$$\rho_j(\zeta,\mu)=\frac{1}{2i\pi}\lim_{\eta\to 0^+}\langle\psi_j|(R_{\zeta+i\eta}-R_{\zeta-i\eta})|\psi_j\rangle \tag{26}$$

as $\mu\to 0$. One finds from (6)

$$\rho_j=\frac{1}{2i\pi}\left(\frac{f_+f_-^*}{\alpha-i\beta}-\frac{f_+^*f_-}{\alpha+i\beta}\right)+\rho_j^0=\frac{\beta}{\pi(\alpha^2+\beta^2)}\mathcal{R}(f_+f_-^*)+\frac{\alpha}{\pi(\alpha^2+\beta^2)}\mathcal{J}(f_+f_-^*)+\rho_j^0, \tag{27}$$

where all the functions depend on the energy ζ; $\rho_j^0(\zeta,\mu)$ is the corresponding density of states of the crossed fields Hamiltonian H^0, $\alpha(\zeta,\mu)$ and $\beta(\zeta,\mu)$ are the functions previously discussed and

$$f_\pm(\zeta)=\lim_{\eta\to 0^+}(00|R^0_{\zeta\pm i\eta}|\psi_j\rangle. \tag{28}$$

In view of (17) and the fact that $\beta(\zeta,\mu)$ tends to zero, the first term in the right-hand side of (27) behaves as a Lorentzian in a neighborhood of ϵ_j for μ small,

$$\frac{\beta_j(\zeta,\mu)}{\pi[(a_j(\mu)(\zeta-\epsilon_j(\mu)))^2+\beta_j(\zeta,\mu)^2]}\mathcal{R}(f_+(\zeta)f_-^*(\zeta))\sim\frac{\frac{1}{2}\Gamma(\mu)}{\pi[(\zeta-\epsilon_j)^2+(\frac{1}{2}\Gamma(\mu))^2]}, \tag{29}$$

with

$$\Gamma_j(\mu)=2\frac{\beta_j(\epsilon_j,\mu)}{a_j}. \tag{30}$$

In (29), we have kept the dominant behavior as $\mu\to 0$ by evaluating $a_j(\mu)$ and $\epsilon_j(\mu)$ at $\mu=0$ and $\beta(\zeta,\ \mu)$, $f_\pm(\zeta)$ at $\zeta=\epsilon_j$. The Lorentzian is properly normalized because $\lim_{\mu\to 0}\mathcal{R}(f_+(\epsilon_j)f_-^*(\epsilon_j))=|(00|R^0_{\epsilon_j}|_{\mu=0}|\psi_j\rangle|^2=a_j$ by (12). The last two terms in (27) remain bounded for ζ in a neighborhood of ϵ_j. Moreover, these two terms vanish as $\mu\to 0$ since $\lim_{\mu\to 0}f_+=\lim_{\mu\to 0}f_-$ is a real quantity and $\lim_{\mu\to 0}\rho_j^0(\zeta,\mu)=0$ when ζ is in between Landau levels.

In (29), $\Gamma(\mu)=((\tau(\mu))^{-1}$ is the inverse lifetime of the jth resonance so that by (30) and (18) $\tau_j(\mu)$ has the form

$$\tau_j(\mu)=C_j\mu\left(\frac{\mu}{\Delta_j}\right)^{2j}\exp\left(\frac{\Delta_j}{\mu}\right)^2, \tag{31}$$

where $\Delta_j=\epsilon_j-(j+1/2)$. The analysis and the results are similar if $\Delta_j=(j+\frac{3}{2})-\epsilon_j$. The lifetime of the resonance corresponding to the lowest energy state ϵ_g is found to be $\tau_g(\mu)=C_g\mu\exp((1/2-\epsilon_g)/\mu)^2$.

V. CONCLUDING REMARKS

We have shown that all impurity states are delocalized under the influence of an electric field, how weak it may be, but with Gaussian long lifetimes. This has to be compared with pure Stark resonances that have exponentially long lifetimes.[8]

Here the calculation has been performed with an attractive δ-potential. (The renormalization procedure given in Section II requires a negative bare coupling constant). The repulsive case is studied in Ref. 3, with a potential with narrow support of diameter d. The infinite n-summations are convergent, and the authors approximate them by finite sums up to a natural cutoff value N determined by the ratio of d to the magnetic length. The result for lifetimes are the same as ours. In addition, they investigate current carrying states as well as the semi-classical regime.

The conclude we remark that our results are sensitive to the potential nature of the impurity interaction. Consider, for instance, the model $H=H^0+\lambda|\phi\rangle\langle\phi|$ obtained by adding a rank-one interaction to the crossed fields Hamiltonian, with $\phi(x,y)$ a square integrable function on $\mathbb{R}^2$, namely the impurity interaction is represented by the nonlocal separable kernel $\lambda\phi(x,y)\phi^*(x',y')$. Energies and lifetimes of resonances are now found from the function

$$g_\phi(z)=\lambda^{-1}+\langle\phi|R_z^0|\phi\rangle \tag{32}$$

in the place of (7) and

$$\beta_\phi(\zeta,\mu)=\frac{\pi}{\mu}\sum_{n=0}^{\infty}|\langle\phi|nk_n(\zeta,\mu)\rangle|^2, \tag{33}$$

$$\langle nk|\phi\rangle=\sum_{n=0}^{\infty}\int dx\, u_n(x)\tilde{\phi}(x,k), \tag{34}$$

where $\tilde{\phi}(x,k)$ is the Fourier transform of $\phi(x,y)$ with respect to the y coordinate. (Here renormalization of the coupling constant is not needed.) Suppose now that

$$\tilde{\phi}(x,k)=0, \quad k\geqslant k_0>0, \tag{35}$$

Then when μ is small enough (say $\mu\ll\Delta_j/k_0$), there exists a neighborhood of ϵ_j such that $k_n(\zeta,\mu)\geqslant k_0$ for all n and thus $\beta_\phi(\zeta,\mu)$ vanishes when ζ is in this neighborhood. This implies that the jth impurity state remains an eigenvector of H with an eigenvalue close to ϵ_j embedded in the continuum. One sees on this example that the interaction has to be sufficiently nonlocal since by the condition (35) the support of $\phi(x,y)$ must extend on the whole y-axis.

APPENDIX A: EXISTENCE OF THE RENORMALIZED MODEL

Introducing (3) in (10) (using also parity of the function u_n), we split the sum in two terms

$$\sum_{n=0}^{\infty}\int dk\,|u_n(-k)|^2\left(\frac{1}{\epsilon_n(k-\mu)-z}-\frac{1}{n+\frac{1}{2}}\right)=I_1+I_2, \tag{A1}$$

$$I_1=\sum_{n=0}^{\infty}\frac{1}{(n+\frac{1}{2})n^{\zeta}}\int_{|k|\leqslant n^{\gamma}}dk\,|u_n(k)|^2 n^{\zeta}\left(\frac{k\mu-(\mu^2/2)+z}{\epsilon_n(k-\mu)-z}\right),$$

$$I_2=\sum_{n=0}^{\infty}\int_{|k|\geqslant n^{\gamma}}dk\,\frac{|u_n(k)|^2}{\epsilon_n(k-\mu)-z}-\sum_{n=0}^{\infty}\int_{|k|\geqslant n^{\gamma}}dk\,\frac{|u_n(k)|^2}{n+\frac{1}{2}},$$

with

$$0<\zeta<\tfrac{1}{4},\quad \tfrac{1}{2}<\gamma=1-2\zeta<1. \tag{A2}$$

One sees in the integrand of I_1 that the fraction

$$\left|n^{\zeta}\left(\frac{z+k\mu-\mu^2/2}{-z+(n+1/2)-\mu k+\mu^2/2}\right)\right|<C<\infty$$

is bounded uniformly with respect to k and n for $|k|\leqslant n^{\gamma}$, $\mathcal{J}z\neq 0$. Hence, since the u_n are normalized, $I_1\leqslant C\sum_{n=0}^{\infty}1/(n+1/2)n^{\zeta}<\infty$. For I_2, since $1/|\epsilon_n(k-\mu)-z|\leqslant 1/|\mathcal{J}z|$, it is sufficient to show that $\sum_{n=0}^{\infty}\int_{|k|\geqslant n^{\gamma}}dk|u_n(k)|^2<\infty$. From the integral representation of the Hermite polynomials[9]

$$H_n(y)=2^n\frac{1}{\sqrt{\pi}}\int_{-\infty}^{+\infty}dt(y+it)^n e^{-t^2}, \tag{A3}$$

one deduces [using $\log(1+y)\leqslant y$]

$$H_n(k)\leqslant\frac{2^n k^n}{\sqrt{\pi}}\int dt\left(1+\left|\frac{t}{k}\right|\right)^n e^{-t^2}\leqslant\frac{2^n k^n}{\sqrt{\pi}}\int dt\,e^{n|t/k|}e^{-t^2}\leqslant 2^{n+1}k^n e^{n^2/4k^2}. \tag{A4}$$

Noting that n sufficiently large ($n\geqslant n_0$) and $|k|>n^{\gamma}$, $\gamma>1/2$ implies $e^{-(k^2/2)(1-n^2/2k^4)}\leqslant e^{-k^2/4}$, one finds from (A4)

$$\begin{aligned}\sum_{n=n_0}^{\infty}\int_{|k|\geqslant n^{\gamma}}dk|u_n(k)|^2&=\frac{1}{2\pi\sqrt{\pi}}\sum_{n=n_0}^{\infty}\frac{1}{2^n n!}\int_{|k|\geqslant n^{\gamma}}dk\,e^{-k^2}H_n^2(k)\\&\leqslant\frac{1}{2\pi\sqrt{\pi}}\sum_{n=n_0}^{\infty}\frac{2^n}{n!}e^{-(1/2)n^{2\gamma}}\int_{|k|\geqslant n^{\gamma}}dk\,e^{-k^2/4}k^{2n}\\&\leqslant\frac{8e^4}{\pi}\sum_{n=n_0}^{\infty}2^n n!\,e^{-(1/2)n^{2\gamma}}<\infty,\end{aligned} \tag{A5}$$

where the last inequality follows from $|k|^n\leqslant n!\,e^{|k|}$. The series (A5) converges for $\gamma>1/2$.

APPENDIX B: PROOF OF THE LEMMA

The lemma is true by inspection for the cases $n=1,2,3$. If $n\geqslant 4$, one uses the formula (A3),

$$H_n\left(\frac{n-x}{\mu}\right)=2^n\left(\frac{n-x}{\mu}\right)^n f_n(\mu),\quad f_n(\mu)=\frac{1}{\sqrt{\pi}}\int dt\left(1+\frac{i\mu t}{n-x}\right)^n e^{-t^2}. \tag{B1}$$

The limited Taylor expansion of $f_n(\mu)$ around $\mu=0$ gives

$$f_n(\mu)=1+\frac{1}{2!}\mu^2 f_n''(0)+\frac{1}{4!}\mu^4 f_n''''(\bar{\mu}),\quad 0\leqslant\bar{\mu}\leqslant\mu, \tag{B2}$$

with

$$f_n''(0)=-\frac{n(n-1)}{(n-x)^2},$$

$$f_n''''(\bar{\mu})=\frac{n!}{(n-4)!(n-x)^4}\frac{1}{\sqrt{\pi}}\int dt\, t^4\left(1+i\frac{\bar{\mu}t}{n-x}\right)^{n-4}e^{-t^2}.$$

If x is not a positive integer, there exists C_1 independent of n, $0<C_1<\infty$, such that $f_n''(0)\geqslant -C_1$. Moreover, one has for $n\geqslant 4$ and using $\log(1+y)\leqslant y$

$$|f_n''''(\bar{\mu})|\leqslant\frac{n!}{(n-4)!(n-x)^4}\frac{1}{\sqrt{\pi}}\int dt\, t^4\left(1+\bar{\mu}\left|\frac{t}{n-x}\right|\right)^{n-4}e^{-t^2}$$

$$\leqslant\frac{n!}{(n-4)(n-x)^4}\frac{1}{\sqrt{\pi}}\int dt\, t^4 e^{(n-4)\bar{\mu}|t|/|n-x|}e^{-t^2}$$

$$\leqslant C_2<\infty,$$

with C_2 independent of n and of $\bar{\mu}$ in compact sets. This leads to the conclusion of the lemma.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 7 JULY 1999

Optimal cloning of pure states, testing single clones

M. Keyl[a)] and R. F. Werner[b)]
Institut für Mathematische Physik, TU Braunschweig, Mendelssohnstraße 3, 38106 Braunschweig, Germany

(Received 4 August 1998; accepted for publication 7 April 1999)

We consider quantum devices for turning a finite number N of d-level quantum systems in the same unknown pure state σ into $M>N$ systems of the same kind, in an approximation of the M-fold tensor product of the state σ. In a previous paper it was shown that this problem has a unique optimal solution, when the quality of the output is judged by arbitrary measurements, involving also the correlations between the clones. We show in this paper, that if the quality judgment is based solely on measurements of single output clones, there is again a unique optimal cloning device, which coincides with the one found previously. © *1999 American Institute of Physics.* [S0022-2488(99)03707-X]

I. INTRODUCTION

According to the well-known ''no-cloning theorem''[1] perfect copying of quantum information is impossible, i.e., there is no machine which takes a quantum system as input and produces two systems of the same kind, both of them indistinguishable from the input. However, from the point of view of practical applications in Quantum Information Theory this Theorem by itself is not very useful, because it only asserts that the cloning task cannot be performed *exactly*—but then no task can be performed exactly by real devices. The fundamental importance of the No-Cloning Theorem is expressed much better in stronger versions of the Theorem, which also give explicit lower bounds on the error made in any attempt to build a cloning device. Some such bounds have been established, as well.[2,3] Even more insight into the cloning problem is given by results showing how to minimize the error, i.e., how to construct *optimal* cloning devices.[4–8] Other recent related work can be found in Refs. 9–15.

In this paper we consider cloning devices, which take as input a certain number N of identically prepared systems, and produce a larger number M of systems as output. Again, the cloning task is to make the output state resemble as much as possible a state of M systems all prepared in the same state as the inputs. This variant of the problem is of interest as a ''quantum amplifier.'' It also has a better chance of reasonable success than a cloning device operating on single input systems: In the limit of many input systems the device can make a good statistical estimate of the input density matrix and hence produce arbitrarily good clones.

Different variants of this problem arise by different choices of the type of systems and the set of states which should be copied, e.g., pure versus mixed states, or a finite number of states arising in a cryptographic protocol. In the present paper we are exclusively concerned with the cloning of arbitrary unknown pure states.

A second choice to be made is the precise notion of approximation between the output states of the cloning device and the (inattainable) target state. Apart from technicalities the basic issue here is whether the full states are compared, or only the one-clone marginals. Approximation in the first sense means that the expectations of all observables, including those testing correlations and entanglement between different clones, are close in the two states being compared. On the other hand, approximation in the second sense means closeness of expectations of single clone observables only. Perhaps this second condition has more of the flavor of the No-Cloning Theo-

[a)]Electronic mail: M.Keyl@tu-bs.de
[b)]Electronic mail: R.Werner@tu-bs.de

rem, since in that theorem, too, the requirement is that each single (!) clone be indistinguishable from the input.

In Ref. 16 we showed that the pure state cloning problem with all-particle test criterion has a unique optimal solution. In this paper we show the same for the single-particle test criterion, and that the two optimal cloning devices are actually the same. The difference between the two results may not seem great. However, the result in the present paper required much heavier mathematical machinery, and we believe it to be considerably deeper. The reason is that one-particle tests by far do not exhaust the linear space of M-particle observables. In particular, all correlations of the cloner's output are ignored by the test, which would make a *unigue* optimal solution appear rather unlikely. Nevertheless, this is what we prove.

II. STATEMENT OF THE PROBLEM AND MAIN RESULT

Let us start with a precise formulation of the question we are going to consider. First of all, we will study throughout this paper only d-level systems with arbitrary but finite d. Hence the one-particle Hilbert space $\mathcal{H}$ we are using is $\mathcal{H}=\mathbb{C}^d$. The Hilbert space for the input to the cloning device is therefore the N-fold tensor product $\mathcal{H}^{\otimes N}$ of $\mathcal{H}$ with itself. In fact, because we only consider tensor powers of pure states as inputs, it suffices to take the subspace of $\mathcal{H}^{\otimes N}$ spanned by vectors of the form $\varphi^{\otimes N}$ with $\varphi\in\mathcal{H}$. This is precisely the ''Bose'' subspace $\mathcal{H}_+^{\otimes N}\subset\mathcal{H}^{\otimes N}$, i.e., the space of vectors invariant under all permutations. The output Hilbert space will be $\mathcal{H}^{\otimes M}$ with $M>N$. On this space we cannot impose an *a priori* symmetry restriction, although such a restriction will come out *a posteriori*, as a special property of optimal cloning devices.

A *cloning map* is a completely positive, unital map $T:\mathcal{B}(\mathcal{H}^{\otimes M})\rightarrow\mathcal{B}(\mathcal{H}_+^{\otimes N})$. This describes the action of the device on observables. Its (pre-)dual, describing the same operation in terms of states, will be denoted[17] by $T_*:\mathcal{B}_*(\mathcal{H}_+^{\otimes N})\rightarrow\mathcal{B}_*(\mathcal{H}^{\otimes M})$. If we identify states with density operators, this means that $\mathrm{tr}(\rho T(A))=\mathrm{tr}(T_*(\rho)A)$ for arbitrary density operators ρ and observables A. The input of the cloning device are N systems, prepared independently according to the same state σ. Thus the overall input state is $\sigma^{\otimes N}$. We will assume σ to be pure, i.e., the density matrix of σ is a one-dimensional projection onto a wave vector $\psi\in\mathcal{H}$, say. Then $\sigma^{\otimes N}$ is the projection onto the vector $\psi^{\otimes N}$. The output of the cloning device is the state $T_*(\sigma^{\otimes N})$, which is a (generally entangled) state of $M>N$ systems. Our aim is to design T so that the output states $T_*(\sigma^{\otimes N})$ approximate the product states $\sigma^{\otimes M}$.

The one particle observables, on which the comparison will be based, will be written as $a_{(k)}=\mathbb{1}^{\otimes(k-1)}\otimes a\otimes\mathbb{1}^{\otimes(M-k)}\in\mathcal{B}(\mathcal{H}^{\otimes M})$, for all $a\in\mathcal{B}(\mathcal{H})$. Thus the optimal cloning problem for arbitrary pure input states T is to make the expectations

$$\mathrm{tr}(a_{(k)}T_*(\sigma^{\otimes N}))=\mathrm{tr}(T(a_{(k)})\sigma^{\otimes N})=\langle\psi^{\otimes N},T(a_{(k)})\psi^{\otimes N}\rangle,$$

$$\mathrm{tr}(a_{(k)}\sigma^{\otimes M})=\mathrm{tr}(a\sigma)=\langle\psi,a\psi\rangle$$

as similar as possible for arbitrary one-particle observables a and one-particle vectors ψ. Of course, when taking a supremum over such differences, the size of a has to be constrained somehow. We will choose the constraint $0\leq a\leq\mathbb{1}$, which is to say that the above two expressions have an immediate interpretation as probabilities. The largest difference of such probabilities is now the error functional for cloning maps, which we will seek to minimize:

$$\Delta_{\mathrm{one}}(T)=\sup_{a,\psi,k}|\langle\psi^{\otimes N},T(a_{(k)})\psi^{\otimes N}\rangle-\langle\psi,a\psi\rangle|, \tag{1}$$

where the supremum is taken over all $\psi\in\mathcal{H}$ with $\|\psi\|=1$, all operators $a\in\mathcal{B}(\mathcal{H})$ with $0\leq a\leq\mathbb{1}$, and all integers $1\leq k\leq M$.

The corresponding quantity based on tests of the full output state (including correlations) is

$$\Delta_{\mathrm{all}}(T)=\sup_A\sup_{\sigma,\mathrm{pure}}|\mathrm{tr}(T(A)\sigma^{\otimes N})-\mathrm{tr}(A\sigma^{\otimes M})|,$$

where the supremum is taken over all $A \in \mathcal{B}(\mathcal{H}^{\otimes M})$ with $0 \leq A \leq \mathbb{1}$ and over all pure states $\sigma \in \mathcal{B}_*(\mathcal{H})$. Due to the properties of the trace norm $\|\cdot\|_1$ this functional can be expressed by

$$\Delta_{\mathrm{all}}(T) = \sup_{\sigma,\mathrm{pure}} \|T_*(\sigma^{\otimes N}) - \sigma^{\otimes M}\|_1 . \tag{2}$$

It turns out that there is exactly one cloning map $\hat{T}$ which minimizes this error functional. This can be proven with a minor adaptation of the arguments in Ref. 16, which start from a slightly different criterion, namely the maximization of the ''fidelity'' $\mathcal{F}(T_*) = \sup_{\sigma,\mathrm{pure}}(\sigma^{\otimes M} T_*(\sigma^{\otimes N}))$. The unique solution $T = \hat{T}$ minimizing (2), or maximizing $\mathcal{F}(T_*)$, is best expressed in terms of its action on states, i.e.,

$$\hat{T}_*(\rho) = \frac{d[N]}{d[M]} S_M(\rho \otimes \mathbb{1}^{M-N}) S_M . \tag{3}$$

Here $d[N] = \binom{d+N-1}{N}$ denotes the dimension of the symmetric subspace $\mathcal{H}_+^{\otimes N}$, S_M is the projection from $\mathcal{H}^{\otimes M}$ to $\mathcal{H}_+^{\otimes M}$, and ρ is an arbitrary density operator on $\mathcal{H}_+^{\otimes N}$. In Ref. 16 we also computed the one-site restriction of the output states of this cloner:

$$\mathrm{tr}(\hat{T}(a_k)\sigma^{\otimes N}) = \gamma(\hat{T})\sigma(a) + (1 - \gamma(\hat{T}))\mathrm{tr}(a)/d,$$

where

$$\gamma(\hat{T}) = \frac{N}{N+d} \frac{M+d}{M}$$

is the so-called Black Cow factor of $\hat{T}$, interpreted as a ''shrinking factor of the Poincaré sphere'' in the discussions of the qubit $(d=2)$ case. This makes it easy to verify the case of equality in the following Theorem, which is our main result.

Theorem 1: *For any cloning map* $T: \mathcal{B}(\mathcal{H}^{\otimes M}) \to \mathcal{B}(\mathcal{H}_+^{\otimes N})$ *we have*

$$\Delta_{\mathrm{one}}(T) \geq \frac{d-1}{d} \left| 1 - \frac{N}{N+d} \frac{M+d}{M} \right|$$

with equality iff $T = \hat{T}$ *with* $\hat{T}$ *from Eq. (3).*

III. FINDING THE OPTIMAL CLONING MAP

A. Reduction to the covariant case

In this section we will give the proof of our main theorem, apart from some group theoretical Lemmas, which will be proved in Appendix A. Throughout, the symmetry of sitewise unitary rotation of clones and input states will play a crucial role. The necessary background information on unitary representations of SU(d) will also be supplied in Appendix A.

We establish some notation first. By U(d) we will denote the group of unitary $d \times d$-matrices, i.e., the unitary group on our underlying one-particle space $\mathcal{H} \equiv \mathbb{C}^d$. Unitary representations of this group will be denoted by the letter π with suitable indices. $\pi_\square$ is the defining representation on $\mathbb{C}^d$, and its nth tensor power, acting on $\mathcal{H}^{\otimes N}$ by the operators $\pi_\square^{\otimes N}(u) = u^{\otimes N}$ is $\pi_\square^{\otimes N}$. The restriction of this representation to the symmetric subspace $\mathcal{H}_+^{\otimes N}$ will be denoted by π_N^+. Thus a cloning map $T: \mathcal{B}(\mathcal{H}^{\otimes M}) \to \mathcal{B}(\mathcal{H}_+^{\otimes N})$ is called U(d)-*covariant*, if

$$T(\pi_\square^{\otimes M}(u) A \pi_\square^{\otimes M}(u)^*) = \pi_N^+(u) T(A) \pi_N^+(u)^* . \tag{4}$$

This equation merely expresses that T does not prefer any direction in $\mathcal{H}$. It would be a natural initial assumption for good cloning devices but, of course, in our case it will come out as a result of the minimization: $\hat{T}$ from Eq. (3) is obviously covariant, because S_M commutes with all $\pi_\square^{\otimes M}(u)$. It is convenient to state the covariance condition as a fixed point property: We define the action τ of unitary rotations on cloning maps by

$$(\tau_u T)(A) = \pi_N^+(u)^* T(\pi_\square^{\otimes M}(u) A \pi_\square^{\otimes M}(u)^*) \pi_N^+(u), \tag{5}$$

so that T is covariant iff $\tau_u(T) = T$ for all $u \in U(d)$. We denote by $\overline{T}$ the average of $\tau_u T$ with respect to u, i.e.,

$$\overline{T} = \int du\ \tau_u(T), \tag{6}$$

where ''du'' denotes the normalized Haar measure on $\mathrm{U}(d)$.

The fact that the cloning error Δ_{one} does not single out a direction on $\mathcal{H}$ either is expressed by the—easily verified—equation

$$\Delta_{\mathrm{one}}(\tau_u T) = \Delta_{\mathrm{one}}(T). \tag{7}$$

Similarly, we can get an estimate of $\Delta_{\mathrm{one}}(\overline{T})$: The functional Δ_{one} is defined as the supremum of a set of convex expressions in T. Therefore, it is convex, and $\Delta_{\mathrm{one}}(\overline{T}) \leqslant \Delta_{\mathrm{one}}(T)$. So as long as we are only interested in finding *some* cloning map with minimal Δ_{one}, we may restrict attention to covariant ones.

There is a similar simplification, which we can make ''without loss of cloning quality'': Δ_{one} is invariant under a change of the ordering of the clones. That is to say, if $V:\mathcal{H}^{\otimes M} \to \mathcal{H}^{\otimes M}$ is a permutation operator, and if we define $\tau_V T$ by $(\tau_V T)(A) = T(VAV^*)$, we may replace T by its average over permutations without loss of cloning quality. That is, we may assume that $\tau_V T = T$ for all permutations V. We will refer to this property as *permutation invariance*.

Our strategy is now to assume $\mathrm{U}(d)$-covariance and permutation invariance of T, and to show that there is a unique solution to the variational problem with these additional properties. The above convexity argument then implies that no other cloning map can do better. But since the functional Δ_{one} is not strictly convex, we will need an extra step to establish uniqueness. This we will do in Sec. III F by showing that any cloning map whose mean is the optimal covariant cloner has to be covariant itself.

B. Reduction to the extremal covariant case

The functional Δ_{one} involves only operators $T(A)$ with A of the special form $A = a_{(k)} = \mathbb{1}^{\otimes(k-1)} \otimes a \otimes \mathbb{1}^{\otimes(M-k)} \in \mathcal{B}(\mathcal{H}^{\otimes M})$. Now due to permutation invariance $T(a_{(k)})$ does not depend on k, and we have

$$T(a_{(k)}) = \frac{1}{M} T\left(\sum_k a_{(k)} \right). \tag{8}$$

What makes Eq. (8) useful is that on the right-hand side T is now applied to one of the generators of the representation $\pi_\square^{\otimes N}$: we have $\exp(i\Sigma_{k=1}^M a_{(k)}) = (\exp(ia))^{\otimes M}$. Because T is covariant, we can determine how the operators in Eq. (8) transform under $\mathrm{U}(d)$-rotations:

$$\pi_N^+(u) T(a_{(k)}) \pi_N^+(u)^* = T((uau^*)_{(k)}), \tag{9}$$

where the multiplication of a and u on the right-hand side is in the $d \times d$-matrices. This property fixes the ''transformation behavior'' of the operators $T(a_{(k)})$, and as we will see, this essentially fixes the tuple of operators $T(a_{(k)})$. Of course, $a = \mathbb{1}$ in (9) simply leads to $T(\mathbb{1}_{(k)}) = T(\mathbb{1}) = \mathbb{1}$. The operator $i\mathbb{1}$ is the (anti-Hermitian) generator of the subgroup of unitaries multiplying each vector with the same phase. More interesting are the generators of $\mathrm{SU}(d)$, in which such trivial phases have been eliminated. These generators, in other words the Lie algebra $\mathfrak{su}(d)$, are exactly the traceless anti-Hermitian $d\times d$-matrices. In the qubit case ($d=2$) $\mathfrak{su}(2)$ is spanned by the Pauli matrices (multiplied by i), and 3-tuples of operators transforming like the generators are known in physics literature as ''vector operators.'' It is well-known that, due to the simple reducibility of SU(2), each irreducible representation of SU(2) contains exactly one vector operator (up to a factor), namely the generators (angular momentum operators) of the representation themselves. So all operators $T(a_{(k)})$ are determined by the single numerical factor relating the operators $T(a_{(k)})$ to the generators of the irreducible representation π_N^+.

It turns out that the same idea works in the SU(d)-case for arbitrary d. In order to state it precisely, we need a notation for the Lie algebra representation associated with a unitary representation of a Lie group. We define $\partial\pi(X)$ to be the anti-Hermitian generator of the one-parameter subgroup generated by X, i.e.,

$$\partial\pi(X)=\frac{d}{dt}\,\pi(e^{tX})\bigg|_{t=0}. \tag{10}$$

Then the desired property of a representation is stated in the following definition:

Definition 2: Let $\pi:G\to\mathcal{B}(\mathcal{H}_\pi)$ *be a finite dimensional unitary representation of a Lie group* G *with Lie algebra* $\mathfrak{g}$. *Then* $\mathfrak{g}$ *is said to be nondegenerate in* $\mathcal{B}(\mathcal{H}_\pi)$ *with respect to* π, *if any linear operator* $L:\mathfrak{g}\to\mathcal{B}(\mathcal{H}_\pi)$ *with the covariance property* $\pi(g)L(X)\pi(g)^*=L(gXg^{-1})$ *is of the form* $L(X)=\lambda\,\partial\pi(X)$, *for some factor* $\lambda\in\mathbb{C}$.

As we argued above, $\mathfrak{su}(2)$ is nondegenerate in *every* irreducible representation of SU(2). However, for $d\geq 3$ we can find representations containing degenerate copies of the generators, and we have to make sure that the special representations occurring in the present problem are of the ''good'' kind. This is the content of the following Lemma, proved in the Appendix.

Lemma 3: $\mathfrak{su}(d)$ *is nondegenerate in* $\mathcal{B}(\mathcal{H}_+^{\otimes N})$ *with respect to* π_N^+.

Corollary 4: Let $\pi:U(d)\to\mathcal{B}(\mathcal{H}_\pi)$ *be a unitary representation, and let* $T:\mathcal{B}(\mathcal{H}_\pi)\to\mathcal{B}(\mathcal{H}_+^{\otimes N})$ *be a completely positive normalized and* U(d)*-covariant map*, i.e., $T(\pi(u)A\pi(u)^*)=\pi_N^+(u)T(A)\pi_N^+(u)^*$. *Then there is a number ω(T) such that*

$$T(\partial\pi(a))=\omega(T)\sum_{k=1}^{N}a_{(k)},$$

for every $a\in\mathcal{B}(\mathcal{H})$ *with* $\mathrm{tr}(a)=0$.

Given $\omega(T)$ for $\pi=\pi_\square^{\otimes M}$, we can compute the cloning error $\Delta_{\mathrm{one}}(T)$ as follows: Given $a\in\mathcal{B}(\mathcal{H})$ with $0\leq a\leq\mathbb{1}$, we can write $a=\alpha\mathbb{1}+a'$ with $\mathrm{tr}\,a'=0$. Then

$$T(a_{(k)})=\alpha\mathbb{1}+\frac{1}{M}T\left(\sum_{l=1}^{M}a'_{(l)}\right)=\alpha\mathbb{1}+\frac{\omega(T)}{M}\left(\sum_{l=1}^{N}a'_{(l)}\right)$$

and with $a'=a-\alpha\mathbb{1}$ and $\alpha=(\mathrm{tr}\,a)/d$

$$T(a_{(k)})=\frac{\mathrm{tr}\,a}{d}\left(1-\frac{N\omega(T)}{M}\right)\mathbb{1}+\frac{\omega(T)}{M}\left(\sum_{l=1}^{N}a_{(l)}\right).$$

In any state $\psi\in\mathcal{H}$ we get

$$\langle\psi,a\psi\rangle-\langle\psi^{\otimes N},T(a_{(k)})\psi^{\otimes N}\rangle=(1-\gamma(T))\left(\langle\psi,a\psi\rangle-\frac{\mathrm{tr}\,a}{d}\right),$$

where $\gamma(T)=(N/M)\omega(T)$ is the Black-Cow factor already mentioned in Sec. II. With

$$\sup_{\psi,a}\left(\langle\psi,a\psi\rangle-\frac{\operatorname{tr}a}{d}\right)=\frac{d-1}{d}$$

we get

$$\Delta_{\rm one}(T)=\frac{d-1}{d}\left|1-\frac{N}{M}\,\omega(T)\right|=\frac{d-1}{d}\left|1-\gamma(T)\right|. \tag{11}$$

We remark that the largest possible $\omega(T)$, to be determined below, still makes the second term in the absolute value less than 1, so we could omit the absolute value signs. In any case, we will only seek to maximize $\omega(T)$ from now on, ignoring the possibility of $\omega(T)>M/N$, anticipating that it will be ruled out by the result of the maximization anyway.

An important observation about the Corollary and formula (11) is that ω is clearly an *affine* functional on the convex set of covariant cloning maps (i.e., ω respects convex combinations). Whereas we previously used the convexity of $\Delta_{\rm one}$ to conclude that averaging over rotations and permutations (and hence a move toward the interior of the convex set of cloning maps) generally improves the cloning quality, we now see that the optimum can be sought, as for any affine functional, on the extreme boundary of the subset of covariant cloning maps. Therefore our next steps will be aimed at the determination of the extremal $\mathrm{U}(d)$-covariant and permutation invariant cloning maps, and, subsequently the solution of the variational problem for these extremal cases.

C. Convex decomposition of covariant cloning maps

For the first reduction step we use the close connection between the permutation operators on $\mathcal{H}^{\otimes M}$ and the representation $\pi_{\square}^{\otimes M}$. Let $(\pi_{\square}^{\otimes M})'$ denote the algebra of all operators on $\mathcal{H}^{\otimes M}$ commuting with all $\pi_{\square}^{\otimes M}(u)\equiv u^{\otimes M}$. This algebra consists precisely of the linear combinations of permutation unitaries (see Theorem IX.11.5 in Ref. 18). So consider a reduction of $\pi_{\square}^{\otimes M}$ into irreducibles, i.e., an orthogonal decomposition of the identity into minimal projections $E_\alpha \in(\pi_{\square}^{\otimes M})'$. Then due to covariance the operators $T(E_\alpha)$ commute with all $\pi_N^+(u)$, and because the latter representation is irreducible, they must be multiples of the identity, $T(E_\alpha)=r_\alpha\mathbb{1}$, say. Because $T(VA)=T(AV)$ for permutation operators V, we also have $T(AE_\alpha)=T(E_\alpha AE_\alpha)$. Hence

$$T_\alpha(A)=r_\alpha^{-1}T(E_\alpha AE_\alpha) \tag{12}$$

is a legitimate cloning map in its own right (provided $r_\alpha\neq 0$). Moreover,

$$T(A)=\sum_\alpha T(AE_\alpha)=\sum_\alpha T(E_\alpha AE_\alpha)=\sum_\alpha r_\alpha T_\alpha(A) \tag{13}$$

is a convex decomposition of the given T into such summands. Maximizing $\omega(T) =\Sigma_\alpha r_\alpha\omega(T_\alpha)$ thus means concentrating the coefficients r_α on those α, for which $\omega(T_\alpha)$ is maximal. At this stage it is perhaps already plausible that only the summand T_α, for which $E_\alpha =S_M$ is the projection onto the symmetric subspace, will give the best $\omega(T_\alpha)$, because this is the space supporting the pure states $\sigma^{\otimes M}$ the cloner is supposed to approximate. In fact, for the optimization of $\Delta_{\rm all}$ in Ref. 16 this idea leads directly to a simple solution. In the present case we found no direct proof of this plausible statement.

We therefore have to enter into the further convex decomposition of each T_α. The output states of this cloning map are supported by $\mathcal{H}_\alpha\equiv E_\alpha\mathcal{H}^{\otimes M}$, and we will restrict T_α accordingly, i.e., we consider it as a covariant map $T_\alpha:\mathcal{B}(\mathcal{H}_\alpha)\rightarrow\mathcal{B}(\mathcal{H}_+^{\otimes N})$, which is covariant with respect to the restricted representation $\pi_\alpha=\pi^{\otimes M}\upharpoonright\mathcal{H}_\alpha$ and π_N^+.

As for any completely positive map, the convex decompositions of T_α are governed by the Stinespring dilation.[19] Since we are looking, more specifically, for decompositions into covariant completely positive maps, we have to invoke a ''covariant'' version of the Stinespring dilation Theorem,[20] which is stated in Appendix B for the convenience of the reader. According to this

Theorem we can write a covariant completely positive $T_\alpha:\mathcal{B}(\mathcal{H}_\alpha)\to\mathcal{B}(\mathcal{H}_+^{\otimes N})$ as $T_\alpha(A)=V^*(A\otimes\mathbb{1}_\mathcal{K})V$, where $\mathcal{K}$ is some auxiliary Hilbert space carrying a unitary representation $\tilde{\pi}:\mathrm{U}(d)\to\mathcal{B}(\mathcal{K})$, and $V:\mathcal{H}_+^{\otimes N}\to\mathcal{H}_\alpha\otimes\mathcal{K}$ is an isometry intertwining the respective representations, i.e.,

$$V\pi_N^+(u)=(\pi_\alpha(u)\otimes\tilde{\pi}(u))V. \tag{14}$$

The convex reduction theory of T_α is now the same as the reduction theory of $\tilde{\pi}$ into irreducibles: if F_β is a minimal projection in the algebra $\tilde{\pi}'$, and hence $\tilde{\pi}\upharpoonright F_\beta\mathcal{K}$ is irreducible, then $A\mapsto V^*(A\otimes F_\beta)V$ is a covariant map, which cannot be further decomposed into a sum of covariant completely positive maps (see Appendix B). Note that $V^*(\mathbb{1}\otimes F_\beta)V$ commutes with the irreducible representation π_N^+, so that once again this summand is normalized up to a factor: $V^*(\mathbb{1}\otimes F_\beta)V=r_\beta\mathbb{1}$. Therefore $T_\alpha=\Sigma_\beta r_\beta T_{\alpha\beta}$, where each $T_{\alpha\beta}(A)=r_\beta^{-1}V^*(A\otimes F_\beta)V$ is again an admissible cloning map. The following statement summarizes the result of the decomposition theory of T.

Proposition 5: Let $T:\mathcal{B}(\mathcal{H}^{\otimes M})\to\mathcal{B}(\mathcal{H}_+^{\otimes N})$ *be a* $\mathrm{U}(d)$*-covariant and permutation invariant cloning map. Then* T *is a convex combination* $T=\Sigma_{\alpha\beta}r_{\alpha\beta}T_{\alpha\beta}$ *such that each* $T_{\alpha\beta}$ *is of the following special form:* $T_{\alpha\beta}(A)=V^*(A\otimes\mathbb{1}_\beta)V$*, where* V *is an intertwining isometry between* π_N^+ *and* $\pi_\alpha\otimes\pi_\beta$*, such that* $\pi_\alpha:\mathrm{U}(d)\to\mathcal{B}(\mathcal{H}_\alpha)$ *is an irreducible subrepresentation of* $\pi_\square^{\otimes M}$*, and* $\pi_\beta:\mathrm{U}(d)\to\mathcal{B}(\mathcal{H}_\beta)$ *is also an irreducible unitary representation.*

This Proposition summarizes all that is needed for the further treatment of the variational problem. However, we could have made a slightly stronger statement by eliminating the nonuniqueness introduced by the choice of the minimal projections E_α. If the subrepresentations π_α and $\pi_{\alpha'}$ are unitarily equivalent, then they can be connected by a unitary, which is again a linear combination of permutations. Hence the contribution of the term $r_\alpha T_\alpha=\Sigma_\beta r_{\alpha\beta}T_{\alpha\beta}$ to $\omega(T)$ depends only on the isomorphism type of π_α.

What we cannot assert in general, however, is that V is determined by the isomorphism types of π_α and π_β: Among the groups $\mathrm{SU}(d)$ only $d=2$ is ''simply reducible,'' which means that the space of intertwiners between π_γ and $\pi_\alpha\otimes\pi_\beta$ is at most one dimensional for arbitrary irreducible representations π_α, π_β, π_γ. In Sec. III D we will therefore focus on the qubit case, and show how to determine $\omega(T_{\alpha\beta})$ from the representations involved. This procedure will then be generalized to arbitrary d, and it will turn out that, perhaps surprisingly, in the general case $\omega(T_{\alpha\beta})$ also depends on π_α, π_β only up to unitary equivalence.

D. Maximizing ω in the case $d=2$

For $d=2$ the representations of SU(2) are conventionally labeled by their ''total angular momentum'' $j=0,1/2,1,\ldots$. The irreducible representation π_j has dimension $2j+1$, and is isomorphic to π_N^+ with $N=2j$ in the notation used above. For $j=1$ we get the three-dimensional representation isomorphic to the rotation group, which is responsible for the importance of this group in physics. In a suitable basis X_1, X_2, X_3 of the Lie algebra $\mathfrak{su}(2)$ we get the commutation relations $[X_1,X_2]=X_3$, and cyclic permutations of the indices thereof. In the $j=1$ representation $\partial\pi_1(X_k)$ generates the rotations around the k axis in 3-space. The Casimir operator of SU(2) is the square of this vector operator, i.e., $\tilde{\mathbf{C}}_2=\Sigma_{k=1}^3X_k^2$. In the representation π_j it is the scalar $j(j+1)$, i.e., if we extend the representation $\partial\pi$ of the Lie algebra to the universal enveloping algebra (which also contains polynomials in the generators), we get $\partial\pi_j(\tilde{\mathbf{C}}_2)=j(j+1)\mathbb{1}$. We can use this to determine $\omega(T_{\alpha\beta})$ for arbitrary irreducible representations. This computation can be seen as an elementary computation of a so-called $6j$-symbol (see also Ref. 21 for a context in which the same computation arises), but we will not need to invoke any of the $6j$-machinery.

So let V be an intertwining isometry between π_γ and $\pi_\alpha\otimes\pi_\beta$, where $\alpha,\beta,\gamma\in\{0,1/2,\ldots\}$ label irreducible representations. Then ω is defined by

$$\omega\cdot\partial\pi_\gamma(X_k)=V^*(\partial\pi_\alpha(X_k)\otimes\mathbb{1}_\beta)V. \tag{15}$$

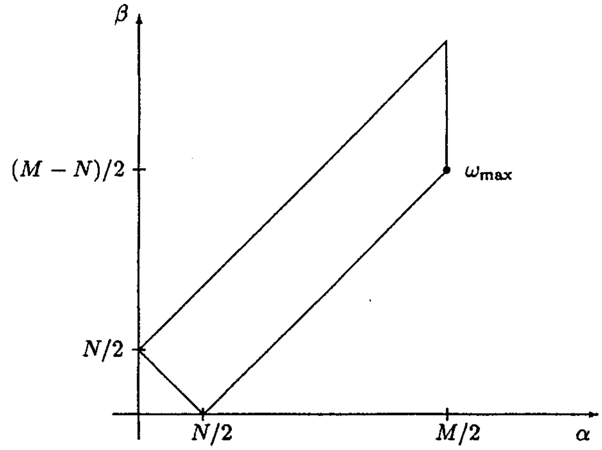

FIG. 1. Area of admissible pairs (α,β).

We multiply this equation by $\partial\pi_\gamma(X_k)$, use the intertwining property of V in the form $V\partial\pi_\gamma(X)=(\partial\pi_\alpha(X)\otimes\mathbb{1}_\beta+\mathbb{1}_\alpha\otimes\partial\pi_\beta(X))V$, and sum over k to get

$$\omega\cdot\partial\pi_\gamma(\tilde{\mathbf{C}}_2)=V^*(\partial\pi_\alpha(\tilde{\mathbf{C}}_2)\otimes\mathbb{1}_\beta)V+\sum_k V^*(\partial\pi_\alpha(X_k)\otimes\partial\pi_\beta(X_k))V.$$

The tensor product in the second summand can be re-expressed in terms of Casimir operators as

$$\sum_k (\partial\pi_\alpha(X_k)\otimes\partial\pi_\beta(X_k))=\frac{1}{2}\sum_k (\partial\pi_\alpha(X_k)\otimes\mathbb{1}_\beta+\mathbb{1}_\alpha\otimes\partial\pi_\beta(X_k))^2-\tfrac{1}{2}\partial\pi_\alpha(\tilde{\mathbf{C}}_2)\otimes\mathbb{1}_\beta-\tfrac{1}{2}\mathbb{1}_\alpha\otimes\partial\pi_\alpha(\tilde{\mathbf{C}}_2).$$

Inserting this into the previous equation, using the intertwining property once again, and inserting the appropriate scalars for $\partial\pi(\tilde{\mathbf{C}}_2)\equiv\tilde{C}_2(\pi)\mathbb{1}$, we find that $\omega\cdot\tilde{C}_2(\pi_\gamma)=\tilde{C}_2(\pi_\alpha)+\frac{1}{2}(\tilde{C}_2(\pi_\gamma)-\tilde{C}_2(\pi_\alpha)-\tilde{C}_2(\pi_\beta))$, and hence

$$\omega=\frac{1}{2}+\frac{\tilde{C}_2(\pi_\alpha)-\tilde{C}_2(\pi_\beta)}{2\tilde{C}_2(\pi_\gamma)}. \tag{16}$$

Note that we have only used the fact that the Casimir operator $\tilde{\mathbf{C}}_2$ is some fixed quadratic expression in the generators. This is also true for SU(d). Hence Eq. (16) also holds in the general case. In particular, we have shown that for the purpose of optimizing $\omega(T_{\alpha\beta})$ only the isomorphism types of π_α and π_β are relevant, but not the particular intertwiner V.

Specializing again to the case $d=2$, we find

$$\omega=\frac{1}{2}+\frac{\alpha(\alpha+1)-\beta(\beta+1)}{2\gamma(\gamma+1)}. \tag{17}$$

Here $\gamma=N/2$ is fixed by the number N of input systems. α is constrained by the condition that π_α must be a subrepresentation of $\pi_{j=1/2}^{\otimes M}$, which is equivalent to $\alpha\leq M/2$. Finally, β is constrained by the condition that there must be a nonzero intertwiner between π_γ and $\pi_\alpha\otimes\pi_\beta$. It is well known that this condition is equivalent to the inequality $|\alpha-\beta|\leq\gamma\leq\alpha+\beta$. This is the same as the ''triangle inequality'': the sum of any two of α,β,γ is larger than the third. The area of admissible pairs (α,β) is represented in Fig. 1.

Since $x \mapsto x(x+1)$ is increasing for $x \geqslant 0$, we maximize ω with respect to β in Eq. (17) if we choose β as small as possible, i.e., $\beta = |\alpha - \gamma|$. Then the numerator in Eq. (17) becomes

$$\alpha(\alpha+1) - \beta(\beta+1) = 2\alpha\gamma - \gamma^2 + \max\{\gamma, 2\alpha - \gamma\},$$

which is strictly increasing in α. Hence the maximum

$$\omega_{\max} = \frac{M+2}{N+2} \tag{18}$$

is attained for and only for $\alpha = M/2$ and $\beta = (M-N)/2$.

Note that the seemingly simpler procedure of first maximizing α and then minimizing β to the smallest value consistent with $\alpha = M/2$ leads to the same result, but is fallacious because it fails to rule out possibly larger values of ω in the lower triangle of the admissible region in Fig. 1. The same problem arises for higher d, and one has to be careful to find a maximization procedure which takes into account all constraints.

E. Maximizing ω in the general case

Let us generalize now the previous discussion to arbitrary but finite d. In this case irreducible representations of U(d) are labeled, according to Appendix A 2 by their highest weight $\mathbf{m} = (m_1, \ldots, m_d)$. Hence we can decompose $T: \mathcal{B}(\mathcal{H}^{\otimes M}) \to \mathcal{B}(\mathcal{H}_+^{\otimes N})$ as described in the Proposition into the sum $T = \Sigma_{(\mathbf{m},\mathbf{n}) \in W} r_{\mathbf{m},\mathbf{n}} T_{\mathbf{m},\mathbf{n}}$, taken over the set

$$W = \{(\mathbf{m},\mathbf{n}) \in \mathbb{Z}_+^d \times \mathbb{Z}_+^d \,|\, \pi_{\mathbf{m}} \subset \pi_{\square}^{\otimes M} \quad \text{and} \quad \pi_N^+ \subset \pi_{\mathbf{m}} \otimes \pi_{\mathbf{n}}\}.$$

Here $\mathbb{Z}_+^d$ is an abbreviation for the set of all possible highest weights of irreducible U(d) representations, i.e., $\mathbb{Z}_+^d = \{(m_1, \ldots, m_d) | m_1 \geqslant m_2 \geqslant \ldots \geqslant m_d\}$.

Our task is now to determine $(\mathbf{m},\mathbf{n}) \in W$ such that $\omega = \omega(T_{\mathbf{m},\mathbf{n}})$ becomes maximal. To this end we consider in analogy to (15) the equation

$$\omega \cdot \partial \pi_N^+(X) = V^*(\partial \pi_{\mathbf{m}}(X) \otimes \mathbb{1}_n) V, \qquad \forall X \in \mathfrak{su}(d), \tag{19}$$

where V is an intertwining isometry between π_N^+ and $\pi_{\mathbf{m}} \otimes \pi_{\mathbf{n}}$. Note that Eq. (19) is valid only for $X \in \mathfrak{su}(d)$ [and not for $X \in \mathfrak{u}(d)$ in general]. Hence we have to consider the second-order Casimir operator $\tilde{\mathbf{C}}_2$ of SU(d) which is given, according to Appendix A 5, by an expression of the form $\tilde{\mathbf{C}}_2 = \Sigma_{jk} g^{jk} X_j X_k$. This is all we needed in the derivation of Eq. (16) in the SU(2)-case. The generalization to arbitrary d hence reads

$$\omega = \frac{1}{2} + \frac{\tilde{C}_2(\pi_{\mathbf{m}}) - \tilde{C}_2(\pi_{\mathbf{n}})}{2\tilde{C}_2(\pi_N^+)}. \tag{20}$$

The concrete form of $\tilde{C}_2(\pi_{\mathbf{m}})$ as a function of the weights $\mathbf{m}$ is given in Eq. (A8), and will be needed only later. Since $\tilde{C}_2(\pi_N^+)$ is a positive constant we have to maximize the function

$$W \ni (\mathbf{m},\mathbf{n}) \mapsto F(\mathbf{m},\mathbf{n}) = \tilde{C}_2(\pi_{\mathbf{m}}) - \tilde{C}_2(\pi_n) \in \mathbb{Z} \tag{21}$$

on its domain W.

The first step in this direction is to reexpress $F(\mathbf{m},\mathbf{n})$ in terms of the U(d) Casimir operators $\mathbf{C}_2$ and $\mathbf{C}_1^2$. Note in this context that although Eq. (19) is, as already stated, valid only for $X \in \mathfrak{su}(d)$ the representations $\pi_{\mathbf{m}}$ and $\pi_{\mathbf{n}}$ are still U(d) representations. Hence we can apply the equation $\tilde{\mathbf{C}}_2 = \mathbf{C}_2 - (1/d)\mathbf{C}_1^2$ given in Appendix A 5:

$$F(\mathbf{m},\mathbf{n}) = C_2(\pi_{\mathbf{m}}) - C_2(\pi_{\mathbf{n}}) - \frac{1}{d}(C_1^2(\pi_{\mathbf{m}}) - C_1^2(\pi_{\mathbf{n}})). \tag{22}$$

This rewriting is helpful, because the invariants C_1 turn out to be independent of the variational parameters: Since $\pi_{\mathbf{m}} \subset \pi_{\square}^{\otimes M}$, and $\partial\pi_{\square}^{\otimes M}(\mathbb{1}_d) = M\mathbb{1}$, we also have $C_1(\pi_{\mathbf{m}}) = M$. On the other hand, the existence of an intertwining isometry V with $V\pi_N^+ = \pi_{\mathbf{m}} \otimes \pi_{\mathbf{n}} V$ implies

$$VC_1(\pi_N^+)\mathbb{1} = V\partial\pi_N^+(\mathbf{C}_1) = (\partial\pi_{\mathbf{m}}(\mathbf{C}_1)\otimes \mathbb{1}_{\mathbf{n}} + \mathbb{1}_{\mathbf{m}} \otimes \partial\pi_{\mathbf{n}}(\mathbf{C}_1))V = (C_1(\pi_{\mathbf{m}})\mathbb{1} + C_1(\pi_{\mathbf{n}})\mathbb{1})V$$

and therefore $C_1(\pi_N^+) = C_1(\pi_{\mathbf{m}}) + C_1(\pi_{\mathbf{n}})$. Since $C_1(\pi_N^+) = N$ and $C_1(\pi_{\mathbf{m}}) = M$ we get $C_1(\pi_{\mathbf{n}}) = N - M$. Inserting this into Eq. (22) we find the functional

$$F(\mathbf{m},\mathbf{n}) = F_1(\mathbf{m},\mathbf{n}) - \frac{2MN - N^2}{d}, \tag{23}$$

where only F_1 depends on the variational parameters, and is expressed explicitly [see Eq. (A7)] as

$$W \ni (\mathbf{m},\mathbf{n}) \mapsto F_1(\mathbf{m},\mathbf{n}) = C_2(\pi_{\mathbf{m}}) - C_2(\pi_{\mathbf{n}}) = \sum_{j=1}^{d} (m_j^2 - n_j^2) + \sum_{k=1}^{d} (d - 2k + 1)(m_k - n_k) \in \mathbb{Z}, \tag{24}$$

which remains to be maximized over W.

To do this we have to express the constraints defining the domain W more explicitly. We have already seen that $\mathbf{m} \in \mathbb{Z}_+^d$ has to satisfy the constraint $\Sigma_{j=1}^d m_j = M$. In addition we get, due to Eq. (A1), $m_d > 0$. To fix the constraints for $\mathbf{n}$ note that according to Eq. (A4) $\pi_N^+ \subset \pi_{\mathbf{m}} \otimes \pi_{\mathbf{n}}$ is equivalent to $\pi_{\mathbf{m}} \subset \pi_N^+ \otimes \pi_{\tilde{\mathbf{n}}}$. Here we have introduced $\tilde{\mathbf{n}} = (\tilde{n}_1, \ldots, \tilde{n}_d) = (-n_d, \ldots, -n_1)$ as a notation for the highest weight of the representation $\overline{\pi_{\mathbf{n}}}$ conjugate to $\pi_{\mathbf{n}}$ (i.e., $\overline{\pi_{\mathbf{n}}} = \pi_{\tilde{\mathbf{n}}}$). Now we can apply Eq. (A3) to get

$$\pi_N^+ \subset \pi_{\mathbf{m}} \otimes \pi_{\mathbf{n}} \Leftrightarrow \tilde{n}_k = m_k - \mu_k$$

with

$$0 \leq \mu_k \leq m_k - m_{k+1} \forall k = 1,\ldots,d-1, \quad \sum_{k=1}^{d} \mu_k = N.$$

In other words

$$W = \{(\mathbf{m},\mathbf{n}) | \tilde{\mathbf{n}} = \mathbf{m} - \mu, \quad \text{and } (\mathbf{m},\mu) \in W_1\}$$

with

$$W_1 = \left\{ (\mathbf{m},\mu) \in \mathbb{Z}_+^d \times \mathbb{Z}^d \,\middle|\, \sum_{k=1}^{d} m_k = M, \quad \sum_{k=1}^{d} \mu_k = N \quad \text{and } 0 \leq \mu_k \leq m_k - m_{k+1} \forall k = 1,\ldots,d-1 \right\}.$$

The function F_1 can now be re-expressed in terms the new variables $(\mathbf{m},\mu)$. To this end note that $C_2(\pi_{\mathbf{n}}) = C_2(\overline{\pi_{\mathbf{n}}}) = C_2(\pi_{\tilde{\mathbf{n}}})$. Hence we have

$$F_1(\mathbf{m},\mathbf{n}) = F_1(\mathbf{m},\tilde{\mathbf{n}}) = F_1(\mathbf{m},\mathbf{m} - \mu)$$

and therefore with Eq. (24):

$$F_1(\mathbf{m},\tilde{\mathbf{n}}) = \sum_{k=1}^{d} \mu_k(2m_k - 2k - \mu_k) + (d+1)\sum_{k=1}^{d} \mu_k = F_2(\mathbf{m},\mu) + (d+1)N \tag{25}$$

with the new function

$$W_1 \ni (\mathbf{m},\mu) \mapsto F_2(\mathbf{m},\mu) = \sum_{k=1}^{d} \mu_k(2m_k - 2k - \mu_k) \in \mathbb{Z}. \tag{26}$$

Hence we have reduced our problem to the following Lemma:

Lemma 6: The function $F_2 : W_1 \to \mathbb{Z}$ defined in Eq. (26) attains its maximum for and only for

$$\mathbf{m}_{\max} = (M,0,...,0) \quad \textit{and} \quad \mu_{\max} = \begin{cases} (N,0,...,0) & \textit{for } N \leqslant M \\ (M,0,...,0,N-M) & \textit{for } N \geqslant M. \end{cases}$$

Proof: We consider a number of cases in each of which we apply a different strategy for increasing F_2. In these procedures we consider d to be a variable parameter, too, because if $\mu_d = m_d = 0$, the further optimization will be treated as a special case of the same problem with d reduced by one.

Case A: $\mu_d > 0$, $\mu_i < m_i - m_{i+1}$ for some $i < d$.

In this case we apply the substitution $\mu_i \mapsto (\mu_i + 1)$, $\mu_d \mapsto (\mu_d - 1)$, which leads to the change

$$\delta F_2 = 2(-\mu_i + \mu_d + (d-i-1) + m_{i+1} - m_d) \geqslant 2(\mu_d + (d-i-1)) > 0$$

in the target functional. In this way we proceed until either all μ_i with $i < d$ satisfy the upper bound with equality (Case B below) or $\mu_d = 0$, i.e., Case C or Case D applies.

Case B: $\mu_d > 0$, $\mu_i = m_i - m_{i+1}$ for all $i < d$. In this case all μ_k, including μ_d, are determined by the m_k and by the normalization ($\mu_d = N - m_1 + m_d$). Inserting these values into F_2, and using the normalization conditions, we get $F_2(\mathbf{m},\mathbf{n}) = F_3(\mathbf{m}) - 2(M + dN) - N^2$ with

$$F_3(\mathbf{m}) = 2(N+d)m_1$$

constrained by

$$m_1 \geqslant \ldots \geqslant m_d \geqslant 0, \quad \sum_k m_k = M, \quad \text{and} \quad m_1 - m_d \leqslant N.$$

This defines a variational problem in its own right. Any step increasing m_1 at the expense of some other m_k increases F_2. This process terminates either when $M = m_1$, and all other $m_k = 0$. This is surely the case for $M < N$, because then $\mu_d = N - m_1 + m_d \geqslant N - M > 0$. This is already the final result claimed in the Lemma. On the other hand, the process may terminate because μ_d reaches 0 or would become negative. In the former case we get $\mu_d = 0$, and hence Case C or Case D. The latter case (termination at $\mu_d = 1$) may occur because the transformation $m_1 \mapsto (m_1 + 1)$, $m_d \mapsto (m_d - 1)$ changes $\mu_d = N - m_1 + m_d$ by -2. There are two basic situations in which changing both m_1 and m_d is the only option for maximizing F_3, namely $d = 2$ and $m_1 = m_2 = \cdots = m_d$. The first case is treated below as Case E. In the latter case we have $1 = N - m_1 + m_d = N$. Then the overall variational problem in the Lemma is trivial, because only one term remains, and one only has to maximize the quantity $2m_k - 2k - 1$, with trivial maximum at $k = 1$, $m_1 = M$.

Case C: $\mu_d = 0$, $m_d > 0$. For $\mu_d = 0$, the number m_d does not enter in the function F_2. Therefore, the move $m_d \mapsto 0$ and $m_1 \mapsto m_1 + m_d$, increases F_2 by $\mu_1 m_d \geqslant 0$. Note that this is always compatible with the constraints, and we end up in Case D.

Case D: $\mu_d = 0$, $m_d = 0$, $d > 2$. Set $d \mapsto (d-1)$. Note that we could now use the extra constraint $\mu_{d'} \leqslant m_{d'}$, where $d' = d - 1$. We will *not* use it, so in principle we might get a larger maximum. However, since we do find a maximizer satisfying all constraints, we still get a valid maximum.

Case E: $d = 2$, $\mu_1 = m_1 - m_2$, $\mu_2 = 1$. In this case $\mathbf{m} = (m_1, m_2)$ is completely fixed by the constraints. We have: $m_1 + m_2 = M$ and $\mu_1 + \mu_2 = m_1 - m_2 + 1 = N$, hence $m_1 - m_2 = N - 1$. This implies $2m_1 = M + N - 1$, $2m_2 = M - N + 1$ and since $m_2 \geqslant 0$ we get $M \geqslant N - 1$. If $M = N - 1$ holds we get $m_1 = N - 1 = M$, $m_2 = 0$ and consequently $\mu_1 = N - 1$. Together with $\mu_2 = 1 = N - M$ these are exactly the parameters where F_2 should take its maximum according to the Lemma. Hence assume $M \geqslant N$. In this case $\mu_2 = 1$ implies that F_2 becomes $NM - 3N - 4$, which is, due to $M \geqslant N$, strictly smaller than $F_2(M,0;N,0) = 2MN - N^2 - 2N$.

Uniqueness: In all cases just discussed the manipulations described lead to a strict increase of $F_2(\mathbf{m},\mu)$ as long as $(\mathbf{m},\mu) \neq (\mathbf{m}_{\max},\mu_{\max})$ holds. The only exception is Case C with $\mu_1 = 0$. In this situation there is a $1 < k < d$ with $\mu_k > 0$. Hence we can apply the maps $d \mapsto d-1$ (Case D) and $m_d \mapsto 0$ and $m_1 \mapsto m_1 + m_d$ (Case C) until we get $\mu_d \neq 0$ (i.e., d reaches k). Since $\mu_1 = 0$ the corresponding $(\mathbf{m},\mu)$ is not equal to $(\mathbf{m}_{\max},\mu_{\max})$. Therefore we can apply one of the manipulations described in Case A, Case B, or Case E which leads to a strict increase of $F_2(\mathbf{m},\mu)$. This shows that $F_2(\mathbf{m},\mu) < F_2(\mathbf{m}_{\max},\mu_{\max})$ as long as $(\mathbf{m},\mu) \neq (\mathbf{m}_{\max},\mu_{\max})$ holds. Consequently the maximum is unique. □

With this result and Eqs. (20), (21), (23), (25), and (26) we can easily calculate $\omega_{\max}$:

$$\omega_{\max} = \omega(\hat{T}) = \frac{M+d}{N+d}$$

and with (11) we get $\Delta(T) \geqslant \Delta(\hat{T})$ with $\Delta(\hat{T})$ from Theorem 1.

F. Proving uniqueness

One part of the uniqueness proof is already given above: There is only one optimal *covariant* cloning map, namely $\hat{T}$. This follows easily from the uniqueness of the maximum found in Lemma 6 and from the fact that the representation π_N^+ is contained exactly once in the tensor product $\pi_M^+ \otimes \overline{\pi_{M-n}^+}$ [see Eq. (A3) and the discussion in Sec. III C].

Suppose now that T is a noncovariant cloning map, which also attains the best value: $\Delta_{\text{one}}(T) = \Delta_{\text{one}}(\hat{T})$. Then we may consider the average $\overline{T}$ of T [see Eq. (6)], which is also optimal and, in addition, covariant. Therefore $\overline{T} = \hat{T}$. The uniqueness part of the proof thus follows immediately from the following proposition:

Proposition 7: Each completely positive, unital map $T: \mathcal{B}(\mathcal{H}^{\otimes M}) \rightarrow \mathcal{B}(\mathcal{H}_+^{\otimes N})$ satisfying the equation $\overline{T} = \hat{T}$ equals $\hat{T}$.

Proof: We trace back this statement to the main theorem of Ref. 16. To this end note that $\overline{T} = \hat{T}$ implies the equivalent equation for the preduals:

$$\overline{T_*} = \int \tau_u T_* \, du = \hat{T}_*,$$

where τ_u acts on T_* by

$$\tau_u T_*(\sigma) = \pi_{\square}^{\otimes M}(u)^* T_*(\pi_N^+(u)\sigma\pi_N^+(u)^*)\pi_{\square}^{\otimes M}(u).$$

Furthermore we know from the main theorem of Ref. 16 that $\text{tr}(\sigma^{\otimes M} T_*(\sigma^{\otimes N})) \leqslant d[N]/d[M]$ is true for all pure states $\sigma \in \mathcal{B}_*(\mathcal{H})$ and that equality holds iff $T = \hat{T}$. Consequently we have

$$\int \left(\frac{d[N]}{d[M]} - \text{tr}(\sigma^{\otimes M} \tau_u T(\sigma^{\otimes N})) \right) du = \frac{d[N]}{d[M]} - \text{tr}(\sigma^{\otimes M} \overline{T}_*(\sigma^{\otimes N})) = \frac{d[N]}{d[M]} - \text{tr}(\sigma^{\otimes M} \hat{T}_*(\sigma^{\otimes N})) = 0.$$

Since the integral on the left-hand site of this equation is taken over positive quantities the integrand has to vanish for all values of $u \in \text{U}(d)$. This implies $\text{tr}(\sigma^{\otimes M} T(\sigma^{\otimes N})) = d[N]/d[M]$ for all pure states $\sigma \in \mathcal{B}_*(\mathcal{H})$. However this is, according to Ref. 16, only possible if $T = \hat{T}$. □

ACKNOWLEDGMENTS

This paper is a response to the many discussions about the cloning problem one of us (R.F.W.) had with participants of the ISI Workshop on Quantum Computing in Torino in July 1997. We would like to thank D. Sondermann for a critical reading of the manuscript.

APPENDIX A: REPRESENTATIONS OF UNITARY GROUPS

Throughout this paper many arguments from representation theory of unitary groups are used. In order to fix the notation and to state the most relevant theorems we will recall in this appendix some well-known facts from representation theory of Lie groups. General references are the books of Barut and Raczka,[22] Zhelobenko,[23] and Simon.[18]

1. The groups and their Lie algebras

Let us consider first the group $\mathrm{U}(d)$ of all complex $d\times d$ unitary matrices. Its Lie algebra $\mathfrak{u}(d)$ can be identified with the Lie algebra of all anti-Hermitian $d\times d$ matrices. The exponential function is then given by the usual matrix exponential $X\mapsto\exp(X)$. $\mathfrak{u}(d)$ is a real Lie algebra. Hence we can consider its complexification $\mathfrak{u}(d)\otimes\mathbb{C}$ which coincides with the set of all $d\times d$ matrices and at the same time with the Lie algebra $\mathfrak{gl}(d,\mathbb{C})$ of the general linear group $\mathrm{GL}(d,\mathbb{C})$. In other words $\mathfrak{u}(d)$ is a real form of $\mathfrak{gl}(d,\mathbb{C})$. A basis of $\mathfrak{gl}(d,\mathbb{C})$ is given by the matrices $E_{jk}=|j\rangle\langle k|$.

The set of elements of $\mathrm{U}(d)$ with determinant one forms the subgroup $\mathrm{SU}(d)$ of $\mathrm{U}(d)$. Its Lie algebra $\mathfrak{su}(d)$ is the subalgebra of $\mathfrak{u}(d)$ consisting of the elements with zero trace. Hence the complexification $\mathfrak{su}(d)\otimes\mathbb{C}$ of $\mathfrak{su}(d)$ is the Lie algebra of trace-free matrices and coincides therefore with the Lie algebra $\mathfrak{sl}(d,\mathbb{C})$ of the special linear group $\mathrm{SL}(d,\mathbb{C})$. As well as in the $\mathrm{U}(d)$ case this means that $\mathfrak{su}(d)$ is a real from of $\mathfrak{sl}(d,\mathbb{C})$. The matrices E_{jk} are no longer a basis for $\mathfrak{sl}(d,\mathbb{C})$ since the E_{jj} are not trace free. Instead we have to consider E_{jk}, $j\neq k$ and $H_j=E_{jj}-E_{j+1,j+1}$, $j=1,...,d-1$. The difference between $\mathfrak{sl}(d,\mathbb{C})$ and $\mathfrak{gl}(d,\mathbb{C})$ is exactly the center of $\mathfrak{gl}(d,\mathbb{C})$, i.e., all complex multiples of the identity matrix. In other words we have $\mathfrak{gl}(d,\mathbb{C})=\mathfrak{sl}(d,\mathbb{C})\oplus\mathbb{C}\mathbb{1}$. A similar result holds for the real forms: $\mathfrak{u}(d)=\mathfrak{su}(d)\oplus\mathbb{R}\mathbb{1}$.

The (real) span of all iE_{jj}, $j=1,...,d$ is a subalgebra of $\mathfrak{u}(d)$ which is maximal Abelian, i.e., a Cartan subalgebra of $\mathfrak{u}(d)$. We will denote it in the following by $\mathfrak{t}(d)$ and its complexification by $\mathfrak{t}_{\mathbb{C}}(d)\subset\mathfrak{gl}(d,\mathbb{C})$. The intersection of $\mathfrak{t}(d)$ with $\mathfrak{su}(d)$ results in a Cartan subalgebra $\mathfrak{st}(d)$ of $\mathfrak{su}(d)$. We will denote the complexification by $\mathfrak{st}_{\mathbb{C}}(d)$. Again the two algebras $\mathfrak{t}(d)$ and $\mathfrak{st}(d)$ differ by the center of $\mathfrak{u}(d)$, i.e., $\mathfrak{t}(d)=\mathfrak{st}(d)\oplus\mathbb{R}\mathbb{1}$ and $\mathfrak{t}_{\mathbb{C}}(d)=\mathfrak{st}_{\mathbb{C}}(d)\oplus\mathbb{C}\mathbb{1}$ in the complexified case.

2. Representations

Consider now a finite-dimensional[24] representation $\pi:\mathrm{U}(d)\to\mathrm{GL}(N,\mathbb{C})$ of $\mathrm{U}(d)$. It is characterized uniquely by the corresponding representation $\partial\pi:\mathfrak{u}(d)\to\mathfrak{gl}(N,\mathbb{C})$ of its Lie algebra, i.e., we have $\pi(\exp(X))=\exp(\partial\pi(X))$. The representation $\partial\pi$ can be extended by complex linearity to a representation of $\mathfrak{gl}(d,\mathbb{C})$ which we will denote by $\partial\pi$ as well. Hence $\partial\pi$ leads to a representation π of the group $\mathrm{GL}(d,\mathbb{C})$. Similar notations we will adopt for representations of $\mathrm{SU}(d)$ and $\mathrm{SL}(d,\mathbb{C})$.

Assume now that π is an irreducible representation of $\mathrm{GL}(d,\mathbb{C})$. An infinitesimal weight of π (or simply a weight in the following) is an element λ of the dual of $\mathfrak{t}_{\mathbb{C}}^*(d)$ of $\mathfrak{t}_{\mathbb{C}}(d)$ such that $\partial\pi(X)x=\lambda(X)x$ holds for all $X\in\mathfrak{t}_{\mathbb{C}}(d)$ and for a nonvanishing $x\in\mathbb{C}^N$. The linear subspace $V_\lambda\subset\mathbb{C}^N$ of all such x is called the weight subspace of the weight λ. The set of weights of π is not empty and, due to irreducibility, there is exactly one weight $\mathbf{m}$, called the highest weight, such that $\partial\pi(E_{jk})x=0$ for all x in the weight subspace of $\mathbf{m}$ and for all $j,k=1,...,d$ with $j<k$. The representation π is (up to unitary equivalence) uniquely determined by its highest weight. On the other hand the weight $\mathbf{m}$ is uniquely determined by its values $\mathbf{m}(E_{jj})=m_j$ on the basis E_{jj} of $\mathfrak{t}_{\mathbb{C}}(d)$. We will express this fact in the following as ''$\mathbf{m}=(m_1,\ldots,m_d)$ is the highest weight of the representation π.'' For each analytic representation of $\mathrm{GL}(d,\mathbb{C})$ the m_j are integers satisfying the inequalities $m_1\geqslant m_2\geqslant\cdots\geqslant m_d$ and the converse is also true: each family of integers with this property defines the highest weight of an analytic, irreducible representation of $\mathrm{GL}(d,\mathbb{C})$.

In a similar way we can define weights and highest weights for representations of the group $SL(d,\mathbb{C})$ as linear forms on the Cartan subalgebra $\mathfrak{st}_{\mathbb{C}}(d)$. As in the $GL(d,\mathbb{C})$-case an irreducible representation π of $SL(d,\mathbb{C})$ is characterized uniquely by its highest weight $\mathbf{m}$. However we cannot evaluate $\mathbf{m}$ on the basis E_{jj} since these matrices are not trace free. One possibility is to consider an arbitrary extension of $\mathbf{m}$ to the algebra $\mathfrak{t}_{\mathbb{C}}(d)=\mathfrak{st}_{\mathbb{C}}(d)\oplus\mathbb{C}\mathbb{1}$. Obviously this extension is not unique. Therefore the values $\mathbf{m}(E_{jj})=m_j$ are unique only up to an additive constant. To circumvent this problem we will use usually the normalization condition $m_d=0$. In this case the integer m_j corresponds to the number of boxes in the jth row of the Young tableau usually used to characterize the irreducible representation π. Another possibility to describe the weight $\mathbf{m}$ is to use the basis H_j of $\mathfrak{st}_{\mathbb{C}}(d)$. We get a sequence of integers $l_j=\mathbf{m}(H_j)$, $j=1,...,d-1$. They are related to the m_j by $l_j=m_j-m_{j+1}$. Each sequence $l_1,\ldots,l_{d-1}$ defines the highest weight of an irreducible representation of $SL(d,\mathbb{C})$ iff the l_j are positive integers.

Finally consider the representation $\overline{\pi}$ conjugate to π, i.e., $\overline{\pi}(u)=\overline{\pi(u)}$. If π is irreducible the same is true for $\overline{\pi}$. Hence $\overline{\pi}$ admits a highest weight which is given by $(-m_d,-m_{d-1},\ldots,-m_1)$. If π is a $SU(d)$ representation we can apply the normalization $m_d=0$. Doing this as well for the conjugate representation we get $(m_1,m_1-m_{d-1},\ldots,m_1-m_2,0)$. In terms of Young tableaus this corresponds to the usual rule to construct the tableau of the conjugate representation: Complete the Young tableau of π to form a $d\times m_1$ rectangle. The complementary tableau rotated by 180° is the Young tableau of $\overline{\pi}$.

3. Tensor products of representations

Consider now two finite dimensional irreducible representations $\pi_{\mathbf{m}}$, $\pi_{\mathbf{n}}$ of $U(d)$ with highest weights $\mathbf{m},\mathbf{n}$. Their tensor product $\pi_{\mathbf{m}}\otimes\pi_{\mathbf{n}}$ is completely reducible. If r_π denotes the multiplicity of the irreducible representation π in $\pi_{\mathbf{m}}\otimes\pi_{\mathbf{n}}$ then this means that $\pi_{\mathbf{m}}\otimes\pi_{\mathbf{n}}=\oplus_\pi r_\pi\pi$. Hence to decompose the representation $\pi_{\mathbf{m}}\otimes\pi_{\mathbf{n}}$ we have to compute the integer valued functions $(\mathbf{m},\mathbf{n})\mapsto r_\pi(\mathbf{m},\mathbf{n})$. There are several general schemes to do this (see, e.g., Chap. XII of Ref. 23). However we are only interested in the following special cases. The highest weight of the representation $\pi_{\mathbf{1}}: U(d)\ni U\mapsto U\in GL(d,\mathbb{C})$ (denoted $\pi_{\square}$ in Sec. III A) is $\mathbf{1}=(1,0,...,0)$. Consider the N-fold tensor product of this representation. It can be decomposed as follows:

$$\pi_{\mathbf{1}}^{\otimes N}=\sum_{\substack{m_1+\cdots+m_d=N\\ m_d\geqslant 0}} r(m_1,\ldots,m_d)\,\pi_{m_1,\ldots,m_d}, \tag{A1}$$

where $\pi_{m_1,\ldots,m_d}$ denotes the irreducible representation with highest weight $(m_1,\ldots,m_d)$. The coefficients $r(m_1,\ldots,m_d)$ are determined by the following recurrence relation:

$$r(m_1,\ldots,m_d)=r(m_1-1,...,m_d)+r(m_1,m_2-1,...,m_d)+\cdots+r(m_1,\ldots,m_d-1). \tag{A2}$$

Consider now the N-fold symmetric tensor product of $\pi_{\mathbf{1}}$ (denoted π_N^+ in Sec. III A). It is irreducible with highest weight $N\mathbf{1}=(N,0,...,0)$ (hence $\pi_N^+=\pi_{N\mathbf{1}}$). The tensor product of this representation with an arbitrary irreducible representation $\pi_{\mathbf{m}}$ [with highest weight $\mathbf{m}=(m_1,\ldots,m_d)$] is

$$\pi_{N\mathbf{1}}\otimes\pi_{\mathbf{m}}=\sum_{\substack{0\leqslant\mu_{k+1}\leqslant m_k-m_{k+1}\\ \mu_1+\cdots+\mu_d=N}} \pi_{m_1+\mu_1,\ldots,m_d+\mu_d}. \tag{A3}$$

From Eq. (A3) we also get a condition for $\pi_{N\mathbf{1}}$ to be contained in an arbitrary tensor product $\pi_{\mathbf{m}}\otimes\pi_{\mathbf{n}}$ which we need in Sec. III E: For arbitrary weights $\mathbf{m},\mathbf{n},\mathbf{p}$ we have

$$\pi_{\mathbf{m}}\subset\pi_{\mathbf{n}}\otimes\pi_{\mathbf{p}}\Leftrightarrow\pi_{\mathbf{n}}\subset\overline{\pi_{\mathbf{p}}}\otimes\pi_{\mathbf{m}}. \tag{A4}$$

If two irreducible representations $\pi_{\mathbf{m}}$, $\pi_{\mathbf{n}}$ of SU(d) are given we can characterize them, as described above, by their highest weights $\mathbf{m}=(m_1,\ldots,m_d)$ and $\mathbf{n}=(n_1,\ldots,n_d)$ using the normalizations $m_d=0$ and $n_d=0$. After applying the stated theorems to the tensor product of the corresponding U(d) representations we can restrict the summands in the resulting spectral decomposition back to SU(d), i.e., we renormalize the highest weights $(m_1,\ldots,m_d)$ to the $m_d=0$ case.

4. Nondegeneracy of $\mathfrak{su}(d)$

We are now ready to discuss the group theoretic part of the proof of our main theorem, i.e., Lemma 3 which we have only stated in Sec. III. According to Definition 2 we have to show that each linear operator $L:\mathfrak{su}(d)\to\mathcal{H}_+^{\otimes N}$ with the covariance property

$$\pi_N^+(g)L(X)\pi_N^+(g^{-1})=L(gXg^{-1}) \tag{A5}$$

is of the form $L(X)=\lambda\partial\pi_+^N(X)$ with a constant factor λ. Here π_N^+ is the irreducible representation of SU(d) introduced in Sec. III A. (Hence we have $\pi_N^+=\pi_{N\mathbf{1}}$ using the notation introduced in Appendix A 3.)

To reformulate this statement note first that the map $g\mapsto\pi_N^+(g)\cdot\pi_N^+(g^{-1})$ can be interpreted as a unitary representation of SU(d) on the representation space $\mathcal{H}_+^{\otimes N}\otimes\mathcal{H}_+^{\otimes N}$. In fact it is (unitarily equivalent to) the tensor product $\pi_N^+\otimes\overline{\pi_N^+}$. Since $\mathrm{SU}(d)\ni g\mapsto g\cdot g^{-1}\in\mathcal{B}(\mathfrak{su}(d))$ is the adjoint representation of SU(d) this implies that each map X satisfying (A5) intertwines $\pi_N^+\otimes\overline{\pi_N^+}$ and the adjoint representation Ad. Note second that the representation $\partial\pi_N^+$ of the Lie algebra $\mathfrak{su}(d)$ satisfies Eq. (A5) in an obvious way (with $\lambda=1$) hence we have to show that all such intertwiners are proportional, or in other words that Ad is contained in $\pi_N^+\otimes\overline{\pi_N^+}$ exactly once.

Let us discuss now the tensor product $\pi_N^+\otimes\overline{\pi_N^+}$. The irreducible representation π_N^+ has highest weight $(N,0,...,0)$ (see Appendix A 2) and consequently the highest weight of its conjugate is $(N,\ldots,N,0)$. We can apply now Eq. (A3), which shows that the adjoint representation whose highest weight is $(2,1,...,1,0)$ is contained in $\pi_N^+\otimes\overline{\pi_N^+}$ exactly once. This shows together with our previous discussion that $\mathfrak{su}(d)$ is nondegenerate in $\mathcal{H}_+^{\otimes N}$ with respect to π_N^+.

5. The Casimir invariants

To each Lie algebra $\mathfrak{g}$ we can associate its universal enveloping algebra $\mathfrak{G}$. It is defined as the quotient of the full tensor algebra $\oplus_{n\in\mathbb{N}_0}\mathfrak{g}^{\otimes n}$ with the two sided ideal $\mathfrak{I}$ generated by $X\otimes Y-Y\otimes X-[X,Y]$, i.e., $\mathfrak{G}$ is an associative algebra. The original Lie algebra $\mathfrak{g}$ can be embedded in its enveloping algebra $\mathfrak{G}$ by $\mathfrak{g}\ni X\mapsto X+\mathfrak{I}\in\mathfrak{G}$. The Lie bracket is then simply given by $[X,Y]=XY-YX$. Moreover $\mathfrak{G}$ is algebraically generated by $\mathfrak{g}$ and $\mathbb{1}$. Hence each representation $\partial\pi$ of $\mathfrak{g}$ generates a unique representation $\partial\pi$ of $\mathfrak{G}$ simply by $\partial\pi(X_1\cdots X_k)=\partial\pi(X_1)\cdots\partial\pi(X_k)$. If $\partial\pi$ is irreducible the induced representation $\partial\pi$ is irreducible as well.

We are interested not in the whole algebra but only in its center $\mathfrak{Z}(\mathfrak{G})$, i.e., the subalgebra consisting of all $Z\in\mathfrak{G}$ commuting with all elements of $\mathfrak{G}$. The elements of $\mathfrak{Z}(\mathfrak{G})$ are called central elements or Casimir elements. If $\partial\pi$ is a representation of $\mathfrak{G}$ the representatives $\partial\pi(Z)$ of Casimir elements commute with all other representatives $\partial\pi(X)$. This implies for irreducible representations that all $\partial\pi(Z)$ are multiples of the identity.

Consider now the case $\mathfrak{g}=\mathfrak{gl}(d,\mathbb{C})$. In this case we can identify the enveloping algebra $\mathfrak{G}$ with the set of all left invariant differential operators on GL($d,\mathbb{C}$) (a similar statement is true for any Lie group). Of special interest for us are the Casimir elements belonging to operators of first and second order. Using the standard basis E_{ij} of $\mathfrak{gl}(d,\mathbb{C})$ introduced in Appendix A 1 they are given by

$$\mathbf{C}_1=\sum_{j=1}^{d}E_{jj}\,,\quad \mathbf{C}_2=\sum_{j,k=1}^{d}E_{jk}E_{kj}\,.$$

Of course $\mathbf{C}_1^2$ is as well of second order and it is linearly independent of $\mathbf{C}_2$. Hence each second-order Casimir element of $\mathfrak{G}$ is a linear combination of $\mathbf{C}_2$ and $\mathbf{C}_1^2$.

If $\partial\pi$ is an irreducible representation of $\mathfrak{gl}(d,\mathbb{C})$ with highest weight $(m_1,\dots,m_d)$ it induces, as described above, an irreducible representation $\partial\pi$ of $\mathfrak{G}$ and the images of $\partial\pi(\mathbf{C}_1)$ and $\partial\pi(\mathbf{C}_2)$ are multiples of the identity, i.e., $\partial\pi(\mathbf{C}_1)=C_1(\pi)\mathbb{1}$ and $\partial\pi(\mathbf{C}_2)=C_2(\pi)\mathbb{1}$ with

$$C_1(\pi)=\sum_{j=1}^{d} m_j, \quad C_2(\pi)=\sum_{j=1}^{d} m_j^2+\sum_{j<k}(m_j-m_k). \tag{A6}$$

Let us discuss now the Casimir elements of $\mathrm{SL}(d,\mathbb{C})$. Since $\mathrm{SL}(d,\mathbb{C})$ is a subgroup of $\mathrm{GL}(d,\mathbb{C})$ its enveloping algebra $\mathfrak{S}$ is a subalgebra of $\mathfrak{G}$. However the corresponding Lie algebras differ only by the center of $\mathfrak{gl}(d,\mathbb{C})$. Hence the center $\mathfrak{Z}(\mathfrak{S})$ of $\mathfrak{G}$ is a subalgebra of $\mathfrak{Z}(\mathfrak{G})$. Since $\mathfrak{sl}(d,\mathbb{C})$ is simple there is no first-order Casimir element and there is only one second-order Casimir element $\tilde{\mathbf{C}}_2$ which is therefore a linear combination $\tilde{\mathbf{C}}_2=\mathbf{C}_2+\alpha\mathbf{C}_1^2$ of $\mathbf{C}_1^2$ and $\mathbf{C}_2$. Obviously the factor α is uniquely determined by the condition that the expression

$$\tilde{C}_2(\pi)=C_1(\pi)+\alpha C_1^2(\pi)=\sum_{j=1}^{d} m_j^2+\sum_{j<k}(m_j-m_k)+\alpha\left(\sum_{j=1}^{d} m_j\right)^2 \tag{A7}$$

with $\partial\pi(\tilde{\mathbf{C}}_2)=\tilde{C}_2(\pi)\mathbb{1}$ is invariant under the renormalization $(m_1,\dots,m_d)\mapsto(m_1+\mu,\dots,m_d+\mu)$ with an arbitrary constant μ. Straightforward calculations show that $\alpha=-1/d$. Hence we get $\tilde{\mathbf{C}}_2=\mathbf{C}_2-(1/d)\mathbf{C}_1^2$ and

$$\tilde{C}_2(\pi)=\frac{1}{d}\left((d-1)\sum_{j=1}^{d} m_j^2-\sum_{j\neq k}^{d} m_j m_k+d\sum_{j<k}(m_j-m_k)\right). \tag{A8}$$

Alternatively $\tilde{\mathbf{C}}_2$ can be expressed in terms of a basis $(X_j)_j$ of $\mathfrak{sl}(d,\mathbb{C})$. In fact there is a symmetric second rank tensor $g^{jk}X_j\otimes X_k\in\mathfrak{sl}(d,\mathbb{C})\otimes\mathfrak{sl}(d,\mathbb{C})$ such that $\tilde{\mathbf{C}}_2$ coincides with the equivalence class of g^{jk} in $\mathfrak{S}$. In other words $\tilde{\mathbf{C}}_2=\Sigma_{jk}g^{jk}X_jX_k$ holds which leads to

$$\tilde{C}_2(\pi)\mathbb{1}=\sum_{jk} g^{jk}\partial\pi(X_i)\partial\pi(X_j)$$

for an irreducible representation π of $\mathrm{SU}(d)$.

