODUCTION

While continuous soliton equations have been under active investigation, only a relatively small portion of the literature was devoted to the subject of discrete systems. However, this situation has been improved by now. Recently there has been a renewal of interest in discrete soliton systems. As a result, various approaches are being further developed to discrete soliton equations, among which Hirota's method is one of the most important ones. As is known, Hirota's bilinear method has played an important role in solitons and integrable systems since its inception.[1] In a series of papers,[2] Hirota discretized several soliton equations and obtained soliton solutions to the discretized equations.

The purpose of this paper is to propose a new differential-difference system and then study it by using Hirota's method. It is noted that recently the so-called Belov–Chaltikian lattice[3]

$$b_t(n)=b(n)(b(n+1)-b(n-1))-c(n)+c(n-1), \tag{1}$$

$$c_t(n)=c(n)(b(n+2)-b(n-1)), \tag{2}$$

and the Blaszak–Marciniak lattice[4]

$$a_t(n)=c(n+1)-c(n-1), \tag{3}$$

$$b_t(n)=a(n-1)c(n-1)-a(n)c(n), \tag{4}$$

$$c_t(n)=c(n)(b(n)-b(n+1)), \tag{5}$$

are transformed into the following bilinear forms:[5,6]

$$(D_t^2 e^{(1/2)D_n}-D_z e^{(1/2)D_n})f(n)\cdot f(n)=0, \tag{6}$$

$$(D_z e^{D_n} - D_t^2 e^{D_n} + 2e^{2D_n} - 2e^{D_n}) f(n)\cdot f(n) = 0, \tag{7}$$

and

$$(D_t^2 - 2D_z e^{D_n}) f(n)\cdot f(n) = 0, \tag{8}$$

$$(D_z D_t - 4\sinh^2(\tfrac{1}{2}D_n)) f(n)\cdot f(n) = 0, \tag{9}$$

respectively, where z is an auxiliary variable and the bilinear operators are defined as follows:[7–9]

$$D_z^m D_t^n a\cdot b \equiv \left(\frac{\partial}{\partial z} - \frac{\partial}{\partial z'}\right)^m \left(\frac{\partial}{\partial t} - \frac{\partial}{\partial t'}\right)^n a(z,t) b(z',t')\Big|_{z'=z, t'=t},$$

$$\exp(\delta D_n) a(n)\cdot b(n) \equiv \exp\left[\delta\left(\frac{\partial}{\partial n} - \frac{\partial}{\partial n'}\right)\right] a(n) b(n')\Big|_{n'=n} = a(n+\delta) b(n-\delta).$$

On the other hand, in Ref. 10 a new, and relatively simple, procedure for finding new integrable differential-difference equation was reported. By combining these two thinkings, it is natural to search for new integrable systems such that the systems have the bilinear forms of the type (6) and (7) and (8) and (9) and the corresponding bilinear Bäcklund transformations could be found. With such a motivation in mind and after some tests and guesses, we now propose the following new system:

$$v_t(n) = v(n)(2u(n) - u(n+1) - u(n-1)), \tag{10}$$

$$u_t(n+1) + u_t(n-1) + v(n) u_t(n) + \tfrac{3}{4}(u(n+1) - u(n-1))^2 + \tfrac{1}{4}(u(n+1) + u(n-1) - 2u(n))^2 + \tfrac{1}{4}(v(n) - 1) = 0. \tag{11}$$

By the dependent variable transformation

$$u(n) = (\ln f(n))_t, \quad v(n) = \frac{f^2(n)}{f(n+1) f(n-1)}$$

and by use of (A1), (A2), (A3), (10) and (11) can be transformed into the following form:

$$[(3D_t^2 e^{D_n} + 3D_t^2 - e^{D_n} + 1) f(n)\cdot f(n)] f(n)^2 + [(1 - e^{D_n}) f(n)\cdot f(n)](D_t^2 f(n)\cdot f(n)) + D_t^2[(e^{D_n} - 1) f(n)\cdot f(n)]\cdot f^2(n) = 0. \tag{12}$$

Further, by introducing an auxiliary variable z and using (A4), we can decouple (12) into the following bilinear form:

$$(D_z D_t - 2e^{D_n} + 2) f(n)\cdot f(n) = 0, \tag{13}$$

$$(D_t^3 D_z + 6D_t^2 e^{D_n} + 6D_t^2 - 2e^{D_n} + 2) f(n)\cdot f(n) = 0. \tag{14}$$

Equation (11) may be rewritten as

$$u_t(n) + (T_+ + T_- + v(n))^{-1}[\tfrac{3}{4}(u(n+1) - u(n-1))^2 + \tfrac{1}{4}(u(n+1) + u(n-1) - 2u(n))^2 + \tfrac{1}{4}(v(n) - 1)] = 0, \tag{15}$$

where $T_\pm u(n) \equiv u(n\pm 1)$. Obviously (15) is nonlocal. However, to our knowledge, most integrable differential-difference systems appeared in literature such as the Toda lattice, Volterra equation are local. Therefore it is far from obvious to find such a transformation if there exists some transformation (point transformation, Miura-like transformation, etc.) which relates the system (10) and (11) to some other one already in the literature. On the other hand, from the viewpoint of bilinear formalism, to our knowledge it is the first time to consider the bilinear equations (13) and (14) simultaneously with z being an auxiliary variable, although (13) is just the bilinear form of the two-dimensional Toda lattice. Based on these explanations, it would be reasonable to view (13) and (14) as a new system.

The paper is organized as follows. In Sec. II we give a Bäcklund transformation for Eqs. (13) and (14). Then in Sec. III, we give a brief proof of a nonlinear superposition formula. Some particular solutions of Eqs. (13) and (14) are then found through this formula. Finally, Sec. IV summarizes the obtained results. An Appendix lists some bilinear operator identities made use of in this paper.

II. A BÄCKLUND TRANSFORMATION

In this section, we shall derive a Bäcklund transformation for Eqs. (13) and (14). The result obtained is:

Proposition 1: A Bäcklund transformation (BT) for (13) and (14) is

$$(D_z+\lambda^{-1}e^{-D_n}+\mu)f(n)\cdot g(n)=0, \tag{16}$$

$$(D_te^{-(1/2)D_n}-\lambda e^{(1/2)D_n}+\gamma e^{-(1/2)D_n})f(n)\cdot g(n)=0, \tag{17}$$

$$\begin{aligned}&[\lambda^{-1}D_t^3e^{-D_n/2}+3D_t^2e^{D_n/2}+3\lambda^{-1}\gamma D_t^2e^{-(1/2)D_n}+6\gamma D_te^{(1/2)D_n}+(6\gamma^2-1)e^{(1/2)D_n}\\&\quad+\omega e^{-(1/2)D_n}]f(n)\cdot g(n)=0,\end{aligned} \tag{18}$$

where λ, μ, γ, and ω are arbitrary constants.

Proof: Let $f(n)$ be a solution of Eqs. (13) and (14). If we can show that Eqs. (16)–(18) guarantee that the following two relations

$$P_1\equiv(D_zD_t-2e^{D_n}+2)g(n)\cdot g(n)=0,$$

$$P_2\equiv(D_t^3D_z+6D_t^2e^{D_n}+6D_t^2-2e^{D_n}+2)g(n)\cdot g(n)=0,$$

hold, then Eqs. (16)–(18) form a Bäcklund transformation.

In fact, same as the proof in Ref. 11, we know that $P_1=0$ can be proved using Eqs. (16) and (17). Thus it suffices to show that $P_2=0$. For this, by making use of (A5)–(A11), (16)–(18), we have

$$\begin{aligned}-f(n)^2P_2&=[(D_t^3D_z+6D_t^2e^{D_n}+6D_t^2-2e^{D_n}+2)f(n)\cdot f(n)]g(n)^2\\&\quad-f(n)^2[(D_t^3D_z+6D_t^2e^{D_n}+6D_t^2-2e^{D_n}+2)g(n)\cdot g(n)]\\&\quad+3[(D_zD_t-2e^{D_n}+2)f(n)\cdot f(n)][D_t^2g(n)\cdot g(n)]\\&\quad-3[D_t^2f(n)\cdot f(n)][(D_zD_t-2e^{D_n}+2)g(n)\cdot g(n)]\\&=2D_t^3(D_zf(n)\cdot g(n))\cdot f(n)g(n)\\&\quad+12D_t\cosh(\tfrac{1}{2}D_n)[(D_te^{(1/2)D_n}f(n)\cdot g(n))\cdot(e^{-(1/2)D_n}f(n)\cdot g(n))\\&\quad-(e^{(1/2)D_n}f(n)\cdot g(n))\cdot(D_te^{-(1/2)D_n}f(n)\cdot g(n))]\\&\quad-4\sinh(\tfrac{1}{2}D_n)(e^{(1/2)D_n}f(n)\cdot g(n))\cdot(e^{-(1/2)D_n}f(n)\cdot g(n))\end{aligned}$$

&\quad -4\sinh(\tfrac{1}{2}D_n)(e^{(1/2)D_n} f(n)\cdot g(n))\cdot(e^{-(1/2)D_n} f(n)\cdot g(n))=0.
\end{aligned}
$$

Thus we have completed the proof of proposition 1.

By using (16)–(18), we can easily obtain the following solutions from the trivial solution $f(n)=1$:

$$g(n)=1+\exp(\eta)$$

with

$$\lambda=\pm\sqrt{\frac{e^{(1/2)p}-e^{-(1/2)p}}{4e^{(1/2)p}-4e^{-(5/2)p}}},\quad \mu=-\lambda^{-1},\quad \gamma=\lambda,\quad \omega=-6\lambda^2+1,$$

where $\eta=pn+qz+rt+\eta^0$, $q=\lambda^{-1}(e^p-1)$, $r=\lambda(1-e^{-p})$.

III. A NONLINEAR SUPERPOSITION FORMULA

In the following, we shall simply denote, without confusion, $f(n,t)=f(n)$ or f. The result reached is

Proposition 2: Let f_0 be a solution of Eqs. (13) and (14) and suppose that f_i $(i=1,2)$ are solutions of (13) and (14) which are related to f_0 under the BT Eqs. (16)–(18) with parameters $(\lambda_i,\mu_i,\gamma_i,\omega_i)$, i.e.,

$$f_0 \xrightarrow{(\lambda_i,\mu_i,\gamma_i,\omega_i)} f_i \quad (i=1,2),\quad \lambda_1\lambda_2\neq 0,\ f_j\neq 0\ \ (j=0,1,2).$$

Then f_{12} defined by

$$\exp(-\tfrac{1}{2}D_n) f_0\cdot f_{12}=k[\lambda_1\exp(-\tfrac{1}{2}D_n)-\lambda_2\exp(\tfrac{1}{2}D_n)] f_1\cdot f_2 \quad (k \text{ is a nonzero constant}) \tag{19}$$

is a new solution which is related to f_1 and f_2 under the BT (16)–(18) with parameters $(\lambda_2,\mu_2,\gamma_2,\omega_2)$, $(\lambda_1,\mu_1,\gamma_1,\omega_1)$, respectively.

Proof: Same as the deduction in Refs. 11 and 6, we can show that

$$(D_z+\lambda_2^{-1}e^{-D_n}+\mu_2)f_1\cdot f_{12}=0, \tag{20}$$

$$(D_z+\lambda_1^{-1}e^{-D_n}+\mu_1)f_2\cdot f_{12}=0, \tag{21}$$

$$(D_te^{-(1/2)D_n}-\lambda_2e^{(1/2)D_n}+\gamma_2e^{-(1/2)D_n})f_1\cdot f_{12}=0, \tag{22}$$

$$(D_te^{-(1/2)D_n}-\lambda_1e^{(1/2)D_n}+\gamma_1e^{-(1/2)D_n})f_2\cdot f_{12}=0, \tag{23}$$

$$-D_zf_1\cdot f_2+(\mu_1-\mu_2)f_1f_2-\frac{1}{k\lambda_1\lambda_2}e^{-D_n}f_0\cdot f_{12}=0, \tag{24}$$

$$(\lambda_2D_te^{(1/2)D_n}+\lambda_1D_te^{-(1/2)D_n}-2\lambda_2\gamma_1e^{(1/2)D_n}+2\lambda_1\gamma_2e^{-(1/2)D_n})f_1\cdot f_2+\frac{1}{k}D_te^{-(1/2)D_n}f_0\cdot f_{12}=0. \tag{25}$$

Therefore in order to prove proposition 2, it suffices to show that

$$[\lambda_2^{-1}D_t^3e^{-D_n/2}+3D_t^2e^{D_n/2}+3\lambda_2^{-1}\gamma_2D_t^2e^{-(1/2)D_n}+6\gamma_2D_te^{(1/2)D_n}+(6\gamma_2^2-1)e^{(1/2)D_n} +\omega_2e^{-(1/2)D_n}]f_1\cdot f_{12}=0, \tag{26}$$

$$[\lambda_1^{-1}D_t^3e^{-(D_n/2)}+3D_t^2e^{(D_n/2)}+3\lambda_1^{-1}\gamma_1D_t^2e^{-(1/2)D_n}+6\gamma_1D_te^{(1/2)D_n}+(6\gamma_1^2-1)e^{(1/2)D_n} +\omega_1e^{-(1/2)D_n}]f_2\cdot f_{12}=0. \tag{27}$$

Since f_1 and f_2 are two solutions of Eqs. (13) and (14), we have, by use of (A5)–(A15), (19), (20), (22), (24), (25) and

$$f_0\xrightarrow{(\lambda_2,\mu_2,\gamma_2,\omega_2)}f_2,$$

that

$$\begin{aligned}

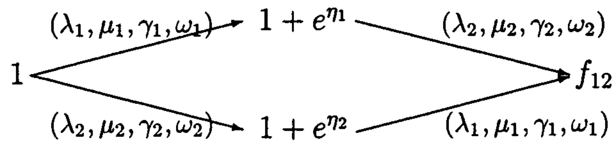
which implies that (26) holds. Similarly we can prove (27) also holds. Therefore we have completed the proof of the proposition 2.

As an application of the result, we can construct soliton solutions of Eqs. (13) and (14). Choose for example $f_0=1$, $c=1/(\lambda_1-\lambda_2)$. It is easily verified that



where

$$f_{12}=1+\frac{\lambda_1 e^{-p_1}-\lambda_2}{\lambda_1-\lambda_2}e^{\eta_1}+\frac{\lambda_1-\lambda_2 e^{-p_2}}{\lambda_1-\lambda_2}e^{\eta_2}+\frac{\lambda_1 e^{-p_1}-\lambda_2 e^{-p_2}}{\lambda_1-\lambda_2}e^{\eta_1+\eta_2}$$

with

$$\eta_i=p_i n+q_i z+r_i t+\eta_i^0,\quad q_i=\lambda_i^{-1}(e^{p_i}-1),\quad r_i=\lambda_i(1-e^{-p_i})$$

and

$$\lambda_i=\pm\sqrt{\frac{e^{(1/2)p_i}-e^{-(1/2)p_i}}{4e^{(1/2)p_i}-4e^{-(5/2)p_i}}},\quad \mu_i=-\lambda_i^{-1},\quad \gamma_i=\lambda_i,\quad \omega_i=-6\lambda_i^2+1.$$

In general, along this line, we can obtain multisoliton solutions for Eqs. (13) and (14) step by step.

IV. CONCLUSION AND DISCUSSIONS

A new integrable differential-difference system is proposed. By the dependent variable transformation, the system is transformed into multilinear form. By introducing an auxiliary variable, we further transform it into the bilinear form. A corresponding Bäcklund transformation for it is obtained. Furthermore a nonlinear superposition formula is presented. As an application of the obtained results, soliton solutions to the system are derived. As is known, it is of both theoretical and practical value to find as many new integrable systems as possible and to elucidate in depth their algebraic and geometric properties. In theory, it will greatly help to formulate a criterion for integrability, which is a long-standing open problem; and in practice it will provide us with dozens of nonlinear systems, which are of potential value in physical applications. Therefore we hope our proposed system (10) and (11) will model the behavior of some physical, or biological system. Moreover, it also would be of interest to study other algebraic and geometric properties for (10) and (11), e.g., to see if it has Hamiltonian structure and belongs to hierarchies associated to some linear problem. Besides, we can further consider the following extended form of (13) and (14):

$$(D_z D_t-2e^{D_n}+2)f(n)\cdot f(n)=0, \tag{28}$$

$$(D_t^3 D_z + 6D_t^2 e^{D_n} + 6D_t^2 + AD_t e^{D_n} - 2e^{D_n} + 2) f(n) \cdot f(n) = 0, \tag{29}$$

where A is an arbitrary constant.

High-frequency soliton-like waves in a relaxing medium

V. O. Vakhnenko[a)]
Division of Geodynamics of Explosion, Institute for Geophysics, 252054 Kyiv, Ukraine

(Received 23 March 1998; accepted for publication 6 October 1998)

A nonlinear evolution equation is suggested to describe the propagation of waves in a relaxing medium. It is shown that for low-frequency approach this equation is reduced to the KdVB equation. The high-frequency perturbations are described by a new nonlinear equation. This equation has ambiguous looplike solutions. It is established that a dissipative term, with a dissipation parameter less than some limit value, does not destroy these looplike solutions. © *1999 American Institute of Physics.* [S0022-2488(99)00503-4]

I. INTRODUCTION

As a rule the behavior of media under the action of high-frequency wave perturbations is not described in the framework of equilibrium models of continuum mechanics. So, to develop physical models for wave propagation through media with complicated inner kinetics, the notions based on the relaxational nature of a phenomenon are regarded to be promising and fruitful.

The description of nonlinear processes arising in different areas of research can often be reduced to the well-known Korteweg–de Vries (KdV) equation.[1,2] It turns out that low-frequency perturbations in a relaxing medium satisfy the KdV equation, too. The high-frequency perturbations are described by a new nonlinear evolution equation which has been investigated in Refs. 3 and 4. This equation has an ambiguous solution in the form of a solitary wave. This work deals with the looplike solutions of the model evolution equation. It is proved that the dissipative term, with a dissipation parameter less than some limit value, does not destroy the looplike solutions.

II. LOW-FREQUENCY AND HIGH-FREQUENCY PERTURBATIONS IN RELAXING MEDIUM

Thermodynamic equilibrium is disturbed owing to the propagation of fast perturbations in a medium. There are processes of the interaction that tend to return the equilibrium. The parameters characterizing this interaction are referred to as the inner variables unlike the macroparameters such as the pressure p, mass velocity u, and density ρ. In essence, the change of macroparameters caused by the changes of inner parameters is a relaxation process. From the nonequilibrium thermodynamics standpoint, the models of a relaxing medium are more general than the equilibrium models for describing the evolution of the wave perturbations.

We restrict our attention to barothropic media. An equilibrium state equation of a barothropic medium is a one-parameter equation. As a result of relaxation, an additional variable ξ (inner parameter) appears in the state equation. It defines the completeness of the relaxation process

$$p=p(\rho,\xi). \tag{2.1}$$

There are two limiting cases:

(*i*) the lack of the relaxation (inner interaction processes are frozen) $\xi=1$.

$$p=p(\rho,1)\equiv p_f(\rho), \tag{2.2}$$

(*ii*) the relaxation complete (there is the local thermodynamic equilibrium) $\xi=0$:

[a)]Electronic mail: vakhnenko@bitp.kiev.ua

$$p = p(\rho,0) \equiv p_e(\rho). \tag{2.3}$$

These relationships enable us to introduce the sound velocities for fast processes

$$c_f^2 = dp_f/d\rho \tag{2.4}$$

and for slow processes

$$c_e^2 = dp_e/d\rho. \tag{2.5}$$

Slow and fast processes are compared by means of the relaxation time τ_p. The dynamic state equation is written down in the form of the differential first-order equation

$$\tau_p\left(\frac{dp}{dt} - c_f^2\frac{d\rho}{dt}\right) + (p - p_e) = 0. \tag{2.6}$$

Clearly, for the fast processes ($\omega\tau_p \gg 1$) we have the relation (2.2), and for the slow ones ($\omega\tau_p \ll 1$) we obtain (2.3).

The substantiation of this equation within the framework of the thermodynamics of irreversible processes has been given in Refs. 5–8. The mechanism of the exchange (inner) processes is not defined concretely when the equation (2.6) is derived, and the thermodynamic and kinetic parameters appear in this equation only. These characteristics can be found by experiment. The dynamic state equation (2.6) enables us to take into account the exchange processes completely. We note that the phenomenological approach for describing the relaxation processes in hydrodynamics is developed in many works.[7–10] The dynamic state equation was used to describe the propagation of sound in a relaxing medium,[7] to take into account the exchange processes within media (gas–solid particles),[8] and to study wave fields in gas-liquid media[9] and in soils.[10] In most works the state equation has been derived from the concept of some concrete mechanism for the inner process.

To analyze the wave motion, we shall use the hydrodynamic equations: the law of the conservation of mass

$$\frac{\partial V}{\partial t} - \frac{\partial u}{\rho_0 \partial x} = 0 \tag{2.7}$$

and the law of the conservation of momentum

$$\frac{\partial u}{\partial t} + \frac{\partial p}{\rho_0 \partial x} = 0. \tag{2.8}$$

Here $V \equiv \rho^{-1}$ is specific volume and x is Lagrangian space coordinate.

The closed system of equations consists of two motion equations (2.7) and (2.8) and the dynamic state equation (2.6). The motion equations (2.7) and (2.8) are written in Lagrangian coordinates, since the state equation (2.6) is related to the element of the mass of medium.

Let us consider a small perturbation $p' < p_0$. The state equations for fast [(2.2)] and slow [(2.3)] processes are considered to be known. They can be expanded as the power series with accuracy $O(p'^2)$

$$V_f(p_0 + p') = V_0 - c_f^{-2} V_0^2 p' + \frac{1}{2}\left.\frac{d^2 V_f}{dp^2}\right|_{p=p_0} p'^2 + \ldots,$$

$$V_e(p_0+p')=V_0-c_e^{-2}V_0^2p'+\frac{1}{2}\frac{d^2V_e}{dp^2}\bigg|_{p=p_0}p'^2+\ \ldots .$$

Hereafter, the velocities c_e, c_f are related to initial pressure p_0. Combining these two relationships with the motion equations (2.7) and (2.8), we obtain the equation in one unknown (the dash in p' is omitted):

$$\tau_p\frac{\partial}{\partial t}\left(\frac{\partial^2 p}{\partial x^2}-c_f^{-2}\frac{\partial^2 p}{\partial t^2}+\frac{1}{2V_0^2}\frac{d^2V_f}{dp^2}\bigg|_{p=p_0}\frac{\partial^2 p^2}{\partial t^2}\right)+\left(\frac{\partial^2 p}{\partial x^2}-c_e^{-2}\frac{\partial^2 p}{\partial t^2}+\frac{1}{2V_0^2}\frac{d^2V_e}{dp^2}\bigg|_{p=p_0}\frac{\partial^2 p^2}{\partial t^2}\right)=0. \tag{2.9}$$

A similar equation has been obtained in Ref. 5, though without nonlinear terms.

Now we shall show that for low-frequency perturbations the equation (2.9) is reduced to the Korteweg–de Vries–Burgers (KdVB) equation, while for high-frequency waves we shall obtain the equation with hydrodynamic nonlinearity and term that appeared in the Klein–Gordon equation.

To analyze the equation (2.9), let us apply the multiscale method.[11,12] The value $\varepsilon\equiv\tau_p\omega$ is chosen to be small (large) parameter where the quantity ω is the characteristic frequency of wave perturbation. For the sake of convenience we rewrite the equation (2.9) as follows:

$$\tau_p\omega\frac{\partial}{\partial t\omega}\left(\frac{\partial^2 p}{\partial (x\omega)^2}-c_f^{-2}\frac{\partial^2 p}{\partial (t\omega)^2}+\alpha_f\frac{\partial^2 p^2}{\partial (t\omega)^2}\right)+\left(\frac{\partial^2 p}{\partial (x\omega)^2}-c_e^{-2}\frac{\partial^2 p}{\partial (t\omega)^2}+\alpha_e\frac{\partial^2 p^2}{\partial (t\omega)^2}\right)=0, \tag{2.10}$$

$$\alpha_f=\frac{1}{2V_0^2}\frac{d^2V_f}{dp^2}\bigg|_{p=p_0},\qquad \alpha_e=\frac{1}{2V_0^2}\frac{d^2V_e}{dp^2}\bigg|_{p=p_0},$$

and introduce new independent variables

$$T_0=t\omega,\quad X_0=x\omega,\quad T_{-2}=t\omega/\varepsilon^2,\quad X_{-2}=x\omega/\varepsilon^2.$$

It is precisely these variables that cause the equations, obtained within the framework of multiscale method[11,12]

$$O(\varepsilon^{+1}):\frac{\partial}{\partial T_0}\left(\frac{\partial^2 p}{\partial X_0^2}-c_f^{-2}\frac{\partial^2 p}{\partial T_0^2}+\alpha_f\frac{\partial^2 p^2}{\partial T_0^2}\right)=0,$$

$$O(\varepsilon^{0}):\frac{\partial^2 p}{\partial X_0^2}-c_e^{-2}\frac{\partial^2 p}{\partial T_0^2}+\alpha_e\frac{\partial^2 p^2}{\partial T_0^2}=0,$$

$$O(\varepsilon^{-1}):\left(\frac{\partial^3}{\partial X_0^2\partial T_{-2}}+2\frac{\partial^3}{\partial T_0\partial X_0\partial X_{-2}}\right)p-3c_f^{-2}\frac{\partial^3 p}{\partial T_0^2\partial T_{-2}}+3\alpha_f\frac{\partial^3 p^2}{\partial T_0^2\partial T_{-2}}=0,$$

$$O(\varepsilon^{-2}):\frac{\partial^2 p}{\partial X_0\partial X_{-2}}-c_e^{-2}\frac{\partial^2 p}{\partial T_0\partial T_{-2}}+\alpha_e\frac{\partial^2 p^2}{\partial T_0\partial T_{-2}}=0, \tag{2.11}$$

$$O(\varepsilon^{-3}):\left(\frac{\partial^3}{\partial T_0\partial X_{-2}^2}+2\frac{\partial^3}{\partial X_0\partial X_{-2}\partial T_{-2}}\right)p-3c_f^{-2}\frac{\partial^3 p}{\partial T_0\partial T_{-2}^2}+3\alpha_f\frac{\partial^3 p^2}{\partial T_0\partial T_{-2}^2}=0,$$

$$O(\varepsilon^{-4}):\frac{\partial^2 p}{\partial X_{-2}^2}-c_e^{-2}\frac{\partial^2 p}{\partial T_{-2}^2}+\alpha_e\frac{\partial^2 p^2}{\partial T_{-2}^2}=0,$$

$$O(\varepsilon^{-5}):\frac{\partial}{\partial T_{-2}}\left(\frac{\partial^2 p}{\partial X_{-2}^2}-c_f^{-2}\frac{\partial^2 p}{\partial T_{-2}^2}+\alpha_f\frac{\partial^2 p^2}{\partial T_{-2}^2}\right)=0,$$

to be partially uncoupled. The two leading equations depend on T_0 and X_0 only, while the last two equations include the independent variables T_{-2} and X_{-2} only. Thus, the low-frequency perturbations are described by the two leading equations, and the high-frequency perturbations are described by the last two equations. An interaction between these perturbations is described by the three center equations.

Let us write out the motion equations for low-frequency and high-frequency perturbations in the initial variables x and t. For low-frequency perturbations the main terms $\partial^2 p/\partial x^2$ and $c_e^{-2}\partial^2 p/\partial t^2$ appear in the second equation of the system (2.11), while for high-frequency perturbations the main terms $\partial^2 p/\partial x^2$ and $c_f^{-2}\partial^2 p/\partial t^2$ appear in the seventh equation of (2.11).

For low-frequency perturbations $(\tau_p\omega\ll 1)$ propagating in one direction, we obtain an evolution equation

$$\frac{\partial p}{\partial t}+c_e\frac{\partial p}{\partial x}+\alpha_e c_e^3 p\frac{\partial p}{\partial x}-\beta_e\frac{\partial^2 p}{\partial x^2}+\gamma_e\frac{\partial^3 p}{\partial x^3}=0,$$

$$\beta_e=\frac{c_e^2\tau_p}{2c_f^2}(c_f^2-c_e^2),\qquad \gamma_e=\frac{c_e^3\tau_p^2}{8c_f^4}(c_f^2-c_e^2)(c_f^2-5c_e^2). \tag{2.12}$$

This equation can be obtained in the following way. A dispersion relation for the linearized equation (2.10) can be written down with an accuracy $O(k^3)$ in the form $\omega=c_e k+i\beta_e k^2-\gamma_e k^3$, if the terms $c_e^{-1}\partial p/\partial t$ and $\partial p/\partial x$ are the main ones. For this dispersion relation we write a linear equation in which a nonlinear term is reconstructed in agreement with the initial equation.

The equation (2.12) is the well-known KdVB equation. It is encountered in many chapters of physics to describe nonlinear wave processes.[1] In Ref. 2 it was shown how hydrodynamic equations reduce to either the KdV or Burgers equation according to the choices for the state equation and the generalized force when analyzing the gasdynamical waves, waves in shallow water,[2] hydrodynamic waves in cold plasma,[13] or ion-acoustic waves in cold plasma.[14] The KdV equation $(\beta_e=0)$ has stationary solutions (solitons). In the case of $\beta_e\neq 0$ the stationary solutions of the equation (2.12) are known also.[15]

For high-frequency perturbations $(\tau_p\omega\gg 1)$, using the last two equations of the system (2.11), we get the following evolution equation:

$$\frac{\partial^2 p}{\partial x^2}-c_f^{-2}\frac{\partial^2 p}{\partial t^2}+\alpha_f c_f^2\frac{\partial^2 p^2}{\partial x^2}+\beta_f\frac{\partial p}{\partial x}+\gamma_f p=0,$$

$$\beta_f=\frac{c_f^2-c_e^2}{\tau_p c_e^2 c_f},\qquad \gamma_f=\frac{c_f^4-c_e^4}{2\tau_p^2 c_e^4 c_f^2}. \tag{2.13}$$

In addition to the nonlinear term with coefficient α_f, the equation has dissipative $\beta_f\,\partial p/\partial x$ and dispersive $\gamma_f p$ terms. If $\alpha_f=\beta_f=0$, this is a linear Klein–Gordon equation. There is a Green's function for this equation[16,17] that enables us to find the solution in quadrature, at least. Numerical solutions of the Klein–Gordon equation modeling the propagation of high-frequency perturbations in gas–liquid media have been presented in Ref. 17. Whitham's monograph[18] has also described a similar evolution equation for high-frequency perturbations, but its form coincides with that of Eq. (2.13) only when $\alpha_f=0$ and $\gamma_f=0$.

Landau and Lifshitz have shown that for high frequencies the dissipative term under high transport of heat agrees with corresponding term in the equation (2.13) (see section 79 and 81 in Ref. 7). Thus, the dynamic state equation (2.6) enable us to take into account the dissipative processes completely. But the form of the dissipative terms describing the inner exchange processes (transport of heat and momentum) are different for the high and low frequencies.

We call attention to the fact that the dispersion relations $\omega=\omega(k)$ for the linearized equations (2.12) and (2.13) have been restricted by the finite power series in k and in k^{-1}, respectively:

$$\omega=c_e k+i\beta_e k^2-\gamma_e k^3, \quad \tau_p\omega\ll 1,$$

$$c_f^{-2}\omega^2=k^2+i\beta_f k-\gamma_f, \quad \tau_p\omega\gg 1.$$

In the general case the equation (2.13) has been investigated insufficiently. It is likely that this is connected with the fact noted by Whitham[18] that the high-frequency perturbations attenuate very fast. However, in Ref. 18 the evolution equation without nonlinear and dispersive terms was considered. Certainly, the lack of such terms restricts the class of solutions. At least, there is no solution in the form of a solitary wave which is caused by nonlinearity and dispersion.

The studies of the equation (2.13) have some scientific interest both from the viewpoint of the investigation of the propagation of high-frequency perturbations and from the viewpoint of the existence of stable wave formations.

III. EVOLUTION EQUATION FOR HIGH-FREQUENCY PERTURBATIONS

The equation (2.13), which we are interested in, is written down in dimensionless form. Let us restrict our consideration to the propagation of high-frequency waves in positive direction x, then with necessary accuracy we can write the operator

$$\frac{\partial^2}{\partial x^2}-c_f^{-2}\frac{\partial^2}{\partial t^2}=\left(\frac{\partial}{\partial x}-c_f^{-1}\frac{\partial}{\partial t}\right)\left(\frac{\partial}{\partial x}+c_f^{-1}\frac{\partial}{\partial t}\right)\rightarrow 2\frac{\partial}{\partial x}\left(\frac{\partial}{\partial x}+c_f^{-1}\frac{\partial}{\partial t}\right)$$

(for example, see section 93 in Ref. 7). In the moving coordinates system with velocity c_f, the equation has the form in dimensionless variables $\tilde{x}=\sqrt{\gamma_f/2}(x-c_f t)$, $\tilde{t}=\sqrt{\gamma_f/2}c_f t$, $\tilde{u}=\alpha_f c_f^2 p$ (tilde over variables $\tilde{x},\tilde{t}$, $\tilde{u}$ is omitted):

$$\frac{\partial}{\partial x}\left(\frac{\partial}{\partial t}+u\frac{\partial}{\partial x}\right)u+\alpha\frac{\partial u}{\partial x}+u=0. \tag{3.1}$$

The constant $\alpha=\beta_f/\sqrt{2\gamma_f}$ is always positive.

The equation (3.1) without the dissipative term has the form of the nonlinear equation[3,4]

$$\frac{\partial}{\partial x}\left(\frac{\partial}{\partial t}+u\frac{\partial}{\partial x}\right)u+u=0. \tag{3.2}$$

These equations are related to that of Whitham[18] with the kernels $K(x)=\frac{1}{2}[\alpha(2\Theta(x)-1)+|x|]$ and $K(x)=\frac{1}{2}|x|$ (see Eq. (2) in Ref. 3) and are written as

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+\alpha u+\frac{1}{2}\int_{-\infty}^{\infty}|x-s|\frac{\partial u}{\partial s}ds=0, \tag{3.3}$$

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+\frac{1}{2}\int_{-\infty}^{\infty}|x-s|\frac{\partial u}{\partial s}ds=0, \tag{3.4}$$

where $\Theta(x)$ is a Heaviside function. There is no derivative in the dissipative term αu of Eq. (3.3).

Papers[3,4] are devoted to the analysis of the equation (3.2). In Ref. 4 it was named Vakhnenko's equation. The equation (3.2) has two families of traveling wave solutions.[3,4] In one case the solutions have looplike form (see Fig. 1 in Ref. 3). Only in this case is there a solitary wave solution. In Ref. 4 it is predicted that both families of solutions are stable to long wavelength perturbations. The existence of singular points, at which the derivatives tend to infinity, required the application of a nonstandard method.[4] The ambiguous structure is similar to the loop soliton solution to an equation that models a stretched rope.[19] The looplike solitons on a vortex filament were investigated by Hasimoto[20] and Lamb, Jr.[21]

The material described below deals with the ambiguous looplike solutions of the equation (3.1). From the mathematical point of view the ambiguous solution does not present difficulties while the physical interpretation of ambiguity always has some difficulties. In this connection the problem of ambiguous solutions is regarded to be important. The problem consists in whether the ambiguity has a physical nature or is related to the incompleteness of mathematical model, in particular to the lack of dissipation.

We will consider the problem related to the singular points when the dissipation takes place. At these points the dissipative term $\alpha\,\partial u/\partial x$ tends to infinity. The question arises: are there solutions of the equation (3.1) in a looplike form? That the dissipation is likely to destroy the looplike solutions can be associated with the following well-known fact.[1] For a simplest nonlinear equation without dispersion and dissipation,

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}=0, \tag{3.5}$$

any initial smooth solution with boundary conditions

$$u|_{x\to+\infty}=0, \quad u|_{x\to-\infty}=u_0=\text{const}>0$$

becomes ambiguous in the final analysis. When the dissipation is considered, we have a Burgers equation[22]

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+\mu\frac{\partial^2 u}{\partial x^2}=0.$$

The dissipative terms of this equation and Eq. (2.13) for low frequency are coincided. The inclusion of the dissipative term transforms the solutions so that they cannot be ambiguous as a result of evolution. The wave parameters are always unambiguous. What happens in our case for the high frequency when the dissipative term has the form αu [Eq. (3.3)]? Will the inclusion of dissipation give rise to unambiguous solutions? It turns out that, and here this has been proved, the dissipative term, with a dissipation parameter less than some limit value, does not destroy the looplike solutions. A physical interpretation is given to ambiguous solutions.

IV. AMBIGUOUS SOLUTIONS

Let us pass to the coordinates in which the equation (3.2) has stationary periodic solutions [see Eq. (7) in Ref. 3]

$$\eta=x-vt, \quad \tau=t, \tag{4.1}$$

where v is a nonzero constant. Eq. (3.2) has looplike solutions when $v>0$. Parkes noted[4] that there are no stationary periodic solution of (3.2) when $v=0$. After substitution of

$$z = u - v$$

into Eq. (3.1) we get the evolution equation

$$z_{\tau\eta} + (z z_\eta)_\eta + (z + v) + \alpha z_\eta = 0. \tag{4.2}$$

We investigate the solution behavior within the neighborhood of singular points $z=0$ where $z_\eta \to \pm\infty$ and $z_\tau \ll z_\eta$. Therefore in the investigated equation (4.2) we neglect the term z in comparison with v, and also discard the term z_τ, to obtain

$$(z z_\eta)_\eta + v + \alpha z_\eta = 0. \tag{4.3}$$

It is convenient to use the inverse function $\eta = \eta(z)$. Taking into account $z_\eta = 1/\eta_z$ and $z_{\eta\eta} = -\eta_{zz}/\eta_z^3$, Eq. (4.3) is rewritten as

$$-z\,\eta_{zz} + v\,\eta_z^3 + \alpha\,\eta_z^2 + \eta_z = 0.$$

Introducing the definition $q \equiv \eta_z$, this equation can be integrated to obtain

$$\int \frac{dq}{q(vq^2 + \alpha q + 1)} = \int \frac{dz}{z}.$$

Depending on the sign of the quantity $1 - \alpha^2/4v$, the latter expression has two different forms. We have introduced the critical value α^* of the parameter α defined by

$$\alpha^* = 2\sqrt{v}. \tag{4.4}$$

For $\alpha < \alpha^*$ (i.e., $1 - \alpha^2/4v > 0$), we get

$$\ln\left[\frac{z^2}{q^2}(vq^2 + \alpha q + 1)\right] = -\frac{2\alpha}{\sqrt{4v - \alpha^2}} \mathrm{tg}^{-1} \frac{2vq + \alpha}{\sqrt{4v - \alpha^2}} + \ln c_1, \tag{4.5}$$

and for $\alpha > \alpha^*$ (i.e., $1 - \alpha^2/4v < 0$), we have

$$\ln\left[\frac{z^2}{q^2}(vq^2 + \alpha q + 1)\right] = \frac{\alpha}{\sqrt{\alpha^2 - 4v}} \ln\left|\frac{2vq + \alpha + \sqrt{\alpha^2 - 4v}}{2vq + \alpha - \sqrt{\alpha^2 - 4v}}\right| + \ln c_2. \tag{4.6}$$

We analyze the expression (4.5). First let us verify the special case $\alpha = 0$. We have

$$\frac{z^2}{q^2}(vq^2 + 1) = c_1,$$

or

$$vz^2 + \frac{1}{4}(z^2)_\eta^2 = c_1.$$

Hence in the vicinity of $z = 0$,

$$\eta + \eta_0 = \pm\frac{1}{2}\int \frac{dz^2}{\sqrt{c_1 - vz^2}} = \mp\frac{\sqrt{c_1 - vz^2}}{v}.$$

We arrive at the result given in Ref. 3, namely that with the lack of dissipation ($\alpha=0$) the integral curves pass over an ellipse at $z=0$.

Now we investigate the case $0<\alpha<\alpha^*$. It is easy to show that the r.h.s. of (4.5) is always bounded for any value $q\equiv z_\eta^{-1}$. In the neighborhood of $z=0$ the r.h.s. of (4.5) is close to value

$$-\frac{2\alpha}{\sqrt{4v-\alpha^2}}\,\mathrm{tg}^{-1}\frac{\alpha}{\sqrt{4v-\alpha^2}}+\ln c_1\equiv\ln c_3.$$

Consequently, we arrive at the equation

$$\frac{z^2}{q^2}(vq^2+\alpha q+1)=c_3.$$

Even not integrating this equation, it is easy to show that at $z=0$ we must have $q=0$ since in general $c_3\neq 0$. This means that at $z=0$ the derivatives have the values

$$\eta_z=0,\ z_\eta=\pm\infty.$$

At $z=0$ the solution becomes ambiguous.

In the case $\alpha>\alpha^*$ there is the solution

$$z=0,\quad q=\eta_z\neq 0,\qquad z_\eta\neq\pm\infty.$$

In fact, at $z=0$ we obtain from the r.h.s. of (4.6)

$$q=\eta_z=-\frac{\alpha}{2v}-\frac{\sqrt{\alpha^2-4v}}{2v}\neq 0. \tag{4.7}$$

Thus, the derivative z_η at $z=0$ is bounded by a finite value. The solution is always unambiguous.

Let us consider the solution behavior in the neighborhood of $z=0$ as $\alpha\to\alpha^*$. We first consider the case $\alpha\to\alpha^*-0$. According to (4.5) the r.h.s. of this equation tends to minus infinity, i.e., at $z\approx 0$ we have $q=\eta_z\neq 0$. Consequently, there is no looplike solution.

When $\alpha\to\alpha^*+0$ there is also a solution with $q=\eta_z\neq 0$ at $z=0$. The root $q=0$ at $z=0$ seems possible in this case since (4.6) transforms to

$$\ln\left[\frac{z^2}{q^2}(vq^2+\alpha q+1)\right]=\frac{2\alpha}{2vq+\alpha}+\ln c_2. \tag{4.8}$$

However, as appears from (4.7), the r.h.s. of the equation (4.8) tends to minus infinity so that $q\neq 0$ at $z=0$. Therefore, in the case $\alpha\to\alpha^*$ the dissipation destroys the looplike solutions.

We have proved the following statement. For values of $\alpha<\alpha^*$ the inclusion of the dissipative term does not change the looplike solutions of equation (3.1), while for $\alpha\geqslant\alpha^*$ there is no solution with an infinite gradient.

The common form of the dissipative term for high-frequency perturbations αu (which does not depend on the nature of the exchange processes) cannot preclude the possibility of a formation of a multi-valued solution from an initial single-valued profile. In this case there are the infinite gradients in contrast to the profiles of a wave for the low frequencies when the dissipative term has the form $\beta\,\partial^2u/\partial x^2$.

The problem of a multi-valued solution can be forestalled in a following way. The equation (3.2) can be rewritten into new independent variables $y=y(x,t)$ and $t_1=t$ so that the dependent variable $u=u(y,t_1)$ will be a single-valued function of y. These variables have been defined by the relationships

$$\varphi dy = dx - u dt, \quad t_1 = t$$

in which the equation (3.2) has been reduced to a system of the equations in the unknowns u and φ:

$$\frac{\partial \varphi}{\partial t_1} = \frac{\partial u}{\partial y}, \quad \frac{\partial^2 \varphi}{\partial t_1^2} + u\varphi = 0.$$

For example, for a one-soliton solution we have $\varphi = 1 - u/v$ [see Eqs. (12) and (14) in Ref. 3]. In the space of new variables y and t_1 a solution is a single-valued function [Eq. (13) from Ref. 3]. Each state has been uniquely defined by the variable y at any time t.

Considering the dependent variable u and the coordinate x as the functions of new variable y we solve the problem of the ambiguous solution. A number of the states with their thermodynamic parameters can occupy one microvolume, but these states are distinguished by the coordinate y. It is assumed that the interaction between the separated states occupying one microvolume can be neglected in comparison with the interaction between the particles of one thermodynamic state. Even if we shall take into account the interaction between the separated states in accord with the dynamic state equation (2.6), then for high frequencies the dissipative term arises which is similar to the corresponding term in Eq. (2.13), but with the other relaxation time. In this sense the separated terms are distributed in space, but describing the wave process we consider them as interpenetratable. The similar situation, when several components with different hydrodynamic parameters occupied one microvolume, has been assumed in the mixture theory (see, for instance Refs. 23 and 24). Such a fundamental assumption in the theory of mixtures is physically impossible (see Ref. 23, p. 7), but it is appropriate in the sense that separated components are multi-velocity interpenetratable continua.

Thus in the frameworks of this model approach, the high-frequency perturbation can be described by the multi-valued functions.

V. CONCLUSIONS

The KdV and KdVB equations are employed to describe a number of evolution processes when the low-frequency approach turns out to be adequate. In these cases thermodynamic parameters of a medium are close to the equilibrium values, the microvolume state is defined by one set of thermodynamic values, and the disturbance from the equilibrium is taken into account by means of expansion in gradients.[25] If the low-order expansions within the framework of such an approach give rise to an inadequate description, we could take into account the terms of higher order and as a result consider higher frequencies. For example, if Eq. (3.5) has an ambiguous solution (or discontinuous solution), the improvement of models by means of adding higher degree derivatives excludes the ambiguous solutions. So, in the low-frequency approach, an ambiguity is connected with the incompleteness of the mathematical model.

In contrast to this, in models for the propagation of high-frequency perturbations the disturbance from the ''frozen'' state is taken into account by means of expansion in integral terms [see Eq. (3.3) and (3.4)]. The integral terms contain the prehistory of the process. We have just established that a higher order of expansion (in particular, the dissipative term) for the high-frequency evolution equation still allows ambiguous solutions. Consequently, the ambiguity of solution does not relate to the incompleteness of the mathematical model, in particular to the lack of dissipation. In addition there is the space of new independent variables where the solution is the single-valued function.

The following three circumstances show that in the framework of the approach considered here there are the multi-valued solutions when we model the high-frequency wave processes: (1) All parts of looplike solutions are stable to perturbations; this was proved by Parkes.[4] (2) The dissipation does not destroy the looplike solutions (the result of this work). (3) The investigation regarding the interaction of the solitons has shown that it is necessary to take into account the whole ambiguous solution, and not just the separate parts.

It is necessary to note that the substantiation of the nonlinear evolution equation (3.1) within the framework of statistic physics remains an important problem. At present this problem is too difficult since it is connected with the description of high nonequilibrium systems.

It is shown that if an asymptotically flat space–time is asymptotically stationary, in the sense that $\mathcal{L}_\xi g_{ab}$ vanishes at the rate $\sim t^{-3}$ for asymptotically timelike vector field ξ^a, and the energy–momentum tensor vanishes at the rate $\sim t^{-4}$, then the space–time is an asymptotically Schwarzschild space–time. This gives a new aspect of the uniqueness theorem of a black hole. © *1999 American Institute of Physics.* [S0022-2488(99)00704-5]

I. INTRODUCTION

There are many astrophysical phenomena that are best explained by black holes, e.g., active galactic nuclei and x-ray binaries. The analyses on the phenomena are done assuming that those black holes are described by the Kerr space–times. This is because the uniqueness theorem of a black hole guarantees that a space–time which is stationary, vacuum, and asymptotically flat is uniquely the Kerr space–time, and we believe that when gravitational collapse takes place and a black hole is formed, the space–time around it becomes vacuum and accordingly stationary. (For details on the uniqueness theorem of a black hole, see Ref. 1.) However, one may argue that such a space–time does not become *exactly* vacuum or *exactly* stationary: the space–time becomes *asymptotically* vacuum, and accordingly *asymptotically* stationary at a certain rate of the time. In this context, a more adequate ''uniqueness theorem'' is the one that states an asymptotically stationary, vacuum and flat space–time is uniquely an asymptotically Schwarzschild space–time. This is what we show in this paper. (One may find it peculiar that an asymptotically *stationary* space–time is an asymptotically Schwarzschild space–time. However, if we define *asymptotically* Schwarzchild space–times as a class of space–times that asymptotically approach the exact Schwarzschild space–time, the space–times comprise a wide class of space–times, including the Kerr space–time, which is stationary. See the end of Sec. IV for details.)

To show the theorem, we use the notion of the asymptotic flat space–time, first introduced by Ashtekar and Romano[2] at spacelike infinity and succeedingly developed in our previous study[3] at timelike infinity. We investigate the asymptotic behavior of the gravitational field at the future timelike infinity, because we would like to know whether the gravitational field approaches asymptotically that of the Schwarzschild space–time at the *late time* when the space–time becomes asymptotically stationary. The standard definition of the asymptotic flatness[4] is based on the conformal completion method, which is used to obtain the Penrose diagram. This method is useful in that spacelike and timelike infinities can be simultaneously treated with null infinity, and thus that investigation concerning the global causal structure can be done. However, the method compresses the spacelike and timelike infinities, which possess rich 3-manifold information, down to points, and this compression results in a complicated differential structure at these points and makes it difficult to obtain the comprehensive picture of the behavior of gravitational fields in

[a)]JSPS Postdoctoral Fellowship for Research Abroad.

general asymptotically flat space–times. In contrast, the completion method introduced by Ref. 2 for definining the asymptotic flatness at spacelike infinity leaves the infinity as a 3-manifold. As a result, the complicated differential structure in the former treatment can be avoided. Subsequently, in our previous study,[3] we applied the method to timelike infinity and clarified that the method leads to a definite picture of hierarchy in the asymptotic behavior of the gravitational field and the symmetry, and that it is suitable to discuss such a notion as an ''asymptotically Schwarzschild space–time.'' (Perng also investigates hierarchy in the asymptotic gravitational field at spacelike infinity,[5] although it does not directly correspond to the hierarchy discussed in Ref. 3.) In this paper, we further investigate the hierarchy and prove the theorem stating that an asymptotically stationary, vacuum and flat space–time is uniquely an asymptotically Schwarzschild space–time.

The plan of this paper is the following. Section II is devoted to preliminaries. The definition of the asymptotic flatness at timelike infinity is recalled, and some of its useful consequences are summarized for the subsequent discussion. In Sec. III, the first-order asymptotic structure is explored, that is, the one order higher structure than the basic asymptotic structure that all the asymptotic flat space–times possess. Then, in Sec. IV, we introduce the notion of asymptotic stationarity and investigate how the condition that an asymptotic flat space–time be asymptotically stationary, constrain the asymptotic structure. The investigation leads to the proof of the main theorem.

Throughout the paper, we follow the notation of Wald.[6]

II. PRELIMINARIES

In this section, we recall the definition of asymptotic flatness at timelike infinity of Ref. 3 that will be used in the main proof and fix the notation.

Definition: A physical space–time $(\hat{\mathcal{M}},\hat{g}_{ab})$ is said to possess an *asymptote at future timelike infinity* $\breve{\imath}^+$ to *order* n(ATI-n) for a non-negative integer n, if there exists a manifold $\mathcal{M}$ with boundary $\mathcal{H}$, a smooth function Ω defined on $\mathcal{M}$, and an imbedding Ψ of an open subset $\hat{\mathcal{F}}$ in $\hat{\mathcal{M}}$ to $\mathcal{M}-\mathcal{H}$ satisfying the following conditions:

(1) $\breve{\imath}^+ := \partial\mathcal{F}\cap(\mathcal{M}-\Psi(\hat{\mathcal{M}}))$ is not empty and $\breve{\imath}^+\subset I^+(\mathcal{F})$ where $\mathcal{F}:=\Psi(\hat{\mathcal{F}})$;
(2) $\Omega \breve{=} 0$ and $\nabla_a\Omega \breve{\neq} 0$, where $\breve{=}$ denotes the equality evaluated on $\breve{\imath}^+$;
(3) $n^a := \Omega^{-4}\Psi^*\hat{g}^{ab}\nabla_b\Omega$ and $q_{ab}:=\Omega^2(\Psi^*\hat{g}_{ab}+\Omega^{-4}F^{-1}\nabla_a\Omega\nabla_b\Omega)$ admit smooth limits to $\breve{\imath}^+$ with q_{ab} having signature$(+++)$ on $\breve{\imath}^+$, where $F:=-\mathcal{L}_n\Omega$; and
(4) $\lim_{\to\breve{\imath}^+}\Omega^{-(2+n)}T_{\hat{\mu}\hat{\nu}}\breve{=}0$ where $\hat{T}_{\hat{\mu}\hat{\nu}}:=\Psi^*[(\hat{e}_\mu)^a(\hat{e}_\nu)^b\hat{T}_{ab}]$ in which $\{(\hat{e}_\mu)^a\}$ and $\hat{T}_{ab}$ are a tetrad and the physical energy–momentum tensor of $(\hat{\mathcal{M}},\hat{g}_{ab})$, respectively.

Henceforth, we use a tetrad consisting of a unit vector field $\hat{n}^a$ that is normal to the Ω-const surfaces and a triad $\{(\hat{e}_{\mathrm{I}})^a\}_{\mathrm{I}=1,2,3}$ of the metric $\hat{q}_{ab}:=\hat{g}_{ab}+\hat{n}_a\hat{n}_b$ on the Ω-const surface. We denote the timelike components with the subscript 0 and the spacelike component with capital-Roman-letter subscript, e.g., $\hat{A}^{\hat{0}}:=\hat{n}_a\hat{A}^a$ and $\hat{A}^{\hat{\mathrm{I}}}:=(\hat{e}_{\mathrm{I}})_a\hat{A}^a$. If a tensor $A^{a\cdots b}{}_{c\cdots d}$ admits a smooth limit to $\breve{\imath}^+$, it is useful to define the nth order term of $A^{a\cdots b}{}_{c\cdots d}$ as

$$^{(0)}A^{a\cdots b}{}_{c\cdots d}:=\lim_{\to\breve{\imath}^+}A^{a\cdots b}{}_{c\cdots d},$$

$$^{(n)}A^{a\cdots b}{}_{c\cdots d}:=\lim_{\to\breve{\imath}^+}\Omega^{-n}\left(A^{a\cdots b}{}_{c\cdots d}-\sum_{\ell=0}^{n-1}{}^{(\ell)}A^{a\cdots b}{}_{c\cdots d}\Omega^{\ell}\right)\quad\text{for } n\geqslant 1. \tag{1}$$

This definition of the nth order terms of a tensor implies that in the vicinity of $\breve{\imath}^+$, $A^{a\cdots b}{}_{c\cdots d}$ can be expanded as

$$A^{a\cdots b}{}_{c\cdots d}=\sum_{n=0}^{\infty}{}^{(n)}A^{a\cdots b}{}_{c\cdots d}\Omega^n. \tag{2}$$

Since all the equations appearing in the following discussion are those on $\mathcal{M}$, unless it may cause ambiguity, we omit hereafter Ψ^* in front of the tensors defined on $\hat{\mathcal{M}}$ for brevity.

Before we examine the properties of ATI-n space–times, we introduce some valuable tensors. First, the projection operator with respect to the Ω-const surface can be introduced as

$$q^a{}_b := \sum_{I=1,2,3} (\hat{e}_I)^a (\hat{e}_I)_b = \delta^a{}_b + F^{-1} n^a \nabla_b \Omega .$$

This operator admits a smooth limit to $\breve{\imath}^+$ by virtue of the definition of an ATI-n space–time. Second, note that the above definition of an ATI-n space–time implies that $\breve{\imath}^+$ is a 3-submanifold of $\mathcal{M}$ with an imbedding, say Π. Hence, if a tensor field $A^{a\cdots b}{}_{c\cdots d}$ is tangential to $\breve{\imath}^+$, or $A^{a\cdots b}{}_{c\cdots d} := q^a{}_e \cdots q^b{}_f q^g{}_c \cdots q^h{}_d A^{e\cdots f}{}_{g\cdots h}$, it is useful to consider the tensor field $\Pi^* A^{a\cdots b}{}_{c\cdots d}$ defined on $\breve{\imath}^+$. Hereafter, we denote such a tensor field in boldface, i.e., $\mathbf{A}^{a\cdots b}{}_{c\cdots d} := \Pi^* A^{a\cdots b}{}_{c\cdots d}$, and say that $A^{a\cdots b}{}_{c\cdots d}$ induces $\mathbf{A}^{a\cdots b}{}_{c\cdots d}$ on $\breve{\imath}^+$.

Now we explore the consequence of the definition of an ATI-n space–time for $n=0$. Solving the Einstein equation under the falloff condition on the energy–momentum tensor, $\lim_{\to \breve{\imath}^+} \Omega^{-2} \hat{T}_{\hat{\mu}\hat{\nu}} = 0$, it is found that

$$\mathbf{F} \stackrel{\smile}{=} 1, \quad \mathbf{q}_{ab} \stackrel{\smile}{=} \mathbf{h}_{ab} \tag{3}$$

in an ATI-0 space–time, where $h_{ab} = (d\chi)_a (d\chi)_b + \sinh^2 \chi [(d\theta)_a (d\theta)_b + \sin^2 \theta (d\phi)_a (d\phi)_b]$ is the 3-metric of the unit timelike 3-hyperboloid. (For the details of the derivation, see Ref. 3.) Because Eq. (3) is a gravitational structure common to all the ATI-0 space–times, we call it the *zeroth order asymptotic structure*. Using conformal time $\eta := \ln \Omega$, these results imply

$$\hat{g}_{ab} = {}^{(0)}\hat{g}_{ab} + \Omega\, {}^{(1)}\hat{g}_{ab} + O(\Omega^2)$$

where

$${}^{(0)}\hat{g}_{ab} = (e^{-\eta})^2 [-(d\eta)_a (d\eta)_b + h_{ab}] \tag{4}$$

in which ${}^{(n)}\hat{g}_{ab}$ is defined by

$${}^{(n)}\hat{g}_{ab} := \sum_{\mu,\nu} (\hat{e}_\mu)_a (\hat{e}_\nu)_b\, {}^{(n)}g_{\hat{\mu}\hat{\nu}} \tag{5}$$

with a function $g_{\hat{\mu}\hat{\nu}} := (\hat{e}_\mu)^a (\hat{e}_\nu)^b \hat{g}_{ab}$ that admits a smooth limit to $\breve{\imath}^+$ and thus is expanded in the manner described in Eq. (1). ${}^{(0)}\hat{g}_{ab}$ is a metric of the Milne universe and is equivalent to the metric of a Minkowski space–time, $\hat{g}^{\mathrm{Min}}_{ab}$. In other words, Eq. (4) tell us that an ATI-0 space–time is an asymptotically Minkowski space–time:

$$\hat{g}_{ab} = \hat{g}^{\mathrm{Min}}_{ab} + O(\Omega). \tag{6}$$

Hence, it is no surprise that the Riemann tensor asymptotically vanishes in such a space–time. The trace part of the Riemann tensor asymptotically vanishes by virtue of the falloff condition on the energy–momentum tensor. The traceless part, or the Weyl tensor $\hat{C}_{ambn}$, can be best investigated by decomposing the tensor into the electric part $\hat{E}_{ab} := \hat{C}_{ambn} \hat{n}^m \hat{n}^n$ and the magnetic part $\hat{B}_{ab} := {}^*\hat{C}_{ambn} \hat{n}^m \hat{n}^n$ where ${}^*\hat{C}_{ambn}$ denotes the dual of the 2-form $\hat{C}_{[am]bn}$. In terms of $\hat{q}_{ab}$ and $\hat{n}^a$, $\hat{E}_{ab}$ and $\hat{B}_{ab}$ are given by

$$\begin{aligned} \hat{E}_{ab} &= \hat{K}_{ar} \hat{K}^r{}_b - \mathcal{L}_{\hat{n}} \hat{K}_{ab} + \hat{D}_{(a} \hat{a}_{b)} + \hat{a}_a \hat{a}_b + \tfrac{1}{2} (\hat{q}^r_a \hat{q}^s_b - \hat{q}_{ab} \hat{n}^r \hat{n}^s) \hat{L}_{rs}, \\ \hat{B}_{ab} &= \hat{\epsilon}_{ra}{}^s \hat{D}^r \hat{K}_{bs} + \tfrac{1}{2} \hat{\epsilon}_{ab}{}^r \hat{n}^s \hat{L}_{rs}, \end{aligned} \tag{7}$$

where $\hat{K}_{ab} := \frac{1}{2}\mathcal{L}_{\hat{n}}\hat{q}_{ab}$, $\hat{L}_{ab} := \hat{R}_{ab} - \frac{1}{6}\hat{R}\hat{g}_{ab}$, $\hat{a}_a := \hat{q}_{ar}\hat{n}^s\nabla_s\hat{n}^r$, and $\hat{D}_a$ and $\hat{\epsilon}_{abc}$ are the derivative operator and the volume element associated with $\hat{q}_{ab}$, respectively. Using the definitions of n^a and q_{ab}, and imposing the falloff condition on the energy–momentum tensor, it can be found that both admit a smooth limit to $\breve{\imath}^+$ and thus can be expanded by the manner described in Eq. (1). Their leading terms are

$$ {}^{(0)}\mathbf{E}_{ab} \doteq 0, \quad {}^{(0)}\mathbf{B}_{ab} \doteq 0. \tag{8}$$

A simple calculation shows that the behaviors of ${}^{(n)}\mathbf{E}_{ab}$ and ${}^{(n)}\mathbf{B}_{ab}$ for $n \geqslant 1$ depend on that of the higher order energy–momentum tensor, which is arbitrary in an ATI-0 space–time. (See Ref. 3 for the derivations.)

III. THE FIRST-ORDER ASYMPTOTIC STRUCTURE

In this section, we derive the first order asymptotic structure, that is, a structure which is possessed by all the ATI-1 space–times but not by ATI-0 space–times. The part of the structure, i.e., the $O(\Omega)$ term of F, has been already derived in Ref. 3. Here, we treat the whole structure in a systematic way. The point is that the first-order asymptotic structure may be considered as the perturbation to the Milne universe, Eq. (4), where Ω plays the role of a small parameter of the perturbation. Hence, we can apply the technique of the cosmological perturbation[7,8] to derive the first-order asymptotic structure.

The energy–momentum tensor of an ATI-1 space–time satisfies a stronger falloff condition, $\lim_{\to \breve{\imath}^+}\Omega^{-3}\hat{T}_{\hat{\mu}\hat{\nu}} = 0$, than that of an ATI-0 and thus the behavior of asymptotic gravitational fields is constrained stronger. In other words, ATI-1 space–times possess more asymptotic gravitational structure in common. The structure can be derived by solving the Einstein equation under the condition $\lim_{\to \breve{\imath}^+}\Omega^{-3}\hat{T}_{\hat{\mu}\hat{\nu}} = 0$. To obtain the equation, we first decompose the first-order metric ${}^{(1)}\hat{g}_{ab}$ as

$$ {}^{(1)}\hat{g}_{ab} = (e^{-\eta})^2[{}^{(1)}F(d\eta)_a(d\eta)_b - 2\,{}^{(1)}\beta_{(a}(d\eta)_{b)} - 2\,{}^{(1)}\psi h_{ab} + 2\,{}^{(1)}\chi_{ab}], \tag{9}$$

where ${}^{(1)}\beta_a$ and ${}^{(1)}\chi_{ab}$ are tangential to the Ω-const surfaces, i.e., $q_a{}^{b}\,{}^{(1)}\beta_b = {}^{(1)}\beta_a$ and $q_a{}^c q_b{}^d\,{}^{(1)}\chi_{cd} = {}^{(1)}\chi_{ab}$; and ${}^{(1)}\chi_{ab}$ is traceless, i.e., $q^{ab}\,{}^{(1)}\chi_{ab} = 0$. With these quantities, the Einstein equation induces on $\breve{\imath}^+$ the following set of differential equations in an ATI-1 space–time satisfying $\lim_{\to \breve{\imath}^+}\Omega^{-3}\hat{T}_{\hat{\mu}\hat{\nu}} = 0$:

$$\begin{aligned} &3\,{}^{(1)}\mathbf{F} + 2\Delta\,{}^{(1)}\boldsymbol{\psi} - 2\mathbf{D}_m\,{}^{(1)}\boldsymbol{\beta}^m + \mathbf{D}^m\mathbf{D}_n\,{}^{(1)}\boldsymbol{\chi}_m{}^n \doteq 0,\\ &\mathbf{D}_a({}^{(1)}\mathbf{F} + 2\,{}^{(1)}\boldsymbol{\psi}) + \tfrac{1}{2}(\Delta - 2){}^{(1)}\boldsymbol{\beta}_a - \tfrac{1}{2}\mathbf{D}_a(\mathbf{D}_m\,{}^{(1)}\boldsymbol{\beta}^m) + \mathbf{D}_m\,{}^{(1)}\boldsymbol{\chi}_a{}^m \doteq 0,\\ &(\mathbf{h}_{ab}\Delta - \mathbf{D}_a\mathbf{D}_b)({}^{(1)}\mathbf{F} + 2\,{}^{(1)}\boldsymbol{\psi}) + 2\mathbf{D}_{(a}\,{}^{(1)}\boldsymbol{\beta}_{b)} + 2(\Delta + 3){}^{(1)}\boldsymbol{\chi}_{ab}\\ &\quad - 2\mathbf{h}_{ab}\mathbf{D}_m\,{}^{(1)}\boldsymbol{\beta}^m - 4\mathbf{D}_{(a}\mathbf{D}^m\,{}^{(1)}\boldsymbol{\chi}_{b)m} + 2\mathbf{h}_{ab}\mathbf{D}^m\mathbf{D}_n\,{}^{(1)}\boldsymbol{\chi}_m{}^n \doteq 0, \end{aligned} \tag{10}$$

where $\mathbf{D}_a$ is the derivative operator associated with the metric $\mathbf{h}_{ab}$ of $\breve{\imath}^+$, and $\Delta := \mathbf{D}^a\mathbf{D}_a$. To simplify the equation above, we consider the Poisson gauge in which ${}^{(1)}\boldsymbol{\beta}_a$ is transverse and ${}^{(1)}\boldsymbol{\chi}_{ab}$ is transverse traceless. Noting that the quantities are transformed as

$$\begin{aligned} &{}^{(1)}\overline{\mathbf{F}} \doteq {}^{(1)}\mathbf{F}, \quad {}^{(1)}\overline{\boldsymbol{\beta}}_a \doteq {}^{(1)}\boldsymbol{\beta}_a + \mathbf{D}_a\mathbf{T} - \mathbf{L}_a,\\ &{}^{(1)}\overline{\boldsymbol{\psi}} \doteq {}^{(1)}\boldsymbol{\psi} + \mathbf{T} - \tfrac{1}{3}\mathbf{D}^a\mathbf{L}_a, \quad {}^{(1)}\overline{\boldsymbol{\chi}}_{ab} \doteq {}^{(1)}\boldsymbol{\chi}_{ab} + \mathbf{D}_{(a}\mathbf{L}_{b)} - \tfrac{1}{3}\mathbf{h}_{ab}\mathbf{D}_m\mathbf{L}^m \end{aligned} \tag{11}$$

under a gauge transformation generated by $\xi^a = \Omega T(\partial_\eta)^a + \Omega L^a$, we find that the Poisson gauge can be always chosen if we set

$$\mathbf{T} :\doteq -\tfrac{1}{2}\Delta^{-1}[3(\Delta-3)^{-1}\mathbf{D}^m\mathbf{D}^{n\,(1)}\boldsymbol{\chi}_{mn}+2\mathbf{D}^{a\,(1)}\boldsymbol{\beta}_a],$$
$$L_a :\doteq \tfrac{1}{2}(\Delta-2)^{-1}\{\mathbf{D}_a[(\Delta-3)^{-1}\mathbf{D}^m\mathbf{D}^{n\,(1)}\boldsymbol{\chi}_{mn}]-4\mathbf{D}^{m\,(1)}\boldsymbol{\chi}_{ma}\}, \tag{12}$$

for the generator $\xi^a=\Omega T(\partial_\eta)^a+\Omega L^a$, which satisfy $\mathbf{D}^{a\,(1)}\boldsymbol{\beta}_{ab}+\mathbf{D}^a\mathbf{D}_{(a}\mathbf{L}_{b)}-\frac{1}{3}\mathbf{D}_b(\mathbf{D}_m\mathbf{L}^m)\doteq 0$ and $\mathbf{D}^{a\,(1)}\boldsymbol{\beta}_a+\Delta\mathbf{T}-\mathbf{D}^a\mathbf{L}_a\doteq 0$. Note that this Poisson gauge is preserved under the transformation generated by $\xi^a=\Omega T(\partial_\eta)^a+\Omega L^a$ where T and L_a satisfies

$$\Delta\mathbf{T}-\mathbf{D}^m\mathbf{L}_m\doteq 0,\quad (\Delta-2)\mathbf{L}_b+\tfrac{1}{3}\mathbf{D}_b\mathbf{D}_m\mathbf{L}^m\doteq 0. \tag{13}$$

In this gauge, the Einstein equation (10) simplifies to

$$3\,{}^{(1)}\mathbf{F}+2\Delta\,{}^{(1)}\boldsymbol{\psi}\doteq 0, \tag{14a}$$

$$\mathbf{D}_a({}^{(1)}\mathbf{F}+2\,{}^{(1)}\boldsymbol{\psi})+\tfrac{1}{2}(\Delta-2)^{(1)}\boldsymbol{\beta}_a^T\doteq 0, \tag{14b}$$

$$(\mathbf{h}_{ab}\Delta-\mathbf{D}_a\mathbf{D}_b)({}^{(1)}\mathbf{F}+2\,{}^{(1)}\boldsymbol{\psi})+2\mathbf{D}_{(a}\,{}^{(1)}\boldsymbol{\beta}_{b)}^T+2(\Delta+3)^{(1)}\boldsymbol{\chi}_{ab}^{\mathrm{TT}}\doteq 0, \tag{14c}$$

where the overbar is omitted which shows that the quantity is transformed and the subscripts T and TT denote that the quantities are transverse and transverse traceless, respectively.

First, we derive the scalar ${}^{(1)}\mathbf{F}$. Subtracting Eq. (14a) from the divergence of Eq. (14b), we obtain

$$(\Delta-3)^{(1)}\mathbf{F}\doteq 0. \tag{15}$$

The general solution of the above equation can be derived by first expanding the function ${}^{(1)}\mathbf{F}$ as

$${}^{(1)}\mathbf{F}(\boldsymbol{\chi},\boldsymbol{\theta},\boldsymbol{\phi})\doteq\sum\ \mathbf{a}_{\ell m}\,{}^{(1)}\mathbf{F}^{\ell m}(\boldsymbol{\chi},\boldsymbol{\theta},\boldsymbol{\phi})$$

where

$${}^{(1)}\mathbf{F}^{\ell m}(\boldsymbol{\chi},\boldsymbol{\theta},\boldsymbol{\phi}):=\mathbf{T}_0^{\ell}(\boldsymbol{\chi})\mathbf{Y}^{\ell m}(\boldsymbol{\theta},\boldsymbol{\phi}) \tag{16}$$

in which the summation is taken over $\ell\in\mathbb{Z}$ and $|m|\leqslant|\ell|$, and $\mathbf{Y}^{\ell m}(\theta,\phi)$ are the two-dimensional spherical harmonics. Substituting Eq. (16) into Eq. (15), it is found that $\mathbf{T}_0^{\ell}$ is given by

$$\mathbf{T}_0^{\ell}(\chi)=\boldsymbol{\mathcal{P}}_2^{\ell}(\chi), \tag{17}$$

where the functions $\boldsymbol{\mathcal{P}}_n^{\ell}(\chi)$ are defined by

$$\boldsymbol{\mathcal{P}}_n^{\ell}(\chi)\doteq\frac{1}{\sqrt{\sinh\boldsymbol{\chi}}}\mathbf{P}_{n-(1/2)}^{\ell+(1/2)}(\cosh\boldsymbol{\chi}), \tag{18}$$

and satisfies

$$\boldsymbol{\mathcal{P}}_n^{\ell\,\prime\prime}(\boldsymbol{\chi})+\frac{2}{\tanh\boldsymbol{\chi}}\boldsymbol{\mathcal{P}}_n^{\ell\,\prime}(\boldsymbol{\chi})-\left(n^2-1+\frac{\ell(\ell+1)}{\sinh^2\boldsymbol{\chi}}\right)\boldsymbol{\mathcal{P}}_n^{\ell}(\boldsymbol{\chi})\doteq 0, \tag{19}$$

where the prime ($'$) denotes the derivative with respect to $\boldsymbol{\chi}$; and $P_\nu^\mu(z)$ is an associated Legendre function normalized as

$$P_\nu^\mu(z):=\frac{1}{\Gamma(1-\mu)}\left(\frac{z+1}{z-1}\right)^{\mu/2}F\left(-\nu,\nu+1,1-\mu;\frac{1-z}{2}\right)\quad\text{for } z>1. \tag{20}$$

[Note here that the unconventional choice of ℓ is taken. It is related to the conventional choice ℓ_c by $\ell = -\ell_c - 1$, and thus it is $\ell \leq -1$ terms that are regular. The reason for the choice is to have the coefficient a_{00} in Eq. (16) correspond to the mass of a space–time. See Eq. (51).]

Second, we derive the scalar ${}^{(1)}\psi$. Adding Eq. (15) to Eq. (14a), we obtain

$$\Delta({}^{(1)}\mathbf{F} + 2\,{}^{(1)}\boldsymbol{\psi}) \doteq 0. \tag{21}$$

Let $\mathbf{A}$ be the solution of $\Delta \mathbf{A} \doteq 0$. Then, ${}^{(1)}\psi$ may be given by

$${}^{(1)}\boldsymbol{\psi} \doteq -\frac{1}{2}\,{}^{(1)}\mathbf{F} + \frac{\mathbf{A}}{2}. \tag{22}$$

Now, perform the gauge transformation generated by $\xi^a = \Omega T(\partial_\eta)^a$ where $\mathbf{T} \doteq -\mathbf{A}/2$. This transformation preserves the Poisson gauge, which can be seen from Eq. (13), and simplifies ${}^{(1)}\psi$:

$${}^{(1)}\boldsymbol{\psi} \doteq -\tfrac{1}{2}\,{}^{(1)}\mathbf{F}. \tag{23}$$

Next, we consider the vector field ${}^{(1)}\boldsymbol{\beta}^T_a$. Substitution of Eq. (23) into Eq. (14b) yields

$$(\Delta - 2)\,{}^{(1)}\boldsymbol{\beta}^T_a \doteq 0. \tag{24}$$

Hence, together with the fact ${}^{(1)}\boldsymbol{\beta}^T_a$ is transverse, we see from Eq. (13) that the gauge transformation generated by $\xi^a = \Omega L^a$ where $\mathbf{L}_a \doteq {}^{(1)}\boldsymbol{\beta}^T_a$ preserves the Poisson gauge, and results in

$${}^{(1)}\boldsymbol{\beta}^T_a \doteq 0. \tag{25}$$

Finally, we derive the tensor field ${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}}_{ab}$. Substituting Eqs. (23)–(25) into Eq. (14c), we obtain

$$(\Delta + 3)\,{}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}}_{ab} \doteq 0. \tag{26}$$

To solve this equation, we consider the spherical harmonic expansion again. As generally done, we decompose ${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}}_{ab}$ into the even (or electric-type) parity part ${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(+)}_{ab}$ and the odd (or magnetic-type) parity part ${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(-)}_{ab}$: ${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}}_{ab} \doteq {}^{(1)}\check{\boldsymbol{\chi}}^{\mathrm{TT}(+)}_{ab} + {}^{(1)}\check{\boldsymbol{\chi}}^{\mathrm{TT}(-)}_{ab}$. In the present case, the even parity part that satisfies Eq. (26) is found to be[9]

$${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(+)}_{ab} \doteq (\mathbf{D}_a \mathbf{D}_b - \mathbf{h}_{ab})\mathbf{X}, \tag{27}$$

where $\mathbf{X}$ is a function that satisfies $(\Delta - 3)\mathbf{X} \doteq 0$. On the other hand, the odd parity part is found to be[10]

$${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(-)}_{ab} \doteq \sum_{\ell \neq 0} \mathbf{b}^{(-)}_{\ell m}\,{}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(-)\ell m}_{ab}, \tag{28}$$

where the summation is taken over $\ell \in \mathbb{Z}$ for $\ell \neq 0$, $|m| \leq |\ell|$; and

$${}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(-)\ell m}_{\chi\chi} :\doteq 0, \quad {}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(-)\ell m}_{\chi A} :\doteq \mathbf{T}^\ell_1(\boldsymbol{\chi})\boldsymbol{\epsilon}_A{}^B \boldsymbol{\mathcal{D}}_B \mathbf{Y}^{\ell m}, \quad {}^{(1)}\boldsymbol{\chi}^{\mathrm{TT}(-)\ell m}_{AB} :\doteq \mathbf{T}^\ell_2(\boldsymbol{\chi})\boldsymbol{\epsilon}^C{}_{(A}\boldsymbol{\mathcal{D}}_{B)}\boldsymbol{\mathcal{D}}_C \mathbf{Y}^{\ell m} \tag{29}$$

in which functions $\mathbf{T}^\ell_1(\boldsymbol{\chi})$ and $\mathbf{T}^\ell_2(\boldsymbol{\chi})$ are given by

$$\mathbf{T}^\ell_1(\boldsymbol{\chi}) \doteq \boldsymbol{\mathcal{P}}^\ell_0(\boldsymbol{\chi}), \quad \mathbf{T}^\ell_2(\boldsymbol{\chi}) \doteq \frac{\sinh^2 \boldsymbol{\chi}}{(\ell - 1)(\ell + 2)}\left[\partial_\chi + 2\,\frac{\cosh \boldsymbol{\chi}}{\sinh \boldsymbol{\chi}}\right]\boldsymbol{\mathcal{P}}^\ell_0(\boldsymbol{\chi}) \quad \text{for } \ell \neq 1, -2. \tag{30}$$

(Here, there is no need to derive $\mathbf{T}_2^{\ell}(\boldsymbol{\chi})$ for $\ell=1$ or $\ell=-2$ since $\boldsymbol{\epsilon}^{c}{}_{(A}\boldsymbol{\mathcal{D}}_{B)}\boldsymbol{\mathcal{D}}_C\mathbf{Y}^{\ell m}$ vanishes for these values of ℓ.) Next, consider the gauge transformation generated by $\xi^a=\Omega T(\partial_\eta)^a+\Omega L^a$ where $\mathbf{T}:\hat{=}-\mathbf{X}$ and $\mathbf{L}_a:\hat{=}-\mathbf{D}_a\mathbf{X}$. This transformation leaves ${}^{(1)}\boldsymbol{\beta}_a$ and ${}^{(1)}\boldsymbol{\psi}$ unchanged and kills the even parity part of ${}^{(1)}\boldsymbol{\chi}_{ab}^{\mathrm{TT}}$:

$$ {}^{(1)}\boldsymbol{\chi}_{ab}^{\mathrm{TT}}\hat{=}\sum_{\ell\neq 0}\mathbf{b}_{\ell m}^{(-)}\,{}^{(1)}\boldsymbol{\chi}_{ab}^{\mathrm{TT}(-)\ell m}. \tag{31} $$

To summarize, the solutions of the Einstein equation (10) is given by

$$ \begin{aligned} {}^{(1)}\overline{\mathbf{F}}&\hat{=}\sum\,\mathbf{a}_{\ell m}\,{}^{(1)}\mathbf{F}^{\ell m}, \quad {}^{(1)}\overline{\boldsymbol{\beta}}_a\hat{=}0,\\ {}^{(1)}\overline{\boldsymbol{\psi}}&\hat{=}-\frac{1}{2}\sum\,\mathbf{a}_{\ell m}\,{}^{(1)}\mathbf{F}^{\ell m}, \quad {}^{(1)}\overline{\boldsymbol{\chi}}_{ab}\hat{=}\sum_{\ell\neq 0}\mathbf{b}_{\ell m}^{(-)}\,{}^{(1)}\boldsymbol{\chi}_{ab}^{\mathrm{TT}(-)\ell m} \end{aligned} \tag{32} $$

in the suitably chosen Poisson gauge. This is the structure of the gravitational field common to all the ATI-1 space–times, and thus we define the *first-order asymptotic structure* as follows.

Definition: ${}^{(1)}\hat{g}_{ab}$ given by Eq. (9) is called the *first-order asymptotic structure* of an AFTI-1 space–time, where ${}^{(1)}\mathbf{F}$, ${}^{(1)}\boldsymbol{\beta}_a$, ${}^{(1)}\boldsymbol{\psi}$, and ${}^{(1)}\boldsymbol{\chi}_{ab}$ takes the form Eq. (32) on $\breve{\imath}^+$, in the Poisson gauge.

In such a space–time, it can be calculated that

$$ {}^{(1)}\mathbf{E}_{ab}\hat{=}\tfrac{1}{2}(\mathbf{D}_a\mathbf{D}_b-\mathbf{h}_{ab})^{(1)}\mathbf{F}, \quad {}^{(1)}\mathbf{B}_{ab}\hat{=}\tfrac{1}{2}\boldsymbol{\epsilon}_{ra}{}^{s}\mathbf{D}^{r(1)}\boldsymbol{\chi}_{bs} \tag{33} $$

and that ${}^{(n)}\mathbf{E}_{ab}$ and ${}^{(n)}\mathbf{B}_{ab}$ for $n\geqslant 2$ depend on the behavior of the higher order energy–momentum tensor, which is arbitrary in an ATI-1 space–time. (See Ref. 3 for the details of the calculation.) Equation (33) clearly shows that ${}^{(1)}\mathbf{F}$ of the first-order asymptotic structure forms the first-order term of the electric part of the Weyl tensor and that ${}^{(1)}\boldsymbol{\chi}_{ab}$ forms the magnetic part. In other words, if we specify the sets of coefficients $\{\mathbf{a}_{\ell m}\}$ and $\{\mathbf{b}_{\ell m}\}$, the first-order terms of the electric part and the magnetic part are determined, respectively.

IV. ASYMPTOTIC STATIONARITY

In this section, we introduce the notion of *asymptotic stationarity* of ATI-n space–times, and prove that an ATI-1 space–time that is asymptotically stationary to order 2 must be an asymptotically Schwarzschild space–time. The plan of the proof is: (1) we derive, in the Poisson gauge, the reduced first asymptotic structure of an ATI-1 space–time that is asymptotically stationary to order 2 in the lemma; (2) we perform a suitable gauge transformation as to show explicitly that such an asymptotic structure approaches asymptotically the Schwarzschild metric in the theorem.

A Killing vector field $\hat{\xi}^a$ is a vector field with respect to which the Lie derivative of the metric vanishes, $\mathcal{L}_{\hat{\xi}}\hat{g}_{ab}=0$. This fact motivates us to define an asymptotic Killing vector field and its order as follows.

Definition: An ATI-m spacetime $(\hat{\mathcal{M}},\hat{g}_{ab})$ is said to admit an *asymptotic Killing field* $\hat{\xi}^a$ to order n if

$$ \lim_{\to\breve{\imath}^+}\Omega^{-n}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}=0, \tag{34} $$

where $(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}:=\Psi^*((\hat{e}_\mu)^a(\hat{e}_\nu)^b\mathcal{L}_{\hat{\xi}}\hat{g}_{ab})$.

Next, we consider how to define asymptotic stationarity, using this notion of an asymptotic Killing vector field. A vector field $\hat{\xi}^a$ is said to be a stationary Killing vector field in an asymptotically flat space–time, if $\hat{\xi}^a$ is a timelike Killing field and satisfies $\hat{g}_{ab}\hat{\xi}^a\hat{\xi}^b=-1$ at infinity. Hence, we define its asymptotic correspondence as follows.

Definition: A vector field ξ^a is said to be an asymptotic stationary Killing vector field to order n of an ATI-m space–time if $\hat{\xi}^a$ is admitted as an asymptotic Killing vector field to order n in the ATI-m space–time and satisfies

$$\hat{g}_{ab}\hat{\xi}^a\hat{\xi}^b \doteq -1 \tag{35}$$

on $\breve{\imath}^+$.

It is important to note that the definition of the asymptotic stationary Killing vector field implies that the leading term of $\hat{\xi}^{\hat{\mu}}=\hat{\xi}^a(\hat{e}_\mu)_a$ is of the order Ω^0. Hence, $\xi^{\hat{\mu}}:=\hat{\xi}^{\hat{\mu}}$ admits a smooth limit to $\breve{\imath}^+$ and can be expanded as

$$\xi^{\hat{\mu}}=\sum_{n=1}^{\infty}{}^{(n)}\xi^{\hat{\mu}}\Omega^n. \tag{36}$$

(Here, ${}^{(n)}\xi^{\hat{0}}$ and ${}^{(n)}\xi^{\hat{\mathrm{I}}}$ correspond to ${}^{(n+2)}\xi^{\hat{0}}$ and ${}^{(n+1)}\xi^{\hat{\mathrm{I}}}$ in Ref. 3. We do not use the notation of Ref. 3 for $\hat{\xi}^a$, because the above notation reflects the nature of the completion more intrinsically.) Simple calculation shows that the function $(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}$ admits a smooth limit to $\breve{\imath}^+$, and thus can be expanded in the manner described by Eq. (1).

Now we are ready to prove the following lemma.

Lemma: An ATI-1 space–time is asymptotically stationary to order 2 if and only if $\mathbf{a}_{\ell m}\doteq 0$ for $\ell\neq 0$ and $\mathbf{b}_{\ell m}\doteq 0$.

Proof of only if: If an ATI-1 space–time is asymptotically stationary to order 2,

$${}^{(n)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}\doteq 0 \quad \text{for } n\leqslant 2, \tag{37}$$

$$\hat{g}_{ab}\hat{\xi}^a\hat{\xi}^b\doteq -1 \tag{38}$$

hold. First, we note that Eq. (38) is equivalent to

$$-({}^{(0)}\boldsymbol{\xi}^{\hat{0}})^2+{}^{(0)}\boldsymbol{\xi}^{a\,(0)}\boldsymbol{\xi}_a\doteq -1, \tag{39}$$

where ${}^{(\ell)}\boldsymbol{\xi}^a:={}^{(\ell)}\boldsymbol{\xi}^{\hat{K}}(\mathbf{e}_K)^a$ and $\{(\mathbf{e}_{\mathrm{I}})_a\}_{\mathrm{I}=1,2,3}$ is a triad of $\mathbf{h}_{ab}$. Second, we simplify the $n\leqslant 1$ part of Eq. (37). In an ATI-1 space–time, the $O(\Omega^0)$ and $O(\Omega^1)$ terms of $(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}$ are given by

$${}^{(0)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{0}\hat{0}}\doteq 0,\quad {}^{(0)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{0}\hat{\mathrm{I}}}\doteq 0,\quad {}^{(0)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mathrm{I}}\hat{\mathrm{J}}}\doteq 0,$$

$${}^{(1)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{0}\hat{0}}\doteq 0,\quad {}^{(1)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{0}\hat{\mathrm{I}}}\doteq[{}^{(0)}\boldsymbol{\xi}_a-\mathbf{D}_a\,{}^{(0)}\boldsymbol{\xi}^{\hat{0}}](\mathbf{e}_{\mathrm{I}})^a,$$

$${}^{(1)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mathrm{I}}\hat{\mathrm{J}}}\doteq[\mathbf{D}_{(a}\,{}^{(0)}\boldsymbol{\xi}_{b)}-{}^{(0)}\boldsymbol{\xi}^{\hat{0}}\mathbf{h}_{ab}](\mathbf{e}_{\mathrm{I}})^a(\mathbf{e}_{\mathrm{J}})^b.$$

Hence, the $n\leqslant 1$ part of Eq. (37) is equivalent to

$${}^{(0)}\boldsymbol{\xi}_a-\mathbf{D}_a\,{}^{(0)}\boldsymbol{\xi}^{\hat{0}}\doteq 0,\quad \mathbf{D}_{(a}\,{}^{(0)}\boldsymbol{\xi}_{b)}-{}^{(0)}\boldsymbol{\xi}^{\hat{0}}\mathbf{h}_{ab}\doteq 0. \tag{40}$$

Solving Eqs. (39) and (40) simultaneously, we find that

$${}^{(0)}\boldsymbol{\xi}^{\hat{0}}\doteq\cosh\boldsymbol{\chi},\quad {}^{(0)}\boldsymbol{\xi}^{\hat{\mathrm{K}}}(\mathbf{e}_{\mathrm{K}})^a\doteq\sinh\boldsymbol{\chi}(\partial_\chi)^a. \tag{41}$$

Next, we consider the $n=2$ part of Eq. (37). Let us choose the Poisson gauge in which the first-order asymptotic structure takes the form Eq. (32) in an ATI-1 space–time. Because

$${}^{(2)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{0}\hat{0}}\doteq -{}^{(1)}\boldsymbol{\xi}^{\hat{0}}+\tfrac{1}{2}({}^{(0)}\boldsymbol{\xi}^{\hat{0}}+{}^{(0)}\boldsymbol{\xi}^m\mathbf{D}_m){}^{(1)}\mathbf{F}, \tag{42}$$

$$^{(2)}(\mathcal{L}_{\hat\xi}\hat g)_{\hat 0\hat{\rm I}} \doteq [2\,^{(1)}\boldsymbol{\xi}_a - \mathbf{D}_a\,^{(1)}\boldsymbol{\xi}^{\hat 0} + (\mathbf{D}_a\,^{(0)}\boldsymbol{\xi}^{\hat 0} - {}^{(0)}\boldsymbol{\xi}_a)\,^{(1)}\mathbf{F} - 2\,^{(0)}\boldsymbol{\xi}_m\,^{(1)}\boldsymbol{\chi}_a{}^m](\mathbf{e}_{\rm I})^a,$$

the $n=2$ part of Eq. (37) for $\hat\mu=\hat 0$ is equivalent to

$$^{(1)}\boldsymbol{\xi}^{\hat 0} \doteq \tfrac{1}{2}(^{(0)}\boldsymbol{\xi}^{\hat 0} + {}^{(0)}\boldsymbol{\xi}^m\mathbf{D}_m)\,^{(1)}\mathbf{F}, \quad ^{(1)}\boldsymbol{\xi}^{\hat{\rm K}}(e_{\rm K})^a \doteq \tfrac{1}{2}[\mathbf{D}_a\,^{(1)}\boldsymbol{\xi}^{\hat 0} - (\mathbf{D}_a\,^{(0)}\boldsymbol{\xi}^{\hat 0} - {}^{(0)}\boldsymbol{\xi}_a)\,^{(1)}\mathbf{F} + 2\,^{(0)}\boldsymbol{\xi}_m\,^{(1)}\boldsymbol{\chi}_a{}^m]. \tag{43}$$

Using Eqs. (41)–(43), we find that $^{(2)}(\mathcal{L}_{\hat\xi}\hat g)_{\hat{\rm I}\hat{\rm J}}$ are given by

$$^{(2)}(\mathcal{L}_{\hat\xi}\hat g)_{\hat{\rm I}\hat{\rm J}} \doteq 2\sinh\boldsymbol{\chi}[\,^1\boldsymbol{\mathcal{L}}_{ab}\,^{(1)}\mathbf{F} + {}^2\boldsymbol{\mathcal{L}}_{(a}{}^{m}\,^{(1)}\boldsymbol{\chi}_{b)m}](\mathbf{e}_{\rm I})^a(\mathbf{e}_{\rm J})^b \tag{44}$$

where the derivative operators $^1\boldsymbol{\mathcal{L}}_{ab}$ and $^2\boldsymbol{\mathcal{L}}_{ab}$ are given by

$$^1\boldsymbol{\mathcal{L}}_{ab} :\doteq \frac{3}{\tanh\boldsymbol{\chi}}(\mathbf{D}_a\mathbf{D}_b - \mathbf{h}_{ab}) + (\partial_\chi)^m\mathbf{D}_{(a}\mathbf{D}_{b)}\mathbf{D}_m - (d\boldsymbol{\chi})_{(a}\mathbf{D}_{b)}, \quad ^2\boldsymbol{\mathcal{L}}_{ab} :\doteq 2(d\boldsymbol{\chi})_p\mathbf{h}_a{}^{[p}\mathbf{h}_b{}^{m]}\mathbf{D}_m, \tag{45}$$

respectively. By the definition of $^{(1)}\mathbf{F}$ and $^{(1)}\boldsymbol{\chi}_{ab}$, $^{(2)}(\mathcal{L}_{\hat\xi}\hat g)_{\hat{\rm I}\hat{\rm J}}$ vanishes if and only if $^1\boldsymbol{\mathcal{L}}_{ab}\,^{(1)}\mathbf{F}$ and $^2\boldsymbol{\mathcal{L}}_{(a}{}^{s}\,^{(1)}\boldsymbol{\chi}_{b)s}$ vanish independently. With the help of eqs. (16)–(32), $^1\boldsymbol{\mathcal{L}}_{ab}\,^{(1)}\mathbf{F}\doteq 0$ can be rewritten as

$$\sum a_{\ell m}\Bigg[\left(\mathbf{T}_0^{\ell\,'''} + \frac{3\mathbf{T}_0^{\ell\,''}}{\tanh\boldsymbol{\chi}} - \mathbf{T}_0^{\ell\,'} - \frac{3\mathbf{T}_0^{\ell}}{\tanh\boldsymbol{\chi}}\right)(d\boldsymbol{\chi})_a(d\boldsymbol{\chi})_b + 2\left(\mathbf{T}_0^{\ell\,''} - \frac{\mathbf{T}_0^{\ell\,'}}{\tanh\boldsymbol{\chi}} - \left(5 + \frac{4}{\sinh^2\boldsymbol{\chi}}\right)\mathbf{T}_0^{\ell}\right)$$
$$\times(d\boldsymbol{\chi})_{(a}\boldsymbol{\mathcal{D}}_{b)} + \sinh\boldsymbol{\chi}\cosh\boldsymbol{\chi}\left(\mathbf{T}_0^{\ell\,''} + \frac{2\mathbf{T}_0^{\ell}}{\tanh\boldsymbol{\chi}} - 3\mathbf{T}_0^{\ell} - \frac{\ell(\ell+1)}{2\sinh\boldsymbol{\chi}\cosh\boldsymbol{\chi}}\left(\mathbf{T}_0^{\ell\,'} + \frac{\mathbf{T}_0^{\ell}}{\tanh\boldsymbol{\chi}}\right)\right)(d\boldsymbol{\sigma})_{ab}$$
$$+\left(\mathbf{T}_0^{\ell\,'} + \frac{\mathbf{T}_0^{\ell}}{\tanh\boldsymbol{\chi}}\right)(\boldsymbol{\mathcal{D}}_a\boldsymbol{\mathcal{D}}_b - \tfrac{1}{2}(d\boldsymbol{\sigma})_{ab}\boldsymbol{\mathcal{D}}^c\boldsymbol{\mathcal{D}}_c)\Bigg]\mathbf{Y}^{\ell m} \doteq 0. \tag{46}$$

We first consider the $\ell\neq 0$ terms of the above equation. Noting that all the components are independent and using Eqs. (17)–(19), it is found that if $\mathbf{a}_{\ell m}\not\doteq 0$ the above equation (46) is equivalent to

$$\frac{\ell(\ell+1)}{\sinh^2\boldsymbol{\chi}}\left(\boldsymbol{\mathcal{P}}_2^{\ell\,'} + \frac{\boldsymbol{\mathcal{P}}_2^{\ell}}{\tanh\boldsymbol{\chi}}\right) \doteq 0, \quad \left(\frac{\ell^2+\ell-4}{\sinh^2\boldsymbol{\chi}} - 2\right)\boldsymbol{\mathcal{P}}_2^{\ell} - 3\boldsymbol{\mathcal{P}}_2^{\ell\,'} \doteq 0, \quad \frac{\ell(\ell+1)}{\sinh^2\boldsymbol{\chi}}\boldsymbol{\mathcal{P}}_2^{\ell} \doteq 0,$$
$$\boldsymbol{\mathcal{P}}_2^{\ell\,'} + \frac{\boldsymbol{\mathcal{P}}_2^{\ell}}{\tanh\boldsymbol{\chi}} \doteq 0. \tag{47}$$

Apparently, there is no integer ℓ that is not equal to 0 and that satisfies Eq. (47), simultaneously. Therefore, $\mathbf{a}_{\ell m}\doteq 0$ for $\ell\neq 0$. Noting that $\boldsymbol{\mathcal{D}}_a\mathbf{Y}^{\ell m}$ vanishes for $\ell=0$, we find that all the components of the $\ell=0$ terms of the right-hand side of Eq. (46) vanish. Therefore, $\mathbf{a}_{00}$ can take arbitrary value. Next consider $^2\boldsymbol{\mathcal{L}}_{(a}{}^{s}\,^{(1)}\boldsymbol{\chi}_{b)s}\doteq 0$. This equation is satisfied if and only if

$$\sum_{\ell\neq 0}\mathbf{b}_{\ell m}\left[\left(\mathbf{T}_1^{\ell\,'} + \frac{\mathbf{T}_1^{\ell}}{\tanh\boldsymbol{\chi}}\right)(d\boldsymbol{\chi})_{(a}\boldsymbol{\epsilon}_{b)}{}^{r}\boldsymbol{\mathcal{D}}_r + \left(\mathbf{T}_2^{\ell\,'} - \frac{\mathbf{T}_2^{\ell}}{\tanh\boldsymbol{\chi}} - \mathbf{T}_1^{\ell}\right)\boldsymbol{\epsilon}^{r}{}_{(a}\boldsymbol{\mathcal{D}}_{b)}\boldsymbol{\mathcal{D}}_r\right]\mathbf{Y}^{\ell m} \doteq 0. \tag{48}$$

With the same reasoning, we find that if $\mathbf{b}_{\ell m}\not\doteq 0$ Eq. (48) is equivalent to

$$\frac{\ell(\ell+1)}{\sinh^2\boldsymbol{\chi}}\boldsymbol{\mathcal{P}}_0^{\ell} \doteq 0, \quad \frac{(\ell+2)(\ell-1)}{\sinh^2\boldsymbol{\chi}}\boldsymbol{\mathcal{P}}_0^{\ell} \doteq 0 \tag{49}$$

and that there is no ℓ that satisfies the above equations simultaneously. Hence, we conclude $\mathbf{b}_{\ell m} \cong 0$. □

Proof of if: If $\mathbf{a}_{\ell m} \cong 0$ for $\ell \neq 0$ and $\mathbf{b}_{\ell m} = 0$ in an ATI-1 space–time, the vector field $\hat{\xi}^a$ whose $O(\Omega^0)$ and $O(\Omega^1)$ terms are given by Eqs. (41)–(43) satisfy ${}^{(n)}(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}} \cong 0$ for $n \leq 2$ and $\hat{g}_{ab}\hat{\xi}^a\hat{\xi}^b \cong -1$. Hence, $\hat{\xi}^a$ is an asymptotically stationary Killing vector field to order 2. □

The fact that $\mathbf{a}_{\ell m} \cong 0$ for $\ell \neq 0$ and $\mathbf{b}_{\ell m} \cong 0$ means that in such an ATI-1 space–time, the first asymptotic structure takes the simple form

$$ {}^{(1)}\mathbf{F} \cong \mathbf{a}_{00}\,{}^{(1)}\mathbf{F}^{00}, \quad {}^{(1)}\boldsymbol{\psi} \cong -\tfrac{1}{2}\mathbf{a}_{00}\,{}^{(1)}\mathbf{F}^{00}, \quad {}^{(1)}\boldsymbol{\beta} \cong 0, \quad {}^{(1)}\boldsymbol{\chi}_{ab} \cong 0. \tag{50} $$

Before we show that such an ATI-1 space–time is an asymptotically Schwarzschild space–time, we remark an important fact relating to the definition of the angular-momentum of an asymptotically flat space–time. To define angular-momentum, one must impose the condition that the $O(\Omega^1)$ term of the magnetic part of the Weyl tensor vanish.[2–4] However, the physical meaning of the condition was left unclear. The lemma and Eqs. (33)–(50) tells us that the meaning is that the angular-momentum of an asymptotically spacetime can be defined if the spacetime is asymptotically stationary to order 2.

Theorem: An ATI-1 space–time which is asymptotically stationary to order 2 is an asymptotically Schwarzschild space–time with mass a_{00} in the sense that the metric takes the form

$$ \hat{g}_{ab} = \hat{g}^{\mathrm{Sch}}_{ab} + O(r^{-2}) + O(t^{-2}) $$

where

$$ \hat{g}^{\mathrm{Sch}}_{ab} := -\left(1 - \frac{2a_{00}}{r}\right)(dt)_a(dt)_b + \left(1 - \frac{2a_{00}}{r}\right)^{-1}(dr)_a(dr)_b + r^2(d\sigma)_{ab} \tag{51} $$

in which $t > r$.

Proof: From the lemma, in an ATl-1 space–time which is asymptotically stationary to order 2, $\mathbf{a}_{\ell m} = 0$ for $\ell \neq 0$ and $\mathbf{b}_{\ell m} = 0$ hold. Thus, the first-order term of the metric ${}^{(1)}\hat{g}_{ab}$ takes the form

$$ {}^{(1)}\hat{g}_{ab} = (e^{-\eta})^2[a_{00}\,{}^{(1)}F^{00}(d\eta)_a(d\eta)_a + a_{00}\,{}^{(1)}F^{00}h_{ab}]. \tag{52} $$

Under a gauge transformation generated by $\xi^a = \Omega T(\partial_\eta)^a + \Omega D^a L$ where

$$ \mathbf{T} :\cong \mathbf{a}_{00}(2\boldsymbol{\chi}\cosh\boldsymbol{\chi} + \sinh\boldsymbol{\chi}), \quad \mathbf{L} :\cong -4\mathbf{a}_{00}\sinh\boldsymbol{\chi} + \mathbf{T}, \tag{53} $$

${}^{(1)}\hat{g}_{ab}$ transforms as

$$ {}^{(1)}\hat{g}_{ab} \mapsto (e^{-\eta})^2[a_{00}\,{}^{(1)}F^{00}(d\eta)_a(d\eta)_a - 8a_{00}\cosh\chi(d\eta)_{(a}(d\chi)_{b)} + a_{00}\,{}^{(1)}F^{00}(d\chi)_a(d\chi)_b]. \tag{54} $$

Then, the change of variables, $t = \Omega^{-1}\cosh\chi$ and $r = \Omega^{-1}\sinh\chi$, leads us to

$$ O(\Omega^2) = \sinh^{-2}\chi O(\Omega^2) + \cosh^{-2}\chi O(\Omega^2) = O(r^{-2}) + O(t^{-2}), \quad \frac{r}{t} = \tanh\chi < 1. \tag{55} $$

and

$$ {}^{(0)}\hat{g}_{ab} + \Omega\,{}^{(1)}\hat{g}_{ab} = \hat{g}^{\mathrm{Sch}}_{ab} + O(\Omega^2). \tag{56} $$

Hence, Eq. (51) holds. □

It is important to note here that asymptotically Schwarzschild space–times, that are defined in Eq. (51), comprise the Kerr space–time also. This can be understood by writing the Kerr metric $\hat{g}^{\mathrm{Ker}}_{ab}$ with the coordinates (Ω,χ) where $t = \cosh\chi$ and $r = \sinh\chi$:

$$\hat{g}_{ab}^{\mathrm{Ker}}=\hat{g}_{ab}^{\mathrm{Sch}}+\Omega^{2}\,{}^{(2)}\hat{g}_{ab}+O(\Omega^3), \tag{57}$$

where

$$\begin{aligned}{}^{(2)}\hat{g}_{ab}=&(4m^2-a^2\sin^2\theta)\left((d\eta)_{(a}(d\eta)_{b)}-2\,\frac{(d\chi)_{(a}(d\eta)_{b)}}{\tanh\chi}\right)+4ma\,\frac{\sin^2\theta}{\tanh\chi}(d\phi)_{(a}(d\eta)_{b)}\\&+\frac{4m^2-a^2\sin^2\theta}{\tanh\chi}(d\chi)_a(d\chi)_b-4am\sin^2\theta^2(d\phi)_{(a}(d\chi)_{b)}+a^2\cos^2\theta(d\theta)_a(d\theta)_b\\&+a^2\sin^2\theta(d\phi)_a(d\phi)_b\,.\end{aligned} \tag{58}$$

In other words, the Kerr space–time is a special space–time of asymptotically Schwarzschild space–times, which possesses a particular second-order asymptotic structure, i.e., ${}^{(2)}\hat{g}_{ab}$ given by Eq. (58).

V. SUMMARY AND REMARKS

In this paper, we have proved that an asymptotically flat space–time as defined in definition 1 of Sec. II is an asymptotically Schwarzschild spacetime in the sense of Eq. (51), if the energy-momentum of the space–time falls off at the rate faster than $O(\Omega^3)$ and the space–time is asymptotically stationary to order 2 in the sense that $(\mathcal{L}_{\hat{\xi}}\hat{g})_{\hat{\mu}\hat{\nu}}$ falls off at the rate faster than $O(\Omega^2)$ for the asymptotically timelike vector $\hat{\xi}^a, \hat{g}_{ab}\hat{\xi}^a\hat{\xi}^b\doteq-1$.

Finally, we give a remark. Although we have solved the Einstein equation (10) and obtained the first-order asymptotic structure, we did not impose any physically suitable boundary conditions on the solutions. Hence, the obtained first-order asymptotic structure may include those that are *unphysical*. For example, a solution that describes an incoming gravitational wave from future null infinity or an outcoming wave from the event horizon. In other words, *physically* acceptable gravitational fields around a black hole may be obtained only after a suitable boundary condition are imposed on the solutions. The derivation of the physical first-order asymptotic structure may be profitable because it may be possible to show that an ATI-1 space–time with such a physical structure is intrinsically asymptotically stationary to order 1, and thus is an asymptotically Schwarzschild space–time. This result is anticipated because we expect that a space–time with a black hole that becomes vacuum also becomes stationary, due to the nature of the black hole. This is an important point that should be clarified.

ACKNOWLEDGMENTS

We would like to thank K. Sato and Y. Suto for their encouragement. The discussion with T. T. Nakamura was very fruitful. U.G. thanks M. Sasaki, M. Shibata, T. Tanaka, and Y. Mino for the valuable discussions. T.S. thanks Gary Gibbons and the Relativity Group at Cambridge for their hospitality. Finally, we wish to thank Misao Sasaki especially for his comments on the draft of this paper. This work is partially supported by the JSPS fellowship.

Weyl-type fields with geodesic lines of force

Brendan S. Guilfoyle[a)]
Department of Mathematics, Institute of Technology
Tralee, Tralee, County Kerry, Ireland

(Received 25 September 1998; accepted for publication 12 January 1999)

The static electrogravitational equations are studied and it is shown that an aligned type D metric that has a Weyl-type relationship between the gravitational and electric potential has shear-free geodesic lines of force. All such fields are then found and turn out to be the fields of a charged sphere, charged infinite rod and charged infinite plate. A further solution is also found with shearing geodesic lines of force. This new solution can have $m>|e|$ or $m<|e|$, but cannot be in the Majumdar–Papapetrou class (in which $m=|e|$). It is algebraically general and has flat equipotential surfaces.
[S0022-2488(99)01604-7]

I. INTRODUCTION

Static fields have been a very fruitful area of study for general relativity. On the one hand, the simplifications in the field equations for static fields are substantial, and on the other hand, it is this area that lends itself most easily to comparison with Newtonian gravitation and classical potential theory. For example, the 44-component of the metric tensor, g_{44}, plays the role of a gravitational potential. This allows one to talk of gravitational equipotential surfaces (surfaces of constant g_{44}) and lines of force (the integral curves of the gradient of g_{44}).

Das[1] and Kota and Perjes[2] investigated vacuum metrics in which the lines of force are geodesic. The Newtonian analog for such a field is one with straight lines of force, which is generated by a sphere or an infinite rod or an infinite plate. Das found that among all vacuum fields with geodesic lines of force is included the exterior field of a sphere and an infinite rod and an infinite plate. These constitute all of the vacuum fields in which the lines of force are, in addition, shear-free. Das also discovered a shearing field with no Newtonian analog.

When the source of the field is an electric field, one also has the electric potential ϕ, and the corresponding electric equipotential surfaces and lines of force. Fields in which there is a functional relationship between the two potentials has been investigated by numerous authors (e.g., Weyl,[3] Majumdar,[4] Papapetrou,[5] Gatreau and Hoffman,[6] Guilfoyle[7]). We will refer to such fields as being of the *Weyl-type*.

In this paper we show that among all Weyl-type fields the algebraically special (type D) ones have shear-free geodesic lines of force. We then go on to find all Weyl-type fields with geodesic lines of force. The shear-free metrics turn out to describe the fields of a charged sphere, an infinite charged rod and an infinite charged plate. The only asymptotically flat member of this class is the Reissner–Nordström metric. Again, there is a further shearing field which is algebraically general and has no Newtonian analog. We find, however, that this is not in the Majumdar–Papapetrou class of electrovac solutions. In fact, the only Majumdar–Papapetrou field with geodesic lines of force is found to be the extreme Reissner–Nordström solution.

II. BACKGROUND AND GENERAL RESULTS

A space–time $(M,g_{\mu\nu})$ is *static* if there exists a timelike hypersurface orthogonal Killing vector ξ^μ on M. With a suitable choice of co-ordinates (x^i,t) the metric takes the form

[a)]Electronic mail: brendan.guilfoyle@ittralee.ie

$$ds^2 = g_{ij}\, dx^i\, dx^j - e^{\omega}\, dt^2,$$

where both the spatial metric g_{ij} and e^{ω} depend only on x^i. Here, and throughout, Greek letters will take values 1 to 4, while Latin letters will take values 1, 2, 3. We will raise and lower all indices using g.

The 3+1 split above induces the following decomposition of the Riemann tensor of $(M, g_{\mu\nu})$ in terms of that of the spatial slices (V^3, g_{ij}) (see Synge[8]):

$$R_{ijkl} = {}^3R_{ijkl}, \quad R_{i44l} = -e^{(1/2)\,\omega}(e^{(1/2)\,\omega})_{|il}, \quad R_{ij4l} = 0. \tag{1}$$

A stroke represents covariant differentiation with respect to the Levi-Çivita connection of the spatial metric g_{ij}. The Ricci tensors of $(M, g_{\mu\nu})$ and (V^3, g_{ij}) are then found to be related by

$$R_{ij} = {}^3R_{ij} + e^{-(1/2)\,\omega}(e^{(1/2)\,\omega})_{|ij}, \tag{2}$$

$$R_{44} = -\tfrac{1}{2} e^{\omega}(\triangle\omega + \tfrac{1}{2}|d\omega|^2), \tag{3}$$

where $\triangle$ is the covariant Laplacian $\triangle\omega = g^{ij}\omega_{|ij}$ and $|d\omega|^2 = g^{ij}\omega_{,i}\omega_{,j}$.

We note that the 3-dimensional Riemann tensor of (V^3, g_{ij}) is entirely determined by the 3-dimensional Ricci tensor through

$${}^3R_{ijkl} = g_{i[l}{}^3R_{k]j} + g_{j[k}{}^3R_{l]i} + \tfrac{1}{2}{}^3R g_{i[k}g_{l]j}, \tag{4}$$

where ${}^3R$ is the Ricci scalar ${}^3R \equiv {}^3R^i_i$. Skew-symmetrization (symmetrization) is denoted by square (round) brackets on pairs of indices.

It is often useful to turn to the conformally related background space $(\overline{V}^3, \overline{g_{ij}})$ given by

$$g_{ij} = e^{-\omega}\overline{g_{ij}}.$$

The relationship between the Ricci curvatures of (V^3, g_{ij}) and $(\overline{V}^3, \overline{g_{ij}})$ is

$${}^3R_{ij} = {}^3\overline{R_{ij}} - e^{-(1/2)\,\omega}(e^{(1/2)\,\omega})_{|ij} + \tfrac{1}{2}\omega_{,i}\omega_{,j} - \tfrac{1}{2}g_{ij}(\triangle\omega + \tfrac{1}{2}|d\omega|^2). \tag{5}$$

Einstein's field equations for the electric field ϕ are

$$R_{ij} = 2e^{-\omega}\phi_{,i}\phi_{,j} - e^{-\omega}|d\phi|^2 g_{ij}, \tag{6}$$

$$\Delta\omega = 2e^{-\omega}|d\phi|^2 - \tfrac{1}{2}|d\omega|^2, \tag{7}$$

$$R = 0, \tag{8}$$

while Maxwell's equations reduce to

$$\Delta\phi = \tfrac{1}{2}\omega^{,i}\phi_{,i}. \tag{9}$$

III. ALGEBRAIC STRUCTURE

We now turn to the algebraic structure of the electrostatic field. The most widely used classification scheme for the gravitational field is due to Petrov[9] (see also Kramer *et al.*,[10] Papapetrou[11] and Synge[12]). In this, a metric is classified by the degeneracy of certain null directions associated with the Weyl conformal curvature tensor. This tensor is given in terms of the Riemann and Ricci curvature tensors by

$$C_{\alpha\beta\gamma\delta} = R_{\alpha\beta\gamma\delta} + \tfrac{1}{2}(g_{\alpha[\gamma}R_{\delta]\beta} + g_{\beta[\delta}R_{\gamma]\alpha}) + \tfrac{1}{6}R g_{\alpha[\delta}g_{\gamma]\beta}.$$

A *principal null direction* (*p.n.d.* for short) of the Weyl tensor is a null vector, k^μ, satisfying

$$k_{[\mu}C_{\alpha]\beta\gamma[\delta}k_{\nu]}k^\beta k^\gamma=0.$$

As the name suggests, a p.n.d. is defined only up to multiplication by a function. A repeated p.n.d. for the Weyl tensor is a null vector, k^μ, satisfying

$$C_{\alpha\beta\gamma[s}k_{\nu]}k^\beta k^\gamma=0.$$

Using Eqs. (1) to (8), this can be shown to be equivalent to

$$e^{-(1/2)\omega}(e^{(1/2)\omega})_{|ij}=e^{-\omega}\phi_{,i}\phi_{,j}-\chi\left(\frac{k_ik_j}{|k|^2}-\frac{1}{3}g_{ij}\right), \tag{10}$$

where

$$\chi\equiv\frac{3}{2|k|^2}[e^{-\omega}(k^i\phi_{,i})^2-e^{-(1/2)\omega}(e^{(1/2)\omega})_{|ij}k^ik^j], \tag{11}$$

and the p.n.d. is

$$k^\mu=(k^i,e^{-(1/2)\omega}|k|). \tag{12}$$

We note as a check on these calculations that contracting (10) gives

$$e^{-(1/2)\omega}\Delta(e^{(1/2)\omega})=e^{-\omega}|d\phi|^2,$$

which is precisely the field equation (7).

Thus, a necessary and sufficient condition that a static electrovac space–time is algebraically special (and therefore, type D) is that there exists a 3-vector k^i satisfying (10) and (11). Then the repeated p.n.d. of the Weyl tensor is given by (12) and the Ricci tensor of $(V^3,g_{ij})$is [put (10) in (2)]

$${}^3R_{ij}=\chi\left(g_{ij}-\frac{3k_ik_j}{|k|^2}\right)+e^{-\omega}(\phi_{,i}\phi_{,j}-|d\phi|^2g_{ij}). \tag{13}$$

In the vacuum case $(\phi=0)$ this tells us that a repeated p.n.d. of the Weyl tensor is also an eigenvector of the spatial Ricci tensor ${}^3R_{ij}$. Furthermore, any vector on (V^3,g_{ij}) that is orthogonal to the spatial component, k^i, of the repeated p.n.d., is also an eigenvector of the spatial Ricci tensor. This decomposition of ${}^3R_{ij}$ allows one to integrate the field equations fully, and determine explicitly all type D static vacuum fields, as was done almost 75 years ago by Levi-Çivita.[13] Although the Schwarzchild solution is of this type, it was found that all the other 6 solutions in this class are unphysical (Kramer *et al.*,[10] Ehlers and Kundt[14]).

If we now include the electromagnetic field, the spatial Ricci tensor differs only by the projection operator onto directions orthogonal to $\phi_{,i}$. Thus, we have the following theorem.

Theorem 1: *A repeated p.n.d. of the Weyl conformal tensor of an algebraically special static electrovac field is also an eigenvector of the spatial Ricci tensor if one of the following holds: (i) The electric field vanishes* $(\phi=0)$*; (ii) The electric field is aligned* $(\phi_{,[i}k_{j]}=0)$*; (iii) The electric field is perpendicular* $(\phi_{,i}k^i=0)$.

Since the field equations are tractable in case *(i)* and the algebraic structure of ${}^3R_{ij}$ is the same in (*i*), (*ii*), and (*iii*), we are led to consider the possibility that all aligned or perpendicular type D static electrovac fields may be explicitly determined using Eq. (13) to integrate the field equations.

We shall look at the case where the field is aligned and $\omega_{,i}$ is also coincident with $\phi_{,i}$. In this case, there is a functional relationship between e^ω and ϕ. It is well known that this must be of the form (see Majumdar[4])

$$e^\omega=A+B\phi+\phi^2,$$

from which we find that

$$\phi,_i=\frac{e^\omega}{2(e^\omega+\lambda)^{1/2}}\omega,_i\,,$$

and

$$|d\phi|^2=\frac{e^{2\omega}|d\omega|^2}{4(e^\omega+\lambda)},$$

where

$$\lambda\equiv\frac{B^2}{4}-A,\quad A,B \textit{ constants.}$$

From these we find that (10) becomes

$$\omega_{|ij}=-\frac{\lambda}{2(e^\omega+\lambda)}\omega,_i\omega,_j+2\chi\left(\frac{1}{3}g_{ij}-\frac{\omega,_i\omega,_j}{|d\omega|^2}\right), \tag{14}$$

or transvecting with $\omega^{,j}$,

$$\omega_{|ij}\omega^{,j}=-\left[\frac{4}{3}\chi+\frac{\lambda|d\omega|^2}{2(e^\omega+\lambda)}\right]\omega,_i\,.$$

This is just the geodesic equation,

$$\omega_{|ij}\omega^{,j}=\frac{\omega_{lk}\omega^{,l}\omega^{,k}}{|d\omega|^2}\omega_{,i}\,.$$

We have therefore established the following theorem

Theorem 2: *If a static Weyl-type electrovac space is aligned and type D, then the lines of force are geodesic in* (V^3,g_{ij}).

In fact, we can go further by looking at these equations in the conformal space $(\overline{V}^3,\overline{g_{ij}})$. There, Eq. (14) becomes

$$\omega_{\|ij}=\left[-\frac{e^\omega}{4(e^\omega+\lambda)}+\frac{3}{2}\frac{\omega^{\|kl}\omega,_k\omega,_l}{\|d\omega\|^4}\right]\omega,_i\omega,_j+\left[\frac{\|d\omega\|^2e^\omega}{4(e^\omega+\lambda)}-\frac{1}{2}\frac{\omega^{\|kl}\omega,_k\omega,_l}{\|d\omega\|^2}\right]\overline{g}_{ij}\,,$$

where we have denoted covariant differentiation with respect to the metric $\overline{g_{ij}}$ by a double stroke subscript and $\|d\omega\|^2=\overline{g^{ij}}\omega_i\omega_j$. Thus, the lines of force are also geodesic in $(\overline{V}^3,\overline{g_{ij}})$. Now, if we let

$$k_i=\frac{\omega,_i}{\|d\omega\|},$$

then k^i is a geodesic in $(\overline{V}^3,\overline{g_{ij}})$ and k^μ [given by (12)] is also a null geodesic in the full space–time $(M,g_{\mu\nu})$. In addition, k^i is shear-free in $(\overline{V}^3,\overline{g_{ij}})$:

$$k_{(i\|j)}k^{i\|j}-(\overline{g^{ij}}k_{i\|j})^2=0.$$

This also means, as one would expect from the Goldberg–Sachs theorem,[15] that the p.n.d. k^μ is shear-free in $(M,g_{\mu\nu})$. Thus we have the following:

Theorem 3: *If a static Weyl-type electrovac space is aligned and type D, then the lines of force are geodesic and shear-free in* $(\overline{V}^3,\overline{g}_{ij})$.

In the next section we determine all such metrics explicitly.

IV. TYPE D FIELDS

It is well known that the Reissner–Nordström solution is the unique static asymptotically flat electrovac field with geodesic shear-free lines of force (or *eigenrays*) Kota and Perjés.[2] In this section we present all static electrovac fields with $g_{44}=g_{44}(\phi)$, which possess shear-free geodesic lines of force.

In the vacuum case, all static fields with geodesic lines of force were found by Das[1] and Kota and Perjés.[2] Here we shall adopt the formalism of Das, generalizing it to include the electrostatic field. This formalism entails the setting up of a 3-dimensional complex triad field in $(\overline{V}^3,\overline{g}_{ij})$ and then expressing the field equations in terms of the associated 3-dimensional Ricci rotation co-efficients.

Let $\lambda^i_{(A)}$ be an orthonormal frame in $(\overline{V}^3,\overline{g}_{ij})$ and

$$\Gamma_{(ABC)}\equiv\lambda_{(A)j\|k}\lambda^j_{(B)}\lambda^k_{(C)},$$

be the associated Ricci rotation co-efficients. Here and throughout we use bracketed capital Latin letters $A,B,...=1,2,3$ to represent frame components and summation is implied over any repeated indices. These satisfy the commutation relations

$$\lambda^i_{(A)},_j\lambda^j_{(B)}-\lambda^i_{(B)},_j\lambda^j_{(A)}+\Gamma_{(C[AB])}\lambda^i_{(C)}=0, \tag{15}$$

and the Riemann curvature of $(\overline{V}^3,\overline{g}_{ij})$ is given in terms of them by

$${}^3\overline{R}_{(ABCD)}=\Gamma_{(AB)[(C),(D)]}+\Gamma_{(ABM)}\Gamma_{(M[CD])}+\Gamma_{(MAD)}\Gamma_{(MBC)}-\Gamma_{(MAC)}\Gamma_{(MBD)}. \tag{16}$$

We choose the frame so that the congruence of $\lambda^i_{(1)}$ is normal to the surface $\omega=\text{const}$. Thus

$$\lambda_{(1)i}=U\omega,_i, \quad \Gamma_{(123)}=\Gamma_{(132)}. \tag{17}$$

We choose co-ordinates so that

$$\omega=x^1, \quad \overline{g}_{12}=\overline{g}_{13}=0.$$

Hence (17) can be raised to give

$$\lambda^i_{(1)}=U^{-1}\delta^i_1.$$

Since the lines of force are geodesic, we have that

$$\Gamma_{(131)}=\Gamma_{(121)}=0.$$

Parallelly propagate $\lambda^i_{(2)}$, $\lambda^i_{(3)}$ along $\lambda^i_{(1)}$, so that

$$\Gamma_{(231)}=0.$$

Finally, since we have vanishing shear,

$$\Gamma_{(122)}=\Gamma_{(133)}, \quad \Gamma_{(123)}=0.$$

Label the remaining nonvanishing rotation co-efficients by

$$H\equiv\tfrac{1}{2}(\Gamma_{(122)}+\Gamma_{(133)}),$$

$$\sigma \equiv \frac{1}{\sqrt{2}}(\Gamma_{(233)} - i\Gamma_{(232)}).$$

Here and throughout capital Latin letters will indicate real valued functions and Greek letters will denote complex valued functions.

Furthermore, we make a formal transformation to complex conjugate co-ordinates defined by

$$z^2 \equiv x^2 + ix^3, \quad z^{\bar{2}} \equiv x^2 - ix^3.$$

It should be noted that a co-ordinate transformation of the form

$$x^1 \rightarrow x'^1 = x^1, \quad z^2 \rightarrow z'^2 = f(x^1, z^2), \quad z^{\bar{2}} \rightarrow z'^{\bar{2}} = \overline{f(x^1, z^2)},$$

where $f(x^1,z^2)$ is an analytic function of x^1,z^2 and the bar denotes complex conjugation, does not alter the static form of the metric. This corresponds to a co-ordinate transformation of (x^2,x^3) on the equipotential surfaces $\omega = x^1 = \text{const}$.

The field equations written in terms of frame components in $(\overline{V}^3, \overline{g}_{ij})$ are

$$^3\overline{R}_{(AB)} = 2e^{-\omega}\phi,_{(A)}\phi,_{(B)} - \tfrac{1}{2}\omega,_{(A)}\omega,_{(B)}, \tag{18}$$

$$\omega,_{(AA)} + \Gamma_{(CAA)}\omega,_{(C)} = 2e^{-\omega}\phi,_{(A)}\phi,_{(A)}, \tag{19}$$

with Maxwell's equation

$$\phi,_{(AA)} + \Gamma_{(CAA)}\phi,_{(C)} = \omega,_{(A)}\phi,_{(A)}. \tag{20}$$

Finally, introduce the complex triad field $\Lambda^j_{(A)}$ in complex co-ordinates by

$$\Lambda^j_{(1)} \equiv \lambda^j_{(1)}, \quad \Lambda^j_{(2)} \equiv \frac{1}{\sqrt{2}}(\lambda^j_{(2)} + i\lambda^j_{(3)}),$$

$$\Lambda^j_{(\bar{2})} \equiv \frac{1}{\sqrt{2}}(\lambda^j_{(2)} - i\lambda^j_{(3)}),$$

where complex frame indices take the values 1, 2, $\bar{2}$. We choose complex co-ordinates on the equipotential surfaces so that

$$\Lambda^j_{(2)} = \Sigma\,\delta^j_2, \quad \Lambda^j_{(\bar{2})} = \overline{\Sigma}\,\delta^j_{\bar{2}}$$

for some complex function Σ.

For a Weyl-type electric field the gravitational and electric potentials are related by

$$e^\omega = B + C\phi + \phi^2, \quad B, C \textit{ constants}.$$

Assembling the field equations (18)–(20) [using (4) and (16) together with the commutation relations (15)] gives

$$(\ln\sigma),_1 = -HU, \tag{21}$$

$$UH,_1 + (HU)^2 + \frac{1}{4}\left(1 + \frac{e^{x^1}}{\lambda}\right)^{-1} = 0, \tag{22}$$

$$H,_2 = 0, \tag{23}$$

$$\Sigma\,\overline{\sigma},_2 + \overline{\Sigma}\,\sigma,_{\bar{2}} + 2|\sigma|^2 + H^2 - \frac{1}{4}U^{-2}\left(1 + \frac{e^{x^1}}{\lambda}\right)^{-1} = 0, \tag{24}$$

$$(\ln U)_{,1} - 2HU + \frac{e^{x^1}}{2\lambda}\left(1 + \frac{e^{x^1}}{\lambda}\right)^{-1} = 0, \tag{25}$$

$$U_{,2} = 0, \tag{26}$$

$$(\ln \Sigma)_{,1} = -HU, \tag{27}$$

$$\bar{\Sigma}\Sigma_{,\bar{2}} + \bar{\sigma}\Sigma = 0, \tag{28}$$

where

$$\lambda \equiv \frac{C^2}{4} - B.$$

By (23), (26) we have that $U = U(x^1)$ and $H = H(x^1)$, and so (22) and (25) are ordinary differential equations. In order to integrate this system of equations, we must consider separately the cases $\lambda = 0$, $\lambda > 0$ and $\lambda < 0$. In the asymptotically flat case these correspond to $m = |e|$, $m > |e|$ and $m < |e|$, respectively.

A. $\lambda = 0$

Here, (22), (24) and (25) reduce to

$$UH_{,1} + (HU)^2 = 0 \tag{29}$$

$$HU_{,1} - 2(HU)^2 + \tfrac{1}{2}HU = 0, \tag{30}$$

$$\bar{\Sigma}\sigma_{,\bar{2}} + \Sigma\bar{\sigma}_{,2} + 2|\sigma|^2 + H^2 = 0., \tag{31}$$

Adding the first two of these, we get the Bernoulli equation

$$\frac{d(HU)}{dx^1} + \frac{1}{2}HU = (HU)^2,$$

with the solution

$$HU = \frac{e^{-(1/2)x^1}}{a + 2e^{-(1/2)x^1}}, \tag{32}$$

where a is an arbitrary constant of integration.

Now, (32) in (30) reads as

$$(\ln U)_{,1} - \frac{2e^{-(1/2)x^1}}{a + 2e^{-(1/2)x^1}} + \frac{1}{2} = 0,$$

or, integrating this up,

$$U = \frac{be^{-(1/2)x^1}}{(a + 2e^{-(1/2)x^1})^2}, \tag{33}$$

with b another arbitrary (nonzero) constant of integration. When this is put in (32), we find that

$$H = \frac{1}{b}(a + 2e^{-(1/2)x^1}). \tag{34}$$

Now, having determined the $\overline{g_{11}}$ component of the metric, we return to Eq. (27), which, using (32), integrates up to

$$\Sigma = (a + 2e^{-(1/2)x^1})e^{S+is},$$

where S and s are otherwise arbitrary real-valued functions of $(z^2, \overline{z^2})$. However, s does not contribute to the metric form and so we can, without loss of generality, put $s=0$. Thus

$$\Sigma = (a + 2e^{-(1/2)x^1})e^{S}, \tag{35}$$

and we need only determine S to completely solve the problem.

We do this by first putting (35) in (28), yielding

$$\sigma = -(a + 2e^{-(1/2)x^1})S_{,2}e^{S}, \tag{36}$$

and then Eqs. (34)–(36) in (31) boils down to the simple equation

$$S_{,2\overline{2}} = \frac{e^{-2S}}{2b^2}. \tag{37}$$

In real co-ordinates this is the 2-dimensional Poisson-type equation,

$$\frac{\partial^2 S}{\partial x^{22}} + \frac{\partial^2 S}{\partial x^{32}} = \frac{e^{-2S}}{2b^2}.$$

The general solution of (37) is (see Nehari[16])

$$e^{S} = \frac{1 + |\psi|^2}{\sqrt{2}|b||\psi_{,2}|}, \tag{38}$$

where ψ is an otherwise arbitrary function of z^2. Finally, (21) is identically satisfied by (32) and (36).

We can now assemble the metric with (33), (35), and (38),

$$ds^2 = b^2 e^{-x^1}\left[\frac{e^{-x^1}}{(a+2e^{-(1/2)x^1})^4}(dx^1)^2 + \frac{4|\psi_{,2}|^2|dz^2|^2}{(a+2e^{-(1/2)x^1})^2(1+|\psi|^2)^2}\right] - e^{x^1}dt^2,$$

or making the co-ordinate transformation,

$$x^1 \to x'^1 \equiv x^1, \quad z^2 \to z'^2 \equiv 2\psi, \quad \overline{z^2} \to \overline{z'^2} \equiv 2\overline{\psi}, \tag{39}$$

and subsequently dropping the primes and returning to real co-ordinates,

$$ds^2 = b^2 e^{-x^1}\left[\frac{e^{-x^1}}{(a+2e^{-(1/2)x^1})^4}(dx^1)^2 + \frac{1}{(a+2e^{-(1/2)x^1})^2}\,\frac{(dx^2)^2 + (dx^3)^2}{(1 + (1/4)[(x^2)^2 + (x^3)^2])^2}\right] - e^{x^1}\,dt^2. \tag{40}$$

By writing this metric on a null tetrad and analyzing it with the REDUCE computer algebra system we find that this metric generates a Petrov type D field, as expected. Furthermore, the surfaces

$x^1=$constant in (40) are 2-spaces of constant positive curvature, i.e., spheres and so we expect, by Birkhoff's Theorem, that (40) is just the extreme Reissner–Nordström solution in an unusual co-ordinate system. To see that this is indeed the case we introduce new co-ordinates (θ,φ) on these 2-spaces, defined by

$$\theta\equiv\tan^{-1}\left[\frac{1}{2}((x^2)^2+(x^3)^2)^{1/2}\right],\quad \varphi\equiv\tan^{-1}\left(\frac{x^3}{x^2}\right), \tag{41}$$

so that (40) reduces to

$$ds^2=b^2e^{-x^1}\left[\frac{e^{-x^1}}{(a+2e^{-(1/2)x^1})^4}(dx^1)^2+\frac{d\theta^2+\sin^2\theta d\varphi^2}{(a+2e^{-(1/2)x^1})^2}\right]-e^{x^1}dt^2.$$

Now, if we relabel the equipotential surfaces with ϱ defined by

$$e^{-(1/2)x^1}=-\frac{a}{2}\left(1+\frac{b}{2\varrho}\right),$$

and rescale the time co-ordinate by

$$t\rightarrow t'\equiv\frac{2t}{a},$$

we find, dropping the primes, that (40) becomes

$$ds^2=\left(1+\frac{b}{2\varrho}\right)^2[d\varrho^2+\varrho^2(d\theta^2+\sin^2\theta\,d\varphi^2)]-\left(1+\frac{b}{2\varrho}\right)^{-2}dt^2,$$

which is precisely the extreme Reissner–Nordström solution with

$$b=2m=2|e|.$$

B. $\lambda>0$

In this case we must solve (21)–(28). We still have, by (23) and (26) $U=U(x^1)$ and $H=H(x^1)$, but when we add (22) and (25) we get the Ricatti equation

$$\frac{d(HU)}{dx^1}-(HU)^2+\frac{1}{2}HU\frac{e^{x^1}}{\lambda}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1}+\frac{1}{4}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1}=0, \tag{42}$$

with the first integral

$$HU=\frac{1}{2}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}.$$

So, returning to (42) with a substitution of the form

$$HU=\frac{1}{2}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}+F(x^1), \tag{43}$$

we get a Bernoulli equation for F with the solution

$$F=\frac{1}{ae^{-I}-1}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}, \tag{44}$$

where a is an arbitrary constant of integration and I is defined,

$$I\equiv\int\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}dx^1.$$

Plugging (44) in (43) gives the general solution to (42) as

$$HU=\frac{1}{2}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}+\frac{e^I}{a-e^I}\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}=\frac{1}{2}\left(\frac{ae^{-I}+1}{ae^{-I}-1}\right)\left(1+\frac{e^{x^1}}{\lambda}\right)^{-1/2}. \tag{45}$$

Putting this in (25) and integrating,

$$U=\frac{be^I}{(1+(e^{x^1}/\lambda))^{1/2}(a-e^I)^2}, \tag{46}$$

where b is a nonzero constant of integration. Then (46) in (45) gives

$$H=\frac{1}{2b}e^{-I}(a^2-e^{2I}). \tag{47}$$

Again, having determined $\overline{g}_{11}$ we return to (27), which, with the help of (46) and (47), integrates to

$$\Sigma=(a-e^I)e^{-(1/2)I}e^{S+is}, \tag{48}$$

where S and s are arbitrary functions of $(z^2,\bar{z}^2)$. Without loss of generality, we can again put $s=0$.

Then, (48) in (28) gives

$$\sigma=-(a-e^I)e^{-(1/2)I}S_{,2}e^S, \tag{49}$$

and (21) is identically satisfied by (48) and (49).

Our remaining equation (24) boils down, from (46)–(49) to

$$S_{,2\bar{2}}=\frac{a}{2b^2}e^{-2S}. \tag{50}$$

Here we must consider the solutions to (50) for $a>0$, $a=0$ and $a<0$ separately. These correspond to the cases where the equipotential surfaces are of constant positive, zero and negative curvature, respectively.

$a>0$: In this case the general solution to (50) is

$$e^S=\sqrt{\frac{a}{2b^2}}\left[\frac{1+|\psi|^2}{|\psi_{,2}|}\right],$$

where ψ is an otherwise arbitrary function of z^2.

Assembling our metric, we find that

$$ds^2=b^2e^{-x^1}\left[\frac{e^{2I}(dx^1)^2}{(1+e^{x^1}/\lambda)(a-e^I)^4}+\frac{4e^I|\psi,_2|^2|dz^2|^2}{a(a-e^I)^2(1+|\psi|^2)^2}\right]-e^{x^1}\,dt^2,$$

and then transforming co-ordinates by (39) and dropping the primes, we find

$$ds^2=b^2e^{-x^1}\left[\frac{e^{2I}(dx^1)^2}{(1+e^{x^1}/\lambda)(a-e^I)^4}+\frac{e^I((dx^2)^2+(dx^3)^2)}{a(a-e^I)^2[1+(1/4)\,((x^2)^2+(x^3)^2)]^2}\right]-e^{x^1}\,dt^2.$$

Again, the field is Petrov type D, the equipotential surfaces are 2-spaces of constant positive curvature, i.e., spheres, and we thus expect it to represent the under-charged ($m>|e|$) or over-charged ($m<|e|$) Reissner–Nordström solution in an unfamiliar co-ordinate system. This is indeed the case, as can be seen by utilizing the co-ordinate transformation (41) and relabeling the equipotential surfaces with ϱ defined by

$$e^I\equiv a\left(\frac{b-\varrho}{b+\varrho}\right),$$

or, equivalently,

$$e^{x^1}\equiv\frac{4\lambda a}{(1-a)^2}\,\frac{(1-b^2/\varrho^2)^2}{[1+2((1+a)/(1-a))(b/\varrho)+(b^2/\varrho^2)]^2}.$$

The metric then becomes

$$ds^2=\frac{(1-a)^2}{64a^3}\left[1+2\left(\frac{1+a}{1-a}\right)\frac{b}{\varrho}+\frac{b^2}{\varrho^2}\right]^2[d\varrho^2+\varrho^2(d\theta^2+\sin^2\theta\,d\varphi^2)]$$
$$-\frac{4\lambda a(1-b^2/\varrho^2)^2}{(1-a)^2}\left[1+2\left(\frac{1+a}{1-a}\right)\frac{b}{\varrho}+\frac{b^2}{\varrho^2}\right]^{-2}dt^2,$$

which, with a final rescaling of

$$t\rightarrow\left(\frac{1-a}{2\sqrt{\lambda a}}\right)t,\qquad \varrho\rightarrow\left(\frac{(4a)^{3/2}}{1-a}\right)\varrho,$$

takes the standard isotropic form

$$ds^2=\left[1+2\left(\frac{1+a}{1-a}\right)\frac{b}{\varrho}+\frac{b^2}{\varrho^2}\right]^2[d\varrho^2+\varrho^2(d\theta^2+\sin^2\theta\,d\varphi^2)]$$
$$-\left(1-\frac{b^2}{\varrho^2}\right)^2\left[1+2\left(\frac{1+a}{1-a}\right)\frac{b}{\varrho}+\frac{b^2}{\varrho^2}\right]^{-2}dt^2,$$

with mass and charge parameters given by

$$m=\frac{2(1+a)b}{1-a},\qquad e^2=\frac{16ab^2}{(1-a)^2}.$$

$a=0$: In this case the general solution to (50) is

$$e^{-S}=b|\psi,_2|,\qquad \psi=\psi(z^2),$$

and using (39) our metric takes the simple form

$$ds^2 = b^2 e^{-x^1}\left[\frac{e^{-2I}}{(1+e^{x^1}/\lambda)}(dx^1)^2 + e^{-I}[(dx^2)^2+(dx^3)^2]\right] - e^{x^1}\,dt^2.$$

From this we can see that the equipotential surfaces are flat, and so our metric represents the field of a charged infinite plate, which also turns out to be of Petrov type D. The fact that it is not an asymptotically flat field can be most easily seen by transforming into isotropic co-ordinates. However, rather than do this here, we shall change to the canonical form of the plane symmetric static Einstein–Maxwell field, as given by McVitie.[17] This is achieved by relabeling the equipotential surfaces by z defined by

$$e^{x^1} \equiv \frac{4(\lambda^2+\lambda)^{1/2}}{bz} + \frac{4(1+\lambda)}{b^2 z^2},$$

and rescaling,

$$t \to t' \equiv \left(\frac{\lambda^{1/2} b^2}{(\lambda+1)^{1/2}}\right) t$$

$$x^2 \to x'^2 \equiv \left(\frac{b^2}{(\lambda+1)^{1/2}}\right) x^2, \quad x^3 \to x'^3 \equiv \left(\frac{b^2}{(\lambda+1)^{1/2}}\right) x^3,$$

we get (dropping the primes)

$$ds^2 = \left(\frac{m}{z} + \frac{e^2}{z^2}\right)^{-1} dz^2 + z^2[(dx^2)^2 + (dx^3)^2] - \left(\frac{m}{z} + \frac{e^2}{z^2}\right) dt^2,$$

where

$$m \equiv \frac{4(\lambda+1)^{3/2}}{\lambda^{1/2} b^5}, \quad e^2 \equiv \frac{4(\lambda+1)^2}{\lambda b^6}.$$

$a<0$: In this case (50) has the general solution

$$e^S = \sqrt{\frac{-a}{2b^2}}\left[\frac{1-|\psi|^2}{|\psi,_2|}\right],$$

and so, assembling our metric we find that, after transforming by (39) that

$$d\overline{s^2} = d\left(\frac{1}{e^I - a}\right)^2 - \frac{e^I}{a(e^I-a)^2}\,\frac{(dx^2)^2+(dx^3)^2}{[1-\frac{1}{4}[(x^2)^2+(x^3)^2]]^2}.$$

If we write the metric for the equipotential 2-surfaces of constant negative curvature in the form Stephani[18]

$$d\overline{\sigma^2} = \frac{du^2}{1+u^2} + u^2\,d\varphi^2,$$

and make the co-ordinate transformations

$$x^1 \to \varrho \equiv \left[\frac{-e^I}{a(e^I-a)^2}\right]^{1/2} u, \quad u \to h \equiv (1+u^2)^{1/2}\left[\frac{1}{4a^2} - \frac{\varrho^2}{u^2}\right]^{1/2},$$

we find that the metric is in the Weyl canonical form for a static axially symmetric field. We furthermore find that the field is singular along the axis of symmetry and has only two principal null directions associated with the Weyl curvature tensor (i.e., it is Petrov type D). We therefore interpret the field as being generated by an infinite rod situated along the axis of symmetry $\varrho = 0$.

C. $\lambda<0$

By a series of calculations similar to the $\lambda>0$ case, one obtains the metric generated by an overcharged ($m<|e|$) sphere, infinite rod and infinite plate.

V. SHEARING FIELDS

By a procedure similar to that of the last section, all Weyl-type fields with shearing geodesic lines of force can be found. The metric $\bar{g}$ turns out to be (for details, see Guilfoyle[19])

$$\bar{g}_{11} = \frac{F^{-2}}{\lambda^2(\lambda+e^{x^1})}[1+2k\lambda F[\tfrac{1}{4}((x^2)^2+(x^3)^2)^2+[(x^2)^2-(x^3)^2]\Omega+\Omega^2]],$$

$$\bar{g}_{12} = -\frac{F^{-1}x^2}{\lambda(\lambda+e^{x^1})^{1/2}}[\tfrac{1}{2}((x^2)^2-3(x^3)^2)+\Omega]$$

$$\bar{g}_{13} = -\frac{F^{-1}x^3}{\lambda(\lambda+e^{x^1})^{1/2}}[\tfrac{1}{2}((x^3)^2-3(x^2)^2)-\Omega]$$

$$\bar{g}_{22} = \bar{g}_{33} = \frac{1}{k\lambda}((x^2)^2+(x^3)^2)F^{-1},$$

where k is a constant, Ω is an arbitrary function of x^1 and

$$F(x^1) = \exp\left[(\lambda+4k^2)^{1/2}\int(\lambda+e^{x^1})^{-1/2}\,dx^1\right] = \begin{cases} \left[\dfrac{(\lambda+e^{x^1})^{1/2}-\lambda^{1/2}}{(\lambda+e^{x^1})^{1/2}+\lambda^{1/2}}\right]^n, & \text{for } \lambda>0 \\ \exp\left[-2n\tan^{-1}\left[-\left(1+\dfrac{e^{x^1}}{\lambda}\right)\right]^{1/2}\right], & \text{for } \lambda<0, \end{cases}$$

for $n \equiv [1+(2k)^2/\lambda]^{1/2}$. As expected, this metric is algebraically general, with shear given by

$$|\beta|^2 = k^2\lambda^2F^2 \neq 0.$$

Therefore this cannot be of the Majumdar–Papapetrou type. That is, $\lambda>0$ or $\lambda<0$, but $\lambda=0$ is not possible.

The equipotential surfaces $x^1=\text{const}$ are easily seen to be flat.

VI. CONCLUSION

We have established that all algebraically special Weyl-type electric fields have shear-free geodesic lines of force. In the over-charged ($m<|e|$) and under-charged ($m>|e|$) cases these are the fields generated by a charged sphere, infinite charged rod and infinite charged plate. These correspond exactly to the fields in Newtonian theory that have straight lines of force. Of these, only the sphere is asymptotically flat. In the Majumdar–Papapetrou case ($m=|e|$) the only solution is the extreme Reissner–Nordström solution. All metrics with shearing geodesic lines of force giving rise to a Weyl-type electric field were also found. This class of solutions depends on an arbitrary function of the gravitational potential and the equipotential surfaces are flat. It is algebraically general and cannot be in the Majumdar–Papapetrou class.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 4 APRIL 1999

On relativistic spin network vertices

Michael P. Reisenberger[a)]
Instituto de Física, Universidad de la República Igua, 4225 esq. Mataojo, C.P. 11400 Montevideo, Uruguay

(Received 30 September 1998; accepted for publication 15 October 1998)

Barrett and Crane have proposed a model of simplicial Euclidean quantum gravity in which a central role is played by a class of Spin(4) spin networks called ''relativistic spin networks'' which satisfy a series of physically motivated constraints. Here a proof is presented that demonstrates that the intertwiner of a vertex of such a spin network is uniquely determined, up to normalization, by the representations on the incident edges and the constraints. Moreover, the constraints, which were formulated for four valent spin networks only, are extended to networks of arbitrary valence, and the generalized relativistic spin networks proposed by Yetter are shown to form the entire solution set (mod normalization) of the extended constraints. Finally, using the extended constraints, the Barrett–Crane model is generalized to arbitrary polyhedral complexes (instead of just simplicial complexes) representing space-time. It is explained how this model, like the Barret–Crane model can be derived from BF theory, a simple topological field theory [G. Horowitz, Commun. Math. Phys. **125**, 417 (1989)], by restricting the sum over histories to ones in which the left-handed and right-handed areas of any 2-surface are equal. It is known that the solutions of classical Euclidean general relativity form a branch of the stationary points of the BF action with respect to variations preserving this condition. [S0022-2488(99)00904-4]

I. INTRODUCTION

The ''Relativistic spin networks'' defined by Barrett and Crane (BC) are a fundamental ingredient of their proposal for a simplicial model of quantum general relativity in four dimensions. In Ref. 1 the space of intertwiners that relativistic spin networks are allowed to carry is defined implicitly by a set of physically motivated constraints. They also exhibit a single solution to these constraints. Soon after Barbieri[2] gave a partial proof of the uniqueness up to normalization of this solution, which relies on some unproven hypothesies. BC's constraints apply only to 4-valent spin networks, but their solution to their constraints has been generalized in a natural way to arbitrary valence by Yetter,[3] and Barrett[4] has given a very transparent characterization of this extension in the non-q-deformed case, $q=1$.

Here a proof (without auxiliary assumptions) will be given showing that the BC solution is the only one, up to normalization, and similarly Yetter's generalization of the solution (for $q=1$) is the unique solution up to normalization of a natural generalization of the BC constraints. In addition a physically motivated extension of the BC model to polyhedral complexes is outlined. The BC model can be obtained from a sum over histories quantization of Spin(4) BF theory by restricting the histories to ones that assign equal (suitably defined) left-handed and right-handed areas to any 2-surface. At the classical continuum level such a constrained BF theory does reproduce general relativity (GR). The solutions of GR form a branch of the stationary points of the Spin(4) BF action with respect to variations that preserve the constraint that the left- and right-handed areas be equal for all 2-surfaces.[5] This procedure for obtaining the BC model generalizes straightforwardly to complexes of convex 4-polyhedra.

For background information on spin networks see Refs. 6–10.

II. DEFINITION OF RELATIVISTIC SPIN NETWORKS

I will adopt the following definition of relativistic spin networks, which generalizes BC's definition from 4-valent vertices to vertices of arbitrary valence.

Definition 1: A relativistic spin network is a Spin(4) spin network such that

(1) on each edge the left-handed spin, j_L, and the right-handed spin, j_R, are equal.

(2) in any expansion of an n-valent vertex into a sum of trivalent trees only trivalent trees with $j_L = j_R$ on each of the internal (virtual) edges appear.

In general the edges of a spin network carry nontrivial irreducible representations (irreps) of the gauge group, and the vertices carry intertwiners. The intertwiner for a vertex can be any invariant tensor of the product representation R formed by the product of the irreps carried by the incoming edges and the duals of the irreps on the outgoing edges. (The dual of a representation D of a group is the representation D^{-1T} formed by the transposes of the inverses of the representation matrices of D. If D is unitary its dual is the complex conjugate representation D^* formed by complex conjugating each matrix element in the representation matrices of D.) The space of invariant tensors of R will be denoted $\mathrm{Inv}(R)$. The *evaluation* of a spin network is a complex number calculated by contracting the intertwiners of the vertices along the edges. An intertwiner carries one index for each incident edge. In the evaluation of a spin network the pair of indices associated with each edge (one index lives at each end) is contracted, leaving ultimately a single $\mathbf{C}$ number. In the BC model histories of the gravitational field determine relativistic spin networks on the boundaries of the 4-simplices that form the simplicial space–time, and the probability amplitude of each history is the product of the evaluations of these spin networks (times some simple further factors associated with the lower dimensional simplices).

Relativistic spin networks are spin networks of Spin(4), the covering group of SO(4). Spin(4) is the product of two SU(2)s: Spin(4)=SU(2)×SU(2), where the first SU(2) factor will be called $\mathrm{SU}(2)_L$, the ''left-handed'' subgroup, and the second $\mathrm{SU}(2)_R$, the ''right-handed'' subgroup. This factorization extends to the irreps of Spin(4). These are tensor products of an irrep of $\mathrm{SU}(2)_L$ and an irrep of $\mathrm{SU}(2)_R$, and their carrying spaces, i.e., the vector spaces on which they act, are the tensor products of the carrying spaces of the $\mathrm{SU}(2)_L$ and $\mathrm{SU}(2)_R$ irreps [M. Tinkham, *Group Theory and Quantum Mechanics* (McGraw-Hill, New York, 1964), p. 43].

The factorization of the irreps implies that the product R of irreps incident on a spin network vertex also factorizes into a left-handed factor, R_L, and a right handed factor, R_R, and hence that the intertwiner space factorizes according to

$$\mathrm{Inv}_{\mathrm{Spin}(4)}(R) = \mathrm{Inv}_{\mathrm{Spin}(4)}(R_L \otimes R_R) = \mathrm{Inv}_{\mathrm{SU}(2)}(R_L) \otimes \mathrm{Inv}_{\mathrm{SU}(2)}(R_R) \tag{1}$$

into a tensor product of two SU(2) intertwiner spaces.

SU(2) irreps are determined by their spin, modulo the freedom to change basis in the carrying space. Spin(4) irreps are therefore characterized in the same sense by the spins (j_L, j_R) of their left- and right-handed factors. To keep the mathematics as concrete as possible it is convenient to fix the bases in the carrying spaces so that the irreps take a standard form completely determined by their spins (j_L, j_R). (Note that the evaluation of a spin network is invariant under changes of basis in the carrying spaces of the irreps on the edges. The contractions of the indices of the intertwiners are all between vector indices of some irrep and corresponding covector indices, i.e., vector indices of the dual of the irrep.) We shall adopt as our standard (j_L, j_R) irrep

$$U^{(j_L)} \otimes U^{(j_R)*}, \tag{2}$$

where for each spin j, $U^{(j)}$ is a particular, *unitary*, spin j SU(2) irrep fixed once and for all by some conventions, and $U^{(j)*}$ is its dual irrep. [For instance we may choose

$$U^{(j)m}{}_n(g) = \binom{2j}{j+m}^{-1/2} \binom{2j}{j+n}^{-1/2} \sum_{\Sigma M_i = m, \Sigma N_i = n} g^{M_1}{}_{N_1} \cdots g^{M_{2j}}{}_{N_{2j}} \quad \forall g \in \mathrm{SU}(2). \tag{3}$$

Here the indices M_i and N_i range over $\{-\frac{1}{2},\frac{1}{2}\}$.] This choice can be made because, first, the compactness of SU(2) implies that its irreps preserve a Hermitean inner product, and are thus unitary in orthonormal bases with respect to this inner product, and second because the dual of a spin j SU(2) irrep is also a spin j irrep, so that the Spin(4) irrep chosen really has right-handed spin j_R.

Now let us consider a spin network vertex. First we will define some notation. Once the bases are fixed the product representation R formed by the incident irreps is completely determined by the incident spins and whether edges are incoming or outgoing. This information can be gathered into two vectors, $\mathbf{j}_L$ and $\mathbf{j}_R$, which we shall, in a slight abuse of language, refer to as the vectors of incident left-handed and right-handed spins. Each entry of $\mathbf{j}_L$ corresponds to an incident edge and consists of the left-handed spin, j_L, if the edge is incoming and $-j_L$ if the edge is outgoing. The left-handed factor of R is then $R_L = R(\mathbf{j}_L)$ where

$$R(\mathbf{j}) = \bigotimes_n U^{(j_n)} \tag{4}$$

(n numbers the edges and we have defined $U^{(-j)} \equiv U^{(j)*}$). $\mathbf{j}_R$ is defined in complete analogy to $\mathbf{j}_L$, so our conventions for the Spin(4) irreps on the edges imply that $R = R(\mathbf{j}_L) \otimes R(\mathbf{j}_R)^*$. If $\mathcal{H}(\mathbf{j})$ is the carrying space of the SU(2) representation $R(\mathbf{j})$, and $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}) \equiv \mathrm{Inv}_{\mathrm{SU(2)}}(R(\mathbf{j}))$ is its invariant subspace then the carrying space of $R = R(\mathbf{j}_L) \otimes R(\mathbf{j}_R)^*$ is $\mathcal{H}(\mathbf{j}_L) \otimes \mathcal{H}(\mathbf{j}_R)^*$ and the Spin(4) intertwiner space is $\mathrm{Inv}_{\mathrm{Spin(4)}}(\mathbf{j}_L, \mathbf{j}_R) = \mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_L) \otimes \mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)^*$.

The inner product preserved by the unitary representation $R(\mathbf{j})$ establishes a one to one correspondence between vectors of $\mathcal{H}(\mathbf{j})^*$ and linear functions $\mathcal{H}(\mathbf{j}) \to \mathbf{C}$. A tensor $\Psi \in \mathcal{H}(\mathbf{j}_L) \otimes \mathcal{H}(\mathbf{j}_R)^*$ can thus be viewed as a linear mapping $\Psi : \mathcal{H}(\mathbf{j}_R) \to \mathcal{H}(\mathbf{j}_L)$. If the tensor Ψ is an intertwiner it maps $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)$ into $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_L)$ and the orthogonal complement of $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)$ in $\mathcal{H}(\mathbf{j}_R)$ to zero.

Condition 1 in the definition of relativistic spin networks implies that $\mathbf{j}_L = \mathbf{j}_R$ at their vertices. Thus a relativistic intertwiner Φ may be viewed as a mapping of $\mathcal{H}(\mathbf{j}_R)$ into *itself*, that furthermore maps $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)$ into itself and the orthogonal complement of $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)$ to zero. It is the composition of the orthogonal projector P onto $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)$ and a linear mapping X of $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j}_R)$ to itself: $\Phi = XP$.

Condition 2 in the definition of relativistic spin networks refers to trivalent tree expansions of spin network vertices. It is well known (see Refs. 6 and 11) that for SU(2) spin networks each trivalent tree graph having the same external edges as a given vertex defines a basis of the intertwiner space $\mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j})$ of the vertex. (The trivalent tree has oriented edges and a cyclic ordering of the edges incident at each vertex.) Each element of such a ''trivalent tree basis'' is associated with an assignment $\mathbf{J}$ of (possibly zero) spins to the internal edges of the tree (also known as ''virtual'' edges because they are not present in the actual spin network). The basis element is evaluated by contracting the intertwiners of the trivalent vertices along the internal edges as in a spin network evaluation. This leaves just the intertwiner indices associated with the external edges free. To complete the definition one needs to specify the trivalent intertwiners. The trivalent intertwiner spaces $\mathrm{Inv}_{\mathrm{SU(2)}}(j_1, j_2, j_3)$ of SU(2) are all one dimensional, so it is sufficient to fix the freedom to multiply the intertwiners by scalar factors. We will choose the trivalent intertwiners to be normalized. Then, if a normalizing factor $\sqrt{2J+1}$ is included for each internal edge, the trivalent tree intertwiners will be normalized. There remains a phase which must be chosen by convention. We will suppose that such a convention has been adopted, so that the trivalent tree T and the vector $\mathbf{J}$ of spins on the internal edges determine a unique intertwiner $|T,\mathbf{j},\mathbf{J}\rangle \in \mathrm{Inv}_{\mathrm{SU(2)}}(\mathbf{j})$. [The Wigner 3-$jm$ symbols, $\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$, with the standard convention[6] that $(-1)^{j_1-j_2+j_3}\begin{pmatrix} j_1 & j_2 & j_3 \\ j_1 & j_3-j_1 & -j_3 \end{pmatrix}$ is real and non-negative for all j_1, j_2, and j_3, form a basis of trivalent intertwiners consistent with the convention for $U^{(j)}$ of (3). Aside from being real this basis also has the attractive feature that the intertwiners have simple symmetry properties under permutations of the incident edges: If $j_1+j_2+j_3$ is even they are symmetric, if it is odd they are antisymmetric.] Spin(4) trivalent tree bases can then be constructed from the SU(2) trivalent tree bases: If the trivalent tree T spans a Spin(4) vertex with incident spins $(\mathbf{j}_L, \mathbf{j}_R)$ then the multiplet

$$\{|T,\mathbf{j}_L,\mathbf{J}_L\rangle \otimes \langle T,\mathbf{j}_R,\mathbf{J}_R|\}_{\mathbf{J}_D,\mathbf{J}_R} \tag{5}$$

spans the intertwiner space $\mathrm{Inv}_{\mathrm{Spin}(4)}(\mathbf{j}_L,\mathbf{j}_R)$. Here $\langle T,\mathbf{j},\mathbf{J}|$ denotes the complex conjugate of the tensor $|T,\mathbf{j},\mathbf{J}\rangle$, which, as has been explained, defines a linear function $\mathcal{H}(\mathbf{j})\to\mathbf{C}$ via the Hermitean inner product, thus justifying the Dirac bra notation. The definition of a relativistic spin network implies that the expansion of an intertwiner Φ of such a spin network on a trivalent tree basis has the form

$$\Phi = \sum_{\mathbf{J}} a^T_{\mathbf{jJ}} |T,\mathbf{j},\mathbf{J}\rangle \otimes \langle T,\mathbf{j},\mathbf{J}|, \tag{6}$$

i.e., the left- and right-handed spins are equal on both external and internal edges, for *any* tree T spanning the vertex.

III. THE SOLUTION TO THE CONSTRAINTS DEFINING RELATIVISTIC VERTICES

Now that relativistic spin networks have been defined and explained we are ready to state and prove our result:

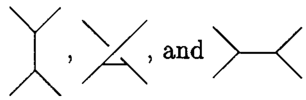
Theorem: *The intertwiner of any vertex in a relativistic spin network is uniquely determined, up to a numerical factor, by the irreps on the incident edges. Let* $\mathbf{j}=\mathbf{j}_L=\mathbf{j}_R$ *be the common value of the vectors of left- and right-handed incident spins (as defined in Sec. II) at a vertex, and let* $\mathcal{H}(\mathbf{j})$ *be the space of tensors transforming under the product of the* SU(2) *irreps with these spins, equipped with the Hermitean inner product preserved by* SU(2). *When the bases in the carrying spaces of the* $\mathrm{SU}(2)_L$ *and* $\mathrm{SU}(2)_R$ *irreps on the edges of the relativistic spin network are chosen so that the* $\mathrm{SU}(2)_L$ *irrep is the dual of the* $\mathrm{SU}(2)_R$ *irrep on each edge incident on the vertex then*

(1) tensors, like the intertwiner, that transform under the product of the incident Spin(4) *irreps live in the tensor product of* $\mathcal{H}(\mathbf{j})$ *and its dual, and can thus be viewed as linear mappings of* $\mathcal{H}(\mathbf{j})$ *to itself, and*

(2) the intertwiner is proportional to the orthogonal projector from $\mathcal{H}(\mathbf{j})$ *to the subspace of invariant tensors* $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})\subset\mathcal{H}(\mathbf{j})$.

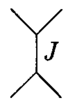
Proof: Part (1) has already been established in Sec. II, so only part (2) remains to be proven. (6) shows that an intertwiner, Φ, of a relativistic spin network is the composition of the projector P from the space $\mathcal{H}(\mathbf{j})$ of tensors with spins $\mathbf{j}$ onto the subspace of intertwiners $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$ and a linear map X of $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$ to itself. (6) furthermore requires that X is *diagonal* in each of the trivalent tree bases of $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$. Obviously $X=c\mathbf{1}$ with $c\in\mathbf{C}$ satisfies this condition, so cP is a relativistic intertwiner. To establish the theorem it remains to be shown that the set of all trivalent tree bases is rich enough so that this is the only solution to the condition.

Let us first consider four valent vertices. There are three (unoriented) trivalent trees matching the four incident edges,

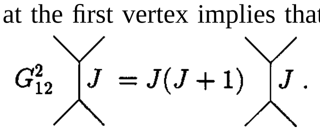


each of which has one internal, or virtual, edge. Once the orientations of the external edges are fixed to match those of the four valent vertex being expanded there remains the freedom to choose the orientation of the internal edge and the cyclic ordering of the incident edges at the two trivalent vertices. However these choices only affect the *signs* of the corresponding trivalent tree basis, modulo sign it is determined by the unoriented tree graph.

Let us number the incident edges 1, 2, 3, 4 clockwise from the top left, and let G_{ni} for $n \in \{1,2,3,4\}$ be the generators, acting in $\mathcal{H}(\mathbf{j})$, of the SU(2) irreps on the incident edges. Let us also define $G_{mni} = (G_m + G_n)_i$. (If the edge n is incoming then $[G_{ni}, G_{nj}] = i\epsilon_{ij}^{k} G_{nk}$. If the edge is outgoing the negatives $-G_{ni}$ satisfy these communication relations. The generators belonging to distinct edges of course commute.) The first of the trivalent trees drawn above corresponds to a pairing of edges 1 and 2, which join at a trivalent vertex. The corresponding basis intertwiners

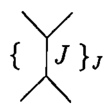


are contractions of a trivalent intertwiner at this vertex and one at the other vertex of the graph. The invariance of the intertwiner at the first vertex implies that



(7)

The intertwiner basis



is thus the eigenbasis of G_{12}^2 in $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$. Similarly the trivalent tree bases associated with the second and third trees diagonalize G_{13}^2 and G_{14}^2, respectively.

Since X, the restriction of Φ to $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$, is diagonal in all the trivalent tree bases it commutes with G_{12}^2, G_{13}^2, and G_{14}^2. Further, since the spectra of these operators $(\{J(J+1)\})$ are nondegenerate, X can be expressed as a function of any one of them. Choosing G_{12}^2 we write

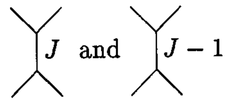
$$X = \sum_{q=0}^{d-1} b_q [G_{12}^2]^q, \tag{8}$$

where d is the dimension of $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$. Since the spin J defined by the eigenvalues $J(J+1)$ of G_{12}^2 can take only d values a polynomial of degree $d-1$ can reproduce any dependence of X on G_{12}^2.

Because X also commutes with G_{13}^2

$$0 = [G_{13}^2, X] = \sum_{q=0}^{d-1} b_q [G_{13}^2, (G_{12}^2)^q]. \tag{9}$$

This condition implies that $b_q = 0\ \forall q \neq 0$, so that $X = b_0 \mathbf{1}$. To prove this it is sufficient to consider the matrix elements of (9) between the basis intertwiners



(which I will denote $|J\rangle$ and $|J-1\rangle$ in the following) for all allowed values of J. $\langle J|[G_{13}^2,(G_{12}^2)^q]|J-1\rangle$ is obviously zero when $q=0$. When $q\geqslant 1$ it equals

$$\sum_{r=0}^{q-1} \langle J|(G_{12}^2)^r[G_{13}^2,G_{12}^2](G_{12}^2)^{q-1-r}|J-1\rangle=\beta_J P_q(J), \tag{10}$$

where $\beta_J=\langle J|[G_{13}^2,G_{12}^2]|J-1\rangle$, and

$$P_q(J)=\sum_{r=0}^{q-1} [(J)(J+1)]^r[(J-1)J]^{q-1-r}. \tag{11}$$

(9) therefore implies

$$0=\beta_J\sum_{q=1}^{d-1} b_q P_q(J). \tag{12}$$

The matrix elements of $[G_{13}^2,G_{12}^2]$ have been worked out explicitly by Levý-Leblond and Levý-Nahas.[12] They find

$$\beta_J=\frac{2j_4+1}{\sqrt{4J^2-1}}\{[(j_1+j_2+1)^2-J^2][J^2-(j_1-j_2)^2]\}^{1/2}\{[(j_3+j_4+1)^2-J^2][J^2-(j_3-j_4)^2]\}^{1/2}. \tag{13}$$

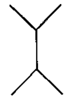
[(13) corresponds to Eq. (2.17) of Ref. 12. Their J is called j_4 in our notation and their l is our J. Our formula has an extra factor $(2j_4+1)$ relative to theirs because, while they are evaluating the matrix element between states of *three* spins having definite values (j_4 and m_4) of the magnitude and 3 axis component of the total spin, we are calculating the matrix elements between states of *four* spins which have total spin zero. In this latter calculation one must sum over the $2j_4+1$ possible values of m_4. It is also interesting to note that the operator $[G_{13}^2,\ G_{12}^2]=-4i\epsilon^{ijk}G_{1i}G_{2j}G_{3k}$ has a physical interpretation in loop quantum gravity. It is $-4i$ times the squared 3-volume associated with the four valent vertex.[13–15]]

The important feature of (13) for us is that it is nonzero for all values of J such that both J and $J-1$ satisfy the triangle inequalities

$$|j_1-j_2|\leqslant \text{spin}\leqslant j_1+j_2, \tag{14}$$

$$|j_3-j_4|\leqslant \text{spin}\leqslant j_3+j_4 \tag{15}$$

for the spin on the internal edge of



.

It is thus nonzero for all but the smallest of the values of J corresponding to the intertwiners $|J\rangle$ spanning $\mathrm{Inv}_{SU(2)}(\mathbf{j})$. The condition (12) therefore implies

$$0=\sum_{q=1}^{d-1} b_q P_q(J) \tag{16}$$

for all but one of the d allowed values of J.

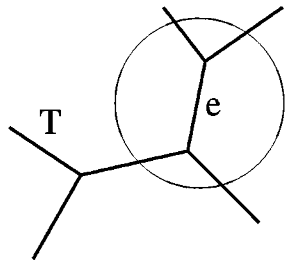


FIG. 1. The circle contains a four valent fragment of the trivalent tree graph T.

Now note that, first, the highest order term in $P_q(J)$ is $J^{2(q-1)}$, and, second, that $P_q(-J) = P_q(J)$. It follows that the P_q have the form $P_q(J) = \Sigma_{p=0}^{d-2} A_{qp} J^{2p}$, where A is a $(d-1)\times(d-1)$ matrix. Moreover, since their leading powers of J are all distinct, the P_q are linearly independent polynomials, implying that A is invertible. From (16) it follows that $\Sigma_{q=1}^{d-1} b_q A_{qp} = 0 \forall p \in \{0,...,d-2\}$. The invertibility of A then shows that $b_q = 0 \forall_q \in \{1,...,d-1\}$. As claimed $X = b_0 \mathbf{1}$.

The result is thus established for four valent vertices. Let us now consider a vertex of arbitrary valence. Fix a particular trivalent tree graph T expanding the vertex and consider a four valent fragment of the graph consisting of an internal edge e, and the four (internal or external) edges attached to it (see Fig. 1). The preceeding arguments relating to four valent vertices can be applied directly to this fragment and show that the eigenvalue $a_{\mathbf{jJ}}^T$ of X on $|T,\mathbf{j},\mathbf{J}\rangle$ is independent of the spin on e. Since this holds for any internal edge of T the eigenvalue is independent of all the internal spins, i.e., it has a common value $c \in \mathbf{C}$ on each element of the basis $\{|T,\mathbf{j},\mathbf{J}\rangle\}_{\mathbf{J}}$. Hence $X = c\mathbf{1}$ and the relativistic intertwiner is cP. ■

I close with a few observations.

(1) The BC model has a simple, physically motivated extension to arbitrary polyhedral complexes (as opposed to simplicial complexes) representing space–time. The generalized BC constraints of definition (1) are equivalent to the requirement that relativistic spin networks define equal left- and right-handed areas for any surface, including ones cutting through vertices. Here the left- and right-handed areas are determined from the left- and right-handed spins on the spin network edges and on the virtual edges of trivalent tree expansions of the vertices using the area operator of loop quantum gravity.[13,16,17]

In Ref. 5 it has been shown that GR is a branch of the theory obtained by restricting SO(4) (or Spin(4)) BF theory to histories in which left-handed and right-handed areas are equal. That is, the solutions of GR form a branch of the stationary points of the SO(4) BF action with respect to variations that respect the constraint that left-handed areas equal right-handed areas. This provides a motivation of the BC model which may be extended to polyhedral complexes: Spin(4) BF theory is just two noninteracting SU(2) BF theories, corresponding to $SU(2)_L$ and $SU(2)_R$, respectively. Thus Ooguri's[18] simplicial lattice sum over histories quantization of SU(2) BF theory [this model is also known as the Crane–Kauffman–Yetter model[19]] immediately provides a simplicial quantization of Spin(4) BF theory. The BC model is then obtained from simplicial Spin(4) BF theory by restricting the histories to ones in which left- and right-handed areas are equal. A history in the Spin(4) BF theory defines a Spin(4) spin network on the boundary of each 4-simplex (or more precisely, on the 1-skeleton of the dual of the boundary seen as a three-dimensional simplicial complex), which plays the role of boundary data in the sense that the spins and intertwiners of the spin networks on two neighboring 4-simplices must match in their mutual boundary. The requirement that left- and right-handed areas be equal then reduces the allowed Spin(4) spin networks to just relativistic spin networks.

Ooguri's quantization of BF theory is most easily generalized to arbitrary polyhedral complexes in the connection formulation (see Ref. 20 for a detailed discussion). In this formulation the boundary data on each 4-cell is a lattice connection [of Spin(4) in our case] defined by the parallel transport matrices across the 2-cells separating the 3-cells of the boundary of the 4-cell. (Equivalently, it is a lattice connection on the 1-skeleton of the dual of the boundary). The amplitude of this connection is a delta distribution with support on flat connections. Clearly the sum over histories yields the same states on the boundary of the space–time (once infinities stemming from redundancies in the delta functions are factored out) whether simplices or arbitrary convex polyhedral 4-cells form the space–time complex.

If one transforms the sum over connection boundary data to a sum over spin network boundary data (see Ref. 20) one finds, for polyhedral complexes as for simplicial complexes, that the amplitudes of each history is just the product of the evaluations of the spin networks on the 4-cells, times a factor $(2j+1)^2$ for each 2-cell, with $j=j_L=j_R$ the common value of the spins carried by the spin network edges crossing that 2-cell. Applying the constraint that left areas equal right areas for all surfaces, even ones crossing the vertices of the spin networks, restricts the spin networks on the boundaries of the 4-cells to be relativistic spin networks in the extended sense of our definition (1). This defines the generalization of the BC model to polyhedral complexes.

(2) To completely determine the BC sum over histories a normalization has to be chosen for the relativistic intertwiners. The four valent relativistic intertwiner given by BC in Ref. 1 seems to be just P. On the other hand, if the sum over histories is to be truly a restriction of the sum over histories for BF theory then the relativistic intertwiner must be normalized in the sense that its contraction on all indices with its complex conjugate must be 1. Thus it must be $P/\sqrt{d}$ up to a phase, where d is the dimensionality of $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$.

(3) Barrett[4] has shown that Yetter's extension to arbitrary valence of the four valent relativistic intertwiner found by BC is equal to

$$\int_{\mathrm{SU}(2)} dg \prod_{j\in\mathbf{j}} U^{(j)}(g) \tag{17}$$

(when the conventions fixing the bases in the irrep carrying spaces are adopted). Here $U^{(j)}(g)$ is the spin j representation matrix of $g\in\mathrm{SU}(2)$ corresponding to the basis convention, and the normalized Haar measure is used to integrate over the group. (17) is precisely the orthogonal projector P on $\mathrm{Inv}_{\mathrm{SU}(2)}(\mathbf{j})$. Thus the theorem shows that the unique solution (mod normalization) of our generalization of BC's constraints is Yetter's extension of their solution.

(4) Since j_R is everywhere equal to j_L the BC state sum can be viewed as a sum over histories of left-handed ''fields,'' i.e., the j_L only. Thus the BC model can be viewed, like the model of Ref. 20 as a (proposal for) a formulation of quantum GR in terms of ''self-dual'' variables. (Note that this does *not* mean that it is a model of only the self-dual sector of GR, in which the anti-self-dual curvature vanishes. It only means that exclusively self-dual variables are used to express the configuration of the gravitational field.)

ACKNOWLEDGMENTS

I would like to thank John Barrett, Rodolfo Gambini, and Carlo Rovelli for encouragement and discussions regarding the subject of this note and closely related issues. This work was funded by the Comision Sectorial de Investigación Cientifica (CSIC) of the Universidad de la República.

Generalized Kronecker and permanent deltas, their spinor and tensor equivalents and applications

R. L. Agacy[a)]
42 Brighton Street, Gulliver, Townsville, Qld 4812, Australia

(Received 14 September 1998; accepted for publication 8 December 1998)

The aim of this paper is fourfold: (i) to introduce a *generalized permanent delta* on an equal footing with the generalized Kronecker delta, to use for the symmetries of any tensor or spinor, (ii) to cite an ancillary reference source of comprehensive tensorial and spinorial combinatorial formulas for both, (iii) to table spinor equivalents of these individual tensors and give examples of their usage, and (iv) to tabulate the tensor equivalents of various useful combinations of their spinor forms.
 [S0022-2488(99)03303-4]

I. INTRODUCTION

The generalized Kronecker delta (gKd) is well known as an alternating function or *antisymmetrizer*, e.g., $\delta^{abc}_{def}X_{abc}=3!X_{[def]}$. In contrast, although symmetric tensors are seen constantly in the mathematical language for general relativity (GR), there does not appear to be employment of any *symmetrizer*, for e.g., $X_{(abc)}$, in analogy with the antisymmetrizer. Historically, nomenclature for both date back to Cauchy 1812 in terms of ''fonctions symétriques alternées'' and ''fonctions symétriques permanentes.''[1] A permanent symmetrized tensor was probably first introduced by Cramlet,[2,3] but seems to have been neglected, never acquiring the same prominence as the gKd. However, it is exactly the combination of *both* types of symmetrizers, treated equally, that give us the flexibility to describe any type of tensor symmetry, being exactly the symmetrizers needed to describe Young tableaux tensors.[4] We define such a ''permanent'' symmetrizer as a generalized permanent delta (gpd) below. Our purpose is to restore an imbalance between the gKd and gpd and cite a reference of combinatorial formulas for them, most of which is not in the literature. The contents of this Ref. 5, referred to as PAPS, which contains a *comprehensive* tabulation of gKd and gpd formulas is amplified at the end of this section. In Sec. II we define the gpd and gKd and state some very basic relations. In Sec. III we illustrate the usage of the generalized deltas in the symmetries of tensors. In Sec. IV examples are given of finding spinor equivalents of simple tensors almost instantly, using gKd and gpd spinors. A table of spinor equivalents of individual tensor generalized deltas are tabulated in Appendix A. Converse to finding spinor equivalents, we next tabulate the tensor equivalents of spinor generalized deltas in Appendix B. They can be applied to obtain a variety of spinor formulas.

General indices range from $1,...,n$. All index sets are permutations of each other. Two-component spinor indices are in capital lower case roman.

The PAPS reference[5] contains the following parts and sections: Part I; formulas for *n*-dimensions, (1) Introduction, (2) Definitions and illustrations of the gKd and gpd, (3) Generalized Kronecker δ, (4) Generalized permanent δ, (5) Combined gKd and gpd, Part II; formulas for tensors and spinors in the mathematical language of GR, (6) Spinor equivalents of gKd and gpd tensors, (7) Tensor equivalents of gKd and gpd spinors. Appendixes A–F provide tabulations of all formulas. The *derivation* of each and every formula is provided in the above sections.

II. DEFINITIONS AND BASICS OF THE gKd AND gpd

Complete symmetry of (a tensor's) indices, as opposed to total antisymmetry, is manifested by all positive signs in any *p*-linear expression. Whereas the gKd's antisymmetry comes about

[a)]Electronic mail: ragacy@ultra.net.au

through a *determinant* (interchanges of rows/columns or indices changes the sign), total positive or pure or *permanent* symmetry, as we term it, comes about through the use of a *permanent*. Then in complete analogy to the gKd we introduce the *generalized permanent delta* or *gpd*. This is defined, like the gKd determinant of a matrix, *except that we take all positive signs*. We use the kernel letter π to denote a gpd and *double* vertical lines for the *permanent* of the defining matrix. The gKd and gpd are completely complementary to each other and are defined, for $p(\leqslant n)$ distinct indices, respectively by,

$$\delta^{i_1\cdots i_p}_{j_1\cdots j_p}=\begin{vmatrix} \delta^{i_1}_{j_1} & . & . & \delta^{i_1}_{j_p} \\ . & . & . & . \\ . & . & . & . \\ \delta^{i_p}_{j_1} & . & . & \delta^{i_p}_{j_p} \end{vmatrix}, \qquad \pi^{i_1\cdots i_p}_{j_1\cdots j_p}=\left\Vert \begin{matrix} \delta^{i_1}_{j_1} & . & . & \delta^{i_1}_{j_p} \\ . & . & . & . \\ . & . & . & . \\ \delta^{i_p}_{j_1} & . & . & \delta^{i_p}_{j_p} \end{matrix} \right\Vert ,$$

where the first is a determinant and the second a permanent. The gKd has value $+1$ (-1) depending on whether $(j_1,\ldots,j_p)$ is an even (odd) permutation of $(i_1,\ldots,i_p)$. The gpd has the *permanent* value $+1$ for any permutation of the index sets. Note that $\pi^a_b=\delta^a_b$. The gpd is a complete *symmetrizer* (*permanent symmetrizer*) and now one easily sees that $\pi^{abc}_{def}X_{abc}=3!X_{(def)}$.

A simple but important interaction between the gKd and gpd is that in any expression containing them as a product, where there is a summation on a pair of indices between them, such expression vanishes. For

$$\delta^{\cdots a\ldots b\cdots}_{\cdots\cdots\cdots\cdots}\pi^{\cdots\cdots\cdots\cdots}_{\cdots a\ldots b\cdots}=\delta^{\cdots a\ldots b\cdots}_{\cdots\cdots\cdots\cdots}\pi^{\cdots\cdots\cdots\cdots}_{\cdots b\ldots a\cdots}=-\delta^{\cdots b\ldots a\cdots}_{\cdots\cdots\cdots\cdots}\pi^{\cdots\cdots\cdots\cdots}_{\cdots b\ldots a\cdots}=-\delta^{\cdots a\ldots b\cdots}_{\cdots\cdots\cdots\cdots}\pi^{\cdots\cdots\cdots\cdots}_{\cdots a\ldots b\cdots}=0.$$

From this it also obviously follows that the product of any gKd and any gpd with *two or more common contracted indices* vanishes.

If $A=[a^i_j]$ is an $n\times n$ matrix its *determinant* and *permanent* are

$$\det A=\frac{1}{n!}a^{i_1}_{j_1}\cdots a^{i_n}_{j_n}\delta^{j_1\cdots j_n}_{i_1\cdots i_n}, \qquad \operatorname{per} A=\frac{1}{n!}a^{i_1}_{j_1}\cdots a^{i_n}_{j_n}\pi^{j_1\cdots j_n}_{i_1\cdots i_n}.$$

III. gKd's AND gpd's IN SYMMETRIES OF TENSORS

The use of symmetrizing parentheses and antisymmetrizing brackets for specification of tensor symmetries can become both convoluted and ambiguous. For example $4T_{[(i|j|]k)}$ can be confusing at first sight; taken to mean performing symmetry in *i, k* and skew symmetry in *i, j*, it is still ambiguous, depending on which operation is performed first. It can be appreciated that symmetry specifications in this way for tensors with a large number of indices and intertwining brackets can be quite horrendous. Specification of tensor symmetries with *generalized deltas* (gd's—collectively gKd's and gpd's) gives clean, unambiguous expressions. Performing symmetry then antisymmetry and vice versa on $4T_{[(i|j|]k)}$ gives two quite different expressions:

$$2(T_{[ij]k}+T_{[kj]i})=(T_{ijk}+T_{kji}-T_{jik}-T_{jki})=\pi^{pn}_{ik}(T_{pjn}-T_{jpn})=\delta^{lm}_{pj}\pi^{pn}_{ik}T_{lmn},$$

$$2(T_{(i|j|k)}-T_{(j|i|k)})=(T_{ijk}-T_{jik}+T_{kji}-T_{kij})=\delta^{pm}_{ij}(T_{pmk}+T_{kmp})=\pi^{ln}_{pk}\delta^{pm}_{ij}T_{lmn}.$$

Specification of what one means by the gd's is unequivocal. They are also exactly what is needed for tensors obeying the symmetry of Young tableaux illustrated next.

The Riemann tensor R_{abcd} is a *Young tableau* (YT) *tensor* in its *algebraic* symmetries, expressible as[4,6] $R_{abcd}=\frac{1}{12}R_{\{ac,bd\}}$, obeying the partial symmetries and antisymmetries as determined by its tableau $\{ac,bd\}$. Fully expanded, it is[4]

$$\begin{aligned}R_{abcd}&=\tfrac{1}{12}R_{\{ac,bd\}}\\&=\tfrac{1}{12}[R_{abcd}+R_{adcb}+R_{cbad}+R_{cdab}-R_{abdc}-R_{acdb}-R_{dbac}-R_{dcab}\\&\quad-R_{bacd}-R_{bdca}-R_{cabd}-R_{cdba}+R_{badc}+R_{bcda}+R_{dabc}+R_{dcba}].\end{aligned}$$

Its symmetries are inbuilt. It is easy to see the skewsymmetry in (a,b) and in (c,d). Then too the interchange $(a,b)\Leftrightarrow(c,d)$ can also be seen, while the cyclic symmetry $R_{abcd}+R_{acdb}+R_{adbc}=0$, though tedious, is easy enough to verify. Conversely, using these symmetries in the rhs does indeed produce the lhs.

The above expression can be put into a convenient form involving gKd's and gpd's. Let E_{abcd} be the expression on the rhs within brackets:

$$\begin{aligned}E_{abcd}&=R_{abcd}+R_{cbad}+R_{adcb}+R_{cdab}-R_{abdc}-R_{dbac}-R_{acdb}-R_{dcab}\\&\quad-R_{bacd}-R_{cabd}-R_{bdca}-R_{cdba}+R_{badc}+R_{dabc}+R_{bcda}+R_{dcba}\\&=\delta^{pq}_{ab}[R_{pqcd}+R_{cqpd}+R_{pdcq}+R_{cdpq}-R_{pqdc}-R_{dqpc}-R_{pcdq}-R_{dcpq}]\\&=\delta^{pq}_{ab}\delta^{rs}_{cd}[R_{pqrs}+R_{rqps}+R_{psrq}+R_{rspq}]\\&=\delta^{pq}_{ab}\delta^{rs}_{cd}\pi^{eg}_{pr}[R_{eqgs}+R_{esgq}]\\&=\delta^{pq}_{ab}\delta^{rs}_{cd}\pi^{eg}_{pr}\pi^{fh}_{qs}R_{efgh},\end{aligned}$$

so that

$$R_{abcd}=\tfrac{1}{12}\delta^{pq}_{ab}\delta^{rs}_{cd}\pi^{eg}_{pr}\pi^{fh}_{qs}R_{efgh}$$

and there are no intertwined, or indeed any parentheses or brackets.

As for recognition of symmetries from this, it is evident that because of the gKd's the expression is skew in (a,b) and in (c,d). With $(a,b)\Leftrightarrow(c,d)$ and slight index manipulation it is also visible that the expression is symmetric. The cyclic identity is not obvious from either the 16 term expression or its compacted gd equivalent. But it is here that the PAPS reference tables come into play.

Observing the gd factor $\delta^{pq}_{ab}\delta^{rs}_{cd}\pi^{eg}_{pr}\pi^{fh}_{gs}$ above and formula **m3** from the table in PAPS Appendix C 7.3.2, i.e., $\delta^{bcd}_{\dots}\delta^{pq}_{.b}\delta^{rs}_{cd}\pi^{..}_{pr}\pi^{..}_{qs}=0$ (dots allow any free indices), we can immediately write down the symmetry/condition as $\delta^{bcd}_{ijk}R_{abcd}=0$. But let us show it in reverse (in fact deriving the **m3** identity).

Multiply the above relation for R_{abcd} by δ^{bcd}_{ijk} to get

$$\begin{aligned}\delta^{bcd}_{ijk}R_{abcd}&=\tfrac{1}{12}\delta^{bcd}_{ijk}\delta^{pq}_{ab}\delta^{rs}_{cd}\pi^{eg}_{pr}\pi^{fh}_{qs}R_{efgh}\\&=\tfrac{1}{6}\delta^{brs}_{ijk}\delta^{pq}_{ab}\pi^{eg}_{pr}\pi^{fh}_{qs}R_{efgh}\quad(\text{or see PAPS-formula }\mathbf{k8}\text{ or, better, Eq. }(4))\\&=\tfrac{1}{6}[\delta^{qrs}_{ijk}\delta^{p}_{a}-\delta^{prs}_{ijk}\delta^{q}_{a}]\pi^{eg}_{pr}\pi^{fh}_{qs}R_{efgh}\\&=0\qquad(\text{two repeated indices for a gKd and a gpd}).\end{aligned}$$

Expanding the lhs (six terms), but using the antisymmetry in the last two indices, produces the cyclic identity. This reverse derivation relied on ''already knowing'' the cyclic identity of the Riemann tensor (by applying δ^{bcd}_{ijk}).

If instead we have the tensor

$$\begin{aligned} U_{abcd} &= T_{abcd} - T_{cbad} + T_{dbac} - T_{dbca} + T_{cbda} - T_{abdc} \\ &\quad + T_{bacd} - T_{bcad} + T_{bdac} - T_{bdca} + T_{bcda} - T_{badc} \\ &= \delta^{pgh}_{acd}(T_{pbgh} + T_{bpgh}) \\ &= \delta^{pgh}_{acd}\pi^{ef}_{pb}T_{efgh} \end{aligned}$$

one may, with some scrutiny, discern the antisymmetry in indices (a,c) and in (a,d) (and hence total antisymmetry in all three of these indices) from the expanded expression. The antisymmetry in (a,c,d) is immediately obvious from the compacted gd expression. However, there is another ''hidden'' symmetry, unobvious from either expression for U_{abcd}. It is

$$U_{abcd} - U_{bcda} + U_{cdab} - U_{dabc} = 0.$$

But how can this be discovered? Here, again, inspection of the identity **o9** in the same table in PAPS, i.e., $\delta^{efgh}_{....}\delta^{p..}_{efg}\pi^{..}_{hp} = 0$, provides the answer. Adapted to our indices by $(e,f,g,h) \rightarrow (a,c,d,b)$ we can write (sign changes do not matter here)

$$\delta^{abcd}_{ijkl}\delta^{pgh}_{acd}\pi^{ef}_{pb}T_{efgh} = 0.$$

Thus the ''hidden'' identity is $\delta^{abcd}_{ijkl}U_{abcd} = 0$. One may wish to leave it like this; however, expansion of it, and using antisymmetry in first, third, and fourth indices produces the 4-term alternating cyclic identity above (with subscripts i,j,k,l). Further, we also remark that while the antisymmetries can be encompassed within the bracketed notation, $U_{abcd} = U_{[a|b|cd]}$, what can be suggested to accommodate the hidden symmetry? Clearly the gd notation to express and ''discover'' symmetries of tensors seems superior.

The simpler Lanczos tensor[7,8] satisfies algebraic (nondifferential, or not involving covariant differentiation) relations $L_{ijk} = -L_{jik}$, $L_{ijk} + L_{jki} + L_{kij} = 0$, and $L_{ij}{}^{j} = 0$ (optional algebraic gauge condition, often accepted). In any case, it is the symmetries of the (free) 3-index object that interests us. These first two symmetries qualify it as a YT tensor, expressible as[4] $L_{ijk} = \frac{1}{3}L_{\{ik,j\}}$. This again is a one-line expression for the tensor, encompassing the first two symmetries. Fully expanded, we have

$$\begin{aligned} L_{ijk} = \tfrac{1}{3}L_{\{ik,j\}} &= \tfrac{1}{3}[L_{ijk} - L_{jik} + L_{kji} - L_{kij}] \\ &= \tfrac{1}{3}\delta^{pm}_{ij}[L_{pmk} + L_{kmp}] \\ &= \tfrac{1}{3}\delta^{pm}_{ij}\pi^{ln}_{kp}L_{lmn}. \end{aligned}$$

It is then easy enough to verify the skewsymmetry and the cyclic symmetry (multiply by δ^{ijk}_{abc}) from this equation—and in reverse; that with these symmetries, employed on the rhs, we do get the lhs. The cyclic relation for the Lanczos tensor gives rise to the identity $\delta^{ijk}_{...}\delta^{p.}_{ij}\pi^{..}_{kp} = 0$, recorded as identity **o2** in the PAPS reference document.

Other than determining symmetries of tensors, the use of gd's may possibly help in ''seeing'' the number of independent components of a tensor with various symmetries.

Some computer algebra packages allow for symmetrization and antisymmetrization of indices. It is suggested that perhaps *specific* gpd and gKd objects (over and above a single Kronecker delta) be constructed in these packages allowing easy expansions of products of them over summed indices. This would be most useful for checking identities and formulas of various sorts.

IV. SPINOR AND TENSOR EQUIVALENTS OF gKd's AND gpd's AND EXAMPLES

A. Spinor equivalents of tensors

It is quite easy to construct spinor equivalents of the gKd's and gpd's from the basic spinor equivalent of the Kronecker δ, i.e., $\delta^{a}_{b} \Leftrightarrow \delta^{A}_{B}\delta^{A'}_{B'}$, and the use of determinants and permanents. This leads to a tabulation of spinor equivalents of individual gKd's and gpd's in Appendix A. The derivation of such formulas can be done by sight and by simple manipulations.

Apart from this table it is also our purpose to demonstrate in a couple of examples that use of the gd's can facilitate extremely quick derivation of spinor equivalents.

In general, if one expresses the symmetries of a tensor using gd's then (using the table of Appendix A) we can write down their spinor equivalents, replacing all tensor indices by corresponding spinor equivalent ones. Once this is done the spinor equivalent is technically found. However, it may involve several relations and consequent algebraic manipulations in order to get decompositions, such as the Weyl and Ricci parts for the Riemann tensor equivalent.

The two illustrations of obtaining the spinor equivalents of 2-index permanent symmetric and skewsymmetric tensors follow.

First, we determine the spinor equivalent of the skewsymmetric tensor $F_{ab}=-F_{ba}=F_{[ab]}$. This can be written as $F_{ab}=\frac{1}{2}F_{cd}\delta^{cd}_{ab}$ in terms of a gKd. Then taking the spinor equivalent (see Δ_2 in Appendix A) gives

$$\begin{aligned} F_{ABA'B'} &= \tfrac{1}{4}F_{CDC'D'}[\delta^{CD}_{AB}\pi^{C'D'}_{A'B'}+\pi^{CD}_{AB}\delta^{C'D'}_{A'B'}] \\ &= -F_{BAB'A'}=F_{[AB](A'B')}+F_{(AB)[A'B']}=\epsilon_{AB}\psi_{A'B'}+\epsilon_{A'B'}\phi_{AB}, \end{aligned}$$

where $\psi_{A'B'}=\frac{1}{2}F_{X}{}^{X}{}_{(A'B')}$ and $\phi_{AB}=\frac{1}{2}F_{(AB)X'}{}^{X'}$. If F_{ab} is *real*, $F_{ab}=\overline{F}_{ab}$, then $\psi_{A'B'}=\overline{\phi}_{A'B'}=\overline{\phi_{AB}}$, so that the spinor equivalent of the real skew-tensor (Maxwell tensor) F_{ab} is

$$F_{ab}=F_{[ab]}\Leftrightarrow\epsilon_{AB}\overline{\phi}_{A'B'}+\epsilon_{A'B'}\phi_{AB}.$$

Second, we determine the spinor equivalent of a permanent symmetric (or just symmetric by common usage if the context is clear) tensor $T_{ab}=T_{ba}=T_{(ab)}$. This can be written $T_{ab}=\frac{1}{2}T_{cd}\pi^{cd}_{ab}$ in terms of a gpd. Then taking the spinor equivalent (see Π_2 in Appendix A) gives

$$\begin{aligned} T_{ABA'B'} &= \tfrac{1}{4}T_{CDC'D'}[\delta^{CD}_{AB}\delta^{C'D'}_{A'B'}+\pi^{CD}_{AB}\pi^{C'D'}_{A'B'}] \\ &= T_{BAB'A'} \\ &= T_{[AB][A'B']}+T_{(AB)(A'B')} \\ &= \tfrac{1}{4}\epsilon_{AB}\epsilon_{A'B'}T+T_{(AB)(A'B')}, \end{aligned}$$

where $T=T_{X}{}^{X}{}_{X'}{}^{X'}=T_{XX'}{}^{XX'}$, which is also the *trace* of the tensor $T_{a}{}^{a}$. Thus

$$T_{ab}=T_{(ab)}\Leftrightarrow\tfrac{1}{4}\epsilon_{AB}\epsilon_{A'B'}T+T_{(AB)(A'B')}.$$

If one writes R in place of T, then the spinor equivalent of the trace-free Ricci tensor is

$$R_{ab}-\tfrac{1}{4}g_{ab}R\Leftrightarrow R_{(AB)(A'B')}.$$

B. Tensor equivalents of spinors

The tensor equivalents of gd spinors in combination are elegantly derived in PAPS. The results, along with related formulas are accumulated in the table in Appendix B.

We feel it worth mentioning at least one formula, one that enables us to easily remember the usual rather complicated formula for the spinor equivalent of the alternating tensor—by using gKd/gpd spinors. Abbreviate by putting

$$\Delta=\delta^{AB}_{CD}\qquad\Pi=\pi^{AB}_{CD}$$
$$\Delta'=\delta^{A'B'}_{C'D'}\quad\Pi'=\pi^{A'B'}_{C'D'}.$$

The formula, with the understanding that the first relation is a symbolic equivalence, is (see full derivation in PAPS)

$$\frac{i}{2}\,\delta^{\Delta\Pi}_{\Delta'\Pi'}\equiv\frac{i}{2}(\Delta\Pi'-\Pi\Delta')=\frac{i}{2}(\delta^{AB}_{CD}\pi^{A'B'}_{C'D'}-\pi^{AB}_{CD}\delta^{A'B'}_{C'D'})\Leftrightarrow\epsilon^{ab}{}_{cd}\,.$$

To give an example from the table, consider the tensor equivalent of the spinor (last but one table entry in Appendix B)

$$\delta^A_C\delta^B_D\delta^{A'}_{D'}\delta^{B'}_{C'}\Leftrightarrow\tfrac{1}{2}(\pi^{ab}_{cd}-g^{ab}g_{cd}-i\epsilon^{ab}{}_{cd}).$$

Multiply the lhs by $H_{ABA'B'}$ and the rhs by its tensor equivalent H_{ab} and one immediately obtains (see Ref. 6, p. 153)

$$H_{CDD'C'}\Leftrightarrow\tfrac{1}{2}(\pi^{ab}_{cd}-g^{ab}g_{cd}-i\epsilon^{ab}{}_{cd})H_{ab}=\tfrac{1}{2}(H_{cd}+H_{dc}-g_{cd}H_a{}^a-i\epsilon_{abcd}H^{ab}).$$

Now take the conjugate of the spinor/tensor equivalent relation, to get $\delta^A_D\delta^B_C\delta^{A'}_{C'}\delta^{B'}_{D'}\Leftrightarrow\tfrac{1}{2}(\pi^{ab}_{cd}-g^{ab}g_{cd}+i\epsilon^{ab}{}_{cd}$, multiply as before by $H_{ABA'B'}$ and its equivalent H_{ab}, and arrive at the *different* tensor equivalent (with unprimed indices interchanged)

$$H_{DCC'D'}\Leftrightarrow\tfrac{1}{2}(H_{cd}+H_{dc}-g_{cd}H_a{}^a+i\epsilon_{abcd}H^{ab}).$$

APPENDIX A: SPINOR EQUIVALENTS FOR THE gKd AND gpd

In the reference formulas below it should be mentioned that there is a good deal of interplay between the gKd and gpd in such specifications, there being a variety of ways to express expansions of some gKd's, gpd's (and also their spinor equivalents).

1. Spinor equivalents of the gKd's

$$\Delta_1=\delta^a_b\Leftrightarrow\delta^A_B\delta^{A'}_{B'}\,,$$

$$\Delta_2=\delta^{ab}_{cd}=\begin{vmatrix}\delta^a_c & \delta^a_d\\ \delta^b_c & \delta^b_d\end{vmatrix}\Leftrightarrow\begin{vmatrix}\delta^A_C\delta^{A'}_{C'} & \delta^A_D\delta^{A'}_{D'}\\ \delta^B_C\delta^{B'}_{C'} & \delta^B_D\delta^{B'}_{D'}\end{vmatrix}=\tfrac{1}{2}[\delta^{AB}_{CD}\pi^{A'B'}_{C'D'}+\pi^{AB}_{CD}\delta^{A'B'}_{C'D'}],$$

$$\Delta_3=\delta^{abc}_{def}=\begin{vmatrix}\delta^a_d & \delta^a_e & \delta^a_f\\ \delta^b_d & \delta^b_e & \delta^b_f\\ \delta^c_d & \delta^c_e & \delta^c_f\end{vmatrix}$$

$$=\delta^a_d\delta^{bc}_{ef}-\delta^a_e\delta^{bc}_{df}+\delta^a_f\delta^{bc}_{de}\Leftrightarrow\tfrac{1}{2}[\delta^A_D\delta^{A'}_{D'}(\delta^{BC}_{EF}\pi^{B'C'}_{E'F'}+\pi^{BC}_{EF}\delta^{B'C'}_{E'F'})$$

$$-\delta^A_E\delta^{A'}_{E'}(\delta^{BC}_{DF}\pi^{B'C'}_{D'F'}+\pi^{BC}_{DF}\delta^{B'C'}_{D'F'})+\delta^A_F\delta^{A'}_{F'}(\delta^{BC}_{DE}\pi^{B'C'}_{D'E'}+\pi^{BC}_{DE}\delta^{B'C'}_{D'E'})].$$

We can expand the gKd with 4 (upper/lower) indices by a Laplace expansion of its first two rows and complementary minors. The result is

$$\Delta_4=\delta^{abcd}_{efgh}=\begin{vmatrix}\delta^a_e & \delta^a_f & \delta^a_g & \delta^a_h\\ \delta^b_e & \delta^b_f & \delta^b_g & \delta^b_h\\ \delta^c_e & \delta^c_f & \delta^c_g & \delta^c_h\\ \delta^d_e & \delta^d_f & \delta^d_g & \delta^d_h\end{vmatrix}$$

$$=\delta^{ab}_{ef}\delta^{cd}_{gh}-\delta^{ab}_{eg}\delta^{cd}_{fh}+\delta^{ab}_{eh}\delta^{cd}_{fg}+\delta^{ab}_{fg}\delta^{cd}_{eh}-\delta^{ab}_{fh}\delta^{cd}_{eg}+gd^{ab}_{gh}\delta^{cd}_{ef}.$$

The rhs can be written as the sum/difference of *permanents* of gKd's, if desired

$$\left\|\begin{matrix}\delta^{ab}_{ef} & \delta^{ab}_{gh}\\ \delta^{cd}_{ef} & \delta^{cd}_{gh}\end{matrix}\right\|-\left\|\begin{matrix}\delta^{ab}_{eg} & \delta^{ab}_{fh}\\ \delta^{cd}_{eg} & \delta^{cd}_{fh}\end{matrix}\right\|+\left\|\begin{matrix}\delta^{ab}_{eh} & \delta^{ab}_{fg}\\ \delta^{cd}_{eh} & \delta^{cd}_{fg}\end{matrix}\right\|.$$

The spinor equivalent of δ^{abcd}_{efgh} is

$$\Delta_4\Leftrightarrow\tfrac{1}{4}[(\delta^{AB}_{EF}\pi^{A'B'}_{E'F'}+\pi^{AB}_{EF}\delta^{A'B'}_{E'F'})(\delta^{CD}_{GH}\pi^{C'D'}_{G'H'}+\pi^{CD}_{GH}\delta^{C'D'}_{G'H'})-(\delta^{AB}_{EG}\pi^{A'B'}_{E'G'}+\pi^{AB}_{EG}\delta^{A'B'}_{E'G'})$$
$$\times(\delta^{CD}_{FH}\pi^{C'D'}_{F'H'}+\pi^{CD}_{FH}\delta^{C'D'}_{F'H'})+(\delta^{AB}_{EH}\pi^{A'B'}_{E'H'}+\pi^{AB}_{EH}\delta^{A'B'}_{E'H'})(\delta^{CD}_{FG}\pi^{C'D'}_{F'G'}+\pi^{CD}_{FG}\delta^{C'D'}_{F'G'})$$
$$+(\delta^{AB}_{FG}\pi^{A'B'}_{F'G'}+\pi^{AB}_{FG}\delta^{A'B'}_{F'G'})(\delta^{CD}_{EH}\pi^{C'D'}_{E'H'}+\pi^{CD}_{EH}\delta^{C'D'}_{E'H'})-(\delta^{AB}_{FH}\pi^{A'B'}_{F'H'}+\pi^{AB}_{FH}\delta^{A'B'}_{F'H'})$$
$$\times(\delta^{CD}_{EG}\pi^{C'D'}_{E'G'}+\pi^{CD}_{EG}\delta^{C'D'}_{E'G'})+(\delta^{AB}_{GH}\pi^{A'B'}_{G'H'}+\pi^{AB}_{GH}\delta^{A'B'}_{G'H'})(\delta^{CD}_{EF}\pi^{C'D'}_{E'F'}+\pi^{CD}_{EF}\delta^{C'D'}_{E'F'})].$$

2. Spinor equivalents of the gpd's

$$\Pi_1=\pi^a_b=\delta^a_b\Leftrightarrow\delta^A_B\delta^{A'}_{B'},$$

$$\Pi_2=\pi^{ab}_{cd}=\left\|\begin{matrix}\delta^a_c & \delta^a_d\\ \delta^b_c & \delta^b_d\end{matrix}\right\|\Leftrightarrow\left\|\begin{matrix}\delta^A_C\delta^{A'}_{C'} & \delta^A_D\delta^{A'}_{D'}\\ \delta^B_C\delta^{B'}_{C'} & \delta^B_D\delta^{B'}_{D'}\end{matrix}\right\|=\tfrac{1}{2}[\delta^{AB}_{CD}\delta^{A'B'}_{C'D'}+\pi^{AB}_{CD}\pi^{A'B'}_{C'D'}],$$

$$\Pi_3=\pi^{abc}_{def}=\left\|\begin{matrix}\delta^a_d & \delta^a_e & \delta^a_f\\ \delta^b_d & \delta^b_e & \delta^b_f\\ \delta^c_d & \delta^c_e & \delta^c_f\end{matrix}\right\|$$

$$=\delta^a_d\pi^{bc}_{ef}+\delta^a_e\pi^{bc}_{df}+\delta^a_f\pi^{bc}_{de}\Leftrightarrow\tfrac{1}{2}[\delta^A_D\delta^{A'}_{D'}(\delta^{BC}_{EF}\delta^{B'C'}_{E'F'}+\pi^{BC}_{EF}\pi^{B'C'}_{E'F'})$$
$$+\delta^A_E\delta^{A'}_{E'}(\delta^{BC}_{DF}\delta^{B'C'}_{D'F'}+\pi^{BC}_{DF}\pi^{B'C'}_{D'F'})+\delta^A_F\delta^{A'}_{F'}(\delta^{BC}_{DE}\delta^{B'C'}_{D'E'}+\pi^{BC}_{DE}\pi^{B'C'}_{D'E'})].$$

Since permanents only involve positive signs, the following Laplace expansion is also clear:

$$\Pi_4=\pi^{abcd}_{efgh}=\left\|\begin{matrix}\delta^a_e & \delta^a_f & \delta^a_g & \delta^a_h\\ \delta^b_e & \delta^b_f & \delta^b_g & \delta^b_h\\ \delta^c_e & \delta^c_f & \delta^c_g & \delta^c_h\\ \delta^d_e & \delta^d_f & \delta^d_g & \delta^d_h\end{matrix}\right\|$$

$$=\pi^{ab}_{ef}\pi^{cd}_{gh}+\pi^{ab}_{eg}\pi^{cd}_{fh}+\pi^{ab}_{eh}\pi^{cd}_{fg}+\pi^{ab}_{fg}\pi^{cd}_{eh}+\pi^{ab}_{fh}\pi^{cd}_{eg}+\pi^{ab}_{gh}\pi^{cd}_{ef}.$$

The rhs can be written as the sum of permanents of permanents, if desired

$$\left\|\begin{matrix}\pi^{ab}_{ef} & \pi^{ab}_{gh}\\ \pi^{cd}_{ef} & \pi^{cd}_{gh}\end{matrix}\right\| + \left\|\begin{matrix}\pi^{ab}_{eg} & \pi^{ab}_{fh}\\ \pi^{cd}_{eg} & \pi^{cd}_{fh}\end{matrix}\right\| + \left\|\begin{matrix}\pi^{ab}_{eh} & \pi^{ab}_{fg}\\ \pi^{cd}_{eh} & \pi^{cd}_{fg}\end{matrix}\right\|.$$

The spinor equivalent of π^{abcd}_{efgh} is

$$\begin{aligned}\Pi_4 \Leftrightarrow \tfrac{1}{4}[&(\delta^{AB}_{EF}\delta^{A'B'}_{E'F'}+\pi^{AB}_{EF}\pi^{A'B'}_{E'F'})(\delta^{CD}_{GH}\delta^{C'D'}_{G'H'}+\pi^{CD}_{GH}\pi^{C'D'}_{G'H'})+(\delta^{AB}_{EG}\delta^{A'B'}_{E'G'}+\pi^{AB}_{EG}\pi^{A'B'}_{E'G'})\\ &\times(\delta^{CD}_{FH}\delta^{C'D'}_{F'H'}+\pi^{CD}_{FH}\pi^{C'D'}_{F'H'})+(\delta^{AB}_{EH}\delta^{A'B'}_{E'H'}+\pi^{AB}_{EH}\pi^{A'B'}_{E'H'})(\delta^{CD}_{FG}\delta^{C'D'}_{F'G'}+\pi^{CD}_{FG}\pi^{C'D'}_{F'G'})\\ &+(\delta^{AB}_{FG}\delta^{A'B'}_{F'G'}+\pi^{AB}_{FG}\pi^{A'B'}_{F'G'})(\delta^{CD}_{EH}\delta^{C'D'}_{E'H'}+\pi^{CD}_{EH}\pi^{C'D'}_{E'H'})+(\delta^{AB}_{FH}\delta^{A'B'}_{F'H'}+\pi^{AB}_{FH}\pi^{A'B'}_{F'H'})\\ &\times(\delta^{CD}_{EG}\delta^{C'D'}_{E'G'}+\pi^{CD}_{EG}\pi^{C'D'}_{E'G'})+(\delta^{AB}_{GH}\delta^{A'B'}_{G'H'}+\pi^{AB}_{GH}\pi^{A'B'}_{G'H'})(\delta^{CD}_{EF}\delta^{C'D'}_{E'F'}+\pi^{CD}_{EF}\pi^{C'D'}_{E'F'})].\end{aligned}$$

[6] In this connection we remark that our definition for the algebraic symmetries of the Riemann tensor $R_{abcd}=\frac{1}{12}R_{\{ac,bd\}}$, agrees with the result in R. Penrose and W. Rindler, *Spinors and Space-time* (Cambridge University Press, England, 1984), Vol. 1, p. 144, $\frac{3}{4}R_{abcd}=R_{\overline{(ac)}\atop(\underline{bd})}$. This is because the symmetrization on two letters introduces a factor of 1/2, which together with 2 rows gives a factor of 1/4. Antisymmetrization of columns produces another factor of 1/4. Hence the rhs of the latter is 1/16 of our result, i.e., $\frac{3}{4}R_{abcd}=\frac{1}{16}R_{\{ac,bd\}}$, agreeing precisely with our definition.

The algebra of two symmetric matrices: Proving completeness and deriving syzygies for a set of invariants of the Riemann tensor

S. Bonanos[a)]
Institute of Nuclear Physics, N.C.S.R. DEMOKRITOS, Aghia Paraskevi, 15310 Greece

(Received 8 October 1998; accepted for publication 9 December 1998)

A large number of Riemann tensor invariants can be written as traces of products of two 3×3 matrices, representing the Weyl tensor and the Weyl-like square of the Ricci tensor. It is pointed out that finding a complete set, $\mathcal{I}$, for all of these invariants is a simple consequence of the more general problem of finding a complete set of symmetric *matrices*, $\mathcal{M}$, in terms of which all symmetric matrix polynomials in these two matrices can be expressed. Such a set is constructed and a formal proof of its completeness is given. Several matrix identities and a scalar syzygy, obtained recently by Sneddon, are rederived and their interrelationships clarified. They are shown to be, ultimately, consequences of the Cayley–Hamilton theorem. A ''minimal set'' of invariants, that must be contained in the complete set of invariants of the general problem, is identified and it is concluded that no set proposed so far is complete. © *1999 American Institute of Physics.* [S0022-2488(99)02503-7]

I. INTRODUCTION

The study of the invariants of the Riemann tensor was originally motivated by their obvious usefulness in the invariant characterization of space–time properties[1–4] and, thereby, in the invariant classification of gravitational fields.[5–8] Gradually, however, interest has focused on more mathematical questions regarding the ''complete set of polynomial curvature invariants.'' *Polynomial curvature invariants* are those that are expressible as contractions of arbitrary products of the curvature tensor R_{abcd}, the metric tensor g_{ab} and the totally antisymmetric tensor η_{abcd}, and are, therefore, polynomials in the curvature components. A *complete set* $\mathcal{I}=\{I_1,I_2,\ldots,I_n\}$ of invariants is one having the property that any polynomial invariant can be expressed as a polynomial in $I_1,\ldots,I_n$ and no invariant in the set can be so expressed in terms of the remaining I_i.[9,10] It is known that such a set will be redundant, i.e., it will contain more than the maximum number $(=14)$ of gauge-independent components of the Riemann tensor.[10] There will then exist $n-14$ polynomial identities (syzygies) relating these invariants.

The mathematical questions alluded to above are:

(i) *How does one decide which invariants to include in a complete set?*
(ii) *How does one prove that a certain set of invariants is complete?*
(iii) *How does one derive the syzygies that relate the invariants of a complete set?*

The answers to these questions are anything but obvious, as is indicated by the number of different sets of invariants that have been proposed,[5,6,11–15] some of which have later been shown to be deficient in some sense,[14,16] and by the lack of any attempt to prove completeness (in the sense used here) for any of them.

In this paper we shall answer these questions for a restricted set of Riemann tensor invariants (to be precisely defined in Sec. II). The essential idea is to consider these invariants as traces of products of a pair of symmetric matrices and obtain the desired result as a corollary of the solution of the more general problem of finding a complete set of *matrices*, $\mathcal{M}$, in terms of which all such

[a)]Electronic mail: sbonano@mail.ariadne-t.gr

symmetric matrix products can be expressed. (Sneddon[17] has also considered the invariants built out of these two matrices.) This more general problem is actually easier to handle because of the Cayley–Hamilton theorem which implies polynomial identities between matrices. In fact, all matrix identities obtained here are consequences of this theorem. In a recent paper,[18] Sneddon gives a reference to work by Spencer and Rivlin[19,20] who apparently solved this problem (in even greater generality) 40 years ago! The proof of completeness given here, however, is different and conceptually simpler. It also leads to a more efficient computer algebra algorithm for simplification of products of matrix polynomials.

In Sec. II we define the set of scalars we will be considering and formulate the problem in terms of traces of products of two symmetric matrices. In Sec. III we systematically construct a set of matrices, $\mathcal{M}$, (and a corresponding set of scalars, $\mathcal{I}$) and prove that it is complete. In Sec. IV we derive a matrix identity satisfied by the matrices of the complete set which leads to a scalar identity (syzygy) between the invariants of the complete set $\mathcal{I}$. This syzygy was first obtained by Sneddon[17] in a rather tortuous manner. We also show that the nine symmetric matrix identities obtained recently by Sneddon[18] are direct consequences of the first one. In Sec. V we show that a wider class of scalars than originally considered can actually be expressed in terms of the complete set obtained. Finally, in Sec. VI we extend our set to a ''minimal set'' that must be contained in the complete set of invariants of the Riemann tensor, and conclude that none of the sets proposed so far can be complete. In particular neither the set of Carminati and McLenaghan[14] nor the set of Zakhary and McIntosh[15] are complete, even though the latter has been shown to yield the required number of invariants for every combination of Petrov and Segre types.

II. MOTIVATION AND FORMULATION OF THE PROBLEM

In the Newman–Penrose formalism the Riemann tensor is described by the (complex) Weyl spinor Ψ_{ABCD}, the traceless Ricci spinor $\Phi_{ABC'D'}$ and the scalar curvature R. The polynomial curvature invariants defined in the introduction can, therefore, be equivalently defined as those that are expressible as complete contractions (with ε^{AB}, $\varepsilon^{A'B'}$) of arbitrary products of the spinors Ψ_{ABCD} and $\Phi_{ABC'D'}$ together with the scalar R.

The 4-index spinors $\Psi_{AB}{}^{CD}$ and $\Phi_{AB}{}^{C'D'}$ can be represented as 3×3 matrices (Ψ symmetric traceless and Φ Hermitian) with respect to an orthonormal basis[21,22] for 2-index spinors as follows:

$$\Psi=\frac{1}{2}\begin{pmatrix} 2\Psi_2-\Psi_0-\Psi_4 & -i(\Psi_0-\Psi_4) & 2(\Psi_1-\Psi_3)\\ -i(\Psi_0-\Psi_4) & 2\Psi_2+\Psi_0+\Psi_4 & 2i(\Psi_1+\Psi_3)\\ 2(\Psi_1-\Psi_3) & 2i(\Psi_1+\Psi_3) & -4\Psi_2\end{pmatrix}, \tag{2.1}$$

$$\Phi=\frac{1}{2}\begin{pmatrix} \Phi_{00}+\Phi_{22}-\Phi_{02}-\Phi_{20} & -i(\Phi_{00}-\Phi_{22}+\Phi_{02}-\Phi_{20}) & 2(\Phi_{21}-\Phi_{01})\\ i(\Phi_{00}-\Phi_{22}-\Phi_{02}+\Phi_{20}) & \Phi_{00}+\Phi_{22}+\Phi_{02}+\Phi_{20} & -2i(\Phi_{21}+\Phi_{01})\\ 2(\Phi_{12}-\Phi_{10}) & 2i(\Phi_{12}+\Phi_{10}) & 4\Phi_{11}\end{pmatrix}. \tag{2.2}$$

Then contraction of two 4-index spinors over a pair of indices (which gives again a 4-index spinor!) corresponds to multiplication of the corresponding matrices, i.e., the matrix products $\Psi\Psi$ and $\Psi\Phi$ have components $\Psi_{AB}{}^{MN}\Psi_{MN}{}^{CD}$ and $\Psi_{AB}{}^{CD}\Phi_{CD}{}^{C'D'}$, respectively, arranged as in (2.1) (the traceless part of $\Psi\Psi$) and (2.2). [The form (2.2) for $\Psi\Phi$ refers to the arrangement of its spinor components only. Reality relations between these components, like those that make the Φ matrix Hermitian, are not implied. The Hermitian conjugate of $\Psi\Phi$ is the matrix $\Phi\bar{\Psi}$, and one must take the combinations $\Psi\Phi+\Phi\bar{\Psi}$ and $i(\Psi\Phi-\Phi\bar{\Psi})$ to obtain Hermitian matrices.]

To avoid the complication of having to distinguish primed from unprimed indices, we will consider in this paper only those scalars that can be formed by contraction of arbitrary products of the following two spinors: Ψ_{ABCD} and $\chi_{ABCD}=\Phi_{(AB}{}^{C'D'}\Phi_{CD)C'D'}$, the Weyl-like square of the Ricci spinor. In addition we will require that contractions between these spinors will always involve *pairs* of indices. (In Sec. V we show that this restriction can be weakened considerably.) Under these conditions, the set of scalars we will be considering can be defined as the set of traces of arbitrary products of the traceless 3×3 matrices Ψ and χ corresponding to ${\Psi_{AB}}^{CD}$ and ${\chi_{AB}}^{CD}$.

As stated in the Introduction, the question of finding a complete set for these traces follows immediately if we have solved the problem of finding a complete set of symmetric matrices in terms of which all symmetric products of two given symmetric matrices can be expressed. The required complete set will consist of the traces of the matrices in the complete set of matrices, together with any other scalars that were used in expressing higher order matrices in terms of those in the complete set. Thus the mathematical problem to be solved becomes:

Given two symmetric, traceless 3×3 matrices A and B, find a set of $\mathcal{M}$ of symmetric matrices such that every symmetric product of A's and B's can be written as a linear combination of the matrices in the set, with coefficients that are scalar combinations of the components of A and B.

Although the problem of finding a complete set of matrices seems, at first, more difficult than the corresponding one for scalars, it is actually easier because of the Cayley–Hamilton theorem, which gives polynomial identities between matrices. For the traceless matrices A and B the Cayley–Hamilton theorem reads

$$A^3 = i_a A + 2 j_a \mathbf{1}, \quad B^3 = i_b B + 2 j_b \mathbf{1}, \tag{2.3}$$

where $i_a = 1/2\,\mathrm{tr}(A^2)$, $2j_a = 1/3\,\mathrm{tr}(A^3) = \det A$ and similarly for i_b and j_b.

Now, if A, B, C are three 3×3 matrices, then evaluating the expression $(A+B+C)^3 - (-A+B+C)^3 - (A-B+C)^3 - (A+B-C)^3$ (i) by expanding each term and (ii) by applying the Cayley–Hamilton theorem to each term we obtain a very useful identity. When A, B, C are traceless, this identity takes the simple form (square brackets denote the trace of the enclosed matrix)

$$ABC + ACB + BCA + BAC + CAB + CBA = A[BC] + B[AC] + C[AB] + ([ABC] + [ACB])\mathbf{1}. \tag{2.4}$$

This identity can also be obtained[17] by antisymmetrizing the outer product of the 3 matrices and the identity over 4 indices. Our derivation shows that it is a simple consequence of the Cayley–Hamilton theorem.

III. SOLUTION OF THE PROBLEM

To build the complete set of matrices $\mathcal{M}$, we will first systematically construct all symmetric matrices of low order (=number of factors) in A and B and collect those that are independent. The symmetric matrices for each order $\leqslant 4$ (after using Eq. (2.3) to eliminate powers of A and B greater than 2) are:

order 1: A, B,
order 2: A^2, $AB+BA$, B^2,
order 3: A^2B+BA^2, ABA, BAB, B^2A+AB^2,
order 4: $A^2BA+ABA^2$, AB^2A, $A^2B^2+B^2A^2$, $ABAB+BABA$, BA^2B, $B^2AB+BAB^2$.

The matrices of order 1 and 2 are clearly independent. Now, putting $C=A$ and $C=B$ in Eq. (2.4) we obtain the identities:

$$A^2B + BA^2 + ABA = i_a B + sA + p\mathbf{1}, \tag{3.1}$$

$$B^2A + AB^2 + BAB = i_b A + sB + q\mathbf{1}, \tag{3.2}$$

where $s=[AB]$, $p=[A^2B]$, and $q=[AB^2]$. Thus, of the third order matrices only A^2B+BA^2 and B^2A+AB^2 need to be included in the complete set, Eqs. (3.1) and (3.2) giving expressions for ABA and BAB in terms of matrices in $\mathcal{M}$. Next, multiplying each of (3.1), (3.2) by A on the left and on the right and adding, and replacing B in (3.1) by the traceless matrix $B^2-(2/3)i_b\mathbf{1}$, we find that all symmetric 4th order matrices can be expressed in terms of $A^2B^2+B^2A^2$ and lower order matrices. Thus, the set[23] $\mathcal{M}$ (so far) includes the matrices

$$\mathcal{M}=\{\mathbf{1},\ A,\ B,\ A^2,\ AB+BA,\ B^2,\ A^2B+BA^2,\ B^2A+AB^2,\ A^2B^2+B^2A^2\}, \tag{3.3}$$

while the set of scalars $\mathcal{I}$ contains the traces of these matrices and of $A^3,\ B^3$,

$$\mathcal{I}=\{i_a,\ i_b,\ j_a,\ j_b,\ s,\ p,\ q,\ t\}, \tag{3.4}$$

where $i_a=1/2[A^2],\ i_b=1/2[B^2],\ j_a=1/6[A^3],\ j_b=1/6[B^3],\ s=[AB],\ p=[A^2B],\ q=[AB^2],\ t=[A^2B^2]$.

Proceeding in a similar manner we can show that all 10 symmetric matrices of fifth order in A, B can be written as linear combinations of the matrices in $\mathcal{M}$ with coefficients that are polynomials in $\mathcal{I}$. In fact, the fifth order matrices are expressible in terms of third or lower order matrices, as there are no first order scalars in $\mathcal{I}$. It thus appears that the set $\mathcal{M}$ may be the required complete set. To prove this we will also need the expressions for the 15 sixth order symmetric matrices. They can be obtained by appropriate multiplication by A and/or B of the lower order equations, or substitutions $A\rightarrow A^2-(2/3)i_a\mathbf{1},\ B\rightarrow B^2-(2/3)i_b\mathbf{1}$ in (3.1), (3.2). The resulting expressions for all 4th, 5th and 6th order symmetric matrices in terms of matrices in $\mathcal{M}$ with coefficients in $\mathcal{I}$ are given in the Appendix.

We are now in a position to formally prove completeness of the set $\mathcal{M}$ (and, hence, of $\mathcal{I}$). We will first make the following definition.

Definition: A symmetric matrix will be called *reducible* if it can be expressed as a linear combination of matrices in $\mathcal{M}$ with coefficients that are polynomials in $\mathcal{I}$.

Now let $P(n)$ stand for the proposition *every symmetric polynomial matrix of order n in A and B is reducible*. We shall prove the following theorem.

Theorem: $P(n)$ holds provided that $P(m)$ holds for all $m\leqslant n-2$.

Having already verified that $P(m)$ holds for all $m\leqslant 6$, this theorem guarantees that $P(n)$ holds for all n. To prove the theorem we shall need the following lemma.

Lemma: For any $M\in\mathcal{M}$, the symmetric matrices (i) *AMA*, (ii) BMB, (iii) $A^\alpha MB^\beta+B^\beta MA^\alpha$ $(\alpha,\beta=1$ or $2)$ are reducible.

Proof of the lemma: As the maximum order of $M\in\mathcal{M}$ is 4, cases (i), (ii), and (iii) for $\alpha=\beta=1$ are trivial because the resulting symmetric matrices are of order $\leqslant 6$, and all such matrices have been shown to be reducible. When either α or β equals 2, we need to consider only those $M\in\mathcal{M}$ for which the resulting matrix in (iii) has order greater than 6. In every such case we can isolate factors that are symmetric matrices of order 5 or 6 and are therefore reducible to matrices of order 3 or 4, respectively. For example,

$$A^2(A^2B+BA^2)B^\beta+B^\beta(A^2B+BA^2)A^2=A^4B^{1+\beta}+A^2BA^2B^\beta+B^\beta A^2BA^2+B^{1+\beta}A^4, \tag{3.5}$$

Substituting for the 5th order symmetric matrix A^2BA^2 in the middle two terms (and for A^4 in the other two) we find that the sum reduces to a symmetric matrix of order $3+\beta<6$. Similarly

$$A^2(A^2B^2+B^2A^2)B^\beta+B^\beta(A^2B^2+B^2A^2)A^2=A^4B^{2+\beta}+A^2B^2A^2B^\beta+B^\beta A^2B^2A^2+B^{2+\beta}A^4 \tag{3.6}$$

and reducibility is effected by substituting for $A^2B^2A^2$ in the middle two terms (and for A^4 in the other two), giving a $4+\beta\leqslant 6$ symmetric matrix, which is again reducible.

Proof of the theorem: An arbitrary symmetric polynomial matrix of order n in A and B will have highest order terms of the form

$$K=A^{\alpha_1}B^{\beta_1}A^{\alpha_2}B^{\beta_2}\cdots A^{\alpha_m}B^{\beta_m}+B^{\beta_m}A^{\alpha_m}\cdots B^{\beta_2}A^{\alpha_2}B^{\beta_1}A^{\alpha_1}, \tag{3.7}$$

where the sum of all exponents α_i and β_i is n. We implicitly define the matrices V and W by writing K in the form

$$K=A^{\alpha_1}VB^{\beta_m}+B^{\beta_m}V^TA^{\alpha_1}=A^{\alpha_1}B^{\beta_1}WA^{\alpha_m}B^{\beta_m}+B^{\beta_m}A^{\alpha_m}W^TB^{\beta_1}A^{\alpha_1}. \tag{3.8}$$

The proof is different depending on whether $\alpha_1\beta_m=0$ or not.

Case (i): If $\alpha_1\beta_m=0$, i.e., the first and last matrix in each term of K is the same (A or B), then we can write K (if, say, $\beta_m=0$) as

$$K=AUA+AU^TA=A(U+U^T)A,$$

where U stands for the remaining factors in the product and is, therefore, of order $n-2$. By using the lemma, K is reducible provided that $U+U^T$ is reducible, proving the theorem for this case.

Case (ii): If neither α_1 nor β_m vanishes, we write K using (3.8) as

$$K=A^{\alpha_1}(V+V^T)B^{\beta_m}+B^{\beta_m}(V+V^T)A^{\alpha_1}-A^{\alpha_1}V^TB^{\beta_m}-B^{\beta_m}VA^{\alpha_1}. \tag{3.7a}$$

Now $V+V^T$ is a symmetric matrix of order $n-\alpha_1-\beta_m\leqslant n-2$ and, by the lemma, the first two terms are reducible if $V+V^T$ is. The last two terms can be written $-A^{\alpha_1+\alpha_m}W^TB^{\beta_1+\beta_m}-B^{\beta_1+\beta_m}WA^{\alpha_1+\alpha_m}$ which is of the same form as K except that the first and last exponents are larger. If either $\alpha_1+\alpha_m$ or $\beta_1+\beta_m$ is greater than 2, the Cayley–Hamilton theorem reduces these two terms to a symmetric matrix of order $n-2$ in A and B, proving the theorem. If not, we can apply again the steps of case (ii) to these two terms, resulting in exponents which are now necessarily greater than 2 (since all α_i and β_i are $\geqslant 1$) and thus the Cayley–Hamilton theorem will be applicable to lower the order of these terms, completing the proof of the theorem.

Corollary: The set of scalars $\mathcal{I}$ is a complete set for the traces of arbitrary matrix products of A and B.

The proof follows trivially from the theorem and the fact that an arbitrary matrix can be written as the sum of a symmetric and an antisymmetric matrix—the latter having vanishing trace!

The proof of this theorem suggests a recursive procedure for fully reducing a symmetric matrix polynomial of arbitrary order in A, B: (i) for each term of order >6 apply the steps of the proof to obtain terms of lower order; (ii) for each term of order $\leqslant 6$ use the expressions in the Appendix. This procedure has been implemented in a set of MATHEMATICA routines which have been used in carrying out the calculations in the next section. (They are available by e-mail from the author.)

IV. A MATRIX IDENTITY AND ITS CONCOMITANTS

Let Q be an *antisymmetric* 3×3 matrix. Then the antisymmetric part of the Cayley–Hamilton theorem for Q reads

$$Q^3=1/2[Q^2]Q \tag{4.1}$$

(the symmetric part is just $\det Q=0$). Multiplying (4.1) by Q, we conclude that the *symmetric* matrix $X=Q^2$ satisfies the identity

$$Z\equiv X^2-1/2[X]X=O. \tag{4.2}$$

Thus, if Q is any antisymmetric matrix polynomial in A and B, then, by the results of the previous section, (4.2) will be an identity relating the matrices in $\mathcal{M}$! Taking $Q=AB-BA$ and evaluating (4.2) we find

$$\begin{aligned}Z=&2(2t^2-s^2t-4i_ai_bt+2ia_ai_bs^2+pqs+12j_aj_bs-8i_aj_bp-8i_bj_aq)\mathbf{1}\\&+2(qt+i_bps-2i_aj_bs-2i_ai_bq-8i_b^2j_a)A+2(pt+i_aqs-2i_bj_as-2i_ai_bp-8i_a^2j_b)B\\&+2(2i_bt-i_bs^2-q^2+6j_bp)A^2+2(2i_at-i_as^2-p^2+6j_aq)B^2+(st+pq-2i_ai_bs-36j_aj_b)\\&\times(AB+BA)+2(i_bp-qs+6i_aj_b)(A^2B+BA^2)+2(i_aq-ps+6i_bj_a)(AB^2+B^2A)\\&+2(s^2-3t+2i_ai_b)(A^2B^2+B^2A^2),\end{aligned} \tag{4.3}$$

while taking $Q=A^2B-BA^2$ we obtain a lengthy expression, Z_1, which can be shown to equal (after proper reduction of all matrix products) to

$$Z_1=\cdots=-2j_a(AZ+ZA). \tag{4.4}$$

Similarly, $Q=A^2B^2-B^2A^2$ gives

$$Z_2=\cdots=4j_aj_b(AZB+BZA+ABZ+ZBA). \tag{4.5}$$

It is clear that there is essentially only one independent matrix identity $Z=0$. One can obtain eight others by multiplying Z, as given by Eq. (4.3), symmetrically by the elements of $\mathcal{M}$ and reducing the resulting expressions. These are precisely the nine symmetric matrix identities relating the elements of $\mathcal{M}$ whose existence was inferred by Sneddon.[18] In fact it can be checked that the matrices S_1, S_2, and S_4 given in his Appendix A are equal, in our notation, to $6S_1=Z$, $24S_2=BZ+ZB$ and $6S_4=AZB+BZA+ABZ+ZBA$.

Now, multiplying Eq. (4.3) by each matrix in $\mathcal{M}$ in turn and taking traces, we find that all but one are identically zero (as polynomials in $\mathcal{I}$). The only nonvanishing trace, written as a polynomial in t, is

$$\begin{aligned}[Z(A^2B^2+B^2A^2)]=&-4t^3+(s^2+20i_ai_b)t^2-2(pqs-36sj_aj_b+2i_ai_bs^2-2i_aq^2-2i_bp^2\\&+12i_aj_bp+12i_bj_aq+16i_a^2i_b^2)t+p^2q^2+4i_a^2i_b^2s^2-16j_aj_bs^3+8i_aj_bps^2\\&+8i_bj_aqs^2-8i_a^2j_bqs-8i_b^2j_aps-96i_ai_bj_aj_bs-4i_a^2i_bq^2-4i_b^2i_ap^2-8j_aq^3\\&-8j_bp^3+72j_aj_bpq+32i_a^2i_bj_bp+32i_b^2i_aj_aq-432j_a^2j_b^2+16i_a^3j_b^2+16i_b^3j_a^2\\&+16i_a^3i_b^3.\end{aligned} \tag{4.6}$$

The vanishing of this expression gives the single syzygy connecting the invariants of the complete set $\mathcal{I}$. This syzygy was first obtained by Sneddon[17] (his Eq. (19)) in a very laborious and rather inelegant way. (Note that in Sneddon's expression the term $+4i_a^2i_b^2s^2$ is missing and the terms $-8i_a^2j_bqs-8i_b^2j_aps$ appear with a plus sign.) Our derivation shows that it is, ultimately, a consequence of the Cayley–Hamilton theorem.

V. DIFFERENT SPINOR CONTRACTIONS

The traceless parts of the eight symmetric matrices in $\mathcal{M}$ define eight symmetric 4-index spinors by the correspondence (2.1). The discussion in Sec. III proved completeness of the set $\mathcal{I}$ for contractions over *pairs* of indices of arbitrary products of these spinors. It is natural to ask what happens when different spinor contractions are performed.

Consider first triple index contractions. If U_{ABCD} and V_{ABCD} are any two of the eight basic spinors, then it is easy to show that the 2-index spinor $Q_{AB}=U_{(A}{}^{CDE}V_{B)CDE}$ corresponds[22] to the antisymmetric matrix $Q=VU-UV$. Thus the scalar $u=U_{(A}{}^{CDE}V_{B)CDE}X^{(A}{}_{PQR}Y^{B)PQR}$ is proportional to the trace of the symmetric matrix $(UV-VU)(XY-YX)+(XY-YX)(UV-VU)$, which, when expanded, is of the form considered in III (symmetric products of elements of $\mathcal{M}$). It follows that scalars like u can be expressed as polynomials in $\mathcal{I}$.

Single index contractions lead to a greater variety of spinors and scalars. Consider next the 4-index spinor (symmetrized over *ABCD*)

$$K_{ABCD}=U_A{}^{KLM}V_{BK}{}^{PQ}X_{CLP}{}^{R}Y_{DMQR}, \tag{5.1}$$

where a single index is contracted between every pair of spinors U, V, X, Y. Is the traceless 3×3 matrix corresponding to K_{ABCD} reducible? The answer can be found by using the fundamental ε identity[24]

$$\varepsilon_{AB}\varepsilon_{CD}=\varepsilon_{AC}\varepsilon_{BD}-\varepsilon_{BC}\varepsilon_{AD}. \tag{5.2}$$

We first write all contractions in terms of ε's

$$K_{ABCD}=U_A{}^{KLM}V_B{}^{K_1PQ}X_C{}^{L_1P_1R}Y_D{}^{M_1Q_1R_1}\varepsilon_{KK_1}\varepsilon_{LL_1}\varepsilon_{MM_1}\varepsilon_{PP_1}\varepsilon_{QQ_1}\varepsilon_{RR_1}$$

and use the identity (5.2) to replace $\varepsilon_{MM_1}\varepsilon_{PP_1}$. Regrouping terms we find that K_{ABCD} can be written as

$$\begin{aligned}&(U_A{}^{KLM}V_B{}^{K_1PQ}\varepsilon_{KK_1}\varepsilon_{MP})(X_C{}^{L_1P_1R}Y_D{}^{M_1Q_1R_1}\varepsilon_{M_1P_1}\varepsilon_{RR_1})\varepsilon_{LL_1}\varepsilon_{QQ_1}\\&\quad-(U_A{}^{KLM}X_C{}^{L_1P_1R}\varepsilon_{LL_1}\varepsilon_{MP_1})(V_B{}^{K_1PQ}Y_D{}^{M_1Q_1R_1}\varepsilon_{PM_1}\varepsilon_{QQ_1})\varepsilon_{KK_1}\varepsilon_{RR_1}\\&\quad=(U_A{}^{KLM}V_{BKM}{}^{Q})(X_C{}^{L_1P_1R}Y_{DR\,P_1}{}^{Q_1})\varepsilon_{LL_1}\varepsilon_{QQ_1}\\&\quad-(U_A{}^{KLM}X_{CLM}{}^{R})(V_B{}^{K_1PQ}Y_{DPQ}{}^{R_1})\varepsilon_{KK_1}\varepsilon_{RR_1}.\end{aligned}\tag{5.3}$$

The last expression involves contractions of *pairs* of indices only and, hence, is reducible.

Consider finally the 6-index spinor $\Pi^{(UV)}{}_{ABCDEF}=U_{(ABC}{}^{S}V_{DEF)S}$. Such a spinor can be formed from any two of the eight 4-index spinors, but cannot be represented in terms of 3×3 matrices (it corresponds to a third-rank tensor). We can form scalars by contracting any number of different spinors $\Pi^{(K)}$ among themselves. For example,

$$s_4=\Pi^{(1)ABCDEF}\Pi^{(2)}{}_{AB}{}^{KLMN}\Pi^{(3)}{}_{CDKL}{}^{RS}\Pi^{(4)}{}_{EFMNRS},$$

$$s_7=\Pi^{(1)ABCDEF}\Pi^{(2)}{}_{A}{}^{GHKLM}\Pi^{(3)}{}_{BG}{}^{PQRS}\Pi^{(4)}{}_{CHP}{}^{TUV}\Pi^{(5)}{}_{DKQT}{}^{XY}\Pi^{(6)}{}_{ELRUX}{}^{Z}\Pi^{(7)}{}_{FMSVYZ}.$$

In s_4 two indices are contracted between any two $\Pi^{(K)}$'s, while in s_7 only one. Clearly, there are many other possibilities. It is very likely that, using the identity (5.2), all such scalars can be reduced to successive contractions over pairs of indices of the constituent 4-spinors. However, lacking a general theorem to this effect, we will not attempt to examine the reducibility of these scalars. In any case, it is safe to say that the technical requirement imposed at the beginning, that only contractions of products of Ψ_{ABCD} and χ_{ABCD} over *pairs* of indices will be considered (which was needed in order to translate the problem into the language of 3×3 matrices), can be weakened considerably if not dropped altogether.

VI. A MINIMAL SET OF RIEMANN TENSOR INVARIANTS

When A is identified with Ψ and B with χ the invariants found in the complete set $\mathcal{I}$ can be identified with known Riemann tensor invariants. Thus i_a and j_a are the two (complex) Weyl tensor invariants I and J. The invariants i_b and j_b, being of 4th and 6th order in $\Phi_{ABC'D'}$, respectively, can be expressed as polynomials in the 2nd, 3rd and 4th order invariants of $\Phi_{ABC'D'}$. Specifically, let

$$\begin{aligned}r_2&=\Phi_{AA'}{}^{BB'}\Phi_{BB'}{}^{AA'},\\r_3&=\Phi_{AA'}{}^{BB'}\Phi_{BB'}{}^{CC'}\Phi_{CC'}{}^{AA'},\\r_4&=\Phi_{AA'}{}^{BB'}\Phi_{BB'}{}^{CC'}\Phi_{CC'}{}^{DD'}\Phi_{DD'}{}^{AA'}.\end{aligned}\tag{6.1}$$

Then it can be shown[8] that

$$i_b=(7/12)r_2^2-r_4,\tag{6.2}$$

$$6j_b=(1/3)r_3^2+(17/36)r_2^3-r_2r_4.\tag{6.3}$$

The introduction of these lower order invariants (r_2,r_3,r_4), however, may make some of the higher order invariants (p,q,t) become dependent on the lower order ones. Counting powers of Ψ and Φ, we find that only the following relations are possible:

$$p=c_1 i_a r_2,$$

$$q=c_2 s r_2, \tag{6.4}$$

$$t=c_3 p r_2+c_4 s^2+c_5 i_a r_4+c_6 i_a r_2^2,$$

where the coefficients c_i are constants. However, it is easy to check that there are no c_i that can make any one of (6.4) an identity in the components of Ψ and Φ. Hence the invariants p, q and t remain independent even when r_2, r_3, and r_4 are added to the set. Including the scalar curvature R, we conclude that the set $\{R,r_2,r_3,r_4,I,J,s,p,q,t\}$ of 4 real and 6 complex invariants (subject to the complex syzygy (4.8)) is a minimal set that must be contained in the complete set of invariants of the Riemann tensor. The set of Carminati and McLenaghan does not contain the invariants q and t, while the set of Zakhary and McIntosh does not contain t. (The additional invariants in these sets, containing both Ψ and $\overline{\Psi}$, cannot be used to write q and t.) Thus neither of these sets can be complete according to the definition used here. Moreover, as the number of invariants minus the number of syzygies for the minimal set equals 14, for every additional invariant that is added to the set an additional syzygy must be found to maintain the number of algebraically independent invariants equal to 14, the number of gauge-independent components of the Riemann tensor.

VII. SUMMARY AND CONCLUSIONS

The main results of this paper are the proof of completeness of the sets $\mathcal{M}$ and $\mathcal{I}$ given in Sec. III and the derivation of the matrix identities, together with the scalar syzygy (4.8), given in Sec. IV. They have all been obtained using entirely elementary means: beginning with Eq. (2.4), everything is a consequence of the Cayley–Hamilton theorem!

Considering the general problem, these results reinforce a conclusion reached recently in a related publication;[25] a definitive study of the Riemann tensor invariants can only be done after the algebra of the matrices Ψ, Φ (and their complex conjugates) has been fully worked out.

Note added in proof: Sneddon (private communication) has pointed out that the conjecture at the end of Sec. V (scalars obtained by different spinor index contractions can be converted to contractions over *pairs* of indices) is correct and can be proved using the rotor (bivector) notation. Particularly useful in the proof is the equation following Eq. (A5) in Appendix A of Ref. 17.

APPENDIX: ALL 4th, 5th AND 6th ORDER SYMMETRIC MATRICES

4th Order:

$$A^2BA+ABA^2=sA^2+pA-2j_aB,$$

$$AB^2A=-(A^2B^2+B^2A^2)+2i_bA^2+i_aB^2+qA+(t-2i_ai_b)\mathbf{1},$$

$$ABAB+BABA=(A^2B^2+B^2A^2)+s(AB+BA)-2(i_bA^2+i_aB^2)+2(2i_ai_b-t)\mathbf{1}.$$

There are two more equations, that can be obtained from the first two through the interchanges, $A\leftrightarrow B$, $i_a\leftrightarrow i_b$, $j_a\leftrightarrow j_b$, $p\leftrightarrow q$.

5th Order:

$$A^2B^2A+AB^2A^2=-2j_aB^2+qA^2+tA+4i_bj_a\mathbf{1},$$

$$A^2BAB+BABA^2=-i_a(AB^2+B^2A)+s(A^2B+BA^2)-2j_aB^2+qA^2-(t-2i_ai_b)A,$$

$$ABA^2B+BA^2BA=i_a(AB^2+B^2A)+p(AB+BA)-2j_aB^2-qA^2+(t-2i_ai_b)A,$$

$$ABABA=-s(A^2B+BA^2)+2j_aB^2+(s^2-t+i_ai_b)A+si_aB+(ps-2i_bj_a)\mathbf{1},$$

$$A^2BA^2=i_a(A^2B+BA^2)-2j_a(AB+BA)+pA^2-i_a^2B+(2sj_a-pi_a)\mathbf{1}.$$

There are five more equations, that can be obtained from these through the interchanges, $A\leftrightarrow B$, $i_a\leftrightarrow i_b$, $j_a\leftrightarrow j_b$, $p\leftrightarrow q$.

6th Order:

$$AB^2A^2B+BA^2B^2A=-s(A^2B^2+B^2A^2)+p(AB^2+B^2A)+q(A^2B+BA^2)+i_ai_b(AB+BA)$$
$$+s(i_bA^2+i_aB^2)+(2i_aj_b-i_bp)A+(2i_bj_a-i_aq)B$$
$$+(st-pq-2si_ai_b-4j_aj_b)\mathbf{1},$$

$$A^2BAB^2+B^2ABA^2=p(AB^2+B^2A)+q(A^2B+BA^2)+(i_ai_b-t)(AB+BA)+s(i_bA^2+i_aB^2)$$
$$-(2i_aj_b+i_bp)A-(2i_bj_a+i_aq)B+(st-pq-2si_ai_b-4j_aj_b)\mathbf{1},$$

$$ABABAB+BABABA=s(A^2B^2+B^2A^2)+(s^2+i_ai_b-t)(AB+BA)-2s(i_bA^2+i_aB^2)$$
$$-2(st-2si_ai_b-4j_aj_b)\mathbf{1},$$

$$AB^2ABA+ABAB^2A=-s(A^2B^2+B^2A^2)-q(A^2B+BA^2)+2si_bA^2+si_aB^2-2(i_aj_b-qs)A$$
$$+i_aqB+(st+pq-2si_ai_b-4j_aj_b)\mathbf{1},$$

$$A^2B^2AB+BAB^2A^2=s(A^2B^2+B^2A^2)-p(AB^2+B^2A)+(t-i_ai_b)(AB+BA)-s(i_bA^2+i_aB^2)$$
$$-(2i_aj_b-i_bp)A+(2i_bj_a+i_aq)B-(st-pq-2si_ai_b+4j_aj_b)\mathbf{1},$$

$$A^2B^2A^2=i_a(A^2B^2+B^2A^2)-2j_a(AB^2+B^2A)+(t-2i_ai_b)A^2-i_a^2B^2+4i_bj_aA$$
$$+(2i_a^2i_b+2qj_a-i_at)\mathbf{1},$$

$$ABA^2BA=-p(A^2B+BA^2)-2j_a(AB^2+B^2A)+(t-i_ai_b)A^2+(ps+2i_bj_a)A+i_apB+p^2\mathbf{1},$$

$$A^2BABA+ABABA^2=2j_a(AB^2+B^2A)+(s^2+2i_ai_b-2t)A^2+(ps-4i_bj_a)A-2sj_aB,$$

$$A^2BA^2B+BA^2BA^2=-i_a(A^2B^2+B^2A^2)+2j_a(AB^2+B^2A)+p(A^2B+BA^2)+2i_a(i_bA^2+i_aB^2)$$
$$-4i_bj_aA-2(2i_a^2i_b+2qj_a-i_at)\mathbf{1}.$$

There are six more equations, that can be obtained from the last six through the interchanges, $A\leftrightarrow B$, $i_a\leftrightarrow i_b$, $j_a\leftrightarrow j_b$, $p\leftrightarrow q$.

(Received 10 June 1998; accepted for publication 9 December 1998)

The Darboux method introduces algebraic solutions quite useful to obtain invariant and first integrals of polynomial differential systems. Here we study the 2D Lotka–Volterra (LVS) and the complex quadratic system (QS) using straight lines for both and conics for the LVS. The conditions needed to obtain these invariants are given and a study of the phase space portrait is done. © *1999 American Institute of Physics.* [S0022-2488(99)02604-3]

I. INTRODUCTION

We consider the search of invariants for the two-dimensional differential system

$$\frac{\mathrm{d}x}{\mathrm{d}t}=P(x,y), \quad \frac{\mathrm{d}y}{\mathrm{d}t}=Q(x,y), \tag{1}$$

where P and Q are polynomials with coefficients in $\mathbf{F}$, where $\mathbf{F}$ is either the real field $\mathbf{R}$ or the complex field $\mathbf{C}$. We say that $m=\max\{\deg P,\deg Q\}$ is the *degree* of the polynomial differential system. This type of equations appear in the modelization of natural phenomena described in different branches of the science such as biology, chemistry, astrophysics, fluid mechanics, electronics, etc. Of particular interest are the systems such that $m=2$. The polynomial differential systems of degree 2 will be called *quadratic systems* (QS). One particularly well known quadratic system is the *Lotka-Volterra system* (LVS) which has been used to model the time evolutions of conflicting species in biology and of chemical reactions.[1,2] Among other applications, we find a QS in the equations of continuity describing the interactions of ions, electrons and neutral species in plasma physics (with the assumption of quasineutrality to eliminate either the ion or electron equation).[3] Moreover a reduced QS is obtained from a generalized Blasius equation for fluid flow around a wedge-shaped obstacle in boundary layer theory.[4] In the context of plasma physics, all the nonlinear terms represent binary interactions or model certain transport across the boundary of the system. There is a long history of research on finding sufficient conditions for which periodic solutions (center problem) exist for systems equivalent to the QS, and numerous results were obtained which we are not able to fully survey.[5] However, most of the previous works assumed that the origin is a linear center (i.e., having eigenvalues $\pm i$) which we do not assume here as starting point.

[a)]Electronic mail: lcairo@labomath.univ-orleans.fr
[b)]Electronic mail: jllibre@mat.uab.es

Although our main interest concerns the integrability, we will also consider cases for which one can exhibit a constant of the motion which is not a *first integral*. As it is well known in 2D a polynomial system is integrable if it possess a first integral. However, it can be interesting sometimes to know if it can have an *invariant*. Roughly speaking, with a first integral we can describe completely the phase portrait of the polynomial system, while with an invariant (a time-dependent first integral) we only can describe its asymptotic behavior. In fact, an invariant is a function $I(x,y,t)$ such that when $(x,y)=(x(t),y(t))$ is a solution of (1), I is a constant. Consequently, I must satisfy the equation

$$\frac{\partial I}{\partial t}+\frac{\partial I}{\partial x}P+\frac{\partial I}{\partial y}Q=0. \tag{2}$$

When I does not depend explicitly of t, the invariant is called a first integral.

In spite of the fact that they differ in the details of computation, all the methods to obtain invariants (Carleman linearization,[6,2] Hamiltonian method[7,8]) are based on an *a priori* hypothesis on the form of the invariant I. So, in the Carleman method this form is introduced in system (1) and the parameters entering in it are selected in order that (2) becomes an identity or, in the Hamiltonian method, through rescaling, the form of the equations leading to this invariant is determined and again we select the different parameters and unknowns which are at our disposal to identify these equations with the one we want to study.

Here we review a method proposed long time ago by Darboux.[9] A survey of many works triggered by the Darboux theorem together with a study of the integrability of real quadratic systems having an invariant conic is given in Ref. 10.

The Darboux method is based on the possibility of writing the invariant [or at least an integrating factor for system (1)] as the product of different functions $f_i(x,y)$ raised at a given power λ_i. It is on the form of these functions f_i that we introduce an ansatz and the subsequent need to identify the parameters. In that sense the Darboux method is not so different from the others cited above. Nevertheless the experience shows that we have somehow divided the difficulties of the unavoidable identification leading to algebraic but nonlinear equations with sometimes a number of equations greater than the number of unknowns with, consequently, conditions imposed on the parameters describing the dynamical system. From a physicist point of view the rule of the game is to find invariants with as few conditions as possible on the parameters of the given system.

The paper is organized as follows. In Sec. II we present the Darboux method, and apply it in Sec. III to the Lotka–Volterra system. In Sec. IV we apply it to the quadratic systems after reduction to a canonical form already used by two of the authors in the Painlevé analysis of such systems.[11] In Sec. V we give our conclusion.

II. THE DARBOUX METHOD

Although the method can be extended to more than 2 dimensions we present it for the planar system (1) where P and Q are polynomials in x and y.

As has been said in the Introduction, the Darboux method is based on the existence of functions $f_i(x,y)$ which are in fact *algebraic solutions* of the differential system. Suppose that we can determine two polynomials $f_i(x,y)$ and $K_i(x,y)$ such that

$$\frac{\partial f_i}{\partial x}P+\frac{\partial f_i}{\partial y}Q=K_i f_i . \tag{3}$$

Then equation $f_i(x,y)=0$ describes an algebraic curve which is formed by trajectories.

These f_i are going to be the ''bricks'' with which we will build the invariants. Suppose that we have obtained q functions f_i. The polynomial K_i is called the *cofactor* of f_i. We look for an invariant of the form

$$I=\prod_{i=1}^{q} f_i^{\mu_i}(x,y)\exp(st). \tag{4}$$

We obtain

$$\frac{\mathrm{d}I}{\mathrm{d}t}=\frac{\partial I}{\partial t}+\frac{\partial I}{\partial x}P+\frac{\partial I}{\partial y}Q=I\left[s+\sum_{i=1}^{q}\frac{\mu_i}{f_i}\left(\frac{\partial f_i}{\partial x}P+\frac{\partial f_i}{\partial y}Q\right)\right]. \tag{5}$$

Taking into account (3) and imposing that I is an invariant, we obtain

$$s+\sum_{i=1}^{q}\mu_i K_i=0. \tag{6}$$

The equations for μ_i are now linear equations. How many f_i do we need? Equation (3) shows that if the system is of degree m, K_i is at most of degree $m-1$ independently of the degree of f_i. The left-hand side of (6) is consequently a polynomial in x,y of degree at most $m-1$ with a total of $m(m+1)/2$ terms. Consequently (6) produces $m(m+1)/2$ equations where the unknowns are the μ_i. We see from (6) that if we allow s to be different from zero the system of equations for the μ_i is inhomogeneous, and we need $q=m(m+1)/2$. If we want a first integral then s must be zero and the system becomes homogeneous and we need a priori either a new f_i, or a new condition by imposing that the determinant of the system of equations for the μ_i is zero. We will call λ_i the solution of this system.

In fact it is not impossible to find cases where q is smaller than $m(m+1)/2$ with μ_i such that $\Sigma\mu_i K_i+s\equiv 0$. We see that the possibility of solving for μ_i in Eq. (6) depends on the conditions we put on the coefficients of (1). We should not forget that some conditions come from Eq. (6) and other ones come from Eq. (3).

Another possibility indicated also by Darboux is to obtain an integrating factor as follows. We seek an integrating factor of the form

$$R=\prod_{i=1}^{q} f_i^{\lambda_i}. \tag{7}$$

For R to be an integrating factor we must have

$$\operatorname{div}(RP,RQ)=\frac{\partial}{\partial x}(RP)+\frac{\partial}{\partial y}(RQ)=0. \tag{8}$$

We have

$$\frac{\partial R}{\partial x}=R\sum_i \frac{\lambda_i}{f_i}\frac{\partial f_i}{\partial x},\qquad \frac{\partial R}{\partial y}=R\sum_i \frac{\lambda_i}{f_i}\frac{\partial f_i}{\partial y}, \tag{9}$$

and

$$\operatorname{div}(RP,RQ)=R\operatorname{div}(P,Q)+R\sum_{i=1}^{q}\frac{\lambda_i}{f_i}\left(P\frac{\partial f_i}{\partial x}+Q\frac{\partial f_i}{\partial y}\right). \tag{10}$$

Taking (3) into account we obtain

$$\operatorname{div}(RP,RQ)=R\left[\operatorname{div}(P,Q)+\sum_{i=1}^{q}\lambda_i K_i\right]=0. \tag{11}$$

Therefore R will be an integrating factor if we can solve for λ_i the following system:

$$\sum_i^q \lambda_i K_i + \mathrm{div}(P,Q) = 0, \tag{12}$$

which is of the same type as Eq. (6). They differ only through the inhomogeneous terms. (12) gives $m(m+1)/2$ equations and, *a priori*, we need the same number of pairs f_i, K_i. However, for some usually nongeneric cases a smaller number can be enough.

A comment is in order about the number of conditions and its variation with m and the order of the algebraic solutions tested. For the existence of algebraic solutions of higher order we require larger number of conditions than for curves of smaller order. Since the number of algebraic solutions needed increases quickly with m, we see that the most interesting cases (i.e., with a not too high number of conditions) will be obtained using straight lines and conics as algebraic solutions for Lotka–Volterra and quadratic systems. This conclusion was already found using the Carleman or Hamiltonian method.

III. LOTKA–VOLTERRA SYSTEM

The bidimensional LVS writes

$$\dot{x} = x(a_1 + b_{11}x + b_{12}y), \quad \dot{y} = y(a_2 + b_{21}x + b_{22}y), \tag{13}$$

We begin with straight lines as algebraic solutions, i.e.,

$$f(x,y) = f_{00} + f_{10}x + f_{01}y, \quad K(x,y) = K_{00} + K_{10}x + K_{01}y. \tag{14}$$

Two first straight lines are obvious,

$$f(x,y) = x, \quad K(x,y) = a_1 + b_{11}x + b_{12}y, \tag{15}$$

$$f(x,y) = y, \quad K(x,y) = a_2 + b_{21}x + b_{22}y. \tag{16}$$

We remark that these two straight lines do not impose any condition. The interest of using these straight lines was noted by Cairó and Feix who were seeking invariants of the form

$$x^\alpha y^\beta P(x,y)\exp(st),$$

and have noted that the two terms $x^\alpha y^\beta$ were giving extra freedom. Now the fulfillment of (3) imposes either $f_{00}=0$ or $K_{00}=0$. We begin with the solution $K_{00}=0$. We obtain

$$K_{10} = b_{11}, \quad K_{01} = b_{22}, \quad f(x,y) = f_{00}\left(1 + \frac{b_{11}}{a_1}x + \frac{b_{22}}{a_2}y\right), \tag{17}$$

but we need one condition, namely,

$$r_{12} = \frac{b_{11}}{a_1}(b_{12} - b_{22}) + \frac{b_{22}}{a_2}(b_{21} - b_{11}) = 0, \tag{18}$$

found in Ref. 2 to obtain the invariant of type III (in fact a first integral).

Note that the straight line $f(x,y)=0$ with f given by (17) joins the two equilibrium points $-a_1/b_{11},0$ and $0,-a_2/b_{22}$ while the cofactor straight line $b_{11}x + b_{22}y = 0$ joins the origin to the equilibrium point outside the axes.

Another invariant straight line is obtained by taking $f_{00}=0$. It is easily proved that we need one condition namely $a_1 = a_2 = a$, and that $K_{10} = b_{11}$, $K_{01} = b_{22}$ and $K_{00} = a$. This condition is needed to obtain the invariant of type II.

TABLE I. Algebraic solutions and conditions for Theorem 1.

$f(x,y)$	$K(x,y)$	Condition	No.
x	$a_1+b_{11}x+b_{12}y$	—	1
y	$a_2+b_{21}x+b_{22}y$	—	2
$a_1+b_{11}x$	$b_{11}x$	$b_{12}=0$	3
$a_2+b_{22}y$	$b_{22}y$	$b_{21}=0$	4
$(b_{21}-b_{11})x+(b_{22}-b_{12})y$	$a_1+b_{11}x+b_{22}y$	$a_1=a_2$	5
$a_1a_2+b_{11}x+b_{22}y$	$b_{11}x+b_{22}y$	$r_{12}=0$	6

Two other possible linear algebraic solutions are $f(x,y)=x+a_1/b_{11}$ with $b_{12}=0$ as condition, and $f(x,y)=y+a_2/b_{22}$ with $b_{21}=0$ as condition. Table I recapitulates the 6 possible invariant straight lines.

We see that to build an invariant with straight lines we must include first the straight lines 1 and 2 which do not bring any condition. If we add the invariant straight line 5 we recover the invariant II of Cairó and Feix, and if we add the straight line 6 we recover invariant III which is in fact a first integral. Straight lines 3 and 4 do not bring interesting invariants since the associated invariant concerns the species fully decoupled from the other (we have either b_{12} or b_{21} equal to zero). Finally we try to build an invariant with no condition, and for that we select the two straight lines $f=x$ and $f=y$. If μ_1 and μ_2 are the respective exponents, we obtain, taking into account the expression of the cofactors,

$$\mu_1a_1+\mu_2a_2+s=0,\quad b_{11}\mu_1+b_{21}\mu_2=0,\quad b_{12}\mu_1+b_{22}\mu_2=0. \tag{19}$$

Since s is at our disposal we can ignore the first equation, but the two others being homogeneous will have a nontrivial solution only if $\Delta=b_{11}b_{22}-b_{12}b_{21}=0$. This is the invariant of type I in Ref. 2. The LVS need at least one condition to posses an invariant. So the following theorem can be established.

Theorem 1: *Let $f_1=x=0$ and $f_2=y=0$ be the two trivial algebraic solutions of a LVS. Then the following statement holds*:

(a) *If $r_{12}=0$ the expression $f_1^{\lambda_1}f_2^{\lambda_2}$ is an integrating factor of the LVS with $\lambda_1=[(a_2-a_1)b_{22}+a_2b_{12}]/(a_1b_{22}-a_2b_{12})$ and $\lambda_2=(2a_1b_{22}-a_2b_{12})/(a_1b_{22}-a_2b_{12})$. If the condition is $\Delta=0$, then the expression $f_1^{\mu_1}f_2^{\mu_2}e^{st}$ is a Darboux invariant of the LVS provided that μ_1 and μ_2 be a solution of the system (19).*
If a LVS has a third algebraic solution $f_3=0$ of degree 1, then modulus the symmetry $(x,y,b_{11},b_{12},a_1,b_{21},b_{22},a_2)\rightarrow(y,x,b_{22},b_{21},a_2,b_{12},b_{11},a_1)$ and provided that the LVS satisfies one of the conditions indicated in Table I, there exist a Darboux invariant $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}e^{st}$ and an integrating factor $f_1^{\lambda_1}f_2^{\lambda_2}f_3^{\lambda_3}$ having the following values for f_3 and the exponents λ_i,μ_i:

(b) *If $a_1b_{11}b_{22}\neq 0$, and condition (3) is satisfied, then*

$$f_3=b_{11}x+a_1,$$

$$\mu_1=-s/a_1,\quad \mu_2=0,\quad \mu_3=s/a_1,$$

$$\lambda_1=(a_2-a_1)b_{11},\quad \lambda_2=-2a_1b_{11},\quad \lambda_3=a_1(b_{21}-b_{11})-a_2b_{11}.$$

(c) *If $a_1(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, and condition (5) is satisfied, then*

$$f_3=(b_{21}-b_{11})x+(b_{22}-b_{12})y,$$

$$\mu_1 = s\frac{b_{22}}{a_1(b_{12}-b_{22})}, \quad \mu_2 = s\frac{b_{11}}{a_1(b_{21}-b_{11})}, \quad \mu_3 = s\frac{b_{11}b_{22}-b_{12}b_{21}}{a_1(b_{12}-b_{22})(b_{21}-b_{11})},$$

$$\lambda_1 = b_{12}(b_{21}-b_{11}), \quad \lambda_2 = b_{21}(b_{12}-b_{22}), \quad \lambda_3 = -[b_{11}(b_{12}-b_{22})+b_{22}(b_{21}-b_{11})].$$

(d) *If* $a_2^2b_{11}^2+a_1^2b_{22}^2\neq 0$, *and condition (6) is satisfied, then there exist a first integral* $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}$ *with*

$$f_3 = 1+\frac{b_{11}}{a_1}x+\frac{b_{22}}{a_2}y,$$

$$\mu_1 = b_{22}(b_{21}-b_{11}), \quad \mu_2 = b_{11}(b_{12}-b_{22}), \quad \mu_3 = b_{11}b_{22}-b_{12}b_{21}.$$

Next we turn to quadratic algebraic solutions $f(x,y)=0$, which we write

$$f(x,y) = f_{00}+f_{10}x+f_{01}y+f_{20}x^2+f_{11}xy+f_{02}y^2.$$

The cofactor is of the form $K(x,y)=K_{00}+K_{10}x+K_{01}y$ but K_{00} must be zero if $f_{00}\neq 0$. The identification of the terms in x^3 and y^3 give

$$f_{20}K_{10} = 2f_{20}b_{11}, \quad f_{02}K_{01} = 2f_{02}b_{22},$$

and if $f_{20}f_{02}\neq 0$ (we will come back to this possibility later on), we get

$$K_{10} = 2b_{11}, \quad K_{01} = 2b_{22}. \tag{20}$$

Taking $f_{00}=1$, the identification of terms in x and y gives

$$f_{10} = \frac{2b_{11}}{a_1}, \quad f_{01} = \frac{2b_{22}}{a_2}. \tag{21}$$

Identification of terms in x^2 and y^2 gives, taking (20) and (21) into account

$$f_{20} = \frac{b_{11}^2}{a_1^2}, \quad f_{02} = \frac{b_{22}^2}{a_2^2}. \tag{22}$$

All quantities except f_{11} are known and we are left with three equations from the identification of terms in xy, x^2y, and xy^2. Consequently we will need two conditions. After some calculations we get

$$f_{11} = -2\frac{b_{11}b_{22}}{a_1a_2},$$

with the two conditions

$$b_{12} = b_{22}\left(2+\frac{a_1}{a_2}\right), \quad b_{21} = b_{11}\left(2+\frac{a_2}{a_1}\right). \tag{23}$$

The conic is

$$f(x,y) = \left(1+\frac{b_{11}}{a_1}x+\frac{b_{22}}{a_2}y\right)^2 - 4\frac{b_{11}b_{22}}{a_1a_2}xy,$$

and the associated cofactor is

$$K(x,y) = 2b_{11}x+2b_{22}y.$$

TABLE II. Consequences of the identification of the different terms of (3).

x	y	x^3	y^3	
$f_{10}=2b_{11}/a_1$	$f_{01}=K_{01}/a_2$	$K_{10}=2b_{11}$	$f_{02}=0$	
x^2	y^2	xy^2	x^2y	xy
$f_{20}=b_{11}^2/a_1^2$	$K_{01}=b_{22}$	$f_{11}=0$	$b_{22}=2b_{12}$	$b_{21}=b_{11}(2+a_2/a_1)$

It must be realized that the presence of two conditions as given by (23) leaves a one parameter LVS equation. Indeed it is easily proved that (13) can be written as a three parameter system. Introducing $X=b_{11}x/a_1$, $Y=b_{22}y/a_2$, $C_1=b_{12}a_2/b_{22}a_1$, $C_2=b_{21}a_1/b_{11}a_2$, (13) becomes

$$\frac{dX}{a_1 dt}=X(1+X+C_1Y), \quad \frac{dY}{a_2 dt}=Y(1+C_2X+Y), \tag{24}$$

where

$$C_1=1+2\frac{a_2}{a_1}, \quad C_2=1+2\frac{a_1}{a_2},$$

and, indeed, writing the system (24) in the form dY/dX, we are left with one relevant parameter, (a_1/a_2).

We briefly discuss the other possibilities. The identification of the coefficients of the terms in x^3 and y^3 can also be obtained by taking f_{20} (for x^3) and f_{02} (for y^3) equal to zero. Identifying both leads to an uninteresting case: either $f_{11}=0$ or $b_{12}=b_{21}=0$. Breaking the symmetry we take $f_{02}=0$. Table II gives the result of the identification of the different terms. We recover again two conditions,

$$b_{22}=2b_{12}, \quad b_{21}=b_{11}\left(2+\frac{a_2}{a_1}\right).$$

One is identical to the previous case, the other is different. However, there is still another case for invariant conics of type (19). The identification of the y^2 term gives $f_{01}b_{22}=K_{01}f_{01}$ and assuming $f_{01}\neq 0$ we deduce $K_{01}=b_{22}$. Finally another solution is possible with $f_{01}=0$. Since (4th column in Table II) $f_{01}=K_{01}/a_2$, we must take $K_{01}=0$ and the table is modified. The identification of the term in xy^2 gives

$$b_{12}+b_{22}=0,$$

which is the first condition. The next term x^2y gives f_{11} and the term in xy gives the second condition

$$b_{21}=b_{11}\left(2+\frac{a_2}{a_1}\right),$$

the same as in the previous two cases.

We must now consider a nonzero constant term in the cofactor with, consequently, no constant term in f with

$$K(x,y)=K_{00}+K_{10}x+K_{01}y,$$

$$f(x,y)=f_{10}x+f_{01}y+f_{20}x^2+f_{11}xy+f_{02}y^2.$$

The terms in x^3 and y^3 provide the usual results $K_{10}=2b_{11}$, $K_{01}=2b_{22}$ with f_{20} and f_{02} different from zero. Then the terms in x and y give $f_{10}K_{00}=f_{10}\,a_1$ and $f_{01}K_{00}=f_{01}a_2$ with a first condition $a_1=a_2$ (assuming $f_{10}\neq 0$ and $f_{01}\neq 0$). However, we have found that this condition is sufficient to provide the invariant II. The existence of a conic as an invariant curve implies a second condition. Obtaining an invariant with this conic and the two straight lines $x=0$, $y=0$ does not present any interest since we can get an invariant with only the first condition. However, could it be that we recover a first integral? Pushing the computation we obtain for the conic the following relations (in addition to $a_1=a_2=a$):

$$f_{10}=(a/b_{11})f_{20}, \quad f_{01}=(a/b_{22})f_{02},$$

$$f_{20}=(b_{21}-b_{11})/[2(b_{22}-b_{12})]f_{11},$$

$$f_{02}=(b_{12}-b_{22})/[2(b_{11}-b_{21})]f_{11}.$$

The second condition comes from the identification of terms in x,y. We get in addition to $r_{12}=0$, the relation

$$3b_{11}b_{22}+b_{12}b_{21}-2b_{11}b_{12}-2b_{22}b_{21}=0, \tag{25}$$

which is the interesting one. Now the three cofactors are

$$a+b_{11}x+b_{12}y, \quad a+b_{21}x+b_{22}y, \quad a+2b_{11}x+2b_{22}y,$$

and we obtain a first integral if the determinant of the matrix

$$\begin{pmatrix} 1 & 1 & 1 \\ b_{11} & b_{21} & 2b_{11} \\ b_{12} & b_{22} & 2b_{22} \end{pmatrix}$$

cancels, but this gives again (25) which together with $a_1=a_2$ provide the two conditions needed to obtain a first integral. If we assume that one of the coefficients, say f_{01}, is zero, then $K_{00}=a_1$ and the cancellation of the terms in x^2 and y^2 gives, respectively,

$$a_1 f_{20}=b_{11}f_{10} \ \text{ and } \ a_1=2a_2. \tag{26}$$

Finally looking at the terms in xy^2, x^2y and xy we obtain

$$f_{11}=2f_{02}(b_{11}-b_{21})/(b_{12}-b_{22}), \tag{27}$$

$$f_{11}=2f_{20}(b_{22}-b_{12})/(b_{21}-b_{11}), \tag{28}$$

$$f_{11}=(2b_{22}-b_{12})f_{10}/a_2. \tag{29}$$

Equations (28) and (29) and the first of (26) give the second condition, the first being $a_1=2a_2$,

$$b_{21}(2b_{22}-b_{12})-b_{11}(3b_{22}-2b_{12})=0.$$

The following theorem recapitulates the five cases obtained with a conic as algebraic solution in addition to the two straight lines $f_1=x, f_2=y$. We note that a trivial interchange between x and y, a_1 and a_2, b_{11} and b_{22}, b_{12} and b_{21}, give three other invariants in cases (a), (b), and (d) while cases (c) and (e) are invariant under this interchange.

Theorem 2: *Let $f_1=x=0$ and $f_2=y=0$. If a LVS has a third algebraic solution $f_3=0$ of degree 2, then modulus the symmetry* $(x,y,b_{11},b_{12},a_1,b_{21},b_{22},a_2)$

TABLE III. Invariant conditions of Theorem 2.

Statement	Condition 1	Condition 2
a	$b_{22}-2b_{12}=0$	$(2a_1+a_2)b_{11}-a_1b_{21}=0$
b	$b_{12}+b_{22}=0$	$(2a_1+a_2)b_{11}-a_1b_{21}=0$
c	$(a_1+2a_2)b_{22}-b_{12}a_2=0$	$(2a_1+a_2)b_{11}-a_1b_{21}=0$

$\rightarrow(y,x,b_{22},b_{21},a_2,b_{12},b_{11},a_1)$, *and under the conditions given in Table III, a Darboux invariant* $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}e^{st}$ *and an integrating factor* $f_1^{\lambda_1}f_2^{\lambda_2}f_3^{\lambda_3}$ *can be found having the following values for* f_3 *and the exponents* μ_i,λ_i:

(a) If $a_1a_2b_{11}\neq 0$, *then*

$$f_3=\left(1+\frac{b_{11}}{a_1}x\right)^2+\frac{b_{22}}{a_2}y,$$

$$\mu_1=-s/a_1,\quad \mu_2=0,\quad \mu_3=s/2a_1,$$

$$\lambda_1=-2,\quad \lambda_2=(a_1-a_2)/a_2,\quad \lambda_3=-(2a_1+a_2)/(2a_2).$$

(b) If $a_1(a_1+a_2)b_{11}\neq 0$, *then*

$$f_3=\left(1+\frac{b_{11}}{a_1}x\right)^2+2\frac{b_{11}b_{22}}{a_1(a_1+a_2)}xy,$$

$$\mu_1=\mu_2=-s/(a_1+a_2),\quad \mu_3=(3a_1+a_2)s/2a_1(a_1+a_2),$$

$$\lambda_1=-a_1/(a_1+a_2),\quad \lambda_2=-(2a_1+a_2)/(a_1+a_2),\quad \lambda_3=(a_1-a_2)/[2(a_1+a_2)].$$

(c) If $a_1a_2b_{11}\neq 0$, *then*

$$f_3=\left(1+\frac{b_{11}}{a_1}x+\frac{b_{22}}{a_2}y\right)^2-4\frac{b_{11}b_{22}}{a_1a_2}xy,$$

$$\mu_1=-s/(2a_1),\quad \mu_2=-s/(2a_2),\quad \mu_3=(a_1+a_2)s/(2a_1a_2),$$

$$\lambda_1=-1,\quad \lambda_2=-1,\quad \lambda_3=-1/2.$$

(d) If $a_1b_{11}(2b_{22}-b_{12})\neq 0$, *then*

$$f_3=a_1b_{11}x+[b_{11}x+(2b_{22}-b_{12})y]^2,$$

$$\mu_1=2b_{22}s/a_1(b_{12}-2b_{22}),\quad \mu_2=2s/a_1,\quad \mu_3=2(b_{22}-b_{12})s/a_1(b_{12}-2b_{22}),$$

$$\lambda_1=(b_{22}-b_{12})/(b_{12}-2b_{22}),\quad \lambda_2=-2,\quad \lambda_3=b_{12}/[2(b_{12}-2b_{22})].$$

(e) Finally, a first integral $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}$ *exists if* $a_1b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$. *Then*

$$f_3=a_1[b_{22}(b_{21}-b_{11})^2x+b_{11}(b_{12}-b_{22})^2y]+b_{11}b_{22}[(b_{21}-b_{11})x-(b_{12}-b_{22})y]^2,$$

$$\mu_1=b_{21}-2b_{11},\quad \mu_2=b_{11},\quad \mu_3=b_{11}-b_{21}.$$

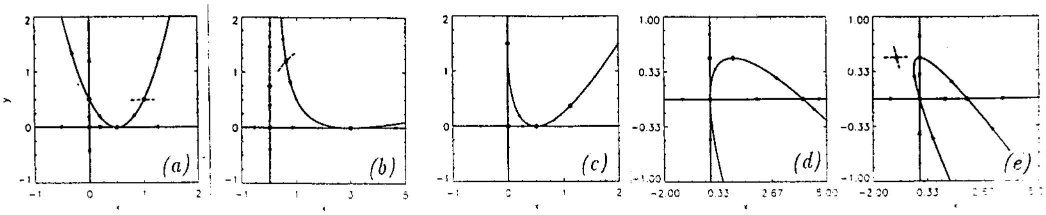

FIG. 1. Typical phase portraits for the LVS having invariants formed with a conic.

The qualitative picture of the phase portrait at finite distance from the origin for each statement of Theorem 2 is given in Fig. 1.

IV. THE COMPLEX QUADRATIC SYSTEM

The LVS are a particular case of the *quadratic systems*. Its most general form is

$$\dot{x}=\frac{dx}{dt}=k_1+a_{11}x+a_{12}y+b_{11}x^2+b_{12}xy+c_1y^2,$$
$$\dot{y}=\frac{dy}{dt}=k_2+a_{21}x+a_{22}y+b_{21}xy+b_{22}y^2+c_2x^2, \tag{30}$$

where the coefficients and the variables x,y are complex, but the independent variable t is real. Here we are going to consider a canonical version of (30), which is the result first, of a translation of the origin eliminating the constant terms k_1 and k_2,

$$x=\overline{x}+m_1, \quad y=\overline{y}+m_2, \tag{31}$$

and second, of a linear transformation

$$x=\alpha_{11}\overline{x}+\alpha_{12}\overline{y}, \quad y=\alpha_{21}\overline{x}+\alpha_{22}\overline{y}, \tag{32}$$

to eliminate the terms c_1y^2 and c_2x^2 in (30). Since the linear transformations (31) and (32) do not introduce higher order terms, we arrive at a new system with the same form as (30) (with of course $k_1=k_2=0$) but with all the terms in overbar variables. Of interest are

$$\overline{c_1}=-\alpha_{12}^3c_2+\alpha_{12}^2\alpha_{22}(b_{11}-b_{21})+\alpha_{12}\alpha_{22}^2(b_{12}-b_{22})+\alpha_{22}^3c_1,$$
$$\overline{c_2}=\alpha_{11}^3c_2-\alpha_{11}^2\alpha_{21}(b_{11}-b_{21})-\alpha_{11}\alpha_{21}^2(b_{12}-b_{22})-\alpha_{21}^3c_1.$$

Introducing

$$l=\frac{\alpha_{12}}{\alpha_{22}}, \quad m=\frac{\alpha_{11}}{\alpha_{21}}, \tag{33}$$

it is easily checked that the two equations $\overline{c_1}=0$ and $\overline{c_2}=0$ coincide and write

$$c_2X^3+(b_{21}-b_{11})X^2+(b_{22}-b_{12})X-c_1=0. \tag{34}$$

In (34) we must take for l and m two different roots, otherwise $\alpha_{11}\alpha_{22}-\alpha_{12}\alpha_{21}=0$ and the linear transformation becomes degenerate. The transformation is nondegenerate if we take different roots among the three roots of (34) for l and m. Note at this point that when two roots are complex conjugate, the resulting complex quadratic system has complex coefficients, without modifying the generality of our subsequent study. Two coefficients (for example α_{11} and α_{22}) are still arbitrary and one could hope to be chosen in order to diagonalize the linear terms. If that were possible, we could reduce the quadratic system to the LVS. To see the impossibility we use (32) to diagonalize the linear terms. We obtain a similar result, namely, that l and m, as given by (33), are the two different roots of the second degree equation

$$a_{21}X^2+(a_{22}-a_{11})X-a_{12}=0. \tag{35}$$

Of course the same l and m cannot be simultaneously the roots of (34) and (35). Excluding the case of a double root we can say that the quadratic system becomes, without loss of generality

$$\begin{aligned}\dot{x}&=a_{11}x+a_{12}y+b_{11}x^2+b_{12}xy,\\ \dot{y}&=a_{21}x+a_{22}y+b_{21}xy+b_{22}y^2,\end{aligned} \tag{36}$$

where we have, once again, dropped the over-bar on the variables. The only—but essential—difference with the LVS is the presence of the off-diagonal terms $a_{12}y$ and $a_{21}x$. It is clear that the above transformation, can in general, generate complex coefficients. For this reason system (36) is called *complex quadratic system*, which in short will be called here QS.

The search for invariant straight lines is quite similar to the one given above for the LVS. To begin with we look for a (complex) straight line going through the origin, i.e.,

$$f(x,y)=f_{10}x+f_{01}y, \quad K(x,y)=K_{00}+K_{10}x+K_{01}y,$$

where we suppose first that f_{10} and f_{01} are different from zero. The terms in x^2 and y^2 in (3) gives $K_{10}=b_{11}$ and $K_{01}=b_{22}$. The terms in xy, x, and y give, respectively,

$$f_{10}(b_{22}-b_{12})+f_{01}(b_{11}-b_{21})=0, \tag{37}$$

$$f_{10}(a_{11}-K_{00})+f_{01}a_{21}=0, \quad f_{10}a_{12}+f_{01}(a_{22}-K_{00})=0. \tag{38}$$

If we suppose $b_{21}\neq b_{11}$ and $b_{12}\neq b_{22}$, we deduce f_{10}/f_{01} from (37) and introducing it in (38) we obtain K_{00} and a condition, the values of which are given below in **(5)** of Proposition 3. A particularly interesting case is obtained when $b_{12}=b_{22}$ and $b_{21}=b_{11}$. Then (37) is automatically fulfilled and the two Eqs. (38) have a nontrivial solution only in the case of K_{00} being the solution of the equation

$$K_{00}^2-(a_{11}+a_{22})K_{00}+\Delta_a=0, \tag{39}$$

where $\Delta_a=a_{11}a_{22}-a_{12}a_{21}$ and the two roots of K_{00} are the eigenvalues of the matrix (a)

$$(a)=\begin{pmatrix} a_{11} & a_{12}\\ a_{21} & a_{22}\end{pmatrix}. \tag{40}$$

The precise values are given below in **(5′)** and **(5″)** of Proposition 3.

The other general case is obtained with

$$f(x,y)=f_{00}+f_{10}x+f_{01}y, \quad K(x,y)=K_{10}x+K_{01}y.$$

Again the terms in x^2 and y^2 give $K_{10}=b_{11}$ and $K_{01}=b_{22}$ (assuming $f_{00},f_{10},f_{01}\neq 0$). The terms in x and y give

$$f_{10}a_{11}+f_{01}a_{21}=f_{00}b_{11}, \quad f_{10}a_{12}+f_{01}a_{22}=f_{00}b_{22}. \tag{41}$$

The solution of (41) give f_{10} and f_{01} which introduced in (37) provides a condition (case **(6)** of Proposition 3).

As in the LVS we must also consider cases where one of f_{10} or f_{01} is equal to zero. In fact we recuperate the two axes and the two parallel to the axes given in Table I (under the numbers 1, 2, 3, and 4) with conditions differently written. Now these straight lines and especially 3 and 4, are more interesting. In the LVS two conditions were needed ($b_{12}=b_{21}=0$), resulting in a decoupling of the two equations, while now, it is a relation between four coefficients (a_{12}, a_{11}, b_{12}, and b_{11}) or (a_{21}, a_{22}, b_{21}, and b_{22}) which are needed. Proposition 3 recapitulates the eight different invariant straight lines, their cofactors, and the conditions for their existence.

Proposition 3: *A QS has a linear algebraic solution* $f=0$ with cofactor K in the following cases:

(1) *If* $a_{12}=0$, *then* $f=x$ *and* $K=a_{11}+b_{11}x+b_{12}y$.
(2) *If* $a_{21}=0$, *then* $f=y$ *and* $K=a_{22}+b_{21}x+b_{22}y$.
(3) *If* $a_{11}b_{11}\neq 0$ *and* $a_{12}=a_{11}b_{12}/b_{11}$, *then* $f=a_{11}+b_{11}x$ *and* $K=b_{11}x+b_{12}y$.
(4) *If* $a_{22}b_{22}\neq 0$ *and* $a_{21}=a_{22}b_{21}/b_{22}$, *then* $f=a_{22}+b_{22}y$ *and* $K=b_{21}x+b_{22}y$.
(5) *If* $(b_{21}-b_{11})(b_{12}-b_{22})\neq 0$ *and* $r_1\equiv(b_{12}-b_{22})(b_{21}-b_{11})(a_{11}-a_{22})+a_{12}(b_{21}-b_{11})^2-a_{21}(b_{12}-b_{22})^2=0$, *then* $f=(b_{21}-b_{11})x+(b_{22}-b_{12})y$ *and* $K=a_{11}-a_{21}(b_{12}-b_{22})/(b_{21}-b_{11})+b_{11}x+b_{22}y$.
(5′) *If* $b_{12}=b_{22}$ *and* $b_{21}=b_{11}$, *then* $f=a_{21}x+(K_{00}^{[1]}-a_{11})y$ *and* $K=K_{00}^{[1]}+b_{11}x+b_{22}y$, *where* $K_{00}^{[1]}$ *is the first root of (39), which writes* $(a_{11}+a_{22})/2+[(a_{11}-a_{22})^2+4a_{12}a_{21}]^{1/2}/2$.
(5″) *If* $b_{12}=b_{22}$ *and* $b_{21}=b_{11}$, *then* $f=a_{12}y+(K_{00}^{[2]}-a_{22})x$ *and* $K=K_{00}^{[2]}+b_{11}x+b_{22}y$, *where* $K_{00}^{[2]}$ *is the second root of (39), which writes* $(a_{11}+a_{22})/2-[(a_{11}-a_{22})^2+4a_{12}a_{21}]^{1/2}/2$.
(6) *If* $b_{11}b_{22}(b_{21}-b_{11})(b_{12}-b_{22})(a_{11}a_{22}-a_{12}a_{21})\neq 0$ *and* $r_2\equiv(a_{12}b_{11}-a_{11}b_{22})(b_{21}-b_{11})+(a_{21}b_{22}-a_{22}b_{11})(b_{12}-b_{22})=0$, *then* $f=a_{11}a_{22}-a_{12}a_{21}+(a_{22}b_{11}-a_{21}b_{22})x+(a_{11}b_{22}-a_{12}b_{11})y$ *and* $K=b_{11}x+b_{22}y$.

A comment is in order about the two invariant straight lines **(5’)** and **(5’’)**. They do not contain any b_{ij} and are the support of the two eigenvectors of the matrix (a). Moreover it is easily shown that in this case ($b_{12}=b_{22}, b_{21}=b_{11}$) we have only three equilibrium points at finite distance from the origin: the origin, one on **(5′)** and the last one on **(5″)**. Moreover the invariant straight line **(6)** goes through these two last points.

Now with these eight ‘‘bricks’’ we are going to build the invariants, first integrals and integrating factors. Let us begin with the obtention of Darboux invariants. Getting q invariant straight lines labeled with i going from 1 to q, we obtain the identity

$$\sum_{i=1}^{q}\mu_i(K_{00i}+K_{10i}x+K_{01i}y)+s=0,$$

i.e., two homogeneous linear equations in μ_i,

$$\sum_{i=1}^{q}K_{10i}\mu_i=0,\quad \sum_{i=1}^{q}K_{01i}\mu_i=0, \tag{42}$$

and the inhomogeneous equation

$$\sum_{i=1}^{q}K_{00i}\mu_i+s=0. \tag{43}$$

Since s is at our disposal, let us leave for a moment (43) which will simply fix s. For the two Eqs. (42) to be fulfilled we need either three straight lines (with 3 μ_i) or two straight lines, but then the determinant of the system must be zero. Since one straight line implies one condition we need in principle three conditions. However, one can find exceptional cases with two straight lines having a determinant automatically equal to zero. For example, the cofactors of straight lines **(5)** and **(6)** have the same K_{10i} and K_{01i} (respectively, b_{11} and b_{22}) and we get an invariant with only two straight lines and two conditions.

Concerning the integrating factor, the things are somewhat similar except that now s is replaced by $\mathrm{div}(P,Q)$, with $\mathrm{div}(P,Q)=A_0+A_1x+A_2y$. We have now three inhomogeneous equations with three conditions.

A priori the most expensive in conditions should be the first integral. Since we get (42) and (43) and this time with $s=0$, we have a system of three homogeneous linear equations. The identification of the determinant plus the obtention of the three straight lines gives four conditions, but again special cases can be found. For example straight lines **(5′)**, **(5″)** and **(6)** altogether, ask for only two conditions ($b_{12}=b_{22}$ and $b_{21}=b_{11}$). Moreover they all possess the same $K_{10i}=b_{11}$ and $K_{01i}=b_{22}$ in their three cofactors and we get a first integral with only two conditions. Consequently each case must be separately examined.

In the rest of the paper we use the following notation: If a first integral, an integrating factor or a Darboux invariant of a complex QS has been obtained using for instance the algebraic solutions of statements **(5)** and **(6)** of Proposition 3, we only say that the integrable case is **(56)**, etc. We present three types of results.

A. Invariant (56)

It is the invariant built with straight lines **(5)** and **(6)**. The coexistence of straight lines **(5)** and **(6)** implies $r_1=r_2=0$ and a first solution is

$$a_{12}=a_{22}(b_{22}-b_{12})/(b_{11}-b_{21}),\qquad a_{21}=a_{11}(b_{11}-b_{21})/(b_{22}-b_{12}),\tag{44}$$

but it is easily checked that under conditions (44), the straight lines **(5)** and **(6)** are identical (the straight line **(6)** passing also through the origin) with, as a consequence, not enough straight lines to build an invariant. Fortunately another solution is possible with

$$b_{11}(b_{22}-b_{12})+b_{22}(b_{11}-b_{21})=0,\tag{45}$$

$$(a_{11}-a_{22})b_{11}b_{22}-a_{12}b_{11}^2+a_{21}b_{22}^2=0.\tag{46}$$

The cofactors being, respectively, $b_{11}x+b_{22}y+K_{00}=0$ for **(5)** and $b_{11}x+b_{22}y=0$ for **(6)**, the equations write

$$b_{11}(\mu_1+\mu_2)=0,\quad b_{22}(\mu_1+\mu_2)=0,\quad K_{00}\mu_1+s=0.$$

Taking $\mu_2=-\mu_1$, we get an invariant with only two conditions, (45) and (46). Now this result must be compared with the two conditions given for that system in Ref. 11. For the passing of the Painlevé test as given in Ref. 11, (45) is the index condition (4.31) and (46) is the compatibility condition (4.33). Indeed with, for example, $\mu_1=1$ and $\mu_2=-1$ we obtain an analytical invariant in agreement with the conclusion obtained in Ref. 11.

B. Invariant (5′5″) and (5′5″6)

In the case where the invariant is built with **(5′)** and **(5″)** or **(5′)**, **(5″)** and **(6)** we have the two conditions $b_{21}=b_{11}$, $b_{12}=b_{22}$ and the corresponding cofactors are $b_{11}x+b_{22}y+K_{00}^{[1]}$, $b_{11}x+b_{22}y+K_{00}^{[2]}$ and $b_{11}x+b_{22}y$, where $K_{00}^{[1]}$ and $K_{00}^{[2]}$ are the eigenvalues of matrix (a) given by (39). First we search an invariant built only with **(5′)** and **(5″)**. We get $\mu_1+\mu_2=0$, $\mu_1K_{00}^{[1]}+\mu_2K_{00}^{[2]}+s=0$ with, for example, $\mu_1=1$, $\mu_2=-1$ and $s=K_{00}^{[2]}-K_{00}^{[1]}$. The invariant writes

$$I=\frac{a_{21}x+(K_{00}^{[1]}-a_{11})y}{(K_{00}^{[2]}-a_{22})x+a_{12}y}\exp(-\sqrt{(a_{11}-a_{22})^2+4a_{12}a_{21}})t.\tag{47}$$

However, we can have a first integral in addition to (47) without introducing new conditions. For that we build with **(5′)**, **(5″)**, and **(6)** obtaining $\mu_1+\mu_2+\mu_3=0$ and $\mu_1 K_{00}^{[1]}+\mu_2 K_{00}^{[2]}+s=0$. The interesting point is that we get twice the equation $\mu_1+\mu_2+\mu_3=0$. Now taking $\mu_1=K_{00}^{[2]}$ and $\mu_2=-K_{00}^{[1]}$ we obtain $s=0$ (and consequently a first integral). Having a first integral and an invariant the problem is now fully algebraic and, consequently, this system can be completely solved and the integration is as complete as possible. Note, however that this case does not pass the Painlevé test, a clear indication that passing the Painlevé test and getting explicit invariant, first integral or explicit solutions are two different approaches not always connected (although correlated in many cases).

C. Other cases

We exclude cases treated above built with both straight lines **(5)** and **(6)** and cases where $b_{12}=b_{22}$, $b_{21}=b_{11}$. Also we omit those invariants involving only one variable obtained when one equation is decoupled from the other one. As a result, 13 invariants are obtained: 8 build with 3 straight lines, 4 with 2 straight lines and 1 with 1 line. We denote the invariants with the names of the straight lines upon which they have been built. With three straight lines we have

(125), **(236)**, **(345)**, **(146)**, which are the generalization of invariant II of the LVS. **(125)** is LVS ($a_{12}=0$, $a_{21}=0$) with the three straight lines passing through one of the equilibrium point.

(126), **(235)**, **(346)**, **(145)**, which are the generalization of invariant III of the LVS. **(126)** is LVS with three straight lines forming a triangle.

With two straight lines, we have

(12), **(14)**, **(23)**, **(34)**, which are the generalization of the invariant I of the LVS (**(12)** is LVS). These four cases require the third condition $\Delta=0$.

A last case can be found with only one line. Obviously the cofactor must be a constant and the only interesting case is given by the straight line **(5)** with $b_{11}=b_{22}=0$. Taking $f=f_{10}x+f_{01}y$ and $K=K_{00}$ we obtain

$$f_{10}b_{12}+f_{01}b_{21}=0, \tag{48}$$

$$f_{10}(a_{11}-K_{00})+f_{01}a_{21}, \quad f_{10}a_{12}+f_{01}(a_{22}-K_{00})=0, \tag{49}$$

and the invariant is

$$I=(b_{21}x-b_{12}y)\exp[(a_{12}b_{21}-a_{22}b_{12})t/b_{12}], \tag{50}$$

with three conditions

$$b_{11}=b_{22}=0, \quad a_{11}-a_{22}=a_{21}\frac{b_{12}}{b_{21}}-a_{12}\frac{b_{21}}{b_{12}}. \tag{51}$$

which is invariant I in Ref. 11.

It is worth to note that in all cases (including the last one) each invariant straight line goes through two equilibrium points. We have seen also that many cases are generalization of the types I, II, and III of the LVS. One of the most interesting invariants (**(56)** since we need only 2 conditions) splits for the LVS in both invariants II and III. The introduction of the canonical form (36) through transformations (31) and (32) has greatly simplified the problem of expliciting invariants and conditions and has shown the very fundamental connection between LVS and QS. We can establish the following theorem.

Theorem 4: *A complex QS has a first integral, an integrating factor or a Darboux invariant formed by invariant straight lines in the following cases:*

(a) If $b_{11}(2b_{22}-b_{12})-b_{21}b_{22}=0$, $r_2=0$ *and* $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, *then the straight lines* $f_1=b_{11}x+b_{22}y=0$ *and* $f_2=a_{11}a_{22}-a_{12}a_{21}+(a_{22}b_{11}-a_{21}b_{22})x+(a_{11}b_{22}-a_{12}b_{11})y=0$ *are algebraic solutions of the QS with cofactors* $K_1=b_{11}x+b_{22}y+a_{11}+a_{21}b_{22}/b_{11}$ *and* $K_2=b_{11}x+b_{22}y$, *respectively, and* $f_1^{\mu_1}f_2^{\mu_2}e^{st}$ *is a Darboux invariant for*

$\mu_1=-\mu_2$ and $\mu_2=sb_{11}/(a_{21}b_{22}+a_{11}b_{11})$. This corresponds to the integrable case **(56)**.

(b) *If $b_{21}=b_{11}$, $b_{12}=b_{22}$, $a_{11}a_{22}b_{11}b_{22}\neq 0$, and let us call $K_{00}^{[1]}$, $K_{00}^{[2]}$ the eigenvalues of matrix (a), then the straight lines $f_1=a_{21}x+(K_{00}^{[1]}-a_{11})y=0$ and $f_2=(K_{00}^{[2]}-a_{22})x+a_{12}y=0$ are algebraic solutions of the QS with cofactors $K_1=b_{11}x+b_{22}y+K_{00}^{[1]}$ and $K_2=b_{11}x+b_{22}y+K_{00}^{[2]}$, respectively, such that $f_1^{\lambda_1}f_2^{\lambda_2}$ is an integrating factor for $\lambda_1=(a_{11}+a_{22})/(2K_{00}^{[1]}-2K_{00}^{[2]})-3/2$ and $\lambda_2=-(a_{11}+a_{22})/(2K_{00}^{[1]}-2K_{00}^{[2]})-3/2$. Moreover $f_1^{\mu_1}f_2^{\mu_2}e^{st}$ is a Darboux invariant for $\mu_1=-s/(K_{00}^{[1]}-K_{00}^{[2]})$ and $\mu_2=-\mu_1$. This corresponds to the integrable case* **(5′5″)**.

(c) *If $b_{21}=b_{11}$, $b_{12}=b_{22}$, $a_{11}a_{22}b_{11}b_{22}\neq 0$, and let us call $K_{00}^{[1]}$, $K_{00}^{[2]}$ the eigenvalues of matrix (a), then the straight lines $f_1=a_{21}x+(K_{00}^{[1]}-a_{11})y=0$, $f_2=(K_{00}^{[2]}-a_{22})x+a_{12}y=0$ and $f_3=a_{11}a_{22}-a_{12}a_{21}+(a_{22}b_{11}-a_{21}b_{22})x+(a_{11}b_{22}-a_{12}b_{11})y=0$ are algebraic solutions of the QS with cofactors $K_1=b_{11}x+b_{22}y+K_{00}^{[1]}$, $K_2=b_{11}x+b_{22}y+K_{00}^{[2]}$ and $K_3=b_{11}x+b_{22}y$, respectively, and $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}$ is a first integral for $\mu_1=K_{00}^{[2]}$, $\mu_2=-K_{00}^{[1]}$ and $\mu_3=K_{00}^{[1]}-K_{00}^{[2]}$. This corresponds to the integrable case* **(5′5″6)**.

(d) *If $a_{12}=0$, $a_{21}=a_{22}b_{21}/b_{22}$, $r_2=0$* and *$a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, then the straight lines $f_1=y=0$, $f_2=a_{11}+b_{11}x=0$ and $f_3=b_{11}x+(b_{22}-b_{12})y+a_{11}a_{22}=0$ are algebraic solutions of the QS with cofactors $K_1=b_{21}x+b_{22}y+a_{22}$, $K_2=b_{11}x+b_{12}y$ and $K_3=b_{11}x+b_{22}y$, respectively, such that $f_1^{\lambda_1}f_2^{\lambda_2}f_3^{\lambda_3}$ is an integrating factor for $\lambda_1=-(a_{11}+a_{22})/a_{22}$, $\lambda_2=b_{12}/(b_{22}-b_{12})$ and $\lambda_3=a_{11}/a_{22}+b_{22}/(b_{12}-b_{22})$. Moreover, $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}e^{st}$ is a Darboux invariant for $\mu_1=-s/a_{11}$, $\mu_2=sb_{11}/[a_{22}(b_{21}-b_{11})]$ and $\mu_3=s/a_{22}+sb_{12}/[a_{11}(b_{12}-b_{22})]$. This corresponds to the integrable case* **(236)**.

(e) *If $a_{12}=a_{11}b_{12}/b_{11}$, $a_{21}=a_{22}b_{21}/b_{22}$, $r_1=0$, and $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$ then there exist the straight lines $f_1=a_{11}+b_{11}x=0$, $f_2=a_{22}+b_{22}y=0$ and $f_3=a_{22}b_{11}x-a_{11}b_{22}y=0$ which are algebraic solutions of the QS with cofactors $K_1=b_{11}x+b_{12}y$, $K_2=b_{21}x+b_{22}y$, $K_3=b_{11}x+b_{22}y-(b_{12}-b_{22})a_{22}/b_{22}$, respectively, such that $f_1^{\lambda_1}f_2^{\lambda_2}f_3^{\lambda_3}$ is an integrating factor for $\lambda_1=a_{22}b_{11}/[a_{11}(b_{11}-b_{21})]-1$, $\lambda_2=b_{21}/(b_{11}-b_{21})$ and $\lambda_3=b_{11}(a_{11}+a_{22})/[a_{11}(b_{21}-b_{11})]$. Moreover, $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}e^{st}$ is a Darboux invariant of the QS for $\mu_1=-s/a_{22}$, $\mu_2=sb_{22}/[a_{11}(b_{22}-b_{12})]$ and $\mu_3=s/a_{22}+sb_{12}/[a_{11}(b_{12}-b_{22})]$. This corresponds to the integrable case* **(345)**.

(f) *If $a_{12}=0$,$a_{21}=a_{22}b_{21}/b_{22}$, $r_2=0$ and $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, then the straight lines $f_1=x=0$, $f_2=a_{22}+b_{22}y=0$ and $f_3=(b_{11}-b_{21})x+b_{22}y+a_{11}a_{22}=0$ are algebraic solutions of the QS with cofactors $K_1=b_{11}x+b_{12}y+a_{11}$, $K_2=b_{21}x+b_{22}y+a_{22}$ and $K_3=b_{11}x+b_{22}y+a_{11}$, respectively, such that $f_1^{\lambda_1}f_2^{\lambda_2}f_3^{\lambda_3}$ is an integrating factor for $\lambda_1=-(a_{11}+a_{22})/a_{11}$, $\lambda_2=b_{21}/(b_{11}-b_{21})$ and $\lambda_3=b_{11}/(b_{21}-b_{11})+a_{22}/a_{11}$. Moreover, $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}e^{st}$ is a Darboux invariant for $\mu_1=-s/a_{11}$,$\mu_2=sb_{11}/[a_{22}(b_{21}-b_{11})]$ and $\mu_3=sb_{21}/[a_{22}(b_{21}-b_{11})]+s/a_{11}$. This corresponds to the integrable case* **(146)**.

(g) *If $a_{12}=a_{11}b_{12}/b_{11}$, $a_{21}=0$, $r_1=0$ and $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, then the straight lines $f_1=y=0$, $f_2=a_{11}+b_{11}x=0$ and $f_3=(b_{21}-b_{11})x-(b_{12}-b_{22})y=0$ are algebraic solutions of the QS with cofactors $K_1=a_{22}+b_{21}x+b_{22}y$, $K_2=b_{11}x+b_{12}y$ and $K_3=a_{11}+b_{11}x+b_{22}y$, respectively, and $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}$ is a first integral for $\mu_1=b_{22}(a_{11}-a_{22})$,$\mu_2=-a_{11}b_{12}$ and $\mu_3=a_{22}b_{12}$. This corresponds to the integrable case* **(235)**.

(h) *If $a_{11}+a_{22}=0$, $a_{12}=a_{11}b_{12}/b_{11}$, $a_{21}=a_{22}b_{21}/b_{22}$ and $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\Delta\neq 0$, then there exist the straight lines $f_1=a_{11}+b_{11}x=0$, $f_2=a_{22}+b_{22}y=0$ and $f_3=a_{11}\Delta-b_{11}b_{22}(b_{21}-b_{11})x+b_{22}b_{11}(b_{12}-b_{22})y=0$ which are algebraic solutions of the QS with the cofactors $K_1=b_{11}x+b_{12}y$, $K_2=b_{21}x+b_{22}y$, $K_3=b_{11}x+b_{22}y$, such that $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}$ is a first integral for $\mu_1=b_{22}(b_{21}-b_{11})$,$\mu_2=b_{11}(b_{12}-b_{22})$ and $\mu_3=\Delta$. This corresponds to the integrable case* **(346)**.

(i) *If $a_{12}=0$, $a_{21}=a_{22}b_{21}/b_{22}$, $r_1=0$ and $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, then the straight lines $f_1=x=0$, $f_2=a_{22}+b_{22}y=0$ and $f_3=(b_{21}-b_{11})x-(b_{12}-b_{22})y=0$ are alge-*

braic solutions of the QS with cofactors $K_1=a_{11}+b_{11}x+b_{12}y$, $K_2=b_{21}x+b_{22}y$ *and* $K_3=a_{22}+b_{11}x+b_{22}y$, *respectively, and* $f_1^{\mu_1}f_2^{\mu_2}f_3^{\mu_3}$ *is a first integral for* $\mu_1=-a_{22}b_{21}$, $\mu_2=b_{11}(a_{22}-a_{11})$ *and* $\mu_3=a_{11}b_{21}$. *This corresponds to the integrable case* **(145)**.

(j) *If* $a_{12}=0$, $a_{21}=a_{22}b_{21}/b_{22}$ *and* $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$, *then the straight lines* $f_1=x=0$ *and* $f_2=a_{22}+b_{22}y=0$ *are algebraic solutions of the QS with cofactors* $K_1=b_{11}x+b_{12}y+a_{11}$ *and* $K_2=b_{21}x+b_{22}y$, *respectively, such that with the additional condition* $r_1=0$, $f_1^{\lambda_1}f_2^{\lambda_2}$ *is an integrating factor for* $\lambda_1=-(a_{11}+a_{22})/a_{11}$ *and* $\lambda_2=(a_{22}b_{12}-2a_{11}b_{22})/(a_{11}b_{22})$. *On the other hand if the additional condition is* $\Delta=0$ *then* $f_1^{\mu_1}f_2^{\mu_2}e^{st}$ *is a Darboux invariant for* $\mu_1=-s/a_{11}$ *and* $\mu_2=sb_{12}/(a_{11}b_{22})$. *This corresponds to the integrable case* **(14)**.

(k) *If* $a_{12}=0$, $a_{21}=a_{22}b_{21}/b_{22}$, $\Delta=0$ *and* $a_{11}a_{22}b_{11}b_{22}(b_{12}-b_{22})(b_{21}-b_{11})\neq 0$ *then the straight lines* $f_1=y=0$ *and* $f_2=a_{11}+b_{11}x=0$ *are algebraic solutions of the QS with cofactors* $K_1=b_{21}x+b_{22}y+a_{22}$ *and* $K_2=b_{11}x+b_{12}y$, *respectively, such that with the additional condition* $r_1=0$, $f_1^{\lambda_1}f_2^{\lambda_2}$ *is an integrating factor for* $\lambda_2=-(a_{11}+a_{22})/a_{22}$ *and* $\lambda_1=(a_{11}b_{21}-2a_{22}b_{11})/(a_{22}b_{11})$. *On the other hand if the additional condition is* $\Delta=0$ *then* $f_1^{\mu_1}f_2^{\mu_2}e^{st}$ *is a Darboux invariant for* $\mu_1=-s/a_{22}$ *and* $\mu_2=sb_{22}/(a_{22}b_{12})$. *This corresponds to the integrable case* **(23)**.

A qualitative picture of the phase space portrait at a finite distance from the origin for each of the statements of Theorem 4 appears in Fig. 2. The figures concerning the invariants **(126)**, **(145)**, **(235)**, and **(346)** deserve a special comment. They suggest that the equilibrium point, which is not a summit of the triangle formed by the three straight lines is a center. Indeed the four cases are first integrals and if we show that this equilibrium point is a linear center, the possession of this first integral will confer a center status.

To check this linear center property we will have to discuss the real or complex nature of the roots of the second degree equation obtained by linearization of the system (36). While the relation between the coefficients of the QS, needed for the existence of the invariants or first integral remains equally valid for complex or real coefficients of (36), we will suppose real in this paragraph all the coefficients of (36).

Let x_0 and y_0 be the coordinates of an equilibrium point. The linearized equation for δx and δy with $x=x_0+\delta x$ and $y=y_0+\delta y$ writes

$$\begin{aligned}\dot{\delta x}&=(a_{11}+2b_{11}x_0+b_{12}y_0)\,\delta x+(a_{12}+b_{12}x_0)\,\delta y,\\ \dot{\delta y}&=(a_{21}+b_{21}y_0)\,\delta x+(a_{22}+2b_{22}y_0+b_{21}x_0)\,\delta y,\end{aligned}\tag{52}$$

which will describe a linear center if the two eigenvalues of the matrix are purely imaginary. As a consequence, two relations are necessary. The first concerns the trace of the matrix of the system. We must have

$$a_{11}+a_{22}+b_{12}y_0+b_{21}x_0+2(b_{11}x_0+b_{22}y_0)=0,\tag{53}$$

relation which can be written, taking into account the fact that x_0,y_0 are the coordinates of an equilibrium point

$$a_{12}(y_0/x_0)+a_{21}(x_0/y_0)=b_{11}x_0+b_{22}y_0.\tag{54}$$

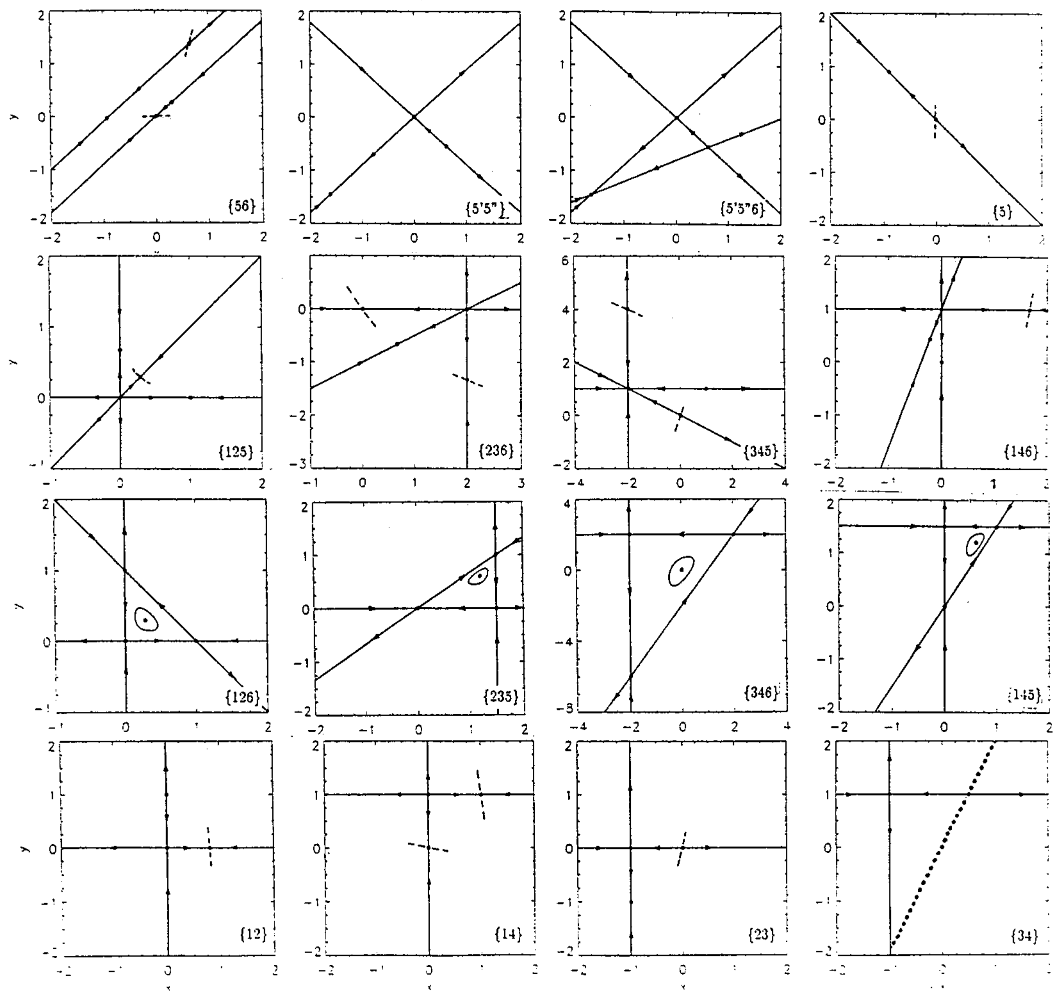

FIG. 2. Typical phase portraits for the QS having invariants or first integrals formed with straight lines.

The second relation is an inequality concerning the sign of the term under the square root to obtain a purely imaginary root. Taking into account (53), the eigenvalues are

$$\lambda_{1,2}=\sqrt{-D}, \tag{55}$$

where

$$D=\begin{vmatrix} a_{11}+2b_{11}x_0+b_{12}y_0, & a_{12}+b_{12}x_0 \\ a_{21}+b_{21}y_0, & a_{22}+2b_{22}y_0+b_{21}x_0 \end{vmatrix}$$

and the inequality to obtain a linear center is $D>0$. Now we show that the four cases mentioned above fulfill (54). We begin with **(346)** where the origin is the candidate to the status of a center. With $x_0=y_0=0$, (53) becomes $a_{11}+a_{22}=0$, which is precisely one of the conditions needed to obtain a first integral. If $a_{11}a_{22}-a_{12}a_{21}>0$ the origin is consequently a center. For **(126)** we are in the LVS case ($a_{12}=a_{21}=0$). Computing x_0 and y_0 and introducing it in (54) we check that this last relation is fulfilled. For values of the parameters such that $D>0$ this equilibrium point will be a center. Finally we consider **(145)** (**(235)** being symmetric). Taking into account the three conditions and doing a little algebra, we obtain for x_0 and y_0,

$$x_0=-a_{11}b_{22}/\Delta, \quad y_0=a_{11}b_{21}/\Delta. \tag{56}$$

Introducing (56) into (53), we see that this last relation is fulfilled and we have just to check that $D>0$.

Consequently the four equilibrium points of figures **(126)**, **(235)**, **(346)**, and **(145)** fulfill the relations needed to have the status of a center and are, indeed, centers if $D>0$.

V. CONCLUSION

Although some of the results presented here have been obtained before, we see that the Darboux method is more systematic and simplifies the obtention and resolution of the resulting algebraic—but nonlinear—equations. These equations are originated from the identification of the different terms after the introduction of ansatzes on the expression of the algebraic solutions (also called invariant curves). Each of these algebraic solutions brings its own conditions to exist. For bidimensional quadratic systems, three algebraic solutions are needed. The simplest are straight lines, each bringing one condition in the QS case. We need altogether three conditions except essentially in two cases. The LVS is the special quadratic system with $a_{12}=a_{21}=0$ and, consequently only one more condition is needed. These algebraic solutions are invariant straight lines connecting two equilibrium points. For the LVS the two axes provide the two first algebraic solutions and if the third one is a conic we need two conditions. The invariant conics also connect two equilibrium points. Both an increase of the dimensionality and the degree of the system increase quickly the number of needed conditions.

(Received 11 August 1998; accepted for publication 19 November 1998)

From the existing methods of singularity analysis only, we derive the two equations which define the Bäcklund transformation of the Tzitzéica equation. This is achieved by defining a truncation in the spirit of the approach of Weiss *et al.*, so as to preserve the Lorentz invariance of the Tzitzéica equation. If one assumes a third-order scattering problem, this truncation admits a unique solution, thus leading to a matrix Lax pair and a Darboux transformation. In order to obtain the Bäcklund transformation (BT), which is the main new result of this paper, one represents the Lax pair by an equivalent two-component Riccati pseudopotential. This yields two different BTs; the first one is a BT for the Hirota–Satsuma equation, while the second one is a BT for the Tzitzéica equation. One of the two equations defining the BT is the fifth ordinary differential equation of Gambier.

I. INTRODUCTION

This paper is a follow-up of a previous article,[1] hereafter referred to as paper I, in which was defined a scheme, based on singularity analysis only, in order to find the auto-Bäcklund transformation (BT) of a given partial differential equation (PDE) when one exists. This general scheme was designed so as to also succeed when the *singular manifold method* of Weiss *et al.*[2,3] and its later improvements, see references in paper I, fail to provide this auto-BT.

After the Kaup–Kupershmidt equation, we consider the Tzitzéica equation

$$E(u) \equiv u_{xt} + \alpha e^{u} + a_2 e^{-2u} = 0, \quad \alpha a_2 \neq 0, \quad (\alpha, a_2)\,\text{const.} \tag{1}$$

Its invariance under the permutation (Lorentz transformation)

$$\mathcal{P}: (\partial_x, \partial_t) \rightarrow (\partial_t, \partial_x), \tag{2}$$

which does not exist for evolution equations like the one considered in paper I, must be present in all the expected results, and this will require some extra care. For the definitions, notation and procedure, we refer to paper I. This equation appears in several domains of mathematics and physics, which we summarize below.

(1) It was originally found in the field of geometry in 1907 by Georges Tzitzéica[4] who looked for surfaces on which the total curvature at each point is proportional to the fourth power of the distance from a fixed point to the tangent plane. One of the beautiful properties of this equation is the periodicity of its Laplace sequence,[5] with a period three. In the opinion of Tzitzéica however (Ref. 6, p. 255), ‘‘...l'intégration de l'équation (1) ...est très difficile.’’

(2) In one-dimensional ideal gas dynamics, when the equation of state is

$$P=\frac{\rho^3}{M^4}, \tag{3}$$

in which P, ρ, M denote the pressure, density and Lagrangian mass, the system of Euler's equations is reducible[7,8] to the Tzitzéica equation. This equation of state is identical, *mutatis mutandis*, to the geometrical definition of Tzitzéica. The geometrical link with the equation for affine spheres[6] has been recently rederived in the context of gas dynamics.[9]

(3) In magnetohydrodynamics, there exits a $2+1$-dimensional system which, after elimination of the magnetic field, becomes

$$r_x+s_y=0, \quad r_t-r_{xxx}+(rs)_x=0, \tag{4}$$

in which (r,s) are the components of the velocity on the x and y axes. The stationary reduction (independence on t) is equivalent to the so-called Hirota–Satsuma PDE,[10] which we define as

$$\mathrm{HS}(w)\equiv[w_{xxt}+(6/a)w_x w_t]_x=0, \quad a\neq 0 \tag{5}$$

[notation is $r=(6/a)w_y$, $s=-(6/a)w_x$, with a constant and y renamed t]. Its potential form

$$\mathrm{pHS}(w)\equiv w_{xxt}+(6/a)w_x w_t+F(t)=0, \quad a\neq 0, \tag{6}$$

in the particular case $F(t)=0$ (this restriction is important, see Sec. II), has a one-to-one correspondence[11] with the Tzitzéica equation, obtained by elimination of a_2 in Eq. (1)

$$\left(F(t)=0, e^u=\frac{2}{a\alpha}w_t\right)\Rightarrow\left(e^{-2u}(e^{2u}E(u))_x=\left(\frac{\mathrm{pHS}(w)}{w_t}\right)_t\right). \tag{7}$$

(4) The search for all equations of the type

$$u_{xt}+f(u)=0 \tag{8}$$

which admit an infinite number of integrals of motion led Dodd and Bullough[12,13] to the following finite list of admissible functions f (up to linear transformations on u): 0 (d'Alembert), u, e^u (Liouville), $\sin u$ or $\sinh u$ (sine- or shine-Gordon, not different in the complex plane), and $e^u - e^{-2u}$ (Tzitzéica). This infinity of integrals of motion for (1) was later found by Zhiber and Shabat.[14]

(5) The search of separating solutions of (8), i.e., of functions φ, X,T of one variable such that

$$u=\varphi(X(x)T(t)) \tag{9}$$

satisfies (8), gives rise[15] to a finite list of admissible f including the above mentioned list.

(6) In the nonlinear SL(3,R) σ-model

$$\mathbf{r}_{xt}+\rho^{-1}(\mathbf{r}_{xt},\mathbf{r}_x,\mathbf{r}_t)^{1/2}\mathbf{r}=0, \quad \rho \ \text{ constant}, \tag{10}$$

$$(\mathbf{r}_{xx},\mathbf{r}_x,\mathbf{r}_t)=(\mathbf{r}_{tt},\mathbf{r}_x,\mathbf{r}_t)=0, \tag{11}$$

in which boldface characters denote vectors in R^3, the field $u=(1/2)\mathrm{Log}(\mathbf{r}_{xt},\mathbf{r}_x,\mathbf{r}_t)$ satisfies the Tzitzéica equation.[16]

(7) Equation (1) is a reduction of the two-dimensional Toda lattice.[17]

The purpose of this paper is to derive all the integrability results of (1) (Lax pair, Darboux transformation and Bäcklund transformation) from singularity analysis *only*.

We handle at the same time all the equations of the type considered by Zhiber and Shabat:[14]

$$E(u) \equiv u_{xt} + \alpha e^{u} + a_1 e^{-u} + a_2 e^{-2u} = 0, \quad \alpha \neq 0, \tag{12}$$

i.e., the Liouville equation $a_1 = a_2 = 0$, the sine-Gordon equation $(a_1 \neq 0,\ a_2 = 0)$ and the Tzitzéica equation $(a_1 = 0,\ a_2 \neq 0)$. The results to be found are the auto-BT of each equation, and for Liouville the hetero-BT to the d'Alembert equation. We use the notation of Ref. 18.

The paper is organized as follows. In Sec. II, we recall the existing results, whether obtained from singularity analysis or from other methods, and we point out what is missing. In Sec. III, we recall the singularity structure of the Tzitzéica PDE and argue that, just like the Kaup–Kupershmidt equation in paper I, it possesses only one relevant family of movable singularities. In the next two sections, we successively choose the order two, then three, for the order of the unknown scattering problem. In Sec. IV, we thus give a very short singularity-based derivation of the hetero-BT between Liouville and d'Alembert equations; we also give a unified derivation of the auto-BT of the Liouville and sine-Gordon equations. In Sec. V, we assume an unknown Lax pair invariant under the Lorentz transformation (2) and define it in its equivalent projective Riccati representation; the truncation which it defines admits a unique solution, thus providing a matrix Lax pair and a Darboux transformation. The last section is divided into two subsections, each corresponding to one of the two possible eliminations leading to a Bäcklund transformation. In Sec. VI A, the first elimination provides the BT of the Hirota–Satsuma PDE (5). In Sec. VI B, the second elimination provides the expected result, namely the BT of the Tzitzéica equation (1). We write this BT as one second-order nonlinear ODE and one first-order PDE, which are both linearizable. The ODE part

$$y'' + 3yy' + y^3 + ry + q = 0, \tag{13}$$

in which q and r depend on a solution of (1) and on the Bäcklund parameter λ, belongs to the fifth equivalence class of Gambier.[19]

II. PREVIOUS RESULTS

Two Lax pairs of (1) are known. The first one has been given by Tzitzéica,[20]

$$-\tau_{xx} + U_x \tau_x + \sqrt{a_2}\lambda e^{-U} \tau_t = 0, \tag{14}$$

$$-\tau_{tt} + U_t \tau_t + \sqrt{a_2}\lambda^{-1} e^{-U} \tau_x = 0, \tag{15}$$

$$-\tau_{xt} - \alpha e^{U} \tau = 0, \tag{16}$$

in which the arbitrary complex constant λ is the spectral parameter [this ''pair'' is in fact a set of three scalar equations in the entire function τ for which the three commutators vanish whenever these three equations hold and U satisfies (1)]. The third-order traceless matrix Lax pair

$$L = \begin{pmatrix} -U_x/2 & 0 & -\sqrt{\alpha}\lambda^{-1} e^{U/2} \\ -\sqrt{a_2} e^{-U} & U_x/2 & 0 \\ 0 & \sqrt{\alpha}\lambda e^{U/2} & 0 \end{pmatrix}, \tag{17}$$

$$M = \begin{pmatrix} U_t/2 & -\sqrt{a_2} e^{-U} & 0 \\ 0 & -U_t/2 & -\sqrt{\alpha}\lambda^{-1} e^{U/2} \\ \sqrt{\alpha}\lambda e^{U/2} & 0 & 0 \end{pmatrix}, \tag{18}$$

$$L_t - M_x + [L, M] = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} E(U) \tag{19}$$

has been established by Mikhailov.[17]

Note that the system (14)–(16) is invariant under the involution[21,8]

$$(\tau,e^U,\lambda)\to\left(\frac{1}{\tau},-e^U-\frac{2}{\alpha}\frac{\tau_x\tau_t}{\tau^2},-\lambda\right), \tag{20}$$

which defines the Darboux transformation

$$e^u=-e^U-\frac{2}{\alpha}\frac{\tau_x\tau_t}{\tau^2} \tag{21}$$

between two different solutions u and U of (1).

Both the prolongation method[22] and the conditional symmetries method[23] allow us to retrieve the Lax pair of Mikhailov in its equivalent projective Riccati representation.

The Bäcklund transformation, according to the classical definition recalled in paper I (see also the fifth step of Sec. II in that paper), is a set of two PDEs in two solutions u and U of (1) such that the PDE in U resulting from the elimination of u is equivalent to $E(U)=0$.

It is worthwhile to underline the fact that the BT is *not* a couple made of a Lax pair and a Darboux transformation; it is the explicit result of the elimination of the solution of the Lax pair between them.

Such a BT has never been obtained for the Tzitzéica equation. All the classical authors (Tzitzéica,[21,24] A. Demoulin and H. Jonas[25]) considered the Lax pair and the DT and none of them gave the explicit form of the Bäcklund transformation. McLaughlin and Scott[26] proved that its type is certainly different from the well-known one of the sine-Gordon equation.

Gaffet was the first modern author to analyze the difficulty of finding the BT (section 5.1 of Ref. 8). His main conclusion is that obtaining the BT would be quite easy if one knew a *scalar* Lax pair whose commutator is equivalent to the PDE (1) and generates the one-soliton solution. Such a pair is given below, Eqs. (114) and (115).

By elimination of ∂_x (resp. ∂_t) between the three scalar linear PDEs (14)–(16), Gaffet obtained[8] the two linear third-order ODEs,

$$\tau_{xxx}-(U_{xx}+U_x^2)\tau_x+\alpha\sqrt{a_2}\lambda\tau=0, \tag{22}$$

$$\tau_{ttt}-(U_{tt}+U_t^2)\tau_t+\alpha\sqrt{a_2}\lambda^{-1}\tau=0, \tag{23}$$

but these two ODEs, taken alone, do not define a scalar Lax pair since their commutator is equivalent to (1) only *modulo* the triplet (14)–(16). Therefore, the elimination of τ between these two ODEs and the DT cannot yield the BT.

Sharipov and Yamilov[27] (see also subsequent papers, Refs. 28 and 29) eliminated τ between the DT (21) and three differential consequences of (14)–(16), to obtain three complicated PDEs, instead of two, without the property that two of them constitute a BT obeying the above definition.

For completion, let us also mention the existence of a nonlinear superposition formula between four different solutions of (1).[25,30,31]

From the correspondence (7) with the Hirota–Satsuma equation, one might think of transposing the well-established results for that equation (Lax pair,[32] DT and BT,[33] all easy to find by singularity analysis[34]) to get the BT of the Tzitzéica equation. Unfortunately, this is impossible because the correspondence (7) restricts the potential form of the Hirota–Satsuma equation to $F(t)=0$. This impossibility is illustrated by the solution to the Hirota–Satsuma equation[35]

$$w_x=-a(P(x-f(t))+Q(x+f(t))), \tag{24}$$

$$w_t=a(P(x-f(t))-Q(x+f(t))f'(t), \quad f'\not\equiv 0, \tag{25}$$

$$P''(z)=6P(z)^2+kz+A, \quad Q''(z)=6Q(z)^2+kz+B, \tag{26}$$

$$F(t)=af'(t)(2kf(t)-A+B), \tag{27}$$

in which k,A,B are arbitrary constants and f is an arbitrary function. Both P and Q are either a first Painlevé function $(k\neq 0)$ or a Weierstrass elliptic function $(k=0)$. This also defines a solution to the Tzitzéica equation only under the two additional restrictions $F(t)=0$, $f''(t)=0$. This implies $k=0$, $A=B$ and thus forbids the first Painlevé function, only leaving the elliptic solution [formula (104) in Ref. 18].

One must therefore turn to the study of the singularity structure of the Tzitzéica equation.

If the underlying scattering problem is not of second order, then the usual truncation of Weiss (as well as its two-singular manifold extension[18,36]) is not adapted and it should generically fail. Indeed, the determining equations generated by the Weiss truncation [condition of identical vanishing of a polynomial in $(\varphi-\varphi_0)^{-1}$] are equivalent[37] to those generated by the assumption that the field ψ defined by

$$\frac{\varphi_x}{\varphi-\varphi_0}-\frac{\varphi_{xx}}{2\varphi_x}=\frac{1}{\chi}=\frac{\psi_x}{\psi} \tag{28}$$

satisfies the *second-order* linear system

$$\psi_{xx}+\frac{S}{2}\psi=0, \tag{29}$$

$$\psi_t+C\psi_x-\tfrac{1}{2}C_x\psi=0, \tag{30}$$

in which S and C are invariant under a homography on φ and linked by the cross-derivative condition

$$X\equiv S_t+CS_x+2C_xS+C_{xxx}=0. \tag{31}$$

As briefly explained in paper I formulas (26) and (27), when the scattering problem is of third order, it is inconsistent to perform the Weiss truncation, then to insert in each of the generated determining equations an assumption for a third-order Lax pair. For the same reason, it is also inconsistent to introduce the so-called *singular manifold equation*. Although such an inconsistency may still provide the full result for some ''robust'' equations (Boussinesq,[38] Sawada–Kotera,[39] Hirota–Satsuma[34]), there do exist equations for which it leads to a failure, and the Kaup–Kupershmidt equation studied in paper I is one of them.

The correct procedure[40] when one assumes a scattering problem with an order $n\geqslant 2$ is to generate determining equations [(27) in paper I] by expansion on a $(n-1)$-component basis.

The Tzitzéica equation is one of the equations which, up to now, has escaped the Weiss truncation, as found by three previous attempts in his formalism:

(1) the truncation of e^{-u} has no solution at all,[41,42] not even the one-soliton;
(2) the truncation of e^{u} (Ref. 18) does provide some particular solutions (in particular a two-wave solution) but, when the involved computations are finished, it should probably fail to provide a Lax pair;
(3) the truncation of e^{u} contains a particular solution[43] linking φ to the pair (τ,τ'), in which τ satisfies the Tzitzéica triplet (14)–(16) and τ' its adjoint.[20,25]

To summarize, the results of singularity analysis which are missing are the following.

(1) Definition of a truncation whose general solution is unique and defines a single Lax pair and a Darboux transformation.
(2) The BT as exactly two DEs, namely one nonlinear ODE (necessarily linearizable) plus one first-order PDE, with a commutator equivalent to the Tzitzéica equation.

III. SINGULARITY STRUCTURE OF THE ZHIBER–SHABAT EQUATIONS

Equation (12) always possesses the family

$$e^{u} \sim -(2/\alpha)\varphi_x\varphi_t(\varphi-\varphi_0)^{-2}, \quad \text{indices } (-1,2), \quad \mathcal{D}=(2/\alpha)\partial_x\partial_t. \tag{32}$$

For the Liouville equation, this is the only family. For Sine-Gordon (SG), there also exists the family

$$e^{-u} \sim (2/a_1)\varphi_x\varphi_t(\varphi-\varphi_0)^{-2}, \quad \text{indices } (-1,2), \quad \mathcal{D}=-(2/a_1)\partial_x\partial_t, \tag{33}$$

which reflects the invariance of SG under $u \to -u + \text{Log}(-a_1/\alpha)$.

For the Tzitzéica equation, there also exists the family

$$e^{-u} \sim \sqrt{(1/a_2)\varphi_x\varphi_t}(\varphi-\varphi_0)^{-1}, \quad \text{indices } (-1,2). \tag{34}$$

However, the existence of the single family for the Hirota–Satsuma equation (6)

$$w \sim a\varphi_x(\varphi-\varphi_0)^{-1}, \quad \text{indices } (-1,1,6), \quad \mathcal{D}=a\partial_x, \tag{35}$$

together with the link (7), proves that this second family (34) is irrelevant and must not be considered. This conclusion is confirmed by the negative result of Weiss[41,42] obtained when performing a truncation on e^{-u}.

All the truncations will accordingly take the form

$$e^{u} = \mathcal{D}\,\text{Log}\,\tau + e^{U}, \quad E(u)=0, \quad \mathcal{D}=(2/\alpha)\partial_x\partial_t, \tag{36}$$

without assuming that U should satisfy $E(U)=0$.

Remark: In paper I, the similar assumption $E(U)=0$ is, also, unnecessary for the equation of Kaup–Kupershmidt, since the condition $E(U)=0$ comes out of the truncation.

IV. ASSUMPTION OF A SECOND-ORDER SCATTERING PROBLEM

We are going to derive, by singularity analysis only, first the general solution of the Liouville equation and its hetero-BT to the d'Alembert equation and second the second-order Lax pair and the auto-BT of both the Liouville and sine-Gordon equations.

A. Hetero-BT between Liouville and d'Alembert equations

The special form of the Liouville equation allows the assumption (36) to be integrated twice to yield

$$u = -2\log\tau + V, \quad E(u) = \sum_{j=0}^{2} E_j \tau^{j-2} = 0, \tag{37}$$

in which nothing is assumed on V. The three determining equations are then quite simple,

$$E_0 \equiv 2\tau_x\tau_t + \alpha e^{V} = 0, \tag{38}$$

$$E_1 \equiv \tau_{xt} = 0, \tag{39}$$

$$E_2 \equiv V_{xt} = 0, \tag{40}$$

and their general solution depends on two arbitrary functions of one variable,

$$\tau = f(x) + g(t), \tag{41}$$

$$e^{V} = -\frac{2}{\alpha}\tau_x\tau_t = -\frac{2}{\alpha}f'(x)g'(t), \tag{42}$$

$$e^u = -\frac{2}{\alpha}\frac{\tau_x\tau_t}{\tau^2} = -\frac{2}{\alpha}\frac{f'(x)g'(t)}{(f(x)+g(t))^2}, \tag{43}$$

$$e^U = \tau^{-2}e^V + \frac{2}{\alpha}\frac{\tau_x\tau_t}{\tau^2} = 0. \tag{44}$$

Thus, the two fields u and V are the general solution of, respectively, the Liouville and d'Alembert equations. The hetero-BT between these two equations is provided by the elimination of f and g between (42), (43) and the x- and t-derivatives of (37):

$$(u-v)_x = \alpha\lambda e^{(u+v)/2}, \tag{45}$$

$$(u+v)_t = -2\lambda^{-1}e^{(u-v)/2}, \tag{46}$$

in which v is another solution of d'Alembert equation defined by

$$e^v = (\lambda\tau_t)^{-2}e^V = -\frac{2}{\alpha}\lambda^{-2}\frac{f'(x)}{g'(t)}. \tag{47}$$

Remark: When performing the truncation (36), Tamizhmani and Lakshmanan[44] already found $e^U=0$, $\tau_{xt}=0$ as a *particular* solution, while the above truncation (37) proves it to be the *general* solution. Another difference between the two truncations is the presence of a field V in (37), which allows one to find in addition the hetero-BT between the Liouville and d'Alembert equations.

B. Auto-BT of Liouville and sine-Gordon equations

One takes here $a_2=0$ and either $a_1=0$ (Liouville) or, by a linear change on variable u, $a_1=-\alpha$ (sine-Gordon). Let us define a unique truncation for both equations.

For sine-Gordon, the two equivalent families provide the two pieces of information

$$e^u = \mathcal{D}\,\mathrm{Log}\,\tau_1 + e^{U_1}, \qquad e^{-u} = \mathcal{D}\,\mathrm{Log}\,\tau_2 + e^{-U_2}, \tag{48}$$

in which each τ_j satisfies some second-order Lax pair and U_1, U_2 are two *a priori* unknown quantities. Consequently, the field

$$Y = \frac{\tau_1}{\tau_2} \tag{49}$$

satisfies a Riccati system. The condition that Y be a homographic transform of χ and vanish as χ when $\varphi-\varphi_0$ goes to zero imposes the existence of two nonzero quantities (A,B) such that[34,36]

$$Y^{-1} = B(\chi^{-1}+A), \quad AB\neq 0; \tag{50}$$

in which the Riccati system satisfied by the expansion variable Y is easily deduced from the canonical one satisfied by χ:

$$\chi_x = 1 + \frac{S}{2}\chi^2, \tag{51}$$

$$\chi_t = -C + C_x\chi - \frac{CS+C_{xx}}{2}\chi^2, \tag{52}$$

with S and C linked by (31). The elimination of (τ_1,τ_2) between (48) and (49) leads to

$$e^u - e^{-u} = \mathcal{D} \operatorname{Log} Y + e^{U_1} - e^{U_2}, \quad E(u) = 0, \tag{53}$$

which can be integrated twice to yield[18,36]

$$u = -2 \operatorname{Log} Y + W, \quad E(u) = 0. \tag{54}$$

For Liouville, if we assume the most general form for the unknown second-order Lax pair, we arrive at an assumption identical to (54).

Accordingly, in both cases, the truncation is

$$u = -2 \operatorname{Log} Y + W, \quad Y^{-1} = B(\chi^{-1} + A), \quad E(u) = \sum_{j=0}^{4} E_j(W,A,B,S,C) Y^{j-2} = 0, \tag{55}$$

in which nothing is imposed on W [it is to avoid any confusion with (37) that we use different symbols V and W]. This generates six determining equations: $E_j = 0$ and (31), in which B and W only contribute by the product $B^2 e^W$. They are solved as usual by ascending values of j:

$$E_0 : B^2 e^W = \frac{2}{\alpha} C, \tag{56}$$

$$E_1 : A = -\tfrac{1}{2} (\operatorname{Log} C)_x, \tag{57}$$

$$E_2 \equiv 0, \tag{58}$$

$$E_3 : S = -F(x) + \frac{C_x^2}{2C^2} - \frac{C_{xx}}{C}, \tag{59}$$

$$E_4 : C C_{xt} - C_x C_t + F(x) C^3 + a_1 \alpha F(x)^{-1} C = 0, \tag{60}$$

$$X : a_1 F'(x) = 0, \tag{61}$$

in which F is a function of integration. For sine-Gordon, $F(x)$ must be a constant

$$F(x) = 2\lambda^2. \tag{62}$$

In the Liouville case, for which the truncation imposes no restriction on $F(x)$, let us also require that $F(x)$ be a constant. Then, for both equations, Log C is proportional to a second solution $\tilde{U}$ of the PDE

$$C = \frac{\alpha}{2} \lambda^{-2} e^{\tilde{U}}, \quad E(\tilde{U}) = 0, \tag{63}$$

and one has obtained the Darboux transformation

$$u = -2 \operatorname{Log} y + \tilde{U}, \quad y = \lambda B Y, \tag{64}$$

in which y satisfies the Riccati system

$$y_x = \lambda + \tilde{U}_x y - \lambda y^2, \tag{65}$$

$$y_t = -\frac{\alpha}{2} \lambda^{-1} e^{\tilde{U}} - \frac{a_1}{2} \lambda^{-1} e^{-\tilde{U}} y^2. \tag{66}$$

The second-order matrix Lax pair (Refs. 45 and 46 in the Liouville case) results from the linearization $y=\psi_1/\psi_2$:

$$(\partial_x - L)\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}=0,\quad L=\begin{pmatrix}\tilde{U}_x/2 & \lambda\\ \lambda & -\tilde{U}_x/2\end{pmatrix}, \tag{67}$$

$$(\partial_t - M)\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}=0,\quad M=\begin{pmatrix}0 & -(\alpha/2)\lambda^{-1}e^{\tilde{U}}\\ (a_1/2)\lambda^{-1}e^{-\tilde{U}} & 0\end{pmatrix}. \tag{68}$$

The auto-BT (classical for sine-Gordon, Ref. 46 for Liouville) results from the substitution $y=e^{-(u-\tilde{U})/2}$ into (65) and (66):

$$(u+\tilde{U})_x=-4\lambda \sinh\frac{u-\tilde{U}}{2}, \tag{69}$$

$$(u-\tilde{U})_t=\lambda^{-1}(\alpha e^{(u+\tilde{U})/2}+a_1 e^{-(u+\tilde{U})/2}). \tag{70}$$

The ODE part of the BT is a Riccati equation, and the link between the entire function τ and the solution ψ of a *scalar* Lax pair is $\tau=\psi$ [see (120) and (121)].

For sine-Gordon, the Riccati system (65) and (66) is invariant under the involutions (denoting $y=\lambda\tau/\tau_x$)

$$(Y,U,\lambda)\to(Y^{-1},U-2\,\mathrm{Log}\,Y,-\lambda),(Y^{-1},-U,\lambda), \tag{71}$$

$$(Y,U,\lambda,u,\partial_x,\partial_t)\to(e^{-U}Y,-U,-\alpha/(2\lambda),u,\partial_t,\partial_x), \tag{72}$$

$$(Y,e^U,\lambda)\to(Y^{-1},e^{-U}+\mathcal{D}\,\mathrm{Log}\,\tau,-\lambda). \tag{73}$$

This defines the two usual forms of the DT of sine-Gordon:

$$e^u=e^{-sU}+\mathcal{D}\,\mathrm{Log}\,\tau, \tag{74}$$

$$u=sU-2\,\mathrm{Log}\,Y, \tag{75}$$

in which s can take either sign ±1.

C. The case of the Tzitzéica equation

We have already summarized in Sec. II the consequences of the assumption of a second-order scattering problem. Although, in our opinion, this question is not settled yet, we will not comment any more on it.

An additional computational complication arises from the existence of a single family. This indeed forbids the integration of the operator $\mathcal{D}$ twice in order to transform the assumption (36) into one with a form similar to either (37) or (54).

V. ASSUMPTION OF A THIRD-ORDER SCATTERING PROBLEM

There only remains the Tzitzéica equation.

The only Lax pair invariant under (2) is the matrix pair in the basis (τ_x,τ_t,τ),

$$(\partial_x - L)\begin{pmatrix}\tau_x\\ \tau_t\\ \tau\end{pmatrix}=0,\quad L=\begin{pmatrix}f_1 & f_2 & f_3\\ g_1 & g_2 & g_3\\ 1 & 0 & 0\end{pmatrix}, \tag{76}$$

$$(\partial_t - M)\begin{pmatrix}\tau_x\\ \tau_t\\ \tau\end{pmatrix} = 0, \quad M = \begin{pmatrix} g_1 & g_2 & g_3\\ h_1 & h_2 & h_3\\ 0 & 1 & 0\end{pmatrix}, \tag{77}$$

in which the nine coefficients f_j, g_j, h_j, $j=1,2,3$, are functions to be determined. We define it in the equivalent projective Riccati components (Y_1, Y_2) with the property $Y_{1,t} = Y_{2,x}$:

$$Y_1 = \frac{\tau_x}{\tau}, \quad Y_2 = \frac{\tau_t}{\tau}, \tag{78}$$

$$Y_{1,x} = -Y_1^2 + f_1 Y_1 + f_2 Y_2 + f_3, \tag{79}$$

$$Y_{2,x} = -Y_1 Y_2 + g_1 Y_1 + g_2 Y_2 + g_3, \tag{80}$$

$$Y_{1,t} = -Y_1 Y_2 + g_1 Y_1 + g_2 Y_2 + g_3, \tag{81}$$

$$Y_{2,t} = -Y_2^2 + h_1 Y_1 + h_2 Y_2 + h_3. \tag{82}$$

The truncation defined by

$$e^u = \mathcal{D} \operatorname{Log} \tau + e^U, \tag{83}$$

$$E(u) \equiv \sum_{k=0}^{3} \sum_{l=0}^{3-k} E_{kl}(f_j, g_j, h_j, U) Y_1^k Y_2^l = 0 \tag{84}$$

generates ten determining equations,

$$\forall k,l : E_{kl}(f_j, g_j, h_j, U) = 0, \tag{85}$$

in U and the nine unknown coefficients. One must add to them the six equations $X_j = 0$ defined by the cross-derivative conditions

$$(Y_{1,x})_t - (Y_{1,t})_x = X_0 + X_1 Y_1 + X_2 Y_2 = 0, \tag{86}$$

$$(Y_{2,x})_t - (Y_{2,t})_x = X_3 + X_4 Y_1 + X_5 Y_2 = 0. \tag{87}$$

During their resolution, one first proves that the product $f_2 h_1$ cannot vanish (otherwise a_2 would be zero). This makes the 16 equations algebraically independent and equivalent to the 15 differential relations

$$f_{j,t}, g_{j,x}, g_{j,t}, h_{j,x}, g_{j,xt} = P(\{f_k, g_k, h_k\}, \quad k=1,2,3), \quad j=1,2,3, \tag{88}$$

with P polynomials whose coefficients depend on U, U_x, U_t, U_{xt}, plus the single algebraic relation

$$E_{00} \equiv a_2 - \frac{4}{\alpha^2}(g_3 + g_1 g_2 + (\alpha/2) e^U)^2 = 0. \tag{89}$$

They are solved successively as [equations are numbered as in (88) and (89)]

$g_{3,xt} - (g_{3,x})_t$, : $E(U) = 0$,
$g_{1,x} - g_{2,t}$: $\exists g_0(x,t) : g_1 = g_{0,t}$, $g_2 = g_{0,x}$
$g_{2,t}$: $g_3 = -\alpha e^U - g_{0,x} g_{0,t} - g_{0,xt}$
E_{00} : $\exists f_0(x,t) \neq 0 : f_2 = \sqrt{a_2} W^{-1} f_0$, $h_1 = \sqrt{a_2} W^{-1} f_0^{-1}$,
notation $W = e^U + (2/\alpha) g_{0,xt}$
$g_{2,x}$: $f_3 = -\sqrt{a_2} W^{-1} f_0 g_{0,t} - f_1 g_{0,x} - g_{0,x}^2 + g_{0,xx}$,

$$
\begin{aligned}
g_{3,x} &: \quad f_1 = W_x/W + 2g_{0,x},\\
f_{2,t} &: \quad h_2 = W_t/W + 2g_{0,t} - f_{0,t}/f_0,\\
h_{1,x} &: \quad f_{0,x} = 0,\\
g_{1,t} &: \quad h_3 = g_{0,t}(-W_t/W + f_{0,t}/f_0 - g_{0,t}) + g_{0,tt} - \sqrt{a_2}W^{-1}g_{0,x}/f_0,\\
g_{3,t} &: \quad f_{0,t} = 0,\\
h_{2,x} &: \quad g_{0,xt} = 0.
\end{aligned}
\tag{90}
$$

The irrelevant arbitrary function g_0 reflects the freedom in the definition (83) of τ and can be absorbed by redefining τ as τe^{-g_0}. Thus the solution is unique: the field U must satisfy the Tzitzéica PDE, and f_0 is an arbitrary nonzero complex constant λ. Accordingly, one has obtained a Lax pair and a Darboux transformation. This Lax pair is the rewriting in matrix form of the scalar triplet; it reads in its equivalent projective Riccati representation

$$Y_{1,x} = -Y_1^2 + U_x Y_1 + \sqrt{a_2}\lambda e^{-U} Y_2, \tag{91}$$

$$Y_{2,x} = -Y_1 Y_2 - \alpha e^U, \tag{92}$$

$$Y_{1,t} = -Y_1 Y_2 - \alpha e^U, \tag{93}$$

$$Y_{2,t} = -Y_2^2 + U_t Y_2 + \sqrt{a_2}\lambda^{-1} e^{-U} Y_1, \tag{94}$$

with cross-derivative conditions proportional to the Tzitzéica equation

$$(Y_{1,x})_t - (Y_{1,t})_x = Y_1 E(U), \quad (Y_{2,x})_t - (Y_{2,t})_x = Y_2 E(U). \tag{95}$$

It admits by construction the involution (20), equivalent to

$$(\tau, e^U, \lambda) \to (1/\tau, e^U + \mathcal{D}\,\mathrm{Log}\,\tau, -\lambda). \tag{96}$$

This defines two equivalent writings for the DT, (21) and (36).

Remark: Knowing these results, one can also write this DT[17,22,23] as a difference of the two fields $u-U$ in terms of the two components of a projective Riccati pseudopotential

$$u = U + \mathrm{Log}(-2\lambda^2 y_1 y_2 - 1), \quad y_j = \alpha^{-1/2}\lambda^{-1} Y_j e^{-U/2}, \tag{97}$$

in a quite similar manner to the DT of Liouville and sine-Gordon (64).

In order to find the BT, one must now eliminate one of the two equivalent projective components, and this defines two possible, different, eliminations.

VI. BÄCKLUND TRANSFORMATION

A. First elimination: BT of the Hirota–Satsuma equation

One takes Y_2 from (91) and substitutes it into the three remaining equations, which results in

$$Y_2 = (Y_{1,x} + Y_1^2 - U_x Y_1) e^U / (\sqrt{\alpha_2}\lambda), \tag{98}$$

$$\mathrm{ODE} \equiv Y_{1,xx} + 3Y_1 Y_{1,x} + Y_1^3 - e^{-U}(e^U)_{xx} Y_1 + \alpha\sqrt{a_2}\lambda = 0, \tag{99}$$

$$\mathrm{PDE} \equiv Y_{1,t} + e^U((Y_1 Y_{1,x} + Y_1^3) - Y_1^2 U_x)/(\sqrt{a_2}\lambda) + \alpha e^U = 0, \tag{100}$$

$$(94) \equiv -Y_1 E(U) - \frac{e^U Y_1}{\sqrt{a_2}\lambda}\mathrm{ODE} + (2Y_1 - U_x + \partial_x)\mathrm{PDE} = 0, \tag{101}$$

$$[\mathrm{ODE}, \mathrm{PDE}] = (Y_{1,xx})_t - (Y_{1,t})_{xx} = Y_1 (e^{2U} E(U))_x. \tag{102}$$

Only two of them are functionally independent, as shown by relation (101), but the commutator (102) of Eqs. (99) and (100) shows that this elimination fails to generate the auto-BT of the Tzitzéica equation.

However, it does provide another result, which we now derive. The ODE (99) belongs to the classification of Gambier—this is the number 5, see Eq. (13). It is linearizable by the transformation $Y_1 = \partial_x \operatorname{Log} \psi$ into the third-order linear ODE (22) considered by Gaffet, with the relation $\tau = \psi$ between the two entire functions. This transformation also linearizes the PDE (100) (the linearization is best seen on the equivalent combination $Y_{1,t} - Y_{2,x}$ of the projective Riccati system), and the resulting linear system.

$$\tau_{xxx} - (U_{xx} + U_x^2)\tau_x + \sqrt{a_2}\alpha\lambda\tau = 0, \tag{103}$$

$$-\sqrt{a_2}\lambda\tau_t + e^U\tau_{xx} - U_x e^U \tau_x = 0, \tag{104}$$

which cannot be a scalar Lax pair of the Tzitzéica equation, is, in fact, the scalar Lax pair of the Hirota–Satsuma equation (5):

$$\tau_{xxx} - (6/a)w_x\tau_x + \Lambda\tau = 0, \tag{105}$$

$$\Lambda\tau_t - (2/a)w_t\tau_{xx} + (2/a)w_{xt}\tau_x = 0, \tag{106}$$

under the change of variables (7).

Thus, the underlying Gambier equation for the Hirota–Satsuma equation is the fifth one (13). Let us recall that the Painlevé analysis of the Hirota–Satsuma equation[34] directly provides this result.

B. Second elimination: BT of the Tzitzéica equation

The second elimination is to take Y_1 from (92) and to substitute it into the three remaining equations:

$$Y_1 = -(Y_{2,x} + \alpha e^U)/Y_2, \tag{107}$$

$$\mathrm{ODE} \equiv Y_2 Y_{2,xx} - 2Y_{2,x}^2 - (U_x Y_2 + 3\alpha e^U)Y_{2,x} + \sqrt{a_2}\lambda e^{-U} Y_2^3 - \alpha^2 e^{2U} = 0, \tag{108}$$

$$\mathrm{PDE} \equiv Y_2 Y_{2,t} + Y_2^3 - U_t Y_2^2 + \sqrt{a_2}\alpha\lambda^{-1}(1 + e^{-U}Y_{2,x}) = 0, \tag{109}$$

$$(93) \equiv E(U) - \sqrt{a_2}\lambda^{-1} e^{-U} Y_2^{-2}\mathrm{ODE} + (-\alpha e^U Y_2^{-1} + \partial_x)\mathrm{PDE} = 0, \tag{110}$$

$$[\mathrm{ODE},\mathrm{PDE}] = (Y_{2,xx})_t - (Y_{2,t})_{xx} = (3\alpha e^U + U_x Y_2 + 3Y_{2,x} - Y_2\partial_x)E(U). \tag{111}$$

Only two of them are functionally independent, as shown by the relation (110), and the vanishing of the commutator (111) of Eqs. (108) and (109) is equivalent to the vanishing of the Tzitzéica equation for U. This elimination therefore generates the auto-BT of the Tzitzéica equation by the substitution

$$Y_2 = (\alpha/2)\int (e^u - e^U)\mathrm{d}x \tag{112}$$

into (108) and (109).

This BT, contrary to all the previously proposed ones, obeys the definition given in Sec. II.

The nonlinear ODE (108) again belongs to the equivalence class of the fifth Gambier equation (13), and its linearization

$$Y_2^{-1} = -\alpha^{-1} e^{-U}\partial_x \operatorname{Log}(e^U\psi) \tag{113}$$

transforms the two equations (108) and (109) into the third-order scalar Lax pair of the Gelfand and Dikii types:

$$\mathcal{L}\psi \equiv \psi_{xxx} + (2U_{xx} - U_x^2)\psi_x + ((2U_{xx} - U_x^2)_x/2 + \sqrt{a_2}\alpha\lambda)\psi = 0, \tag{114}$$

$$\mathcal{M}\psi \equiv \psi_t + \sqrt{a_2}(\alpha\lambda)^{-1}e^{-2U}(\psi_{xx} + U_x\psi_x + U_{xx}\psi) + \left(U_t + \int (\alpha e^U + a_2 e^{-2U})\mathrm{d}x\right)\psi = 0, \tag{115}$$

$$[\mathcal{L},\mathcal{M}] = 3E\partial_x^2 + (2(e^U)_x E + E_x)\partial_x + (e^U)_x E_x + (3U_{xx} - U_x^2)E, \quad E = E(U). \tag{116}$$

Remarks:

(1) The results of these two different eliminations show that the scalar Lax pair deduced from a matrix one crucially depends on the choice of the scalar component.

(2) In the third step of the method presented in paper I, which we have not strictly followed here, one had to assume a link $\partial_x\partial_t$ Log $\tau = f(\psi)$ between the two entire functions τ and ψ. This link is here *a posteriori* provided by the linearizing formula (113) and the Riccati equation (93); this is the invertible transformation

$$\tau = e^{-U}(e^U\psi)_x, \quad \psi = -(1/\alpha)e^{-U}\tau_t. \tag{117}$$

(3) The number three, rather than two, of linear scalar equations (14)–(16) in τ has been the source of all the difficulties to obtain the correct BT. Its reduction to two, i.e., to a true scalar Lax pair, is achieved by taking the parametric representation of the third one (16),

$$\exists\Psi: \tau = e^{-U}\Psi_x, \quad \tau_t = -\alpha\Psi, \tag{118}$$

and by inserting it in the two other equations. After the rescaling $\Psi = e^U\psi$, Eq.(14) becomes exactly (114), but Eq. (15) becomes (115) without its last term $(\int E(U)dx)\psi$; this one is recovered by adding a suitable term $e\psi$ with $e_t = 0$ so as to match the cross-derivative condition $(\psi_{xxx})_t = (\psi_t)_{xxx}$ with the condition $E(U) = 0$. Note that such a matching term also arises in the sine-Gordon case[36] when converting the Riccati form (65) and (66) into a one-component scalar Lax pair:

$$y^{-1} = \lambda^{-1}\partial_x \operatorname{Log} \tau, \tag{119}$$

$$L_1\tau \equiv \tau_{xx} + U_x\tau_x - \lambda\tau = 0, \tag{120}$$

$$L_2\tau \equiv \tau_t + \frac{\alpha}{2\lambda}e^U\tau_x - \left(\int (\alpha e^U + a_1 e^{-U})\mathrm{d}x\right)\tau = 0, \tag{121}$$

$$[L_1, L_2] = -E(U)\partial_x. \tag{122}$$

(4) Denoting (τ_1, τ_2, τ_3) the wave vectors of the Lax pair of Mikhailov (17) and (18), the correspondence is

$$\tau_1 = (\sqrt{\alpha}\lambda)^{-1}e^{-U/2}\tau_t, \quad \tau_2 = (\sqrt{\alpha}\lambda)^{-1}e^{-U/2}\tau_x, \quad \tau_3 = \tau. \tag{123}$$

VII. CONCLUSION

The results of this paper are twofold: the explicit analytic expression for the Bäcklund transformation, and the proof that there indeed exists an application of the truncation method able to yield all the integrability results. This reinforces the power of the singularity approach to PDEs initiated by Weiss *et al.*

TABLE I. The two writings of the Darboux transformation (on e^u or on u) of the Liouville, sine-Gordon and Tzitzéica equations $E(u) \equiv u_{xt} + f(u) = 0$. The fields u and U satisfy the same PDE and are linked by the auto-BT. The symbol $\mathcal{D}$ is $(2/\alpha)\partial_x\partial_t$. The Liouville case has two entries, one for its hetero-BT with the d'Alembert equation for v, and one for its auto-BT. For sine-Gordon, $s = \pm 1$ and the coordinate z is either x or t.

$f(u)$	DT on e^u	DT on u	Lax pair
αe^u	$e^u = \mathcal{D}\,\text{Log}\,\tau$	$u = -2\,\text{Log}((\lambda\tau_t)^{-1}\tau) + v$	$\tau_{xt} = 0,\ v_{xt} = 0$
αe^u	$e^u = \mathcal{D}\,\text{Log}\,y + e^U$	$u = -2\,\text{Log}\,y + U$	Riccati(y), $y = \dfrac{\psi_1}{\psi_2}$
$\alpha(e^u - e^{-u})$	$e^u = \mathcal{D}\,\text{Log}\,\tau + e^{-sU}$	$u = -2\,\text{Log}\,Y + sU$	Riccati(y), $\dfrac{\lambda}{y} = \dfrac{\tau_z}{\tau}$
$\alpha e^u + a_2 e^{-2u}$	$e^u = \mathcal{D}\,\text{Log}\,\tau + e^U$	$u = \text{Log}(-2\lambda^2 y_1 y_2 - 1) + U$	Proj. Riccati $\left(\dfrac{\tau_x}{\tau}, \dfrac{\tau_t}{\tau}\right)$

Table I represents a unified picture of the Darboux transformation of each of the three equations of the Zhiber–Shabat group.

On the Groenewold–Van Hove problem for $\mathbf{R}^{2n}$

Mark J. Gotay[a)]
Department of Mathematics, University of Hawaii,
2565 The Mall, Honolulu, Hawaii 96822

(Received 28 September 1998; accepted for publication 16 December 1998)

We discuss the Groenewold–Van Hove problem for $\mathbf{R}^{2n}$, and completely solve it when $n=1$. We rigorously show that there exists an obstruction to quantizing the Poisson algebra of polynomials on $\mathbf{R}^{2n}$, thereby filling a gap in Groenewold's original proof. Moreover, when $n=1$ we determine the largest Lie subalgebras of polynomials which can be consistently quantized, and explicitly construct all their possible quantizations. © *1999 American Institute of Physics.* [S0022-2488(99)00304-7]

I. INTRODUCTION

In 1946 Groenewold[1] presented a remarkable result which states that one cannot consistently quantize the Poisson algebra of all polynomials in the positions q^i and momenta p_i on $\mathbf{R}^{2n}$ as symmetric operators on some Hilbert space $\mathcal{H}$, subject to the requirement that the q^i and p_i be irreducibly represented. Van Hove[2] subsequently refined Groenewold's result. Thus it is *in principle* impossible to quantize—by *any* means—every classical observable on $\mathbf{R}^{2n}$, or even every polynomial observable, in a way consistent with Schrödinger quantization (which, according to the Stone–Von Neumann theorem, is the import of the irreducibility requirement on the q^i and p_i). At most one can consistently quantize certain Lie subalgebras of observables, for instance polynomials which are at most quadratic, or observables which are affine functions of the momenta.

This is not quite the end of the story, however; there are two loose ends which need to be tied up. The first is that there is a technical gap in Groenewold's proof.[3] This gap has been filled in Ref. 2 (see also Ref. 4) by means of a certain functional analytic assumption. Although ''small,'' this gap is nevertheless vexing, and its elimination in this manner is not entirely satisfactory. Second, in the absence of such a polynomial quantization, it is important to determine the largest Lie subalgebras of polynomials that can be consistently quantized along with their quantizations. While some results are known along these lines, this program has not yet been fully carried out.

In this paper we consider the Groenewold–Van Hove problem for $\mathbf{R}^{2n}$. We present two variants of Groenewold's theorem (''strong'' and ''weak''); the weak one is the version that Groenewold actually proved, while the strong one is the result referred to above. We then show that the strong version follows from the weak one *without* introducing extra hypotheses. Thus we fill the gap in Groenewold's proof. Moreover, when $n=1$ we determine the largest quantizable Lie subalgebras of polynomials and explicitly construct all their possible quantizations.

To make the presentation self-contained, we include a detailed discussion of previous work on the Groenewold–Van Hove problem.

II. BACKGROUND

Let $P(2n)$ denote the Poisson algebra of polynomials on $\mathbf{R}^{2n}$ with Poisson bracket

$$\{f,g\}=\sum_{k=1}^{n}\left[\frac{\partial f}{\partial p_k}\frac{\partial g}{\partial q^k}-\frac{\partial g}{\partial p_k}\frac{\partial f}{\partial q^k}\right].$$

a)Electronic mail: gotay@math.hawaii.edu

$P(2n)$ contains several distinguished Lie subalgebras: The *Heisenberg algebra*

$$\mathrm{h}(2n)=\mathrm{span}\{1,q^i,p_i|i=1,\ldots,n\};$$

the *symplectic algebra*

$$\mathrm{sp}(2n,\mathbf{R})=\mathrm{span}\{q^iq^j,q^ip_j,p_ip_j|i,j=1,\ldots,n\};$$

the *extended* (or *inhomogeneous*) *symplectic algebra*

$$\mathrm{hsp}(2n,\mathbf{R})=\mathrm{span}\{1,q^i,p_j,q^iq^j,q^ip_j,p_ip_j|i,j=1,\ldots,n\},$$

which is the semidirect product of $\mathrm{h}(2n)$ with $\mathrm{sp}(2n,\mathbf{R})$; and the *coordinate* (or *position*) *algebra*

$$C(2n)=\left\{\sum_{i=1}^{n} f^i(q)p_i+g(q)\right\},$$

where f^i and g are polynomials. All of these will play an important role in our development.

Let $P^k(2n)$ denote the subspace of polynomials of degree at most *k*, and $P_k(2n)$ the subspace of homogeneous polynomials of degree *k*. Then $P^1(2n)=\mathrm{h}(2n)$, $P_2(2n)=\mathrm{sp}(2n,\mathbf{R})$, and $P^2(2n)=\mathrm{hsp}(2n,\mathbf{R})$. When *n* is fixed, we simply write $P=P(2n)$, etc.

We now state what it means to ''quantize'' a Lie algebra of polynomials on $\mathbf{R}^{2n}$. Throughout, the Heisenberg algebra $\mathrm{h}(2n)$ is regarded as a ''basic algebra of observables.''[5]

Definition 1: Let $\mathcal{O}$ be a Lie subalgebra of $P(2n)$ containing the Heisenberg algebra $\mathrm{h}(2n)$. A *quantization* of $\mathcal{O}$ is a linear map $\mathcal{Q}$ from $\mathcal{O}$ to the linear space $\mathrm{Op}(D)$ of symmetric operators which preserve a fixed dense domain *D* in some separable Hilbert space $\mathcal{H}$, such that for all $f,g\in\mathcal{O}$,

(Q1) $\mathcal{Q}(\{f,g\})=i/\hbar[\mathcal{Q}(f),\mathcal{Q}(g)]$,

(Q2) $\mathcal{Q}(1)=I$,

(Q3) If the Hamiltonian vector field X_f of *f* is complete, then $\mathcal{Q}(f)$ is essentially self-adjoint on *D*,

(Q4) $\mathcal{Q}$ represents $\mathrm{h}(2n)$ irreducibly, and

(Q5) *D* contains a dense set of separately analytic vectors for the standard basis of $\mathcal{Q}(\mathrm{h}(2n))$.

We briefly comment on these conditions; a full exposition along with detailed motivation is given in Ref. 5.

Condition (Q1) is Dirac's famous ''Poisson bracket→commutator'' rule; here $\hbar$ is Planck's reduced constant. The second condition reflects the fact that if an observable *f* is a constant *c*, then the probability of measuring $f=c$ is one regardless of which quantum state the system is in. Regarding (Q3), we remark that in contradistinction with Van Hove,[2] we do not confine our considerations to only those classical observables whose Hamiltonian vector fields are complete. Rather than taking the point of view that ''incomplete'' classical observables cannot be quantized, we simply do not demand that the corresponding quantum operators be essentially self-adjoint (''e.s.a.'').

(Q4) and (Q5) emphasize the fundamental role of the Heisenberg algebra. The technical condition (Q5) guarantees the integrability of the Lie algebra representation $\mathcal{Q}(\mathrm{h}(2n))$ on *D*.[6] [There do exist nonintegrable representations of the Heisenberg algebra;[7] however, none of them seem to have physical significance. (Q5) thus serves to eliminate these ''spurious'' representations.] By virtue of the Stone–Von Neumann theorem, (Q5) along with the irreducibility criterion (Q4) imply that $\mathcal{Q}(\mathrm{h}(2n))$ is unitarily equivalent to a restriction of the *Schrödinger quantization* $d\Pi$*:*

$$q^i\mapsto q^i,\quad p_j\mapsto -i\hbar\,\partial/\partial q^j,\quad \text{and}\quad 1\mapsto I \tag{1}$$

on the Schwartz space $\mathcal{S}(\mathbf{R}^n)\subset L^2(\mathbf{R}^n)$. Indeed, by (Q5) $\mathcal{Q}(\mathrm{h}(2n))$ can be integrated to a representation τ of the Heisenberg group $\mathrm{H}(2n)$ which, according to (Q4), is irreducible. The Stone–Von Neumann theorem then states that this representation of $\mathrm{H}(2n)$ is unitarily equivalent to the Schrödinger representation Π, and hence $\tau=U\Pi U^{-1}$ for some unitary map $U:L^2(\mathbf{R}^n)\rightarrow\mathcal{H}$. Consequently,[8] $\mathcal{Q}(f)=U\overline{d\Pi(f)}U^{-1}\restriction D$ for all $f\in\mathrm{h}(2n)$, where the bar denotes closure. It now follows from (1), the invariance of the domain D, and Sobolev's lemma that $U^{-1}D\subseteq\mathcal{S}(\mathbf{R}^n)$, so that $U^{-1}\mathcal{Q}U$ is the restriction of $d\Pi$ to $U^{-1}D$.

Finally, there is a sixth criterion that a quantization must satisfy in general, viz., that $\mathcal{Q}$ be faithful when restricted to the given basic algebra of observables.[5] In the case of the Heisenberg algebra, however, this follows automatically by virtue of (Q1) and (Q2).

III. THE WEAK NO-GO THEOREM

In the next two sections we argue that there are no quantizations of $P(2n)$. Extensive discussions can be found in Refs. 1–4 and 9–13. We shall state the main results for $\mathbf{R}^{2n}$ but, for convenience, usually prove them only for $n=1$. The proofs for higher dimensions are immediate generalizations of these.

We begin by observing that there *does* exist a quantization $d\varpi$ of $\mathrm{hsp}(2n,\mathbf{R})$. It is given by the familiar formulas

$$d\varpi(q^i)=q^i,\quad d\varpi(1)=I,\quad d\varpi(p_j)=-i\hbar\frac{\partial}{\partial q^j},$$

$$d\varpi(q^iq^j)=q^iq^j,\quad d\varpi(p_ip_j)=-\hbar^2\frac{\partial^2}{\partial q^i\partial q^j},\tag{2}$$

$$d\varpi(q^ip_j)=-i\hbar\left(q^i\frac{\partial}{\partial q^j}+\frac{1}{2}\delta^i_j\right),\tag{3}$$

on the domain $\mathcal{S}(\mathbf{R}^n)\subset L^2(\mathbf{R}^n)$. Properties (Q1)–(Q3) are readily verified. (Q4) follows automatically since the restriction of $d\varpi$ to P^1 is just the Schrödinger representation. For (Q5) we recall that the Hermite functions $h_{k_1\cdots k_n}(q^1,\ldots,q^n)=h_{k_1}(q^1)\cdots h_{k_n}(q^n)$, where

$$h_k(q)=e^{q^2/2}\frac{d^k}{dq^k}e^{-q^2}$$

for $k=0,1,2,\ldots$, form a dense set of separately analytic vectors for $d\varpi(P^1)$. As these functions are also separately analytic vectors for $d\varpi(P_2)$,[14] the operator algebra $d\varpi(P^2)$ is integrable to a unique representation ϖ of the universal cover $\widetilde{\mathrm{HSp}}(2n,\mathbf{R})$ of the extended (or inhomogeneous) symplectic group $\mathrm{HSp}(2n,\mathbf{R})$ (thereby justifying our notation "$d\varpi$").[15] ϖ is known as the "extended metaplectic representation;" detailed discussions of it may be found in Refs. 10 and 13.

We call $d\varpi$ the "extended metaplectic quantization." It has the following crucial property.

Proposition 1: The extended metaplectic quantization is the *unique* quantization of $\mathrm{hsp}(2n,\mathbf{R})$ which exponentiates to a unitary representation of $\widetilde{\mathrm{HSp}}(2n,\mathbf{R})$.

By "unique," we mean up to unitary equivalence and restriction of representations.

Proof: Suppose $\mathcal{Q}$ were another such quantization of $\mathrm{hsp}(2n,\mathbf{R})$ on some domain D in a Hilbert space $\mathcal{H}$. Then $\mathcal{Q}(\mathrm{hsp}(2n,\mathbf{R}))$ can be integrated to a representation τ of $\widetilde{\mathrm{HSp}}(2n,\mathbf{R})$, and (Q4) implies that τ, when restricted to $\mathrm{H}(2n)\subset\widetilde{\mathrm{HSp}}(2n,\mathbf{R})$, is irreducible. The Stone–Von Neumann theorem then states that this representation of $\mathrm{H}(2n)$ is unitarily equivalent to the Schrödinger representation, and hence $\tau=U\varpi U^{-1}$ for some unitary map $U:L^2(\mathbf{R}^n)\rightarrow\mathcal{H}$.[16] Consequently, $\mathcal{Q}(f)=U\overline{d\varpi(f)}U^{-1}\restriction D$ for all $f\in \mathrm{hsp}(2n,\mathbf{R})$. Arguing as in the discussion following Definition 1, we see that $U^{-1}\mathcal{Q}U$ is in fact the *restriction* of $d\varpi$ to $U^{-1}D\subseteq \mathcal{S}(\mathbf{R}^n)$. □

The existence of an obstruction to quantization now follows from Theorem 2.

Theorem 2 (Weak No-Go Theorem): The extended metaplectic quantization of P^2 cannot be extended beyond P^2 in P.

Since P^2 is a maximal Lie subalgebra of P,[17] (Q1) implies that any quantization which extends $d\varpi$ must be defined on all of P. Thus we may restate this as: *There exists no quantization of P which reduces to the extended metaplectic quantization on* P^2.

Proof: Let $\mathcal{Q}$ be a quantization of P which extends the metaplectic quantization of P^2. As noted previously, we may assume that the domain $D\subseteq \mathcal{S}(\mathbf{R}^n)$. We will show that a contradiction arises when cubic polynomials are considered.

Take $n=1$. By inspection of (1)–(3) we see that the ''Von Neumann rules''

$$\mathcal{Q}(q^2)=\mathcal{Q}(q)^2,\quad \mathcal{Q}(p^2)=\mathcal{Q}(p)^2, \tag{4}$$

$$\mathcal{Q}(qp)=\tfrac{1}{2}(\mathcal{Q}(q)\mathcal{Q}(p)+\mathcal{Q}(p)\mathcal{Q}(q)), \tag{5}$$

hold. These in turn lead to higher degree Von Neumann rules.[9,10]

Lemma 1: For all real-valued polynomials r,

$$\mathcal{Q}(r(q))=r(\mathcal{Q}(q)),\quad \mathcal{Q}(r(p))=r(\mathcal{Q}(p)),$$

$$\mathcal{Q}(r(q)p)=\tfrac{1}{2}[r(\mathcal{Q}(q))\mathcal{Q}(p)+\mathcal{Q}(p)r(\mathcal{Q}(q))],$$

$$\mathcal{Q}(qr(p))=\tfrac{1}{2}[\mathcal{Q}(q)r(\mathcal{Q}(p))+r(\mathcal{Q}(p))\mathcal{Q}(q)].$$

Proof: We illustrate this for $r(q)=q^3$. The other rules follow similarly using induction. Now $\{q^3,q\}=0$ whence by (Q1) we have $[\mathcal{Q}(q^3),\mathcal{Q}(q)]=0$. Since also $[\mathcal{Q}(q)^3,\mathcal{Q}(q)]=0$, we may write $\mathcal{Q}(q^3)=\mathcal{Q}(q)^3+T$ for some operator T which (weakly) commutes with $\mathcal{Q}(q)$. We likewise have using (4)

$$[\mathcal{Q}(q^3),\mathcal{Q}(p)]=-i\hbar\,\mathcal{Q}(\{q^3,p\})=3i\hbar\,\mathcal{Q}(q^2)=3i\hbar\,\mathcal{Q}(q^2)=[\mathcal{Q}(q)^3,\mathcal{Q}(p)]$$

from which we see that T commutes with $\mathcal{Q}(p)$ as well. Consequently, T also commutes with $\mathcal{Q}(q)\mathcal{Q}(p)+\mathcal{Q}(p)\mathcal{Q}(q)$. But then from (5),

$$\begin{aligned}\mathcal{Q}(q^3)=\frac{1}{3}\mathcal{Q}(\{pq,q^3\})&=\frac{i}{3\hbar}[\mathcal{Q}(pq),\mathcal{Q}(q^3)]\\ &=\frac{i}{3\hbar}\left[\frac{1}{2}(\mathcal{Q}(q)\mathcal{Q}(p)+\mathcal{Q}(p)\mathcal{Q}(q)),\mathcal{Q}(q)^3+T\right]\\ &=\frac{i}{6\hbar}[\mathcal{Q}(q)\mathcal{Q}(p)+\mathcal{Q}(p)\mathcal{Q}(q),\mathcal{Q}(q)^3]=\mathcal{Q}(q)^3.\end{aligned}$$ ▽

With this lemma in hand, it is now a simple matter to prove the no-go theorem. Consider the classical equality

$$\tfrac{1}{9}\{q^3,p^3\}=\tfrac{1}{3}\{q^2p,p^2q\}.$$

Quantizing and then simplifying this, the formulas in Lemma 1 give

$$\mathcal{Q}(q)^2\mathcal{Q}(p)^2-2i\hbar\,\mathcal{Q}(q)\mathcal{Q}(p)-\tfrac{2}{3}\hbar^2I$$

for the lhs, and

$$\mathcal{Q}(q)^2\mathcal{Q}(p)^2-2i\hbar\,\mathcal{Q}(q)\mathcal{Q}(p)-\tfrac{1}{3}\hbar^2 I$$

for the rhs, which is a contradiction. □

IV. THE STRONG NO-GO THEOREM

In Groenewold's paper[1] a stronger result was claimed: His assertion was that there is no quantization of P, period. This is *not* what Theorem 2 states. For if $\mathcal{Q}$ is a quantization of P, then while of course $\mathcal{Q}(P^1)$ must coincide with Schrödinger quantization, it is not obvious that $\mathcal{Q}$ need be the extended metaplectic quantization when restricted to P^2. Referring to Proposition 1, the problem is that $\mathcal{Q}(P^2)$ is not *a priori* integrable; (Q5) only guarantees that $\mathcal{Q}(P^1)$ can be integrated. From a different point of view, the problem lies in *deducing* the relations (2) and (3) or, equivalently, the Von Neumann rules ([4]) and (5) from the quantization axioms (Q1)–(Q5) and the properties of the extended symplectic algebra alone.

Van Hove[2] supplied an extra assumption guaranteeing the integrability of $\mathcal{Q}(P^2)$, which in particular implies: If the Hamiltonian vector fields of f,g are complete and $\{f,g\}=0$, then $\mathcal{Q}(f)$ and $\mathcal{Q}(g)$ *strongly* commute.[18] This assumption is used to derive relations (2) and (3) in Refs. 4 and 9. It is also possible to enforce the integrability of $\mathcal{Q}(P^2)$ in a more direct manner.[3]

We now show that Van Hove's assumption is unnecessary; in fact, we may establish the integrability of $\mathcal{Q}(P^2)$ directly, via the following generalization of Proposition 1.

Proposition 3: Let $\mathcal{Q}$ be a quantization of P^2 on a dense invariant domain D in a Hilbert space $\mathcal{H}$. Then there is a unitary transformation U: $L^2(\mathbf{R}^n)\to\mathcal{H}$ such that $\mathcal{Q}(f)=U d\varpi(f)U^{-1}\restriction D$ for all $f\in P^2$.

Thus, up to unitary equivalence, $\mathcal{Q}$ must be either $d\varpi$ or a restriction thereof. As such, $\mathcal{Q}(P^2)$ must be integrable and, consequently, Van Hove's strong commutativity assumption holds for elements of P^2.

Before giving the proof, we establish two technical lemmas.

Lemma 2: Let A be an e.s.a. operator on a Hilbert space, and B a closable operator, both of which have a common dense invariant domain D. Suppose that D consists of analytic vectors for A, and that A (weakly) commutes with B. Then $\exp(i\overline{A})$ (weakly) commutes with $\overline{B}$ on D.

Proof: Recall that as $\psi\in D$ is analytic for A,

$$e^{i\overline{A}}\psi=\sum_{k=0}^{\infty}\frac{1}{k!}(iA)^k\psi=:\phi.$$

Define the partial sums

$$\phi_K=\sum_{k=0}^{K}\frac{1}{k!}(iA)^k\psi\in D;$$

then using the (weak) commutativity of A and B,

$$B\phi_K=\sum_{k=0}^{K}\frac{1}{k!}(iA)^k B\psi\in D.$$

Since $B\psi\in D$ is analytic for A, the sequence $B\phi_K$ converges:

$$\chi:=\lim_{K\to\infty}B\phi_K=e^{i\overline{A}}B\psi=e^{i\overline{A}}\overline{B}\psi.$$

But $\overline{B}$ is closed, hence $\phi=\lim_{K\to\infty}\phi_K$ is in the domain of $\overline{B}$ and $\chi=\overline{B}\phi$, i.e.,

$$e^{i\overline{A}}\overline{B}\psi=\overline{B}e^{i\overline{A}}\psi$$

for all $\psi\in D$. ▽

Lemma 3: Let B be a closable operator. If a bounded operator T (weakly) commutes with B on $D(B)$, then they also commute on $D(\bar{B})$.

Proof: If $\psi\in D(\bar{B})$, then from the definition of closure there exists a sequence $\{\psi_k\}$ in $D(B)$ with $\psi_k\to\psi$ such that $B\psi_k\to\bar{B}\psi$. Because the operator T is continuous,

$$T\bar{B}\psi = T\lim_{k\to\infty} B\psi_k = \lim_{k\to\infty} TB\psi_k = \lim_{k\to\infty} \bar{B}T\psi_k$$

as T commutes with $\bar{B}$ on $D(B)$. Again applying the definition of closure to the sequence $\{T\psi_k\}$ in $D(\bar{B})$, we get that $\lim_{k\to\infty}T\psi_k = T\psi\in D(\bar{B})$ and

$$\bar{B}T\psi = \lim_{k\to\infty}\bar{B}T\psi_k = T\bar{B}\psi$$

for every $\psi\in D(\bar{B})$. ▽

Proof of Proposition 3: Let $\mathcal{Q}$ be a quantization of P^2. As discussed earlier, we may assume that $\mathcal{Q}(P^1)$ is the Schrödinger representation (1) on $L^2(\mathbf{R}^n)$, and that the domain $D\subseteq\mathcal{S}(\mathbf{R}^n)$. Again taking $n=1$, we will prove by brute force that the Von Neumann rules (4) and (5) hold.

We begin by determining $\mathcal{Q}(q^2)$. Set $\Delta=\mathcal{Q}(q^2)-\mathcal{Q}(q)^2$. We readily verify that $[\Delta,\mathcal{Q}(q)]=0$ and $[\Delta,\mathcal{Q}(p)]=0$ on D. Now let $D_\omega\subseteq D$ be the space of separately analytic vectors for $\mathcal{Q}(q)$ and $\mathcal{Q}(p)$; by (Q5) we have that D_ω is dense. According to Proposition 1 of Ref. 6, Δ leaves D_ω invariant. By Corollary 2 in Sec. X.6 of Ref. 7, $\mathcal{Q}(q)\restriction D_\omega$ is e.s.a.; moreover, $\Delta_\omega := \Delta\restriction D_\omega$ is symmetric and hence closable. Upon taking $A=\mathcal{Q}(q)\restriction D_\omega$ and $B=\Delta_\omega$ in Lemma 2, it follows that $\exp(i\overline{\mathcal{Q}(q)\restriction D_\omega})=\exp(i\overline{\mathcal{Q}(q)})$ and Δ_ω commute on D_ω. Lemma 3 than shows that $\exp(i\overline{\mathcal{Q}(q)})$ and $\overline{\Delta_\omega}$ commute on $D(\overline{\Delta_\omega})$. Likewise $\exp(i\overline{\mathcal{Q}(p)})$ and $\overline{\Delta_\omega}$ commute on $D(\overline{\Delta_\omega})$. But now the unbounded version of Schur's lemma[19] implies that $\overline{\Delta_\omega}=EI$ for some real constant E on $D(\overline{\Delta_\omega})=L^2(\mathbf{R})$. Since $\overline{\Delta_\omega}$ is the smallest closed extension of Δ_ω and $\Delta_\omega\subset\Delta\subset\bar{\Delta}$, it follows that $\bar{\Delta}=EI$, whence Δ itself is a constant multiple of the identity on D. Thus $\mathcal{Q}(q^2)=\mathcal{Q}(q)^2+EI$ on D.

An identical argument yields $\mathcal{Q}(p^2)=\mathcal{Q}(p)^2+FI$ on D. Quantizing the relation $4pq=\{p^2,q^2\}$ and using these formulas then gives

$$\mathcal{Q}(pq)=\tfrac{1}{2}(\mathcal{Q}(p)\mathcal{Q}(q)+\mathcal{Q}(q)\mathcal{Q}(p))$$

on D. But upon quantizing $2q^2=\{pq,q^2\}$ we find that $E=0$. Similarly $F=0$. It follows from (1)–(3) that $\mathcal{Q}=d\varpi\restriction D$. □

Thus, up to unitary equivalence and restriction of representations, we may as well suppose that $D=\mathcal{S}(\mathbf{R}^n)$. If we were to take this as our starting point, then we could reverse our constructions and derive (4) and (5) in a simpler fashion, cf. Sec. 5.1 of Ref. 5.

If $\mathcal{Q}$ were a quantization of P, $\mathcal{Q}(P^2)$ must therefore be unitarily equivalent to (a restriction of) the extended metaplectic quantization, and this contradicts Theorem 2. Thus we have proven our main result.

Theorem 4 (Strong No-Go Theorem): There is no quantization of P.

Van Hove[2] gave a slightly different analysis using only those observables $f\in C^\infty(\mathbf{R}^{2n})$ with complete Hamiltonian vector fields, and still obtained an obstruction [but now to quantizing all of $C^\infty(\mathbf{R}^{2n})$]. Yet other variants of Groenewold's theorem are presented in Refs. 12 and 20. Related results can be found in Refs. 21 and 22.

V. QUANTIZABLE LIE SUBALGEBRAS OF POLYNOMIALS

We hasten to add that there are Lie subalgebras of $P(2n)$ other than $P^2(2n)$ which can be quantized. For example, consider the coordinate subalgebra $C(2n)$. It is straightforward to verify that for each $\eta\in\mathbf{R}$, the map $\sigma_\eta : C(2n)\to\mathrm{Op}(\mathcal{S}(\mathbf{R}^n))$ given by

$$\sigma_\eta\left(\sum_{i=1}^n f^i(q)p_i+g(q)\right)=-i\hbar\sum_{i=1}^n\left(f^i(q)\frac{\partial}{\partial q^i}+\left[\frac{1}{2}+i\eta\right]\frac{\partial f^i(q)}{\partial q^i}\right)+g(q) \tag{6}$$

is a quantization of $C(2n)$. σ_0 is the familiar ''position'' or ''coordinate representation.'' The significance of the parameter η is explained in Ref. 23 and 24 (see also Ref. 25). There it is shown that while the quantizations σ_η and $\sigma_{\eta'}$ are unitarily inequivalent if $\eta\neq\eta'$, they are related by a *nonlinear* norm-preserving isomorphism.

Proposition 5: C is a maximal Lie subalgebra of *P*.

Proof: We take $n=1$. Suppose that *V* were a Lie subalgebra of *P* strictly containing *C*. *V* must contain a polynomial *h* of the form

$$h(q,p)=f(q)p^k+\text{terms of degree at most } k-1 \text{ in } p$$

for some $k>1$ and some polynomial $f\neq 0$ of degree *l*. Now both $q,p\in V$, and so by bracketing *h* with q $(k-2)$-times, we get

$$\frac{k!}{2}f(q)p^2+\text{terms of degree at most degree 1 in } p\in V.$$

Since $C\subset V$ this implies that $f(q)p^2\in V$. By bracketing this expression with *p* *l*-times, we conclude that $p^2\in V$. Now both $q^2,qp\in V$, so $P^2\subset V$. The maximality of P^2 implies that $V=P$, whence *C* is maximal. □

As a consequence, any quantization which extends σ_η must be defined on all of *P*. Thus Theorem 4 yields

Corollary 6: The quantizations σ_η of *C* cannot be extended beyond *C* in *P*.

Furthermore a variant of Proposition 3 (see also Theorem 8 in Ref. 25) yields ''uniqueness:''

Proposition 7: Let $\mathcal{Q}$ be a quantization of *C* on a dense invariant domain *D* in a Hilbert space $\mathcal{H}$. Then there is an $\eta\in\mathbf{R}$ and a unitary transformation $U:L^2(\mathbf{R}^n)\to\mathcal{H}$ such that $\mathcal{Q}(f)=U\sigma_\eta(f)U^{-1}\restriction D$ for all $f\in C$.

Proof: Again set $n=1$. As in the proof of Proposition 3, we may assume that $\mathcal{Q}(P^1)$ is given by (1) on $L^2(\mathbf{R})$ and that $D\subseteq\mathcal{S}(\mathbf{R})$.

Just as before, we first compute that $\mathcal{Q}(q^2)=\mathcal{Q}(q)^2+EI$ on *D* for some real constant *E*.

Now consider $\mathcal{Q}(q,p)$. Set

$$\Delta=\mathcal{Q}(qp)-\tfrac{1}{2}(\mathcal{Q}(q)\mathcal{Q}(p)+\mathcal{Q}(p)\mathcal{Q}(q)).$$

It is straightforward to verify that Δ commutes with both $\mathcal{Q}(q)$ and $\mathcal{Q}(p)$. The same argument based on Lemmas 2 and 3 and the unbounded Schur's lemma that was used in the proof of Propositin 3 can be applied *mutatis mutandis* to give $\Delta=GI$ on *D* for some real constant *G*. Thus

$$\mathcal{Q}(qp)=\tfrac{1}{2}(\mathcal{Q}(q)\mathcal{Q}(p)+\mathcal{Q}(p)\mathcal{Q}(q))+GI \tag{7}$$

on *D*. By quantizing the Poisson bracket relation $\{qp,q^2\}=2q^2$ we find that $E=0$. Arguing as in the proof of Lemma 1, we then find that on *D*

$$\mathcal{Q}(q^k)=\mathcal{Q}(q)^k. \tag{8}$$

Next, quantizing the Poisson bracket relations $\{q^kp,q\}=q^k$ and $\{q^kp,p\}=-kq^{k-1}p$ yields

$$[\mathcal{Q}(q^kp),\mathcal{Q}(q)]=-i\hbar\mathcal{Q}(q^k)\quad\text{and}\quad[\mathcal{Q}(q^kp),\mathcal{Q}(p)]=i\hbar k\mathcal{Q}(q^{k-1}p), \tag{9}$$

respectively. Now consider the classical relation $(1-k)q^kp=\{q^kp,qp\}$. Quantizing this and simplifying by means of (7), (9), and (8) produces the recursion relation

$$\mathcal{Q}(q^k p) = \frac{1}{1-k}(\mathcal{Q}(q^k)\mathcal{Q}(p) - k\mathcal{Q}(q)\mathcal{Q}(q^{k-1}p)).$$

Iterating this computation $(k-1)$-times gives

$$\mathcal{Q}(q^k p) = (1-k)\mathcal{Q}(q^k)\mathcal{Q}(p) + k\mathcal{Q}(q)^{k-1}\mathcal{Q}(qp).$$

Again using (7) and simplifying, we finally get

$$\mathcal{Q}(q^k p) = \mathcal{Q}(q^k)\mathcal{Q}(p) + k\left(G - \frac{i\hbar}{2}\right)\mathcal{Q}(q)^{k-1}.$$

Recalling (1) and (8), this can be rewritten

$$\mathcal{Q}(q^k p) = -i\hbar\left[q^k\frac{d}{dq} + \left(\frac{1}{2} + \frac{iG}{\hbar}\right)\frac{dq^k}{dq}\right]$$

on D. Consolidating this with (8), we obtain (6) where $\eta = G/\hbar$. We thus have $\mathcal{Q} = \sigma_\eta \restriction D$, as claimed. □

Notice that unlike in the proof of Proposition 3, we cannot quantize the Poisson bracket relation $\{q^2, p^2\} = -4qp$ to obtain $G=0$ since $p^2 \notin C$. The fact that G remains arbitrary is mirrored by the presence of the parameter η in (6).

Thus far we have encountered two maximal Lie subalgebras of P containing P^1: P^2 and C. When $n=1$, it turns out that these are essentially the *only* such subalgebras.

Theorem 8: $(n=1)$ Up to isomorphism, P^2 and C are the only maximal Lie subalgebras of P which contain P^1.

Proof: Suppose that W were a maximal Lie subalgebra of P containing P^1, distinct from P^2. We will show that W must be isomorphic to C. Denote $W^k = W \cap P^k$, etc.

Since $W \neq P^2$ there must exist a polynomial of degree $k, k>2$, in W. By bracketing this polynomial $(k-2)$ times with an appropriate number of $p, q \in W$, we obtain a nonzero polynomial $h \in W^2$. Since $P^1 \subset W$, we may subtract off terms of degree one or less, so we may assume that h is homogeneous quadratic. By means of a rotation we may diagonalize h; thus we may further suppose that canonical coordinates have been chosen so that $h(q,p) = ap^2 + cq^2$. Now $\dim W_2 \neq 3$, for otherwise $P^2 \subset W$, and then the maximality of P^2 implies that $W = P$. We break the argument into parts, depending on whether $\dim W_2 = 1$ or 2.

(i) $\dim W_2 = 1$: Then W_2 is spanned by h. We first claim that either $W^3 = W^2$ or $W^3 \subset C^3$. Indeed, if $f \in W^3$, then the quadratic terms of both $\{p,f\},\{f,q\} \in W^2$ must be proportional to h: $\{p,f\} = rh + \text{l.d.t.}$ and $\{f,q\} = sh + \text{l.d.t.}$, where "l.d.t." means lower degree terms. The particular form of h then implies that

$$f(q,p) = \tfrac{1}{3}(sap^3 + rcq^3) + \text{l.d.t.},$$

along with $sc=0$ and $ra=0$. Since $h \neq 0$, both a, c cannot vanish. If both $r, s = 0$, then $f \in W^2$ and so $W^3 = W^2$. If both $s, a = 0$, then h is proportional to q^2 and f must be of the form

$$\tfrac{1}{3}rcq^3 + \alpha q^2 + \beta qp + \gamma p^2 + \text{l.d.t.}$$

But then $\{f,h\} \propto 2\beta q^2 + 4\gamma qp \in W^2$, which forces $\gamma = 0$. Thus $W^3 \subset C^3$. The canonical transformation $q \mapsto p$, $p \mapsto -q$ reduces the subcase with $r, c = 0$ to the previous one.

If $W^3 = W^2$ then $W = W^2 \subset P^2$, which contradicts the assumed maximality of W.

If $W^3 \subset C^3$, then a similar argument shows that $W^4 \subset C^4$, and so on. Thus $W \subset C$, which again contradicts the maximality of W.

(ii) $\dim W_2 = 2$: Now we may suppose that h, g form a basis for W_2, where h is as above and

$$g(q,p) = rp^2 + spq + tq^2.$$

If $s=0$ then, as h,g are linearly independent, both $p^2,q^2\in W_2$. But then $\{p^2,q^2\}=4pq\in W$, so that $\dim W_2=3$. Without loss of generality, we may thus assume that $s=1$.

Now $\{h,g\}\in W_2$, and a computation shows that $h,g,\{h,g\}$ are linearly dependent iff

$$ac+(at-cr)^2=0. \tag{10}$$

Again we consider various subcases. If $a=0$ then (10) gives $r=0$, and it follows from the above expressions for h,g that $W_2=C_2$. As in case (i), the subcase $c=0$ can be reduced to that of $a=0$ by means of a linear canonical transformation. It remains to consider the subcase $ac \neq 0$. We may suppose that $a=1$; (10) then implies that $c<0$. Setting $\beta=t-rc$, we may thus take

$$h=p^2-\beta^2q^2 \quad \text{and} \quad \{g,h\}=2(p^2+2\beta pq+\beta^2q^2).$$

as a basis for W_2. But now the canonical transformation

$$p\mapsto\frac{1}{\sqrt{2}\beta}(p-\beta q), \quad q\mapsto\frac{1}{\sqrt{2}}(p+\beta q)$$

reduces this subcase to that of $a=0$. Thus up to isomorphism we have $W_2=C_2$.

Similarly we have $W_k\subseteq C_k$, and so $W\subseteq C$. The maximality of W now implies that $W=C$.□

In particular, the subalgebras $\{f(\mu p+q)(p-\mu q)+g(\mu p+q)\}$, where f,g are polynomials and $\mu\in\mathbf{R}$, are all maximal Lie subalgebras of $P(2)$ containing $P^1(2)$ isomorphic to $C(2)$. [These are the normalizers in $P(2)$ of the polarizations $\{g(\mu p+q)\}$.] So is the ''momentum algebra'' consisting of polynomials which are at most affine in the position.

As both $P^2(2)$ and $C(2)$ are quantizable, it follows from Theorem 2 and Corollary 6 that the following corollary is true.

Corollary 9: Up to isomorphism, $P^2(2)$ and $C(2)$ are the largest quantizable subalgebras of $P(2)$ containing $P^1(2)$.

Unfortunately, neither Theorem 8 nor Corollary 9 hold in higher dimensions. To see this, take $n=2$ and consider the Lie algebra

$$\{f(q^1)p_1+g(q^1,q^2,p_2)\},$$

where f,g are polynomials. This subalgebra is maximal, but not isomorphic to either $C(4)$ or $P^2(4)$. It is also not quantizable—if it were, we would obtain a quantization of the polynomial algebra in q^2,p_2, contrary to the Strong No-Go Theorem. Furthermore, the subalgebra thereof for which g is at most quadratic in q^2,p_2 is maximal quantizable, but also not isomorphic to either $C(4)$ or $P^2(4)$.

VI. DISCUSSION

We have thus completely solved the Groenewold–Van Hove problem for $\mathbf{R}^2$ in that we have identified (the isomorphism classes of) the largest quantizable Lie subalgebras of $P(2)$ [viz. $P^2(2)$ and $C(2)$] and explicitly constructed all their possible quantizations [given by (1)–(3) and (6), respectively]. It remains to carry out this program in higher dimensions; the key missing ingredient is a classification of the maximal Lie subalgebras of $P(2n)$ containing $P^1(2n)$. Unfortunately, this appears to be a difficult problem. We emphasize, however, that all the results of this paper other than Theorem 8 and Corollary 9 hold for arbitrary n.

Of course, Groenewold's classical result is valid only for $\mathbf{R}^{2n}$. Similar obstructions appear when trying to quantize certain other phase spaces, e.g., S^2 and T^*S^1. Complete solutions of the corresponding Groenewold–Van Hove problems in these two examples are given in Refs. 26 and 25, respectively. On the other hand, in some instances there are *no* obstructions to quantization, such as T^2 and $T^*\mathbf{R}_+$, cf. Refs. 27 and 12, respectively. (Although probably not of physical interest, it is amusing to wonder what happens for $\mathbf{R}^{2n}$, $n>1$, with an exotic symplectic structure.)

It is important, therefore, to understand the mechanisms which are responsible for these divergent outcomes. Already some results have been established along these lines, to the effect that under certain circumstances there are obstructions to quantizing both compact and noncompact phase spaces.[12,28–30] We refer the reader to Ref. 5 for an up-to-date summary.

ACKNOWLEDGMENTS

We wish to thank H. Grundling for valuable discussions, including his help in pointing out and correcting an error in a previous version of this manuscript. This research was supported in part by NSF Grant No. DMS 96-23083.

The Jacobi polynomial ensemble and the Painlevé VI equation

Luc Haine[a)] and Jean-Pierre Semengue
Department of Mathematics, Université Catholique de Louvain, Chemin du Cyclotron 2, 1348 Louvain-la-Neuve, Belgium

(Received 11 September 1998; accepted for publication 9 December 1998)

We consider the Jacobi polynomial ensemble of $n\times n$ random matrices. We show that the probability of finding no eigenvalues in the interval $[-1,z]$ for a random matrix chosen from the ensemble, viewed as a function of z, satisfies a second-order differential equation. After a simple change of variable, this equation can be reduced to the Okamoto–Jimbo–Miwa form of the Painlevé VI equation. The result is achieved by a comparison of the Tracy–Widom and the Virasoro approaches to the problem, which both lead to different third-order differential equations. The Virasoro constraints satisfied by the tau functions are obtained by a systematic use of the moments, which drastically simplifies the computations. © *1999 American Institute of Physics.* [S0022-2488(99)02203-3]

I. INTRODUCTION

Consider a family of orthonormal polynomials $P_n(x)$, $n=0,1,2,...$, on an interval $[a,b]$, for a weight function $w(x)=\exp(-V(x))$. The associated orthogonal polynomial ensemble assigns a probability measure on the space of $n\times n$ Hermitian matrices proportional to

$$\exp(-\mathrm{Tr}\,V(M))dM, \tag{1.1}$$

with dM the product of Lebesgue measures over the independent elements of the Hermitian matrix M. As in the case of the unitary group, where the probability measure is the Haar measure, there is an exact analog of the Weyl integral formula, giving the induced density distribution on the eigenvalues of the matrices:

$$\prod_{1\leq k<l\leq n}(x_k-x_l)^2\prod_{j=1}^{n}w(x_j)dx_j\,. \tag{1.2}$$

We refer the reader to the book of Mehta,[1] as well as to the introductory lectures by Tracy and Widom,[2] for a discussion of this material.

In this paper, we shall be concerned with the (finite Fredholm) determinant,

$$\det(\mathbf{I}-K(z)), \tag{1.3}$$

viewed as a function of z, where $K(z)=(K_{ij}(z))_{0\leq i,j\leq n-1}$, denotes the $n\times n$ matrix with entries

$$K_{ij}(z)=\int_a^z P_i(x)P_j(x)w(x)dx. \tag{1.4}$$

The determinant (1.3) gives the probability of finding no eigenvalues in the interval $[a,z]$ for a random matrix chosen from the ensemble.[1,2] Tracy and Widom[3] have shown that, in the case of the Hermite and the Laguerre polynomials, as a function of z, the logarithmic derivatives of the

[a)]Electronic mail: haine@agel.ucl.ac.be

determinants (1.3) (multiplied by an appropriate factor related to the interval of orthogonality) solve, respectively, the Painlevé IV and the Painlevé V equations. In the case of the Jacobi polynomials, they have obtained[3] a third-order differential equation that they could not recognize as being connected with some Painlevé transcendents.

The methodology of Tracy and Widom goes well beyond the special examples mentioned above. It extends very successfully the pioneering work of Jimbo, Miwa, Môri, and Sato,[4] who showed that the Fredholm determinant constructed from the sine kernel solves the Painlevé V equation. Adler, Shiota, and van Moerbeke[5] have proposed another approach to the problem, based on the use of ''Virasoro constraints decoupling into a time-part and a boundary-part.'' As examples of orthogonal polynomial ensembles, the authors discuss the cases of the Hermite and the Laguerre polynomials, which lead to the same equations as those obtained by Tracy and Widom.[3]

We note that, in the case of the Hermite and the Laguerre polynomials, the ''Virasoro constraints without boundary-part'' were first obtained by Haine and Horozov.[6] The latter paper was motivated by the explicit construction of all the highest weight representations of the Virasoro algebra (with central charge $c=1$) in terms of tau functions. The Jacobi polynomials did not play any role in that construction. Grünbaum and Haine[7] came back to the Jacobi case, in relation with a discrete-continuous version of the bispectral problem, but more about this below.

We are now ready to state the results of our paper. We show that, in the case of the Jacobi polynomials, the Tracy–Widom and the Virasoro approaches lead to *different third-order* differential equations for the determinants (1.3). Comparing the results gives then a *second-order* differential equation, which, after some manipulations, we recognize as the Okamoto–Jimbo–Miwa ''σ representation'' of the Painlevé VI equation (Theorem IV.3). The derivation of our result depends on a new construction of the so-called master symmetries of the (semi-infinite) Toda lattice hierarchy. It is based on the classical correspondence (valid under appropriate hypothesis),

$$\{\mu_0,\mu_1,\mu_2,\ldots\}\to L, \tag{1.5}$$

between sequences of moments and semi-infinite tridiagonal matrices, as explained, for instance, in the treatises of Akhiezer[8] or Chihara.[9] Thus, we do not assume any knowledge of Sato's Grassmannian from the reader. Our main tool, Theorem III.1, allows us to establish the Virasoro constraints by checking some ''trivial'' relations satisfied by the moments [see Lemma IV.1 and formulas (A2) and (A8) in the Appendix, for illustrations of this principle].

There is, in fact, an intimate relation between some subalgebras of the algebra of master symmetries of the Toda lattice hierarchy, which appear naturally in the context of the *bispectral problem*,[7,10] and the *special* solutions of the Painlevé equations that we consider here. To explain this, let us introduce the moments

$$\mu_k(z)=\int_z^b x^k w(x)\,dx, \quad z\in[a,b]. \tag{1.6}$$

Elementary row and column manipulations show that

$$\det(I-K(z))=\frac{\tau_n(z)}{\tau_n(a)}, \tag{1.7}$$

with

$$\tau_n(z)=\det(\mu_{i+j}(z))_{0\leq i,j\leq n-1}. \tag{1.8}$$

The bispectral problem, in the form that is relevant to the considerations of this paper, asks for all families of orthogonal polynomials that are eigenfunctions of a second-order differential equation. In this (special) form, the problem was already solved by Bochner:[11] all the solutions are given by the classical orthogonal polynomials. Although the above mentioned work[7] was concerned with a bi-infinite version of the problem, it contains, in particular, the result that all the (semi-infinite) tridiagonal matrices L, which solve the problem, are *fixed points of some subalgebras of the algebra of master symmetries* of the Toda lattice hierarchy. Under the identification (1.5), the corresponding sequences of moments are obtained by putting $z=a$ and $w(x)$ to be the weight function of any family of classical orthogonal polynomials in (1.6). In a nutshell, our proof that (1.8) is a tau function for the appropriate Painlevé equations, amounts to checking that precisely the *same subalgebras of symmetries* become *tangent* along the curve (1.6), obtained by letting z move away from a.

II. ORTHOGONAL POLYNOMIALS AND SATO THEORY

In this section we summarize some of the results of Haine and Horozov,[6] where a precise connection was established between Sato's theory[12] and the theory of orthogonal polynomials. We have, however, removed all ''Grassmannian considerations,'' hoping to make the material accessible to a larger audience. Our starting point is the classical correspondence,[8,9]

$$\{\mu_0,\mu_1,\mu_2,\ldots\}\to L, \tag{2.1}$$

between sequences of moments and (semi-infinite) Jacobi matrices. We shall deal with monic orthogonal polynomials and consequently write L in the form

$$L=\begin{pmatrix} b_1 & 1 & & & & \\ a_1 & b_2 & 1 & & & \\ & a_2 & b_3 & 1 & & \\ & & \cdot & \cdot & \cdot & \\ & & & \cdot & \cdot & \cdot \\ & & & & \cdot & \cdot & \cdot \end{pmatrix}. \tag{2.2}$$

The correspondence is valid with the assumption that all entries a_n are nonzero and that all the $n\times n(n=1,2,3,...)$ determinants,

$$\tau_n=\det(\mu_{i+j})_{0\leqslant i,j\leqslant n-1}, \tag{2.3}$$

do not vanish. In one direction, it is given by the formulas

$$a_n=\frac{\tau_{n-1}\tau_{n+1}}{\tau_n^2},\quad b_n=\frac{\dot{\tau}_n}{\tau_n}-\frac{\dot{\tau}_{n-1}}{\tau_{n-1}}, \tag{2.4}$$

where, by convention, $\tau_0=1$, $\dot{\tau}_0=0$, and $\dot{\tau}_n$ denotes the determinant

$$\dot{\tau}_n=\det(\mu_{ij}^{(n)})_{0\leqslant i,j\leqslant n-1}, \tag{2.5}$$

with

$$\mu_{ij}^{(n)}=\mu_{i+j}\quad\text{for}\quad j\leqslant n-2\quad\text{and}\quad\mu_{in-1}^{(n)}=\mu_{i+n}.$$

Conversely, given the Jacobi matrix L, one constructs inductively the sequence of polynomials,

$$p_n(x)=(x-b_n)p_{n-1}(x)-a_{n-1}p_{n-2}(x),\quad n\geqslant 1, \tag{2.6}$$

with

$$p_{-1}(x)=0 \quad \text{and} \quad p_0(x)=1. \tag{2.7}$$

By Favard's theorem,[9] as long as the entries a_n are nonzero, there exists a unique (up to a multiplicative constant) sequence $\{\mu_n\}_{n\geq 0}$, such that the sequence $\{p_n(x)\}_{n\geq 0}$ is an orthogonal polynomial sequence for the associated moment functional M, that is

$$M(p_n p_m)=0, \quad \text{for} \quad m\neq n \quad \text{and} \quad M(p_n^2)\neq 0.$$

We remind the reader that the moment functional M corresponding to the sequence $\{\mu_n\}_{n\geq 0}$, is defined by $M(x^n)=\mu_n$ and then extended to the vector space of all polynomials by linearity.

It is a beautiful and elementary fact that, under the correspondence (2.1), the vector field,

$$\dot{\mu}_k=\mu_{k+1}, \tag{2.8}$$

translates on the Jacobi matrix L into the celebrated Toda lattice equation. More generally, the sequence of vector fields,

$$T_i: \frac{\partial \mu_k}{\partial t_{i+1}}=\mu_{k+i+1}, \quad i\geq -1, \tag{2.9}$$

with T_0, giving (2.8), form a family of commuting vector fields,

$$[T_i,T_j]=0, \tag{2.10}$$

and we have the following.

Theorem II.1:[13,14] *Under the correspondence* (2.1), *the vector fields* (2.9) *translate on the Jacobi matrix L into the Toda lattice hierarchy,*

$$T_i: \frac{\partial L}{\partial t_{i+1}}=[L_+^{i+1},L], \tag{2.11}$$

where L_+^i *denotes the upper part (including the diagonal) of* L^i.

Remark: Although the proof of the above theorem is elementary, to the best of our knowledge, in the context of semi-infinite matrices, it was first formulated by Witten.[14] In that paper, Witten considers polynomials orthogonal with respect to some measure $d\sigma_0$ and shows that the time deformation of the measure

$$d\sigma_t=\exp\left(\sum_n t_n x^n\right) d\sigma_0, \tag{2.12}$$

defines orthogonal polynomials for which the corresponding Jacobi matrices satisfy the Toda lattice hierarchy. Starting with the Hermite polynomials leads then to the partition function of two-dimensional (2-D)-lattice quantum gravity. This corresponds to the situation when the moment functional M is defined by a measure (i.e., all $a_n>0$). It is straightforward to check that the deformation (2.12) induces the flows (2.9) on the moments. When the starting measure $d\sigma_0$ is purely discrete, one is led to the finite Toda lattice, and Eq. (2.12) can be traced back to the integration by Moser[13] of the finite Toda lattice, via the inverse Stieltjes transform.

The next theorem[6] establishes the precise link between Sato's theory[12] and the theory of orthogonal polynomials. For the convenience of the reader we present here an elementary proof, which avoids the use of Grassmannians. Let $t=(t_1,t_2,t_3,\ldots)$ and let us denote by

$$\tau_n(t)=\det(\mu_{i+j}(t))_{0\leq i,j\leq n-1}, \tag{2.13}$$

the determinants obtained by flowing from (2.3) under the flows of the commuting vector fields T_i defined in (2.9). With a similar definition for $L(t)$, we have the following.

Theorem II.2: *The functions* $\tau_n(t)$, $t=(t_1,t_2,t_3,\ldots)$, *are tau functions in the precise sense of Sato theory, that is,*

$$p_n(x,t)=x^n\frac{\tau_n(t-[x^{-1}])}{\tau_n(t)}, \tag{2.14}$$

where $p_n(x,t)$ *denote the (monic) orthogonal polynomials defined by the Jacobi matrix* $L(t)$ *and*

$$[x]=(x,\tfrac{1}{2}x^2,\tfrac{1}{3}x^3,\ldots). \tag{2.15}$$

Proof: Introduce the elementary Schur polynomials via the generating function

$$\exp\left(\sum_{k=1}^{\infty} t_k x^k\right)=\sum_{n\in\mathbf{Z}} S_n(t)x^n. \tag{2.16}$$

The (formal) solution of the family of commuting flows T_i in (2.9) is given by

$$\mu_k(t)=\sum_{n\in\mathbf{Z}} S_n(t)\mu_{n+k}(0). \tag{2.17}$$

From (2.16), we deduce easily that

$$S_n(t-[x^{-1}])=S_n(t)-x^{-1}S_{n-1}(t), \tag{2.18}$$

which, using (2.17), gives

$$\mu_k(t-[x^{-1}])=\mu_k(t)-x^{-1}\mu_{k+1}(t), \tag{2.19}$$

and therefore

$$x^n\tau_n(t-[x^{-1}])=\begin{vmatrix} \mu_0(t) & \mu_1(t) & \cdots & \mu_n(t)\\ \vdots & \vdots & & \vdots\\ \mu_{n-1}(t) & \mu_n(t) & \cdots & \mu_{2n-1}(t)\\ 1 & x & \cdots & x^n \end{vmatrix}, \tag{2.20}$$

which can be checked by expanding the determinant along the last line. The ratio of the right-hand side of (2.20) by $\tau_n(t)$ is the classical formula[9] that expresses the (monic) orthogonal polynomials $p_n(x,t)$ in terms of the moments $\mu_k(t)$. This establishes the theorem.

It follows from Theorem II.2 that each of the functions $\tau_n(t)$, $n=1,2,3,4,\ldots$, must be a solution of the system of Hirota's bilinear equations,[12,15] which characterizes tau functions. In what follows we shall just need to know that they satisfy the first equation of this hierarchy, which is the classical Kadomtzev–Petviashvili (KP in short) equation:

$$\left(\frac{\partial^4}{\partial t_1^4}+3\frac{\partial^2}{\partial t_2^2}-4\frac{\partial^2}{\partial t_1\partial t_3}\right)\log\tau_n(t)+6\left(\frac{\partial^2}{\partial t_1^2}\log\tau_n(t)\right)^2=0. \tag{2.21}$$

III. OSCILLATOR REPRESENTATIONS OF THE VIRASORO ALGEBRA AND MASTER SYMMETRIES OF THE TODA LATTICE HIERARCHY

We introduce the following vector fields on the space of moments:

$$V_i:\frac{\partial\mu_k}{\partial s_i}=(i+k+1)\mu_{i+k},\quad i\geqslant -1. \tag{3.1}$$

These vector fields satisfy the commutation relations,

$$[V_i,V_j]=(j-i)V_{i+j}. \tag{3.2}$$

They can be used to generate, via commutators, the vector fields T_i of the Toda lattice hierarchy (2.9),

$$[V_i,T_j]=(j+1)T_{i+j}, \tag{3.3}$$

and, for this reason, they are often called master symmetries.

In order to formulate the result of this section, we shall need the so-called oscillator representations of the Virasoro algebra:[15]

$$\begin{aligned} L_0^{(n)}&=n^2+\sum_{k=1}^{\infty} kt_k\frac{\partial}{\partial t_k},\\ L_j^{(n)}&=\sum_{k=1}^{j-1}\frac{\partial^2}{\partial t_k\partial t_{j-k}}+2n\frac{\partial}{\partial t_j}+\sum_{k=1}^{\infty} kt_k\frac{\partial}{\partial t_{k+j}},\quad j\geqslant 1,\\ L_{-j}^{(n)}&=\frac{1}{4}\sum_{k=1}^{j-1}k(j-k)t_kt_{j-k}+njt_j+\sum_{k=j+1}^{\infty}kt_k\frac{\partial}{\partial t_{k-j}},\quad j\geqslant 1. \end{aligned} \tag{3.4}$$

The operators $L_j^{(n)}$ satisfy the commutation relations of the Virasoro algebra, with central charge $c=1$:

$$[L_i^{(n)},L_j^{(n)}]=(i-j)L_{i+j}^{(n)}+\delta_{i,-j}\frac{i^3-i}{12}. \tag{3.5}$$

Starting with a sequence $\{\tau_n\}$ as in (2.3), let us denote by $\{\tau_n^{s_j}(t)\}$ the sequence that is obtained by first flowing along the vector field V_j during a time s_j, and then flowing along the (commuting) family of Toda flows. Notice that, since the master symmetries and the Toda flows *do not* commute between themselves, it is very important to specify *in which order* the flows are followed. With this convention, we can formulate our main result.

Theorem III.1: For $j\geqslant -1$,

$$\frac{\partial}{\partial s_j}\tau_n^{s_j}(t)|_{s_j=0}=L_j^{(n)}\tau_n(t). \tag{3.6}$$

This theorem is *the key* to the derivation of the various ''Virasoro-type constraints'' that are satisfied by *special* (Toda-type) tau functions. Indeed, it tells us, for example, that if the vector field V_j vanishes at $\{\tau_n\equiv\tau_n(0)\}$ (that is, at $\{\mu_n\equiv\mu_n(0)\}$), then, by definition, $\tau_n^{s_j}(t)$ is independent of s_j, and thus $L_j^{(n)}\tau_n(t)=0$, for all n. The proof of Theorem III.1 will depend on an expansion of the tau function in terms of Schur polynomials.

For any partition $j_1\geqslant j_2\geqslant\cdots\geqslant j_k>0$, with k parts, the Schur polynomials $S_{j_1,\ldots,j_k}(t)$ are defined in terms of the elementary Schur polynomials (2.16) by the determinants

$$S_{j_1,\ldots,j_k}(t)=\det(S_{j_r+s-r}(t))_{1\leqslant r,s\leqslant k}. \tag{3.7}$$

Substituting (2.17) into (2.13), one computes that the tau functions $\tau_n(t)$ admit the following expansion (which is a particular case of a formula of Sato[12] for general tau functions):

$$\tau_n(t)=\sum_{0\leqslant i_1<i_2<\cdots<i_n} p_{i_1,i_2,\ldots,i_n}S_{i_n-n+1,i_{n-1}-n+2,\ldots,i_1}(t), \tag{3.8}$$

where $p_{i_1,i_2,\ldots,i_n}$ denote the Plücker coordinates:

$$p_{i_1,i_2,\ldots,i_n}=\begin{vmatrix} \mu_{i_1} & \mu_{i_2} & \cdots & \mu_{i_n} \\ \mu_{i_1+1} & \mu_{i_2+1} & \cdots & \mu_{i_n+1} \\ \vdots & \vdots & \cdots & \vdots \\ \vdots & \vdots & \cdots & \vdots \\ \mu_{i_1+n-1} & \mu_{i_2+n-1} & \cdots & \mu_{i_n+n-1} \end{vmatrix}. \tag{3.9}$$

We shall need three lemmas. In order to formulate them, we introduce some notations. Given n vectors $x_1,\ldots,x_n\in\mathbf{R}^n$, we shall denote by $|x_1x_2\cdots x_n|$ the determinant of the $n\times n$ matrix formed with the columns x_i. Also, given two vectors x and y, $x\wedge y$ denotes the usual wedge product, with components $(x\wedge y)_{rs}=x_ry_s-x_sy_r$. Finally, for an $n\times n$ matrix A, A_r will denote the rth column of A and $\mathrm{tr}(A)$ will mean the trace of A. With these conventions, we have the following.

Lemma III.2: Let A and B be $n\times n$ matrices, with A invertible, and let D be an $n\times n$ diagonal matrix $D=\mathrm{diag}(d_1,d_2,\ldots,d_n)$; then

$$(i)\ \ \Sigma_{r=1}^n|A_1\cdots A_{r-1}(DB)_rA_{r+1}\cdots A_n|=(\det A)\mathrm{tr}(DBA^{-1}),$$

$$(ii)\ \ \Sigma_{1\leqslant r<s\leqslant n}|A_1\cdots A_{r-1}(DB)_rA_{r+1}\cdots A_{s-1}(DB)_sA_{s+1}\cdots A_n|$$
$$=(\det A)\sum_{1\leqslant r<s\leqslant n}((DBA^{-1})_r\wedge(DBA^{-1})_s)_{rs}.$$

Proof: Both assertions are easy consequences of Cramer's formula. For simplicity of notations, we just establish (i). One has

$$\text{the left-hand side of } (i)=(\det A)\sum_{r=1}^n(A^{-1}DB)_{rr}, \text{ by Cramer's formula,}$$
$$=(\det A)\mathrm{tr}(A^{-1}DB)=(\det A)\mathrm{tr}(DBA^{-1}). \tag{3.10}$$

This proves Lemma III.2.

The next lemma translates the master symmetries on Plücker coordinates.

Lemma III.3: Let $V_jp_{i_1,\ldots,i_n}$ denote the Lie derivative of the Plücker coordinates (3.9) *in the direction of the vector fields V_j introduced in* (3.1); *then*

$$(i)\ \ V_{-1}\ \ p_{i_1,\ldots,i_n}=\sum_{r=1}^n i_rp_{i_1,\ldots,i_r-1,\ldots,i_n},$$

$$(ii)\ \ V_0\ \ p_{i_1,\ldots,i_n}=\left(\frac{n(n+1)}{2}+\sum_{r=1}^n i_r\right)p_{i_1,\ldots,i_n},$$

$$(iii)\ \ V_1\ \ p_{i_1,\ldots,i_n}=\sum_{r=1}^n(n+1+i_r)p_{i_1,\ldots,i_r+1,\ldots,i_n},$$

$$(iv)\ \ V_2\ \ p_{i_1,\ldots,i_n}=\sum_{r=1}^n(n+2+i_r)p_{i_1,\ldots,i_r+2,\ldots,i_n}+\sum_{1\leqslant r<s\leqslant n}p_{i_1,\ldots,i_r+1,\ldots,i_s+1,\ldots,i_n}.$$

Proof: Let us fix $0\leqslant i_1<i_2<\cdots<i_n$ and introduce the $n\times n$ matrices,

$$A=(\mu_{i_{s+1}+r})_{0\leqslant r,s\leqslant n-1},\quad B_j=(\mu_{i_{s+1}+r+j})_{0\leqslant r,s\leqslant n-1}, \tag{3.11}$$

as well as the $n\times n$ diagonal matrix,

$$D=\mathrm{diag}(0,1,2,...,n-1). \tag{3.12}$$

Notice that, by the definition (3.9) of the Plücker coordinates, we have

$$\det A=p_{i_1,\dots,i_n}. \tag{3.13}$$

From the definition of V_j and of the Plücker coordinates, respectively, in (3.1) and (3.9), using first Leibniz rule and then Lemma III.2 (i), we find

$$\begin{aligned} V_j p_{i_1,\dots,i_n} &= \sum_{r=1}^{n} (j+i_r+1) p_{i_1,\dots,i_r+j,\dots,i_n} + \sum_{r=1}^{n} |A_1\cdots A_{r-1}(DB_j)_r A_{r+1}\cdots A_n|, \\ &= \sum_{r=1}^{n} (j+i_r+1) p_{i_1,\dots,i_r+j,\dots,i_n} + (\det A)\mathrm{tr}(DB_j A^{-1}). \end{aligned} \tag{3.14}$$

When $j=-1$, one checks easily that $\mathrm{tr}(DB_{-1}A^{-1})=0$, using (3.11) and (3.12), which gives (i). When $j=0$, $B_0=A$, and thus $\mathrm{tr}(DB_0A^{-1})=\mathrm{tr}(D)=n(n-1)/2$ which, using (3.13), gives (ii).

When $j=1$,

$$\begin{aligned} (\det A)\mathrm{tr}(DB_1A^{-1}) &= (n-1)(\det A)\mathrm{tr}(B_1A^{-1}) \\ &\qquad [\text{using the definition of } B_1 \text{ and } D \text{ in (3.11) and (3.12)}], \\ &= (n-1)\sum_{r=1}^{n} p_{i_1,\dots,i_r+1,\dots,i_n} \quad (\text{using Lemma III.2 (i) with } D=\text{identity}), \end{aligned} \tag{3.15}$$

and thus (3.14) reduces to (iii).

It remains to discuss the case $j=2$ of (3.14). One computes that

$$\begin{aligned} (\det A)\mathrm{tr}(DB_2A^{-1}) &= (n-1)(\det A)\mathrm{tr}(B_2A^{-1}) \\ &\quad + (\det A)\sum_{1\leqslant r<s\leqslant n} ((B_1A^{-1})_r \wedge (B_1A^{-1})_s)_{rs}, \end{aligned} \tag{3.16}$$

noticing that, in the last sum, only the term $r=n-1$, $s=n$ is nonzero. Using Lemma III.2 (i) and (ii), both with $D=$identity, it follows that

$$\begin{aligned} (\det A)\mathrm{tr}(DB_2A^{-1}) &= (n-1)\sum_{r=1}^{n} p_{i_1,\dots,i_r+2,\dots,i_n} \\ &\quad + \sum_{1\leqslant r<s\leqslant n} p_{i_1,\dots,i_r+1,\dots,i_s+1,\dots,i_n}, \end{aligned} \tag{3.17}$$

which shows that (3.14), with $j=2$, reduces to (iv). This concludes the proof of Lemma III.3.

The last lemma computes the action of the Virasoro operators, defined in (3.4), on the Schur polynomials.

Lemma III.4: Let $0\leqslant i_1<\cdots<i_k$; *then*

$$(i)\quad L_{-1}^{(n)}S_{i_k-k+1,\ldots,i_1}(t)=\sum_{r=1}^{k}(i_r+1)S_{i_k-k+1,\ldots,i_r-r+2,\ldots,i_1}(t)+(n-k)t_1S_{i_k-k+1,\ldots,i_1}(t),$$

$$(ii)\quad L_0^{(n)}S_{i_k-k+1,\ldots,i_1}(t)=\left(n^2-\frac{k(k-1)}{2}+\sum_{r=1}^{k}i_r\right)S_{i_k-k+1,\ldots,i_1}(t),$$

$$(iii)\quad L_1^{(n)}S_{i_k-k+1,\ldots,i_1}(t)=\sum_{r=1}^{k}(2n-k+i_r)S_{i_k-k+1,\ldots,i_r-r,\ldots,i_1}(t),$$

$$(iv)\quad L_2^{(n)}S_{i_k-k+1,\ldots,i_1}(t)=\sum_{r=1}^{k}(2n-k+i_r)S_{i_k-k+1,\ldots,i_r-r-1,\ldots,i_1}(t)+\sum_{1\leqslant r<s\leqslant k}S_{i_k-k+1,\ldots,i_r-r,\ldots,i_s-s,\ldots,i_1}(t).$$

Proof: The proof is very similar in spirit to the proof of Lemma III.3, so we just sketch the main steps. We introduce the operators

$$M_{-1}=\sum_{k=2}^{\infty}kt_k\frac{\partial}{\partial t_{k-1}}\quad\text{and}\quad M_j=\sum_{k=1}^{\infty}kt_k\frac{\partial}{\partial t_{k+j}},\quad j\geqslant 0. \tag{3.18}$$

From the definition of the elementary Schur polynomials in (2.16), it follows easily that

$$M_{-1}S_i(t)=(i+1)S_{i+1}(t)-t_1S_i(t)\quad\text{and}\quad M_jS_i(t)=(i-j)S_{i-j}(t),\quad j\geqslant 0. \tag{3.19}$$

We introduce the $n\times n$ matrices,

$$A=(S_{i_{s+1}-r}(t))_{0\leqslant r,s\leqslant k-1},\quad B_j=(S_{i_{s+1}-r-j}(t))_{0\leqslant r,s\leqslant k-1}, \tag{3.20}$$

as well as the diagonal matrix,

$$D=\mathrm{diag}(0,-1,-2,\ldots,-(k-1)). \tag{3.21}$$

Notice that

$$\det A=S_{i_k-k+1,\ldots,i_1}(t). \tag{3.22}$$

Since the operators M_j, $j=-1,0,1,2$, act as derivations on the space of polynomials in $t_1,t_2,t_3,\ldots,$ using (3.19), (3.20), (3.21), and (3.22), one derives explicit formulas for $M_jS_{i_k-k+1,\ldots,i_1}(t)$ in terms of Schur polynomials, using exactly the same arguments as in the proof of Lemma III.3. From these formulas, using that

$$\frac{\partial}{\partial t_j}S_i(t)=S_{i-j}(t), \tag{3.23}$$

one deduces easily formulas (i), (ii), (iii), and (iv), giving the action of the Virasoro operators on the Schur polynomials. This finishes the proof of Lemma III.4.

Given the previous lemmas, the proof of Theorem III.1 is now straightforward.

Proof of Theorem III.1: We shall use the shorthand notation

$$\tau_n(t)=\Sigma_I p_I S_I(t), \tag{3.24}$$

for the Plücker expansion (3.8). For $j=-1,0,1,2$, we have

$$\begin{aligned}\frac{\partial}{\partial s_j}\tau_n^{s_j}(t)|_{s_j=0}&=\Sigma_I(V_jp_I)S_I(t),\\&=\Sigma_I p_I(L_j^{(n)}S_I(t)),\quad \text{using Lemmas III.3 and III.4, with}\\&\quad k=n,\ \text{and some relabeling of the indices},\\&=L_j^{(n)}\tau_n(t).\end{aligned}\tag{3.25}$$

The rest of the argument follows from the commutation relations (3.2) and (3.5), that are satisfied by the master symmetries and the Virasoro operators. Notice that for $j\geqslant -1$, they differ by a sign! Assuming the theorem for some $j\geqslant 2$, we establish it for $j+1$. Indeed,

$$\begin{aligned}(j-1)\frac{\partial}{\partial s_{j+1}}\tau_n^{s_{j+1}}(t)|_{s_{j+1}=0}&=\Sigma_I([V_1,V_j]p_I)S_I(t),\ \text{using (3.2)},\\&=\Sigma_I p_I([L_j^{(n)},L_1^{(n)}]S_I(t)),\ \text{by induction hypothesis},\\&=(j-1)L_{j+1}^{(n)}\tau_n(t),\ \text{using (3.5)}.\end{aligned}\tag{3.26}$$

This establishes Theorem III.1.

Using Theorem III.1 and formula (2.4), which gives the entries a_n and b_n of the tridiagonal matrix L in (2.2) in terms of $\{\tau_n\}$, it is possible to obtain an expression for the master symmetries V_j, $j\geqslant -1$, acting on L, in terms of a Lax pair. Let us define P to be the strictly lower matrix, which represents d/dx in the basis formed by the *monic* orthogonal polynomials $p_n(x)$:

$$\frac{d}{dx}p=Pp,\quad \text{with } p=(p_0(x)=1,p_1(x),p_2(x),\ldots)^T.\tag{3.27}$$

For a semi-infinite matrix $A=(a_{ij})_{i,j\geqslant 0}$, we denote by $\operatorname{tr}A=(a_{00},a_{00}+a_{11},a_{00}+a_{11}+a_{22},\ldots)$, the diagonal matrix formed with the partial traces of A. Also, A_- means the strictly lower part of A, and A_{++}, the strictly upper part of A. With these notations, we have

$$\frac{\partial L}{\partial s_j}=\left[-(PL^{j+1})_- - \sum_{k=0}^{j-1}(\operatorname{tr}L^k)L_-^{j-k}-\sum_{k=1}^{j-2}(L_{++}^kL_-^{j-k})_-,L\right],\quad j\geqslant -1.\tag{3.28}$$

This Lax pair is different from the one obtained by Adler and van Moerbeke,[16] which requires L to be in symmetric form. We shall not pursue this aspect here, since it will not be needed in what follows. We refer the interested reader to the Ph.D. thesis of the second author,[17] for a detailed proof. To the best of our knowledge, the theory of master symmetries of Toda-type systems has not yet been extended beyond tridiagonal matrices. We feel that (3.28) may be useful in this regard since, in general, a finite-band matrix cannot be assumed to be in symmetric form. As a final comment, we mention that, specializing our theory to the case of discrete orthogonal polynomials, we find back the master symmetries of the finite Toda lattice, which were studied by Damianou[18] and Fernandes.[19] However, a general Lax pair formulation was not given in these works.

IV. THE JACOBI POLYNOMIALS AND THE PAINLEVÉ VI EQUATION

In this section, we illustrate the use of Theorem III.1. The choice of the Jacobi polynomials is motivated by the fact that, as explained in the Introduction, the study of this example allows us to connect the Jacobi polynomial ensemble to the Painlevé VI equation. To the best of our knowledge this result is new.

Let α and β denote real numbers with $\alpha>-1$ and $\beta>-1$. We consider the following curve in the space of moments:

$$\mu_k(z)=\int_z^1 x^k(1-x)^\alpha(1+x)^\beta\,dx,\quad z\in[-1,1]. \tag{4.1}$$

When $z=-1$, the μ_k's are the moments of the orthogonality measure for the Jacobi polynomials. Thinking of z as a parameter, we shall denote by $\tau_n(z,t)$ the tau functions associated with the sequence $\{\mu_k(z)\}$, i.e.,

$$\tau_n(z,t)=\det[(\mu_{i+j}(z))(t)]_{0\leqslant i,j\leqslant n-1}. \tag{4.2}$$

The key to our story is the following.

Lemma IV.1: For all $k\geqslant 0$ and for all $j\geqslant 0$, we have

$$z^j(z^2-1)\frac{d}{dz}\mu_k(z)=[V_{j+1}-V_{j-1}+(\alpha+\beta)T_j+(\alpha-\beta)T_{j-1}]\mu_k(z), \tag{4.3}$$

where the notation on the right-hand side of (4.3) means the Lie derivative in the direction of the vector field between the brackets.

Proof: By definition of the vector fields T_j and V_j in (2.9) and (3.1), the right-hand side of (4.3) is equal to

$$\begin{aligned}
&(k+j+2+\alpha+\beta)\mu_{k+j+1}(z)+(\alpha-\beta)\mu_{k+j}(z)-(k+j)\mu_{k+j-1}(z),\\
&=\int_z^1[(i+2+\alpha+\beta)x^{i+1}+(\alpha-\beta)x^i-ix^{i-1}](1-x)^\alpha(1+x)^\beta\,dx,\quad \text{with}\ \ i=j+k,\\
&=\int_z^1-\frac{d}{dx}[x^i(1-x)^{\alpha+1}(1+x)^{\beta+1}]dx,\\
&=\text{the left-hand side of (4.3)},
\end{aligned} \tag{4.4}$$

which proves the lemma.

It was observed in Grünbaum and Haine[7] that the vector fields,

$$\mathcal{V}_j=V_{j+1}-V_{j-1}+(\alpha+\beta)T_j+(\alpha-\beta)T_{j-1},\quad j=0,1,2,..., \tag{4.5}$$

form a subalgebra of the algebra of master symmetries,

$$[\mathcal{V}_i,\mathcal{V}_j]=(j-i)(\mathcal{V}_{i+j+1}-\mathcal{V}_{i+j-1}), \tag{4.6}$$

and that the *vanishing* of *all* these vector fields characterize the Jacobi polynomials, which correspond to $z=-1$. In a similar spirit, we can interpret the lemma above as saying that *all* vector fields $\mathcal{V}_j$, $j\geqslant 0$, become *tangent* along the curve (4.1).

Combining Lemma IV.1 with Theorem III.1, we obtain the following.

Corollary IV.2: The tau functions $\tau_n(z,t)$, as defined in (4.2), satisfy the following ''Virasoro type'' constraints,

$$z^j(z^2-1)\frac{\partial}{\partial z}\tau_n(z,t)=\left[L_{j+1}^{(n)}-L_{j-1}^{(n)}+(\alpha+\beta)\frac{\partial}{\partial t_{j+1}}+(\alpha-\beta)\frac{\partial}{\partial t_j}\right]\tau_n(z,t), \tag{4.7}$$

for $j=0,1,2,...$, with $L_j^{(n)}$ defined as in (3.4), *where $\partial/\partial t_0\ \tau_n(z,t)$ is interpreted as $n\tau_n(z,t)$.*

Proof: Expanding (4.2) in Plücker coordinates as in (3.8), and using Lemma IV.1, we have that

$$z^j(z^2-1)\frac{\partial}{\partial z}\tau_n(z,t)=\sum_{0\leq i_1<\cdots<i_n}\mathcal{V}_j p_{i_1,\ldots,i_n}(z)S_{i_n-n+1,\ldots,i_1}(t), \tag{4.8}$$

where $p_{i_1,\ldots,i_n}(z)$ are the Plücker coordinates (3.9) formed with the moments $\mu_k(z)$, and $\mathcal{V}_j p_{i_1,\ldots,i_n}(z)$ denotes the Lie derivative in the direction of the vector field $\mathcal{V}_j$, defined in (4.5). Equation (4.8) can be rewritten as

$$z^j(z^2-1)\frac{\partial}{\partial z}\tau_n(z,t)=\frac{\partial}{\partial s_{j+1}}\tau_n^{s_{j+1}}(z,t)\bigg|_{s_{j+1}=0}-\frac{\partial}{\partial s_{j-1}}\tau_n^{s_{j-1}}(z,t)\bigg|_{s_{j-1}=0}$$
$$+\left[(\alpha+\beta)\frac{\partial}{\partial t_{j+1}}+(\alpha-\beta)\frac{\partial}{\partial t_j}\right]\tau_n(z,t). \tag{4.9}$$

By Theorem III.1, the right-hand side of (4.9) is identical with the right-hand side of (4.7), which establishes the corollary.

We shall now show that the Virasoro constraints (4.7) combined with the KP equation (2.21) imply that the functions

$$r(z)=(z^2-1)\frac{d}{dz}\log\tau_n(z),\quad n=1,2,3,\ldots, \tag{4.10}$$

with $\tau_n(z)\equiv\tau_n(z,0)$, all satisfy (after some manipulations) the Painlevé VI equation. Put

$$f(z,t)=\log\tau_n(z,t). \tag{4.11}$$

From now on we fix the integer n and, for this reason, we drop n from our notations.

Remembering the definition of $L_j^{(n)}$ in (3.4), we can rewrite the first three Virasoro constraints in (4.7), for $j=0,1,2$, as follows:

$$(z^2-1)\frac{\partial f}{\partial z}=n(\alpha-\beta-t_1)+(2n+\alpha+\beta)\frac{\partial f}{\partial t_1}+t_1\frac{\partial f}{\partial t_2}$$
$$+\sum_{k=2}^{\infty}kt_k\left(\frac{\partial}{\partial t_{k+1}}-\frac{\partial}{\partial t_{k-1}}\right)f, \tag{4.12}$$

$$z(z^2-1)\frac{\partial f}{\partial z}=-n^2+(\alpha-\beta)\frac{\partial f}{\partial t_1}+(2n+\alpha+\beta)\frac{\partial f}{\partial t_2}+\frac{\partial^2 f}{\partial t_1^2}+\left(\frac{\partial f}{\partial t_1}\right)^2$$
$$+\sum_{k=1}^{\infty}kt_k\left(\frac{\partial}{\partial t_{k+2}}-\frac{\partial}{\partial t_k}\right)f, \tag{4.13}$$

$$z^2(z^2-1)\frac{\partial f}{\partial z}=-2n\frac{\partial f}{\partial t_1}+(\alpha-\beta)\frac{\partial f}{\partial t_2}+(2n+\alpha+\beta)\frac{\partial f}{\partial t_3}$$
$$+2\frac{\partial^2 f}{\partial t_1\partial t_2}+2\frac{\partial f}{\partial t_1}\frac{\partial f}{\partial t_2}+\sum_{k=1}^{\infty}kt_k\left(\frac{\partial}{\partial t_{k+3}}-\frac{\partial}{\partial t_{k+1}}\right)f. \tag{4.14}$$

These three equations can be exploited to express all the partial t derivatives of f, involved in the KP equation (2.21), at $t\equiv(t_1,t_2,t_3,\ldots)=(0,0,0,\ldots)$, in terms of z derivatives of the function $r(z)$ defined in (4.10). We note that a similar method[20] was already used in the case of the tau functions associated with the Laguerre polynomials, to show that the Virasoro constraints uniquely characterize these tau functions (up to a constant).

The constraint (4.12) evaluated at $t\equiv(t_1,t_2,t_3,\dots)=(0,0,0,...)$ gives, remembering the definition of $r(z)$ in (4.10),

$$\left.\frac{\partial f}{\partial t_1}\right|_{t=0}=\frac{r(z)-n(\alpha-\beta)}{2n+\alpha+\beta}. \tag{4.15}$$

We then proceed by induction. We call

$$\frac{\partial^n f}{\partial t_{j_1}\cdots\partial t_{j_n}}, \tag{4.16}$$

a t derivative of weighted degree $|j|=j_1+\cdots+j_n$. Then, for $k\geqslant 1$, we compute the system formed by

$$\begin{aligned}&\text{all } t-\text{derivatives of weighted degree } k \text{ of the constraint (4.12)},\\ &\text{all } t-\text{derivatives of weighted degree } k-1 \text{ of the constraint (4.13)},\\ &\text{all } t-\text{derivatives of weighted degree } k-2 \text{ of the constraint (4.14)},\\ &\qquad\qquad\qquad\qquad\text{evaluated at } t=0.\end{aligned} \tag{4.17}$$

For instance, for $k=1$, (4.17) reduces to

$$\begin{aligned}(z^2-1)\frac{d}{dz}\left(\left.\frac{\partial f}{\partial t_1}\right|_{t=0}\right)&=-n+(2n+\alpha+\beta)\left.\frac{\partial^2 f}{\partial t_1^2}\right|_{t=0}+\left.\frac{\partial f}{\partial t_2}\right|_{t=0},\\ zr(z)=-n^2+(\alpha-\beta)\left.\frac{\partial f}{\partial t_1}\right|_{t=0}&+(2n+\alpha+\beta)\left.\frac{\partial f}{\partial t_2}\right|_{t=0}+\left.\frac{\partial^2 f}{\partial t_1^2}\right|_{t=0}+\left(\left.\frac{\partial f}{\partial t_1}\right|_{t=0}\right)^2,\end{aligned} \tag{4.18}$$

which, after substitution of (4.15), can be solved for $\partial^2 f/\partial t_1^2|_{t=0}$ and $\partial f/\partial t_2|_{t=0}$ in terms of $r(z)$ and $r'(z)$.

In general, the system (4.17) is an (overdetermined) system that can be solved for all t derivatives of f of weighted degree $k+1$, evaluated at $t=0$, in terms of lower (weighted) degree t derivatives of f (at $t=0$). Assuming, by induction, that the latter have already been expressed in terms of $r(z)$ and its first $k-1$ derivatives, we conclude that all t derivatives of f of weighted degree $k+1$, at $t=0$, can be expressed purely in z, in terms of $r(z)$ and its first k derivatives.

Since the KP equation (2.21) contains t derivatives of f of weighted degree less or equal to 4, by performing the above scheme up to $k=3$, we can express all these derivatives, evaluated at $t=0$, in terms of $r(z)$ and its first three derivatives, which gives us *a third-order* differential equation for $r(z)$:

$$\begin{aligned}(1-z^2)^2r'''=&\,2z(1-z^2)r''+6(1-z^2)(r')^2+8zrr'\\ &-[4n^2+4(\alpha+\beta)n-(\alpha-\beta)^2+2(\beta^2-\alpha^2)z-(2n+\alpha+\beta)^2z^2]r'\\ &-2r^2-[\alpha^2-\beta^2+(2n+\alpha+\beta)^2z]r.\end{aligned} \tag{4.19}$$

Now Tracy and Widom,[3] using a different method, find that $r(z)$ satisfies *another third-order* differential equation,

$$\begin{aligned}(1-z^2)^2r'''=&\,(1-z^2)^2\frac{(r'')^2}{r'}+2z(1-z^2)r''+2(1-z^2)(r')^2\\ &+2\left(1-\frac{2\alpha_1^2}{r'}\right)r^2+4\alpha_1(\alpha_0+\alpha_1 z)r,\end{aligned} \tag{4.20}$$

with

$$\alpha_0=\frac{\beta^2-\alpha^2}{2(2n+\alpha+\beta)},\quad \alpha_1=-\left(n+\frac{\alpha+\beta}{2}\right). \tag{4.21}$$

Substracting Eq. (4.20) from Eq. (4.19), shows that, in fact, $r(z)$ does satisfy a *second-order* differential equation. We now show that this second-order equation is nothing but the celebrated Painlevé VI equation in disguised form.

Let us put

$$r(z)=2\rho\left(\frac{z+1}{2}\right), \tag{4.22}$$

which amounts to normalizing the Jacobi polynomials to be orthogonal on the interval [0,1], and to reparametrize our curve of moments (4.1) in terms of the variable

$$s=\frac{z+1}{2}. \tag{4.23}$$

Then, one computes that $\rho(s)$ satisfies the following second-order equation:

$$\begin{aligned}(4.19)-(4.20)\Leftrightarrow &(s(s-1)\rho'')^2+4s(s-1)(\rho')^3+4\rho'\rho^2-(2n+\alpha+\beta)^2\rho^2+4(1-2s)\rho(\rho')^2\\ &-2[2n^2+2(\alpha+\beta)n+\beta(\alpha+\beta)-(2n+\alpha+\beta)^2s]\rho\rho'\\ &-[\beta^2-2(2n^2+2(\alpha+\beta)n+\beta(\alpha+\beta))s+(2n+\alpha+\beta)^2s^2](\rho')^2=0.\end{aligned} \tag{4.24}$$

We can now state the following.

Theorem IV.3: *Let $r(z)=(z^2-1)(d/dz)\log\tau_n(z)$ be defined as in (4.10). Then, the function*

$$\sigma(s)=\frac{1}{2}r(2s-1)-\frac{(2n+\alpha+\beta)^2}{4}s+\frac{2n^2+2(\alpha+\beta)n+\alpha(\alpha+\beta)}{4}, \tag{4.25}$$

satisfies the Okamoto–Jimbo–Miwa form[21] *of the Painlevé VI equation:*

$$\begin{aligned}&\sigma'(s(s-1)\sigma'')^2+\{(2s-1)(\sigma')^2-2\sigma\sigma'-\nu_1\nu_2\nu_3\nu_4\}^2\\ &=(\sigma'+\nu_1^2)(\sigma'+\nu_2^2)(\sigma'+\nu_3^2)(\sigma'+\nu_4^2),\end{aligned} \tag{4.26}$$

with ν_i, $1\leqslant i\leqslant 4$, specified in terms of n, α and β as in the equations (4.28), (4.31), (4.32), (4.33) and (4.34) below.

Proof: Observe that, in fact, σ' factors out of Eq. (4.26), so that it can be written in the less elegant form

$$\begin{aligned}&(s(s-1)\sigma'')^2+4s(s-1)(\sigma')^3+4\sigma'\sigma^2+4(1-2s)\sigma(\sigma')^2\\ &-c_1(\sigma')^2+[2(1-2s)c_4-c_2]\sigma'+4c_4\sigma-c_3=0,\end{aligned} \tag{4.27}$$

with

$$c_1=\sum_i \nu_i^2,\quad c_2=\sum_{i<j}\nu_i^2\nu_j^2,$$

$$c_3=\sum_{i<j<k}\nu_i^2\nu_j^2\nu_k^2,\quad c_4=\nu_1\nu_2\nu_3\nu_4. \tag{4.28}$$

We try to match (4.24) with (4.27) by putting

$$\rho(s)=\sigma(s)+xs+y, \tag{4.29}$$

and determining the constants x and y to eliminate the coefficients of ρ^2 and $\rho\rho'$ in (4.24). We find that

$$x=\frac{(2n+\alpha+\beta)^2}{4} \quad \text{and} \quad y=-\frac{2n^2+2(\alpha+\beta)n+\alpha(\alpha+\beta)}{4}. \tag{4.30}$$

With this choice of x and y, the new function $\sigma(s)$ satisfies Eq. (4.27) if we take

$$c_1=2n^2+2(\alpha+\beta)n+\alpha^2+\alpha\beta+\beta^2, \tag{4.31}$$

$$\begin{aligned} c_2=\tfrac{1}{8}[&3(\alpha+\beta)^2(\alpha^2+\beta^2)+4(\alpha+\beta)(3\alpha^2+2\alpha\beta+3\beta^2)n \\ &+4(5\alpha^2+6\alpha\beta+5\beta^2)n^2+16(\alpha+\beta)n^3+8n^4], \end{aligned} \tag{4.32}$$

$$\begin{aligned} c_3=&\frac{(2n+\alpha+\beta)^2}{16} \\ &\times[(\alpha+\beta)^2(\alpha^2-\alpha\beta+\beta^2)+2(\alpha+\beta)(\alpha^2+\beta^2)n+2(\alpha^2+\beta^2)n^2], \end{aligned} \tag{4.33}$$

$$c_4=\frac{(\alpha^2-\beta^2)(2n+\alpha+\beta)^2}{16}. \tag{4.34}$$

Remembering the relations between the functions $r(z)$, $\rho(s)$, and $\sigma(s)$ in (4.22), (4.29), and (4.30), Theorem IV.3 is established.

Remarks: (1) One can check that

$$\begin{aligned} &2r''(z)\times(\text{left-hand side–right-hand side) of (4.19)} \\ &=\frac{d}{dz}r'(z)\times[\text{right-hand side of (4.20)–right-hand side of (4.19)}]. \end{aligned} \tag{4.35}$$

This shows that, in fact, the third-order equation (4.19), which is obtained by the ''Virasoro method,'' can indeed be integrated into a second-order equation, which we know to be equivalent [via (4.25)] to the Painlevé VI equation. Thus, in principle, we could have derived our result without using the equation (4.20) found by Tracy and Widom. But (4.35) is not so easy to guess *a priori*!

(2) From our point of view, it is no more difficult to obtain systems of partial differential equations satisfied by the probability of finding no eigenvalues in a disjoint union of intervals $\cup_{i=1}^{r}[z_{2i-1},z_{2i}]\subset[-1,1]$, as a function of the boundary points. One just needs to consider the ''manifolds'' in the space of moments,

$$\mu_k(z_1,\ldots,z_{2r})=\sum_{i=0}^{r}\int_{z_{2i}}^{z_{2i+1}}x^k(1-x)^\alpha(1+x)^\beta\,dx, \tag{4.36}$$

with $z_0=-1$ and $z_{2r+1}=1$, the crucial point being that the quantity under the integral sign in (4.4) is an *exact derivative*. One then replaces the ordinary differential operator in z on the left-hand side of (4.3) by the partial differential operator

$$\sum_{i=1}^{2r} z_i^j(z_i^2-1)\frac{\partial}{\partial z_i}. \tag{4.37}$$

Using a recipe similar to the one described in (4.17), one can express all the time derivatives of the logarithmic derivative of the tau function, evaluated at time $t=0$, in terms of partial derivatives with respect to the variables z_i, $1\leqslant i\leqslant 2r$. Substituting the result into Hirota's hierarchy of bilinear equations satisfied by the tau function, produces the desired system of partial differential equations.

APPENDIX: THE HERMITE AND LAGUERRE ENSEMBLES

For the sake of completeness, we write the analogues of Eqs. (4.3) and (4.7), in the cases of the Laguerre and the Hermite polynomials, though it does not lead to new results on the corresponding orthogonal polynomial ensembles. Only the methodology is different.

In the case of the Laguerre polynomials the curve of moments,

$$\mu_k(z)=\int_z^\infty x^{k+\alpha}e^{-x}\,dx, \quad z\in[0,\infty[,\alpha>-1, \tag{A1}$$

satisfies

$$z^{j+1}\frac{d}{dz}\mu_k(z)=(V_j-T_j+\alpha T_{j-1})\mu_k(z), \quad j=0,1,2,..., \tag{A2}$$

which, using Theorem III.1, immediately leads to the Virasoro constraints on $\tau_n(z,t)$:

$$z^{j+1}\frac{\partial}{\partial z}\tau_n(z,t)=\left(L_j^{(n)}-\frac{\partial}{\partial t_{j+1}}+\alpha\frac{\partial}{\partial t_j}\right)\tau_n(z,t), \quad j=0,1,2,\dots . \tag{A3}$$

The functions

$$\sigma(z)=z\frac{d}{dz}\log\tau_n(z), \tag{A4}$$

satisfy the Okamoto–Jimbo–Miwa form[21] of the Painlevé V equation:

$$\begin{aligned}(z\sigma'')^2=(\sigma-z\sigma'+2(\sigma')^2+(\nu_0+\nu_1+\nu_2+\nu_3)\sigma')^2\\ -4(\sigma'+\nu_0)(\sigma'+\nu_1)(\sigma'+\nu_2)(\sigma'+\nu_3),\end{aligned} \tag{A5}$$

with

$$\nu_0=n, \quad \nu_1=n+\alpha, \quad \nu_2=\nu_3=0. \tag{A6}$$

For the Hermite polynomials, the curve of moments,

$$\mu_k(z)=\int_z^\infty x^k e^{-x^2}\,dx, \quad z\in]-\infty,\infty[, \tag{A7}$$

satisfies

$$z^{j+1}\frac{d}{dz}\mu_k(z)=(V_j-2T_{j+1})\mu_k(z), \quad j=-1,0,1,2,..., \tag{A8}$$

leading to the Virasoro constraints

$$z^{j+1}\frac{\partial}{\partial z}\tau_n(z,t)=\left(L_j^{(n)}-2\frac{\partial}{\partial t_{j+2}}\right)\tau_n(z,t), \quad j=-1,0,1,2,\dots . \tag{A9}$$

The functions

$$\sigma(z)=\frac{d}{dz}\log\tau_n(z), \tag{A10}$$

satisfy the Okamoto–Jimbo–Miwa form[21] of the Painlevé IV equation:

$$(\sigma'')^2=4(z\sigma'-\sigma)^2-4(\sigma'+\nu_0)(\sigma'+\nu_1)(\sigma'+\nu_2), \tag{A11}$$

with

$$\nu_0=2n, \quad \nu_1=\nu_2=0. \tag{A12}$$

We notice that, both in (A2) and (A8), the subalgebra $\{\mathcal{V}_i\}$ of the algebra of master symmetries, which becomes tangent along the curves of moments (A1) and (A7), satisfies the commutation relations

$$[\mathcal{V}_i,\mathcal{V}_j]=(j-i)\mathcal{V}_{i+j}. \tag{A13}$$

Equations (A5) and (A11) were first obtained by Tracy and Widom.[3] When $z\to 0$ (respectively, $z\to-\infty$), the left-hand side of (A2) [respectively, (A8)] vanishes; the corresponding Virasoro constraints for the tau functions (A3) [respectively (A9)] were obtained by Haine and Horozov.[6] The introduction of a ''boundary-part'' into (A3) and (A9) appears in Adler, Shiota, and van Moerbeke.[5] We hope that the methodology developed in this paper will bring further progress in the field.

(Received 18 March 1998; accepted for publication 30 September 1998)

An algebra homomorphism ψ from the nonstandard q-deformed (cyclically symmetric) algebra $U_q(so_3)$ to the extension $\hat{U}_q(sl_2)$ of the Hopf algebra $U_q(sl_2)$ is constructed. Not all irreducible representations of $U_q(sl_2)$ can be extended to representations of $\hat{U}_q(sl_2)$. Composing the homomorphism ψ with irreducible representations of $\hat{U}_q(sl_2)$ we obtain representations of $U_q(so_3)$. Not all of these representations of $U_q(so_3)$ are irreducible. Reducible representations of $U_q(so_3)$ are decomposed into irreducible components. In this way we obtain all irreducible representations of $U_q(so_3)$ when q is not a root of unity. A part of these representations turns into irreducible representations of the Lie algebra so_3 when $q\to 1$. Representations of the other part have no classical analog. Using the homomorphism ψ it is shown how to construct tensor products of finite-dimensional representations of $U_q(so_3)$. Irreducible representations of $U_q(so_3)$ when q is a root of unity are constructed. Some of them are obtained from irreducible representations of $\hat{U}_q(sl_2)$ by means of the homomorphism ψ. *© 1999 American Institute of Physics.* [S0022-2488(99)01003-8]

I. INTRODUCTION

It is well known that the Lie algebras sl_2 and so_3 of the Lie groups $SL(2,C)$ and $SO(3)$, respectively, are isomorphic. But these algebras differ from each other if we consider their embedding to the wider Lie algebra sl_3. There is no automorphism of sl_3 which transfers the embedding $sl_2\subset sl_3$ to the embedding $so_3\subset sl_3$. Note that the embedding $so_3\subset sl_3$ is of great importance for nuclear physics: it is used in spectroscopy.

The definition of the q-analog of the universal enveloping algebra $U(sl_2)$ is well known. It is the quantum algebra $U_q(sl_2)$ which is a Hopf algebra. If we wish to have a q-analog of the universal enveloping algebra so_3 such that at $q\to 1$ we obtain the classical embedding $so_3\subset sl_3$, then the algebra sl_2 is not appropriate for this role. By other words, an algebra $U_q(so_3)$ must differ from $U_q(sl_2)$. This algebra $U_q(so_3)$ is well known. It is the associative algebra generated by three elements I_1, I_2, and I_3 satisfying the relations

$$q^{1/2}I_1I_2-q^{-1/2}I_2I_1=I_3, \tag{1}$$

$$q^{1/2}I_2I_3-q^{-1/2}I_3I_2=I_1, \tag{2}$$

$$q^{1/2}I_3I_1-q^{-1/2}I_1I_3=I_2. \tag{3}$$

Such (and more general) deformation of the commutator $[I_i, I_j]=I_iI_j-I_jI_i$ was defined in 1967 by R. Santilli in Ref. 1 (see also Refs. 2 and 3) under studying a generalization of the Lie theory. Afterwards (in 1990), the algebra $U_q(so_3)$ with commutation relations (1)–(3) was determined by D. Fairlie (see Ref. 4). An algebra which can be reduced to $U_q(so_3)$ was defined in 1986 by M. Odesski in Ref. 5.

Fairlie gave finite-dimensional irreducible representations of the algebra $U_q(so_3)$ which at $q\to 1$ give the well-known finite-dimensional irreducible representations of the Lie algebra so_3 (see Ref. 4). These representations are given by integral or half-integral non-negative numbers. Odesski also gave some classes of irreducible representations in Ref. 5.

It was shown in Refs. 5–7 that the algebra $U_q(so_3)$ has irreducible finite-dimensional representations which have no classical analog (that is, which do not admit the limit $q\to 1$). It was not clear why such strange representations of the algebra $U_q(so_3)$ appear. What is their nature? The answer to this question is one of the aims of this paper.

We construct a homomorphism from $U_q(so_3)$ to the algebra $\hat{U}_q(sl_2)$ which is an extension of the well-known quantum algebra $U_q(sl_2)$ [note that there is no homomorphism from $U_q(so_3)$ to $U_q(sl_2)$]. Irreducible finite-dimensional representations of $U_q(sl_2)$ (but not all) can be extended to finite-dimensional representations of the algebra $\hat{U}_q(sl_2)$. Composing a homomorphism $U_q(so_3)\to\hat{U}_q(sl_2)$ with these representations of $\hat{U}_q(sl_2)$, we obtain representations of the algebra $U_q(so_3)$. But some irreducible representations of $\hat{U}_q(sl_2)$ lead to reducible representations of the algebra $U_q(so_3)$. Decomposing these reducible representations of $U_q(so_3)$ we obtain irreducible representations of this algebra which have no analog for the Lie algebra so_3. If q is not a root of unity, then in this way we obtain all finite-dimensional irreducible representations of $U_q(so_3)$. But there are infinite-dimensional irreducible representations of $U_q(so_3)$ which cannot be obtained in this way.

Existence of the homomorphism $U_q(so_3)\to\hat{U}_q(sl_2)$ allows us to define tensor products of representations of the algebra $U_q(so_3)$ which is not a Hopf algebra.

Using the homomorphism $U_q(so_3)\to\hat{U}_q(sl_2)$ and irreducible representations of $\hat{U}_q(sl_2)$ we obtain representations of $U_q(so_3)$ when q is a root of unity. Taking irreducible representations of $U_q(so_3)$ obtained in this way and decomposing reducible representations, we obtain several series of irreducible representations of $U_q(so_3)$. In addition, we construct irreducible representations of $U_q(so_3)$ which cannot be derived from $\hat{U}_q(sl_2)$.

When q is not a root of unity, then each irreducible (finite or infinite dimensional) representation of $U_q(so_3)$ is equivalent to one of the representations constructed below. (We do not give a proof of this assertion in this paper because it would take much space; this proof will be given in a separate paper.) We think that in this paper we constructed also all irreducible representations of $U_q(so_3)$ when q is a root of unity. But in this case we have no proof of this assertion. The reason of this is that in this case there are many classes of irreducible representations and a proof of completeness of irreducible representations becomes very tedious.

Let us remark that in Ref. 5 there were constructed irreducible finite-dimensional representations of $U_q(so_3)$ when q is not a root of unity and a part of irreducible infinite-dimensional representations. In Refs. 6 and 7, there were constructed irreducible representations of $U_q(so_3)$ which satisfy the conditions of $*$-representations [that is, such that $T(I_j^*)=-T(I_j)$, $j=1,2$]. These $*$-representations are a part of irreducible representations of $U_q(so_3)$ constructed in this paper. We started to study irreducible representations of $U_q(so_3)$ for q a root of unity in Ref. 8, where a part of irreducible representations for this case were constructed. Note that in Refs. 5–8 there are no relations of representations of $U_q(so_3)$ to representations of $\hat{U}_q(sl_2)$. This relation makes representations of $U_q(so_3)$ clear and understandable.

We suppose that in Secs. II and III q is any complex number different from -1. In Secs. IV–VII, q is not a root of unity. In Secs. VIII–X, q is a root of unity.

II. THE ALGEBRAS $\mathrm{U}_q(\mathrm{so}_3)$ AND $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$

The algebra $\mathrm{U}_q(\mathrm{so}_3)$ is obtained by a q-deformation of the standard commutation relations

$$[I_1,I_2]=I_3,\quad [I_2,I_3]=I_1,\quad [I_3,I_1]=I_2$$

of the Lie algebra so_3. So, $\mathrm{U}_q(\mathrm{so}_3)$ is defined as the complex associative algebra with unit element generated by the elements I_1,I_2,I_3 satisfying the defining relations

$$[I_1,I_2]_q:=q^{1/2}I_1I_2-q^{-1/2}I_2I_1=I_3, \tag{4}$$

$$[I_2,I_3]_q:=q^{1/2}I_2I_3-q^{-1/2}I_3I_2=I_1, \tag{5}$$

$$[I_3,I_1]_q:=q^{1/2}I_3I_1-q^{-1/2}I_1I_3=I_2. \tag{6}$$

Unfortunately, a Hopf algebra structure is not known on $\mathrm{U}_q(\mathrm{so}_3)$. However, it can be embedded into the Hopf algebra $\mathrm{U}_q(\mathrm{sl}_3)$ as a Hopf coideal (see Ref. 9). This embedding is very important for the possible application in spectroscopy.

It follows from the relations (4)–(6) that for the algebra $\mathrm{U}_q(\mathrm{so}_3)$ the Poincaré–Birkhoff–Witt theorem is true and this theorem can be formulated as: *The elements* $I_1^kI_2^mI_3^n$, $k,m,n=0,1,2,...$, *form a basis of the linear space* $\mathrm{U}_q(\mathrm{so}_3)$. Indeed, by using the relations (4)–(6) any product $I_{j_1}I_{j_2}\cdots I_{j_s}$, $j_1,j_2,\cdots,j_s=1,2,3$, can be reduced to a sum of the elements $I_1^kI_2^mI_3^n$ with complex coefficients.

Note that by (4) the element I_3 is not independent: it is determined by the elements I_1 and I_2. Thus, the algebra $\mathrm{U}_q(\mathrm{so}_3)$ is generated by I_1 and I_2, but now instead of quadratic relations (4)–(6) we must take the relations

$$I_1I_2^2-(q+q^{-1})I_2I_1I_2+I_2^2I_1=-I_1, \tag{7}$$

$$I_2I_1^2-(q+q^{-1})I_1I_2I_1+I_1^2I_2=-I_2, \tag{8}$$

which are obtained if we substitute the expression (4) for I_3 into (5) and (6). The equation $I_3=q^{1/2}I_1I_2-q^{-1/2}I_2I_1$ and the relations (7) and (8) restore the relations (4)–(6).

Remark that the definition of $\mathrm{U}_q(\mathrm{so}_3)$ by means of relations (7) and (8) was used in Ref. 9 for the embedding of $\mathrm{U}_q(\mathrm{so}_3)$ to $\mathrm{U}_q(\mathrm{sl}_3)$. The relations (7) and (8) differ from Serre's relations in the definition of quantum algebras by V. Drinfeld and M. Jimbo by the appearance of nonvanishing right-hand sides.

The algebra $\mathrm{U}_q(\mathrm{so}_3)$ is closely related to (but does not coincide with) the quantum algebra $\mathrm{U}_q(\mathrm{sl}_2)$. The last algebra is generated by the elements q^H, q^{-H}, E, and F satisfying the relations

$$q^Hq^{-H}=q^{-H}q^H=1,\quad q^HEq^{-H}=qE,\quad q^HFq^{-H}=q^{-1}F, \tag{9}$$

$$[E,F]:=EF-FE=\frac{q^{2H}-q^{-2H}}{q-q^{-1}}. \tag{10}$$

Note that $\mathrm{U}_q(\mathrm{sl}_2)$ is the associative algebra equipped with a Hopf algebra structure (a comultiplication, a counit, and an antipode). In particular, the comultiplication Δ is determined by the formulas

$$\Delta(q^{\pm H})=q^{\pm H}\otimes q^{\pm H},\quad \Delta(E)=E\otimes q^H+q^{-H}\otimes E,\quad \Delta(F)=F\otimes q^H+q^{-H}\otimes F.$$

In order to relate the algebras $\mathrm{U}_q(\mathrm{so}_3)$ and $\mathrm{U}_q(\mathrm{sl}_2)$ we need to extend $\mathrm{U}_q(\mathrm{sl}_2)$ by the elements $(q^kq^H+q^{-k}q^{-H})^{-1}$ in the sense of Ref. 10. We denote by $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ the associative algebra with unit element generated by the elements

$$q^H,\quad q^{-H},\quad E,\quad F,\quad (q^k q^H+q^{-k}q^{-H})^{-1},\quad k\in\mathbf{Z},$$

satisfying the defining relations (9) and (10) of the algebra $\mathrm{U}_q(\mathrm{sl}_2)$ and the following natural relations:

$$(q^kq^H+q^{-k}q^{-H})^{-1}(q^kq^H+q^{-k}q^{-H})=(q^kq^H+q^{-k}q^{-H})(q^kq^H+q^{-k}q^{-H})^{-1}=1, \tag{11}$$

$$q^{\pm H}(q^kq^H+q^{-k}q^{-H})^{-1}=(q^kq^H+q^{-k}q^{-H})^{-1}q^{\pm H}, \tag{12}$$

$$(q^kq^H+q^{-k}q^{-H})^{-1}E=E(q^{k+1}q^H+q^{-k-1}q^{-H})^{-1}, \tag{13}$$

$$(q^kq^H+q^{-k}q^{-H})^{-1}F=F(q^{k-1}q^H+q^{-k+1}q^{-H})^{-1}. \tag{14}$$

Note that the algebra $\mathrm{U}_q(\mathrm{sl}_2)$ has finite-dimensional irreducible representations $T_l\equiv T_l^{(1)}$, $T_l^{(-1)}$, $T_l^{(i)}$, $T_l^{(-i)}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,$ acting on the vector spaces $\mathcal{H}_l$ with bases $|m\rangle$, $m=-l,-l+1,...,l$. These representations are given by the formulas

$$T_l^{(1)}(q^H)|m\rangle=q^m|m\rangle,\quad T_l^{(1)}(E)|m\rangle=[l-m]|m+1\rangle, \tag{15}$$

$$T_l^{(1)}(F)|m\rangle=[l+m]|m-1\rangle, \tag{16}$$

where a number in square brackets means a q-number, defined by the formula

$$[a]=\frac{q^a-q^{-a}}{q-q^{-1}},$$

and by the formulas

$$T_l^{(-1)}(q^H)|m\rangle=-q^m|m\rangle,\quad T_l^{(-1)}(E)=T_l^{(1)}(E),\quad T_l^{(-1)}(F)=T_l^{(1)}(F), \tag{17}$$

$$T_l^{(i)}(q^H)|m\rangle=iq^m|m\rangle,\quad T_l^{(i)}(E)=T_l^{(1)}(E),\quad T_l^{(i)}(F)=-T_l^{(1)}(F), \tag{18}$$

$$T_l^{(-i)}(q^H)|m\rangle=-iq^m|m\rangle,\quad T_l^{(-i)}(E)=T_l^{(1)}(E),\quad T_l^{(-i)}(F)=-T_l^{(1)}(F). \tag{19}$$

The representations $T_l^{(1)}$, $T_l^{(-1)}$, $T_l^{(i)}$, $T_l^{(-i)}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,$ are pairwise nonequivalent, and any finite-dimensional irreducible representation of $\mathrm{U}_q(\mathrm{sl}_2)$ is equivalent to one of these representations (see, for example, Ref. 11, Chap. 3).

Now we wish to extend these representations of $\mathrm{U}_q(\mathrm{sl}_2)$ to the representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ by using the relation

$$T((q^kq^H+q^{-k}q^{-H})^{-1}):=(q^kT(q^H)+q^{-k}T(q^{-H}))^{-1}.$$

Clearly, only those irreducible representations T of $\mathrm{U}_q(\mathrm{sl}_2)$ can be extended to $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ for which the operators $q^kT(q^H)+q^{-k}T(q^{-H})$ are invertible. From formulas (15)–(19) it is clear that these operators are always invertible for the representations $T_l^{(1)}$, $T_l^{(-1)}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,$ and for the representations $T_l^{(i)}$, $T_l^{(-i)}$, $l=\frac{1}{2},\frac{3}{2},\frac{5}{2},\ldots$. For the representations $T_l^{(i)}$, $T_l^{(-i)}$, $l=0,1,2,...$, some of these operators are not invertible since they have zero eigenvalue. Denoting the extended representations by the same symbols, we can formulate the following statement:

Proposition 1: The algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ *has the irreducible finite-dimensional representations* $T_l^{(1)}$, $T_l^{(-1)}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,$ *and* $T_l^{(i)}$, $T_l^{(-i)}$, $l=\frac{1}{2},\frac{3}{2},\frac{5}{2},\ldots$. *Any irreducible finite-dimensional representation of* $\mathrm{U}_q(\mathrm{sl}_2)$ *is equivalent to one of these representations.*

III. THE ALGEBRA HOMOMORPHISM $\mathrm{U}_q(\mathrm{so}_3) \to \hat{\mathrm{U}}_q(\mathrm{sl}_2)$

The aim of this section is to give (in an explicit form) the homomorphism of the algebra $\mathrm{U}_q(\mathrm{so}_3)$ to $\hat{U}_q(\mathrm{sl}_2)$. This homomorphism is described by the following proposition:

Proposition 2: There exists a unique algebra homomorphism $\psi:\mathrm{U}_q(\mathrm{so}_3)\to\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ *such that*

$$\psi(I_1)=\frac{i}{q-q^{-1}}(q^H-q^{-H}), \tag{20}$$

$$\psi(I_2)=(E-F)(q^H+q^{-H})^{-1}, \tag{21}$$

$$\psi(I_3)=(iq^{H-1/2}E+iq^{-H-1/2}F)(q^H+q^{-H})^{-1}, \tag{22}$$

where $q^{H+a}:=q^Hq^a$ *for* $a\in\mathbf{C}$.

Proof: In order to prove this proposition we have to show that

$$\begin{aligned} &q^{1/2}\psi(I_1)\psi(I_2)-q^{-1/2}\psi(I_2)\psi(I_1)=\psi(I_3),\\ &q^{1/2}\psi(I_2)\psi(I_3)-q^{-1/2}\psi(I_3)\psi(I_2)=\psi(I_1),\\ &q^{1/2}\psi(I_3)\psi(I_1)-q^{-1/2}\psi(I_1)\psi(I_3)=\psi(I_2).\end{aligned} \tag{23}$$

Let us prove the relation (23). (Other relations are proved similarly.) Substituting the expressions (20)–(22) for $\psi(I_i)$, $i=1,2,3$, into (23) we have [after multiplying both sides of the equality by (q^H+q^{-H}) on the right], the relation

$$\begin{aligned} &q(E-F)Eq^H(qq^H+q^{-1}q^{-H})^{-1}+q(E-F)Fq^{-H}(q^{-1}q^H+qq^{-H})^{-1}\\ &\quad -qE^2q^H(qq^H+q^{-1}q^{-H})^{-1}-q^{-1}FEq^{-H}(qq^H+q^{-1}q^{-H})^{-1}\\ &\quad +q^{-1}EFq^H(q^{-1}q^H+qq^{-H})^{-1}+qF^2q^{-H}(q^{-1}q^H+qq^{-H})^{-1}=i\,\frac{q^{2H}-q^{-2H}}{q-q^{-1}}.\end{aligned}$$

The formula (23) is true if and only if this relation is correct. We multiply both its sides by $(qq^H+q^{-1}q^{-H})(q^{-1}q^H+qq^{-H})$ on the right and obtain the relation in the algebra $\mathrm{U}_q(\mathrm{sl}_2)$ [that is, without the expressions $(q^kq^H+q^{-k}q^{-H})^{-1}$]. This relation is easily verified by using the defining relations (9) and (10) of the algebra $\mathrm{U}_q(\mathrm{sl}_2)$. Proposition is proved.

IV. FINITE-DIMENSIONAL REPRESENTATIONS OF $\mathrm{U}_q(\mathrm{so}_3)$: q IS NOT A ROOT OF UNITY

We assume in Secs. IV–VII that q is not a root of unity.

If T is a representation of the algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ on a linear space $\mathcal{V}$, then the mapping $R:\mathrm{U}_q(\mathrm{so}_3)\to\mathcal{V}$ defined as the composition $R=T\circ\psi$, where ψ is the homomorphism from Proposition 2, is a representation of $\mathrm{U}_q(\mathrm{so}_3)$. Let us consider the representations

$$R_l^{(1)}=T_l^{(1)}\circ\psi,\quad R_l^{(-1)}=T_l^{(-1)}\circ\psi,\quad R_l^{(i)}=T_l^{(i)}\circ\psi,\quad R_l^{(-i)}=T_l^{(-i)}\circ\psi$$

of $\mathrm{U}_q(\mathrm{so}_3)$, where $T_l^{(1)}$, $T_l^{(-1)}$, $T_l^{(i)}$, and $T_l^{(-i)}$ are the irreducible representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ from Proposition 1.

Using formulas for the representations $T_l^{(\pm1)}$ of $\mathrm{U}_q(\mathrm{sl}_2)$ and the expressions (20)–(22) for $\psi(I_j)$, $j=1,2,3$, we find that

$$R_l^{(1)}(I_1)|m\rangle=i[m]|m\rangle,$$

$$R_l^{(1)}(I_2)|m\rangle = \frac{1}{q^m+q^{-m}}\{[l-m]|m+1\rangle - [l+m]|m-1\rangle\},$$

$$R_l^{(1)}(I_3)|m\rangle = \frac{iq^{1/2}}{q^m+q^{-m}}\{q^m[l-m]|m+1\rangle + q^{-m}[l+m]|m-1\rangle\}$$

for the representation $R_l^{(1)}$ and

$$R_l^{(-1)}(I_1)|m\rangle = -i[m]|m\rangle,\quad R_l^{(-1)}(I_2) = -R_l^{(1)}(I_2),\quad R_l^{(-1)}(I_3) = R_l^{(1)}(I_3).$$

Denoting the vectors $|m\rangle$ by $|-m\rangle$ for the representation $R_l^{(-1)}$ we easily find that the matrices of the representation $R_l^{(-1)}$ in the basis $|-m\rangle$, $m=-l,-l+1,...,l$, coincide with the corresponding matrices of the representation $R_l^{(1)}$. Thus, the nonequivalent representations $T_l^{(1)}$ and $T_l^{(-1)}$ of the algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ lead to equivalent representations of $\mathrm{U}_q(\mathrm{so}_3)$.

For the representations $R_l^{(i)}$ and $R_l^{(-i)}$ we have

$$R_l^{(i)}(I_1)|m\rangle = -\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle,$$

$$R_l^{(i)}(I_2)|m\rangle = i\frac{[l-m]}{q^m-q^{-m}}|m+1\rangle + i\frac{[l+m]}{q^m-q^{-m}}|m-1\rangle,$$

$$R_l^{(i)}(I_3)|m\rangle = -\frac{iq^{m+1/2}[l-m]}{q^m-q^{-m}}|m+1\rangle - \frac{iq^{-m+1/2}[l+m]}{q^m-q^{-m}}|m-1\rangle,$$

and

$$R_l^{(-i)}(I_1)|m\rangle = \frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle,$$

$$R_l^{(-i)}(I_2)|m\rangle = -i\frac{[l-m]}{q^m-q^{-m}}|m+1\rangle - i\frac{[l+m]}{q^m-q^{-m}}|m-1\rangle,$$

$$R_l^{(-i)}(I_3)|m\rangle = -\frac{iq^{m+1/2}[l-m]}{q^m-q^{-m}}|m+1\rangle - \frac{iq^{-m+1/2}[l+m]}{q^m-q^{-m}}|m-1\rangle.$$

Proposition 3: The representations $R_l^{(1)}$ of $\mathrm{U}_q(\mathrm{so}_3)$ *are irreducible. The representations $R_l^{(i)}$ and $R_l^{(-i)}$ are reducible.*

Proof: To prove the first part of the proposition we first note that since q is not a root of unity, the eigenvalues $i[m]$, $m=-l,-l+1,...,l$, of the operator $R_l^{(1)}(I_1)$ are pairwise different.

Let V be an invariant subspace of the space $\mathcal{H}_l$ of the representation $R_l^{(1)}$, and let $\mathbf{v} \equiv \Sigma_{m_i}\alpha_i|m_i\rangle \in V$, where $|m_i\rangle$ are eigenvectors of $R_l^{(1)}(I_1)$. Then $|m_i\rangle \in V$. We prove this for the case when $\mathbf{v}=\alpha_1|m_1\rangle+\alpha_2|m_2\rangle$. (The case with a larger number of summands is proved similarly.) We have $R_l^{(1)}(I_1)\mathbf{v}=i\alpha_1[m_1]|m_1\rangle+i\alpha_2[m_2]|m_2\rangle$. Since

$$\mathbf{v}=\alpha_1|m_1\rangle+\alpha_2|m_2\rangle \in V,\quad \mathbf{v}'\equiv i\alpha_1[m_1]|m_1\rangle+i\alpha_2[m_2]|m_2\rangle \in V,$$

one derives that

$$i[m_1]\mathbf{v}-\mathbf{v}' = i\alpha_2([m_1]-[m_2])|m_2\rangle \in V.$$

Since $[m_1]\neq[m_2]$, then $|m_2\rangle \in V$ and hence $|m_1\rangle \in V$.

In order to prove that $V=\mathcal{H}_l$ we obtain from the above formulas for $R_l^{(1)}(I_2)|m\rangle$ and $R_l^{(1)}(I_3)|m\rangle$ that

$$\{R_l^{(1)}(I_3)-iq^{m+1/2}R_l^{(1)}(I_2)\}|m\rangle=iq^{1/2}|m-1\rangle,$$

$$\{R_l^{(1)}(I_3)+iq^{-m+1/2}R_l^{(1)}(I_2)\}|m\rangle=iq^{1/2}|m+1\rangle.$$

Since V contains at least one basis vector $|m\rangle$, it follows from these relations that V contains the vectors $|m-1\rangle,|m-2\rangle,\dots,|-l\rangle$ and the vectors $|m+1\rangle,|m+2\rangle,\dots,|l\rangle$. This means that $V=\mathcal{H}_l$ and the representation $R_l^{(1)}$ is irreducible.

Let us show that the representations $R_l^{(i)}$ are reducible. The eigenvalues of the operator $R_l^{(i)}(I_1)$ are

$$-\frac{q^m+q^{-m}}{q-q^{-1}},\quad m=-l,-l+1,\dots,l,$$

that is, every spectral point has multiplicity 2. Namely, the pairs of vectors $|m\rangle$ and $|-m\rangle$ are of the same eigenvalue. Let V_1 be the subspace of the representation space $\mathcal{H}_l$ spanned by the vectors

$$|\tfrac{1}{2}\rangle+i|-\tfrac{1}{2}\rangle,\quad |\tfrac{3}{2}\rangle-i|-\tfrac{3}{2}\rangle,\quad |\tfrac{5}{2}\rangle+i|-\tfrac{5}{2}\rangle,\quad |\tfrac{7}{2}\rangle-i|-\tfrac{7}{2}\rangle,\quad \dots, \tag{24}$$

and let V_2 be the subspace spanned by the vectors

$$|\tfrac{1}{2}\rangle-i|-\tfrac{1}{2}\rangle,\quad |\tfrac{3}{2}\rangle+i|-\tfrac{3}{2}\rangle,\quad |\tfrac{5}{2}\rangle-i|-\tfrac{5}{2}\rangle,\quad |\tfrac{7}{2}\rangle+i|-\tfrac{7}{2}\rangle,\quad \dots . \tag{25}$$

We denote the vectors (24) by

$$|\tfrac{1}{2}\rangle',\quad |\tfrac{3}{2}\rangle',\quad |\tfrac{5}{2}\rangle',\quad |\tfrac{7}{2}\rangle',\dots \tag{26}$$

and the vectors (25) by

$$|\tfrac{1}{2}\rangle'',\quad |\tfrac{3}{2}\rangle'',\quad |\tfrac{5}{2}\rangle'',\quad |\tfrac{7}{2}\rangle'',\quad \dots . \tag{27}$$

Then

$$R_l^{(i)}(I_1)|m\rangle'=-\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle',\quad R_l^{(i)}(I_1)|m\rangle''=-\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle''.$$

We also have

$$R_l^{(i)}(I_2)|\tfrac{1}{2}\rangle'=i\frac{[l-\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|\tfrac{3}{2}\rangle+i\frac{[l+\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|-\tfrac{1}{2}\rangle+\frac{[l+\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|\tfrac{1}{2}\rangle+\frac{[l-\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|-\tfrac{3}{2}\rangle$$
$$=\frac{[l+\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|\tfrac{1}{2}\rangle'+i\frac{[l-\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|\tfrac{3}{2}\rangle'.$$

We derive similarly that

$$R_l^{(i)}(I_2)|\tfrac{1}{2}\rangle''=-\frac{[l+\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|\tfrac{1}{2}\rangle''+i\frac{[l-\frac{1}{2}]}{q^{1/2}-q^{-1/2}}|\tfrac{3}{2}\rangle''$$

and that

$$R_l^{(i)}(I_2)|m\rangle' = i\,\frac{[l-m]}{q^m-q^{-m}}|m+1\rangle' + i\,\frac{[l+m]}{q^m-q^{-m}}|m-1\rangle', \quad m>\tfrac{1}{2},$$

$$R_l^{(i)}(I_2)|m\rangle'' = i\,\frac{[l-m]}{q^m-q^{-m}}|m+1\rangle'' + i\,\frac{[l+m]}{q^m-q^{-m}}|m-1\rangle'', \quad m>\tfrac{1}{2}.$$

Thus, the subspaces V_1 and V_2 are invariant with respect to the operators $R_l^{(i)}(I_1)$ and $R_l^{(i)}(I_2)$. This means that they are invariant with respect to the representation $R_l^{(i)}$.

It is proved similarly that the subspace V_1 of the space $\mathcal{H}_l$ of the representation $R_l^{(-i)}$ spanned by the vectors (24) and the subspace V_2 of $\mathcal{H}_l$ spanned by the vectors (25) are invariant with respect to the operators $R_l^{(-i)}(I_1)$ and $R_l^{(-i)}(I_2)$. That is, the representation $R_l^{(-i)}$ is also reducible. Proposition is proved.

Let $R_n^{(i,+)}$ and $R_n^{(i,-)}$, $n=l+\frac{1}{2}=\dim V_1=\dim V_2$, be the representations of $\mathrm{U}_q(\mathrm{so}_3)$ which are restrictions of $R_l^{(i)}$ to the subspaces V_1 and V_2, respectively. Denoting the vectors (26) of the subspace V_1 by

$$|1\rangle,|2\rangle,|3\rangle,|4\rangle,\ldots,|n\rangle \equiv |l+\tfrac{1}{2}\rangle, \tag{28}$$

respectively, we have

$$R_n^{(i,+)}(I_1)|k\rangle = -\frac{q^{k-1/2}+q^{-k+1/2}}{q-q^{-1}}|k\rangle,$$

$$R_n^{(i,+)}(I_2)|1\rangle = \frac{[n]}{q^{1/2}-q^{-1/2}}|1\rangle + i\,\frac{[n-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_n^{(i,+)}(I_2)|k\rangle = i\,\frac{[n-k]}{q^{k-1/2}-q^{-k+1/2}}|k+1\rangle + i\,\frac{[n+k-1]}{q^{k-1/2}-q^{-k+1/2}}|k-1\rangle, \quad k\neq 1.$$

For the operator $R_n^{(i,+)}(I_3)$ we have

$$R_n^{(i,+)}(I_3)|1\rangle = -\frac{[n]}{q^{1/2}-q^{-1/2}}|1\rangle - i\,\frac{q[n-1]}{q^{1/2}-q^{1/2}}|2\rangle,$$

$$R_n^{(i,+)}(I_3)|k\rangle = -i\,\frac{q^k[n-k]}{q^{k-1/2}-q^{-k+1/2}}|k+1\rangle - i\,\frac{q^{-k+1}[n+k-1]}{q^{k-1/2}-q^{-k+1/2}}|k-1\rangle, \quad k\neq 1.$$

Denoting the vectors (27) of the subspace V_2 by the symbols (28), respectively, we obtain

$$R_n^{(i,-)}(I_1)|k\rangle = -\frac{q^{k-1/2}+q^{-k+1/2}}{q-q^{-1}}|k\rangle,$$

$$R_n^{(i,-)}(I_2)|1\rangle = -\frac{[n]}{q^{1/2}-q^{-1/2}}|1\rangle + i\,\frac{[n-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_n^{(i,-)}(I_2)|k\rangle = R_n^{(i,+)}(I_2)|k\rangle, \quad k\neq 1.$$

For the operator $R_l^{(i,-)}(I_3)$ we find that

$$R_n^{(i,-)}(I_3)|1\rangle = \frac{[n]}{q^{1/2}-q^{-1/2}}|1\rangle - i\,\frac{q[n-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_n^{(i,-)}(I_3)|k\rangle = R_n^{(i,+)}(I_3)|k\rangle, \quad k\neq 1.$$

Let now $R_n^{(-i,+)}$ and $R_n^{(-i,-)}$, $n=l+\frac{1}{2}$, be the representations of $U_q(so_3)$ which are restrictions of the representation $R_l^{(-i)}$ to the subspaces V_1 and V_2, respectively. Introducing the vectors similar to the vectors (28), for the representation $R_n^{(-i,+)}$ we have

$$R_n^{(-i,+)}(I_1)|k\rangle = \frac{q^{k-1/2}+q^{-k+1/2}}{q-q^{-1}}|k\rangle, \quad R_n^{(-i,+)}(I_2) = -R_n^{(i,+)}(I_2),$$

$$R_n^{(-i,+)}(I_3)|1\rangle = \frac{[n]}{q^{1/2}-q^{-1/2}}|1\rangle + i\frac{q[n-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_n^{(-i,+)}(I_3)|k\rangle = i\frac{q^k[n-k]}{q^{k-1/2}-q^{-k+1/2}}|k+1\rangle + i\frac{q^{-k+1}[n+k-1]}{q^{k-1/2}-q^{-k+1/2}}|k-1\rangle, \quad k\neq 1.$$

For the representation $R_l^{(-i,-)}(I_3)$ we obtain

$$R_n^{(-i,-)}(I_1)|k\rangle = \frac{q^{k-1/2}+q^{-k+1/2}}{q-q^{-1}}|k\rangle, \quad R_n^{(-i,-)}(I_2) = -R_n^{(i,-)}(I_2),$$

$$R_n^{(-i,-)}(I_3)|1\rangle = -\frac{[n]}{q^{1/2}-q^{-1/2}}|1\rangle + i\frac{q[n-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_n^{(-i,-)}(I_3)|k\rangle = R_n^{(-i,+)}(I_3)|k\rangle.$$

Thus, we constructed the representations $R_n^{(i,+)}$, $R_n^{(i,-)}$, $R_n^{(-i,+)}$, and $R_n^{(-i,-)}$ of the algebra $U_q(so_3)$. The following theorem characterizes them.

Theorem 1: *The representations $R_n^{(i,+)}$, $R_n^{(i,-)}$, $R_n^{(-i,+)}$, and $R_n^{(-i,-)}$ are irreducible and pairwise nonequivalent. For any l the representation $R_l^{(1)}$ is not equivalent to any of these representations.*

Proof: The irreducibility is proved exactly in the same way as in Proposition 3. Equivalence relations may exist only for irreducible representations of the same dimension. That is, we have to show that under fixed n no pair of the representations $R_n^{(i,+)}$, $R_n^{(i,-)}$, $R_n^{(-i,+)}$, and $R_n^{(-i,-)}$ is equivalent. It follows from the above formulas that the operators $R_n^{(i,+)}(I_1)$ and $R_n^{(i,-)}(I_1)$, as well as the operators $R_n^{(-i,+)}(I_1)$ and $R_n^{(-i,-)}(I_1)$, have the same set of eigenvalues. Moreover, the spectrum of the first pair of operators differs from that of the second pair. Hence, neither of the representations $R_n^{(i,+)}$ and $R_n^{(i,-)}$ is equivalent to $R_n^{(-i,+)}$ or $R_n^{(-i,-)}$. The representations $R_n^{(i,+)}$ and $R_n^{(i,-)}$ are not equivalent since the operators $R_n^{(i,+)}(I_2)$ and $R_n^{(i,-)}(I_2)$ have different traces (for equivalent representations these operators must have the same trace). For the same reason, the representations $R_n^{(-i,+)}$ and $R_n^{(-i,-)}$ are not equivalent. The last assertion of the theorem follows from the fact that the spectrum of the operator $R_l^{(1)}(I_3)$ differs from the spectra of the operators $R_n^{(i,+)}(I_1)$, $R_n^{(i,-)}(I_1)$, $R_n^{(-i,+)}(I_1)$, and $R_n^{(-i,-)}(I_1)$. Theorem is proved.

Clearly, the reducible representations $R_n^{(i)}$ and $R_n^{(-i)}$ decompose into irreducible components as

$$R_n^{(i)} = R_n^{(i,+)} \oplus R_n^{(i,-)}, \quad R_n^{(-i)} = R_n^{(-i,+)} \oplus R_n^{(-i,-)}. \tag{29}$$

It can be proved that *every irreducible finite-dimensional representation of* $U_q(so_3)$ *is equivalent to one of the representations* $R_l^{(1)}$, $R_n^{(i,+)}$, $R_n^{(i,-)}$, $R_n^{(-i,+)}$, $R_n^{(-i,-)}$. That is, these representations exhaust, up to equivalence, all irreducible finite-dimensional representations of $U_q(so_3)$. A proof of this statement will be given in a separate paper.

V. TENSOR PRODUCTS OF REPRESENTATIONS OF $U_q(so_3)$

As mentioned above, no Hopf algebra structure is known for the algebra $U_q(so_3)$. Therefore, we cannot construct a tensor product of finite-dimensional representations of $U_q(so_3)$ by using a comultiplication as we do in the case of the quantum algebra $U_q(sl_2)$. However, we may construct some tensor product representations by using the algebra homomorphism of Proposition 2.

First we determine which tensor products of irreducible representations of $U_q(sl_2)$ can be extended to representations of the algebra $\hat{U}_q(sl_2)$. Verifying for which tensor products $T=T'\otimes T''$ of irreducible representations of $U_q(sl_2)$ the operators

$$q^k T(q^H)+q^{-k}T(q^{-H}), \quad k\in \mathbf{Z},$$

are invertible, we conclude that only the tensor products

$$T_l^{(\pm 1)}\otimes T_{l'}^{(\pm 1)}, \quad T_l^{(\pm 1)}\otimes T_{l'}^{(\mp 1)}, \quad l,l'=0,\tfrac{1}{2},1,\tfrac{3}{2},\dots,$$

$$T_l^{(\pm 1)}\otimes T_{l'}^{(\pm i)}, \quad T_l^{(\pm 1)}\otimes T_{l'}^{(\mp i)}, \quad l=0,1,2,..., \quad l'=\tfrac{1}{2},\tfrac{3}{2},\tfrac{5}{2},\dots,$$

$$T_l^{(\pm i)}\otimes T_{l'}^{(\pm 1)}, \quad T_l^{(\pm i)}\otimes T_{l'}^{(\mp 1)}, \quad l=\tfrac{1}{2},\tfrac{3}{2},\tfrac{5}{2},\dots, \quad l'=0,1,2,...,$$

$$T_l^{(\pm i)}\otimes T_{l'}^{(\pm i)}, \quad T_l^{(\pm i)}\otimes T_{l'}^{(\mp i)}, \quad l,l'=\tfrac{1}{2},\tfrac{3}{2},\tfrac{5}{2},\dots,$$

can be extended to the algebra $\hat{U}_q(sl_2)$. Taking into account the decompositions of tensor products of irreducible representations of $U_q(sl_2)$ (see, for example, the end of Subsection 3.2.1 and Proposition 3.22 in Ref. 11) we find that

$$T_l^{(\omega)}\otimes T_{l'}^{(\omega')}\simeq T_{l+l'}^{(\omega\omega')}\oplus T_{l+l'-1}^{(\omega\omega')}\oplus\cdots\oplus T_{|l+l'|}^{(\omega\omega')}, \tag{30}$$

$$T_l^{(\omega)}\otimes t_{l'}^{(\pm i)}\simeq T_{l+l'}^{(\pm\omega i)}\oplus T_{l+l'-1}^{(\pm\omega i)}\oplus\cdots\oplus T_{|l+l'|}^{(\pm\omega i)}, \tag{31}$$

$$T_l^{(\pm i)}\otimes T_{l'}^{(\omega)}\simeq T_{l+l'}^{(\pm\omega i)}\oplus T_{l+l'-1}^{(\pm\omega i)}\oplus\cdots\oplus T_{|l+l'|}^{(\pm\omega i)}, \tag{32}$$

$$T_l^{(\omega i)}\otimes T_{l'}^{(\omega' i)}\simeq T_{l+l'}^{(-\omega\omega')}\oplus T_{l+l'-1}^{(-\omega\omega')}\oplus\cdots\oplus T_{|l+l'|}^{(-\omega\omega')}, \tag{33}$$

where $\omega,\omega'=\pm 1$.

Now we define tensor products of representations of $U_q(so_3)$ corresponding to the above tensor product representations of $\hat{U}_q(sl_2)$ as

$$R\otimes R'=(T\otimes T')\circ\psi,$$

where $R=T\circ\psi$ and $R'=T'\circ\psi$. Taking into account the definitions of tensor products of representations of $U_q(sl_2)$ by means of the comultiplication and the definition of the mapping ψ we have

$$\begin{aligned}(R\otimes R')(I_1)&=(T\otimes T')\circ\psi(I_1)\\ &=\frac{i}{q-q^{-1}}(T(q^H)\otimes T'(q^H)-T(q^{-H})\otimes T'(q^{-H})).\end{aligned}$$

Similarly,

$$\begin{aligned}(R\otimes R')(I_2)=&(T(E)\otimes T'(q^H)+T(q^{-H})\otimes T'(E)-T(F)\otimes T'(q^H)\\ &-(T(q^{-H})\otimes T'(F))(T(q^H)\otimes T'(q^H)+T(q^{-H})\otimes T'(q^{-H}))^{-1}.\end{aligned}$$

Composing both sides of the relations (30)–(33) with the mapping ψ of Proposition 2, we find the decomposition into representations of $U_q(so_3)$ for the tensor products

$$R_l^{(1)}\otimes R_{l'}^{(1)},\quad R_l^{(1)}\otimes R_{l'}^{(\pm i)},\quad R_{l'}^{(\pm i)}\otimes R_l^{(1)},\quad R_l^{(\pm i)}\otimes R_{l'}^{(\pm i)},\quad R_l^{(\pm i)}\otimes R_{l'}^{(\mp i)},$$

where the second and the third tensor products are defined only for $l=0,1,2,\ldots$. (Note that the representations $R_l^{(\pm i)}$ are defined only for $l=\frac{1}{2},\frac{3}{2},\frac{5}{2},\ldots$.) We have

$$R_l^{(1)}\otimes R_{l'}^{(1)}\simeq R_{l+l'}^{(1)}\oplus R_{l+l'-1}^{(1)}\oplus\cdots\oplus R_{|l-l'|}^{(1)},$$

$$R_l^{(1)}\otimes R_{l'}^{(\pm i)}\simeq R_{l+l'}^{(\pm i)}\oplus R_{l+l'-1}^{(\pm i)}\oplus\cdots\oplus R_{|l-l'|}^{(\pm i)},$$

$$R_l^{(\pm i)}\otimes R_{l'}^{(1)}\simeq R_{l+l'}^{(\pm i)}\oplus R_{l+l'-1}^{(\pm i)}\oplus\cdots\oplus R_{|l-l'|}^{(\pm i)},$$

$$R_l^{(\omega i)}\otimes R_{l'}^{(\omega' i)}\simeq R_{l+l'}^{(1)}\oplus R_{l+l'-1}^{(1)}\oplus\cdots\oplus R_{|l-l'|}^{(1)}.$$

In these formulas the representations $R_l^{(\pm i)}$ are reducible. Unfortunately, our definition of tensor products of representations of $U_q(so_3)$ does not allow us to determine the tensor products containing the irreducible representations $R_n^{(\pm i,\pm)}$ and $R_n^{(\pm i,\mp)}$.

VI. INFINITE-DIMENSIONAL REPRESENTATIONS OF $U_q(so_3)$ OBTAINED FROM REPRESENTATIONS OF $U_q(sl_2)$

By using the homomorphism $\psi:U_q(so_3)\to\hat{U}_q(sl_2)$ from Proposition 2 and infinite-dimensional irreducible representations of the algebra $\hat{U}_q(sl_2)$ we can construct infinite-dimensional irreducible representations of the algebra $U_q(so_3)$.

Let us first describe irreducible infinite-dimensional representations of the algebra $U_q(sl_2)$. Note that by an infinite-dimensional representation T of $U_q(sl_2)$ we mean a homomorphism of $U_q(sl_2)$ into the algebra of linear operators (bounded or unbounded) on a Hilbert space, defined on an everywhere dense invariant subspace D, such that the operator $T(q^H)$ can be diagonalized, has a discrete spectrum, and its eigenvectors belong to D. Infinite-dimensional representations T of $U_q(so_3)$ are described in the same way replacing the operator $T(q^H)$ by $T(I_1)$.

Two representations T and T' of $U_q(sl_2)$ on spaces $\mathcal{H}$ and $\mathcal{H}'$, respectively, are called (algebraically) equivalent if there exist everywhere dence invariant subspaces $V\subset\mathcal{H}$ and $V'\subset\mathcal{H}'$ and a one-to-one linear operator $A:V\to V'$ such that $AT(a)\mathbf{v}=T'(a)A\mathbf{v}$ for all $a\in U_q(sl_2)$ and $\mathbf{v}\in V$. Equivalence of infinite-dimensional representations of $U_q(so_3)$ is defined in the same way.

Let ϵ be a fixed complex number such that $0\leqslant \mathrm{Re}\,\epsilon<1$, and let $\mathcal{H}_\epsilon$ be a complex Hilbert space with the orthonormal basis

$$|m\rangle,\quad m=n+\epsilon,\quad n=0,\pm1,\pm2,\ldots . \tag{34}$$

For every complex number a we construct the representation $T_{a\epsilon}$ on the Hilbert space $\mathcal{H}_\epsilon$ defined by

$$T_{a\epsilon}(q^H)|m\rangle=q^m|m\rangle,\quad T_{a\epsilon}(E)|m\rangle=[a-m]|m+1\rangle,\quad T_{a\epsilon}(F)|m\rangle=[a+m]|m-1\rangle,$$

where $[a\pm m]$ is the q-number (see, for example, Ref. 12). The equivalence relations in the set of the representations $T_{a\epsilon}$ can be extracted from Ref. 12.

Note that the representation $T_{a\epsilon}$ is irreducible if and only if $a\neq\pm\epsilon(\mathrm{mod}\,\mathbf{Z})$.

All the representations $T_{a\epsilon}$ can be extended to representations of the algebra $\hat{U}_q(sl_2)$ except for the case when $\epsilon=\pm i\pi/2\tau$, where $q=e^\tau$. (We suppose below that $\epsilon\neq\pm i\pi/2\tau$.) We denote these extended representations by the same symbols $T_{a\epsilon}$.

The formula $R_{a\epsilon}=T_{a\epsilon}\circ\psi$ associates with every irreducible representation $T_{a\epsilon}$, $\epsilon\neq\pm i\pi/2\tau$, of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ a representation of the algebra $\mathrm{U}_q(\mathrm{so}_3)$.

Let $\epsilon\neq\pm i\pi/2\tau$ and $\epsilon\neq\pm i\pi/2\tau+\frac{1}{2}$. Then for the representations $R_{a\epsilon}$ of $\mathrm{U}_q(\mathrm{so}_3)$ we have

$$R_{a\epsilon}(I_1)|m\rangle=i[m]|m\rangle, \tag{35a}$$

$$R_{a\epsilon}(I_2)|m\rangle=\frac{1}{q^m+q^{-m}}\{[a-m]|m+1\rangle-[a+m]|m-1\rangle\}, \tag{35b}$$

$$R_{a\epsilon}(I_3)|m\rangle=\frac{iq^{1/2}}{q^m+q^{-m}}\{q^m[a-m]|m+1\rangle+q^{-m}[a+m]|m-1\rangle\}. \tag{35c}$$

If $\epsilon=i\pi/2\tau+\frac{1}{2}$, then denoting the basis elements $|m\rangle$, $m=n+\epsilon$, $n\in\mathbf{Z}$, by $|n+\frac{1}{2}\rangle$, $n\in\mathbf{Z}$, respectively, we obtain

$$R_{a\epsilon}(I_1)|k\rangle=-\frac{q^k+q^{-k}}{q-q^{-1}}|k\rangle,$$

$$R_{a\epsilon}(I_2)|k\rangle=i\,\frac{[a'-k]}{q^k-q^{-k}}|k+1\rangle+i\,\frac{[a'+k]}{q^k-q^{-k}}|k-1\rangle,$$

$$R_{a\epsilon}(I_3)|k\rangle=-\frac{iq^{k+1/2}[a'-k]}{q^k-q^{-k}}|k+1\rangle-\frac{iq^{-k+1/2}[a'+k]}{q^k-q^{-k}}|k-1\rangle,$$

where $a'=a+i\pi/2\tau$ and $k=n+\frac{1}{2}$. If $\epsilon=-i\pi/2\tau+\frac{1}{2}$, then using the same notations for basis elements we obtain

$$R'_{a\epsilon}(I_1)|k\rangle=\frac{q^k+q^{-k}}{q-q^{-1}}|k\rangle,$$

$$R'_{a\epsilon}(I_2)|k\rangle=-i\,\frac{[a'-k]}{q^k-q^{-k}}|k+1\rangle-i\,\frac{[a'+k]}{q^k-q^{-k}}|k-1\rangle,$$

$$R'_{a\epsilon}(I_3)|k\rangle=-\frac{iq^{k+1/2}[a'-k]}{q^k-q^{-k}}|k+1\rangle-\frac{iq^{-k+1/2}[a'+k]}{q^k-q^{-k}}|k-1\rangle$$

(to distinguish these representations from the previous ones we supplied $R_{a\epsilon}$ with a prime).

Proposition 4: The representations $R_{a\epsilon}$ *of* $\mathrm{U}_q(\mathrm{so}_3)$ *are irreducible for irreducible representations* $T_{a\epsilon}$, $\epsilon\neq\pm i\pi/2\tau+\frac{1}{2}$ of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$. *The representations* $R_{a\epsilon}$, $\epsilon=i\pi/2\tau+\frac{1}{2}$, *and* $R'_{a\epsilon}$, $\epsilon=-i\pi/2\tau+\frac{1}{2}$, *are reducible.*

Proof is given in the same way as in the case of Proposition 3.

As in the case of finite-dimensional representations in Sec. IV, decomposing the representations $R_{a\epsilon}$, $\epsilon=i\pi/2\tau+\frac{1}{2}$, and $R'_{a\epsilon}$, $\epsilon=-i\pi/2\tau+\frac{1}{2}$, we obtain irreducible infinite-dimensional representations of $\mathrm{U}_q(\mathrm{so}_3)$ which will be denoted by $R_{a'}^{(i,\pm)}$ and $R_{a'}^{(-i,\pm)}$, $a'=a+i\pi/2\tau$. In the basis

$$|n\rangle,\quad n=1,2,3,...,$$

they are given by the formulas

$$R_{a'}^{(i,\pm)}(I_1)|k\rangle=-\frac{q^{k-1/2}+q^{-k+1/2}}{q-q^{-1}}|k\rangle,$$

$$R_{a'}^{(i,\pm)}(I_2)|1\rangle = \pm\frac{[a']}{q^{1/2}-q^{-1/2}}|1\rangle + i\,\frac{[a'-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_{a'}^{(i,\pm)}(I_2)|k\rangle = i\,\frac{[a'-k]}{q^{k-1/2}-q^{-k+1/2}}|k+1\rangle + i\,\frac{[a'+k-1]}{q^{k-1/2}-q^{-k+1/2}}|k-1\rangle, \quad k\neq 1.$$

$$R_{a'}^{(i,\pm)}(I_3)|1\rangle = \mp\frac{[a']}{q^{1/2}-q^{-1/2}}|1\rangle - i\,\frac{q[a'-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_{a'}^{(i,\pm)}(I_3)|k\rangle = -i\,\frac{q^k[a'-k]}{q^{k-1/2}-q^{-k+1/2}}|k+1\rangle - i\,\frac{q^{-k+1}[a'+k-1]}{q^{k-1/2}-q^{-k+1/2}}|k-1\rangle, \quad k\neq 1$$

and by the formulas

$$R_{a'}^{(-i,\pm)}(I_1)|k\rangle = \frac{q^{k-1/2}+q^{-k+1/2}}{q-q^{-1}}|k\rangle, \quad R_{a'}^{(-i,\pm)}(I_2) = -R_{a'}^{(i,\pm)}(I_2),$$

$$R_{a'}^{(-i,\pm)}(I_3)|1\rangle = \pm\frac{[a']}{q^{1/2}-q^{-1/2}}|1\rangle + i\,\frac{q[a'-1]}{q^{1/2}-q^{-1/2}}|2\rangle,$$

$$R_{a'}^{(-i,\pm)}(I_3)|k\rangle = i\,\frac{q^k[a'-k]}{q^{k-1/2}-q^{-k+1/2}}|k+1\rangle + i\,\frac{q^{-k+1}[a'+k-1]}{q^{k-1/2}-q^{-k+1/2}}|k-1\rangle, \quad k\neq 1.$$

Theorem 2: *The representations* $R_{a'}^{(i,\pm)}$ and $R_{a'}^{(-i,\pm)}$ *are irreducible and pairwise nonequivalent. For any a the irreducible representation* $R_{a\epsilon}$ *is not equivalent to some of these representations*.

Proof is given in the same way as in the finite-dimensional case (see the proof of Theorem 1).

The algebra $U_q(sl_2)$ also has irreducible infinite-dimensional representations with highest weights or with lowest weights. They are classified in Ref. 12. All of these representations T can be extended to the algebra $\hat{U}_q(sl_2)$. Using the composition $R=T\circ\psi$ we obtain the corresponding representations R of $U_q(so_3)$. As above, it can be easily proved that to nonequivalent representations T of $\hat{U}_q(sl_2)$ with highest or lowest weight there correspond nonequivalent irreducible representations of $U_q(so_3)$. We give a list of these representations.

Let $l=\frac{1}{2},1,\frac{3}{2},2,\ldots$. We denote by R_l^+ the representation of $U_q(so_3)$ acting on the Hilbert space $\mathcal{H}_l$ with the orthonormal basis $|m\rangle$, $m=l,l+1,l+2,\ldots$, and given by formulas (35) with $a=-l$. By R_l^- we denote the representation of $U_q(so_3)$ acting on the Hilbert space $\hat{\mathcal{H}}_l$ with the orthonormal basis $|m\rangle$, $m=-l,-l-1,-l-2,\ldots$, and given by formulas (35) with $a=l$.

Now let $a\neq 0(\mathrm{mod}\,\mathbf{Z})$ and $a\neq\frac{1}{2}(\mathrm{mod}\,\mathbf{Z})$. We denote by $\mathcal{H}_a$ the Hilbert space with the orthonormal basis $|m\rangle$, $m=-a,-a+1,-a+2,\ldots$. On this space the representation R_a^+ acts as given by formulas (35). On the Hilbert space $\hat{\mathcal{H}}_a$ with the orthonormal basis $|m\rangle$, $m=a,a-1,a-2,\ldots$, the representation R_a^- acts as given by formulas (35).

Proposition 5: The above representations $R_l^{\pm}$ *and* $R_a^{\pm}$ *are irreducible and pairwise nonequivalent.*

Proof of this proposition is contained in Ref. 13.

VII. OTHER INFINITE DIMENSIONAL REPRESENTATIONS OF $U_q(so_3)$

The algebra $U_q(so_3)$ has also irreducible infinite-dimensional representations which cannot be obtained from representations of $\hat{U}_q(sl_2)$. We describe these representations in this section.

Let $\mathcal{H}$ be the infinite-dimensional vector space with the basis $|m\rangle$, $m=0,\pm 1,\pm 2,\ldots$, and let $\lambda=q^{\tau}$ be a nonzero complex number such that $0\leqslant \mathrm{Re}\,\tau<1$. Then a direct calculation shows that the operators $Q_\lambda^+(I_1)$ and $Q_\lambda^+(I_2)$ given by the formulas

$$Q_\lambda^+(I_1)|m\rangle = \frac{\lambda q^m + \lambda^{-1} q^{-m}}{q-q^{-1}}|m\rangle,$$

$$Q_\lambda^+(I_2)|m\rangle = \frac{1}{q-q^{-1}}|m+1\rangle + \frac{1}{q-q^{-1}}|m-1\rangle$$

satisfy the relations (7) and (8) and hence determine a representation of $U_q(so_3)$ which will be denoted by Q_λ^+. Similarly, the operators $Q_\lambda^-(I_1)$ and $Q_\lambda^-(I_2)$ given on the space $\mathcal{H}$ by

$$Q_\lambda^-(I_1)|m\rangle = -\frac{\lambda q^m + \lambda^1 q^{-m}}{q-q^1}|m\rangle, \quad Q_\lambda^-(I_2) := Q_\lambda^+(I_2)$$

determine a representation of $U_q(so_3)$ which is denoted by Q_λ^-. The operators $Q_\lambda^\pm(I_3)$ can be calculated by means of formula (4).

Proposition 6: If $\lambda \neq 1$ and $\lambda \neq q^{1/2}$, then the representations Q_λ^+ and Q_λ^- are irreducible. The representations $Q_1^\pm$ and $Q_{\sqrt{q}}^\pm$ are reducible.

Proof: The first part is proved in the same way as that of Proposition 3. Let us prove the second part. The representations $Q_1^\pm$ and $Q_{\sqrt{q}}^\pm$ are the only representations in the set $\{Q_\lambda^\pm\}$ for which the operator $Q_\lambda^\pm(I_1)$ has not a simple spectrum. The operators $Q_1^\pm(I_1)$ has the spectrum

$$\ldots, \quad q^{-2}+q^2, \quad q^{-1}+q, \quad 2, \quad q+q^{-1}, \quad q^2+q^{-2}, \quad \ldots .$$

Thus, only the spectral point 2 has multiplicity 1. All other points have multiplicity 2. Let V_1 and V_2 be the vector subspaces of $\mathcal{H}$ with the bases

$$|0\rangle, \quad |m\rangle' = |m\rangle - |-m\rangle, \quad m=1,2,\ldots,$$

and

$$|m\rangle'' = |m\rangle + |-m\rangle, \quad m=1,2,\ldots,$$

respectively. These basis vectors are eigenvectors of the operator $Q_1^\pm(I_1)$:

$$Q_1^\pm(I_1)|m\rangle' = \pm\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle', \quad Q_1^\pm(I_1)|m\rangle'' = \pm\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle'',$$

and

$$Q_1^\pm(I_2)|0\rangle = \frac{1}{q-q^{-1}}|1\rangle', \quad Q_1^\pm(I_2)|1\rangle'' = \frac{1}{q-q^{-1}}|2\rangle'',$$

$$Q_1^\pm(I_2)|m\rangle' = \frac{1}{q-q^{-1}}|m+1\rangle' + \frac{1}{q-q^{-1}}|m-1\rangle', \quad m>0,$$

$$Q_1^\pm(I_2)|m\rangle'' = \frac{1}{q-q^{-1}}|m+1\rangle'' + \frac{1}{q-q^{-1}}|m-1\rangle'', \quad m>1.$$

Thus, the subspaces V_1 and V_2 are invariant with respect to the representation Q_1^+ (and the representation Q_1^-). We denote the subrepresentations of $Q_1^\pm$ realized on V_1 and V_2 by $Q_1^{1,\pm}$ and $Q_1^{2,\pm}$, respectively.

The eigenvalues of the operators $Q_{\sqrt{q}}^\pm(I_1)$ are

$$\ldots, \quad q^{-3/2}+q^{3/2}, \quad q^{-1/2}+q^{1/2}, \quad q^{1/2}+q^{-1/2}, \quad q^{3/2}+q^{-3/2}, \quad \ldots .$$

Thus, every spectral point has multiplicity 2. We denote by W_1 and W_2 the vector subspaces of $\mathcal{H}$ spanned by the basis vectors

$$|\tfrac{1}{2}\rangle' = |0\rangle - |-1\rangle, |\tfrac{3}{2}\rangle' = |1\rangle - |-2\rangle, \ldots, |m+\tfrac{1}{2}\rangle' = |m\rangle - |-m-1\rangle, \ldots$$

and

$$|\tfrac{1}{2}\rangle'' = |0\rangle + |-1\rangle, |\tfrac{3}{2}\rangle'' = |1\rangle + |-2\rangle, \ldots, |m+\tfrac{1}{2}\rangle'' = |m\rangle + |-m-1\rangle, \ldots,$$

respectively. These basis vectors are eigenvectors of the operator $Q^{\pm}_{\sqrt{q}}(I_1)$:

$$Q^{\pm}_{\sqrt{q}}(I_1)|m+\tfrac{1}{2}\rangle' = \pm \frac{q^{m+1/2}+q^{-m-1/2}}{q-q^{-1}}|m+\tfrac{1}{2}\rangle',$$

$$Q^{\pm}_{\sqrt{q}}(I_1)|m+\tfrac{1}{2}\rangle'' = \pm \frac{q^{m+1/2}+q^{-m-1/2}}{q-q^{1}}|m+\tfrac{1}{2}\rangle'',$$

and

$$Q^{\pm}_{\sqrt{q}}(I_2)|\tfrac{1}{2}\rangle' = -\frac{1}{q-q^{-1}}|\tfrac{1}{2}\rangle' + \frac{1}{q-q^{-1}}|\tfrac{3}{2}\rangle',$$

$$Q^{\pm}_{\sqrt{q}}(I_2)|m+\tfrac{1}{2}\rangle' = \frac{1}{q-q^{-1}}|m+\tfrac{3}{2}\rangle' + \frac{1}{q-q^{-1}}|m-\tfrac{1}{2}\rangle', \quad m>0,$$

$$Q^{\pm}_{\sqrt{q}}(I_2)|\tfrac{1}{2}\rangle'' = \frac{1}{q-q^{-1}}|\tfrac{1}{2}\rangle'' + \frac{1}{q-q^{-1}}|\tfrac{3}{2}\rangle'',$$

$$Q^{\pm}_{\sqrt{q}}(I_2)|m+\tfrac{1}{2}\rangle'' = \frac{1}{q-q^{-1}}|m+\tfrac{3}{2}\rangle'' + \frac{1}{q-q^{-1}}|m-\tfrac{1}{2}\rangle'', \quad m>0.$$

Thus, the subspaces W_1 and W_2 are invariant with respect to the representations $Q^{\pm}_{\sqrt{q}}$. We denote the subrepresentations of $Q^{\pm}_{\sqrt{q}}$ realized on W_1 and W_2 by $Q^{1,\pm}_{\sqrt{q}}$ and $Q^{2,\pm}_{\sqrt{q}}$, respectively. Proposition is proved.

Theorem 3: *The representations $Q^{1,\pm}_{1}$, $Q^{2,\pm}_{1}$, $Q^{1,\pm}_{\sqrt{q}}$, and $Q^{2,\pm}_{\sqrt{q}}$ are irreducible and pairwise nonequivalent. For any admissible value of λ the representation Q^{+}_{λ} (as well as the representation Q^{-}_{λ}) is not equivalent to some of these representations.*

Proof: Proof is similar to that of Theorem 1 if to take into account spectra of the operators $Q^{1,\pm}_{1}(I_1)$, $Q^{2,\pm}_{1}(I_1)$, $Q^{1,\pm}_{\sqrt{q}}(I_1)$, $Q^{2,\pm}_{\sqrt{q}}(I_1)$, and $Q^{\pm}_{\lambda}(I_1)$ and traces of the operators $Q^{1,\pm}_{1}(I_2)$, $Q^{2,\pm}_{1}(I_2)$, $Q^{1,\pm}_{\sqrt{q}}(I_2)$, and $Q^{2,\pm}_{\sqrt{q}}(I_2)$.

It will be proved in a separate paper that every irreducible infinite-dimensional representation of $U_q(so_3)$ is equivalent to one of the representations described in this and previous sections.

VIII. FINITE-DIMENSIONAL REPRESENTATIONS OF $\hat{U}_q(sl_2)$: q IS A ROOT OF UNITY

Everywhere below q is a root of unity, that is, there is a smallest positive integer p such that $q^p=1$. We suppose that $p\neq 1,2$. We introduce the number p' setting $p'=p$ if p is odd and $p'=p/2$ if p is even.

As in the case of the algebra $U_q(sl_2)$ (see Ref. 11, Chap. 3), if q is a root of unity, then $U_q(so_3)$ is a finite-dimensional vector space over the center of $U_q(so_3)$. If q is a primitive root of unity, then this assertion is stated in Ref. 5. If q is any root of unity, then this assertion may be proved in the following way. If $q^p=1$, then the center $\mathcal{C}$ of $U_q(so_3)$ contains the elements

$$P_p = I_j^p + aI_j^{p-2} + bI_j^{p-4} + \cdots + dI_j^r, \quad j=1,2,3,$$

where $r=0$ if p is even and $r=1$ if p is odd and $a,b,\ldots,d$ are certain fixed complex numbers expressed in terms of q. [They are the polynomials P defined in Ref. 5 if q is a primitive root of unity. Unfortunately, we could not find the explicit expressions for the coefficients $a,b,\ldots,d$. But note that $P_3 = I_j^3 + I_j$, $P_4 = I_j^4 + I_j^2$, and $P_5 = I_j^5 + (1+(q+q^{-1})^{-1})I_j^3 + (q+q^{-1})^{-1}I_j$.] Therefore, I_j^s, $s>n$, can be reduced to the linear combination of I_j^i, $i<n$, with coefficients from the center $\mathcal{C}$. Now our assertion follows from this and from the Poincaré–Birkhoff–Witt theorem for $\mathrm{U}_q(\mathrm{so}_3)$.

Theorem 4: *If q is a root of unity, then any irreducible representation of* $\mathrm{U}_q(\mathrm{so}_3)$ *is finite dimensional.*

Proof: Let T be an irreducible representation of $\mathrm{U}_q(\mathrm{so}_3)$. Then T maps central elements into scalar operators. Since the linear space $\mathrm{U}_q(\mathrm{so}_3)$ is finite dimensional over the center $\mathcal{C}$ with the basis $I_1^k I_2^m I_3^n$, $k,m,n<p$ then for any $a \in \mathrm{U}_q(\mathrm{so}_3)$ we have $T(a) = \Sigma_{k,m,n<p} T(I_1^k I_2^m I_3^n)$. Hence, if $\mathbf{v}$ is a nonzero vector of the representation space $\mathcal{V}$, then $T(\mathrm{U}_q(\mathrm{so}_3))\mathbf{v} = \mathcal{V}$ and $\mathcal{V}$ is finite dimensional. Theorem is proved.

Taking into account Theorem 4, below we consider only finite-dimensional representations of $\mathrm{U}_q(\mathrm{so}_3)$.

In order to find irreducible representations of $\mathrm{U}_q(\mathrm{so}_3)$ for q a root of unity, we use the same method as before, that is, we apply the homomorphism ψ from Proposition 2 and irreducible representations of the algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ for q a root of unity.

Let us find irreducible representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$ for q a root of unity. The quantum algebra $\mathrm{U}_q(\mathrm{sl}_2)$ for q a root of unity has the following irreducible representations (see Ref. 11, Subsection 3.3.2):

(a) The representations $T_l^{(1)}$, $T_l^{(-1)}$, $T_l^{(i)}$, $T_l^{(-i)}$, $2l<p'$, given by the formulas (15)–(19).

(b) The representations $T_{ab\lambda}$, a, b, $\lambda \in \mathbf{C}$, $\lambda \neq 0$, acting on a p'-dimensional vector space $\mathcal{H}$ with the basis $|j\rangle$, $j=0,1,2,\ldots,p'-1$, and given by the formulas

$$T_{ab\lambda}(q^H)|i\rangle = q^{-i}\lambda|i\rangle, \quad T_{ab\lambda}(F)|p'-1\rangle = b|0\rangle, \tag{36}$$

$$T_{ab\lambda}(F)|i\rangle = |i+1\rangle, \quad i<p'-1, \quad T_{ab\lambda}(E)|0\rangle = a|p'-1\rangle, \tag{37}$$

$$T_{ab\lambda}(E)|i\rangle = \left(ab + [i]\frac{\lambda^2 q^{1-i} - \lambda^{-2} q^{i-1}}{q-q^{-1}} \right)|i-1\rangle, \quad i>0. \tag{38}$$

The representations $T_{ab\lambda}$ with $(a,b)=(0,0)$ and $\lambda = \pm q^n$, $n=0,1,2,\ldots,p'-2$, are reducible and must be taken out from this set.

(c) The representations $T'_{0b\lambda}$, b, $\lambda \in \mathbf{C}$, $\lambda \neq 0$, acting on a p'-dimensional vector space $\mathcal{H}$ with the basis $|j\rangle$, $j=0,1,2,\ldots,p'-1$, and given by the formulas

$$T'_{0b\lambda}(q^H)|i\rangle = q^i \lambda^{-1}|i\rangle, \quad T'_{0b\lambda}(E)|p'-1\rangle = b|0\rangle, \tag{39}$$

$$T'_{0b\lambda}(E)|i\rangle = |i+1\rangle, \quad i<p'-1, \quad T_{0b\lambda}(F)|0\rangle = 0, \tag{40}$$

$$T'_{0b\lambda}(F)|i\rangle = [i]\frac{\lambda^2 q^{1-i} - \lambda^{-2} q^{i-1}}{q-q^{-1}}|i-1\rangle, \quad i>0. \tag{41}$$

The representations $T'_{00\lambda}$ with $\lambda = \pm q^n$, $n=0,1,2,\ldots,p'-2$, are reducible and must be taken out from this set.

Remark 1: In the set of representations (a)–(c) there exist equivalent representations (see, for example, Propositions 3.17 and 3.18 in Ref. 11).

Remark 2: In Ref. 11, Subsection 3.3.2, irreducible representations of the algebra generated by the elements $E,F,K := q^{2H}$, $K^{-1} := q^{-2H} \in \mathrm{U}_q(\mathrm{sl}_2)$ are given. Clearly, this algebra is a subalgebra in $U_q(sl_2)$. It is easy to generalize the results of Subsection 3.3.2 in Ref. 11 for $U_q(sl_2)$. Let us note that the algebra $U_q(sl_2)$ has a unique automorphism φ such that $\varphi(q^H)=iq^H$, $\varphi(E)=-E$, and $\varphi(F)=F$. (If q is not a root of unity, then this automorphism transforms the representations $T_l^{(1)}$ to the representations $T_l^{(i)}$, respectively.) Therefore, the mapping $\tilde{T}_{-a,b,\lambda}=T_{ab\lambda}\circ\varphi$ is also a representation of $U_q(sl_2)$. We have

$$\tilde{T}_{ab\lambda}(q^H)|i\rangle=iq^{-i}\lambda|i\rangle,\quad \tilde{T}_{ab\lambda}(F)|p'-1\rangle=b|0\rangle, \tag{42}$$

$$\tilde{T}_{ab\lambda}(F)|i\rangle=|i+1\rangle,\quad i<p'-1,\quad \tilde{T}_{ab\lambda}(E)|0\rangle=a|p'-1\rangle, \tag{43}$$

$$\tilde{T}_{ab\lambda}(E)|i\rangle=\left(ab-[i]\frac{\lambda^2q^{1-i}-\lambda^{-2}q^{i-1}}{q-q^{-1}}\right)|i-1\rangle,\quad i>0. \tag{44}$$

However, it is easy to see by comparing (36)–(38) with (42)–(44) that the representation $\tilde{T}_{ab\lambda}$ is equivalent to $T_{a,b,i\lambda}$. This means that for q a root of unity we do not obtain new representations of $U_q(sl_2)$ from $T_{ab\lambda}$ applying the automorphism φ as in the case of the representations $T_l^{(1)}$.

We have described irreducible representations of the algebra $U_q(sl_2)$. Now we wish to extend these representations to obtain representations of the algebra $\hat{U}_q(sl_2)$ by using the relation

$$T((q^kq^H+q^{-k}q^{-H})^{-1}):=(q^kT(q^H)+q^{-k}T(q^{-H}))^{-1}.$$

Clearly, only those irreducible representations T of $U_q(sl_2)$ can be extended to $\hat{U}_q(sl_2)$ for which the operators $q^kT(q^H)+q^{-k}T(q^{-H})$ are invertible. From formulas (15)–(19) it is clear that these operators are always invertible for the irreducible representations $T_l^{(1)}$, $T_l^{(-1)}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,(p'-1)/2$, and for the irreducible representations $T_l^{(i)}$, $T_l^{(-i)}$, $l=\frac{1}{2},\frac{3}{2},\frac{5}{2},\ldots,(p'-1)/2$ [or $(p'-2)/2$.] (For the representations $T_l^{(i)}$, $T_l^{(-i)}$, $l=0,1,2,\ldots$, some of these operators are not invertible since they have zero eigenvalue.) We denote the extended representations by the same symbols $T_l^{(1)}$, $T_l^{(-1)}$, $T_l^{(i)}$, and $T_l^{(-i)}$, respectively.

Similarly, the representation $T_{ab\lambda}$ (and the representation $T'_{0b\lambda}$) can be extended to a representation of the algebra $\hat{U}_q(sl_2)$ if and only if $\lambda\neq\pm iq^k$, $k\in\mathbf{Z}$.

Proposition 7: The algebra $\hat{U}_q(sl_2)$ *for q a root of unity has the irreducible representations* $T_l^{(1)}$, $T_l^{(-1)}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,(p'-1)/2$, *the irreducible representations* $T_l^{(i)}$, $T_l^{(-i)}$, $l=\frac{1}{2},\frac{3}{2},\frac{5}{2},\ldots,(p'-1)/2$ [*or* $(p'-2)/2$], *and the irreducible representations* $T_{ab\lambda}$, $T'_{0b\lambda}$, $\lambda\neq\pm iq^k$, $k\in\mathbf{Z}$. *Any irreducible representation of* $\hat{U}_q(sl_2)$ *for q a root of unity is equivalent to one of these representations.*

IX. REPRESENTATIONS OF $U_q(so_3)$ FOR q A ROOT OF UNITY OBTAINED FROM THOSE OF $\hat{U}_q(sl_2)$

As in Sec. IV, we shall obtain representations of $U_q(so_3)$ for q a root of unity by applying the homomorphism ψ from Proposition 2. Namely, if T is a representation of $\hat{U}_q(sl_2)$, then

$$R=T\circ\psi \tag{45}$$

is a representation of $U_q(so_3)$. As in Sec. IV, application of this method to the pair of the irreducible representations $T_l^{(1)}$ and $T_l^{(-1)}$ of $\hat{U}_q(sl_2)$ leads to the same representation of $U_q(so_3)$ which will be denoted by $R_l^{(1)}$. Applying the formula (45) to the irreducible representations $T_l^{(i)}$ and $T_l^{(-i)}$ of $\hat{U}_q(sl_2)$ gives the representations of $U_q(so_3)$ which will be denoted by $R_l^{(i)}$ and $R_l^{(-i)}$, respectively.

Proposition 8: The representations $R_l^{(1)}$ *of* $U_q(so_3)$ *are irreducible. The representations* $R_l^{(i)}$ *and* $R_l^{(-i)}$ *are reducible.*

Proof of this proposition is the same as that of Proposition 3.

Repeating word-by-word the reasoning of Sec. IV, we decompose the representations $R_l^{(i)}$ and $R_l^{(-i)}$ into the direct sums of representations of $U_q(\mathrm{so}_3)$ which are denoted by $R_n^{(\pm i,+)}$ and $R_n^{(\pm i,-)}$:

$$R_l^{(i)}=R_n^{(i,+)}\oplus R_n^{(i,-)},\quad R_l^{(-i)}=R_n^{(-i,+)}\oplus R_n^{(-i,-)},\quad n=l+\tfrac{1}{2}.$$

Moreover, the representations $R_n^{(\pm i,+)}$ and $R_n^{(\pm i,-)}$ are given in the appropriate bases $|1\rangle,|2\rangle,\ldots,|n\rangle$ by the corresponding formulas of Sec. IV.

Theorem 5: *The representations $R_n^{(i,+)}$, $R_n^{(i,-)}$, $R_n^{(-i,+)}$, and $R_n^{(-i,-)}$, $n=1,2,3,...,p'/2$ [or $(p'-1)/2$] are irreducible and pairwise nonequivalent. For any l, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots,(p'-1)/2$, the representation $R_l^{(1)}$ is not equivalent to some of these representations.*

Proof is the same as that of Theorem 1.

Now we apply formula (45) to the representations $T_{ab\lambda}$ and $T'_{0b\lambda}$. As a result, we obtain the representations

$$R_{ab\lambda}=T_{-a,b,-i\lambda}\circ\psi,\quad R'_{0b\lambda}=T'_{0,b-i\lambda}$$

given in the bases $|j\rangle$, $j=0,1,2,...,p'-1$, by the formulas

$$R_{ab\lambda}(I_1)|i\rangle=\frac{-1}{q-q^{-1}}(q^{-i}\lambda+q^{i}\lambda^{-1})|i\rangle, \tag{46}$$

$$R_{ab\lambda}(I_2)|0\rangle=\frac{i}{\lambda-\lambda^{-1}}(a|p'-1\rangle+|1\rangle), \tag{47}$$

$$R_{ab\lambda}(I_2)|p'-1\rangle=\frac{i}{q^{-p'+1}\lambda-q^{p'-1}\lambda^{-1}}\times\left\{b|0\rangle+\left(ab+[p'-1]\frac{q^{-p'+2}\lambda^2-q^{p'-2}\lambda^{-2}}{q-q^{-1}}\right)|p'-2\rangle\right\}, \tag{48}$$

$$R_{ab\lambda}(I_2)|i\rangle=\frac{i}{q^{-i}\lambda-q^{i}\lambda^{-1}}\left\{\left(ab+[i]\frac{q^{-i+1}\lambda^2-q^{i-1}\lambda^{-2}}{q-q^{-1}}\right)|i-1\rangle+|i+1\rangle\right\},\quad 0<i<p'-1, \tag{49}$$

and by the formulas

$$R'_{0b\lambda}(I_1)|i\rangle=\frac{1}{q-q^{-1}}(q^{-i}\lambda+q^{i}\lambda^{-1})|i\rangle,\quad R'_{0b\lambda}(I_2)|0\rangle=\frac{-i}{\lambda-\lambda^{-1}}|1\rangle,$$

$$R'_{0b\lambda}(I_2)|p'-1\rangle=\frac{-i}{q^{-p'+1}\lambda-q^{p'-1}\lambda^{-1}}\left(b|0\rangle+[p'-1]\frac{q^{-p'+2}\lambda^2-q^{p'-2}\lambda^{-2}}{q-q^{-1}}|p'-2\rangle\right),$$

$$R'_{0b\lambda}(I_2)|i\rangle=\frac{-i}{q^{-i}\lambda-q^{i}\lambda^{-1}}\left(|i+1\rangle+[i]\frac{q^{-i+1}\lambda^2-q^{i-1}\lambda^{-2}}{q-q^{-1}}|i-1\rangle\right),\quad 0<i<p'-1.$$

The operators $R_{ab\lambda}(I_3)$ and $R'_{0b\lambda}(I_3)$ can be calculated by means of the relation

$$R(I_3)=q^{1/2}R(I_1)R(I_2)-q^{-1/2}R(I_2)R(I_1).$$

Recall that the representations $R_{ab\lambda}$ and $R'_{0b\lambda}$ are determined for $\lambda\neq 0$ and $\lambda\neq\pm q^k$, $k\in\mathbf{Z}$.

It is seen from the above formulas that

$$R'_{0b\lambda}(I_1)=R_{0,b,-\lambda}(I_1),\quad R'_{0b\lambda}(I_2)=R_{0,b,-\lambda}(I_2),$$

that is, the representations $R_{0,b,-\lambda}$ and $R'_{0b\lambda}$ are equivalent. For this reason, we consider below only the representations $R_{ab\lambda}$.

In order to study the representations $R_{ab\lambda}$ of $\mathrm{U}_q(\mathrm{so}_3)$ we consider the spectrum of the operator $R_{ab\lambda}(I_1)$. It coincides with the set of points

$$-\frac{\lambda+\lambda^{-1}}{q-q^{-1}},\quad -\frac{q^{-1}\lambda+q\lambda^{-1}}{q-q^{-1}},\quad -\frac{q^{-2}\lambda+q^2\lambda^{-1}}{q-q^{-1}},\quad \ldots,\quad -\frac{q^{1-p'}\lambda+q^{p'-1}\lambda^{-1}}{q-q^{-1}}. \tag{50}$$

It is easy to see that there exist coinciding points in this set if and only if λ is equal to one of the numbers

$$\pm q^{1/2},\pm q^{3/2},\pm q^{5/2},\ldots,\pm q^{(p'-1)/2}\quad (\text{or}\ \ \pm q^{(p'-2)/2}).$$

(Here we have to take $\pm q^{(p'-1)/2}$ if p' is even and $\pm q^{(p'-2)/2}$ if p' is odd.) Moreover, the set (50) splits into pairs of coinciding points if and only if $\lambda=\pm q^{(p'-1)/2}$. In all other cases there exists at least one spectral point which coincides with no other point. In particular, if $\lambda=\pm q^{(p'-2)/2}$, then in this set there exists only one eigenvalue with multiplicity 1. In all other cases there are more than one eigenvalue with multiplicity 1.

Proposition 9: If $\lambda\neq\pm q^{(p'-1)/2}$ for even p' and $\lambda\neq\pm q^{(p'-2)/2}$ for odd p', then the representation $R_{ab\lambda}$ is irreducible.

Proof: Let $\lambda\neq\pm q^{(p'-1)/2}$ for even p' and $\lambda\neq\pm q^{(p'-2)/2}$ for odd p'. We distinguish two cases: when the spectrum of the operator $R_{ab\lambda}(I_1)$ is simple and when there exists at least one spectral point of this operator having multiplicity 2. In the first case the proof is the same as the first part of the proof of Proposition 3. For the second case, we give a proof only for $\lambda=q^{1/2}$. (Proofs for other values of q are similar.) Then in the set (50) there are only two coinciding points $-(\lambda+\lambda^{-1})/(q-q^{-1})$ and $-(q^{-1}\lambda+q\lambda^{-1})/(q-q^{-1})$ corresponding to the eigenvectors $|0\rangle$ and $|1\rangle$. Let V be an invariant subspace of the representation space $\mathcal{H}$. As in the proof of Proposition 3, it is shown that V is a linear span of eigenvectors of the operator $R_{ab\lambda}(I_1)$, that is, a certain part of the vectors $|i\rangle$, $i\neq 0$, 1, $\alpha_0|0\rangle+\alpha_1|1\rangle$, $\beta_0|0\rangle+\beta_1|1\rangle$ constitutes a basis of V. Let V contain some basis vector $|j\rangle$. Then as in the proof of Proposition 3, acting successively upon $|j\rangle$ by certain linear combinations of the operators $R_{ab\lambda}(I_2)$ and $R_{ab\lambda}(I_3)$ we generate all the vectors $|i\rangle$, $i=0,1,\ldots,\frac{1}{2}(p'-1)$. This means that $V=\mathcal{H}$ and the representation $R_{ab\lambda}$ is irreducible. If V contains no vector $|j\rangle$, $j\neq 0,1$, then some linear combination $\alpha_0|0\rangle+\alpha_1|1\rangle$ belongs to V. Then the vector $\mathbf{v}=R_{ab\lambda}(I_2)(\alpha_0|0\rangle+\alpha_1|1\rangle)$ belongs to V. Since $\mathbf{v}$ contains the summand $\alpha|2\rangle$ with nonzero coefficient α, then $|2\rangle\in V$. This is a contradiction. Hence, the representation $R_{ab\lambda}$ is irreducible. Proposition is proved.

Let p' be even. Let us study the representations $R_{ab\lambda}$ for $\lambda=\pm q^{(p'-1)/2}$. For $\lambda=q^{(p'-1)/2}$ we have

$$R_{ab\lambda}(I_1)|i\rangle=\frac{-1}{q-q^{-1}}(q^{-i+(p'-1)/2}+q^{i-(p'-1)/2})|i\rangle, \tag{51}$$

$$R_{ab\lambda}(I_2)|0\rangle=c_{(p'-1)/2}(a|p'-1\rangle+|1\rangle), \tag{52}$$

$$R_{ab\lambda}(I_2)|p'-1\rangle=-c_{(p'-1)/2}((ab+[p'-1]^2)|p'-2\rangle+b|0\rangle), \tag{53}$$

$$R_{ab\lambda}(I_2)|i\rangle=c_{-i+(p'-1)/2}((ab+[i]^2)|i-1\rangle+|i+1\rangle), \tag{54}$$

where

$$c_j=\frac{i}{q^j-q^{-j}}.$$

The operator $R_{a,b,(p'-1)/2}(I_1)$ has the spectrum

$$\frac{-1}{q-q^{-1}}(q^{-i+(p'-1)2}+q^{i-(p'-1)/2}),\quad i=0,1,2,...,p'-1,$$

that is, if p' is even, then all spectral points are of multiplicity 2.