APPENDIX B: STINESPRING THEOREM FOR COVARIANT CP-MAPS

In this appendix we will state the covariant version of Stinespring's theorem[20] which we have used in the proof of Theorem 1. However, as in the rest of the paper, we will restrict the discussion to finite dimensional Hilbert spaces (i.e., only cp-maps between finite von Neumann factors are considered).

Theorem 8: *Let G be a group with finite dimensional unitary representations* $\pi_i:G\to\mathcal{B}(\mathcal{H}_i)(i=1,2)$, *and* $T:\mathcal{B}(\mathcal{H}_2)\to\mathcal{B}(\mathcal{H}_1)$ *a completely positive map with the covariance property* $\pi_1(g)T(X)\pi_1(g)^*=T(\pi_2(g)X\pi_2(g)^*)$.

(1) Then there is another finite dimensional unitary representation $\tilde{\pi}:G\to\mathcal{B}(\tilde{\mathcal{H}})$ and an intertwiner $V:\mathcal{H}_1\to\mathcal{H}_2\otimes\tilde{\mathcal{H}}$ with $V\pi_1(g)=\pi_2\otimes\tilde{\pi}V$ such that $T(X)=V^*(X\otimes\mathbb{1})V$ holds.
(2) If $T=\Sigma_\alpha T^\alpha$ is a decomposition of T in completely positive terms, there is a decomposition $\mathbb{1}=\Sigma_\alpha F^\alpha$ of the identity operator on $\tilde{\mathcal{H}}$ into positive operators $F^\alpha\in\mathcal{B}(\tilde{\mathcal{H}})$ with $[F^\alpha,\tilde{\pi}(g)]=0$ such that $T^\alpha(X)=V^*(X\otimes F^\alpha)V$.

We only sketch the main ideas of the proof. The first step is Stinespring's theorem in its general form:[19] There exists a representation $\eta:\mathcal{B}(\mathcal{H}_2)\to\mathcal{B}(\mathcal{K})$ of the C^*-algebra $\mathcal{B}(\mathcal{H}_2)$ on a

Hilbert space $\mathcal{K}$ and a bounded operator $V:\mathcal{H}_1\rightarrow\mathcal{K}$ such that $T(X)=V^*\eta(X)V$ holds. Up to unitary equivalence there is exactly one such triple $(\mathcal{K},V,\pi)$ such that the vectors $\pi(A)V\psi\in\mathcal{K}$ with $\psi\in\mathcal{H}_1$ and $A\in\mathcal{B}(\mathcal{H}_2)$ span $\mathcal{K}$.

It is this uniqueness, from which the representation $\tilde{\pi}$ of G is constructed. Indeed, the objects $V_g=V\pi_1(g)$, and $\eta_g(X)=\eta(\pi_2(g)X\pi_2(g)^*)$ form a Stinespring dilation of the completely positive map $T_g(X)=\pi_1(g)^*T(\pi_2(g)X\pi_2(g)^*)\pi_1(g)$, which by covariance is equal to T. Hence by ''uniqueness up to unitary equivalence'' there is a unique unitary operator $U_g\in\mathcal{B}(\mathcal{K})$ such that $V_g=V\pi_1(g)=U_gV$, and $\eta_g(X)=\eta(\pi_2(g)X\pi_2(g)^*)=U_g\eta(X)U_g^*$. This can be simplified a bit further by the observation that according to the second equation the operators $\tilde{U}_g=\eta(\pi_2(g))^*U_g$ commute with all $\eta(X)$. It is easy to see that the U_g are a representation, and hence so is $\tilde{U}$: we have $\tilde{U}_g\tilde{U}_h=\eta(\pi_2(g))^*U_g\eta(\pi_2(h)^*)U_h=\eta(\pi_2(g))^*\eta(\pi_2(g)\pi_2(h)^*\times\pi_2(g)^*)U_gU_h=\eta(\pi_2(g)^*\pi_2(g)\pi_2(h)^*\pi_2(g)^*)U_{gh}=\eta(\pi_2(gh)^*)U_{gh}=\tilde{U}_{gh}$.

For a proof of part (1) we now only need to invoke the observation that all representations of $\mathcal{B}(\mathcal{H}_2)$ are of the form $\eta\simeq\mathrm{id}\otimes\mathbb{1}$ with $\mathcal{K}=\mathcal{H}_2\otimes\tilde{\mathcal{H}}$. (Here ''$\simeq$'' denotes a unitary equivalence, which we will include as a factor in V.) Since $\tilde{U}_g$ commutes with all $\eta(X)=X\otimes\mathbb{1}$, it is of the form $\tilde{U}_g=\mathbb{1}\otimes\tilde{\pi}(g)$, which proves the assertion.

The second part of the theorem stated for a trivial group $G=\{e\}$ is also known as the Radon–Nikodyn theorem coming with the Stinespring theorem. In general it asserts the existence of a partition of the identity operator on $\mathcal{K}$ into operators $\tilde{F}^\alpha$ commuting with all $\eta(X)$, giving the decomposition of T as $T^\alpha=V^*\eta(X)F^\alpha V$. Again, we can write these as $\tilde{F}^\alpha=\mathbb{1}\otimes F^\alpha$. Since the $F^\alpha V$ are uniquely determined by the T^α, it is easy to see that covariance of T^α is equivalent to $F^\alpha=\tilde{\pi}_gF^\alpha\tilde{\pi}_g^*$.

Tunneling of a massless field through a 3D Gaussian barrier

(Received 29 July 1998; accepted for publication 26 January 1999)

We propose a method for the approximate computation of the Green function of a scalar massless field ϕ subjected to potential barriers of given size and shape in space–time. This technique is applied to the case of a 3D Gaussian ellipsoidlike barrier, placed on the axis between two pointlike sources of the field. Instead of the Green function we compute its temporal integral, that gives the static potential energy of the interaction of the two sources. Such interaction takes place in part by tunneling of the quanta of ϕ across the barrier. We evaluate numerically the correction to the potential in dependence on the barrier size and on the barrier-sources distance. © *1999 American Institute of Physics.* [S0022-2488(99)04906-3]

I. INTRODUCTION

In Quantum Field Theory it is useful in several occasions to have a general expression for the Euclidean two-point correlation function of a massless scalar field ϕ in the presence of potential ''barriers'' in space–time of the form

$$V(\phi(x)) = \xi J_\Omega(x)[\phi^2(x) - \phi_0^2]^2, \tag{1}$$

$J_\Omega(x)$ being the characteristic function of the 4-region Ω where the potential has support ($J_\Omega = 1$ for $x \epsilon \Omega$, $J_\Omega = 0$ elsewhere). The region Ω can be multiple connected, thus representing several barriers placed at different points in space–time.

Possible applications are connected for instance to the fact that a potential of the form (1) represents a localized imaginary mass term ($m^2 < 0$) in the action of the scalar field ϕ. Terms of this kind can be present in cosmological models with inflationary fields. It is also known that every quantum field with nonvanishing vacuum expectation value (VEV) has a global imaginary mass term in its Lagrangian,[1] which couples to the gravitational field as a cosmological term; one can show[2] that if the VEV is not constant but depends on x, it becomes a *local* cosmological term for the gravitational field.

More generally, suppose we have a system of two interacting fields and regard one of them (or its VEV) as a fixed external source. The coupling term of the two fields becomes a local constraint for the dynamical field, a sort of external potential localized in the regions where the external field has support. It is therefore important to study the tunneling of the dynamical field through these regions, that is, its Green functions. Note that in systems like this translational invariance is generally lost.

It is easy to check that the potential $V(\phi)$ in Eq. (1) implements in fact a constraint in the functional integral of the field; writing this integral as

$$z = \int d[\phi] \exp\left[-\int d^4x (\partial\phi)^2 - \int d^4x V(\phi) \right],$$

one sees that for large ξ the square of the field is forced to take the value ϕ_0^2 within the region Ω.

[a)]Electronic mail: modanese@science.unitn.it

For a characteristic function $J_\Omega(x)$ like the one specified above we say that the constraint is imposed in a ''sharp'' way; in space–time the potential barrier looks like a step at the boundary of Ω. Smoothing J_Ω we can obtain a smooth potential barrier. In the following we shall be more interested in this second case.

Note that the potential (1) has the shape of a double *well*, as long as considered only a function of the field ϕ, but regarded as a function of x it is positive and reminds much more a *barrier*.

Let us focus on the case of weak fields, such that ϕ (Ref. 4) can be disregarded with respect to ϕ^2. If the product $\gamma\equiv\xi\phi_0^2$ is small, then the effect of the barriers on field correlations is small, too, and can be treated as a perturbation. One can solve the equation for the modified propagator $G'(x_1,x_2)=\langle\phi(x_1)\phi(x_2)\rangle_V$ in closed form (see the Appendix), finding that G' is given by a double inverse Fourier transform, with the direct transform of J_Ω evaluated at $(p+k)$,

$$G(x_1,x_2)=G^0(x_1,x_2)+\gamma G'(x_1,x_2),$$

$$G^0(x_1,x_2)=\int d^4k e^{-ik(x_1-x_2)},$$

$$G'(x_1,x_2)=\int d^4p\int d^4k e^{ipx_1}e^{ikx_2}\frac{\tilde{J}_\Omega(p+k)}{k^2p^2}. \tag{2}$$

In finite-dimensional quantum mechanics computing $G'(x_1,x_2)$ corresponds to compute the Feynman transition amplitude, related in turn to the system's wave function in the presence of barriers. In field theory the intuitive meaning of $G'(x_1,x_2)$ is less immediate. However, we can derive from $G'(x_1,x_2)$ a quantity with a direct physical interpretation; the static potential $U(\mathbf{x}_1,\mathbf{x}_2)$ of the interaction of two pointlike sources q_1 and q_2 of the field ϕ at rest. This interaction is mediated by the exchange of quanta of ϕ. If the barriers are placed somewhere between the sources, the interaction is clearly affected, but it still takes place—provided the product γ is small—with the quanta of ϕ ''tunneling'' through the barriers (or passing over the wells, depending on the interpretation).

The leading contribution to the static potential $U(\mathbf{x}_1,\mathbf{x}_2)$ is obtained from (2) as follows.[3] First one defines $J_\Omega(x)$ as the product of a 3D function $j_\Omega(\mathbf{x})$ and a function constant in time, then one integrates over t_1 and t_2, multiplies by q_1q_2 and divides by $-T$, taking the limit for $T\to\infty$. The result is

$$\begin{aligned}U(\mathbf{x}_1,\mathbf{x}_2)&=U^0(\mathbf{x}_1,\mathbf{x}_2)+\gamma U'(\mathbf{x}_1,\mathbf{x}_2)\\&=\frac{q_1q_2}{|\mathbf{x}_1-\mathbf{x}_2|}-\gamma(2\pi)^8q_1q_2\int d\mathbf{p}\int d\mathbf{k}e^{i\mathbf{p}\mathbf{x}_1}e^{i\mathbf{k}\mathbf{x}_2}\frac{\tilde{j}_\Omega(\mathbf{p}+\mathbf{k})}{\mathbf{k}^2\mathbf{p}^2}.\end{aligned} \tag{3}$$

This formula is easily generalized to the case of N charges $q_1,\ldots,q_N$, placed, respectively, at $\mathbf{x}_1,\ldots,\mathbf{x}_N$.

A limit case of the physical situation we are considering is represented by the electrostatic potential of pointlike charges in the presence of perfect conductors. In this case the field is exactly zero within the region Ω, and Ω has sharp boundaries—thus $j_\Omega(\mathbf{x})$ is a step function and $\tilde{j}_\Omega(\mathbf{p})$ a strongly oscillating function. Equation (3) could be applied to this case only if the parameters ϕ_0 and ξ could be chosen in such a way that $\phi_0\to0$ and $\xi\to\infty$, the product $\gamma=\xi\phi_0^2$ still being finite and small. We know, however, that usually in an electrostatic system the change in potential energy due to the presence of perfect conductors is not just a small correction. (It can be computed exactly, in principle, solving a classical field equation with suitable boundary conditions.)

The case of interest here is actually more subtle. In the following $j_\Omega(\mathbf{x})$ is supposed to be a smooth function and both ϕ_0 and ξ are taken to be finite. The field square has only a certain probability to be equal to ϕ_0^2 within Ω. This probability is maximum at the center of Ω and decreases towards the boundary of Ω. Since $j_\Omega(\mathbf{x})$ is smooth (a Gaussian function), its Fourier transform $\tilde{j}_\Omega(\mathbf{p})$ is smooth too, and the integral (3) can be computed numerically.

It is interesting to study U' in dependence on the geometrical features of the barrier Ω and on the position of q_1 and q_2 with respect to it. Take, for instance, a finite size barrier (Gaussian ellipsoid, see Sec. II) lying on the axis joining $\mathbf{x}_1$ to $\mathbf{x}_2$. We may expect that if one of the two charges is close to Ω, then $|U'/U^0|$ is larger, decreasing if both charges are far away from Ω—or if Ω is not on their axis. This behavior is confirmed and specified by our numerical results.

The paper is organized as follows. In Sec. II we compute the leading correction to the static potential for a barrier with the shape of an ellipsoid. Due to the peculiar behavior of the integrand, the procedure for numerical integration is not trivial and requires some care. We describe it in detail. Results are given in Sec. III. They concern in particular the dependence of the correction to $U(\mathbf{x}_1,\mathbf{x}_2)$ on the geometrical setting (size of the barrier and its position with respect to the pointlike sources). Far from exploring all the conceivable variations and related phenomenology, the main aim of this work is to show that the general technique can be successfully applied to real cases.

II. THE CASE OF TWO STATIC SOURCES

Let us focus now on a configuration with two static sources and one barrier only. We choose our reference frame in such a way that the sources lie on the z-axis,

$$\mathbf{x}_1=(0,0,L_1);\quad \mathbf{x}_2=(0,0,-L_2).$$

The spatial shape and size of the barrier are defined by the function

$$j_\Omega(\mathbf{x})=\exp\left(-\frac{x^2+y^2}{a^2}-\frac{z^2}{b^2}\right). \tag{4}$$

This means that the region Ω is like an ellipsoid centered at the origin, with simmetry axis along Oz, radius of the order of a and thickness of the order of b. We suppose that $a>b$, thus the ellipsoid is ''squeezed'' on the xy-plane. More precisely, the region Ω itself is not sharply defined, but the surfaces where $j_\Omega(\mathbf{x})$ is constant are ellipsoids. For instance, on the surface defined by

$$\frac{x^2+y^2}{a^2}+\frac{z^2}{b^2}=1,$$

the function $j_\Omega(\mathbf{x})$ is constant and equal to e^{-1}.

The Fourier transform of (4) is

$$\tilde{j}_\Omega(\mathbf{p})=\pi^{3/2}a^2b\,\exp\{\tfrac{1}{4}[-a^2(p_x^2+p_y^2)-b^2p_z^2]\}. \tag{5}$$

The charges q_1 and q_2 can be taken to be unitary and the distances L_1 and L_2 expressed as multiples of the ellipsoid radius a: $L_1\equiv n_1a$, $L_2\equiv n_2a$. From (3), (5) we obtain

$$U'(\mathbf{x}_1,\mathbf{x}_2)=-(2\pi)^8\pi^{3/2}a^2b\int d\mathbf{p}\int d\mathbf{k}\,\frac{e^{ik_zn_1a-ip_zn_2a}}{\mathbf{k}^2\mathbf{p}^2}\exp\left[-\frac{1}{4}a^2(\mathbf{p}+\mathbf{k})_{xy}^2-\frac{1}{4}b^2(p_z+k_z)^2\right],$$

where $\mathbf{V}_{xy}$ denotes the component of a vector $\mathbf{V}$ in the plane xy. In the following we shall be most interested in the case with one charge far from the barrier $(n_1\gg 1)$, while the other charge is close to it (typically in our numerical calculations n_2 ranges between 1 and 15). Accordingly we set $n_1^{-1}=\varepsilon$, $n_2=n$. After rescaling $k_z\to\varepsilon k_z$ we obtain

$$U'(\mathbf{x}_1,\mathbf{x}_2)=-(2\pi)^8\pi^{3/2}\frac{a^3b}{L_1}\int d\mathbf{p}\int d\mathbf{k}\frac{e^{ik_za-ip_zna}}{\mathbf{p}^2(k_x^2+k_y^2+\varepsilon k_z^2)}$$
$$\times\exp\left[-\frac{1}{4}a^2(\mathbf{p}+\mathbf{k})_{xy}^2-\frac{1}{4}b^2(p_z+\varepsilon k_z)^2\right].$$

Then we eliminate any further dimensional parameters by rescaling $k\rightarrow 2k/a$ and $p\rightarrow 2p/a$, obtaining

$$U'(\mathbf{x}_1,\mathbf{x}_2)=-(2\pi)^8\pi^{3/2}\frac{4ab}{L_1}\int d\mathbf{p}\int d\mathbf{k}\frac{e^{ik_z-ip_zn}}{\mathbf{p}^2(k_x^2+k_y^2+\varepsilon k_z^2)}\exp[-(\mathbf{p}+\mathbf{k})_{xy}^2-\rho^2(p_z+\varepsilon k_z)^2],$$

where $\rho=b/a$ is the ratio between the thickness b and the radius a of the ellipsoid.

Next we introduce the polar variables θ_k, θ_p, θ_k, and ϕ_p. In the following k and p will not denote four-vectors anymore, but $|\mathbf{k}|$ and $|\mathbf{p}|$, respectively. The square of the component of the vector $(\mathbf{p}+\mathbf{k})$ in the xy plane is

$$(\mathbf{p}+\mathbf{k})_{xy}^2=p^2\sin^2\theta_p+k^2\sin^2\theta_k+2pk\sin\theta_p\sin\theta_k\cos(\phi_k-\phi_p).$$

The other components are

$$k_z=k\cos\theta_k;\quad p_z=p\cos\theta_p;$$

$$k_x^2+k_y^2=\mathbf{k}_{xy}^2=k^2\sin^2\theta_k.$$

Finally, introducing the variables

$$s=\cos\theta_k,\quad t=\cos\theta_p,\quad \phi=(\phi_k-\phi_p),$$

one obtains, remembering that the integrand is even in s,t, the following basic formula:

$$U'(\mathbf{x}_1,\mathbf{x}_2)=-\frac{(2\pi)^{10}}{\sqrt{\pi}}\frac{ab}{L_1}2\pi\int_0^{2\pi}d\phi\int_{-1}^1 ds\int_{-1}^1 dt\int_0^\infty dk\int_0^\infty dp\frac{\cos(ks-npt)}{1-s^2(1-\varepsilon^2)}$$
$$\times\exp[-\rho^2(pt+\varepsilon ks)^2-p^2(1-t^2)-k^2(1-s^2)-2pk\cos\phi\sqrt{(1-t^2)(1-s^2)}]$$
$$\equiv-\frac{(2\pi)^{11}}{\sqrt{\pi}}\frac{ab}{L_1}\int_0^{2\pi}d\phi\int_{-1}^1 ds\int_{-1}^1 dt\int_0^\infty dk\int_0^\infty dp f(\phi,s,t,k,p;\varepsilon,\rho,n)$$
$$\equiv-\frac{(2\pi)^{11}}{\sqrt{\pi}}\frac{ab}{L_1}F(\varepsilon,\rho,n). \tag{6}$$

A. Preliminary study of the integrand

It is important to discuss in advance the case in which ρ and ε take values much smaller than 1, that is, Ω is very thin and the distance of the first charge from Ω is much larger than a. When t and s approach $+1$ or -1, for small values of ρ the integral over k and p converges very slowly at infinity and the factor $\cos(ks-npt)$ performs a large number of oscillations. For very small ε there are many more oscillations in k than in p. (In the limit $\rho\rightarrow 0$ the integral makes sense only as a distribution. We shall never approach this limit, however.)

Let us set, for instance, $s=1$, $t=1$ and $\phi=\pi/2$ in the argument of the exponential in (6). We obtain the exponential factors

$$\exp[-\rho^2(pt+\varepsilon ks)^2]=\exp[-(\rho p)^2]\exp[-(\rho\varepsilon k)^2]\exp[-2\rho^2\varepsilon kp]. \tag{7}$$

TABLE I. Integration ranges in the four domains, for some values of ε,ρ.

ϵ	ρ	$\mathbf{K}_1$	$\mathbf{P}_1$	$\mathbf{K}_2$	$\mathbf{P}_2$	$\mathbf{K}_3$	$\mathbf{P}_3$	$\mathbf{K}_4$	$\mathbf{P}_4$
0.1	0.3	12	10	80	10	12	10	80	10
0.1	0.1	10	10	100	25	20	20	120	40
0.1	0.032	10	10	600	20	20	60	600	60
0.1	0.01	20	20	1500	30	20	200	1500	200
0.032	0.032	10	10	2000	15	20	70	1800	80
0.032	0.01	12	12	6000	15	15	180	6000	250
0.01	0.032	10	10	7500	15	10	70	7500	90
0.032	0.0032	15	15	18000	15	15	650	18000	700

The first factor on the r.h.s. of (7) has a range in p of the order of ρ^{-1} and the second factor has a range in k of the order of $(\rho\varepsilon)^{-1}$. The third factor has a range in p, for fixed k, of the order of $(\rho\sqrt{\varepsilon k})^{-1}$ and a range in k, for fixed p, of the order of $(\rho\sqrt{\varepsilon p})^{-1}$. Fortunately this latter factor is not relevant; if its range is larger than the other two ranges then it does not play any role; if it is

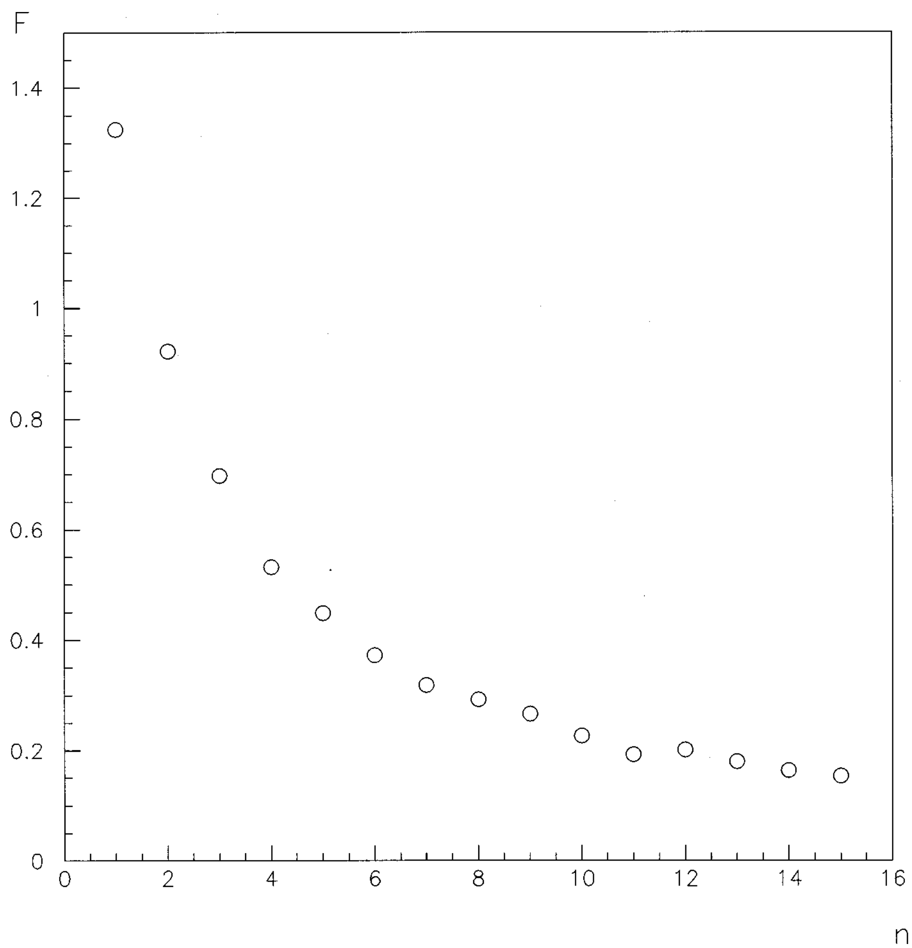

FIG. 1. Dependence of $F(\varepsilon,\rho,n)$ on n, in the range $n=1-15$, for $\varepsilon=0.1$ and $\rho=0.3$. Errors are ~ 0.01.

smaller then it is sufficient to refer to the other ranges.

As soon as s^2 and t^2 go away from 1, the number of oscillations of the integrand decreases. For instance, setting $s=t=0.98$ we obtain the exponential factors

$$\sim\exp[-(\rho p)^2-(\rho\varepsilon k)^2-2\rho^2\varepsilon kp]\exp[-0.04p^2-0.04k^2].$$

When ρ is much smaller than 1 the range of this product is determined by the second exponential and does not depend on ρ.

It is also easy to take into account the term proportional to cos ϕ. After setting $\phi=\pi$ that term gives a positive contribution to the argument of the exponential; thus studying the range of the resulting expression we obtain an upper limit valid for any ϕ.

B. Integration domains

Independently of the considerations above, it is possible to plot the integrand $f(\phi,s,t,k,p;\varepsilon,\rho,n)$ for several different values of ρ and ε and check the ranges of the exponentials. In order to better control the oscillations of f, we study it in 4 different domains of the variables s,t,

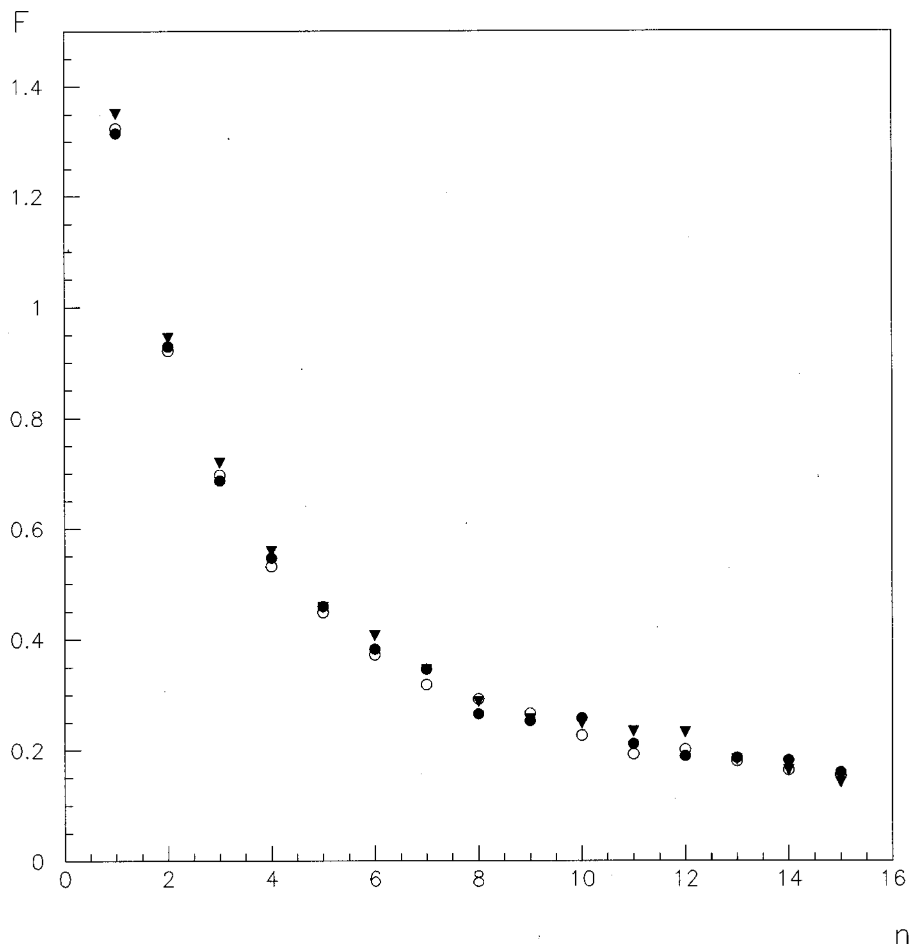

FIG. 2. Comparison of the values of $F(\varepsilon,\rho,n)$ for $\varepsilon=0.1$ and $\rho=0.3$ (white circles), $\rho=0.1$ (black triangles), and $\rho=0.032$ (black circles).

$$\text{Domain 1: } t,s\epsilon[0,1-\alpha];$$
$$\text{Domain 2: } t\epsilon[0,1-\alpha];s\epsilon[1-\alpha,1];$$
$$\text{Domain 3: } t\epsilon[1-\alpha,1];s\epsilon[0,1-\alpha];$$
$$\text{Domain 4: } t,s\epsilon[1-\alpha,1-\alpha].$$

A typical value of α employed in the program is $\alpha=0.02$. The total integration domain in s,t is obtained by ''reflecting'' each of the domains above with respect to one axis and then reflecting again the result with respect to the origin $(s\rightarrow -s,\ t\rightarrow -t,\ s,t\rightarrow -s,\ -t)$. In each domain i there is a maximum value for the variables k and p, beyond which f is equal to zero for any practical purpose. Denoting by K_i and P_i these ranges, Table I shows the results found for some considered values of ε and ρ.

Since the integration over k and p is extended to wide ranges, the most reasonable technique for the numerical computation of the integral (6) appears to be a Monte Carlo sampling of the integrand. The sampling algorithm evaluates the average value of f in each domain, extending the values of k and p up to the maximum range necessary for that domain. At the end the global average is computed, weighing each single average with the ratio between the domain volume and the total volume. Denoting by f_i the average of f in the domain i and by V_i the domain volume we have

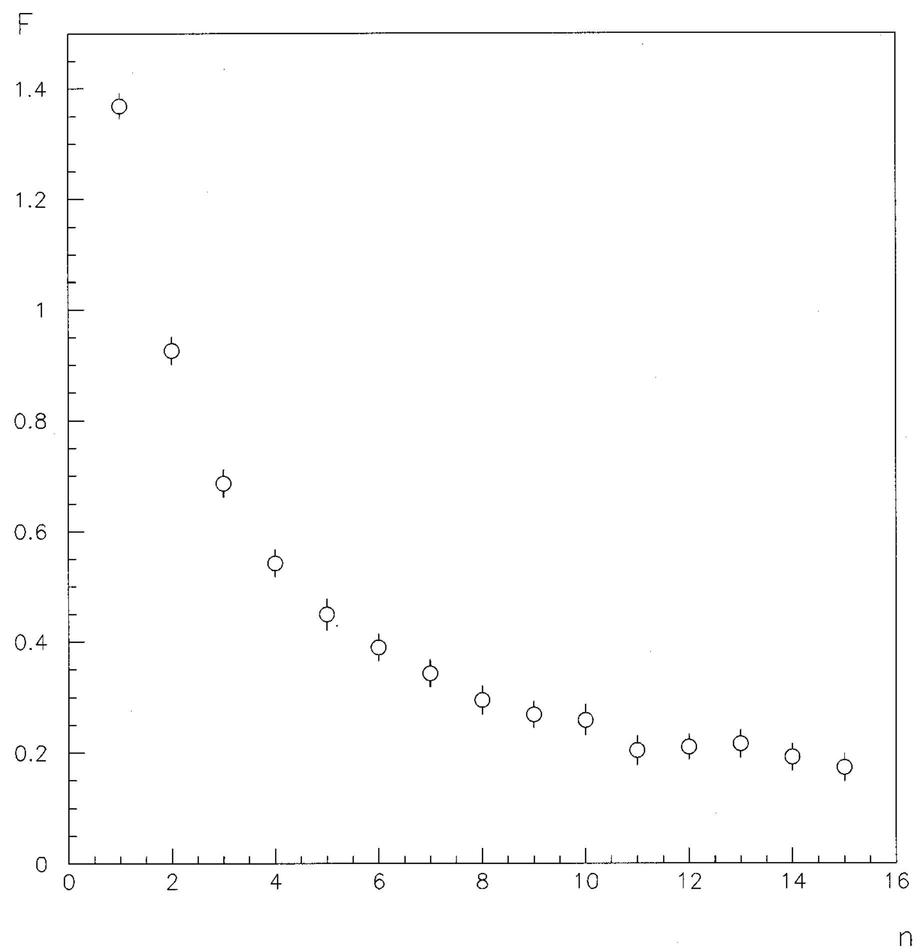

FIG. 3. Same as in Fig. 1, for $\varepsilon=0.05$. Errors are larger, as shown.

TABLE II. Results of the best fit $F(n)=\exp(-mn+q)+b$.

	b	m	q
$\varepsilon=0.1$ (Fig. 1)	0.14	0.29	0.3
with $n>2$	0.12	0.24	0.1
$\varepsilon=0.05$ (Fig. 3)	0.17	0.32	0.4
with $n>2$	0.16	0.26	0.1

$$F=\sum_{i=1}^{4} f_i V_i = 8\pi[(1-\alpha)^2 K_1 P_1 f_1 + \alpha(1-\alpha) K_2 P_2 f_2 + \alpha(1-\alpha) K_3 P_3 f_3 + \alpha^2 K_4 P_4 f_4]. \quad (8)$$

III. RESULTS OF THE NUMERICAL INTEGRATION

The contributions of the domains 2, 3, and 4 to the integral F (compare (8)) are found to be small with respect to the contribution of domain 1. The fluctuations of the average of f in domains 2 and 4 (where s^2 approaches 1) may be very large. In order to achieve a sufficient precision these regions have been sampled with a large number of points (up to $\sim 10^{10}$). The standard routine ''ran2'' (Ref. 4) was used for random numbers generation.

The dependence of the integral F on the parameters ε and ρ is very weak, thus U' depends on a, b and L_1 mainly as ab/L_1 (see Eq. (6)). The study of the dependence of U' on n is more difficult, because this dependence is entirely contained in the integral F and can be evaluated only numerically. One needs to insert in the program a cycle which samples the integrand for different values of n, typically between 1 and 15. This is possible because the ranges P_i, K_i do not depend on n.

The numerical evaluation of F as a function of n in the range $n=1-15$, with $\varepsilon=0.1$ and $\rho=0.3$, gives the results shown in Fig. 1. With $\rho=0.1$ and $\rho=0.032$ one obtains very similar results, thus confirming the weak dependence on ρ (Fig. 2). As expected varying ε does not affect much the value of F either, since the dependence on the distance L_1 is already factorized out of the integral (compare Fig. 3).

Figures 1, 2, 3 reveal an exponential behavior of $F(n)$ of the form

$$F(n)\sim\exp(-mn+q)+b.$$

It is also clear just from the graphs that the exponential decrease of F for large n leaves an asymptotic value $F=b$, with b in the interval 0.1–0.2. This is an interesting behavior, as it means that the ''shadow'' produced by the barrier in the static field of the two sources has a long, constant tail.

A least-squares fit of the data gives the results of Table II. Excluding from the fit the first two points ($n=1,2$) we obtain better estimates for the distribution tail and for b. The errors on the parameters of the fit, in particular those on b, are small. They can be estimated knowing that the least-squares sum of the perceptual errors $S=\Sigma_n\{1-[\exp(-mn+q)+b]/F(n)\}^2$ has a minimum value $S_{\min}\sim 0.05$ and that its second partial derivatives at the minimum are of the order of $(\partial^2 S/\partial b^2)\sim 4\cdot 10^2$, $(\partial^2 S/\partial m^2)\sim 10^2$, $(\partial^2 S/\partial q^2)\sim 10$.

IV. CONCLUSIONS

Our technique for the computation of the Green function and the static potential of two pointlike sources appears to work well for weak fields, yielding reasonable results. The method is based upon a double 3D Fourier transform of the function which represents size and position in space of the potential well or barrier. This double transform is necessary, due to the lack of translational invariance of the system. Its numerical evaluation requires a preliminary analytical study and a subdivision of the integration volume in a few domains, because the range of the real exponential factors in the integrand varies considerably.

We studied the case of a smooth barrier with the form of a Gaussian ellipsoid in coordinate and momentum space. For values of ρ and ε not much smaller than 1 a good precision was obtained. (ρ is the ratio between the lengths a and b of the ellipsoids axes and ε is the ratio between the length of the major axis a and the distance L_1 of the first source from the ellipsoid.)

Denoting by n the distance of the second source in units of the major axis, we found that the correction to the interaction potential along the line joining the two sources and the barrier has the following form (compare Eqs. (3), (6)):

$$U=U^0+\gamma U'=\frac{1}{|\mathbf{x}_1-\mathbf{x}_2|}-\frac{(2\pi)^{11}}{\sqrt{\pi}}\frac{\gamma ab}{L_1}F(\varepsilon,\rho,n)$$
$$=\frac{1}{|\mathbf{x}_1-\mathbf{x}_2|}\left[1-\frac{(2\pi)^{11}}{\sqrt{\pi}}\gamma ab(1+n\varepsilon)F(\varepsilon,\rho,n)\right].$$

The function F depends very weakly on ρ and ε. Its dependence on n is displayed in Figs. 1–3 and shows an exponential decay followed by a constant tail.

The behavior summarized above is interesting in itself, being the result of a sort of ''tunneling'' of the scalar field through a region where it is constrained or has imaginary mass. We have seen that the local imaginary mass term affects the propagation of the field also outside the region Ω where it has support. This feature is easily understood from the physical point of view; we gave here a method for its quantitative evaluation.

APPENDIX: PROOF OF THE EXPRESSIONS FOR G', U'

We give here the proof of Eqs. (2) and (3) of the main text. Expanding the square in (1) we obtain for $W[J]$,

$$W[J]=\int d[\phi]\exp\left\{-\int d^4x[(\partial\phi)^2-2\xi\phi_0^2J_\Omega(x)\phi^2(x)+\xi J_\Omega(x)\phi^4(x)+\xi J_\Omega(x)\phi_0^4]\right\}.$$

The last term in the square bracket is constant with respect to $\phi(x)$ and its exponential can be factorized out of the functional integral. In a first instance—for weak fields—we can disregard the $\phi^4(x)$ term. We are then led to consider a quadratic functional integral, and the ''modified propagator'' $G(x,y)=\langle\phi(x)\phi(y)\rangle_J$, which by definition satisfies the equation

$$[\partial_x^2+\gamma J_\Omega(x)]G(x,y)=-(2\pi)^4\delta^4(x-y), \tag{9}$$

where $\gamma=2\xi\phi_0^2>0$. Let us focus on the case when $\phi_0^2=0$ inside the regions Ω_i and let us take the limit $\phi_0\to 0$ and $\xi\to\infty$ in such a way that γ is finite and very small, so that the term $\gamma J_\Omega(x)$ in Eq. (9) constitutes only a small perturbation, compared to the kinetic term. Then we can set

$$G(x,y)=G^0(x,y)+\gamma G'(x,y),$$

where $G^0(x,y)$ is the propagator of the free scalar field, and we find immediately that $G'(x,y)$ satisfies the equation

$$\partial_x^2G'(x,y)=-J_\Omega(x)G^0(x,y). \tag{10}$$

Unlike $G^0(x,y)$, in general $G'(x,y)$ will not depend only on $(x-y)$, because the source breaks the translation invariance of the system. In order to go to momentum space it will therefore be necessary to consider the Fourier transform of $G'(x,y)$ with respect to both arguments. We define $\tilde{G}'(p,k)$ and $\tilde{J}_\Omega(p)$ as follows:

$$G'(x,y)=\int d^4p\int d^4k e^{ipx}e^{iky}\tilde{G}'(p,k)$$

and

$$J_\Omega(x)=\int d^4p e^{ipx}\tilde{J}_\Omega(p),\quad G^0(x,y)=\int d^4k\frac{e^{-ik(x-y)}}{k^2}.$$

The right-hand side of (10) can be rewritten as

$$J_\Omega(x)G^0(x,y)=\int d^4p\int d^4k e^{ipx}\tilde{J}_\Omega(p)\frac{e^{-ik(x-y)}}{k^2}=\int d^4k\int d^4p e^{iky}e^{ipx}\frac{\tilde{J}_\Omega(p+k)}{k^2},$$

and we obtain the following algebraic equation for the double Fourier transform of the first order correction to the propagator:

$$p^2\tilde{G}'(p,k)=\frac{\tilde{J}_\Omega(p+k)}{k^2}.$$

Transforming back, in conclusion we find Eq. (2) of the main text, namely,

$$G'(x,y)=\int d^4p\int d^4k e^{ipx}e^{iky}\frac{\tilde{J}_\Omega(p+k)}{k^2p^2}. \tag{11}$$

Therefore, if we know the Fourier transform of the characteristic function J_Ω of the space–time region where the constraint is imposed, we can in principle compute the leading order correction to the field propagator and thus to $W[J]$.

It is known[5] that the vacuum-to-vacuum amplitude $W[J]=\langle 0^+|0^-\rangle_J$ of a field system in the presence of an external source J is related to the logarithm of the systems' ground state energy,

$$E_0[J]=-T^{-1}\ln W[J],$$

where the functional integral is supposed to be suitably normalized and the source vanishes outside the temporal interval $[-T/2,+T/2]$, with T eventually approaching infinity. (We use units in which $\hbar=c=1$.)

An interesting application of (11) occurs in the case when the field $\phi(x)$ also interacts with N static pointlike sources placed at $\mathbf{x}_1,\mathbf{x}_2\ldots\mathbf{x}_N$. Namely, let us add a further, linear coupling term S_Q to the action of the system,

$$S_Q=\int d^4xQ(x)\phi(x),\ \ \text{with}\ \ Q(x)=\sum_{j=1}^{N}q_j\delta^3(\mathbf{x}-\mathbf{x}_j).$$

The ground state energy of the system corresponds, up to a constant, to the static potential energy of the interaction of the sources through the field ϕ. As before, it is obtained from the functional average of the interaction term, computed keeping the constraint into account,

$$E_0[J,Q]=U(\mathbf{x}_1,\ldots,\mathbf{x}_N)=-T^{-1}\ln\langle\exp\{-S_Q\}\rangle_J. \tag{12}$$

Expanding (12) one finds that to leading order in the $q_j s$, $U(\mathbf{x}_1,\ldots,\mathbf{x}_N)$ is given by a sum of propagators integrated on time,

$$U(\mathbf{x}_1,\ldots,\mathbf{x}_N) = -T^{-1}\sum_{j,l=1}^{N} q_j q_l \int dt_j \int dt_l \langle \phi(t_j,\mathbf{x}_j)\phi(t_l,\mathbf{x}_l)\rangle_J ,$$

where $t_j, t_l \epsilon [-T/2,+T/2]$. Since the regions Ω_i are infinitely elongated in the temporal direction the function $\tilde{J}_\Omega(p+k)$ gets factorized as

$$\tilde{J}_\Omega(p+k) = (2\pi)^4 \delta(p_0+k_0)\tilde{j}_\Omega(\mathbf{p}+\mathbf{k}). \tag{13}$$

Clearly the potential is disturbed by the presence of the ''barriers'' $j_\Omega(\mathbf{x})$. To first order in γ we can write

$$U(\mathbf{x}_1,\ldots,\mathbf{x}_N) = U^0(\mathbf{x}_1,\ldots,\mathbf{x}_N) + \gamma U'(\mathbf{x}_1,\ldots,\mathbf{x}_N)$$

and taking into account Eqs. (11), (13) we find

$$\begin{aligned} U'(\mathbf{x}_1,\ldots,\mathbf{x}_N) &= -T^{-1}\sum_{j,l=1}^{N} q_j q_l \int dt_j \int dt_l G'(x_j,x_l) \\ &= -(2\pi)^4 T^{-1}\sum_{j,l=1}^{N} q_j q_l \int dt_j \int dt_l \int d^4p \int d^4k \, \frac{e^{ipx_j+ikx_l}\tilde{J}_\Omega(p+k)}{k^2p^2} \\ &= -(2\pi)^8 T^{-1}\sum_{j,l=1}^{N} q_j q_l \int dt_j \int dt_l \int d^4p \int d\mathbf{k} \, \frac{e^{ip_0(t_j-t_l)+i\mathbf{p}\mathbf{x}_j+i\mathbf{k}\mathbf{x}_l}\tilde{j}_\Omega(\mathbf{p}+\mathbf{k})}{(p_0^2+\mathbf{k}^2)(p_0^2+\mathbf{p}^2)}. \end{aligned}$$

Changing to variables $t=t_j-t_l$ and $s=t_j+t_l$ and integrating we finally obtain the contribution of the perturbation to the static potential energy [Eq. (3) of the main text],

$$U'(\mathbf{x}_1,\ldots,\mathbf{x}_N) = -(2\pi)^8 \sum_{j,l=1}^{N} q_j q_l \int d\mathbf{p} \int d\mathbf{k} e^{i\mathbf{p}\mathbf{x}_j+i\mathbf{k}\mathbf{x}_l} \frac{\tilde{j}_\Omega(\mathbf{p}+\mathbf{k})}{\mathbf{k}^2\mathbf{p}^2}.$$

Generalized adiabatic product expansion: A nonperturbative method of solving the time-dependent Schrödinger equation

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, Istinye 80860 Istanbul, Turkey

(Received 6 January 1999; accepted for publication 17 March 1999)

We outline a method based on successive canonical transformations which yields a product expansion for the evolution operator of a general (possibly non-Hermitian) Hamiltonian. For a class of such Hamiltonians this expansion involves a finite number of terms, and our method gives the exact solution of the corresponding time-dependent Schrödinger equation. We apply this method to study the dynamics of a general nondegenerate two-level quantum system, a time-dependent classical harmonic oscillator, and a degenerate system consisting of a spin 1 particle interacting with a time-dependent electric field $\vec{\mathcal{E}}(t)$ through the Stark Hamiltonian $H=\lambda(\vec{J}\cdot\vec{\mathcal{E}})^2$. © *1999 American Institute of Physics.* [S0022-2488(99)02207-0]

I. INTRODUCTION

Recently, a method based on successive canonical transformations has been used to obtain exact solution of the Schrödinger equation

$$i\frac{d}{dt}|\psi(t)\rangle=H(t)|\psi(t)\rangle \tag{1}$$

for a class of dipole Hamiltonians[1–3] and time-dependent harmonic oscillators.[4] For these systems the Hamiltonian is a nondegenerate Hermitian operator. The purpose of the present article is to extend the application of this method to the cases where the Hamiltonian is non-Hermitian and involves degenerate eigenvalues.

Non-Hermitian Hamiltonians have been used to model a variety of physical systems involving decaying states.[5] The solution of the Schrödinger equation for a time-dependent two-level non-Hermitian Hamiltonian has been considered in Refs. 6 and 7. Another motivation for the study of the Schrödinger equation for a time-dependent non-Hermitian Hamiltonian is the fact that the solution of every linear ordinary differential equation (ODE) may be reduced to the solution of a system of first-order linear ODEs which can be written in the form of the time-dependent Schrödinger equation (1) or alternatively

$$|\psi(t)\rangle=U(t)|\psi(0)\rangle, \tag{2}$$

$$i\frac{d}{dt}U(t)=H(t)U(t), \tag{3}$$

$$U(t)=1, \tag{4}$$

where $U(t)$ is the evolution operator. For a general linear ODE the corresponding Hamiltonian $H(t)$ may be a non-Hermitian matrix with degenerate eigenvalues.

[a)]Electronic mail: amostafazadeh@ku.edu.tr

The method of *adiabatic product expansion* developed in Refs. 1 and 2 does not directly apply to quantum systems with non-Hermitian Hamiltonians. In this article we shall present a generalization of this method which applies to arbitrary (possibly) non-Hermitian Hamiltonians with degenerate as well as nondegenerate eigenvalues.

The organization of the article is as follows. In Sec. II we review the basic results concerning the adiabatic approximation for degenerate and non-Hermitian Hamiltonians. In Sec. III we discuss the generalization of the method of adiabatic product expansion to these Hamiltonians. In Sec. IV we use the results of Sec. III to study the solution of the Schrödinger equation for a general nondegenerate non-Hermitian two-level Hamiltonian. In Sec. V, we apply the general results obtained in Sec. IV to treat the classical equation of motion for a harmonic oscillator with a time-dependent frequency. In Sec. VI, we discuss the application of the adiabatic product expansion to study the quadrupole interaction of a spin 1 particle with a time-dependent electric field $\vec{\mathcal{E}}=(\mathcal{E}_1(t),\mathcal{E}_2(t),0)$. We show that the corresponding Hamiltonian which has a degenerate and a nondegenerate eigenvalue is canonically equivalent to a Hamiltonian which has only nondegenerate eigenvalues. Furthermore, we show that if the direction of the electric field depends in a particular way on its magnitude, then our method yields the exact solution of the Schrödinger equation. Finally we present our conclusions in Sec. VII.

II. ADIABATIC APPROXIMATION FOR NON-HERMITIAN HAMILTONIANS

Let $H=H[R]$ be a parametric Hamiltonian which depends on a set of real parameters $R=(R^1,R^2,\ldots,R^d)$ labeling the points of a smooth manifold M. Let $E_n[R]$ denote the eigenvalues of $H[R]$ and $\mathcal{H}_n[R]$ be the degeneracy subspace associated with $E_n[R]$. Let $\mathcal{N}$ denote the degree of degeneracy of $E_n[R]$, i.e., the complex dimension of $\mathcal{H}_n[R]$. We shall assume that the spectrum of $H[R]$ is discrete and $\mathcal{N}$ does not depend on R.

Now let $|\psi_n,a;R\rangle$ and $|\phi_n,a;R\rangle$ form a complete biorthonormal basis of the Hilbert space.[8,9] This means that $|\psi_n,a;R\rangle$ with $a\in\{1,2,...,\mathcal{N}\}$ form a basis of $\mathcal{H}_n[R]$, in particular

$$H[R]|\psi_n,a;R\rangle=E_n[R]|\psi_n,a;R\rangle, \tag{5}$$

and $|\phi_n,a;R\rangle$ satisfy

$$H[R]^\dagger|\phi_n,a;R\rangle=E_n^*[R]|\phi_n,a;R\rangle, \tag{6}$$

$$\langle\phi_m,b;R|\psi_n,a;R\rangle=\delta_{mn}\delta_{ab}, \tag{7}$$

$$\sum_n\sum_{a=1}^{\mathcal{N}}|\psi_n,a;R\rangle\langle\phi_n,a;R|=1. \tag{8}$$

Next suppose that the parameters R^i depend on time t, then $R(t)$ defines a curve $\mathcal{C}$ in the parameter space M, and the Hamiltonian, its eigenvalues, and eigenvectors become time dependent. In this case we use the notation $H(t):=H[R(t)]$, $E_n(t):=E_n[R(t)]$, $|\psi_n,a;t\rangle:=|\psi_n,a;R(t)\rangle$, and $|\phi_n,a;t\rangle:=|\phi_n,a;R(t)\rangle$. We shall assume that $E_n(t)$, $|\psi_n,a;t\rangle$ and $|\phi_n,a;t\rangle$ are smooth functions of t and that during the evolution of the system the eigenvalues of the Hamiltonian do not cross, i.e., if $E_m(0)<E_n(0)$, then for all $t\in[0,\tau]$, $E_m(t)<E_n(t)$, where τ denotes the duration of the evolution of the system.

Differentiating both sides of Eq. (5) with respect to t, taking the inner product of both sides of the resulting equation with $|\phi_m,b;t\rangle$, for arbitrary m and b, and using Eqs. (5)–(7), we have

$$[E_m(t)-E_n(t)]\langle\phi_m,b;t|\frac{d}{dt}|\psi_n,a;t\rangle+\langle\phi_m,b;t|\dot{H}(t)|\psi_n,a;t\rangle-\delta_{mn}\delta_{ab}\dot{E}(t)=0. \tag{9}$$

Here a dot denotes differentiation with respect to t. For $m\neq n$, Eq. (9) reads

$$\langle \phi_m, b; t | \frac{d}{dt} | \psi_n, a; t \rangle = \frac{\langle \phi_m, b; t | \dot{H}(t) | \psi_n, a; t \rangle}{E_n(t) - E_m(t)} \quad \text{for } m \neq n. \tag{10}$$

Now let us express the solution of the Schrödinger equation (1) in the basis $\{|\psi_n, a; t\rangle\}$. Then

$$|\psi(t)\rangle = \sum_n \sum_{a=1}^{\mathcal{N}} C_a^n(t) |\psi_n, a; t\rangle, \tag{11}$$

where $C_a^n(t)$ are complex coefficients. Substituting Eq. (11) in the Schrödinger equation (1), taking the inner product of both sides of the resulting equation with $|\phi_m, b; t\rangle$, and making use of Eqs. (5), (6), (7), and (10), we find

$$i\dot{C}_b^m - E_m C_b^m + \sum_{a=1}^{\mathcal{N}} i \left\langle \phi_m, b; t \left| \frac{d}{dt} \psi_m, a; t \right. \right\rangle C_a^m = -i \sum_{n \neq m} \sum_{a=1}^{\mathcal{N}} \frac{\langle \phi_m, b; t | \dot{H}(t) | \psi_n, a; t \rangle}{E_n(t) - E_m(t)}. \tag{12}$$

The special case of this equation with $\mathcal{N} = 1$, i.e., the nondegenerate case, has been originally derived by Garrison and Wright[9] in their investigation of the adiabatic geometric phase[10] for non-Hermitian Hamiltonians.[9,11–14]

If the right-hand side of Eq. (12) is negligible, then one says that the system undergoes an adiabatic evolution.[15,16,2,9,17] In this case, the equations for C_a^n decouple and their solution is given by

$$C_a^n(t) = \sum_{b=1}^{\mathcal{N}} K_{ab}^n(t) C_b^n(0), \tag{13}$$

where $K_{ab}^n(t)$ are entries of the invertible matrix

$$K^n(t) := e^{-i\int_0^t E_n(s)ds} \mathcal{P} \exp\left[i \int_{R(0)}^{R(t)} \mathcal{A}^n[R] \right], \tag{14}$$

$\mathcal{P}$ denotes the path-ordering operator, $\mathcal{A}^n$ is the matrix of one-forms with entries

$$\mathcal{A}_{ab}^n[R] := i \langle \phi_n, a; R | d | \psi_n, b; R \rangle, \tag{15}$$

d stands for the exterior derivative with respect to R^i, and the line integral in Eq. (14) is evaluated along the curve $\mathcal{C}$ defined by $R(t)$. If $\mathcal{C}$ is a closed curve in M, the Hamiltonian has a periodic time dependence and the path-ordered exponential in Eq. (14), which takes the form

$$\mathcal{P} \exp\left[i \oint_{\mathcal{C}} \mathcal{A}^n[R] \right], \tag{16}$$

is the *non-Hermitian* analog of the *non-Abelian adiabatic geometric phase*.[18]

Note that if the initial vector $|\psi(0)\rangle$ is an eigenvector of the initial Hamiltonian $H(0)$, then the adiabaticity of the evolution implies that $|\psi(t)\rangle$ is an eigenvector of $H(t)$ for all $t \in [0, \tau]$. In terms of the time-evolution operator $U(t)$ of Eq. (3) this is expressed by

$$U(t) \approx U^{(0)}(t), \tag{17}$$

where

$$U^{(0)}(t) := \sum_n \sum_{a,b=1}^{\mathcal{N}} K_{ab}^n(t) |\psi_n, a; t\rangle \langle \phi_n, b; 0|. \tag{18}$$

One can easily show that $U^{(0)}(t)$ is invertible, and its inverse is given by

$$U^{(0)^{-1}}(t)=\sum_n\sum_{a,b=1}^{\mathcal{N}}K_{ab}^{n^{-1}}(t)|\psi_n,a;0\rangle\langle\phi_n,b;t|,\tag{19}$$

where $K^{n^{-1}}(t)$ is the inverse of $K^n(t)$.

III. ADIABATIC CANONICAL TRANSFORMATIONS AND THE GENERALIZED ADIABATIC PRODUCT EXPANSION

Let $g(t)$ be an invertible linear operator acting on the Hilbert space. Then the transformations:

$$|\psi(t)\rangle\rightarrow|\psi'(t)\rangle:=g(t)|\psi(t)\rangle,\tag{20}$$

$$H(t)\rightarrow H'(t):=g(t)H(t)g(t)^{-1}-ig(t)\frac{d}{dt}g(t)^{-1},\tag{21}$$

$$U(t)\rightarrow U'(t):=g(t)U(t)g(0)^{-1},\tag{22}$$

leave the form of the Schrödinger equation invariant. We shall call such a transformation a *canonical transformation*.

Now let us investigate the consequences of the canonical transformation defined by $g(t)=U^{(0)}(t)^{-1}$. We shall call this transformation the *adiabatic canonical transformation*. Denoting the transformed Hamiltonian H' by $H^{(1)}$, we have

$$H^{(1)}(t)=\sum_{n,m\neq n}\sum_{a=1}^{\mathcal{N}}\sum_{b=1}^{\mathcal{M}}H_{ab}^{(1)^{nm}}(t)|\psi_n,a;0\rangle\langle\phi_m,b;0|,\tag{23}$$

where

$$H_{ab}^{(1)nm}(t):=-K_{ac}^{(n)}(t)^{-1}A_{cd}^{nm}(t)K_{db}^{m}(t),\quad A_{cd}^{nm}(t):=i\langle\phi_nc;t|\frac{d}{dt}|\psi_m,d;t\rangle.\tag{24}$$

Because $g(0)=U^{(0)}(0)^{-1}=1$, the transformed evolution operator is given by

$$U'(t)=U^{(0)}(t)^{-1}U(t).\tag{25}$$

Clearly if the adiabatic approximation is valid, $H^{(1)}(t)\approx 0$ and $U'(t)\approx 1$.

Let us suppose that $H^{(1)}(t)$ has a discrete spectrum and denote by $E_{n_1}^{(1)}(t)$ and $\mathcal{N}_1$ the eigenvalues of $H^{(1)}(t)$ and their degree of degeneracy. Furthermore, let $\{|\psi_{n_1}^{(1)},a_1;t\rangle,|\phi_n^{(1)},a_1;t\rangle\}$ be a biorthonormal eigenbasis of the Hilbert space, i.e.,

$$H^{(1)}(t)|\psi_{n_1}^{(1)},a_1;t\rangle=E_{n_1}^{(1)}(t)|\psi_{n_1}^{(1)},a_1;t\rangle,$$

$$H^{(1)}(t)^{\dagger}|\phi_{n_1}^{(1)},a_1;t\rangle=E_{n_1}^{(1)*}(t)|\phi_{n_1}^{(1)},a_1;t\rangle,$$

$$\langle\phi_{m_1}^{(1)},b_1;t|\psi_{n_1}^{(1)},a_1;t\rangle=\delta_{m_1n_1}\delta_{a_1b_1},\quad\sum_{n_1}\sum_{a_1=1}^{\mathcal{N}_1}|\psi_{n_1}^{(1)},a_1;t\rangle\langle\phi_{n_1}^{(1)},a_1;t|=1.$$

Then $H^{(1)}(t)$ shares the properties of the original Hamiltonian $H(t)$, and we can repeat the above analysis using $H^{(1)}(t)$ in place of $H(t)$. In this way the adiabatic approximation yields the approximate evolution operator

$$U^{(1)}(t)=\sum_{n_1}\sum_{a_1,b_1=1}^{\mathcal{N}_1} K^{(1)n_1}_{a_1b_1}(t)|\psi^{(1)}_{n_1},a_1;t\rangle\langle\phi^{(1)}_{n_1},b_1;0| \tag{26}$$

for $H^{(1)}(t)$, where $K^{(1)n_1}_{a_1b_1}(t)$ are the entries of the matrix $K^{(1)n_1}$ obtained by replacing $E_n(t)$, $|\psi_n,a;t\rangle$ and $|\phi_n,a;t\rangle$ in Eqs. (14) and (15) by $E^{(1)}_{n_1}(t)$, $|\psi^{(1)}_{n_1},a_1;t\rangle$, and $|\phi^{(1)}_{n_1},a_1;t\rangle$, respectively.

Next we perform the adiabatic canonical transformation defined by $g(t)=U^{(1)}(t)^{-1}$. This leads to a transformed Hamiltonian $H^{(2)}(t)$ which is related to $H^{(1)}(t)$ according to Eqs. (23) and (24) with K^n, $|\psi_n,a;t\rangle$, and $|\phi_n,b;t\rangle$ replaced by $K^{(1)n_1}$, $|\psi^{(1)}_{n_1},a_1;t\rangle$, and $|\phi^{(1)}_{n_1},a_1;t\rangle$. The transformed evolution operator is given by

$$U^{(1)}(t)^{-1}U^{(0)}(t)^{-1}U(t).$$

Repeating this procedure we obtain, after N successive adiabatic canonical transformations, a transformed Hamiltonian $H^{(N)}(t)$ and a transformed evolution operator which is given by

$$U^{(N-1)}(t)^{-1}U^{(N-2)}(t)^{-1}\cdots U^{(0)}(t)^{-1}U(t).$$

Here $U^{(\ell)}(t)$, with $\ell\in\{1,2,...,N-1\}$, denotes the approximate evolution operator obtained by performing adiabatic approximation on the Hamiltonian $H^{(\ell)}(t)$.

If for some N the adiabatic approximation yields the exact solution of the Schrödinger equation for the Hamiltonian $H^{(N)}(t)$, then by construction $H^{(N+1)}(t)=0$ and $U^{(N+1)}(t)=1$. In this case, the original evolution operator is given by

$$U(t)=U^{(0)}(t)U^{(1)}(t)\cdots U^{(N)}(t). \tag{27}$$

If the adiabatic approximation fails for all $H^{(N)}(t)$, then there are two possibilities

(i) One obtains an infinite product expansion for the evolution operator

$$U(t)=\prod_{\ell=0}^{\infty} U^{(\ell)}(t):=U^{(0)}(t)U^{(1)}(t)\cdots U^{(\ell)}(t)\cdots. \tag{28}$$

In this case, one may view Eq. (27) as a *generalization* of the adiabatic approximation.

(ii) One obtains $H^{(i)}(t)=H^{(j)}(t)$ for some i and j with $i\neq j$. In this case a direct application of the method of adiabatic product expansion does not produce a solution. However, as we shall see in Sec. IV, sometimes it is possible to modify this method by combining the adiabatic canonical transformation with other canonical transformations, so that one obtains a finite or an infinite product expansion with distinct terms.

IV. APPLICATION TO TWO-LEVEL HAMILTONIANS

Two-level nondegenerate Hamiltonians provide the simplest nontrivial quantum systems. This has been one of the main reasons for the study of these Hamiltonians since the early days of quantum mechanics. In this section we shall consider the most general nondegenerate two-level Hamiltonian which may or may not be Hermitian.

In an arbitrary basis of the Hilbert space ($\mathbb{C}^2$), the Hamiltonian is given by a two-by-two complex matrix $\overline{H}$. One can perform a quantum canonical transformation (21) defined by $g(t)=\exp\{i\int_0^t[\mathrm{tr}\,\overline{H}(s)]ds/2\}$ to map the Hamiltonian $\overline{H}$ to a traceless Hamiltonian of the form

$$H:=\begin{pmatrix} a & b\\ c & -a\end{pmatrix}, \tag{29}$$

where $\mathrm{tr}\,\overline{H}$ denotes the trace of $\overline{H}$, and $a=a(t)$, $b=b(t)$, $c=c(t)$ are complex-valued smooth functions of t.

We can easily solve the eigenvalue problem for the Hamiltonian (29). The eigenvalues are given by

$$E_1(t):=-E(t), \quad E_2(t):=E(t),$$

where

$$E:=\sqrt{a^2+bc}. \tag{30}$$

We shall demand that during the time interval $[0,\tau]$ of interest $E\neq 0$, so that the eigenvalues are nondegenerate. In particular, no level crossings occur. Then a possible choice for a biorthonormal eigenbasis is

$$|\psi_1;R\rangle=\begin{pmatrix} -b \\ a+E \end{pmatrix}, \quad |\psi_2;R\rangle=\begin{pmatrix} a+E \\ c \end{pmatrix}, \tag{31}$$

$$|\phi_1;R\rangle=\frac{1}{N^*}\begin{pmatrix} -c^* \\ a^*+E^* \end{pmatrix}, \quad |\phi_2;R\rangle=\frac{1}{N^*}\begin{pmatrix} a^*+E^* \\ b^* \end{pmatrix}, \tag{32}$$

where $R=(a,b,c)$ and $N:=2E(a+E)$.

Next we compute $U^{(0)}$ and $H^{(1)}$. Using Eqs. (18), (14), (15), and (23), we find

$$U^{(0)}(t)=K^1(t)|\psi_1;t\rangle\langle\phi_1;0|+K^2(t)|\psi_2;t\rangle\langle\phi_2;0|, \tag{33}$$

$$H^{(1)}(t)=\xi(t)|\psi_1;0\rangle\langle\phi_2;0|+\zeta(t)|\psi_2;0\rangle\langle\phi_1;0|, \tag{34}$$

where

$$K^1(t):=K^1_{11}(t)=\exp\left(\frac{i\eta(t)}{2}-\int_{R(0)}^{R(t)}\left[(2E)^{-1}\left(da+dE+\frac{cdb}{a+E}\right)\right]\right),$$

$$K^2(t):=K^2_{11}(t)=\exp\left(\frac{-i\eta(t)}{2}-\int_{R(0)}^{R(t)}\left[(2E)^{-1}\left(da+dE+\frac{bdc}{a+E}\right)\right]\right), \tag{35}$$

$$\eta(t):=2\int_0^t E(s)ds,$$

$$\xi(t):=H^{12}_{11}(t)=\left(-\frac{ie^{-2i\alpha(t)}}{2}\right)\left[1+\frac{a(t)}{E(t)}\right]\frac{d}{dt}\left[\frac{c(t)}{a(t)+E(t)}\right], \tag{36}$$

$$\zeta(t):=H^{21}_{11}(t)=\left(\frac{ie^{2i\alpha(t)}}{2}\right)\left[1+\frac{a(t)}{E(t)}\right]\frac{d}{dt}\left[\frac{b(t)}{a(t)+E(t)}\right], \tag{37}$$

$$\alpha(t):=\frac{\eta(t)}{2}+\frac{i}{4}\int_{R(0)}^{R(t)}\frac{cdb-bdc}{E(E+a)}. \tag{38}$$

The transformed Hamiltonian has the following matrix expression:

$$H^{(1)}(t)=\begin{pmatrix} a^{(1)}(t) & b^{(1)}(t) \\ c^{(1)}(t) & -a^{(1)}(t) \end{pmatrix}, \tag{39}$$

where

$$a^{(1)}(t):=-\frac{b_0\xi(t)+c_0\zeta(t)}{2E_0}, \tag{40}$$

$$b^{(1)}(t):=-\frac{b_0^2\xi(t)-(a_0+E_0)^2\zeta(t)}{2E_0(E_0+a_0)}, \tag{41}$$

$$c^{(1)}(t):=-\frac{-(a_0+E_0)^2\xi(t)+c_0^2\zeta(t)}{2E_0(E_0+a_0)}, \tag{42}$$

$a_0:=a(0)$, $b_0:=b(0)$, $c_0:=c(0)$, $E_0:=E(0)$, and we have used Eqs. (31), (32), and (34).

Note that the transformed Hamiltonian $H^{(1)}(t)$ is traceless, and one can obtain $H^{(2)}(t)$ by substituting $a^{(1)}$ for $a, b^{(1)}$ for $b, c^{(1)}$ for c, and $E^{(1)}:=\sqrt{(a^{(1)})^2+b^{(1)}c^{(1)}}$ for E in Eqs. (34), and (36)–(38). Clearly this can be repeated indefinitely, and one can compute $H^{(\ell)}$ for arbitrary ℓ.

The adiabatic approximation corresponds to the cases where the matrix elements of $H^{(1)}(t)$ can be neglected. As seen from Eqs. (39) to (42) this happens whenever both ξ and ζ are negligible. One can also check that if only one of these quantities is negligible, then $H^{(1)}(t)$ is equal to the other times a constant matrix. This means that $H^{(1)}(t)$ has essentially stationary eigenvectors and the adiabatic approximation would yield the solution of the Schrödinger equation for $H^{(1)}$. In fact, it is not difficult to check that for the cases that either ξ or ζ is negligible, $H^{(2)}(t)\approx 0$. In particular, setting $\xi=0$ or $\zeta=0$ implies $H^{(2)}(t)=0$ and the evolution operator is given by

$$U(t)=U^{(0)}(t)U^{(1)}(t). \tag{43}$$

Therefore, the conditions $\xi=0$ and $\zeta=0$ each define a class of exactly solvable two-level systems. In view of Eqs. (36) and (37), these are as follows.

Class 1: The two-level systems for which $c/(a+E)=\mu=\text{constant}$, or alternatively $c=\mu(\mu b+\sqrt{4a^2+\mu^2b^2})/2$.

Class 2: The two-level systems for which $b/(a+E)=\nu=\text{constant}$, or alternatively $c=b/\nu^2-a^2/b$.

In general ξ and ζ do not vanish and the adiabatic product expansion does not terminate. There is also a special class of two-level systems for which the product expansion has a periodic structure in the sense of case (ii) of Sec. III. This is

Class 3: The two-level systems for which $a=0$.

Setting $a=0$ in Eqs. (38), (35), (36), and (37) and defining $f(t):=i\sqrt{c(t)/b(t)}$, we have

$$\alpha(t)=\frac{\eta(t)}{2}+\frac{i}{4}\ln\left(\frac{c_0b(t)}{b_0c(t)}\right), \quad \eta(t)=2\int_0^t\sqrt{b(s)c(s)}\,ds,$$

$$\xi(t)=-\frac{f_0\dot{f}(t)e^{-i\eta(t)}}{2\,f(t)}, \quad \zeta(t)=\frac{\dot{f}(t)e^{i\eta(t)}}{2\,f_0f(t)},$$

where $f_0:=f(0)$. Substituting these equations in Eq. (39), we obtain

$$H^{(1)}(t)=E^{(1)}(t)\begin{pmatrix}\cos\eta(t) & f_0^{-1}\sin\eta(t)\\ f_0\sin\eta(t) & -\cos\eta(t)\end{pmatrix}, \tag{44}$$

where

$$E^{(1)}(t)=\frac{i\dot{f}(t)}{2\,f(t)}.$$

This Hamiltonian has two interesting properties.

(1) If $b_0=c_0$, then $f_0=i$ and

$$H^{(1)}(t)=E^{(1)}(t)[\sin\eta(t)\sigma_2+\cos\eta(t)\sigma_3]=E^{(1)}(t)e^{i\eta(t)\sigma_1/2}\sigma_3e^{-i\eta(t)\sigma_1/2}, \tag{45}$$

where σ_i are Pauli matrices, and we have used the identity

$$e^{-i\varphi\sigma_i}\sigma_j e^{i\varphi\sigma_i}=\cos(2\varphi)\sigma_j+\sin(2\varphi)\sum_{k=1}^{3}\epsilon_{ijk}\sigma_k \quad \text{for } i\neq k. \tag{46}$$

In Eq. (46), φ is an arbitrary complex variable and ϵ_{ijk} is the totally antisymmetric Levi–Civita symbol with $\epsilon_{123}=1$. For the time periods during which $\sqrt{b(t)c(t)}$ is real, $\eta(t)$, is real, and the Hamiltonian (45) is anti-Hermitian. In particular, its eigenvectors are orthogonal. Up to a factor of i this Hamiltonian describes the interaction of a spin 1/2 magnetic dipole with a changing magnetic field. This system has an SU(2) dynamical group.[19,20,1,3] For the time periods during which $\sqrt{b(t)c(t)}$ is imaginary, $\eta(t)$ is imaginary, and up to a factor of i the Hamiltonian (45) describes a quantum system with a SU(1,1) dynamical group. A Hermitian analog of such a system is the time-dependent generalized harmonic oscillator.[21,20,22]

(2) Performing the adiabatic canonical transformation on (45), we arrive at the unexpected result

$$H^{(2)}(t)=H(t). \tag{47}$$

Therefore, direct application of the method of adiabatic product expansion does not lead to a solution.

Next we shall describe a modification of the method of adiabatic product expansion which yields an infinite product expansion for the evolution operator of the Class 3 systems which involve distinct terms.

Consider the transformed Hamiltonian (44). We can express this Hamiltonian using Eq. (39) with

$$a^{(1)}(t)=E^{(1)}(t)\cos\eta(t),\quad b^{(1)}(t)=f_0^{-1}E^{(1)}(t)\sin\eta(t),\quad c^{(1)}(t)=f_0E^{(1)}(t)\sin\eta(t). \tag{48}$$

Although this Hamiltonian does not belong to Class 3, it can be canonically transformed to a Hamiltonian which belongs to Class 3, i.e., its diagonal matrix elements vanish. This transformation is defined by $g(t)=\exp\{i\int_0^t a^{(1)}(s)ds\sigma_3\}$. The corresponding transformed Hamiltonian is given by

$$H_1(t)=\begin{pmatrix} 0 & b_1(t)\\ c_1(t) & 0\end{pmatrix}, \tag{49}$$

where

$$b_1(t):=b^{(1)}(t)e^{i\gamma_1(t)},\quad c_1(t):=c^{(1)}(t)e^{-i\gamma_1(t)},\quad \gamma_1(t):=2\int_0^t a^{(1)}(s)ds. \tag{50}$$

The evolution operator U_1 of H_1 is related to the evolution operator of the original Hamiltonian H according to

$$U_1(t)=\exp\left(i\int_0^t a^{(1)}(s)ds\sigma_3\right)U^{(0)}(t)^\dagger U(t), \tag{51}$$

where we have used Eq. (22).

Now since H_1 has the same form as H, we can repeat the above analysis using H_1 in place of H. Performing an adiabatic canonical transformation on H_1 we obtain the transformed Hamiltonian

$$H_1^{(1)}(t)=\begin{pmatrix} a_1^{(1)}(t) & b_1^{(1)}(t) \\ c_1^{(1)} & -a_1^{(1)}(t) \end{pmatrix}, \tag{52}$$

where

$$\begin{gathered} a_1^{(1)}(t):=E_1^{(1)}(t)\cos\eta_1(t), \quad b_1^{(1)}(t):=f_{1,0}^{-1}E_1^{(1)}\sin\eta_1(t), \\ c_1^{(1)}(t):=f_{1,0}E_1^{(1)}(t)\sin\eta_1(t), \quad E_1^{(1)}(t):=E^{(1)}(t)\cos\eta(t), \\ f_1(t):=i\sqrt{\frac{c_1(t)}{b_1(t)}}=if_0e^{-i\gamma_1(t)}, \quad f_{1,0}:=f_1(0)=if_0, \\ \eta_1(t):=2\int_0^t E^{(1)}(s)\sin\eta(s)ds. \end{gathered} \tag{53}$$

Clearly we can repeat this procedure indefinitely and construct an infinite product expansion for the evolution operator. Again if we compute only a finite number of terms in this expansion, then we obtain a generalization of the adiabatic approximation. The validity of this approximation may be checked by computing the transformed Hamiltonians. It is not difficult to show that the transformed Hamiltonian obtained after ℓ adiabatic canonical transformations is of the form

$$H_\ell^{(1)}(t)=h_\ell(t)S(t),$$

where

$$H_\ell(t)=E^{(1)}(t)\cos\eta(t)\cos\eta_1(t)\cos\eta_2(t)\cdots\cos\eta_{\ell-1}(t),$$

$$\eta_j(t):=2\int_0^t E^{(1)}(s)\cos\eta(s)\cos\eta_1(s)\cdots\cos\eta_{j-1}(s)\sin\eta_{j-1}(s)ds,$$

where $j\in\{2,3,...,\ell-1\}$ and $S(t)$ is a two-by-two matrix of unit determinant. Clearly if for some ℓ, $h_\ell(t)$ is negligible, then the above-mentioned generalization of the adiabatic approximation is valid.

Finally let us note that in general the initial Hamiltonian (29) can be written in the form

$$H(t)=\alpha_1(t)\sigma_1+\alpha_2(t)\sigma_2+a(t)\sigma_3, \tag{54}$$

with $\alpha_1=(b+c)/2$ and $\alpha_2=i(b-c)/2$. Performing the canonical transformation (21) defined by $g(t)=\exp\{i\int_0^t\alpha_2(s)ds\,\sigma_2\}$, we transform the Hamiltonian (54) into

$$H'(t)=\alpha'(t)\sigma_1+a'(t)\sigma_3=\begin{pmatrix} a'(t) & \alpha'(t) \\ \alpha'(t) & -a'(t) \end{pmatrix},$$

where

$$\alpha'(t):=\alpha_1(t)\cos\xi(t)-a(t)\sin\xi(t), \quad a'(t):=\alpha_1(t)\sin\xi(t)+a(t)\cos\xi(t),$$

$$\xi(t):=\int_0^t\alpha_2(s)ds. \tag{55}$$

Here we have used Eqs. (21) and (46). Next we perform another canonical transformation, namely the one defined by $g(t)=\exp\{i\int_0^t a'(s)ds\,\sigma_3\}$. This transformation maps the Hamiltonian (55) into

$$H''(t)=\alpha'(t)e^{i\eta'(t)\sigma_3/2}\sigma_1 e^{-i\eta'(t)\sigma_3/2}$$
$$=\alpha'(t)[\cos\eta'(t)\sigma_1-\sin\eta'(t)\sigma_2]=\alpha'(t)\begin{pmatrix}0 & e^{i\eta'(t)}\\ e^{-i\eta'(t)} & 0\end{pmatrix}, \tag{56}$$

where $\eta'(t):=2\int_0^t a'(s)ds$. This Hamiltonian is not only a member of Class 3 Hamiltonians, but initially (at $t=0$) its off-diagonal matrix elements are equal. In particular, it has the properties 1 in the above list. Note that we can carry out these canonical transformations on any two-level Hamiltonian. Therefore, every two-level Hamiltonian is canonically equivalent to a Class 3 Hamiltonian of the form (56). This means that the results obtained for Class 3 Hamiltonians apply to arbitrary two-level Hamiltonians.

V. TIME-DEPENDENT SIMPLE HARMONIC OSCILLATOR

It is well-known that the solution of every second-order linear ODE[23] can be reduced to the classical equation of motion for a simple harmonic oscillator with a time-dependent frequency $\omega=\omega(t)$,

$$\ddot{x}(t)+\omega^2(t)x(t)=0. \tag{57}$$

It is also well-known that one can reduce both the classical and quantum equations of motion for a generalized harmonic oscillator to Eq. (57).[24,25,22,26] This equation has, therefore, many physical applications.[25,27] Yet an exact analytic expression for the general solution of this equation is not known even for the case of real frequency.[28] The lack of an exact analytic solution of Eq. (57) is not surprising. One way to see this is to recall that the time-independent Schrödinger equation for an arbitrary potential $V(x)$ in one dimension is given by

$$\frac{d^2\psi_n}{dx^2}+\left(\frac{\hbar^2[E_n-V(x)]}{2m}\right)\psi_n=0, \tag{58}$$

where E_n and ψ_n are the energy eigenvalues and eigenfunctions, respectively. Equation (58) can be easily identified with Eq. (57) provided that one makes the change of variables: $x\to t$, $\psi_n\to x$, and $\{\hbar^2[E-V(x)]\}/(2m)\to\omega^2(t)$. This shows that if one was able to find the exact analytic solution of Eq. (57) for arbitrary frequency ω, then one would have been able to find the general solution of the time-independent Schrödinger equation for any potential V.

In the following we shall consider the case of an ordinary time-dependent harmonic oscillator (57) with real frequency. In order to apply the results of Sec. IV to Eq. (57), we first express it in the form of a system of first-order ODEs. Defining,

$$|\psi(t)\rangle:=\begin{pmatrix}x(t)\\ v(t)\end{pmatrix},\quad v(t):=\dot{x}(t),$$

we can write Eq. (57) in the form of the Schrödinger equation (1) with a two-level Hamiltonian of the form (29) with

$$a=0,\quad b=i,\quad c=-i\omega(t)^2,\quad E=\omega(t). \tag{59}$$

Since $a=0$, this system belongs to the Class 3 of Sec. IV with

$$f(t)=\omega(t), \quad \eta(t)=2\int_0^t \omega(s)ds,$$
$$H^{(1)}=E^{(1)}(t)\begin{pmatrix} \cos\eta(t) & \dfrac{\sin\eta(t)}{\omega_0} \\ \omega_0\sin\eta(t) & \cos\eta(t)\end{pmatrix}, \quad E^{(1)}(t):=\frac{i\dot{\omega}(t)}{2\omega(t)}. \tag{60}$$

Clearly, for real frequency $\omega(t)$ we can scale the time variable t so that $\omega_0=1$. Then the transformed Hamiltonian (60) takes the form

$$H^{(1)}(t)=E^{(1)}(t)[\sin\eta(t)\sigma_1+\cos\eta(t)\sigma_3]=E^{(1)}(t)e^{-i\eta(t)\sigma_2/2}\sigma_3 e^{i\eta(t)\sigma_2/2}. \tag{61}$$

Note that since $\eta(t)$ is real, the Hamiltonian (61) is an anti-Hermitian matrix with orthogonal eigenvectors. Therefore, up to a factor of i it describes a two-level spin system with a SU(2) dynamical group.[19,3] [Note that one can absorb the factor of i in the definition of the time variable t, i.e., by defining the imaginary time variable $\tau:=-it$. Therefore, the dynamics given by the Hamiltonian (61) may be viewed as the dynamics of a spin system with imaginary time.] This is rather surprising, for it is well-known that the quantum harmonic oscillator has SU(1,1) dynamical group and that its Schrödinger equation may be reduced to Eq. (57) by means of a quantum canonical transformation corresponding to a time-dependent dilatation.[26]

In view of the fact that $E^{(1)}$ is proportional to the derivative of $\ln\omega$, we can make a change of independent variable, namely $t\to\eta$. Note that η is the integral of a positive real function of t. Hence, it is a monotonically increasing function of t. Making this change of variable the Schrödinger equation for the Hamiltonian (61) becomes

$$i\frac{d}{d\eta}\tilde{U}(\eta)=\tilde{H}(\eta)\tilde{U}(\eta), \quad \tilde{U}(\eta)=1,$$

where $\tilde{U}(\eta):=U'(t(\eta))$, $U'(t)$ is the evolution operator for the the Hamiltonian (61),

$$\tilde{H}(\eta):=\tilde{E}(\eta)e^{-i\eta\sigma_2/2}\sigma_3 e^{i\eta\sigma_2/2}=\tilde{E}(\eta)(\sin\eta\sigma_1+\cos\eta\sigma_3), \tag{62}$$

$$\tilde{E}(\eta):=\frac{i\omega'(\eta)}{2\omega(\eta)}, \quad \omega':=\frac{d\omega}{d\eta}. \tag{63}$$

Up to a factor of i, the Hamiltonian (62) describes the interaction of a spin 1/2 magnetic dipole with a changing magnetic field whose direction rotates uniformly in the $x-z$ plane.

As we mentioned in Sec. IV for the Class 3 systems $H^{(2)}(t)=H(t)$. Hence direct application of the method of the adiabatic product expansion does not lead to a solution of the Schrödinger equation for the Hamiltonian (61) or (62). In this case, either one constructs the modified adiabatic product expansion of Sec. IV or examines the adiabatic series expansion of Ref. 2. The latter yields a series expansion for the evolution operator $\tilde{U}(\eta)$ of the Hamiltonian $\tilde{H}(\eta)$, namely

$$\begin{aligned}\tilde{U}(\eta)&=\mathcal{T}\exp\left(-i\int_0^\eta \tilde{H}(s)ds\right)\\ &=1-i\int_0^\eta \tilde{H}(s)ds+\frac{(-i)^2}{2}\int_0^\eta\int_0^\eta \mathcal{T}[\tilde{H}(s_1)\tilde{H}(s_2)]ds_1\,ds_2+\cdots+\frac{(-i)^n}{n!}\\ &\quad\times\int_0^\eta\cdots\int_0^\eta \mathcal{T}[\tilde{H}(s_1)\cdots\tilde{H}(s_n)]ds_1\cdots ds_n+\cdots,\end{aligned} \tag{64}$$

where $\mathcal{T}$ stands for the time-ordering operator. Since $\tilde{H}(\eta)$ is proportional to $\omega'(\eta)$, for slowly varying ω one obtains an approximate expression for $\tilde{U}(\eta)$ by computing a finite number of terms in this series. This is in fact another generalization of the adiabatic approximation, because if one keeps only the first term in this series and neglects the other terms one is essentially neglecting $\tilde{H}$ or alternatively $H^{(1)}$. As we explained above, this is just the adiabatic approximation. If one keeps more terms in this series, then one obtains a better approximation than the adiabatic approximation.

VI. QUADRUPOLE INTERACTION OF A SPIN 1 PARTICLE WITH A CHANGING ELECTRIC FIELD

Consider a spin 1 particle interacting with a changing electric field $\vec{\mathcal{E}}(t) = (\mathcal{E}_1(t),\mathcal{E}_2(t),\mathcal{E}_3(t))$ according to the Stark Hamiltonian

$$H(t)=\lambda[\vec{J}\cdot\vec{\mathcal{E}}(t)]^2, \tag{65}$$

where λ is a real coupling constant and $\vec{J}$ is the angular momentum of the particle. The quadrupole interactions of the form (65) have been extensively studied for fermionic systems in relation with the non-Abelian geometric phases[29–31] (See also Ref. 32.) The occurrence of non-Abelian geometric phases for the degenerate spin 1 systems has been pointed out in Ref. 33. For these systems, the particle has a definite angular momentum $j=1$ and the Hamiltonian is a 3×3 matrix. Using the spin $j=1$ representation of J_i, we can express the Stark Hamiltonin (65) in the form

$$H=\left(\frac{\lambda r^2}{2}\right)\begin{pmatrix} 1+2z^2 & \sqrt{2}ze^{-i\theta} & e^{-2i\theta} \\ \sqrt{2}ze^{i\theta} & 2 & -\sqrt{2}ze^{-i\theta} \\ e^{2i\theta} & -\sqrt{2}ze^{i\theta} & 1+2z^2 \end{pmatrix}, \tag{66}$$

where r, θ, and z are defined by

$$r:=\sqrt{\mathcal{E}_1^2+\mathcal{E}_2^2},\quad e^{i\theta}:=\frac{\mathcal{E}_1+i\mathcal{E}_2}{r},\quad z:=\frac{\mathcal{E}_3}{r}.$$

In view of the general results of Ref. 33, if $r\neq 0$ then the Hamiltonian (66) has a degenerate and a nondegenerate eigenvalue. In the following we shall consider the case where $\mathcal{E}_3=0$. The general case $\mathcal{E}_3\neq 0$ can be similarly treated.

If $\mathcal{E}_3=0$, then $z=0$ and

$$H=\left(\frac{\lambda r^2}{2}\right)\begin{pmatrix} 1 & 0 & e^{-2i\theta} \\ 0 & 2 & 0 \\ e^{2i\theta} & 0 & 1 \end{pmatrix}. \tag{67}$$

The eigenvalues of this Hamiltonian are given by

$$E_1=0,\quad E_2=\lambda r^2. \tag{68}$$

For $r\neq 0$, E_1 is nondegenerate and E_2 is doubly degenerate. A set of orthonormal eigenvectors of this Hamiltonian is given by

$$|\psi_1;R\rangle:=\frac{1}{\sqrt{2}}\begin{pmatrix} -1 \\ 0 \\ e^{2i\theta} \end{pmatrix},\quad |\psi_2,1;R\rangle:=\frac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ 0 \\ e^{2i\theta} \end{pmatrix},\quad |\psi_2,2;R\rangle:=\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \tag{69}$$

where $R=(r,\theta)$.

Next we compute $U^{(0)}(t)$ for this system. In order to do this we first use Eq. (15) to calculate $\mathcal{A}^n$. In view of the fact that the Hamiltonian (67) is Hermitian, $|\phi_n,a;R\rangle=|\psi_n,a;R\rangle$ and Eq. (15) leads to

$$\mathcal{A}^1=-d\theta, \quad \mathcal{A}^2=\begin{pmatrix} -d\theta & 0 \\ 0 & 0 \end{pmatrix}. \tag{70}$$

Substituting Eqs. (70) into Eq. (14) and making use of Eq. (68), we find

$$K^1(t)=e^{-i[\theta(t)-\theta_0]}, \quad K^2(t)=e^{-i\rho(t)}\begin{pmatrix} e^{-i[\theta(t)-\theta_0]} & 0 \\ 0 & 1 \end{pmatrix}, \tag{71}$$

where

$$\theta_0:=\theta(0), \quad \rho(t):=\lambda\int_0^t r(s)^2\,ds. \tag{72}$$

Using Eqs. (18) and (69), we have

$$U^{(0)}(t)=\frac{1}{2}\begin{pmatrix} (1+e^{-i\rho(t)})e^{i\theta_-(t)} & 0 & (-1+e^{-i\rho(t)})e^{-i\theta_+(t)} \\ 0 & 2e^{-i\rho(t)} & 0 \\ (-1+e^{-i\rho(t)})e^{i\theta_+(t)} & 0 & (1+e^{-i\rho(t)})e^{i\theta_-(t)} \end{pmatrix}, \tag{73}$$

where $\theta_\pm(t):=\theta(t)\pm\theta_0$.

Next we compute the Hamiltonian $H^{(1)}(t)$. This involves the calculation of $A_{ab}^{nm}(t)$ and $H_{ab}^{mn}(t)$ for $m\neq n$. Using Eqs. (24) and (69) we have

$$A_{11}^{12}=A_{11}^{21}=-\dot{\theta}, \quad A_{12}^{12}=A_{21}^{21}=0,$$

$$H_{11}^{21}=H_{11}^{12}=\dot{\theta}e^{i\rho(t)}, \quad H_{12}^{12}=H_{21}^{21}=0.$$

Substituting these equations in Eq. (23) and using Eq. (69), we obtain

$$H^{(1)}(t)=-\dot{\theta}(t)\begin{pmatrix} \cos\rho(t) & 0 & -i\sin\rho(t) \\ 0 & 0 & 0 \\ i\sin\rho(t) & 0 & -\cos\rho(t) \end{pmatrix}=-\dot{\theta}(t)[\sin\rho(t)\Sigma_2+\cos\rho(t)\Sigma_3], \tag{74}$$

where

$$\Sigma_2:=\begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix}, \quad \Sigma_3:=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \tag{75}$$

It is not difficult to recognize Σ_2 and Σ_3 as the Pauli matrices σ_2 and σ_3 represented in a $(0+1/2)$ representation of SU(2). In view of this identification we can express $H^{(1)}(t)$ in the form

$$H^{(1)}(t)=-\dot{\theta}(t)e^{i\rho(t)\Sigma_1/2}\Sigma_3e^{-i\rho(t)\Sigma_1/2}, \tag{76}$$

where

$$\Sigma_1 := \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix},$$

and we have used Eq. (46).

The Hamiltonian $H^{(1)}(t)$ has the following interesting properties.

(a) For $\theta=0$, i.e., $\theta=$constant, the adiabatic approximation is exact and $U(t)=U^{(0)}(t)$.

(b) In view of Eq. (76) for $\dot\theta\neq 0$, $H^{(1)}(t)$ has three nondegenerate eigenvalues, namely $-\dot\theta$, 0, and $\dot\theta$. This is quite remarkable because it shows that the adiabatic canonical transformation maps the degenerate Hamiltonian (67) into the nondegenerate Hamiltonian (76).

(c) Since Σ_i is a representation of the Pauli matrix σ_i, the Hamiltonian (76) belongs to a representation of the Lie algebra of SU(2). This means that one can reduce the Schrödinger equation for this Hamiltonian to that of the dipole Hamiltonian[2,3]

$$H_{\rm dp} = -2\,\dot\theta(t) e^{i\rho(t)J_1} J_3 e^{-i\rho(t)J_1}.$$

(d) We can perform another canonical transformation, namely the one defined by $g(t) = \exp[-i\rho(t)\Sigma_1/2]$ to transform the Hamiltonian (76) into

$$H^{(1)'}(t) = \frac{r(t)^2}{2}\Sigma_1 - \dot\theta(t)\Sigma_3, \tag{77}$$

where we have used Eqs. (76), (21), and (72). In particular if $\dot\theta$ and r^2 happen to be proportional, i.e., for some $c\in\mathbb{R}$

$$\dot\theta(t) = c\,r(t)^2, \tag{78}$$

then $H^{(1)'}(t) = r(t)^2(\frac{1}{2}\Sigma_1 - c\Sigma_3)$. In this case the eigenvectors of $H^{(1)'}(t)$ are constant and the adiabatic approximation yields the exact solution of the Schrödinger equation for $H^{(1)'}(t)$. The corresponding evolution operator is then given by

$$U^{(1)'}(t) = \exp\left(i\left(\frac{1}{2}\Sigma_1 - c\Sigma_3\right)\int_0^t r(s)^2\, ds\right). \tag{79}$$

Having obtained the evolution operator for $H^{(1)'}(t)$ we can use Eq. (22) to obtain the evolution operator for $H^{(1)}(t)$ and $H(t)$. This yields the following expression for the evolution operator for $H(t)$:

$$U(t) = U^{(0)}(t) e^{i\rho(t)\Sigma_1/2} U^{(1)'}(t), \tag{80}$$

where $U^{(0)}(t)$ and $U^{(1)'}(t)$ are given by Eqs. (73) and (79).

The above analysis shows that the condition (78) defines a class of exactly solvable time-dependent Stark Hamiltonians. If $\theta=\omega t$, for some constant frequency ω, this condition corresponds to the case of the rotating electric field $\vec E = r(\sin\omega t, \cos\omega t, 0)$ with magnitude r.

VII. CONCLUSION

In this article we have extended the method of the adiabatic product expansion to non-Hermitian and degenerate Hamiltonians. We showed that in general there were three possibilities for the adiabatic product expansion.

(1) The expansion terminates after a finite number of iteractions. This happens when one of the transformed Hamiltonians vanishes. In this case the method yields the exact solution for the Schrödinger equation.

(2) The expansion consists of an infinite number of distinct terms. In this case, the method does not lead to an exact solution, but it gives rise to a generalization of the adiabatic approximation. This approximation is performed by keeping a finite number of terms in the product expansion. The general asymptotic behavior of the adiabatic product expansion has not been studied. However, one can interpret this approximation by recalling that the condition for the termination of the product expansion corresponds to the validity of the conventional adiabatic approximation for one of the transformed Hamiltonians.

(3) The expansion involves terms which are not distinct. In this case the expansion does not lead to a solution. However, usually one can make another time-dependent canonical transformation after each adiabatic transformation and obtain an infinite product expansion with the properties of case (2) above.

We have considered some specific problems that one can attempt to solve using this method. We treated the case of a general nondegenerate two-level system and applied our general results to the more specific case of the classical equation of motion for a harmonic oscillator with a time-dependent frequency. In this case, we showed that the adiabatic canonical transformation mapped the corresponding two-level quantum system to a quantum system with an anti-Hermitian Hamiltonian. Although the direct application of the method of adiabatic product expansion did not yield a solution, we could construct the modified adiabatic product expansion. We have also outlined an adiabatic series expansion for the time-evolution operator of this system which led to another generalization of the adiabatic approximation. Finally, we considered the application of our method to treat the quadrupole interaction of a spin 1 particle with a changing electric field. The corresponding (Stark) Hamiltonian had a nondegenerate as well as a degenerate eigenvalue. We showed that the adiabatic canonical transformation mapped this Hamiltonian to a Hamiltonian which had nondegenerate eigenvalues and belonged to a reducible $(0+1/2)$ representation of the Lie algebra of SU(2). This means that we can directly use the results of Refs. 2 and 3 which treat the Schrödinger equation for a nondegenerate Hamiltonian belonging to (an irreducible representation of) the Lie algebra of SU(2). Furthermore, we identified a class of exactly solvable spin 1 quadruple Hamiltonians.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 7 JULY 1999

Geometric algebra and the causal approach to multiparticle quantum mechanics

Shyamal Somaroo, Anthony Lasenby, and Chris Doran[a)]
Astrophysics Group, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE, United Kingdom

(Received 28 January 1998; accepted 14 February 1999)

It is argued that geometric algebra, in the form of the multiparticle spacetime algebra, is well suited to the study of multiparticle quantum theory, with advantages over conventional techniques both in ease of calculation and in providing an intuitive geometric understanding of the results. This is illustrated by comparing the geometric algebra approach for a system of two spin-1/2 particles with the nonrelativistic approach of Holland [Phys. Rep. **169**, 294 (1988)]. © *1999 American Institute of Physics.* [S0022-2488(99)00907-X]

I. INTRODUCTION

Geometric (Clifford) algebra is a powerful algebraic tool with applications throughout the fields of physics and engineering. The geometric algebra of space–time—the spacetime algebra or STA—is well suited to describing many aspects of classical and quantum relativistic physics[1–4] including gravitation.[5] In Refs. 2 and 6 the multiparticle spacetime algebra (MSTA) was introduced and applied to relativistic multiparticle quantum theory. In the present paper the algebraic advantages of the MSTA approach are demonstrated through a comparison with work on a causal approach to nonrelativistic multiparticle quantum theory based on the Pauli equation.[7,8] We show that the MSTA elucidates a number of features of the multiparticle causal theory and, in particular, clarifies its geometric content.

The causal, or Bohmian, approach to quantum mechanics is an interpretation in which the statistical results of quantum theory are recovered from an ensemble of deterministically evolving systems. The approach is based on establishing a connection between the wave equation and a deterministic model that is supposed to underlie the quantum process. In the case of one spin-1/2 particle, this model consists of a classical spinning rigid body under the additional influence of a quantum potential.[7] In this way physical properties can be associated with the quantum particle, and equations for their evolution obtained from the conventional wave equation. Furthermore, the variables (including spin) on which the wave function depends are consistently interpreted as the spatial position and orientation of the particle through this model.

In n-particle nonrelativistic quantum theory the wave function depends on a dynamical configuration space of dimension $3n$, as well as on a temporal parameter t. To apply a causal approach to this system one must first associate the wave function in configuration space with a set of physical properties. These are then interpreted as the properties of the individual particles in the ensemble making up the system under consideration. Equations describing the evolution of these properties are then derived from the conventional n-particle Pauli wave equation.

Holland[7,8] has addressed the problem of extracting a set of physical properties from the n-particle wave function. His method is to construct a set of tensor variables from quadratic combinations of the spinorial wave function. These tensor variables are more easily associated with a set physical properties than the underlying spinorial degrees of freedom.

Here we show that the MSTA formulation of multiparticle quantum theory considerably simplifies the task of extracting these physical variables. Its lack of redundant mathematical

[a)]Electronic mail: C.Doran@mrao.cam.ac.uk

complications considerably simplifies calculations, as well as clarifying the relation between the spinorial and tensorial degrees of freedom. Furthermore, the method of construction readily lends itself to an interpretation in terms of an underlying physical model, though such considerations are not pursued here. In fact, since we are only concerned with nonrelativistic quantum theory, only a fraction of the full power of the MSTA is brought into play here. An introduction to the MSTA approach to relativistic multiparticle quantum theory is contained in Ref. 2 (see also Ref. 6).

We start with an outline of the MSTA and introduce our conventions and notations. We then give a schematic overview of Holland's method of relating spinorial and tensorial variables. In Sec. IV we study the one-particle case, giving a detailed account of the correspondence scheme between the MSTA and Holland's approach. In Sec. V we turn to the two-particle case, as discussed first in Ref. 8. We show how the various physical variables are found more easily in the MSTA approach, and reveal their simple geometric origins. We end with a brief look at how the MSTA approach generalizes to the *n*-particle case.

II. MULTIPARTICLE SPACE–TIME ALGEBRA

Spacetime algebra is the geometric, or Clifford, algebra of Minkowski space–time. Both geometric and spacetime algebra have been widely discussed by many authors (see Refs. 1, 2, 9, and 10 for further material). The multiparticle spacetime algebra (MSTA) was introduced to tackle the problem of formulating relativistic multiparticle mechanics within geometric algebra.[2,6] It is the geometric algebra of *n*-particle configuration space which, for relativistic systems, consists of *n* copies of Minkowski space–time. We usually refer to each copy as a "one-particle space."

An appropriate orthonormal basis for the MSTA is provided by the set $\{\gamma_\mu^a\}$, where $\mu=0,...,3$ labels the space–time vector, and $a=1,...,n$ labels the particle space. For cases where only one particle is present this index is often omitted. These vectors have an associative (geometric) product denoted by juxtaposition. The symmetrized product is denoted by a dot and satisfies

$$\gamma_\mu^a \cdot \gamma_\nu^b = \tfrac{1}{2}(\gamma_\mu^a \gamma_\nu^b + \gamma_\nu^a \gamma_\mu^b) = \eta_{\mu\nu}\delta^{ab}, \tag{2.1}$$

where $\eta_{\mu\nu}=\mathrm{diag}(+,-,-,-)$. Vectors from different particle spaces anticommute as a consequence of their orthogonality. The remaining, antisymmetrized product is denoted by a wedge and generates a bivector,

$$\gamma_\mu^i \wedge \gamma_\nu^j \equiv \tfrac{1}{2}(\gamma_\mu^i \gamma_\nu^j - \gamma_\nu^i \gamma_\mu^j). \tag{2.2}$$

In this manner a basis for the entire MSTA can be constructed. This has 2^{4n} degrees of freedom. A general element of the MSTA is termed a *multivector*.

In this paper we deal only with nonrelativistic quantum mechanics. We therefore need to pick out a preferred timelike vector for each of the particle spaces. We take this vector to be γ_0^a for each *a*. Spatial vectors relative to these timelike vectors are modeled as bivectors through a "space–time split."[3,4] For these we introduce the notation (with no sum over *a*)

$$\sigma_j^a \equiv \gamma_j^a \gamma_0^a, \quad j=1,...,3, \quad a=1,...,n. \tag{2.3}$$

For each particle space the set $\{\sigma_j^a\}$ generates the geometric algebra of relative space, which we denote $\mathcal{G}_3$. Each has a basis of the form

$$1, \quad \{\sigma_j\}, \quad \{i\sigma_j\}, \quad i, \tag{2.4}$$

where the volume element i is defined by

$$i \equiv \sigma_1 \sigma_2 \sigma_3 \tag{2.5}$$

and we have suppressed the particle-space indices. The notation reflects the fact that the geometric algebra of (relative) space is isomorphic to the Pauli algebra, though we stress that the $\{\sigma_j^a\}$ are a basis set of vectors for three-space, and not abstract operators in spin-space. The even subalgebra of the basis (2.4) is spanned by $\{1,\ i\sigma_j\}$ and is isomorphic to the quaternion algebra.

An important property of the $\{\sigma_j^a\}$ is that, unlike space–time basis vectors, relative vectors from separate particle spaces commute. This follows immediately from their definition:

$$\sigma_i^a\sigma_j^b=\gamma_i^a\gamma_0^a\gamma_j^b\gamma_0^b=\gamma_i^a\gamma_j^b\gamma_0^b\gamma_0^a=\gamma_j^b\gamma_0^b\gamma_i^a\gamma_0^a=\sigma_j^b\sigma_i^a \quad (a\neq b). \tag{2.6}$$

It follows that the $\{\sigma_j^a\}$ generate the direct product space $\mathcal{G}_3^n\equiv\mathcal{G}_3\otimes\cdots\otimes\mathcal{G}_3$ of n copies of the geometric algebra of three-dimensional space $\mathcal{G}_3$. All properties of this space follow from the properties of the fully relativistic MSTA.

Within the Pauli algebra of space, an important role is played by *rotors*. These are elements of the even subalgebra of the Pauli algebra satisfying the relation

$$R\tilde{R}=1, \tag{2.7}$$

where the tilde denotes the operation of reversing the order of the vectors in any geometric product in the MSTA. The operation of rotating a multivector is performed by

$$A\mapsto A'=RA\tilde{R}, \tag{2.8}$$

which is easily shown to keep lengths and angles unchanged.

A spinor transforms single sidedly under the action of a rotor, and can be defined as an element of a linear space that is closed under left multiplication by the rotor group. Traditionally, Pauli spinors are either taken as complex column vectors acted on by the 2×2 Pauli matrices, or as elements of a minimal left ideal of the Pauli algebra.[11] A third approach, which turns out to be very powerful in applications, is to represent spinors as elements of the even subalgebra of the Pauli algebra. This space has four real dimensions, and is closed under the action of the rotor group. It is a straightforward matter to establish a $1\leftrightarrow 1$ map between Pauli column spinors and elements of the even subalgebra.[2,12] We start with the Pauli spin matrices in the form

$$\hat{\sigma}_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \hat{\sigma}_2=\begin{pmatrix}0 & -j\\ j & 0\end{pmatrix},\quad \hat{\sigma}_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \tag{2.9}$$

where the carets denote that the $\{\hat{\sigma}_i\}$ are explicitly matrices, and j is used for the scalar unit imaginary of quantum mechanics since the symbol i is already employed for the spatial volume element. A column spinor ψ^a is then placed into a $1\leftrightarrow 1$ correspondence with an element of the even subalgebra as follows:

$$\psi^a=\begin{pmatrix}a^0+ja^3\\ -a^2+ja^1\end{pmatrix}\leftrightarrow\psi=a^0+a^k i\sigma_k. \tag{2.10}$$

The action of the quantum operators $\{\hat{\sigma}_k\}$ and j is now replaced by the operations

$$\hat{\sigma}_k|\psi\rangle\leftrightarrow\sigma_k\psi\sigma_3 \quad (k=1,...,3), \tag{2.11}$$

$$j|\psi\rangle\leftrightarrow\psi i\sigma_3. \tag{2.12}$$

Every calculation that can be performed with the column spinor ψ^a can also be performed with the even element ψ, and in practice the latter approach is usually easier. One reason for this is the natural decomposition of ψ into a density term and a rotor:

$$\psi=\rho^{1/2}R, \tag{2.13}$$

where

$$\rho \equiv \psi\tilde{\psi}. \tag{2.14}$$

The rotor R is an instruction to rotate the fixed $\{\sigma_i\}$ frame onto the frame of observables. This establishes a natural link with the description of a rotating rigid body.[9,12]

Nonrelativistic multiparticle spinors are formed from direct products of single particle spinors. If we denote the even subalgebra of $\mathcal{G}_3$ by $\mathcal{G}_3^+$, we see that nonrelativistic MSTA spinors belong to $(\mathcal{G}_3^+)^n = \mathcal{G}_3^+ \otimes \cdots \otimes \mathcal{G}_3^+$. An advantage of the MSTA approach is that this direct product coincides with the geometric product already defined. At this point it is useful to introduce the notation

$$i\sigma_j^a = i^a \sigma_j^a, \tag{2.15}$$

which removes some superscripts without introducing any ambiguity. Multiparticle spinors therefore belong to the space generated by the elements $\{1,\ i\sigma_j^a\}$. This space is closed under the left-sided action of the group of rotors of the form $R^1R^2,\ldots,R^n$, where each R^a denotes a copy of the same rotor for each particle space.

In Eq. (2.12) we saw that the role of the unit imaginary of traditional quantum theory is played by right multiplication by $i\sigma_3$. For the n-particle case there will be n copies of $i\sigma_3$, and right-multiplication by all of these must yield the same result. This is achieved by introducing the n-particle ''correlator''[2]

$$E_n \equiv \tfrac{1}{2}(1 - i\sigma_3^1 i\sigma_3^2)\cdots\tfrac{1}{2}(1 - i\sigma_3^1 i\sigma_3^n), \tag{2.16}$$

which locks the various one-particle complex structures;

$$E_n i\sigma_3^1 = E_n i\sigma_3^2 = \cdots = E_n i\sigma_3^n \equiv J_n. \tag{2.17}$$

The E_n and J_n satisfy

$$E_nE_n = E_n, \quad J_nJ_n = -E_n. \tag{2.18}$$

Correlating all n-particle states $\psi \in (\mathcal{G}_3^+)^n$ by right-multiplying by the idempotent E_n ensures that the conventional complex structure is reproduced by the operation of right multiplication by any of the $i\sigma_3^a$ or J_n. The correlator also reduces the degrees of freedom in an n-particle spinor from 4^n to the expected 2^{n+1}. It is worth noting that one effect of the correlator is to ''phase lock'' all one-particle phase-factors:

$$e^{\alpha i\sigma_3^1}E_n = e^{\alpha i\sigma_3^2}E_n = \cdots = e^{\alpha J_n}E_n. \tag{2.19}$$

This suggests an interesting substructure to the theory, which could prove useful in constructing a suitable particle model for a causal interpretation.

As an example of the above scheme, consider the MSTA analog of the spin singlet state

$$|\epsilon\rangle = \frac{1}{\sqrt{2}}\left\{\begin{pmatrix}1\\0\end{pmatrix}\otimes\begin{pmatrix}0\\1\end{pmatrix} - \begin{pmatrix}0\\1\end{pmatrix}\otimes\begin{pmatrix}1\\0\end{pmatrix}\right\}. \tag{2.20}$$

This is represented in the two-particle MSTA by the multivector

$$\epsilon = \frac{1}{\sqrt{2}}(i\sigma_2^1 - i\sigma_2^2)\,\frac{1}{2}(1 - i\sigma_3^1 i\sigma_3^2). \tag{2.21}$$

It can be shown that ϵ satisfies[2]

$$M^1\epsilon = \tilde{M}^2\epsilon \tag{2.22}$$

for an arbitrary Pauli-even multivector M. This result quickly establishes the rotation invariance of ϵ, since under a rotation in two-particle space, ϵ transforms as

$$\epsilon \mapsto R^1 R^2 \epsilon = R^1 \tilde{R}^1 \epsilon = \epsilon. \tag{2.23}$$

Throughout this paper superscripts on one-particle multivectors denote the one-particle space being referred to. For example, ϕ^k denotes a copy of the one-particle spinor ϕ in the particle-k space. Information regarding the kth particle is extracted from an arbitrary MSTA multivector by projecting it onto the particle-k space. Following Holland, Pauli spin indices are denoted by lower case letters $a-h$, and matrices are denoted by ''caretted'' versions of symbols denoting their algebraic analogs. When considered as a matrix algebra generated by (2.9) over the complex field, the Pauli algebra is denoted as $\mathcal{P}$, with $\mathcal{P}^n$ being the corresponding n-copy direct product. The range $i-l$ is used to denote spatial tensor indices, and the Einstein summation convention also applies throughout unless stated otherwise.

III. THE CAUSAL APPROACH TO MULTIPARTICLE STATES

Conventionally, a nonrelativistic spin-1/2 particle is described by a Pauli spinor ψ^a, usually viewed as a complex linear combination of the spin basis states $|\uparrow\rangle$ and $|\downarrow\rangle$, or more explicitly as a 2×1 complex column matrix. Two spin-1/2 particles are described by a rank-2 spinor, or spin tensor, ψ^{ab}. A basis for this is taken to be a complex linear combination of the direct product of two copies of the spin basis $\{|\uparrow\rangle, |\downarrow\rangle\}$. We may also view ψ^{ab} as a 4×1 complex column matrix by considering the two separate spin indices a and b in ψ^{ab} as one compounded index $\Delta=[ab]$, $\Delta=1,...,4$. This extends to a rank-n spinor $\psi^{abc\cdots}$, which describes a system of n spin-1/2 particles. $\psi^{abc\ldots}$ has 2^n complex degrees of freedom and can be viewed as a $2^n\times 1$ complex column matrix ψ^Δ, where Δ is the compounded index $\Delta=[abc\ldots]$.

Following Holland,[8] a tensor can be constructed from a pair of spinors $\psi^\Delta \equiv \psi^{abc\ldots}$ and $\xi^{efg\cdots}\equiv \xi^\Theta$ of the same rank (2^n) by first constructing the $2^n\times 2^n$ complex matrix

$$A^\Delta{}_\Theta = A^{abc\cdots}{}_{efg\ldots} \equiv \psi^{abc\cdots}(\xi_{efg\ldots})^T = \psi^\Delta(\xi_\Theta)^T, \tag{3.1}$$

where the superscript T denotes matrix transposition. Spinor indices are raised and lowered by the spin metric[13]

$$\epsilon_{ab} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = j\hat{\sigma}_2 . \tag{3.2}$$

(Conventionally, raised or lowered indices on an object indicate different coordinate representations of the same object. Here however, its significance is to indicate a distinct object which carries the same information as the original but in a different form.)

Any $2^n\times 2^n$ (complex) matrix may be expanded in terms of a set of independent basis matrices $\{(\hat{e}_{klm\ldots})^\Delta{}_\Theta\}$ for the direct product of n Pauli algebras $\mathcal{P}^n$,

$$A^\Delta{}_\Theta = \sum_{k,l,m,\ldots} c_{klm\ldots}(\hat{e}_{klm\ldots})^\Delta{}_\Theta . \tag{3.3}$$

The basis matrices $\{(\hat{e}_{klm\ldots})^\Delta{}_\Theta\}$ carry both spinor indices (Δ and Θ) and tensor indices ($\{k,l,m,\ldots\}$) which they inherit from the Pauli matrices. The complex expansion coefficients $c_{klm\ldots}$ are spatial tensors and may be determined from A via

$$c_{klm\ldots} = \frac{1}{2^n}\mathrm{Tr}[\psi^\Delta \xi_\Theta(\hat{e}_{klm\ldots})^\Theta{}_\Omega] = \frac{1}{2^n}\xi_\Theta(\hat{e}_{klm\ldots})^\Theta{}_\Delta \psi^\Delta, \tag{3.4}$$

where Tr denotes the matrix trace.

If ξ_Θ is obtained directly from ψ^Δ then $c_{klm\ldots}$ will characterize some of the information in ψ^Δ. This is the basis of Holland's approach. Note that, since A satisfies the relation

$$A^2 = A^\Delta{}_\Theta A^\Theta{}_\Omega = \psi^\Delta(\xi_\Theta)^T \psi^\Theta(\xi_\Omega)^T = A^\Theta{}_\Theta A^\Delta{}_\Omega = \mathrm{Tr}(A)A, \tag{3.5}$$

A therefore belongs to an ideal of the algebra $\mathcal{P}^n$. It is via this ''ideal'' characterization of ψ^Δ that Holland associates the tensors $c_{klm\ldots}$ with spinor degrees of freedom. We now study how geometric algebra both simplifies this scheme, and reveals much of the hidden geometry relating spinors to tensors. We start with an analysis of the one-particle setup.

IV. THE ONE-PARTICLE CASE

In the one-particle setup we expand the 2×2 complex matrix $A^a{}_b$ in terms of the Pauli matrices:

$$A^a{}_b \equiv \psi^a(\xi_b)^T \equiv s + u_k\hat{\sigma}_k = \Re(s) + j\Im(s) + [\Re(u_k) + j\Im(u_k)]\hat{\sigma}_k. \tag{4.1}$$

We can construct a MSTA version of this by first writing out $A^a{}_b$ explicitly in terms of the spinor components

$$\psi^a = \begin{pmatrix} \psi^1 \\ \psi^2 \end{pmatrix}, \quad \xi^a = \begin{pmatrix} \xi^1 \\ \xi^2 \end{pmatrix}. \tag{4.2}$$

The matrix $A^a{}_b$ then has components

$$A^a{}_b = \begin{pmatrix} \psi^1\xi^2 & -\psi^1\xi^1 \\ \psi^2\xi^2 & -\psi^2\xi^1 \end{pmatrix} = \begin{pmatrix} \psi^1 & 0 \\ \psi^2 & 0 \end{pmatrix} \begin{pmatrix} \xi^2 & 0 \\ -\xi^1 & 0 \end{pmatrix}^T. \tag{4.3}$$

By writing this as the product of two matrices, we can easily establish an equivalent expression within the one-particle geometric algebra of space. First, we note the following equivalence:

$$\begin{pmatrix} \psi^1 & 0 \\ \psi^2 & 0 \end{pmatrix} \leftrightarrow \psi\tfrac{1}{2}(1+\sigma_3), \tag{4.4}$$

where ψ is the Pauli-even multivector formed from ψ^a according to Eq. (2.10). Second, we need the analog of matrix transposition for multivectors. It is easily confirmed that this is performed by

$$M^T = \sigma_2 \tilde{M} \sigma_2. \tag{4.5}$$

If we now denote the multivector equivalent of $A^a{}_b$ by A, we find that

$$A = \psi\tfrac{1}{2}(1+\sigma_3)[i\sigma_2\xi\tfrac{1}{2}(1+\sigma_3)]^T = \psi\tfrac{1}{2}(1+\sigma_3)\sigma_2\tfrac{1}{2}(1-\sigma_3)\tilde{\xi}(-i\sigma_2)\sigma_2 = -\psi\tfrac{1}{2}(\sigma_1 + i\sigma_2)\tilde{\xi}, \tag{4.6}$$

which immediately gives all of the components s and $\{u_k\}$ by simply reading off the terms of different grades. Each grade returns a genuine geometric object, since under the rotation $\psi \mapsto R\psi$, $\xi \mapsto R\xi$, we find that A transforms as

$$A \mapsto RA\tilde{R}, \tag{4.7}$$

which is the correct transformation law for geometric objects. The same approach extends easily to the case where the rotor R includes Lorentz transformations. This is not such a surprise when one considers that the algebraic manipulations described here closely resemble those of the 2-spinor calculus,[13,14] which are designed to be fully relativistic. We can now give the following explicit formulas for the s and $\{u_k\}$:

$$\Re(s) = -\tfrac{1}{2}\langle \psi i \sigma_2 \tilde{\xi}\rangle, \quad \Im(s) = \tfrac{1}{2}\langle \psi i \sigma_1 \tilde{\xi}\rangle,$$
$$\Re(u_k) = -\tfrac{1}{2}\langle \psi \sigma_1 \tilde{\xi} \sigma_k\rangle, \quad \Im(u_k) = -\tfrac{1}{2}\langle \psi \sigma_2 \tilde{\xi}\sigma_k\rangle, \tag{4.8}$$

where $\langle M\rangle$ denotes the result of projecting out the scalar part of the multivector M.

Having established the correspondence between the matrix formalism and geometric algebra, it is now straightforward to consider the choices Holland makes for ξ_b and the resulting tensors obtained.[8] The first choice is

$$\xi_b = \psi^{a*} \tag{4.9}$$

$$\Rightarrow \xi^a = \epsilon^{ab}\xi_b = -\epsilon_{ab}\psi^{a*}. \tag{4.10}$$

The multivector analog of complex conjugation is defined by

$$\psi^* = \sigma_2 \psi \sigma_2, \tag{4.11}$$

so this choice corresponds to setting

$$\xi = (-i\sigma_2)\sigma_2\psi\sigma_2 = -\psi i \sigma_2. \tag{4.12}$$

It follows that A is given by

$$A = \psi \tfrac{1}{2}(1+\sigma_3)\tilde{\psi} = \tfrac{1}{2}\psi\tilde{\psi} + \tfrac{1}{2}\psi\sigma_3\tilde{\psi}, \tag{4.13}$$

and from (4.8) we find

$$\rho \equiv 2s = \psi\tilde{\psi}, \tag{4.14}$$

$$S \equiv 2u_k\sigma_k = \psi\sigma_3\tilde{\psi}, \tag{4.15}$$

where ρ and S are the symbols used by Holland. As expected, we have isolated the scalar density $\psi\tilde{\psi}$ and the spin vector $\psi\sigma_3\tilde{\psi}$. On decomposing ψ in the form

$$\psi = \rho^{1/2} R = \rho^{1/2} e^{i\sigma_3\theta/2} e^{i\sigma_1\varphi/2} e^{i\sigma_3\chi/2}, \tag{4.16}$$

where we have written the rotor R in terms of the Euler angles, we see that the scalar ρ and the vector

$$S = \rho[\sin(\theta)\cos(\varphi)\sigma_1 + \sin(\theta)\sin(\varphi)\sigma_2 + \cos(\theta)\sigma_3] \tag{4.17}$$

are independent of the phase χ. This pair of tensors therefore only embodies three of the four degrees of freedom in ψ and consequently an additional characterization of ψ is required. From our geometric viewpoint it is clear that the only other tensors that can be obtained from ψ are the vectors $\psi\sigma_1\tilde{\psi}$ and $\psi\sigma_2\tilde{\psi}$, or their corresponding duals. To verify this, consider Holland's other choice:

$$\xi_b = \psi_b \Rightarrow \xi = \psi. \tag{4.18}$$

On substituting this into (4.13) we find that

$$A = -\psi\tfrac{1}{2}(1+\sigma_3) i \sigma_2 \tilde{\psi} = -\tfrac{1}{2}(\psi i \sigma_2 \tilde{\psi} + \psi \sigma_1 \tilde{\psi}). \tag{4.19}$$

Clearly for this choice of ξ, $s=0$ and from (4.8)

$$M \equiv 2\Re(\mathbf{u}) = -\psi\sigma_1\tilde{\psi}, \quad N \equiv 2\Im(\mathbf{u}) = -\psi\sigma_2\tilde{\psi}, \tag{4.20}$$

where M and N are Holland's Cartan–Kramers vectors.

The mutual geometric relations of M, N, and S are transparent from the geometric point of view, since the set is obtained by a rotation and dilation of the orthonormal basis $\{\sigma_1, \sigma_2, \sigma_3\}$. It follows immediately that

$$\rho = |M| = |N| = |S| \tag{4.21}$$

and that M, N, and S are mutually orthogonal. Since the phase factor $\exp\{i\sigma_3\chi/2\}$ does not commute with either of σ_1 or σ_2, the pair $\{M,N\}$ contain information about all four degrees of freedom in ψ. Indeed, any pair from the set $\{S,M,N\}$ contains information about all four degrees of freedom in ψ, and can be used to reconstruct ψ (and hence ψ^a, if required) up to an arbitrary sign. The simple manner in which the triad $\{M,N,S\}$ is formed and understood in the geometric algebra approach fully demonstrates its advantages.

V. THE TWO-PARTICLE CASE

Two-particle states are conventionally represented by rank-2 spinors ψ^{ab}. From these we construct the matrix

$$A^{ab}{}_{cd} = \psi^{ab}(\xi_{cd})^T, \tag{5.1}$$

which is a 4×4 complex matrix, where the transpose is understood to be with respect to the compounded index $[cd]$. This matrix can be expanded in the 16-dimensional basis

$$\begin{aligned} \mathbf{1}^{ab}_{cd} &= \delta^a{}_c \delta^b{}_d, \quad (\hat{e}_{1k})^{ab}{}_{cd} = \hat{\sigma}_k{}^a{}_c \delta^b{}_d \\ (\hat{e}_{2l})^{ab}{}_{cd} &= \delta^a{}_c \hat{\sigma}_l{}^b{}_d, \quad (\hat{e}_{1k}\hat{e}_{2l})^{ab}{}_{cd} = \hat{\sigma}_k{}^a{}_c \hat{\sigma}_l{}^b{}_d \end{aligned} \tag{5.2}$$

belonging to $\mathcal{P}^2$. With a suppression of spinor indices, we can write (following Ref. 8)

$$A = s\mathbf{1} + c_k\hat{e}_{1k} + d_k\hat{e}_{2k} + f_{kl}\hat{e}_{1k}\hat{e}_{2l}. \tag{5.3}$$

These coefficients are not independent because of the relation $A^2 = \mathrm{Tr}(A)A$.

A complete basis for two-particle spin states, together with their MSTA analogs, is provided by

$$\begin{aligned} \begin{pmatrix}1\\0\end{pmatrix} \otimes \begin{pmatrix}1\\0\end{pmatrix} &\leftrightarrow E, \\ \begin{pmatrix}0\\1\end{pmatrix} \otimes \begin{pmatrix}1\\0\end{pmatrix} &\leftrightarrow -i\sigma_2^1 E, \\ \begin{pmatrix}1\\0\end{pmatrix} \otimes \begin{pmatrix}0\\1\end{pmatrix} &\leftrightarrow -i\sigma_2^2 E, \\ \begin{pmatrix}0\\1\end{pmatrix} \otimes \begin{pmatrix}0\\1\end{pmatrix} &\leftrightarrow i\sigma_2^1 i\sigma_2^2 E, \end{aligned} \tag{5.4}$$

where $E = \frac{1}{2}(1 - i\sigma_3^1 i\sigma_3^2)$ is the two-particle correlator. A rank-2 spinor ψ^{ab} can be expanded in terms of this basis and hence mapped directly to the MSTA element $\psi = \psi E \in (\mathcal{G}_3^+)^2$, where

$$\psi = (\phi_1 - i\sigma_2^1\phi_2 - i\sigma_2^2\phi_3 + i\sigma_2^1 i\sigma_2^2\phi_4)E \tag{5.5}$$

and ϕ_n, $n=1,...,4$ are the combinations of 1 and J appropriate to the expansion of ψ^{ab}. All MSTA spinors $\psi \in (\mathcal{G}_3^+)^2$ contain an implicit factor of E. This is only shown explicitly in cases where its presence increases clarity.

We can again construct the matrix $A^{ab}{}_{cd}$ by first introducing the MSTA analog of a 4×4 complex matrix in which ψ^{ab} is the first and only nonzero column. The multivector equivalent of this is

$$\psi\tfrac{1}{2}(1+\sigma_3^1)\tfrac{1}{2}(1+\sigma_3^2)E=\psi\tfrac{1}{2}(1+\sigma_3^1)\tfrac{1}{2}(1+\sigma_3^1)\tfrac{1}{2}(1-i^1i^2). \tag{5.6}$$

The analog of the matrix transpose operation is now

$$M^T=\sigma_2^1\sigma_2^2\tilde{M}\sigma_2^1\sigma_2^2 \tag{5.7}$$

and we find that the information contained in $A^{ab}{}_{cd}$ can be encoded in the multivector

$$A=\psi\tfrac{1}{2}(\sigma_1^1+i\sigma_2^1)\tfrac{1}{2}(\sigma_1^2+i\sigma_2^2)E\tilde{\xi}=\psi\tfrac{1}{2}(\sigma_1^1+i\sigma_2^1)\tfrac{1}{2}(\sigma_1^2+i\sigma_2^2)\tilde{\xi}(1-i^1i^2). \tag{5.8}$$

The fact that A satisfies $A=A\tfrac{1}{2}(1-i^1i^2)$ is to be expected. The tensor product $\mathcal{G}_3\otimes\mathcal{G}_3$ defines a space of 64 real dimensions, whereas the product $\mathcal{P}\otimes\mathcal{P}$ defines a 16-dimensional complex space, with 32 real dimensions. The space $\mathcal{P}\otimes\mathcal{P}$ therefore fails to provide a matrix representation of the full algebra $\mathcal{G}_3\otimes\mathcal{G}_3$, the reason being that the two pseudoscalars i^1 and i^2 are given the same representation in terms of the unit imaginary j. The only multivectors in $\mathcal{G}_3\otimes\mathcal{G}_3$ which do correspond directly to matrices in $\mathcal{P}\otimes\mathcal{P}$ are therefore those which contain a factor of the idempotent $\tfrac{1}{2}(1-i^1i^2)$, which links the pseudoscalars together.

The quantities of interest are the complex tensor coefficients s, c_k, d_l, and f_{kl} in (5.3). These can all be recovered by taking appropriate traces of the form

$$\tfrac{1}{4}\mathrm{Tr}(A^{ab}{}_{cd}\Gamma^{cd}{}_{ef})=\tfrac{1}{4}\xi_{cd}\Gamma^{cd}{}_{ab}\psi^{ab}, \tag{5.9}$$

where Γ is some combination of the basis elements (5.2). From the above scheme, a general matrix of the form $A^{ab}{}_{cd}\Gamma^{cd}{}_{ef}$ will have a multivector equivalent $M=M\tfrac{1}{2}(1-i^1i^2)$. With this multivector we have the explicit relations

$$\begin{aligned}\Re(\tfrac{1}{4}\xi_{cd}\Gamma^{cd}{}_{ab}\psi^{ab})&=2\langle M\rangle,\\ \Im(\tfrac{1}{4}\xi_{cd}\Gamma^{cd}{}_{ab}\psi^{ab})&=-2\langle Mi^1\rangle.\end{aligned} \tag{5.10}$$

The extra factor of 2 is required because of the presence of the factor of $\tfrac{1}{2}(1-i^1i^2)$ in M.

We now have analogs for most of the operations performed on rank-2 spinors. The one remaining operation is that of particle interchange

$$\psi^{ab}\mapsto\psi^{ba}. \tag{5.11}$$

The algebraic effect of this on the MSTA spinor ψ is

$$\psi\mapsto\psi^I=(\phi_1-i\sigma_2^2\phi_2-i\sigma_2^1\phi_3+i\sigma_2^1i\sigma_2^2\phi_4)E. \tag{5.12}$$

This operation has no one-particle analog. As an algebraic operation it can be expressed as

$$\psi\to\psi^I=E\psi E-i\sigma_2^1i\sigma_2^2\bar{E}\psi E=\tfrac{1}{2}(1-i\sigma_k^1i\sigma_k^2)\psi, \tag{5.13}$$

where $\bar{E}\equiv\tfrac{1}{2}(1+i\sigma_3^1i\sigma_3^2)$. If we recall the definition of the MSTA rotation singlet state from Sec. II,

$$\epsilon \equiv \frac{1}{\sqrt{2}}(i\sigma_2^1 - i\sigma_2^2)E, \tag{5.14}$$

we find that

$$\epsilon\tilde{\epsilon} = \tfrac{1}{2}(1 + i\sigma_k^1 i\sigma_k^2). \tag{5.15}$$

It follows that

$$\psi^I = (1 - \epsilon\tilde{\epsilon})\psi, \tag{5.16}$$

confirming that the antisymmetrized state $\psi - \psi^I = \epsilon\tilde{\epsilon}\psi$ is a rotation singlet. Equation (2.23) ensures that the interchange operation is rotationally covariant,

$$R^1R^2(1-\epsilon\tilde{\epsilon})\psi = R^1R^2\psi - \epsilon\tilde{\epsilon}\psi = (1-\epsilon\tilde{\epsilon})R^1R^2\psi, \tag{5.17}$$

as expected.

We are now in a position to give explicit MSTA formulas for the two-particle tensors constructed in Ref. 8. With ψ the direct map of ψ^{ab}, according to Eq. (5.5), we find that

$$\begin{aligned} \rho &\equiv \psi^{ab}\psi^{*ab} = 2\langle \psi\tilde{\psi}\rangle, \\ S_{1k} &\equiv \psi^{*ab} e_{1k}{}^{ab}{}_{cd}\psi^{cd} = -2(\psi J\tilde{\psi})\cdot(i\sigma_k^1), \\ S_{2k} &\equiv \psi^{*ab} e_{2k}{}^{ab}{}_{cd}\psi^{cd} = -2(\psi J\tilde{\psi})\cdot(i\sigma_k^2), \\ S_{kl} &\equiv \psi^{*ab} e_{1k}{}^{ab}{}_{cd} e_{2k}{}^{cd}{}_{ef}\psi^{ef} = -2(\psi\tilde{\psi})\cdot(i\sigma_k^1 i\sigma_l^2). \end{aligned} \tag{5.18}$$

The only terms involved in the MSTA approach are the scalar + four-vector quantities $\psi\tilde{\psi} = \psi E\tilde{\psi}$ and the bivector $\psi J\tilde{\psi}$. This information is summarized in the single multivector

$$A = \psi\tfrac{1}{2}(1+\sigma_3^1)\tfrac{1}{2}(1+\sigma_3^2)\tilde{\psi}, \tag{5.19}$$

as expected.

Holland interprets S_{kl} as a spin correlation tensor, an observation justified by that fact that S_{kl} encodes the four-vector component of the ''expectation,'' $\psi E\tilde{\psi}$, of the correlator E in the MSTA formulation. The quantity $\psi J\tilde{\psi}$ is a bivector on account of its even grade and reversion asymmetry. Since we work in the closed algebra $(\mathcal{G}_3^+)^2$, it can only have $i\sigma_k^1$ and $i\sigma_k^2$ parts. We can therefore write

$$\psi J\tilde{\psi} = \tfrac{1}{2}(S_1^1 + S_2^2), \tag{5.20}$$

where S_1^1 and S_2^2 are one-particle bivectors. The subscripts indicate that S_1 and S_2 are separate variables, while the superscripts denote the particle spaces these quantities are expressed in. The quantity $\psi J\tilde{\psi}$ is the two-particle spin bivector whose one-particle projections S_1 and S_2 are the spin bivectors of particle-1 and particle-2, respectively.[2]

One surprising result proved in Ref. 8 is that the spin bivectors S_1 and S_2 have the same magnitude, $|S_1| = |S_2|$. This result is obviously true for direct-product states, but it is not intuitively obvious why it should hold for general superpositions. It is therefore instructive to see how to prove the result in the MSTA. We start by noting that the components of S_1 are given by

$$-\tfrac{1}{2}S_{1k} = \tfrac{1}{2}S_1^1\cdot(i\sigma_k^1) = (\psi J\tilde{\psi})\cdot(i\sigma_k^1) = (\tilde{\psi} i\sigma_k^1\psi)\cdot(i\sigma_3^1). \tag{5.21}$$

The implicit idempotent E on either side of the bivector $\tilde{\psi} i\sigma_k^1 \psi = E\tilde{\psi} i\sigma_k^1 \psi E$, acts as a projection and implies that $\tilde{\psi} i\sigma_k^1 \psi$ can only contain an equal linear combination of $i\sigma_3^1$ and $i\sigma_3^2$. We can therefore write

$$\tilde{\psi} i\sigma_k^1 \psi = S_{1k} J, \quad \tilde{\psi} i\sigma_k^2 \psi = S_{2k} J. \tag{5.22}$$

From this we deduce that the magnitudes of S_1 and S_2 are given by

$$|S_a|^2 = S_{ak} S_{ak} = -2\langle S_{ak} J S_{ak} J\rangle = -2\langle \tilde{\psi} i\sigma_k^a \psi \tilde{\psi} i\sigma_k^a \psi\rangle, \tag{5.23}$$

where $a = 1,2$ and no summation over a is implied. Since $\psi\tilde{\psi}$ is even and reversion symmetric, it contains only a scalar and four-vector part. The four-vector part necessarily has the form $B^1 C^2$, where B^1 and C^2 are bivectors in the separate one-particle spaces. Employing the one-particle identity

$$i\sigma_k^1 B^1 i\sigma_k^1 = B^1, \tag{5.24}$$

we see that (with no sum over a)

$$i\sigma_k^a \psi\tilde{\psi} i\sigma_k^a = i\sigma_k^a (\langle \psi\tilde{\psi}\rangle + \langle \psi\tilde{\psi}\rangle_4) i\sigma_k^a = -3\langle \psi\tilde{\psi}\rangle + \langle \psi\tilde{\psi}\rangle_4 = \psi\tilde{\psi} - 4\langle \psi\tilde{\psi}\rangle. \tag{5.25}$$

This result is independent of the label a, and upon substitution into (5.23) implies that $|S_1|^2 = |S_2|^2$. Specifically,

$$|S_a|^2 = -2\langle \tilde{\psi}(\psi\tilde{\psi} - 4\langle \psi\tilde{\psi}\rangle)\psi\rangle = -2\langle \tilde{\psi}\psi\tilde{\psi}\psi\rangle + 2\rho^2. \tag{5.26}$$

This result does not generalize to higher particle numbers.

In Ref. 8 the quantity Ω is defined as

$$|S_1|^2 = |S_2|^2 = 2\Omega - \rho^2, \tag{5.27}$$

and it follows from Eq. (5.26) that we can write

$$\Omega = \tfrac{3}{2}\rho^2 - \langle \tilde{\psi}\psi\tilde{\psi}\psi\rangle. \tag{5.28}$$

Since the elements S_{kl} are the components of $-2\langle \psi\tilde{\psi}\rangle_4$, we can substitute

$$\psi\tilde{\psi} = \tfrac{1}{2}(\rho - S_{kl} i\sigma_k^1 i\sigma_l^2) \tag{5.29}$$

into the preceding expression for Ω to obtain

$$\Omega = \tfrac{1}{4}(5\rho^2 - S_{kl} S_{kl}), \tag{5.30}$$

recovering Ω in terms of previously defined quantities. This result is not so easily deduced in the spin-tensor approach.

A second choice of ξ_{cd} considered in Ref. 8 is

$$\xi_{cd} = \psi^{*dc}. \tag{5.31}$$

The equivalent MSTA spinor is

$$\xi = (1 - \epsilon\tilde{\epsilon})\psi i\sigma_2^1 i\sigma_2^2, \tag{5.32}$$

leading to the new multivector

$$A' = \psi \tfrac{1}{2}(1 + \sigma_3^1)\tfrac{1}{2}(1 + \sigma_3^2)\tilde{\psi}(1 - \epsilon\tilde{\epsilon}) = A(1 - \epsilon\tilde{\epsilon}), \tag{5.33}$$

where A is as defined in Eq. (5.19). This expression makes it immediately clear that A' contains precisely the same information as A. This conclusion is much harder to reach in the tensor approach, where one is forced to consider each of the terms in the matrix $\psi^{ab}\psi^{*dc}$ and show that they can be written in terms of the $\psi^{ab}\psi^{cd}$.

It is clear from the expressions $\psi\tilde{\psi}$ and $\psi J\tilde{\psi}$ that $\{\rho, S_{1k}, S_{2l}, S_{kl}\}$ are invariant under an overall phase change of ψ. Consequently, this set only encodes seven of the eight degrees of freedom in ψ and some other form for ξ must be used to recover all of the information in ψ. The MSTA approach enables us to immediately write down two further geometric entities which pick up the phase information. These are

$$\tfrac{1}{2}W \equiv \psi i\sigma_2^1 i\sigma_2^2 \tilde{\psi}, \quad \tfrac{1}{2}V \equiv \psi J i\sigma_2^1 i\sigma_2^2 \tilde{\psi}. \tag{5.34}$$

With these we can proceed to give MSTA equivalents of the remaining tensors defined in Ref. 8. The first set are formed by taking $\xi_{ab} = \psi_{ab}$, yielding the two new quantities

$$\overline{\rho} \equiv \psi_{ab}\psi^{ab} = 2\langle i\sigma_2^1 i\sigma_2^2 \tilde{\psi}\psi\rangle - 2\langle i\sigma_2^1 i\sigma_2^2 \tilde{\psi}\psi J\rangle j = \langle W\rangle - j\langle V\rangle \tag{5.35}$$

and

$$\begin{aligned} T_{kl} \equiv \psi_{ab} e_{1k}{}^{ab}{}_{cd} e_{2k}{}^{cd}{}_{ef} \psi^{ef} &= -2\langle i\sigma_2^1 i\sigma_2^2 \tilde{\psi} i\sigma_k^1 i\sigma_l^2 \psi\rangle + 2j\langle i\sigma_2^1 i\sigma_2^2 \tilde{\psi} i\sigma_k^1 i\sigma_l^2 \psi J\rangle \\ &= -W\cdot(i\sigma_k^1 i\sigma_l^2) + jV\cdot(i\sigma_k^1 i\sigma_l^2). \end{aligned} \tag{5.36}$$

As expected, V and W are the only quantities necessary for the evaluation of these coefficients. Since $i\sigma_2^1 i\sigma_2^2$ and $i\sigma_1^1 i\sigma_2^2$ anticommute with J, the phase transformation $\psi \to \psi e^{\theta J}$ implies that

$$W \to \cos(2\theta)W + \sin(2\theta)V, \quad V \to \cos(2\theta)V - \sin(2\theta)W. \tag{5.37}$$

By taking scalar parts of these transformations we can deduce the behavior of $\overline{\rho}$ under phase changes. Similarly, taking the four-vector parts gives us the phase transformation properties for the real and imaginary parts of T_{kl}.

The remaining quantities defined in Ref. 8 are obtained from the choice $\xi_{ab} = \psi_{ba}$. Again, the MSTA equivalent for this choice,

$$\xi = (1 - \epsilon\tilde{\epsilon})\psi \tag{5.38}$$

makes it clear that this choice yields nothing new, and that all of the tensor coefficients derived by setting $\xi_{ab} = \psi_{ba}$ can be recovered from V and W.

One remaining MSTA construct is the scalar + four-vector quantity $\tilde{\psi}\psi$. By its construction this quantity is automatically invariant under rotations. The scalar term is just the density ρ already defined. The four-vector invariant is more interesting since it picks up phase information. In terms of the decomposition (5.5) we have explicitly

$$\tilde{\psi}\psi = [\rho + 2i\sigma_2^1 i\sigma_2^2(\phi_1\phi_4 - \phi_2\phi_3)]E, \tag{5.39}$$

which demonstrates that it is the complex quantity $\phi_1\phi_4 - \phi_2\phi_3$ which picks up the phase information. The same information is encoded in the trace T_{kk}, so $\tilde{\psi}\psi$ yields no new information.

In summary, we see that all of the information required to completely encode ψ in tensor form is contained in the set of multivectors

$$\{\psi\tilde{\psi},\ \psi J\tilde{\psi},\ \psi i\sigma_2^1 i\sigma_2^2 \tilde{\psi},\ \psi i\sigma_2^1 i\sigma_2^2 J\tilde{\psi}\}. \tag{5.40}$$

This is the complete set of distinct objects obtainable by taking any basis element Γ of the direct product of two Pauli algebras and forming the bilinear construct $\psi\Gamma\tilde{\psi}$. The other objects one might try to construct would be of the form $\psi i\sigma_1^1\tilde{\psi}$, but the presence of the idempotent E ensures that all quantities of this form vanish. (If one looks to construct models beyond those suggested by quantum theory, however, one can contemplate not correlating the phases of the particles, in which case such quantities would come into consideration.)

The set (5.40) is directly analogous to the one-particle set $\{\rho, iM, iN, iS\}$ which can be written as

$$\{\psi\tilde{\psi},\ \ \psi J_1\tilde{\psi},\ \ \psi i\sigma_2\tilde{\psi},\ \ \psi i\sigma_2 J_1\tilde{\psi}\}. \tag{5.41}$$

We are now in a position to appreciate just how systematic and simple the MSTA approach is. The full set of distinct objects (5.40) could have been written down easily at the start of the analysis, and all terms calculated simply with the MSTA, without requiring laborious matrix and tensor manipulations. Furthermore, the MSTA approach is very amenable to generalization to higher dimensions, as discussed in Sec. VI.

VI. EXTENSIONS AND FURTHER WORK

As in the one-particle and two-particle cases, the n-particle spinor $\psi^{abc\cdots}$ can be mapped directly to an element in the direct product of n Pauli-even algebras $(\mathcal{G}_3^+)^n$. The ambiguity in the complex structure for each of the factors in $(\mathcal{G}_3^+)^n$ requires the introduction of the n-particle correlator E_n defined at Eq. (2.16). We find that the spinor ψ can be written as a combination of 2^n terms:

$$\psi = \left(\phi + \sum_{a=1}^{n} i\sigma_2^a \phi_a + \sum_{a<b} i\sigma_2^a i\sigma_2^b \phi_{ab} + \cdots + i\sigma_2^1 i\sigma_2^2 \cdots i\sigma_2^n \phi_{12\ldots n} \right) E_n, \tag{6.1}$$

where the ϕ are complex combinations of 1 and J_n. The tensor observables formed from two n-particle spinors are summarized in the multivector

$$A = \psi\left(\tfrac{1}{2}(\sigma_1^1 + i\sigma_2^1)\cdots\tfrac{1}{2}(\sigma_1^n + i\sigma_2^n)\right)\tilde{\xi}, \tag{6.2}$$

and it is clear that the various tensors one might construct correspond to the various multivector parts of bilinear constructs of the form $\psi\Gamma\tilde{\psi}$, where Γ is some fixed set of MSTA basis elements.

For example, one of the key objects to analyze is the multivector $\psi J\tilde{\psi}$. This has grade-2, grade-6,..., components, of which the grade-2 component is the multiparticle spin bivector[2]

$$S \equiv 2^{n-1}\langle \psi J_n \tilde{\psi}\rangle_2 . \tag{6.3}$$

Interpretations for the other components of $\psi J\tilde{\psi}$ can be made in terms of spin correlations between particles. This approach to constructing tensors from spinors is clearly more economic than the matrix/tensor approach, which gets progressively worse with increasing particle number due to the large degree of redundancy in the tensor coefficients contained in the various bilinear constructs.

A further advantage of the MSTA approach is that it is easily generalized to the relativistic domain. A discussion of this is contained in Ref. 2 and further details are contained in Ref. 6. Such an extension is essential if this approach is to shed light on questions of nonlocality in Einstein–Podolski–Rosen- (EPR)-type experiments—in particular a full analysis of these must incorporate relativity, as this lies at the heart of the paradox. A simple model for two-particle relativistic spin correlations is contained in Ref. 2, though more work is needed to extend this work to model an EPR-type setup. Finally, it should be borne in mind that the MSTA is equally applicable to classical as well as quantum physics, and many of the techniques described here are useful for studying multiparticle classical relativistic dynamics, a notoriously difficult subject.

A differential-geometric interpretation of Kirchhoff's elastic rods

Kai Hu[a)]
Department of Mathematics, University of California, Los Angeles, Los Angeles, California 90095-1555

(Received 28 July 1998; accepted for publication 2 April 1999)

In this article, Kirchhoff's elasticity theory of rods is revisited but from a viewpoint of Riemannian geometry. By means of the Cayley–Klein parameter, the theory under clamped-end conditions can be regarded as a geometry of paths on some geometrically distorted three-sphere produced by a constrained elastic energy functional. Using this geometric formulation, the uniqueness of elasticae with prescribed initial values of the strains can be easily shown. On the other hand, a family of elasticae with prescribed values of orthonormal frames at two endpoints is demonstrated to be parametrized by an open set in $\mathbb{R}^3$. In particular, a criterion of the nonuniqueness of elasticae satisfying clamped-end conditions is given in terms of a geometric concept—conjugate points. © *1999 American Institute of Physics.* [S0022-2488(99)01307-9]

I. INTRODUCTION

Over the last two decades, Kirchhoff's elasticity theory has been extensively applied to study shapes of two-stranded polymers, like DNA (suggested by Fuller[1]). Also, the theory provides energetic explanations of supercoiling of DNA which is important for DNA functions like recombination, DNA being a torus knot observed under electron microscopy.[2] Recently, an interesting area from molecular biology deals with the study of a special case of Kirchhoff's theory of which the stress-free state is not a (twisted) straight line anymore.[3–8] Some relaxed DNA observed in experiments form a closed circle, such as SV40.[4,5] Thus, intrinsically curved elasticity is needed to model circular DNA. Indeed, theoretically, one cannot simply ignore, for instance, base stacking and hydrogen bonding energies existing in DNA. Therefore, in this article we turn our attention to general elasticity theory, particularly with an emphasis on geometric methods.

An elastic rod is *inextensible* (resp. *unshearable*) if the length of its axis (resp. the normal cross sections being normal to its axis) is unaltered while undergoing deformations. These are reasonable assumptions when we study conformations of DNA. Mathematically, an elastic rod can be simplified to a *framed curve* (C,ν) consisting of an immersed, unit-speed space curve C, called axis, and a preferred unit normal vector field ν defined along C, called material direction. Therefore, it is easy to see that an unshearable elastic rod under deformation can be thought of as a framed curve being perturbed within the family of framed curves. How we take inextensibility into account will be demonstrated in Sec. III.

According to Kirchhoff's theory, an *elastica* is a critical point of the so-called *elastic energy* functional,[7]

$$\mathcal{E}=\frac{1}{2}\int_0^l \rho_1(\omega_1-\kappa_1)^2+\rho_2(\omega_2-\kappa_2)^2+\rho_3(\omega_3-\kappa_3)^2\,ds, \tag{1}$$

where ρ_1 and ρ_2 are both called *bending stiffnesses* and ρ_3 is called *twisting stiffness*. All ρ_i's are assumed positive constants; ω_i's are called *strains* and ω_3 is specially called *twisting density*

[a)]Electronic mail: khu@math.ucla.edu

(I will explain how the strains of an elastic rod can be computed). Here κ_1, κ_2 are called *intrinsic curvatures*, and κ_3 is called *intrinsic twisting density*. In fact, κ_i's are the ω_i's of the stress-free state (and this state is also called relaxed state in molecular biology). Also, s is the arc-length parameter of the axis of an elastic rod and l is its length. The sum of the first two terms of (1) is called *bending energy* and the remaining term alone is called *twisting energy*. An elastic rod is called *isotropic* if $\rho_1 = \rho_2$. It is obvious that, for example, if the largest stiffness is ρ_3, then torsional fluctuations are less energetically favorable.

In the application to molecular biology, unless DNA is denatured, it is always possible to determine the axis of DNA as a curve traced out by the centers of base pairs. In fact, what we are concerned with here is the so-called B-form DNA which occurs when DNA is fully hydrated as it is *in vivo*. While a framed curve is employed to model such DNA, one may assume that C is exactly the axis and oriented by the $3'-5'$ direction of the leading backbone of the double helix; ν is chosen to be parallel to the long axis of the plane containing a base pair, pointing in the direction of the leading backbone.[7] Thus, κ_3 represents the naturally helical structure of DNA. Especially, κ_3 may be regarded as a constant because the structure is uniform. The bending and twisting stiffnesses usually vary according to different environmental factors, such as temperature, pH, and ion concentration of solutions, because these factors have influence on the elastic stiffnesses.[9]

In this article, I continue the use of the Cayley–Klein parameter[10] inspired by Li and Maddocks' paper.[6] By means of this parameter, the whole elasticity theory of rods can be transformed to a geometry of paths on a geometrically distorted S^3 governed by the elastic energy functional. In particular, in the case of *intrinisically straight* elasticity defined by each $\kappa_i = 0$, the theory is transformed exactly into the geometry of paths determined by the Dirichlet functional, which is well understood in Riemannian geometry.

This geometric method is heavily applied to derive Euler–Lagrange equations in Sec. III (all geometric calculations involved there can be found in Chern's lecture notes).[11] We set up a clamped-end variational principle such that the theory has no symmetry of rigid motions of $\mathbb{R}^3$ generically also a correspondence between deformations of elastic rods (satisfying three out of four clamped-end conditions and length preserving) and variations of paths (with endpoints fixed), see Lemma 1. Additionally, regularity of elasticae is established and basic properties of elasticae in the general case are developed. In Sec. IV, we formulate two questions. Physically, Question 1 asks if one can find an elastica whenever the initial values of the strains are known and when such an elastica is unique; Question 2 asks the same thing if the boundary values of orthonormal frames [i.e., conditions (13) and (14)] are given instead. Both answers to Question 1 are affirmative, but they are uncertain for Question 2—Theorems 4 and 5 are partial answers. Moreover, we give a geometric criterion of the nonuniqueness of clamped-end elasticae (Theorem 6). All geometry terminologies used in Sec. IV can be found in Cheeger and Ebin's book.[12]

Author's apology. There exists a vast collection of papers on both elasticity theory and elastic models on DNA. Therefore, I most sincerely apologize to those esteemed scientists whose work is not mentioned in this article. I only list those papers having direct influence on this article.

II. THE GEOMETRIC FORMULATION OF ELASTIC ENERGY

Given a framed curve (C,ν), one may assume e_1, the unit tangent vector of C, $e_2 = \nu$, and $e_3 = e_1 \times e_2$, which points in the direction of the major groove of DNA and is parallel to the short axis of the base plane when modeling DNA is the concern.[7] Arising from (i,j,k) the standard basis of $\mathbb{R}^3$, such an orthonormal frame (e_1, e_2, e_3) gives a curve in SO(3). Recall the double cover π:SU(2)$\rightarrow$SO(3) given by $\pi(q)$ acting on $\mathbb{R}^3$ via $q^{-1}xq$, where $q^{-1}xq$ should be realized as a product of quaternions and $x \in \mathbb{R}^3$ identified with the purely imaginary quaternions. Therefore, the aforementioned curve in SO(3) can be lifted to SU(2), called the *Cayley–Klein* parameter of (C,ν).

Using the facts $q = q_1 + iq_2 + jq_3 + kq_4$, $q^{-1} = \overline{q}$ (because $q \in S^3$), and $i^2 = j^2 = k^2 = -1$, $ij = -ji = k$, $jk = -kj = i$, $ki = -ik = j$, one can derive some useful equations relating e_i's of a framed curve to its Cayley–Klein parameter q as follows:

$$e_1 = q^{-1} i q = \begin{pmatrix} q_1^2 + q_2^2 - q_3^2 - q_4^2 \\ 2(q_2 q_3 - q_1 q_4) \\ 2(q_1 q_3 + q_2 q_4) \end{pmatrix}, \tag{2}$$

$$e_2 = q^{-1} j q = \begin{pmatrix} 2(q_1 q_4 + q_2 q_3) \\ q_1^2 - q_2^2 + q_3^2 - q_4^2 \\ 2(q_3 q_4 - q_1 q_2) \end{pmatrix}, \tag{3}$$

$$e_3 = q^{-1} k q = \begin{pmatrix} 2(q_2 q_4 - q_1 q_3) \\ 2(q_1 q_2 + q_3 q_4) \\ q_1^2 - q_2^2 - q_3^2 + q_4^2 \end{pmatrix}. \tag{4}$$

The structure equations[11] of (C,ν) are given by $de_i = \omega_{ij} e_j$, where ω_{ij} is the connection one-form satisfying $\omega_{ij} + \omega_{ji} = 0$, $1 \leqslant i,j \leqslant 3$. Then the strains are given by $\omega_1 = \omega_{12}(e_1)$, $\omega_2 = \omega_{13}(e_1)$, and $\omega_3 = \omega_{23}(e_1)$, where $\omega_{..}(e_.)$ denotes the natural pairing between one-forms and vector fields. So $k^2 = \omega_1^2 + \omega_2^2$, where k is the (principal normal) curvature of C. On the other hand, by means of (2)–(4), one has

$$\omega_1 = 2(\dot q_1 q_4 + \dot q_2 q_3 - \dot q_3 q_2 - \dot q_4 q_1) = 2\dot q \cdot \mathrm{B}_1 q, \tag{5}$$

$$\omega_2 = 2(-\dot q_1 q_3 + \dot q_2 q_4 + \dot q_3 q_1 - \dot q_4 q_2) = 2\dot q \cdot \mathrm{B}_2 q, \tag{6}$$

$$\omega_3 = 2(\dot q_1 q_2 - \dot q_2 q_1 + \dot q_3 q_4 - \dot q_4 q_3) = 2\dot q \cdot \mathrm{B}_3 q, \tag{7}$$

where $\dot q$ means the tangent vector of Cayley–Klein parameter q, the dot between $\dot q$ and $\mathrm{B}_i q$ denotes the standard inner product of $\mathbb{R}^4$, and

$$\mathrm{B}_1 q = q_4 \frac{\partial}{\partial q_1} + q_3 \frac{\partial}{\partial q_2} - q_2 \frac{\partial}{\partial q_3} - q_1 \frac{\partial}{\partial q_4},$$

$$\mathrm{B}_2 q = -q_3 \frac{\partial}{\partial q_1} + q_4 \frac{\partial}{\partial q_2} + q_1 \frac{\partial}{\partial q_3} - q_2 \frac{\partial}{\partial q_4},$$

$$\mathrm{B}_3 q = q_2 \frac{\partial}{\partial q_1} - q_1 \frac{\partial}{\partial q_2} + q_4 \frac{\partial}{\partial q_3} - q_3 \frac{\partial}{\partial q_4}.$$

One thus can obtain the Lie bracket of $\mathrm{B}_i q$ and $\mathrm{B}_j q$ as follows:

$$[\mathrm{B}_i q, \mathrm{B}_j q] = 2\epsilon_{ijk} \mathrm{B}_k q, \quad \text{for all } i,j,k, \tag{8}$$

where ϵ_{ijk} is the permutation sign of (ijk). Equations (5)–(7) also suggest that we write $\dot q$ as

$$\dot q = \sum_{i=1}^{3} \frac{\omega_i}{2} \mathrm{B}_i q. \tag{9}$$

Notice that with respect to the standard orientation on $S^3, \mathrm{B}_1 q, \mathrm{B}_2 q, \mathrm{B}_3 q$ forms a negatively oriented basis of $T_q S^3$. It is also worth emphasizing that if the Frenét frame of C exists, then $\omega_1 = k \cos\theta$, $\omega_2 = k \sin\theta$, and $\omega_3 = \tau - \dot\theta$, where τ is the geometric torsion of C and θ is the angle measured from the principal normal of C to e_2. Thus, the relations are very useful in uncovering complete information of an elastica once its axis is *nondegenerate*, i.e., $k > 0$.

Equipped with (5)–(7), one can rewrite (1) as

$$\mathcal{E}(q)=\frac{1}{2}\int_0^l \rho_1(2\dot{q}\cdot \mathrm{B}_1 q-\kappa_1)^2+\rho_2(2\dot{q}\cdot \mathrm{B}_2 q-\kappa_2)^2+\rho_3(2\dot{q}\cdot \mathrm{B}_3 q-\kappa_3)^2\,ds.$$

Because $\mathrm{B}_i q$'s, for $1\leqslant i\leqslant 3$, also form an orthonormal frame on S^3 with respect to the standard metric tensor written as

$$g_{\mathrm{std}}=(\sigma_1)^2+(\sigma_2)^2+(\sigma_3)^2,$$

where σ_i is the one-form dual to $\mathrm{B}_i q$, one can introduce a change of g_{std} immediately shown below:

$$g=\rho_1(\sigma_1)^2+\rho_2(\sigma_2)^2+\rho_3(\sigma_3)^2.$$

Therefore, the elastic energy functional can be formulated as

$$\mathcal{E}(q)=2\int_0^l \|\dot{q}\|^2\,ds-2\sum_{i=1}^{3}\int_0^l \kappa_i\langle \dot{q},\mathrm{B}_i q\rangle\,ds+\frac{1}{2}\sum_{i=1}^{3}\int_0^l \rho_i\kappa_i^2\,ds. \tag{10}$$

Here, the first term of (10) is four times the Dirichlet functional and the $\langle\cdot,\cdot\rangle$ in the second term is the inner product on (S^3,g).

III. EULER–LAGRANGE EQUATIONS OF ELASTIC ENERGY FUNCTIONAL

A. Clamped-end variational principle

In this article, we are interested in the elasticity of *clamped ends:*

$$C(0)=\mathbf{0}, \tag{11}$$

$$C(l)=(a_1,a_2,a_3), \tag{12}$$

$$(e_1(0),e_2(0),e_3(0))=(i,j,k), \tag{13}$$

$$(e_1(l),e_2(l),e_3(l))=(v_1,v_2,v_3), \tag{14}$$

where $\mathbf{0}$ is the origin of $\mathbb{R}^3$,a_i's are real numbers satisfying $\Sigma_{i=1}^3 a_i^2\leqslant l^2$, and (v_1,v_2,v_3) is a set of orthonormal frame at $C(l)$.

Because of (13), we are interested in those Cayley–Klein parameters starting at $1=(1,0,0,0)\in S^3\subset\mathbb{R}^4$. The other endpoint of such a Cayley–Klein parameter corresponding to condition (14) is usually denoted by x.

Lemma 1: The relation between deformations of framed curves and variations of their Cayley–Klein parameters is that a variation of curves on S^3 starting at 1 and ending at a given x can be realized as a deformation of framed curves satisfying (11), (13), and (14) and a property that each framed curve in the deformation has the same length, and vice versa.

Proof: A variation of curves on S^3 starting at 1 and ending at x is a mapping $h:[0,l]\times[0,1]\rightarrow S^3$ satisfying $h(0,\epsilon)=1$ and $h(l,\epsilon)=x$. By means of (2)–(4), one may construct one-parameter families of e_1 and e_2 corresponding to h_ϵ where $h_\epsilon=h(\cdot,\epsilon)$. Thus, one obtains a deformation of framed curves with the required properties.

Conversely, suppose that a deformation of framed curves of equal lengths is given by $H:[0,l]\times[0,1]\rightarrow T\mathbb{R}^3$ where $H(\cdot,\epsilon)=(C_\epsilon,\nu_\epsilon)$ satisfies conditions (11), (13), and (14). With the corresponding frames $(e_1^\epsilon,e_2^\epsilon,e_3^\epsilon)$ where $(e_1^\epsilon,e_2^\epsilon,e_3^\epsilon)$ is the orthonormal frame constructed by $(C_\epsilon,\nu_\epsilon)$, one can produce the associated one-parameter family of curves in SO(3) when compared with (i,j,k). Notice that all curves of the family start and end at the same points, respectively. By means of the homotopy lifting property, these curves can be lifted to SU(2) which all start at 1 and end at x. □

Because the Cayley–Klein parameter only describes motion of the orthonormal frame, condition (12) should be captured by incorporating a Lagrange multiplier with elastic energy as follows:

$$\mathcal{E}_c(q)=\mathcal{E}(q)-\int_0^l \lambda\cdot\left(e_1-\frac{a}{l}\right)ds,$$

where λ is a vector-valued Lagrange multiplier, and the dot appearing in the integrand of the second term of $\mathcal{E}_c$ is the standard inner product of $\mathbb{R}^3$.

B. The Euler–Lagrange equations

The structure equations of the standard S^3 are $d\sigma_i=\sigma_j\wedge\sigma_{ij}$, where the connection one-form $\sigma_{ij}=\epsilon_{ijk}\sigma_k$ can be deduced from (8). Let $f_i=\mathrm{B}_i q/\sqrt{\rho_i}$ and the dual one-form $\eta_i=\sqrt{\rho_i}\sigma_i$ and notice that $g=(\eta_1)^2+(\eta_2)^2+(\eta_3)^2$.

Lemma 2: Let the structure equations of (S^3,g) *be written as* $d\eta_i=\eta_j\wedge\eta_{ij}$, *where* η_{ij} *is the connection one-form. Then*

$$\eta_{ij}=\epsilon_{ijk}\frac{\rho_i+\rho_j-\rho_k}{\sqrt{\rho_i\rho_j\rho_k}}\,\eta_k\,.$$

Proof: Since $\eta_i=\sqrt{\rho_i}\sigma_i$ and

$$d\eta_i=\epsilon_{ijk}\frac{\rho_i}{\sqrt{\rho_i\rho_j\rho_k}}\,\eta_j\wedge\eta_k\,,$$

by means of $d\eta_i=\eta_j\wedge\eta_{ij}$, one has

$$\eta_j\wedge\left(\eta_{ij}-\epsilon_{ijk}\frac{\rho_i}{\sqrt{\rho_i\rho_j\rho_k}}\,\eta_k\right)=0.$$

By Cartan's lemma,[13] there exists (locally defined) functions a_{ijk}'s satisfying $a_{ijk}=a_{ikj}$ such that

$$\eta_{ij}-\epsilon_{ijk}\frac{\rho_i}{\sqrt{\rho_i\rho_j\rho_k}}\,\eta_k=a_{ijk}\eta_k\,.$$

After rearrangement, due to $\eta_{ij}+\eta_{ji}=0$, an identity is obtained

$$a_{ijk}+a_{jik}=\epsilon_{ijk}\frac{\rho_j-\rho_i}{\sqrt{\rho_i\rho_j\rho_k}}.$$

Consider the following three equations:

$$a_{ijk}+a_{jik}=\epsilon_{ijk}\frac{\rho_j-\rho_i}{\sqrt{\rho_i\rho_j\rho_k}},$$

$$a_{jki}+a_{kji}=\epsilon_{jki}\frac{\rho_k-\rho_j}{\sqrt{\rho_i\rho_j\rho_k}},$$

$$a_{kij}+a_{ikj}=\epsilon_{kij}\frac{\rho_i-\rho_k}{\sqrt{\rho_i\rho_j\rho_k}}.$$

Now, we subtract the second equation from the sum of the first and third ones to get

$$a_{ijk}=\epsilon_{ijk}\frac{\rho_j-\rho_k}{\sqrt{\rho_i\rho_j\rho_k}}.$$

Thus, the expression of η_{ij} is obtained. □

Now, one can derive the differential-equation part of the Euler–Lagrange equations of $\mathcal{E}_c$.

Lemma 3: An elastica must satisfy the following equation, where ∇ *is the covariant differentiation on* (S^3,g) *given by* $\nabla_{f_j}f_i=\eta_{ik}(f_j)f_k$,

$$\begin{aligned}2\nabla_{\dot q}\dot q=&(-\lambda\cdot e_2+\rho_1\dot\kappa_1+\rho_3\kappa_3\omega_2-\rho_2\kappa_2\omega_3)\frac{f_1}{\sqrt{\rho_1}}\\&+(-\lambda\cdot e_3+\rho_2\dot\kappa_2-\rho_3\kappa_3\omega_1+\rho_1\kappa_1\omega_3)\frac{f_2}{\sqrt{\rho_2}}\\&+(\rho_3\dot\kappa_3+\rho_2\kappa_2\omega_1-\rho_1\kappa_1\omega_2)\frac{f_3}{\sqrt{\rho_3}}.\end{aligned}\tag{15}$$

Notice that the other part of the Euler–Lagrange equations is simply condition (12).

Sketch of Proof: We will use physicists' notation to help derive the equation:

$$\delta\left(2\int_0^l\|\dot q\|^2\,ds\right)=\int_0^l\langle\delta q,-4\nabla_{\dot q}\dot q\rangle ds,$$

$$\delta\left(-2\sum_{i=1}^3\int_0^l\kappa_i\langle\dot q,\mathrm{B}_iq\rangle ds\right)=\int_0^l\left\langle\delta q,2\sum_{i=1}^3\left(\dot\kappa_i\sqrt{\rho_i}f_i+\rho_i\kappa_i\epsilon_{ikj}\frac{\omega_j}{\sqrt{\rho_k}}f_k\right)\right\rangle ds$$

and

$$\delta\left(-\int_0^l\lambda\cdot\left(e_1-\frac{a}{l}\right)ds\right)=\int_0^l\left\langle\delta q,\frac{-2\lambda\cdot e_2}{\sqrt{\rho_1}}f_1+\frac{-2\lambda\cdot e_3}{\sqrt{\rho_2}}f_2\right\rangle ds.$$

Because $\delta\mathcal{E}_c=0$, we obtain (15). □

Componentwise, one has

$$\rho_1\dot\omega_1+(\rho_3-\rho_2)\omega_2\omega_3=-\lambda\cdot e_2+\rho_1\dot\kappa_1+\rho_3\kappa_3\omega_2-\rho_2\kappa_2\omega_3,\tag{16}$$

$$\rho_2\dot\omega_2+(\rho_1-\rho_3)\omega_1\omega_3=-\lambda\cdot e_3+\rho_2\dot\kappa_2-\rho_3\kappa_3\omega_1+\rho_1\kappa_1\omega_3,\tag{17}$$

$$\rho_3\dot\omega_3+(\rho_2-\rho_1)\omega_1\omega_2=\rho_3\dot\kappa_3+\rho_2\kappa_2\omega_1-\rho_1\kappa_1\omega_2.\tag{18}$$

An immediate consequence is the regularity of solutions to the above Euler–Lagrange equations when all κ_i's are assumed smooth.

Corollary 1: Each elastica is smooth, i.e., C and ν *are both* C^∞.

Proof: Considering (15), since it is elliptic of second order with respect to q, any solution to (15) is smooth [notice that (15) differs from the equation of harmonic mappings[14] by lower-order terms with respect to q]. Then by (2) and (3), the result is obtained. □

In fact, a stronger regularity of elasticae can be also obtained—each elastica is (real) analytic if each κ_i is assumed analytic. This is because SU(2), as a Lie group, is an analytic manifold; also the metric tensor g is analytic. Therefore, q as a solution to (15) is an analytic mapping from $[0,l]$ to S^3 (by the same reason used in the proof of the last corollary). Although the analyticity of solutions is obtained, it is hardly useful in helping us to understand elasticae in this article. Perhaps, the only usefulness is $k>0$ a.e. over $[0,l]$ unless $k=0$ identically.[15]

No matter which regularity one is going to make use of, it is important to notice that although each elastica is smooth (or analytic), the axis might yet have a discontinuity between $C^{(k)}(0)$ and $C^{(k)}(l)$ for some k if $C(0)=C(l)$, where $C^{(k)}$ denotes the kth-order derivative of C. This is because C has been parametrized over $[0,l]$, not S^1.

C. Basic properties of elasticae

Now consider the inner product of $2\nabla_{\dot q}\dot q$ with $\dot q$. By means of (15), one obtains

$$\langle 2\nabla_{\dot q}\dot q,\dot q\rangle=-\lambda\cdot\left(\frac{\omega_1}{2}e_2+\frac{\omega_2}{2}e_3\right)+\frac{1}{2}\sum_{i=1}^{3}\rho_i\dot\kappa_i\omega_i\,. \tag{19}$$

The lhs is equal to the derivative of $\|\dot q\|^2$ with respect to s and the first term of the rhs is exactly the derivative of $-\frac{1}{2}\lambda\cdot e_1$. Therefore,

$$\|\dot q\|^2+\frac{1}{2}\lambda\cdot e_1=\frac{c}{2}+\frac{1}{2}\sum_{i=1}^{3}\int_0^s\rho_i\dot\kappa_i\omega_i\,,$$

where $c=2\|\dot q(0)\|^2+\lambda\cdot i$.

Let *total energy* of (C,ν) be defined by

$$H=2\|\dot q\|^2+\lambda\cdot e_1\,.$$

In the expression of H, the term $2\|\dot q\|^2$ can be regarded as *kinetic energy* and the other term $\lambda\cdot e_1$ as *potential energy* since it is the price one pays for fixing endpoint $C(l)$.

An elastic rod is *uniform* if each κ_i is a constant. Under such an assumption, total energy is a conserved quantity for each elastica, known to G. Kirchhoff and A. Clebsch.[16]

Theorem 1: *Total energy is a conserved quantity for a uniform elastica.*

By (16) and (17), one can write λ as

$$\lambda=\lambda_1e_1-\lambda_2e_2-\lambda_3e_3\,,$$

where λ_1 is potential energy, and

$$\lambda_2=\rho_1\dot\omega_1+(\rho_3-\rho_2)\omega_2\omega_3-\rho_1\dot\kappa_1-\rho_3\kappa_3\omega_2+\rho_2\kappa_2\omega_3\,,$$

$$\lambda_3=\rho_2\dot\omega_2+(\rho_1-\rho_3)\omega_1\omega_3-\rho_2\dot\kappa_2+\rho_3\kappa_3\omega_1-\rho_1\kappa_1\omega_3\,.$$

Since $d\lambda=0$, one obtains

$$\dot\lambda_1+\lambda_2\omega_1+\lambda_3\omega_2=0, \tag{20}$$

$$\lambda_1\omega_1-\dot\lambda_2+\lambda_3\omega_3=0, \tag{21}$$

$$\lambda_1\omega_2-\lambda_2\omega_3-\dot\lambda_3=0. \tag{22}$$

Note (20) is exactly (19) [we need (18) to verify the claim]. The importance of (21) and (22) is that they are bases from which one can solve for elasticae. [Observe that (16) and (17) still involve e_2 and e_3, respectively, and they make solving for elasticae more difficult.] Also, one may make use of (21), (22) and (18) to write a system of differential equations which is equivalent to the (differential equation part of) Euler–Lagrange equations, and then the regularity proved in Corollary 1 is merely a direct application of Cauchy's theorem of differential equations.[17]

Recall that a relaxed state is a state of zero elastic energy. Thus, $\omega_i = \kappa_i$ for each i. Using the above expression of λ, we have $\lambda = \lambda_1 e_1$ for a relaxed state.

Corollary 2: A relaxed state has $\lambda = \lambda_1 e_1$ *where* λ_1 *is a constant. Moreover, if* $\kappa_1^2 + \kappa_2^2 \neq 0$ *at some point in* $[0,l]$, *then* $\lambda_1 = 0$.

Proof: Equations (20)–(22) become

$$\dot{\lambda}_1 = 0 \quad \text{and} \quad \lambda_1 \kappa_1 = \lambda_1 \kappa_2 = 0,$$

respectively. Therefore, one may conclude the corollary. □

To see the existence and uniqueness of a relaxed state, one has to know the differential equation of it:

$$\dot{q} = \sum_{i=1}^{3} \frac{\sqrt{\rho_i}}{2} \kappa_i f_i .$$

The above expression can be derived from the facts $\omega_i = \kappa_i$, $\mathrm{B}_i q = \sqrt{\rho_i} f_i$, and (9).

Theorem 2: *A relaxed state exists uniquely.*

Proof: The result may be obtained by the fundamental theorem of differential equations.[17] □

IV. MAIN RESULTS

Let us study the following two fundamental questions:

Question 1: Given a point $1 \in S^3$ *and a vector* $v \in T_1 S^3$, *is there an elastica whose Cayley–Klein parameter q satisfies* $q(0) = 1$ *and* $\dot{q}(0) = v$? *Such an elastica (if it exists) should be unique with respect to the initial conditions.*

Question 2: Given two points 1, $x \in S^3$, *is there an elastica whose Cayley–Klein parameter connects these two points? Under what condition is such an elastica unique with respect to the boundary conditions?*

The answer to Question 1 is the following.

Theorem 3: *There exists uniquely a solution curve to (15) satisfying the prescribed initial conditions* $q(0) = 1$ *and* $\dot{q}(0) = v$.

Sketch of Proof: On TS^3, let (q,p) be the canonical coordinates. A solution curve one seeks thus corresponds to an integral curve of the following differential equations defined on TS^3.

$$\dot{q} = p,$$

$$\dot{p} = \text{one-half of the r.h.s. of (15)}.$$

By means of the fundamental theorem of differential equations, one obtains the result. □

A partial answer to Question 2 may be given as follows. Let Ω be the path space of all paths on S^3 from 1 to x; here paths are assumed sufficient differentiability and parametrized over $[0,l]$. While proving the next theorem, we do not need that each κ_i is smooth, only C^2. Therefore, Corollary 1 can be restated as: The strains of each elastica are C^{k+1} if all κ_i's are C^k. This implies that the axis of an elastica is C^{k+3} and the material direction is C^{k+2}.

Once κ_1, κ_2, and κ_3 are written collectively as $\kappa = (\kappa_1, \kappa_2, \kappa_3)$, we define $\mathcal{P} = C^2[0,l] \times C^2[0,l] \times C^2[0,l]$ with product topology where $C^2[0,l]$ is topologized by $\mathcal{C}^2$-norm

$$\|u\|_{\mathcal{C}^2} = \max_{x \in [0,l]} |u(x)| + |\dot{u}(x)| + |\ddot{u}(x)|, \quad \text{for } u \in C^2[0,l].$$

Let $\mathcal{V}_q$ be the space of all vector fields defined along $q \in \Omega$ and $\mathcal{V} = \amalg_{q \in \Omega} \mathcal{V}_q$, where ⨿ denotes the disjoint union.