We assume that $ab\neq-[j]^2$, $j=0,1,...,p'-1$, and go over from the basis $\{|i\rangle\}$ to the basis $\{|i\rangle^\circ\}$, where

$$|i\rangle^\circ=\prod_{j=0}^{i}(ab+[j]^2)^{-1/2}|i\rangle,\quad i=0,1,2,...,p'-1.$$

Then the formula (51) does not change and the formulas (52)–(54) turn into

$$R_{ab\lambda}(I_2)|0\rangle^\circ=c_{(p'-1)/2}\left(a\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2}|p'-1\rangle^\circ+(ab+1)^{1/2}|1\rangle^\circ\right),$$

$$R_{ab\lambda}(I_2)|p'-1\rangle^\circ=-c_{(p'-1)/2}\left((ab+1)^{1/2}|p'-2\rangle^\circ+\frac{b}{\Pi_{j=1}^{p'-1}(ab+[j]^2)^{1/2}}|0\rangle^\circ\right),$$

$$R_{ab\lambda}(I_2)|i\rangle^\circ=c_{-i+(p'-1)/2}((ab+[i]^2)^{1/2}|i-1\rangle^\circ+(ab+[i+1]^2)^{1/2}|i+1\rangle^\circ).$$

We split the representation space $\mathcal{H}$ into the direct sum of two linear subspaces $\mathcal{H}_1$ and $\mathcal{H}_2$ spanned by the basis vectors $|j\rangle'$, $j=0,1,2,...,\frac{1}{2}(p'-2)$, and $|j\rangle''$, $j=0,1,2,...,\frac{1}{2}(p'-2)$, where

$$|j\rangle'=|j\rangle^\circ+i(-1)^{-j-1+p'/2}|p'-j-1\rangle^\circ,\quad |j\rangle''=|j\rangle^\circ+i(-1)^{-j+p'/2}|p'-j-1\rangle^\circ.$$

Then as in Sec. IV, we derive

$$R_{a,b,(p'-1)/2}(I_1)|j\rangle'=\frac{-1}{q-q^{-1}}(q^{-j+(p'-1)/2}+q^{j-(p'-1)/2})|j\rangle',$$

$$R_{a,b,(p'-1)/2}(I_1)|j\rangle''=\frac{-1}{q-q^{-1}}(q^{-j+(p'+1)/2}+q^{j-(p'-1)/2})|j\rangle'',$$

for the operator $R_{a,b,(p'-1)/2}(I_1)$ and

$$R_{a,b,(p'-1)/2}(I_2)|j\rangle'=c_{-j+(p'-1)/2}((ab+[j+1]^2)^{1/2}|j+1\rangle'+(ab+[j]^2)^{1/2}|j-1\rangle'),$$

$$R_{a,b,(p'-1)/2}(I_2)|j\rangle''=c_{-j+(p'-1)/2}((ab+[j+1]^2)^{1/2}|j+1\rangle''+(ab+[j]^2)^{1/2}|j-1\rangle''),$$

where $j\neq0$, $p'/2-1$,

$$R_{a,b,(p'-1)/2}(I_2)\left|\frac{p'}{2}-1\right\rangle'=\frac{1}{q^{1/2}-q^{1/2}}\left(ab+\left[\frac{p'}{2}\right]^2\right)^{1/2}\left|\frac{p'}{2}-1\right\rangle'$$
$$+\frac{i}{q^{1/2}-q^{-1/2}}\left(ab+\left[\frac{p'}{2}-1\right]^2\right)^{1/2}\left|\frac{p'}{2}-2\right\rangle',$$

$$R_{a,b,(p'-1)/2}(I_2)\left|\frac{p'}{2}-1\right\rangle'' = -\frac{1}{q^{1/2}-q^{-1/2}}\left(ab+\left[\frac{p'}{2}\right]^2\right)^{1/2}\left|\frac{p'}{2}-1\right\rangle'' + \frac{i}{q^{1/2}-q^{-1/2}}\left(ab+\left[\frac{p'}{2}-1\right]^2\right)^{1/2}\left|\frac{p'}{2}-2\right\rangle'',$$

$$R_{a,b,(p'-1)/2}(I_2)|0\rangle' = c_{(p'-1)/2}\left(a\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2}|p'-1\rangle^\circ + (ab+1)^{1/2}|1\rangle^\circ\right) - i(-1)^{(p'-2)/2}c_{(p'-1)/2}\left((ab+1)^{1/2}|p'-2\rangle^\circ + \frac{b}{\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2}}|0\rangle^\circ\right).$$

When

$$a\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2} = \frac{b}{\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2}}, \tag{55}$$

then the last relation reduces to

$$R_{a,b,(p'-1)/2}(I_2)|0\rangle' = \frac{(-1)^{(p'-2)/2}}{q^{(p'-1)/2}-q^{-(p'-1)/2}}a\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2}|0\rangle' + c_{(p'-1)/2}(ab+1)^{1/2}|1\rangle'.$$

Similarly, if the condition (55) is fulfilled, then

$$R_{a,b,(p'-1)/2}(I_2)|0\rangle'' = \frac{(-1)^{p'/2}}{q^{(p'-1)/2}-q^{-(p'-1)/2}}a\prod_{j=1}^{p'-1}(ab+[j]^2)^{1/2}|0\rangle'' + c_{(p'-1)/2}(ab+1)^{1/2}|1\rangle''.$$

Thus, the subspaces $\mathcal{H}_1$ and $\mathcal{H}_2$ are invariant with respect to the representation $R_{a,b,(p'-1)/2}$ if the condition (55) is fulfilled. We denote the corresponding subrepresentations by $R^{1,+}_{a,b,(p'-1)/2}$ and $R^{2,+}_{a,b,(p'-1)/2}$, respectively.

Similarly, if $\lambda = -q^{(p'-1)/2}$, then

$$R_{a,b,-(p'-1)/2}(I_1) = -R_{a,b,(p'-1)2}(I_1), \quad R_{a,b,-(p'-1)/2}(I_2) = -R_{a,b,(p'-1)/2}(I_2)$$

and the subspaces $\mathcal{H}_1$ and $\mathcal{H}_2$ are invariant with respect to the representation $R_{a,b,-(p'-1)/2}$ if the condition (55) is fulfilled. We denote the corresponding subrepresentations by $R^{1,-}_{a,b,-(p'-1)/2}$ and $R^{2,-}_{a,b,-(p'-1)/2}$, respectively.

Proposition 10: Let the condition (55) be satisfied. Then the representations $R^{i,+}_{a,b,(p'-1)/2}$ *and* $R^{i,-}_{a,b,-(p'-1)/2}$, $i=1,2$, *of the algebra* $\mathrm{U}_q(\mathrm{so}_3)$ *are irreducible and pairwise nonequivalent. If the condition (55) is not satisfied, then the representations* $R_{a,b,(p'-1)/2}$ *and* $R_{a,b,-(p'-1)/2}$ *are irreducible.*

Proof is similar to that of the previous propositions and we omit it.

Remark that the representations $R^{i,+}_{a,b,(p'-1)/2}$ and $R^{i,-}_{a,b,-(p'-1)/2}$, $i=1,2$, have two nonzero diagonal matrix elements $\langle p'/2-1|R|p'/2-1\rangle$ and $\langle 0|R|0\rangle$.

Let now p' be odd and $\lambda = q^{(p'-2)/2}$. For this value of λ we have

$$R_{ab\lambda}(I_1)|i\rangle = \frac{-1}{q-q^{-1}}(q^{-i+(p'-2)/2}+q^{i-(p'-2)/2})|i\rangle,$$

$$R_{ab\lambda}(I_2)|0\rangle = c_{(p'-2)/2}(a|p'-1\rangle + |1\rangle),$$

$$R_{ab\lambda}(I_2)|p'-1\rangle = -c_{p'/2}((ab+\epsilon[p'-1][p'])|p'-2\rangle + b|0\rangle),$$

$$R_{ab\lambda}(I_2)|i\rangle = c_{-i+(p'-2)/2}((ab+\epsilon[i][i+1])|i-1\rangle + |i+1\rangle),$$

where $\epsilon=1$ for $p'=p/2$, $\epsilon=-1$ for $p'=p$, and c_j is such as in (51)–(54). The operator $R_{a,b,(p'-2)/2}(I_1)$ has the spectrum

$$\frac{-1}{q-q^{-1}}(q^{-i+(p'-2)/2}+q^{i-(p'-2)/2}), \quad i=0,1,2,...,p'-1,$$

that is, all spectral points are of multiplicity 2 except for the point $-(q^{p'/2}+q^{-p'/2})/(q-q^{-1})$ which is of multiplicity 1.

We assume that $ab \neq -\epsilon[j][j+1]$, $j=0,1,...,p'-1$, and go over from the basis $\{|i\rangle\}$ to the basis $\{|i\rangle^\circ\}$, where

$$|i\rangle^\circ = \prod_{j=0}^{i}(ab+\epsilon[j][j+1])^{-1/2}|i\rangle, \quad i=0,1,2,...,p'-1.$$

Then

$$R_{ab\lambda}(I_1)|i\rangle^\circ = \frac{-1}{q-q^{-1}}(q^{-i+(p'-2)/2}+q^{i-(p'-2)/2})|i\rangle^\circ,$$

$$R_{ab\lambda}(I_2)|0\rangle^\circ = c_{(p'-2)/2}\left(a\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}|p'-1\rangle^\circ + (ab+\epsilon[2])^{1/2}|1\rangle^\circ\right),$$

$$R_{ab\lambda}(I_2)|p'-1\rangle^\circ = c_{p'/2}\left((ab+\epsilon[p'-1][p'])^{1/2}|p'-2\rangle^\circ + b\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{-1/2}|0\rangle^\circ\right),$$

$$R_{ab\lambda}(I_2)|i\rangle^\circ = c_{-i+(p'-2)/2}((ab+\epsilon[i][i+1])^{1/2}|i-1\rangle^\circ + (ab+\epsilon[i+1][i+2])^{1/2}|i+1\rangle^\circ),$$

where $\lambda = q^{(p'-2)/2}$. Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be two linear subspaces of the representation space $\mathcal{H}$ spanned by the basis vectors

$$|j\rangle' = |j\rangle^\circ + i(-1)^j|p'-j-2\rangle^\circ, \quad j=0,1,2,...,\frac{p'-3}{2},$$

and the basis vectors

$$|j\rangle'' = |j\rangle^\circ + i(-1)^{j+1}|p'-j-2\rangle^\circ, \quad j=0,1,2,...,\frac{p'-3}{2},$$

respectively. Then the operator $R_{a,b,(p'-2)/2}(I_1)$ acts on the basis elements $|j\rangle'$ and $|j\rangle''$ as on the vectors $|j\rangle$ and

$$R_{a,b,(p'-1)/2}(I_2)|j\rangle' = c_{-j+(p'-2)/2}((ab+\epsilon[j+1][j+2])^{1/2}|j+1\rangle' + (ab+\epsilon[j][j+1])^{1/2}|j-1\rangle'),$$

$$R_{a,b,(p'-2)/2}(I_2)|j\rangle'' = c_{-j+(p'-2)/2}((ab+\epsilon[j+1][j+2])^{1/2}|j+1\rangle'' + (ab+\epsilon[j][j+1])^{1/2}|j-1\rangle''),$$

where $j\neq 0,(p'-3)/2$,

$$R_{a,b,(p'-2)/2}(I_2)\left|\frac{p'-3}{2}\right\rangle' = \frac{(-1)^{(p'-3)/2}}{q^{1/2}-q^{-1/2}}\left(ab+\epsilon\left[\frac{p'-1}{2}\right]\left[\frac{p'+1}{2}\right]\right)^{1/2}\left|\frac{p'-3}{2}\right\rangle' + \frac{i}{q^{1/2}-q^{-1/2}}\left(ab+\epsilon\left[\frac{p'-1}{2}\right]\left[\frac{p'-3}{2}\right]\right)^{1/2}\left|\frac{p'-5}{2}\right\rangle',$$

$$R_{a,b,(p'-2)/2}(I_2)\left|\frac{p'-3}{2}\right\rangle'' = -\frac{(-1)^{(p'-3)/2}}{q^{1/2}-q^{-1/2}}\left(ab+\epsilon\left[\frac{p'-1}{2}\right]\left[\frac{p'+1}{2}\right]\right)^{12}\left|\frac{p'-3}{2}\right\rangle'' + \frac{i}{q^{1/2}-q^{-1/2}}\left(ab+\epsilon\left[\frac{p'-1}{2}\right]\left[\frac{p'-3}{2}\right]\right)^{1/2}\left|\frac{p'-5}{2}\right\rangle'',$$

$$R_{a,b,(p'-2)/2}(I_2)|0\rangle' = c_{(p'-2)/2}\left(a\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}|p'-1\rangle^\circ + (ab+\epsilon[2])^{1/2}|1\rangle^\circ - i(ab+\epsilon[2])^{1/2}|p'-1\rangle^\circ - i(ab+\epsilon[p'-2][p'-1])^{1/2}|p'-3\rangle^\circ\right),$$

$$R_{a,b,(p'-2)/2}(I_2)|0\rangle'' = c_{(p'-2)/2}\left(a\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}|p'-1\rangle^\circ + (ab+\epsilon[2])^{1/2}|1\rangle^\circ + i(ab+\epsilon[2])^{1/2}|p'-1\rangle^\circ + i(ab+\epsilon[p'-2][p'-1])^{1/2}|p'-3\rangle^\circ\right).$$

If

$$a\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2} + i(ab+\epsilon[2])^{1/2} = 0, \tag{56}$$

$$(ab+\epsilon[2])^{1/2}\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2} = ib, \tag{57}$$

then

$$R_{a,b,(p'-2)/2}(I_2)|p'-1\rangle = \frac{-bc_{p'/2}}{\Pi_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}}|0\rangle',$$

$$R_{a,b,(p'-2)/2}(I_2)|0\rangle' = \frac{i(ab+\epsilon[2])^{1/2}}{q^{(p'-2)/2}-q^{-(p'-2)/2}}|1\rangle' + c|p'-1\rangle',$$

$$R_{a,b,(p'-2)/2}(I_2)|0\rangle'' = \frac{i(ab+\epsilon[2])^{1/2}}{q^{(p'-2)/2}-q^{-(p'-2)/2}}|1\rangle'',$$

where c is a nonzero coefficient easily determined from the above formulas. Hence, the subspaces $\mathcal{H}_1+\mathbf{C}|p'-1\rangle$ and $\mathcal{H}_2$ of the representation space are invariant with respect to the representation $R_{a,b,(p'-2)/2}$ (we denote these subrepresentations by $R^1_{a,b,(p'-2)/2}$ and $R^2_{a,b,(p'-2)/2}$, respectively). Remark that

$$\dim \mathcal{H}_1+\mathbf{C}|p'-1\rangle=\tfrac{1}{2}(p'+1),\quad \dim \mathcal{H}_2=\tfrac{1}{2}(p'-1).$$

If

$$a\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}-i(ab+\epsilon[2])^{1/2}=0, \tag{58}$$

$$(ab+\epsilon[2])^{1/2}\prod_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}=-ib, \tag{59}$$

then

$$R_{a,b,(p'-2)/2}(I_2)|p'-1\rangle=\frac{-bc_{p'/2}}{\Pi_{j=1}^{p'-1}(ab+\epsilon[j][j+1])^{1/2}}|0\rangle'',$$

$$R_{a,b,(p'-2)/2}(I_2)|0\rangle'=\frac{i(ab+\epsilon[2])^{1/2}}{q^{(p'-2)/2}-q^{-(p'-2)/2}}|1\rangle',$$

$$R_{a,b,(p'-2)/2}(I_2)|0\rangle''=\frac{i(ab+\epsilon[2])^{1/2}}{q^{(p'-2)/2}-q^{-(p'-2)/2}}|1\rangle''+c|p'-1\rangle,$$

where c is a nonzero coefficient. Hence, now the subspaces $\mathcal{H}_1$ and $\mathcal{H}_2+\mathbf{C}|p'-1\rangle$ of the representation space are invariant. We denote the subrepresentations on these subspaces by $\hat{R}^1_{a,b,(p'-2)/2}$ and $\hat{R}^2_{a,b,(p'-2)/2}$, respectively). Note that the representation $\hat{R}^1_{a,b,(p'-2)/2}$ is not equivalent to $R^2_{a,b,(p'-2)/2}$ (and the representation $\hat{R}^2_{a,b,(p'-2)/2}$ is not equivalent to $R^1_{a,b,(p'-2)/2}$) since the parameters a and b determining these representations satisfy different equations.

If a and b do not satisfy the relations (56) and (57) or the relations (58) and (59), then the representation $R_{a,b,(p'-2)/2}$ is irreducible.

Let now p' be odd and $\lambda=-q^{(p'-2)/2}$. In this case, the representation $R_{a,b,-(p'-2)/2}$ is irreducible if a and b do not satisfy the relations (56) and (57) or the relations (58) and (59). If a and b satisfy the relations (56) and (57), then $R_{a,b,-(p'-2)/2}$ is a reducible representation and decomposes into the direct sum of two subrepresentations acting on the subspaces $\mathcal{H}_1+\mathbf{C}|p'-1\rangle$ and $\mathcal{H}_2$. These subrepresentations are denoted by $\hat{R}^1_{a,b,-(p'-2)/2}$ and $R^2_{a,b,-(p'-2)/2}$, respectively, and are determined as

$$R^i_{a,b,-(p'-2)/2}(I_1)=-R^i_{a,b,(p'-2)/2}(I_1),\quad R^i_{a,b,-(p'-2)/2}(I_2)=-R^i_{a,b,(p'-2)/2}(I_2),\quad i=1,2.$$

Similarly, if a and b satisfy the relations (58) and (59), then $R_{a,b,-(p'-2)/2}$ is a reducible representation and decomposes into the direct sum of two subrepresentations acting on the subspaces $\mathcal{H}_1$ and $\mathcal{H}_2+\mathbf{C}|p'-1\rangle$. These subrepresentations are denoted by $\hat{R}^1_{a,b,-(p'-2)/2}$ and $\hat{R}^2_{a,b,-(p'-2)/2}$, respectively, and are determined as

$$\hat{R}^i_{a,b,-(p'-2)/2}(I_1)=-\hat{R}^i_{a,b,(p'-2)/2}(I_1),\quad \hat{R}^i_{a,b,-(p'-2)/2}(I_2)=-\hat{R}^i_{a,b,(p'-2)/2}(I_2),\quad i=1,2.$$

Proposition 11: Let the conditions (56) and (57) be satisfied. Then the representations $R^1_{a,b,(p'-2)/2}$, $R^2_{a,b,(p'-2)/2}$, $R^1_{a,b,-(p'-2)/2}$, *and* $R^2_{a,b,-(p'-2)/2}$ *are irreducible and pairwise nonequivalent. If the conditions (58) and (59) are satisfied, the representations* $\hat{R}^1_{a,b,(p'-2)/2}$, $\hat{R}^2_{a,b,(p'-2)/2}$, $\hat{R}^1_{a,b,-(p'-2)/2}$, *and* $\hat{R}^2_{a,b,-(p'-2)/2}$ *are irreducible and pairwise nonequivalent.*

Proof is similar to that of the previous propositions and we omit it.

X. OTHER REPRESENTATIONS OF $U_q(so_3)$ FOR q A ROOT OF UNITY

In the previous section we described irreducible representations of $U_q(so_3)$ obtained from irreducible representations of the algebra $\hat{U}_q(sl_2)$ for q a root of unity. However, at q a root of unity the algebra $U_q(so_3)$ has irreducible representations which cannot be derived from those of $\hat{U}_q(sl_2)$. They are obtained as irreducible components of the representations Q_λ from Sec. VII when one put q equal to a root of unity. We describe these representations of $U_q(so_3)$ in this section.

Let $\lambda = q^\tau$ be a nonzero complex number such that $0 \leq \mathrm{Re}\,\tau < 1$ and let $\mathcal{H}$ be the p'-dimensional complex vector space with basis

$$|m\rangle, \quad m=0,1,2,...,p'-1.$$

We define on this space the operators $Q'_\lambda(I_1)$ and $Q'_\lambda(I_2)$ determined by the formulas

$$Q'_\lambda(I_1)|m\rangle = \frac{\lambda q^m + \lambda^{-1} q^{-m}}{q-q^{-1}}|m\rangle,$$

$$Q'_\lambda(I_2)|0\rangle = \frac{1}{q-q^{-1}}|1\rangle + \frac{1}{q-q^{-1}}|p'-1\rangle,$$

$$Q'_\lambda(I_2)|p'-1\rangle = \frac{1}{q-q^{-1}}|p'-2\rangle + \frac{1}{q-q^{-1}}|0\rangle,$$

$$Q'_\lambda(I_2)|m\rangle = \frac{1}{q-q^{-1}}|m-1\rangle + \frac{1}{q-q^{-1}}|m+1\rangle, \quad m \neq 0, p'-1.$$

A direct computation shows that these operators satisfy the relations (7) and (8) and hence determine a representation of $U_q(so_3)$ which will be denoted by Q'_λ.

Theorem 6: *If* $\lambda \neq 1$ *and* $\lambda \neq q^{1/2}$, *then the representation* Q'_λ *is irreducible.*

Proof of this proposition is the same as that of the first part of Proposition 3.

The representations Q'_1 and $Q'_{\sqrt{q}}$ are studied in the same way as the representations Q_1 and $Q_{\sqrt{q}}$ in Sec. VII. This study leads to the irreducible representations of $U_q(so_3)$ which are described below. (Note that the description of these representations for p' even and for p' odd is different.)

Let p' be odd. We denote by $\mathcal{H}_r$ and $\mathcal{H}_s$, $r=\frac{1}{2}(p'+1)$ and $s=\frac{1}{2}(p'-1)$, the complex vector spaces with the bases

$$|0\rangle, |1\rangle, |2\rangle, \ldots, |\tfrac{1}{2}(p'-1)\rangle, \quad \text{and} \quad |1\rangle, |2\rangle, \ldots, |\tfrac{1}{2}(p'-1)\rangle,$$

respectively. Four representations $Q_1^{\pm,\pm}$ act on the space $\mathcal{H}_r$ and are given by the formulas

$$Q_1^{+,\pm}(I_1)|m\rangle = \frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-1), \tag{60}$$

$$Q_1^{+,\pm}(I_2)|\tfrac{1}{2}(p'-1)\rangle = \pm\frac{1}{q-q^{-1}}|\tfrac{1}{2}(p'-1)\rangle + \frac{1}{q-q^{-1}}|\tfrac{1}{2}(p'-3)\rangle, \tag{61}$$

$$Q_1^{+,\pm}(I_2)|m\rangle = \frac{1}{q-q^{-1}}|m+1\rangle + \frac{1}{q-q^{-1}}|m-1\rangle, \quad m<\tfrac{1}{2}(p'-1), \tag{62}$$

and by the formulas

$$Q_1^{-,\pm}(I_1)|m\rangle = -\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-1), \tag{63}$$

$$Q_1^{-,\pm}(I_2) := Q_1^{+,\pm}(I_2). \tag{64}$$

Note that the upper sign corresponds to the representations $Q_1^{+,+}$ and $Q_1^{-,+}$ and the lower sign to the representations $Q_1^{+,-}$ and $Q_1^{-,-}$.

On the space $\mathcal{H}_s$, four representations $\hat{Q}_1^{\pm,\pm}$ act by the corresponding formulas (60)–(64), but now m runs over the values $1,2,3,...,\frac{1}{2}(p'-1)$.

Let now $\mathcal{H}_r'$ and $\mathcal{H}_s'$, $r=\frac{1}{2}(p'+1)$ and $s=\frac{1}{2}(p'-1)$, be the complex vector spaces with the bases

$$|m+\tfrac{1}{2}\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-1), \quad \text{and} \quad |m+\tfrac{1}{2}\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-3),$$

respectively. The four representations $Q_{\sqrt{q}}^{\pm,\pm}$ act on the space $\mathcal{H}_r'$ and are given by the formulas

$$Q_{\sqrt{q}}^{+,\pm}(I_1)|m+\tfrac{1}{2}\rangle = \frac{q^{m+1/2}+q^{-m-1/2}}{q-q^{-1}}|m+\tfrac{1}{2}\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-1), \tag{65}$$

$$Q_{\sqrt{q}}^{+,\pm}(I_2)|\tfrac{1}{2}\rangle = \pm\frac{1}{q-q^{-1}}|\tfrac{1}{2}\rangle + \frac{1}{q-q^{-1}}|\tfrac{3}{2}\rangle, \tag{66}$$

$$Q_{\sqrt{q}}^{+,\pm}(I_2)|m+\tfrac{1}{2}\rangle = \frac{1}{q-q^{-1}}|m+\tfrac{3}{2}\rangle + \frac{1}{q-q^{-1}}|m-\tfrac{1}{2}\rangle, \quad m\neq 0, \tag{67}$$

where $|m+\frac{3}{2}\rangle \equiv 0$ if $m=\frac{1}{2}(p'-1)$, and by the formulas

$$Q_{\sqrt{q}}^{-,\pm}(I_1)|m+\tfrac{1}{2}\rangle = -\frac{q^{m+1/2}+q^{-m-1/2}}{q-q^{-1}}|m+\tfrac{1}{2}\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-1), \tag{68}$$

$$Q_{\sqrt{q}}^{-,\pm}(I_2) := Q_{\sqrt{q}}^{+,\pm}(I_2). \tag{69}$$

On the space $\mathcal{H}_s'$, four representations $\check{Q}_{\sqrt{q}}^{\pm,\pm}$ act by the corresponding formulas (65)–(69), but now m runs through the values $0,1,2,...,\frac{1}{2}(p'-3)$.

Let now p' be even. We denote by $\mathcal{H}_r$ and $\mathcal{H}_s$, $r=\frac{1}{2}(p'+2)$ and $s=\frac{1}{2}(p'-2)$, the complex vector spaces with the bases

$$|0\rangle,|1\rangle,|2\rangle,\ldots,|\tfrac{1}{2}p'\rangle, \quad \text{and} \quad |1\rangle,|2\rangle,\ldots,|\tfrac{1}{2}(p'-2)\rangle,$$

respectively. The representations $Q_1^{1,\pm}$ and $Q_1^{2,\pm}$ act on $\mathcal{H}_r$ and $\mathcal{H}_s$, respectively, which are given by the formulas

$$Q_1^{i,\pm}(I_1)|m\rangle = \pm\frac{q^m+q^{-m}}{q-q^{-1}}|m\rangle, \quad i=1,2,$$

$$Q_1^{i,\pm}(I_2)|m\rangle = \frac{1}{q-q^{-1}}|m+1\rangle + \frac{1}{q-q^{-1}}|m-1\rangle, \quad i=1,2,$$

where $|m+1\rangle$ or $|m-1\rangle$ must be put equal to 0 if the corresponding vector does not exist.

Let $\mathcal{H}_{p'/2}$ be the complex vector space with the basis

$$|m+\tfrac{1}{2}\rangle, \quad m=0,1,2,...,\tfrac{1}{2}(p'-2).$$

Four representations $\hat{Q}^{\pm,\pm}_{\sqrt{q}}$ act on this space which are given by the formulas

$$\hat{Q}^{+,\pm}_{\sqrt{q}}(I_1)|m+\tfrac{1}{2}\rangle=\frac{q^{m+1/2}+q^{-m-1/2}}{q-q^{-1}}|m+\tfrac{1}{2}\rangle,$$

$$\hat{Q}^{+,\pm}_{\sqrt{q}}(I_2)|\tfrac{1}{2}\rangle=\pm\frac{1}{q-q^{-1}}|\tfrac{1}{2}\rangle+\frac{1}{q-q^{-1}}|\tfrac{3}{2}\rangle,$$

$$\hat{Q}^{+,\pm}_{\sqrt{q}}(I_2)|\tfrac{1}{2}(p'-2)\rangle=\pm\frac{1}{q-q^{-1}}|\tfrac{3}{2}(p'-2)\rangle+\frac{1}{q-q^{-1}}|\tfrac{1}{2}(p'-4)\rangle,$$

$$\hat{Q}^{+,\pm}_{\sqrt{q}}(I_2)|m+\tfrac{1}{2}\rangle=\frac{1}{q-q^{-1}}|m-\tfrac{1}{2}\rangle+\frac{1}{q-q^{-1}}|m+\tfrac{3}{2}\rangle, \quad m\neq\tfrac{1}{2},\tfrac{1}{2}(p'-2),$$

and by the formulas

$$\hat{Q}^{-,\pm}_{\sqrt{q}}(I_1)|m+\tfrac{1}{2}\rangle=-\frac{q^{m+1/2}+q^{-m-1/2}}{q-q^{-1}}|m+\tfrac{1}{2}\rangle,$$

$$\hat{Q}^{-,\pm}_{\sqrt{q}}(I_2)=\hat{Q}^{+,\pm}_{\sqrt{q}}(I_2).$$

Let us mention peculiarities of the representations described above. The operators $Q_1^{\pm,\pm}(I_2)$, $Q^{\pm,\pm}_{\sqrt{q}}(I_2)$, $\check{Q}^{\pm,\pm}_{\sqrt{q}}(I_2)$, and $\hat{Q}^{\pm,\pm}_{\sqrt{q}}(I_2)$ have nonzero diagonal matrix elements and nonzero traces. Moreover, the operators $\hat{Q}^{\pm,\pm}_{\sqrt{q}}(I_2)$ have two such diagonal elements. Spectra of the operators $Q_1^{\pm,\pm}(I_1)$, $Q^{\pm,\pm}_{\sqrt{q}}(I_1)$, $Q_1^{1,\pm}(I_1)$, $Q_1^{2,\pm}(I_1)$, and $\hat{Q}^{\pm,\pm}_{\sqrt{q}}(I_1)$ are not symmetric with respect to the zero point.

Proposition 12: The representations $Q_1^{\pm,\pm}$, $Q^{\pm,\pm}_{\sqrt{q}}$, $\check{Q}^{\pm,\pm}_{\sqrt{q}}$, $Q_1^{1,\pm}$, $Q_1^{2,\pm}$, and $\hat{Q}^{\pm,\pm}_{\sqrt{q}}$ *are irreducible and pairwise nonequivalent. No representation* Q'_λ *is equivalent to any of them.*

Proof is the same as that of Proposition 3.

Alternative sets of hyperspherical harmonics: Satisfying cusp conditions through frame transformations

Thomas A. Heim[a)] and Dmitry Green[b)]
James Franck Institute, University of Chicago, Chicago, Illinois 60637

(Received 4 February 1998; accepted for publication 30 November 1998)

By extending the concept of Euler-angle rotations to more than three dimensions, we develop the systematics under rotations in higher-dimensional space for a novel set of hyperspherical harmonics. Applying this formalism, we determine all pairwise Coulomb interactions in a few-body system without recourse to multipole expansions. Our approach combines the advantages of relative coordinates with those of the hyperspherical description. In the present method, each Coulomb matrix element reduces to the ''$1/r$'' form familiar from the two-body problem. Consequently, our calculation accounts for all the cusps in the wave function whenever an interparticle separation vanishes. Unlike a truncated multipole expansion, the calculation presented here is exact. Following the systematic development of the procedure for an arbitrary number of particles, we demonstrate it explicitly with the simplest nontrivial example, the three-body system. © *1999 American Institute of Physics.* [S0022-2488(99)02804-2]

I. INTRODUCTION

A system consisting of N charged particles gives rise to $N(N-1)/2$ pairwise Coulomb interaction terms in its Hamiltonian. Since only the two-body problem ($N=2$) can actually be solved exactly, conventional atomic physics methods view the complete system of particles at the outset as a conglomerate of independent two-body systems, adding the interactions between these independent particles in a second step. This approach amounts to selecting a suitable subset of the $N(N-1)/2$ Coulomb terms for which a solution in terms of ''simultaneous two-body wave functions'' can be given. For instance, the independent-particle model for atomic systems treats each electron as interacting primarily with the nucleus (or with the ionic core in the case of valence electrons). Each (valence) electron's position introduces an independent spherical direction. Just as in the familiar solution of the hydrogen atom, each electron contributes to the angular part of the total system's wave function a spherical harmonic Y_{lm} of the angles specifying its direction in space. In the next step, all the electron–electron interactions are calculated by expanding the corresponding separations into Legendre polynomials of the interelectronic angles, thus yielding the familiar multipole expansion. In more general terms, the independent-particle model first selects a specific particle 1 (on physical grounds, typically the nucleus or the ionic core) and solves for each of the remaining $N-1$ particles the two-body problem $\{1,j\}$, $j=2,\ldots,N$, thereby providing a basis for expanding the total wave function. In the next step, the interaction between particles i and j is calculated by adapting the reciprocal of their separation, $1/r_{ij}$, to the coordinate system pertaining to the ''two-body'' basis functions for i and j ($i,j=2,\ldots,N$).

The Coulomb interaction is singular whenever an interparticle separation vanishes. Since these singularities are isolated from one another, they do not pose fundamental difficulties in calculating the Hamiltonian matrix. However, they give rise to *cusps* (discontinuous derivatives) in the wave function,[1] thus slowing down the convergence of partial-wave expansions of the wave function in their vicinity.[2,3] The independent-particle wave functions can only account (through

the corresponding *s*-wave components) for the cusps arising from vanishing separations r_{1j}, $j=2,\ldots,N$. Cusps due to vanishing r_{ij} with $i\neq 1$ are not reproduced. Possible remedies to these shortcomings include the explicit use of coordinates like the interelectronic angle θ_{ij} or even r_{ij} besides r_i and r_j; various approximations for $1/r_{ij}$;[4] or replacing r_i,r_j by $r_<=\min(r_i,r_j)$,$r_>=\max(r_i,r_j)$ in the Hamiltonian.[5] All these approaches amount to *adapting the interaction operator* $1/r_{ij}$ to a single coordinate system.

The present investigation explores the alternative approach of *adapting the basis functions* to match the relevant interparticle separations r_{ij} by utilizing several coordinate systems simultaneously. We calculate a specific interaction term $\sim 1/r_{ij}$ in the coordinate system best suited for this particular purpose. Thus, the particle separations r_{ij} dictate the choice of coordinate systems, the wave functions being transformed between the relevant reference frames to evaluate the different terms of the Hamiltonian. The success of this approach hinges on our ability to perform the numerous transformations between reference frames with high efficiency. Section II describes hyperspherical Jacobi coordinates appropriate for this task. Section III provides the main results by implementing the relevant transformations for a system with an arbitrary number of particles and by constructing basis functions (harmonics) suitable for extensive transformation between reference frames. The resulting set of hyperspherical harmonics, derived here in the context of calculating the Hamiltonian matrix for a system of *N* charged particles, has in fact much wider applicability.

Hyperspherical coordinates and corresponding hyperspherical harmonics have been applied in various areas of physics since the 1950s, for instance, in three-body scattering,[6–8] nuclear[9,10] and atomic[11–19] physics, as well as in quantum chemistry.[20,21] However, the sets of functions introduced in the present investigation are equivalent to, but much more flexible than, the hyperspherical harmonics discussed in Refs. 6–21. Beyond constituting a complete orthogonal set of functions appropriate for expansions, their frame independence affords greater flexibility in analyzing selection rules and other relations between harmonics. These aspects are conveniently investigated through ladder operators; they are determined entirely by the symmetry properties of the *N*-particle system, independent of any coordinate representation. Only calculating the nonvanishing matrix elements requires an appropriate coordinate representation of the generic basis functions. Section IV illustrates the relevant procedures with the simplest nontrivial example, the three-body problem. The concluding Sec. V discusses advantages and limitations of the new technique, as compared to the conventional multipole expansion.

II. HYPERSPHERICAL JACOBI COORDINATES

The inverse proportionality between pairwise interaction and interparticle separation suggests replacing individual particles' positions with *relative* (Jacobi) coordinates. Starting from one pair of particles, the construction of Jacobi coordinates proceeds hierarchically by joining (the centers of mass of) increasingly complex groups of particles. This hierarchical structure is commonly referred to as a ''Jacobi tree.''[10] Alternative choices for the initial particle pair, as well as the ordering of successive particle groups, correspond to different Jacobi trees. In the next step, mass scaling of the Jacobi coordinates fully exposes the symmetry of the kinetic energy operator for the multiparticle system. Let p,q denote two (groups of) particles with masses M_p,M_q and center of mass positions $\boldsymbol{r}_p$ and $\boldsymbol{r}_q$, respectively. Appropriate mass scaling of the relative coordinate in the form[8] $\boldsymbol{\xi}_{p,q}=\{M_pM_q/(M_p+M_q)\}^{1/2}(\boldsymbol{r}_p-\boldsymbol{r}_q)$ removes the individual mass dependence from the expression for the kinetic energy:

$$-\sum_{i=1}^{N}\frac{\hbar^2}{2M_i}\Delta_{\boldsymbol{r}_i}=-\frac{\hbar^2}{2}\sum_{k=1}^{N-1}\Delta_{\boldsymbol{\xi}_k}-\frac{\hbar^2}{2M_{\text{tot}}}\Delta_{\boldsymbol{r}_{\text{c.m.}}}. \tag{2.1}$$

Setting the origin at the center of mass of the whole system allows discarding the c.m.'s position and motion. With the individual mass factors removed, the kinetic energy (generalized Laplacian) displays complete symmetry under rotations in $(3N-3)$-dimensional space.

Hyperspherical coordinates exploit this symmetry by separating the ''shape'' of the system (described by $3N-4$ angular coordinates) from its overall ''size'' $R^2=\Sigma_k \boldsymbol{\xi}_k^2$ (with the dimension of a moment of inertia). Eigenfunctions of the Laplacian's angular part, termed ''hyperspherical harmonics'' by generalizing the two- and three-dimensional cases, constitute a basis for expanding the complete wave function. In higher-dimensional spaces, the angular Laplacian's eigenvalues $\Lambda(\Lambda+3N-5)$ are highly degenerate. In addition to the ''grand angular momentum'' Λ,[8] the hyperspherical harmonics thus require numerous labels—analogs of the single ''magnetic'' quantum number m for three-dimensional spherical harmonics—for their unique specification. Different sets of hyperspherical harmonics, resulting from solving the Laplacian eigenvalue problem by separation of variables in alternative sets of coordinates, have been investigated extensively (see, e.g., Refs. 10,17, and 21 for systematic studies). However, their construction through separation of variables inevitably ties these harmonics to a specific coordinate system. They are thus not well suited for extensive transformation between different reference frames. The definition of harmonics based only on their behavior under the relevant transformations is the main result of this paper, to be derived in Sec. III.

The construction of each Jacobi tree starts with a pair of particles. Thus, each Jacobi tree contains at least one Jacobi vector joining two particles only (rather than centers of mass of particle *groups*). We denote such a vector as a ''primary'' coordinate. In any one Jacobi tree, up to $\lfloor N/2 \rfloor$ Jacobi vectors are directly proportional to actual interparticle separations, $\boldsymbol{r}_{ij}$, the remaining relative coordinates necessarily involving larger complexes of particles. (Here and in the following, $\lfloor x \rfloor$ denotes the largest integer not exceeding x.) We will calculate each of the $N(N-1)/2$ Coulomb terms of the Hamiltonian in a Jacobi tree where it occurs as a ''primary'' coordinate. Obviously, all these terms then take the same form as the simple one-electron integral over $1/r$ in hydrogen, but the variables now refer to a multitude of different reference frames. Having thus eliminated all nested integrations, our next task consists in determining the transformations between different Jacobi trees.

The most general transformation from one Jacobi tree to another (for the same system of particles) resolves into a sequence of elementary operations. Each elementary step consists in ''transplanting'' a subcomplex q from some particle complex $\{pq\}$ to a complex $\{qr\}$;[10] it is achieved by a two-dimensional kinematic rotation[8] through the angle

$$\phi=\tan^{-1}\sqrt{M_q(M_p+M_q+M_r)/M_pM_r} \tag{2.2}$$

in the $(\boldsymbol{\xi}_{p,q},\boldsymbol{\xi}_{pq,r})$-plane of the $(N-1)$-dimensional space of mass-scaled Jacobi vectors:

$$\boldsymbol{\xi}'_{q,r}=\cos\phi\,\boldsymbol{\xi}_{p,q}-\sin\phi\,\boldsymbol{\xi}_{pq,r}, \tag{2.3a}$$

$$\boldsymbol{\xi}'_{p,qr}=\sin\phi\,\boldsymbol{\xi}_{p,q}+\cos\phi\,\boldsymbol{\xi}_{pq,r}. \tag{2.3b}$$

As each Jacobi vector is a vector in three-dimensional physical space, the basic rotation in the $(\boldsymbol{\xi}_j,\boldsymbol{\xi}_k)$ plane implies three rotations through the same angle ϕ in the (x_j,x_k), the (y_j,y_k), and the (z_j,z_k) planes, where (x,y,z) denote the Cartesian components of $\boldsymbol{\xi}$. An elementary kinematic rotation through a finite angle ϕ in the $(\boldsymbol{\xi}_j,\boldsymbol{\xi}_k)$ plane then reads[22]

$$T_{\boldsymbol{\xi}_j,\boldsymbol{\xi}_k}(\phi)=\exp(i\phi J_{x_jx_k})\exp(i\phi J_{y_jy_k})\exp(i\phi J_{z_jz_k}), \tag{2.4}$$

with infinitesimal rotation operators

$$J_{uv}\equiv -i\left(u\frac{\partial}{\partial v}-v\frac{\partial}{\partial u}\right),\quad (u,v)=(x_j,x_k),(y_j,y_k),(z_j,z_k). \tag{2.5}$$

[For a heuristic explanation of (2.4), recall the Taylor expansion of $f(x+\Delta x)$ which may formally be written as $\exp(i\Delta xp)f(x)$ with the infinitesimal ''translation operator'' $p\equiv -i(\partial/\partial x)$ corresponding to the quantum mechanical linear momentum (with $\hbar\equiv 1$). In the present context, the translation from x to $x+\Delta x$ is replaced by a rotation through an angle ϕ from some direction in multidimensional space to a new direction.] In order to determine T_{ξ_j,ξ_k}'s effect on the basis functions, we need to (i) express the generic rotation operators J_{uv} in terms of ''ladder operators'' whose action on the basis functions is straightforward to calculate, and (ii) construct basis functions suitable for such transformations.

This section concludes with the outline of a strategy for determining the most efficient sequence of two-dimensional rotations to achieve the transformation between arbitrary Jacobi trees. Note first that the individual terms in the Hamiltonian are referred to by means of *particle labels*, implying the need for appropriate antisymmetrization of the total wave function under interchange of identical particles. This consideration dominates the construction of the first Jacobi tree to which all subsequent transformations are applied. In an atomic or molecular system, antisymmetrization concerns primarily the electronic part of the wave function. Thus the basic Jacobi tree starts out with a pair of electrons. It grows by adding one electron at a time, finishing with the addition of nuclei or ionic core(s). This procedure results in a ''canonical'' Jacobi tree,[10] represented by the sequence of particle labels

$$(\cdots((((12)3)4)5)\ \ldots), \tag{2.6}$$

whose parentheses separate subcomplexes. Alternatively, one could start by first forming as many *pairs* of particles as possible, i.e., $\lfloor N/2 \rfloor$ pairs, before joining these pairs into larger complexes. Although the antisymmetrization of an electron pair is particularly compact (namely, their relative angular momentum and their spin must add to an *even* value), antisymmetrization among different pairs requires breaking up all these pairs, in essence going back to a canonical tree. Since breaking up subcomplexes involves about as many elementary rotations as forming the new complexes, this procedure is not efficient. Nevertheless, a set of N (for odd particle number) or $N-1$ (even particle number) trees with the maximum number of $\lfloor N/2 \rfloor$ pairs suffices to isolate all the $N(N-1)/2$ interparticle separations. A successful strategy therefore aims at building these particular Jacobi trees from the canonical tree. The simplest of these ''pair trees,'' $(\cdots((12)(34))\times(56)\ \ldots)$, is obtained from the canonical tree with only $\lfloor N/2 \rfloor-1$ rotations. In general, the pair (jk) with $j<k$ is $(k-j-\delta_{j,1})$ rotations away from the canonical tree, but many other ''useful'' pairs are formed in the course of these ''transplantations.''

III. TRANSFORMING THE BASIS FUNCTIONS

This section provides the tools required to rotate harmonics from one coordinate system to another. The reader familiar with Lie algebra will of course recognize the relevant aspects of the algebra of rotations in $(3N-3)$ dimensional space, so $(3N-3)$. However, such familiarity is not presumed, and we hardly use the terminology of group theory. The presentation reflects a more pragmatic point of view, emphasizing both the technical implementation as well as its relation to the physical application at hand, rather than full mathematical generality, let alone mathematical rigor. For the latter aspects, the reader should turn to the mathematical literature.[23]

A. Rotations in *d*-dimensional space

The most intuitive description of a rotation in three dimensions requires two elements: the (invariant) *axis*, and the *angle* of rotation. The rotation itself occurs in a *plane* perpendicular to the axis of rotation. In three dimensions, specifying the direction of the axis of rotation is equivalent to, but more economical than, describing the actual plane of rotation. For a higher dimensional space this is no longer the case, because there are several invariant directions perpendicular to a given plane. Thus, in *d*-dimensional space, a basic rotation is more appropriately characterized as occurring in the *plane* spanned by two coordinates rather than by an invariant axis orthogonal to it. The generic infinitesimal rotation operators then take the form (2.5). The number of different planes, $\frac{1}{2}d(d-1)$ in d dimensions, equals the number of basic rotations. Because rotations occurring in nonintersecting planes affect different pairs of coordinates, they are evidently independent of each other; the corresponding rotation operators commute with one another. As there are $\lfloor d/2 \rfloor$

nonintersecting planes in a d-dimensional space, the largest set of simultaneously commuting operators J_{uv} contains $\ell \equiv \lfloor d/2 \rfloor$ elements. These commuting operators are commonly denoted as H_j, $j=1,\ldots,\ell$.[23] For our application, the power of the Lie algebraic method derives from the structure and the properties of rotations being completely independent of any particular coordinate representation of the operators H_j. In fact, the following manipulations are most efficiently carried out in generic Cartesian coordinates without any reference to a specific Jacobi tree.

Simultaneous eigenfunctions of the H_j with (integer) eigenvalues m_j, $j=1,\ldots,\ell$, provide a basis for building hyperspherical harmonics suitable for extensive rotations between reference frames. If the infinitesimal rotation corresponding to H_j occurs in the (u_j,v_j) plane, the simultaneous eigenfunction of the ℓH_j with eigenvalues m_j, respectively, reads

$$F(\ldots)\times\prod_{j=1}^{\ell}(u_j+iv_j)^{m_j} \tag{3.1}$$

with a function F that bears further specification in Sec. III C. At this point, we only require that $H_j F\equiv 0$ for all j. The set of eigenvalues $\boldsymbol{\mu}=\{m_1,m_2,\ldots,m_\ell\}$ serves as a label identifying different harmonics with the same value of $\Lambda(\Lambda+d-2)$ in the angular Laplacian's eigenvalue equation. Additional labels required for a unique specification will be introduced in Sec. III C.

Appropriate linear combinations of the remaining infinitesimal rotation operators act as *ladder operators* $E_{\boldsymbol{\alpha}}$ satisfying

$$[H_j,E_\alpha]=\alpha_j E_\alpha, \quad j=1,\ldots,\ell, \tag{3.2}$$

with an ℓ-dimensional vector index $\boldsymbol{\alpha}$ with components $\alpha_j=0,\pm 1$. Here $\alpha_j=0$ indicates that $E_{\boldsymbol{\alpha}}$ does not change the part of the eigenfunction pertaining to H_j, whereas $\alpha_j=\pm 1$ means that it maps this part to the eigenfunction with eigenvalue $m_j\pm 1$. The ladder operators interrelate eigenfunctions with different $\boldsymbol{\mu}$ but degenerate Λ. Raising and lowering operators form Hermitian conjugate pairs $E_{-\boldsymbol{\alpha}}=E_{\boldsymbol{\alpha}}^\dagger$.

In general (for $\ell>1$), each ladder operator affects two of the m_j simultaneously; for odd-dimensional spaces a subset of ℓ pairs of raising and lowering operators change one of the m_j only.[23] Abbreviating the vector label $\boldsymbol{\alpha}$ by giving only its two nonvanishing components α_j and α_k, the ladder operator that raises m_j and simultaneously lowers m_k takes the form

$$E_{jk}^{+-}=-\frac{i}{2}\left((u_j+i\,v_j)\frac{\partial}{\partial(u_k+iv_k)}-(u_k-iv_k)\frac{\partial}{\partial(u_j-iv_j)}\right), \tag{3.3a}$$

whereas the operator raising both m_j and m_k is represented by

$$E_{jk}^{++}=-\frac{i}{2}\left((u_j+iv_j)\frac{\partial}{\partial(u_k-iv_k)}-(u_k+iv_k)\frac{\partial}{\partial(u_j-iv_j)}\right). \tag{3.3b}$$

[Straightforward application of these operators to eigenfunctions (3.1) verifies their behaving as ladder operators: they contribute to, or remove from, (3.1) factors $(u_j\pm iv_j)$ and $(u_k\pm iv_k)$ as appropriate for the intended ''ladder operator action.''] For odd-dimensional spaces, a residual coordinate, denoted here by w, does not occur in any of the H_j. The ladder operators changing only m_j (rather than a pair m_j,m_k) read then

$$E_j^{\pm}=-i\left((u_j\pm iv_j)\frac{\partial}{\partial w}-w\frac{\partial}{\partial(u_j\mp iv_j)}\right), \quad j=1,\ldots,\ell. \tag{3.3c}$$

[For $d=3$, setting $(u,v,w)=(x,y,z)$ and transforming the derivatives reveals the familiar pair of ladder operators $l_x\pm i\,l_y$, the single H_j occurring in this case coinciding with l_z.] This symbolic representation allows for efficient implementation on the computer.

A subset of ℓ ladder operators $E_{\boldsymbol{\epsilon}_j}$ (and their Hermitian conjugates) suffices to interrelate all harmonics with the same eigenvalue Λ. A convenient choice[23] for these $E_{\boldsymbol{\epsilon}_j}$ is given by the ladder operators that raise m_j and simultaneously lower m_{j+1} for $j=1,\ldots,\ell-1$. $E_{\boldsymbol{\epsilon}_\ell}$'s form depends on whether d is even or odd. For d even, $E_{\boldsymbol{\epsilon}_\ell}$ raises both $m_{\ell-1}$ and m_ℓ, and for odd d, it raises m_ℓ only, without changing any of the other m_j. The set $\{\boldsymbol{\epsilon}_j\}$, $j=1,\ldots,\ell$, then provides a basis for the ℓ-dimensional space of the vector labels $\boldsymbol{\alpha}$ and $\boldsymbol{\mu}$. In an ℓ-component vector notation, this basis reads (we assume $\ell \geqslant 5$ in order to expose the generic structure clearly)

$$\begin{aligned}
\boldsymbol{\epsilon}_1&=(1,-1,0,0,\ldots,0),\\
\boldsymbol{\epsilon}_2&=(0,1,-1,0,\ldots,0),\\
\boldsymbol{\epsilon}_3&=(0,0,1,-1,\ldots,0),\\
&\vdots\\
\boldsymbol{\epsilon}_{\ell-1}&=(0,0,\ldots,0,1,-1),\\
\boldsymbol{\epsilon}_\ell&=\begin{cases}(0,0,\ldots,0,1,1) & \text{for } d=2\ell\\ (0,0,\ldots,0,0,1) & \text{for } d=2\ell+1.\end{cases}
\end{aligned} \tag{3.4}$$

In general these basis vectors are *not* orthogonal in ℓ-dimensional space. Note, however, the following special cases: (i) In four-dimensional space (with $\ell=2$), the two basis vectors $\boldsymbol{\epsilon}_1=(1,-1)$ and $\boldsymbol{\epsilon}_2=(1,1)$ *are orthogonal*, indicating that the two basic ladder operator pairs, $E_{\pm\boldsymbol{\epsilon}_1}$ and $E_{\pm\boldsymbol{\epsilon}_2}$, commute with each other. In group theoretical language, this feature reflects the direct product structure $SO(4)=SO(3)\otimes SO(3)$. However, the two $SO(3)$ components do not refer to m_1 and m_2 directly, but rather to $(m_1-m_2)/2$ and $(m_1+m_2)/2$. (ii) For rotations in three-dimensional space, we have $\ell=1$, thus only one quantum number m which is being changed by one pair of ladder operators $E_{\pm\boldsymbol{\epsilon}_1}\equiv l_\pm$. (iii) In $d=2$ dimensions, *there are no ladder operators*. Since all rotations occur in the same plane (the ''only'' plane of two-dimensional space), the order in which rotations through different angles are performed does not matter; they are all independent of each other. In the present formulation, the (single) rotation operator H_1 generates all rotations. Each rotation is associated with its own harmonic function, $\exp(i\phi)$, the phase functions for different rotations (i.e., for different rotation angles ϕ) not being related to one another through linear operators.

B. Rotation of hyperspherical harmonics

We now turn to the analysis of the transformation described by (2.4). Note first that the three rotations occur in three nonintersecting planes, affording the more suitable representation $\exp(i\phi[J_{x_jx_k}+J_{y_jy_k}])\exp(i\phi J_{z_jz_k})$. Arranging the Cartesian components of the $N-1$ mass-scaled Jacobi vectors $\boldsymbol{\xi}_k$ in the form

$$\{x_1,y_1,x_2,y_2,\ldots,x_{N-1},y_{N-1},z_1,z_2,\ldots,z_{N-1}\}, \tag{3.5}$$

we choose the H_j by selecting pairs of coordinates from this list, starting from the left:

$$H_j=J_{x_jy_j},\quad j=1,\ldots,N-1, \tag{3.6a}$$

$$H_{N-1+k}=J_{z_{2k-1}z_{2k}},\quad k=1,\ldots,\left\lfloor\frac{N-1}{2}\right\rfloor, \tag{3.6b}$$

in the notation of (2.5). We have stressed repeatedly our aim of defining hyperspherical harmonics entirely through their behavior when acted upon by the operators H_j and E_{ϵ_j}, because these operators embody the structure and symmetry of the whole system in a frame-independent way. The explicit coordinate representation (3.6a)–(3.6b) of the relevant operators appears at variance with our intended frame independence. However, the spatial coordinates, (x_j,y_j,z_j), $j=1,\ldots,N-1$, in (3.6a)–(3.6b) should be viewed as *generic Cartesian coordinates*; they are *not* tied to any particular Jacobi tree. Arranging the generic Cartesian coordinates as we did in (3.5), on the other hand, does reflect physical considerations beyond the purely mathematical structure of rotations in higher-dimensional space: The latter would instead label the coordinates most appropriately as $(X_1,X_{-1},X_2,X_{-2},\ldots,X_\ell,X_{-\ell})$, supplemented possibly with an X_0 for odd-dimensional spaces. Our arrangement takes into account that the dimension $(3N-3)$ arises from a *product structure* of an $(N-1)$-dimensional particle space with the three-dimensional physical space of each Jacobi vector. In particular, the arrangement (3.5) affords attributing *relevant physical meaning* to the first $(N-1)$ eigenvalues m_j, $(j=1,\ldots,N-1)$: They represent the z projections of physical angular momenta; their sum constitutes the z projection L_z of the total orbital angular momentum, an invariant of the system.

As is evident from (3.6a), the coordinates (x_j,x_k,y_j,y_k)occur in H_j and H_k. The x and y parts of the rotation (2.4) thus involve the ladder operators that change m_j and m_k only. A more detailed analysis shows that (3.3a–c) can be inverted to read:

$$J_{x_jx_k}+J_{y_jy_k}=E_{jk}^{+-}+E_{jk}^{-+}\equiv E_{\boldsymbol{\alpha}(jk)}+E_{-\boldsymbol{\alpha}(jk)}, \tag{3.7}$$

for $1\leq j<k\leq N-1$, with $\boldsymbol{\alpha}(jk)=\sum_{s=j}^{k-1}\boldsymbol{\epsilon}_s$, i.e., the ℓ-component vector with $+1$ as its jth component and -1 as its kth component, all other entries being 0.

The following consideration is central to our development, providing the crucial link between the ladder operator representation (3.7) for $(J_{x_jx_k}+J_{y_jy_k})$ and their transformation matrix elements, by means of Euler-angle rotations. In analogy to the relation $l_x=\frac{1}{2}(l_++l_-)$ familiar from rotations in three dimensions, we view the sum of a ladder operator $E_{\boldsymbol{\alpha}(jk)}$ and its inverse (Hermitian conjugate) $E_{-\boldsymbol{\alpha}(jk)}$ as describing a rotation about an analog of the x axis. In three dimensions, an arbitrary rotation conventionally resolves into a sequence of three rotations: about the z axis, about the resulting y' axis, and about the new z' axis, through the Euler angles (φ,θ,ψ), respectively.[22] In terms of these three Euler-angle rotations, a rotation about the x axis through an angle ϕ results from the following sequence of operations: The first Euler-angle rotation about the z axis through the angle $\varphi=-\pi/2$ rotates the y axis onto the original x axis; in the second step one rotates about this y' axis (which is the original x axis) through the angle $\theta=\phi$; the third Euler-angle rotation finally moves the x' axis back to the original x direction by rotating about the z' axis (lying in the original (yz) plane) through the angle $\psi=\pi/2$. Wigner's d-symbol is the matrix element for the rotation of a spherical harmonic about the y axis, $d_{m'm}^{(l)}(\phi)=\langle Y_{lm'}|\exp(i\phi l_y)|Y_{lm}\rangle$, whereas the two z-type rotations only contribute phase factors $\exp(im'\pi/2-im\pi/2)$,[22] giving for the rotation of a spherical harmonic about the x axis

$$\langle Y_{lm'}|\exp(i\phi l_x)|Y_{lm}\rangle=e^{im'(\pi/2)d_{m'm}^{(l)}(\phi)e^{-im(\pi/2)}}. \tag{3.8}$$

Generalization of the concept of Euler-angle rotations from three to more dimensions hinges on the following key observations: m and m' serve to distinguish between degenerate harmonics with the same l. In higher-dimensional spaces, the vector indices $\boldsymbol{\mu}$ and $\boldsymbol{\mu}'$ play the same role. However, the parameter l in the d-symbol indicates not only the angular Laplacian's eigenvalue $l(l+1)$, but also—more importantly—the range of possible m values, $-l\leq(m,m')\leq l$. More precisely, it sets the upper limit of $2l$ for the number of times either one of the two ladder operators l_+,l_- can act in direct succession before necessarily mapping any spherical harmonic Y_{lm} to zero. Viewed in this way, the harmonic's parameter m indicates its ''position'' along the string (of length $2l+1$) of degenerate harmonics interrelated by a ladder operator. We now extend these concepts to rotations in more than three dimensions.

The single m (l_z's eigenvalue) in three dimensions belongs to a string ranging from $-l$ to $+l$, accessed by the single pair of ladder operators l_+, l_-. In more than three dimensions, we replace it with an ℓ-component vector $\boldsymbol{\mu}$ whose components are changed (typically in pairs) along different strings labeled by corresponding ladder operator pairs $E_{\boldsymbol{\alpha}}$ and $E_{-\boldsymbol{\alpha}}$. (Recall, however, that the ℓ vectors $\boldsymbol{\epsilon}_j$ provide a basis for the vectors $\boldsymbol{\alpha}$; thus any ladder operator $E_{\boldsymbol{\alpha}}$ can be expressed as products of $E_{\boldsymbol{\epsilon}_j}$.) The role of m as an indicator of the harmonic's position along the single string in three dimensions extends therefore to higher dimensions if we project the ''indicator'' $\boldsymbol{\mu}$ onto the ''direction'' of any particular string $\boldsymbol{\alpha}$ of interest, i.e., if we define

$$m_{\boldsymbol{\alpha}}=\frac{\boldsymbol{\mu}\cdot\boldsymbol{\alpha}}{\boldsymbol{\alpha}\cdot\boldsymbol{\alpha}}, \quad m'_{\boldsymbol{\alpha}}=\frac{\boldsymbol{\mu}'\cdot\boldsymbol{\alpha}}{\boldsymbol{\alpha}\cdot\boldsymbol{\alpha}}, \tag{3.9}$$

where the scalar product in the denominators accounts for $\boldsymbol{\alpha}$'s *two* nonzero components in the case of a pairwise change of m_j's. In analogy to l in the three-dimensional case, a parameter $\lambda_{\boldsymbol{\alpha}}$ determines how many times the ladder operators $E_{\pm\boldsymbol{\alpha}}$ can be applied in direct succession. The modulus of $m_{\boldsymbol{\alpha}}$ in (3.9) provides a lower limit for the relevant ''string length'' $\lambda_{\boldsymbol{\alpha}}$. Since the $\boldsymbol{\epsilon}_j$ form a basis for the $\boldsymbol{\alpha}$, we anticipate that $\lambda_{\boldsymbol{\alpha}}$ emerges from an ℓ-component vector $\boldsymbol{\lambda}=(\lambda_{\boldsymbol{\epsilon}_1},\ldots,\lambda_{\boldsymbol{\epsilon}_\ell})$. The latter provides the additional parameters required for a unique specification of harmonics (besides $\boldsymbol{\mu}$ and the eigenvalue Λ) . Note that in the general case $\lambda_{\boldsymbol{\alpha}}$ is not identical with the eigenvalue Λ, at variance with the situation in three dimensions.

To summarize the procedure so far, we note that the x and y parts of the finite rotation (2.4) affect only the two components m_j and m_k of the vector $\boldsymbol{\mu}$, shifting m_j by an integer amount n while simultaneously changing m_k by the same amount in the opposite direction. The projections (3.9) evaluate to

$$m_{\boldsymbol{\alpha}(jk)}=\tfrac{1}{2}(m_j-m_k), \tag{3.10a}$$

$$m'_{\boldsymbol{\alpha}(jk)}=\tfrac{1}{2}(m'_j-m'_k)=m_{\boldsymbol{\alpha}(jk)}+n, \tag{3.10b}$$

with nonvanishing matrix elements for the rotation of a hyperspherical harmonic $Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}$ into another harmonic $Y_{\Lambda',\boldsymbol{\mu}',\boldsymbol{\lambda}'}$ occurring only if $\boldsymbol{\mu}$ and $\boldsymbol{\mu}'$ lie along the *same* $\boldsymbol{\alpha}$-string of harmonics with degenerate Λ, i.e., if an integral number n of ladder operator steps $E_{\pm\boldsymbol{\alpha}(jk)}$ separates $\boldsymbol{\mu}'$ from $\boldsymbol{\mu}$. With our previous considerations on Euler-angle rotations leading to (3.8), this matrix element reads

$$\langle Y_{\Lambda',\boldsymbol{\mu}',\boldsymbol{\lambda}'}|\exp(i\phi[J_{x_jx_k}+J_{y_jy_k}])|Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}\rangle=e^{i(m'_{\boldsymbol{\alpha}}-m_{\boldsymbol{\alpha}})\pi/2}\,d^{(\lambda_{\boldsymbol{\alpha}})}_{m'_{\boldsymbol{\alpha}}m_{\boldsymbol{\alpha}}}(2\phi)\,\delta_{\Lambda',\Lambda}\,\delta_{\boldsymbol{\lambda}',\boldsymbol{\lambda}}\,\delta_{\boldsymbol{\mu}',\boldsymbol{\mu}+n\boldsymbol{\alpha}}, \tag{3.11}$$

where we omitted $\boldsymbol{\alpha}$'s parameters j,k for brevity. The Kronecker symbols δ ensure that only harmonics with the same eigenvalue Λ, lying along the same $\boldsymbol{\alpha}$-string, are connected. The factor 2 multiplying the rotation angle ϕ reflects the absence of the factor 1/2 on the right-hand side of (3.7), as compared to the expression for $l_x=\frac{1}{2}(l_++l_-)$, thereby effectively doubling the rotation angle in (3.8).

It remains to apply the same concepts to the z part of the rotation (2.4). This part affects only $\boldsymbol{\mu}$'s components that correspond to the H_κ involving z_j and z_k. Because we chose to gather all the z coordinates after all (xy) pairs in (3.5), the Jacobi vector indices j,k are shifted relative to $\boldsymbol{\mu}$'s components for the z coordinates. To simplify the notation, we use

$$\iota\equiv N-1+\left\lfloor\frac{j+1}{2}\right\rfloor;\quad \kappa\equiv N-1+\left\lfloor\frac{k+1}{2}\right\rfloor, \tag{3.12}$$

so that H_ι and m_ι now refer to the operator and quantum number pertaining to the coordinate z_j, with the same connection between H_κ, m_κ, and z_k. Depending on the indices j and k, i.e., depending on the positions of the coordinates z_j and z_k in the sequence (3.5), $J_{z_j z_k}$ takes alternative forms in terms of ladder operators or H_κ. The possible cases are:

(1) k even and $j=k-1$. According to (3.6b), $J_{z_j z_k}$ coincides with $H_{N-1+k/2}\equiv H_\kappa$. The rotation matrix element is simply

$$\langle Y_{\Lambda',\boldsymbol{\mu}',\boldsymbol{\lambda}'}|\exp(i\phi J_{z_j z_k})|Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}\rangle=\exp(im_\kappa\phi)\delta_{\Lambda',\Lambda}\delta_{\boldsymbol{\lambda}',\boldsymbol{\lambda}}\delta_{\boldsymbol{\mu}',\boldsymbol{\mu}}. \tag{3.13}$$

(2) k even and $j<k-1$ even. We find

$$J_{z_j z_k}=\tfrac{1}{4}(E_{\iota\kappa}^{+-}+E_{\iota\kappa}^{-+}+E_{\iota\kappa}^{++}+E_{\iota\kappa}^{--}). \tag{3.14}$$

Viewing again the sum of a ladder operator and its inverse (Hermitian conjugate) as proportional to an analog of a rotation about the x axis, we readily recognize the last expression as the sum of *two* x-type rotations [compare with (3.7)'s central expression]. With the explicit formulas (3.3a)–(3.3b), it is straightforward to verify that the ladder operator $E_{\iota\kappa}^{+-}$ raising m_ι and lowering m_κ commutes with the ''raising–raising'' operator $E_{\iota\kappa}^{++}$. The two x-type rotations are therefore independent of each other. As in the previous discussion of the x and y parts, an integer number of steps $E_{\iota\kappa}^{+-}$ must connect (m_ι,m_κ) to (m'_ι,m'_κ), i.e., $m'_\iota=m_\iota+n_1$, $m'_\kappa=m_\kappa-n_1$. However, the second rotation involves the same components of $\boldsymbol{\mu}$, only this time changing both in the *same* direction: $m'_\iota=m_\iota+n_2$, $m'_\kappa=m_\kappa+n_2$. Compatibility of the two conditions requires $n_1=n_2=0$, thus

$$m_{\boldsymbol{\beta}_-(\iota\kappa)}=\tfrac{1}{2}(m_\iota-m_\kappa)=m'_{\boldsymbol{\beta}_-(\iota\kappa)}, \tag{3.15a}$$

$$m_{\boldsymbol{\beta}_+(\iota\kappa)}=\tfrac{1}{2}(m_\iota+m_\kappa)=m'_{\boldsymbol{\beta}_+(\iota\kappa)}, \tag{3.15b}$$

and the extra phase factors occurring in (3.11) drop out in this case:

$$\langle Y_{\Lambda',\boldsymbol{\mu}',\boldsymbol{\lambda}'}|\exp(i\phi J_{z_j z_k})|Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}\rangle=d^{(\lambda_{\boldsymbol{\beta}_-})}_{m_{\boldsymbol{\beta}_-},m_{\boldsymbol{\beta}_-}}(\phi/2)\,d^{(\lambda_{\boldsymbol{\beta}_+})}_{m_{\boldsymbol{\beta}_+},m_{\boldsymbol{\beta}_+}}(\phi/2)\;\delta_{\Lambda',\Lambda}\delta_{\boldsymbol{\lambda}',\boldsymbol{\lambda}}\delta_{\boldsymbol{\mu}',\boldsymbol{\mu}}. \tag{3.16}$$

The factor 1/2 multiplying the rotation angle stems of course from the factor 1/4 in (3.14).

(3) k even and $j<k-1$ odd. In this case,

$$J_{z_j z_k}=\frac{1}{4i}(E_{\iota\kappa}^{+-}-E_{\iota\kappa}^{-+}+E_{\iota\kappa}^{++}-E_{\iota\kappa}^{--}), \tag{3.17}$$

obviously the sum of two y-type rotations. The ''selection rules'' for m_ι and m_κ are the same as in the previous case, and since the extra phase factors distinguishing an x from a y-type rotation cancel in (3.16), the *matrix element is identical to the one in case (2).*

(4) $k<N-1$ odd and j even. $J_{z_j z_k}$ turns into

$$J_{z_j z_k}=\frac{1}{4i}(E_{\iota\kappa}^{+-}-E_{\iota\kappa}^{-+}-E_{\iota\kappa}^{++}+E_{\iota\kappa}^{--}). \tag{3.18}$$

Exactly the same considerations apply again, except that the *difference* of two y-type rotations corresponds to a rotation through the angle $-\phi/2$ for the $E_{\iota\kappa}^{++}$ part.

(5) $k<N-1$ odd and j even, yielding

$$J_{z_j z_k}=\tfrac{1}{4}(E_{\iota\kappa}^{+-}+E_{\iota\kappa}^{-+}-E_{\iota\kappa}^{++}-E_{\iota\kappa}^{--}), \tag{3.19}$$

i.e., the difference of two x-type rotations. The matrix element coincides with the one of case (4).

(6) $k=N-1$ odd and j even. z_k does not occur in any of the H_κ, and the relevant ladder operators act on m_ι only:

$$J_{z_j z_k}=\tfrac{1}{2}(E_\iota^{+}+E_\iota^{-}). \tag{3.20}$$

This is an x-type rotation, exactly as in three dimensions. Projecting $\boldsymbol{\mu}$ and $\boldsymbol{\mu}'$ onto the appropriate direction $\boldsymbol{\gamma}(\iota)$: $m_{\boldsymbol{\gamma}(\iota)}=m_\iota$, $m'_{\boldsymbol{\gamma}(\iota)}=m'_\iota=m_{\boldsymbol{\gamma}(\iota)}+\nu$, we obtain for the matrix element

$$\langle Y_{\Lambda',\boldsymbol{\mu}',\boldsymbol{\lambda}'}|\exp(i\phi J_{z_jz_k})|Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}\rangle = d^{(\lambda_\gamma)}_{m'_\gamma,m_\gamma}(\phi)e^{i(m'_\gamma - m_\gamma)\pi/2}\delta_{\Lambda',\Lambda}\delta_{\boldsymbol{\lambda}',\boldsymbol{\lambda}}\delta_{\boldsymbol{\mu}',\boldsymbol{\mu}+\nu\boldsymbol{\gamma}}. \quad (3.21)$$

(7) $k=N-1$ odd and j odd.

$$J_{z_jz_k} = \frac{1}{2i}(E^+_\iota - E^-_\iota), \quad (3.22)$$

a y-type rotation. Its matrix element differs from the one in case (6) only by the absence of the phase factor $\exp(i\nu\pi/2)$.

Thus, the z part of the rotation (2.4) takes essentially three different forms: (i) a phase factor $\exp(im_\kappa\phi)$, diagonal in the $\boldsymbol{\mu}$, if $J_{z_jz_k}$ coincides with H_κ; (ii) an x or y-type rotation through the angle ϕ, changing m_ι into $m'_\iota = m_\iota + \nu$, as in three dimensions, if z_k is the unpaired coordinate z_{N-1} of an odd-dimensional space; (iii) the product of two rotations through the angles $\phi/2$ and $(-1)^k\phi/2$, respectively, but diagonal in $\boldsymbol{\mu}$, if z_j and z_k belong to different H_ι and H_κ.

C. Harmonics suitable for rotation

In Sec. III B, we have completely determined the matrix elements for the rotations of our interest when applied to hyperspherical harmonics, before actually specifying these functions explicitly. This was possible because we expressed the matrix elements in terms of the labels (''quantum numbers'') $(\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda})$ identifying the harmonics, rather than through integrals in coordinate space. So far, the harmonics are functions of the generic Cartesian coordinates (x_j,y_j,z_j). Upon rotation from one Jacobi tree to another, these coordinates transform into another set (x'_j,y'_j,z'_j), $j=1,\ldots,N-1$, but the harmonics, when expressed in terms of the new coordinates, retain their functional form. In this sense, these hyperspherical harmonics are frame independent.

Direct solution of the angular Laplacian's eigenvalue problem by separation of the $(3N-4)$ coordinates in the second-order differential equation leads to hyperspherical harmonics represented by standard spherical harmonics and Jacobi or Gegenbauer polynomials, depending on the choice of hyperspherical coordinates.[10,17,21] However, these harmonics are not simultaneous eigenfunctions of all the H_j. Consequently, they are not suitable for our purpose, because rotating the harmonics requires knowledge of the ladder operators' effects on these functions, at least for the base set of ladder operators $E_{\pm\boldsymbol{\epsilon}_j}$, $j=1,\ldots,\ell$, which in turn requires uniquely specifying the harmonics with labels $(\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda})$. We now construct complete sets of functions defined exclusively by their behavior under the action of the first-order differential operators H_j and $E_{\pm\boldsymbol{\epsilon}_j}$, $j=1,\ldots,\ell$. The resulting functions are ''hyperspherical harmonics,'' too, because they satisfy the generalized Laplacian's symmetry under rotations.

The hyperspherical description separates the ''hyperradial'' momentum from the generalized angular momentum. Each of the Cartesian coordinates x_j,y_j,z_j, $(j=1,\ldots,N-1)$, is proportional to the ''hyperradius'' R. The angular Laplacian's eigenvalue parameter Λ determines the harmonic's *degree* by setting the radial scale as R^Λ. Neither the H_j nor the ladder operators $E_{\pm\boldsymbol{\epsilon}_j}$ affect this radial factor, as is to be expected of angular momentum-like operators. With $(3N-4)$ angular coordinates, a complete specification of the harmonics requires $(3N-5)$ labels in addition to Λ. The vector $\boldsymbol{\mu}$ provides $\ell=\lfloor(3N-3)/2\rfloor$ of them in the form of the eigenvalues m_j of all the H_j. The remaining labels are taken from the ℓ-component vector $\boldsymbol{\lambda}$ consisting of the ''string lengths'' $\lambda_{\boldsymbol{\epsilon}_j}$ for the ladder operators $E_{\pm\boldsymbol{\epsilon}_j}$. The first $(\ell-2)$ components of $\boldsymbol{\lambda}$ suffice to reach a total of $(3N-4)$ labels if N is odd, as do the first $(\ell-1)$ components for N even.

It remains to determine the function F introduced in (3.1). The requirement $H_jF\equiv 0$ for all j implies that F depends only on $(u_j^2+v_j^2)$ [and possibly on the single unpaired coordinate w in case $(3N-3)$ is odd]. Furthermore, if $\Sigma_j|m_j|=\Lambda$ the product $\Pi_j(u_j+i\,v_j)^{m_j}$ already accounts for the radial factor R^Λ, i.e., $F=\text{const}$ in this case. This circumstance suggests constructing complete sets of degenerate harmonics with the same Λ as follows: We set m_1 to its maximum value and all other $m_j=0$, i.e., $\boldsymbol{\mu}=(\Lambda,0,\ldots,0)$.[24] For $j=1,\ldots,\ell$, the modulus of the projection $m_{\boldsymbol{\epsilon}_j}=\boldsymbol{\mu}\cdot\boldsymbol{\epsilon}_j/(\boldsymbol{\epsilon}_j\cdot\boldsymbol{\epsilon}_j)$ sets the lower limit for the corresponding string length $\lambda_{\boldsymbol{\epsilon}_j}$. However, $\lambda_{\boldsymbol{\epsilon}_j}$ cannot be larger than $m_{\boldsymbol{\epsilon}_j}$ either, for applying any of the *raising* operators $E_{+\boldsymbol{\epsilon}_j}$ necessarily results in a vector $\boldsymbol{\mu}'=\boldsymbol{\mu}+\boldsymbol{\epsilon}_j$ having $\Sigma_j|m_j'|>\Lambda$, i.e., in a harmonic not belonging to the same set of degenerate functions. With $\boldsymbol{\lambda}$ completely specified, the first harmonic reads

$$Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}=c_\Lambda(x_1+iy_1)^\Lambda,\quad \boldsymbol{\lambda}=(m_{\boldsymbol{\epsilon}_1},0,...,0),\quad \boldsymbol{\mu}=(\Lambda,0,...,0),\tag{3.23}$$

where c_Λ denotes a normalization constant. Starting from this first function, we generate harmonics by applying all the lowering operators $E_{-\boldsymbol{\epsilon}_j}$ first to (3.23), then applying the $E_{-\boldsymbol{\epsilon}_j}$ to the harmonics so obtained, and so on in a *recursive procedure*:

$$Y_{\Lambda,\boldsymbol{\mu}-\boldsymbol{\epsilon}_j,\boldsymbol{\lambda}'}=\frac{1}{\sqrt{(\lambda_{\boldsymbol{\epsilon}_j}+m_{\boldsymbol{\epsilon}_j})(\lambda_{\boldsymbol{\epsilon}_j}-m_{\boldsymbol{\epsilon}_j}+1)}}E_{-\boldsymbol{\epsilon}_j}Y_{\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda}}\tag{3.24}$$

for all $\boldsymbol{\epsilon}_j$ strings that have not yet terminated, i.e., the strings having $m_{\boldsymbol{\epsilon}_j}>-\lambda_{\boldsymbol{\epsilon}_j}$. The recursive nature of the process suggests gathering together the harmonics in ''levels,'' with the level of a harmonic indicating the number of lowering operator steps separating it from the first harmonic (3.23). At level 0 with the harmonic (3.23), the $\boldsymbol{\epsilon}_1$ string is the only string with nonzero length, and we can only generate one harmonic of level 1. But for $\ell>1$, this level-1 harmonic will already have several nonvanishing $m'_{\boldsymbol{\epsilon}_j}$ and corresponding $\lambda'_{\boldsymbol{\epsilon}_j}$, giving rise to additional $\boldsymbol{\epsilon}_j$ strings starting from this level. Repeating this procedure level by level, we work our way down until finally reaching the last harmonic with $\boldsymbol{\mu}=(-\Lambda,0,\ldots,0)$. The procedure stops automatically, because applying any of the lowering operators to this last harmonic maps it to zero (exactly as $l_-Y_{l,-l}\equiv 0$ in three dimensions).

In d dimensions, the total number of different hyperspherical harmonics with the same ''grand angular momentum'' Λ is (Ref. 22, p. 265).

$$\dim(\Lambda;d)=\frac{2\Lambda+d-2}{\Lambda+d-2}\binom{\Lambda+d-2}{d-2}.\tag{3.25}$$

For a given Λ, the procedure outlined above generates exactly $\dim(\Lambda,d)$ independent functions, i.e., a complete set of hyperspherical harmonics. However, some of these harmonics still require modifying for our purpose, as the following observations illustrate.

Note first that with our choice for $E_{\boldsymbol{\epsilon}_j}$, the first $(\ell-1)$ ladder operators always change two m_j in opposite directions, thus leaving $\Sigma_j|m_j|=\Lambda$ invariant when starting from the first harmonic. For all these harmonics, the function F reduces to a constant. At some stage during the above construction, however, an $\boldsymbol{\epsilon}_\ell$ string will appear along which the sum $\Sigma_j|m_j|$ no longer remains constant. Since the ladder operators do not change the overall radial factor R^Λ, the function F accounts for any ''missing powers'' in $\Pi_j(u_j+iv_j)^{m_j}$ for harmonics having $\boldsymbol{\mu}$ with $\Sigma_j|m_j|<\Lambda$. For instance, in three dimensions the lowering operator l_- [E_1^- in (3.3c)'s notation] removes one power of $(x+iy)$ from the ''highest'' harmonic $r^lY_{ll}\sim(x+iy)^l=r^l\sin^l\theta\exp(il\phi)$ while simultaneously adding a factor $F=z=r\cos\theta$ to the next harmonic $r^lY_{l,l-1}\sim z\,(x+iy)^{l-1}=r^l\cos\theta\sin^{l-1}\theta\exp(i[l-1]\phi)$. In the same way, repeated application of l_- generates the higher-degree Legendre polynomials in $\cos\theta$ making up F in this case.

So far, Λ and the vector $\boldsymbol{\mu}$ provide enough information to uniquely specify the hyperspherical harmonics; we need their additional label $\boldsymbol{\lambda}$ only for the purpose of determining transformation matrix elements, not to distinguish the harmonics from one another. For these harmonics, the construction described above provides the appropriate function F.

In a higher-dimensional setting, however, the $E_{\boldsymbol{\epsilon}_j}$ do not all commute with each other. It is thus possible to arrive at *different* functions with the *same* $\boldsymbol{\mu}$ along different ladder operator sequences, starting from the first harmonic (3.23). This is exactly the situation of ''degenerate eigenvalues:'' in this case, $\boldsymbol{\mu}$, the set of eigenvalues of the H_j, has multiplicity higher than one. Although our construction generates the appropriate number of independent functions, thus providing a basis system for the higher-dimensional eigenspace associated with $\boldsymbol{\mu}$, we now need additional labels—to be taken from $\boldsymbol{\lambda}$—to distinguish the different eigenfunctions with degenerate eigenvalue $\boldsymbol{\mu}$. Suppose, therefore, the vector $\boldsymbol{\mu}$ occurs with multiplicity $\nu>1$. Our procedure generates ν independent functions Φ_ρ, $\rho=1,\ldots,\nu$, all having the same $\Pi_j(u_j+iv_j)^{m_j}$. These functions differ only in their F. Harmonics suitable for the calculation of rotation matrix elements are expressed as linear combinations

$$\tilde{\Phi}_\sigma=\sum_{\rho=1}^{\nu} a_{\sigma\rho}\Phi_\rho, \tag{3.26}$$

and the requirement

$$(E_{+\boldsymbol{\epsilon}_j})^{\lambda_{\boldsymbol{\epsilon}_j}-m_{\boldsymbol{\epsilon}_j}+1}\tilde{\Phi}_\sigma=0, \qquad \text{for } j=1,\ldots,j_{\max} \tag{3.27}$$

determines the coefficients $a_{\sigma\rho}$ for $\sigma=1,\ldots,\nu$ (and thus the functions F). In this way, appropriate sets of parameters $(\lambda_{\boldsymbol{\epsilon}_1},\ldots,\lambda_{\boldsymbol{\epsilon}_{j_{\max}}})$ serve to distinguish the harmonics by enforcing specific lengths for the different $\boldsymbol{\epsilon}_j$ strings. As noted previously, the number of additional labels required is $j_{\max}=\ell-2$ (or $\ell-1$) for even (or odd)-dimensional spaces, respectively. With this modification, even the harmonics corresponding to degenerate vectors $\boldsymbol{\mu}$ show the desired behavior under rotations in d dimensions, and their transformation matrix elements can be deduced from their ''quantum numbers'' $(\Lambda,\boldsymbol{\mu},\boldsymbol{\lambda})$ directly.

Finally, a remark concerning the degeneracy of $\boldsymbol{\mu}$ seems in order. In three dimensions, it is impossible to arrive at the same $\boldsymbol{\mu}\equiv m$ along different strings, because there is *only one pair of ladder operators*. Nevertheless, even in this case we note that the m components arising for a given l $(\equiv\Lambda)$ occur again for $l'>l$. Due to the mostly pairwise change of m_j in higher-dimensional spaces, we expect that a vector $\boldsymbol{\mu}$ occurring for a given Λ will appear again as a label for harmonics with $\Lambda'=\Lambda+2,\Lambda+4,\ldots$. For $d>4$ there are noncommuting ladder operators. Because the number of different pathways leading from the highest harmonic to a specific $\boldsymbol{\mu}$ increases with the length of this path, $\boldsymbol{\mu}$'s multiplicity increases with Λ. Furthermore, since different functions F imply contributions from different $(u_j^2+v_j^2)$ terms, higher multiplicity—even in spaces with more than three dimensions—can only arise for $\Lambda-\Sigma_j|m_j|\geqslant 2$. A detailed analysis of the recursion in Λ with $\boldsymbol{\mu}$ held fixed confirms these expectations, yielding for the multiplicity of $\boldsymbol{\mu}$

$$\mathrm{mult}(\boldsymbol{\mu};\Lambda,d)=\binom{p+q}{q} \tag{3.28}$$

$$\text{with } p=\left\lfloor\frac{\Lambda-\Sigma_j|m_j|}{2}\right\rfloor, \quad q=\left\lfloor\frac{d-3}{2}\right\rfloor,$$

a useful result to test the implementation of the (recursive) procedure.

IV. EXAMPLE: TWO-ELECTRON SYSTEM

For the purpose of illustration, we apply the method outlined in the preceding sections to a Coulombic three-body system. Specifically, we consider a two-electron atom or ion with atomic number Z, i.e., a system with only one heavy particle. The case of diatomic molecules (two-center Coulomb system) requires additional modifications of the hyperspherical approach.[25]

A. Coulomb interactions among three particles

After elimination of the c.m. motion, a three-particle system requires two Jacobi vectors for its description. We use three different Jacobi trees, $\boldsymbol{\xi}_i$, $\boldsymbol{\eta}_i$, $\boldsymbol{\zeta}_i$, $(i=1,2)$. With $\boldsymbol{r}_1$, $\boldsymbol{r}_2$, and $\boldsymbol{r}_N$ denoting the positions of the two electrons and the nucleus, respectively, the relevant mass-weighted Jacobi vectors read

$$\boldsymbol{\xi}_1=\sqrt{\frac{M_e}{2}}(\boldsymbol{r}_1-\boldsymbol{r}_2), \tag{4.1a}$$

$$\boldsymbol{\xi}_2=\sqrt{\frac{2M_eM_N}{M_N+2M_e}}\left(\frac{\boldsymbol{r}_1+\boldsymbol{r}_2}{2}-\boldsymbol{r}_N\right), \tag{4.1b}$$

$$\boldsymbol{\eta}_1=\sqrt{\frac{M_NM_e}{M_N+M_e}}\,(\boldsymbol{r}_N-\boldsymbol{r}_1)=\cos\beta\boldsymbol{\xi}_1+\sin\beta\boldsymbol{\xi}_2, \tag{4.2}$$

$$\boldsymbol{\zeta}_1=\sqrt{\frac{M_NM_e}{M_N+M_e}}\,(\boldsymbol{r}_2-\boldsymbol{r}_N)=\cos\gamma\boldsymbol{\xi}_1+\sin\gamma\boldsymbol{\xi}_2, \tag{4.3}$$

where

$$\cos\beta=-\sqrt{\frac{M_N}{2(M_N+M_e)}}, \tag{4.4a}$$

$$\sin\beta=-\sqrt{\frac{M_N+2M_e}{2(M_N+M_e)}}, \tag{4.4b}$$

and $\gamma=-\beta$. M_N and M_e denote the nuclear and electron mass, respectively. The vectors $\boldsymbol{\eta}_2$ and $\boldsymbol{\zeta}_2$ will not be needed, since the Coulomb interaction among the three particles takes the form

$$V_C=\sqrt{\frac{M_e}{2}}\frac{1}{|\boldsymbol{\xi}_1|}-\sqrt{\frac{M_NM_e}{M_N+M_e}}\left(\frac{Z}{|\boldsymbol{\eta}_1|}+\frac{Z}{|\boldsymbol{\zeta}_1|}\right). \tag{4.5}$$

At this point, the familiar approach using the transformation of the *coordinates* would exploit (4.2)–(4.3) in a multipole expansion of the electron–nucleus interactions in terms of the coordinates $\boldsymbol{\xi}_1$ and $\boldsymbol{\xi}_2$. In our method, however, we apply the (kinematic) rotations (4.2)–(4.3) to the *wave functions* instead. This amounts to calculating the three interaction matrix elements in three different coordinate systems. The immediately obvious advantage of this method is that each of the three terms takes exactly the same form. Each of the integrals reduces to the same radial integral as in the textbook example of hydrogen. Higher-order multipoles and nested integrations over powers of the coordinates do not occur.

B. Choice of H_j and ladder operators

The kinetic energy has rotational symmetry in six dimensions. Partitioning the six coordinates into pairs defines three nonintersecting planes, and thus $\ell=3$ mutually commuting rotations. We choose the corresponding first-order operators H_j as $J_{x_1y_1}$, $J_{x_2y_2}$, and $J_{z_1z_2}$. Here $\{x_1,y_1,z_1,x_2,y_2,z_2\}$ denote the Cartesian components of the mass-weighted Jacobi vectors. Accordingly, the harmonics—simultaneous eigenfunctions of the three H_j with eigenvalues $\boldsymbol{\mu}=(m_1,m_2,m_3)$—take the form

$$F(x_1^2+y_1^2,\,x_2^2+y_2^2,z_1^2+z_2^2)\prod_{j=1}^{2}\,(x_j+i\,\mathrm{sign}(m_j)\,y_j)^{|m_j|}(z_1+i\,\mathrm{sign}(m_3)\,z_2)^{|m_3|}, \tag{4.6}$$

where we have rewritten (3.1) so as to yield non-negative powers of the hyperradius for either sign of the m_j. The appropriate base set of three ladder operator pairs $E_{\pm\boldsymbol{\epsilon}_j}$ is then specified by the vector labels $\boldsymbol{\epsilon}_1=(1,-1,0)$, $\boldsymbol{\epsilon}_2=(0,1,-1)$, and $\boldsymbol{\epsilon}_3=(0,1,1)$, corresponding to $E_{12}^{\pm\mp}$, $E_{23}^{\pm\mp}$, and $E_{23}^{\pm\pm}$ in (3.3a)–(3.3b).

C. Labeling the basis functions

Five angles specify each point on a sphere of fixed hyperradius R in six-dimensional space. Consequently, our hyperspherical harmonics require five labels—related to the numbers of nodes in the five angular variables—for their identification. Besides Λ and $\boldsymbol{\mu}=(m_1,m_2,m_3)$ we need one more label, $\lambda_{\boldsymbol{\epsilon}_1}$, the string length along the ladder operator sequences spanned by $E_{\pm\boldsymbol{\epsilon}_1}$.

The set of harmonics so defined differs from the more familiar set labeled by quantum numbers $(l_1,m_1,l_2,m_2,n_\alpha)$.[17,22] However, the latter set of harmonics does not make use of the third eigenvalue m_3. Since rotating the harmonics is accomplished by acting on them with ladder operators which in turn act on *all* the m_j, the conventional harmonics specified by $(l_1,m_1,l_2,m_2,n_\alpha)$ are not suited for our purpose. They may, of course, still serve as a basis set in an application, being then expanded into the new set labeled by $(\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1})$ prior to the actual rotation. A straightforward transformation links the two basis sets.

D. Explicit construction of harmonics with degenerate $\boldsymbol{\mu}$

As an example, we derive the expressions for some harmonics that are not completely characterized by Λ and $\boldsymbol{\mu}$. Consider for instance harmonics with $\Lambda=4$, $\boldsymbol{\mu}=(1,0,1)$. According to (3.28), there are two harmonics with these labels, to be distinguished by the additional parameter $\lambda_{\boldsymbol{\epsilon}_1}$. With the particular vector $\boldsymbol{\mu}$ of this example, we obtain $m_{\boldsymbol{\epsilon}_1}=\frac{1}{2}$, thus setting the lower limit for $\lambda_{\boldsymbol{\epsilon}_1}$. The two essentially different ways of arriving at the set of labels $(1,0,1)$ from harmonics of the next-lower level are given by an $E_{-\boldsymbol{\epsilon}_1}$-step from $\boldsymbol{\mu}'=(2,-1,1)$, and by an $E_{-\boldsymbol{\epsilon}_3}$-step from $\boldsymbol{\mu}''=(1,1,2)$. Both of these labels have multiplicity 1 since $\Sigma_j|m_j|=\Lambda$; the function $F(\ldots)$ in the corresponding harmonics reduces to a normalization constant. Up to these normalizing factors, c_1 and c_2, (4.6) gives these harmonics as

$$Y_{4,(2,-1,1),\,3/2}=c_1(x_1+iy_1)^2(x_2-iy_2)(z_1+iz_2), \tag{4.7a}$$

$$Y_{4,(1,1,2),1}=c_2(x_1+iy_1)(x_2+iy_2)(z_1+iz_2)^2. \tag{4.7b}$$

Applying the appropriate ladder operators to these harmonics provides a basis for the two-dimensional eigenspace of degenerate $\boldsymbol{\mu}=(1,0,1)$:

$$\Phi_1=E_{-\boldsymbol{\epsilon}_1}Y_{4,(2,-1,1),\,3/2}=c_3\,(x_1+iy_1)(z_1+iz_2)([x_1^2+y_1^2]-2[x_2^2+y_2^2]), \tag{4.8a}$$

$$\Phi_2=E_{-\boldsymbol{\epsilon}_3}Y_{4,(1,1,2),1}=c_4(x_1+iy_1)(z_1+iz_2)(2[x_2^2+y_2^2]-[z_1^2+z_1^2]), \tag{4.8b}$$

with constant factors c_3, c_4 to be ultimately absorbed into the normalization. Because Φ_1 is obtained from $Y_{4,(2,-1,1),3/2}$ by applying $E_{-\boldsymbol{\epsilon}_1}$, it behaves under the relevant rotations exactly as is required for $Y_{4,(1,0,1),3/2}$. Apart from the normalization constant c_3, we thus find

$$Y_{4,(1,0,1),\,3/2}=c_3(x_1+iy_1)(z_1+iz_2)([x_1^2+y_1^2]-2[x_2^2+y_2^2]). \tag{4.9}$$

However, the second harmonic with the same $\boldsymbol{\mu}=(1,0,1)$ does not simply coincide with Φ_2, because the latter has the same string-length $\lambda_{\boldsymbol{\epsilon}_1}=\frac{3}{2}$ as Φ_1: One easily verifies that

$$E_{\boldsymbol{\epsilon}_1}\Phi_2\neq 0. \tag{4.10}$$

We can, however, construct a harmonic $Y_{4,(1,0,1),1/2}$ as a linear combination of Φ_1 and Φ_2 by requiring

$$E_{\boldsymbol{\epsilon}_1}(a\Phi_1+b\Phi_2)\equiv 0, \tag{4.11}$$

yielding the condition $3ac_3-2bc_4=0$ and thus

$$Y_{4,(1,0,1),\,1/2}=c_5(x_1+iy_1)(z_1+iz_2)(2[x_1^2+y_1^2]+2[x_2^2+y_2^2]-3[z_1^2+z_2^2]). \tag{4.12}$$

The two harmonics with ''degenerate'' $\boldsymbol{\mu}=(1,0,1)$ are now distinguished by their respective $\lambda_{\boldsymbol{\epsilon}_1}$.

E. Rotating the harmonics

Equation (4.2) describes the *coordinate* transformation between the Jacobi trees $(\boldsymbol{\xi}_1,\boldsymbol{\xi}_2)$ and $(\boldsymbol{\eta}_1,\boldsymbol{\eta}_2)$. Accordingly, the hyperspherical harmonics transform as

$$|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle_{\boldsymbol{\xi}}=\sum_{\boldsymbol{\mu}'} D^{(\lambda_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}',\boldsymbol{\mu}}(\beta)|\Lambda,\boldsymbol{\mu}',\lambda_{\boldsymbol{\epsilon}_1}\rangle_{\boldsymbol{\eta}} \tag{4.13}$$

where the subscripts on the ket vectors indicate the respective Jacobi tree. The transformation matrix elements are given by

$$\begin{aligned} D^{(\lambda_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}',\boldsymbol{\mu}}(\beta)&=\langle\Lambda,\boldsymbol{\mu}',\lambda_{\boldsymbol{\epsilon}_1}|\exp(i\beta[J_{x_1x_2}+J_{y_1y_2}+J_{z_1z_2}])|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle\\ &=\langle\Lambda,\boldsymbol{\mu}',\lambda_{\boldsymbol{\epsilon}_1}|\exp(i\beta[E_{\boldsymbol{\epsilon}_1}+E_{-\boldsymbol{\epsilon}_1}+H_3])|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle, \end{aligned} \tag{4.14}$$

according to Sec. III B. Following the analysis given there, we find

$$D^{(\lambda_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}',\boldsymbol{\mu}}(\beta)=e^{i[m'-m]\pi/2}d^{(\lambda_{\boldsymbol{\epsilon}_1})}_{m',m}(2\beta)e^{im_3\beta}\delta_{\boldsymbol{\mu}',\boldsymbol{\mu}+n\boldsymbol{\epsilon}_1}, \tag{4.15}$$

with

$$m=\tfrac{1}{2}(m_1-m_2), \tag{4.16a}$$

$$m'=\tfrac{1}{2}(m_1'-m_2'), \tag{4.16b}$$

$$n=m_1'-m_1=-m_2'+m_2 \tag{4.16c}$$

in terms of $\boldsymbol{\mu}$ components. Replacing the angle β with $\gamma=-\beta$ yields the expressions for the transformation to Jacobi tree $\boldsymbol{\zeta}$.

F. Symmetry properties of basis functions

Due to the very high degeneracy of harmonics with the same grand angular momentum Λ as expressed in (3.25), it is important to exploit various symmetries of the functions in order to reduce the size of the hyperspherical basis. Reflection through the origin of the coordinate system transforms all six coordinates into their negatives. According to (4.6), the harmonic $|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle$ picks up a factor $(-1)^{|m_1|+|m_2|+|m_3|}$ under this operation. Since all the ladder operators change two of the m_j at a time, the sum in the exponent has the same parity as Λ. This first observation thus restricts the basis set by allowing only even Λ for even-parity states and odd Λ for odd-parity states.

Consider next the harmonics' symmetry under interchange of identical particles (i.e., the two electrons). This interchange is most easily described in the Jacobi tree $\{\boldsymbol{\xi}_1,\boldsymbol{\xi}_2\}$:

$$\boldsymbol{\xi}_1 \leftrightarrow -\boldsymbol{\xi}_1, \quad \boldsymbol{\xi}_2 \leftrightarrow \boldsymbol{\xi}_2. \tag{4.17}$$

Accordingly, the harmonic $|\Lambda,m_1,m_2,m_3,\lambda_{\boldsymbol{\epsilon}_1}\rangle$ turns into the harmonic $|\Lambda,m_1,m_2,-m_3,\lambda_{\boldsymbol{\epsilon}_1}\rangle$ under interchange of the electrons while acquiring a factor $(-1)^{m_1+m_3+S}$ (where S denotes the total spin of the two electrons). Antisymmetrized basis functions may thus be labeled by non-negative m_3 only, and $m_3=0$ is possible only for harmonics with (m_1+S) *even*.

Furthermore, when choosing the first-order operators H_j we have arranged the six coordinates in a way that allows us to identify m_1 and m_2 with the z projections of the three-dimensional relative angular momenta $\boldsymbol{l}_1$ and $\boldsymbol{l}_2$. Therefore, the sum $m_1+m_2=m_{\text{tot}}$ is the z component of the coupled (total) orbital angular momentum L. The fact that the Coulomb interaction does not couple states with different m_{tot} reduces the size of a basis consisting of antisymmetrized harmonics accordingly. This point is particularly interesting because the system's invariant m_{tot} restricts our basis, even though the corresponding total orbital angular momentum L is *not defined* in this basis. The reason for this seemingly surprising fact lies in our use of first-order operators only; hence L_z can be identified, but not the second-order operators $\boldsymbol{l}_j^2$ or L^2. The absence of the invariant three-dimensional L is the main trade-off we have to accept when treating all transformations as rotations in a genuinely six-dimensional space (Ref. 22, especially Sec. 10.2., p. 267ff).

G. Calculation of matrix elements

While Cartesian coordinates prove most appropriate for manipulating the hyperspherical harmonics using ladder operators, hyperspherical coordinates lend themselves for the calculation of matrix elements. Specifically, the familiar representation of Cartesian coordinates

$$\begin{aligned} x_1 &= R\cos\alpha\sin\theta_1\cos\varphi_1, \quad x_2 = R\sin\alpha\sin\theta_2\cos\varphi_2, \\ y_1 &= R\cos\alpha\sin\theta_1\sin\varphi_1, \quad y_2 = R\sin\alpha\sin\theta_2\sin\varphi_2 \\ z_1 &= R\cos\alpha\cos\theta_1, \quad z_2 = R\sin\alpha\cos\theta_2, \end{aligned} \tag{4.18}$$

transforms (4.6) into

$$R^{\Lambda}F\sin^{|m_1|}\theta_1 e^{im_1\varphi_1}\sin^{|m_2|}\theta_2 e^{im_2\varphi_2}(\cos\alpha\cos\theta_1 + i\,\text{sign}(m_3)\sin\alpha\cos\theta_2)^{|m_3|}, \tag{4.19}$$

where F is a function of $(\cos^2\alpha\sin^2\theta_1)$, $(\sin^2\alpha\sin^2\theta_2)$, and $(\cos^2\alpha\cos^2\theta_1+\sin^2\alpha\cos^2\theta_2)$. Note that this form remains the same, regardless of whether the Cartesian components (x,y,z) refer to the Jacobi vectors in tree $\boldsymbol{\xi}$, in $\boldsymbol{\eta}$, or in $\boldsymbol{\zeta}$. The relevant interaction operator entering into the matrix element is always $1/(R\cos\alpha)$, for each of the three pairwise Coulomb interactions, with the angle α referring to a different coordinate system in each case. The θ and α integrals arising in the calculation are related to the Euler beta function,[26] namely,

$$\int_0^{2\pi} d\phi e^{i(m'-m)\varphi} = 2\pi\delta_{m'm}, \tag{4.20a}$$

$$\int_0^{\pi} d\theta\sin^p\theta\cos^q\theta = (1+(-1)^q)\,\frac{(p-1)!!(q-1)!!}{(p+q)!!}c_{pq}, \tag{4.20b}$$

$$\int_0^{\pi/2} d\alpha\sin^p\alpha\cos^q\alpha = \frac{(p-1)!!(q-1)!!}{(p+q)!!}c_{pq}, \tag{4.20c}$$

where

$$c_{pq}=\begin{cases} \frac{\pi}{2} & p,q \text{ both even} \\ 1 & \text{otherwise.} \end{cases} \tag{4.21}$$

A multipole expansion would have forced us to split the last integral into two parts, with different integrands depending on whether $|\cos\beta\boldsymbol{\xi}_1|$ is greater or smaller than $|\sin\beta\boldsymbol{\xi}_2|$. The resulting integral could only be expressed as a sum of factorial quotients, rather than *a single term*, as in (4.20c).

Gathering together all the pieces developed in this section, we find for the angular part of the matrix elements

$$\langle\Lambda',\boldsymbol{\mu}',\lambda'_{\boldsymbol{\epsilon}_1}|V_C|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle=\langle\Lambda',\boldsymbol{\mu}',\lambda'_{\boldsymbol{\epsilon}_1}|\frac{1}{r_{12}}-\frac{Z}{r_{1N}}-\frac{Z}{r_{2N}}|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle \tag{4.22}$$

$$=\frac{1}{R}\sqrt{\frac{M_e}{2}}\langle\Lambda',\boldsymbol{\mu}',\lambda'_{\boldsymbol{\epsilon}_1}|\frac{1}{\cos\alpha}|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle-\frac{Z}{R}\sqrt{\frac{M_NM_e}{M_N+M_e}}$$

$$\times\sum_{\boldsymbol{\mu}_1,\boldsymbol{\mu}_2}\{(D^{(\lambda'_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}_1,\boldsymbol{\mu}'}(\beta))^\dagger D^{(\lambda_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}_2,\boldsymbol{\mu}}(\beta)+(D^{(\lambda'_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}_1,\boldsymbol{\mu}'}(\gamma))^\dagger D^{(\lambda_{\boldsymbol{\epsilon}_1})}_{\boldsymbol{\mu}_2,\boldsymbol{\mu}}(\gamma)\}$$

$$\times\langle\Lambda',\boldsymbol{\mu}_1,\lambda'_{\boldsymbol{\epsilon}_1}|\frac{1}{\cos\alpha}|\Lambda,\boldsymbol{\mu}_2,\lambda_{\boldsymbol{\epsilon}_1}\rangle, \tag{4.23}$$

with the further simplification $\gamma=-\beta$. The double summation (transforming the bra and ket vectors between Jacobi trees) seems to spoil the present approach's advantage over a multipole expansion. After all, the latter also leads to two summations, namely, a sum over the multipole order and another summation stemming from the analytical evaluation of the nested integral over α. Note, however, that the present method achieves significantly more with two summations: it accounts for *all the cusps* in the wave functions whenever an interparticle separation vanishes.

Finally, the particular case of a three-body system involves two relevant Jacobi vectors only. All possible Jacobi trees are thus related to one another by rotations in the *same plane* $(\boldsymbol{\xi}_1,\boldsymbol{\xi}_2)$. This particularity of the three-body problem might suggest arranging the Cartesian coordinates of the Jacobi vectors in the following way:

$$\{x_1,x_2,y_1,y_2,z_1,z_2\}, \tag{4.24}$$

rather than our choice (3.5). The H_j resulting from the above arrangement of coordinates coincide with $J_{x_1x_2}$, $J_{y_1y_2}$, and $J_{z_1z_2}$, thereby simplifying the rotation of harmonics: *All* rotations reduce to the first case of (z_1z_2)-type rotations discussed in Sec. III B, with matrix elements

$$\langle\Lambda',\boldsymbol{\mu}',\lambda'_{\boldsymbol{\epsilon}_1}|\exp(i\beta[J_{x_1x_2}+J_{y_1y_2}+J_{z_1z_2}])|\Lambda,\boldsymbol{\mu},\lambda_{\boldsymbol{\epsilon}_1}\rangle=e^{i(m_1+m_2+m_3)\beta}\delta_{\Lambda'\Lambda}\delta_{\boldsymbol{\mu}'\boldsymbol{\mu}}\delta_{\lambda'_{\boldsymbol{\epsilon}_1}\lambda_{\boldsymbol{\epsilon}_1}}. \tag{4.25}$$

This orthogonality relation virtually eliminates the double summation over $\boldsymbol{\mu}_1,\boldsymbol{\mu}_2$ in (4.23). However, the corresponding harmonics are now functions of $(x_1\pm ix_2)$, $(y_1\pm iy_2)$, and $(z_1\pm iz_2)$. Transforming to hyperspherical coordinates using

$$x_1=R\sin\alpha_1\cos\alpha_2\cos\varphi_1,\quad x_2=R\sin\alpha_1\cos\alpha_2\sin\varphi_1,$$

$$y_1=R\sin\alpha_1\sin\alpha_2\cos\varphi_2,\quad y_2=R\sin\alpha_1\sin\alpha_2\sin\varphi_2, \tag{4.26}$$

$$z_1=R\cos\alpha_1\cos\varphi_3,\quad z_2=R\cos\alpha_1\sin\varphi_3,$$

yields $H_j = -i(\partial/\partial\varphi_j)$, with $0 \leqslant \varphi_j \leqslant 2\pi$ and $0 \leqslant \alpha_k \leqslant \pi/2$. While the H_j, as well as the harmonics, now obviously attain their simplest form, the choice (4.24) has two serious drawbacks: (i) None of the three eigenvalues m_j of the H_j have physical significance, and (ii) $1/|\boldsymbol{\xi}_1| = (x_1^2 + y_1^2 + z_1^2)^{-1/2}$ is a (complicated) function of all five angles $(\alpha_1, \alpha_2, \varphi_1, \varphi_2, \varphi_3)$. The latter problem is solved by using hyperspherical coordinates (4.18) instead of (4.26), yielding for each of the combinations $(x_1 \pm i x_2)$, $(y_1 \pm i y_2)$, and $(z_1 \pm i z_2)$ a sum of two terms [as opposed to the single terms obtained for $(x_j \pm i y_j)$ in the previous subsections]. Expanding powers of these binomials leads to two additional summations, leaving us with no net gain.

V. CONCLUSION

Recognizing the independent-particle model's failure to account for cusps due to variables on which the wave function does not depend explicitly, we have developed a method that satisfies Kato's cusp condition through reference frame transformations. By transforming the *wave function* to the appropriate reference frame, we expose the wave function's cusp arising from vanishing of any given particle separation r_{ij}. In addition to satisfying the cusp condition on the wave function, this technique also simplifies the calculation of the pairwise Coulomb interaction $\sim 1/r_{ij}$, as compared to the conventional multipole expansion.

Implementation of the approach outlined above resolves into three major tasks, all addressed in the present investigation: (i) the systematic study of the relevant transformations between reference frames; (ii) the definition of functions suitable for such transformations; (iii) the determination of the transformation matrix. While the literature on Lie algebra provides ready-made solutions to problem (i), it usually fails to do so for (ii) and (iii). Furthermore, the mathematical literature does not exploit the particularity of an atomic or molecular N-body system.

More specifically, problem (i) is solved by using mass-scaled Jacobi coordinates, since the transformations between reference frames reduce then to generalized rotations in $(3N-3)$ dimensions. The Lie algebra so$(3N-3)$ describes these transformations completely, embodied in the sets of commuting rotation operators $\{H_j\}$ and ladder operators $\{E_{\pm\boldsymbol{\epsilon}_j}\}$, $j = 1, \ldots, \lfloor (3N-3)/2 \rfloor$. To solve problem (ii) mentioned above, we have introduced basis functions defined entirely through their behavior under infinitesimal rotations, i.e., when acted upon by the operators H_j and $E_{\pm\boldsymbol{\epsilon}_j}$. Simultaneous eigenfunctions of all the H_j constitute appropriate basis functions, classified further according to their matrix elements for the transformation between reference frames. The latter step removes possible ambiguities whenever the H_j have degenerate eigenvalues. Finally, by extending the concept of Euler-angle rotations from three to higher dimensions, we have provided the solution to task (iii), the determination of the transformation matrix elements. For an arbitrary N-body system, each change of reference frames considered here resolves into a sequence of basic transformations described by these matrix elements.

In an N-body system, the high dimensionality arises from the *product structure* of the $(N-1)$-dimensional particle space and the three-dimensional physical space. The basic step in the transformation between reference frames reduces to a two-dimensional rotation in a plane of particle space. Upon expansion of the particle space variables into their physical-space components, the basic rotation induces three two-dimensional rotations in $(3N-3)$-dimensional space that are analyzed using the Lie algebra so$(3N-3)$. To take advantage of the efficiency offered by the Lie algebraic method, we treat the transformations as rotations in a genuine $(3N-3)$-dimensional space. Thus, we work with the *first-order* differential operators H_j and $E_{\pm\boldsymbol{\epsilon}_j}$ throughout. Arranging the generic Cartesian components (x_j, y_j, z_j) of the particle-space variables $\boldsymbol{\xi}_j$ appropriately, we can *partially* recover the product structure characteristic for the physical application at hand: The eigenvalues of $(N-1)$ among the H_j carry physical significance; and we interpret them as z projections of orbital angular momenta. Their sum represents the total angular momentum's z projection, an invariant of the system. However, neither the individual angular momenta, nor the coupled (total) angular momentum can appear in our treatment, as they are represented by second-order operators. Other methods exploit the product structure of the $(3N-3)$-dimensional coordinate space to a larger extent by solving the Laplacian's (second-order) eigenvalue problem through separation of variables. However, the resulting hyperspherical harmonics incorporate these features of the three-dimensional physical space at considerable cost: Transforming these functions between reference frames proves very inefficient, requiring essentially their expansion into the equivalent sets of harmonics introduced in the present investigation.

In conclusion, we have demonstrated by explicit construction the possibility of describing a system of N charged particles without recourse to multipole expansions. Kato's cusp condition is satisfied implicitly through reference frame transformations of the *wave function*. We introduced appropriate basis functions and discussed their symmetries under particle interchange and reflection through the origin. We derived the matrix elements for the transformation between reference frames for arbitrary numbers of particles, and we showed that the interaction matrix elements attain a simpler form as compared to the conventional multipole expansion. Because the formalism underlying our approach relies exclusively on first-order differential operators, it does not incorporate angular momenta, thereby limiting its usefulness for bound state problems. However, the technique introduced here provides significant simplifications in scattering problems where partial angular momenta are not resolved.

Note added in proof. Our transformation matrices are analogous to the so-called Raynal–Revai coefficients. See, e.g., A. Novoselsky and J. Katriel, Phys. Rev. A **49**, 833 (1994), especially Sec. 5.

ACKNOWLEDGMENT

The operator integral $\int f\,dE$ of a complex valued measurable function f with respect to a positive operator measure E is considered. If F is a Neumark dilation of E into a projection measure, then the ''projected'' operator integral $\mathrm{pr}(\int f dF)$ is a restriction of the operator $\int f\,dE$. Necessary and sufficient conditions for the equality $\mathrm{pr}(\int f\,dF) = \int f\,dE$ are obtained. The results are applied to determine the moment operators of the phase space observables generated by the number states. © *1999 American Institute of Physics.* [S0022-2488(99)01104-4]

I. INTRODUCTION

The operator integral of a complex valued measurable function f with respect to an operator measure E is defined as the unique linear operator $L^E(f)$ for which the number $\langle \psi | L^E(f)\varphi\rangle$ equals the integral of f with respect to the complex measure $E_{\psi,\varphi}$ defined by E and the vectors ψ and φ, with ψ ranging over the whole of the Hilbert space $\mathcal{H}$ and φ the natural domain of $L^E(f)$. For positive operator measures E this domain contains, as a subspace, the set of those vectors φ for which f is square integrable with respect to the positive measure $E_{\varphi,\varphi}$. For a positive operator measure E one may also use a Neumark dilation of E into a projection measure F to obtain a ''projected'' operator integral $\mathrm{pr}(L^F(f))$. In general, the thus obtained operator $\mathrm{pr}(L^F(f))$ is a restriction of the operator $L^E(f)$. It will be shown that the two operators are the same exactly when the domain of $L^E(f)$ consists only of those vectors φ for which f is square integrable with respect to $E_{\varphi,\varphi}$. The theory of operator integrals, developed here and in a previous article,[1] will be applied to the so-called phase space observables generated by the number eigenstates.

The structure of the paper is as follows. Section II reviews the basic notions and results of the theory of operator integrals. Section III relates this theory in the case of positive operator measures to the operator integrals obtained via the Neumark dilation theory. In Sec. IV the general results will be applied to determine the moment operators of the number state generated phase space observables and their Cartesian margins.

II. INTEGRATION WITHOUT DILATION

A. The operator integral

Let $\mathcal{H}$ be a complex Hilbert space, with the inner product $\langle\cdot|\cdot\rangle$, and let $\mathcal{L}(\mathcal{H})$ denote the set of bounded operators on $\mathcal{H}$. Let Ω be a nonempty set and $\mathcal{A}$ a σ algebra of subsets of Ω. Let $E:\mathcal{A}\to\mathcal{L}(\mathcal{H})$ be an operator measure, i.e., a set function which is σ additive with respect to the weak, or, equivalently, the strong operator topology of $\mathcal{L}(\mathcal{H})$. For any $\varphi,\psi\in\mathcal{H}$ we denote by $E_{\psi,\varphi}$ the complex measure defined by $E_{\psi,\varphi}(X) = \langle\psi|E(X)\varphi\rangle$. Let $f:\Omega\to\mathbf{C}$ be an $\mathcal{A}$-measurable function and let $\mathcal{D}(L^E(f))$ denote the set of those vectors $\varphi\in\mathcal{H}$ for which f is $E_{\psi,\varphi}$ integrable for each $\psi\in\mathcal{H}$. $\mathcal{D}(L^E(f))$ is a vector subspace of $\mathcal{H}$ and there is a unique linear operator $L^E(f)$, with the domain $\mathcal{D}(L^E(f))$, such that

[b]Electronic mail: juhpello@utu.fi
[c]Electronic mail: ylinen@utu.fi

$$\langle \psi | L^E(f)\varphi \rangle = \int_\Omega f \, dE_{\psi,\varphi}$$

for all $\psi \in \mathcal{H}$. We call $L^E(f)$ the *integral* of f with respect to E and we also write $L^E(f) = \int f \, dE$. For further details, see Ref. 1.

Let $\mathcal{D}_f^E$ denote the set of those vectors $\varphi \in \mathcal{H}$ for which $|f|^2$ is $E_{\varphi,\varphi}$ integrable. The following result, proved in Ref. 1, will be important.

Theorem: (a) If the operator measure E is positive, that is, $E(X) \geqslant O$ for each $X \in \mathcal{A}$, then $\mathcal{D}_f^E$ is a subspace of $\mathcal{H}$ and

$$\mathcal{D}_f^E \subseteq \mathcal{D}(L^E(f)).$$

(b) If the operator measure E is projection valued, that is, $E(X)^2 = E(X) = E(X)^*$ for all $X \in \mathcal{A}$, then $\mathcal{D}_f^E = \mathcal{D}(L^E(f))$.

We note that in the above case (a) the inclusion may be proper. Indeed, if $\mu:\mathcal{A} \to [0,1]$ is a probability measure and $E:X \mapsto E(X) := \mu(X)I$, then for any f which is μ integrable, $L^E(f) = (\int f \, d\mu)I$, with $\mathcal{D}(L^E(f)) = \mathcal{H}$, but, if $|f|^2$ is not μ integrable, then $\mathcal{D}_f^E = \{0\}$. It is equally obvious that the equality $\mathcal{D}_f^E = \mathcal{D}(L^E(f))$ does not require E to be projection valued. For instance, if E is a projection valued measure and $g:\Omega \to [a,b]$, with $0 < a < b < \infty$, an $\mathcal{A}$-measurable function, then $F(X) := \int_X g \, dE$ defines a positive operator measure. Then, for any f, and for all $\psi, \varphi \in \mathcal{H}$, the integral $\int f \, dF_{\psi,\varphi}$ exists exactly when the integral $\int fg \, dE_{\psi,\varphi}$ exists, which, in turn, exists if and only if $\int f \, dE_{\psi,\varphi}$ exists. This shows that $\mathcal{D}_f^F = \mathcal{D}_f^E = \mathcal{D}(L^E(f)) = \mathcal{D}(L^F(f))$. Clearly, if f is bounded, then $\mathcal{D}_f^E = \mathcal{D}(L^E(f)) = \mathcal{H}$ for any positive operator measure E. Finally, we note that the equality $\|L^E(f)\varphi\|^2 = \int |f|^2 dE_{\varphi,\varphi}$, $\varphi \in \mathcal{D}_f^E$, does not hold, in general. Section IV D provides examples of this phenomenon.

B. Remarks on the literature

In mathematical literature the operator integrals $L^E(f)$ are mostly discussed only for positive operator measures and the domain of the operator $L^E(f)$ is taken to be $\mathcal{D}_f^E$ instead of the wider domain $\mathcal{D}(L^E(f))$. See, e.g., Refs. 2–5. Riesz and Sz.-Nagy,[2] however, point out on page 460 that the integral $\int f \, dE_{\psi,\varphi}$, $\psi \in \mathcal{H}$, can also converge for certain φ which do not belong to $\mathcal{D}_f^E$. On the other hand, Akhiezer and Glazman[4] report on page 132 of Vol. II an example for which the set $\mathcal{D}_f^E$, as well as the set $\mathcal{D}(L^E(f))$, consists only of the null vector. Schroeck[6] develops a theory of operator integrals under the additional assumption that the positive operator measures involved are absolutely continuous; the question of the domain is not explicitly addressed there. As an example of recent physics literature we mention Ozawa,[7] who also takes the set $\mathcal{D}_f^E$ as the domain of the operator defined by the integral of a measurable function f with respect to a positive operator measure E. The natural domain of the linear operator $L^E(f)$ is, however, the wider set $\mathcal{D}(L^E(f))$. In Sec. III we shall see that the restriction of the operator $L^E(f)$ to $\mathcal{D}_f^E$ equals the projected operator integral $\mathrm{pr}(L^F(f))$ obtained via a Neumark dilation of the (positive) operator measure E into a projection measure F.

C. Densely defined operator integrals

From now on we assume that the operator measure E is positive and so normalized that $E(\Omega) = I$.

Let $\overline{f}$ be the complex conjugate of f. The operator $L^E(\overline{f})$ has the domain $\mathcal{D}(L^E(\overline{f})) = \mathcal{D}(L^E(f))$. If $L^E(f)$ is densely defined, then the adjoint of $L^E(f)$ exists and it extends the operator $L^E(\overline{f})$, that is, $L^E(\overline{f}) \subseteq L^E(f)^*$ (Ref. 1, Lemma A4). Furthermore, if $\mathcal{D}(L^E(f))$ is dense in $\mathcal{H}$, then also $L^E(f)^*$ is densely defined, implying that $L^E(f)$ is closable, with $L^E(f)^{**}$ being the smallest closed linear extension of $L^E(f)$ (Ref. 2, Theorem on p. 305). Thus, if $L^E(f)$ is densely defined, we have

$$L^E(\overline{f}) \subseteq L^E(f)^*,$$

$$L^E(f)\subseteq L^E(f)^{**}.$$

It is well known that $L^E(\overline{f})=L^E(f)^*$ whenever E is projection valued. But it is obvious that this is not a necessary condition for the equality $L^E(\overline{f})=L^E(f)^*$. The operator measure $E(X)=\mu(X)I$ defined by a probability measure μ also demonstrates this statement. Indeed, if f is μ integrable, then $L^E(f)^*=L^E(\overline{f})$, though E is not projection valued. Finally, we recall that $L^E(f)=L^E(f)^{**}$ holds if and only if $L^E(f)$ is densely defined and closed.

D. Symmetric operator integrals

Assume that the function f is real valued. Then the operator $L^E(f)$ is symmetric, that is, for any $\varphi,\psi\in\mathcal{D}(L^E(f))$,

$$\langle\psi|L^E(f)\varphi\rangle=\langle L^E(f)\psi|\varphi\rangle,$$

see Ref. 1 for a proof. Therefore, if, in addition, $L^E(f)$ is densely defined one has the extensions

$$L^E(f)\subseteq L^E(f)^{**}\subseteq L^E(f)^*.$$

E. The real and imaginary parts

Let $f=f_1+if_2$ be the decomposition of f into its real and imaginary parts. Then f is $E_{\psi,\varphi}$ integrable if and only if f_1 and f_2 are $E_{\psi,\varphi}$ integrable, in which case $\int f\,dE_{\psi,\varphi}=\int f_1\,dE_{\psi,\varphi}+i\int f_2\,dE_{\psi,\varphi}$. We thus have the operator equalities

$$L^E(f)=L^E(f_1)+iL^E(f_2),$$

$$L^E(\overline{f})=L^E(f_1)-iL^E(f_2),$$

with $\mathcal{D}(L^E(f))=\mathcal{D}(L^E(\overline{f}))=\mathcal{D}(L^E(f_1))\cap\mathcal{D}(L^E(f_2))$. Assume now that $\overline{\mathcal{D}(L^E(f))}=\mathcal{H}$. Then $L^E(\overline{f})\subset L^E(f)^*$ so that the operators $\alpha L^E(f)+\beta L^E(\overline{f})$ and $\alpha L^E(f)+\beta L^E(f)^*$ are equal for all nonzero α, $\beta\in\mathbf{C}$, and, in particular,

$$\mathrm{Re}\,L^E(f):=\tfrac{1}{2}[L^E(f)+L^E(f)^*]=\tfrac{1}{2}[L^E(f)+L^E(\overline{f})],$$

$$\mathrm{Im}\,L^E(f):=\frac{1}{2i}[L^E(f)-L^E(f)^*]=\frac{1}{2i}[L^E(f)-L^E(\overline{f})].$$

By definition, $\mathcal{D}(\mathrm{Re}(L^E(f)))=\mathcal{D}(L^E(f))\subseteq\mathcal{D}(L^E(\mathrm{Re}\,f))$, and for any $\psi\in\mathcal{H}$, $\varphi\in\mathcal{D}(L^E(f))$,

$$\langle\psi|\mathrm{Re}(L^E(f))\varphi\rangle=\langle\psi|\tfrac{1}{2}(L^E(f)+L^E(\overline{f}))\varphi\rangle=\langle\psi|L^E(\tfrac{1}{2}(f+\overline{f}))\varphi\rangle=\langle\psi|L^E(\mathrm{Re}\,f)\varphi\rangle,$$

which shows that $\mathrm{Re}(L^E(f))\subseteq L^E(\mathrm{Re}\,f)$. Since the functions $\mathrm{Re}\,f$ and $\mathrm{Im}\,f$ are real the operators $L^E(\mathrm{Re}\,f)$ and $L^E(\mathrm{Im}\,f)$, as well as their restrictions $\mathrm{Re}\,L^E(f)$ and $\mathrm{Im}\,L^E(f)$, are symmetric.

III. INTEGRATION VIA DILATION

A. Neumark dilation

Consider the (positive normalized) operator measure $E:\mathcal{A}\to\mathcal{L}(\mathcal{H})$ and let $F:\mathcal{A}\to\mathcal{L}(\mathcal{K})$ be a (Neumark) dilation of it into a projection measure acting on a Hilbert space $\mathcal{K}$. Let $V:\mathcal{H}\to\mathcal{K}$ be the isometry such that

$$E(X)=V^*F(X)V$$

for all $X\in\mathcal{A}$. For any $\mathcal{A}$-measurable $f:\Omega\to\mathbf{C}$ the operator $L^F(f)=\int f\,dF$ is densely defined with the domain $\mathcal{D}(L^F(f))=\mathcal{D}_f^F$. The question arises under which conditions the ''projected'' operator $\mathrm{pr}(L^F(f)):=V^*L^F(f)V$ equals the operator $L^E(f)$. This will be answered next.

Theorem: With the above notations, the operator $V^*L^F(f)V$ is the restriction of the operator $L^E(f)$ to $\mathcal{D}_f^E$, so that $V^*L^F(f)V=L^E(f)$ if and only if $\mathcal{D}_f^E=\mathcal{D}(L^E(f))$.

Proof: For any $\varphi,\psi\in\mathcal{H}$ the complex measures $E_{\psi,\varphi}$ and $F_{V\psi,V\varphi}$ are the same. Hence, for any $\varphi\in\mathcal{D}_f^E$,

$$\int |f|^2 dF_{V\varphi,V\varphi}=\int |f|^2 dE_{\varphi,\varphi}<\infty,$$

showing that $V(\mathcal{D}_f^E)\subseteq\mathcal{D}_f^F=\mathcal{D}(L^F(f))$. But then for any $\varphi\in\mathcal{D}_f^E$ and for each $\psi\in\mathcal{H}$,

$$\langle\psi|L^E(f)\varphi\rangle=\int f\,dE_{\psi,\varphi}=\int f\,dF_{V\psi,V\varphi}=\langle V\psi|L^F(f)V\varphi\rangle=\langle\psi|V^*L^F(f)V\varphi\rangle.$$

This means that

$$L^E(f)|_{\mathcal{D}_f^E}=V^*L^F(f)V|_{\mathcal{D}_f^E}.$$

But we have

$$\begin{aligned}\mathcal{D}(V^*L^F(f)V)&=\mathcal{D}(L^F(f)V)=\{\varphi\in\mathcal{H}|V\varphi\in\mathcal{D}(L^F(f))\}\\&=\left\{\varphi\in\mathcal{H}\,\middle|\,\int |f|^2 dF_{V\varphi,V\varphi}<\infty\right\}=\left\{\varphi\in\mathcal{H}\,\middle|\,\int |f|^2 dE_{\varphi,\varphi}<\infty\right\}\\&=\mathcal{D}_f^E\subseteq\mathcal{D}(L^E(f)).\end{aligned}$$

Therefore, $V^*L^F(f)V$ is the restriction of $L^E(f)$ to $\mathcal{D}_f^E$, and $V^*L^F(f)V=L^E(f)$ if and only if $\mathcal{D}_f^E=\mathcal{D}(L^E(f))$.

Remark: For compactly supported operator measures E and for functions f which are bounded on the support of the measure, the equality $V^*L^F(f)V=L^E(f)$ is already proved in Ref. 8. The authors are indebted to an anonymous referee for bringing this reference to their attention. In the general case, however, the inclusion $\mathcal{D}_f^E\subset\mathcal{D}(L^E(f))$ may be proper, as pointed out in Sec. II A.

B. A theorem of Foiaş

As an application of the above result we obtain a slight generalization of a theorem of Foiaş[3] which characterizes subnormal operators in terms of operator measures. To that end, assume now that E is defined on the σ-algebra $\mathcal{B}(\mathbf{C})$ of Borel subsets of the complex plane $\mathbf{C}$. Let F and V be as in Sec. III A and choose f to be the identity function id on $\mathbf{C}$. Let A stand for the operator $\int z\,dE(z)$. The operator $N:=\int z\,dF(z)$ is now normal and by the proof of the above theorem we have $V^*NV=A|_{\mathcal{D}_{\mathrm{id}}^E}$, where $\mathcal{D}_{\mathrm{id}}^E=\{\varphi\in\mathcal{H}|\int|z|^2 dE_{\varphi,\varphi}<\infty\}$. We also recall[9] that a (not necessarily densely defined) operator $B:\mathcal{D}(B)\to\mathcal{H}$ is said to be subnormal if there is a Hilbert space $\mathcal{K}$, a linear isometry $V:\mathcal{H}\to\mathcal{K}$, and a normal operator $N:\mathcal{D}(N)\to\mathcal{K}$ such that $\mathcal{D}(B)\subseteq V^*(V(\mathcal{H})\cap\mathcal{D}(N))$, $N(V(\mathcal{D}(B)))\subseteq V(\mathcal{H})$, and $B\varphi=V^*NV\varphi$ for all $\varphi\in\mathcal{D}(B)$.

Theorem: An operator $B:\mathcal{D}(B)\to\mathcal{H}$ is subnormal if and only if there is a positive normalized operator measure $E:\mathcal{B}(\mathbf{C})\to\mathcal{L}(\mathcal{H})$ such that for each $\psi\in\mathcal{H}$, $\varphi\in\mathcal{D}(B)$, the following two conditions are satisfied:

$$\text{(a)}\qquad \langle\psi|B\varphi\rangle=\int z\,dE_{\psi,\varphi},$$

$$\text{(b)}\qquad \|B\varphi\|^2=\int |z|^2 dE_{\varphi,\varphi}.$$

Proof: Assume that B is subnormal, and let $N:\mathcal{D}(N)\to\mathcal{K}$ be a normal extension of it on the Hilbert space $\mathcal{K}$, with $V:\mathcal{H}\to\mathcal{K}$ being the accompanying isometry as described above. Let $F:\mathcal{B}(\mathbf{C})\to\mathcal{L}(\mathcal{K})$ be the spectral measure of N. Then $E(Z):=V^*F(Z)V$ defines a positive normalized operator measure $E:\mathcal{B}(\mathbf{C})\to\mathcal{L}(\mathcal{H})$ which satisfies for all $\psi\in\mathcal{H}$, $\psi\in\mathcal{D}(B)$, the conditions:

$$\begin{aligned}\langle\psi|B\varphi\rangle&=\langle\psi|V^*NV\varphi\rangle=\langle V\psi|NV\varphi\rangle\\&=\int z\,dF_{V\psi,V\varphi}=\int z\,dE_{\psi,\varphi},\end{aligned}$$

$$\begin{aligned}\|B\varphi\|^2=\|V^*NV\varphi\|^2&=\langle V^*NV\varphi|V^*NV\varphi\rangle\\&=\langle NV\varphi|VV^*NV\varphi\rangle\\&=\langle NV\varphi|NV\varphi\rangle\\&=\int |z|^2\,dF_{V\varphi,V\varphi}=\int |z|^2\,dE_{\varphi,\varphi},\end{aligned}$$

where we have used the fact that VV^* is the projection onto $V(\mathcal{H})$ and that $N(V(\mathcal{D}(B)))\subseteq V(\mathcal{H})$.

Conversely, assume that there is a normalized positive operator measure E associated with B via the formulas (a) and (b). We observe first that these conditions imply that B is a restriction of $A|_{\mathcal{D}^E_{\rm id}}$, that is, $B\subseteq A|_{\mathcal{D}^E_{\rm id}}$, where A denotes $\int z\,dE$. Let $F:\mathcal{B}(\mathbf{C})\to\mathcal{L}(\mathcal{K})$ be a dilation of E into a projection measure, $N=\int z\,dF$, and let $V:\mathcal{H}\to\mathcal{K}$ be the associated isometry. Then, by the theorem of Sec. II A, for any $\varphi\in\mathcal{D}(B)$,

$$B\varphi=A\varphi=V^*NV\varphi,$$

and

$$\|B\varphi\|^2=\int |z|^2\,dE_{\varphi,\varphi}=\int |z|^2\,dF_{V\varphi,V\varphi}=\|NV\varphi\|^2.$$

Since $\|NV\varphi\|=\|B\varphi\|=\|V^*NV\varphi\|=\|VV^*NV\varphi\|$ for all $\varphi\in\mathcal{D}(B)$, and VV^* is the projection onto $V(\mathcal{H})$, this gives $VV^*(NV\varphi)=NV\varphi$ for all $\varphi\in\mathcal{D}(B)$, that is, $N(V(\mathcal{D}(B)))\subseteq V(\mathcal{H})$, which concludes the proof that B is subnormal.

Let E,F,V,f be as in Sec. III A. We then have $V^*L^F(\mathrm{Re}\,f)V\subseteq L^E(\mathrm{Re}\,f)$, with the equality sign if and only if $\mathcal{D}^E_{\mathrm{Re}\,f}=\mathcal{D}(L^E(\mathrm{Re}\,f))$. Moreover,

$$\begin{aligned}\mathrm{Re}(V^*L^F(f)V)&=\tfrac{1}{2}[V^*L^F(f)V+(V^*L^F(f)V)^*]\\&=\tfrac{1}{2}[V^*L^F(f)V+V^*L^F(f)^*V)]\\&=V^*\,\mathrm{Re}(L^F(f))V\subseteq V^*L^F(\mathrm{Re}\,f)V,\end{aligned}$$

where the second equality is due to the fact that $(V^*L^F(f)V)^* \supseteq V^*L^F(f)^*V$ and $\mathcal{D}(V^*L^F(f)V) = \mathcal{D}(V^*L^F(f)^*V) \subseteq \mathcal{D}((V^*L^F(f)V)^*)$.

IV. EXAMPLES

In this section we apply the above results to some phase space observables and their Cartesian margins. From now on the Hilbert space $\mathcal{H}$ will be separable.

A. The phase space observable $A_{|s\rangle}$

For any $\varphi,\psi\in\mathcal{H}$ we let $|\varphi\rangle\langle\psi|$ denote the rank one operator $|\varphi\rangle\langle\psi|(\eta) = \langle\psi|\eta\rangle\varphi$. Let $\{|n\rangle\}_{n\geq 0}$ be a fixed orthonormal basis of $\mathcal{H}$. Let $N=\Sigma_{n\geq 0} n|n\rangle\langle n|$, $a=\Sigma_{n\geq 0}\sqrt{n+1}|n\rangle\langle n+1|$, and $a^* = \Sigma_{n\geq 0}\sqrt{n+1}|n+1\rangle\langle n|$ be the associated number, lowering, and raising operators, respectively. Their domains are $\mathcal{D}(N)=\{\varphi\in\mathcal{H}|\Sigma_{n\geq 0}n^2|\langle n|\varphi\rangle|^2<\infty\}$, and $\mathcal{D}(a)=\mathcal{D}(a^*)=\{\varphi\in\mathcal{H}|\Sigma_{n\geq 0}n|\langle n|\varphi\rangle|^2<\infty\}$. Clearly, $a^*a=N$ and $aa^*=N+I$. Moreover, $\mathrm{Re}(a)$ and $\mathrm{Im}(a)$ are (densely defined) symmetric operators whose closures are, apart from a scaling factor, the canonical position and momentum operators Q and P, respectively, that is, $\sqrt{2}\,\mathrm{Re}(a)^{**}=Q$, $\sqrt{2}\,\mathrm{Im}(a)^{**}=P$.

Let $\lambda:\mathcal{B}(\mathbf{C})\to[0,\infty]$ be the two-dimensional Lebesgue measure. Let $D_z=e^{za^*-\bar{z}a}$, $z\in\mathbf{C}$, be the (unitary) shift operator, and let $|s\rangle$ be a fixed number state. The map $\mathbf{C}\ni z\mapsto D_z|s\rangle\in\mathcal{H}$ is norm-continuous and $1/\pi\int_{\mathbf{C}}D_z|s\rangle\langle s|D_z^*d\lambda(z)=I$, where the integral converges in the weak operator topology. The formula

$$A_{|s\rangle}(Z) := \frac{1}{\pi}\int_Z D_z|s\rangle\langle s|D_z^* d\lambda(z)\in\mathcal{L}(\mathcal{H}),\quad Z\in\mathcal{B}(\mathbf{C}),$$

thus defines a normalized positive operator measure, the phase space observable $A_{|s\rangle}$ associated with the number state $|s\rangle$. For further details on the phase space observables and their dilations (Sec. IV B) the reader may wish to consult Refs. 10 and 11.

B. A dilation of $A_{|s\rangle}$

Let $\mathcal{K}$ denote the Hilbert space $L^2(\mathbf{C},(1/\pi)d\lambda)$ and let $F:\mathcal{B}(\mathbf{C})\to\mathcal{L}(\mathcal{K})$ be the canonical spectral measure $(F(Z)\phi=\chi_Z\phi)$. Consider the mapping $V_{|s\rangle}:\mathcal{H}\to\mathcal{K}$, with

$$(V_{|s\rangle}\varphi)(z) := \langle s|D_z^*\varphi\rangle_{\mathcal{H}},\quad z\in\mathbf{C}.$$

$V_{|s\rangle}$ is linear and preserves the norm:

$$\|V_{|s\rangle}\varphi\|_{\mathcal{K}}^2=\frac{1}{\pi}\int_{\mathbf{C}}\overline{(V_{|s\rangle}\varphi)(z)}(V_{|s\rangle}\varphi)(z)d\lambda=\frac{1}{\pi}\int_{\mathbf{C}}\langle\varphi|D_z|s\rangle\langle s|D_z^*\varphi\rangle d\lambda=\|\varphi\|_{\mathcal{H}}^2$$

for any $\varphi\in\mathcal{H}$. The final projection of this isometry $V_{|s\rangle}$, that is, the projection onto the closed subspace $V_{|s\rangle}(\mathcal{H})=\{V_{|s\rangle}\varphi|\varphi\in\mathcal{H}\}\subset\mathcal{K}$, is easily seen to be $P_{|s\rangle}=\Sigma_{n=0}^{\infty}P[\phi_n^s]$, where $\phi_n^s=V_{|s\rangle}|n\rangle$, $n\geq 0$.

For any $\varphi,\psi\in\mathcal{H}$, and for each $Z\in\mathcal{B}(\mathbf{C})$,

$$\langle\varphi|A_{|s\rangle}(Z)\psi\rangle=\langle V_{|s\rangle}\varphi|F(Z)V_{|s\rangle}\psi\rangle,$$

which shows that the projection measure F is a dilation of the operator measure $A_{|s\rangle}$.

Let $L^F(f)=\int_{\mathbf{C}}f(z)dF(z)$ be the normal operator defined by the canonical projection measure $F(Z)\phi=\chi_Z\phi$ and the Borel function $f:\mathbf{C}\to\mathbf{C}$. Then $L(f)$ is a multiplication operator, $(L^F(f)\phi)(z)=f(z)\phi(z)$, $z\in\mathbf{C}$, $\phi\in\mathcal{D}(L^F(f))$. By the theorem of Sec. III A we now have that $V_{|s\rangle}^*L^F(f)V_{|s\rangle}\subseteq L^{A_{|s\rangle}}(f)$ and the domain of $V_{|s\rangle}^*L^F(f)V_{|s\rangle}$ is $D_f^{A_{|s\rangle}}$.

C. A completeness relation

For each $s=0,1,2,...$ the functions ϕ_n^s, $n=0,1,2,...$, are mutually orthogonal unit vectors. We shall proceed to show that the set $\{\phi_n^s|s,n=0,1,2,...\}$ is a complete orthonormal system. The orthogonality of the functions ϕ_n^s can readily be computed. Indeed, these functions are related to the associated Laguerre polynomials as follows:

$$\begin{aligned}\phi_n^s(z)&=\langle s|D_z^*|n\rangle\\&=\frac{1}{\sqrt{s!}}e^{-|z|^2/2}\sum_{l=0}^{\min\{s,n\}}(-1)^{s-l}\binom{s}{l}\frac{\sqrt{n!}}{(n-l)!}z^{s-l}\overline{z}^{n-l}\\&=e^{i(s-n)\theta}(-1)^{\max\{0,s-n\}}e^{-|z|^2/2}\sqrt{\frac{(\min\{n,s\})!}{(\max\{n,s\})!}}|z|^{|s-n|}L_{\min\{n,s\}}^{|s-n|}(|z|^2),\end{aligned}$$

where $z=|z|e^{i\theta}$ and L_m^k, $k\in\mathbf{Z}$, $m\in\mathbf{N}$, is the associated Laguerre polynomial. Using the Vandermonde convolution formula[12] or the properties of the Laguerre polynomials it is a straightforward computation to confirm that for any $s,r,n,m\geqslant 0$

$$\langle\phi_n^s|\phi_m^r\rangle=\frac{1}{\pi}\int_{\mathbf{C}}\overline{\phi_n^s(z)}\phi_m^r(z)d\lambda=\frac{1}{\pi}\int_{\mathbf{C}}\langle n|D_z|s\rangle\langle r|D_z^*|m\rangle d\lambda=\delta_{sr}\delta_{nm}.$$

This shows that for $s\neq r$ the operator measures $A_{|s\rangle}$ and $A_{|r\rangle}$ are Neumark projections of F into mutually orthogonal subspaces $V_{|s\rangle}(\mathcal{H})$ and $V_{|r\rangle}(\mathcal{H})$ of $\mathcal{K}$. To show that the functions $\phi_n^s,s,n=0,1,2,...$, constitute a complete system we write

$$L^2\left(\mathbf{C},\frac{1}{\pi}d\lambda(z)\right)\simeq L^2\left([0,2\pi),\frac{d\theta}{2\pi}\right)\otimes L^2(\mathbf{R}^+,d(r^2)),$$

and recall that the functions $e^{ik\theta}$, $k\in\mathbf{Z}$, and

$$\sqrt{\frac{m!}{(l+m)!}}e^{-r^2/2}r^lL_m^l(r^2),$$

$l,m\in\mathbf{N}$, form orthonormal bases for the respective component spaces. We may thus conclude that

$$\sum_{s=0}^{\infty}P_{|s\rangle}=\sum_{s=0}^{\infty}\sum_{n=0}^{\infty}P[\phi_n^s]=I_{\mathcal{K}}.$$

In other words, we have the orthogonal decomposition of the bigger space

$$\mathcal{K}=L^2\left(\mathbf{C},\frac{1}{\pi}d\lambda(z)\right)=V_{|0\rangle}(\mathcal{H})\oplus V_{|1\rangle}(\mathcal{H})\oplus V_{|2\rangle}(\mathcal{H})\oplus\cdots.$$

D. The moment operators of $A_{|s\rangle}$

In Ref. 1 all the operator integrals $L^{A_{|s\rangle}}(f)$ for the functions $z\mapsto z^k$ and $z\mapsto\overline{z}^k$, with $k=0,1,2,...$, were determined. They are:

$$\text{(a)}\qquad L^{A_{|s\rangle}}(z^k)=\int_{\mathbf{C}}z^k dA_{|s\rangle}=a^k,$$

$$\text{(b)}\qquad L^{A_{|s\rangle}}(\overline{z}^k)=\int_{C}\overline{z}^k dA_{|s\rangle}=(a^*)^k,$$

with the domains

$$\mathcal{D}^{A_{|s\rangle}}_{\mathrm{id}^k}=\mathcal{D}(L^{A_{|s\rangle}}(z^k))=\mathcal{D}(a^k)=\mathcal{D}(a^{*k}).$$

Accordingly, we also have:

$$a^k=V^*_{|s\rangle}L^F(z^k)V_{|s\rangle}=V^*_{|s\rangle}L^F(z)^kV_{|s\rangle}=(V^*_{|s\rangle}L^F(z)V_{|s\rangle})^k,$$

$$(a^*)^k=V^*_{|s\rangle}L^F(\overline{z}^k)V_{|s\rangle}=V^*_{|s\rangle}(L^F(z)^*)^kV_{|s\rangle}=(V^*_{|s\rangle}L^F(z)^*V_{|s\rangle})^k,$$

where $(L^F(z)\phi)(z)=z\phi(z)$, $z\in\mathbf{C}$, for all $\phi\in\mathcal{D}(L^F(z))$.

In Ref. 1 it was shown, in addition, that for any $s=0,1,2,...$,

$$\text{(c)} \qquad \int_{\mathbf{C}}|z|^2dA_{|s\rangle}=N+(s+1)I.$$

Since $aa^*=N+I$ we observe that the operator integral (c) equals aa^* exactly when $s=0$. Indeed, the phase space measure $A_{|0\rangle}$, associated with the ground state $|0\rangle$, satisfies the condition

$$\text{(d)} \qquad a^k(a^*)^l=\int_{\mathbf{C}}z^k\overline{z}^l\,dA_{|0\rangle}$$

for $k,l=0,1$. This shows the well-known fact that the operator a^* is subnormal. Holevo[13] referred to the subnormality of a^* as an explanation of the validity of the formulas (a)–(d) for the operator measure $A_{|0\rangle}$. It is worth mentioning that the operator a is not subnormal[14] so that there is no positive operator measure $E:\mathcal{B}(\mathbf{C})\to\mathcal{L}(\mathcal{H})$ for which $a=\int_{\mathbf{C}}z\,dE$, $a^*=\int_{\mathbf{C}}\overline{z}\,dE$, and $a^*a=\int_{\mathbf{C}}|z|^2\,dE$. This is in accordance with formula (c) which gives $a^*a=\int|z|^2\,dA_{|s\rangle}-(s+1)I$.

E. The real and imaginary parts of $L^{A_{|s\rangle}}(z^k)$

The above results (a) and (b) give immediately

$$\mathrm{Re}\,L^{A_{|s\rangle}}(z^k)=\tfrac{1}{2}(L^{A_{|s\rangle}}(z^k)+L^{A_{|s\rangle}}(\overline{z}^k))=\tfrac{1}{2}(a^k+a^{*k}),$$

$$\mathrm{Im}\,L^{A_{|s\rangle}}(z^k)=\frac{1}{2i}(L^{A_{|s\rangle}}(z^k)-L^{A_{|s\rangle}}(\overline{z}^k))=\frac{1}{2i}(a^k-a^{*k}),$$

with the domain $\mathcal{D}(a^k)$. Writing $z=x+iy$ we also have that the operators $L^{A_{|s\rangle}}(x)$ and $L^{A_{|s\rangle}}(y)$ extend the operators $\frac{1}{2}(a+a^*)$ and $(1/2i)(a-a^*)$, respectively. Since $L^{A_{|s\rangle}}(x)$ and $L^{A_{|s\rangle}}(y)$ are densely defined symmetric operators, and since $\mathrm{Re}(a)^{**}=1/\sqrt{2}Q$ and $\mathrm{Im}(a)^{**}=1/\sqrt{2}P$, we conclude that

$$\frac{1}{2}(a+a^*)\subset L^{A_{|s\rangle}}(x)\subset L^{A_{|s\rangle}}(x)^{**}=\frac{1}{\sqrt{2}}Q,$$

$$\frac{1}{2i}(a-a^*)\subset L^{A_{|s\rangle}}(y)\subset L^{A_{|s\rangle}}(y)^{**}=\frac{1}{\sqrt{2}}P.$$

Similarly, one gets:

$$\tfrac{1}{2}[N+(s+1)I+\tfrac{1}{2}(a^2+a^{*2})]=\tfrac{1}{2}[L^{A_{|s\rangle}}(|z|^2)+\tfrac{1}{2}(a^2+a^{*2})]$$
$$\subset L^{A_{|s\rangle}}(x^2)\subset L^{A_{|s\rangle}}(x^2)^{**}$$
$$=\tfrac{1}{2}Q^2+\tfrac{1}{2}(s+\tfrac{1}{2})I,$$
$$\tfrac{1}{2}[N+(s+1)I-\tfrac{1}{2}(a^2+a^{*2})]=\tfrac{1}{2}[L^{A_{|s\rangle}}(|z|^2)-\tfrac{1}{2}(a^2+a^{*2})]$$
$$\subset L^{A_{|s\rangle}}(y^2)\subset L^{A_{|s\rangle}}(y^2)^{**}$$
$$=\tfrac{1}{2}P^2+\tfrac{1}{2}(s+\tfrac{1}{2})I,$$
$$\frac{1}{4i}(a^2-a^{*2})\subset L^{A_{|s\rangle}}(xy)\subset L^{A_{|s\rangle}}(xy)^{**}=\frac{1}{4}(QP+PQ).$$

Finally, we note that the operator measure $A_{|s\rangle}$ and its Cartesian marginal measures $X\mapsto A_{|s\rangle}(X\times\mathbf{R})=:A^x_{|s\rangle}(X)$ and $Y\mapsto A_{|s\rangle}(\mathbf{R}\times Y)=:A^y_{|s\rangle}(Y)$ carry the following respective noises:

$$R(A_{|s\rangle}):=L^{A_{|s\rangle}}(z^2)-L^{A_{|s\rangle}}(z)^2=O,$$
$$R(A^x_{|s\rangle}):=L^{A_{|s\rangle}}(x^2)-L^{A_{|s\rangle}}(x)^2=\tfrac{1}{2}(s+\tfrac{1}{2})I,$$
$$R(A^y_{|s\rangle}):=L^{A_{|s\rangle}}(y^2)-L^{A_{|s\rangle}}(y)^2=\tfrac{1}{2}(s+\tfrac{1}{2})I.$$

The fact that the positive operators $R(A^x_{|s\rangle})$ and $R(A^y_{|s\rangle})$ are nonzero reflects the fact that the margins $A^x_{|s\rangle}$ and $A^y_{|s\rangle}$ are not projection valued.[2] Recalling that the marginal measures $A^x_{|s\rangle}$ and $A^y_{|s\rangle}$ are—apart from the scaling factor $\sqrt{2}$—unsharp position and momentum observables, the above noise equations lead to the following s-dependent uncertainty product for these observables (with $q=\sqrt{2}x$ and $p=\sqrt{2}y$):

$$\begin{aligned}\mathrm{Var}(A^q_{|s\rangle},\varphi)\mathrm{Var}(A^p_{|s\rangle},\varphi)&=(\mathrm{Var}(Q,\varphi)+\langle\varphi|R(A^q_{|s\rangle})\varphi\rangle)(\mathrm{Var}(P,\varphi)+\langle\varphi|R(A^p_{|s\rangle})\varphi\rangle)\\&=(\mathrm{Var}(Q,\varphi)+(s+\tfrac{1}{2}))(\mathrm{Var}(P,\varphi)+(s+\tfrac{1}{2}))\\&=(\mathrm{Var}(Q,\varphi)\mathrm{Var}(P,\varphi)+(s+\tfrac{1}{2})(\mathrm{Var}(Q,\varphi)+\mathrm{Var}(P,\varphi))+(s+\tfrac{1}{2})^2\\&\geqslant(s+1)^2.\end{aligned}$$

For $s=0$, this result is well known, see, e.g., Ref. 11, p. 55.

Conjectural bases for irreducible representation spaces of simple Lie algebras, due to Verma, have been described by Li, Moody, Nicolescu, and Patera. In this paper the basis conjecture for the algebras of type A_n is established. © *1999 American Institute of Physics.* [S0022-2488(99)02504-9]

I. INTRODUCTION

Conjectural bases for irreducible representation spaces of simple Lie algebras, due to Verma, are described in Ref. 1. The purpose of the present paper is to establish the basis conjecture for the algebras of type A_n.

The proof consists of two steps. Recall that isomorphism classes of irreducible representation spaces are in one-to-one correspondence with shapes of Young tableaus. The first step in the proof is to exhibit a ''natural'' bijective correspondence between the conjectural basis vectors of an irreducible representation space on the one hand and the standard tableaus of the corresponding shape on the other. From the well-known result that the number of such standard tableaus equals the dimension of the representation, we conclude that the basis vectors are right in number. It then remains only to prove that they are linearly independent, and this is step two of the proof.

The set up for step two is borrowed from Ref. 2. In fact, the linear independence can be deduced as a special case of the main Proposition 7.1 of Ref. 2. In the present paper, we deduce the linear independence as an immediate consequence of Proposition 2 below. Although the two propositions appear at first sight to be identical, they are not so, for the partial orders are different. The proof of linear independence in the present paper is much simpler than the proof in Ref. 2 even after specializing the latter to the case of type A_n. Referring to Ref. 2 for the proof of linear independence would greatly reduce the readability of the present paper.

Another strategy for a proof of the basis conjecture, quite different from the one of our proof, is outlined in Ref. 1 itself (see Sec. V of that paper). We believe the conjectures on which this strategy is based to be true, but our attempts at obtaining a proof along these lines have not met with success.

There naturally arises the question whether our method of proof can be generalized to cover the other types of algebras. A ''natural'' bijective correspondence between the conjectural basis vectors and standard tableaus presumably exists for the other types too, but we do not see it. Of course, even after getting hold of such a correspondence, one still has to establish the linear independence of conjectural basis vectors.

The organization of this paper is as follows. In Sec. II we recall the basis conjecture for the algebras of type A_n. The bijective correspondence between the basis vectors and the standard tableaus is the subject of Sec. III. The proof of linear independence is straight forward for the fundamental representations as pointed out in Sec. IV. The linear independence in the case of a non-fundamental representation is established in Sec. V.

II. THE VERMA CONJECTURE

Let $\mathfrak{g}=sl(n;\mathbb{C})$, the Lie algebra of $n\times n$ matrices of trace 0 over the complex numbers. When we speak of roots, weights, positive roots, and such other terms, it is to be understood that these

---

[a]Electronic mail: knr@smi.ernet.in
[b]Electronic mail: sankaran@smi.ernet.in

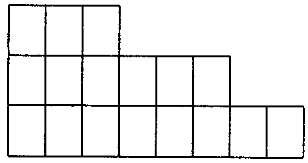

FIG. 1.

are with respect to the standard Cartan subalgebra (the subalgebra of traceless diagonal matrices) and the standard Borel subalgebra (the subalgebra of traceless upper triangular matrices).

Let $l:=n-1$, the *rank* of $\mathfrak{g}$. Let $\varpi_1,\ldots,\varpi_l$ be the fundamental weights. A weight λ is *dominant integral* if, in the expression $\lambda=m_1\varpi_1+\cdots+m_l\varpi_l$, the m_i are all non-negative integers. Recall that isomorphism classes of irreducible finite dimensional $\mathfrak{g}$-modules are in bijective correspondence with dominant integral weights. Given an irreducible $\mathfrak{g}$-module, the corresponding dominant integral weight is just the highest weight of that $\mathfrak{g}$-module.

Let $\lambda=m_1\varpi_1+\cdots+m_l\varpi_l$ be a dominant integral weight, V_λ the corresponding irreducible finite dimensional $\mathfrak{g}$-module, and v_λ a highest weight vector in V_λ. (The vector v_λ is uniquely determined up to a scalar factor.) Note that $s_1(s_2s_1)\cdots(s_i\cdots s_1)\cdots(s_l\cdots s_1)$ is a reduced expression for the longest element of the Weyl group of $\mathfrak{g}$; here s_i denotes the simple reflection corresponding to the simple root α_i which corresponds to the fundamental weight ϖ_i. Thus the vectors obtained by the action on v_λ of the monomials

$$Y_1^{(a_1^1)}(Y_2^{(a_2^2)}Y_1^{(a_1^2)})\cdots(Y_i^{(a_i^i)}Y_{i-1}^{(a_{i-1}^i)}\cdots Y_2^{(a_2^i)}Y_1^{(a_1^i)})\cdots(Y_l^{(a_l^l)}\cdots Y_1^{(a_1^l)}) \tag{1}$$

span V_λ; here Y_i is the lower triangular matrix with all but one entry being 0, the sole non-zero entry being 1 on row $i+1$ and column i, a_k^c are non-negative integers, and $Y_i^{(a)}$ denotes $Y_i^a/a!$. It was conjectured by Verma[1] that the subset of these vectors defined by the following constraint forms a basis for V_λ: for each pair (c,k) such that $1\leqslant k\leqslant c\leqslant l$,

$$0\leqslant a_k^c\leqslant \min\{a_{k-1}^c+m_{l-c+k},a_{k+1}^{c+1}\}, \tag{2}$$

where

$$a_k^{l+1}:=\infty \quad \text{and} \quad a_0^c:=0.$$

Let us call those monomials (1) that are subject to the constraint (2) the *Verma monomials*. Let us call *Verma vectors* those vectors obtained by the action of the Verma monomials on v_λ. The theorem of the present paper can now be phrased thus:

Theorem 1 (Verma's Conjecture): *The Verma vectors form a basis for* V_λ. The proof is given in Sec. V.

III. STANDARD TABLEAUS AND VERMA MONOMIALS

The purpose of this section is to establish a bijective correspondence between the set of standard tableaus of a fixed shape λ on the one hand and the Verma monomials associated to λ on the other. We first recall the notion of tableaus and standard tableaus.

Fix a positive integer l. Let $\lambda=(m_l,\ldots,m_1)$ be an l-tuple of non-negative integers. To λ we associate a *shape* as follows. The shape consists of boxes $lm_l+(l-1)m_{l-1}+\cdots+1\cdot m_1$ in number, left-justified and bottom-justified, with l boxes in the first m_l columns, $l-1$ boxes in the next m_{l-1} columns, and so on. For example, if $l=3$, the shape corresponding to $\lambda=(3,3,2)$ is shown in Fig. 1.

A *tableau* of shape λ is a filling up of the boxes in the shape associated to λ by integers $1,\ldots,n:=l+1$, such that the entries in each column are strictly increasing downwards. A tableau is

2	1	1					
3	2	3	3	2	3		
4	3	4	4	3	4	4	2

FIG. 2.

standard if the numbers in each row are non-increasing rightwards. For example, if $l=3$ and $\lambda=(3,3,2)$, the tableau in Fig. 2 is not standard while the one in Fig. 3 is standard.

In what follows, l and λ are fixed, and (c,k) denotes an ordered pair of integers satisfying $1\leqslant c\leqslant l$ and $1\leqslant k\leqslant c$. Given a standard tableau σ, define for each (c,k) the integer b_k^c to be the number of entries on row c of σ that are (strictly) greater than k, where the topmost row is row 1, the one just below it is row 2, and so on until the bottom-most row is row l. It is clear, from the definition of b_k^c, that $b_k^c\leqslant b_{k-1}^c$ and further, since σ is a tableau, that $b_k^c\leqslant b_{k+1}^{c+1}$. In other words, the b_k^c satisfy

$$b_k^c\leqslant \min\{b_{k-1}^c,b_{k+1}^{c+1}\},$$

$$b_k^c\leqslant m_l+\cdots+m_{l-c+1}. \tag{3}$$

Conversely, given integers b_k^c subject to the constraint (3), we can construct a standard tableau as follows. Fill up the shape corresponding to λ with integers so that in row c there are precisely b_k^c entries greater than k and the entries in each row are nonincreasing rightwards. There is clearly a unique way of doing this. The result is a tableau since $b_k^c\leqslant b_{k+1}^{c+1}$, and it is standard by construction. Thus the standard tableaus are in bijective correspondence with sets of integers $\{b_k^c\}$ subject to (3).

Setting $a_k^c:=b_k^c-(m_l+\cdots+m_{l-c+k+1})$, it is easily checked that (3) transforms to (2). Thus the Verma monomials are in bijective correspondence with $\{b_k^c\}$ subject to (3) and so also with standard tableaus. The Verma monomial corresponding to the standard tableau of Fig. 3 is

$$Y_1^{(1)}(Y_2^{(2)}Y_1^{(2)})(Y_3^{(2)}Y_2^{(3)}Y_1^{(1)}).$$

IV. THE CASE OF A FUNDAMENTAL REPRESENTATION

Let $V_1,\ldots,V_l$ denote the representations that correspond respectively to the fundamental weights $\varpi_1,\ldots,\varpi_l$. These representations admit the following simple description. The representation V_1 is the *standard representation* of $\mathfrak{g}=sl(n;\mathbb{C})$: the elements of V_1 are complex matrices of size $n\times 1$ and $\mathfrak{g}$ acts on V_1 by left multiplication. For $1\leqslant j\leqslant l$, the representation V_j is the exterior product $\wedge^j V_1$. Let e_i denote the $n\times 1$ matrix with the entry on row i being 1 and all other entries being 0. The vector $v_j:=e_1\wedge\cdots\wedge e_j$ is a highest weight vector in V_j.

A standard tableau σ of shape ϖ_j consists of a column of j integers $1\leqslant i_1<\cdots<i_j\leqslant n$ arranged in increasing order downwards. The Verma monomial corresponding to σ is

$$(Y_{i_1-1}\cdots Y_2Y_1)\cdots(Y_{i_{j-k+1}-1}\cdots Y_{j-k+2}Y_{j-k+1})\cdots(Y_{i_{j-1}-1}\cdots Y_jY_{j-1})(Y_{i_j-1}\cdots Y_{j+2}Y_{j+1}Y_j).$$

As can be readily checked, the action of this on v_j results in $e_{i_1}\wedge\cdots\wedge e_{i_j}$, which we denote $u(\sigma)$. Since the $u(\sigma)$ form a basis for V_j as σ varies over (standard) tableaus, Theorem 1 holds for a fundamental representation.

FIG. 3.

V. THE CASE OF A GENERAL REPRESENTATION

Let $\lambda = m_l \varpi_l + \cdots + m_1 \varpi_1$ be an arbitrary dominant integral weight. Let V_λ be the corresponding finite dimensional irreducible representation. We can realize V_λ as follows. Consider the tensor product representation

$$V := \underbrace{V_l \otimes \cdots \otimes V_l}_{m_l \text{ times}} \otimes \cdots \otimes \underbrace{V_1 \otimes \cdots \otimes V_1}_{m_1 \text{ times}}.$$

The element

$$v_\lambda := \underbrace{v_l \otimes \cdots \otimes v_l}_{m_l \text{ times}} \otimes \cdots \otimes \underbrace{v_1 \otimes \cdots \otimes v_1}_{m_1 \text{ times}}$$

of V then is a highest weight vector and the $\mathfrak{g}$-submodule of V generated by v_λ is a model for V_λ.

We think of a tableau ζ of shape λ as a concatenation $\zeta = (\zeta_1, \ldots, \zeta_m)$, where $m := m_l + \cdots + m_1$; $\zeta_1, \ldots, \zeta_{m_l}$ are tableaus of shape ϖ_l; $\zeta_{m_l+1}, \ldots, \zeta_{m_l+m_{l-1}}$ are tableaus of shape ϖ_{l-1}; and so on. We associate to ζ the vector $u(\zeta) := u(\zeta_1) \otimes \cdots \otimes u(\zeta_m)$ of V, where $u(\zeta_j)$ is the basis vector of $V_{r(j)}$ associated as in Sec. IV to ζ_j, where $r(j)$ is the number of rows in ζ_j. It is clear that as ζ varies over all tableaus of shape λ, standard or otherwise, the $u(\zeta)$ form a basis for V.

Proof of Theorem 1: For a fundamental weight λ, the proof was given in Sec. IV. Now let λ be a nonfundamental weight, σ be a standard tableau of shape λ, and $v(\sigma)$ be the corresponding Verma vector in V_λ. Thinking of $v(\sigma)$ as a vector in V, we can express it as a sum of the basis vectors $u(\zeta)$, ζ varying over all tableaus. Proposition 2 below is an assertion about this expression. It follows immediately from the proposition that the Verma vectors $v(\sigma)$ are linearly independent and therefore also that they form a basis (since the number of standard tableaus is well-known to equal the dimension of V_λ). □

To state Proposition 2, we introduce the following partial order on the set of all tableaus of shape λ. Given a tableau ζ of shape λ, let $\zeta(i,j)$ denote the entry of ζ on row i and column j, where the rows and columns are indexed as for a matrix—of course, in the case of a tableau as opposed to that of a matrix, the range of possible values for j depends on the value of i and vice versa. We call those pairs (i,j) *admissible* for which $\zeta(i,j)$ makes sense. For admissible pairs (i,j) and (i',j'), we say $(i,j) \leqslant (i',j')$ if either $i < i'$ or $i = i'$ and $j \leqslant j'$. For tableaus ζ, ζ' of shape λ, we say $\zeta \leqslant \zeta'$ if $\zeta(i,j) \leqslant \zeta'(i,j)$ for the smallest such pair (i,j) that $\zeta(i,j) \neq \zeta'(i,j)$.

There clearly exists a smallest tableau of a given shape. The smallest tableau of shape (3,3,2) is shown in Fig. 4. The exponents a_k^c in the Verma monomial of the smallest tableau are all 0. For

1	1	1					
2	2	2	1	1	1		
3	3	3	2	2	2	1	1

FIG. 4.

a standard tableau σ, the relation between the numbers b_k^c and a_k^c defined in Sec. III may be rephrased thus

$$a_k^c(\sigma)=b_k^c(\sigma)-b_k^c(\tau), \tag{4}$$

where τ is the smallest tableau of the same shape as σ.

Proposition 2: With notation as above, one has

$$v(\sigma)=u(\sigma)+\sum_{\zeta\lessdot\sigma} q(\zeta)u(\zeta),$$

where $q(\zeta)$ are some scalars (in fact, integers).

Proof: We proceed by an induction on the order $\leqslant$ defined above. If σ is the smallest tableau of shape λ with respect to $\leqslant$, then $v(\sigma)=u(\sigma)=v_\lambda$ and the statement is clear.

So suppose that σ is not the smallest tableau. Let a_k^c be the exponents in the Verma monomial corresponding to σ. Let C be the smallest such value of c that $a_k^c\neq 0$ for some k. Let K be the largest such value that $a_K^C\neq 0$. Changing a_K^C to 0 but leaving the remaining a_k^c unchanged, we get another Verma monomial, the standard tableau corresponding to which we denote by μ. It is readily checked that μ and σ satisfy the following:

(1) In positions $(i,j)\leqslant(C,m_l+\cdots+m_{l-C+K})$, the entries of μ are equal to the corresponding entries of the smallest tableau [see Eq. (4)]. In particular, for $(i,j)\leqslant(C,m_l+\cdots+m_{l-C+K+1})$, if $\mu(i,j)=K$, then $i<C$ and $\mu(i+1,j)=K+1$.

(2) To go from μ to σ the only change that needs to be made is to replace K by $K+1$ in certain boxes, a_K^C in number, on row C. The boxes figuring in these changes occur in consecutive columns starting with the column $m_l+\cdots+m_{l-C+K+1}+1$. In each of these columns of μ, K occurs but not $K+1$.

Note that $\mu\lessdot\sigma$. The induction hypothesis applied to μ says

$$v(\mu)=u(\mu)+\sum_{\eta\lessdot\mu} q(\eta)u(\eta)$$

and so

$$v(\sigma)=Y_K^{(p)}u(\mu)+\sum_{\eta\lessdot\mu} q(\eta)Y_K^{(p)}u(\eta),$$

where we have written p for a_K^C for simplicity of notation.

We now investigate $Y_K^{(p)}u(\eta)$ for a general tableau η. An entry of η is called *marked* if it equals K and is either on the last row or the entry immediately below it is not $K+1$. Let $S(\eta,K)$ be the set of marked positions of η, and let $Z(\eta):=Z(\eta,K,p)$ be the subsets of cardinality p of $S(\eta,K)$. For t an element of $Z(\eta)$, let η_t be the tableau obtained by changing the entries of η from K to $K+1$ in those marked positions that belong to t. We have

$$Y_K^{(p)}u(\eta)=\sum_{t\in Z(\eta)} u(\eta_t)$$

and so

$$v(\sigma)=\sum_{t\in Z(\mu)} u(\mu_t)+\sum_{\eta\lessdot\mu}\ \sum_{t\in Z(\eta)} q(\eta)u(\eta_t). \tag{5}$$

Let t and t' be sets of cardinality p of positions (i,j) admissible for the shape λ. We say $t \leqslant t'$ if $t_r \lessdot t'_r$ for the least such r that $t_r \neq t'_r$, where $t=\{t_1 \lessdot \cdots \lessdot t_p\}$ and $t'=\{t'_1 \lessdot \cdots \lessdot t'_p\}$ are arranged in increasing order.

Let η,ζ be tableaus of shape λ. Let $s \in Z(\eta)$ and $t \in Z(\zeta)$. The following statements are easily seen to be true:

(a) If $\eta \leqslant \zeta$ and $s \geqslant t$, then $\eta_s \leqslant \zeta_t$.
(b) If $\eta \leqslant \zeta$, $s \geqslant t$, and either $\eta \lessdot \zeta$ or $s \gtrdot t$, then $\eta_s \lessdot \zeta_t$.

Let $\eta \leqslant \mu$. It is clear that statement (1) above holds for η because it holds for μ. Thus every element s of $Z(\eta)$ satisfies

$$s \geqslant s_0 := \{(C, m_l + \cdots + m_{l-C+K+1} + 1), \ldots, (C, m_l + \cdots + m_{l-C+K+1} + p)\}.$$

By statement (2) above, we see that s_0 belongs to $Z(\mu)$ and that $\sigma = \mu_{s_0}$. Now by the statements (a) and (b) above, we obtain $\eta_s \leqslant \mu_{s_0} = \sigma$ and that equality holds if and only if $\eta = \mu$ and $s = s_0$. The proposition now follows from Equation (5). $\square$

The value of the coupling constant $\sigma_{xx}^{(0)}$ computed in Sec. VII A is not correct. Its calculation was based on the reasonable but false assumption that the field configurations which dominate at large wavelengths are smooth. As a matter of fact, the relevant configurations contain a small high-momentum component due to the alternating structure of the Chalker–Coddington network. When this is taken into account, the value of the longitudinal conductivity changes to $\sigma_{xx}^{(0)}=1/2$ for the single-channel model and $\sigma_{xx}^{(0)}=N/2$ for the N-channel model. The rest of the paper is unaffected by this change.

$\mathcal{PT}$-symmetric quantum mechanics

This paper proposes to broaden the canonical formulation of quantum mechanics. Ordinarily, one imposes the condition $H^{\dagger}=H$ on the Hamiltonian, where † represents the mathematical operation of complex conjugation and matrix transposition. This conventional Hermiticity condition is sufficient to ensure that the Hamiltonian H has a real spectrum. However, replacing this mathematical condition by the weaker and more physical requirement $H^{\ddagger}=H$, where ‡ represents combined parity reflection and time reversal $\mathcal{PT}$, one obtains new classes of complex Hamiltonians whose spectra are still real and positive. This generalization of Hermiticity is investigated using a complex deformation $H=p^2+x^2(ix)^{\epsilon}$ of the harmonic oscillator Hamiltonian, where ϵ is a real parameter. The system exhibits two phases: When $\epsilon\geqslant 0$, the energy spectrum of H is real and positive as a consequence of $\mathcal{PT}$ symmetry. However, when $-1<\epsilon<0$, the spectrum contains an infinite number of complex eigenvalues and a finite number of real, positive eigenvalues because $\mathcal{PT}$ symmetry is spontaneously broken. The phase transition that occurs at $\epsilon=0$ manifests itself in both the quantum-mechanical system and the underlying classical system. Similar qualitative features are exhibited by complex deformations of other standard real Hamiltonians $H=p^2+x^{2N}(ix)^{\epsilon}$ with N integer and $\epsilon>-N$; each of these complex Hamiltonians exhibits a phase transition at $\epsilon=0$. These $\mathcal{PT}$-symmetric theories may be viewed as analytic continuations of conventional theories from real to complex phase space.
[S0022-2488(99)00105-X]

I. INTRODUCTION

In a recent letter[1] a class of complex quantum-mechanical Hamiltonians of the form

$$H=p^2+x^2(ix)^{\epsilon}\quad(\epsilon\ \text{real})\tag{1.1}$$

was investigated. Despite the lack of conventional Hermiticity the spectrum of H is real and positive for all $\epsilon\geqslant 0$. As shown in Fig. 11 in this paper and Fig. 1 of Ref. 1, the spectrum is discrete and each of the energy levels increases as a function of increasing ϵ. We will argue below that the reality of the spectrum is a consequence of $\mathcal{PT}$ invariance.

The operator $\mathcal{P}$ represents parity reflection and the operator $\mathcal{T}$ represents time reversal. These operators are defined by their action on the position and momentum operators x and p:

$$\begin{aligned}\mathcal{P}&:x\to -x,\quad p\to -p,\\ \mathcal{T}&:x\to x,\quad p\to -p,\quad i\to -i.\end{aligned}\tag{1.2}$$

When the operators x and p are real, the canonical commutation relation $[x,p]=i$ is invariant under both parity reflection and time reversal. We emphasize that this commutation relation remains invariant under $\mathcal{P}$ and $\mathcal{T}$ even if x and p are complex provided that the above transformations hold. In terms of the real and imaginary parts of x and p, $x=\mathrm{Re}\,x+i\,\mathrm{Im}\,x$ and $p=\mathrm{Re}\,p+i\,\mathrm{Im}\,p$, we have

$$\begin{aligned}\mathcal{P}&:\mathrm{Re}\,x\to-\mathrm{Re}\,x,\quad \mathrm{Im}\,x\to-\mathrm{Im}\,x,\\ &\mathrm{Re}\,p\to-\mathrm{Re}\,p,\quad \mathrm{Im}\,p\to-\mathrm{Im}\,p,\\ \mathcal{T}&:\mathrm{Re}\,x\to\mathrm{Re}\,x,\quad \mathrm{Im}\,x\to-\mathrm{Im}\,x,\\ &\mathrm{Re}\,p\to-\mathrm{Re}\,p,\quad \mathrm{Im}\,p\to\mathrm{Im}\,p.\end{aligned}\tag{1.3}$$

While there is as yet no proof that the spectrum of H in Eq. (1.1) is real,[2] we can gain some insight regarding the reality of the spectrum of a $\mathcal{PT}$-invariant Hamiltonian H as follows: Note that eigenvalues of the operator $\mathcal{PT}$ have the form $e^{i\theta}$. To see this, let Ψ be an eigenfunction of $\mathcal{PT}$ with eigenvalue λ: $\mathcal{PT}\Psi=\lambda\Psi$. Recalling that $(\mathcal{PT})^2=1$, we multiply this eigenvalue equation by $\mathcal{PT}$ and obtain $\lambda^*\lambda=1$, where we have used the fact that $i\to-i$ under $\mathcal{PT}$. Thus, $\lambda=e^{i\theta}$. We know that if two linear operators commute, they can be simultaneously diagonalized. By assumption, the operator $\mathcal{PT}$ commutes with H. Of course, the situation here is complicated by the nonlinearity of the $\mathcal{PT}$ operator ($\mathcal{T}$ involves complex conjugation). However, let us suppose for now that the eigenfunctions ψ of H are simultaneously eigenfunctions of the operator $\mathcal{PT}$ with eigenvalue $e^{i\theta}$. Then applying $\mathcal{PT}$ to the eigenvalue equation $H\psi=E\psi$, we find that the energy E is real: $E=E^*$.

We have numerically verified the supposition that the eigenfunctions of H in Eq. (1.1) are also eigenfunctions of the operator $\mathcal{PT}$ when $\epsilon\geqslant0$. However, when $\epsilon<0$, the $\mathcal{PT}$ symmetry of the Hamiltonian is spontaneously broken; even though $\mathcal{PT}$ commutes with H, the eigenfunctions of H are *not* all simultaneously eigenfunctions of $\mathcal{PT}$. For these eigenfunctions of H the energies are complex. Thus, a transition occurs at $\epsilon=0$. As ϵ goes below 0, the eigenvalues as functions of ϵ pair off and become complex, starting with the highest-energy eigenvalues. As ϵ decreases, there are fewer and fewer real eigenvalues and below approximately $\epsilon=-0.57\,793$ only one real energy remains. This energy then begins to increase with decreasing ϵ and becomes infinite as ϵ approaches -1. In summary, the theory defined by Eq. (1.1) exhibits two phases, an unbroken-symmetry phase with a purely real energy spectrum when $\epsilon\geqslant0$ and a spontaneously-broken-symmetry phase with a partly real and partly complex spectrum when $\epsilon<0$.

A primary objective of this paper is to analyze the phase transition at $\epsilon=0$. We will demonstrate that this transition occurs in the classical as well as in the quantum theory. As a classical theory, the Hamiltonian H describes a particle subject to complex forces, and therefore the trajectory of the particle lies in the complex-x plane. The position and momentum coordinates of the particle are complex functions of t, a real time parameter. We are interested only in solutions to the classical equations of motion for which the energy of the particle is real. We will see that in the $\mathcal{PT}$-symmetric phase of the theory, the classical motion is periodic and is thus a complex generalization of a pendulum. We actually observe two kinds of closed classical orbits, one in which the particle oscillates between two complex turning points and another in which the particle follows a closed orbit. In many cases these closed orbits lie on an elaborate multisheeted Riemann surface. On such Riemann surfaces the closed periodic orbits exhibit remarkable knotlike topological structures. All of these orbits exhibit $\mathcal{PT}$ symmetry; they are left–right symmetric with respect to reflections about the imaginary-x axis in accordance with Eq. (1.3). In the broken-symmetry phase classical trajectories are no longer closed. Instead, the classical path spirals out to infinity. These spirals lack $\mathcal{PT}$ symmetry.

There have been many previous instances of non-Hermitian $\mathcal{PT}$-invariant Hamiltonians in physics. Energies of solitons on a *complex* Toda lattice have been found to be real.[3] Hamiltonians rendered non-Hermitian by an imaginary external field have been used to study population biology[4] and to study delocalization transitions such as vortex flux-line depinning in type II superconductors.[5] In these cases, initially real eigenvalues bifurcate into the complex plane due to the increasing external field, indicating the growth of populations or the unbinding of vortices.

The $\mathcal{PT}$-symmetric Hamiltonian considered in this paper has many generalizations: (i) Introducing a mass term of the form m^2x^2 yields a theory that exhibits several phase transitions; transitions occur at $\epsilon=-1$ and $\epsilon=-2$ as well as at $\epsilon=0$.[1] (ii) Replacing the condition of Hermiticity by the weaker constraint of $\mathcal{PT}$ symmetry also allows one to construct new classes of quasi-exactly solvable quantum theories.[6] (iii) In this paper we consider complex deformations of real Hamiltonians other than the harmonic oscillator. We show that Hamiltonians of the form

$$H=p^2+x^{2K}(ix)^{\epsilon} \tag{1.4}$$

have the same qualitative properties as H in Eq. (1.1). As ϵ decreases below 0, all of these theories exhibit a phase transition from an unbroken $\mathcal{PT}$-symmetric regime to a regime in which $\mathcal{PT}$ symmetry is spontaneously broken.

The Hamiltonian H in (1.1) is especially interesting because it can be generalized to quantum field theory. A number of such generalizations have recently been examined. The $\mathcal{PT}$-symmetric scalar field theory described by the Lagrangian[7]

$$\mathcal{L}=\tfrac{1}{2}(\partial\phi)^2+\tfrac{1}{2}m^2\phi^2+g\phi^2(i\phi)^{\epsilon}\quad(\epsilon\geqslant 0) \tag{1.5}$$

is intriguing because it is not invariant under parity reflection. This is manifested by a nonzero value of $\langle\phi\rangle$. It is interesting that this broken symmetry persists even when $\epsilon>0$ is an even integer.[7] The Hamiltonian for this theory is not Hermitian and, therefore, the theory is not unitary in the conventional sense. However, there is strong evidence that the spectrum for this theory is real and bounded below. For $\epsilon=1$ one can understand the positivity of the spectrum in terms of summability. The weak-coupling expansion for a conventional $g\phi^3$ theory is real, and apart from a possible overall factor of g, the Green's functions are formal power series in g^2. These series are not Borel summable because they do not alternate in sign. Nonsummability reflects the fact that the spectrum of the underlying theory is not bounded below. However, when we replace g by ig, the perturbation series remains real but now alternates in sign. Thus, the perturbation series becomes summable, and this suggests that the underlying theory has a real positive spectrum.

Replacing conventional $g\phi^4$ or $g\phi^3$ theories by $\mathcal{PT}$-symmetric $-g\phi^4$ or $ig\phi^3$ theories has the effect of reversing signs in the beta function. Thus, theories that are not asymptotically free become asymptotically free and theories that lack stable critical points develop such points. There is evidence that $-g\phi^4$ in four dimensions is nontrivial.[8]

Supersymmetric quantum field theory that is $\mathcal{PT}$ invariant has also been studied.[9] When we construct a two-dimensional supersymmetric quantum field theory by using a superpotential of the form $S(\phi)=-ig(i\phi)^{1+\epsilon}$, the supersymmetric Lagrangian resulting from this superpotential is

$$\begin{aligned}\mathcal{L}&=\tfrac{1}{2}(\partial\phi)^2+\tfrac{1}{2}i\bar{\psi}\partial\!\!\!/\psi+\tfrac{1}{2}S'(\phi)\bar{\psi}\psi+\tfrac{1}{2}[S(\phi)]^2\\&=\tfrac{1}{2}(\partial\phi)^2+\tfrac{1}{2}i\bar{\psi}\partial\!\!\!/\psi+\tfrac{1}{2}g(1+\epsilon)(i\phi)^{\epsilon}\bar{\psi}\psi-\tfrac{1}{2}g^2(i\phi)^{2+2\epsilon},\end{aligned} \tag{1.6}$$

where ψ is a Majorana spinor. The Lagrangian (1.3) has a broken parity symmetry. This poses the question, Does the parity violation induce a breaking of supersymmetry? To answer this question, both the ground-state energy E_0 and the fermion–boson mass ratio R were calculated as series in powers of the parameter ϵ. Through second order in ϵ, $E_0=0$ and $R=1$, which strongly suggests that supersymmetry remains unbroken. We believe that these results are valid to all orders in powers of ϵ. This work and our unpublished numerical studies of SUSY quantum mechanics show that complex deformations do not break supersymmetry.

Quantum field theories having the property of $\mathcal{PT}$ invariance exhibit other interesting features. For example, the Ising limit of a $\mathcal{PT}$-invariant scalar quantum field theory is intriguing because it is dominated by solitons rather than by instantons as in a conventional quantum field theory.[10] In addition, a model of $\mathcal{PT}$-invariant quantum electrodynamics has been studied.[11] The massless theory exhibits a stable, nontrivial fixed point at which the renormalized theory is finite. Moreover, such a theory allows one to revive successfully the original electron model of Casimir.

Since $\langle\phi\rangle \neq 0$ in $\mathcal{PT}$-symmetric theories, one can in principle calculate directly (using the Schwinger–Dyson equations, for example) the real positive Higgs mass in a renormalizable $\mathcal{PT}$-symmetric theory in which symmetry breaking occurs naturally. No symmetry-breaking parameter needs to be introduced. This most intriguing idea could lead to an experimental vindication of our proposed generalization of the notion of Hermiticity to $\mathcal{PT}$ symmetry.

This paper is organized as follows: In Sec. II we study the classical version of the Hamiltonian in Eq. (1.1). The behavior of classical orbits reveals the nature of the phase transition at $\epsilon = 0$. Next, in Sec. III we analyze the quantum version of this Hamiltonian. We derive several asymptotic results regarding the behavior of the energy levels near the phase transition. In Sec. IV we discuss the classical and quantum properties of the broad class of $\mathcal{PT}$-symmetric Hamiltonians in Eq. (1.4) of which H in Eq. (1.1) is a special case.

II. CLASSICAL THEORY

The classical equation of motion for a particle described by H in (1.1) is obtained from Hamilton's equations:

$$\frac{dx}{dt} = \frac{\partial H}{\partial p} = 2p,$$
$$\frac{dp}{dt} = -\frac{\partial H}{\partial x} = i(2+\epsilon)(ix)^{1+\epsilon}. \tag{2.1}$$

Combining these two equations gives

$$\frac{d^2x}{dt^2} = 2i(2+\epsilon)(ix)^{1+\epsilon}, \tag{2.2}$$

which is the complex version of Newton's second law, $F = ma$.

Equation (2.2) can be integrated once to give[12]

$$\frac{1}{2}\frac{dx}{dt} = \pm\sqrt{E + (ix)^{2+\epsilon}}, \tag{2.3}$$

where E is the energy of the classical particle (the time-independent value of H). We treat time t as a real variable that parametrizes the complex path $x(t)$ of this particle.

This section is devoted to studying and classifying the solutions to Eq. (2.3). By virtue of the $\mathcal{PT}$ invariance of the Hamiltonian H, it seems reasonable to restrict our attention to real values of E. Given this restriction, we can always rescale x and t by real numbers so that without loss of generality Eq. (2.3) reduces to

$$\frac{dx}{dt} = \pm\sqrt{1 + (ix)^{2+\epsilon}}. \tag{2.4}$$

The trajectories satisfying Eq. (2.4) lie on a multi-sheeted Riemann surface. On this surface the function $\sqrt{1+(ix)^{2+\epsilon}}$ is single valued. There are two sets of branch cuts. The cuts in the first set radiate outward from the roots of

$$1 + (ix)^{2+\epsilon} = 0. \tag{2.5}$$

These roots are the classical turning points of the motion. There are many turning points, all lying at a distance of unity from the origin. The angular separation between consecutive turning points

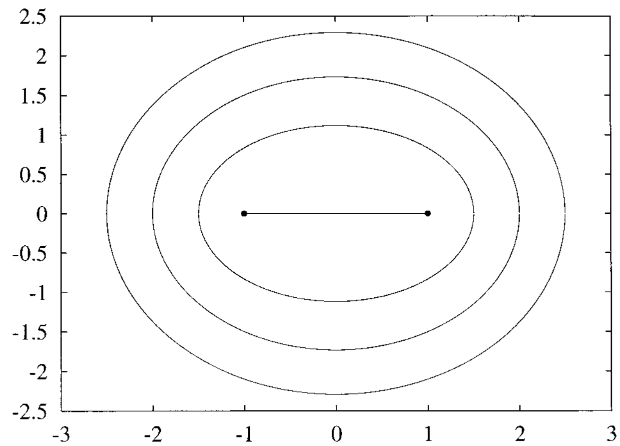

FIG. 1. Classical trajectories in the complex-x plane for the harmonic oscillator whose Hamiltonian is $H=p^2+x^2$. These trajectories represent the possible paths of a particle whose energy is $E=1$. The trajectories are nested ellipses with foci located at the turning points at $x=\pm 1$. The real line segment (degenerate ellipse) connecting the turning points is the usual periodic classical solution to the harmonic oscillator. All closed paths [see Eq. (2.6)] have the same period 2π.

is $2\pi/(2+\epsilon)$. The second set of branch cuts is present only when ϵ is noninteger. In order to maintain explicit $\mathcal{PT}$ symmetry (left–right symmetry in the complex-x plane), we choose these branch cuts to run from the origin to infinity along the positive imaginary axis.

A. Case $\epsilon=0$

Because the classical solutions to Eq. (2.4) have a very elaborate structure, we begin by considering some special values of ϵ. The simplest case is $\epsilon=0$. For this case there are only two turning points and these lie on the real axis at ± 1.

In order to solve Eq. (2.4) we need to specify an initial condition $x(0)$. The simplest choice for $x(0)$ is a turning point. If the path begins at ± 1, there is a unique direction in the complex-x plane along which the phases of the left side and the right side of Eq. (2.4) agree. This gives rise to a trajectory on the real axis that oscillates between the two turning points. This is the well-known sinusoidal motion of the harmonic oscillator.

Note that once the turning points have been fixed, the energy is determined. Thus, choosing the initial position of the particle determines the initial velocity (up to a plus or minus sign) as well. So, if the path of the particle begins anywhere on the real axis between the turning points, the initial velocity is fixed up to a sign and the trajectory of the particle still oscillates between the turning points.

Ordinarily, in conventional classical mechanics the only possible initial positions for the particle lie on the real-x axis between the turning points because the velocity is real; all other points on the real axis lie in the classically forbidden region. However, because we are analytically continuing classical mechanics into the complex plane, we can choose any point $x(0)$ in the complex plane as an initial position. For all complex initial positions outside of the conventional classically allowed region the classical trajectory is an ellipse whose foci are the turning points. The ellipses are nested because no trajectories may cross. (See Fig. 1.) The exact solution to Eq. (2.4) is

$$x(t)=\cos[\arccos x(0)\pm t], \tag{2.6}$$

where the sign of t determines the direction (clockwise or anticlockwise) in which the particle traces the ellipse. For *any* ellipse the period of the motion is 2π. The period is the same for all trajectories because we can join the square-root branch cuts emanating from the turning points,

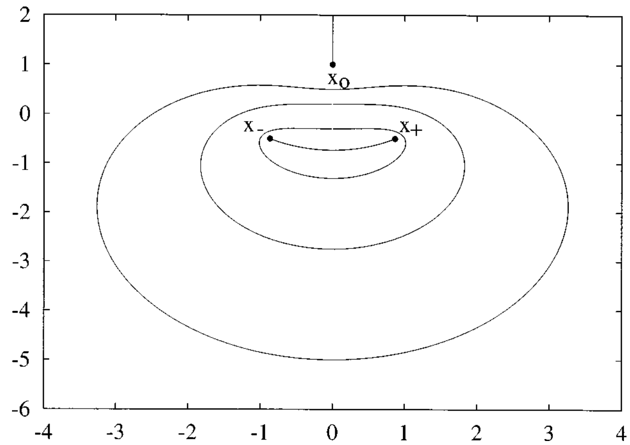

FIG. 2. Classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2+ix^3$ and having energy $E=1$. An oscillatory trajectory connects the turning points $x_\pm$. This trajectory is enclosed by a set of closed, nested paths that fill the finite complex-x plane except for points on the imaginary axis at or above the turning point $x_0=i$. Trajectories originating at one of these exceptional points go off to $i\infty$ or else they approach x_0, stop, turn around, and then move up the imaginary axis to $i\infty$.

creating a single finite branch cut lying along the real axis from $x=-1$ to $x=1$. The complex path integral that determines the period can then be shrunk (by Cauchy's theorem) to the usual real integral joining the turning points.

Finally, we remark that all of the classical paths (elliptical orbits) are symmetric with respect to parity $\mathcal{P}$ (reflections through the origin) and time reversal $\mathcal{T}$ (reflections about the real axis), as well as $\mathcal{PT}$ (reflections about the imaginary axis). Furthermore, $\mathcal{P}$ and $\mathcal{T}$ individually preserve the directions in which the ellipses are traversed.

B. Case $\epsilon=1$

The case $\epsilon=1$ is significantly more complicated. Now there are three turning points. Two are located below the real axis and these are symmetric with respect to the imaginary axis: $x_-=e^{-5i\pi/6}$ and $x_+=e^{-i\pi/6}$. That is, under $\mathcal{PT}$ reflection x_- and x_+ are interchanged. The third turning point lies on the imaginary axis at $x_0=i$.

As in the case $\epsilon=0$, the trajectory of a particle that begins at the turning point x_- follows a unique path in the complex-x plane to the turning point at x_+. Then, the particle retraces its path back to the turning point at x_-, and it continues to oscillate between these two turning points. This path is shown on Fig. 2. The period of this motion is $2\sqrt{3\pi}\Gamma(\frac{4}{3})/\Gamma(\frac{5}{6})$. The periodic motion between $x_\pm$ is clearly time-reversal symmetric.

A particle beginning at the third turning point x_0 exhibits a completely distinct motion: It travels up the imaginary axis and reaches $i\infty$ in a finite time $\sqrt{\pi}\Gamma(\frac{4}{3})/\Gamma(\frac{5}{6})$. This motion is not periodic and is not symmetric under time reversal.

Paths originating from all other points in the finite complex-x plane follow closed periodic orbits. No two orbits may intersect; rather they are all nested, like the ellipses for the case $\epsilon=0$. All of these orbits encircle the turning points $x_\pm$ and, by virtue of Cauchy's theorem, have the same period $2\sqrt{3\pi}\Gamma(\frac{4}{3})/\Gamma(\frac{5}{6})$ as the oscillatory path connecting $x_\pm$. Because these orbits must avoid crossing the trajectory that runs up the positive imaginary axis from the turning point $x_0=i$, they are pinched in the region just below x_0, as shown on Fig. 2.

As these orbits become larger they develop sharper indentations in the vicinity of x_0. We observe that the characteristic radius of a large orbit approaches the reciprocal of the distance d between x_0 and the point where the orbit intersects the positive imaginary axis. Thus, it is appropriate to study these orbits from the point of view of the renormalization group: We scale the distance d down by a factor L and then plot the resulting orbit on a graph whose axis are scaled

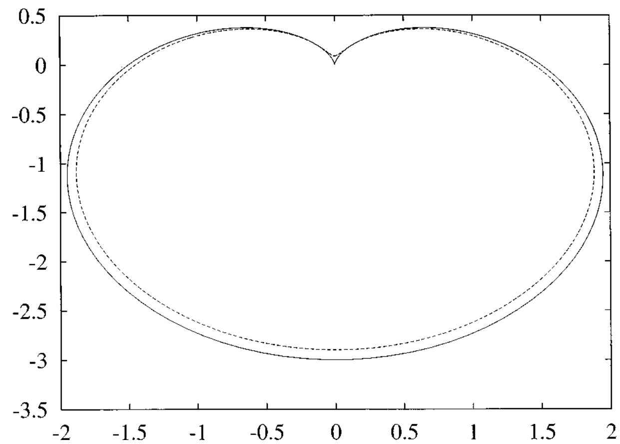

FIG. 3. Approach to the limiting cardioid in Eq. (2.8). As the orbits shown in Fig. 2 approach the turning point x_0, they get larger. Using a renormalization-group approach, we plot successively larger orbits (one such orbit is shown as a dashed line) scaled down by the characteristic size of the orbit. The limiting cardioid is indicated by a solid line. The indentation in the limiting cardioid develops because classical trajectories may not intersect and thus must avoid crossing the trajectory (shown in Fig. 2) on the imaginary axis above x_0.

down by the same factor L. Repeated scaling gives a limiting orbit whose shape resembles a cardioid (see Fig. 3). The equation of this limiting orbit is obtained in the asymptotic regime where we neglect the dimensionless energy 1 in Eq. (2.4):

$$\frac{dx}{dt}=\pm(ix)^{3/2}. \tag{2.7}$$

The solution to this differential equation, scaled so that it crosses the negative imaginary axis at $-3i$, is

$$x(t)=\frac{4i}{(t+2i/\sqrt{3})^2} \quad (-\infty<t<\infty). \tag{2.8}$$

This curve is shown as the solid line in Fig. 3. (Strictly speaking, this curve is not a true cardioid, but its shape so closely resembles a true cardioid that we shall refer to it in this paper as the *limiting* cardioid.)

In the infinite scaling limit all periodic orbits [all these orbits have period $2\sqrt{3\pi}\Gamma(\frac{4}{3})/\Gamma(\frac{5}{6})$], which originally filled the entire finite complex-x plane, have been squeezed into the region inside the limiting cardioid (2.8). The nonperiodic orbit still runs up the positive imaginary axis. The obvious question is, What complex classical dynamics is associated with all of the other points in the scaled complex-x plane that lie outside of the limiting cardioid? We emphasize that all of these points were originally at infinity in the unscaled complex-x plane.

We do not know the exact answer to this question, but we can draw a striking and suggestive analogy with some previously published work. It is generally true that the region of convergence in the complex-x plane for an infinitely iterated function is a cardioid-shaped region. For example, consider the continued exponential function

$$f(x)=e^{xe^{xe^x}}. \tag{2.9}$$

The sequence $e^x, e^{xe^x}, \ldots$ is known to converge in a cardioid-shaped region of the complex-x plane (see Figs. 2–4 in Ref. 13). It diverges on the straight line that emerges from the indentation of the cardioid. The remaining part of the complex-x plane is divided into an extremely elaborate mosaic of regions in which this sequence converges to limit cycles of period 2, period 3, period 4, and so

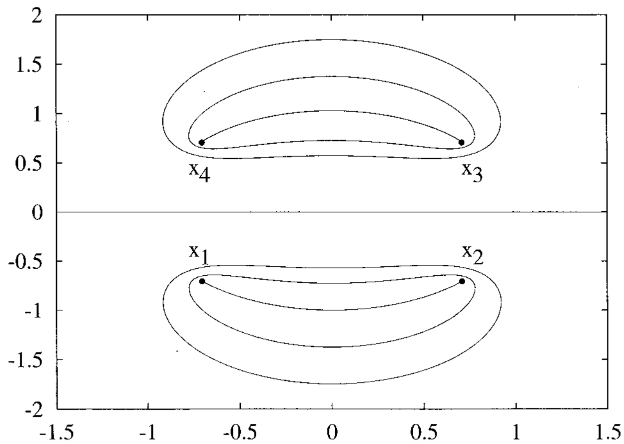

FIG. 4. Classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2-x^4$ and having energy $E=1$. There are two oscillatory trajectories connecting the pairs of turning points x_1 and x_2 in the lower-half x-plane and x_3 and x_4 in the upper-half x-plane. [A trajectory joining any other pair of turning points is forbidden because it would violate $\mathcal{PT}$ (left-right) symmetry.] The oscillatory trajectories are surrounded by closed orbits of the same period. In contrast to these periodic orbits there is a class of trajectories having unbounded path length and running along the real-x axis. These are the only paths that violate time-reversal symmetry.

on. These regions have fractal structure. It would be interesting if unbounded complex classical motion exhibits this remarkable fractal structure. In other words, does the breaking of $\mathcal{P}$ and $\mathcal{T}$ symmetry allow for unbounded chaotic solutions?

C. Case $\epsilon=2$

When $\epsilon=2$ there are four turning points, two located below the real axis and symmetric with respect to the imaginary axis, $x_1=e^{-3i\pi/4}$ and $x_2=e^{-i\pi/4}$, and two more located above the real axis and symmetric with respect to the imaginary axis, $x_3=e^{i\pi/4}$ and $x_4=e^{3i\pi/4}$. Classical trajectories that oscillate between the pair x_1 and x_2 and the pair x_3 and x_4 are shown on Fig. 4. The period of these oscillations is $2\sqrt{2\pi}\Gamma(\frac{5}{4})/\Gamma(\frac{3}{4})$. Trajectories that begin elsewhere in the complex-x plane are also shown on Fig. 4. Note that by virtue of Cauchy's theorem all these nested nonintersecting trajectories have the same period. All motion is periodic except for trajectories that begin on the real axis; a particle that begins on the real-x axis runs off to $\pm\infty$, depending on the sign of the initial velocity. These are the only trajectories that are nonperiodic.

The rescaling argument that gives the cardioid for the case $\epsilon=1$ yields a doubly indented cardioid for the case $\epsilon=2$ (see Fig. 5). This cardioid is similar to that in Fig. 5 of Ref. 13. However, for the case $\epsilon=2$ the limiting double cardioid consists of two perfect circles, which are tangent to one another at the origin $x=0$. Circles appear because at $\epsilon=2$ in the scaling limit the equation corresponding to (2.7) is $dx/dt=\pm x^2$. The solutions to this equation are the inversions $x(t)=\pm[1/(t+i)]$, which map the real-t axis into circles in the complex-x plane.

D. Case $\epsilon=5$

When $\epsilon=5$ there are seven turning points, one located at i and three pairs, each pair symmetric with respect to reflection about the imaginary axis ($\mathcal{PT}$ symmetric). We find that each of these pairs of turning points is joined by an oscillatory classical trajectory. (A trajectory joining any other two turning points would violate $\mathcal{PT}$ symmetry.) Surrounding each of the oscillatory trajectories are nested closed loops, each loop having the same period as the oscillatory trajectory it encloses. These classical trajectories are shown on Fig. 6. The periods for these three families of trajectories are

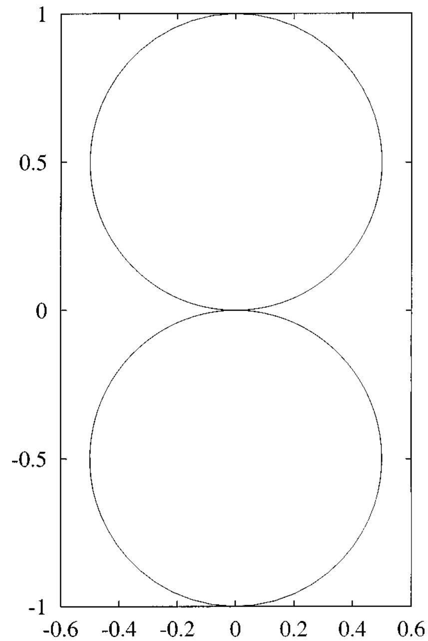

FIG. 5. Limiting double cardioid for the case $\epsilon=2$. As the orbits in Fig. 4 approach the real axis, they get larger. If we scale successively larger orbits down by their characteristic size, then in the limiting case the orbits approach two circles tangent at the origin. In this limit the four turning points in Fig. 4 coalesce at the point of tangency.

$$4\sqrt{\pi}\frac{\Gamma(8/7)}{\Gamma(9/14)}\cos\theta,$$

where $\theta=5\pi/14$ for the lowest pair of turning points, $\theta=\pi/14$ for the middle pair, and $\theta=3\pi/14$ for the pair above the real axis.

One other class of trajectory is possible. If the initial position of the classical particle lies on the imaginary axis at or above the turning point at i, then depending on the sign of the initial

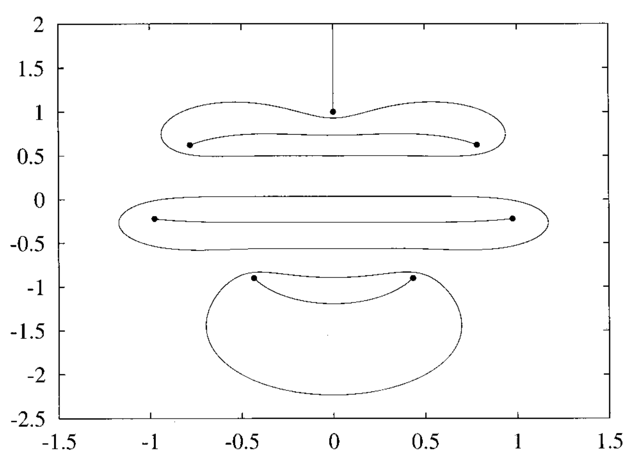

FIG. 6. Classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2+ix^7$ and having energy $E=1$. Shown are oscillatory trajectories surrounded by periodic trajectories. Unbounded trajectories run along the positive-imaginary axis above $x=i$.

velocity, the particle either runs off to $i\infty$ or it approaches the turning point, reverses its direction, and then goes off to $i\infty$. These purely imaginary paths are the only possible nonperiodic trajectories. They are also shown on Fig. 6.

E. General case: Noninteger values of $\epsilon>0$

Because Eq. (2.4) contains a square root function, the turning points, which are solutions to Eq. (2.5), are square root branch points for all values of ϵ. Thus, in principle, the complex trajectories $x(t)$ lie on a multi-sheeted Riemann surface. However, when ϵ is a non-negative integer, we can define the branch cuts so that the classical trajectories satisfying Eq. (2.4) never leave the principal sheet of this Riemann surface. We do this as follows: We choose to join the $\mathcal{PT}$-symmetric (left–right-symmetric) pairs of turning points by branch cuts that follow exactly the oscillatory solutions connecting these pairs. (There are three such pairs in Fig. 6, two in Fig. 4, and one in Figs. 2 and 1.) If ϵ is odd, there is one extra turning point that lies on the positive imaginary axis (see Figs. 2 and 6); the branch cut emanating from this turning point runs up the imaginary-x axis to $i\infty$. Since classical paths never cross, there are no trajectories that leave the principal sheet of the Riemann surface.

When ϵ is noninteger, we can see from the argument of the square root function in Eq. (2.4) that there is an entirely new branch cut, which emerges from the origin in the complex-x plane. To preserve $\mathcal{PT}$ symmetry we choose this branch cut to run off to ∞ along the positive-imaginary x-axis. If ϵ is rational, the Riemann surface has a finite number of sheets, but if ϵ is irrational, then there are an infinite number of sheets.

If a classical trajectory crosses the branch cut emanating from the origin, then this trajectory leaves the principal sheet of the Riemann surface. In Fig. 7 we illustrate some of the possible classical trajectories for the case $\epsilon=\pi-2$. The top plot shows some trajectories that do not cross the positive-imaginary-x axis and thus do not leave the principal sheet of the Riemann surface. The trajectories shown are qualitatively similar to those in Fig. 2; all trajectories have the same period.

In the middle plot of Fig. 7 is a trajectory that crosses the positive-imaginary-x axis and visits *three* sheets of the Riemann surface. The solid line and the dotted line outside of the solid line lie on the principal sheet, while the remaining two portions of the dotted line lie on two other sheets. Note that this trajectory does *not* cross itself; we have plotted the projection of the trajectory onto the principal sheet. The trajectory continues to exhibit $\mathcal{PT}$ symmetry. The period of the trajectory is greater than that of the period of the trajectories shown in the top plot. This is because the trajectory encloses turning points that are not on the principal sheet. In general, as the size of the trajectory increases, it encloses more and more complex turning points; each time a new pair of turning points is surrounded by the trajectory the period jumps by a discrete quantity.

Although the trajectory in the bottom plot in Fig. 7 has the same topology as that in the middle plot, it is larger. As the trajectory continues to grow, we observe a phenomenon that seems to be universal; namely, the appearance of a limiting cardioid shape (solid line) on the principal surface. The remaining portion of the trajectory (dotted line) shrinks relative to the cardioid and becomes compact and knotlike.

In Fig. 8 we examine the case $\epsilon=0.5$. In this figure we observe behavior that is qualitatively similar to that seen in Fig. 7; namely, as the trajectory on the principal sheet of the Riemann surface becomes larger and approaches a limiting cardioid, the remaining portion of the trajectory becomes relatively small and knotlike.

To summarize, for any $\epsilon>0$ the classical paths are always $\mathcal{PT}$ symmetric. The simplest such path describes oscillatory motion between the pair of turning points that lie just below the real axis on the principal sheet. In general, the period of this motion as a function of ϵ is given by

$$T=4\sqrt{\pi}E^{-\epsilon/(4+2\epsilon)}\frac{\Gamma((3+\epsilon)/(2+\epsilon))}{\Gamma((4+\epsilon)/(4+2\epsilon))}\cos\left(\frac{\epsilon\pi}{4+2\epsilon}\right). \tag{2.10}$$

Other closed paths having more complicated topologies (and longer periods) also exist, as shown in Figs. 7 and 8.

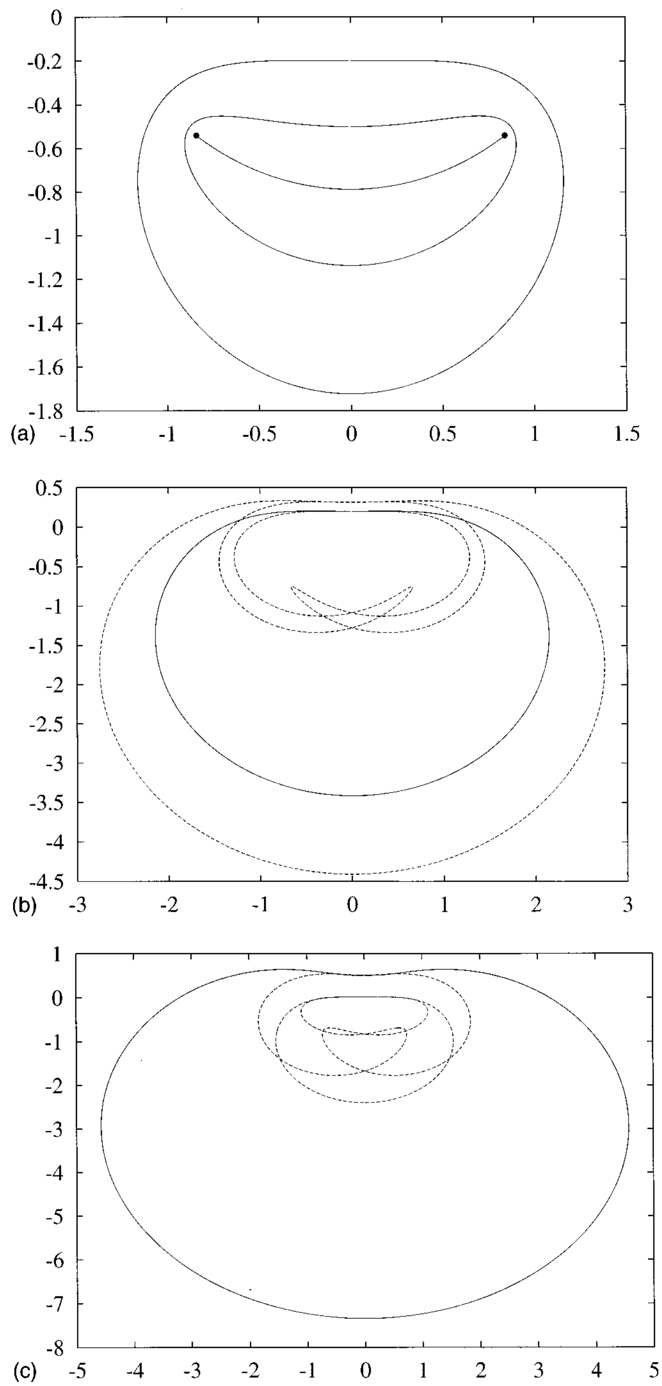

FIG. 7. Classical trajectories for $H=p^2-(ix)^\pi$ corresponding to the case $\epsilon=\pi-2$. Observe that as the classical trajectory increases in size, a limiting cardioid appears on the principal sheet of the Riemann surface. On the other sheets the trajectory becomes relatively small and knotlike.

Whenever the classical motion is periodic, we expect, the quantized version of the theory to exhibit real eigenvalues. Although we have not yet done so, we intend to investigate the consequences of quantizing a theory whose underlying classical paths have complicated topological structures traversing several sheets of a Riemann surface. The properties of such a theory of quantum knots might well be novel.

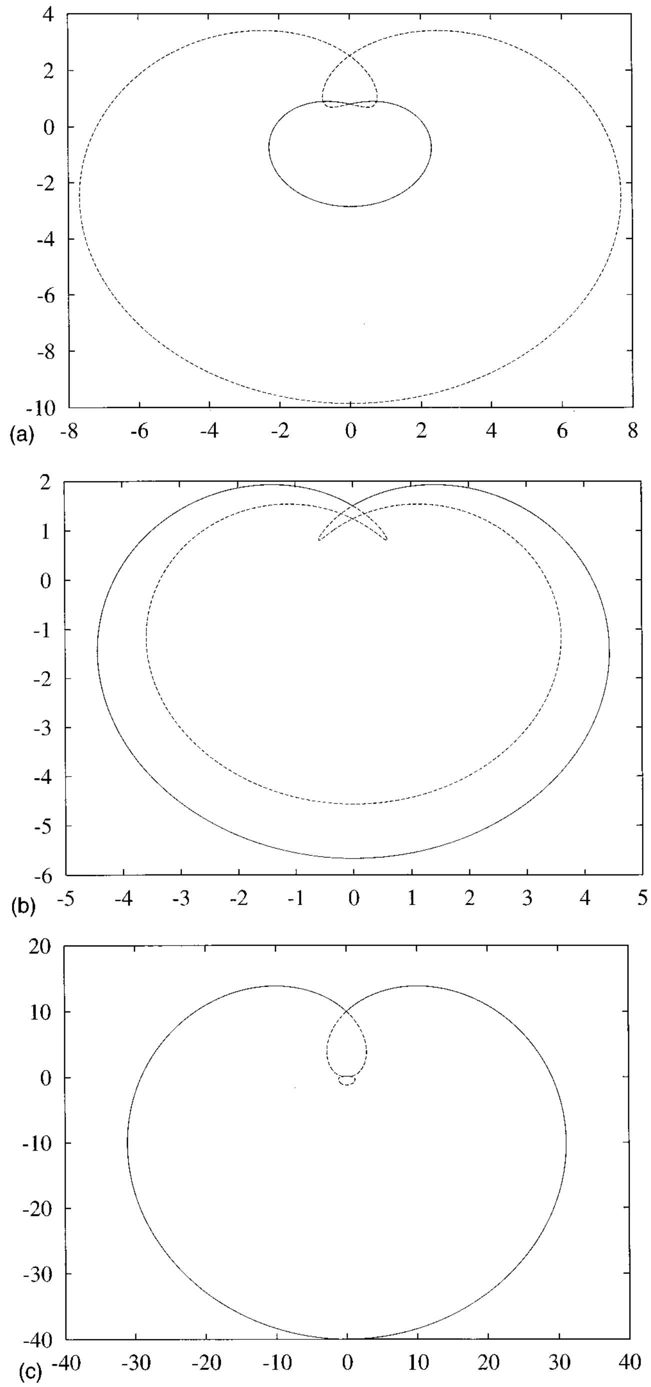

FIG. 8. Classical trajectories for the case $\epsilon=0.5$. As the classical path on the principal sheet of the Riemann surface increases in size it approaches a limiting cardioid, just as in Fig. 7. The remaining portion of the path becomes relatively small and knotlike.

F. Case $-1<\epsilon<0$

Classical paths for negative values of ϵ are fundamentally different from those corresponding to non-negative values of ϵ; such paths no longer exhibit $\mathcal{PT}$ symmetry. Furthermore, we no longer see paths that are periodic; all paths eventually spiral outwards to infinity. In general, the time that it takes for a particle to reach infinity is infinite.

We interpret the abrupt change in the global nature of the classical behavior that occurs as ϵ passes through 0 as a change in phase. For all values of ϵ the Hamiltonian in Eq. (1.1) is $\mathcal{PT}$ (left–right) symmetric. However, for $\epsilon<0$ the solutions cease to exhibit $\mathcal{PT}$ symmetry. Thus, we say that $\epsilon\geqslant 0$ is a $\mathcal{PT}$-symmetric phase and that $\epsilon<0$ is a spontaneously broken $\mathcal{PT}$-symmetric phase.

To illustrate the loss of $\mathcal{PT}$ (left–right) symmetry, we plot in Fig. 9 the classical trajectory for a particle that starts at a turning point $x_-=-\pi(4+\epsilon)/(4+2\epsilon)$ in the second quadrant of the complex-x plane (Re $x<0$, Im $x>0$) for three values of ϵ: -0.2, -0.15, and -0.1. We observe that a path starting at this turning point moves toward but *misses* the $\mathcal{PT}$-symmetric turning point $x_+=-\pi(\epsilon/(4+2\epsilon))$ because it crosses the branch cut on the positive-imaginary-x axis. This path spirals outward, crossing from sheet to sheet on the Riemann surface, and eventually veers off to infinity asymptotic to the angle θ_∞, where

$$\theta_\infty=-\frac{2+\epsilon}{2\epsilon}\pi. \tag{2.11}$$

This formula shows that the total angular rotation of the spiral is finite for all $\epsilon\neq 0$ but becomes infinite as $\epsilon\rightarrow 0^-$. In the top figure ($\epsilon=-0.2$) the spiral makes $2\frac{1}{4}$ turns before moving off to infinity; in the middle figure ($\epsilon=-0.15$) the spiral makes $3\frac{1}{12}$ turns; in the bottom figure ($\epsilon=-0.1$) the spiral makes $4\frac{3}{4}$ turns.

Note that the spirals in Fig. 9 pass many classical turning points as they spiral clockwise from x_-. {From Eq. (2.5) we see that the nth turning point lies at the angle $[(4-\epsilon-4n)/(4+2\epsilon)]\pi$ (x_- corresponds to $n=0$).} As ϵ approaches 0 from below, when the classical trajectory passes a new turning point, there is a corresponding merging of the quantum energy levels (as shown in Fig. 11). As pointed out in Ref. 1, this correspondence becomes exact in the limit $\epsilon\rightarrow 0^-$ and is a manifestation of Ehrenfest's theorem.

G. Case $\epsilon=-1$

For this special case we can solve the equation (2.4) exactly. The result,

$$x(t)=(1-b^2+\tfrac{1}{4}t^2)i+bt \quad (b \text{ real}), \tag{2.12}$$

represents a family of parabolas that are symmetric with respect to the imaginary axis (see Fig. 10). Note that there is one degenerate parabola corresponding to $b=0$ that lies on the positive imaginary axis above i.

III. QUANTUM THEORY

In this section we discuss the quantum properties of the Hamiltonian H in Eq. (1.1). The spectrum of this Hamiltonian is obtained by solving the corresponding Schrödinger equation

$$-\psi''(x)+[x^2(ix)^\epsilon-E]\psi(x)=0 \tag{3.1}$$

subject to appropriate boundary conditions imposed in the complex-x plane. These boundary conditions are described in Ref. 1. A plot of the spectrum of H is shown in Fig. 11.

There are several ways to obtain the spectrum that is displayed in Fig. 11. The simplest and most direct technique is to integrate the differential equation using Runge–Kutta. To do so, we convert the complex differential equation (3.1) to a system of coupled, real, second-order equations. We find that the convergence is most rapid when we integrate along anti-Stokes lines and then patch the two solutions together at the origin. This procedure, which is described in Ref. 1, gives highly accurate numerical results.

To verify the Runge–Kutta approach, we have solved the differential equation (3.1) using an independent and alternative procedure. We construct a matrix representation of the Hamiltonian in Eq. (1.1) in harmonic oscillator basis functions $e^{-x^2/2}H_n(x)\pi^{-1/4}/\sqrt{2^n n!}$:

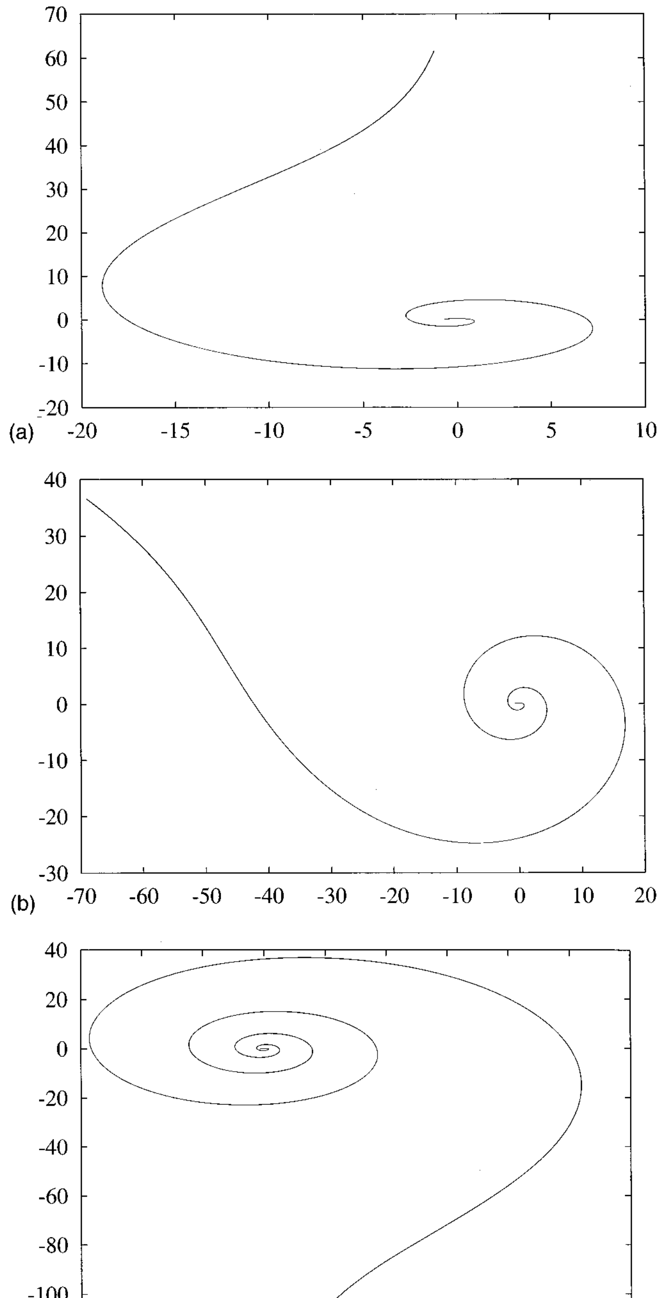

FIG. 9. Classical trajectories that violate $\mathcal{PT}$ symmetry. The top plot corresponds to the case $\epsilon=-0.2$, the middle plot to $\epsilon=-0.15$, and the bottom plot to $\epsilon=-0.1$. The paths in each plot begin at a turning point and spiral outwards to infinity in an infinite amount of time.

$$M_{m,n}=-\int_{-\infty}^{\infty}dx\,\frac{1}{\sqrt{\pi 2^{m+n}m!n!}}e^{-x^2/2}H_m(x)\left\{\frac{d^2}{dx^2}-i^{m+n}\right.$$
$$\left.\times\cos\left[\frac{\pi}{2}(\epsilon-m-n)\right]|x|^{2+\epsilon}\right\}e^{-x^2/2}H_n(x). \tag{3.2}$$

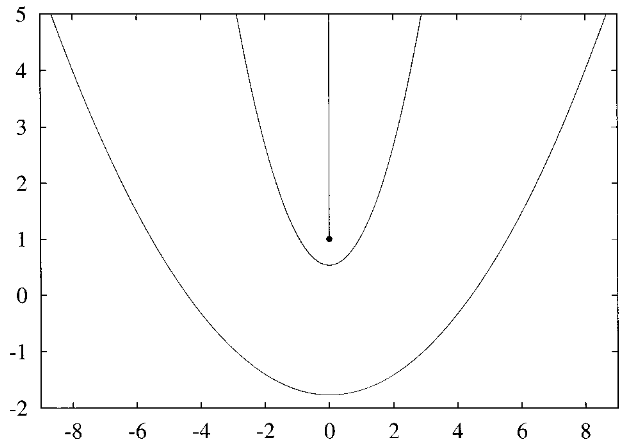

FIG. 10. Classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2-ix$ and having energy $E=1$. Shown are parabolic trajectories and a turning point at i. All trajectories are unbounded.

The Kth approximant to the spectrum comes from diagonalizing a truncated version of this matrix $M_{m,n}$ $(0\leqslant m,\ n\leqslant K)$. One drawback of this method is that the eigenvalues of $M_{m,n}$ approximate those of the Hamiltonian H in (1.1) only if $-1<\epsilon<2$. Another drawback is that the convergence to the exact eigenvalues is slow and not monotone because the Hamiltonian H is not Hermitian in a conventional sense. We illustrate the convergence of this truncation and diagonalization procedure for $\epsilon=-\frac{1}{2}$ in Fig. 12.

A third method for finding the eigenvalues in Fig. 11 is to use WKB (Wentzel–Kramers–Brillouin). Complex WKB theory (see Ref. 1) gives an excellent analytical approximation to the spectrum.

In the next two subsections we examine two aspects of the spectrum in Fig. 11. First, we study

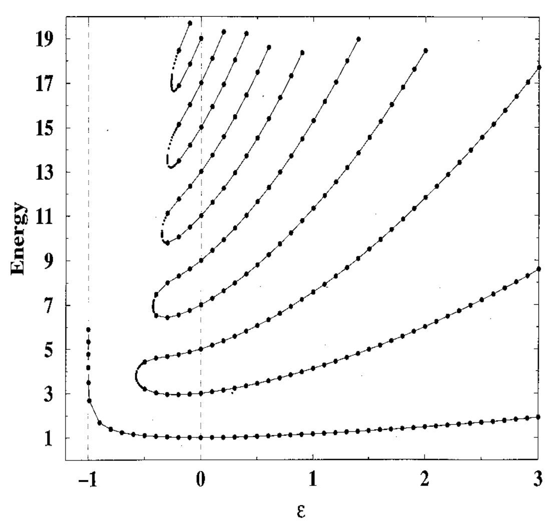

FIG. 11. Energy levels of the Hamiltonian $H=p^2+x^2(ix)^\epsilon$ as a function of the parameter ϵ. There are three regions.: When $\epsilon\geqslant 0$, the spectrum is real and positive and the energy levels rise with increasing ϵ. The lower bound of this region, $\epsilon=0$, corresponds to the harmonic oscillator, whose energy levels are $E_n=2n+1$. When $-1<\epsilon<0$, there are a finite number of real positive eigenvalues and an infinite number of complex conjugate pairs of eigenvalues. As ϵ decreases from 0 to -1, the number of real eigenvalues decreases; when $\epsilon\leqslant -0.57793$, the only real eigenvalue is the ground-state energy. As ϵ approaches -1^+, the ground-state energy diverges. For $\epsilon\leqslant -1$ there are no real eigenvalues.

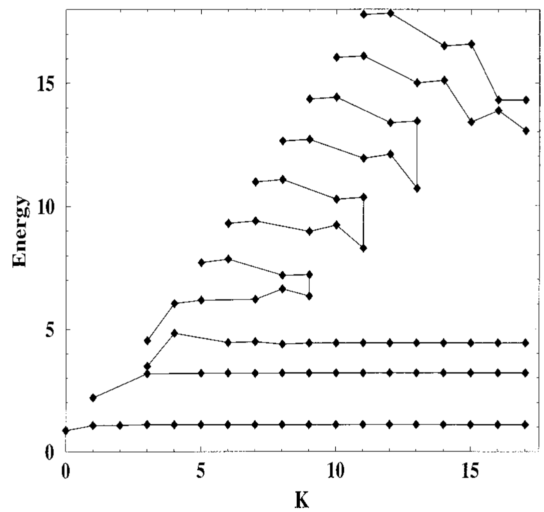

FIG. 12. Real eigenvalues of the $(K+1)\times(K+1)$ truncated matrix $M_{m,n}$ in Eq. (3.2) ($K=0,1,...,17$) for $\epsilon=-\frac{1}{2}$. As K increases, the three lowest eigenvalues converge to the three real energy levels in Fig. 11 at $\epsilon=-\frac{1}{2}$. The other real eigenvalues do not stabilize, and instead disappear in pairs.

the asymptotic behavior of the ground-state energy as $\epsilon\to-1$. Second, we examine the phase transition in the vicinity of $\epsilon=0$.

A. Behavior of the ground-state energy near $\epsilon=-1$

In this subsection we give an analytic derivation of the behavior of the lowest real energy level in Fig. 11 as $\epsilon\to-1$. We show that in this limit the eigenvalue grows logarithmically.

When $\epsilon=-1$, the differential equation (3.1) reduces to

$$-\psi''(x)-ix\psi(x)=E\psi(x), \tag{3.3}$$

which can be solved exactly in terms of Airy functions.[14] The anti-Stokes lines at $\epsilon=-1$ lie at 30° and at $-210°$ in the complex-x plane. We find the solution that vanishes exponentially along each of these rays and then rotate back to the real-x axis to obtain

$$\psi_{L,R}(x)=C_{L,R}\ \ \mathrm{Ai}(\mp xe^{\pm i\pi/6}+Ee^{\pm 2i\pi/3}). \tag{3.4}$$

We must patch these solutions together at $x=0$ according to the patching condition

$$\frac{d}{dx}|\psi(x)|^2\bigg|_{x=0}=0. \tag{3.5}$$

But for real E, the Wronskian identity for the Airy function[14] is

$$\frac{d}{dx}|\mathrm{Ai}(xe^{-i\pi/6}+Ee^{-2i\pi/3})|^2\bigg|_{x=0}=-\frac{1}{2\pi} \tag{3.6}$$

instead of 0. Hence, there is no real eigenvalue.

Next, we perform an asymptotic analysis for $\epsilon=-1+\delta$ where δ is small and positive:

$$\begin{gathered}-\psi''(x)-(ix)^{1+\delta}\psi(x)=E\psi(x),\\ \psi(x)\sim y_0(x)+\delta y_1(x)+O(\delta^2)\quad(\delta\to0+).\end{gathered} \tag{3.7}$$

We assume that $E\to\infty$ as $\delta\to 0+$ and obtain

$$\begin{aligned} y_0''(x)+ixy_0(x)+Ey_0(x)&=0,\\ y_1''(x)+ixy_1(x)+Ey_1(x)&=-ix\ln(ix)y_0(x), \end{aligned} \tag{3.8}$$

and so on.

To leading order we again obtain the Airy equation (3.3) for $y_0(x)$. The solution for $y_0(x)$ $(x\geqslant 0)$ is given by $\psi_R(x)$ in Eq. (3.4) and we are free to choose $C_R=1$. We can expand the Airy function in $y_0(x)$ for large argument in the limit $E\to\infty$:

$$y_0(x)=\mathrm{Ai}(xe^{-i\pi/6}+Ee^{-2i\pi/3})\sim(xe^{-i\pi/6}+Ee^{-2i\pi/3})^{-1/4}\exp[\tfrac{2}{3}(xe^{-i\pi/6}+Ee^{-2i\pi/3})^{3/2}]. \tag{3.9}$$

At $x=0$ we get

$$y_0(0)=\mathrm{Ai}(Ee^{-2i\pi/3})\sim e^{i\pi/6}E^{-1/4}e^{(2/3)E^{3/2}}/(2\sqrt{\pi}). \tag{3.10}$$

To next order in ϵ we simplify the differential equation for $y_1(x)$ in (3.8) by substituting

$$y_1(x)=Q(x)y_0(x). \tag{3.11}$$

Using the differential equation for $y_0(x)$ in (3.8), we get

$$y_0(x)Q''(x)+2y_0'(x)Q'(x)=-ix\ln(ix)y_0(x). \tag{3.12}$$

Multiplying this equation by the integrating factor $y_0(x)$, we obtain

$$[y_0^2(x)Q'(x)]'=-ix\ln(ix)y_0^2(x), \tag{3.13}$$

which integrates to

$$Q'(x)=\frac{i}{y_0^2(x)}\int_x^\infty dt\, t\ln(it)y_0^2(t), \tag{3.14}$$

where the upper limit of the integral ensures that $Q'(x)$ is bounded for $x\to\infty$. Thus, we obtain

$$Q'(0)=\frac{i}{y_0^2(0)}\int_0^\infty dx\, x\ln(ix)y_0^2(x). \tag{3.15}$$

To determine the asymptotic behavior of the ground-state eigenvalue as $\delta\to 0$, we insert

$$\psi(x)\sim y_0(x)+\delta y_1(x)+O(\delta^2)=y_0(x)[1+\delta Q(x)]+O(\delta^2) \tag{3.16}$$

into the quantization condition:

$$\begin{aligned} 0=\frac{d}{dx}[\psi^*(x)\psi(x)]\Big|_{x=0}&\sim\frac{d}{dx}[|y_0(x)|^2(1+\delta Q^*(x))(1+\delta Q(x))]\Big|_{x=0}\\ &\sim\frac{d}{dx}[|y_0(x)|^2]\Big|_{x=0}+2\delta|y_0(0)|^2\,\mathrm{Re}[Q'(0)]\\ &\quad+2\delta\frac{d}{dx}[|y_0(x)|^2]\Big|_{x=0}\mathrm{Re}[Q(0)]. \end{aligned} \tag{3.17}$$

TABLE I. Comparison of the exact ground-state energy E near $\epsilon=-1$ and the asymptotic results in Eq. (3.21). The explicit dependence of E on $\epsilon=-1+\delta$ is roughly $E\propto(-\ln\delta)^{2/3}$ as $\delta-0+$.

δ	E_{exact}	Eq. (3.21)
0.01	1.6837	2.0955
0.01	2.6797	3.9624
0.001	3.4947	3.6723
0.0001	4.1753	4.3013
0.00 001	4.7798	4.8776
0.000 001	5.3383	5.4158
0.0 000 001	5.8943	5.9244

We are free to choose $Q(0)=0$, and doing so eliminates the last term on the right side. The leading-order result for the quantization condition in Eq. (3.6) then gives

$$\frac{1}{2\pi}\sim 2\delta|y_0(0)|^2\,\mathrm{Re}[Q'(0)]. \tag{3.18}$$

Next, we substitute the asymptotic form for y_0 in Eq. (3.10) and the result for $Q'(0)$ in Eq. (3.15) and obtain

$$\sqrt{E}e^{-(4/3)E^{3/2}}\sim 2\delta\,\mathrm{Re}\int_0^\infty dx\,ix\ln(ix)\left[\frac{y_0(x)}{y_0(0)}\right]^2. \tag{3.19}$$

Because the ratio of the unperturbed wave functions in the integrand in Eq. (3.19) is bounded and vanishes exponentially for large x, we know that the integral can grow at most as a power of E. Thus,

$$\delta\sim CE^\alpha e^{-(4/3)E^{3/2}} \tag{3.20}$$

for some power α and constant C and the controling behavior of the ground-state energy as $\delta\to0$ is given by

$$E\sim[-\tfrac{3}{4}\ln\delta]^{2/3}, \tag{3.21}$$

where we have neglected terms that vary at most like $\ln(\ln\delta)$. Equation (3.21) gives the asymptotic behavior of the lowest energy level and is the result that we have sought. This asymptotic behavior is verified numerically in Table I.

B. Behavior of energy levels near $\epsilon=0$

In this subsection we examine analytically the phase transition that occurs at $\epsilon=0$. In particular, we study high-lying eigenvalues for small negative values of ϵ and verify that adjacent pairs of eigenvalues pinch off and become complex.

For small ϵ we approximate H in Eq. (1.1) to first order in ϵ:

$$H=p^2+x^2+\epsilon x^2\ln(ix)+O(\epsilon^2). \tag{3.22}$$

Using the identity $\ln(ix)=\ln(|x|)+\frac{1}{2}i\pi\,\mathrm{sgn}(x)$, we then have

$$H=p^2+x^2+\epsilon x^2\left[\ln(|x|)+\frac{i\pi}{2}\mathrm{sgn}(x)\right]+O(\epsilon^2). \tag{3.23}$$

The simplest way to continue is to truncate this approximate Hamiltonian to a 2×2 matrix. We introduce a harmonic oscillator basis as follows: The nth eigenvalue of the harmonic oscillator Hamiltonian p^2+x^2 is $E_n=2n+1$ and the corresponding x-space normalized eigenstate $|n\rangle$ is

$$\psi_n(x)=\frac{\pi^{-1/4}}{\sqrt{2^n n!}}e^{-x^2/2}H_n(x), \tag{3.24}$$

where $H_n(x)$ is the nth Hermite polynomial $[H_0(x)=1,\ H_1(x)=2x,\ H_2(x)=4x^2-2,\ H_3(x)=8x^3-12x$, and so on]. We then have the following diagonal matrix elements:

$$\langle n|p^2+x^2|n\rangle=2n+1, \tag{3.25}$$

$$\langle n|x^2\ln(|x|)|n\rangle=a_n-\left(\frac{\gamma}{2}+\ln 2\right)\left(n+\frac{1}{2}\right), \tag{3.26}$$

where γ is Euler's constant and

$$a_n=n+1+\left[\frac{n}{2}\right]+\left(n+\frac{1}{2}\right)\sum_{0}^{[n+1/2]}\frac{1}{2k-1}. \tag{3.27}$$

We also have the off-diagonal matrix element

$$\langle 2n-1|\frac{1}{2}i\pi x^2\,\mathrm{sgn}(x)|2n\rangle=\frac{1}{3}i(8n+1)\left[\frac{\Gamma^2(n+1/2)}{n!(n-1)!}\right]^{1/2}. \tag{3.28}$$

In the $(2n-1)-(2n)$ subspace, the matrix $H-E$ then reduces to the following 2×2 matrix:

$$\begin{pmatrix} A-E & iB \\ iB & C-E \end{pmatrix}, \tag{3.29}$$

where for large n and small ϵ we have

$$\begin{aligned} A&\sim 4n-1+\epsilon(n-1/2)\ln(2n),\\ B&\sim \tfrac{8}{3}\epsilon n,\\ C&\sim 4n+1+\epsilon n\ln(2n). \end{aligned} \tag{3.30}$$

The determinant of the matrix in Eq. (3.\29) gives the following roots for E:

$$E=\tfrac{1}{2}\left(A+C\pm\sqrt{(A-C)^2-4B^2}\right). \tag{3.31}$$

We observe that the roots E are degenerate when the discriminant (the square root) in Eq. (3.31) vanishes. This happens when the condition

$$\epsilon=\frac{3}{8n} \tag{3.32}$$

is met. Hence, the sequence of points in Fig. 11 where the eigenvalues pinch off approaches $\epsilon=0$ as $n\to\infty$. For example, Eq. (3.32) predicts (using $n=4$) that E_7 and E_8 become degenerate and move off into the complex plane at $\epsilon\approx-0.1$. In Fig. 13 we compare our prediction for the behavior of E in Eq. (3.31) with a blow-up of of a small portion of Fig. 11. We find that while our prediction is qualitatively good, the numerical accuracy is not particularly good. The lack of accuracy is not associated with truncating the expansion in powers of ϵ but rather with truncating

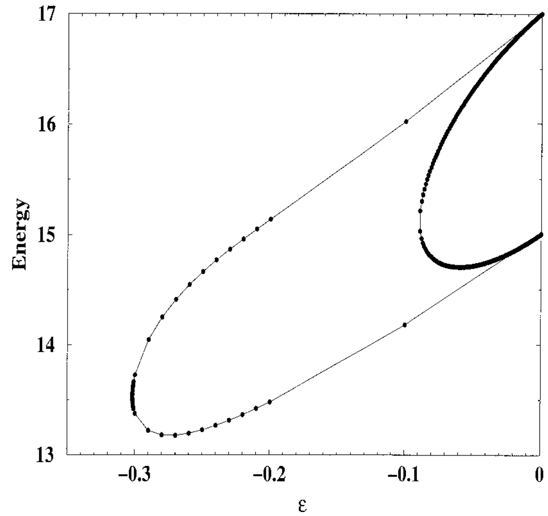

FIG. 13. A comparison of the prediction in Eq. (3.31) and a magnification of Fig. 11. Our prediction for the point at which E_7 and E_8 become degenerate is not very accurate numerically but is qualitatively quite good.

the Hamiltonian H to a 2×2 matrix. Our numerical studies indicate that as the size of the matrix truncation increases, we obtain more accurate approximations to the behavior of the energy levels E in Fig. 11.

IV. MORE GENERAL CLASSES OF THEORIES

In this section we generalize the results of Secs. II and III to a much wider class of theories. In particular, we consider a complex deformation of the x^{2K} anharmonic oscillator, where $K=1,2,3,\ldots$ [see Eq. (1.4)]. The Schrödinger equation for this oscillator has the form

$$-\psi''(x)+[x^{2K}(ix)^{\epsilon}-E]\psi(x)=0. \tag{4.1}$$

To determine the energy levels E as functions of the deformation parameter ϵ, we must impose appropriate boundary conditions on Eq. (4.1). We require that the wave function vanish as $|x|\to\infty$ inside of two wedges symmetrically placed about the imaginary-x axis. The right wedge is centered about the angle $\theta_{\rm right}$, where

$$\theta_{\rm right}=-\frac{\epsilon\pi}{4K+2\epsilon+4}, \tag{4.2}$$

and the left wedge is centered about the angle $\theta_{\rm left}$, where

$$\theta_{\rm left}=-\pi+\frac{\epsilon\pi}{4K+2\epsilon+4}. \tag{4.3}$$

The opening angle of each of these wedges is

$$\frac{2\pi}{2K+\epsilon+2}. \tag{4.4}$$

This pair of wedges is $\mathcal{PT}$ (left–right) symmetric.

The orientation of these wedges is determined by analytically continuing the differential equation eigenvalue problem (4.1) and associated boundary conditions in the variable ϵ using the techniques explained in Ref. 15. The rotation of the boundary conditions is obtained from the asymptotic behavior of the solution $\psi(x)$ for large $|x|$:

$$\psi(x)\sim\exp\left(\pm\frac{i^{\epsilon/2}x^{K+1+\epsilon/2}}{K+1+\epsilon/2}\right). \tag{4.5}$$

(In this formula we give the *controlling factor* of the asymptotic behavior of the wave function; we neglect algebraic contributions.) Note that at the center of the wedges the behavior of the wave function is most strongly exponential; the centerline of each wedge is an anti-Stokes line. At the edges of the wedges the asymptotic behavior is oscillatory. The lines marking the edges of the wedges are Stokes lines.

For all positive integer values of K the results are qualitatively similar. At $\epsilon=0$ the two wedges are centered about the positive and negative real axes. As ϵ increases from 0 the wedges rotate downward and become thinner. In the region $\epsilon\geqslant 0$ the eigenvalues are all real and positive and they rise with increasing ϵ. As $\epsilon\to\infty$, the two wedges become infinitely thin and lie along the negative imaginary axis. There is no eigenvalue problem in this limit because the solution contour for the Schrödinger equation (4.1) can be pushed off to infinity. Indeed, we find that in this limit the eigenvalues all become infinite.

When ϵ is negative, the wedges rotate upward and become thicker. The eigenvalues gradually pair off and become complex starting with the highest eigenvalues. Thus, $\mathcal{PT}$ symmetry is spontaneously broken for $\epsilon<0$. Eventually, as ϵ approaches $-K$, only the lowest eigenvalue remains real. At $\epsilon=-K$ the two wedges join at the positive imaginary axis. Thus, again there is no eigenvalue problem and there are no eigenvalues at all. In the limit $\epsilon\to-K$ the one remaining real eigenvalue diverges logarithmically.

The spectrum for the case of arbitrary positive integer K is quite similar to that for $K=1$. However, in general, when $K>1$, a novel feature emerges: A new transition appears for all negative integer values of ϵ between 0 and $-K$. At these isolated points the spectrum is entirely real. Just above each of these negative-integer values of ϵ the energy levels reemerge in pairs from the complex plane and just below these special values of ϵ the energy levels once again pinch off and become complex.

A. Quantum $x^4(ix)^\epsilon$ theory

The spectrum for the case $K=2$ is displayed in Fig. 14. This figure resembles Fig. 11 for the case $K=1$. However, at $\epsilon=-1$ there is a new transition. This transition is examined in detail in Fig. 15.

An important feature of the spectrum in Fig. 14 is the disappearance of the eigenvalues and divergence of the lowest eigenvalue as ϵ decreases to -2. Following the approach of Sec. III A, we now derive the asymptotic behavior of the ground-state energy as $\epsilon\to-2^+$. To do so we let $\epsilon=-2+\delta$ and obtain from Eq. (4.1) the Schrödinger equation

$$-\psi''(x)-x^2(ix)^\delta\psi(x)=E\psi(x). \tag{4.6}$$

We study this differential equation for small positive δ.

When $\delta=0$ this differential equation (4.6) reduces to

$$-\psi''(x)-x^2\psi(x)=E\psi(x). \tag{4.7}$$

The anti-Stokes lines for this equation lie at 45° and at $-225°$. Thus, we rotate the integration contour from the real axis to the anti-Stokes lines and substitute

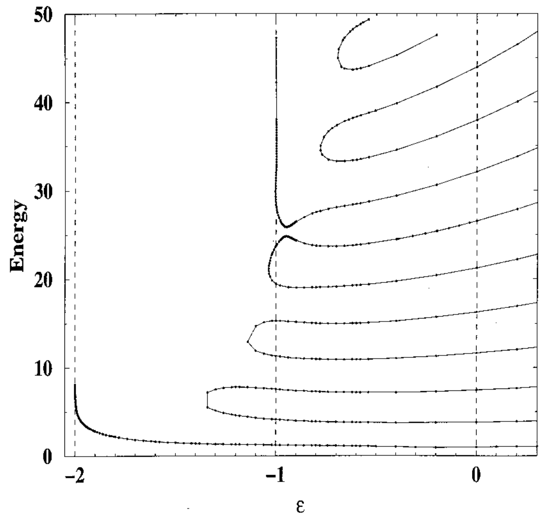

FIG. 14. Energy levels of the Hamiltonian $H=p^2+x^4(ix)^\epsilon$ as a function of the parameter ϵ. This figure is similar to Fig. 11, but now there are four regions: When $\epsilon\geqslant 0$, the spectrum is real and positive and it rises monotonically with increasing ϵ. The lower bound $\epsilon=0$ of this $\mathcal{PT}$-symmetric region corresponds to the pure quartic anharmonic oscillator, whose Hamiltonian is given by $H=p^2+x^4$. When $-1<\epsilon<0$, $\mathcal{PT}$ symmetry is spontaneously broken. There are a finite number of real positive eigenvalues and an infinite number of complex conjugate pairs of eigenvalues; as a function of ϵ the eigenvalues pinch off in pairs and move off into the complex plane. By the time $\epsilon=-1$ only eight real eigenvalues remain; these eigenvalues are continuous at $\epsilon=1$. Just as ϵ approaches -1 the entire spectrum reemerges from the complex plane and becomes real. (Note that at $\epsilon=-1$ the entire spectrum agrees with the entire spectrum in Fig. 11 at $\epsilon=1$.) This reemergence is difficult to see in this figure but is much clearer in Fig. 15 in which the vicinity of $\epsilon=-1$ is blown up. Just below $\epsilon=-1$, the eigenvalues once again begin to pinch off and disappear in pairs into the complex plane. However, this pairing is different from the pairing in the region $-1<\epsilon<0$. Above $\epsilon=-1$ the lower member of a pinching pair is even and the upper member is odd (that is, E_8 and E_9 combine, E_{10} and E_{11} combine, and so on); below $\epsilon=-1$ this pattern reverses (that is, E_7 combines with E_8, E_9 combines with E_{10}, and so on). As ϵ decreases from -1 to -2, the number of real eigenvalues continues to decrease until the only real eigenvalue is the ground-state energy. Then, as ϵ approaches -2^+, the ground-state energy diverges logarithmically. For $\epsilon\leqslant -2$ there are no real eigenvalues.

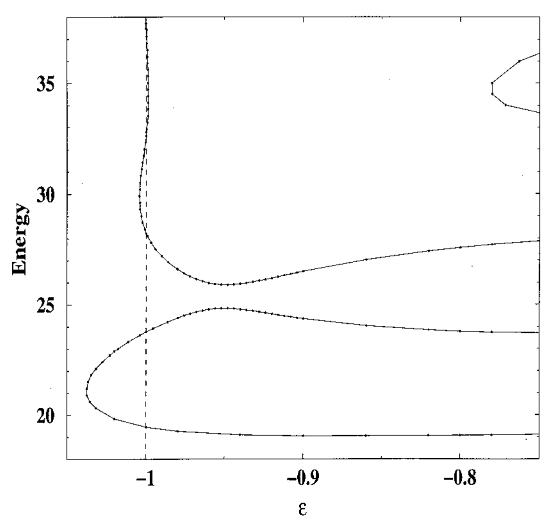

FIG. 15. A magnification of Fig. 14 in the vicinity of the transition at $\epsilon=-1$. Just above $\epsilon=-1$ the entire spectrum reemerges from the complex plane, and just below $\epsilon=-1$ it continues to disappear into the complex plane. The spectrum is entirely real at $\epsilon=-1$.

$$x=\begin{cases}\dfrac{s}{\sqrt{2}}e^{-5i\pi/4} & (\mathrm{Re}\,x<0),\\[2ex] \dfrac{r}{\sqrt{2}}e^{i\pi/4} & (\mathrm{Re}\,x>0),\end{cases} \tag{4.8}$$

for x in the left-half and in the right-half complex plane, respectively. Note as s and r increase, x moves towards complex infinity in both the left- and right-half plane.

The wave function in the left-half plane, $\psi_L(s)$, and the wave function in the right-half plane, $\psi_R(r)$, satisfy the differential equations

$$\begin{aligned}-\frac{d^2}{ds^2}\psi_L(s)+\left(\frac{s^2}{4}-\frac{1}{2}\right)\psi_L(s)=\nu\psi_L(s),\\ -\frac{d^2}{dr^2}\psi_R(r)+\left(\frac{r^2}{4}-\frac{1}{2}\right)\psi_R(r)=(-\nu-1)\psi_R(r),\end{aligned} \tag{4.9}$$

where we have set $\nu=-(i/2)E-\frac{1}{2}$. For each of these equations the solution that vanishes at infinity is a parabolic cylinder function:[16]

$$\begin{aligned}\psi_L(s)=C_L D_\nu(s)=C_L D_\nu(x\sqrt{2}e^{5i\pi/4}),\\ \psi_R(r)=C_R D_{-\nu-1}(r)=C_R D_{-\nu-1}(x\sqrt{2}e^{-i\pi/4}),\end{aligned} \tag{4.10}$$

where C_L and C_R are arbitrary constants.

We impose the quantization condition by patching these solutions together at $x=0$ on the real-x axis according to the patching conditions

$$\begin{aligned}\psi_L(x)\big|_{x=0}=\psi_R(x)\big|_{x=0},\\ \frac{d}{dx}\psi_L(x)\bigg|_{x=0}=\frac{d}{dx}\psi_R(x)\bigg|_{x=0}\end{aligned} \tag{4.11}$$

To eliminate the constants C_L and C_R we take the ratio of these two equations and simplify the result by cross multiplying:

$$\left[\psi_R(x)\frac{d}{dx}\psi_L(x)-\psi_L(x)\frac{d}{dx}\psi_R(x)\right]\bigg|_{x=0}=0. \tag{4.12}$$

We now show that this condition cannot be satisfied by the $\delta=0$ wave function in Eq. (4.10). For this case, the quantization condition (4.12) states that

$$D_\nu(s)\frac{d}{ds}D_{-\nu-1}(is)-D_{-\nu-1}(is)\frac{d}{ds}D_\nu(s) \tag{4.13}$$

vanishes at $s=0$. (We have simplified the argument by setting $s=x\sqrt{2}e^{5i\pi/4}$). But Eq. (4.13) for any value of s is just the Wronskian for parabolic cylinder functions[16] and this Wronskian equals $-ie^{-i\nu\pi/2}$. This is a *nonzero* result. Thus, when $\delta=0$, there cannot be any eigenvalue E, real or complex, and the spectrum is empty.

The quantization condition (4.12) can be satisfied when $\delta>0$. We investigate this region for the case when δ is small and positive by performing an asymptotic analysis. We assume that $E\to\infty$ as $\delta\to 0+$, but slower than any power of δ, and that the wave function $\psi(x)$ has a formal power series expansion in δ:

$$\psi(x) \sim y_0(x) + \delta y_1(x) + O(\delta^2) \quad (\delta \to 0+). \tag{4.14}$$

Next, we expand the Schrödinger equation (4.6) in powers of δ:

$$\begin{aligned} y_0''(x) + x^2 y_0(x) + E y_0(x) &= 0, \\ y_1''(x) + x^2 y_1(x) + E y_1(x) &= -x^2 \ln(ix) y_0(x), \end{aligned} \tag{4.15}$$

and so on.

Of course, to zeroth order in δ we obtain Eq. (4.7) for $y_0(x)$. Thus, in the left- and right-half complex x-plane we get

$$\begin{aligned} y_0^L(x) &= C_L D_\nu(x\sqrt{2} e^{5i\pi/4}), \\ y_0^R(x) &= C_R D_{-\nu-1}(x\sqrt{2} e^{-i\pi/4}). \end{aligned} \tag{4.16}$$

To first order in δ, we simplify the differential equation for $y_1(x)$ in (4.15) by substituting

$$y_1(x) = Q(x) y_0(x). \tag{4.17}$$

Using the differential equation for $y_0(x)$ in (4.15), we get

$$y_0(x) Q''(x) + 2 y_0'(x) Q'(x) = -x^2 \ln(ix) y_0(x). \tag{4.18}$$

Multiplying this equation by the integrating factor $y_0(x)$, we obtain

$$[y_0^2(x) Q'(x)]' = -x^2 \ln(ix) y_0^2(x). \tag{4.19}$$

The integral of this equation gives

$$\begin{aligned} Q_L'(x) &= \int_x^{\infty e^{-5i\pi/4}} dt\, t^2 \ln(it) \left[\frac{y_0^L(t)}{y_0^L(x)} \right]^2, \\ Q_R'(x) &= \int_x^{\infty e^{i\pi/4}} dt\, t^2 \ln(it) \left[\frac{y_0^R(t)}{y_0^R(x)} \right]^2, \end{aligned} \tag{4.20}$$

where the limit of the integral at infinity ensures that $Q'(x)$ is bounded for $|x| \to \infty$.

To determine the asymptotic behavior of the ground-state eigenvalue as $\delta \to 0^+$, we insert

$$\psi_{L,R}(x) \sim y_0^{L,R}(x) + \delta_{y_1}^{L,R}(x) + O(\delta^2) = y_0^{L,R}(x)[1 + \delta Q^{L,R}(x)] \tag{4.21}$$

into the quantization condition (4.12):

$$\begin{aligned} 0 &= \left[\psi_R(x) \frac{d}{dx} \psi_L(x) - \psi_L(x) \frac{d}{dx} \psi_R(x) \right] \Bigg|_{x=0} \\ &= \left[y_0^R(x) \frac{d}{dx} y_0^L(x) - y_0^L(x) \frac{d}{dx} y_0^R(x) \right] \Bigg|_{x=0} [1 + \delta(Q_R(0) + Q_L(0))] \\ &\quad + \delta y_0^R(0) y_0^L(0) [Q_L'(0) - Q_R'(0)]. \end{aligned} \tag{4.22}$$

We are free to choose $Q_R(0) + Q_L(0) = 0$ to simplify this result.

Substituting the Wronskian for the parabolic cylinder function and the result for $y_0(0)$ in Eq. (4.16), we obtain

$$\sqrt{2}e^{-\pi E/4} \sim \delta D_\nu(0) D_{-\nu-1}(0)[Q_R'(0) - Q_L'(0)]. \tag{4.23}$$

We can simplify this result using the identity

$$D_\nu(0) = \frac{\sqrt{\pi}2^{\nu/2}}{\Gamma(\frac{1}{2} - \nu/2)} \tag{4.24}$$

and $\nu = -(i/2)E - \frac{1}{2}$ to obtain

$$D_\nu(0) D_{-\nu-1}(0) = \frac{\Gamma(\frac{1}{2} + \nu/2)\cos(\pi\nu/2)}{\Gamma(1+\nu/2)\sqrt{2}} \sim \frac{\epsilon^{(\pi/4)E}}{\sqrt{E}}, \tag{4.25}$$

where we have used the reflection formula, $\Gamma(z)\Gamma(1-z) = \pi/\sin(\pi z)$, and the asymptotic behavior $\Gamma(x+1/2)/\Gamma(x+1) \sim x^{-1/2}$ for large x. Thus, Eq. (4.23) reduces to

$$\frac{\sqrt{2E}}{\delta} e^{-\pi E/2} \sim Q_R'(0) - Q_L'(0). \tag{4.26}$$

We can further show that

$$\begin{aligned} Q_R'(0) - Q_L'(0) &= \int_0^{\infty e^{i\pi/4}} dt\, t^2 \ln(it) \left[\frac{D_{-\nu-1}(\sqrt{2}te^{-i\pi/4})}{D_{-\nu-1}(0)} \right]^2 - \int_0^{\infty e^{-5i\pi/4}} dt\, t^2 \ln(it) \left[\frac{D_\nu(\sqrt{2}te^{5i\pi/4})}{D_\nu(0)} \right]^2 \\ &= -\int_0^\infty \frac{t^2 dt}{2^{3/2}} e^{-i\pi/4} \ln\left(\frac{s}{\sqrt{2}} e^{3i\pi/4} \right) \left[\frac{D_{-\nu-1}(t)}{D_{-\nu-1}(0)} \right]^2 \\ &\quad - \int_{0\infty} \frac{t^2 dt}{2^{3/2}} e^{i\pi/4} \ln\left(\frac{s}{\sqrt{2}} e^{-3i\pi/4} \right) \left[\frac{D_\nu(t)}{D_\nu(0)} \right]^2. \end{aligned} \tag{4.27}$$

We observe that the previous expression is real because $\nu^* = -\nu - 1$ implies that $D_\nu(t)^* = D_{-\nu-1}(t)$ and thus the two integrals are complex conjugates. Thus, Eq. (4.27) is real, and E is a real function of δ. Furthermore, because the ratio $D_\nu(t)/D_\nu(0)$ appears in both integrals, the expression can at most vary as a power of E. Hence, the contribution of $Q_R'(0) - Q_L'(0)$ to the balance in Eq. (4.26) is subdominant and can be neglected. Our final result for the small-δ behavior of the lowest eigenvalue is that

$$E \sim -\frac{2}{\pi} \ln \delta + O[\ln(\ln \delta)] \quad (\delta \to 0^+). \tag{4.28}$$

In Fig. 16 we show that Eq. (4.28) compares well with the numerical data for the lowest eigenvalue in the limit as $\delta \to 0$.

B. Classical $x^4(ix)^\epsilon$ theory

It is instructive to compare the quantum mechanical and classical mechanical theories for the case $K=2$. Our objective in doing so is to understand more deeply the breaking of $\mathcal{PT}$ symmetry that occurs at $\epsilon = 0$. For the case $K=1$ we found that $\mathcal{PT}$ symmetry is broken at the classical level in a rather obvious way: Left–right symmetric classical trajectories become spirals as ϵ becomes negative (see Fig. 9). However, we find that when $K=2$ spirals do not occur until $\epsilon < -2$. The classical manifestation of $\mathcal{PT}$ symmetry breaking for $-2 \leq \epsilon < 0$ and the transition that occurs at $\epsilon = 0$ is actually quite subtle.

For purposes of comparison we begin by examining the classical trajectories for the positive value $\epsilon = 0.7$. In Fig. 17 we plot three classical trajectories in the complex-x plane. The first is an

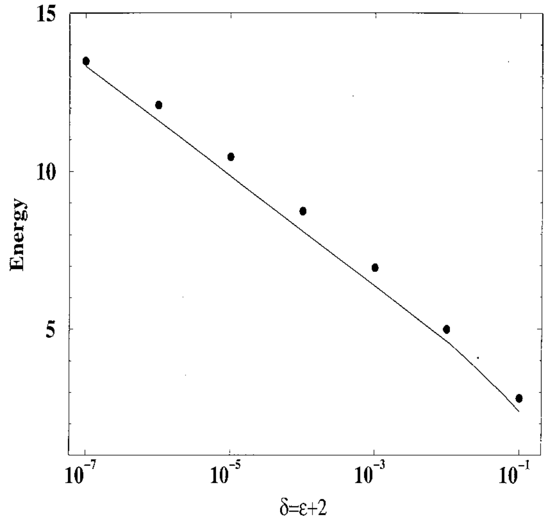

FIG. 16. A comparison of the lowest eigenvalue of the Hamiltonian $H=p^2+x^4(ix)^\epsilon$ (solid circles) with the asymptotic prediction in (4.28) (solid line) near $\epsilon=-2$. The solid line includes a one parameter fit of terms that grow like ln(ln δ) as $\delta\to 0^+$.

arc that joins the classical turning points in the lower-half plane. The other two are closed orbits that surround this arc. The smaller closed orbit remains on the principal sheet and has a period $(T\approx 4.9)$, which is equal to that of the arc. The more complicated trajectory is left–right symmetric but extends to three sheets of the Riemann surface. The period $(T\approx 26.1)$ of this third orbit is significantly different from and larger than the period of the other two.

Next, we consider the negative value $\epsilon=-0.7$. In Fig. 18 we plot two classical trajectories for this value. The first (solid line) is an arc joining the classical turning points in the upper-half plane. This arc extends to three sheets of the Riemann surface. The other trajectory (dashed line) is a closed orbit that surrounds this arc. Both have the period $T\approx 22.3$. This figure illustrates the first

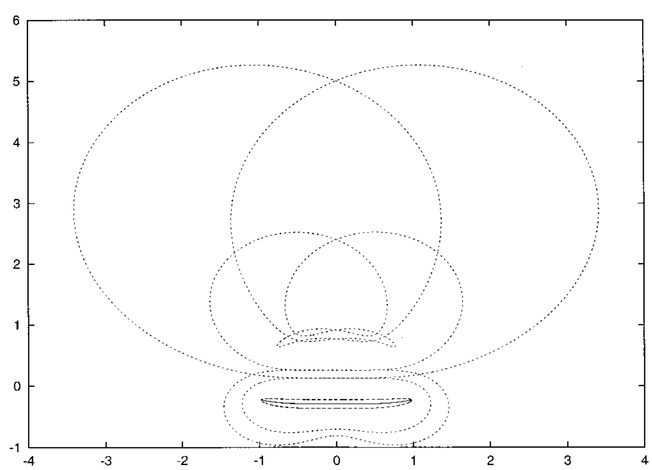

FIG. 17. Three classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2+x^4(ix)^\epsilon$ with $\epsilon=0.7$. The solid line represents oscillatory motion between the classical turning points. The long-dashed line is a nearby trajectory that encloses and has the same period as the solid-line trajectory. The short dashed line has a different topology (it enters three sheets of the Riemann surface) from the long-dashed line, even though these trajectories are very near one another in the vicinity of the turning points. The period of this motion is much longer than that of the solid and long-dashed trajectories.

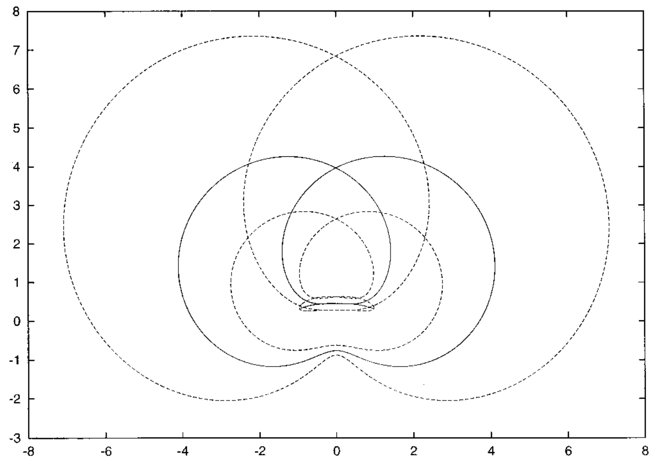

FIG. 18. Two classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2+x^4(ix)^\epsilon$ with $\epsilon=-0.7$. The solid line represents oscillatory motion between the classical turning points. This trajectory enters three sheets of the Riemann surface. The dashed line is a nearby trajectory that encloses and has the same period as the solid-line trajectory.

of two important changes that occur as ϵ goes below zero. The trajectory that joins the two turning points no longer lies on the principal sheet of the Riemann surface; it exhibits a multisheeted structure.

Figure 19 illustrates the second important change that occurs as ϵ goes below zero. On this figure we again plot two classical trajectories for the negative value $\epsilon=-0.7$. The first (solid line) is the arc joining the classical turning points in the upper-half plane. This arc is also shown on Fig. 18. The second trajectory (dashed line) is a closed orbit that passes near the turning points. The two trajectories do not cross; the apparent points of intersection are on different sheets of the Riemann surface. The period of the dashed trajectory is $T\approx 13.7$, which is considerably *smaller* than that of the solid line. Indeed, on the basis of extensive numerical studies, it appears that all trajectories for $-2<\epsilon<0$, while they are $\mathcal{PT}$ (left–right) symmetric, have periods that are less than or equal to that of the solid line. When $\epsilon>0$, the periods of trajectories increase as the trajectories move away from the oscillatory trajectory connecting the turning points.

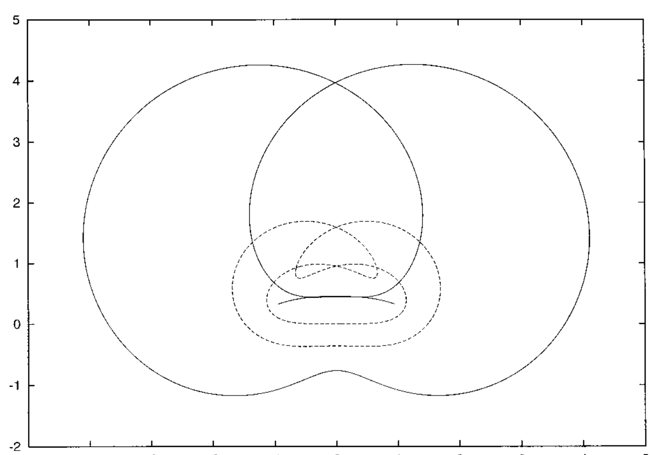

FIG. 19. Two classical trajectories in the complex-x plane for a particle described by the Hamiltonian $H=p^2+x^4(ix)^\epsilon$ with $\epsilon=-0.7$. The solid line represents oscillatory motion between the classical turning points and is the same as that in Fig. 18. The dashed line is a nearby trajectory whose period is smaller than the period of the solid-line trajectory.

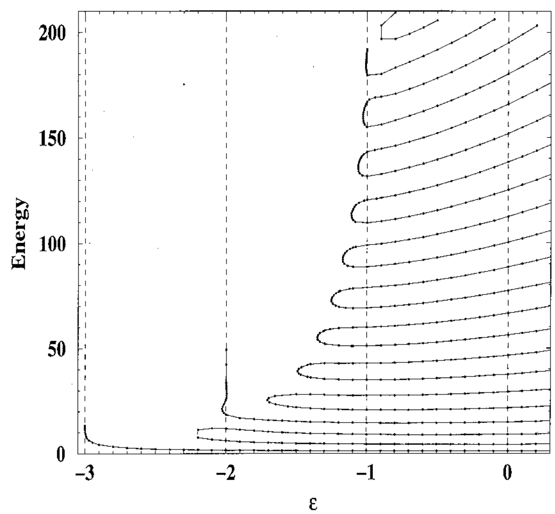

FIG. 20. Energy levels of the Hamiltonian $H=p^2+x^6(ix)^\epsilon$ as a function of the parameter ϵ. This figure is similar to Fig. 14, but now there are five regions: When $\epsilon \geqslant 0$, the spectrum is real and positive and it rises monotonically with increasing ϵ. The lower bound $\epsilon=0$ of this $\mathcal{PT}$-symmetric region corresponds to the pure sextic anharmonic oscillator, whose Hamiltonian is given by $H=p^2+x^6$. The other four regions are $-1<\epsilon<0$, $-2<\epsilon<-1$, $-3<\epsilon<-2$, and $\epsilon<-3$. The $\mathcal{PT}$ symmetry is spontaneously broken when ϵ is negative, and the number of real eigenvalues decreases as ϵ becomes more negative. However, at the boundaries $\epsilon=-1,-2$ there is a complete real positive spectrum. When $\epsilon=-1$, the eigenspectrum is identical to the eigenspectrum in Fig. 14 at $\epsilon=1$. For $\epsilon \leqslant -3$ there are no real eigenvalues.

We speculate that for negative values of ϵ the appearance of complex eigenvalues in the quantum theory (see Fig. 14) is associated with an instability. The path integral for a quantum theory is ordinarily dominated by paths in the vicinity of the classical trajectory connecting the turning points. However, when ϵ is negative, we believe that these trajectories no longer dominate the path integral because there are more remote trajectories whose classical periods are *smaller*. Thus, the action is no longer dominated by a stationary point in the form of a classical path having $\mathcal{PT}$ symmetry. Hence, the spectrum can contain complex eigenvalues.

The appearance of a purely real spectrum for the special value $\epsilon=-1$ is consistent with this conjecture. For integer values of $\epsilon>-2$ we find that all classical trajectories lie on the principal sheet of the Riemann surface and have the *same* period.

C. Quantum $x^6(ix)^\epsilon$ theory

The spectrum for the case $K=3$ is displayed in Fig. 20. This figure resembles Fig. 14 for the case $K=2$. However, now there are transitions at both $\epsilon=-1$ and $\epsilon=-2$.