Lemma 4: $\mathcal{V}$ *is a vector bundle over* Ω.

Proof: Only the local triviality of $\mathcal{V}$ is proved here. First, we pick an open neighborhood $\mathcal{O}$ of q in Ω (equipped with compact-open topology) such that for any $\tilde{q}$ in the neighborhood, there exists a unique minimal geodesic connecting $\tilde{q}(s)$ and $q(s)$ for all $s \in [0,l]$. Therefore, using parallel transport along these minimal geodesics, we can establish a one-to-one correspondence between vector fields defined along q and $\tilde{q}$. Such a correspondence gives local triviality of $\mathcal{V}$ as a product of $\mathcal{O}$ and $\mathcal{V}_q$. □

Let F be a functional

$$F:\Omega \times \mathcal{P} \to \mathcal{V}$$

defined by

$$(q,\kappa) \mapsto \left(q, \nabla_{\dot{q}}\dot{q} - \sum_{i=1}^{3} \frac{\alpha_i}{2\sqrt{\rho_i}} f_i \right),$$

where α_i is the coefficient of $f_i/\sqrt{\rho_i}$ of the rhs of (15).

Theorem 4: *Let q_0, from 1 to x, be a Cayley–Klein parameter of some elastica whose intrinsic curvatures and twisting density are κ_1^0, κ_2^0, and κ_3^0, simply written as $\kappa^0 = (\kappa_1^0, \kappa_2^0, \kappa_3^0) \in \mathcal{P}$. Then there is an open neighborhood of κ^0 in $\mathcal{P}$ such that a family of solution curves to* (15) *exists and is parametrized by the neighborhood.*

Note, elasticae of the family have the same λ.

Proof: Let $\tilde{q}(\epsilon), -1 < \epsilon < 1$, be a curve in Ω such that $\tilde{q}(0) = q_0$. The tangent vector to $\tilde{q}$ at $\epsilon = 0$ is a vector field W defined along q_0 while it is realized on S^3. Thus,

$$\left(\frac{\partial}{\partial q} \nabla_{\dot{q}}\dot{q} \right)(q_0,\kappa^0) = \left. \frac{\partial}{\partial \epsilon} \right|_{\epsilon=0} \nabla_{\dot{\tilde{q}}}\dot{\tilde{q}} = \nabla_W \nabla_{\dot{\tilde{q}}}\dot{\tilde{q}}|_{\epsilon=0}$$

and the rhs of the last equality is equal to $\nabla_{\dot{q}_0}\nabla_{\dot{q}_0}W + R(W,\dot{q}_0)\dot{q}_0$, where $R(\cdot,\cdot)\cdot$ is the curvature tensor of (S^3,g), by means of the following identities:[17]

$$\nabla_{\tilde{W}}\nabla_{\dot{\tilde{q}}}\dot{\tilde{q}} - \nabla_{\dot{\tilde{q}}}\nabla_{\tilde{W}}\dot{\tilde{q}} - \nabla_{[\tilde{W},\dot{\tilde{q}}]}\dot{\tilde{q}} = R(\tilde{W},\dot{\tilde{q}})\dot{\tilde{q}} \quad \text{and} \quad \nabla_{\tilde{W}}\dot{\tilde{q}} - \nabla_{\dot{\tilde{q}}}\tilde{W} = [\tilde{W},\dot{\tilde{q}}] = 0,$$

where

$$\tilde{W} = V_*\left(\frac{\partial}{\partial \epsilon} \right) \quad \text{and} \quad \dot{\tilde{q}} = V_*\left(\frac{\partial}{\partial s} \right),$$

and V is a one-parameter variation of q_0 which can be regarded as a realization of a curve in Ω on S^3. More precisely, if

$$\left. \frac{d}{d\epsilon} \right|_{\epsilon=0} \tilde{q} = W \in T_{q_0}\Omega,$$

then V is a mapping $V:]-1,1[\times[0,l] \to S^3$ such that $V(\epsilon,0) = 1$, $V(\epsilon,l) = x$ for $\epsilon \in]-1,1[$, $V(0,\cdot) = q_0$ and $W = \tilde{W}(0,\cdot)$ [of course, $\dot{q}_0 = \dot{\tilde{q}}(0,\cdot)$]. Let us write $W = \Sigma W_i f_i$.

Similarly, one can compute

$$\left(\frac{\partial}{\partial q} f_i \right)(q_0,\kappa^0) = \left. \frac{\partial}{\partial \epsilon} \right|_{\epsilon=0} f_i = \nabla_{\tilde{W}} f_i|_{\epsilon=0} = \sum_{j,k} \epsilon_{ikj} W_j \frac{\rho_i + \rho_k - \rho_j}{\sqrt{\rho_i \rho_j \rho_k}} f_k,$$

$$\left(\frac{\partial}{\partial q} (-\lambda \cdot e_2) \right)(q_0,\kappa^0) = \left. \frac{\partial}{\partial \epsilon} \right|_{\epsilon=0} (-\lambda \cdot e_2) = 2(W_1 \lambda \cdot e_1 - W_3 \lambda \cdot e_3),$$

$$\left(\frac{\partial}{\partial q}(-\lambda\cdot e_3)\right)(q_0,\kappa^0)=\frac{\partial}{\partial\epsilon}\bigg|_{\epsilon=0}(-\lambda\cdot e_3)=2(W_2\lambda\cdot e_1+W_3\lambda\cdot e_2),$$

$$\left(\frac{\partial}{\partial q}\omega_i\right)(q_0,\kappa^0)=\frac{\partial}{\partial\epsilon}\bigg|_{\epsilon=0}\tilde{\omega}_i=\frac{2}{\sqrt{\rho_i}}\left(\dot{W}_i+\epsilon_{ikj}W_j\omega_k\sqrt{\frac{\rho_i}{\rho_j}}\right),$$

where $\tilde{\omega}_i=2\langle\dot{\tilde{q}},f_i\rangle/\sqrt{\rho_i}$. Therefore, we can write

$$\frac{\partial F}{\partial q}(q_0,\kappa^0)(W)=(\nabla_{\dot{q}_0})^2W+R(W,\dot{q}_0)\dot{q}_0-\sum_{i=1}^{3}\beta_i f_i, \tag{23}$$

where β_i's are functions involved with W_i's and their first-order derivatives (and of course also with λ, κ_i's, and ω_i's).

Now, let $K\subset T_{q_0}\Omega$ and R denote the kernel and range of $(\partial F/\partial q)(q_0,\kappa^0)$, respectively. Then K is finite dimensional and R has finite codimension since (23) is an elliptic differential equation in W. Because there is a natural inner product on $T_{q_0}\Omega$ defined by

$$\langle U,V\rangle_{q_0}=\int_0^l\langle U(s),V(s)\rangle ds,$$

one can identify the quotient space $T_{q_0}\Omega/K$ with the orthogonal complement of K in $T_{q_0}\Omega$, written as $K^\perp$. Let Ω^* be the image of $K^\perp$ under the exponential map at q_0,

$$\mathrm{Exp}_{q_0}(U)\in\Omega \quad \text{defined by} \quad \mathrm{Exp}_{q_0}(U)(s)=\exp_{q_0(s)}U(s).$$

Then the restriction of F to $\Omega^*\times\mathcal{P}$ (if necessary, we also need to replace $\mathcal{V}$ by the image of R under the corresponding exponential map when $\mathcal{V}$ is regarded as a manifold) has $\partial F/\partial q$ as an isomorphism at (q_0,κ^0). By the implicit function theorem, one obtains the theorem. □

The geometric picture of the proof of the above theorem is clearer if we restrict our attention to the so-called *geodesic elastica*,[18] especially in the case of intrinsically straight elasticity. An elastica is called geodesic if its Cayley–Klein parameter is a geodesic on (S^3,g). The reason for considering geodesic elasticae is that given any two points on S^3, there is always a geodesic connecting them. However, not every geodesic can be a Cayley–Klein parameter of some elastica. Now if we consider the intrinsically straight elasticity, all β_i's in (23) are zero for a geodesic elastica whose axis is not a straight line. This implies that the kernel is the space of Jacobi fields vanishing at endpoints. Therefore, x is a conjugate point of 1 along q_0 if the kernel is nontrivial.

Motivated by the last explanation of the proof of Theorem 4, let us call an elasticity *geometric* if every geodesic is a Cayley–Klein parameter of some elastica. Such a special category includes intrinsically straight elasticity and isotropic elasticity of zero intrinsic curvatures, but not isotropic O-ring elasticity[3] defined by κ_1 being a constant and $\kappa_2=\kappa_3=0$ because a geodesic being a Cayley–Klein parameter of some O-ring elastica must have $\omega_2=0$ and ω_3 as a constant. Now employing Theorem 4 alone, one can show that Question 2 has an affirmative answer to the existence under some condition on intrinsic curvatures and twisting density. For this we first assume a geodesic elastica of some geometric elasticity whose Cayley–Klein parameter solves Question 2, and then applying Theorem 4 to this elastica we are able to get an elastica whose intrinsic curvatures and twisting density are close (with respect to the product topology of $\mathcal{P}$) to those of the assumed geodesic elastica.

Using the proof of Theorem 4, one can also show the following.

Theorem 5: *Suppose that there is an elastica whose Cayley–Klein parameter is from 1 to x, say* (q_0,λ_0). *Then there exists a family of solution curves to (15) also connecting 1 and x. Moreover, along with the presumed elastica, such a family can be parametrized by an open set in* $\mathbb{R}^3$.

Notice that in order to prove Theorem 5, we replace F by

$$G:\Omega\times\mathbb{R}^3\rightarrow\mathcal{V}$$

defined by

$$(q,\lambda)\mapsto\left(q,\nabla_{\dot q}\dot q-\sum_{i=1}^{3}\frac{\alpha_i}{2\sqrt{\rho_i}}f_i\right).$$

So, elasticae of the family have the same intrinsic curvatures and twisting density.

An interesting application of Theorem 5 is to demonstrate the following.

Theorem 6: *Let q_0, from 1 to x, be a Cayley-Klein parameter of some geodesic elastica of a geometric elasticity such that x is a conjugate point of 1 along q_0. Then there are two distinct solution curves to (15) such that the corresponding elasticae satisfy the same conditions (11)–(14).*

Proof: Consider the given geodesic elastica and all perturbed solutions obtained by Theorem 5, written as q_λ. Since the integral $\int_0^l e_1(q_\lambda)ds$ is continuous in q_λ (or more accurately λ), it is true that either (i) there are two different values of λ, say λ_α and λ_β, such that the elasticae whose Cayley–Klein parameters are q_{λ_α}, and q_{λ_β}, respectively, share the same endpoint [condition (12)], or (ii) the total integral of e_1 regarded as a mapping of λ is one-to-one. In the latter, since q_0 is a geodesic whose endpoints are conjugate to each other, there must be a variation of q_0 consisting of geodesics from 1 to x.[12] Since elasticae whose Cayley–Klein parameters are q_λ exhaust neighboring points of $\int_0^l e_1(q_0)ds$, there must be one elastica whose Cayley–Klein parameter is in the aforementioned geodesic variation such that its endpoint at $s=l$ lies in the image resulting from the elasticae associated to q_λ. Thus, the proof is completed. □

ACKNOWLEDGMENTS

I want to thank my advisor, Professor James White, for his constant encouragement, very patient guidance, and support. Gratitude also goes to Professor John Maddocks, Professor Robert Manning, and Professor Hong Qian for many helpful discussions, and to Professor Joseph Rudnick for his comments. I very much appreciate the referee for the comments and suggestions used to revise this paper.

[15] The result can be proved by the fact: if u defined on $[0,l]$ is analytic, then $u^{-1}(c)$ either is the whole interval or contains no intervals. For the latter, such $u^{-1}(c)$ is called zero-dimensional. A characterization of some zero-dimensional spaces is that such a space is a union of the Cantor set and an open countable subset, which is applicable to what we are interested in. [18] General properties of geodesic elasticae will not be presented in this paper because there are few geodesic elasticae when nontrivial intrinsic curvatures exist. This situation is very conceivable, because the geodesic equation $\nabla_{\dot{q}}\dot{q}=0$ is independent of intrinsic curvatures, yet the existence of the latter puts restrictions on a geodesic [cf. the both sides of (16)–(18)]. In fact, in my previous study on this topic in the case of the isotropic elasticity in which $\kappa_2=\kappa_3=0$, it was shown that if κ_1 is neither a linear function nor a harmonic oscillation, then there is no geodesic elastica.

Symplectic-energy-momentum preserving variational integrators

The purpose of this paper is to develop variational integrators for conservative mechanical systems that are symplectic and energy and momentum conserving. To do this, a space–time view of variational integrators is employed and time step adaptation is used to impose the constraint of conservation of energy. Criteria for the solvability of the time steps and some numerical examples are given. [S0022-2488(99)01707-7]

I. INTRODUCTION

The purpose of this paper is to develop variational integrators for conservative mechanical systems with adaptive time steps. The resulting algorithms are symplectic, energy preserving, and they also preserve the momentum maps (Noether quantities) associated with symmetry groups.

An important idea for how to develop such integrators comes from the paper of Marsden, Patrick, and Shkoller[1] in which the space–time view is stressed. This viewpoint is very important for two main reasons:

(1) to avoid conflicts with well-known theorems (Ge and Marsden[2]), which limit the possibility that *constant time stepping* algorithms be symplectic and energy and momentum preserving; and
(2) to give meaning to the term *symplectic* in the context of adaptive time stepping algorithms since the algorithm is not given by a single mapping associated with a constant time step.

The basic algorithm itself consists of two parts. First, to update positions, the variational approach of Veselov,[3,4] and Moser and Veselov[5] is adopted; these ideas were implemented numerically by Wendlandt and Marsden.[6] Second, to compute the time steps themselves, energy preservation is imposed. Roughly speaking, we make use of the fact that time and energy are conjugate variables.

In this paper, our main purpose is the following:

(1) to set up the basic algorithm that implements these symplectic-energy-momentum (SEM) integrators;
(2) to make precise the sense in which the algorithms are symplectic;
(3) to investigate the solvability conditions for the time step; and
(4) to give some simple numerical examples.

With regard to solving for the time step, we shall indicate how the solvability conditions are closely related to the positivity of the numerically computed kinetic energy. In particular, when one is close to a location with zero velocity (roughly speaking, ‘‘turning points’’), our solvability criterion and examples indicate that one should move through such points using a criterion other than energy preservation. Numerically, this causes a slight adjustment to the energy. How one should best treat these points requires further investigation. *It is not the purpose of this paper to give any extensive numerical tests or implementations of these methods*. This is a nontrivial task, but clearly needs to be done, and is planned for other publications.

In future papers we will also investigate the use of these ideas in our collision algorithms[7] and how one can incorporate dissipative effects.

II. BRIEF REVIEW OF VARIATIONAL INTEGRATORS

In this section, we recall some of the essential features of variational integrators that are needed in this paper. For additional details, see Refs. 6 and 1.

A. Limitations on mechanical integrators

There has been a large literature developing on the use of energy-momentum and symplectic-momentum integrators. We shall not attempt to survey this all here, but rather refer the reader to some of the recent literature, such as the collection of papers in Ref. 8 and Ref. 9. We do mention that for time stepping algorithms with fixed time steps, the theorem of Ge and Marsden[2] has led to a general division of algorithms into those that are energy-momentum preserving and those that are symplectic-momentum preserving. One of our main points is that if one takes a space–time view of variational integrators, as is advocated in Ref. 1, then one can have all three of these properties. Papers typified by Simo and Tarnow,[10] Simo, Tarnow, and Wong,[11] and Gonzalez[12] have focused on energy preserving algorithms, but they presumably fail (except, perhaps, in special cases, such as integrable systems) to be symplectic. Other approaches based on Hamilton's principle are those of Shibberu[13] and Lewis.[14] See also the work by Lee.[15]

B. Accuracy of solutions

We should, at the outset, make another point clear. We are not claiming anything about the accuracy of individual trajectories. Indeed, it is well known that structure preservation alone does not guarantee this. (See, e.g., Refs. 16, 17.) For systems with complicated, unstable, or chaotic trajectories, it is not clear that accuracy of individual trajectories is the correct question to ask. Rather, one should probably concentrate on statistical properties of solutions. These are deep questions that we do not attempt to address here, but one hopes that by preserving as much of the structure as possible, one is closer to addressing such issues. In some cases the advantage of being symplectic is clear; for instance, the condition of being symplectic guarantees that the phase space volume is preserved and this can be an obvious limitation on many integrators; even after relatively short times, one can see phase space volume not preserved in many integrators.

C. Some common integrators

In structural mechanics, the $\beta=0$, $\gamma=\frac{1}{2}$ member of the widely used Newmark family is a variational integrator (see, for example, Ref. 11) and therefore is symplectic and momentum preserving. In fact, the whole Newmark family of algorithms is variational.[18] Our methods can be used to make these integrators also preserve energy by using time-adaptive stepping. We also mention that the popular Verlet methods and shake algorithms are variational integrators (see Refs. 6 and 18 for further discussion and references).

D. Dissipation and constraints

While dissipation and forcing are of course very important, as we have mentioned, we leave their discussion for future publications. One possibility is that dissipative effects can be dealt with by means of product formulas, as in Refs. 19–21, for example. Another is to incorporate the dissipative effects into the variational principle, as in Refs. 18 and 22.

Constraints are also very important for integrators. We also do not discuss these in any detail in this paper. However, we do mention that variational integrators handle constraints in a simple and efficient way.

Variational methods also generalize to partial differential equations (PDE's) using multisymplectic geometry with the result being a class of multisymplectic momentum integrators. See Ref. 1 for details and numerical examples. This type of approach should ultimately be of use in elastodynamics as well as ocean dynamics, for example.

E. Symmetry and reduction

We should also mention that for mechanical systems with symmetry, the investigation of discrete versions of reduction theory, such as Euler–Poincaré reduction,[23] are of current interest.[24,25] We will not be making use of this reduction theory in this paper, but it is related since our integrators are intended to preserve symmetry. It would be of interest to develop time-adapted integrators in the sense of the present paper in the general context of discrete reduction.

F. The discrete variational principle

Given a *configuration space* Q, a **discrete Lagrangian** is a map

$$L_d : Q \times Q \to \mathbb{R}.$$

In practice, L_d is obtained by approximating a given Lagrangian as we shall discuss later, but regard L_d as given for the moment. The time step information will be contained in L_d and we regard L_d as a function of 2 nearby points (q_k, q_{k+1}).

For a positive integer N, the **action sum** is the map $S_d : Q^{N+1} \to \mathbb{R}$ defined by

$$S_d = \sum_{k=0}^{N-1} L_d(q_k, q_{k+1}),$$

where $q_k \in Q$ and k is a nonnegative integer. The action sum is the discrete analog of the action integral in mechanics.

The **discrete variational principle** states that the evolution equations extremize the action sum given fixed end points, q_0 and q_N. Extremizing S_d over $q_1, \ldots, q_{N-1}$ leads to the **discrete Euler–Lagrange (DEL) equations:**

$$D_1 L_d(q_k, q_{k+1}) + D_2 L_d(q_{k-1}, q_k) = 0$$

for all $k = 1,...,N-1$. We can write this equation in terms of a discrete **algorithm**

$$\Phi : Q \times Q \to Q \times Q$$

defined implicitly by

$$D_1 L_d \circ \Phi + D_2 L_d = 0,$$

i.e.,

$$\Phi(q_{k-1}, q_k) = (q_k, q_{k+1}).$$

If, for each $q \in Q$, $D_1 L_d(q,q) : T_q Q \to T_q^* Q$ is invertible, then $D_1 L_d : Q \times Q \to T^*Q$ is locally invertible and so the algorithm Φ, which flows the system forward in discrete time, is well defined for small time steps.

G. Variational algorithms are symplectic

To explain the sense in which the algorithm is symplectic, first define the **fiber derivative** (or the discrete Legendre transform) by

$$\mathbb{F}L_d : Q \times Q \to T^*Q; \quad (q_0, q_1) \mapsto (q_0, D_1 L_d(q_0, q_1)),$$

and define the two-form ω on $Q\times Q$ by pulling back the canonical two-form $\Omega_{\text{CAN}}=dq^i\wedge dp_i$ from T^*Q to $Q\times Q$:

$$\omega=\mathbb{F}L_d^*(\Omega_{\text{CAN}}).$$

The fiber derivative is analogous to the standard Legendre transform.

The coordinate expression for ω is

$$\omega=\frac{\partial^2 L_d}{\partial q_k^i \partial q_{k+1}^j}(q_k,q_{k+1})dq_k^i\wedge dq_{k+1}^j.$$

A fundamental fact is that

the algorithm Φ exactly preserves the symplectic form ω.

One proof of this is to simply verify it with a straightforward calculation—see Ref. 6 for the details. Another is to derive the same conclusion directly from the variational structure, as is done in Ref. 1.

H. The algorithm preserves momentum

Recall that *Noether's theorem* states that a continuous symmetry of the Lagrangian leads to conserved quantities, as with linear and angular momentum. A nice way to derive these conservation laws (the way Noether did it) is to use the *invariance of the variational principle*.

Assume that the discrete Lagrangian is invariant under the action of a Lie group G on Q, and let $\xi\in\mathfrak{g}$, the Lie algebra of G. By analogy with the continuous case, define the **discrete momentum map**, $\mathbf{J}_d:Q\times Q\to\mathfrak{g}^*$ by

$$\langle\mathbf{J}_d(q_k,q_{k+1}),\xi\rangle:=\langle D_1L_d(q_k,q_{k+1}),\xi_Q(q_k)\rangle.$$

A second fundamental fact is that

the algorithm Φ exactly preserves the momentum map.

I. Construction of mechanical integrators

Assume we have a mechanical system with a constraint manifold, $Q\subset V$, where V is a real finite-dimensional vector space, and that we have an unconstrained Lagrangian, $L:TV\to\mathbb{R}$ which, by restriction of L to TQ, defines a **constrained Lagrangian**, $L^c:TQ\to\mathbb{R}$. Roughly speaking, V is a containing vector space in which the computer arithmetic will take place. In particular, coordinate charts on Q are *not* chosen for this purpose. In fact, apart from the use of the containing vector space V, the algorithms developed here are independent of the use of coordinates on Q.

We also assume that we have a vector-valued **constraint function**, $g:V\to\mathbb{R}^k$, such that our constraint manifold is given by $g^{-1}(0)=Q\subset V$, with 0 a regular value of g. The dimension of V is denoted n and therefore, the dimension of Q is $m=n-k$.

Define a **discrete, unconstrained Lagrangian**, $L_d:V\times V\to\mathbb{R}$ in some consistent manner, such as

$$L_d(x,y)=L\left(\gamma x+(1-\gamma)y,\frac{y-x}{h}\right), \tag{II.1}$$

where $h\in\mathbb{R}_+$ is the time step and $0\leqslant\gamma\leqslant1$ is an interpolation parameter.

The corresponding discrete Euler–Lagrange equations give an algorithm closely related to (in a sense made precise in Ref. 18) the **Newmark algorithm** for the standard choice of Lagrangian given by kinetic minus potential energy. We get the *central difference method* for $\gamma=\frac{1}{2}$ and we get the *shake* algorithm with $\gamma=1$ (the *Verlet* algorithm is the unconstrained version of the shake algorithm). We also note that the *Moser–Veselov discrete Lagrangian* for the rigid body is constructed using either $\gamma=1$ or $\gamma=0$ (see Ref. 24 for details).

We remark in passing that other choices for discrete Lagrangians are also possible, such as

$$L_d(x,y)=\sigma L\left(\gamma_1 x+(1-\gamma_1)y,\frac{y-x}{h}\right)+(1-\sigma)L\left(\gamma_2 x+(1-\gamma_2)y,\frac{y-x}{h}\right),$$

where σ, λ_1, and λ_2 are between 0 and 1. These other choices, which give algorithms such as the midpoint rule, are not investigated here (see Ref. 18). Alternative choices, of which this is an example, as well as issues of local truncation error and accuracy are investigated in Ref. 26.

The **unconstrained action sum** is defined by

$$S_d=\sum_{k=0}^{N-1} L_d(x_k,x_{k+1}).$$

Extremize $S_d:V^{N+1}\to\mathbb{R}$ *subject to the constraint* that $x_k\in Q\subset V$ for $k=1,...,N-1$, i.e., solve

$$D_1L_d(x_k,x_{k+1})+D_2L_d(x_{k-1},x_k)+\lambda_k^T Dg(x_k)=0$$

(no sum on k) with $g(x_k)=0$ for $k=1,...,N-1$. Here, the λ_k are *Lagrange multipliers*, chosen to enforce the constraints.

Thus, the algorithm is defined by starting with x_k and x_{k-1} in $Q\subset V$, i.e., $g(x_k)=0$ and $g(x_{k-1})=0$, and solving

$$D_1L_d(x_k,x_{k+1})+D_2L_d(x_{k-1},x_k)+\lambda_k^T Dg(x_k)=0$$

subject to $g(x_{k+1})=0$, for x_{k+1} and λ_k. In terms of the *unconstrained Lagrangian*, the algorithm reads as follows:

$$\begin{aligned}&\frac{1}{h}\left[\frac{\partial L}{\partial \dot{x}}\left(\gamma x_{k-1}+(1-\gamma)x_k,\frac{x_k-x_{k-1}}{h}\right)-\frac{\partial L}{\partial \dot{x}}\left(\gamma x_k+(1-\gamma)x_{k+1},\frac{x_{k+1}-x_k}{h}\right)\right]\\&\quad\times(1-\gamma)\frac{\partial L}{\partial x}\left(\gamma x_{k-1}+(1-\gamma)x_k,\frac{x_k-x_{k-1}}{h}\right)\\&\quad+\gamma\frac{\partial L}{\partial x}\left(\gamma x_k+(1-\gamma)x_{k+1},\frac{x_{k+1}-x_k}{h}\right)+D^Tg(x_k)\lambda_k=0\end{aligned}$$

together with $g(x_{k+1})=0$.

Example: If the continuous Lagrangian is

$$L(q,\dot{q})=\tfrac{1}{2}\dot{q}^T M\dot{q}-V(q)$$

with constraint $g(q)=0$, where M is a constant mass matrix, and V is the potential energy, then the DEL equations are

$$\begin{aligned}&M\left(\frac{x_{k+1}-2x_k+x_{k-1}}{h^2}\right)+(1-\gamma)\frac{\partial V}{\partial q}(\gamma x_{k-1}+(1-\gamma)x_k)\\&\quad+\gamma\frac{\partial V}{\partial q}(\gamma x_k+(1-\gamma)x_{k+1})-D^Tg(x_k)\lambda_k=0\end{aligned}$$

with $g(x_{k+1})=0$.

Wendlandt and Marsden[6] show that *the algorithm defined using Lagrange multipliers coincides with that defined intrinsically using the constrained discrete Lagrangian on* $Q\times Q$, *so it is symplectic and momentum preserving.*

J. An intrinsic variational viewpoint

Recall that given a Lagrangian function $L:TQ\to\mathbb{R}$, we construct the corresponding **action functional** $\mathfrak{S}$ on C^2 curves $q(t)$ by (using coordinate notation)

$$\mathfrak{S}(q(\cdot))\equiv\int_a^b L\left(q^i(t),\frac{dq^i}{dt}(t)\right)dt. \tag{II.2}$$

The action functional depends on a and b, but this is not explicit in the notation. Hamilton's principle seeks the curves $q(t)$ for which the functional $\mathfrak{S}$ is stationary under variations of $q^i(t)$ with fixed endpoints. It will be useful to recall this calculation; namely, we seek curves $q(t)$ which satisfy

$$\mathbf{d}\mathfrak{S}(q(t))\cdot\delta q(t)\equiv\left.\frac{d}{d\epsilon}\right|_{\epsilon=0}\mathfrak{S}(q(t)+\epsilon\delta q(t))=0 \tag{II.3}$$

for all $\delta q(t)$ with $\delta q(a)=\delta q(b)=0$. Abbreviating $q_\epsilon\equiv q+\epsilon\delta q$, and using integration by parts, the calculation is

$$\mathbf{d}\mathfrak{S}(q(t))\cdot\delta q(t)=\left.\frac{d}{d\epsilon}\right|_{\epsilon=0}\int_a^b L\left(q_\epsilon^i(t),\frac{dq_\epsilon^i}{dt}(t)\right)dt=\int_a^b\delta q^i\left(\frac{\partial L}{\partial q^i}-\frac{d}{dt}\frac{\partial L}{\partial\dot{q}^i}\right)dt+\left.\frac{\partial L}{\partial\dot{q}^i}\delta q^i\right|_a^b. \tag{II.4}$$

The last term in (II.4) vanishes since $\delta q(a)=\delta q(b)=0$, so that the requirement (II.3) for $\mathfrak{S}$ to be stationary yields the **Euler–Lagrange equations**

$$\frac{\partial L}{\partial q^i}-\frac{d}{dt}\frac{\partial L}{\partial\dot{q}^i}=0. \tag{II.5}$$

Notice that the boundary term in the first variation of the action is the canonical one form $p_i\dot{q}^i$. This is the starting point for the variational proof that the algorithm is symplectic. The idea is to restrict $\mathfrak{S}$ to the space of solutions and to use the general identity $d^2\mathfrak{S}=0$ to derive the symplectic nature of flow of the Euler–Lagrange equations. The point is that *this type of derivation also is valid for the discrete case*, as is shown in Ref. 1.

We also mention that one can similarly give a derivation of the conservation of momentum maps entirely based on the variational principle as well.

We end this section with one further important remark. Namely, one may think that the discrete symplectic form and momentum map that are conserved by the variational algorithm are somehow ''concocted'' to be conserved. This is not the case. Indeed, one can, via the discrete Legendre transform, transfer the algorithm to position-momentum space. Transferred to these variables, the algorithm will preserve the *standard* symplectic form $dq^i\wedge dp_i$ and the *standard* momentum map. As M. West pointed out to us, to get a corresponding algorithm that is consistent with the corresponding continuous Hamiltonian system on T^*Q, and one that is also in line with our discrete energy developed below, one should really use the map

$$(q_0,q_1)\mapsto(q_0,-hD_1L_d(q_0,q_1)),$$

where h is the time step, but this does not affect the results here.

III. REVIEW OF ENERGY AND SYMPLECTICITY CONSERVATION IN THE CONTINUOUS CASE

The main issue addressed in the following section is how we can achieve conservation of energy using adaptive time steps. We shall see that apart from some exceptional circumstances, which we can algorithmically identify, one can achieve this.

To address these issues, we first consider the continuous time case.

A. Conservation of energy

We will first recall how conservation of energy is derived directly from Hamilton's principle in the case where $L(q,\dot{q})$ is time independent. This provides a clue about how one should proceed with the time-adaptive steps.

Assume that $q(t)$ is a solution of the Euler–Lagrange equations. Let $s_\varepsilon(t)$ be a family of functions of t depending on the parameter ε and with $s_0(t)=t$ and with $s_\varepsilon(a)=a$, $s_\varepsilon(b)=b$. Let

$$\delta s(t)=\frac{d}{d\varepsilon}s_\varepsilon\bigg|_{\varepsilon=0}.$$

We consider the associated family of curves $q(s_\varepsilon(t))$ which has the variation

$$\delta q(t)=\delta s(t)\dot{q}(t).$$

Hamilton's principle $(\delta\int L\,dt=0)$ in this case gives us

$$\int \frac{\partial L}{\partial q}\delta q+\frac{\partial L}{\partial \dot{q}}(\dot{\delta q})=\int\left(\frac{\partial L}{\partial q}-\frac{d}{dt}\frac{\partial L}{\partial \dot{q}}\right)\delta q. \tag{III.1}$$

Using the special form of the variation, this becomes

$$\int \frac{\partial L}{\partial q}\dot{q}\,\delta s-\left(\frac{d}{dt}\frac{\partial L}{\partial \dot{q}}\right)\dot{q}\,\delta s\,dt=0. \tag{III.2}$$

Equation (III.2) gives

$$\frac{\partial L}{\partial q}\dot{q}-\frac{d}{dt}\frac{\partial L}{\partial \dot{q}}\dot{q}=0=\frac{dE}{dt}, \tag{III.3}$$

where, as usual,

$$E=\frac{\partial L}{\partial \dot{q}}\dot{q}-L(q,\dot{q}). \tag{III.4}$$

The point here is that we see a sense in which the Hamiltonian H arises naturally when one considers variations of the curve $q(t)$ that are given by time reparametrizations.

B. Symplecticity in the space–time sense

In Ref. 1 it is shown how the variational principle naturally leads to boundary terms in both the continuous and the discrete case that leads to a deeper understanding of why the Euler–Lagrange and Hamilton equations themselves preserve the symplectic structure, as well as their discrete counterparts. We shall make use of this type of argument below in the discrete case. To help motivate the result, we make some relevant remarks here.

Consider a (possibly time dependent) Hamiltonian $H(q,p,t)$ in the canonically conjugate variables q^i, p_i and introduce an extended Hamiltonian $\bar{H}$, a function of q, p and two new real variables q_0 and p_0 by

$$\bar{H}(q,p,q_0,p_0)=H(q,p,q_0)+p_0.$$

Hamilton's equations for this new autonomous Hamiltonian agree with the time-dependent equations for the original H if we identify q_0 with the time and p_0 with $-H$. In addition, this leads one to the conservation of the canonical symplectic structure in the space–time sense, namely,

$$\Omega_H=\omega+dH\wedge dt,$$

where $\omega = \Sigma_i dq_i \wedge dp_i$ is the canonical symplectic form. What is interesting for us later is the following remark in case H is time independent (so H is conserved). Consider the flow $\bar{F}_s$ of the extended Hamiltonian $\bar{H}$, which is given by advancing the time by an amount s:

$$(q(t),p(t),t,H) \mapsto (q(t+s),p(t+s),t+s,H),$$

where q and p advance by the flow F_s of the original Hamiltonian system. Imagine, for later purposes, that s is a function of the initial point and t, so that ds is a nontrivial differential. Then the statement that the flow $\bar{F}_s$ preserves the symplectic form above reads: $\bar{F}_s^* \Omega_H = \Omega_H$ or, equivalently,

$$F_s^* \omega + dH \wedge d(t+s) = \omega + dH \wedge dt.$$

Cancelling $dH \wedge dt$, this reads

$$F_s^* \omega + dH \wedge ds = \Omega_0. \tag{III.5}$$

If we think of s as the time advancement, or the time step, then below we will prove a discrete analog of this identity, which is how we will interpret symplecticity in the time-dependent sense.

Following the arguments in the discrete case later, or the methods of Marsden *et al.*,[1] one can also derive a Lagrangian version of this identity from the variational principle.

IV. THE VARIATIONAL ENERGY ALGORITHM

We consider a discrete Lagrangian that is (possibly) time dependent and has an associated time step h_1 that may be coupled to the current choice of points (q_1,q_2); we denote this discrete Lagrangian by $L_{h_1}(q_1,q_2) := L_d(q_1,q_2,h_1)$.

Given (q_0,q_1,h_0), we seek to find (q_1,q_2,h_1). In general, this will give us a way to pass from data (q_{k-1},q_k,h_{k-1}) to (q_k,q_{k+1},h_k).

This setup differs from the usual discrete Lagrangian procedures in the inclusion of time step information h_k that is coupled to the current configuration data (q_k,q_{k+1}).

We will find q_2 and h_1 together, by solving an equation similar to the discrete Euler–Lagrange equation for q_2, while we solve for h_1 using the equation $E_d(q_0,q_1,h_0) = E_d(q_1,q_2,h_1)$ where E_d is the discrete energy function, defined below.

(a) The discrete action. One choice of discrete action is obtained by just using the following approximation to the action integral for the first two sets of points, (q_0,q_1,h_0) and (q_1,q_2,h_1):

$$[h_0 L_d(q_0,q_1,h_0) + h_1 L_d(q_1,q_2,h_1)]. \tag{IV.1}$$

One could also use other, more accurate methods to approximate the action integral. This might lead to some interesting new, more accurate algorithms, but we shall not explore them in this paper.

(b) The discrete algorithm. To derive the algorithm, we consider the same discrete variational principle as before, but now parametrized by the time step information:

$$\frac{\partial}{\partial q_1}[h_0 L_d(q_0,q_1,h_0) + h_1 L_d(q_1,q_2,h_1)] = 0. \tag{IV.2}$$

We also write this as

$$h_0 D_2 L_d(q_0,q_1,h_0) + h_1 D_1 L_d(q_1,q_2,h_1) = 0.$$

In this relation, the time steps h_0,h_1 are held fixed. We will later derive the symplectic relation by considering variations of solutions, just as in the continuous case.

A. The discrete energy

The above variational equation (IV.2) will be coupled with an energy equation that will enable us to solve for both q_2 and h_2.

We define the **discrete energy** as follows:

$$E_d(q_0,q_1,h_0) = -h_0 D_3 L_d(q_0,q_1,h_0) - L_d(q_0,q_1,h_0) = -\frac{\partial}{\partial h_0}[h_0 L_d(q_0,q_1,h_0)]. \quad \text{(IV.3)}$$

This intrinsic definition is motivated in part by the fact that for Lagrangians of the form of kinetic minus potential energy, and with the choice of discrete Lagrangian given by (II.1), the discrete energy is given by the expression one would naturally think of, namely it is easily verified that, in this case, we have

$$E_d(q_0,q_1,h_0) = \frac{1}{2}\left(\frac{q_1-q_0}{h_0}\right)^T M \left(\frac{q_1-q_0}{h_0}\right) + V(\gamma q_0 + (1-\gamma) q_1). \quad \text{(IV.4)}$$

In this case, this can also be written as

$$E_d(q_0,q_1,h_0) = E\left(\gamma q_0 + (1-\gamma) q_1, \left(\frac{q_1-q_0}{h_0}\right)\right), \quad \text{(IV.5)}$$

where $E(q,\dot{q})$ is the energy associated with the original Lagrangian $L(q,\dot{q})$. As pointed out to us by Matt West, one can also motivate this definition of the energy using the variational principle and a discrete version of the Hamilton-Jacobi equation.

The main second equation defining the algorithm is

$$E_d(q_0,q_1,h_0) = E_d(q_1,q_2,h_1), \quad \text{(IV.6)}$$

or, with algorithmic notation,

$$E_{k-1} := E_d(q_{k-1},q_k,h_{k-1}) = E_d(q_k,q_{k+1},h_k) := E_k. \quad \text{(IV.7)}$$

For example, in the case the Lagrangian equals kinetic plus potential energy, the condition $E_0 = E_1$ is equivalent to

$$h_1^2 = \frac{(q_2-q_1)^T M (q_2-q_1)}{2[E_0 - V(\gamma q_1 + (1-\gamma) q_2)]}. \quad \text{(IV.8)}$$

For this to remain meaningful as we compute, we need to make sure that the *computed kinetic energy*

$$E_0 - V(\gamma q_1 + (1-\gamma) q_2) \quad \text{(IV.9)}$$

remains positive.

To realize this condition, one can consider verifying it *a posteriori* as follows.

(1) First compute the square of the new time step h_1.

(2) Substitute h_1^2 in the relation

$$h_0 D_2 L_{h_0}(q_0,q_1) + h_1 D_1 L_{h_1}(q_1,q_2) = 0, \quad \text{(IV.10)}$$

which gives an implicit equation for q_2.

(3) Compute q_2 implicitly.

(4) Verify from the formula for h_1^2 that one gets a positive answer.

(5) If so, we proceed. If not, we keep the time step from the last iterate and proceed.

This approach will of course induce an energy variation in such cases. As we shall see below in greater detail, *this will only happen near ''turning points;'' that is, near points where the velocity is nearly zero.*

In the specific example, the equation for q_2 reads

$$m\left[\frac{(q_1-q_0)}{h_0^2}-(1-\gamma)V'(\gamma q_0+(1-\gamma)q_1)\right]h_0+\left[-\frac{m}{h_1^2}(q_2-q_1)-\gamma V'(\gamma q_1+(1-\gamma)q_2)\right]h_1=0.$$

We define $B(q_0,q_1,h_0)$ to be

$$B(q_0,q_1,h_0):=\left[m\,\frac{(q_1-q_0)}{h_0^2}-(1-\gamma)V'(\gamma q_0+(1-\gamma)q_1)\right]h_0,$$

and we let, for notational convenience, $u=\gamma q_1+(1-\gamma)q_2$. We then have

$$B=\left[2(1-\gamma)\frac{M(E_0-V(u))}{(u-q_1)^TM(u-q_1)}(u-q_1)+\gamma V'(u)\right]\sqrt{2\,\frac{(u-q_1)^TM(u-q_1)}{E_0-V(u)}}. \tag{IV.11}$$

In the particular case where $\gamma=\frac{1}{2}$ and q_1,q_2 are scalars, this expression simplifies to

$$B=\left[\frac{E_0-V(u)}{u-q_1}+\frac{1}{2}V'(u)\right]\sqrt{\frac{2(u-q_1)^2M}{E_0-V(u)}}. \tag{IV.12}$$

In other words,

$$E_0-V(u)+\frac{1}{2}V'(u)(u-q_1)-\frac{\sqrt{E_0-V(u)}}{\sqrt{2M}}B=0. \tag{IV.13}$$

We solve the previous equation for u. Then q_2 follows in a straightforward way.

V. TIME STEP SOLVABILITY AND AN OPTIMIZATION METHOD

We have seen previously that the condition $E_0-V(u)>0$ should be verified in order to compute the next time step h_1, given h_0. To clarify the exposition, we write $E_0=K_0+V_0$ and we take $V_1=V(u)$. It follows that

$$E_0-V(u)=K_0+V_0-V_1.$$

Our condition for solvability is therefore

$$K_0+V_0-V_1>0. \tag{V.1}$$

If K_0 is large and the time step small, then in this case (V.1) is automatically verified. Indeed, K_0 large and $V_0\simeq V_1$ implies that the computed kinetic energy is positive. If $q_1\simeq q_2$ and h_0 is not so small, this is a rather delicate situation but can be explored by writing

$$\frac{1}{2}\,\frac{(q_1-q_0)^Tm(q_1-q_0)}{h_0^2}+V(\gamma q_0+(1-\gamma)q_1)-V(\gamma q_1+(1-\gamma)q_2). \tag{V.2}$$

Taylor expanding the potential terms when $\gamma=\frac{1}{2}$ gives

$$V\left(\frac{q_0+q_1}{2}\right)-V\left(\frac{q_1+q_2}{2}\right)=-\frac{1}{2}V'\left(\frac{q_0+q_1}{2}\right)\frac{q_2-q_0}{2}. \tag{V.3}$$

When the kinetic term is small, the condition should reduce to the condition that q_2-q_0 has the same sign as $-V'((q_0+q_1)/2)$. This tells one in which direction q_2 should move.

(a) An optimization method. An alternative strategy to deal with this issue of how to compute the time steps near turning points, which is the one we adapt in this paper, is to adopt the following optimization technique. Given $h_0,\ q_0,\ q_1$ we have to find $h_1,\ q_2$ such that q_2 is determined by the DEL equations

$$g(q_0,q_1,q_2,h_0,h_1) := h_0 D_2 L(q_0,q_1,h_0)+h_1 D_1 L(q_1,q_2,h_1)=0 \tag{V.4}$$

and the energy condition

$$f(q_0,q_1,q_2,h_0,h_1) := E(q_1,q_2,h_1)-E(q_0,q_1,h_0)=0. \tag{V.5}$$

The basic equations we want to solve are thus

$$f(q_0,q_1,q_2,h_0,h_1)=0, \tag{V.6}$$

$$g(q_0,q_1,q_2,h_0,h_1)=0, \tag{V.7}$$

to be solved for the variables q_2 and h_1 as a function of q_0, q_1, and h_0. The technique we use is to minimize the quantity

$$\mathcal{B}=[f(q_0,q_1,q_2,h_0,h_1)]^2+[g(q_0,q_1,q_2,h_0,h_1)]^2 \tag{V.8}$$

over the variables $h_1,\ q_2$, with the other variables given, and *subject to the constraint* $h_1>0$. As above, this constraint means, in practice, that the computed kinetic energy is positive. Of course, this is then iterated and defines our algorithm as a map

$$(q_{k-1},q_k,h_{k-1})\mapsto(q_k,q_{k+1},h_k).$$

This method may be implemented in a standard way using a quasi-Newton algorithm, as in Ref. 27 (see also Ref. 28). Of course, other methods for efficiently solving the system of equations (VIII.9) can be considered as well, but as we have mentioned, we do not carry out any extensive comparitive or implementation tests in this paper. In the simple examples we do give in the section below, we use this optimization method.

VI. SYMPLECTIC NATURE OF THE ALGORITHM

We now show the sense in which the algorithm above is symplectic. This will be in the form of an identity that the mapping

$$\Phi: Q\times Q\times\mathbb{R}\to Q\times Q\times\mathbb{R}$$

defined by

$$(q_0,q_1,h_0)\mapsto(q_1,q_2,h_1),$$

where, as we have seen, q_2 and h_1 are defined by

$$h_0 D_2 L_d(q_0,q_1,h_0)+h_1 D_1 L_d(q_1,q_2,h_1)=0$$

and

$$E_d(q_0,q_1,h_0)=E_d(q_1,q_2,h_1),$$

where we recall that the discrete energy is defined by

$$E_d(q_0,q_1,h_0) = -D_{h_0}[h_0 L_d(q_0,q_1,h_0)].$$

To determine the symplectic nature of the mapping $\bar{\Phi}$, we follow the general line of reasoning in Ref. 1. Namely, we consider the action sum

$$S = [h_0 L_d(q_0,q_1,h_0) + h_1 L_d(q_1,q_2,h_1)]$$

and take its full differential as a function of all the variables, keeping in mind that h_1 and q_2 are functions of (q_0,q_1,h_0). Using the definition of the discrete energy, we get

$$dS = h_0 D_1 L_d(q_0,q_1,h_0)dq_0 + h_0 D_2 L_d(q_0,q_1,h_0)dq_1 + h_1 D_1 L_d(q_1,q_2,h_1)dq_1 + h_1 D_2 L_d(q_1,q_2,h_1)dq_2 - E_d(q_0,q_1,h_0)dh_0 - E_d(q_1,q_2,h_1)dh_1.$$

Because of the discrete Euler–Lagrange equations, this simplifies to

$$dS = h_0 D_1 L_d(q_0,q_1,h_0)dq_0 + h_1 D_2 L_d(q_1,q_2,h_1)dq_2 - E_d(q_0,q_1,h_0)dh_0 - E_d(q_1,q_2,h_1)dh_1.$$

In view of the equations defining the algorithm, we can write this as

$$dS = \Theta_L^- + \bar{\Phi}^* \Theta_L^+, \tag{VI.1}$$

where the one-forms Θ_L^- and Θ_L^+ are defined by

$$\Theta_L^-(q_0,q_1,h_0) = h_0 D_1 L_d(q_0,q_1,h_0)dq_0 - E_d dh_0$$

and

$$\Theta_L^+(q_0,q_1,h_0) = h_0 D_2 L_d(q_0,q_1,h_0)dq_1 - E_d dh_0.$$

Now notice that because of the definition of E_d, we have

$$\Theta_L^-(q_0,q_1,h_0) + \Theta_L^+(q_0,q_1,h_0) = d[h_0 L_d] - E_d dh_0. \tag{VI.2}$$

Substituting (VI.2) into (VI.1) gives

$$dS = d[h_0 L_d] - \theta_d^+ + \bar{\Phi}^* \Theta_L^+, \tag{VI.3}$$

where θ_d^+ is the discrete analog of the canonical one form, $p_i dq^i$, namely

$$\theta_d^+ = \Theta_d^+ + E_d dh_0 = h_0 D_2 L_d(q_0,q_1,h_0)dq_1.$$

Taking the differential of (VI.3), using $d^2=0$ and the fact that pull back commutes with the differential gives our final identity, namely

$$\bar{\Phi}^* \Omega_d = \omega_d, \tag{VI.4}$$

where

$$\Omega_d = -d\Theta_d^+$$

is the discrete analog of the space–time symplectic form and where

$$\omega_d = -d\theta_d^+$$

is the discrete analog of the phase space symplectic form. Notice that the identity (VI.4) is the discrete analog of the identity (III.5) in the continuous case. Thus, we may interpret the identity (VI.4) as the symplectic nature of the algorithm.

(a) Momentum conservation. We note that one proves conservation of momentum for algorithms invariant under a symmetry group in the same way as usual, following, Ref. 1; we need not repeat the argument.

VII. SUMMARY OF THE FEATURES OF THE ALGORITHM

In this section we summarize the three main features of the algorithm.

(1) The algorithm conserves energy.
(2) The algorithm is symplectic in the sense spelled out in the previous section.
(3) The algorithm conserves momentum.

We have designed it to preserve energy. The discrete version of the arguments given in the continuous case shows the ''space–time'' sense in which the algorithm is symplectic, as we have explained.

VIII. NUMERICAL EXAMPLES

The first example is one-dimensional and integrable and the second example consists of the first one coupled to an oscillator.

In each case, we will compare the constant time step method, which will show the orbits in phase space and variations in the energy as a function of time, with the corresponding results for the adaptive time step algorithm.

A. One degree of freedom example

We will use a Lagrangian that is of the standard form kinetic minus potential, namely

$$L(q,\dot{q})=\frac{m}{2}\dot{q}^2-V(q),$$

where q and $\dot{q}$ are real numbers, with the corresponding discrete Lagrangian (with $\gamma=\frac{1}{2}$) given by

$$L_d(q_0,q_1,h)=\frac{1}{2}m\left(\frac{q_1-q_0}{h}\right)^2-V\left(\frac{q_0+q_1}{2}\right),$$

where q_0, q_1, and $h>0$ are also real numbers. The corresponding energy, according to formula (IV.4) is given by

$$E_h(q_0,q_1)=\frac{1}{2}m\left(\frac{q_1-q_0}{h}\right)^2+V\left(\frac{q_0+q_1}{2}\right).$$

(a) Constant time step algorithm. We find q_2 using the DEL equations:

$$h[D_2L(q_0,q_1)+D_1L(q_1,q_2)]=0. \tag{VIII.1}$$

As $h\neq 0$, Eq. (VIII.1) leads to

$$\frac{m}{h^2}(q_1-q_0)-\frac{1}{2}V'\left(\frac{q_0+q_1}{2}\right)-\frac{m}{h^2}(q_2-q_1)-V'\left(\frac{q_1+q_2}{2}\right)=0 \tag{VIII.2}$$

to be solved for q_2. Keeping h fixed, this is the variational integrator that we use for the constant time step algorithm.

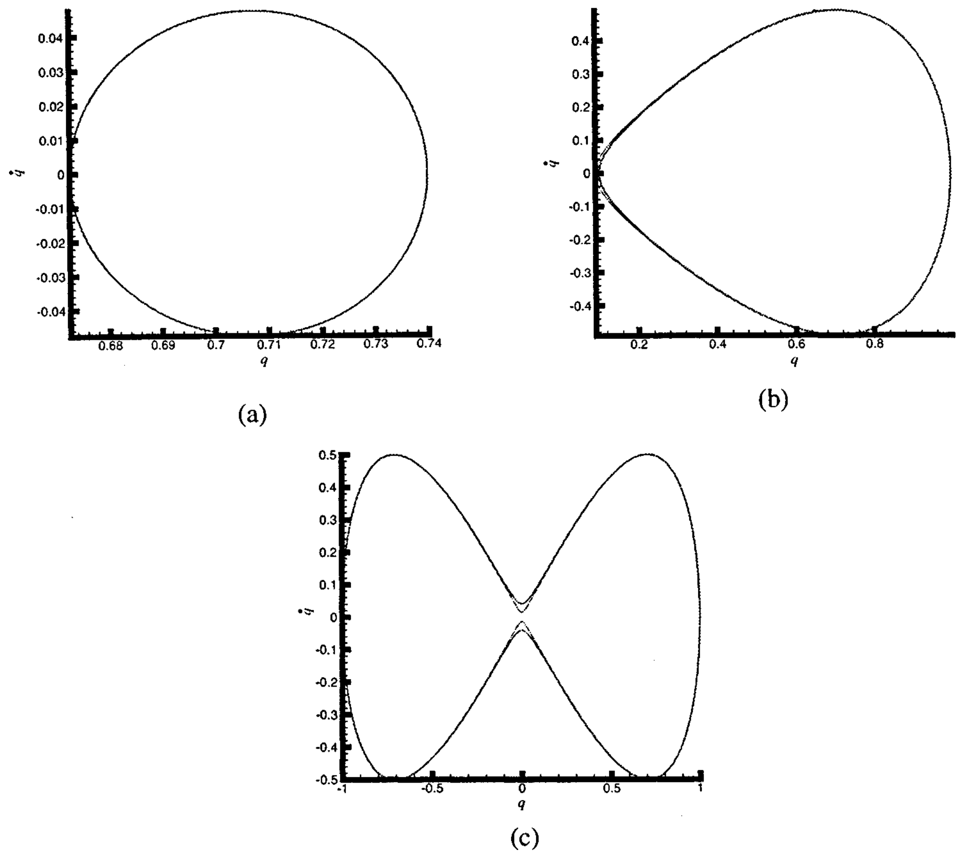

FIG. 1. Three initial conditions are studied for the particle in the double well potential. The orbits for both the fixed time step and the adaptive time step algorithms are plotted. The initial time step used in all cases is $h_0=0.1$. The initial data is (a) $q_0=q_1=0.74$, (b) $q_0=q_1=0.995$, and (c) $q_0=1.0$, $q_1=1.0$. The two orbits in each figure are nearly indistinguishable to the eye, but the adaptive time step computation is somewhat more accurate.

(b) Adaptive time step algorithm. Given $h_0,\ q_0,\ q_1$ we have to find $h_1,\ q_2$ such that q_2 is determined by the DEL equations

$$h_0 D_2 L(q_0,q_1,h_0)+h_1 D_1 L(q_1,q_2,h_1)=0 \tag{VIII.3}$$

and the energy condition

$$E(q_0,q_1,h_0)=E(q_1,q_2,h_1). \tag{VIII.4}$$

We write the energy condition as follows. Define

$$\begin{aligned} f(q_0,q_1,q_2,h_0,h_1)&=E(q_1,q_2,h_1)-E(q_0,q_1,h_0)\\ &=\frac{1}{2}m\,\frac{(q_2-q_1)^2}{h_1^2}+V\left(\frac{q_1+q_2}{2}\right)-E(q_0,q_1,h_0). \end{aligned} \tag{VIII.5}$$

The energy equation is written this way because $E_0 \coloneqq E(q_0,q_1,h_0)$ will have been computed and stored at the previous step.

The DEL equation (VIII.3) is written as follows:

$$g(q_0,q_1,q_2,h_0,h_1)=h_0 B_0+h_1\left[-m\,\frac{q_2-q_1}{h_1^2}-\frac{1}{2}V'\left(\frac{q_1+q_2}{2}\right)\right], \tag{VIII.6}$$

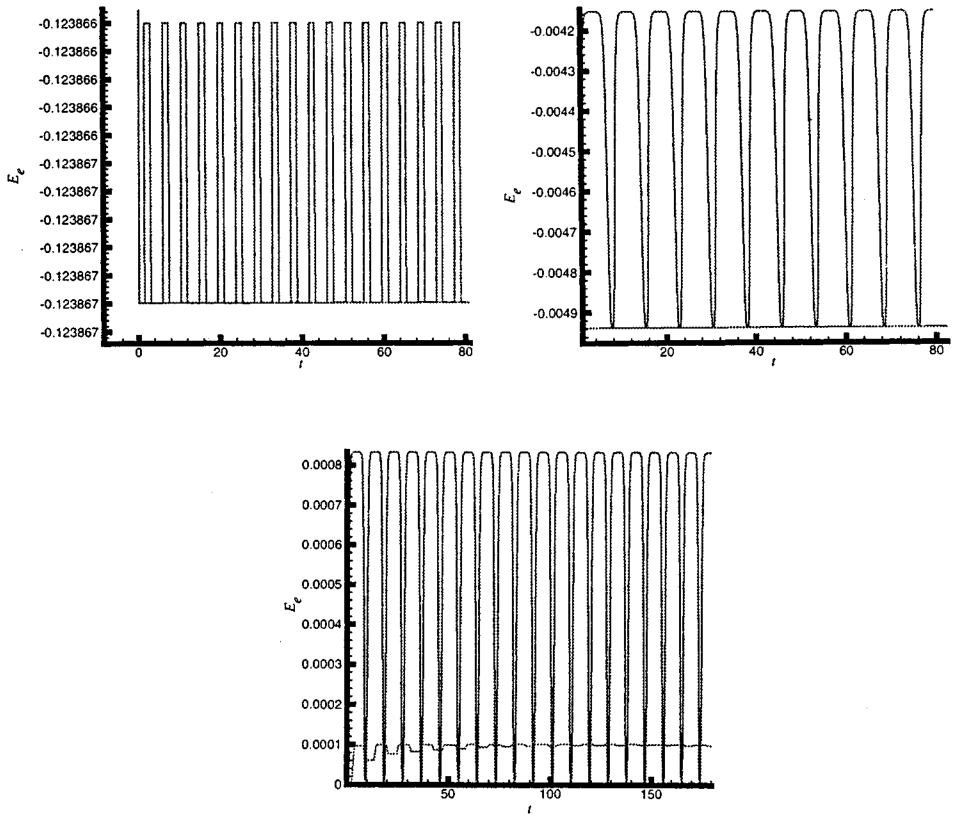

FIG. 2. The relatively large amplitude curve shows the (small) energy error for the constant time step algorithm as a function of time, while the lower curve shows the energy error for the adaptive time step algorithm. The initial data correspond to the three regions shown in the preceding figure.

where

$$B_0 = \left[m \frac{q_1 - q_0}{h_0^2} - \frac{1}{2} V' \left(\frac{q_0 + q_1}{2} \right) \right], \tag{VIII.7}$$

again, a quantity that will have been computed at the previous step.

(c) The numerical technique. The basic equations we want to solve are the following:

$$f(q_0, q_1, q_2, h_0, h_1) = 0, \tag{VIII.8}$$

$$g(q_0, q_1, q_2, h_0, h_1) = 0, \tag{VIII.9}$$

to be solved for the variables q_2 and h_1 as a function of q_0, q_1, and h_0. The technique we use is to minimize the quantity

$$\mathcal{B} = [f(q_0, q_1, q_2, h_0, h_1)]^2 + [g(q_0, q_1, q_2, h_0, h_1)]^2 \tag{VIII.10}$$

over the variables h_1, q_2, with the other variables given, and subject to the constraint $h_1 > 0$. As mentioned in the general theory, this method is implemented using descent methods, following Byrd *et al.*[27] and Zhu *et al.*[28]

(d) The double well potential. To illustrate the procedures, we choose $m = 1$ and take

$$V(q) = \tfrac{1}{2}(q^4 - q^2). \tag{VIII.11}$$

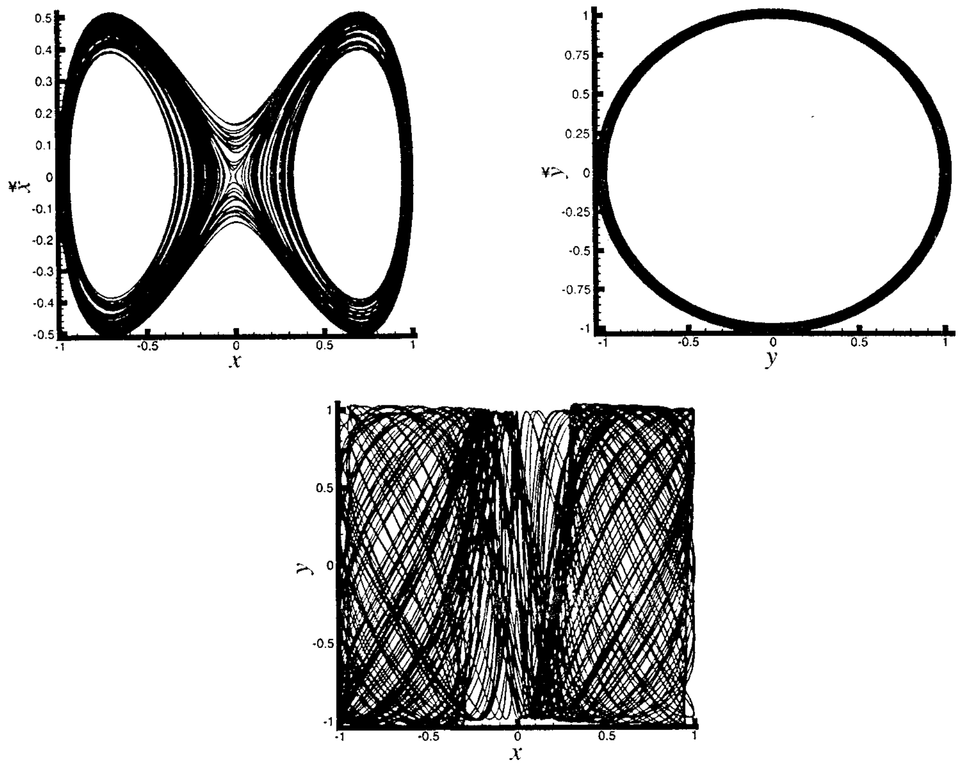

FIG. 3. An orbit in the coupled double well–oscillator system. In this plot, the initial conditions used were $x_0=y_0=x_1=y_1=1.00$, $h_0=0.1$, and $\epsilon=0.01$.

We study three regions of phase space as shown in Fig. 1. The axes show the computed position $q=(q_k+q_{k+1})/2$ and the computed velocity $\dot{q}=(q_{k+1}-q_k)/h_k$ as functions of time. The orbit in Fig. 1(a) is a periodic orbit that oscillates around the stable equilibrium position $q=1/\sqrt{2}$, $\dot{q}=0$. That in Fig. 1(b) is a periodic orbit with high period just inside the homoclinic orbit in the positive q half-space, while that in Fig. 1(c) is a periodic orbit just outside the homoclinic orbit.

The energy errors for both the constant time step and the adaptive time step algorithms are shown in Fig. 2. The amplitude in the variation of the energy depends on the time step. The smaller the time step, the smaller the amplitude, but we note that there is not a big difference in the periods. The same sort of behavior can also be seen in the corresponding plots in Ref. 6.

The small changes in the energy are, we believe, due to the effect of the turning points as we explained earlier. Of course, one can contemplate methods whereby these can be compensated or reduced further, but we do not explore these issues in this paper.

B. A two degree of freedom example

Now we consider an oscillator coupled with our previous double well potential example. The system now has chaotic orbits, so it is somewhat more interesting.

The continuous Lagrangian we choose is given by

$$L(x,y,\dot{x},\dot{y})=\tfrac{1}{2}\dot{x}^2-V(x)+\tfrac{1}{2}\dot{y}^2-\tfrac{1}{2}y^2+\varepsilon xy, \tag{VIII.12}$$

where ε introduces a small perturbation. This is a very simple example of a chaotic system arising as a perturbation of an integrable one. Shortly we will choose V to be the potential used in the preceding subsection.

Using the notation

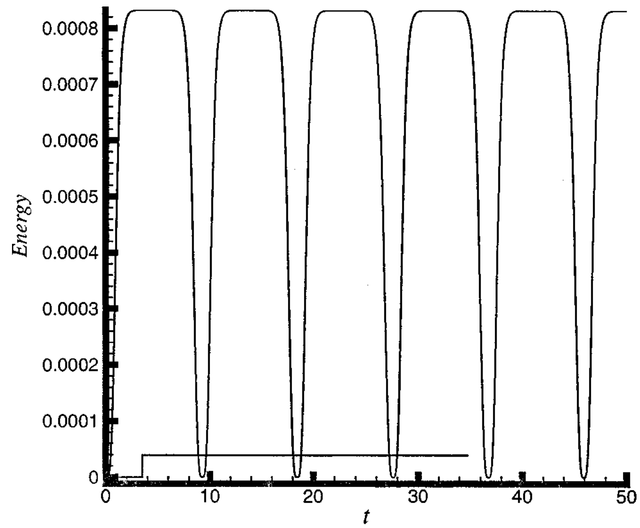

FIG. 4. The energy behavior for the variational versus the symplectic-energy method in the coupled double well–oscillator system.

$$q_0=(x_0,y_0),q_1=(x_1,y_1),$$

the corresponding discrete Lagrangian is

$$L_d(x_0,y_0,x_1,y_1,h_0)=\frac{1}{2}\frac{(x_1-x_0)^2}{h_0^2}-V\left(\frac{x_0+x_1}{2}\right)+\frac{1}{2}\frac{(y_1-y_0)^2}{h_0^2}-\frac{1}{2}\left(\frac{y_0+y_1}{2}\right)+\epsilon\left(\frac{x_0+x_1}{2}\right)\left(\frac{y_0+y_1}{2}\right). \tag{VIII.13}$$

Given $h_0,\ x_0,\ y_0,\ x_1,\ y_1$ we have to find $h_1,\ x_2,\ y_2$ such that the DEL equations

$$h_0D_2L(x_0,y_0,x_1,y_1,h_0)+h_1D_1L(x_1,y_1,x_2,y_2,h_1)=0 \tag{VIII.14}$$

and the energy condition

$$E(x_0,y_0,x_1,y_1,h_0)=E(x_1,y_1,x_2,y_2,h_1). \tag{VIII.15}$$

We write the energy condition in the form $f=0$ as follows. Define

$$\begin{aligned}f(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)&=E(x_1,y_1,x_2,y_2,h_1)-E(x_0,y_0,x_1,y_1,h_0)\\&=\frac{1}{2}\frac{(x_2-x_1)^2}{h_1^2}+V\left(\frac{x_1+x_2}{2}\right)+\frac{1}{2}\frac{(y_2-y_1)^2}{h_1^2}+\frac{1}{2}\left(\frac{y_1+y_2}{2}\right)^2\\&\quad-\epsilon\left(\frac{x_1+x_2}{2}\right)\left(\frac{y_1+y_2}{2}\right)-E(x_0,y_0,x_1,y_1,h_0).\end{aligned} \tag{VIII.16}$$

The DEL equation (VIII.14) is written in the form of a system $g=0$, $k=0$ as follows. Define g by

$$g(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)=h_0B_0+h_1\left[-\frac{x_2-x_1}{h_1^2}-\frac{1}{2}V'\left(\frac{x_1+x_2}{2}\right)+\frac{\epsilon}{2}\left(\frac{y_1+y_2}{2}\right)\right], \tag{VIII.17}$$

where

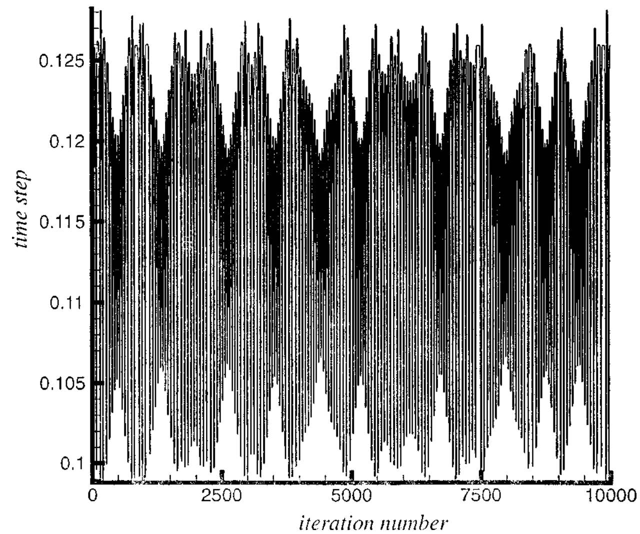

FIG. 5. The time step versus the iteration number for the symplectic-energy method.

$$B_0=\left[\frac{x_1-x_0}{h_0^2}-\frac{1}{2}V'\left(\frac{x_0+x_1}{2}\right)+\frac{\epsilon}{2}\left(\frac{y_0+y_1}{2}\right)\right]. \tag{VIII.18}$$

Define k by

$$k(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)=h_0C_0+h_1\left[-\frac{y_2-y_1}{h_1^2}-\frac{1}{2}\left(\frac{y_1+y_2}{2}\right)+\frac{\epsilon}{2}\left(\frac{x_1+x_2}{2}\right)\right], \tag{VIII.19}$$

where

$$C_0=\left[\frac{y_1-y_0}{h_0^2}-\frac{1}{2}\left(\frac{y_0+y_1}{2}\right)+\frac{\epsilon}{2}\left(\frac{x_0+x_1}{2}\right)\right]. \tag{VIII.20}$$

(e) The numerical technique. The basic equations we want to solve are the following:

$$f(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)=0, \tag{VIII.21}$$

$$g(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)=0,$$

$$k(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)=0, \tag{VIII.22}$$

to be solved for the variables x_2, y_2 and h_1 as a function of x_0, y_0, x_1, y_1 and h_0.

The technique used is to minimize the quantity

$$\mathcal{B}=[f(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)]^2+[g(x_0,y_0,x_1,y_1,x_2,y_2,h_0,h_1)]^2 \tag{VIII.23}$$

over the variables h_1, x_2, y_2, with the other variables given, and subject to the constraint $h_1>0$. This method is then implemented by the same method as in the preceding example.

(f) The double well potential coupled with an oscillator. To illustrate the procedures, we choose, as before,

$$V(x)=\tfrac{1}{2}(x^4-x^2). \tag{VIII.24}$$

We study a single chaotic orbit shown in Fig. 3. The different projections of the orbit, to the $x, \dot{x}$ and the $y, \dot{y}$ spaces and to the configuration space x, y, are shown.

Figure 4 shows the energy behavior, as before, for the standard variational integrator versus our symplectic-energy algorithm.

Finally, Fig. 5 shows how the time step varies with the iteration.

Magnetohydrodynamic boundary layer on a flat plate: Further analytic results

Bhimsen K. Shivamoggi and David K. Rollins[a)]
Department of Mathematics, University of Central Florida, Orlando, Florida 32816

(Received 2 June 1998; accepted for publication 4 March 1999)

Further analytic results are deduced with the magnetohydrodynamic boundary layer equations for a flat plate. The asymptotic behavior of the solutions is deduced using the scaling group method. Then, an analytic perturbative procedure is used to determine an approximate solution that exhibits this asymptotic behavior. © *1999 American Institute of Physics.* [S0022-2488(99)02906-0]

I. INTRODUCTION

Greenspan and Carrier[1] considered the flow of a viscous, electrically conducting, incompressible fluid past a semi-infinite flat plate in the presence of a magnetic field which is uniform at infinity and parallel to the stream. They reduced the boundary-layer equations then to a pair of coupled nonlinear ordinary differential equations—

$$g'' + \mu(fg' - f'g) = 0, \tag{1}$$

$$f''' + ff'' - \frac{1}{A^2} gg'' = 0, \tag{2}$$

subject to the boundary conditions

$$\eta = 0: f = 0, \quad f' = 0, \quad g = 0, \tag{3a}$$

$$\eta \Rightarrow \infty: f \approx 2\eta, \quad g \approx 2\eta. \tag{3b}$$

Here, primes denote differentiation with respect to the independent variable $\eta = \frac{1}{2} y \sqrt{U/\nu x}$; y measures the distance from the plate, x is the distance along the plate from the leading edge, U is the undisturbed velocity, and ν is the kinematic viscosity. Further, if u and B_x are the x components of the velocity and magnetic fields, then

$$u = \tfrac{1}{2} U f'(\eta), \quad B_x = \tfrac{1}{2} B_0 g'(\eta),$$

B_0 being the ambient magnetic field intensity. Finally, $A \equiv U/V_{\mathrm{A}}$, where V_{A} is the Alfvén velocity $V_{\mathrm{A}} \equiv B_0/\sqrt{4\pi\rho}$, and $\mu \equiv 4\pi\sigma\nu$, ρ being the density and σ the electrical conductivity of the fluid.

For sub-Alfvénic flows $(A<1)$, disturbances travel upstream of the plate, invalidating the notion of a boundary layer originating at the leading edge of the plate. As Greenspan and Carrier[1] pointed out, this can be clearly seen by considering the case with infinite electrical conductivity, $\mu \Rightarrow \infty$. For this case, Eqs. (1) and (2) become $g = f$, $f''' + (1 + (1/A^2)) ff'' = 0$, so that one needs $A^2 > 1$ in order to preserve the usual boundary-layer situation. Reuter and Stewartson[2] showed that, for this case, the problem is mathematically ill posed, in the sense that it does not admit any solutions such that $f''(0) > 0$ and $g'(0) > 0$. Stewartson and Wilson[3] showed further that, even for certain values of $A > 1$, the solutions turn out to be nonunique whenever $\mu < 1$.

[a)]Electronic mail: drollins@pegasus.cc.ucf.edu

Equations (1) and (2) are, on the other hand, highly nonlinear and, therefore, one may not anticipate explicit analytical solutions for them. In this paper, we first deduce the asymptotic behavior of the solutions of Eqs. (1) and (2) using the scaling group method (Bluman and Kumei[4]). We then use an analytical perturbative procedure due to Bender *et al.*[5] to determine an approximate solution that has the above asymptotic behavior.

II. ASYMPTOTIC BEHAVIOR OF THE SOLUTION

In order to find the asymptotic behavior of the solutions of (1)–(3), note first that Eqs. (1) and (2) admit solutions of the form

$$f \sim \frac{1}{\eta}, \quad g \sim \frac{1}{\eta}; \tag{4}$$

(4) implies that Eqs. (1) and (2) have the scaling group

$$\overline{f} = \alpha^{-1} f, \quad \overline{g} = \alpha^{-1} g, \quad \overline{\eta} = \alpha \eta. \tag{5}$$

We may therefore introduce the following canonical coordinates

$$s = f\eta, \quad t = \eta^2 \frac{df}{d\eta}, \quad q = \eta g. \tag{6}$$

The transformation from (s,t) to (f,η) is given differentially by

$$\frac{ds}{t+s} = \frac{d\eta}{\eta}. \tag{7}$$

The transformation rules of the various derivatives are

$$\begin{gathered}
\frac{d^2 f}{d\eta^2} = -\frac{2t}{\eta^3} + \frac{1}{\eta^3}(t+s)\frac{dt}{ds}, \\
\frac{d^3 f}{d\eta^3} = \frac{6t}{\eta^4} - \frac{5}{\eta^4}(t+s)\frac{dt}{ds} + \frac{1}{\eta^4}(t+s)^2\frac{d^2 t}{ds^2} + \frac{1}{\eta^4}(t+s)\frac{dt}{ds}\left(\frac{dt}{ds}+1\right), \\
\frac{dg}{d\eta} = -\frac{q}{\eta^2} + \frac{1}{\eta^2}(t+s)\frac{dq}{ds}, \\
\frac{d^2 g}{d\eta^2} = \frac{2}{\eta^3}q - \frac{3}{\eta^3}(t+s)\frac{dq}{ds} + \frac{1}{\eta^3}(t+s)^2\frac{d^2 q}{ds^2} + \frac{1}{\eta^3}(t+s)\frac{dq}{ds}\left(\frac{dt}{ds}+1\right).
\end{gathered} \tag{8}$$

In terms of the new variables (s,t,q), the boundary-value problem (1)–(3) becomes

$$\begin{aligned}
&6t - 5(t+s)\frac{dt}{ds} + (t+s)^2\frac{d^2 t}{ds^2} + (t+s)\frac{dt}{ds}\left(\frac{dt}{ds}+1\right) - 2st + s(t+s)\frac{dt}{ds} \\
&\qquad - \frac{1}{A^2} q[2q - 3(t+s)]\frac{dq}{ds} + (t+s)^2\frac{d^2 q}{ds^2} + (t+s)\frac{dq}{ds}\left(\frac{dt}{ds}+1\right) = 0,
\end{aligned} \tag{9}$$

$$2q - 3(t+s)\frac{dq}{ds} + (t+s)^2\frac{d^2 q}{ds^2} + (t+s)\frac{dq}{ds}\left(\frac{dt}{ds}+1\right) + \mu\left[s(t+s)\frac{dq}{ds} - q(t+s)\right] = 0, \tag{10}$$

$$s = 0: t = 0, \quad q = 0, \tag{11}$$

$$s \Rightarrow \infty : t \Rightarrow \infty, \quad q \Rightarrow \infty. \tag{12}$$

Near $s=0$, Eqs. (9) and (10) show that

$$t \approx \lambda_1 s, \quad q \approx \lambda_2 s^p, \tag{13}$$

with

$$6\lambda_1 - 5\lambda_1(\lambda_1+1) + \lambda_1(\lambda_1+1)^2 \approx 0, \tag{14a}$$

$$2\lambda_2 - 3p\lambda_2(\lambda_1+1) + p(p-1)\lambda_2(\lambda_1+1)^2\lambda_2 p(\lambda_1+1)^2 \approx 0, \tag{15a}$$

or

$$\lambda_1 = 1,2, \tag{14b}$$

$$\lambda_1 = 2, \lambda_2 \ \text{ arbitrary and } \ p = \tfrac{1}{3}, \tfrac{2}{3}. \tag{15b}$$

$\lambda_1 = 1$ turns out to be the spurious root. The root $p=\frac{1}{3}$ is to be discarded because we require from (6) and (13) that $2p > 1$.

For $\lambda_1 = 2$, we obtain from (7) and (13),

$$s \sim \eta^3. \tag{16}$$

Using (16), we have from (6),

$$\eta \Rightarrow 0 : f \sim \eta^2, \quad g \sim \eta \tag{17}$$

Near $s \Rightarrow \infty$, equations (9) and (10) show that

$$t \approx \tilde{\lambda}_1 s, \quad q \approx \tilde{\lambda}_2 s, \tag{18}$$

with

$$-2\tilde{\lambda}_1 + \tilde{\lambda}_1(\tilde{\lambda}_1+1) - \frac{1}{A^2}\tilde{\lambda}_2[2\tilde{\lambda}_2 - 3\tilde{\lambda}_2(\tilde{\lambda}_1+1) + \tilde{\lambda}_2(\tilde{\lambda}_1+1)^2] \approx 0, \tag{19a}$$

$$2\tilde{\lambda}_2 - 3\tilde{\lambda}_2(\tilde{\lambda}_1+1) + \tilde{\lambda}_2(\tilde{\lambda}_1+1)^2 \approx 0, \tag{20a}$$

or

$$\tilde{\lambda}_1 = 1, \tag{19b}$$

$$\tilde{\lambda}_2 \ \text{ arbitrary.} \tag{20b}$$

Using (19) and (20), we obtain from (7) and (18),

$$s \sim \eta^2. \tag{21}$$

Using (21), we have from (6),

$$\eta \Rightarrow \infty : f \sim \eta, \quad g \sim \eta. \tag{22}$$

Observe that the asymptotic behavior of the solutions, as exhibited by (17) and (22), is independent of the Alfvén number A.

III. AN ANALYTIC PERTURBATIVE SOLUTION

We now use a perturbative procedure due to Bender *et al.*[5] to solve Eqs. (1) and (2) analytically. This method has been used recently (Shivamoggi and Rollins[6]) to solve the Kadomtsev equation for a heavy atom in a very strong magnetic field with very good results. We first replace Eqs. (1) and (2) by ones that contain a parameter δ, i.e.,

$$g'' + \mu[g' f^{\delta} - f' g^{\delta}] = 0, \tag{23}$$

$$f''' + f'' f^{\delta} - \frac{1}{A^2} g'' g^{\delta} = 0. \tag{24}$$

Note that Eqs. (1) and (2) are recovered when $\delta = 1$, and $\delta = 0$ corresponds to the linear zeroth-order approximation. By identifying δ as the perturbation parameter, the solution (f,g) is then expanded in a power series in δ,

$$\begin{aligned} f &= f_0 + \delta f_1 + \delta^2 f_2 + \cdots, \\ g &= g_0 + \delta g_1 + \delta^2 g_2 + \cdots. \end{aligned} \tag{25}$$

This then leads to a set of linear equations for (f_n, g_n): $O(1)$,

$$g_0'' + \mu(g_0' - f_0') = 0, \tag{26}$$

$$f_0''' + f_0'' - \frac{1}{A^2} g_0'' = 0; \tag{27}$$

$O(\delta)$,

$$g_1'' + \mu(g_1' - f_1') = -\mu(g_0' \cdot \ln f_0 - f_0' \cdot \ln g_0), \tag{28}$$

$$f_1''' + f_1'' - \frac{1}{A^2} g_1'' = -f_0'' \cdot \ln f_0 + \frac{1}{A^2} g_0'' \cdot \ln g_0, \tag{29}$$

etc.

Successive integrations of Eqs. (26) and (27), along with the use of (3), lead to

$$g_0' + \mu(g_0 - f_0) = \alpha, \tag{30}$$

$$f_0' + f_0 - \frac{1}{A^2} g_0 = c\eta, \tag{31}$$

where c is an arbitrary constant and

$$\alpha \equiv g_0'(0) > 0. \tag{32}$$

Using the boundary condition (3) at $\eta \Rightarrow \infty$, we obtain, from (31),

$$c = 2\epsilon, \tag{33}$$

where

$$\epsilon \equiv 1 - \frac{1}{A^2} > 0.$$

We have, from Eqs. (30) and (31),

$$f_0''+(1+\mu)f_0'+\epsilon\mu f_0=2\epsilon\mu\eta+2\epsilon+\alpha(1-\epsilon), \tag{34}$$

from which

$$f_0=(D_1e^{\sigma_1\eta}+D_2e^{\sigma_2\eta})-\frac{2\mu+(2-\alpha)(1-\epsilon)}{\mu\epsilon}+2\eta, \tag{35}$$

where

$$\sigma_{1,2}=\tfrac{1}{2}[-(1+\mu)\pm\sqrt{(1+\mu)^2-4\mu\epsilon}].$$

Using the boundary condition (3) at $\eta=0$, we obtain

$$D_1=-\frac{1}{\sigma_1-\sigma_2}\left[\sigma_2\frac{2\mu+(2-\alpha)(1-\epsilon)}{\mu\epsilon}+2\right],$$

$$D_2=\frac{1}{\sigma_1-\sigma_2}\left[\sigma_1\frac{2\mu+(2-\alpha)(1-\epsilon)}{\mu\epsilon}+2\right]. \tag{36}$$

We have from (32) and (35) and (36), for small η,

$$f_0\approx\tfrac{1}{2}[\alpha(1-\epsilon)+2\epsilon]\eta^2, \tag{37a}$$

$$g_0\approx\alpha\eta. \tag{37b}$$

One may also obtain (37) directly from Eqs. (30) and (31).

Observe from (37a) that, for super-Alfvénic flows ($\epsilon>0$), $f_0''(0)>0$, because

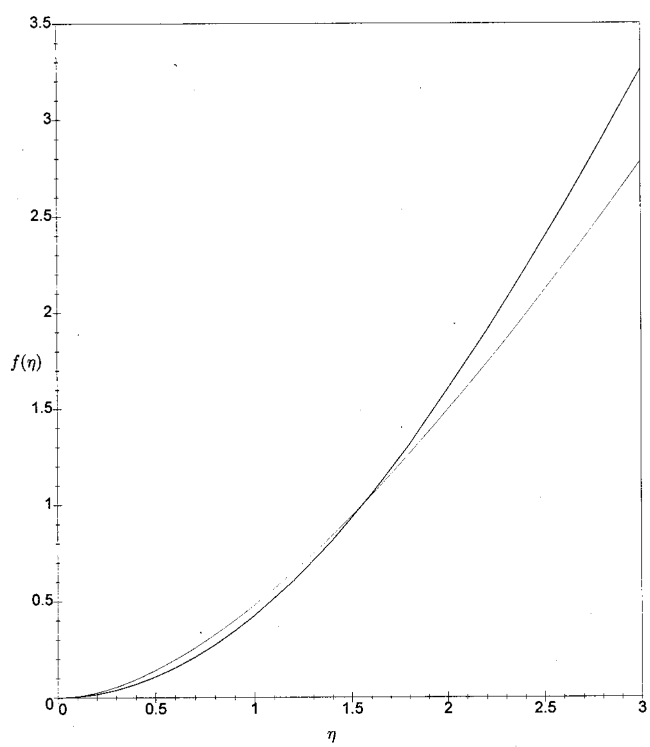

FIG. 1. Comparison of zeroth order approximate solution and numerical solution (bold) for nonlinear boundary value problem for magnetohydrodynamic case.

$$\alpha(1-\epsilon)+2\epsilon>0,$$

on noting (32) and that $(1-\epsilon)>0$.

Further, we have from (31), (33), and (35), for large η,

$$f_0 \approx 2\eta, \tag{38a}$$

$$g_0 \approx 2\eta. \tag{38b}$$

One may also obtain (38) directly from Eqs. (30) and (31).

The agreement of (37) with (17) on the one hand, and (38) with (3b) on the other hand, indicates that the asymptotic behavior (for *both* small and large η) of the solution of Eqs. (1) and (2) can be accurately provided by the linearized versions of the latter. Indeed, the linearized (or the zeroth-order) solution turns out to provide a reasonably accurate representation of the exact numerical solution of Eqs. (1) and (2) elsewhere as well.

In Fig. 1, the zeroth-order approximate analytic solution f_0 given in (35) is compared with the exact numerical solution of Eqs. (1) and (2). The agreement seems to be very good, even though f_0 is meant to be only a crude approximation to the exact solution. In fact, this feature is a carryover from the hydrodynamic case. In the latter case, (35) reduces to

$$f_0(\eta)=2e^{-\eta}-2+2\eta, \tag{39}$$

in agreement with the one given by Bender *et al.*[5] In Fig. 2, the zeroth-order approximate analytic solution given by (39) is compared with the exact numerical solution of the Blasius equation,

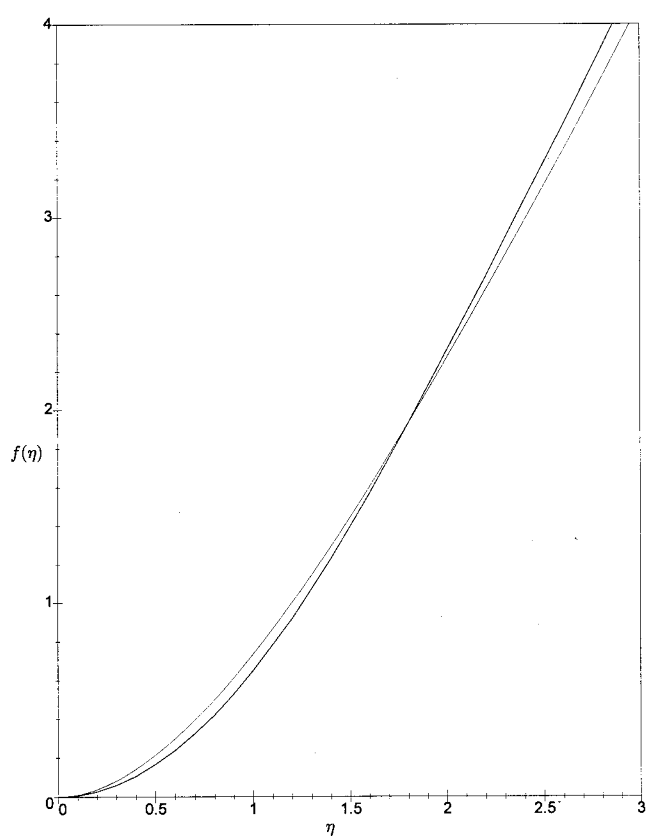

FIG. 2. Comparison of zeroth order approximate solution and numerical solution (bold) for nonlinear boundary value problem for hydrodynamic case.

$$f''' + ff'' = 0. \tag{40}$$

Again, the agreement seems to be very good.