(Received 23 September 1998; accepted for publication 1 December 1998)

The first quantized theory of $N=2$, $D=3$ massive superparticles with arbitrary fixed central charge and (half) integer or fractional superspin is constructed. The quantum states are realized on the fields carrying a finite-dimensional, or a unitary infinite-dimensional, representation of the supergroups OSp $(2|2)$ or SU $(1,1|2)$. The construction originates from quantization of a classical model of the superparticle we suggest. The physical phase space of the classical superparticle is embedded in a symplectic superspace $T^*(R^{1,2})\times\mathcal{L}^{1|2}$, where the inner Kähler supermanifold $\mathcal{L}^{1|2}\cong\mathrm{OSp}(2|2)/[\mathrm{U}(1)\times\mathrm{U}(1)]\cong\mathrm{SU}(1,1|2)/[\mathrm{U}(2|2)\times\mathrm{U}(1)]$ provides the particle with superspin degrees of freedom. We find the relationship between Hamiltonian generators of the global Poincaré supersymmetry and the ''internal'' SU$(1,1|2)$ one. Quantization of the superparticle combines the Berezin quantization on $\mathcal{L}^{1|2}$ and the conventional Dirac quantization with respect to space–time degrees of freedom. Surprisingly, to retain the supersymmetry, quantum corrections are required for the classical $N=2$ supercharges as compared to the conventional Berezin method. These corrections are derived and the Berezin correspondence principle for $\mathcal{L}^{1|2}$ underlying their origin is verified.

I. INTRODUCTION

In this paper we construct an $N=2$, $D=1+2$ massive spinning superparticle model and study the symplectic supergeometry behind it. This supergeometry is compatible with the Berezin quantization method which is applied to construct the one-particle quantum theory. The main part of our consideration is based on the observation that the $N=2$ superextension of the $D=3$ spinning particle results in the classical model which possesses simultaneously Poincaré supersymmetry (SUSY) and Lorentz supersymmetry of the superspin degrees of freedom. This ''double'' supersymmetry can be lifted to the quantum level and we obtain the realization of the $N=2$, $D=3$ Poincaré supermultiplet on the fields carrying an irreducible representation of the supergroup SU$(1,1|2)$ [''Lorentz supergroup'' whose even part is $\mathrm{SO}^{\uparrow}(1,2)\times\mathrm{U}(2)\times$central charge]. A nonlinear mutual involvement of the Hamiltonian generators of two supersymmetries requires the careful geometric quantization of the superparticle. At first, we try to explain the most important motivations of the problem.

In the hierarchy of all known entities, the particles living in three-dimensional space–time stand out mostly due to a possibility of fractional spin and statistics (anyons). Anyon excitations are actually presented in some planar physics phenomena,[1,2] and the relevant theoretical concept has both topological[3–5] and group-theoretical[6–8] grounds. It is well known that in the field theory

[a)]Electronic mail: ivan@phys.tsu.ru
[b)]Electronic mail: sll@phys.tsu.ru

fractional statistics originates usually from a coupling of the matter fields to the gauge field with the Chern–Simons mass term.[9,10] The supersymmetric extension of this approach[11] implies a direct interaction between anyon excitations.

The group-theoretical methods may give an alternative way to understand the anyon concept. One can start from the mechanical model of the $D=3$ spinning particle, whose quantization leads to the one-particle quantum mechanics for the fractional spin state.[12,13,8,14–17] It is established that $D=3$ spinning particles possess the following remarkable features: (i) the spinning particle carries as many physical degrees of freedom as a spinless one; (ii) there is the so-called *canonical model*[12] of the spinning particle, which implies a deformation of the canonical symplectic structure of the spinless particle by the use of the Dirac monopole two-form, without extension of the phase space introducing any ''spinning'' variables; (iii) it is a promising feature of the canonical model to be adapted for the construction of consistent couplings of the particle to external fields[18,19,15,20,16] and self-interaction of anyons.[21,22] In higher dimensions, the interaction problem for spinning particles becomes more involved, although some progress has recently been achieved there as well;[23,24] (iv) the anyon wave equations may be formulated in analogy with the ones for bosons and fermions. An essential difference is that the fractional spin, in contrast to the (half) integer, is naturally described in terms of infinite component fields carrying infinite-dimensional representations of the universal covering group $\overline{SO^{\uparrow}(1,2)} \cong \overline{SU(1,1)}$; (v) representations of fractional spin are multivalued.

There is no consistent quantum field theory of anyons up to now; nevertheless, the Chern–Simons and group-theoretical constructions are deemed to lead to a unified consistent theory. In this regard, it would be interesting to understand how the supersymmetry may be included into a group-theoretical description of anyons in terms of the infinite component fields.

Another reason to investigate the $D=3$ superparticle is the exceptional fact that not only the Poincaré supersymmetry is possible in $1+2$ dimensions, but the Lorentz one is, too. The Lorentz group $SO^{\uparrow}(1,2)$ coincides with the $D=2$ anti-de Sitter group; the latter admits the superextension regardless of specific space–time dimension. Although the Lorentz and the Poincaré supersymmetries are not compatible with each other, surprisingly, we will show that the Lorentz supersymmetry of the $D=3$ spinning superparticle (which is invariant by construction with respect to the global Poincaré SUSY transformations) manifests itself as a hidden supersymmetry of internal degrees of freedom associated to the particle superspin and to the underlying superextended monopolelike symplectic structure.

The hidden $OSp(2|2)$ supersymmetry of $N=1$ superanyons has been found in Ref. 25 where the respective model is constructed. The presence of the $OSp(2|2)$ supersymmetry already in the classical mechanics appears to be crucial for a consistent first quantization of the $N=1$, $D=3$ superanyon. As a result, one obtains in quantum theory the realization of the $N=1$ Poincaré supermultiplet on the fields carrying an atypical unitary infinite-dimensional representation of the $OSp(2|2)$.[25] It is a direct $N=1$ superextension of description in terms of infinite-dimensional unitary representation of the $D=3$ Lorentz group[6–8] or the ones of the deformed Heisenberg algebra.[26] We argued in this manner the relevance of the group-theoretical approach for $N=1$ supersymmetric anyons. In this paper we suggest a nontrivial generalization of this construction to the case of the $N=2$, $D=3$ massive spinning superparticle with arbitrary fixed central charge.

We construct a superparticle model, which gives $N=2$ superextension of the canonical description of the $D=3$ spinning particle mentioned above. It is essential for our consideration that the Hamiltonian formalism of the canonical model may be built either in terms of the minimal phase space, or in an extended phase space restricted by constraints.[14,16,17,25] In both cases the reduced phase space could be thought of as a space of motion of a Souriau's ''elementary system.''[27]

A general concept of elementary physical systems, including spinning particles and superparticles, is based on the so-called Kostant–Souriau–Kirillov (KSK) construction.[28,27,29] The idea of the KSK construction is to identify the *physical phase space (=space of motion)* of any elementary system with a *coadjoint orbit* $\mathcal{O}$ of the symmetry group G. The symplectic action G on $\mathcal{O}$ (classical mechanics) lifts to a representation of the group in a space of functions $\mathcal{H}$ on the classical manifold (prequantization). Then the quantization problem reduces to an appropriate choice of polarization, that is, a global Lagrangian section in $T(\mathcal{O})$ being invariant under the action of the symmetry group.

In the special case of Kähler homogeneous spaces, perfect results can be achieved in the framework of the Berezin quantization method,[30,31] which implies one-to-one correspondence between the phase-space functions (covariant Berezin symbols) and linear operators in a Hilbert space. The latter is realized by holomorphic sections, because the Kähler homogeneous manifold admits a natural complex polarization.[32] Moreover, the multiplication of the operators in the Hilbert space induces a noncommutative binary $*$-operation for the covariant Berezin symbols and a correspondence principle can be proved.[30,31]

Physically speaking, it would not always be satisfactory to describe elementary systems in terms of the coadjoint orbits. In particular, the dynamics of relativistic particles and superparticles is usually supposed to evolve in a fiber bundle $\mathcal{M}$ over a *space–time manifold* that is crucial for the interaction problem. Thus, the coadjoint orbit of the spinning (super)particle arises from embedding into evolution (super)space. The projection π: $\mathcal{M}\rightarrow\mathcal{O}_G$, where G is a Poincaré (super)group, generates G-invariant constraints and gauge symmetries in $\mathcal{M}$. The construction of interactions, being consistent with the gauge symmetries, and the quantization problem for π provide a subject of current interest in the problems of spinning particle and superparticle models.[12,33–35]

Concerning the $D=3$ spinning particle, it is established[13,14,16,25] that the quantization problem for the canonical model is naturally solved by means of an embedding of the maximal (four-dimensional) coadjoint orbit of the group $\mathrm{ISO}^{\uparrow}(1,2)$ into eight-dimensional phase space (that is, *extended phase space*) $\mathcal{M}^8\cong T^*(R^{1,2})\times\mathcal{L}$. Here $\mathcal{L}\cong\mathrm{SU}(1,1)/\mathrm{U}(1)$ is a Lobachevsky plane and the character $\cong$ denotes a symplectomorphism. The projection π: $\mathcal{M}^8\rightarrow\mathcal{O}_{m,s}$ onto coorbit $\mathcal{O}_{m,s}$ of the particle of mass m and spin s is provided by the constraints. The auxiliary variables parametrizing $\mathcal{L}$ are used to describe the particle spin. One can interpret the (holomorphic) automorphisms of the Lobachevskian Kähler metric as a hidden symmetry of the internal particle's structure, which is related to the spin. In this approach the quantization of the anyon could be achieved as a compromise of the conventional Dirac quantization on $T^*(R^{1,2})$ and of the geometric quantization in the Lobachevsky plane. Constraints of the classical mechanics are converted into wave equations of the anyon according to the Dirac prescriptions.

The starting point of this paper is a mechanical model of $N=2$ superparticles with arbitrary fixed mass $m>0$, superspin $s\neq 0$, and central charge $\mathcal{Z}\equiv mb$, $|b|\leqslant 1$, briefly announced before.[36] For this elementary system the maximal coadjoint orbit $\mathcal{O}_{m,s,b}$ of real dimension 4/4 is related to the case $|b|<1$. In our model, this orbit appears embedded into 8/4-dimensional extended phase superspace $\mathcal{M}^{8|4}$ of a special geometry: $\mathcal{M}^{8|4}\cong T^*(R^{1,2})\times\mathcal{L}^{1|2}$, where $\mathcal{L}^{1|2}=\mathrm{SU}(1,1|2)/[\mathrm{U}(2|2)\times\mathrm{U}(1)]\cong\mathrm{OSp}(2|2)/[\mathrm{U}(1)\times\mathrm{U}(1)]$ is an atypical Kähler coadjoint orbit of the supergroup SU (1,1|2) and the typical one of OSp (2|2). The inner supermanifold $\mathcal{L}^{1|2}$, providing the particle model with a nonzero superspin, was studied originally in Refs. 38 and 39 in relation to OSp (2|2) supercoherent states and called the $N=2$ *superunit disc*. The projection of $\mathcal{M}^{8|4}$ onto physical subspace follows similarly to the nonsupersymmetric model. In fact, introducing the supersymmetry for the $D=3$ particle, we need to superextend only the inner submanifold $\mathcal{L}$ of the extended phase space. The extended phase superspace $\mathcal{M}^{8|4}\cong T^*(R^{1,2})\times\mathcal{L}^{1|2}$ carries ''double supersymmetry:'' one is related to the Poincaré supergroup and acts on the associated coorbit $\mathcal{O}_{m,s,b}\subset\mathcal{M}^{8|4}$, another one lives in the inner subsupermanifold $\mathcal{L}^{1|2}$. Moreover, the model allows an extended hidden $N=4$ supersymmetry with special values of the central charges saturating the Bogomol'ny–Prassad–Sommerfield (BPS) bound.

We will quantize the theory similarly to the quantization of the canonical model of the particle on $\mathcal{M}^8$.[16,25] Specifically, we combine the geometric quantization in the inner subsupermanifold $\mathcal{L}^{1|2}$ for the internal SU (1,1|2) supersymmetry and the canonical Dirac quantization in $T^*(R^{1,2})$.

This quantization scheme implies from the outset that the mentioned ''double supersymmetry'' must survive in the quantum theory. The crucial point is to express the Hamiltonian generators of the Poincaré supersymmetry in $\mathcal{M}^{8|4}$ in terms of the ones of internal SU (1,1|2) supersymmetry (as well as of space–time coordinates and momenta). These expressions appear to be *nonlinear*. As a consequence, some renormalization of the Poincaré supergenerators should be required for the closure of the Poincaré supersymmetry algebra. Roughly speaking, the corrections to generators could be treated as a manifestation of the ordering ambiguity for operators in quantum theory. We will see that the origin of the corrections may also be clarified from the viewpoint of the Berezin quantization in $\mathcal{L}^{1|2}$ and the underlying correspondence principle. However, the Berezin method itself does not provide a regular technique of deriving the closing corrections which have to recover the representation of the Poincaré superalgebra in quantum theory. Moreover, it is unclear *a priori* whether the consistent corrections exist at all. Surprisingly, the problem is solved if a simple ansatz is taken for the renormalized Poincaré generators. Then the closing corrections, which appear in the order of $\mathcal{O}(s^{-2})$, can be *exactly* calculated.

We arrive eventually to the realization of the unitary representation of the $N=2$, $D=3$ supermultiplet on the fields carrying atypical irreps of the supergroup SU(1,1|2) and the typical ones of the subsupergroup OSp(2|2). These irreps are certainly infinite dimensional for the case of fractional superspin, but for the habitual case of (half) integer superspin they may be chosen to be finite dimensional.

The model of the $N=2$ superparticle reduces to the one of the $N=1$ superparticle in the Bogomol'ny–Prassad–Sommerfield (BPS) limit for central charge, when $|b|=1$. One can trace the BPS limit both at the classical and quantum levels. Classically, it corresponds to the degenerate coadjoint orbit of the $D=3$, $N=2$ superparticle of dimension 4/2. When $|b|=1$, the extended phase superspace becomes degenerate and reduces to $\mathcal{M}^{8|2}\cong T^*(R^{1,2})\times\mathcal{L}^{1|1}$ with inner supermanifold $\mathcal{L}^{1|1}\cong \mathrm{OSp}(2|2)/\mathrm{U}(1|1)\cong \mathrm{OSp}(1|2)/\mathrm{U}(1)$. $\mathcal{M}^{8|2}$ is exactly the extended phase superspace of the $N=1$ superanyon.[25] In this exceptional case, the generators of the $N=1$ Poincaré supersymmetry and the internal OSp(2|2) one are *linearly* expressible to one another. Thus, the geometric quantization immediately gives the quantum theory of the $N=1$ superparticle, without extra constructions and corrections. In this paper we touched on the BPS limit briefly; the detailed theory is considered in Refs. 25 and 37.

The geometric quantization in the OSp(2|2) coadjoint orbits was constructed in Refs. 38 and 39 and we follow these results. At the same time we have to clarify two important points, which have seemingly been unknown. First, we found out that the Kähler geometry of the regular coorbit $\mathcal{L}^{1|2}$ admits the symplectic holomorphic action of the supergroup SU(1,1|2), which is larger than the supergroup OSp(2|2) in itself. We construct the geometric quantization on $\mathcal{L}^{1|2}$ provided for this extended supersymmetry supergroup. Second, we perform Berezin quantization for $\mathcal{L}^{1|2}$ to establish a correspondence principle and to explain the origin of quantum corrections to the $N=2$ Poincaré supercharges in $\mathcal{M}^{8|4}$.

The paper is organized as follows. In Sec. II we recall briefly the canonical model of the $D=3$ spinning particle in terms of the minimal and extended phase spaces. Specifically, we focus on symplectic structure and symmetries of the minimal and extended spaces.

Then we are going to construct the superextension of the canonical model. The classical mechanics of the $N=2$, $D=3$ massive spinning superparticle with arbitrary central charge is considered in Sec. III. Starting from a first-order Lagrangian we study the supergeometry of the phase superspace and identify it with $\mathcal{M}^{8|4}=T^*(R^{1,2})\times\mathcal{L}^{1|2}$. We construct explicitly the embeddings of the $N=2$ Poincaré and Lorentz supergroup's coadjoint orbits into $\mathcal{M}^{8|4}$ and find out the Hamiltonian generators of corresponding supersymmetries. The relation, being crucial for quantization, is established between the $N=2$ Poincaré and SU(1,1|2) Hamiltonian generators. We also reveal a degenerate $N=4$ supersymmetry in the model and a special case of degenerate coorbits, which appear in the BPS limit.

In Sec. IV we suggest a quantization procedure for the classical mechanics constructed in Sec. III. At first the Berezin quantization is considered on the regular OSp(2|2) coadjoint orbit. In particular, we construct the correspondence between symbols and operators on $\mathcal{L}^{1|2}$ and prove the underlying correspondence principle. Then these results are applied to the consistent quantization of the $D=3$, $N=2$ superparticle, which is the final object of construction.

II. MINIMAL AND EXTENDED PHASE SPACES OF A CANONICAL MODEL OF SPINNING PARTICLE

First consider the nonsupersymmetric canonical model of the particle (various formulations, see Refs. 12, 6, 7, 14, and 17), which serves as an initial subject for further generalizations. The particle lives originally on six-dimensional phase space $\mathcal{M}^6$ with a symplectic two-form

$$\Omega_s = -dx^a \wedge dp_a + \Omega_m, \quad \Omega_m = \frac{s}{2}\frac{\epsilon^{abc} p_a dp_b \wedge dp_c}{(-p^2)^{3/2}}, \quad p^2 < 0, \tag{2.1}$$

where Ω_m is known as the Dirac monopole form. [We use Latin letters to denote the $D=3$ Lorentz vectors and Greek letters for the SU(1,1) spinors; the Minkowski metric is chosen to be $\eta_{ab} = \mathrm{diag}(-1,1,1)$, the totally antisymmetric tensor is normalized by the condition $\epsilon_{012} = -\epsilon^{012} = 1$; the spinor indices are raised and lowered with the use of the spinor metric $\epsilon^{\alpha\beta} = -\epsilon^{\beta\alpha} = -\epsilon_{\alpha\beta}$ $(\alpha,\beta = 0,1)$, $\epsilon^{01} = -1$ by the rule $\psi_\alpha = \epsilon_{\alpha\beta}\psi^\beta$, $\psi^\alpha = \epsilon^{\alpha\beta}\psi_\beta$.] The Poincaré transformations are generated by the following functions:

$$\mathcal{P}_a = p_a, \quad \mathcal{J}_a = \epsilon_{abc} x^b p^c - s\frac{p_a}{(-p^2)^{1/2}}, \tag{2.2}$$

which constitute the $D=3$ Poincaré algebra with respect to Poisson brackets (PBs)

$$\{\mathcal{P}_a, \mathcal{P}_b\} = 0, \quad \{\mathcal{J}_a, \mathcal{P}_b\} = \epsilon_{abc}\mathcal{P}^c, \quad \{\mathcal{J}_a, \mathcal{J}_b\} = \epsilon_{abc}\mathcal{J}^c, \tag{2.3}$$

The fundamental PBs read

$$\{x^a, x^b\} = s\frac{\epsilon^{abc} p_c}{(-p^2)^{3/2}}, \quad \{x^a, p_b\} = \delta^a{}_b, \quad \{p_a, p_b\} = 0. \tag{2.4}$$

The last two PBs mean that x^a and p_a transform as coordinates and momenta by Poincaré translations. Moreover, they are Lorentz vectors because of $\{\mathcal{J}_a, x_b\} = \epsilon_{abc} x^c$ and $\{\mathcal{J}_a, p_b\} = \epsilon_{abc} p^c$.

Let us assume that the particle dynamics on $\mathcal{M}^6$ is governed by the mass shell *constraint*

$$p^2 + m^2 = 0, \tag{2.5}$$

whereas the canonical Hamilton function is identically zero. On the mass shell, the Casimir functions of the enveloping Poincaré algebra are identically conserved: $\mathcal{P}^2 = -m^2$, $(\mathcal{P},\mathcal{J}) = ms$. We conclude that the $D=3$ particle of mass *m*, spin *s*, and energy sign $p^0/|p^0|$ lives on mass shell. From now on, we take a further restriction $p^0 > 0$, bearing in mind the supersymmetric theory, when the energy is positive essentially. The mass shell constraint generates the reparametrization (gauge) invariance for every world line of the particle. The set of world lines, being considered modulo to the gauge equivalence, is named the particle history space, the latter is isomorphic to the physical state space $\mathcal{O}_{m,s}$ of the spinning particle. The reduced symplectic manifold $\mathcal{O}_{m,s}$ is symplectomorphic to the maximal *coadjoint orbit*[27,29,32] of the $D=3$ Poincaré group.

There is a standard way to extend the canonical model to the Poincaré supersymmetry. One may substitute $dx^a \to dx^a - i(\gamma^a)_{\alpha\beta}\theta^{\alpha I} d\theta^{\beta I}$ in Eq. (2.1), introducing real Grassmann variables $\theta^{\alpha I}$, $I = 1,...,N$. The resulting symplectic superform appears to be invariant under the *N*-extended Poincaré supergroup without central charges. One may further generate central charges introducing some Wess–Zumino-type terms[40,34] in Eq. (2.1). Then, imposing the mass shell constraint (2.5), one may build the classical model of the $D=3$ superparticle of mass *m*, superspin *s*, and arbitrary fixed central charges in the 6/2*N*-dimensional phase superspace. However, it is hardly possible to conceive satisfactory quantization of this model.

Even for the canonical model without supersymmetry the realization of the coordinate operators $\hat{x}^a$ is a nontrivial problem accounting for the complicated form of the first Poisson bracket in Eqs. (2.4). A detailed analysis of Ref. 14 shows that the manifest covariance of the canonical model, being formulated in terms of the ''minimal'' phase space $\mathcal{M}^6$, is inevitably lost in quantum theory. The superextension of the canonical model makes the Poisson brackets, being quantized, much more complicated. In fact, the quantization problem in the reduced nonlinear phase superspace is not solved even for the spinless $D=3$ superparticle. Thus we will reformulate from the outset the canonical model in an ''extended'' phase space, where a hidden symmetry of the spinning particle becomes transparent and gives an efficient method for quantization making use of this symmetry. Moreover, the construction will be appropriate for intriguing superextension.

An adapted reformulation of the canonical model is suggested in Refs. 16 and 25. We observe, that the monopole two-form Ω_m in Eq. (2.1) is nothing else but the Kähler two-form on the mass hyperboloid (2.5), which gives the realization of the Lobachevsky plane $\mathcal{L}$. It will be convenient to make use of another realization of $\mathcal{L}\cong\{z\in C^1,|z|<1\}$ by an open unit disc of complex plane C^1. We rewrite the symplectic two-form (2.1) as follows:

$$\Omega_s=-dx^a\wedge dp_a+\Omega_{\mathcal{L}},\quad \Omega_{\mathcal{L}}=-2is\frac{dz\wedge d\overline{z}}{(1-z\overline{z})^2}, \tag{2.6}$$

where (recall that $p^2<0$ and we have taken $p^0>0$)

$$p^a=\sqrt{-p^2}n^a,\quad n^a=\left(\frac{1+z\overline{z}}{1-z\overline{z}},-\frac{z+\overline{z}}{1-z\overline{z}},i\frac{\overline{z}-z}{1-z\overline{z}}\right),\quad n^2\equiv-1. \tag{2.7}$$

The unit timelike Lorentz vector n^a parametrizes the points of the Lobachevsky plane.

Let us look at Eq. (2.6) from a different viewpoint. Consider a new phase space $\mathcal{M}^8\cong T^*(R^{1,2})\times\mathcal{L}$ with a symplectic two-form (2.6) and an elementary system on $\mathcal{M}^8$, whose dynamics is subjected by three constraints

$$p^a=mn^a. \tag{2.8}$$

Apparently these constraints project the extended phase space $\mathcal{M}^8$ into the same coadjoint orbit as the mass shell constraint (2.5) does for $\mathcal{M}^6$. Alternatively, one can solve explicitly only two constraints $p^a=\sqrt{-p^2}n^a$ providing the reduction $\pi_1:\mathcal{M}^8\to\mathcal{M}^6$ of extended phase space to the minimal one. In other words, we have constructed the sequence of embeddings $\mathcal{O}_{m,s}\subset\mathcal{M}^6\subset\mathcal{M}^8$. Hence, we get an equivalent description of the $D=3$ spinning particle in terms of the extended phase space $T^*(R^{1,2})\times\mathcal{L}$. The Hamiltonian generators of the canonical Poincaré transformations in $\mathcal{M}^8$ read

$$\mathcal{P}_a=p_a,\quad \mathcal{J}_a=\epsilon_{abc}x^bp^c+J_a, \tag{2.9}$$

where the spin vector J_a is expressed in terms of the ''inner'' space $\mathcal{L}$:

$$J_a=-sn_a. \tag{2.10}$$

The Hamiltonians (2.9) generate the Poincaré algebra with respect to PBs in $\mathcal{M}^8$, whereas the spin generators (2.10) span the internal Lorentz algebra related to the (holomorphic) automorphism group of the Lobachevsky plane. The latter group can be recognized as a hidden symmetry of the internal structure of spinning particle. Although this concept may seem artificial at the moment, below we will observe essentially nontrivial superextension of the hidden symmetry.

The Poincaré Casimir functions are identically conserved owing to constraints (2.8):

$$p^2+m^2=0,\quad (p,J)-ms=0. \tag{2.11}$$

A crucial detail is that the equations (2.11) define the same surface in the extended phase space as the constraints (2.8) do.

The quantization of the model in $\mathcal{M}^8$ is almost transparent. We can combine the canonical Dirac quantization in $T^*(R^{1,2})$ and the Berezin quantization in the Lobachevsky plane.[25] Constraints (2.11) will be imposed in Hilbert space to separate the one-particle states.

Finally, write down the Lagrangian of the theory. One may choose the action functional as an integrand of the one-form Θ, where $d\Theta=\Omega_s+V$ and V vanishes on shell. Let us take

$$S=\int\Theta,\quad \Theta=p_a dx^a+is\frac{\bar{z}dz-zd\bar{z}}{1-z\bar{z}}\equiv p_a dx^a+\Sigma_{\mathcal{L}},\quad d\Sigma_{\mathcal{L}}=\Omega_{\mathcal{L}}. \tag{2.12}$$

It is implied here that the virtual paths lay in the constraint surface (2.8). Excluding the momenta accounting for constraints (2.8) and making pull back of Θ, one obtains the action functional

$$S=\int_{\tau_1}^{\tau_2}L\,d\tau,\quad L=m(\dot{x},n)+is\frac{\bar{z}\dot{z}-z\dot{\bar{z}}}{1-z\bar{z}}, \tag{2.13}$$

with the first-order Lagrangian being invariant under reparametrizations. Notice that the Lagrangian is also strongly invariant under translations and spatial rotations, whereas the Lorentz boosts change it by a total derivative.

III. CLASSICAL MODEL OF $D=3$ SPINNING SUPERPARTICLE

A. A first-order Lagrangian

Introduce an $N=2$ superextension of the Lagrangian (2.13) providing both the super-Poincaré invariance of the theory and other hidden supersymmetry as well. Introducing a pair of Majorana anticommuting spinors $\theta^{\alpha I}=(\theta^\alpha,\chi^\alpha)$, $I=1,2$, we suggest

$$L=m(\Pi,n)+mb(\theta_\alpha\dot{\chi}^\alpha-\chi_\alpha\dot{\theta}^\alpha)-mb\,\theta^\alpha n_{\alpha\gamma}\dot{n}^\gamma{}_\beta\chi^\beta+is\frac{\bar{z}\dot{z}-z\dot{\bar{z}}}{1-z\bar{z}}, \tag{3.1}$$

where m,b,s are real parameters, n^a is a unit Lorentz vector in the Lobachevsky plane, being defined by Eq. (2.7), and

$$n_{\alpha\beta}\equiv n^a\gamma_{a\alpha\beta},\quad \Pi^a=\dot{x}^a-i\gamma^a_{\alpha\beta}(\theta^\alpha\dot{\theta}^\beta+\chi^\alpha\dot{\chi}^\beta).$$

The three-dimensional Dirac matrices γ_a are chosen in the form

$$(\gamma_0)_{\alpha\beta}=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad(\gamma_1)_{\alpha\beta}=\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad(\gamma_2)_{\alpha\beta}=\begin{pmatrix}-i&0\\0&i\end{pmatrix},$$

$$(\gamma_a)_{\alpha\gamma}(\gamma_b)^\gamma{}_\beta=i\epsilon_{abc}(\gamma^c)_{\alpha\beta}-\eta_{ab}\epsilon_{\alpha\beta}.$$

[One may wonder why the γ-matrices are not Hermitian. It is instructive to note that the reality condition for SU(1,1) spinor formalism is not trivial, as for isomorphic SL(2,$\mathbb{R}$) ones. For any $g\in$ SU(1,1) the complex conjugation reads $\bar{g}=cgc$, where $c=c^{-1}=\mathrm{antidiag}(-1,-1)$. The matrices $c\gamma^a$ are truly Hermitian. The covariant Majorana (reality) condition looks like

$$c\bar{\psi}=\psi \tag{3.2}$$

for two-component SU(1,1)-spinor ψ.] The first term in the Lagrangian (3.1) is a conventional superextension of the respective expression in Eq. (2.13) and the second addend represents the Wess–Zumino-type term generating the central charge for the supersymmetry.[40] At last, the third term accounts for the specific of the $D=3$ spinning superparticle model. Owing to this addend, the supertranslations, underlying Poincaré supersymmetry of the Lagrangian, read rather unusually:

$$\delta_\epsilon x^a = i\gamma^a_{\alpha\beta}\epsilon^\alpha\theta^\beta + ib\epsilon^{abc}n_b\gamma_{c\alpha\beta}\epsilon^\alpha\chi^\beta + bn^a\epsilon^\alpha\chi_\alpha, \quad \delta_\epsilon\theta^\alpha = \epsilon^\alpha, \quad \delta_\epsilon\chi^\alpha = 0, \quad \delta_\epsilon z = 0$$
$$\delta_\eta x^a = i\gamma^a_{\alpha\beta}\eta^\alpha\chi^\beta - ib\epsilon^{abc}n_b\gamma_{c\alpha\beta}\eta^\alpha\theta^\beta - bn^a\eta^\alpha\theta_\alpha, \quad \delta_\eta\theta^\alpha = 0, \quad \delta_\eta\chi^\alpha = \eta^\alpha, \quad \delta_\eta z = 0. \tag{3.3}$$

Here ϵ^α and η^α are odd real parameters. For completeness, expose also the even infinitesimal Poincaré transformations and U(1) transformations as well:

$$\delta_\omega x^a = \epsilon^{abc}\omega_b x_c, \quad \delta_\omega\theta^\alpha = -\frac{i}{2}\omega^a\gamma_a{}^\alpha{}_\beta\theta^\beta \quad \delta_\omega\chi^\alpha = -\frac{i}{2}\omega^a\gamma_a{}^\alpha{}_\beta\chi^\beta, \quad \delta_\omega z = i\omega^a\xi_a,$$
$$\delta_f x^a = f^a, \quad \delta_f\theta^\alpha = \delta_f\chi^\alpha = 0, \quad \delta_f z = 0, \tag{3.4}$$
$$\delta_\mu x^a = 0, \quad \delta_\mu\theta^\alpha = -\mu\theta^\alpha, \quad \delta_\mu\chi^\alpha = \mu\theta^\alpha, \quad \delta_\mu z = 0,$$

with the even real parameters ω^a, f^a, and μ and the holomorphic object $\xi_a = -1/2(2z, 1+z^2, i(1-z^2))$. The infinitesimal transformations (3.4) and (3.3) generate the $N=2$ Poincaré superalgebra, which is discussed in Sec. III C.

B. Extended phase superspace

We show in this subsection that the superparticle being described by the Lagrangian (3.1) lives in a supersymplectic phase space $\mathcal{M}^{8|4}$ of very special supergeometry: $\mathcal{M}^{8|4} \cong T^*(R^{1,2}) \times \mathcal{L}^{1|2}$. Then we identify $\mathcal{L}^{1|2}$ with regular (when $|b|<1$) or degenerate (when $|b|=1$) coadjoint orbit of the OSp(2|2) supergroup. Having the goal to quantize the theory in $\mathcal{M}^{8|4}$, we will need detailed information about SUSYs and quantization in $\mathcal{L}^{1|2}$. The supersymplectic geometry of $\mathcal{L}^{1|2}$ is considered in Sec. III D, while the Berezin quantization will be constructed in IV A.

The model (3.1) fits naturally into the formulation in symplectic language. The theory originates from the action functional

$$S = \int \Theta^{\mathrm{SUSY}}, \quad \Theta^{\mathrm{SUSY}} = p_a dx^a + \Sigma_{\mathcal{L}^{1|2}}, \tag{3.5}$$

$$\Sigma_{\mathcal{L}^{1|2}} = -imn_{\alpha\beta}\theta^\alpha d\theta^\beta - imn_{\alpha\beta}\chi^\alpha d\chi^\beta + mb\theta_\alpha d\chi^\alpha - mb\chi_\alpha d\theta^\alpha$$
$$-2mb\frac{z^\alpha z^\beta\theta_\alpha\chi_\beta d\bar{z} - \bar{z}^\alpha\bar{z}^\beta\theta_\alpha\chi_\beta dz}{(1-z\bar{z})^2} + is\frac{\bar{z}dz - zd\bar{z}}{1-z\bar{z}}, \tag{3.6}$$

where the virtual paths belong to the surface

$$p^a = mn^a, \tag{3.7}$$

as follows from the definition $p_a = \partial L/\partial\dot{x}^a$. Introduce the objects

$$z^\alpha \equiv (1,z), \quad \bar{z}^\alpha \equiv (\bar{z},1), \quad \alpha = 0,1, \tag{3.8}$$

which simplifies Eq. (3.6) and many of the forthcoming formulas.

Relation (3.5) shows that the particle dynamics is embedded in phase superspace $\mathcal{M}^{8|4} \cong T^*(R^{1,2}) \times \mathcal{L}^{1|2}$ with some inner superspace of a real dimension 2/4 denoted by $\mathcal{L}^{1|2}$. The symplectic two-superform in $\mathcal{M}^{8|4}$ reads

$$\Omega_s^{\mathrm{SUSY}} = d\Theta^{\mathrm{SUSY}} = -dx^a \wedge dp_a + \Omega_{\mathcal{L}^{1|2}}, \quad \Omega_{\mathcal{L}^{1|2}} = d\Sigma_{\mathcal{L}^{1|2}}. \tag{3.9}$$

The inner superspace is an $N=2$ superextension of the Lobachevsky plane. We show at first that $\mathcal{L}^{1|2}$ coincides with a coadjoint orbit of the OSp(2|2) supergroup. Let us introduce new complex Grassmann variables ($m\neq 0$, $s\neq 0$)

$$\theta=\sqrt{\frac{m}{s}}(iz^{\alpha}\chi_{\alpha}-z^{\alpha}\theta_{\alpha})\left[1+m\frac{1-b}{4s}(\theta^{\alpha}\theta_{\alpha}+\chi^{\alpha}\chi_{\alpha})\right],\quad \bar{\theta}=\overline{(\theta)},$$
$$\chi=\sqrt{\frac{m}{s}}(iz^{\alpha}\theta_{\alpha}-z^{\alpha}\chi_{\alpha})\left[1+m\frac{1+b}{4s}(\theta^{\alpha}\theta_{\alpha}+\chi^{\alpha}\chi_{\alpha})\right],\quad \bar{\chi}=\overline{(\chi)}, \tag{3.10}$$

which are in one-to-one correspondence with the Majorana spinors θ^{α} and χ^{α} used before.

It is easy to check that the symplectic two-superform

$$\Omega_{\mathcal{L}^{1|2}}=d\Sigma_{\mathcal{L}^{1|2}} \tag{3.11}$$

in the new holomorphic variables (3.10) exactly coincides with the one deduced by Gradechi and Nieto[39] in the supercoherent state's approach for the OSp(2|2) coadjoint orbits. $\Omega_{\mathcal{L}^{1|2}}$ is nondegenerate iff $|b|\neq 1$. In the case $|b|<1$, the supermanifold $\mathcal{L}^{1|2}$ is the regular OSp(2|2) coadjoint orbit $\mathcal{L}^{1|2}\cong$OSp(2|2)/[U(1)×U(1)] and is called the $N=2$ superunit disc. The degenerate orbit OSp(2|2)/U(1|1), which is denoted usually by $\mathcal{L}^{1|1}$ and called the $N=1$ superunit disc, appears when $|b|=1$. The other possibility, $|b|>1$, has no physical significance: neither the Poincaré supersymmetry nor the internal OSp(2|2) one admit unitary representations. It is seen from further consideration that the inequality $|b|>1$ contradicts the BPS bound.

C. Observables and the physical subspace

Consider in detail the realization of the Poincaré supersymmetry in the extended phase superspace $\mathcal{M}^{8|4}\cong T^{*}(R^{1,2})\times\mathcal{L}^{1|2}$. The Poincaré supergroup is realized by a symplectic action leaving the coadjoint orbit (3.7) invariant. The vector superfields generating the transformations (3.3) and (3.4) are related to the corresponding canonical Hamiltonian generators by

$$X_{H}\lrcorner\Omega_{s}^{\mathrm{SUSY}}=-(-1)^{\epsilon_{H}}dH, \tag{3.12}$$

where ϵ_{H} is the Grassmann parity of the Hamiltonian H. Solving these equations one gets the following Hamiltonian generators [we denote the generator of isotopic U(1) rotations by P_{3}]:

$$\mathcal{P}_{a}=p_{a},\quad \mathcal{J}_{a}=\epsilon_{abc}x^{b}p^{c}-sn_{a}+\tfrac{1}{2}mn_{a}(\theta^{\alpha}\theta_{\alpha}+\chi^{\alpha}\chi_{\alpha}-2ibn_{\alpha\beta}\theta^{\alpha}\chi^{\beta}),$$
$$\mathcal{Q}_{\alpha}^{1}=ip_{\alpha\beta}(\theta^{\beta}-ibn^{\beta}{}_{\gamma}\chi^{\gamma})+m(in_{\alpha\beta}\theta^{\beta}+b\chi_{\alpha}),\quad p_{\alpha\beta}\equiv p_{a}\gamma^{a}_{\alpha\beta},$$
$$\mathcal{Q}_{\alpha}^{2}=ip_{\alpha\beta}(\chi^{\beta}+ibn^{\beta}{}_{\gamma}\theta^{\gamma})+m(in_{\alpha\beta}\chi^{\beta}-b\theta_{\alpha}), \tag{3.13}$$
$$P_{3}=imn_{\alpha\beta}\theta^{\alpha}\chi^{\beta}-\frac{mb}{2}(\theta^{\alpha}\theta_{\alpha}+\chi^{\alpha}\chi_{\alpha}).$$

With respect to Poisson superbrackets on $\mathcal{M}^{8|4}$ they generate the following superalgebra:

$$\{\mathcal{J}_{a},\mathcal{J}_{b}\}=\epsilon_{abc}\mathcal{J}^{c},\quad \{\mathcal{J}_{a},\mathcal{P}_{b}\}=\epsilon_{abc}\mathcal{P}^{c},\quad \{\mathcal{J}_{a},\mathcal{Q}_{\alpha}^{I}\}=-\frac{i}{2}(\gamma_{a})_{\alpha}{}^{\beta}\mathcal{Q}_{\beta}^{I},$$
$$\{\mathcal{Q}_{\alpha}^{I},P_{3}\}=-\tfrac{1}{2}\epsilon^{IJ}\mathcal{Q}_{\alpha}^{J},\quad \{\mathcal{Q}_{\alpha}^{I},\mathcal{Q}_{\beta}^{J}\}\approx-2i\delta^{IJ}p_{\alpha\beta}-2\epsilon^{IJ}\epsilon_{\alpha\beta}\mathcal{Z},\quad \mathcal{Z}=mb, \tag{3.14}$$

the other brackets being equal to zero and $I,J=1,2$, $\epsilon^{IJ}=-\epsilon^{JI}$, $\epsilon^{01}=1$. We stress that the latter bracket $\{\mathcal{Q}_{\alpha}^{I},\mathcal{Q}_{\beta}^{J}\}$ is closed only in a weak sense, that is, modulo to constraints (3.7). What we have obtained is the $N=2$, $D=3$ Poincaré superalgebra with central charge $\mathcal{Z}=mb$ and isotopic charge P_{3} acting on the internal indices of supercharges $\mathcal{Q}_{\alpha}^{I}$.

One can easily examine that the mass and the spin Casimir functions of the superalgebra (3.14) read $C_1 \equiv \mathcal{P}^a \mathcal{P}_a = p^2$ and $C_2 \equiv \mathcal{P}^a \mathcal{J}_a + \frac{1}{8} \mathcal{Q}^{I\,\alpha} \mathcal{Q}^I_\alpha - \mathcal{Z} P_3 = -s(p,n)$. On the constraint surface (3.7),

$$p^2 + m^2 = 0, \quad (p,n) + m = 0, \tag{3.15}$$

the Casimirs are conserved identically. Equations (3.15) and (3.7) are completely equivalent to each other, in other words, they define one and the same surface in the phase superspace $\mathcal{M}^{8|4}$. We conclude that the mechanical model describes the $N=2$, $D=3$ superparticle of mass m, superspin s, and central charge mb.

Regular and degenerate cases are essentially distinguished for the coadjoint orbit, being associated for the superparticle. Since the massless and spinless particles are not covered in our model, the Bogomol'nyi–Prassad–Sommerfield bound of central charge (see, for instance, Ref. 41) assumes the only possibility for the degeneracy. The BPS bound $m \geqslant |\mathcal{Z}|$ provides, as is known, consistency of the quantum theory; the opposite inequality breaks the unitarity. As we have the goal to construct the quantum theory, we may restrict the consideration to the case of $|b| \leqslant 1$. Furthermore, the limiting point $|b| = 1$ corresponds to the multiplet-shortening.[41] It is the case $m = |\mathcal{Z}|$ when the massive multiplet contains the same number of particles as a massless one. These massive multiplets are called hypermultiplets. In the case of the $N=2$, $D=3$ Poincaré superalgebra, a massive supermultiplet of superspin s describes a quartet of particles with spins $s, s+\frac{1}{2}, s+\frac{1}{2}, s+1$ for $m > |\mathcal{Z}|$ and a doublet $s, s+\frac{1}{2}$ for $m = |\mathcal{Z}|$. The shortening of the superparticle multiplet has the respective origin in the classical mechanics: the number of odd physical degrees of freedom of the superparticle halved in the BPS limit. Let us show that it is the case which is described by our model.

Reducing to the constraints (3.15) [or, equivalently, (3.7)] we come to the smaller 5/4-dimensional phase space $\mathcal{M}^{5|4} \subset \mathcal{M}^{8|4}$ with a degenerate symplectic two-superform

$$\Omega_s^{\mathrm{SUSY}}\big|_{p_a = m n_a} \equiv \Omega_s^{\mathrm{red}} = -m\, dx^a \wedge dn_a + \Omega_{\mathcal{L}^{1|2}}, \quad dn_a \equiv \frac{2\xi_a d\bar{z} + 2\bar{\xi}_a dz}{(1 - z\bar{z})^2}, \tag{3.16}$$

where $\Omega_{\mathcal{L}^{1|2}}$ is defined by Eq. (3.11) and

$$\xi_a = -\tfrac{1}{2}(\gamma_a)_{\alpha\beta} z^\alpha z^\beta = -\tfrac{1}{2}(2z, 1+z^2, i(z^2-1)), \quad \bar{\xi}_a = \overline{(\xi_a)}. \tag{3.17}$$

The kernel of the two-superform (3.16) contains obviously the even one-dimensional null space $\mathrm{Ker}_0 \Omega_s^{\mathrm{red}}$, related to the reparametrization invariance of the world lines. In the coset superspace $\mathcal{O}_{m,s,b} = \mathcal{M}^{5|4} / \mathrm{Ker}_0\, \Omega_s^{\mathrm{red}}$ the induced symplectic two-superform is nondegenerate when $|b| < 1$; the same is true in $\mathcal{L}^{1|2}$ for the respective superform $\Omega_{\mathcal{L}^{1|2}}$. Therefore, $\mathcal{O}_{m,s,b}$, $\dim \mathcal{O}_{m,s,b} = 4/4$, $|b| < 1$ is isomorphic to a regular coadjoint orbit of the $N=2$, $D=3$ Poincaré supergroup. We have established both the embedding of the regular orbit into the original phase superspace and the underlying projection $\pi: \mathcal{M}^{8|4} \to \mathcal{O}_{m,s,b}$, provided by constraints (3.15).

In the BPS limit $|b| = 1$, the inner two-superform $\Omega_{\mathcal{L}^{1|2}}$ generates a 0/2-dimensional null-vector superspace. To make the degeneracy more evident we introduce for a while new odd variables

$$\tilde{\theta}^\alpha = \theta^\alpha - i n^\alpha{}_\beta \chi^\beta, \quad \tilde{\chi}^\alpha = \chi^\alpha - i n^\alpha{}_\beta \theta^\beta$$

instead of $\theta^\alpha, \chi^\alpha$. This change of the odd variables is one-to-one, and the original Lagrangian (3.1) reads in new variables as

$$L = m(\dot{x}, n) - im \frac{1+b}{2} n_{\alpha\beta} \tilde{\theta}^\alpha \dot{\tilde{\theta}}^\beta - im \frac{1-b}{2} n_{\alpha\beta} \tilde{\chi}^\alpha \dot{\tilde{\chi}}^\beta + is \frac{\bar{z}\dot{z} - z\dot{\bar{z}}}{1 - z\bar{z}}. \tag{3.1$'$}$$

It is seen immediately that half of the odd degrees of freedom of the superparticle drops out from the theory in the case of $|b|=1$. The full kernel Ker Ω_s^{red} of the symplectic two-superform on $\mathcal{M}^{5|4}$ becomes 1/2-dimensional if $|b|=1$. The 4/2-dimensional coset superspace $\mathcal{O}_{m,s}=\mathcal{M}^{5|4}/\mathrm{Ker}\,\Omega_s^{\mathrm{red}}$ corresponds to a degenerate orbit of the $N=2$ Poincaré supergroup. Hence, the number of odd physical degrees of freedom of the $N=2$, $D=3$ superparticle halved actually in the BPS limit and we observe an evident classical analog of the multiplet-shortening. Moreover, in the BPS limit, expression (3.1′) reduces to the Lagrangian of the $N=1$, $D=3$ superparticle[25] and does describe after quantization not a superquartet, but a supersymmetric doublet of particles of equal mass m and spins s and $s+\frac{1}{2}$ only.

D. Hidden su(1,1|2) supersymmetry of the superspin degrees of freedom

We have shown that the superparticle dynamics is embedded in the phase superspace $\mathcal{M}^{8|4}\cong T^*(R^{1,2})\times\mathcal{L}^{1|2}$. One can imply that the inner supermanifold $\mathcal{L}^{1|2}$ carries internal (both even and odd) degrees of freedom of the $D=3$ particle. Then the symplectomorphisms of $\mathcal{L}^{1|2}$ should be treated as the hidden supersymmetry of the particle internal structure. Consider this supersymmetry in more detail. To be specific, let us assume that $|b|<1$. The degenerate case is already discussed in Ref. 25.

We have already mentioned that $\mathcal{L}^{1|2}$ is a homogeneous OSp(2|2) superspace. Introducing new odd complex variables (3.10), we established that the symplectic two-superform (3.11) reduces to the superform on the regular OSp(2|2) coadjoint orbit obtained earlier in Refs. 38 and 39 in the framework of the supercoherent state technique. A crucial point is that $\mathcal{L}^{1|2}$ reveals a *Kähler* supermanifold structure with the superpotential

$$\Phi=-2s\ln(1-z\bar{z})-s(1+b)\frac{\theta\bar{\theta}}{1-z\bar{z}}-s(1-b)\frac{\chi\bar{\chi}}{1-z\bar{z}}+\frac{s(1-b^2)}{2}\frac{\theta\bar{\theta}\chi\bar{\chi}}{(1-z\bar{z})^2},\tag{3.18}$$

so that

$$\Omega_{\mathcal{L}^{1|2}}=i\left(d\bar{z}\frac{\partial}{\partial\bar{z}}+d\bar{\theta}\frac{\vec{\partial}}{\partial\bar{\theta}}+d\bar{\chi}\frac{\vec{\partial}}{\partial\bar{\chi}}\right)\wedge\left(dz\frac{\partial}{\partial z}+d\theta\frac{\vec{\partial}}{\partial\theta}+d\chi\frac{\vec{\partial}}{\partial\chi}\right)\Phi,$$

and OSp(2|2) acts on the $N=2$ superunit disc by the *superholomorphic* transformations. Moreover, the supergroup of the superholomorphic symplectomorphisms of $\mathcal{L}^{1|2}$ is, in fact, essentially larger than OSp(2|2) and it contains at least the supergroup SU(1,1|2). The corresponding infinitesimal transformations read

$$\delta z=i\omega^a\xi_a-\frac{\sqrt{1+b}}{2}\epsilon_\alpha z^\alpha\theta-\frac{\sqrt{1-b}}{2}\eta_\alpha z^\alpha\chi,$$

$$\delta\theta=\frac{i}{2}\omega^a\partial\xi_a\theta+\frac{i}{2}\sqrt{\frac{1-b}{1+b}}\mu_1\chi-\frac{i}{2}(\mu_2+\mu_3)\theta-\frac{1}{\sqrt{1+b}}\bar{\epsilon}_\alpha z^\alpha-\frac{\sqrt{1-b}}{2}\eta_\alpha\partial z^\alpha\theta\chi,\tag{3.19}$$

$$\delta\chi=\frac{i}{2}\omega^a\partial\xi_a\chi-\frac{i}{2}\sqrt{\frac{1+b}{1-b}}\bar{\mu}_1\theta-\frac{i}{2}(\mu_2-\mu_3)\chi+\frac{\sqrt{1+b}}{2}\epsilon_\alpha\partial z^\alpha\theta\chi-\frac{1}{\sqrt{1-b}}\bar{\eta}_\alpha z^\alpha,$$

where $\partial\equiv\partial/\partial z$, even parameters ω^a, μ_2, and μ_3 are real, even parameter μ_1 is complex, and the odd ones ϵ_α and η_α are complex. Transformations (3.19) are generated by the following Hamiltonians, which may be obtained straightforwardly solving Eqs. (3.12). There are seven (real) even Hamiltonians,

$$J_a=-sn_a\left(1-\frac{1+b}{2}\frac{\theta\overline{\theta}}{1-z\overline{z}}-\frac{1-b}{2}\frac{\chi\overline{\chi}}{1-z\overline{z}}+\frac{1-b^2}{2}\frac{\theta\overline{\theta}\chi\overline{\chi}}{(1-z\overline{z})^2}\right),$$

$$P_1=s\frac{\sqrt{1-b^2}}{2}\frac{\theta\overline{\chi}-\overline{\theta}\chi}{1-z\overline{z}},\quad P_3=-s\left(\frac{1+b}{2}\frac{\theta\overline{\theta}}{1-z\overline{z}}-\frac{1-b}{2}\frac{\chi\overline{\chi}}{1-z\overline{z}}\right), \tag{3.20a}$$

$$P_2=is\frac{\sqrt{1-b^2}}{2}\frac{\theta\overline{\chi}+\overline{\theta}\chi}{1-z\overline{z}},\quad P_4=-s\left(\frac{1+b}{2}\frac{\theta\overline{\theta}}{1-z\overline{z}}+\frac{1-b}{2}\frac{\chi\overline{\chi}}{1-z\overline{z}}-\frac{1-b^2}{2}\frac{\theta\overline{\theta}\chi\overline{\chi}}{(1-z\overline{z})^2}\right),$$

and eight odd ones,

$$E^\alpha=s\sqrt{1+b}\left(\frac{z^\alpha\overline{\theta}-\overline{z}^\alpha\theta}{1-z\overline{z}}\right)\left(1-\frac{1-b}{2}\frac{\chi\overline{\chi}}{1-z\overline{z}}\right),\quad F^\alpha=in^\alpha{}_\beta E^\beta$$

$$G^\alpha=s\sqrt{1-b}\left(\frac{z^\alpha\overline{\chi}-\overline{z}^\alpha\chi}{1-z\overline{z}}\right)\left(1-\frac{1+b}{2}\frac{\theta\overline{\theta}}{1-z\overline{z}}\right),\quad H^\alpha=in^\alpha{}_\beta G^\beta. \tag{3.20b}$$

These Hamiltonians, together with one more even element $Z\equiv s$, generate a closed superalgebra with respect to Poisson superbrackets on $\mathcal{L}^{1|2}$ (the explicit form of these superbrackets may be found in Ref. 36). This is the so-called su(1,1|2) superalgebra,[42] whose even part is $\mathrm{su}(1,1|2)_0=\mathrm{su}(1,1)\oplus\mathrm{u}(2)\oplus R=\{J_a,P_I,Z\}$ and the odd part constitutes an eight-dimensional module of the even part; Z presents a central charge. The osp(2|2) subsuperalgebra found in Refs. 38 and 39 is spanned by J_a, B, $\sqrt{ms}V^\alpha$, and $\sqrt{ms}W^\alpha$, where V^α and W^α are defined below by Eqs. (3.26) and, $B=P_3-bZ$. We reveal that the $N=2$ superunit disc is not only a typical coadjoint orbit of the OSp(2|2) supergroup, $\mathcal{L}^{1|2}\cong\mathrm{OSp}(2|2)/[\mathrm{U}(1)\times\mathrm{U}(1)]$, but it can be treated simultaneously as an atypical Kähler orbit of the supergroup $\mathrm{SU}(1,1|2):\mathcal{L}^{1|2}\cong\mathrm{SU}(1,1|2)/[\mathrm{U}(2|2)\times\mathrm{U}(1)]$.

E. Hidden $N=4$ Poincaré supersymmetry

Subalgebra u(2) of the internal su(1,1|2) superalgebra acts on the odd variables, as is seen from Eqs. (3.19). It is exactly the subalgebra of the isotopic symmetry. However, the isotopic U(2) symmetry may now be involved in the Poincaré supersymmetry. The isotopic rotations together with the $N=2$ Poincaré transformations (3.3) and (3.4) generate (when $|b|\neq 1$) the wider $D=3$, $N=4$ Poincaré superalgebra. In addition to (3.3) there are the following supersymmetry transformations:

$$\delta_{\tilde{\epsilon}}x^a=ib\gamma^a_{\alpha\beta}\tilde{\epsilon}^\alpha\chi^\beta-i\epsilon^{abc}n_b\gamma_{c\alpha\beta}\tilde{\epsilon}^\alpha\theta^\beta+n^a\tilde{\epsilon}^\alpha\theta_\alpha,\quad \delta_{\tilde{\epsilon}}\theta^\alpha=-in^\alpha{}_\beta\tilde{\epsilon}^\beta,\quad \delta_{\tilde{\epsilon}}\chi^\alpha=\delta_{\tilde{\epsilon}}z=0,$$

$$\delta_{\tilde{\eta}}x^a=-ib\gamma^a_{\alpha\beta}\tilde{\eta}^\alpha\theta^\beta-i\epsilon^{abc}n_b\gamma_{c\alpha\beta}\tilde{\eta}^\alpha\chi^\beta+n^a\tilde{\eta}^\alpha\chi_\alpha,\quad \delta_{\tilde{\eta}}\chi^\alpha=-in^\alpha{}_\beta\tilde{\eta}^\beta,\quad \delta_{\tilde{\eta}}\theta^\alpha=\delta_{\tilde{\eta}}z=0, \tag{3.21}$$

where $\overline{\epsilon}^\alpha,\overline{\eta}^\alpha$ are odd infinitesimal parameters. The respective Hamiltonians on $\mathcal{M}^{8|4}$ read

$$\tilde{\mathcal{Q}}^1_\alpha=ip_{\alpha\beta}(in^\beta{}_\gamma\theta^\gamma+b\chi^\beta)-m(\theta_\alpha-ibn_{\alpha\beta}\chi^\beta)\approx-\frac{i}{m}p_\alpha{}^\beta\mathcal{Q}^1_\beta,$$

$$\tilde{\mathcal{Q}}^2_\alpha=ip_{\alpha\beta}(in^\beta{}_\gamma\chi^\gamma-b\theta^\beta)-m(\chi_\alpha+ibn_{\alpha\beta}\theta^\beta)\approx-\frac{i}{m}p_\alpha{}^\beta\mathcal{Q}^2_\beta. \tag{3.22}$$

New supercharges together with $N=2$ superpoincaré Hamiltonians (3.13) and isotopic U(2) Hamiltonians P^I, $I=1,2,3,4$ generate the closed $N=4$ Poincaré superalgebra with one central charge. It can be seen by introducing a new basis for supercharges $2\mathcal{R}^I_\alpha=(\mathcal{Q}^1_\alpha+\tilde{\mathcal{Q}}^2_\alpha,\mathcal{Q}^2_\alpha-\tilde{\mathcal{Q}}^1_\alpha)$, $2\tilde{\mathcal{R}}^I_\alpha=(\tilde{\mathcal{Q}}^1_\alpha+\mathcal{Q}^2_\alpha,\tilde{\mathcal{Q}}^2_\alpha-\mathcal{Q}^1_\alpha)$, $I=1,2$. On shell (3.7) we have

$$\{\mathcal{R}^I_\alpha,\mathcal{R}^J_\beta\}\approx(1-b)(-i\delta^{IJ}p_{\alpha\beta}+m\epsilon^{IJ}\epsilon_{\alpha\beta}),$$
$$\{\tilde{\mathcal{R}}^I_\alpha,\tilde{\mathcal{R}}^J_\beta\}\approx(1+b)(-i\delta^{IJ}p_{\alpha\beta}+m\epsilon^{IJ}\epsilon_{\alpha\beta}),\quad \{\mathcal{R}^I_\alpha,\tilde{\mathcal{R}}^J_\beta\}\approx 0. \tag{3.23}$$

The invariance of the original Lagrangian (3.1) under the transformations (3.21) can be examined straightforwardly. Thus, the model, being $N=2$ super-Poincaré invariant by construction, allows the hidden $N=4$ supersymmetry. The appearance of the enhanced supersymmetry is hardly surprising in the model. This $N=4$ supersymmetry is degenerate in a sense that the corresponding central charges equals to m and, so, they saturate the BPS bound for the $N=4$ Poincaré superalgebra. It reflects the degeneracy of the $N=4$ supersymmetry and the shortening of the $N=4$ superparticle multiplet to the $N=2$ supermultiplet in quantum theory. Moreover, it is a general property of extended supersymmetry that some of the degenerate multiplets of a larger SUSY (those which saturate the BPS bound) have the same particle content, as is observed in the respective multiplets of a smaller SUSY. This fact provides a simple reason why some of supersymmetric theories may have the extended supersymmetries. The precedents are known both for $D=4,6,10$ superparticle models[43] and supersymmetric field theories (for example, the theories with nontrivial topological charge[44]). The $D=3$, $N=1$ superparticle allows the hidden $N=2$ SUSY.[25]

F. Relationship between Hamiltonian generators of the Poincaré and internal supersymmetries

We have observed that the model contains both the global Poincaré SUSY and the hidden SU(1,1|2). The latter is closely related to the superspin intrinsic structure. Thus, the relevant quantization procedure should make a provision for either symmetry to survive in quantum theory. This quantization can be based on the simple fact that the Hamiltonian generators (3.13) and (3.22) of the Poincaré supersymmetries, being the functions on $\mathcal{M}^{8|4}\cong T^*(R^{1,2})\times\mathcal{L}^{1|2}$, can be expressed in terms of the Minkowski-space coordinates and momenta (x^a,p_a) and of the su(1,1|2) Hamiltonians J_a, P_I, E^α, F^α, G^α, and H^α (3.20), which parametrize the coadjoint orbit $\mathcal{L}^{1|2}$. We give here the explicit form of these expressions:

$$\mathcal{J}_a=\epsilon_{abc}x^bp^c+J_a,\quad \mathcal{P}_a=p_a,\quad \mathcal{Z}=mb,$$
$$\mathcal{Q}^1_\alpha=(ip_{\alpha\beta}W^\beta+m\tilde{W}_\alpha)[1+q^{cl}(bP_3-\sqrt{1-b^2}P_2-P_4)], \tag{3.24}$$
$$\mathcal{Q}^2_\alpha=(ip_{\alpha\beta}V^\beta+m\tilde{V}_\alpha)[1+q^{cl}(bP_3+\sqrt{1-b^2}P_2-P_4)],$$

$$\tilde{\mathcal{Q}}^1_\alpha=(ip_{\alpha\beta}\tilde{W}^\beta-mW_\alpha)[1+q^{cl}(bP_3-\sqrt{1-b^2}P_2-P_4)],$$
$$\tilde{\mathcal{Q}}^2_\alpha=(ip_{\alpha\beta}\tilde{V}^\beta-mV_\alpha)[1+q^{cl}(bP_3+\sqrt{1-b^2}P_2-P_4)], \tag{3.25}$$

where

$$W^\alpha=\frac{1}{2\sqrt{ms}}(\sqrt{1+b}E^\alpha+\sqrt{1-b}H^\alpha),\quad \tilde{W}^\alpha=\frac{1}{2\sqrt{ms}}(\sqrt{1+b}F^\alpha-\sqrt{1-b}G^\alpha),$$
$$V^\alpha=\frac{1}{2\sqrt{ms}}(\sqrt{1+b}F^\alpha+\sqrt{1-b}G^\alpha),\quad \tilde{V}^\alpha=\frac{1}{2\sqrt{ms}}(\sqrt{1-b}H^\alpha-\sqrt{1+b}E^\alpha), \tag{3.26}$$

and constant q^{cl} reads as

$$q^{cl}=\frac{1}{4s}. \tag{3.27}$$

To construct an appropriate operator realization of these expressions we shall quantize (x^a, p_a) canonically and extend simultaneously su(1,1|2) Hamiltonian vector fields to a representation by Hermitian operators in Hilbert space.

Notice at once some important details in relation to the quantization which should be compatible to the full symmetry of the superparticle. First, expressions (3.24) and (3.25) are essentially *nonlinear* in the generators (3.20) of the inner su(1,1|2) superalgebra. Thus, even though the operator realization of the Poisson su(1,1|2) superalgebra is found and the corresponding operators are substituted in Eq. (3.24), we may not be sure that the representation of the Poincaré superalgebra (neither $N=2$ nor $N=4$) is reproduced for certain in quantum theory. Because of the nonlinearity, the superalgebra of operators, corresponding to (3.24), might be disclosed, and it is the parameter q that controls the possible disclosure of the Poincaré superalgebra. We will see that the parameter q^{cl} should be renormalized in quantum theory to reproduce a representation of the Poincaré supersymmetry.

Second, it is a matter of direct verification that the Hamiltonians W^α and $\tilde{W}^\alpha$ have vanishing Poisson superbrackets with $bP_3 - \sqrt{1-b^2}P_2 - P_4$, whereas V^α and $\tilde{V}^\alpha$ commute to $bP_3 + \sqrt{1-b^2}P_2 - P_4$. This point is important for Hermitian properties of supercharge operators in quantum mechanics.

IV. FIRST QUANTIZATION OF THE SUPERPARTICLE

It is a primary objective of previous consideration to present the classical model of the $N=2$, $D=3$ superparticle in the form, well adapted for a quantizing procedure. We have obtained an embedding of the (maximal) coadjoint orbit of the $N=2$ Poincaré supergroup in the extended phase superspace $\mathcal{M}^{8|4} \cong T^*(R^{1,2}) \times \mathcal{L}^{1|2}$. Going to quantum theory we will combine the canonical Dirac quantization on $T^*(R^{1,2})$ and the geometric quantization methods on the SU(1,1|2) coorbit $\mathcal{L}^{1|2}$. In particular, a combination of the standard real polarization in $T^*(R^{1,2})$ and the Kähler one in $\mathcal{L}^{1|2}$ will be used to construct the superparticle's Hilbert space.

The quantization scheme implies from the outset that the internal SU(1,1|2) supersymmetry must survive at the quantum level. Mutual relation between Hamiltonians of SU(1,1|2) and Poincaré supersymmetries, being expressed by Eq. (3.24) and (3.25), is crucial in our approach. At first, we construct the operator realization for the Hamiltonians of the su(1,1|2) superalgebra in the framework of Berezin quantization. Then the expressions (3.24) [possibly together with (3.25)] are used to obtain the realization of a unitary irreducible representation (UIR) for the $N=2$ (respectively, enhanced $N=4$) Poincaré superalgebra. We find that the classical meaning of the parameter q in (3.27) in the relations (3.24) and (3.25) should be accompanied by certain quantum corrections, referred to as a renormalization, for consistency of the quantum theory.

Eventually we obtain the straightforward $N=2$ supergeneralization of the conventional realization of the unitary irreducible representations (UIRs) of the $D=3$ Poincaré group on the fields carrying representations of $\overline{\mathrm{SO}^{\uparrow}(1,2)}$.[6,13] Two cases should be distinguished among these representations. The fields describing fractional superspin (superanyons) carry a atypical unitary *infinite-dimensional* UIRs of SU(1,1|2), whereas the UIRs of (half) integer superspin can be realized on the spin-tensor fields carrying atypical *finite dimensional* nonunitary representations of SU(1,1|2). The realization of the superparticle Hilbert space is slightly different in these two cases.

A. Berezin quantization on $\mathcal{L}^{1|2}$

The Berezin technique[30,31,45,46] provides the perfect quantization method for the Kähler homogeneous spaces. We consider here briefly the application of this method to the supermanifold $\mathcal{L}^{1|2} \cong \mathrm{OSp}(2|2)/[\mathrm{U}(1)\times\mathrm{U}(1)] \cong \mathrm{SU}(1,1|2)/[\mathrm{U}(2|2)\times\mathrm{U}(1)]$ with the nondegenerate symplectic structure when $|b|<1$. The geometric quantization on $\mathcal{L}^{1|2}$, being considered as a regular coadjoint orbit, is studied in Refs. 38 and 39 in detail. However, as we know, $\mathcal{L}^{1|2}$ has not been considered as an irregular SU(1,1|2) coorbit nor as a detailed Berezin quantization, and the underlying correspondence principle is not explicitly established.

In the following subsection we apply the obtained results for quantization of the $D=3$ superparticle.

1. Antiholomorphic sections and an inner product

Let us consider the space $\mathcal{O}_{s,b}$ of superantiholomorphic sections of the superholomorphic line bundle over $\mathcal{L}^{1|2}$, whose elements are represented by functions

$$f(\overline{\Gamma})\equiv f(\overline{z},\overline{\theta},\overline{\chi})=f_0(\overline{z})+\sqrt{s(1+b)}\,\overline{\theta}f_1(\overline{z})+\sqrt{s(1-b)}\,\overline{\chi}f_2(\overline{z})+\sqrt{s(s+1/2)(1-b^2)}\,\overline{\theta}\overline{\chi}f_3(\overline{z}), \tag{4.1}$$

where $f_i(\overline{z})$, $i=0,1,2,3$, are ordinary antiholomorphic functions on the unit disc of the complex plane. We denote by $\Gamma\equiv\{\Gamma^A\}=\{z,\theta,\chi\}$ and $\overline{\Gamma}\equiv\{\overline{\Gamma}^A\}=\{\overline{z},\overline{\theta},\overline{\chi}\}$ the sets of the superholomorphic and superantiholomorphic variables, respectively. The space $\mathcal{O}_{s,b}$ is equipped naturally by an inner product

$$\langle f|g\rangle_{\mathcal{L}^{1|2}}=\int_{\mathcal{L}^{1|2}}\overline{f(\overline{\Gamma})}g(\overline{\Gamma})e^{-\Phi(\Gamma,\overline{\Gamma})}\,d\mu(\Gamma,\overline{\Gamma}). \tag{4.2a}$$

Here $\Phi(\Gamma,\overline{\Gamma})$ is the Kähler superpotential (3.18) and $d\mu(\Gamma,\overline{\Gamma})$ is an SU(1,1|2) invariant Liouville supermeasure on $\mathcal{L}^{1|2}$. Taking into account the definition of the symplectic two-superform (3.11) $\Omega_{\mathcal{L}^{1|2}}\equiv d\Gamma^A\Omega_{A\overline{B}}d\overline{\Gamma}^B$, one can derive the supermeasure explicitly:[38,39]

$$d\mu(\Gamma,\overline{\Gamma})=-\frac{1}{4\pi}\,\mathrm{sdet}\|\Omega_{A\overline{B}}\|\,d\Gamma d\overline{\Gamma}=\frac{d\Gamma d\overline{\Gamma}}{i\pi s(1-b^2)},\quad d\Gamma d\overline{\Gamma}\equiv dz\,d\overline{z}\,d\theta\,d\overline{\theta}\,d\chi\,d\overline{\chi}. \tag{4.3}$$

Using Eqs. (3.18), (4.1), and (4.3) we can integrate out the Grassmann variables in Eq. (4.2a), which reduces the inner product to the following form:

$$\langle f|g\rangle_{\mathcal{L}^{1|2}}=\langle f_0|g_0\rangle_{\mathcal{L}}^{s}+\langle f_1|g_1\rangle_{\mathcal{L}}^{s+1/2}+\langle f_2|g_2\rangle_{\mathcal{L}}^{s+1/2}+\langle f_3|g_3\rangle_{\mathcal{L}}^{s+1}, \tag{4.2b}$$

where

$$\langle\varphi|\chi\rangle_{\mathcal{L}}^{l}=(2l-1)\int_{|z|<1}\frac{dz\,d\overline{z}}{2\pi i}(1-z\overline{z})^{2l-2}\overline{\varphi(\overline{z})}\chi(\overline{z}) \tag{4.4}$$

is an inner product in the representation space D_+^l of $\overline{\mathrm{SO}^{\uparrow}(1,2)}$ discrete series bounded below, being realized by antiholomorphic functions in the unit disc $|z|<1$. {The monomials $\phi_n^l=[\Gamma(2l+n)/\Gamma(n-1)\Gamma(2l)]^{1/2}\overline{z}^n$, n is a non-negative integer, serve as a standard orthonormal basis in D_+^l.} The inner product (4.4) is well defined and positive if $l>\frac{1}{2}$. Moreover, for values $0<l<1/2$ one can still use Eq. (4.4) if suitable analytic continuations are made. The case of $l=\frac{1}{2}$ should be understood in the sense of the limit. We conclude that the inner product (4.2) in $\mathcal{O}_{s,b}$ is well defined if $s>0$ (and, of course, if $|b|<1$.).

In view of the transformation law for Kähler superpotential $\Phi(\Gamma,\overline{\Gamma})$ under the action of SU(1,1|2) supergroup, the inner product (4.2) holds to be SU(1,1|2) invariant, if an appropriate transformation law for $f(\Gamma)\in\mathcal{O}_{s,b}$ is implemented. In other terms, the Hamiltonian action of SU(1,1|2) on $\mathcal{L}^{1|2}$ can be lifted to a unitary representation in $\mathcal{O}_{s,b}$. We give below an infinitesimal form of this representation only, that is, explicit representation of corresponding superalgebra su(1,1|2). To obtain it, we first consider a conventional correspondence between linear operators in $\mathcal{O}_{s,b}$ and Berezin's symbols.

2. Classical observables and operators

Let $A(\underline{\Gamma},\overline{\Gamma})$ be a "classical observable," that means it is a real function on $\mathcal{L}^{1|2}$ to be continuously differentiable in $z,\overline{z}$ that the integrals considered below do exist. We associate a linear operator $\hat{A}$ in $\mathcal{O}_{s,b}$ to the classical observable $A(\underline{\Gamma},\overline{\Gamma})$ by the rule

$$(\hat{A}f)(\overline{\Gamma})=\int_{\mathcal{L}^{1|2}} A(\underline{\Gamma}_1,\overline{\Gamma})f(\overline{\Gamma}_1)L_{s,b}(\underline{\Gamma}_1,\overline{\Gamma})e^{-\Phi(\underline{\Gamma}_1\overline{\Gamma}_1)}\,d\mu(\underline{\Gamma}_1,\overline{\Gamma}_1), \tag{4.5}$$

where $A(\underline{\Gamma}_1,\overline{\Gamma})$ serves only as an analytic continuation in $\mathcal{L}^{1|2}\times\mathcal{L}^{1|2}$ for classical observable $A(\underline{\Gamma},\overline{\Gamma})$. The generating kernel $L_{s,b}(\underline{\Gamma}_1,\overline{\Gamma})$ can be constructed by the use of an arbitrary complete orthonormal basis $f_k(\overline{\Gamma})$ in $\mathcal{O}_{s,b}$, and appears to be related immediately to the analytic continuation in $\mathcal{L}^{1|2}\times\mathcal{L}^{1|2}$ of the Kähler superpotential:

$$L_{s,b}(\underline{\Gamma}_1,\overline{\Gamma})=\sum_{k=1}^{\infty} f_k(\overline{\Gamma})\overline{f_k(\overline{\Gamma}_1)}=\exp[\Phi(\underline{\Gamma}_1,\overline{\Gamma})]. \tag{4.6}$$

The state, being presented by the function $\Phi_{\underline{\Gamma}}(\overline{\Gamma}_1)=L_{s,b}(\underline{\Gamma},\overline{\Gamma}_1)$ with fixed $\underline{\Gamma}\equiv\{\overline{z},\overline{\theta},\overline{\chi}\}$ is denoted by $|\overline{z},\overline{\theta},\overline{\chi}\rangle$, is called as an SU(1,1|2) [or OSp(2|2)] supercoherent state. The analytic continuation in $\mathcal{L}^{1|2}\times\mathcal{L}^{1|2}$ for any classical observable could be expressed in terms of the supercoherent states as follows:

$$A(\underline{\Gamma}_1,\overline{\Gamma}_2)=\frac{\langle\Phi_{\overline{\Gamma}_2}|\hat{A}|\Phi_{\overline{\Gamma}_1}\rangle_{\mathcal{L}^{1|2}}}{\langle\Phi_{\overline{\Gamma}_2}|\Phi_{\overline{\Gamma}_1}\rangle_{\mathcal{L}^{1|2}}}. \tag{4.7}$$

So, the symbol of the unit operator $\hat{I}$ is just 1. Hence, the one-to-one correspondence between classical observables on $\mathcal{L}^{1|2}$ and linear operators in $\mathcal{O}_{s,b}$ is established. In view of Eq. (4.7), classical observables are also referred to as (covariant) Berezin symbols.

3. Atypical unitary and finite-dimensional representations of the su(1,1|2) superalgebra

Using Eq. (4.5), one can now obtain the operators which correspond to the Hamiltonian generators (3.20) of holomorphic transformations of the $N=2$ superunit disc. One gets

$$\hat{J}_a=-\overline{\xi_a}\overline{\partial}-(\overline{\partial\xi_a})\left(s+\frac{1}{2}\overline{\theta}\frac{\partial}{\partial\overline{\theta}}+\frac{1}{2}\overline{\chi}\frac{\partial}{\partial\overline{\chi}}\right),\quad \hat{Z}=s\hat{I},$$

$$\hat{P}_1=-\frac{1}{\sqrt{1-b^2}}\left(\frac{1-b}{2}\overline{\chi}\frac{\partial}{\partial\overline{\theta}}+\frac{1+b}{2}\overline{\theta}\frac{\partial}{\partial\overline{\chi}}\right),\quad \hat{P}_3=\frac{1}{2}\overline{\theta}\frac{\partial}{\partial\overline{\theta}}-\frac{1}{2}\overline{\chi}\frac{\partial}{\partial\overline{\chi}},$$

$$\hat{P}_2=\frac{i}{\sqrt{1-b^2}}\left(\frac{1-b}{2}\overline{\chi}\frac{\partial}{\partial\overline{\theta}}-\frac{1+b}{2}\overline{\theta}\frac{\partial}{\partial\overline{\chi}}\right),\quad \hat{P}_4=\frac{1}{2}\overline{\theta}\frac{\partial}{\partial\overline{\theta}}+\frac{1}{2}\overline{\chi}\frac{\partial}{\partial\overline{\chi}},$$

$$\hat{E}^{\alpha}=\frac{\sqrt{1+b}}{2}\overline{\theta}\left[\overline{z^{\alpha}}\overline{\partial}+(\overline{\partial}\overline{z^{\alpha}})\left(2s+\overline{\chi}\frac{\partial}{\partial\overline{\chi}}\right)\right]-\frac{1}{\sqrt{1+b}}\overline{z^{\alpha}}\frac{\partial}{\partial\overline{\theta}}, \tag{4.8}$$

$$\hat{F}^{\alpha}=-i\frac{\sqrt{1+b}}{2}\overline{\theta}\left[\overline{z^{\alpha}}\overline{\partial}+(\overline{\partial}\overline{z^{\alpha}})\left(2s+\overline{\chi}\frac{\partial}{\partial\overline{\chi}}\right)\right]-i\frac{1}{\sqrt{1+b}}\overline{z^{\alpha}}\frac{\partial}{\partial\overline{\theta}},$$

$$\hat{G}^{\alpha}=\frac{\sqrt{1-b}}{2}\overline{\chi}\left[\overline{z^{\alpha}}\overline{\partial}+(\overline{\partial}\overline{z}^{\alpha})\left(2s+\overline{\theta}\frac{\partial}{\partial\overline{\theta}}\right)\right]-\frac{1}{\sqrt{1-b}}\overline{z}^{\alpha}\frac{\partial}{\partial\overline{\chi}},$$

$$\hat{H}^{\alpha}=-i\,\frac{\sqrt{1-b}}{2}\overline{\chi}\left[\overline{z^{\alpha}}\overline{\partial}+(\overline{\partial}\overline{z}^{\alpha})\left(2s+\overline{\theta}\frac{\partial}{\partial\overline{\theta}}\right)\right]-i\,\frac{1}{\sqrt{1-b}}\overline{z}^{\alpha}\frac{\partial}{\partial\overline{\chi}},$$

where $\overline{\partial}\equiv\partial/\partial\overline{z},$ all the derivatives are left, and $\overline{\xi_a},\overline{z^{\alpha}}$ are defined by Eqs. (3.17) and (3.8), respectively. It is readily verified that the derived operators generate an irreducible representation of the su(1,1|2) superalgebra, and it is the same case for any values s and b, not only for $s>0$ and $|b|<1$. The anticommutation relations for operators (4.8) completely correspond to the Poisson superbrackets of the classical observables (3.20), and it is sufficient to apply the correspondence rules, that is, to replace $\{,\}\rightarrow 1/i[\,,]_{\mp}$ (anticommutator for two odd operators and commutator in the rest cases). By reduction to the orthosymplectic subsuperalgebra we reproduce just the typical UIRs of the osp(2|2) obtained in Refs. 38 and 39.

The constructed representation is infinite dimensional for $s>0$ and $|b|<1$, and unitary in the sense that the operators (4.8) are Hermitian with respect to inner product (4.2). It means, in particular, that $\langle f|\hat{J}_a|g\rangle_{\mathcal{L}^{1|2}}=\langle g|\hat{J}_a|f\rangle_{\mathcal{L}^{1|2}}$ and $\langle f|\hat{P}_I|g\rangle_{\mathcal{L}^{1|2}}=\langle g|\hat{P}_I|f\rangle_{\mathcal{L}^{1|2}}$ for any $f,g\in\mathcal{O}_{s,b}$. The Hermitian self-conjugation conditions for the odd operators may reveal some subtlety. Any odd classical observable among (3.20) is the Majorana spinor and we have, for example, $\overline{E^0}=-E^1$, $\overline{E^1}=-E^0$ with respect to the reality condition (3.2). $\hat{E}^{\alpha}$ (and any odd operator with the spinor index) is Hermitian in the sense that $\langle f|\hat{E}^0|g\rangle_{\mathcal{L}^{1|2}}=-\langle g|\hat{E}^1|f\rangle_{\mathcal{L}^{1|2}}$.

We denote the UIR obtained by $\mathbf{D}_{+}^{s,b}$. With respect to the su(1,1) subalgebra, it is decomposed into the direct sum $D_{+}^{s}\oplus D_{+}^{s+1/2}\oplus D_{+}^{s+1/2}\oplus D_{+}^{s+1}$ of the unitary representations of discrete series, and the components $f_0, f_{1,2}, f_3$ of the state (4.1) transform by the representations of higher weights s, $s+1/2$, and $s+1$, respectively.

The representations being obtained for $s\leqslant 0$ or $|b|>1$ are nonunitary. The case of $s+1=-j$, j is non-negative integer or half integer, is special. Then the operators (4.8) generate a finite-dimensional representation $\mathbf{D}^{j}$ of dimension $8j+8$. It is a superquartet of finite-dimensional representations of su(1,1), $\mathbf{D}^{j}=D^{j+1}\oplus D^{j+1/2}\oplus D^{j+1/2}\oplus D^{j}$, and the state's components $f_0, f_{1,2}, f_3$ transform by the $2j+3$-, $2j+2$-, and $2j+1$-dimensional representations, respectively.

It should be mentioned that the representations of the su(1,1|2) being considered here correspond to an *irregular* coadjoint orbit $\mathcal{L}^{1|2}$ of the supergroup SU(1,1|2) and, hence, they are *atypical* representations. By reduction to the orthosymplectic subsuperalgebra we get just the *typical* representations of the osp(2|2).

Keeping in mind the spinning superparticle, we remember that the representations D_{+}^{s} of the universal covering $\overline{\mathrm{SO}^{\uparrow}(1,2)}$ are commonly used for conventional realizations of the UIRs of the $D=3$ Poincaré symmetry of fractional spin,[6,7,14] whereas the finite-dimensional irreps D^{j} serve the ones of integer or of half-integer spin. It will be natural to extend these realizations to the $N=2$ Poincaré supersymmetry by means of representations $\mathbf{D}_{+}^{s,b}$ and $\mathbf{D}^{j}$ of the inner su(1,1|2) superalgebra.

4. The correspondence principle

To complete the quantization procedure on $\mathcal{L}^{1|2}$ let us return to the relation between observables and linear operators. We have examined for the supersymmetry generators of the su(1,1|2) superalgebra that there is an exact correspondence between supercommutators of the operators in $\mathcal{O}_{s,b}$ and the Poisson superbrackets of respective classical observables. In this sense we do have ''the quantization'' of a classical mechanics on the $N=2$ superunit disc. Consider now the correspondence between the algebras of *arbitrary* linear operators in the Hilbert space and their symbols.

The problem we are concerned with is thoroughly studied for Kähler homogeneous manifolds. Berezin proved the general ''correspondence principle,''[30,31] which roughly consists of the following. The multiplication of operators induces a binary $*$-operation for corresponding symbols; $*$-multiplication is noncommutative. Furthermore, the theory contains a ''Planck constant'' h related to one of the quantum numbers, and in the limit when $h \to 0$ $*$-algebra transforms to the ordinary commutative algebra of functions on the manifold. Finally, the first-order reset with respect to h of the commutator of symbols coincides with their Poisson bracket. The Lobachevsky plane has originally served as a test example for the Berezin technique.[31] The parameter s^{-1} plays the role of the Planck constant.

Similar principles hold true for the $N=2$ superunit disc being a natural $N=2$ superextension of the Lobachevsky plane.

Let $\hat{A}_1$ and $\hat{A}_2$ be two linear operators in $\mathcal{O}_{s,b}$ and $A_1(\underline{\Gamma},\overline{\Gamma})$ and $A_2(\underline{\Gamma},\overline{\Gamma})$ be the respective Berezin covariant symbols. It follows from Eq. (4.5) that the symbol being corresponded to the product $\hat{A}_2 \cdot \hat{A}_1$ (and denoted by $A_2 * A_1$) reads

$$A_2 * A_1(\underline{\Gamma},\overline{\Gamma}) = \int_{\mathcal{L}_{1|2}} A_2(\underline{\Gamma}_1,\overline{\Gamma}) A_1(\underline{\Gamma},\overline{\Gamma}_1) \frac{L_{s,b}(\underline{\Gamma},\overline{\Gamma}_1) L_{s,b}(\underline{\Gamma}_1,\overline{\Gamma})}{L_{s,b}(\underline{\Gamma}_1,\overline{\Gamma}_1) L_{s,b}(\underline{\Gamma},\overline{\Gamma})} d\mu(\underline{\Gamma}_1,\overline{\Gamma}_1). \tag{4.9}$$

Hence the multiplication of the operators induces the $*$-multiplications of the symbols.

Theorem (the correspondence principle): The following estimations take place:

$$(1) \quad \lim_{s\to\infty} A_2 * A_1(\underline{\Gamma},\overline{\Gamma}) = A_2(\underline{\Gamma},\overline{\Gamma}) \cdot A_1(\underline{\Gamma},\overline{\Gamma})$$

$$(2) \quad \lim_{s\to\infty} s\big(A_2 * A_1(\underline{\Gamma},\overline{\Gamma}) - A_1 * A_2(\underline{\Gamma},\overline{\Gamma})\big) = is\{A_2,A_1\},$$

where $\{,\}$ is the Poisson superbracket on $\mathcal{L}^{1|2}$.

Proof: It is based on the asymptotic estimation

$$A_2 * A_1(\underline{\Gamma},\overline{\Gamma}) = A_2(\underline{\Gamma},\overline{\Gamma}) \cdot A_1(\underline{\Gamma},\overline{\Gamma}) + i A_2(\underline{\Gamma},\overline{\Gamma}) \frac{\overleftarrow{\partial}}{\partial \underline{\Gamma}^A} \Omega^{A\overline{B}} \frac{\overrightarrow{\partial}}{\partial \overline{\underline{\Gamma}^B}} A_1(\underline{\Gamma},\overline{\Gamma}) + \mathcal{O}(s^{-2}), \tag{4.10}$$

from which both propositions of the theorem are easily obtained. Here $\Omega^{A\overline{B}} = \{\underline{\Gamma}^A, \overline{\underline{\Gamma}^B}\}$ are fundamental Poisson superbrachets on $\mathcal{L}^{1|2}$, whose explicit form is written down in the extended version of this paper.[37] The validity of the relation (4.10) is sufficient to prove when $z=0$. If it is the case, Eqs. (4.10) hold true at any z in consequence of the SU(1,1) invariance of the symplectic structure. Taking this fact into account, the verification of Eq. (4.10) is made by means of an ordinary expansion of the symbols in (finite) series in the odd variables and the comparison of the lhs and rhs of Eqs. (4.10) for the respective components. It is a trivial but cumbersome exercise, which may be successfully performed using the known estimation[31]

$$\hat{T}_l[\varphi] \equiv \frac{2l-1}{2\pi i} \int_{|z|<1} \varphi(z,\overline{z})(1-z\overline{z})^{2l-2}\, dz d\overline{z} = \varphi(0,0) + \frac{1}{2l} \Delta \varphi(z,\overline{z}) \Big|_{z=\overline{z}=0} + \mathcal{O}(l^{-2}) \tag{4.11}$$

and its consequence

$$l(\hat{T}_1[\varphi] - \hat{T}_{l+1/2}[\varphi]) = \frac{1}{4l} \Delta \varphi(z,\overline{z})|_{z=\overline{z}=0} + \mathcal{O}(l^{-2}).$$

Here $l>\frac{1}{2}$, $\varphi(z,\overline{z})$ is an arbitrary function to be continuously differentiable into the unit disc in a complex plane, and $\Delta=(1-z\overline{z})^2\partial\overline{\partial}$ is an invariant Laplace–Beltrami operator in $\mathcal{L}$. It is exactly the estimation (4.11) that was originally applied by Berezin for the proof of the correspondence principle in the Lobachevsky plane.[31] In this sense, we reduce the correspondence principle in $\mathcal{L}^{1|2}$ to the one in $\mathcal{L}$ by means of the expansion in the odd variables. ■

B. Operator realization of the Poincaré superalgebra. Renormalization of the supercharges

Now we are in a position to proceed directly to the quantization of the $D=3$ spinning superparticle. Consider the space $\mathcal{H}$ of functions of the form

$$F(p,\overline{\Gamma})\equiv F(p,\overline{z},\overline{\theta},\overline{\chi})=F_0(p,\overline{z})+\sqrt{s(1+b)}\,\overline{\theta}F_1(p,\overline{z})+\sqrt{s(1-b)}\,\overline{\chi}F_2(p,\overline{z})$$
$$+\sqrt{s(s+1/2)(1-b^2)}\,\overline{\theta}\overline{\chi}F_3(p,\overline{z}),\qquad(4.12)$$

where $p\equiv p^a\in R^{1,2}$, and $F_p(\overline{\Gamma})\equiv F(p,\overline{\Gamma})\in\mathcal{O}_{s,b}$ at each fixed p. We would like to suppose that the Hamiltonians (3.24) [which are the same as in relation (3.13)] present "the classical symbols" of respective operators of the $N=2$ Poincaré superalgebra acting in $\mathcal{H}$. We take the following ansatz for these operators:

$$\hat{\mathcal{J}}_a=-i\epsilon_{abc}p^b\frac{\partial}{\partial p_c}+\overline{J}_a,\quad \overline{\mathcal{P}}_a=p_a,\quad \overline{\mathcal{Z}}=mb,$$

$$\hat{\mathcal{Q}}^1_\alpha=(ip_{\alpha\beta}\hat{W}^\beta+m\hat{\hat{W}}_\alpha)[1+q(b\hat{P}_3-\sqrt{1-b^2}\hat{P}_2-\hat{P}_4)],\qquad(4.13)$$

$$\hat{\mathcal{Q}}^2_\alpha=(ip_{\alpha\beta}\hat{V}^\beta+m\hat{\hat{V}}_\alpha)[1+q(b\hat{P}_3+\sqrt{1-b^2}\hat{P}_2-\hat{P}_4)].$$

Here the operators $\hat{W}^\alpha$, $\hat{\hat{W}}^\alpha$, $\hat{V}^\alpha$, and $\hat{\hat{V}}^\alpha$ are expressed as linear combinations of $\hat{E}^\alpha$, $\hat{F}^\alpha$, $\hat{G}^\alpha$, and $\hat{H}^\alpha$ according to relations (3.26), whereas the latter, together with the operators $\hat{J}_a$ and $\hat{P}_I$, are defined by the expressions (4.8).

Recall that the classical observables (3.24) or (3.13) generate the Poincaré superalgebra on shell only, that is, modulo to the constraints (3.15). The operator counterparts of the constraints are now imposed to annihilate the physical states according to Dirac quantization prescriptions. The linear operator in $\mathcal{O}_{s,b}$, which corresponds to the Berezin covariant symbol $-sn_a(s>0)$, reads

$$\widehat{-sn}_a=\hat{J}_a\left(1-\frac{2}{2s+1}\hat{P}_4+\frac{2}{(2s+1)(2s+2)}\overline{\theta}\frac{\vec{\partial}}{\partial\overline{\theta}}\overline{\chi}\frac{\vec{\partial}}{\partial\overline{\chi}}\right)=\hat{J}_a\left(1+\frac{1}{s}\hat{P}_4\right)^{-1}.$$

Thus, the wave equations for the superparticle are easily brought to the form

$$(p^2+m^2)F^{\mathrm{phys}}(p,\overline{z},\overline{\theta},\overline{\chi})=0,\quad[(p,\hat{J})-m\hat{P}_4-ms]F^{\mathrm{phys}}(p,\overline{z},\overline{\theta},\overline{\chi})=0.\qquad(4.14)$$

[It is worth noting that the second constraint equation (3.15) should be written in an equivalent form $(p,J)-mP_4-ms=0$.] Solutions of the wave equations generate a subspace $\mathcal{H}_{m,s,b}$ in $\mathcal{H}$. Furthermore, if $F\in\mathcal{H}_{m,s,b}$ and $\hat{\mathcal{S}}$ is any one of the operators (4.13), then $\hat{\mathcal{S}}F$ is a physical state again, regardless of the particular value of the parameter q. In this sense, the wave equations are super-Poincaré invariant.

It is crucial now to examine explicitly whether the operators (4.13) actually generate the $N=2$ Poincaré superalgebra. One gets in $\mathcal{H}$ [compare with Eq. (3.13)]

$$[\hat{\mathcal{J}}_a,\hat{\mathcal{J}}_b]_-=i\epsilon_{abc}\hat{\mathcal{J}}^c,\quad[\hat{\mathcal{J}}_a,\hat{\mathcal{P}}_b]_-=i\epsilon_{abc}\hat{\mathcal{P}}^c,\quad[\hat{\mathcal{P}}_a,\hat{\mathcal{P}}_b]_-=0,\qquad(4.15)$$

$$[\hat{\mathcal{J}}_a,\hat{\mathcal{Q}}^I_\alpha]_- = \frac{1}{2}(\gamma_a)_\alpha{}^\beta\hat{\mathcal{Q}}^I_\beta,\quad [\hat{\mathcal{P}}_a,\hat{\mathcal{Q}}^I_\alpha]_- = 0,\quad [\hat{\mathcal{Q}}^I_\alpha,\hat{P}_3]_- = -\frac{i}{2}\epsilon^{IJ}\hat{\mathcal{Q}}^J_\alpha .$$

These relations hold true with an arbitrary number taken for q. However, the anticommutator of the supercharges is strongly dependent on the particular value of q:

$$[\hat{\mathcal{Q}}^I_\alpha,\hat{\mathcal{Q}}^J_\beta]_+ = 2\delta^{IJ}p_{\alpha\beta} - 2imb\epsilon^{IJ}\epsilon_{\alpha\beta} + c^{1IJ}_{\alpha\beta}(p^2+m^2) + c^{2IJ}_{\alpha\beta}((p,\hat{J}) - m\hat{P}_4 - ms) + \mathcal{O}(s^{-2}), \tag{4.16}$$

where $c^{\cdot IJ}_{\alpha\beta}$ are some functions, and $\mathcal{O}(s^{-2})$ are the corrections of higher orders in s^{-1}, which depend on q and the other parameters like m and b. These corrections do not vanish if $q=q^{cl}=1/4s$.

Notice that the quantum value of q is not uniquely determined. The value $q^{cl}=1/4s$ is derived from the expressions (3.24), when the relationship between the super-Poincaré and su(1,1|2) generators (3.20) is taken into account. However, one can start immediately from the symbols (3.13) and restore the operators applying the correspondence rule (4.5). What is remarkable is that one obtains the same operators (4.13), but the parameter q changes, and q^{cl} appears to be $q^{cl}_1=1/(4s+2)$. But the Poincaré superalgebra is disclosed by $q=1/(4s+2)$; the same is true for $q=1/4s$ too.

Both the appearance of corrections $\mathcal{O}(s^{-2})$ on the rhs of Eq. (4.16) and the ambiguity in the definition of q have the same origin, that is, a *nonlinearity* of the Poincaré supercharge operators (4.13) in the generators (4.8) of the inner su(1,1|2) superalgebra. In consequence of the nonlinearity, different operator factor orderings may lead to the different forms for $\hat{\mathcal{Q}}^I_\alpha$, and the corrections appear in response to the correspondence principle in $\mathcal{L}^{1|2}$.

We show that the disclosure of the Poincaré superalgebra at the quantum level has transparent mathematical ground in view of the Berezin correspondence principle. However, this disclosure is quite unsatisfactory from the physical viewpoint for the quantization of the elementary system. The latter is completely characterized by its inherent symmetries (in the present case it is the $D=3$ Poincaré SUSY). *It is the representation of these symmetries in Hilbert space that allows us to identify the obtained quantum theory with the quantized elementary system*. According to these reasons, to quantize the $D=3$ superparticle we now have to provide an *exact* realization of the representation of the Poincaré superalgebra in the physical Hilbert space, without any corrections in the parameters of the model. To find the true quantum realization for the representation, we can try, starting from Eqs. (4.13)–(4.16), to introduce some renormalized terms in the observables (4.13), which should be sufficient for the closure of the anticommutators (4.16).

Certainly, we do not have an *a priori* reason, which may ensure the consistency of the renormalization procedure; a structure of the possible higher-order corrections to (4.13) is unclear in general. Surprisingly, the exact corrections may be obtained from the simplest ansatz (4.13) for the quantum observables. In other words, a true ordering exists for the su(1,1|2) superalgebra operators, entering in $\hat{\mathcal{Q}}^I_\alpha$ in Eq. (4.13), that *allows us to restore a representation of the Poincaré superalgebra by the renormalization of the only parameter q*.

It is examined by a direct calculation that the corrections $\mathcal{O}(s^{-2})$ on the rhs of Eq. (4.16) vanish and the operators (4.13) generate the closed Poincaré superalgebra if, and only if,

$$q = q^{\text{quant}}_\mp = 1 \mp \sqrt{1-\frac{1}{2s+1}}. \tag{4.17}$$

Some details of calculations of the anticommutators (4.16) are given in the Appendix of Ref. 37. The renormalized value $q^{\text{quant}}_- = q^{cl} + \mathcal{O}(s^{-2})$ can be treated as a perturbative correction to the classical symbols of the supercharges. The other possible value q^{quant}_+ emerges from the hidden $N=4$ supersymmetry and could be understood from the following reasons.

Let $q=q_-$. The operators of supercharges corresponding to the classical observables (3.25) [see also Eqs. (3.22)] and providing the hidden $N=4$ supersymmetry in $\mathcal{H}_{m,s,b}$ are presented by

$$\hat{\bar{\mathcal{Q}}}^I_\alpha = -\frac{i}{m} p_\alpha{}^\beta \hat{\mathcal{Q}}^I_\beta = i\hat{K}\cdot\hat{\mathcal{Q}}^I_\alpha\Big|_{q\to 2-q}, \tag{4.18}$$

where the *parity operator* $\hat{K}$ is introduced. It acts on the components of the wave function (4.12) by the rule

$$\hat{K}: F=(F_0,F_1,F_2,F_3)\to\hat{K}F=(F_0,-F_1,-F_2,F_3), \quad \hat{K}^2=\hat{I}, \tag{4.19}$$

and $\hat{\mathcal{Q}}^I_\alpha|_{q\to 2-q}$ denote the supercharges (4.13) being considered when the constant q is substituted for the expression $(2-q)$.

The same critical values (4.17) evidently provide the closure of the $N=4$ Poincaré superalgebra. Moreover, the parity operator (4.19) possesses remarkable features: it commutes with the even generators of the $N=4$ Poincaré superalgebra and anticommutes with the supercharges:

$$[\hat{\mathcal{J}}_a,\hat{K}]_-=[\hat{\mathcal{P}}_a,\hat{K}]_-=0, \quad [\hat{P}_I,\hat{K}]_-=0, \quad I=1,2,3,4,$$
$$[\hat{\mathcal{Q}}^I_\alpha,\hat{K}]_+=[\hat{\bar{\mathcal{Q}}}^I_\alpha,\hat{K}]_+=0, \quad I=1,2. \tag{4.20}$$

Therefore, the operators $\hat{\mathcal{Q}}'^I_\alpha=-i\hat{K}\hat{\mathcal{Q}}^I_\alpha=\hat{\bar{\mathcal{Q}}}^I_\alpha|_{q\to 2-q}$ and $\hat{\bar{\mathcal{Q}}}'^I_\alpha=-i\hat{K}\hat{\bar{\mathcal{Q}}}^I_\alpha=\hat{\mathcal{Q}}^I_\alpha|_{q\to 2-q}$ satisfy the (anti)commutation relations being identical with Eqs. (4.15) and (4.16) for the supercharges $\hat{\mathcal{Q}}^I_\alpha$ and $\hat{\bar{\mathcal{Q}}}^I_\alpha$ themselves. This observation clarifies to some extent the origin of the nonperturbative value q_+^{quant} for the parameter q. Notice that two representations of the Poincaré superalgebra corresponding to either possible value q are equivalent to each other. It is seen straightforwardly from relations

$$\hat{\mathcal{Q}}'^I_\alpha=\hat{U}\hat{\bar{\mathcal{Q}}}^I_\alpha\hat{U}, \quad \hat{\bar{\mathcal{Q}}}'^I_\alpha=\hat{U}\hat{\mathcal{Q}}^I_\alpha\hat{U}, \quad [\hat{\mathcal{J}}_a,\hat{U}]_-=[\hat{\mathcal{P}}_a,\hat{U}]_-=[\hat{P}_I,\hat{U}]_-=0,$$

where the operator $\hat{U}$ reads

$$\hat{U}=1-2\bar{\theta}\frac{\vec{\partial}}{\partial\bar{\theta}}\bar{\chi}\frac{\vec{\partial}}{\partial\bar{\chi}}, \quad \hat{U}^2=\hat{I}.$$

We do not observe, however, either any classical counterpart for the supercharges $\hat{\mathcal{Q}}'^I_\alpha, \hat{\bar{\mathcal{Q}}}'^I_\alpha$ or any algebraic construction (for instance, superalgebra) involving both sets of the $N=4$ supercharges $\hat{\mathcal{Q}}^I_\alpha, \hat{\bar{\mathcal{Q}}}^I_\alpha$ and $\hat{\mathcal{Q}}'^I_\alpha, \hat{\bar{\mathcal{Q}}}'^I_\alpha$ on equal footing.

To summarize briefly, the ''double'' SUSY of the classical mechanics of the $D=3$ spinning superparticle can be lifted to the operator representation in the quantum theory. The key step of the construction is the renormalization (4.17) for the Poincaré supercharges (4.13). Equation (4.17) displays two exceptional values of the parameter q providing the closure for the anticommutator of supercharges (4.16) and recovering the consistent representation of the Poincaré superalgebra. In accordance with the analysis of Sec. IV A 3 we conclude that the off-shell wave function (4.12) carries the representation of the superalgebra su(1, 1|2) which is unitary infinite dimensional when $s>0$, and nonunitary finite dimensional when $s+1=j,j$ being non-negative integer or half-integer. The first possibility corresponds to the $N=2$ superanyon, whereas in the second case we obtain conventional realization of the representations of a habitual half-integer superspin. One can easily establish that the theory describes the massive quartet of $N=2$, $D=3$ superparticles when $|b|<1$, and this quartet contracts to the $N=1$ superdoublet[25] in the BPS limit $|b|=1$.

The last remarkable step is that the representations of the Poincaré superalgebra obtained are *unitary*. For example, in the case of fractional superspin $(s>0)$, the physical space $\mathcal{H}_{m,s,b}$ is naturally endowed by an inner product

$$(F|G)=\mathcal{N}\int \frac{d\mathbf{p}}{p^0}\langle F|G\rangle_{\mathcal{L}^{1|2}}, \quad p^0=\sqrt{\mathbf{p}^2+m^2}<0, \tag{4.21}$$

where $\langle F|G\rangle_{\mathcal{L}^{1|2}}$ denotes the inner product (4.2) in $\mathcal{O}_{s,b}$, $p^a=(p^0,\mathbf{p})$, and $\mathcal{N}$ is an arbitrary normalization constant. The operators (4.13) of the $N=2$ Poincaré superalgebra are Hermitian with respect to the inner product. However, the integrand in Eq. (4.2) [and, thus, (4.21)] has the inherent singularity at $|z|=1$ in the case of $s<0$, and it is ill defined in the BPS limit $|b|=1$. The correct realization of the inner product for the case of half-integer superspin and in the BPS limit has been found in Refs. 37 and 25, respectively.

V. SUMMARY AND DISCUSSION

In the present paper we have constructed the consistent first quantized theory of an $N=2$, $D=3$ superanyon as well as the one of massive superparticle of the habitual (half) integer superspin. The starting point for the quantization is the classical model of the superparticle in the nonlinear phase superspace $\mathcal{M}^{8|4}=T^*(R^{1,2})\times\mathcal{L}^{1|2}$, which is different from the standard approach.

A traditional viewpoint in the construction of the spinning particle models[34] is to describe the spinning degrees of freedom by some variables being simultaneously translation invariant and Lorentz covariant (as usual, those are Lorentz vectors or spinors). Such variables parametrize some linear space L and then the extended phase space is chosen to be $\mathcal{M}=T^*(R^{1,D-1})\times L$ or $\mathcal{M}=T^*(R^{1,D-1}\times L)$. The only difference for superparticles is to replace D-dimensional Minkowski space $R^{1,D-1}$ by the respective superspace. The advantage of the covariant (super) space $\mathcal{M}$ is in the linear (''covariant'') action of the Poincaré supergroup. In this approach, however, an embedding of the (super)particle physical space $\mathcal{O}$ (that is, the underlying coadjoint orbit) in the covariant phase (super)space may be ambiguous. Moreover, it is a common usage in this approach to give little attention to the geometry underlying the embedding $\mathcal{O}\rightarrow\mathcal{M}$.

We have demonstrated that the nonlinear phase superspace $\mathcal{M}^{8|4}=T^*(R^{1,2})\times\mathcal{L}^{1|2}$ of the $D=3$ spinning superparticle has the following remarkable features:

(i) The embedding of an appropriate coadjoint $\mathcal{O}_{m,s,b}$ orbit, being associated to the $N=2$, $D=3$ superparticle of arbitrary fixed mass $m>0$, superspin $s\neq 0$, and central charge mb ($|b|<1$ in $\mathcal{M}^{8|4}$), is realized by two constraints, which provide the identical conservation of any Casimir function of the Hamiltonian Poincaré superalgebra. These constraints have transparent geometric origin and, after quantization, they are converted into wave equations of the superparticle in a natural way.

(ii) The ''inner'' subsupermanifold $\mathcal{L}^{1|2}$ of $\mathcal{M}^{8|4}$ appears to be in itself the coadjoint orbit for some supergroups. $\mathcal{L}^{1|2}$ is shown to be symplectomorphic to the Kähler homogeneous superspace of the supergroup SU(1, 1|2) or its subsupergroup OSp(2|2). In this sense the model admits the second supersymmetry [SU(1, 1|2) SUSY] along with the original Poincaré one.

To describe the superparticle in a standard way, it is convenient, starting from an ordinary particle living in $R^{1,D-1}$, to extend the geometry of the Minkowski space to the supergeometry of the respective Minkowski superspace. We have found an alternative way, at least for dimension $D=3$. The intrinsic structure of $D=3$ spinning particle may be described in terms of the Lobachevsky geometry. To introduce the supersymmetry we may extend the inner manifold, going to the Lobachevsky supergeometry.

The following interpretation is admissible. The $D=3$ particle lives in an ordinary Minkowski space $R^{1,2}$. In addition the *super*spin degrees of freedom are associated to its internal structure and generate the internal phase superspace $\mathcal{L}^{1|2}$ with an inherent SU(1, 1|2) supersymmetry, which is different from the Poincaré (super)symmetry.

(iii) We suggest nontrivial quantization of the superparticle in the extended phase superspace $\mathcal{M}^{8|4}$, which combines the canonical quantization in $T^*(R^{1,2})$ and the Berezin quantization in the inner phase superspace $\mathcal{L}^{1|2}$. This quantization scheme leads naturally to the fields carrying infinite-dimensional or finite-dimensional representation of the supergroup SU(1, 1|2) depending on the fractional or habitual (half)integer value of spin. The results are completely consistent with the previous known description of $D=3$ nonsupersymmetric particles as mechanical systems.[6,13,14]

Surprisingly, there are two, unitary equivalent to one another, series of $N=2$ supercharges in quantum theory, which correspond to different possibilities for the parameter q in Eq. (4.17). Only one of them, namely q_-, is related directly to a conventional classical limit. Another possible value q_+ is shown to be related to the special properties (4.20) of the parity operator (4.19). However, the classical counterpart of this parity structure remains unclear, and the origin of the second possible value for q may seem enigmatic. Notice that the parity operator generates the structure of the deformed Heisenberg algebra in Hilbert space of anyon[26] or $N=1$ superanyon.[25] It would be interesting to understand what is a geometry behind the parity operator for the $N=2$ superanyon.

The significance of this one-particle theory may vary, in particular, depending on the possibility of an efficient second quantization of the model. One of the problems here is to construct a Lagrangian of the theory, which leads to the one-particle wave equation we have deduced from the classical mechanical action. The first step of construction may be to present two independent wave equations of superanyon [like Eqs. (4.14)] in the form of one spinor equation, when the mass and spin shell fixing conditions may emerge as integrability conditions. It is known that the similar construction for anyons gives a simple action functional,[8,26] which may be relevant for the second quantization of fractional spin particles. An adequate superextension (at least for $N=1$) may be constructed probably using the representations of the su(1, 1|2) superalgebra in the same way, as the spinor set of the anyon wave equations was constructed in Ref. 26 using the atypical UIRs of osp(2|2). In this connection it should be noted that the exploitation of the atypical UIRs of the osp(2|2) superalgebra and of the deformed Heisenberg algebra produces the linear set of spinor wave equations of the $N=1$, $D=3$ superparticle only for special (half) integer $j=\frac{1}{2}$ and $j=1$ values of the superspin.[26]

And, of course, the consistent interaction of (super)anyons remains an intriguing problem. Even in the first quantized theory the suggested approach to the description of anyon, being attempted for the extension to an interaction with an external field, implies (in the framework of minimal phase space) a perturbative representation for nonlinear commutation relations in terms of a series in powers of the field strengths.[18] In particular, it is unclear whether any consistent generalization exists for the wave equations of (super)anyons obtained in this paper in the presence of arbitrary external fields.

An inversion inequality for potentials in quantum mechanics

Richard L. Hall[a)]
Department of Mathematics and Statistics, Concordia University, 1455 de Maisonneuve Boulevard West, Montréal, Québec H3G 1M8, Canada

(Received 19 November 1998; accepted for publication 2 February 1999)

We suppose: (1) that the ground-state eigenvalue $E=F(v)$ of the Schrödinger Hamiltonian $H=-\Delta+vf(x)$ in one dimension is known for all values of the coupling $v>0$; and (2) that the potential shape can be expressed in the form $f(x)=g(x^2)$, where g is monotone increasing and convex. The inversion inequality $f(x)\leqslant \bar{f}(1/4x^2)$ is established, in which the ''kinetic potential'' $\bar{f}(s)$ is related to the energy function $F(v)$ by the transformation $\{\bar{f}(s)=F'(v),\ s=F(v)-vF'(v)\}$. As an example, f is approximately reconstructed from the energy function F for the potential $f(x)=ax^2+b/(c+x^2)$.
[S0022-2488(99)01705-3]

I. INTRODUCTION

We suppose that a discrete eigenvalue $E=F(v)$ of the Schrödinger Hamiltonian,

$$H=-\Delta+vf(x), \tag{1.1}$$

is known for all sufficiently large values of the coupling parameter $v>v_c$, and we try to use this data to reconstruct the potential shape f. Here v_c is the critical value of the coupling parameter for the eigenvalue considered. For the present discussion we shall assume that the potential shape $f(x)$ is nonconstant, symmetric, and monotone increasing for $x>0$. The usual ''forward'' problem would be the following: given the potential (shape) f, find the energy trajectory F; ''geometric spectral inversion'' is the inverse of this, that is to say, $F\rightarrow f$.

This problem should be distinguished from the ''inverse problem in the coupling constant'' discussed, for example, by Chadan and Sabatier.[1] In this latter problem, the discrete part of the ''input data'' is a set $\{v_n\}$ of values of the coupling constant that all yield the identical energy eigenvalue E. The index n might typically represent the number of nodes in the corresponding eigenfunction. In contrast, for the problem discussed in the present paper, n is kept fixed and the input data is the graph $(F_n(v),v)$, where the coupling parameter has any value $v>v_c(n)$, and $v_c(n)$ is the critical value of v for the support of a discrete eigenvalue with n nodes; for the ground state in one dimension we have, in general, $v_c(0)=0$. For the excited states, the critical coupling depends on the potential shape; for example, in the case of the square well, $v_c(n)=(n\pi/2)^2$; for the sech-squared potential with shape $f(x)=-\mathrm{sech}^2(x)$, we have[2] $v_c(n)=n(n+1)$, $n=0,1,2,\ldots$. There are strong indications on the basis of studies involving the inversion of the WKB approximation[3] that inversion from a single fixed energy trajectory F_n becomes more efficient as n increases (and the problem becomes more classical). However, the present paper will be concerned only with inversion from the ground-state energy function $F_0(v)=F(v)$ for the problem in one spatial dimension.

By making suitable assumptions concerning the class of potential shapes, theoretical progress has already been made with this inversion problem.[4–7] In Ref. 5 a ''concentration lemma'' is proved. If we suppose that $H\psi=E\psi$ and $\|\psi\|=1$, this lemma quantifies the monotone increase in

[a)]Electronic mail: rhall@cicma.concordia.ca

concentration toward $x=0$ of the probability density $\psi^2(x,v)$ with increasing v. In Ref. 6 this lemma is used to establish the uniqueness of the potential shape f corresponding to a given energy function F. The class of potentials for which this uniqueness proof applies are those nonconstant potential shapes f that are symmetric, continuous at $x=0$, piecewise analytic,[8] and monotone increasing for $x>0$. The ''envelope inversion'' discussed in Ref. 6 involved a class of potentials that could be expressed as a smooth monotone transformation $f(x)=g(h(x))$ of a soluble potential $h(x)$. The approximation obtained was *ad hoc*, in the sense that nothing was known *a priori* concerning the relationship between the approximation and the (unknown) exact potential corresponding to the given energy function $F(v)$. In the present paper we establish an inversion *inequality* for a special case of envelope inversion, namely the case in which the ''envelope basis'' is the harmonic-oscillator shape $h(x)=x^2$. Thus, we assume that the potential shape $f(x)$ has the representation

$$f(x)=g(x^2), \tag{1.2}$$

where g is monotone increasing and convex $(g''>0)$. This is a strong assumption, but, as we prove in Sec. II, it yields a corresponding strong result, that is to say,

$$f(x)\leqslant \bar{f}\left(\frac{1}{4x^2}\right), \tag{1.3}$$

where $\bar{f}(s)$ is the ''kinetic potential'' corresponding to the potential $f(x)$. The parameter s is equal to the mean kinetic energy $\langle -\Delta\rangle$ and, in terms of s, the eigenvalue $F(v)$ may be represented[9] *exactly* by the semiclassical expression

$$E=F(v)=\min_{s>0}\{s+v\bar{f}(s)\}. \tag{1.4}$$

The transformations $F\leftrightarrow\bar{f}$ are essentially Legendre transformations.[10] This is so because we know[5] that F and $\bar{f}$ have definite and opposite convexity; more particularly, we know

$$\bar{f}''(s)F''(v)=-\frac{1}{v^3}<0. \tag{1.5}$$

The transformation in the direction needed here $F\rightarrow\bar{f}$ will be given explicitly in Sec. II, below where we also prove the inequality (1.3), the main result of this paper. In Section (III) we discuss an example for which we compare the upper approximation given by (1.3) with the corresponding exact result.

II. PROOF OF THE INVERSION INEQUALITY

We suppose that the exact normalized wave function corresponding to the potential $vf(x)$ is given by $\psi(x,v)$, where the coupling parameter $v>0$. Thus, $(\psi,H\psi)=F(v)$. We know how this total expectation value is divided between kinetic and potential energies for, in more detail, we have

$$\begin{aligned}\langle -\Delta\rangle=(\psi,-\Delta\psi)=F(v)-vF'(v)=s,\\ \langle f\rangle=(\psi,f\psi)=F'(v)=\bar{f}(s).\end{aligned} \tag{2.1}$$

These equations also define the kinetic potential $\bar{f}(s)$ parametrically in terms of the parameter $v>0$. We first use Heisenberg's uncertainty inequality, which gives us

$$\langle -\Delta\rangle\langle x^2\rangle=s\langle x^2\rangle\geqslant\tfrac{1}{4}. \tag{2.2}$$

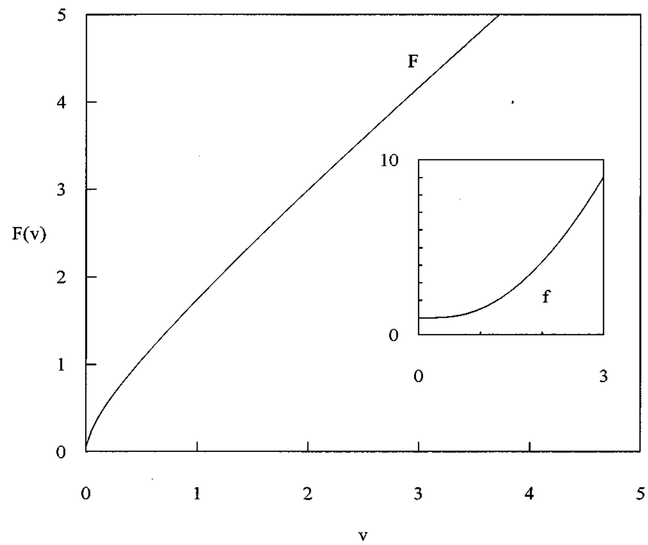

FIG. 1. The potential $f(x)=x^2+1/(1+x^2)$ is shown in the inset graph, along with the corresponding ground-state energy function $E=F(v)$. The aim of geometric spectral inversion is to reconstruct f from F.

We now consider

$$\overline{f}(s)=\langle f(x)\rangle=\langle g(x^2)\rangle\geqslant g(\langle x^2\rangle). \tag{2.3}$$

This inequality follows from Jensen's inequality[11] and the fact that g is convex. By applying (2.2) in (2.3), and using the monotony of g, we find

$$\overline{f}(s)\geqslant g\left(\frac{1}{4s}\right)=f\left(\frac{1}{2\sqrt{s}}\right). \tag{2.4}$$

Finally, by letting $x=1/2\sqrt{s}$ we establish the inversion inequality,

$$f(x)\leqslant\overline{f}\left(\frac{1}{4x^2}\right). \tag{2.5}$$

□

Since the transformation in the direction $F\rightarrow\overline{f}$ is already expressed by (2.1), the upper approximation provided by the inversion inequality is now completely determined.

III. AN EXAMPLE

We consider the potential shape given by

$$f(x)=ax^2+b/(c+x^2), \quad a,b,c>0. \tag{3.1}$$

The case $a=b=c=1$ is illustrated in Fig. 1, which shows the potential shape $f(x)$, in the inset graph, and also the ground-state energy function $F(v)$ generated from it. In Fig. 2 the upper approximation A obtained by the inversion inequality is shown along with the exact potential shape f itself. The set of corresponding ''exact'' wave functions $\psi(x,v)$ are also shown for $3\times10^{-4}\leqslant v\leqslant 10$. The wave function normalization is arbitrarily taken here to be $\psi(0,v)=20$, so that the graphs fit on the same figure as the potentials. As the coupling v increases, the wave functions become monotonically more concentrated near zero, in agreement with the ''concentration lemma'' mentioned in Sec. I.

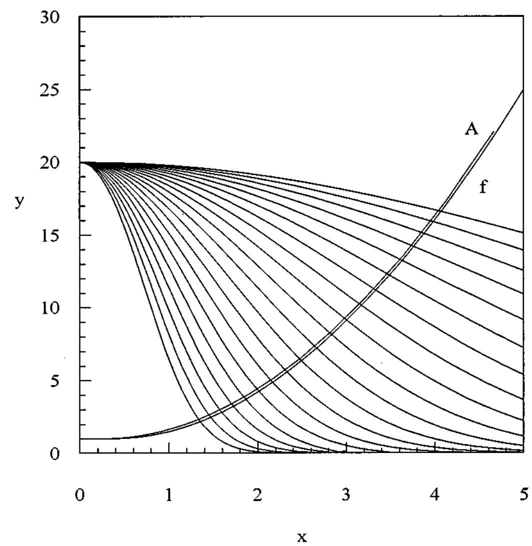

FIG. 2. The approximation *A* obtained from the inversion inequality (2.5) is compared to the exact potential *f*. The family of corresponding ''exact'' wave functions $\psi(x,v)$ satisfying $\psi(0,v)=20$ is also shown: the wave functions become monotonically concentrated toward zero as v is increased from $v=3\times10^{-4}$ to 10.

IV. CONCLUSION

Although the assumption behind the inversion inequality is strong, the fact that such an inequality exists may be important, especially if it can eventually be generalized. The expression of this result in terms of kinetic potentials could be avoided, in principle. However, the representation of the energy functions $F(v)$ in terms of $\bar{f}(s)$ has already yielded some very effective bounds in the forward direction, and it is natural to explore this same apparatus for the more difficult inversion problem. For example, in the forward direction the envelope method[9] may be expressed succinctly as

$$f(x)=g(h(x))\Rightarrow\bar{f}(s)\approx g(\bar{h}(s)), \tag{4.1}$$

where $\approx=\geqslant$ if g is convex and $\approx=\leqslant$ if g is concave. Once one has such an approximation for $\bar{f}(s)$, it can immediately be inserted in the expression (1.4) to yield an approximation for the corresponding eigenvalue $E=F(v)$. In the present paper we have found one case $h(x)=x^2$ for which an inequality is retained for the inverse problem. In Ref. 6 we also explored the idea of inverting the Rayleigh–Ritz variational method, and we obtained an inversion approximation with respect to a chosen family of ''trial'' functions. However, unlike the situation in the forward direction, the inversion approximation obtained was again *not* an inequality. Our experience with this problem so far suggests that it is difficult to generate potential inequalities for geometric spectral inversion.

(Received 26 October 1998; accepted for publication 22 December 1998)

An algorithm to obtain the Weyl anomaly in higher dimensions is presented. It is based on the heat-kernel method. Feynman rules, such as the vertex rule and the propagator rule, are given in (regularized) coordinate space. A graphical calculation is introduced. The six-dimensional scalar-gravity theory is taken as an example, and its explicit result is obtained. © *1999 American Institute of Physics.* [S0022-2488(99)01805-8]

I. INTRODUCTION

The anomaly phenomenon is, as well as the renormalization, one of the important aspects of the quantum field theories. It is a local quantum effect originating from regularization of the continuous space–time. We may say it is the problem of how to define the space–time as the continuum. Generally, the symmetry, imposed at the classical level does not hold at the quantum level due to the anomaly. As for the chiral anomaly, which is the anomaly concerned with the γ_5 symmetry (chiral symmetry), the general form is well established in arbitrary even dimensions.[1] It is fixed, except for an overall coefficient, by its cohomology structure, and is given in a beautiful form in terms of the differential form: $\mathrm{tr}(R\wedge R\wedge\cdots\wedge R)$, $\mathrm{tr}(F\wedge F\wedge\cdots\wedge F)$. The topological nature due to the γ_5 projection is the origin of its simplicity. On the other hand, as for the Weyl anomaly, the general form in higher dimensions is not so simple. This is the anomaly concerned with local scale transformations. Cohomology analysis restricts the Weyl anomaly to some extent, but there generally remains numerous candidate terms in higher dimensions.[2–5] The undetermined coefficients of those terms must be fixed in some way. The situation originates from the ''rich'' structure of the functional space on which the scale transformation acts. In the development of the string theory or *M* theory, it becomes more and more necessary to investigate the Weyl anomaly in higher-dimensional field theories.[6] At this circumstance we present a new formalism for it.

The Weyl anomaly itself is not harmful to the construction of physical theories because we know that realistic theories have some dimensional parameters, such as the mass or the cosmological constant, and they break the Weyl symmetry. However, when we try to understand the origin of those massive parameters, the Weyl anomaly is so important because it triggers the symmetry breaking of the conformal invariant vacuum. In this sense the Weyl anomaly can be regarded as a ''softer'' anomaly than the chiral one. The latter threatens the consistency of the theory whereas the former does not. The nonrenormalization theorem is valid for the latter, whereas generally not for the former.

In supersymmetric theories, however, it is also known that both anomalies make a supermultiplet together with the super-current.[7] Under the supersymmetric treatment, both anomalies are intimately related. In this connection there has been a lot of work. Because our interest here is to establish a general algorithm to treat the Weyl anomaly of the higher-dimensional theories, we

[a)]On leave of absence from the Department of Physics, University of Shizuoka, Yada 52-1, Shizuoka 422, Japan. Electronic mail: ichinose@u-shizuoka-ken.ac.jp
[b)]Electronic mail: nori@kurims.kyoto-u.ac.jp

do not consider supersymmetry here. We suppose, using the present result, that we can investigate how the Weyl anomaly is constrained by the supersymmetry.

We analyze the Weyl anomaly in the heat-kernel regularization. The content is essentially the same as, or overlaps with, topics with other names such as the effective action analysis, the background field method, the Schwinger–De Witt technique, Seeley series, etc. They all treat some background functional that represents (one-loop) quantum effects. It has a long history since Schwinger,[8] DeWitt,[9] and Seeley.[10] Especially the first author, in 1951, treated quantum matter theories in external gauge fields, keeping the gauge invariance of the effective action. He introduced an additional ''coordinate'' into the ordinary space(–time) coordinates, called ''proper time'' or ''temperature'' in a natural way. It was exploited by Alvarez-Gaumé and Witten[1] in the modern problem of the chiral anomaly of the gravitational theories. Later it was generalized to the Weyl anomaly by a SUNY group.[11,12]

The effective action has been analyzed in various ways. Its divergent part was systematically and algorithmically analyzed by t'Hooft[13] in 1973 and with Veltman[14] in 1974 using dimensional regularization. As will be shown later, the Weyl anomaly is obtained from the ''heat kernel,'' which is the one-loop effective action, with the proper time as the ultraviolet regularization. The evaluation of the heat kernel has been well developed by many people.[10,15–21] Each of them has their own characteristic formalisms. Generally they start with expressing a differential operator by some general background quantities. Most of them put an emphasis on the covariance in the formulas in the intermediate stages. As originally done by tHooft,[13] the ''intermediate covariance'' is powerful as far as the lower-order calculations, such as the heat kernel on two and four dimensions, are concerned. However, at higher order (this means higher dimensions too), it hinders one from performing explicit calculations because many more ''intermediate invariants'' appear than those appearing in the final explicit answer. The important thing is not the formulas at intermediate stages, but the final explicit result. Aiming at the treatment of the Weyl anomaly in higher dimensions, we present a new algorithm that is based on a simple weak-field expansion. Of course, we assume the invariance of the general coordinate and gauge symmetries at the final result, because it is guaranteed by the background (effective action) formalism.[9,13,22]

The following are new points of the present approach.

(1) We take a formalism in the regularized coordinate space, that is, the space with the ordinary space(–time) coordinates and the proper time.[23,24] The Feynman rules in the coordinate space are given for the anomaly (effective action) calculation.[25] The ultraviolet regularization is done with the Schwinger's parameter (proper time). The regularization lets us properly evaluate both chiral and Weyl anomalies.[26,27] The Feynman rules help us to investigate the Weyl anomaly in higher-dimensional theories.

(2) The graphical representation is taken at all stages. The familiar procedures in the ordinary perturbative treatment, such as the propagator rule and the vertex rule, are all graphically represented in coordinate space. The expanded terms themselves are also graphically represented. Especially, we introduce a ''graphical calculation.'' This makes the higher-order calculation transparent and the Weyl anomaly calculation in the higher dimensions tractable.

(3) We have not introduced any covariant quantities in intermediate stages. It is based on the weak-field perturbation. Although losing manifest general covariance in intermediate stages, the expanded elements have the simplest symmetry (w.r.t. the suffix permutation) and are preferable for the computer algorithm.

(4) We focus only on a special type of term: $(\partial\partial h)^n$, in the n-dimensional space. These are the lowest order of the product of n Riemann tensors. We demonstrate that they can determine the Weyl anomaly up to ''trivial terms.''

In Sec. II we briefly give the present formalism of the Weyl anomaly. The anomaly is given by the trace of the heat kernel. In Sec. III we present the Feynman rules to compute the heat kernel *to any higher order*. They are naturally expressed in the *regularized* coordinate space, that is, the space of n-dim ordinary space coordinates plus the the proper time. As always in perturbative approaches, a graphical representation helps to systematically compute the heat kernel at the higher order. The Taylor expansion, with respect to the ''regularization'' parameter t, is explained in Sec. IV. The more the number of space dimensions becomes, the more expansion is necessary. We apply the general algorithm to the 6-dim scalar-gravity theory in Sec. V. We focus on four special graphs and introduce a new graphical calculation. The final result of the Weyl anomaly for the model is obtained in Sec. VI. We conclude in Sec. VII. Four appendices are provided to supplement the text. The propagator rules are given in Appendix A. Some supplementary calculation, relegated by Sec. V of the text, is done in Appendix B. Weak field expansion of the 6-dim scalar gravity is graphically given in Appendix C. The table of coefficients, when some general invariants are weak-field expanded, is given in Appendix D.

II. FORMALISM

Let us explain the present formulation of anomalies taking a simple example: n-dim Euclidean gravity-scalar coupled system (see Ref. 26),

$$\mathcal{L}[g_{\mu\nu},\phi]=\sqrt{g}\,\phi\left(-\tfrac{1}{2}\nabla^2+\tfrac{1}{2}qR\right)\phi\equiv\tfrac{1}{2}\tilde{\phi}\,\mathbf{D}\tilde{\phi},$$
$$q=-\frac{n-2}{4(n-1)},\quad \mathbf{D}_x\equiv\sqrt[4]{g}\left(-\nabla_x^2-\frac{n-2}{4(n-1)}R(x)\right)\frac{1}{\sqrt[4]{g}},\tag{1}$$

where $g_{\mu\nu}$ and ϕ are the metric field and the scalar field, respectively. We have introduced $\tilde{\phi}\equiv\sqrt[4]{g}\,\phi$ for the measure $\mathcal{D}\tilde{\phi}$ to be general coordinate (BRS) invariant.[28] This Lagrangian is invariant under the local Weyl transformation:

$$g^{\mu\nu}(x)'=e^{2\alpha(x)}g^{\mu\nu}(x),\quad \tilde{\phi}(x)'=e^{-\alpha(x)}\tilde{\phi}(x)\quad [\phi(x)'=e^{(n-2)\alpha(x)/2}\phi(x)],\tag{2}$$

where $\alpha(x)$ is the parameter of the local Weyl transformation.

Even if the Lagrangian is Weyl invariant, the quantum theory is generally not (Weyl anomaly). The effective action $\Gamma[g_{\mu\nu}]$, defined by

$$e^{-\Gamma[g_{\mu\nu}]}=\int\mathcal{D}\tilde{\phi}\exp\left\{-\int d^nx\,\mathcal{L}[g_{\mu\nu},\phi]\right\},\tag{3}$$

changes as

$$e^{-\Gamma[g'_{\mu\nu}]}=\int\mathcal{D}\tilde{\phi}'\exp\left\{-\int d^nx\,\mathcal{L}[g'_{\mu\nu},\phi']\right\}$$
$$=\int\mathcal{D}\tilde{\phi}(x)\det\frac{\partial\tilde{\phi}'(y)}{\partial\tilde{\phi}(x)}\exp\left\{-\int d^nx\,\mathcal{L}[g_{\mu\nu},\phi]\right\}.\tag{4}$$

The Weyl anomaly is given by the Jacobian,[29,30]

$$J\equiv\det\left[\frac{\partial\tilde{\phi}'(y)}{\partial\tilde{\phi}(x)}\right]=\exp(-\mathrm{Tr}\,\alpha(x)\delta^n(x-y)+O(\alpha^2)).\tag{5}$$

Taking the heat-kernel regularization, we obtain the expression for the Weyl anomaly as

$$J=\exp\Big(-\lim_{t\to+0}\mathrm{Tr}[\alpha(x)G(x,y;t)]+O(\alpha^2)\Big),$$
$$\text{Weyl anomaly}=\left.\frac{\delta\Gamma}{\delta\alpha(x)}\right|_{\alpha=0}=-\left.\frac{\delta\ln J}{\delta\alpha(x)}\right|_{\alpha=0}=-2g^{\mu\nu}\langle T_{\mu\nu}\rangle=\lim_{t\to+0}\mathrm{Tr}\,G(x,y;t),\tag{6}$$

where $G(x,y;t)$ is the heat kernel defined by

$$\left(\frac{\partial}{\partial t}+\mathbf{D}_x\right)G(x,y;t)=0,\quad G(x,y;t)\left(\frac{\overleftarrow{\partial}}{\partial t}+\overleftarrow{D}_y^{\dagger}\right)=0,$$
$$\lim_{t\to+0} G(x,y;t)=\delta^n(x-y), \tag{7}$$

where $\overleftarrow{D}_x$ means it operates on the left. The parameter t is regarded here as a regularization parameter and is called Schwinger's *proper time*.[8] The last equation expresses the regularization of the delta function $\delta^n(x-y)$.[31,32] $G(x,y;t)$ can be symbolically written as

$$G(x,y;t)\equiv\langle x|e^{-t\mathbf{D}}|y\rangle,\quad t>0. \tag{8}$$

We note here the physical dimension of the space coordinate x^μ and the proper time t are

$$[x^\mu]=L,\quad [t]=L^2, \tag{9}$$

where L is some length. For other (conformally invariant) theories, the Weyl anomaly is obtained by replacing the operator $\mathbf{D}$ above. See Ref. 26 for details.

III. FEYNMAN RULES IN COORDINATE SPACE

A. Heat kernel and Feynman graph

Let us solve Eq. (7) in weak-field perturbation theory. For a general theory with the derivative couplings up to the second order, the operator $\mathbf{D}_x^{ij}$ can be always divided into the field-independent (free) part and the field-dependent (perturbation) one:

$$\mathbf{D}_x^{ij}=-\delta_{\mu\nu}\delta^{ij}\,\partial_\mu\partial_\nu-\mathbf{V}^{ij}(x),$$
$$\mathbf{V}^{ij}(x)\equiv W_{\mu\nu}^{ij}(x)\partial_\mu\partial_\nu+N_\mu^{ij}(x)\partial_\mu+M^{ij}(x), \tag{10}$$
$$i,j=1,2,...,N,$$

where $W_{\mu\nu}^{ij}$, N_μ^{ij}, and M^{ij} are external fields (background coefficient fields) and the field suffixes (such as a fermion suffix and a vector suffix) i,j are introduced for general use. In the present example (1), the above quantities are explicitly written as $(N=1)$

$$\mathbf{V}(x)=\sqrt[4]{g}(\boldsymbol{\nabla}^\mu\boldsymbol{\nabla}_\mu-qR)\frac{1}{\sqrt[4]{g}}-\delta_{\mu\nu}\partial_\mu\partial_\nu,$$
$$W_{\mu\nu}=g^{\mu\nu}-\delta_{\mu\nu}=-h_{\mu\nu}+h_{\mu\lambda}h_{\lambda\nu}+O(h^3),$$
$$N_\lambda=-g^{\mu\nu}\Gamma^\lambda_{\mu\nu}-g^{\lambda\mu}\Gamma^\nu_{\mu\nu}=-\partial_\mu h_{\lambda\mu}+O(h^2), \tag{11}$$
$$M=-qR+\tfrac{1}{4}g^{\mu\nu}\{\Gamma^\lambda_{\mu\lambda}\Gamma^\sigma_{\nu\sigma}+2\Gamma^\lambda_{\mu\nu}\Gamma^\sigma_{\lambda\sigma}-2\partial_\nu\Gamma^\lambda_{\mu\lambda}\}=-q(\partial^2h-\partial_\alpha\partial_\beta h_{\alpha\beta})-\tfrac{1}{4}\partial^2h+O(h^2),$$

where $g_{\mu\nu}=\delta_{\mu\nu}+h_{\mu\nu}$, $h\equiv h_{\mu\mu}$. The graphical representation of $W_{\mu\nu}$, N_λ, and M above is given, up to h^3 order, for the $n=6$-dim case in Appendix C: Fig. 16 for $W_{\mu\nu}$ and N_λ, Figs. 17–21 for M. The usage of general coefficients $W_{\mu\nu}^{ij}$, N_μ^{ij}, and M^{ij}, instead of their concrete contents, makes it possible to perform the general treatment valid for many theories.[26,33,34] All equations below are valid for all theories insofar as they have no higher-derivative interactions. Let us solve the differential equation (7) perturbatively for the case of weak external fields $(W_{\mu\nu}^{ij},N_\mu^{ij},M^{ij})$. (In the present example, this corresponds to perturbation around *flat* space.) The differential equation (7) becomes

$$\left(\frac{\partial}{\partial t}-\partial^2\right)G^{ij}(x,y;t)=\mathbf{V}^{ik}(x)G^{kj}(x,y;t),$$
$$\partial^2\equiv\delta_{\mu\nu}\partial_\mu\partial_\nu=\sum_{\mu=1}^{n}\left(\frac{\partial}{\partial x^\mu}\right)^2. \tag{12}$$

In the following we suppress the field suffixes $i,j,\ldots,$ and take the matrix notation. This equation (12) is the n-dim heat equation with the small perturbation $\mathbf{V}$. We give two important quantities in order to obtain the solution. (This approach is popular in the perturbative quantum field theory under the name *propagator approach*.[35] In Ref. 35, the momentum representation is taken, which is to be compared with the coordinate one of the present approach. The Weyl anomaly in the string theory was analyzed in this approach by Alvarez.[36])

1. Heat equation

The heat equation,

$$\left(\frac{\partial}{\partial t}-\partial^2\right)G_0(x,y;t)=0,\quad t>0, \tag{13}$$

has the solution

$$G_0(x,y;t)=G_0(x-y;t)=\int\frac{d^nk}{(2\pi)^n}\exp\{-k^2t+ik^\mu(x-y)^\mu\}I_N=\frac{1}{(4\pi t)^{n/2}}c^{-(x-y)^2/4t}I_N,$$
$$k^2\equiv\sum_{\mu=1}^{n}(k^\mu)^2, \tag{14}$$

where I_N is the identity matrix of the size $N\times N$. G_0 satisfies the initial condition: $\lim_{t\to+0}G_0(x-y;t)=\delta^n(x-y)I_N$. We define

$$G_0(x,y;t)=0,\quad \text{for } t\leqslant 0. \tag{15}$$

2. Heat propagator

The heat equation with the delta-function source defines the heat propagator,

$$\left(\frac{\partial}{\partial t}-\partial^2\right)S(x,y;t-s)=\delta(t-s)\delta^n(x-y)I_N,$$
$$S(x,y;t)=S(x-y;t)=\int\frac{d^nk}{(2\pi)^n}\frac{dk^0}{2\pi}\frac{\exp\{-ik^0t+ik\cdot(x-y)\}}{-ik^0+k^2}I_N=\theta(t)G_0(x-y;t), \tag{16}$$
$$k^2\equiv\sum_{\mu=1}^{n}k^\mu k^\mu,\quad k\cdot x\equiv\sum_{\mu=1}^{n}k^\mu x^\mu.$$

$\theta(t)$ is the *step function* defined by $\theta(t)=1$ for $t>0$; $\theta(t)=0$ for $t<0$. $S(x-y;t)$ satisfies the initial condition $\lim_{t\to+0}S(x-y;t)=\delta^n(x-y)I_N$ and $S(x,y;t)=0$ for $t\leqslant 0$.

Now the formal solution of (12) with the initial condition (7) is given by

$$G(x,y;t)=G_0(x-y;t)+\int d^nz\int_{-\infty}^{\infty}ds\,S(x-z;t-s)\mathbf{V}(z)G(z,y;s). \tag{17}$$

$G(x,y;t)$ appears in both sides above. We can iteratively solve (17) as[8]

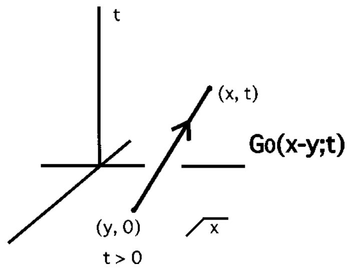

FIG. 1. Graph of $G_0(x-y;t)$.

$$
\begin{aligned}
G(x,y;t)&=G_0(x-y;t)+\int S\mathbf{V}G_0+\int S\mathbf{V}\int S\mathbf{V}G_0+\cdots,\\
G_1(x,y;t)&\equiv\int S\mathbf{V}G_0=\int d^nz\,dsS(x-z;t-s)\mathbf{V}(z)G_0(z-y;s)\\
&=\int d^nz\int_0^t ds\,G_0(x-z;t-s)\mathbf{V}(z)G_0(z-y;s),\\
G_2(x,y;t)&\equiv\int S\mathbf{V}\int S\mathbf{V}G_0=\int d^nz'\,ds'\,S(x-z';t-s')\mathbf{V}(z')\\
&\quad\times\int d^nz\,ds\,S(z'-z;s'-s)\mathbf{V}(z)G_0(z-y;s)\\
&=\int d^nz'\int_0^t ds'\,G_0(x-z';t-s')\mathbf{V}(z')\\
&\quad\times\int d^nz\int_0^{s'} ds\,G_0(z'-z;s'-s)\mathbf{V}(z)G_0(z-y;s),
\end{aligned}
\tag{18}
$$

$$
\begin{aligned}
G_3(x,y;t)&=\int d^nz''\int_0^t ds''\,G_0(x-z'';t-s'')\mathbf{V}(z'')\int d^nz'\int_0^{s''} ds'\,G_0(z''-z';s''-s')\mathbf{V}(z')\\
&\quad\times\int d^nz\int_0^{s'} ds\,G_0(z'-z;s'-s)\mathbf{V}(z)G_0(z-y;s).
\end{aligned}
$$

Expressions for higher-order terms are similarly obtained.

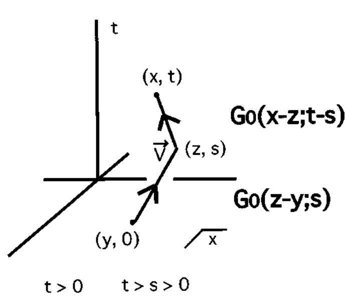

FIG. 2. Graph of $G_1(x,y;t)$.

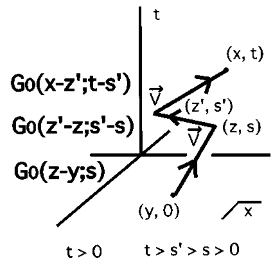

FIG. 3. Graph of $G_2(x,y;t)$.

As in the ordinary field theory, it is illuminating to represent this perturbative solution in graphs. We do it in the $(n+1)$-dimensional space, which is composed of the space of the ordinary n-dim (Euclidean) space plus 1-dim positive proper time. In the above solution, $G_0(x-y;t)$ plays the role of ''propagator.'' It is represented by a directed[37] straight line as in Fig. 1. $\mathbf{V}(z)$ plays the role of ''vertex,'' which acts on the system, during the process of ''propagation of particles,'' sometimes according to the perturbation order. The situation up to the third order is represented in Figs. 2–4. We can easily write down the expression of any higher order, $G_k(x,y;t)$, with the help of this graphical representation.

Generally, in n-dim, the terms up to $G_{n/2}$ are sufficient for the anomaly calculation.[26] In this sense, the present expansion looks like that with respect to the space(–time) dimension.

B. Factoring out the scale parameter *t*

Because of the presence of the positive regularization parameter t, we can safely (without singularity) take the trace part, $x=y$, in the above equations:

$$G(x,x;t)=G_0(0;t)+G_1(x,x;t)+G_2(x,x;t)+G_3(x,x;t)+\cdots,$$
$$G_0(0;t)=\frac{1}{(4\pi t)^{n/2}}I_N. \tag{19}$$

As shown in (6), the t^0 part of $G(x,x;t)$ is the Weyl anomaly. In order to see their t dependence, it is best to replace the dimensional coordinate variables such as (z,s) in (18) by the dimensionless ones (w,r),

$$G_1(x,x;t)\equiv\int S\mathbf{V}G_0\Big|_{x=y}=\frac{1}{t^{(n/2)-1}}\int d^nw\int_0^1 dr\, G_0(w;1-r)\mathbf{V}(x+\sqrt{t}w)G_0(w;r), \tag{20}$$

$$1>r=\frac{s}{t}>0,\quad w=(z-x)/\sqrt{t}, \tag{21}$$

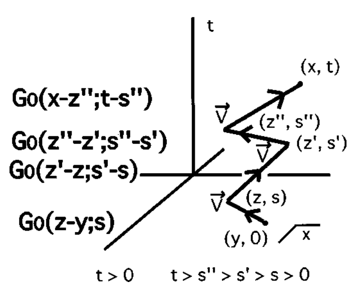

FIG. 4. Graph of $G_3(x,y;t)$.

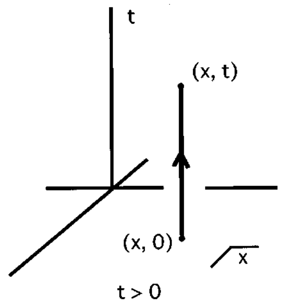

FIG. 5. Graph of $G_0(0;t)$.

where the relation (A2) is used. In the same way, we obtain

$$G_2(x,x;t) \equiv \int S\mathbf{V} \int S\mathbf{V} G_0 \bigg|_{x=y} = \frac{1}{t^{(n/2)-2}} \int d^n w' \int_0^1 dr' \, G_0(w';1-r')\mathbf{V}(x+\sqrt{t}w')$$

$$\times \int d^n w \int_0^{r'} dr \, G_0(w'-w;r'-r)\mathbf{V}(x+\sqrt{t}w) G_0(w;r), \tag{22}$$

where

$$1 > r' = s'/t > r = s/t > 0, \quad w' = (z'-x)/\sqrt{t}, \quad w = (z-x)/\sqrt{t},$$

$$G_3(x,x;t) \equiv \int S\mathbf{V} \int S\mathbf{V} \int S\mathbf{V} G_0 \bigg|_{x=y} = \frac{1}{t^{(n/2)-3}} \int d^n w'' \int_0^1 dr'' \, G_0(w'';1-r'')\mathbf{V}(x+\sqrt{t}w'')$$

$$\times \int d^n w' \int_0^{r''} dr' \, G_0(w''-w';r''-r')\mathbf{V}(x+\sqrt{t}w')$$

$$\times \int d^n w \int_0^{r'} dr \, G_0(w'-w;r'-r)\mathbf{V}(x+\sqrt{t}w) G_0(w;r), \tag{23}$$

where

$$1 > r'' = s''/t > r' = s'/t > r = s/t > 0,$$

$$w'' = (z''-x)/\sqrt{t}, \quad w' = (z'-x)/\sqrt{t}, \quad w = (z-x)/\sqrt{t}.$$

The above quantities of $G_k(x,x;t)$, $(k=0,...,3)$ are depicted in Figs. 5–8, with the dimensionless

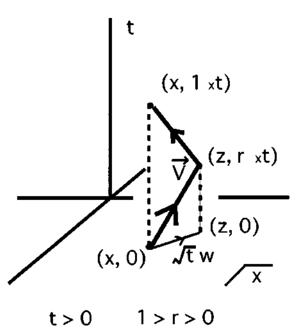

FIG. 6. Graph of $G_1(x,x;t)$.

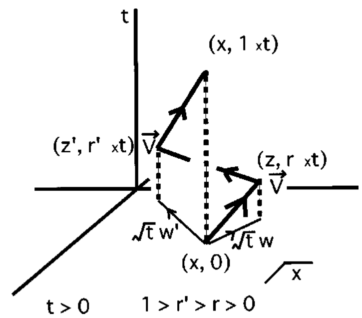

FIG. 7. Graph of $G_2(x,x;t)$.

quantities. We can easily write down higher-order terms with the help of graphs.

C. Vertex and propagator rules

The vertex operator $\mathbf{V}(x+\sqrt{t}w)$ in the expression $G_k(x,x;t)$ has differentials,

$$\mathbf{V}(x+\sqrt{t}w)=\frac{1}{t}W_{\mu\nu}(x+\sqrt{t}w)\frac{\partial}{\partial w^\mu}\frac{\partial}{\partial w^\nu}+\frac{1}{\sqrt{t}}N_\mu(x+\sqrt{t}w)\frac{\partial}{\partial w^\mu}+M(x+\sqrt{t}w), \tag{24}$$

and acts only on the ''adjacently right'' G_0 in Eqs. (20)–(23). Here we have the following *vertex rule*: Vertex Rule 1,

$$\begin{aligned}\mathbf{V}(x+\sqrt{t}w')G_0(w'-w;r'-r)&=\frac{1}{\{4\pi(r'-r)\}^{n/2}}\mathbf{V}(x+\sqrt{t}w')e^{-(w'-w)^2/4(r'-r)}\\&=\left\{\frac{1}{t}W_{\mu\nu}(x+\sqrt{t}w')\left(-\frac{\delta_{\mu\nu}}{2(r'-r)}+\frac{(w'-w)_\mu(w'-w)_\nu}{4(r'-r)^2}\right)\right.\\&\quad\left.+\frac{1}{\sqrt{t}}N_\mu(x+\sqrt{t}w')\left(-\frac{(w'-w)_\mu}{2(r'-r)}\right)+M(x+\sqrt{t}w')\right\}\\&\quad\times G_0(w'-w;r'-r)\\&=V(x+\sqrt{t}w';w'-w,r'-r;t)G_0(w'-w;r'-r),\end{aligned}$$

where

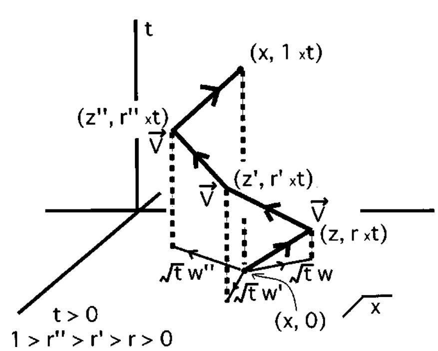

FIG. 8. Graph of $G_3(x,x;t)$.

$$V(x;w,r;t)\equiv\frac{1}{t}W_{\mu\nu}(x)\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\frac{1}{\sqrt{t}}N_\mu(x)\left(-\frac{w_\mu}{2r}\right)+M(x), \tag{25}$$

where V does *not* have differentials. Especially taking $r=0$, $w=0$ in the above and dropping primes ($'$), we obtain the following relation: Vertex Rule 2,

$$\begin{aligned}\mathbf{V}(x+\sqrt{t}w)G_0(w;r)&=\left\{\frac{1}{t}W_{\mu\nu}(x+\sqrt{t}w)\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)\right.\\&\quad\left.+\frac{1}{\sqrt{t}}N_\mu(x+\sqrt{t}w)\left(-\frac{w_\mu}{2r}\right)+M(x+\sqrt{t}w)\right\}G_0(w;r)\\&=V(x+\sqrt{t}w;w,r;t)G_0(w;r).\end{aligned}\tag{26}$$

Making use of the above rule, we can evaluate $G_1(x,x;t)$ of Eq. (20) as

$$\begin{aligned}G_1(x,x;t)&=\frac{1}{t^{(n/2)-1}}\int d^nw\int_0^1 dr\,G_0(w;1-r)G_0(w;r)V(x+\sqrt{t}w;w,r;t)\\&=\frac{1}{(4\pi)^{n/2}t^{(n/2)-1}}\int d^nw\int_0^1 dr\,G_0(w;(1-r)r)V(x+\sqrt{t}w;w,r;t),\end{aligned}\tag{27}$$

where the relation $G_0(w;1-k)G_0(w;r)=[1/(4\pi)^{n/2}]G_0(w;(1-r)r)$, $1>r>0$, which is derived from a *propagator rule* 4 (A8), is used in order to reduce the number of G_0's by one. In Appendix A, we list the propagator rules (A5)–(A8), and their graphical (''geometrical'') expressions in the coordinate space: Figs. 10–13. $G_2(x,x;t)$ of Eq. (22) is written, in terms of V, as

$$\begin{aligned}G_2(x,x;t)=&\frac{1}{t^{(n/2)-2}}\int d^nw'\int_0^1 dr'\,G_0(w';1-r')\int d^nw\int_0^{r'} dr\,V(x+\sqrt{t}w';w'-w,r'-r;t)\\&\times G_0(w'-w;r'-r)V(x+\sqrt{t}w;w,r;t)G_0(w;r).\end{aligned}\tag{28}$$

By changing the integration variable w' to a new one $\overline{w}$ defined below, we can make all G_0's have space variables independent of each other. Using the following relations:

$$G_0(w';1-r')G_0(w'-w;r'-r)=G_0\left(\overline{w};\frac{(1-r')(r'-r)}{1-r}\right)G_0(w;1-r),$$

$$1>r'>r,\quad \overline{w}=w'-\frac{1-r'}{1-r}w, \tag{29}$$

$$G_0(w;1-r)G_0(w;r)=\frac{1}{(4\pi)^{n/2}}G_0(w;(1-r)r),\quad 1>r>0,$$

which are obtained from Rule 2, (A6), and Rule 3, (A8), respectively, we can finally evaluate Eq. (28) as

$$\begin{aligned}G_2(x,x;t)=&\frac{1}{(4\pi)^{n/2}t^{(n/2)-2}}\int d^n\overline{w}\int_0^1 dr'\int d^nw\int_0^{r'} dr G_0\left(\overline{w};\frac{(1-r')(r'-r)}{1-r}\right)\\&\times G_0(w;(1-r)r)V(x+\sqrt{t}w';w'-w,r'-r;t)V(x+\sqrt{t}w;w,r;t),\\&w'=\overline{w}+\frac{1-r'}{1-r}w,\end{aligned}\tag{30}$$

where the integration variable w' is changed to $\overline{w}$ ($\det[\partial(w',w)/\partial(\overline{w},w)]=1$). We note the following things in the above evaluation.

(1) The number of propagators, G_0's, decreases by one and becomes the same as that of the space integration variables.
(2) All ''Gaussian'' coordinates in G_0's ($\overline{w}$ and w in the present case) can be taken to be independent.
(3) In the above reduction, we have applied the propagator rules on G_0's from ''left'' to ''right.'' There are some other choices (for example, from ''right'' to ''left'') which give expressions different from (30) in appearance.

These properties are valid for any order of $G_k(x,x;t)$.

Similarly, we can evaluate G_3 as

$$G_3(x,x;t)=\frac{1}{(4\pi)^{n/2}t^{(n/2)-3}}\int d^n\bar{\bar{w}}\int d^n\overline{w}\int d^nw\int_0^1 dr''\int_0^{r''}dr'\int_0^{r'}dr$$
$$\times G_0\left(\bar{\bar{w}};\frac{(1-r'')(r''-r')}{1-r'}\right)G_0\left(\overline{w};\frac{(1-r')(r'-r)}{1-r}\right)G_0(w;(1-r)r)$$
$$\times V(x+\sqrt{t}w'';w''-w',r''-r';t)V(x+\sqrt{t}w';w'-w,r'-r;t)V(x+\sqrt{t}w;w,r;t), \tag{31}$$
$$w''=\bar{\bar{w}}+\frac{1-r''}{1-r'}\overline{w}+\frac{1-r''}{1-r}w,\quad w'=\overline{w}+\frac{1-r'}{1-r}w,$$

where the integration variables w'' and w' are changed to $\bar{\bar{w}}$ and $\overline{w}$ ($\det[\partial(w'',w',w)/\partial(\bar{\bar{w}},\overline{w},w)]=1$). As in G_2, there are some different expressions depending on how we apply the propagator rules in G_0's.

Because of the integration formulas (A3) of Appendix A, the space integrations in (27), (30) and (31) give a product of Kronecker's deltas times some rational function of dimensionless parameters. From the above results we can write down $G_k(x,x;t)$ for any higher k. $G_k(x,x;t)$ has k-fold parameter integrals.

IV. EVALUATION OF t^0 PART OF $G(x,x;t)$—TAYLOR EXPANSION FOR TAKING THE LIMIT $t\to+0$—

Let us evaluate $G(x,x;t)|_{t^0}$. We consider $n=6$-dim space. We focus on the $(\partial\partial h)^3$-type terms, because that part has the sufficient information to determine the Weyl anomaly in 6 dim. Taking the Taylor expansion of $W_{\mu\nu}(x+\sqrt{t}v)$, $N_\mu(x+\sqrt{t}v)$, and $M(x+\sqrt{t}v)$ around $\sqrt{t}v=0$, $V(x+\sqrt{t}v;w,r;t)$ can be expanded as

$$V(x+\sqrt{t}v;w,r;t)=\frac{1}{t}W_{\mu\nu}(x+\sqrt{t}v)\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\frac{1}{\sqrt{t}}N_\mu(x+\sqrt{t}v)\left(-\frac{w_\mu}{2r}\right)+M(x+\sqrt{t}v)$$
$$=\frac{1}{t}V_{-1}(x,v;w,r)+V_0('')+tV_1('')+\cdots+\frac{1}{\sqrt{t}}V_{-1/2}('')+\sqrt{t}V_{1/2}('')+\cdots, \tag{32}$$

where $V_{-1/2}$, $V_{1/2},\ldots,$ are irrelevant parts because they all have odd-time derivatives of h's: ∂h, $\partial\partial\partial h,\ldots$. $V_{-1}('')=W_{\mu\nu}(x)(-\delta_{\mu\nu}/2r+w_\mu w_\nu/4r^2)$ is also irrelevant because it has no derivatives of h's.[38] V_0, V_1, V_2 are given by

$$V_0(x,v;w,r)=\frac{1}{2!}\partial_{\alpha_1}\partial_{\alpha_2}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\partial_{\alpha_1}N_\mu\cdot v^{\alpha_1}\left(-\frac{w_\mu}{2r}\right)+M,$$

$$V_1(x,v;w,r)=\frac{1}{4!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_4}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_4}\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\frac{1}{3!}\partial_{\alpha_1}\partial_{\alpha_2}\partial_{\alpha_3}N_\mu \cdot v^{\alpha_1}v^{\alpha_2}v^{\alpha_3}\left(-\frac{w_\mu}{2r}\right)+\frac{1}{2!}\partial_{\alpha_1}\partial_{\alpha_2}M\cdot v^{\alpha_1}v^{\alpha_2}, \tag{33}$$

$$V_2(x,v;w,r)=\frac{1}{6!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_6}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_6}\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\frac{1}{5!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_5}N_\mu \cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_5}\left(-\frac{w_\mu}{2r}\right)+\frac{1}{4!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_4}M\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_4}.$$

The Taylor expansion of $W_{\mu\nu}$, N_μ, M, for the case of the 6-dim scalar-gravity theory is graphically shown in Appendix C: (C3) for V_0, (C5) for V_1, and (C7) for V_2.

Now we pick up the t^0 part[39] and focus on the $(\partial\partial h)^3$ terms in the final form. For $G_1(x,x;t)$,

$$G_1(x,x;t)=\frac{1}{(4\pi)^3}\int_0^1 dr\int d^6w G_0(w;(1-r)r)\left[\frac{1}{t^2}V(x+\sqrt{t}w;w,r;t)\right],$$
$$\left.\left[\frac{1}{t^2}V('')\right]\right|_{t^0}=V_2(x,w;w,r). \tag{34}$$

We notice the $w^{\alpha_1}w^{\alpha_2}\cdots$ parts give, after the w integration, different products of Kronecker's deltas times powers of $(1-r)r$. See (A3).

As for $G_2(x,x;t)$, from (30),

$$G_2(x,x;t)=\frac{1}{(4\pi)^3}\int_0^1 dr'\int_0^{r'} dr\int d^6\overline{w}\int d^6w G_0\left(\overline{w};\frac{(1-r')(r'-r)}{1-r}\right)G_0(w;(1-r)r)\times\left[\frac{1}{t}V(x+\sqrt{t}w';w'-w,r'-r;t)V(x+\sqrt{t}w;w,r;t)\right],$$

$$\left.\left[\frac{1}{t}V('')V(''')\right]\right|_{t^0}=V_1(x,w';w'-w,r'-r)V_0(x,w;w,r)+V_0(x,w';w'-w,r'-r)V_1(x,w;w,r)+\text{irrel. terms},$$
$$w'=\overline{w}+R_1w,\quad w'-w=\overline{w}-S_1w, \tag{35}$$

$$R_1\equiv\frac{1-r'}{1-r}\equiv R(r,r'),\quad S_1\equiv\frac{r'-r}{1-r}\equiv S(r,r'),\quad R_1>0,\quad S_1>0,\quad R_1+S_1=1.$$

The functions $R(r,r')$ and $S(r,r')$ will be used in (37). The irrelevant terms (''irrel. terms'') are such ones as V_2V_{-1}, $V_{1/2}V_{1/2}$, etc.

As for $G_3(x,x;t)$, from (31),

$$G_3(x,x;t)=\frac{1}{(4\pi)^3}\int_0^1 dr''\int_0^{r''}dr'\int_0^{r'}dr\int d^6\bar{\bar{w}}\int d^6\overline{w}\int d^6w\,G_0\left(\bar{\bar{w}};\frac{(1-r'')(r''-r')}{1-r'}\right)$$
$$\times G_0\left(\overline{w};\frac{(1-r')(r'-r)}{1-r}\right)G_0(w;(1-r)r)[V(x+\sqrt{t}w'';w''-w',r''-r';t)$$
$$\times V(x+\sqrt{t}w';w'-w,r'-r;t)V(x+\sqrt{t}w;w,r;t)],$$
$$[V('')V(''')V('''')]|_{t^0}=V_0(x,w'';w''-w',r''-r')V_0(x,w';w'-w,r'-r)V_0(x,w;w,r)$$
$$+\text{irrel. terms},\tag{36}$$

where ''irrel. terms'' above are such ones as $V_1V_{-1}V_0$, $V_{1/2}V_{1/2}V_0$, etc. In the above, the coordinate variables in the integrand are written by the integration variables $\bar{\bar{w}}$, $\overline{w}$, and w as

$$w''=\bar{\bar{w}}+R_2\overline{w}+R_3w,\quad w''-w'=\bar{\bar{w}}-S_2\overline{w}-T_1w,$$
$$w'=\overline{w}+R_1w,\quad w'-w=\overline{w}-S_1w,$$

where

$$R_1=R(r,r')=\frac{1-r'}{1-r},\quad R_2=R(r',r'')=\frac{1-r''}{1-r'},\quad R_3=R(r,r'')=\frac{1-r''}{1-r},$$
$$S_1=S(r,r')=\frac{r'-r}{1-r},\quad S_2=S(r',r'')=\frac{r''-r'}{1-r'},\quad T_1=\frac{r''-r'}{1-r}\equiv T(r,r',r''),\tag{37}$$

where $R(r,r')$ and $S(r,r')$ was introduced in the previous order (35), and $T(r,r',r'')$ is a new function. R_i, S_i, and T_1 have the following relations:

$$R_1+S_1=1,\quad R_2+S_2=1,\quad R_3+T_1=R_1,\quad \frac{R_3}{R_2}=R_1,\quad \frac{T_1}{S_2}=R_1,$$
$$R_1,R_2,R_3,S_1,S_2,T_1>0.\tag{38}$$

Here we finish treating the Weyl anomaly $G(x,x;t)|_{t^0}$ in terms of the general ones: $(W_{\mu\nu},N_\lambda,M)$ and their derivatives. Their explicit forms depend on each model. The content of Appendix C comes from the 6-dim scalar-gravity theory (11). In the following two sections, we explain how we obtain the explicit form of the Weyl anomaly using the obtained formulas.

V. FOUR SPECIAL GRAPHS

In the 6-dim space, there are four ''important general invariants'' as the Weyl anomaly terms, which will be explained in the next section. In order to obtain the four coefficients of those terms, let us determine the coefficients of the following four $(\partial\partial h)^3$ terms that appear in $G(x,x;t)|_{t^0}$,

$$\text{Graph }3=\partial_\sigma\partial_\tau h_{\mu\nu}\cdot\partial_\nu\partial_\lambda h_{\tau\omega}\cdot\partial_\omega\partial_\mu h_{\lambda\sigma},$$
$$\text{Graph }67=\partial_\tau\partial_\omega h_{\mu\nu}\cdot\partial_\mu\partial_\nu h_{\lambda\sigma}\cdot\partial_\lambda\partial_\sigma h_{\tau\omega},$$
$$\text{Graph }1=\partial_\mu\partial_\nu h_{\nu\lambda}\cdot\partial_\lambda\partial_\sigma h_{\sigma\tau}\cdot\partial_\tau\partial_\omega h_{\omega\mu},$$
$$\text{Graph }2=\partial_\mu\partial_\nu h_{\tau\sigma}\cdot\partial_\sigma\partial_\lambda h_{\lambda\nu}\cdot\partial_\tau\partial_\omega h_{\omega\mu}.\tag{39}$$

Here we introduce a useful graphical representation to express SO(n) invariants like those given above. (See Ref. 40 for details.) We graphically express the basic ingredient $\partial_\mu\partial_\nu h_{\lambda\sigma}$ as

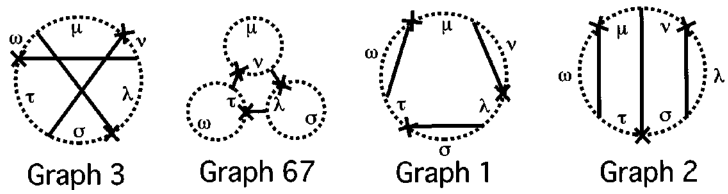

FIG. 9. Four Graphs of 3, 67, 1, and 2. See the (40) for the definition of the graph.

 $\equiv \partial_\mu \partial_\nu h_{\lambda\sigma}.$ (40)

The contraction of suffixes is expressed by gluing the corresponding suffix lines. Then the above four terms (39) are graphically shown in Fig. 9. The advantage of this representation is that the way suffixes are contracted can be read by the topology of the graph. We need not bother about the dummy contracted suffixes. For later use, we introduce the following usage too:

 $\equiv \partial_\mu \partial_\nu h_{\lambda\sigma} \cdot v^\mu v^\nu,$  $\equiv \partial_\mu \partial_\nu h_{\lambda\sigma} \cdot v^\mu v^\nu w^\lambda w^\sigma.$ (41)

The choice of those graphs (39) is an important step of this algorithm. As will be explained in Sec. VI, it is done by looking at the table of Appendix D and the content of the ''important invariants.'' In the evaluation, we exploit the topology of graphs in order to efficiently select relevant terms. All four graphs above come only from $G_3(x,x;t)|_{t^0}$. It is graphically seen by the following common features:

- There is no ,
- No tadpoles (),

the structure of G_1 and G_2:

$$G_1(x,x;t)|_{t^0} \sim \int dr \int d^6w\, G_0(w;(1-r)r) V_2(x,w;w,r),$$
$$G_2(x,x;t)|_{t^0} \sim \int dr' \int dr \int d^6\overline{w} \int d^6w\, G_0\left(\overline{w}; \frac{(1-r')(r'-r)}{1-r}\right) G_0(w;(1-r)r)$$
$$\{V_1(x,w';w'-w,r'-r)V_0(x,w;w,r) + V_0(x,w';w'-w,r'-r)V_1(x,w;w,r)\}, \quad (42)$$

where V_2, V_1, and V_0 are graphically shown in Appendix C 2. Both $G_1|_{t=0}$ and $G_2|_{t=0}$ contain, at least, one of two graph ingredients itemized above. For simplicity we focus, in this section, only on Graphs 3 and 67. Graph 1 and 2 are evaluated in Appendix B. Because of the following common features of Graph 3 and 67:

- No tadpoles,

- There is no  ,

we can reduce the expression of $G_3(x,x;t)|_{t^0}$, (36) with V_0 given by (C2) and (C3), to the following form as the relevant part:

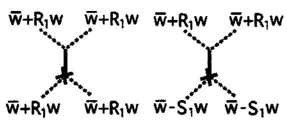
$$G_3(x,x;t)|_{t^0}=\frac{1}{(4\pi)^3}\int_0^1 dr''\int_0^{r''}dr'\int_0^{r'}dr\int d^6\bar{\bar{w}}\int d^6\bar{w}\int d^6w$$

$$\times G_0\left(\bar{\bar{w}};\frac{(1-r'')(r''-r')}{1-r'}\right)G_0\left(\bar{w};\frac{(1-r')(r'-r)}{1-r}\right)G_0(w;(1-r)r)$$

$$\times\left(-\frac{1}{2}\right)^3\times\frac{1}{4(r''-r')^2}\times\frac{1}{4(r'-r)^2}\times\frac{1}{4r^2}\times(R_2)^2(S_2)^2$$

$\times$ 
+irrelevant terms, (43)

where the relations $R_3/R_2=R_1$, $T_1/S_2=R_1$ are used [see (38)]. Furthermore, again by the common features of the Graphs 3 and 67, we see no contribution comes from $\overline{w}^8$ and $\overline{w}^6$ terms.[41]



= 
$$\times\{(R_1)^6(S_1)^2w^{\alpha_1}w^{\alpha_2}w^{\mu}w^{\nu}w^{\beta_1}w^{\beta_2}w^{\lambda}w^{\sigma}$$
$$+(R_1)^6w^{\alpha_1}w^{\alpha_2}w^{\mu}w^{\nu}w^{\beta_1}w^{\beta_2}\bar{w}^{\lambda}\bar{w}^{\sigma}$$
$$-(R_1)^5S_1(w^{\alpha_1}w^{\alpha_2}w^{\mu}w^{\nu}w^{\beta_1}\bar{w}^{\beta_2}+{}_6C_1)\bar{w}^{\lambda}w^{\sigma}\times 2$$
$$+(R_1)^4(S_1)^2(w^{\alpha_1}w^{\alpha_2}w^{\mu}w^{\nu}\bar{w}^{\beta_1}\bar{w}^{\beta_2}+{}_6C_2)w^{\lambda}w^{\sigma}$$
$$+(R_1)^2(S_1)^2(\bar{w}^{\alpha_1}\bar{w}^{\alpha_2}\bar{w}^{\mu}\bar{w}^{\nu}w^{\beta_1}w^{\beta_2}+{}_6C_4)w^{\lambda}w^{\sigma}$$
$$-(R_1)^3(S_1)(\bar{w}^{\alpha_1}\bar{w}^{\alpha_2}\bar{w}^{\mu}w^{\nu}w^{\beta_1}w^{\beta_2}+{}_6C_3)\bar{w}^{\lambda}w^{\sigma}\times 2$$
$$+(R_1)^4(\bar{w}^{\alpha_1}\bar{w}^{\alpha_2}w^{\mu}w^{\nu}w^{\beta_1}w^{\beta_2}+{}_6C_2)\bar{w}^{\lambda}\bar{w}^{\sigma}\}+O(\bar{w}^6)+O(\bar{w}^8),$$

(44)

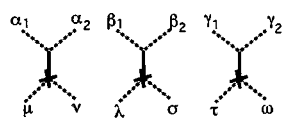
where ${}_mC_r$ means ''other choices of $r\overline{w}$'s among m suffixes appearing in the first term within the brackets.'' The $\bar{\bar{w}}$, $\overline{w}$, w integrations are three independent Gaussian integrations, and they give the product of two parts for each term. One part is a rational function of the parameters and the other is a symmetrized product of the Kronecker's deltas. In terms of a ''components'' notation:

$$\langle c_1,c_2\rangle\equiv c_1(\text{Graph } 3)+c_2(\text{Graph } 67), \tag{45}$$

the final result is evaluated as

$$G_3(x,x;t)|_{t^0}=\frac{1}{(4\pi)^3}\int_0^1 dr''\int_0^{r''}dr'\int_0^{r'}dr\times\left(-\frac{1}{2}\right)^3\times\frac{1}{4(r''-r')^2}\times\frac{1}{4(r'-r)^2}\times\frac{1}{4r^2}$$
$$\times(R_2)^2(S_2)^2\times\Bigg[(R_1)^6(S_1)^2\{2(1-r)r\}^6\times\langle 64,16\rangle$$
$$+2\,\frac{(1-r')(r'-r)}{1-r}\{2(1-r)r\}^5\times\{(R_1)^6\langle 0,0\rangle-2(R_1)^5S_1\langle 32,8\rangle$$
$$+(R_1)^4(S_1)^2\langle 64,16\rangle\}+\left\{2\,\frac{(1-r')(r'-r)}{1-r}\right\}^2\{2(1-r)r\}^4\times\{(R_1)^2(S_1)^2\langle 0,8\rangle$$
$$-2(R_1)^3S_1\langle 32,0\rangle+(R_1)^4\langle 0,8\rangle\}\Bigg]+\text{other graph terms}$$
$$=\frac{1}{(4\pi)^3}\left\langle\frac{4}{27\times 105},-\frac{1}{36\times 63}\right\rangle+\text{other graph terms.}\tag{46}$$

The above numbers $\langle c_1,c_2\rangle$ are obtained by a computer calculation.[42] The numbers c_1 and c_2 show the ‘‘weights’’ when a symmetrized product of Kronecker’s deltas are multiplied to a $(\partial\partial h)^3$ tensor. For example the first one of (46), $\langle 64,16\rangle$, says



$$\times[\alpha_1\alpha_2\mu\nu\beta_1\beta_2\lambda\sigma\gamma_1\gamma_2\tau\omega]$$
$$=64(\text{Graph }3)+16(\text{Graph }67)+\text{other graph terms,}\tag{47}$$

where the notation $[\alpha_1\alpha_2\cdots]$ is the symmetrized product of Kronecker’s deltas and is defined in (A4) of Appendix A. Note that in the expression just before the parameter integral, poles at $r=1$, $r'=1$ cancel out and there remain no divergences of the parameter integrals. This occurs also in the calculation in Appendix B. Adding the result for Graph 1 and 2 explained in Appendix B, we obtain finally the total contribution of $G(x,x;t)|_{t^0}$ to the four graphs as

$$G(x,x;t)|_{t^0}=\frac{1}{(4\pi)^3}\left\{\frac{4}{27\times 105}(\text{Graph }3)-\frac{1}{36\times 63}(\text{Graph }67)+\frac{1}{36\times 630}(\text{Graph }1)\right.$$
$$\left.+\frac{1}{36\times 35}(\text{Graph }2)\right\}+\text{other terms.}\tag{48}$$

VI. FINAL INVARIANT FORM OF 6-DIM WEYL ANOMALY

The general structure of the Weyl anomaly has been analyzed by Refs. 43–45. They claim that the Weyl anomaly is composed of three types of terms: (a) the Euler term; (b) conformal invariants; (c) trivial terms. Trivial terms are those that can be absorbed by local counterterms made of the metric. This statement is checked by the cohomology analysis up to six dimensions.[2] We called, in Sec. V, the (a) and (b) terms ‘‘important invariants.’’ Therefore we may write, for the present 6-dim case,

$$G(x,x;t)|_{t^0}=\frac{1}{(4\pi)^3}\sqrt{g}\{xC_1+yC_2+zC_3+wE+\text{trivial terms}\}$$

$$C_1=C_{\mu\nu\lambda\sigma}C^{\sigma\lambda\alpha\beta}C_{\beta\alpha}{}^{\nu\mu},\quad C_2=C_{\mu\nu\alpha\sigma}C^{\nu\lambda\beta\alpha}C_\lambda{}^{\mu\sigma}{}_\beta,$$

$$C_3\sim C_{\mu\nu\alpha\beta}\nabla^2C^{\mu\nu\alpha\beta}+\cdots,\quad E\sim R_{\mu\nu\alpha\beta}R_{\lambda\sigma\gamma\delta}R_{\tau\omega\epsilon\theta}\epsilon^{\mu\nu\lambda\sigma\tau\omega}\epsilon^{\alpha\beta\gamma\delta\epsilon\theta}, \tag{49}$$

$$C^\lambda_{\mu\nu\sigma}=R^\lambda{}_{\mu\nu\sigma}+\frac{1}{4}(\delta^\lambda_\nu R_{\mu\sigma}+g_{\mu\sigma}R^\lambda_\nu-\nu\leftrightarrow\sigma)+\frac{1}{20}(\delta^\lambda_\sigma g_{\mu\nu}-\nu\leftrightarrow\sigma)R,$$

where $C^\lambda{}_{\mu\nu\sigma}$ is the Weyl tensor, C_1, C_2, and C_3 are three independent conformal invariants, and E is the Euler term. x,y,z, and w are some constants to be determined. It is well established that all possible independent invariants (parity even) with mass dimension 6 are, in the 6 and higher space dimensions, given by the following 17 terms:[2,46,47]

$$P_1=RRR,\quad P_2=RR_{\mu\nu}R^{\mu\nu},\quad P_3=RR_{\mu\nu\lambda\sigma}R^{\mu\nu\lambda\sigma},$$

$$P_4=R_{\mu\nu}R^{\nu\lambda}R_\lambda{}^\mu,\quad P_5=-R_{\mu\nu\lambda\sigma}R^{\mu\lambda}R^{\nu\sigma},\quad P_6=R_{\mu\nu\lambda\sigma}R_\tau{}^{\nu\lambda\sigma}R^{\mu\tau},$$

$$A_1=R_{\mu\nu\lambda\sigma}R^{\sigma\lambda}{}_{\tau\omega}R^{\omega\tau\nu\mu},\quad B_1=R_{\mu\nu\tau\sigma}R^\nu{}_{\lambda\omega}{}^\tau R^{\lambda\mu\sigma\omega},$$

$$O_1=\nabla^\mu R\cdot\nabla_\mu R,\quad O_2=\nabla^\mu R_{\lambda\sigma}\cdot\nabla_\mu R^{\lambda\sigma},$$

$$O_3=\nabla^\mu R^{\lambda\rho\sigma\tau}\cdot\nabla_\mu R_{\lambda\rho\sigma\tau},\quad O_4=\nabla^\mu R_{\lambda\nu}\cdot\nabla^\nu R^\lambda{}_\mu, \tag{50}$$

$$T_1=\nabla^2R\cdot R,\quad T_2=\nabla^2R_{\lambda\sigma}\cdot R^{\lambda\sigma},\quad T_3=\nabla^2R_{\lambda\rho\sigma\tau}\cdot R^{\lambda\rho\sigma\tau},$$

$$T_4=\nabla^\mu\nabla^\nu R\cdot R_{\mu\nu},$$

$$S=\nabla^2\nabla^2R.$$

In terms of the above 17 ''basis,'' we can rewrite (49) as follows:

$$C_1=\tfrac{9}{200}P_1-\tfrac{27}{40}P_2+\tfrac{3}{10}P_3+\tfrac{5}{4}P_4+\tfrac{3}{2}P_5-3P_6+A_1,$$

$$C_2=-\tfrac{19}{800}P_1+\tfrac{57}{160}P_2-\tfrac{3}{40}P_3-\tfrac{7}{16}P_4-\tfrac{9}{8}P_5+\tfrac{3}{4}P_6+B_1,$$

$$C_3=P_1-8P_2-2P_3+10P_4+10P_5-\tfrac{1}{2}T_1+5T_2-5T_3, \tag{51}$$

$$E=P_1-12P_2+3P_3+16P_4+24P_5-24P_6+4A_1-8B_1,$$

$$G(x,x,t)|_{t^0}=\frac{1}{(4\pi)^3}\sqrt{g}\left\{(x+4w)A_1+(y-8w)B_1+\left(\frac{5}{4}x-\frac{7}{16}y+10z+16w\right)P_4\right.$$
$$\left.+\left(\frac{3}{2}x-\frac{9}{8}y+10z+24w\right)P_5+\text{other invariants}\right\},$$

where ''other invariants'' means other than A_1, B_1, P_4, and P_5. Now we see how nicely we have chosen the four graphs in Sec. V.

(i) We note that the trivial terms are written in the total derivative form, therefore they do not contain any one of A_1, B_1, P_4, and P_5.

(ii) Now we know, from Appendix D,

$$P_4|_{(\partial\partial h)^3} = -\tfrac{1}{4}(\text{Graph1}) + \text{other } (\partial\partial h)^3 \text{ terms},$$

$$P_5|_{(\partial\partial h)^3} = \tfrac{1}{4}(\text{Graph2}) + \text{other } (\partial\partial h)^3 \text{ terms},$$

$$A_1|_{(\partial\partial h)^3} = -(\text{Graph3}) + \text{other } (\partial\partial h)^3 \text{ terms},$$

$$B_1|_{(\partial\partial h)^3} = -\tfrac{1}{4}(\text{Graph3}) + \tfrac{1}{4}(\text{Graph67}) + \text{other } (\partial\partial h)^3 \text{ terms}, \tag{52}$$

where ''other $(\partial\partial h)^3$ terms'' means ''other terms than Graph1,2,3 and 67''.[48]

(iii) We also note, again from Appendix D, Graphs 1, 2, 3, and 67 do not come from other invariants than (A_1, B_1, P_4, P_5).

These properties are due to the chosen four graphs. Then we can rewrite (51) as

$$\begin{aligned} G(x,x;t)|_{t^0,(\partial\partial h)^3} = \frac{1}{(4\pi)^3}\Bigg\{ & \left(-x - \frac{1}{4}y - 2w\right)(\text{Graph3}) + \frac{1}{4}(y - 8w)(\text{Graph67}) \\ & + \frac{1}{4}\left(\frac{3}{2}x - \frac{9}{8}y + 10z + 24w\right)(\text{Graph2}) \\ & - \frac{1}{4}\left(\frac{5}{4}x - \frac{7}{16}y + 10z + 16w\right)(\text{Graph1}) + \text{other } (\partial\partial h)^3 \text{ terms}\Bigg\}. \end{aligned} \tag{53}$$

Comparing the result of Sec. V, we finally obtain

$$\begin{gathered} x = -\frac{83}{189\times 60}, \quad y = \frac{31}{189\times 15}, \quad z = -\frac{11}{189\times 50}, \quad w = \frac{3}{189\times 10}, \\ G(x,x;t)|_{t^0} = -2g^{\mu\nu}\langle T_{\mu\nu}\rangle = \frac{1}{(4\pi)^3}\frac{1}{189}\sqrt{g}\left\{-\frac{83}{60}C_1 + \frac{31}{15}C_2 - \frac{11}{50}C_3 + \frac{3}{10}E + \text{trivial terms}\right\}. \end{gathered} \tag{54}$$

The trivial terms can be similarly obtained, but they do change by introducing the local counterterms in the action and seem to be unimportant. This result (54) is similar to that of Ref. 17.

VII. DISCUSSION AND CONCLUSION

We have presented a new algorithm to obtain the Weyl anomaly in the higher dimensions. The Feynman rules in coordinate space are presented. The graphical representation is exploited at all stages. Especially the graphical calculation is taken to efficiently compute the coefficients of the four graphs given in Sec. V. An explicit result of the Weyl anomaly for the 6-dim scalar gravity is obtained.

As the space–time dimension increases, the number of suffixes to deal with increases because we must treat higher products of Riemann tensors. The aid of the computer is indispensable in this algebraic calculation. As mentioned at some places in the text and the Appendices, the weight

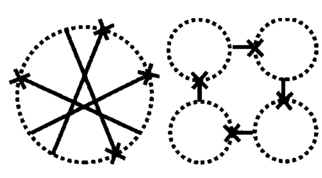


FIG. 10. Two important $(\partial\partial h)^4$ graphs in 8 dim.

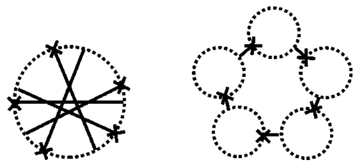

FIG. 11. Two important $(\partial\partial h)^5$ graphs in 10 dim.

calculation in the contraction of multisuffixed quantities relies on a computer (a C program[42]). Although we do not touch on the computer algorithm in the present paper, it helps to obtain the concrete results.

In the recent rapid development of string theory, the low-energy effective actions play an important role. They are field theories (supergravities) on various (higher) dimensions. The chiral anomalies of gravitational and gauge symmetries were well analyzed for those low-energy effective actions. The famous one is the pioneering work by Green and Schwarz,[49] where they found the SO(32) and $E_8\times E_8$ gauge group from the analysis of the chiral anomaly structure of 10-dim $N=1$ supergravity. Clearly the analysis from the Weyl anomaly side is lacking. From the present standpoint, we stress the importance of examining the string from the structure of the Weyl anomaly in the low-energy effective theories.[50] One reason is we know some important models often have vanishing Weyl anomaly due to conformal symmetry. Another is that the supersymmetry surely relates the Weyl anomaly to the chiral one. We can examine the role of supersymmetry from this point. Reference 51 recently analyzed the Weyl anomaly of conformal field theories using the adS/CFT correspondence conjectured by Ref. 52. Weyl anomalies are explicitly obtained for some theories in 2, 4, and 6 dimensions. We hope the present result will become useful when we go over the quantum field theory through the string theory.

We have most experience with quantization only in 0–4-dim field theories. Higher-dimensional quantum field theories have not been so thoroughly examined (at least systematically) so far, because they are unrenormalizable except for free theories. In the text we consider free theories on curved space. It is meaningful if we ignore the trivial terms and the divergent massive terms, which should be explained by the quantum gravitational mode. It might be possible to find a clue to make meaningful the higher-dimensional field theories through the present analysis.

Although the nonperturbative aspect is recently stressed in string theory, the perturbative analysis is still important because it is one of few reliable approaches to analyze dynamical aspects systematically. We suppose the analysis will become important to understand how the quantum field theory is generalized in the coming new era of Planck physics. Finally, we point out that the graphs shown in Figs. 10 and 11 are expected to become some of the ''important graphs'' in the Weyl anomaly calculation in 8-dim and 10-dim, respectively.

APPENDIX A: PROPAGATOR RULES

$G_0(x;t)$ is the solution of the heat equation, Eq. (13), and is given by

$$G_0(x;t)=\frac{1}{(4\pi t)^{n/2}}e^{-x^2/4t}I_N,\quad t>0,\quad x^2=(x_1)^2+(x_2)^2+\cdots+(x_n)^2, \tag{A1}$$

where I_N is the $N\times N$ unit matrix and $x=(x_1,x_2,\ldots,x_n)$ is the n-dim Euclidean space coordinates. It has the basic properties

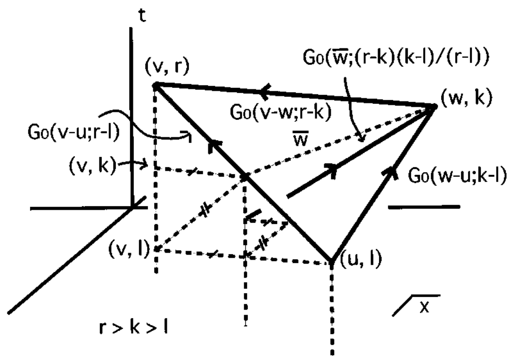

FIG. 12. Propagator Rule 1, Eq. (A5).

$$G_0(x;t)=G_0(-x;t)\text{:even function of } x,$$
$$G_0(\sqrt{a}x;at)=a^{-n/2}G_0(x;t), \quad a>0. \tag{A2}$$

The integral formula is given by

$$\int d^nx\, x^{\mu_1}\cdots x^{\mu_{2s}}G_0(x;t)=[\mu_1\cdots\mu_{2s}](2t)^sI_N, \tag{A3}$$

where $[\mu_1\cdots\mu_{2s}]$ is the totally symmetric sum of products of Kronecker's deltas and is concretely defined by

$$[\mu\nu]\equiv\delta^{\mu\nu},$$
$$[\mu\nu\lambda\sigma]\equiv\delta^{\mu\nu}\delta^{\lambda\sigma}+\delta^{\mu\sigma}\delta^{\nu\lambda}+\delta^{\mu\lambda}\delta^{\nu\sigma},$$
$$[\mu_1\cdots\mu_6]\equiv\delta^{\mu_1\mu_2}[\mu_3\cdots\mu_6]+\delta^{\mu_1\mu_3}[\cdots]+\cdots+\delta^{\mu_1\mu_6}[\cdots],$$
$$\cdots \tag{A4}$$
$$\cdots$$
$$[\mu_1\cdots\mu_{2s}]\equiv\delta^{\mu_1\mu_2}[\mu_3\cdots\mu_{2s}]+\delta^{\mu_1\mu_3}[\cdots]+\cdots+\delta^{\mu_1\mu_{2s}}[\cdots].$$

$G_0(x,t)$ has the ''convolution'' property. Propagator Rule 1:

$$G_0(v-w;r-k)G_0(w-u;k-l)=G_0\left(\bar{w};\frac{(r-k)(k-l)}{r-l}\right)G_0(v-u;r-l),$$
$$r>k>l, \quad \bar{w}=w-\frac{(k-l)v+(r-k)u}{r-l}. \tag{A5}$$

This relation is geometrically expressed in the coordinate space as in Fig. 12. Some special cases of above are given by Propagator Rule 2: $v=0$, $r=1$ in Eq. (A5),

$$G_0(w;1-k)G_0(w-u;k-l)=G_0\left(\bar{w};\frac{(1-k)(k-1)}{1-l}\right)G_0(u;1-l),$$
$$1>k>l, \quad \bar{w}=w-\frac{1-k}{1-l}u; \tag{A6}$$

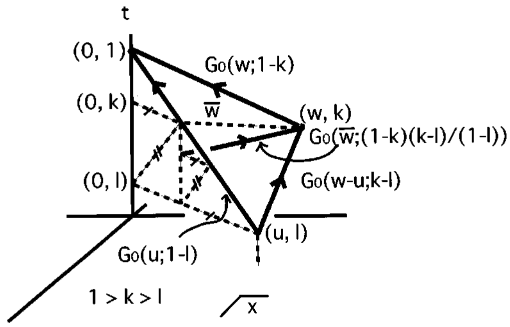

FIG. 13. Propagator Rule 2, Eq. (A6).

Propagator Rule 3: $u=0$, $l=0$ in Eq. (A5),

$$G_0(v-w;r-k)G_0(w;k)=G_0\left(\overline{w};\frac{(r-k)k}{r}\right)G_0(v;r),$$
$$r>k>0,\quad \overline{w}=w-\frac{k}{r}v; \tag{A7}$$

Propagator Rule 4: $u=0$, $v=0$, $l=0$, in Eq. (A5),

$$G_0(w;r-k)G_0(w;k)=\frac{1}{(4\pi r)^{n/2}}G_0\left(w;\frac{(r-k)k}{r}\right),\quad r>k>0. \tag{A8}$$

The above three relations are geometrically represented as in Figs. 13–15.

APPENDIX B: SUPPLEMENTARY CALCULATION OF SEC. V

In Sec. V of the text, we have evaluated $G(x,x;t)|_{t^0}$, focusing on four special $(\partial\partial h)^3$ terms (graphs) in order to fix four coefficients of the main Weyl anomaly terms given in (49). Among the four graphs, Graph3 and 67 only are explained for simplicity. We evaluate the remaining graphs, Graph1 and 2 to supplement Sec. V.

From (36),

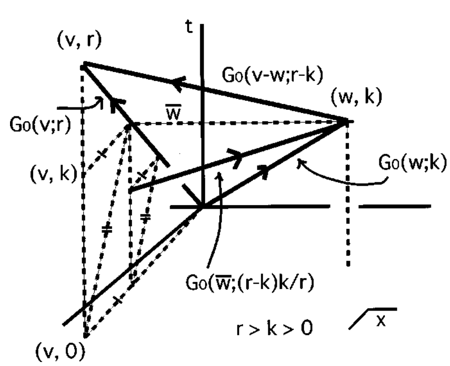

FIG. 14. Propagator Rule 3, Eq. (A7).

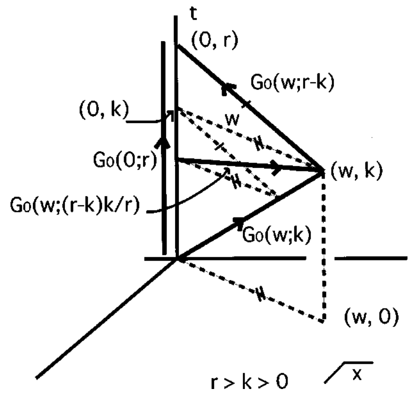

FIG. 15. Propagator Rule 4, Eq. (A8).

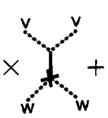
$$
G_3(x,x;t)|_{t^0} = \frac{1}{(4\pi)^3} \int d^6\bar{\bar{w}} \int d^6\overline{w} \int d^6 w \int_0^1 dr'' \int_0^{r''} dr' \int_0^{r'} dr
$$
$$
\times G_0\left(\bar{\bar{w}}; \frac{(1-r'')(r''-r')}{1-r'} \right) G_0\left(\overline{w}; \frac{(1-r')(r'-r)}{1-r} \right) G_0(w;(1-r)r)
$$
$$
\times V_0(x,w'';w''-w',r''-r') V_0(x,w';w'-w,r'-r) V_0(x,w;w,r) + \text{irrel.},
$$

$$
w'' = \bar{\bar{w}} + R_2 \overline{w} + R_3 w, \quad w'' - w' = \bar{\bar{w}} - S_2 \overline{w} - T_1 w, \tag{B1}
$$

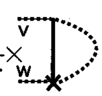
$$
w' = \overline{w} + R_1 w, \quad w' - w = \overline{w} - S_1 w,
$$

where R_i, S_i, and T_1 are defined in (37). Because Graph1 and 2 do not have tadpoles and  subgraph, we can reduce V_0 of (C2) with (C3) to the following relevant form:

$$
V_0(x,v;w,r) = -\frac{1}{2} \times \frac{1}{4r^2} \times
$$



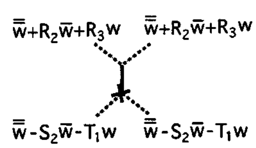
$$
+ \frac{1}{2r} \times
$$



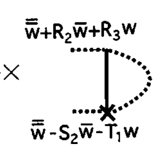
$$
+ \text{irrel. terms.} \tag{B2}
$$

The first V_0 in (B1) is evaluated as

$$
V_0(x,w'';w''-w',r''-r') = -\frac{1}{8(r''-r')^2} \times
$$

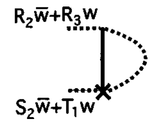


$$
+ \frac{1}{2(r''-r')} \times
$$



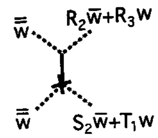
$$
+ \text{irrel. terms,} \tag{B3}
$$

$$\text{Second term of (B3)}=\frac{1\times(-1)}{2(r''-r')}\times$$

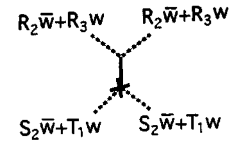


$$+\text{irrel. terms,}$$

$$\text{First term of (B3)}=-\frac{1}{8(r''-r')^2}\Bigg(2\times2\times(-1)\times$$



$$+$$

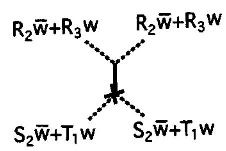


$$\Bigg)+\text{irrel. terms.} \qquad \text{(B4)}$$

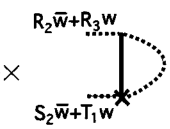
The above V_0, with the $\bar{\bar{w}}$ integration, gives

$$\int d^6\bar{\bar{w}}\, V_0(x,w'';w''-w',r''-r')$$

$$=-\frac{1}{8(r''-r')^2}\times$$

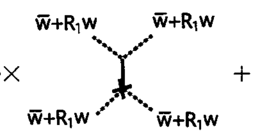


$$+\left\{\frac{-1}{2(r''-r')}+\frac{2\times2}{8(r''-r')^2}\times2\frac{(1-r'')(r''-r')}{(1-r')}\right\}\times$$

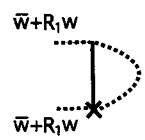


$$+\text{irrel. terms}$$

$$=-\frac{(R_2)^2(S_2)^2}{8(r''-r')^2}\times$$



$$+\frac{1+r'-2r''}{2(r''-r')(1-r')}R_2S_2$$

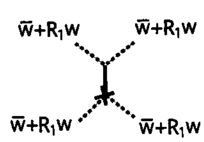


$$+\text{irrel. terms,} \qquad \text{(B5)}$$

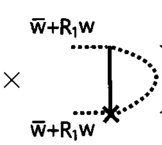
where $\bar{\bar{w}}$ is integrated out and the relations $R_3/R_2=T_1/S_2=R_1$ are used. Therefore the $V_0V_0V_0$ part of (B1), with the $\bar{\bar{w}}$ integration, can be written as

$$\int d^6\bar{\bar{w}} V_0(x,w'';w''-w',r''-r')V_0(x,w';w'-w,r'-r)V_0(x,w;w,r)$$

$$=\left\{-\frac{(1-r'')^2}{8(1-r')^4}\times\right.$$

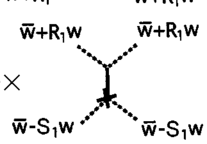


$$+\frac{(1+r'-2r'')(1-r'')}{2(1-r')^3}\times$$

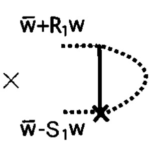


$$\left.\right\}$$

$$\times\left\{-\frac{1}{8(r'-r)^2}\times\right.$$

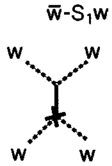


$$+\frac{1}{2(r'-r)}\times$$

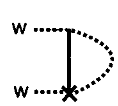


$$\left.\right\}$$

$$\times\left\{-\frac{1}{8r^2}\times\right.$$



$$+\frac{1}{2r}\times$$



$$\left.\right\}+\text{irrel.} \qquad \text{(B6)}$$

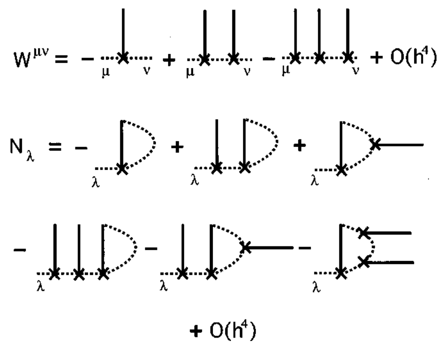


FIG. 16. $W^{\mu\nu}$ and N_λ.

Now we can further evaluate (B1) by picking up relevant powers of $\overline{w}$ in (B6) in the same way as Sec. V. After integration of the remaining coordinates $(\overline{w},w)$ and the parameters (r,r',r''), the final result is

$$G_3(x,x;t)|_{t^0}=\frac{1}{(4\pi)^3}\left\{\frac{1}{36\times 630}(\text{Graph1})+\frac{1}{36\times 35}(\text{Graph2})\right\}+\text{other terms.} \tag{B7}$$

APPENDIX C: WEAK FIELD EXPANSION OF 6-DIM SCALAR-GRAVITY THEORY

In the text, we have taken 6-dim scalar-gravity theory (1) as a higher-dimensional model. The expressions for the general theories are expressed in terms of $W_{\mu\nu}$, N_λ, and M (10). In this appendix we graphically express those general expressions for the case of the explicit model.

1. Graphs of *W*, *N*, and *M*

For the 6-dim scalar-gravity theory, $W_{\mu\nu}$, N_λ, and M are given by (11). Their weak-field expansions ($g_{\mu\nu}=\delta_{\mu\nu}+h_{\mu\nu}$) up to $O(h^3)$ are given in Fig. 16 for $W_{\mu\nu}$ and N_λ, and in Figs. 17–21 for M. Especially they are classified by the number of closed suffix loops.

2. Taylor Expansion of *W*, *N*, and *M*

In Sec. IV of the text, we have Taylor expanded $W_{\mu\nu}$, N_μ, and M, which are the background functional appearing in the differential operator **D**

$$\begin{aligned}W_{\mu\nu}(x+v)&=W_{\mu\nu}(x)+\partial_{\alpha_1}W_{\mu\nu}\cdot v^{\alpha_1}+\tfrac{1}{2}\partial_{\alpha_1}\partial_{\alpha_2}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}+\cdots,\\ N_\mu(x+v)&=N_\mu(x)+\partial_{\alpha_1}N_\mu\cdot v^{\alpha_1}+\tfrac{1}{2}\partial_{\alpha_1}\partial_{\alpha_2}N_\mu\cdot v^{\alpha_1}v^{\alpha_2}+\cdots,\\ M(x+v)&=M(x)+\partial_{\alpha_1}M\cdot v^{\alpha_1}+\tfrac{1}{2}\partial_{\alpha_1}\partial_{\alpha_2}M\cdot v^{\alpha_1}v^{\alpha_2}+\cdots.\end{aligned} \tag{C1}$$

We focus on those terms that have only $\partial\partial h$-type ones. They are sufficient to determine the Weyl anomaly, and are used in the text.

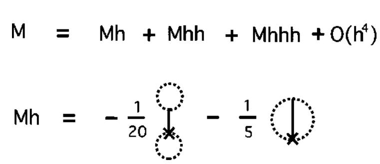

FIG. 17. M, order of h.

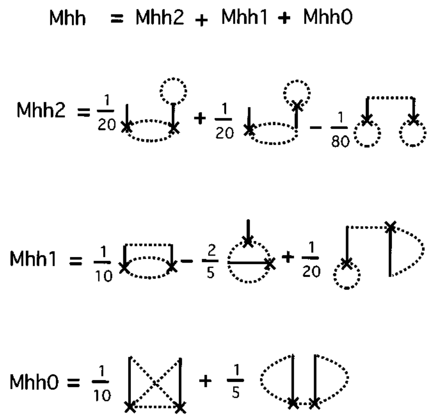

FIG. 18. *M*, order of h^2.

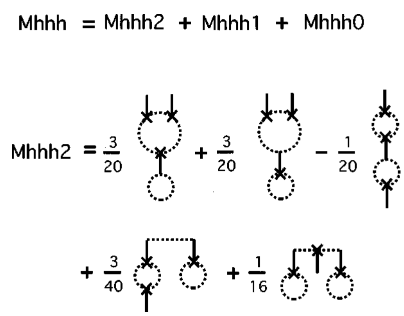

FIG. 19. *M*, order of h^3 and loop No.=2.

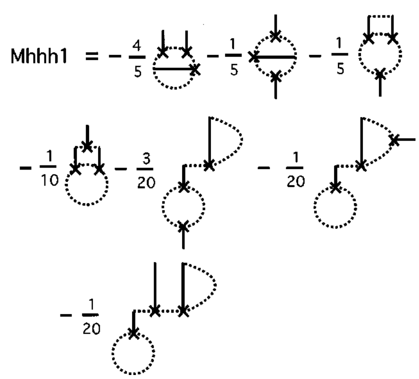

FIG. 20. *M*, order of h^3 and loop No.=1.

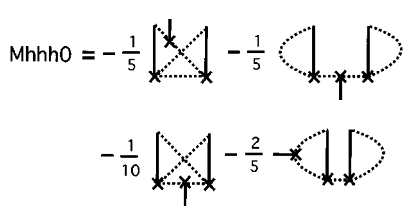

FIG. 21. *M*, order of h^3 and loop No.=0.

(i) Expansion terms appearing in V_0 of (33),

$$V_0(x,v;w,r)=\frac{1}{2!}\partial_{\alpha_1}\partial_{\alpha_2}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\partial_{\alpha_1}N_\mu\cdot v^{\alpha_1}\left(-\frac{w_\mu}{2r}\right)+M, \quad \text{(C2)}$$

$\frac{1}{2!}\partial_{\alpha_1}\partial_{\alpha_2}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}= -\frac{1}{2}$  + irrel. terms,

$\partial_{\alpha_1}N_\lambda\cdot v^{\alpha_1}= -$  + irrel. terms,

$M= -\frac{1}{20}$  $-\frac{1}{5}$  + irrel. terms. (C3)

(ii) Expansion terms appearing in V_1 of (33),

$$V_1(x,v;w,r)=\frac{1}{4!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_4}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_4}\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\frac{1}{3!}\partial_{\alpha_1}\partial_{\alpha_2}\partial_{\alpha_3}N_\mu$$

$$\cdot v^{\alpha_1}v^{\alpha_2}v^{\alpha_3}\left(-\frac{w_\mu}{2r}\right)+\frac{1}{2!}\partial_{\alpha_1}\partial_{\alpha_2}M\cdot v^{\alpha_1}v^{\alpha_2}, \quad \text{(C4)}$$

$\frac{1}{4}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_4}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_4}= \frac{1}{2}$  + irrel. terms,

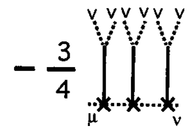
$\frac{1}{3!}\partial_{\alpha_1}\partial_{\alpha_2}\partial_{\alpha_3}N_\lambda\cdot v^{\alpha_1}v^{\alpha_2}v^{\alpha_3}= \frac{1}{2}\Bigg[$  +  $\Bigg]$ + irrel. terms,

$\frac{1}{2!}\partial_{\alpha_1}\partial_{\alpha_2}M\cdot v^{\alpha_1}v^{\alpha_2}=\frac{1}{2}\Bigg\{\frac{1}{20}$  $+\frac{1}{20}$  $-\frac{2}{80}$ 
$+\frac{2}{10}$  $-\frac{2}{5}$  $+\frac{2}{20}$ 
$+\frac{2}{10}$  $+\frac{2}{5}$  $\Bigg\}$ + irrel. terms. (C5)

(iii) Expansion terms appearing in V_2 of (33),

$$V_2(x,v;w,r)=\frac{1}{6!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_6}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_6}\left(-\frac{\delta_{\mu\nu}}{2r}+\frac{w_\mu w_\nu}{4r^2}\right)+\frac{1}{5!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_5}N_\mu \cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_5}\left(-\frac{w_\mu}{2r}\right)+\frac{1}{4!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_4}M\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_4}. \tag{C6}$$

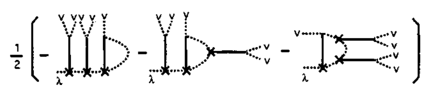
$$\frac{1}{6!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_6}W_{\mu\nu}\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_6}=-\frac{3}{4}$$



$+$ irrel. terms,

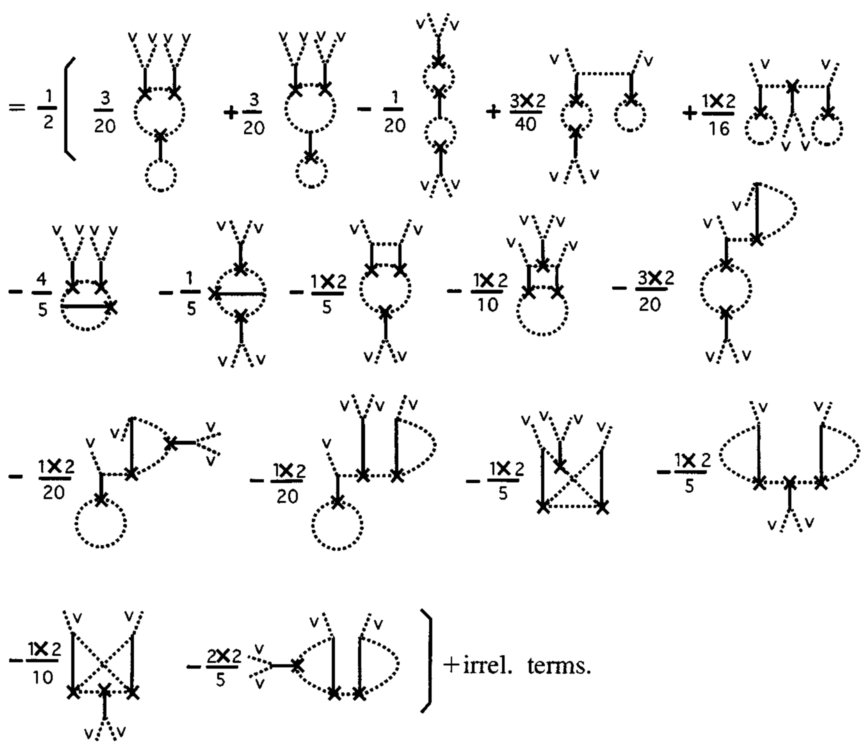
$$\frac{1}{5!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_5}N_\lambda\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_5}$$

$=$



$+$ irrel. terms,

$$\frac{1}{4!}\partial_{\alpha_1}\partial_{\alpha_2}\cdots\partial_{\alpha_4}M\cdot v^{\alpha_1}v^{\alpha_2}\cdots v^{\alpha_4}$$



$+$ irrel. terms. (C7)

APPENDIX D: WEAK-EXPANSION OF INVARIANTS WITH (MASS)^6-DIM

In 6-dim space, there are totally 17 independent general invariants given in (50). In this appendix, we list the coefficients of $(\partial\partial h)^3$ terms when the invariants are weak-field expanded $(g_{\mu\nu}=\delta_{\mu\nu}+h_{\mu\nu})$. They are obtained by a computer using a C program.[42] Among 17 ones, $O_i(i=1-4)$ terms do not have $(\partial\partial h)^3$ terms. As shown in the first column of Table I, there are 90 independent $(\partial\partial h)^3$ terms. Some terms (G3,G67,G1,G2) are given, in the ordinary literal form, in (39) and graphically in Fig. 9. Their complete list is graphically given in Ref. 40. For example, the A_1 column says

TABLE I. Weak Expansion of Invariants with (Mass)^6-Dim: $(\partial\partial h)^3$. (a) G1–G13($\underline{l}$[No of suffix loops]$=1$); (b) G14-G42 ($\underline{l}=2$); (c) G43-G69 ($\underline{l}=3$); (d) G70-G85 ($\underline{l}=4$); (e) G86-G89 ($\underline{l}=5$); (f) G90 ($\underline{l}=6$).

(Received 14 December 1998; accepted for publication 7 January 1999)

This work is devoted to the investigation of the quantum mechanical systems on the two-dimensional hyperboloid which admits separation of variables in at least two coordinate systems. Here we consider two potentials introduced in a paper of C. P. Boyer, E. G. Kalnins, and P. Winternitz [J. Math. Phys. **24**, 2022 (1983)], which have not yet been studied. We give an example of an interbasis expansion and work out the structure of the quadratic algebra generated by the integrals of motion. © *1999 American Institute of Physics.* [S0022-2488(99)00505-8]

I. INTRODUCTION

Superintegrable systems on the two-dimensional hyperboloid were introduced and developed in Refs. 1–3. In distinction to the cases of two-dimensional Euclidean space and the two-sphere, the classification of superintegrable systems on the hyperboloid is difficult. To date only the four potentials studied in Ref. 3 and two more listed in Ref. 1 are known. In the present paper two potentials are considered, which were constructed in Ref. 1 but have not previously been investigated. These potentials both have only a finite number of bound states. At this point we have treated all the potentials that arise by restriction from Hermitean hyperbolic space. We follow the approach of Ref. 3, which contains an introduction and motivation.

The two-dimensional hyperboloid is characterized via the Cartesian coordinates $\omega_0, \omega_1, \omega_2$ where $\omega_0^2-\omega_1^2-\omega_2^2=1$, $\omega_0>1$. The requirement $\omega_0>1$ means that we consider only the upper sheet of the double-sheet hyperboloid. Throughout this paper we will consider the Schrödinger equation on the hyperboloid in the form ($\hbar=m=1$)

$$H\Psi\equiv\left(-\tfrac{1}{2}\Delta_{\mathrm{LB}}+V\right)\Psi=E\Psi, \tag{1}$$

where V is a potential function and the Laplace–Beltrami operator Δ_{LB} is written as

$$\Delta_{\mathrm{LB}}=K_3^2+K_2^2-M_1^2. \tag{2}$$

Here K_3, K_2, M_1 generate the Lie algebra so(2,1) (Refs. 4 and 5):

$$K_3=\omega_0\partial_{\omega_1}+\omega_1\partial_{\omega_0}, \quad K_2=\omega_0\partial_{\omega_2}+\omega_2\partial_{\omega_0}, \quad M_1=\omega_1\partial_{\omega_2}-\omega_2\partial_{\omega_1}, \tag{3}$$

and

$$[K_3,K_2]=M_1, \quad [K_2,M_1]=-K_3, \quad [K_3,M_1]=K_2. \tag{4}$$

The Schrödinger equation (1) for $V=0$ separates in nine coordinate systems.[6] Introduction of a potential breaks the symmetry and, in general, reduces the number of coordinate systems permitting separability, usually to zero. We consider the following two potentials (see Table I), constructed in Ref. 1, for which (1) is superintegrable.

TABLE I. Superintegrable potentials.

Potential $V(\omega)$	Coordinate system
$V_1=\frac{\alpha^2}{\omega_2^2}-\frac{\gamma^2}{(\omega_0-\omega_1)^2}+\beta^2\frac{\omega_0+\omega_1}{(\omega_0-\omega_1)^3}$	Equidistant Elliptic-parabolic Hyperbolic-parabolic Horicyclic
$V_2=\frac{\alpha^2}{\omega_2^2}+\gamma^2\frac{\omega_0\omega_1}{(\omega_0^2+\omega_1^2)^2}+(\alpha^2-\beta^2)\frac{\omega_0^2-\omega_1^2}{(\omega_0^2+\omega_1^2)^2}$	Equidistant Semi-hyperbolic

Recall that (1) is *superintegrable* for a given potential V if it is separable simultaneously in at least two coordinate systems.

II. FIRST POTENTIAL

The first considered potential is

$$V_1=\frac{\alpha^2}{\omega_2^2}-\frac{\gamma^2}{(\omega_0-\omega_1)^2}+\beta^2\frac{\omega_0+\omega_1}{(\omega_0-\omega_1)^3}, \tag{5}$$

where α, β, γ are positive constants. The corresponding Schrödinger equation admits separable solutions in four coordinate systems: equidistant, elliptic–parabolic, hyperbolic–parabolic, and horicyclic.

A. Solutions of the Schrödinger equation

1. Equidistant coordinates

In this coordinate system

$$\omega_0=\cosh\tau_1\cosh\tau_2,\quad \omega_1=\cosh\tau_1\sinh\tau_2,\quad \omega_2=\sinh\tau_1$$

$[\tau_1,\tau_2\in(-\infty,\infty)]$, the potential V_1 has the form

$$V_1(\tau_1,\tau_2)=\frac{\alpha^2}{\sinh^2\tau_1}+\frac{1}{\cosh^2\tau_1}\frac{\beta^2-\gamma^2(\cosh\tau_2-\sinh\tau_2)^2}{(\cosh\tau_2-\sinh\tau_2)^4}. \tag{6}$$

After putting

$$\Psi(\tau_1,\tau_2)=(\cosh\tau_1)^{-1/2}S_1(\tau_1)S_1(\tau_2), \tag{7}$$

we come to the system of equations:

$$\frac{d^2S_2}{d\tau_2^2}+[-\mu^2-2\beta^2e^{4\tau_2}+2\gamma^2e^{2\tau_2}]S_2=0, \tag{8}$$

$$\frac{d^2S_1}{d\tau_1^2}+\left[\left(2E-\frac{1}{4}\right)+\frac{\mu^2-\frac{1}{4}}{\cosh^2\tau_1}-\frac{2\alpha^2}{\sinh^2\tau_1}\right]S_1=0, \tag{9}$$

where μ is the equidistant separation constant. The first equation (8) could be considered as a one-dimensional Schrödinger equation for the Morse potential[7] and the orthonormalized solution is given by the expression

$$S_2(\tau_2)\equiv S_m^{(\beta,\mu)}(z)=\sqrt{\frac{2\mu\Gamma(m+\mu+1)}{m!\Gamma^2(\mu+1)}}e^{-z/2}z^{\mu/2}{}_2F_1(-m,\mu+1;z)$$

$$=\sqrt{\frac{2\mu m!}{\Gamma(m+\mu+1)}}e^{-z/2}z^{\mu/2}L_m^{\mu}(z),\quad z=\sqrt{2}\beta e^{2\tau_2} \tag{10}$$

where $L_m^{\mu}(z)$ are the Laguerre polynomials.[8] The separation constant is quantized as

$$\mu=-2m-1+\frac{\gamma^2}{\sqrt{2}\beta},\quad 0\leqslant m\leqslant\left[\frac{1}{2}\left(\frac{\gamma^2}{\sqrt{2}\beta}-1\right)\right]. \tag{11}$$

The second equation (9) represents the modified Pöschl–Teller equation.[3,9] The orthonormalized wave function is given by

$$S_1(\tau_1)\equiv S_n^{(\alpha,\mu)}(\tau_1)=\sqrt{\frac{2(\mu-\sqrt{2\alpha^2+1/4}-2n-1)\Gamma(\mu-n)n!}{\Gamma(\mu-\sqrt{2\alpha^2+1/4}-n)\Gamma(1+n+\sqrt{2\alpha^2+1/4})}}$$

$$\times(\sinh\tau_1)^{1/2+\sqrt{2\alpha^2+1/4}}(\cosh\tau_1)^{1/2-\mu}P_n^{(\sqrt{2\alpha^2+1/4},-\mu)}(\cosh 2\tau_1), \tag{12}$$

with $n=0,1,...,[\frac{1}{2}(\mu-1-\sqrt{2\alpha^2+\frac{1}{4}})]$, where $P_n^{(\alpha,\beta)}(x)$ is the Jacobi polynomial.[8] The quantized energy is

$$E_N=-\frac{1}{2}\left(\mu-\sqrt{2\alpha^2+\frac{1}{4}}-2n-1\right)^2+\frac{1}{8}=-\frac{1}{2}\left(2N+2+\sqrt{2\alpha^2+\frac{1}{4}}-\frac{\gamma^2}{\sqrt{2}\beta}\right)^2+\frac{1}{8}, \tag{13}$$

where $N=m+n$ is the principal quantum number and the bound states occur for

$$0\leqslant N\leqslant\left[\frac{1}{2}\left(\frac{\gamma^2}{\sqrt{2}\beta}-\sqrt{2\alpha^2+1/4}-2\right)\right]. \tag{14}$$

The orthonormalized total wave function $\Psi_{nm}(\tau_1,\tau_2)$ is given by (7), (10), and (12).

The symmetry operator describing this coordinate system is

$$L_1\Psi_{nm}(\tau_1,\tau_2)\equiv\left[K_3^2-2\beta^2\left(\frac{\omega_0+\omega_1}{\omega_0-\omega_1}\right)^2+2\gamma^2\frac{\omega_0+\omega_1}{\omega_0-\omega_1}\right]\Psi_{nm}(\tau_1,\tau_2)$$

$$=\left(-2m-1+\frac{\gamma^2}{\sqrt{2}\beta}\right)^2\Psi_{nm}(\tau_1,\tau_2). \tag{15}$$

2. Horicyclic coordinates

In the horicyclic coordinates,

$$\omega_0=\frac{x^2+y^2+1}{2y},\quad \omega_1=\frac{x^2+y^2-1}{2y},\quad \omega_2=\frac{x}{y} \tag{16}$$

$[y>0, x\in(-\infty,\infty)]$, the potential V_1 is

$$V_1(x,y)=y^2\left[\frac{\alpha^2}{x^2}+\beta^2(x^2+y^2)-\gamma^2\right] \tag{17}$$

and the Schrödinger equation has the following form:

$$-\frac{1}{2}y^2\left[\frac{\partial^2}{\partial x^2}-\frac{2\alpha^2}{x^2}-2\beta^2x^2+\frac{\partial^2}{\partial y^2}-2\beta^2y^2+2\gamma^2\right]\Psi(x,y)=E\Psi(x,y). \tag{18}$$

Via putting

$$\Psi(x,y)=\psi_1(x)\psi_2(y), \tag{19}$$

it admits a separation

$$\frac{d^2\psi_1}{dx^2}+2\left[\gamma^2(\lambda_1+1)-\beta^2x^2-\frac{\alpha^2}{x^2}\right]\psi_1=0, \tag{20}$$

$$\frac{d^2\psi_2}{dy^2}+2\left[\gamma^2(\lambda_2-1)-\beta^2y^2+\frac{E}{y^2}\right]\psi_2=0, \tag{21}$$

where λ_1 and λ_2 are the horicyclic separation constants with the relation $\lambda_1+\lambda_2=1$.

The orthonormalized solutions of the equations (20) and (21) for $(-2E+\frac{1}{4})>0$ are

$$\psi_1(x)\equiv\psi_{n_1}^{(\alpha,\beta)}(x)=\sqrt{\frac{n_1!(\sqrt{2}\beta)^{1/2}}{\Gamma(n_1+\sqrt{2\alpha^2+\frac{1}{4}}+1)}}e^{-\beta x^2/\sqrt{2}}(\sqrt{\sqrt{2}\beta x^2})^{1/2+\sqrt{2\alpha^2+1/4}}L_{n_1}^{\sqrt{2\alpha^2+1/4}}(\sqrt{2}\beta x^2), \tag{22}$$

$$\psi_2(y)\equiv\psi_{n_2}^{(\gamma,\beta)}(y)=\sqrt{\frac{n_2!(\sqrt{2}\beta)^{1/2}}{\Gamma(n_2+\sqrt{-2E+\frac{1}{4}}+1)}}e^{-\beta y^2/\sqrt{2}}(\sqrt{\sqrt{2}\beta y^2})^{1/2+\sqrt{-2E+1/4}}L_{n_2}^{\sqrt{-2E+1/4}}(\sqrt{2}\beta y^2). \tag{23}$$

The separation constants λ_1,λ_2 are quantized as

$$\lambda_1=\frac{\sqrt{2}\beta}{\gamma^2}\left(2n_1+\sqrt{2\alpha^2+\frac{1}{4}}+1\right)-1;\quad \lambda_2=\frac{\sqrt{2}\beta}{\gamma^2}\left(2n_2+\sqrt{-2E+\frac{1}{4}}+1\right)+1, \tag{24}$$

and according to the relation $\lambda_1+\lambda_2=1$, we come to the energy spectrum as in (13). The operator characterizing the separation in horicyclic coordinates is

$$\begin{aligned}L_2\Psi_{n_1n_2}(x,y)&\equiv\left[(K_2-M_1)^2-\frac{2\beta^2\omega_2^2}{(\omega_0-\omega_1)^2}-\frac{2\alpha^2(\omega_0-\omega_1)^2}{\omega_2^2}+2\gamma^2\right]\Psi_{n_1n_2}(x,y)\\&=-[2\sqrt{2}\beta(2n_1+\sqrt{2\alpha^2+\tfrac{1}{4}}+1)+2\gamma^2]\Psi_{n_1n_2}(x,y).\end{aligned} \tag{25}$$

3. Elliptic–parabolic coordinates

In this coordinate system,

$$\omega_0=\frac{\cosh^2 a+\cos^2\theta}{2\cosh a\cos\theta},\quad \omega_1=\frac{\sinh^2 a-\sin^2\theta}{2\cosh a\cos\theta},\quad \omega_2=\tanh a\tan\theta \tag{26}$$

$[a>0,\ \theta\in(-\pi/2,\pi/2)]$, the potential V_1 has the form

$$V_1(a,\theta)=\frac{\cosh^2 a\cos^2\theta}{\cosh^2 a-\cos^2\theta}\Bigg[\beta^2(\cosh^2 a\sinh^2 a+\cos^2\theta\sin^2\theta)-\gamma^2(\cosh^2 a-\cos^2\theta)+\alpha^2\left(\frac{1}{\sinh^2 a}+\frac{1}{\sin^2\theta}\right)\Bigg]. \tag{27}$$

The Schrödinger equation is

$$-\frac{1}{2}\,\frac{\cosh^2 a\cos^2\theta}{\cosh^2 a-\cos^2\theta}\Bigg[\frac{\partial^2}{\partial a^2}-2\beta^2\cosh^2 a\sinh^2 a+2\gamma^2\cosh^2 a-\frac{2\alpha^2}{\sinh^2 a}+\frac{\partial^2}{\partial\theta^2}-2\beta^2\cos^2\theta\sin^2\theta-2\gamma^2\cos^2\theta-\frac{2\alpha^2}{\sin^2\theta}\Bigg]\Psi(a,\theta)=E\Psi(a,\theta). \tag{28}$$

Putting for the wave function $\Psi(a,\theta)=S(a)S(\theta)$, after separation of variables we get two identical equations:

$$\frac{d^2S(\rho)}{d\rho^2}+\left[\lambda-2\beta^2\cosh^2\rho\sinh^2\rho+2\gamma^2\cosh^2\rho-\frac{2\alpha^2}{\sinh^2\rho}-\frac{2E}{\cosh^2\rho}\right]S(\rho)=0, \tag{29}$$

where λ is the elliptic–parabolic separation constant and $\rho\equiv a,i\theta$. After changing the variables $x=\cosh^2\rho$ in Eq. (29), we obtain

$$4x(x-1)\frac{d^2S}{dx^2}+2(2x-1)\frac{dS}{dx}+\left[\lambda-2\beta^2x(x-1)+2\gamma^2x-\frac{2\alpha^2}{x-1}-\frac{2E}{x}\right]S=0. \tag{30}$$

Thus the region $x\in[1,\infty]$ in Eq. (30) belongs to the wave function $S(a)$ and $x\in[0,1]$ to the wave function $S(\theta)$. Putting

$$S(x)=(x-1)^s x^t e^{-\beta x/\sqrt{2}}G(x), \tag{31}$$

where

$$s=\frac{1}{4}+\frac{1}{\sqrt{2}}\sqrt{\alpha^2+\frac{1}{8}},\qquad t=\frac{1}{4}+\frac{1}{\sqrt{2}}\sqrt{-E+\frac{1}{8}}, \tag{32}$$

we get

$$\frac{d^2G}{dx^2}+\frac{1}{2}\left[\frac{1+4t}{x}+\frac{1+4s}{x-1}-\frac{4\beta}{\sqrt{2}}\right]\frac{dG}{dx}+\frac{1}{4}\left\{\frac{[2\gamma^2-4\beta(1+2(t+s))/\sqrt{2}]x+\nu+\sqrt{2}\beta(1+4t)+4(t+s)^2}{x(x-1)}\right\}G=0. \tag{33}$$

If we now substitute

$$G(x)=\prod_{i=1}^{N}(x-\theta_i) \tag{34}$$

and take into account (32), we find that θ_i satisfies the equation

$$2\theta_i(1-\theta_i)\left(\sum_{\substack{k=1\\k\neq i}}^{N}\frac{1}{\theta_k-\theta_i}+\frac{\beta}{\sqrt{2}}\right)+2(1-\theta_i)N+\frac{\sqrt{2}\gamma^2}{4\beta}\theta_i+\frac{\gamma^2}{\sqrt{2}\beta}+\sqrt{2\alpha^2+\frac{1}{4}}+1=0. \quad (35)$$

The quantization for the energy is given via

$$\sqrt{-2E+\frac{1}{4}}+\sqrt{2\alpha^2+\frac{1}{4}}+2N+2-\frac{\gamma^2}{\sqrt{2}\beta}=0, \quad (36)$$

and we obtain the expression (13). The separation constant λ is

$$\lambda=\frac{8\beta}{\sqrt{2}}\sum_{i=1}^{N}\theta_i-\left(\frac{\gamma^2}{\sqrt{2}\beta}-1\right)^2+\frac{4\beta}{\sqrt{2}}\left(1+\sqrt{2\alpha^2+\frac{1}{4}}\right)-2\gamma^2. \quad (37)$$

Thus the total solution $\Psi(a,\theta)$ is represented as

$$\begin{aligned}\Psi_{Npq}(a,\theta)&=S_{Np}(a)S_{Nq}(\theta)\\&=(\sinh a\sin\theta)^{1/2+\sqrt{2\alpha^2+1/4}}(\cosh a\cos\theta)^{\gamma^2/\sqrt{2}\beta-\sqrt{2\alpha^2+1/4}-2N-3/2}\\&\quad\times\exp\left\{-\frac{\beta}{\sqrt{2}}(\cosh^2 a+\cos^2\theta)\right\}\prod_{i=1}^{N}(\cosh^2 a-\theta_i)(\cos^2\theta-\theta_i),\end{aligned} \quad (38)$$

where p and q are the number of zeros for the wave functions $S(a)$ and $S(\theta)$ in the regions $[0,1]$, $[1,\infty]$ correspondingly, and the total number of zeros is $N=p+q$.

Eliminating the energy E from Eq. (30), we see that the additional integral of motion here is

$$\begin{aligned}L_3\Psi_{Npq}(a,\theta)&=\frac{1}{\cos^2\theta-\cosh^2 a}\left\{\cosh^2 a\frac{\partial^2}{\partial a^2}+\cos^2\theta\frac{\partial^2}{\partial\theta^2}-2\beta^2(\cosh^4 a\sinh^2 a+\cos^4\theta\sin^2\theta)\right.\\&\qquad\left.+2\gamma^2(\cosh^4 a-\cos^4\theta)-2\alpha^2(\coth^2 a-\cot^2\theta)\right\}\Psi_{Npq}(a,\theta)\\&=\left\{-(K_2-M_1)^2-K_3^2+2\beta^2\frac{(w_0+w_1)^2+w_2^2}{(w_0-w_1)^2}+2\alpha^2\left(\frac{w_0-w_1}{w_2}\right)^2\right.\\&\qquad\left.-4\gamma^2\frac{w_0}{w_0-w_1}\right\}\Psi_{Npq}(a,\theta)\\&=\lambda\Psi_{Npq}(a,\theta).\end{aligned} \quad (39)$$

4. Hyperbolic–parabolic coordinates

In this coordinate system,

$$\omega_0=\frac{\cosh^2 b+\cos^2\theta}{2\sinh b\sin\theta},\quad \omega_1=\frac{\sinh^2 b-\sin^2\theta}{2\sinh b\sin\theta},\quad \omega_2=\coth b\cot\theta \quad (40)$$

$[b>0,\theta\in(-\pi/2,\pi/2)]$, the potential V_1 has the form

$$\begin{aligned}V_1(b,\theta)=\frac{\sinh^2 b\sin^2\theta}{\sinh^2 b+\sin^2\theta}&\left[\beta^2(\sinh^2 b\cosh^2 b+\sin^2\theta\cos^2\theta)\right.\\&\left.-\gamma^2(\sinh^2 b+\sin^2\theta)+\alpha^2\left(\frac{1}{\cos^2\theta}-\frac{1}{\cosh^2 b}\right)\right].\end{aligned} \quad (41)$$

The Schrödinger equation is

$$-\frac{1}{2}\frac{\sinh^2 b\sin^2\theta}{\sinh^2 b+\sin^2\theta}\left[\frac{\partial^2}{\partial b^2}-2\beta^2\sinh^2 b\cosh^2 b+2\gamma^2\sinh^2 b+\frac{2\alpha^2}{\cosh^2 b}\right.$$
$$\left.+\frac{\partial^2}{\partial\theta^2}-2\beta^2\sin^2\theta\cos^2\theta+2\gamma^2\sin^2\theta-\frac{2\alpha^2}{\cos^2\theta}\right]\Psi(b,\theta)=E\Psi(b,\theta). \quad (42)$$

Putting for the wave function $\Psi(b,\theta)=S(b)S(\theta)$, after separation of variables we get two identical equations:

$$\frac{d^2S(\rho)}{d\rho^2}+2\left[\frac{\tau}{2}-\beta^2\sinh^2\rho\cosh^2\rho+\gamma^2\sinh^2\rho+\frac{\alpha^2}{\cosh^2\rho}+\frac{E}{\sinh^2\rho}\right]S(\rho)=0, \quad (43)$$

where τ is the hyperbolic–parabolic separation constant and $\rho\equiv b,i\theta$. After changing the variables $x=\sinh^2\rho$ in Eq. (43), we come to the equation

$$4x(x+1)\frac{d^2S}{dx^2}+2(2x+1)\frac{dS}{dx}+\left[\tau-2\beta^2x(x+1)+2\gamma^2x+\frac{2\alpha^2}{x+1}+\frac{2E}{x}\right]S=0. \quad (44)$$

Choosing

$$P(x)=(1+x)^s x^t e^{-\beta x/\sqrt{2}}\prod_{i=1}^{N}(x-\theta_i), \quad (45)$$

where t and s are given by the formulas (32), we obtain the energy spectrum (36). Here θ_i satisfies the equations

$$2\theta_i(1+\theta_i)\left(\sum_{\substack{k=1\\k\neq i}}^{N}\frac{1}{\theta_i-\theta_k}-\frac{\beta}{\sqrt{2}}\right)-2(1+\theta_i)N+\frac{\sqrt{2}\gamma^2}{4\beta}\theta_i+\frac{\gamma^2}{\sqrt{2}\beta}-\sqrt{2\alpha^2+\frac{1}{4}}-1=0. \quad (46)$$

The separation constant τ is

$$\tau=\frac{8\beta}{\sqrt{2}}\sum_{i=1}^{N}\theta_i-\left(\frac{\gamma^2}{\sqrt{2}\beta}-1\right)^2-\frac{4\beta}{\sqrt{2}}\left(1+\sqrt{2\alpha^2+\frac{1}{4}}\right)+2\gamma^2, \quad (47)$$

so the total solution $\Psi(b,\theta)$ is represented as

$$\Psi_{Nlk}(b,\theta)=S_{Nl}(b)S_{Nk}(\theta)$$
$$=(\cosh b\cos\theta)^{1/2+\sqrt{2\alpha^2+1/4}}(\sinh b\sin\theta)^{\gamma^2/\sqrt{2}\beta-\sqrt{2\alpha^2+1/4}-2N-3/2}$$
$$\cdot\exp\left\{-\frac{\beta}{\sqrt{2}}(\sinh^2 b-\sin^2\theta)\right\}\prod_{i=1}^{N}(\sinh^2 b-\theta_i)(\sin^2\theta+\theta_i). \quad (48)$$

The total number of zeros is N, and k of them are located in the interval $[-1,0]$ and l are in $[0,\infty]$.

Each solution $\Psi_{Nlk}(b,\theta)$ satisfies the eigenvalue equation

$$
\begin{aligned}
L_4\Psi_{Nlk}(b,\theta) = & -\frac{1}{\sin^2 b+\sin^2\theta}\left\{\sinh^2 b\,\frac{\partial^2}{\partial b^2}-\sin^2\theta\,\frac{\partial^2}{\partial\theta^2}-2\beta^2(\cosh^2 b\,\sinh^4 b-\cos^2\theta\,\sin^4\theta)\right.\\
&\left.+2\gamma^2(\sinh^4 b-\sin^4\theta)+2\alpha^2(\tanh^2 b+\tan^2\theta)\right\}\Psi_{Nlk}(b,\theta)\\
=&\left\{(K_2-M_1)^2-K_3^2+2\beta^2\frac{(w_0+w_1)^2-w_2^2}{(w_0-w_1)^2}-2\alpha^2\left(\frac{w_0-w_1}{w_2}\right)^2\right.\\
&\left.-4\gamma^2\frac{w_1}{w_0-w_1}\right\}\Psi_{Nlk}(b,\theta)=\tau\Psi_{Nlk}(b,\theta).
\end{aligned}
\tag{49}
$$

B. Algebra

Among the operators $\{L_1,L_2,L_3,L_4\}$, corresponding to the four separable coordinate systems, only two are independent, as

$$
L_3=-L_2-L_1,\quad L_4=L_2-L_1. \tag{50}
$$

Consider the operators N_1, N_2, and R where

$$
\begin{aligned}
N_1=&\tilde{L}_2=L_1,\quad N_2=\tilde{L}_1=L_2-2\gamma^2,\\
R\equiv[N_1,N_2]=&2\{K_3,\{K_2,M_1\}\}-2\{K_3,K_2^2\}-2\{K_3,M_1^2\}\\
&+8\left[\alpha^2\left(\frac{\omega_0-\omega_1}{\omega_2}\right)^2+\beta^2\left(\frac{\omega_2}{\omega_0-\omega_1}\right)^2\right]K_3+\frac{16\beta^2\omega_2}{(\omega_0-\omega_1)^2}(\omega_0K_2-\omega_1M_1)\\
&+\frac{8\gamma^2\omega_2}{\omega_0-\omega_1}(M_1-K_2)-4\left[\gamma^2+2\alpha^2\left(\frac{\omega_0-\omega_1}{\omega_2}\right)^2-2\beta^2\frac{1+2\omega_2^2}{(\omega_0-\omega_1)^2}\right].
\end{aligned}
\tag{51}
$$

We have

$$
[R,N_2]=-8N_2^2-64\beta^2H-16\gamma^2N_2-32\beta^2N_1+16\beta^2(4\alpha^2-1), \tag{52}
$$

$$
[R,N_1]=4\{N_1,N_2\}+32\gamma^2H-16N_2+16\gamma^2N_1+16\gamma^2(2\alpha-1), \tag{53}
$$

$$
\begin{aligned}
R^2=&\tfrac{8}{3}\{N_2,N_2,L_1\}-\tfrac{176}{3}N_2^2+32\beta^2N_1^2+128\beta^2H^2+64\gamma^2HN_2+128\beta^2HN_1\\
&+16\gamma^2\{N_1,N_2\}+(\tfrac{128}{3}+256\alpha^2\beta^2)H+(64\alpha^2\gamma^2-\tfrac{352}{3}\gamma^2)N_2+(\tfrac{352}{3}-128\alpha^2\beta^2)N_1\\
&+(128\alpha^4\beta^2+128\gamma^4\alpha^2-\tfrac{128}{3}\alpha^2\beta^2-\tfrac{64}{3}\beta^2-48\gamma^2),
\end{aligned}
$$

where $\{A,B\}=AB+BA$ and

$$
\{A,B,C\}=ABC+ACB+BCA+BAC+CAB+CBA.
$$

The integrals of motion N_1, N_2, and H generate a quadratic algebra.

C. Interbasis expansion

For a fixed value of energy, we can write the equidistant wave function (7) in terms of the horicyclic ones (19) as

$$
\Psi_{n_1n_2}(x,y)=\sum_{m=0}^{n_1+n_2}W_{n_1n_2}^{nm}(\alpha,\beta,\gamma)\Psi_{nm}(a,b), \tag{54}
$$

where $n_1+n_2=n+m$. The connection between the equidistant (a,b) and horicyclic (x,y) coordinates is

$$x=e^b \tanh a, \quad y=e^b\frac{1}{\cosh a}. \tag{55}$$

Going over to the horicyclic coordinates on the left side of expansion (54), then considering the limit $b\to\infty$ and using the asymptotic formula for Laguerre polynomials[8]

$$\lim_{x\to\infty} L_n^{\alpha}(x)\to(-1)^n\frac{x^n}{n!}, \tag{56}$$

we see that dependence on b cancels on both sides of (54). Now, using the orthogonality condition for the angular wave functions (12), we find the following expression for the interbasis coefficients $W_{n_1n_2}^{nm}$:

$$W_{n_1n_2}^{nm}=(-1)^n\sqrt{\frac{m!n!\sqrt{2}\beta(\mu-d-2n-1)\Gamma(\mu+m+1)\Gamma(\mu-n)}{n_1!n_2!\mu\Gamma(n_1+d+1)\Gamma(n_2+d+1)\Gamma(n+d+1)\Gamma(\mu-d-n)}}B_{n_1n_2}^{nm}, \tag{57}$$

where

$$B_{n_1n_2}^{nm}=\int_{-\infty}^{+\infty}(\sinh a)^{1+2d+2n_1}(\cosh a)^{1-2\mu-2m}P_n^{(d,-\mu)}(\cosh 2a)da \tag{58}$$

and $d=\sqrt{2\alpha^2+\frac{1}{4}}$. The integral B_{n_1,n_2}^{nm} can be evaluated by expressing the Jacobi polynomial through the hypergeometric function ${}_2F_1$:[8]

$$P_n^{(\alpha,\beta)}(x)=(-1)^n\frac{\Gamma(n+\beta+1)}{\Gamma(\beta+1)n!}\,{}_2F_1\left(\begin{matrix}-n,n+\alpha+\beta+1\\ \beta+1\end{matrix}\middle|\frac{1+x}{2}\right). \tag{59}$$

Representing the function ${}_2F_1$ as a series we come to a sum of integrals, each of which can be calculated by using the formula[8]

$$\int_0^{+\infty}(\sinh\tau)^{\alpha}(\cosh\tau)^{-\beta}\,d\tau=\frac{1}{2}B\left(\frac{1+\alpha}{2},\frac{\beta-\alpha}{2}\right) \quad [\mathrm{Re}\,\alpha>-1,\mathrm{Re}(\alpha-\beta)<0]. \tag{60}$$

We thus obtain

$$W_{n_1n_2}^{nm}=\frac{(-1)^n}{2}\sqrt{\frac{m!\sqrt{2}\beta(\mu-d-2n-1)(\mu+m)\Gamma(n_1+d+1)}{n!n_1!n_2!\mu\Gamma(n_2+d+1)\Gamma(n+d+1)\Gamma(\mu-n-d)}}$$
$$\times\frac{\Gamma(\mu)\Gamma(\mu+m-d-n_1-1)}{\sqrt{\Gamma(\mu-n)\Gamma(\mu+m)}}\,{}_3F_2\left(\begin{matrix}-n,n+d-\mu+1,1-\mu-m\\ 1-\mu,2+n_1+d-\mu-m\end{matrix}\middle|1\right). \tag{61}$$

Alternatively, by using the formula[10] for the Hahn polynomials $h_n^{(\alpha,\beta)}(x,N)$,

$$h_n^{(\alpha,\beta)}(x,N)=\frac{(-1)^n\Gamma(N)\Gamma(\beta+n+1)}{n!\Gamma(N-n)\Gamma(\beta+1)}\,{}_3F_2\left(\begin{matrix}-n;\alpha+\beta+n+1;-x\\ \beta+1;1-N\end{matrix}\middle|1\right), \tag{62}$$

we obtain the following expression for the expansion coefficients:

$$W_{n_1 n_2}^{nm}=\frac{(-1)^n}{2}\sqrt{\frac{m!n!\sqrt{2}\beta(\mu-d-2n-1)(\mu+m)}{n_1!n_2!\mu\Gamma(n+d+1)\Gamma(\mu-n-d)}}\cdot\sqrt{\frac{\Gamma(n_1+d+1)\Gamma(\mu-n)}{\Gamma(n_2+d+1)\Gamma(\mu+m)}}$$
$$\times\Gamma(\mu+m-d-n_1-n-1)\cdot h_n^{(d,-\mu)}(\mu+m+1,\mu+m-d-n_1-1), \tag{63}$$

in terms of Hahn polynomials.

III. SECOND POTENTIAL

The second considered potential is

$$V_2=\frac{\alpha^2}{\omega_2^2}+\gamma^2\frac{\omega_0\omega_1}{(\omega_0^2+\omega_1^2)^2}+(\alpha^2-\beta^2)\frac{\omega_0^2-\omega_1^2}{(\omega_0^2+\omega_1^2)^2}, \tag{64}$$

where α, β, and γ are positive constants. The corresponding Schrödinger equation admits separable solutions in two coordinate systems: equidistant and semi-hyperbolic.

A. Solutions of the Schrödinger equation

1. Equidistant coordinates

In this coordinate system,

$$\omega_0=\cosh\tau_1\cosh\tau_2,\quad \omega_1=\cosh\tau_1\sinh\tau_2,\quad \omega_2=\sinh\tau_1 \tag{65}$$

$[\tau_1,\tau_2\in(-\infty,\infty)]$, the potential V_2 has the form

$$V_2(\tau_1,\tau_2)=-\frac{\alpha^2}{\sinh^2\tau_1}+\frac{1}{\cosh^2\tau_1}\frac{\alpha^2-\beta^2+\gamma^2\cosh\tau_2\sinh\tau_2}{(\cosh^2\tau_2+\sinh^2\tau_2)^2}. \tag{66}$$

After putting

$$\Psi(\tau_1,\tau_2)=(\cosh\tau_1)^{-1/2}Z(\tau_1)S(\tau_2), \tag{67}$$

we arrive at two equations:

$$\frac{d^2S}{d\tau_2^2}+\left[-\mu^2-\frac{2(\alpha^2-\beta^2)+\gamma^2\sinh(2\tau_2)}{\cosh^2(2\tau_2)}\right]S=0, \tag{68}$$

$$\frac{d^2Z}{d\tau_1^2}+\left[2E-\frac{1}{4}+\frac{\mu^2-\frac{1}{4}}{\cosh^2\tau_1}-\frac{2\alpha^2}{\sinh^2\tau_1}\right]Z=0, \tag{69}$$

where μ is the equidistant separation constant.

Let us consider the first equation (68). The substitution $x=\sinh 2\tau_2$ transforms this equation to

$$4(1+x^2)\frac{d^2S}{dx^2}+4x\frac{dS}{dx}+\left[-\mu^2+\frac{2(\beta^2-\alpha^2)-\gamma^2x}{(1+x^2)}\right]S=0, \tag{70}$$

where the physical region is $x\in(-\infty,\infty)$. The equation (68) has three regular singularities in the points $x=-i,i,\infty$ and may be solved in term of hypergeometric functions. The solution of the equation (68) for a large $|x|$ can be written as

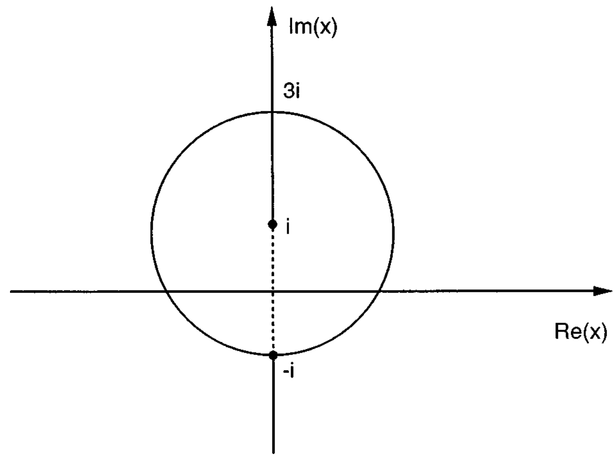

FIG. 1. Domain of convergence.

$$S(x)=A_1(x-i)^{-(b+\mu)/2-1/4}(x+i)^{b/2+1/4}\,{}_2F_1\left(\frac{a+b+1+\mu}{2},\frac{b-a+1+\mu}{2};1+\mu;\frac{2i}{i-x}\right)$$
$$+A_2(x-i)^{-(b-\mu)/2-1/4}(x+i)^{b/2+1/4}\,{}_2F_1\left(\frac{a+b+1-\mu}{2},\frac{b-a+1-\mu}{2};1-\mu;\frac{2i}{i-x}\right) \tag{71}$$

with

$$a^2=(b^2)^*=\frac{2\beta^2-2\alpha^2+1-i\gamma^2}{4}. \tag{72}$$

Let the separation constant μ be a positive number [the equation (71) is symmetric with respect to the replacement $\mu\to-\mu$]. Then the second term in formula (71) behaves like $|x|^{\mu/2}$ at ∞ and must be omitted. Thus for $S(x)$ we obtain

$$S(x)=A(x-i)^{-(b+\mu)/2-1/4}(x+i)^{b/2+1/4}\,{}_2F_1\left(\frac{a+b+1+\mu}{2},\frac{b-a+1+\mu}{2};\mu+1;\frac{2i}{i-x}\right). \tag{73}$$

The hypergeometric function in Eq. (73) converges if x lies out of the circle C on Fig. 1, defined by $|i-x|=2$, and converges on the circle C with the condition $\mathrm{Re}(b)<0$. The function $S(x)$ exists everywhere inside C except the interval $x\in[-i,i]$, since the hypergeometric function in (73) has a cut along the argument $2i/(i-x)\in[1,\infty)$. That means that the solution (73) along the real axes inside C in general is not a continuous function and may have a jump at the point $x=0$. Let us now consider the analytic continuation of (73) inside the circle C:

$$S(x)=A\Bigg\{(x-i)^{a/2+1/4}(x+i)^{b/2+1/4}\frac{\Gamma(\mu+1)\Gamma(-a)}{\Gamma((b-a+1+\mu)/2)\Gamma((-b-a+1+\mu)/2)(2i)^{(a+b+1+\mu)/2}}$$
$$\cdot{}_2F_1\left(\frac{a+b+1+\mu}{2},\frac{a+b+1-\mu}{2};a+1;\frac{i-x}{2i}\right)$$
$$+(x-i)^{-a/2+1/4}(x+i)^{b/2+1/4}\frac{\Gamma(\mu+1)\Gamma(a)}{\Gamma((b+a+1+\mu)/2)\Gamma((-b+a+1+\mu)/2)(2i)^{(-a+b+1+\mu)/2}}$$
$$\cdot{}_2F_1\left(\frac{-a+b+1+\mu}{2},\frac{-a+b+1-\mu}{2};-a+1;\frac{i-x}{2i}\right)\Bigg\}. \tag{74}$$

From Eq. (72) follow two possibilities

$$a=b^*,\quad a=-b^*. \tag{75}$$

Putting the $a=b^*$ [Re(a)=Re(b)<0] we find that the first term in (74) represents an analytic function, while the second term is discontinuous at $x=0$. [Note since the both terms in Eq. (74) transform to each other with replacement $a\to-a$, the choice $a=-b^*$ means that the first term in (74) is discontinuous while the second term is continuous at $x=0$.] Thus the *sufficient* condition for the existence of the continuous solution requires the relation

$$\mu+a+a^*+1=-2m,\quad m=0,1,2,...,\left[-\frac{a+a^*+1}{2}\right], \tag{76}$$

so from (72) we have

$$\mu=-2m-1+\frac{1}{\sqrt{2}}\sqrt{2\beta^2-2\alpha^2+1+\sqrt{(2\beta^2-2\alpha^2+1)^2+\gamma^4}}. \tag{77}$$

Finally, the orthonormalized eigenfunction of Eq. (68) may be written in the form

$$S(\tau_2)=(-1)^{3m/2}\Gamma(-a)\sqrt{\frac{(-2m-a-a^*-1)\Gamma(-m-a^*)}{\pi m!2^{a+a^*+1}\Gamma(-m-a)\Gamma(-m-a-a^*)}}$$
$$\cdot(1+i\sinh 2\tau_2)^{a/2+1/4}(1-i\sinh 2\tau_2)^{a^*/2+1/4}$$
$$\cdot{}_2F_1\left(-m,m+a+a^*+1;a+1;\frac{1+i\sinh 2\tau_2}{2}\right)$$
$$=(-1)^{m/2}\sqrt{\frac{(-2m-a-a^*-1)m!\Gamma(-m-a)\Gamma(-m-a^*)}{\pi 2^{a+a^*+1}\Gamma(-m-a-a^*)}}$$
$$\cdot(1+i\sinh 2\tau_2)^{a/2+1/4}(1-i\sinh 2\tau_2)^{a^*/2+1/4}P_m^{(a,a^*)}(-i\sinh 2\tau_2), \tag{78}$$

where

$$a=\frac{1}{2^{3/2}}\{-\sqrt{\sqrt{(2\beta^2-2\alpha^2+1)^2+\gamma^4}+2\beta^2-2\alpha^2+1}$$
$$+i\sqrt{\sqrt{(2\beta^2-2\alpha^2+1)^2+\gamma^4}-(2\beta^2-2\alpha^2+1)}\}.$$

The second equation (69) is quite like (9) and has a solution

$$Z(\tau_1)\equiv S_n^{(\alpha,\mu)}(\tau_1)=\sqrt{\frac{2(\mu-\sqrt{2\alpha^2+\frac{1}{4}}-2n-1)\Gamma(\mu-n)n!}{\Gamma(\mu-\sqrt{2\alpha^2+\frac{1}{4}}-n)\Gamma(1+n+\sqrt{2\alpha^2+\frac{1}{4}})}}$$
$$\times(\sinh\tau_1)^{1/2+\sqrt{2\alpha^2+1/4}}(\cosh\tau_1)^{1/2-\mu}P_n^{(\alpha,-\mu)}(\cosh 2\tau_1) \tag{79}$$

with $n=0,1,\ldots$.

The quantized energy is

$$E=-\frac{1}{2}(\mu-\sqrt{2\alpha^2+1/4}-2n-1)^2+\frac{1}{8}$$
$$=-\frac{1}{2}\left\{2N+2+\sqrt{2\alpha^2+\tfrac{1}{4}}-\frac{1}{\sqrt{2}}\sqrt{2\beta^2-2\alpha^2+1\sqrt{(2\beta^2-2\alpha^2+1)^2+\gamma^4}}\right\}^2+\frac{1}{8}, \tag{80}$$

where $N=n+m$ is the principal quantum number and the bound state occurs for

$$0\leqslant N\leqslant\left[\frac{1}{\sqrt{8}}\sqrt{2\beta^2-2\alpha^2+1+\sqrt{(2\beta^2-2\alpha^2+1)^2+\gamma^4}}-\frac{1}{2}\sqrt{2\alpha^2+\tfrac{1}{4}}-1\right]. \tag{81}$$

The additional operator describing this coordinate system is

$$L_1\Psi_{nm}(\tau_1,\tau_2)\equiv\left[K_3^2-2(\alpha^2-\beta^2)\left(\frac{\omega_0^2-\omega_1^2}{\omega_0^2+\omega_1^2}\right)^2-2\gamma^2\frac{\omega_0\omega_1(\omega_0^2-\omega_1^2)}{(\omega_0^2+\omega_1^2)^2}\right]\Psi_{nm}(\tau_1,\tau_2)$$
$$=\left\{2m+1-\frac{1}{\sqrt{2}}\sqrt{2\beta^2-2\alpha^2+1+\sqrt{(2\beta^2-2\alpha^2+1)^2+\gamma^4}}\right\}^2\Psi_{nm}(\tau_1,\tau_2). \tag{82}$$

2. Semi-hyperbolic coordinates

Here

$$\omega_0^2=-\frac{(\mu-e_3)(\nu-e_3)}{2[(e_3-a)^2+b^2]}+\frac{1}{2}-\frac{1}{2b}\left[\frac{[(\mu-a)^2+b^2][(\nu-a)^2+b^2]}{(e_3-a)^2+b^2}\right]^{1/2},$$
$$\omega_1^2=\frac{(\mu-e_3)(\nu-e_3)}{2[(e_3-a)^2+b^2]}-\frac{1}{2}-\frac{1}{2b}\left[\frac{[(\mu-a)^2+b^2][(\nu-a)^2+b^2]}{(e_3-a)^2+b^2}\right]^{1/2}, \tag{83}$$
$$\omega_2^2=-\frac{(\mu-e_3)(\nu-e_3)}{(e_3-a)^2+b^2}$$

$[\nu<e_3<\mu]$, where $\sinh 2f=(e_3-a)/b$ and $2f$ is the distance between the focii of the semi-hyperbolas and the bases of their equidistants.[6]

If we change variables according to

$$\omega_0=\frac{(s_1+s_2)}{\sqrt{2}},\quad \omega_1=\frac{-i(s_1-s_2)}{\sqrt{2}},\quad \omega_2=-is_3, \tag{84}$$

the Schrödinger equation becomes

$$\frac{1}{2}\left[\left(s_1\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_1}\right)^2+\left(s_1\frac{\partial}{\partial s_3}-s_3\frac{\partial}{\partial s_1}\right)^2+\left(s_3\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_3}\right)^2\right]\Psi$$
$$+\left[-E-\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{s_1^2}+\frac{k_2^2-\frac{1}{4}}{s_2^2}+\frac{k_3^2-\frac{1}{4}}{s_3^2}\right)\right]\Psi=0 \tag{85}$$

with

$$\frac{1}{2}\left(k_1^2-\frac{1}{4}\right)=\frac{1}{4}(\beta^2-\alpha^2)-\frac{i}{8}\gamma^2,\quad \frac{1}{2}\left(k_2^2-\frac{1}{4}\right)=\frac{1}{4}(\beta^2-\alpha^2)+\frac{i}{8}\gamma^2,\quad \frac{1}{2}\left(k_3^2-\frac{1}{4}\right)=\alpha^2.$$

Noting

$$\omega_0^2-\omega_1^2-\omega_2^2=s_1^2+s_2^2+s_3^2=1$$

and considering Eq. (85), we see that the problem we wish to solve using the real coordinates ω_0, ω_1, and ω_2 is a real case of the corresponding problem on the sphere with coordinates s_1,s_2,s_3 and energy $\varepsilon=-E$.

Inverting the relations (84) we have

$$s_1=\frac{(\omega_0+i\omega_1)}{\sqrt{2}},\quad s_2=\frac{(\omega_0-i\omega_1)}{\sqrt{2}},\quad s_3=i\omega_2.$$

Now choose elliptic coordinates on the complex sphere according to

$$s_1^2=\frac{(\mu-e_1)(\nu-e_1)}{(e_1-e_2)(e_1-e_3)},\quad s_2^2=\frac{(\mu-e_2)(\nu-e_2)}{(e_2-e_1)(e_2-e_3)},\quad s_3^2=\frac{(\mu-e_3)(\nu-e_3)}{(e_3-e_2)(e_3-e_1)}.$$

This choice of real coordinates μ,ν will work for the real coordinates ω_k, $k=0,1,2$, if we take $e_1=e_2^*=a+ib,a,b$ real and $\nu<e_3<\mu$.

In terms of the coordinates μ and ν the Schrödinger equation has the form

$$\frac{4}{(\mu-\nu)}\left\{(\mu-e_2^*)(\mu-e_2)(\mu-e_3)\left[\frac{\partial^2\Psi}{\partial\mu^2}+\frac{1}{2}\left(\frac{1}{\mu-e_2^*}+\frac{1}{\mu-e_2}+\frac{1}{\mu-e_3}\right)\frac{\partial\Psi}{\partial\mu}\right]\right.$$
$$\left.-(\nu-e_2^*)(\nu-e_2)(\nu-e_3)\left[\frac{\partial^2\Psi}{\partial\nu^2}-\frac{1}{2}\left(\frac{1}{\nu-e_2^*}+\frac{1}{\nu-e_2}+\frac{1}{\nu-e_3}\right)\frac{\partial\Psi}{\partial\nu}\right]\right\}$$
$$+\left[\left(k_1^2-\frac{1}{4}\right)\frac{(e_2^*-e_2)(e_2^*-e_3)}{(\mu-e_2^*)(\nu-e_2^*)}+\left(k_2^2-\frac{1}{4}\right)\frac{(e_2-e_2^*)(e_2-e_3)}{(\mu-e_2)(\nu-e_2)}\right.$$
$$\left.+\left(k_3^2-\frac{1}{4}\right)\frac{(e_3-e_2)(e_3-e_2^*)}{(\mu-e_3)(\nu-e_3)}\right]\Psi=-2E\Psi. \tag{86}$$

The separation equations are

$$(\rho-e_2^*)(\rho-e_2)(\rho-e_3)\left[\frac{d^2\Psi}{d\rho^2}+\frac{1}{2}\left(\frac{1}{\rho-e_2^*}+\frac{1}{\rho-e_2}+\frac{1}{\rho-e_3}\right)\frac{d\Psi}{d\rho}\right]$$
$$-\frac{1}{4}\left[\left(k_1^2-\frac{1}{4}\right)\frac{(e_2^*-e_2)(e_2^*-e_3)}{(\rho-e_2^*)}+\left(k_2^2-\frac{1}{4}\right)\frac{(e_2-e_2^*)(e_2-e_3)}{(\rho-e_2)}\right.$$
$$\left.+\left(k_3^2-\frac{1}{4}\right)\frac{(e_3-e_2)(e_3-e_2^*)}{(\rho-e_3)}-2E\rho+\lambda\right]\psi(\rho)=0, \tag{87}$$

where $\rho=\mu,\nu$. The operator L_2 with eigenvalue λ is

$$L_2\Psi=\frac{-4}{(\mu-\nu)}\left\{\nu(\mu-e_1)(\mu-e_2)(\mu-e_3)\left[\frac{\partial^2\Psi}{\partial\mu^2}+\frac{1}{2}\left(\frac{1}{\mu-e_2^*}+\frac{1}{\mu-e_2}+\frac{1}{\mu-e_3}\right)\frac{\partial\Psi}{\partial\mu}\right]\right.$$
$$\left.-\mu\left[(\nu-e_1)(\nu-e_2)(\nu-e_3)\left[\frac{\partial^2\Psi}{\partial\nu^2}+\frac{1}{2}\left(\frac{1}{\nu-e_2^*}+\frac{1}{\nu-e_2}+\frac{1}{\nu-e_3}\right)\frac{\partial\Psi}{\partial\nu}\right]\right]\right\}$$
$$-\left[\left(k_1^2-\frac{1}{4}\right)\frac{(e_2^*-e_2)(e_2^*-e_3)}{(\mu-e_2^*)(\nu-e_2^*)}(\mu+\nu-e_2^*)+\left(k_2^2-\frac{1}{4}\right)\frac{(e_2-e_2^*)(e_2-e_3)}{(\mu-e_2)(\nu-e_2)}(\mu+\nu-e_2)\right.$$
$$\left.+\left(k_3^2-\frac{1}{4}\right)\frac{(e_3-e_2)(e_3-e_2^*)}{(\mu-e_3)(\nu-e_3)}(\mu+\nu-e_3)\right]\Psi. \tag{88}$$

In order to find the bound state solutions of this system in semi-hyperbolic coordinates we first observe the identity

$$\frac{s_1^2}{\theta_j-e_2^*}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}=\frac{(\omega_0^2-\omega_1^2)(\theta_j-a)-2\omega_0\omega_1 b}{(\theta_j-a)^2+b^2}-\frac{\omega_2^2}{\theta_j-e_3}$$
$$=\frac{(\mu-\theta_j)(\nu-\theta_j)}{(\theta_j-e_2^*)(\theta_j-e_2)(\theta_j-e_3)}. \tag{89}$$

If we then look for solutions of the form

$$\Psi=\prod_{\ell=1}^{3}s_\ell^{k_\ell+1/2}\prod_{j=1}^{N}\left(\frac{s_1^2}{\theta_j-e_2^*}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}\right), \tag{90}$$

we see that the corresponding zeros satisfy the equations

$$\frac{k_1+1}{\theta_m-e_2^*}+\frac{k_2+1}{\theta_m-e_2}+\frac{k_3+1}{\theta_m-e_3}+\sum_{j\neq m}^{N}\frac{2}{(\theta_m-\theta_j)}=0. \tag{91}$$

For the energy E we have

$$E=-\tfrac{1}{2}(2N+2+k_1+k_2+k_3)^2+\tfrac{1}{8}, \tag{92}$$

which coincides with the formula (73) [note (86)]. For the separation constant λ we obtain

$$\lambda=-2[k_1(e_2+e_3)+k_2(e_2^*+e_3)+k_3(e_2+e_2^*)]-2[e_3k_1k_2+e_2k_1k_3+e_2^*k_2k_3]$$
$$-\frac{3}{2}(e_2^*+e_2+e_3)-4e_2e_3(k_1+1)\sum_{m=1}^{q}\frac{1}{(\theta_m-e_2^*)}-e_2^*e_3(k_2+1)\sum_{m=1}^{q}\frac{1}{(\theta_m-e_2)}$$
$$-4e_2e_2^*(k_3+1)\sum_{m=1}^{q}\frac{1}{(\theta_m-e_3)}. \tag{93}$$

In terms of variables w_i the total wave function is written

$$\Psi=\left(\frac{\omega_0+i\omega_1}{\sqrt{2}}\right)^{k_1+1/2}\left(\frac{\omega_0-i\omega_1}{\sqrt{2}}\right)^{k_2+1/2}(i\omega_2)^{k_3+1/2}\prod_{j=1}^{N}\left[\frac{(\omega_0^2-\omega_1^2)(\theta_j-a)-2\omega_0\omega_1 b}{(\theta_j-a)^2+b^2}-\frac{\omega_2^2}{\theta_j-e_3}\right].$$

The algebra of second-order symmetries for this potential is generated by the operators

$$L_{jk}=(s_j\partial_{s_k}-s_k\partial_{s_j})^2+\left(\frac{1}{4}-k_j^2\right)\frac{s_k^2}{s_j^2}+\left(\frac{1}{4}-k_k^2\right)\frac{s_j^2}{s_k^2} \tag{94}$$

for $j,k=1,2,3$ and $j\neq k$. The Hamiltonian of the system is expressed in terms of L_{jk} as

$$H=\frac{1}{2}(L_{12}+L_{13}+L_{23})-\frac{1}{2}\sum_{i=1}^{3} k_i^2+\frac{3}{4}. \tag{95}$$

The relevant generators in the real case we are considering are then

$$L_{12}=-K_3^2+\left(\frac{1}{4}-k_1^2\right)\left(\frac{\omega_0-i\omega_1}{\omega_0+i\omega_1}\right)^2+\left(\frac{1}{4}-k_2^2\right)\left(\frac{\omega_0+i\omega_1}{\omega_0-i\omega_1}\right)^2, \tag{96}$$

$$L_{13}=\frac{1}{2}(M_1-iK_2)^2+\left(\beta^2-\alpha^2-\frac{i}{2}\gamma^2\right)\frac{\omega_2^2}{(\omega_0+i\omega_1)^2}+\alpha^2\frac{(\omega_0+i\omega_1)^2}{\omega_2^2}, \tag{97}$$

$$L_{23}=\frac{1}{2}(M_1+iK_2)^2+\left(\beta^2-\alpha^2+\frac{i}{2}\gamma^2\right)\frac{\omega_2^2}{(\omega_0-i\omega_1)^2}+\alpha^2\frac{(\omega_0-i\omega_1)^2}{\omega_2^2}. \tag{98}$$

The commutation relations and resulting quadratic algebra can then be deduced from the relations for the complex forms in terms of the L_{ij}. It is easy to show that the additional integrals of motion, corresponding to the separation in equidistant and semi-hyperbolic coordinates, can be written as

$$L_1=-L_{12}+\beta^2-\alpha^2 \tag{99}$$

and

$$L_2=e_3L_{12}+e_2L_{13}+e_1L_{32}-k_1^2(e_2+e_3-e_1)-k_2^2(e_1+e_3-e_2)-k_3^2(e_1+e_2-e_3)+\tfrac{1}{4}(e_1+e_2+e_3). \tag{100}$$

The algebra for the operators (99) and (100) is found in Ref. 11.

On the Coulomb Sturmian matrix elements of relativistic Coulomb Green's operators

B. Kónya and Z. Papp[a)]

(Received 28 October 1998; accepted for publication 16 November 1998)

The Hamiltonian of the radial Coulomb Klein–Gordon and second order Dirac equations are shown to possess an infinite symmetric tridiagonal matrix structure on the relativistic Coulomb Sturmian basis. This allows us to give an analytic representation for the corresponding Coulomb Green's operators in terms of continued fractions. The poles of the Green's matrix reproduce the exact relativistic hydrogen spectrum. © *1999 American Institute of Physics.*

I. INTRODUCTION

In quantum mechanics the knowledge of the Green's operator is equivalent to the complete knowledge of the system. So, having an analytic basis representation for the Green's operator can tremendously simplify the actual calculations. If we know the Green's operator only of the asymptotic part of the Hamiltonian we can treat the remaining terms as perturbations and approximate them by finite matrices.

In a recent publication, Ref. 1, we have proposed a method for calculating matrix representation of Green's operators. If, in some basis representation, the Hamiltonian possesses an infinite symmetric tridiagonal (Jacobi) matrix structure the corresponding Green's operator can be given in terms of continued fractions. In Ref. 1, this theorem was exemplified with the Green's operator of the nonrelativistic Coulomb and harmonic oscillator Hamiltonian, and, in Ref. 2, an exactly solvable nonrelativistic potential problem was considered which provides a smooth transition between the Coulomb and the harmonic oscillator problems.

Our aim in this paper is to extend this result for relativistic Coulomb Green's operators, i.e., for the Coulomb Green's operator of the Klein–Gordon and of the second order Dirac equations. This later is equivalent to the conventional Dirac equation and seems to have several advantages. For details see Ref. 3 and references therein. The Coulomb Sturmian matrix elements of the second order Dirac equation has already been obtained by Hostler[3] via evaluating complicated contour integrals. Our derivation, however, is much simpler, it relies only on the Jacobi-matrix structure of the Hamiltonian, and the result obtained is also better suited for numerical calculations. In Ref. 3 the result appears in terms of Γ and hypergeometric functions, while our procedure results in an easily computable and analytically continuable continued fraction.

II. MATRIX ELEMENTS OF RELATIVISTIC COULOMB–GREEN'S OPERATORS

The radial Klein–Gordon and second order Dirac equations for Coulomb interaction are given by

$$H_u|\xi^u\rangle = 0, \tag{1}$$

where

[a)]Electronic mail: pz@indigo.atomki.hu

$$H_u = \left(\frac{E}{\hbar c}\right)^2 - \mu^2 + \frac{2\alpha Z}{\hbar c}\frac{E}{r} + \frac{d^2}{dr^2} - \frac{u(u+1)}{r^2}. \tag{2}$$

Here $\mu = mc/\hbar$, $\alpha = e^2/\hbar c$, m is the mass and Z denotes the charge. For the Klein–Gordon case u is given by

$$u = -\tfrac{1}{2} + \sqrt{\tfrac{1}{4} + l(l+1) - (Z\alpha)^2}, \tag{3}$$

and in the case of the second order Dirac equation for the different spin states we have

$$u_{\pm} = -\tfrac{1}{2} \mp \tfrac{1}{2} + \sqrt{(j+\tfrac{1}{2})^2 - (Z\alpha)^2}. \tag{4}$$

The relativistic Coulomb Green's operator is defined as the inverse of the Hamiltonian H_u:

$$H_u G_u = G_u H_u = \mathbf{1}_u, \tag{5}$$

where $\mathbf{1}_u$ denotes the unit operator of the radial Hilbert space $\mathcal{H}_u$.