Next, using (31) and (35) in the $O(\delta)$ equations (28) and (29), we see that a closed-form analytic solution of these equations becomes very difficult to find.

IV. DISCUSSION

In this paper, we have deduced further analytic results with the magnetohydrodynamic boundary layer equations (1) and (2) for a flat plate. We first derived the asymptotic behavior of the solutions using the scaling group method (Bluman and Kumei[4]). We then sought to use an analytic perturbative procedure due to Bender *et al.*[5] to determine an approximate solution. However, the linearized (or the zeroth-order) solution of the boundary-layer equations (1) and (2) turned out to provide not only the required asymptotic behavior (for both small and large η) of the exact numerical solution of Eqs. (1) and (2), but also a reasonably accurate representation of the exact numerical solution elsewhere.

(Received 27 July 1998; accepted for publication 5 March 1999)

The integrability of a system which describes constant mean curvature surfaces by means of the adapted Weierstrass–Enneper inducing formula is studied. This is carried out by using a specific transformation which reduces the initial system to the completely integrable two-dimensional Euclidean nonlinear sigma model. Through the use of the apparatus of differential forms and Cartan theory of systems in involution, it is demonstrated that the general analytic solutions of both systems possess the same degree of freedom. Furthermore, a new linear spectral problem equivalent to the initial Weierstrass–Enneper system is derived via the method of differential constraints. A new procedure for constructing solutions to this system is proposed and illustrated by several elementary examples, including a multi-soliton solution. © *1999 American Institute of Physics.* [S0022-2488(99)03307-1]

I. INTRODUCTION

Since the last century, the problems of surfaces and their deformations under various types of dynamics have generated a great deal of interest and activity in several mathematical as well as physical fields of research.[1–9] In particular, surfaces with constant mean curvature have been shown to play an essential role in several applications to nonlinear phenomena in such areas of physics as two-dimensional gravity,[4,10] quantum field theory,[4,11] statistical physics,[3,12] and fluid dynamics.[13,14] The Weierstrass–Enneper formula for inducing minimal surfaces has been studied for several years,[15–17] most recently by B. Konopelchenko and I. Taimanov.[18,19] They established a direct connection between certain classes of constant curvature surfaces and an integrable finite-dimensional Hamiltonian system (for a summary of their results, see Ref. 19). In general, it was shown by B. Konopelchenko[18] that the following infinite-dimensional Hamiltonian system describes constant mean curvature surfaces,

$$\partial\psi_1 = 2H(|\psi_1|^2 + |\psi_2|^2)\psi_2, \quad \bar{\partial}\psi_2 = -2H(|\psi_1|^2 + |\psi_2|^2)\psi_1, \tag{1.1}$$

where ψ_1 and ψ_2 are complex functions of the complex variables $(z,\bar{z})$. The bar denotes the complex conjugate, $\partial = \partial/\partial z$ and $\bar{\partial} = \partial/\partial\bar{z}$, and H denotes the constant mean curvature of the surface. One can assume, without loss of generality, $H = \frac{1}{2}$. Then, system (1.1) takes the form

$$\partial\psi_1 = p\psi_2, \quad \bar{\partial}\psi_2 = -p\psi_1, \quad p = |\psi_1|^2 + |\psi_2|^2, \tag{1.2a}$$

and its respective complex conjugate is

[a)]Electronic mail: bracken@CRM.UMontreal.ca
[b)]Electronic mail: grundlan@CRM.UMontreal.ca
[c)]Electronic mail: martina@le.infn.it

$$\overline{\partial \psi_1} = p \overline{\psi_2}, \quad \overline{\partial \psi_2} = -p \overline{\psi_1}. \tag{1.2b}$$

The above system can be considered a variant of the original Weierstrass–Enneper (WE) system and we will refer to it as such.

The system (1.2) determines a set of constant mean curvature surfaces obtained by the following parametrization $(z,\bar{z}) \to (X_1(z,\bar{z}), X_2(z,\bar{z}), X_3(z,\bar{z}))$

$$X_1 + iX_2 = 2i \int_{z_0}^{z} (\overline{\psi_1^2}\, dz' - \overline{\psi_2^2} d\overline{z'}),$$

$$X_1 - iX_2 = 2i \int_{z_0}^{z} (\psi_2^2\, dz' - \psi_1^2 d\overline{z'}), \tag{1.3}$$

$$X_3 = -2 \int_{z_0}^{z} (\psi_2 \overline{\psi_1}\, dz' + \psi_1 \overline{\psi_2}\, d\overline{z'}).$$

Using the standard formulas, we find that the first fundamental form on the surface is given by

$$\Omega = 4p^2\, dz d\bar{z}, \tag{1.4}$$

and the Gaussian curvature is[18]

$$K = -\frac{\partial \bar{\partial} (\ln p)}{p^2} \tag{1.5}$$

in isothermic coordinates.

The results obtained in Ref. 19 give a certain indication suggesting complete integrability of the WE system (1.2). However, a systematic approach to its integrability still remains an open problem. It will be shown here that the WE system (1.2) passes the Painlevé test, which means that it satisfies the necessary condition for complete integrability. This fact will be deduced from the existence of a linear spectral problem for the WE system (1.2). Moreover, the Lie algebra of infinitesimal symmetries of the WE system (1.2) is spanned by the vector fields

$$\alpha_1 = \partial, \quad \alpha_2 = \bar{\partial}, \quad \beta = \psi_1 \partial_{\psi_1} - \overline{\psi_1} \partial_{\overline{\psi_1}} + \psi_2 \partial_{\psi_2} - \overline{\psi_2} \partial_{\overline{\psi_2}} \tag{1.6}$$

and

$$\alpha_\xi = \xi \partial + \overline{\xi \partial} - \tfrac{1}{2} [\psi_1 (\overline{\partial \xi}) \partial_{\psi_1} + \overline{\psi_1} (\partial \xi) \partial_{\overline{\psi_1}} + \psi_2 (\partial \xi) \partial_{\psi_2} + \overline{\psi_2} (\overline{\partial \xi}) \partial_{\overline{\psi_2}}], \tag{1.7}$$

where $\xi(z)$ is an arbitrary analytic function and $\bar{\xi}(\bar{z})$ denotes its complex conjugate. Then, the set $\{\alpha_\xi\}$ generates an infinite-dimensional Lie algebra, realizing the conformal symmetry property of the system (1.2). This algebra contains a Virasoro subalgebra,[20] which has translations and dilations as special elements and sl(2) as unique simple subalgebras. The vector field β commutes with the α_ξ and it describes a scaling transformation involving only the dependent variables ψ_i and $\bar{\psi}_i$.

To obtain a one-parameter subgroup, we integrate α_ξ. Thus, we obtain the transformations

$$z'(\lambda, z) = F^{-1}(\lambda + F(z)) = \int_{z_0}^{z} \frac{\xi[z'(\lambda, w)]}{\xi(w)} dw,$$

$$\psi_1'(\lambda, \psi_1) = \psi_1 \left(\frac{\bar{\xi}(\bar{z})}{\xi(\overline{z'}(\lambda, z))} \right)^{1/2}, \quad \psi_2'(\lambda, \psi_2) = \psi_2 \left(\frac{\xi(z'(\lambda, z))}{\xi(z)} \right)^{1/2},$$

where

$$F(z)=\int_c^z \frac{ds}{\xi(s)},$$

with z_0 and c suitable complex numbers. Although the existence of a conformal symmetry does not imply in general complete integrability, it is, however, a strong indication in this direction.

Moreover, the WE system (1.2) possesses several conserved quantities.[10] The conservation of current which is defined by

$$J=\bar{\psi}_1\partial\psi_2-\psi_2\partial\bar{\psi}_1 \tag{1.8}$$

leads to interesting consequences. Differentiation of J gives

$$\begin{aligned}\bar{\partial}J=\bar{\partial}(\bar{\psi}_1\partial\psi_2-\psi_2\partial\bar{\psi}_1)&=(\overline{\partial\psi_1})\partial\psi_2+\bar{\psi}_1(\bar{\partial}\partial\psi_2)-(\bar{\partial}\psi_2)(\partial\bar{\psi}_1)-\psi_2(\bar{\partial}\partial\bar{\psi}_1)\\&=p\bar{\psi}_2\partial\psi_2+\bar{\psi}_1(\bar{\partial}\partial\psi_2)+p\psi_1\partial\bar{\psi}_1-\psi_2(\bar{\partial}\partial\bar{\psi}_1).\end{aligned} \tag{1.9}$$

The mixed derivatives obtained from (1.2) are

$$\begin{aligned}\partial\overline{\partial\psi_1}&=\partial(p\bar{\psi}_2)=(\partial p)\bar{\psi}_2+p\partial\bar{\psi}_2=(\partial p)\bar{\psi}_2-p^2\bar{\psi}_1,\\ \partial\bar{\partial}\psi_2&=-\partial(p\psi_1)=-(\partial p)\psi_1-p\partial\psi_1=-(\partial p)\psi_1-p^2\psi_2.\end{aligned} \tag{1.10}$$

Consequently, the derivative of J vanishes,

$$\begin{aligned}\bar{\partial}J&=p\bar{\psi}_2\partial\psi_2-|\psi_1|^2(\partial p)-p^2\bar{\psi}_1\psi_2+p\psi_1\partial\bar{\psi}_1-|\psi_2|^2(\partial p)+p^2\bar{\psi}_1\psi_2\\&=-p(\partial p)+p(\bar{\psi}_2\partial\psi_2+\psi_1\partial\bar{\psi}_1)=-p(\partial p)+p(\partial p)=0.\end{aligned} \tag{1.11}$$

Note that $\bar{\partial}J=0$ holds even when no restriction has been placed on ∂p. Exactly the same situation occurs for the conjugate equation, $\partial\bar{J}=0$. This means that the current J is an entire function.

In this paper, we examine certain aspects of complete integrability of the WE system (1.2) in the context of a two-dimensional Euclidean sigma model. In particular, we focus on constructing a linear spectral problem for this system where the explicit form has not been known up to now.

This paper is organized as follows. In Sec. II, we perform the reduction of the original system to a certain second-order system of partial differential equations (PDEs). In Sec. III, we present an estimation of the degree of freedom of the general analytic solutions of both systems. This analysis is carried out by means of the Cartan theory of systems in involution. In Sec. IV, a linear spectral problem is derived for the WE system via a two-dimensional nonlinear sigma model based on the related second-order system. This procedure amounts to a new technique for generating certain classes of solutions of the WE system which is illustrated with several examples in Sec V. Section VI contains final remarks and possible future developments.

II. THE SECOND-ORDER SYSTEM ASSOCIATED WITH THE WEIERSTRASS–ENNEPER SYSTEM

In our investigation of the integrability of the WE system (1.2), we subject it to several transformations in order to simplify its structure.

We start by introducing the new complex variable

$$\rho=\frac{\psi_1}{\psi_2}. \tag{2.1}$$

Using Eqs. (1.2) and the relation $p=|\psi_2|^2(1+|\rho|^2)$, one obtains

$$\partial\rho=\frac{\partial\psi_1}{\psi_2}-\frac{\psi_1}{\psi_2^2}\partial\bar{\psi}_2=\frac{p\psi_2}{\psi_2}-\frac{\psi_1}{\psi_2^2}(-p\bar{\psi}_1)=\frac{p^2}{\psi_2^2}=(1+|\rho|^2)^2\psi_2^2. \tag{2.2}$$

Note that $\partial\rho$ and ψ_2^2 are related by a real function $(1+|\rho|^2)^2$. Consequently, they have the same polar angle in the complex plane. Dividing (2.2) by $(1+|\rho|^2)^2$ and taking the principal square root, one obtains ψ_2. The complex conjugate of ψ_2 is found in the usual way by reflecting through the real axis. Using (2.1), ψ_1 can be obtained from the product of ρ and $\bar{\psi}_2$. This generates the following transformation from the variable ρ into the set of variables ψ_i,

$$\psi_1=\epsilon\rho\frac{(\overline{\partial\rho})^{1/2}}{1+|\rho|^2},\quad \psi_2=\epsilon\frac{(\partial\rho)^{1/2}}{1+|\rho|^2}\quad (\epsilon^2=1). \tag{2.3}$$

Let us now state the following proposition.

Proposition 1: If ψ_1 and ψ_2 are solutions of the system (1.2), then the function ρ defined by (2.1) is a solution of the following second-order system,

$$\partial\bar{\partial}\rho-\frac{2\bar{\rho}}{1+|\rho|^2}\partial\rho\bar{\partial}\rho=0, \tag{2.4a}$$

$$\partial\bar{\partial}\bar{\rho}-\frac{2\rho}{1+|\rho|^2}\partial\bar{\rho}\bar{\partial}\bar{\rho}=0. \tag{2.4b}$$

Proof: Differentiation of Eq. (2.1) with respect to $\bar{z}$ yields

$$\bar{\partial}\rho=\frac{\bar{\partial}\psi_1}{\bar{\psi}_2}-\frac{\psi_1}{\bar{\psi}_2^2}\overline{\partial\psi_2}=(\bar{\psi}_2)^{-2}[\bar{\psi}_2\bar{\partial}\psi_1-\psi_1\overline{\partial\psi_2}]. \tag{2.5}$$

By an easy computation, one obtains from (2.2) and (2.5)

$$\begin{aligned}\partial\bar{\partial}\rho&=\frac{\partial\bar{\partial}\psi_1}{\bar{\psi}_2}-\frac{\bar{\partial}\psi_1}{(\bar{\psi}_2)^2}\partial\bar{\psi}_2-\frac{\partial\psi_1}{(\bar{\psi}_2)^2}\overline{\partial\psi_2}+2\frac{\psi_1}{(\bar{\psi}_2)^3}\partial\bar{\psi}_2\overline{\partial\psi_2}-\frac{\psi_1}{(\bar{\psi}_2)^2}\partial\overline{\partial\psi_2}\\&=(\bar{\psi}_2)^{-3}[\bar{\psi}_2^2(\partial\bar{\partial}\psi_1)-\bar{\psi}_2\bar{\partial}\psi_1\partial\bar{\psi}_2-\bar{\psi}_2\partial\psi_1\overline{\partial\psi_2}+2\psi_1(\partial\bar{\psi}_2)(\overline{\partial\psi_2})-\psi_1\bar{\psi}_2(\partial\overline{\partial\psi_2})]\\&=(\bar{\psi}_2)^{-3}[\bar{\psi}_2^2(\partial\bar{\partial}\psi_1)+p\bar{\psi}_2\bar{\psi}_1\bar{\partial}\psi_1-p|\psi_2|^2\overline{\partial\psi_2}-2p|\psi_1|^2\overline{\partial\psi_2}-\psi_1\bar{\psi}_2(\partial\overline{\partial\psi_2})],\end{aligned} \tag{2.6}$$

and its respective complex conjugate equation is

$$\partial\bar{\partial}\bar{\rho}=(\psi_2)^{-3}[\psi_2^2(\bar{\partial}\partial\psi_1)+p\psi_2\psi_1\partial\bar{\psi}_1-p|\psi_2|^2\partial\psi_2-2p|\psi_1|^2\partial\psi_2-\bar{\psi}_1\psi_2(\bar{\partial}\partial\psi_2)]. \tag{2.7}$$

Using (1.2) the second derivatives (1.9) become

$$\begin{aligned}\partial\overline{\partial\psi_1}&=(\psi_1\partial\bar{\psi}_1+\bar{\psi}_2\partial\psi_2)\bar{\psi}_2-p^2\bar{\psi}_1,\\ \bar{\partial}\partial\psi_1&=(\bar{\psi}_1\bar{\partial}\psi_1+\psi_2\overline{\partial\psi_2})\psi_2-p^2\psi_1,\\ \partial\bar{\partial}\psi_2&=-(\psi_1\partial\bar{\psi}_1+\bar{\psi}_2\partial\psi_2)\psi_1-p^2\psi_2,\\ \bar{\partial}\partial\bar{\psi}_2&=-(\bar{\psi}_1\bar{\partial}\psi_1+\psi_2\overline{\partial\psi_2})\bar{\psi}_1-p^2\bar{\psi}_2.\end{aligned} \tag{2.8}$$

Substituting (2.8) into (2.6) and (2.7), the following compact formulas for the mixed ρ derivatives can be obtained:

$$\partial\bar{\partial}\rho = \frac{2\bar{\psi}_1 p}{\psi_2^3}\left(\bar{\psi}_2\bar{\partial}\psi_1 - \psi_1\overline{\partial\psi_2}\right),$$
$$\bar{\partial}\partial\bar{\rho} = \frac{2\psi_1 p}{\psi_2^3}\left(\psi_2\partial\bar{\psi}_1 - \bar{\psi}_1\partial\psi_2\right). \tag{2.9}$$

Substituting (2.1), (2.2), (2.5), and (2.9) into the left-hand side of (2.4a), one obtains

$$\begin{aligned}\partial\bar{\partial}\rho - \frac{2\bar{\rho}}{1+|\rho|^2}\partial\rho\bar{\partial}\rho &= \frac{2\bar{\psi}_1 p}{\psi_2^3}\left(\bar{\psi}_2\bar{\partial}\psi_1 - \psi_1\overline{\partial\psi_2}\right) - \frac{2\bar{\psi}_1\psi_2}{\psi_2^2}(1+|\rho|^2)\left(\bar{\psi}_2\bar{\partial}\psi_1 - \psi_1\overline{\partial\psi_2}\right)\\ &= \frac{2\bar{\psi}_1 p}{\psi_2^3}\left(\bar{\psi}_2\bar{\partial}\psi_1 - \psi_1\overline{\partial\psi_2}\right) - \frac{2\bar{\psi}_1 p}{\psi_2^3}\left(\bar{\psi}_2\bar{\partial}\psi_1 - \psi_1\overline{\partial\psi_2}\right) = 0.\end{aligned}$$

An analogous result holds for the conjugate equation (2.4b). Q.E.D.

Similar formulas to those of (2.4) can be found in the literature[10,11] in the context involving conformal immersions of a Riemann surface in $\mathbb{R}^n$.

The converse of Proposition 1 can be formulated as follows.

Proposition 2: If ρ is a solution to the system (2.4), then the functions ψ_1 and ψ_2 defined by (2.3) in terms of ρ satisfy the WE system (1.2).

Proof: Differentiating (2.3) with respect to z, we obtain

$$\partial\psi_1 = \epsilon\left\{\partial\rho\frac{(\bar{\partial}\bar{\rho})^{1/2}}{1+|\rho|^2} + \rho\frac{(\bar{\partial}\bar{\rho})^{\sqrt{-1/2}}}{2(1+|\rho|^2)}\partial\bar{\partial}\bar{\rho} - \rho\frac{(\bar{\partial}\bar{\rho})^{1/2}}{(1+|\rho|^2)^2}(\rho\partial\bar{\rho} + \bar{\rho}\partial\rho)\right\}.$$

Substituting Eq. (2.4) into this expression, we get

$$\partial\psi_1 = \epsilon\left\{\partial\rho\frac{(\bar{\partial}\bar{\rho})^{1/2}}{1+|\rho|^2} - |\rho|^2\frac{(\bar{\partial}\bar{\rho})^{1/2}}{(1+|\rho|^2)^2}\partial\rho\right\} = \frac{(\partial\rho\bar{\partial}\bar{\rho})^{1/2}}{(1+|\rho|^2)}\psi_2. \tag{2.10}$$

Multiplying both equations in (2.3) together, the following expression for p results:

$$p = \frac{(\partial\rho\bar{\partial}\bar{\rho})^{1/2}}{(1+|\rho|^2)}. \tag{2.11}$$

Therefore,

$$\partial\psi_1 = \frac{(\partial\rho\bar{\partial}\bar{\rho})^{1/2}}{(1+|\rho|^2)}\psi_2 = p\psi_2.$$

Similarly, differentiation of (2.3) with respect to $\bar{z}$ gives

$$\bar{\partial}\psi_2 = \epsilon\left\{\frac{(\partial\rho)^{-1/2}}{2(1+|\rho|^2)}\bar{\partial}\partial\rho - \frac{(\partial\rho)^{1/2}}{(1+|\rho|^2)^2}(\rho\bar{\partial}\bar{\rho} + \bar{\rho}\bar{\partial}\rho)\right\}. \tag{2.12}$$

Substituting (2.4) and (2.11) into (2.12), we obtain

$$\bar{\partial}\psi_2 = -\frac{(\bar{\partial}\bar{\rho}\partial\rho)^{1/2}}{(1+|\rho|^2)}\psi_1 = -p\psi_1,$$

which completes the proof. Q.E.D.

In some cases, it is more convenient to deal with (2.4) than the original system (1.2), since it consists of only two equations for two dependent variables ρ and $\bar{\rho}$. For example, a very large class of solutions of (2.4) can be found simply by requiring the holomorphicity ($\bar{\partial}\rho=0$) or antiholomorphicity ($\partial\rho=0$) of the function ρ. We will show later in Sec. V some examples of this type of solution. In the context of differential geometry, the system (2.4) was introduced by Kenmotsu in his seminal paper,[15] and then often used by subsequent authors.[10,18,19]

It is worth noting that, as in the case of system (1.2), the classical symmetry groups of (2.4) are conformal and scaling transformations. The corresponding symmetry algebra is spanned by

$$\alpha_1=\xi(z)\partial, \quad \alpha_2=\eta(\bar{z})\bar{\partial}, \quad \alpha_3=\rho\partial_p-\bar{\rho}\partial_{\bar{\rho}}, \tag{2.13}$$

where ξ and η are arbitrary functions of their arguments. This algebra can be decomposed as a direct sum of two infinite-dimensional simple Lie subalgebras with direct sum a one-dimensional algebra generated by α_3. Assuming that the functions ξ and η are analytic in a proper open subset Ω of $\mathbb{C}$, they can be developed in a Laurent series so we can provide a base for two centerless Virasoro algebras. Finite-dimensional subalgebras are spanned by $\{\partial\}$, $\{\partial,z\partial\}$, $\{\partial,z\partial,z^2\partial\}$,... and $\{\bar{\partial}\}$, $\{\bar{\partial},\bar{z}\bar{\partial}\}$, $\{\bar{\partial},\bar{z}\bar{\partial},\bar{z}^2\bar{\partial}\}$,..., respectively. In particular, the invariants of the one-dimensional subalgebra $\{\partial\}$ are given by $\{\bar{z},\rho\}$. Then, the invariant solutions are any antiholomorphic functions ρ of $\bar{z}$. A detailed study of solutions invariant under vector fields (2.13) is beyond the scope of the present work, but there is no difficulty in treating them.

Finally, an interesting feature of the WE system (1.2) can be derived from the Gaussian curvature (1.5). It can be expanded in the following way:

$$p^2K=-\bar{\partial}\partial\ln(p)=-\bar{\partial}\left(\frac{1}{p}\partial p\right)=\frac{1}{p^2}(\partial p)(\bar{\partial}p)-\frac{1}{p}\bar{\partial}\partial p.$$

Using the system of equations (1.2), the differentiation of the function p with respect to z and $\bar{z}$, respectively, yields

$$\partial p=\psi_1(\partial\bar{\psi}_1)+\bar{\psi}_2(\partial\psi_2), \quad \bar{\partial}p=\bar{\psi}_1(\bar{\partial}\psi_1)+\psi_2(\overline{\partial\psi_2}). \tag{2.14}$$

The mixed derivative of p becomes

$$\bar{\partial}\partial p=\bar{\partial}\psi_1\partial\bar{\psi}_1+\psi_1\bar{\partial}\partial\bar{\psi}_1+\bar{\psi}_2\bar{\partial}\partial\psi_2+\partial\psi_2\overline{\partial\psi_2}=\bar{\partial}\psi_1\partial\bar{\psi}_1+\partial\psi_2\overline{\partial\psi_2}-p^3. \tag{2.15}$$

The product of the derivatives (2.14) is given by

$$\bar{\partial}p\,\partial p=|\psi_1|^2(\bar{\partial}\psi_1)(\partial\bar{\psi}_1)+\psi_1\psi_2(\partial\bar{\psi}_1)(\overline{\partial\psi_2})+\bar{\psi}_1\bar{\psi}_2(\bar{\partial}\psi_1)(\partial\psi_2)+|\psi_2|^2(\partial\psi_2)(\overline{\partial\psi_2}).$$

Substituting these derivatives into the expression for p^2K, we obtain the following result:

$$p^4K=\psi_1\psi_2(\partial\bar{\psi}_1)(\overline{\partial\psi_2})+\bar{\psi}_1\bar{\psi}_2(\bar{\partial}\psi_1)(\partial\psi_2)-|\psi_1|^2(\partial\psi_2)(\overline{\partial\psi_2})-|\psi_2|^2(\bar{\partial}\psi_1)(\partial\bar{\psi}_1)+p^4. \tag{2.16}$$

This gives an explicit form for the Gaussian curvature K in terms of the functions ψ_1 and ψ_2.

III. THE ESTIMATION OF DEGREE OF INDETERMINANCY OF GENERAL SOLUTIONS

Now, let us demonstrate that the general analytic solutions of the Weierstrass–Enneper system (1.2) and system (2.4) possess the same degree of freedom. To this end, we employ Cartan's theory of systems in involution.[21] For more information on this subject, see Refs. 22–24.

For computational purposes, it is useful to examine the systems of Pfaffian forms equivalent to the considered systems of equations (1.2) and (2.4). We determine the Cartan numbers of these systems and the numbers of arbitrary parameters admitted by the general solutions of their polar equations.[21]

A. The Weierstrass–Enneper system

If one introduces the following notation,

$$x^1=\overline{z}, \quad x^2=z, \quad u_1=\psi_1, \quad u_2=\psi_2, \quad u_3=\overline{\psi_1}, \quad u_4=\overline{\psi_2},$$
$$u_5=\partial\psi_1, \quad u_6=\overline{\partial}\psi_2, \quad u_7=\overline{\partial\psi_1}, \quad u_8=\partial\overline{\psi_2}, \tag{3.1}$$

and

$$\xi^1=\overline{\partial}\psi_1, \quad \xi^2=\partial\psi_2, \quad \xi^3=\partial\overline{\psi_1}, \quad \xi^4=\overline{\partial\psi_2}, \tag{3.2}$$

then system (1.2) takes the form

$$u_5=(u_1u_3+u_2u_4)u_2, \quad u_7=(u_1u_3+u_2u_4)u_4,$$
$$u_6=-(u_1u_3+u_2u_4)u_1, \quad u_8=-(u_1u_3+u_2u_4)u_3. \tag{3.3}$$

If one chooses (3.2) as parameters, then, in terms of (3.1), Eq. (3.3) can be written as a system of differential one-forms,

$$\omega_1=du_1-(\xi^1dx^1+u_5dx^2)=0,$$
$$\omega_2=du_2-(u_6dx^1+\xi^2dx^2)=0,$$
$$\omega_3=du_3-(u_7dx^1+\xi^3dx^2)=0,$$
$$\omega_4=du_4-(\xi^4dx^1+u_8dx^2)=0,$$
$$\omega_5=du_5-\{[(\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_2+(u_1u_3+u_2u_4)u_6]dx^1$$
$$+[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_2+(u_1u_3+u_2u_4)\xi^2]dx^2\}=0,$$
$$\omega_6=du_6+\{[(\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_1+(u_1u_3+u_2u_4)\xi^1]dx^1$$
$$+[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_1+(u_1u_3+u_2u_4)u_5]dx^2\}=0,$$
$$\omega_7=du_7-\{[(\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_4+(u_1u_3+u_2u_4)\xi^4]dx^1$$
$$+[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_4+(u_1u_3+u_2u_4)u_8]dx^2\}=0,$$
$$\omega_8=du_8+\{[(\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_3+(u_1u_3+u_2u_4)u_7]dx^1$$
$$+[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_3+(u_1u_3+u_2u_4)\xi^3]dx^2\}=0. \tag{3.4}$$

Here, we interpret $\overline{z}$ and z as independent coordinates x^1 and x^2, respectively, in $\mathbb{R}^2$ space. The variables $u=(u_1,\ldots,u_8)$ are considered as coordinates in $\mathbb{R}^8$ space. The quantity $\xi=(\xi^1,\ldots,\xi^4)$ represents a vector of all first derivatives of ψ_i which do not appear in WE system (1.2). If we consider the variables u and ξ as unknown functions of $x=(x^1,x^2)$, then, in terms of (3.1) and (3.2), the WE system (1.2) is equivalent to the system of differential one-forms (3.4). After exterior differentiation of (3.4) we obtain the following system of two-forms, modulo (3.4),

$$\Omega_1\equiv d\omega_1=dx^1\wedge d\xi^1-[(\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_2+(u_1u_3+u_2u_4)u_6]dx^1\wedge dx^2,$$
$$\Omega_2\equiv d\omega_2=-[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_1+(u_1u_3+u_2u_4)u_5]dx^1\wedge dx^2+dx^2\wedge d\xi^2,$$
$$\Omega_3\equiv d\omega_3=[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_4+(u_1u_3+u_2u_4)u_8]dx^1\wedge dx^2+dx^2\wedge d\xi^3,$$

$$\Omega_4 \equiv d\omega_4 = dx^1 \wedge d\xi^4 + [(\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_3 + (u_1 u_3 + u_2 u_4) u_7] dx^1 \wedge dx^2,$$

$$\begin{aligned}\Omega_5 \equiv d\omega_5 = & -u_2 u_3 d\xi^1 \wedge dx^1 + u_2^2 dx^1 \wedge d\xi^4 - u_1 u_2 d\xi^3 \wedge dx^2 - (u_1 u_3 + 2u_2 u_4) d\xi^2 \wedge dx^2 \\ & + [u_1 u_2((u_3 u_5 + u_1 \xi^3 + \xi^2 u_4 + u_2 u_8) u_4 + (u_1 u_3 + u_2 u_4) u_8) - (u_1 u_3 + 2u_2 u_4)((u_3 u_5 \\ & + u_1 \xi^3 + \xi^2 u_4 + u_2 u_8) u_1 + (u_1 u_3 + u_2 u_4) u_5) - u_2 u_3((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_2 \\ & + (u_1 u_3 + u_2 u_4) u_6) + u_2^2((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_3 \\ & + (u_1 u_3 + u_2 u_4) u_7)] dx^1 \wedge dx^2,\end{aligned} \tag{3.5}$$

$$\begin{aligned}\Omega_6 \equiv d\omega_6 = & -(2u_1 u_3 + u_2 u_4) dx^1 \wedge d\xi^1 - u_1 u_2 dx^1 \wedge d\xi^4 - u_1 u_4 dx^2 \wedge d\xi^2 - u_1^2 dx^2 \wedge d\xi^3 \\ & + [-u_1^2((u_3 u_5 + u_1 \xi^3 + \xi^2 u_4 + u_2 u_8) u_4 + (u_1 u_3 + u_2 u_4) u_8) + u_1 u_4((u_3 u_5 + u_1 \xi^3 \\ & + \xi^2 u_4 + u_2 u_8) u_1 + (u_1 u_3 + u_2 u_4) u_5) - u_1 u_2((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_3 \\ & + (u_1 u_3 + u_2 u_4) u_7) + ((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_2 \\ & + (u_1 u_3 + u_2 u_4) u_6)(2u_1 u_3 + u_2 u_4)] dx^1 \wedge dx^2,\end{aligned}$$

$$\begin{aligned}\Omega_7 \equiv d\omega_7 = & \, u_3 u_4 dx^1 \wedge d\xi^1 + (u_1 u_3 + 2u_2 u_4) dx^1 \wedge d\xi^4 + u_4^2 dx^2 \wedge d\xi^2 + u_1 u_4 dx^2 \wedge d\xi^3 \\ & + [u_1 u_4((u_3 u_5 + u_1 \xi^3 + u_4 \xi^2 + u_2 u_8) u_4 + (u_1 u_3 + u_2 u_4) u_8) - u_4^2 \\ & \times ((u_3 u_5 + u_1 \xi^3 + u_4 \xi^2 + u_2 u_8) u_1 + (u_1 u_3 + u_2 u_4) u_5) - u_3 u_4((\xi^1 u_3 + u_1 u_7 + u_4 u_6 \\ & + u_2 \xi^4) u_2 + (u_1 u_3 + u_2 u_4) u_6) + (u_1 u_3 + 2u_2 u_4)((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_3 \\ & + (u_1 u_3 + u_2 u_4) u_7)] dx^1 \wedge dx^2,\end{aligned}$$

$$\begin{aligned}\Omega_8 \equiv d\omega_8 = & -u_3^2 dx^1 \wedge d\xi^1 - u_2 u_3 dx^1 \wedge d\xi^4 - u_3 u_4 dx^2 \wedge d\xi^2 - (2u_1 u_3 + u_2 u_4) dx^2 \wedge d\xi^3 \\ & + [u_3 u_4((u_3 u_5 + u_1 \xi^3 + \xi^2 u_4 + u_2 u_8) u_1 + (u_1 u_3 + u_2 u_4) u_5) - (2u_1 u_3 + u_2 u_4) \\ & \times ((u_3 u_5 + u_1 \xi^3 + \xi^2 u_4 + u_2 u_8) u_4 + (u_1 u_3 + u_2 u_4) u_8) \\ & + u_3^2((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_2 + (u_1 u_3 + u_2 u_4) u_6) \\ & - u_2 u_3((\xi^1 u_3 + u_1 u_7 + u_4 u_6 + u_2 \xi^4) u_3 + (u_1 u_3 + u_2 u_4) u_7)] dx^1 \wedge dx^2.\end{aligned}$$

Note that the quantities ξ^i enter linearly into the expressions (3.4) and (3.5).

The vector fields Y_j, $j=1,2$ which annihilate the one-forms ω_s and the two-forms Ω_s, satisfy the polar equations,

$$\langle \omega_s \lrcorner Y_j \rangle = 0, \quad \langle \Omega_s \lrcorner Y_1, Y_2 \rangle = 0, \quad s = 1,...,8, \quad j = 1,2. \tag{3.6}$$

From conditions (3.6) one finds

$$\begin{aligned}Y_1 = & \, \partial_{x^1} + \sum_{r=1}^{4} a^r \partial_{\xi^r} + \xi^1 \partial_{u_1} + u_6 \partial_{u_2} + u_7 \partial_{u_3} + \xi^4 \partial_{u_4} - [(\xi^1 u_3 + u_1 u_7 + u_6 u_4 + u_2 \xi^4) u_2 \\ & + (u_1 u_3 + u_2 u_4) u_6] \partial_{u_5} + [(\xi^1 u_3 + u_1 u_7 + u_6 u_4 + u_2 \xi^4) u_1 + (u_1 u_3 + u_2 u_4) \xi^1] \partial_{u_6} \\ & - [(\xi^1 u_3 + u_1 u_7 + u_6 u_4 + u_2 \xi^4) u_4 + (u_1 u_3 + u_2 u_4) \xi^4] \partial_{u_7} \\ & + [(\xi^1 u_3 + u_1 u_7 + u_6 u_4 + u_2 \xi^4) u_3 + (u_1 u_3 + u_2 u_4) u_7] \partial_{u_8},\end{aligned}$$

and

$$Y_2=\partial_{x^2}+\sum_{r=1}^{4} b^r\partial_{\xi^r}+u_5\partial_{u_1}+\xi^2\partial_{u_2}+\xi^3\partial_{u_3}+u_8\partial_{u_4}-[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_2$$
$$+(u_1u_3+u_2u_4)\xi^2]\partial_{u_5}+[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_1+(u_1u_3+u_2u_4)u_5]\partial_{u_6}$$
$$-[(u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_4+(u_1u_3+u_2u_4)u_8]\partial_{u_7}$$
$$+[(u_5u_3+u_1\xi_3+\xi^2u_4+u_2u_8)u_3+(u_1u_3+u_2u_4)\xi^3]\partial_{u_8},$$

where

$$a^2=-((u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_1+(u_1u_3+u_2u_4)u_5),$$
$$a^3=((u_5u_3+u_1\xi^3+\xi^2u_4+u_2u_8)u_4+(u_1u_3+u_2u_4)u_8),$$
$$b^1=((\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_2+(u_1u_3+u_2u_4)u_6),$$
$$b^4=-((\xi^1u_3+u_1u_7+u_6u_4+u_2\xi^4)u_3+(u_1u_3+u_2u_4)u_7),$$

and the quantities a^1,a^4,b^2,b^3 are arbitrary. Thus the number of free parameters in (3.6) is

$$N=4. \tag{3.7}$$

Under the chosen notation (3.1) and (3.2) the Pfaffian system (3.4) takes the abbreviated form

$$\omega_s=du_s-G_{s\mu}(x,\xi,u)dx^\mu,\quad s=1,...,8,\quad \mu=1,2, \tag{3.8}$$

where

$$x=(x^1,x^2),\quad \xi=(\xi^1,\ldots,\xi^4),\quad u=(u^1,\ldots,u^8),$$

and $G_{s\mu}$ depends linearly on ξ. The elements of the 8×4 matrix,

$$a_{sr}=\left(\frac{\partial G_{s\mu}}{\partial\xi^r}(x,\xi,u)X^\mu\right),\quad X=(X^1,X^2)\in\mathbb{R}^2, \tag{3.9}$$

determine the values of the Cartan quasicharacters s_i, $i=1,2$. The nonzero elements of the matrix (a_{sr}) are

$$a_{11}=X^1\quad a_{51}=u_3u_2X^1\quad a_{61}=-(2u_1u_3+u_2u_4)X^1$$
$$a_{22}=X^2\quad a_{52}=(2u_2u_4+u_1u_3)X^2\quad a_{62}=-u_1u_4X^2$$
$$a_{33}=X^2\quad a_{53}=u_1u_2X^2\quad a_{63}=-u_1^2X^2$$
$$a_{44}=X^1\quad a_{54}=u_2^2X^1\quad a_{64}=-u_1u_2X^1$$
$$a_{71}=u_3u_4X^1\quad a_{81}=-u_3^2X^1$$
$$a_{72}=u_4^2X^2\quad a_{82}=-u_2u_3X^1$$
$$a_{73}=u_1u_4X^2\quad a_{83}=-(2u_1u_3+u_2u_4)X^2$$
$$a_{74}=(u_1u_3+2u_2u_4)X^1\quad a_{84}=-u_3u_4X^2.$$

Thus, the Cartan quasicharacters are given by

$$s_1=\max_{X\in\mathbb{R}^2}\operatorname{rank}(a_{sr})=4,\quad s_2=p-s_1=0,$$

where p is the number of coordinates ξ, that is, $p=4$. From the definition of the Cartan number Q one has

$$Q=s_1+2s_2=4. \tag{3.10}$$

Since the number N of free parameters appearing in (3.6) equals 4, one has $Q=N$. Thus, according to Cartan's theorem,[21] system (3.4) [as well as (1.2)] is in involution. Its general analytic solution exists in some neighborhood of a regular point (x_0,ξ_0,u_0) and depends on four arbitrary real analytic functions of one real variable.

B. The second–order system of PDEs

Now, for the system (2.4), a similar analysis is performed. We demonstrate that locally the solution space of (2.4) has the same dimension as the system (1.2). For computational purposes, it is useful to write Eqs. (2.4) in the form

$$\begin{aligned} &u_{1,x^1x^2}-\frac{2u_2}{1+u_1u_2}u_{1,x^1}u_{1,x^2}=0,\\ &u_{2,x^1x^2}-\frac{2u_1}{1+u_1u_2}u_{2,x^1}u_{2,x^2}=0, \end{aligned} \tag{3.11}$$

where the following notation has been used:

$$x^1=z,\quad x^2=\overline{z},\quad u_1=\rho,\quad u_2=\overline{\rho}. \tag{3.12}$$

The system of differential one-forms corresponding to (3.11) can be written as follows:

$$\begin{aligned} &\omega_1=du_1-u_3dx^1-u_5dx^2=0,\\ &\omega_2=du_2-u_4dx^1-u_6dx^2=0,\\ &\omega_3=du_3-\xi^1dx^1-\frac{2u_2}{1+u_1u_2}u_3u_5dx^2=0,\\ &\omega_4=du_4-\xi^2dx^1-\frac{2u_1}{1+u_1u_2}u_4u_6dx^2=0,\\ &\omega_5=du_5-\frac{2u_2}{1+u_1u_2}u_3u_5dx^1-\xi^3dx^2=0,\\ &\omega_6=du_6-\frac{2u_1}{1+u_1u_2}u_4u_6dx^1-\xi^4dx^2=0,\\ &\omega_7=du_7-u_{11}dx^1-u_{12}dx^2,\\ &\omega_8=du_8-u_{21}dx^1-u_{22}dx^2, \end{aligned} \tag{3.13}$$

where we use the standard notation

$$u_3=u_{1,x^1},\quad u_4=u_{2,x^1},\quad u_5=u_{1,x^2},\quad u_6=u_{2,x^2},\quad u_7=u_{1,x^1x^2},\quad u_8=u_{2,x^1x^2}, \tag{3.14}$$

and, for the sake of simplicity, introduce the additional notation

$$u_{11}=2\left(\frac{u_2u_3u_5}{1+u_1u_2}\right)_{x^1}=2\left[\frac{u_3u_4u_5+u_2u_5\xi^1+u_2u_3u_7}{1+u_1u_2}-\frac{(u_2u_3u_5)(u_2u_3+u_1u_4)}{(1+u_1u_2)^2}\right],$$

$$u_{12}=2\left(\frac{u_2u_3u_5}{1+u_1u_2}\right)_{x^2}=2\left[\frac{u_3u_5u_6+u_2u_5u_7+u_2u_3\xi^3}{1+u_1u_2}-\frac{(u_2u_3u_5)(u_2u_5+u_1u_6)}{(1+u_1u_2)^2}\right],$$

$$u_{21}=2\left(\frac{u_1u_4u_6}{1+u_1u_2}\right)_{x^1}=2\left[\frac{u_3u_4u_6+u_1u_6\xi^2+u_1u_4u_8}{1+u_1u_2}-\frac{(u_1u_4u_6)(u_2u_3+u_1u_4)}{(1+u_1u_2)^2}\right],$$

$$u_{22}=2\left(\frac{u_1u_4u_6}{1+u_1u_2}\right)_{x^2}=2\left[\frac{u_4u_5u_6+u_1u_6u_8+u_1u_4\xi^4}{1+u_1u_2}-\frac{(u_1u_4u_6)(u_2u_5+u_1u_6)}{(1+u_1u_2)}\right].$$

We choose as parameters

$$\xi^1=u_{1,x^1x^1},\quad \xi^2=u_{1,x^2x^2},\quad \xi^3=u_{2,x^1x^1},\quad \xi^4=u_{2,x^2x^2}. \tag{3.15}$$

As in the previous case, given the chosen notation (3.12), the Pfaffian system (3.13) takes the form (3.8). Note that, in this case, the matrix (3.9) has the same dimension 8×4 as in the case of system (1.2). The nonzero elements of the matrix (a_{sr}) are

$$a_1^3=X^1,\quad a_2^4=-X^1,\quad a_3^5=-X^2,\quad a_4^6=-X^2.$$

Thus, the Cartan quasi-characters are given by

$$s_1=\max_{X\in\mathbb{R}^2}\operatorname{rank}(a_{sr})=4,\quad s_2=p-s_1=0,$$

where p is the number of coordinates ξ, that is, $p=4$. Consequently, the Cartan number Q equals

$$Q=s_1+2s_2=4. \tag{3.16}$$

After exterior differentiation system (3.13) with the chosen notation (3.12), (3.14), and (3.15) takes the form

$$\Omega_l\equiv d\omega_l\equiv 0,\quad l=1,2,7,8,$$

$$\Omega_3\equiv d\omega_3=-dx^1\wedge d\xi^1-u_{11}dx^1\wedge dx^2,$$

$$\Omega_4\equiv d\omega_4=-dx^1\wedge d\xi^2-u_{21}dx^1\wedge dx^2,$$

$$\Omega_5\equiv d\omega_5=u_{12}dx^1\wedge dx^2+dx^2\wedge d\xi^3,$$

$$\Omega_6\equiv d\omega_6=u_{22}dx^1\wedge dx^2+dx^2\wedge d\xi^4,$$

which is satisfied modulo (3.13).

The vector fields Y_j, $j=1,2$, which annihilate the one-forms ω_s and the two-forms Ω_s satisfy the polar equations (3.6). From these equations we have

$$Y_1=\partial_{x^1}+\sum_{r=1}^{4} a^r\partial_{\xi^r}+u_3\partial_{u^1}+u_4\partial_{u^2}+\xi^1\partial_{u^3}+\xi^2\partial_{u^4}+2\,\frac{u_2u_3u_5}{1+u_1u_2}\,\partial_{u_5}$$
$$+2\,\frac{u_1u_4u_6}{1+u_1u_2}\,\partial_{u_6}+u_{11}\partial_{u_7}+u_{21}\partial_{u_8},$$
$$Y_2=\partial_{x^2}+\sum_{r=1}^{4} b^r\partial_{\xi^r}+u_5\partial_{u_1}+u_6\partial_{u_2}+2\,\frac{u_2u_3u_5}{1+u_1u_2}\,\partial_{u_3}+2\,\frac{u_1u_4u_6}{1+u_1u_2}\,\partial_{u_4}+\xi^3\partial_{u_5}$$
$$+\xi^4\partial_{u_6}+u_{12}\partial_{u_7}+u_{22}\partial_{u_8}, \tag{3.17}$$

where

$$b^1=-u_{11},\quad b^2=-u_{21},\quad a^3=u_{12},\quad a^4=u_{22}.$$

As in the previous case, we have four free parameters, a^1,a^2,b^3,b^4. Thus, we get $Q=N$ and, according to Cartan's theorem, system (3.11) [as well as (2.4)] is in involution. Its general analytic solution depends on four arbitrary real analytic functions of one real variable.

Note that, since the systems of one-forms (3.4) and (3.13) are equivalent to systems (1.2) and (2.4), respectively, the Cartan theorem implies the existence of the general analytic solutions of (1.2) and (2.4). Now, if we interpret $\bar{z}$ and z as coordinates in the complex plane $\mathbb{C}$ and ψ_i and $\bar{\psi}_i$ as complex and complex conjugate functions on $\mathbb{C}$, then the general solutions of both systems (1.2) and (2.4) depend on two arbitrary complex analytic functions of one complex variable and their complex conjugate functions.

We have shown that systems (1.2) and (2.4) possess the same degree of freedom in terms of their general analytic solutions. Using Cartan's theorem, we can formulate the following conclusion.

Proposition 3: Suppose the systems (1.2) and (2.4) are both in involution at regular points (z_0,ξ_0,ψ_0) and (z_0,ξ_0,ρ_0), respectively. Then their general analytic solutions exist in some neighborhood of these regular points and both depend on two arbitrary complex analytic functions of one complex variable, and their complex conjugate functions.

Note that the mapping given by (2.1), from the solution of (2.4) to the solution of (1.2), does not restrict the type of boundary value conditions imposed on (2.4) and (1.2).

IV. COMPLETE INTEGRABILITY OF THE WEIERSTRASS–ENNEPER SYSTEM IN THE CONTEXT OF THE SIGMA MODEL

A. The linear spectral problem associated with the Weierstrass–Enneper system

The objective of this section is to demonstrate a connection between the Weierstrass–Enneper system (1.2) and the completely integrable Euclidean sigma model in two dimensions and, next, to derive through this link the linear spectral problem for the Weierstrass–Enneper system.

Let us identify (2.3) with the stereographic coordinate representation[25] of the two-dimensional Euclidean nonlinear sigma model

$$[S,\partial\bar{\partial}S]=0, \tag{4.1}$$

where the spin matrix

$$S=\begin{pmatrix} s_3 & \bar{s}_+ \\ s_+ & -s_3 \end{pmatrix},\quad \det S=-1,$$

belongs to the Hermitian space SU(2)/U(1). In the stereographic coordinate representation, the matrix S is given by

$$S=\frac{1}{1+|\rho|^2}\begin{pmatrix}1-|\rho|^2 & 2\bar{\rho}\\ 2\rho & -1+|\rho|^2\end{pmatrix}, \tag{4.2a}$$

where

$$s_+=\frac{2\rho}{1+|\rho|^2},\quad s_3=\frac{1-|\rho|^2}{1+|\rho|^2}. \tag{4.2b}$$

By substituting the matrix S given by (4.2) into (4.1), we obtain the following condition,

$$\left[\bar{\rho}\left(\bar{\partial}\partial\rho-\frac{2\bar{\rho}}{1+|\rho|^2}\partial\rho\bar{\partial}\rho\right)-\rho\left(\partial\bar{\partial}\bar{\rho}-\frac{2\rho}{1+|\rho|^2}\bar{\partial}\bar{\rho}\partial\bar{\rho}\right)\right]I=0,$$

where I is the unit matrix in this equation. This is identically satisfied whenever Eqs. (2.4) hold.

In terms of the complex functions ψ_i and $\bar{\psi}_i$, $i=1,2$, which appear in (1.2), the spin matrix S takes the form

$$S=\frac{1}{p}\begin{pmatrix}-|\psi_1|^2+|\psi_2|^2 & 2\bar{\psi}_1\bar{\psi}_2\\ 2\psi_1\psi_2 & |\psi_1|^2-|\psi_2|^2\end{pmatrix}. \tag{4.3}$$

From (2.3), we obtain that the inverse mapping of (4.3) is double valued and is provided by

$$\psi_1=\frac{\epsilon}{2}s_+\left[\bar{\partial}\left(\frac{\bar{s}_+}{1+s_3}\right)\right]^{1/2},\quad \psi_2=\frac{\epsilon}{2}(1+s_3)\left[\partial\left(\frac{s_+}{1+s_3}\right)\right]^{1/2},\quad \epsilon^2=1, \tag{4.4a}$$

where

$$\rho=\frac{s_+}{1+s_3},\quad \bar{\rho}=\frac{\bar{s}_+}{1+s_3}. \tag{4.4b}$$

Proposition 4: If ψ_1 and ψ_2 are solutions of the WE system (1.2), then the spin matrix S given by (4.3) is a solution of the sigma model equation (4.1).

Proof: The results are directly obtained by substituting the spin matrix S given by (4.3) into the commutator (4.1) and assuming that the functions ψ_i satisfy (1.2). This computation leads to a vanishing commutator (4.1). Q.E.D.

The procedure for constructing solutions to (1.2) can be reduced to the following. Take any solution of the sigma model (4.1) and substitute it into Eqs. (4.4b). The function ρ thus obtained provides us, by means of transformation (2.3), with solutions ψ_1 and ψ_2 of the WE system (1.2). The possibility of constructing such solutions is demonstrated in the next section.

We now consider the possibility of constructing a linear spectral problem for the WE system (1.2). Let us introduce a new set of complex functions φ_1 and $\varphi_2:\mathbb{C}\to\mathbb{C}$ which are related to the complex functions ψ_1 and ψ_2 in the following way:

$$\begin{aligned}\psi_1&=f(z,\bar{z})\varphi_1,\quad \bar{\psi}_2=f(z,\bar{z})\bar{\varphi}_2,\\ \bar{\psi}_1&=\bar{f}(\bar{z},z)\bar{\varphi}_1,\quad \psi_2=\bar{f}(\bar{z},z)\varphi_2,\end{aligned} \tag{4.5}$$

for any complex function $f:\mathbb{C}\to\mathbb{C}$. From the definition (2.1), it is evident that the transformation (4.5) leaves the functions ρ and $\bar{\rho}$ invariant,

$$\rho=\frac{\varphi_1}{\bar{\varphi}_2},\quad \bar{\rho}=\frac{\bar{\varphi}_1}{\varphi_2}, \tag{4.6}$$

and the structure of the spin matrix S given by (4.3) is also preserved. This means that there exists a freedom which resembles a type of gauge freedom in the definition of the ρ variable, since the numerator and denominator of (4.6) can be multiplied by any complex function. The crux of the matter is that it is not required that the set of functions φ_i satisfy the original system (1.2), but that the ratio of φ_1 over $\overline{\varphi_2}$ satisfy (2.4). Let us express Eqs. (1.2) in terms of φ_i and f. The derivatives of ψ_1 and ψ_2 take the form

$$\partial\psi_1 = (\partial f)\varphi_1 + f(\partial\varphi_1), \quad \bar{\partial}\psi_2 = (\overline{\partial f})\varphi_2 + f(\bar{\partial}\varphi_2).$$

We define the variable $q = |\varphi_1|^2 + |\varphi_2|^2$, and from (1.2a) it follows that $p = |f|^2 q$. Taking the above into account we can write (1.2) as

$$(\partial f)\varphi_1 + f(\partial\varphi_1) = p\bar{f}\varphi_2, \quad (\overline{\partial f})\varphi_2 + \overline{f}(\bar{\partial}\varphi_2) = -pf\varphi_1.$$

Solving the above equations for $\partial\varphi_1$ and $\bar{\partial}\varphi_2$, respectively, we obtain the equations of motion,

$$\begin{aligned} \partial\varphi_1 &= q\overline{f^2}\varphi_2 - (\partial \ln f)\varphi_1, \quad \bar{\partial}\varphi_2 = -qf^2\varphi_1 - (\bar{\partial}\ln\bar{f})\varphi_2, \\ \bar{\partial}\overline{\varphi_1} &= qf^2\overline{\varphi_2} - (\bar{\partial}\ln\bar{f})\overline{\varphi_1}, \quad \partial\overline{\varphi_2} = -q\overline{f^2}\,\overline{\varphi_1} - (\partial\ln f)\overline{\varphi_2}. \end{aligned} \tag{4.7}$$

Using (4.7), the differentiation of Eqs. (4.6) with respect to z and $\bar{z}$, respectively, yields a pair of relations similar to (2.3) which relate the functions φ_i to ρ and a nonzero f,

$$\varphi_1 = \epsilon\rho\frac{(\bar{\partial}\bar{\rho})^{1/2}}{f(1+|\rho|^2)}, \quad \varphi_2 = \epsilon\frac{(\partial\rho)^{1/2}}{f(1+|\rho|^2)}. \tag{4.8}$$

Relations (4.8) can also be obtained in a more straightforward way by substituting (4.5) into Eqs. (2.3). Note that as well as (2.3), the transformations (4.8) are doubled valued. Now we can formulate the following.

Proposition 5: If the function ρ defined by (4.6) is a solution of the system (2.4), then the functions φ_1 and φ_2 satisfy the following system of equations:

$$\begin{aligned} \partial\varphi_1 &= q\overline{f^2}\varphi_2, \quad \bar{\partial}\overline{\varphi_1} = qf^2\overline{\varphi_2}, \\ \bar{\partial}\varphi_2 &= -qf^2\varphi_1, \quad \partial\overline{\varphi_2} = -q\overline{f^2}\,\overline{\varphi_1}, \end{aligned} \tag{4.9}$$

for any function $f:\mathbb{C}\to\mathbb{C}$ satisfying

$$\partial f = 0. \tag{4.10}$$

Proof: Indeed, by an easy computation, one obtains from (4.6) and (4.7) the first derivatives of ρ and $\bar{\rho}$,

$$\begin{aligned} \partial\rho &= q^2|f|^2(\overline{\varphi_2})^{-2}, \quad \partial\bar{\rho} = (\varphi_2)^{-2}(\varphi_2\partial\overline{\varphi_1} - \overline{\varphi_1}\partial\varphi_2), \\ \bar{\partial}\rho &= (\overline{\varphi_2})^{-2}(\overline{\varphi_2}\bar{\partial}\varphi_1 - \varphi_1\bar{\partial}\overline{\varphi_2}), \quad \bar{\partial}\bar{\rho} = q^2|f|^2(\varphi_2)^{-2}, \end{aligned} \tag{4.11a}$$

and the second derivatives of ρ and $\bar{\rho}$,

$$\begin{aligned} \partial\bar{\partial}\rho &= (\overline{\varphi_2})^{-3}[2q\overline{f^2}\,\overline{\varphi_1}\,\overline{\varphi_2}\bar{\partial}\varphi_1 - q\overline{f^2}(q+|\varphi_1|^2-|\varphi_2|^2)\bar{\partial}\overline{\varphi_2}], \\ \partial\bar{\partial}\bar{\rho} &= (\varphi_2)^{-3}[2qf^2\varphi_1\varphi_2\partial\overline{\varphi_1} - qf^2(q+|\varphi_1|^2-|\varphi_2|^2)\partial\varphi_2]. \end{aligned} \tag{4.11b}$$

Substituting expressions (4.11) into (2.4), we get a differential constraint for the function f and its respective complex conjugate

$$(\overline{f}^2-1)\overline{\partial f}=0, \quad (f^2-1)\partial f=0. \tag{4.12}$$

Thus, the general solution of system (4.12) is given by any antiholomorphic function f such that relation (4.10) holds. Consequently, the equations of motion (4.7) become those in (4.9). Q.E.D.

Proposition 6: If the boundary value problem for the WE system (1.2) is given by two arbitrary complex analytic functions of one complex variable (and their complex conjugate functions), then the solution of (1.2) is unique up to a gauge transformation (4.5).

Proof: By virtue of Propositions 1 and 2, the map from Eqs. (1.2) to (2.4) is one-to-one. The map from Eqs. (2.4) to the sigma model (4.1) is also one-to-one because of the transformation (4.2b). The solution of the boundary value problem for (4.1) possesses a unique solution.[25] Hence, from Proposition 3 and Eqs. (4.5) and (4.8), it follows that the solution of the boundary value problem for WE system (1.2) is unique up to multiplication by any function $f(\overline{z})$ satisfying (4.10). This means that the freedom of solutions to (1.2) and (2.4) is the same, up to a gauge function f. Q.E.D.

Now we examine certain aspects of complete integrability of the equations of motion (4.9) in the context of a two-dimensional Euclidean sigma model (4.1).

As it was shown by A. V. Mikhailov in Ref. 26, Eq. (4.1) is a compatibility condition for the two linear spectral problems

$$\partial\Phi=\frac{1}{\lambda+1}\mathcal{U}\Phi, \quad \overline{\partial}\Phi=\frac{1}{\lambda-1}\mathcal{U}^{\dagger}\Phi. \tag{4.13}$$

Here, $\mathcal{U}=\partial SS$, $\mathcal{U}^{\dagger}=S\overline{\partial}S$ with S given by (4.3), and $\Phi(z,\overline{z},\lambda)$ is a matrix of fundamental solutions, while λ represents the spectral parameter. The denominators which contain the spectral parameter cannot be absorbed in the derivatives $\partial\Phi$ and $\overline{\partial}\Phi$. Note that there is a direct connection between the matrix eigenfunction $\Phi(z,\overline{z},\lambda)$ in expression (4.13) and the fields ψ_i, through the mapping (4.4) since there exists the relation[26]

$$S=\Phi(z,\overline{z},0). \tag{4.14}$$

Then we could say that the WE system (1.2) is completely integrable, because of the mappings (4.3) and (4.4). Indeed, by expressing the spin matrix S in terms of the functions φ_i and $\overline{\varphi}_i$, one obtains the explicit form of the linear spectral problem (4.13) for the equation of motion (4.9)

$$\partial\Phi=\frac{2}{\lambda+1}M\Phi, \quad \overline{\partial}\Phi=\frac{2}{\lambda-1}M^{\dagger}\Phi, \tag{4.15}$$

where

$$M=\begin{pmatrix} b/2 & a \\ -c & -b/2 \end{pmatrix}. \tag{4.16}$$

We introduce the following notation:

$$\begin{aligned} a&=-\overline{f}^2\overline{\varphi}_1^2+\frac{1}{fq^2}[\overline{\varphi}_1\overline{\varphi}_2^2\partial(\overline{f}\varphi_2)-\overline{\varphi}_2|\varphi_2|^2\partial(\overline{f}\overline{\varphi}_1)],\\ b&=2\left[-\overline{f}^2\overline{\varphi}_1\varphi_2+\frac{1}{fq^2}(\varphi_1|\varphi_2|^2\partial(\overline{f}\overline{\varphi}_1)-\overline{\varphi}_2|\varphi_1|^2\partial(\overline{f}\varphi_2))\right],\\ c&=-\overline{f}^2\varphi_2^2+\frac{1}{fq^2}[\varphi_1|\varphi_1|^2\partial(\overline{f}\varphi_2)-\varphi_1^2\varphi_2\partial(\overline{f}\overline{\varphi}_1)]. \end{aligned} \tag{4.17}$$

Making use of (4.5), one can find an explicit form for the coefficients (4.17) in terms of the functions ψ_i. The matrix M can be written in the form

$$M=A+\frac{J}{p^2}A^\dagger, \quad \det M=-\frac{2J}{p^2}, \tag{4.18}$$

where J is the current (1.8) and A is a degenerate nilpotent matrix which can be decomposed as follows,

$$A=-\overline{\psi_1}\psi_2\sigma_3-\overline{\psi_1^2}\sigma_+ +\psi_2^2\sigma_-, \quad \sigma_\pm=\tfrac{1}{2}(\sigma_1\pm i\sigma_2), \tag{4.19}$$

where σ_1, σ_2, σ_3 are Pauli matrices

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}, \quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

However, in order to be able to use results from the inverse scattering method to construct soliton solutions of the WE system (1.2), it is convenient to simplify the form of the linear spectral problem (4.15).

Proposition 7: For any bounded entire function J, the linear spectral problem for the WE system (1.2) has the form

$$\partial\Phi=\frac{2}{\lambda+1}A\Phi, \quad \bar{\partial}\Phi=\frac{2}{\lambda-1}A^\dagger\Phi. \tag{4.20}$$

Proof: Indeed, if we substitute (4.18) into the system (4.15), then the system takes the form

$$\partial\Phi=\frac{2}{\lambda+1}\left(A+\frac{J}{p^2}A^\dagger\right)\Phi, \tag{4.21}$$

$$\bar{\partial}\Phi=\frac{2}{\lambda-1}\left(A^\dagger+\frac{\bar{J}}{p^2}A\right)\Phi. \tag{4.22}$$

From the conservation of the current (1.11), we obtain that the current J is a holomorphic function. According to Liouville's theorem if $J(z)$ is an entire function, and if $|J(z)|\leqslant M$ for all $z\in\mathbb{C}$, then $J(z)\equiv$ constant. Consequently, one can take the current J to be equal to zero, hence Eqs. (4.21) and (4.22) become (4.20). The compatibility condition for the two equations in (4.20), namely,

$$\bar{\partial}A-\partial A^\dagger+[A,A^\dagger]=0,$$

is satisfied, whenever the WE system (1.2) holds. Under these circumstances, the linear spectral problem (4.20) holds for the WE system (1.2). So, matrices A and $A^\dagger$ can be identified as the Lax pair for the WE system. Q.E.D.

Moreover, an interesting feature of the WE system (1.2) has been observed. Namely, the system (4.20) has the WE system of equations as compatibility conditions for any function $J(z)$, not necessarily bounded. This fact can be easily verified by direct calculation.

Note that the system of Riccati equations corresponding to (4.20) is

$$\partial y=-\frac{2}{\lambda+1}(\overline{\psi_1}+\psi_2 y)^2, \quad \bar{\partial}y=\frac{2}{\lambda-1}(\overline{\psi_2}-\psi_1 y)^2,$$

where y is a complex function (called the pseudopotential[27] given by the ratio of the components of the vector Φ, that is, $y=\phi_1/\phi_2$). We conclude that the existence of the linear spectral problem (4.20) for the WE system implies that this system is completely integrable.

Finally, a property of the WE system (1.2) in the context of the sigma model is the existence of a topological charge. Indeed, it is well known that the sigma model (4.1) possesses a topological charge,[27–29] which we denote by I. Making use of the current J, the transformations (4.3), and the equations of motion (1.2), one finds that if the integral

$$I=\frac{i}{8\pi}\int_C \mathrm{Tr}\,(\mathbf{S}\cdot[\partial\mathbf{S},\bar{\partial}\mathbf{S}])\,dz d\bar{z}=-\frac{i}{2\pi}\int_C \frac{1}{p^2}[|J|^2-p^4]\,dz d\bar{z} \tag{4.23}$$

exists, it is an integer, where J is given by Eq. (1.8).

B. Reduction of the Weierstrass–Enneper system to a decoupled linear system

Now we discuss a set of conditions which allow the system (1.2) to become a linear decoupled system of equations.

Proposition 8: If the functions ψ_1 and ψ_2 satisfy the overdetermined system composed of the equations of motion (1.2) and differential conditions

$$\bar{\psi}_1\bar{\partial}\psi_1+\psi_2\overline{\partial\psi_2}=0,\quad \bar{\psi}_2\partial\psi_2+\psi_1\partial\bar{\psi}_1=0, \tag{4.24}$$

then the overdetermined system is equivalent to a linear decoupled system of the form

$$\begin{gathered}\partial\bar{\partial}\psi_i+p_0^2\psi_i=0,\quad \partial\overline{\partial\psi_i}+p_0^2\bar{\psi}_i=0,\quad i=1,2,\\ |\psi_1|^2+|\psi_2|^2=p_0\in\mathbb{R}.\end{gathered} \tag{4.25}$$

Proof: Making use of (1.2) and conditions (4.24) we obtain that the derivatives of p given by (2.14) vanish:

$$\partial p=\psi_1(\partial\bar{\psi}_1)+\bar{\psi}_2(\partial\psi_2)=0,\quad \bar{\partial}p=\bar{\psi}_1(\bar{\partial}\psi_1)+\psi_2(\overline{\partial\psi_2})=0. \tag{4.26}$$

This means that if (4.24) holds, then p is a real constant, say p_0. Thus,

$$|\psi_1|^2+|\psi_2|^2=p_0 \tag{4.27}$$

is a conserved quantity. Hence, the Weierstrass–Enneper system (1.2) becomes a linear system which can be decoupled in terms of the functions ψ_i such that (4.25) holds. Q.E.D.

Let us now investigate the case in which all the derivatives of the functions ψ_i and $\bar{\psi}_i$ are specified. This means that we supplement the WE system (1.2) with some additional differential constraints, so we can formulate the following.

If the conditions (4.24) hold, then we show that the system (1.2) can be extended to the system of the form

$$\partial\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}=\begin{pmatrix}p\psi_2\\ \alpha\end{pmatrix},\quad \bar{\partial}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}=\begin{pmatrix}\beta\\ -p\psi_1\end{pmatrix}, \tag{4.28a}$$

and the respective conjugate system,

$$\partial\begin{pmatrix}\bar{\psi}_1\\ \bar{\psi}_2\end{pmatrix}=\begin{pmatrix}\bar{\beta}\\ -p\bar{\psi}_1\end{pmatrix},\quad \bar{\partial}\begin{pmatrix}\bar{\psi}_1\\ \bar{\psi}_2\end{pmatrix}=\begin{pmatrix}p\bar{\psi}_2\\ \bar{\alpha}\end{pmatrix}, \tag{4.28b}$$

where the quantities α and β are assumed to be some polynomial functions expressible in terms of ψ_i and $\bar{\psi}_i$, with constant coefficients. The system (4.28) will be called the augmented system. Our aim is to find an explicit form for α and β in such a way that they do not provide any additional differential constraints on ψ_i and $\bar{\psi}_i$ other than (1.2) and (4.24) when the compatibility conditions for (4.28) are added, namely, (2.8) and

$$\begin{aligned}\partial\partial\psi_1&=\partial(p\psi_2)=(\psi_1\partial\bar{\psi}_1+\bar{\psi}_2\partial\psi_2)\psi_2+p\partial\psi_2,\\ \overline{\partial\partial\psi_1}&=\bar{\partial}(p\bar{\psi}_2)=(\bar{\psi}_1\bar{\partial}\psi_1+\psi_2\overline{\partial\psi_2})\bar{\psi}_2+p\overline{\partial\psi_2},\\ \overline{\partial}\partial\psi_2&=-\bar{\partial}(p\psi_1)=-(\bar{\psi}_1\bar{\partial}\psi_1+\psi_2\overline{\partial\psi_2})\psi_1-p\bar{\partial}\psi_1,\\ \partial\partial\bar{\psi}_2&=-\partial(p\bar{\psi}_1)=-(\psi_1\partial\bar{\psi}_1+\bar{\psi}_2\partial\psi_2)\bar{\psi}_1-p\partial\bar{\psi}_1.\end{aligned}\tag{4.29}$$

Indeed, from the compatibility conditions (2.8) and (4.29), the analysis of the dominant terms in the ψ_i and $\bar{\psi}_i$ functions leads to the requirement that all unknown derivatives, $(\partial\psi_1,\partial\bar{\psi}_1,\partial\psi_2,\partial\bar{\psi}_2)$, other than those appearing in (1.2), have to be cubic in terms of the fields ψ_i and $\bar{\psi}_i$. Moreover, if one assumes that the discrete symmetry of the system (1.2), invariant under the reflection symmetry in the space of dependent and independent variables, namely,

$$\psi_i\to-\psi_j,\quad \bar{\psi}_i\to-\bar{\psi}_j,\quad i\neq j=1,2,\quad \partial\to-\bar{\partial},\quad \bar{\partial}\to-\partial,\tag{4.30}$$

can be extended to the augmented system (4.28), then one obtains the following relations,

$$\begin{aligned}\partial\bar{\psi}_1&=-p[\bar{c}_2\bar{\psi}_1+\bar{c}_1\bar{\psi}_2+\bar{c}_4\psi_1+\bar{c}_3\psi_2],\\ \bar{\partial}\psi_1&=-p[c_2\psi_1+c_1\psi_2+c_4\bar{\psi}_1+c_3\bar{\psi}_2],\\ \partial\psi_2&=p[c_1\psi_1+c_2\psi_2+c_3\bar{\psi}_1+c_4\bar{\psi}_2],\\ \overline{\partial\psi_2}&=p[\bar{c}_1\bar{\psi}_1+\bar{c}_2\bar{\psi}_2+\bar{c}_3\psi_1+\bar{c}_4\psi_2].\end{aligned}\tag{4.31}$$

It is assumed that the c_i, $i=1,...,4$, are constants to be determined from the compatibility conditions for (2.8) and (4.29). Substituting (4.31) into (4.29) leads us to a system of equations which are polynomial in ψ_i and $\bar{\psi}_i$. The unique solution of this system has the form

$$\partial\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}=p\begin{pmatrix}\psi_2\\ -\psi_1\end{pmatrix}=\bar{\partial}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}\tag{4.32a}$$

and its respective conjugate system

$$\partial\begin{pmatrix}\bar{\psi}_1\\ \bar{\psi}_2\end{pmatrix}=p\begin{pmatrix}\bar{\psi}_2\\ -\bar{\psi}_1\end{pmatrix}=\bar{\partial}\begin{pmatrix}\bar{\psi}_1\\ \bar{\psi}_2\end{pmatrix}.\tag{4.32b}$$

Note that the same formula (4.32) can be found in Ref. 10. Under the conditions (4.24), we show that the system (1.2) admits a conserved quantity (4.27) with p a real constant. This means that in this case by virtue of (1.5), the Gaussian curvature $K=0$, which implies the space is flat.

Proposition 9: If the functions ψ_1 and ψ_2 satisfy the overdetermined system composed of the WE system (1.2) and the following differential constraint,

$$-(\bar{\psi}_1\bar{\partial}\psi_1+\psi_2\overline{\partial\psi_2})+(\psi_1\partial\bar{\psi}_1+\bar{\psi}_2\partial\psi_2)=0,\tag{4.33}$$

then the conserved quantity p is a real-valued function of a real argument $(z+\bar{z})/2$ and

$$|\psi_1|^2+|\psi_2|^2=p((z+\bar{z})/2).\tag{4.34}$$

Proof: Indeed, using the derivatives of p, and taking into account (4.33), we obtain

$$(\partial-\bar{\partial})p=\psi_1(\partial\bar{\psi}_1)+\bar{\psi}_2(\partial\psi_2)-\bar{\psi}_1(\bar{\partial}\psi_1)-\psi_2(\overline{\partial\psi_2})=0.$$

This completes the proof. Q.E.D.

Consequently, in the case when (4.33) holds, the first fundamental form (1.4) and the Gaussian curvature (1.5) take the following form:

$$\Omega = 4p^2(x)dzd\bar{z}, \quad K = -\ddot{p}(x)/p^2(x),$$

respectively. Here, we introduce the notation $\ddot{p} = d^2p/dx^2$.

V. EXAMPLES AND APPLICATIONS

At this point, we would like to illustrate the proposed procedure for constructing solutions of the WE system (1.2) with several elementary examples.

Now, let us discuss some classes of solutions to the WE system (1.2), which can be obtained directly by applying the transformation (2.3). First, we consider the class of solutions which correspond to analytic choices of the function ρ. It is easy to check that for this class of solutions the conserved density J in (1.11) is identically equal to zero.

(1) The simplest solutions of this type are given by

$$\rho = \left[\frac{(z-z_0)}{\lambda}\right]^n, \tag{5.1}$$

where λ and z_0 are arbitrary real and complex numbers, respectively. From the point of view of the sigma model, this form of ρ corresponds to the instanton of charge $I = -n$ located at z_0 and of size λ. By virtue of the invariance of the system (1.2) under conformal transformations, we can set without loss of generality, $z_0 = 0$ and $\lambda = 1$. Then, using (2.3) we find that the solutions of (1.2) are given by

$$\psi_1 = \epsilon n^{1/2} \frac{z^n \bar{z}^{(n-1)/2}}{1+|z|^{2n}}, \quad \psi_2 = \epsilon n^{1/2} \frac{z^{(n-1)/2}}{1+|z|^{2n}}. \tag{5.2}$$

Each of these solutions belongs to a different topological sector of index n. Furthermore, notice that for all even n, the solutions are double valued. Nevertheless, this fact has no influence on the surfaces parametrized by the relations (1.3). Actually, the solutions (5.2) correspond to only one constant mean curvature surface, which is covered n times as z runs over the complex plane. This surface is obtained (modulo translations) by revolving the curve

$$X_2 = (X_3 - 2)\left(\frac{X_3}{4-X_3}\right)^{1/2} \tag{5.3}$$

around the axis X_3. It possesses a conic point in (0,0,2).

(2) Another class of solutions is provided by the analytic function

$$\rho = e^{\lambda z}, \tag{5.4}$$

corresponding to a static domain wall in the isotropic $O(3)$ magnet. The associated solution of the system (1.2) is

$$\psi_1 = \epsilon \bar{\lambda}^{1/2} \frac{e^{\bar{\lambda}\bar{z}/2}}{e^{-\lambda z} + e^{\bar{\lambda}\bar{z}}}, \quad \psi_2 = \epsilon \lambda^{1/2} \frac{e^{-\lambda z/2}}{e^{-\lambda z} + e^{\bar{\lambda}\bar{z}}}. \tag{5.5}$$

Also in this case, the whole class of solutions parametrized by λ represents a unique constant mean curvature surface (modulo translations), obtained from (1.3) by revolving the following curve around the X_3 axis:

$$X_3 = 2\,\frac{X_2^2}{1 \pm \sqrt{1 - X_2^2}}. \tag{5.6}$$

Many other solutions of (1.2) admitting ρ to be a meromorphic function can be found. For the present, we do not discuss them.

(3) Let us assume now, as opposed to the previous cases, that the conserved current density in (1.8) is a nonvanishing holomorphic function. In such a case, one can check that the matrix $\mathcal{U}$ in the spectral problem (4.13) has a nonvanishing $\mathrm{Tr}\,\mathcal{U}^2$. The simplest choice is to put

$$\mathcal{U} = g(z)\sigma_3. \tag{5.7}$$

The solution of the corresponding spectral problem can be readily obtained:[26]

$$\Phi = \exp[2i\chi\sigma_3]\sigma_1, \tag{5.8}$$

where σ_i are Pauli matrices, $\chi = \mathrm{Im}\int_\Gamma g(z)\,dz$ and Γ is an arbitrary curve in the domain in which g is analytic. Then, resorting to the relations (4.14) and (4.4), one obtains the following solutions to Eq. (1.2):

$$\psi_1 = -\frac{\epsilon}{2} i e^{-i\chi} \bar{g}^{1/2}, \quad \psi_2 = \frac{\epsilon}{2} i e^{-i\chi} g^{1/2}. \tag{5.9}$$

The associated surface is given by the parametric equations

$$\begin{gathered} X_1 = \sin 2\chi + X_{10}, \quad X_2 = -\cos 2\chi + X_{20}, \\ X_3 = \omega + X_{30} \quad \left(\omega = \mathrm{Re}\int_\Gamma f(z)\,dz\right), \end{gathered} \tag{5.10}$$

which describe a cylinder having X_3 as a symmetry axis. Nontrivial deformations of this type of solution can be found by using the recurrence N-soliton wave function formula[26] in expression (4.14).

Now, let us discuss a simple example to illustrate the construction introduced in Sec. IV.

(4) Consider the possibility where f is real and $f = q^{-1/2}$ with φ_i chosen to make $\partial f = 0$. In this case, from (4.9) one has

$$\partial\varphi_1 = q\bar{f}^2\varphi_2 = \varphi_2, \quad \bar{\partial}\varphi_2 = -qf^2\varphi_1 = -\varphi_1. \tag{5.11}$$

This system reduces to two second-order linear equations of the form (4.25)

$$\partial\bar{\partial}\varphi_i + \varphi_i = 0, \quad i = 1,2.$$

For example, let us write a simple set of solutions to this equation

$$\begin{gathered} \varphi_1 = -ie^{i(z+\bar{z})}, \quad \bar{\varphi}_1 = ie^{-i(z+\bar{z})}, \\ \varphi_2 = e^{i(z+\bar{z})}, \quad \bar{\varphi}_2 = e^{-i(z+\bar{z})}. \end{gathered}$$

Therefore, one has

$$q = |\varphi_1|^2 + |\varphi_2|^2 = 2, \quad f = \frac{1}{\sqrt{2}}.$$

Note that for these functions φ_i, conditions (4.24) are identically satisfied. From (4.6), we obtain

$$\rho = -ie^{2i(z+\bar{z})}.$$

It is also easy to show that for this class of solutions ρ, Eqs. (2.4) are identically satisfied. Substituting the functions ρ and f into Eqs. (4.8), one obtains an explicit solution of the WE system (1.2):

$$\psi_1 = -i\frac{\epsilon}{\sqrt{2}}e^{i(z+\bar{z})}, \quad \psi_2 = \frac{\epsilon}{\sqrt{2}}e^{i(z+\bar{z})}.$$

This solution represents a phase plane wave since the argument is one-dimensional $x=z+\bar{z}$, its absolute value is constant, and the solution has exponential form.

(5) A special class of exponential solutions to (1.2) can be found to hold when p is constant. According to Proposition 8, we have to solve (4.25). Thus, a vacuum solution takes the form

$$\psi_1 = c_1 e^{i(hz+k\bar{z})}, \qquad \psi_2 = ic_1\frac{h}{p}e^{i(hz+k\bar{z})}, \tag{5.12}$$

where c_1 is a complex constant and h, k are real constants such that

$$|c_1|^2 = \frac{p^3}{(p^2+h^2)}, \quad p = hk.$$

Due to the linearity of Eqs. (4.25), we can look for a more general class of solutions which represent a superposition of exponential functions. The one-soliton solution of (4.25) is given by

$$\psi_1 = c_1 e^{i(h_1 z + k_1\bar{z})} + c_2 e^{i(h_2 z + k_2\bar{z})}, \qquad \psi_2 = \frac{i}{p}(h_1 c_1 e^{i(h_1 z + k_1\bar{z})} + h_2 c_2 e^{i(h_2 z + k_2\bar{z})}), \tag{5.13}$$

where the c_i are complex constants and the h_i, k_i are real constants which satisfy

$$h_1 k_1 = p^2, \quad h_2 k_2 = p^2, \quad h_1 h_2 = -p^2,$$

and

$$|c_2|^2 = \frac{p - |c_1|^2(1+h_1^2/p^2)}{1+p^2/h_1^2}.$$

From (2.1), we obtain the expression for ρ corresponding to the one-soliton solutions,

$$\rho = -i\frac{c_1 e^{ih_1(z+\bar{z})} + c_2 e^{-ih_1(z+\bar{z})}}{\bar{c}_1 e^{ih_1(z+z)} - \bar{c}_2 e^{ih_1(z+z)}},$$

for which condition (2.4) is identically satisfied.

(6) Now, let us discuss the construction of multi-soliton solutions to the WE system (1.2), which can be obtained by exploiting the linear spectral problem (4.15). According to the first step of the procedure, we choose an antiholomorphic function of the form

$$f = \epsilon(a-b)\frac{(2\bar{z}-a-b)z - a(\bar{z}-a) - b(\bar{z}-b)}{|z-a|^2+|z-b|^2}, \quad \epsilon = \pm 1, \quad a,b \in \mathbb{R} \tag{5.14}$$

and look for a nontrivial solution ρ of the system (2.4),

$$\rho=\frac{z-a}{z-b}. \tag{5.15}$$

The substitution of (5.14) and (5.15) into the relations (4.8) gives

$$\varphi_1=\frac{z-a}{(2\bar{z}-a-b)z-a(\bar{z}-a)-b(\bar{z}-b)},\qquad \varphi_2=\frac{\bar{z}-b}{(2z-a-b)\bar{z}-a(z-a)-b(z-b)}. \tag{5.16}$$

Finally, from the solution of the linear spectral problem (4.15) and relations (4.14) and (4.4), we obtain an explicit one-soliton solution of the WE system (1.2):

$$\psi_1=\epsilon(a-b)\frac{z-a}{|z-a|^2+|z-b|^2},\qquad \psi_2=\epsilon(a-b)\frac{\bar{z}-b}{|z-a|^2+|z-b|^2}. \tag{5.17}$$

A similar computation can be performed for the case in which ρ satisfies (2.4) and has a more general form than (5.15):

$$\rho=\prod_{j=1}^{N}\frac{z-a_j}{z-b_j},\qquad a_j,b_j\in\mathbb{R}, \tag{5.18}$$

with distinct parameters such that a and b are replaced by a_j and b_j, respectively. The same process is done with the function f in (5.14). Thus, we can determine explicitly the corresponding form of a multi-soliton solution by applying the recurrence N-soliton wave function formula[26] in the expression (4.14) to obtain

$$\psi_1=\epsilon\frac{\Pi_{j=1}^{N}(z-a_j)/(z-b_j)}{1+\Pi_{j=1}^{N}|(z-a_j)/(z-b_j)|^2}\left(\sum_{s=1}^{N}\frac{1}{(\bar{z}-b_s)}\left(\prod_{\substack{j=1\\ j\neq s}}^{N}\frac{(\bar{z}-a_j)}{(\bar{z}-b_j)}-\prod_{j=1}^{N}\frac{(\bar{z}-a_j)}{(\bar{z}-b_j)}\right)\right)^{1/2},$$
$$\psi_2=\frac{\epsilon}{1+\Pi_{j=1}^{N}|(z-a_j)/(z-b_j)|^2}\left(\sum_{s=1}^{N}\frac{1}{(z-b_s)}\left(\prod_{\substack{j=1\\ j\neq s}}^{N}\frac{(z-a_j)}{(z-b_j)}-\prod_{j=1}^{N}\frac{(z-a_j)}{(z-b_j)}\right)\right)^{1/2}. \tag{5.19}$$

Note that this solution admits simple poles. The topological charge (4.23) for each of the instanton solutions (5.19) corresponds to $I=\epsilon N$.

VI. FUTURE OUTLOOK

In this paper, we have shown that the adapted WE system (1.2), proposed by B. Konopelchenko and I. A. Taimanov as a tool to induce constant mean curvature surfaces, is closely related to the nonlinear Euclidean sigma-model SU(2). This link enabled us to propose a new approach to the construction of solutions, based on the intermediate system of equations (4.9) with which the sigma model (4.1) is associated.

Let us now consider a system of the form

$$\partial\psi_1=h(z,\bar{z})p\,\psi_2,\qquad \overline{\partial\psi_1}=h(z,\bar{z})p\,\bar{\psi}_2,$$
$$\bar{\partial}\psi_2=-h(z,\bar{z})p\,\psi_1,\qquad \partial\bar{\psi}_2=-h(z,\bar{z})p\,\bar{\psi}_1, \tag{6.1}$$

where h is assumed to be a real function of z and $\bar{z}$ not equal to one. Otherwise, we have the previous case. We are interested in conditions under which system (6.1) becomes a completely integrable one.

Making use of the transformation (2.1), by calculations similar to those done in Sec. II, we find

$$\psi_1=\epsilon\rho\frac{(\overline{\partial\rho})^{1/2}}{h^{1/2}(1+|\rho|^2)},\quad \psi_2=\epsilon\frac{(\partial\rho)^{1/2}}{h^{1/2}(1+|\rho|^2)},\quad \epsilon^2=1, \tag{6.2}$$

and system (6.1) becomes

$$\bar{\partial}\partial\rho=\frac{2\bar{\rho}}{1+|\rho|^2}\partial\rho\bar{\partial}\rho+(\partial(\ln h))(\partial\rho), \tag{6.3a}$$

$$\partial\bar{\partial}\rho=\frac{2\rho}{1+|\rho|^2}\overline{\partial\rho}\,\overline{\partial\rho}+(\bar{\partial}(\ln h))(\overline{\partial\rho}). \tag{6.3b}$$

The above form is more convenient to analyze than the equations (6.1). Employing the conditional symmetry method,[30,31] we look for conditions necessary for solvability of a class of equations (6.3) which admit compatible first-order differential constraints. We consider here the simplest case where the differential constraints are based on an sl(2,$\mathbb{C}$) representation. So, we assume that they take the form of coupled Riccati equations (and their complex conjugate equations) with nonconstant coefficients,

$$\begin{aligned}\partial\rho&=A_1^0(z,\bar{z})+A_1^1(z,\bar{z})\rho+A_1^2(z,\bar{z})\rho^2,\\ \bar{\partial}\rho&=A_2^0(z,\bar{z})+A_2^1(z,\bar{z})\rho+A_2^2(z,\bar{z})\rho^2.\end{aligned} \tag{6.4}$$

The compatibility condition for the system (6.4) requires appending to it the zero curvature conditions,

$$A^l_{[\mu,\nu]}+\tfrac{1}{2}C^l_{ab}A^a_\mu A^b_\nu=0,\quad a,b,l=0,1,2\quad \mu,\nu=1,2, \tag{6.5}$$

where $(z^\mu)=(z,\bar{z})$ and C^l_{ab} are structure constants of sl(2,$\mathbb{C}$). The brackets $[\mu,\nu]$ denote here the alternation with respect to the indices μ and ν. We look for conditions on the function h which ensures that the overdetermined system composed of the equations (6.3), differential constraints (6.4), and conditions (6.5) are in involution. These involutivity conditions give us the specific differential restrictions on the class of function *h:*

$$\bar{\partial}\partial\left(\frac{1}{h}\right)=0. \tag{6.6}$$

The general solution of (6.6) is given by

$$h(z,\bar{z})=\frac{1}{r(z)+r(\bar{z})}. \tag{6.7}$$

Here, r is an arbitrary real function. Then, system (6.1) becomes

$$\begin{aligned}\partial\psi_1&=\frac{p}{r(z)+r(\bar{z})}\psi_2,\quad \overline{\partial\psi_1}=\frac{p}{r(z)+r(\bar{z})}\bar{\psi}_2,\\ \bar{\partial}\psi_2&=-\frac{p}{r(z)+r(\bar{z})}\psi_1,\quad \partial\bar{\psi}_2=-\frac{p}{r(z)+r(\bar{z})}\bar{\psi}_1,\end{aligned} \tag{6.8}$$

and, consequently, system (6.3) takes the form

$$
\begin{aligned}
\bar\partial\partial\rho &= \frac{2\bar\rho}{1+|\rho|^2}\,\partial\rho\,\bar\partial\rho - \frac{\partial r}{r(z)+r(\bar z)}\,(\partial\rho),\\
\bar\partial\partial\bar\rho &= \frac{2\rho}{1+|\rho|^2}\,\bar\partial\bar\rho\,\partial\bar\rho - \frac{\bar\partial r}{r(z)+r(\bar z)}\,(\bar\partial\bar\rho).
\end{aligned}
\tag{6.9}
$$

It is easy to show that system (6.8) cannot be transformed into the original WE system (1.1), corresponding to constant mean curvature surfaces, by any change of independent variables. Particular case of system (6.8) has been recently discussed.[32]

An analysis of system (6.9) similar to the one carried out in Sec. IV, can provide us with an explicit form of the spectral problem for (6.9). Since system (1.1) constitutes a special case of system (6.1), it is evident that our approach can be applied to systems which describe much more diverse types of surfaces. This task will be undertaken in future work.