In complete analogy with the nonrelativistic case we can define the relativistic Coulomb Sturmian functions as solutions of the Sturm–Liouville problem,

$$\left(-\frac{d^2}{dr^2} + \eta^2 + \frac{u(u+1)}{r^2} - \frac{2\eta(n+u+1)}{r}\right) S^u_{n;\eta}(r) = 0, \tag{6}$$

where η is a real parameter and $n = 0,1,2,\ldots,\infty$ is the radial quantum number. In coordinate space representation they take the form

$$\langle r|nu;\eta\rangle = \left[\frac{n!}{(n+2u+1)!}\right]^{1/2} (2\eta r)^{u+1} e^{-\eta r} L_n^{2u+1}(2\eta r), \tag{7}$$

where L is a Laguerre-polinom. The Coulomb Sturmian functions, together with their biorthogonal partner $\langle r|\widetilde{nu;\eta}\rangle = 1/r \cdot \langle r|nu;\eta\rangle$, form a basis: i.e., they are orthogonal,

$$\langle \widetilde{nu;\eta}|mu;\eta = \langle nu;\eta|\widetilde{mu;\eta}\rangle = \delta_{nm}, \tag{8}$$

and form a complete set in $\mathcal{H}_u$,

$$\sum_{n=0}^{\infty} |nu;\eta\rangle\langle\widetilde{nu;\eta}| = \sum_{n=0}^{\infty} |nu;\eta\rangle\langle\widetilde{nu;\eta}| = \mathbf{1}_u. \tag{9}$$

A straightforward calculation yields

$$\langle nu;\eta|mu;\eta\rangle = \frac{1}{2\eta}[\delta_{nm}(2u+2n+2) - \delta_{nm-1}\sqrt{(n+1)(n+2u+2)} - \delta_{nm+1}\sqrt{n(2u+n+1)}]. \tag{10}$$

Utilizing this relation and considering Eq. (6) we can easily calculate the Coulomb Sturmian matrix elements of H_u,

TABLE I. Energy levels of hydrogen-like atoms in atomic units. E_{cf} is the relativistic spectrum calculated via a continued fraction, E_D and E_S are textbook values of the relativistic Dirac and the nonrelativistic Schrödinger spectrum, respectively.

	Energy levels	E_{cf}	E_{D}	E_{S}
Hydrogen	$1S_{1/2}$	−0.5000066521	−0.5000066521	−0.5

	$2P_{3/2}$	−0.1250004160	−0.1250004160	−0.125
	$50P_{1/2}$	−0.0002000002	−0.0002000002	−0.0002
	$50P_{3/2}$	−0.0002000001	−0.0002000001	−0.0002
Uranium	$1S_{1/2}$	−4861.1483347	−4861.1483347	−4232
$Z=92$	$100D_{3/2}$	−0.4241695002	−0.4241695002	−0.4232
	$100D_{5/2}$	−0.4238303306	−0.4238303306	−0.4232

$$\underline{H}_{nm}:=\langle nu;\eta|H_u|mu;\eta\rangle=+\delta_{nm}\left(\frac{2\alpha zE}{\hbar c}-2(u+n+1)\eta+2(u+n+1)\frac{(E/\hbar c)^2-\mu^2+\eta^2}{2\eta}\right)$$
$$-\delta_{nm-1}\left(\frac{(E/\hbar c)^2-\mu^2+\eta^2}{2\eta}\sqrt{(n+1)(n+2u+2)}\right)$$
$$-\delta_{nm+1}\left(\frac{(E/\hbar c)^2-\mu^2+\eta^2}{2\eta}\sqrt{n(n+2u+1)}\right), \tag{11}$$

which happens to possess a Jacobi-matrix structure. So, the theorem of Ref. 1 is readily applicable here.

Let us consider the $\infty\times\infty$ Green's matrix,

$$(\underline{G}_u)_{nm}\equiv\langle\widetilde{nu;\eta}|G_u|\widetilde{mu;\eta}\rangle, \tag{12}$$

and let us denote its rank-N leading principal submatrix by $\underline{G}_u^{(N)}$. Then, according to Ref. 1,

$$(\underline{G}_u^{(N)})_{ij}^{-1}=\underline{H}_{ij}+\delta_{jN}\delta_{iN}\underline{H}_{NN+1}\mathcal{F}, \tag{13}$$

where $\mathcal{F}$ is a continued fraction,

$$\mathcal{F}=-K_{i=N}^{\infty}\left(\frac{a_i}{b_i}\right)=-\frac{a_{1+N}}{b_{1+N}+}\frac{a_{2+N}}{b_{2+N}+}\cdots+\frac{a_{n+N}}{b_{n+N}+}\cdots, \tag{14}$$

whose coefficients are related to the Jacobi matrix

$$a_i=-\frac{\underline{H}_{ii-1}}{\underline{H}_{ii+1}},\quad b_i=-\frac{\underline{H}_{ii}}{\underline{H}_{ii+1}}. \tag{15}$$

This continued fraction convergent for bound-state energies, but, by using the method presented in Ref. 1, can be continued analytically to the whole complex energy plane. Simple matrix inversion now gives the desired Green's matrix.

In Table I we demonstrate the numerical accuracy of the method by evaluating the ground and some highly excited sates of relativistic hydrogen-like atoms, which, in fact, correspond to the poles of the Dirac Coulomb Green's matrix. In particular, the zeros of the determinant of (13) were located. It should be noted that irrespective of the rank N the zeros should provide the exact Dirac results. In Table I we have taken 2×2 matrices. Indeed, the results of this method, E_{cf}, agree with the exact one in all cases, practically up to the machine accuracy, allowing thus to study the fine structure splitting.

III. SUMMARY

In this paper we have presented a practical and easy-to-apply procedure for calculating the Coulomb Sturmian matrix elements of the Coulomb Green's operator of the Klein–Gordon and of the second order Dirac equations. The method is relied only on the Jacobi-matrix structure of the corresponding Hamiltonians and results in a continued fraction which can be continued analytically to the whole complex energy plane.

Quantum geometry of field extensions

Shahn Majid[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge CB3 9EW, United Kingdom

(Received 9 October 1998; accepted for publication 20 October 1998)

We introduce a new kind of topological gauge configuration or ''soliton'' associated to the extension $\mathbb{C}\supseteq\mathbb{R}$ of the real numbers to the complex ones. These configurations describe zero-curvature gauge fields and nontrivial cohomology over the real line, but with a quantum choice of differential calculus. In general, the quantum differential 1-forms on the line with coordinate algebra $k[x]$ are in correspondence with field extensions of k, and the quantum cohomology detects the nontriviality of the extension.
[S0022-2488(99)04002-5]

I. INTRODUCTION

Usually quantum differential geometry aims to model or q-deform classical geometrical constructions, e.g., Ref. 1 as a step towards a more general geometry appropriate to quantum integrable systems and (in principle) to the Planck scale. In this paper we observe that in quantum differential geometry one also has the possibility of entirely new kinds of topological gauge configurations or ''solitons'' not even visible classically. We demonstrate the ideas explicitly for the real line, which we work with algebraically as the coordinate algebra of real polynomials $\mathbb{R}[x]$ in one variable. The existence of these topological configurations implies, among other things, a novel quantum geometrical approach to number theory that we have not seen considered elsewhere. From a physical point of view, the extension from real numbers to complex ones is particularly central to physics and the introduction of a geometrical way of looking at it is a unification that could certainly be significant at the Planck scale.

First, note that the differential calculus on a space is additional information to the space itself, but for Lie groups there is a unique translation-invariant calculus which is usually assumed. In quantum differential geometry we drop the assumption that the product of coordinate functions and differential 1-forms from the left and right coincide, i.e., in 1-variable we allow $x\,dx \neq (dx)x$. This is the natural situation, for example, on a lattice, where multiplication from the left and right differ due to the difference between the starting-point and end-point of a finite-difference differential. On the other hand, the choice of differential calculus is then no longer unique, even for covariant ones[2] on a classical (or quantum) group. A lot of attention in recent years has been given to classifying the possible covariant calculi on various groups and quantum groups, a project recently solved generically for finite groups and for the coordinate algebras of standard quantum groups $U_q(g)$.[3]

In the present paper we will concentrate on the simplest Hopf algebra of all, namely the coordinate algebra $k[x]$ of the line, but where k is a general field. In this case the classification of calculi itself is quite elementary, although we have not seen it treated explicitly elsewhere. We provide this explicit treatment in the preliminary Sec. II and see that the coirreducible calculi are of the form $k_\lambda[x]$, where $k_\lambda\supseteq k$ is a field extension of k. We then proceed in Sec. III to compute the quantum differentials associated to the extension $\mathbb{C}\supseteq\mathbb{R}$ (so the functions are $\mathbb{R}[x]$ and the 1-forms are $\mathbb{C}[x]$). In Sec. IV we consider quantum cohomology and gauge theory in this case, and compute the moduli of algebraic flat connections. In both cases we find nontrivial configurations

reflecting the nontriviality of the field extension from real to complex numbers. Section V concludes with some further quantum geometric considerations.

Note that the possible quantum differentials in 1-variable over the field $\mathbb{C}$ are already known[4] to be parametrized by $\lambda_0\in\mathbb{C}$ and have the form

$$\mathrm{d}f(x)=\mathrm{d}x\,\frac{f(x+\lambda_0)-f(x)}{\lambda_0},\quad x\,\mathrm{d}x-(\mathrm{d}x)x=\lambda_0.$$

Of these, $\lambda_0=0$ is the classical Newtonian calculus while the others are clearly the natural differential calculi for a version of lattice geometry based on finite differences. The calculi in these cases do not have nontrivial cohomology; the new phenomenon to be described in the present paper arises only when we consider quantum differentials over a nonalgebraically closed field such as $\mathbb{R}$.

II. Ω^1 AND FIELD EXTENSIONS

Let A be an algebra, which we consider as playing the role of ''co-ordinates'' in algebraic geometry, except that we do not require the algebra to be commutative. The appropriate notion of cotangent space or differential 1-forms in this case is the following:[2]

1. Ω^1 an A-bimodule.
2. $\mathrm{d}:A\to\Omega^1$ a linear map obeying the Leibniz rule $\mathrm{d}(ab)=a\,\mathrm{d}b+(\mathrm{d}a)b$ for all $a,b\in A$.
3. The map $A\otimes A\to\Omega^1$, $a\otimes b\mapsto a\,\mathrm{d}b$ is surjective.

When A has a Hopf algebra structure with coproduct $\Delta:A\to A\otimes A$ and counit $\epsilon:A\to k$ (k the ground field), we say that Ω^1 is bicovariant if the following occurs:

4. Ω^1 is a bicomodule with coactions $\Delta_L:\Omega^1\to A\otimes\Omega^1$, $\Delta_R:\Omega^1\to\Omega^1\otimes A$ bimodule maps (with the tensor product bimodule structure on the target spaces, where A is a bimodule by left and right multiplication).
5. d is a bicomodule map with the left and right regular coactions on A provided by Δ.

A morphism of calculi means a bimodule and bicomodule map forming a commuting triangle with the respective d maps. One says[3] that a calculus is coirreducible if it has no proper quotients.

Note that we do not demand that $a\,\mathrm{d}b=(\mathrm{d}b)a$, for in this case axiom 2 would imply that $\mathrm{d}(ab-ba)=0$, which we cannot naturally suppose when A is noncommutative. This possible noncommutativity of forms and ''functions'' is the main generalization featuring in the above axioms; we say that a differential calculus is noncommutative or ''quantum'' if the left and right multiplication of forms by functions do not coincide. Also, given Ω^1, there are natural prolongations to higher order differential forms, i.e., the entire exterior algebra $\Omega^\cdot$. We recall this when it is needed, in Sec. IV. Note that this approach is somewhat different from Ref. 5, where an entire $\Omega^\cdot$ on an algebra is effectively specified via a ''spectral triple.''

On the other hand, when Ω^1 is required to be bicovariant, there is a standard argument[2] that it must be of the form

$$\Omega^1=\Omega_0\otimes A,\quad \mathrm{d}a=(\pi\otimes\mathrm{id})(\Delta a-1\otimes a),$$

where $\Omega_0=\ker\epsilon/\mathcal{M}$ with canonical projection $\pi:\ker\epsilon\to\Omega_0$ and $\mathcal{M}$ is a left ideal contained in $\ker\epsilon$ and stable under the Hopf algebra adjoint coaction Ad. The right (co)module structures are those of A alone by (co)multiplication. The left (co)module structures are the tensor product of those on Ω_0 as inherited from $\ker\epsilon\subset A$ (where A acts by left multiplication and coacts by Ad) and those on A by (co)multiplication. We recall that modules and comodules of a Hopf algebra A have a tensor product induced by the coproduct and product of A, respectively. Then bicovariant Ω^1 are in 1–1 correspondence with the Ad-stable left ideals $\mathcal{M}\subseteq\ker\epsilon$. When A is cocommutative the adjoint coaction Ad is trivial.

Proposition 2.1: When $A=k[x]$, the coirreducible bicovariant Ω^1 are in 1–1 correspondence with irreducible monic polynomials $m\in k[\lambda]$, and take the form $\Omega^1=k_\lambda[x]$, where $k_\lambda=k[\lambda]/\langle m\rangle$ is the corresponding field extension. The bimodule structures and d differential are

$$f(x)\cdot P(\lambda,x)=f(x+\lambda)P(\lambda,x),\quad P(\lambda,x)\cdot f(x)=P(\lambda,x)f(x),\quad \mathrm{d}f(x)=\frac{f(x+\lambda)-f(x)}{\lambda}$$

for all $f\in k[x]$, $P\in k_\lambda[x]$.

Proof: We are interested in $A=k[x]$, the polynomials over a field k, forming a Hopf algebra with its additive coproduct counit and antipode,

$$\Delta x=x\otimes 1+1\otimes x,\quad \epsilon x=0,\quad Sx=-x.$$

According to the above, bicovariant differential calculi on $k[x]$ are in 1–1 correspondence with ideals $\mathcal{M}\subseteq\ker\epsilon$. Here $\ker\epsilon=\langle x\rangle$, the ideal generated by x in $k[x]$. Since $k[x]$ is a principal ideal domain (P.I.D.), the ideal $\mathcal{M}$ above is generated by a polynomial. Since $\mathcal{M}\subseteq\ker\epsilon$, this polynomial is divisible by x, i.e., $\mathcal{M}=\langle xm\rangle$. Coirreducible calculi correspond to m irreducible and monic.

We identify the corresponding $\Omega_0=\langle x\rangle/\langle xm\rangle\cong k[\lambda]/\langle m\rangle=k_\lambda$ by $xf(x)\mapsto f(\lambda)$. Under this identification, $\Omega^1=\Omega_0\otimes k[x]\cong k_\lambda[x]$. The action from the right is by the inclusion $k[x]\subset k_\lambda[x]$. The action from the left is by

$$f(x)\cdot x^m\otimes x^n=f(x\otimes 1+1\otimes x)x^m\otimes x^n,$$

as the tensor product action. Hence $f(x)\cdot\lambda^{m-1}x^n=f(\lambda+x)\lambda^{m-1}x^n$ under our identification. The quotient by $\langle xm(x)\rangle$ or $\langle m(\lambda)\rangle$ is understood in these expressions.

We compute $\mathrm{d}f=f(x\otimes 1+1\otimes x)-1\otimes f(x)$ modulo $\langle xm\rangle$ in the first tensor factor. Under our isomorphism this is $[f(\lambda+x)-f(x)]/\lambda$ modulo $\langle m(\lambda)\rangle$. Note that $\mathrm{d}x=x\otimes 1$ modulo $\langle xm\rangle$ becomes $\mathrm{d}x=1\in k_\lambda[x]$.

To see explicitly that the correspondence here is indeed 1–1, suppose that $k_{\lambda_1}[x]\cong k_{\lambda_2}[x]$ as quantum differential calculi associated to $m_1(\lambda_1)$ and $m_2(\lambda_2)$. Since the isomorphism is, in particular, a right module map under $k[x]$, it restricts to the identity on $k[x]$. And since the isomorphism forms a commutative triangle with the d maps, it identifies $[f(x+\lambda_1)-f(x)]/\lambda_1$ with $[f(x+\lambda_2)-f(x)]/\lambda_2$ for all f. Taking $f=x^2$ we have $2x+\lambda_1$ and $2x+\lambda_2$ identified, hence λ_1,λ_2 identified. Similarly by induction λ_1^n and λ_2^n are identified for all $n\geqslant 0$. One can also use the left module map property to conclude this. Hence $m_1(\lambda_2)=0$ in k_{λ_2}. Hence m_2 divides m_1. Since m_1 is monic and irreducible, we conclude that $m_1=m_2$ as required. The converse direction is clear. □

This generalizes the observation in Ref. 4 that coirreducible bicovariant quantum differential calculi over $\mathbb{C}[x]$ are parametrized by $\lambda_0\in\mathbb{C}$ (say). Here $m(\lambda)=\lambda-\lambda_0$ and $\pi(\lambda)=\lambda_0$. Hence, in this case,

$$\mathrm{d}f=\mathrm{d}x\,\frac{f(x+\lambda_0)-f(x)}{\lambda_0}. \tag{1}$$

The ratio on the right should be understood as the coefficient of λ_0 in $f(x+\lambda_0)-f(x)$, i.e., we include the usual differential calculus as the case $\lambda_0=0$. More generally, if the extension is Galois, the roots λ_i of m are as many as its degree and are primitive elements of k_λ, i.e., $k_\lambda\cong k[\lambda_i]$ by setting $\lambda=\lambda_i$, for each i. This gives us different ways of thinking of the differentials in Proposition 2.1 concretely as finite differences, all of them equivalent via the action of the Galois group of k_λ automorphisms that permute the λ_i.

It is easy to verify that Ω^1 in Proposition 2.1 is bicovariant under the left and right coactions,

$$\Delta_R P(\lambda,x)=P(\lambda,x+y)\in k_\lambda[x]\otimes k[y],\quad \Delta_L P(\lambda,x)=P(\lambda,y+x)\in k[y]\otimes k_\lambda[x], \tag{2}$$

induced by the coproduct Δ, as it must be by construction. Here the coacting copy of A is denoted by $k[y]$. The space Ω_0 is the subspace of Ω^1 invariant under the left coaction Δ_L, again by the general theory. Clearly, the dimension of Ω_0 over k, which is the dimension of the quantum differential calculus, is the degree of m, the degree of the associated field extension. The elements $\{1=\mathrm{d}x,\lambda,\cdots,\lambda^{\deg(m)-1}\}$ of $k_\lambda[x]$ are a basis of right-invariant 1-forms.

III. QUANTUM DIFFERENTIALS FOR THE COMPLEX EXTENSION OF THE REALS

In this section we consider in detail the case $k=\mathbb{R}$ and $m(\lambda)=\lambda^2+1$. Then $k_\lambda=\mathbb{C}$. The space of right-invariant 1-forms has the basis

$$\Omega_0=\{1=\mathrm{d}x,\quad \lambda=\mathrm{d}x^2-2(\mathrm{d}x)x\}.$$

We use the notations $\mathrm{d}x$ and $\omega\equiv\mathrm{d}x^2-2(\mathrm{d}x)x=x\,\mathrm{d}x-(\mathrm{d}x)x$ (by the Leibniz rule) for these two 1-forms in what follows.

Lemma 3.1: The left part of the bimodule structure on Ω^1 in this basis is given by

$$x\cdot\mathrm{d}x=(\mathrm{d}x)x+\omega,\quad x\cdot\omega=\omega x-\mathrm{d}x.$$

Proof: The first equality is the definition of ω (given the Leibniz rule). The second depends on the irreducible polynomial m according to $x\cdot\omega=(x+\lambda)\lambda=\lambda x-1=\omega x-\mathrm{d}x$. □

Proposition 3.2: The exterior differential is given by

$$\mathrm{d}f(x)=(\mathrm{d}x)\mathfrak{I}f(x+\iota)+\omega(f(x)-\mathfrak{R}f(x+\iota)),$$

where $f\in\mathbb{R}[x]$ is continued to $\mathbb{C}$ and $\mathfrak{I}$, $\mathfrak{R}$ denote imaginary and real parts. The left and right multiplication of forms by functions are related by

$$f(x)\cdot(\mathrm{d}x\quad\omega)=(\mathrm{d}x\quad\omega)\begin{pmatrix}\mathfrak{R} & -\mathfrak{I}\\ \mathfrak{I} & \mathfrak{R}\end{pmatrix}f(x+\iota).$$

Proof: This follows directly as an example of Proposition 2.1 on writing $\lambda=\iota$. Here we provide a more conventional direct proof based on the more conventional description in Lemma 3.1. First we write Lemma 3.1 in matrix form

$$x\cdot(\mathrm{d}x\quad\omega)=(\mathrm{d}x\quad\omega)\begin{pmatrix}x & -1\\ 1 & x\end{pmatrix}.$$

Then $f(x)\cdot\mathrm{d}x=(\mathrm{d}x)f(x+\Lambda)^1{}_1+\omega f(x+\Lambda)^2{}_1$ where $\Lambda=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}$ and the numerical indices denote the matrix element. We regard x for these purposes as multiplied by the identity matrix. Similarly for $f(x)\cdot\omega$.

Now, by induction on the Leibniz rule,

$$\begin{aligned}\mathrm{d}x^m&=x^{m-1}\,\mathrm{d}x+x^{m-2}(\mathrm{d}x)x+\cdots+(\mathrm{d}x)x^{m-1}\\ &=(\mathrm{d}x\quad\omega)(x^{m-1}+x^{m-2}(x+\Lambda)+\cdots+x(x+\Lambda)^{m-2}+(x+\Lambda)^{m-1})\begin{pmatrix}1\\0\end{pmatrix}\\ &=(\mathrm{d}x\quad\omega)\left(\frac{(x+\Lambda)^m-x^m}{\Lambda}\right)\begin{pmatrix}1\\0\end{pmatrix}\\ &=(\mathrm{d}x\quad\omega)((x+\Lambda)^m-x^m)\begin{pmatrix}0\\-1\end{pmatrix}.\end{aligned}$$

This provides the formula

$$\mathrm{d}f=(\mathrm{d}x\quad \omega)(f(x+\Lambda)-f(x))\begin{pmatrix}0\\-1\end{pmatrix}.$$

Since $\Lambda^2=-1$, we then identify the Λ^0 and Λ^1 parts of $f(x+\Lambda)-f(x)$ with the real and imaginary parts of $f(x+\iota)-f(x)$ as stated. Similarly for $f(x)\cdot \mathrm{d}x$ and $f(x)\cdot\omega$. □

To gain further insight into this differential calculus it is useful to embed it in the 1-parameter family corresponding to $m(\lambda)=\lambda^2+q^2$, $q\in\mathbb{R}$. This is isomorphic to the above $q=1$ case for all $q\neq 0$ and not irreducible for $q=0$. It does, however, have an interesting limit as $q\to 0$. Briefly, the relevant formulas are

$$x\cdot(\mathrm{d}x\quad \omega)=(\mathrm{d}x\quad \omega)\begin{pmatrix}x & -q^2\\ 1 & x\end{pmatrix}, \tag{3}$$

resulting in

$$\mathrm{d}f=q^{-2}\omega(f(x)-\Re f(x+\iota q))+q^{-1}(\mathrm{d}x)\Im f(x+\iota q). \tag{4}$$

This has a limit as $q\to 0$:

$$x\omega=\omega x,\quad x\,\mathrm{d}x=(\mathrm{d}x)x+\omega,\quad \mathrm{d}f=\omega\,\tfrac{1}{2}f''+(\mathrm{d}x)f', \tag{5}$$

in terms of the usual Newtonian derivative f'. This is the 2-jet calculus in Ref. 4 whereby up to second order derivatives are viewed as ''first order'' with respect to the new calculus and an appropriate ''braided derivation''[3] rule. We see that this calculus, although not coirreducible, arises naturally as a degenerate limit of coirreducibles corresponding to the extension $\mathbb{R}\subset\mathbb{C}$.

IV. QUANTUM COHOMOLOGY AND GAUGE THEORY OF FIELD EXTENSIONS

In this section, we consider two natural prolongations of the $\Omega^1(k[x])$ associated to a field extension to ''exterior algebras'' $\Omega^n(k[x])$ of degree $n>1$. We compute the first quantum cohomology for each prolongation in the case of the extension $\mathbb{R}\subseteq\mathbb{C}$, and the associated gauge theory.

We recall first that a differential graded algebra $\Omega^{\cdot}$ over a unital algebra A means a graded algebra with degree zero part A itself, and $\mathrm{d}:\Omega^{\cdot}\to\Omega^{\cdot}$ which increases the degree by 1 and obeys $\mathrm{d}^2=0$ and the graded Leibniz rule. In other words, $\Omega^{\cdot}$ has the algebraic properties of an ''exterior algebra'' in DeRahm theory and one may likewise compute its ''quantum de Rahm cohomology.'' Thus,

$$H^1=\{\omega\in\Omega^1|\mathrm{d}\omega=0\}/\{\mathrm{d}a|a\in A\}. \tag{6}$$

Given Ω^1, its maximal prolongation is defined as follows. First of all, we recall that in view of Axiom 3 above we can write Ω^1 as a quotient of the universal calculus $\Omega^1_U=\ker(\cdot:A\otimes A\to A)$ by a sub-bimodule $\mathcal{N}$. Here Ω^1_U has the obvious bimodule structure from $A\otimes A$ and $\mathrm{d}_U a=a\otimes 1-1\otimes a$. [Note that when A is a Hopf algebra then $A\otimes A\cong A\otimes A$ by $a\otimes b\mapsto(\Delta a)b$ restricts to $\Omega^1_U\cong\ker\epsilon\otimes A$ and $\mathcal{N}\cong\mathcal{M}\otimes A$, giving the description used in Sec. II.] Moreover, Ω^1_U is the degree 1 part of a canonical $\Omega^{\cdot}_U$ (albeit with trivial quantum cohomology). Here $\Omega^n_U\subset A^{\otimes n+1}$ as elements in the joint kernel of all product maps $\cdot_i$ multiplying the $i,i+1$'th copies of A. This can also be identified with $\Omega^n_U=\Omega^1_U\otimes_A\cdots\otimes_A\Omega^1_U$ in the obvious way; see Refs. 5 and 1. Here

$$\mathrm{d}_U(a_0\otimes a_1\cdots\otimes a_n)=\sum_{i=0}^{n+1}(-1)^{n+1-i}a_0\otimes\cdots\otimes a_{i-1}\otimes 1\otimes a_i\otimes\cdots\otimes a_n. \tag{7}$$

One may check that $\mathrm{d}_U\circ\mathrm{d}_U=0$. The product $\wedge$ of $\Omega^{\cdot}_U$ is given by multiplication between the two adjacent copies of A. A general $\Omega^{\cdot}$ over A is a quotient of $\Omega^{\cdot}_U$ by a differential graded ideal (i.e., an ideal stable under d_U). Without loss of generality we assume that the degree 0 part of the ideal is zero. The degree 1 part is some subbimodule $\mathcal{N}\subseteq\Omega^1_U$ and conversely, given $\mathcal{N}$ the maximal prolongation is provided by the differential ideal generated by $\mathcal{N}$. Its degree 2 part is $\mathcal{F}=\Omega^1_U\wedge\mathcal{N}+\mathcal{N}\wedge\Omega^1_U+d_U\mathcal{N}$ and $\Omega^2=\Omega^2_U/\mathcal{F}$.

Lemma 4.1: For the field extension $\mathbb{R}\subset\mathbb{C}$, the maximal Ω^2 is generated as an $\mathbb{R}[x]$-module by the two forms $\mathrm{d}x\wedge\mathrm{d}x$ and $\mathrm{d}x\wedge\omega$. Moreover,

$$d\omega=2\,\mathrm{d}x\wedge\mathrm{d}x=2\,\omega\wedge\omega,\quad \mathrm{d}x\wedge\omega=-\omega\wedge\mathrm{d}x.$$

Proof: The subbimodule $\mathcal{N}$ in our case is generated by $x\omega-\omega x+\mathrm{d}x$ where ω is defined as above. Now, $\mathrm{d}\omega=\mathrm{d}(x\,\mathrm{d}x-(\mathrm{d}x)x)=2\,\mathrm{d}x\wedge\mathrm{d}x$ from the definition of ω and the graded Leibniz rule and $\mathrm{d}^2=0$. Hence the subbimodule $\mathcal{F}$ is generated by $\Omega^1_U\wedge\mathcal{N}$, $\mathcal{N}\wedge\Omega^1_U$ and $\mathrm{d}x\wedge\omega+\omega\wedge\mathrm{d}x+2x\,\mathrm{d}x\wedge\mathrm{d}x-2(\mathrm{d}x\wedge\mathrm{d}x)x$. From Lemma 3.1 we have $x\,\mathrm{d}x\wedge\mathrm{d}x=(\mathrm{d}x)\wedge x\,\mathrm{d}x+\omega\wedge\mathrm{d}x=(\mathrm{d}x\wedge\mathrm{d}x)x+\mathrm{d}x\wedge\omega+\omega\wedge\mathrm{d}x$ up to terms in $\Omega^1_U\wedge\mathcal{N}$, $\mathcal{N}\wedge\Omega^1_U$. Therefore, $\mathcal{F}$ is generated by these and $\omega\wedge\mathrm{d}x+\mathrm{d}x\wedge\omega$.

Finally, from the definition of ω, and the relations in Ω^1 and $\mathcal{N}$, we have

$$\begin{aligned}\omega\wedge\omega&=(x\,\mathrm{d}x-(\mathrm{d}x)x)\wedge\omega\\&=-x\omega\wedge\mathrm{d}x-(\mathrm{d}x)x\wedge\omega\\&=\mathrm{d}x\wedge\mathrm{d}x-\omega\wedge x\,\mathrm{d}x-(\mathrm{d}x)x\wedge\omega\\&=\mathrm{d}x\wedge\mathrm{d}x-\omega\wedge\omega-\omega\wedge\mathrm{d}x\,x+\mathrm{d}x\wedge\mathrm{d}x-(\mathrm{d}x)\wedge\omega x\\&=2\,\mathrm{d}x\wedge\mathrm{d}x-\omega\wedge\omega,\end{aligned}$$

which gives the stated description of Ω^2 as a quotient of the tensor square over $\mathbb{R}[x]$ of Ω^1. □

Proposition 4.2: With the maximal Ω^2, the quantum de Rahm cohomology H^1 associated to $\mathbb{R}\subset\mathbb{C}$ vanishes.

Proof: Suppose $\mathrm{d}((\mathrm{d}x)f+\omega g)=0$, i.e., $-\mathrm{d}x\wedge\mathrm{d}f+2(\mathrm{d}x\wedge\mathrm{d}x)g-\omega\wedge\mathrm{d}g=0$. Putting in the form of $\mathrm{d}f$ and $\mathrm{d}g$ from Proposition 3.2, we see this is equivalent to

$$\mathfrak{I}g(x+\iota)=f(x)-\mathfrak{R}f(x+\iota),\quad \mathfrak{R}g(x+\iota)+g(x)=\mathfrak{I}f(x+\iota),$$

which can be combined into the single equation

$$f(x+\iota)-f(x)=\iota(g(x)+g(x+\iota)). \tag{8}$$

We now show that such f,g are necessarily of the form

$$f=\mathfrak{I}h(x+\iota),\quad g=h(x)-\mathfrak{R}h(x+\iota),$$

for some $h(x)$. Note first that if (f,g) obey (8) and without loss of generality $f=nx^{n-1}+\text{lower}$ degree, say, then

$$g=\frac{n(n-1)}{2}x^{n-2}+\text{lower degree}.$$

Indeed, writing $g=\mu x^p+\text{lower degree}$, the second half of (8) implies that $\mu x^p+\mu\mathfrak{R}(x+\iota)^p+\cdots=2\mu x^p+\cdots=n\mathfrak{I}(x+\iota)^{n-1}-nx^{n-1}+\cdots=n(n-1)x^{n-2}+\cdots$. Equating leading terms gives $p=n-2$ and $2\mu=n(n-1)$.

Now let

$$f_n=\mathfrak{I}(x+\iota)^n,\quad g_n=x^n-\mathfrak{R}(x+\iota)^n=x^n-(x+\iota)^n+\iota f_n,$$

for $n>0$. Note that the leading term of f_n is nx^{n-1} and the leading term of g_n is $[n(n-1)/2]x^{n-2}$. Hence

$$f=f_n+\overline{f},\quad g=g_n+\overline{g}$$

defines two polynomials $\overline{f},\overline{g}$ of lower degree. Now, since (f_n,g_n) are the components of the differential of x^n, and since $d^2=0$, we know that they obey (8). Hence $(\overline{f},\overline{g})$ obeys (8) and has a lower degree.

Therefore we have a proof by induction. The case where $n=2$ is easily seen to be true. That is, if $f=2x+\mu$ then (8) implies as above that $g=1$. Then, indeed, $f=\mathfrak{I}((x+\iota)^2+\mu(x+\iota))$ and $x^2+\mu x-\mathfrak{R}((x+\iota)^2+\mu(x+\iota))=1=g$, as required. In terms of differential forms, the assertion is that if $(\mathrm{d}x)(2x+\mu)+\omega h(x)$ is closed then $h(x)=1$ and the form is $\mathrm{d}(x^2+\mu x)$. This may also be verified directly from the relations in Lemma 4.1. □

Next we consider a natural quotient of the above prolongation which always exists when A is a Hopf algebra and Ω^1 is bicovariant. In this case $\Omega^1=\Omega_0\otimes A$ as explained in Sec. II, and $\Omega^\cdot$ is defined in such a way that the invariant differential forms ''braided-anticommute'' where the braiding is the one associated to the quantum double of A.[2] Fortunately, in our case where A is commutative and cocommutative, the quantum double braiding is the trivial flip map (the usual transposition). Hence, in this case we have simply $\Omega^n=\Lambda^n\Omega_0\otimes A$, where Λ^n denotes the usual exterior algebra of the vector space Ω_0. We call this the skew exterior algebra.

Proposition 4.3: The skew Ω^2 in the case $\mathbb{R}\subset\mathbb{C}$ is 1-dimensional with basis $\mathrm{d}x\wedge\omega$ [i.e., as in Lemma 3.1, with the additional relations $(\mathrm{d}x)^2=0=\omega^2$]. The first quantum cohomology in this case is $H^1=\mathbb{R}\omega$, i.e., 1-dimensional and spanned by ω.

Proof: This time $\mathrm{d}((\mathrm{d}x)f+\omega g)=0$ and $\mathrm{d}f,\mathrm{d}g$ from Proposition 3.2 implies only that

$$\mathfrak{I}g(x+\iota)=f(x)-\mathfrak{R}f(x+\iota), \tag{9}$$

as the coefficient of $\mathrm{d}x\wedge\omega$. [The first half of (8) does not apply since $\mathrm{d}x\wedge\mathrm{d}x=0$.] This equation still implies that if $f=nx^{n-1}+$lower degree and $n>2$ then $g=[n(n-1)/2]x^{n-2}+$lower degree, as before. Indeed, if $g=\mu x^p+\cdots$ then it says $\mu p x^{p-1}+\cdots=n(n-1)(n-2)/2+\cdots$. This is weaker than before because it does not fix μ when $n=2$. We proceed as before by writing $f=f_n+\overline{f}$, $g=g_n+\overline{g}$ so that $\overline{f},\overline{g}$ obey (9) and have a lower degree. In this way we obtain (without loss of generality by scaling f,g suitably) $f=F+2x+\mu$ and $g=G+\tau$ where $(\mathrm{d}x)F+\omega G=\mathrm{d}h$ for some h. Adding $f_2+\mu f_1$ and $g_2=1$ (here $g_1=0$) to F,G, we have $(\mathrm{d}x)f+\omega g=(1-\tau)\omega+\mathrm{d}h'$ for $h'=h+x^2+\mu x$. Hence $H^1=\mathbb{R}\omega$. Indeed $\mathrm{d}\omega=0$ for this choice of Ω^2 but ω is not exact. □

Finally, associated to any $\Omega^\cdot$ over a unital algebra A one has further ''quantum geometrical'' constructions, such as gauge theory. In its simplest form we consider a gauge field as any $\alpha\in\Omega^1$ and a gauge transform as an any invertible $\gamma\in A$. The group of gauge transforms acts on the set of α by

$$\alpha^\gamma=\gamma^{-1}\alpha\gamma+\gamma^{-1}\,\mathrm{d}\gamma. \tag{10}$$

The fundamental lemma of gauge theory is that the curvature

$$F(\alpha)=\mathrm{d}\alpha+\alpha\wedge\alpha\in\Omega^2 \tag{11}$$

is covariant in the sense that $F(\alpha^\gamma)=\gamma^{-1}F(\alpha)\gamma$. Moreover, one can consider sections $\psi\in A$ and a covariant derivative $\nabla\psi=\mathrm{d}\psi+\alpha\psi\in\Omega^1$. One has an action of the group of gauge transformations by $\psi^\gamma=\gamma^{-1}\psi$ and $\nabla^\gamma\psi^\gamma=(\nabla\psi)^\gamma$. These facts require only that Ω^1,Ω^2 obey the natural axioms as part of a differential graded algebra; see Ref. 4. Note that when Ω^1 is ''quantum,'' the nonlinearity in F does not necessarily collapse, even though the ''structure group'' here is trivial, i.e., one has many of the features of non-Abelian gauge theory. One may also consider α with values in some other algebra.

In our present setting where $A=k[x]$, only 1 will be invertible as a polynomial. One may enlarge A and our constructions above to handle this. Alternatively, instead of the ''finite'' gauge transformations γ one can consider only ''infinitesimal'' ones. Here an infinitesimal gauge transformation means $\theta\in k[x]$ acting by

$$\alpha^\theta=\alpha+\mathrm{d}\theta+\alpha\theta-\theta\alpha,\quad F(\alpha^\theta)=F(\alpha)+F(\alpha)\theta-\theta F(\alpha),\tag{12}$$

to lowest order in θ. This can be stated more formally as a vector field associated to each θ on the space of connections, etc., in the usual way. The covariant derivative $\nabla=\mathrm{d}+\alpha\wedge$ is covariant to lowest order under $\psi^\theta=\psi-\theta\psi$. By the same methods as in Ref. 4, one may check that any Ω^1,Ω^2 which are part of an exterior algebra will do for these features of gauge theory. Covariance of the curvature means that the vector fields associated to θ restrict to vector fields on the space of flat connections. They may not, however, restrict to only the algebraic (i.e., polynomial) part.

Proposition 4.4: For the extension $\mathbb{R}\subset\mathbb{C}$ and the maximal prolongation Ω^2 we write $\alpha=(\mathrm{d}x)a+\omega b$ and $F(\alpha)=(\mathrm{d}x)^2F_0+\mathrm{d}x\wedge\omega F_1$, say, then

$$F_0+\iota F_1=(a(x)+\iota(b(x)+1))(a(x+\iota)-\iota(b(x+\iota)+1))-1,$$

and the infinitesimal gauge transformations are

$$(a(x)+\iota(b(x)+1))\mapsto(a(x)+\iota(b(x)+1))(1+\theta(x)-\theta(x+\iota)).$$

The algebraic part of the space of flat connections is a circle,

$$\mathrm{Flat}=\{\mathrm{d}x\,s+\omega t|s,t\in\mathbb{R},\quad s^2+(t+1)^2=1\}=S^1\subset\mathbb{C}.$$

Here $s+\iota t\in\mathbb{C}\subset\mathbb{C}[x]\subset\Omega^1$ is a circle of unit radius centered at $-\iota$. The action of $\theta(x)=x$ is a unit vector field along the circle, so that the algebraic moduli space is the class of the zero connection.

Proof: We use Proposition 3.2 to compute $\mathrm{d}\alpha+\alpha\wedge\alpha$ in Ω^2. We then use Lemma 4.1 and collect the coefficients of $\mathrm{d}x\wedge\mathrm{d}x$ and $\mathrm{d}x\wedge\omega$ as

$$F_0=(-\Im a(x+\iota)+\Re b(x+\iota))(1+b(x))+b(x)+(\Re a(x+\iota)+\Im b(x+\iota))a(x),$$

$$F_1=(\Re a(x+\iota)+\Im b(x+\iota))(1+b(x))-a(x)+(\Im a(x+\iota)-\Re b(x+\iota))a(x).$$

Likewise from Proposition 3.2, the action of infinitesimal gauge transformation $\theta\in\mathbb{R}[x]$ is

$$a\mapsto a(x)(1+\theta(x))+\Im\theta(x+\iota)(1+b(x))-\Re\theta(x+\iota)a(x),$$

$$b\mapsto b(x)(1+\theta(x))+\theta-\Re\theta(x+\iota)(1+b(x))-\Im\theta(x+\iota)a(x).$$

We can then combine these expressions into the expressions shown for $F_0+\iota F_1$ and $a+\iota b$. Note that $\alpha=\mathrm{d}x\,a+\omega b=a+\iota b$ in the identification of Proposition 2.1, and similarly $F(\alpha)=\mathrm{d}x\wedge(F_0+\iota F_1)$ by an extension of this identification.

Next we compute the algebraic part of the space of flat connections. Suppose that

$$\alpha=a+\iota b=sx^n+\cdots+\iota(tx^m+\cdots),\quad s,t\neq0$$

are the leading terms for the real and imaginary parts. Here, $n,m\geqslant0$. Then

$$\begin{aligned}F(\alpha)=&-snx^{n-1}-\iota s\frac{n(n-1)}{2}x^{n-2}+2tx^m+\iota tmx^{m-1}+(sx^n+\iota tx^m)\\&\times\left(sx^n-\iota tx^m+\iota snx^{n-1}+tmx^{m-1}-s\frac{n(n-1)}{2}x^{n-2}+\iota t\frac{m(m-1)}{2}x^{m-2}\right)+\cdots\\=&-snx^{n-1}-\iota s\frac{n(n-1)}{2}x^{n-2}+2tx^m+\iota tmx^{m-1}+s^2x^{2n}+t^2x^{2m}+\iota s^2nx^{2n-1}+\iota t^2mx^{2m-1}\\&+st(m-n)x^{m+n-1}+\frac{\iota}{2}st(m(m-1)-n(n-1))x^{m+n-2}+\cdots.\end{aligned}$$

Now, since $n\geqslant 0$ the x^{n-1} and ιx^{n-2} terms can be dropped against the x^{2n} and ιx^{2n-1} terms, respectively.

Suppose that $m\geqslant 1$. Then the x^m and ιx^{m-1} terms can likewise be dropped. If $m=n$ then $(s^2+t^2)x^{2n}+\iota(s^2+t^2)nx^{2n-1}$ is dominant, in which case $F=0$ would imply $s=0$, $t=0$. So this case is excluded under our initial assumption. If $m>n$ then $t^2x^{2m}+\iota t^2mx^{2m-1}$ is dominant, in which case $t=0$. Likewise $m<n$ would imply $s=0$.

Hence $m=0$ for a flat connection under our assumption $s,t\neq 0$. In this case, if $n\geqslant 1$ then $s^2x^{2n}+\iota s^2nx^{2n-1}$ is dominant and $F=0$ would imply that $s=0$. Hence $n=0$ as well for a flat connection.

It remains to consider the simpler cases where $t=0$ or $s=0$ in our leading terms (i.e., real or imaginary α). If $t=0$ and $s\neq 0$ we similarly conclude that $n=0$ for a nonzero flat connection. And if $s=0$ and $t\neq 0$ then $m=0$ for a nonzero flat connection in the same way. Hence, for an algebraic connection of zero curvature, we are left with $\alpha=s+\iota t$ for $s,t\in\mathbb{R}$. Then

$$F(\mathrm{d}x\, s+\omega t)=\mathrm{d}(\mathrm{d}x\, s+\omega t)+(\mathrm{d}x\, s+\omega t)\wedge(\mathrm{d}x\, s+\omega t)=(t^2+2t+s^2)\mathrm{d}x\wedge\mathrm{d}x,$$

via Lemma 4.1, which tells us that $s^2+(t+1)^2=1$ for zero curvature.

For $\theta(x)=x\epsilon$, where $\epsilon\in\mathbb{R}$, we have the infinitesimal gauge transform $s+\iota(t+1)\mapsto(s+\iota(t+1))(1-\iota\epsilon)$ to lowest order in ϵ. This is an infinitesimal rotation of $s+\iota t$ about $-\iota$. □

Although we can consider only infinitesimal gauge transformations in our present algebraic setup, it is clear that the exponentiation of the infinitesimal gauge transformations associated to $\theta(x)=x\epsilon$ rotate us around the stated S^1. Since this S^1 passes through the origin, we see that all the algebraic zero curvature solutions stated are connected in this way to the zero connection by finite gauge transformations. Note also that infinitesimal gauge transformations by $\theta(x)=x^n\epsilon$, $n>1$ take us out of the space of algebraic zero curvature connections. This tells us that additional zero curvature connections beyond those in the proposition certainly exist in a suitable context, just not as polynomials. For example, the formal exponentiation of the gauge transform by $\theta(x)=x^2\epsilon$ of the $\alpha=-2\iota$ solution is

$$\alpha=-\iota(1+e^{\tau(1-2x\iota)}),\quad \tau\in\mathbb{R}.$$

It corresponds to the gauge transformation of $\alpha=-2\iota$ by $\gamma(x)=e^{\tau x^2}$, where (10) for the $\mathbb{R}\subset\mathbb{C}$ calculus comes out as

$$\alpha^\gamma+\iota=(\alpha+\iota)\frac{\gamma(x)}{\gamma(x+\iota)}. \tag{13}$$

Although we are not able to consider such finite gauge transformations and exponentials in our polynomial setting, we see that the infinitesimal gauge transforms do give us some information about the entire space of solutions.

Proposition 4.5: For the extension $\mathbb{R}\subset\mathbb{C}$ and the skew prolongation Ω^2 we write $\alpha=(\mathrm{d}x)a+\omega b$ as above and $F(\alpha)=\mathrm{d}x\wedge\omega F_1$, say. Then

$$F_1=(\Re a(x+\iota)+\Im b(x+\iota))(1+b(x))-a(x)+(\Im a(x+\iota)-\Re b(x+\iota))a(x),$$

and the infinitesimal gauge transformations by θ as in the preceding proposition. The algebraic part of the space of flat connections is the complex plane,

$$\mathrm{Flat}=\{\mathrm{d}s+\omega t|s,t\in\mathbb{R}\}=\mathbb{C},$$

where $s+\iota t\in\mathbb{C}\subset\mathbb{C}[x]=\Omega^1$. The algebraic moduli space of flat connections modulo gauge transformations is the half-line $\mathbb{R}_+$.

Proof: We take the same form for α with leading coefficients *s,t* as in the preceding proof. This time, however, the zero-curvature condition is only half of the preceding one. Indeed,

$$F_1=-s\frac{n(n-1)}{2}x^{n-2}+tmx^{m-1}+tx^m\left(-s\frac{n(n-1)}{2}x^{n-2}+tmx^{m-1}\right)$$
$$+sx^n\left(snx^{n-1}+t\frac{m(m-1)}{2}x^{m-2}\right)+\cdots,$$

for the leading terms after cancellations. We used the same expression for F_1 as the coefficient of $\mathrm{d}x\wedge\omega$ in the preceding proof. We drop x^{n-2} against x^{2n-1} and, assuming $m\geqslant 1$ we drop x^{m-1} as well. If $m=n$ we drop x^{m+n-2} and the dominant term is $(s^2+t^2)nx^{2n-1}$, which would imply $s=t=0$ for a flat connection. If $m>n$ the dominant term is t^2x^{2m-1} which would imply $t=0$. If $m<n$ the dominant term is s^2x^{2n-1} which would imply $s=0$. Hence $m=0$. Hence the dominant term is s^2nx^{2n-1} which would imply $s=0$ if $n\geqslant 1$. Hence $n=0$ as well. Finally, if we consider the similar form of α with $s=0$, the leading term for $m\geqslant 1$ would be t^2x^{2m-1} and imply $\alpha=0$, so $m=0$ in this case for a nonzero flat connection. If we consider α with $t=0$ then the leading term is s^2nx^{2n-1} as before, which would imply $n=0$. These are similar arguments to those in the preceding proof but relying now only on the imaginary part of the curvature. We deduce that an algebraic flat connection is of the form $\alpha=\mathrm{d}x\,s+\omega t$. This time, however, $F(\alpha)=0$ for all $s,t\in\mathbb{R}$ since $\mathrm{d}x\wedge\mathrm{d}x=0$ in the skew prolongation.

Infinitesimal gauge transformations are computed as before without change. Hence, the ones of the form $\theta(x)=x\epsilon$ rotate about $-\iota$ in the $s+\iota t$ plane. The orbits are circles of constant radius $s^2+(t+1)^2\in\mathbb{R}_+$. The different orbits are, however, inequivalent at least by such θ. (On the other hand, higher degree θ take us out of the class of polynomial connections.) Hence the algebraic part of the moduli space of flat connections is $\mathbb{R}_+$. □

Finally, the cohomology and moduli spaces in the maximal and skew prolongations are much more easily computed in the simpler 2-jet calculus resulting from the degenerate $q\to 0$ limit of the parametrized version of the $\mathbb{R}\subset\mathbb{C}$ extension. We first compute the maximal prolongation as having relations

$$\omega\wedge\omega=q^2\,\mathrm{d}x\wedge\mathrm{d}x,\quad \mathrm{d}\omega=2\,\mathrm{d}x\wedge\mathrm{d}x,\quad \mathrm{d}x\wedge\omega=-\omega\wedge\mathrm{d}x. \tag{14}$$

The proof is entirely similar to that of Lemma 4.1 (and equivalent to it after a rescaling), so we omit it. The degenerate limit is therefore

$$\omega\wedge\omega=0,\quad \mathrm{d}\omega=2\,\mathrm{d}x\wedge\mathrm{d}x,\quad \mathrm{d}x\wedge\omega=-\omega\wedge\mathrm{d}x. \tag{15}$$

The skew prolongation has the additional relation $\mathrm{d}x\wedge\mathrm{d}x=0$.

Proposition 4.6: The quantum cohomology for the 2-jet calculus is $H^1=0$ in the maximal prolongation and $H^1=\mathbb{R}\omega$ in the skew prolongation.

Proof: Here $\mathrm{d}((\mathrm{d}x)f+\omega g)=0$ implies

$$\tfrac{1}{2}f'=g,\quad \tfrac{1}{2}f''=g'.$$

Letting h be such that $h'=f$, we have $(\mathrm{d}x)f+\omega g=\mathrm{d}h$, so that H^1 is trivial. For the skew prolongation we have only $(1/2)f''=g'$, which implies $(1/2)f'=g-\mu$ where $\mu\in\mathbb{R}$. Choosing h such that $f=h'$, we have $(\mathrm{d}x)f+\omega g=\mathrm{d}h+\mu\omega$, so that $H^1=\mathbb{R}\omega$. □

Gauge theory in the $q\to 0$ limit is described in Ref. 4, and we now compute the moduli space of flat connections in this case.

Proposition 4.7: Writing $\alpha=(\mathrm{d}x)a+\omega b$, the curvature in the 2-jet calculus with the maximal prolongation is

$$F(\alpha)=\mathrm{d}x\wedge\mathrm{d}x(2b-a'+a^2)+\mathrm{d}x\wedge\omega(b'-\tfrac{1}{2}a''+a'a),$$

and is invariant under the gauge transformation,

$$a\mapsto a+\theta',\quad b\mapsto b-a\theta'+\tfrac{1}{2}(\theta''-(\theta')^2),$$

by $\theta\in\mathbb{R}[x]$. The moduli space of flat connections in the maximal prolongation is trivial and in the skew prolongation is $\mathbb{R}$, with flat connections gauge equivalent to $\alpha=\mu\omega$ for unique $\mu\in\mathbb{R}$.

Proof: We compute $F(\alpha)$ using the relations in Ω^2 and the commutation rules for Ω^1 at the end of Sec. III. The gauge transformation is likewise the infinitesimal gauge transformations as above but computed for this calculus, and corrected by the $-1/2(\theta')^2$ to make, in the present case, an exact gauge symmetry of the curvature (not only to lowest order in θ). These formulas are obtained by formally writing $\gamma=e^{\theta}$ in the finite gauge transformation formulas computed for the 2-jet calculus in Ref. 4; in our present case the result involves only polynomials in derivatives of θ, i.e., makes sense in terms of θ at our algebraic level. One then verifies directly at this level that $F(\alpha^{\theta})=F(\alpha)$.

The zero-curvature condition in the maximal prolongation is therefore

$$b=\tfrac{1}{2}(a'-a^2).$$

If this is the case then choose θ such that $\theta'=-a$. This gauge transforms $a\mapsto 0$. On the other hand, $b\mapsto b-a(-a)+1/2(-a'-a^2)=b+1/2(a^2-a')=0$ as well. Hence every flat connection is gauge equivalent to the zero one. By contrast, in the skew prolongation, the zero-curvature equation is

$$b'=\tfrac{1}{2}a''-a'a,$$

which means $b=1/2(a'-a^2)+\mu$ for some constant $\mu\in\mathbb{R}$. Making the same gauge transformation as before now sends $a\mapsto 0$ and $b\mapsto\mu$. Any further gauge transformation preserving $a=0$ would require $\theta'=0$, which would therefore not change the b component, i.e., the different μ cannot be related by any further gauge transformation. Hence the moduli space is $\mathbb{R}$ in the skew prolongation. □

V. CONCLUDING REMARKS

We conclude the paper with two miscellaneous pieces of general theory, demonstrated for our particular quantum exterior algebras. First, by Ref. 6, the Woronowicz $\Omega^{\cdot}$ (which in our case means the skew prolongation) is always a $\mathbb{Z}_2$-graded Hopf algebra with the coproduct extended by $\Delta=\Delta_L+\Delta_R$ on Ω^1. The same applies, in general, to the maximal prolongation, which again gives a $\mathbb{Z}_2$-graded Hopf algebra. From (2), we know (for any field extension) that $\Delta_L\lambda^n=1\otimes\lambda^n$ and $\Delta_R\lambda^n=\lambda^n\otimes 1$ (i.e., $\Omega_0=k_\lambda$ is left and right invariant). Hence the coproduct structure is with the basis of Ω_0 primitive, and the original coproduct of $k[x]$.

For example, for the extension $\mathbb{R}\subset\mathbb{C}$ we have the maximal prolongation $\Omega^{\cdot}$ as the $\mathbb{Z}_2$-graded Hopf algebra generated over $\mathbb{R}$ by x of degree zero and $\theta\equiv dx$, ω of degree 1, and the relations and coproduct

$$\begin{gathered} x\theta-\theta x=\omega,\quad x\omega-\omega x=-\theta,\quad \omega\theta=-\theta\omega,\quad \theta^2=\omega^2,\\ \Delta x=x\otimes 1+1\otimes x,\quad \Delta\theta=\theta\otimes 1+1\otimes\theta,\quad \Delta\omega=\omega\otimes 1+1\otimes\omega. \end{gathered}\tag{16}$$

The skew prolongation is the quotient of this by the additional relation $\theta^2=0$.

Finally, we consider what should be the notion of ''differentiable'' map $k[x]\to k[x]$ where the source and target are considered with differential calculi defined by m_1, m_2, respectively. A full analysis of the dependence of the above quantum geometric constructions on the choice of m will be developed elsewhere, but one may conjecture that at least some ''geometric'' invariants obtained from constructions of this type will be invariants of the field extension; i.e., if m_1, m_2 give isomorphic field extensions then some of the invariants should coincide. This is a long-term goal suggested by the above results, and would have applications in number theory (where the question of which monic polynomials give equivalent extensions is poorly understood for many fields k). The analysis of which maps $k[x]\to k[x]$ are indeed differentiable should be a first step in this geometric program.

We recall that any $\Omega^1(A)$ over a unital algebra A is a quotient $\Omega^1_U A/\mathcal{N}_A$ of the universal 1-forms $\Omega^1_U A\subset A\otimes A$. Any algebra map $\phi:A\to B$ (between unital algebras A,B) clearly induces a map $\phi\otimes\phi:\Omega^1_U A\to\Omega^1_U B$. Given this situation, we say that ϕ is differentiable if $\phi\otimes\phi$ descends to a map $\Omega^1(A)\to\Omega^1(B)$. If so, we denote the map by ϕ_* and note that it obeys the commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{\phi} & B \\ \mathrm{d}\downarrow & & \downarrow\mathrm{d} \\ \Omega^1(A) & \xrightarrow{\phi_*} & \Omega^1(B) \end{array}, \tag{17}$$

since the universal d_U for A,B clearly obey this. The condition for differentiability is that $(\phi\otimes\phi)(\mathcal{N}_A)\subseteq\mathcal{N}_B$.

Proposition 5.1: In the setting of Proposition 2.1, an algebra map $\phi:k[x]\to k[x]$ defined by $\phi(x)=\Phi\in k[x]$ is differentiable with respect to calculi defined by $m_1(\lambda_1)$, $m_2(\lambda_2)$ on the source and target, respectively, iff

$$\mathrm{d}\Phi=0,\quad \text{or}\quad m_1(\Phi(\lambda_2+x)-\Phi(x))=0,$$

in $k_{\lambda_2}[x]$. Then $\phi_*(P(\lambda_1,x))=(\mathrm{d}\Phi)P(\Phi(\lambda_2+x)-\Phi(x),\Phi(x))$, where the product is in $k_{\lambda_2}[x]$.

Proof: We use the explicit isomorphism $\theta:\Omega^1_U A\cong\ker\epsilon\otimes A$ provided by $\theta(a\otimes b)=a_{(1)}\otimes a_{(2)}b$ and $\theta^{-1}(a\otimes b)=a_{(1)}\otimes(Sa_{(2)})b$ where S is the antipode and $\Delta a=a_{(1)}\otimes a_{(2)}$ (the summation is understood). In view of this, the map $\phi\otimes\phi$ becomes the map $\phi^U_*:\ker\epsilon\otimes A\to\ker\epsilon\otimes A$ as given by

$$\phi^U_*(a\otimes b)=\theta(\phi(a_{(1)})\otimes\phi(Sa_{(2)})\phi(b))=\phi(a_{(1)})_{(1)}\otimes\phi(a_{(1)})_{(2)}\phi(Sa_{(2)})\phi(b),$$

for all $a\in\ker\epsilon$ and $b\in A$. In the present setting, this becomes

$$\phi^U_*(yg(y)\otimes f(x))=(\Phi(y+x)-\Phi(x))g(\Phi(y+x)-\Phi(x))f(\Phi(x)),$$

for polynomials f,g (we write $A\otimes A=k[y,x]$). As in the proof of Proposition 2.1, we further identify the source $\ker\epsilon=k[\lambda_1]$ by $yg(y)\mapsto g(\lambda)$. We likewise identify the target $\ker\epsilon=k[\lambda_2]$ in the similar, say. With these identifications understood, we have

$$\phi^U_*(g(\lambda_1)\otimes f(x))=\frac{\Phi(\lambda_2+x)-\Phi(x)}{\lambda_2}g(\Phi(\lambda_2+x)-\Phi(x))f(\Phi(x)).$$

This map descends to the quotients $k_{\lambda_1}=k[\lambda_1]/\langle m_1\rangle$ and $k_{\lambda_2}=k[\lambda_2]/\langle m_2\rangle$ iff

$$\phi^U_*(m_1(\lambda_1)\otimes 1)=0,$$

in $k_{\lambda_2}[x]$, i.e., iff

$$(\mathrm{d}\Phi)m_1(\Phi(\lambda_2+x)-\Phi(x))=0,$$

in $k_{\lambda_2}[x]$, where we used the description of d in the target calculus from Proposition 2.1. This is the condition stated. Of the two possibilities, the second is more interesting in view of the form of ϕ_*. □

For example, for the differential calculus associated to $\mathbb{R}\subset\mathbb{C}$ in the source and target, the differentiability condition is

$$\Phi(x+\iota)-\Phi(x)=\begin{cases}0,\\ \pm\iota,\end{cases} \tag{18}$$

which at the algebraic level means $\Phi(x)=\pm x+\mu$ or $\Phi(x)=\mu$ for $\mu\in\mathbb{R}$. If we allow nonpolynomials then other possibilities, such as $\Phi(x)=e^{2\pi x}$, certainly open up. By contrast, for the degenerate 2-jet calculus in the source and target, the differentiability condition is automatically satisfied for all $\Phi\in\mathbb{R}[x]$. Here $m(\lambda)=\lambda^2$ is not irreducible but one can use the same formulas (the calculus is merely not coirreducible). Then $\Phi(\lambda+x)-\Phi(x)=\lambda\Phi'$ and $m(\lambda\Phi')=\lambda^2(\Phi')^2=0$ for all Φ.

ACKNOWLEDGMENT

I would like to thank D. Solomon for useful discussions at the start of the project.

(Received 13 November 1997; accepted for publication 7 January 1999)

A novel realization of the classical SU(2) algebra is introduced for the Dirac relativistic hydrogen atom defining a set of operators that allow the factorization of the problem. An extra phase is needed as a new variable in order to define the algebra. We take advantage of the operators to solve the Dirac equation using algebraic methods. A similar path to the one used in the angular momentum case is used; hence, the radial eigenfunctions so calculated comprise nonunitary representations of the algebra. One of the interesting properties of such nonunitary representations is that they are not labeled by integer nor by half-integer numbers, as occurs in the usual angular momentum representation. © *1999 American Institute of Physics.* [S0022-2488(99)02004-6]

I. INTRODUCTION

The unitary representations of groups and algebras are of a great interest in physics. We can mention the ubiquitous example of angular momentum or the SU(2) algebra. In this instance, as it is well known, the representations are labeled by two real numbers j and m, which may take only integer or half-integer values; the representations depend only on two parameters, θ and ϕ, say, which are defined in the compact sets $[0, \pi]$ and $[0, 2\pi]$, respectively.[1] However, there are many other physically interesting groups or algebras that are not unitary. In such a case, the representations are not restricted to parameters defined in compact sets nor are its generators necessarily Hermitian, but they nevertheless can play an important role in physics. The Lorentz group being a very important example of the class of physically relevant noncompact groups whose algebra is not necessarily unitary.[2]

It is our purpose in this article to introduce a realization of the cyclic SU(2) algebra in terms of non-Hermitian operators and then to use these operators to factorize and solve the relativistic Dirac hydrogen atom. The solution is obtained using algebraic methods, using the basic operators of the system following a route parallel to the unitary compact case, but introducing an extra variable (it is found below to play the role of a phase), which is required in our approach.[3]

The use of algebraic techniques has been common for these sort of problems. For example, in the relativistic hydrogen atom à la Dirac, one approach has been the use of shift operators;[4] whereas in the nonrelativistic case a successful approach requires the use of ladder operators and the factorization method.[5,6] Our approach is more akin to the introduction of ladder operators than to the shift operator method customarily used for this problem.[4]

The paper is organized as follows. In Sec. II we introduce the equations of the problem and define our notation. In Sec. III we construct the basic operators spanning the SU(2) algebra as a useful tool for the problem. In Sec. IV we define the inner product needed to investigate the

properties of our basic operators. In Sec. V some nonunitary representations of the symmetry algebra are constructed as the radial eigenfunctions of the problem. We find that they are noncompact representations that play an equivalent role to the spherical harmonics in the unitary case. In order to write such representations we find it convenient to define a family of polynomials. In Sec. VI, using algebraic methods and the operators defined in Sec. II, we find the energy spectrum of the hydrogen atom. In Sec. VII we give our conclusions. In the Appendix, we list and plot the explicit expressions of the first six mentioned polynomials; they are then explicitly related to the generalized associated Laguerre polynomials previously used by Davis for expressing the radial eigenfunctions of the hydrogen atom.[7]

II. THE DIRAC HYDROGEN ATOM

The symmetry algebra for the bound states of the nonrelativistic hydrogen atom, even in the classical case, is well known to be the SO(4),[8,9] but in the relativistic case the situation is different, as it is well known. The algebra associated with the symmetry of the radial part of the problem can be regarded as SU(2), as occurs with the angular momentum. The beautiful thing that follows is that we can then proceed to solve the relativistic hydrogen atom following a method that essentially parallels the calculation of eigenfunctions and eigenvalues of the angular momentum at the only expense of introducing an extra phase.

Let us begin with the Dirac Hamiltonian of the hydrogen atom,

$$H_{\mathrm{D}}=\boldsymbol{\alpha}\cdot\mathbf{p}+\beta m-\frac{Ze^2}{r}, \tag{1}$$

where m is the mass of an electron and $\boldsymbol{\alpha}$ and β are the standard Dirac matrices,[10]

$$\boldsymbol{\alpha}=\begin{pmatrix}0 & \boldsymbol{\sigma}\\ \boldsymbol{\sigma} & 0\end{pmatrix}, \quad \beta=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \tag{2}$$

where the 1's and 0's stand, respectively, for 2×2 unit and zero matrices and the $\boldsymbol{\sigma}$ is the standard vector composed by the three Pauli matrices $\boldsymbol{\sigma}=(\sigma_x,\sigma_y,\sigma_z)$. Since the Hamiltonian (1) is invariant under rotations, the solutions of the problem can be written in the form

$$\psi(r,\theta,\phi)=\frac{1}{r}\begin{pmatrix}F(r)\mathcal{Y}_{jm}(\theta,\phi)\\ iG(r)\mathcal{Y}'_{jm}(\theta,\phi)\end{pmatrix}, \tag{3}$$

where $\mathcal{Y}_{jm}$ and $\mathcal{Y}'_{jm}$ are spinor spherical harmonics of opposed parity. Parity is a good quantum number in the problem because the Coulomb potential is invariant under reflections; parity goes as $(-1)^l$ and, according to the triangle's rule of addition of momenta, the orbital angular momentum l is given by $l=j\pm\frac{1}{2}$. But, instead of working directly with parity, we prefer to introduce the quantum number ϵ, defined by

$$\epsilon=\begin{cases}1, & \text{if } l=j+\frac{1}{2},\\ -1, & \text{if } l=j-\frac{1}{2}.\end{cases} \tag{4}$$

Thus $l=j+\epsilon/2$ in all cases; we also define $l'=j-\epsilon/2$. Accordingly, the spherical spinor $\mathcal{Y}_{jm}$ depends on l, whereas the spherical spinor $\mathcal{Y}'_{jm}$, which has an opposite parity, depends on l'. Writing the solutions in the form (3) completely solves the angular part of the problem.

Let us now address the radial part of the problem; we are interested in its bound states, then of the quantity $k\equiv\sqrt{m^2-E^2}$ is positive definite; furthermore, let us define

$$\zeta\equiv Ze^2, \quad \tau_j\equiv\epsilon\left(j+\frac{1}{2}\right), \quad \nu\equiv\sqrt{\frac{m-E}{m+E}}; \tag{5}$$

then, we can write the differential equations for the radial part of the problem, in terms of the dimensionless variable $\rho = kr$, as

$$\left(-\frac{d}{d\rho} + \frac{\tau_j}{\rho} \right) G(\rho) = \left(-\nu + \frac{\zeta}{\rho} \right) F(\rho), \tag{6}$$

and

$$\left(+\frac{d}{d\rho} + \frac{\tau_j}{\rho} \right) F(\rho) = \left(\nu^{-1} + \frac{\zeta}{\rho} \right) G(\rho); \tag{7}$$

these equations are to be regarded as the initial formulation of our problem.

The first thing we want to do is to show that Eqs. (6) and (7) can be rewritten using a set of three operators whose commutation relations define a SU(2) algebra. To this end, let us first introduce the new variable x through the relation [but please notice that this change is not required for any of the conclusions that follow; see the second remark below after Eq. (15)]

$$\rho = e^x, \tag{8}$$

so x is defined in the open interval $(-\infty, \infty)$ and redefine the radial functions $F(\rho)$ and $G(\rho)$, introduced in Eqs. (6) and (7), in the form

$$F(\rho(x)) = \sqrt{m+E}\, [\psi_-(x) + \psi_+(x)], \tag{9}$$

$$G(\rho(x)) = \sqrt{m-E}\, [\psi_-(x) - \psi_+(x)]. \tag{10}$$

In terms of the new functions, $\psi_+(x)$ and $\psi_-(x)$, we thus arrive at the following set of equations for our problem:

$$\left[\frac{d}{dx} + e^x - \frac{\zeta E}{\sqrt{m^2 - E^2}} \right] \psi_+(x) = \left(\frac{\zeta m}{\sqrt{m^2 - E^2}} - \tau_j \right) \psi_-(x), \tag{11}$$

and

$$-\left[\frac{d}{dx} - e^x + \frac{\zeta E}{\sqrt{m^2 - E^2}} \right] \psi_-(x) = \left(\frac{\zeta m}{\sqrt{m^2 - E^2}} + \tau_j \right) \psi_+(x). \tag{12}$$

This first-order system can be uncoupled, multiplying by the left the first equation [Eq. (11)] times the operators that appear between square brackets in the second equation and, *vice versa*, by multiplying the second equation [Eq. (12)] times the operators that appear (between square brackets) in the first one. This procedure gives us the second-order system,

$$\left[\frac{d^2}{dx^2} + 2\mu e^x - e^{2x} - \frac{1}{4} \right] \psi_+(x) = \left(\tau_j^2 - \zeta^2 - \frac{1}{4} \right) \psi_+(x), \tag{13}$$

and

$$\left[\frac{d^2}{dx^2} + 2(\mu - 1) e^x - e^{2x} - \frac{1}{4} \right] \psi_-(x) = \left(\tau_j^2 - \zeta^2 - \frac{1}{4} \right) \psi_-(x), \tag{14}$$

where we have defined

$$\mu \equiv \frac{\zeta E}{\sqrt{m^2 - E^2}} + 1. \tag{15}$$

At this point there are several remarks that need be made. First, in the next section the seemingly odd term $-\frac{1}{4}$ in Eqs. (13) and (14) is shown to be necessary to construct the algebra. Second, as we said before, the change of variable from ρ to x is not really necessary for any of the calculations in the article, however, we prefer to work in the x rather than in the ρ variable because this choice simplifies the appearance of some of the equations and, mainly, because it makes the inner product introduced in Sec. III [in Eq. (33)] to look more familiar; but to make contact with the usual description, we sometimes, at our convenience, revert to the variable ρ. As a third remark, notice that we can regard Eqs. (13) and (14) as two eigenvalue equations, where the common eigenvalue ω is given by

$$\omega=\tau_j^2-\zeta^2-\tfrac{1}{4}=j(j+1)-\zeta^2; \tag{16}$$

as it is obvious, we do not need to calculate ω because it follows directly from the radial symmetry of the problem and from the intensity of the interaction that is needed to set the scale. The fourth remark we want to make is that, as the minimum value of j is $\frac{1}{2}$, then $\omega\geqslant 0$ for at least $Z=1,2,...,$ up to 118; for a discussion of the significance of this number see Ref. 4, p. 236.

III. AN OPERATOR ALGEBRA FOR THE DIRAC HYDROGEN ATOM

Our main purpose of this article is the construction of nonunitary representations of the SU(2) algebra for the Dirac hydrogen atom;[3] let us introduce the operator

$$\Omega_3\equiv -i\frac{\partial}{\partial\xi}, \tag{17}$$

depending exclusively on the new variable ξ, which is essentially an extra phase, as must be clear in what follows, and

$$\Omega_{\pm}\equiv e^{\pm i\xi}\left(\frac{\partial}{\partial x}\mp e^{x}\mp i\frac{\partial}{\partial\xi}+\frac{1}{2}\right), \tag{18}$$

which depend both on ξ and on the transformed ''radial'' variable x. These three operators satisfy the following algebraic relations:

$$[\Omega_3,\Omega_{\pm}]=\pm\Omega_{\pm}, \tag{19}$$

and

$$[\Omega_+,\Omega_-]=2\Omega_3. \tag{20}$$

We can alternatively define the two operators, Ω_1 and Ω_2, as

$$\Omega_1=\frac{1}{2}(\Omega_++\Omega_-),\quad \Omega_2=\frac{1}{2i}(\Omega_+-\Omega_-), \tag{21}$$

in terms of which the algebraic properties (19) and (20) read as

$$[\Omega_i,\Omega_j]=i\epsilon_{ijk}\Omega_k,\quad i,j,k=1,2,3. \tag{22}$$

It is now clear that the commutation relations (19) and (20)—or just (22)—correspond to an SU(2) algebra.[1,3,8] To complete the discussion, we also need to introduce the Casimir operator of the algebra; let us consider the operator

$$\Omega^2=\Omega_1^2+\Omega_2^2+\Omega_3^2; \tag{23}$$

we can easily show that (23) is indeed a Casimir for the algebra (19) and (20) [or (22)],

$$[\Omega^2,\Omega_i]=0, \quad \text{for} \quad i=1,2,3. \tag{24}$$

Here, as in the angular momentum case, we can regard Ω^2 as the square of $\mathbf{\Omega}=\Omega_1\hat{\mathbf{i}}+\Omega_2\hat{\mathbf{j}}+\Omega_3\hat{\mathbf{k}}$. To obtain the explicit expression of Ω^2, it is better to calculate first the product $\Omega_-\Omega_+$:

$$\Omega_-\Omega_+=\frac{\partial^2}{\partial x^2}-e^{2x}-2ie^x\frac{\partial}{\partial\xi}+i\frac{\partial}{\partial\xi}+\frac{\partial^2}{\partial\xi^2}-\frac{1}{4}, \tag{25}$$

and obtain the Casimir operator from the relationship $\Omega^2=\Omega_-\Omega_++\Omega_3(\Omega_3-1)$. We remark that we do not have a linear term in $\partial/\partial x$ in Eq. (22) because we choose the last constant in Eq. (18) precisely as $\frac{1}{2}$. We then easily conclude that the Casimir operator is given explicitly by

$$\Omega^2=\frac{\partial^2}{\partial x^2}-e^{2x}-2ie^x\frac{\partial}{\partial\xi}-\frac{1}{4}. \tag{26}$$

Although we are not restricted to a compact set of parameters anymore due to the presence of the variable x, in analogy with the conventions used for the *spherical harmonics* $Y_l^m(\theta,\phi)$, we label the simultaneous eigenfunctions of Ω^2 and Ω_3 as $V_\omega^\mu(x,\alpha)$, where the numbers ω are the eigenvalues of Ω^2 and the numbers μ are the eigenvalues of Ω_3. Therefore, we write

$$\Omega_3V_\omega^\mu(x,\xi)=\mu V_\omega^\mu(x,\xi) \tag{27}$$

and

$$\Omega^2V_\omega^\mu(x,\xi)=\omega V_\omega^\mu(x,\xi); \tag{28}$$

we thus have

$$V_\omega^\mu(x,\xi)=e^{i\mu\xi}\mathcal{P}_\omega^\mu(x), \tag{29}$$

where, again, we have used the angular momentum analogy to write the x functions as $\mathcal{P}_\omega^\mu(x)$, resembling the usual notation for the Legendre polynomials $P_l^m(\theta)$. In this equation it becomes clear the role of ξ as just an extra phase.

A comparison with Eqs. (13) and (14) tells us that

$$\psi_+(x)=\mathcal{P}_\omega^\mu(x), \tag{30}$$

$$\psi_-(x)=\mathcal{P}_\omega^{\mu-1}(x). \tag{31}$$

The operators $\Omega_\pm$ are thus ladder operators for the problem; they move along the set of eigenfunctions, changing the eigenvalue μ to the eigenvalue $\mu\pm1$, in a completely analogous way to the the case of the angular momentum algebra,

$$\Omega_\pm V_\omega^\mu(x,\xi)\propto V_\omega^{\mu\pm1}(x,\xi); \tag{32}$$

the required proportionality constants are evaluated in Sec. V [Eq. (52)].

IV. THE INNER PRODUCT AND RELATED PROPERTIES OF THE OPERATORS

To establish the properties of the Ω operators and to construct the representations of the SU(2) algebra they span, we need a properly defined inner product. Here we cannot longer rely on the angular momentum analogy, since two of the parameters of the algebra we purport to construct are defined over the noncompact interval $(-\infty,\infty)$, making it completely different from the angular momentum. This situation implies that not all the generators of the algebra are to be Hermitian (indeed, Ω_3 is found to be Hermitian but Ω_1 and Ω_2 are are found to be anti-Hermitian) and, as a consequence, that the corresponding group could not be unitary.

Let us consider the operation

$$(\phi,\psi)=\int_0^{2\pi}\frac{d\xi}{2\pi}\int_{-\infty}^{\infty}\phi^*(\xi,x)\psi(\xi,x)dx. \tag{33}$$

It is easy to show that Eq. (33) defines an inner product, since, as it is not difficult to prove, it satisfies the three basic properties: (i) If $\psi(x)=0$, then $(\psi,\psi)=0$; (ii) if $\psi(x)\neq 0$, then $(\psi,\psi)\geqslant 0$; (iii) if c is any complex number, then $(\psi,c\phi)=c(\psi,\phi)$ and $(c\psi,\phi)=c^*(\psi,\phi)$.

To study the behavior of the generators of the algebra in terms of the inner product (33), we consider a certain function $\psi(x,\xi)$ associated with a certain fixed value μ_0. We define the elements of the associated Hilbert space H_{μ_0} with functions of the form

$$\psi(x,\xi)=e^{i(\mu_0+m-n)\xi}\mathcal{F}(x), \tag{34}$$

where m and n are integer numbers and $\mathcal{F}(x)$ is a well-behaved function depending only on x. As we exhibit in Sec. V, this is actually the general form of the functions inhabiting the Hilbert space of our problem.

With the help of the inner product (33), we can establish the properties of the Ω_a $(a=1,2,3)$ operators. Let us consider first Ω_3; in this case the important product is

$$(\psi',\Omega_3\psi)=\delta_{m'-n',m-n}(\mu_0+m-n)\int_{-\infty}^{\infty}\mathcal{F}^*(x)\mathcal{F}(x)dx; \tag{35}$$

this last equation, due to the presence of the Kronecker delta, can be written as

$$\int_0^{2\pi}\frac{d\xi}{2\pi}\int_{-\infty}^{\infty}\left[i\frac{\partial}{\partial\xi}e^{-i(\mu_0+m'-n')\xi}\right]e^{-i(\mu_0+m-n)\xi}\mathcal{F}^*(x)\mathcal{F}(x)dx, \tag{36}$$

and this is precisely $(\Omega_3\psi',\psi)$. We have in this way proved that Ω_3 is a Hermitian operator:

$$\Omega_3^\dagger=\Omega_3. \tag{37}$$

To study the operators $\Omega_\pm$, let us first consider Ω_+ and evaluate the product

$$(\psi',\Omega_+\psi)=\int_0^{2\pi}\frac{d\xi}{2\pi}\int_{\infty}^{\infty}e^{-i(\mu_0+m'-n')\xi}\mathcal{F}^*(x)dx\,e^{i\xi}\left(\frac{\partial}{\partial x}-e^x-i\frac{\partial}{\partial\xi}+\frac{1}{2}\right)e^{i(\mu_0+m-n)\xi}\mathcal{F}(x)dx. \tag{38}$$

To analyze this integral, it is simpler to split it in two parts. Let us consider first the $e^{i\xi}(-\partial/\partial\xi+1/2)$ part; its contribution to the inner product (38) is

$$\left(\mu_0+m-n+\frac{1}{2}\right)\delta_{m'-n',m-n+1}\int_{-\infty}^{\infty}\mathcal{F}^*(x)\mathcal{F}(x)dx; \tag{39}$$

this expression can be written as

$$-\int_0^{2\pi}\frac{d\xi}{2\pi}\left[e^{-i\xi}\left(i\frac{\partial}{\partial\xi}+\frac{1}{2}\right)e^{i(\mu_0+m'-n')\xi}\mathcal{F}(x)\right]^\dagger e^{i(\mu_0+m-n)\xi}\mathcal{F}(x)dx. \tag{40}$$

We now take care of the contribution of the term $e^{i\xi}(\partial/\partial\xi-e^x)$. After a partial integration this contribution becomes

$$\delta_{m'-n'-1,m-n}\int_{-\infty}^{\infty}\left[-\left(\frac{\partial}{\partial x}+e^{x}\right)\mathcal{F}(x)\right]^{\dagger}\mathcal{F}(x)\,dx. \tag{41}$$

Taking together the two previous results, it is easy to see that the operator complies with $\Omega_{+}^{\dagger} = -\Omega_{-}$. A similar calculation establish the analogous property $\Omega_{-}^{\dagger} = -\Omega_{+}$. Therefore, we have established that

$$\Omega_{\pm}^{\dagger} = -\Omega_{\mp}. \tag{42}$$

We have proved that not all the operators are Hermitian, thence arriving to the anticipated results: We showed that the operator Ω_3 is indeed Hermitian; as a consequence, we expect the range of the only parameter it depends on, ξ, to be compact; this is certainly the case since $\xi \in [0,2\pi]$, a compact set. The other two operators Ω_1 and Ω_2 depend upon x, a variable defined over the noncompact set $(-\infty, \infty)$, but here such operators are anti-Hermitian,

$$\Omega_a^{\dagger} = -\Omega_a, \quad a=1,2, \tag{43}$$

as it is easy to show from Eqs. (21) and (42).

V. REPRESENTATIONS OF THE SU(2) ALGEBRA (RADIAL EIGENFUNCTIONS OF THE PROBLEM)

With the inner product defined in the previous section, we are in the position of introducing a complete orthogonal basis of simultaneous eigenfunctions for Ω^2 and Ω_3, which, accordingly, must carry a representation of the algebra—and, besides, they solve our radial eigenvalue problem [Eqs. (6) and (7)]. We have decided to choose the commuting operators in a similar fashion to the standard SU(2) case. Let us define then

$$V_{\omega}^{\mu}(x,\xi) \equiv |\omega\mu\rangle, \tag{44}$$

where the kets $|\omega\mu\rangle$ are both assumed orthogonal and normalized respect the inner product (33),

$$\langle \omega' \mu' | \omega\mu\rangle = \delta_{\omega,\omega'}\delta_{\mu,\mu'}. \tag{45}$$

Now, as Ω_1 and Ω_2 are not Hermitian, the Casimir operator Ω^2 defined in (23) is not necessarily positive definite, we can nevertheless introduce a positive definite operator as

$$\boldsymbol{\Omega}^{\dagger}\cdot\boldsymbol{\Omega} = -\Omega_1^2 - \Omega_2^2 + \Omega_3^2 = 2\Omega_3^2 - \Omega^2; \tag{46}$$

the positivity of this operator allows us to show that

$$2\mu^2 \geqslant \omega, \tag{47}$$

that is, $|\mu|$ is bounded by below. As a consequence, there must exist a minimum value for $|\mu|$, let us say $\lambda \equiv |\mu|_{\min}$. We also know the that the ket $|\omega\lambda\rangle$ is annihilated by Ω_- or, equivalently, that $\Omega_+\Omega_-|\omega\lambda\rangle = 0$; so

$$\omega - \lambda^2 - \lambda = 0 \quad \text{or} \quad \omega = \lambda(\lambda-1). \tag{48}$$

Given Eq. (47), let us introduce a slight change in notation, writing λ instead of ω in the eigenfunctions $\mathcal{P}_{\omega}^{\mu}(x)$ of Eq. (29), that is, $\mathcal{P}_{\omega}^{\mu}(x)$ is to be replaced by $\mathcal{P}_{\lambda}^{\mu}(x)$. Furthermore, as λ has to be positive and since $\omega = \tau_j^2 - \zeta^2 - \frac{1}{4}$, we find that the minimum $|\mu|$ value is

$$|\mu|_{\min} \equiv \lambda = s + \tfrac{1}{2}, \tag{49}$$

where we have defined

$$s \equiv +\sqrt{\tau_j^2-\zeta^2}=\sqrt{(j+\tfrac{1}{2})^2-\zeta^2}. \tag{50}$$

Notice that s is a real quantity for $Z=1,2,3,...,137$.

However, the most important conclusion we can draw from Eqs. (49) and (50), is that λ no longer has to be an integer or half-integer number, as necessarily occurs in the unitary compact angular momentum case. We may see that this result is a direct consequence of both Ω_1 and Ω_2 not being Hermitian operators. So the operators introduced for the SU(2) algebra associated with the Dirac hydrogen atom lead naturally to nonunitary representations labeled by real numbers, or, at least, not necessarily integer nor half-integer ones.

For constructing the functions comprising the representations, let us introduce the constants $C_\mu^\pm$ as follows [compare with Eq. (32)]:

$$\Omega_\pm|\omega\mu\rangle = C_\mu^\pm|\omega\mu\pm 1\rangle; \tag{51}$$

these constants can be explicitly evaluated from $\langle\omega\mu|\Omega_+\Omega_-|\omega\mu\rangle = C_\mu^- C_{\mu-1}^+$ and from $(C_{\mu-1}^+)^* = -C_\mu^-$; if we further assume these constants to be real, we easily get

$$C_\mu^\pm = \pm\sqrt{\mu(\mu\pm 1)-\lambda(\lambda-1)}, \tag{52}$$

a result with a slightly different form than in the analogous angular momentum case.[4,8]

The ground state of the hydrogen atom can be obtained from the equation $\Omega_-|\lambda\lambda\rangle=0$ for the positive set of eigenvalues. Such an equation becomes

$$e^{-i\xi}\left(\frac{\partial}{\partial x}+e^x-\lambda+\frac{1}{2}\right)e^{i\lambda\xi}\mathcal{P}_\lambda^\lambda(x)=0, \tag{53}$$

whose solution is

$$\mathcal{P}_\lambda^\lambda(x)=d_\lambda e^{sx}\exp(-e^x)=d_\lambda e^{(\lambda-1/2)x}\exp(-e^x), \tag{54}$$

where

$$d_\lambda \equiv \frac{2^{(\lambda-1/2)}}{\sqrt{\Gamma(2\lambda-1)}}, \tag{55}$$

is a normalization constant and $\Gamma(y)$ stands for the Euler-gamma function. Since λ is the lowest eigenvalue, in this instance we should have

$$\psi_+(x)=\mathcal{P}_\lambda^\lambda(x), \tag{56}$$

and

$$\psi_-(x)=0. \tag{57}$$

In terms of the radial variable ρ, we can see from Eqs. (9) and (10) that the ground state solutions are

$$F(\rho)=\sqrt{\frac{(m+E)}{2m(\lambda-1/2)}}\,\rho^s e^{-\rho}, \tag{58}$$

and

$$G(\rho)=-\sqrt{\frac{(m-E)}{2m(\lambda-1/2)}}\,\rho^s e^{-\rho}, \tag{59}$$

normalized in the sense

$$\int_0^\infty (|F(\rho)|^2+|G(\rho)|^2)d\rho=1. \tag{60}$$

We can also see that in the case of negative eigenvalues the solutions behave as $\sim\rho^s e^\rho$, giving divergent behavior as $\rho\to\infty$. This behavior makes the negative energy solutions not square integrable; therefore, we have to discard them if we want to describe physically realizable states.[2,3,10]

The excited states can be obtained, as we do in the Appendix, by applying successively Ω_+ to the ground state $|\lambda\lambda\rangle$, as it is customarily done for the spherical harmonics. The result involves the functions $\mathcal{P}_\lambda^\mu(x)$ introduced by Eqs. (29) and (34). The $\mathcal{P}_\lambda^\mu(x)$ are polynomials multiplied by the weight factor $W(\rho)=\rho^{\lambda-1/2}e^{-\rho}$. This weight factor assures that the behavior of the big and the small components of the spinor are regular both at the origin as well as $\rho\to\infty$. As an illustration of the solutions discussed here, we quote in the Appendix the first few cases of $\mathcal{P}_\lambda^{\lambda+p}(x)$, for $p=0,...,5$; there we also plot these polynomial parts of the functions [i.e., we plot $\mathcal{P}_\lambda^\mu(x)$ without the weight factors] for the first five excited energy levels. Notice that the polynomial part in the eigenfunction $\mathcal{P}_\lambda^{\lambda+p}(x)$ is always of order p.

The matrix representations of the Ω_a, $a=1,2,3$, for $\lambda=s+\frac{1}{2}+p$, $p=0,1,2,3,...$, are constructed from Eqs. (27), (28), (51), and (52). In contrast with the standard SU(2) case, here the representations are non-Hermitian and infinite dimensional for each λ, except for Ω_3. The matrix elements of the operator Ω_3, including the negative eigenvalues series, are given by

$$\langle\omega\mu|\Omega_3|\omega\mu'\rangle=\mu\delta_{\mu\mu'}, \tag{61}$$

where $\mu=\pm(\lambda+p)$, $p=0,1,2,...$; therefore, its trace vanishes and the determinant of any element of the corresponding group with the form $\exp(i\Omega_3)\xi$, is always 1.

For the other two operators the only nonvanishing matrix elements are

$$\langle\omega\mu|\Omega_1|\omega\mu\pm1\rangle=\mp\tfrac{1}{2}\sqrt{\mu(\mu\pm1)-\lambda(\lambda-1)}, \tag{62}$$

$$\langle\omega\mu|\Omega_2|\omega\mu\pm1\rangle=-\frac{i}{2}\sqrt{\mu(\mu\pm1)-\lambda(\lambda-1)}. \tag{63}$$

This means again that the trace of both Ω_1 and Ω_2 vanish. Notice also that the determinant of a group element generated by Ω_1 or Ω_2 is 1 only for a purely imaginary parameter.

VI. THE ENERGY SPECTRUM

We can now evaluate the bound energy spectrum for the problem. As we mentioned in Sec. V, the bound state energy spectrum comprises only the positive series eigenvalues.[2,10] Let us first express the energy in terms of the eigenvalue μ from Eq. (15),

$$E=m\left[1+\frac{\zeta^2}{(\mu-1/2)^2}\right]^{-1/2}; \tag{64}$$

then, for the case of positive eigenvalues—the only ones with physically appropriate eigenfunctions—we have that $\mu=\lambda+p$, where p is a non-negative integer $p=0,1,2,...$, or, equivalently, that $\mu-\frac{1}{2}=s+p$. This gives precisely the energy spectrum of the relativistic hydrogen atom. To rewrite our result in a more familiar form, we need only to define the principal quantum number n and the auxiliary quantity ϵ_j as follows:

$$n=j+\tfrac{1}{2}+p, \tag{65}$$

$$\epsilon_j=n-s-p=j+\tfrac{1}{2}-s; \tag{66}$$

we then finally conclude that $\mu-\frac{1}{2}=s+p=n-\epsilon_j$, which gives precisely the well-known energy spectrum.[10]

VII. CONCLUDING REMARKS

In summary, we have constructed a SU(2) algebra for the hydrogen atom in the Dirac formulation, introducing the Hermitian operator Ω_3 and the anti-Hermitian operators Ω_1 and Ω_2. The result of all of this is that the representations are labeled by numbers λ that are neither integers nor half-integers, as in the case of the more familiar unitary representations. Nevertheless, the algebra introduced predicts precisely the energy eigenvalues and eigenfunctions of the Dirac hydrogen atom. One of the most noteworthy features of the representations reported here is the mixing of a spinorial angular momentum character, implying an equally spaced spectrum, with the energy requirements of the problem—requiring a differently spaced spectrum; the interplay of these two spectral requirements is basically reflected in the fact that the eigenvalues associated with Eqs. (13) and (14) follows from both the generic radial symmetry and the specific features of the interaction in the Dirac equation (1). From Eq. (15), it also follows that in the limit of a vanishing interaction, i.e., $\zeta\to 0$, our representations collapse and, in this special case, $\mu=1$ always. Such behavior is precisely as expected because there is no longer any restriction over the eigenvalues and thus the spectrum becomes continuous, corresponding to a free Dirac particle. The operator algebra we introduced allows an essentially algebraic solution of the Dirac hydrogen atom, which may have various applications.[3,4,6]

It is to be noted also the possible connections that our formulation may have with systems with hidden supersymmetric properties,[11–14] as we will discuss in a forthcoming article. The energy spectrum of the problem has some peculiarities that also appear in the spectrum of a Dirac oscillator;[12,13,15] in particular, the equally spaced energy solutions for $\psi_+(x)$ and $\psi_-(x)$ resemble, respectively, the behavior of the big and the small components of the aforementioned system. As a result of this resemblance, we are studying the hidden supersymmetric properties and the superconformal algebra, in the sense of Refs. 13 and 16, associated with this problem. The similitude of Eqs. (13) and (14) with the corresponding ones for a Morse oscillator should be also noticed.[6]

It is worth pinpointing that we are forced to introduce the new variable ξ in order to define the algebra; in terms of the solutions of the Dirac equation, ξ just plays the role of a phase. To exemplify, when we perform a ''rotation'' using Ω_3, the big component changes from $F(x)\propto[\psi_-(x)+\psi_+(x)]$ to $F(x)\propto[e^{i(\mu-1)\xi}\psi_-(x)+e^{i\mu\xi}\psi_+(x)]=e^{i\mu\xi}[e^{-i\xi\psi_-(x)+\psi_+(x)}]$. The phase $e^{i\mu\xi}$ does not play any observable role, but the term $e^{-i\xi}$ changes the relative phase between the $\psi_+(x)$ and the $\psi_-(x)$ components of the eigenfunction and, in consequence, changes the radial function $F(\rho)$ itself although the energy spectrum is still invariant under such a transformation; this is a consequence of the fact that $|\omega\mu\rangle$ and $\Omega_3|\omega\mu\rangle$ both correspond to the same eigenvalue μ. In a way, this resembles what happens when there are superselection rules in a system.[17–19]

To finalize, let us comment that it is not widely known that the radial eigenfunctions of the Dirac hydrogen atom can be expressed in terms of generalized associated Laguerre polynomials, as was realized by Davis a long time ago.[7,20] These polynomials, which are a generalization to nonintegral indices of the usual associated Laguerre polynomials, are defined as[7]

$$\mathcal{L}_p^{\alpha}(x)=\frac{\Gamma(\alpha+p+1)}{n!\,\Gamma(\alpha+1)}\,{}_1F_1(-p;\alpha+1;x), \tag{67}$$

where $\Gamma(x)$ is again the Euler gamma function, p is a positive integer, and ${}_1F_1(-p,\alpha+1;x)$ stands for the confluent hypergeometric function—having one of their arguments negative, the hypergeometric function reduces to a polynomial.[21] The polynomial representation of the radial eigenfunctions introduced here is related to that used by Davis in Eqs. (A8) and (A9) of the Appendix.

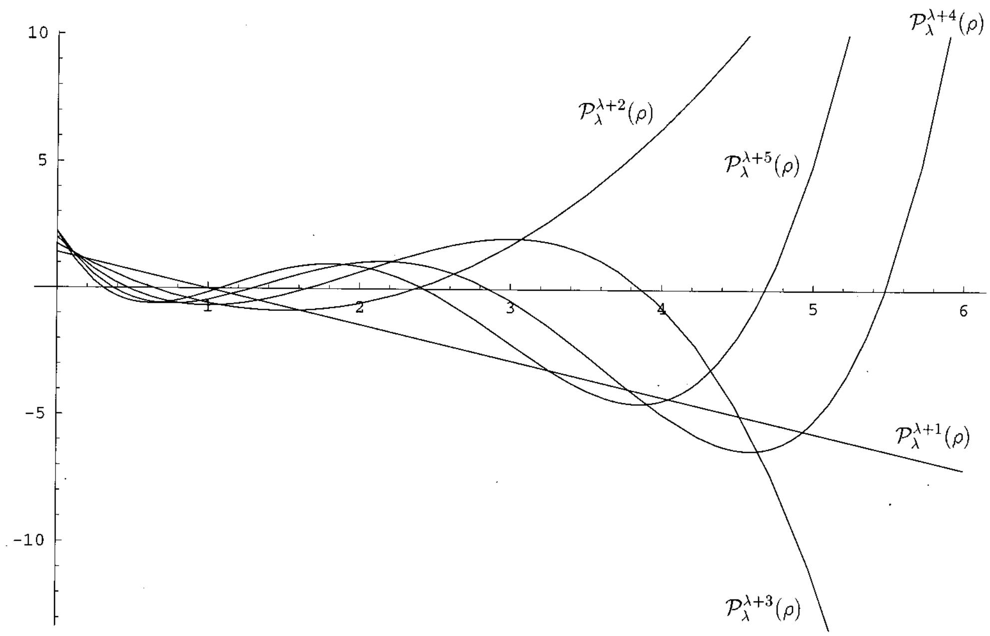

FIG. 1. We show the graph of the first polynomials $\mathcal{P}_\lambda^{\lambda+p}(\rho)/W(\rho)$, for $p=1,2,3,4,5$, $Z=1$, and $j=\frac{1}{2}$. Notice the similarity of the behavior of all polynomials near the origin.

APPENDIX: THE POLYNOMIAL PART OF THE RADIAL EIGENFUNCTIONS

Our purpose in this appendix is to illustrate the behavior of the first few polynomials associated with the radial eigenfunction of the hydrogen atom in the base $|\lambda\mu\rangle$ and to relate this description to the old but little known results of Davis.[7,11] We explicitly calculate the first six functions of the positive eigenvalue series; such functions are always of the form of the weight factor $W(\rho)$ times a polynomial; the weight factor is $W(\rho)=\rho^s e^{-\rho}$. The polynomials are plotted in Fig. 1. The radial eigenfunctions are essentially generated from the basic relationship $\Omega_+|\omega\mu\rangle=C_\mu^+|\omega\mu+1\rangle$. In the ρ variable, the first equation in the series can be written as

$$e^{+i\xi}\left(\rho\frac{\partial}{\partial\rho}-\rho-i\frac{\partial}{\partial\xi}+\frac{1}{2}\right)e^{i\mu\xi}\mathcal{P}_\lambda^\lambda(\rho)=C_\mu^+e^{i(\mu+1)\xi}\mathcal{P}_\lambda^{\lambda+1}(\rho), \tag{A1}$$

which is just the first term in the whole ascending series $\mathcal{P}_\lambda^{\lambda+p}(\rho)=\Omega_+^p\mathcal{P}_\lambda^\lambda(\rho)$ used to recursively calculate (A2)–(A7). Note that the polynomial part of the function $\mathcal{P}_\lambda^{\lambda+p}(x)$ is always of the form $\Sigma_{i=0}^p C_i(\lambda)\rho^i$, where $C_i(\lambda)$ is also an order $(p-i)$ polynomial in λ.

Starting with $\mu=\lambda$, the first few functions in the positive series are then given by

$$\mathcal{P}_\lambda^\lambda(\rho)=W(\rho), \tag{A2}$$

$$\mathcal{P}_{\lambda}^{\lambda+\mathbf{1}}(\rho)=\sqrt{\frac{2}{\lambda}}(\lambda-\rho)W(\rho), \tag{A3}$$

$$\mathcal{P}_{\lambda}^{\lambda+\mathbf{2}}(\rho)=\frac{W(\rho)}{\sqrt{2\lambda(\lambda+1/2)}}[2\rho^2-(2\lambda+1)(2\rho-\lambda)], \tag{A4}$$

$$\mathcal{P}_{\lambda}^{\lambda+\mathbf{3}}(\rho)=\frac{W(\rho)}{\sqrt{3\lambda(\lambda+1/2)(\lambda+1)}}[-2\rho^3+6\rho^2(\lambda+1)-3\rho(2\lambda^2+3\lambda+1)+\lambda(2\lambda^2+3\lambda+1)], \tag{A5}$$

$$\mathcal{P}_{\lambda}^{\lambda+\mathbf{4}}(\rho)=\sqrt{\frac{2}{3}}\frac{W(\rho)}{\sqrt{\lambda(\lambda+1/2)(\lambda+1)(\lambda+3/2)}}\Bigg[\rho^4-2(3+2\lambda)\rho^3+3(3+5\lambda+2\lambda^2)\rho^2 -(3+11\lambda+12\lambda^2+4\lambda^3)\rho+\left(\lambda^3+3\lambda^2+\frac{11}{4}\lambda+\frac{3}{4}\right)\lambda\Bigg], \tag{A6}$$

$$\mathcal{P}_{\lambda}^{\lambda+\mathbf{5}}(\rho)=\frac{W(\rho)}{\sqrt{15\lambda(\lambda+1/2)(\lambda+1)(\lambda+3/2)(\lambda+2)}}\Bigg[-\rho^5+\left(5\lambda+\frac{29}{2}\right)\rho^4-(10\lambda^2+51\lambda+54)\rho^3 +\left(10\lambda^3+66\lambda^2+\frac{235}{2}\lambda+\frac{123}{2}\right)\rho^2-\left(5\lambda^4+37\lambda^3+\frac{319}{4}\lambda^2+\frac{257}{4}\lambda+\frac{33}{2}\right)\rho+\lambda^5 +\frac{15}{2}\lambda^4+\frac{65}{4}\lambda^3+\frac{105}{8}\lambda^2+\frac{27}{8}\lambda\Bigg]. \tag{A7}$$

The relationship of these polynomials to those used by Davis can be seen from Eqs. (13) and (14), putting $\rho=\exp x$ and introducing the function $v(\rho)$ according to $\psi_+\equiv\rho^s\exp(-\rho)v(\rho)$, and, finally, using $\mathcal{L}(\rho)\equiv v(\rho/2)$, to get

$$\rho\frac{d^2\mathcal{L}}{d\rho^2}+[(2s+1)-\rho]\frac{d\mathcal{L}}{d\rho}+\left[\frac{(s^2+\zeta^2-\tau_j^2)}{\rho}+(\mu-s-1/2)\right]\mathcal{L}=0, \tag{A8}$$

where $\mu=s+\frac{1}{2}+n'$. This equation can be regarded as a generalization to a noninteger index of the usual associated Laguerre differential equation. The equation corresponding to ψ_- can be obtained in an analogous fashion. This equation reduces to the one used by Davis if and only if $s^2=\tau_j^2-\zeta^2$, a result that just recovers the definition in Eq. (50). Now we can give the explicit relationship between our representation of the radial eigenfunctions to that used by Davis as

$$\psi_+(\rho)=\mathcal{P}_{s+1/2}^{s+1/2+n'}(\rho)=\rho^s\exp(-\rho)\mathcal{L}_{n'}^{2s}(2\rho),$$

$$\psi_-(\rho)=\mathcal{P}_{s+1/2}^{s-1/2+n'}(\rho)=\rho^s\exp(-\rho)\mathcal{L}_{n'-1}^{2s}(2\rho) \tag{A9}$$

save for normalization factors (unimportant for the point at hand), where $s=\lambda-\frac{1}{2}$, and where the generalized associated Laguerre polynomials used by Davis are defined in Eq. (67).

(Received 27 April 1998; accepted for publication 17 December 1998)

Well known methods of measure theory on infinite dimensional spaces are used to study physical properties of measures relevant to quantum field theory. The difference of typical configurations of free massive scalar field theories with different masses is studied. We apply the same methods to study the Ashtekar–Lewandowski (AL) measure on spaces of connections. In particular we prove that the diffeomorphism group acts ergodically, with respect to the AL measure, on the Ashtekar–Isham space of quantum connections modulo gauge transformations. We also prove that a typical, with respect to the AL measure, quantum connection restricted to a (piecewise analytic) curve leads to a parallel transport discontinuous at every point of the curve.
[S0022-2488(99)00404-1]

I. INTRODUCTION

Path integrals play an important role in modern quantum field theory. The application in this context of methods of the mathematical theory of measures on infinite dimensional spaces is due to constructive quantum field theorists.[1–5] With the help of these methods important physical results have been obtained, especially concerning two and three dimensional theories. Recently analogous methods have been applied within the framework of Ashtekar nonperturbative quantum gravity to give a rigorous meaning to the connection representation,[6–10] solve the diffeomorphism constraint,[11] and define the Hamiltonian constraint.[12–18] These works all crucially depend on the use of (generalized) Wilson loop variables which have been considered for the first time, within a Hamiltonian formulation of gauge theories, by Gambini, Trias, and collaborators[19–21] and were rediscovered for canonical quantum gravity by Rovelli and Smolin.[22] In fact, instead of working in the connection representation for which Wilson loops are just convenient functions, one can use a so-called loop representation (see Ref. 23 and references therein) by means of which a rich arsenal of (formal) results was obtained which complement those obtained in the connection representation. For previous works on measures on spaces of connections see, e.g., Refs. 24 and 25.

The present paper has two main goals. The first consists of studying physical properties of the support of the path integral measure of free massive scalar fields. We use a system with a countable number of simple random variables which probe the typical scalar fields over cubes, with volume L^{d+1}, placed far away in (Euclidean) space–time. With these probes we are able to study the difference between the supports of two free scalar field theories with different masses.

[a)]Electronic mail: jmourao@galaxia.ist.utl.pt
[b)]Electronic mail: thiemann@aeipotsdam.mpg.de
[c)]Electronic mail: jvelhi@ualg.pt

The results that we obtain provide a characterization of the supports which is physically more transparent than those obtained previously.[26–30]

Our second goal consists of providing the proof of analogous results for the Ashtekar–Lewandowski (AL) measure on the space $\overline{\mathcal{A}/\mathcal{G}}$ of quantum connections modulo gauge transformations.[6,7] First we prove that the group of diffeomorphisms acts ergodically, with respect to the AL measure, on $\overline{\mathcal{A}/\mathcal{G}}$. Second we show that the AL measure is supported on connections which, restricted to a curve, lead to parallel transports discontinuous at every point of the curve.

Quantum scalar field theories have been intensively studied both from the mathematical and the physical point of view. Divergences in Schwinger functions (which, in measure theoretical terminology, are the moments of the measure) are directly related with the fact that the relevant measures are supported not on the space of nice smooth scalar field configurations, that enter the classical action, but rather on spaces of distributions. This gives a strong motivation for more detailed studies of the support of relevant measures. In physical terms this corresponds to finding ''typical (quantum) scalar field configurations,'' the set of which has measure one.

The present paper is organized as follows. In Sec. II we recall some results from the theory of measures on infinite dimensional spaces. Namely Bochner–Minlos theorems are stated and the concept of ergodicity of (semi-)group actions is introduced. In Sec. III we study properties of simple measures: The countable product of identical one-dimensional Gaussian measures and the white noise measure. In the first example we illustrate the disjointness of the support of different measures, which are invariant under a fixed ergodic action of the same group. For the white noise measure we choose random variables which probe the support and which will be also used in Sec. IV to study the support of massive scalar field theories. In Sec. V we obtain properties of the support of the AL measure that complement previously obtained results[8] and prove that the diffeomorphism group acts ergodically on the space of connections modulo gauge transformations. In Sec. VI we present our conclusions.

II. REVIEW OF RESULTS FROM MEASURE THEORY

A. Bochner–Minlos theorems

In the characterization of typical configurations of measures on functional spaces the so-called Bochner–Minlos theorems play a very important role. These theorems are infinite dimensional generalizations of the Bochner theorem for probability measures on $\mathbb{R}^N$. Let us, for the convenience of the reader, recall the latter result. Consider any (Borel) probability measure μ on $\mathbb{R}^N$, i.e., a finite measure, normalized so that $\mu(\mathbb{R}^N)=1$. The generating functional χ_μ of this measure is its Fourier transform, given by the following function on $\mathbb{R}^N$ [$\cong(\mathbb{R}^N)'$, the prime denotes the topological dual, see below]

$$\chi_\mu(\lambda)=\int_{\mathbb{R}^N} d\mu(x)e^{i(\lambda,x)}, \tag{1}$$

where $(\lambda,x)=\Sigma_{j=1}^N \lambda^j x_j$. Generating functionals of measures satisfy the following three basic conditions,

(i) Normalization: $\chi(0)=1$;
(ii) Continuity: χ is continuous on $\mathbb{R}^N$;
(iii) Positivity: $\Sigma_{k,l=1}^m c_k\overline{c_l}\chi(\lambda_k-\lambda_l)\geqslant 0$, for all $m\in\mathbb{N}$, $c_1,\ldots,c_m\in\mathbb{C}$ and $\lambda_1,\ldots,\lambda_m\in\mathbb{R}^N$.

The last condition comes from the fact that $\|f\|_\mu\geqslant 0$, for $f(x)=\Sigma_k^m c_k e^{i(\lambda_k,x)}$, where $\|\cdot\|_\mu$ denotes the $L^2(\mathbb{R}^N,d\mu)$ norm. The finite dimensional Bochner theorem states that the converse is also true. Namely, for any function χ on $\mathbb{R}^N$ satisfying (i), (ii), and (iii) there exists a unique probability measure on $\mathbb{R}^N$ such that χ is its generating functional.

Both in statistical mechanics and in quantum field theory one is interested in the so-called correlators, or in probabilistic terminology, the moments of the measure μ,

$$\langle (x_{i_1})^{p_1} \dots (x_{i_k})^{p_k} \rangle := \int_{\mathbb{R}^N} d\mu(x) (x_{i_1})^{p_1} \dots (x_{i_k})^{p_k}. \tag{2}$$

For the correlators of any order to exist the measure μ must have a rapid decay at x-infinity, in order to compensate the polynomial growth in (2) (examples are Gaussian measures and measures with compact support). In the λ-space the latter condition turns out to be equivalent to χ being infinitely differentiable (C^∞). The correlators are then just equal to partial derivatives of χ at the origin, multiplied by an appropriate power of $-i$.

Let us now turn to the infinite dimensional case. The role of the space of λ's will be played by $\mathcal{S}(\mathbb{R}^{d+1})$, the Schwarz space of C^∞-functions on (Euclideanized) space-time with fast decay at infinity. So we have the indices $\lambda(i) := \lambda^i$ replaced by $f(x)$. The space $\mathcal{S}(\mathbb{R}^{d+1})$ has a standard (nuclear) topology. Its elements are functions with regularity properties both for small and for large distances. The physically interesting measures will ''live'' on spaces dual to $\mathcal{S}(\mathbb{R}^{d+1})$. Consider the space $\mathcal{S}'(\mathbb{R}^{d+1})$ of all continuous linear functionals on $\mathcal{S}(\mathbb{R}^{d+1})$ [i.e., the topological dual of $\mathcal{S}(\mathbb{R}^{d+1})$]. This is the so-called space of tempered distributions, which includes delta functions and their derivatives, as well as functions which grow polynomially at infinity. We will consider also the even bigger space $\mathcal{S}^a(\mathbb{R}^{d+1})$ of all linear (not necessarily continuous) functionals on $\mathcal{S}(\mathbb{R}^{d+1})$. Then the simplest generalization of the Bochner theorem states that a function $\chi(f)$ on $\mathcal{S}(\mathbb{R}^{d+1})$ satisfies the following conditions,

(i′) Normalization: $\chi(0)=1$;
(ii′) Continuity: χ is continuous on any finite dimensional subspace of $\mathcal{S}(\mathbb{R}^{d+1})$;
(iii′) Positivity: $\Sigma_{k,l=1}^m c_k \overline{c_l} \chi(f_k - f_l) \geqslant 0$, for all $m \in \mathbb{N}$, $c_1,\dots,c_m \in \mathbb{C}$ and $f_1,\dots,f_m \in \mathcal{S}(\mathbb{R}^{d+1})$,

if and only if it is the Fourier transform of a probability measure μ on $\mathcal{S}^a(\mathbb{R}^{d+1})$, i.e.,

$$\chi(f) = \int_{\mathcal{S}^a(\mathbb{R}^{d+1})} d\mu(\phi) e^{i\phi(f)}. \tag{3}$$

The topology of convergence on finite dimensional subspaces of $\mathcal{S}(\mathbb{R}^{d+1})$ is unnaturally strong. Demanding in (ii′) continuity of χ with respect to the much weaker standard nuclear topology on $\mathcal{S}(\mathbb{R}^{d+1})$ yields a measure supported on the topological dual $\mathcal{S}'(\mathbb{R}^{d+1})$ of $\mathcal{S}(\mathbb{R}^{d+1})$.[31] This is the first version of the Bochner–Minlos theorem. Further refinement can be achieved if χ is continuous with respect to an even weaker topology induced by an inner product. We present a special version of this result, suitable for the purposes of the present work; for different, more general formulations see Refs. 3 and 32. Let P be a linear continuous operator from $\mathcal{S}(\mathbb{R}^{d+1})$ onto $\mathcal{S}(\mathbb{R}^{d+1})$, with continuous inverse. Suppose further that P is positive when viewed as an operator on $L^2(\mathbb{R}^{d+1}, d^{d+1}x)$ and that the bilinear form

$$\langle f_1, f_2 \rangle_{P^{1/2}} := (P^{1/2} f_1, P^{1/2} f_2), \quad f_1, f_2 \in \mathcal{S}(\mathbb{R}^{d+1}) \tag{4}$$

defines an inner product on $\mathcal{S}(\mathbb{R}^{d+1})$, where (,) denotes the $L^2(\mathbb{R}^{d+1}, d^{d+1}x)$ inner product. Let χ satisfy (i′), (iii′) and be continuous with respect to the norm associated with the inner product $\langle , \rangle_{P^{1/2}}$. Natural examples are provided by Gaussian measures μ_C with covariance C and Fourier transform

$$\chi_C(f) = e^{-(1/2)(f, Cf)}, \tag{5}$$

in which case one can take the positive operator P to be the covariance C itself. A particular case is the path integral measure for free massive scalar fields with mass m, which is the Gaussian measure with covariance

$$C_m = (-\Delta + m^2)^{-1}, \tag{6}$$

where Δ denotes the Laplacian on $\mathbb{R}^{d+1}$. In the general (not necessarily Gaussian) case let $\mathcal{H}_{P^{1/2}}(\mathcal{H}_{P^{-1/2}})$ denote the completion of $\mathcal{S}(\mathbb{R}^{d+1})$ with respect to the inner product $\langle,\rangle_{P^{1/2}}(\langle,\rangle_{P^{-1/2}})$. Then the measure on $\mathcal{S}'(\mathbb{R}^{d+1})$ corresponding to χ is actually supported on a proper subset of $\mathcal{S}'(\mathbb{R}^{d+1})$ given by an extension of $\mathcal{H}_{P^{-1/2}}$ defined by a Hilbert–Schmidt operator on $\mathcal{H}_{P^{1/2}}$. We see that in the scalar field case $\mathcal{H}_{C_m^{-1/2}}$ is the space of finite action configurations and therefore typical quantum configurations live in a bigger space. In order to define the extension mentioned above, recall that an operator H on a Hilbert space is said to be Hilbert–Schmidt if given an (arbitrary) orthonormal basis $\{e_k\}$ one has

$$\sum_{k=1}^{\infty} \langle He_k, He_k \rangle < \infty.$$

Given such a Hilbert–Schmidt operator H on $\mathcal{H}_{P^{1/2}}$, which we require to be invertible, self-adjoint and such that $H(\mathcal{S}(\mathbb{R}^{d+1})) \subset \mathcal{S}(\mathbb{R}^{d+1})$, define the new inner product $\langle,\rangle_{P^{-1/2}H}$ on $\mathcal{S}(\mathbb{R}^{d+1})$ by

$$\langle f_1, f_2 \rangle_{P^{-1/2}H} := (P^{-1/2}Hf_1, P^{-1/2}Hf_2), \quad f_1, f_2 \in \mathcal{S}(\mathbb{R}^{d+1}). \tag{7}$$

Consider $\mathcal{H}_{P^{-1/2}H}$, the completion of $\mathcal{S}(\mathbb{R}^{d+1})$ with respect to the inner product $\langle,\rangle_{P^{-1/2}H}$, and identify its elements with linear functionals on $\mathcal{S}(\mathbb{R}^{d+1})$ through the $L^2(\mathbb{R}^{d+1}, d^{d+1}x)$ inner product. Under the above conditions, the (second version of the) Bochner–Minlos Theorem states that

> **(Bochner–Minlos):** A generating functional χ, continuous with respect to the inner product $\langle,\rangle_{P^{1/2}}$, is the Fourier transform of a unique measure supported on $\mathcal{H}_{P^{-1/2}H}$, for every Hilbert–Schimdt operator H on $\mathcal{H}_{P^{1/2}}$ such that $\mathcal{S}(\mathbb{R}^{d+1}) \subset \mathrm{Ran}\, H$, $H^{-1}(\mathcal{S}(\mathbb{R}^{d+1}))$ is dense and H^{-1}: $\mathcal{S}(\mathbb{R}^{d+1}) \to \mathcal{H}_{\langle,\rangle_{P^{1/2}}}$ is continuous.

In Sec. III A we will also use an obvious adaptation of this result to the space of infinite sequences $\mathbb{R}^N$.

A common feature of the two versions of the Bochner–Minlos theorem is that they give the support as a linear subspace of the original measure space. Nonlinear properties of the support have to be obtained in a different way. In particular one can show (see Sec. III B) that the white noise measures with

$$\chi_{\sigma_1}(f) := e^{-(\sigma_1/2)(f,f)} \tag{8}$$

and

$$\chi_{\sigma_2}(f) := e^{-(\sigma_2/2)(f,f)} \tag{9}$$

have disjoint supports for $\sigma_1, \sigma_2 > 0$, and $\sigma_1 \neq \sigma_2$, while the Bochner–Minlos theorem would give the same results in both cases.

B. Ergodic actions

We review here some concepts and results from ergodic theory.[32,33] Let φ denote an action of the group G on the space M, endowed with a probability measure μ, by measure preserving transformations $\varphi_g : M \to M$, $g \in G$, i.e., $\varphi_{g_*}\mu = \mu$, $\forall g \in G$ or, equivalently, for every measurable set $A \subset M$ and for every $g \in G$, the measure of A equals the measure of the pre-image of A by φ_g. The action φ is said to be ergodic if all G-invariant sets have either measure zero or one. The fact that φ is measure preserving implies that the (right) linear representation U of G on $L^2(M, d\mu)$ induced by φ

$$(U_g\psi)(x) := \psi(\varphi_g x) \tag{10}$$

is unitary. The action φ on M is ergodic if and only if the only U_G-invariant vectors on $L^2(M, d\mu)$ are the (almost everywhere) constant functions. This follows easily from the fact that the linear space spanned by characteristic functions of measurable sets (equal to one on the set and zero outside) is dense in $L^2(M,d\mu)$. The above also applies for a discrete semi-group generated by a single (not necessarily invertible) measure preserving transformation *T*, in which case the role of the group *G* is played by the additive semi-group $\mathbb{N}$, *T* being identified with φ_1. Notice that in the latter case the linear representation on $L^2(M,d\mu)$ may fail to be unitary, although isometry still holds. For actions of $\mathbb{R}$ and $\mathbb{N}$, respectively, the following properties are equivalent to ergodicity[33]

$$\lim_{\tau\to\infty}\frac{1}{2\tau}\int_{-\tau}^{\tau}dt\,\psi(\varphi_t x_0)=\int_M d\mu(x)\psi(x), \tag{11a}$$

$$\lim_{N\to\infty}\frac{1}{N+1}\sum_{n=0}^{N}\psi(\varphi_n x_0)=\int_M d\mu(x)\psi(x), \tag{11b}$$

where $\varphi_n:=\varphi_1^n$ and the equalities hold for μ-almost every x_0 and for all $\psi\in L^1(M,d\mu)$. One important consequence of (11) is that if μ_1 and μ_2 are two different measures and a given action φ is ergodic with respect to both μ_1 and μ_2 then these measures must have disjoint supports [points x_0 for which (11) holds]. Recall also that the action of $\mathbb{R}$ and $\mathbb{N}$, respectively, is called mixing if for every $\psi_1,\psi_2\in L^2(M,d\mu)$ we have

$$\lim_{t\to\infty}\langle\psi_1,U_t\psi_2\rangle=\langle\psi_1,1\rangle\langle 1,\psi_2\rangle, \tag{12a}$$

$$\lim_{n\to\infty}\langle\psi_1,U_n\psi_2\rangle=\langle\psi_1,1\rangle\langle 1,\psi_2\rangle. \tag{12b}$$

It follows from (12) that every *U*-invariant $L^2(M,d\mu)$-function is constant almost everywhere and therefore every mixing action is ergodic (see Ref. 33 for details). If *M* is a linear space then (11) gives a nonlinear characterization of the support. Indeed if x_1 and x_2 are typical configurations, in the sense that (11) holds for them, then x_1+x_2 and λx_1 for $\lambda\neq 1$, are in general not typical configurations. The nonlinearity of supports is best illustrated by the action of $\mathbb{N}$ on the space of infinite sequences endowed with a Gaussian measure that we recall in the next subsection.

III. SUPPORT PROPERTIES OF SIMPLE MEASURES

A. Countable product of Gaussian measures

We will consider here the simplest case of a Gaussian measure in an infinite dimensional space. We will see however that many aspects of Gaussian measures on functional spaces can be rephrased in this simple context.

Let $M=\mathbb{R}^N$, the set of all real sequences (maps from $\mathbb{N}$ to $\mathbb{R}$)

$$x=\{x_1,x_2,\ldots\}$$

and consider on this space the measure given by the infinite product of identical Gaussian measures on $\mathbb{R}$, of mean zero and variance ρ

$$d\mu_\rho(x)=\prod_{n=1}^{\infty}e^{-x_n^2/2\rho}\frac{dx_n}{\sqrt{2\pi\rho}}. \tag{13}$$

As we saw above, an equivalent way of defining μ_ρ is by giving its Fourier transform. Let

$$\langle y,z\rangle_{\sqrt{\rho}}:=\rho(y,z),\quad y,z\in\mathcal{S}, \tag{14}$$

where $(y,z)=\Sigma_{n=1}^{\infty}y_n z_n$ and $\mathcal{S}$ is the space of rapidly decreasing sequences

$$\mathcal{S}:=\left\{y\in\mathbb{R}^{N}:\quad \sum_{n=1}^{\infty} n^k y_n^2\langle\infty,\forall k\rangle 0\right\}.$$

Then

$$\chi_\rho(y):=e^{-(1/2)\langle y,y\rangle_{\sqrt{\rho}}}=\int e^{i(y,x)}d\mu_\rho(x), \tag{15}$$

where $y\in\mathcal{S},\ x\in\mathbb{R}^{N}$.

Consider now the ergodic (in fact mixing) action φ of $\mathbb{N}$ generated by $T\equiv\varphi_1$,

$$(\varphi_1(x))_n:=x_{n+1},\quad x\in\mathbb{R}^{N} \tag{16}$$

which, as we will see, is a discrete analog of the action of $\mathbb{R}$ by translations on the quantum configuration space of a free scalar field theory. The transformation φ_1 is clearly measurable and measure preserving, since all the measures in the product (13) are equal. It is also not difficult to see that φ is mixing. In fact, invoking linearity and continuity, one only needs to show that (12b) is verified for a set of L^2-functions whose span is dense. The functions of the form $\exp(i(y,x))$, $y\in\mathcal{S}$ form such a set, and one has for them

$$\lim_{n\to\infty}\langle e^{i(y,x)},U_n e^{i(z,x)}\rangle=e^{-(1/2)(\langle z,z\rangle_{\sqrt{\rho}}+\langle y,y\rangle_{\sqrt{\rho}})}=\langle e^{i(y,x)},1\rangle\langle 1,e^{i(z,x)}\rangle,\quad \forall y,z\in\mathcal{S},$$

where, in the first and last terms, $\langle,\rangle$ denotes the $L^2(\mathbb{R}^N,d\mu_\rho)$ inner product and U denotes the isometric representation associated with φ. Thus, φ is an ergodic action with respect to μ_ρ, for any ρ. Of course, $\rho\neq\rho'$ implies $\mu_\rho\neq\mu_{\rho'}$ and one concludes that μ_ρ and $\mu_{\rho'}$ must be mutually singular (i.e., have disjoint supports). In fact, taking in (11b) $\psi(x)=\exp(i(y,x))$ for both μ_ρ and $\mu_{\rho'}$ leads to a contradiction, unless a x_0 satisfying (11b) for both μ_ρ and $\mu_{\rho'}$ cannot be found.

The aim now is to find properties of typical configurations which allow us to distinguish the supports of μ_ρ and $\mu_{\rho'}$. Unfortunately the Bochner–Minlos theorem cannot help, due to the fact that the inner products (14), that define the measures μ_ρ and $\mu_{\rho'}$ via (15), are proportional to each other and therefore the corresponding extensions in the Bochner–Minlos theorem are equal: $\mathcal{H}_{\rho^{-1/2}H}=\mathcal{H}_{\rho'^{-1/2}H}(=\mathcal{H}_H)$ for any ρ,ρ'.

Let us now find a better characterization of the support, for which the mutual singularity of μ_ρ and $\mu_{\rho'}$ becomes explicit. In order to achieve this we use a slight modification of an argument given in Ref. 1, that provides convenient sets, both of measure zero and one.

Proposition 1: Given a sequence $\{\Delta_j\}$, $\Delta_j>1$ the μ_ρ-measure of the set

$$Z_\rho(\{\Delta_j\}):=\{x:\exists N_x\in\mathbb{N}\ \text{s.t.}\ |x_n|<\sqrt{2\rho\ln\Delta n},\ \text{for}\ n\geq N_x\} \tag{17}$$

is one (zero) if $\Sigma 1/(\Delta_j\sqrt{\ln\Delta_j})$ converges (diverges).

This can be proven as follows. For fixed integer N and positive sequence $\{\Lambda_j\}$ define sets $Z_N(\{\Lambda_j\})$ by

$$Z_N(\{\Lambda_j\}):=\{x:|x_n|<\Lambda_n,\ \text{for}\ n\geq N\}. \tag{18}$$

The μ_ρ-measure of each of these sets is

$$\mu_\rho(Z_N(\{\Lambda_j\}))=\prod_{n=N}^{\infty}\mathrm{Erf}\left(\frac{\Lambda_n}{\sqrt{2\rho}}\right), \tag{19}$$

where $\mathrm{Erf}(x)=1/\sqrt{\pi}\int_{-x}^{x}e^{-\xi^2}d\xi$ is the error function. The sequence of sets $Z_N(\{\Lambda_j\})$ is an increasing sequence for fixed $\{\Lambda_j\}$, and the set $Z_\rho(\{\Delta_j\})$ defined in (17) is just their infinite union, for $\Delta_j=\exp(\Lambda_j^2/2\rho)$:

$$Z_\rho(\{\Delta_j\}) = \bigcup_{N\in\mathbb{N}} Z_N(\{\Lambda_j\}). \tag{20}$$

From σ-additivity one gets

$$\mu_\rho(Z_\rho(\{\Delta_j\})) = \lim_{N\to\infty} \mu_\rho(Z_N(\{\Lambda_j\})) \tag{21}$$

and therefore

$$\mu_\rho(Z_\rho(\{\Delta_j\})) = \exp\left(\lim_{N\to\infty} \sum_{n=N}^{\infty} \ln(\mathrm{Erf}(\sqrt{\ln \Delta_n}))\right). \tag{22}$$

Notice that the exponent is the limit of the remainder of order N of a series. Since only divergent sequences $\{\Delta_j\}$ may lead to a nonzero measure, one can use the asymptotic expression for $\mathrm{Erf}(x)$, which gives

$$\mu_\rho(Z_\rho(\{\Delta_j\})) = \exp\left(-\lim_{N\to\infty} \sum_{n=N}^{\infty} \frac{1}{\Delta_n \sqrt{\ln \Delta_n}}\right). \tag{23}$$

Depending on the sequence $\{\Delta_j\}$, only two cases are possible: either the series exists, or it diverges to plus infinity, since $\Delta_j > 1$, $\forall j$. In the first case the limit of the remainder is zero, and so the measure of $Z_\rho(\{\Delta_j\})$ will be one. If the sum diverges so does the remainder of any order and therefore the measure of $Z_\rho(\{\Delta_j\})$ is zero. □

Let us now discuss the meaning of this result. To begin with, it is easy to present disjoint sets A, A' s.t $\mu_\rho(A)=1$, $\mu_{\rho'}(A)=0$ and $\mu_\rho(A')=0$, $\mu_{\rho'}(A')=1$, for $\rho\neq\rho'$. Without loss of generality, take $\rho = a\rho'$, $a>1$. The set $Z_\rho(\{n\})$ has μ_ρ-measure zero, since $\Sigma 1/(n\sqrt{\ln n})$ diverges. But $Z_\rho(\{n\}) = Z_{\rho'}(\{n^a\})$ (see (17)) and $Z_{\rho'}(\{n^a\})$ has $\mu_{\rho'}$-measure one, since $\Sigma 1/(n^a \sqrt{\ln n^a})$ converges, for $a>1$. On the other hand the sets $Z_\rho(\{n^{1+\epsilon}\})$ are such that

$$\mu_\rho(Z_\rho(\{n^{1+\epsilon}\})) = \mu_{\rho'}(Z_\rho(\{n^{1+\epsilon}\})) = 1, \quad \forall \epsilon > 0$$

and since $Z_\rho(\{n\}) \subset Z_\rho(\{n^{1+\epsilon}\})$, $\forall \epsilon>0$, the difference sets

$$A_\rho^\epsilon := Z_\rho(\{n^{1+\epsilon}\}) \setminus Z_\rho(\{n\}) \tag{24}$$

are such that $\mu_\rho(A_\rho^\epsilon)=1$ and $\mu_{\rho'}(A_\rho^\epsilon)=0$, $\forall \epsilon>0$.

Notice that the ''square-root-of-logarithm'' nature of the support A_ρ^ϵ of μ_ρ does not mean that the typical sequence x approaches $\sqrt{2\rho \ln n}$, as $n\to\infty$. To clarify this point let us appeal to the Bochner–Minlos Theorem (see Sec. II A). Take $\mathcal{H}_{P^{1/2}}$ to be l^2, the completion of $\mathcal{S}$ with respect to the inner product (,):

$$l^2 = \left\{ y \in \mathbb{R}^{\mathbb{N}} : \sum_{n=1}^{\infty} y_n^2 < \infty \right\}.$$

Consider a vector $a = \{a_1, a_2, \ldots\} \in l^2$ and a Hilbert–Schmidt operator H_a defined by

$$(H_a(x))_n := a_n x_n, \quad x \in l^2. \tag{25}$$

Then the Bochner–Minlos Theorem leads to the conclusion that a typical sequence x in the support of the measure must satisfy

$$\sum_{n=1}^{\infty} a_n^2 x_n^2 < \infty, \tag{26}$$

which is certainly not true for a sequence behaving asymptotically like $\sqrt{2\rho\ln n}$, if we choose appropriately $a\in l^2$. However, the Bochner–Minlos theorem does not forbid the appearance of a subsequence behaving asymptotically even worse than $\sqrt{2\rho\ln n}$. Therefore proposition 1 means that in a typical sequence $\{x_n\}$ no subsequence $\{x_{n_k}\}$ can be found such that, $\forall n_k$, $|x_{n_k}| > \sqrt{2(1+\epsilon)\rho\ln n_k}$, for any arbitrary but fixed ϵ greater than zero, and that one is certainly found if ϵ is taken to be zero. But this subsequence is rather sparse, as demanded by the Bochner–Minlos Theorem; from a stochastic point of view the occurrence of values $|x_n|$ greater than $\sqrt{2\rho\ln n}$ is a rare event. The typical sequence in the support is one that is generated with a probability distribution given by the measure. The measure in this case is just a product of identical Gaussian measures in $\mathbb{R}$, so the typical sequence is one obtained by throwing a ''Gaussian dice'' an infinite number of times.

Notice that a typical $\mu_{\rho'}$ sequence can be obtained from a μ_ρ typical sequence simply by multiplying by $\sqrt{\rho'/\rho}$. This follows from the fact that the map $x\mapsto\sqrt{\rho'/\rho}x$ is an isomorphism of measure spaces $(\mathbb{R}^{\mathbb{N}},\mu_\rho)\to(\mathbb{R}^{\mathbb{N}},\mu_{\rho'})$.

B. The white noise measure

We consider now the so called ''white noise'' measure, which in some sense is the continuous analog of the previous case.[4] Again, we will look for convenient sets of measure one, in the sense given in Sec. III A. This will be achieved by a proper choice of random variables, i.e., measurable functions, which will reduce the present case to the previous discrete one.

As mentioned in Sec. II A the $d+1$-dimensional white noise is the Gaussian measure μ_σ with Fourier transform $\chi_\sigma(f)=\exp(-\sigma/2(f,f))$. Notice that here σ has dimensions of inverse mass squared.

The Euclidean group $\mathcal{E}$ acts on $\mathcal{S}(\mathbb{R}^{d+1})$, $\mathcal{S}'(\mathbb{R}^{d+1})$ and (unitarily) on $L^2(\mathcal{S}'(\mathbb{R}^{d+1}),d\mu_\sigma)$, respectively, by

$$
\begin{aligned}
(\tilde{\varphi}_g f)(x)&=f(g^{-1}x),\\
(\varphi_g\phi)(f)&=\phi(\tilde{\varphi}_{g^{-1}}f),\\
(U_g\psi)(\phi)&=\psi(\varphi_g\phi),
\end{aligned}
\tag{27}
$$

where $g\in\mathcal{E}$, gx denotes the standard action of $\mathcal{E}$ on $\mathbb{R}^{d+1}$ by translations, rotations and reflections, $f\in\mathcal{S}(\mathbb{R}^{d+1})$, $\phi\in\mathcal{S}'(\mathbb{R}^{d+1})$ and $\psi\in L^2(\mathcal{S}'(\mathbb{R}^{d+1}),d\mu_\sigma)$.

It is easy to see that a subgroup of translations in a fixed direction, say the time direction, is mixing. One just has to consider the set with dense span of L^2-functions of the form $\exp(i\phi(f))$, $f\in\mathcal{S}(\mathbb{R}^{d+1})$ and use the Riemann–Lebesgue Lemma to prove that

$$\lim_{t\to\infty}\int f(x_0+t,\ldots,x_d)g(x_0,\ldots,x_d)d^{d+1}x=0,\ \ \forall f,g\in\mathcal{S}(\mathbb{R}^{d+1}). \tag{28}$$

This implies that the measures μ_σ and $\mu_{\sigma'}$ for $\sigma\neq\sigma'$ have disjoint supports, even though the Bochner–Minlos theorem gives us for the support in both cases an extension of $L^2(\mathbb{R}^{d+1},d^{d+1}x)$ through a Hilbert–Schmidt operator (see Sec. III A). Since the choice of a complete $(\ ,\ )$-orthonormal system $\{f_n\}$ gives us an isomorphism of measure spaces

$$
\begin{aligned}
(\mathcal{S}'(\mathbb{R}^{d+1}),\mu_\sigma)&\to(\mathbb{R}^{\mathbb{N}},\mu_\rho)_{|_{\rho=\sigma}}\\
\phi&\mapsto\{\phi(f_n)\},
\end{aligned}
\tag{29}
$$

for every such basis one can find sets of the type of those found in the previous subsection and which put in evidence the mutual singularity of μ_σ and $\mu_{\sigma'}$. However, for the convenience of our analysis of free massive scalar fields in the next section, let us study the x-behavior of typical white noise configurations ϕ. Since

$$\delta_x : \phi \mapsto \phi(x) \tag{30}$$

is not a good random variable, we fix in $\mathbb{R}^{d+1}$ a family of nonintersecting cubic boxes, $\{B_j\}_{j=1}^{\infty}$, with sides of length L. Then the mean value of ϕ over B_j is a well defined random variable

$$F_{B_j} : \phi \mapsto F_{B_j}(\phi) \equiv \phi(f_j) = \frac{1}{L^{d+1}} \int_{B_j} \phi(x) d^{d+1}x, \tag{31}$$

where f_j denotes the characteristic function of the set B_j divided by the volume L^{d+1}, and the map

$$\mathcal{S}'(\mathbb{R}^{d+1}) \to \mathbb{R}^{\mathbb{N}}$$

$$\phi \mapsto \{\phi(f_j)\} \tag{32}$$

defines (by push-forward) a measure on $\mathbb{R}^{\mathbb{N}}$ of the form (13) with $\rho = \sigma/L^{d+1}$. This can be seen from the fact that

$$\int_{\mathcal{S}'(\mathbb{R}^{d+1})} d\mu_\sigma \exp\left(i \sum_{j=1}^{\infty} y_j \phi(f_j) \right) = \exp\left(-\frac{\sigma}{L^{d+1}} \frac{\Sigma_{j=1}^{\infty} y_j^2}{2} \right). \tag{33}$$

We then conclude from Sec. III A that the sets

$$W_\sigma^\epsilon := \{\phi \in \mathcal{S}'(\mathbb{R}^{d+1}) : \exists N_\phi \in \mathbb{N} \text{s.t.} |\phi(f_n)| < \sqrt{2(1+\epsilon)(\sigma/L^{d+1}) \ln n}, \quad \text{for } n \geqslant N_\phi\} \tag{34}$$

have μ_σ-measure one for every positive ϵ, and that for $\sigma' > \sigma$ an $\epsilon(\sigma') > 0$ can be found such that $\mu_{\sigma'}(W_\sigma^{\epsilon(\sigma')}) = 0$. This shows that the supremum of the mean value of ϕ over N boxes with volume L^{d+1} goes like $\sqrt{2(1+\epsilon)(\sigma/L^{d+1}) \ln N}$. A white noise with a bigger variance $\sigma' > \sigma$ has the latter behavior on larger boxes with volume $L'^{d+1} = (\sigma'/\sigma) L^{d+1}$.

IV. QUANTUM SCALAR FIELD THEORIES

A. Constructive quantum scalar field theories

Here we recall briefly some aspects of constructive quantum field theory that will be relevant for the next subsection.[2] A quantum scalar field theory on $d+1$-dimensional (flat Euclideanized) space-time is a measure μ on $\mathcal{S}'(\mathbb{R}^{d+1})$ with Fourier transform χ (generating functional or $\chi(f) = Z(-if)/Z(0)$ in theoretical physics terminology) satisfying the Osterwalder–Schrader (OS) axioms. We will be interested in the axioms which state the Euclidean invariance of the measure (OS2) and ergodicity of the action of the time translation subgroup (OS4), i.e., for $g = T_t$: $T_t(t',x) = (t'+t,x)$,

$$\lim_{\tau \to \infty} \frac{1}{2\tau} \int_{-\tau}^{\tau} dt \, \psi(\varphi_{T_t} \phi_0) =_{\text{a.e.}} \int_{\mathcal{S}'(\mathbb{R}^{d+1})} \psi(\phi) d\mu(\phi). \tag{35}$$

The action of the Euclidean group on $\mathcal{S}(\mathbb{R}^{d+1})$, $\mathcal{S}'(\mathbb{R}^{d+1})$ and $L^2(\mathcal{S}'(\mathbb{R}^{d+1}), d\mu)$ is defined as in Sec. III B. So OS2 states that $\varphi_{g*}\mu = \mu$ for all elements g of the Euclidean group $\mathcal{E}$. Notice that OS2+OS4 imply that ergodicity under the subgroup of time translations is equivalent to ergodicity under the full Euclidean group. The vacua of the theory correspond to Euclidean invariant vectors on $L^2(\mathcal{S}'(\mathbb{R}^{d+1}), d\mu)$ and the axioms OS2 and OS4 imply that the vacuum is unique and given by the constant function. Examples of measures satisfying the OS axioms are the Gaussian measures μ_{C_m} corresponding to free massive quantum scalar field theories [see Eqs. (5) and (6)].

B. Support of free scalar field measures

Since the Euclidean group $\mathcal{E}$ acts ergodically on $(\mathcal{S}'(\mathbb{R}^{d+1}),\mu_{C_m})$ we conclude that the measures μ_{C_m} and $\mu_{C_{m'}}$ [see Eq. (6)] with $m\neq m'$ must have disjoint supports. Like in Sec. III B we will characterize the difference of supports in terms of the mean value of ϕ over a region with volume L^{d+1}. Before going into the details of the calculations notice that the map

$$(\mathcal{S}'(\mathbb{R}^{d+1}),\mu_\sigma)\to\mathcal{S}'(\mathbb{R}^{d+1}),\mu_{C_m})$$

$$\phi\mapsto[\sigma(-\Delta+m^2)]^{-1/2}\phi \tag{36}$$

is an isomorphism of measure spaces which maps typical white noise configurations to typical μ_{C_m}-configurations. Heuristically this means that for big distances $(\Delta x\gg 1/m)$ or small momenta the correlation imposed by the kinetic term in the action is lost and the typical configurations approach those of white noise with $\sigma=1/m^2$. Let us now obtain a formal derivation of this fact as far as the x-space behavior of typical configurations of free massive scalar fields is concerned.

Consider the same random variables F_{B_j} as in Sec. III B but, in order to eliminate the correlation, the cubic boxes B_j will be chosen centered in the points $x^j=(x_0^j,\ldots,x_d^j)=(j^2/m,0,...,0)$ and with sides parallel to the coordinate axes. The push-forward of μ_{C_m} with respect to the map

$$\mathcal{S}(\mathbb{R}^{d+1})\to\mathbb{R}^{\mathbb{N}}$$

$$\phi\mapsto\{\phi(f_j)\} \tag{37}$$

is a Gaussian measure μ_{M_m} in $\mathbb{R}^{\mathbb{N}}$ with covariance matrix M_m given by

$$(M_m)_{jl}=C_m(f_j,f_l)=\left(\frac{2}{\pi}\right)^{d+1}\frac{1}{L^{2(d+1)}}\int_{\mathbb{R}^{d+1}}d^{d+1}p\,e^{i(p_0/m)(j^2-l^2)}\frac{1}{p^2+m^2}\prod_{k=0}^{d}\frac{\sin^2(p_kL/2)}{p_k^2}. \tag{38}$$

Let us denote the (constant) value of the diagonal elements of M_m by C_m^L, i.e.,

$$C_m^L:=(M_m)_{ii}=\left(\frac{2}{\pi}\right)^{d+1}\frac{1}{L^{2(d+1)}}\int_{\mathbb{R}^{d+1}}d^{d+1}p\,\frac{1}{p^2+m^2}\prod_{k=0}^{d}\frac{\sin^2(p_kL/2)}{p_k^2}. \tag{39}$$

Proposition 2: The set

$$Y^{\epsilon}_{(m)}:=\{\phi\in\mathcal{S}'(\mathbb{R}^{d+1}):\exists N_\phi\in\mathbb{N}\ \text{ s.t.}|\phi(f_n)|<\sqrt{2(1+\epsilon)C_m^L\ln n},\ \ n\geq N_\phi\} \tag{40}$$

has μ_{C_m}-measure one for any $\epsilon>0$.

Like in Sec. III B, we will show that the μ_{M_m}-measure of the image of $Y^{\epsilon}_{(m)}$ in $\mathbb{R}^{\mathbb{N}}$ is one. To prove this we will relate the measure μ_{M_m} with a diagonal Gaussian measure of the form (13). Let $\mu_{C_m^L}$ be the Gaussian measure in $\mathbb{R}^{\mathbb{N}}$ with diagonal covariance matrix $C_m^L\delta_{ij}$.

Lemma 1: The measures μ_{M_m} and $\mu_{C_m^L}$ are mutually absolutely continuous, i.e., have the same zero measure sets.

To prove the lemma we will rely on Theorem I.23 on p. 41 of Ref. 1 (see also Theorem 10.1 on p. 160 of Ref. 32), which gives necessary and sufficient conditions for two covariances to give rise to mutually absolutely continuous Gaussian measures. In our case, since the covariance of $\mu_{C_m^L}$ is proportional to the identity, it is sufficient to show that (i) the operator $T:=M_m-C_m^L\mathbf{1}$ is

Hilbert–Schmidt and (ii) the operator M_m is bounded, positive with bounded inverse in l^2. Let us first prove that T is Hilbert–Schmidt. The matrix elements of T are $T_{ii}=0$ and $T_{jl}=(M_m)_{jl}$, for $j\neq l$. One can see from (38) that the off-diagonal elements of $(M_m)_{jl}$ are the values at the points j^2-l^2 of the Fourier transform of a real function f. Explicitly,

$$(M_m)_{jl}=\int_{\mathbb{R}} d\nu_0 e^{i\nu_0(j^2-l^2)} f(\nu_0), \tag{41}$$

where

$$f(\nu_0):=\left(\frac{2}{\pi}\right)^{d+1} \frac{1}{m^{d+3}L^{2(d+1)}} \frac{\sin^2(mL\nu_0/2)}{\nu_0^2} \cdot \int_{\mathbb{R}^d} d^d\nu \frac{1}{1+\nu_0^2+\Sigma_1^d \nu_k^2} \prod_1^d \frac{\sin^2(mL\nu_k/2)}{\nu_k^2}. \tag{42}$$

Since both f and its derivative f' and L^1, one gets for the Fourier transform $\tilde{f}$ of f:

$$|\tilde{f}(t)|=\frac{|\tilde{f}'(t)|}{|t|}, \tag{43}$$

with $\tilde{f}'$ continuous, bounded, and approaching zero at infinity. Therefore $A>0$ exists such that

$$|(M_m)_{jl}|^2 \leq \frac{A}{(j^2-l^2)^2}, \quad \text{for } j\neq l, \tag{44}$$

and therefore

$$\sum_{j,l} |T_{jl}|^2 \leq A \sum_{j\neq l} \frac{1}{(j^2-l^2)^2} < \infty, \tag{45}$$

thus proving that T is Hilbert–Schmidt. Let us now prove (ii). The operator M_m is a positive operator on l^2 since it is given by the restriction of the positive covariance C_m on $L^2(\mathbb{R}^{d+1})$ to the linearly independent system $\{f_j\}_{j\in\mathbb{N}}$. Positivity of M_m and the fact that $M_m=C_m^L\mathbf{1}+T$, T being compact (in fact Hilbert–Schmidt), implies that M_m is bounded, has a trivial kernel and therefore is invertible with bounded inverse (see, e.g., Theorem 4.25 and open mapping theorem in Ref. 34). Proposition 2 now follows, given the characterization of the support of $\mu_{C_m^L}$ one gets from Sec. III A. □

Using the fact that

$$\frac{1}{\alpha\pi} \frac{\sin^2(\alpha p)}{p^2} \tag{46}$$

tends to $\delta(p)$ when $\alpha\to\infty$, one sees from (39) that

$$\lim_{L\to\infty} L^{d+1} C_m^L = \frac{1}{m^2}. \tag{47}$$

Thus, comparing (40) with (34) we see that, in accordance with the discussion above, when averaged over widely separated large boxes ($L \gg 1/m$), the typical free field distribution approaches white noise with $\sigma=1/m^2$.

The explicitness of the mutual singularity of μ_{C_m} and $\mu_{C_{m'}}$, with $m \neq m'$ now follows easily from (24), (40), and the fact that C_m^L is a monotonous (decreasing) function of *m*.

V. PROPERTIES OF THE ASHTEKAR–LEWANDOWSKI MEASURE ON SPACES OF CONNECTIONS

A. Ergodic action of the group of diffeomorphisms

The diffeomorphism-invariant Ashtekar–Lewandowski measure μ_{AL} on the space of connections modulo gauge transformations $\mathcal{A}/\mathcal{G}$ over the manifold Σ plays an important role in rigorous attempts to find a quantization of canonical general relativity. In the present section we study properties of this measure. We show that $\mathrm{Diff}_0(\Sigma)$, the connected component of the group of diffeomorphisms of (the connected analytic manifold) Σ, acts ergodically on $\overline{\mathcal{A}/\mathcal{G}}$. In the next subsection we also obtain results concerning the properties of the support of μ_{AL}.

Let us recall the definition of μ_{AL}. We denote by a hoop $[\alpha]$ in Σ the equivalence class of (piecewise analytic) loops $\{\tilde{\alpha}\}$ based on $x_0 \in \Sigma$ such that

$$U_{\tilde{\alpha}}(A) = U_\alpha(A), \quad \forall A \in \mathcal{A}, \tag{48}$$

where $U_\alpha(A)$ denotes the holonomy corresponding to the loop α, the connection A and a chosen point in the fiber over x_0 of the (fixed) principal G-bundle over Σ and $\mathcal{A}$ is the space of all connections on this bundle. The set of all hoops forms a group $\mathcal{HG}$, called the hoop group.[7] We note that for all $G = \mathrm{SU}(N)$ with $N \geqslant 2$ the group $\mathcal{HG}$ does not depend on N nor on the principal bundle.[7] Throughout the present section we will assume G to be a compact connected Lie group. It is well known that a connection A defines through $U(A)$ a homomorphism from $\mathcal{HG}$ to the gauge group G: $[\alpha] \mapsto U_\alpha(A)$. In fact, the space $\mathcal{A}/\mathcal{G}$ is in a natural bijection with the space of all appropriately smooth homomorphisms of this type, modulo conjugation at the base point.[35–37] On the other hand, and as expected from the example of scalar fields, the measure μ_{AL} lives in a space bigger than the classical space $\mathcal{A}/\mathcal{G}$. This is the space of all, not necessarily smooth or even continuous, homomorphisms from $\mathcal{HG}$ to G modulo conjugation, denoted by $\overline{\mathcal{A}/\mathcal{G}}$.[6,7] The space $\mathcal{A}/\mathcal{G}$ of smooth classes $[A]$ was shown to be of zero measure in $\overline{\mathcal{A}/\mathcal{G}}$.[8] In the next subsection we will deepen this result.

The measure μ_{AL} is, as in the scalar field case, completely specified by giving the result of integrating the so-called cylindrical functions, which in this case are gauge-invariant functions of a finite number of parallel transports along (analytic embedded) edges

$$f(\bar{A}) = F(\bar{A}(e_1), \ldots, \bar{A}(e_n)), \tag{49}$$

where different edges may intersect only on the ends and $\bar{A} \in \bar{\mathcal{A}}$, the space of all connections realized as parallel transports in a natural way.[9,11] The measure μ_{AL} is then defined by

$$\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_{AL}\, f(\bar{A}) = \int_{G^n} dg_1 \cdots dg_n F(g_1, \ldots, g_n), \tag{50}$$

where dg is the normalized Haar measure on G.

The group $\mathrm{Diff}_0(\Sigma)$ has a natural action on $\bar{\mathcal{A}}$ which leaves μ_{AL} invariant

$$\varphi^* \bar{A}(e) := \bar{A}(\varphi \cdot e). \tag{51}$$

As we have seen in Sec. II B this action induces a unitary action of $\mathrm{Diff}_0(\Sigma)$ on $L^2(\overline{\mathcal{A}/\mathcal{G}}, d\mu_{AL})$

$$(U_\varphi f) = f(\varphi^* \bar{A}). \tag{52}$$

Consider now the so-called spin-network states[38–40] $\{T_s\}$, indexed by triples $s = (\gamma, \pi, c)$, where γ is a graph, $\pi := (\pi_1, \ldots, \pi_n)$ is a labeling of the edges of γ with nontrivial irreducible representations π_i of G and $c:=(c_1,\ldots,c_m)$ is a labeling of the vertices $v_1,\ldots,v_m$ of γ with contractors c_j, i.e., nonzero intertwining operators from the tensor product of the representations corresponding to the incoming edges at v_j to the tensor product of the representations associated with the outgoing edges. The unitary action of $\mathrm{Diff}_0(\Sigma)$ on the spin-network states is particularly simple, being given by

$$U_\varphi T_{\gamma,\pi,c}=T_{\varphi\gamma,\varphi\pi,\varphi c} \tag{53}$$

or, in short

$$U_\varphi T_s=T_{\varphi s}, \tag{54}$$

where $\varphi\gamma$ is the image of the graph γ under the diffeomorphism φ and $\varphi\pi$ and φc are the corresponding representations and contractors associated with $\varphi\gamma$. A crucial property is that the contractors can be chosen in such a way that the spin-network states form an orthonormal basis on $L^2(\overline{\mathcal{A}/\mathcal{G}},d\mu_{AL})$.[39–41] We will assume that this has been done to prove the following.

Theorem 1: The group $\mathrm{Diff}_0(\Sigma)$ acts ergodically on $\overline{\mathcal{A}/\mathcal{G}}$, with respect to the measure μ_{AL}.

To prove the theorem, we will show that the only $\mathrm{Diff}_0(\Sigma)$-invariant vector on $L^2(\overline{\mathcal{A}/\mathcal{G}},d\mu_{AL})$ is the constant function. Therefore there can be no measurable $\mathrm{Diff}_0(\Sigma)$-invariant subsets of $\overline{\mathcal{A}/\mathcal{G}}$ with measure different from zero or one.

Using the completeness of the spin-network states, every $\psi\in L^2(\overline{\mathcal{A}/\mathcal{G}},d\mu_{AL})$ can be represented in the form

$$\psi=\sum_s c_s T_s, \tag{55}$$

where no more than countably many coefficients c_s are nonzero. Since for any s and any diffeomorphism φ, $T_{\varphi s}$ belongs to the same orthonormal basis ($\varphi s\neq s \Rightarrow T_{\varphi s}\perp T_s$), we conclude that ψ in (55) is $\mathrm{Diff}_0(\Sigma)$-invariant if and only if

$$c_{\varphi s}=c_s \quad \forall \varphi\in \mathrm{Diff}_0(\Sigma). \tag{56}$$

An L^2-vector cannot have more than finitely many equal coefficients, and since for every nontrivial spin-network (with nontrivial graph and representations) there is an infinite (actually uncountable) number of (distinct) spin-networks in the orbit

$$\mathrm{Diff}_0(\Sigma)s:=\{\varphi s,\varphi\in \mathrm{Diff}_0(\Sigma)\}, \tag{57}$$

we conclude that an invariant ψ in (55) is necessarily constant almost everywhere. □

From the proof it follows that if H is a subgroup of $\mathrm{Diff}_0(\Sigma)$ s.t. the H-orbit Hs through every nontrivial spin-network s is infinite, then H acts ergodically on $\overline{\mathcal{A}/\mathcal{G}}$. So for example

Corollary 1: If $\Sigma=\mathbb{R}^N$ or $\Sigma=T^N$ the measure space $(\overline{\mathcal{A}/\mathcal{G}},\mu_{AL})$ admits the ergodic action of subgroups H of $\mathrm{Diff}_0(\Sigma)$ isomorphic to $\mathbb{Z}$.

For $\Sigma=\mathbb{R}^N$ we take the $\mathbb{Z}$-subgroup of $\mathrm{Diff}_0(\Sigma)$ generated by φ_0:

$$\varphi_0(x^1,\ldots,x^N)=(x^1+\omega^1,\ldots x^N+\omega^N), \tag{58}$$

where $(\omega^1,\ldots,\omega^N)$ is a fixed nonvanishing vector in $\mathbb{R}^N$ (recall that spin-networks are defined here only for finite graphs). If $\Sigma=T^N$ we take in (58) the vector $(\omega^1,\ldots,\omega^N)$ to have (at least) two irrational and incommensurable components, where $(x^1,\ldots,x^N)$ are now mod 1 coordinates of T^N. In both cases for every nontrivial spin network s, $\{\varphi_0^n s,n\in\mathbb{Z}\}$ contains an infinite number of distinct spin networks and so the group $\{\varphi_0^n,n\in\mathbb{Z}\}$ acts ergodically on $(\overline{\mathcal{A}/\mathcal{G}},\mu_{AL})$. □

B. Support properties

As we mentioned in the beginning of Sec. V A the space $\mathcal{A}/\mathcal{G}$ of smooth connections modulo gauge transformations is contained in a zero measure subset of $\overline{\mathcal{A}/\mathcal{G}}$, the space where the measure μ_{AL} is naturally defined.[6–8] The latter space is naturally identified with the space of all (not necessarily continuous) homomorphisms from the hoop group $\mathcal{HG}$ to the gauge group G modulo conjugation at the base point.[9] In the present subsection we deepen the result of Ref. 8 by showing that the parallel transport of a μ_{AL}-typical connection $\bar{A}\in\bar{\mathcal{A}}$ along an edge e leads to a nowhere continuous map

$$g(\cdot):[0,1]\to G. \tag{59}$$

Indeed let e: $[0,1]\to\Sigma$ be an arbitrary edge and consider for $s\in[0,1]$ the part of the edge e_s given by

$$e_s(t)=e(st),\quad t\in[0,1].$$

We then have a map

$$v:\bar{\mathcal{A}}\to G^{[0,1]}$$

$$\bar{A}\mapsto v_{\bar{A}},\quad v_{\bar{A}}(s):=\bar{A}(e_s), \tag{60}$$

where $G^{[0,1]}$ denotes the space of all maps from $[0,1]$ to G. By choosing in $G^{[0,1]}$ the standard product space topology and as algebra of measurable sets the Borel σ-algebra map v becomes measurable.

It is easy to see that, due to the properties of the Haar measure, the push-forward $v_*\mu_{AL}$ of μ_{AL}[42] to $G^{[0,1]}$ is a product of Haar measures, one for each point $s\in[0,1]$:

$$d\nu(g(\cdot))=v_* d\mu_{AL}=\prod_{s\in[0,1]} dg(s). \tag{61}$$

The main result of this subsection is the following.

Theorem 2: The measure μ_{AL} is supported on the set W of all connections $\bar{A}$ such that $v_{\bar{A}}$ is everywhere discontinuous as a map from $[0,1]$ to G.

Since $W=v^{-1}(W_1)$, where

$$W_1=\{g(\cdot)\in G^{[0,1]},\quad \text{s.t. } g(\cdot) \text{ is nowhere continuous}\}, \tag{62}$$

it is sufficient to prove that the complement of W_1,

$$W_1^c=\{g(\cdot)\in G^{[0,1]}:\exists s_0\in[0,1] \text{ s.t. } g(\cdot) \text{ is continuous at } s_0\}, \tag{63}$$

is contained in a zero ν-measure subset of $G^{[0,1]}$. Consider the sets

$$\Theta_U=\{g(\cdot)\in G^{[0,1]}:\exists I \text{ s.t. } g(I)\subset U\}, \tag{64}$$

where U is a (measurable) subset of G with $0<\mu_H(U)<1$ ($\mu_H(U)$ denoting the Haar measure of U) and I is an open subset of $[0,1]$. We need the following.

Lemma 2: For every $U\subset G$ with $0<\mu_H(U)<1$ the set Θ_U is contained in a zero measure subset of $G^{[0,1]}$.

To prove the lemma recall that the open balls

$$B(q,1/m)=\{s\in[0,1]:|s=q|<1/m\} \tag{65}$$

with rational q and integer m are a countable basis for the topology of $[0,1]$. Thus Θ_U is the countable union of the sets

$$\Theta_{U,q,m} := \{g(\cdot) \in G^{[0,1]} : g(B(q,1/m)) \subset U\}, \quad q \in \mathbb{Q}, m \in \mathbb{N}. \tag{66}$$

It is easy to construct zero measure subsets containing $\Theta_{U,q,m}$. For this fix an infinite sequence $\{s_i\}_{i=1}^{\infty} \subset B(q,1/m)$ of distinct points, $s_i \neq s_j$ for $i \neq j$. Then the set $Z = \{g(\cdot) \in G^{[0,1]} : g(s_i) \in U, i \in \mathbb{N}\}$ contains $\Theta_{U,q,m}$ and has zero measure:

$$\nu(Z) = \lim_{n \to \infty} (\mu_H(U))^n = 0.$$

From the σ-additivity of ν we conclude that, for every subset $U \subset G$ with Haar measure less than one, the set Θ_U is contained in a zero ν-measure subset. □

We can now conclude the proof of the theorem. Let us choose a number r, $0 < r < 1$ and a finite open covering $\{U_i\}_{i=1}^{k}$ of the compact group G with $\mu_H(U_i) = r$, $i = 1,...,k$. This is clearly possible since we can take a neighborhood of each point with measure r and then take a finite subcovering. Consider $g(\cdot) \in W_1^c$. Then there exists a $s_0 \in [0,1]$ such that $g(\cdot)$ is continuous at s_0. Let i_0 be such that $g(s_0) \in U_{i_0}$. Continuity implies that there exists a neighborhood I of s_0 such that $g(I) \subset U_{i_0}$ and therefore we have $W_1^c \subset \cup_{i=1}^{k} \Theta_{U_i}$. □

VI. CONCLUSION AND DISCUSSION

The knowledge of the support of measures on infinite dimensional spaces, used in quantum field theory, gives a grasp on the behavior of typical quantum field configurations associated with these measures. This may be important for a better understanding, both from the physical and mathematical points of view, of problems afflicting interacting theories like the problem of divergences.

The Bochner–Minlos theorem is very effective in capturing linear properties of the support of measures on the space $\mathcal{S}'(\mathbb{R}^{d+1})$ of quantum scalar field configurations [the support is a linear subspace of $\mathcal{S}'(\mathbb{R}^{d+1})$ spanned by configurations with a given norm finite]. It allows, e.g., to distinguish the support of the measure μC_m, corresponding to free scalar field theory with mass m, from that of the white noise measure. However, this theorem would predict the same support for the measures μ_{C_m} and $\mu_{C_{m'}}$ with $m \neq m'$ even though these measures must have disjoint supports. The latter is due to the fact that any one parameter subgroup of translations of $\mathbb{R}^{d+1}$ acts ergodically on $\mathcal{S}'(\mathbb{R}^{d+1})$ with respect to both measures. The above two claims do not contradict and rather complement each other since the subset of a ''support'' which is thick, i.e., such that any measurable subset of its complement has measure zero, is also a (finer) support for the same measure. So, to distinguish between μ_{C_m} and $\mu_{C_{m'}}$, one has to find properties of the supports which complement those given by the Bochner–Minlos theorem. Support properties of μ_{C_m} were studied in Refs. 26 and 27 (see also Refs. 28–30). Our goal in Sec. IV B consisted in showing that a simple system of random variables can be used to study the difference of supports of μ_{C_m} and $\mu_{C_{m'}}$ for large distances. This simplifies part of the results of Refs. 26 and 27 and makes them physically more transparent.

The use of the AL measure in attempts to construct a quantum theory of gravity[6–18,43–51] justifies the importance to study its properties. In Sec. V we improved the results of Ref. 8. We fixed an arbitrary edge e, or equivalently a piecewise analytic curve on Σ, and considered the random variables given by $\bar{A} \mapsto \bar{A}(e_s)$, where $\bar{A}$ is a quantum connection, e_s represents the edge e up to the value $s \in [0,1]$ of the parameter, and $\bar{A}(e_s)$ is the parallel transport corresponding to $\bar{A}$ and e_s. These random variables were suggested to the authors by Abhay Ashtekar and were motivated by studies of the volume operator in quantum gravity.[43–53] Varying s we obtain a (measurable) map v from the space of quantum connections $\bar{\mathcal{A}}$ to the space $G^{[0,1]}$ of maps,

, $g(\cdot):[0,1]\rightarrow G$. The *AL* measure becomes, by push-forward, an infinite product of Haar measures. Using this we have shown that for a typical μ_{AL}-connection $\bar{A}$ the parallel transport $\bar{A}(e_s)$ is everywhere discontinuous.

We also showed that $\mathrm{Diff}_0(\Sigma)$ acts ergodically on $\overline{\mathcal{A}/\mathcal{G}}$ with respect to the *AL* measure. The importance of this stems from the fact that in quantum gravity one has to solve the diffeomorphism constraint and therefore naively one would have to take functions on the quotient

$$\overline{\mathcal{A}/\mathcal{G}}/\mathrm{Diff}_0(\Sigma).$$

The ergodicity of the action of $\mathrm{Diff}_0(\Sigma)$ on $\overline{\mathcal{A}/\mathcal{G}}$ implies that the only solution to the diffeomorphism constraint in $L^2(\overline{\mathcal{A}/\mathcal{G}},d\mu_{AL})$ is the constant function. This explains why in Ref. 11, and even though $\overline{\mathcal{A}/\mathcal{G}}$ is compact, one had to use distributional elements to solve the diffeomorphism constraint. If the action were not ergodic one would have diffeomorphism invariant measurable subsets of $\overline{\mathcal{A}/\mathcal{G}}$ (pre-images of sets in $\overline{\mathcal{A}/\mathcal{G}}/\mathrm{Diff}_0(\Sigma)$) with μ_{AL}-measure different from zero or one. The characteristic functions of these sets would provide L^2 solutions to the diffeomorphism constraint.

(Received 20 July 1998; accepted for publication 23 October 1998)

We construct a new family of boson coherent states using a specially designed function which is a solution of a functional equation $d\epsilon(q,x)/dx=\epsilon(q,qx)$ with $0\leq q\leq 1$ and $\epsilon(q,0)=1$. We use this function in place of the usual exponential to generate new coherent states $|q,z\rangle$ from the vacuum, which are normalized and continuous in their label z. These states allow the resolution of unity, and a corresponding weight function is furnished by the exact solution of the associated Stieltjes moment problem. They also permit exact evaluation of matrix elements of an arbitrary polynomial given as a normally-ordered function of boson operators. We exemplify this by showing that the photon number statistics for these states is sub-Poissonian. For any $q<1$ the states $|q,z\rangle$ are squeezed; we obtain and discuss their signal to quantum noise ratio. The function $\epsilon(q,x)$ allows a natural generation of multiboson coherent states of arbitrary multiplicity, which is impossible for the usual coherent states. For $q=1$ all the above results reduce to those for conventional coherent states. Finally, we establish a link with q-deformed bosons. © *1999 American Institute of Physics.* [S0022-2488(99)01404-8]

I. INTRODUCTION

The conventional boson coherent states are a family of collective states of the harmonic oscillator which are parameterized by a single complex number z.[1] They are sums of the eigenstates of the number operator $N=a^\dagger a$, with $[a,a^\dagger]=1$,

$$N|n\rangle=n|n\rangle,\quad (a^\dagger)^n|0\rangle=\sqrt{n!}|n\rangle,\quad \langle n|n'\rangle=\delta_{n,n'}, \tag{1}$$

with coefficients given by the exponential function. More precisely, the coherent state $|z\rangle$ is defined by

$$|z\rangle=\mathcal{N}^{-1/2}\exp(za^\dagger)|0\rangle, \tag{2}$$

$$=\mathcal{N}^{-1/2}\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}}|n\rangle, \tag{3}$$

with the normalization $\mathcal{N}(|z|^2)=\exp(|z|^2)$. Whereas the states $|z\rangle$ are normalized, $\langle z|z\rangle=1$, their overlap is nonvanishing,[2]

$$\langle z|z'\rangle=\exp(-\tfrac{1}{2}|z-z'|^2+i\,\mathrm{Im}(z^*z')). \tag{4}$$

[a)]Electronic mail: penson@lptl.jussieu.fr
[b)]Electronic mail: a.i.solomon@open.ac.uk

The eigenfunctions of N form a complete set and their resolution of unity is given by a sum of orthogonal projection operators, $\Sigma_{n=0}^{\infty}|n\rangle\langle n|=I$. The set $|z\rangle$ gives a resolution of unity with weight function $W(z)$ if

$$\int\int d^2z|z\rangle W(z)\langle z|=I. \tag{5}$$

Consequently, the requirement that $|z\rangle$ form a complete (in fact, an overcomplete) set is equivalent to the condition

$$\sum_{n=0}^{\infty}\left\{\frac{\pi}{n!}\int_0^{\infty}e^{-x}x^nW(x)dx\right\}|n\rangle\langle n|=I, \tag{6}$$

where $x\equiv|z|^2$, from which a (trivial) Stieltjes power-moment problem[3] results, namely, determine a positive weight function $\widetilde{W}(x)$ with $\widetilde{W}(x)\equiv e^{-x}W(x)$, such that

$$\int_0^{\infty}x^n\widetilde{W}(x)dx=\frac{n!}{\pi}\quad(n=0,1,2,\ldots,\infty), \tag{7}$$

which immediately yields a (unique) solution $W(x)=1/\pi$. The reason for the appearance of the weight function in

$$\int\int d^2z|z\rangle W(|z|^2)\langle z|=I$$

is that the states $|z\rangle$ are eigenstates of a non-Hermitian operator $a, a|z\rangle=z|z\rangle$; then in the resolution of unity for $|z\rangle$ we have a weighted sum of nonorthogonal projection operators $|z\rangle\langle z|$ as in Eq. (4). Following the prescription of Klauder,[4] a general coherent state is defined as one satisfying the following minimal set of conditions:[1]

The states $|\mu\rangle$ are coherent states if the following occurs

(1) $|\mu\rangle$ are normalizable, i.e., $\langle\mu|\mu\rangle=1$.
(2) $|\mu\rangle$ are continuous in the label μ, i.e.,

$$|\mu-\mu'|\rightarrow 0\Rightarrow\||\mu\rangle-|\mu'\rangle|^2\rightarrow 0.$$

(3) The set $|\mu\rangle$ allows a resolution of unity, i.e., there exists a weight function $W(|\mu|^2)>0$ such that

$$\int\int d^2\mu|\mu\rangle W(|\mu|^2)|\langle\mu|=I.$$

Whereas Condition 1 is evident for any allowable vector in the Hilbert space by definition, Condition 2 follows from the continuity of the overlapping factor through

$$||\mu\rangle|-|\mu'\rangle|^2=2(1-\mathrm{Re}\,\langle\mu|\mu'\rangle), \tag{8}$$

and can be realized rather easily in practice. However, Condition 3 imposes very severe restrictions on possible sets $|\mu\rangle$. In this paper we present results obtained by creating a set of states through a specially designed function $\epsilon(q,z)$. These states are coherent in the sense described above, in that the requirements 1, 2 and 3 are satisfied. One remark appears in order, concerning the weight function $W(|\mu|^2)$: if the coherent states are based on an underlying group structure [Heisenberg–Weyl, $SU(2)$ (Ref. 5) or $SU(1,1)$ (Ref. 6) coherent states, for example] then finding $W(|\mu|^2)$ is equivalent to considering the Kähler potential $F(\mu,\mu^*)$ defined by[7]

$$F(\mu,\mu^*)=\log(|\langle 0|\mu\rangle|^{-2}), \tag{9}$$

from which the weight function, up to a multiplicative constant, can be *uniquely* obtained through

$$W(|\mu|^2)=\frac{\partial^2}{\partial\mu\partial\mu^*}F(\mu,\mu^*). \tag{10}$$

The Kähler potential mirrors the geometry and the group structure of the underlying phase space. In the following we set aside any group structure and will use exclusively analytic methods.

II. NEW GENERALIZED EXPONENTIAL FUNCTION AND THE STIELTJES MOMENT PROBLEM

Consider the following functional equation for a function of the complex variable:

$$d\epsilon(q,z)/dz=\epsilon(q,qz), \quad (\epsilon(q,0)=1, \quad 0\leqslant q\leqslant 1). \tag{11}$$

When $q=1$ these are defining equations for exp(z). When $q\neq 1$, then $\epsilon(q,z)\neq\exp(z)$ and a solution analytic in some neighborhood of $z=0$ may be assumed to be given by $\epsilon(q,z)=\Sigma_{n=0}^{\infty}a_n(q)z^n$. Equation (11) produces the following recursion relation:

$$a_{n+1}(q)=a_n(q)\frac{q^n}{(n+1)}, \qquad n=1,2,\ldots,\infty, \quad a_0=1, \tag{12}$$

with solution $a_n(q)=q^{n(n-1)/2}/n!$ and

$$\epsilon(q,z)=\sum_{n=0}^{\infty} q^{n(n-1)/2}z^n/n!, \tag{13}$$

which is convergent for all z when $q\leqslant 1$. Note that $\epsilon(q,z)$ interpolates between $\epsilon(0,z)=1+z$ and $\epsilon(1,z)=\exp(z)$. The function $\epsilon(q,z)$ has an infinitely countable number of roots, of which none lies on the positive real axis.

We now define a new family of physical states $|q,z\rangle$ labeled by q and z,

$$|q,z\rangle=\{\mathcal{N}(q,|z|^2)\}^{-1/2}\epsilon(q,za^\dagger)|0\rangle, \tag{14}$$

and show that the states $|q,z\rangle$ are coherent in the general sense described above:

A. Normalization

From $\langle q,z|q,z\rangle=1$ we obtain the normalization

$$\mathcal{N}(q,|z|^2)=\sum_{n=0}^{\infty}\frac{q^{n(n-1)}}{n!}|z|^{2n}, \tag{15}$$

$$=\epsilon(q^2,|z|^2)>0. \tag{16}$$

Then the normalized state is

$$|q,z\rangle=[\epsilon(q^2,|z|^2)]^{-1/2}\sum_{n=0}^{\infty}\frac{q^{\frac{n(n-1)}{2}}}{\sqrt{n!}}z^n|n\rangle. \tag{17}$$

Note that $|q,z\rangle$ is not an eigenstate of a. For a given q we calculate the overlap,

$$\langle q,z|q,z'\rangle=[\epsilon(q^2,|z|^2)\epsilon(q^2,|z'|^2)]^{-1/2}\sum_{n=0}^{\infty} q^{n(n-1)}(z'z^*)^n/n!$$

$$=[\epsilon(q^2,|z|^2)\epsilon(q^2,|z'|^2)]^{-1/2}\epsilon(q^2,z^*z'). \tag{18}$$

For z fixed we can always choose z' such that $z^*z'=r_p(q)$, where $r_p(q)$ is the pth root of $\epsilon(q^2,z)$ $(p=1,2,\ldots)$. It follows that the state $|q,z\rangle$ can be made orthogonal to an infinity of states $|q,z'\rangle$. However, since the infinite set of roots $r_p(q)$ is still of measure zero with respect to the whole complex plane, we conclude that $\langle q,z|q,z'\rangle$ never vanishes except on a set of measure zero. [We recall that the $SU(2)$ coherent states $|\mu\rangle$ and $|\mu'\rangle$ are never orthogonal, except for $\mu'=-1/\mu^*$, since $\langle\mu|\mu'\rangle$ has only one root.[5]]

B. Continuity in z

We use Eq. (18) and substitute it into Eq. (8), which after a few standard steps leads to

$$||q,z'\rangle-|q,z\rangle|^2\leqslant|z-z'|D_q(z',z), \tag{19}$$

where

$$D_q(z',z)=\sum_{p=1}^{\infty}\frac{q^{p(p-1)}}{p!}\sum_{k=0}^{p-1}(z'^*)^k z^{(p-1-k)}, \tag{20}$$

with $D_q(z,z)\geqslant 0$. Therefore the states $|q,z\rangle$ are continuous in their label, as are the canonical coherent states.

C. Resolution of unity

In close analogy with Eq. (5) the condition for the resolution of unity for the set of states $|q,z\rangle$ is

$$\int\int d^2z|q,z\rangle W(q,|z|^2)\langle q,z|=I, \tag{21}$$

which transforms into ($x\equiv|z|^2$)

$$\sum_{n=0}^{\infty}\left[\frac{\pi q^{n(n-1)}}{n!}\int_0^{\infty}\frac{x^n W(q,x)}{\epsilon(q^2,x)}dx\right]|n\rangle\langle n|=I, \tag{22}$$

where the unknown positive weight function $W(q,x)$ is the solution of the following Stieltjes power-moment problem for $\widetilde{W(q,x)}\equiv W(q,x)/\epsilon(q^2,x)$:

$$\int_0^{\infty}x^n\widetilde{W(q,x)}dx=\frac{n!}{\pi q^{n(n-1)}}\equiv c_q(n),\quad n=1,2,\ldots,\infty. \tag{23}$$

The general theory of the Stieltjes power-moment problem[3] tells us that a condition for the solvability of Eq. (23) is the positivity of the two series $\{h_0^{(n)}\},\{h_1^{(n)}\}(n=1,2,\ldots,\infty)$ of so-called Hankel–Hadamard matrices (HH-matrices), defined by

$$h_0^{(n)}(i,j)=c_q(i+j-2)=\frac{(i+j-2)!}{q^{(i+j-2)(i+j-3)}}\quad(i,j=1,2,\ldots,n), \tag{24}$$

$$h_1^{(n)}(i,j)=c_q(i+j-1)=\frac{(i+j-1)!}{q^{(i+j-1)(i+j-2)}}\quad (i,j=1,2,\ldots,n). \tag{25}$$

It turns out that indeed all the left-upper corner determinants of HH-matrices are positive.[8] Therefore a solution of Eq. (23) exists. However, in contradistinction to the case of group-defined coherent states, the solution here is not unique. In fact, there exists an infinity of solutions, as the so-called Carleman criterion[3] indicates,

$$\sum_{n=0}^{\infty}[c_q(n)]^{-1/2n}<\infty. \tag{26}$$

We have generated a few families of solutions of Eq. (23) using the combined methods of Mellin and Laplace transforms.[9,10,11] We quote here the simplest solution,

$$\widetilde{W}(q,x)=[2q(\pi)^{3/2}\sqrt{\log(q^{-1})}]^{-1}\int_0^{\infty}\exp\left(-\frac{xy}{q}-\frac{(\log y)^2}{4\log(q^{-1})}\right)dy, \tag{27}$$

which is effectively the Laplace transform with respect to x/q of the lognormal distribution function. It satisfies $\widetilde{W}(q,0)=\pi q^{-2}$ and $\widetilde{W}(q,\infty)=0$. With the change of variable $y=q^{-2}\exp(2\sqrt{\log(q^{-1})}s)$, $\widetilde{W}(q,x)$ transforms into

$$\widetilde{W}(q,x)=[q^2(\pi)^{3/2}]^{-1}\int_{-\infty}^{\infty}\exp\left(-\frac{x}{q^3}e^{2\sqrt{\log(q^{-1})}s}-s^2\right)ds, \tag{28}$$

from which we observe that for $q\to 1$, $\widetilde{W}(q,x)\to\pi^{-1}\exp(-x)$. A detailed derivation of these results, together with a discussion of analyticity properties and a graphical representation of Eq. (27), as well as of other solutions of Eq. (23), will be given in a forthcoming publication.[11] The above results have two main consequences.

First, it follows from Eq. (21) that $\langle q,z|q,z'\rangle$ is a reproducing kernel, since

$$\int\int d^2z\langle q,z'|q,z\rangle W(q,|z|^2)\langle q,z|q,z''\rangle=\langle q,z'|q,z''\rangle. \tag{29}$$

Equivalently, any state $|q,z'\rangle$ can be expressed in terms of the others through

$$|q,z'\rangle=\int\int d^2z|q,z\rangle\langle q,z|q,z'\rangle|W(q,|z|^2). \tag{30}$$

Second, any arbitrary state $|\phi\rangle$ can be expressed in terms of states $|q,z\rangle$

$$|\phi\rangle=\int\int d^2z|q,z\rangle|W(q,|z|^2)\langle q,z|\phi\rangle, \tag{31}$$

where from Eq. (17),

$$\langle q,z|\phi\rangle=[\epsilon(q^2,|z|^2)]^{-1/2}\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{\sqrt{n!}}z^n\langle\phi|n\rangle. \tag{32}$$

We conclude from these considerations that the family of $|q,z\rangle$ states is a fully-fledged family of coherent states in the sense described above.

III. PHYSICAL APPLICATIONS

The utility of the general coherent states $|q,z\rangle$ in physical applications is enhanced by the observation that the following quite general matrix element can be calculated exactly for $p,r=0,1,2,\ldots,$

$$\langle q,z|(a^{\dagger})^r a^p|q,z\rangle=(z^*)^r z^p q^{(1/2)(r^2+p^2-r-p)}\frac{\epsilon(q^2,q^{(p+r)}|z|^2)}{\epsilon(q^2,|z|^2)}. \tag{33}$$

More generally, the nondiagonal matrix elements $\langle q,z|(a^{\dagger})^r a^p|q,z'\rangle$ are also readily evaluated, but will not be quoted here.

We now give three simple physical applications of the formula of Eq. (33).

A. Photon number distribution

First, the average number of photons in the state $|q,z\rangle$ is given by

$$\langle q,z|N|q,z\rangle=|z|^2\frac{\epsilon(q^2,q^2|z|^2)}{\epsilon(q^2,|z|^2)}\leqslant|z|^2 \quad (N\equiv a^{\dagger}a). \tag{34}$$

The variance $(\Delta Q)^2$ of an operator Q in the state $|\psi\rangle$ is defined by

$$(\Delta Q)^2=\langle\psi|Q^2|\psi\rangle-\langle\psi|Q|\psi\rangle^2. \tag{35}$$

We have the following expression for the number variance in the state $|q,z\rangle$:

$$(\Delta N)^2\equiv\langle q,z|N^2|q,z\rangle-\langle q,z|N|q,z\rangle^2 \tag{36}$$

$$=x\frac{\epsilon(q^2,x)\epsilon(q^2,q^2x)+x[q^2\epsilon(q^2,x)\epsilon(q^2,q^4x)-\epsilon^2(q^2,q^2x)]}{\epsilon^2(q^2,x)}, \tag{37}$$

where $x\equiv|z|^2$. Upon closer inspection one sees that the number variance is always smaller than $\langle N\rangle$. Consequently, the probability distribution generated by $\epsilon(q,x)$ is sub-Poissonian. (The ordinary coherent states are exactly Poissonian.)

B. Squeezing properties

Introduce the self-adjoint quadrature operators $X=(a+a^{\dagger})/\sqrt{2}$ and $P=(a-a^{\dagger})/i\sqrt{2}$ which satisfy $[X,P]=iI$. The variances of X and P in any state $|\psi\rangle$ satisfy the Heisenberg uncertainty relation,

$$(\Delta X)^2(\Delta P)^2\geqslant\tfrac{1}{4}. \tag{38}$$

A state $|\psi\rangle$ is called *squeezed* for the quadrature X if $(\Delta X)^2<\frac{1}{2}$ (the vacuum value). We now show that for $q<1$, there is a neighborhood of $z=0$ for which the state $|q,z\rangle$ is squeezed. To this end we observe that $(\Delta X)^2<\frac{1}{2}$ may be rewritten as

$$\langle a^2\rangle-\langle a\rangle^2+\langle a^{\dagger}a\rangle-\langle a\rangle\langle a^{\dagger}\rangle<0, \tag{39}$$

where all the averages in Eq. (39) are understood as taken in the state $|q,z\rangle$. Using Eq. (33) gives the following condition for squeezing ($x\equiv|z|^2$):

$$(1+q)\epsilon(q^2,q^2x)\epsilon(q^2,x)-2\epsilon^2(q^2,qx)<0. \tag{40}$$

We note that the inequality (40) is always satisfied for $x=0$, as it then reduces to $q<1$, which is true by hypothesis. From the continuity of $\epsilon(q,x)$ for fixed q there is therefore a neighborhood of $x=0$ for which the inequality (40) is satisfied; that is, there is a constant $\delta(q)>0$ such that squeezing in X occurs for $0<x<\delta(q)$.

C. Signal-to-quantum noise ratio

The last physical quantity calculated in the state $|q,z\rangle$ will be the signal-to-quantum noise ratio σ, which is defined by

$$\sigma=\frac{\langle X\rangle^2}{(\Delta X)^2}. \tag{41}$$

Repeated use of Eq. (33) yields the result

$$\sigma(q,x)=2x\epsilon^2(q^2,qx)/\{x[(1+q)\epsilon(q^2,x)\epsilon(q^2,q^2x)-2\epsilon^2(q^2,qx)]+\tfrac{1}{2}\epsilon^2(q^2,x)\}. \tag{42}$$

For the standard coherent states ($q=1$) the quantity $\sigma(1,x)$ attains the value $4N_s$, where N_s is the number of photons in the signal, $N_s=N_s(1,x)$, where $N_s(q,x)=\langle q,z|a^\dagger a|q,z\rangle$. In our case we may show that in a positive neighborhood of x,

$$\frac{\sigma(q,x)}{4N_s(q,x)}=1+(1-q^2)x\cdots, \tag{43}$$

which is greater than 1 for $q^2<1$, thus improving on the usual coherent state value.

The classical result of Yuen,[12,13] valid for any state whatsoever, implies that

$$\sigma(q,x)\leqslant 4N_s(q,x)(N_s(q,x)+1), \tag{44}$$

where the upper value is attained by a conventional squeezed state.[14] Calculations on our coherent state $|q,z\rangle$, which as we have seen above is a squeezed state, confirm this upper bound.

IV. TIME EVOLUTION

Since the state $|q,z\rangle$ is not an eigenstate of the Hamiltonian $H=\omega a^\dagger a$, it is natural to analyze its time dependence, obtained from the time-dependent Schrödinger equation

$$i\frac{\partial}{\partial t}|q,z;t\rangle=H|q,z;t\rangle \quad (\hbar=1). \tag{45}$$

The time-dependent state $|q,z;t\rangle$ is obtained by acting on $|q,z\rangle\equiv|q,z;0\rangle$ by the time-evolution operator $U(t)=\exp(-iHt)$. That is,

$$\begin{aligned}|q,z;t\rangle&=\exp(-iHt)|q,z;0\rangle=\exp(-iHt)[\epsilon(q^2,|z|^2)]^{-1/2}\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{\sqrt{n!}}z^n|n\rangle\\ &=[\epsilon(q^2,|z(t)|^2)]^{-1/2}\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{\sqrt{n!}}z(t)^n|n\rangle=|q,z(t)\rangle,\end{aligned} \tag{46}$$

where $z(t)\equiv z\exp(-i\omega t)$. The eigenproperties of the set $|n\rangle$ have been used, $\exp(-iHt)|n\rangle=\exp(-in\omega t)|n\rangle$. The corresponding evolution of the propagator,

$$\langle q,z|q,z';t\rangle=\langle q,z|q,\exp(-i\omega t)z'\rangle=\langle q,\exp(i\omega t)z|q,z'\rangle, \tag{47}$$

indicates that the coherent state $|q,z'\rangle$ goes over into another coherent state described by $z'(t)\equiv z'\exp(-i\omega t)$ under the action of the time-evolution operator; this latter state is simply the time-dependent state of a *classical* harmonic oscillator. Then, very much as for standard coherent states, the set of all states $|q,z\rangle$ is invariant under time evolution with the Hamiltonian H. The state $|q,z\rangle$ remains as close as possible to its classical analog.

V. RELATION TO DEFORMED BOSONS

The reader will have noticed by now that the states $|q,z\rangle$ share practically all the properties of the usual coherent states $|z\rangle \equiv |1,z\rangle$ except one: $|q,z\rangle$ is not an eigenstate of a, whereas $|z\rangle$ is, $a|z\rangle = z|z\rangle$. Although this did not impair our ability to apply the new states $|q,z\rangle$ in actual calculations, it is legitimate to ask the following question: is the state $|q,z\rangle$ an eigenstate of some non-Hermitian operator b ? The answer to that question is affirmative, with the operator b and its Hermitian conjugate playing the role of *deformed bosons*; in other words, one has to deform the basic commutation relations in order to introduce the so-called deformed bosons. It is natural in our context to parametrize such a deformation by the parameter q, i.e., $b \equiv b(q)$ and $b^\dagger \equiv b^\dagger(q)$ with $b(1) = a$. The study of deformed commutation relations and their representations (more specifically as *quantum groups*) has been the subject of much activity in recent years.[15,16] Of course, there exists an infinite number of possible deformations. All of them can be systematically investigated using the function $[x]_q$ (''box'' x),[17] which enters the deformed commutator as follows:

$$b(q)b^\dagger(q) - b^\dagger(q)b(q) = [N+1]_q - [N]_q, \tag{48}$$

where $N = a^\dagger a$, $N|n\rangle = n|n\rangle$. Furthermore, it is possible to assume that $b^\dagger(q)$ and $a^\dagger$ (along with their conjugates) act on the same Fock space with basis $\{|n\rangle\}$. From Eq. (48), it follows that

$$b(q)|n\rangle = \sqrt{[n]_q}|n-1\rangle,$$

so the operators $b(q)$ may be thought of as functions of a according to $b(q) = \sqrt{[N+1]_q/(N+1)}a$, etc.

For historical reasons some specific forms of the function $[N]_q$ gained a particular popularity.[18–20] The general coherent states $|q,z\rangle$ of this paper are related naturally to a specific ''box'' function, and a particular set of deformed commutation relations. Defining $[n]_q \equiv nq^{2(1-n)}$, then

$$[n]_q! = [n]_q[n-1]_q \cdots [1]_q = n!/q^{n(n-1)},$$

and the state $|q,z\rangle$ of Eq. (17) may be rewritten as

$$|q,z\rangle = [\epsilon(q^2,|z|^2)]^{-1/2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{[n]_q!}}|n\rangle. \tag{49}$$

This shows that $|q,z\rangle$ is an eigenstate of a q-deformed boson $b(q)$ satisfying

$$b(q)|q,z\rangle = z|q,z\rangle, \tag{50}$$

where, from Eq. (48), the operators $b(q)$ satisfy the following commutation relations:

$$b(q)b^\dagger(q) - (1/q^2)b^\dagger(q)b(q) = q^{-2N}. \tag{51}$$

This gives a new q-deformation, different from the ones previously used. Note that the coherent state of Eq. (14) or Eq. (49) corresponds to a new q-exponential function $\epsilon(q,x) = \Sigma x^n/[n]!$, where $[n]$ is defined above, and $[n]! = [n][n-1]\cdots[1], [0]! = 1$. This is not one of the family of q-exponential functions considered, for example, by Exton,[21] but may be thought of as a member of a 3-parameter family,

$$E(p,q,\lambda;x)\equiv\sum\frac{x^n q^{\lambda n(n-1)}}{[n]_p!};$$

namely, $\epsilon(q,x)=E(1,q,1;x)$ with $[n]_p\equiv(1-p^n)/(1-p)$ here being the traditional definition.

VI. MULTIBOSON STATES

The use of the function $\epsilon(q,x)$ can be extended to investigate multiboson coherent states. First, recall that if we set out to create k excitations of the harmonic oscillator at the time, we are led to use, for fixed k,

$$(a^\dagger)^{kn}|0\rangle=\sqrt{(kn)!}|kn\rangle,\quad n=0,1,\ldots,\infty. \tag{52}$$

Using the conventional exponential function to create such a k-state leads us to consider, for complex z,

$$|k,z\rangle=\mathcal{N}^{-1/2}(k,|z|^2)\sum_{n=0}^{\infty}\frac{[z(a^\dagger)^k]^n}{n!}|0\rangle=\mathcal{N}^{-1/2}(k,|z|^2)\sum_{n=0}^{\infty}\frac{z^n\sqrt{(kn)!}}{n!}|kn\rangle, \tag{53}$$

where the normalization is

$$\mathcal{N}(k,|z|^2)=\sum_{n=0}^{\infty}\frac{|z|^{2n}(kn)!}{(n!)^2}. \tag{54}$$

(The functions $|k,z\rangle$ are not of only theoretical interest: $|2,z\rangle$ was the first example of an exponentially-generated state displaying squeezing.[14]) Unfortunately, the power series in Eq. (54) diverges for $k>2$.[22] Therefore no multiboson coherent states for $k>2$ exist when generated by the usual exponential, unless a number-dependent convergence factor is introduced.[23] We now turn to $\epsilon(q,z)$ and define

$$|q,k,z\rangle=\mathcal{N}^{-1/2}(q,k,|z|^2)\epsilon(q,z(a^\dagger)^k)|0\rangle=\mathcal{N}^{-1/2}(q,k,|z|^2)\sum_{n=0}^{\infty}\frac{z^n\sqrt{(kn)!}q^{n(n-1)/2}}{n!}|kn\rangle, \tag{55}$$

where the normalization is now

$$\mathcal{N}(q,k,|z|^2)=\sum_{n=0}^{\infty}\frac{|z|^{2n}(kn)!q^{n(n-1)}}{(n!)^2}, \tag{56}$$

and for $q<1$ is a convergent series for all $|z|^2$ and for $k=1,2,\ldots$. This allows us to define normalizable multiboson states of any multiplicity k. However, the $|q,k,z\rangle$ do not form a complete set as their Stieltjes problem does not possess a positive weight function. However, such states can be understood to be ''complete'' in a different sense: there is a way to extract every eigenstate, say $|k,m\rangle$, from a state of the type Eq. (55) either by taking derivatives at $z=0$, or by dividing by $m+1$ and performing a contour integral about $z=0$. We refer to Ref. 24 for a description of such an approach.

VII. CONCLUSIONS

We have shown how to define new coherent states by the introduction of a variant of the exponential function $\epsilon(q,x)$. We have shown these states to be coherent in that we have explicitly given the weight function which satisfies the associated Stieltjes power-moment problem and thus the resolution of unity property. The analytic behavior of this new exponential is such as to enable ready evaluation of matrix elements of operators in these new coherent states, and we have exemplified this by evaluating their squeezing and related physical properties, as well as their time dependence. Further, the stronger convergence behavior of $\epsilon(q,x)$ allows the definition of multi-boson coherent states, not permitted in the convention exponential case. Finally, we have shown that the new function may be considered as the q-exponential associated with a simple deformation of the boson commutation relations, and the related coherent states as the q-boson eigenstates. As a postscript, we mention another construction of coherent states which follows what might be termed an inverse path as compared to our construction of Eqs. (23) and (27). Any positive function having well-behaved moments can serve as a weight function for a family of coherent states. In this way one may define new and interesting coherent states with particularly interesting geometrical properties.[25,26]

The new coherent state defined in this paper possesses a combination of strong convergence properties and easy evaluability which make it a good candidate for the description of solvable model systems.

ACKNOWLEDGMENTS

The authors are grateful to L. Haddad for a significant contribution to this work, H. Widom for providing an ingenious proof of the positivity of the Hankel–Hadamard matrices of Eqs. (24) and (25), and A. Comtet, D. Zeilberger, and M. Ismail for interesting discussions.

(Received 17 June 1998; accepted for publication 17 November 1998)

We examine three overlapping problems in the application of five-dimensional (5D) manifolds to physics. First, we linearize the 5D theory along the lines of the four-dimensional (4D) theory, using the harmonic gauge condition. The resulting wave equations have sources, and can in principle describe gravitons and scalar particles with finite masses, but the natural choice of gauge parameters makes both massless. Second, we generalize the 5D metric by including separate conformal factors on its 4D and extra parts. Then the 5D harmonic gauge gives back the 4D harmonic gauge of gravitational waves and the Lorentz gauge of electromagnetic waves, but both particles are massless. Third, we again take a conformally rescaled metric, but rewrite the field equations in a novel manner. This allows us to interpret the finite masses of ordinary particles in terms of the wavelengths associated with 4D spaces embedded in a 5D space.
[S0022-2488(99)01304-3]

I. INTRODUCTION

Five-dimensional (5D) Kaluza–Klein theory is a generalization of 4D Einstein theory and is commonly regarded as a unified theory of the gravitational, electromagnetic, and scalar field whose quantum analogs are the spin-2 graviton, spin-1 photon, and the spin-0 scalar (for a recent review of Kaluza–Klein theory see Ref. 1). As a possible bridge between classical field theory and quantum theory, there has in recent years been significant work on wavelike solutions on 5D manifolds which might be interpreted as four-dimensional (4D) particles.[2–5] In the present work we wish to give fairly generic accounts of three overlapping problems in this area.

In Sec. II we take a new look at the case where the 5D metric can be written as a flat piece plus a perturbation. The linearized 5D field equations can be made algebraically tractable if one chooses the 5D harmonic gauge. This gives a wave equation for the 4D components of the perturbation and a Klein–Gordon type equation for the extra part of the perturbation. These wave equations in general have sources, and can represent gravitons and scalar particles with finite masses. However, both masses go to zero for what should be considered the most natural choice of gauge parameters. In Sec. III, we generalize the metric by conformally rescaling its 4D and 5D parts separately. We consider the full (nonlinearized) field equations and again choose the 5D harmonic gauge. For a certain choice of constant parameters involved in the conformal rescaling, the general equations reduce to the 4D harmonic gauge and the Lorentz gauge. In Sec. IV we use the results derived in previous sections to explore the relationship between 5D field theory and 4D particle mass following lines suggested by previous work.[6–8] We find that particle masses may be interpreted as a wavelength in the 4D subspace of a 5D space.

II. WAVES IN LINEARIZED 5D THEORY

To linearize 5D gravity we assume as in the 4D problem that the metric can be written as

$$\hat{g}_{AB}=\hat{\eta}_{AB}+\hat{h}_{AB}, \tag{2.1}$$

where $\hat{h}_{AB}$ is viewed as a small perturbation from flat 5D Minkowski space. Here and in what follows we use careted 5D objects and uncareted 4D ones. Also, upper-case Latin letters run from 0 to 4, Greek letters run from 0 to 3, and the block diagonal form for the 5D Minkowski space is $\hat{\eta}_{AB}=(\hat{\eta}_{\alpha\beta},\epsilon)$ where ϵ can be spacelike (-1) or timelike $(+1)$. The inverse of the above metric to $O(\hat{h})$ is

$$\hat{g}^{AB}=\hat{\eta}^{AB}-\hat{h}^{AB}, \tag{2.2}$$

and the Christoffel symbols to $O(\hat{h})$ are

$$\hat{\Gamma}^{A}_{BC}=\tfrac{1}{2}(\partial_B\hat{h}^{A}{}_{C}+\partial_C\hat{h}^{A}{}_{B}-\partial^{A}\hat{h}_{BC}). \tag{2.3}$$

Here $\partial_A=\partial/\partial x^{A}$ and the flat-space metric is responsible for raising and lowering indices $(\hat{h}^{A}{}_{C}=\hat{\eta}^{AB}\hat{h}_{BC}=\hat{h}_{C}{}^{A})$. We take as our starting point the 15 field equations representing the 5D vacuum:

$$\hat{R}_{AB}=0. \tag{2.4}$$

These to $O(\hat{h})$ give

$$\hat{R}_{AB}=\tfrac{1}{2}(\partial_A\partial_C\hat{h}^{C}{}_{B}+\partial_B\partial_C\hat{h}^{C}{}_{A}-\hat{\Box}\hat{h}_{AB}-\partial_A\partial_B\hat{h}^{C}{}_{C}), \tag{2.5}$$

where the trace of $\hat{h}_{AB}$ is defined as

$$\hat{h}\equiv\hat{h}^{A}{}_{A}=\hat{\eta}^{AB}\hat{h}_{AB} \tag{2.6}$$

and the 5D box operator is defined as

$$\hat{\Box}\equiv\hat{\eta}^{AB}\partial_A\partial_B. \tag{2.7}$$

In order to reduce the algebraic complexity of the 5D Ricci tensor we now choose the harmonic gauge:

$$\hat{\Gamma}^{C}\equiv\hat{g}^{AB}\hat{\Gamma}^{C}_{AB}=0. \tag{2.8}$$

This to $O(\hat{h})$ gives

$$\partial_A\hat{h}^{AC}=\tfrac{1}{2}\partial^{C}\hat{h}, \tag{2.9}$$

and the 5D Ricci tensor reduces to

$$\hat{R}_{AB}=\tfrac{1}{2}\hat{\Box}\hat{h}_{AB}. \tag{2.10}$$

If we now impose (2.4), we obtain a wave equation for the $\hat{h}_{AB}$, namely

$$\hat{\Box}\hat{h}_{AB}=0. \tag{2.11}$$

The trace of this gives

$$\hat{R}=\tfrac{1}{2}\hat{\Box}\hat{h}=0. \tag{2.12}$$

However, it is sometimes more convenient to use the tensor

$$\hat{\psi}_{AB}\equiv\hat{h}_{AB}-\tfrac{1}{2}\hat{\eta}_{AB}\hat{h}, \tag{2.13}$$

and by using (2.10) and (2.12) we see that $\hat{\psi}_{AB}$ satisfies the wave equation

$$\hat{G}^{AB}=\tfrac{1}{2}\hat{\Box}\hat{\psi}^{AB}=0. \tag{2.14}$$

Now the harmonic gauge (2.8) applied to $\hat{\psi}_{AB}$ becomes

$$\partial_A\hat{\psi}^{AB}=0. \tag{2.15}$$

Since this equation is a manifestation of the (noncovariant) harmonic gauge, we cannot demand that it be invariant under arbitrary 5D coordinate transformations. Instead what we do demand (as in 4D theory) is that (2.15) be invariant to $O(\hat{\xi})$ for the transformation

$$x^A\rightarrow x'^A=x^A+\hat{\xi}^A, \tag{2.16}$$

where $\hat{\xi}^A$ is an infinitesimal vector. Under this transformation $\hat{h}_{AB}, \hat{\psi}_{AB}$ and the gauge condition transform as

$$\hat{h}_{AB}\rightarrow\hat{h}'_{AB}=\hat{h}_{AB}-\partial_B\hat{\xi}_A-\partial_A\hat{\xi}_B\,, \tag{2.17}$$

$$\hat{\psi}_{AB}\rightarrow\hat{\psi}'_{AB}=\hat{\psi}_{AB}-\partial_B\hat{\xi}_A-\partial_A\hat{\xi}_B+\hat{\eta}_{AB}\partial_C\hat{\xi}^C, \tag{2.18}$$

$$\partial_A\hat{\psi}^{AB}\rightarrow\partial'_A\hat{\psi}'^{AB}=\partial_A\hat{\psi}^{AB}-\hat{\Box}\hat{\xi}^B. \tag{2.19}$$

The invariance of (2.15) under the gauge transformation (2.16) then holds provided the following wave equation for $\hat{\xi}^B$ is satisfied:

$$\hat{\Box}\hat{\xi}^B=0. \tag{2.20}$$

The transformation (2.16) represents the only gauge freedom left in the theory and is important in deducing the actual degrees of freedom of the metric $\hat{h}_{AB}$. Now $\hat{h}_{AB}$ has fifteen independent components. But we have used five coordinate degrees of freedom in (2.16) and imposed five constraints through (2.8). We therefore conclude that $\hat{h}_{AB}$ has only $15-5-5=5$ degrees of freedom left. These correspond to two degrees of freedom for the gravitational field, two degrees for the electromagnetic field, and one degree for the scalar field.

We now turn to the field equations and look at their reduction to 4D quantities and interpret their meaning. The field equations for 5D linearized theory are

$$\hat{R}^{AB}=\tfrac{1}{2}\hat{\Box}\hat{h}^{AB}=0$$

or

$$\hat{G}^{AB}=\tfrac{1}{2}\hat{\Box}\hat{\psi}^{AB}=0, \tag{2.21}$$

$$\partial_A\hat{h}^{AB}=\tfrac{1}{2}\partial^B\hat{h}$$

or

$$\partial_A \hat{\psi}^{AB} = 0, \tag{2.22}$$

$$\hat{\Box} \hat{\xi}^A = 0. \tag{2.23}$$

Looking at the $(\alpha\beta)$, $(\alpha 4)$, and (44) components of the right part of (2.21) we obtain

$$G^{\alpha\beta} = \tfrac{1}{2}\Box_M \hat{\psi}^{\alpha\beta} = \tfrac{1}{2}(-2\,\hat{\eta}^{4\gamma}\partial_4\partial_\gamma\hat{\psi}^{\alpha\beta} - \hat{\eta}^{44}\partial_4^2\hat{\psi}^{\alpha\beta}), \tag{2.24}$$

$$\tfrac{1}{2}\Box_M \hat{\psi}^{4\alpha} = \tfrac{1}{2}(-2\,\hat{\eta}^{4\gamma}\partial_4\hat{\psi}^{4\alpha} - \hat{\eta}^{44}\partial_4^2\hat{\psi}^{4\alpha}), \tag{2.25}$$

$$\tfrac{1}{2}\Box_M \hat{\psi}^{44} = \tfrac{1}{2}(-2\,\hat{\eta}^{4\gamma}\partial_4\partial_\gamma\hat{\psi}^{44} - \hat{\eta}^{44}\partial_4^2\hat{\psi}^{44}). \tag{2.26}$$

The β and fourth components of the constraint equations yield

$$\partial_\alpha \hat{\psi}^{\alpha\beta} = -\partial_4 \hat{\psi}^{4\beta}, \tag{2.27}$$

$$\partial_\alpha \hat{\psi}^{4\alpha} = -\partial_4 \hat{\psi}^{44}. \tag{2.28}$$

And the wave equation for $\hat{\xi}^A$ gives

$$\Box_M \hat{\xi}^\alpha = -2\,\hat{\eta}^{4\beta}\partial_4\partial_\beta\hat{\xi}^\alpha - \hat{\eta}^{44}\partial_4^2\hat{\xi}^\alpha, \tag{2.29}$$

$$\Box_M \hat{\xi}^4 = -2\,\hat{\eta}^{4\beta}\partial_\beta\partial_4\hat{\xi}^4 - \hat{\eta}^{44}\partial_4^2\hat{\xi}^4. \tag{2.30}$$

In the above, the 5D box operator was expanded as

$$\hat{\Box} \equiv \hat{\eta}^{AB}\partial_A\partial_B = \hat{\eta}^{\alpha\beta}\partial_\alpha\partial_\beta + 2\,\hat{\eta}^{4\alpha}\partial_4\partial_\alpha + \hat{\eta}^{44}\partial_4^2, \tag{2.31}$$

and using the 4D Minkowski box operator $\Box_M \equiv \hat{\eta}^{\alpha\beta}\partial_\alpha\partial_\beta$ (2.31) reduces to

$$\hat{\Box} = \Box_M + 2\,\hat{\eta}^{4\alpha}\partial_4\partial_\alpha + \hat{\eta}^{44}\partial_4^2. \tag{2.32}$$

The most important of the sets of equations given above is (2.24) since it describes an induced energy–momentum tensor from the definition $G^{\alpha\beta} \equiv T^{\alpha\beta}$ (with $8\pi G = c = \hbar = 1$). Its explicit form and the wave equation it satisfies are

$$T^{\alpha\beta} \equiv \tfrac{1}{2}(-2\,\hat{\eta}^{4\gamma}\partial_4\partial_\gamma\hat{\psi}^{\alpha\beta} - \hat{\eta}^{44}\partial_4^2\hat{\psi}^{\alpha\beta}), \tag{2.33}$$

$$\Box_M \hat{\psi}^{\alpha\beta} = 2T^{\alpha\beta}. \tag{2.34}$$

These are the equations for 4D linearized gravity,[5] but with a source term. It should be noted that the procedure used above, wherein 5D terms are shifted in a vacuum relation to produce a 4D type of equation with a source, is now in common use (see Ref. 1 for a review). In our case, it would be necessary to have $\partial_4\hat{g}_{AB} = 0$, $\hat{g}_{4A} = 0$ and $\hat{g}_{44} = \text{const.}$ for a 5D vacuum to go to a 4D vacuum. These conditions will not in general be met by significant solutions of the 5D field equations (2.4). So, in general, Kaluza–Klein theory in 5D generates an energy–momentum tensor for Einstein theory in 4D.

The question of whether the induced energy–momentum tensor is conserved is now addressed. Since $T^{\alpha\beta}$ is of $O(\hat{\psi})$ we only need to verify that

$$\partial_\alpha T^{\alpha\beta} = 0, \tag{2.35}$$

since the product of $T^{\alpha\beta}$ and the Christoffel symbols is of $O(\hat{\psi}^2)$, which we neglect in our approximation. Taking the partial derivative of both sides of (2.34) and using (2.27) we obtain

$$\partial_\alpha T^{\alpha\beta} = \tfrac{1}{2}\Box_M \partial_\alpha \hat{\psi}^{\alpha\beta} = -\tfrac{1}{2}\Box_M \partial_4 \hat{\psi}^{4\beta}. \tag{2.36}$$

Therefore, for the induced stress–energy to be conserved in our approximation we must have $\Box_M \partial_4 \hat{\psi}^{4\beta}=0$. There are three cases in which this statement will hold, and these are worked out in detail in the Appendix. The first case is when $\Box_M \hat{\psi}^{4\alpha}=0$ which implies a massless spin-1 field, and leaves open the possibility for massive gravitons and scalar particles. The second case is when $\partial_4 \hat{\psi}^{4\beta}=0$ so that the spin-1 field has no x^4 dependence. The spin-1 field in this case is massless, but the graviton and the scalar field may be massive. The third and final case is when $\hat{\psi}^{4\beta}=0$ by a choice of the coordinate frame. This can be achieved by setting from the outset $\hat{\eta}_{4\beta}=\hat{h}_{4\beta}=0$, and this defines what we will refer to as the natural frame. This condition removes the spin-1 field (up to a coordinate transformation involving the extra coordinate), and allows for either massive or massless gravitons, but constrains the scalar field to be massless.

We now look at a simple example of plane waves in the natural frame. The flat-space metric and the perturbation are

$$\hat{\eta}_{AB} = \begin{pmatrix} \hat{\eta}_{\alpha\beta} & 0 \\ 0 & \epsilon \end{pmatrix}, \tag{2.37}$$

$$\hat{h}_{AB} = \begin{pmatrix} \hat{h}_{\alpha\beta} & 0 \\ 0 & \hat{h}_{44} \end{pmatrix}. \tag{2.38}$$

We can assume that $\hat{\psi}_{\alpha\beta}$ has the form of a 4D gravitational wave and a scalar wave:

$$\hat{\psi}^{AB} = \begin{pmatrix} \hat{\psi}^{\alpha\beta} & 0 \\ 0 & \hat{\psi}^{44} \end{pmatrix}, \tag{2.39}$$

$$\hat{\psi}^{AB} = \begin{pmatrix} A^{\alpha\beta} e^{i(k_\alpha x^\alpha + a x^4)} & 0 \\ 0 & A^{44} e^{i l_\alpha x^\alpha} \end{pmatrix}. \tag{2.40}$$

Here $A^{\alpha\beta}$ is the 4D polarization tensor, A^{44} is the amplitude of the scalar wave, and a is a constant with dimensions of inverse length which parametrizes the extra coordinate dependence. The field equations (2.24)–(2.26) simplify considerably and give

$$\Box_M \hat{\psi}^{\alpha\beta} = -\epsilon \partial_4^2 \hat{\psi}^{\alpha\beta} \Rightarrow k_\gamma k^\gamma = -\epsilon a^2, \tag{2.41}$$

$$\Box_M \hat{\psi}^{44} = -\epsilon \partial_4^2 \hat{\psi}^{44} \Rightarrow l_\gamma l^\gamma = 0. \tag{2.42}$$

We see that (2.42) can be interpreted as a massless scalar field, while (2.41) can be interpreted as a massive graviton when the parameter a is identified as

$$a = \pm i \sqrt{\epsilon} m. \tag{2.43}$$

The induced stress–energy is

$$T^{\alpha\beta} = -\frac{\epsilon}{2} a^2 A^{\alpha\beta} e^{i(k_\alpha x^\alpha + a x^4)}, \tag{2.44}$$

and its trace is given by

$$T^{\alpha}{}_{\alpha} = -\frac{\epsilon}{2} a^2 A^{\alpha}{}_{\alpha} e^{i(k_\alpha x^\alpha + a x^4)}. \tag{2.45}$$

This will be zero either if the 4D polarization tensor can be put into a trace-free form or if we choose $a=0$ (or both). This would imply a radiationlike equation of state induced on the 4D manifold representing gravitational radiation. The gauge condition (2.27) gives

$$k_\beta A^{\alpha\beta} = 0, \tag{2.46}$$

so the propagation of the 4D gravitational plane wave is transverse as it is in 4D theory.

So far there exists little difference in the qualitative features of 5D and 4D linearized theory, but the difference becomes apparent when the gauge freedom in $\hat{\xi}^A$ is used to obtain a transverse-traceless (TT) representation for $A^{\alpha\beta}$. The wave equations for the components of $\hat{\xi}^A$ which must be satisfied are

$$\Box_M \hat{\xi}^\alpha = -\epsilon \partial_4^2 \hat{\xi}^\alpha, \tag{2.47}$$

$$\Box_M \hat{\xi}^4 = -\epsilon \partial_4^2 \hat{\xi}^4. \tag{2.48}$$

The choice

$$\hat{\xi}^\alpha = (\hat{\xi}^\alpha, \hat{\xi}^4) = (-i e^\alpha e^{i(k_\gamma x^\gamma + a x^4)}, -i \epsilon e^4 e^{i(l_\gamma x^\gamma)}) \tag{2.49}$$

satisfies these wave equations, since (2.41) and (2.42) hold. In the natural frame, the transformations for the polarization components of $\hat{\psi}^{AB}$ under the gauge transformation are given by the following [see (2.18)]:

$$A'^{\alpha\beta} = A^{\alpha\beta} - k^\alpha e^\beta - k^\beta e^\alpha + \eta^{\alpha\beta} k_\gamma e^\gamma, \tag{2.50}$$

$$A'^{4\alpha} = -a \epsilon e^\alpha e^{i(k_\gamma x^\gamma + a x^4)} - \epsilon e^4 l_\alpha e^{i l_\gamma x^\gamma}, \tag{2.51}$$

$$A'^{44} = A^{44} + \epsilon k_\alpha e^\alpha e^{i[(k-l)_\gamma x^\gamma + a x^4]}. \tag{2.52}$$

We see that off-diagonal amplitudes have been generated and that the scalar amplitude has also been changed. What is interesting about the off-diagonal components is that they are a linear superposition of plane waves with different wave vectors, and functions of all five coordinates. The choice of setting $a = e^4 = 0$ is consistent with all the equations derived above but physically limiting since is sets the off-diagonal components in the transformed natural frame to zero, and therefore removes the electromagnetic effects which are usually associated with these components. This choice also sets the graviton mass to zero, and hence the 5D theory would give a conventional TT 4D gravitational wave and a scalar wave with an oscillating amplitude. Another simplification that takes place is if one chooses to remove the periodic behavior from the scalar field amplitude with the choice $k_\alpha = l_\alpha$. Since l_α is null, this forces k_α to be null as well, and hence a must equal zero, which implies a massless graviton again. In this case, the off-diagonal terms survive and give a simple expression:

$$A'^{4\alpha} = -\epsilon k^\alpha e^4 e^{i k_\gamma x^\gamma}. \tag{2.53}$$

This has the form of an electromagnetic plane wave propagating with the same null wave vector as the gravitational plane wave.

Let us now consider an example of a plane gravitational wave in the natural frame propagating in the z direction. The wave vector is

$$k_\gamma = (\omega, 0, 0, k), \tag{2.54}$$

and obeys the conditions (2.41), (2.43) and (2.46). These give

$$\omega^2-k^2=m^2,\qquad \omega A^{0\alpha}=kA^{3\alpha}. \tag{2.55}$$

Performing the gauge transformations and using the above we see that the only independent components of the $\hat{\psi}^{AB}$ are

$$\begin{aligned}
A'^{00}&=A^{00}-\omega e^0-ke^3,\\
A'^{01}&=A^{01}-\omega e^1,\\
A'^{02}&=A^{02}-\omega e^2,\\
A'^{11}&=A^{11}-\omega e^0+ke^3,\\
A'^{12}&=A^{12},\\
A'^{22}&=A^{22}-\omega e^0+ke^3,\\
A'^{44}&=A^{44}-\epsilon(\omega e^0-ke^3).
\end{aligned} \tag{2.56}$$

Then the choice

$$\begin{aligned}
e^0&=\frac{1}{2\omega}\left(A^{00}+\frac{1}{2}A^{11}+\frac{1}{2}A^{22}\right),\\
e^1&=A^{01},\\
e^2&=A^{02},\\
e^3&=\frac{1}{2k}\left(A^{00}-\frac{1}{2}A^{11}-\frac{1}{2}A^{22}\right)
\end{aligned} \tag{2.57}$$

will bring the 4D polarization tensor to a transverse-traceless form, but will generate off-diagonal terms and an oscillating scalar field amplitude. The choice $e^4=a=0$ corresponds to setting the off-diagonal terms to zero, and the $\hat{\psi}^{AB}$ represents a massless TT gravitational wave and a scalar wave. If we choose $l_\alpha=k_\alpha$ (which again forces the graviton mass to zero), the 4D gravitional wave is again TT, but the off-diagonal components with the choice of $e^4=\epsilon C/k$ (where $C\ll 1$ is a constant), are:

$$A'^{04}=-Ce^{ik_\gamma x^\gamma},\qquad A'^{34}=Ce^{ik_\gamma x^\gamma}. \tag{2.58}$$

These are simple plane waves with constant amplitude.

What we have shown in this section is that 5D gravity can be linearized in the same way as 4D gravity, but that the harmonic gauge (2.8) is very restrictive; and since it is noncovariant, conservation of the induced energy–momentum tensor on the 4D subspace holds only when certain restrictions are imposed on the extra off-diagonal components of the perturbation tensor. Also, while the equations allow in principle for massive gravitons, the most natural choice of parameters which removes electromagnetic effects also reduces the graviton mass to zero.

III. WAVES IN CONFORMAL 5D GRAVITY

In this section we investigate the consequences of imposing the 5D harmonic gauge condition for a metric with two conformal factors, one for the 4D part of the metric and another for the 5D off-diagonal components. We then look at the propagation of electromagnetic waves and their interaction with the scalar field. To end this section we give a solution to the field equations which has physical relevance.

Let us consider the metric

$$dS^2=\phi^{2a}g_{\alpha\beta}\,dx^\alpha\,dx^\beta-\phi^{2b}(dx^4+A_\alpha\,dx^\alpha)^2, \tag{3.1}$$

where a and b are constants. The demand that this metric satisfy the 5D harmonic gauge condition (2.8) gives two equations:

$$\hat{\Gamma}^\gamma\equiv\hat{g}^{AB}\hat{\Gamma}^\gamma_{AB}=0\Rightarrow g^{\alpha\beta}\Gamma^\gamma{}_{\alpha\beta}+(2a+b)\,\frac{\phi^\gamma}{\phi}=0, \tag{3.2}$$

$$\hat{\Gamma}^4\equiv\hat{g}^{AB}\hat{\Gamma}^4_{AB}=0\Rightarrow\nabla_\alpha A^\alpha+(2a+b)\,\frac{\phi_\alpha A^\alpha}{\phi}=0. \tag{3.3}$$

Here ∇_α is the 4D covariant derivative operator associated with the metric $g_{\alpha\beta}$. In order for the 5D harmonic gauge to induce the 4D harmonic gauge as well as the Lorentz gauge, we are forced to choose $2a+b=0$. With this constraint and changing the conformal factor to $\phi=e^{2\sigma/b\sqrt{3}}$, the metric takes the form

$$dS^2=e^{-2\sigma/\sqrt{3}}g_{\alpha\beta}\,dx^\alpha dx^\beta-e^{4\sigma/\sqrt{3}}(dx^4+A_\alpha\,dx^\alpha)^2, \tag{3.4}$$

which is the usual metric for Kaluza–Klein gravity in the Einstein frame.[9] The field equations are obtained by calculating the $(\alpha\beta)$, (4α), and (44) components of $\hat{R}_{AB}=0$. We obtain

$$R_{\alpha\beta}=-\tfrac{1}{2}e^{2\sqrt{3}\sigma}(F_{\alpha\gamma}F_\beta{}^\gamma-\tfrac{1}{4}g_{\alpha\beta}F^2)+2\sigma_\alpha\sigma_\beta, \tag{3.5}$$

$$\nabla_\beta(e^{2\sqrt{3}\sigma}F^{\alpha\beta})=0, \tag{3.6}$$

$$\Box\sigma+\frac{\sqrt{3}}{8}e^{2\sqrt{3}\sigma}F^2=0. \tag{3.7}$$

The Einstein tensor can be used to give the induced matter of an electromagnetic field coupled to a massless scalar field. Thus

$$G_{\alpha\beta}\equiv T^{\mathrm{EM}}_{\alpha\beta}+T^S_{\alpha\beta}, \tag{3.8}$$

where

$$T^{\mathrm{EM}}_{\alpha\beta}=-\tfrac{1}{2}e^{2\sqrt{3}\sigma}(F_{\alpha\gamma}F_\beta{}^\gamma-\tfrac{1}{4}g_{\alpha\beta}F^2), \tag{3.9}$$

$$T^S_{\alpha\beta}=2(\sigma_\alpha\sigma_\beta-\tfrac{1}{2}g_{\alpha\beta}\sigma^\gamma\sigma_\gamma). \tag{3.10}$$

The Ricci scalar is simply

$$R=2\sigma^\gamma\sigma_\gamma. \tag{3.11}$$

We now investigate the propagation of electromagnetic waves using the Lorentz gauge (3.3) with $2a+b=0$ and Maxwell's equations (3.6). We postpone the use of the 4D harmonic gauge so the following equations hold 4D covariantly for the induced matter from the Kaluza–Klein metric in the Einstein frame. The 4D harmonic gauge will however be imposed when we discuss an exact solution at the end of this section. The ansatz for the electromagnetic vector potential is

$$A_\alpha = a_\alpha e^{i\omega S}, \tag{3.12}$$

where $a_\alpha \in \mathrm{Im}$, $S \in \mathrm{Re}$, and this assumption represents a good approximation for large ω only. Substituting this ansatz into both the Lorentz gauge condition and Maxwell's equations and setting the coefficients of ω^2 and ω separately to zero, gives, respectively,

$$\nabla_\alpha A^\alpha = 0 \Rightarrow k_\alpha a^\alpha = 0, \tag{3.13}$$

$$O(\omega^2):\ \ k_\alpha k^\alpha = 0, \tag{3.14}$$

$$O(\omega):\ \ k^\alpha \nabla_\beta a^\beta - a^\alpha \nabla_\beta k^\beta - 2k^\beta \nabla_\beta a^\alpha = -2\sqrt{3}\sigma_\beta (k^\alpha a^\beta - k^\beta a^\alpha). \tag{3.15}$$

Here $k_\alpha \equiv \partial_\alpha S$ is the gradient to surfaces of constant phase, and as such the null condition implies that the k_α propagate on null geodesics:

$$k^\beta \nabla_\beta k^\alpha = 0. \tag{3.16}$$

The contraction of (3.15) with $\overline{a_\alpha}$ and the orthogonality condition (3.13) allows us to obtain

$$\nabla_\alpha (a^2 k^\alpha) = -\sqrt{3}\sigma_\alpha (a^2 k^\alpha), \tag{3.17}$$

where $a^2 \equiv a_\alpha \overline{a^\alpha}$. If we define a photon current $j^\alpha \equiv a^2 k^\alpha$, the right-hand side here can be interpreted as a violation of photon number due to the coupling of the gradient of the scalar field to the wave vector. The equation governing the propagation of the unit polarization vector can be obtained from (3.17) by the substitution of $f^\alpha = a^\alpha / a^2$, and is

$$k^\beta \nabla_\beta f^\alpha = \sqrt{3}\sigma_\beta f^\alpha + \frac{1}{2}\left(\nabla_\beta f^\beta + \frac{f^\beta \nabla_\beta a}{a} \right) k^\alpha. \tag{3.18}$$

This again differs from the usual 4D result due to the scalar-field coupling. Since the photons follow 4D null geodesics, their motion in the 4D part of the 5D space is the same as their motion in 4D space–time. However, the scalar field does modify the conservation equation for photon number, and also introduces a new term to the propagation of the unit polarization vector. Both things could in principle be tested.

So far we have not used the 4D harmonic gauge in deriving the above equations (3.5)–(3.18). We will illustrate the use of this gauge by deriving an exact, gravitational plane wave solution accompanied by a plane electromagnetic wave and a scalar wave. The choice of an electromagnetic plane wave simplifies the induced 4D field equations since $F^2 = 0$ for plane waves. This reduces the field equations (3.5)–(3.7) along with the 4D harmonic and Lorentz gauge to

$$R^H_{\alpha\beta} = -\tfrac{1}{2} e^{2\sqrt{3}\sigma} F_{\alpha\gamma} F_\beta{}^\gamma + 2\sigma_\alpha \sigma_\beta, \tag{3.19}$$

$$\partial_\alpha F^{\alpha\beta} + \partial_\alpha (\ln \sqrt{g} F^{\alpha\beta}) = -2\sqrt{3}\sigma_\alpha F^{\alpha\beta}, \tag{3.20}$$

$$\Box \sigma = g^{\alpha\beta} \partial_\alpha \partial_\beta \sigma = 0, \tag{3.21}$$

$$g^{\alpha\beta} \Gamma^\gamma_{\alpha\beta} = 0, \tag{3.22}$$

$$\nabla_\alpha A^\alpha = g^{\alpha\beta} \partial_\alpha A_\beta = 0. \tag{3.23}$$

Here $R^H_{\alpha\beta}$ is the Ricci tensor in the harmonic gauge. We would like a 4D gravitational wave metric that would simplify these equations even further. The candidate metric should have a determinant equal to a constant, which would remove the second term on the left-hand side of (3.20), while also satisfying the 4D harmonic gauge (3.22). A simple metric which satisfies these conditions is that of an exact gravitational plane wave with parallel rays (*pp*-wave) traveling along the z direction. Such a metric has the form:[10]

$$ds^2 = K(u,\xi,\overline{\xi})du^2 + 2\,du\,dv - d\xi\,d\overline{\xi}. \tag{3.24}$$

Here u and v are retarded and advanced coordinates, and $\xi = x + iy$ and $\overline{\xi} = x - iy$ are complex transverse coordinates. If we choose the electromagnetic vector potential and the scalar field to be independent of the complex transverse coordinates, we have

$$A_\alpha = (0,0,\tfrac{1}{2}A(u),\tfrac{1}{2}A(u)), \quad \sigma = \sigma(u). \tag{3.25}$$

The vector potential then corresponds to an electric field oscillating in the x direction and a magnetic field oscillating in the y direction, while the wave propagates in the z direction. One can check that the scalar wave equation (3.21) and Maxwell's equations (3.20) are satisfied by arbitrary functions $\sigma(u)$ and $A(u)$, and that the only surviving component of the Ricci tensor is R_{uu}, which gives for (3.19) the equation

$$\partial_\xi \partial_{\overline{\xi}} K(u,\xi,\overline{\xi}) = \tfrac{1}{4} e^{2\sqrt{3}\sigma}[\partial_u A(u)]^2 + [\partial_u \sigma(u)]^2. \tag{3.26}$$

This equation can be integrated immediately to give

$$K(u,\xi,\overline{\xi}) = (\tfrac{1}{4} e^{2\sqrt{3}\sigma}[\partial_u A(u)]^2 + [\partial_u \sigma(u)]^2)\xi\overline{\xi} + f(u)\xi^2 + \overline{f}(u)\overline{\xi}^2, \tag{3.27}$$

where $f(u)$ is an arbitrary complex function which represents the solution to the homogeneous equation. Since we are interested in electromagnetic and scalar waves we assume that they can be written as

$$A(u) = \mathrm{Re}\, A_0 e^{i\omega u}, \quad \sigma(u) = \mathrm{Re}\, \sigma_0 e^{i\lambda u}, \tag{3.28}$$

where A_0 and σ_0 are real constants. This gives on taking the real parts only,

$$K(u,\xi,\overline{\xi}) = (\tfrac{1}{4} e^{2\sqrt{3}\sigma_0 \cos(\lambda u)}[A_0^2 \omega^2 \sin^2(\omega u)] + \sigma_0^2 \lambda^2 \sin^2(\lambda u))\xi\overline{\xi}. \tag{3.29}$$

This particular solution is simple and realistic, and would probably repay future investigation. However, all of the work we have done in this section presumes the 5D harmonic gauge, in which the graviton and photon are massless. This is acceptable, but leaves open the question of how the theory should be interpreted in order to accommodate the many kinds of particles in nature which have finite masses. We turn our attention to this now.

IV. PARTICLE MASSES IN CONFORMAL 5D FIELD THEORY

It is now well known that because Einstein's equations with matter are a subset of the Kaluza–Klein equations in vacuum, phenomenological fluids in 4D can be generated by appropriate coordinate transformations in 5D.[1] The idea behind this, namely that 4D matter is a manifestation of 5D geometry, can in principle be extended from continuous fluids to particles.[6–8] For example, a connection between the mass of a particle as measured by its Compton wavelength and the dimension of the geometry as measured by its Ricci scalar was put forward as a realization of Mach's principle.[6] An extension of this approach was to envisage 4D space–time as having principle curvatures related via de Broglie waves to the 4-momenta of a particle, the mass again being determined by the scalar curvature.[7] The latter proposal involved a reinterpretation of the right-hand side of Einstein's field equations, and an alternative way of doing this has recently been proposed that introduces the Planck length as a fundamental parameter and derives particle energies dependent on wave modes in the extra dimension.[8] In this section, we wish to inquire into the possible relationship between the mass of a particle and a conformal factor in the geometry.

Following Sec. III and Ref. 7, let us consider metric (3.1) with $a=1$ and $A_\alpha=0$ (this does not restrict the 4D metric but removes electromagnetic effects). Thus the metric we consider has the form

$$\begin{aligned} dS^2 &= \phi^2\, ds^2 - \phi^{2b}(dx^4)^2, \\ ds^2 &= g_{\alpha\beta}\, dx^\alpha\, dx^\beta. \end{aligned} \tag{4.1}$$

Using as elsewhere a caret to distinguish 5D quantities from purely 4D quantities as conventionally defined, the Christoffel symbols of the second kind for (4.1) are

$$\begin{aligned} \hat\Gamma^\alpha_{\beta\gamma} &= \Gamma^\alpha_{\beta\gamma} + \phi^{-1}(\delta^\alpha_\beta\phi_\gamma + \delta^\alpha_\gamma\phi_\beta - g_{\alpha\beta}\phi^\alpha), \\ \hat\Gamma^\alpha_{\beta\alpha} &= \Gamma^\alpha_{\beta\alpha} + 4\,\frac{\phi_\alpha}{\phi}, \\ \hat\Gamma^\alpha_{44} &= b\,\phi^{2b-3}\phi^\alpha, \\ \hat\Gamma^\alpha_{4\beta} &= \hat\Gamma^4_{\alpha\beta} = \hat\Gamma^4_{44} = 0, \\ \hat\Gamma^4_{4\alpha} &= b\,\frac{\phi_\alpha}{\phi}, \\ \hat\Gamma^D_{\alpha D} &= \Gamma^\delta_{\alpha\delta} + (b+4)\,\frac{\phi_\alpha}{\phi}, \\ \hat\Gamma^D_{4D} &= 0. \end{aligned} \tag{4.2}$$

Here as before, $\phi_\alpha \equiv \partial_\alpha\phi$ and $\phi^\alpha \equiv g^{\alpha\beta}\phi_\beta$. The components of the 5D Ricci tensor are

$$\hat R_{\alpha\beta} = R_{\alpha\beta} - (b+2)\phi^{-1}\nabla_\alpha\phi_\beta - (b+1)(b-4))\phi^{-2}\phi_\alpha\phi_\beta - \phi^{-2}[\phi\nabla_\gamma\phi^\gamma + (b+1)\phi_\gamma\phi^\gamma]g_{\alpha\beta}, \tag{4.3}$$

$$\hat R_{4\alpha} = 0, \tag{4.4}$$

$$\hat R_{44} = b\,\phi^{2b-4}[\phi\nabla_\alpha\phi^\alpha + (b+1)\phi_\alpha\phi^\alpha]. \tag{4.5}$$

Clearly, the electromagnetic components of the field equations $\hat R_{AB}=0$ are trivially satisfied, while the remaining equations read

$$R_{\alpha\beta} = (b+2)\phi^{-1}\nabla_\alpha\phi_\beta + (b+1)(b-4)\phi^{-2}\phi_\alpha\phi_\beta, \tag{4.6}$$

$$\phi\nabla_\alpha\phi^\alpha + (b+1)\phi_\alpha\phi^\alpha = 0. \tag{4.7}$$

These are a set of ten tensor equations and one scalar equation, and are what we will be concerned with in what follows.

From (4.6) using (4.7) we find that the 4D Ricci scalar is

$$R = -6(b+1)\,\frac{\phi_\alpha\phi^\alpha}{\phi^2}. \tag{4.8}$$

This combined with (4.6) allows us to form the Einstein tensor $G_{\alpha\beta}=R_{\alpha\beta}-\frac{1}{2}Rg_{\alpha\beta}$. Then Einstein's equations $G_{\alpha\beta}\equiv T_{\alpha\beta}$ define the induced energy–momentum tensor:

$$T_{\alpha\beta}=(b+2)\phi^{-1}\nabla_{\alpha}\phi_{\beta}+(b+1)(b-4)\phi^{-2}\phi_{\alpha}\phi_{\beta}+3(b+1)\phi^{-2}\phi_{\gamma}\phi^{\gamma}g_{\alpha\beta}. \tag{4.9}$$

This obviously contains a term that is second order in the derivatives of the scalar field, and two terms that are first order as in ordinary quantum field theory. We can in principle have matter that depends solely on second derivatives by setting $b=-1$, or matter that depends solely on first derivatives by setting $b=-2$. However, we have not so far imposed the 5D harmonic gauge (3.2), and if we do so then it corresponds to setting $b=-2$, and we specialize to this case in what follows. Thus the 5D line element is given by

$$dS^2=\phi^2\,ds^2-\phi^{-4}(dx^4)^2, \tag{4.10}$$

where ds^2 is the 4D line element and the metric components are independent of the extra coordinate $(\partial_4 g_{\alpha\beta}=\partial_4\phi=0)$. The 5D field equations $\hat{R}^{AB}=0$ then yield the 4D ones

$$R_{\alpha\beta}=6\,\frac{\phi_{\alpha}\phi_{\beta}}{\phi^2}, \tag{4.11}$$

$$\nabla_{\alpha}\phi^{\alpha}=\frac{\phi_{\alpha}\phi^{\alpha}}{\phi}, \tag{4.12}$$

with an effective 4D energy–momentum tensor

$$T_{\alpha\beta}=6\phi^{-2}(\phi_{\alpha}\phi_{\beta}-\tfrac{1}{2}\phi^{\gamma}\phi_{\gamma}g_{\alpha\beta}). \tag{4.13}$$

It is our objective to evaluate this for a particle.

To this end, let us briefly review 4D particle dynamics. The Lagrangian is

$$L\equiv m\,\frac{ds}{d\lambda}=m\sqrt{g_{\alpha\beta}\,\frac{dx^{\alpha}}{d\lambda}\,\frac{dx^{\beta}}{d\lambda}}, \tag{4.14}$$

where λ is a parameter and m is the particle mass, which we assume to be constant. The covariant and contravariant components of the 4-momenta are

$$p_{\alpha}=\frac{\partial L}{\partial\left(\dfrac{dx^{\alpha}}{d\lambda}\right)}=mg_{\alpha\beta}\,\frac{dx^{\beta}}{ds}, \tag{4.15}$$

$$p^{\alpha}=g^{\alpha\beta}p_{\beta}=m\,\frac{dx^{\alpha}}{ds}, \tag{4.16}$$

and obey $p_{\alpha}p^{\alpha}=m^2$. The action corresponding to the Lagrangian is

$$I=\int L\,d\lambda=\int\left(m\,\frac{ds}{d\lambda}\right)d\lambda=\int m\,ds=\int m\left(g_{\alpha\beta}\,\frac{dx^{\alpha}}{ds}\,\frac{dx^{\beta}}{ds}\right)ds=\int p_{\alpha}\,dx^{\alpha}, \tag{4.17}$$

where we have used (4.14) and (4.15), respectively. However, in place of the action we can use a wave function

$$\Psi\equiv e^{-iI/\hbar} \tag{4.18}$$

involving Planck's constant. In terms of this, the momenta are given by

$$-i\hbar\nabla_\alpha\Psi=\frac{\partial}{\partial x^\alpha}\Psi\equiv p_\alpha\Psi. \tag{4.19}$$

If the p_α were constants as in flat space–time, they would be the eigenvalues and Ψ the eigenfunction of the 4D momentum operator. Now the p_α are not generally constants in curved space–time, but we can keep (4.19) as the defining relation for the momenta because the preceeding relations (4.14)–(4.18) are covariant. Then following the philosophy of induced-matter theory, the question is how to relate the particle formalism involving Ψ to the Kaluza–Klein equations (4.7) involving ϕ.

We answer this by adopting the ansatz

$$\phi\equiv\Psi^d, \tag{4.20}$$

where d is a dimensionless parameter. Then (4.11), (4.12) with (4.19), (4.20) give

$$R_{\alpha\beta}=-\frac{6d^2}{\hbar^2}p_\alpha p_\beta, \tag{4.21}$$

$$\Box\Psi+\frac{m^2}{\hbar^2}\Psi=0. \tag{4.22}$$

The corresponding induced energy–momentum tensor (4.13) is

$$T_{\alpha\beta}=-6\frac{d^2}{\hbar^2}\left(p_\alpha p_\beta-\frac{m^2}{2}g_{\alpha\beta}\right). \tag{4.23}$$

These relations make sense in the context of induced-matter theory and justify the assumption (4.20). Thus (4.22) is the curved-space–time Klein–Gordon equation. The implication is that for the harmonic gauge the extra potential of the 5D space is related to the wave function of the 4D space. That wave function, by (4.1), represents a conformal modification of space–time. It can be regarded, alternatively, as a particle with mass m and momenta p_α. Then (4.21) says that the de Broglie wavelengths associated with p_α describe by their product $p_\alpha p_\beta$ the curvature of the 4D space as represented by the Ricci tensor $R_{\alpha\beta}$. The corresponding energy–momentum tensor (4.13) is really a dynamical quantity, which by virtue of $\nabla_\alpha T^{\alpha\beta}=0$ can be shown to yield the standard equations of motion $p^\beta\nabla_\beta p^\alpha=0$. [See Ref. 6: It can be shown by some tedious algebra that the 4D Bianchi identities $\nabla_\alpha G^{\alpha\beta}=\nabla_\alpha T^{\alpha\beta}=0$ with (4.13) give relations which are the same as those derived from the 4D part of the 5D geodesic equation.] In other words, (4.13)–(4.20) are the field equations for what might be called Kaluza–Klein–Gordon field theory.

To go further, we need exact solutions. The most convenient way to show such is to write the 4D part of the metric as

$$ds^2=dt^2-e^{2\lambda}dx^2-e^{2\mu}dy^2-dz^2, \tag{4.24}$$

where $\lambda=\lambda(t,z)$ and $\mu=\mu(t,z)$. This metric can describe a plane wave moving in the z-direction.[10] We expect the associated particle to have momenta which are constants and given by (4.15) as

$$p_0=m\frac{dt}{ds}\equiv E,\quad p_1=0,\quad p_2=0,\quad p_3=-m\frac{dz}{ds}\equiv -p. \tag{4.25}$$

These particle properties are connected to the wave properties by the field equations (4.21) and (4.22). The components of (4.21) can be evaluated using (4.25) and read

$$
\begin{aligned}
R_{00} &= -(\lambda+\mu)_{00} - (\lambda_0^2+\mu_0^2) = -6d^2E^2/\hbar^2, \\
R_{03} &= -(\lambda+\mu)_{03} - (\lambda_0\lambda_3+\mu_0\mu_3) = 6d^2Ep/\hbar^2, \\
R_{33} &= -(\lambda+\mu)_{33} - (\lambda_3^2+\mu_3^2) = -6a^2p^2/\hbar^2, \\
R_{11} &= e^{2\lambda}[\lambda_{00}-\lambda_{33}+\lambda_0(\lambda+\mu)_0-\lambda_3(\lambda+\mu)_3] = 0, \\
R_{22} &= e^{2\mu}[\mu_{00}-\mu_{33}+\mu_0(\lambda+\mu)_0-\mu_3(\lambda+\mu)_3] = 0, \\
R_{\alpha\beta} &= 0 \quad \text{otherwise.}
\end{aligned}
\tag{4.26}
$$

It is obvious when written in this way that there is a solution given by

$$
\lambda = -\mu = \sqrt{3}a(Et-pz)/\hbar. \tag{4.27}
$$

This with (4.17) and (4.18) gives the action and the wave function, respectively,

$$
I = \int p_\alpha \, dx^\alpha = Et - pz, \tag{4.28}
$$

$$
\Psi = e^{-i(Et-pz)/\hbar}. \tag{4.29}
$$

The latter should satisfy the fifth or Klein–Gordon part of the field equations (4.22) and we find that it does so. The induced or effective 4D energy–momentum tensor given by (4.23) and (4.25) has the following nonzero components:

$$
\begin{aligned}
T^0{}_0 &= -6d^2(E^2-m^2/2)/\hbar^2, \\
T^0{}_3 &= -T^3{}_0 = 6d^2Ep/\hbar^2, \\
T^1{}_1 &= T^2{}_2 = 3d^2m^2/\hbar^2, \\
T^3{}_3 &= 6d^2(p^2+m^2/2)/\hbar^2.
\end{aligned}
\tag{4.30}
$$

These obey $T^\alpha{}_\alpha = 6d^2m^2/\hbar^2$, and we recall from (4.15) and (4.16) that E, p, and m are related by $p_\alpha p^\alpha = E^2 - p^2 = m^2$. This constraint means that we have a class of exact solutions that depends on two constants, E and p. [The dimensionless constant d which we introduced in (4.20) to connect the scalar field and the wave function could in principle be absorbed into E and p, or into $\hbar$.] We can sum up the 5D wave solutions by

$$
dS^2 = \Psi^{2d}\, ds^2 - \Psi^{-4d}\, dx^{4^2}, \tag{4.31}
$$

$$
ds^2 = dt^2 - e^{2\lambda}\, dx^2 - e^{-2\lambda}\, dy^2 - dz^2, \tag{4.32}
$$

$$
\Psi = e^{-i(Et-pz)/\hbar}, \quad \lambda = \sqrt{3}d(Et-pz)/\hbar. \tag{4.33}
$$

We have examined the algebraic properties of this class of solutions using GRTENSOR,[11] and apart from confirming $\hat{R}_{AB}=0$, we find $\hat{R}_{ABCD}\neq 0$ so that these solutions are not 4D curved and 5D flat like some others in the literature. [See Ref. 1; for (4.31)–(4.33) above we find for example that $\hat{R}_{1414} = -2d^2(3E^2+p^2)\Psi^{-4d}\neq 0$ and $K \equiv \hat{R}_{ABCD}\hat{R}^{ABCD}\neq 0$.] However, while the solutions (4.31)–(4.33) are in general curved, they have $\sqrt{-g}=1$ for the determinant of the 4D metric and so are algebraically special.

It is useful to review the argument of this section before discussing some implications. The nonelectromagnetic metric (4.1) with $\hat{R}_{AB}=0$ yields field equations (4.6), (4.7) with tensor and scalar parts. Together they give a Ricci scalar (4.8), and in the induced-matter picture[1] an energy–momentum tensor (4.9), both of which depend on a free parameter b. This is fixed as $b=-2$ by the harmonic condition (3.2), or alternatively by the requirement that matter depend on first-order derivatives of the scalar field. The resulting metric (4.10) has field equations (4.11), (4.12) and energy–momentum tensor (4.13). Conventional particle dynamics (4.14)–(4.19) can be connected to classical field theory via the ansatz (4.20), which effectively says that the wave function depends on the scalar field or fifth part of the metric, or equivalently on the conformal factor that modifies the 4D metric. The field equations are then (4.21) and (4.22), of which the latter is the Klein–Gordon equation with an effective particle mass m. The induced energy–momentum tensor (4.23) is actually a dynamical quantity, and the Bianchi identities of field theory yield the standard equations of motion of particle physics. The special solution (4.33) satisfies the field equations of classical Kaluza–Klein theory, but is written in terms of a wave function associated with quantum theory.

The implications of this are clear and can be summed up succinctly by the relation

$$m^2=\frac{k\hbar^2}{c^2}R. \tag{4.34}$$

Here we have conventional units for Planck's constant and the speed of light, and k is a coupling constant. But the essential thing is that a particle's rest mass can be related to the scalar curvature of the 4D subspace of a 5D manifold. This idea is not new (see Refs. 6–8), but the results of this section are significant in that they demonstrate its viability for a fairly wide class of x^4-independent metrics. However, two comments need to be made. First, it is not always possible to write the 4D Ricci tensor as a product of two (momentum) vectors as in (4.21). More work is needed on this, presumably using the Segré classification of the Ricci tensor. Second, we recall from differential geometry that the Ricci tensor $\tilde{R}$ in the frame where there is a 4D conformal factor ϕ^{2a} is related to the Ricci tensor R in the frame where there is no conformal factor by

$$\tilde{R}=\phi^{-2a}\left(R-6a\,\frac{\Box\phi}{\phi}+6a(1-a)\,\frac{\phi_\gamma\phi^\gamma}{\phi^2}\right). \tag{4.35}$$

This means that if the mass is known in one frame it is different in another frame by an amount that depends on the conformal factor. More work is needed on this in order to see how conformal factors relate to the observed hierarchy of particle masses.

V. CONCLUSION

The equations of 4D general relativity are succinct and in the form $R_{\alpha\beta}=0$ are known from the classical tests to be in agreement with observation. However, the dimensionality of the equations, as recognized by Einstein and Kaluza, is open. This has led to much work on Kaluza–Klein theory, supergravity, and superstrings. In the present article, we have gone back to basic issues, and looked at three overlapping problems in 5D theory with the field equations $\hat{R}_{AB}=0$.

Waves in 5D can be approached as in 4D, using a linearized metric and the harmonic gauge condition. However, the last is algebraically restrictive, and physically implies that the particle analogs of the gravitational and scalar waves are massless. Introducing conformal factors into the metric (a traditional step in Kaluza–Klein theory) generalizes the field equations, and imposing the harmonic gauge describes massless gravitons and photons. Now there is nothing heinous about this, but if 5D theory is to describe the real world then one needs to find a way to codify particles of finite mass. This can apparently be done if, again using a conformal factor, the field equations are rewritten so that the mass of a particle is defined by the scalar curvature of a 4D space embedded in a 5D space.

Our results follow because, as in the induced-matter approach to fluids,[1] we allow dependency on the extra coordinate. This algebraic latitude has not hitherto been much applied to elucidating the physical properties of waves and particles; and as noted at several places above, in this regard there are vistas to be explored.

APPENDIX: CONSERVATION OF THE LINEARIZED INDUCED STRESS–ENERGY TENSOR

As discussed in Sec. II, conservation of the induced stress–energy tensor in our linearized approximation will hold only if

$$\Box_M \partial_4 \hat{\psi}^{4\alpha} = 0. \tag{A1}$$

There are three cases in which this is satisfied and they are presented here.

Case 1: $\Box_M \hat{\psi}^{4\alpha} = 0$. The spin-1 field in this case is massless, and implies from the right-hand side of (2.25) that

$$-2\,\hat{\eta}^{4\gamma}\partial_\gamma \partial_4 \hat{\psi}^{4\alpha} = \hat{\eta}^{44}\partial_4^2 \hat{\psi}^{4\alpha}. \tag{A2}$$

This constraint does not have a direct physical interpretation but follows from the requirement that the stress–energy be conserved. The wave equations (2.24) and (2.26) allow for massive gravitons $(\partial_4 \hat{\psi}^{\alpha\beta} \neq 0)$ or massless gravitons $(\partial_4 \hat{\psi}^{\alpha\beta} = 0)$, and a massive $(\partial_4 \hat{\psi}^{44} \neq 0)$ or massless $(\partial_4 \hat{\psi}^{44} = 0)$ scalar field.

Case 2: $\partial_4 \hat{\psi}^{4\alpha} = 0$. This implies that the spin-1 field has no x^4 dependence and so $\hat{\psi}^{4\alpha} = \hat{\psi}^{4\alpha}(x^\Sigma)$. The gauge constraint equations (2.27) and (2.28) then reduce to

$$\partial_\alpha \hat{\psi}^{\alpha\beta} = 0, \tag{A3}$$

$$\partial_\alpha \hat{\psi}^{4\alpha} = -\partial_4 \hat{\psi}^{44}, \tag{A4}$$

and by operating on (A4) with ∂_4 and using the commutation of partial derivatives along with $\partial_4 \hat{\psi}^{4\alpha} = 0$, we see that

$$\partial_4^2 \hat{\psi}^{44} = 0. \tag{A5}$$

The wave equations (2.24)–(2.26) then reduce to

$$\Box_M \hat{\psi}^{\alpha\beta} = -2\,\hat{\eta}^{4\gamma}\partial_4 \partial_\gamma \hat{\psi}^{\alpha\beta} - \hat{\eta}^{44}\partial_4^2 \hat{\psi}^{\alpha\beta}, \tag{A6}$$

$$\Box_M \hat{\psi}^{4\alpha} = 0, \tag{A7}$$

$$\Box_M \hat{\psi}^{44} = -2\,\hat{\eta}^{4\gamma}\partial_4 \partial_\gamma \hat{\psi}^{44}. \tag{A8}$$

These are the wave equations for a massive graviton $(\partial_4 \hat{\psi}^{\alpha\beta} \neq 0)$ or massless graviton $(\partial_4 \hat{\psi}^{\alpha\beta} = 0)$, a massless spin-1 field and massive $(\partial_4 \hat{\psi}^{44} \neq 0)$ or massless $(\partial_4 \hat{\psi}^{44} = 0)$ scalar field.

Case 3: $\hat{\eta}_{4\alpha} = \hat{h}_{4\alpha} = 0 \Rightarrow \hat{g}_{4\alpha} = 0$. In this case the off-diagonal components of the flat-space metric and the perturbation tensor are set to zero from the outset, defining what we refer to as the natural frame. This automatically sets $\hat{\psi}_{4\alpha} = 0$ by the definition (2.13). Therefore the spin-1 field is removed from the theory in this frame, but can be reintroduced using a coordinate transformation involving the extra coordinate. The gauge constraints (2.27) and (2.28) reduce to

$$\partial_\alpha \hat{\psi}^{\alpha\beta} = 0, \tag{A9}$$

$$\partial_4 \hat{\psi}^{44} = 0. \tag{A10}$$

These simplify the wave equations (2.24) and (2.26) in the natural frame so [using (A10) in (2.26)] they become

$$\Box_M \hat{\psi}^{\alpha\beta} = -\hat{\eta}^{44} \partial_4^2 \hat{\psi}^{\alpha\beta}, \tag{A11}$$

$$\Box_M \hat{\psi}^{44} = 0. \tag{A12}$$

The scalar field in this case is massless, and the gravitons are massive if $\partial_4 \hat{\psi}^{\alpha\beta} \neq 0$ and massless if $\partial_4 \hat{\psi}^{\alpha\beta} = 0$. Since off-diagonal components are absent in the natural frame, we can use the coordinate transformation (2.16) to generate off-diagonal terms. In the natural frame, the coordinate transformation for the extra coordinate is

$$x^4 \rightarrow x'^4 = x^4 + \hat{\xi}^4 (x^\Sigma), \tag{A13}$$

where $\hat{\xi}^4$ obeys the wave equation

$$\Box_M \hat{\xi}^4 = 0. \tag{A14}$$

The off-diagonal components $\hat{\psi}_{4\alpha}$ transform [using $\partial_4 \hat{\xi}_\alpha = 0$ and (2.18)] as

$$\hat{\psi}_{4\alpha} \rightarrow \hat{\psi}'_{4\alpha} = \hat{\psi}_{4\alpha} - \partial_\alpha \hat{\xi}_4 . \tag{A15}$$

These equations can be compared to the coordinate transformation which shifts the electromagnetic vector potential in regular 5D Klauza–Klein theory

$$x^4 \rightarrow x'^4 = x^4 + \lambda (x^\Sigma), \tag{A16}$$

$$A_\alpha \rightarrow A'_\alpha = A_\alpha + \partial_\alpha \lambda (x^\Sigma).$$

This is the usual gauge freedom in electromagnetism, where the function λ satisfies

$$\Box_M \lambda = 0.$$

This implies that off-diagonal components $\hat{\psi}^{4\alpha}$ can be created in the same way as electromagnetic potentials A^α, and hence should resemble electromagnetic terms.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 5 MAY 1999

Classical and quantum mechanics of jointed rigid bodies with vanishing total angular momentum

Toshihiro Iwai
Department of Applied Mathematics and Physics, Kyoto University, Kyoto 606-8501, Japan

(Received 19 October 1998; accepted for publication 8 February 1999)

A gauge theoretical treatment proves to have been successful in the study of systems of point particles; the center-of-mass system is made into a principal fiber bundle, on which is defined a natural connection. The gauge theoretical approach may be generalized to be applicable to a system of rigid bodies. The present article deals with a system of two identical axially symmetric cylinders jointed together by a special type of joint. This system is the model made by Kane and Scher and reformulated later by Montgomery, in order to study the falling cats who can land on their legs when released upside down. With the no-twist condition, the system turns out to have the configuration space diffeomorphic with SO(3), which is made into a principal O(2) bundle over $\mathbf{R}P^2$, the real projective space of dimension two, and endowed with a natural connection. An optimal control problem for this system with the vanishing total angular momentum is satisfactorily treated in this bundle picture. Along with a certain performance index, the Maximum Principle gives rise to a Hamiltonian system on the cotangent bundle $T^*(\mathrm{SO}(3))$ of SO(3). This Hamiltonian system is shown to admit a symmetry group O(2), which is not the structure group, but comes from the material symmetry of the respective cylinders. Moreover, quantization of this ''classical'' system is carried out, giving rise to a quantum system with the constraints of the vanishing total angular momentum. Through the symmetry by the structure group O(2), the reduction procedure is performed for both the classical and the quantum systems. It then turns out that the respective reduced systems, classical and quantum, admit the material symmetry group O(2), in general.

I. INTRODUCTION

Systems of point particles have been successfully studied in the gauge theoretical manner; the center-of-mass system is made into a principal fiber bundle, on which is defined a natural connection. The bundle picture (or gauge theoretical method) for systems of point particles dates back to 1984 when Guichardet[1] first defined rotational and vibrational motions precisely and thereby showed that rotations cannot be separated from vibrations by the use of the connection theory or the gauge theory. As Guichardet[1] pointed out, the nonseparability of rotation and vibration has been known to cats who can land on their legs when launched in the air, that is, who can accomplish a rotation after a vibrational motion. The gauge theoretical method has been developed to study and analyze classical and quantum mechanics of many-particle systems.[2–10]

Systems of rigid bodies are more suitable than systems of point particles in the understanding of falling cats. In fact, before introduction of the bundle picture for many-particle systems, Kane and Scher[11] considered a system of rigid bodies as a model of the falling cat, and later Montgomery[12] gave it a bundle picture. In this article, the gauge theoretical approach is generalized to be applicable to systems of rigid bodies. In particular, a system of two identical axially symmetric cylinders jointed along their symmetry axes by a special kind of joint is studied in an explicit manner, after Kane and Scher[11] and Montgomery.[12] Under the no-twist condition, the present system has the configuration space diffeomorphic with SO(3), which is made into an O(2) principal fiber bundle over $\mathbf{R}P^2$, the real projective space of dimension two. This fact was first observed by Montgomery.[12] A natural connection is defined on this bundle, like the natural connection for systems of point particles. In this bundle picture, a control problem is well formulated for the jointed cylinders to move with the vanishing total angular momentum. Along with a performance index which describes the horizontal (or vibrational) kinetic energy, the Maximum Principle applied to the optimal control problem provides an optimal Hamiltonian system on the cotangent bundle $T^*(\mathrm{SO}(3))$ of SO(3), whose Hamiltonian flows, when projected on SO(3), bring about optimal paths for the control problem. The reduction of the optimal Hamiltonian system is performed through the structure group symmetry to show that, in general, the reduced phase space is not the cotangent bundle $T^*(\mathbf{R}P^2)$ of $\mathbf{R}P^2$, but a double cover of $T^*(\mathbf{R}P^2)$. Further, the reduced system is shown to admit the ''material'' symmetry group O(2).

With the optimal Hamiltonian system is associated a quantum system on SO(3), which may be looked upon as a quantum system with the constraint of the vanishing total angular momentum. In a simplified case, the energy eigenvalues and eigenfunctions can be calculated explicitly. Like the ''classical'' system, the quantum system on SO(3) is reduced, through the structure group symmetry, to a system defined on the vector bundle over $\mathbf{R}P^2$ with fiber $\mathbf{C}^2$, in general. It will be shown further that the ''material'' symmetry group O(2) has unitary representations in energy eigenspaces.

The organization of this article is as follows: Section II contains the setting up of a system of two identical axially symmetric cylinders jointed together by a special type of joint. The configuration space of this system is SO(3)$\times$SO(3), clearly made into an SO(3) principal fiber bundle with base space SO(3), a local section of which is obtained explicitly. In Sec. III, the no-twist condition is taken into account, with which the motion of the jointed cylinders is restricted to that without twist at the joint. It turns out that the no-twist configuration space is diffeomorphic with SO(3), which is made into a principal O(2) bundle over $\mathbf{R}P^2$. A close look is given at the structure group O(2) and at its action on SO(3) along with the explicit expression in terms of local coordinates. Section IV is concerned with the connection and the curvature defined on the principal bundle $\mathrm{SO}(3)\to\mathbf{R}P^2$. By using the connection, a control problem is well formulated for the jointed cylinders to move under the condition of the vanishing total angular momentum. In Sec. V, a metric is defined on SO(3) in association with the kinetic energy of the jointed cylinders. This metric is decomposed into the horizontal (or vibrational) and vertical (or rotational) components. By the use of the horizontal part of the metric, a performance index is defined to be the vibrational energy of the jointed cylinders, and thereby the above-mentioned control problem is set up as an optimal control problem. The Maximum Principle can then be applied to give rise to an optimal Hamiltonian system on the cotangent bundle $T^*(\mathrm{SO}(3))$ of SO(3), whose Hamiltonian function is equal to the vibrational energy of the jointed cylinders. In Sec. VI, the reduction of the optimal Hamiltonian system is performed through the symmetry by the structure group O(2) action. The reduced phase space proves to be not $T^*(\mathbf{R}P^2)$ but a double cover of it, in general. Section VII is concerned with the symmetry of the jointed cylinders, which results from the material symmetry of the cylinders. It is shown that both the optimal Hamiltonian system and its reduced system admits O(2) as a symmetry group. Section VIII is devoted to the quantization of the optimal Hamiltonian system obtained in Sec. V. The vibrational energy functional of wave functions gives rise to a Hamiltonian operator corresponding to the optimal Hamiltonian function. If the Hamiltonian operator is chosen in a simplified form, its eigenvalues can be obtained quite easily. Section IX contains the reduction and the symmetry of the quantum system set up in Sec. VIII. The reduced quantum system is defined on the vector bundle associated with the O(2) bundle $\mathrm{SO}(3)\to\mathbf{R}P^2$. The energy eigenspaces are obtained, in which the symmetry group O(2) is represented unitarily.

II. SETTING UP

Let a rigid body be laid in the space $\mathbf{R}^3$ in such a way that the principal axes of the inertia tensor relative to the center of mass of the rigid body are parallel to the standard basis $\mathbf{e}_j$, j

$=1,2,3$, of $\mathbf{R}^3$. Let $\mathbf{X}_\alpha$ denote the position vector of a point of the rigid body with respect to the frame of the principal axes placed at the center of mass, where α is a continuous parameter. Then a generic position vector $\mathbf{x}_\alpha$ of points of the rigid body is expressed as

$$\mathbf{x}_\alpha=\mathbf{r}+g\mathbf{X}_\alpha, \tag{2.1}$$

where $\mathbf{r}$ is the position vector of the center of mass of the rigid body and $g\in \mathrm{SO}(3)$. Equation (2.1) implies that one needs a pair $(\mathbf{r},g)\in\mathbf{R}^3\times\mathbf{SO}(3)$ to specify the position and the attitude of the rigid body.

In what follows, our interest will center on a system of two identical rigid bodies in the center-of-mass system. This means that we assume that the center of mass of the two identical rigid bodies are kept fixed at the origin of $\mathbf{R}^3$. Further, we assume that the rigid bodies are axially symmetric cylinders jointed together along their symmetry axes by a special type of joint. The joint is supposed to be ball-and-socket; that is, the joint will give no constraint on the relative motion of the cylinders other than that they are jointed. We assume that the symmetry axes of the respective cylinder are parallel to $g_1\mathbf{e}_3$ and $g_2\mathbf{e}_3$, where $g_1,g_2\in\mathrm{SO}(3)$ denote the attitude of each body half. Let ℓ be the distance of each body half's center of mass from the joint. Then the center of mass of each body half is pointed by $\mathbf{r}_i=\ell g_i\mathbf{e}_3-\ell/2(g_1\mathbf{e}_3+g_2\mathbf{e}_3)$, $i=1,2$. This means that $\mathbf{r}_1$ and $\mathbf{r}_2$ are determined by g_1 and g_2. Hence, the configuration of our jointed cylinders is described by a pair (g_1,g_2) of rotation matrices. Thus, the configuration space of our system is the product space $Q:=\mathrm{SO}(3)\times\mathrm{SO}(3)$, on which the rotation group SO(3) acts in a natural manner,

$$(g_1,g_2)\mapsto(kg_1,kg_2),\quad k\in\mathrm{SO}(3). \tag{2.2}$$

Since SO(3) is compact and acts freely on Q, the factor space $Q/\mathrm{SO}(3)$ becomes a manifold. The natural projection to the factor space is obviously given by

$$\pi:(g_1,g_2)\mapsto g_1^{-1}g_2, \tag{2.3}$$

which means that the factor space is diffeomorphic with SO(3). This factor space is called the shape space, which consists of shapes of our jointed cylinders.

Let $g_1^{-1}g_2\in\mathrm{SO}(3)$ be expressed in terms of the Euler angles such that

$$g_1^{-1}g_2=e^{-\theta_1\hat{\mathbf{e}}_3}e^{\psi\hat{\mathbf{e}}_1}e^{\theta_2\hat{\mathbf{e}}_3},\quad 0\leqslant\theta_1\leqslant 2\pi,\;\; 0\leqslant\psi\leqslant\pi,\;\; 0\leqslant\theta_2\leqslant 2\pi, \tag{2.4}$$

where $\hat{\mathbf{e}}_j$, $j=1,2,3$, are the 3×3 skew-symmetric matrices defined, in general, to be

$$\hat{\mathbf{a}}=\begin{pmatrix} 0 & -a_3 & a_2 \\ a_3 & 0 & -a_1 \\ -a_2 & a_1 & 0 \end{pmatrix}\quad \text{for}\;\; \mathbf{a}=\sum_{j=1}^{3} a_j\mathbf{e}_j\in\mathbf{R}^3. \tag{2.5}$$

Then we are allowed to describe (g_1,g_2) as

$$\begin{aligned} g_1&=he^{-\psi/2\hat{\mathbf{e}}_1}e^{\theta_1\hat{\mathbf{e}}_3},\\ g_2&=he^{\psi/2\hat{\mathbf{e}}_1}e^{\theta_2\hat{\mathbf{e}}_3}, \end{aligned}\quad h\in\mathrm{SO}(3). \tag{2.6}$$

This expression is capable of natural interpretation; the body half 1 (respectively, 2) is first laid in the space $\mathbf{R}^3$ in such a way that its symmetry axis is parallel to $\mathbf{e}_3$, and then rotated around the $\mathbf{e}_3$ axis by θ_1 (respectively, by θ_2) and further on around the $\mathbf{e}_1$ axis by $-\psi/2$ (respectively, by $\psi/2$). Thus ψ stands for the angle made by the symmetry axes of respective body halves, and θ_1 and θ_2 are the rotation angles of the respective body halves around their symmetry axes. The jointed rigid bodies laid tentatively along the $\mathbf{e}_2-\mathbf{e}_3$ plane are acted on by $h\in\mathrm{SO}(3)$ to take a generic attitude in the space $\mathbf{R}^3$.

We have to point out here that if $\psi=0$ or π a pair of rotation angles (θ_1,θ_2) are not determined uniquely from the shape of the jointed cylinders. In fact, if $\psi=0$ (respectively, $\psi=\pi$), the shapes of the jointed cylinders designated by the pairs of rotation angles (θ_1,θ_2) and (θ_1+c,θ_2+c) [respectively, (θ_1,θ_2) and (θ_1-c,θ_2+c)] with $c\in\mathbf{R}^3$ are not distinguished from each other. This singularity of the Euler angles at $\psi=0$ or π can be observed from (2.4) as well.

Equation (2.6) also describes the local triviality of our principal SO(3) bundle, $Q\to SO(3)$. In fact, for an open subset U of SO(3) designated by the Euler angles (θ_1,θ_2,ψ) with $\psi\neq 0$, π, a local section $\sigma=(\sigma_1,\sigma_2)$: U→SO(3)×SO(3) is defined to be

$$\begin{aligned}\sigma_1(\theta_1,\theta_2,\psi)&=e^{-\psi/2\hat{\mathbf{e}}_1}e^{\theta_1\hat{\mathbf{e}}_3},\\ \sigma_2(\theta_1,\theta_2,\psi)&=e^{\psi/2\hat{\mathbf{e}}_1}e^{\theta_2\hat{\mathbf{e}}_3},\end{aligned}\tag{2.7}$$

and thereby the local triviality $\pi^{-1}(\mathrm{U})\cong\mathrm{U}\times SO(3)$ is realized as $(g_1,g_2)=(h\sigma_1,h\sigma_2)$, as is seen from (2.6).

Another local coordinate system is also possible. If we start with

$$g_1^{-1}g_2=e^{-\theta_1\hat{\mathbf{e}}_2}e^{2\phi\hat{\mathbf{e}}_1}e^{\theta_2\hat{\mathbf{e}}_2},\quad 0\leqslant\theta_1\leqslant 2\pi,\ \ 0\leqslant 2\phi\leqslant\pi,\ \ 0\leqslant\theta_2\leqslant 2\pi,\tag{2.8}$$

in place of (2.4), we will obtain the following local section in place of (2.7);

$$\begin{aligned}\tau_1(\theta_1,\theta_2,\phi)&=e^{-\phi\hat{\mathbf{e}}_1}e^{\theta_1\hat{\mathbf{e}}_2},\\ \tau_2(\theta_1,\theta_2,\phi)&=e^{\phi\hat{\mathbf{e}}_1}e^{\theta_2\hat{\mathbf{e}}_2}.\end{aligned}\tag{2.9}$$

This local section allows of an interpretation; at first we assume that the symmetry axes of respective body halves are oriented in such a way that the positive direction is outward from the joint. With this assumption, the body half 1 (respectively, 2) is set in such a way that its symmetry axis is in parallel with $-\mathbf{e}_2$ (respectively, $\mathbf{e}_2$), then rotated around $\mathbf{e}_2$ by θ_1 (respectively, θ_2) and further on around $\mathbf{e}_1$ by $-\phi$ (respectively, ϕ). Thus, the jointed body halves are laid tentatively in the $\mathbf{e}_2-\mathbf{e}_3$ plane, which will be rotated, as a whole, by the action of SO(3) to take its generic position;

$$(g_1,g_2)=(k\tau_1,k\tau_2),\quad k\in SO(3).\tag{2.10}$$

III. NO-TWIST CONFIGURATION SPACE

Our system of jointed cylinders is a model of the cat that somersaults when launched in the air. Kane and Scher[11] imposed the no-twist condition on the jointed cylinders, which implies that two of body halves rotate around the respective symmetry axes without twist at the joint. According to Montgomery,[12] the no-twist condition is characterized as follows: Let ϵ be a rotation such that $\epsilon^2=I$. Then an involution i acting on SO(3)×SO(3) is defined as

$$i(g_1,g_2)=(\epsilon g_2\epsilon,\epsilon g_1\epsilon).\tag{3.1}$$

The no-twist configuration space is defined to be the subset of fixed points for i,

$$Q_0=\{(g_1,g_2)\in SO(3)\times SO(3);\ \ i(g_1,g_2)=(g_1,g_2)\}.\tag{3.2}$$

The fixed-point condition $\epsilon g_1\epsilon=g_2$ implies that Q_0 is diffeomorphic with SO(3),

$$Q_0=\{(g,\epsilon g\epsilon);\quad g\in SO(3)\}\cong SO(3).\tag{3.3}$$

Further, to see that Q_0 is indeed subject to the no-twist condition of Kane and Scher, we choose to express ϵ and an arbitrary point (g_1,g_2) of the total space, respectively, as

$$\epsilon = e^{\pi \hat{\mathbf{e}}_2}, \quad \begin{cases} g_1 = e^{\chi_1 \hat{\mathbf{e}}_2} e^{\phi_1 \hat{\mathbf{e}}_1} e^{\theta_1 \hat{\mathbf{e}}_2}, \\ g_2 = e^{\chi_2 \hat{\mathbf{e}}_2} e^{\phi_2 \hat{\mathbf{e}}_1} e^{\theta_2 \hat{\mathbf{e}}_2}. \end{cases} \tag{3.4}$$

Then, the condition $\epsilon g_2 \epsilon = g_1$ implies that

$$\chi_1 = \chi_2, \quad \phi_1 = -\phi_2, \quad \theta_1 = \theta_2, \tag{3.5}$$

where use has been made of $e^{\pi \hat{\mathbf{e}}_2} e^{t \hat{\mathbf{e}}_1} = e^{-t \hat{\mathbf{e}}_1} e^{\pi \hat{\mathbf{e}}_2}$, $t \in \mathbf{R}$. Setting $\chi_1 = \chi_2 = \chi$, $\phi_1 = -\phi_2 = -\phi$, $\theta_1 = \theta_2 = \theta$ in (3.4), one has

$$\begin{aligned} g_1 &= e^{\chi \hat{\mathbf{e}}_2} e^{-\phi \hat{\mathbf{e}}_1} e^{\theta \hat{\mathbf{e}}_2}, \\ g_2 &= e^{\chi \hat{\mathbf{e}}_2} e^{\phi \hat{\mathbf{e}}_1} e^{\theta \hat{\mathbf{e}}_2}, \end{aligned} \quad 0 \leqslant \chi \leqslant 2\pi, \ 0 \leqslant \phi \leqslant \pi, \ 0 \leqslant \theta \leqslant 2\pi, \tag{3.6}$$

which is a specialization of (2.9) and (2.10). We are then allowed to interpret that the body halves are rotated by the same angle θ around respective symmetry axes without twist at the joint. However, the structure group SO(3) has reduced to a subgroup.

Now we wish to study to what subgroup the structure group reduces. A first glance at (3.6) will tempt us to be convinced that the structure group SO(3) has reduced to a one-parameter subgroup SO(2) which consists of $e^{\chi \hat{\mathbf{e}}_2}$. However, the reduced structure group is not SO(2) but O(2).[12] To see this, one has to be aware of the fact that if ϕ is increased by $\pi (\phi \mapsto \phi + \pi)$, each of the body halves is rotated about $\mathbf{e}_1$ to be set in the direction opposite to the previous one, so that the shape of the jointed cylinders is not altered. In fact, one verifies from (3.6) that $\pi(g_1, g_2) = e^{-\theta \hat{\mathbf{e}}_2} e^{2\phi \hat{\mathbf{e}}_1} e^{\theta \hat{\mathbf{e}}_2}$ does not change under the transformation $\theta \mapsto \phi + \pi$. This means that the jointed cylinders do not change in shape. Under the transformation $\phi \mapsto \phi + \pi$, one has the factor $e^{\chi \hat{\mathbf{e}}_2} e^{\pi \hat{\mathbf{e}}_1}$ in the expression of g_1 and g_2 in (3.6). Written out, $e^{\chi \hat{\mathbf{e}}_2} e^{\pi \hat{\mathbf{e}}_1}$ is expressed as

$$e^{\chi \hat{\mathbf{e}}_2} e^{\pi \hat{\mathbf{e}}_1} = \begin{pmatrix} \cos\chi & 0 & -\sin\chi \\ 0 & -1 & 0 \\ -\sin\chi & 0 & -\cos\chi \end{pmatrix}, \tag{3.7}$$

which describes an action of O(2) in the $\mathbf{e}_3 - \mathbf{e}_1$ plane. Thus the reduced structure group turns out to be O(2);

$$\mathrm{O}(2) = \mathrm{SO}(2) \cup \mathrm{SO}(2) e^{\pi \hat{\mathbf{e}}_1} \quad \text{with } \mathrm{SO}(2) = \{ e^{\chi \hat{\mathbf{e}}_2} \}. \tag{3.8}$$

We notice, for confirmation, that this subgroup is indeed closed under multiplication. In fact, one can easily verify that

$$e^{\chi_1 \hat{\mathbf{e}}_2} e^{\pi \hat{\mathbf{e}}_1} e^{\chi_2 \hat{\mathbf{e}}_2} e^{\pi \hat{\mathbf{e}}_1} = e^{(\chi_1 - \chi_2) \hat{\mathbf{e}}_2} \tag{3.9}$$

which also implies that O(2) is not Abelian.

Accompanying the reduction of the structure group, the base space will reduce to $Q_0/\mathrm{O}(2) \cong \mathrm{SO}(3)/\mathrm{O}(2)$, which is diffeomorphic with $S^2/Z_2 \cong \mathbf{R}P^2$, the real projective space of dimension two. Restricting the projection given in (2.3) to the subset Q_0 ($\pi_0 := \pi|_{Q_0}$), one must have $\pi_0(Q_0) \cong \mathbf{R}P^2$. That is, $\pi_0(Q_0)$ must be an embedding of $\mathbf{R}P^2$ in SO(3), which can be verified as follows: From (3.6) it follows that

$$\pi_0(g_1, g_2) = g_1^{-1} g_2 = e^{-\theta \hat{\mathbf{e}}_2} e^{2\phi \hat{\mathbf{e}}_1} e^{\theta \hat{\mathbf{e}}_2}. \tag{3.10}$$

We then set

$$\begin{aligned} x_3 &= \sin\phi \cos\theta, \\ x_1 &= \sin\phi \sin\theta, \\ x_2 &= \cos\phi, \end{aligned} \quad 0 \leqslant \theta \leqslant 2\pi, \ 0 \leqslant \phi \leqslant \pi/2, \tag{3.11}$$

and form the matrix $X=(x_i x_j)$, $i,j=1,2,3$, which represents a point of $\mathbf{R}P^2$. Then we obtain, after calculation,

$$\mathrm{diag}(1,-1,-1)(I_3-2X)\mathrm{diag}(1,1,-1)=e^{-\theta\hat{\mathbf{e}}_2}e^{2\phi\hat{\mathbf{e}}_1}e^{\theta\hat{\mathbf{e}}_2}, \tag{3.12}$$

where I_3 is the 3×3 identity matrix. This provides the embedding of $\mathbf{R}P^2$ into SO(3). From (3.10) and (3.12), it follows that $\pi_0(Q_0)\cong\mathbf{R}P^2$. We note in addition that

$$e^{-\theta\hat{\mathbf{e}}_2}e^{2\phi\hat{\mathbf{e}}_1}e^{\theta\hat{\mathbf{e}}_2}=e^{2\phi(\hat{\mathbf{e}}_1\cos\theta+\hat{\mathbf{e}}_3\sin\theta)}, \tag{3.13}$$

which means that $(2\phi,\theta)$ serve as ''polar'' coordinates of the projective plane $\mathbf{R}P^2$. Thus we have the following:

Proposition 1: The configuration space Q_0 of the jointed cylinders with no-twist condition is diffeomorphic with SO(3), which is made into a principal O(2) bundle with base space $\mathbf{R}P^2$. Equation (3.6) provides a local coordinate system of this bundle.

In conclusion, we are to describe the structure group action in terms of local coordinates (χ,ϕ,θ). Letting $e^{t\hat{\mathbf{e}}_2}$ and $e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}$ act to the left on Q_0, one obtains, from (3.6),

$$\begin{aligned} e^{t\hat{\mathbf{e}}_2}&: \quad (\chi,\phi,\theta)\mapsto(\chi+t,\phi,\theta),\\ e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}&: \quad (\chi,\phi,\theta)\mapsto(-\chi+t,\phi+\pi,\theta), \end{aligned} \tag{3.14}$$

respectively, where use has been made of $e^{\pi\hat{\mathbf{e}}_1}e^{\chi\hat{\mathbf{e}}_2}=e^{-\chi\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}$.

IV. CONNECTION AND CURVATURE

We are interested in making our system move with the condition of the vanishing total angular momentum. To this end, we calculate both the total angular momentum and the total inertia tensor of our system, and thereby define a connection form.

From (2.1), the angular momentum of a rigid body is given by and calculated as

$$\sum_\alpha m_\alpha \mathbf{x}_\alpha\times d\mathbf{x}_\alpha=m\mathbf{r}\times d\mathbf{r}+gA_0\mathbf{\Theta}, \tag{4.1}$$

where Σ_α stands for the sum throughout the body, $m=\Sigma_\alpha m_\alpha$ is the total mass of the rigid body, A_0 is the inertia tensor of the rigid body around its center of mass, which is expressed, from the assumption we have made in the last paragraph of Sec. II, as

$$A_0=\mathrm{diag}(I_1,I_2,I_3), \quad I_3=I_1 \tag{4.2}$$

with respect to the standard basis $\mathbf{e}_j$, $j=1,2,3$, and $\mathbf{\Theta}$ is the vector of one-forms defined through

$$g^{-1}dg=\hat{\mathbf{\Theta}}. \tag{4.3}$$

The total angular momentum, $\mathbf{\Lambda}$, of our system is the sum of the angular momentum of the respective cylinders;

$$\mathbf{\Lambda}=\sum_{i=1}^{2} m\mathbf{r}_i\times d\mathbf{r}_i+\sum_{i=1}^{2} g_i A_0\mathbf{\Theta}_i, \tag{4.4}$$

where the subscripts $i=1,2$ indicate that the subscripted quantities ($\mathbf{r}_i$, etc.) are concerned with the respective body halves 1 and 2.

We are going to calculate the total angular momentum $\mathbf{\Lambda}$ in terms of the local coordinates given in (3.6). We assume that our system is a center-of-mass system, that is, the center of mass of the jointed cylinders is kept fixed at the origin. The position vectors, $\mathbf{r}_1$ and $\mathbf{r}_2$, of the center of mass of the respective body halves are then given by

$$\mathbf{r}_1 = -\ell (g_1 \mathbf{e}_2 \cdot \mathbf{e}_2)\mathbf{e}_2, \quad \mathbf{r}_2 = \ell (g_2 \mathbf{e}_2 \cdot \mathbf{e}_2)\mathbf{e}_2, \tag{4.5}$$

where ℓ is the distance of the center of mass of the respective body halves from the joint, and g_1, g_2 are the matrices given in (3.6). A straightforward calculation then provides

$$\mathbf{r}_1 \times d\mathbf{r}_1 + \mathbf{r}_2 \times d\mathbf{r}_2 = 0, \tag{4.6}$$

which implies that the first term of the right-hand side of (4.4) vanishes. As for the latter term of the right-hand side of (4.4), we obtain, after a straightforward calculation,

$$\sum_{i=1}^{2} g_i A_0 \mathbf{\Theta}_i = 2((I_1 \sin^2\phi + I_2 \cos^2\phi)d\chi + I_2 \cos\phi\, d\theta)\mathbf{e}_2. \tag{4.7}$$

From (4.4) along with (4.6), and (4.7), it follows that

$$\mathbf{\Lambda} = 2((I_1 \sin^2\phi + I_2 \cos^2\phi)d\chi + I_2 \cos\phi d\theta)\mathbf{e}_2. \tag{4.8}$$

We turn to the inertia tensor of the jointed cylinders. From (2.1), the inertia tensor of a rigid body as a map of $\mathbf{R}^3$ to $\mathbf{R}^3$ is defined to be and calculated as

$$\sum_{\alpha} m_\alpha \mathbf{x}_\alpha \times (\mathbf{v} \times \mathbf{x}_\alpha) = m\mathbf{r} \times (\mathbf{v} \times \mathbf{r}) + gA_0 g^{-1}\mathbf{v}, \tag{4.9}$$

where $\mathbf{v} \in \mathbf{R}^3$, and m and A_0 are the same as those in (4.1). The total inertia tensor, A_q: $\mathbf{R}^3 \to \mathbf{R}^3$, $q \in Q_0$, is the sum of those for respective body halves;

$$A_q \mathbf{v} = \sum_{i=1}^{2} m\mathbf{r}_i \times (\mathbf{v} \times \mathbf{r}_i) + \sum_{i=1}^{2} g_i A_0 g_i^{-1}\mathbf{v}, \quad q \in Q_0. \tag{4.10}$$

As for the first term on the right-hand side of (4.10), one obtains, after a calculation, the matrix,

$$\left(\mathbf{e}_j \cdot \sum_{i=1}^{2} (\mathbf{r}_i \times (m\mathbf{e}_k \times \mathbf{r}_i)) \right)_{j,k=1,2,3} = 2m\ell^2 \operatorname{diag}(\cos^2\phi, 0, \cos^2\phi). \tag{4.11}$$

Further calculation with g_1 and g_2 given in (3.6) provides

$$\sum_{i=1}^{2} g_i A_0 g_i^{-1} = 2\begin{pmatrix} A_1\cos^2\chi + A_3\sin^2\chi & 0 & -A_1\cos\chi\sin\chi + A_3\cos\chi\sin\chi \\ 0 & A_2 & 0 \\ -A_1\cos\chi\sin\chi + A_3\cos\chi\sin\chi & 0 & A_1\sin^2\chi + A_3\cos^2\chi \end{pmatrix}, \tag{4.12}$$

where

$$\begin{aligned} A_1 &= I_1, \\ A_2 &= I_1 \sin^2\phi + I_2 \cos^2\phi, \\ A_3 &= I_1 \cos^2\phi + I_2 \sin^2\phi. \end{aligned} \tag{4.13}$$

Hence the total inertia tensor A_q is put in the matrix form as the sum of the right-hand sides of (4.11) and (4.12).

In the same manner as in particle systems, the connection form is defined to be

$$\omega_q = \widehat{A_q^{-1}\Lambda_q}, \quad q \in Q_0, \tag{4.14}$$

and turns out, from (4.8), (4.11), and (4.12), to be expressed as

$$\omega = \left(d\chi + \frac{I_2 \cos\phi}{I_1 \sin^2\phi + I_2 \cos^2\phi} d\theta \right) \hat{\mathbf{e}}_2 . \tag{4.15}$$

We have to notice here that the ω satisfies the following equations:

$$\omega\left(\frac{\partial}{\partial\chi}\right) = \hat{\mathbf{e}}_2, \quad \frac{\partial}{\partial\chi} = \frac{d}{dt} e^{t\hat{\mathbf{e}}_2} q \bigg|_{t=0},$$

$$\omega_{gq} = \mathrm{Ad}_g\, \omega_q, \quad g \in \mathrm{O}(2), \quad q \in Q_0 . \tag{4.16}$$

In what follows, we introduce the parameter

$$\lambda = I_2 / I_1 . \tag{4.17}$$

Then the ω takes the form

$$\omega = \left(d\chi + \frac{\lambda \cos\phi\, d\theta}{\sin^2\phi + \lambda \cos^2\phi} \right) \hat{\mathbf{e}}_2 . \tag{4.18}$$

A vector field X on Q_0 is called horizontal (or vibrational) if it satisfies $\omega(X)=0$. One can easily observe, from (4.18), that the following vector fields are independent horizontal ones:

$$X_1 = \frac{\partial}{\partial\phi}, \quad X_2 = \frac{\partial}{\partial\theta} - \frac{\lambda\cos\phi}{\sin^2\phi + \lambda\cos^2\phi} \frac{\partial}{\partial\chi}. \tag{4.19}$$

A curve $q(t)$ in Q_0 is called horizontal, if its tangent vector $\dot{q}(t)$ is horizontal at any point $q(t)$. Hence, any smooth horizontal curve $q(t)$ is subject to a differential equation

$$\frac{dq}{dt} = u_1 X_1 + u_2 X_2, \tag{4.20}$$

where u_1, u_2 are functions of t. Since $\omega(\dot{q})=0$ is equivalent to $\Lambda_q(\dot{q})=0$, as is observed from (4.14), Eq. (4.20) means kinematically that a curve $q(t)$ satisfying (4.20) describes a motion of the no-twist jointed cylinders with the vanishing total angular momentum.

The curvature of the connection ω is defined, in general, to be

$$\Omega = d\omega - \omega \wedge \omega, \tag{4.21}$$

where the minus sign on the right-hand side of (4.21) is due to the left action of the structure group, in our case. We notice here that from (4.16) the Ω is also subject to the transformation

$$\Omega_{gq} = \mathrm{Ad}_g\, \Omega_q, \quad g \in \mathrm{O}(2), \quad q \in Q_0 . \tag{4.22}$$

Applying the formula (4.21) to (4.18), we obtain the connection form Ω on Q_0,

$$\Omega = -\lambda \frac{1 + (1-\lambda)\cos^2\phi}{(\sin^2\phi + \lambda\cos^2\phi)^2} \sin\phi\, d\phi \wedge d\theta\ \hat{\mathbf{e}}_2 . \tag{4.23}$$

A casual glance at (4.23) makes us tend to think of Ω as defined on the base space $\mathbf{R}P^2$, since (4.23) is independent of χ, the vertical coordinate. However, the curvature form Ω defined on Q_0 does not project to a two form on $\mathbf{R}P^2$. This is because Ω is not invariant under the action of the structure group O(2). In fact, for $g=e^{\pi\hat{\mathbf{e}}_1}\in \mathrm{O}(2)$, on account of (4.22) along with $e^{\pi\hat{\mathbf{e}}_1}\hat{\mathbf{e}}_2 e^{-\pi\hat{\mathbf{e}}_1}=-\hat{\mathbf{e}}_2$, the curvature form Ω is subject to $\Omega_{gq}=-\Omega_q$.

The curvature form (4.23) seems to vanish if $\phi=0$, i.e., if the body halves get in line. However, it does not vanish, as we show in the following. The factor two-form $\sin\phi\, d\phi\wedge d\theta$ on the right-hand side of (4.23) does not vanish even if $\phi=0$, since this form is a kind of an area form defined in an open subset containing the ''origin'' of the polar coordinates $(2\phi,\theta)$ [see (3.13)] in the projective plane $\mathbf{R}P^2$. In fact, on setting $\xi_1=\sin(\phi/2)\cos\theta$, $\xi_2=\sin(\phi/2)\sin\theta$, one obtains $d\xi_1\wedge d\xi_2=\frac{1}{4}\sin\phi\, d\phi\wedge d\theta$. On the other hand, if $\lambda>2$, one has $1+(1-\lambda)\cos^2\phi>0$ in (4.23). However, the condition $\lambda>2$ is satisfied for any axially symmetric cylinder. In the same manner, we see that Ω does not vanish if $\phi=\pi$. Thus we observe that the curvature form vanishes nowhere on Q_0.

V. AN OPTIMAL HAMILTONIAN SYSTEM

Equation (4.20) defines a control problem, if u_1 and u_2 are regarded as control variables, and if a performance index is given. To define a performance index, we consider the metric on Q_0 which is associated with the kinetic energy of the no-twist jointed cylinders.

By using (2.1), the metric associated with the kinetic energy for a rigid body is given by and calculated as

$$\sum_{\alpha} m_\alpha d\mathbf{x}_\alpha\cdot d\mathbf{x}_\alpha=m\, d\mathbf{r}\cdot d\mathbf{r}+\mathbf{\Theta}\cdot A_0\mathbf{\Theta}, \tag{5.1}$$

where m is the mass of the rigid body and $\mathbf{\Theta}$ is the vector of one-forms defined by (4.3). The metric of our system is then defined to be

$$ds^2=\sum_{i=1}^{2} m\, d\mathbf{r}_i\cdot d\mathbf{r}_i+\sum_{i=1}^{2}\mathbf{\Theta}_i\cdot A_0\mathbf{\Theta}_i. \tag{5.2}$$

From (4.5), it follows that

$$\sum_{i=1}^{2} m\, d\mathbf{r}_i\cdot d\mathbf{r}_i=2m\ell^2\sin^2\phi\, d\phi^2. \tag{5.3}$$

In a similar manner, one obtains

$$\sum_{i=1}^{2}\mathbf{\Theta}_i\cdot A_0\mathbf{\Theta}_i=2I_1(\sin^2\phi\, d\chi^2+d\phi^2)+2I_2(\cos\phi\, d\chi+d\theta)^2. \tag{5.4}$$

The sum of the right-hand sides of (5.3) and (5.4) provides the metric ds^2, as is desired. In view of the connection form (4.18), we put the metric in the form

$$\begin{aligned} ds^2=2I_1&\left[(1+\kappa\sin^2\phi)d\phi^2+\frac{\lambda\sin^2\phi}{\sin^2\phi+\lambda\cos^2\phi}d\theta^2\right]\\ &+2I_1\left[(\sin^2\phi+\lambda\cos^2\phi)\left(d\chi+\frac{\lambda\cos\phi}{\sin^2\phi+\lambda\cos^2\phi}d\theta\right)^2\right], \end{aligned}\tag{5.5}$$

where

$$\kappa=m\ell^2/I_1. \tag{5.6}$$

The last term of the right-hand side of (5.5) is the vertical (or rotational) component which vanishes for X_1, X_2 given in (4.19), and the first term is the horizontal (or vibrational) component which vanishes for the vertical vector field $\partial/\partial\chi$, the infinitesimal generator of the structure group action. Since ds^2 is O(2) invariant, as is observed from the transformation (3.14) applied to (5.5), the metric ds^2 projects to the base space $Q_0/\mathrm{O}(2)\cong \mathbf{R}P^2$, defining a metric

$$ds_0^2 := 2I_1\left[(1+\kappa\sin^2\phi)d\phi^2 + \frac{\lambda\sin^2\phi}{\sin^2\phi+\lambda\cos^2\phi}d\theta^2\right]. \tag{5.7}$$

To be strict, ds_0^2 is defined through

$$ds_0^2(\partial/\partial\phi,\partial/\partial\theta) := ds^2(X_1,X_2), \quad \text{etc.}, \tag{5.8}$$

where X_1, X_2 are the horizontal vector fields given in (4.19), which project to $\partial/\partial\phi$, $\partial/\partial\theta$, respectively; $\pi_{0*}X_1 = \partial/\partial\phi$, $\pi_{0*}X_2 = \partial/\partial\theta$.

We proceed to the cotangent bundle $T^*(Q_0)\cong T^*(\mathrm{SO}(3))$ which is endowed with the standard one-form expressed as

$$\Theta = p_\chi d\chi + p_\phi d\phi + p_\theta d\theta, \tag{5.9}$$

where $(p_\chi, p_\phi, p_\theta)$ are related to tangent vectors $(\dot\chi, \dot\phi, \dot\theta)$ through ds^2;

$$p_\chi d\chi + p_\phi d\phi + p_\theta d\theta = ds^2\left(\dot\chi\frac{\partial}{\partial\chi} + \dot\phi\frac{\partial}{\partial\phi} + \dot\theta\frac{\partial}{\partial\theta}, \cdot\right). \tag{5.10}$$

Let us denote the horizontal metric tensor by

$$h_{ij} := ds^2(X_i, X_j), \quad i,j=1,2, \tag{5.11}$$

which are actually given in (5.7), because of (5.8).

Now we are going to consider the control problem (4.20), wishing to determine controls u_1, u_2 in such a way that the performance index

$$\frac{1}{2}\int_0^T \sum_{i,j=1}^{2} h_{ij}(q(t))u_i(t)u_j(t)dt \tag{5.12}$$

is minimized among all controls which steer the state $q(t)\in Q_0$ from an initial state q_0 to a final state q_1 in time T. To apply the Maximum Principle to this problem, we define the conjugate variables by

$$P_1 := \Theta(X_1) = p_\phi, \quad P_2 := \Theta(X_2) = p_\theta - \frac{\lambda\cos\phi}{\sin^2\phi+\lambda\cos^2\phi}p_\chi, \tag{5.13}$$

where X_1, X_2 are given by (4.19). Then the Maximum Principle tells us that optimal controls for normal extremals are determined so that the function

$$\mathcal{H} = \sum_{i=1}^{2} u_i P_i - \frac{1}{2}\sum_{i,j=1}^{2} h_{ij}u_i u_j \tag{5.14}$$

may take its maximum value in u_i. Thus one obtains the optimal control $u_i = \Sigma_{j=1}^2 h^{ij}P_j$ with $(h^{ij}) = (h_{ij})^{-1}$, and thereby the optimal Hamiltonian

$$H=\frac{1}{2}\sum_{i,j=1}^{2} h^{ij}P_iP_j=\frac{1}{4I_1}\left(\frac{1}{1+\kappa\sin^2\phi}p_\phi^2+\frac{\sin^2\phi+\lambda\cos^2\phi}{\lambda\sin^2\phi}\left(p_\theta-\frac{\lambda\cos\phi}{\sin^2\phi+\lambda\cos^2\phi}p_\chi\right)^2\right). \tag{5.15}$$

Thus we have the following:

Proposition 2: The optimal control problem described by (4.20) together with the performance index (5.12) gives rise to the Hamiltonian system $(T^*(Q_0),d\Theta,H)$, where $d\Theta$ is the differential of (5.9) and H is the Hamiltonian given by (5.15).

According to Montgomery,[11] abnormal extremals for $\mathcal{H}$ do not occur when the curvature does not vanish, so that our optimal control problem can be solved through the normal extremals only. Hence, optimal paths are obtained by projecting trajectories for the optimal Hamiltonian system $(T^*(Q_0),d\Theta,H)$ to the base space Q_0.

We note in addition that the Hamiltonian (5.15) is just equal to the horizontal (or vibrational) part of the total kinetic energy T that can be obtained in the usual manner as follows:

$$T=\frac{1}{4I_1}\left(\frac{1}{1+\kappa\sin^2\phi}p_\phi^2+\frac{\sin^2\phi+\lambda\cos^2\phi}{\lambda\sin^2\phi}\left(p_\theta-\frac{\lambda\cos\phi}{\sin^2\phi+\lambda\cos^2\phi}p_\chi\right)^2\right)$$
$$+\frac{1}{4I_1}\frac{1}{(\sin^2\phi+\lambda\cos^2\phi)}p_\chi^2. \tag{5.16}$$

In fact, the Lagrangian defined through (5.5) is Legendre transformed into (5.16) by using (5.10). Note that the last term of the right-hand side of (5.16) stands for the rotational energy associated with the total angular momentum. Thus we understand that the optimal Hamiltonian system describes the motion with the vanishing total angular momentum.

In conclusion, we should mention that the choice of the performance index is not unique, of course, rather it is in our hands. Hence, we may choose a simpler one. If we set $\kappa=0$, i.e., $\ell=0$, then the metric (5.5) becomes the metric known as that for a symmetrical top. Further, if $\lambda=1$ in addition, the metric (5.12) takes the form

$$ds^2_{\mathrm{can}}=2I_1(d\chi^2+d\phi^2+d\theta^2+2\cos\phi\,d\chi\,d\theta), \tag{5.17}$$

which is known, within a constant multiple, as the canonical metric on SO(3) expressed in the Euler angles. If we start with ds^2_{can}, the optimal Hamiltonian takes a simpler form,

$$H'=\frac{1}{4I_1}\left(p_\phi^2+\frac{1}{\sin^2\phi}(p_\theta-\cos\phi p_\chi)^2\right). \tag{5.18}$$

VI. REDUCTION

The equations of motion of the optimal Hamiltonian system $(T^*(Q_0),d\Theta,H)$ are obtained, as usual, through the Hamiltonian vector field X_H determined by $\iota(X_H)d\Theta=-dH$; $dp/dt=X_H$, $p\in T^*(Q_0)$. One of the equations is expressed as $dp_\chi/dt=-\partial H/\partial\chi=0$, so that $p_\chi=\mu=\mathrm{const}$. This constant of motion must be a consequence of the O(2) symmetry of our system. However, since O(2) is neither connected nor Abelian, we must be careful in treating the O(2) symmetry. First, the O(2) action on Q_0 is lifted to that on $T^*(Q_0)$ so that the lifted action may preserve the standard one-form Θ. According to (3.14), the O(2) action on Q_0 gives rise to the transformation $(d\chi,d\phi,d\theta)\mapsto(-d\chi,d\phi,d\theta)$ for $e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}$, so that one has $(p_\chi,p_\phi,p_\theta)\mapsto(-p_\chi,p_\phi,p_\theta)$ from the invariance of Θ. Thus the lifted action is expressed, in terms of local coordinates of $T^*(Q_0)$, as

$$e^{t\hat{\mathbf{e}}_2}:\begin{cases}(\chi,\phi,\theta)\mapsto(\chi+t,\phi,\theta),\\(p_\chi,p_\phi,p_\theta)\mapsto(p_\chi,p_\phi,p_\theta),\end{cases}$$
$$e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}:\begin{cases}(\chi,\phi,\theta)\mapsto(-\chi+t,\phi+\pi,\theta),\\(p_\chi,p_\phi,p_\theta)\mapsto(-p_\chi,p_\phi,p_\theta).\end{cases}\tag{6.1}$$

The momentum map J associated with the O(2) symmetry, which takes its value in the Lie algebra of O(2), proves to be adjoint-equivariant on account of (6.1) and of $e^{\pi\hat{\mathbf{e}}_1}\hat{\mathbf{e}}_2e^{-\pi\hat{\mathbf{e}}_1}=-\hat{\mathbf{e}}_2$;

$$J:=\Theta(\partial/\partial\chi)\hat{\mathbf{e}}_2=p_\chi\hat{\mathbf{e}}_2,$$
$$J(gp)=\mathrm{Ad}_g\,J(p),\quad g\in\mathrm{O}(2),\quad p\in T^*(Q_0).\tag{6.2}$$

We should note here that J is not O(2)-invariant. However, the Hamiltonian (5.15) is O(2)-invariant, i.e., invariant under (6.1).

The submanifold determined by $J^{-1}(\mu)$ with $\mu\neq 0$ is not invariant under the action of O(2) but invariant under that of SO(2). Thus the reduced phase space should be

$$P_\mu:=J^{-1}(\mu)/\mathrm{SO}(2)=J^{-1}(\mu)\times_{\mathrm{O}(2)}(\mathrm{O}(2)/\mathrm{SO}(2))=J^{-1}(\mu)\times_{\mathrm{O}(2)}\mathbf{Z}_2,\tag{6.3}$$

so that P_μ is a fiber bundle with base space $T^*(\mathbf{R}P^2)$ and fiber $\mathbf{Z}_2$, that is, a double cover of $T^*(\mathbf{R}P^2)$. The reduced symplectic form $d\Theta_\mu$ and the reduced Hamiltonian H_μ are apparently expressed in terms of local coordinates as

$$d\Theta_\mu=dp_\phi\wedge d\phi+dp_\theta\wedge d\theta,\tag{6.4}$$

$$H_\mu=\frac{1}{4I_1}\left(\frac{1}{1+\kappa\sin^2\phi}p_\phi^2+\frac{\sin^2\phi+\lambda\cos^2\phi}{\lambda\sin^2\phi}\left(p_\theta-\frac{\lambda\cos\phi}{\sin^2\phi+\lambda\cos^2\phi}\mu\right)^2\right),\tag{6.5}$$

respectively. It is to be noted here that H_μ is a function not on $T^*(\mathbf{R}P^2)$ but on P_μ. In fact, it is not a single-valued function on $T^*(\mathbf{R}P^2)$, that is, it is not invariant when $(\phi,\theta,p_\phi,p_\theta)$ is replaced by $(\phi+\pi,\theta,p_\phi,p_\theta)$. If $\mu=0$, the phase space P_μ becomes $T^*(\mathbf{R}P^2)$. In this case, H_0 is a function on $T^*(\mathbf{R}P^2)$, of course.

Theorem 3: The optimal Hamiltonian system $(T^*(Q_0),d\Theta,H)$ is reduced to a Hamiltonian system $(P_\mu,d\Theta_\mu,H_\mu)$, where P_μ with $\mu\neq 0$ is a double cover of $T^*(\mathbf{R}P^2)$, and $d\Theta_\mu$ and H_μ are given, respectively, by (6.4) and (6.5). If $\mu=0$, the P_μ becomes $T^*(\mathbf{R}P^2)$.

In conclusion, we have to point out that the mechanical system $(T^*(Q_0),d\Theta,T)$ has also the constant of motion $p_\chi=\mu=\mathrm{const}$, and reduces to $(P_\mu,d\Theta_\mu,T_\mu)$, where T_μ is defined from (5.16) along with $p_\chi=\mu$. If $\mu=0$, then $T_0=H_0$, so that the two reduced systems coincide. This implies that if $p_\chi=0$ the mechanical and the controlled system have the same trajectories.

VII. SYMMETRY

We wish to discuss the symmetry of the jointed cylinders. Since each of the body halves is an axially symmetric cylinder, the system of jointed cylinders has to admit symmetry arising from the axial symmetry of the body halves.

We have assumed in Sec. II that the reference attitude of the respective body halves are such that their principal axes are set in parallel to the standard basis $\mathbf{e}_j$, $j=1,2,3$, of $\mathbf{R}^3$. However, the choice of the reference attitude of the body halves is not unique. We can choose to set the body halves in such a way that the principal axes are parallel to $h\mathbf{e}_j$, $h\in\mathrm{SO}(3)$. Then the inertia tensor of each body half becomes expressed as $h^{-1}A_0h$, where A_0 is the diagonal inertia tensor given in (4.2). For the rigid body in this attitude, the position vector of a generic point from its center of mass is described as $gh\mathbf{X}_\alpha$ in place of $g\mathbf{X}_\alpha$. This implies that SO(3) acts on the configuration space Q_0 to the right,

$$(g_1,g_2)\mapsto(g_1h,g_2h),\quad h\in \mathrm{SO}(3). \tag{7.1}$$

In what follows, we are to ask how the system of jointed cylinders is transformed under the right action of SO(3). We first observe that under the right action, the vector, $\mathbf{\Theta}$, of one-forms defined by (4.3) receives the transformation

$$(gh)^{-1}d(gh)=h^{-1}\hat{\mathbf{\Theta}}h=\widehat{h^{-1}\mathbf{\Theta}}. \tag{7.2}$$

In view of this and the transformation $A_0\rightarrow h^{-1}A_0h$, we conceive that the subgroup

$$G_0=\{h\in \mathrm{SO}(3);\ \ A_0=h^{-1}A_0h\} \tag{7.3}$$

will provide a symmetry group of the jointed cylinders. It turns out from (4.2) and (7.3) that

$$G_0\cong\begin{cases}\mathrm{O}(2) & \text{for } \lambda\neq 1\\ \mathrm{SO}(3) & \text{for } \lambda=1,\end{cases} \tag{7.4}$$

where O(2) is a subgroup of SO(3) expressed as

$$\left\{\begin{pmatrix} a & 0 & b\\ 0 & 1 & 0\\ c & 0 & d\end{pmatrix},\ \begin{pmatrix} a' & 0 & b'\\ 0 & -1 & 0\\ c' & 0 & d'\end{pmatrix};\quad \begin{matrix}\kappa=\begin{pmatrix} a & b\\ c & d\end{pmatrix},\ \ \nu=\begin{pmatrix} a' & b'\\ c' & d'\end{pmatrix}\in \mathrm{O}(2),\\ \det\kappa=1, \det\nu=-1\end{matrix}\right\}. \tag{7.5}$$

On the other hand, under the right action of h, the position vector of the center of mass of the body half 1 is subject to the transformation

$$\mathbf{r}_1=-\ell(g_1\mathbf{e}_2\cdot\mathbf{e}_2)\mathbf{e}_2\mapsto\mathbf{r}_1'=-\ell(g_1h\mathbf{e}_2\cdot h\mathbf{e}_2)h\mathbf{e}_2. \tag{7.6}$$

Since $h\mathbf{e}_2=\pm\mathbf{e}_2$ for $h\in G_0\cong\mathrm{O}(2)$ with $\lambda\neq 1$, one has $\mathbf{r}_1'=\pm\mathbf{r}_1$. However, for $h\in G_0\cong\mathrm{SO}(3)$ with $\lambda=1$, one has $\mathbf{r}_1'\neq\pm\mathbf{r}_1$ in general. For the body half 2, similar equations hold.

Thus, from the definitions (4.4), (4.10), (4.14), and (5.2), one has the following.

Proposition 4: Both the connection form ω and the metric ds^2 on the no-twist configuration space Q_0 are invariant under the right action of $G_0\cong\mathrm{O}(2)$. The metric ds_0^2 on the shape space $Q_0/\mathrm{O}(2)\cong\mathbf{R}P^2$ is invariant under G_0 as well, since the structure group O(2) and the symmetry group G_0 commute. In the case of $\lambda=1$ and $\kappa=0$ [see (4.17) and (5.6)], both ω and ds^2 become invariant under the symmetry group $G_0\cong\mathrm{SO}(3)$.

Now it is clear that the optimal Hamiltonian system $(T^*(Q_0),d\Theta,H)$ referred to in Proposition 5 will be also invariant under the $G_0\cong\mathrm{O}(2)$ action, where one should note that the action on Q_0 is naturally lifted to a symplectic action on the cotangent bundle $T^*(Q_0)$. To show this in an explicit manner, we describe the right action of O(2) in local coordinates. We notice first that the group $G_0\cong\mathrm{O}(2)$ given in (7.5) is put in the form

$$\mathrm{O}(2)=\mathrm{SO}(2)\cup e^{\pi\hat{\mathbf{e}}_1}\mathrm{SO}(2),\quad \mathrm{SO}(2)=\{e^{t\hat{\mathbf{e}}_2}\}. \tag{7.7}$$

Letting $e^{t\hat{\mathbf{e}}_2}$ and $e^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2}$ act to the right on Q_0 with the local expression (3.6), one obtains

$$\begin{aligned} e^{t\hat{\mathbf{e}}_2}:&\quad (\chi,\phi,\theta)\mapsto(\chi,\phi,\theta+t),\\ e^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2}:&\quad (\chi,\phi,\theta)\mapsto(\chi,\phi+\pi,-\theta+t),\end{aligned} \tag{7.8}$$

on account of $e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}=e^{\pi\hat{\mathbf{e}}_1}e^{-t\hat{\mathbf{e}}_2}$. The lifted symplectic action is then expressed as

$$e^{t\hat{\mathbf{e}}_2}: \quad \begin{cases} (\chi,\phi,\theta)\mapsto(\chi,\phi,\theta+t), \\ (p_\chi,p_\phi,p_\theta)\mapsto(p_\chi,p_\phi,p_\theta), \end{cases}$$
$$e^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2}: \quad \begin{cases} (\chi,\phi,\theta)\mapsto(\chi,\phi+\pi,-\theta+t), \\ (p_\chi,p_\phi,p_\theta)\mapsto(p_\chi,p_\phi,-p_\theta). \end{cases} \tag{7.9}$$

The following Proposition is now easy to prove.

Proposition 5: The Hamiltonian system $(T^*(Q_0),d\Theta,H)$ admits a symmetry group $G_0 \cong \mathrm{O}(2)$ which acts on the phase space to the right. If $\lambda=1$ and $\kappa=0$ [see (4.17) and (5.6)], the symmetry group G_0 becomes SO(3).

Since the symmetry group and the structure group commute, the reduced system admits the same symmetry group G_0 as well.

Theorem 6: The reduced system $(P_\mu,d\Theta_\mu,H_\mu)$ admits the symmetry group O(2) as well. If $\lambda=1$ and $\kappa=0$, the symmetry group becomes SO(3).

VIII. QUANTIZATION

We have obtained in Sec. V the Hamiltonian system arising from the optimal control problem. We now wish to quantize this system, regarding the jointed cylinders as a model of a molecule.

For convenience' sake, we choose to treat the optimal Hamiltonian given by (5.18) along with $I_1=1/2$. The canonical metric ds^2_{can} is now expressed as

$$ds^2_{\mathrm{can}}=d\phi^2+\sin^2\phi\, d\theta^2+(d\chi+\cos\phi\, d\theta)^2. \tag{8.1}$$

Then the volume element is defined to be

$$d\phi\wedge\sin\phi\, d\theta\wedge(d\chi+\cos\phi\, d\theta)=\sin\phi\, d\phi\wedge d\theta\wedge d\chi, \tag{8.2}$$

and the horizontal metric tensor and horizontal vector fields become, respectively,

$$(h_{ij})=\mathrm{diag}(1,\sin^2\phi), \quad (h^{ij})=(h_{ij})^{-1}, \tag{8.3}$$

$$X_1=\frac{\partial}{\partial\phi}, \quad X_2=\frac{\partial}{\partial\theta}-\cos\phi\frac{\partial}{\partial\chi}. \tag{8.4}$$

By the use of these quantities, the horizontal (or vibrational) energy functional for wave functions f on Q_0 is expressed as

$$\frac{1}{2}\int_{Q_0}\sum_{i,j=1}^{2} h^{ij}\overline{X_i f}X_j f\sqrt{|h|}dq, \tag{8.5}$$

where the overbar denotes the complex conjugate, and

$$\sqrt{|h|}dq=\sin\phi\, d\phi\wedge d\theta\wedge d\chi, \quad |h|=\det(h_{ij})=\sin^2\phi. \tag{8.6}$$

Assuming that f is a function of compact support in the local coordinate system, we carry out the integration of (8.5) by part to obtain

$$-\frac{1}{2}\int_{Q_0}\bar{f}\frac{1}{\sqrt{|h|}}\sum_{i,j=1}^{2} X_i(h^{ij}\sqrt{|h|}X_j f)\sqrt{|h|}dq, \tag{8.7}$$

which provides the Hamiltonian operator $\hat{H}'$ in the form

$$\hat{H}' = -\frac{1}{2}\frac{1}{\sqrt{|h|}}\sum_{i,j=1}^{2} X_i(h^{ij}\sqrt{|h|}X_j) = -\frac{1}{2}\left(\frac{1}{\sin\phi}\frac{\partial}{\partial\phi}\left(\sin\phi\frac{\partial}{\partial\phi}\right) + \frac{1}{\sin^2\phi}\left(\frac{\partial}{\partial\theta} - \cos\phi\frac{\partial}{\partial\chi}\right)^2\right). \tag{8.8}$$

This operator is manifestly O(2) invariant, as is observed by using (3.14).

On the other hand, we denote by Δ_3 the Laplacian on $Q_0 \cong \mathrm{SO}(3)$ with respect to the canonical metric given in (8.1). By definition, Δ_3 is expressed as

$$\Delta_3 = -\frac{1}{\sqrt{|h|}}\sum_{k,\ell=1}^{3}\frac{\partial}{\partial q_k}\left(g^{k\ell}\sqrt{|h|}\frac{\partial}{\partial q_\ell}\right), \quad (q_k) = (\phi,\theta,\chi), \tag{8.9}$$

where $(g^{k\ell}) = (g_{k\ell})^{-1}$ with $ds^2_{\mathrm{can}} = \Sigma^3_{k,\ell=1} g_{k\ell}\, dq_k\, dq_\ell$, and we have used the fact that $\det(g_{k\ell}) = \det(h_{ij})$. The Δ_3 can also be obtained from the total energy functional which is broken up into the sum of the horizontal (or vibrational) and the vertical (or rotational) energy functionals;

$$\frac{1}{2}\int_{Q_0}\sum_{k,\ell=1}^{3} g^{k\ell}\overline{\frac{\partial f}{\partial q_k}}\frac{\partial f}{\partial q_\ell}\sqrt{|h|}dq = \frac{1}{2}\int_{Q_0}\left(\sum_{i,j=1}^{2} h^{ij}\overline{X_i f}X_j f + \overline{\frac{\partial f}{\partial\chi}}\frac{\partial f}{\partial\chi}\right)\sqrt{|h|}dq. \tag{8.10}$$

The integration of (8.10) by part yields

$$\frac{1}{2}\Delta_3 = \hat{H}' - \frac{1}{2}\frac{\partial^2}{\partial\chi^2}. \tag{8.11}$$

This means that $\hat{H}'$ is the horizontal part of the total energy operator $\frac{1}{2}\Delta_3$. This fact is the same as that H' is the horizontal part of the total energy T', where T' is T with $\kappa = 0$, $\lambda = 1$, and $I_1 = 1/2$. Thus, the operator $\hat{H}'$ should be regarded as a quantization of the classical Hamiltonian H' given by (5.18) with $I_1 = 1/2$. In other words, the $\hat{H}'$ is a quantization of the classical Hamiltonian satisfying the nonholonomic constraint of the vanishing total angular momentum.

Using the relation (8.11), we can find the eigenvalues of $\hat{H}'$. As for Δ_3, its eigenvalues and the associated eigenfunctions are known,[13] respectively, to be given by

$$J(J+1), \quad J = 0,1,2,\ldots, \tag{8.12}$$

$$Y_{JKM}(\phi,\theta,\chi) = \Phi_{JKM}(\phi)e^{iK\theta}e^{iM\chi}, \quad |K| \leqslant J, |M| \leqslant J, \tag{8.13}$$

where $\Phi_{JKM}(\phi)$ is defined, by the use of the Jacobi polynomial $P^{(\alpha,\beta)}_{\gamma}(x)$, to be

$$\Phi_{JKM}(\phi) = \left(\sin\frac{\phi}{2}\right)^{\alpha}\left(\cos\frac{\phi}{2}\right)^{\beta} P^{(\alpha,\beta)}_{\gamma}(\cos\phi),$$
$$\alpha = |K-M|, \quad \beta = |K+M|, \quad \gamma = J - \tfrac{1}{2}|K-M| - \tfrac{1}{2}|K+M|. \tag{8.14}$$

Applying $\hat{H}'$ to Y_{JKM} results in

$$\hat{H}' Y_{JKM} = \tfrac{1}{2}(J(J+1) - M^2)Y_{JKM}, \quad J = 0,1,2,\ldots, \quad |M| \leqslant J, \tag{8.15}$$

which provides the eigenvalues of $\hat{H}'$.

Theorem 7: The classical Hamiltonian system having the Hamiltonian function H' given by (5.18) with $I_1 = 1/2$ is quantized to be a quantum system having the Hamiltonian operator $\hat{H}'$ given in (8.8), whose eigenvalues and associated eigenfunctions are given in (8.15) and (8.13), respectively.

It is possible to define the Hamiltonian operator corresponding to the optimal Hamiltonian (5.15). To do this, we put the ds^2, given in (5.5), in the form

$$ds^2 = 2I_1 \sum_{\alpha,\beta=1}^{3} g_{\alpha\beta}\nu_\alpha\nu_\beta, \tag{8.16}$$

where ν_α are one-forms defined to be

$$\begin{aligned} \nu_1 &= d\phi, \\ \nu_2 &= d\theta, \\ \nu_3 &= d\chi + \frac{\lambda \cos\phi}{\sin^2\phi + \lambda\cos^2\phi} d\theta. \end{aligned} \tag{8.17}$$

Let $(g^{\alpha\beta}) = (g_{\alpha\beta})^{-1}$, and let X_α be the dual vector fields to (8.17), $\nu_\alpha(X_\beta) = \delta_{\alpha\beta}$, where X_1 and X_2 are equal to those given in (4.19) and $X_3 = \partial/\partial\chi$. The volume element is then defined, from (8.16), to be

$$\sqrt{|g|}dq = \sqrt{\lambda}\sqrt{1+\kappa\sin^2\phi}\sin\phi d\phi\wedge d\theta\wedge d\chi. \tag{8.18}$$

With this set up, the kinetic energy functional is put in the form

$$\begin{gathered} \frac{1}{4I_1}\int_{Q_0}\sum_{\alpha\beta=1}^{3} g^{\alpha\beta}\overline{X_\alpha f}X_\beta f\sqrt{|g|}dq = \frac{1}{4I_1}\int_{Q_0}\left[\sum_{i,j=1}^{2} h^{ij}\overline{X_i f}X_j f + g^{33}\overline{X_3 f}X_3 f\right]\sqrt{|g|}dq, \\ (h^{ij}) = (g^{ij}), \quad i,j=1,2. \end{gathered} \tag{8.19}$$

Thus one defines the Hamiltonian operator $\hat{H}$ corresponding to the optimal Hamiltonian (5.15) to be

$$\begin{aligned} \hat{H} &= -\frac{1}{4I_1}\frac{1}{\sqrt{|g|}}\sum_{i,j=1}^{2} X_i(h^{ij}\sqrt{|g|}X_j) \\ &= -\frac{1}{4I_1}\left[\frac{1}{\sqrt{1+\kappa\sin^2\phi}\sin\phi}\frac{\partial}{\partial\phi}\left(\frac{\sin\phi}{\sqrt{1+\kappa\sin^2\phi}}\frac{\partial}{\partial\phi}\right)\right. \\ &\quad \left. + \frac{\sin^2\phi+\lambda\cos^2\phi}{\lambda\sin^2\phi}\left(\frac{\partial}{\partial\theta} - \frac{\lambda\cos\phi}{\sin^2\phi+\lambda\cos^2\phi}\frac{\partial}{\partial\chi}\right)^2\right], \end{aligned} \tag{8.20}$$

which is the horizontal (or vibrational) part of the full energy operator $\hat{T}$,

$$\begin{aligned} \hat{T} &= -\frac{1}{4I_1}\frac{1}{\sqrt{|g|}}\sum_{\alpha,\beta=1}^{3} X_\alpha(g^{\alpha\beta}\sqrt{|g|}X_\beta) \\ &= -\frac{1}{4I_1}\left[\frac{1}{\sqrt{1+\kappa\sin^2\phi}\sin\phi}\frac{\partial}{\partial\phi}\left(\frac{\sin\phi}{\sqrt{1+\kappa\sin^2\phi}}\frac{\partial}{\partial\phi}\right)\right. \\ &\quad \left. + \left(\frac{\cos^2\phi}{\sin^2\phi} + \frac{1}{\lambda}\right)\frac{\partial^2}{\partial\theta^2} - \frac{2\cos\phi}{\sin^2\phi}\frac{\partial^2}{\partial\chi\partial\theta} + \frac{1}{\sin^2\phi}\frac{\partial^2}{\partial\chi^2}\right] \\ &= \hat{H} - \frac{1}{4I_1(\sin^2\phi+\lambda\cos^2\phi)}\frac{\partial^2}{\partial\chi^2}. \end{aligned} \tag{8.21}$$

If $\kappa=0$, the $\hat{T}$ becomes the operator known as the Hamiltonian operator for a symmetrical top,[13] the eigenfunctions and eigenvalues of which are known[13] to be given by Y_{JKM} and

$$E=\frac{1}{4I_1}\left(J(J+1)+K^2\left(\frac{1}{\lambda}-1\right)\right), \tag{8.22}$$

respectively. If $\kappa\neq 0$, the eigenvalue problem becomes quite difficult to solve.

IX. REDUCTION AND SYMMETRY OF THE QUANTUM SYSTEM

We wish to reduce the quantum system on $Q_0\cong \mathrm{SO}(3)$ with the Hamiltonian $\hat{H}'$ to a quantum system on $Q_0/\mathrm{O}(2)\cong \mathbf{R}P^2$. To do this, we have to set up vector bundles associated with the principal O(2) bundle, $Q_0\to Q_0/\mathrm{O}(2)$. Let ρ be a unitary irreducible representation of the structure group O(2) in a complex vector space V. For example, in the vector space $\mathbf{C}^2$, one has a unitary irreducible representation ρ_M such that

$$\rho_M(e^{t\hat{\mathbf{e}}_2})\mathbf{u}_1=e^{iMt}\mathbf{u}_1,\quad \rho_M(e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1})\mathbf{u}_1=e^{-iMt}\mathbf{u}_2,$$
$$\rho_M(e^{t\hat{\mathbf{e}}_2})\mathbf{u}_2=e^{-iMt}\mathbf{u}_2,\quad \rho_M(e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1})\mathbf{u}_2=e^{iMt}\mathbf{u}_1, \tag{9.1}$$

where $\mathbf{u}_i$, $i=1,2$, are the standard basis of $\mathbf{C}^2$ and M is an integer. It is an easy matter to observe that ρ_M is indeed a homomorphism. For example, one has

$$\rho_M(e^{t_1\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}e^{t_2\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1})=\rho_M(e^{t_1\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1})\rho_M(e^{t_2\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}). \tag{9.2}$$

We are to give the definition of the vector bundle associated with a representation ρ. First we define a left action of O(2) on $Q_0\times V$ by

$$(q,v)\mapsto(gq,\rho(g)v),\quad (q,v)\in Q_0\times V,\quad g\in \mathrm{O}(2). \tag{9.3}$$

This action gives an equivalence relation in $Q_0\times V$, and then yields the quotient manifold, denoted by $V_\rho := Q_0\times_\rho V$, which is made into a complex vector bundle with base space $Q_0/\mathrm{O}(2)$ and fiber V.

A V-valued function F on Q_0 is called equivariant with respect to ρ (or ρ-equivariant), if it satisfies

$$F(gq)=\rho(g)F(q),\quad g\in \mathrm{O}(2),\ q\in Q_0. \tag{9.4}$$

A map $s:B:=Q_0/\mathrm{O}(2)\to V_\rho$ is called a cross section in V_ρ, if $\pi\circ s=\mathrm{id}_B$, where id_B is the identity map of B. The ρ-equivariant functions are in one-to-one correspondence with the cross sections in V_ρ. In fact, one has the correspondence $s(\pi(q))=[(q,F(q))]$, where $[\cdot]$ denotes an equivalence class in $Q_0\times V$. We denote by $q_\rho^\#$ the correspondence; $q_\rho^\# s=F$.

We proceed to the linear connection associated with the connection ω defined on the principal O(2) bundle $Q_0\to B$. Let ξ be a vector field on the base space B and ξ^* its horizontal lift; $\omega(\xi^*)=0$, $\pi_*\xi_q^*=\xi_{\pi(q)}$, $q\in Q_0$. Then, for a cross section s in V_ρ, its covariant derivative with respect to ξ is defined to be

$$\nabla_\xi s=q_\rho^{\#^{-1}}\xi^*(q_\rho^\# s). \tag{9.5}$$

In the same manner, the reduced Hamiltonian operator $\hat{H}'_\rho$ is defined through

$$\hat{H}'_\rho s=q_\rho^{\#^{-1}}\hat{H}'(q_\rho^\# s). \tag{9.6}$$

This is because $\hat{H}'$ is O(2) invariant, so that $\hat{H}'(q_\rho^\# s)$ is ρ-equivariant. It then follows that if F is a ρ-equivariant eigenfunction of $\hat{H}'$ with an eigenvalue E then $s=q_\rho^{\#^{-1}}F$ becomes an eigen-cross section of $\hat{H}'_\rho$ with the same eigenvalue E.

We are going to work with the representation ρ_M given in (9.1). For the ρ_M, we choose to denote the vector bundle V_ρ and the correspondence $q_\rho^\#$ by V_M and by $q_M^\#$, respectively. Applying (9.6) to (8.8), one has the reduced Hamiltonian operator $\hat{H}'_M=q_M^{\#^{-1}}\hat{H}' q_M^\#$ expressed as

$$\hat{H}'_M=-\frac{1}{2}\frac{1}{\sqrt{|h|}}\sum_{i,j=1}^{2}\nabla_i(h^{ij}\sqrt{|h|}\nabla_j), \tag{9.7}$$

where ∇_1, ∇_2 are the covariant differential operators with respect to $\partial/\partial\phi$ and $\partial/\partial\theta$, respectively.

We now turn to the eigenfunctions Y_{JKM} for $\hat{H}'$, in order to obtain eigenvalues and eigen-cross sections of $\hat{H}'_M$. The first task for us to do is to find ρ_M-equivariant $\mathbf{C}^2$-valued functions in terms of $Y_{JKM}(q)$, $q\in Q_0$. A calculation along with (3.14), (8.13), and (8.14) provides

$$\begin{aligned} Y_{JKM}(e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}q)&=(-1)^{\beta+\gamma}e^{iMt}Y_{JK,-M}(q),\\ Y_{JK,-M}(e^{t\hat{\mathbf{e}}_2}e^{\pi\hat{\mathbf{e}}_1}q)&=(-1)^{\alpha+\gamma}e^{-iMt}Y_{JKM}(q), \end{aligned} \tag{9.8}$$

where we have used the following formula for the Jacobi polynomials;

$$P_\gamma^{(\alpha,\beta)}(-x)=(-1)^\gamma P_\gamma^{(\beta,\alpha)}(x). \tag{9.9}$$

It turns out from (9.8) that, for $M\neq 0$, the $\mathbf{C}^2$-valued function

$$F_{JKM}=Y_{JKM}\mathbf{u}_1+Y_{JK,-M}\mathbf{u}_2 \tag{9.10}$$

becomes ρ_M-equivariant if both $\beta+\gamma$ and $\alpha+\gamma$ are even numbers. Incidentally, this condition is satisfied, if all of *J, M, K* are either even or odd. Hence the F_{JKM} proves to be a ρ_M-equivariant function if all of *J, M, K* are either even or odd. We denote by $\gamma_{JKM}=q_M^{\#^{-1}}F_{JKM}$ the associated cross section in the complex vector bundle V_M. If $M=0$, one has

$$Y_{JK0}(\phi,\theta,\chi)=\frac{J!}{(J+|K|)!}P_J^{|K|}(\cos\phi)e^{iK\theta}, \tag{9.11}$$

which seem to be spherical harmonics on S^2. However, under the antipodal map $(\phi,\theta)\to(\phi+\pi,\theta+\pi)$, Y_{JK0} transforms to $(-1)^{J+K}Y_{JK0}$. In our case, since J and K are even or odd simultaneously, Y_{JK0} has the same value on a pair of antipodal points of S^2. Thus Y_{JK0} becomes a function on $\mathbf{R}P^2\cong Q_0/\mathrm{O}(2)$.

Theorem 8: The quantum system on $Q_0\cong\mathrm{SO}(3)$ with the Hamiltonian operator $\hat{H}'$ is reduced to a quantum system on $Q_0/\mathrm{O}(2)\cong\mathbf{R}P^2$, which consists of the complex vector bundle V_M $(M\neq 0)$ with base space $\mathbf{R}P^2$ and fiber $\mathbf{C}^2$, and the Hamiltonian operator $\hat{H}'_M$ acting on the space of cross sections in V_M. The local expressions of $\hat{H}'_M$ are of the form (9.7). The eigenvalues and the associated eigen-cross sections for $\hat{H}'_M$ are given by $\frac{1}{2}(J(J+1)-M^2)$, $J=|M|,|M|+2,|M|+4,\ldots$, and γ_{JKM}, $K=-J,-J+2,\ldots,J-2,J$, respectively, where γ_{JKM} are the cross sections corresponding to F_{JKM} given in (9.10). If $M=0$, the complex vector bundle V_M is replaced by a trivial complex line bundle over $\mathbf{R}P^2$, and the eigen-cross sections become the eigenfunctions on $\mathbf{R}P^2$.

Now it is an easy matter to find the symmetry of the quantum reduced system. Like the classical reduced system, the quantum reduced system is expected to admit the symmetry group O(2) which acts on eigenspaces of $\hat{H}'_M$. We wish to find how O(2) is represented in the eigenspace. In a similar manner to (9.8), a calculation along with (7.8) provides

$$Y_{JKM}(qe^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2})=e^{iKt}Y_{J,-KM}(q),$$
$$Y_{J,-KM}(qe^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2})=e^{-iKt}Y_{JKM}(q), \tag{9.12}$$

where we have used the assumption that all of J, K, M are either even or odd. Thus one finds that the ρ_M-equivariant functions F_{JKM} given in (9.10) are subject to the transformation

$$F_{JKM}(qe^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2})=e^{iKt}F_{J,-KM}(q),$$
$$F_{J,-KM}(qe^{\pi\hat{\mathbf{e}}_1}e^{t\hat{\mathbf{e}}_2})=e^{-iKt}F_{JKM}(q). \tag{9.13}$$

This equation implies that the symmetry group O(2) is unitarily irreducibly represented in the two-dimensional subspace spanned by eigen-cross sections γ_{JKM} and $\gamma_{J,-KM}$ in the energy eigenspace, if $K\neq 0$. If $K=0$, the symmetry group O(2) is trivially represented in the one-dimensional subspace spanned by γ_{J0M}.

Theorem 9: If $M\neq 0$, the reduced quantum system $(V_M,\hat{H}'_M)$ admits the symmetry group O(2), which is unitarily represented in the energy eigenspace associated with the eigenvalue $\frac{1}{2}(J(J+1)-M^2)$. If both J and M are odd, the eigenspace is completely reducible to the direct sum of two-dimensional irreducible subspaces spanned by γ_{JKM} and $\gamma_{J,-KM}$ with J, M fixed and $K=-J,-J+2,...,J$. If both J and M are even, the one-dimensional subspace spanned by γ_{J0M} occurs in addition to the two-dimensional subspace spanned by γ_{JKM} and $\gamma_{J,-KM}$. If $M=0$, the symmetry group becomes SO(3), which acts on the energy eigenspace spanned by γ_{JK0} with J a non-negative even number and $K=-J,-J+2,...,J$.

In conclusion, we have to mention that the quantum system on $Q_0\cong \mathrm{SO}(3)$ with the Hamiltonian operator $\frac{1}{2}\Delta_3$ [see (8.9)] is reduced to a quantum system on $\mathbf{R}P^2$, which consists of the vector bundle $V_M(M\neq 0)$ and the Hamiltonian operator $\hat{T}_M:=\hat{H}'_M+M^2/2$. If $M=0$, one has $\hat{T}_0=\hat{H}_0$, and the eigenfunction are the same for both of $\hat{T}_0$ and $\hat{H}_0$. This implies that if $M=0$, the free and the controlled quantum systems have the same states.

(Received 7 January 1998; accepted for publication 20 January 1999)

An algebraic structure related to discrete zero curvature equations is established. It is used to give an approach for generating master symmetries of the first degree for systems of discrete evolution equations and an answer to why there exist such master symmetries. The key of the theory is to generate nonisospectral flows ($\lambda_t = \lambda^l, l \geqslant 0$) from the discrete spectral problem associated with a given system of discrete evolution equations. Three examples are given. © *1999 American Institute of Physics.* [S0022-2488(99)01305-5]

I. INTRODUCTION

The theory of integrable systems has various aspects, although the term ''integrable'' is somewhat ambiguous, especially for systems of partial differential equations. Symmetries are one of those important aspects and have a deep mathematical and physical background. When any special character, for example the Lax pair, has not been found for a given system of continuous or discrete equations, among the most efficient ways is to consider its symmetries in order to obtain exact solutions. It is through symmetries that Russian scientists *et al.* developed some theories for testing the integrability of systems of evolution equations, both continuous and discrete, and classified many types of systems of nonlinear equations that possess higher differential or differential-difference degree symmetries (for example, see Refs. 1 and 2). Usually an integrable system of equations is referred to as a system possessing infinitely many symmetries.[3,4] Moreover, these symmetries form nice and interesting algebraic structures.[3,4]

For a given system of evolution equations $u_t = K(u)$, both continuous and discrete, a vector field $\sigma(u)$ is called its symmetry if $\sigma(u)$ satisfies its linearized system,

$$\frac{d\sigma(u)}{dt} = K'[\sigma], \quad \text{i.e.,} \quad \frac{\partial \sigma}{\partial t} = [K,\sigma] := K'[\sigma] - \sigma'[K], \tag{1}$$

where the prime means the Gateaux derivative. Starting from a Lie-point symmetry, we can often construct the corresponding explicit group-invariant solutions. A symmetry σ may, of course, depend explicitly on the evolution variable *t*. If a symmetry σ of the system $u_t = K(u)$ not depending explicitly on *t* is a polynomial in *t*, i.e.,

$$\sigma(t,u) = \sum_{i=0}^{n} \frac{t^i}{i!} \rho_i(u), \quad n \geqslant 1, \tag{2}$$

then we have

[a)]Electronic mail: mawx@cityu.edu.hk
[b)]Electronic mail: benno@uni-paderborn.de

$$\rho_i=[K,\rho_{i-1}],\quad 1\leqslant i\leqslant n, \tag{3}$$

and

$$(\mathrm{ad}_K)^{n+1}\rho_0=0,\quad \text{where } (\mathrm{ad}_K)\rho_0=[K,\rho_0]. \tag{4}$$

Therefore the symmetry (2) is totally determined by a vector field ρ_0 satisfying (4). This kind of vector field ρ_0 has been discussed in considerable detail and is called a master symmetry of degree n of $u_t=K(u)$ by one of the authors (BF) in Ref. 5.

The appearance of first degree master symmetries gives a common character for integrable systems of continuous evolution equations, both in $1+1$ dimensions and in $2+1$ dimensions, for example, the KdV equation and the KP equation. The resulting symmetries are sometimes called τ-symmetries (for more information, see Ref. 6, for example) and usually constitute centerless Virasoro algebras together with time-independent symmetries.[7–9] Moreover these τ-symmetries may be generated by use of zero curvature equations or Lax equations,[10] and the corresponding master symmetry flows may also be solved by the inverse scattering method.[11,12] In the case of systems of discrete evolution equations, there exist some similar results. For example, many systems of discrete evolution equations have τ-symmetries and centerless Virasoro symmetry algebras,[13–15] and the inverse scattering method may still be applied in solving themselves and their master symmetry flows.[16–19] So far, however, to the best of our knowledge, there has not been a systematic mathematical theory to explain why there exist τ-symmetries for systems of discrete evolution equations and how we can construct those τ-symmetries when they exist, from the point of discrete zero curvature equations.

Throughout this paper, ''master symmetries'' is used to express the first degree master symmetries that generate τ-symmetries. Our purpose is to give an algebraic explanation of the first question above and to provide a procedure to generate those master symmetries for a given lattice hierarchy. The discrete zero curvature equation is our basic tool to give rise to our answer and procedure. The Volterra lattice hierarchy, the Toda lattice hierarchy, and a sub-KP lattice hierarchy are chosen and analyzed as some illustrative examples, which have one dependent variable, two dependent variables, and three dependent variables, respectively.

Let us now describe our notation. Assume that $u=(u_1,\ldots,u_q)^T$, where $u_i=u_i(t,n)$, $1\leqslant i\leqslant q$, are real functions defined over $\mathbb{R}\times Z$ (in the case of the complex function, the discussion is similar), and let $\mathcal{B}$ denote all real functions $P[u]=P(t,n,u)$, which are C^∞ differentiable with respect to t and n, and C^∞-Gateaux differentiable with respect to u. We always write E as a shift operator and

$$(E^m x)(n)=x^{(m)}(n)=x(m+n),\quad \text{where } x:Z\to\mathbb{R},\quad m,n\in Z. \tag{5}$$

Note that $x^{(m)}$ here does not mean the mth derivative. Set $\mathcal{B}^r=\{(P_1,\ldots,P_r)^T|P_i\in\mathcal{B},1\leqslant i\leqslant r\}$, and denote by $\mathcal{V}^r$ all matrix operators $\Phi=(\Phi_{ij})_{r\times r}$, where the entries $\Phi_{ij}=\Phi_{ij}(t,n,u)\in\mathcal{B}$, and by $\tilde{\mathcal{V}}^r$, all matrix operators depending on a parameter λ: $U=(U_{ij})_{r\times r}$, where the entries $U_{ij}=U_{ij}(t,n,u,\lambda)\in\mathcal{B}$ for all λ, being C^∞ differentiable with respect to λ.

We will need a multiplication operator,

$$[n]:\mathcal{B}\to\mathcal{B},\quad P[u]\mapsto[n]P[u],\quad ([n]P[u])(m)=m(P[u])(m), \tag{6}$$

which is often involved in the construction of master symmetries. This avoids an unclear expression $nP[u]$, which may also mean $(nP[u])(m)=n(P[u])(m)$. For example, it is absolutely clear that $([n]P[u])(m)=mu(m-1)+mu(m)$, when $P[u]=E^{-1}u+u$. We also need a difference operator $\Delta=E-E^{-1}$, whose inverse operator may be defined by

$$(\Delta^{-1}u)(n)=((E-E^{-1})^{-1}u)(n):=\frac{1}{2}\left(\sum_{k=-\infty}^{-1}u(n+1+2k)-\sum_{k=1}^{\infty}u(n-1+2k)\right), \tag{7}$$

where u is required to be rapidly vanishing at the infinity. Moreover, we define

$$(\Delta^{-1}\alpha)=(1/2)\alpha[n], \quad \text{i.e.,} \quad (\Delta^{-1}\alpha)(n)=(1/2)\alpha n, \quad \alpha=\text{const.} \tag{8}$$

Obviously, we can find that

$$(E-1)^{-1}=\Delta^{-1}(1+E^{-1}), \quad (1-E^{-1})^{-1}=\Delta^{-1}(E+1), \tag{9}$$

and thus

$$(E-1)^{-1}\alpha=\alpha[n], \quad (1-E^{-1})^{-1}\alpha=\alpha[n], \quad \alpha=\text{const.}, \tag{10}$$

which may also be viewed as a definition of two inverse operators $(E-1)^{-1}$ and $(1-E^{-1})^{-1}$. Note that here we have used the operator $[n]$ so that two functions $(E-1)^{-1}\alpha$ and $(1-E^{-1})^{-1}\alpha$ have the other clear expressions. The operators Δ^{-1}, $(E-1)^{-1}$, and $(1-E^{-1})^{-1}$ often appears in the expressions of master symmetries, and thus master symmetries are usually nonlocal vector fields belonging to $\mathcal{B}^q$.

In order to carefully analyze algebraic structures related to symmetries, we specify the definition of the Gateaux derivative $X'[S]$ of any vector-valued function $X\in\mathcal{B}^r$ at a direction $S\in\mathcal{B}^q$ as follows:

$$X'[S]=\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} X(u+\epsilon S), \tag{11}$$

which implies that X' is an operator from $\mathcal{B}^q$ to $\mathcal{B}^r$, and need the following two product operations:

$$[K,S]=K'[S]-S'[K], \quad K,S\in\mathcal{B}^q, \tag{12}$$

$$[\![f,g]\!](\lambda)=f'(\lambda)g(\lambda)-f(\lambda)g'(\lambda), \quad f,g\in C^\infty(\mathbb{R}), \tag{13}$$

where $C^\infty(\mathbb{R})$ denotes the space of smooth functions defined over $\mathbb{R}$. It is known that $(\mathcal{B}^q,[\cdot,\cdot])$ and $(C^\infty(\mathbb{R}),[\![\cdot,\cdot]\!])$ are all Lie algebras.

We now assume that $U\in\tilde{\mathcal{V}}^r$ and the Gateaux derivative operator U' is injective throughout the paper. Let us consider the discrete spectral problem,

$$E\phi=U\phi=U(n,u,\lambda)\phi, \quad \phi_t=V\phi=V(n,u,\lambda)\phi, \tag{14}$$

where $V\in\tilde{\mathcal{V}}^r$. Its adjoint system reads as

$$E^{-1}\psi=U\psi=U(n,u,\lambda)\psi, \quad \psi_t=(EV)\psi=(EV(n,u,\lambda))\psi.$$

Their integrability conditions are given by the following discrete zero curvature equation:

$$U_t=(EV)U-UV. \tag{15}$$

If the operator equation (15) is equivalent to a system of discrete evolution equations $u_t=K(n,u)$, $K\in\mathcal{B}^q$, then it is called a discrete zero curvature representation of $u_t=K(n,u)$. Evidently,

$$U_t=U'[u_t]+f(\lambda)U_\lambda, \quad \text{if } \lambda_t=f(\lambda),$$

where $U_\lambda=\partial U/\partial\lambda$. Therefore a system of discrete evolution equations $u_t=K(n,u)$, $K\in\mathcal{B}^q$, is the integrability condition of (14) with the evolution law $\lambda_t=f(\lambda)$ if and only if

$$U'[K]+fU_\lambda=(EV)U-UV. \tag{16}$$

Note that the injective property of U' is indispensable in deriving zero curvature representations of systems of evolution equations. The equation (16) exposes an essential relation between a system of discrete evolution equations and its discrete zero curvature representation. It will play an important role in the context of our construction of master symmetries.

The paper is divided into five sections. The next section will be devoted to a general algebraic structure related to discrete zero curvature equations. Then in the third section we will establish an approach for constructing master symmetries by the use of discrete zero curvature representations, along with an explanation of why there exist master symmetries for systems of discrete evolution equations. In the fourth section, we will go on to illustrate our approach by three concrete examples of lattice hierarchies. Finally, the fifth section provides a conclusion and some remarks.

II. BASIC ALGEBRAIC STRUCTURE

We aim to discuss Lie algebraic structures of symmetries, including master symmetries, by using zero curvature equations. It is natural to ask what algebraic structure exists, related to zero curvature equations. To answer this question, we first plan to expose a Lie algebraic structure for the space $(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))$.

Let $(K,V,f),(S,W,g)\in(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))$, in other words, K,S are vector fields, V,W are $r\times r$ matrix operators, and f,g are smooth functions. We introduce their product:

$$[\![(K,V,f),(S,W,g)]\!]=([K,S],[\![V,W]\!],[\![f,g]\!]), \tag{17}$$

where $[K,S]$, $[\![f,g]\!]$ are defined by (12), (13), respectively, and $[\![V,W]\!]$ is defined by

$$[\![V,W]\!]=V'[S]-W'[K]+[V,W]+gV_\lambda-fW_\lambda, \tag{18}$$

where $[V,W]=VW-WV$. The same product as (18) has been introduced for the continuous case in Ref. 20.

Theorem 1: (Lie algebra) *The space* $((\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R})),[\![\cdot,\cdot]\!])$ *is a Lie algebra, the product* $[\![\cdot,\cdot]\!]$ *being defined by (17), i.e.,*

$$[\![(K,V,f),(S,W,g)]\!]=([K,S],[\![V,W]\!],[\![f,g]\!]),$$

where

$$[K,S]=K'[S]-S'[K],$$

$$[\![V,W]\!]=V'[S]-W'[K]+[V,W]+gV_\lambda-fW_\lambda,$$

$$[\![f,g]\!](\lambda)=f'(\lambda)g(\lambda)-f(\lambda)g'(\lambda).$$

The proof of the theorem will be given in Appendix A. Upon looking at the product a little bit more carefully, we can find that the Lie algebra $((\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R})),[\![\cdot,\cdot]\!])$ has a Lie subalgebra $((\mathcal{B}^q,\tilde{\mathcal{V}}^r,0),[\![\cdot,\cdot]\!])$, for which everything corresponds to the isospectral case. Moreover, the center of an element of this Lie subalgebra is often Abelian.

The above theorem exposes that a Lie algebraic structure hidden in the back of vector fields, Lax operators, and spectral evolution laws. Usually we just touch Lie algebraic structures of vector fields while discussing symmetries. If we analyze symmetries from the point of zero curvature equations, it is natural that we need to find and handle the Lie algebraic structure for all triples $(K,V,f)\in(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))$, where K, V, and f are related to each other by zero curvature equations. In other words, we need to observe how two triples (K,V,f), (S,W,g) that appear in zero curvature equations connect with each other. The following theorem tells us that such a kind of connection can be reflected by the Lie algebraic operation of $(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))$ in Theorem 1. Its proof can be found in Appendix B.

Theorem 2: (Algebraic structure of representations) *Let* $V,W\in\tilde{\mathcal{V}}^r$, $K,S\in\mathcal{B}^q$, *and* $f,g\in C^\infty(\mathbb{R})$. *If two equalities,*

$$(EV)U-UV=U'[K]+fU_\lambda, \tag{19}$$

$$(EW)U-UW=U'[S]+gU_\lambda, \tag{20}$$

hold, then we have a third equality,

$$(E[\![V,W]\!])U-U[\![V,W]\!]=U'[T]+[\![f,g]\!]U_\lambda,\quad T=[K,S], \tag{21}$$

where $[\![V,W]\!]$,[K,S] *and* $[\![f,g]\!]$ *are defined by (18), (12), and (13), respectively.*

According to this theorem, we can easily find that if a system $u_t=K(n,u)$ is isospectral, i.e., $\lambda_t=f=0$, then the product system $u_t=[K,S]$ for any $S\in\mathcal{B}^q$ can be viewed to be still isospectral because we have $[\![f,g]\!]=[\![0,g]\!]=0$, where g is the evolution law corresponding $u_t=S(n,u)$. Actually, the above theorem gives a discrete zero curvature representation for a product system $u_t=[K,S]$, which possesses the same order matrix operators as ones for the original systems $u_t=K(n,u)$ and $u_t=S(n,u)$ (see Refs. 20 and 21 for the continuous case). Combining two theorems above can show the following.

Corollary 1: The space defined by

$$\{(K,V,f)\in(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))\,|\,U'[K]+fU_\lambda=(EV)U-UV\},$$

is a Lie subalgebra of $(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))$ *under the Lie product (17).*

This corollary tells us a Lie algebraic structure about zero curvature equations, which will help us to establish Lie algebraic structures of symmetries, including master symmetries.

However, for zero curvature representations, some interesting problems remain to be solved. For example, assuming that two initial systems $u_t=K(n,u)$ and $u_t=S(n,u)$ have zero curvature representations possessing different-order matrix operators, we want to know whether there exist any zero curvature representations for the product system $u_t=[K,S]$ and what structures the resulting zero curvature representations possess if the answer is yes. It is likely to be helpful in solving this problem to use the Kronecker product, as in Ref. 22.

III. LAX OPERATORS AND MASTER SYMMETRIES

Assume that we already have a hierarchy of isospectral integrable systems of discrete evolution equations of the form

$$u_t=K_k=\Phi^kK_0,\quad \Phi\in\mathcal{V}^q,\quad K_0\in\mathcal{B}^q,\quad k\geqslant 0, \tag{22}$$

or of the form

$$u_t=K_k=JG_k=MG_{k-1},\quad J,M\in V^q,\quad G_{k-1}\in\mathcal{B}^q,\quad k\geqslant 0, \tag{23}$$

associated with a discrete spectral problem,

$$E\phi=U\phi,\quad \phi=(\phi_1,\ldots,\phi_r)^T. \tag{24}$$

The second form (23) occurs more often than the first form (22), although it is simpler to deal with the first form (22). Generally speaking, the operator Φ above is a hereditary symmetry operator (see Ref. 23 for a definition) determined by the spectral problem (24) and J,M constitute a bi-Hamiltonian pair.[24,25] If we choose $\Phi=MJ^{-1}$ when J is invertible, then the form (23) may be changed into the form (22). Usually Φ involves nonlocal operators, for example, Δ^{-1}, but J,M often involves only local operators. Our examples are all local Hamiltonian systems.

A. Structures of Lax operators

For a given $X\in\mathcal{B}^q$ or $G\in\mathcal{B}^q$, let us introduce an operator equation of $\Omega\in\tilde{\mathcal{V}}^r$:

$$(E\Omega(X))U-U\Omega(X)=U'[\Phi X]-\lambda U'[X], \tag{25}$$

in the case of (22), or an operator equation of $\Omega_J\in\tilde{\mathcal{V}}^r$:

$$(E\Omega_J(G))U-U\Omega_J(G)=U'[MG]-\lambda U'[JG], \tag{26}$$

in the case of (23). We call them the characteristic operator equations of U. The introduction of the operator equation (25) [or (26)] is an important step in our manipulation. Obviously, we can choose $\Omega_J(G)=\Omega(JG)$ when $\Phi=MJ^{-1}$. We demand that (25) [or (26)] has solutions, and $\Omega=\Omega(X)$ [or $\Omega_J(G)$] is a particular solution at X (or at G). Usually (25) [or (26)] has infinitely many solutions once one solution exists, because we can construct others $\Omega(X)+fV$ for any $f\in C^\infty(\mathbb{R})$ when $V\in\mathcal{V}^r\otimes C[\lambda,\lambda^{-1}]$ solves the stationary discrete zero curvature equation $(EV)U-UV=0$. The existence of solutions of $(EV)U-UV=0$ may result from the existence of an isospectral hierarchy associated with $E\phi=U\phi$.

Theorem 3: (structure of Lax operators) *Let two matrices $V_0,W_0\in\tilde{\mathcal{V}}^r$ and two vector fields $K_0,\rho_0\in\mathcal{B}^q$ (or $\rho_0=J\gamma_0$, $\gamma_0\in\mathcal{B}^q$) satisfy*

$$(EV_0)U-UV_0=U'[K_0], \tag{27}$$

$$(EW_0)U-UW_0=U'[\rho_0]+\lambda U_\lambda. \tag{28}$$

If we define ρ_l, $l\geqslant 1$, V_k, $k\geqslant 1$, and W_l, $l\geqslant 1$, as follows:

$$\rho_l=\Phi^l\rho_0,\quad l\geqslant 1\ \ [or\ \ \rho_l=J\gamma_l=M\gamma_{l-1},\ \ \gamma_l\in\mathcal{B}^q,\quad l\geqslant 1], \tag{29}$$

$$V_k=\lambda^kV_0+\sum_{i=1}^{k}\lambda^{k-i}\Omega(K_{i-1})\ \ [or\ \ \Omega_J(G_{i-l})],\quad k\geqslant 1, \tag{30}$$

$$W_l=\lambda^lW_0+\sum_{j=1}^{l}\lambda^{l-j}\Omega(\rho_{j-1})\ \ [or\ \ \Omega_J(\gamma_{j-1})],\quad l\geqslant 1, \tag{31}$$

then V_k, W_l, $k,l\geqslant 0$, satisfy

$$(EV_k)U-UV_k=U'[K_k],\quad (EW_l)U-UW_l=U'[\rho_l]+\lambda^{l+1}U_\lambda,\quad k,l\geqslant 0. \tag{32}$$

Therefore for any k,l⩾0, the systems of discrete evolution equations $u_t=K_k$ and $u_t=\rho_l$ possess the isospectral $(\lambda_t=0)$ and nonisospectral $(\lambda_t=\lambda^{l+1})$ *discrete zero curvature representations,*

$$U_t=(EV_k)U-UV_k,\quad U_t=(EW_l)U-UW_l,$$

respectively.

The theorem shows that the Lax operators associated with two hierarchies of interesting vector fields can be constructed simply by a unified form. Its proof is left to Appendix C. We are successful, thanks to introducing a characteristic operator equation. The difficulty is now transferred to seeking a solution to the characteristic operator equation. However, this can automatically be solved on the basis of the structure of Lax operators of isospectral hierarchies, which will be seen in the next Sec. III B.

B. A method for constructing master symmetries

Now we focus our attention on the construction problem of master symmetries. Theorem 3 already shows the structure of Lax operators associated with the isospectral and nonisospectral hierarchies (refer to Ref. 26 for the continuous case). When an isospectral hierarchy (22) [or (23)] is known, the theorem also provides us with a method to construct a nonisospectral hierarchy associated with the discrete spectral problem (24) by solving an initial discrete zero curvature equation (28) and solving a characteristic operator equation (25) [or (26)].

However, a solution to (25) [or (26)] may easily be generated by observing the resulting Lax operators. In fact, we have

$$\Omega(K_k)\ \ [\text{or}\ \ \Omega_J(G_k)]=V_{k+1}-\lambda V_k. \tag{33}$$

This may be checked, say, for the case of (22), as follows:

$$V_{k+1}-\lambda V_k=\left(\lambda^{k+1}V_0+\sum_{i=1}^{k+1}\lambda^{k-i+1}\Omega(K_{i-1})\right)-\lambda\left(\lambda^kV_0+\sum_{i=1}^{k}\lambda^{k-i}\Omega(K_{i-1})\right)=\Omega(K_k),$$

by using (30). Now by the first equality of (32), we may compute the following:

$$\begin{aligned}(E\Omega(K_k))U-U\Omega(K_k)&=(EV_{k+1}-\lambda EV_k)U-U(V_{k+1}-\lambda V_k)\\&=((EV_{k+1})U-UV_{k+1})-\lambda((EV_k)U-UV_k)\\&=U'[K_{k+1}]-\lambda U'[K_k]=U'[\Phi K_k]-\lambda U'[K_k],\end{aligned}$$

for example, for the case of (22). Therefore we see that a possible solution $\Omega(X)$ to (25) [or $\Omega_J(G)$ to (26)] may be generated by replacing the element K_k (or G_k) in the equality (33) with X (or G).

The Lax operator matrices V_{k+1} and V_k are known, when the isospectral hierarchy has already been found. Thus we do not have to directly solve the characteristic operator equations, and then the whole process of construction of the nonisospectral hierarchy becomes *an easy task*: finding ρ_0, W_0 to satisfy (28) and computing $V_{k+1}-\lambda V_k$ to find a solution to (25) [or (26)].

The nonisospectral hierarchy (29) is exactly the master symmetries that we need to find. The reasons are that the product systems between the isospectral hierarchy and the nonisospectral hierarchy are still isospectral by Theorem 2, or as we said before in Sec. II, and that usually all systems of the isospectral hierarchy commute with each other. Therefore it is because there exists a nonisospectral hierarchy that there exist master symmetries for isospectral systems of discrete evolution equations derived from a given discrete spectral problem.

In the next section, we shall in detail illustrate our construction process by three concrete examples and establish the corresponding centerless Virasoro symmetry algebras.

IV. APPLICATIONS

We illustrate only by three examples how to apply the method in the last section to construct master symmetries for various lattice hierarchies.

To make the process clearer, we introduce a conception for a given discrete spectral problem $E\phi=U\phi$, which has an injective Gateaux derivative U'. That is a uniqueness property similar to the one in the continuous case:[27] *if* $(EV)U-UV=U'[K]$, $V\in\mathcal{V}^r\otimes C[\lambda,\lambda^{-1}]$, $K\in\mathcal{B}^q$, *and* $V|_{u=0}=0$, *then* $V=0$, and further $K=0$ by the injective property of U'. It means that if an isospectral $(\lambda_t=0)$ Lax operator V equals zero at $u=0$, then so does V itself. Actually, this property corresponds to the uniqueness of an integrable hierarchy associated with a spectral problem $E\phi=U\phi$. That is to say, when initial conditions and constants of inverse difference operators are fixed [for example, as in (7) and (8)], the associated isospectral hierarchy is uniquely determined. Most of the discrete spectral problems share the uniqueness property. The following three spectral problems are exactly examples that share such a property.

A. The Volterra lattice hierarchy

Let us first consider the following discrete spectral problem:[15]

$$E\phi=U\phi,\quad U=\begin{pmatrix}1 & u\\ \lambda^{-1} & 0\end{pmatrix},\quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}. \tag{34}$$

The corresponding isospectral integrable lattice hierarchy reads as

$$u_t=K_k=\Phi^kK_0=u(a_{k+1}^{(1)}-a_{k+1}^{(-1)}),\quad K_0=u(u^{(-1)}-u^{(1)}),\quad k\geqslant 0. \tag{35}$$

Here the matrix

$$V=\Sigma_{i\geqslant 0}\begin{pmatrix}a_i & uc_{i+1}^{(1)}\\ c_i & a_i\end{pmatrix}\lambda^{-i}$$

solves the stationary discrete zero curvature equation $(EV)U-UV=0$, where we choose the initial conditions

$$a_0=\tfrac{1}{2},\quad c_0=0,\quad a_1=-u,\quad c_1=1,$$

and the hereditary operator Φ is given by

$$\Phi=u(1+E^{-1})(-u^{(1)}E^2+u)(E-1)^{-1}u^{-1}, \tag{36}$$

where $(E-1)^{-1}$ is determined by (9). It is worth pointing out that each system in (35) is local and polynomially dependent on u, although the hereditary operator Φ has nonlocal and nonpolynomially dependent features.

The first discrete evolution equation is the Volterra lattice equation,[28]

$$(u(n))_t=u(n)(u(n-1)-u(n+1)),$$

which is significantly generalized by Bogoyavlensky.[29] The associated Lax operators are as follows:

$$V_k=(\lambda^{k+1}V)_{\geqslant 1}+\begin{pmatrix}a_{k+1} & 0\\ c_{k+1} & a_{k+1}^{(-1)}\end{pmatrix},\quad k\geqslant 0, \tag{37}$$

where $(P)_{\geqslant 1}$ denotes the selection of the terms with degrees of λ no less than 1. In particular, the initial isospectral Lax operator reads as

$$V_0=\begin{pmatrix}\frac{1}{2}\lambda-u & \lambda u\\ 1 & -\frac{1}{2}\lambda-u^{(-1)}\end{pmatrix}. \tag{38}$$

The result until here can be obtained from (34) by using a powerful method in Ref. 30.

We easily obtain the corresponding quantities in the nonisospectral $(\lambda_t=\lambda)$ initial discrete zero curvature equation (28):

$$\rho_0=u,\quad W_0=\begin{pmatrix}\frac{1}{2} & 0\\ 0 & -\frac{1}{2}\end{pmatrix}, \tag{39}$$

and a solution to the characteristic operator equation (25) by (33):

$$\Omega(X)=\begin{pmatrix}\Omega_{11}(X) & \Omega_{12}(X)\\ \Omega_{21}(X) & \Omega_{22}(X)\end{pmatrix}, \tag{40}$$

where $\Omega_{ij}(X)$, $i,j=1,2$, are given by

$$\Omega_{11}(X)=(E-1)^{-1}(-u^{(1)}E^2+u)(E-1)^{-1}u^{-1}X,$$

$$\Omega_{12}(X)=\lambda uE(E-1)^{-1}u^{-1}X,$$

$$\Omega_{21}(X)=(E-1)^{-1}u^{-1}X,$$

$$\Omega_{22}(X)=-\lambda(E-1)^{-1}u^{-1}X+E^{-1}(E-1)^{-1}(-u^{(1)}E^2+u)(E-1)^{-1}u^{-1}X.$$

Now by Theorem 3, we obtain a hierarchy of nonisospectral discrete evolution equations $u_t=\rho_l=\Phi^l\rho_0$, $l\geqslant 0$, associated with the spectral problem (34).

Let us now consider how to compute the corresponding symmetry algebra. The idea below can be applied to other cases. We first make the following computation at $u=0$:

$$K_k|_{u=0}=0,\quad \rho_l|_{u=0}=\Phi^l\rho_0|_{u=0}=0,\quad k,l\geqslant 0,$$

$$V_k|_{u=0}=\lambda^k\begin{pmatrix}\frac{1}{2}\lambda & 0\\ 1 & -\frac{1}{2}\lambda\end{pmatrix},\quad k\geqslant 0,$$

$$W_l|_{u=0}=\lambda^l\begin{pmatrix}\frac{1}{2} & 0\\ 0 & -\frac{1}{2}\end{pmatrix}+(1-\delta_{l0})\lambda^{l-1}\begin{pmatrix}0 & 0\\ [n] & -\lambda[n]\end{pmatrix},\quad l\geqslant 0,$$

$$V_{k\lambda}|_{u=0}=k\lambda^{k-1}\begin{pmatrix}\frac{1}{2}\lambda & 0\\ 1 & -\frac{1}{2}\lambda\end{pmatrix}+\lambda^k\begin{pmatrix}\frac{1}{2} & 0\\ 0 & -\frac{1}{2}\end{pmatrix},\quad k\geqslant 0,$$

$$W_{l\lambda}|_{u=0}=l\lambda^{l-1}\begin{pmatrix}\frac{1}{2} & 0\\ 0 & -\frac{1}{2}\end{pmatrix}+(1-\delta_{l0})\begin{pmatrix}0 & 0\\ (l-1)\lambda^{l-2}[n] & -l\lambda^{l-1}[n]\end{pmatrix},\quad l\geqslant 0,$$

where V_k, W_l, $k,l\geqslant 0$, are given as in Theorem 3 and δ_{l0} represents the Kronecker symbol. While computing $W_l|_{u=0}$, we need to note that $\Omega(\rho_0)|_{u=0}\neq 0$, but $\Omega(\rho_l)|_{u=0}=0, l\geqslant 1$. The other two examples below have a similar character, too. Now we can find by the definition (18) of the product of two Lax operators that

$$[\![V_k,V_l]\!]|_{u=0}=0,\quad k,l\geqslant 0,$$

$$[\![V_k,W_l]\!]|_{u=0}=(k+1)V_{k+l}|_{u=0},\quad k,l\geqslant 0, \tag{41}$$

$$[\![W_k,W_l]\!]|_{u=0}=(k-l)W_{k+l}|_{u=0},\quad k,l\geqslant 0.$$

For example, we can compute that

$$
\begin{aligned}
[\![V_k,W_l]\!]|_{u=0} &= [V_k|_{u=0},W_l|_{u=0}]+\lambda^{l+1}V_{k\lambda}|_{u=0}\\
&= \lambda^{k+l}\left[\begin{pmatrix}\frac12\lambda & 0\\ 1 & -\frac12\lambda\end{pmatrix},\begin{pmatrix}\frac12 & 0\\ 0 & -\frac12\end{pmatrix}+(1-\delta_{l0})\lambda^{-1}\begin{pmatrix}0 & 0\\ [n]-\lambda[n] & \end{pmatrix}\right]\\
&\quad +\lambda^{l+1}\left(k\lambda^{k-1}\begin{pmatrix}\frac12\lambda & 0\\ 1 & -\frac12\lambda\end{pmatrix}+\lambda^{k}\begin{pmatrix}\frac12 & 0\\ 0 & -\frac12\end{pmatrix}\right)\\
&= \lambda^{k+l}\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}+k\lambda^{k+l}\begin{pmatrix}\frac12\lambda & 0\\ 1 & -\frac12\lambda\end{pmatrix}+\lambda^{k+l+1}\begin{pmatrix}\frac12 & 0\\ 0 & -\frac12\end{pmatrix}\\
&= (k+1)\lambda^{k+l}\begin{pmatrix}\frac12\lambda & 0\\ 1 & -\frac12\lambda\end{pmatrix}=(k+1)V_{k+l}|_{u=0}.
\end{aligned}
$$

Because $[\![V_k,V_l]\!]$, $[\![V_k,W_l]\!]-(k+1)V_{k+l}$, $[\![W_k,W_l]\!]-(k-l)W_{k+l}$, $k,l\geqslant 0$, are all isospectral ($\lambda_t=0$) Lax operators belonging to $\mathcal{V}^2\otimes C[\lambda,\lambda^{-1}]$ by Theorem 2, based upon (41) we obtain a Lax operator algebra by the uniqueness property of the spectral problem (34),

$$
\begin{aligned}
&[\![V_k,V_l]\!]=0,\quad k,l\geqslant 0,\\
&[\![V_k,W_l]\!]=(k+1)V_{k+l},\quad k,l\geqslant 0,\\
&[\![W_k,W_l]\!]=(k-1)W_{k+l},\quad k,l\geqslant 0.
\end{aligned}
\tag{42}
$$

Further, due to the injective property of U', we finally obtain a vector field algebra of the isospectral hierarchy and the nonisospectral hierarchy,

$$
\begin{aligned}
&[K_k,K_l]=0,\quad k,l\geqslant 0,\\
&[K_k,\rho_l]=(k+1)K_{k+l},\quad k,l\geqslant 0,\\
&[\rho_k,\rho_l]=(k-l)\rho_{k+l},\quad k,l\geqslant 0.
\end{aligned}
\tag{43}
$$

This implies that ρ_l, $l\geqslant 0$, are all master symmetries of each lattice equation $u_t=K_{k_0}$ in the isospectral hierarchy, and the symmetries,

$$K_k,\quad k\geqslant 0,\quad \text{and}\quad \tau_l^{(k_0)}=t[K_{k_0},\rho_l]+\rho_l,\quad l\geqslant 0,$$

constitute a symmetry algebra of Virasoro type possessing the same commutator relations as (43).

B. The Toda lattice hierarchy

Second, let us consider the discrete spectral problem:[30]

$$E\phi=U\phi,\quad U=\begin{pmatrix}0 & 1\\ -v & \lambda-p\end{pmatrix},\quad u=\begin{pmatrix}p\\ v\end{pmatrix},\quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}. \tag{44}$$

The corresponding isospectral integrable Toda lattice hierarchy[31] reads as

$$u_t=K_k=\Phi^kK_0=\begin{pmatrix}a_{k+2}-a_{k+2}^{(1)}\\ v(b_{k+2}^{(1)}-b_{k+2})\end{pmatrix},\quad K_0=\begin{pmatrix}v-v^{(1)}\\ v(p-p^{(-1)})\end{pmatrix},\quad k\geqslant 0. \tag{45}$$

Here

$$V=\Sigma_{i\geqslant 0}\begin{pmatrix} a_i & b_i \\ -vb_i^{(1)} & -a_i \end{pmatrix}\lambda^{-i}$$

solves $(EV)U-UV=0$, in which we choose

$$a_0=\tfrac{1}{2},\quad b_0=0,\quad a_1=0,\quad b_1=-1,$$

and the hereditary operator Φ is determined by

$$\Phi=\begin{pmatrix} p & (v^{(1)}E^2-v)(E-1)^{-1}v^{-1} \\ v(E^{-1}+1) & v(pE-p^{(-1)})(E-1)^{-1}v^{-1} \end{pmatrix}. \tag{46}$$

The first system of discrete evolution equations is the Toda lattice,[32]

$$(p(n))_t=v(n)-v(n+1),$$

$$(v(n))_t=v(n)(p(n)-p(n-1)),$$

up to a transform of dependent variables. The lattice hierarchy above has a local tri-Hamiltonian structure,

$$u_t=K_k=J\frac{\delta H_{k+2}}{\delta u}=M\frac{\delta H_{k+1}}{\delta u}=N\frac{\delta H_k}{\delta u},\quad k\geqslant 0,$$

where the Hamiltonian operators J,M,N and the conserved quantities H_k, defined by

$$J=\begin{pmatrix} 0 & (1-E)v \\ v(E^{-1}-1) & 0 \end{pmatrix},$$

$$M=J\Phi^{\dagger}=-\Phi J=\begin{pmatrix} Ev-vE^{-1} & p(E-1)v \\ v(1-E^{-1})p & v(E-E^{-1})v \end{pmatrix},$$

$$N=M\Phi^{\dagger}=-\Phi M$$
$$=\begin{pmatrix} p(vE^{-1}-Ev)+(vE^{-1}-Ev)p & p^2(1-E)v+(vE^{-1}-Ev)(1+E)v \\ v(E^{-1}+1)(vE^{-1}-Ev)+v(E^{-1}-1)p^2 & 2v(E^{-1}p-pE)v \end{pmatrix},$$

$$H_0=p+\tfrac{1}{2}\ln v,\quad H_k=-\frac{b_{k+1}}{k},\quad k\geqslant 1,$$

where $\Phi^{\dagger}$ denotes the conjugate operator of Φ. Note that this tri-Hamiltonian structure may be established through a trace identity.[30] The corresponding Lax operators read as

$$V_k=(\lambda^{k+1}V)_+ + \begin{pmatrix} b_{k+2} & 0 \\ 0 & 0 \end{pmatrix},\quad k\geqslant 0, \tag{47}$$

where the subscript $+$ denotes selecting the non-negative part. Hence, in particular,

$$V_0=\begin{pmatrix} \tfrac{1}{2}\lambda-p^{(-1)} & -1 \\ v & -\tfrac{1}{2}\lambda \end{pmatrix}. \tag{48}$$

It is easy to find the corresponding quantities in the nonisospectral ($\lambda_t=\lambda$) initial discrete zero curvature equation (28):

$$\rho_0=\begin{pmatrix} p \\ 2v \end{pmatrix},\quad W_0=\begin{pmatrix} [n]-1 & 0 \\ 0 & [n] \end{pmatrix}, \tag{49}$$

where $[n]$ is the multiplication operator defined by (6), and a solution to the characteristic operator equation (25) by (33):

$$\Omega(X)=\begin{pmatrix} \Omega_{11}(X) & \Omega_{12}(X) \\ \Omega_{21}(X) & \Omega_{22}(X) \end{pmatrix},\quad X=\begin{pmatrix} X_1 \\ X_2 \end{pmatrix}, \tag{50}$$

where $\Omega_{ij}(X)$, $i,j=1,2$, are given by

$$\Omega_{11}(X)=E^{-1}(E-1)^{-1}X_1+(p^{(-1)}-\lambda)(E-1)^{-1}v^{-1}X_2,$$

$$\Omega_{12}(X)=(E-1)^{-1}v^{-1}X_2,$$

$$\Omega_{21}(X)=vE(E-1)^{-1}v^{-1}X_2,$$

$$\Omega_{22}(X)=(E-1)^{-1}X_1.$$

In this way, we obtain a hierarchy of nonisospectral systems of discrete evolution equations $\rho_l=\Phi^l\rho_0$, $l\geqslant 0$, associated with the spectral problem (44).

In order to construct a vector field algebra, we make a similar computation at $u=0$:

$$K_k|_{u=0}=0,\quad \rho_l|_{u=0}=\Phi^l\rho_0|_{u=0}=0,\quad k,l\geqslant 0,$$

$$V_k|_{u=0}=\lambda^k\begin{pmatrix} \frac{1}{2}\lambda & -1 \\ 0 & -\frac{1}{2}\lambda \end{pmatrix},\quad k\geqslant 0,$$

$$W_l|_{u=0}=\lambda^l\begin{pmatrix} [n]-1 & 0 \\ 0 & [n] \end{pmatrix}+(1-\delta_{l0})\begin{pmatrix} -2\lambda[n] & 2[n] \\ 0 & 0 \end{pmatrix},\quad l\geqslant 0,$$

$$V_{k\lambda}|_{u=0}=k\lambda^{k-1}\begin{pmatrix} \frac{1}{2}\lambda & -1 \\ 0 & -\frac{1}{2}\lambda \end{pmatrix}+\lambda^k\begin{pmatrix} \frac{1}{2} & 0 \\ 0 & -\frac{1}{2} \end{pmatrix},\quad k\geqslant 0,$$

$$W_{l\lambda}|_{u=0}=l\lambda^{l-1}\begin{pmatrix} [n]-1 & 0 \\ 0 & [n] \end{pmatrix}+(1-\delta_{l0})\begin{pmatrix} -2l\lambda^{l-1}[n] & 2(l-1)\lambda^{l-2}[n] \\ 0 & 0 \end{pmatrix},\quad l\geqslant 0.$$

Now we can find through the product definition of $[\![\cdot,\cdot]\!]$ in (18) that

$$[\![V_k,V_l]\!]|_{u=0}=0,\quad k,l\geqslant 0,$$

$$[\![V_k,W_l]\!]|_{u=0}=(k+1)V_{k+1}|_{u=0},\quad k,l\geqslant 0, \tag{51}$$

$$[\![W_k,W_l]\!]|_{u=0}=(k-l)W_{k+l}|_{u=0},\quad k,l\geqslant 0.$$

A similar argument yields a Lax operator algebra by the uniqueness property of the spectral problem (44),

$$
\begin{aligned}
&[\![V_k,V_l]\!]=0, \quad k,l\geqslant 0,\\
&[\![V_k,W_l]\!]=(k+1)V_{k+1}, \quad k,l\geqslant 0,\\
&[\![W_k,W_l]\!]=(k-l)W_{k+l}, \quad k,l\geqslant 0.
\end{aligned}
\tag{52}
$$

And then because of the injective property of U', we obtain a semiproduct Lie algebra of the isospectral hierarchy and the nonisospectral hierarchy,

$$
\begin{aligned}
&[K_k,K_l]=0, \quad k,l\geqslant 0,\\
&[K_k,\rho_l]=(k+1)K_{k+1}, \quad k,l\geqslant 0,\\
&[\rho_k,\rho_l]=(k-l)\rho_{k+l}, \quad k,l\geqslant 0,
\end{aligned}
\tag{53}
$$

which gives rise to a symmetry algebra of the Virasoro type for the isospectral Toda hierarchy (45).

C. A sub-KP lattice hierarchy

Let us finally consider the discrete spectral problem:[33]

$$
E\phi=U\phi, \quad U=\begin{pmatrix} 0 & 1 & 0\\ b-\lambda & a & 1\\ c & 0 & 0\end{pmatrix}, \quad u=\begin{pmatrix} a\\ b\\ c\end{pmatrix}, \quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\\ \phi_3\end{pmatrix},
\tag{54}
$$

which is equivalent to $(-E^2+b+aE+E^{-1}c)\phi_1=\lambda\phi_1$, a sub-KP discrete spectral problem.[34] The corresponding isospectral integrable lattice hierarchy reads as

$$
u_t=K_k=JG_k=MG_{k-1}, \quad k\geqslant 0,
\tag{55}
$$

where a Hamiltonian pair J, M and G_{-1}, G_0, G_1 are defined by

$$
J=\begin{pmatrix} E-E^{-1} & 0 & 0\\ 0 & 0 & (E^{-1}-1)c\\ 0 & -c(E-1) & 0\end{pmatrix},
$$

$$
M=\begin{pmatrix} Eb-bE^{-1}+a\Delta_+\Delta^{-1}\Delta_-a & EcE-E^{-1}c & -a\Delta_+\Delta^{-1}\Delta_-c\\ cE-E^{-1}cE^{-1} & E^{-1}ac-acE & -b\Delta_-c\\ c\Delta_+-\Delta^{-1}\Delta_-a & -c\Delta_+b & c[\Delta_+\Delta^{-1}\Delta_--\Delta_--\Delta_+]c\end{pmatrix},
$$

$$
G_{-1}=\begin{pmatrix}0\\ 1\\ 0\end{pmatrix}, \quad G_0=\begin{pmatrix}c\\ b\\ a\end{pmatrix}, \quad G_1=\begin{pmatrix} c(Eb+b)\\ b^2+ac+E^{-1}ac\\ a(Eb+b)-Ec-E^{-1}c\end{pmatrix},
$$

where Δ_+, Δ_- are the difference operators: $\Delta_+=E-1, \Delta_-=1-E^{-1}$. The first nonlinear system of discrete evolution equations is

$$
\begin{aligned}
&(a(n))_t=c(n+1)-c(n-1),\\
&(b(n))_t=a(n-1)c(n-1)-a(n)c(n),\\
&(c(n))_t=c(n)(b(n)-b(n+1)).
\end{aligned}
$$

We easily find the corresponding quantities in (27) and (28):

$$K_0=\begin{pmatrix}(E-E^{-1})c\\(E^{-1}-1)ac\\c(1-E)b\end{pmatrix},\quad V_0=\begin{pmatrix}0&0&1\\c&0&0\\-E^{-1}ac&E^{-1}c&\lambda-b\end{pmatrix},$$

$$\rho_0=J\gamma_0=M\gamma_{-1}=J\begin{pmatrix}\frac{1}{2}\Delta^{-1}a\\-\frac{3}{2}[n]\\-c^{-1}\Delta_-^{-1}b\end{pmatrix}=M\begin{pmatrix}0\\0\\-([n]+\frac{3}{2})c^{-1}\end{pmatrix}=\begin{pmatrix}\frac{1}{2}a\\b\\\frac{3}{2}c\end{pmatrix},$$

$$W_0=\begin{pmatrix}\frac{1}{2}[n]&0&0\\0&\frac{1}{2}([n]+1)&0\\0&0&\frac{1}{2}([n]+2)\end{pmatrix}.$$

We can also obtain a solution to the characteristic operator equation (26) by (33):

$$\Omega_J(G)=\begin{pmatrix}\Omega_{11}(G)&\Omega_{12}(G)&\Omega_{13}(G)\\\Omega_{21}(G)&\Omega_{22}(G)&\Omega_{23}(G)\\\Omega_{31}(G)&\Omega_{32}(G)&\Omega_{33}(G)\end{pmatrix},\quad G=\begin{pmatrix}G_{(1)}\\G_{(2)}\\G_{(3)}\end{pmatrix},\tag{56}$$

where $\Omega_{ij}(G)$, $i,j=1,2,3$, are determined by

$$\Omega_{11}(G)=-(E^2+E)^{-1}(cG_{(3)}+EaG_{(1)}),$$
$$\Omega_{12}(G)=E^{-1}G_{(1)},\quad \Omega_{13}(G)=G_{(2)},$$
$$\Omega_{21}(G)=cEG_{(2)}+(b-\lambda)G_{(1)},$$
$$\Omega_{22}(G)=-(E+1)^{-1}(cG_{(3)}+EaG_{(1)})+aG_{(1)},\quad \Omega_{23}(G)=G_{(1)},\tag{57}$$
$$\Omega_{31}(G)=E^{-1}cE^{-1}G_{(1)}-E^{-1}acG_{(2)},\quad \Omega_{32}(G)=E^{-1}cG_{(2)},$$
$$\Omega_{33}(G)=-E(E+1)^{-1}(cG_{(3)}+EaG_{(1)})+\Delta_+aG_{(1)}-(b-\lambda G_{(2)}.$$

By Theorem 3, we get a hierarchy of nonisospectral systems of discrete evolution equations $u_t=\rho_l=\Phi^l\rho_0$, $l\geqslant 0$, associated with the spectral problem (54).

In order to generate a vector field algebra of the isospectral hierarchy and the nonisospectral hierarchy, we need the following quantities, which may be directly worked out:

$$K_k|_{u=0}=0,\quad \rho_0|_{u=0}=J\gamma_0|_{u=0}=0,\quad \rho_l|_{u=0}=J\gamma_l|_{u=0}=M\gamma_{l-1}|_{u=0}=0,\quad k\geqslant 0,\quad l\geqslant 1,$$

$$V_k|_{u=0}=\lambda^k\begin{pmatrix}0&0&1\\0&0&0\\0&0&\lambda\end{pmatrix},$$

$$W_l|_{u=0}=\lambda^l\begin{pmatrix}\frac{1}{2}&0&0\\0&\frac{1}{2}([n]+1)&0\\0&0&\frac{1}{2}([n]+2)\end{pmatrix}+(1-\delta_{l0})\lambda^{l-1}\begin{pmatrix}0&0&-\frac{3}{2}[n]\\0&0&0\\0&0&-\frac{3}{2}\lambda[n]\end{pmatrix},$$

$$V_{k\lambda}|_{u=0}=k\lambda^{k-1}\begin{pmatrix}0&0&1\\0&0&0\\0&0&\lambda\end{pmatrix}+\lambda^k\begin{pmatrix}0&0&0\\0&0&0\\0&0&1\end{pmatrix},$$

$$W_{l\lambda}|_{u=0}=l\lambda^{l-1}\begin{pmatrix}\frac{1}{2}[n]&0&0\\0&\frac{1}{2}([n]+1)&0\\0&0&\frac{1}{2}([n]+2)\end{pmatrix}+(1-\delta_{l0})\begin{pmatrix}0&0&-\frac{3}{2}(l-1)\lambda^{l-2}[n]\\0&0&0\\0&0&-\frac{3}{2}l\lambda^{l-1}[n]\end{pmatrix}.$$

Now we easily find, according to the product definition of $[\![\cdot,\cdot]\!]$, that

$$[\![V_k,V_l]\!]|_{u=0}=0,\quad k,l\geqslant 0,$$

$$[\![V_k,W_l]\!]|_{u=0}=(k+1)V_{k+l}|_{u=0},\quad k,l\geqslant 0,$$

$$[\![W_k,W_l]\!]|_{u=0}=(k-l)W_{k+l}|_{u=0},\quad k,l\geqslant 0.$$

The same deduction leads to a Lax operator algebra,

$$\begin{aligned}&[\![V_k,V_l]\!]=0,\quad k,l\geqslant 0,\\&[\![V_k,W_l]\!]=(k+1)V_{k+l},\quad k,l\geqslant 0,\\&[\![W_k,W_l]\!]=(k-l)W_{k+l},\quad k,l\geqslant 0,\end{aligned}\tag{58}$$

and further a vector field algebra,

$$\begin{aligned}&[K_k,K_l]=0,\quad k,l\geqslant 0,\\&[K_k,\rho_l]=(k+1)K_{k+l},\quad k,l\geqslant 0,\\&[\rho_k,\rho_l]=(k-l)\rho_{k+l},\quad k,l\geqslant 0,\end{aligned}\tag{59}$$

which may generate a master symmetry algebra possessing the same algebraic structure as (59).

V. CONCLUSION AND REMARKS

We have established an algebraic structure related to discrete zero curvature equations and further introduced a simple but systematic approach for constructing master symmetries of the first degree for isospectral lattice hierarchies associated with discrete spectral problems. The resulting algebraic structures also leads to an explanation of why there exist master symmetries of the first degree. Some complicated calculation in our construction is saved by using a characteristic operator equation (25) [or (26)] and a uniqueness property of discrete spectral problems. The crucial step is the construction of the corresponding nonisospectral lattice hierarchies, which can be found by solving an initial nonisospectral discrete zero curvature equation. Three lattice hierarchies are shown as illustrative examples, and the corresponding master symmetry algebras of the centerless Virasoro type are exhibited. Some of the results in this paper have been reported at SIDE II, UK.[35]

It is worth noting that three examples described in the last section possess the same commutator relations between their isospectral and nonisospectral vector fields. In general, we have $[K_k,\rho_l]=(k+\gamma)K_{k+1}$, γ=const., but the other two equalities of the whole Virasoro algebra do not change. This is also a common phenomenon for continuous integrable hierarchies.[36,37] Furthermore, we may add a nonisospectral master symmetry with $\lambda_t=1$ to the whole Virasoro symmetry algebra, but this often requires additional checking. For example, a nonisospectral master symmetry with $\lambda_t=1$ of the sub-KP lattice hierarchy (55) is $\rho_{-1}=J_{\gamma-1}=(0,1,0)^T$. On the other hand, similar to the theory in Ref. 37, we may also choose an operator solution $\Omega(X)$ [or $\Omega_J(G)$] satisfying $\Omega(X)|_{X=0}=0$ [or $\Omega_J(G)|_{G=0}=0$] (all three examples in the last section have this property), and then we only need to compute $[\![V_0,W_0]\!]|_{u=0}$ so as to give Lax operator algebras at $u=0$ and finally give Lax operator algebras generally.

In our discussion, in fact, we have not used the hereditary property of the recursion operator Φ (or the bi-Hamiltonian property of J and M), while we construct Virasoro symmetry algebras for integrable lattice hierarchies, and thus it can also be applied to lattice hierarchies that possess nonhereditary recursion operators. The advantage of our scheme is to fully utilize discrete zero curvature equations so that the whole process to generate master symmetries of the first degree becomes an easy task. There were also an algorithm implemented in MuPAD[38] and other direct tricks[13–15,39] to compute master symmetries of first degree for systems of discrete evolution equations. However, our theory focuses on seeking an answer to the existence and structure problem of master symmetries of the first degree.

We should mention that there exists a large variety of other theories or methods to discuss integrable properties of systems of nonlinear discrete equations, which include Hamiltonian theory,[40,41] Bäcklund–Darboux transformation,[42,43] The R-matrix method,[34,44] symmetry reduction,[45] etc. Moreover, we can consider the time discretization problem[46] and periodic initial and boundary value problems of time discretizations[47] for symmetry flows of systems of discrete evolution equations. The resulting difference equations and mappings should be useful in discussing the integrability of the underlying systems of discrete evolution equations themselves. We are also curious about the following natural problem: Are there any higher degree master symmetries for systems of discrete evolution equations that do not depend explicitly on the evolution variable? If the answer is yes, can we establish any relations between those higher degree master symmetries and discrete zero curvature equations as we did for the first degree master symmetries?

ACKNOWLEDGMENTS

The authors are indebted to the referee for invaluable comments. One of the authors (W. X. Ma) would like to thank the Alexander von Humboldt Foundation of Germany, the City University of Hong Kong, and the Research Grants Council of Hong Kong for financial support. He is also grateful to J. Leon, W. Oevel, and W. Strampp for their helpful and stimulating discussions, and to R. K. Bullough and P. J. Caudrey for their warm hospitality during his visit at UMIST, UK.

APPENDIX A: PROOF OF THEOREM 1

Let $(K_i,V_i,f_i)\in(\mathcal{B}^q,\tilde{\mathcal{V}}^r,C^\infty(\mathbb{R}))$, $1\leq i\leq 3$. Because the bilinearity and the skew symmetry of the product (17) are self-evident and we already know that the products defined by (12) and (13) are Lie products, we only need to prove the following Jacobi identity:

$$[\![[\![V_1,V_2]\!],V_3]\!]+\text{cycle}(1,2,3)=0. \tag{A1}$$

Let us first compute by (18) that

$$\begin{aligned}[\![[\![V_1,V_2]\!],V_3]\!]&=([\![V_1,V_2]\!])'[K_3]-V_3'[[K_1,K_2]]+[[\![V_1,V_2]\!],V_3]+f_3[\![V_1,V_2]\!]_\lambda-[\![f_1,f_2]\!]V_{3\lambda}\\&=(V_1'[K_2])'[K_3]-(V_2'[K_1])'[K_3]+[V_1,V_2]'[K_3]+f_2(V_{1\lambda})'[K_3]\\&\quad-f_1(V_{2\lambda})'[K_3]-V_3'[[K_1,K_2]]+[V_1'[K_2],V_3]-[V_2'[K_1],V_3]+[[V_1,V_2],V_3]\\&\quad+f_2[V_{1\lambda},V_3]-f_1[V_{2\lambda},V_3]+f_3(V_1'[K_2])_\lambda-f_3(V_2'[K_1])_\lambda+f_3[V_1,V_2]_\lambda\\&\quad+f_{2\lambda}f_3V_{1\lambda}+f_2f_3V_{1\lambda\lambda}-f_{1\lambda}f_3V_{2\lambda}-f_1f_3V_{2\lambda\lambda}-[\![f_1,f_2]\!]V_{3\lambda}.\end{aligned} \tag{A2}$$

We need to use the following fundamental equalities:

$$(V_\lambda)'[K]=(V'[K])_\lambda,\quad V\in\tilde{\mathcal{V}}^r,\quad K\in\mathcal{B}^q,$$

$$[V,W]_\lambda=[V_\lambda,W]+[V,W_\lambda],\quad V,W\in\tilde{\mathcal{V}}^r,$$

$$[V,W]'[K]=[V'[K],W]+[V,W'[K]],\quad V,W\in\tilde{\mathcal{V}}^r,\quad K\in\mathcal{B}^q,$$

$$V'[T]=(V'[K])'[S]-(V'[S])'[K],\quad T=[K,S],\quad V\in\tilde{\mathcal{V}}^r,\quad K,S\in\mathcal{B}^q,$$

which may be shown by a direct computation and the last equality of which is a similar result as in Ref. 21. Now we can go on to compute that

$$\begin{aligned}\Delta_a^{123}&:=(V_1'[K_2])'[K_3]-(V_2'[K_1])'[K_3]-V_3'[[K_1,K_2]]\\&=(V_1'[K_2])'[K_3]-(V_2'[K_1])'[K_3-(V_3'[K_1])'[K_2+(V_3'[K_2])'[K_1],\end{aligned}$$

$$\begin{aligned}\Delta_b^{123}&:=[V_1,V_2]'[K_3]+[V_1'[K_2],V_3]-[V_2'[K_1],V_3]\\&=[V_1'[K_3],V_2]-[V_2'[K_3],V_1]+[V_1'[K_2],V_3]-[V_2'[K_1],V_3],\end{aligned}$$

$$\begin{aligned}\Delta_c^{123}&:=f_2(V_{1\lambda})'[K_3]-f_1(V_{2\lambda})'[K_3]+f_3(V_1'[K_2])_\lambda-f_3(V_2'[K_1])_\lambda\\&=f_2(V_{1\lambda})'[K_3]-f_1(V_{2\lambda})'[K_3]+f_3(V_{1\lambda})'[K_2]-f_3(V_{2\lambda})'[K_1],\end{aligned}$$

$$\begin{aligned}\Delta_d^{123}&:=f_2[V_{1\lambda},V_3]-f_1[V_{2\lambda},V_3]+f_3[V_1,V_2]_\lambda\\&=f_2[V_{1\lambda},V_3]-f_1[V_{2\lambda},V_3]+f_3[V_{1\lambda},V_2]-f_3[V_{2\lambda},V_1],\end{aligned}$$

$$\begin{aligned}\Delta_e^{123}&:=f_{2\lambda}f_3V_{1\lambda}+f_2f_3V_{1\lambda\lambda}-f_{1\lambda}f_3V_{2\lambda}-f_1f_3V_{2\lambda\lambda}-[\![f_1,f_2]\!]V_{3\lambda},\\&=f_{2\lambda}f_3V_{1\lambda}+f_2f_3V_{1\lambda\lambda}-f_{1\lambda}f_3V_{2\lambda}-f_1f_3V_{2\lambda\lambda}-f_{1\lambda}f_2V_{3\lambda}+f_1f_{2\lambda}V_{3\lambda}.\end{aligned}$$

A direct check can result in that

$$\Delta_*^{123}+\text{cycle}(1,2,3)=0,\quad\text{where}\quad *=a,b,c,d\quad\text{or}\quad e.$$

Noting (A2), it follows therefore that

$$[\![[\![V_1,V_2]\!],V_3]\!]+\text{cycle}(1,2,3)=\Delta_a^{123}+\Delta_b^{123}+\Delta_c^{123}+\Delta_d^{123}+\Delta_e^{123}+[[V_1,V_2],V_3]+\text{cycle}(1,2,3)=0,$$

which is exactly the Jacobi identity (A1) and thus completes the proof.

APPENDIX B: PROOF OF THEOREM 2

The proof is an application of the equalities (19) and (20) and the third equality,

$$(U'[K])'[S]-(U'[S])'[K]=U'[T],\quad T=[K,S],\tag{B1}$$

which has been mentioned in the proof of the first theorem. We observe that

$$[\text{Eq. }(19)]'[S]-[\text{Eq. }(20)]'[K]+g[\text{Eq. }(19)]_\lambda-f[\text{Eq. }(20)]_\lambda.$$

The resulting equality reads as

$$\begin{aligned}(U'[K])'[S]&-(U'[S])'[K]+[\![f,g]\!]U_\lambda\\&=(EV'[S])U+(EV)U'[S]-U'[S]V-UV'[S]-(EW'[K])U-(EW)U'[K]\\&\quad+U'[K]W+UW'[K]+g(EV_\lambda)U+g(EV)U_\lambda-gU_\lambda V\\&\quad-gUV_\lambda-f(EW_\lambda)U-f(EW)U_\lambda+fU_\lambda W+fUW_\lambda.\end{aligned}\tag{B2}$$

On the other hand, we have immediately

$$(E[\![V,W]\!])U-U[\![V,W]\!]=(EV'[S])U-(EW'[K])U+(EV)(EW)U-(EW)(EV)U+g(EV_\lambda)U \\ -f(EW_\lambda)U-UV'[S]+UW'[K]-UVW+UWV-gUV_\lambda+fUW_\lambda. \tag{B3}$$

It follows, therefore from (B1), (B2), and (B3) that

$$\begin{aligned}
&(E[\![V,W]\!])U-U[\![V,W]\!]-U'[T]-[\![f,g]\!]U_\lambda\\
&\quad=(E[\![V,W]\!])U-U[\![V,W]\!]-(U'[K])'[S]+(U'[S])'[K]-[\![f,g]\!]U_\lambda\\
&\quad=(EV)\{(EW)U-V'[S]-gU_\lambda\}-(EW)\{(EV)U-U'[K]-fU_\lambda\}\\
&\qquad-UVW+UWV+gU_\lambda V-fU_\lambda W+U'[S]V-U'[K]W\\
&\quad=(EV)UW-(EW)UV-UVW+UWV+gU_\lambda V-fU_\lambda W+U'[S]V-U'[K]W\\
&\quad=\{(EV)U-UV-fU_\lambda-U'[K]\}W-\{(EW)U-UW-gU_\lambda-U'[S]\}V=0,
\end{aligned}$$

which is what we need to prove.

APPENDIX C: PROOF OF THEOREM 3

We prove two equalities in (32). The rest is obvious. We compute that

$$\begin{aligned}
(EV_k)U-UV_k&=\lambda^k[(EV_0)U-UV_0]+\sum_{i=1}^{k}\lambda^{k-i}\{(E\Omega(K_{i-1}))U-U\Omega(K_{i-1})\}\\
&=\lambda^kU'[K_0]+\sum_{i=1}^{k}\lambda^{k-i}\{U'[\Phi K_{i-1}]-\lambda U'[K_{i-1}]\}\\
&=\lambda^kU'[K_0]+\sum_{i=1}^{k}\lambda^{k-i}\{U'[K_i]-\lambda U'[K_{i-1}]\}=U'[K_k],\quad k\geqslant 1;
\end{aligned}$$

$$\begin{aligned}
(EW_l)U-UW_l&=\lambda^l[(EW_0)U-UW_0]+\sum_{j=1}^{l}\lambda^{l-j}\{(E\Omega(\rho_{j-1}))U-U\Omega(\rho_{j-1})\}\\
&=\lambda^l\{U'[\rho_0]+\lambda U_\lambda\}+\sum_{j=1}^{l}\lambda^{l-j}\{U'[\Phi\rho_{j-1}]-\lambda U'[\rho_{j-1}]\}\\
&=\lambda^l\{U'[\rho_0]+\lambda U_\lambda\}+\sum_{j=1}^{l}\lambda^{l-j}\{U'[\rho_j]-\lambda U'[\rho_{j-1}]\}\\
&=U'[\rho_l]+\lambda^{l+1}U_\lambda,\\
&\qquad l\geqslant 1.
\end{aligned}$$

Note that we have used the characteristic operator equation (25), but the situation in the case of (26) is completely similar. The proof is therefore finished.

On the Fay identity for Korteweg–de Vries tau functions and the identity for the Wronskian of squared solutions of Sturm–Liouville equation

Yordan P. Mishev[a)]
Research Institute for Mathematical Sciences, Kyoto University, Sakyo-ku 606, Kyoto, Japan

(Received 9 April 1998; accepted for publication 20 January 1999)

We show that the well-known identity for the Wronskian of squared solutions of a Sturm–Liouville equation follows from the Fay identity. We also study some odd-order $[(2^n-1)$-order, $n=2,3,...]$ identities which are specific for tau functions, related to the KdV hierarchy.
[S0022-2488(99)00705-7]

I. INTRODUCTION

We began this research as a study of the expression of the Wronskian of squared solutions of the Sturm–Liouville equation by Korteweg–de Vries (KdV) tau functions and the Fay identity. Now, when the desired result is obtained (cf. Theorem 1.1), we realize that this is a story of the common origin of the following three relations for the functions: x, $\sin(x)$, and $\theta_{11}(x)$ respectively $(x,z_1,z_2\in\mathbb{C})$:

$$(z_2-z_1)[(x+z_1+z_2)(x-z_1)(x-z_2)-(x-z_1-z_2)(x+z_1)(x+z_2)]$$
$$=(z_1+z_2)[(x+z_1-z_2)(x-z_1)(x+z_2)-(x-z_1+z_2)(x+z_1)(x-z_2)],$$

$$\sin(z_2-z_1)[\sin(x+z_1+z_2)\sin(x-z_1)\sin(x-z_2)-\sin(x-z_1-z_2)\sin(x+z_1)\sin(x+z_2)]$$
$$=\sin(z_1+z_2)[\sin(x+z_1-z_2)\sin(x-z_1)\sin(x+z_2)$$
$$-\sin(x-z_1+z_2)\sin(x+z_1)\sin(x-z_2)],$$

$$\theta_{11}(z_2-z_1)[\theta_{11}(x+z_1+z_2)\theta_{11}(x-z_1)\theta_{11}(x-z_2)-\theta_{11}(x-z_1-z_2)\theta_{11}(x+z_1)\theta_{11}(x+z_2)]$$
$$=\theta_{11}(z_1+z_2)[\theta_{11}(x+z_1-z_2)\theta_{11}(x-z_1)\theta_{11}(x+z_2)$$
$$-\theta_{11}(x-z_1+z_2)\theta_{11}(x+z_1)\theta_{11}(x-z_2)]$$

(we use the notations for theta functions from Ref. 1).

In the present paper we will prove an identity for general KdV tau functions (it will be a third-order identity for tau). The mentioned three types of functions are, roughly speaking, three types of KdV tau functions for stationary (t-independent) solutions of the KdV equation: $u_t=6uu_x+u_{xxx}$. So, the polynomial relation follows from this cubic identity for KdV taus, but there are some specific problems to translate the identity for the general KdV taus to the cases of trigonometric functions and elliptic theta functions. We will postpone the solution of these problems to some next publication.

This way, the status of the three relations is quite different: the first one is easy to prove directly (and it also follows from the cubic identity for KdV taus); the second one is not difficult

[a)]On leave from Forestry University, Sofia, Bulgaria. Electronic mail: mishevyp@kurims.kyoto-u.ac.jp to prove directly, using the well-known trigonometric identities; and the third one is still conjectural (we could not derive it from the Riemann relations, we could only check it numerically, using the system Mathematica 3.0 at RIMS, Kyoto University).

Let $\tau(t)$, $t\equiv(t_1,t_2,t_3,\dots)\in\mathbb{C}^\infty$, $t_1\equiv x$, be an arbitrary tau function, related to the Kadomtzev–Petviashvili (KP) hierarchy (Ref. 2). Let us denote ($z\in\mathbb{C}$)

$$[z]:=(z,z^2/2,z^3/3,\dots)\in\mathbb{C}^\infty,$$

$$\tau(t+[z]):=\tau(t_1+z,t_2+z^2/2,t_3+z^3/3,\dots).$$

The following identity ($z_0,z_1,z_2,z_3\in\mathbb{C}$),

$$(z_0-z_1)(z_2-z_3)\tau(t+[z_0]+[z_1])\tau(t+[z_2]+[z_3])+(z_0-z_2)(z_3-z_1)\tau(t+[z_0]+[z_2])\tau(t+[z_3]+[z_1])+(z_0-z_3)(z_1-z_2)\tau(t+[z_0]+[z_3])\tau(t+[z_1]+[z_2])=0 \tag{1.1}$$

is called the *Fay identity* (Ref. 3) for the KP tau function τ. It was first obtained (Ref. 4) for theta functions related to Jacobians. In genus $g=1$ case its form is

$$\theta_{11}(z_0-z_1)\theta_{11}(z_2-z_3)\theta_{11}(t+z_0+z_1)\theta_{11}(t+z_2+z_3)+\theta_{11}(z_0-z_2)\theta_{11}(z_3-z_1)\theta_{11}(t+z_0+z_2)\theta_{11}(t+z_3+z_1)+\theta_{11}(z_0-z_3)\theta_{11}(z_1-z_2)\theta_{11}(t+z_0+z_3)\theta_{11}(t+z_1+z_2)=0.$$

Afterwards it was used (Ref. 1) in geometric treatment of soliton equations. Later it was generalized for tau functions (Ref. 3).

The Fay identity is fulfilled at also for tau functions related to the nth ($n=2,3,4,\dots$) Gel'fand–Dickey reduction of the KP hierarchy. In the present paper we will consider only the $n=2$ reduction, i.e., the KdV hierarchy. Such tau functions we will call KdV tau functions. They can be characterized by the conditions ($\partial_{t_{2k}}\equiv\partial/\partial t_{2k}$)

$$\partial_{t_{2k}}\tau(t)=0,\quad k=1,2,3,\dots,$$

which imply for every $z\in\mathbb{C}$

$$\tau(t-[z])=\tau(t+[-z]). \tag{1.2}$$

There are two main goals in the present article. The first aim is to show that the famous identity for the Wronskian $[W(f,g):=fg'-f'g,\ '\equiv\partial_x\equiv\partial/\partial x]$ of squared solutions of the Sturm–Liouville equation (Ref. 5) follows from the Fay identity for KdV tau functions. The second aim is to obtain some specific relations for the KdV tau functions.

We came to these results when studying the problem of finding a dictionary between the tau functions and some formulas related to squared solutions of the Sturm–Liouville equation (especially the mentioned identity for the Wronskian of squared solutions–an important ingredient of this area (Refs. 5 and 6). Such a dictionary will be useful in examining some features of Miura transformations. It is well known that squared solutions span the kernels of the Frechet derivatives $\mathfrak{M}'_\pm(v)=2v\pm\partial_x$ of Miura transformations $u_\pm=\mathfrak{M}_\pm v:=v^2\pm v_x$ ($v_x\equiv\partial_x v$), where v is a solution of the mKdV equation and $u_\pm$ are solutions of the KdV equation. Also well known (Ref. 7) is the interpretation of Miura transformations as projections from flag to corresponding subspace (in Sato Grassmannian), which is intimately connected to tau functions. Some parts of the dictionary were known: e.g., a formula, which expresses the squared solutions by means of $\tau(t)$ and vertex operators (Ref. 2) [in this paper the so-called Λ-operators (Ref. 5) are also mentioned]. There were no relations to the tau functions of the identity for the Wronskian of squared solutions, but there was a well-known expression of the Wronskian of two solutions by means of $\tau(t)$ (Refs. 2 and 8).

Because of the fact that in the proof of the latest formula, the Fay identity was used, we expected that the same identity will be useful in the ‘‘paraphrase’’ of the Wronskian of squared solutions.

We need such a dictionary, because we observed some similarities between Matsuo and Cherednik transformations (Ref. 9):

Knizhniv-Zamolodchikov equation→quantum Calogero-Sutherland system on the one hand and Miura transformation on the other hand. Our opinion is that such similarities will be easier explained on the language of tau functions, flag and Grassmann manifolds, etc. So, the ‘‘paraphrase’’ of the relations for the Wronskian of squared solutions of the Sturm–Liouville equation is only the first step in this direction. We also expect that the presented connections between squared solutions and tau functions will be useful in another areas of the subject (cf. Refs. 10 and 11).

In order to explain the main results of the present article, let us review some notations (Refs. 2 and 8). Let $\psi(x,z)$ and $\psi^*(x,z)$ be two linearly independent solutions (cf. Sec. II) of the Sturm–Liouville equation:

$$(\partial_x^2+u(x))\psi(x,z)=z^2\psi(x,z). \tag{1.3}$$

Then the following relations,

$$\begin{aligned}W(\psi(x,z_1)\psi^*(x,z_1),\psi(x,z_2)\psi^*(x,z_2))&\\ =-(z_1^2-z_2^2)^{-1}\partial_x[W(\psi(x,z_1),\psi(x,z_2))W(\psi^*(x,z_1),\psi^*(x,z_2))]&\\ =-(z_1^2-z_2^2)^{-1}\partial_x[W(\psi(x,z_1),\psi^*(x,z_2))W(\psi^*(x,z_1),\psi(x,z_2))]&\end{aligned} \tag{1.4}$$

$(z_1,z_2\in\mathbb{C})$, we will call the *Faddeev–Tahtajan identity*. This relation has a long history. It was used in the theory of inverse spectral problems for the Sturm–Liouville operators. Afterwards the Faddeev–Tahtajan identity played an important role in the first years of soliton theory. In Ref. 5 the origin of the identity is interpreted in terms of classical *r*-matrixes. Here we will explain the origin of the Faddeev–Tahtajan identity using the language of tau functions.

The first main result in this paper is given in the following.

Theorem 1.1: *The Faddeev–Tahiajan identity (1.4) follows from the Fay identity (1.1) for KdV tau functions.*

The second main result in the present article is given in the following.

Theorem 1.2: *Let $\tau(t)$, $t\in\mathbb{C}^\infty$ be an arbitrary KdV tau function. Then*

(i) for every $z_1,z_2\in\mathbb{C}$,

$$\begin{aligned}(z_2-z_1)[\tau(t+[z_1]+[z_2])\tau(t-[z_1])\tau(t-[z_2])-\tau(t-[z_1]-[z_2])\tau(t+[z_1])\tau(t+[z_2])]&\\ =(z_2+z_1)[\tau(t+[z_1]-[z_2])\tau(t-[z_1])\tau(t+[z_2])-\tau(t-[z_1]+[z_2])\tau(t+[z_1])&\\ \times\tau(t-[z_2])];&\end{aligned}$$

(ii) for every $z\in\mathbb{C}$

$$\begin{aligned}\tau(t+2[z])\tau^2(t-[z])-\tau(t-2[z])\tau^2(t+[z])&\\ =2\sum_{k=0}^{\infty}z^{2k+1}[\tau(t-[z])W_{2k+1}(\tau(t),\tau(t+[z]))+\tau(t+[z])W_{2k+1}(\tau(t),\tau(t-[z]))],&\end{aligned}$$

where we denote $W_{2k+1}(f,g):=f(\partial_{t_{2k+1}}g)-(\partial_{t_{2k+1}}f)g$, $k=0,1,2,\ldots$.

Remark 1.3: Let us mention that the identities from Theorem 1.2 are cubic in τ relations (contrary to the Fay identity, which is quadratic in the τ relation) and they are specific only for the KdV tau functions.

Remark 1.4: The proof of Theorem 1.2 is based *only* on the following three facts:

(i) The Fay identity (1.1) (which is common for all tau functions),
(ii) the relation (1.2) (which is specific only for KdV tau functions), and
(iii) the obvious identity for Wronskians:

$$W(f_1f_2,g_1g_2)=f_1g_1W(f_2,g_2)+f_2g_2W(f_1,g_1)=f_1g_2W(f_2,g_1)+f_2g_1W(f_1,g_2). \qquad (1.5)$$

The paper consists of four sections. In Sec. II we give some preliminary results. The proofs of Theorems 1.1 and 1.2 are given in Sec. III. In Sec. IV we give some examples and comments of the main statements. A preliminary (and from different viewpoint) version of some of the results is presented in Refs. 12 and 13.

II. PRELIMINARY RESULTS

First, let us mention some obvious relations for Wronskians.
Lemma 2.1:

$$\text{(i)}\quad W(e^{z_1x}f,e^{z_2x}g)=e^{(z_1+z_2)x}[W(f,g)-(z_1-z_2)fg],$$

$$\text{(ii)}\quad W\left(\frac{f_1}{g},\frac{f_2}{g}\right)=\frac{W(f_1,f_2)}{g^2},$$

$$\text{(iii)}\quad \partial_x\left(\frac{f_1f_2}{g^2}\right)=-\frac{f_1W(f_2,g)+f_2W(f_1,g)}{g^3}.$$

Instead of Fay identity (1.1) we will use the differential Fay identity of Ref. 8 ($z_1,z_2\in\mathbb{C}$):

$$W(\tau(t+[z_1]),\tau(t+[z_2]))=(z_2^{-1}-z_1^{-1})[\tau(t+[z_1])\tau(t+[z_2])-\tau(t)\tau(t+[z_1]+[z_2])]. \qquad (2.1)$$

Shifting the argument t respectively to $(t-[z_1]-[z_2])$, $(t-[z_2])$, and $(t-[z_1])$ we could obtain expressions respectively for the following Wronskians:

$$W(\tau(t-[z_1],\tau(t-[z_2])),\quad W(\tau(t+[z_1]-[z_2]),\tau(t)),\quad W(\tau(t-[z_1]+[z_2]),\tau(t)).$$

But, shifting t we cannot obtain an expression, e.g., for the Wronskian:

$$W(\tau(t+[z_1]),\tau(t-[z_2])).$$

This is possible for KdV tau functions. Using (2.1) and (1.2), it is easy to see that

$$W(\tau(t+[z_1]),\tau(t-[z_2]))=-(z_2^{-1}+z_1^{-1})[\tau(t+[z_1])\tau(t-[z_2])-\tau(t)\tau(t+[z_1]-[z_2])].$$

This way we obtain the following expressions for the Wronskians of KdV tau functions.
Lemma 2.2: Let $\tau(t)$ be an arbitrary KdV tau function. Then we have

$$\text{(i)}\quad W(\tau(t+[z_1]),\tau(t+[z_2]))=(z_2^{-1}-z_1^{-1})[\tau(t+[z_1])\tau(t+[z_2])-\tau(t)\tau(t+[z_1]+[z_2])],$$

$$W(\tau(t-[z_1]),\tau(t-[z_2]))=-(z_2^{-1}-z_1^{-1})[\tau(t-[z_1])\tau(t-[z_2])-\tau(t)\tau(t-[z_1]-[z_2])],$$

$$W(\tau(t-[z_1]),\tau(t+[z_2]))=(z_2^{-1}+z_1^{-1})[\tau(t-[z_1])\tau(t+[z_2])-\tau(t)\tau(t-[z_1]+[z_2])],$$

$$W(\tau(t+[z_1]),\tau(t-[z_2]))=-(z_2^{-1}+z_1^{-1})[\tau(t+[z_1])\tau(t-[z_2])-\tau(t)\tau(t+[z_1]-[z_2])],$$

$$\text{(ii)}\quad W(\tau(t+[z_1]-[z_2]),\tau(t))=(z_2^{-1}-z_1^{-1})[\tau(t+[z_1]-[z_2])\tau(t)-\tau(t+[z_1])\tau(t-[z_2])],$$

$$W(\tau(t-[z_1]+[z_2]),\tau(t))=-(z_2^{-1}-z_1^{-1})[\tau(t-[z_1]+[z_2])\tau(t)-\tau(t-[z_1])\tau(t+[z_2])],$$

$$W(\tau(t-[z_1]-[z_2]),\tau(t))=(z_2^{-1}+z_1^{-1})[\tau(t-[z_1]-[z_2])\tau(t)-\tau(t-[z_1])\tau(t-[z_2])],$$

$$W(\tau(t+[z_1]+[z_2]),\tau(t))=-(z_2^{-1}+z_1^{-1})[\tau(t+[z_1]+[z_2])\tau(t)-\tau(t+[z_1])\tau(t+[z_2])].$$

Let us define the *wave functions* $\psi(t,z)$ and $\psi^*(t,z)$ in Ref. 8 by expressions

$$\psi(t,z):=\exp\left(\sum_{k=1}^{\infty} t_k z^k\right)\frac{\tau(t-[z^{-1}])}{\tau(t)},$$

$$\psi^*(t,z):=\exp\left(-\sum_{k=1}^{\infty} t_k z^k\right)\frac{\tau(t+[z^{-1}])}{\tau(t)}.$$

For an arbitrary KdV tau function $\tau(t)$, denoting $u(t):=2\partial_x^2 \ln \tau(t)$, it is well-known (Ref. 8) that the wave functions $\psi(t,z)$ and $\psi^*(t,z)$ satisfy the Sturm–Liouville equation (1.3) ($t_1\equiv x$ and $t_3,t_5,\ldots$ are parameters). Using the relations of Lemma 2.2 we can explain the Wronskians of the wave functions $\psi(t,z)$ and $\psi^*(t,z)$ in terms of the tau function $\tau(t)$.

Lemma 2.3: Let $\tau(t)$ be an arbitrary KdV tau function and $\psi(t,z)$ and $\psi^*(t,z)$ are the corresponding wave functions. Then we have ($z_1,z_2\in\mathbb{C}$)

$$\text{(i)}\quad W(\psi(t,z_1),\psi(t,z_2))=(z_1-z_2)\exp\left(\sum_{k=0}^{\infty} t_{2k+1}(z_1^{2k+1}+z_2^{2k+1})\right)\frac{\tau(t-[z_1^{-1}]-[z_2^{-1}])}{\tau(t)},$$

$$\text{(ii)}\quad W(\psi^*(t,z_1),\psi^*(t,z_2))=-(z_1-z_2)\exp\left(-\sum_{k=0}^{\infty} t_{2k+1}(z_1^{2k+1}+z_2^{2k+1})\right)\times\frac{\tau(t+[z_1^{-1}]+[z_2^{-1}])}{\tau(t)},$$

$$\text{(iii)}\quad W(\psi(t,z_1),\psi^*(t,z_2))=(z_1+z_2)\exp\left(\sum_{k=0}^{\infty} t_{2k+1}(z_1^{2k+1}-z_2^{2k+1})\right)\frac{\tau(t-[z_1^{-1}]+[z_2^{-1}])}{\tau(t)},$$

$$\text{(iv)}\quad W(\psi^*(t,z_1),\psi(t,z_2))=-(z_1+z_2)\exp\left(-\sum_{k=0}^{\infty} t_{2k+1}(z_1^{2k+1}-z_2^{2k+1})\right)\frac{\tau(t+[z_1^{-1}]-[z_2^{-1}])}{\tau(t)}.$$

Proof: Let us denote the functions

$$\varphi(t,z):=e^{zx}\frac{\tau(t-[z^{-1}])}{\tau(t)},\qquad \varphi^*(t,z):=e^{zx}\frac{\tau(t+[z^{-1}])}{\tau(t)}.$$

Then we have

$$\psi(t,z)=\exp\left(\sum_{k=1}^{\infty} t_{2k+1}z^{2k+1}\right)\varphi(t,z),\qquad \psi^*(t,z)=\exp\left(-\sum_{k=1}^{\infty} t_{2k+1}z^{2k+1}\right)\varphi^*(t,z),$$

and consequently we have

$$W(\psi(t,z_1),\psi(t,z_2))=\exp\left(\sum_{k=1}^{\infty} t_{2k+1}(z_1^{2k+1}+z_2^{2k+1})\right)W(\varphi(t,z_1),\varphi(t,z_2)),\qquad \text{etc.}$$

Using the relations of Lemmas 2.1 and 2.2 we obtain

$$
\begin{aligned}
W(\varphi(t,z_1),\varphi(t,z_2)) &= W\left(e^{z_1 x}\frac{\tau(t-[z_1^{-1}])}{\tau(t)}, e^{z_2 x}\frac{\tau(t-[z_2^{-1}])}{\tau(t)} \right)\\
&= e^{(z_1+z_2)x}\left[W\left(\frac{\tau(t-[z_1^{-1}])}{\tau(t)}, \frac{\tau(t-[z_2^{-1}])}{\tau(t)} \right) \right.\\
&\quad \left. -(z_1-z_2)\frac{\tau(t-[z_1^{-1}])\tau(t-[z_2^{-1}])}{\tau^2(t)} \right]\\
&= e^{(z_1+z_2)x}\left[\frac{W(\tau(t-[z_1^{-1}]),\tau(t-[z_2^{-1}]))}{\tau^2(t)} \right.\\
&\quad \left. -(z_1-z_2)\frac{\tau(t-[z_1^{-1}])\tau(t-[z_2^{-1}])}{\tau^2(t)} \right]\\
&= \frac{e^{(z_1+z_2)x}}{\tau^2(t)}[(z_1-z_2)(\tau(t-[z_1^{-1}])\tau(t-[z_2^{-1}])-\tau(t)\tau(t-[z_1^{-1}]-[z_2^{-1}]))\\
&\quad -(z_1-z_2)\tau(t-[z_1^{-1}])\tau(t-[z_2^{-1}])]\\
&= (z_1-z_2)e^{x(z_1+z_2)}\frac{\tau(t-[z_1^{-1}]-[z_2^{-1}])}{\tau(t)}.
\end{aligned}
$$

From here follows (i), because we have ($t_1 \equiv x$)

$$
e^{x(z_1+z_2)}\exp\left(\sum_{k=1}^{\infty} t_{2k+1}(z_1^{2k+1}+z_2^{2k+1}) \right) = \exp\left(\sum_{k=0}^{\infty} t_{2k+1}(z_1^{2k+1}+z_2^{2k+1}) \right).
$$

It is easy to proove (ii), (iii), and (iv) in the same way. □

III. PROOF OF THE MAIN RESULTS

Proof of Theorem 1.2: First we will prove the identity (i). Using the identities of Lemma 2.2 and (1.5), let us expand the following Wronskian:

$$
W(\tau(t+[z_1])\tau(t-[z_1]),\tau(t+[z_2])\tau(t-[z_2]))
$$

in two different ways. From the first line of (1.5) we obtain

$$
\begin{aligned}
&(z_2^{-1}-z_1^{-1})\tau(t)[\tau(t-[z_1]-[z_2])\tau(t+[z_1])\tau(t+[z_2])\\
&\quad -\tau(t+[z_1]+[z_2])\tau(t-[z_1])\tau(t-[z_2])],
\end{aligned}
$$

and from the second line of (1.5) we obtain

$$
\begin{aligned}
&(z_2^{-1}+z_1^{-1})\tau(t)[\tau(t+[z_1]-[z_2])\tau(t-[z_1])\tau(t+[z_2])\\
&\quad -\tau(t-[z_1]+[z_2])\tau(t+[z_1])\tau(t-[z_2])].
\end{aligned}
$$

But $(z_2^{-1}-z_1^{-1})=(z_1-z_2/z_1z_2$ and $(z_2^{-1}+z_1^{-1})=(z_1+z_2)/z_1z_2$, so we have

$$
\frac{\tau(t)}{z_1z_2}[\text{lhs of } (i)] = \frac{\tau(t)}{z_1z_2}[\text{rhs of } (i)].
$$

The proof of the first identity of Theorem 1.2 is completed.

Now we will obtain the second identity (ii) of Theorem 1.2 letting z_2 tend to z_1 in the first identity (i) (we will denote $z_1=z_2=z$). The lhs of (ii) is clear. In order to obtain the rhs of (ii) we mention that:

$$\partial_{z_2}(\tau(t+[z_1]-[z_2]))\big|_{z_2=z_1=z}=\partial_{z_2}\left[\tau\left((x+z_1)-z_2,\left(t_3+\frac{z_1^3}{3}\right)-\frac{z_2^3}{3},\left(t_5+\frac{z_1^5}{5}\right)-\frac{z_2^5}{5},\dots\right)\right]\Bigg|_{z_2=z_1=z}$$

$$=-\sum_{k=0}^{\infty} z^{2k}\partial_{t_{2k+1}}\tau(t).$$

In the same way we obtain

$$\partial_{z_2}(\tau(t-[z_1]+[z_2]))\big|_{z_2=z_1=z}=\sum_{k=0}^{\infty} z^{2k}\partial_{t_{2k+1}}\tau(t),$$

$$\partial_{z_2}(\tau(t+[z_2]))\big|_{z_2=z}=\sum_{k=0}^{\infty} z^{2k}\partial_{t_{2k+1}}\tau(t+[z]),$$

$$\partial_{z_2}(\tau(t-[z_2]))\big|_{z_2=z}=-\sum_{k=0}^{\infty} z^{2k}\partial_{t_{2k+1}}\tau(t-[z]),$$

So, from the rhs of (i) we obtain

$$\tau(t-[z])\sum_{k=0}^{\infty} 2z^{2k+1}[\tau(t)\partial_{t_{2k+1}}\tau(t+[z])-\tau(t+[z])\partial_{t_{2k+1}}\tau(t)]$$
$$+\tau(t+[z])\sum_{k=0}^{\infty} 2z^{2k+1}[\tau(t)\partial_{t_{2k+1}}\tau(t-[z])-\tau(t-[z])\partial_{t_{2k+1}}\tau(t)],$$

which gives the rhs of (ii). □

Proof of Theorem 1.1: On the one hand, using the expressions of the wave functions $\psi(t,z)$ and $\psi^*(t,z)$ in terms of tau function $\tau(t)$ (in our case τ is an arbitrary KdV tau function) we obtain from the first line of (1.4)

$$\mathbf{W}\equiv W[\psi(t,z_1)\psi^*(t,z_1),\psi(t,z_2)\psi^*(t,z_2)]$$
$$=W\left(\frac{\tau(t+[z_1^{-1}])\tau(t-[z_1^{-1}])}{\tau^2(t)},\frac{\tau(t+[z_2^{-1}])\tau(t-[z_2^{-1}])}{\tau^2(t)}\right)$$
$$=\frac{1}{\tau^4(t)}W(\tau(t+[z_1^{-1}])\tau(t-[z_1^{-1}]),\tau(t+[z_2^{-1}])\tau(t-[z_2^{-1}])).$$

From the proof of the identity (i) of the Theorem 1.2 we know that this equals either

$$\frac{z_2-z_1}{\tau^3(t)}[\tau(t-[z_1^{-1}]-[z_2^{-1}])\tau(t+[z_1^{-1}])\tau(t+[z_2^{-1}])$$
$$-\tau(t+[z_1^{-1}]+[z_2^{-1}])\tau(t-[z_1^{-1}])\tau(t-[z_2^{-1}])],$$

or

$$\frac{z_2+z_1}{\tau^3(t)}[\tau(t+[z_1^{-1}]-[z_2^{-1}])\tau(t-[z_1^{-1}])\tau(t+[z_2^{-1}])$$
$$-\tau(t-[z_1^{-1}]+[z_2^{-1}])\tau(t+[z_1^{-1}])\tau(t-[z_2^{-1}])].$$

On the other hand, using the relations from Lemmas 2.1–2.3, we obtain from the the second line of (1.4)

$$\mathbf{W}_1\equiv-(z_1^2-z_2^2)^{-1}\partial_x[W[\psi(t,z_1),\psi(t,z_2)]W[\psi^*(t,z_1),\psi^*(t,z_2)]]$$
$$=(z_1-z_2)^2(z_1^2-z_2^2)^{-1}\partial_x\left[\frac{\tau(t-[z_1^{-1}]-[z_2^{-1}])\tau(t+[z_1^{-1}]+[z_2^{-1}])}{\tau^2(t)}\right]-\frac{z_1-z_2}{z_1+z_2}\tau^{-3}(t)$$
$$\times[\tau(t-[z_1^{-1}]-[z_2^{-1}])W(\tau(t+[z_1^{-1}]+[z_2^{-1}]),\tau(t))+\tau(t+[z_1^{-1}]+[z_2^{-1}])$$
$$\times W(\tau(t-[z_1^{-1}]-[z_2^{-1}]),\tau(t))]$$
$$=\frac{z_2-z_1}{z_1+z_2}\tau^{-3}(t)[\tau(t-[z_1^{-1}]-[z_2^{-1}])(-(z_1+z_2)(\tau(t+[z_1^{-1}]+[z_2^{-1}])\tau(t)-\tau(t+[z_1^{-1}])$$
$$\times\tau(t+[z_2^{-1}])))+\tau(t+[z_1^{-1}]+[z_2^{-1}])((z_1+z_2)(\tau(t-[z_1^{-1}]-[z_2^{-1}])\tau(t)-\tau(t-[z_1^{-1}])$$
$$\times\tau(t-[z_2^{-1}])))]$$
$$=\frac{z_2-z_1}{\tau^3(t)}[\tau(t-[z_1^{-1}]-[z_2^{-1}])\tau(t+[z_1^{-1}])\tau(t+[z_2^{-1}])-\tau(t+[z_1^{-1}]+[z_2^{-1}])\tau(t-[z_1^{-1}])$$
$$\times\tau(t-[z_2^{-1}])], \qquad \blacksquare$$

and for the third line of (1.4)

$$\mathbf{W}_2\equiv-(z_1^2-z_2^2)^{-1}\partial_x[W[\psi(t,z_1),\psi^*(t,z_2)]W[\psi^*(t,z_1),\psi^*(t,z_2)]]$$
$$=(z_1+z_2)^2(z_1^2-z_2^2)^{-1}\partial_x\left[\frac{\tau(t-[z_1^{-1}]+[z_2^{-1}])\tau(t+[z_1^{-1}]-[z_2^{-1}])}{\tau^2(t)}\right]$$
$$=-\frac{z_1+z_2}{z_1-z_2}\tau^{-3}(t)[\tau(t-[z_1^{-1}]+[z_2^{-1}])W(\tau(t+[z_1^{-1}]-[z_2^{-1}]),\tau(t))+\tau(t+[z_1^{-1}]$$
$$-[z_2^{-1}])W(\tau(t-[z_1^{-1}]+[z_2^{-1}]),\tau(t))]$$
$$=\frac{z_2+z_1}{z_1-z_2}\tau^{-3}(t)[\tau(t-[z_1^{-1}]+[z_2^{-1}])(-(z_1-z_2)(\tau(t+[z_1^{-1}]-[z_2^{-1}])\tau(t)-\tau(t+[z_1^{-1}])$$
$$\times\tau(t-[z_2^{-1}])))+\tau(t+[z_1^{-1}]-[z_2^{-1}])((z_1-z_2)(\tau(t-[z_1^{-1}]+[z_2^{-1}])\tau(t)-\tau(t-[z_1^{-1}])$$
$$\times\tau(t+[z_2^{-1}])))]$$
$$=\frac{z_2+z_1}{\tau^3(t)}[\tau(t+[z_1^{-1}]-[z_2^{-1}])\tau(t-[z_1^{-1}])\tau(t+[z_2^{-1}])-\tau(t-[z_1^{-1}]+[z_2^{-1}])\tau(t+[z_1^{-1}])$$
$$\times\tau(t-[z_2^{-1}])]. \qquad \blacksquare$$

This way we obtain that **W** equals to $\mathbf{W}_1$ or $\mathbf{W}_2$, i.e., the Faddeev–Tahtajan identity is fulfilled. □

IV. CONCLUSION REMARKS AND EXAMPLES

First we illustrate the identities from Theorem 1.2 by examples with polynomial KdV tau functions. The author thanks F. A. Grünbaum for suggestions that include these examples in the body of the paper.

Example 4.1: The first nontrivial polynomial KdV tau function is $\tau_1(t) := t_1$. In this case the examination of the identities (i) and (ii) of Theorem 1, is easy to do directly and the result is that the both sides of (i) are equal to $2z_1z_2^3 - 2z_1^3z_2$ and the both sides of (ii) are equal to $4z^3$.

Example 4.2: The next polynomial KdV tau function is of degree 3: $\tau_3(t) := t_1^3 - 3t_3$ and as is clear from the results, the examination of the identities (i) and (ii) of Theorem 1, in this case is difficult to do directly. We used the system Maple V Release 4 at RIMS, Kyoto University. So, the both sides of (i) are equal to

$$6(z_1z_2^3 - z_1^3z_2)t_1^6 + 36(z_1^5z_2 - z_1z_2^5)t_1^4 + 126(z_1z_2^3 - z_1^3z_2)t_1^3t_3 + 54(z_1^3z_2^5 - z_1^5z_2^3)t_1^2 + 54(z_1^5z_2 - z_1z_2^5)t_1t_3 + 54(z_1z_2^3 - z_1^3z_2)t_3^2,$$

and the both sides of (ii) are equal to

$$12z^3t_1^6 - 144z^5t_1^4 + 252z^3t_1^3t_3 + 108z^7t_1^2 - 216z^5t_1t_3 + 108z^3t_3^2.$$

There were some problems with fixing the correct form of the KdV tau function $\tau_3(t)$-polynomial of the form $t_1^3 - at_3$. The function $t_1^3 - at_3$ satisfies the Fay identity (1.1) iff $a = 3$.

Remark 4.3: Applying the identities (1.5) to the Wronskian,

$$W(\tau(t+[z_1])\tau(t-[z_1])\tau(t+[z_3])\tau(t-[z_3]), \tau(t+[z_2])\tau(t-[z_2])\tau(t+[z_4])\tau(t-[z_4]))$$

$(z_1, z_2, z_3, z_4 \in \mathbb{C})$, we can obtain eight different (equivalent) expessions where we have Wronskians of two tau functions only (i.e., without any Wronskian of products of tau functions). The expressions are separated in two groups and applying Lemma 2.2 we could see that the resulting identities among the expressions in each group are easily obtained using the result of Theorem 1.2 (i). The equality of the given bellow expressions (from the two groups) is a nontrivial seventh-order (specific for KdV tau functions only) identity:

$$\begin{aligned}
&(z_4^{-1} - z_3^{-1})\tau(t+[z_1])\tau(t-[z_1])\tau(t+[z_2])\tau(t-[z_2])[\tau(t+[z_3])\tau(t+[z_4])\tau(t-[z_3]-[z_4]) \\
&\quad - \tau(t-[z_3])\tau(t-[z_4])\tau(t+[z_3]+[z_4])] + (z_2^{-1} - z_1^{-1})\tau(t+[z_3])\tau(t-[z_3])\tau(t+[z_4])\tau(t \\
&\quad -[z_4])[\tau(t+[z_1])\tau(t+[z_2])\tau(t-[z_1]-[z_2]) - \tau(t-[z_1])\tau(t-[z_2])\tau(t+[z_1]+[z_2])] \\
&\quad = (z_2^{-1} - z_3^{-1})\tau(t+[z_1])\tau(t-[z_1])\tau(t+[z_4])\tau(t-[z_4])[\tau(t+[z_2])\tau(t+[z_3])\tau(t-[z_2] \\
&\qquad -[z_3]) - \tau(t-[z_2])\tau(t-[z_3])\tau(t+[z_2]+[z_3])] \\
&\qquad + (z_4^{-1} - z_1^{-1})\tau(t+[z_2])\tau(t-[z_2])\tau(t+[z_3])\tau(t-[z_3])[\tau(t+[z_1])\tau(t+[z_4])\tau(t-[z_1] \\
&\qquad -[z_4]) - \tau(t-[z_1])\tau(t-[z_4])\tau(t+[z_1]+[z_4])].
\end{aligned}$$

It is clear that this way we can obtain generalized identities of order $2^n - 1$ for any $n = 4,5,\ldots$. The identities from Theorem 1.2 and Remark 4.3 correspond to the cases $n = 2$ and $n = 3$, respectively.

Example 4.4: For the first polynomial tau function $\tau_1(t) = t_1$, both sides of the identity from Remark 4.3 are equal to

$$2(-z_1^2 + z_2^2 - z_3^2 + z_4^2)t_1^4 + 4(z_1^2z_3^2 - z_2^2z_4^2)t_1^2 + 2(-z_1^2z_2^2z_3^2 + z_1^2z_2^2z_4^2 - z_1^2z_3^3z_4^2 + z_2^2z_3^2z_4^2).$$

For the next polynomial KdV tau function $\tau_3(t) = t_1^3 - 3t_3$, both sides of this identity have too many terms (more than 250).

Remark 4.5: As we mentioned in the Introduction, there are some problems to translate the identity (i) from Theorem 1.2 to the cases when KdV tau function is expressed by trigonometric functions or elliptic theta functions. The problems come, roughly speaking, from the fact that in the original Fay identity (i.e., for theta functions related to Jacobians) is used the ''Prime Form'' [e.g., in the $g=1$ case: $\theta_{11}(z_0-z_1)(\theta'_{11}(0))^{-1}$], but in the Fay identity (1.1) for KP tau functions is used the difference (z_0-z_1) instead. Our next task is to fix these problems and to find a ''geometric'' explanation of the identities from the present paper. It will be done in some future article.

Remark 4.6: The ''elliptic version'' of the identity (ii) from Theorem 1.2 is the following relation:

$$\theta'_{11}(0)[\theta_{11}(x+2z)0^2_{11}(x-z)-\theta_{11}(x-2z)\theta^2_{11}(x+z)]$$
$$=\theta_{11}(2z)[\theta_{11}(x-z)W(\theta_{11}(x),\theta_{11}(x+z))+\theta_{11}(x+z)W(\theta_{11}(x),\theta_{11}(x-z))].$$

It is easily obtained from the elliptic version of the identity (i) from Theorem 1.2 (cf. the Introduction) letting $z_1\to z_2$ and denoting $z_1=z_2\equiv z$.

ACKNOWLEDGMENTS

First I would like to express my sincere thanks to my host researcher Professor T. Miwa and to Professor M. Jimbo for making it possible to be at RIMS. I wish to acknowledge the useful discussions with F. A. Grünbaum, M. Jimbo, T. Miwa, M. Ohmiya, E. Previato, T. Shiota, and B. Sturmfels. I am also thankful to all the people at RIMS for warm hospitality. The work was done under JSPS Postdoctoral Fellowship for Foreign Researchers.

An integrable nonlinear partial differential equation typically extends to a hierarchy of integrable equations. There exist several recursive schemes for obtaining these hierarchies. Recently, explicit expressions for the KdV hierarchy have been found. We derive explicit expressions for the hierarchy associated with the KP equation. The main tools are Sato's theory, Hirota's formalism, and Bell's polynomials.
 [S0022-2488(99)00805-1]

I. INTRODUCTION

In this paper we derive some new formulas for the Kadomtsev–Petviashvili (KP) and the Korteweg–de Vries (KdV) hierarchies of solitonic partial differential equations. The proofs rely on the properties of the so-called Bell polynomials and their transforms.

The KdV hierarchy[1] consists of a sequence of evolution equations

$$\frac{\partial u}{\partial t_{2n-1}} = K_{2n-1}[u], \quad n \geq 2, \tag{1}$$

the flows of which commute with each other. Here u depends on an infinite set of variables $t_1, t_3, t_5, \ldots$ and $K_n[u]$ is a polynomial in the variable u and its t_1 derivatives up to some higher order. The first equation of the hierarchy, i.e., the KdV equation itself, reads

$$\frac{\partial u}{\partial t_3} = \frac{1}{4} u^{(3)} + 3uu^{(1)}, \tag{2}$$

where we use the notation

$$u^{(k)} = \frac{\partial^k u}{\partial t_1^k}.$$

It is well known that the KdV hierarchy is generated by Lenard's recursion[1]

$$K_{2n+1}[u] = RK_{2n-1}[u],$$

where the recursion operator reads

$$R = \frac{1}{4}\left(\frac{\partial}{\partial t_1}\right)^2 + 2u + u^{(1)}\left(\frac{\partial}{\partial t_1}\right)^{-1}.$$

Hirota[2,3] succeeded in finding bilinear forms for a large number of solitonic equations. Let us recall the definition of Hirota's bilinear operators D_j acting on pairs of functions $\tau(\mathbf{t})$ and $\sigma(\mathbf{t})$:

$$D_j(\tau\cdot\sigma)(\mathbf{t})=\frac{\partial}{\partial z_j}(\tau(\mathbf{t}+\mathbf{z})\sigma(\mathbf{t}-\mathbf{z}))\bigg|_{\mathbf{z}=\mathbf{0}}, \tag{3}$$

where

$$\mathbf{t}=(t_1,t_2,t_3,\ldots)$$

denotes a sequence of real variables t_n and

$$\mathbf{z}=(z_1,z_2,z_3,\ldots)$$

is an auxiliary sequence. More generally, let P denote a polynomial in several variables with constant coefficients. Then Hirota defines

$$P(\mathbf{D})(\tau\cdot\sigma)(\mathbf{t})=P\left(\frac{\partial}{\partial\mathbf{z}}\right)(\tau(\mathbf{t}+\mathbf{z})\sigma(\mathbf{t}\text{-}\mathbf{z}))\bigg|_{\mathbf{z}=\mathbf{0}}, \tag{4}$$

with the symbolic sequences

$$\mathbf{D}=(D_1,D_2,D_3,\ldots)$$

and

$$\frac{\partial}{\partial\mathbf{z}}=\left(\frac{\partial}{\partial z_1},\frac{\partial}{\partial z_2},\frac{\partial}{\partial z_3},\cdots\right).$$

The so-called τ-function is introduced by

$$u=\frac{\partial^2}{\partial t_1^2}\log(\tau).$$

Then the following bilinear expression for the KdV equation holds:

$$(4D_1D_3-D_1^4)(\tau\cdot\tau)=0. \tag{5}$$

The KdV hierarchy can be viewed as a reduction of the more general KP hierarchy[4] which begins with the KP equation itself:

$$\frac{\partial u}{\partial t_3}=\frac{1}{4}u^{(3)}+3uu^{(1)}+\frac{3}{4}\int\frac{\partial^2 u}{\partial t_2^2}dt_1, \tag{6}$$

where u now depends on an infinite set of variables $t_1,t_2,t_3,\ldots$. The Lenard recursion has been extended to some complicated bilocal recursion scheme for the KP equation by Fokas and Santini:[5]

$$\frac{\partial u}{\partial t_n}=K_{n,\mathrm{KP}}[u],\quad n\geqslant 3, \tag{7}$$

where now $K_{n,\mathrm{KP}}[u]$ is a polynomial depending on u, $\int(\partial^2u/\partial t_2^2)dt_1$ and their higher t_1 derivatives up to some order. The higher KP equations generate symmetries for the lower ones.

Sato's theory[4,6] describes the KP hierarchy by means of pseudodifferential operators and a so-called τ-function. This theory allows a compact formulation of this hierarchy in bilinear terms:[7,9]

$$\tfrac{1}{2}D_1 D_n(\tau\cdot\tau)=S_{n+1}(\mathbf{D})(\tau\cdot\tau),\quad n\geqslant 3. \tag{8}$$

The KdV hierarchy emerges from the KP hierarchy by a two-reduction, which means, in particular, that all $t_2,t_4,t_6,\ldots$ dependencies disappear.

The right-hand side of (8) is given by the $(n+1)$-th Schur polynomial S_{n+1}. The sequence of the Schur polynomials $S_n(\mathbf{t})=S_n(t_1,\ldots,t_n)$ is defined through the generating function

$$\exp\left(\sum_{n=1}^{\infty} t_n\frac{h^n}{n}\right)=\sum_{n=0}^{\infty} S_n(t_1,\ldots,t_n)h^n.$$

Let us also introduce a modification $P_n(\mathbf{t})=P_n(t_1,\ldots,t_n)$ of the Schur polynomials which is defined through the generating function

$$\exp\left(\sum_{n=1}^{\infty} t_n h^n\right)=\sum_{n=0}^{\infty} P_n(t_1,\ldots,t_n)h^n.$$

Starting from (8), we have found the following explicit expression of the KP hierarchy:

$$\frac{\partial^2\tilde{u}}{\partial t_1\partial t_n}=\sum_{k=0}^{n} P_k\left(S_1\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}),\cdots,S_k\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u})\right)P_{n-k}\left(S_1\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}),\cdots,S_{n-k}\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u})\right),$$

in terms of the function

$$\tilde{u}=\int\int u\,dt_1\,dt_1=\log(\tau)$$

and of the symbolic sequence

$$\frac{\partial}{\partial\mathbf{t}}=\left(\frac{\partial}{\partial t_1},\frac{\partial}{\partial t_2},\frac{\partial}{\partial t_3},\cdots\right).$$

Moreover, in terms of the function u and of two sequences of functions z_n and z_n^*, which are recursively defined by

$$z_n=-\frac{1}{2}\left(\frac{\partial z_{n-1}}{\partial t_1}-\int\frac{\partial z_{n-1}}{\partial t_2}dt_1+\sum_{k=1}^{n-2} z_k z_{n-1-k}\right),\quad z_1=-u,$$

$$z_n^*=-\frac{1}{2}\left(\frac{\partial z_{n-1}^*}{\partial t_1}+\int\frac{\partial z_{n-1}^*}{\partial t_2}dt_1+\sum_{k=1}^{n-2} z_k^* z_{n-1-k}^*\right),\quad z_1^*=u,$$

the KP hierarchy assumes the form:

$$\frac{\partial u}{\partial t_n}=\frac{\partial}{\partial t_1}P_{n+1}\left(\int(z_1+z_1^*)dt_1,\cdots,\int(z_n+z_n^*)dt_1\right),\quad n\geqslant 3.$$

Finally, in the KdV case the analogous explicit expression takes the form

$$\frac{\partial u}{\partial t_{2n-1}}=\frac{\partial}{\partial t_1}P_n\left(2\int z_2\,dt_1,\cdots,2\int z_{2n}\,dt_1\right),\quad n\geqslant 3,$$

where now

$$z_n = -\frac{1}{2}\left(\frac{\partial z_{n-1}}{\partial t_1} + \sum_{k=1}^{n-2} z_k z_{n-1-k}\right), \quad z_1 = -u.$$

II. THE BELL POLYNOMIALS

In this section, we introduce the Bell polynomials together with some of their transforms and list several properties. In particular, we derive a new determinant representation.

The sequence of the Bell polynomials $B_n(\mathbf{t}) = B_n(t_1,\ldots,t_n)$, $n=1,2,3,...$, in real variables $t_1,t_2,t_3,\ldots$ is defined by the bilinear recursion[10,11]

$$B_{n+1}(\mathbf{t}) = \sum_{k=0}^{n} \binom{n}{k} B_k(\mathbf{t}) t_{n+1-k}, \quad B_0(\mathbf{t}) = 1. \tag{9}$$

Equivalently, the Bell polynomials can be introduced through the generating function:[12]

$$\exp\left(\sum_{n=1}^{\infty} t_n \frac{h^n}{n!}\right) = \sum_{n=0}^{\infty} B_n(\mathbf{t}) \frac{h^n}{n!}. \tag{10}$$

The first few Bell polynomials read as follows:

$$B_0(\mathbf{t}) = 1,$$

$$B_1(\mathbf{t}) = t_1,$$

$$B_2(\mathbf{t}) = t_1^2 + t_2,$$

$$B_3(\mathbf{t}) = t_1^3 + 3t_1t_2 + t_3,$$

$$B_4(\mathbf{t}) = t_1^4 + 6t_1^2t_2 + 3t_2^2 + 4t_1t_3 + t_4,$$

$$B_5(\mathbf{t}) = t_1^5 + 10t_1^3t_2 + 15t_1t_2^2 + 10t_1^2t_3 + 10t_2t_3 + 5t_1t_4 + t_5.$$

The following explicit formula goes back to Faá di Bruno:[13]

$$B_n(\mathbf{t}) = \sum_{\|\mathbf{m}\|=n} \frac{n!}{\mathbf{m}!}\left(\frac{t_1}{1!}\right)^{m_1}\left(\frac{t_2}{2!}\right)^{m_2}\cdots\left(\frac{t_n}{n!}\right)^{m_n}, \tag{11}$$

where we use some multiindex notation for non-negative integers $m_1,\ldots,m_n$:

$$\mathbf{m} = (m_1,m_2,\ldots,m_n), \quad \mathbf{m}! = m_1!m_2!\cdots m_n!,$$

$$\|\mathbf{m}\| = 1\cdot m_1 + 2\cdot m_2 + \cdots + n\cdot m_n.$$

We shall also consider some close relatives of the Bell polynomials, namely, the Schur polynomials $S_n(\mathbf{t}) = S_n(t_1,\ldots,t_n)$ defined by

$$\exp\left(\sum_{n=1}^{\infty} t_n \frac{h^n}{n}\right) = \sum_{n=0}^{\infty} S_n(t_1,\ldots,t_n) h^n \tag{12}$$

and the modified Schur polynomials $P_n(\mathbf{t}) = P_n(t_1,\ldots,t_n)$ defined by

$$\exp\left(\sum_{n=1}^{\infty} t_n h^n\right) = \sum_{n=0}^{\infty} P_n(t_1,\ldots,t_n)h^n. \tag{13}$$

Both these are closely related to the Bell polynomials, namely,

$$S_n(t_1,\ldots,t_n) = \frac{1}{n!} B_n(0!t_1,\ldots,(n-1)!t_n), \tag{14}$$

$$P_n(t_1,\ldots,t_n) = \frac{1}{n!} B_n(1!t_1,\ldots,n!t_n). \tag{15}$$

Let us further consider the ''thinned Bell polynomials'' where either the even variables $t_2,t_4,\ldots$ or the odd variables $t_1,t_3,\ldots$ are set to zero.

Proposition 1: For $n \geqslant 0$ there holds

$$B_{2n}(-t_1,0,-t_3,0,\ldots,-t_{2n-1},0) = B_{2n}(t_1,0,t_3,0,\ldots,t_{2n-1},0),$$

$$B_{2n+1}(-t_1,0,-t_3,0,\ldots,-t_{2n+1}) = -B_{2n+1}(t_1,0,t_3,0,\ldots,t_{2n+1}),$$

$$B_{2n+1}(0,t_2,0,t_4,\ldots,0) = 0,$$

$$B_{2n}(0,t_2,0,t_4,\ldots t_{2n}) = \frac{(2n)!}{n!} B_n\left(\frac{1!}{2!}t_2, \frac{2!}{4!}t_4,, \cdots, \frac{n!}{(2n)!}t_{2n}\right).$$

Proof: From

$$\exp\left(\sum_{n=1}^{\infty} (-t_{2n-1}) \frac{h^{2n-1}}{(2n-1)!}\right) = \exp\left(\sum_{n=1}^{\infty} t_{2n-1} \frac{(-h)^{2n-1}}{(2n-1)!}\right)$$

we obtain immediately

$$\sum_{n=0}^{\infty} B_n(-t_1,0,-t_3,0,\cdots,) \frac{h^n}{n!} = \sum_{n=0}^{\infty} B_n(t_1,0,t_3,0,\cdots,) \frac{(-h)^n}{n!}.$$

Further, from the generating function we have on the one hand,

$$\exp\left(\sum_{n=1}^{\infty} t_{2n} \frac{h^{2n}}{(2n)!}\right) = \sum_{n=0}^{\infty} B_n(0,t_2,0,t_4,\cdots) \frac{h^n}{n!},$$

and, on the other hand,

$$\begin{aligned}\exp\left(\sum_{n=1}^{\infty} t_{2n} \frac{h^{2n}}{(2n)!}\right) &= \exp\left(\sum_{n=1}^{\infty} t_{2n} \frac{n!}{(2n)!} \frac{(h^2)^n}{n!}\right)\\ &= \sum_{n=0}^{\infty} B_n\left(\frac{1!}{2!}t_2, \frac{2!}{4!}t_4, \cdots, \frac{n!}{(2n)!}t_{2n}\right) \frac{(h^2)^n}{n!}\\ &= \sum_{n=0}^{\infty} \frac{(2n)!}{n!} B_n\left(\frac{1!}{2!}t_2, \frac{2!}{4!}t_4, \cdots, \frac{n!}{(2n)!}t_{2n}\right) \frac{h^{2n}}{(2n)!}.\end{aligned}$$

The results follow.

Let us also introduce the inverse Bell polynomials $B_n^-(\mathbf{t}) = B_n^-(t_1,\ldots,t_n)$ by the bilinear recursion

$$B_{n+1}^{-}(\mathbf{t})=t_{n+1}-\sum_{k=1}^{n}\binom{n}{k-1}B_{k}^{-}(\mathbf{t})t_{n+1-k}, \quad B_0^{-}(\mathbf{t})=1. \tag{16}$$

They naturally appear if the system (9) is inverted, i.e., solved for the variables $t_1,t_2,t_3,\ldots$. Namely, if we replace in (9) t_n by B_n^- and vice versa we get

$$t_{n+1}=\sum_{k=0}^{n}\binom{n}{k}t_kB_{n+1-k}^{-}(\mathbf{t}),$$

which is nothing but (16). The same replacement transforms (10) into

$$\exp\left(\sum_{n=1}^{\infty}B_n^{-}\frac{h^n}{n!}\right)=\sum_{n=0}^{\infty}t_n\frac{h^n}{n!}, \quad t_0=1, \tag{17}$$

becoming equivalent to

$$\log\left(1+\sum_{n=1}^{\infty}t_n\frac{h^n}{n!}\right)=\sum_{n=1}^{\infty}B_n^{-}(\mathbf{t})\frac{h^n}{n!}. \tag{18}$$

Thus we have found the generating function of the inverse Bell polynomials $B_n^{-}(t_1,\ldots,t_n)$. The first few of them read as follows:

$$B_1^{-}(\mathbf{t})=t_1,$$

$$B_2^{-}(\mathbf{t})=-t_1^2+t_2,$$

$$B_3^{-}(\mathbf{t})=2t_1^3-3t_1t_2+t_3,$$

$$B_4^{-}(\mathbf{t})=-6t_1^4+12t_1^2t_2-3t_2^2-4t_1t_3+t_4,$$

$$B_5^{-}(\mathbf{t})=24t_1^5-60t_1^3t_2+30t_1t_2^2+20t_1^2t_3-10t_2t_3-5t_1t_4+l_5.$$

Finally, we derive a representation of the Bell polynomials in the form of a determinant:

Proposition 2: There holds for $n\geqslant 2$:

$$B_n=\begin{vmatrix} \binom{0}{0}t_1 & -1 & 0 & \cdots & 0 \\ \binom{1}{0}t_2 & \binom{1}{1}t_1 & -1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \binom{n-2}{0}t_{n-1} & \binom{n-2}{1}t_{n-2} & \binom{n-2}{2}t_{n-3} & \cdots & -1 \\ \binom{n-1}{0}t_n & \binom{n-1}{1}t_{n-1} & \binom{n-1}{2}t_{n-2} & \cdots & \binom{n-1}{n-1}t_1 \end{vmatrix}.$$

Proof: We shall show that the determinant $|M_n|$ of the matrix M_n given by the right-hand side of the above identity satisfies the bilinear recursion (9). To this end we expand the determinant $|M_n|$ with respect to the last row. The element $\binom{n-1}{k}t_{n-k}$ is multiplied by its algebraic complement

$$(-1)^{n-k-1}\begin{vmatrix} M_k & O_k \\ H_k & T_k \end{vmatrix} = (-1)^{n-k-1}|M_k||T_k| = (-1)^{n-k-1}|M_k|(-1)^{n-k-1} = |M_k|.$$

Here O_k stands for the $k\times(n-k-1)$ zero matrix and H_k is some $(n-k-1)\times k$ matrix of less importance. T_k is a $(n-k-1)\times(n-k-1)$ lower triangular matrix with diagonal elements -1, hence $|T_k|=(-1)^{n-k}$. Furthermore, we set $|M_0|=1$, $|M_1|=t_1$ and $|T_0|=1$. All together, we obtain

$$|M_n|\sum_{k=0}^{n-1}\binom{n-1}{k}|M_k|t_{n-k}, \quad |M_0|=1,$$

and the proof is completed.

Notice that instead of the variables $\mathbf{t}=(t_1,t_2,t_3,\ldots)$, any other commutative variables can be inserted into the Bell polynomials. For instance, inserting the differentiations

$$\frac{\partial}{\partial \mathbf{t}} = \left(\frac{\partial}{\partial t_1},\frac{\partial}{\partial t_2},\frac{\partial}{\partial t_3},\cdots\right),$$

we obtain from the Faá di Bruno formula (11):

$$B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t})) = \sum_{\|\mathbf{m}\|=n}^{\infty}\frac{n!}{\mathbf{m}!}\left(\frac{1}{1!}\frac{\partial}{\partial t_1}\right)^{m_1}\left(\frac{2}{2!}\frac{\partial}{\partial t_2}\right)^{m_2}\cdots\left(\frac{1}{n!}\frac{\partial}{\partial t_n}\right)^{m_n}(\tau(\mathbf{t})). \tag{19}$$

This enables us to handle the formal Taylor expansion:

$$\begin{aligned}\tau(\mathbf{t}+\mathbf{h}) &= \sum_{n=0}^{\infty}\frac{1}{n!}\left(\mathbf{h}\cdot\frac{\partial}{\partial \mathbf{t}}\right)^n(\tau(\mathbf{t}))\\ &= \exp\left(\mathbf{h}\cdot\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))\\ &= \sum_{n=0}^{\infty}B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))\frac{h^n}{n!}\\ &= \sum_{n=0}^{\infty}S_n\left(\frac{1}{0!}\frac{\partial}{\partial t_1},\cdots,\frac{1}{(n-1)!}\frac{\partial}{\partial t_n}\right)(\tau(\mathbf{t}))h^n,\end{aligned}$$

where $\mathbf{h}$ is the sequence

$$\mathbf{h} = \left(\frac{h}{1!},\frac{h^2}{2!},\frac{h^3}{3!},\cdots\right)$$

and

$$\mathbf{h}\cdot\frac{\partial}{\partial \mathbf{t}} = \frac{h}{1!}\frac{\partial}{\partial t_1} + \frac{h^2}{2!}\frac{\partial}{\partial t_2} + \frac{h^3}{3!}\frac{\partial}{\partial t_3} + \cdots.$$

For later convenience we derive the following formula:

Proposition 3: There holds for $n\geqslant 0$,

$$\exp(-\tau(\mathbf{t}))B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\exp(\tau(\mathbf{t}))) = B_n\left(B_1\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t})),\cdots,B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))\right).$$

Proof: Through Taylor expansion we obtain on the one hand

$$\exp(\tau(\mathbf{t}+\mathbf{h}))=\sum_{n=0}^{\infty} B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\exp(\tau(\mathbf{t})))\frac{h^n}{n!},$$

and on the other hand

$$\exp(\tau(\mathbf{t}+\mathbf{h}))=\exp\left(\tau(\mathbf{t})+\sum_{n=1}^{\infty} B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))\frac{h^n}{n!}\right)$$

$$=\exp(\tau(\mathbf{t}))\sum_{n=0}^{\infty} B_n\left(B_1\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t})),\cdots,B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))\right)\frac{h^n}{n!}.$$

Comparison of the coefficients of $h^n/n!$ gives the result.

Next we shall produce some Hirota-type Leibniz rule.

Proposition 4: There holds for $n\geqslant 1$,

$$B_n(\mathbf{D})(\tau\cdot\sigma)(\mathbf{t})=\sum_{k=0}^{n}\binom{n}{k}B_k\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))B_{n-k}\left(-\frac{\partial}{\partial \mathbf{t}}\right)(\sigma(\mathbf{t})).$$

Proof: We obtain by Taylor expansion

$$\tau(\mathbf{t}+(\mathbf{z}+\mathbf{h}))\sigma(\mathbf{t}-(\mathbf{z}+\mathbf{h}))=\sum_{n=0}^{\infty} B_n\left(\frac{\partial}{\partial z_1},\frac{\partial}{\partial z_2},\frac{\partial}{\partial z_3},\cdots\right)(\tau(\mathbf{t}+\mathbf{z})\sigma(\mathbf{t}-\mathbf{z}))\frac{h^n}{n!}.$$

Here we set $\mathbf{z}=\mathbf{0}$:

$$\tau(\mathbf{t}+\mathbf{h})\sigma(\mathbf{t}-\mathbf{h})=\sum_{n=0}^{\infty} B_n(\mathbf{D})(\tau\cdot\sigma)(\mathbf{t})\frac{h^n}{n!}.$$

Multiplication of the series expansions of τ and σ gives, alternatively,

$$\tau(\mathbf{t}+\mathbf{h})\sigma(\mathbf{t}-\mathbf{h})=\sum_{n=0}^{\infty} B_n\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))\frac{h^n}{n!}\sum_{n=0}^{\infty} B_n\left(-\frac{\partial}{\partial \mathbf{t}}\right)(\sigma(\mathbf{t}))\frac{h^n}{n!}$$

$$=\sum_{n=0}^{\infty}\sum_{k=0}^{n} B_k\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))B_{n-k}\left(-\frac{\partial}{\partial \mathbf{t}}\right)(\sigma(\mathbf{t}))\frac{h^n}{k!(n-k)!}$$

$$=\sum_{n=0}^{\infty}\left(\sum_{k=0}^{n}\binom{n}{k}B_k\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tau(\mathbf{t}))B_{n-k}\left(-\frac{\partial}{\partial \mathbf{t}}\right)(\sigma(\mathbf{t}))\right)\frac{h^n}{n!}.$$

Comparison of the coefficients of $h^n/n!$ gives the result.

III. HIROTA'S FORMALISM AND THE KdV EQUATION

Let us make explicit some expressions which appear in Hirota's formalism.[2,3] By using

$$\tau(\mathbf{t})=\exp\left(\int\int u(\mathbf{t})\,dt_1\,dt_1\right)$$

we now will express the bilinear quantities $D_1^n(\tau\cdot\tau)(\mathbf{t})$ as differential polynomials in $u(\mathbf{t})=(\partial^2/\partial t_1^2)\log(\tau(\mathbf{t}))$. Here $\int u(\mathbf{t})\,dt_1$ denotes any primitive of $u(\mathbf{t})$ and $\int\int u(\mathbf{t})\,dt_1\,dt_1$ any two-fold primitive.

From the observation $B_n(l_1,0,...,0)=t_1^n$ we obtain the special formulas:

$$B_n\left(\frac{\partial}{\partial t_1},0,\cdots,0\right)(\tau(t_1))=\left(\frac{d}{dt_1}\right)^n(\tau(t_1)),$$

$$B_n\left(-\frac{\partial}{\partial t_1},0,\cdots,0\right)(\tau(t_1))=(-1)^n\left(\frac{d}{dt_1}\right)^n(\tau(t_1)),$$

$$B_n(D_1,0,...,0)(\tau\cdot\tau)(t_1)=D_1^n(\tau\cdot\tau)(t_1).$$

Notice that generally

$$D_1^{2n+1}(\tau\cdot\tau)(\mathbf{t})=0,\quad n\geqslant 0.$$

The even expressions $D_1^{2n}(\tau\cdot\tau)(\mathbf{t})$ do not vanish and we just now calculate these.

Proposition 5: There holds for $n\geqslant 1$,

$$D_1^{2n}(\tau\cdot\tau)=\frac{(2n)!}{n!}(\tau)^2 B_n\left(2\frac{1!}{2!}u,2\frac{2!}{4!}u^{(2)},\cdots,2\frac{n!}{(2n)!}u^{(2n-2)}\right),$$

where

$$u=\frac{\partial^2}{\partial t_1^2}\log(\tau),\quad u^{(k)}=\left(\frac{\partial}{\partial t_1}\right)^k u.$$

Proof: We can confine ourselves to functions depending only on t_1. Then Taylor expansion gives

$$\tau(t_1+h)\tau(t_1-h)=\sum_{n=0}^{\infty}D_1^n(\tau\cdot\tau)(t_1)\frac{h^n}{n!}=\sum_{n=0}^{\infty}D_1^{2n}(\tau\cdot\tau)(t_1)\frac{h^{2n}}{(2n)!}.$$

By insertion of

$$\tau(t_1)=\exp\left(\int\int u(t_1)\,dt_1\,dt_1\right)=\exp(\tilde{u}(t_1))$$

and again by Taylor expansion we obtain

$$\begin{aligned}\tau(t_1+h)\tau(t_1-h)&=\exp(\tilde{u}(t_1+h)+\tilde{u}(t_1-h))\\&=\exp\left(\sum_{n=0}^{\infty}2\tilde{u}^{(2n)}(t_1)\frac{h^{2n}}{(2n)!}\right)\\&=\tau(t_1)^2\exp\left(\sum_{n=1}^{\infty}2\tilde{u}^{(2n)}(t_1)\frac{h^{2n}}{(2n)!}\right)\\&=\tau(t_1)^2\sum_{n=0}^{\infty}B_n(0,2\tilde{u}^{(2)}(t_1),0,2\tilde{u}^{(4)}(t_1),\ldots 0,2\tilde{u}^{(2n)}(t_1))\frac{h^n}{n!}.\end{aligned}$$

The result follows.

As a consequence from Proposition 5 we obtain, by virtue of the inverse Bell polynomials B_n^-, the following propesition.

Proposition 6: There holds for $n\geqslant 1$,

$$u^{(2n-2)}=\frac{(2n)!}{2n!}B_n^{-}\left(\frac{1!}{(2\cdot 1)!}\frac{1}{\tau^2}D^{2\cdot 1}(\tau\cdot\tau),\cdots,\frac{n!}{(2n)!}\frac{1}{\tau^2}D^{2n}(\tau\cdot\tau)\right),$$

where B_n^{-} denotes the nth inverse Bell polynomial.

As a further consequence we obtain the following.

Proposition 7: There holds for $n\geqslant 1$,

$$\frac{n!}{(2n)!}\frac{1}{\tau^2}D_1^{2n}(\tau\cdot\tau)=\begin{vmatrix} \binom{1}{0}2u & -1 & \cdots & 0 \\ \binom{3}{0}2u^{(2)} & \binom{3}{2}2u & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ \binom{2n-2}{0}2u^{(2(n-1)-2)} & \binom{2n-2}{2}u^{(2(n-2)-2)} & \cdots & -1 \\ \binom{2n-1}{0}2u^{(2n-2)} & \binom{2n-1}{2}2u^{(2(n-1)-2)} & \cdots & \binom{2n-1}{2n-2}2u \end{vmatrix}.$$

Proof: The proof relies on Proposition 6 and uses determinant rules and proceeds similar to the proof of Proposition 2.

A natural continuation of the KdV equation would be given by the sequence

$$\frac{\partial u}{\partial t_{2n-1}}=\frac{1}{2}\left(\frac{1}{4}\right)^{n-1}\frac{(2n)!}{n!}\frac{\partial}{\partial t_1}B_n\left(2\frac{1!}{2!}u,2\frac{2!}{4!}u^{(2)},\cdots,2\frac{n!}{(2n)!}u^{(2n-2)}\right). \tag{20}$$

It is well known that the stationary KdV equation

$$\tfrac{1}{4}u^{(2)}+\tfrac{3}{2}u^2=c_3$$

is an ordinary differential equation (ODE) of the Painleve type. The question arises whether or not the following ODE's,

$$B_n\left(2\frac{1!}{2!}u,2\frac{2!}{4!}u^{(2)},\cdots,2\frac{n!}{(2n)!}u^{(2n-2)}\right)=c_{2n-1},$$

represent nontrivial integrable equations of the Painleve type.

IV. THE KP AND KdV HIGHER-ORDER EQUATIONS

Let us briefly recall some facts from Sato's theory.[4,6] With the pseudodifferential operator

$$L=\partial_1+u_2\partial_1^{-1}+u_3\partial_1^{-2}+\cdots,\quad \frac{\partial}{\partial t_1},$$

its adjoint

$$L^*=-\partial_1-\partial_1^{-1}u_2-\partial_1^{-2}u_3+\cdots,$$

and a real eigenvalue parameter $h\neq 0$ we build up the linear problems

$$L\psi=h\psi,\quad \frac{\partial\psi}{\partial t_n}=(L^n)_+\psi, \tag{21}$$

$$L^*\psi^* = h\psi, \quad \frac{\partial \psi^*}{\partial t_n} = -(L^n)_+^*\psi^*, \tag{22}$$

where the differential operator $(L^n)_+$ is defined as the non-negative part of the pseudodifferential operator L^n. The first three operators $(L^n)_+$, $(L^n)_+^*$ read as

$$(L^1)_+ = \partial_1,$$

$$(L^2)_+ = \partial_1^2 + 2u_2,$$

$$(L^3)_+ = \partial_1^3 + 3u_2\partial_1 + 3u_3 + 3\frac{\partial u_2}{\partial t_1},$$

$$(L^1)_+^* = -\partial_1,$$

$$(L^2)_+^* = \partial_1^2 + 2u_2,$$

$$(L^3)_+^* = -\partial_1^3 - 3u_2\partial_1 + 3u_3.$$

The linear problems (21) and (22) admit formal solutions, called wave functions,[4,6]

$$\psi(\mathbf{t}) = \exp\left(\sum_{n=1}^{\infty} t_n h^n\right)\frac{\tau(\mathbf{t}-\mathbf{h}^{-1})}{\tau(\mathbf{t})}, \tag{23}$$

$$\psi^*(\mathbf{t}) = \exp\left(-\sum_{n=1}^{\infty} t_n h^n\right)\frac{\tau(\mathbf{t}+\mathbf{h}^{-1})}{\tau(\mathbf{t})}, \tag{24}$$

where

$$\mathbf{h}^{-1} = \left(\frac{h^{-1}}{1}, \frac{h^{-2}}{2}, \frac{h^{-3}}{3}, \cdots\right).$$

We obtain by means of Taylor expansion

$$\log\left(\frac{\tau(\mathbf{t}\mp\mathbf{h}^{-1})}{\tau(\mathbf{t})}\right) = \log(\tau(\mathbf{t}\mp\mathbf{h}^{-1})) - \log(\tau(\mathbf{t}))$$

$$= \sum_{n=0}^{\infty} S_n\left(\mp\frac{\partial}{\partial t}\right)(\log(\tau(\mathbf{t})))h^{-n} - \log(\tau(t))$$

$$= \sum_{n=1}^{\infty} S_n\left(\mp\frac{\partial}{\partial \mathbf{t}}\right)(\log(\tau(\mathbf{t})))h^{-n}.$$

This yields

$$\frac{\tau(\mathbf{t}\mp\mathbf{h}^{-1})}{\tau(\mathbf{t})} = \exp\left(\sum_{n=1}^{\infty} S_n\left(\mp\frac{\partial}{\partial t}\right)(\log(\tau(\mathbf{t})))h^{-n}\right)$$

$$= \exp\left(\sum_{n=1}^{\infty} \int S_n\left(\mp\frac{\partial}{\partial \mathbf{t}}\right)\left(\frac{\partial}{\partial t_1}\log(\tau(\mathbf{t}))\right)h^{-n}\right)$$

and gives the following expression for the wave functions (23) and (24):

$$\psi(\mathbf{t}) = \exp\left(\sum_{n=1}^{\infty} t_n h^n\right) \exp\left(\sum_{n=1}^{\infty} \int S_n\left(-\frac{\partial}{\partial \mathbf{t}}\right)\left(\frac{(\partial\tau/\partial t_1)(\mathbf{t})}{\tau(\mathbf{t})}\right) dt_1 h^{-n}\right)$$

$$= \exp\left(\sum_{n=1}^{\infty} t_n h^n\right) \exp\left(\sum_{n=1}^{\infty} \int z_n(\mathbf{t})\, dt_1 h^{-n}\right), \tag{25}$$

$$\psi^*(\mathbf{t}) = \exp\left(-\sum_{n=1}^{\infty} t_n h^n\right) \exp\left(\sum_{n=1}^{\infty} \int S_n\left(\frac{\partial}{\partial \mathbf{t}}\right)\left(\frac{(\partial\tau/\partial t_1)(\mathbf{t})}{\tau(\mathbf{t})}\right) dt_1 h^{-n}\right)$$

$$= \exp\left(-\sum_{n=1}^{\infty} t_n h^n\right) \exp\left(\sum_{n=1}^{\infty} \int z_n^*(\mathbf{t})\, dt_1 h^{-n}\right), \tag{26}$$

where

$$z_n = S_n\left(-\frac{\partial}{\partial \mathbf{t}}\right)\left(\frac{(\partial\tau/\partial t_1)(\mathbf{t})}{\tau(\mathbf{t})}\right), \quad z_n^* = S_n\left(\frac{\partial}{\partial \mathbf{t}}\right)\left(\frac{(\partial\tau/\partial t_1)(\mathbf{t})}{\tau(\mathbf{t})}\right).$$

In Sato's theory, the KP hierarchy arises from the Lax equations

$$\frac{\partial}{\partial t_n} L = [(L^n)_+, L)],$$

and the so-called τ-function serves as a potential for the function u_n, in particular

$$u = u_2 = \frac{\partial^2}{\partial t_1^2} \log(\tau).$$

Based on the bilinear form (8) we shall now find explicit representations of the polynomials $K_{n,\mathrm{KP}}[u]$ in (7).

Proposition 8: The KP hierarchy can be written as

$$\frac{\partial^2 \tilde{u}}{\partial t_1 \partial t_n} = \sum_{k=0}^{n} P_k\left(S_1\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tilde{u}), \ldots, S_k\left(\frac{\partial}{\partial \mathbf{t}}\right)(\tilde{u})\right) P_{n-k}\left(S_1\left(-\frac{\partial}{\partial \mathbf{t}}\right)(\tilde{u}), \ldots, S_{n-k}\left(-\frac{\partial}{\partial \mathbf{t}}\right)(\tilde{u})\right),$$

where S_n and P_n denote the Schur polynomials and the modified Schur polynomials, respectively. Moreover, there holds

$$\frac{\partial u}{\partial t_n} = \frac{\partial}{\partial t_1} P_{n+1}\left(\int (z_1 + z_1^*)\, dt_1, \cdots, \int (z_n + z_n^*)\, dt_1\right), \quad n \geqslant 3.$$

Proof: We use again

$$\tau(\mathbf{t}) = \exp\left(\int\int u(\mathbf{t})\, dt_1\, dt_1\right) = \exp(\tilde{u}(\mathbf{t})).$$

Then by straightforward calculation we obtain the left-hand side of the bilinear KP equations (8):

$$\tfrac{1}{2}D_1D_n(\tau\cdot\tau)=\tfrac{1}{2}D_1D_n(\exp(\tilde{u})\cdot\exp(\tilde{u}))$$
$$=\exp(2\tilde{u})\int\frac{\partial u}{\partial t_n}\,dt_1.$$

Therefore, the KP hierarchy in bilinear form reads as:

$$\exp(2\tilde{u})\frac{\partial^2\tilde{u}}{\partial t_1\partial t_n}=S_n(\mathbf{D})(\exp(\tilde{u})\cdot\exp(\tilde{u})).$$

From Propositions 3 and 4 the first assertion follows immediately.

The right-hand side of the bilinear KP can be transformed by Taylor expansion similar to the proof of Proposition 3. There holds on the one hand

$$\exp(\tilde{u}(\mathbf{t}+\mathbf{h}^{-1})+\tilde{u}(\mathbf{t}-\mathbf{h}^{-1}))=\exp(2\tilde{u}(\mathbf{t}))\exp\left(\sum_{n=1}^{\infty}\left(S_n\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}(\mathbf{t}))+S_n\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}(\mathbf{t}))\right)h^{-n}\right)$$
$$=\exp(2\tilde{u}(\mathbf{t}))$$
$$\sum_{n=0}^{\infty}P_n\left(S_1\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}(\mathbf{t}))+S_1\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tau(\mathbf{t})),\cdots,\right.$$
$$\left.S_n\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}(\mathbf{t}))+S_n\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}(\mathbf{t}))\right)h^{-n},$$

while we obtain on the other hand

$$\exp(\tilde{u}(\mathbf{t}+\mathbf{h}^{-1})+\tilde{u}(\mathbf{t}-\mathbf{h}^{-1}))=\sum_{n=0}^{\infty}S_n(\mathbf{D})(\exp(\tilde{u}(\mathbf{t}))\cdot\exp(\tilde{u}(\mathbf{t}))h^{-n}).$$

Comparing both expressions gives

$$S_n(\mathbf{D})(\exp(\tilde{u})\cdot\exp(\tilde{u}))$$
$$=\exp(2\tilde{u})P_n\left(S_1\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u})+S_1\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u}),\cdots,S_n\left(\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u})+S_n\left(-\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u})\right).$$

Now the definition of the quantities z_n and z_n^*, together with

$$S_n\left(\pm\frac{\partial}{\partial\mathbf{t}}\right)(\tilde{u})=S_n\left(\pm\frac{\partial}{\partial\mathbf{t}}\right)\left(\int\int u\,dt_1\,dt_1\right)$$
$$=\int S_n\left(\pm\frac{\partial}{\partial\mathbf{t}}\right)\left(\int u\,dt_1\right)dt_1$$
$$=\int S_n\left(\pm\frac{\partial}{\partial\mathbf{t}}\right)\left(\frac{\partial}{\partial t_1}\log(\tau(\mathbf{t}))\right)dt_1,$$

completes the proof.

Insertion of the wave functions (25) and (26) into

$$\frac{\partial\psi}{\partial t_2}=\frac{\partial^2\psi}{\partial t_1^2}+2u\psi,\quad \frac{\partial\psi^*}{\partial t_n}=-\frac{\partial^2\psi}{\partial t_1^2}-2u\psi^*$$

produces the following recursion formulas:

$$z_n = -\frac{1}{2}\left(\frac{\partial z_{n-1}}{\partial t_1} - \int \frac{\partial z_{n-1}}{\partial t_2}\,dt_1 + \sum_{k=1}^{n-2} z_k z_{n-1-k}\right), \quad z_1 = -u, \tag{27}$$

$$z_n^* = -\frac{1}{2}\left(\frac{\partial z_{n-1}^*}{\partial t_1} + \int \frac{\partial z_{n-1}^*}{\partial t_2}\,dt_1 + \sum_{k=1}^{n-2} z_k^* z_{n-1-k}^*\right), \quad z_1^* = u. \tag{28}$$

These define z_n and z_n^* as polynomials in the variables u, $\int(\partial u/\partial t_2)\,dt_1$ and their higher t_1-derivatives.

Let us finally discuss the KdV case. Here the τ-function and thus u depend only on $t_1, t_3, t_5, \ldots$. Furthermore, the linear problem $\partial\psi/\partial t_2 = B_2\psi$ reads as

$$h^2\psi = \frac{\partial^2\psi}{\partial t_1^2} + 2u\psi,$$

and its adjoint version takes the same form,

$$h^2\psi^* = \frac{\partial^2\psi}{\partial t_1^2} + 2u\psi^*,$$

while the recursion for the z_n becomes

$$z_n = -\frac{1}{2}\left(\frac{\partial z_{n-1}}{\partial t_1} + \sum_{k=1}^{n-2} z_k z_{n-1-k}\right), \quad z_1 = -u. \tag{29}$$

From properties of the B_n (cf. Proposition 1) or equivalently of the P_n and from

$$z_n = S_n\left(-\frac{\partial}{\partial t_1}, 0, -\frac{\partial}{\partial t_3}, 0, \cdots\right)\left(\frac{(\partial\tau/\partial t_1)(\mathbf{t})}{\tau}\right),$$

$$z_n^* = S_n\left(\frac{\partial}{\partial t_1}, 0, \frac{\partial}{\partial t_3}, 0, \cdots\right)\left(\frac{(\partial\tau/\partial t_1)(\mathbf{t})}{\tau}\right),$$

we get

$$z_{2n+1}^* = -z_{2n+1}, \quad z_{2n}^* = z_{2n}.$$

Therefore the KdV equations become for $n \geqslant 1$

$$\frac{\partial u}{\partial t_{2n-1}} = \frac{\partial}{\partial t_1} P_{2n}\left(0, 2\int z_2, \cdots, 0, 2\int z_{2n}\right)$$
$$= \frac{\partial}{\partial t_1} P_n\left(2\int z_2, \ldots, 2\int z_{2n}\right). \tag{30}$$

V. DISCUSSION

The partial differential equations of solitonic type appeared, historically, as physical models. These soliton equations became then seed equations to solitonic hierarchies, i.e., sequencies of PDEs of evolution type with increasing order. The higher-order equations can be interpreted as infinitesimal symmetries to the seed equations, i.e., their flows are one-parameter symmetries to the latter. The most prominent equations or hierarchies are the Korteweg–de Vries (KdV) and the Kadomtsev–Petviashvili (KP) ones. We have studied these here by means of Hirota's bilinear formalism and of pseudodifferential operators of Sato–Gelfand–Dickey type. In Sato's theory the

τ-function is governed by a set of equations arising from the condition $res_\lambda \psi(\mathbf{t})\psi*(\mathbf{t}')=0$ which is just the KP hierarchy. In Ref. 7 this hierarchy has been related to the hierarchy of symmetries of the KP equation studied in Ref. 4 through formula (8). In Refs. 8 and 9 constraints of those hierarchies and their trilinear forms have been considered. In the present paper the representation of the KP hierarchy (Proposition 8) and the KdV hierarchy [Eq. (30)] in terms of the Bell polynomials and their transforms are the main results. These representations are explicit (nonrecursive) expressions since several explicit formulas for the Bell polynomials are known. To these we add some new determinant formulas.

The Bell polynomials and their transforms have been, since the days of Faá di Bruno,[13] studied from different points of view. Recently, one of the authors (RS *et al.*) studied the noncommutative Bell polynomials, i.e., the generalization from real variables $t_1, t_2, t_3, \ldots$ to noncommutative algebra-valued variables.[10,11]

One of the authors (RS) had found an explicit expression for the KdV hierarchy,[14,15] alternative to the expression found in this paper. Progress has been made with the recent paper,[16] where ''full explicitness'' has been achieved: the constant coefficients of the differential polynomials are given by multiple sums and by products of binomial coefficients.

APPENDIX: EXAMPLES BY MATHEMATICA

Considering the generating functions as functions of the variable h shows that the modified Schur polynomials P_n can be calculated according to

$$P_n(t_1,\ldots,t_n)=\frac{1}{n!}\left(\frac{d}{dh}\right)^n \exp(t_1 h+\cdots+t_n h^n)\bigg|_{h=0}.$$

This formula can be easily evaluated by MATHEMATICA and the polynomials $P_1,\ldots,P_6$ are implemented as follows:

$$\xi[\mathrm{t1\_,t2\_,t3\_,t4\_,t5\_,t6\_}]:=\mathrm{t1*h+t2*h\hat{}2+t3*h\hat{}3+t4*h\hat{}4+t5*h\hat{}5+t6*h\hat{}6}$$

$$\mathrm{P[1,t1\_]:=\ Expand}\left[\frac{\partial_{\{h,1\}}\exp[\xi[\mathrm{t1,t2,t3,t4,t5,t6}]]}{1!}/.\mathrm{h}\to 0\right]$$

$$\mathrm{P[2,t1\_,t2\_]:=\ Expand}\left[\frac{\partial_{\{h,2\}}\exp[\xi[\mathrm{t1,t2,t3,t4,t5,t6}]]}{2!}/.\mathrm{h}\to 0\right]$$

$$\mathrm{P[3,t1\_,t2\_,t3\_]:=\ Expand}\left[\frac{\partial_{\{h,3\}}\exp[\xi[\mathrm{t1,t2,t3,t4,t5,t6}]]}{3!}/.\mathrm{h}\to 0\right]$$

$$\mathrm{P[4,t1\_,t2\_,t3\_,t4\_]:=\ Expand}[\partial_{\{h,4\}}\exp[\xi[\mathrm{t1,t2,t3,t4,t5,t6}]]/4!/.\mathrm{h}\to 0]$$

$$\mathrm{P[5,t1\_,t2\_,t3\_,t4\_,t5\_]:=\ Expand}\left[\frac{\partial_{\{h,5\}}\exp[\xi[\mathrm{t1,t2,t3,t4,t5,t6}]]}{5!}/.\mathrm{h}\to 0\right]$$

$$\mathrm{P[6,t1\_,t2\_,t3\_,t4\_,t5\_,t6\_]:=\ Expand}\left[\frac{\partial_{\{h,6\}}\exp[\xi[\mathrm{t1,t2,t3,t4,t5,t6}]]}{6!}/.\mathrm{h}\to 0\right]$$

Next, the recursion formula (29) for the KdV case is programmed:

$$\mathrm{z[n\_]}:=-\frac{1}{2}\left(\partial_x \mathrm{z[n-1]}+\sum_{k=1}^{n-2}\mathrm{z[k]z[n-1-k]}\right);\mathrm{z[1]}:=-\mathrm{u[x]}$$

Let us calculate the differential polynomials z_2, z_4, z_6 needed for the KdV equation itself and for the next higher equation in the hierarchy:

z[2]//Simplify

$$\frac{u'[x]}{2}$$

z[4]//Simplify

$$u[x]u'[x]+\tfrac{1}{8}u^{(3)}[x]$$

z[6]//Simplify

$$\tfrac{1}{32}(64u[x]^2u'[x]+36u'[x]u''[x]+16u[x]u^{(3)}[x]+u^{(5)}[x]).$$

According to (30), we obtain the right-hand side of the first two members of the KdV hierarchy $\partial u/\partial t_3 = K_3[u]$ and $\partial u/\partial t_5 = K_5[u]$:

D[P[2,2∗Integrate[z[2],x],2∗Integrate[z[4],x]],x]//

Simplify

$$3u[x]u'[x]+\tfrac{1}{4}u^{(3)}[x]$$

D[P[3,2∗Integrate[z[2],x],

2∗Integrate[z[4],x],2∗Integrate[z[6],x]],x]//

Simplify

$$\tfrac{1}{16}(120u[x]^2u'[x]+40u'[x]u''[x]+20u[x]u^{(3)}[x]+u^{(5)}[x]).$$

In this paper we deal with the asymptotic behavior of solutions for the Klein–Gordon–Schrödinger equation. We prove the existence of compact global attractors for this model in the space $H^l \times H^l \times H^{l-1}$ for each integer $l \geqslant 1$. © *1999 American Institute of Physics.* [S0022-2488(99)00405-3]

I. INTRODUCTION

In this paper, we investigate the long time behavior of solutions for the dissipative Klein–Gordon–Schrödinger system in a bounded domain of $\mathbb{R}^n$ with $n \leqslant 3$. This model is concerned with a complex-valued function ψ and a real-valued function ϕ and takes the form

$$i\psi_t + \Delta\psi + i\nu\psi + \phi\psi = f, \tag{1.1}$$

$$\phi_{tt} + \gamma\phi_t - \Delta\phi + \phi - |\psi|^2 = g, \tag{1.2}$$

where ν and λ are positive constants, f and g driving terms. System (1.1)–(1.2) describes the interaction of a nucleon field ψ and a meson field ϕ through the Yukawa coupling. The dissipative mechanism of this model is introduced by the terms $i\nu\psi$ and $\gamma\phi_t$.

The well-posedness problem of system (1.1)–(1.2) has been studied by many authors such as Bachelot;[1] Hayashi and von Wahl;[2] Fukuda and Tsutsumi,[3,4] and the references therein.

The long time behavior of solutions for this model has been studied by Biler;[5] Li;[6] and Guo and Li.[7] In Ref. 5, the author proved the existence of the weak global attractor in the Hilbert space $H^1 \times H^1$. The finite dimensionality of the weak global attractor was also obtained there. The existence of the strong global attractor in $H^2 \times H^2$ was investigated in Refs. 6 and 7.

In this paper, we first intend to establish the continuity property of solutions on initial data in $H^1 \times H^1$, which was left open in Ref. 5. For system (1.1)–(1.2), it seems difficult to show this continuity by usual methods. We here apply an energy equation to achieve our goal. The energy equation method was essentially due to Ball[8] (see also Ref. 9). The continuity property of solutions is needed for us to construct the strong global attractor and also interesting by itself.

The second purpose of this paper is to present the asymptotic compactness of solutions in $H^l \times H^l$ for each $l \geqslant 1$. In general, this kind of compactness is more difficult to obtain for weakly dissipative equations such as (1.1)–(1.2) than strongly dissipative ones, such as the Navier–Stokes equaion; see, e.g., Refs. 10–14. Again, we, here, employ an energy equation to establish the desired compactness for the Klein–Gordon–Schrödinger model.

As a result of the asymptotic compactness, the existence of the strong global attractor in $H^1 \times H^1$ follows. Obviously, this strong global attractor coincides with the weak one. We mention that here we obtain the existence of the compact global attractor by assuming the driving terms f and g only in L^2, which is weaker than the corresponding condition $f \in H^2$ in Ref. 5.

[a)]Electronic mail: wang@math.byu.edu

Our third task in this paper is to show the existence of the strong global attractor in $H^{k+2}\times H^{k+2}$ when driving terms f and g in H^k with $k\geqslant 0$. This is achieved by similar methods as above, except some more complicated computations.

The organization of this paper is as follows. In the next section, we derive *a priori* estimates on the solutions of system (1.1)–(1.2) in $H^{k+2}\times H^{k+2}$ when f and g belong to H^k with $k\geqslant 0$. These estimates are needed for the proof of the existence of bounded absorbing sets and the asymptotic compactness. Then, in Sec. III, we establish the existence of the dynamical systems associated to problem (1.1)–(1.2) in the space $H^l\times H^l$ for each $l\geqslant 1$. Finally, in Sec. IV, we first prove the asymptotic compactness of the dynamical system and then present the existence of the strong global attractor in each space $H^l\times H^l$ with $l\geqslant 1$.

II. *A PRIORI* ESTIMATES

In this section, we formally derive *a priori* estimates on solutions of the Klein–Gordon–Schrödinger equation. These estimates hold for smooth functions and will become rigorous by a limiting process (e.g., the Galerkin method).

We first introduce the transformation $\theta=\phi_t+\delta\phi$ with δ a small positive constant that will be specified below. Then system (1.1)–(1.2) becomes

$$i\psi_t+\Delta\psi+i\nu\psi+\phi\psi=f,\quad \text{in}\ \ \Omega\times\mathbb{R}^+, \tag{2.1}$$

$$\phi_t+\delta\phi=\theta,\quad \text{in}\ \ \Omega\times\mathbb{R}^+, \tag{2.2}$$

$$\theta_t+(\gamma-\delta)\theta-\Delta\phi+(1-\delta(\gamma-\delta))\phi-|\psi|^2=g,\quad \text{in}\ \ \Omega\times\mathbb{R}^+, \tag{2.3}$$

where Ω is a smooth (e.g., C^2) bounded domain in $\mathbb{R}^n$ with $n\leqslant 3$. Problem (2.1)–(2.3) is supplemented with the initial condition

$$\psi(x,0)=\psi_0(x),\quad \phi(x,0)=\phi_0(x),\quad \theta(x,0)=\theta_0(x),\quad x\in\Omega, \tag{2.4}$$

and the boundary condition

$$(\psi,\phi,\theta)|_{\partial\Omega}=0\quad \text{or}\quad (\psi,\phi,\theta)\ \ \text{is}\ \ \Omega\ \ \text{periodic}. \tag{2.5}$$

In the sequel, we denote by $H^s(\Omega)$ both the standard real and complex Sobolev spaces and $H=L^2(\Omega)$. We also use $\|\cdot\|$ and $(\cdot,\cdot)$ for the usual norm and inner product of $L^2(\Omega)$. For any $1\leqslant p\leqslant\infty$, we denote by $\|\cdot\|_p$ the norm of $L^p(\Omega)$ ($\|\cdot\|_2=\|\cdot\|$). In general, $\|\cdot\|_X$ denotes the norm of any Banach space X.

We are now in a position to derive the estimates on solutions of problem (2.1)–(2.5). We start with the estimates in $H^1\times H^1\times H$.

Lemma 2.1: Assume that f and g belong to H. Then there exists a constant δ_1 such that when $\delta\leqslant\delta_1$, every solution (ψ,ϕ,θ) of problem (2.1)–(2.5) satisfies

$$\|\psi(t)\|_{H^1}+\|\phi(t)\|_{H^1}+\|\theta(t)\|\leqslant M,\quad t\geqslant t_2,$$

where M depends on $(\nu,\gamma,\delta,\|f\|,\|g\|)$; t_2 depends on $(\nu,\gamma,\delta,\|f\|,\|g\|)$ and R when $\|(\psi_0,\phi_0,\theta_0)\|_{H^1\times H^1\times H}\leqslant R$.

Proof: The proof of this lemma is similar to Proposition 2.1 in Ref. 5. Therefore, here we only sketch it.

Taking the imaginary part of the inner product of (2.1) with ψ in H, we get

$$\frac{1}{2}\frac{d}{dt}\|\psi\|^2+\nu\|\psi\|^2=\operatorname{Im}\int_\Omega f\overline{\psi}. \tag{2.6}$$

In the sequel, we denote by $\overline{\psi}$ the conjugate of ψ. Then, taking the real part of the inner product of (2.1) with $-\psi_t-\nu\psi$ in H, we get

$$\frac{1}{2}\frac{d}{dt}\|\nabla\psi\|^2+\nu\|\nabla\psi\|^2-\nu\int_\Omega\phi|\psi|^2+\nu\,\mathrm{Re}\int_\Omega f\overline{\psi}-\frac{1}{2}\int_\Omega\phi\frac{\partial}{\partial t}|\psi|^2+\mathrm{Re}\int_\Omega f\overline{\psi_t}=0. \quad (2.7)$$

Using (2.2), we find

$$\int_\Omega\phi\frac{\partial}{\partial t}|\psi|^2=\frac{d}{dt}\int_\Omega\phi|\psi|^2-\int_\Omega\phi_t|\psi|^2=\frac{d}{dt}\int_\Omega\phi|\psi|^2+\delta\int_\Omega\phi|\psi|^2-\int_\Omega\theta|\psi|^2. \quad (2.8)$$

By (2.6)–(2.8), we have

$$\frac{1}{2}\frac{d}{dt}\left(\|\psi\|^2+\|\nabla\psi\|^2-\int_\Omega\phi|\psi|^2+2\,\mathrm{Re}\int_\Omega f\overline{\psi}\right)+\nu\|\psi\|^2+\nu\|\nabla\psi\|^2-\left(\nu+\frac{1}{2}\delta\right)\int_\Omega\phi|\psi|^2$$
$$+\frac{1}{2}\int_\Omega\theta|\psi|^2+\nu\,\mathrm{Re}\int_\Omega f\overline{\psi}-\mathrm{Im}\int_\Omega f\overline{\psi}=0. \quad (2.9)$$

Taking the inner product of (2.3) with θ in H, we have

$$\frac{1}{2}\frac{d}{dt}\|\theta\|^2+(\gamma-\delta)\|\theta\|^2-\int_\Omega\theta\,\Delta\phi+(1-\delta(\gamma-\delta))\int_\Omega\phi\theta-\int_\Omega|\psi|^2\theta=\int_\Omega g\theta. \quad (2.10)$$

Using (2.2), we get from (2.10) that

$$\frac{1}{2}\frac{d}{dt}(\|\theta\|^2+(1-\delta(\gamma-\delta))\|\phi\|^2+\|\nabla\phi\|^2)+(\gamma-\delta)\|\theta\|^2$$
$$+\delta(1-\delta(\gamma-\delta))\|\phi\|^2+\delta\|\nabla\phi\|^2-\int_\Omega|\psi|^2\theta=\int_\Omega g\theta. \quad (2.11)$$

Then, by $4\times(2.9)+2\times(2.11)$, we obtain

$$\frac{d}{dt}E(\psi,\phi,\theta)+2\delta E(\psi,\phi,\theta)=F(\psi,\phi,\theta), \quad (2.12)$$

where

$$E(\psi,\phi,\theta)=2\|\psi\|^2+2\|\nabla\psi\|^2+(1-\delta(\gamma-\delta))\|\phi\|^2+\|\nabla\phi\|^2+\|\theta\|^2-2\int_\Omega|\psi|^2\phi+4\,\mathrm{Re}\int_\Omega f\overline{\psi}, \quad (2.13)$$

and

$$F(\psi,\phi,\theta)=-4(\nu-\delta)(\|\psi\|^2+\|\nabla\psi\|^2)-2(\gamma-2\delta)\|\theta\|^2$$
$$+2(2\nu-\delta)\int_\Omega\phi|\psi|^2+4\,\mathrm{Im}\int_\Omega f\overline{\psi}+4(2\delta-\nu)\mathrm{Re}\int_\Omega f\overline{\psi}+2\int_\Omega g\theta. \quad (2.14)$$

Using (2.12) and proceeding as in Ref. 5, we can easily get the lemma. The details are omitted here and then the proof is finished. □

We remark that the energy equation (2.12) will play a crucial role in the proof of the continuity of solutions on initial data in $H^1\times H^1\times H$ in the next section. Equation (2.12) is also an important tool for the proof of the asymptotic compactness of solutions in Sec. IV.

Below, we improve the estimates in the previous lemma to the space $H^{k+2}\times H^{k+2}\times H^{k+1}$ when f and g belong to H^k with $k\geqslant 0$.

Lemma 2.2: Assume that f and g belong to $H^k(\Omega)$ with $k\geqslant 0$. Then every solution (ψ,ϕ,θ) of problem (2.1)–(2.5) satisfies

$$\|\psi(t)\|_{H^{k+2}}+\|\phi(t)\|_{H^{k+2}}+\|\theta(t)\|_{H^{k+1}}\leqslant M_k,\quad t\geqslant t_k,$$

where M_k depends on $(\nu,\gamma,\delta,\|f\|_{H^k},\|g\|_{H^k})$ and k; t_k depends on $(\nu,\gamma,\delta,\|f\|_{H^k},\|g\|_{H^k})$ and k and R when $\|(\psi_0,\phi_0,\theta_0)\|_{H^{k+2}\times H^{k+2}\times H^{k+1}}\leqslant R$.

Proof: taking the real part of the inner product of (2.1) with $(-1)^k(\Delta^{k+1}\psi_t+\nu\Delta^{k+1}\psi)$ in H, we get that

$$\frac{1}{2}\frac{d}{dt}\|\nabla^{k+2}\psi\|^2+\nu\|\nabla^{k+2}\psi\|^2+\nu\ \mathrm{Re}\int_\Omega\nabla^{k+2}\psi\cdot\nabla^k(\phi\overline{\psi})-\nu\ \mathrm{Re}\int_\Omega\nabla^k f\cdot\nabla^{k+2}\overline{\psi}$$
$$+(-1)^k\ \mathrm{Re}\int_\Omega\phi\psi\ \Delta^{k+1}\overline{\psi_t}-\mathrm{Re}\int_\Omega\nabla^k f\cdot\nabla^{k+2}\overline{\psi_t}=0. \tag{2.15}$$

Note that

$$(-1)^k\ \mathrm{Re}\int_\Omega\phi\psi\,\Delta^{k+1}\overline{\psi_t}=\mathrm{Re}\int_\Omega\nabla^k(\phi\overline{\psi})\cdot\nabla^{k+2}\psi_t$$
$$=\frac{d}{dt}\mathrm{Re}\int_\Omega\nabla^k(\phi\overline{\psi})\cdot\nabla^{k+2}\psi-\mathrm{Re}\int_\Omega\nabla^k(\phi_t\overline{\psi})\cdot\nabla^{k+2}\psi$$
$$-\mathrm{Re}\int_\Omega\nabla^k(\phi\overline{\psi_t})\cdot\nabla^{k+2}\psi. \tag{2.16}$$

By (2.1) and (2.2), we first substitute ψ_t and ϕ_t into (2.16), and then from (2.15) we find that

$$\frac{1}{2}\frac{d}{dt}\left(\|\nabla^{k+2}\psi\|^2+2\ \mathrm{Re}\int_\Omega\nabla^k(\phi\overline{\psi})\cdot\nabla^{k+2}\psi-2\ \mathrm{Re}\int_\Omega\nabla^k f\cdot\nabla^{k+2}\overline{\psi}\right)+\nu\|\nabla^{k+2}\psi\|^2$$
$$+(2\nu+\delta)\mathrm{Re}\int_\Omega\nabla^k(\phi\overline{\psi})\cdot\nabla^{k+2}\overline{\psi}-\nu\ \mathrm{Re}\int_\Omega\nabla^k f\cdot\nabla^{k+2}\overline{\psi}-\mathrm{Re}\int_\Omega\nabla^k(\theta\overline{\psi})\cdot\nabla^{k+2}\psi$$
$$-\mathrm{Im}\int_\Omega\nabla^k(\phi\,\Delta\overline{\psi})\cdot\nabla^{k+2}\psi-\mathrm{Im}\int_\Omega\nabla^k(\phi^2\overline{\psi})\cdot\nabla^{k+2}\psi+\mathrm{Im}\int_\Omega\nabla^k(\phi f)\cdot\nabla^{k+2}\overline{\psi}=0. \tag{2.17}$$

Now, we derive an energy equation for ϕ and θ. Taking the inner product of (2.3) with $(-1)^{k+1}\Delta^{k+1}\theta$ in H, we find

$$\frac{1}{2}\frac{d}{dt}\|\nabla^{k+1}\theta\|^2+(\gamma-\delta)\|\nabla^{k+1}\theta\|^2-(-1)^{k+1}\int_\Omega\Delta\phi\,\Delta^{k+1}\theta+(-1)^{k+1}(1-\delta(\gamma-\delta))$$
$$\times\int_\Omega\phi\,\Delta^{k+1}\theta-(-1)^{k+1}\int_\Omega|\psi|^2\,\Delta^{k+1}\theta=(-1)^{k+1}\int_\Omega g\,\Delta^{k+1}\theta. \tag{2.18}$$

By (2.2) we have

$$-\int_\Omega \Delta\phi\,\Delta^{k+1}\theta+(-1)^{k+1}(1-\delta(\gamma-\delta))\int_\Omega \phi\,\Delta^{k+1}\theta$$
$$=\frac{1}{2}(1-\delta(\gamma-\delta))\frac{d}{dt}\|\nabla^{k+1}\phi\|^2$$
$$+\delta(1-\delta(\gamma-\delta))\|\nabla^{k+1}\phi\|^2+\frac{1}{2}\frac{d}{dt}\|\nabla^{k+2}\phi\|^2+\delta\|\nabla^{k+2}\phi\|^2, \tag{2.19}$$

and

$$(-1)^{k+1}\int_\Omega g\,\Delta^{k+1}\theta=-\frac{d}{dt}\int_\Omega \nabla^k g\cdot\nabla^{k+2}\phi-\delta\int_\Omega \nabla^k g\cdot\nabla^{k+2}\phi. \tag{2.20}$$

Then, it follows from (2.18)–(2.20) that

$$\frac{1}{2}\frac{d}{dt}\left(\|\nabla^{k+1}\theta\|^2+(1-\delta(\gamma-\delta))\|\nabla^{k+1}\phi\|^2+\|\nabla^{k+2}\phi\|^2+2\int_\Omega \nabla^k g\cdot\nabla^{k+2}\phi\right)$$
$$+(\gamma-\delta)\|\nabla^{k+1}\theta\|^2+\delta(1-\delta(\gamma-\delta))\|\nabla^{k+1}\phi\|^2+\delta\|\nabla^{k+2}\phi\|^2$$
$$+\delta\int_\Omega \nabla^k g\cdot\nabla^{k+2}\phi-\int_\Omega \nabla^{k+1}|\psi|^2\cdot\nabla\theta=0. \tag{2.21}$$

Summing up (2.17) and (2.21), we get that

$$\frac{d}{dt}E_k(\psi(t),\phi(t),\theta(t))+\delta E_k(\psi(t),\phi(t),\theta(t))=F_k(\psi(t),\phi(t),\theta(t)), \tag{2.22}$$

where

$$E_k(\psi,\phi,\theta)=\|\nabla^{k+2}\psi\|^2+(1-\delta(\gamma-\delta))\|\nabla^{k+1}\phi\|^2+\|\nabla^{k+2}\phi\|^2+\|\nabla^{k+1}\theta\|^2$$
$$+2\,\mathrm{Re}\int_\Omega \nabla^k(\phi\overline{\psi})\cdot\nabla^{k+2}\psi-2\,\mathrm{Re}\int_\Omega \nabla^k f\cdot\nabla^{k+2}\overline{\psi}+2\int_\Omega \nabla^k g\cdot\nabla^{k+2}\phi,$$

and

$$F_k(\psi,\phi,\theta)=-(2\nu-\delta)\|\nabla^{k+2}\psi\|^2-\delta(1-\delta(\gamma-\delta))\|\nabla^{k+1}\phi\|^2-\delta\|\nabla^{k+2}\phi\|^2$$
$$-(2\gamma-3\delta)\|\nabla^{k+1}\theta\|^2-4\nu\,\mathrm{Re}\int_\Omega \nabla^k(\phi\overline{\psi})\cdot\nabla^{k+2}\psi-2(\gamma-\nu)\mathrm{Re}\int_\Omega \nabla^k f\cdot\nabla^{k+2}\overline{\psi}$$
$$+2\,\mathrm{Re}\int_\Omega \nabla^k(\theta\overline{\psi})\cdot\nabla^{k+2}\psi+2\,\mathrm{Im}\int_\Omega \nabla^k(\phi\,\Delta\overline{\psi})\cdot\nabla^{k+2}\psi$$
$$+2\,\mathrm{Im}\int_\Omega \nabla^k(\phi^2\overline{\psi})\cdot\nabla^{k+2}\psi-2\,\mathrm{Im}\int_\Omega \nabla^k(\phi f)\nabla^{k+2}\overline{\psi}+2\int_\Omega \nabla^{k+1}|\psi|^2\cdot\nabla^{k+1}\theta.$$

Thus, this lemma follows from (2.21) and Gronwall's lemma. The details are omitted here. □

In what follows, we state some estimates on the solutions in a finite time interval that will be used when we establish the existence and uniqueness and continuity of solutions. By (2.12) we can easily get the following result.

Lemma 2.3: Assume that f and g belong to H. Then every solution (ψ,ϕ,θ) *of problem (2.1)–(2.5) satisfies*

$$\|\psi(t)\|_{H^1}+\|\phi(t)\|_{H^1}+\|\theta(t)\|\leqslant L,\quad 0\leqslant t\leqslant T,$$

where L depends on $(\nu,\gamma,\delta,\|f\|,\|g\|)$, *T and* $\|(\psi_0,\phi_0,\theta_0)\|_{H^1\times H^1\times H}$.

The following fact is the analog of Lemma 2.2.

Lemma 2.4: Assume that f and g belong to $H^k(\Omega)$ *with* $k\geqslant 0$. *Then every solution* (ψ,ϕ,θ) *of problem (2.1)–(2.5) satisfies*

$$\|\psi(t)\|_{H^{k+2}}+\|\phi(t)\|_{H^{k+2}}+\|\theta(t)\|_{H^{k+1}}\leqslant L_k,\quad 0\leqslant t\leqslant T,$$

where L_k *depends on* $(\nu,\gamma,\delta,\|f\|_{H^k},\|g\|_{H^k})$ *and T and k and* $\|(\psi_0,\phi_0,\theta_0)\|_{H^{k+2}\times H^{k+2}\times H^{k+1}}$.

III. THE SOLUTION SEMIGROUP

In this section, we establish the existence of the dynamical system associated to problem (2.1)–(2.5). What is more, we shall show the existence and uniqueness and continuity of solutions in the space $H^l\times H^l\times H^{l-1}$ for each $l\geqslant 1$. The existence and uniqueness of solutions follow from standard methods and estimates in Lemmas 2.3 and 2.4. Similar results for $l\leqslant 2$ was also obtained in Ref. 5. Lemmas 2.3 and 2.4 are also sufficient to establish the continuity property of solutions on initial data in $H^l\times H^l\times H^{l-1}$ when $l\geqslant 2$. However, the continuity property in $H^1\times H^1\times H$ is not so easy and needs to be treated separately. The main purpose of this section is to prove the solution is indeed continuous on initial data in $H^1\times H^1\times H$. To this end, the energy equation obtained in the previous section will play a key role; see Theorem 3.4 below.

By Lemma 2.3, we have the following existence and uniqueness result.

Theorem 3.1: *Let f,* $g\in H$ *and* $(\psi_0,\phi_0,\theta_0)\in H^1\times H^1\times H$. *Then problem (2.1)–(2.5) has a unique solution* $(\psi,\phi,\theta)\in C(\mathbb{R}^+,H^1\times H^1\times H)$.

For the proof of this theorem, we refer the readers to Ref. 5 and the references therein. Here we state it just for our purpose below.

The next result can be proved by Lemma 2.4 and the details will be omitted here.

Theorem 3.2: *Let f,* $g\in H^k$ *and* $(\psi_0,\phi_0,\theta_0)\in H^{k+2}\times H^{k+2}\times H^{k+1}$ *with* $k\geqslant 0$. *Then problem (2.1)–(2.5) has a unique solution* $(\psi,\phi,\theta)\in C(\mathbb{R}^+,H^{k+2}\times H^{k+2}\times H^{k+1})$.

We remark that by Theorem 3.2, one has the existence and uniqueness of solutions in $H^2\times H^2\times H^1$ under the assumption of the driving terms in *H*, which is weaker than the corresponding condition $g\in H^1$ in Ref. 5.

The following statement is concerned with the continuity of solutions on initial data in $H^{k+2}\times H^{k+2}\times H^{k+1}$ for each $k\geqslant 0$.

Theorem 3.3: *Assume that the hypothesis of Theorem 3.2 holds. Then the solution* (ψ,ϕ,θ) *of problem (2.1)–(2.5) is continuous with respect to initial data in* $H^{k+2}\times H^{k+2}\times H^{k+1}$.

Proof: We shall sketch the proof below and the details will be omitted.

Consider two solutions (ψ_1,ϕ_1,θ_1) and (ψ_2,ϕ_2,θ_2) of problem (2.1)–(2.5). Then the difference $(\psi,\phi,\theta)=(\psi_1-\psi_2,\phi_1-\phi_2,\theta_1-\theta_2)$ satisfies

$$i\psi_t+\Delta\psi+i\nu\psi+\phi\psi_1+\phi_2\psi=0,\tag{3.1}$$

$$\phi_t+\delta\phi=\theta,\tag{3.2}$$

$$\theta_t+(\gamma-\delta)\theta-\Delta\psi+(1-\delta(\gamma-\delta))\phi+\psi\overline{\psi_1}-\overline{\psi}\psi_2=0.\tag{3.3}$$

Taking the real part of the inner product of (3.1) with $(-1)^k(\Delta^{k+1}\psi_t+\nu\Delta^{k+1}\psi)$ in *H*, and then using Lemma 2.4 to estimate the terms in the resulting identity, after some computations we can get

$$\frac{d}{dt}\|\psi\|^2_{H^{k+2}}\leqslant C(\|\psi\|^2_{H^{k+2}}+\|\phi\|^2_{H^{k+2}}).\tag{3.4}$$

Similarly, taking the inner product of (3.3) with $(-1)^{k+1}\Delta^{k+1}\theta$ in H, then using (3.2) and Lemma 2.4, we can derive the inequality

$$\frac{d}{dt}((1-\delta(\gamma-\delta))\|\phi\|^2_{H^{k+1}}+\|\phi\|^2_{H^{k+2}}+\|\theta\|^2_{H^{k+1}}) \leq C((1-\delta(\gamma-\delta))\|\phi\|^2_{H^{k+1}}+\|\phi\|^2_{H^{k+2}}+\|\theta\|^2_{H^{k+1}}). \tag{3.5}$$

It follows from (3.4) and (3.5) that

$$\frac{d}{dt}(\|\psi\|^2_{H^{k+2}}+(1-\delta(\gamma-\delta))\|\phi\|^2_{H^{k+1}}+\|\phi\|^2_{H^{k+2}}+\|\theta\|^2_{H^{k+1}}) \leq C(\|\psi\|^2_{H^{k+2}}+(1-\delta(\gamma-\delta))\|\phi\|^2_{H^{k+1}}+\|\phi\|^2_{H^{k+2}}+\|\theta\|^2_{H^{k+1}}). \tag{3.6}$$

This and Gronwall's lemma give the Lipschitz continuity of solutions in $H^{k+2}\times H^{k+2}\times H^{k+1}$. The proof is complete. □

We remark that the inequality similar to (3.6) is not easy to get in the space $H^1\times H^1\times H$. So the above method does no longer apply. Below, we shall use the energy equation method to prove the continuity in this case.

Theorem 3.4: *Assume that f and g belong to H. Then the solution* $(\psi,\phi,\theta)\in C(\mathbb{R}^+, H^1\times H^1\times H)$ *of system (2.1)–(2.5) depends continuously on the initial data in* $H^1\times H^1\times H$.

Proof: Assume that $(\psi_{0,n},\phi_{0,n},\theta_{0,n})\to(\psi_0,\phi_0,\theta_0)$ in $H^1\times H^1\times H$; we want to prove $S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n})\to S(t)(\psi_0,\phi_0,\theta_0)$ for each $t>0$ as $n\to\infty$.

Given $t>0$, we choose $T>t$. By the convergence of $(\psi_{0,n},\phi_{0,n},\theta_{0,n})$, we know that $(\psi_{0,n},\phi_{0,n},\theta_{0,n})$ is bounded in $H^1\times H^1\times H$. Thus, it follows from Lemma 2.3 that

$$\|\psi_n(\tau)\|_{H^1}+\|\phi_n(\tau)\|_{H^1}+\|\theta_n(\tau)\|\leq C,\quad 0\leq\tau\leq T, \tag{3.7}$$

where we set $(\psi_n(\tau),\phi_n(\tau),\theta_n(\tau))=S(\tau)(\psi_{0,n},\phi_{0,n},\theta_{0,n})$. By (3.7) and system (2.1)–(2.5) we can also deduce that

$$\left\|\frac{\partial}{\partial\tau}\psi_n\right\|_{L^2(0,T;H^{-1})}+\left\|\frac{\partial}{\partial\tau}\phi_n\right\|_{L^2(0,T;H)}\leq C. \tag{3.8}$$

And, therefore, there exists $(\psi(\tau),\phi(\tau),\theta(\tau))\in L^\infty(0,T;H^1\times H^1\times H)$, such that

$$(\psi_n(\tau),\phi_n(\tau),\theta_n(\tau))\to(\psi(\tau),\phi(\tau),\theta(\tau))\ \text{weakly in}\ L^2(0,T;H^1\times H^1\times H), \tag{3.9}$$

and

$$\frac{\partial}{\partial\tau}\psi_n\to\frac{\partial}{\partial\tau}\psi,\quad\text{weakly in}\ L^2(0,T;H^{-1}), \tag{3.10}$$

$$\frac{\partial}{\partial\tau}\phi_n\to\frac{\partial}{\partial\tau}\phi,\quad\text{weakly in}\ L^2(0,T;H). \tag{3.11}$$

By (3.9)–(3.11) and a standard compactness result, we have

$$(\psi_n,\phi_n)\to(\psi,\phi),\ \text{strongly in}\ L^2(0,T;H\times H). \tag{3.12}$$

Again, for a fixed t, by (3.7) we see that there exists $\xi\in H^1\times H^1\times H$ such that

$$(\psi_n(t),\phi_n(t),\theta_n(t))\to\xi,\ \text{weakly in}\ H^1\times H^1\times H. \tag{3.13}$$

Then, similar to the proof of the existence of solutions (see Ref. 4, for example), we can easily deduce that (ψ,ϕ,θ) is the solution of problem (2.1)–(2.5) with $(\psi(0),\phi(0),\theta(0))=(\psi_0,\phi_0,\theta_0)$ and $(\psi(t),\phi(t),\theta(t))=\xi$ for a fixed t. This fact, together with (3.13), implies the weak convergence of $S(t)$, that is,

$$S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n})\rightarrow S(t)(\psi_0,\phi_0,\theta_0), \quad \text{weakly in } H^1\times H^1\times H. \tag{3.14}$$

We now prove that the weak convergence is, in fact, the strong convergence. To this end, we shall use the energy equation (2.12). In fact, by (2.12) we have

$$E(t)=e^{-2\delta t}E(0)+\int_0^t e^{-2\delta(t-\tau)}F(\psi(\tau),\phi(\tau),\theta(\tau))d\tau, \tag{3.15}$$

where E and F is given by (2.13) and (2.14), respectively. Note that (3.15) means that any solution $(\psi(t),\phi(t),\theta(t))=S(t)(\psi_0,\phi_0,\theta_0)$ of problem (2.1)–(2.5) verifies

$$E(S(t)(\psi_0,\phi_0,\theta_0))=e^{-2\delta t}E(\psi_0,\phi_0,\theta_0)+\int_0^t e^{-2\delta(t-\tau)}F(S(\tau)(\psi_0,\phi_0,\theta_0))d\tau. \tag{3.16}$$

Applying (3.16) to the solution $S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n})$, we get

$$E(S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n}))=e^{-2\delta t}E(\psi_{0,n},\phi_{0,n},\theta_{0,n})+\int_0^t e^{-2\delta(t-\tau)}F(S(\tau)(\psi_{0,n},\phi_{0,n},\theta_{0,n}))d\tau. \tag{3.17}$$

Since $(\psi_{0,n},\phi_{0,n},\theta_{0,n})\rightarrow(\psi_0,\phi_0,\theta_0)$ in $H^1\times H^1\times H$, by the definition of E in (2.13), we can deduce that, as $n\rightarrow\infty$,

$$E(\psi_{0,n},\phi_{0,n},\theta_{0,n})\rightarrow E(\psi_0,\phi_0,\theta_0). \tag{3.18}$$

Below, we deal with the limit of the second term on the right-hand side of (3.17). By (2.14) we have

$$\begin{aligned}
&\int_0^t e^{-2\delta(t-\tau)}F(S(\tau)(\psi_{0,n},\phi_{0,n},\theta_{0,n}))d\tau\\
&\quad=-2\int_0^t e^{-2\delta(t-\tau)}(2(\nu-\delta)(\|S(\tau)\psi_{0,n}\|^2+\|\nabla S(\tau)\psi_{0,n}\|^2)+(\gamma-2\delta)\|S(\tau)\theta_{0,n}\|^2)\\
&\qquad+2\int_0^t e^{-2\delta(t-\tau)}\left((2\nu-\delta)\int_\Omega S(\tau)\phi_{0,n}|S(\tau)\psi_{0,n}|^2+2\,\mathrm{Im}\int_\Omega f\overline{S(\tau)\psi_{0,n}}\right)\\
&\qquad+2\int_0^t e^{-2\delta(t-\tau)}\left(2(2\delta-\nu)\mathrm{Re}\int_\Omega f\overline{S(\tau)\psi_{0,n}}+\int_\Omega gS(\tau)\theta_{0,n}\right).
\end{aligned} \tag{3.19}$$

We now handle the first term on the right-hand side of (3.19). By the weak convergence (3.9), we have

$$e^{-\delta(t-\tau)}S(\tau)\psi_{0,n}\rightarrow e^{-\delta(t-\tau)}S(\tau)\psi_0, \text{ weakly in } L^2(0,t;H^1),$$

and

$$e^{-\delta(t-\tau)}S(\tau)\theta_{0,n}\rightarrow e^{-\delta(t-\tau)}S(\tau)\theta_0, \text{ weakly in } L^2(0,t;H).$$

So we find that

$$\liminf_{n\to\infty} \|e^{-\delta(t-\tau)}S(\tau)\psi_{0,n}\|_{L^2(0,t;H^1)} \geq \|e^{-\delta(t-\tau)}S(\tau)\psi_0\|_{L^2(0,t;H^1)}, \tag{3.20}$$

and

$$\liminf_{n\to\infty} \|e^{-\delta(t-\tau)}S(\tau)\theta_{0,n}\|_{L^2(0,t;H)} \geq \|e^{-\delta(t-\tau)}S(\tau)\theta_0\|_{L^2(0,t;H)}. \tag{3.21}$$

Then, choosing δ small enough such that $\nu-\delta>0$, and $\gamma-2\delta>0$, we have the following estimates for the first term on the right-hand side of (3.19):

$$\limsup_{n\to\infty} -2\int_0^t e^{-2\delta(t-\tau)}(2(\nu-\delta)(\|S(\tau)\psi_{0,n}\|^2+\|\nabla S(\tau)\psi_{0,n}\|^2)+(\gamma-2\delta)\|S(\tau)\theta_{0,n}\|^2)$$
$$\leq -2\int_0^t e^{-2\delta(t-\tau)}(2(\nu-\delta)(\|S(\tau)\psi_0\|^2+\|\nabla S(\tau)\psi_0\|^2)+(\gamma-2\delta)\|S(\tau)\theta_0\|^2). \tag{3.22}$$

For the second term on the right-hand side of (3.19), we want to prove its convergence. We first treat the convergence of

$$\int_0^t e^{-2\delta(t-\tau)}\int_\Omega S(\tau)\phi_{0,n}|S(\tau)\psi_{0,n}|^2 \to \int_0^t e^{-2\delta(t-\tau)}\int_\Omega S(\tau)\phi_0|S(\tau)\psi_0|^2. \tag{3.23}$$

Note that

$$\int_0^t e^{-2\delta(t-\tau)}\int_\Omega S(\tau)\phi_{0,n}|S(\tau)\psi_{0,n}|^2 - \int_0^t e^{-2\delta(t-\tau)}\int_\Omega S(\tau)\phi_0|S(\tau)\psi_0|^2$$
$$=\int_0^t\int_\Omega e^{-2\delta(t-\tau)}(S(\tau)\phi_{0,n}-S(\tau)\phi_0)|S(\tau)\psi_{0,n}|^2$$
$$+\int_0^t\int_\Omega e^{-2\delta(t-\tau)}S(\tau)\phi_0(|S(\tau)\psi_{0,n}|+|S(\tau)\psi_0|)(|S(\tau)\psi_{0,n}|-|S(\tau)\psi_0|)=\mathrm{I}+\mathrm{II},$$

where I and II denotes by the first and second term, respectively. We now show I and II converge to zero as $n\to\infty$. First we have

$$|I| \leq \int_0^t \|S(\tau)\psi_{0,n}\|_4^2\|S(\tau)\phi_{0,n}-S(\tau)\phi_0\| \leq \|S(\tau)\psi_{0,n}\|^2_{L^\infty(0,t;H^1)}\int_0^t\|S(\tau)\phi_{0,n}-S(\tau)\phi_0\|\to 0;$$

the last relation is obtained by (3.12) and Lemma 2.3. Similarly, by (3.12) and Lemma 2.3 again, we can deduce that $\mathrm{II}\to 0$. And then (3.23) follows. Therefore, by (3.12) we can get

$$2\int_0^t e^{-2\delta(t-\tau)}\left((2\nu-\delta)\int_\Omega S(\tau)\phi_{0,n}|S(\tau)\psi_{0,n}|^2+2\,\mathrm{Im}\int_\Omega f\overline{S(\tau)\psi_{0,n}}\right)$$
$$+2\int_0^t e^{-2\delta(t-\tau)}\left(2(2\delta-\nu)\mathrm{Re}\int_\Omega f\overline{S(\tau)\psi_{0,n}}+\int_\Omega gS(\tau)\theta_{0,n}\right)$$
$$\to 2\int_0^t e^{-2\delta(t-\tau)}\left((2\nu-\delta)\int_\Omega S(\tau)\phi_0|S(\tau)\psi_0|^2+2\,\mathrm{Im}\int_\Omega f\overline{S(\tau)\psi_0}\right)$$
$$+2\int_0^t e^{-2\delta(t-\tau)}\left(2(2\delta-\nu)\mathrm{Re}\int_\Omega f\overline{S(\tau)\psi_0}+\int_\Omega gS(\tau)\theta_0\right). \tag{3.24}$$

So, by (3.17)–(3.19), (3.22), and (3.24) and the definition of F in (2.14), we finally get

$$\limsup_{n\to\infty} E(S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n}))$$
$$\leq e^{-2\delta t}E(\psi_0,\phi_0,\theta_0)-2\int_0^t e^{-2\delta(t-\tau)}(2(\nu-\delta)(\|S(\tau)\psi_0\|^2+\|\nabla S(\tau)\psi_0\|^2)$$
$$+(\gamma-2\delta)\|S(\tau)\theta_0\|^2)+2\int_0^t e^{-2\delta(t-\tau)}\left((2\nu-\delta)\int_\Omega S(\tau)\phi_0|S(\tau)\psi_0|^2+2\,\mathrm{Im}\int_\Omega f\overline{S(\tau)\psi_0}\right)$$
$$+2\int_0^t e^{-2\delta(t-\tau)}\left(2(2\delta-\nu)\mathrm{Re}\int_\Omega f\overline{S(\tau)\psi_0}+\int_\Omega gS(\tau)\theta_0\right). \tag{3.25}$$

By (3.16) we see that the right-hand side of (3.25) is exactly $E(S(t)(\psi_0,\phi_0,\theta_0))$, so we have

$$\limsup_{n\to\infty} E(S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n}))\leq E(S(t)(\psi_0,\phi_0,\theta_0)). \tag{3.26}$$

By the weak convergence (3.14) and the compact imbedding $H^1\subset H$, we find

$$S(t)(\psi_{0,n},\phi_{0,n})\to S(t)(\psi_0,\phi_0),\ \text{ strongly in } H,$$

so it is easy to prove

$$\int_\Omega S(t)\phi_{0,n}|S(t)\psi_{0,n}|^2\to\int_\Omega S(t)\phi_0|S(t)\psi_0|^2, \tag{3.27}$$

and

$$\int_\Omega f\overline{S(t)\psi_{0,n}}\to\int_\Omega f\overline{S(t)\psi_0}. \tag{3.28}$$

By (3.26)–(3.28) and the definition of E, we finally get that

$$\limsup_{n\to\infty}\ (2\|S(t)\psi_{0,n}\|_{H^1}^2+(1-\delta(\gamma-\delta))\|S(t)\phi_{0,n}\|^2+\|\nabla S(t)\phi_{0,n}\|^2+\|S(t)\theta_{0,n}\|^2)$$
$$\leq 2\|S(t)\psi_0\|_{H^1}^2+(1-\delta(\gamma-\delta))\|S(t)\phi_0\|^2+\|\nabla S(t)\phi_0\|^2+\|S(t)\theta_0\|^2.$$

We note that the right-hand side of the above is equivalent to the norm of $H^1\times H^1\times H$, so, without loss of generality, we can assume that the norm of $H^1\times H^1\times H$ is defined by it. Then we have

$$\limsup_{n\to\infty}\ \|S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n})\|_{H^1\times H^1\times H}\leq\|S(t)(\psi_0,\phi_0,\theta_0)\|_{H^1\times H^1\times H}. \tag{3.29}$$

On the other hand, the weak convergence (3.14) implies

$$\liminf_{n\to\infty}\ \|S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n})\|_{H^1\times H^1\times H}\geq\|S(t)(\psi_0,\phi_0,\theta_0)\|_{H^1H^1\times H}. \tag{3.30}$$

Then, (3.29) and (3.30) and (3.14) yield

$$S(t)(\psi_{0,n},\phi_{0,n},\theta_{0,n})\to S(t)(\psi_0,\phi_0,\theta_0),\quad \text{strongly in } H^1\times H^1\times H.$$

The proof is complete. □

IV. GLOBAL ATTRACTORS

In this section, we establish the existence of the global attractor for the dynamical system $S(t)$ in the space $H^l \times H^l \times H^{l-1}$ for each $l \geqslant 1$. To this end, we first need to prove the asymptotic compactness of solutions. The technique used here is the energy equation method that was due to Ball.[8] The existence of the global attractor follows from the abstract result[9] (see also Refs. 12 and 13) once the asymptotic compactness of $S(t)$ is established.

In the sequel, we denote by B_1 the ball

$$B_1 = \{(\psi,\phi,\theta) \in H^1 \times H^1 \times H : \|\psi\|_{H^1} + \|\phi\|_{H^1} + \|\theta\| \leqslant M\}, \tag{4.1}$$

where M is the constant in Lemma 2.1, and B_{k+2} the ball

$$B_{k+2} = \{(\psi,\phi,\theta) \in H^{k+2} \times H^{k+2} \times H^{k+1} : \|\psi\|_{H^{k+2}} + \|\phi\|_{H^{k+2}} + \|\theta\|_{H^{k+1}} \leqslant M_k\}, \tag{4.2}$$

for each $k \geqslant 0$, where M_k is the constant in Lemma 2.2.

Then by Lemmas 2.1 and 2.2, we know that B_1 and B_{k+2} $(k \geqslant 0)$ is a bounded absorbing set for $S(t)$ in $H^1 \times H^1 \times H$ and $H^{k+2} \times H^{k+2} \times H^{k+1}$, respectively.

We now prove the asymptotic compactness of $S(t)$ in $H^1 \times H^1 \times H$.

Theorem 4.1: *Assume that f and g belong to H. Then the dynamical system $S(t)$ is asymptotically compact in $H^1 \times H^1 \times H$, that is, if $(\psi_n, \phi_n, \theta_n)$ is bounded in $H^1 \times H^1 \times H$ and $t_n \to \infty$, then $S(t_n)(\psi_n, \phi_n, \theta_n)$ is precompact.*

Proof: Since $(\psi_n, \phi_n, \theta_n)$ is bounded, we can assume that $\|(\psi_n, \phi_n, \theta_n)\|_{H^1 \times H^1 \times H} \leqslant R$ for a suitable constant R. Then by Lemma 2.1, we infer that there exists a constant $T(R)$ depending on R, such that

$$S(t)(\psi_n, \phi_n, \theta_n) \in B_1, \quad \forall t \geqslant T(R), \tag{4.3}$$

where B_1 is the absorbing set in (4.1). Since $t_n \to \infty$, there exists $N_1(R)$ such that if $n \geqslant N_1$, then $t_n \geqslant T(R)$, and hence

$$S(t_n)(\psi_n, \phi_n, \theta_n) \in B_1, \quad \forall n \geqslant N_1. \tag{4.4}$$

By (4.4) we know that there exists $(\psi,\phi,\theta) \in B_1$ such that, up to a subsequence,

$$S(t_n)(\psi_n, \phi_n, \theta_n) \to (\psi,\phi,\theta), \quad \text{weakly in } H^1 \times H^1 \times H. \tag{4.5}$$

For every $T > 0$, again by $t_n \to \infty$, there exists $N_2(R,T)$ such that for $n \geqslant N_2$, we have $t_n - T \geqslant T(R)$. So, by (4.3) we get

$$S(t_n - T)(\psi_n, \phi_n, \theta_n) \in B_1, \quad \forall n \geqslant N_2. \tag{4.6}$$

By (4.6) we infer that there exists $(\psi_T, \phi_T, \theta_T) \in B_1$, such that

$$S(t_n - T)(\psi_n, \phi_n, \theta_n) \to (\psi_T, \phi_T, \theta_T), \quad \text{weakly in } H^1 \times H^1 \times H. \tag{4.7}$$

Following the proof of (3.14), by (4.7), we can get

$$S(T)(S(t_n - T)(\psi_n, \phi_n, \theta_n)) \to S(T)(\psi_T, \phi_T, \theta_T), \quad \text{weakly in } H^1 \times H^1 \times H. \tag{4.8}$$

It follows from (4.5) and (4.8) that

$$(\psi,\phi,\theta) = S(T)(\psi_T, \phi_t, \theta_T). \tag{4.9}$$

By the weak convergence (4.5), we get

$$\liminf_{n\to\infty} \|S(t_n)(\psi_n, \phi_n, \theta_n)\|_{H^1 \times H^1 \times H} \geqslant \|(\psi,\phi,\theta)\|_{H^1 \times H^1 \times H}. \tag{4.10}$$

If we can also prove that

$$\limsup_{n\to\infty} \|S(t_n)(\psi_n,\phi_n,\theta_n)\|_{H^1\times H^1\times H} \leqslant \|(\psi,\phi,\theta)\|_{H^1\times H^1\times H}, \tag{4.11}$$

then (4.5) and (4.10) and (4.11) will imply

$$S(t_n)(\psi_n,\phi_n,\theta_n)\to(\psi,\phi,\theta), \quad \text{strongly in } H^1\times H^1\times H.$$

So, the proof will be finished once (4.11) is verified. In what follows, we apply the energy equation (2.12) to prove (4.11). Here, the idea is analogous to Theorem 3.4. And, therefore, only the main steps will be given below.

Applying (3.16) to the solution $S(T)(S(t_n-T)(\psi_n,\phi_n,\theta_n))$, we find

$$\begin{aligned} E(S(t_n)(\psi_n,\phi_n,\theta_n)) &= E(S(T)(S(t_n-T)(\psi_n,\phi_n,\theta_n))) \\ &= e^{-2\delta T}E(S(t_n-T)(\psi_n,\phi_n,\theta_n)) \\ &\quad + \int_0^T e^{-2\delta(T-\tau)}F(S(\tau)(S(t_n-T)(\psi_n,\phi_n,\theta_n)))\,d\tau. \end{aligned} \tag{4.12}$$

Since (4.6) shows that $S(t_n-T)(\psi_n,\phi_n,\theta_n)$ is bounded, we derive from the definition of E in (2.13) that

$$e^{-2\delta T}E(S(t_n-T)(\psi_n,\phi_n,\theta_n)) \leqslant Ce^{-2\delta T}, \quad \forall n \geqslant N_2. \tag{4.13}$$

For the second term on the right-hand side of (4.12), using (4.7) and proceeding as the proof of (3.22) and (3.24), we can finally get

$$\limsup_{n\to\infty}\int_0^T e^{-2\delta(T-\tau)}F(S(\tau)(S(t_n-T)(\psi_n,\phi_n,\theta_n)))\,d\tau \leqslant \int_0^T e^{-2\delta(T-\tau)}F(S(\tau)(\psi_T,\phi_T,\theta_T))\,d\tau. \tag{4.14}$$

It follows from (4.12)–(4.14) that

$$\limsup_{n\to\infty} E(S(T)(S(t_n-T)(\psi_n,\phi_n,\theta_n))) \leqslant Ce^{-2\delta T} + \int_0^T e^{-2\delta(T-\tau)}F(S(\tau)(\psi_T,\phi_T,\theta_T))\,d\tau. \tag{4.15}$$

Again, applying (3.16) to the solution $(\psi,\phi,\theta)=S(T)(\psi_T,\phi_T,\theta_T)$, we find

$$\begin{aligned} E(\psi,\phi,\theta) &= E(S(T)(\psi_T,\phi_T,\theta_T)) \\ &= e^{-2\delta T}E(\psi_T,\phi_T,\theta_T) + \int_0^T e^{-2\delta(T-\tau)}F(S(\tau)(\psi_T,\phi_T,\theta_T))\,d\tau. \end{aligned} \tag{4.16}$$

It follows from (4.15) and (4.16) that

$$\begin{aligned} \limsup_{n\to\infty} E(S(t_n)(\psi_n,\phi_n,\theta_n)) &\leqslant Ce^{-2\delta T} - e^{-2\delta T}E(\psi_T,\phi_T,\theta_T) + E(\psi,\phi,\theta) \\ &\leqslant C_1e^{-2\delta T} + E(\psi,\phi,\theta) [\text{by } (\psi_T,\phi_T,\theta_T)\in B_1]. \end{aligned}$$

Let $T\to+\infty$, we find

$$\limsup_{n\to\infty} E(S(t_n)(\psi_n,\phi_n,\theta_n)) \leqslant E(\psi,\phi,\theta).$$

Then, by the definition of E in (2.13), and repeating the procedure of (3.27)–(3.29), we can easily obtain (4.11). And then, the proof is complete. □

We now prove that the dynamical system $S(t)$ is asymptotically compact in a more regular space if the driving terms are smoother.

Theorem 4.2: *Assume that f and g belong to* H^k *with* $k \geqslant 0$. *Then the dynamical system* $S(t)$ *is asymptotically compact in* $H^{k+2} \times H^{k+2} \times H^{k+1}$.

Proof: The proof of this theorem is quite similar to Theorem 4.1. In this case, the energy equation (2.22) and the bounded absorbing set B_{k+2} should be used instead of the energy equation (2.12) and the bounded absorbing set B_1. Since the idea is analogous, we will not repeat the details here. □

We are now in a position to state our main result.

Theorem 4.3: *Assume that f and g belong to H. Then problem (2.1)–(2.5) possesses a strong compact global attractor in* $H^1 \times H^1 \times H$.

Theorem 4.4: *Assume that f and g belong to* H^k *with* $k \geqslant 0$. *Then problem (2.1)–(2.5) possesses a strong compact global attractor in* $H^{k+2} \times H^{k+2} \times H^{k+1}$.

The proof of Theorems 4.3 and 4.4 is now obvious. Since we have established the existence of bounded absorbing sets and the asymptotic compactness for $S(t)$ in $H^1 \times H^1 \times H$ and $H^{k+2} \times H^{k+2} \times H^{k+1}$, respectively, then Theorems 4.3 and 4.4 follow from the abstract result (Ref. 9, Theorem 3.3) (see also Refs. 12 and 13).

We remark that by Theorem 4.3 we have the existence of the strong global attractor that is compact in the norm topology of $H^1 \times H^1 \times H$ when f belongs to H, which is weaker than the corresponding condition $f \in H^2$ in Ref. 5.

(Received 25 March 1998; accepted for publication 30 September 1998)

Anisotropic fluid spherically symmetric space–times admitting a kinematic self-similar vector are investigated. The geodesic case is considered, and some special subcases in which the anisotropic fluid satisfies additional physical conditions are investigated in detail. A number of other special cases are studied. Particular attention is focused on the possible asymptotic behavior of the models, and it is shown that the models considered always asymptote towards an exact homothetic solution, which is in general either a perfect fluid model or a static solution. [S0022-2488(99)01602-3]

I. INTRODUCTION

In a recent paper spherically symmetric space–times which admit a kinematic self-similarity of the second (or zeroth) kind were studied when the source of the gravitational field was assumed to be a perfect fluid.[1] In that paper several particular subclasses of models were studied in depth, including the subcases ''$M_1=0$'' and ''$M_2=0$'' (which includes the static models as a further subcase). Note that these particular subcases refer to specific forms for the first integral *m(r,t)* of the EFEs. The precise definitions of these subcases in terms of *m(r,t)* are not necessary here; see Benoit and Coley[1] for more details. These subclasses of models, in which exact solutions were obtained, were found to be of particular interest since their qualitative properties were representative of the asymptotic behavior of more general models.

The metric, in comoving coordinates, is given by

$$ds^2=-e^{2\phi}dt^2+e^{2\psi}dr^2+r^2S^2d\Omega^2, \tag{1.1}$$

where the functions ϕ, ψ and S and depend only on the self-similarity coordinate

$$\xi=r(\alpha t)^{-1/\alpha}, \tag{1.2}$$

where α is the self-similar index (and we shall assume henceforward that $\alpha\neq 0$). The kinematic self-similar generator is given by[2]

$$\boldsymbol{\xi}=\xi^a\frac{\partial}{\partial x^a}=\alpha t\frac{\partial}{\partial t}+r\frac{\partial}{\partial r}. \tag{1.3}$$

It follows from (1.1) and (1.3) that

$$\mathcal{L}_{\boldsymbol{\xi}}h_{ab}=2h_{ab}, \tag{1.4}$$

[a)]Electronic mail: pbenoit@stfx.ca
[b)]Electronic mail: aac@mscs.dal.ca

and

$$\mathcal{L}_{\xi} u_a = \alpha u_a, \tag{1.5}$$

where $h_{ab}=g_{ab}+u_a u_b$ is the projection tensor. Hence $\boldsymbol{\xi}$, as given by (1.3) with $\alpha \neq 1$, is a *kinematic self-similar* vector and corresponds to the natural relativistic counterpart of self-similarity of the more general second kind.[3] We note that in the case $\alpha=1$, $\boldsymbol{\xi}$ is a homothetic vector, corresponding to self-similarity of the first kind. We shall adopt the notation and terminology of Benoit and Coley[1] and for brevity we shall not repeat here the motivation or the discussion of self-similarity given in that paper.

In this paper we shall generalize the perfect fluid solutions in Benoit and Coley[4] to the case of an anisotropic fluid, in which stress-energy tensor is given by

$$T_{ab} = \mu u_a u_b + p_{\parallel} n_a n_b + p_{\perp}(g_{ab} + u_a u_b - n_a n_b), \tag{1.6}$$

where u^a is the comoving fluid velocity vector and n^a is a unit spacelike vector orthogonal to u^a (i.e., $u_a n^a = 0$). The stress-energy tensor (1.6) possesses and eigenvalue degeneracy (and hence is not the most general anisotropic fluid stress-energy tensor) consistent with the assumption of spherical symmetry (see metric (1.1)). For the metric (1.1), $\mathbf{n}$ is given by

$$\mathbf{n} = n^a \frac{\partial}{\partial x^a} = e^{-\psi} \frac{\partial}{\partial r}. \tag{1.7}$$

Using Eqs. (1.1)–(1.3), it therefore follows immediately that

$$\mathcal{L}_{\xi} n_a = n_a \tag{1.8}$$

is satisfied identically, so that the form for $\mathbf{n}$ is consistent with the similarity assumption. The scalars $p_{\parallel}$ and $p_{\perp}$ are the pressures parallel to and perpendicular to n^a, respectively, and μ is the energy-density. The perfect fluid case corresponds to the case in which $p_{\parallel} = p_{\perp}$.

Fluids with an anisotropic pressure have been studied for many reasons (see the discussion in Coley and Tupper).[5] For example, in several cases in which the stress-energy tensor is more general than that of a perfect fluid (due to, e.g., a two perfect fluid source, an imperfect fluid source or in the region of interaction of two colliding plane impulsive gravitation waves), the energy-momentum tensor is formally of the form (1.6). In particular, a strong magnetic field in a plasma in which the particle collision density is low can cause the pressure along and perpendicular to the magnetic field lines to be unequal.[6] If the source of the gravitational field can be represented by the sum of a perfect fluid and a local magnetic field $H^a = H n^a$ (as measured by u^a), then the stress-energy tensor can be written in the form (1.6) with

$$\mu = \overline{\mu} + \pi, \quad p_{\parallel} = \overline{p} - \pi, \quad p_{\perp} = \overline{p} + \pi, \tag{1.9}$$

where $\pi = \frac{1}{2}\lambda H^2$ and λ is the magnetic permeability. Other possible sources of anisotropic stresses, in addition to cosmological magnetic and electric fields, include, for example, populations of collisionless particles like gravitons,[7] photons[8] or relativistic neutrinos,[9] Yang–Mills fields,[10] axion fields in low-energy string theory,[11] long wavelength gravitational waves,[12] and topological defects like global monopoles, cosmic strings, and domain walls.[13–15]

Most anisotropic models that have been studied are also spherically symmetric (see references cited in Ref. 5), and have applications especially in relativistic astrophysics (e.g., stellar models); in particular, static anisotropic spheres have received much attention.[5] In addition, such models with additional symmetries, including homothetic vectors and conformal Killing vectors, have also been studied (see Refs. 6, 5, and references within).

For the metric (1.1) the Einstein field equations (EFEs) yield the following expressions for the physical variables:

$$\mu = \frac{W^1(x)}{r^2} + \frac{W^2(x)}{t^2},$$

$$p_\parallel = \frac{P_\parallel^1(x)}{r^2} + \frac{P_\parallel^2(x)}{t^2}, \tag{1.10}$$

$$p_\perp = \frac{P_\perp^1(x)}{r^2} + \frac{P_\perp^2(x)}{t^2},$$

where

$$W^1(x) = \frac{1}{S^2} - e^{-2\psi}[(1+y)^2 + 2y\dot{\phi}],$$

$$W^2(x) = \frac{e^{-2\phi}}{\alpha^2} y[y + 2\dot{\psi}],$$

$$P_\parallel^1(x) = -\frac{1}{S^2} + e^{-2\psi}(1+y)[1+y+2\dot{\phi}],$$

$$P_\parallel^2(x) = -\frac{e^{-2\phi}}{\alpha^2}[2\dot{y} + 2\alpha y + 3y^2 - 2y\dot{\phi}],$$

$$P_\perp^1(x) = e^{-2\psi}[2y\dot{\phi} + \dot{\phi}^2 + \ddot{\phi} - \dot{\phi}\dot{\psi}],$$

$$P_\perp^2(x) = -\frac{e^{-2\phi}}{\alpha^2}[(\alpha-1)y + 2y\dot{\psi} + \dot{\psi} + \alpha\dot{\psi} + \dot{\psi}^2 + \ddot{\psi} - \dot{\phi}\dot{\psi}], \tag{1.11}$$

and where $y \equiv \dot{S}/S$, $x \equiv \ln \xi$ and $\dot{f} = df/dx$. The final EFE (that ensures that the Einstein tensor is diagonal) becomes

$$\dot{y} = y\dot{\phi} + (\dot{\psi} - y)(1+y). \tag{1.12}$$

Clearly there exists a variety of anisotropic fluid spherically symmetric kinematic self-similar space–times satisfying Eqs. (1.10)-(1.12).