ACKNOWLEDGMENTS

The authors thank J. Harnad (Concordia University) and B. Konopelchenko (Universita di Lecce) for helpful and interesting discussions on the topic of this paper. We also thank W. Hereman (Colorado School of Mines) for providing computer generated symmetry calculations of the WE system (1.2).

Unitary deformations and complex soliton equations

Péter Varga[a)]
Institute of Mathematics and Informatics, Lajos Kossuth University, H-4010 Debrecen, Hungary

(Received 18 January 1999; accepted for publication 8 February 1999)

The generalized Lax-equation $\dot{L}=i(AL-LB)$ leaves the spectrum of L^*L invariant if A and B are self-adjoint operators. Consequently such equations possess many conversed quantities. With the help of this scheme, complex equations of Korteweg–de Vries type are derived. [S0022-2488(99)03607-5]

Since the Lax-equation

$$\dot{L}=PL-LP$$

is the infinitesimal form of the similarity transformation $L\to e^{tP}Le^{-tP}$, such equations leave invariant the ''spectrum'' of L,[1] ensuring the existence of nontrivial conserved quantities. In many cases this scheme leads to the complete integrability of the corresponding equation (see Ref. 2 for a textbook account). The following modification

$$\dot{L}=PL-LQ, \tag{1}$$

of the Lax-equation arises in several situation. It was noted by Drinfeld and Sokolov,[3] that the spectrum of L_1L_2 is preserved by the following transformations: $L_1\to e^{tP}L_1e^{-tQ}$, $L_2\to e^{tQ}L_2e^{-tP}$. The infinitesimal form of these transformations are

$$\dot{L}_1=PL_1-L_1Q, \quad \dot{L}_2=QL_2-L_2P.$$

With the choice of $L_1=\partial_x^2+u+\phi$, $L_2=\partial_x^2+u-\phi$ one obtains the Hirota–Satsuma equations.[4,5] Another example of this scheme is the constrained KP hierarchy (cKP).[6–10] Here the spectrum of $L_1^{-1}L_2$ is preserved by the $L_1\to e^{tP}L_1e^{-tQ}$, $L_2\to e^{tP}L_2e^{-tQ}$ transformations. A somewhat different type of Eq. (1) occurs in the works of Semenov–Tian–Shansky on integrable lattice systems. There P and Q are related by $Q=\tau(P)$, where τ is an automorphism which commutes with the ''R-matrix'' of the problem (see, Ref. 11 for details).

The generalized Lax-equation also arises if L can be regarded as a linear operator on a Hilbert-space $\mathfrak{h}$. In this case one can try to preserve the spectrums of L^*L and LL^* instead of L's one. In fact, it is fairly natural to associate the operator L^*L to L, since every $L\in\mathbf{B}(\mathfrak{h})$ can be uniquely written as $L=U|L|$, where L's absolute value $|L|=(L^*L)^{1/2}$ is a positive operator, while U is a partial isometry.[12]

The spectrum of L^*L is not preserved by general similarity transformations of L. However, the transformation

$$L\to e^{itP}Le^{-itQ}$$

does leave it invariant if e^{itP} and e^{-itQ} are unitary, i.e., if P and Q are self-adjoint operators. Indeed

[a)]Electronic mail: varga@math.klte.hu

$$LL^* \to (e^{itP}Le^{-itQ})((e^{-itQ})^* L^* (e^{itP})^*) = e^{itP}LL^* e^{-itP}.$$

These considerations suggest that it might be possible to obtain integrable equations in the following form:

$$\dot{L} = i(PL - LQ), \quad P = P^*, \quad Q = Q^*. \tag{2}$$

As an illustration, we apply this method to the $L = \partial_x^2 + v(x)\partial_x + u(x)$ operator, where $u(x)$ and $v(x)$ are complex functions. If $v(x) = 0$, then the obtained equations are simple reductions of the (complex) Hirota–Satsamura equations. The $v(x) = 0$ constraint is not preserved by the even flows of the hierarchy.

First, let us recall the Gelfand–Dickey[13,2] construction of the Korteweg–de Vries (KdV) hierarchy. Their starting point is the Schrödinger operator

$$L = \partial^2 + u(x),$$

$(\partial = \partial_x)$. Its square root $L^{1/2}$ is a pseudodifferential operator

$$L^{1/2} = \partial + l_{-1}^{[1/2]}\partial^{-1} + l_{-2}^{[1/2]}\partial^{-2} + l_{-3}^{[1/2]}\partial^{-3} + \cdots,$$

where the $l_i^{[1/2]}$'s are polynomials of u and its derivatives. They are recursively determined by the condition $(L^{1/2})^2 = L$. The crucial property of $L^{1/2}$ is that

$$[L, L^{1/2}] = 0.$$

Then

$$0 = [L, L^{k/2}] = [L, (L^{k/2})_+ + (L^{k/2})_-] \Rightarrow [L, (L^{k/2})_+] = -[L, (L^{k/2})_-],$$

where $(L^{k/2})_+$ is a differential operator containing the non-negative powers of ∂, while $(L^{k/2})_-$ consists of terms of negative powers of ∂. Since $[L, (L^{k/2})_+]$ is a differential operator, and $[L, (L^{k/2})_-]$ cannot contain positive powers of ∂, both expressions must be polynomials of u and its derivatives, so

$$\partial_{t_k} L = \partial_{t_k} u = [L, (L^{k/2})_+] = -[L, (L^{k/2})_-]$$

is a partial differential equation for $u(x,t)$.

With some minor modification, this scheme works for the generalized Lax-equation, too. As the self-adjointness of operators has an important role, we use the self-adjoint derivation $D = i\partial$ instead of ∂. Let

$$L = D^2 + v(x)D + u(x),$$

where u and v are complex functions of x. Instead of $L^{1/2}$ (which is not self-adjoint), we would like to obtain self-adjoint pseudodifferential operators

$$A = D + a_0 + a_{-1}D^{-1} + a_{-2}D^{-2} + \cdots,$$

$$B = D + b_0 + b_{-1}D^{-1} + b_{-2}D^{-2} + \cdots,$$

satisfying

$$i(AL - LB) = 0.$$

So

$$AL=LB\Rightarrow L^{-1}AL=B=B^*=L^*AL^{-1*}\Rightarrow A(LL^*)=(LL^*)A,$$

which implies that

$$A=(LL^*)^{1/4},\quad B=(L^*L)^{1/4}.$$

The operator equations

$$\partial_{t_k}L=\partial_{t_k}vD+\partial_{t_k}u=i\{(A^k)_+L-L(B^k)_+\}=-i\{(A^k)_-L-L(B^k)_-\} \tag{3}$$

generate integrable equations for $u(x,t)$ and $v(x,t)$. Note that the splitting $X=X_++X_-$ respects self-adjointness, i.e., $X=X^*\Rightarrow(X_+=X_+^*\wedge X_-=X_-^*)$. This property would not be true, if the adjoint was computed with respect to a more general $(\psi_1,\psi_2)=\int\overline{\psi_1}F\psi_2\,dx$ inner product, where F is some pseudodifferential operator. In the KdV hierarchy v can be set to zero, since the term containing ∂ drops out from

$$\partial_{t_k}L=\partial_{t_k}(\partial^2+u)=-[(\partial^2+u),(L^{k/2})_-]=-[\partial^2+u,l_{-1}^{[1/2]}\partial_{-1}+l_{-2}^{[1/2]}\partial_{-2}+\cdots].$$

This reduction does not necessarily work in our case, since

$$\begin{aligned}-i((A^k)_-(D^2+u)-(D^2+u)(B^k)_-)&=-i((a_{-1}^{[k]}D^{-1}+\cdots)(D^2+u)-(D^2+u)(b_{-1}^{[k]}D^{-1}+\cdots))\\&=-i(a_{-1}^{[k]}-b_{-1}^{[k]})D,\end{aligned}$$

so the constraints $v(x)=0$ can be violated by the evolution equation. Since the evolution of LL^* and L^*L have the usual Lax form

$$\partial_{t_k}(LL^*)=i[(A^k)_+,LL^*],\quad \partial_{t_k}(L^*L)=i[(B^k)_+,L^*L],$$

the standard machinery of the KdV equations[2] can be applied. For example, the integrals of motion are

$$\int \operatorname{res}A^k\,dx,\quad \int\operatorname{res}B^k\,dx,\quad k=1,2,3,\ldots,$$

where $\operatorname{res}X$ is the coefficient of D^{-1} in the pseudodifferential operator X. The fact that Eq. (3) can be embedded into the KdV hierarchy generated by the Lax-operator

$$L^{(4)}=D^4+u_3D^3+u_2D^2+u_1D1+u_0$$

ensures their integrability. The embedding is determined by the constraints

$$L^{(4)}=LL^*=(D^2+vD+u)(D^2+D\overline{v}+\overline{u})=D^4+(v+\overline{v})D^3+\cdots.$$

Since in the KdV hierarchy of $L^{(4)}$ the constraint $u_3=0$ is preserved by the evolution equations, the constraint $v+\overline{v}=0\to\Re v=0$ can be imposed on Eq. (3), too. However, even $v=0$ is compatible with (3) for odd k, as these equations are basically equivalent to the Hirota–Satsamura hierarchy.

Now we (me and a symbolic algebra package) compute the explicit forms of the first few of the hierarchy (3). For the odd flows, we present only their constrained, $v=0$ form, while for the even flows, v's value is constrained to be pure imaginary ($v=iw$).

(1) Flow:

$$\partial_{t_1}u=u'.$$

(2) Flow:

$$\partial_{t_2} w = 2\mathfrak{F} u',$$

$$\partial_{t_2} u = \frac{i}{2}(w''' - w'(2w' + 2w^2 - 4u) - w(u' - \overline{u}' - w'')).$$

(3) Flow:

$$\partial_{t_3} u = \tfrac{1}{8}(u''' - 3\overline{u}''' - 6uu' + 6u'\overline{u} + 12u\overline{u}').$$

(4) Flow:

$$\partial_{t_4} u = \partial_{t_4} w = 0.$$

(5) Flow:

$$\partial_{t_5} u = \tfrac{1}{32}\{-3u^{(5)} + 5\overline{u}^{(5)} + 5u'''(3u - \overline{u}) + 5\overline{u}'''(-5u + \overline{u}) + 5u'(-3u^2 + 6u\overline{u} + \overline{u}^2 - 3u'' - 5\overline{u}'') + 5\overline{u}'(4u^2 + 4u\overline{u} - 3u'' - 3\overline{u}'')\}.$$

The presented construction can be applied to other integrable systems, too. For example, a Kadomtsev–Petviashvilli type hierarchy[2] can be derived without any difficulty. Let

$$L = D + u_0 + u_{-1}D^{-1} + u_{-2}D^{-2} + \cdots,$$

$$\partial_m L = i(B_m L - L\overline{B_m}), \quad B_m = (LL^*)^m_+ \quad \overline{B_m} = (L^*L)^m_+ .$$

Then the zero-curvature condition

$$\partial_m B_n - \partial_n B_m - i[B_m, B_n] = 0$$

provides the equations of a KP type hierarchy. The proof of the zero-curvature condition is almost the same as for the standard KP equations:

$$\partial_m B_n - \partial_n B_m - i[B_m, B_n] = i\left(\sum_{j=0}^{n-1} (LL^*)^{n-1-j}([B_m L - L\overline{B_m}]L^* + L[\overline{B_m}L^* - L^* B_m])(LL^*)^j - (n \leftrightarrow m)\right)_+ - [B_m, B_n]$$

$$= i([B_m, (LL^*)^n]_+ - [B_n, (LL^*)^m]_+ - [B_m, B_n])$$

$$= i([B_n - (LL^*)^n, B_m - (LL^*)^m]_+ = [(LL^*)^m_-, (LL^*)^n_-]) = 0.$$

These computations are very similar to the ones which appear in the theory of the constrained KP hierarchy.[10] This is not surprising, since here we isospectrally deform LL^*, while in the case of the cKP hierarchy $L_1^{-1}L_2$'s deformation is isospectral. The verification of the commutativity of the flows ∂_m is standard.

Finally we present another variation on the theme of this paper. We determine those $L \to e^{tA}Le^{-tB}$ transformations which generate isospectral deformations of $L\overline{L}$. Since $L\overline{L} \to e^{tA}Le^{-tB}\overline{e^{tA}}\overline{L}\overline{e^{-tB}}$, we obtain that $B = \overline{A}$. With the $A = (L\overline{L})^{k/n}_+$, $B = (\overline{L}L)^{k/n}_+$ choices, it is possible to repeat the steps of the derivation of the Hirota–Satsamura type coupled KdV hierarchy. Note, however, that this sort of scheme does not work for the LL^T product. In that case A and B should satisfy $B = -A^T$, but this condition does not hold for $A = (LL^T)^\alpha$ and $B = (L^T L)^\alpha$. So it seems that it is possible to modify only the complex KdV equations.

(Received 2 November 1998; accepted for publication 17 March 1999)

Under a constraint between the potentials and the eigenfunctions, the 3×3 AKNS matrix spectral problem and its adjoint spectral problem associated with the three-wave interaction equations are nonlinearized so as to be a new finite-dimensional Hamiltonian system. A general scheme for generating involutive systems of conserved integrals and their two new generators are proposed, by which the finite-dimensional Hamiltonian system is further proved to be completely integrable in the Liouville sense. Moreover, the involutive solutions of the three-wave interaction equations are given.

I. INTRODUCTION

It has been known that there are several systematic approaches to obtain explicit solutions of soliton equations, such as the inverse scattering transformation, the Hirota technique, the algebra–geometric method, the polar expansion solution method, etc.[1–6] Some interesting explicit solutions have been found, the most important among which are pure-soliton solutions, finite-band solutions and polar expansion solutions.

The observation that all the explicit solutions mentioned above have a finite number of parameters, which means that they satisfy some kind of ordinary differential equations, suggests an important approach to get new finite-dimensional integrable systems from soliton equations. Recently an effective method, the so-called nonlinearization of eigenvalue problems or Lax pairs,[7–9] has been developed and applied to various soliton hierarchies associated with 2×2 zero-trace matrix spectral problems, from which a considerable number of new finite-dimensional systems are obtained that are completely integrable in the Liouville sense. Another important application of the nonlinearization method is that it provides a way of solving soliton equations, integrable nonlinear partial differential equations, by separation of spatial and temporal variables. At the same time the inter-relation between soliton equations and finite-dimensional integrable systems is revealed. The method is sometimes called the method of separation of variables for nonlinear partial differential equations, which generalizes the corresponding method for linear ones.

A similar method, the restricted flow technique, for bi-Hamiltonian soliton hierarchies is proposed in Refs. 10, 11 and bi-Hamiltonian structures for the resulting finite-dimensional integrable systems can also be worked out through a Miura map.[11,12] There are attempts to apply the nonlinearization method or the restricted flow technique to discrete systems in order to get integrable symplectic maps.[13–17]

Very recently, the nonlinearization method has been generalized to discuss Lax pairs and adjoint Lax pairs of soliton equations[18–21] so that it may also be suitable for the cases of 2×2 nonzero-trace matrix spectral problems. It has been applied successfully to the hierarchy of Harry

Dym type equations and the Blaszak discrete soliton hierarchy,[20,21] which correspond to 3×3 matrix spectral problems.

The key to the complete integrability of a finite-dimensional Hamiltonian system is the existence of an involutive system of conserved integrals. However, it is difficult for us to search for an involutive system of conserved integrals of a given finite-dimensional Hamiltonian system. In this paper, based on the above works we are going to discuss the nonlinearization for a 3×3 AKNS matrix spectral problem and its adjoint spectral problem associated with the three-wave interaction equations,[1,22] from which a new finite-dimensional Hamiltonian system is obtained. Resorting to the characteristic polynomial of solution matrix of the stationary zero-curvature equation, we propose a general scheme for generating involutive systems of enough conserved integrals of the resulting finite-dimensional Hamiltonian system. To prove the functional independence of conserved integrals, two new generators of involutive systems of conserved integrals are introduced, which are two natural generalizations of the 2×2 case.[23] This shows that the finite-dimensional Hamiltonian system is completely integrable in the Liouville sense.

Consider the $n\times n$ matrix spectral problem

$$\psi_x=U(u,\lambda)\psi,\quad \psi=(\psi^1,\ldots,\psi^n)^T. \tag{1.1}$$

In order to derive the isospectral hierarchy associated with Eq. (1.1), we proceed first to solve the stationary zero-curvature equation,

$$V_x-[U,V]=0,\quad V=\sum_{j\geqslant0}V^{(j)}\lambda^{-j}, \tag{1.2}$$

which usually is equivalent to Lenard recursive equation

$$KG_{j-1}=JG_j,\quad JG_{-1}=0,\quad j\geqslant0. \tag{1.3}$$

Here K and J are two skew-symmetric operators. The soliton hierarchy $u_t=JG_m$ has a Lax pair, the spectral problem (1.1) and the auxiliary problem

$$\psi_{t_m}=V_m\psi,\quad V_m=(\lambda^mV)_+, \tag{1.4}$$

where the symbol $+$ stands for the choice of non-negative power of λ. The introduction of the adjoint problem of Eq. (1.1),

$$\phi_x=-U(u,\lambda)^T\phi,\quad \phi=(\phi^1,\ldots,\phi^n)^T \tag{1.5}$$

allows the calculation of the functional gradient of the eigenvalues with regard to the potential u (see, e.g., Sec. III). Usually such a functional gradient $\nabla\lambda_j$ satisfies the following equation:

$$K\nabla\lambda_j=\rho(\lambda_j)J\nabla\lambda_j,\quad \rho(\lambda_j)=c_1\lambda_j+c_2\lambda_j^2,\quad 1\leqslant j\leqslant N, \tag{1.6}$$

where $\lambda_1,\ldots,\lambda_N$ are the eigenvalues of Eqs. (1.1) and (1.5), c_1 and c_2 are constants. The following two kinds of constraints:

$$G_0=\sum_{j=1}^N\nabla\lambda_j,\quad G_{-1}=\sum_{j=1}^N\nabla\lambda_j, \tag{1.7}$$

which are called the Bargmann and Neumann constraints, respectively, play a central role in the process of nonlinearization of the eigenvalue problems (1.1) and (1.5). From (1.7) we can obtain the relations

$$u=f(q,p)\quad\text{and}\quad g(q,p)=0,\quad u=f(q,p), \tag{1.8}$$

where $q=(q_1^1,\ldots,q_N^1,\ldots,q_1^n,\ldots,q_N^n)^T$, $p=(p_1^1,\ldots,p_N^1,\ldots,p_1^n,\ldots,p_N^n)^T$, $q_j^i=\psi^i(\lambda_j)$, $p_j^i=\phi^i(\lambda_j)$, $1\leqslant i\leqslant n$, $1\leqslant j\leqslant N$. Under the two constraints, N replicas of the spectral problems (1.1) and (1.5) associated with $\lambda_1,\ldots,\lambda_N$ are nonlinearized into two finite-dimensional Hamiltonian systems

$$q_x=U(f(q,p),\Lambda)q,\quad p_x=-U(f(q,p),\Lambda)^Tp,\quad \Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_N), \tag{1.9}$$

$$q_x=U(f(q,p),\Lambda)q,\quad p_x=-U(f(q,p),\Lambda)^Tp,\quad g(q,p)=0, \tag{1.10}$$

which are called the Bargmann and Neumann systems, respectively. In the following, we propose a general scheme for generating conserved integrals of Eq. (1.9) or (1.10). Noticing the matrix $\mu I-V$ is also a solution of the stationary zero-curvature equation (1.2), which implies that $\det(\mu I-V)$ is a constant with respect to the variable x, for each value of the spectral parameter λ. Here μ is a parameter, I is an $n\times n$ matrix. Let us consider the characteristic polynomial of solution matrix V of Eq. (1.2),

$$\det(\mu I-V)=\mu^n-\mathcal{F}_\lambda^{(0)}\mu^{n-1}+\mathcal{F}_\lambda^{(1)}\mu^{n-2}+\cdots+(-1)^n\mathcal{F}_\lambda^{(n-1)}, \tag{1.11}$$

where

$$\mathcal{F}_\lambda^{(0)}=\mathrm{tr}\,V,\quad \mathcal{F}_\lambda^{(1)}=\sum_{1\leqslant i<j\leqslant n}\begin{vmatrix}V_{ii} & V_{ij}\\ V_{ji} & V_{jj}\end{vmatrix},$$

$$\mathcal{F}_\lambda^{(2)}=\sum_{1\leqslant i<j<k\leqslant n}\begin{vmatrix}V_{ii} & V_{ij} & V_{ik}\\ V_{ji} & V_{jj} & V_{jk}\\ V_{ki} & V_{kj} & V_{kk}\end{vmatrix},\ldots,\quad \mathcal{F}_\lambda^{(n-1)}=\det V. \tag{1.12}$$

By using Eqs. (1.3), (1.6) and the corresponding constraint, Eqs. (1.12) are reduced to generating functions of the conserved integrals of the Bargmann system (1.9), or the Neumann system (1.10). Sometimes some modifications are made, especially for the Neumann system. Thus we easily get the conserved integrals of the system (1.9) or (1.10) from their generating functions.

The outline of the paper is as follows: In Sec. II, we shall reconstruct the soliton hierarchy associated with the 3×3 AKNS spectral problem and establish their Hamiltonian structures. In Sec. III, we shall introduce the Bargmann constraint between the potentials and eigenfunctions. Under the constraint, a new finite-dimensional Hamiltonian system is obtained by nonlinearization of the 3×3 AKNS spectral problem and its adjoint one. In Sec. IV, we shall show how the scheme is applied to generate involutive systems of conserved integrals of the finite-dimensional Hamiltonian system. Further we prove that the finite-dimensional Hamiltonian system is completely integrable in the Liouville sense. In Sec. V, the representation of involutive solutions of the three-wave interaction equations and the soliton hierarchy is given. Finally in the Appendix, by means of the generating functions of conserved integrals, we give the involutivity of conserved integrals. Then we introduce two new generators of involutive systems of conserved integrals and prove the functional independence of conserved integrals.

II. THE SOLITION HIERARCHY AND HAMILTONIAN STRUCTURES

Let us consider the 3×3 AKNS matrix spectral problem

$$\psi_x=U(u,\lambda)\psi,\quad \psi=\begin{pmatrix}\psi^1\\ \psi^2\\ \psi^3\end{pmatrix},\quad U=\begin{pmatrix}\alpha_1\lambda & u_{12} & u_{13}\\ u_{21} & \alpha_2\lambda & u_{23}\\ u_{31} & u_{32} & \alpha_3\lambda\end{pmatrix}, \tag{2.1}$$

where the potential $u=(u_{12},u_{21},u_{13},u_{31},u_{23},u_{32})^T$, λ is a constant spectral parameter, $\alpha_i' s(1\leqslant i\leqslant 3)$ are three distinct constants. Our aim is to engender the soliton hierarchy from the spectral problem (2.1). To this end, we first solve the stationary zero-curvature equation,

$$V_x-[U,V]=0,\quad V=(V_{ij})_{3\times 3}, \tag{2.2}$$

which is equivalent to

$$V_{ijx}+u_{ij}(V_{ii}-V_{jj})+\sum_{\substack{k=1\\k\neq i,j}}^{3}(u_{kj}V_{ik}-u_{ik}V_{kj})-\lambda(\alpha_i-\alpha_j)V_{ij}=0,\quad i\neq j, \tag{2.3a}$$

$$V_{iix}=\sum_{\substack{k=1\\k\neq i}}^{3}(u_{ik}V_{ki}-u_{ki}V_{ik}),\quad 1\leqslant i,j\leqslant 3. \tag{2.3b}$$

Substitution the expansion

$$V_{ij}=\sum_{n\geqslant 0}V_{ij}^{(n)}\lambda^{-n} \tag{2.4}$$

into Eq. (2.3), we obtain the recurrence relations

$$V_{iix}^{(0)}=0,\quad V_{ij}^{(0)}=0,\quad (i\neq j),$$

$$V_{ijx}^{(n)}+u_{ij}(V_{ii}^{(n)}-V_{jj}^{(n)})+\sum_{\substack{k=1\\k\neq i,j}}^{3}(u_{kj}V_{ik}^{(n)}-u_{ik}V_{kj}^{(n)})-(\alpha_i-\alpha_j)V_{ij}^{(n+1)}=0,\quad i\neq j,$$

$$V_{iix}^{(n)}=\sum_{\substack{k=1\\k\neq i}}^{3}(u_{ik}V_{ki}^{(n)}-u_{ki}V_{ik}^{(n)}),\quad 1\leqslant i,j\leqslant 3,n\geqslant 0. \tag{2.5}$$

By Eq. (2.5) we have

$$V_{ii}^{(0)}=\beta_i(\text{constant}),\qquad V_{ij}^{(0)}=0,\quad i\neq j,$$

$$V_{ii}^{(1)}=0,\quad V_{ij}^{(1)}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ij},\quad i\neq j, \tag{2.6}$$

and require that

$$\beta_i\neq\beta_j(i\neq j),\qquad V_{ij}^{(n)}|_{u=0}=0,\quad n\geqslant 1, \tag{2.7}$$

where the condition (2.7) means to identify constants of the integration to be zero. Hence $V_{ij}^{(n)}$ is uniquely determined. It is easy to calculate that

$$V_{ij}^{(2)}=\frac{\beta_i-\beta_j}{(\alpha_i-\alpha_j)^2}u_{ijx}+\frac{1}{\alpha_i-\alpha_j}\sum_{\substack{k=1\\k\neq i,j}}^{3}\left(\frac{\beta_k-\beta_i}{\alpha_k-\alpha_i}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj},\qquad i\neq j, \tag{2.8a}$$

$$V_{ii}^{(2)}=\sum_{\substack{k=1\\k\neq i}}^{3}\frac{\beta_k-\beta_i}{(\alpha_k-\alpha_i)^2}u_{ik}u_{ki}. \tag{2.8b}$$

Equations (2.5)–(2.7) can be equivalently written as the Lenard form

$$KG_{n-1}=JG_n\,,\quad G_{n-1}=(V_{21}^{(n)},V_{12}^{(n)},V_{31}^{(n)},V_{13}^{(n)},V_{32}^{(n)},V_{23}^{(n)})^T,\qquad n\geqslant 1, \tag{2.9a}$$

$$G_0=\left(\frac{\beta_1-\beta_2}{\alpha_1-\alpha_2}u_{21},\frac{\beta_1-\beta_2}{\alpha_1-\alpha_2}u_{12},\frac{\beta_1-\beta_3}{\alpha_1-\alpha_3}u_{31},\frac{\beta_1-\beta_3}{\alpha_1-\alpha_3}u_{13},\frac{\beta_2-\beta_3}{\alpha_2-\alpha_3}u_{32},\frac{\beta_2-\beta_3}{\alpha_2-\alpha_3}u_{23}\right)^T \tag{2.9b}$$

with $G_n|_{u=0}=0$. Here J and K are two skew-symmetric operators,

$$J=\begin{pmatrix} 0 & \alpha_1-\alpha_2 & 0 & 0 & 0 & 0\\ \alpha_2-\alpha_1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & \alpha_1-\alpha_3 & 0 & 0\\ 0 & 0 & \alpha_3-\alpha_1 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & \alpha_2-\alpha_3\\ 0 & 0 & 0 & 0 & \alpha_3-\alpha_2 & 0 \end{pmatrix},$$

$$K=(K_{lm})_{6\times 6},\quad K_{ml}^*=-K_{lm}$$

with

$$K_{11}=2u_{12}\partial^{-1}u_{12},\quad K_{12}=\partial-2u_{12}\partial^{-1}u_{21},\quad K_{13}=u_{12}\partial^{-1}u_{13},\quad K_{14}=u_{32}-u_{12}\partial^{-1}u_{31},$$

$$K_{15}=-u_{13}-u_{12}\partial^{-1}u_{23},\quad K_{16}=u_{12}\partial^{-1}u_{32},\quad K_{22}=2u_{21}\partial^{-1}u_{21},\quad K_{23}=-u_{23}-u_{21}\partial^{-1}u_{13},$$

$$K_{24}=u_{21}\partial^{-1}u_{31},\quad K_{25}=u_{21}\partial^{-1}u_{23},\quad K_{26}=u_{31}-u_{21}\partial^{-1}u_{32},\quad K_{33}=2u_{13}\partial^{-1}u_{13},$$

$$K_{34}=\partial-2u_{13}\partial^{-1}u_{31},\quad K_{35}=u_{13}\partial^{-1}u_{23},\quad K_{36}=-u_{12}-u_{13}\partial^{-1}u_{32},\quad K_{44}=2u_{31}\partial^{-1}u_{31},$$

$$K_{45}=u_{21}-u_{31}\partial^{-1}u_{23},\quad K_{46}=u_{31}\partial^{-1}u_{32},\quad K_{55}=2u_{23}\partial^{-1}u_{23},\quad K_{56}=\partial-2u_{23}\partial^{-1}u_{32},$$

$$K_{66}=2u_{32}\partial^{-1}u_{32},\quad \partial=\partial/\partial x,\quad \partial\partial^{-1}=\partial^{-1}\partial=1.$$

Using the trace identity technique,[24] we have

$$\frac{\delta H_n}{\delta u_{ij}}=V_{ji}^{(n)},\quad H_n=-\frac{1}{n}(\alpha_1V_{11}^{(n+1)}+\alpha_2V_{22}^{(n+1)}+\alpha_3V_{33}^{(n+1)}), \tag{2.10}$$

where the potentials $u_{ij},i\neq j$, are assumed to belong to the Schwartz space $\mathcal{S}(\Omega)$, $\Omega=(-\infty,\infty)$.

Now we introduce the auxiliary problem of the spectral problem (2.1),

$$\psi_{t_m}=V^{(m)}\psi,\quad V^{(m)}=V^{(m)}(u,\lambda)=(\lambda^mV)_+\,,\quad m\geqslant 1. \tag{2.11}$$

The compatibility condition between Eqs. (2.1) and (2.11) leads to the zero-curvature equation, $U_t-V_x+[U,V]=0$, that is the hierarchy of soliton equations with bi-Hamiltonian forms

$$u_{t_m}=X_m=K\frac{\delta H_m}{\delta u}=J\frac{\delta H_{m+1}}{\delta u},\quad m\geqslant 1, \tag{2.12}$$

where the vector field $X_m=KG_{m-1}=JG_m$ and Eq. (2.10) is used. The typical nonlinear system in the hierarchy is the famous three-wave interaction equations,

$$u_{ijt_1}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ijx}+\sum_{\substack{k=1\\k\neq i,j}}^{3}\left(\frac{\beta_k-\beta_i}{\alpha_k-\alpha_i}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj},\quad i\neq j,\quad 1\leqslant i,\quad j\leqslant 3, \tag{2.13}$$

which has important applications in physics.[1,22,25]

III. A FINITE-DIMENSIONAL HAMILTONIAN SYSTEM

In order to give the constraint between the potentials and the eigenfunctions, it is necessary to calculate the functional gradient of the eigenvalue with respect to the potential. We introduce the adjoint spectral problem of (2.1),

$$\phi_x=-U(u,\lambda)^T\phi,\quad \phi=(\phi^1,\phi^2,\phi^3)^T. \tag{3.1}$$

Suppose that $u_{ij}\to u_{ij}+\epsilon\delta u_{ij}$, $1\leqslant i\neq j\leqslant 3$, denote $\partial/\partial\epsilon|_{\epsilon=0}$ by a dot. The underlying interval Ω is $(-\infty,\infty)$ under the decaying condition at infinity. A direct calculation shows by Eqs. (2.1) and (3.1) that

$$(\phi^T\dot{\psi})_x=\phi^T\dot{U}\psi. \tag{3.2}$$

If λ is an eigenvalue of the spectral problems (2.1) and (3.1), the integration of the left-hand side of equality (3.2) vanishes because of the boundary conditions. Then we have

$$\int_\Omega \phi^T\dot{U}\psi dx=0. \tag{3.3}$$

Let $\lambda_1,\ldots,\lambda_N$ be N distinct eigenvalues. Then the systems associated with spectral problems (2.1) and (3.1) can be written in the form

$$(q_l^1,q_l^2,q_l^3)_x=(q_l^1,q_l^2,q_l^3)U(u,\lambda_l)^T,\quad (p_l^1,p_l^2,p_l^3)_x=-(p_l^1,p_l^2,p_l^3)U(u,\lambda_l), \tag{3.4}$$

where $q_l^i=\psi^i(\lambda_l)$, $p_l^i=\phi^i(\lambda_l)$, $1\leqslant i\leqslant 3$, $1\leqslant l\leqslant N$, are eigenfunctions. Noticing Eq. (3.4) and $\dot{U}(u,\lambda_l)=U(\delta u,\delta\lambda_l)$, we obtain by Eq. (3.3) that

$$\int_\Omega(p_l^1,p_l^2,p_l^3)U(\delta u,\delta\lambda_l)(q_l^1,q_l^2,q_l^3)^Tdx=0,$$

which implies that the functional gradient of the eigenvalue λ_l with regard to the potential u is

$$\nabla\lambda_l=\frac{\delta\lambda_l}{\delta u}=\left(\frac{\delta\lambda_l}{\delta u_{12}},\frac{\delta\lambda_l}{\delta u_{21}},\frac{\delta\lambda_l}{\delta u_{13}},\frac{\delta\lambda_l}{\delta u_{31}},\frac{\delta\lambda_l}{\delta u_{23}},\frac{\delta\lambda_l}{\delta u_{32}}\right)^T=(q_l^2p_l^1,q_l^1p_l^2,q_l^3p_l^1,q_l^1p_l^3,q_l^3p_l^2,q_l^2p_l^3)^T, \tag{3.5}$$

where we assume that

$$\int_\Omega(\alpha_1q_l^1p_l^1+\alpha_2q_l^2p_l^2+\alpha_3q_l^3p_l^3)dx=-1.$$

A direct calculation shows that the gradient $\nabla\lambda_l$ satisfies the following equation:

$$K\nabla\lambda_l=\lambda_lJ\nabla\lambda_l. \tag{3.6}$$

As a matter of fact, we obtain from Eq. (3.4) that

$$(q_l^1p_l^1)_x-(q_l^2p_l^2)_x=2u_{12}q_l^2p_l^1-2u_{21}q_l^1p_l^2+u_{13}q_l^3p_l^1-u_{31}q_l^1p_l^3-u_{23}q_l^3p_l^2+u_{32}q_l^2p_l^3, \tag{3.7}$$

$$(q_l^1 p_l^2)_x + u_{32} q_l^1 p_l^3 - u_{13} q_l^3 p_l^2 = u_{12}(q_l^2 p_l^2 - q_l^1 p_l^1) + \lambda_l(\alpha_1 - \alpha_2) q_l^1 p_l^2. \tag{3.8}$$

Noticing Eqs. (3.7) and (3.8), we have

$$\begin{aligned} &K_{11} q_l^2 p_l^1 + K_{12} q_l^1 p_l^2 + K_{13} q_l^3 p_l^1 + K_{14} q_l^1 p_l^3 + K_{15} q_l^3 p_l^2 + K_{16} q_l^2 p_l^3 \\ &\quad = u_{12} \partial^{-1}(2u_{12} q_l^2 p_l^1 - 2u_{21} q_l^1 p_l^2 + u_{13} q_l^3 p_l^1 - u_{31} q_l^1 p_l^3 - u_{23} q_l^3 p_l^2 + u_{32} q_l^2 p_l^3) \\ &\qquad + (q_l^1 p_l^2)_x + u_{32} q_l^1 p_l^3 - u_{13} q_l^3 p_l^2 = \lambda_l(\alpha_1 - \alpha_2) q_l^1 p_l^2, \end{aligned} \tag{3.9}$$

which implies that the sign of equality in the first row of Eq. (3.6) holds. In a similar way, we may prove that other rows of Eq. (3.6) are also identical equations.

Now we consider the Bargmann constraint

$$G_0 = \sum_{l=1}^{N} \nabla \lambda_l , \tag{3.10}$$

which implies

$$u_{ij} = \frac{\alpha_i - \alpha_j}{\beta_i - \beta_j} \langle q^i, p^j \rangle, \quad i \neq j, \ \ 1 \leqslant i,j \leqslant 3, \tag{3.11}$$

where $\langle \cdot , \cdot \rangle$ is the standard inner-product in $\mathcal{R}^N$, $q^i = (q_1^i, \ldots, q_N^i)^T$, $p^i = (p_1^i, \ldots, p_N^i)^T$. Substituting Eq. (3.11) into Eq. (3.4), we obtain a finite-dimensional Hamiltonian system

$$q_x^i = \frac{\partial H}{\partial p^i}, \quad p_x^i = -\frac{\partial H}{\partial q^i}, \quad 1 \leqslant i \leqslant 3, \tag{3.12}$$

with the Hamiltonian

$$\begin{aligned} H = {} & \alpha_1 \langle \Lambda q^1, p^1 \rangle + \alpha_2 \langle \Lambda q^2, p^2 \rangle + \alpha_3 \langle \Lambda q^3, p^3 \rangle + \frac{\alpha_1 - \alpha_2}{\beta_1 - \beta_2} \langle q^1, p^2 \rangle \langle q^2, p^1 \rangle \\ & + \frac{\alpha_1 - \alpha_3}{\beta_1 - \beta_3} \langle q^1, p^3 \rangle \langle q^3, p^1 \rangle + \frac{\alpha_2 - \alpha_3}{\beta_2 - \beta_3} \langle q^2, p^3 \rangle \langle q^3, p^2 \rangle, \end{aligned}$$

where $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_N)$. Moreover, we have from Eq. (3.4) that

$$[(q_l^1, q_l^2, q_l^3)(p_l^1, p_l^2, p_l^3)^T]_x = 0,$$

which implies

$$q_l^1 p_l^1 + q_l^2 p_l^2 + q_l^3 p_l^3 = \text{constant}. \tag{3.13}$$

It is easy to see that Eq. (3.13) are the conserved integrals of the system (3.12).

IV. THE INTEGRABILITY

In this section, we shall show how the characteristic polynomial of the solution matrix of Eq. (2.2) is used to generate the involutive systems of conserved integrals of the finite-dimensional Hamiltonian system (3.12). To this end, we first consider the characteristic polynomial

$$\det(\mu I - V) = \mu^3 - \mathcal{F}_\lambda^{(0)} \mu^2 + \mathcal{F}_\lambda^{(1)} \mu - \mathcal{F}_\lambda^{(2)}, \tag{4.1}$$

where

$$\mathcal{F}_\lambda^{(0)}=\operatorname{tr} V,\quad \mathcal{F}_\lambda^{(1)}=\sum_{1\leqslant i<j\leqslant 3}\begin{vmatrix} V_{ii} & V_{ij} \\ V_{ji} & V_{jj}\end{vmatrix},\quad \mathcal{F}_\lambda^{(2)}=\begin{vmatrix} V_{11} & V_{12} & V_{13} \\ V_{21} & V_{22} & V_{23} \\ V_{31} & V_{32} & V_{33}\end{vmatrix}. \tag{4.2}$$

It is easy to see that $\mathcal{F}_\lambda^{(0)},\mathcal{F}_\lambda^{(1)},\mathcal{F}_\lambda^{(2)}$ are constants with respect to the variable x. For the sake of convenience, we introduce a bilinear function $\overset{ij}{Q}_\lambda$ on $\mathcal{R}^N$ and its partial-fraction expansion and Laurent expansion,

$$\overset{ij}{Q}_\lambda=\langle(\lambda-\Lambda)^{-1}q^i,p^j\rangle=\sum_{l=1}^{N}\frac{q_l^i p_l^j}{\lambda-\lambda_l}=\sum_{n\geqslant 0}\lambda^{-n-1}\langle\Lambda^n q^i,p^j\rangle.$$

By using Eqs. (2.9), (3.6) and the constraint (3.10), we take the following restriction:

$$G_n=\sum_{l=1}^{N}\lambda_l^n\nabla\lambda_l, \tag{4.3}$$

which is a special solution of Eq. (2.9) and can be written as follows:

$$V_{ij}^{(n)}=\langle\Lambda^{n-1}q^i,p^j\rangle,\quad i\neq j,\quad 1\leqslant i,\quad j\leqslant 3,\quad n\geqslant 1. \tag{4.4a}$$

From Eq. (4.4a) and the third expression of Eq. (2.5), we have

$$V_{ii}^{(n)}=\langle\Lambda^{n-1}q^i,p^i\rangle,\quad 1\leqslant i\leqslant 3, n\geqslant 1. \tag{4.4b}$$

By utilizing Eqs. (2.4) and (4.4), we get

$$V_{ij}=\sum_{n\geqslant 1}\langle\Lambda^{n-1}q^i,p^j\rangle\lambda^{-n}=\overset{ij}{Q}_\lambda,\quad i\neq j,\quad 1\leqslant i,j\leqslant 3, \tag{4.5a}$$

$$V_{ii}=\beta_i+\sum_{n\geqslant 1}\langle\Lambda^{n-1}q^i,p^i\rangle\lambda^{-n}=\beta_i+\overset{ii}{Q}_\lambda,\quad 1\leqslant i\leqslant 3. \tag{4.5b}$$

Substituting Eq. (4.5) into Eq. (4.2) yields generating functions of integrals of motion for Eq. (3.12),

$$\hat{\mathcal{F}}_\lambda^{(0)}=\overset{11}{Q}_\lambda+\overset{22}{Q}_\lambda+\overset{33}{Q}_\lambda, \tag{4.6}$$

$$\hat{\mathcal{F}}_\lambda^{(1)}=(\beta_2+\beta_3)\overset{11}{Q}_\lambda+(\beta_1+\beta_3)\overset{22}{Q}_\lambda+(\beta_1+\beta_2)\overset{33}{Q}_\lambda+\sum_{1\leqslant i<j\leqslant 3}(\overset{ii}{Q}_\lambda\overset{jj}{Q}_\lambda-\overset{ij}{Q}_\lambda\overset{ji}{Q}_\lambda), \tag{4.7}$$

$$\hat{\mathcal{F}}_\lambda^{(2)}=\beta_2\beta_3\overset{11}{Q}_\lambda+\beta_1\beta_3\overset{22}{Q}_\lambda+\beta_1\beta_2\overset{33}{Q}_\lambda+\sum_{1\leqslant i<j\leqslant 3}\beta_{6-i-j}(\overset{ii}{Q}_\lambda\overset{jj}{Q}_\lambda-\overset{ij}{Q}_\lambda\overset{ji}{Q}_\lambda)+\begin{vmatrix} \overset{11}{Q}_\lambda & \overset{12}{Q}_\lambda & \overset{13}{Q}_\lambda \\ \overset{21}{Q}_\lambda & \overset{22}{Q}_\lambda & \overset{23}{Q}_\lambda \\ \overset{31}{Q}_\lambda & \overset{32}{Q}_\lambda & \overset{33}{Q}_\lambda\end{vmatrix}, \tag{4.8}$$

where $\hat{\mathcal{F}}_\lambda^{(0)}$, $\hat{\mathcal{F}}_\lambda^{(1)}$, and $\hat{\mathcal{F}}_\lambda^{(2)}$ are defined by

$$\hat{\mathcal{F}}_\lambda^{(0)}=\hat{\mathcal{F}}_\lambda^{(0)}-\beta_1-\beta_2-\beta_3,\quad \hat{\mathcal{F}}_\lambda^{(1)}=\mathcal{F}_\lambda^{(1)}-\beta_1\beta_2-\beta_1\beta_3-\beta_2\beta_3,$$

$$\hat{\mathcal{F}}_\lambda^{(2)}=\mathcal{F}_\lambda^{(2)}-\beta_1\beta_2\beta_3.$$

Substituting the Laurent expansion of $\overset{ik}{Q_\lambda}$ into Eqs. (4.6)–(4.8), respectively, we have

$$\hat{\mathcal{F}}_\lambda^{(0)}=\sum_{m\geqslant 0}\lambda^{-m-1}F_m^{(0)},\quad \hat{\mathcal{F}}_\lambda^{(1)}=\sum_{m\geqslant 0}\lambda^{-m-1}F_m^{(1)},\quad \hat{\mathcal{F}}_\lambda^{(2)}=\sum_{m\geqslant 0}\lambda^{-m-1}F_m^{(2)},\tag{4.9}$$

where

$$F_m^{(0)}=\langle\Lambda^m q^1,p^1\rangle+\langle\Lambda^m q^2,p^2\rangle+\langle\Lambda^m q^3,p^3\rangle,\quad m\geqslant 0,\tag{4.10}$$

$$F_0^{(1)}=(\beta_2+\beta_3)\langle q^1,p^1\rangle+(\beta_1+\beta_3)\langle q^2,p^2\rangle+(\beta_1+\beta_2)\langle q^3,p^3\rangle,\tag{4.11a}$$

$$F_m^{(1)}=(\beta_2+\beta_3)\langle\Lambda^m q^1,p^1\rangle+(\beta_1+\beta_3)\langle\Lambda^m q^2,p^2\rangle+(\beta_1+\beta_2)\langle\Lambda^m q^3,p^3\rangle$$
$$+\sum_{1\leqslant i<j\leqslant 3}\sum_{l=1}^{m}\begin{vmatrix}\langle\Lambda^{l-1}q^i,p^i\rangle & \langle\Lambda^{m-l}q^j,p^i\rangle\\ \langle\Lambda^{l-1}q^i,p^j\rangle & \langle\Lambda^{m-l}q^j,p^j\rangle\end{vmatrix},\quad m\geqslant 1,\tag{4.11b}$$

$$F_0^{(2)}=\beta_2\beta_3\langle q^1,p^1\rangle+\beta_1\beta_3\langle q^2,p^2\rangle+\beta_1\beta_2\langle q^3,p^3\rangle,\tag{4.12a}$$

$$F_1^{(2)}=\beta_2\beta_3\langle\Lambda q^1,p^1\rangle+\beta_1\beta_3\langle\Lambda q^2,p^2\rangle+\beta_1\beta_2\langle\Lambda q^3,p^3\rangle$$
$$+\sum_{1\leqslant i<j\leqslant 3}\beta_{6-i-j}\begin{vmatrix}\langle q^i,p^i\rangle & \langle q^j,p^i\rangle\\ \langle q^i,p^j\rangle & \langle q^j,p^j\rangle\end{vmatrix},\tag{4.12b}$$

$$F_m^{(2)}=\beta_2\beta_3\langle\Lambda^m q^1,p^1\rangle+\beta_1\beta_3\langle\Lambda^m q^2,p^2\rangle+\beta_1\beta_2\langle\Lambda^m q^3,p^3\rangle$$
$$+\sum_{1\leqslant i<j\leqslant 3}\sum_{\substack{l+n=m-1\\ l,n\geqslant 0}}\beta_{6-i-j}\begin{vmatrix}\langle\Lambda^l q^i,p^i\rangle & \langle\Lambda^n q^j,p^i\rangle\\ \langle\Lambda^l q^i,p^j\rangle & \langle\Lambda^n q^j,p^j\rangle\end{vmatrix}$$
$$+\sum_{\substack{l+n+s=m-2\\ l,n,s\geqslant 0}}\begin{vmatrix}\langle\Lambda^l q^1,p^1\rangle & \langle\Lambda^n q^1,p^2\rangle & \langle\Lambda^s q^1,p^3\rangle\\ \langle\Lambda^l q^2,p^1\rangle & \langle\Lambda^n q^2,p^2\rangle & \langle\Lambda^s q^2,p^3\rangle\\ \langle\Lambda^l q^3,p^1\rangle & \langle\Lambda^n q^3,p^2\rangle & \langle\Lambda^s q^3,p^3\rangle\end{vmatrix},\quad m\geqslant 2.\tag{4.12c}$$

In this way, we obtain the conserved integrals $\{F_m^{(i)}\}$, $0\leqslant i\leqslant 2$, of the Hamiltonian system (3.12). The Poisson bracket of two functions in the symplectic space $(\mathcal{R}^{6N},\Sigma_{i=1}^3 dp^i\wedge dq^i)$ is defined as

$$\{f,g\}=\sum_{j=1}^{N}\sum_{i=1}^{3}\left(\frac{\partial f}{\partial q_j^i}\frac{\partial g}{\partial p_j^i}-\frac{\partial f}{\partial p_j^i}\frac{\partial g}{\partial q_j^i}\right)=\sum_{i=1}^{3}\left(\left\langle\frac{\partial f}{\partial q^i},\frac{\partial g}{\partial p^i}\right\rangle-\left\langle\frac{\partial f}{\partial p^i},\frac{\partial g}{\partial q^i}\right\rangle\right).$$

We can prove the following assertions:

Theorem 4.1: The functions $\{F_m^{(i)}\}$, $0\leqslant i\leqslant 2$, $m\geqslant 0$, are in involution in pairs, $\{F_m^{(i)},F_l^{(j)}\}=0$, $0\leqslant i,\ j\leqslant 2$, for any $m,l\geqslant 0$.

Theorem 4.2: The $3N$ 1-forms $dF_l^{(i)}$, $1\leqslant l\leqslant N$, $0\leqslant i\leqslant 2$, are linearly independent. The proof of the above two theorems is given in the Appendix.

A direct calculation shows that the Hamiltonian function H of the system (3.12) can be rewritten as follows:

$$H=\gamma_0F_1^{(0)}+\gamma_1F_1^{(1)}+\gamma_2F_1^{(2)}+\gamma_3(\beta_1^2F_0^{(0)}-\beta_1F_0^{(1)}+F_0^{(2)})(\beta_2^2F_0^{(0)}\beta_2F_0^{(1)}+F_0^{(2)})$$
$$+\gamma_4(\beta_1^2F_0^{(0)}-\beta_1F_0^{(1)}+F_0^{(2)})(\beta_3^2F_0^{(0)}-\beta_3F_0^{(1)}$$
$$+F_0^{(2)})+\gamma_5(\beta_2^2F_0^{(0)}-\beta_2F_0^{(1)}+F_0^{(2)})(\beta_3^2F_0^{(0)}-\beta_3F_0^{(1)}+F_0^{(2)}), \tag{4.13}$$

where

$$\gamma_0=\frac{\alpha_1(\beta_2-\beta_3)\beta_1^2+\alpha_2(\beta_3-\beta_1)\beta_2^2+\alpha_3(\beta_1-\beta_2)\beta_3^2}{(\beta_1-\beta_2)(\beta_2-\beta_3)(\beta_1-\beta_3)},$$

$$\gamma_1=-\frac{\alpha_1(\beta_2-\beta_3)\beta_1+\alpha_2(\beta_3-\beta_1)\beta_2+\alpha_3(\beta_1-\beta_2)\beta_3}{(\beta_1-\beta_2)(\beta_2-\beta_3)(\beta_1-\beta_3)},$$

$$\gamma_2=\frac{\alpha_1(\beta_2-\beta_3)+\alpha_2(\beta_3-\beta_1)+\alpha_3(\beta_1-\beta_2)}{(\beta_1-\beta_2)(\beta_2-\beta_3)(\beta_1-\beta_3)},\quad \gamma_3=\frac{\alpha_2-\alpha_1}{(\beta_1-\beta_2)^3(\beta_1-\beta_3)(\beta_2-\beta_3)},$$

$$\gamma_4=\frac{\alpha_1-\alpha_3}{(\beta_1-\beta_3)^3(\beta_1-\beta_2)(\beta_2-\beta_3)},\quad \gamma_5=\frac{\alpha_3-\alpha_2}{(\beta_2-\beta_3)^3(\beta_1-\beta_2)(\beta_1-\beta_3)}.$$

Hence the integrability of Eq. (3.12) is established resorting to Theorems 4.1 and 4.2.

Theorem 4.3: The finite-dimensional Hamiltonian system (3.12) is completely integrable in the Liouville sense.

V. THE INVOLUTIVE REPRESENTATION OF SOLUTIONS

In this section, we shall give the involutive representation of solutions of the AKNS soliton hierarchy. We first introduce the Lenard gradients $g_l^{(i)}$ defined recursively by

$$Kg_{l-1}^{(i)}=Jg_l^{(i)},\quad g_l^{(i)}|_{u=0}=0,\quad 1\leqslant i\leqslant 3,\quad l\geqslant 1, \tag{5.1}$$

with

$$g_0^{(1)}=\left(\frac{u_{21}}{\alpha_1-\alpha_2},\frac{u_{12}}{\alpha_1-\alpha_2},\frac{u_{31}}{\alpha_1-\alpha_3},\frac{u_{13}}{\alpha_1-\alpha_3},0,0\right)^T, \tag{5.2}$$

$$g_0^{(2)}=\left(\frac{u_{21}}{\alpha_2-\alpha_1},\frac{u_{12}}{\alpha_2-\alpha_1},0,0,\frac{u_{32}}{\alpha_2-\alpha_3},\frac{u_{23}}{\alpha_2-\alpha_3}\right)^T, \tag{5.3}$$

$$g_0^{(3)}=\left(0,0,\frac{u_{31}}{\alpha_3-\alpha_1},\frac{u_{13}}{\alpha_3-\alpha_1},\frac{u_{32}}{\alpha_3-\alpha_2},\frac{u_{23}}{\alpha_3-\alpha_2}\right)^T. \tag{5.4}$$

The corresponding mth order vector is represented by

$$X_m(u,\omega)=J(\omega_1g_m^{(1)}+\omega_2g_m^{(2)}+\omega_3g_m^{(3)}),\quad \omega=(\omega_1,\omega_2,\omega_3), \tag{5.5}$$

from which it is easy to see that $X_m=X_m(u,\beta)$, $\beta=(\beta_1,\beta_2,\beta_3)$. Now we consider the canonical system of the $\overline{F}_m^{(1)}$-flow with $\overline{F}_m^{(1)}=-F_m^{(1)}$,

$$\frac{\partial q^i}{\partial t_m}=\frac{\partial\overline{F}_m^{(1)}}{\partial p^i},\quad \frac{\partial p^i}{\partial t_m}=-\frac{\partial\overline{F}_m^{(1)}}{\partial q^i},\quad 1\leqslant i\leqslant 3,\quad m\geqslant 1. \tag{5.6}$$

Then the systems (3.12) and (5.6) are compatible and their Hamiltonian phase flows $g_H^x, g_{F_m}^{t_m}$ commute,[26] which imply that there exists the involutive solution[26,9] of the consistent system of Eqs. (3.12) and (5.6), represented by

$$q^i(x,t_m)=q_H^x g_{F_m}^{t_m} q^i(0,0),\ \ p^i(x,t_m)=g_H^x g_{F_m}^{t_m} p^i(0,0),\ \ 1\leqslant i\leqslant 3.$$

Here $q^i(0,0), p^i(0,0),\ 1\leqslant i\leqslant 3$ are the given initial values.

Theorem 5.1: Let $\lambda_1,\ldots,\lambda_N$ be N distinct parameters. If $(q^i(x,t_1),p^i(x,t_1)),\ 1\leqslant i\leqslant 3$, is an involutive solution of the system of Eqs. (3.12) and (5.6) with $m=1$, then

$$u_{ij}(x,t_1)=\frac{\alpha_i-\alpha_j}{\beta_i-\beta_j}\langle q^i(x,t_1),p^j(x,t_1)\rangle,\ \ 1\leqslant i,\ \ j\leqslant 3,\ \ i\neq j, \tag{5.7}$$

solve the three-wave interaction equations

$$u_{ijt_1}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ijx}+\sum_{\substack{k=1\\k\neq i,j}}^{3}\left(\frac{\beta_k-\beta_i}{\alpha_k-\alpha_i}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj}+a_{ij}u_{ij},\ \ i\neq j,\ \ 1\leqslant i,\ \ j\leqslant 3, \tag{5.8}$$

where $a_{ij}=\langle q^i(0,0),p^i(0,0)\rangle-\langle q^j(0,0),p^j(0,0)\rangle,\ i\neq j,\ 1\leqslant i,\ j\leqslant 3$, are constants independent of x,t.

Proof: Using Eqs. (4.10), (4.11a), and (4.12a), we have

$$\langle q^1,p^1\rangle=\frac{F_0^{(2)}-\beta_1F_0^{(1)}+\beta_1^2F_0^{(0)}}{(\beta_1-\beta_2)(\beta_1-\beta_3)},\quad \langle q^2,p^2\rangle=\frac{-F_0^{(2)}+\beta_2F_0^{(1)}-\beta_2^2F_0^{(0)}}{(\beta_1-\beta_2)(\beta_2-\beta_3)},$$

$$\langle q^3,p^3\rangle=\frac{F_0^{(2)}-\beta_3F_0^{(1)}+\beta_3^2F_0^{(0)}}{(\beta_1-\beta_3)(\beta_2-\beta_3)},$$

which imply that $\langle q^i,p^i\rangle=\langle q^i(0,0),p^i(0,0)\rangle,\ 1\leqslant i\leqslant 3$, are constants. Noticing Eqs. (3.12) and (5.6) with $m=1$, through direct calculations we get

$$\langle q^i,p^j\rangle_x=(\alpha_i-\alpha_j)\langle\Lambda q^i,p^j\rangle-\frac{\alpha_i-\alpha_j}{\beta_i-\beta_j}a_{ij}\langle q^i,p^j\rangle+\sum_{\substack{k=1\\k\neq i,j}}^{3}\left(\frac{\alpha_k-\alpha_i}{\beta_k-\beta_i}-\frac{\alpha_k-\alpha_j}{\beta_k-\beta_j}\right)\langle q^i,p^k\rangle\langle q^k,p^j\rangle,$$

$$\langle q^i,p^j\rangle_{t_1}=(\beta_i-\beta_j)\langle\Lambda q^i,p^j\rangle,\ \ i\neq j,1\leqslant i,j\leqslant 3.$$

Combining these results together yield the desired three-wave interaction equations (5.8).

Generally, we have the following fact:

Theorem 5.2: Let $\lambda_1,\ldots,\lambda_N$ be N distinct parameters. If $(q^i(x,t_m),p^i(x,t_m)),\ 1\leqslant i\leqslant 3$, is an involutive solution of the system of Eqs. (3.12) and (5.6), then

$$u_{ij}(x,t_m)=\frac{\alpha_i-\alpha_j}{\beta_i-\beta_j}\langle q^i(x,t_m),p^j(x,t_m)\rangle,\ \ 1\leqslant i,j\leqslant 3,i\neq j, \tag{5.9}$$

satisfy the soliton equations

$$u_{t_m}=X_m(u,\beta)+X_{m-1}(u,\sigma^{(0)})+\cdots+X_0(u,\sigma^{(m-1)}),\ \ m\geqslant 0, \tag{5.10}$$

with suitably chosen constant vectors $\sigma^{(l)}=(\sigma_1^{(l)},\sigma_2^{(l)},\sigma_3^{(l)}),\ 0\leqslant l\leqslant m-1$.

Proof: By using Eqs. (5.9) and (5.6), a direct calculation gives

$$u_{t_m}=J\sum_{l=1}^{N}\lambda_l^m\nabla\lambda_l. \tag{5.11}$$

Operating with the operator $(J^{-1}K)^m$ upon the constraint $G_0=\Sigma_{l=1}^{N}\nabla\lambda_l$, we have

$$G_m+\sum_{l=0}^{m-1}(\sigma_1^{(l)}g_{m-l-1}^{(1)}+\sigma_2^{(l)}g_{m-l-1}^{(2)}+\sigma_3^{(l)}g_{m-l-1}^{(3)})=\sum_{l=1}^{N}\lambda_l^m\nabla\lambda_l, \tag{5.12}$$

where $\sigma_i^{(l)}$, $0\leqslant l\leqslant m-1$, $1\leqslant i\leqslant 3$, are integral constants. Substituting Eq. (5.12) into Eq. (5.11) and noticing Eq. (5.5), we obtain Eq. (5.10). The proof is finished.

VI. SUMMARY AND CONCLUSIONS

The procedure for the nonlinearization of the $n\times n$ matrix spectral problem and its adjoint spectral problem has been described briefly. To illustrate the general principles, the nonlinearization of the 3×3 AKNS matrix spectral problem and its adjoint spectral problem associated with the three-wave interaction equations is discussed in detail. The characteristic polynomial of solution matrix of the stationary zero-curvature equation is used to generate involutive system of enough conserved integrals of the resulting finite-dimensional Hamiltonian system. This scheme is general, which is suitable for the other systems. It is interesting that the canonical equations of the $F_m^{(1)}$-flow (up to a constant factor) given by $\mathcal{F}_\lambda^{(1)}$ of Eq. (4.1) are exactly the nonlinearized temporal parts of the Lax pairs and adjoint Lax pairs for soliton hierarchy related to the 3×3 AKNS matrix spectral problem. The solutions of the three-wave interaction equations are reduced to solving the two compatible systems of ordinary differential equations. Two generators of involutive systems of conserved integrals are introduced, from which the functional independence of conserved integrals is rigorously proved (see Appendix). We point out that the method used here is general, which is suitable for the cases of $n\times n$ matrix spectral problems. Similar results will be left to a future publication. Moreover, we may also consider construction of action-angle variables for the finite dimensional integrable system and further give the finite-band solutions for the three-wave interaction equations, which will be discussed in other papers.

APPENDIX:

1. The proof of theorem 4.1

In order to prove theorem 4.1, We first introduce the notations

$$I_\lambda^{(1)}=(\beta_2+\beta_3)\overset{11}{Q}_\lambda+(\beta_1+\beta_3)\overset{22}{Q}_\lambda+(\beta_1+\beta_2)\overset{33}{Q}_\lambda, \tag{A1}$$

$$T_\lambda^{(1)}=\sum_{1\leqslant i<j\leqslant 3}(\overset{ii}{Q}_\lambda\overset{jj}{Q}_\lambda-\overset{ij}{Q}_\lambda\overset{ji}{Q}_\lambda), \tag{A2}$$

$$I_\lambda^{(2)}=\beta_2\beta_3\overset{11}{Q}_\lambda+\beta_1\beta_3\overset{22}{Q}_\lambda+\beta_1\beta_2\overset{33}{Q}_\lambda, \tag{A3}$$

$$T_\lambda^{(2)}=\sum_{1\leqslant i<j\leqslant 3}\beta_{6-i-j}(\overset{ii}{Q}_\lambda\overset{jj}{Q}_\lambda-\overset{ij}{Q}_\lambda\overset{ji}{Q}_\lambda), \tag{A4}$$

$$R_\lambda = \begin{vmatrix} \overset{11}{Q}_\lambda & \overset{12}{Q}_\lambda & \overset{13}{Q}_\lambda \\ \overset{21}{Q}_\lambda & \overset{22}{Q}_\lambda & \overset{23}{Q}_\lambda \\ \overset{31}{Q}_\lambda & \overset{32}{Q}_\lambda & \overset{33}{Q}_\lambda \end{vmatrix}, \tag{A5}$$

and prove the following several assertions:

Lemma A.1: Let

$$I_\lambda(\sigma) = \sigma_1 \overset{11}{Q}_\lambda + \sigma_2 \overset{22}{Q}_\lambda + \sigma_3 \overset{33}{Q}_\lambda, \quad \sigma = (\sigma_1, \sigma_2, \sigma_3) \in \mathcal{C}^3. \tag{A6}$$

Then we have

$$\{I_\mu(\sigma), I_\lambda(\tau)\} = 0, \quad \tau = (\tau_1, \tau_2, \tau_3) \in \mathcal{C}^3, \tag{A7}$$

$$\begin{aligned}(\mu-\lambda)\{I_\mu(\sigma), R_\lambda\} = {} & (\sigma_1-\sigma_2)[\overset{12}{Q}_\mu(\overset{23}{Q}_\lambda \overset{31}{Q}_\lambda - \overset{21}{Q}_\lambda \overset{33}{Q}_\lambda) - \overset{21}{Q}_\mu(\overset{13}{Q}_\lambda \overset{32}{Q}_\lambda - \overset{12}{Q}_\lambda \overset{33}{Q}_\lambda)] + (\sigma_1-\sigma_3) \\ & \times[\overset{13}{Q}_\mu(\overset{21}{Q}_\lambda \overset{32}{Q}_\lambda - \overset{22}{Q}_\lambda \overset{31}{Q}_\lambda) - \overset{31}{Q}_\mu(\overset{12}{Q}_\lambda \overset{23}{Q}_\lambda - \overset{13}{Q}_\lambda \overset{22}{Q}_\lambda)] + (\sigma_2-\sigma_3) \\ & \times[\overset{23}{Q}_\mu(\overset{12}{Q}_\lambda \overset{31}{Q}_\lambda - \overset{11}{Q}_\lambda \overset{32}{Q}_\lambda) - \overset{32}{Q}_\mu(\overset{13}{Q}_\lambda \overset{21}{Q}_\lambda - \overset{11}{Q}_\lambda \overset{23}{Q}_\lambda)], \quad \forall \lambda, \mu \in \mathcal{C}. \end{aligned} \tag{A8}$$

Proof: By using the definition of the Poisson bracket, we have

$$\{\overset{ii}{Q}_\mu, \overset{ii}{Q}_\lambda\} = \left\langle \frac{\partial \overset{ii}{Q}_\mu}{\partial q^i}, \frac{\partial \overset{ii}{Q}_\lambda}{\partial p^i} \right\rangle - \left\langle \frac{\partial \overset{ii}{Q}_\mu}{\partial p^i}, \frac{\partial \overset{ii}{Q}_\lambda}{\partial q^i} \right\rangle \quad \{\overset{ii}{Q}_\mu, \overset{jj}{Q}_\lambda\} = 0, \quad (i \neq j),$$

which together with the equalities

$$\frac{\partial \overset{ij}{Q}_\lambda}{\partial q^k} = \delta_{ik}(\lambda - \Lambda)^{-1} p^j, \quad \frac{\partial \overset{ij}{Q}_\lambda}{\partial p^k} = \delta_{jk}(\lambda - \Lambda)^{-1} q^i, \quad 1 \leqslant i,j,k \leqslant 3 \tag{A9}$$

leads to

$$\{\overset{ii}{Q}_\mu, \overset{jj}{Q}_\lambda\} = 0, \quad 1 \leqslant i,j \leqslant 3. \tag{A10}$$

Resorting to Eq. (A10) and the bilinear property of the Poisson bracket, a direct calculation shows that Eq. (A7) holds. Let

$$f_1(\mu,\lambda) = (\mu-\lambda) \sum_{k=1}^{3} \sigma_k \left(\left\langle \frac{\partial \overset{kk}{Q}_\mu}{\partial q^k}, \frac{\partial R_\lambda}{\partial p^k} \right\rangle - \left\langle \frac{\partial \overset{kk}{Q}_\mu}{\partial p^k}, \frac{\partial R_\lambda}{\partial q^k} \right\rangle \right). \tag{A11}$$

It is easy to see that

$$(\mu-\lambda)\{I_\mu(\sigma), R_\lambda\} = f_1(\mu,\lambda). \tag{A12}$$

In the following calculations of the *Mathematica*, we usually write $\overset{ij}{Q}_\lambda = Q_{\lambda,ij}$ for the sake of convenience. By using the *Mathematica*, we can verify Eq. (A8),

$$a_{11}[\lambda\_] := Q_{\lambda,22}Q_{\lambda,33} - Q_{\lambda,23}Q_{\lambda,32}; \quad a_{12}[\lambda\_] := Q_{\lambda,23}Q_{\lambda,31} - Q_{\lambda,21}Q_{\lambda,33};$$

$$a_{13}[\lambda\_] := Q_{\lambda,21}Q_{\lambda,32} - Q_{\lambda,22}Q_{\lambda,31}; \quad a_{21}[\lambda\_] := Q_{\lambda,13}Q_{\lambda,32} - Q_{\lambda,12}Q_{\lambda,33};$$

$$a_{22}[\lambda\_] := Q_{\lambda,11}Q_{\lambda,33} - Q_{\lambda,13}Q_{\lambda,31}; \quad a_{23}[\lambda\_] := Q_{\lambda,12}Q_{\lambda,31} - Q_{\lambda,11}Q_{\lambda,32};$$

$$a_{31}[\lambda\_] := Q_{\lambda,12}Q_{\lambda,23} - Q_{\lambda,13}Q_{\lambda,22}; \quad a_{32}[\lambda\_] := Q_{\lambda,13}Q_{\lambda,21} - Q_{\lambda,11}Q_{\lambda,23};$$

$$a_{33}[\lambda\_] := Q_{\lambda,11}Q_{\lambda,22} - Q_{\lambda,12}Q_{\lambda,21};$$

$$\begin{aligned} f_1[\mu\_,\lambda\_] :=& \sigma_1(a_{21}[\lambda](Q_{\lambda,21}-Q_{\mu,21}) + a_{31}[\lambda](Q_{\lambda,31}-Q_{\mu,31}) - a_{12}[\lambda](Q_{\lambda,12}-Q_{\mu,12}) - a_{13}[\lambda] \\ &\times(Q_{\lambda,13}-Q_{\mu,12})) + \sigma_2(a_{12}[\lambda](Q_{\lambda,12}-Q_{\mu,12}) + a_{32}[\lambda](Q_{\lambda,32}-Q_{\mu,32}) - a_{21}[\lambda] \\ &\times(Q_{\lambda,21}-Q_{\mu,21}) - a_{23}[\lambda](Q_{\lambda,23}-Q_{\mu,23})) + \sigma_3(a_{13}[\lambda](Q_{\lambda,13}-Q_{\mu,13}) + a_{23}[\lambda] \\ &\times(Q_{\lambda,23}-Q_{\mu,23}) - a_{31}[\lambda]Q_{\lambda,31}-Q_{\mu,31}) - a_{32}[\lambda](Q_{\lambda,32}-Q_{\mu,32})); \end{aligned}$$

$$\begin{aligned} g_1 =& (\sigma_1-\sigma_2)(a_{12}[\lambda]Q_{\mu,12} - a_{21}[\lambda]Q_{\mu,21}) + (\sigma_1-\sigma_3)(a_{13}[\lambda]Q_{\mu,13} - a_{31}[\lambda]Q_{\mu,31}) \\ &+ (\sigma_2-\sigma_3)(a_{23}[\lambda]Q_{\mu,23} - a_{32}[\lambda]Q_{\mu,32}); \end{aligned}$$

$$\mathrm{Simplify}[f_1[\mu,\lambda] - g_1]$$

$$\mathrm{Out}[1] = 0.$$

Here the expression of $f_1[\mu\_,\lambda\_]$ can be obtained by substituting Eq. (A5) into Eq. (A11) and using Eq. (A9) and the equality

$$\langle(\mu-\Lambda)^{-1}(\lambda-\Lambda)^{-1}q^i,p^j\rangle = (\mu-\lambda)^{-1}(\overset{ij}{Q}_\lambda - \overset{ij}{Q}_\mu). \tag{A13}$$

Lemma A.2: Let

$$T_\lambda(\sigma) = \sum_{1\le i<j\le 3} \sigma_{6-i-j}(\overset{ii}{Q}_\lambda \overset{jj}{Q}_\lambda - \overset{ij}{Q}_\lambda \overset{ji}{Q}_\lambda), \quad \sigma = (\sigma_1,\sigma_2,\sigma_3) \in \mathcal{C}^3. \tag{A14}$$

Then we have

$$\begin{aligned} (\mu-\lambda)\{I_\mu(\sigma),T_\lambda(\tau)\} =& \tau_3(\sigma_1-\sigma_2)(\overset{21}{Q}_\mu \overset{12}{Q}_\lambda - \overset{12}{Q}_\mu \overset{21}{Q}_\lambda) + \tau_2(\sigma_1-\sigma_3) \\ &\times(\overset{31}{Q}_\mu \overset{13}{Q}_\lambda - \overset{13}{Q}_\mu \overset{31}{Q}_\lambda) + \tau_1(\sigma_2-\sigma_3)(\overset{32}{Q}_\mu \overset{23}{Q}_\lambda - \overset{23}{Q}_\mu \overset{32}{Q}_\lambda), \end{aligned} \tag{A15}$$

$$\begin{aligned} (\mu-\lambda)\{T_\mu(\tau),T_\lambda(\sigma)\} =& \tau_1\sigma_2W_1(\mu,\lambda) + \tau_2\sigma_1W_1(\lambda,\mu) + \tau_2\sigma_3W_2(\mu,\lambda) \\ &+ \tau_3\sigma_2W_2(\lambda,\mu) + \tau_1\sigma_3W_3(\mu,\lambda) + \tau_3\sigma_1W_3(\lambda,\mu), \\ &\forall\lambda,\mu\in\mathcal{C}, \tau=(\tau_1,\tau_2,\tau_3)\in\mathcal{C}^3, \end{aligned} \tag{A16}$$

where

$$\begin{aligned} W_1(\mu,\lambda) = {} & Q^{31}_\lambda(Q^{13}_\mu Q^{22}_\mu - Q^{12}_\mu Q^{23}_\mu) + Q^{13}_\lambda(Q^{32}_\mu Q^{21}_\mu - Q^{22}_\mu Q^{31}_\mu) \\ & + Q^{32}_\mu(Q^{11}_\lambda Q^{23}_\lambda - Q^{13}_\lambda Q^{21}_\lambda) + Q^{23}_\mu(Q^{12}_\lambda Q^{31}_\lambda - Q^{11}_\lambda Q^{32}_\lambda), \end{aligned}$$

$$\begin{aligned} W_2(\mu,\lambda) = {} & Q^{12}_\lambda(Q^{21}_\mu Q^{33}_\mu - Q^{23}_\mu Q^{31}_\mu) + Q^{21}_\lambda(Q^{13}_\mu Q^{32}_\mu - Q^{12}_\mu Q^{33}_\mu) \\ & + Q^{13}_\mu(Q^{22}_\lambda Q^{31}_\lambda - Q^{21}_\lambda Q^{32}_\lambda) + Q^{31}_\mu(Q^{12}_\lambda Q^{23}_\lambda - Q^{13}_\lambda Q^{22}_\lambda), \end{aligned}$$

$$\begin{aligned} W_3(\mu,\lambda) = {} & Q^{21}_\lambda(Q^{12}_\mu Q^{33}_\mu - Q^{13}_\mu Q^{32}_\mu) + Q^{12}_\lambda(Q^{23}_\mu Q^{31}_\mu - Q^{21}_\mu Q^{33}_\mu) \\ & + Q^{23}_\mu(Q^{11}_\lambda Q^{32}_\lambda - Q^{12}_\lambda Q^{31}_\lambda) + Q^{32}_\mu(Q^{13}_\lambda Q^{21}_\lambda - Q^{11}_\lambda Q^{23}_\lambda). \end{aligned}$$

Proof: In a way similar to the proof of Eq. (A8), we can verify Eq. (A15). Now we prove Eq. (A16). Let

$$f_2(\mu,\lambda) = (\mu-\lambda)\sum_{k=1}^{3}\left(\left\langle \frac{\partial T_\mu(\tau)}{\partial q^k}, \frac{\partial T_\lambda(\sigma)}{\partial p^k}\right\rangle - \left\langle \frac{\partial T_\mu(\tau)}{\partial p^k}, \frac{\partial T_\lambda(\sigma)}{\partial q^k}\right\rangle\right). \tag{A17}$$

Then we have

$$(\mu-\lambda)\{T_\mu(\tau), T_\mu(\sigma)\} = f_2(\mu,\lambda). \tag{A18}$$

In the following, we shall prove by using the *Mathematica* that Eq. (A16) holds

$$b_1[\lambda\_] = \sigma_3 Q_{\lambda,22} + \sigma_2 Q_{\lambda,33}; \quad b_2[\lambda\_] = \sigma_3 Q_{\lambda,11} + \sigma_1 Q_{\lambda,33};$$

$$b_3[\lambda\_] = \sigma_2 Q_{\lambda,11} + \sigma_1 Q_{\lambda,22};$$

$$c_1[\mu\_] = \tau_3 Q_{\mu,22} + \tau_2 Q_{\mu,33}; \quad c_2[\mu\_] = \tau_3 Q_{\mu,11} + \tau_1 Q_{\mu,33};$$

$$c_3[\mu\_] = \tau_2 Q_{\mu,11} + \tau_1 Q_{\mu,22};$$

$$\begin{aligned} f_2[\mu\_,\lambda\_] := {} & c_1[\mu](b_1[\lambda](Q_{\lambda,11} - Q_{\mu,11}) - \sigma_3 Q_{\lambda,12}(Q_{\lambda,21} - Q_{\mu,21}) - \sigma_2 Q_{\lambda,13}(Q_{\lambda,31} - Q_{\mu,31})) \\ & - \tau_3 Q_{\mu,21}(b_1[\lambda](Q_{\lambda,12} - Q_{\mu,12}) - \sigma_3 Q_{\lambda,12}(Q_{\lambda,22} - Q_{\mu,22}) - \sigma_2 Q_{\lambda,13}(Q_{\lambda,32} - Q_{\mu,32})) \\ & - \tau_2 Q_{\mu,31}(b_1[\lambda](Q_{\lambda,13} - Q_{\mu,13}) - \sigma_3 Q_{\lambda,12}(Q_{\lambda,23} - Q_{\mu,23}) - \sigma_2 Q_{\lambda,13}(Q_{\lambda,33} - Q_{\mu,33})) \\ & + c_2[\mu](b_2[\lambda](Q_{\lambda,22} - Q_{\mu,22}) - \sigma_3 Q_{\lambda,21}(Q_{\lambda,12} - Q_{\mu,12}) - \sigma_1 Q_{\lambda,23}(Q_{\lambda,32} - Q_{\mu,32})) \\ & - \tau_3 Q_{\mu,12}(b_2[\lambda](Q_{\lambda,21} - Q_{\mu,21}) - \sigma_3 Q_{\lambda,21}(Q_{\lambda,11} - Q_{\mu,11}) - \sigma_1 Q_{\lambda,23}(Q_{\lambda,31} - Q_{\mu,31})) \\ & - \tau_1 Q_{\mu,32}(b_2[\lambda](Q_{\lambda,23} - Q_{\mu,23}) - \sigma_3 Q_{\lambda,21}(Q_{\lambda,13} - Q_{\mu,13}) - \sigma_1 Q_{\lambda,23}(Q_{\lambda,33} - Q_{\mu,33})) \\ & + c_3[\mu](b_3[\lambda](Q_{\lambda,33} - Q_{\mu,33}) - \sigma_2 Q_{\lambda,31}(Q_{\lambda,13} - Q_{\mu,13}) - \sigma_1 Q_{\lambda,32}(Q_{\lambda,23} - Q_{\mu,23})) \\ & - \tau_2 Q_{\mu,13}(b_3[\lambda](Q_{\lambda,31} - Q_{\mu,31}) - \sigma_2 Q_{\lambda,31}(Q_{\lambda,11} - Q_{\mu,11}) - \sigma_1 Q_{\lambda,32}(Q_{\lambda,21} - Q_{\mu,21})) \\ & - \tau_1 Q_{\mu,23}(b_3[\lambda](Q_{\lambda,32} - Q_{\mu,32}) - \sigma_2 Q_{\lambda,31}(Q_{\lambda,12} - Q_{\mu,12}) - \sigma_1 Q_{\lambda,32}(Q_{\lambda,22} - Q_{\mu,22})) \\ & + b_1[\lambda](c_1[\mu](Q_{\mu,11} - Q_{\lambda,11}) - \tau_3 Q_{\mu,12}(Q_{\mu,21} - Q_{\lambda,21}) - \tau_2 Q_{\mu,13}(Q_{\mu,31} - Q_{\lambda,31})) \\ & - \sigma_3 Q_{\lambda,21}(c_1[\mu](Q_{\mu,12} - Q_{\lambda,12}) - \tau_3 Q_{\mu,12}(Q_{\mu,22} - Q_{\lambda,22}) - \tau_2 Q_{\mu,13}(Q_{\mu,32} - Q_{\lambda,32})) \end{aligned}$$

$$-\sigma_2 Q_{\lambda,31}(c_1[\mu](Q_{\mu,13}-Q_{\lambda,13})-\tau_3 Q_{\mu,12}(Q_{\mu,23}-Q_{\lambda,23})-\tau_2 Q_{\mu,13}(Q_{\mu,33}-Q_{\lambda,33}))$$
$$+b_2[\lambda](c_2[\mu](Q_{\mu,22}-Q_{\lambda,22})-\tau_3 Q_{\mu,21}(Q_{\mu,12}-Q_{\lambda,12})-\tau_1 Q_{\mu,23}(Q_{\mu,32}-Q_{\lambda,32}))$$
$$-\sigma_3 Q_{\lambda,12}(c_2[\mu](Q_{\mu,21}-Q_{\lambda,21})-\tau_3 Q_{\mu,21}(Q_{\mu,11}-Q_{\lambda,11})-\tau_1 Q_{\mu,23}(Q_{\mu,31}-Q_{\lambda,31}))$$
$$-\sigma_1 Q_{\lambda,32}(c_2[\mu](Q_{\mu,23}-Q_{\lambda,23})-\tau_3 Q_{\mu,21}(Q_{\mu,13}-Q_{\lambda,13})-\tau_1 Q_{\mu,23}(Q_{\mu,33}-Q_{\lambda,33}))$$
$$+b_3[\lambda](c_3[\mu](Q_{\mu,33}-Q_{\lambda,33})-\tau_2 Q_{\mu,31}(Q_{\mu,13}-Q_{\lambda,13})-\tau_1 Q_{\mu,32}(Q_{\mu,23}-Q_{\lambda,23}))$$
$$-\sigma_2 Q_{\lambda,13}(c_3[\mu](Q_{\mu,31}-Q_{\lambda,31})-\tau_2 Q_{\mu,31}(Q_{\mu,11}-Q_{\lambda,11})-\tau_1 Q_{\mu,32}(Q_{\mu,21}-Q_{\lambda,21}))$$
$$-\sigma_1 Q_{\lambda,23}(c_3[\mu](Q_{\mu,32}-Q_{\lambda,32})-\tau_2 Q_{\mu,31}(Q_{\mu,12}-Q_{\lambda,12})-\tau_1 Q_{\mu,32}(Q_{\mu,22}$$
$$-Q_{\lambda,22}));$$

$$W_1[\mu\_,\lambda\_]:=a_{13}[\mu]Q_{\lambda,13}-a_{31}[\mu]Q_{\lambda,31}-a_{32}[\lambda]Q_{\mu,32}+a_{23}[\lambda]Q_{\mu,23};$$

$$W_2[\mu\_,\lambda\_]:=a_{21}[\mu]Q_{\lambda,21}-a_{12}[\mu]Q_{\lambda,12}-a_{13}[\lambda]Q_{\mu,13}+a_{31}[\lambda]Q_{\mu,31};$$

$$W_3[\mu\_,\lambda\_]:=a_{12}[\mu]Q_{\lambda,12}-a_{21}[\mu]Q_{\lambda,21}-a_{23}[\lambda]Q_{\mu,23}+a_{32}[\lambda]Q_{\mu,32};$$

$$g_2=\tau_1\sigma_2 W_1[\mu,\lambda]+\tau_2\sigma_1 W_1[\lambda,\mu]+\tau_2\sigma_3 W_2[\mu,\lambda]+\tau_3\sigma_2 W_2[\lambda,\mu]$$
$$+\tau_1\sigma_3 W_3[\mu,\lambda]+\tau_3\sigma_1 W_3[\lambda,\mu];$$

$$\text{Simplify}[f_2[\mu,\lambda]-g_2]$$

$$\text{Out}[2]=0.$$

Lemma A.3: Under the same assumption as the Lemma A.2, we have

$$(\mu-\lambda)\{T_\mu(\sigma),R_\lambda\}=\sigma_1[Y_1(\mu,\lambda)-Y_2(\mu,\lambda)]+\sigma_2[Y_3(\mu,\lambda)-Y_1(\mu,\lambda)]$$
$$+\sigma_3[Y_2(\mu,\lambda)-Y_3(\mu,\lambda)],$$
$$\forall\lambda,\mu\in\mathcal{C}. \tag{A19}$$

where

$$Y_1(\mu,\lambda)=(\overset{21}{Q}_\mu\overset{33}{Q}_\mu-\overset{23}{Q}_\mu\overset{31}{Q}_\mu)(\overset{13}{Q}_\lambda\overset{32}{Q}_\lambda-\overset{12}{Q}_\lambda\overset{33}{Q}_\lambda)+(\overset{13}{Q}_\mu\overset{32}{Q}_\mu-\overset{12}{Q}_\mu\overset{33}{Q}_\mu)(\overset{23}{Q}_\lambda\overset{31}{Q}_\lambda-\overset{21}{Q}_\lambda\overset{33}{Q}_\lambda),$$

$$Y_2(\mu,\lambda)=(\overset{22}{Q}_\mu\overset{13}{Q}_\mu-\overset{12}{Q}_\mu\overset{23}{Q}_\mu)(\overset{21}{Q}_\lambda\overset{32}{Q}_\lambda-\overset{22}{Q}_\lambda\overset{31}{Q}_\lambda)+(\overset{21}{Q}_\mu\overset{32}{Q}_\mu-\overset{22}{Q}_\mu\overset{31}{Q}_\mu)(\overset{12}{Q}_\lambda\overset{23}{Q}_\lambda-\overset{13}{Q}_\lambda\overset{22}{Q}_\lambda),$$

$$Y_3(\mu,\lambda)=(\overset{11}{Q}_\mu\overset{32}{Q}_\mu-\overset{12}{Q}_\mu\overset{31}{Q}_\mu)(\overset{13}{Q}_\lambda\overset{21}{Q}_\lambda-\overset{11}{Q}_\lambda\overset{23}{Q}_\lambda)+(\overset{13}{Q}_\mu\overset{21}{Q}_\mu-\overset{11}{Q}_\mu\overset{23}{Q}_\mu)(\overset{12}{Q}_\lambda\overset{31}{Q}_\lambda-\overset{11}{Q}_\lambda\overset{32}{Q}_\lambda).$$

Proof: Let

$$f_3(\mu,\lambda)=(\mu-\lambda)\sum_{k=1}^{3}\left(\left\langle\frac{\partial T(\sigma)_\mu}{\partial q^k},\frac{\partial R_\lambda}{\partial p^k}\right\rangle-\left\langle\frac{\partial T(\sigma)_\mu}{\partial p^k},\frac{\partial R_\lambda}{\partial q^k}\right\rangle\right). \tag{A20}$$

Then we have

$$(\mu-\lambda)\{T(\sigma)_\mu,R_\lambda\}=f_3(\mu,\lambda). \tag{A21}$$

With the help of the *Mathematica*, we can verify Eq. (A19)

$$
\begin{aligned}
f_3[\mu\_,\lambda\_] := & b_1[\mu](a_{11}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{21}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{31}[\lambda](Q_{\lambda,31}-Q_{\mu,31}))\\
&-\sigma_3 Q_{\mu,21}(a_{11}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{21}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{31}[\lambda](Q_{\lambda,32}-Q_{\mu,32}))\\
&-\sigma_2 Q_{\mu,31}(a_{11}[\lambda](Q_{\lambda,13}-Q_{\mu,13})+a_{21}[\lambda](Q_{\lambda,23}-Q_{\mu,23})+a_{31}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&-b_1[\mu](a_{11}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{12}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{13}[\lambda](Q_{\lambda,13}-Q_{\mu,13}))\\
&+\sigma_3 Q_{\mu,12}(a_{11}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{12}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{13}[\lambda](Q_{\lambda,23}-Q_{\mu,23}))\\
&+\sigma_2 Q_{\mu,13}(a_{11}[\lambda](Q_{\lambda,31}-Q_{\mu,31})+a_{12}[\lambda](Q_{\lambda,32}-Q_{\mu,32})+a_{13}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&+b_2[\mu](a_{12}[\lambda](Q_{\lambda,2}-Q_{\mu,12})+a_{22}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{32}[\lambda](Q_{\lambda,32}-Q_{\mu,32}))\\
&-\sigma_3 Q_{\mu,12}(a_{12}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{22}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{32}[\lambda](Q_{\lambda,31}-Q_{\mu,31}))\\
&-\sigma_1 Q_{\mu,32}(a_{12}[\lambda](Q_{\lambda,13}-Q_{\mu,13})+a_{22}[\lambda](Q_{\lambda,23}-Q_{\mu,23})+a_{32}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&-b_2[\mu](a_{21}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{22}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{23}[\lambda](Q_{\lambda,23}-Q_{\mu,23}))\\
&+\sigma_3 Q_{\mu,21}(a_{21}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{22}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{23}[\lambda](Q_{\lambda,13}-Q_{\mu,13}))\\
&+\sigma_1 Q_{\mu,23}(a_{21}[\lambda](Q_{\lambda,31}-Q_{\mu,31})+a_{22}[\lambda](Q_{\lambda,32}-Q_{\mu,32})+a_{23}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&+b_3[\mu](a_{13}[\lambda](Q_{\lambda,13}-Q_{\mu,13})+a_{23}[\lambda](Q_{\lambda,23}-Q_{\mu,23})+a_{33}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&-\sigma_2 Q_{\mu,13}(a_{13}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{23}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{33}[\lambda](Q_{\lambda,31}-Q_{\mu,31}))\\
&-\sigma_1 Q_{\mu,23}(a_{13}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{23}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{33}[\lambda](Q_{\lambda,32}-Q_{\mu,32}))\\
&-b_3[\mu](a_{31}[\lambda](Q_{\lambda,31}-Q_{\mu,31})+a_{32}[\lambda](Q_{\lambda,32}-Q_{\mu,32})+a_{33}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&+\sigma_2 Q_{\mu,31}(a_{31}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{32}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{33}[\lambda](Q_{\lambda,13}-Q_{\mu,13}))\\
&+\sigma_1 Q_{\mu,32}(a_{31}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{32}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{33}[\lambda](Q_{\lambda,23}-Q_{\mu,23}));
\end{aligned}
$$

$$Y_1=a_{21}[\mu]a_{12}[\lambda]-a_{12}[\mu]a_{21}[\lambda];\quad Y_2=a_{13}[\mu]a_{31}[\lambda]-a_{31}[\mu]a_{13}[\lambda];$$

$$Y_3=a_{32}[\mu]a_{23}[\lambda]-a_{23}[\mu]a_{32}[\lambda];\quad g_3=\sigma_1(Y_1-Y_2)+\sigma_2(Y_3-Y_1)+\sigma_3(Y_2-Y_3);$$

$$\text{Simplify}[f_3[\mu,\lambda]-g_3]$$

$$\text{Out}[3]=0.$$

Lemma A.4:

$$\{T_\mu^{(1)},T_\lambda^{(1)}\}=0,\quad \{R_\mu,R_\lambda\}=0,\quad \{T_\mu^{(1)},R_\lambda\}=0,\quad \forall\lambda,\mu\in\mathcal{C}. \tag{A22}$$

Proof: By Eqs. (A16) and (A19), we get that

$$\{T_\mu^{(1)},T_\lambda^{(1)}\}=\{T_\mu(\tau),T_\lambda(\sigma)\}|_{\tau=\sigma=(1,1,1)}=0,\quad \{T_\mu^{(1)},R_\lambda\}=\{T_\mu(\sigma),R_\lambda\}|_{\sigma=(1,1,1)}=0.$$

Let

$$f_4(\mu,\lambda)=(\mu-\lambda)\sum_{k=1}^{3}\left(\left\langle\frac{\partial R_\mu}{\partial q^k},\frac{\partial R_\lambda}{\partial p^k}\right\rangle\right). \tag{A23}$$

It is easy to see that

$$(\mu-\lambda)\{R_\mu,R_\lambda\}=f_4(\mu,\lambda)+f_4(\lambda,\mu). \tag{A24}$$

The second expression of Eq. (A22) can be verified by the *Mathematica*,

$$
\begin{aligned}
f_4[\mu\_,\lambda\_]:=a_{11}[\mu](&a_{11}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{11}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{31}[\lambda](Q_{\lambda,31}-Q_{\mu,31}))\\
&+a_{12}[\mu](a_{11}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{21}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{31}[\lambda](Q_{\lambda,32}-Q_{\mu,32}))\\
&+a_{13}[\mu](a_{11}[\lambda](Q_{\lambda,13}-Q_{\mu,13})+a_{21}[\lambda](Q_{\lambda,23}-Q_{\mu,23})+a_{31}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&+a_{21}[\mu](a_{12}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{22}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{32}[\lambda](Q_{\lambda,31}-Q_{\mu,31}))\\
&+a_{22}[\mu](a_{12}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{22}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{32}[\lambda](Q_{\lambda,32}-Q_{\mu,32}))\\
&+a_{23}[\mu](a_{12}[\lambda](Q_{\lambda,13}-Q_{\mu,13})+a_{22}[\lambda](Q_{\lambda,23}-Q_{\mu,23})+a_{32}[\lambda](Q_{\lambda,33}-Q_{\mu,33}))\\
&+a_{31}[\mu](a_{13}[\lambda](Q_{\lambda,11}-Q_{\mu,11})+a_{23}[\lambda](Q_{\lambda,21}-Q_{\mu,21})+a_{33}[\lambda](Q_{\lambda,31}-Q_{\mu,31}))\\
&+a_{32}[\mu](a_{13}[\lambda](Q_{\lambda,12}-Q_{\mu,12})+a_{23}[\lambda](Q_{\lambda,22}-Q_{\mu,22})+a_{33}[\lambda](Q_{\lambda,32}-Q_{\mu,32}))\\
&+a_{33}[\mu](a_{13}[\lambda](Q_{\lambda,13}-Q_{\mu,13})+a_{23}[\lambda](Q_{\lambda,23}-Q_{\mu,23})+a_{33}[\lambda](Q_{\lambda,33}-Q_{\mu,33}));
\end{aligned}
$$

$$\mathrm{Simplify}[f_4[\mu,\lambda]+f_4[\lambda,\mu]]$$

$$\mathrm{Out}[4]=0.$$

Proposition A.5:

$$\{\hat{\mathcal{F}}_\mu^{(i)},\hat{\mathcal{F}}_\lambda^{(j)}\}=0,\quad 1\leqslant i,j\leqslant 3,\forall\lambda,\mu\in\mathcal{C}, \tag{A25}$$

with $\hat{\mathcal{F}}_\lambda^{(1)}=I_\lambda^{(1)}+T_\lambda^{(1)}$, $\hat{\mathcal{F}}_\lambda^{(2)}=I_\lambda^{(2)}+T_\lambda^{(2)}+R_\lambda$.