If we assume that the physical quantities also obey similarity conditions of the form

$$\mathcal{L}_\xi \mu = a\mu, \quad \mathcal{L}_\xi p_\parallel = b_\parallel p_\parallel, \quad \mathcal{L}_\xi p_\perp = b_\perp p_\perp, \tag{1.13}$$

where a, $b_\parallel$ and $b_\perp$ are constants, then it can easily be shown that:

$$\text{(i)} \quad W^1 = 0 \quad \textit{or} \quad W^2 = 0$$

and

$$\text{(ii)} \quad P_\parallel^1 = 0 \quad \textit{or} \quad P_\parallel^2 = 0$$

and

$$\text{(iii)} \quad P_\perp^1 = 0 \quad \textit{or} \quad P_\perp^2 = 0.$$

The special subcases $W^i=0$ with either $P_\parallel^i\neq 0$ or $P_\perp^i\neq 0$ $(i=1,2)$ are not of physical interest. The special subcase $W^1=P_\parallel^1=P_\perp^1=0$ corresponds to the special subcase ''$M_1=0$.'' Finally, the special subcase $W^2=P_\parallel^2=P_\perp^2=0$ is related to the special subcase ''$M_2=0$,'' and the static models are included within this subclass of models.

It turns out (Benoit and Coley,[1] in particular, see the Appendix therein) that all *static* spherically symmetric kinematic self-similar solutions belong to the subclass ''$M_2=0$,'' regardless of the form of the stress-energy tensor, and, moreover, that all such static spacetimes necessarily admit a *homothetic vector*. Consequently, no new static anisotropic solutions can be obtained that admit a proper kinematic self-similarity. Hence we shall concentrate here on the special subcase ''$M_1=0$.''

II. GEODESIC MODELS

The geodesic case, in which the acceleration of the comoving fluid velocity vector is zero, is characterized by $\dot{\phi}=0$ and is equivalent to the special subcase ''$M_1=0$'' considered in Benoit and Coley.[1] In this model, Eq. (1.12) gives (for $S+\dot{S}\neq 0$)

$$e^{2\phi}=1,\quad \dot{\psi}=\frac{\dot{S}+\ddot{S}}{S+\dot{S}}=\frac{\dot{y}+y^2+y}{1+y},\tag{2.1}$$

whence the metric (1.1) becomes

$$ds^2=-dt^2+(S+\dot{S})^2dr^2+r^2S^2d\Omega^2.\tag{2.2}$$

Assuming the first of conditions (2.1), the second condition guarantees the resulting Einstein tensor is diagonal and hence the remaining EFEs simply yield the following expressions for μ, $p_\parallel$ and $p_\perp$:

$$\mu=W(x)t^{-2},\quad p_\parallel=P_\parallel(x)t^{-2},\quad p_\perp=P_\perp(x)t^{-2},\tag{2.3}$$

(where we have now omitted the index ''2'' for convenience), so that Eqs. (1.13) are automatically satisfied with $a=b_\parallel=b_\perp=-2\alpha$, where

$$W(x)\equiv\frac{y}{\alpha^2(1+y)}(3y+3y^2+2\dot{y}),$$

$$P_\parallel(x)\equiv-(3y^2+2\alpha y+2\dot{y})/\alpha^2,\tag{2.4}$$

$$P_\perp(x)\equiv-\frac{(1+y)(2\dot{y}+3y^2+2\alpha y)+3y\dot{y}+\alpha\dot{y}+\ddot{y}}{\alpha^2(1+y)}.$$

Equations (2.2)–(2.4) represent a class of anisotropic fluid solutions depending upon the arbitrary function $S(x)$.

We note that the following relationships result from the definitions given in Eqs. (2.3):

$$P_\perp=P_\parallel+\frac{\dot{P}_\parallel}{2(1+y)},$$

$$W=\frac{-y[(2\alpha-3)y+\alpha^2P_\parallel]}{\alpha^2(1+y)}.$$

A. Perfect fluid models

In the perfect fluid case we have that $P_{\parallel}=P_{\perp}$, and hence from Eqs. (2.4) we obtain the following differential equation for the function $y(x)$ [and hence $S(x)$] in the metric (2.2):

$$2\dot{y}+3y^2+2\alpha y+\alpha^2 p_0=0. \tag{2.5}$$

In Eq. (2.5) p_0 is an arbitrary integration constant. In the perfect fluid case μ is obtained from Eqs. (2.3) and (2.4) and we have that

$$p=p_0 t^{-2}, \tag{2.6}$$

and hence the significance of p_0 is that it constitutes a dimensional constant (appearing in the pressure) characterizing the physical problem; this property is characteristic of self-similarity of the second kind.[3] It can be shown that these perfect fluid solutions (for $\alpha\neq 1$) cannot, in general, admit any homothetic vectors.[4]

The perfect fluid solutions were studied in detail in Benoit and Coley;[1] in fact, exact solutions were obtained and the qualitative properties of the whole class of models were studied. In particular, in the pressure-free case we obtain the exact dust solution of the Tolman family studied by Lynden-Bell and Lemos[16] and Carter and Henriksen,[2] and we found that all solutions are asymptotic to exact, power-law (flat) FRW models (which admit a homothety).

B. Solutions with $S+\dot{S}=0$

In Benoit and Coley (1998) we showed that the case $S+\dot{S}=0$, which implies that $S=s_0 e^{-x}$, could be factored out of the analysis as it could not lead to a perfect fluid solution. For that reason, we consider it as a special case here. (This case is not contained in the geodesic models studied above.)

When $S=s_0 e^{-x}$ (i.e., $y=-1$), the EFEs yield

$$\dot{\phi}=0, \tag{2.7}$$

whence we can choose coordinates so that $e^{2\phi}=1$, and

$$\mu=s_0^{-2}e^{2x}r^{-2}+(1-2\dot{\psi})\alpha^{-2}t^{-2}, \tag{2.8}$$

$$p_{\parallel}(x)=-s_0^2 e^{2x}r^{-2}+(2\alpha-3)\alpha^{-2}t^{-2}, \tag{2.9}$$

$$p_{\perp}(x)=-[(1-\alpha)(1-\dot{\psi})+\dot{\psi}^2+\ddot{\psi}]\alpha^{-2}t^{-2}. \tag{2.10}$$

The fluid described by these equations will further satisfy Eq. (1.13) in one of two cases. Either (i) $\alpha=1$, and the solution admits a homothetic vector, or (ii) $\dot{\psi}=1/2$, $\alpha=3/2$.

In the first case, i.e., $\alpha=1$, the solution is given by

$$ds^2=-dt^2+e^{2\psi}dr^2+s_0 t^{-2}d\Omega^2, \tag{2.11}$$

with

$$\mu=(s_0^{-2}+1-2\dot{\psi})t^{-2}, \tag{2.12}$$

$$p_{\parallel}=-(s_0^{-2}+1)t^{-2}, \tag{2.13}$$

$$p_{\perp}=-(\dot{\psi}^2+\ddot{\psi})t^{-2}, \tag{2.14}$$

where the function $\psi(x)$ is arbitrary.

In the second case the solution is given (after a coordinate redefinition) by

$$ds^2=-dt^2+t^{-2/3}dr^2+t^{4/3}d\Omega^2, \tag{2.15}$$

with

$$\mu=\mu_0 t^{-4/3}, \tag{2.16}$$

$$p_\parallel=-\mu, \tag{2.17}$$

$$p_\perp=0, \tag{2.18}$$

where μ_0 is a constant. It can be easily shown that the metric (2.15) does not admit a proper homothetic vector. Curiously, cosmic strings satisfy ''equations of state'' of the form $\mu+p_\parallel=0$, $p_\perp=0$.[17]

III. SPECIAL CASES

There are a variety of models which satisfy additional constraints. We consider here two such models.

A. Case A: Dimensional constants

If we assume that $P_\perp=p_0$, a constant, then Eqs. (2.4) yield

$$\dot{P}_\parallel(x)=2(1+y)(p_0-P_\parallel(x)). \tag{3.1}$$

This equation can be integrated to yield

$$P_\parallel(x)=p_0+ce^{-2x}S^{-2}, \tag{3.2}$$

where c is an arbitrary constant. Using this expression for $P_\parallel$, we obtain

$$W(x)=\frac{y}{\alpha^2(1+y)}[y(3-2\alpha)-\alpha^2 p_0-c\alpha^2 e^{-2x}S^{-2}], \tag{3.3}$$

and the differential equation

$$2\dot{y}+3y^2+2\alpha y=-\alpha^2 p_0-\alpha^2 ce^{-2x}S^{-2}. \tag{3.4}$$

Note that when $c=0$ (i.e., $P_\parallel=P_\perp=p_0$, corresponding to a perfect fluid) Eq. (3.4) is related to Eq. (2.56) in Benoit and Coley.[1]

If we had begun the analysis of this section with the assumption that $P_\parallel=p_0$, then Eqs. (2.4) automatically imply that $P_\parallel=P_\perp=p_0$, the perfect fluid case considered in Benoit and Coley.[1]

The pressures $p_\parallel$ and $p_\perp$ are positive if the constants p_0 and c are non-negative. The energy conditions will constrain these constants further (for a given value of α) through (3.3).

B. Case B: Equations of state

We can also consider the subclass of solutions which satisfy equations of state of the form:

$$p_\parallel=f_\parallel(\mu), \quad p_\perp=f_\perp(\mu), \tag{3.5}$$

for arbitrary functions $f_\parallel$ and $f_\perp$. From Eqs. (2.3), conditions (3.5) automatically yield

$$p_\parallel=c_\parallel\mu \quad \text{and} \quad p_\perp=c_\perp\mu, \tag{3.6}$$

where $c_\parallel$ and $c_\perp$ are constants. Substituting these conditions into the definitions (2.4) then yields

$$\mu = \mu_0 t^{-2}[Se^x]^{-2(1-c_\perp/c_\parallel)} \tag{3.7}$$

and the differential equation for y:

$$2\dot{y} + 3y^2 + 2\alpha y = -\alpha^2 c_\parallel \mu_0 [Se^x]^{-2(1-c_\perp/c_\parallel)}. \tag{3.8}$$

Once again we note that when $c_\parallel = c_\perp$ (i.e., the perfect fluid case), we recover Eq. (2.5) as expected.

A positive value for the constant μ_0 guarantees that the energy density is positive. If $|c_\parallel| \leqslant \mu_0$ and $|c_\perp| \leqslant \mu_0$, the energy conditions are satisfied. The pressures are non-negative if $c_\parallel \geqslant 0$ and $c_\perp \geqslant 0$.

IV. ANALYSIS OF SPECIAL CASES

The behavior of each of the special cases derived in Sec. III can be studied qualitatively since each of the ordinary differential equations governing the model is autonomous.

The special cases A(dimensional constants) and B(equations of state) can be considered simultaneously using the following change of variables:

$$\nu = b[Se^x]^{-2n}, \tag{4.1}$$

where b is a non-negative constant. The resulting system is then

$$\dot{y} = -\tfrac{1}{2}(3y^2 + 2\alpha y + k + \nu), \tag{4.2}$$

$$\dot{\nu} = -2n\nu(1+y). \tag{4.3}$$

Using these definitions, case A is characterized by $n=1$, $k=\alpha^2 p_0$, and case B is characterized by $n = 1 + c_\perp/c_\parallel$ and $k=0$.

It is important to note that the invariant set $\nu=0$ of Eqs. (4.2)/(4.3) defines the perfect fluid solutions. We also note that $y=0$ represents the static solutions. Each of these cases is examined in detail in Benoit and Coley.[1]

If we consider only the case of positive pressures and positive energy density, we can impose the necessary (though not necessarily sufficient) condition that the parameters in our equations must satisfy $k \geqslant 0$, $n \geqslant 1$ and $\nu \geqslant 0$. With these restrictions, we find that there are at most three singular points at finite values. We note that $\nu=0$ is an invariant set of the system (4.2)/(4.3), as is the set $\nu>0$. As a result we need only consider the dynamics (and hence the singular points) in the half-plane $\nu \geqslant 0$.

The finite singular points (y_0, ν_0) are given by:

$$Q_1 = (\tfrac{1}{3}(-\alpha + (\alpha^2 - 3k)^{1/2}, 0),$$

$$Q_2 = (\tfrac{1}{3}(-\alpha - (\alpha^2 - 3k)^{1/2}, 0),$$

$$Q_3 = (-1, 2\alpha - 3 - k).$$

The nature of these singular points, which can be determined using standard techniques,[18] depends upon the relationship between the parameters α and k. The results are summarized in Table I. Note that only those singular points which are located in the physical phase space are listed in this table. It is important to note that each of the cases I–IV is possible when considering the Eqs. (4.2)/(4.3) in case A. In case B, however, we find that only the cases labeled (I) and (II) in Table I yield consistent constraints on the parameter α.

TABLE I. Summary of the nature of the finite singular points for the system (4.2)/(4.3). ''N/A'' indicates that the given point is not located in the physical region $\nu \geqslant 0$. The two cases (i) $\alpha^2=3k$, $2\alpha-3>k$ and (ii) $\alpha^2<3k$, $2\alpha-3\geqslant k$ are omitted since they do not give any real solutions for k and α.

	$\alpha^2>3k$		$\alpha^2=3k$	$\alpha^2<3k$
	$2\alpha-3\leqslant k$ I	$2\alpha-3>k$ II	$2\alpha-3\leqslant k$ III	$2\alpha-3<k$ IV
$\mathbf{Q}_1$	sink	sink	saddle-node	N/A
$\mathbf{Q}_2$	source	saddle	($\equiv \mathbf{Q}_1$)	N/A
$\mathbf{Q}_3$	saddle	N/A	N/A	N/A

We can complete the qualitative analysis of these two cases by considering the stability of the singular points at infinity. To perform the analysis at infinity, we apply the following Poincaré transformation to our system (4.2)/(4.3) in order to compactify the phase space:

$$Y=\frac{y}{(1+y^2+\nu^2)^{1/2}}, \quad V=\frac{\nu}{(1+y^2+\nu^2)^{1/2}}. \tag{4.4}$$

In these new variables, the phase space has been compactified to the region $\Theta^2=1-(Y^2+V^2)\geqslant 0$, and all infinite points of the original system are found on the boundary $\Theta=0$. The restriction that $\nu\geqslant 0$ implies that $V\geqslant 0$, and all finite singular points remain at finite values of Y and V and are of the same sign in the new coordinate system (Y,V).

The transformed Eqs. (4.1)/(4.2) are then given by:

$$Y'=\tfrac{1}{2}(4n-3)Y^2V^2+\Theta[\tfrac{1}{2}Y+(2n-\alpha)V]-\tfrac{1}{2}\Theta^2[3Y^2+kV^2]-\Theta^3[\alpha Y+\tfrac{1}{2}V]-\tfrac{1}{2}k\Theta^4, \tag{4.5}$$

$$V'=-\tfrac{1}{2}(4n-3)Y^3V+\Theta YV[\tfrac{1}{2}V-(2n-\alpha)Y]+\tfrac{1}{2}\Theta^2YV[k-4n]-2nV\Theta^3, \tag{4.6}$$

where $f'=\Theta\dot{f}$. There are four singular points at infinity located on the boundary $Y^2+V^2=1$, which are given by

$$R_\pm=(0,\pm 1), \quad S_\pm=(\pm 1,0). \tag{4.7}$$

The points $S_\pm$ correspond to perfect fluid solutions, and $R_\pm$ correspond to static solutions. A local stability analysis shows that the points $S_\pm$ are both saddles. R_+ is a nonhyperbolic point containing both stable and unstable manifolds for all values of α and k. The stable manifold of R_+ lies in an elliptic sector of R_+ and corresponds to homoclinic orbits. The fixed point R_- is not in the physical phase space.

The phase portraits in the compactified phase space $(V^2+Y^2\leqslant 1, V\geqslant 0)$ are given in Fig. 1. From these portraits it is immediately evident that the only stable singular points (both to the past and the future) either lie in the $V=0$ invariant set, occur at the infinite singular point R_+, or occur at $\mathbf{Q}_3$ (when it exists in the phase space). Recall that the invariant set $V=0$ represents the perfect fluid solutions studied previously,[1] where in the equivalent ''$M_1=0$'' case the solutions were shown to asymptote towards a flat FRW model. The fixed point R_+ has $y=0$, and hence is a static solution. Finally, the fixed point $\mathbf{Q}_3$ has the property $y=-1$ (or $S+\dot{S}=0$), which was examined in Sec. II B. Since all of the solutions in the phase space, and in particular those asymptoting to the point $\mathbf{Q}_3$, have the property that $p_\parallel=P_\parallel(x)t^{-2}$, $p_\perp=P_\perp(x)t^{-2}$, and $\mu=W(x)t^{-2}$, by continuity so must the solution at $\mathbf{Q}_3$. Therefore the solution represented by the point Q_3 must be given by the metric (2.11).

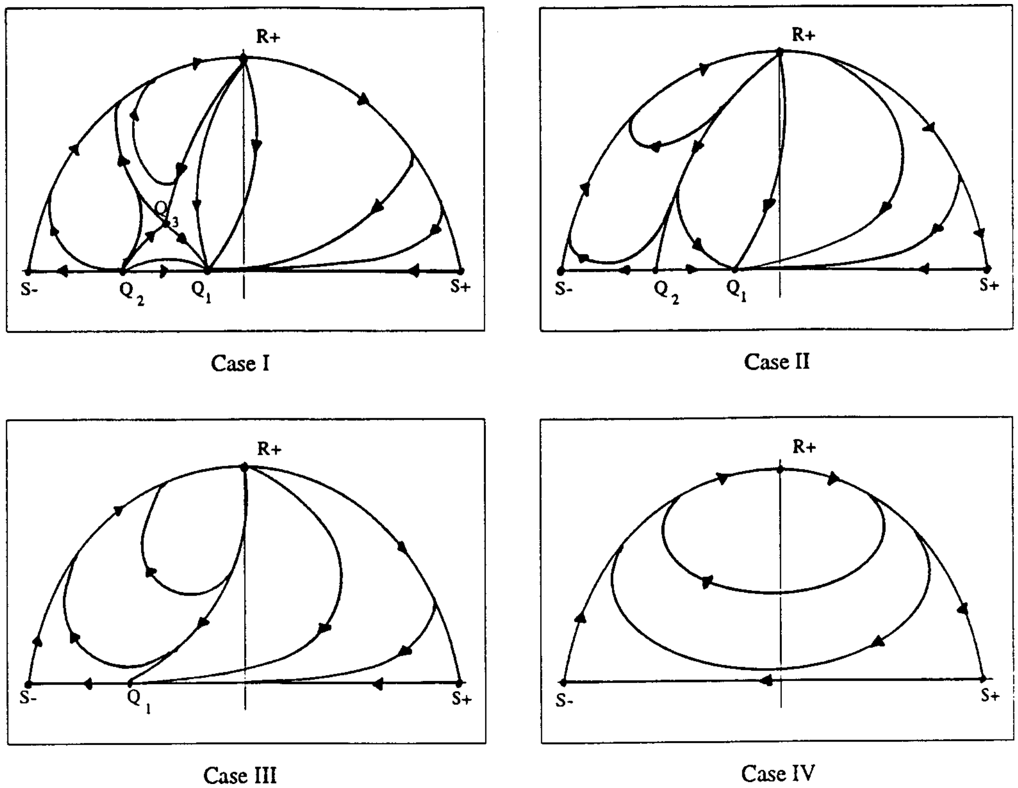

FIG. 1. Phase portraits. The phase portraits for the system (4.5)/(4.6) for various ranges of values of α and k are given, where the particular cases are as listed in Table I.

Consequently we see that in the analysis of the two cases considered in Sec. III A and III B above the asymptotic behavior is described by either a flat FRW perfect fluid model, a static model, or by that of the metric (2.11). In all cases these exact asymptotic models admit a homothetic vector.

V. DISCUSSION

We note that in the cases studied in this paper the dynamics of the models is governed by a system of the form:

$$\dot{y} = -\tfrac{1}{2}(3y^2 + 2\alpha y) + f(\nu), \tag{5.1}$$

$$\dot{\nu} = -2n\nu(1+y). \tag{5.2}$$

The variable ν is defined by Eq. (4.1) and the function $f(\nu)$ depends on the specific case being studied. In the cases considered in Sec. III we had that:

Case A: Dimensional Constants : $f(\nu) = -\tfrac{1}{2}(\nu + \alpha^2 p_0)$.

Case B: Equations of State : $f(\nu) = -\tfrac{1}{2}\nu$.

The system (5.1)/(5.2) results whenever we impose the condition

$$P_{\parallel}(x) = -2\alpha^{-2} f(\nu). \tag{5.3}$$

In the cases examined in Sec. III it was shown that all solutions necessarily asymptote to an exact solution admitting a homothetic vector. It is of interest to consider whether there are any possible asymptotic states for the geodesic anisotropic models which satisfy Eq. (5.3) that do *not* admit a homothetic vector.

As was the case in Sec. IV, the perfect fluid solutions are located in the invariant set $\nu=0$. The definition of ν requires that it be greater than or equal to zero. In the relevant phase space there are then (at most) three finite singular points of the system (5.1)/(5.2). These singular points, equivalent to those studied in Sec. IV, are given by:

$$Q_1=(\tfrac{1}{3}[-\alpha+(\alpha^2+6f(0))^{1/2}],0),$$

$$Q_2=(\tfrac{1}{3}[-\alpha-(\alpha^2+6f(0))^{1/2}],0),$$

$$Q_3=(-1,f^{-1}(3/2-\alpha)).$$

The singular points Q_1 and Q_2 represent perfect fluid models, and Q_3 (as in Sec. IV) is represented by the metric (2.11). In each case the model represented by the finite singular point admits a homothetic vector.

The only possibility for the asymptotic behavior not to be governed by an exact homothetic model is then (i) the model is represented asymptotically by a periodic orbit in the phase space, or (ii) the model is represented by a singular point at infinity not located on one of the coordinate axes $\nu=0$ or $y=0$.

In the first case we can impose necessary conditions for the existence of a periodic orbit. Any periodic orbit in a plane must necessarily enclose a singular point. As a result we must have that the point Q_3 is in the phase space in which case we necessarily have that $f^{-1}(3/2-\alpha)$ is positive. The energy conditions requiring that the pressures and density are positive will result in the further condition that $f(\nu)\leqslant 0$, and therefore $\alpha\geqslant 3/2$ and $y\geqslant 0$. We consider the existence of a periodic orbit which encloses Q_3 by examining the horizontal and vertical isoclines of the system (5.1)/(5.2). The horizontal isoclines are located at (i) $\nu=0$, an invariant line, and (ii) $y=-1$. The second case indicates that if there exists a periodic orbit about the point Q_3 then there must be vertical isoclines on either side of the line $y=-1$. Solving Eq. (5.2), we find that the vertical isoclines are given by

$$y_{\pm}=\tfrac{1}{3}(-\alpha\pm(\alpha^2+3f(\nu))^{1/2}). \tag{5.4}$$

Imposing the energy conditions $f(\nu)\leqslant 0$ and $\alpha\geqslant 3/2$, we find that the y-values of the vertical isoclines must satisfy

$$-1\leqslant y\leqslant 0; \tag{5.5}$$

i.e., $y_{\pm}$ cannot take on values less than -1. Therefore, there can be no periodic orbits enclosing the point Q_3 if the energy conditions are to be satisfied.

If there is an asymptotic solution at infinite values of y and/or ν which is not homothetic then the corresponding singular point at infinity must be such that $y\neq 0$ or $\nu\neq 0$. This will occur when $\lim_{\nu\to\infty}f(\nu)\nu^{-2}\neq 0$. In such cases the infinite fixed point may represent a nonhomothetic asymptotic solution. Therefore, geodesic models for which Eq. (5.3) and the energy conditions are satisfied will not admit a nonhomothetic asymptotic solution whenever $\lim_{\nu\to\infty}f(\nu)\nu^{-2}$ is exactly zero.

VI. OTHER MODELS

Additional anisotropic fluid models can be investigated. For example, we can consider the case in which the source is a combination of *a perfect fluid and a magnetic field* satisfying Eqs. (1.9). Assuming $\overline{p}=(\gamma-1)\overline{\mu}$ (where γ is a constant), in the geodesic case we can immediately derive the governing system as:

$$\dot{y}=-\tfrac{1}{2}(3y^2+2\alpha y)-\tfrac{1}{2}\alpha^2\eta, \tag{6.1}$$

$$\dot{\eta}=-4(1+n)y\eta-4(n-1)(3-2\alpha)\alpha^{-2}y^2, \tag{6.2}$$

where $\eta\equiv-\alpha^{-2}(3y^2+2\alpha y+2\dot{y})=P_\parallel$ and $n\equiv 1/\gamma$. The system (6.1)/(6.2) is of a similar form to Eqs. (5.1) and (5.2) and can be analyzed using similar techniques. In the special cases $\gamma=1$ ($n=1$) and $\alpha=3/2$, Eq. (6.2) can be integrated immediately and exact solutions can be obtained. We note that at the equilibrium points of the system (6.1)/(6.2), $P_\parallel=$ constant ($\dot{P}_\parallel=0$), and hence from Eqs. (1.9), (2.3) and (2.4) we have that

$$\pi=\frac{1}{2}(p_\perp-p_\parallel)=\frac{\dot{P}_\parallel}{2t^2(1+y)}=0; \tag{6.3}$$

hence these equilibrium points correspond to perfect fluid models.

However, in order to study the physics of this particular model we note that $\pi=\lambda H^2/2$ and Eqs. (6.1) and (6.2) need to be supplemented by an additional differential equation (for H, derived from Maxwell's equations) and an assumption on the form of the magnetic permeability, λ.

Finally, we note that in the case in which $\pi=\text{constant}=\pi_0$ (with an unrestricted equation of state) it can be shown that the governing equations reduce to

$$\dot{y}=-\tfrac{1}{2}(3y^2+2\alpha y)-\alpha^2\pi_0\ln(\nu), \tag{6.4}$$

$$\dot{\nu}=-\nu(1+y). \tag{6.5}$$

This system is of the same form as that of (5.1)/(5.2) with $f(\nu)=-\alpha^2\pi_0\ln(\nu)$ and with the constant $n=\frac{1}{2}$. Since (6.3)/(6.4) is of the same form we can immediately conclude that the only asymptotic states of the system necessarily admit a homothetic vector. Note that in this case $f(\nu)$ is not analytic at $\nu=0$; however the physical phase space has $\nu>0$.

The generalized thin-sandwich problem and its local solvability

Domenico Giulini[a)]
Institut für Theoretische Physik, Universität Zürich, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland

(Received 5 October 1998; accepted for publication 18 January 1999)

We consider Einstein gravity coupled to matter consisting of a gauge field with any compact gauge group and minimally coupled scalar fields. We investigate under what conditions a free specification of a spatial field configuration and its time derivative allows us to solve the constraints for lapse, shift, and other gauge parameters and hence determine a solution to the field equations (thin-sandwich problem). We establish sufficient conditions under which the thin-sandwich problem can be solved locally in field space. © *1999 American Institute of Physics.* [S0022-2488(99)00305-9]

I. INTRODUCTION

In this paper we consider the initial value problem for Einstein gravity plus matter in space–times $\Sigma\times\mathbf{R}$, where Σ is a closed orientable three-manifold. We are interested in the question of how to find initial data which satisfy the constraints. The most popular approach here is a powerful method devised by Lichnerowicz, Choquet-Bruhat, York, and others, henceforth referred to as the ''conformal method.'' (See Ref. 1 for a brief review and Ref. 2 for more details.) Of the gravitational variables it allows us to freely specify the conformal class of the initial three-metric, the conformally rescaled transverse-traceless components of the extrinsic curvature, and a constant trace thereof (i.e., Σ must have constant mean curvature). Given these data, the constraints turn into a quasilinear elliptic system of second order for the conformal factor (scalar function) and the transverse momentum (vector field), which decouples due to the constant mean-curvature condition. The disadvantages of this method are that it does not easily generalize to data of variable mean curvature and, more important for us, that it does not allow us to control the local scales of the physical quantities initially, since the freely specifiable data (gravitational and non-gravitational) are related to the actual physical quantities by some rescalings with suitable powers of the conformal factor. In particular, one has no control over the conformal part of the initial three-geometry.

In this paper we are concerned with the so-called ''thin-sandwich method,'' which differs from the one just mentioned insofar as it aims to define solutions to the Einstein equations by a *free* specification of the initial field configuration and its coordinate-time-derivative. The constraints are now read as equations for the gauge parameters (lapse, shift,...). From the conformal point of view this means that one tries to trade in the freedom to specify the initial gauge parameters for the freedom to specify the conformal part of the metric and the longitudinal part of the momentum. The disadvantages mentioned above would then be overcome, but unfortunately the equations (for the gauge parameters) turn out to be nonelliptic in general.[3,4] (By ellipticity of nonlinear differential operators we mean the ellipticity of its linearization, which depends on the point (in field space) about which one linearizes. The usual statement that the thin-sandwich equations are not elliptic merely asserts the existence of points where the linearization is not elliptic, but not that the domain of ellipticity is empty.) However, for certain open subsets of initial data they are elliptic and can be locally solved. This was first shown in Ref. 5 and will here be

a)Electronic mail: giulini@physik.unizh.ch

generalized to the full system including dynamical matter in the form of scalar and vector gauge fields.

We note that historically this approach arose from the question (then formulated as a conjecture) of whether the specification of two three-geometries uniquely determine an interpolating Einstein space–time (thick-sandwich problem). For nearby geometries infinitesimally close in time this turns into the thin-sandwich problem (see Ref. 6, Chap. 4, and Ref. 7) which we now describe in more detail.

In a space–time neighborhood $\Sigma\times\mathbf{R}$ of the Cauchy surface Σ, we use the standard parametrization of the space–time metric $g^{(4)}$,

$$g^{(4)}=-\alpha^2 dt\otimes dt+g_{ab}(dx^a+\beta^a dt)\otimes(dx^b+\beta^b dt), \tag{1.1}$$

where g is the (t-dependent) Riemannian metric of Σ and α and β are (t-dependent) scalar and vector fields on Σ, known as lapse and shift. The extrinsic curvature reads

$$K=\frac{1}{2\alpha}(\partial_t-L_\beta)g, \tag{1.2}$$

where L_β denotes the Lie derivative along β. Written in terms of (g,K), the constraints do not depend on α and β and hence constrain the set of allowed values for the data (g,K). The constraints read

$$K_{ab}K^{ab}-(K_a^a)^2-R=-2T_{\perp\perp}, \tag{1.3}$$

$$\nabla^b(K_b^a-\delta_b^a K_c^c)=T_\perp^a, \tag{1.4}$$

where T is the energy-momentum tensor of the matter and $\perp$ denotes the component along the future pointing normal n of Σ.

Alternatively, one may write the constraints in terms of g and $\dot g:=\partial_t g$ by replacing K via (1.2). Then they explicitly involve α and β and one may ask whether it is possible to *freely* specify $(g,\dot g)$ and let the constraints determine α and β. This is the thin-sandwich problem (TSP). If we abbreviate $\Psi:=(g,\dot g)$, $X:=(\alpha,\beta)$, the constraints take the form of the thin-sandwich equation (TSE):

$$F[\Psi,X]=0. \tag{1.5}$$

The TSP now asks for existence and uniqueness of solutions of the TSE, read as equation for X given Ψ. Once this is solved, we can construct (g,K) satisfying (1.3) and (1.4), which uniquely determine space–time via the Einstein evolution equations.[2]

It has long been discussed in the literature that, in general, existence and uniqueness should fail,[3] although some arguments merely showed this under the additional assumption (*a priori*) of constant lapse function α (Ref. 4) (see also Ref. 8 for a related issue). However, more recently it was shown that given a solution (Ψ,X) of the TSE, which satisfies certain bounds on geometric quantities and which admits no nontrivial solutions of the spatially projected Killing equation, there exist unique solutions $X(\Psi')$ for all Ψ' in a neighborhood of Ψ. This was achieved by an implicit function theorem for a reduced version of (1.5) with already eliminated lapse function.

Note that in this formulation of the TSP the right-hand sides of the constraints, that is $T_{\perp\perp}$ and $T_\perp^a$, are assumed given. These are *not* the components of T that an observer along ∂_t would measure. The relation between the two sets of components involve α and β. For example, if the matter is represented by some dynamical field ϕ, the quantities $T_{\perp\perp}$ and $T_\perp^a$ cannot be calculated from the initial data $(\phi,\dot\phi)$ without the use of α and β. Hence there is a certain inconsistency in the traditional formulation of the TSP in that it eliminates any appearance of the normal n in favor of ∂_t, lapse, and shift on the left side (the gravitational part), but not on the right side (matter part) of the constraints. This inconsistency was already felt by others (see, e.g., Sec. IV of Ref. 3), but no alternative formulation was hitherto attempted.

In this paper we consider a generalized thin-sandwich problem (GTSP) for the initial data of the full system of coupled gravitational and matter fields, which avoids the difficulty just mentioned. As matter we shall consider coupled systems of scalar and gauge fields, further specified below. By Φ we shall collectively denote all dynamical fields of the theory. We ask: Under what conditions do input data $\Phi := (\Phi, \dot{\Phi})$ uniquely specify a solution to the Einstein matter equations? In the same fashion as for (1.5), one obtains a now *generalized* thin-sandwich equation (GTSE) from which one tries to determine the "gauge parameters" X given the data Ψ. One nontrivial aspect of our generalization is due to the possible presence of gauge matter fields. In this case X comprises lapse, shift, and *additional* functions with values in the Lie algebra of the gauge group. Our main result will consist of an implicit function theorem for this extended set of variables, which for our GTSP is precisely analogous to the result proven in Ref. 5 for the traditional form of the thin-sandwich problem. But note that the two formulations differ even without gauge fields.

II. THE GENERALIZED FRAMEWORK

The dynamical fields we consider involve the gravitational field, a gauge field with compact gauge group **G** of dimension N and an M-component scalar field with values in an associated $\mathbf{R}^M$-vector-bundle. It couples to both previous fields in the standard minimal fashion. For simplicity we assume the **G**-principal bundle to be trivial. Since the frame bundle of any orientable three-manifold is always trivial, we may choose global trivializations of these bundles and represent fields by their globally defined component fields on space–time. For fixed time, a configuration of fields is given by the $6+3N+M$ component fields on Σ,

$$\Phi^A := (g_{ab}, A_a^\mu, \phi^\alpha), \tag{2.1}$$

where indices $\mu,\nu,...$ denote components in the Lie algebra **LG** and $\alpha,\beta,...$ denote components in $\mathbf{R}^M$. Hence we think of a field configuration as mapping

$$\Phi: \Sigma \to S_2^+(\mathbf{R}^3) \times \mathbf{R}^{3N} \times \mathbf{R}^M, \tag{2.2}$$

where $S_2^+(\mathbf{R}^3)$ denotes the space of symmetric, positive definite, bilinear forms on $\mathbf{R}^3$, in which g_{ab} is valued. Looking ahead, we remark that this space may be identified (via polar decomposition) with the homogeneous manifold GL(3,**R**)/O(3), a fact that is useful when studying the Lorentzian structure (2.11).[8] The total target space, whose dimension is $6+3N+M$, will be denoted by Θ, and the space of mappings $\Sigma \to \Theta$ (to be further specified) by $\mathcal{M}$.

Compactness of the gauge-group **G** implies the existence of **G**-invariant, symmetric, positive definite, bilinear forms $k_{\mu\nu}$ and $h_{\alpha\beta}$ on **LG** and $\mathbf{R}^M$, respectively. The class of models we shall consider here are characterized by the Lagrange four-form

$$\mathcal{L} = \tfrac{1}{2} * R^{(4)} - \tfrac{1}{4} k_{\mu\nu} \Omega^\mu \wedge * \Omega^\nu - \tfrac{1}{2} h^{\alpha\beta} \nabla \phi_\alpha \wedge * \nabla \phi_\beta - W, \tag{2.3}$$

where $*$ is the Hodge-duality map wrt $g^{(4)}$ and Ω is the curvature of A. For notational simplicity we shall denote all the covariant derivatives acting on sections in the various vector bundles by the same symbol ∇. In general, it will therefore involve the Christoffel symbols as well as the gauge connection A in the appropriate representation of **LG**. The potential W depends on the fields and their first spatial derivatives. Its precise form is not important, except that we need to explicitly exclude second (or higher) derivative couplings, in particular, the so-called conformal coupling of the scalar and gravitational field. The reason for this will be explained below. The Hamiltonian constraint for (2.3) has the general form

$$\mathcal{H} = \tfrac{1}{2} G_{AB} V^A V^B + U = 0, \tag{2.4}$$

where the potential is the following sum:

$$U = -R + \tfrac{1}{4} k_{\mu\nu} g^{ac} g^{bd} \Omega^{\mu}_{ab} \Omega^{\nu}_{cd} + h_{\alpha\beta} g^{ab} \nabla_a \phi^{\alpha} \nabla_b \phi^{\beta} + W, \tag{2.5}$$

whose terms represent the contributions of the gravitational, gauge, and scalar fields (two terms), respectively, to the potential energy. R denotes the Ricci scalar for g and Ω now denotes the curvature of the pulled-back **G**-bundle over Σ. The covariant derivative ∇_a refers from now on to the connection in the splicing of the frame bundle of Σ with the pulled-back **G**-bundle. The ''canonical velocities,'' V^A, can be written in terms of the ''coordinate velocities'' $\dot{\Phi}^A := \partial_t \Phi^A$ and the ''gauge-parameters'' α and $\xi := (\beta, \lambda)$. The general structure is [compare (1.2)]

$$V = \frac{1}{\alpha} \Gamma = \frac{1}{\alpha} (\dot{\Phi} + f_{\xi}), \tag{2.6}$$

where f_{ξ} represents the variations generated by the infinitesimal diffeomorphism and gauge-transformation with parameters β and λ, respectively. Resolved in terms of the individual fields (2.1), the components of Γ, and hence of f_{ξ}, read

$$\Gamma_{ab} = \dot{g}_{ab} - 2 \nabla_{(a} \beta_{b)}, \tag{2.7}$$

$$\Gamma^{\mu}_{a} = \dot{A}^{\mu}_{a} - \beta^{b} \Omega^{\mu}_{ba} - \nabla_a \lambda^{\mu}, \tag{2.8}$$

$$\Gamma^{\alpha} = \dot{\phi}^{\alpha} - \beta^{a} \nabla_a \phi^{\alpha} + \lambda^{\mu} \rho^{\alpha}_{\mu\beta} \phi^{\beta}, \tag{2.9}$$

where ρ denotes the representation of **LG** in $\mathrm{gl}(M, \mathbf{R})$.

Finally, following the decomposition of Θ as Cartesian product, the ''kinetic-energy-metric'' G_{AB} on Θ which appears in (2.4) has the following block structure:

$$G_{AB} = G^{ab\,cd} \oplus k_{\mu\nu} g^{ab} \oplus h_{\alpha\beta}, \tag{2.10}$$

where the first 6×6 block is given by the DeWitt metric

$$G^{ab\,cd} = \tfrac{1}{4} (g^{ac} g^{bd} + g^{ad} g^{bc} - 2 g^{ab} g^{cd}), \tag{2.11}$$

which is a Lorentz metric of signature (1.5). Hence G_{AB} itself is a Lorentz metric of signature $(1, 5 + 3N + M)$ on the manifold Θ, which is homeomorphic to $\mathbf{R}^{6+3N+M}$. We shall sometimes denote this metric simply by G and write $G(\cdot, \cdot)$ for the inner product. We will see that the Lorentzian signature of G is *the* important feature on which the proofs of our main results rest. This is also the reason why we had to exclude higher derivative (e.g., conformal) couplings of the scalar and gravitational fields, since they will, in general, destroy this signature structure.[9] On the other hand, our proofs will still apply to more complicated self-couplings of the scalar field. For example, nonlinear σ-models would be allowed, since here the target space metric of the scalar field, $h_{\alpha\beta}$, simply becomes ϕ^{α} dependent, which is unimportant to our proofs as long as it stays positive definite.

The (undensitized) momenta of the field Φ^A are just given by the covariant components—with respect to G—of the velocities: $P_A := G_{AB} V^B$. For the individual fields we write $P_A = (\pi^{ab}, \pi^{a}_{\mu}, \pi_{\alpha})$. In the canonical theory, the phase space function that generates infinitesimal diffeomorphisms and gauge transformations with parameter ξ' is given by

$$\mathcal{P}_{\xi'} := \int_{\Sigma} d\mu \, P_A f^{A}_{\xi'}, \tag{2.12}$$

where here and below we set $d\mu := \sqrt{\det\{g_{ab}\}}d^3x$ for the measure on Σ. For completeness we remark that, using (2.7)–(2.9), a straightforward calculation yields the following familiar Poisson-bracket relation, which involves the curvature tensor Ω of the gauge field on Σ:

$$\{\mathcal{P}_{\xi'}, \mathcal{P}_{\xi''}\} = P_{\xi'''}, \tag{2.13}$$

where $\xi''' = (\beta''', \lambda''')$ reads

$$\beta''' = -[\beta', \beta''], \tag{2.14}$$

$$\lambda''' = [\lambda', \lambda''] - \Omega(\beta', \beta''). \tag{2.15}$$

The diffeomorphism- and Gauss-constraints are just given by $\mathcal{P}_{\xi'} = 0\ \forall \xi'$, which may be expressed by saying that the velocity field V is L^2G-orthogonal to all ''vertical'' vector fields $f_{\xi'}$. Hence we must have

$$0 = \int_\Sigma P_A f^A_{\xi'}\, d\mu = \int_\Sigma \frac{1}{\alpha} G(\Gamma, f_{\xi'}) d\mu =: \int_\Sigma (g_{ab}\beta'^a \mathcal{D}^b + k_{\mu\nu}\lambda'^\mu \mathcal{G}^\nu) d\mu, \tag{2.16}$$

for all, say C^∞, vector fields β' and **LG**-valued functions λ'. This is equivalent to $\mathcal{D}^a = 0$ (diffeomorphism constraint) and $\mathcal{G}^\mu = 0$ (Gauss constraint). Explicitly we get

$$\mathcal{D}^a = 2G^{abcd}\nabla_b\left(\frac{1}{\alpha}\Gamma_{cd}\right) - \frac{1}{\alpha} g^{ab} k_{\mu\nu} \Omega^\mu_{bc} g^{cd} \Gamma^\nu_d - \frac{1}{\alpha} g^{ab} (\nabla_b \phi^\alpha) h_{\alpha\beta} \Gamma^\beta, \tag{2.17}$$

$$\mathcal{G}^\mu = \nabla_a\left(\frac{1}{\alpha} g^{ab} \Gamma^\mu_b\right) + \frac{1}{\alpha} k^{\mu\nu} \rho^\alpha_{\nu\beta} \phi^\beta h_{\alpha\gamma} \Gamma^\gamma. \tag{2.18}$$

Given Φ and $\dot{\Phi}$ we now have the $4+N$ equations $0 = \mathcal{H} = \mathcal{D}^a = \mathcal{G}^\mu$ for the $4+N$ unknowns $\alpha, \beta^a, \lambda^\mu$. The first step consists of inserting (2.6) into (2.4) and solving for α^2:

$$\alpha^2 = -\frac{G(\Gamma, \Gamma)}{2U}. \tag{2.19}$$

For this to make sense the right-hand side must be positive. But for the following analysis it turns out that we need to put the following stronger condition.

Condition 1 (a priori):

$$U > 0, \tag{2.20}$$

$$G(\Gamma, \Gamma) < 0. \tag{2.21}$$

Note that (2.20) just involves the initial data, whereas (2.21) contains as well the unknowns β and λ (hence ''*a priori*''). Note that (2.21) says that the system must, at each point of Σ, move in a ''timelike'' direction with respect to the Lorentz metric G. The need for such an *a priori* bound implies that our results will only be perturbative. Given these bounds, we set α equal to the positive square root of the right-hand side of (2.19). We can then eliminate α from (2.17) and (2.18) and obtain a set of $3+N$ equations for the $3+N$ unknowns $\xi = (\beta, \lambda)$, which we call the generalized *reduced* thin-sandwich equation (GRTSE):

$$F[\Psi, \xi] = 0. \tag{2.22}$$

Now consider the following functional over configurations satisfying Condition 1:

$$S[\Psi,\,\xi]=\int_\Sigma \sqrt{-2UG(\Gamma,\Gamma)}\,d\mu. \tag{2.23}$$

Then solutions to the GRTSE are stationary points with respect to variations in ξ. More precisely, let D_2 denote the partial (functional) derivative in the second argument and denote the L^2 inner product of ξ_1 and ξ_2 by $\langle\xi_1|\xi_2\rangle:=\int_\Sigma d\mu(k_{\mu\nu}\lambda_1^\mu\lambda_2^\nu+g_{ab}\beta_1^a\beta_2^b)$. We then have the following.

Lemma 1:

$$D_2S[\Psi,\,\xi](\xi')=-\langle\xi'|F[\Psi,\,\xi]\rangle. \tag{2.24}$$

Proof: For $s\in(-\epsilon,\epsilon)$ set $\eta(s)=\xi+s\xi'$ and $\Gamma(s)=\dot{\Phi}+f_{\eta(s)}$. Hence $(d/ds)|_{s=0}\Gamma(s)=f_{\xi'}$. Then, recalling (2.16),

$$\frac{d}{ds}\bigg|_{s=0}S[\Psi,\,\eta(s)]=-\int_\Sigma\sqrt{\frac{-2U}{G(\Gamma,\Gamma)}}\,G(\Gamma,f_{\xi'})d\mu=-\langle\xi'|F[\Psi,\,\xi]\rangle. \tag{2.25}$$

III. MAIN RESULTS

In this section we are mainly concerned with the linearization of the GRTSE, except at the end where we will discuss global uniqueness. The corresponding linear operator will be called L, without explicit indication that it depends on Ψ and ξ. It is defined by

$$\langle\xi'|L\xi''\rangle:=\frac{d}{ds}\bigg|_{s=0}\langle\xi'|F[\Psi,\,\xi+s\xi'']\rangle=\int_\Sigma d\mu\,\frac{d}{ds}\bigg|_{s=0}\frac{G(f_{\xi'},\Gamma(s))}{\alpha(s)}, \tag{3.1}$$

where $\Gamma(s)=\dot{\Phi}+f_{\xi+s\xi''}$ and $\alpha(s)=[-G(\Gamma(s),\Gamma(s))/2U]^{1/2}$. Setting $\Gamma(s=0)=\Gamma$, $\alpha(s=0)=\alpha$, and noting that $(d/dt)|_{s=0}\Gamma(s)=f_{\xi''}$, we get

$$\frac{d}{ds}\bigg|_{s=0}\alpha(s)=-\frac{G(f_{\xi''},\Gamma)}{2\alpha U}=\alpha\,\frac{G(f_{\xi''},\Gamma)}{G(\Gamma,\Gamma)}, \tag{3.2}$$

where we used (2.4) to eliminate U in the last step. Hence

$$\frac{d}{ds}\bigg|_{s=0}\frac{G(f_{\xi'},\Gamma(s))}{\alpha(s)}=\frac{1}{\alpha}\left[G(f_{\xi'},f_{\xi''})-\frac{G(f_{\xi'},\Gamma)G(f_{\xi''},\Gamma)}{G(\Gamma,\Gamma)}\right]=\frac{G(f_{\xi'}^\perp,f_{\xi''}^\perp)}{\alpha}, \tag{3.3}$$

where

$$f_{\xi'}^\perp:=f_{\xi'}-\Gamma\,\frac{G(f_{\xi'},\Gamma)}{G(\Gamma,\Gamma)} \tag{3.4}$$

is the G-orthogonal projection of $f_{\xi'}$ pointwise perpendicular to Γ. This leads to the following expression for L's matrix elements:

$$\langle\xi'|L\xi''\rangle=\int_\Sigma d\mu\,\frac{1}{\alpha}\,G(f_{\xi'}^\perp,f_{\xi''}^\perp), \tag{3.5}$$

where α is the square-root of the rhs of (2.19). If (2.21) holds, Γ is ''timelike'' (pointwise on Σ) and hence the $f^\perp$'s are ''spacelike'' or zero. Since the metric G is Lorentzian, it is positive definite on ''spacelike'' vectors. Hence we have shown the following.

Lemma 2: Suppose Condition 1 holds. Then L is self-adjoint and non-negative. Furthermore, $\xi'\in kernel(L)\Leftrightarrow\exists\,\kappa:\Sigma\to\mathbf{R}$ *such that*

$$f_{\xi'} = \kappa \Gamma. \tag{3.6}$$

Remark: Symmetry is expected, for consider the rhs of (2.23) as functional of Ψ and Γ, denoting it by $S[\Psi,\Gamma]$. Then the calculation of the rhs of (3.5) was just that of $-D_2^2 S[\Psi,\Gamma] \times(\Gamma',\Gamma'')$ for $\Gamma'=f_{\xi'}$ and $\Gamma''=f_{\xi''}$.

We will next show that under the same hypotheses L is, in fact, elliptic. For this we will need the following.

Lemma 3: If Condition 1 holds, π^{ab} is a positive or negative definite matrix.

Proof: Condition 1 implies $G^{AB}P_A P_B<0 \Rightarrow G_{ab\,cd}\pi^{ab}\pi^{cd}=2(\pi_{ab}\pi^{ab}-\frac{1}{2}(\pi^a_a)^2)<0$. Choosing a frame where $g_{ab}=\delta_{ab}$ and $\pi^{ab}=\mathrm{diag}\,(p_1,p_2,p_3)$, this is equivalent to the following condition on the eigenvalue vector $\vec{p}:=(p_1,p_2,p_3)$:

$$\left|\frac{\vec{n}\cdot\vec{p}}{\|\vec{p}\|}\right| > \sqrt{\frac{2}{3}}, \tag{3.7}$$

where $\vec{n}=(1,1,1)/\sqrt{3}$, which means that $\vec{p}$ lies in the interior of the double cone with axis along $\vec{n}$ and opening angle $\theta<\cos^{-1}(2/3)^{1/2}$ about its axis. This cone just touches the walls of the positive and negative octants along the bisecting lines, and since $\vec{p}$ must be in its interior, all eigenvalues are either strictly positive or strictly negative. □

Proposition 1: Suppose Condition 1 holds. Then the second-order differential operator L is elliptic.

Proof: For later purposes we shall prove slightly more, namely that the definiteness of π^{ab} is equivalent to the ellipticity of L. This we do by a direct calculation of L's principal symbol. For this we to go back to the explicit formulas (2.17) and (2.18) for the full nonlinear problem and explicitly linearize them, but keeping track only of the highest (second) derivatives. By $\overset{2}{=}$ we shall denote equality in the second derivative terms. We set again $\Gamma(s)=\dot{\Phi}+f_{\xi+s\xi'}$, etc., with $\xi'=(\beta',\lambda')$. It will be convenient to express things in terms of the momenta, using $\alpha P_A=G_{AB}\Gamma^B$, and accordingly write (3.2) in the form

$$\left.\frac{d}{ds}\right|_{s=0}\alpha(s)=-\frac{P_A f^A_{\xi'}}{2U}. \tag{3.8}$$

Then

$$\left.\frac{d}{ds}\right|_{s=0}\mathcal{D}^a \overset{2}{=} \partial_b\left[\frac{P_A f^A_{\xi'}}{\alpha U}\pi^{ab}-\frac{4}{\alpha}G^{ab\,cd}\partial_c\beta'_d\right]$$

$$\overset{2}{=}-\frac{1}{\alpha}\left[\frac{2\pi^{ac}\pi^{de}g_{db}\partial_c\partial_e\beta'^b+\pi^{ab}\pi^c_\nu\partial_b\partial_c\lambda'^\nu}{U}+g^{bc}\partial_b\partial_c\beta'^a-g^{ac}\partial_c\partial_b\beta'^b\right], \tag{3.9}$$

$$\left.\frac{d}{ds}\right|_{s=0}\mathcal{G}^\mu \overset{2}{=} \partial_a\left[\frac{P_A f^A_{\xi'}}{2\alpha U}k^{\mu\nu}\pi^a_\nu-\frac{1}{\alpha}g^{ab}\partial_b\lambda'^\mu\right]$$

$$\overset{2}{=}-\frac{1}{\alpha}\left[\frac{2k^{\mu\nu}\pi^a_\nu g_{bc}\pi^{cd}\partial_a\partial_d\beta'^b+k^{\mu\sigma}\pi^a_\sigma\pi^b_\nu\partial_a\partial_b\lambda'^\nu}{2U}+g^{ab}\partial_a\partial_b\lambda'^\mu\right]. \tag{3.10}$$

Replacing $\partial_a\to k_a$ we can just read off the matrix of the principal symbol $\sigma(k)$ in the general form

$$\begin{bmatrix} \sigma^\mu_\nu & \sigma^\mu_b \\ \sigma^a_\nu & \sigma^a_b \end{bmatrix}, \tag{3.11}$$

where we have chosen to order the $N+3$ rows and columns so that we first count the N components of λ' and then the three components of β'. In order to calculate the determinant we make the following simplifications: We call $\pi^{ab}k_b =: p^a$, $\pi^a_\mu k_a =: \pi_\mu$, $\pi^\mu := k^{\mu\nu}\pi_\nu$, and choose a spatial frame where $g_{ab} = \delta_{ab}$, $k_a = (\|k\|,0,0)$ and $p^a = (p_1, p_2, 0)$. Then (3.11) reads explicitly

$$\sigma(k) = -\frac{1}{\alpha}\begin{bmatrix} \frac{\pi^\mu\pi_\nu}{2U} + \|k\|^2\delta^\mu_\nu & \frac{\pi^\mu p_1}{U} & \frac{\pi^\mu p_2}{U} & 0 \\ \frac{p_1\pi_\nu}{U} & \frac{2p_1^2}{U} & \frac{2p_1p_2}{U} & 0 \\ \frac{p_2\pi_\nu}{U} & \frac{2p_1p_2}{U} & \frac{2p_2^2}{U} + \|k\|^2 & 0 \\ 0 & 0 & 0 & \|k\|^2 \end{bmatrix}. \tag{3.12}$$

Now, for $k \neq 0$, $p_1 = \|k\|\pi(\hat{k},\hat{k})$, where $\hat{k} := k/\|k\|$. Lemma 3 then ensures that $p_1 \neq 0$. In order to calculate det $\{\sigma(k)\}$, we simplify this matrix as follows: We subtract $\pi^\mu/2p_1$ times the $(N+1)$st row from the μth row, for each $1 \leq \mu \leq N$, and also subtract p_2/p_1 times the $(N+1)$st row from the $(N+2)$nd row. The resulting matrix reads

$$-\frac{1}{\alpha}\begin{bmatrix} \|k\|^2\delta^\mu_\nu & 0 & 0 & 0 \\ \frac{p_1\pi_\nu}{U} & \frac{2p_1^2}{U} & \frac{2p_1p_2}{U} & 0 \\ 0 & 0 & \|k\|^2 & 0 \\ 0 & 0 & 0 & \|k\|^2 \end{bmatrix}. \tag{3.13}$$

Its determinant, which equals that of $\sigma(k)$, is now easily calculated:

$$\det\{\sigma(k)\} = \frac{2p_1^2}{U}\|k\|^{2(N+2)}\left[-\frac{1}{\alpha}\right]^{N+3} = 2\left[-\frac{\|k\|^2}{\alpha}\right]^{N+3}\frac{[\pi(\hat{k},\hat{k})]^2}{U}. \tag{3.14}$$

Lemma 3 implies that this is zero $\Leftrightarrow k=0$, which finally proves ellipticity of L. □

Remark: It is interesting to see that all momenta of matter fields in (3.12) drop out when taking the determinant, and that the result is $\propto [\pi(\hat{k},\hat{k})]^2$, just as in the vacuum case.[5] The underlying reason is the fact that $(f_\xi)_{\text{matter}}$ depends ultralocally (i.e., without derivatives) on β [see (2.8) and (2.9)], which implies that the lower-right 3×3-matrix in (3.12) is independent of the momenta for matter fields and hence identical to the principal symbol in the vacuum case. We also note that there is a simple argument that ellipticity of L is implied by the definiteness of π^{ab}. In brief, the argument is simply this: (Here I follow a suggestion made by the referee.) Replacing $\partial_a \to k_a$, any kernel element of the quadratic form (3.5) must, according to (3.6), satisfy $-2k_{(a}\beta_{b)} = \kappa\Gamma_{ab}$, where $\kappa \not\equiv 0$, which immediately implies $\pi(k,k)=0$. Hence a definite π^{ab} implies a trivial kernel. (3.14) shows that this condition is also necessary.

The results obtained so far suffice to deduce an implicit function theorem. To state it precisely, we need to choose appropriate function spaces. It is natural to choose Sobolev spaces which are also used in showing existence of the time evolution.[2] To begin with, it is convenient to summarize the order of spatial differentiation by which the various fields enter the quantities Γ, U, α, and hence the GRTSE, by the following matrix:

	Γ	U	α	GRTSE
g_{ab}	1	2	2	3
A_a^μ	1	1	1	2
ϕ^α	1	1	1	2
$\dot{g}_{ab}$	0	—	0	1
$\dot{A}_a^\mu$	0	—	0	1
$\dot{\phi}^\alpha$	0	—	0	1
β^a	1	—	1	2
λ^μ	1	—	1	2

(3.15)

Note that we assumed that U only contained first derivatives of the matter fields, whereas it contains second derivatives of the gravitational field through the Ricci scalar. Hence g_{ab} enters the GRTSE thrice differentiated. (This seems to have been overlooked in Ref. 5.)

By $H^n(V)$ we shall denote the Sobolev space of V-valued functions on Σ with L^2-norm in the first n derivatives (i.e., generalizing $H^n = W^{n,2}$ using an inner product in V). We shall have $V = T_2^0$ for g_{ab} and $\dot{g}_{ab}$, $V = T_1^0 \otimes \mathbf{LG}$ for A_a^μ and $\dot{A}_a^\mu$, $V = \mathbf{R}^M$ for ϕ^α and $\dot{\phi}^\alpha$, $V = T_0^1$ for β^a, and $V = \mathbf{LG}$ for λ^μ. The inner products for the various V's are just as in the metric G, except for the gravitational field where instead of $G^{ab\,cd}$, which is not positive definite, we choose the positive definite form $g^{ac}g^{bd}$ [compare (2.11)]. Now we define the Sobolev spaces

$$H_\Phi^n := H^{n+3}(T_2^0) \times H^{n+2}(T_1^0 \otimes \mathbf{LG}) \times H^{n+2}(\mathbf{R}^M), \tag{3.16}$$

$$H_{\dot{\Phi}}^n := H^{n+1}(T_2^0) \times H^{n+1}(T_1^0 \otimes \mathbf{LG}) \times H^{n+1}(\mathbf{R}^M), \tag{3.17}$$

$$H_\Psi^n := H_\Phi^n \times H_{\dot{\Phi}}^n, \tag{3.18}$$

$$H_\xi^n := H^n(T_0^1) \times H^n(\mathbf{LG}). \tag{3.19}$$

One may now show that the operator F in the GRTSE, $F[\Psi,\xi]=0$, defines a C^1-map

$$F: H_\Psi^n \times H_\xi^{n+2} \to H_\xi^n \quad \text{for } n \geqslant 2 \tag{3.20}$$

on the domain of fields (Ψ, ξ) which satisfy Condition 1. [The Sobolev embedding theorem for three-dimensional domains and L^2-norms implies a continuous embedding $H^n(V) \hookrightarrow C^k(V)$ for $k < n - 3/2$. $n \geqslant 2$ is needed to guarantee continuity of the functions and gain pointwise control, which is needed in the proof for F being C^1.] For this we need to impose suitable but very mild regularity conditions on the unspecified function W in (2.5). The linear map L is the first derivative of F wrt the second argument: $D_2F[\Psi,\xi]$. Ellipticity implies that Image $(L) := L(H_\xi^{n+2}) \subseteq H_\xi^n$ is closed and hence H_ξ^n splits as orthogonal sum of closed subspaces, given by L's image and the kernel of L's adjoint. Hence, since L is self-adjoint, $H_\xi^n = \text{image}\,(L) \oplus \text{kernel}\,(L)$. We now get an implicit function theorem for the map F if $D_2F[\Psi,\xi]$ is a linear isomorphism, i.e., if kernel $(L) = \{0\}$. But since L is elliptic, any nontrivial element in the kernel may be represented by a C^∞ function ξ' which must then satisfy (3.6). Hence a trivial kernel is equivalent to the following condition for smooth functions:

Condition 2:

$$f_{\xi'} = \kappa\Gamma \quad \text{implies} \quad \xi' = 0, \quad \kappa = 0. \tag{3.21}$$

Hence we arrive at the following formulation of an implicit function theorem for the generalized thin-sandwich problem. It may be seen as generalization of Theorem 2 (or 3) in Ref. 5.

Theorem: *Let $n \geqslant 2$ and $(\Psi,\xi) \in H^n_\Psi \times H^{n+2}_\xi$ be a solution to the GRTSE, $F[\Psi,\xi]=0$, which satisfies Condition 1 [i.e., (2.20 and 2.21)] and Condition 2 [i.e., (3.21)]. Then there exist open neighborhoods $V \subset H^n_\Psi$ of Ψ and $W \subset H^n_\Psi \times H^{n+2}_\xi$ of (Ψ, ξ) and a C^1 map $\sigma: V \to H^{n+2}_\xi$ such that $F[\Psi',\xi']=0$ for $(\Psi',\xi') \in W \Leftrightarrow \Psi' \in V$ and $\xi' = \sigma(\Psi')$.*

Consider the action T of $\dot{\mathbf{R}} := \mathbf{R} - \{0\}$ on $H^n_\Psi \times H^{n+2}_\xi$, given by $T_\delta(\Phi,\dot\Phi,\xi) := (\Phi,\delta\dot\Phi,\delta\xi)$ for $\delta \in \dot{\mathbf{R}}$. It leaves individually invariant the three subsets of points (Ψ, ξ) which (1) obey Condition 1, (2) obey Condition 2, and (3) solve the GRTSE. To see this, recall that f_ξ is linear in ξ, hence $T_\delta \Gamma = \delta\Gamma$. Invariance of the first set is now obvious. Further, if $f_{\xi'} = \kappa\Gamma$ has only the trivial solution, then so does $f_{\xi'} = \kappa T_\delta \Gamma$, since otherwise $(\delta^{-1}\xi',\kappa)$ would be a nontrivial solution to the first equation. Hence the second set is invariant. Finally, since Γ scales with δ and the square root of expression (2.19) for α with $|\delta|$, the GRTSE (2.16) changes at most by an overall sign, which proves invariance of the third set.

We can now repeat the Theorem for each point $T_\delta(\Psi,\xi)$ on the $\dot{\mathbf{R}}$ orbit of (Ψ, ξ) with open sets V_δ, W_δ and solution maps σ_δ. In this way the solution map σ extends to a solution map σ^*: $V^* \to H^{n+2}_\xi$, where $V^* := \cup_{\delta\in\dot{\mathbf{R}}} V_\delta$, which uniquely represents all solutions in $W^* := \cup_{\delta\in\dot{\mathbf{R}}} W_\delta$. By construction it satisfies $\sigma^*(\Phi,\delta\dot\Phi) = \delta\sigma(\Phi,\dot\Phi) \forall \delta \in \dot{\mathbf{R}}$. Dropping the superscript $*$, we formulate this as follows.

Corollary 1: Let (Ψ, ξ) be as in the Theorem. Then there exist open neighborhoods $V \subset H^n_\Psi$ of $\cup_{\delta\in\dot{\mathbf{R}}} T_\delta \Psi$ and $W \subset H^n_\Psi \times H^{n+2}_\xi$ of $\cup_{\delta\in\dot{\mathbf{R}}} T_\delta(\Psi,\xi)$ and a C^1 map $\sigma: V \to H^{n+2}_\xi$ such that $F[\Psi',\xi']=0$ for $(\Psi',\xi') \in W \Leftrightarrow \Psi' \in V$ and $\xi' = \sigma(\Psi')$. Moreover,

$$\sigma(\Phi,\delta\dot\Phi) = \delta\sigma(\Phi,\dot\Phi), \quad \forall \delta \in \dot{\mathbf{R}} \tag{3.22}$$

Finally we prove that Condition 2 not only ensures local but also global uniqueness. It generalizes the analogous result for the traditional RTSE, proven in Ref. 3. [The full statement and proof given in Ref. 3 contains an additional part which is erroneous, as was first pointed out in Ref. 5. If transcribed to our setting, the incorrect part would amount to the claim that (3.23) implied $r \equiv 1$ without using Condition 2.]

Proposition 2: Let (Ψ, ξ) and $(\Psi, \tilde\xi)$ satisfy Condition 1 and (Ψ, ξ) the GRTSE. Then $(\Psi,\tilde\xi)$ satisfies the GRTSE $\Leftrightarrow$ there exists a positive function r: $\Sigma \to \mathbf{R}_+$ such that $\Gamma = \dot\Phi + f_\xi$ and $\tilde\Gamma = \dot\Phi + f_{\tilde\xi}$ are related by

$$\tilde\Gamma = r\Gamma. \tag{3.23}$$

Proof: $\Leftarrow$: This follows trivially from the fact that the GRTSE, i.e., Eqs. (2.17) and (2.18), contain ξ only through the combination $(1/\alpha)\Gamma$.

$\Rightarrow$: For $s \in [0,1]$, consider the convex combinations $\xi(s) := s\xi + (1-s)\tilde\xi$ and $\Gamma_s := \dot\Phi + f_{\xi(s)} = s\Gamma + (1-s)\tilde\Gamma$. In the following it is useful to think of each Γ_s as section in the pulled-back bundle $\Phi^* T(\Theta)$ whose fiber at $p \in \Sigma$ is a Minkowski space $\mathbf{R}^{1,5+3N+M}$ with metric $G_{\Phi(p)}$. Condition 1 requires $\Gamma(p)$ and $\tilde\Gamma(p)$ to be "timelike," so that $s \mapsto \Gamma_s(p)$ is the straight path connecting these two "timelike" vectors. First we show that $\Gamma(p)$ and $\tilde\Gamma(p)$ lie in the interior of the same "light-cone" for some, and hence all, $p \in \Sigma$. To see this, we consider, for each p, the inner product $G(\Gamma - \tilde\Gamma, \mathcal{V})$ with the timelike vector $\mathcal{V} := g_{ab}\partial/\partial g_{ab}$ of constant length-squared $G(\mathcal{V},\mathcal{V}) = -3$. Now,

$$\int_\Sigma G(\Gamma - \tilde\Gamma, \mathcal{V})\, d\mu = 2\int_\Sigma \nabla_a(\beta^a - \tilde\beta^a)\, d\mu = 0, \tag{3.24}$$

so that, because Σ is connected, there exists a point $p\in\Sigma$ where $G(\Gamma-\tilde{\Gamma},\mathcal{V})(p)=0$. Hence $\Gamma(p)$ and $\tilde{\Gamma}(p)$ point in the same half of the ''light-cone,'' and so does $\Gamma_s(p)$, since the interior of the half ''light-cone'' is a convex set. By continuity this must then be true at each point $p\in\Sigma$ so that $G(\Gamma_s,\Gamma_s)$ is a negative-valued function on Σ for each s.

Next we consider the function

$$I(s):=S[\Psi,\,\xi(s)]=\int_\Sigma \sqrt{-2UG(\Gamma_s,\Gamma_s)}\,d\mu. \tag{3.25}$$

We have $I'(0)=0=I'(1)$, where $'=d/ds$, since ξ and $\tilde{\xi}$ solve the GRTSE. Furthermore, a straightforward calculation yields

$$I''(s)=\int_\Sigma \frac{[2U]^{1/2}}{[-G(\Gamma_s,\Gamma_s)]^{3/2}}\,G(\Gamma,\Gamma)G(\tilde{\Gamma}_\perp,\tilde{\Gamma}_\perp)\,d\mu\leqslant 0, \tag{3.26}$$

with

$$\tilde{\Gamma}_\perp:=\tilde{\Gamma}-\Gamma\,\frac{\Gamma(\Gamma,\tilde{\Gamma})}{G(\Gamma,\Gamma)}. \tag{3.27}$$

The inequality in (3.26) results from Γ being ''timelike'' and $\tilde{\Gamma}_\perp$ being ''spacelike'' or zero. But $I'(0)=I'(1)=0$ and $I''(s)\leqslant 0$ imply $I''\equiv 0$. On the other hand, equality in (3.26) can only be achieved for $\tilde{\Gamma}_\perp=0$ which is equivalent to (3.23), where r must be positive valued since Γ and $\tilde{\Gamma}$ point in the same half of the ''light cone.'' □

Now (3.23) implies (3.6) with $\xi'=\tilde{\xi}-\xi$ and $\kappa=r-1$, so that Condition 2 will enforce $r=1$ and $\xi=\tilde{\xi}$. Hence we have the following corollary.

Corollary 2: If $(\Psi,\,\xi)$ *and* $(\Psi,\tilde{\xi})$ *satisfy the GRTSE and Conditions 1 and 2, then* $\xi=\tilde{\xi}$.

IV. DISCUSSION

It is obvious that the strategy of the (generalized) thin-sandwich approach cannot work for all data. Obvious bad data are those for which the Hamiltonian constraint cannot be solved for a nowhere vanishing α. For example, consider fields Φ such that $U>0$ and velocities $\dot{\Phi}$ whose gravitational part is pure gauge: $\dot{g}_{ab}=2\nabla_{(a}\xi'_{b)}$. The Hamiltonian constraint implies $(\nabla_a\eta^a)^2\geqslant U\alpha^2$, where $\eta=\xi'-\xi$, showing that α must vanish somewhere since $\int_\Sigma d\mu\,\nabla_a\eta^a=0$ and Σ is connected. To avoid such situations, Condition 1 or its reversed version, $U<0$ and $G(\Gamma,\Gamma)>0$, may be imposed. However, if the second condition is chosen, formula (3.14) together with the proof of Lemma 3 show that L manifestly fails to be elliptic, thus leaving only Condition 1.

The technical Condition 2 has an interpretation in terms of the ''canonical data'' (Φ,V), where $\alpha V=\dot{\Phi}+f_\xi$ and where we assume $(\Phi,\dot{\Phi},\xi)$ to satisfy Condition 1 in order to have $\alpha\neq 0$. Namely, if $f_{\xi'}=\kappa\Gamma$ for some nonzero $(\dot{\xi}',\kappa)$, then $f_{\xi'}=\alpha\kappa V$ says that the same canonical data admit a representation in terms of the new lapse function $\alpha_{\text{new}}=\kappa\alpha$ (now possibly with zeros), gauge functions $\xi_{\text{new}}=\xi'$, and coordinate-velocities $\dot{\Phi}_{\text{new}}=0$. Conversely, if an α_{new} exists such that $\alpha_{\text{new}}V=f_{\xi_{\text{new}}}$, then $f_{\xi'}=\kappa\Gamma$ with $\kappa=\alpha_{\text{new}}/\alpha$ and $\xi'=\xi_{\text{new}}$. Hence Condition 2 precisely excludes the existence of other representations of the same canonical data with vanishing coordinate velocities $\dot{\Phi}$. We note that Condition 2 may itself be implied by simple geometric conditions on Φ. One such set of conditions is provided by the following.

Proposition 3: Condition 2 is implied by Condition 1 and the following conditions on Φ*:*

$$(i)\quad \mathrm{Ric}<0\quad (\mathrm{Ric}=\textit{Ricci tensor of } g), \tag{4.1}$$

$$(ii) \quad \nabla_a \lambda^\mu = 0 \quad \text{and} \quad \lambda^\mu \rho^\alpha_{\mu\beta} \phi^\beta = 0 \quad \textit{imply} \quad \lambda^\mu = 0. \tag{4.2}$$

Proof: Let $f_{\xi'} = \kappa\Gamma$. Then $G(\Gamma,\Gamma) < 0 \Rightarrow G(f_{\xi'}, f_{\xi'}) \leq 0 \Rightarrow$

$$\int_\Sigma d\mu [G^{ab\,cd} 4\nabla_{(a}\beta'_{b)} \nabla_{(c}\beta'_{d)}] = \int_\Sigma d\mu 2[\nabla_{[a}\beta'_{b]}\nabla^{[a}\beta'^{b]} - R_{ab}\beta'^a\beta'^b] \leq 0 \tag{4.3}$$

$\Rightarrow \beta' = 0$. Since G is positive definite on $f_{\xi'}$'s for which $\beta' = 0$, $G(f_{\xi'}, f_{\xi'}) \leq 0$ implies $f_{\xi'} = 0$ which for $\beta' = 0$ is equivalent to the first two equations in (4.2). □

We recall that metrics with Ric<0 exist on any three-manifold Σ (Ref. 10) (e.g., quite in contrast to Ric>0, which is well known to imply a finite fundamental group). Equation (4.2) should be read as a mild genericity condition for the matter fields. For example, if we have a single U(1) gauge field and a charged scalar field [here represented by a real doublet (ϕ^1, ϕ^2)], then condition (4.2) is satisfied if the scalar field is not identically zero.

Finally we comment on the functional $S[\Psi, \xi]$ defined in (2.23). Given that Condition 1 is satisfied, solutions to the GRTSE are stationary points with respect to variations in ξ (Lemma 1). Lemma 2 asserts that these must be minima which are stable if Condition 2 is satisfied. We now assume Conditions 1 and 2 to hold and evaluate $S[\Psi, \xi]$ at a solution $\xi = \sigma(\Psi)$. We get a C^1-function $S_*: H^n_\Psi \to \mathbf{R}_+$,

$$S_*[\Phi, \dot\Phi] = \int_\Sigma d\mu \sqrt{-2UG(\dot\Phi + f_{\sigma(\Phi,\dot\Phi)}, \quad \dot\Phi + f_{\sigma(\Phi,\dot\Phi)})}, \tag{4.4}$$

which satisfies

$$S_*[\Phi, \delta\dot\Phi] = |\delta| S_*[\Phi, \dot\Phi] \tag{4.5}$$

for all $\delta \in \dot{\mathbf{R}}$. Standard consequences are

$$D_2 S_*[\Phi, \delta\dot\Phi](\dot\Phi) = \text{sign}\,(\delta) S_*[\Phi, \dot\Phi], \tag{4.6}$$

$$D_2^2 S_*[\Phi, \delta\dot\Phi](\dot\Phi, \dot\Phi) = 0, \tag{4.7}$$

where in (4.7) we assumed C^2 smoothness of σ. It is tempting to try and regard S_* as a kind of metric on at least an open subset of the tangent bundle of the space of fields. For pure gravity it generalizes a previously considered expression which is valid only for constant lapse function[8] and also gives rigorous meaning to a formal definition of a distance function given in Ref. 4. However, presently it is unclear to us whether S_* indeed defines an interesting geometric structure. {One may wonder whether it defined a Finsler metric. For this one would have to show that the bilinear form $D_2^2 S_*^2[\Phi, \dot\Phi]$ is (weakly) nondegenerate. But this is not even the case in finite dimensions for functions of the form (4.4) (i.e., sum of square roots rather than square root of sum). Take, e.g., the function $f(y_1, \ldots, y_n) = \Sigma_i \sqrt{y_i^2}$. Then $\partial_i \partial_j f^2 = 2\partial_i f \partial_j f$, which is obviously just of rank one.}

Null cones from $\mathcal{I}^+$ and Legendre submanifolds

Mirta Iriondo, Carlos N. Kozameh, and Alejandra T. Rojas
FaMAF, Universidad Nacional de Córdoba, 5000 Córdoba, Argentina

(Received 29 May 1998; accepted for publication 27 January 1999)

It is shown that the main variable Z of the null surface formulation of GR is the generating family of a constrained Lagrange submanifold that lives on the energy surface $H=0$ and that its level surfaces $Z=\text{const}$ yield Legendre submanifolds on that energy surface. Thus, the singularity structure of past null cones with apex at $\mathcal{I}^+$ is obtained by studying the projection map of the Legendre submanifolds to the configuration space. The behavior of the coordinate system defined by the variable Z at the caustic points is analyzed. It is shown that a single function $Z(x^a,\zeta,\overline{\zeta})$ cannot generate the conformal structure of an asymptotically flat space–time that satisfies the generic and weak energy condition. © *1999 American Institute of Physics.* [S0022-2488(99)02105-2]

I. INTRODUCTION

In the last several years a formalism has been developed where null surfaces play a dynamical role replacing the metric as a basic variable.[1–4] The goal of the null surface formulation of General Relativity (GR), or NSF for short, is to introduce a new variable such that from its knowledge one can obtain *all* the conformal structure of the space–time. Field equations equivalent to Einstein's equation then determine the dynamical evolution of those surfaces. By casting GR as a theory of surfaces rather than a theory of fields the NSF provides a completely new point of view with emphasis on the geometrical character of the theory. The basic variable is a function $Z(x^a,\zeta,\overline{\zeta})$ with x^a representing points on the space–time and $(\zeta,\overline{\zeta})$ parametrizing the sphere of null directions. At each point on the space–time the function Z satisfies

$$g^{ab}(x^c)\partial_a Z(x^c,\zeta,\overline{\zeta})\partial_b Z(x^c,\zeta,\overline{\zeta})=0, \tag{1}$$

and the level surfaces of this function, namely $Z=\text{const}$ are null hypersurfaces on the space–time. The reader should be aware that the above construction is done at a local level and that in general it might not be possible to find a single function satisfying these conditions on the whole space–time. Weyl curvature induces self-intersections and caustics on null congruences. Thus, even if one locally obtains a smooth hypersurface, extending such surface along the generators of its null geodesics will fail to be smooth. This generalized null surface is called a *wave front* and cannot be described as the level surface of a single function Z.

In this work we introduce a generalized variable $\hat{Z}$ to describe the wave fronts. By studying the geometry of these fronts we analyze the singularities of our variable. We are also able to determine under what circumstances a single function Z suffices to construct the entire conformal structure, or how many different functions must be given to cover the space–time. We only consider a specific class of space–times which are asymptotically flat along future null directions. For those space–times Z represents past null cones from the future null boundary $\mathcal{I}^+$.

Note that Z can be thought of as the action of the Hamilton–Jacobi equation for the Hamiltonian $H(x,p)=g^{ab}p_a p_b$. Since Eq. (1) can be written as

$$H(x,\partial_a Z)=0,$$

Z is the action of the time-independent Hamilton–Jacobi equation and the study of the unicity of the solution and its global properties can be carried out using the tools of analytical mechanics. It is worth mentioning that the study of the solutions of the Hamilton–Jacobi equations led to the development of the theory of Lagrange submanifolds on cotangent bundles and the loss of unicity on the solutions is directly related to the singularities of the projection map of these submanifolds onto the configuration space.[5–10]

We show that $\hat{Z}$ is the generating family of a constrained Lagrange submanifold that lives on the energy surface $H=0$ of the cotangent bundle T^*M and that its level surfaces are Legendre submanifolds. Thus, the singularity structure of the wave fronts can be obtained by studying the projection maps to the configuration space. We thus, define the caustic set as the points on the Lagrange or Legendre submanifold with singular projection and the projection of those points as the caustics. Since Lagrange and Legendre submanifolds are smooth surfaces in T^*M this work suggests that one can redefine the main variable of the NSF in a way that is free from the singularities and self-intersections that are naturally associated with characteristic wave fronts in GR.

In Sec. II we introduce the necessary mathematical background needed for this work. In this context we also prove that the hypersurfaces of a constrained Lagrange submanifold defined as the restriction of this Lagrange submanifold to the level surfaces of its generating family are Legendre submanifolds on the energy surface $H=\text{const}$.

In Sec. III we study the singularity structure of our variable Z and the main results are found. We show that the caustic points are obtained by choosing the points where $\eth\bar{\eth}Z$, the parameter space Laplacian of Z, blows up. We also show that at those points $(Z,\eth Z,\bar{\eth}Z)$ remain finite whereas $\eth^2 Z$ diverges. Using available singularity theorems we find as a proposition that a single function $Z(x^a,\zeta,\bar{\zeta})$ cannot generate the conformal structure of an asymptotical space–time that satisfies the generic and weak energy condition. Thus, in order to properly study the global behavior of the main variable in the NSF one must abandon the idea of using a single function on the space–time and instead one has to think of our variable as a generating family $\hat{Z}$ of a Lagrange submanifold on the cotangent bundle of the space–time. We close this work with some comments of how to deal with the dynamics of the new variable.

II. LAGRANGE AND LEGENDRE SUBMANIFOLDS

In this section we review the notions of Lagrange and Legendre manifolds in a given cotangent bundle T^*M of an n-dimensional manifold M. Exhaustive treatises at a high mathematical level and/or with applications to different areas in physics can be found in the literature.[5,7–13] We present here a brief review of some basic results needed for the present work. In Secs. II A and II B we introduce the concept of *constrained Lagrange and Legendre submanifolds* in order to reinterpret our variable Z as the generating family of a Lagrange manifold. Moreover, we prove in proposition II.3 that the hypersurfaces of a constrained Lagrange submanifold defined as the restriction of the Lagrange submanifold to the level surfaces of its generating family are Legendre submanifolds on the energy surface $H=\text{const}$.

A. Lagrange manifolds

Recall that (P,ω) is a symplectic manifold if P is an even-dimensional differentiable manifold and ω is a closed, nondegenerate, differential two-form on P. We consider a particular submanifold of P called a *Lagrange manifold*, defined as a manifold whose dimension is the same as the configuration space and where the pullback of the symplectic form vanishes on the manifold.

From now on we will restrict ourselves to a particular class of symplectic manifolds, the cotangent bundle of an n-dimensional manifold M, denoted by T^*M. This bundle can be assigned local coordinates (q^i,p_i), with (q^i) representing points of M and p_i the local coordinates of the covectors at the point (q^i). In these local coordinates the closed nondegenerate differential two-form ω on T^*M can be written as $\omega=dq^i\wedge dp_i$.

If L is a Lagrange submanifold of (T^*M,ω), then the projection map $\pi:T^*M\rightarrow M$ is called the *Lagrange map*. The set of points where the rank of π^* drops are called the *singular set* and the image of this set is called the *caustic*.

Notice also that if $S:M\rightarrow\mathbf{R}$, then the graph of dS is a Lagrange submanifold and π is a diffeomorphism.

The converse is also true, if π is locally a diffeomorphism, then L is the graph of dS, where $S:M\rightarrow\mathbf{R}$.

Now, consider the Hamiltonian system (T^*M,ω,H), where $H:T^*M\rightarrow\mathbf{R}$ is a Hamiltonian function. We introduce the notion of *constrained Lagrange submanifolds* as follows:

Definition II.1: Let $\hat{L}$ be a Lagrange submanifold of T^*M and H a Hamiltonian function, we say that $\hat{L}$ is a constrained Lagrange manifold if $\hat{L}\subset\hat{H}$, where $\hat{H}$ is an energy surface.

Note that constrained Lagrange manifolds are invariant under the flow of the Hamiltonian vector field X_H (Ref. 10, Proposition 5.3.32). This, can be easily proved using the fact that X_H is tangent to the hypersurface $H=\text{const}$ and that $\hat{L}$ is of maximal dimension.

If $\hat{L}$ is the graph of dS, where $S:M\rightarrow\mathbf{R}$, then S must satisfy the time-independent Hamilton–Jacobi equation

$$H\left(q^j,\frac{\partial S}{\partial q^i}\right)=\text{const}, \tag{2}$$

and conversely, a solution of (2) locally defines a constrained Lagrange manifold with a diffeomorphic projection to M.

However, in general (and in the problem we want to address) the projection of $\hat{L}$ will not be globally diffeomorphic to M.

Let us briefly analyze how to construct our constrained Lagrange manifold from the solutions to the time-independent Hamilton–Jacobi equation. From now on we shall assume that $\hat{H}$ is the hypersurface defined by $H=0$.

Since the Hamiltonian flow is tangent to $\hat{L}$, we may solve Hamilton's canonical equations with initial values $(q^i(0),p_i(0))\in\tilde{N}$, where $\tilde{N}$ is constructed as follows. Consider a hypersurface $N\subset M$ and a null covector field on N that is a restriction of a differential of some function on M, then this field defines an $n-1$ dimensional surface $\tilde{N}\subset\hat{H}$ diffeomorphic to N. The initial data shall be the Cauchy data of the Hamilton–Jacobi equation.

To solve Hamilton's canonical equations we look for a generating function of a canonical transformation $g:(q^i,p_i)\rightarrow(Q^i,P_i)$ such that in the new variables the Hamiltonian becomes a function which depends only on the variables Q^i, i.e., $H=K(Q^i)$.

It is easy to show that the difference between the canonical one-forms associated with the two coordinates is exact,[5,7–9] i.e.,

$$p_i dq^i - P_i dQ^i = dS(q^i,Q^j). \tag{3}$$

The function S is called *the generating function* of the canonical transformation. Furthermore, if $S(q^i,Q^j)$ is a solution to the differential equation

$$H\left(q^i,\frac{\partial S}{\partial q^j}\right)=K(Q^i), \tag{4}$$

with Q^i parameters such that $|\partial^2 S/(\partial Q^i \partial q^j)|\neq 0$, then Hamilton's canonical equations can be solved by quadratures and the functions $Q^i=Q^i(q^i,p_j)$ determined by the equations $p_i=\partial S/\partial q^i$ are first integrals of the canonical equations. (Jacobi's Theorem—Refs. 5 and 14).

Given a solution $S(q^i,Q^j)$ to Eq. (4) the corresponding constrained Lagrange manifold in $\hat{H}$, is obtained by first requiring that $K(Q^i)=0$. Then, the function $\hat{S}=S(q^i,Q^j)|_{K(Q^i)=0}$ is a generating family of $\hat{L}$ given by

$$\hat{L}=(q^i,p_j)|p_j=\frac{\partial\hat{S}}{\partial q_j} \text{ and } \frac{\partial\hat{S}}{\partial Q^i}=0.$$

Note that if we can solve for $Q^l=Q^l(q^i)$ from

$$K(Q^i)=0,\quad \frac{\partial S}{\partial Q^l}=0, \tag{5}$$

then $\hat{L}$ is locally the graph of dS, with $S(q^i)=S'(q^i,Q^j(q^i))$ and the *Lagrange map* $\overline{\pi}$ is a diffeomorphism. This can be guaranteed in a neighborhood of a point if the rank of the system built by (5) is $r=n$ in the variables Q^l. If $r=k<n$ then there exists $Q^J=Q^J(q^i)$, for $J=1\cdots k$ and $\hat{S}=\hat{S}(q^i,Q^I)$, for $I=k+1\cdots n$. In this case the rank of $\overline{\pi}^*$ drops at some points and this can be related to the presence of these parameters Q^I, for $I=k+1\cdots n$.

Then $\hat{S}(q^i,Q^I)$, defines a Lagrange submanifold $\hat{L}\subset\hat{H}$ embedded into T^*M by setting:

$$p_i=\frac{\partial\hat{S}}{\partial q^i},\quad 1\leqslant i\leqslant n, \tag{6}$$

and imposing the constraints

$$0=\frac{\partial\hat{S}}{\partial Q^I}. \tag{7}$$

Since the rank of (7) is $n-k$ in the q^I variables, then there exist $q^I=q^I(Q^I,q^J)$, and $\hat{L}$ and $\pi(\hat{L})$ are parametrized by (Q^I,q^J). The derivative $\overline{\pi}^*$ can be written as

$$\begin{pmatrix} \frac{\partial q^I}{\partial Q^I} & \frac{\partial q^I}{\partial q_J} \\ 0 & I \end{pmatrix},$$

where I is the identity matrix $k\times k$, therefore it is clear that the rank of $\pi^*\geqslant k$ and it shall be strictly less than n when

$$\left|\frac{\partial q^I}{\partial Q^I}\right|=0.$$

The set of singular points and thus the caustic set shall be isolated points, curves or in general a set of points of zero measure with respect to the topology of M, since the rank of $\overline{\pi}^*$ cannot drop more than $n-2$.[6]

B. Legendre manifolds

Odd-dimensional manifolds do not admit a *symplectic structure*. The analog of a symplectic structure for odd-dimensional manifolds is a *contact structure*.

We define a *contact manifold* as a pair $(\hat{P},\hat{\omega})$, consisting of an odd-dimensional manifold $\hat{P}$ and a closed two-form $\hat{\omega}$ of maximal rank on this manifold. An exact contact manifold $(\hat{P},\hat{\kappa})$ consists of a $(2n-1)$-dimensional manifold $\hat{P}$ and a one-form $\hat{\kappa}$ on $\hat{P}$ such that $\hat{\omega}=-d\hat{\kappa}$ is of maximal rank on $\hat{P}$.

Moreover, an analogous notion to a Lagrange manifold can also be given. An $(n-1)$-dimensional manifold N of $\hat{P}$ is called a *Legendre submanifold* if the pullback of the contact form $\hat{\kappa}$ vanishes on N.

Now, consider the Hamiltonian system (T^*M,ω,H), the next proposition ensures that we can find, in a natural way, a *contact submanifold* of T^*M.

Proposition II.2: Let (T^*M,ω,H) *be a Hamiltonian system and* $\hat{H}$ *a regular energy surface, defined by* $H=\text{const}$. *Then* $(\hat{H},i^*\omega)$ *is a contact manifold, where* $i:\hat{H}\to T^*M$ *is an inclusion (Ref. 10, Proposition 5.1.7).*

Thus the Legendre submanifolds we will consider are those that are submanifolds of the contact manifold $(\hat{H},i^*\omega)$. Moreover they are hypersurfaces of *constrained Lagrange manifold* of a given Hamiltonian system and the projection map $\pi:T^*M\to M$ will induce a map $\hat{\pi}$ defined as $\hat{\pi}=\pi\circ\hat{e}$ and called the *Legendre map*.

The next proposition gives a description of this kind of manifold.

Proposition II.3: Let $\hat{L}$ *be a constrained Lagrange submanifold of the Hamiltonian system* (T^*M,ω,H) *and* $\hat{S}$ *its generating family, i.e., a solution of the time independent Hamilton–Jacobi equation. Then the hypersurface* $\hat{N}$ *of* $\hat{L}$, *defined as the restriction of* $\hat{L}$ *to* $\hat{S}=\text{const}$, *is a Legendre submanifold of* $\hat{H}$.

Proof: Given a Hamiltonian system, Proposition II.2 ensures that $(\hat{H},i^*\kappa)$ is a contact manifold and since $\hat{L}$ is a constrained Lagrange manifold, the generating family $\hat{S}(q^i,Q^I)$ of $\hat{L}$ satisfies $H(q^i,\partial S/\partial q^j)=0$. Then $\hat{S}$ defines a Legendre submanifold $\hat{N}$ of $\hat{H}$ by setting

$$p_i=\frac{\partial\hat{S}}{\partial q^i},\quad 1\leqslant i\leqslant n, \tag{8}$$

imposing the constraints

$$\hat{S}=u_0,\quad \frac{\partial\hat{S}}{\partial Q^I}=0, \tag{9}$$

and requiring that the rank of (9) shall be $n-k+1$ in the q^I variables.

Recall that (9) is an algebraic nonlinear system of equations. Then if we define the function $\mathbf{G}=(\hat{S}-u_0,\partial\hat{S}/\partial Q^I)$, a solution of (9) satisfies $\mathbf{G}=\mathbf{0}$, that is, it belongs to the kernel of the map $\mathbf{G}$. Therefore demanding that the rank of the derivative of $\mathbf{G}$ be $n-k+1$ in the variables q^I and in one of the q^J variables, the implicit function theorem guarantees that $q^i=q^i(q^j,Q^I)$ for $i\in I+1$ and $j\in J-1$.

Observe that the Legendre manifold constructed in this way becomes an hypersurface of $\hat{L}$ and that both are submanifold of the energy surface $\hat{H}$. □

The image of the Legendre map is called the *wave front* and the image of the constrained Lagrange manifold can be considered as a wave front family. As in the case of the Lagrange manifolds, the set of points where the rank of $\hat{\pi}^*$ drops are called the *singular set* and the image of this set is called the *caustic*. If the singular set of $\hat{L}$ is known then intersection of this set with $\hat{S}=u_0$ yields the singular set of the associated Legendre submanifold.

III. THE FUNCTION Z IN ASYMPTOTICALLY FLAT SPACE–TIME

In this section we will use the results developed in Sec. II to analyze the behavior of null cones on asymptotically flat space–times with a future null boundary diffeomorphic to $S^2\times R$.[15] Those space–times represent compact objects that can emit gravitational radiation.

To define our variable Z we consider the intersection of the future null cone from x^a with the null boundary $\mathcal{I}^+$. This intersection is called a *light cone cut of null infinity* and in general it is a complicated surface with caustics, self-intersections, etc. Introducing Bondi coordinates $(u,\zeta,\bar{\zeta})$ on $\mathcal{I}^+$ [with u representing a Killing time and $(\zeta,\bar{\zeta})$ being stereographic coordinates on the unit sphere] it is possible to give a parametric representation of light cone cuts for points x^a close enough to $\mathcal{I}^+$ so that their future light cones have no caustic points before or at $\mathcal{I}^+$. Under those conditions the light cone cuts can be described as

$$u=Z(x^a,\zeta,\overline{\zeta}). \tag{10}$$

On Minkowski space–time the light cone cuts adopt a very simple form, $u=x^a l_a$ with l_a a null covector constructed from the spherical harmonics $Y_{0,0},Y_{1,-1},Y_{1,0},Y_{1,1}$. On an arbitrary asymptotically flat space–time, the cuts develop singularities and self-intersections. Thus, the function Z becomes, in general, multivalued. However, it can be shown that for regular space–times the index number is always one. Therefore, a light cone cut (as complicated as it might be) is always a continuous deformation of the sphere of null directions above each point x^a. It can also be shown that generically the light cone cuts can only have two kinds of singularities, cusps and swallowtails, since they represent the projection of 2-dim Legendre submanifolds on $\mathcal{I}^+$.[16]

A second meaning can be assigned to our variable $Z(x^a,\zeta,\overline{\zeta})$. Fixing a point $(u,\zeta,\overline{\zeta})$ of $\mathcal{I}^+$, the collection of interior points x^a that satisfy

$$Z(x^a,\zeta,\overline{\zeta})=u=\text{const}, \tag{11}$$

form the past null cone of $(u,\zeta,\overline{\zeta})$. Moreover, from knowledge of Z we can construct a null coordinate system as follows.

Starting with our variable and taking $(\zeta,\overline{\zeta})$ derivatives of $Z(x^a,\zeta,\overline{\zeta})$ we construct the following set of scalars;

$$\theta^i(x^a,\zeta,\overline{\zeta})\equiv(\theta^0,\theta^+,\theta^-,\theta^1)\equiv(u,w,\overline{w},R)\equiv(Z,\eth Z,\bar{\eth}Z,\eth\bar{\eth}Z). \tag{12}$$

For fixed values of $(\zeta,\overline{\zeta})$ they define a coordinate system with the following geometric meaning: $u=\text{const}$ denotes the past null cone from $(u,\zeta,\overline{\zeta})$; $(w,\overline{w})=\text{const}$ single out a null geodesic on that surface; $R=\text{const}$ identifies a point on that geodesic.

However, one knows that null cones can develop caustics and singularities. One also knows that past those singularities the null cone is no longer smooth (it is called a wave front) and thus, a null coordinate system like the one above breaks down past those singular points. Since the main goal of the NSF is to replace the metric with a function Z such that its level surfaces are past null cones from $\mathcal{I}^+$, we immediately face a nontrivial problem: If the null cones develop self-intersections and singularities that cannot be analyzed with a single function Z, then the construction given above is only valid on a neighborhood of $\mathcal{I}^+$. However, we also know that null wave fronts are projections of Legendre submanifolds that live on $T^*(M)$. It would then appear that the best way to deal with this lack of smoothness is to think of our variable as the generating family $\hat{Z}$ of a constrained Lagrange submanifold. An outline of this construction is presented below.

As was done before, we assume that our variable Z describing the past light cone from a point $(u,\zeta,\overline{\zeta})$ at $\mathcal{I}^+$ is a solution to the equation

$$H(x^a,\partial_b Z)=g^{ab}Z_{,a}Z_{,b}=0, \tag{13}$$

with g^{ab} a metric that is asymptotically flat.

In a neighborhood of $\mathcal{I}^+$ this solution is single valued since the (unphysical) metric is ''almost'' conformally flat and thus the past null cones are free from caustics and singularities.

For each value of $(\zeta,\overline{\zeta})$, one then uses this smooth function $Z(x^a,\zeta,\overline{\zeta})$ as the generating family of a constrained Lagrange manifold $\hat{L}$ given by

$$\hat{L}=\left\{\left(x^a,p_b=\frac{\partial Z}{\partial x^b}\right):e^*\kappa=dZ\right\}. \tag{14}$$

Note that Proposition II.3 ensures that the surface $\hat{N}$ defined by $Z=\text{const}$ is a Legendre submanifold of the energy surface given by $H=0$, i.e.,

$$\hat{N}=\left\{\left(x^a,p_b=\frac{\partial Z}{\partial x^b}\right):\hat{e}^*\hat{\kappa}=d(e^*Z)=0\right\}.$$

Thus, we have constructed a constrained Legendre submanifold $\hat{N}$ and a constrained Lagrange submanifold $\hat{L}$ of $\hat{H}$ using our fundamental variable $Z(x^a,\zeta,\overline{\zeta})$.

The idea is to extend this construction to regions where caustics develop. As we mentioned before, in these regions the Lagrange submanifold is not diffeomorphic to its projection. We will thus assume that the generating family describing the past null cone from $(u,\zeta,\overline{\zeta})$ can be written as $\hat{Z}=\hat{Z}(x^a,w,\overline{w},\zeta,\overline{\zeta})$ with $(w,\overline{w})$ parameters labeling the past geodesics. Note that the function $\hat{Z}$ depends on two parameters since the rank of the projection map cannot drop more than two.[5] Note also that $(w,\overline{w})$ are two of our null coordinates θ^i since we are considering $\hat{Z}$ as the generating function of the canonical transformation between x^a and θ^i restricted to $\hat{H}$. The constrained Lagrange submanifold $\hat{L}$ is then given by

$$p_a=\frac{\partial\overline{Z}}{\partial x^a},$$

together with the constraint

$$\frac{\partial\hat{Z}}{\partial w}=0,\quad \frac{\partial\hat{Z}}{\partial\overline{w}}=0. \tag{15}$$

Observe that if we can solve (15) uniquely for $(w,\overline{w})$ in a neighborhood of a point, i.e., $(w,\overline{w})=(w(x^b),\overline{w}(x^b))$, then $\hat{Z}=Z$ and we are back in the previous diffeomorphic region. In general, one will obtain multivalued solutions of (15). Inserting the different solutions of $(w,\overline{w})$ into $\hat{Z}(x^a,w,\overline{w},\zeta,\overline{\zeta})$ one obtains a multiple-valued function $Z(x^a,\zeta,\overline{\zeta})$. The Legendre submanifold is obtained by setting $\hat{Z}=\text{const}$. Conversely, if several functions Z_i are given, one can reconstruct the Lagrange submanifold by imposing (14) on the different Z's. The construction defines the Lagrange submanifold except for the caustic set.

Finally, we would like to determine under what circumstances it is possible to find a single function Z that would yield for us a global coordinate system $(u,R,w,\overline{w})$ on an asymptotically flat space–time. In other words we want to know if there exists space–times that are diffeomorphic to the corresponding Lagrange manifolds. At the same time we would like to know when and how this coordinate system breaks down due to the presence of conjugate points. We are therefore interested in describing the relationship between our fundamental variable Z and the loss of the rank of the derivative of the Legendre map $\hat{\pi}$, i.e., we want to described the singular set in terms of Z.

When the Lagrange manifold is a constrained one, the loss of rank of the Lagrange map indicates the nonexistence of global solutions of the Hamilton–Jacobi equation and the loss of rank of the associated Legendre map is related to the *existence of conjugate points of a congruence of null geodesics*.

In order to clarify this assertion, we consider the local description of the wave front (the projection of the Legendre manifold). We assume that the wave front is locally described by

$$x^a=f^a(u_0,s,w,\overline{w},\zeta_0,\overline{\zeta_0})$$

with s an affine length. The vectors

$$L^a = \frac{\partial f^a}{\partial s}, \quad M^a = \frac{\partial f^a}{\partial w}, \quad \bar{M}^a = \frac{\partial f^a}{\partial \bar{w}}$$

are tangent to the wave front. L^a is directed along the null geodesics whereas M^a and $\bar{M}^a$ are geodesic deviation vectors.

The derivative of the Legendre map losses its rank when these three vectors become linearly dependent. This dependence is related to the existence of conjugate points on the congruence of null geodesic with apex at $\mathcal{I}^+$ and null tangent vector L^a as follows.

We introduce the parallel propagated null triad $\{l^a, m^a, \bar{m}^a\}$, satisfying

$$l^a m_a = 0 \quad m^a \bar{m}_a = -1 \quad l^a \nabla_a m^b = 0. \tag{16}$$

In terms of this triad,

$$L^a = l^a, \quad M^a = \xi m^a + \overline{\eta m^a}, \quad \bar{M}^a = \bar{\xi} \bar{m}^a + \eta m^a, \tag{17}$$

therefore this set of vectors becomes linearly dependent when

$$\begin{vmatrix} \xi & \eta \\ \bar{\eta} & \bar{\xi} \end{vmatrix} = (\xi\bar{\xi} - \eta\bar{\eta}) = 0. \tag{18}$$

On the other hand, this quantity is related to the divergence ρ, and the shear σ of the congruence with apex in $\mathcal{I}^+$. To see this, consider the optical parameters

$$\rho = m^a \bar{m}^b \nabla_a l_b, \quad \sigma = m^a m^b \nabla_a l_b.$$

Using Eq. (17) together with the fact that M^a is Lie propagated along the null direction L^a we get (Ref. 3)

$$\sigma = \frac{\bar{\eta}^2}{A} D\left(\frac{\bar{\xi}}{\bar{\eta}}\right), \quad \rho = \frac{DA}{2A}$$

with $A = (\xi\bar{\xi} - \eta\bar{\eta})$ and where we have used the fact that ρ is real.

Hence, at those points where the Legendre map looses its rank, the divergence of the congruence becomes unbounded, i.e., $\lim \rho_{s \to s_0} = \infty$, where s is the affine parameter and s_0 corresponds to a conjugate point.

Note that $Z(x^a, \zeta, \bar{\zeta})$ is a single valued function for points x^a near $\mathcal{I}^+$. Therefore, $(u, R, w, \bar{w})$ is a well-behaved coordinate system since there are no conjugate points in that region. The question is what happens to our coordinates as we approach a generic conjugate point. Given that our variable has a second meaning, namely, the intersection of the future light cone from x^a with $\mathcal{I}^+$, a related question is what happens to this cut as the apex recedes into the interior of the space–time until a caustic develops at $\mathcal{I}^+$. We first answer the latter question since the results obtained are then used in the analysis of the behavior of the coordinates $(u, R, w, \bar{w})$ near a caustic point.

A. Light cone cuts

We consider the future light cone from a point x^a near $\mathcal{I}^+$ such that the intersection with the null boundary is locally described by a single valued $Z(x^a, \zeta, \bar{\zeta})$.

Lemma III.1. If the apex x^a moves into the interior until the cut develops a generic caustic point, then at this first conjugate point the components of the extrinsic curvature of the cut given by $R = \eth\bar{\eth}Z$ and $\Lambda = \eth^2 Z$ become infinite.

Proof: We first introduce Bondi coordinates $(\Omega, u, \zeta, \bar{\zeta})$ in a neighborhood of $\mathcal{I}^+$ such that this boundary is described by $\Omega = 0$. We then introduce a null geodesic λ that connects the point x^a

with $\mathcal{I}^+$ and an affine length s such that the apex is labeled as s_0. Furthermore, we suppose that the description of the null cone is given by $F=0$, where $F=F(\Omega,u,\zeta,\bar{\zeta},s_0)$. Near $\mathcal{I}^+$ the function F can be written as

$$F=F^0(u,\zeta,\bar{\zeta},s_0)+\Omega F^1(u,\zeta,\bar{\zeta},s_0)+\mathcal{O}(\Omega^2).$$

where $F^0=u-Z$. Then, the divergence and the shear of the light cone congruence with apex at s_0 containing the null geodesic λ and defined by (see Ref. 17)

$$\rho=m^a\bar{m}^b\nabla_aF_b,\quad \sigma=m^am^b\nabla_aF_b,$$

respectively, are calculated at $\mathcal{I}^+$ as

$$\rho(s_0,\mathcal{I}^+)=m^a\bar{m}^b\nabla_a(u-Z)=\rho_B-R(s_0), \tag{19}$$

$$\sigma(s_0,\mathcal{I}^+)=m^am^b\nabla_a(u-Z)=\sigma_B-\Lambda(s_0), \tag{20}$$

where ρ_B and σ_B are the divergence and the shear of a Bondi congruence.

Now, we move the apex x^a (i.e., s_0) into the interior along the null geodesic λ until the cut develops a caustic point. Since at a generic conjugate point at $\mathcal{I}^+$, the divergence and the shear of the light cone congruence become infinite, whereas ρ_B and σ_B are bounded quantities, we prove the statement. □

It is worth mentioning that it is possible to find degenerate conjugate points where the shear goes to zero instead of infinity. Those, however, are not generic singularities since they are removable by a small perturbation of the initial values of the optical parameters in the geodesic deviation equation.

B. Past null cones from $\mathcal{I}^+$

As was shown before, our function $Z(x^a,\zeta,\bar{\zeta})$ is a generating family of past null cone congruences with apex $(u,\zeta,\bar{\zeta})$ at $\mathcal{I}^+$. Furthermore, for fixed values of $(\zeta,\bar{\zeta})$ this function generates a null coordinate system $(u,R,w,\bar{w})$ which is then used in the derivation of the most important results in the NSF formulation. It is therefore very relevant to analyze the range of validity of this coordinate system. To do so we use a reciprocity theorem for null congruences together with the previous lemma.

We first state a reciprocity theorem relating null cone congruences.[18,19]

Theorem: *Given two null cone congruences having a common null geodesic* λ, *denoting by* X_1 *and* X_2 *the matrices whose elements are the tetrad components of the complex deviation vectors associated with the null cone congruences with apex at a point* p_1 *and* p_2 *along* λ, *then*

$$X_1(at\ \ p_2)=-X_2(at\ \ p_1).$$

We now prove the following lemma:

Lemma III.2. Assume $Z=\text{const}$ *describes the past null cone from* $(u,\zeta,\bar{\zeta})$ *at* $\mathcal{I}^+$. *Then, at a conjugate point* $R\to-\infty$ *and* $|\Lambda|\to\infty$.

Proof: Consider the past null cone from $(u,\zeta,\bar{\zeta})$ at $\mathcal{I}^+$, take a geodesic labeled by $(u,w,\bar{w})$ on this congruence, introduce an affine length s on this geodesic, and denote by ρ_1,σ_1 the optical parameters associated with this congruence. If a conjugate point is reached at $s=s_0$ then at this point ρ_1 and σ_1 become infinite.

On the other hand, if we consider the future light cone congruence from s and denote by ρ_2, σ_2 the corresponding optical parameters, then the reciprocity theorem shows that this congruence has a conjugate point at $(u,\zeta,\bar{\zeta})$ when $s\to s_0$. Thus, $\rho_2(s_0,\mathcal{I}^+)\to\infty$, $|\sigma_2(s_0,\mathcal{I}^+)|\to\infty$ and from Lemma III.1 $R(s_0)\to-\infty$ and $|\Lambda(s_0)|\to\infty$. □

The first consequence of this lemma is that our coordinate system is well defined in the domain $R \in (-\infty, \infty)$, in other words from our coordinate system we cannot detect the caustics that arise in the past null cones as we move into the space–time. It is easy to show that $w = \eth Z$ and $\overline{w} = \bar{\eth} Z$ remain finite at a conjugate point. This follows from the fact that both are constants along a null geodesic.

The lemma is also useful to answer the question we posed before, namely, if there exist asymptotically flat space–times that can be covered with a global canonical coordinate system constructed from a single function *Z*. Using proposition 4.4.5 (Ref. 15) which states that on an asymptotically flat space–time that satisfies the generic and weak energy conditions, any null congruence along a geodesic such that the affine length can be extended arbitrarily has a pair of conjugate points and lemma III.1 we conclude that the coordinate system $(u, w, \overline{w}, R)$ derived from *Z* cannot cover such a space–time. We conclude that

Proposition III.3: A single function $Z(x^a, \zeta, \overline{\zeta})$ cannot generate the conformal structure of an asymptotically flat space–time that satisfies the weak energy and generic conditions.

It is also of interest to analyze the behavior of the conformal factor Ω, and the metric components near a caustic point.

It can be shown that the conformal factor can be written as[3]

$$\Omega^2 = g^{01} := g^{ab} Z_{,a} \eth \bar{\eth} Z_{,b} = \frac{dR}{ds}.$$

Since $R(s)$ diverges as s approaches a conjugate point while the affine length is a smooth nonvanishing function along the null geodesic, it follows that g^{01} also blows up at that point.

IV. CONCLUSIONS

We have shown that our main variable $\hat{Z}$ is the generating family of a constrained Lagrange submanifold and that its level surfaces are constrained Legendre submanifolds that project down to past null cones from $\mathcal{I}^+$. For a generic asymptotically flat space–time the projection of this Lagrange submanifold starts diffeomorphic to the configuration space but it later develops caustic sets. Thus, except for Minkowski space, a single function *Z* on configuration space does not give the conformal structure of the space–time. At the caustic points, $\eth \bar{\eth} Z$ diverges. This means that the coordinate system constructed on the null cones is only locally defined but on the other hand one never sees the caustics since they are pushed out to $R = -\infty$.

Although the entire treatment so far has been kinematical, we would like to think of our variable as coming from the solution of a set of field equations given on the space–time.[3,4]

It is clear from the previous results that the solution of those field equations must have multiple valuedness in order to generate the multiple branches needed to construct the generating family $\hat{Z}$ of the Lagrange submanifold. These solutions are defined in a six-dimensional space, four-space–time coordinates and two parameters on the sphere, $(\zeta, \overline{\zeta})$. We demand the solution to be globally defined with respect to the parameters $(\zeta, \overline{\zeta})$, that is, it shall be a piecewise smooth function on the sphere (it could be multiple valued but always finite on the sphere).

Alternatively, we could try to find field equations given on T^*M. In this case the solution would yield a global generating family $\hat{Z}$ of a constrained Lagrange submanifold that coincides with *Z* in a neighborhood of $\mathcal{I}^+$. This last approach will be further explored.

Hopf algebra structure of $\mathrm{Gr}_q(1|1)$ related to $\mathrm{GL}_q(1|1)$

Salih Çelik[a)]
Mimar Sinan University, Department of Mathematics, 80690 Besiktas, Istanbul, Turkey

(Received 13 January 1998; accepted for publication 20 November 1998)

We show that the algebra of functions on the Grassmann supergroup $\mathrm{Gr}_q(1|1)$ has a (graded) Hopf algebra structure related to $\mathrm{GL}_q(1|1)$. © *1999 American Institute of Physics.* [S0022-2488(99)01603-5]

In the past few years, quantum groups[1] and q-deformed universal enveloping algebras[2] have been intensively studied both by mathematicians and mathematical physicists. From a mathematical point of view, these algebraic structures are just special classes of noncommutative Hopf algebras.

The algebraic structure underlying quantum groups extends the theory of the supergroups.[3] The simplest quantum supergroup is $\mathrm{GL}_q(1|1)$, i.e., the deformation of the supergroup of 2×2 matrices with two bosonic (even) and two fermionic (odd) matrix entries.

The aim of the present work is to construct the (graded) Hopf algebra structure of the Grassmann supergroup $\mathrm{Gr}_q(1|1)$, the superdual of $\mathrm{GL}_q(1|1)$, which was introduced in Ref. 4. Before discussing the (graded) Hopf algebra structure of $\mathrm{Gr}_q(1|1)$, let us first give some notations and useful formulas about the quantum Grassmann supergroup $\mathrm{Gr}_q(1|1)$.

A Grassmann supermatrix $\hat{T}$ which is an element of $\mathrm{Gr}(1|1)$ is of the form

$$\hat{T}=\begin{pmatrix}\alpha & b\\ c & \delta\end{pmatrix}$$

with two odd (Greek letters) and two even (Latin letters) matrix elements. The symbol *hat* is used to distinguish $\hat{T}$ from an element T of $\mathrm{GL}_q(1|1)$.

The q-deformation of the Grassman supergroup $\mathrm{Gr}(1|1)$ as a quantum matrix supergroup $\mathrm{Gr}_q(1|1)$ is generated by α, b, c, δ with the relations[4]

$$\begin{aligned}&\alpha b=q^{-1}b\alpha,\quad \alpha c=q^{-1}c\alpha,\\ &\delta b=q^{-1}b\delta,\quad \delta c=q^{-1}c\delta,\\ &\alpha\delta+\delta\alpha=0,\quad \alpha^2=0=\delta^2,\\ &bc=cb+(q-q^{-1})\delta\alpha,\end{aligned}\tag{1}$$

where q is a nonzero complex number and $q^2\neq1$. The associative algebra (1) is equivalent to equation[5]

$$R^1\hat{T}_1\hat{T}_2=-\hat{T}_2\hat{T}_1R^2,\tag{2}$$

where

$$R^1=\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & q-q^{-1} & -1 & 0 \\ 0 & 0 & 0 & q^{-1} \end{pmatrix}, \quad R^2=\begin{pmatrix} q^{-1} & 0 & 0 & 0 \\ 0 & -1 & q^{-1}-q & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & q \end{pmatrix} \tag{3}$$

are both the solutions of the quantum (graded) Yang–Baxter equation. Here, we used the tensoring convention

$$(\hat{T}_1)^{ij}_{kl}=(\hat{T}\otimes I)^{ij}_{kl}=\hat{T}^i_k\delta^j_l,$$

$$(\hat{T}_2)^{ij}_{kl}=(I\otimes\hat{T})^{ij}_{kl}=(-1)^{i(j+l)}\hat{T}^j_l\delta^i_k. \tag{4}$$

The central element of the algebra (1) is[4]

$$\hat{D}_q=bc^{-1}-\alpha c^{-1}\delta c^{-1}=c^{-1}b-c^{-1}\alpha c^{-1}\delta. \tag{5}$$

We now denote the algebra generated by the elements α, b, c, δ with the relations (1) by $\hat{\mathcal{A}}$. We want to make the algebra $\hat{\mathcal{A}}$ into a (graded) Hopf algebra related to the quantum supergroup $\mathrm{GL}_q(1|1)$. Because of this, we state briefly some properties of the quantum supergroup $\mathrm{GL}_q(1|1)$ we are going to need in this work.

The quantum supergroup $\mathrm{GL}_q(1|1)$ is generated by four generators a, β, γ, d and the q-commutation relations[3]

$$\begin{aligned} a\beta&=q\beta a, \quad d\beta=q\beta d,\\ a\gamma&=q\gamma a, \quad d\gamma=q\gamma d,\\ \beta\gamma+\gamma\beta&=0, \quad \beta^2=0=\gamma^2,\\ ad&=da+(q-q^{-1})\gamma\beta. \end{aligned} \tag{6}$$

The generators satisfying the relations (6) generate the algebra called the algebra of functions on the quantum supergroup $\mathrm{GL}_q(1|1)$ and we shall denote it by $\mathcal{A}$. We know that the algebra $\mathcal{A}$ is a (graded) Hopf algebra whose structure we now discuss. We represent the set of generators a, β, γ, d in the form of a matrix

$$T=\begin{pmatrix} a & \beta \\ \gamma & d \end{pmatrix}.$$

Then the relations (6) are equivalent to equation

$$RT_1T_2=T_2T_1R, \tag{7}$$

where

$$R=\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & q-q^{-1} & 1 & 0 \\ 0 & 0 & 0 & q^{-1} \end{pmatrix}. \tag{8}$$

The superinverse of T is given by[3]

$$T^{-1}=\begin{pmatrix} A & \Omega \\ \Gamma & D \end{pmatrix}=\begin{pmatrix} a^{-1}+a^{-1}\beta d^{-1}\gamma a^{-1} & -a^{-1}\beta d^{-1} \\ -d^{-1}\gamma a^{-1} & d^{-1}+d^{-1}\gamma a^{-1}\beta d^{-1} \end{pmatrix}, \tag{9}$$

and the superdeterminant is

$$D_q=ad^{-1}-\beta d^{-1}\gamma d^{-1}. \tag{10}$$

It is easy to verify that D_q commutes with all matrix elements of T. Note that the matrix elements of T with those of T^{-1} satisfy the following relations:

$$\begin{gathered} aA=q^2Aa+1-q^2, \quad dA=Ad, \\ aD=Da, \quad dD=q^2Dd+1-q^2, \\ a\Omega=q\Omega a, \quad d\Omega=q\Omega d, \\ a\Gamma=q\Gamma a, \quad d\Gamma=q\Gamma d, \\ \beta A=qA\beta, \quad \gamma A=qA\gamma, \\ \beta D=qD\beta, \quad \gamma D=qD\gamma, \\ \beta\Omega=\Omega\beta, \quad \gamma\Omega=-q^2\Omega\gamma, \\ \beta\Gamma=-q^2\Gamma\beta, \quad \gamma\Gamma=\Gamma\gamma. \end{gathered} \tag{11}$$

The usual coproduct is given by

$$\Delta:\mathcal{A}\rightarrow\mathcal{A}\otimes\mathcal{A}, \quad \Delta(t^i_j)=t^i_k\otimes t^k_j, \tag{12}$$

where summation over repeated indices is understood. One can rewrite the last formula in the following nice and elegant form,

$$\Delta(T)=T\dot{\otimes}T, \tag{13}$$

where $\otimes$ stands for the usual tensor product and the dot refers to the summation over repeated indices and reminds us about the usual matrix multiplication. The counit is given by

$$\varepsilon:\mathcal{A}\rightarrow\mathcal{C}, \quad \varepsilon(t^i_j)=\delta^i_j. \tag{14}$$

The coinverse (antipode) is given by

$$S:\mathcal{A}\rightarrow\mathcal{A}, \quad S(T)=T^{-1}. \tag{15}$$

It is not difficult to verify the following properties of the co-structures:

$$(\Delta\otimes\mathrm{id})\circ\Delta=(\mathrm{id}\otimes\Delta)\circ\Delta, \tag{16}$$

$$\mu\circ(\varepsilon\otimes\mathrm{id})\circ\Delta=\mu'\circ(\mathrm{id}\otimes\varepsilon)\circ\Delta, \tag{17}$$

$$m\circ(S\otimes\mathrm{id})\circ\Delta=\varepsilon=m\circ(\mathrm{id}\otimes S)\circ\Delta, \tag{18}$$

where id denotes the identity mapping,

$$\mu:\mathcal{C}\otimes\mathcal{A}\rightarrow\mathcal{A}, \quad \mu':\mathcal{A}\otimes\mathcal{C}\rightarrow\mathcal{A} \tag{19}$$

are the canonical isomorphisms, defined by

$$\mu(k\otimes a)=ka=\mu'(a\otimes k), \quad \forall a\in\mathcal{A}, \quad \forall k\in\mathcal{C}, \tag{20}$$

and m is the multiplication map

$$m:\mathcal{A}\otimes\mathcal{A}\rightarrow\mathcal{A}, \quad m(a\otimes b)=ab. \tag{21}$$

The multiplication in $\mathcal{A}\otimes\mathcal{A}$ follows the rule

$$(A\otimes B)(C\otimes D)=(-1)^{p(B)p(C)}AC\otimes BD, \tag{22}$$

where $p(X)$ is the z_2-grade of X, i.e., $p(X)=0$ for even variables and $p(X)=1$ for odd variables.

Since the (graded) Hopf algebra structure of $\mathrm{Gr}_q(1|1)$ is related to those of $\mathrm{GL}_q(1|1)$ it is necessary to obtain the commutation relations of the generators of $\hat{\mathcal{A}}$ with those of $\mathcal{A}$. We define the (mixed) commutation relations between the generators of $\hat{\mathcal{A}}$ and $\mathcal{A}$ as follows:

$$R\hat{T}_1T_2=(-1)^{p(T_2)}T_2\hat{T}_1R', \quad R'=R-(q-q^{-1})P, \tag{23}$$

where P is the superpermutation matrix. The equation (23) gives the mixed relations

$$\begin{aligned}
&a\alpha=q^2\alpha a, \quad \beta\alpha=-q\alpha\beta,\\
&ab=qba+(q^2-1)\alpha\beta, \quad \beta b=b\beta,\\
&ac=qca+(q^2-1)\alpha\gamma, \quad \beta c=c\beta+(q-q^{-1})\alpha d,\\
&a\delta=\delta a+(q-q^{-1})(\beta c-b\gamma), \quad \beta\delta=-q^{-1}\delta\beta+(1-q^{-2})bd,\\
&d\alpha=\alpha d, \quad \gamma\alpha=-q\alpha\gamma,\\
&db=q^{-1}bd, \quad \gamma b=b\gamma-(q-q^{-1})\alpha d,\\
&dc=q^{-1}cd, \quad \gamma c=c\gamma,\\
&d\delta=q^{-2}\delta d, \quad \gamma\delta=-q^{-1}\delta\gamma+(1-q^{-2})cd.
\end{aligned} \tag{24}$$

Using these relations, it is easy to verify that $\hat{D}_q$, which is given by (5), is still a central element, i.e., $\hat{D}_q$ also commutes with the generators of $\mathcal{A}$.

After some algebra the commutation relations between the matrix elements of $\hat{T}$ with T^{-1} are obtained to be

$$\begin{aligned}
&\alpha A=q^2A\alpha, \quad \delta A=A\delta,\\
&\alpha D=D\alpha, \quad \delta D=q^{-2}D\delta+(q-q^{-1})^2A\alpha+(q^{-2}-1)(\Omega c-\Gamma b),\\
&\alpha\Omega=-q\Omega\alpha, \quad \delta\Omega=-q^{-1}\Omega\delta+(q^{-1}-q)Ab,\\
&\alpha\Gamma=-q\Gamma\alpha, \quad \delta\Gamma=-q^{-1}\Gamma\delta+(q^{-1}-q)Ac,\\
&bA=qAb, \quad cA=qAc,\\
&bD=q^{-1}Db+(q-q^{-1})\Omega\alpha, \quad cD=q^{-1}Dc+(q-q^{-1})\Gamma\alpha.\\
&b\Omega=\Omega b, \quad c\Omega=\Omega c+(q^2-1)A\alpha,
\end{aligned} \tag{25}$$

$$b\Gamma=\Gamma b+(1-q^2)A\alpha,\quad c\Gamma=\Gamma c,$$

and

$$D_q u=q^2 u D_q,\quad u\in\{\alpha,b,c,\delta\}. \tag{26}$$

Before defining a coproduct on the algebra $\hat{\mathcal{A}}$, let us note the following facts. Let $\hat{T}$ and $\hat{T}'$ be any two supercommuting matrices that satisfy (1). We denote a product $\hat{T}\hat{T}'$ by T. Then, it can be verified that the matrix elements of T satisfy the commutation relations (6) of $\mathrm{GL}_q(1|1)$, i.e., if

$$T=\begin{pmatrix}\alpha & b\\ c & \delta\end{pmatrix}\begin{pmatrix}\alpha' & b'\\ c' & \delta'\end{pmatrix},$$

then we have the relations (6). In short,

$$\hat{T},\hat{T}'\in \mathrm{Gr}_q(1|1)\Rightarrow T=\hat{T}\hat{T}'\in \mathrm{GL}_q(1|1).$$

In view of these facts, we can say that there may be no coproduct of the usual form $\Delta(\hat{T})=\hat{T}\dot{\otimes}\hat{T}$. For this coproduct, if it existed, would be invariant under the q-commutation relations (6) of $\mathrm{GL}_q(1|1)$. But we can define a map on the algebra $\hat{\mathcal{A}}$ as follows:

$$\hat{\Delta}:\hat{\mathcal{A}}\to\hat{\mathcal{A}}\otimes\hat{\mathcal{A}},\quad \hat{\Delta}(\hat{T})=\hat{T}\dot{\otimes}T+(-1)^{p(T)}T\dot{\otimes}\hat{T}. \tag{27}$$

Explicitly,

$$\begin{aligned}
\hat{\Delta}(\alpha)&=\alpha\otimes a+b\otimes\gamma+a\otimes\alpha-\beta\otimes c,\\
\hat{\Delta}(b)&=b\otimes d+\alpha\otimes\beta+a\otimes b-\beta\otimes\delta,\\
\hat{\Delta}(c)&=c\otimes a+\delta\otimes\gamma-\gamma\otimes\alpha+d\otimes c,\\
\hat{\Delta}(\delta)&=\delta\otimes d+c\otimes\beta-\gamma\otimes b+d\otimes\delta.
\end{aligned} \tag{28}$$

The action on the generators of $\hat{\mathcal{A}}$ of $\hat{\varepsilon}:\hat{\mathcal{A}}\to\mathcal{C}$ is

$$\hat{\varepsilon}(\alpha)=\hat{\varepsilon}(b)=\hat{\varepsilon}(c)=\hat{\varepsilon}(\delta)=0. \tag{29}$$

Finally, we define the coinverse as

$$\hat{S}:\hat{\mathcal{A}}\to\hat{\mathcal{A}},\quad \hat{S}(\hat{T})=-(-1)^{p(T^{-1})}T^{-1}\hat{T}T^{-1}. \tag{30}$$

The action of $\hat{S}$ on the generators of $\hat{\mathcal{A}}$ is

$$\begin{aligned}
\hat{S}(\alpha)&=-(\alpha A+b\Gamma)A+q(cA+\delta\Gamma)\Omega,\\
\hat{S}(b)&=-(\alpha A-c\Omega)\Omega-q(bA+\delta\Omega)D,\\
\hat{S}(c)&=-(\alpha A+b\Gamma)\Gamma-q(cA+\delta\Gamma)D,\\
\hat{S}(\delta)&=q^2(\alpha A-c\Omega)D+q(\alpha\Omega+q^2 bD)\Gamma-(\alpha A+q^2\delta D)D.
\end{aligned} \tag{31}$$

It is not difficult to check that the maps $\hat{\Delta}$ and $\hat{\varepsilon}$ are both algebra homomorphisms and $\hat{S}$ is an algebra anti-homomorphism and also the three maps satisfy the properties (16)–(18), and they preserve the relations (24) provided that the action on the generators of $\mathcal{A}$ of $\hat{\Delta}$ is the same with (13).

The coproduct, counit, and coinverse which are specified above supply $\mathrm{Gr}_q(1|1)$ with a structure, which can be called a quasi-Hopf algebra.

It is interesting to note that there is a close connection with the differential calculus[6] on the quantum supergroup $\mathrm{GL}_q(1|1)$ via the equation (23). In fact, we have observed that the matrix elements of $\hat{T} \in \mathrm{Gr}_q(1|1)$ are just the differentials of the matrix elements of $T \in \mathrm{GL}_q(1|1)$. In other words, we can interpret the generating elements of $\mathrm{Gr}_q(1|1)$ as differentials of coordinate functions on $\mathrm{GL}_q(1|1)$. In this case, we can write $\hat{T} = \mathsf{d}T$ (more information on these issues are given in Ref. 6). Then the extended algebra can be interpreted as an algebra of differential forms on $\mathrm{GL}_q(1|1)$. Thus the coproduct is interpreted as a (left and right) coaction of the quatum supergroup $\mathrm{GL}_q(1|1)$ on differential forms. To this end, we consider the two maps

$$\Delta_R : \Gamma \to \Gamma \otimes \mathcal{A}, \quad \Delta_R \circ \mathsf{d} = (\mathsf{d} \otimes \mathrm{id}) \circ \Delta \tag{32a}$$

and

$$\Delta_L : \Gamma \to \mathcal{A} \otimes \Gamma, \quad \Delta_L \circ \mathsf{d} = (\tau \otimes \mathsf{d}) \circ \Delta, \tag{32b}$$

where Γ denotes the differential algebra of $\mathcal{A}$. Here τ: $\Gamma \to \Gamma$ is the linear map of degree zero which gives $\tau(a) = (-1)^{p(a)} a$. We now define a map ϕ_R as follows,

$$\phi_R(u_1 \mathsf{d} v_1 + \mathsf{d} v_2 u_2) = \Delta(u_1) \Delta_R(\mathsf{d} v_1) + \Delta_R(\mathsf{d} v_2) \Delta(u_2), \tag{33}$$

and another map ϕ_L by replacing L with R. The following identities are satisfied.

$$(\phi_R \otimes \mathrm{id}) \circ \phi_R = (\mathrm{id} \otimes \Delta) \circ \phi_R, \quad (\mathrm{id} \otimes \epsilon) \circ \phi_R = \mathrm{id}, \tag{34a}$$

and

$$(\mathrm{id} \otimes \phi_L) \circ \phi_L = (\Delta \otimes \mathrm{id}) \circ \phi_L, \quad (\epsilon \otimes \mathrm{id}) \circ \phi_L = \mathrm{id}. \tag{34b}$$

Consequently, we define the map $\hat{\Delta}$, in (27), as

$$\hat{\Delta} = \phi_R + \phi_L. \tag{35}$$

(Received 9 July 1997; accepted for publication 15 October 1998)

Applying the harmonic map ansatz we find new classes of SU(N) and SO(N) chiral fields. We write the corresponding one-dimensional subgroups of SU(N) and SO(N) chiral fields in terms of one and two harmonic maps and the corresponding two-dimensional subgroups in terms of SU(2) and SO(3) chiral fields. In other words, we reduce the SU(N) and SO(N) chiral equations to harmonic maps in one- and two-dimensional spaces.

I. INTRODUCTION

One of the most important and interesting models in mathematical physics are the models called nonlinear σ models or principal chiral models. These are important for different reasons: they have similar properties to the four-dimensional Yang–Mills theories,[1] they have an infinite number of conservation laws,[1,2] they contain soliton solutions,[3,4] and they are used as approximate models in particle physics. Their applications as field equations in various theories also makes these models very attractive and interesting. In general relativity and gravitational theories, the Einstein's field equations in a space–time with two Killing vectors reduce to a nonlinear σ model with invariant group SU(1,1) for the vacuum case, and with invariant group SU(2,1) for the electrovacuum case.[5] The n-dimensional Einstein's equations with a $(n-2)$-dimensional isometry group reduce to a nonlinear σ model with invariant group $\mathrm{SL}(n-2,\mathcal{R})$.[6] But one of the most interesting features of the σ models is that self-dual Yang–Mills fields and self-dual general relativity reduce to the field equations of the σ models[5] (see Refs. 7 and 8). In the first case the field equations reduce to a SU(N) nonlinear σ model, and in the last case the field equations reduce to a $\mathrm{SU}(\infty)\sim\mathrm{Diff}(\Sigma^2)$-$\sigma$ model.[7,8] In this work we deal with SU(N) and SO(N)-σ models. These are defined by means of the following Lagrangian density:

$$\mathcal{L}=\frac{\alpha}{4}\mathrm{Tr}(g_{,z}g^{-1}g_{,\bar{z}}g^{-1}), \tag{1}$$

where $g\in\mathrm{SU}(N)$, $(\mathrm{SO}(N))$, i.e.,

$$gg^{\dagger}=1 \quad (gg^{T}=1), \quad \mathrm{Det}\, g=\alpha^2=1, \tag{2}$$

[a]Electronic mail: tmatos@fis.cinvestav.mx
[b]Electronic mail: ulises@fis.cinvestav.mx
[c]Electronic mail: biene@ctrl.cinvestav.mx

where z is a complex coordinate and $\overline{z}$ its complex conjugate, g^T is the transpose of g, and $g^\dagger = \overline{g}^T$. Even if $\alpha = 1$ for the groups studied here, we shall write it explicitly; the only difference appears in the harmonic map equations, but our results are written in terms of these harmonic maps, which will be supposed to be arbitrary in this work. The corresponding Euler–Lagrange equations of (2) are given by

$$(\alpha g_{,z} g^{-1})_{,\overline{z}} + (\alpha g_{,\overline{z}} g^{-1})_{,z} = 0, \tag{3}$$

which are the chiral equations.

Solutions to chiral equations have been found by the application of various methods, e.g., by Bäcklund transformations (see Ref. 1), by the inverse scattering method (see Refs. 3 and 4), and recently, Uhlenbeck has deduced the form of all classical solutions of the chiral equations with constraints from a factorization theorem proved by herself.[9] In this work we will apply the method developed by Matos in Ref. 10, which permits us to suppose g to be an arbitrary element of a Lie group G, where the dimension of G can even be infinite. The most important feature of this method is that we can write the chiral fields, i.e., the solutions of the chiral equations, in terms of explicit functions which are solutions of a well-known differential equation like the Laplace equation or minimal surfaces equation in two dimensions. We obtain classes of solutions in terms of these arbitrary harmonic maps. The solutions can be then interpreted physically. In this work we will give a set of exact solutions of the chiral equations for the Lie groups SU(N) and SO(N) in terms of harmonic maps. In order to make this paper self-contained, we will resume the harmonic map ansatz method of Ref. 10 in Sec. II. In Sec. III we will analyze one-dimensional subspaces, and in Sec. IV the two-dimensional ones.

II. THE HARMONIC MAP ANSATZ METHOD

In this section we briefly give a general treatment of the harmonic map ansatz. For full details we refer the reader to Ref. 10. Let G be a Lie group and

$$g:\mathcal{C}\times\mathcal{C}\to G, \quad (z,\overline{z})\mapsto g(z,\overline{z}) \in G, \tag{4}$$

where g is a solution of (3) and it depends on the complex variables z and $\overline{z}$. Let w_R be the Maurer–Cartan form in G:

$$w_R = dg\, g^{-1}, \quad g \in G, \tag{5}$$

then w_R is right invariant on G, that is

$$R_c^*(dg\, g^{-1}) = dg\, g^{-1}. \tag{6}$$

R_c is the right translation associated with the element $c \in G$. Furthermore, we define the functions A_z and $A_{\overline{z}}$ by

$$g\mapsto A_z(g) = g_{,z} g^{-1}, \quad g\mapsto A_{\overline{z}}(g) = g_{,\overline{z}} g^{-1}, \tag{7}$$

where $A_z, A_{\overline{z}} \in \mathcal{G}$, $\mathcal{G}$ being the corresponding Lie algebra of G. Then, using (7), the Maurer–Cartan form in G can be written in terms of the Lie algebra valued functions A_z and $A_{\overline{z}}$ as

$$w_R = A_z\, dz + A_{\overline{z}}\, d\overline{z} = g_{,z} g^{-1}\, dz + g_{,\overline{z}} g^{-1}\, d\overline{z}. \tag{8}$$

Now, let us suppose that the matrix g depends on a set of functions $\lambda^i(z,\overline{z})$, which are local coordinates of an arbitrary Riemannian manifold M_r, that is

$$\lambda^i: M_r \to \Re, \quad \forall i = 1,2,...,r, \quad g = g(\lambda^i), \quad \forall i = 1,2,...,r. \tag{9}$$

The harmonic map ansatz consists of assuming that the parameters λ^i build minimal surfaces in the Riemannian manifold M_r, that is, they satisfy the following equation:

$$(\alpha\lambda^i{}_{,z})_{,\bar{z}}+(\alpha\lambda^i{}_{,\bar{z}})_{,z}+2\alpha\Gamma^i_{jk}\lambda^j{}_{,z}\lambda^k{}_{,\bar{z}}=0, \quad \forall i=1,2,...,r, \tag{10}$$

where Γ^i_{jk} represents the Christoffel's symbols in the Riemannian manifold M_r. If we do so, the chiral equations reduce to a Killing equation in the Riemannian manifold M_r.

In order to see this, we substitute (9) in the chiral equations (3), getting

$$\alpha[(g_{,i}g^{-1})_{,j}+(g_{,j}g^{-1})_{,i}]\lambda^i_{,z}\lambda^i_{,\bar{z}}+g_{,i}g^{-1}[(\alpha\lambda^i_{,z})_{,\bar{z}}+(\alpha\lambda^i_{,\bar{z}})_{,z}]=0. \tag{11}$$

The substitution of (10) in (11) gives

$$[(g_{,i}g^{-1})_{,j}+(g_{,j}g^{-1})_{,i}-2\Gamma^k_{ij}g_{,k}g^{-1}]\lambda^j{}_{,\bar{z}}\lambda^i{}_{,z}=0. \tag{12}$$

From Eq. (12) it follows

$$(g_{,i}g^{-1})_{,j}+(g_{,j}g^{-1})_{,i}-2\Gamma^k_{ij}g_{,k}g^{-1}=0. \tag{13}$$

Analogously, we can define the functions

$$A_i:G\rightarrow\mathcal{G}, \quad g\mapsto A_i(g)=g_{,i}g^{-1}, \quad \forall i=1,2,...,r. \tag{14}$$

Again, the matrices $A_i(g)$ belong to the Lie algebra of G. Then, the Maurer–Cartan matrix one-form w can be written as

$$w(g)=A_i(g)d\lambda^i=g_{,i}g^{-1}\,d\lambda^i. \tag{15}$$

The covariant derivative in the Riemannian manifold M_r is given by

$$\nabla_jA_i=A_{i,j}-\Gamma^k_{ij}A_k. \tag{16}$$

Using (14) and (16) in (13), it is easy to see that the chiral equations (3) become

$$\nabla_jA_i+\nabla_iA_j=0. \tag{17}$$

The matrices $A_i(g)$ also satisfy the relation

$$\nabla_jA_i-\nabla_iA_j-[A_j,A_i]=0; \tag{18}$$

the last relation means that the matrices $A_i(g)$ are pure gauge potentials. (17) and (18) together reduce to

$$\nabla_jA_i=\tfrac{1}{2}[A_j,A_i]. \tag{19}$$

Let the matrices σ^j be a basis of the Lie algebra $\mathcal{G}$. We can write the matrices A_i in this basis,

$$A_i(g)=\epsilon_i^j\sigma_j. \tag{20}$$

Using (20) and (17), we obtain

$$[\nabla_j\epsilon_i^k+\nabla_i\epsilon_j^k]\sigma_k=0. \tag{21}$$

Because the matrices σ^k are linearly independent we can conclude that

$$\nabla_j\epsilon_i^k+\nabla_i\epsilon_j^k=0. \tag{22}$$

Equation (22) is the Killing equation on the Riemannian manifold M_r. Using the following relation, which is satisfied for any Killing vector field ϵ^k:

$$\nabla_l \nabla_j \epsilon_i^k = R_{lji}^m \epsilon_m^k, \tag{23}$$

we find that the covariant derivative of the Riemann tensor on the Riemannian manifold M_r vanishes, then M_r is a symmetric manifold. Any symmetric manifold contains $r(r+1)/2$ linearly independent Killing vector fields.[11] Then if we know the Riemannian manifold M_r we have the Killing vector space. Let $\{\epsilon^k\}$ be a basis of Killing fields on M_r, and write the matrices A_i in terms of this basis. The substitution of (20) in (19) yields the algebra of the $\{\sigma^k\}$ matrices. The next step is to choose a representation of this algebra and to solve the following system of first-order differential equations:

$$A_i(g) = g_{,i} g^{-1}, \quad \forall i = 1,2,...,r. \tag{24}$$

Observe that the field equations (3) are invariant under the transformation

$$g \mapsto g' = L_h g = hg, \quad h \in G_c, \tag{25}$$

where $G_c = \{c \in G | c \text{ is a constant matrix}\}$ and L_h is the left action of G_c on G. In other words, if g is solution of the field equations (3), then g' is solution of them too. Under the transformation (25), the matrices $A_i(g)$ transform into A_i':

$$A_i \mapsto A_i' = h A_i h^{-1}. \tag{26}$$

The relation (26) separates the set of matrices $\{A_i\}$ in equivalent classes. Now let us work with a representation of each class. After integrating the equations (24) for this representation, we can find all the solutions in this class to the field equations (3) by means of the transformation (25). The problem of solving the chiral equations is then reduced to finding harmonic maps, i.e., to solve the system of coupled linear differential equations (10) for the parameters λ^i.

III. ONE-DIMENSIONAL SUBSPACES

One-dimensional subspaces are characterized by a one-dimensional manifold M_1, with only one parameter λ, and a metric given by

$$ds^2 = d\lambda^2. \tag{27}$$

The metric (27) is symmetric and has a constant Killing vector field. The harmonic map ansatz is then

$$g = g(\lambda), \quad \lambda = \lambda(z, \bar{z}). \tag{28}$$

From (13) we can see that A_λ is a constant matrix [A_λ belongs to the corresponding Lie algebra of SU(N)]. The Lie algebra su(N), corresponding to SU(N), is the set of traceless anti-Hermitian complex $N \times N$ matrices

$$\mathrm{su}(N) = \{A \in GL(N,C) | A = -A^\dagger, \ \mathrm{Tr}\, A = 0\}. \tag{29}$$

For the su(N) algebra, the Jordan normal form is always diagonal. We use this form by integrating the matrix differential equation $g_{,\lambda} = A_\lambda g$. We have only the following representation for N even, $N = 2n$:

$$A_\lambda = \begin{pmatrix} a_1 i & 0 & \cdot & \cdot & 0 & 0 \\ 0 & -a_1 i & \cdot & \cdot & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & \cdot & a_n i & 0 \\ 0 & 0 & \cdot & \cdot & 0 & -a_n i \end{pmatrix}, \tag{30}$$

and the following one for N odd, $N=2n+1$:

$$A_\lambda = \begin{pmatrix} a_1 i & 0 & \cdot & \cdot & 0 & 0 & 0 \\ 0 & -a_1 i & \cdot & \cdot & 0 & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & \cdot & a_n i & 0 & 0 \\ 0 & 0 & \cdot & \cdot & 0 & -a_n i & 0 \\ 0 & 0 & \cdot & \cdot & 0 & 0 & 0 \end{pmatrix}, \tag{31}$$

where $a_1,\ldots,a_n \in \mathcal{R}$, $a_i \neq 0$, $i=1,...,n$.

For the case $N=2n$, we integrate the differential equation $g_{,\lambda}=A_\lambda g$, and obtain

$$g = \begin{pmatrix} u_{1,1}\exp(a_1 i\lambda) & \cdot & \cdot & \cdot & \cdot & u_{1,2n}\exp(a_1 i\lambda) \\ u_{2,1}\exp(-a_1 i\lambda) & \cdot & \cdot & \cdot & \cdot & u_{2,2n}\exp(-a_1 i\lambda) \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ u_{2n-1,1}\exp(a_n i\lambda) & \cdot & \cdot & \cdot & \cdot & u_{2n-1,2n}\exp(a_n i\lambda) \\ u_{2n,1}\exp(-a_n i\lambda) & \cdot & \cdot & \cdot & \cdot & u_{2n,2n}\exp(-a_n i\lambda) \end{pmatrix}. \tag{32}$$

Under the conditions $g^{-1}=g^\dagger$, $\det g=1$, the $(2n)^2$ complex constants $u_{i,j}$, $i,j=1,...,2n$ satisfy

$$\begin{pmatrix} u_{1,1} & \cdot & \cdot & \cdot & \cdot & u_{1,2n} \\ u_{2,1} & \cdot & \cdot & \cdot & \cdot & u_{2,2n} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ u_{2n-1,1} & \cdot & \cdot & \cdot & \cdot & u_{2n-1,2n} \\ u_{2n,1} & \cdot & \cdot & \cdot & \cdot & u_{2n,2n} \end{pmatrix} \in \mathrm{SU}(N). \tag{33}$$

Analogously, for the case $N=2n+1$ we obtain

$$g = \begin{pmatrix} u_{1,1}\exp(a_1 i\lambda) & \cdot & \cdot & \cdot & \cdot & \cdot & u_{1,2n+1}\exp(a_1 i\lambda) \\ u_{2,1}\exp(-a_1 i\lambda) & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2,2n+1}\exp(-a_1 i\lambda) \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ u_{2n-1,1}\exp(a_n i\lambda) & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2n-1,2n+1}\exp(a_n i\lambda) \\ u_{2n,1}\exp(-a_n i\lambda) & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2n,2n+1}\exp(-a_n i\lambda) \\ u_{2n+1,1} & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2n+1,2n+1} \end{pmatrix}. \tag{34}$$

Under the restrictions $g^{-1}=g^\dagger$, $\det g=1$, the $(2n+1)^2$ complex constants $u_{i,j}$, $i,j=1,...,2n+1$ satisfy

$$\begin{pmatrix} u_{1,1} & \cdot & \cdot & \cdot & \cdot & \cdot & u_{1,2n+1} \\ u_{2,1} & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2,2n+1} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ u_{2n-1,1} & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2n-1,2n+1} \\ u_{2n,1} & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2n,2n+1} \\ u_{2n+1,1} & \cdot & \cdot & \cdot & \cdot & \cdot & u_{2n+1,2n+1} \end{pmatrix} \in \mathrm{SU}(N). \tag{35}$$

From (10) we see that the parameter λ must satisfy the Laplace equation, that is

$$(\alpha\lambda_{,z})_{,\bar{z}} + (\alpha\lambda_{,\bar{z}})_{,z} = 0. \tag{36}$$

For each solution λ of the Laplace equation, we obtain a different matrix solution of the chiral equations by means of matrices (32) and (34).

IV. TWO-DIMENSIONAL SUBSPACES

A. Two-dimensional subalgebras of su(N)

Two-dimensional subspaces are characterized by a two-dimensional manifold M_2 with parameters $\lambda^1 = \lambda$, $\lambda^2 = \tau$, and a metric given by

$$ds^2 = \frac{d\lambda\, d\tau}{(1 + k\lambda\tau)^2}. \tag{37}$$

The metric (37) is symmetric and has a constant curvature k. The harmonic map ansatz is then

$$g = g(\lambda, \tau), \quad \lambda = \lambda(z, \bar{z}), \quad \tau = \tau(z, \bar{z}). \tag{38}$$

The matrices A_λ, and A_τ, satisfy Eqs. (17) and (19), this is,

$$\begin{aligned} &\nabla_\lambda A_\tau + \nabla_\tau A_\lambda = 0, \\ &\Delta_\lambda A_\tau = \tfrac{1}{2}[A_\lambda, A_\tau], \\ &\nabla_\tau A_\lambda = \tfrac{1}{2}[A_\tau, A_\lambda]. \end{aligned} \tag{39}$$

The Killing vector space of the metric (37) can be obtained by solving the Killing equation (22)

$$\begin{aligned} &\epsilon_{\lambda,\lambda} + \frac{2k\tau}{(1 + k\lambda\tau)} \epsilon_\lambda = 0, \\ &\epsilon_{\tau,\tau} + \frac{2k\lambda}{(1 + k\lambda\tau)} \epsilon_\tau = 0, \\ &\epsilon_{\lambda,\tau} + \epsilon_{\tau,\lambda} = 0. \end{aligned} \tag{40}$$

The components of the Killing vector fields are

$$\epsilon_\lambda = \frac{1}{V^2}(ak\tau^2 + b\tau + c),$$

$$\epsilon_\tau = \frac{1}{V^2}(ck\lambda^2 - b\lambda + a), \tag{41}$$

with

$$V = (1 + k\lambda\tau),$$

We choose three independent Killing vectors on the manifold M_2:

$$\phi = \frac{1}{V^2}(1, k\lambda^2), \quad \xi = \frac{1}{V^2}(-2\tau, 2\lambda), \quad \zeta = \frac{1}{V^2}(k\tau^2, 1). \tag{42}$$

Using Eq. (20) we can define the matrix vector $A = (A_\lambda, A_\tau)$ by

$$A = \phi\sigma_1 + \xi\sigma_2 + \zeta\sigma_3. \tag{43}$$

The matrices σ_1, σ_2, σ_3 form a basis of a Lie subalgebra of su(N). These matrices have the following expressions:

$$A_\lambda = \frac{1}{V^2}[\sigma_1 - 2\tau\sigma_2 + k\tau^2\sigma_3], \quad A_\tau = \frac{1}{V^2}[k\lambda^2\sigma_1 + 2\lambda\sigma_2 + \sigma_3]. \tag{44}$$

Introducing Eqs. (44) into (39) we obtain the commutation relations of the subalgebra of σ_k matrices

$$[\sigma_1, \sigma_2] = 2k\sigma_1, \quad [\sigma_2, \sigma_3] = 2k\sigma_3, \quad [\sigma_3, \sigma_1] = -4\sigma_2. \tag{45}$$

We take the case $k=0$ and $\sigma_2 = 0$. The manifold M_2 is therefore flat. The commutation relations of the two-dimensional Abelian subalgebras of su(N) are

$$[\sigma_3, \sigma_1] = 0. \tag{46}$$

From (44), the matrices A_λ, A_τ are reduced to

$$g_{,\lambda}g^{-1} = A_\lambda = \sigma_1, \quad g_{,\tau}g^{-1} = A_\tau = \sigma_3. \tag{47}$$

Since the group SU(N) has range $(N-1)$, its algebra has $(N-1)$ diagonal commuting elements. The two-dimensional Abelian subalgebras of su(N) can be written in the basis σ_1, σ_3, where

$$\sigma_1 = \begin{pmatrix} a_1 i & 0 & \cdot & \cdot & 0 & 0 \\ 0 & a_2 i & \cdot & \cdot & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & 0 & \cdot & \cdot & 0 & a_N i \end{pmatrix},$$

and

$$\sigma_3=\begin{pmatrix} b_1 i & 0 & \cdot & \cdot & 0 & 0 \\ 0 & b_2 i & \cdot & \cdot & 0 & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & 0 & \cdot & \cdot & 0 & b_N i \end{pmatrix}, \tag{48}$$

here $a_1+\cdots+a_N=0$, $a_1,\ldots,a_N\in\mathfrak{R}$, $b_1+\cdots+b_N=0$, $b_1,\ldots,b_N\in\mathfrak{R}$.

The constants $b_1,\ldots,b_N,a_1,\ldots,a_N$ must be chosen in such a way that the matrices σ_1 and σ_3 are linearly independent. We integrate the differential equations $g_{,\lambda}=A_\lambda g$, and $g_{,\tau}=A_\tau g$, we obtain

$$g=\begin{pmatrix} u_{1,1}\exp(a_1 i\lambda+b_1 i\tau) & \cdot & \cdot & \cdot & u_{1,N}\exp(a_1 i\lambda+b_1 i\tau) \\ u_{2,1}\exp(a_2 i\lambda+b_2 i\tau) & \cdot & \cdot & \cdot & u_{2,N}\exp(a_2 i\lambda+b_2 i\tau) \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ u_{N,1}\exp(a_N i\lambda+b_N i\tau) & \cdot & \cdot & \cdot & u_{N,N}\exp(a_N i\lambda+b_N i\tau) \end{pmatrix},$$

where the complex constants satisfy the condition

$$\begin{pmatrix} u_{1,1} & \cdot & \cdot & \cdot & u_{1,N} \\ u_{2,1} & \cdot & \cdot & \cdot & u_{2,N} \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ u_{N,1} & \cdot & \cdot & \cdot & u_{N,N} \end{pmatrix}\in \mathrm{SU}(N). \tag{49}$$

From Eq. (10), we see that the parameters λ and τ satisfy the Laplace equation

$$(\alpha\lambda_{,z})_{,\bar{z}}+(\alpha\lambda_{,\bar{z}})_{,z}=0, \quad (\alpha\tau_{,z})_{,\bar{z}}+(\alpha\tau_{,\bar{z}})_{,z}=0. \tag{50}$$

For each solution λ and τ of the Laplace equation we obtain a new matrix solution for the chiral equations by applying the matrix (49).

B. Three-dimensional subalgebras of su(*N*) and so(*N*)

Let us consider now a nonflat manifold M_2 with constant curvature $k\neq 0$. Let $\lambda^1=x$, $\lambda^2=y$, be the local coordinates of M_2. Then we choose the following metric on M_2,

$$ds^2=\frac{dx^2+dy^2}{[1+k(x^2+y^2)]^2}. \tag{51}$$

The matrices g depend on the coordinates x,y,

$$g=g(x,y), \quad x=x(z,\bar{z}), \quad y=y(z,\bar{z}). \tag{52}$$

For convenience, we perform a transformation from the variables x,y in the complex variables $w,\bar{w}$, defined by

$$w=x+iy, \quad \bar{w}=x-iy. \tag{53}$$

Then the matrices g are functions of the variables $w,\bar{w}$,

$$g=g(w,\bar{w}), \quad w=w(z,\bar{z}), \quad \bar{w}=\bar{w}(z,\bar{z}). \tag{54}$$

Equations (17) and (19), rewritten in terms of the complex variables w and $\overline{w}$, become

$$\nabla_w A_{\overline{w}} + \nabla_{\overline{w}} A_w = 0, \quad \nabla_w A_{\overline{w}} = \tfrac{1}{2}[A_w, A_{\overline{w}}], \quad \nabla_{\overline{w}} A_w = \tfrac{1}{2}[A_{\overline{w}}, A_w]. \tag{55}$$

Metric (51) can be written in terms of the new variables $w, \overline{w}$ as

$$ds^2 = \frac{dw\, d\overline{w}}{(1+kw\overline{w})^2}. \tag{56}$$

The Killing equations for the metric (56) are

$$\epsilon_{w,w} + \frac{2k\overline{w}}{(1+kw\overline{w})}\epsilon_w = 0, \quad \epsilon_{\overline{w},\overline{w}} + \frac{2kw}{(1+kw\overline{w})}\epsilon_{\overline{w}} = 0, \quad \epsilon_{w,\overline{w}} + \epsilon_{\overline{w},w} = 0. \tag{57}$$

Solving the above differential equations, we obtain

$$\epsilon_w = \frac{1}{V^2}(yk\overline{w}^2 + ai\overline{w} + \overline{\gamma}), \quad \epsilon_{\overline{w}} = \frac{1}{V^2}(\overline{\gamma}kw^2 - aiw + \gamma), \tag{58}$$

with

$$V = (1+kw\overline{w}), \quad \gamma \in C, \quad a \in \mathfrak{R}.$$

Now, we choose three linearly independent Killing vectors

$$\phi = \frac{1}{V^2}(\gamma k\overline{w}^2 + \overline{\gamma}, \overline{\gamma}kw^2 + \gamma),$$

$$\xi = \frac{1}{V^2}(-ai\overline{w}, aiw), \tag{59}$$

$$\zeta = \frac{1}{V^2}(\overline{\gamma}k\overline{w}^2 + \gamma, \gamma kw^2 + \overline{\gamma}).$$

Then the matrix vector $A = (A_w, A_{\overline{w}})$ can be written in the form

$$A = \phi\sigma_1 + \xi\sigma_2 + \zeta\sigma_3, \tag{60}$$

where the matrices $A = (A_w, A_{\overline{w}})$ read

$$A_w = \frac{1}{V^2}[(\gamma k\overline{w}^2 + \overline{\gamma})\sigma_1 - ai\overline{w}\sigma_2 + (\overline{\gamma}k\overline{w}^2 + \gamma)\sigma_3],$$

$$A_{\overline{w}} = \frac{1}{V^2}[(\overline{\gamma}kw^2 + \gamma)\sigma_1 + aiw\sigma_2 + (\gamma kw^2 + \overline{\gamma})\sigma_3]. \tag{61}$$

Introducing Eq. (60) in Eq. (55), we obtain the commutation relations for the σ_k matrices,

$$[\sigma_1, \sigma_2] = \sigma_3, \quad [\sigma_2, \sigma_3] = \sigma_3, \quad [\sigma_3, \sigma_1] = \sigma_2, \tag{62}$$

where we have chosen the constants $\gamma = 1 + i$, $a = 2$, $k = \frac{1}{2}$.

The three-dimensional subalgebra of su(N), fulfilling relations (62), is the three-dimensional algebra su(2). A vector basis of the three-dimensional subalgebra of su(N) in terms of the su(2) basis is given by $\{\sigma_1, \sigma_2, \sigma_3\}$, where

$$\sigma_1=\frac{1}{2}\begin{pmatrix} 0 & i & 0 & \cdot & \cdot & 0\\ i & 0 & 0 & \cdot & \cdot & 0\\ 0 & 0 & 0 & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix}, \quad \sigma_2=\frac{1}{2}\begin{pmatrix} 0 & 1 & 0 & \cdot & \cdot & 0\\ -1 & 0 & 0 & \cdot & \cdot & 0\\ 0 & 0 & 0 & \cdot & \cdot & 0\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix},$$
$$\sigma_3=\frac{1}{2}\begin{pmatrix} -i & 0 & 0 & \cdot & \cdot & 0\\ 0 & i & 0 & \cdot & \cdot & 0\\ 0 & 0 & 0 & \cdot & \cdot & 0\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix}. \tag{63}$$

Introducing this basis in (61) we obtain for $A=(A_w,A_{\bar{w}})$,

$$A_w=\frac{i}{2V^2}\begin{pmatrix} -(\bar{\gamma}k\bar{w}^2+\gamma) & (\gamma k\bar{w}^2+\bar{\gamma}-a\bar{w}) & 0 & \cdot & \cdot & 0\\ (\gamma k\bar{w}^2+\bar{\gamma}+a\bar{w}) & (\bar{\gamma}k\bar{w}^2+\gamma) & 0 & \cdot & \cdot & 0\\ 0 & 0 & 0 & \cdot & \cdot & 0\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix},$$
$$A_{\bar{w}}=\frac{i}{2V^2}\begin{pmatrix} -(\gamma kw^2+\bar{\gamma}) & (\bar{\gamma}kw^2+\gamma+aw) & 0 & \cdot & \cdot & 0\\ (\bar{\gamma}kw^2+\gamma-aw) & (\gamma kw^2+\bar{\gamma}) & 0 & \cdot & \cdot & 0\\ 0 & 0 & 0 & \cdot & \cdot & 0\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix}. \tag{64}$$

Now we go into the group SU(N). This can be done by means of the exponential map or by integration. Let us integrate them. We must solve the matrix differential system

$$g_{,w}g^{-1}=A_w, \quad g_{,\bar{w}}g^{-1}=A_{\bar{w}}, \tag{65}$$

writing (65) in components, it is easy to obtain the next $2N^2$-differential equations

$$g_{1i,w}=\frac{i}{2V^2}[-(\bar{\gamma}k\bar{w}^2+\gamma)g_{1i}+(\gamma k\bar{w}^2+\bar{\gamma}-a\bar{w})g_{2i}],$$
$$g_{2i,w}=\frac{i}{2V^2}[(\gamma k\bar{w}^2+\bar{\gamma}+a\bar{w})g_{1i}+(\bar{\gamma}k\bar{w}^2+\gamma)g_{2i}],$$
$$g_{ji,w}=0,$$
$$g_{1i,\bar{w}}=\frac{i}{2V^2}[-(\gamma kw^2+\bar{\gamma})g_{1i}+(\bar{\gamma}kw^2+\gamma+aw)g_{2i}],$$
$$g_{2i,\bar{w}}=\frac{i}{2V^2}[(\bar{\gamma}kw^2+\gamma-aw)g_{1i}+(\gamma kw^2+\bar{\gamma})g_{2i}],$$
$$g_{ji,\bar{w}}=0, \tag{66}$$

where $i=1,2,...,N$, and $j=3,4,...,N$.

This system has the solution

$$g_{1i}(w,\overline{w})=\frac{[2d_{0i}+(\gamma f_{0i}-\overline{\gamma}d_{0i})i\overline{w}+(\overline{\gamma}f_{0i}-\gamma d_{0i})iw-d_{0i}w\overline{w}]}{2(1+kw\overline{w})},$$

$$g_{2i}(w,\overline{w})=\frac{[2f_{0i}+(\gamma f_{0i}+\overline{\gamma}d_{0i})iw+(\overline{\gamma}f_{0i}+\gamma d_{0i})i\overline{w}-f_{0i}w\overline{w}]}{2(1+kw\overline{w})}, \tag{67}$$

$$g_{ji}(w,\overline{w})=c_{ji}, \quad c_{ji}\in\mathbf{C},$$

for $i=1,2,...,N$, and $j=3,4,...,N$.

Because this solution (67) must fulfill the constraint $g^{-1}=g^{\dagger}$, $\det g=1$, the constants d_{0i},f_{0i},c_{ji}, must satisfy,

$$\begin{pmatrix} d_{01} & d_{02} & \cdot & \cdot & \cdot & d_{0N} \\ f_{01} & f_{02} & \cdot & \cdot & \cdot & f_{0N} \\ c_{31} & c_{32} & \cdot & \cdot & \cdot & c_{3N} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ c_{N1} & c_{N2} & \cdot & \cdot & \cdot & c_{NN} \end{pmatrix} \in \mathrm{SU}(N). \tag{68}$$

For the so(N) algebra, the three-dimensional subalgebra that fulfills the relations (62), is the so(3) algebra which has the three basis elements

$$\sigma_1=\begin{pmatrix} 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & -1 & 0 & \cdot & \cdot & 0 \\ 0 & 1 & 0 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix}, \quad \sigma_2=\begin{pmatrix} 0 & 0 & 1 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ -1 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix}, \tag{69}$$

$$\sigma_3=\begin{pmatrix} 0 & -1 & 0 & \cdot & \cdot & \cdot & 0 \\ 1 & 0 & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & 0 & 0 & \cdot & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & \cdot & \cdot & \cdot & 0 \end{pmatrix}.$$

The introduction of the basis (69) in Eq. (61) gives for the matrix vector $A=(A_w,A_{\overline{w}})$

$$A_w=\frac{1}{V^2}\begin{pmatrix} 0 & -(\overline{\gamma}k\overline{w}^2+\gamma) & (-ai\overline{w}) & 0 & \cdot & \cdot & 0 \\ (\overline{\gamma}k\overline{w}^2+\gamma) & 0 & -(\gamma k\overline{w}^2+\overline{\gamma}) & 0 & \cdot & \cdot & 0 \\ (ai\overline{w}) & (\gamma k\overline{w}^2+\overline{\gamma}) & 0 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix},$$

$$(70)$$

$$A_{\overline{w}}=\frac{1}{V^2}\begin{pmatrix} 0 & -(\gamma kw^2+\overline{\gamma}) & (aiw) & 0 & \cdot & \cdot & 0 \\ (\gamma kw^2+\overline{\gamma}) & 0 & -(\overline{\gamma}kw^2+\gamma) & 0 & \cdot & \cdot & 0 \\ (-aiw) & (\overline{\gamma}kw^2+\gamma) & 0 & 0 & \cdot & \cdot & 0 \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & 0 & 0 & \cdot & \cdot & 0 \end{pmatrix}.$$

Again, we must integrate Eq. (65) in order to obtain the elements of the group. We obtain the $2N^2$-differential equations

$$g_{1i,w}=\frac{1}{V^2}[-(\overline{\gamma}k\overline{w}^2+\gamma)g_{2i}-(ai\overline{w})g_{3i}],$$

$$g_{2i,w}=\frac{1}{V^2}[(\overline{\gamma}k\overline{w}^2+\gamma)g_{1i}-(\gamma k\overline{w}^2+\overline{\gamma})g_{3i}],$$

$$g_{3i,w}=\frac{1}{V^2}[(ai\overline{w})g_{1i}+(\gamma k\overline{w}^2+\overline{\gamma})g_{2i}],$$

$$g_{ji,w}=0,$$

$$g_{1i,\overline{w}}=\frac{1}{V^2}[-(\gamma kw^2+\overline{\gamma})g_{2i}+(aiw)g_{3i}],$$

$$g_{2i,\overline{w}}=\frac{1}{V^2}[(\gamma kw^2+\overline{\gamma})g_{1i}-(\overline{\gamma}kw^2+\gamma)g_{3i}],$$

$$g_{3i,\overline{w}}=\frac{1}{V^2}[-(aiw)g_{1i}+(\overline{\gamma}kw^2+\gamma)g_{2i}],$$

$$g_{ji,\overline{w}}=0,$$

where $i=1,2,...,N$, and $j=4,...,N$.

This system has a solution given by

$$g_{1i}(w,\overline{w})=\Bigg[d_{0i}-d_{0i}w\overline{w}-f_{0i}\gamma w-\overline{\gamma}f_{0i}\overline{w}+(e_{0i}-id_{0i})w^2+(e_{0i}+id_{0i})\overline{w}^2+\frac{\gamma f_{0i}}{2}w^2\overline{w}$$
$$+\frac{\overline{\gamma}f_{0i}}{2}\overline{w}^2w+\frac{d_{0i}}{4}\overline{w}^2w^2\Bigg]\Bigg/(1+kw\overline{w})^2,$$

$$g_{2i}(w,\overline{w})=\Bigg[f_{0i}-3f_{0i}w\overline{w}-(e_{0i}-id_{0i})\overline{\gamma}w-(e_{0i}+id_{0i})\gamma\overline{w}+\frac{\overline{\gamma}}{2}(e_{0i}-id_{0i})\overline{w}w^2$$
$$+\frac{\gamma}{2}(e_{0i}+id_{0i})w\overline{w}^2+\frac{f_{0i}}{4}\overline{w}^2w^2\Bigg]\Bigg/(1+kw\overline{w})^2,$$
$$(71)$$
$$g_{3i}(w,\overline{w})=\Bigg[e_{0i}-e_{0i}w\overline{w}+\overline{\gamma}f_{0i}w+\gamma f_{0i}\overline{w}+i(e_{0i}-id_{0i})w^2-i(e_{0i}+id_{0i})\overline{w}^2-\frac{\overline{\gamma}}{2}f_{0i}\overline{w}w^2$$
$$-\frac{\gamma}{2}f_{0i}w\overline{w}^2+\frac{e_{0i}}{4}\overline{w}^2w^2\Bigg]\Bigg/(1+kw\overline{w})^2,$$

$$g_{ji}(w,\overline{w})=c_{ji},\quad c_{ji}\in\Re$$

for $i=1,2,...,N$, and $j=4,...,N$.

The solution (71) must fulfill the constraints $g^{-1}=g^T$, $\det g=1$, which implies that the constants d_{0i}, f_{0i}, c_{ji}, must satisfy

$$\begin{pmatrix} d_{01} & d_{02} & \cdot & \cdot & \cdot & d_{0N}\\ f_{01} & f_{02} & \cdot & \cdot & \cdot & f_{0N}\\ e_{01} & e_{02} & \cdot & \cdot & \cdot & e_{0N}\\ c_{41} & c_{42} & \cdot & \cdot & \cdot & c_{4N}\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot\\ c_{N1} & c_{N2} & \cdot & \cdot & \cdot & c_{NN}\end{pmatrix}\in SO(N). \qquad (72)$$

The complex parameters w, $\overline{w}$ must satisfy the harmonic equation in M_2 given by

$$(\alpha w_{,z})_{,\overline{z}}+(\alpha w_{,\overline{z}})_{,z}-\frac{4\alpha k\overline{w}}{(1+kw\overline{w})}w_{,z}w_{,\overline{z}}=0,$$
$$(73)$$
$$(\alpha\overline{w}_{,z})_{,\overline{z}}+(\alpha\overline{w}_{,\overline{z}})_{,z}-\frac{4\alpha kw}{(1+kw\overline{w})}\overline{w}_{,z}\overline{w}_{,\overline{z}}=0.$$

For each solution of Eq. (73), we get a new solution, g, of the chiral equations given by (67) for SU(N), and by (71) for SO(N).

V. CONCLUSIONS

We have found three classes of exact solutions of the SU(N)- and SO(N)-chiral equations (3). The first class depends on a harmonic map which corresponds to a one-dimensional Riemannian space. Any one-dimensional space is flat, and its harmonic functions are solutions of the Laplace equation (36). For the two-dimensional Riemannian spaces we found two classes depending on two harmonic maps, which are the local coordinates of the two-dimensional symmetric Riemannian space M_2. All the two-dimensional Riemannian spaces are conformally flat, and all the two-dimensional symmetric spaces have constant curvature. The first two-dimensional class has zero curvature and it is flat, while the second class has nonzero curvature. This last class corresponds to the three-dimensional subalgebras of su(N) and so(N), they can be put in terms of the su(2) and so(3) respective vector space basis. For the flat two-dimensional class, the harmonic maps correspond to a system of two decoupled Laplace equations, while for the nonflat class, the harmonic maps are minimal surfaces on a two-dimensional Riemannian space with positive curvature. The corresponding group elements can be found by the exponential map or by integration. We have integrated all the group elements to obtain explicit expressions of the chiral field in terms of the harmonic maps.

q-Trinomial identities

S. Ole Warnaar[a)]
Instituut voor Theoretische Fysica, Universiteit van Amsterdam, Valckenierstraat 65, 1018 XE Amsterdam, The Netherlands

(Received 10 November 1998; accepted for publication 8 December 1998)

We obtain connection coefficients between q-binomial and q-trinomial coefficients. Using these, one can transform q-binomial identities into q-trinomial identities and back again. To demonstrate the usefulness of this procedure we rederive some known trinomial identities related to partition theory and prove many of the conjectures of Berkovich, McCoy and Pearce, which have recently arisen in their study of the $\phi_{2,1}$ and $\phi_{1,5}$ perturbations of minimal conformal field theory. © *1999 American Institute of Physics.* [S0022-2488(99)01105-6]

I. INTRODUCTION

The q-binomial coefficients can be defined by the q-analog of Newton's binomial expansion,

$$(1+x)(1+qx)\cdots(1+q^{n-1}x)=\sum_{a=0}^{n} x^a q^{a(a-1)/2}\begin{bmatrix} n \\ a \end{bmatrix}. \tag{1}$$

An explicit expression for the q-binomial coefficients is given by

$$\begin{bmatrix} n \\ a \end{bmatrix}_q=\begin{bmatrix} n \\ a \end{bmatrix}=\begin{cases} \dfrac{(q)_n}{(q)_a(q)_{n-a}} & \text{for } 0\leqslant a\leqslant n, \\ 0, & \text{otherwise,} \end{cases}$$

where

$$(q)_n=\prod_{j=1}^{n}(1-q^j), \quad n\geqslant 1 \quad \text{and} \quad (q)_0=1.$$

q-Binomials play an essential role in combinatorics, partition theory, and statistical mechanics; see, e.g., Refs. 1–4, and one of MacMahon's famous results is that $\begin{bmatrix} n+m \\ m \end{bmatrix}$ is the generating function of partitions with no more than m parts, no part exceeding n. Less well understood are the q-trinomial coefficients, defined as q-analogs of the numbers appearing in the generalized Pascal triangle

$$\begin{array}{ccccccccc} & & & & 1 & & & & \\ & & & 1 & 1 & 1 & & & \\ & & 1 & 2 & 3 & 2 & 1 & & \\ & 1 & 3 & 6 & 7 & 6 & 3 & 1 & \\ . & . & . & . & . & . & . & . & . \end{array}. \tag{2}$$

Andrews, Baxter, and Forrester[5,6] were the first to encounter q-trinomial coefficients, and in Ref. 6 Andrews and Baxter defined

[a)]Electronic mail: warnaar@wins.uva.nl

$$\begin{bmatrix} L,b;q \\ a \end{bmatrix}_2 = \begin{bmatrix} L,b \\ a \end{bmatrix}_2 = \sum_{k\geqslant 0} q^{k(k+b)} \begin{bmatrix} L \\ k \end{bmatrix} \begin{bmatrix} L-k \\ k+a \end{bmatrix} \tag{3}$$

and

$$T_n(L,a;q) = T_n(L,a) = q^{(L-a)(L+a-n)/2} \begin{bmatrix} L,a-n;q^{-1} \\ a \end{bmatrix}_2 . \tag{4}$$

The q-trinomial T_n can be expressed explicitly as

$$T_n(L,a) = \sum_{\substack{r=0 \\ L-a-r \text{ even}}}^{L-|a|} \frac{q^{r(r-n)/2}(q)_L}{(q)_{(L-a-r)/2}(q)_{(L+a-r)/2}(q)_r} . \tag{5}$$

Clearly, the q-trinomial coefficients are nonzero for $a=-L,-L+1,...,L$ only and satisfy the symmetries

$$\begin{bmatrix} L,b;q \\ a \end{bmatrix}_2 = q^{a(a-b)} \begin{bmatrix} L,b-2a \\ -a \end{bmatrix}_2 \quad \text{and} \quad T_n(L,a) = T_n(L,-a).$$

To see that (3) indeed defines q-analogs of the trinomial coefficients, set $q=1$ and twice apply the binomial formula to find that

$$\sum_{a=-L}^{L} x^a \begin{bmatrix} L,b;1 \\ a \end{bmatrix}_2 = (1+x+x^{-1})^L,$$

in accordance with (2). The only further properties of q-trinomials needed in this paper are the limiting formulas[6]

$$\lim_{\substack{L\to\infty \\ L-a \text{ even}}} T_0(L,a) = \frac{(-q^{1/2})_\infty + (q^{1/2})_\infty}{2(q)_\infty}, \tag{6}$$

$$\lim_{\substack{L\to\infty \\ L-a \text{ odd}}} T_0(L,a) = \frac{(-q^{1/2})_\infty - (q^{1/2})_\infty}{2(q)_\infty}, \tag{7}$$

and

$$\lim_{L\to\infty} \begin{bmatrix} L,a \\ a \end{bmatrix}_2 = \frac{1}{(q)_\infty} . \tag{8}$$

Finally, we introduce the abbreviation

$$\begin{bmatrix} L,a \\ a \end{bmatrix}_2 = \begin{bmatrix} L \\ a \end{bmatrix}_2 .$$

Since their discovery about a decade ago, q-trinomials have found numerous applications in, again, combinatorics, partition theory, and statistical mechanics.[5–23] Among the most striking results is a q-trinomial proof of Schur's partition theorem and Capparelli's (then) conjecture,[9] a q-trinomial proof of the Göllnitz–Gordon partition theorem[7] and their Andrews–Bressoud generalizations,[13,16] the proof of an E_8 Rogers–Ramanujan-type identity,[10] and a trinomial analog of Bailey's lemma.[19]

Most of the above-cited papers contain q-trinomial identities. Upon close inspection of many of these identities, one is struck by their similarity with well-known q-binomial identities. This strongly suggests that many q-trinomial identities can be simply viewed as corollaries of q-binomial identities. In an earlier paper[23] we made a first, only partially successful, attempt to relate q-trinomial identities to q-binomial identities, showing that each Bailey pair (which implies a q-binomial identity) implies a trinomial Bailey pair (which implies a q-trinomial identity). The problem with the idea of Ref. 23 is that it applies to q-trinomial identities in which the parameter a in (3) and (4) takes even values only. Therefore, q-trinomial identities in which a takes arbitrary integer values remained irreducible to q-binomial identities.

In this paper we intend to deal with this problem, and in the next section connection coefficients between q-binomial and q-trinomial coefficients are obtained. Using these coefficients and the idea of Ref. 23, many q-trinomial identities are derived from known q-binomial identities. In Sect. III, several q-trinomial identities related to partitions are obtained and in Sec. IV general classes of q-trinomial identities are proved, including many of the recent conjectures of Berkovich, McCoy, and Pearce.[21] To make contact with the recently discovered trinomial analog of Bailey's lemma, our results are finally formulated in the language of Bailey pairs in Sec. V. In the Appendix some necessary formulas for q-binomial coefficients are collected.

II. CONNECTION COEFFICIENTS

To relate q-binomials and q-trinomials, we consider the simple problem of finding the coefficients $C_{L,k}$ and $C'_{L,k}$, such that

$$T_0(L,a)=\sum_{k=0}^{L} C_{L,k}(a)\begin{bmatrix}2k\\ k-a\end{bmatrix} \tag{9}$$

and

$$\begin{bmatrix}2L\\ L-a\end{bmatrix}=\sum_{k=0}^{L} C'_{L,k}(a)T_0(k,a). \tag{10}$$

Of course, the two equations imply that

$$\sum_{k=M}^{L} C_{L,k}(a)C'_{k,M}(a)=\delta_{L,M}. \tag{11}$$

The answer to the above connection coefficient problem is given by the following lemma.

Lemma II.1: For $C_{L,k}$ and $C'_{L,k}$ as above,

$$C_{L,k}(a)=(-1)^{L-k}q^{\binom{L-k}{2}+(a^2-L^2)/2}\begin{bmatrix}L\\ k\end{bmatrix}, \tag{12}$$

$$C'_{L,k}(a)=q^{(k^2-a^2)/2}\begin{bmatrix}L\\ k\end{bmatrix}. \tag{13}$$

Proof: Substitution of the expression for $C'_{L,k}$ into the right-hand side of (10) and using Eq. (5) for T_0 gives

$$\sum_{k=0}^{L} C'_{L,k}(a)T_0(k,a)=\sum_{k=0}^{L}\sum_{\substack{r=0\\ k-a-r\ \text{even}}}^{k-|a|}\frac{q^{(k^2-a^2+r^2)/2}(q)_L}{(q)_{L-k}(q)_{(k-a-r)/2}(q)_{(k+a-r)/2}(q)_r}.$$

To proceed, we introduce new summation variables i,j defined by $k=i+j+a$ and $r=i-j$, and apply the q-Chu–Vandermonde sum, i.e.,

$$\sum_{k=0}^{L} C'_{L,k}(a)T_0(k,a)=\sum_{i=0}^{L}\sum_{j=0}^{i} q^{i(i+a)+j(j+a)}\begin{bmatrix}L\\i\end{bmatrix}\begin{bmatrix}i\\j\end{bmatrix}\begin{bmatrix}L-i\\j+a\end{bmatrix} \overset{\text{by (A1)}}{=} \sum_{i=0}^{L} q^{i(i+a)}\begin{bmatrix}L\\i\end{bmatrix}\begin{bmatrix}L\\i+a\end{bmatrix}$$

$$\overset{\text{by (A1)}}{=} \begin{bmatrix}2L\\L-a\end{bmatrix}.$$

This settles (13), and to prove (12) we show that (11) holds. Taking the left-hand side of (11) and substituting the claim of the lemma, we find

$$\sum_{k=M}^{L} C_{L,k}(a)C'_{k,M}(a)=\sum_{k=M}^{L}(-1)^{L-k}q^{\binom{L-k}{2}+(M^2-L^2)/2}\begin{bmatrix}L\\k\end{bmatrix}\begin{bmatrix}k\\M\end{bmatrix}$$

$$=q^{(M^2-L^2)/2}\begin{bmatrix}L\\M\end{bmatrix}\sum_{k=0}^{L-M}(-1)^k q^{\binom{k}{2}}\begin{bmatrix}L-M\\k\end{bmatrix}=\delta_{L,M},$$

where in the last step we have used (1) with $x=-1$. □

We note that a proof of (12) that does not rely on (13) is implied by Eqs. (2.12) and (2.35) of Ref. 6.

The analogous result involving T_1 instead of T_0 can be stated as follows. Define $D_{L,k}$ and $D'_{L,k}$ by

$$T_1(L,a)=\sum_{k=0}^{L} D_{L,k}(a)\begin{bmatrix}2k\\k-a\end{bmatrix}$$

and

$$\begin{bmatrix}2L\\L-a\end{bmatrix}=\sum_{k=0}^{L} D'_{L,k}(a)T_1(k,a). \tag{14}$$

Lemma II.2: For $D_{L,k}$ and $D'_{L,k}$ as above,

$$D_{L,k}(a)=(-1)^{L-k}q^{\binom{L-k}{2}+\binom{a}{2}-\binom{L}{2}}\frac{1+q^a}{1+q^k}\begin{bmatrix}L\\k\end{bmatrix}, \tag{15}$$

$$D'_{L,k}(a)=q^{\binom{k}{2}-\binom{a}{2}}\frac{1+q^L}{1+q^a}\begin{bmatrix}L\\k\end{bmatrix}. \tag{16}$$

Proof: Following the proof of Lemma II.1 with T_0 replaced by T_1, one finds after application of the q-Chu–Vandermonde sum (A1), that the right-hand side of (14) is equal to

$$\frac{1+q^L}{1+q^a}\sum_{i=0}^{L} q^{i(i+a-1)}\begin{bmatrix}L\\i\end{bmatrix}\begin{bmatrix}L\\i+a\end{bmatrix}.$$

Before (A1) can again be applied, the recurrence (A5) is needed to rewrite this as

$$\frac{1+q^L}{1+q^a}\left\{\sum_{i=0}^{L} q^{i(i+a-1)}\begin{bmatrix}L\\i\end{bmatrix}\begin{bmatrix}L-1\\i+a-1\end{bmatrix}+q^a\sum_{i=0}^{L} q^{i(i+a)}\begin{bmatrix}L\\i\end{bmatrix}\begin{bmatrix}L-1\\i+a\end{bmatrix}\right\}.$$

Using (A1) and combining terms gives $\left[\begin{smallmatrix}2L\\L-a\end{smallmatrix}\right]$. To prove (15) it again suffices to consider $\Sigma_{k=M}^{L} D_{L,k}(a)D'_{k,M}(a)$. After substituting the results for D and D' and replacing $k\to L-k$, one finds that this becomes $\delta_{L,M}$ after using (1) with $x=-1$. □

To conclude this section, we note that the representations (3) and (5) for the q-trinomial coefficients can also be written as a relation between q-trinomials and q-binomials. That is,

$$T_n(L,2a)=\sum_{k\geqslant 0} q^{(L-2k)(L-2k-n)/2}\begin{bmatrix} L \\ 2k \end{bmatrix}\begin{bmatrix} 2k \\ k-a \end{bmatrix} \tag{17}$$

and

$$\begin{bmatrix} L,b \\ 2a \end{bmatrix}_2=\sum_{k\geqslant 0} q^{(k-a)(k-a+b)}\begin{bmatrix} L \\ 2k \end{bmatrix}\begin{bmatrix} 2k \\ k-a \end{bmatrix}. \tag{18}$$

These results, which, unlike the previous transformations are not invertible, will be needed later.

III. SIMPLE EXAMPLES FROM PARTITION THEORY

Before proving general series of q-trinomial identities using the results of the previous section, we treat some simple examples related to partition identities first.

The first example concerns the following result of Andrews[7] (see also Ref. 21). It is well known[24] that the (first) Rogers–Ramanujan identity can be obtained as a limiting case of the polynomial identity,

$$\sum_{n\geqslant 0} q^{n^2}\begin{bmatrix} L-n \\ n \end{bmatrix}=\sum_{j=-\infty}^{\infty} (-1)^j q^{j(5j+1)/2}\begin{bmatrix} L \\ (L-5j)/2 \end{bmatrix}. \tag{19}$$

Here the polynomials appearing on either side are known to be the generating function of partitions with the difference between parts of at least two and the largest part not exceeding $L-1$.[4,25] In Ref. 7, Andrews remarks that it is "most surprising and intriguing" that the following also holds:

$$\sum_{n\geqslant 0} q^{n^2}\begin{bmatrix} L-n \\ n \end{bmatrix}=\sum_{j=-\infty}^{\infty}\left\{ q^{j(10j+1)}\begin{bmatrix} L \\ 5j \end{bmatrix}_2 - q^{(2j+1)(5j+2)}\begin{bmatrix} L \\ 5j+2 \end{bmatrix}_2\right\}. \tag{20}$$

We now show that (20) is a corollary of (19), or for those who prefer to decrease instead of increase complexity, that (19) is a corollary of (20). Replacing $q\to 1/q$ in (9) and (12), using (4) and (A7), we find that [see also Ref. 6, Eqs. (2.12) and (2.35)]

$$\begin{bmatrix} L \\ a \end{bmatrix}_2=\sum_{k=0}^{L} (-1)^{L-k} q^{(L-k)(L+k+1)/2}\begin{bmatrix} L \\ k \end{bmatrix}\begin{bmatrix} 2k \\ k-a \end{bmatrix}.$$

If we thus take (19) with L replaced by $2k$, multiply by $(-1)^{L-k}q^{(L-k)(L+k+1)/2}\left[\begin{smallmatrix} L \\ k \end{smallmatrix}\right]$ and sum over k, we arrive at

$$\sum_{k\geqslant 0}\sum_{n\geqslant 0} (-1)^{L-k} q^{(L-k)(L+k+1)/2+n^2}\begin{bmatrix} L \\ k \end{bmatrix}\begin{bmatrix} 2k-n \\ n \end{bmatrix}$$
$$=\sum_{j=-\infty}^{\infty}\left\{ q^{j(10j+1)}\begin{bmatrix} L \\ 5j \end{bmatrix}_2 - q^{(2j+1)(5j+1)}\begin{bmatrix} L \\ 5j+2 \end{bmatrix}_2\right\}.$$

To simplify the left-hand side, we set $k=L-m+n$ followed by $n\to m-n$ to get

$$\sum_{m\geqslant 0} q^{m^2}\sum_{n\geqslant 0} (-1)^n q^{\binom{n}{2}+n(L-2m+1)}\begin{bmatrix} L \\ n \end{bmatrix}\begin{bmatrix} 2L-m-n \\ m-n \end{bmatrix}=\sum_{m\geqslant 0} q^{m^2}\begin{bmatrix} L-m \\ m \end{bmatrix},$$

where the sum over n has been performed using the q-Chu–Vandermonde summation (A3). As remarked before, one can equally well take the reverse route and starting from (20), using Lemma II.1, one readily obtains (19). We leave this to the reader.

Our second example concerns the following identity of Slater[26] related to the (first) Göllnitz–Gordon partition identity:[27,28]

$$\sum_{n=0}^{\infty} \frac{q^{n^2}(-q;q^2)_n}{(q^2;q^2)_n} = \prod_{n=0}^{\infty} \frac{1}{(1-q^{8j+1})(1-q^{8j+4})(1-q^{8j+7})}. \tag{21}$$

A polynomial identity that implies this equation is given by[13,16]

$$\sum_{m,n\geqslant 0} q^{(m^2+n^2)/2} \begin{bmatrix} L-m \\ n \end{bmatrix} \begin{bmatrix} n \\ m \end{bmatrix} = \sum_{j=-\infty}^{\infty} (-1)^j q^{2j^2+j/2} \{T_0(L,4j)+T_0(L,4j+1)\}. \tag{22}$$

It was observed in Ref. 7 that for fixed L the polynomial appearing on the right-hand side with q replaced by q^2 is the generating function of partitions $\lambda=(\lambda_1,\lambda_2,\ldots)$ with $\lambda_i-\lambda_{i+1}\geqslant 2$ for λ_i odd, $\lambda_i-\lambda_{i+1}\geqslant 3$ for λ_i even, and with the largest part not exceeding $2L-1$. To see that (22) indeed implies (21), let L tend to infinity using (6), (7), and (A6). Hence,

$$\sum_{m,n\geqslant 0} \frac{q^{(m^2+n^2)/2}}{(q)_n} \begin{bmatrix} n \\ m \end{bmatrix} = \frac{(-q^{1/2})_\infty}{(q)_\infty} \sum_{j=-\infty}^{\infty} (-1)^j q^{2j^2+j/2}.$$

Using Jacobi's triple product identity [Eq. (2.2.10) of Ref. 1] and Eq. (1) with $x=q^{1/2}$ gives

$$\sum_{n\geqslant 0} \frac{q^{n^2/2}(-q^{1/2})_n}{(q)_n} = \frac{(-q^{1/2})_\infty (q^{3/2};q^4)_\infty (q^{5/2};q^4)_\infty (q^4;q^4)_\infty}{(q)_\infty}.$$

Letting $q\to q^2$ and cleaning up the right-hand side finally yields (21).

The companion q-binomial identity of (22) is given by the following identity of Refs. 29 and 30:

$$\sum_{\substack{m_1,m_2\geqslant 0\\ m_1+m_2 \text{ even}}} q^{(m_1^2+m_2^2)/4} \begin{bmatrix} L+\frac{1}{2}(m_1-m_2) \\ m_1 \end{bmatrix} \begin{bmatrix} \frac{1}{2}(m_1+m_2) \\ m_2 \end{bmatrix} = \sum_{j=-\infty}^{\infty} (-1)^j \left\{ q^{j(20j+1)/2} \begin{bmatrix} 2L \\ L-4j \end{bmatrix} + q^{(4j+1)(5j+1)/2} \begin{bmatrix} 2L \\ L-4j-1 \end{bmatrix} \right\}.$$

To prove this we replace L by k, multiply by $q^{-a^2/2}C_{L,k}(a)$ as given by (12), and sum over k using (9). The resulting equation is

$$\begin{aligned} &\sum_{j=-\infty}^{\infty} (-1)^j q^{2j^2+j/2} \{T_0(L,4j)+T_0(L,4j+1)\} \\ &= \sum_{\substack{m_1,m_2\geqslant 0\\ m_1+m_2 \text{ even}}} q^{(m_1^2+m_2^2-2L^2)/4} \begin{bmatrix} \frac{1}{2}(m_1+m_2) \\ m_2 \end{bmatrix} \sum_{k=0}^{L} (-1)^k q^{\binom{k}{2}} \begin{bmatrix} L \\ k \end{bmatrix} \begin{bmatrix} L-k+\frac{1}{2}(m_1-m_2) \\ m_1 \end{bmatrix} \\ &\overset{\text{by (A2)}}{=} \sum_{\substack{m_1,m_2\geqslant 0\\ m_1+m_2 \text{ even}}} q^{((m_1-L)^2+(m_2-L)^2)/4} \begin{bmatrix} \frac{1}{2}(m_1+m_2) \\ m_2 \end{bmatrix} \begin{bmatrix} \frac{1}{2}(m_1-m_2) \\ m_1-L \end{bmatrix}. \end{aligned}$$

Making the variable change $m_1\to L+n-m$ and $m_2\to L-n-m$, we find Eq. (22).

IV. *q*-TRINOMIAL IDENTITIES

After the previous examples, we now derive general classes of q-trinomial identities, as stated in Propositions IV.1–IV.5 below. The setup will be as follows. First we describe a family of q-binomial identities for bounded analogs of Virasoro characters, based on continued fraction expansions. We then transform these identities into q-trinomial identities, by either using (9) or (18). Many of the q-trinomial identities available in the literature are contained in Propositions IV.1–IV.5 or can be derived in a completely analogous fashion.

A. *q*-binomial identities for bounded Virasoro characters

Using the inclusion–exclusion construction of Feigin and Fuchs,[31] the (normalized) characters of the Virasoro algebra of central charge $c=1-6(p'-p)^2/pp'$, with p,p' integers such that $1<p<p'$ and $\gcd(p,p')=1$, are given by[32,33]

$$\chi_{r,s}^{(p,p')}(q)=\frac{1}{(q)_\infty}\sum_{j=-\infty}^{\infty}\{q^{j(pp'j+p'r-ps)}-q^{(pj+r)(p'j+s)}\}.$$

Here $r=1,...,p-1$ and $s=1,...,p'-1$ label the highest weight representations.

For simplicity we only deal with the ''vacuum'' character, determined by $|p'r-ps|=1$. The following polynomial analogs of the vacuum Virasoro characters have arisen in the context of statistical mechanics[34,35] and partition theory,[36]

$$B_L(p,p';q)=\sum_{j=-\infty}^{\infty}\left\{q^{j(pp'j+1)}\begin{bmatrix}2L\\L-p'j\end{bmatrix}-q^{(pj+r)(p'j+s)}\begin{bmatrix}2L\\L-p'j-s\end{bmatrix}\right\}. \tag{23}$$

The polynomials $B_L(p,p')$ are known to be related to the minimal conformal field theory $M(p,p')$ perturbed by the operator $\phi_{1,3}$.

Recently, very different, so-called fermionic representations for the above polynomials have been obtained by Berkovich, McCoy and Schilling using continued fractions.[29,30] Assume $p<p'<2p$, $\gcd(p,p')=1$ and define non-negative integers n and $\nu_0,\ldots,\nu_n$ by the continued fraction expansion

$$\frac{p}{p'-p}=\nu_0+\cfrac{1}{\nu_1+\cfrac{1}{\nu_2+\cdots+\cfrac{1}{\nu_n+2}}}=[\nu_0,\ldots,\nu_{n-1},\nu_n+2].$$

Using n and ν_j, set

$$t_m=\sum_{j=0}^{m-1}\nu_j,\quad 1\le m\le n\quad\text{and}\quad d=\sum_{j=0}^{n}\nu_j. \tag{24}$$

The t_m and d are used to define a fractional incidence matrix $\mathcal{I}$ and a fractional Cartan-type matrix $2B=2I-\mathcal{I}$ (with I the d by d unit matrix) as follows:

$$\mathcal{I}_{i,j}=\begin{cases}\delta_{i,j+1}+\delta_{i,j-1}, & \text{for } 1\le i<d,\quad i\ne t_m,\\ \delta_{i,j+1}+\delta_{i,j}-\delta_{i,j-1}, & \text{for } i=t_m,\quad 1\le m\le n-\delta_{\nu_n,0},\\ \delta_{i,j+1}+\delta_{\nu_n,0}\delta_{i,j}, & \text{for } i=d.\end{cases} \tag{25}$$

When $p'=p+1$, the incidence matrix $\mathcal{I}$ has components $\mathcal{I}_{i,j}=\delta_{|i-j|,1}$ $(i,j=1,...,p-2)$, so that $2B$ corresponds to the Cartan matrix of the Lie algebra A_{p-3}. When $p=2k-1$ and $p'=2k+1$ the matrix $\mathcal{I}$ has components $\mathcal{I}_{i,j}=\delta_{|i-j|,1}+\delta_{i,j}\delta_{i,k-1}$ $(i,j=1,...,k-1)$, so that $2B$ corresponds to the Cartan-type matrix of the tadpole graph of $k-1$ nodes.

Using the above definition, the fermionic representation for the bounded Virasoro characters with $p<p'<2p$ can be given as

$$F_L(p,p';q)=\sum_{m\in 2\mathbb{Z}^d} q^{mBm/2}\prod_{j=1}^{d}\begin{bmatrix} L\,\delta_{j,1}+\frac{1}{2}(\mathcal{I}m)_j \\ m_j\end{bmatrix}. \tag{26}$$

Here we use the notations $vMw=\Sigma_{j,k}v_jM_{j,k}w_k$, $(Mv)_j=\Sigma_k M_{j,k}v_k$ and $(vM)_j=\Sigma_k v_k M_{k,j}$. These conventions are important since, generally, $M(=\mathcal{I},B)$ is not a symmetric matrix. The general form (26) for $F_L(p,p')$ can be found in Refs. 29 and 30 (see also Ref. 37). The important special cases $(p,p')=(p,p+1)$ and $(2k-1,2k+1)$ were proven prior to this is in Refs. 38, 39 and Ref. 40, respectively.

The expression for $F_L(p,p';q)$ with $p'>2p$ follows from the duality transformation

$$F_L(p,p';1/q)=q^{-L^2}F_L(p'-p,p';q). \tag{27}$$

To obtain fermionic character formulas for $\chi_{r,s}^{(p,p')}(q)$ with $|p'r-ps|=1$, one simply lets L tend to infinity in (26).

Before we proceed to use the identity,

$$F_L(p,p';q)=B_L(p,p';q), \tag{28}$$

to derive trinomial identities, let us comment on the convention of writing $2B$ for a Cartan-type matrix in the above formulas. This has its origin in the work of Ref. 41, where, in more general situations, the matrix B has a (nontrivial) tensor product structure, $B=b_1\otimes b_2$. In the identities of this section the matrix b_1 is simply the inverse of the A_1 Cartan matrix, $(b_1)=(\frac{1}{2})$. In Sec. IV D, however, we indeed encounter a different situation, b_1 being the (still trivial) Cartan-type matrix of the tadpole graph with just a single node, so that $b_1=(1)$.

B. *q*-trinomial identities I

We start with the q-binomial identity (28) for $p<p'<2p$, assuming that $d\geqslant 2$. Applying Eq. (9), with $C_{L,k}$ given by (12), we find

$$\begin{aligned}
&\sum_{j=-\infty}^{\infty}\{q^{(p'(2p-p')j+2)j/2}T_0(L,p'j)-q^{((2p-p')j+2r-s)(p'j+s)/2}T_0(L,p'j+s)\}\\
&\quad=\sum_{k=0}^{L}(-1)^{L-k}q^{\binom{L-k}{2}-L^2/2}\begin{bmatrix}L\\k\end{bmatrix}F_k(p,p';q)\\
&\quad=\sum_{m\in 2\mathbb{Z}^d}q^{(mBm-L^2)/2}\left(\prod_{j=2}^{d}\begin{bmatrix}\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix}\right)\sum_{k=0}^{L}(-1)^k q^{\binom{k}{2}}\begin{bmatrix}L\\k\end{bmatrix}\begin{bmatrix}L-k+\frac{1}{2}(\mathcal{I}m)_1\\ m_1\end{bmatrix}\\
&\quad\overset{\text{by (A2)}}{=}q^{L^2/2}\sum_{m\in 2\mathbb{Z}^d}q^{mBm/2-L(Bm)_1}\begin{bmatrix}\frac{1}{2}(\mathcal{I}m)_1\\ m_1-L\end{bmatrix}\prod_{j=2}^{d}\begin{bmatrix}\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix}\\
&\quad=q^{L^2\mathcal{I}_{1,1}/2}\sum_{m+Le_1\in 2\mathbb{Z}^d}q^{mBm/2+L(mB-Bm)_1/2}\prod_{j=1}^{d}\begin{bmatrix}\frac{1}{2}L\mathcal{I}_{j,1}+\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix},
\end{aligned}$$

with e_j $(j=1,...,d)$ the standard unit vectors in $\mathbb{Z}^d$. We now have to distinguish two cases according to whether $\nu_0=1$ (so that $3p/2<p'<2p$) or $\nu_0>1$ (so that $p<p'\leqslant 3p/2$). In the latter case $\mathcal{I}_{1,j}=\mathcal{I}_{j,1}=\delta_{1,j-1}$, and we obtain the following polynomial identities.

Proposition IV.1: For integers p,p′ with $p<p'\leqslant 3p/2$ *and* $\gcd(p,p')=1$, *let integers* $1\leqslant r<p$ *and* $1\leqslant s<p'$ *be fixed by* $|p'r-ps|=1$ *and let* $\mathcal{I}$ *and B be defined by (24) and (25). Then the following polynomial identity holds for* $L\in\mathbb{Z}$:

$$\sum_{m+Le_1\in 2\mathbb{Z}^d} q^{mBm/2}\prod_{j=1}^{d}\begin{bmatrix}\frac{1}{2}L\,\delta_{j,2}+\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix}$$
$$=\sum_{j=-\infty}^{\infty}\{q^{(p'(2p-p')j+2)j/2}T_0(L,p'j)-q^{((2p-p')j+2r-s)(p'j+s)/2}T_0(L,p'j+s)\}.$$

The admissible pairs $(p,p')=(3,4)$ and $(p,p')=(2,3)$ have been neglected in our derivation due to the assumption that $d\geqslant 2$. These two cases can be treated in a similar fashion, and when $(p,p')=(3,4)$ the left-hand side is 1 for L even and 0 for L odd. When $(p,p')=(2,3)$, in which case $F_L(2,3;q)=1$, the left-hand side becomes $\delta_{L,0}$. All of the identities of Proposition IV.1 have been derived before, and for $p'=p+1$ they were first found by Schilling.[42,14] The more general case can be found in Ref. 22.

Next we treat the case $\nu_0=1$. When this occurs $\mathcal{I}_{1,j}=\delta_{j,1}-\delta_{1,j-1}$ and $\mathcal{I}_{j,1}=\delta_{j,1}+\delta_{1,j-1}$, and we obtain the following polynomial identities.

Proposition IV.2: For integers p,p′ with $3p/2<p'<2p$ *and* $\gcd(p,p')=1$ *let integers* $1\leqslant r<p$ *and* $1\leqslant s<p'$ *be fixed by* $|p'r-ps|=1$ *and let* $\mathcal{I}$ *and B defined by (24) and (25). Then the following polynomial identity holds for* $L\in\mathbb{Z}$:

$$\sum_{m+Le_1\in 2\mathbb{Z}^d} q^{L(L-2m_2)/4+mBm/2}\prod_{j=1}^{d}\begin{bmatrix}\frac{1}{2}L(\delta_{j,1}+\delta_{j,2})+\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix}$$
$$=\sum_{j=-\infty}^{\infty}\{q^{(p'(2p-p')j+2)j/2}T_0(L,p'j)-q^{((2p-p')j+2r-s)(p'j+s)/2}T_0(L,p'j+s)\}.$$

The case $(p,p')=(3,5)$ has again escaped a proper derivation, but has, in fact, been treated previously, corresponding to identity (20) with q replaced by $1/q$. Apart from this special case due to Andrews,[7] the identities of Proposition IV.2 have been proved by Berkovich, McCoy, and Orrick[13,16] for $(p,p')=(2\nu+1,4\nu)$ and were conjectured for general p and p' by Berkovich, McCoy, and Pearce [Eq. (8.8) of Ref. 21].

C. *q*-trinomial identities II

Our starting point for deriving q-trinomial identities is again Eq. (28), but this time we rely on (18). This implies that (28) with L replaced by k, multiplied by $q^{k^2}\begin{bmatrix}L\\2k\end{bmatrix}$, and summed over k yields

$$\sum_{k\geqslant 0} q^{k^2}\begin{bmatrix}L\\2k\end{bmatrix}F_k(p,p';q)=\sum_{j=-\infty}^{\infty}\left\{q^{j(p'(p+p')j+1)}\begin{bmatrix}L\\2p'j\end{bmatrix}_2-q^{(p'j+s)((p+p')j+r+s)}\begin{bmatrix}L\\2p'j+2s\end{bmatrix}_2\right\}. \tag{29}$$

To transform this into explicit polynomial identities we need to distinguish between $p<p'<2p$ and $p'>2p$.

First, assume that $p<p'<2p$. After substituting expression (26) for F_L, the left side of (29) is

$$\sum_{k\geqslant 0}\sum_{m\in 2\mathbb{Z}^d} q^{k^2+mBm/4}\begin{bmatrix}L\\2k\end{bmatrix}\prod_{j=1}^{d}\begin{bmatrix}k\,\delta_{j,1}+\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix}.$$

By the q-Chu–Vandermonde summation (A1), with $L\to L-k+m_1/2$, $a\to k-m_1/2$, and $b\to -k-m_1/2$, this can be rewritten as

$$\sum_{i,k\geqslant 0}\sum_{m\in 2\mathbb{Z}^d} q^{i(i-k-m_1/2)+k^2+mBm/4}\begin{bmatrix} L-k+\frac{1}{2}m_1 \\ i\end{bmatrix}\begin{bmatrix} k-\frac{1}{2}m_1 \\ 2k-i\end{bmatrix}\prod_{j=1}^{d}\begin{bmatrix} k\delta_{j,1}+\frac{1}{2}(\mathcal{I}m)_j \\ m_j\end{bmatrix}.$$

Replacing $m_j\to m_{j+2}$, $j=1,...,d$, followed by $k\to(m_1+m_2)/2$ and $i\to m_1$ yields

$$\sum{}' q^{(3m_1^2+m_2^2-2m_1m_3)/4+\Sigma_{j,k=1}^{d}m_{j+2}B_{j,k}m_{k+2}/4}$$
$$\times\begin{bmatrix} L-\frac{1}{2}(m_1+m_2-m_3) \\ m_1\end{bmatrix}\begin{bmatrix} \frac{1}{2}(m_1+m_2-m_3) \\ m_2\end{bmatrix}\prod_{j=1}^{d}\begin{bmatrix} \frac{1}{2}(m_1+m_2)\delta_{j,1}+\frac{1}{2}\Sigma_{k=1}^{d}\mathcal{I}_{j,k}m_{k+2} \\ m_j+2\end{bmatrix},$$

where the primed sum denotes a sum over $m\in\mathbb{Z}^{d+2}$ such that m_1+m_2 and $m_3,\ldots,m_{d+2}$ are all even.

Now define a new incidence matrix $\mathcal{I}'$ and Cartan-type matrix $2B'=2I-\mathcal{I}'$ of dimension $d'=d+1$ by replacing the continued fraction expansion $[\nu_0,\ldots\nu_n+2]$ by $[1,\nu_0,\ldots,\nu_n+2]$, so that $\mathcal{I}'$ becomes the incidence matrix corresponding to the continued fraction expansion of p'/p. Also define $\mathcal{I}''$ and $2B''=2I-\mathcal{I}''$ of dimension $d''=d+2$ as

$$\mathcal{I}''_{i,j}=\begin{cases} -\delta_{i,1}\delta_{j,1}+\delta_{i,2}+\delta_{i,3}-\delta_{j,2}+\delta_{j,3}, & \text{for } i=1 \text{ or } j=1,\\ \mathcal{I}'_{i-1,j-1}, & \text{for } i,j=2,...,d+2.\end{cases} \tag{30}$$

Then the above sequence of transformations implies the following proposition.

Proposition IV.3: For integers p,p' with $p<p'<2$ and $\gcd(p,p')=1$ let integers $1\leqslant r<p$ and $1\leqslant s<p'$ be fixed by $|p'r-ps|=1$ and let $\mathcal{I}''$ and B'' be defined by (30). Then the following polynomial identity holds for $L\in\mathbb{Z}$:

$$\sum{}' q^{mB''m/4}\prod_{j=1}^{d''}\begin{bmatrix} L\delta_{j,1}+\frac{1}{2}(\mathcal{I}''m)_j \\ m_j\end{bmatrix}$$
$$=\sum_{j=-\infty}^{\infty}\left\{q^{j(p'(p+p')j+1)}\begin{bmatrix} L \\ 2p'j\end{bmatrix}_2-q^{(p'j+s)((p+p')j+r+s)}\begin{bmatrix} L \\ 2p'j+2s\end{bmatrix}_2\right\}.$$

The identities of Proposition IV.3 are the $n=0$ case of the conjectured equation (8.11) [which contains the $n=0$ instances of (6.19) and (8.3)] of Ref. 21, and are related to the $\phi_{2,1}$ perturbation of the minimal conformal field theory $M(p',p+p')$.

When $p'>2p$ we replace $p\to p'-p$ in (29) and use the duality property (27). Hence

$$\sum_{k\geqslant 0} q^{2k^2}\begin{bmatrix} L \\ 2k\end{bmatrix}F_k(p,p';q^{-1})$$
$$=\sum_{j=-\infty}^{\infty}\left\{q^{j(p'(2p'-p)j+1)}\begin{bmatrix} L \\ 2p'j\end{bmatrix}_2-q^{(p'j+s)((2p'-p)j+r+s)}\begin{bmatrix} L \\ 2p'j+2s\end{bmatrix}_2\right\}. \tag{31}$$

Observe that the transformation carried out above implies $p<p'<2p$ and $|p'(r-s)+ps|=1$.

Substituting expression (26) for F_L and using (A7), the left side of (31) yields

$$\sum_{k\geqslant 0}\sum_{m\in 2\mathbb{Z}^d} q^{k(2k-m_1)+mBm/4}\begin{bmatrix} L \\ 2k\end{bmatrix}\prod_{j=1}^{d}\begin{bmatrix} k\delta_{j,1}+\frac{1}{2}(\mathcal{I}m)_j \\ m_j\end{bmatrix}.$$

By the q-Chu–Vandermonde summation (A1), with $L\to L-m_1/2$, $a\to m_1/2$, $b\to m_1/2-2k$, this can be rewritten as

$$\sum_{i,k\geqslant 0}\sum_{m\in 2\mathbb{Z}^d} q^{i(i-2k+m_1/2)+k(2k-m_1)+mBm/4}\begin{bmatrix} L-\frac{1}{2}m_1 \\ i\end{bmatrix}\begin{bmatrix}\frac{1}{2}m_1\\ 2k-1\end{bmatrix}\prod_{j=1}^{d}\begin{bmatrix}k\delta_{j,1}+\frac{1}{2}(\mathcal{I}m)_j\\ m_j\end{bmatrix}.$$

Replacing $m_j\to m_{j+2}$, $j=1,...,d$, followed by $t\to m_1+m_2$ and $i\to m_1$, gives

$$\sum{}' q^{(m_1^2+m_2^2-m_2m_3)/2+\Sigma_{j,k=1}^{d}m_{j+2}B_{j,k}m_{k+2}/4}\begin{bmatrix}L-\frac{1}{2}m_3\\ m_1\end{bmatrix}$$
$$\times\begin{bmatrix}\frac{1}{2}m_3\\ m_2\end{bmatrix}\prod_{j=1}^{d}\begin{bmatrix}\frac{1}{2}(m_1+m_2)\delta_{j,1}+\frac{1}{2}\Sigma_{k=1}^{d}\mathcal{I}_{j,k}m_{k+2}\\ m_{j+2}\end{bmatrix},$$

where the primed sum again denotes a sum over $m\in\mathbb{Z}^{d+2}$ such that m_1+m_2 and $m_3,\ldots,m_{d+2}$ are all even.

Now define a new incidence matrix $\mathcal{I}$ and Cartan-type matrix $2B'=2I-\mathcal{I}$ of dimension $d'=d+1$ by replacing the continued fraction expansion $[\nu_0,\ldots,\nu_n+2]$ by $[\nu_0+1,\nu_1,\ldots,\nu_n+2]$, so that $\mathcal{I}'$ becomes the incidence matrix corresponding to the continued fraction expansion of $p'/(p'-p)$. Also define $\mathcal{I}''$ and $2B''=2I-\mathcal{I}''$ of dimension $d''=d+2$ as

$$\mathcal{I}''_{i,j}=\begin{cases}\delta_{i,3}-\delta_{j,3}, & \text{for } i=1 \text{ or } j=1,\\ \mathcal{I}'_{i-1,j-1}, & \text{for } i,j=2,...,d+2.\end{cases} \tag{32}$$

Then the above sequence of transformations implies the following proposition.

Proposition IV.4: For integers p,p' with $p<p'<3p/2$ and $gcd(p,p')=1$ let integers $1\leqslant r<p$ and $1\leqslant s<p'$ be fixed by $|p'(r-s)r+ps|=1$ and let $\mathcal{I}$ and B be defined by (32). Then the following polynomial identity holds for $L\in\mathbb{Z}$:

$$\sum{}' q^{mB''m/4}\prod_{j=1}^{d''}\begin{bmatrix}L\delta_{j,1}+\frac{1}{2}(\mathcal{I}''m)_j\\ m_j\end{bmatrix}$$
$$=\sum_{j=-\infty}^{\infty}\left\{q^{j(p'(2p'-p)j+1)}\begin{bmatrix}L\\ 2p'j\end{bmatrix}_2-q^{(p'j+s)((2p'-p)j+r+s)}\begin{bmatrix}L\\ 2p'j+2s\end{bmatrix}_2\right\}.$$

The identities of Proposition IV. 4, which are related to the $\phi_{2,1}$ perturbation of the conformal field theory $M(p',2p'-p)$, were conjectured in Ref. 21 [as Eq. (6.9)]. For $p=p'-1$ a proof using recurrences was recently given in Ref. 20.

D. *q*-trinomial identities III

There are, of course, many more q-trinomial identities that can be derived using the techniques of the previous sections. Our final application is to show that in some cases a bit more ingenuity is required to arrive at the desired result. The identities we set out to prove here were again conjectured by Berkovich, McCoy, and Pearce [Eq. (9.4) of Ref. 21] and are interesting, as they contain the (polynomial) Rogers–Ramanujan identity (20) as the simplest case. It also provides an example for which the matrix $B=b_1\otimes b_2$ (in the proposition below denoted as C_n) of Sec. IV A has $b_1=(1)$ and not $(\frac{1}{2})$.

Proposition IV.5: For $n\geqslant 1$, let C_n be the Cartan matrix of A_n. Then for all $L\in\mathbb{Z}$,

$$\sum_{m\in\mathbb{Z}^n} q^{mC_nm/2}\prod_{j=1}^{n}\begin{bmatrix}L\delta_{j,1}+m_j-(C_nm)_j\\ m_j\end{bmatrix}$$
$$=\sum_{j=-\infty}^{\infty}\left\{q^{((n+3)(n+4)j+2)j/2}\begin{bmatrix}L\\ (n+4)_j\end{bmatrix}_2-q^{((n+3)j+2)((n+4)j+2)/2}\begin{bmatrix}L\\ (n+4)j+2\end{bmatrix}_2\right\}. \tag{33}$$

Letting L tend to infinity using (8) and (A6), this yields the following Virasoro-character identities.

Corollary IV.1: For $n\geqslant 1$ and $|q|<1$,

$$\sum_{m\in\mathbb{Z}^n}\frac{q^{mC_n m/2}}{(q)_{m_1}}\prod_{j=2}^{n}\begin{bmatrix} m_j-(C_n m)_j \\ m_j\end{bmatrix}=\begin{cases}\chi_{1,2}^{((n+3)/2,n+4)}(q), & n \text{ odd},\\ \chi_{1,2}^{((n+4)/2,n+3)}(q), & n \text{ even}.\end{cases} \tag{34}$$

In Ref. 21, the identities (33) and (34) were associated with the $\phi_{2,1}$ perturbation of the conformal field theories $M((n+4)/2,n+3)$ when n is odd and the $\phi_{1,5}$ perturbation of $M((n+3)/2,n+4)$ when n is even.

Proof: The corollary betrays a hidden parity dependence of (33), which also plays a role in the proof. Treating n being odd first, we set $n=2k-1$. The left-hand side of (33) then reads as

$$\sum_{m\in\mathbb{Z}^{2k-1}} q^{mC_{2k-1}m/2}\prod_{j=1}^{2k-1}\begin{bmatrix}\frac{1}{2}L\,\delta_{j,1}+m_{j-1}-m_j+m_{j+1}\\ m_j\end{bmatrix}, \tag{35}$$

with the convention that $m_0=L/2$ and $m_{2k}=0$. We eliminate the variables m_{2j-1}, $j=1,...,k$ in favor of new variables $M_1,\ldots,M_k$, defined as

$$m_{2j-1}=m_{2j-2}-\tfrac{1}{2}(M_j-M_{j+1}),$$

where $M_{k+1}=0$. If after this replacement we relabel m_{2j} to m_j for $j=1,...,k$ (so that $m_k=0$), expression (35) becomes

$$\sum_{M+Le_1\in 2\mathbb{Z}^k} q^{(L(L-2M_1)+M_1^2+\Sigma_{i,j=2}^{k}M_i(C_{k-1})_{i,j}M_j)/4}$$
$$\times\sum_{m_1,\ldots,m_{k-1}} q^{\Sigma_{j=1}^{k-1}(M_{j+1}-m_j)(m_{j-1}-m_j-(M_j-M_{j+2})/2)}$$
$$\times\begin{bmatrix}m_0+m_1+\frac{1}{2}(M_1-M_2)\\ m_0-\frac{1}{2}(M_1-M_2)\end{bmatrix}\prod_{j=1}^{k-1}\begin{bmatrix}m_{j-1}-\frac{1}{2}(M_j-M_{j+2})\\ m_j\end{bmatrix}\begin{bmatrix}m_{j+1}+\frac{1}{2}(M_{j+1}-M_{j+2})\\ M_j-\frac{1}{2}(M_{j+1}-M_{j+2})\end{bmatrix}. \tag{36}$$

This allows for successive summation over $m_{k-1},\ldots,m_1$ by the q-Saalschütz sum (A4). When summing over m_j, we take (A4) with $L\to m_{j-1}-(M_j-M_{j+2})/2$, $a\to(M_{j+1}-M_{j+2})/2$, $b\to -(M_{j+1}+M_{j+2})/2$, $c\to(M_j-M_{j+1})/2$ (for $j\geqslant 2$), and $c\to m_0+(M_1-M_2)/2$ (for $j=1$). As a result, (36) collapses into

$$\sum_{M+Le_1\in 2\mathbb{Z}^k} q^{L(L-2M_1)/4+MBM/2}\prod_{j=1}^{k}\begin{bmatrix}\frac{1}{2}L(\delta_{j,1}+\delta_{j,2})+\frac{1}{2}(\mathcal{I}M)_j\\ M_j\end{bmatrix}, \tag{37}$$

with matrices $\mathcal{I}$ and $2B=2I-\mathcal{I}$ defined in Eqs. (24) and (25) corresponding to the continued fraction expansion of $(k+2)/(k+1)=[1,k-1]$, i.e.,

$$\mathcal{I}_{i,j}=\begin{cases}\delta_{i,1}\delta_{j,1}+\delta_{i,2}-\delta_{j,2}, & \text{for } i=1 \text{ or } j=1,\\ \delta_{i,j-1}+\delta_{i,j+1}, & \text{for } i,j=2,...,k.\end{cases}$$

The last part of the proof consists of the observation that the identity obtained by equating (37) with the right-hand side of (33) (with $n=2k-1$) is nothing but the identity of Proposition IV.2 with $(p,p')=(k+2,2k+3)$ after letting $q\to 1/q$. This is readily seen using (4) and (A7).

Next, we deal with n being even, setting $n=2k$. The left-hand side of (33) then is

$$\sum_{m\in\mathbb{Z}^{2k}} q^{mC_{2k}m/2}\prod_{j=1}^{2k}\begin{bmatrix} L\delta_{j,1}+m_{j-1}-m_j+m_{j+1} \\ m_j\end{bmatrix}, \tag{38}$$

where $m_0=m_{2k+1}=0$. We eliminate the variables m_{2j}, $j=1,...,k$, introducing new variables $m_0,\ldots,M_{k-1}$ by

$$m_{2j}=m_{2j-1}-\tfrac{1}{2}(M_{j-1}-M_j),$$

where $M_k=0$. After this replacement we shift $m_{2j-1}\to m_j$ for $j=1,...,k$ so that expression (38) becomes

$$\sum_{\substack{M_0,\ldots,M_{k-1}\\ M_j\ \text{even}}} q^{(M_0^2+\Sigma_{i,j=1}^{k-1}M_i(C_{k-1})_{i,j}M_j)/4}$$
$$\times\sum_{m_1,\ldots,m_k} q^{m_1(m_1-(M_0+M_1)/2)+\Sigma_{j=2}^{k}(M_{j-1}-m_j)(m_{j-1}-m_j-(M_{j-2}-M_j)/2)}$$
$$\times\begin{bmatrix} L-\frac{1}{2}(M_0-M_1) \\ m_1\end{bmatrix}\left(\prod_{j=2}^{k}\begin{bmatrix} m_{j-1}-\frac{1}{2}(M_{j-2}-M_j) \\ m_j\end{bmatrix}\right)\prod_{j=1}^{k}\begin{bmatrix} m_{j+1}+\frac{1}{2}(M_{j-1}-M_j) \\ m_j-\frac{1}{2}(M_{j-1}-M_j)\end{bmatrix}.$$

We now sum over $m_k,\ldots,m_3$ by successive application of the q-Saalschütz sum (A4). When summing over m_j we take (A4) with $L\to m_{j-1}-(M_{j-2}-M_j)/2$, $a\to(M_{j-1}-M_j)/2$, $b\to-(M_{j-1}+M_j)/2$, and $c\to(M_{j-2}-M_{j-1})/2$. The final sum over m_1 follows from (A1) with $L\to L-(M_0-M_1)/2$, $a\to(M_0-M_1)/2$, and $b\to-(M_0+M_1)/2$. Setting $M_0\to 2i$, the resulting expression is

$$\sum_{i\geqslant 0} q^{i^2}\begin{bmatrix} L \\ 2i\end{bmatrix}\sum_{M\in 2\mathbb{Z}^{k-1}} q^{MC_{k-1}M/4}\prod_{j=1}^{k-1}\begin{bmatrix} i\delta_{j,1}+M_j-\frac{1}{2}(C_{k-1}M)_j \\ M_j\end{bmatrix}.$$

Equating this with the right-hand side of (33) for $n=2k$, we recognize identity (29) with $(p,p')=(k+1,k+2)$. □

V. THE TRINOMIAL BAILEY LEMMA

In this final section of our paper we formulate some of our results in the language of Bailey pairs. As we will see, the connection coefficients obtained in Sec. II provide a very elementary proof of the trinomial analog of Bailey's lemma recently obtained by Andrews and Berkovich.[19]

First, some definitions are needed. In subsequent formulas, $T_n(L,a)/(q)_L$ will be abbreviated to $Q_n(L,a)$.

Definition V.1: A pair of sequences $\alpha=\{\alpha_L\}_{L\geqslant 0}$ *and* $\beta=\{\beta_L\}_{L\geqslant 0}$ *that satisfies*

$$\beta_L=\sum_{r=0}^{L}\frac{\alpha_r}{(q)_{L-r}(aq)_{L+r}},$$

forms a (binomial) Bailey pair relative to a.

Definition V.2: A pair of sequences $A=\{A_L\}_{L\geqslant 0}$ *and* $B=\{B_L\}_{L\geqslant 0}$ *that satisfies*

$$B_L=\sum_{r=0}^{L} Q_n(L,r)A_r,$$

forms a trinomial Bailey pair relative to n.

The Bailey lemma[43] and trinomial Bailey lemma[19] can now be stated as the following summation formulas.

Lemma V.1. Let (α,β) be a Bailey pair relative to a. Then

$$\sum_{L=0}^{M} \frac{(\rho_1)_L(\rho_2)_L(aq/\rho_1\rho_2)^L\alpha_L}{(aq/\rho_1)_L(aq/\rho_2)_L(q)_{M-L}(aq)_{M+L}} = \sum_{L=0}^{M} \frac{(\rho_1)_L(\rho_2)_L(aq/\rho_1\rho_2)^L(aq/\rho_1\rho_2)_{M-L}\beta_L}{(aq/\rho_1)_M(aq/\rho_2)_M(q)_{M-L}}.$$

Lemma V.2. Let (A,B) form a trinomial Bailey pair relative to 0. Then

$$\sum_{L=0}^{M} (-1)_L q^{L/2} B_L = (-1)_{M+1} \sum_{L=0}^{M} q^{L/2} A_L \frac{Q_1(M,L)}{1+q^L}. \tag{39}$$

If (A,B) is a trinomial Bailey pair relative to 1, then

$$\sum_{L=0}^{M} (-q^{-1})_L q^L B_L = (-1)_M \sum_{L=0}^{M} A_L \left\{ Q_1(M,L) - \frac{Q_1(M-1,L+1)}{1+q^{-L-1}} - \frac{Q_1(M-1,L-1)}{1+q^{L-1}} \right\}.$$

Before we translate the results of Sec. II in the language of Bailey pairs, let us point out that the connection coefficients between q binomials and q trinomials can be applied to yield a very simple proof of the trinomial Bailey lemma. At the heart of the proof of Lemma V.2 is the following identity derived in Ref. 19 by a considerable amount of work,

$$T_0(L,a) = q^{(a-L)/2} \left\{ \frac{1+q^L}{1+q^a} T_1(L,a) - \frac{1-q^L}{1+q^a} T_1(L-1,a) \right\}. \tag{40}$$

To see, for example, that this implies (39), we multiply (40) by $q^{L/2}(-1)_L/(q)_L$ and sum over L from a to M. On the right-hand side all but one term cancels, so that

$$\sum_{L=a}^{M} q^{L/2}(-1)_L Q_0(L,a) = \frac{q^{a/2}}{1+q^a}(-1)_{M+1} Q_1(M,a),$$

which obviously implies (39).

By Eqs. (9)–(13), Eq. (40) is proved if we can show its validity when multiplied by $C_{M,L}(a)$ and summed over L. Doing this and using (10), one finds (replacing $L \to k$ and $M \to L$)

$$\begin{aligned}
\begin{bmatrix} 2L \\ L-a \end{bmatrix} &= \sum_{k=0}^{L} q^{\binom{k}{2}-\binom{a}{2}} \begin{bmatrix} L \\ k \end{bmatrix} \left\{ \frac{1+q^k}{1+q^a} T_1(k,a) - \frac{1-q^k}{1+q^a} T_1(k-1,a) \right\} \\
&= \sum_{k=0}^{L} q^{\binom{k}{2}-\binom{a}{2}} \left\{ \frac{1+q^k}{1+q^a} \begin{bmatrix} L \\ k \end{bmatrix} - q^k \frac{1-q^{k+1}}{1+q^a} \begin{bmatrix} L \\ k+1 \end{bmatrix} \right\} T_1(k,a) \\
&= \sum_{k=0}^{L} q^{\binom{k}{2}-\binom{a}{2}} \frac{1+q^L}{1+q^a} \begin{bmatrix} L \\ k \end{bmatrix} T_1(k,a).
\end{aligned}$$

But the extremes of this string of equations is nothing but Eq. (14), with $D'_{L,k}(a)$ given by Eq. (16) of Lemma II.2, establishing (40).

We now give a series of lemmas that are all straightforward consequences of the results of Sec. II.

Lemma V.3: Let (α,β) be a Bailey pair relative to 1. Then

$$A_L = q^{-L^2/2}\alpha_L, \quad B_L = \sum_{k=0}^{L} \frac{(-1)^{L-k} q^{\binom{L-k}{2} - L^2/2}(q)_{2k}}{(q)_k(q)_{L-k}} \beta_k$$

is a trinomial Bailey pair relative to 0 and

$$A_L=\frac{q^{-\binom{L}{2}}}{1+q^L}\alpha_L\,,\quad B_L=\sum_{k=0}^{L}\frac{(-1)^{L-k}q^{\binom{L-k}{2}-\binom{L}{2}}(q)_{2k}}{(1+q^k)(q)_k(q)_{L-k}}\beta_k$$

is a trinomial Bailey pair relative to 1.

The converse statement is as follows.

Lemma V.4: Let $(A(n),B(n))$ *be a trinomial Bailey pair relative to n. Then,*

$$\alpha_L=q^{L^2/2}A_L(0),\quad \beta_L=\frac{(q)_L}{(q)_{2L}}\sum_{k=0}^{L}\frac{q^{k^2/2}}{(q)_{L-k}}B_k(0)$$

and

$$\alpha_L=q^{\binom{L}{2}}(1+q^L)A_L(1),\quad \beta_L=\frac{(q)_L}{(q)_{2L}}(1+q^L)\sum_{k=0}^{L}\frac{q^{\binom{k}{2}}}{(q)_{L-k}}B_k(1),$$

are Bailey pairs relative to 1.

Lemma V.3 is to be compared with the following result of Ref. 23.

Lemma V.5: Let l be a non-negative integer and (α,β) a Bailey pair relative to $a=q^l$. *Then*

$$A_L=\begin{cases}\alpha_{(L-l)/2}\,, & \text{for } L=l,l+2,\ldots,\\ 0, & \text{otherwise;}\end{cases}$$

$$B_L=\begin{cases}\displaystyle\sum_{k=0}^{[(L-l)/2]}\frac{q^{(L-l-2k)(L-l-2k-n)/2}}{(q)_l(q)_{L-l-2k}}\beta_k\,, & \textit{for } L\geqslant l;\\ 0, & \text{otherwise,}\end{cases}$$

forms a trinomial Bailey pair relative to n.

APPENDIX: SOME *q*-BINOMIAL FORMULAS

In this appendix we list some standard q-binomial identities that are repeatedly used in the main text.

The following three formulas all hold for integers a, b, L such that a, $L\geqslant 0$,

$$\sum_{k=0}^{L}q^{k(k+b)}\begin{bmatrix}L\\k\end{bmatrix}\begin{bmatrix}a\\k+b\end{bmatrix}=\begin{bmatrix}a+L\\b+L\end{bmatrix}, \tag{A1}$$

$$\sum_{k=0}^{L}(-1)^k q^{\binom{k}{2}}\begin{bmatrix}L\\k\end{bmatrix}\begin{bmatrix}L+a-k\\b\end{bmatrix}=q^{L(L+a-b)}\begin{bmatrix}a\\b-L\end{bmatrix}, \tag{A2}$$

$$\sum_{k=0}^{L}(-1)^k q^{\binom{k}{2}+k(b-L+1)}\begin{bmatrix}L\\k\end{bmatrix}\begin{bmatrix}L+a-k\\b\end{bmatrix}=\begin{bmatrix}a\\b-L\end{bmatrix}. \tag{A3}$$

The first two equations are specializations of the q-Chu–Vandermonde sum (II.7) of Ref. 3 and the last equation is a specialization of the q-Chu–Vandermonde sum (II.6) of Ref. 3. Identity (A2) is also given in Ref. 1 as Eq. (3.3.10). A useful specialization of the q-Saalschütz sum [(II.12) of Ref. 3] is given by

$$\sum_{k=0}^{L} q^{(a-b-k)(L-k)}\begin{bmatrix} L \\ k \end{bmatrix}\begin{bmatrix} a \\ k+b \end{bmatrix}\begin{bmatrix} k+c \\ a+L \end{bmatrix}=\begin{bmatrix} c \\ b+L \end{bmatrix}\begin{bmatrix} c-b \\ a-b \end{bmatrix}, \tag{A4}$$

true for integers a, b, c, L such that a, c, $L \geqslant 0$. This is Eq. (3.3.11) of Ref. 1. Finally, we list the elementary results:

$$\begin{bmatrix} L \\ a \end{bmatrix}=\begin{bmatrix} L-1 \\ a-1 \end{bmatrix}+q^{a}\begin{bmatrix} L-1 \\ a \end{bmatrix}, \quad \text{for } L,a \geqslant 0, \quad L+a \neq 0, \tag{A5}$$

$$\lim_{L\to\infty}\begin{bmatrix} L \\ a \end{bmatrix}=\frac{1}{(q)_a} \tag{A6}$$

and

$$\begin{bmatrix} L \\ a \end{bmatrix}_{1/q}=q^{-a(L-a)}\begin{bmatrix} L \\ a \end{bmatrix}_{q}. \tag{A7}$$

Comment on phase-space representation of quantum state vectors

Klaus B. Møller[a)]
Arthur Amos Noyes Laboratory of Chemical Physics, California Institute of Technology, Pasadena, California 91125

(Received 13 July 1998; accepted for publication 1 February 1999)

A simple approach to phase-space representation of quantum state vectors using the displacement-operator formalism is presented. Although the resulting expressions for the fundamental operators (position and momentum) are equivalent to those obtained by other methods, this approach provides both alternative mathematical foundation as well as physical interpretation of phase-space representation of quantum state vectors.
[S0022-2488(99)01605-9]

I. INTRODUCTION

Over the past few years there has been a renewed interest in phase-space descriptions of quantum systems. In a recent paper by Ban[1] a novel approach to phase-space representation of quantum state vectors is obtained within the relative-state formulation, and in this Comment we make a few remarks on the physical contents of this construction. Also, we relate it to another approach to phase-space representation of quantum state vectors, the so-called displacement-operator approach.

The idea of phase-space representation of quantum state vectors, i.e., representation of a quantum state as a probability amplitude depending on *two real* variables related to the position and momentum coordinates goes back to the works of Fock[2] and Bargmann.[3] In their formulation, a quantum state is represented as a complex function depending on *one complex* coordinate whose real and imaginary part is proportional to the position and momentum coordinate, respectively. This is a result of regarding the bosonic creation and annihilation operators as the fundamental operators.

The relative-state formulation, on the other hand, treats the position and momentum operators themselves as the fundamental operators and is therefore more closely related to the works of Torres-Vega and Frederick[4] and Harriman.[5] Both of these works rely to a certain extent on Dirac's representation theory of quantum mechanics,[6] either as a Hilbert-space-vector approach postulating the existence of a complete set of states depending on two real parameters that can be used as a basis in phase space or a linear transformation onto phase space from position or momentum space.

In fact, the relative-state representation of Ban[1] becomes, under certain conditions, equivalent to those of Torres-Vega and Frederick[4] and Harriman.[5] The relative-state formulation may therefore serve as a mathematical and physical foundation for the representations presented by these authors since it is derived from first principles without assumptions or transformations from other representations.

However, the relative-state formulation is not the only way to construct a phase-space representation of quantum state vectors from first principles that becomes equivalent to those of Torres-Vega and Frederick[4] and Harriman.[5] Below, we present an alternative construction, using the displacement operators, and discuss the mathematical and physical differences between this method the relative-state approach.

[a)]Electronic mail: klaus@cco.caltech.edu

The displacement-operator approach is essentially equivalent to the coherent-state formalism as put forward by, for instance, Klauder and Skagerstam[7] and studied in some detail by the present author.[8] Hence, the presentation given here is extracted from these earlier works and put in a form relevant for the present discussion. For a thorough review and analysis of the use of displacement operators, the reader is referred to Refs. 7 and 8 and the references therein.

II. RELATIVE-STATE FORMULATION

The relative-state formulation is presented in great detail by Ban[1] and here we only include a few results relevant for the further discussion. The key of this approach is to enlarge the Hilbert space $\mathcal{H}$ of a quantum system by introducing an auxiliary (reference) quantum system and treat quantum state vectors in the extended Hilbert space $\tilde{\mathcal{H}}=\mathcal{H}\otimes\mathcal{H}_r$, where $\mathcal{H}_r$ is the Hilbert space of the reference system. A state vector in the extended Hilbert space $\tilde{\mathcal{H}}$ then becomes $|\Psi\rangle\rangle\equiv|\psi\rangle\otimes|\phi\rangle_r$ where $|\phi\rangle_r$ is the reference state.

A set of state vectors $\{|\omega(r,k;s)\rangle\rangle|r,k\in\mathbf{R}\}$ may be introduced[1] that becomes a complete orthonormal system in $\tilde{\mathcal{H}}$. These state vectors, which can be written on the following form:

$$|\omega(r,k;s)\rangle\rangle\equiv\frac{1}{\sqrt{2\pi}}e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx\, e^{ikx}|x\rangle\otimes|x-r\rangle_r \tag{1}$$

(as in Ref. 1, we set $\hbar=1$ throughout this Comment) are simultaneous eigenstates of the operators $\hat{x}-\hat{x}_r$, and $\hat{p}+\hat{p}_r$,

$$(\hat{x}-\hat{x}_r)|\omega(r,k;s)\rangle\rangle=r|\omega(r,k;s)\rangle\rangle, \tag{2}$$

$$(\hat{p}+\hat{p}_r)|\omega(r,k;s)\rangle\rangle=k|\omega(r,k;s)\rangle\rangle. \tag{3}$$

However, when we investigate the properties of the relevant quantum system, we only need a description of this system in the Hilbert space $\mathcal{H}$. Thus, the extended Hilbert space is reduced again by fixing the state vector of the reference system. For any fixed state vector $|\phi\rangle_r$ of the reference system, the set $\{|\omega(r,k;s)\rangle|r,k\in\mathbf{R}\}$, where

$$|\omega(r,k;s)\rangle\equiv{}_r\langle\phi|\omega(r,k;s)\rangle\rangle=\frac{1}{\sqrt{2\pi}}e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx\, e^{ikx}\phi^*(x-r)|x\rangle, \tag{4}$$

becomes an overcomplete system in the Hilbert space $\mathcal{H}$.[1] Therefore, the relevant quantum system can be represented by an $\mathcal{L}^2(2)$ normalized wave function $\psi_\omega(r,k;s)\equiv\langle\omega(r,k;s)|\psi\rangle$ depending of the two real parameters k and r. In this representation, the fundamental operators $\hat{x}$ and $\hat{p}$ take the form

$$\langle\omega(r,k;s)|\hat{x}|\psi\rangle=\left[\frac{1}{2}(1+s)r+i\frac{\partial}{\partial k}\right]\psi_\omega(r,k;s), \tag{5}$$

$$\langle\omega(r,k;s)|\hat{p}|\psi\rangle=\left[\frac{1}{2}(1-s)k-i\frac{\partial}{\partial r}\right]\psi_\omega(r,k;s). \tag{6}$$

Apart from some notational differences these are essentially the expressions given by Torres-Vega and Frederick[4] and Harriman[5] in their representations. Thus, the construction by Ban[1] may serve as a mathematical foundation for the work of Torres-Vega and Frederick[4] and Harriman.[5] Furthermore, the relative-state formulation provides a physical interpretation of the wave function $\psi_\omega(r,k;s)$ and the parameters k and r as phase-space coordinates. In light of Eqs. (2) and (3), the function $|\psi_\omega(r,k;s)|^2$ represents the probability distributions of the eigenvalues of the operators $\hat{x}-\hat{x}_r$ and $\hat{p}+\hat{p}_r$ in the extended Hilbert space $\tilde{\mathcal{H}}$.

Alternatively, one may utilize $|\psi_\omega(r,k;s)|^2$ as a combined probability distribution directly in the r,k-parametrized space as follows:

$$\overline{r} \equiv \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk\, r |\psi_\omega(r,k;s)|^2 = x_\psi - x_\phi, \tag{7}$$

$$\overline{k} \equiv \int_{-\infty}^{\infty} dr \int_{-\infty}^{\infty} dk\, k |\psi_\omega(r,k;s)|^2 = p_\psi + p_\phi. \tag{8}$$

Here, $x_\psi = \langle \psi | \hat{x} | \psi \rangle$ and so on. Thus, r and k may be interpreted as phase-space coordinates in the sense that the average value of r equals the relative position between the relevant and the reference system, and the average value of k equals the sum of the momenta of the relevant and the reference system. Hence, the physical interpretation of the wave function depends on the reference state, although the operator expressions, Eqs. (5) and (6), do not, and from this point of view the most satisfactory representation is obtained using a reference state with $\langle \phi | \hat{x} | \phi \rangle = 0$ and $\langle \phi | \hat{p} | \phi \rangle = 0$. In general, also the physical interpretation of higher momenta of r and k depend on the reference system.[1]

III. DISPLACEMENT-OPERATOR APPROACH

Here we present an alternative derivation from first principles of the phase-space representation of quantum state vectors that also becomes equivalent to the ones of Torres-Vega and Frederick[4] and Harriman[5] and therefore to the result of Ban,[1] as well. However, the derivation presented here differs from the one obtained in the relative-state formulation in both the mathematical foundation and in the physical interpretation of the phase-space wave functions. In fact, it resembles closely Dirac's construction of the usual position and momentum representations.[6]

Two things are important for the definitions of these representations. First, the basis states, denoted by $|r\rangle_x$ and $|k\rangle_p$, are eigenstates of the position and momentum operator, respectively,

$$\hat{x}|r\rangle_x = r|r\rangle_x \quad \text{and} \quad \hat{p}|k\rangle_p = k|k\rangle_p. \tag{9}$$

Second, the position (momentum) eigenstate with eigenvalue $r(k)$ can be generated from the eigenstate with eigenvalue $r=0$ $(k=0)$ by a displacement operator,

$$|r\rangle_x = \hat{D}_x(r)|0\rangle_x \quad \text{and} \quad |k\rangle_p = \hat{D}_p(k)|0\rangle_p, \tag{10}$$

where the displacement operators are given as $\hat{D}_x(r) = \exp(-ir\hat{p})$ and $\hat{D}_p(k) = \exp(ik\hat{x})$.[6] The wave function in position (momentum) space is then obtained by projection onto a position (momentum) eigenstate, $\psi(r) \equiv \langle r | \psi \rangle$ $(\psi(k) \equiv \langle k | \psi \rangle)$. This implies that the displacement operators when acting on a state displace the expectation value of the position or momentum by r and k, respectively.

An identical approach to a phase-space representation of quantum state vectors would require the existence of an Hermitian operator representing a point in phase space. Torres-Vega and Frederick[4] claim that such an operator exist but without proof and, in fact, the existence of such an operator would violate the Heisenberg uncertainty relation. In the relative-state formulation, a close resemblance is obtained for the basis states $|\omega(r,k;s)\rangle\rangle$ in the extended Hilbert space; cf. Eqs. (2) and (3).

Nevertheless, an r,k-parametrized basis *can* be constructed utilizing displacement operators. In general, a displacement operator that displaces the expectation values of the position and momentum for any state by r and k simultaneously, can be defined as[7,8]

$$\hat{D}_s(r,k) = \exp[i(k\hat{x} - r\hat{p} - skr/2)], \tag{11}$$

where s is real number determining the phase such that $\hat{D}_1(r,k)=\hat{D}_q(r)\hat{D}_p(k)$, $\hat{D}_{-1}(r,k)=\hat{D}_p(k)\hat{D}_q(r)$, and $\hat{D}_0(r,k)$ is a symmetric combination. An r,k-parametrized state vector may then be defined as $|\Omega(r,k;s)\rangle\equiv(2\pi)^{-1/2}\hat{D}_s(r,k)|\chi\rangle$, where $|\chi\rangle$ is an arbitrary normalized state, and the set $\{|\Omega(r,k;s)\rangle|r,k\in\mathbf{R}\}$ becomes an overcomplete set of normalized vectors.[7] The set $\{|\Omega(r,k;s)\rangle|r,k\in\mathbf{R}\}$ can therefore be used as a basis and the relevant quantum system represented by the $\mathcal{L}^2(2)$ normalized wave function $\psi_\Omega(r,k;s)\equiv\langle\Omega(r,k;s)|\psi\rangle$, depending on the two real parameters k and r. These basis vectors obviously satisfy the displacement relation

$$|\Omega(r,k;s)\rangle=\hat{D}_s(r,k)|\Omega(0,0;s)\rangle. \tag{12}$$

Using that

$$i\frac{\partial}{\partial k}\hat{D}(r,k;s)=\left[\frac{1}{2}(1+s)r-\hat{x}\right]\hat{D}(r,k;s), \tag{13}$$

$$i\frac{\partial}{\partial r}\hat{D}(r,k;s)=-\left[\frac{1}{2}(1-s)k-\hat{p}\right]\hat{D}(r,k;s), \tag{14}$$

it is seen that in this representation, the fundamental operators $\hat{x}$ and $\hat{p}$ take the same form as in the relative-state formulation, given by Eqs. (5) and (6).

Therefore, the displacement-operator approach provides an alternative derivation from first principles to the results obtained within the relative-state formalism. Here, the state of the relevant system is projected onto an auxiliary (reference) state $|\chi\rangle$, displaced by r and k, whereas the auxiliary state $|\phi\rangle$ in the relative-state formulation is utilized to project the orthonormal basis in the extended Hilbert space onto a reduced Hilbert space. Thus, the auxiliary states play different physical roles, as can also be seen from the relations

$$\overline{r}\equiv\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk\, r|\psi_\Omega(r,k;s)|^2=x_\psi-x_\chi, \tag{15}$$

$$\overline{k}\equiv\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk\, k|\psi_\Omega(r,k;s)|^2=p_\psi-p_\chi. \tag{16}$$

Hence, r and k may here be interpreted as phase space coordinates, in the sense that the average values obtained using $|\psi_\Omega(r,k;s)|^2$ as a combined probability distribution equal the relative position and momentum, respectively, between the relevant and the auxiliary system. Hence, the displacement-operator approach provides a more symmetrical interpretation of the r,k-parametrized representation of the quantum state vector.

Since

$$\hat{D}_s(r,k)|\chi\rangle=e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx\, e^{ikx}\chi(x-r)|x\rangle, \tag{17}$$

we see that the displacement-operator approach and the phase-space representation obtained within the relative-state formulation become formally identical if $\chi(x)=\phi^*(x)$; cf. Eq. (4), which implies that $p_\phi=-p_\chi$, as expected [compare Eqs. (8) and (16)].

In conclusion, we have shown that the two different mathematical approaches to a phase-space representation of quantum state vectors lead to identical expressions for the fundamental operators. However, usage of the well-known technique of displacement operators is in spirit closer to the construction of the usual position and momentum representations and, also, it provides a more transparent physical interpretation of the auxiliary state as a ‘‘probe’’ state in phase space.[8] With this interpretation, phase-space representation of quantum state vectors becomes a powerful tool and has been applied recently in the study of quantum dynamics directly in phase space[9] or as a route to semiclassical approximations.[10]

Moyal–Nahm equations

L. M. Baker[a] and D. B. Fairlie[b]
Department of Mathematical Sciences, Science Laboratories, University of Durham, Durham DH1 3LE, England

(Received 28 January 1999; accepted for publication 10 March 1999)

Various aspects of the Nahm equations in three and seven dimensions are investigated. The residues of the variables at simple poles in the seven-dimensional case form an algebra. A large class of matrix representations of this algebra is constructed. The large N limit of these equations is taken by replacing the commutators by Moyal brackets, and a set of nontrivial solutions in a generalized form of Wigner distribution functions is obtained. © *1999 American Institute of Physics.* [S0022-2488(99)03706-8]

I. INTRODUCTION

When the study of self-dual gauge fields was very fashionable, there was some interest in extending the theory to higher dimensions.[1–3] In recent years interest in this subject has been revived[4] partly because of the occurrence of Yang–Mills gauge actions in the M(atrix) theory approximation to string theories.[5–7] The present article is a study of a class of solutions to the Nahm equations[8] in seven dimensions, which are a particular form of the self-dual Yang–Mills equations in Euclidean eight-dimensional space, where the gauge fields A^μ, $\mu=1,...,7$ depend only upon the eighth coordinate, τ, and we work in a gauge where $A^8=0$. These equations take the form

$$\begin{aligned}
&\frac{\partial A^1}{\partial\tau}-[A^2,A^7]-[A^6,A^3]-[A^5,A^4]=0,\\
&\frac{\partial A^2}{\partial\tau}-[A^7,A^1]-[A^5,A^3]-[A^4,A^6]=0,\\
&\frac{\partial A^3}{\partial\tau}-[A^1,A^6]-[A^2,A^5]-[A^4,A^7]=0,\\
&\frac{\partial A^4}{\partial\tau}-[A^1,A^5]-[A^6,A^2]-[A^7,A^3]=0,\\
&\frac{\partial A^5}{\partial\tau}-[A^4,A^1]-[A^3,A^2]-[A^6,A^7]=0,\\
&\frac{\partial A^6}{\partial\tau}-[A^3,A^1]-[A^2,A^4]-[A^7,A^5]=0,\\
&\frac{\partial A^7}{\partial\tau}-[A^1,A^2]-[A^3,A^4]-[A^5,A^6]=0.
\end{aligned} \tag{1}$$

The sum of the squares of the left-hand sides of these equations give the Lagrangian density for Yang–Mills theory in eight dimensions dependent only upon τ in the gauge $A^8=0$, up to divergence terms. This is just the Bogomol'nyi property of Eq. (1). Alternatively, the equations may be iterated to obtain the equations of motion for the Yang–Mills field. Note that when the τ dependence of A^μ is a simple pole, then the equations for the residues are just algebraic. The first objective of this paper is to initiate a study of the algebraic solution to such equations. It is known that a solution to (1) takes the form

$$A^i=\frac{-1}{2\tau}e_i, \quad i=1,...,7, \tag{2}$$

where the e_i form a basis for the imaginary octonions, but since these do not possess a matrix representation, as they are nonassociative, one might wonder whether a matrix valued solution exists. Indeed many such solutions exist, and we determine the allowable τ dependence of some of them. We find a particular solution, modeled upon the structure constants for octonionic multiplication and a more general solution in the form of a direct sum of SU(2) representations.

The second objective of this paper is to consider the infinite limit of the Nahm equations in both three and seven dimensions in the limit of large N for the gauge group SU(N). The motivation for this is a possible application to string theory and matrix models. In this case the matrices A^μ go over to functions $X^\mu(x,p)$ on phase space (x,p). The matrix elements may be regarded as the Fourier components of X^μ. The commutator goes over to the Moyal bracket.[9] This we recall is the antisymmetric part of the star product, which acts on functions in phase space (x,p). The star product of two functions $f(x,p)$ and $g(x,p)$ is defined as

$$f(x,p)\star g(x,p)=f(x,p)e^{i\lambda(\overleftarrow{\partial}_x\overrightarrow{\partial}_p-\overleftarrow{\partial}_p\overrightarrow{\partial}_x)}g(x,p), \tag{3}$$

where λ is a parameter. The Moyal bracket is proportional to the antisymmetric part of the star product and so the Moyal bracket of two functions $f(x,p)$ and $g(x,p)$ is written as

$$\{f,g\}_{\rm MB}=\frac{1}{2i}(f\star g-g\star f). \tag{4}$$

It is the unique one-parameter associative deformation of the Poisson bracket.[10–12] As $N=2\pi/\lambda$ passes through the odd integers the Moyal bracket $\{X^\mu,X^\nu\}_{\rm MB}$ degenerates into an infinite direct sum of copies of the commutator $[A^\mu,A^\nu]$, where A^μ, A^ν are SU(N) matrices, the large N limit of which is the Poisson bracket,

$$\{X^\mu,X^\nu\}_{\rm PB}=\frac{\partial X^\mu}{\partial x}\frac{\partial X^\nu}{\partial p}-\frac{\partial X^\mu}{\partial p}\frac{\partial X^\nu}{\partial x}. \tag{5}$$

The square of this quantity is just the Schild[13,14] form of the string Lagrangian, giving the same classical equations of motion as does the NambuGoto string. Thus the large N limit of the Yang–Mills Lagrangian in the strong coupling limit, where it is simply proportional to the square of the trace of the commutator, is equivalent to the string Lagrangian.[14] This may be viewed as a primitive form of a type of Maldacena conjecture,[15] relating a field theory in the large N limit to a string theory. The phase space coordinates x,p are to be interpreted as coordinate parametrizations on the world sheet of the string. The idea had been advanced that the target space coordinates X^μ (D_0 branes) may be represented by a generalized form of the Wigner function familiar from quantum mechanics.[16,17] We shall demonstrate solutions of the Moyal–Nahm equations (where the commutators are replaced by Moyal brackets) which take the form of a generalized Wigner function.

II. SEVEN-DIMENSIONAL NAHM EQUATIONS

Equation (1) can be written more succinctly with the aid of totally antiysmmetric structure constants C_{ijk} which, in fact, define the multiplication table of octonions of different index;

$$e_i \times e_j = C_{ijk} e_k \tag{6}$$

in the same way as the ϵ_{ijk} symbol does for the quaternions. The Nahm equations may then be written in the form

$$\frac{\partial A_i}{\partial \tau} = \frac{1}{2} C_{ijk} [A_j, A_k] \tag{7}$$

with a solution for the residues B_i of the simple poles in $A_i = -(1/\tau) B_i$ given by

$$B_i = C_{ijk}. \tag{8}$$

An explicit set of matrices B_i is listed in the Appendix. No more general τ-dependent solution of this type has been found. However, a very large class of solutions whose matrices take the form of a direct sum of representations of the SU(2) algebra, but which have a nontrivial τ dependence and are different for each B_i does exist and we proceed to explain their construction. Let

$$\begin{gathered}
B_1 = -i \begin{pmatrix} \sigma_3 & 0 & 0 \\ 0 & \sigma_3 & 0 \\ 0 & 0 & \sigma_3 \end{pmatrix}, \quad B_2 = -i \begin{pmatrix} \sigma_1 & 0 & 0 \\ 0 & b\sigma_2 & 0 \\ 0 & 0 & ic\sigma_3 \end{pmatrix}, \\
B_3 = -i \begin{pmatrix} a\sigma_3 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & ic\sigma_2 \end{pmatrix}, \quad B_4 = -i \begin{pmatrix} ia\sigma_2 & 0 & 0 \\ 0 & b\sigma_3 & 0 \\ 0 & 0 & \sigma_2 \end{pmatrix}, \\
B_5 = -i \begin{pmatrix} a\sigma_2 & 0 & 0 \\ 0 & -ib\sigma_3 & 0 \\ 0 & 0 & \sigma_1 \end{pmatrix}, \quad B_6 = -i \begin{pmatrix} ia\sigma_3 & 0 & 0 \\ 0 & \sigma_1 & 0 \\ 0 & 0 & c\sigma_2 \end{pmatrix}, \\
B_7 = -i \begin{pmatrix} \sigma_2 & 0 & 0 \\ 0 & ib\sigma_2 & 0 \\ 0 & 0 & c\sigma_3 \end{pmatrix}.
\end{gathered} \tag{9}$$

It is somewhat surprising to find that this solution involves three arbitrary parameters, yet none of these parameters can be set to zero in such a way that the solution remains faithful, i.e., each matrix is different. Obviously many such solutions of direct sum form can be constructed where the σ's in each row can be replaced by representations of SU(2) of arbitrary dimension.

In particular, a representation of the Nahm algebra with 4×4 matrices can be found, by simply omitting the last two rows in the above matrices (9). Our next task will be to search for the presence of solutions with nontrivial τ dependence. An attempt was made to find a solution to the Nahm equations using the matrices B_i (setting $a=1$, $b=1$, $c=1$). Each of these matrices was multiplied by a function of τ, $f_i(\tau)$. Therefore,

$$A_i = f_i(\tau) B_i, \quad i = 1,...,7. \tag{10}$$

However this ansatz is not sufficiently flexible and the previous result, $f_i(\tau) = -1/2\tau$ is all that is recovered. A more general ansatz for a solution is to multiply each matrix B_i by a diagonal matrix C_i given by

$$C_i=\begin{pmatrix} f_i(\tau)\mathbb{1} & 0 & 0 \\ 0 & g_i(\tau)\mathbb{1} & 0 \\ 0 & 0 & h_i(\tau)\mathbb{1} \end{pmatrix}. \tag{11}$$

(This amounts to multiplying each σ matrix entry in each matrix B_i by a different τ-dependent function.) It is easiest to consider each row of σ matrices separately. First, we shall look at the top row of sigma matrices and put in the τ dependence by multiplying each matrix by a function $f_i(\tau)$. Putting these 2×2 matrices into the Nahm equations gives the following set of differential equations:

$$\frac{\partial f_2}{\partial \tau}=2\, f_1 f_7+2\, f_5 f_3-2\, f_4 f_6,$$

$$\frac{\partial f_1}{\partial \tau}=2\, f_2 f_7, \quad \frac{\partial f_3}{\partial \tau}=2\, f_2 f_5, \quad \frac{\partial f_4}{\partial \tau}=2\, f_2 f_6, \tag{12}$$

$$\frac{\partial f_5}{\partial \tau}=2\, f_2 f_3, \quad \frac{\partial f_6}{\partial \tau}=2\, f_2 f_4, \quad \frac{\partial f_7}{\partial \tau}=2\, f_2 f_1$$

and the following constraints:

$$f_7 f_3=f_1 f_5, \quad f_6 f_7=f_1 f_4, \quad f_3 f_4=f_5 f_6. \tag{13}$$

Note that all of the differential equations involve f_2, but none of the constraints do. These can be solved in terms of elliptic functions. It was found that

$$f_6=K_1 f_3=K_1 M_1 f_1=\tfrac{1}{2} K_1 M_1 Q_1 \,\mathrm{sn}(q_1\tau+d_1),$$

$$f_4=K_1 f_5=K_1 M_1 f_7=\frac{-i}{2} K_1 M_1 Q_1 \,\mathrm{cn}(q_1\tau+d_1), \tag{14}$$

$$f_2=\frac{i}{2} q_1 \,\mathrm{dn}(q_1\tau+d_1),$$

where cn, sn, dn are elliptic functions and K_1, M_1, q_1, Q_1, d_1 are all constants. The elliptic functions are related to each other by a parameter k_1 as follows:

$$\mathrm{sn}^2(x)+\mathrm{cn}^2(x)=1, \quad \mathrm{dn}^2(x)+k_1^2\,\mathrm{sn}^2(x)=1, \tag{15}$$

where $k_1=(Q_1/q_1)\sqrt{1+M_1^2(1-k_1^2)}$.

The following set of matrices solve Nahm's equations:

$$A_1=-i\begin{pmatrix} f_1\sigma_3 & 0 & 0 \\ 0 & g_1\sigma_3 & 0 \\ 0 & 0 & h_1\sigma_3 \end{pmatrix}, \quad A_2=-i\begin{pmatrix} f_2\sigma_1 & 0 & 0 \\ 0 & g_2\sigma_2 & 0 \\ 0 & 0 & ih_2\dot{\sigma}_3 \end{pmatrix},$$

$$A_3=-i\begin{pmatrix} f_3\sigma_3 & 0 & 0 \\ 0 & g_3\sigma_2 & 0 \\ 0 & 0 & ih_3\sigma_2 \end{pmatrix}, \quad A_4=-i\begin{pmatrix} if_4\sigma_2 & 0 & 0 \\ 0 & g_4\sigma_3 & 0 \\ 0 & 0 & h_4\sigma_2 \end{pmatrix}, \tag{16}$$

$$A_5=-i\begin{pmatrix} f_5\sigma_2 & 0 & 0 \\ 0 & -ig_5\sigma_3 & 0 \\ 0 & 0 & h_5\sigma_1 \end{pmatrix}, \quad A_6=-i\begin{pmatrix} if_6\sigma_3 & 0 & 0 \\ 0 & g_6\sigma_1 & 0 \\ 0 & 0 & h_6\sigma_2 \end{pmatrix},$$

$$A_7=-i\begin{pmatrix} f_7\sigma_2 & 0 & 0 \\ 0 & ig_7\sigma_2 & 0 \\ 0 & 0 & h_7\sigma_3 \end{pmatrix},$$

where the other τ-dependent functions are given by

$$g_5=K_2g_4=K_2M_2g_1=\tfrac{1}{2}K_2M_2Q_2\,\mathrm{sn}(q_2\tau+d_2),$$

$$g_7=K_2g_2=K_2M_2g_3=\frac{-i}{2}K_2M_2Q_2\,\mathrm{cn}(q_2\tau+d_2), \tag{17}$$

$$g_6=\frac{i}{2}q_2\,\mathrm{dn}(q_2\tau+d_2),$$

$$h_6=K_3h_3=K_3M_3h_1=\tfrac{1}{2}K_3M_3Q_3\,\mathrm{sn}(q_3\tau+d_3),$$

$$h_4=K_3h_5=K_3M_3h_7=\frac{-i}{2}K_3M_3Q_3\,\mathrm{cn}(q_3\tau+d_3), \tag{18}$$

$$h_2=\frac{i}{2}q_3\,\mathrm{dn}(q_3\tau+d_3).$$

III. MOYAL–NAHM EQUATIONS

Consider a field X^k $(k=0,1,2,3)$ in four dimensions where X^k depends upon only one coordinate (in this case t) and phase space (x,p). The gauge is fixed so X^0 is a constant. The Moyal–Nahm equations in three dimensions are:

$$\frac{\partial X^1}{\partial t}=\{X^2,X^3\}_{\mathrm{MB}}, \quad \frac{\partial X^2}{\partial t}=\{X^3,X^1\}_{\mathrm{MB}}, \quad \frac{\partial X^3}{\partial t}=\{X^1,X^2\}_{\mathrm{MB}}. \tag{19}$$

If the Moyal brackets were to be replaced by commutators and the functions $X^k(t,x,p)$ were replaced by matrices $X^k(t)$ then the equations would become the Nahm equations for a self-dual field. The main idea to solve these Moyal–Nahm equations is to use the following ansatz:

$$X^i=i\int_{-\infty}^{\infty}\psi_j^{\dagger}(x-y,t)\,\epsilon^{ijk}\psi_k(x+y,t)\,e^{2\pi ipy/\lambda}\,\mathrm{d}y, \tag{20}$$

where $\psi(x,t)$ are three component wave functions. These wave functions were chosen to be of the following form:

$$\psi(x,t)=\begin{pmatrix}\psi_1(x,t)\\ \psi_2(x,t)\\ \psi_3(x,t)\end{pmatrix}=\begin{pmatrix}f_1(t)\phi_1(x)\\ f_2(t)\phi_2(x)\\ f_3(t)\phi_3(x)\end{pmatrix}, \tag{21}$$

where the $\phi_i(x)$ are orthonormal wave functions. The star product of X^j and X^k is calculated as follows:

$$
\begin{aligned}
X^j\star X^k &= -\int\int \psi_i^\dagger(x-y,t)\epsilon^{jil}\psi_l(x+y,t)e^{2\pi ipy/\lambda}\star\psi_m^\dagger(x-y',t)\\
&\quad\times\epsilon^{kmn}\psi_n(x+y',t)e^{2\pi ipy'/\lambda}\,\mathrm{d}y\,\mathrm{d}y'\\
&= -\int\int \psi_i^\dagger(x-y+y',t)\epsilon^{jil}\psi_l(x+y+y',t)\\
&\quad\times e^{2\pi ipy/\lambda}\psi_m^\dagger(x-y'-y,t)\epsilon^{kmn}\psi_n(x+y'-y,t)e^{2\pi ipy'/\lambda}\,\mathrm{d}y\,\mathrm{d}y'\\
&= -\frac{1}{2}\int \psi_m^\dagger(x-y,t)\epsilon^{kmn}Z(t)\epsilon^{jil}\psi_l(x+y,t)e^{2\pi ipy/\lambda}\,\mathrm{d}y\\
&= -\frac{1}{2}\int \phi_m^\dagger(x-y)f_{ms}^\dagger(t)\epsilon^{ksn}Z(t)\epsilon^{jir}f_{rl}(t)\phi_l(x+y)e^{2\pi ipy/\lambda}\,\mathrm{d}y,
\end{aligned}
\tag{22}
$$

where orthogonality of the $\phi_k(x)$ is assumed to be of the form

$$
\int_{-\infty}^{\infty}\phi_j^\dagger(x)\phi_k(x)\mathrm{d}x=\delta_{jk} \tag{23}
$$

and

$$
Z(t)=f^\dagger f,
$$

$$
\text{where } f=\begin{pmatrix} f_1(t) & 0 & 0\\ 0 & f_2(t) & 0\\ 0 & 0 & f_3(t)\end{pmatrix}. \tag{24}
$$

The partial derivative $\partial X^i/\partial t$ can be written as

$$
\frac{\partial X^i}{\partial t}=i\int \phi_j^\dagger(x-y)\frac{\partial}{\partial t}(f^\dagger(t)\epsilon^{ijk}f(t))\phi_k(x+y)e^{2\pi ipy/\lambda}\,\mathrm{d}y. \tag{25}
$$

By putting these into the Moyal–Nahm equations one obtains three matrix equations of the form

$$
i\frac{\partial}{\partial t}(f^\dagger(t)\epsilon^1 f(t))=\frac{-1}{4i}(f^\dagger(t)\epsilon^3 Z(t)\epsilon^2 f(t)-f^\dagger(t)\epsilon^2 Z(t)\epsilon^3 f(t)), \tag{26}
$$

where ϵ^i is a 3×3 matrix with jkth entry ϵ^{ijk}. Equating the entries in the matrices gives differential equations of the form

$$
\frac{\partial}{\partial t}(f_2^* f_3)=-\frac{1}{4}|f_1|^2(f_2^* f_3),\quad \frac{\partial}{\partial t}(f_3^* f_2)=-\frac{1}{4}|f_1|^2(f_3^* f_2) \tag{27}
$$

and cycle combinations of these. These can be used to create the following set of three differential equations:

$$\frac{\partial}{\partial t}(|f_2|^2|f_3|^2) = -\frac{1}{2}|f_1|^2|f_2|^2|f_3|^2,$$

$$\frac{\partial}{\partial t}(|f_3|^2|f_1|^2) = -\frac{1}{2}|f_1|^2|f_2|^2|f_3|^2, \tag{28}$$

$$\frac{\partial}{\partial t}(|f_1|^2|f_2|^2) = -\frac{1}{2}|f_1|^2|f_2|^2|f_3|^2.$$

Note that for each of the above, the right-hand side of the equations is always the same.

A. Simplest solution

The simplest solution is to set all the f_i equal to each other. This gives the solution

$$|f_1|^2 = |f_2|^2 = |f_3|^2 = \frac{4}{t+K}, \tag{29}$$

so that

$$f_1(t) = f_2(t) = f_3(t) = \frac{2}{\sqrt{t+K}}, \tag{30}$$

where K is an arbitrary constant.

B. Another simple solution

By setting two of the f_i equal to each other then a solution in terms of the hyperbolic functions can be found.

$$|f_1|^2 = |f_2|^2 = 4q \coth(qt+K), \quad |f_3|^2 = 8q \operatorname{csch}(2qt+2K), \tag{31}$$

so that

$$f_1(t) = f_2(t) = 2\sqrt{q \coth(qt+K)}, \quad f_3(t) = 2\sqrt{2q \operatorname{csch}(2qt+2K)}, \tag{32}$$

where K and q are both real constants.

C. General solution

However, ideally we want a general solution to these equations. In this case the solutions are written in terms of elliptic functions sn, cn, and dn. The most general solution was found to be:

$$|f_1|^2 = 4qk \operatorname{sn}(qt+c),$$

$$|f_2|^2 = 2qk \operatorname{sn}(qt+c) + \frac{2q(\operatorname{dn}(qt+c)\operatorname{cn}(qt+c)+1)}{\operatorname{sn}(qt+c)}, \tag{33}$$

$$|f_3|^2 = 2qk \operatorname{sn}(qt+c) + \frac{2q(\operatorname{dn}(qt+c)\operatorname{cn}(qt+c)-1)}{\operatorname{sn}(qt+c)}.$$

k, q, and c are all constants but may have to be carefully chosen in order to ensure that all the $|f_i|^2$ are positive. k depends on the elliptic functions.

A more aesthetically pleasing form of solution is as follows:

$$|f_1|^2 = 4qk^2 \frac{\mathrm{sn}(qt+c)\mathrm{cn}(qt+c)}{\mathrm{dn}(qt+c)},$$

$$|f_2|^2 = -4q \frac{\mathrm{cn}(qt+c)\mathrm{dn}(qt+c)}{\mathrm{sn}(qt+c)}, \tag{34}$$

$$|f_3|^2 = 4q \frac{\mathrm{dn}(qt+c)\mathrm{sn}(qt+c)}{\mathrm{cn}(qt+c)}.$$

q, c, and k are all constants. Again, k depends on the elliptic functions.

IV. SEVEN-DIMENSIONAL MOYAL EQUATIONS AGAIN

The Moyal–Nahm equations in seven dimensions are:

$$\frac{\partial X^1}{\partial t} = \{X^2, X^7\}_{\mathrm{MB}} + \{X^6, X^3\}_{\mathrm{MB}} + \{X^5, X^4\}_{\mathrm{MB}},$$

$$\frac{\partial X^2}{\partial t} = \{X^7, X^1\}_{\mathrm{MB}} + \{X^5, X^3\}_{\mathrm{MB}} + \{X^4, X^6\}_{\mathrm{MB}},$$

$$\frac{\partial X^3}{\partial t} = \{X^1, X^6\}_{\mathrm{MB}} + \{X^2, X^5\}_{\mathrm{MB}} + \{X^4, X^7\}_{\mathrm{MB}},$$

$$\frac{\partial X^4}{\partial t} = \{X^1, X^5\}_{\mathrm{MB}} + \{X^6, X^2\}_{\mathrm{MB}} + \{X^7, X^3\}_{\mathrm{MB}}, \tag{35}$$

$$\frac{\partial X^5}{\partial t} = \{X^4, X^1\}_{\mathrm{MB}} + \{X^3, X^2\}_{\mathrm{MB}} + \{X^6, X^7\}_{\mathrm{MB}},$$

$$\frac{\partial X^6}{\partial t} = \{X^3, X^1\}_{\mathrm{MB}} + \{X^2, X^4\}_{\mathrm{MB}} + \{X^7, X^5\}_{\mathrm{MB}},$$

$$\frac{\partial X^7}{\partial t} = \{X^1, X^2\}_{\mathrm{MB}} + \{X^3, X^4\}_{\mathrm{MB}} + \{X^5, X^6\}_{\mathrm{MB}}.$$

The set of matrices B_i can also be used to find a solution to Eq. (35). Using the ansatz

$$A_i = i \int_{-\infty}^{\infty} \psi^{\dagger}(x-y,\tau) B_i \psi(x+y,\tau) e^{2\pi i p y/\lambda}\, \mathrm{d}y, \tag{36}$$

where $\psi(x,t)$ are six component wave functions of the form

$$\psi_j = f_j(\tau)\phi(x)_j, \quad j \ \text{not summed} \tag{37}$$

we find a rather simple solution in terms of this ansatz of the form

$$\{f_1, f_2, f_3, f_4, f_5, f_6\} = \left\{ \frac{2\sqrt{K_1} e^{i\theta_1}}{\sqrt{1-e^{-K_1\tau}}}, \frac{2\sqrt{K_1} e^{i\theta_2}}{\sqrt{e^{K_1\tau}-1}}, \frac{2\sqrt{K_2} e^{i\theta_3}}{\sqrt{1-e^{-K_2\tau}}}, \frac{2\sqrt{K_2} e^{i\theta_4}}{\sqrt{e^{K_2\tau}-1}}, \frac{2\sqrt{K_3} e^{i\theta_5}}{\sqrt{1-e^{-K_3\tau}}}, \frac{2\sqrt{K_3} e^{i\theta_6}}{\sqrt{e^{K_3\tau}-1}} \right\}.$$

All K_i and θ_j are constants.