Proof: It is easy to see that the equalities

$$\hat{\mathcal{F}}_\lambda^{(0)}=I_\lambda(\sigma)|_{\sigma=(1,1,1)},\quad I_\lambda^{(1)}=I_\lambda(\sigma)|_{\sigma=(\beta_2+\beta_3,\beta_1+\beta_3,\beta_1+\beta_2)},$$

$$I_\lambda^{(2)}=I_\lambda(\sigma)|_{\sigma=(\beta_2\beta_3,\beta_1\beta_3,\beta_1\beta_2)},\quad T_\lambda^{(1)}=T_\lambda(\sigma)|_{\sigma=(1,1,1)},\quad T_\lambda^{(2)}=T_\lambda(\sigma)|_{\sigma=(\beta_1,\beta_2,\beta_3)}.$$

Obviously $\{\hat{\mathcal{F}}_\mu^{(0)},\hat{\mathcal{F}}_\lambda^{(0)}\}=0$ from Eq. (A7). Using Eq. (A7) and the symmetry of Eq. (A15), we obtain

$$\{I_\mu^{(i)},I_\lambda^{(i)}\}=0,\quad \{I_\mu^{(i)},T_\lambda^{(i)}\}+\{T_\mu^{(i)},I_\lambda^{(i)}\}=0,\quad i=1,2, \tag{A26}$$

which together with the first expression of Eq. (A22) imply $\{\hat{\mathcal{F}}_\mu^{(1)},\hat{\mathcal{F}}_\lambda^{(1)}\}=0$ resorting to the bilinear property of the Poisson bracket. Noticing Eqs. (A8), (A16), and (A19), we get that

$$\{I_\mu^{(2)},R_\lambda\}+\{R_\mu,I_\lambda^{(2)}\}+\{T_\mu^{(2)},T_\lambda^{(2)}\}=0,\quad \{T_\mu^{(2)},R_\lambda\}+\{R_\mu,T_\lambda^{(2)}\}=0, \tag{A27}$$

which together with Eqs. (A26) and (A22) lead up to $\{\hat{\mathcal{F}}_\mu^{(2)},\hat{\mathcal{F}}_\lambda^{(2)}\}=0$. In view of Eqs. (A7), (A8), and (A15), we obtain

$$\{\hat{\mathcal{F}}_\mu^{(0)},I_\lambda^{(i)}\}=0,\quad \{\hat{\mathcal{F}}_\mu^{(0)},R_\lambda\}=0,\quad \{\hat{\mathcal{F}}_\mu^{(0)},T^{(i)}\}=0,\quad i=1,2,$$

$$\{I_\mu^{(1)},I_\lambda^{(2)}\}=0,\quad \{I_\mu^{(1)},R_\lambda\}+\{T_\mu^{(1)},T_\lambda^{(2)}\}=0,\quad \{I_\mu^{(1)},T_\lambda^{(2)}\}+\{T_\mu^{(1)},I_\lambda^{(2)}\}=0. \tag{A28}$$

By using Eq. (A28) and the third expression of Eq. (A22), we have

$$\{\hat{\mathcal{F}}_\mu^{(0)},\hat{\mathcal{F}}_\lambda^{(i)}\}=0,\quad \{\hat{\mathcal{F}}_\mu^{(1)},\hat{\mathcal{F}}_\lambda^{(2)}\}=0,\quad i=1,2.$$

The proof is completed.

Equation (4.9) and Proposition A.5 imply Theorem 4.1.

2. Two generators and the proof of Theorem 4.2

To prove Theorem 4.2, we introduce two generators of involutive systems of conserved integrals

$$\Gamma_l^{(ij)}=\sum_{\substack{k=1\\k\neq l}}^{N}\frac{B_{lk}^{(ij)}}{\lambda_l-\lambda_k},\quad B_{lk}^{(ij)}=(q_l^iq_k^j-q_k^iq_l^j)(p_l^ip_k^j-p_k^ip_l^j),\tag{A29}$$

$$\Upsilon_l=\sum_{\substack{s=1\\s\neq k}}^{N}\sum_{\substack{k=1\\k\neq l}}^{N}\frac{A_{lks}}{(\lambda_l-\lambda_k)(\lambda_k-\lambda_s)},\quad A_{lks}=\begin{vmatrix}q_l^1 & q_l^2 & q_l^3\\ q_k^1 & q_k^2 & q_k^3\\ q_s^1 & q_s^2 & q_s^3\end{vmatrix}\begin{vmatrix}p_l^1 & p_l^2 & p_l^3\\ p_k^1 & p_k^2 & p_k^3\\ p_s^1 & p_s^2 & p_s^3\end{vmatrix},\tag{A30}$$

which are two natural generalizations of the 2×2 case.[22]

Proposition A.6:

$$\overset{ii}{Q}_\lambda\overset{jj}{Q}_\lambda-\overset{ij}{Q}_\lambda\overset{ji}{Q}_\lambda=\sum_{l=1}^{N}\frac{\Gamma_l^{(ij)}}{\lambda-\lambda_l},\quad 1\leqslant i,j\leqslant 3,\tag{A31}$$

$$R_\lambda=\sum_{l=1}^{N}\frac{\Upsilon_l}{\lambda-\lambda_l}.\tag{A32}$$

Proof: Put the partial-fraction expansion of $\overset{ij}{Q}_\lambda$, i.e.,

$$\overset{ij}{Q}_\lambda=\sum_{l=1}^{N}\frac{q_l^ip_l^j}{\lambda-\lambda_l},\tag{A33}$$

into the right-hand side of Eq. (A31). The left-hand side of Eq. (A31) is obtained through direct calculations on account of

$$\frac{1}{(\lambda-\lambda_l)(\lambda-\lambda_k)}=\frac{1}{\lambda_l-\lambda_k}\left(\frac{1}{\lambda-\lambda_l}-\frac{1}{\lambda-\lambda_k}\right).\tag{A34}$$

Substituting Eq. (A33) into Eq. (A5) yields

$$\begin{aligned}R_\lambda&=\sum_{l=1}^{N}\sum_{k=1}^{N}\sum_{s=1}^{N}\frac{q_l^1q_k^2q_s^3}{(\lambda-\lambda_l)(\lambda-\lambda_k)(\lambda-\lambda_s)}\begin{vmatrix}p_l^1 & p_l^2 & p_l^3\\ p_k^1 & p_k^2 & p_k^3\\ p_s^1 & p_s^2 & p_s^3\end{vmatrix}\\&=\frac{1}{6}\sum_{l=1}^{N}\sum_{k=1}^{N}\sum_{s=1}^{N}\frac{A_{lks}}{(\lambda-\lambda_l)(\lambda-\lambda_k)(\lambda-\lambda_s)}.\end{aligned}$$

Resorting to Eq. (A34), we get

$$
\begin{aligned}
R_\lambda &= \frac{1}{6}\sum_l \sum_k \sum_{s\neq k} \frac{A_{lks}}{(\lambda_k-\lambda_s)(\lambda-\lambda_l)}\left(\frac{1}{\lambda-\lambda_k}-\frac{1}{\lambda-\lambda_s}\right)\\
&= \frac{1}{6}\sum_l \sum_{k\neq l} \sum_{s\neq k,l} \frac{A_{lks}}{\lambda_k-\lambda_s}\left[\frac{1}{\lambda_l-\lambda_k}\left(\frac{1}{\lambda-\lambda_l}-\frac{1}{\lambda-\lambda_k}\right)-\frac{1}{\lambda_l-\lambda_s}\left(\frac{1}{\lambda-\lambda_l}-\frac{1}{\lambda-\lambda_s}\right)\right]\\
&= \frac{2}{6}\sum_{l=1}^N \frac{\Upsilon_l}{\lambda-\lambda_l}+\frac{2}{6}\sum_l \sum_k \sum_{s\neq k,l} \frac{A_{lks}}{(\lambda_k-\lambda_s)(\lambda_l-\lambda_s)(\lambda-\lambda_s)}\\
&= \frac{2}{6}\sum_{l=1}^N \frac{\Upsilon_l}{\lambda-\lambda_l}+\frac{2}{6}\sum_l \sum_{k\neq l} \sum_{s\neq k,l} \frac{A_{lks}}{(\lambda-\lambda_s)(\lambda_l-\lambda_k)}\left(\frac{1}{\lambda_k-\lambda_s}-\frac{1}{\lambda_l-\lambda_s}\right)\\
&= \sum_{l=1}^N \frac{\Upsilon_l}{\lambda-\lambda_l},
\end{aligned}
$$

where it is used that $A_{llk}=A_{lkl}=A_{lkk}=0$, $A_{lks}=A_{lsk}=A_{skl}$. The proof is completed.

Proposition A.7: Let $E_1^{(i)},\ldots,E_N^{(i)}$ $(0\leqslant i\leqslant 2)$ defined as follows:

$$E_l^{(0)}=q_l^1p_l^1+q_l^2p_l^2+q_l^3p_l^3, \tag{A35}$$

$$E_l^{(1)}=(\beta_2+\beta_3)q_l^1p_l^1+(\beta_1+\beta_3)q_l^2p_l^2+(\beta_1+\beta_2)q_l^3p_l^3+\Gamma_l^{(12)}+\Gamma_l^{(13)}+\Gamma_l^{(23)}, \tag{A36}$$

$$E_l^{(2)}=\beta_2\beta_3q_l^1p_l^1+\beta_1\beta_3q_l^2p_l^2+\beta_1\beta_2q_l^3p_l^3+\beta_3\Gamma_l^{(12)}+\beta_2\Gamma_l^{(13)}+\beta_1\Gamma_l^{(23)}+\Upsilon_l. \tag{A37}$$

Then

$$F_m^{(i)}=\sum_{l=1}^N \lambda_l^m E_l^{(i)},\quad 0\leqslant i\leqslant 2. \tag{A38}$$

Proof: By Proposition A.6 and Eq. (A33), it is easy to see that

$$\mathcal{F}_\lambda^{(i)}=\sum_{l=1}^N \frac{E_l^{(i)}}{\lambda-\lambda_l}. \tag{A39}$$

Expanding $(\lambda-\lambda_l)^{-1}$ as a power series in λ^{-1} and substituting into Eq. (A39), we obtain

$$\mathcal{F}_\lambda^{(i)}=\sum_{l=0}^\infty \lambda^{-m-1}\sum_{l=1}^N \lambda_l^m E_l^{(i)},$$

which together with Eq. (4.9) gives $F_m^{(i)}=\sum_{l=1}^N\lambda_l^mE_l^{(i)}$.

Proposition A.8: The $3N$ 1-forms $dE_l^{(i)}$, $1\leqslant l\leqslant N$, $0\leqslant i\leqslant 2$, are linearly independent.

Proof: Suppose that there exist $3N$ constants $c_l^{(i)}$, $1\leqslant l\leqslant N$, $0\leqslant i\leqslant 2$, satisfying

$$\sum_{l=1}^N (c_l^{(0)}dE_l^{(0)}+c_l^{(1)}dE_l^{(1)}+c_l^{(2)}dE_l^{(2)})=0. \tag{A40}$$

Then Eq. (A40) implies

$$\sum_{l=1}^N \left(c_l^{(0)}\frac{\partial E_l^{(0)}}{\partial p^i}+c_l^{(1)}\frac{\partial E_l^{(1)}}{\partial p^i}+c_l^{(2)}\frac{\partial E_l^{(2)}}{\partial p^i}\right)=0,\quad 1\leqslant i\leqslant 3. \tag{A41}$$

In order to deduce all constants $c_l^{(i)}=0$, $1\leqslant l\leqslant N$, $0\leqslant i\leqslant 2$, we demand the following equalities, which can be calculated directly:

$$\frac{\partial^2 E_l^{(0)}}{\partial q^i \partial p^i}=(\underbrace{0,\ldots,0}_{l-1},1,\underbrace{0,\ldots,0}_{N-l})^T,\quad 1\leqslant i\leqslant 3, \tag{A42}$$

$$\frac{\partial^2 \Gamma_l^{(ij)}}{\partial q^i \partial p^i}=\left(\frac{q_l^j p_l^j}{\lambda_l-\lambda_1},\ldots,\frac{q_l^j p_l^j}{\lambda_l-\lambda_{l-1}},\sum_{\substack{k=1\\k\neq l}}^N \frac{q_k^j p_k^j}{\lambda_l-\lambda_k},\frac{q_l^j p_l^j}{\lambda_l-\lambda_{l+1}},\ldots,\frac{q_l^j p_l^j}{\lambda_l-\lambda_N}\right)^T, \tag{A43a}$$

$$\frac{\partial^2 \Gamma_l^{(ij)}}{\partial q^j \partial p^j}=\left(\frac{q_l^i p_l^i}{\lambda_l-\lambda_1},\ldots,\frac{q_l^i p_l^i}{\lambda_l-\lambda_{l-1}},\sum_{\substack{k=1\\k\neq l}}^N \frac{q_k^i p_k^i}{\lambda_l-\lambda_k},\frac{q_l^i p_l^i}{\lambda_l-\lambda_{l+1}},\ldots,\frac{q_l^i p_l^i}{\lambda_l-\lambda_N}\right)^T,\quad 1\leqslant i<j\leqslant 3, \tag{A43b}$$

$$\partial^2 \Gamma_l^{(ij)}/(\partial q^k \partial p^k)=0,\quad k\neq i,j. \tag{A43c}$$

Now we introduce the operator

$$D_s^{(j)}=\mathrm{diag}(\underbrace{\partial^2/(\partial q_s^j \partial p_s^j),\ldots,\partial^2/(\partial q_s^j \partial p_s^j)}_{N}),\quad 1\leqslant j\leqslant 3, 1\leqslant s\leqslant N.$$

Then we have from Eq. (A43) that

$$D_s^{(j)}\frac{\partial^2 \Gamma_l^{(ij)}}{\partial q^i \partial p^i}=\begin{cases}\left(\frac{1}{\lambda_l-\lambda_1},\ldots,\frac{1}{\lambda_l-\lambda_{l-1}},0,\frac{1}{\lambda_l-\lambda_{l+1}},\ldots,\frac{1}{\lambda_l-\lambda_N}\right)^T, & l=s\\ 0,\quad l\neq s, 1\leqslant i<j\leqslant 3,\end{cases} \tag{A44a}$$

$$D_s^{(i)}\frac{\partial^2 \Gamma_l^{(1j)}}{\partial q^1 \partial p^1}=0,\quad D_s^{(j)}\frac{\partial^2 \Gamma_l^{(23)}}{\partial q^1 \partial p^1}=0,\quad D_s^{(3)}\frac{\partial^2 \Gamma_l^{(1j)}}{\partial q^2 \partial p^2}=0,\quad 2\leqslant i,j\leqslant 3, i\neq j. \tag{A44b}$$

Acting with the operator $D_s^{(j)}\partial/(\partial q^i)|_{q=p=0}$, $(1\leqslant i<j\leqslant 3, 1\leqslant s\leqslant N)$, upon Eq. (A41), we get

$$c_s^{(1)}+\beta_1 c_s^{(2)}=0,\quad c_s^{(1)}+\beta_2 c_s^{(2)}=0,\quad c_s^{(1)}+\beta_3 c_s^{(2)}=0,\quad 1\leqslant s\leqslant N, \tag{A45}$$

in view of Eq. (A44) and the following equality:

$$D_s^{(j)}\frac{\partial^2 \Upsilon_l}{\partial q^i \partial p^i}\bigg|_{q=p=0}=0,\quad q=(q^1,q^2,q^3),\quad p=(p^1,p^2,p^3),\quad 1\leqslant i,j\leqslant 3, 1\leqslant l,s\leqslant N.$$

Equations (A45) imply $c_s^{(1)}=c_s^{(2)}=0$, $1\leqslant s\leqslant N$. Operating with $\partial/(\partial q^i)$ on Eq. (A41) and noticing $c_l^{(1)}=c_l^{(2)}=0$, we derive $c_l^{(0)}=0$, $1\leqslant l\leqslant N$. Hence the $3N$ 1-forms $dE_l^{(i)}$, $0\leqslant i\leqslant 2$, $1\leqslant l\leqslant N$, are linearly independent.

The proof of Theorem 4.2: Assume that there exist $3N$ constants $b_m^{(i)}$, $1\leqslant m\leqslant N$, $0\leqslant i\leqslant 2$, so that

$$\sum_{m=1}^N (b_m^{(0)}dF_m^{(0)}+b_m^{(1)}dF_m^{(1)}+b_m^{(2)}dF_m^{(2)})=0. \tag{A46}$$

Substituting Eq. (A38) into Eq. (A46) and noting the independence of the $dE_l^{(i)}$, $1\leqslant l\leqslant N$, $0\leqslant i\leqslant 2$, we get

$$\sum_{m=1}^{N} b_m^{(i)}\lambda_l^{m-1}=0, \quad 1\leqslant l\leqslant N, 0\leqslant i\leqslant 2,$$

which implies $b_m^{(i)}=0$, $1\leqslant m\leqslant N$, $0\leqslant i\leqslant 2$, by utilizing that Vandermonde determinant is not zero. The proof is finished.

(Received 13 July 1998; accepted for publication 11 December 1998)

Let (P,π,B,G) be a G-principal fiber bundle. The action of G on the cotangent bundle T^*P is free and Hamiltonian. By Liberman and Marle [*Symplectic Geometry and Analytical Mechanics* (Reidel, Dortrecht, 1987)] and Marsden and Ratiu [Lett. Math. Phys. **11**, 161 (1981)] the quotient space T^*P/G is a Poisson manifold. We will determine the Poisson bracket on the reduced Poisson manifold T^*P/G, and its symplectic leaves. © *1999 American Institute of Physics.* [S0022-2488(99)02606-7]

I. INTRODUCTION

When a Lie group G acts on a manifold Q, it may foliate it into the orbits under the action. The quotient with respect to this foliation is Q/G. Under certain assumptions Q/G is a manifold with smooth projection from Q to Q/G. If Q is the phase space of a mechanical system, Q/G will often play the role of a reduced phase manifold, the carrier manifold of a reduced system. For this reason there is some interest in how structures, and more generally properties of Q, carry down to Q/G. Assume that Q is a Poisson manifold and that G acts on Q, with a Hamiltonian and free action. A result of Marsden and Ratiu[2] shows that the Poisson bracket on Q, projects onto a Poisson bracket on the quotient space Q/G. In particular, when Q is the phase space of a mechanical system, endowed with a free and Hamiltonian action of a Lie group G, the quotient space is a Poisson manifold.

Let G be a Lie group, $\mathcal{G}$ its Lie algebra, and (P,π,B,G) a G-principal bundle with total space P, base space B, and a principal action on the left

$$\Phi: G\times P\to P,$$

$$(g,p)\mapsto\Phi(g,p).$$

The canonical lifting $\hat{\Phi}$ of Φ to the cotangent bundle T^*P is a free and Hamiltonian action. By Refs. 1 and 2, the quotient space T^*P/G has a unique Poisson structure for which the canonical projection $\tau: T^*P\to T^*P/G$ is a Poisson map.

When a connection is given on P, we show that T^*P/G can be considered as a vector bundle over T^*B with $\mathcal{G}^*$ as typical fiber, and that its Poisson structure is the sum of three terms: the first one comes from the canonical symplectic structure of T^*B, the second one from the Lie–Poisson structure on $\mathcal{G}^*$, and the third one involves the curvature of the connection on P. Finally we show that the symplectic leaves of T^*P/G are bundles over T^*B with coadjoint orbit in $\mathcal{G}^*$ as a typical fiber. These fiber bundles are introduced by Sternberg in Ref. 3, who has given their symplectic structure, thus giving a symplectic formulation of the motion of a particule in a Yang–Mills field. Weinstein[4] has shown that these manifolds are reduced manifolds at $0\in\mathcal{G}^*$ of the diagonal action of G on the product $T^*P\times\mathcal{O}$, where $\mathcal{O}$ is a coadjoint orbit in $\mathcal{G}^*$. Note that Kummer[5] has shown that there is a symplectomorphism between the reduced symplectic manifold of T^*P at a G-invariant point $\mu\in\mathcal{G}^*$, and the symplectic space T^*B endowed with the symplectic form, sum of its canonical symplectic form and of a magnetique term depending on the curvature of the connection on P.

Those authors (Sternberg, Weinstein, and Kummer), were interested in the symplectic structures of the leaves of T^*P/G, by considering each one separately. We are interested in the Poisson structure of T^*P/G, which gathers together all of the symplectic structures of the leaves of T^*P/G.

Note also that Montgomery[6] has given a global formula of the Poisson bracket on T^*P/G, without proof. One of the principal objects of this paper is to give a proof of this formula.

It is important to remark that the Poisson structure on T^*P/G is useful especially for the study of the stability of some motions of a mechanical system, whose phase space is T^*P, when a Lie group G of symmetry of the system acts freely on the configuration space P, which is the set of all possible configurations of the mechanical system.

II. CONNECTION AND CANONICAL SYMPLECTIC FORM

Let (P,π,B,G) be a G-principal fiber bundle. This means we are given a free action, that we suppose left action

$$\Phi: G\times P\to P, \quad (g,p)\mapsto \Phi(g,p).$$

The canonical lift of Φ is a free and Hamiltonian action $\hat{\Phi}$ of G on T^*P, with moment mapping (see the definition in Refs. 1 or 7–9) $J: T^*P\to \mathcal{G}^*$, given for all $z\in T^*P$ and $\xi\in\mathcal{G}$ by

$$\langle J(z),\xi\rangle = \langle z,\xi_P(q_P(z))\rangle,$$

where $q_P: T^*P\to P$ is the canonical projection and ξ_P is the fundamental vector field on P associated with ξ, given by

$$\xi_P(p) = \frac{d}{dt}\Phi(\exp(-t\xi),p)\big|_{t=0}.$$

Suppose we are given a connection on P (see Refs. 10 and 11). It is a G-equivariant one-form ω on P with values in $\mathcal{G}$, $\Phi_g^*\omega = \mathrm{Ad}_g\omega$, and such that for all $p\in P$ and $\xi\in\mathcal{G}$, $\omega(\xi_P(p)) = \xi$. The tangent space at p splits into a direct sum $T_pP = V_pP\oplus H_pP$, where $V_pP = \ker T_p\pi$ is the vertical subspace and $H_pP = \ker\omega$ is the horizontal subspace defined by the connection. Then ω restricted to V_pP is the inverse of the mapping

$$u_p: \mathcal{G}\to V_p,$$

$$\xi\mapsto \xi_P(p).$$

The horizontal subspace H_pP is isomorphic to $T_{\pi(p)}B$, therefore, the cotangent space at p splits into the direct sum $T_p^*P = V_p^*P\oplus T_{\pi(p)}^*B$. Thus we obtain a projection

$$k_p: T_p^*P\to T_{\pi(p)}^*B,$$

which is the transpose of the horizontal lifting of vectors in $T_{\pi(p)}B$ to horizontal vectors in T_pP.

Let $z\in T_p^*P$, $Z\in T_z(T^*P)$ and $X = Tq_P(Z)\in T_pP$. Let $z = z_{\mathrm{ver}} + z_{\mathrm{hor}}$, $X = X_{\mathrm{ver}} + X_{\mathrm{hor}}$, be the decompositions of z and X relative to the direct sum decompositions given above, then the Liouville one-form evaluated on Z is

$$(\alpha_P)_z(Z) = \langle z,X\rangle = \langle z, X_{\mathrm{ver}} + X_{\mathrm{hor}}\rangle = \langle z,\xi_P(p)\rangle + \langle z, X_{\mathrm{hor}}\rangle.$$

Now, by definition of J,k and the connection one form ω, we have

$$\langle z,\xi_P(p)\rangle = \langle J(z),\xi\rangle, \quad \langle z,X_{\mathrm{hor}}\rangle = \langle k_p(z), T_p\pi(X)\rangle, \quad \omega(\xi_P(p)) = \xi,$$

therefore,

$$
\begin{aligned}
(\alpha_P)_z(Z) = \langle J(z),\xi\rangle + \langle k_p(z), T_p\pi(X)\rangle &= \langle J(z),\omega(\xi_P)\rangle + \langle k_p(z), T_p\pi(X)\rangle \\
&= \langle J(z),\omega(X)\rangle + \langle k_p(z), T_p\pi(X)\rangle \\
&= \langle J(z),(q_P^*\omega)(Z)\rangle + \langle k_p(z), Tk(Z)\rangle,
\end{aligned}
$$

and then we have the following proposition.

Proposition II.1: The Liouville one-form α_P and the canonical symplectic two-form $d\alpha_P$ on T^*P, are expressed by the following formulas:

$$\alpha_P = \langle J, q_P^*\omega\rangle + k^*\alpha_B, \quad d\alpha_P = dJ\wedge q_P^*\omega + \langle J, q_P^* d\omega\rangle + k^* d\alpha_B.$$

III. DECOMPOSITION OF THE COTANGENT BUNDLE

We denote by $\tilde{P} = \{(\beta,p)\in T^*B\times P / q_P(\beta) = \pi(p)\}$, the fiber product of T^*B and P over B. Let $\hat{\pi}:\tilde{P}\to P$ and $\tilde{\pi}:\tilde{P}\to T^*B$ be the first and the second projections. Then the following diagram is commutative:

$$
\begin{array}{ccc}
\tilde{P} & \xrightarrow{\hat{\pi}} & P \\
\tilde{\pi}\downarrow & & \downarrow\pi \\
T^*B & \xrightarrow{q_B} & B
\end{array}
$$

and $(\tilde{P},\tilde{\pi},T^*B,G)$ is a G-principal fiber bundle. The mapping $\hat{\pi}$ is a G-principal fiber bundles homomorphism. The mapping $\tilde{\omega} = \hat{\pi}^*\omega$ is then a connection on $\tilde{P}$. Let $\tilde{\Omega}$ be its curvature form. We have $\tilde{\Omega} = \tilde{\pi}^*\Omega$, where Ω is the curvature two-form of ω. It is a basic two-form on $\tilde{P}$ with values in $\mathcal{G}$, it can be thought as a two-form on T^*B with values in the associated fiber bundle to $\tilde{P}$ with typical fiber $\mathcal{G}$:$\tilde{P}\times_G\mathcal{G}$ (see Ref. 10).

Proposition III.1: (Maurer–Cartan equation). The curvature form Ω, satisfies the structure equation of Maurer–Cartan:

$$\text{for all } p\in P, X \text{ and } Y\in T_pP, \quad \Omega(X,Y) = d\omega(X,Y) + [\omega(X),\omega(Y)].$$

Proof: Since $TP = VP\oplus HP$, it is sufficient to consider the three following cases:
First case: X,Y are horizontal.

In this case, $\omega(X)=\omega(Y)=0$, $X_{\rm hor}=X$, and $Y_{\rm hor}=Y$, the equality reduces to the definition of Ω, $\Omega(X,Y) = d\omega(X_{\rm hor},Y_{\rm hor})$.
Second case: X,Y are vertical.

In this case, there exist ξ and ξ' in $\mathcal{G}$ such that $X=\xi_P(p)$ and $Y=\xi'_P(p)$

$$\omega(X)=\xi \text{ and } \omega(Y)=\xi'$$

$$X_{\rm hor}=Y_{\rm hor}=0 \text{ then } \Omega(X,Y)=0.$$

On the other hand,

$$d\omega(X,Y)+[\omega(X),\omega(Y)] = \xi_P(\omega(\xi'_P)) - \xi'_P(\omega(\xi_P)) - \omega([\xi_P,\xi'_P]) + [\omega(\xi_P),\omega(\xi'_P)].$$

Now, $\omega(\xi_P)$ and $\omega(\xi'_P)$ are two constant functions on P, then the two first right terms cancel. We have $[\xi_P,\xi'_P]=[\xi,\xi']_P$ then, $d\omega(\xi_P,\xi'_P)+[\xi,\xi'] = -[\xi,\xi']+[\xi,\xi']=0$.
Third case: X horizontal and Y vertical.
In this case, $X_{\rm hor}=X$, $Y_{\rm hor}=0$, $\omega(X)=0$, and $\omega(Y)=\xi$, where ξ is the unique element of $\mathcal{G}$, such that $\xi_P(p)=Y$.

We extend X to a horizontal vector field on P, which will be also denoted by X

$$\Omega(X,Y)=d\omega(X_{\text{hor}},Y_{\text{hor}})=0.$$

On the other hand,

$$d\omega(X,Y)+[\omega(X),\omega(Y)]=X(\omega(\xi_P))-\xi_P(\omega(X))-\omega([X,\xi_P])+[\omega(X),\omega(\xi_P)]=\omega([X,\xi])$$

Since X is horizontal, then $[X,\xi_P]$ also, therefore $\omega([X,\xi_P])=0$. ■

We assume that $\mathcal{G}^*$ is equipped with its canonical Lie–Poisson structure defined by the following bracket:

$$\text{for} \quad f_1 \ \text{and} \ f_2 \ \text{in} \ C^\infty(\mathcal{G}^*), \quad \{f_1,f_2\}(\mu)=-\langle \mu,[d_\mu f_1,d_\mu f_2]\rangle.$$

Here $\mathcal{G}^{**}$ is identified with $\mathcal{G}$ and [,] is the Lie bracket on $\mathcal{G}$.
We consider the following action on the product $\tilde{P}\times\mathcal{G}^*$, for $g\in G,(\beta,p)\in\tilde{P}$ and $\mu\in\mathcal{G}^*,g((\beta,p),\mu)=((\beta,\Phi(g,p)),\text{Ad}_g^*\mu)$.

In this case, the mapping

$$\psi:\tilde{P}\times\mathcal{G}^*\rightarrow T^*P, \quad ((\beta,p),\mu)\mapsto\beta+{}^t\omega_p(\mu),$$

is a G-equivariant isomorphism with inverse

$$\psi^{-1}:T^*P\rightarrow\tilde{P}\times\mathcal{G}^*, \quad z=z_{\text{ver}}+z_{\text{hor}}\mapsto(z_{\text{hor}},{}^tu(z)).$$

Thus, T^*P is isomorphic to $\tilde{P}\times\mathcal{G}^*$ and T^*P/G to the associated fiber bundle $\tilde{P}\times_G\mathcal{G}^*$, with base space T^*B and fiber $\mathcal{G}^*$. We denote $\pi_{\mathcal{G}^*}:\tilde{P}\times_G\mathcal{G}^*\rightarrow T^*B$ the canonical projection on the base space.

A. Moment mapping and canonical symplectic form

Let $z\in T^*P$ and $\xi\in\mathcal{G}$,

$$\langle {}^tu(z),\xi\rangle=\langle z,u(\xi)\rangle=\langle z,\xi_P(p)\rangle=\langle J(z),\xi\rangle.$$

The moment mapping J is then identified with the second projection from $\tilde{P}\times\mathcal{G}^*$ to $\mathcal{G}^*$, the mapping k with the projection $\tilde{\pi}\circ pr_1$, where $pr_1:\tilde{P}\times\mathcal{G}^*\rightarrow\tilde{P}$ is the first projection, and the mapping q_P is identified with $\hat{\pi}\circ pr_1$.

By proposition (II.1), $\alpha_P=\langle J,q_P^*\omega\rangle+k^*\alpha_B$, then after identification of T^*P with $\tilde{P}\times\mathcal{G}^*$, for all $z=(\beta,p,\mu)\in\tilde{P}\times\mathcal{G}^*$

$$\alpha_P(z)=\langle J,\tilde{\omega}\rangle+k^*\alpha_B(\beta).$$

A vector $Z\in T_z(\tilde{P}\times\mathcal{G}^*)$ can be written as $Z=(Z',\eta)$, where $Z'\in T_{(\beta,p)}\tilde{P}$ and $\eta\in T_\mu\mathcal{G}^*\equiv\mathcal{G}^*$, $\eta=T_zJ(Z)$.

Let $\xi=\tilde{\omega}(Z')$. In this case,

$$\alpha_P(Z)=\langle J,\tilde{\omega}\rangle(Z)+k^*\alpha_B(\beta)(Z)=\langle\mu,\xi\rangle+\alpha_B(\beta)(Tk(Z')).$$

Then, for all $Z_1=(Z_1',\eta_1)$ and $Z_2=(Z_2',\eta_2)$ in $T_z(\tilde{P}\times\mathcal{G}^*)$,

$$d\alpha_P(Z_1,Z_2)=dJ\wedge\tilde{\omega}(Z_1,Z_2)+\langle\mu,d\tilde{\omega}(Z_1',Z_2')\rangle+d\alpha_B(\beta)(Tk(Z_1'),Tk(Z_2')).$$

Now by the Maurer–Cartan equation (Proposition III.1), applied to $\tilde{\Omega}$, we have

$$d\tilde{\omega}(Z_1',Z_2')=\tilde{\Omega}(Z_1',Z_2')-[\tilde{\omega}(Z_1'),\tilde{\omega}(Z_2')],$$

then, if $\tilde{\omega}(Z_1')=\xi_1$ and $\tilde{\omega}(Z_2')=\xi_2$, we obtain

$$d\alpha_P(Z_1,Z_2)=dJ\wedge\tilde{\omega}(Z_1,Z_2)+\langle\mu,\tilde{\Omega}(Z_1',Z_2')\rangle-\langle\mu,[\xi_1,\xi_2]\rangle+d\alpha_B(\beta)(Tk(Z_1'),Tk(Z_2')). \tag{1}$$

B. Covariant differential of a function

The connection $\tilde{\omega}$ on $\tilde{P}$ generates a connection on the associated bundle $\tilde{P}\times_G\mathcal{G}^*$, which is given by a horizontal subbundle $H(\tilde{P}\times_G\mathcal{G}^*)$, complementary in $T(\tilde{P}\times_G\mathcal{G}^*)$ to the vertical subbundle $V(\tilde{P}\times_G\mathcal{G}^*)=\ker\pi_{\mathcal{G}^*}$. Let h be the horizontal lifting of the tangent vectors on T^*B to the horizontal vectors on $\tilde{P}\times_G\mathcal{G}^*$.

Definition: We define the covariant differential of a function $f\in C^\infty(\tilde{P}\times_G\mathcal{G}^*)$ on $\hat{z}\in\tilde{P}\times_G\mathcal{G}^*$ to be that covector $d_{\tilde{\omega}}f(\hat{z})$ on $\beta=\pi_{\mathcal{G}^*}(\hat{z})\in T^*B$, given for all $V_\beta\in T_\beta(T^*B)$ by

$$\langle d_{\tilde{\omega}}f(\hat{z}),V_\beta\rangle=\langle df(\hat{z}),hV_\beta\rangle.$$

This may be thought of as the horizontal part of $df(\hat{z})$. The vertical part may be thought of as an element in the dual bundle to $\tilde{P}\times_G\mathcal{G}^*$ which is the adjoint bundle $\tilde{P}\times_G\mathcal{G}$, with base space T^*B and fiber $\mathcal{G}$. This vertical part is the differential of f with respect to the variable $\hat{\mu}$ in the fiber $(\mathcal{G}^*)_{\hat{z}}$ through $\hat{z}$. Thus,

$$df(\hat{z})=d_{\tilde{\omega}}f(\hat{z})+d_{\hat{\mu}}f(\hat{z}).$$

The associated fiber bundle $\tilde{P}\times_G\mathcal{G}$ is a bundle with base space T^*B and typical fibre $\mathcal{G}$. Then every fiber over an element $\beta\in T^*B$ has a Lie algebra structure. We denote by $[,]$ its Lie bracket.

IV. REDUCED POISSON BRACKET

Theorem IV.1: Let (P,π,B,G) be a G-principal fiber bundle, and ω a connection on P. The quotient space T^*P/G has a unique Poisson structure for which the canonical projection is a Poisson map, and after the identification of T^*P/G with $\tilde{P}\times_G\mathcal{G}^*$, the Poisson bracket of two functions f_1 and f_2 in $C^\infty(\tilde{P}\times_G\mathcal{G}^*)$, evaluated at a point $\hat{z}$ in $\tilde{P}\times_G\mathcal{G}^*$, is

$$\{f_1,f_2\}(\hat{z})=d\alpha_B(\beta)(d_{\tilde{\omega}}f_1^\sharp(\hat{z}),d_{\tilde{\omega}}f_2^\sharp(\hat{z}))+\langle\hat{z},\tilde{\Omega}(\beta)(d_{\tilde{\omega}}f_1^\sharp(\hat{z}),d_{\tilde{\omega}}f_2^\sharp(\hat{z}))\rangle$$
$$-\langle\hat{z},[d_{\hat{\mu}}f_1(\hat{z}),d_{\hat{\mu}}f_2(\hat{z})]\rangle.$$

In this formula, the vector $d_{\tilde{\omega}}f^\sharp(\hat{z})$ is the unique vector in $T_\beta(T^*B)$, associated to $d_{\tilde{\omega}}f(\hat{z})$ by the isomorphism generated by the symplectic form $d\alpha_B$, between $T^*(T^*B)$ and $T(T^*B)$. The two-form $\tilde{\Omega}$ is considered as a two-form on T^*B with values in $\tilde{P}\times_G\mathcal{G}$, by the mapping

$$(V_\beta,W_\beta)\mapsto(\beta,\tilde{\Omega}(hV_\beta,hW_\beta)),$$

where $\beta\in T^*B$, V_β and $W_\beta\in T^*B$, and hV_β,hW_β are their corresponding horizontal liftings, with respect to the connection $\tilde{\omega}$.

Proof: Let $\tau_{\mathcal{G}^*}:\tilde{P}\times\mathcal{G}^*\to\tilde{P}\times_G\mathcal{G}^*$, be the canonical projection, which maps a point $z=(\beta,p,\mu)\in\tilde{P}\times\mathcal{G}^*$, to its G orbit, $\hat{z}=\tau_{\mathcal{G}^*}(z)\in\tilde{P}\times_G\mathcal{G}^*$.
As show by Marsden and Ratiu in Ref. 2, the quotient space of a Poisson manifold by a Hamiltonian and free action of a Lie group, has a unique Poisson structure, for which the projection, which sends a point to its orbit, is a Poisson map.

The associated fiber bundle $\tilde{P}\times_G\mathcal{G}^*$ is endowed with the unique Poisson structure for which the projection $\tau_{\mathcal{G}^*}$ is a Poisson map. Then, if f_1,f_2 are in $C^\infty(\tilde{P}\times_G\mathcal{G}^*)$, we have

$$\{f_1,f_2\}(\hat{z})=d\alpha_P(z)(d(f_1\circ\tau_{\mathcal{G}^*})^\sharp,d(f_2\circ\tau_{\mathcal{G}^*})^\sharp).$$

Now,

$$df_i(\hat{z}) = d_{\tilde{\omega}} f_i(\hat{z}) + d_{\hat{n}} f_i(\hat{z}) \quad \text{for } i=1,2,$$

and by formula (1), we have

$$d\alpha_P(z)(d(f_1\circ\tau_{\mathcal{G}^*})^\sharp, d(f_1\circ\tau_{\mathcal{G}^*})^\sharp) = dJ\wedge\tilde{\omega}(d(f_1\circ\tau_{\mathcal{G}^*})^\sharp, d(f_2\circ\tau_{\mathcal{G}^*})^\sharp) + \langle J(z), \tilde{\Omega}(z) \times (d_{\tilde{\omega}}(f_1\circ\tau_{\mathcal{G}^*})^\sharp, d_{\tilde{\omega}}(f_2\circ\tau_{\mathcal{G}^*})^\sharp)\rangle - \langle J(z), [d_\mu(f_1\circ\tau_{\mathcal{G}^*})^\sharp, d_\mu \times (f_2\circ\tau_{\mathcal{G}^*})^\sharp]\rangle + d\alpha_B(\beta)(d_{\tilde{\omega}}(f_1\circ\tau_{\mathcal{G}^*})^\sharp, d_{\tilde{\omega}}(f_2\circ\tau_{\mathcal{G}^*})^\sharp).$$

The quadruple $(\tilde{P}\times\mathcal{G}^*, \tau_{\mathcal{G}^*}, \tilde{P}\times_G\mathcal{G}^*, G)$ is a G-principal fiber bundle (see Kobayashi and Nomizu[11]). The connection one-form $\tilde{\omega}$ on $\tilde{P}$ can be thought of as a one-form on $\tilde{P}\times\mathcal{G}^*$ (depending only on coordinates in $\tilde{P}$). For $i=1,2$ $f_i\circ\tau_{\mathcal{G}^*}$ is a G-invariant function on $\tilde{P}\times\mathcal{G}^*$. There is an isomorphism between the set of functions on $\tilde{P}\times_G\mathcal{G}^*$ and the set of G-invariant functions on $\tilde{P}\times\mathcal{G}^*$. Then, $d(f_i\circ\tau_{\mathcal{G}^*})(z)^\sharp$ is the horizontal lifting of $df_i^\sharp(\hat{z})$ to $\tilde{P}\times\mathcal{G}^*$. It is then a horizontal vector. We have then

$$\tilde{\omega}(d(f_i\circ\tau_{\mathcal{G}^*})^\sharp) = 0 \quad dJ\wedge\tilde{\omega}(d(f_1\circ\tau_{\mathcal{G}^*})^\sharp, d(f_2\circ\tau_{\mathcal{G}^*})^\sharp) = 0.$$

On the other hand the moment mapping J is the second projection from $\tilde{P}\times\mathcal{G}^*$ to $\mathcal{G}^*$. It generates a mapping $\tilde{J}$ from $\tilde{P}\times_G\mathcal{G}^*$ on $\tilde{P}\times_G\mathcal{G}^*$, which is the identity mapping. Then,

$$\begin{aligned}\{f_1,f_2\}(\hat{z}) &= d\alpha_B(\beta)(d_{\tilde{\omega}}f_1^\sharp(\tau_{\mathcal{G}^*}(z), d_{\tilde{\omega}}f_2^\sharp(\tau_{\mathcal{G}^*}(z))) + \langle\tilde{J}(\hat{z}), \tilde{\Omega}(\beta)(d_{\tilde{\omega}}f_1^\sharp(\tau_{\mathcal{G}^*}(z)), d_{\tilde{\omega}}f_2^\sharp(\tau_{\mathcal{G}^*}(z)))\rangle \\ &\quad - \langle\tilde{J}(\hat{z}), [d_{\hat{\mu}}f_1(\tau_{\mathcal{G}^*}(z)), d_{\hat{\mu}}f_2(\tau_{\mathcal{G}^*}(z))]\rangle \\ &= d\alpha_B(\beta)(d_{\tilde{\omega}}f_1^\sharp(\hat{z}), d_{\tilde{\omega}}f_2^\sharp(\hat{z})) + \langle\hat{z}, \tilde{\Omega}(\beta)(d_{\tilde{\omega}}f_1^\sharp(\hat{z}), d_{\tilde{\omega}}f_2^\sharp(\hat{z})\rangle - \langle\hat{z}, [d_{\hat{\mu}}f_1(\hat{z}), d_{\hat{\mu}}f_2(\hat{z})]\rangle.\end{aligned}$$

■

V. SYMPLECTIC LEAVES

Let us recall a result of Sternberg.[3] Let (F,Ω_F) be a symplectic manifold with symplectic form Ω_F, on which a Lie group G acts by a Hamiltonian action on the right, with a G-equivariant moment $J_F: F\to\mathcal{G}^*$. Then the choice of a connection on P determines a symplectic structure on the associated bundle $\tilde{P}\times_G F$. The symplectic form on $\tilde{P}\times_G F$ is

$$\sigma = \pi_F^* d\alpha_B - \langle\tilde{J}_F, \pi_F^*\tilde{\Omega}\rangle + \tilde{\Omega}_F,$$

where $\tilde{J}$ is the mapping on $\tilde{P}\times_G F$ with values in $\tilde{P}\times_G\mathcal{G}^*$ generated by the G-equivariant moment map J_F, which makes the following diagram commutative:

$$\begin{array}{ccc} \tilde{P}\times F & \xrightarrow{id_{\tilde{P}}\times J_F} & \tilde{P}\times\mathcal{G}^* \\ \downarrow & & \downarrow \\ \tilde{P}\times_G F & \xrightarrow{\tilde{J}_F} & \tilde{P}\times_G\mathcal{G}^* \end{array}$$

The curvature two-form $\tilde{\Omega}$ on $\tilde{P}$ is equivariant and cancels on vertical vector fields. It can be considered as a two-form on T^*B with values in $\tilde{P}\times_G\mathcal{G}$ (see Ref. 10). The form $\tilde{\Omega}_F$ is the two-form on $\tilde{P}\times_G F$ generated by the G-invariant symplectic two-form Ω_F. The mapping $\pi_F: \tilde{P}\times_G F\to T^*B$ is the canonical projection on the base space.

Let us take $F=\mathcal{O}$ a coadjoint orbit in $\mathcal{G}^*$, with its canonical symplectic two-form $\Omega_{\mathcal{O}}$, given for all $\mu\in\mathcal{O}$ and $\xi,\zeta\in\mathcal{G}$, by

$$\Omega_{\mathcal{O}}(\mu)(\xi_{\mathcal{O}},\zeta_{\mathcal{O}})=-\langle\mu,[\xi,\zeta]\rangle.$$

Then the moment map $J_{\mathcal{O}}$ is equal to $-i_{\mathcal{O}}$, where $i_{\mathcal{O}}$ is the injection of $\mathcal{O}$ in $\mathcal{G}^*$. Consequently the mapping $-\tilde{J}_{\mathcal{O}}$ is the injection of $\tilde{P}\times_G\mathcal{O}$ in $\tilde{P}\times_G\mathcal{G}^*$: we have $\tilde{J}_{\mathcal{O}}(\hat{z})=-\hat{z}$. The symplectic two-form on the symplectic space $\tilde{P}\times_G\mathcal{O}$, evaluated at a point $\hat{z}\in\tilde{P}\times_G\mathcal{O}$, $\beta=\pi_{\mathcal{O}}(\hat{z})\in T^*B$, and $\hat{Z}_1,\hat{Z}_2\in T_{\hat{z}}(\tilde{P}\times_G\mathcal{O})$ is

$$\sigma(\hat{Z}_1,\hat{Z}_2)=d\alpha_B(T\pi_{\mathcal{O}}(\hat{Z}_1),T\pi_{\mathcal{O}}(\hat{Z}_2))+\langle\hat{z},\tilde{\Omega}(T\pi_{\mathcal{O}}(\hat{Z}_1),T\pi_{\mathcal{O}}(\hat{Z}_2))\rangle-\langle\hat{z},[\hat{Z}_{1\mathrm{ver}},\hat{Z}_{2\mathrm{ver}}]\rangle.$$

Theorem V.1: The symplectic leaves of $\tilde{P}\times_G\mathcal{G}^*$ are the symplectic fiber bundles $\tilde{P}\times_G\mathcal{O}$, associated to the principal fiber bundle $\tilde{P}$, with base space T^*B and typical fiber a coadjoint orbit $\mathcal{O}$ in $\mathcal{G}^*$.

Proof: The symplectic leaves of T^*P/G are the Marsden–Weinstein reduced spaces (see Ref. 12) $J^{-1}(\mu)/G_\mu$, where $\mu\in\mathcal{G}^*$ and G_μ its isotropy subgroup with respect to the coadjoint action of G on $\mathcal{G}^*$. By Marle[13] the reduced space $J^{-1}(\mu)/G_\mu$ is symplectomorphic to the symplectic space $J^{-1}(\mathcal{O})/G$, where $\mathcal{O}$ is the coadjoint orbit containing μ. After identification of T^*P with $\tilde{P}\times\mathcal{G}^*$, the moment mapping J, is the second projection from $\tilde{P}\times\mathcal{G}^*$ to $\mathcal{G}^*$. Therefore,

$$J^{-1}(\mathcal{O})=\tilde{P}\times\mathcal{O}\quad\text{and}\quad J^{-1}(\mathcal{O})/G=\tilde{P}\times_G\mathcal{O}.$$

Let us take $\hat{z}\in\tilde{P}\times_G\mathcal{O}$, $\beta=\pi_{\mathcal{O}}(\hat{z})\in T^*B$, f_1 and f_2 in $C^\infty(\tilde{P}\times_G\mathcal{O})$, and let us denote by, $\hat{Z}_{f_i}$ the value on $\hat{z}$, of the Hamiltonian vector field associated to f_i, for $i=1,2$, then

$$\begin{aligned}\sigma_{\hat{z}}(\hat{Z}_{f_1},\hat{Z}_{f_2})&=d\alpha_B(\beta)(T\pi_{\mathcal{O}}(\hat{Z}_{f_1}),T\pi_{\mathcal{O}}(\hat{Z}_{f_2})+\langle\hat{z},\tilde{\Omega}(\beta)(T\pi_{\mathcal{O}}(\hat{Z}_{f_1}),T\pi_{\mathcal{O}}(\hat{Z}_{f_2}))\rangle\\&\quad-\langle\hat{z},[(\hat{Z}_{f_1})_{\mathrm{ver}},(\hat{Z}_{f_2})_{\mathrm{ver}}]\rangle\\&=d\alpha_B(\beta)(d_{\tilde{\omega}}f_1^\sharp(\tau_{\mathcal{O}}(z)),d_{\tilde{\omega}}f_2^\sharp(\tau_{\mathcal{O}}(z)))+\langle\hat{z},\tilde{\Omega}(\beta)(d_{\tilde{\omega}}f_1^\sharp(\tau_{\mathcal{O}}(z)),d_{\tilde{\omega}}f_2^\sharp(\tau_{\mathcal{O}}(z)))\rangle\\&\quad-\langle\hat{z},[d_{\hat{\mu}}f_1^\sharp(\tau_{\mathcal{O}}(z)),d_{\hat{\mu}}f_2^\sharp(\tau_{\mathcal{O}}(z))]\rangle\\&=\{f_1,f_2\}_{T^*P/G}.\end{aligned}$$

We see that the restriction of the Poisson bracket of $\tilde{P}\times_G\mathcal{G}^*$ to $\tilde{P}\times_G\mathcal{O}$, is equal to the Poisson bracket generated by the symplectic form on $\tilde{P}\times_G\mathcal{O}$. This proves the theorem V.1. ■

VI. EXAMPLE

Let $G=\mathrm{SO}(3)$, be the rotation group of the Euclidean three space $\mathbb{R}^3$ about its origin, and let $K=S^1$ be the rotation group of the plane $\mathbb{R}^2$ considered as a subgroup of G, by identification with elements of the form

$$\begin{pmatrix}a&-b&0\\b&a&0\\0&0&1\end{pmatrix},\quad a^2+b^2=1.$$

Let us consider the action Φ of K on G given by the restriction of the left translations of G to $K\times G$

$$\Phi:K\times G\to G,\quad (k,g)\mapsto kg.$$

The set of orbits $\mathrm{SO}(3)/S^1$ can be identified with S^2. Let $\pi_K:\mathrm{SO}(3)\rightarrow S^2$, be the canonical projection which sends an element $A\in \mathrm{SO}(3)$ to its K orbit. In this case (G,π_K,S^2,S^1) is a S^1-principal fiber bundle with total space SO(3) and base space S^2. The Lie algebra so(3) of SO(3), endowed with its Lie bracket

$$[A,B]=AB-BA,$$

is identified with $\mathbb{R}^3$ endowed with the vector product $\times$ (see Ref. 7). The tangent fiber bundle to SO(3) is identified with $\mathrm{SO}(3)\times\mathbb{R}^3$ (see Ref. 1). The Lie algebra of S^1 is identified with $\mathbb{R}$, with trivial Lie bracket. The mapping which sends $(A,a), A\in \mathrm{SO}(3)$ and $a=(a_1,a_2,a_3)\in\mathbb{R}^3$, to a_3, is a connection on $(\mathrm{SO}(3),\pi_K,S^2,S^1)$. Its curvature two-form is the mapping Ω, evaluated at a pair $((A,a),(A',a'))\in T\mathrm{SO}(3)\times T\mathrm{SO}(3)$, is (by Ref. 10)

$$\Omega((A,a),(A',a'))=-(a\times a')_3=a_1a_2'-a_2a_1'.$$

The orbit set of the canonical lifting $\hat{\Phi}$ of Φ to the cotangent bundle $T^*\mathrm{SO}(3)$, is a fiber bundle with base space T^*S^2 and typical fiber $\mathbb{R}$. The covariant differential of a function $f\in C^\infty(T^*\mathrm{SO}(3)/S^1)$ is the differential with respect to $(s,(a_1,a_2))$, where $s\in S^2$ and $(a_1,a_2)\in T_s^*S^2$.

The reduced Poisson bracket of two functions f_1 and $f_2\in C^\infty(T^*\mathrm{SO}(3)/S^1)$, evaluated at a point $(s,(a_1,a_2),a_3)\in T^*\mathrm{SO}(3)/S^1$, is

$$\begin{aligned}\{f_1,f_2\}&=d\alpha_{S^2}(d_{(s,(a_1,a_2))}f_1^\#,d_{(s,(a_1,a_2))}f_2^\#)+\langle a_3,-(df_1\times df_2)_3\rangle\\&=\langle d_sf_1,d_{(a_1,a_2)}f_2(s)\rangle-\langle d_sf_2,d_{(a_1,a_2)}f_1(s)\rangle-\langle a_3,(df_1\times df_2)_3\rangle\\&=\langle d_sf_1,d_{(a_1,a_2)}f_2(s)\rangle-\langle d_sf_2,d_{(a_1,a_2)}f_1(s)\rangle-a_3\left(\frac{\partial f_1}{\partial a_1}\frac{\partial f_2}{\partial a_2}-\frac{\partial f_1}{\partial a_2}\frac{\partial f_2}{\partial a_1}\right).\end{aligned}$$

The Lie bracket on the Lie algebra of S^1 is trivial. Then the symplectic leaves of the reduced cotangent bundle to SO(3) are all diffeomorphic to T^*S^2. ■

Cauchy analysis of the linearized skew sector of the massive nonsymmetric gravitational theory

P. Baki[a] and J. O. Malo[a]
Department of Physics, University of Nairobi, Box 30197, Nairobi, Kenya

(Received 4 November 1998; accepted for publication 14 December 1998)

Cauchy analysis of the linearized field equations of the skew sector of the massive nonsymmetric gravitational theory shows that small perturbations give rise to bounded accelerations thereby ensuring good asymptotic behavior for the skew part of the fundamental tensor.
[S0022-2488(99)04406-0]

I. INTRODUCTION

The nonsymmetric gravitational theory (NGT) arose out of a reinterpretation of Einstein's unified field theory[1,2] as purely a theory of gravitation.[3–5] However, the original versions of NGT were confronted with perturbative consistency problems due to the absence of a massless gauge invariance in the skew sector of the theory. The only gauge invariance was that associated with general covariance of the theory[6–8] which was clarified by Damour *et al.*, who showed that the wave solutions of the weak-field equations did not decrease at large distances from the source along the forward light cone.[9,10] They proposed that the theory should reduce to the massive Kalb–Ramond theory, which does not require gauge invariance for well behaved positive energy solutions.

The theory was subsequently altered to massive nonsymmetric gravitational theory (MNGT)[11–13] by requiring that the linearized field equations reduce to those of a massive Kalb–Ramond field,[14] guaranteeing that the linearized fields are well behaved asymptotically far from the source.[15] A study of the instabilities of the linearized MNGT showed that the instabilities arise from the fact that small skew sector perturbations lead to unboundedly large accelerations.[16] However, it will be shown that such instabilities may not in fact exist.

The organization of the paper is as follows: Section II presents an overview of the skew sector of MNGT on a general relativity (GR) background, while in Sec. III the linearized field equations are expressed in $3+1$ decomposed form. The analysis of these equations is carried out in Sec. IV, while in the Appendix we give the mathematical details of Sec. III.

II. THE LINEARIZED SKEW SECTOR OF MNGT

The linearized MNGT presented here is that due to Clayton,[15] in which the dynamics of the theory are determined from the first-order action ($G=c=1$):

$$S=\int d^4x\left\{-\hat{g}^{\mu\nu}R^{NS}_{\mu\nu}(\Gamma)-\hat{g}^{\mu\nu}\partial_{[\mu W\nu]}+\hat{l}^{\mu}\Gamma_{\mu}+\frac{1}{2}\lambda\hat{g}^{(\mu\nu)}W_{\mu}W_{\nu}+\frac{1}{4}m^2\hat{g}^{[\mu\nu]}g_{[\mu\nu]}\right\}+S_M \tag{1}$$

where the quantities with a caret are densitized, and

$$\frac{\delta S_M}{\delta g^{\mu\nu}}=\hat{T}_{\mu\nu}$$

[a]Electronic mail: physics@ken.healthnet.org

is the matter stress energy tensor derived from the variation of the matter action S_M, that acts as a source in the gravitational field equations. The analysis of the theory is carried out in the context of the Palatini formalism and takes place at the level of the field equations. Thus performing a variation of the action with respect to $g_{\mu\nu}$ yields the field equations:

$$\frac{\delta S}{\delta \hat{g}^{\mu\nu}}=R^{NS}_{\mu\nu}+\partial_{[\mu W_{\nu}]}-\frac{1}{2}\lambda W_\mu W_\nu-\frac{1}{4}m^2\left(g_{[\mu\nu]}-g_{\alpha\mu}g_{\nu\beta}g^{[\alpha\beta]}+\frac{1}{2}g_{\nu\mu}g^{[\alpha\beta]}g_{[\alpha\beta]}\right)=\hat{T}_{\mu\nu}-\frac{1}{2}g_{\mu\nu}\hat{T}. \tag{2}$$

If one considers all the antisymmetric parts of the fundamental tensor as perturbations about a symmetric GR background,[15,7,13] i.e.,

$$g_{\mu\nu}\rightarrow g_{(\mu\nu)}+h_{\mu\nu} \tag{3}$$

and also the affine connections as:

$$\Gamma^{\alpha}_{\mu\nu}\rightarrow\left\{\begin{matrix}\alpha\\ \mu\nu\end{matrix}\right\}+\gamma^{\alpha}_{\mu\nu}, \tag{4}$$

where $h_{\mu\nu}$ and $\gamma^{\alpha}_{\mu\nu}$ are the perturbed quantities, and $g_{(\mu\nu)}$ and $\{{}^{\alpha}_{\mu\nu}\}$ are the symmetric background metric and christoffel symbols, respectively; with the fundamental tensor defined by

$$g_{\mu\nu}g^{\alpha\nu}=\delta^{\nu}_{\mu}. \tag{5}$$

Following Eq. (2), the field equations of MNGT expanded to first order about a GR background yields

$${}^1R_{\mu\nu}+\frac{1}{\lambda}\nabla_{[\mu}\nabla^{\alpha}h_{[\mu\nu]]}-\frac{1}{2}m^2h_{[\mu\nu]}=\hat{T}_{\mu\nu}-\frac{1}{2}g_{\mu\nu}\hat{T}, \tag{6}$$

where the first-order correction to Ricci-like tensor in NGT is given by

$${}^1R_{\mu\nu}=\nabla_{\alpha}\gamma^{\alpha}_{\mu\nu}-\nabla_{(\nu}\gamma^{\alpha}_{\alpha\mu)}. \tag{7}$$

By ignoring symmetric GR perturbations, the antisymmetric part of (6) is obtained as:

$$\begin{aligned}\nabla_{\alpha}\gamma^{\alpha}_{[\mu\nu]}+\frac{1}{\lambda}\nabla_{[\mu}\nabla^{\alpha}h_{[\mu\nu]]}-\frac{1}{2}m^2h_{[\mu\nu]}&=\frac{1}{2}(\nabla_{\alpha}F_{\mu\nu\alpha}+m^2h_{[\mu\nu]})-2\nabla^{\alpha}\nabla_{[\mu}h_{[\alpha\nu]]}\\&\quad+\frac{1}{\lambda}[1+\tfrac{2}{3}\lambda]\nabla_{[\mu}\nabla^{\alpha}h_{[\alpha\nu]]}\\&=\hat{T}_{[\mu\nu]},\end{aligned} \tag{8}$$

where

$$F_{\mu\nu\alpha}=(\partial_{\mu}h_{\nu\alpha}+\partial_{\alpha}h_{\mu\nu}+\partial_{\nu}h_{\alpha\mu}). \tag{9}$$

If one expands the action (1) to second order, ignores the surface terms, and imposes the compatibility conditions following the removal of the torsion vector $W_{\mu\nu}$ from the dynamics,[15] then one obtains the action as:

$$S=\tfrac{1}{12}F^{\mu\nu\alpha}F_{\mu\nu\alpha}-\tfrac{1}{4}m^2h^{[\mu\nu]}h_{[\mu\nu]}-\nabla^{\alpha}h^{[\mu\nu]}\nabla_{\mu}h_{[\alpha\mu]}(-\tfrac{1}{2}\lambda+\tfrac{1}{3})\nabla_{\nu}h^{[\mu\nu]}\nabla^{\alpha}h_{[\mu\alpha]}. \tag{10}$$

And by choosing $\lambda=\frac{3}{4}$ one obtains kinetic terms identical to those of Kalb–Ramond theory on a GR background, giving the skew sector action

$$S_s = \tfrac{1}{12} F^{\mu\nu\alpha} F_{\mu\nu\alpha} - \tfrac{1}{4} m^2 h^{[\mu\nu]} h_{[\mu\nu]} - h^{[\mu\nu]} h^{[\alpha\beta]} R_{\alpha\mu\beta\nu}, \tag{11}$$

where ${}^0R_{\alpha\mu\beta\nu}$ designates the background curvature. By taking a variation of the action (11) with respect to $h^{[\mu\nu]}$ one obtains the linearized field equations

$$\nabla_\alpha F_{\mu\nu\alpha} + m^2 h_{[\mu\nu]} - 4 h^{[\alpha\beta]} R_{\alpha\mu\beta\nu} = 2\hat{T}_{[\mu\nu]}. \tag{12}$$

III. 3+1 DECOMPOSITION OF THE LINEARIZED FIELD EQUATIONS

One considers space–time as composed of three-dimensional spacelike surface and time, embedded in four-dimensional Riemann space. If one treats these spacelike surfaces as the element of a family of surfaces to which one could define non-null normal vectors n^μ such that

$$n_\nu n^\mu = \epsilon = \pm 1, \tag{13}$$

where the components of the normal vectors are denoted by

$$n_\mu = (0,0,0,\epsilon N), \quad n^\mu = \left(-\frac{N^a}{N}, \frac{1}{N} \right), \tag{14}$$

$\mu,\nu,\ldots = 0,1,2,3$ and $a,b,\ldots = 1,2,3$, then the metric tensor of the hypersurface, written in terms of the skew part of the 3-metric h_{ab} takes the form

$$dS^2 = h_{ab}\, dx^a\, dx^b \tag{15}$$

and the skew metric tensor $h_{\mu\nu}$ of space–time is given by

$$dS^2 = h_{\mu\nu}\, dx^\mu\, dx^\nu, \tag{16}$$

the two being related as

$$dS^2 = h_{\mu\nu}\, dx^\mu\, dx^\nu = h_{ab}(dx^a + N^a dx^0)(dx^b + N^b\, dx^0) + \epsilon (N\, dx^0)^2, \tag{17}$$

where N and N^a are, respectively, the lapse function and shift vector, and the quantity x^0 is timelike. In the same way the $3+1$ split of metric tensor leads to:

$$\begin{aligned} h_{\mu\nu} &= {}^3h_{\mu\nu}, \quad h_{0\delta} = N_\delta, \\ h_{\gamma 0} &= N_\gamma, \quad h_{00} = N_\eta N^\eta, \end{aligned} \tag{18}$$

with its inverse as

$$\begin{aligned} h^{\mu\nu} &= h^{ab} + \frac{\epsilon}{N^2} N^a N^b, \quad h^{0\delta} = -\epsilon \frac{N^a}{N^2}, \\ h^{\gamma 0} &= -\epsilon \frac{N^b}{N^2}, \quad h^{00} = -\frac{\epsilon}{N^2}. \end{aligned} \tag{19}$$

Since our primary goal is to express the field equations (12) in $3+1$ decomposed form, we perform the split of the background curvature into components parallel or perpendicular to the normal vector to the hypersurface by making use of the projection tensor as in Appendix A. Thus one obtains the components of the background curvature tensor as

$$R_{cdba} = {}^3R_{cdba} + \epsilon (K_{da} K_{cb} - K_{db} K_{ca}), \tag{20}$$

$$R^\mu_{dab} n_\mu = (K_{db|a} - K_{da|b}), \tag{21}$$

$$R^{\mu}_{d\rho b} n_{\mu} n^{\rho} = \dot{n}_{(d;b)} + K_{da} K^{a}_{b} - \epsilon \dot{n}_{d} \dot{n}_{b} + \& K_{ab} . \tag{22}$$

Equations (20) and (21) are analogous to the Gauss–Codazzi equations. The quantities K_{da}, K_{cb}, etc. denote extrinsic curvatures while & denotes the Lie derivative. By choosing the coordinates such that the $X^a = constant$ lines are normal to the hypersurface, one obtains $N^a = 0$ and Eqs. (20)–(22) simplify to

$$R_{cdab} = {}^{3}R_{cdab} + \epsilon (K_{da} K_{cb} - K_{db} K_{ca}), \tag{23a}$$

$$R^{0}_{dab} = \frac{\epsilon}{N} (K_{db|a} - K_{da|b}), \tag{23b}$$

$$R^{0}_{do\nu} = \frac{\epsilon}{N} (K_{db,o} - N_{,d|b}) + \epsilon K_{cd} K^{c}_{b} . \tag{23c}$$

Equations (23a)–(23c) are then used to rewrite the linearized field equations (12) in $3+1$ decomposed form as in Appendix B, resulting in two sets of field equations:

$${}^{3}R_{cdab} - K_{da} K_{cb} + K_{db} K_{ca} = 0, \tag{24a}$$

$$K_{db,0} - N_{,d|b} + N K_{cd} K^{c}_{b} = 0. \tag{24b}$$

IV. ANALYSIS OF THE DECOMPOSED FIELD EQUATIONS

An examination of the field equations shows the following.

(a) The linearized field equations (24a) contain only the spiral derivatives of the metric tensors and their corresponding extrinsic curvatures and consequently the initial values of, say, h_{cb} and K_{cb} cannot be chosen freely. Thus the equations play the role of constraint equations. These 14 equations are also connected by 4 Bianchi identities, thus reducing the actual number of constraints to 10.

(b) Since the highest time derivative occurs in Eq. (24b) namely $K_{db,0}$ and given that the equation has no curvature terms the antisymmetric components of the fundamental tensor ensure good asymptotic behavior. This contrasts with what had been found by Clayton,[16] who showed by an examination of the exact field equations of MNGT near initially GR field configuration, that arbitrarily small antisymmetric sector fields lead to large accelerations, thereby giving the possibility of linearization instability of MNGT. Our results suggest that the existence of such an instability is suspect on these grounds.

Now since it had been shown[16] that small skew sector data lead to nonsingular evolution for the majority of the possible choices of perturbatively small skew sector initial data, we are of the opinion that our results would be a good starting point for probing the phenomenological results on galaxy dynamics, i.e., whether the collapse of a spherically symmetric matter would be nonsingular.

V. CONCLUSION

It has been shown that the linearized field equations of MNGT have a dynamical part which leads to bounded accelerations, thus giving promising results to the effect that the skew part of the fundamental tensor exhibits good fall-off.

Thus our results effectively strengthen the view that the skew part of the fundamental tensor could be considered just as a perturbation of the symmetric GR background in the linear approximation.

APPENDIX A: 3+1 DECOMPOSITION OF BACKGROUND CURVATURE TENSOR

In order to decompose tensors into components parallel or perpendicular to the normal vector to the hypersurface, one defines a projection tensor $P_{\mu\nu}=h_{\mu\nu}-\epsilon n_\mu P_\nu$ which has the properties[17]

$$P_{\mu\nu}P^{\nu}_{\mu}=P_{\mu\alpha}, \quad P_{\mu\nu}n^{\mu}=0,$$
$$P_{cd}=h_{cd}, \quad P^{cd}=h^{cd}, \tag{A1}$$
$$h^{0}_{\nu}=0, \quad P^{d}_{m}=\delta^{d}_{m}.$$

Since curvature tensors are obtained from covariant derivatives of normal vectors, we may obtain the $3+1$ dimensional split of the background curvature tensor $R_{\alpha\mu\beta\nu}$ by making use of projection tensors as follows:

$$(T_{d|a|b}-T_{c|b|a})P^{d}_{\nu}P^{a}_{\rho}P^{b}_{\lambda}=(T_{\sigma;\eta}P^{\sigma}_{\gamma}P^{\eta}_{\delta});\xi P^{\gamma}_{\nu}(P^{\delta}_{\rho}P^{\xi}_{\lambda}-P^{\delta}_{\lambda}P^{\xi}_{\delta})$$
$$=(T_{\sigma;\eta;\xi}-T_{\sigma;\xi;\eta})P^{\sigma}_{\nu}P^{\eta}_{\rho}P^{\xi}_{\lambda}+T_{\sigma;\eta}(P^{\eta}_{\gamma}P^{\eta}_{\delta});P^{\gamma}_{\nu}(P^{\delta}_{\rho}P^{\xi}_{\lambda}-P^{\delta}_{\lambda}P^{\xi}_{\rho}), \tag{A2}$$

where, say, T_d, etc., are three vectors and $T_{d|a}$ etc refer to 3-dim covariant derivative of the three vectors. From this equation one obtains the relation

$${}^{3}R_{cdab}T^{c}P^{d}_{\nu}P^{a}_{\rho}P^{b}_{\lambda}=R_{c\sigma\eta\xi}T^{c}P^{\sigma}_{\nu}P^{\eta}_{\rho}P^{\xi}_{\lambda}+\epsilon(K_{\lambda\nu}K_{\rho c}-K_{\nu\rho}K_{\lambda c})T^{c}. \tag{A3}$$

Since the equation holds for every vector T^c, one obtains the relation

$$R_{cdab}={}^{3}R_{cdba}+\epsilon(K_{da}K_{cb}-K_{db}K_{ac}), \tag{A4}$$

analogous to the Gauss equation. Now since the covariant derivative of the projection tensor $P_{\mu\nu;\gamma}$ is given by

$$P_{\mu\nu;\gamma}=-(\dot{n}_\mu n_\nu+n_\mu\dot{n}_\nu)n_\gamma+\epsilon(K_{\mu\gamma}n_\nu+K_{\mu\gamma}n_\mu) \tag{A5}$$

and the covariant derivatives of the vector T is given by

$$P^{\gamma}_{\mu}P^{\delta}_{\nu}T_{\gamma;\delta}=P^{c}_{d}P^{d}_{\nu}T_{c|d}, \tag{A6a}$$

$$T_{c|d}=T_{c,d}-{}^{3}\Gamma^{m}_{cd}T_{m} \tag{A6b}$$

we have that

$$(n_{\xi;\sigma;\eta}-n_{\xi;\eta;\sigma})P^{\xi}_{\nu}P^{\sigma}_{\rho}P^{\eta}_{\lambda}=[(n_{\xi;\gamma}P^{\gamma}_{\sigma})_{;\eta}-(n_{\xi;\gamma}P^{\gamma}_{\eta})_{;\sigma}]P^{\xi}_{\nu}P^{\sigma}_{\rho}P^{\eta}_{\lambda}$$
$$=(K_{\xi\eta;\sigma}-K_{\xi\sigma;\eta})P^{\xi}_{\nu}P^{\sigma}_{\rho}P^{\eta}_{\lambda}=(K_{db|a}-K_{da|b})P^{c}_{\nu}P^{a}_{\rho}P^{b}_{\lambda},$$

from which we obtain the expression

$$R^{\mu}_{dab}n_\mu=(K_{db|a}-K_{da|b}). \tag{A7}$$

Analogously from

$$(n_{\xi;\sigma;\eta}-n_{\xi;\eta;\sigma})P^{\xi}_{\nu}n^{\sigma}P^{\eta}_{\lambda}=[(\epsilon\dot{n}_{\xi}n_{\sigma}-K_{\xi\sigma})_{;\eta}-\epsilon(\dot{n}_{\xi}n_{\eta}-K_{\xi\eta})_{;\sigma}]n^{\sigma}P^{\xi}_{\nu}P^{\eta}_{\lambda}$$
$$=\dot{n}_{\xi;\eta}P^{\eta}_{\nu}P^{\eta}_{\lambda}+K_{\xi\sigma}n^{\sigma}_{;\eta}P^{\xi}_{\nu}P^{\eta}_{\lambda}-\epsilon\dot{n}_{\mu}\dot{n}_{\lambda}+K_{\nu\lambda;\sigma}n^{\sigma}-K_{\xi\eta}(P^{\xi}_{\nu}P^{\eta}_{\lambda})_{;\sigma}n^{\sigma},$$

from which it follows that

$$R^{\mu}_{d\rho b}n_{\mu}n^{\rho}=\dot{n}_{(d;b)}+K_{da}K^{a}_{b}-\epsilon\dot{n}_{d}\dot{n}_{b}+\&K_{db}\,, \tag{A8}$$

where & denotes the Lie derivative and K_{db}, etc., are the extrinsic curvature tensors

Now for the special case when the shift vector $N^{\alpha}=0$, Eqs. (A4)–(A8) simplify to

$$R_{cdab}={}^{3}R_{cdab}=\epsilon(K_{da}K_{cb}-K_{db}K_{ca}), \tag{A9a}$$

$$R^{0}_{dab}=\frac{\epsilon}{N}(K_{db|a}-K_{da|b}), \tag{A9b}$$

$$R^{0}_{d0\nu}=\frac{\epsilon}{N}(K_{db,0}-N_{,d|b})+\epsilon K_{cd}K^{c}_{b}\,, \tag{A9c}$$

which are the decomposed components of the background curvature tensor ${}^{0}R_{\alpha\mu\beta\nu}$.

APPENDIX B: DECOMPOSITION OF FIELD EQUATIONS

The decomposed background curvature tensor (A9) may be used to rewrite the linearized field equations (12) in $3+1$ decomposed form as follows:

$$\nabla^{\alpha}F_{\mu\nu\alpha}+m^{2}h_{[\mu\nu]}-4h^{[\alpha\beta]}\,{}^{3}R_{cdab}+4h^{[\alpha\beta]}\epsilon(K_{da}K_{cb}-K_{db}K_{ca})=-2\hat{T}_{[\mu\nu]}\,, \tag{B1}$$

$$\nabla^{\alpha}F_{\mu\nu\alpha}+m^{2}h_{[\mu\nu]}-4h^{[\alpha\beta]}\frac{\epsilon}{N}(K_{db|a}-K_{da|b})=-2\hat{T}_{[\mu\nu]}\,, \tag{B2}$$

$$\nabla^{\alpha}F_{\mu\nu\alpha}+m^{2}h_{[\mu\nu]}-4h^{[\alpha\beta]}\frac{\epsilon}{N}\{(K_{db,0}-N_{,d|b})+K_{cd}K^{c}_{b}\}=-2\hat{T}_{[\mu\nu]}\,. \tag{B3}$$

Now since each of these equations are equal, we may subtract Eq. (B2) from the remaining two and after some rearrangement, we end up with two sets of field equations:

$${}^{3}R_{cdab}-K_{da}K_{cb}+K_{db}K_{ca}=0, \tag{B4}$$

and

$$K_{db,0}-N_{,d|b}+NK_{cd}K^{c}_{b}=0, \tag{B5}$$

which are, respectively, the constraint equations and the evolution equations.

Almost-complex and almost-product Einstein manifolds from a variational principle

Andrzej Borowiec,[a] Marco Ferraris, Mauro Francaviglia, and Igor Volovich[b]
Dipartimento di Matematica, Università di Torino, Via C. Alberto 10, 10123 Torino, Italy

(Received 7 July 1997; accepted for publication 2 February 1999)

It is shown that the first-order (Palatini) variational principle for a generic nonlinear metric-affine Lagrangian depending on the (symmetrized) Ricci square invariant leads to an almost-product Einstein structure or to an almost-complex anti-Hermitian Einstein structure on a manifold. It is proved that a real anti-Hermitian metric on a complex manifold satisfies the Kähler condition on the same manifold treated as a real manifold if and only if the metric is the real part of a holomorphic metric. A characterization of anti-Kähler Einstein manifolds and almost-product Einstein manifolds is obtained. Examples of such manifolds are considered. © *1999 American Institute of Physics.* [S0022-2488(99)03107-2]

I. INTRODUCTION

Almost-complex and almost-product structures are among the most important geometrical structures which can be considered on a manifold.[1–4] The aim of this paper is to show that structures of this kind appear in a natural way from a variational principle based on a general class of Lagrangians depending on the Ricci square invariant constructed out of a metric and a symmetric connection; in particular we will show that an anti-Hermitian metric and its special case, the so-called ''anti-Kählerian'' metric, appear naturally from our variational principle. Manifolds with such metrics are much less studied than the familiar Hermitian and Kählerian cases. We hope that our variational principle and ''the universality of the Einstein equations'' (see below) will provide an additional motivation for investigating these manifolds.

Let M be a differentiable manifold of dimension n and $L(M)$ be its frame bundle, a principal fiber bundle over M with group $\mathrm{GL}(n;\mathbb{R})$. Let G be a Lie subgroup of $\mathrm{GL}(n;\mathbb{R})$. A differentiable subbundle Q of $L(M)$ with structure group G is called a *G-structure on M*.[2,4] The classification and integrability of G-structures have been studied in differential geometry; algebraic-topological conditions on M which are necessary for the existence of a G-structure on M can be given in terms of characteristic classes (see, for example, Ref. 5). We also recall that there is a natural one-to-one correspondence between pseudo-Riemannian metrics of signature q on M and $\mathrm{O}(p,q;\mathbb{R})$-structures on M, with $p+q=n$. An $\mathrm{O}(p,q;\mathbb{R})$-structure is integrable if and only if the corresponding pseudo-Riemannian metric has vanishing Riemann curvature. If $G=\mathrm{GL}(p;\mathbb{R})\times\mathrm{GL}(q;\mathbb{R})$, then the G-structure is called an *almost-product structure*;[3,6,7] if $G=\mathrm{O}(r,s;\mathbb{R})\times\mathrm{O}(k,l;\mathbb{R})$, then the G-structure is called a *(pseudo-) Riemannian almost-product structure*.[3,8,9] If n is even, $n=2m$, and one considers $\mathrm{GL}(m;\mathbb{C})$ as a subgroup of $\mathrm{GL}(2m;\mathbb{R})$, then a $\mathrm{GL}(m;\mathbb{C})$-structure is called an *almost-complex structure*;[3,4] if, moreover, one considers $\mathrm{O}(m;\mathbb{C})$ as a subgroup of $\mathrm{GL}(m;\mathbb{C})$, then an $\mathrm{O}(m;\mathbb{C})$-structure defines an *almost-complex anti-Hermitian structure*.[10–14]

We will here use an equivalent description of these G-structures. Let M be a manifold and P be an endomorphism of the tangent bundle TM satisfying $P^2=I$, where I=*identity*. Then P

[a]On leave from the Institute of Theoretical Physics, University of Wrocław, pl. Maksa Borna 9, 50-204 Wroclaw, Poland. Electronic mail: borow@ift.uni.wroc.pl
[b]Permanent address: Steklov Mathematical Institute, Russian Academy of Sciences, Vavilov St. 42, GSP-1, 117966 Moscow, Russia.

defines an almost-product structure on M. If g is a metric on M such that $g(PX,PY)=g(X,Y)$ for arbitrary vectorfields X and Y on M, then the triple (M,g,P) defines a (pseudo-) Riemannian almost-product structure. Geometric properties of (pseudo-) Riemannian almost-product structures have been studied in Refs. 1, 3, 6, 8, 9, and 15–19. If, moreover, g is an Einstein metric [i.e., $\mathrm{Ric}(g)=\gamma g$ holds, where $\mathrm{Ric}(g)$ is the Ricci tensor and γ is a constant], then the triple (M,g,P) shall be called an *almost-product Einstein manifold*.

Analogously, if J is an endomorphism of the tangent bundle TM satisfying $J^2=-I$, then J defines an almost-complex structure on M. An almost-complex structure is integrable if and only if it comes from a complex structure (see Ref. 20). If g is a metric on M such that $g(JX,JY)=-g(X,Y)$ for arbitrary vectorfields X and Y on M, then the triple (M,g,J) defines an almost-complex anti-Hermitian structure. The metric g in this case is called a *Norden metric* and in complex coordinates it has the form

$$ds^2=g_{ab}dz^a dz^b+g_{\bar{a}\bar{b}}d\bar{z}^{\bar{a}}d\bar{z}^{\bar{b}},$$

where $g_{\bar{a}\bar{b}}=\overline{g_{ab}}$. This canonical form differs from the well-known form of a Hermitian metric $ds^2=2g_{a\bar{b}}dz^a d\bar{z}^b$. We will show (Theorem 4.2) that the condition $\nabla J=0$, where ∇ is the Levi–Civita connection, is equivalent in this case to analyticity of the metric: $\partial_{\bar{c}}g_{ab}=0$. Such anti-Hermitian metrics shall be called *anti-Kählerian metrics* since for a Hermitian metric the condition $\nabla J=0$ defines a Kählerian metric.

If g is an Einstein metric, i.e., $\mathrm{Ric}(g)=\gamma g$ holds, then the almost-complex anti-Hermitian manifold (M,g,J) is called an *anti-Hermitian Einstein manifold*. We will consider an important particular class of such manifolds, namely those characterized by *anti-Kählerian Einstein metrics*. Let us stress that we treat *the whole* complex manifold as a real manifold and in this way we get a real Einstein metric with signature (m,m). Another approach to complex Einstein equations, dealing with a *real section* of a complex manifold and aiming to get the Lorentz signature, has been considered in Refs. 21–26.

These G-structures can be conveniently defined as a triple (M,g,K), where g is a metric on M and K is a (1,1) tensor field on M such that $K^2=\epsilon I$ and $g(KX,KY)=\epsilon g(X,Y)$ for arbitrary vectorfields X and Y on M ($\epsilon\neq 0$ is a real constant). We shall also call them *K-structures*. If $\epsilon=1$, then K defines an almost-product structure on M; if $\epsilon=-1$, then K defines an almost-complex structure on M. The more general case $\epsilon>0$ can be reduced to $\epsilon=1$ by a suitable rescaling, while the case $\epsilon<0$ is reduced to $\epsilon=-1$. In any coordinate system one has $K^\mu_\alpha K^\alpha_\nu=\epsilon\delta^\mu_\nu$ and $K^t gK=\epsilon g$, where K^t is the transpose matrix, $\mu,\nu,\alpha=1,2,...,n=\dim(M)$, and δ^μ_ν is the Kronecker symbol.

One can then define a new metric h by the relation $h(X,Y)=g(KX,Y)$, or equivalently $h=gK$, i.e., in local coordinates $h_{\mu\nu}=g_{\mu\alpha}K^\alpha_\nu$. Then the following holds:

$$(g^{-1}h)^2=\epsilon I. \tag{1.1}$$

The relation (1.1) for $\epsilon=+1$ or -1 is equivalent to $(h^{-1}g)^2=\epsilon I$ and there is a one-to-one correspondence between the G-structure (M,g,K) and the G-structure (M,h,K^{-1}). Hence the G-structure given by the triple (M,g,K) can be equivalently described by the triple (M,g,h), where g and h are metrics on M satisfying (1.1). We call such metrics *twin metrics* or *dual metrics*.

In this paper, starting from a manifold M endowed with a metric $h=(h_{\mu\nu})$ and a symmetric linear connection $\Gamma=(\Gamma^\alpha_{\mu\nu})$, we obtain a K-structure as

$$K^\alpha_\mu=h^{\alpha\nu}S_{\mu\nu},$$

where $S_{\mu\nu}\equiv R_{(\mu\nu)}(\Gamma)$ is the symmetric part of the Ricci tensor of the given connection Γ. The general idea is the following. Let us first set $g_{\mu\nu}=R_{(\mu\nu)}(\Gamma)$. According to the results of our earlier paper,[27] one can show that g is, in fact, a new metric and that h and g are ‘‘twin metrics’’ if one assumes a suitable variational principle based on the action

$$A(\Gamma,h)=\int_M f(S)\sqrt{h}\,dx \tag{1.2}$$

and imposes independent variations over the metric and the connection. Here $f(S)$ is a given function of one real variable, which we assume to be analytic, while the scalar $S=S(\Gamma,h)$ is the Ricci square invariant

$$S=h^{\mu\alpha}h^{\nu\beta}S_{\alpha\beta}S_{\mu\nu}.$$

If f is a generic analytic function and $n>2$, one gets either a (pseudo-) Riemannian almost-product structure or an almost-complex structure. In fact, as we shall see below (Theorem 2.4), the Euler–Lagrange equations for (1.2) are generically equivalent to the following system of equations for two metrics $h_{\mu\nu}$ and $g_{\mu\nu}$:

$$(h^{-1}g)^2=\frac{c}{n}I, \tag{1.3}$$

$$\mathrm{Ric}\,(g)=g, \tag{1.4}$$

where the real number c is a root of the equation

$$f'(S)S-\frac{n}{4}f(S)=0. \tag{1.5}$$

As an example, if one takes $f(S)=(nS+c(8-n))^2$, then $S=c$ is a solution of (1.5) if $n\neq 8$ and another (degenerate) solution is $S=c(n-8)/n$. Turning to the general discussion, if $c>0$, then, as it was explained above, solutions of (1.3) and (1.4) are in one-to-one correspondence with almost-product Einstein manifolds (M,g,P), while for $c<0$ one gets anti-Hermitian Einstein manifolds (M,g,J).

Before proceeding further let us explain why the action (1.2) is interesting and important in mathematical physics and especially in the theory of gravity.

As is well known, gravitational Lagrangians which are nonlinear in the scalar curvature of a metric give rise to equations with higher (more than second) derivatives or to the appearance of additional matter fields.[28,29] This strongly depends on having taken a metric as the only basic variable and the equations ensuing from such Lagrangians show an explicit dependence on the Lagrangian itself. An important example of a nonlinear Lagrangian leading to equations with higher derivatives is given by Calabi's variational principle,[30] which shall be discussed in a forthcoming paper.

It was shown in Ref. 31 that, in contrast, working in the first-order (Palatini) formalism, i.e., assuming independent variations with respect to a metric and a symmetric connection, then, for a large class of Lagrangians of the form $f(R)$, where R is the scalar curvature, the equations obtained are almost independent on the Lagrangian, the only such dependence being, in fact, encoded into constants (cosmological and Newton's ones). In this sense the equations obtained are ''universal'' and turn out to be Einstein equations in generic cases. Considering nonlinear gravitational Lagrangians which still generate Einstein equations is particularly important since they provide a simple but general approach to governing topology in dimension two[32] and in view of applications to string theory.[33]

In a previous paper of ours[27] this discussion was extended to the case of Lagrangians with an arbitrary dependence on the square of the symmetrized Ricci tensor of a metric and a (torsionless) connection, finding roughly that the universality of Einstein equations also extends to this class of space–times. In this case, however, new important properties appear: as we have already mentioned above, depending, in fact, on the form of the Lagrangian and on the signature of the metric, one gets an almost-product Einsteinian structure or an almost-complex Einsteinian structure. Topological and geometrical obstructions for the global existence of a solution of the variational problem for this class of Lagrangians will be here considered in Secs. V and VI.

Recently there has been some interest in the problem of signature change in general relativity;[34–36] the nonstandard signature $(10+2)$ has been considered also in superstring theory (F-theory[37]) and extra timelike dimensions in Kaluza–Klein theory are considered in Refs. 38–40. Our results seem, therefore, to show new aspects of this problem which can be relevant also for quantum gravity. For a mathematical consideration of metrics with arbitrary signature which can be relevant to mathematical physics, see, for examples Refs. 41–43.

This paper is organized as follows. In the next section it will be shortly recalled how to get Eqs. (1.3) and (1.4) from the action (1.2). In Sec. III it is shown that Eq. (1.3) can be always solved locally for any given metric g, in particular satisfying (1.4). In Sec. IV we discuss the K-structures. In Sec. V we discuss the problems of the global existence as well as the classification of almost-product Einstein manifolds. In Sec. VI we prove that a real anti-Hermitian metric on a complex manifold satisfies the Kähler condition on the same manifold treated as a real manifold if and only if the metric is the real part of a holomorphic metric on this manifold. Finally, we consider also examples of almost-product Einstein manifolds and anti-Kählerian Einstein manifolds. Theorems of Sec. III are proved in the Appendix.

II. FIELD EQUATIONS

In this section we shall present in a more geometrical form the results of our earlier paper,[27] which form the basis of the further results presented hereafter. Consider, in the first-order (Palatini) formalism, the family of actions

$$A(\Gamma,h)=\int_M f(S)\sqrt{h}\,dx, \tag{2.1}$$

where M is an n-dimensional manifold $(n>2)$ endowed with a metric $h_{\mu\nu}$ and a torsionless (i.e., symmetric) connection $\Gamma^{\sigma}_{\mu\nu}$; the Lagrangian density is $L=f(S)\sqrt{h}$, where $f(S)$ is a given function of one real variable, which we assume to be analytic and $\sqrt{h}$ is a shorthand for $|\det(h_{\mu\nu})|^{1/2}$; and the scalar S is the symmetric part of Ricci square-invariant, considered as a first-order scalar concomitant of a metric and (torsionless) connection, i.e.,

$$S=S(h,\Gamma)=h^{\mu\alpha}h^{\nu\beta}S_{\alpha\beta}S_{\mu\nu} \tag{2.2}$$

being $S_{\mu\nu}=R_{(\mu\nu)}(\Gamma)$ the symmetric part of Ricci tensor, defined according to

$$R^{\lambda}_{\mu\nu\sigma}(\Gamma)=\partial_\nu\Gamma^{\lambda}_{\mu\sigma}-\partial_\sigma\Gamma^{\lambda}_{\mu\nu}+\Gamma^{\lambda}_{\alpha\nu}\Gamma^{\alpha}_{\mu\sigma}-\Gamma^{\lambda}_{\alpha\sigma}\Gamma^{\alpha}_{\mu\nu},$$

$$R_{\mu\sigma}(\Gamma)=R^{\nu}_{\mu\nu\sigma}(\Gamma)\quad(\alpha,\mu,\nu,\ldots=1,\ldots,n).$$

Following Ref. 27, the Euler–Lagrange equations of the action (2.1) with respect to independent variations of h and Γ are

$$f'(S)h^{\alpha\beta}S_{\mu\alpha}S_{\nu\beta}-\tfrac{1}{4}f(S)h_{\mu\nu}=0, \tag{2.3}$$

$$\nabla_\lambda(f'(S)\sqrt{h}h^{\mu\alpha}h^{\nu\beta}S_{\alpha\beta})=0, \tag{2.4}$$

where ∇_λ is the covariant derivative with respect to Γ. Transvecting (2.3) with $h^{\mu\nu}$ tells us that the scalar S has to obey the following real analytic equation,

$$f'(S)S-\frac{n}{4}f(S)=0, \tag{2.5}$$

which allows the description of the general features of the nonlinear system (2.3) and (2.4) and tells us, in turn, that S is generically forced to be a constant. More precisely, it was shown in Ref. 27 that whenever (2.5) admits an (isolated) simple root $S=c$, then the system is ''essentially equivalent'' to Einstein equations for a new metric g with a cosmological constant, in the precise sense which is hereafter described in greater detail. Consider, in fact, any solution

$$S=c \tag{2.6}$$

of Eq. (2.5) and assume that $f'(c)\neq 0$. Then Eq. (2.4) reduces to

$$\nabla_\lambda(\sqrt{h}h^{\mu\alpha}h^{\nu\beta}S_{\alpha\beta})=0, \tag{2.7}$$

while Eq. (2.3) reduces to

$$h^{\alpha\beta}S_{\mu\alpha}S_{\nu\beta}=\epsilon h_{\mu\nu}, \tag{2.8}$$

where a new constant ϵ depending on c arises according to the rule

$$\epsilon=f(c)/4f'(c)=c/n. \tag{2.9}$$

From (2.8) the regularity condition

$$[\det(S_{\mu\nu})]^2=\epsilon^n[\det(h_{\mu\nu})]^2 \tag{2.10}$$

follows, which entails, in particular, that $\det(S_{\mu\nu})\neq 0$ provided $\epsilon\neq 0$. Under this last hypothesis, let $S^{\mu\nu}$ be the inverse matrix of $S_{\mu\nu}$, so that from (2.8) we have

$$h^{\mu\alpha}h^{\nu\beta}S_{\alpha\beta}=\epsilon S^{\mu\nu}. \tag{2.11}$$

By using (2.10) and (2.11), we finally rewrite (2.7) as follows:

$$\nabla_\lambda[\sqrt{|\det(S_{\alpha\beta}(\Gamma))|}S^{\mu\nu}(\Gamma)]=0, \tag{2.12}$$

which will be considered as a new equation in Γ.

Let us recall now the following well-known result, essentially due to Levi-Civita: for $n>2$, any metric g, and any symmetric connection Γ, the general solution of the equation

$$\nabla_\alpha(\sqrt{g}g^{\mu\nu})=0 \tag{2.13}$$

considered as an equation for Γ is the Levi-Civita connection $\Gamma=\Gamma_{\mathrm{LC}}(g)$, i.e., locally

$$\Gamma^\sigma_{\mu\nu}(g)=\tfrac{1}{2}g^{\sigma\alpha}(\partial_\mu g_{\nu\alpha}+\partial_\nu g_{\mu\alpha}-\partial_\alpha g_{\mu\nu}). \tag{2.14}$$

Therefore, the Ricci tensor $R_{\mu\nu}(\Gamma)$ of Γ is automatically symmetric and, in fact, identical to the Ricci tensor $R_{\mu\nu}(g)$ of the metric g itself.

We can then prove the following:

Proposition 2.1: Let us assume that $\det(S_{\alpha\beta})\neq 0$. *Then a connection* Γ *satisfies Eq. (2.12) if and only if there exists a metric* $g_{\mu\nu}$ *such that*

$$R_{\mu\nu}(g)=g_{\mu\nu} \tag{2.15}$$

and $\Gamma=\Gamma_{\mathrm{LC}}(g)$ *is the Levi-Civita connection of* g.

Proof: Let Γ be a connection satisfying Eq. (2.12) and let us set

$$g_{\mu\nu}=S_{\mu\nu}(\Gamma). \tag{2.16}$$

The tensorfield g is a metric due to the condition $\det(S_{\alpha\beta})\neq 0$. Then it follows that Γ has to be the Levi-Civita connection of the metric g; moreover, one has

$$S_{\mu\nu}(\Gamma)=R_{(\mu\nu)}(\Gamma)=R_{\mu\nu}(g), \tag{2.17}$$

so that (2.15) follows from (2.16) and (2.17).

Conversely, let us give a metric $g_{\mu\nu}$ satisfying (2.15) and let us take $\Gamma=\Gamma_{\mathrm{LC}}(g)$. One has again relations (2.17). From (2.17) and (2.15) it follows then that (2.16) holds. Therefore $g^{\mu\nu}=S^{\mu\nu}(\Gamma)$ and $\det(S_{\mu\nu}(\Gamma))=\det(g_{\mu\nu})\neq 0$. Hence we see that Eq. (2.12) reduces to (2.13), which is satisfied since $\Gamma=\Gamma_{\mathrm{LC}}(g)$. Our claim is then proved. (Q.E.D.)

According to the previous discussion, we see that the Euler–Lagrange equations (2.3) and (2.4) are hence equivalent to the following equations for two metrics h and g:

$$h^{\alpha\beta}g_{\mu\alpha}g_{\nu\beta}=\epsilon h_{\mu\nu}, \tag{2.18}$$

$$R_{\mu\nu}(g)=g_{\mu\nu}, \tag{2.19}$$

which are, in fact, nothing but Eqs. (1.3) and (1.4) of the Introduction. The relation between the system (2.18) and (2.19) and the Euler–Lagrange equations in the form (2.3) and (2.4) or (2.11) and (2.12) is given by setting $g_{\mu\nu}=R_{(\mu\nu)}(\Gamma)$.

We will now use the description of (pseudo-) Riemannian almost-product structures and almost-complex structures with a Norden metric in terms of a pair of metrics (twin or dual metrics). Let us consider a triple (M,h,K), where M is a differentiable manifold, h is a metric on M, and K is a (1,1) tensorfield on M such that the following holds:

$$K^2=\epsilon I, \quad K^t hK=\epsilon h.$$

As we said in the Introduction, such a triple defines a (pseudo-)Riemannian almost-product structure if $\epsilon=1$, while it defines an almost-complex structure with a Norden metric h if $\epsilon=-1$. The triple (M,h,K) admits an equivalent description as another triple (M,h,g), where g is a metric on M satisfying the relation $(h^{-1}g)^2=\epsilon I$ or the equivalent relation $(g^{-1}h)^2=cI$, because of the following elementary proposition.

Proposition 2.2: Let K and h be real $n\times n$ matrices and $\epsilon=+1$ or -1. Then the matrices K and h satisfy the relations

$$h^t=h, \quad \det h\neq 0, \quad K^2=\epsilon I, \quad K^t hK=\epsilon h \tag{2.20}$$

if and only if there exists a real matrix g such that g and h satisfy the relations

$$h^t=h, \quad \det h\neq 0, \quad g^t=g, \quad (h^{-1}g)^2=\epsilon I. \tag{2.21}$$

Moreover, one has

$$g=hK \tag{2.22}$$

and

$$(K^{-1})^2=\epsilon l, \quad K^{-1t}gK^{-1}=\epsilon g. \tag{2.23}$$

Proof: If one has (2.20), then define g by (2.22) and check (2.21) and (2.23). Conversely, if one has (2.21), then define $K=h^{-1}g$ and check (2.20). The claim is proved. (Q.E.D.)

We can therefore state the following theorem.

Theorem 2.3: *Let M be a n-dimensional manifold, $n>2$, with a metric h and a symmetric connection Γ and let us consider the Euler–Lagrange equations (2.3) and (2.4) for the action*

(2.1). Let us assume that the analytic function $f(S)$ is such that Eq. (2.5) has an isolated root $S=c$ with $f'(c)\neq 0$. Setting then $g_{\mu\nu}=R_{(\mu\nu)}(\Gamma)$, the Euler–Lagrange equations imply the relations $(h^{-1}g)^2=\epsilon I$, $\mathrm{Ric}\,(g)=g$. Therefore,

(i) if $\epsilon>0$, after rescaling and denoting $P=g^{-1}h$ one gets an almost-product Einstein manifold (M,g,P), i.e.,

$$\mathrm{Ric}\,(g)=\gamma g,$$

$$P^2=1,\quad g(PX,PY)=g(X,Y),\quad X,Y\in\chi(M).$$

(ii) If $c<0$, after rescaling and denoting $J=g^{-1}h$ one gets instead an anti-Hermitian Einstein manifold (M,g,J), i.e.,

$$\mathrm{Ric}\,(g)=\gamma g,$$

$$J^2=-I,\quad g(JX,JY)=-g(X,Y),\quad X,Y\in\chi(M).$$

Here $\chi(M)$ is the Lie algebra of vectorfields on M.

Notice that the signatures of the metrics h and g in the almost-product case can be, in principle, arbitrary, while in the almost-complex case the signature is (m,m). In any case they will be lower-semicontinuous functions, so that without any restriction we can assume that they remain constant in the neighborhood of a generic point; in particular, they will not change in connected components of the manifold. In the next section we will therefore study the equation $(h^{-1}g)^2=\epsilon I$ for a generic point on the manifold, i.e., study it algebraically as a matrix equation.

Remark: Notice that $\epsilon=0$ corresponds to the case $S=0$, which holds iff $f(0)=0$. Then we have to distinguish two subcases $f'(0)=0$ and $f'(0)\neq 0$. In the first subcase both Eqs. (2.3) and (2.4) are automatically satisfied and no condition for g and Γ arise. Therefore, any pair (g,Γ) solves this subcase. When $f'(0)\neq 0$, then (2.3) is instead equivalent to the algebraic equation $[h^{-1}S(\Gamma)]^2=0$, which leads to an *almost-tangent* structure,[44] while (2.4) remains unchanged. We shall not discuss this case in the present paper.

III. SOLUTIONS OF THE MATRIX EQUATIONS

Let us then consider the matrix equation

$$(h^{-1}g)^2=\epsilon\mathbf{I}_n,\tag{3.1}$$

where h and g are symmetric nondegenerate real $n\times n$ matrices, $\mathbf{I}_n$ is the identity matrix in n dimensions, and ϵ is a nonvanishing real number.

In order to solve Eq. (3.1) we first notice that it is manifestly $\mathrm{Gl}(n,\mathbb{R})$-invariant under the canonical right-action $(h,g)\mapsto(A^thA,A^tgA)$, where A^t denotes the matrix transpose to A. More exactly, transforming h and g as metrics one can observe that $P=h^{-1}g$ transforms by a similarity transformation $P\to A^{-1}PA$ [i.e., as a (1,1) tensor]. Equation (3.1) is also invariant under the transformation $(h,g,\epsilon)\mapsto(g,h,\epsilon^{-1})$. Moreover, we have $(\det(g)/\det(h))^2=\epsilon^n$, so that when n is even there are no restrictions on the sign of ϵ, while ϵ has to be positive when n is odd.

It is always possible to rescale g by $\sqrt{|\epsilon|}$ and reduce (3.1) to the canonical form $(h^{-1}g)^2=\pm\mathbf{I}_n$.

When ϵ is positive, Eq. (3.1) admits always the trivial solution $g=\sqrt{\epsilon}h$; however, this does not exhaust all the possible solutions. Let us first observe, in fact, by standard minimal-polynomial arguments (see, e.g., Ref. 45), that the matrix equation

$$P^2=\mathbf{I}_n\tag{3.2}$$

admits only solutions of the form $P=M^{-1}D_kM$ for some nonsingular matrix M, where the matrices D_k (Jordan forms) are diagonal,

$$D_k=\begin{pmatrix} -\mathbf{I}_k & 0 \\ 0 & \mathbf{I}_{n-k} \end{pmatrix}, \tag{3.3}$$

and $k=0,...,n$. This result can be restated as follows: *if an automorphism P of the vector space* $\mathbb{R}^n$ *satisfies (3.2), then there exists a basis in which P is represented by one of the matrices* D_k. The non-negative integer k is an invariant of this authomorphism. In fact, such an automorphism P ($P^2=id$) represents an almost-product structure on $\mathbb{R}^n$. The set of all solutions of the equation $(h^{-1}g)^2=\mathbf{I}_n$ is then described by the following theorem (compare Ref. 45, Th. 4.5.15, case II b):

Theorem 3.1: *Let* $g=g^t$ *and* $h=h^t$ *be two real (symmetric) nondegenerate matrices (metrics). Then the following are equivalent*:

(a) $(h^{-1}g)^2=\mathbf{I}_n$.

(b) *The two metrics h and g are simultaneously diagonalizable with* ± 1 *on the diagonal, i.e., there exists a real nondegenerate matrix R such that*

$$h=R^tD_hR, \quad g=R^tD_gR,$$

and D_h *and* D_g *are diagonal matrices with* $+1$ *or* -1 *on the diagonal*.

The proof of this theorem is given in the Appendix.

Let us proceed to discuss the case $(h^{-1}g)^2=-\mathbf{I}_n$. It is known that if J is any $n\times n$ real matrix satisfying the relation

$$J^2=-\mathbf{I}_n, \tag{3.4}$$

then n must be even, $n=2m$, J can be represented as

$$J=MJ_oM^{-1}$$

where J_o is the canonical form

$$J_o=\begin{pmatrix} 0 & \mathbf{I}_m \\ -\mathbf{I}_m & 0 \end{pmatrix}, \tag{3.5}$$

and M is a nondegenerate real matrix. In fact, one deals with a complex structure and the matrix J_o gives the canonical complex structure on $\mathbb{R}^{2m}$. The following holds true:

Theorem 3.2: *Let* $h=h^t$ *and* $g=g^t$ *be two* $2m\times 2m$ *real (symmetric) nondegenerate matrices (metrics). Then the following are equivalent:*

(a) $(h^{-1}g)^2=-\mathbf{I}_{2m}$.

(b) *There exists a real nondegenerate matrix R such that*

$$h=R^t\begin{pmatrix} \mathbf{I}_m & 0 \\ 0 & -\mathbf{I}_m \end{pmatrix}R, \quad g=R^t\begin{pmatrix} 0 & \mathbf{I}_m \\ \mathbf{I}_m & 0 \end{pmatrix}R,$$

i.e., in the appropriate coordinate system the two metrics g and h take the following canonical forms:

$$K_h=\begin{pmatrix} \mathbf{I}_m & 0 \\ 0 & -\mathbf{I}_m \end{pmatrix}, \quad K_g=\begin{pmatrix} 0 & \mathbf{I}_m \\ \mathbf{I}_m & 0 \end{pmatrix}.$$

This proof is also given in the Appendix.

From Theorems 3.1 and 3.2 it follows that locally for any given metric g one can construct a twin metric h. If g satisfies $\mathrm{Ric}(g)=g$, this means that locally one produces an almost-product or an almost-complex Einsteinian structure.

IV. *K*-STRUCTURES AND KÄHLER-LIKE MANIFOLDS

We first present here a formalism which at once describes properties of various structures important in differential geometry, such as almost-complex and almost-product structures, Hermitian and anti-Hermitian metrics, Kähler manifolds and locally decomposable manifolds, etc., and then, in the next sections, consider in more detail the pseudo-Kählerian and anti-Käherian metrics.

Let M be a smooth manifold, TM its tangent bundle, and $\chi(M)$ the algebra of vectorfields on M. A (K,ϵ)-*structure* (K-*structure* in short) on M is a field of endomorphisms K on TM such that $K^2=\epsilon I$, where $\epsilon=\pm 1$. Thus $\epsilon=1$ corresponds to an almost-product structure, while $\epsilon=-1$ provides an almost-complex structure.

Let $\nabla:\chi(M)\times\chi(M)\to\chi(M)$ be a connection, denoted by $(X,Y)\to\nabla_X Y$. A K-structure is *integrable* iff there exists a linear torsionless connection on M such that $\nabla K=0$, or, equivalently, the Nijenhuis tensor N,

$$N(X,Y)=[KX,KY]-K[KX,Y]-K[X,KY]+\epsilon[X,Y],$$

vanishes. If K is integrable, then there exists an atlas of adapted coordinate charts on M in which K takes a canonical form (see e.g., Ref. 4).

Definition 1: A five-tuple (M,K,g,ϵ,σ) is called a (K,g)-*manifold* if g is a metric on M and K is a K-structure, $K^2=\epsilon I$, such that

$$g(KX,KY)=\sigma g(X,Y) \tag{4.1}$$

for all vectorfields X and Y on M. Here $\sigma=\pm 1$. In this case, we shall say that the metric g is *K-compatible* (or a *K-metric* in short).

The definition above unifies the following four cases: the case $\epsilon=1$, $\sigma=1$ corresponds to a (pseudo-) Riemannian almost-product structure; the case $\epsilon=1$, $\sigma=-1$ provides an almost para-Hermitian structure; the case $\epsilon=-1$, $\sigma=1$ is known as an almost-(pseudo)-Hermitian structure; and, finally, the case $\epsilon=-1$, $\sigma=-1$ corresponds to an almost-complex structure with a Norden metric.

Introduce a (0,2) tensorfield h, the *twin* of g, by

$$h(X,Y)=g(KX,Y). \tag{4.2}$$

Then

$$h(X,Y)=\epsilon\sigma h(Y,X), \quad h(KX,KY)=\sigma h(X,Y). \tag{4.3}$$

Notice that for $\epsilon\sigma=1$ the twin tensor is a metric (and this is, in fact, the case we have obtained from our variational principle), while for $\epsilon\sigma=-1$ the twin tensor is a two-form (and one deals with an almost-Hermitian or almost para-Hermitian structure).

Let ψ be a (0,3) tensorfield defined by the formulas

$$\psi(X,Y,Z)=g((\nabla_X K)Y,Z)\equiv(\nabla_X h)(Y,Z). \tag{4.4}$$

In a coordinate language $\psi_{\alpha\mu\nu}$ is nothing but $\nabla_\alpha h_{\mu\nu}$. It possesses the following properties:

$$\psi(X,Y,Z)=-\sigma\psi(X,KY,KZ)=\sigma\epsilon\psi(X,Z,Y). \tag{4.5}$$

Notice that the classification of almost-Hermitian structures,[46] Riemannian almost-product structures[15] as well as almost-complex structures with a Norden metric[11] is based on algebraic properties of ψ: namely, one decomposes ψ into irreducible components under the action of the appropriate group. The most restrictive class is Kähler-like, when simply $\psi=0$. If the tensorfield ψ

vanishes, then automatically $\nabla K=0$ for a torsionless (Levi-Civita) connection and the Nijenhuis tensor N is forced to vanish, too [Refs. 3 and 7, cf. also formulas (6.7)]. Therefore, the corresponding K-structure is integrable. It leads to the following definition:

Definition 2: A metric g on a (K,g)-manifold is called a *Kähler-like metric* if $\nabla K=0$, i.e.,

$$\nabla_X(KY)=K\nabla_X Y, \quad X,Y\in\chi(M), \tag{4.6}$$

where ∇ is the Levi-Civita connection of g itself.

If $\epsilon=-1$, $\sigma=1$, then a K-metric is called a Kähler metric. If $\epsilon=1$, $\sigma=1$ then a K-metric shall be called a *pseudo-Kählerian metric* [it is also called a (pseudo-) Riemannian locally decomposable metric]. The case $\epsilon=1$, $\sigma=-1$ shall be considered in a forthcoming publication[47] (see also Refs. 48 and 43). Our results on anti-Kählerian manifolds ($\epsilon=-1$, $\sigma=-1$) will be presented in Secs. VI and VII. The following Proposition extends Proposition 3.6 in Ref. 20 to an arbitrary (K,g,ϵ,σ)-structure.

Proposition 4.1: The Riemann curvature $R(X,Y)Z$ and the Ricci tensor $S(X,Y)$ of a Kähler-like manifold (M,K,g) satisfy the following properties:

$$R(X,Y)\circ K=K\circ R(X,Y), \quad R(KX,KY)=\sigma R(X,Y), \tag{4.7}$$

$$S(KX,KY)=\sigma S(X,Y), \quad (\sigma-\epsilon)S(X,Y)=\mathrm{tr}\,[V\mapsto K(R(X,KY)V)]. \tag{4.8}$$

Proof: The proof is a simple repetition of the proof of Proposition 3.6 in Ref. 20, provided one suitably takes into account formulas (4.3). (Q.E.D.)

Consider now the twin F of the Ricci tensor S:

$$F(X,Y)=S(KX,Y). \tag{4.9}$$

Then,

$$F(X,Y)=\epsilon\sigma F(Y,X), \quad F(KX,KY)=\sigma F(X,Y). \tag{4.10}$$

Notice that the symmetry property of F is exactly the same as for h. Therefore, we conclude the following:

Lemma 4.2: A Kähler-like manifold is Einstein iff the dual of S is proportional to the dual of g, i.e., $F(X,Y)\sim h(X,Y)$.

Notice that for $\epsilon\sigma=-1$ both twins F and h are two-forms. This lemma in the Kählerian case leads to a necessary condition on the first Chern class for a manifold to have an Einstein–Kähler metric.[30,49] Recall the Goldberg conjecture[50] (see also Refs. 51 and 52) saying that almost-Kähler Einsteinian manifold is a complex one. It means that an Einstein almost-Hermitian manifold with a closed Kähler form is automatically Hermitian, i.e., its almost-complex structure is integrable. An extension of the Goldberg conjecture to the other Kähler-like manifolds will be discuss elsewhere.[47]

V. ALMOST-PRODUCT EINSTEIN MANIFOLDS

In this section we consider the problems of the global existence and classification of almost-product Einstein manifolds. At the beginning we shall recall some basic facts about almost-product and (pseudo-) Riemannian almost-product structures.

The simplest examples of almost-product structures are product manifolds, i.e., manifolds which are the Cartesian product of two manifolds

$$M=M_1\times M_2. \tag{5.1}$$

In this case the tangent bundle splits as $TM=TM_1\oplus TM_2$ and $P=P_2-P_1$, where P_i are the corresponding projections on TM_i, $i=1,2$. More generally, giving an almost-product structure is equivalent to splitting the tangent bundle into two complementary subbundles (*distributions* or *almost-foliations*): $TM=V\oplus H$; in this case $P=P_V-P_H$. P is integrable iff both the distributions are integrable (i.e., they are *foliations*). Integrable almost-product structures are also called *locally product manifolds*[3] since locally they have the form (5.1). It means that locally (around any point), there exists an adapted coordinate system (x^a,y^α), $a=1,...,k$ and $\alpha=1,...,n-k$, such that the tensorfield P takes the canonical form (3.3), i.e., $P\partial_a=-\partial_a$ and $P\partial_\alpha=\partial_\alpha$.

Similarly, one can consider other structures: for example, a (pseudo-) Riemannian product manifold as a product of two (pseudo-) Riemannian manifolds,

$$(M,g)=(M_1,g_1)\times(M_2,g_2), \tag{5.2}$$

where $g=g_1\oplus g_2$. More generally, an almost-product (pseudo-) Riemannian structure (M,P,g) is integrable iff $\nabla^g P=0$ for the Levi-Civita connection ∇^g of g. In this case we speak of a *locally decomposable* (pseudo-) Riemannian manifold; in the present article we shall, however, propose to call it a *pseudo-Kähler manifold*. For locally decomposable (pseudo-) Riemannian structures both foliations are *totally geodesic*.[3,7] In an adapted coordinate system the metric g ''separates the variables'' (see Refs. 3 and 7)

$$ds^2=g_{ab}(x)dx^a dx^b+g_{\alpha\beta}(y)dy^\alpha dy^\beta. \tag{5.3}$$

The twin metric has the form $h=h_1\ominus h_2$, i.e.,

$$ds_h^2=g_{ab}(x)dx^a dx^b-g_{\alpha\beta}(y)dy^\alpha dy^\beta:$$

Since $\nabla^g_\mu h_{\alpha\beta}\equiv\psi_{\mu\alpha\beta}=0$, then we have in this case $\Gamma(g)=\Gamma(h)$. In fact, this property gives an equivalent definition of pseudo-Kähler manifolds, provided g and h are twin metrics.

Recall that an almost-product Einstein manifold is a triple (M,g,P), where g is a metric and P is a (1,1) tensorfield which satisfy

$$\mathrm{Ric}\,(g)=\gamma g, \tag{5.4}$$

$$P^2=I,\quad g(PX,PY)=g(X,Y),\quad X,Y\epsilon\chi(M). \tag{5.5}$$

Notice that $P=I$ and $P=-I$ give trivial examples of an almost-product structure. Nontrivial examples are given by the following:

Proposition 5.1: Let (M^n,g) *be an Einstein manifold satisfying (5.4) with an indefinite metric* g *of signature* q, $1\leqslant q<n$. *Then there exists on* M^n *a nontrivial almost-product structure* P *satisfying (5.5) and therefore one gets an almost-product Einstein manifold (M,g,P).*

Proof: If g is a pseudo-Riemannian metric on M, then it was proved in Ref. 17 that there exist a (strictly) Riemannian metric h and an almost-product structure P on M such that $g(X,Y)=h(PX,Y)$ and $h(PX,PY)=h(X,Y)$ for all vectorfields X and Y on M. Therefore, one gets the relations (5.5). The almost-product structure P is nontrivial since if $P=\pm I$, then $g=\pm h$; but, in fact, the metric g is pseudo-Riemannian while h is strictly Riemannian. (Q.E.D.)

It follows from the proposition above that any manifold with a strictly pseudo-Riemannian Einstein metric serves as an example of a pseudo-Riemannian almost-product Einsteinian manifold.

It should also be noted that construction of P for a given pseudo-Riemannian metric g is not a canonical one (and, in fact, depends on a choice of some ''background'' Riemannian metric on M). Therefore, a single (possibly Einstein) pseudo-Riemannian metric leads, in principle, to several almost-product (Einsteinian) manifolds. It makes a striking difference between the solutions of our variational problem corresponding to the positive roots of the fundamental equation (2.5) and those corresponding to the negative roots. In the second case, as we shall see in the next section, there are further topological obstructions for the existence of an almost-complex structure.

Let M be a pseudo-Kähler manifold, i.e., (locally) in adapted coordinate systems (x^a,y^α) the metric g splits as $g=g_1\oplus g_2$, where $g_{ab}=g_1(x)$ and $g_{\alpha\beta}=g_2(y)$. If both metrics in (5.3) are Einstein,

$$R_{ab}(g_1)=\gamma g_{ab}, \quad R_{\alpha\beta}(g_2)=\gamma g_{\alpha\beta}, \tag{5.6}$$

for the same constant γ, then it follows

$$R_{AB}(g)=\gamma g_{AB}. \tag{5.7}$$

Therefore, one has the following.

Proposition 5.2: A pseudo-Kählerian manifold is Einstein iff in any adapted coordinates (x^a,y^α) *both metrics are Einslein for the same constant* γ.

Proof: See Refs. 3 and 7. (Q.E.D.)

Interesting examples of locally product (pseudo-) Riemannian manifolds which are not locally decomposable are given by *warped product* space–times.[53–55] Given two (pseudo-) Riemannian manifolds (M_i,g_i), $i=1,2$, and a smooth function θ: $M_1\rightarrow\mathbb{R}$, on the product manifold $M=M_1\times M_2$ put the metric $g=g_1\oplus e^{2\theta}g_2$. The resulting (pseudo-) Riemannian manifold $M=M_1\times_\theta M_2$ is called a *warped product* manifold. It is, of course, an almost-product (pseudo-) Riemannian manifold and it is conformal to a locally decomposable one. It is an interesting and intriguing fact that many exact solutions of Einstein equations (including, e.g., Schwarzschild, Robertson–Walker, Reissner–Nordström, de Sitter, etc.,) and also p-brane solutions (see, e.g., Ref. 56) are, in fact, warped product space–times.[55] Therefore, these exact solutions provide beautiful examples of almost-product Einstein manifolds. Some other examples are provided by the Kaluza-Klein-type theories, $n+m$ decompositions, and more generally so-called *split* structures.[57] The explicit form of the zeta function on product spaces and of the multiplicative anomaly has been derived recently in Ref. 58.

There are topological restrictions on a (paracompact) manifold M for the existence of an almost-product structure of rank k, which are the same as for the existence of a (strictly) pseudo-Riemannian metric of signature $(k,n-k)$, which are again the same as for the existence of a k-dimensional distribution. For example, for the existence of a metric with Lorentz signature on a compact manifold M (i.e., for the existence of a nowhere-vanishing vectorfield), the necessary and sufficient condition is that the Euler characteristic number vanishes.

VI. ANTI-KÄHLERIAN MANIFOLDS

Now we consider in some detail the case of a K-metric with $\epsilon=-1$, $\sigma=-1$, which we call an anti-Kählerian metric.

Definition 3: A triple (M,g,J), where J is an almost-complex structure and the metric g is anti-Hermitian: $g(JX,JY)=-g(X,Y), X,Y\epsilon\chi(M)$ is called an *anti-Kählerian manifold* if $\nabla J=0$, where ∇ is the Levi-Civita connection.

We will prove that a real anti-Hermitian metric on a complex manifold satisfies the Kähler condition $\nabla J=0$ on the same manifold treated as a real manifold if and only if the metric is the real part of a holomorphic metric on this manifold.

Let (M,J) be a $2m$-dimensional almost-complex real manifold and let g be an anti-Hermitian metric on M. We extend J, g, and the Levi-Civita connection ∇ by $\mathbb{C}$-linearity to the complexification of the tangent bundle $T_CM=T_M\otimes\mathbb{C}$. We use the same notation for the complex extended g, J, and ∇. Then the Levi-Civita connection is the mapping $(X,Y)\rightarrow\nabla_XY$, where X and Y are now complex vectorfields (i.e., sections of T_CM). Then the (complex extended) torsion tensor T vanishes,

$$T(X,Y)=\nabla_XY-\nabla_YX-[X,Y]=0,$$

and the ordinary formulas are valid for the connection,

$$\nabla_Xg(Y,Z)=Xg(Y,Z)-g(\nabla_XY,Z)-g(Y,\nabla_XZ)=0, \tag{6.1}$$

and for the Riemann tensor,

$$R(X,Y)Z=[\nabla_X,\nabla_Y]Z-\nabla_{[X,Y]}Z, \tag{6.2}$$

where *X*, *Y*, *Z* are complex vectorfields. For the sake of clarity, we stress that for the moment we are just complexifying the tangent bundle, but we do not assume the almost-complex structure *J* is integrable. Let us now fix a (real) basis $\{X_1,\dots,X_m,JX_1,\dots,JX_m\}$ in each tangent space T_xM. Then, the set $\{Z_a,Z_{\bar a}\}$, where $Z_a=X_a-iJX_a$, $Z_{\bar a}=X_a+iJX_a$, forms a basis for each complexified tangent space $T_xM\otimes\mathbb{C}$. Unless otherwise stated, little Latin indices $a,b,c,\dots$ run from *l* to *m*, while Latin capitals $A,B,C,\dots$ run through $1,\dots,m$, $\bar 1,\dots,\bar m$; for notational convenience we shall also use bar capital indices and we shall assume $\bar{\bar A}=A$. One has $JZ_a=iZ_a$ and $JZ_{\bar a}=-iZ_{\bar a}$. We set $g_{AB}=g(Z_A,Z_B)=g_{BA}$. Then the following holds:

Proposition 6.1: Let (M,J) *be an almost-complex manifold and g be an anti-Hermitian metric on it. Then the complex extended metric g (in the complex basis constructed above) satisfies the following conditions*:

$$g_{a\bar b}=g_{\bar b a}=0, \tag{6.3}$$

$$g_{\bar A\bar B}=\overline{g_{AB}}. \tag{6.4}$$

Proof: Since the metric *g* is anti-Hermitian, we have

$$g(Z_a,Z_{\bar b})=-g(JZ_a,JZ_{\bar b})=-g(iZ_a,-iZ_{\bar b})=-g(Z_a,Z_{\bar b}).$$

Therefore, $g_{a\bar b}=0$, which proves (6.3). The proof of (6.4) is well known. In fact, we have

$$\begin{aligned} g_{\bar a\bar b}=g(Z_{\bar a},Z_{\bar b})&=g(X_a+iJX_a,X_b+iJX_b)\\ &=g(X_a,X_b)-g(JX_a,JX_b)+ig(JX_a,X_b)+ig(X_a,JX_b)\end{aligned}$$

and

$$g_{ab}=g(X_a-iJX_a,X_b-iJX_b)=g(X_a,X_b)-g(JX_a,JX_b)-ig(JX_a,X_b)-ig(X_a,JX_b).$$

Therefore, we get $g_{\bar a\bar b}=\overline{g_{ab}}$. Similarly we consider the other components of g_{AB} and thence we prove (6.4). (Q.E.D.)

It is customary to write a metric satisfying (6.3) and (6.4) as

$$ds^2=g_{ab}dz^a dz^b+g_{\bar a\bar b}dz^{\bar a}dz^{\bar b}. \tag{6.5}$$

We define now the complex Christoffel symbols Γ^C_{AB} as

$$\nabla_{Z_A}Z_B=\Gamma^C_{AB}Z_C. \tag{6.6}$$

It is known[1,3,20] that if $\nabla J=0$, then the torsion *T* and the Nijenhuis tensor *N* satisfy the identity

$$T(JX,JY)=\tfrac{1}{2}N(X,Y) \tag{6.7}$$

for any vectorfields *X* and *Y*. Since the complex extended Levi-Civita connection ∇ has no torsion, the complex Christoffel symbols are symmetric. In this case the complex structure *J* is integrable so that the real manifold *M* inherits the structure of a complex manifold. Let us now recall (see, e.g., Ref. 20) that there is a one-to-one correspondence between complex manifolds and real manifolds with an integrable complex structure. This means that there exist real, adapted (local) coordinates $(x^1,\dots,x^m,y^1,\dots,y^m)$ such that

$$J\left(\frac{\partial}{\partial x^a}\right)=\frac{\partial}{\partial y^a},\quad J\left(\frac{\partial}{\partial y^a}\right)=-\frac{\partial}{\partial x^a}.$$

Setting $z^a = x^a + iy^a$ and taking $X_a = \partial/\partial x^a$ one gets

$$Z_a = X_a - iJX_a = 2\partial/\partial z^a = 2\partial_a, \quad Z_{\bar{a}} = X_a + iJX_a = 2\partial/\partial \overline{z^a} = 2\partial_{\bar{a}},$$

where $\partial_A = \partial/\partial z^A$ and $z^{\bar{a}} = \overline{z^a}$. It appears that z^a's form a complex (analytic) coordinate chart on M. Now from (6.1) one gets

$$\Gamma^C_{AB} = \tfrac{1}{2} g^{CD}(Z_A g_{DB} + Z_B g_{DA} - Z_D g_{AB}) = g^{CD}(\partial_A g_{DB} + \partial_B g_{DA} - \partial_D g_{AB}). \tag{6.8}$$

Notice that the relation (6.1) is valid for the complex extended metric g and complex vector fields X, Y, Z if and only if it is valid for real vectorfields.

Theorem 6.2: *Let M be an m-dimensional complex manifold, thought as a real 2m-dimensional manifold with a complex structure J. Let us further assume that M is provided with an anti-Hermitian metric g. We extend J, g and the Levi-Civita connection* ∇ *by* $\mathbb{C}$*-linearity to the complexified tangent bundle* $T_{\mathbb{C}}M$. *Then the following conditions are equivalent*:

(i)

$$\nabla_X(JY) = J\nabla_X Y, \tag{6.9}$$

where X and Y are arbitrary real vectorfields.

(ii) The (complex) Christoffel symbols satisfy

$$\Gamma^C_{AB} = 0 \quad \textit{except for} \quad \Gamma^c_{ab} \quad \textit{and} \quad \Gamma^{\bar{c}}_{\bar{a}\bar{b}} = \overline{\Gamma^c_{ab}}. \tag{6.10}$$

(iii) There exists a local complex coordinate system $(z^1,\ldots,z^m)$ *on M such that the components of the complex extended metric* g_{ab} *in the canonical form (6.5) are holomorphic functions*

$$\partial_{\bar{c}} g_{ab} = 0. \tag{6.11}$$

Proof: From (6.6) we have

$$\overline{\Gamma^C_{AB}} = \Gamma^{\bar{C}}_{\bar{A}\bar{B}}.$$

The connection satisfies the conditions

$$\nabla_{Z_B}(JZ_c) = J\nabla_{Z_B} Z_c = i\nabla_{Z_B}(Z_c),$$

$$\nabla_{Z_B}(JZ_{\bar{c}}) = J\nabla_{Z_B} Z_{\bar{c}} = -i\nabla_{Z_B}(Z_{\bar{c}}),$$

if and only if

$$\Gamma^a_{B\bar{c}} = \Gamma^{\bar{a}}_{Bc} = 0. \tag{6.12}$$

This proves the equivalence between (*i*) and (*ii*). Then, for the Christoffel symbols (6.8) by taking (6.3) into account one gets

$$\Gamma^a_{b\bar{c}} = g^{aD}(\partial_b g_{D\bar{c}} + \partial_{\bar{c}} g_{Db} - \partial_D g_{D\bar{c}}) = g^{ad}\partial_{\bar{c}} g_{bd}, \tag{6.13}$$

and from (6.12) it follows that

$$\partial_{\bar{c}} g_{bd} = 0. \tag{6.14}$$

The other relations (6.12) also are reduced to (6.14) or its complex conjugated. Therefore, the relation (6.14) is equivalent to (6.11). This proves the equivalence between (*i*) and (*iii*). Our claim is hence proved. (Q.E.D.)

We have proved that a real anti-Hermitian metric on a complex manifold satisfies the Kähler condition $\nabla J=0$ on the same manifold treated as a real manifold if and only if the metric is the real part of a holomorphic metric on this manifold. Therefore, there exists a one-to-one correspondence between anti-Kähler manifolds and complex Riemannian manifolds with a holomorphic metric as they were defined in Ref. 23 (see also, Ref. 13). It should be also remarked that the theory of complex manifolds with holomorphic metric (so-called *complex Riemannian* manifolds) has become one of the cornerstones of the twistor theory.[25] This includes a *nonlinear graviton*,[21] *ambitwistor* formalism,[23] and theory of *H-spaces*.[59]

From an algebraic viewpoint, let us mention that we have been dealing with the following construction. Let V be a real vector space with a complex structure J and let G be a complex-valued bilinear form on V. Let us set

$$F(X,Y)=G(X,Y)-G(JX,JY)-iG(X,JY)-iG(JX,Y).$$

Then we have

$$F(JX,JY)=-F(X,Y).$$

Now one takes the real (or imaginary) part of F to get a real anti-Hermitian bilinear form on V.

VII. ANTI-KÄHLERIAN EINSTEIN MANIFOLDS

In this section we consider the problems of the global existence and classification of anti-Hermitian Einstein manifolds. Recall that an anti-Hermitian Einstein manifold is a triple (M,g,J) where g is a metric and J is a (1,1) tensorfield which satisfy

$$\mathrm{Ric}\,(g)=\gamma g, \tag{7.1}$$

$$J^2=-I, \quad g(JX,JY)=-g(X,Y), \quad X,Y\in\chi(M). \tag{7.2}$$

Then the metric g has necessarily the signature (m,m) (see Sec. III), being $2m=\dim M$. Let us show that by taking the real part of a holomorphic Einstein metric on a complex manifold of complex dimension m one can get a real Einstein manifold of real dimension $2m$.

From (4.8) we have for the Ricci tensor

$$\mathrm{Ric}\,(g)(JX,JY)=-\mathrm{Ric}\,(g)(X,Y), \quad X,Y\epsilon\chi(M).$$

Therefore, analogously to (6.3), we have

$$R_{a\bar{b}}=0. \tag{7.3}$$

We shall not attempt here to consider solutions of Einstein equations for a generic metric of the form (6.5), but consider only the case when g_{ab} is a holomorphic function:

$$\partial_{\bar{c}}g_{ab}=0. \tag{7.4}$$

From (7.4) and (4.7) we get for the Riemann tensor

$$R^D_{ABC}=0 \quad \text{except for } R^d_{abc} \quad \text{and} \quad R^{\bar{d}}_{\bar{a}\bar{b}\bar{c}}=\overline{R^d_{abc}}. \tag{7.5}$$

The (complex) Einstein equations

$$R_{AB}(g)=\gamma g_{AB} \tag{7.6}$$

are hence equivalent to a pair of equations

$$R_{ab}(g_{cd})=\gamma g_{ab}, \tag{7.7a}$$

$$R_{\overline{ab}}(g_{\overline{cd}})=\gamma g_{\overline{ab}}. \tag{7.7b}$$

To get a real solution of Einstein equations (7.1) from (7.7) one uses real coordinates (x^μ), $\mu=1,...,2m$ on M, i.e., $z^a=x^a+ix^{m+a}$, $a=1,...,m$, and writes the metric (6.5) as

$$ds^2=g_{ab}dz^a dz^b+g_{\overline{ab}}d\overline{z^a}d\overline{z^b}=g_{\mu\nu}dx^\mu dx^\nu, \tag{7.8}$$

where $g_{\mu\nu}$ is a real metric. We have hence proved the following theorem:

Theorem 7.1: *If* (M,g,J) *is an anti-Kählerian manifold, i.e., a complex manifold of complex dimension m with a holomorphic metric* $g_{ab}(z),a,b=1,...,m$, *and a real metric* $g_{\mu\nu}(x),\mu,\nu=1,...,2m$, *defined by (7.8), then the holomorphic metric* $g_{ab}(z)$ *satisfies (7.7a) if and only if the real metric* $g_{\mu\nu}(x)$ *is a solution of the Einstein equations (7.1):*

$$R_{\mu\nu}(g)=\gamma g_{\mu\nu}. \tag{7.9}$$

As an example, one can take a complex analytic continuation of any real analytic solution of Einstein equations. A simple example is

$$ds^2=dz^a dz^a+\frac{(z^a dz^a)^2}{1-z^a z^a}+\text{complex conj.}=g_{\mu\nu}dx^\mu dx^\nu. \tag{7.10}$$

This metric $g_{\mu\nu}$ on ‘‘the complex sphere,’’ $w_1^2+\cdots+w_{m+1}^2=1$ (which can be interpreted as a quadric $\zeta_1^2+\cdots+\zeta_{m+1}^2-\zeta_{m+2}^2=0$ in $\mathbb{C}P^{m+1}$ if one takes $w_i=\zeta_i/\zeta_{m+2},$), gives a solution of the Einstein equations (7.8) and provides an example of an anti-Hermitian Einstein manifold (M,g,J).

In particular, for $m=2$ we get a real solution of Einstein equations on the four-dimensional real manifold $(w_1^2+w_2^2+w_3^2=1, w_i\in\mathbb{C})$ with a metric of signature $(++--)$.

Notice also that any Einstein metric on a compact Riemannian manifold M^n leads to an anti-Kählerian Einstein metric on another real manifold $\mathcal{M}^{2n}$. It follows from the known fact[60] that any Einstein metric is analytic in a certain atlas on M^n. Therefore there exists a complex analytic continuation of the metric to a complex manifold of complex dimension n which is a real anti-Kählerian manifold $\mathcal{M}^{2n}$.

APPENDIX: PROOF OF THEOREMS 3.1 AND 3.2

Proof of Theorem 3.1: The proof $(b)\Rightarrow(a)$ follows obviously from the fact that each two diagonal matrices with ± 1 on their diagonals do satisfy our equation, which is invariant under the appropriate transformation.

The converse $(a)\Rightarrow(b)$ is less obvious. As we already know, there exists a real nondegenerate matrix M such

$$h^{-1}g=MD_kM^{-1}. \tag{A1}$$

From this one gets

$$\tilde{g}=\tilde{h}D_k,$$

where $\tilde{g}=M^tgM$ and $\tilde{h}=M^thM$. Since $\tilde{g}$, $\tilde{h}$, and D_k are symmetric matrices one has hence

$$\tilde{h}D_k=D_k\tilde{h}. \tag{A2}$$

Let us now represent $\tilde{h}$ in block form:

$$\begin{pmatrix} \tilde{h}_{11} & \tilde{h}_{12} \\ \tilde{h}_{12}^t & \tilde{h}_{22} \end{pmatrix},$$

where $\tilde{h}_{11}^t=\tilde{h}_{11}$, $\tilde{h}_{22}^t=\tilde{h}_{22}$, and $\tilde{h}_{11}$ is a $k\times k$ matrix. Then from (A2) we obtain

$$\begin{pmatrix} \tilde{h}_{11} & -\tilde{h}_{12} \\ \tilde{h}_{12}^t & -\tilde{h}_{22} \end{pmatrix}=\begin{pmatrix} \tilde{h}_{11} & \tilde{h}_{12} \\ -\tilde{h}_{12}^t & -\tilde{h}_{22} \end{pmatrix}$$

Therefore $\tilde{h}_{12}=0$ and one gets

$$\tilde{h}=\begin{pmatrix} \tilde{h}_{11} & 0 \\ 0 & \tilde{h}_{22} \end{pmatrix}, \quad \tilde{g}=D_k\tilde{h}=\begin{pmatrix} \tilde{h}_{11} & 0 \\ 0 & -\tilde{h}_{22} \end{pmatrix}. \tag{A3}$$

Now we make use of the fact that any real nondegenerate symmetric matrix is ^{t}-congruent to a diagonal matrix whose diagonal elements are equal to $+1$ or -1 i.e., $h_{11}=S_1^tD_{h_{11}}S_1$ (and analogously $h_{22}=S_2^tD_{h_{22}}S_2$), where $D_{h_{11}}$ (resp. $D_{h_{22}}$) is a diagonal matrix with ±1 along the diagonal. Therefore one has

$$\tilde{h}=S^t\begin{pmatrix} D_{h_{11}} & 0 \\ 0 & D_{h_{22}} \end{pmatrix}S, \quad \tilde{g}=S^t\begin{pmatrix} D_{h_{11}} & 0 \\ 0 & -D_{h_{22}} \end{pmatrix}S,$$

where $S=\left(\begin{smallmatrix} S_t & 0 \\ 0 & S_2 \end{smallmatrix}\right)$. Notice that S commutes with D_k, i.e., $SD_k=D_kS$. Taking then $R=SM$ the theorem is proved. (Q.E.D.)

Proof of Theorem 3.2: To prove $(b)\Rightarrow(a)$, check that $K_h^{-1}K_g=J_o$ and then make use of the appropriate transformation properties.

In order to prove the converse $(a)\Rightarrow(b)$, in full analogy with the previous case one makes use of the fact that $h^{-1}g=MJ_oM^{-1}$. Now this leads to the condition (with the same notation)

$$\tilde{h}J_o=-J_o\tilde{h}. \tag{A4}$$

Writing then $\tilde{h}$ in block form,

$$\tilde{h}=\begin{pmatrix} a & b \\ b^t & d \end{pmatrix},$$

one has from (A4)

$$\begin{pmatrix} -b & a \\ -d & b^t \end{pmatrix}=\begin{pmatrix} b^t & d \\ -a & -b \end{pmatrix}$$

Therefore $a=-d$, $b=b^t$ and we have

$$\tilde{h}=\begin{pmatrix} a & b \\ b & -a \end{pmatrix}, \tag{A5a}$$

$$\tilde{g}=\tilde{h}J_o=\tilde{h}=\begin{pmatrix} -b & a \\ a & b \end{pmatrix}. \tag{A5b}$$

Let us further show that there exists a real matrix S such that

$$SJ_o=J_oS, \tag{A6}$$

$$\tilde{h}=S^tK_hS, \tag{A7a}$$

$$\tilde{g}=S^tK_gS. \tag{A7b}$$

To be sure that (A6) holds, take the matrix S in the form

$$S=\begin{pmatrix} s & u \\ -u & s \end{pmatrix},$$

where s and u are real $m\times m$ matrices to be determined from the conditions (A7a) and (A7b). Equation (A7a) reads as

$$\begin{pmatrix} s^ts-u^tu & s^tu+u^ts \\ u^ts+s^tu & u^tu-s^ts \end{pmatrix}=\begin{pmatrix} a & b \\ b & -a \end{pmatrix}, \tag{A8a}$$

while the equation (A7b) gives

$$\begin{pmatrix} -u^ts-s^tu & s^ts-u^tu \\ s^ts-u^tu & s^tu+u^ts \end{pmatrix}=\begin{pmatrix} -b & a \\ a & b \end{pmatrix}. \tag{A8b}$$

Notice that Eq. (A8a) is equivalent to (A8b) so that we are left with the following conditions:

$$s^ts-u^tu=a, \quad s^tu+u^ts=b.$$

This last equation can be rewritten in the complex form

$$(s+iu)^t(s+iu)=a+ib.$$

Now it is known (see, for example, Ref. 45) that any nondegenerate symmetric complex matrix $a+ib$ can be represented in the form

$$a+ib=N^tN,$$

where N is a (nondegenerate) complex matrix. Taking $s+iu=N$ and $R=SM^{-1}$ the theorem is proved. (Q.E.D.)

(Received 18 May 1998; accepted for publication 16 April 1999)

We obtain a class of exact solutions representing null particles moving in three-dimensional (anti-) de Sitter spaces by boosting the corresponding static point source solutions given by Deser and Jackiw. In de Sitter space the resulting solution describes two null particles moving on the (circular) cosmological horizon, while in anti-de Sitter space it describes a single null particle propagating from one side of the universe to the other. We also boost the Bañados–Teitelboim–Zanelli black hole solution to the ultrarelativistic limit and obtain the solution for a spinning null particle moving in anti-de Sitter space. We find that the ultrarelativistic geometry of the black hole is exactly the same as that resulting from boosting the Deser–Jackiw solution when the angular momentum of the hole vanishes. A general class of solutions is also obtained which represents several null particles propagating in the Deser–Jackiw background. The differences between the three-dimensional and four-dimensional cases are also discussed. [S0022-2488(99)03907-9]

I. INTRODUCTION

Although the Einstein equations still hold in three-dimensional space–time, the nature of gravity is quite different from that in four-dimensional space–time. Because the Einstein and Riemann tensors are equivalent in three-dimensional space–time, general relativity is dynamically trivial there. That is, the vacuum space–time is flat. The localized sources have effects only on the global geometry. In 1984, Deser, Jackiw, and 't Hooft[1] investigated in detail the Einstein gravity with static point sources in three-dimensional space–time. For a single static particle, the geometry is given by cutting a sector out of the Euclidean two-plane along two straight lines, and identifying the edges to form a cone. Gravity theories with lightlike sources and spacelike source in three-dimensional flat space–time have also been analyzed in Refs. 2 and 3, respectively.

When a nonvanishing cosmological constant is introduced to the three-dimensional Einstein gravity, some significant changes occur. In this case, the space–time has constant curvature and corresponds either to de Sitter or to anti-de Sitter space. In the de Sitter space, the static two-particle solution is a sphere minus a wedge with the edges identified. This is because the two-space is a sphere in a three-dimensional covering space. To obtain the effect of a point particle one can cut the sphere from the location of the source along two great circles. On a sphere, these cuts meet again at the antipodal point. By identifying along the cuts, this procedure automatically creates a ‘‘mirror’’ source. There is no pure one-particle solution globally. For the anti-de Sitter case, the two-space is a hyperboloid. This can be cut along two lines and the cuts identified to produce single particle solutions. Deser and Jackiw[4] have obtained a metric (hereafter denoted the

[a)]Electronic mail: cai@wormhole.snu.ac.kr
[b)]Electronic mail: J. B. Griffiths@Lboro.ac.uk

DJ solution) and confirmed the above geometrical picture for static point sources by directly solving the Einstein equations with a cosmological constant.

In this paper we investigate the Einstein gravity with null particle sources in the three-dimensional de Sitter and anti-de Sitter spaces. Initially, we employ the boost method that was first used by Aichelburg and Sexl[5] to derive the gravitational field generated by a photon. By boosting the Schwarzschild solution to the ultrarelativistic limit in which the velocity of the source approaches the speed of light and the mass is scaled to zero in an appropriate manner, Aichelburg and Sexl derived a solution describing an impulsive gravitational wave propagating in a flat space–time. This method has subsequently been widely used to investigate the gravitational fields generated by various null sources moving in flat space–times (for a brief review see Ref. 6 and references cited therein). Due to the fact that the four-dimensional (anti-) de Sitter space can be represented as a four-dimensional hyperboloid embedded in a five-dimensional flat space–time, Hotta and Tanaka[7] succeeded in obtaining exact solutions for null particles moving in (anti-) de Sitter space–times by boosting the Schwarzschild–(anti-)de Sitter solutions. The impulsive wave surfaces generated have been discussed in detail by Podolský and Griffiths.[8] Further they considered more general gravitational wave solutions in (anti-) de Sitter spaces.[9] These can be interpreted as impulsive gravitational waves generated by an arbitrary distribution of null particles each with arbitrary multipole structure.

The plan of this paper is as follows. In Sec. II, we will introduce the DJ solution and boost the space–time to the ultrarelativistic limit in the three-dimensional de Sitter and anti-de Sitter spaces and then analyze the resulting geometries. We will also boost the Bañados–Teitelboim–Zanelli (BTZ) black hole[10] in the anti-de Sitter space in Sec. III. Although the BTZ black hole solution is quite different from the DJ solution globally, we find that, when the angular momentum of the BTZ black hole vanishes, the resulting geometries are equivalent to each other. In Sec. IV we will consider the null-particle solution in the DJ background, and further confirm the result derived using the boost method. A brief discussion of the main results is included in Sec. V.

II. BOOSTING THE DJ SOLUTIONS IN THE (ANTI-) DE SITTER SPACES

The three-dimensional Einstein equations with a nonvanishing cosmological constant can be written as

$$R_{\mu\nu}-\tfrac{1}{2}Rg_{\mu\nu}+\Lambda g_{\mu\nu}=8\pi T_{\mu\nu}, \tag{1}$$

where Λ denotes the cosmological constant and $T_{\mu\nu}$ the energy–momentum tensor of the sources. Here the gravitational constant G has been set to one.

The solutions which describe a static point particle at the origin in the (anti-) de Sitter spaces were found to be[4]

$$ds^2=-N^2(R)dt^2+\Phi(R)(dR^2+R^2\,d\phi^2), \tag{2}$$

where

$$\Phi(R)=\frac{4\alpha^2}{\Lambda R^2[(R/R_0)^{\alpha}+(R/R_0)^{-\alpha}]^2},$$
$$N(R)=\frac{(R/R_0)^{\alpha}-(R/R_0)^{-\alpha}}{(R/R_0)^{\alpha}+(R/R_0)^{-\alpha}}, \tag{3}$$

R_0 is an integration constant and $\alpha=1-4M$. The constant M is the mass of the point particle. Performing a simple coordinate transformation in (2) gives

$$ds^2=-(1-\Lambda r^2/\alpha^2)dt^2+\alpha^{-2}(1-\Lambda r^2/\alpha^2)^{-1}\,dr^2+r^2\,d\phi^2. \tag{4}$$

When $\Lambda>0$, the solution (4) has a cosmological event horizon at $r_c=\alpha/\sqrt{\Lambda}$ with surface gravity $\kappa=\sqrt{\Lambda}$. When $\alpha=1$, that is for the vacuum case $M=0$, the DJ solution (4) reduces to the familiar form

$$ds^2=-(1-\Lambda r^2)dt^2+(1-\Lambda r^2)^{-1}\,dr^2+r^2\,d\phi^2, \tag{5}$$

which is just the three-dimensional de Sitter ($\Lambda>0$) or anti-de Sitter ($\Lambda<0$) space in static coordinates.

Similar to the case in four dimensions, the three-dimensional (anti-) de Sitter space can also be represented as a hyperboloid embedded in a four-dimensional flat space–time. Let us first consider the case of the de Sitter space.

(i) *In de Sitter space.* In this case, the hyperboloid satisfies

$$-Z_0^2+Z_1^2+Z_2^2+Z_3^2=a^2, \tag{6}$$

where $a^2=1/\Lambda$. The de Sitter space can be expressed as the following SO(1,3) invariant line element satisfying the constraint (6):

$$ds_{\mathrm{dS}}^2=-dZ_0^2+dZ_1^2+dZ_2^2+dZ_3^2. \tag{7}$$

Obviously, when we parametrize the hypersurface (6) with the following coordinates:

$$\begin{aligned} Z_0&=\sqrt{a^2-r^2}\,\sinh(t/a), \quad Z_1=r\cos\phi,\\ Z_3&=\pm\sqrt{a^2-r^2}\,\cosh(t/a), \quad Z_2=r\sin\phi, \end{aligned} \tag{8}$$

the metric (5) can be deduced from (7). When boosting the DJ solution in the de Sitter space (7), it is appropriate first to expand the solution (4) up to the first order of the mass M (higher order contributions will vanish due to the boost). This yields

$$ds^2\approx ds_{\mathrm{dS}}^2+8M\Lambda r^2\,dt^2+\frac{8M}{(1-\Lambda r^2)^2}\,dr^2, \tag{9}$$

where ds_{dS}^2 denotes the de Sitter space (5). Using the coordinates (8), we can rewrite (9) as

$$ds^2=ds_{\mathrm{dS}}^2+\frac{8M}{(Z_3^2-Z_0^2)^2}\left[(a^2+Z_0^2-Z_3^2)(Z_3dZ_0-Z_0dZ_3)^2+\frac{a^4}{(a^2+Z_0^2+Z_3^2)}(Z_3dZ_3-Z_0dZ_0)^2\right]. \tag{10}$$

We now make a Lorentz boost in the Z_1 direction, that is, a Lorentz transformation

$$Z_0\rightarrow\frac{Z_0+vZ_1}{\sqrt{1-v^2}}, \quad Z_1\rightarrow\frac{vZ_0+Z_1}{\sqrt{1-v^2}}, \quad Z_2\rightarrow Z_2, \quad Z_3\rightarrow Z_3, \tag{11}$$

where v is the boost velocity. To obtain a result of physical interest, the mass must be reduced to zero in an appropriate way. Following Ref. 5, we scale mass as

$$M=p\sqrt{1-v^2}, \tag{12}$$

where p is a constant which can be interpreted as the energy of the null particle. Substituting (11) and (12) into (10), we obtain

$$ds^2=ds_{\mathrm{dS}}^2+\frac{8p\sqrt{1-v^2}}{(Z_3^2-z^2)^2}\left[(a^2+z^2-Z_3^2)(Z_3\,dz-z\,dZ_3)^2+\frac{a^4}{(a^2+z^2-Z_3)}(Z_3dZ_3-z\,dz)^2\right], \tag{13}$$

where $z^2=(Z_0+vZ_1)^2/(1-v^2)$. Using the identity

$$\lim_{v\to 1}\frac{1}{\sqrt{1-v^2}}f(z^2)=\delta(Z_0+Z_1)\int_{-\infty}^{\infty}f(z^2)dz, \tag{14}$$

and taking the limit $v\to 1$ in (13), we obtain

$$ds^2=ds_{\rm dS}^2-8\pi p|Z_2|\delta(Z_0+Z_1)(dZ_0+dZ_1)^2. \tag{15}$$

This looks like an impulsive wave solution in the de Sitter space, located on the surface $Z_0+Z_1=0$, $Z_2^2+Z_3^2=a^2$ which at any time is a circle of constant radius.

In order to further analyze this solution, it proves convenient to use the following coordinates:[8]

$$Z_0=\frac{1}{2\eta}[a^2-\eta^2+(x-a)^2+y^2],\quad Z_1=\frac{a}{\eta}(x-a),$$
$$Z_3=\frac{1}{2\eta}[a^2+\eta^2-(x-a)^2-y^2],\quad Z_2=\frac{a}{\eta}y. \tag{16}$$

Further we can put

$$x=\rho\cos\phi,\quad y=\rho\sin\phi, \tag{17}$$

with $\rho\in[0,\infty)$, $\phi\in[0,2\pi)$. The de Sitter space can then be described as

$$ds_{\rm dS}^2=\frac{a^2}{\eta^2}(-d\eta^2+d\rho^2+\rho^2\,d\phi^2), \tag{18}$$

which is in conformally flat form. The solution (15) can then be rewritten as

$$ds^2=ds_{\rm dS}^2-8\pi pa|\sin\phi|[\delta(\eta-\rho)(d\eta-d\rho)^2+\delta(\eta+\rho)(d\eta+d\rho)^2]. \tag{19}$$

This looks like two impulsive wave fronts. However, as pointed out in Ref. 8 in the four-dimensional case, both components are required for the conformal picture to be geodesically complete. Because $\rho\geqslant 0$, the term $\delta(\eta-\rho)$ does not vanish for $\eta\geqslant 0$ only, while $\delta(\eta+\rho)$ is required for $\eta\leqslant 0$. From (19), it is clear that the particles are located on the circle $\rho=|\eta|$ which is the cosmological horizon of the de Sitter space.

It can then be shown that the energy–momentum tensor is only nonzero at the two points $Z_0+Z_1=0$, $Z_2=0$, $Z_3=\pm a$, which thus represent two null particles. At all other points on this null surface, the impulsive component can in fact be removed by a discontinuous coordinate transformation. The solution can thus be represented as a three-dimensional de Sitter space cut along the cosmological horizon $Z_0+Z_1=0$, with the two halves reattached in such a way as to create two null particles at the points $Z_2=0$, or $y=0$, or $\phi=0,\pi$, which are at opposite points on the horizon. This situation is very like that in the four-dimensional case, in which instead of the circle the wave surface is spherical and the particles are located at opposite poles. The significant difference, however, is that in the four-dimensional case the Weyl tensor has some nonzero components on the spherical surface and these can be interpreted as describing gravitational wave components generated by the null particles. In the three-dimensional theory such free gravitational waves cannot occur.

(ii) *In anti-de Sitter space.* We now turn to the case of the three-dimensional anti-de Sitter space. This can be regarded as a hyperboloid

$$-Z_0^2+Z_1^2+Z_2^2-Z_3^2=-a^2, \tag{20}$$

embedded in an SO(2,2) invariant four-dimensional flat space–time

$$ds^2_{\mathrm{adS}} = -dZ_0^2 + dZ_1^2 + dZ_2^2 - dZ_3^2, \tag{21}$$

where $a^2 = -1/\Lambda > 0$. Obviously, the anti-de Sitter space (5) can be parametrized by the following coordinates:

$$\begin{aligned} Z_0 &= \sqrt{a^2+r^2}\,\sin(t/a), \quad Z_1 = r\cos\phi, \\ Z_3 &= \sqrt{a^2+r^2}\,\cos(t/a), \quad Z_2 = r\sin\phi. \end{aligned} \tag{22}$$

We now boost the DJ solution in the anti-de Sitter space. Again expanding the solution up to the first order in the mass M and using the coordinates (22), we arrive at

$$\begin{aligned} ds^2 = ds^2_{\mathrm{adS}} + \frac{8M}{(Z_0^2+Z_3^2)^2}\bigg[&(Z_0^2+Z_3^2-a^2)(Z_3 dZ_0 - Z_0 dZ_3)^2 \\ &+ \frac{a^4}{(Z_0^2+Z_3^2-a^2)}(Z_3 dZ_3 - Z_0 dZ_0)^2 \bigg]. \end{aligned} \tag{23}$$

Repeating the same steps as in the case of the de Sitter space, that is, using the Lorentz transformation (11), rescaling the mass as (12), and taking the limit $v \to 1$, finally we can obtain

$$ds^2 = ds^2_{\mathrm{adS}} - 8\pi p|Z_2|\,\delta(Z_0+Z_1)(dZ_0+dZ_1)^2. \tag{24}$$

Comparing with (15), it is easy to see that the expression for the apparent impulsive part is the same as that in the de Sitter space. However, the interpretation is quite different. In this case the impulsive component is given by the surface $Z_0+Z_1=0$, $Z_2^2-Z_3^2=-a^2$, which at any time is a hyperbola. Let us now analyze this solution.

In the anti-de Sitter space, introduce first the following coordinates:

$$\begin{aligned} Z_0 &= \frac{1}{2x}[a^2-\eta^2+x^2+(y-a)^2], \quad Z_1 = \frac{a}{x}(y-a), \\ Z_2 &= \frac{1}{2x}[a^2+\eta^2-x^2-(y-a)^2], \quad Z_3 = \frac{a}{x}\,\eta, \end{aligned} \tag{25}$$

and then use

$$x = \rho\cos\phi, \quad y = \rho\sin\phi. \tag{26}$$

This produces the anti-de Sitter space written in the conformally flat form

$$ds^2_{\mathrm{adS}} = \frac{a^2}{\rho^2\cos^2\phi}[-d\eta^2 + d\rho^2 + \rho^2\,d\phi^2]. \tag{27}$$

The solution (24) can be rewritten in these coordinates as

$$ds^2 = ds^2_{\mathrm{adS}} - \frac{8\pi pa|\sin\phi|}{\cos^2\phi}[\delta(\eta-\rho)(d\eta-d\rho)^2 + \delta(\eta+\rho)(d\eta+d\rho)^2]. \tag{28}$$

Here it should be stressed that the solution (28) does not mean two impulses again. As in the de Sitter case, $\delta(\eta-\rho)$ works only for $\eta>0$ while $\delta(\eta+\rho)$ for $\eta<0$. The two components are required for globally geodesic completeness. From (28), it is clear that the impulsive component is located on the line $\rho=|\eta|$, or $x^2+y^2=\eta^2$. However, this is not a circle—according to (27) it is conformal to a circle, and the coordinate ϕ is restricted to $-\pi/2<\phi<\pi/2$. In fact it is a hyperbola. It can then be shown that this solution represents a single null particle located at $Z_2=0$ on the null surface $Z_0+Z_1=0$, i.e., at $y=0$, $x=\eta$ (or $x=-\eta$). The particle thus clearly propagates from one side of the universe to the other and (since this space–time contains closed timelike lines) may then be considered to propagate back in the opposite direction.

Thus, by boosting the DJ solutions, we have obtained two kinds of exact solutions describing null particles moving in the three-dimensional de Sitter and anti-de Sitter spaces. (In Sec. IV we will further confirm these results by directly solving the Einstein equations.) Although static particles only have effect on the global geometry, which is quite different from the situation in the four-dimensional case, we still find that the boost method is sufficiently powerful to derive null particle solutions from their corresponding static particle solutions. In Sec. III we will boost the BTZ black hole solution in the anti-de Sitter space. In the static situation, this is quite different from the DJ solution from the aspect of global properties. However, the resulting ultrarelativistic geometry is found to be identical, at least in the nonrotating case.

III. BOOSTING THE BTZ BLACK HOLE SOLUTION IN THE ANTI-DE SITTER SPACE

Due to the special properties of three-dimensional gravity, it was a surprising discovery when Bañados, Teitelboim, and Zanelli[10] claimed that they found a black hole solution in the Einstein gravity with a negative cosmological constant. The solution they found is

$$ds^2=-N^2(r)dt^2+N^{-2}\,dr^2+r^2(N^\phi(r)dt+d\phi)^2, \tag{29}$$

where

$$N^2=-8M+\frac{r^2}{a^2}+\frac{16J^2}{r^2},\quad N^\phi=-\frac{4J}{r^2}. \tag{30}$$

Here $-1/a^2$ denotes the negative cosmological constant. The integration constants M and J can be interpreted as the mass and angular momentum of the black hole. This black hole has two horizons at

$$r_\pm^2=4Ma^2\left[1\pm\sqrt{1-\left(\frac{J}{Ma}\right)^2}\right], \tag{31}$$

provided $M>0$ and $J<Ma$. This solution is asymptotically an anti-de Sitter space–time and can be constructed by identifying some discrete points in the three-dimensional anti-de Sitter space. It is of interest to note, however, that when the mass and angular momentum of the hole vanish, the solution does not reduce to the anti-de Sitter space. Rather, the anti-de Sitter space–time (5) can only be obtained from (29) in the limit as $8M\to-1$ and $J\to 0$.

Before boosting the BTZ solution, it is first appropriate to expand it about the background of the anti-de Sitter space. To achieve this, we expand the BTZ solution (29) to first order in the mass term $8M+1$ and the angular momentum J. The result is

$$ds^2\approx ds^2_{\mathrm{adS}}+(8M+1)dt^2+\frac{8M+1}{(1+r^2/a^2)^2}\,dr^2-8J\,dt\,d\phi. \tag{32}$$

Using the coordinates in (22), the above metric can be rewritten as

$$\begin{aligned}ds^2=ds^2_{\mathrm{adS}}&+\frac{(8M+1)a^2}{(Z_0^2+Z_3^2)^2}\left[(Z_3dZ_0-Z_0dZ_3)^2+\frac{a^2}{Z_3^2+Z_0^2-a^2}(Z_3dZ_3+Z_0dZ_0)^2\right]\\&-\frac{8Ja}{(Z_3^2+Z_0^2)(Z_3^2+Z_0^2-a^2)}(Z_3dZ_0-Z_0dZ_3)(Z_1dZ_2-Z_2dZ_1).\end{aligned} \tag{33}$$

We now make a Lorentz boost (11) in the Z_1 direction, rescaling the mass and angular momentum as

$$8M+1=8p\sqrt{1-v^2}, \quad J=s\sqrt{1-v^2}. \tag{34}$$

We then proceed to the ultrarelativistic limit $v\to 1$. In this case, the two constants p and s can be interpreted physically as the energy and spin angular momentum of the resulting null particle, respectively. It may be observed that, in this limit, the inequality $J<Ma$ mentioned above is strictly violated. This is because the mass M and angular momentum J are rescaled in different ways. However, the limit is still an exact solution even though it is not strictly the limit of a real rotating black hole. Using this procedure in (33), we obtain

$$\begin{aligned} ds^2 = {} & ds^2_{\text{adS}} + 8\pi p(Z_3-\sqrt{Z_3-a^2})\,\delta(Z_0+Z_1)(dZ_0+dZ_1)^2 \\ & -\frac{8\pi s}{a}\left[Z_2-\frac{Z_2Z_3}{\sqrt{Z_3^2-a^2}}\right]\delta(Z_0+Z_1)(dZ_0+dZ_1)^2. \end{aligned} \tag{35}$$

The two linear terms in the solution (35) can be removed by the following discontinuous linear transformation:

$$\begin{aligned} & Z_2\to Z_2-\frac{4\pi s}{a}U\Theta(U), \\ & Z_3\to Z_3-4\pi pU\Theta(U), \\ & U\to U, \\ & V\to V-16\pi^2p^2U\Theta(U)+8\pi pZ_3\Theta(U)+\frac{16\pi^2s^2}{a^2}U\Theta(U)-\frac{8\pi s}{a}Z_2\Theta(U), \end{aligned} \tag{36}$$

where $U=Z_0+Z_1$, $V=Z_0-Z_1$, and Θ is the Heaviside step function. Therefore, the solution (35) can be reduced to

$$ds^2=ds^2_{\text{adS}}-8\pi p|Z_2|\,\delta(Z_0+Z_1)(dZ_0+dZ_1)^2+\frac{8\pi sZ_3}{a}\operatorname{sign}(Z_2)\,\delta(Z_0+Z_1)(dZ_0+dZ_1)^2. \tag{37}$$

It is now easy to see that when $s=0$, that is when the angular momentum vanishes in the original BTZ solution, the solution (37) is identical to (24). Thus, both ultrarelativistic limits of the DJ solution for $\Lambda<0$ and the spinless BTZ solution are equivalent to each other. Obviously, the third term in (37) is the spin effect of the null particle. In the coordinates (25) and (26), we can rewrite (37) as

$$\begin{aligned} ds^2 &= ds^2_{\text{adS}}+\left(-8\pi pa\frac{|\sin\phi|}{\cos^2\phi}+\frac{8\pi s\ \operatorname{sign}(\tan\phi)}{\cos\phi|\cos\phi|}\right)[\delta(\eta-\rho)(d\eta-d\rho)^2+\delta(\eta+\rho)(d\eta+d\rho)^2] \\ &= ds^2_{\text{adS}}+\left(-8\pi pa\frac{|\sin\phi|}{\cos^2\phi}+\frac{8\pi s}{\cos^2\phi}\operatorname{sign}(\sin\phi)\right)[\delta(\eta-\rho)(d\eta-d\rho)^2+\delta(\eta+\rho)(d\eta+d\rho)^2] \end{aligned} \tag{38}$$

which is clearly identical to (28) when $s=0$.

IV. NULL PARTICLES IN THE DJ BACKGROUND

In this section we will directly solve the Einstein equations with null particle sources and re-obtain some of the results of previous sections that were derived by the boost method. In Ref. 11 Dray and 't Hooft considered a particle moving with the speed of light on the Schwarzschild black hole horizon, and investigated the back reaction of the particle on the geometry. In this case, the particle produces an impulsive gravitational wave located on the Schwarzschild horizon. Loustó and Sánchez[12] and Sfetsos[13] further extended the work of Dray and 't Hooft to nonvacuum backgrounds and investigated the conditions that should be satisfied when an impulsive wave is introduced into curved space–times. The null particle solution in the BTZ background (29) has already been considered in Ref. 13.

Here we first note that the DJ solution (4) can be rewritten, after rescaling the coordinate r, as

$$ds^2 = -(1-\Lambda r^2)dt^2 + (1-\Lambda r^2)^{-1}\,dr^2 + \alpha^2 r^2\,d\phi^2. \tag{39}$$

Further defining $\phi' = \alpha\phi$ with $\phi' \in [0,2\pi\alpha)$, we have

$$ds^2 = -(1-\Lambda r^2)dt^2 + (1-\Lambda r^2)^{-1}\,dr^2 + r^2\,d\phi'^2, \tag{40}$$

which is obviously equivalent to the de Sitter space locally, but has a deficit angle $\delta = (1-\alpha)2\pi$. We will first discuss solutions with null particles located on the cosmological horizon of the de Sitter case $(\Lambda = 1/a^2 > 0)$. The metric (39) or (40) also can be regarded as a hypersurface embedded in the flat space–time (7) with

$$\begin{aligned} Z_0 &= \sqrt{a^2-r^2}\,\sinh(t/a), \quad Z_1 = r\cos(\alpha\phi), \\ Z_3 &= \pm\sqrt{a^2-r^2}\,\cosh(t/a), \quad Z_2 = r\sin(\alpha\phi). \end{aligned} \tag{41}$$

Introducing the null coordinates

$$u = e^{t/a}F(r), \quad v = e^{-t/a}F(r), \tag{42}$$

where the function $F(r)$ is defined as

$$F(r) \equiv \exp\left(-\frac{1}{a}\int \frac{dr}{(1-r^2/a^2)}\right) = \left(\frac{a-r}{a+r}\right)^{1/2}, \tag{43}$$

we can reexpress the DJ solution (40) as

$$ds^2 = 2A(u,v)du\,dv + r^2(u,v)d\phi'^2, \tag{44}$$

where

$$A(u,v) = \frac{(a^2-r^2)}{2F^2(r)}, \quad r(u,v) = \frac{a(1-uv)}{1+uv}. \tag{45}$$

We can now consider the effect of null particles located on the null surface $u=0$ which is clearly the cosmological horizon $r=a$. In this three-dimensional theory, this horizon is circular. Following Refs. 11 and 13, we can adopt the coordinate shift method on the background (40). That is, the following ansatz is employed: For $u<0$ the space–time is still the background (44) while for $u>0$ the space–time is (44) with v shifted as $v \to v + f(\phi')$. The function $f(\phi')$ which will be determined later describes the effect of the sources. Using this approach, the new solution has the form

$$ds^2 = 2A(u,v)du\,dv - 2A(u,v)f(\phi')\delta(u)du^2 + r^2(u,v)d\phi'^2, \tag{46}$$

which comes from (44) after making the coordinate shift:

$$u \to u, \quad v \to v - f(\phi')\Theta(u), \quad \phi' \to \phi'. \tag{47}$$

For this solution to be consistent with the Einstein equations, the following conditions must be satisfied at $u=0$:[13]

$$A_{,v} = r^2_{,v} = T_{vv} = 0, \tag{48}$$

$$\frac{d^2 f}{d\phi'^2} - \frac{r^2_{,uv}}{2A} f = \frac{8\pi r^2}{A} \tilde{T}_{uu}, \tag{49}$$

where T is the energy–momentum tensor of matter generating the DJ geometry, that is, the cosmological constant and possibly some static point particles, and $\tilde{T}$ is the energy–momentum tensor of any null particles located on the surface. Here it should be noticed that the only non-vanishing component of the energy–momentum tensor for null particles is $\tilde{T}_{uu}$, and that this is zero everywhere except at the points where the particles are located.

At the $u=0$ null surface—that is, on the cosmological horizon $r_c = a = 1/\sqrt{\