The previous solution used the two-dimensional σ matrix representation of SU(2). If instead the three-dimensional representation of SU(2), which involves the completely antisymmetric matrices ϵ_{ijk}, is used to construct the B_i a more general τ-dependent solution can be found along similar lines to that in Sec. III. This time the matrices B_i were taken to be

$$B_1=-\begin{pmatrix}\epsilon_3 & 0\\ 0 & \epsilon_3\end{pmatrix},\quad B_2=-\begin{pmatrix}\epsilon_1 & 0\\ 0 & \epsilon_2\end{pmatrix},\quad B_3=-\begin{pmatrix}\epsilon_3 & 0\\ 0 & \epsilon_2\end{pmatrix},\quad B_4=-\begin{pmatrix}i\epsilon_2 & 0\\ 0 & \epsilon_3\end{pmatrix},$$
$$B_5=-\begin{pmatrix}\epsilon_2 & 0\\ 0 & i\epsilon_3\end{pmatrix},\quad B_6=-\begin{pmatrix}i\epsilon_3 & 0\\ 0 & \epsilon_1\end{pmatrix},\quad B_7=-\begin{pmatrix}\epsilon_2 & 0\\ 0 & i\epsilon_2\end{pmatrix}, \tag{38}$$

where the jkth entry of the matrix ϵ_i is given by the totally antisymmetric tensor ϵ_{ijk}.

The same ansatz (36), (37) was used as before but with the new B_i matrices. The τ-dependent functions f_i were found to be of the same form as the solution to the three-dimensional Moyal–Nahm equations when solved using ϵ matrices (34). They are as follows:

$$|f_1|^2=4qk^2\frac{\mathrm{sn}(q\tau+c)\mathrm{cn}(q\tau+c)}{\mathrm{dn}(q\tau+c)},\quad |f_4|^2=4QK^2\frac{\mathrm{sn}(Q\tau+b)\mathrm{cn}(Q\tau+b)}{\mathrm{dn}(Q\tau+b)},$$
$$|f_2|^2=-4q\,\frac{\mathrm{cn}(q\tau+c)\mathrm{dn}(q\tau+c)}{\mathrm{sn}(q\tau+c)},\quad |f_5|^2=-4Q\,\frac{\mathrm{cn}(Q\tau+b)\mathrm{dn}(Q\tau+b)}{\mathrm{sn}(Q\tau+b)}, \tag{39}$$
$$|f_3|^2=4q\,\frac{\mathrm{dn}(q\tau+c)\mathrm{sn}(q\tau+c)}{\mathrm{cn}(q\tau+c)},\quad |f_6|^2=4Q\,\frac{\mathrm{dn}(Q\tau+b)\mathrm{sn}(Q\tau+b)}{\mathrm{cn}(Q\tau+b)}.$$

These solutions can be extended for direct sums of more than two ϵ_i matrices.

APPENDIX: MATRIX REPRESENTATION OF STRUCTURE CONSTANTS

The following 7×7 matrices which solve the Nahm algebra are created using the octonionic structure constants c_{ijk} which are taken to be:

$$c_{127}=c_{631}=c_{541}=c_{532}=c_{246}=c_{347}=c_{567}=1. \tag{A1}$$

These are totally antisymmetric. All other c_{ijk} are zero. The jkth entry of the matrix m_i is given by $[m_i]_{jk}=c_{ijk}$,

$$m_1=\begin{pmatrix}0&0&0&0&0&0&0\\0&0&0&0&0&0&1\\0&0&0&0&0&-1&0\\0&0&0&0&-1&0&0\\0&0&0&1&0&0&0\\0&0&1&0&0&0&0\\0&-1&0&0&0&0&0\end{pmatrix},\quad m_2=\begin{pmatrix}0&0&0&0&0&0&-1\\0&0&0&0&0&0&0\\0&0&0&0&-1&0&0\\0&0&0&0&0&1&0\\0&0&1&0&0&0&0\\0&0&0&-1&0&0&0\\1&0&0&0&0&0&0\end{pmatrix},$$

$$m_3=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 0 & 1 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 1\\ 0 & -1 & 0 & 0 & 0 & 0 & 0\\ -1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & -1 & 0 & 0 & 0 \end{pmatrix}, \quad m_4=\begin{pmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & -1 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & -1\\ 0 & 0 & 0 & 0 & 0 & 0 & 0\\ -1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$m_5=\begin{pmatrix} 0 & 0 & 0 & -1 & 0 & 0 & 0\\ 0 & 0 & -1 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 1\\ 0 & 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}, \quad m_6=\begin{pmatrix} 0 & 0 & -1 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & -1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & -1\\ 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \end{pmatrix},$$

$$m_7=\begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0\\ -1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0 & 0 & 0\\ 0 & 0 & -1 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 0 & -1 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

(Received 20 November 1998; accepted for publication 8 February 1999)

Adapting ideas of Daubechies and Klauder [J. Math. Phys. **26**, 2239 (1985)] we derive a rigorous continuum path-integral formula for the semigroup generated by a spin Hamiltonian. More precisely, we use spin coherent vectors parametrized by complex numbers to relate the coherent representation of this semigroup to a suitable Schrödinger semigroup on the Hilbert space $L^2(\mathbb{R}^2)$ of Lebesgue square-integrable functions on the Euclidean plane $\mathbb{R}^2$. The path-integral formula emerges from the standard Feynman–Kac–Itô formula for the Schrödinger semigroup in the ultradiffusive limit of the underlying Brownian bridge on $\mathbb{R}^2$. In a similar vein, a path-integral formula can be constructed for the coherent representation of the unitary time evolution generated by the spin Hamiltonian. © *1999 American Institute of Physics.* [S0022-2488(99)02005-8]

I. INTRODUCTION

Even 50 years after the appearance of Feynman's celebrated paper[1] that introduced the path-integral formalism[2–6] into quantum theory in a heuristic but convincing manner, there is no general consensus on how to treat a quantum spin within this framework. To the best of our knowledge, among the various approaches over the years, see, for example, Refs. 7–22, the only rigorous expression for the dynamics of a quantum spin in terms of an integral over continuous paths is due to Daubechies and Klauder.[12] These authors were able to write the coherent representation of the unitary time-evolution operator of a spin with a definite quantum number as a Wiener-regularized path integral, more precisely, as the ultradiffusive limit of a well-defined integral over spherical Brownian-motion paths.

The main goal of the present paper is to show that one may equally well perform the Wiener regularization by employing planar Brownian motion. In this way also a closer contact to symbolic continuum path-integral formulas widely discussed in the recent literature[23–28] is established. One may hope that the wealth of analytical tools associated with the flat-space Wiener measure helps clarifying some subtle points there.

II. BASIC DEFINITIONS, RESULT, AND COMMENTS

We consider a single spin with fixed *quantum number* $j\in\{0,1/2,1,3/2,...\}$, that is, using physical units where Planck's constant $2\pi\hbar$ equals 2π,

$$\tfrac{1}{2}(\mathcal{J}_+\mathcal{J}_-+\mathcal{J}_-\mathcal{J}_+)+\mathcal{J}_3^2=j(j+1)\mathbf{1}. \tag{1}$$

The *spin operators* $\mathcal{J}_+$, $\mathcal{J}_-$, and $\mathcal{J}_3$ obey the usual angular-momentum commutation relations $\mathcal{J}_+\mathcal{J}_--\mathcal{J}_-\mathcal{J}_+=2\mathcal{J}_3$, $\mathcal{J}_3\mathcal{J}_\pm-\mathcal{J}_\pm\mathcal{J}_3=\pm\mathcal{J}_\pm$ and are viewed as acting on the $(2j+1)$-

TABLE I. Contravariant symbols for selected operators on $\mathbb{C}^{2j+1}$, which are bounded and continuous.

Operator	Contravariant symbol	Operator	Contravariant symbol
$\mathcal{J}_+$	$2(j+1)\dfrac{z^*}{1+\lvert z\rvert^2}$	$\mathcal{J}_+\mathcal{J}_-$	$-2(j+1)\dfrac{1-2(j+1)\lvert z\rvert^2}{(1+\lvert z\rvert^2)^2}$
$\mathcal{J}_-$	$2(j+1)\dfrac{z}{1+\lvert z\rvert^2}$	$\mathcal{J}_-\mathcal{J}_+$	$2(j+1)\dfrac{2(j+1)\lvert z\rvert^2-\lvert z\rvert^4}{(1+\lvert z\rvert^2)^2}$
$\mathcal{J}_3$	$-(j+1)\dfrac{1-\lvert z\rvert^2}{1+\lvert z\rvert^2}$	$\mathcal{J}_3^2$	$(j+1)(j+\frac{3}{2})\left(\dfrac{1-\lvert z\rvert^2}{1+\lvert z\rvert^2}\right)^2-\dfrac{j+1}{2}$

dimensional complex Hilbert space $\mathbb{C}^{2j+1}$. Its standard scalar product is denoted as $\langle\cdot|\cdot\rangle$ and, by convention, antilinear in the first argument. The unit operator on $\mathbb{C}^{2j+1}$ is denoted by **1**.

Non-normalized so-called *coherent vectors*[9,29] in this Hilbert space,

$$|z\rangle := g(z)e^{z\mathcal{J}_+}|j,-j\rangle, \quad z\in\mathbb{C}, \tag{2}$$

are parametrized by complex numbers z. Henceforth, z^* will refer to their complex conjugates, $z_1:=(z+z^*)/2$ and $z_2:=(z-z^*)/2i$ to their real and imaginary parts, and we write $f^*(z) := (f(z))^*$ for the values of complex-conjugated functions f^*. For later notational convenience the strictly positive prefactor is taken as

$$g(z) := \left(\frac{2j+1}{\pi}\right)^{1/2}(1+|z|^2)^{-j-1}, \tag{3}$$

and a normalized *spin-down vector* $|j,-j\rangle\in\mathbb{C}^{2j+1}$, obeying $\mathcal{J}_-|j,-j\rangle=0$ and $\langle j,-j|j,-j\rangle=1$, serves as the reference vector. Every vector $|\psi\rangle\in\mathbb{C}^{2j+1}$ is characterized by its so-called *coherent representation* $\langle z|\psi\rangle$, a function of the form $g(z)$ times a polynomial in z^* of maximal degree $2j$. The scalar product of two coherent vectors $\langle z|z'\rangle = g(z)g(z')(1+z^*z')^{2j}$ is an example. Given an arbitrary operator $\mathcal{B}$ on $\mathbb{C}^{2j+1}$, the scalar product $\langle z|\mathcal{B}|z'\rangle$ of $|z\rangle$ and $\mathcal{B}|z'\rangle$ is called the *coherent representation* of $\mathcal{B}$. The mapping $(z,z')\mapsto\langle z|\mathcal{B}|z'\rangle$ is continuous, because $z\mapsto|z\rangle$ is continuous, every operator $\mathcal{B}$ on $\mathbb{C}^{2j+1}$ is bounded, and the scalar product $(|\varphi\rangle,|\psi\rangle)\mapsto\langle\varphi|\psi\rangle$ is continuous. An example is $\langle z|e^{2\lambda\mathcal{J}_3}|z'\rangle = g(z)g(z')(e^{-\lambda}+z^*z'e^{\lambda})^{2j}$, $\lambda\in\mathbb{C}$.

In what follows, it is a comforting fact that whatever the *spin Hamiltonian* $\mathcal{H}$ may be—given as a (self-adjoint) operator on $\mathbb{C}^{2j+1}$—it is polynomial in the spin operators $\mathcal{J}_+$, $\mathcal{J}_-$, and $\mathcal{J}_3$, and it is always possible to write it in *pseudodiagonal form*,

$$\mathcal{H} = \int_{\mathbb{C}} d^2z\, h(z)|z\rangle\langle z|. \tag{4}$$

Here the (real-valued) function h on $\mathbb{C}\cong\mathbb{R}\times\mathbb{R}$ may be chosen bounded and continuous,[30–32] the operator $|z\rangle\langle z|/\langle z|z\rangle$ denotes the orthogonal projection onto the one-dimensional subspace spanned by $|z\rangle\in\mathbb{C}^{2j+1}$, and $d^2z := dz_1\,dz_2$ is the two-dimensional Lebesgue measure on the Euclidean plane $\mathbb{R}\times\mathbb{R}=:\mathbb{R}^2$. Following Ref. 33, we call h a *contravariant symbol* of $\mathcal{H}$, elsewhere called an upper[34] or lower[35] symbol. In particular, the unit operator **1** has the constant 1 as a contravariant symbol. In this sense, the coherent vectors are *unity-resolving* and hence (over-)complete. Other examples for contravariant symbols are listed in Table I; confer Ref. 36.

After these preparations we are able to state the main result of the present paper, namely, a rigorous expression for the *spin semigroup* $\{e^{-t\mathcal{H}}\}_{t\geqslant 0}$ as the *ultradiffusive limit* of a Wiener type of integral over Brownian-motion paths $\{s \mapsto b(s) = b_1(s) + i b_2(s)\}_{s \geq 0}$ on the complex plane $\mathbb{C} \cong \mathbb{R} \times \mathbb{R}$. More precisely, the coherent representation of $e^{-t\mathcal{H}}$ may, for all $z, z' \in \mathbb{C}$ and $t > 0$, be written as

$$\langle z | e^{-t\mathcal{H}} | z' \rangle = \lim_{\nu \to \infty} \int d\mu^{(\nu)}_{z,0;z',t}(b) \exp\left\{ 4(j+1)\nu \int_0^t \frac{ds}{(1+|b(s)|^2)^2} \right\} \times \exp\left\{ (j+1) \int_0^t ds \, \frac{\dot{b}(s) b^*(s) - \dot{b}^*(s) b(s)}{1+|b(s)|^2} - \int_0^t ds \, h(b(s)) \right\}. \tag{5}$$

Here for given z, $z' \in \mathbb{C}$, $t > 0$, and $\nu > 0$ the path integration is defined by

$$\int d\mu^{(\nu)}_{z,0;z',t}(b)(\cdot) := \frac{1}{4\pi t \nu} e^{-|z-z'|^2/4t\nu} \mathbb{E}(\cdot), \tag{6}$$

where $\mathbb{E}(\cdot)$ indicates the probabilistic expectation with respect to the *two-dimensional Brownian bridge*, with diffusion constant ν starting in $z = b(0)$ and arriving at $z' = b(t)$ a time t later.[3,6,37–39] As a Gaussian stochastic process with continuous paths on $\mathbb{C} \cong \mathbb{R} \times \mathbb{R}$ the Brownian bridge, in its turn, is uniquely determined by its mean,

$$\mathbb{E}(b(s)) = z + (z' - z) \frac{s}{t}, \quad s \in [0, t], \tag{7}$$

and covariances,

$$\mathbb{E}(b^*(r) b(s)) - \mathbb{E}(b^*(r)) \mathbb{E}(b(s)) = 4\nu \left(\min\{r, s\} - \frac{rs}{t} \right), \tag{8}$$

$$\mathbb{E}(b(r) b(s)) - \mathbb{E}(b(r)) \mathbb{E}(b(s)) = 0, \quad r, s \in [0, t]. \tag{9}$$

The second integral in the exponent on the right-hand side of (5) is a purely imaginary stochastic (line) integral,[37–39] which is understood in the sense of Fisk and Stratonovich and to which one is therefore allowed to apply the rules of ordinary calculus,[40] although the time derivative $\dot{b}$ does not exist.

Several comments apply.

(i) By the Itô formula[3,37–39] it can be seen that the stochastic integral in (5) may equally well be interpreted as a stochastic integral in the sense of Itô. Moreover, using the Itô formula in a different way, the sum of this integral and the first (Lebesgue) integral in the exponent of the right-hand side of (5) can be converted[41] according to

$$4\nu \int_0^t \frac{ds}{(1+|b(s)|^2)^2} + \int_0^t ds \, \frac{\dot{b}(s) b^*(s) - \dot{b}^*(s) b(s)}{1+|b(s)|^2} = \ln\left(\frac{1+|b(t)|^2}{1+|b(0)|^2} \right) - 2 \int_0^t \frac{db^*(s) b(s)}{1+|b(s)|^2}. \tag{10}$$

Here the complex stochastic integral $\int_0^t db^*(s) b(s) / [1+|b(s)|^2]$ has to be understood in the sense of Itô. It contains the only ν-dependence of the right-hand side. By using (10) in the path integrand in (5), the logarithmic term results in the prefactor $[(1+|z'|^2)/(1+|z|^2)]^{j+1} = g(z)/g(z')$.

(ii) The stochastic integral in (5) is of kinematical origin and reflects the symplectic structure, which renders the complex plane a phase space for the so-called classical spin;[42,43,31] also see the concluding remarks.

(iii) If one wants to use (5) to express the trace $\int_{\mathbb{C}} d^2 z \langle z | e^{-t\mathcal{H}} | z \rangle$ of $e^{-t\mathcal{H}}$ as a path integral, one should resist the temptation to interchange the integration with respect to z with the ultradiffusive limit $\nu \to \infty$, because the resulting prelimit expression would be infinite.

(iv) Instead of taking the ultradiffusive limit, one may perform the regularization also by a *long-time limit*, in the sense that

$$\langle z|e^{-t\mathcal{H}}|z'\rangle=\lim_{u\to\infty}\int d\mu^{(\nu)}_{z,0;z',u}(b)\exp\left\{4(j+1)\nu\int_0^u\frac{ds}{(1+|b(s)|^2)^2}\right\}$$
$$\times\exp\left\{(j+1)\int_0^u ds\,\frac{\dot b(s)b^*(s)-\dot b^*(s)b(s)}{1+|b(s)|^2}-\frac{t}{u}\int_0^u ds\,h(b(s))\right\}. \qquad (11)$$

This formula can be deduced from (5) by suitably scaling the Brownian bridge, holds for all $\nu>0$, and, in contrast to (5), makes sense as it stands even for $t\leqslant 0$, hence for all $t\in\mathbb{R}$. One should notice that the time-parameter set of the Brownian bridge used in (11) is the closed interval $[0,u]$ and not $[0,t]$.

(v) Replacing h by ih in (5) or (11) yields analogous expressions for the coherent representation of the (unitary) *spin time-evolution* operator $e^{-it\mathcal{H}}$. A rigorous justification relies on the boundedness and continuity of h and requires extending the subsequent proof by showing analyticity of both sides of (5) in a coupling parameter $\lambda\in\mathbb{C}$ multiplying h. The left-hand side and the prelimit expression in (5) are easily seen to be analytic in λ. Analyticity in λ in the limit $\nu\to\infty$ is then proved with the help of an equation analogous to (29) and uniform convergence in $\nu>2\nu_0>0$ of the perturbation series in λ of the relevant operator and functions there.

(vi) The flat-space Wiener-regularized path-integral expression (5) for the spin semigroup is an alternative to a result first given and proved in Ref. 12. There the authors integrate over Brownian-motion paths on the unit-sphere in the three-dimensional Euclidean space $\mathbb{R}^3$ to obtain the coherent representation of $e^{-it\mathcal{H}}$. Unlike in Ref. 12, the regularizing path measure $d\mu^{(\nu)}_{z,0;z',t}(b)\exp\{4(j+1)\nu\int_0^t ds(1+|b(s)|^2)^{-2}\}$ used in (5) is not invariant under the full special unitary group SU(2) when the latter is realized by suitable Möbius transformations on the (extended) complex plane. Yet in the limit $\nu\to\infty$ all symmetries of a given spin Hamiltonian are restored. Contrary to what one might expect, Eq. (5) cannot be obtained from the corresponding result in Ref. 12 merely by stereographically projecting the paths from the sphere onto the (extended) plane. Nevertheless, the proof given in the next section shows that the key ideas behind both constructions are the same; also see the concluding remarks.

(vii) So far we have considered a fixed spin quantum number j. In order to make contact with the Wiener-regularized path-integral expression associated with a canonical degree of freedom, also proved in Ref. 12, one has to contract[44,45] the algebra of SU(2) to the Heisenberg–Weyl algebra by taking the *high-spin limit* $j\to\infty$. More explicitly, in the given (polynomial) spin Hamiltonian $\mathcal{H}$ on $\mathbb{C}^{2j+1}$, one has to replace $\mathcal{J}_+$, $\mathcal{J}_-$, and $\mathcal{J}_3$ by $\mathcal{J}_+/\sqrt{2j}$, $\mathcal{J}_-/\sqrt{2j}$, and $\mathcal{J}_3+j\mathbf{1}$, respectively. If $\mathcal{H}_j=\int_{\mathbb{C}}d^2z\,h_j(z)|z\rangle\langle z|$ denotes the resulting operator, one then finds the relation

$$\lim_{j\to\infty}\frac{\pi}{2j}\langle z/\sqrt{2j}|e^{-t\mathcal{H}_j}|z'/\sqrt{2j}\rangle=\langle\langle z|e^{-t\mathsf{H}}|z'\rangle\rangle, \qquad (12)$$

where $|z\rangle\rangle\in L^2(\mathbb{R})$ is a normalized canonical coherent vector[30–32] and the Hamiltonian H on $L^2(\mathbb{R})$, the Hilbert space of Lebesgue square-integrable complex-valued functions on the real line $\mathbb{R}$, is defined by

$$\mathsf{H}:=\int_{\mathbb{C}}\frac{d^2z}{\pi}\mathsf{h}(z)|z\rangle\rangle\langle\langle z|, \quad \text{with } \mathsf{h}(z):=\lim_{j\to\infty}h_j(z/\sqrt{2j}). \qquad (13)$$

By using (5) for the prelimit expression in (12), suitably rescaling the Brownian bridge, and interchanging the order of the limits $j\to\infty$ and $\nu\to\infty$, one arrives at the path-integral formula

$$\langle\langle z|e^{-t\mathsf{H}}|z'\rangle\rangle=\pi\lim_{\nu\to\infty}e^{2t\nu}\int d\mu^{(\nu)}_{z,0;z',t}(b)\exp\left\{\frac{1}{2}\int_0^t ds[\dot b(s)b^*(s)-\dot b^*(s)b(s)]\right\}$$
$$\times\exp\left\{-\int_0^t ds\,\mathsf{h}(b(s))\right\}, \qquad (14)$$

in agreement with Eq. (1.3) in Ref. 12; also see Refs. 46 and 35. Formula (14) can be shown to hold not only for the polynomial Hamiltonians $\mathcal{H}$ resulting from the contraction, but for a wider class of operators whose conditions are stated in Theorem 2.4 of Ref. 12.

(viii) With regard to some of the symbolic path-integral expressions for spin systems frequently encountered in the literature, see, for example, Refs. 10, 11, and 23–28, it might be illuminating to recognize certain formal similarities between these expressions and the above result (5). While the kinematical and dynamical terms in the exponents of all the corresponding path integrands look essentially the same, only the above result is based on a genuine path measure, namely, $d\mu^{(\nu)}_{z,0;z',t}(b)\exp\{4(j+1)\nu\int_0^t ds(1+|b(s)|^2)^{-2}\}$, but requires taking the limit $\nu\to\infty$. Here, the Wiener type of measure $d\mu^{(\nu)}_{z,0;z',t}(b)$ is often symbolically written as $\delta^2 b\ \delta(b(0)-z)\,\delta(b(t)-z')\exp\{-(1/4\nu)\int_0^t ds|\dot{b}(s)|^2\}$, or similarly. In any case, the necessity to regularize by some ultradiffusive limit was observed several times also in nonrigorous works.[10,17–19,27]

III. PROOF

The proof of (5) consists of three major steps, adapting key ideas of Ref. 12. First, the spin Hilbert space $\mathbb{C}^{2j+1}$ is embedded into $L^2(\mathbb{C})$, the Hilbert space of Lebesgue square-integrable complex-valued functions on $\mathbb{C}$. Next, it is identified with the $(2j+1)$-dimensional ground-state eigenspace of a suitable Schrödinger operator R acting on $L^2(\mathbb{C})$. Then the spin semigroup, now realized on $L^2(\mathbb{C})$, is shown to be the limit $\nu\to\infty$ of a Schrödinger semigroup generated by a suitably perturbed νR. Rewriting this Schrödinger semigroup with the help of the standard Feynman–Kac–Itô path-integral formula finally gives (5).

A. The embedding of the spin Hilbert space

The embedding of the spin Hilbert space $\mathbb{C}^{2j+1}$ into the infinite-dimensional Hilbert space $L^2(\mathbb{C})$, equipped with the standard scalar product $(\varphi|\psi):=\int_{\mathbb{C}} d^2z\ \varphi^*(z)\psi(z)$, is accomplished by interpreting the coherent representation as a linear isometric mapping,

$$I:\ \mathbb{C}^{2j+1}\to L^2(\mathbb{C}),\quad |\psi\rangle\mapsto\psi, \tag{15}$$

where the function ψ on $\mathbb{C}\cong\mathbb{R}\times\mathbb{R}$ is defined by its values $\psi(z):=\langle z|\psi\rangle$.

The (Hilbert) adjoint $I^\dagger$ of I explicitly reads as

$$I^\dagger:\ L^2(\mathbb{C})\to\mathbb{C}^{2j+1},\quad \varphi\mapsto\int_{\mathbb{C}} d^2z\ \varphi(z)|z\rangle, \tag{16}$$

and the isometric property is simply stated as $I^\dagger I=\mathbf{1}$. The orthogonal projection from $L^2(\mathbb{C})$ onto $I(\mathbb{C}^{2j+1})$ is the operator $II^\dagger=:E_0$.

Every operator $\mathcal{B}$ on $\mathbb{C}^{2j+1}$ can be realized by the unitary equivalent $I\mathcal{B}I^\dagger$ on $E_0(L^2(\mathbb{C}))=I(\mathbb{C}^{2j+1})$, which trivially extends to the whole of $L^2(\mathbb{C})$. In particular, it follows from (4) that

$$I\mathcal{H}I^\dagger=E_0HE_0, \tag{17}$$

where H is the bounded multiplication operator on $L^2(\mathbb{C})$ defined by the function h, that is, $(H\varphi)(z):=h(z)\varphi(z)$ for all $\varphi\in L^2(\mathbb{C})$. Furthermore, the embedded operator $I\mathcal{H}I^\dagger$ possesses a continuous integral kernel $I\mathcal{H}I^\dagger(z,z')$ (also known as its position representation) given by the coherent representation of $\mathcal{H}$, that is,

$$I\mathcal{H}I^\dagger(z,z')=\langle z|\mathcal{H}|z'\rangle. \tag{18}$$

Using (17), one can now verify the identify $Ie^{-t\mathcal{H}}I^\dagger=E_0e^{-tE_0HE_0}$ to all orders in t, which, analogous to (18), shows that $E_0e^{-tE_0HE_0}$ has a continuous integral kernel given by the equation

$$E_0e^{-tE_0HE_0}(z,z')=\langle z|e^{-t\mathcal{H}}|z'\rangle. \tag{19}$$

B. A Schrödinger operator and its ground-state eigenspace

Consider on $L^2(\mathbb{C})$ the ‘‘magnetic’’ Schrödinger operator,

$$R := (i\partial_1 + A_1)^2 + (i\partial_2 + A_2)^2 + V, \tag{20}$$

with the partial differential operators $\partial_1 := \partial/\partial z_1$, $\partial_2 := \partial/\partial z_2$ and the vector and scalar potentials $\binom{A_1}{A_2}$ and V acting as multiplication operators defined by the bounded and continuous functions,

$$\begin{pmatrix} a_1(z) \\ a_2(z) \end{pmatrix} := \begin{pmatrix} -\partial_2 \\ \partial_1 \end{pmatrix} \ln g(z) = \frac{2(j+1)}{1+|z|^2} \begin{pmatrix} z_2 \\ -z_1 \end{pmatrix}, \tag{21}$$

$$v(z) := \partial_1 a_2(z) \text{-} \partial_2 a_1(z) = -\frac{4(j+1)}{(1+|z|^2)^2}. \tag{22}$$

The self-adjoint operator R is tailored such that its ground-state eigenspace is identical to $E_0(L^2(\mathbb{C}))$ and the corresponding eigenvalue vanishes. In essence, this follows from a result of Aharonov and Casher[47] on zero-energy eigenstates. Since the proof is quite short, we will give it, thereby closely following the presentation in Ref. 48. Factorized like $R = D^\dagger D$, where $D := i\partial_1 + \partial_2 + A_1 - iA_2$, the positivity of R becomes manifest. Its null space consists of all those functions ψ in $L^2(\mathbb{C})$ with $D\psi = 0$. The general solution of this differential equation is a product $\psi = g\phi$, where ϕ is any function analytic in z^*, that is, $(\partial_1 - i\partial_2)\phi = 0$. Due to (3), square integrability then requires ϕ to be any polynomial in z^* of maximal degree $2j$, which proves that the ground-state eigenspace of R and the subspace $E_0(L^2(\mathbb{C})) = I(\mathbb{C}^{2j+1})$ are identical.

Two remarks are in order.

(i) The spectrum of R coincides with the positive half-line, as can be inferred from Theorem 6.1 in Ref. 48. Following arguments as in the proof of Theorem 6.2 in Ref. 48, one sees that zero is the only eigenvalue. Therefore the nature of the spectrum and the ground-state eigenfunctions are explicitly known. However, we are not aware of explicit results on generalized eigenfunctions corresponding to strictly positive spectral values.

(ii) Employing the spectral theorem, one proves that the semigroup generated by νR converges strongly to the ground-state projection E_0, in the sense that

$$\lim_{\nu\to\infty} \| e^{-t\nu R}\varphi - E_0\varphi \| = 0, \quad \text{for all} \quad \varphi \in L^2(\mathbb{C}) \quad \text{and} \quad t > 0, \tag{23}$$

where the norm $\|\cdot\| := (\cdot|\cdot)^{1/2}$ corresponds to the standard scalar product on $L^2(\mathbb{C})$.

C. The spin semigroup as the limit of a Schrödinger semigroup

With the material gathered in Secs. III A and III B we can isolate the central reason for the validity of the main result (5) of the present paper. The point is that the spin semigroup, now realized on $L^2(\mathbb{C})$, can be understood as the limit $\nu \to \infty$ of the Schrödinger semigroup generated by $\nu R + H$. More precisely, we will show that the continuous integral kernel given in (19) is the pointwise limit

$$E_0 e^{-tE_0HE_0}(z,z') = \lim_{\nu\to\infty} e^{-t(\nu R + H)}(z,z'), \quad \text{for all} \quad z,z' \in \mathbb{C} \quad \text{and} \quad t > 0, \tag{24}$$

where the prelimit expression is the continuous integral kernel of $\exp\{-t(\nu R + H)\}$. By expressing this integral kernel in terms of the *Feynman–Kac–Itô formula*[49,50] (observing $\partial_1 a_1 + \partial_2 a_2 = 0$)

$$e^{-t(\nu R+H)}(z,z')=\int d\mu^{(\nu)}_{z,0;z',t}(b)\exp\left\{(j+1)\int_0^t ds\,\frac{\dot{b}(s)b^*(s)-\dot{b}^*(s)b(s)}{1+|b(s)|^2}\right\}$$
$$\times\exp\left\{4(j+1)\nu\int_0^t\frac{ds}{(1+|b(s)|^2)^2}-\int_0^t ds\,h(b(s))\right\},\tag{25}$$

the right-hand sides of (24) and (5) are seen to coincide.

The proof of (24) makes essential use of the semigroup property of $e^{-t(\nu R+H)}$. Throughout the proof we fix $t>0$ and pick some reference diffusion constant $\nu_0>0$. As a starting point we define

$$\eta_w^{(\lambda)}(z):=e^{-t(\nu_0 R+\lambda H)}(z,w),\tag{26}$$

for all $\lambda\in\mathbb{R}$ and $w,z\in\mathbb{C}$. We assert that the function $\eta_w^{(\lambda)}:z\mapsto\eta_w^{(\lambda)}(z)$ is continuous, bounded, and lies in $L^2(\mathbb{C})$. The continuity follows from that of the integral kernel in (25). Boundedness and square integrability result from the inequality

$$|\eta_w^{(\lambda)}(z)|\leqslant e^{4(j+1)t\nu_0}e^{t|\lambda|\|h\|_\infty}(4\pi t\nu_0)^{-1}e^{-|z-w|^2/4t\nu_0},\tag{27}$$

where $\|h\|_\infty:=\sup_{z\in\mathbb{C}}|h(z)|<\infty$ denotes the supremum norm of h. This inequality, in turn, is found by estimating the path integral in (25). We also state that the mappings $w\mapsto\eta_w^{(\lambda)}$ and $\lambda\mapsto\eta_w^{(\lambda)}$ are strongly continuous. The first statement holds because of $(\eta_w^{(\lambda)}|\eta_{w'}^{(\lambda)})=e^{-2t(\nu_0 R+\lambda H)}(w,w')$ and the continuity of the integral kernel. The second one is a consequence of the inequality

$$\|\eta_w^{(\lambda)}-\eta_w^{(\lambda')}\|\leqslant\sqrt{\frac{t}{8\pi\nu_0}}|\lambda-\lambda'|\|h\|_\infty e^{4(j+1)t\nu_0}e^{t\max\{|\lambda|,|\lambda'|\}\|h\|_\infty},\tag{28}$$

which is derived by estimating the difference of two path integrals of type (25) using the elementary inequality $|e^x-e^y|\leqslant|x-y|e^{\max\{x,y\}}$, for $x,y\in\mathbb{R}$.

The following two steps of the proof are based on writing the integral kernel for $\nu>2\nu_0$ as a scalar product,

$$e^{-t(\nu R+H)}(z,z')=(\eta_z^{(\nu_0/\nu)}|e^{-t(\nu-2\nu_0)(R+H/\nu)}\eta_{z'}^{(\nu_0/\nu)}).\tag{29}$$

In the first step, we claim that

$$\lim_{\nu\to\infty}(\eta_z^{(\nu_0/\nu)}|e^{-t(\nu-2\nu_0)(R+H/\nu)}\eta_{z'}^{(\nu_0/\nu)})=(\eta_z^{(0)}|E_0e^{-tE_0HE_0}\eta_{z'}^{(0)}),\tag{30}$$

for all $z,z'\in\mathbb{C}$.

Due to the strong continuity of $\lambda\mapsto\eta_w^{(\lambda)}$, the boundedness of $e^{-t(\nu-2\nu_0)(R+H/\nu)}$, which is uniform in ν, and the continuity of the scalar product $(\cdot|\cdot)$, it suffices to show that

$$\lim_{\nu\to\infty}\|e^{-t(\nu-2\nu_0)(R+H/\nu)}\varphi-E_0e^{-tE_0HE_0}\varphi\|=0,\quad\text{for all}\quad\varphi\in L^2(\mathbb{C}).\tag{31}$$

To prove this strong operator convergence we employ the Duhamel–Dyson–Phillips perturbation expansion,

$$e^{-t(\nu-2\nu_0)(R+H/\nu)}\varphi=e^{-t(\nu-2\nu_0)R}\varphi+\sum_{n=1}^{\infty}\left(\frac{2\nu_0-\nu}{\nu}\right)^n\int_0^t ds_n\cdots\int_0^{s_3}ds_2\int_0^{s_2}ds_1\,e^{-(t-s_n)(\nu-2\nu_0)R}$$
$$\times H\times\cdots\times e^{-(s_2-s_1)(\nu-2\nu_0)R}He^{-s_1(\nu-2\nu_0)R}\varphi,\tag{32}$$

which converges uniformly in $\nu\in]2\nu_0,\infty[$ with respect to the norm on $L^2(\mathbb{C})$. This holds because the norm of the series is dominated by the exponential series $\Sigma_{n=0}^{\infty}(t^n/n!)\|h\|_\infty^n\|\varphi\|$, independent of ν. Thus, the limit $\nu\rightarrow\infty$ can be interchanged with the summation and, using (23) and the dominated-convergence theorem, we obtain the expansion of $E_0 e^{-tE_0HE_0}\varphi$.

In the second and final step we claim that the right-hand side of (30) is already the desired integral kernel, that is,

$$(\eta_z^{(0)}|E_0 e^{-tE_0HE_0}\eta_{z'}^{(0)})=E_0 e^{-tE_0HE_0}(z,z'),\quad \text{for all } z,z'\in\mathbb{C}. \tag{33}$$

This is verified by checking that the mapping $(z,z')\mapsto(\eta_z^{(0)}|E_0 e^{-tE_0HE_0}\eta_{z'}^{(0)})$ constitutes an integral kernel of $E_0 e^{-tE_0HE_0}$ and is, in fact, continuous. The former is true since $e^{-t\nu_0 R}E_0=E_0$. The latter holds because the mapping $w\mapsto\eta_w^{(0)}$ is strongly continuous, the operator $E_0 e^{-tE_0HE_0}$ is bounded, and the scalar product $(\cdot|\cdot)$ is continuous.

IV. CONCLUDING REMARKS

We conclude the paper with six remarks.

(i) As already mentioned in Sec. II, the main result (5) cannot be obtained from a result in Ref. 12 merely by stereographically projecting the Brownian paths from the two-sphere S^2 onto the (extended) Euclidean plane $\mathbb{R}^2$. The reason can be traced back to the different operators, or equivalently path measures, used for regularization. The stereographic projection corresponds to reexpressing the differential operator on $L^2(S^2)$ used by the authors of Ref. 12 in flat Cartesian coordinates. The resulting operator is not of the standard Schrödinger form, acts on a weighted Hilbert space, and is not related to planar Brownian motion.

(ii) In contrast to Ref. 12 the regulatizing operator R used in the proof of (24), and hence of (5), has no spectral gap above its ground-state eigenvalue. Accordingly, $e^{-t\nu R}$ only converges strongly, and not in operator norm, to the corresponding eigenprojection E_0 as $\nu\rightarrow\infty$. As a consequence, the foregoing proof of the pointwise convergence of integral kernels required a strategy different from that in Ref. 12.

(iii) From a fundamental point of view, it is gratifying that a spin system can be related to a limit of a well-defined integral over continuous Brownian-motion paths. From a practical point of view, it would be desirable to apply to (5) the well-established theory and computational possibilities associated with the flat-space Wiener measure,[3,39,51] in order to attack specific spin problems of physical interest. One such problem, which has been extensively discussed in the recent literature,[23–28] is to understand the nature of the saddle-point approximation for the evaluation of continuum path integrals connected with simple spin Hamiltonians. Looking at Table I and the resulting j-dependence of the path integrand in (5), this approximation is expected to be the more reliable the larger the spin quantum number is. Moreover, for Hamiltonians $\mathcal{H}$ linear in the spin operators, the saddle-point approximation is believed[23–27] to give the (explicitly known) exact result already for given finite j. In this context, when dealing with symbolic continuum path integrals one has to overcome the so-called overspecification problem due to missing regularizing terms in the action functionals of those path integrals.[10,27] Rigorous continuum path integrals as used in (5) do not suffer from this problem by their very construction. Of course, the details for the saddle-point approximation of the Wiener type of path integral in the ultradiffusive limit still have to be worked out.

(iv) In Refs. 52 and 53, the ground-state eigenspace of a charged point mass under the influence of a certain magnetic field on an even-dimensional Riemannian manifold is studied, thereby extending the Aharonov–Casher theorem.[47,48] This result lies at the heart of the quantization procedure proposed in Refs. 53–55. A quantum system is hereby represented on the ground-state eigenspace of such a generalized Landau Hamiltonian on the Hilbert space of functions over its classical phase space. The symplectic structure of the latter determines the magnetic field. In this sense, Eq. (5) read from right to left can be viewed as a *quantization prescription* for a classical spin system.

In this context it is worth mentioning that the path integral in (5) is well-defined for all values of j taken from the positive half-line. Even more, in the limit $\nu\to\infty$ it manages to single out the set of allowed spin quantum numbers, {0,1/2,1,3/2,...}, from the ''classical continuum $[0,\infty[$.

More precisely, for a given bounded and continuous h: $\mathbb{C}\to\mathbb{C}$ and $j\in[0,\infty[$ we assert that the right-hand side of (5) is equal to $\langle\psi(z)|e^{-t\mathcal{H}_\psi}|\psi(z')\rangle$. Here the set of vectors,

$$|\psi(z)\rangle := g(z)\sum_{n=0}^{2(j)}\sqrt{\binom{2j}{n}}z^n|\psi_n\rangle,\quad z\in\mathbb{C}, \tag{34}$$

is unity-resolving in $\mathbb{C}^{2(j)+1}$, where (j) denotes the smallest integer or half-integer equal to or larger than j, and $\{|\psi_n\rangle\}$ is a fixed but arbitrary orthonormal basis in $\mathbb{C}^{2(j)+1}$. The binomial coefficient can be defined recursively by $\binom{2j}{0}:=1$ and $\binom{2j}{n+1}:=[(2j-n)/(n+1)]\binom{2j}{n}$, and $g(z)$ is defined by (3) as it stands for general $j\in[0,\infty[$. Finally, $\mathcal{H}_\psi$ is an operator on $\mathbb{C}^{2(j)+1}$ associated to the given h by the definition

$$\mathcal{H}_\psi := \int_{\mathbb{C}} d^2z\,h(z)|\psi(z)\rangle\langle\psi(z)|. \tag{35}$$

This association can be viewed as a quantization, which maps the pair (j,h) to the pair $((j),\mathcal{H}_\psi)$ with $\mathcal{H}_\psi$ being interpreted as the Hamiltonian of a spin with quantum number (j). While $\mathcal{H}_\psi$ in general depends on the chosen basis $\{|\psi_n\rangle\}$, the expression $\langle\psi(z)|e^{-t\mathcal{H}_\psi}|\psi(z')\rangle$ does not because of unitary invariance.

For the proof of the above assertion we remark that the latter is identical to (5) in the case $j=(j)$, because then $|\psi(z)\rangle=|z\rangle$ when choosing $|\psi_n\rangle=|j,n-j\rangle$, the usual orthonormal eigenbasis of $\mathcal{J}_3$. In the case $j<(j)$, the proof follows from (25), equations analogous to (24) and (19), and the Aharonov-Casher theorem, which in our setting states that the ground-state eigenspace of the ''magnetic'' Schödinger operator R [stemming from g, confer (20)–(22)] has a dimension equal to the largest integer strictly smaller than $|\int_{\mathbb{C}}d^2z\,v(z)|/2\pi=2j+2$ and is spanned by the set of orthonormal functions $z\mapsto\langle\psi(z)|\psi_n\rangle$, $n=0,1,\ldots,2(j)$.

(v) It is straightforward to generalize formula (5) to systems where the Hamiltonian $\mathcal{H}$ depends explicitly on time and/or several (coupled) spins. The formula in the latter case, like its older ''spherical relative'' in Ref. 12, may then serve as a rigorous starting point for the derivation of effective field theories, which aim to describe the low-energy excitations of quantum lattice models for magnetism. Confer, for example, Refs. 17, 56, 57, and references therein.

(vi) Following the reasoning of the present paper it should also be straightforward to derive flat-space Wiener-regularized path integrals also for physical systems with degrees of freedom that are neither of the canonical nor of the spin type.

ACKNOWLEDGMENTS

(Received 24 November 1997; accepted for publication 1 February 1999)

Using a discrete curve mapping procedure, we reformulate the problem of nonlinear spin dynamics in three different discrete Heisenberg ferromagnetic spin chain models with different magnetic interactions. The procedure helps to rewrite the Landau–Lifshitz equations that govern the dynamics of spins in these ferromagnetic spin systems as equivalent to the integrable discretization of the completely integrable nonlinear Schrödinger family of equations. The elementary spin excitations in these spin systems are governed by lattice solitons. © *1999 American Institute of Physics.* [S0022-2488(99)00706-9]

I. INTRODUCTION

The one-dimensional classical continuum Heisenberg ferromagnetic spin chain models with different magnetic interactions have been identified as one of the interesting class of nonlinear dynamical systems exhibiting complete integrability and soliton spin excitations on many occasions.[1–12] Notable among them are the one-dimensional isotropic Heisenberg ferromagnetic spin chain with bilinear[3,4] and also biquadratic[5] exchange interactions, anisotropic interaction,[6] interaction with external magnetic fields,[7] spin-phonon coupling,[8–10] weak interaction,[11,12] etc. The dynamics of spins in these classical continuum Heisenberg ferromagnetic spin systems are governed by the Landau–Lifshitz (L–L) equations, a highly nontrivial vector nonlinear partial differential equation. In addition to linear magnons an interesting class of nonlinear elementary spin excitations that occur are solitons, domain walls, kinks, breathers, etc.[1–12] in one-dimensional chains and line solitons, lump solitons, dromions, etc.[13] in higher dimensional spin systems. Solving the L–L equations for classical spin systems in its natural vector form for understanding the underlying nonlinear dynamics is a difficult task in general. Hence, attempts were made to relate the L–L equations as equivalent to nonlinear equations which have been already studied. Notable among them are the geometric equivalence or mapping the spin chain with a moving continuous space curve[14] and the gauge equivalence technique.[15,16] Both these methods have helped to rewrite the L–L equations as equivalent to the nonlinear Schrödinger (NLS) family of equations depending on the nature of magnetic interactions involved. For instance, the nonlinear spin dynamics of the isotropic bilinear ferromagnetic spin chain can be represented equivalently in terms of the completely integrable cubic NLS equation through geometric and gauge equivalence methods[3,15] and the biquadratic ferromagnetic chain to the fourth order completely integrable NLS equation.[5] As the above integrable NLS family of equations admit N-soliton solutions, the elementary spin excitations in these magnetic systems can then be expressed in terms of soliton modes. Later, these methods have been extensively used in the case of several other physically interesting and mathematically generalized ferromagnetic spin models, which resulted in the identification of new integrable spin systems.[17] The dynamics of a continuous moving space curve has played an important role in identifying integrable models not only in the case of classical continuum ferromagnets but also in several other contexts. We have many physical examples in which geometric considerations yield NLS family of equations and also the motion of the continuous space curve and its elementary geometric properties were proved to select integrable dynamics of several soliton equations.[18–24]

Though several classical continuum Heisenberg ferromagnetic spin models have been identified as completely integrable systems through continuous space curve mapping, this procedure has not been adapted in the case of more realistic discrete or lattice spin chain models so far. In a recent paper Doliwa and Santini[25] from the elementary geometric properties of a discrete moving curve showed that the motion of it on a sphere selects integrable dynamics of the Ablowitz–Ladik[26] hierarchy of evolution equations. The theory of discrete curves found in Ref. 25 motivated us to develop a discrete generalized mapping procedure[27] for the lattice models of few integrable classical Heisenberg ferromagnetic spin chains which can help to rewrite the discrete dynamical equations in the L–L form in terms of the integrable discretized version of the NLS family of equations thus making the analysis of the underlying dynamics more simple. After presenting a brief account of this discrete mapping procedure in Sec. II, we employ the procedure in the case of three different integrable discrete classical Heisenberg ferromagnetic spin chain models with different magnetic interactions. In Sec. III, we map the integrable discrete isotropic bilinear Heisenberg spin chain model originally proposed by Ishimori to the integrable discretized version of the completely integrable cubic NLS equation using the discrete curve mapping procedure developed in Sec. II. Also, using the same procedure we map a higher order integrable discrete ferromagnetic spin chain model to the completely integrable discrete Hirota equation and a new generalized isotropic Heisenberg ferromagnetic discrete spin chain model involving higher order and next nearest neighbor exchange interactions to the integrable discretization of the fourth order integrable NLS equation. The results are concluded in Sec. IV.

II. MOTION OF A DISCRETE CURVE

Before attempting to map integrable discrete ferromagnetic spin systems to integrable discretization of the completely integrable nonlinear Schrödinger family of equations, in this section, we present a brief account of a generalization of the theory of discrete moving space curves closely following the procedure presented by Doliwa and Santini in Ref. 25. The motion of the discrete curve is considered to be taking place on a sphere with origin at O and $\mathbf{r}_n$ is the unit vector at the point n of the sequence pointing along the direction of the position vector $\mathbf{R}_n$ (see Fig. 1). The unit vectors $\mathbf{t}_n$ and $\mathbf{t}'_n$ are tangent to the big circle passing through the points $\mathbf{r}_n$ and $\mathbf{r}_{n+1}$ at the points, respectively, and the angle between $\mathbf{r}_n$ and $\mathbf{r}_{n+1}$ is defined as θ_n. A third unit vector $\mathbf{b}_n$ is defined as normal to both $\mathbf{r}_n$ and $\mathbf{t}_n$ (i.e) $\mathbf{b}_n=\mathbf{r}_n\wedge\mathbf{t}_n$. The angle between $\mathbf{t}'_{n-1}$ and $\mathbf{t}_n$ is denoted by ϕ_{n-1}. The transition from the basis $(\mathbf{r}_n,\mathbf{t}_n,\mathbf{b}_n)$ at the nth point to the next basis $(\mathbf{r}_{n+1},\mathbf{t}_{n+1},\mathbf{b}_{n+1})$ at the neighboring $(n+1)$th point can be represented by[25,27]

$$(\mathbf{r}_{n+1}\ \ \mathbf{t}_{n+1}\ \ \mathbf{b}_{n+1})^T=[M](\mathbf{r}_n\ \ \mathbf{t}_n\ \ \mathbf{b}_n)^T, \tag{2.1a}$$

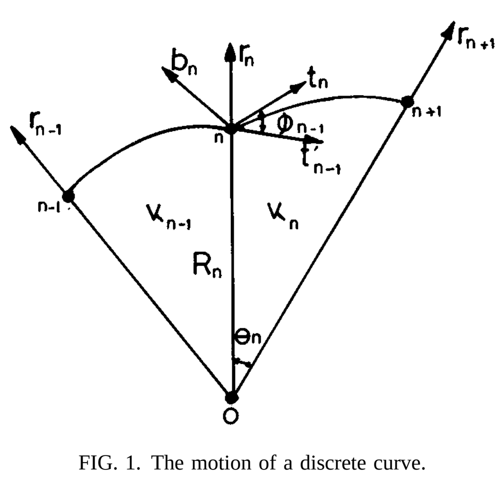

FIG. 1. The motion of a discrete curve.

where

$$[M]=\begin{pmatrix} \cos\theta_n & \sin\theta_n & 0 \\ -\cos\phi_n \sin\theta_n & \cos\phi_n\cos\theta_n & \sin\phi_n \\ \sin\phi_n\sin\theta_n & -\sin\phi_n\cos\theta_n & \cos\phi_n \end{pmatrix}, \tag{2.1b}$$

and T means the transpose of the matrix. Similarly, the basis $(\mathbf{r}_{n-1},\mathbf{t}_{n-1},\mathbf{b}_{n-1})$ associated with the point $(n-1)$ of the sequence can be obtained from $(\mathbf{r}_n,\mathbf{t}_n,\mathbf{b}_n)$ by using the matrix $[M]^{-1}$ (with n replaced by $(n-1)$). In a similar way the next nearest bases, namely, $(\mathbf{r}_{n+2},\mathbf{t}_{n+2},\mathbf{b}_{n+2})$ and $(\mathbf{r}_{n-2},\mathbf{t}_{n-2},\mathbf{b}_{n-2})$ can be generated in terms of $(\mathbf{r}_n,\mathbf{t}_n,\mathbf{b}_n)$.

As the motion of the discrete curve takes place on the surface of the sphere, the velocity field must always be tangent to the surface. The evolution of the orthonormal frame $(\mathbf{r}_n,\mathbf{t}_n,\mathbf{b}_n)$ can then be described by the antisymmetric matrix equation[25]

$$\frac{d}{dt}\begin{pmatrix}\mathbf{r}_n\\ \mathbf{t}_n\\ \mathbf{b}_n\end{pmatrix}=\begin{pmatrix} 0 & V_n & U_n \\ -V_n & 0 & W_n \\ -U_n & -W_n & 0\end{pmatrix}\begin{pmatrix}\mathbf{r}_n\\ \mathbf{t}_n\\ \mathbf{b}_n\end{pmatrix}. \tag{2.2}$$

Here V_n and U_n are the velocity field components parallel to $\mathbf{t}_n$ and $\mathbf{b}_n$, respectively, and W_n is an unknown function to be determined. The compatibility between Eqs. (2.1) and (2.2) then provides the following evolution equations[25] for θ_n and ϕ_n,

$$\frac{d\theta_n}{dt}=\cos\phi_n V_{n+1}-\sin\phi_n U_{n+1}-V_n, \tag{2.3a}$$

$$\frac{d\phi_n}{dt}=W_{n+1}-\cos\theta_n W_n+\sin\theta_n U_n, \tag{2.3b}$$

and the unknown function W_n as

$$W_n=\frac{1}{\sin\theta_n}[\cos\phi_n U_{n+1}+\sin\phi_n V_{n+1}-\cos\theta_n U_n]. \tag{2.3c}$$

Thus the motion of the discrete curve on the surface of the sphere is governed by the coupled evolution equations for the two angles θ_n and ϕ_n. Specific values of the field components V_n and U_n will give rise to different nonlinear evolution equations. Experience gained in the case of continuous space curve mapping suggests to rewrite the coupled evolution equations for θ_n and ϕ_n given in Eqs. (2.3a) and (2.3b) as a single evolution equation in terms of a new variable using a suitable transformation involving θ_n and ϕ_n. This may be advantageous because it leads to identification of the resultant equation with standard nonlinear discrete evolution equations. Now in the forthcoming sections, we employ our discrete mapping procedure developed in this section to find geometrically equivalent representations of few integrable discrete classical Heisenberg ferromagnetic spin chain models.

III. GEOMETRIC EQUIVALENCE OF CERTAIN DISCRETE HEISENBERG SPIN CHAINS

Integrable classical Heisenberg ferromagnetic spin chain models are of great interest because they exhibit an interesting class of nonlinear elementary spin excitations namely solitons. Though real ferromagnets exist in lattice, soliton excitations could be identified mostly in the classical continuum limit. In the following, we consider three one-dimensional discrete classical Heisenberg ferromagnetic spin chain models and employ our discrete curve mapping procedure to identify them with standard discrete integrable nonlinear evolution equations so that solitons can be constructed readily.

A. Ishimori model of the discrete spin chain

An integrable discrete classical Heisenberg ferromagnetic spin chain model originally proposed by Ishimori[28] is governed by the equation of motion

$$\frac{d\mathbf{S}_n(t)}{dt}=2\mathbf{S}_n\wedge\left[\frac{\mathbf{S}_{n+1}}{1+\mathbf{S}_n\cdot\mathbf{S}_{n+1}}+\frac{\mathbf{S}_{n-1}}{1+\mathbf{S}_n\cdot\mathbf{S}_{n-1}}\right], \tag{3.1a}$$

$$\mathbf{S}_n=(S_n^x,S_n^y,S_n^z), \tag{3.1b}$$

$$\mathbf{S}_n^2=1. \tag{3.1c}$$

Here $\mathbf{S}_n$ represents the three component classical spin vector at the lattice site n, the evolution of which is governed by the interaction of it with its nearest neighbors in the form of a bilinear exchange. Now, we employ our mapping procedure developed in the previous section on the Ishimori model by identifying the three-component classical spin vector $\mathbf{S}_n(t)$ of Eq. (3.1) with the unit vector $\mathbf{r}_n(t)$ of the discrete curve. Because of this identification, Eq. (3.1) can be rewritten as

$$\frac{d\mathbf{r}_n}{dt}=2\mathbf{r}_n\wedge\left[\frac{\mathbf{r}_{n+1}}{1+\mathbf{r}_n\cdot\mathbf{r}_{n+1}}+\frac{\mathbf{r}_{n-1}}{1+\mathbf{r}_n\cdot\mathbf{r}_{n-1}}\right]. \tag{3.2}$$

Substituting $\mathbf{r}_{n+1}$ and $\mathbf{r}_{n-1}$ from Eqs. (2.1) in Eq. (3.2), we obtain

$$\frac{d\mathbf{r}_n}{dt}=-2\left(\tan\frac{\theta_{n-1}}{2}\sin\phi_{n-1}\right)\mathbf{t}_n-2\left(\tan\frac{\theta_{n-1}}{2}\cos\phi_{n-1}-\tan\frac{\theta_n}{2}\right)\mathbf{b}_n\,. \tag{3.3}$$

On comparing Eq. (3.3) with Eq. (2.2) the velocity fields V_n and U_n can be identified as

$$V_n=-2\tan\frac{\theta_{n-1}}{2}\sin\phi_{n-1}, \tag{3.4a}$$

$$U_n=2\left(\tan\frac{\theta_n}{2}-\tan\frac{\theta_{n-1}}{2}\cos\phi_{n-1}\right). \tag{3.4b}$$

Substituting the above values of V_n and U_n in Eqs. (2.3), the evolution equations for θ_n and ϕ_n can be written as

$$\frac{d\theta_n}{dt}=2\left(\tan\frac{\theta_{n-1}}{2}\sin\phi_{n-1}-\tan\frac{\theta_{n+1}}{2}\sin\phi_n\right), \tag{3.5a}$$

$$\begin{aligned}\frac{d\phi_n}{dt}=&\frac{2}{\sin\theta_{n+1}}\left(\tan\frac{\theta_{n+2}}{2}\cos\phi_{n+1}+\tan\frac{\theta_n}{2}\cos\phi_n\right)\\&-\frac{2}{\sin\theta_n}\left(\tan\frac{\theta_{n+1}}{2}\cos\phi_n+\tan\frac{\theta_{n-1}}{2}\cos\phi_{n-1}\right).\end{aligned} \tag{3.5b}$$

Defining a new angle Ψ_n as the difference between ϕ_{n-1} and ϕ_n (i.e.),

$$\phi_n=\Psi_{n-1}-\Psi_n, \tag{3.6}$$

Eqs. (3.5) can be rewritten as

$$\frac{d\theta_n}{dt}=-2\tan\frac{\theta_{n+1}}{2}\sin(\Psi_{n-1}-\Psi_n)+2\tan\frac{\theta_{n-1}}{2}\sin(\Psi_{n-2}-\Psi_{n-1}), \tag{3.7a}$$

$$\frac{d\Psi_n}{dt}=2\left(1-\frac{1}{\sin\theta_{n+1}}\tan\frac{\theta_{n+2}}{2}\cos(\Psi_n-\Psi_{n+1})\right)-\left(\frac{2}{\sin\theta_{n+1}}\tan\frac{\theta_n}{2}\cos(\Psi_{n-1}-\Psi_n)\right). \tag{3.7b}$$

In order to indentify Eqs. (3.7) with standard nonlinear differential-difference equations, we make the transformation

$$q_n=\tan\frac{\theta_n}{2}\exp(i\Psi_{n-1}), \tag{3.8}$$

and hence Eqs. (3.7) can be rewritten as

$$i\frac{dq_n}{dt}=(1+|q_n|^2)[q_{n+1}+q_{n-1}]-2q_n. \tag{3.9}$$

Equation (3.9) is the integrable discretization of the completely integrable cubic NLS equation,

$$i\frac{\partial q}{\partial t}+\frac{\partial^2 q}{\partial x^2}+2|q|^2q=0. \tag{3.10}$$

Thus the discrete isotropic classical Heisenberg ferromagnetic spin chain model proposed by Ishimori which is governed by the equation of motion (3.1) is proved to be geometrically equivalent to the integrable discrete NLS equation (3.9) via our mapping procedure for discrete curves. Equation (3.9) can be solved by the inverse scattering transform (IST) method and found to admit N-soliton solutions.[28,29]

B. A discrete higher order spin chain

Another integrable classical discrete Heisenberg ferromagnetic spin chain model with higher order magnetic interactions is described by the equation of motion[30]

$$\begin{aligned}\frac{d\mathbf{S}_n(t)}{dt}&=2a\left[\frac{(\mathbf{S}_n\cdot\mathbf{S}_{n+1})\mathbf{S}_n-\mathbf{S}_{n+1}}{1+\mathbf{S}_n\cdot\mathbf{S}_{n+1}}-\frac{(\mathbf{S}_n\cdot\mathbf{S}_{n-1})\mathbf{S}_n-\mathbf{S}_{n-1}}{1+\mathbf{S}_n\cdot\mathbf{S}_{n-1}}\right]\\&\quad+2b\mathbf{S}_n\wedge\left[\frac{\mathbf{S}_{n+1}}{1+\mathbf{S}_n\cdot\mathbf{S}_{n+1}}+\frac{\mathbf{S}_{n-1}}{1+\mathbf{S}_n\cdot\mathbf{S}_{n-1}}\right],\\ \mathbf{S}_n^2&=1.\end{aligned} \tag{3.11}$$

Here a and b are constant parameters. In Eq. (3.11) higher order interactions are represented by terms proportional to a. It may be noted that in the continuum limit using the continuous space curve mapping procedure and also by the gauge transformation,[30] Eq. (3.11) is shown to be equivalent to the continuous third order NLS equation (Hirota equation),

$$\frac{\partial q}{\partial t}=a\left[\frac{\partial^3 q}{\partial x^3}+6|q|^2\frac{\partial q}{\partial x}\right]+ib\left[\frac{\partial^2 q}{\partial x^2}+2|q|^2q\right]. \tag{3.12}$$

Thus a natural question arises as to see whether using our mapping procedure for discrete curves developed in Sec. II, Eq. (3.11) can be mapped to the integrable discretization of the completely integrable Hirota equation (3.12). For this we map the discrete higher order ferromagnetic spin chain governed by the equation of motion (3.11) onto the discrete moving curve on the sphere and identify the spin vector $\mathbf{S}_n(t)$ with the unit vector $\mathbf{r}_n(t)$ of the discrete curve. Following the procedure adapted in the case of Ishimori model, we finally arrive at the following equation:

$$i\frac{dq_n}{dt}=-ia(1+|q_n|^2)[q_{n+1}-q_{n-1}]+b[(1+|q_n|^2)(q_{n+1}+q_{n-1})-2q_n]. \tag{3.13}$$

Equation (3.13) is the integrable discretization of the Hirota equation (3.12) which is a completely integrable system possessing *N*-soliton solutions.[30] Again when $a=0$, Eq. (3.13) reduces to the integrable discretization of the completely integrable cubic NLS Eq. (3.9).

Thus the dynamics of the discrete higher order ferromagnetic spin model represented by Eq. (3.11) is found equivalent to the integrable discretization of the completely integrable Hirota equation given by Eq. (3.13). As the integrable discrete Eq. (3.13) admits multisoliton solutions the spin excitations can also be expressed in terms of solitons.[30]

C. A discrete generalized Heisenberg spin chain with higher order and next nearest neighbor interactions

Finally, we consider a classical discrete generalized Heisenberg ferromagnetic spin chain characterized by higher order and next nearest neighbor spin–spin interactions in addition to the interaction corresponding to the Ishimori model described by the generalized new Hamiltonian,

$$H=-2(1-2K)\sum_i \log(1+\mathbf{S}_i\cdot\mathbf{S}_{i+1})-4K\sum_i\left[\frac{1+\mathbf{S}_i\cdot\mathbf{S}_{i+1}+\mathbf{S}_i\cdot\mathbf{S}_{i+2}+\mathbf{S}_{i+1}\cdot\mathbf{S}_{i+2}}{(1+\mathbf{S}_i\cdot\mathbf{S}_{i+1})(1+\mathbf{S}_{i+1}\cdot\mathbf{S}_{i+2})}\right]. \tag{3.14}$$

When $K=0$, Hamiltonian (3.14) will reduce to the isotropic bilinear exchange Hamiltonian of the Ishmori model.[28] The equation of motion representing the spin dynamics of the model corresponding to the above Hamiltonian (3.14) can be written as

$$\frac{d\mathbf{S}_n}{dt}=\mathbf{S}_n\wedge[A\mathbf{S}_{n+1}+B\mathbf{S}_{n-1}+C\mathbf{S}_{n+2}+D\mathbf{S}_{n-2}],\quad \mathbf{S}_n^2=1, \tag{3.15a}$$

where *A*, *B*, *C* and *D* are spin functions as given below,

$$A=\left[\frac{2(1-2K)}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n+1})}-\frac{4K}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n+1})^2}\left\{\frac{(\mathbf{S}_n+\mathbf{S}_{n+1})\cdot\mathbf{S}_{n+2}}{(1+\mathbf{S}_{n+1}\cdot\mathbf{S}_{n+2})}+\frac{(\mathbf{S}_n+\mathbf{S}_{n+1})\cdot\mathbf{S}_{n-1}}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n-1})}\right\}\right], \tag{3.15b}$$

$$B=\left[\frac{2(1-2K)}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n-1})}-\frac{4K}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n-1})^2}\left\{\frac{(\mathbf{S}_n+\mathbf{S}_{n-1})\cdot\mathbf{S}_{n-2}}{(1+\mathbf{S}_{n-1}\cdot\mathbf{S}_{n-2})}+\frac{(\mathbf{S}_n+\mathbf{S}_{n-1})\cdot\mathbf{S}_{n+1}}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n+1})}\right\}\right], \tag{3.15c}$$

$$C=\frac{4K}{(1+\mathbf{s}_n\cdot\mathbf{S}_{n+1})(1+\mathbf{S}_{n+1}\cdot\mathbf{S}_{n+2})}, \tag{3.15d}$$

$$D=\frac{4K}{(1+\mathbf{S}_n\cdot\mathbf{S}_{n-1})(1+\mathbf{S}_{n-1}\cdot\mathbf{S}_{n-2})}. \tag{3.15e}$$

When the angle between the orientation of the neighboring spins are maintained small and in the continuum limit, Eq. (3.15) represents the dynamics of spins in a classical Heisenberg ferromagnetic spin chain.[5] For specific values of *K* and lattice parameter, in the small angle and continuum limits, through the methods of continuous space curve mapping and gauge transformation, Eq. (3.15) has been proven to be equivalent to the completely integrable fourth order NLS equation[5] given by

$$i\frac{\partial q}{\partial t}+\frac{\partial^2 q}{\partial x^2}+2|q|^2q+\gamma_1\left[\frac{\partial^4 q}{\partial x^4}+8|q|^2\frac{\partial^2 q}{\partial x^2}+2q^2\frac{\partial^2 q^*}{\partial x^2}+4q\left|\frac{\partial q}{\partial x}\right|^2+6q^*\left(\frac{\partial q}{\partial x}\right)^2+6|q|^4q\right]=0. \tag{3.16}$$

Now we consider the discrete generalized Heisenberg spin chain described by the Hamiltonian (3.14) and the equation of motion (3.15) and see whether Eq. (3.15) can be mapped to the integrable discretization of the complete integrable fourth order NLS equation given by Eq. (3.16). For this as before we rewrite Eq. (3.15) by replacing $\mathbf{S}_n$ by $\mathbf{r}_n$ and by substituting for $\mathbf{r}_{n+1}$, $\mathbf{r}_{n-1}$, $\mathbf{r}_{n+2}$, and $\mathbf{r}_{n-2}$ from Eqs. (2.1), we obtain the velocity field components V_n and U_n in the form

$$V_n=-2(1-2K)\tan\frac{\theta_{n-1}}{2}\sin\phi_{n-1}-2K\left\{\tan\frac{\theta_{n-2}}{2}\sec^2\frac{\theta_{n-1}}{2}\sin(\phi_{n-1}+\phi_{n-2})\right.$$
$$+\tan\frac{\theta_n}{2}\tan^2\frac{\theta_{n-1}}{2}\sin 2\phi_{n-1}+\tan\frac{\theta_{n+1}}{2}\sec^2\frac{\theta_n}{2}\sin\phi_n$$
$$\left.+\tan\frac{\theta_{n-1}}{2}\sec^2\frac{\theta_n}{2}\sin\phi_{n-1}-4\tan\frac{\theta_{n-1}}{2}\sin\phi_{n-1}\right\}, \tag{3.17a}$$

$$U_n=2(1-2K)\left(\tan\frac{\theta_n}{2}-\tan\frac{\theta_{n-1}}{2}\cos\phi_{n-1}\right)-2K\left\{\tan\frac{\theta_{n-2}}{2}\sec^2\frac{\theta_{n-1}}{2}\cos(\phi_{n-1}+\phi_{n-2})\right.$$
$$+\tan\frac{\theta_n}{2}\tan^2\frac{\theta_{n-1}}{2}\cos 2\phi_{n-1}-\tan\frac{\theta_{n+1}}{2}\sec^2\frac{\theta_n}{2}\cos\phi_n$$
$$\left.-\tan\frac{\theta_{n-1}}{2}\sec^2\frac{\theta_n}{2}\cos\phi_{n-1}+3\tan\frac{\theta_n}{2}-2\tan\frac{\theta_{n-1}}{2}\cos\phi_{n-1}\right\}. \tag{3.17b}$$

Substituting Eqs. (3.17) in Eqs. (2.3) and using Eqs. (3.6) and (3.8), the set of coupled equations for θ_n and ϕ_n can be rewritten as a single equation given by

$$i\frac{dq_n}{dt}=(1+|q_n|^2)(q_{n+1}+q_{n-1})-2q_n+K\{(1+|q_n|^2)[(1+|q_{n+1}|^2)q_{n+2}+(1+|q_{n-1}|^2)q_{n-2}$$
$$+(q_{n+1}^2+q_{n-1}^2)q_n^*+(q_{n+1}^*q_{n-1}+q_{n-1}^*q_{n+1})q_n-4(q_{n+1}+q_{n-1})]+6q_n\}. \tag{3.18}$$

Equation (3.18) is the integrable discretized version of the completely integrable fourth order NLS Eq. (3.16). When $K=0$, Eq. (3.18) will reduce to the integrable discrete cubic NLS Eq. (3.9). Equation (3.18) can also be derived through the AKNS formulation (for details see Refs. 29, 31).

For all the above three completely integrable spin models the Lax pair and soliton solutions can be constructed at the discrete level and in the continuum limit in terms of the spin (S_n) and the q_n variables. Hence the elementary spin excitations in all these three models are governed by solitons. More details on this aspect can be found in Refs. 5, 28–31.

IV. CONCLUSIONS

In this paper, we have reformulated the problem of nonlinear spin dynamics of certain discrete classical Heisenberg ferromagnetic spin chain models using a mapping procedure for discrete curves. As the L–L equations that govern the spin dynamics are normally highly nontrivial vector nonlinear partial differential equations, the purpose of the paper was to find equivalent representations for discrete spin models so that the analysis of the spin dynamics becomes easier in the new representation and identification of integrable lattice spin models in a more direct way. Here we specifically considered three one-dimensional discrete Heisenberg spin chain models namely the simple isotropic spin chain with bilinear exchange interaction (Ishimori model), a higher order discrete spin chain, and finally a new generalized spin chain involving next nearest neighbor and higher order spin–spin interactions. Our discrete curve mapping procedure helped to rewrite the L–L equations representing the spin dynamics of the isotropic bilinear chain as equivalent to the integrable discretization of the completely integrable cubic NLS equation. Similarly, the dynamics of the higher order spin chain is equivalently expressed in terms of the integrable discretization of the completely integrable Hirota equation. Finally, the generalized discrete spin chain considered here is found to be equivalent to the integrable discretization of the completely integrable fourth order NLS equation. It was interestingly noted that under the small angle approximation and in the continuum limit the above generalized spin model is found to correspond to the one-dimensional continuum biquadratic Heisenberg spin chain for which the integrability properties are known and the elementary spin excitations are governed by solitons. In all the three models the elementary spin excitations are found to be governed by soliton modes. Thus the discrete curve mapping procedure helps to indentify integrable discrete spin models admitting soliton spin excitations. There are few other ferromagnetic lattice spin models available which are integrable in the continuum limit and not at the discrete level. Our attempt on mapping these discrete spin models (which are not integrable) onto discrete curves on spheres does not fetch equivalent representations in terms of generalized or perturbed discrete NLS family of equations through the transformation (3.8). Hence work is under progress to map these lattice spin chain models to the discrete curve in the space (not on the sphere) and the results will be reported elsewhere.

(Received 11 September 1998; accepted for publication 23 November 1998)

We examine the geometry of the state space of a relativistic quantum field. The mathematical tools used involve complex algebraic geometry and Hilbert space theory. We consider the Kähler geometry of the state space of any quantum field theory based on a linear classical field equation. The state space is viewed as an infinite-dimensional complex projective space. In the case of boson fields, a special role is played by the coherent states, the totality of which constitutes a nonlinear submanifold $\mathcal{C}$ of the projective Fock space $P\mathcal{F}$. We derive the metric on $\mathcal{C}$ induced from the ambient Fubini–Study metric on $P\mathcal{F}$. Arguments from differential geometric, algebraic, and Kählerian points of view are presented, leading to the result that the induced metric is flat, and that the intrinsic geometry of $\mathcal{C}$ is Euclidean. The coordinates for the single-particle Hilbert space of solutions are shown to be complex Euclidean coordinates for $\mathcal{C}$. A transversal intersection property of complex projective lines in $P\mathcal{F}$ with $\mathcal{C}$ is derived, and it is shown that the intrinsic geodesic distance between any two coherent states is strictly greater than the corresponding geodesic distance in the ambient Fubini–Study geometry. The functional metric norm of a difference field is shown to give the intrinsic geodesic distance between two coherent states, and the metric overlap expression is shown to measure the angle subtended by two coherent states at the vacuum, which acts as a preferred origin in the Euclidean geometry of $\mathcal{C}$. Using the flatness of $\mathcal{C}$ we demonstrate the relationship between the manifold complex structure on $P\mathcal{F}$ and the quantum complex structure viewed as an active transformation on the single-particle Hilbert space. These properties of $\mathcal{C}$ hold independently of the specific details of the single-particle Hilbert space. We show how $\mathcal{C}$ arises as the affine part of its compactification obtained by setting the vacuum part of the state vector to zero. We discuss the relationship between unitary orbits and geodesics on $\mathcal{C}$ and on $P\mathcal{F}$. We show that for a Fock space in which the expectation of the total number operator is bounded above, the coherent state submanifold is Kähler and has finite conformal curvature. I. INTRODUCTION

The existence of complex structures in quantum theory, and their possible role in a theory of quantum gravity, is a subject of much interest. Such structures are essential mechanics to express the idea that the state vector evolves unitarily according to appropriate dynamical equations. One of the main applications of complex structures in physics recently has been the subject of *geometric quantum mechanics*, an area that has been developed by a number of authors (Refs. 1–11). In this picture the natural geometry of the quantum phase space is shown to be characterized not merely by a symplectic structure, but also by a compatible complex structure and a Riemannian metric, from which one derives the concepts of quantum mechanical uncertainty and expectation.

In this paper we explore geometric aspects of the complex structures on function spaces that arise in quantum theory. By a complex structure J we mean a linear operator acting on the Hilbert space V of solutions to a linear field equation, satisfying $J^2 = -1$. The operator J is an endomorphism of V, and if we complexify V to define the single-particle Hilbert space $\mathcal{H}$ then J has eigenspaces with eigenvalues $\pm\sqrt{-1}$, which we refer to as the positive and negative frequency single-particle Hilbert spaces. From this $\mathcal{H}$ we define the Fock space $\mathcal{F}$ via tensor products of $\mathcal{H}$ with itself. In addition to the complex structure J we also have the quantum mechanical symplectic form Ω and the real Hilbert space metric g, all of which are mutually compatible. Then the triple $\{J,\Omega,g\}$ constitutes a *quantum Kähler structure*. Such structures have received much attention in the literature, and form the basis of the relationship between classical and quantum field theories. On a classical level, the J operation bridges the symplectic and metric structures, and for real boson fields enables one to obtain a classical expression for the norms of fields. Considerations of quantum field theory and the introduction of Planck's constant then show that the squared norm is equal to the expectation of the quantum number operator in a corresponding coherent state (see, e.g., Ref. 11).

In classical Hamiltonian mechanics the symplectic structure Ω, when taken together with a preferred Hamiltonian function H on the phase space, determines the system completely. It is in the passage to quantum theory that additional structure is required, namely, the quantum complex structure. When compatibility of the elements of the quantum Kähler structure is assumed, any two of its elements imply the other, and thus quantization can be viewed as the addition of either J or g to the classical system. In geometric quantum mechanics it is the complex projective space CP^n, the quantum mechanical state space, that replaces the classical phase space. This is a Kähler manifold, endowed with the Fubini–Study metric. It is also a symplectic manifold, and thus the geometry of Hamiltonian classical mechanics carries over to the quantum state space. In particular, the equation governing the evolution of a quantum mechanical state, Schrödinger's equation, becomes Hamilton's equations of classical mechanics. In other words, Schrödinger trajectories are given by the orbits of a Hamiltonian vector field on the quantum state space. The extra ingredient of quantum theory is the quantum metric g, which takes the form of a real Riemannian structure on the state manifold, enabling one to calculate quantum mechanical transition amplitudes and uncertainties.

A further modification that quantum theory entails is that uncertainty terms appear in the Hamiltonian function of the system, in addition to the function obtained by replacing classical phase space coordinates by the expectations of their associated operators. The harmonic oscillator is an example of this phenomenon, for which the quantum Hamiltonian function is equal to $x^2+p^2+(\Delta x)^2+(\Delta p)^2$. In this context we are naturally led to consider the *coherent states* (Refs. 12–14; cf. also Refs. 15, 30), which are in some respects classical in behavior. These states saturate the quantum mechanical uncertainty inequality $\Delta x\,\Delta p \geqslant \hbar/2$, and their quantum mechanical evolution corresponds closely to classical evolution.

In this paper we address various aspects of the quantum Kähler structure, with an emphasis on the geometric features of Fock space. Our main results are as follows. We begin by developing geometric quantum mechanics for relativistic quantum field theory, thus extending existing results in the literature to projective Fock space $P\mathcal{F}$. We see how this applies to coherent states and derive geometric properties of the coherent state submanifold $\mathcal{C}$. In particular, in Theorem 1 we show that the intrinsic geometry of $\mathcal{C}$ is complex Euclidean, and that the single-particle state vectors serve as complex Euclidean coordinates for this submanifold. This enables one to deduce other properties of $\mathcal{C}$, and provides a relationship between the complex structure on the single-particle Hilbert space $\mathcal{H}$ and that on the ambient state manifold. We discuss the geodesic and unitary orbits of $\mathcal{C}$, observing that $\mathcal{C}$ and the state space $P\mathcal{F}$ share no geodesics, and that the geodesic orbits of $\mathcal{C}$ are nonunitary. We discuss the corresponding situation for truncated Fock spaces, for which the expectation of the total number operator is bounded above. In particular, we deduce that the associated submanifold of coherent states has finite conformal curvature.

We conclude with a discussion of some physical issues. We indicate the relationship between the theory of positive operator measures (POMs) and coherent states in the context of our results, and in this connection remark on prospects for a model of stochastic state vector reduction.

In the generation of a quantum Fock space, we consider the Hilbert spaces of real and complex solutions to a set of linear classical field equations. In the former case, there is only one available complex structure, since this maps real solutions of the field equations to themselves. In terms of the Fourier transform $\hat{\varphi}(k)$ of the field, multiplication by a complex number $\alpha=a+ib$ is replaced by the action of the operator $a+Jb$ on φ, where J acts linearly and multiplies the positive and negative frequency parts of the field by $+i$ and $-i$, respectively. We say that J is the *quantum complex structure* acting on the Hilbert space. In the case of a complex-valued field there are two possible complex structures, namely (a) the one given above, and (b) multiplication of $\hat{\varphi}$ by the complex number α. It is only the former choice that leads to positive values for the expectation of energy (Ref. 16).

II. THE QUANTUM KÄHLER STRUCTURE

Let V denote the Hilbert space of normalizable real solutions to a classical linear field equation, and define the single-particle Hilbert space $\mathcal{H}=V\otimes C$. We adopt the notation $\mathcal{H}^n\equiv\mathcal{H}^{\otimes n}$ for the n-fold tensor product of $\mathcal{H}$ with itself, where $\otimes$ denotes the symmetric tensor product for bosons and antisymmetric tensor product for fermions. Then $\mathcal{H}^n$ is said to be the n-particle Hilbert space, and we define Fock space as the Hilbert space $\mathcal{F}=C\oplus\mathcal{H}\oplus\mathcal{H}^2\oplus\cdots\oplus\mathcal{H}^n\oplus\cdots$ (see e.g., Ref. 17 for various technical details of this construction, which are not as relevant for the present discussion). We introduce the *quantum complex structure J*, a linear map $J:V\rightarrow V$ such that $J^2\equiv-\mathbf{1}$. Then, if we extend V to $V\otimes C$, the map J admits eigenspaces with eigenvalues $+i$ and $-i$ that we call the spaces of positive and negative frequency solutions, denoted by $\mathcal{H}_+$ and $\mathcal{H}_-$, respectively, so $\mathcal{H}=\mathcal{H}_+\oplus\mathcal{H}_-$. The spaces $\mathcal{H}_\pm$ give rise naturally to the positive and negative frequency Fock spaces $\mathcal{F}_\pm$ according to the scheme $\mathcal{F}_\pm=C\oplus\mathcal{H}_\pm\oplus\mathcal{H}_\pm^2\oplus\cdots\oplus\mathcal{H}_\pm^n\oplus\cdots$. We use an abstract index notation (Ref. 18) for elements of $\mathcal{H}$, so for a typical element of $\mathcal{H}$ we write ξ^a. See Refs. 16, 19, and 20 for more details of the abstract index notation in a Hilbert space context. We take $\mathcal{H}$ to have a countably infinite basis, so the index on ξ can be thought of as running over the natural numbers. There are some technicalities associated with the fact that one deals with an infinite-dimensional Fock space, which is itself built up from an infinite-dimensional single particle Hilbert space $\mathcal{H}^1$. However, in practice it is reasonable to assume that the underlying single-particle Hilbert space is separable[21] so any vector can be decomposed along countably many basis states, as occurs in the Fourier series analysis of an oscillator with boundary conditions. In the case of a state not built up in this way one usually argues via continuity in the relevant function space (for further discussion of these issues, see Ref. 22).

We now develop in further detail the abstract index notation. For a positive frequency field we use an unprimed Greek index, so, for example, $\xi^\alpha\in\mathcal{H}_+^1$; for a negative frequency field we use a primed Greek index. Then we can regard the italic index a as "composite" by writing $a\equiv\alpha,\alpha'$, where ξ^α and $\xi^{\alpha'}$ have eigenvalues $+i$ and $-i$ under the action of J, respectively, so $J^\alpha{}_\beta\xi^\beta=i\xi^\alpha$ and $J^{\alpha'}{}_{\beta'}\xi^{\beta'}=-i\xi^{\alpha'}$. A general complex field ξ decomposes into independent positive and negative frequency parts $\xi^a\equiv\xi^{\alpha,\alpha'}=\xi^\alpha\oplus\xi^{\alpha'}$. We refer to ξ^α and $\xi^{\alpha'}$, respectively, as the positive and negative frequency parts of the complex field ξ^a. For all ϕ^α the action of complex conjugation will be denoted $\phi^\alpha\mapsto\overline{\phi^\alpha}=\bar{\phi}^{\alpha'}$, and thus it interchanges the index type. For a real field we have $\phi^\alpha=\overline{\phi^{\alpha'}}$ and thus $\phi^a=\phi^\alpha\oplus\bar{\phi}^{\alpha'}$, indicating that in this case the positive and negative frequency parts are complex conjugates of each other.

We can also represent the metric, the symplectic structure, and the complex structure in matrix form according to this scheme. For the metric we have

$$g_{ab}=\begin{pmatrix} 0 & g_{\alpha\beta'} \\ g_{\alpha'\beta} & 0 \end{pmatrix}, \tag{2.1a}$$

in which the tensor $g_{\alpha\beta'}$ is Hermitian (or real) in a sense explained below. Note that, as in the case of the algebra of two-component spinors, a primed index "commutes" with any unprimed index, so that for any multivalence tensor we have $T_{\alpha\cdots\delta\rho'\cdots\tau'}\equiv T_{\rho'\cdots\tau'\alpha\cdots\delta}$. Now complex conjugation interchanges index type according to the scheme $\overline{T_{\alpha\beta\cdots\delta\rho'\sigma'\cdots\tau'}}=\overline{T}_{\alpha'\beta'\cdots\delta'\rho\sigma\cdots\tau}$. Again, as in the case of two-component spinors, a tensor can only be Hermitian if it has equal numbers of primed and unprimed indices, in which case the Hermitian condition is $\overline{T_{\alpha\beta\cdots\gamma\alpha'\beta'\cdots\gamma'}} = T_{\alpha\beta\cdots\gamma\alpha'\beta'\cdots\gamma'}$. For the metric $g_{\alpha\beta'}$, in particular, we have $\overline{g_{\alpha\beta'}} \equiv \bar{g}_{\alpha'\beta} = g_{\alpha'\beta} \equiv g_{\beta\alpha'}$. Similarly, we write the symplectic structure

$$\Omega_{ab} = \begin{pmatrix} 0 & ig_{\alpha\beta'} \\ -ig_{\alpha'\beta} & 0 \end{pmatrix}. \tag{2.1b}$$

This is compatible with the complex structure in that $\Omega(\phi,\psi) = \Omega(J[\phi],J[\psi])$. The action of the metric is given by $g(\phi,\psi) = g_{ab}\phi^a\psi^b = g_{\alpha\beta'}\phi^\alpha\psi^{\beta'} + g_{\alpha'\beta}\phi^{\alpha'}\psi^\beta$, and thus $g(\phi,\psi)$ is real for all real fields ϕ and ψ. The action of the symplectic structure is given by $\Omega(\phi,\psi) = ig_{\alpha\beta'}\phi^\alpha\psi^{\beta'} - ig_{\alpha'\beta}\phi^{\alpha'}\psi^\beta$. We write the quantum complex structure in matrix form as

$$J^a{}_b = \begin{pmatrix} i\delta^\alpha_\beta & 0 \\ 0 & -i\delta^{\alpha'}_{\beta'} \end{pmatrix}. \tag{2.1c}$$

The Dirac or ''quantum mechanical'' scalar product between the fields ϕ and ψ is defined by $F(\phi,\psi) \equiv \frac{1}{2}(g+i\Omega)(\phi,\psi) = g_{\alpha'\beta}\phi^{\alpha'}\psi^\beta$ and is Hermitian in the sense that $F(\phi,\psi) = \overline{F(\psi,\phi)}$ for all real fields ϕ and ψ. We can use $g_{\alpha'\beta}$ to lower indices by writing $\phi_\alpha = g_{\alpha\beta'}\phi^{\beta'}$, and $\phi_{\alpha'} = g_{\alpha'\beta}\phi^\beta$. The complex structure satisfies $J^a{}_cJ^c{}_b = -\delta^a_b$. The compatibility of the set $\{g,\Omega,J\}$ can be represented by the following conditions:

$$g_{ac} = \Omega_{ab}J^b{}_c, \tag{2.2a}$$

$$g_{ab}J^a{}_cJ^b{}_d = g_{cd}, \tag{2.2b}$$

$$\Omega_{ab}J^a{}_cJ^b{}_d = \Omega_{cd}, \tag{2.2c}$$

$$g^{ap}g^{bq}\Omega_{ab} = \Omega^{pq}. \tag{2.2d}$$

Condition (2.2a) is the expression for the positive definite quantum metric in terms of the symplectic form and complex structure, i.e., $g(\phi,\psi) \equiv \Omega(\phi,J\psi)$. A straightforward consequence is that $g(\phi,J\phi) \equiv 0$ for any ϕ. Condition (2.2b) states that the metric g is compatible with the complex structure J, i.e., that the metric g is Hermitian (Ref. 23), so $g(\phi,\psi) \equiv g(J\phi,J\psi)$. We note that the term ''Hermitian'' is used conventionally in two related but rather different ways. First, it can be used to indicate a reality condition on noncomposite tensors of equally mixed rank, as indicated above, i.e., for tensors belonging to the subspace $\mathcal{H}^n_+ \otimes \mathcal{H}^n_-$. On the other hand, we say that a tensor of general even rank, belonging to $\mathcal{H}^{2n}$, is Hermitian if $J^p_aJ^q_b\cdots J^r_cJ^s_dT_{pq\cdots rs} = T_{ab\cdots cd}$. The context will usually indicate in exactly which sense the term is being applied. Thus (2.2c) states that Ω is Hermitian in the latter sense. Some authors use a convention for the symplectic tensor Ω_{ab} that differs by a factor of 2 from the one used here (e.g., Ref. 24). We adopt conventions such that the tensor Ω with its indices raised according to (2.2d) above is the inverse to Ω_{ab}, so $\Omega^{ab}\Omega_{cb} = \delta^a_c$. We refer to the compatible set $\{g,\Omega,J\}$ as the *quantum Kähler structure* (cf. Ref. 25). Observe that condition (2.2a) above implies that any two of $\{g,\Omega,J\}$ are sufficient to determine the quantum Kähler structure.

We now proceed briefly to examine various operations on Fock space in this spirit. A state vector in Fock space $\mathcal{F}$ can be written $|\xi\rangle = (\xi,\xi^\alpha,\xi^{\alpha\beta},\ldots)$, where $\xi^\alpha \in \mathcal{H}^1$, $\xi^{\alpha\beta} \in \mathcal{H}^2$, and so on. The evaluation of the squared Hilbert space norm of a vector $|\xi\rangle$ in $\mathcal{F}$ is given by $\|\xi\|^2 = \xi\bar{\xi} + \xi^\alpha\bar{\xi}_\alpha + \xi^{\alpha\beta}\bar{\xi}_{\alpha\beta} + \cdots$. For any $\sigma^\alpha \in \mathcal{H}^1$ we define the annihilation and creation operators $\hat{A}^\alpha$ and $\hat{C}_\alpha$ according to the prescription

$$\hat{A}^{\alpha}\overline{\sigma}_{\alpha}|\xi\rangle=\hat{A}(\overline{\sigma})|\xi\rangle=(\xi^{\mu}\overline{\sigma}_{\mu},\sqrt{2}\xi^{\mu\alpha}\overline{\sigma}_{\mu},\sqrt{3}\xi^{\mu\alpha\beta}\overline{\sigma}_{\mu},\ldots),\tag{2.3a}$$

$$\hat{C}_{\alpha}\sigma^{\alpha}|\xi\rangle=\hat{C}(\sigma)|\xi\rangle=(0,\sigma^{\alpha}\xi,\sqrt{2}\sigma^{(\alpha}\xi^{\beta)},\sqrt{3}\sigma^{(\alpha}\xi^{\beta\gamma)},\ldots).\tag{2.3b}$$

These obey the commutation relations $[\hat{C}(\sigma),\hat{C}(\sigma')]=0$, $[\hat{A}(\overline{\sigma}),\hat{A}(\overline{\sigma}')]=0$, and $[\hat{A}^{\alpha},\hat{C}_{\beta}]=\delta^{\alpha}_{\beta}$ or, equivalently, $[\hat{A}(\overline{\sigma}),\hat{C}(\sigma)]=(\sigma\cdot\overline{\sigma})I$. These operators are adjoints of each other in the sense that for any vector $\phi\in\mathcal{F}$ we have $\langle\hat{C}(\sigma)\psi,\phi\rangle=\langle\psi,\hat{A}(\overline{\sigma})\phi\rangle$.

We then define the number operator associated with $\sigma\in\mathcal{H}^1$ $(\sigma\neq 0)$ by $\hat{N}(\sigma)=\|\sigma\|^{-2}\hat{C}(\sigma)\hat{A}(\overline{\sigma})$, from which it follows that $\hat{N}(\sigma)\xi=\|\sigma\|^2(0,\sigma^{\alpha}\xi^{\mu}\overline{\sigma}_{\mu},2\sigma^{(\alpha}\xi^{\beta)\mu}\overline{\sigma}_{\mu},\ldots)$. Summing over an orthonormal basis $\{\sigma^{\alpha}\}$ using the identity $\Sigma_N\sigma^{\alpha}\overline{\sigma}_{\mu}=\delta^{\alpha}_{\mu}$ we obtain the total number operator $\hat{N}$, given by $\hat{N}\xi=(0,\xi^{\alpha},2\xi^{\alpha\beta},3\xi^{\alpha\beta\gamma},\ldots)$. The number operators satisfy the following commutation relations: $[\hat{N}(\sigma),\hat{C}(\sigma)]=[\hat{N},\hat{C}(\sigma)]=\hat{C}(\sigma)$, $[\hat{N}(\sigma),\hat{A}(\overline{\sigma})]=[\hat{N},\hat{A}(\overline{\sigma})]=-\hat{A}(\overline{\sigma})$, and $[\hat{N}(\sigma),\hat{N}]=0$. For further details of these and other relations see Refs. 16 and 19.

III. COHERENT STATES

There are various characterizations of coherent states in quantum field theory. First, we give a definition via exponentiation of the single-particle Hilbert space $\mathcal{H}^1$. We begin with a vector $\xi^a\in\mathcal{H}^1$ and construct from this a unique element of $\mathcal{F}$, obtained by exponentiating ξ^a, denoted $|\xi_c\rangle$. Explicitly, we have

$$\xi^{\alpha}\mapsto\mathcal{E}(\xi^{\alpha})=\exp(\xi^{\alpha}\hat{C}_{\alpha})|0\rangle(1,\xi^{\alpha},\xi^{\alpha}\xi^{\beta}/\sqrt{2!},\ldots,\xi^{\alpha}\xi^{\beta}\cdots\xi^{\delta}/\sqrt{n!},\ldots)=:|\xi_c\rangle\in\mathcal{F},\tag{3.1}$$

where the term containing $\sqrt{n!}$ has n indices [cf. the discussion of Perelomov's ''generalized coherent states'' in proof (b) of Theorem 1 below]. The element $|\xi_c\rangle$ is said to be a coherent state vector. Now we introduce the projection operator P from the Fock space $\mathcal{F}$ down to the state space $P\mathcal{F}$ so the totality of coherent states form a submanifold $\mathcal{C}$ of $P\mathcal{F}$. It is important to note that if $\xi^a\neq 0$ then $P\circ\mathcal{E}(\lambda\xi^a)=P\circ\mathcal{E}(\mu\xi^a)$ if and only if $\lambda=\mu$. Note, however, that although $\lambda\xi^a,\mu\xi^b$ define different vectors in $\mathcal{H}^1$ for $\lambda\neq\mu$, they define the same single-particle state for all nonzero λ, μ, because the single-particle states are elements of $P\mathcal{H}^1$, not $\mathcal{H}^1$. Therefore changing the phase or scale of a single-particle state vector changes the associated coherent state. We can consider the *universal bundle* $\mathcal{U}$ over the single-particle state space with projection $\Pi:\mathcal{U}\to P\mathcal{H}^1$, defined so the fiber above any point or state is the ray in the Hilbert space that it represents. The map $\mathcal{E}:\mathcal{U}\to\mathcal{F}$ defined in (3.1) is a map from this bundle to Fock space, and this is nonconstant along the fibers $\Pi^{-1}(s)$ for all $s\in P\mathcal{H}^1$.

The action of the creation and annihilation operators on coherent states is as follows. Let τ^{α} be an element of $\mathcal{H}^1_+$ and $|\psi_c\rangle$ a coherent state vector defined as before. Then from (2.3a) we have

$$\hat{A}(\overline{\tau})|\psi_c\rangle=(\xi\cdot\overline{\tau})|\psi_c\rangle,\tag{3.2a}$$

or, equivalently, $\hat{A}^{\alpha}|\psi_c\rangle=\psi^{\alpha}|\psi_c\rangle$, from which it follows that *coherent states are eigenstates of the annihilation operator* $\hat{A}(\overline{\tau})$ for any vector $\tau^a\in\mathcal{H}^1$. On the other hand, from (2.3b) it follows that the action of the creation operator on a coherent state vector is given by differentiation with respect to $\mathcal{H}^1$, so

$$\hat{C}_{\alpha}|\psi_c\rangle=\frac{d|\psi_c\rangle}{d\psi^{\alpha}}.\tag{3.2b}$$

For convenience we set $\Lambda:=\xi^{\alpha}\overline{\xi}_{\alpha}$. Then $\langle\psi_c|\psi_c\rangle=e^{\Lambda}$, so we have to divide by this factor to calculate the expectation of any operator from its matrix element with a coherent state vector. For the expectation of the number operator $\hat{N}(\sigma)$ in a coherent state $P|\xi_c\rangle$ we obtain $\langle\hat{N}(\sigma)\rangle=\|\sigma\|^{-2}(\sigma\cdot\overline{\xi})(\xi\cdot\overline{\sigma})$, and for the total number operator $\hat{N}$ we have $\langle\hat{N}\rangle=\Lambda$. More generally, we observe that for any vector $\xi^a \in \mathcal{H}^1$ with norm $\Lambda = \xi^\alpha \xi_\alpha$ the probability distribution for the total number of particles in the coherent state associated with ξ^a is $\mathrm{Prob}[\hat{N}=n] = \Lambda^n e^{-\Lambda}/n!$, the *Poisson distribution* with mean and variance Λ. By a resolution of the identity we mean an expansion of the unit operator of the form

$$\int_{t\in\mathcal{A}} p_t |c_t\rangle\langle c_t| = 1, \tag{3.3}$$

where t is an element of some (generally multidimensional) index set $\mathcal{A}$, endowed with a notion of continuity, and p_t is positive. In the case of coherent states the choice $\mathcal{A}=\mathcal{H}$ determines p_t uniquely (see Ref. 14). This uniqueness property holds, even though the coherent states are not mutually orthogonal and form an over complete basis [in our Hilbert space notation $\langle \xi_c | \psi_c \rangle = \exp(\psi\cdot\bar{\xi})$, which is never zero]. The resolution of the identity (3.3) leads to an important concept in quantum measurement theory and quantum optics known as a *positive operator measure* (POM). We return to a discussion of POMs in Sec. VI.

In the case of the quantum harmonic oscillator the space of coherent states evolves into itself under the unitary evolution associated with the Hamiltonian operator $\hat{H}$. The orbits in classical phase space are identical to the quantum mechanical orbits in the ‘‘expectation phase space’’ coordinatized by the expectation values of the position and momentum operators $\langle \hat{Q} \rangle$ and $\langle \hat{P} \rangle$. In this sense the coherent state description of the quantum harmonic oscillator is suggestively classical. Moreover, the uncertainty relation $(\Delta\hat{Q})(\Delta\hat{P}) \geqslant \hbar/2$ is saturated by the coherent states, and $(\Delta\hat{Q}),(\Delta\hat{P})$ remain constant under unitary Hamiltonian time evolution. These properties hold in the more general case of a system of coupled harmonic oscillators (see Ref. 13).

Now consider the fiber bundle $\mathcal{V}=\Gamma\times F$, where Γ is the classical phase space of elementary Hamiltonian mechanics, and the fiber F above any point $(x,p)\in\Gamma$ is the set of quantum mechanical states $P|\psi\rangle$ such that $\langle\psi|(\hat{X},\hat{P})|\psi\rangle = (x,p)$. In geometric quantum mechanics the evolution can be viewed as taking place in $\mathcal{V}$. The quantum Hamiltonian operator $\hat{H}$ is obtained by promoting x and p to the corresponding position and momentum operators $\hat{X}$ and $\hat{P}$, so that $\hat{H}=\hat{X}^2 + \hat{P}^2$ in appropriate physical units. However, the quantum Hamiltonian function $h=\langle\psi|\hat{H}|\psi\rangle$ is equal to $[x^2+p^2]+[(\Delta\hat{X})^2+(\Delta\hat{P})^2]$. Let us label the two bracketed terms h_0, h_Δ, respectively. The term h_Δ comes from the quantum metric g of Sec. I and is the essential extra ingredient in quantum theory. We can separate the Hamiltonian vector field $X_h^a = \Omega^{ab}\nabla_b h$ uniquely into horizontal and vertical parts X_0, X_Δ, respectively, in the bundle $\mathcal{V}$. For the quantum harmonic oscillator the projection to Γ of any trajectory in $\mathcal{V}$ is always the classical orbit in Γ, corresponding to X_0. The coherent states are characterized by the fact that the Heisenberg inequality $(\Delta x)(\Delta p) \geqslant \hbar/2$ is saturated, and this fixes the values of $\Delta x, \Delta p$. The coherent state evolution has $X_\Delta = 0$, and thus the trajectory is purely horizontal in $\mathcal{V}$ (cf. Ref. 22).

In the case of the quantum electrodynamics of a free photon field, the quantum field is essentially an infinite collection of harmonic oscillators (see Ref. 26), and the properties of coherent states apply. Thus, a ‘‘classical’’ state of the quantum electromagnetic field can be represented by a coherent state in $P\mathcal{F}$, where the Fock space $\mathcal{F}$ is built up in the standard way from $\mathcal{H}_{\mathrm{M}}$, the space of square integrable real solutions of Maxwell's equations. The creation and annihilation operators are based on the electromagnetic 4-potential A^μ, and the field operator is defined as $\hat{A}+\hat{A}^\dagger$. The expectation of this operator in a coherent state $|\xi_c\rangle$ is the corresponding ‘‘ancestor’’ classical solution of Maxwell's equations $\xi^a \in \mathcal{H}_{\mathrm{M}}$ (cf. the discussion of Sec. VI).

IV. THE FUBINI–STUDY GEOMETRY

The projective form of the Fubini–Study metric on CP^n that one usually encounters in quantum theory (see, e.g., Refs. 23, 27, and 7) can be written in the elegant form

$$ds^2 = \frac{8Z^\alpha\, dZ^\beta \overline{Z}_{[\alpha}\, d\overline{Z}_{\beta]}}{k(Z^\gamma \overline{Z}_\gamma)^2}, \tag{4.1a}$$

where Z^α are homogeneous coordinates for CP^n with $\alpha = 0,1,...,n$, and k is the holomorphic sectional curvature, which in subsequent calculations we take to equal one. In application to coherent states it will be useful also to have this metric expressed in nonhomogeneous coordinates, since if Z^0 is the coordinate of the vacuum part of a coherent state then it is necessarily nonvanishing. Thus, the coherent states form a submanifold $\mathcal{G}$ of the affine part of the projective Fock space, the latter consisting of elements of the form $\{(1,\xi^a,\xi^{ab},\ldots)\} =: \mathcal{A} \supset \mathcal{C} \cong C^\infty$ and whose compactification is $\{P(0,\psi^a,\psi^{ab},\ldots)\} =: \mathcal{B} \cong CP^\infty$, i.e., states for which the probability of no quanta being present is zero. Observe that the image of any state vector $|\psi\rangle$ under the creation operator $\hat{C}(\sigma)$ lies within the compactification, i.e., $\hat{C}(\sigma)|\psi\rangle \in \mathcal{B}_+$, $\forall|\psi\rangle \in \mathcal{F}_+$, $\sigma^\alpha \in \mathcal{H}^1_+$. From now on we deal with coherent states viewed as forming a submanifold of $\mathcal{A}$ and we shall make use of the following result (Ref. 23).

Lemma 2: The nonprojective form of the Fubini–Study metric on CP^n is given by

$$ds^2 = 4\,\frac{(1+\zeta^\alpha \overline{\zeta}_\alpha) d\zeta^\alpha\, d\overline{\zeta}_\alpha - (\zeta^\alpha\, d\overline{\zeta}_\alpha)(\overline{\zeta}_\alpha\, d\zeta^\alpha)}{k(1+\zeta^\gamma \overline{\zeta}_\gamma)^2}, \tag{4.1b}$$

where $\zeta^\alpha = Z^\alpha/Z^0$, $\alpha = 1,2,...,n$ are inhomogeneous coordinates.

Proof: We have $d\zeta^\alpha = (Z^0\, dZ^\alpha - Z^\alpha\, dZ^0)/(Z^0)^2$, together with its complex conjugate, and thus $d\zeta^\alpha\, d\overline{\zeta}_\alpha = (Z^0 \overline{Z}_0\, dZ^\alpha\, d\overline{Z}_\alpha - \overline{Z}_0 Z^\alpha\, dZ^0\, d\overline{Z}_\alpha - Z^0 \overline{Z}_\alpha\, d\overline{Z}_0\, dZ^\alpha + Z^\alpha \overline{Z}_\alpha\, dZ^0\, d\overline{Z}_0)/(Z^0 \overline{Z}_0)^2$. Also, $\overline{\zeta}_\alpha\, d\zeta^\alpha = [1/Z_0(Z^0)^2](Z^0 \overline{Z}_\alpha\, dZ^\alpha - Z^\alpha \overline{Z}_\alpha\, dZ^0)$ and similarly for its complex conjugate. Straightforward algebra then shows that the numerator of the right-hand side of (4.1b) is equal to $[(Z^\alpha \overline{Z}_\alpha) \times (dZ^\alpha\, d\overline{Z}_\alpha) + (Z^0 \overline{Z}_0)(dZ^\alpha\, d\overline{Z}_\alpha) - (Z^\beta\, d\overline{Z}_\beta)(dZ^\alpha\, \overline{Z}_\alpha) - (Z^0\, d\overline{Z}_0)(dZ^\alpha\, \overline{Z}_\alpha)]/(Z^0 \overline{Z}_0)^2$. Further manipulation shows that the bracket in the above expression is equal to $(Z^\alpha \overline{Z}_\alpha)(dZ^\alpha\, d\overline{Z}_\alpha) - (Z^\alpha\, d\overline{Z}_\alpha)(dZ^\alpha\, \overline{Z}_\alpha) \equiv 2Z^{[\alpha}\, dZ^{\beta]}\, \overline{Z}_\alpha\, d\overline{Z}_\beta$, and dividing through by $(1+\zeta^\alpha \overline{\zeta}_\alpha)^2$ completes the proof. ■

We shall use this lemma to provide a differential geometric proof of Theorem 1 below, which concerns the intrinsic geometry of the submanifold of coherent states. Before stating this result, we make some general remarks on the curvature tensor of the Fubini–Study geometry and of Kähler manifolds in general.

Consider again the Fubini–Study line element (4.1a). This provides a one-parameter family of Fubini–Study metrics on CP^n. The Riemann tensor derived from the associated metric connection is given by (Refs. 23, 27, and 7) $R_{abcd} = -\frac{1}{2}k(g_{a[c}g_{b|d]} + \Omega_{a[c}\Omega_{b|d]} + \Omega_{ab}\Omega_{cd})$, the Ricci tensor by $R_{ab} = -\frac{1}{2}k(n+1)g_{ab}$, and the Ricci scalar by $R = -kn(n+1)$. We adopt the convention that $k=1$, and in this case for $n=1$ the Fubini–Study metric becomes the intrinsic distance measure on the 2-sphere of the unit radius.

Kähler geometries have a special curvature property that relates to Theorem 1 below. First, we give the definition of a Kähler manifold (cf. Ref. 28).

Definition 2: A complex manifold M is said to be Kähler if it comes equipped with a Hermitian metric $h_{\alpha\beta'}$ with $ds^2 = h_{\alpha\beta'}\, dz^\alpha \otimes d\overline{z}^{\beta'}$ such that the real 2-form $\Omega = i h_{\alpha\beta'}\, dz^\alpha \wedge d\overline{z}^{\beta'}$ is closed. Then Ω is said to be a Kähler form for M.

This is equivalent (Ref. 28) to the existence on M of a real-valued function K, the Kähler scalar function, such that $\Omega = i\partial\overline{\partial}K$, or equivalently $h_{\alpha\beta'} = \partial_\alpha \overline{\partial}_{\beta'} K$. Consequently, a complex submanifold N of a Kähler manifold M is itself Kähler, since the restriction of the function K to N provides the intrinsic Kähler form by applying the operator $\sqrt{-1}\partial\overline{\partial}$. In the case of the Fubini–Study metric on CP^n, the Kähler scalar function takes the form $K = 4k^{-1}\log[1+k(|\zeta^1|^2 + |\zeta^2|^2 + \cdots + |\zeta^n|^2)]$, where ζ^α are inhomogeneous coordinates on CP^n.

Proposition 1: Let Ω be a positive (1,1)-form on a complex manifold M. Then Ω is a Kähler form for M if and only if for all $x_0 \in M$ there exist holomorphic ''Euclidean'' coordinates $z^1,\ldots,z^n$ around x_0, such that $\Omega = i h_{\alpha\beta'}\, dz^\alpha \wedge d\bar{z}^{\beta'}$ and $h_{\alpha\beta'} = \delta_{\alpha\beta'} + O(|z|^2)$ at x_0, and thus the Kähler metric osculates the flat Euclidean metric to second order.

Proof: The implication toward Ω being a Kähler form is clear. To prove the reverse implication, begin with holomorphic coordinates $z^1,\ldots,z^n$, such that $dz^1,\ldots,dz^n$ give an orthonormal basis of T^*_{M,x_0}, the dual tangent space to M at x_0. This implies that $\Omega = i\tilde{h}_{\alpha\beta'}\, dz^\alpha \wedge d\bar{z}^{\beta'}$, where $\tilde{h}_{\alpha\beta'} = \delta_{\alpha\beta'} + \Sigma_{1\leq\gamma\leq n}(a_{\gamma\alpha\beta'} z^\gamma + a'_{\gamma'\alpha\beta'}\bar{z}^{\gamma'}) + O(|z|^2)$. That Ω is real implies $a'_{\gamma'\alpha\beta'} = \bar{a}_{\gamma'\beta'\alpha}$. The Kähler condition $\partial h_{\alpha\beta'}/\partial z^\gamma = \partial h_{\gamma\beta'}/\partial z^\alpha$ at x_0 implies that $a_{\alpha\gamma\beta'} = a_{(\alpha\gamma)\beta'}$. To complete the proof, we define holomorphic Euclidean coordinates $\hat{z}^\alpha$ as $\hat{z}^\beta := z^\beta + \frac{1}{2}\Sigma_{\gamma,\alpha} a_{\gamma\alpha\beta'}\, \delta^{\beta\beta'} z^\gamma z^\alpha$. ■

V. THE GEOMETRY OF COHERENT STATES

We begin our discussion with a result concerning the ''nonlinear'' geometry of the coherent state submanifold.

Lemma 3: Given a pair of distinct coherent states, the complex projective line $L \subset P\mathcal{F}$ joining them intersects $\mathcal{C}$ exactly twice, at the coherent states themselves.

Proof: Suppose that L intersects $\mathcal{C}$ in three or more distinct points. This implies a relation of the form $|\alpha_c\rangle + \lambda|\beta_c\rangle = \mu|\gamma_c\rangle$ for $|\alpha\rangle$, $|\beta\rangle$, $|\gamma\rangle$ normalized, with $\lambda\mu \neq 0$. In the harmonic oscillator case we expand this equation according to $|\alpha_c\rangle = \Sigma_{n=0}^\infty(\alpha^n/\sqrt{n!})\cdot\exp(-\frac{1}{2}\alpha\bar{\alpha})|n\rangle$ for energy eigenstates $|n\rangle$. Taking the Dirac product with $\langle m|$ for all m gives infinitely many linear equations for the two unknowns λ and μ, whose solution space is empty for distinct α, β, γ. A similar argument applies if we generalize the coherent states according to their algebraic characterization, via the exponential map $\mathcal{E}$ of (3.1) (i.e., we do not specialize to the case of the harmonic oscillator). Then suppose $\mathcal{E}(\xi^a) + \lambda\mathcal{E}(\theta^a) = (1+\lambda)\mathcal{E}(\eta^a)$ with ξ^a, θ^a, η^a nonzero distinct elements of $\mathcal{H}^1$. This relation implies infinitely many equations to be satisfied by λ. The square of the $\mathcal{H}^n$ part of the relation gives $(\xi^2)^n + \lambda^2(\theta^2)^n + 2(\xi\cdot\theta)^n\lambda = (1+\lambda)^2(\eta^2)^n$. If all of ξ^2, θ^2, η^2 are nonzero, and not all equal to unity, then these equations have no solution. So, for a solution in λ to exist, we must have ξ^2, θ^2, η^2 all equal to unity. Thus, ξ^a, η^a, θ^a are unit vectors and $1+\lambda^2+2(\xi\cdot\theta)^n\lambda = (1+\lambda)^2$, $\forall n$. This has no solution for nonzero λ unless $(\xi\cdot\theta)=1$, in which case ξ^a, θ^a are the same unit vectors. ■

However, any normalized coherent state vector $|\alpha_c\rangle$ is decomposable as a continuous integral over the states of $\mathcal{C}$ via the resolution of unity (3.3). Provided an analyticity assumption holds, this decomposition is unique (see Sec. IV of Ref. 12 for a proof of this result).

We now state our main result concerning the geometry of $\mathcal{C}$ (cf. also Refs. 29 and 11).

Theorem 1a: *The metric induced on the coherent state submanifold $\mathcal{C}$ from the ambient Fubini–Study metric on the quantum state space is intrinsically flat. The coordinates ξ^a on the single-particle Hilbert space $\mathcal{H}^1$ are complex Euclidean coordinates for $\mathcal{C}$.*

If instead we begin with the coherent state submanifold and decide, *a priori*, to place on it the complex Euclidean metric, giving us the manifold with metric $\mathcal{C}_E$, then we have the following equivalent result.

Theorem 1b: *The Euclidean coherent state submanifold has an isometric embedding into the Fubini–Study state manifold.*

We remark that this theorem relates to the work of Rawnsley,[30] which discusses the geometric quantization of a Kähler manifold K, and how the resulting coherent states give a map $\mathcal{E}$ from K into the quantum mechanical projective state space. In particular, following Corollary 6, it is remarked that, by Kodaira's theorem on Hodge manifolds (Refs. 31 and 28), there exists a holomorphic line bundle connection over K for which the map $\mathcal{E}$ is an embedding. This result is independent of the curvature of K, which is determined by the Poisson bracket of the classical field theory being quantized. In our theorem we have effectively adopted complex Cartesian coordinates for K so that K is complex Euclidean space and so trivially a Kähler manifold (cf. Corollary 1 below, and also Lemma 6 to follow on truncated Fock spaces). Our approach differs from that of Rawnsley, in that we have focused on geometric quantum mechanics rather than geometric quantization. It is nevertheless noteworthy that the two approaches yield descriptions of the coherent states with essentially the same underlying geometry. With regard to the choice of Cartesian coordinates, we note the remarks of Dirac (p. 114 of Ref. 26). For further background to the material covered in Ref. 30 see Ref. 24. Observe that our theorem is independent of the details of the single-particle Hilbert space $\mathcal{H}^1$.

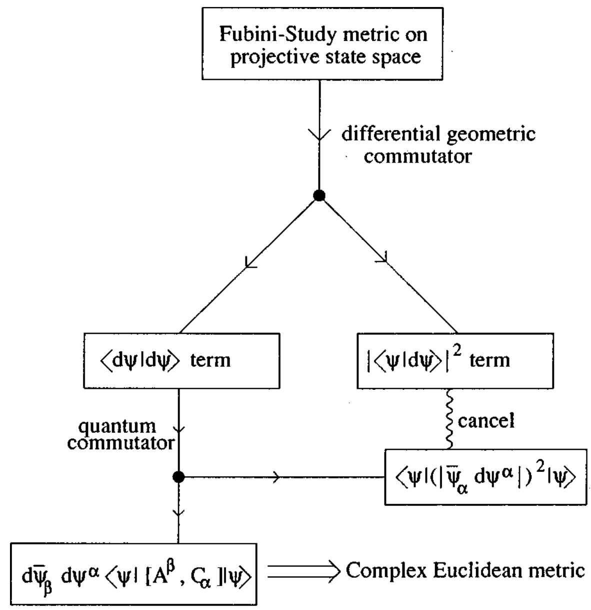
Proof: We give three independent proofs of this result, from the points of view of differential geometry, operator algebra, and the Kähler form.

(a) Differential geometry. From the way that we defined coherent state vectors, we can regard $\xi^a \in \mathcal{H}^1$ as complex coordinate functions for the coherent state submanifold. It will be helpful to introduce some further notation. We define $\xi^{(n)} := \xi^{(\alpha}\xi^{\beta}\cdots\xi^{\delta)}/\sqrt{n!}$ so that $\xi^{(n)}$ is the tensor contribution to the coherent state vector $|\xi_c\rangle$, which lies in $\mathcal{H}^n$, there being n factors in the symmetrized tensor product; we define $\overline{\xi}_{(n)}$ similarly. Then setting $\Lambda = \xi^\alpha \overline{\xi}_\alpha$, we find $\xi^{(n)}\overline{\xi}_{(n)} = \Lambda^n/n!$. Restricted down to the coherent state submanifold $\mathcal{C}$, we can calculate the tangent vector to a coherent state induced by an element $d\overline{\xi}$ of $T^*\mathcal{H}$. The component in $\mathcal{H}^n$ of the (dual) tangent vector is given by $d\xi^{(n)} = n\, d\xi^{(\alpha}\,\xi^{\beta}\xi^{\gamma}\cdots\xi^{\delta)}/\sqrt{n!}$ and similarly for the complex conjugate expression. To calculate the Fubini–Study line element we find the coordinate inner product of a tangent vector with itself. The contribution to this of any pair of vectors lying in distinct $\mathcal{H}^n$ vanishes, as follows from our expression for the Hilbert space norm given earlier. Thus, when evaluating the inner product of two Fock space vectors in the abstract index notation, we contract over vectors and their conjugates with the same number of indices. Hence $d\xi^{(n)}\, d\overline{\xi}_{(m)} \equiv \delta^{(n)}_{(m)} \cdot [1/(n-1)!] \times [\Lambda^{n-1}\, d\xi^\alpha\, d\overline{\xi}_\alpha + (n-1)\Lambda^{n-2}|\xi^\alpha\, d\overline{\xi}_\alpha|^2]$ for all $n \geqslant 1$. We also need the coordinate inner product expression $\overline{\xi}_{(m)} d\xi^{(n)} = \delta^{(n)}_{(m)} \cdot \overline{\xi}_{(\alpha}\overline{\xi}_{\beta}\cdots\overline{\xi}_{\delta)}/\sqrt{n!}\cdot(n/\sqrt{n!})\, d\xi^{(\alpha}\xi^{\beta}\xi^{\gamma}\cdots\xi^{\delta)} \equiv \delta^{(n)}_{(m)} \cdot [1/(n-1)!] \times (\overline{\xi}_\alpha\, d\xi^\alpha)\Lambda^{n-1}$, and, similarly, $\xi^{(n)}\, d\overline{\xi}_{(m)} \equiv \delta^{(n)}_{(m)} \cdot [1/(n-1)!](\xi^\alpha\, d\overline{\xi}_\alpha)\Lambda^{n-1}$ for all $n \geqslant 1$. In (4.1b) above a vector ξ is given by the collection $\{\xi^{(n)}\}$ for all values of n, and thus to evaluate the line element induced on the coherent state submanifold $\mathcal{C}$ we must sum over all $1 \leqslant m, n \leqslant \infty$ in the above identities. This yields $\Sigma_{m,n}\, d\xi^{(n)}\, d\overline{\xi}_{(m)} = e^{\Lambda}(d\xi^\alpha\, d\overline{\xi}_\alpha + |d\xi^\alpha\, \overline{\xi}_\alpha|^2)$ and $\Sigma_{m,n}\overline{\xi}_{(m)}\, d\xi^{(n)} = e^{\Lambda} \cdot \overline{\xi}_\alpha\, d\xi^\alpha$, together with its complex conjugate. The denominator in the Fubini–Study line element equals $1 + \Sigma_{m,n}\xi^{(n)}\overline{\xi}_{(m)} = e^{\Lambda}$, and thus the induced line element reduces to $ds^2 = 4\, d\xi^\alpha\, d\overline{\xi}_\alpha$, as required. ■

(b) Operator algebra. Here we shall assume only the canonical commutation relations (CCR) for the creation and annihilation operators $[\hat{A}^\alpha, \hat{C}_\beta] = \delta^\alpha_\beta$, together with (3.2a) and (3.2b), for these properties characterize the coherent states up to unitary transformations (Refs. 14, 32). The proof that follows thus applies in the case of Perelomov's ''generalized coherent states'' (Ref. 32) since the CCR and properties (3.2) are preserved under the action of the unitary group. We shall adopt the Dirac notation for state vectors according to $Z^\alpha \leftrightarrow |\psi\rangle$, $\overline{Z}_\alpha \leftrightarrow \langle\psi|$. In this notation the Fubini–Study line element becomes

$$ds^2_{\text{F.S.}} = 4\left\{\frac{\langle d\psi|d\psi\rangle}{\langle\psi|\psi\rangle} - \frac{\langle\psi|d\psi\rangle\langle d\psi|\psi\rangle}{\langle\psi|\psi\rangle^2}\right\}. \tag{5.1}$$

We abbreviate so that $|\psi\rangle \in \mathcal{F}$ denotes the coherent state vector associated with $\psi^\alpha \in \mathcal{H}^1$. Then by (3.2a) and (3.2b), we have $|d\psi\rangle = \hat{C}_\alpha|\psi\rangle d\phi^\alpha$ and $\langle d\psi| = d\overline{\phi}_\beta\langle\psi|\hat{A}^\beta$. Using the relations $[\hat{A}^\alpha, \hat{C}_\beta] = \delta^\alpha_\beta$ we calculate $\langle d\psi|d\psi\rangle = d\overline{\phi}_\beta\, d\phi^\alpha\langle\psi|\hat{A}^\beta\hat{C}_\alpha|\psi\rangle$. Rewriting the operator in the matrix element in terms of a commutator gives $d\overline{\phi}_\beta\, d\phi^\alpha\langle\psi|[\hat{A}^\beta, \hat{C}_\alpha] + \hat{C}_\alpha\hat{A}^\beta|\psi\rangle$, which by the CCR and (3.2) equals $[d\phi^\alpha\, d\overline{\phi}_\alpha + (\phi^\beta\, d\overline{\phi}_\beta)(\overline{\phi}_\alpha\, d\phi^\alpha)]\langle\psi|\psi\rangle$. Similarly, $\langle\psi|d\psi\rangle = \langle\psi|\hat{C}_\alpha|\psi\rangle d\phi^\alpha = \langle\psi|\overline{\phi}_\alpha|\psi\rangle d\phi^\alpha = \langle\psi|\psi\rangle(\overline{\phi}_\alpha\, d\phi^\alpha)$. Thus, the line element induced on $\mathcal{C}$ reduces to $ds^2 = 4(d\phi^\alpha\, d\overline{\phi}_\alpha)^2$, as required. The proof is illustrated below. ■



(c) Kähler form. Recall the Kähler scalar function for CP^n, where now we take n to be countable infinity $\aleph_0$. For $\mathcal{A}\subset\mathcal{F}$ defined in Sec. IV, we have $K=4\log(1+|\xi^{(1)}|^2+\cdots+|\xi^{(j)}|^2+\cdots)$, where $\xi^{(j)}=\xi^{\alpha_1\cdots\alpha_j}$ as before. For $\mathcal{C}$ we have the coherent state vector associated with $\psi^\alpha\in\mathcal{H}^1$ given by $\psi^{(j)}=(\psi^\alpha)^{\otimes_s^j}/\sqrt{j!}$, and thus $|\psi^{(j)}|^2=\Lambda^j j!$ with $\Lambda=\psi^\alpha\overline{\psi}_\alpha$. Summing over j to infinity (to sum to infinity is, in fact, necessary for flatness, as we discuss below) we obtain the simple relation

$$K|_{\mathcal{C}}=4\Lambda. \tag{5.2}$$

Then the induced metric on $\mathcal{C}$ is given by $h_{\alpha\beta'}=4\partial_\alpha\overline{\partial}_{\beta'}(\psi^\gamma\overline{\psi}_\gamma)=4\delta_{\alpha\beta'}$, as required. ■

The theorem has the following immediate consequence.

Corollary 1: The coherent state submanifold is a Kähler manifold.

We see therefore that the theorem asserts a global geometric property of the coherent state submanifold (in itself Kähler), which, by comparison with Proposition 1, is a special case of a *second-order* flatness property that applies locally to any Kähler manifold.

We have seen in Lemma 3 that the coherent state submanifold $\mathcal{C}$ is nonlinear, in the sense that the complex projective line joining two distinct coherent states lies in the complement of $\mathcal{C}$, except at its two intersection points. This is an algebraic result whose proof relies upon the uniqueness of decomposition of any given state into coherent states. It suggests the following geometric property of the coherent state submanifold (Refs. 29 and 11).

Proposition 2: Given any two distinct coherent states, the complex projective line joining them intersects $\mathcal{C}$ transversally; that is to say, the line joining the two coherent states does not lie in the tangent space to $\mathcal{C}$ at either intersection point.

Proof: Since $\mathcal{C}$ is homogeneous, we can assume that one of the coherent states is the vacuum state, that is, $P|0\rangle$, where $|0\rangle$ is the element of Fock space that is the exponential of the origin in the vector space $\mathcal{H}^1$. Then from Theorem 1 the intrinsic geodesic distance s from $P|0\rangle$ to $P|\xi_c\rangle(\xi\neq 0)$ is given by $s=2\Lambda^{1/2}$. Recall (e.g., Ref. 7) that the geodesic distance θ between the two states in $P\mathcal{F}$ with respect to the ambient Fubini–Study metric on $P\mathcal{F}$ is determined by the cross ratio

$$\frac{1}{2}(1+\cos\theta)=\frac{\langle\xi_c|0\rangle\langle 0|\xi_c\rangle}{\langle 0|0\rangle\langle\xi_c|\xi_c\rangle}, \tag{5.3}$$

where we take θ to be the principal value determined by this equation, $0\leqslant\theta\leqslant\pi$. Clearly $\langle 0|0\rangle=\langle 0|\xi_c\rangle=\langle\xi_c|0\rangle=1$, and thus $\theta=\cos^{-1}(2e^{-\Lambda}-1)$. It follows that $d\theta/d\Lambda=(e^{\Lambda}-1)^{-1/2}$, and so $d\theta/ds=[\Lambda/(e^{\Lambda}-1)]^{1/2}$. Thus, $d\theta/ds$ is a monotone decreasing function of Λ, beginning at $d\theta/ds=1$, where $\Lambda=0$, and decaying to zero as Λ tends to infinity. Tangency at $P|\xi_c\rangle$ would require $d\theta/ds=1$ for some $\Lambda\neq 0$, and this is not possible given the form of the function $d\theta/ds$. ■

The method above proves another result that is intuitive from the nonlinear geometric property of $\mathcal{C}$ derived in Lemma 3.

Corollary 2: The geodesic distance along the projective line in $P\mathcal{F}$ joining two distinct coherent states is strictly less than the intrinsic geodesic distance within $\mathcal{C}$.

Theorem 1 also establishes the following simple geometric properties of $\mathcal{C}$.

Lemma 4: The intrinsic $\mathcal{C}$ geodesic distance between two coherent states is given by the Hilbert space norm of the difference field of the two corresponding vectors in $\mathcal{H}^1$. The corresponding distance of a coherent state from the vacuum is equal to its Hilbert space norm.

Lemma 5: The overlap $\mathrm{Re}\langle\xi_c|\psi_c\rangle$ *of two normalized coherent state vectors is the cosine of the angle that these states subtend at the vacuum state in the intrinsic geometry of $\mathcal{C}$.*

These results illustrate the geometric character of two emergent linear structures in quantum theory. On the one hand, the addition of elements of the Hilbert space $\mathcal{H}^1$ of solutions to some classical linear field equation yields a new classical field. As we have seen, the intrinsic geometry of the associated coherent states is Euclidean, with the elements of $\mathcal{H}^1$ serving as Euclidean coordinates. On the other hand, any two distinct coherent states can be superposed in the quantum mechanical sense of joining them with the unique complex projective line in the ambient Fubini–Study geometry of the underlying state space $P\mathcal{F}$; we have seen that this superposition is ''noncoherent.'' These two features are present in a linear theory of gravity (cf. the discussion in Ref. 33). The coherent states provide a natural preferred basis, together with a unique probability distribution for the associated resolution of unity. The state space geometry illustrates how a quantum superposition of distinct classical field configurations is outside the classical domain (see Fig. 1).

Theorem 1 has an important consequence for the relationship between the quantum complex structure J of Sec. I and the manifold complex structure on the state space $P\mathcal{F}$. This theorem shows that, in a suitable sense, these two complex structures are identical. Since the coherent state submanifold is Euclidean, and has as Euclidean coordinates the single-particle state vectors themselves, the active transformation J of (2.1c) induces a corresponding transformation on the tangent space to $\mathcal{C}$ at the vacuum state $P|0\rangle$. (This is because the notion of finite displacement from some origin in any Euclidean space is vectorial.) Thus, to find the action of the manifold complex

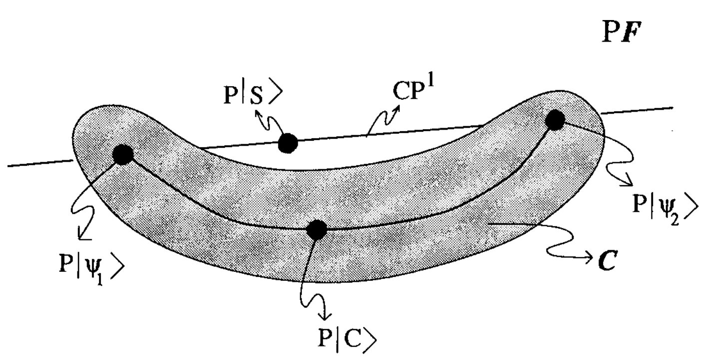


FIG. 1. Coherent state submanifold, embedded inside projective Fock space. For the states shown, $|S\rangle=\lambda|\psi_1\rangle+\mu|\psi_2\rangle$, $\lambda\mu\neq 0$, and $|C\rangle=\mathcal{E}[u\psi_1^a+(1-u)\psi_2^a]$, $u\neq 0,1$, $\psi_i^a\in\mathcal{H}^1$.

structure of the state space on any tangent vector $\mathbf{V}$ to $\mathcal{C}$ at the vacuum, we regard this vector as a displacement in the Euclidean space $\mathcal{C}$ and accordingly as a coherent state given by this displacement from the vacuum. Then we act on the corresponding $\mathcal{H}^1$ element with J and exponentiate this according to (3.1) to give a new displacement vector in $\mathcal{C}$. In turn, this is associated with a unique tangent vector to $\mathcal{C}$ at $P|0\rangle$, which gives the required action of the manifold complex structure on the original vector $\mathbf{V}$.

It is profitable to think in terms of the geometry of the embedding of $\mathcal{C}$ into $P\mathcal{F}$ as an affine subspace whose compactification is the set of states for which the vacuum entry is zero. In this way symmetry is broken in affine $\mathcal{C}$ via the specification of the location of the vacuum state. The geodesics in $\mathcal{C}$, which are straight lines, pass through infinity, or, more precisely, they pass through the infinite-dimensional complex projective space $P\Pi$, where $\Pi=\{(0,\psi^\alpha,\psi^{\alpha\beta},\ldots)\in\mathcal{F}\}$. The only geodesics in the ambient geometry that pass through a given point $P_\infty\in P\Pi$ are circles that pass through an antipodal point, for example the vacuum. Observe however that $\mathcal{C}$ and $P\mathcal{F}$ share no geodesics in common, since any geodesic in the state space has length 2π, whereas Theorem 1 implies that geodesics of $\mathcal{C}$ have infinite length with respect to the same distance measure. Motion of a coherent state along such a geodesic corresponds to scaling the amplitude of its associated single-particle state vector. As this amplitude tends to infinity, the compactification of $\mathcal{C}$ is approached, and the expectation of the total number operator approaches infinity.

The isometry group of $\mathcal{C}$ corresponds to Killing vector fields of the induced Euclidean metric, and consists of rigid rotations and translations, giving rise to orbits that are circles or straight lines inside $\mathcal{C}$. Observe that the projective unitary group $PSU(\infty)$ is isomorphic to the isometry group of the Fubini–Study metric. Hence, the Killing orbits of $\mathcal{C}$ will not, in general, be unitary orbits of the ambient state space.

We examine to what extent the infinite dimensionality of the situation described above affects the result of Theorem 1. Suppose we truncate the Fock space at the N particle states, and define $\mathcal{F}_T=C\oplus\mathcal{H}^1\oplus\cdots\oplus\mathcal{H}^N$ for some finite positive integer N. We define analogs of coherent states as previously, where now the coordinates $\xi^{(n)}$ for $n>N$ are assumed to vanish. The above procedure for calculating the induced metric on the resulting submanifold can be followed closely, and some interesting features of the truncated coherent state submanifold $\mathcal{C}_T$ emerge. We define the real function $S_N(\Lambda):=1+\Sigma_{n=1}^N(1/n!)\Lambda^n$ with Λ as above. In physical terms, the truncated Fock space $\mathcal{F}_T$ is appropriate for a situation in which the expectation of the total number operator $\hat{N}$ is bounded above by N. For example, one might consider the quantum electrodynamics of a photon field constrained inside a finite spatial volume with a saturation density. For a coherent state vector $|\xi_c\rangle$ we have $\langle\hat{N}\rangle=\Lambda S_{N-1}(\Lambda)/S_N(\Lambda)$. Thus, $\langle\hat{N}\rangle<N$, since $\Lambda S_{N-1}(\Lambda)<NS_N(\Lambda)$, as is straightforward to verify. In the limit $\xi^a\mapsto\lambda\xi^a$, $|\lambda|\to\infty$ we find $\langle\hat{N}\rangle\to N$, and thus the distribution among the n particle states becomes more strongly peaked at the N particle states, as the amplitude increases without bound.

Following the same argument as given in proof (a) of Theorem 1, we obtain the following expression for the induced metric on $\mathcal{C}_T$:

$$ds^2=4\left\{\frac{S_{N-1}(\Lambda)}{S_N(\Lambda)}d\xi^a\,d\overline{\xi}_a+\left(\frac{S_{N-2}(\Lambda)}{S_N(\Lambda)}-\frac{S_{N-1}^2(\Lambda)}{S_N^2(\Lambda)}\right)|d\xi^a\overline{\xi}_a|^2\right\}. \tag{5.4}$$

The case of Theorem 1 is given by setting $N=\aleph_0$, and then $S_\infty(\Lambda)=e^\Lambda$ so that the above line element reduces to the flat Euclidean line element. It is natural to ask, in the case of finite N, whether the submanifold $\mathcal{C}_T$ is Kähler, and whether it possesses intrinsic curvature. As regards the Kähler geometry, we have the following result.

Lemma 6: The induced metric on $\mathcal{C}_T$ is Kähler, with a Kähler scalar function given by $K_N=\log S_N(\Lambda)$.

Proof: There are two ways of proceeding. Simplest is to use the same argument as in the Kählerian proof (c) of Theorem 1, summing only to finite N in the expression for K. This incorporates a proof of Theorem 1 as a special case in the limit $N\to\infty$, since $S_{\aleph_0}=e^\Lambda$, and thus

$K_{\mathfrak{N}_0}=4\Lambda$ as in (5.2). Alternatively, it suffices to evaluate the 2-form associated with K_N and show that this is identical to the line element (5.4) upon replacement $\wedge\mapsto\otimes$. We have $\partial K=(S_{N-1}(\Lambda)/S_N(\Lambda))\overline{\xi}_a\,d\xi^a$, and thus $\overline{\partial}\partial K=S_{N-1}(\Lambda)/S_N(\Lambda)d\overline{\xi}_a\wedge d\xi^a+[S_N(\Lambda)S_{N-2}(\Lambda)-S_{N-1}^2(\Lambda)]/S_N^2(\Lambda)(\xi^b\,d\overline{\xi}_b)\wedge(\overline{\xi}_a\,d\xi^a)$, which is of the required form. ■

As regards the intrinsic curvature, we adopt coordinates $\xi^a=(\xi^\alpha,\overline{\xi}^{\alpha'})$ on $\mathcal{C}_T$ and write the induced metric as $g_{\alpha\beta'}=K_N'\delta_{\alpha\beta'}+K_N''\xi_{\beta'}\overline{\xi}_\alpha$. Here the prime operation is $d/d\Lambda$, and we adopt the index notation, as explained in Sec. II. That g is Hermitian implies $\overline{g_{\alpha\beta'}}\equiv\overline{g}_{\alpha'\beta}=g_{\alpha'\beta}=K_N'\delta_{\alpha'\beta}+K_N''\overline{\xi}_\beta\xi_{\alpha'}$. To calculate the Christoffel connection, we need the inverse metric to g_{ab}, written as in (2.1a) with all raised indices, and, by inspection, we find $g^{\alpha\beta'}=(1/K_N')\delta^{\alpha\beta'}-(H_N/K_N')\xi^\alpha\overline{\xi}^{\beta'}$, where the function H_N is defined by $H_N:=K_N''/(K_N'+\Lambda K_N'')$. The derivatives of Λ are $\partial_\alpha\Lambda=\overline{\xi}_\alpha$, $\overline{\partial}_{\alpha'}\Lambda=\xi_{\alpha'}$, and so $\overline{\partial}_{\gamma'}g_{\alpha\beta'}=2K_N''\delta_{\alpha(\beta'}\xi_{\gamma')}+K_N'''\overline{\xi}_\alpha\xi_{\beta'}\xi_{\gamma'}$ and $\partial_\gamma g_{\alpha\beta'}=2K_N''\delta_{\beta'(\alpha}\overline{\xi}_{\gamma)}+K_N'''\xi_{\beta'}\overline{\xi}_\alpha\overline{\xi}_\gamma$. Observe that these relations imply the symmetries $\overline{\partial}_{\gamma'}g_{\beta'\alpha}\equiv\overline{\partial}_{(\gamma'}g_{\beta')\alpha}$, $\partial_\gamma g_{\alpha\beta'}\equiv\partial_{(\gamma}g_{\alpha)\beta'}$, which, in fact, hold for an arbitrary Kähler manifold (as follows directly from $g_{\alpha\beta'}\propto\partial_\alpha\partial_{\beta'}K$ and that $\partial_\alpha,\overline{\partial}_{\beta'}$ commute among one another). The Christoffel symbols are defined by $\Gamma^a{}_{bc}=\frac{1}{2}g^{ad}(\partial_c g_{bd}+\partial_b g_{cd}-\partial_d g_{bc})$ and the calculation of these proceeds using the above identities. We find $\Gamma^\alpha{}_{\beta\gamma}=g^{\alpha\delta'}\partial_{(\gamma}g_{\beta)\delta'}=(1/K_N')(2K_N''\delta^\alpha_{(\gamma}\overline{\xi}_{\beta)}+\Theta_N\xi^\alpha\overline{\xi}_\gamma\overline{\xi}_\beta)$, where the function Θ_N is defined by $\Theta_N:=(K_N'''-2H_NK_N''-\Lambda H_NK_N''')$. The calculation of $\Gamma^{\alpha'}{}_{\beta'\gamma'}$ proceeds in the same way with the roles of ξ and $\overline{\xi}$ interchanged, so that $\Gamma^{\alpha'}{}_{\beta'\gamma'}=(1/K_N')(2K_N''\delta^{\alpha'}_{(\beta'}\xi_{\gamma')}+\Theta_N\overline{\xi}^{\alpha'}\xi_{\beta'}\xi_{\gamma'})$. The ''mixed'' symbol $\Gamma^\alpha{}_{\beta\gamma'}$ vanishes, since $\Gamma^\alpha{}_{\beta\gamma'}=g^{\alpha\delta'}\overline{\partial}_{[\gamma'}g_{\delta']\beta}\equiv 0$. Thus, $\Gamma^\alpha{}_{\beta\gamma'}$, $\Gamma^{\alpha'}{}_{\beta'\gamma}\equiv 0$. The remaining Christoffel symbols $\Gamma^{\alpha'}{}_{\beta\gamma}$ and $\Gamma^\alpha{}_{\beta'\gamma'}$ vanish by the identities $g_{\alpha\beta}=g_{\alpha'\beta'}\equiv 0$. In summary, only the symbols $\Gamma^\alpha{}_{\beta\gamma}$ and $\Gamma^{\alpha'}{}_{\beta'\gamma'}$ are nonzero. (This property holds for a general Kähler manifold, since the above symmetries of the derivatives of g hold in the general case cf. remark following Definition 2 above.) For a general Kähler manifold there exist simple identities for the Riemann curvature tensor in terms of the Christoffel connection. We have in particular (Ref. 34) $\Gamma^\alpha{}_{\beta\gamma}=g^{\alpha\delta'}\,\partial^3K/\partial\xi^\beta\,\partial\xi^\gamma\,\partial\overline{\xi}^{\delta'}$, $\Gamma^{\alpha'}{}_{\beta'\gamma'}=g^{\delta\alpha'}\,\partial^3K/\partial\xi^\delta\,\partial\overline{\xi}^{\beta'}\,\partial\overline{\xi}^{\gamma'}$; and $\Gamma^\alpha{}_{\beta\gamma'}=\Gamma^\alpha{}_{\beta'\gamma}=\Gamma^{\alpha'}{}_{\beta\gamma}=\Gamma^\alpha{}_{\beta'\gamma'}=\Gamma^{\alpha'}{}_{\beta'\gamma}=\Gamma^{\alpha'}{}_{\beta\gamma'}=0$. It follows that for a general Kähler manifold the only nonvanishing components of the Riemann tensor are $R_{\alpha\beta'\gamma\delta'}$, $R_{\alpha\beta'\gamma'\delta}$, $R_{\alpha'\beta\gamma\delta'}$, $R_{\alpha'\beta\gamma'\delta}$, and these possess the Hermitian and symmetry properties $R_\lambda{}^\alpha{}_\mu{}^\beta=R_\lambda{}^{(\alpha}{}_\mu{}^{\beta)}=R_{(\lambda}{}^{(\alpha}{}_{\mu)}{}^{\beta)}=\overline{R}_\lambda{}^\alpha{}_\mu{}^\beta=\overline{R_{\lambda'}{}^{\alpha'}{}_{\mu'}{}^{\beta'}}$. As a consequence, the Ricci tensor is determined by a Hermitian $R_{\alpha\beta'}$, and the Ricci scalar R is real. For a general Kähler manifold we have (Ref. 34) the useful simplifying identity $R_{\alpha\beta'\lambda}{}^\mu\equiv\overline{\partial}_{\beta'}\Gamma^\mu{}_{\alpha\lambda}$, so that in our case we find

$$R_\alpha{}^\beta{}_\lambda{}^\mu=-R_\alpha{}^{\beta\mu}{}_\lambda=-\left(\frac{2K_N''}{K_N'}\right)'\delta^\mu_{(\alpha}\overline{\xi}_{\lambda)}\xi^\beta-\frac{2K_N''}{K_N'}\delta^\mu_{(\alpha}\delta^\beta_{\lambda)}-\frac{2\Theta_N}{K_N'}\xi^\mu\overline{\xi}_{(\alpha}\delta^\beta_{\lambda)}-\left(\frac{\Theta_N}{K_N'}\right)'\xi^\beta\xi^\mu\overline{\xi}_\alpha\overline{\xi}_\lambda. \tag{5.5a}$$

Thus, with indices in any position, the Riemann curvature vanishes in the limit that $N\to\mathfrak{N}_0$, for then $K'=1$ and Θ, K'' both vanish. This is in accordance with Theorem 1. (It makes sense to discuss the limit $N\to\mathfrak{N}_0$, since the underlying $\mathcal{H}^1$ serves to coordinatize $\mathcal{C}_T$ for each N.) We calculate the Ricci tensor of $\mathcal{C}_T$ by taking the trace on β and λ in the expression for $R_\alpha{}^{\beta\mu}{}_\lambda$ from (5.5a). We obtain

$$R_\alpha{}^\mu=\xi^\mu\overline{\xi}_\alpha[(K_N''/K_N')'+(n+1)(\Theta_N/K_N')+\Lambda(\Theta_N/K_N')']+\delta^\mu_\alpha[\Lambda(K_N''/K_N')'+(n+1)(K_N''/K_N')], \tag{5.5b}$$

where n is the holomorphic dimension of $\mathcal{H}^1$, and this $R_\alpha{}^\mu$ is Hermitian. For the Ricci scalar R we find

$$R=(n+1)\Lambda\left(\frac{2K_N''}{K_N'}\right)'+n(n+1)\frac{K_N''}{K_N'}+(n+1)\Lambda\frac{\Theta_N}{K_N'}+\Lambda^2\left(\frac{\Theta_N}{K_N'}\right)', \tag{5.5c}$$

which is real. Observe that both the Ricci tensor and Ricci scalar diverge as the holomorphic dimension n approaches $\aleph_0$. Nevertheless, the Weyl curvature is well defined in this limit, as we demonstrate. The Weyl tensor (e.g., Ref. 18) of a $2n$-real dimensional Kähler manifold is determined by $C_\alpha{}^\beta{}_\gamma{}^\delta - R_\alpha{}^\beta{}_\gamma{}^\delta = [1/(2n-2)](\delta_\alpha^\delta R_\gamma{}^\beta + \delta_\gamma^\beta R_\alpha{}^\delta) - [1/(2n-1)(2n-2)]R\,\delta_\alpha^\delta \delta_\gamma^\beta$ so that in our case, as $n = \dim_{\mathbf{C}}(\mathcal{H}^1)$ approaches $\aleph_0$, we obtain

$$C_\alpha{}^\beta{}_\gamma{}^\delta - R_\alpha{}^\beta{}_\gamma{}^\delta = \frac{1}{2}\,\frac{\Theta_N}{K_N'}\,(\delta_\alpha^\delta \xi^\beta \overline{\xi}_\gamma + \delta_\gamma^\beta \xi^\delta \overline{\xi}_\alpha) + \frac{3}{4}\,\frac{K_N''}{K_N'}\,\delta_\alpha^\delta \delta_\gamma^\beta. \tag{5.6}$$

We observe that this quantity is finite, which has the following consequences.

Proposition 3: For the complete Fock space $(N = \aleph_0)$, *the Weyl curvature of the coherent state submanifold vanishes for all values of* $\dim \mathcal{H}^1$, *including countable infinity* $\aleph_0$. *This is despite the divergence of the Ricci tensor in the limit* $\dim \mathcal{H}^1 \to \aleph_0$. *Thus,* $\mathcal{C}$ *is conformally flat for all single-particle Hilbert spaces* $\mathcal{H}^1$.

Proposition 4: For the Fock space $\mathcal{F}_T$ *(N finite), the submanifold* $\mathcal{C}_T$ *has finite conformal curvature for any single-particle Hilbert space* $\mathcal{H}^1$.

By comparison, the Fubini–Study geometry of the underlying state manifold $P\mathcal{F}$ has a divergent Ricci tensor and scalar for $\dim \mathcal{H}^1 = \aleph_0$, and finite nonzero Riemann and Weyl curvatures proportional to the holomorphic sectional curvature k, for all $\mathcal{H}^1$.

VI. DISCUSSION

Theories of stochastic state vector reduction processes have recently been extensively studied (see, e.g., Refs. 35 and articles cited therein). In particular, a proposal of this kind has been given in the context of geometric quantum mechanics). (See Ref. 7.) It would be interesting to see whether such an approach is viable in the infinite-dimensional case that arises in the context of quantum field theory, with the geometry we have described above. The submanifold of coherent states suggests itself as a natural geometric object to study in the context of a stochastic model, in which the coherent states provide the preferred basis for state vector reduction (cf. Ref. 7, where the energy eigenstates feature in this respect). The physical motivation for such a model is that the coherent states are precisely those from which a unique classical field configuration can be inferred in a quantum field theoretic context. In this way the coherent states play an important role in many quantization procedures (cf. Refs. 30, 24, and 36). We take the view therefore that coherent states are central in understanding the results of quantum measurement. Evidence for this exists in the theory of quantum optics, in which the empirically determined photon numbers obey the Poisson statistics of coherent states (cf. Ref. 14). The theory of positive operator-valued measures (Ref. 37) is important in this regard. As remarked in Sec. III, a POM provides a resolution of the unit operator among nonorthogonal states, and constitutes the spectrum for an associated measurement (a consistent theory of POM measurements has been developed in Refs. 37, 38, and 39). We have observed that the space of coherent states provides a natural POM, and that the underlying geometry of the coherent state manifold relates to the notion of quantum versus classical superposition in a physically intuitive way, as discussed in Sec. V. We envisage a stochastic process on the state manifold, with a drift oriented toward the coherent state submanifold $\mathcal{C}$, and a vanishing diffusion tensor on $\mathcal{C}$. An initial incoherent state is driven toward $\mathcal{C}$ via the stochastic evolution combined with drift, until $\mathcal{C}$ is reached, when ordinary unitary evolution proceeds according to the Hamiltonian flow. Thus $\mathcal{C}$ becomes an invariant attractor for the stochastic evolution (see Ref. 13, which discusses the preservation of coherent states under unitary evolution for a wide class of Hamiltonians). The stochastic differential geometry of processes on CP^n is well understood (cf. Ref. 7) and appears to generalize naturally to the infinite dimensional case. A suggestion for a stochastic differential equation governing this type of evolution is given in Chap. 8 of Ref. 11.

We have not addressed the issue of boundedness of the field operators associated with a given $\mathcal{H}^1$, and their kinematical representation. While the former can be dealt with by introducing the corresponding Weyl form of the canonical commutation relations (Refs. 40 and 41), the latter amounts to the choice of vacuum state together with a representation of the quantum complex structure J on some kinematical background, e.g., spacetime. For massless fields on Minkowski space and linearized gravity in vacuum, various representations of J and the associated metric g are given in Ref. 11.

An open problem is that of constructing a geometric phase space formulation of quantum field theory for which the state space is an arbitrary Kähler manifold. Our present view is that the study of stochastic processes on CP^{∞} may suggest a consistent measurement theory in which certain modifications of the state space geometry become necessary. We have seen that field theory based on a linear $\mathcal{H}^1$ can be formulated naturally in geometric terms. As occurs with spacetime in the passage from Maxwell's theory to Einstein's general relativity, the quantum state space may require global departures from the standard complex projective geometry and maximal isometry group, in order to accommodate the quantum description of nonlinear phenomena such as gravitation.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 6 JUNE 1999

A new type of loop independence and SU(N) quantum Yang–Mills theory in two dimensions

Christian Fleischhack[a)]
Institut für Theoretische Physik, Fakultät für Physik und Geowissenschaften, Universität Leipzig, Augustusplatz 10/11, 04109 Leipzig, Germany and Max-Planck-Institut für Mathematik in den Naturwissenschaften, Inselstrasse 22-26, 04103 Leipzig, Germany

(Received 3 September 1998; accepted for publication 9 February 1999)

The expectation values of Wilson loop products for the pure Euclidean Yang–Mills theory on $\mathbb{R}\times\mathbb{R}$ given by Ashtekar *et al.* in the article ''SU(N) Quantum Yang–Mills Theory in Two Dimensions: A Complete Solution'' [J. Math. Phys. **38**, 5453 (1997)] are determined directly for all piecewise analytic loops. For that purpose we enlarge their calculations from quadratic lattices to general floating lattices introducing a new kind of loop independence and slightly modifying the regularization scheme. © *1999 American Institute of Physics.* [S0022-2488(99)01606-0]

I. INTRODUCTION

For quite a long time the quantization of Yang–Mills theories has been investigated. One of the main emphases is the approach via functional integration. The crucial point is the definition of an appropriate measure $d\mu$ on the space $\mathcal{A}/\mathcal{G}$ of all connections modulo gauge transformations. Heuristically one sets simply $d\mu := e^{-S(A)}\mathcal{D}A$, where $S(A)$ is the Yang–Mills action and $\mathcal{D}A$ is a kinematical measure on $\mathcal{A}/\mathcal{G}$, but the resulting mathematical problems are enormous. Some years ago, Ashtekar and Isham[1] developed an interesting idea to overcome these difficulties. They considered a certain completion of $\mathcal{A}/\mathcal{G}$, the compact Hausdorff space $\overline{\mathcal{A}/\mathcal{G}}$. Now, Ashtekar and Lewandowski[2] were able to construct a natural kinematical measure $d\mu_0$ corresponding to $\mathcal{D}A$, but the extension of S onto the whole $\overline{\mathcal{A}/\mathcal{G}}$ remained difficult. This problem was circumvented using the duality between measures on $\overline{\mathcal{A}/\mathcal{G}}$ and positive linear functionals on the space of all Wilson loop products. Using the lattice regularization, Thiemann[3] and Ashtekar *et al.*[4] defined these expectation values and received the measure $d\mu$.

Nevertheless, some technical problems remained open. The authors of Ref. 4 did not specify the type of hoop independence used for the projection $\overline{\mathcal{A}/\mathcal{G}}\to\mathbf{G}^n$. Both the strong independence and the weak independence[2] are not applicable—the former because obviously the lattice loops $\beta_{x,y}=\rho_{x,y}\Box_{x,y}\rho_{x,y}^{-1}$ cannot be strongly independent for lattices with more than two rows and columns, and the latter because then the integral would become illdefined.[2] Furthermore, the authors of Ref. 4 used the completeness of the plaquette loops $\beta_{x,y}$, i.e., that the subgroup of the hoop group generated by the $\beta_{x,y}$ coincides with the subgroup generated by all loops in the lattice. But, in general, the completeness is not guaranteed if one chooses arbitrary paths $\rho_{x,y}$ from the base point to the plaquette (x,y). So we will prove that there *exists* a choice for the $\rho_{x,y}$ such that the plaquette loops $\beta_{x,y}$ are complete. For the same reasons, the proof of the decomposition lemma, which ensures that any loop α without self-intersections can be expressed by a product of the loops corresponding to the plaquettes in the interior of α, has to be modified.

The present article is intended to provide these missing mathematical details. Moreover, we drop the restriction on quadratic lattices. We admit now any finite connected graph—a ''floating'' lattice—for the regularization. For this we slightly modify the regularization of the Yang–Mills action simply replacing a^2 (a...lattice spacing) by the area $|G|$ of the plaquette (see also Ref. 5) and

---

a)Electronic mail: Christian.Fleischhack@itp.uni-leipzig.de *or* Christian.Fleischhack@mis.mpg.de adapting the regularization to the given loops and not, as usual, the opposite. Thus, the use of floating lattices allows us to calculate the Wilson loop expectation values for all sets of hoops directly, i.e., without approximating them in a certain sense by loops in a quadratic lattice and without a subsequent (naive) limit. On the other hand we need a little bit more sophisticated—and, unfortunately, more technical—analysis, even if we would consider only quadratic lattices. At the beginning we define a new type of independence—the so-called moderate independence, which stands between the strong and the weak independence and is well suited to making the calculations mathematically rigorous. We prove that it is strong enough to make the integration calculus still applicable. Then we generalize the propositions in Ref. 4 to the case of floating lattices. The loops $\beta_{x,y}$ correspond now to the so-called flags f_G, i.e., loops that run from the base point m to the interior domain G—the generalized plaquette—traverse G once, and return to m. Choosing a flag to each interior domain we get a flag world. The crucial point is now the proof that there is a (moderately) independent and complete flag world for any graph. Moreover, the generalized decomposition lemma yields that, if one refines the underlying graph, any flag world can be naturally refined to a new (again moderately independent and complete) flag world and each flag f of the old flag world is a product of exactly the flags of the new one that correspond to domains in the interior of f.

By means of these propositions we can finally compute the Wilson loop expectation values reusing the calculations of Thiemann and Ashtekar *et al.*

II. PRELIMINARIES

In this section we summarize the basic facts about the space $\overline{\mathcal{A}/\mathcal{G}}$ of generalized connections modulo gauge transformations following Refs. 1, 2, and 4.

Let P be a fixed principal fiber bundle over the base manifold M with structure group $\mathbf{G}$ and m any fixed point in M. Furthermore, let $\{U_i\}$ be a covering of M,$\{\chi_i\}$ a trivialization of P over $\{U_i\}$ and j a fixed index with $m \in U_j$. In the following we suppose $\mathbf{G}$ to be either $\mathrm{SU}(N)$, $N \geqslant 2$, or $\mathrm{U}(1)$. Connections on P are described by their connection one-form A on P or, equivalently, their localized forms A_i on U_i. Similarly, we describe a gauge transformation by its corresponding equivariant map $\rho: P \to \mathbf{G}$ or its localized forms $\rho_i : U_i \to \mathbf{G}$. We will only consider C^∞ connections and C^∞ gauge transformations. The spaces of all connections and all gauge transformations are denoted by $\mathcal{A}$ and $\mathcal{G}$, respectively, and their quotient with respect to the natural action of $\mathcal{G}$ on $\mathcal{A}$ is denoted by $\mathcal{A}/\mathcal{G}$.

Next, we define $\mathcal{L}_m$ to be the set of all piecewise analytic loops in M with base point m, i.e., all piecewise analytic maps $\alpha:[0,1] \to M$, $\alpha(0) = \alpha(1) = m$. Two loops α_1 and α_2 are multiplied by

$$\alpha_1 \circ \alpha_2(t) := \begin{cases} \alpha_1(2t) & \text{for } t \in [0, \frac{1}{2}] \\ \alpha_2(2t-1) & \text{for } t \in [\frac{1}{2}, 1] \end{cases}.$$

Note, that $\circ$ is not associative. For any $\alpha \in \mathcal{L}_m$ and $A \in \mathcal{A}$ we define the holonomy $h_\alpha(A) = h_A(\alpha) = h(\alpha, A) \in \mathbf{G}$ as the group element, which corresponds to the parallel transport with respect to A of $\chi_j^{-1}(m, e_{\mathbf{G}})$ along α. In the trivialization χ_j we have $h(\alpha, A) = \mathcal{P} \exp - (\oint_\alpha A_j)$ if α is completely contained in U_j. A change of the trivialization yields only a conjugation of $h(\alpha, A)$ independent of α. (Since such a conjugation is irrelevant for our purpose, we fix now a certain chart U_j for the computation of the holonomies.) Moreover, we have $h_\alpha h_\beta = h_{\alpha \circ \beta}$ for all $\alpha, \beta \in \mathcal{L}_m$.

The fundamental idea of Ashtekar and Isham was to use the description of connections by the traces of their holonomies, the so-called Wilson loops. First, they defined an equivalence relation on $\mathcal{L}_m$. Two loops $\alpha_1, \alpha_2 \in \mathcal{L}_m$ are said to be holonomically equivalent $\alpha_1 \sim \alpha_2$ iff $h_{\alpha_1}(A) = h_{\alpha_2}(A)$ for any $A \in \mathcal{A}$. The equivalence classes $[\alpha]$ are called hoops. [In the following we often drop the brackets. Then the equal sign (=) means the equality of loops and the symbol $\sim$ means equality of hoops.] The hoop group $\mathcal{HG}$ is the set of all hoops with the well-defined projected multiplication of $\mathcal{L}_m:[\alpha_1]\circ[\alpha_2]=[\alpha_1\circ\alpha_2]$ and $[\alpha]^{-1}=[\beta]$ with $\beta(t)=\alpha(1-t)$. For instance, two loops are holonomically equivalent if they can be obtained from each other by reparametrization or insertion of retracings. Second, Ashtekar and Isham made use of the so-called Wilson loops $T_\alpha:\mathcal{A}\to\mathbb{C}$ defined by $T(\alpha,A)=T_\alpha(A)=(1/N)\operatorname{tr} h_\alpha(A)$. Obviously, T factorizes over $\sim$ and $\mathcal{G}$, i.e., $T:\mathcal{HG}\times\mathcal{A}/\mathcal{G}\to\mathbb{C}$. Next, they defined the algebra $\mathcal{HA}:=\{f:\mathcal{A}/\mathcal{G}\to\mathbb{C}|f=\Sigma_{i=1}^n c_i\Pi_{j_i=1}^{n_i} T_{\alpha_{j_i}}|n,n_i\in\mathbb{N},c_i\in\mathbb{C}\}$ of all finite linear combinations of finite products of Wilson loops and called its completion $\overline{\mathcal{HA}}$ with respect to the sup-norm on $\mathcal{A}/\mathcal{G}$ holonomy algebra. Clearly, $\overline{\mathcal{HA}}$ is a commutative $\mathcal{C}^*$ algebra. This allows to use the powerful tools provided by the theory of $\mathcal{C}^*$ algebras. Due to the Gelfand–Naimark theorem there exists a compact Hausdorff space $\mathcal{M}(\overline{\mathcal{HA}})$, the space of all characters of $\overline{\mathcal{HA}}$, i.e., all nontrivial, linear, multiplicative functionals on $\overline{\mathcal{HA}}$, such that $\overline{\mathcal{HA}}\cong\mathcal{C}(\mathcal{M}(\overline{\mathcal{HA}}))$. Giles[6] had proved that given all Wilson loops one can reconstruct the corresponding connection up to a gauge transformation. Rendall[7] observed that, therefore, $\mathcal{A}/\mathcal{G}$ can be densely embedded into $\mathcal{M}(\overline{\mathcal{HA}})$. This justifies the Ashtekar–Isham definition $\overline{\mathcal{A}/\mathcal{G}}:=\mathcal{M}(\overline{\mathcal{HA}})$ of the space of the generalized connections modulo gauge transformations. The elements of $\overline{\mathcal{A}/\mathcal{G}}$ are denoted by $\bar{A}$. The isomorphism between $\overline{\mathcal{HA}}$ and $\mathcal{C}(\mathcal{M}(\overline{\mathcal{HA}}))$ is given by the Gelfand transformation

$$\sim:\overline{\mathcal{HA}}\to C(\overline{\mathcal{A}/\mathcal{G}})\quad\text{with}\quad \tilde{f}:\overline{\mathcal{A}/\mathcal{G}}\to\mathbb{C},$$

$$f\mapsto\tilde{f},\quad \bar{A}\mapsto\bar{A}(f).$$

The theory of $\mathcal{C}^*$ algebras yields also the measure theory and representation theory on $\overline{\mathcal{A}/\mathcal{G}}$. There is a one-to-one correspondence between Borel measures μ on $\overline{\mathcal{A}/\mathcal{G}}$, linear continuous positive functionals F on $\overline{\mathcal{HA}}$, and continuous cyclic Hilbert space representations ϕ of $\overline{\mathcal{HA}}$. More precisely, any such functional F can be obtained by $F(f)=\int_{\overline{\mathcal{A}/\mathcal{G}}}\tilde{f}\,d\mu_F$ with a certain unique Borel measure μ_F and any such ϕ is unitary equivalent to the representation φ of $\overline{\mathcal{HA}}$ on $L^2(\overline{\mathcal{A}/\mathcal{G}},d\mu_\phi)$ by multiplication operators $\varphi(f)\psi=\tilde{f}\cdot\psi$ with a certain measure μ_ϕ.

Ashtekar and Lewandowski[2] (in the following denoted by AL) discovered a second description of $\overline{\mathcal{A}/\mathcal{G}}$ via the hoop group $\mathcal{HG}$. (Marolf and Mourão[8] obtained a third description of $\overline{\mathcal{A}/\mathcal{G}}$ via projective limits. However, this approach is unimportant for our purpose and we only mention it for completeness.) They defined two kinds of independence on $\mathcal{L}_m$. A finite subset $\boldsymbol{\beta}:=\{\beta_i\}$ of $\mathcal{L}_m$ is called strongly independent iff each β_i contains an open segment which is traced once and only once by β_i and which is intersected by the remaining β_j at most in a finite set of points. $\boldsymbol{\beta}$ is weakly independent iff to any $(g_1,\ldots,g_n)\in\mathbf{G}^n$ there exists an $A\in\mathcal{A}$ such that $h_{\beta_i}(A)=g_i$ for all i. They proved that strong independence implies weak independence. Then they could give a bijection between $\overline{\mathcal{A}/\mathcal{G}}$ and the space $\operatorname{Hom}(\mathcal{HG},\mathbf{G})/\operatorname{Ad}$ of *all* homomorphisms from $\mathcal{HG}$ to $\mathbf{G}$ modulo a hoop independent conjugation. More precisely, any $h\in\operatorname{Hom}(\mathcal{HG},\mathbf{G})/\operatorname{Ad}$ yields an $\bar{A}_h\in\overline{\mathcal{A}/\mathcal{G}}$ via $\bar{A}_h(T_\alpha):=(1/N)\operatorname{tr} h(\alpha)$ and vice versa.

This graph-theoretical approach was used by AL to define a natural integration measure, the so-called induced Haar measure.[2] They introduced an equivalence relation on $\overline{\mathcal{A}/\mathcal{G}}$ for finitely generated subgroups $\mathcal{HG}(\boldsymbol{\beta})\subseteq\mathcal{HG}$:$\bar{A}_1\sim\bar{A}_2$ with respect to $\mathcal{HG}(\beta)$ iff $h_{\bar{A}_1}(\gamma)=g^{-1}h_{\bar{A}_2}(\gamma)g$ for all $\gamma\in\mathcal{HG}(\boldsymbol{\beta})$ with a (hoop independent) $g\in\mathbf{G}$. $\pi_\beta\overline{\mathcal{A}/\mathcal{G}}:\to\overline{\mathcal{A}/\mathcal{G}}\sim$ is the corresponding projection. Thus, there is a bijection $\overline{\mathcal{A}/\mathcal{G}}\sim\leftrightarrow\operatorname{Hom}(\mathcal{HG}(\boldsymbol{\beta}),\mathbf{G})/\operatorname{Ad}$ as for $\overline{\mathcal{A}/\mathcal{G}}$ and $\operatorname{Hom}(\mathcal{HG},\mathbf{G})/\operatorname{Ad}$. $\operatorname{Hom}(\mathcal{HG}(\beta),\mathbf{G})/\operatorname{Ad}$ itself is isomorphic to $\mathbf{G}^{\#\boldsymbol{\beta}}/\operatorname{Ad}$ if $\boldsymbol{\beta}$ is weakly independent. Therefore AL could reduce the integration over $\overline{\mathcal{A}/\mathcal{G}}$ under certain circumstances to the case of the integration over a finite dimensional Lie group. In detail, they defined cylindrical functions, i.e., functions f being pullbacks $\pi_{\boldsymbol{\beta}}f_{\boldsymbol{\beta}}$ of continuous functions $f_{\boldsymbol{\beta}}$ on $\operatorname{Hom}(\mathcal{HG}(\beta),\mathbf{G})/\operatorname{Ad}=\mathbf{G}^{\#\boldsymbol{\beta}}/\operatorname{Ad}$ with strongly independent β and showed that the set $\mathcal{C}$ of all such functions is dense in $\overline{\mathcal{HA}}=\mathcal{C}(\overline{\mathcal{A}/\mathcal{G}})$. Now,

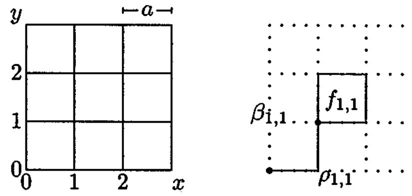

FIG. 1. Example of a lattice ($l=3$) and the loop $\beta_{1,1}$.

they defined $\int_{\overline{\mathcal{A}/\mathcal{G}}} f\, d\mu_0 := \int_{\mathbf{G}^{\#\beta}/\mathrm{Ad}} f_{\boldsymbol{\beta}} d\mu_{\boldsymbol{\beta}}$ and chose $d\mu_{\boldsymbol{\beta}}$ to be the Haar measure for each $\boldsymbol{\beta}$. Thus they got a well-defined, regular and positive measure μ_0 on $\overline{\mathcal{A}/\mathcal{G}}$, the so-called induced Haar measure.

Ashtekar and Lewandowski realized that μ_0 could serve as a kinematical measure of physical theories in the functional integral approach. Since the elements of $\mathcal{A}/\mathcal{G}$ are classical potential configurations, the completion $\overline{\mathcal{A}/\mathcal{G}}$ seems to be a candidate for the space of histories in the quantum regime and the physical measure is built from $d\mu_0$ by multiplication with e^{-S}, where S is the physical action of the theory. The crucial point was to choose such an S defined not only on $\mathcal{A}/\mathcal{G}$ but on $\overline{\mathcal{A}/\mathcal{G}}$. Neglecting that fact, one could compute via $\langle f\rangle = \int e^{-S} f\, d\mu_0$ any expectation value of the theory supposed f to be a function on $\overline{\mathcal{A}/\mathcal{G}}$. Thiemann[3] and Ashtekar *et al.*[4] (in the following denoted by TA^+) proposed a solution of that problem in the case of the two-dimensional quantum Yang–Mills theory using lattice regularization. The main problem was the replacement of the Yang–Mills action $S_{\mathrm{YM}} = \frac{1}{4}\int_M F_{\mu\nu}F^{\mu\nu}\, dx$ by an expression whose domain is $\overline{\mathcal{A}/\mathcal{G}}$. The only *a priori* available quantities are the generalized holonomies. This indicates the use of Wilson's lattice regularization. For this one places a finite quadratic lattice with spacing a and length R on the 2-plane and defines $S_{\mathrm{YM}}^{\mathrm{req}} = (N/g^2a^2)\Sigma_\Box(1-(1/N)\mathrm{Re}\,\mathrm{tr}\, h_\Box)$ where the sum goes over all plaquettes of the lattice. $h_\Box$ denotes the holonomy around the plaquette $\Box$. In the limit $a\to 0$ and $R\to\infty$ one can show naively the regularized action to converge to S_{YM}. The advantage of $S_{\mathrm{YM}}^{\mathrm{req}}$ is its natural extendability to $\overline{\mathcal{A}/\mathcal{G}}$. Now, TA^+ could compute the expectation values of the Wilson loops expected to determine the whole pure quantum YM_2 theory:

$$\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle = \frac{1}{Z}\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_0\, e^{-\lim_{\alpha\to 0,R\to\infty} S_{\mathrm{YM}}^{\mathrm{reg}}} T_{\alpha_1}\cdots T_{\alpha_n} = \lim_{a\to 0,R\to\infty}\frac{1}{Z_{a,R}}\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu_0\, e^{-S_{\mathrm{YM}}^{\mathrm{reg}}} T_{\alpha_1}\cdots T_{\alpha_n} \tag{1}$$

after exchanging limit and integral. (The factor $1/Z$ guarantees $\langle T_1\rangle = 1$.) Afterwards they expressed each loop $\alpha_1,\ldots,\alpha_n$ and each plaquette loop $\Box$ by a product of ‘‘simple’’ loops (i.e., loops traversing exactly one plaquette and connecting it with the base point m by conjugation), provided, however, $\alpha_1,\ldots,\alpha_n$ are contained in the lattice. Under the assumption that these loops are independent they could reduce the integration over $\overline{\mathcal{A}/\mathcal{G}}$ to the integration over G^n, n finite. Finally, they computed the integrals explicitly and got an algebraic expression depending only on the areas enclosed by the loops. For general $\alpha_1,\ldots,\alpha_n$ they suggested to approximate these loops naively by lattice loops and to consider the limit of the expectation values, but this is simply given by the limit of the enclosed areas.

III. MODERATE INDEPENDENCE

In this section we will introduce a new type of independence being crucial for the considerations below—the so-called moderate independence.

A. Why a new type of independence?

We consider a quadratic lattice with spacing a and length $R = la$, $l\in\mathbb{N}^+$, i.e., with l^2 plaquettes, see, e.g., Fig. 1. Now we assign (see Ref. 4) a loop $\beta_{x,y} := \rho_{x,y}\circ f_{x,y}\circ\rho_{x,y}^{-1}$ to each plaquette $\Box_{x,y}$. x,y indicates the position of the plaquette, as follows: First, choose a path $\rho_{x,y}$

from the base point m to the bottom left-hand corner (x,y) and then define $\beta_{x,y}:=\rho_{x,y}\circ f_{x,y}\circ\rho_{x,y}^{-1}$ where $f_{x,y}$ is a path traversing $\Box_{x,y}$ counterclockwise. For our example, we choose $\rho_{x,y}$ to consist of a horizontal and a subsequent vertical path as in Fig. 1.

Obviously, the set $\boldsymbol{\beta}$ of all these loops $\beta_{x,y}$ is not strongly independent (for the exact definition see Sec. III B) because, e.g., $\beta_{1,1}$ does not have a segment which is intersected by any other $\beta_{x,y}$ at most in a finite number of points. Of course, one can prove that $\boldsymbol{\beta}$ is weakly independent, but this is not sufficient to allow the application of the integration calculus. Therefore we need a third type of independence between these two ones; this will be the moderate independence.

B. Moderate independence: Definition and position among the independencies

In the following, $\boldsymbol{\beta}$ denotes any finite subset $\{\beta_i\}$ of $\mathcal{L}_m$ (or $\mathcal{HG}$) and $\mathcal{HG}(\boldsymbol{\beta})$ the subgroup of $\mathcal{HG}$ generated by $\boldsymbol{\beta}$. (To avoid technical complications we set $\mathcal{HG}(\emptyset)=\{[1]\}$.) First, we recall the definition of the strong independence.[2]

Definition 3.1: Strong independence in $\mathcal{L}_m$. $\boldsymbol{\beta}\subseteq\mathcal{L}_m$ is *strongly independent* iff any $\beta_i\in\boldsymbol{\beta}$ contains an open segment e_i, the so-called *free segment*, traced exactly once by β_i and intersected by any β_j, $j\neq i$, in at most a finite number of points. (The intersection condition can be replaced by "$e_i\cap\beta_j=\emptyset \quad \forall_j\neq i$." However, this yields to an equivalent definition.)

Our definition of the moderate independence differs very little from the previous one. We only replace $j\neq i$ by $j<i$.

Definition 3.2: Moderate Independence in $\mathcal{L}_m$. $\boldsymbol{\beta}\subseteq\mathcal{L}_m$ is *moderately independent* iff any $\beta_i\in\boldsymbol{\beta}$ contains an open segment e_i, the so-called *free segment*, traced exactly once by β_i and intersected by any β_j, $j<i$, in at most a finite number of points. (The remark in Definition 3.1 holds analogously in the case of moderate independence: "$e_i\cap\beta_j=\emptyset \quad \forall_j<i$".)

We have simply replaced the rigid condition of a simultaneous freeness of segments by the flexible condition of an iterative freeness. We will see that this keeps the integration calculus valid and makes the set of all plaquette loops (cf. Fig. 1) independent.

We mention that the simple specification of the elements of a moderately independent set $\boldsymbol{\beta}$ is not sufficient. If we say "$\boldsymbol{\beta}$ is moderately independent" then there is an order of the elements $\beta_i\in\boldsymbol{\beta}$, such that the above criterion is valid. Analogously, the specification "$\{\beta_1,\beta_2\}$ or $\{\beta_2,\beta_1\}$, respectively, are moderately independent" should be clear.

Finally, we recall the definition of weak independence.[2]

Definition 3.3: Weak Independence in $\mathcal{L}_m$. $\boldsymbol{\beta}\subseteq\mathcal{L}_m$ is *weakly independent* iff for any $(g_1,\ldots,g_n)\in\mathbf{G}^n$, $n=\#\boldsymbol{\beta}$, there is an $A\in\mathcal{A}$, such that $h_{\beta_i}(A)=g_i$ for all $i=1,\ldots,n$.

Obviously, this kind of independence can be extended from $\mathcal{L}_m$ to $\mathcal{HG}$.

Instead of the previous two definitions being graph-theoretical we have here an algebraic condition. Weak independence of $\boldsymbol{\beta}$ means no relations between the holonomies h_{β_i} and so it ensures the freeness of the corresponding subgroup $\mathcal{HG}(\boldsymbol{\beta})\subseteq\mathcal{HG}$, see Sec. III C.

The position of the moderate independence clarifies the next

Proposition 3.1: $\boldsymbol{\beta}$ strongly independent $\Rightarrow\boldsymbol{\beta}$ moderately independent $\Rightarrow\boldsymbol{\beta}$ weakly independent.

Proof: (1) The first implication is obvious. (2) The proof of the second implication is technical and can be found in the Appendix. **qed**

C. Algebraic consequences of the weak independence

Proposition 3.2: Let $\boldsymbol{\beta}\subseteq\mathcal{HG}$ be weakly independent. Then the following holds:

(1) $\mathcal{HG}(\boldsymbol{\beta})$ is freely generated by $\boldsymbol{\beta}$. [In the case $\mathbf{G}=U(1)$ we understand by "free" anytime "Abelian free."]

(2) Let there be given a $\boldsymbol{\gamma}\subseteq\mathcal{HG}$, such that $\mathcal{HG}(\beta)=\mathcal{HG}(\boldsymbol{\gamma})$. Then we have: $\boldsymbol{\gamma}$ is weakly independent$\Leftrightarrow\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ have the same cardinality.

Proof: (1) See Ref. 2.

(2) $\Leftarrow$

(a) For $\mathcal{HG}(\boldsymbol{\gamma})=\mathcal{HG}(\boldsymbol{\beta})$ there are expressions

$$\gamma_i \sim \prod_{k_i=1}^{K_i} \beta_{j(i,k_i)}^{\epsilon(i,k_i)} \quad \text{and} \quad \beta_j \sim \prod_{l_j=1}^{L_j} \gamma_{i(j,l_j)}^{\eta(j,l_j)}$$

for any $i,j \in [1,n]$, $n := \#\boldsymbol{\beta} = \#\boldsymbol{\gamma}$, and thus

$$\gamma_i \sim \prod_{k_i=1}^{K_i} \left(\prod_{l_{j(i,k_i)}=1}^{L_{j(i,k_i)}} \gamma_{i(j(i,k_i)l_{j(i,k_i)})}^{\eta(j(i,k_i)l_{j(i,k_i)})} \right)^{\epsilon(i,k_i)} \qquad \forall i \in [1,n].$$

(b) Due to the first point $\boldsymbol{\beta}$ is a free system of generators for $\mathcal{HG}(\boldsymbol{\beta})$. Since $\boldsymbol{\gamma}$ also generates $\mathcal{HG}(\boldsymbol{\beta})=\mathcal{HG}(\boldsymbol{\gamma})$ and $\#\boldsymbol{\gamma}=\#\boldsymbol{\beta}$, $\boldsymbol{\gamma}$ is a free system of generators for $\mathcal{HG}(\boldsymbol{\beta})=\mathcal{HG}(\boldsymbol{\gamma})$ (Ref. 9).

(c) Let there be given $(g_1,\ldots,g_n) \in \mathbf{G}^n$ and let $\mathbf{H}$ be the group generated by $\{g_1,\ldots,g_n\}$. Since $\mathcal{HG}(\boldsymbol{\gamma})$ has the free rank n there is (Ref. 9) an epimorphism $\pi:\mathcal{HG}(\boldsymbol{\gamma}) \rightarrow \mathbf{H}$ with $\pi(\gamma_i)=g_i$.

(d) Since $\boldsymbol{\beta}$ is weakly independent, there exists an $A \in \mathcal{A}$ with $h_{\beta_j}(A)=\prod_{l_j=1}^{L_j} g_{i(j,l_j)}^{\eta(j,l_j)} \forall_j$, i.e., we have for all $i \in [1,n]$

$$\begin{aligned} h_{\gamma_i}(A) = h_{\prod_{k_i=1}^{K_i} \beta_{j(i,k_i)}^{\epsilon(i,k_i)}}(A) &= \prod_{k_i=1}^{K_i} \left(\prod_{l_j(i,k_i)=1}^{L_{j(i,k_i)}} g_{i(j(i,k_i),l_{j(i,k_i)})}^{\eta(j,(i,k_i),l_{j(i,k_i)})} \right)^{\epsilon(i,k_i)} \\ &= \pi\left(\prod_{k_i=1}^{K_i} \left(\prod_{l_{j(i,k_i)}=1}^{L_{j(i,k_i)}} \gamma_{i(j(i,k_i),l_{j(i,k_i)})}^{\eta(j(i,k_i),l_{j(i,k_i)})} \right)^{\epsilon(i,k_i)} \right) = \pi(\gamma_i) = g_i . \end{aligned}$$

Thus, $\boldsymbol{\gamma}$ is weakly independent.

$\Rightarrow$

Let $\boldsymbol{\gamma}$ be weakly independent, i.e., $\mathcal{HG}(\boldsymbol{\gamma})=\mathcal{HG}(\boldsymbol{\beta})$ is free. Consequently, $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ have the same cardinality.[9] **qed**

D. Graphs and loops

We recall some fundamental facts about graphs (see, e.g., Ref. 10).

A graph (X,X_0) consists of a Hausdorff space X and a discrete subspace X_0, the space of the so-called vertices. $X \backslash X_0$ is a disjoint union of edges, i.e., open subsets e_i isomorphic to the interval (0, 1). e_i can connect one or two vertices. In the first case e_i is called sling. Two vertices are connected by a multiple edge iff there are at least two different edges connecting these vertices. Iff a graph has neither slings nor multiple edges, it is called ordinary. Furthermore, (X,X_0) is finite iff both the set of edges and the set of vertices are finite. A graph (X',X_0') is called subgraph (or refinement) of a graph (X,X_0) iff $X' \subseteq X$ and $X_0' \subseteq X_0$. Obviously, any (finite) graph is subgraph of an ordinary (finite) graph. In the following we will briefly denote a graph by X instead of (X,X_0). Additionally, $X \leqslant X'$ means that X is a subgraph of X'.

In a natural way one can choose an orientation to any edge. The initial (terminal) vertex of an edge e is denoted by $v_e^-(v_e^+)$. A path f in a graph is a finite sequence of (oriented) edges $(e_1,\ldots,e_n)$, $n \leqslant 0$, such that the terminal vertex of e_i coincides with the initial vertex of e_{i+1} $(1 \leqslant i < n)$ with respect to the chosen orientation. Iff $n=0$, f is called trivial. Iff the initial vertex v_f^- and the terminal vertex v_f^+ of f are equal, f is called closed path or loop with base point $v_f = v_f^\pm$. f is called reduced iff no edge is retraced immediately and is called genuine iff no vertex is traced twice (exception: initial and terminal vertex can be equal). Finally, a tree T is a graph without any nontrivial genuine closed path.

Obviously, any graph contains trees. If we partially order the set of all trees in a graph using the inclusion, i.e., subgraph relation, we get

Lemma 3.3: Any tree in a graph X is contained in a maximal tree in X. If X is connected, then a tree T in X is maximal if and only if T contained all vertices of X.
Using this lemma one can construct explicitly the fundamental group of a connected graph. First choose a vertex v_0 and a maximal tree. Let $\{e_\lambda | \lambda \in \Lambda\}$ be the set of all edges of X not contained in T and choose an orientation for each e_λ. Now denote by t_λ^- and t_λ^+ the (unique) reduced path along T from v_0 to the initial vertex of e_λ and, respectively, from the terminal vertex of e_λ to v_0. Finally, define α_λ to be the product of t_λ^-, e_λ and t_λ^+. We have

Proposition 3.4: The fundamental group $\pi(X,v_0)$ is the free group generated by $\{\alpha_\lambda | \lambda \in \Lambda\}$, where α_λ denotes here not the loop itself, but its homotopy class.
The Euler–Poincaré characteristic $\chi(X)$ of a finite graph is per definition the difference of the number of vertices and the number of edges.

Proposition 3.5: Let X be finite and connected. Then $\pi(X,v_0)$ is a free group with $1-\chi(X)$ generators and X is a tree iff $\chi(X)=1$.
Let there be given now a finite set of loops $\boldsymbol{\beta}=\{\beta_i\}\subseteq\mathcal{L}_m$ in a manifold M. Note that $\mathcal{L}_m$ contains only piecewise analytic loops. The image of $\boldsymbol{\beta}$ in M defines naturally a finite connected graph $\Gamma_{\boldsymbol{\beta}}$ via the following (see also Ref. 2).

Construction 3.4: (1) Mark all end points of overlapping intervals of two loops and all intersection points outside those overlapping intervals. These points become the vertices of $\Gamma_{\boldsymbol{\beta}}$. Due to the piecewise analyticity the number of vertices is finite.

(2) Divide any β_i into paths between ''neighboring'' vertices and call these paths edges of $\Gamma_{\boldsymbol{\beta}}$. Again due to the piecewise analyticity the set of edges is finite.

(3) Since any β_i is a loop with base point m, $\Gamma_{\boldsymbol{\beta}}$ is connected.

E. Relations between the fundamental group and the hoop group of a graph

In this section Γ is a finite connected graph and m an arbitrary, but fixed vertex of Γ. Furthermore, we denote by $\mathcal{HG}(\Gamma)$ the subgroup of $\mathcal{HG}$ generated by all loops in Γ.

It was an important observation of Ashtekar and Lewandowski[2] that there is a close relation between the representation of a loop as a hoop and as an equivalence class with respect to the homotopy in a graph. In detail, they got

Lemma 3.6: Two homotopically equivalent loops are holonomically equivalent, i.e., there is an epimorphism $\phi:\pi(\Gamma,m)\rightarrow\mathcal{HG}(\Gamma)$. ϕ is an isomorphism if $\mathbf{G}=\mathrm{SU}(N)$. For $\mathbf{G}=\mathrm{U}(1)$ we have $\ker\phi=[\pi(\Gamma,m),\pi(\Gamma,m)]$.
Consequently, in the case $\mathbf{G}=\mathrm{SU}(N)$ two loops are holonomically equivalent if and only if they can be obtained from each other by reparametrizations or (if necessary successively) canceling retracings. Obviously, we have

Lemma 3.7: Let T be a maximal tree and $\{\alpha_\lambda\}$ the set of the corresponding generators of $\pi(\Gamma,m)$ as in Proposition 3.4. Then $\{\alpha_\lambda\}$ is strongly independent and complete in Γ, i.e., we have $\mathcal{HG}(\{\alpha_\lambda\})=\mathcal{HG}(\Gamma)$.
The free segments are the edges e_λ not contained in T. Additionally, one can express any finite set of hoops by a finite set of strongly independent hoops.[2]

Lemma 3.8: For any finite set $[\boldsymbol{\beta}]$ of hoops there is a set $\boldsymbol{\alpha}\subseteq\mathcal{L}_m$, such that

(1) $\mathcal{HG}(\boldsymbol{\beta})\subseteq\mathcal{HG}(\boldsymbol{\alpha})$,
(2) $\boldsymbol{\alpha}$ is strongly independent, and
(3) $\#\boldsymbol{\alpha}=\mathrm{rank}\,\pi(\Gamma_{\boldsymbol{\beta}},m)$.

For this choose the natural graph $\Gamma_{\boldsymbol{\beta}}$ of $\boldsymbol{\beta}$. Choose now some generating set $\boldsymbol{\alpha}$ of the fundamental group $\pi(\Gamma_{\boldsymbol{\beta}},m)$. Obviously, $\boldsymbol{\alpha}$ fulfills the required conditions.

Now we want to investigate the independence of loops.

Lemma 3.9: Let n be the rank of $\pi(\Gamma,m)$. Then any $\boldsymbol{\beta}\subseteq\mathcal{L}_m$ with $\#\boldsymbol{\beta}=n$ and $\mathcal{HG}(\boldsymbol{\beta})=\mathcal{HG}(\Gamma)$ is weakly independent.

Proof: Choose any maximal tree T in Γ and a corresponding system $\{\alpha_\lambda\}$ of generators of $\pi(\Gamma,m)$. $\{\alpha_\lambda\}$ has n elements and is a free generating system. Due to Lemma 3.7 $\{\alpha_\lambda\}$ is strongly independent and thus weakly independent. Proposition 3.2 finishes the proof. **qed**

Generally, one cannot conclude that $\boldsymbol{\beta}$ is even moderately independent. To see this let $\pi(\Gamma,m)$ be generated by two loops α_1,α_2 as in Proposition 3.4. Set $\beta_1:=\alpha_1\alpha_2\alpha_1^{-1}$ and $\beta_2:=\alpha_1\alpha_2$.

(1) We have $\mathcal{HG}(\boldsymbol{\beta})=\mathcal{HG}(\Gamma)=\mathcal{HG}(\{\alpha_1,\alpha_2\})$, because $\alpha_1=\beta_1^{-1}\beta_2$ and $\alpha_2=\beta_2^{-1}\beta_1\beta_2$.

(2) Suppose $\{\beta_1,\beta_2\}$ are moderately independent. Any segment of β_2 is already traced by β_1. This is a contradiction to the assumption β_2 has a free segment.

The case ''$\{\beta_2,\beta_1\}$ are moderately independent'' yields an analogous contradiction. Thus $\boldsymbol{\beta}$ is not moderately independent.

We finish this section with a criterion for the completeness of loops in a given graph.

Proposition 3.10: Let Γ be a finite connected graph and $\boldsymbol{\beta}$ a set of moderately independent loops in Γ. Then is $\boldsymbol{\beta}$ complete with respect to Γ if and only if the cardinality of $\boldsymbol{\beta}$ equals the rank of $\pi(\Gamma,m)$.

Proof: The $\Rightarrow$ direction is simple. Due to Lemma 3.8 there is a set $\boldsymbol{\alpha}$ with $\mathcal{HG}(\alpha)=\mathcal{HG}(\Gamma)=\mathcal{HG}(\boldsymbol{\beta})$, whose cardinality is just equal to the rank of $\pi(\Gamma,m)$. Proposition 3.2 yields that $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ have the same cardinality.

The $\Leftarrow$ direction is a little bit technical.

The free segments of the β_i are as usual denoted by e_i and the cardinality of $\boldsymbol{\beta}$ by n. Suppose first that no β_i has a retracing interval.

(1) W.l.o.g. the free segments e_i of β_i are edges of Γ. Otherwise, if necessary, restrict any e_i, such that it is still contained in only one edge k_i. Since β_i has no retracing intervals, the whole k_i is a free segment of β_i. Thus one can set $e_i:=k_i$.

(2) The graph $T:=\Gamma\setminus\cup_{i=1}^n\{e_i\}$ created by removing all free segments is again a connected graph.

Set $\Gamma_j:=\Gamma\setminus\cup_{i=j}^n\{e_i\}$. Then $\Gamma_{n+1}=\Gamma$, $\Gamma_1=T$. Due to the moderate independence of the β_i we have $\beta_i\cap e_{\tau'}=\emptyset\ \ \forall i'>i$, i.e., β_i is a loop in Γ_{i+1}. Suppose T is not connected. Then there would exist a $j\in[1,n]$, such that all Γ_i with $i>j$ are connected, but Γ_j is not connected. Since β_j is a loop in Γ_{j+1} and β_j passes e_j,β_j has to pass vertices of both connected components of $\Gamma_j=\Gamma_{j+1}\setminus\{e_j\}$. Thus e_j must be passed at least once in each direction by β_j, i.e., we have a contradiction to the assumption that e_j is a free segment. Thus, Γ_i is connected for all $i\in[1,n+1]$.

(3) T is a maximal tree in Γ.

Due to Proposition 3.5 we have $n=\operatorname{rank}\pi(\Gamma,m)=1-\chi(\Gamma)=1-\epsilon_\Gamma+\kappa_\Gamma$, where ϵ_Γ and κ_Γ are the numbers of vertices and edges of Γ, respectively. Since $T=\Gamma\setminus\cup_{i=1}^n\{e_i\}$ we have $\kappa_T=\kappa_\Gamma-n$ and obviously $\epsilon_T=\epsilon_\Gamma$. For T connected, we have $\chi(T)=\epsilon_T-\kappa_T=\epsilon_\Gamma-\kappa_\Gamma+n=\chi(\Gamma)+n=1$. Thus T is a tree in Γ due to Proposition 3.5. T is even maximal because T contains all vertices of Γ.

(4) Let $\boldsymbol{\alpha}:=\{\alpha_i\}$ be a free system of generators of $\pi(\Gamma,m)$ due to Proposition 3.4 for the just constructed maximal tree T and the edges $\{e_i\}$. Thus, $\boldsymbol{\alpha}$ fulfills $\mathcal{HG}(\boldsymbol{\alpha})=\mathcal{HG}(\Gamma)$. W.l.o.g. α_i traces the edge e_i in the same direction as β_i. We show that $\boldsymbol{\beta}$ is complete in Γ.

(a) β_1 is a loop in $T\cup\{e_1\}=\Gamma_{1+1}$, where e_1 is traced once and in the same direction as α_1 is. Thus $\beta_1=t_+e_1t_-\sim\alpha_1$ with certain paths $t_\pm$ in T, i.e., $\mathcal{HG}(\{\beta_1\})=\mathcal{HG}(\{\alpha_1\})$, i.e., $\{\beta_1\}$ is complete in Γ_{1+1}.

(b) Let $\mathcal{HG}(\{\beta_1,\ldots,\beta_i\})=\mathcal{HG}(\Gamma_{i+1})=\mathcal{HG}(\{\alpha_1,\ldots,\alpha_i\})$ hold for all $i<j$. We have now $\beta_j=k_{j,+}e_jk_{j,-1}$, where $k_{j,\pm}$ are some paths in $\Gamma_{j+1}\setminus\{e_j\}=\Gamma_j$. Furthermore, we have $\alpha_j=t_{j,+}e_jt_{j,-}$ with $t_{j,\pm}\subseteq T\subseteq\Gamma_j$. Thus $\beta_j\sim k_{j,+}t_{j,+}^{-1}\alpha_jt_{j,-}^{-1}k_{j,-}$. Since $k_{j,+}t_{j,+}^{-1}$ and $t_{j,-}^{-1}k_{j,-}$ are loops in Γ_j, we have $[k_{j,+}t_{j,+}^{-1}],[t_{j,-}^{-1}k_{j,-}]\in\mathcal{HG}(\Gamma_j)=\mathcal{HG}(\{\alpha_1,\ldots,\alpha_{j-1}\})=\mathcal{HG}(\{\beta_1,\ldots,\beta_{j-1}\})$. Due to $\alpha_j\sim t_{j,+}k_{j,+}^{-1}\beta_jk_{j,-}^{-1}t_{j,-}\in\mathcal{HG}(\{\beta_1,\ldots,\beta_j\})$ we have $\mathcal{HG}(\{\alpha_1,\ldots,\alpha_{j-1}\}\cup\{\alpha_j\})\subseteq\mathcal{HG}(\{\beta_1,\ldots,\beta_j\})$. Since β_j is a loop in Γ_{j+1}, we get immediately the $\supseteq$ relation, i.e., $\mathcal{HG}(\Gamma_{j+1})=\mathcal{HG}(\{\alpha_1,\ldots,\alpha_j\})=\mathcal{HG}(\{\beta_1,\ldots,\beta_j\})$. Thus $\{\beta_1,\ldots,\beta_j\}$ is complete in Γ_{j+1}.

The induction yields also $\mathcal{HG}(\boldsymbol{\beta})=\mathcal{HG}(\boldsymbol{\alpha})=\mathcal{HG}(\Gamma_{n+1})$, i.e., $\boldsymbol{\beta}$ is complete in $\Gamma_{n+1}=\Gamma$. We allow now the β_i to have retracing intervals. Denote by β_i' the loop that remains after canceling all these intervals in β_i. Obviously, β_i' lies in the same hoop class as β_i, i.e., $\mathcal{HG}(\boldsymbol{\beta})=\mathcal{HG}(\boldsymbol{\beta}')$. Thus, since we have already proven the proposition for the retracing-free $\boldsymbol{\beta}'$, we get immediately the claim for arbitrary $\boldsymbol{\beta}$. **qed**

IV. FLAG WORLDS

This section provides some facts about the hoop group of a graph (''lattice'') Γ in the two-dimensional manifold $M=\mathbb{R}^2$. For this we can specialize the facts of Sec. III E to the case of planar graphs (see, e.g., Ref. 11). These have a crucial advantage: one can define domains enclosed by the graph edges. The set of all these domains induces a basis of the corresponding hoop group $\mathcal{HG}(\Gamma)$. Finally, we will investigate the behavior of that set under refinement of the graph Γ generalizing the results of TA^+.

A. Planar graphs

This section collects some basic and simple facts about planar graphs and is intended to clarify the notations. We call a graph *X planar* iff there exists a homomorphism $\iota:X\rightarrow\Gamma\subseteq\mathbb{R}^2$. We identify X and Γ in the sequel. Furthermore, in the following any graph is supposed to be planar, finite, and connected.

Any graph is the complement of a disjoint union of domains. Exactly one of them if unbounded—the so-called exterior domain G_{ext}. The set of the remaining domains, the so-called interior domains, is denoted by $L_{\mathrm{int}}(\Gamma)$ and we set $L(\Gamma):=L_{\mathrm{int}}(\Gamma)\cup\{G_{\mathrm{ext}}\}$. We say that a domain G is contained in Γ iff its boundary ∂G is in Γ and $G\cap G_{\mathrm{ext}}=\emptyset$.

One easily proves Euler's polyhedron formula $\epsilon-\kappa+\lambda=2$, where ϵ, κ, and λ are the numbers of vertices, edges, and domains, respectively, of the graph. Since $\lambda-1=1-(\epsilon-\kappa)=1-\chi(\Gamma)$, we have using Proposition 3.5

Lemma 4.1: The number of interior domains of a graph Γ is equal to the rank of $\pi(\Gamma,m)$. We are now interested in the behavior of $L(\Gamma')$ under refinement of Γ'. Clearly, if we refine a graph Γ' to a graph Γ, then any domain of Γ' is refined into a certain set of domains in Γ (see, e.g., Fig. 2). We have in detail the simple

Proposition 4.2: Let $\Gamma'\leq\Gamma$. Then the following holds:

(1) For any $G\in L(\Gamma),G'\in L(\Gamma')$ we have $G\cap G'\neq\emptyset\Rightarrow G\subseteq G'$. Especially, two interior domains of one and the same graph are disjoint or equal.
(2) For any $G\in L(\Gamma)$ there exists exactly one $G'\in L(\Gamma')$ with $G\cap G'\neq\emptyset$.
(3) For any $G'\in L(\Gamma')$ there exists exactly one $L_{G'}\subseteq L(\Gamma)$, such that $G\cap G'\neq\emptyset\Leftrightarrow G\in L_{G'}$ and $\bigcup_{G\in L_{G'}}G\supseteq G'$.
(4) Now let G' be any domain in Γ, not necessarily an interior domain. There is exactly one set $L_{G'}(\Gamma)\subseteq L_{\mathrm{int}}(\Gamma)$, such that for all interior domains G holds: $G\in L_{G'}(\Gamma)\Leftrightarrow G\cap G'\neq\emptyset$ and $\bigcup_{G\in L_{G'}}G\supseteq G'$.

We call $L(\Gamma)$ a refinement of $L(\Gamma')$ (and analogously for L_{int}) iff Γ is a refinement if Γ'.

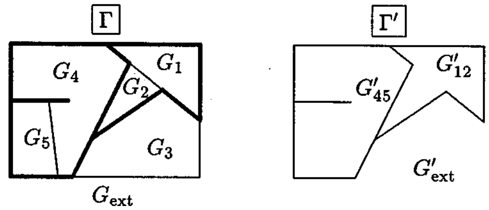

FIG. 2. Example for the decomposition of domains.

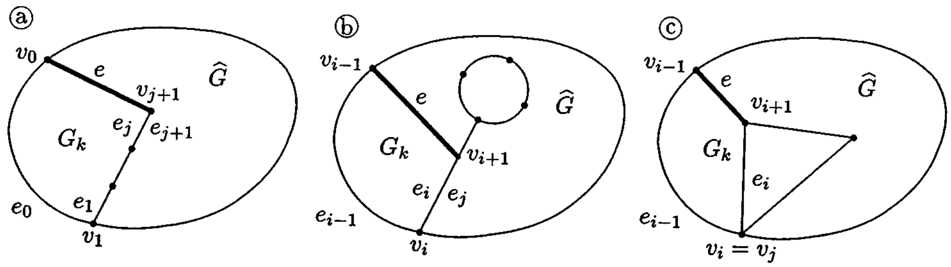

FIG. 3. Canceling (a) retracings, (b) repetition of edges, (c) repetition of vertices.

Definition 4.1: A domain $G \subseteq \mathbb{R}^2$ is called *simple* iff it is the interior of a Jordan curve. A graph Γ is called *simple* iff each of its interior domains is simple.

Finally we need

Proposition 4.3: Any ordinary graph Γ is subgraph of a simple, ordinary graph Γ' whose exterior domain coincides with that of Γ.

The proof is quite easy. First one eliminates the retracing, then the repetitions of edges, and finally the repetitions of vertices by inserting appropriate edges as demonstrated in Fig. 3.

B. Boundary loops and flags

We start with a simple

Lemma 4.4: For any simple domain $G \subseteq \Gamma$ and any $\tilde{m} \in \Gamma_0 \cap \partial G$ there is exactly one genuine loop $\alpha_{G,\tilde{m}}$ in Γ with base point $\tilde{m}$, such that (we recall that we do not distinguish between loops and hoops in the sequel—the equal sign means equality of loops and the symbol $\sim$ means equality of hoops)

(1) $\alpha_{G,\tilde{m}} = \partial G$ and
(2) $\alpha_{G,\tilde{m}}$ traverses the domain G counterclockwise.

By contrast, any such loop determines exactly one simple $G \subseteq \Gamma$. We call $\alpha_{G,\tilde{m}}$ the *boundary loop* of G with base point $\tilde{m}$.

Analogously, for any $G \subseteq \Gamma$ and any $\tilde{m} \in \Gamma_0 \cap \partial G$ there exists a loop $\alpha_{G,\tilde{m}}$ in Γ with base point $\tilde{m}$ and the properties above.

Now we are interested in loops with base point m, that traverse only one domain G in Γ. This is provided by

Definition 4.2: Flag. Let G be a simple domain in a graph Γ. We call a loop $f_{G,m,\tilde{m}}$ *flag* with base point m, flag point $\tilde{m}$, and domain G iff

(1) $f = \rho_{m\tilde{m}} \alpha_{G,\tilde{m}} \rho_{m\tilde{m}}^{-1}$,
(2) $\alpha_{G,\tilde{m}}$ is a boundary loop of G with base point $\tilde{m}$ and
(3) $\rho_{m\tilde{m}}$ is a path from m to $\tilde{m}$ in Γ;
(4) there is a $v \in \partial G$, such that
 (a) $\rho_{m\tilde{m}} = \rho_{mv} \rho_{v\tilde{m}}$,
 (b) $\rho_{mv} \cap \partial G = \{v\}$,
 (c) ρ_{mv} traces neither an edge nor a vertex twice and
 (d) $\rho_{v\tilde{m}} \subseteq \partial G$ holds.

Then $\rho_{m\tilde{m}}$ is called *flagpole*. We call $f_{G,m,\tilde{m}}$ *minimal* iff $v = \tilde{m}$.

Since Γ is connected, we get from Lemma 4.4

Lemma 4.5: For any triple $\{G, m, \tilde{m}\}$ with the above properties there exists a corresponding flag $f_{G,m,\tilde{m}}$ (Fig. 4).

Remark: (1) To any simple domain G and any $m\in\Gamma_0$ there exists a minimal flag. For this choose a maximal tree T and an $m'\in\partial G\cap\Gamma_0$. Furthermore, choose the shortest path ρ from m to m' along T. Let $\tilde{m}$ be the nearest to m (with respect to the up to there traced edges of ρ) point in $\partial G\cap\rho$ and $\rho_{m\tilde{m}}$ the corresponding initial path of ρ from m to $\tilde{m}$. Obviously, $f_{G,m,\tilde{m}} :=\rho_{m,\tilde{m}}\alpha_{G,\tilde{m}}\rho_{m\tilde{m}}^{-1}$ with the boundary loop $\alpha_{G,\tilde{m}}$ is a minimal flag for G.

(2) All flags beginning with the same ρ_{mv} are equal modulo holonomy equivalence, especially any flag is holonomically equivalent to a minimal flag.

(3) For $\mathbf{G}=\mathrm{U}(1)$ all flags to one and the same domain are holonomically equivalent.

Let $f_i=\rho_{m\tilde{m}_i}\alpha_{G,\tilde{m}_i}\rho_{m\tilde{m}_i}^{-1}$, $i=1,2$. We have

$$\begin{aligned} f_1=\rho_{m\tilde{m}_i}\alpha_{G,\tilde{m}_i}\rho_{m\tilde{m}_1}^{-1}&\sim\rho_{m\tilde{m}_1}\rho_{\tilde{m}_1\tilde{m}_2}\alpha_{G,\tilde{m}_2}\rho_{\tilde{m}_1\tilde{m}_2}^{-1}\rho_{m\tilde{m}_1}^{-1}\\ &\sim\rho_{m\tilde{m}_1}\rho_{\tilde{m}_1\tilde{m}_2}\rho_{m\tilde{m}_2}^{-1}\rho_{m\tilde{m}_2}\alpha_{G,\tilde{m}_2}\rho_{m\tilde{m}_2}^{-1}\rho_{m\tilde{m}_2}\rho_{\tilde{m}_1\tilde{m}_2}^{-1}\rho_{m\tilde{m}_1}^{-1}\\ &\sim\rho_{m\tilde{m}_1}\rho_{\tilde{m}_1\tilde{m}_2}\rho_{m\tilde{m}_2}^{-1}\rho_{m\tilde{m}_2}\rho_{\tilde{m}_1\tilde{m}_2}^{-1}\rho_{m\tilde{m}_1}^{-1}\rho_{m\tilde{m}_2}\alpha_{G,\tilde{m}_2}\rho_{m\tilde{m}_2}^{-1}\sim f_2. \end{aligned}$$

$\rho_{\tilde{m}_1\tilde{m}_2}$ is any path from $\tilde{m}_1$ to $\tilde{m}_2$ along ∂G. In the last but one step we used the commutativity of $\mathcal{HG}\supseteq\mathcal{HG}(\Gamma)$ induced by the commutativity of U(1).

(4) Two flags to disjoint domains are nonoverlapping.

C. Flag worlds: Definition and existence

In this section and Sec. IV D we only consider simple graphs, i.e., graphs with only simple interior domains, to avoid technical complications.

We are looking for a set $\boldsymbol{\beta}$ of hoops, such that any hoop in Γ can be expressed by a product of elements of $\boldsymbol{\beta}$, i.e., $\mathcal{HG}(\beta)=\mathcal{HG}(\Gamma)$ holds. Furthermore, we are interested in integrating cylindrical functions over $\mathcal{HG}(\boldsymbol{\beta})$. For this we need the moderate independence of $\boldsymbol{\beta}$, that means at least the weak independence. Due to Proposition 3.2 that is guaranteed only if the number of elements of $\boldsymbol{\beta}$ equals the number of generators of $\mathcal{HG}(\Gamma)$, i.e., equals the number of generators of the fundamental group $\pi(\Gamma,m)$. With this in mind one could choose $\boldsymbol{\beta}$ to be a system of generators as in Proposition 3.4. But, because of our regularization we need loops enclosing an area being as tiny as possible, i.e., enclosing only one interior domain. For this the above defined flags are well suited. We already know that the number of interior domains of Γ equals the rank of the fundamental group (cf. Euler's polyhedron formula in Sec. IV A). Thus the following definition is obvious.

Definition 4.3: Flag World. A set $\mathcal{F}$ of flags is called *flag world* to the simple graph Γ (with base point m) iff $\mathcal{F}=\{f_G|G\in L_{\mathrm{int}}(\Gamma)\}$, where f_G is any flag to the domain G and to the base point m. $\mathcal{F}$ is called *complete* iff $\mathcal{HG}(\mathcal{F})=\mathcal{HG}(\Gamma)$.

Using Proposition 3.2 we have immediately

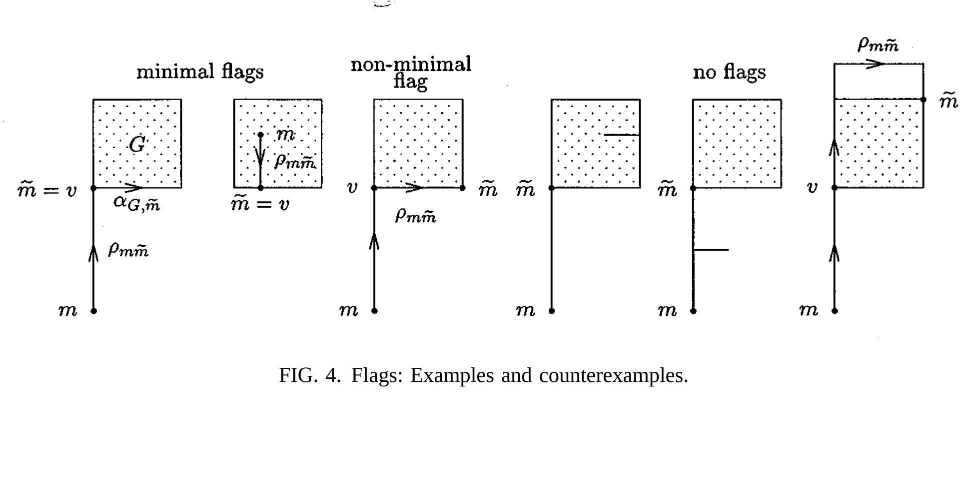

FIG. 4. Flags: Examples and counterexamples.

Corollary 4.6: The flags of a complete flag world are weakly independent.

Now we are interested in moderately independent flag worlds because they are necessary for the integration calculus and because of

Proposition 4.7: Let $\mathcal{F}$ be a moderately independent flag world in a simple graph Γ. Then $\mathcal{F}$ is complete.

Proof: Γ is a finite, connected graph and $\mathcal{F}$ is a moderately independent set of loops in Γ, whose cardinality is equal to the rank of $\pi(\Gamma,m)$ due to Lemma 4.1. Proposition 3.10 finishes the proof. **qed**

We can construct naturally a flag world to any tree as follows.

Definition 4.4: Let T be a maximal tree in a simple graph Γ.

$\mathcal{F}$ is called T-flag world for Γ iff the following holds for all flags $f\in\mathcal{F}$:

(1) f is a minimal flag.
(2) The flagpole of f is a path in T.

Proposition 4.8: Let T be a maximal tree in a simple graph Γ.

(1) There is a T-flag world for Γ.
(2) Any T-flag world for Γ is moderately independent.

From this we get the crucial

Corollary 4.9: For any simple graph Γ there exists a moderately independent, i.e., also complete flag world.

Corollary 4.10: Any loop in Γ is holonomically equivalent to a product of mutually nonoverlapping loops.

Proof (Proposition 4.8):

(i) First, let Γ be a tree, i.e., $\Gamma=T$. Then there is no interior domain and therefore no flag, too. We have $\mathcal{F}=\emptyset$ and $\mathcal{HG}(\mathcal{F})=\{1\}=\mathcal{HG}(\Gamma)$.

(ii) Now, Γ is not a tree. Let T be a maximal tree in Γ and $E:=\{e_\lambda\}$ the corresponding set of edges of Γ not contained in T. Now we can construct Γ from T inserting successively edges e_λ. The intermediate graphs are denoted by Γ_λ. This allows us to use induction on the number of interior domains increased exactly by 1 in each step. We can insert these edges, such that any new edge e_λ lies on the boundary of the corresponding graph Γ_λ. (Suppose there is a tree T' with $\partial\Gamma\subseteq T'$. Then $\partial\Gamma$ is a tree itself and $\partial\Gamma$ has no interior domain. Consequently, Γ has no interior domain, i.e., Γ is a tree. Thus, there is no tree T' with $\partial\Gamma\subseteq T'$ and so for any tree T in Γ there is an edge $e_\lambda\subseteq\partial\Gamma$ that is not contained in T.) Thus the interior domains of the intermediate graphs are simple due to $L_{\mathrm{int}}(\Gamma_\lambda)\subseteq L_{\mathrm{int}}(\Gamma)$. Obviously, any Γ_λ is finite, planar, and connected.

(iii) Suppose the proposition holds for any graph with $k-1\geqslant 0$ interior domains. Now, Γ has k interior domains, T and E are chosen as above and $e\in E$ is an edge in $\partial\Gamma$. We set $\Gamma':=\Gamma\backslash\{e\}$ and $E':=E\backslash\{e\}$. By inserting e in Γ' we get a new (simple) interior domain G, i.e., $L_{\mathrm{int}}(\Gamma)=L_{\mathrm{int}}(\Gamma')\cup\{G\}$. Obviously, T is also a maximal tree in Γ' and E' is the set of all edges of Γ' not contained in T. Γ' has exactly $k-1$ interior domains and we have by induction:

(1) There exists a T-flag world for Γ'.
(2) Any T-flag world for Γ' is moderately independent.

(1) Existence of a T-flag world for Γ

We construct a flag for G. Since any vertex of Γ is contained in T, there is a path in T from m to a vertex of ∂G. We choose from among these paths a path ρ which is minimal with respect to the number of traced edges. The terminal vertex of ρ is denoted by $\tilde{m}$, $\tilde{m}\in\partial G$. Due to Lemma 4.4 we choose a boundary loop α of G with base point $\tilde{m}$. $f:=\rho\alpha\rho^{-1}$ is now a minimal flag for G and $\mathcal{F}:=\mathcal{F}'\cup\{f\}$ is a T-flag world for Γ.

(2) Moderate independence of any T-flag world for Γ

Γ', E', and G are still chosen as above. Set $\mathcal{F}':=\mathcal{F}\backslash\{f_G\}$, where $f_G\in\mathcal{F}$, $f_G=\rho\alpha\rho^{-1}$, is the flag

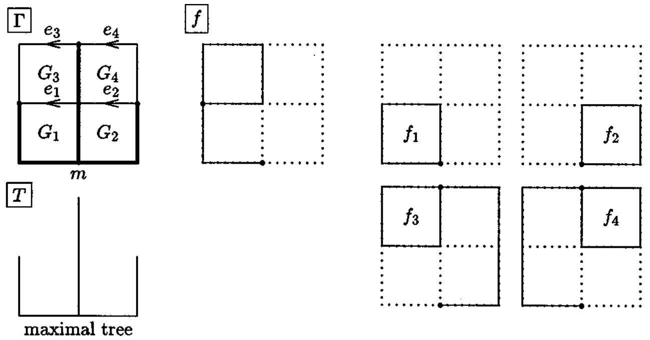

FIG. 5. Example of a noncomplete flag world.

for G with flagpole $\rho \subseteq T$. Obviously, $\mathcal{F}'$ is a T-flag world for Γ', and therefore moderately independent by induction.

Since f_G is minimal, e is traced exactly once by f_G, and because $\mathcal{F}'$ is a flag world in $\Gamma' = \Gamma \setminus e$, not any $f_i \in \mathcal{F}'$ traces e. Therefore e is now a free segment of f_G.

Finally, $\mathcal{F}'$ itself is moderately independent with the free segments e_i of the corresponding $f_i \in \mathcal{F}'$. Thus, $\mathcal{F} = \mathcal{F}' \cup \{f_G\}$ is moderately independent with the free segments $\{e_1,\ldots,e_{k-1},e\}$. **qed**

Remark: For $\mathbf{G} = \mathrm{U}(1)$ even any flag world $\mathcal{F}$ is complete.

To prove this choose any complete flag world $\mathcal{F}'$ for Γ. Since [for $\mathbf{G} = \mathrm{U}(1)$] all flags belonging to one and the same domain are equal up to holonomy equivalence, we have $\mathcal{HG}(\mathcal{F}) = \mathcal{HG}(\mathcal{F})' = \mathcal{HG}(\Gamma)$, i.e., $\mathcal{F}$ is complete.

In other words, for U(1) all flag worlds to one and the same graph Γ are equal modulo holonomy equivalence.

The completeness of a flag world is not at all trivial for the SU(N) because of

Proposition 4.11: Let $\mathbf{G} = \mathrm{SU}(N)$. Then there exists a simple graph Γ, such that a noncomplete (and so also not moderately independent) flag world exists to Γ.

Proof: It is sufficient to give an example. Due to $\mathbf{G} = \mathrm{SU}(N)$ holonomy equivalence equals homotopy equivalence and we will indentify hoops and the corresponding elements of the fundamental group $\pi(\Gamma,m)$. It is sufficient to construct a flag world $\mathcal{F}$, such that there is a loop $f \in \pi(\Gamma,m) = \mathcal{HG}(\Gamma)$ not contained in the subgroup $\mathcal{HG}(\mathcal{F})$ of the fundamental group generated by $\mathcal{F}$.

Let Γ be the graph in Fig. 5 with the flag world $\mathcal{F} := \{f_1,f_2,f_3,f_4\}$, the maximal tree T, and the corresponding free edges e_1,e_2,e_3,e_4. We constuct from T and e_i the free generators $\alpha_1,\ldots,\alpha_4$ of $\pi(\Gamma,m)$ as in Proposition 3.4. We will prove, that $\mathcal{F}$ is not complete showing that $f \notin \mathcal{HG}(\mathcal{F})$, where f is the loop defined in Fig. 5.

A simple calculation shows:

$$f \sim \alpha_1^{-1}\alpha_3,$$

$$f_1 \sim \alpha_1,$$

$$f_2 \sim \alpha_2,$$

$$f_3 \sim \alpha_4\alpha_3\alpha_1^{-1}\alpha_4^{-1},$$

$$f_4 \sim \alpha_3^{-1}\alpha_2^{-1}\alpha_4\alpha_3.$$

Suppose $f \in \mathcal{HG}(\mathcal{F})$, i.e., $f \sim \Pi_{j=1}^{J} f_{i_j}^{\eta_j} \sim \Pi_k \alpha_{\lambda_k}^{\epsilon_k}$ with $\eta_j \in \mathbb{Z}$ and $\epsilon_k \in \{-1,+1\}$. Choose this decomposition, such that the number J of used factors $f_{i_j}^{\eta_j}$ is minimal. Due to the freeness of $\mathcal{HG}(\Gamma) = \pi(\Gamma,m)$ there must exist a j' with $i_{j'} = 3$ and $\eta_{j'} \geq +1$, i.e.,

$$\alpha_1^{-1}\alpha_3 \sim f \sim \prod_{j=1}^{j'-1} f_{i_j}^{\eta_j} f_3^{\eta_{j'}} \prod_{j=j'+1}^{J} f_{i_j}^{\eta_j} \sim \prod_k \alpha_{\lambda_k}^{\epsilon_k} \alpha_4 \prod^{\eta_{j'}} (\alpha_3 \alpha_1^{-1}) \alpha_4^{-1} \prod_{k'} \alpha_{\lambda_{k'}}^{\epsilon_{k'}}.$$

In the last step f_j^{η} has been replaced by the corresponding reduced representation in the α_λ (see above), e.g., f_3^{η} by $\alpha_4(\alpha_3\alpha_1^{-1})^{\eta}\alpha_4^{-1}$ [i.e., not by $(\alpha_4\alpha_3\alpha_1^{-1}\alpha_4^{-1})^{\eta}$, since here (for $|\eta|>1$) the $\alpha_4\alpha_4^{-1}$ terms are not reduced].

The right-hand decomposition of f in α_λ is (with respect to the number of used factors) longer than the left-hand one. Again by the freeness of $\mathcal{HG}(\Gamma)$ there must exist in the right-hand decomposition of f in α_λ a k with $\alpha_{\lambda_k}^{\epsilon_k} = \alpha_{\lambda_{k+1}}^{-\epsilon_{k+1}}$. This case does not occur in the decompositions of the f_i in α_λ above, thus this must occur during the multiplication $f_{i_j}^{\eta_j} f_{i_{j+1}}^{\eta_{j+1}}$ of two flags. From the decompositions above we see that such a collision of α_λ is only possible, if $i_j = i_{j+1}$. This is a contradiction to the minimality of the decomposition of f into a product of flags $f_i^{\eta} \in \mathcal{F}$.
Thus, $f \notin \mathcal{HG}(\mathcal{F})$, and $\mathcal{F}$ is not complete. **qed**

Remark: (1) Up to now, we do not know, whether noncomplete flag worlds can be constructed for graphs with less than four interior domains.

(2) Simultaneously, we have constructed an example for the fact that from $\mathcal{HG}(\boldsymbol{\beta}) \subseteq \mathcal{HG}(\boldsymbol{\alpha})$ and the equality of the cardinalities of $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ not generally follows, that $\mathcal{HG}(\boldsymbol{\beta}) = \mathcal{HG}(\boldsymbol{\alpha})$.

But, obviously, $\mathcal{HG}(\mathcal{F})$ is freely generated by $\{f_1, f_2, f_3, f_4\}$. Thus, we have constructed a genuine (free) subgroup of $\mathcal{HG}(\Gamma)$ having the same rank as $\mathcal{HG}(\Gamma)$.

D. Refinement of flag worlds

Now we want to investigate the behavior of flag worlds under refinement of the underlying graph. We need the following:

Lemma 4.12: Let Γ be a simple graph and G a simple domain in $\Gamma(m \notin G)$ with corresponding refinement $\{G_i | i \in I\} \subseteq L_{\text{int}}(\Gamma)$. Let f be a minimal flag belonging to G with base point m. Furthermore, e is an arbitrary edge of Γ on ∂G. Then, there exist minimal flags f_i with base point m, such that:

(1) f_i is a flag to domain G_i for all $i \in I$;
(2) f is holonomically equivalent to the product of all f_i in a certain order;
(3) $\{f_i\}$ is moderately independent and any of the free segments lies in $\text{int}\, G \cup e$.

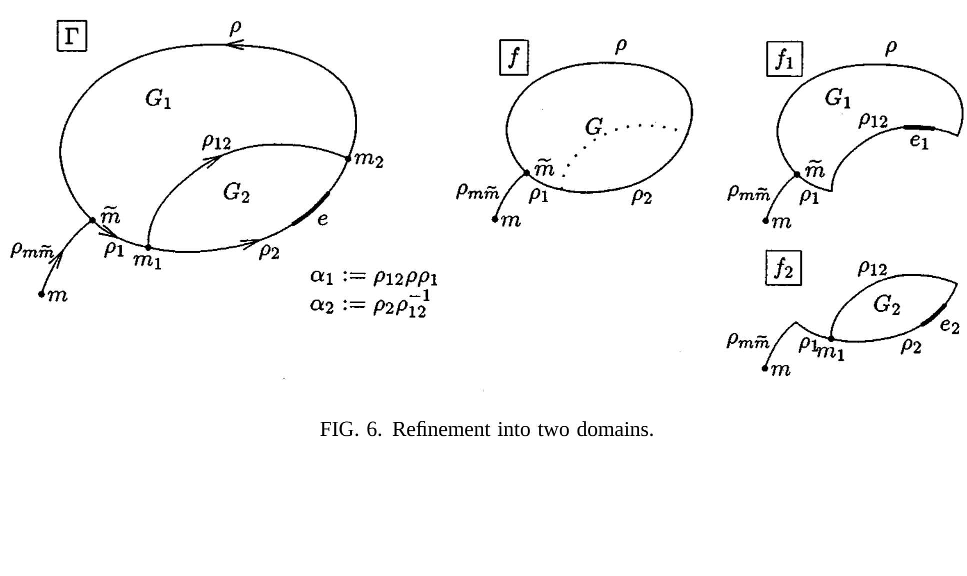

FIG. 6. Refinement into two domains.

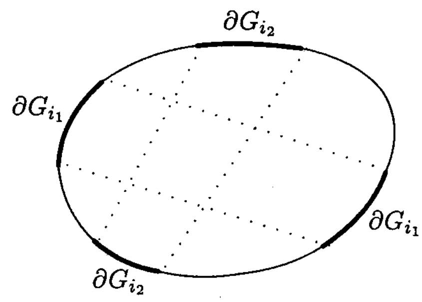

FIG. 7. Existence of a G_k with connected $\partial G_k \cap \partial G$.

Proof: Induction on the cardinality of I. [I is finite, since Γ is finite and thus $L_{\text{int}}(\Gamma)$ is finite.]

(1) $I=1$ is trivial, i.e., $G=G_i$ is an interior domain itself.

(2) First, we consider the case $I=\{1,2\}$.

We consider the case that e and $\tilde{m}$ do not lie on the boundary of one and the same interior domain. Topologically, we have the situation of Fig. 6; if necessary, one has to exchange the domains 1 and 2. Let $\rho_{m\tilde{m}}$ be the flagpoles of f from m to $\tilde{m},\rho,\rho_1,\rho_2,\rho_{12}$ as in Fig. 6 and α_i the corresponding boundary loop for G_i with base point m_1.

We set $f_i := \rho_{m\tilde{m}}\rho_1\alpha_i\rho_1^{-1}\rho_{m\tilde{m}}^{-1}$ for $i=1,2$, after canceling possible retracings, i.e., we consider f_i to be minimal.

(a) Obviously, f_i is a flag for G_i.

(b) We have $f \sim f_2 f_1$.

(c) Choose an edge $e_1 \subseteq \partial G_1 \cap \partial G_2$, i.e., $e_1 \subseteq \rho_{12}$, and set $e_2 := e$. Then $\{f_1,f_2\}$ is obviously moderately independent with the free segments $e_1,e_2 \subseteq \text{int}\, G \cup e$. In the case that e and $\tilde{m}$ lie on the boundary of one and the same domain, one has to exchange, if necessary, ρ_1 and ρ in the construction above, such that $e \cap \rho_1 = \emptyset$. The rest of the proof is completely analogous.

(3) Suppose the lemma is proven for refinements by $k-1 \geqslant 2$ domains and now let $\{G_i\}$ be a refinement of G by $k \geqslant 3$ domains.

(a) Choose any $i \in I$, such that $\overline{G_i} \cap \partial G$ contains at least one edge of Γ and the domain $\tilde{G}$ built from the remaining G_j is again simple (W.l.o.g. we set $i=k$ and j runs in the following from 1 to $k-1$.) More precisely: ∂G, ∂G_k, and $\rho_{m\tilde{m}}$ span a finite and for $\overline{G_k} \cap \partial G \neq \emptyset$ again connected graph. We demand that the set of the interior domains in this graph is equal to $\{\tilde{G},G_k\}$ and that $\tilde{G}$ is simple.

It remains the question, whether such a G_k exists. The first condition is trivial. To prove the second one it is sufficient to choose a domain G_k, such that $\partial G_k \cap \partial G$ is connected.

To see this let α be a boundary loop of G. One gets an $\tilde{\alpha}$ from this, if one replaces the subpath α_k of α belonging to ∂G_k by the path $\tilde{\alpha}_k$ corresponding to the boundary $\partial G_k \setminus \partial G$. Obviously, $\tilde{\alpha}$ is a path in Γ. $\tilde{\alpha}$ has neither repetitions of vertices nor of edges, because neither α nor α_k have the like and because $\tilde{\alpha}_k$ touches α only in its initial and terminal vertex (these are distinct). Otherwise, we would have a contradiction to the connectivity of $\partial G_k \cap \partial G$. Therefore $\tilde{\alpha}$ is a Jordan path, i.e., a boundary of exactly one simple interior domain $\tilde{G}$.

It remains now to ask for the existence of such a domain. Suppose not any $\partial G_i \cap \partial G$ is connected. Then there would exist a pair of indices (i_1,i_2), such that we have the situation in Fig. 7. Obviously, this is a contradiction to the connectivity of G_{i_1} and G_{i_2}.

Thus, there is a refinement of G into two simple domains $\{\tilde{G},G_k\}$, such that $\tilde{G}$ itself has a refinement into $\{G_j\}$ in Γ.

(b) Due to point (2) there are minimal flags $\tilde{f},f_k$ for $\tilde{G}$ and G_k, respectively, such that

(i) $f \sim \tilde{f} f_k$ (or $f_k \tilde{f}$);

(ii) $\{\tilde{f}, f_k\}$ or $\{f_k, \tilde{f}\}$ is moderately independent, where the free segments $\tilde{e}$ and e_k lie in $\operatorname{int} G \cup e$.

(c) Let $\tilde{e}$ be the free segment of $\tilde{f}$. It is obviously an edge in $\Gamma \cap \partial \tilde{G}$. Thus, by induction there are minimal flags f_j, such that:

(i) $\tilde{f}$ is a product of the f_j in a certain order;

(ii) $\{f_j\}$ is moderately independent, where any of the free segments e_j lies in $\operatorname{int} \tilde{G} \cup \tilde{e}$.

(d) Thus, f can be represented as a hoop product of the f_i in a certain order.

(e) The proof of the moderate independence of $\{f_j\} \cup \{f_k\}$ goes completely analogously to the case of two domains.

(i) Let $\{\tilde{f}, f_k\}$ be moderately independent. Then e_k lies in $(\operatorname{int} G \cup e) \setminus \tilde{f}$, otherwise e_k would already be traced by $\tilde{f}$. Thus, $e_k = e$, since $(\operatorname{int} G \setminus \tilde{f}) \cap f_k = \emptyset$, and so $\tilde{e} \subseteq \operatorname{int} G$. Due to $e_j \subseteq \operatorname{int} \tilde{G} \cup \tilde{e} \subseteq \operatorname{int} G$ we have e_j, $e_k \subseteq \operatorname{int} G \cup e$.
$\{f_1, \ldots, f_{k-1}, f_k\}$ is moderately independent because $e_1, \ldots, e_{k-1}$ are free segments of $f_1, \ldots, f_{k-1}$, and e_k is free, because $e_k \cap f_j \subseteq e_k \cap (\tilde{f} \cup \operatorname{int} \tilde{G}) = (e_k \cap \tilde{f}) \cup (e_k \cap \operatorname{int} \tilde{G}) = \theta$. The second intersection vanishes obviously and the first one does because $\{\tilde{f}, f_k\}$ are moderately independent.

(ii) Let $\{f_k, \tilde{f}\}$ be moderately independent. The argumentation is analogous to the other case, however, here $\{f_k, f_1, \ldots, f_{k-1}\}$ is moderately independent. **qed**

We have now

Proposition 4.13: Let Γ, Γ' be simple graphs, Γ' a refinement of Γ and $m \in \Gamma$. Then there exists for any moderately independent flag world $\mathcal{F}$ of Γ a moderately independent flag world $\mathcal{F}'$ of Γ', such that the following holds for all interior domains G_I of Γ: The flag $f_I \in \mathcal{F}$ to G_I is the hoop product of exactly these flags $f_{I,i_I} \in \mathcal{F}'$, that belong to the interior domains G_{I,i_I} with $G_{I,i_I} \subseteq G_I$, in a certain order.

Proof: Obviously, we have $m \notin G_I$ for all $G_I \in L_{\text{int}}(\Gamma)$ because $m \in \Gamma$. First, we define Γ'' to be the graph built from all interior domains of Γ' that are contained in the exterior domain of Γ and from all interior domains of Γ. Obviously, Γ'' is simple, $\Gamma \leqslant \Gamma'' \leqslant \Gamma'$ and the exterior domains of Γ'' and Γ' coincide. Now let $\mathcal{F} = \{f_I\} = \{f_1, \ldots, f_\Lambda\}$ be moderately independent with the free segments e_I. We can refine $\mathcal{F}$ to a moderately independent flag world $\mathcal{F}'' = \{f_1, \ldots, f_{\Lambda''}\} \supseteq \mathcal{F}$ of Γ'', where Λ'' is the number of interior domains of Γ'', analogous to the proof of Proposition 4.8. Next, we consider for any interior domain of Γ the corresponding refinement of G_I into the $G_{I,i_I} \in L_{\text{int}}(\Gamma')$. Due to Lemma 4.12 there exist minimal flags f_{I,i_I} with base point m, such that:

(1) f_{I,i_I} is a flag to the domain G_{I,i_I}.
(2) f_I is holonomically equivalent to the product of all f_{I,i_I} in a certain order.
(3) $\{f_{I,i_I}\}$ is moderately independent and any free segment e_{I,i_I} is contained in $\operatorname{int} G_I \cup e_I$. (W.l.o.g. e_I is an edge of Γ on ∂G_I.)

The flags f_I in $\mathcal{F}'' \setminus \mathcal{F}$, i.e., those flags that belong to the interior domain of Γ', but are contained in the exterior domain of Γ, are left untouched. We only set $\lambda_I := 1$ and $f_{I,i_I} := f_I$. Now (λ_I is the number of domains, that the G_I are refined into) $\mathcal{F}' = \{f_{1,1}, \ldots, f_{1,\lambda_1}, f_{2,1}, \ldots, f_{2,\lambda_2}, \ldots, f_{\Lambda'',1}, \ldots, f_{\Lambda'',\lambda_{\Lambda''}}\}$ is a moderately independent flag world of Γ' because:

(i) e_{I,i_I} is traced exactly once by f_{I,i_I} per constructionem and is not traced by any $f_{I,j}$ with $j < i_I$ due to the just stated point (3). $\{f_{I,j} | j \in [1, \lambda_I]\}$ is moderately independent with the free segments $e_{I,j}$ for a fixed I.
(ii) But, e_{I,i_I} is also not traced by $f_{J,j}$ with $J < I$:

$f_{J,j}$ traces only $f_J \cup \operatorname{int} G_J$ and we have $e_{I,i_I} \subseteq \operatorname{int} G_I \cup e_I$. Since the domains of Γ are disjoint, we have $\operatorname{int} G_J \cap \operatorname{int} G_I = \emptyset$, $f_J \cap \operatorname{int} G_I = \emptyset$ and $\operatorname{int} G_J \cap e_I = \emptyset$. Finally, we have $f_J \cap e_I = \emptyset$ since $\mathcal{F}'' = \{f_1, \ldots, f_{\Lambda''}\}$ itself is moderately independent. Thus, $f_{J,j} \cap e_{I,i_I} = \emptyset$.

Thus, e_{I,i_I} fits all conditions for a free segment. Since $\mathcal{F}'$ is obviously a flag world of Γ', we get the proof. **qed**

E. Conclusions

We collect the most important facts with regard to the applications in Sec. VI sometimes neglecting mathematical details. Any graph is finite, planar, connected, and nonempty.

Let there be given an arbitrary graph Γ.

(1) There is a refinement of Γ to an ordinary graph Γ'.

(2) Any graph can be naturally associated with a finite set of connected interior domains and an exterior domain (Sec. IV A). By a refinement of Γ this set is refined.

(3) A graph is called simple iff its interior domains are simple, i.e., are bounded by Jordan loops.

(4) Any ordinary graph Γ' is subgraph of a simple, ordinary graph Γ''. The exterior domains of both graphs are the same (Proposition 4.3).

(5) Any simple domain G in a graph can be naturally associated with a flag, i.e., a loop running from a base point m to ∂G, traversing G exactly once and running back to m (Definition 4.2).

(6) By choosing a flag to each interior domain one gets a flag world (Definition 4.3). It is called complete iff it spans the full hoop group of Γ.

(7) We are looking for moderately independent and complete flag worlds. The completeness ensures that any loop in Γ can be expressed by elements of a flag world. The moderate independence is necessary for the integration of cylindrical functions. Fortunately, the moderate independence implies the completeness (Proposition 4.7).

(8) One can naturally construct flag worlds to any simple graph. For this one chooses a maximal tree in this graph and then for any interior domain a flag consisting of a path along the tree, a boundary loop of the corresponding domain and the inverse initial path. Any such flag world is moderately independent (Proposition 4.8).

(9) There is a moderately independent flag world for any simple graph (Corollary 4.9). Thus, any hoop can be represented as a hoop product of mutually nonoverlapping loops.

(10) Under refinement of a simple domain G with a flag f one can choose flags f_i to the new domains G_i such that these generate all hoops ''in G'' and that f can be expressed as a hoop product of the f_i in a certain order (Lemma 4.12).

(11) In simple graphs Γ' any moderately independent flag world $\mathcal{F}$ of a simple subgraph Γ can be refined to a moderately independent flag world $\mathcal{F}'$ von Γ' such that any flag $f_G \in \mathcal{F}$ is a product of the flags $f_{G'} \in \mathcal{F}'$ to the interior domains $G' \subseteq G$ in a certain order (Proposition 4.13).

In Sec. VI we will see that especially the last point is crucial for the regularization of the Wilson loop functionals. We can now decompose the ''banner'' of a given flag in smaller ''banners.'' But all small ''banners'' have ''equal rights'' since $f_I \sim f_{I,1} \cdots f_{I,\lambda_I}$. That is why they give identical contributions if we integrate cylindrical functions in f_I.

V. INTEGRATION ON $\overline{\mathcal{A}/\mathcal{G}}$

In this section we slightly generalize the integration calculus on $\overline{\mathcal{A}/\mathcal{G}}$ which was in detail investigated by Ashtekar and Lewandowski.[2] Their key idea was to first define an equivalence relation on $\overline{\mathcal{A}/\mathcal{G}}$ which identifies two connections iff their holonomies on a certain finite set $\boldsymbol{\beta}$ of hoops are equal (up to conjugation), i.e., factorizing with respect to that relation they extracted the properties of a generalized connection on that finite set. But, if one knows these properties for all finite sets of hoops, one can reconstruct via $\overline{\mathcal{A}/\mathcal{G}} \sim \mathrm{Hom}(\mathcal{HG},\mathbf{G})/\mathrm{Ad}$ the generalized connection in $\overline{\mathcal{A}/\mathcal{G}}$. The main advantage of the factorization is the reduction of the infinite-dimensional problem to a finite-dimensional one, since $\overline{\mathcal{A}/\mathcal{G}}/\sim \cong \mathrm{Hom}(\mathcal{HG}(\beta),\mathbf{G})/\mathrm{Ad} \cong \mathbf{G}^{\#\boldsymbol{\beta}}/\mathrm{Ad}$. Comparing that situation with the case of infinite-dimensional topological vector spaces, AL defined first cylindrical functions as functions on $\overline{\mathcal{A}/\mathcal{G}}/\sim$ and second the integral of cylindrical functions $f = \pi_{\boldsymbol{\beta}}^* f_{\boldsymbol{\beta}}$ via

$\int_{\overline{\mathcal{A/G}}} f, d\mu = \int_{\overline{\mathcal{A/G}}/\sim} f_{\boldsymbol{\beta}} d\mu_{\boldsymbol{\beta}}$, where $d\mu_{\boldsymbol{\beta}}$ is a measure on $\overline{\mathcal{A/G}}/\sim \cong \mathbf{G}^{\#\boldsymbol{\beta}}/\mathrm{Ad}$. The main problem is to guarantee that this integral is well defined. AL could prove this for the choice that $d\mu_{\boldsymbol{\beta}}$ is the Haar measure on $\mathbf{G}^{\#\boldsymbol{\beta}}/\mathrm{Ad}$, and if only *strongly* independent $\boldsymbol{\beta}$ are allowed for calculating the integral above. The use of merely weakly independent $\boldsymbol{\beta}$ leads to contradicitons. Our task is now to prove that the use of *moderately* independent $\boldsymbol{\beta}$ keeps instead the definition valid. This point is crucial for the calculation of the Wilson loop expectation values using the not strongly, but moderately independent flag worlds.

A. Equivalence of connections

We recall[2] the following.

Definition 5.1: Equivalence of Connections. Let $\mathcal{HG}(\boldsymbol{\beta}) \subseteq \mathcal{HG}$ be a finitely generated subgroup of the hoop group $\mathcal{HG}$ with weakly independent $\boldsymbol{\beta}$. Two (generalized) connections $\overline{A}_1$ and $\overline{A}_2$ are called *equivalent with respect to* $\mathcal{HG}(\boldsymbol{\beta})$ iff

$$h_{\overline{A}_1}(\gamma) = g^{-1} h_{\overline{A}_2}(\gamma) g, \quad \forall \gamma \in \mathcal{HG}(\boldsymbol{\beta})$$

with a fixed (hoop independent) $g \in \mathbf{G}$.
Furthermore, let $\pi_{\boldsymbol{\beta}}: \overline{\mathcal{A/G}} \to \overline{\mathcal{A/G}}/\sim$ be the corresponding canonical projection.
Using the bijection $\overline{\mathcal{A/G}} \leftrightarrow \mathrm{Hom}(\mathcal{HG}, \mathbf{G})/\mathrm{Ad}$ Ashtekar and Lewandowski[2] could easily analyze the structure of $\overline{\mathcal{A/G}}/\sim$.

Lemma 5.1: (1) There is a bijection $\overline{\mathcal{A/G}}/\sim \to \mathrm{Hom}(\mathcal{HG}(\boldsymbol{\beta}), \mathbf{G})/\mathrm{Ad}$. That means, two generalized connections are equivalent if and only if they coincide mod Ad on $\mathcal{HG}(\boldsymbol{\beta})$.

(2) Any choice of n weakly independent generators $\beta_i \in \mathcal{HG}(\boldsymbol{\beta})$ yields a bijection $\phi_{\boldsymbol{\beta}}: \overline{\mathcal{A/G}}/\sim \to \mathbf{G}^n/\mathrm{Ad}$.

(3) Given $\mathcal{HG}(\boldsymbol{\beta}) \subseteq \mathcal{HG}$ the topology on $\overline{\mathcal{A/G}}/\sim$ induced by the last point is independent of the choice of generators.
Furthermore, we have[2]

Corollary 5.2: Let $\mathcal{HG}(\boldsymbol{\beta})$ be a finitely generated subgroup of the hoop group and $\sim$ the induced equivalence relation on $\overline{\mathcal{A/G}}$. Then any equivalence class $[\overline{A}] \in \overline{\mathcal{A/G}}/\sim$ contains a regular connection.

B. Cylindrical functions

In the following we set $\mathcal{B}_{\boldsymbol{\beta}} := \mathrm{Hom}(\mathcal{HG}(\boldsymbol{\beta}), \mathbf{G})/\mathrm{Ad} \cong \mathbf{G}^n/\mathrm{Ad}$ with $\boldsymbol{\beta}$ a weakly independent set of n hoops. Furthermore we usually do not distinguish between a function $f \in \overline{\mathcal{HA}}$ and its Gelfand transform $\tilde{f}: \overline{\mathcal{A/G}} \to \mathbb{C}$.

We now provide a slightly modified version of the Ashtekar–Lewandowski definition of a cylindrical function.

Definition 5.2: Cylindrical Function. $f: \overline{\mathcal{A/G}} \to \mathbb{C}$ is called *cylindrical function* iff there is a finite set $\boldsymbol{\beta}$ of weakly independent hoops and a continuous $f_{\boldsymbol{\beta}}: \mathcal{B}_{\boldsymbol{\beta}} \to \mathbb{C}$, such that $f = \pi^*_{\boldsymbol{\beta}} f_{\boldsymbol{\beta}}$. Iff f can be obtained that way for a given $\boldsymbol{\beta}$, f is called *cylindrical* with respect to $\boldsymbol{\beta}$.

The set of all cylindrical functions is denoted by $\mathcal{C}$.
It is very simple to verify

Lemma 5.3: Let f be cylindrical with respect to $\boldsymbol{\beta}$. Then f is cylindrical with respect to $\boldsymbol{\alpha}$, if the following holds:

(1) $\boldsymbol{\alpha}$ is weakly independent.
(2) $\mathcal{HG}(\boldsymbol{\alpha}) \supseteq \mathcal{HG}(\boldsymbol{\beta})$.

Remark: In contrast to Ref. 2 we define cylindrical functions not only on strongly independent, but also on weakly independent $\boldsymbol{\beta}$. For the present the set of cylindrical functions seems to be enlarged. But, it is easy to see, that given an $f \in \mathcal{C}$ there is a set $\boldsymbol{\alpha}$ of strongly independent loops, such that f is cylindrical with respect to $\mathcal{B}_{\boldsymbol{\alpha}}$.

Let $f\in\mathcal{C}$, i.e., there is a finite set $\boldsymbol{\beta}$ of weakly independent hoops with respect to that f is cylindrical. Following Lemma 3.8 there is a set $\boldsymbol{\alpha}$ of strongly independent loops, such that $\mathcal{HG}(\boldsymbol{\beta})\subseteq\mathcal{HG}(\boldsymbol{\alpha})$. Due to the just proven lemma f is cylindrical with respect to the strongly independent set $\boldsymbol{\alpha}$. Thus, our definition is equivalent to that one in Ref. 2.
Finally, we quote[2]

Proposition 5.4: $\mathcal{C}$ is a normed $*$-algebra and $\overline{\mathcal{C}}$ is isomorphic to $\overline{\mathcal{HA}}$.

C. The induced Haar measure on $\overline{\mathcal{A}/\mathcal{G}}$

Definition 5.3: Let be $f\in\mathcal{C}$ and $\boldsymbol{\beta}\subseteq\mathcal{HG}$ be a moderately independent set of n hoops, such that f is cylindrical with respect to $\boldsymbol{\beta}$, i.e., $f=\pi^*_{\boldsymbol{\beta}}f_{\boldsymbol{\beta}}$ with a continuous function $f_{\boldsymbol{\beta}}:\boldsymbol{\mathcal{B}}_\beta\to\mathbb{C}$. Furthermore, $d\mu_{\boldsymbol{\beta}}$ is an arbitrary measure on $\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}$. Then we define $\int_{\overline{\mathcal{A}/\mathcal{G}}}f\,d\mu:=\int_{\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}}f_{\boldsymbol{\beta}}\,d\mu_{\boldsymbol{\beta}}$.
We have to guarantee that the measures on the distinct $\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}$ are compatible in order to make the integral in the definition above well-defined.

Ashtekar and Lewandowski suggested to choose the Haar measure on each $\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}$, $\boldsymbol{\beta}$ strongly independent, induced from $\mathbf{G}^n/\mathrm{Ad}$ with n the cardinality of $\boldsymbol{\beta}$. Indeed, they could prove that the definition above provides a well-defined integral on $\overline{\mathcal{A}/\mathcal{G}}$. We are only left with the proof that the integral is still well-defined if we allow $\boldsymbol{\beta}$ to be merely moderately independent instead of strongly independent. Fortunately, for this we can reuse the AL proof with slight modifications. Thus, we have

Theorem 5.5: Let $\int_{\overline{\mathcal{A}/\mathcal{G}}}f\,d\mu_0$ be defined as in Definition 5.3, where the measure on $\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}$ is in each case the Haar measure on $d^n\mu_{\mathrm{Haar}}$.

(1) The integral $\int_{\overline{\mathcal{A}/\mathcal{G}}}f\,d\mu_0$ is well-defined.
(2) The functional $F:\overline{\mathcal{HA}}\to\mathbb{C}$, $f\mapsto\int_{\overline{\mathcal{A}/\mathcal{G}}}f(\overline{A})\,d\mu_0(\overline{A})$ is linear, continuous, positive and Diff(M) invariant.
(3) The cylindrical measure $d\mu_0$ is a regular, positive and Diff(M)-invariant measure on $\overline{\mathcal{A}/\mathcal{G}}$.

Proof: It remains to prove the integral to be well defined. If it is, then our measure coincides with the AL measure defined only by the use of strongly independent hoops, since the AL measure is unique and we did not remove any of the conditions the integral has to fulfill—because any strongly independent $\boldsymbol{\beta}$ is moderately independent. Consequently, all the other assertions of the theorem already proven in Ref. 2 using the strong independence can be generalized to our problem.

(1) Let there be given an $f\in\mathcal{C}$ and two sets $\beta',\beta''\subseteq\mathcal{L}_m$ of moderately independent loops, such that f is cylindrical with respect to $\mathcal{B}_{\boldsymbol{\beta}'}$ and $\mathcal{B}_{\boldsymbol{\beta}''}$.

(2) W.l.o.g. choose the free segments $e'_{i'},e''_{i''}$ of $\beta'_{i'},\beta''_{i''}$, such that they are in each case completely contained in an edge of $\Gamma_{\boldsymbol{\beta}'\cup\boldsymbol{\beta}''}$. (If necessary, free $\boldsymbol{\beta}'$ and $\boldsymbol{\beta}''$ from retracings and then use the argumentation of Proposition 3.10. For the definition of $\Gamma_{\boldsymbol{\beta}'\cup\boldsymbol{\beta}''}$ see Construction 3.4.) Now connect any vertex $v\neq m$ of $\Gamma_{\boldsymbol{\beta}'\cup\boldsymbol{\beta}''}$ with the base point m by a piecewise analytic Jordan path h_v, such that $h_v\cap h_{v'}$, $\forall v\neq v'$ and $h_v\cap\Gamma_{\boldsymbol{\beta}'\cup\boldsymbol{\beta}''}$ consist of at most a finite number of points. Construct all paths $\beta_i:=h_{e_i^-}e_ih_{e_i^+}^{-1}$, where e_i runs over all edges of $\Gamma_{\boldsymbol{\beta}'\cup\boldsymbol{\beta}''}$. Obviously, $\boldsymbol{\beta}',\boldsymbol{\beta}''\subseteq\mathcal{HG}(\boldsymbol{\beta}),\boldsymbol{\beta}:=\{\beta_i|i=1,...,n\}$, and also $\mathcal{HG}(\boldsymbol{\beta}'),\mathcal{HG}(\boldsymbol{\beta}'')\subseteq\mathcal{HG}(\boldsymbol{\beta})$. More precisely: Let $\beta'_j=\prod_{k_j=1}^{K_j}e_{i(j,k_j)}^{\epsilon(j,k_j)}$ be a (minimal) decomposition of β'_j into a sequence of edges, so $\beta'_j\sim\prod_{k_j=1}^{K_j}\beta_{i(j,k_j)}^{\epsilon(j,k_j)}$ is a (minimal) decomposition of β'_j in β_i. The same holds for β''_j.
Next, $\boldsymbol{\beta}$ is strongly independent with the free segments e_i.
Since $\mathcal{HG}(\boldsymbol{\beta}'),\mathcal{HG}(\boldsymbol{\beta}'')\subseteq\mathcal{HG}(\boldsymbol{\beta})$, f is also cylindrical with respect to $\mathcal{B}_{\boldsymbol{\beta}}$. Thus, it is sufficient to prove $\int_{\mathcal{B}_{\boldsymbol{\beta}'}}f_{\boldsymbol{\beta}''}\,d\mu_{\mathcal{B}_{\boldsymbol{\beta}'}}=\int_{\mathcal{B}_{\boldsymbol{\beta}}}f_{\boldsymbol{\beta}}\,d\mu_{\mathcal{B}_{\boldsymbol{\beta}}}$.

(3) Now we can express any $\beta'_i\in\boldsymbol{\beta}'$ by a product of $\beta_i\in\boldsymbol{\beta}$, such that for all $i\in[1,n']$ there exists a $K(i')\in[1,n]$ and that the following holds:

(a) $i\neq j'\Leftrightarrow K(i')\neq K(j')$;

(b) $\beta_{K(i')}$ is not used in any decomposition of the $\beta'_{j'}$, $j'<i'$, into elements of $\boldsymbol{\beta}$;

(c) $\beta_{K(i')}$ (or $\beta_{K(i')}^{-1}$) is used in any decomposition of $\beta_{i'}$ exactly once.
To see this choose $K(i')$, such that $e_{K(i')}$ contains the free segment of $\beta'_{i'}$. Since there is a bijection $e_i \leftrightarrow \beta_i$, these three conditions are only a reformulation of the criteria for the moderate independence of the $\beta'_{i'}$.

(4) Since f is as well cylindrical with respect to β as with respect to $\boldsymbol{\beta}'$, $f = \pi_{\boldsymbol{\beta}}^* f_{\boldsymbol{\beta}} = \pi_{\boldsymbol{\beta}'}^* f_{\boldsymbol{\beta}'}$. Analogously to Lemma 5.3 we have $\pi_{\boldsymbol{\beta}'} = \pi \pi_{\boldsymbol{\beta}}$, where

$$\begin{array}{rccc} \pi: & \mathbf{G}^n/\mathrm{Ad} & \to & \mathbf{G}^{n'}/\mathrm{Ad} \\ & [g_1,\ldots,g_n]_{\mathrm{Ad}} & \mapsto & \left[\prod_{k_1=1}^{K_1} g_{i(1,k_1)}^{\epsilon(1,k_1)}, \ldots, \prod_{k_{n'}=1}^{K_{n'}} g_{i(n',k_{n'})}^{\epsilon(n',k_{n'})} \right]_{\mathrm{Ad}} \end{array}$$

is defined due to the decompositions

$$\beta'_{i'} = \prod_{k'_i=1}^{K_{i'}} e_{i(i',k_{i'})}^{\epsilon(i',k_{i'})}.$$

Thus, we have

$$f_\beta = \pi^* f_{\boldsymbol{\beta}'}, \quad \text{i.e.,} \quad f_\beta([g_1,\ldots,g_n]_{\mathrm{Ad}}) = (\pi^* f_{\boldsymbol{\beta}'})([g_1,\ldots,g_n]_{\mathrm{Ad}})$$
$$= f_{\beta'}\left(\left[\prod_{k_1=1}^{K_1} g_{i(1,k_1)}^{\epsilon(1,k_1)}, \ldots, \prod_{k_{n'}=1}^{K_{n'}} g_{i(n',k_{n'})}^{\epsilon(n',k_{n'})} \right]_{\mathrm{Ad}} \right).$$

(5) Since we fixed the generators of $\mathcal{HG}(\boldsymbol{\beta})$, we can interpret the integration on $\boldsymbol{\mathcal{B}}_\beta$ as an integration on $\mathbf{G}^n/\mathrm{Ad}$. Since the Haar measure is Ad invariant, we can pull back any function of $\mathbf{G}^n/\mathrm{Ad}$ onto the whole $\mathbf{G}^n$ and integrate hereon. The analogon holds for $\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}'}$.

(6) Now we can integrate (considering $f_{\boldsymbol{\beta}}$ to be both a function on $\mathbf{G}^n$ and $\mathbf{G}^n/\mathrm{Ad}$):

$$\int_{\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}} f_{\boldsymbol{\beta}} \, d\mu_{\boldsymbol{\mathcal{B}}_{\boldsymbol{\beta}}} = \int_{\mathbf{G}^n} \prod_{i=1}^{n} d\mu_i \, f_{\boldsymbol{\beta}}(g_1,\ldots,g_n)$$
$$= \int_{\mathbf{G}^n} \prod_{i=1}^{n} d\mu_i \, f_{\boldsymbol{\beta}'}\left(\prod_{k_1=1}^{K_1} g_{i(1,k_1)}^{\epsilon(1,k_1)}, \ldots, \prod_{k_{n'}=1}^{K_{n'}} g_{i(n',k_{n'})}^{\epsilon(n',k_{n'})} \right)$$
$$= \int_{\mathbf{G}^{n-n'}} \prod_{i=1, i \notin K([1,n'])}^{n} d\mu_i \int_{\mathbf{G}} d\mu_{K(1)} \cdots$$
$$\times \int_{\mathbf{G}} d\mu_{K(n')} f_{\boldsymbol{\beta}}{}'(\ldots, g_{K(1)} \ldots, \ldots, \ldots, g_{K(n')}, \ldots)$$

(permutation of the order of integration. The three dots in $\ldots, g_{K(i')} \ldots$ denote a product of g_i, which because of the construction above does not contain a $g_{K(j')}$ with $j' \geqslant i'$.)

$$= \int_{\mathbf{G}^{n-n'}} \prod_{i=1, i \notin K([1,n'])}^{n} d\mu_i \int_{\mathbf{G}} d\mu_{K(n')} \int_{\mathbf{G}} d\mu_{K(1)} \cdots$$
$$\times \int_{\mathbf{G}} d\mu_{K(n'-1)} f_{\boldsymbol{\beta}'}(\ldots, g_{K(1)} \ldots, \ldots, \ldots, g_{K(n'-1)}, \ldots, g_{K(n')})$$

(results from the translation invariance of the Haar measure, since for all $j'<n',\ldots,g_{K(j')},\ldots$ does not contain a factor $g_{K(n')}$ and since $g_{K(n')}$ appears in ..., $g_{K(n')},\ldots$ exactly once.)

$$\vdots$$

$$=\int_{\mathbf{G}^{n-n'}}\prod_{i=1,i\notin K([1,n'])}^{n} d\mu_i \int_{\mathbf{G}} d\mu_{K(1)}\cdots$$

$$\times\int_{\mathbf{G}} d\mu_{K(n')} f_{\beta'}(g_{K(1)},\ldots,g_{K(n')})$$

(We used successively the translation invariance of the Haar measure in order to eliminate the $\cdots$ products as in the step above.)

$$=\int_{\mathbf{G}^{n'}}\prod_{i=1}^{n'} d\mu_i\, f_{\boldsymbol{\beta}'}(g_1,\ldots,g_{n'})$$

(Normalization of the Haar measure and bijection $i'\leftrightarrow K(i')$)

$$=\int_{\mathcal{B}_{\beta'}} f_{\boldsymbol{\beta}'}\, d\mu_{\mathcal{B}_{\beta'}}.$$

(7) Thus, $\int_{\overline{\mathcal{A}/\mathcal{G}}} f\, d\mu_0$ is well-defined. (We assumed in our calculation, that in any case $\ldots,g_{K(i')},\ldots$ appears and $\ldots,g_{K(i')}^{-1},\ldots$ does not. Otherwise in all steps but the but the third we get a function partially in $g_{K(i')}^{-1}$. The claim remains valid since the Haar measure is invariant under inversions, i.e., we have $\int_{\mathbf{G}} d\mu_{\mathrm{Haar}} f(g)=\int_{\mathbf{G}} d\mu_{\mathrm{Haar}} f(g^{-1})$.)

Remark: The proof that the integral is well-defined gives us the earlier mentioned importance of moderate independence. Though the flag worlds in Sec. IV are usually not strongly independent, they can be used for the integration calculus. If one instead demanded only the weak independence for the definition of the integral, the integral would become *ill-defined*. Let, e.g., $\mathbf{G}=\mathrm{SU}(2)$ and β be a strongly or, equivalently, a moderately independent loop. $\gamma:=\beta^2$ is no longer moderately independent, but, of course, still weakly independent, since extracting the square root is possible in SU(2). Let now $f=\mathrm{tr}\, h_\gamma=\mathrm{tr}\, h_\beta^2$. f is cylindrical with respect to γ and with respect to β. We integrate f with respect to γ and receive $\int_{\overline{\mathcal{A}/\mathcal{G}}} f\, d\mu_0=\int_{\mathbf{G}}\mathrm{tr}\, g\, d\mu_{\mathrm{Haar}}=0$. But, with respect to β we have $\int_{\overline{\mathcal{A}/\mathcal{G}}} f\, d\mu_0=\int_{\mathbf{G}} tr\, g^2\, d\mu_{\mathrm{Haar}}=-1$, i.e., the integral is ill-defined. Thus, the moderate independence is best-suited for the mathematically rigorous calculation of the Wilson loop expectation values in Sec. VI.

VI. CALCULATION OF THE WILSON LOOP EXPECTATION VALUES

In this section the expectation values of the Wilson loop products $\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle$ of the pure Yang–Mills theory are computed. Thiemann[3] and Ashtekar *et al.*[4] were the first who succeeded in calculating $\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle$—at least for loops α_i that lie in a certain quadratic lattice—in the Ashtekar framework. Our goal is now to generalize their results for arbitrary α_i.

It is well known[2] that given the expectation values $\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle$ for all α_i one can reconstruct the measure $d\mu_{\mathrm{YM}}$ of the theory and vice versa. A direct definition $d\mu_{\mathrm{YM}}:=e^{-S[\overline{A}]}d\mu_0$ is difficult since one has to define the action S not only on $\mathcal{A}/\mathcal{G}$ but on the whole $\overline{\mathcal{A}/\mathcal{G}}$. The first step to overcome this problem is an appropriate regularization $S^W_{\mathrm{reg}}(A)$ of $S_{\mathrm{YM}}(A)=\int_M \frac{1}{4}\,\mathrm{tr}\,F_{\mu\nu}F^{\mu\nu}\,dx$. Since the only variables used *a priori* in the Ashtekar approach are the Wilson loops, it seems very likely to use the lattice regularization. Strictly speaking, TA$^+$ set

$$S^W_{\mathrm{reg}}(A):=\frac{N}{g^2a^2}\sum_{\Box}\left(1-\frac{1}{N}\mathrm{Re}\,\mathrm{tr}\,h_{\Box}(A)\right), \tag{2}$$

where a denotes the lattice spacing, $\Box$ runs over all plaquettes of the lattice, and $h_{\Box}(A)$ is the holonomy around the boundary of $\Box$. On the one hand, S^W_{reg} converges naively to S_{YM}, when the lattice grows ad infinitum and a goes to zero, and on the other hand, S^W_{reg} is a function of Wilson loops, i.e., it can be naturally extended from $\mathcal{A}/\mathcal{G}$ onto the whole $\overline{\mathcal{A}/\mathcal{G}}$. The second step of TA$^+$ was now the definition of $\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle$ exchanging limit and integration (L is the length of the lattice):

$$\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle:=\lim_{a\to 0,L\to\infty}\frac{1}{Z_{a,L}}\int_{\overline{\mathcal{A}/\mathcal{G}}}d\mu_0\,e^{-S^W_{\mathrm{reg}}}T_{\alpha_1}\cdots T_{\alpha_n}\text{``}=\text{''}\frac{1}{Z}\int_{\overline{\mathcal{A}/\mathcal{G}}}d\mu_0\,e^{-\lim_{a\to 0,L\to\infty}S^W_{\mathrm{reg}}}T_{\alpha_1}\cdots T_{\alpha_n}.$$

Now they were able to calculate explicitly the expectation values for all $\alpha_1,\ldots,\alpha_n$ contained in a quadratic lattice. Finally, they suggested to compute these values for general α_i by approximating them by certain lattice loops.

We avoid this problem using a slightly modified regularization. The idea is to adapt the regularization to the given loops and not vice versa. We consider any finite lattice with certain interior domains G generalizing the quadratic plaquettes $\Box$. Then we replace in (2) $\Box$ by G and also a^2 by $|G|$, the area of the interior domain G, in the denominator. Following the calculations of TA$^+$ we get an explicit formula for $\langle T_{\alpha_1}\cdots T_{\alpha_n}\rangle$ with arbitrary $\alpha_1,\ldots,\alpha_n$ that coincides with the naive limit of TA$^+$.

A. Regularization of the Wilson loop functionals

In this section we want to introduce our regularization.

Definition 6.1: Generalized Yang–Mills action. Let G be a simple domain in $\mathbb{R}^2$,$|G|$ its area, α_G a boundary loop of G and $[A]\in\mathcal{A}/\mathcal{G}$. Then we set

$$S_G([A]):=\frac{N}{g^2}\frac{1}{|G|}\left(1-\frac{1}{N}\mathrm{Re}\,\mathrm{tr}\,h_{\alpha_G}(A)\right)=\frac{N}{g^2}\frac{1}{|G|}(1-\mathrm{Re}\,T_{\alpha_G}(A)).$$

(This definition is obviously independent of the choice of the boundary loop and the chosen $A\in[A]$.)

Now let Γ be a finite simple graph in $\mathbb{R}^2$ with interior domains G. $\Gamma\to\mathbb{R}^2$ means that the supremum $\sup_{G\in\Gamma}\mathrm{diam}\,G$ of the diameters of the interior domains goes to 0 and the supremum of the diameters of all circles with center in m, which are completely contained in $\cup\overline{G}$ goes to ∞. (The choice of m is arbitrary. One can choose any point in $M=\mathbb{R}^2$, but one has to fix that point once for all.)

We set the *regularized Yang–Mills action* to be $S_\Gamma([A]):=\Sigma_G\,S_G([A])$ and define $S(A)\equiv S([A]):=\lim_{\Gamma\to\mathbb{R}^2}S_\Gamma([A])$.

Finally let $\overline{A}\in\overline{\mathcal{A}/\mathcal{G}}$. We define $S(\overline{A}):=\lim_{\Gamma\to\mathbb{R}^2}\Sigma_G\,S_G(\overline{A})$ to be the *generalized Yang–Mills action*.

Remark: While we have written the present paper the article ‘‘Study of Wilson loop functionals in 2D Yang–Mills theories’’ of Aroca and Kubyshin[5] appeared. They used an analogous regularization, i.e., they also permitted arbitrarily bounded domains instead of the usual quadratic plaquettes. They even considered a more general class of actions $S_\Gamma(A):=\Sigma_G\,S_1(h_{\alpha_G}(A))$, where G runs over all plaquettes which the lattice on the (compact) two-dimensional manifold is divided into and where S_1 has to fulfill the following axioms

(1) $S_1(g)=S_1(g^{-1})$ for all $g\in\mathbf{G}$;
(2) $S_1(g)$ has an absolute minimum in $g=e_{\mathbf{G}}$;
(3) $\lim_{G\to\{x\}}(1/|G|)S_1(h_{\alpha_G}(A))=\frac{1}{2}\operatorname{tr}F_{\mu\nu}(x)F^{\mu\nu}(x)$.

Our definition reduces to that of Thiemann, Ashtekar *et al.*[3,4,12] if all domains G are quadratic and congruent with area $|G|=a^2$ (a... lattice spacing). One can prove—at least in a naive limit—that $S(A)$ converges pointwise to $S_{\mathrm{YM}}:=\frac{1}{4}\int_M \operatorname{tr}F_{\mu\nu}F^{\mu\nu}\,dx$ with $F_{\mu\nu}=\partial_{[\mu}A_{\nu]}-ig[A_\mu,A_\nu]$.

Note that the limit $S(\overline{A})$ is very formal because one can easily prove that this limit neither is unique nor exists for general $\overline{A}\in\overline{\mathcal{A}/\mathcal{G}}$ However, why should we need the existence or uniqueness of the limit $S(\overline{A})$? Actually, we only have to calculate terms like

$$\int_{\overline{\mathcal{A}/\mathcal{G}}}\exp\left[-\lim_{\Gamma\to\mathbb{R}^2}\sum_G S_G(\overline{A})\right]\widetilde{T}_{\alpha_1}(\overline{A})\cdots\widetilde{T}_{\alpha_n}(\overline{A})\,d\mu_0.$$

In order to use the integration calculus one has to exchange the limit and the integral. *A priori* we do not know, whether this is—at least mathematically—correct. Astonishingly, one can prove that such an exchange makes the limit *of the integrals* independent of the limiting process. By now, we do not really know which effect is responsible for that behavior.

B. Results

Given a finite set $\boldsymbol{\alpha}=\{\alpha_1,\ldots,\alpha_n\}$ of loops. We have to calculate the following expressions:

$$\chi(\boldsymbol{\alpha}):=\lim_{\Gamma\to\mathbb{R}^2}\frac{1}{Z}\int_{\overline{\mathcal{A}/\mathcal{G}}}\exp\left[-\sum_G S_G(\overline{A})\right]\widetilde{T}_{\alpha_1}(\overline{A})\cdots\widetilde{T}_{\alpha_n}(\overline{A})\,d\mu_0.$$

Z is chosen here so that we have $\chi(1)=1$. (Strictly speaking, Z actually depends on Γ, but we suppress this here and in the sequel.)

Due to the analyticity of the loops the set $\boldsymbol{\alpha}$ generates a finite, nonempty, planar and connected graph $\Gamma_{\boldsymbol{\alpha}}$. We enlarge $\Gamma_{\boldsymbol{\alpha}}$ to an ordinary graph (Sec. III D) and afterwards to a simple, ordinary graph (Proposition 4.3) again denoted by $\Gamma_{\boldsymbol{\alpha}}$ with the interior domains G_I, $I=1,\ldots,\lambda$. Furthermore we choose any moderately independent flag world $\mathcal{F}=\{f_I\}$ for $\Gamma_{\boldsymbol{\alpha}}$ existing due to Proposition 4.9. Now, due to Corollary 4.10 any hoop in $\Gamma_{\boldsymbol{\alpha}}$ can be expressed by a hoop product of flags in $\mathcal{F}$, i.e., by a product of nonoverlapping loops:

$$\alpha_i=\prod_{j=1}^{j_i} f_{I(i,j)}^{\epsilon(i,j)},\quad \forall i=1,\ldots,n;\epsilon(i,j)=\pm 1.$$

Finally, we demand that any graph Γ in the limiting process is a refinement of Γ_α.

Thus, we arrived at the point where we can reuse the calculations of TA^+. We have to replace simply the plaquette loops in TA^+ by the flags and, analogously, the corresponding refinements. Therefore we skip the technical details (for that purpose, see, e.g., Ref. 13 and present only the result:
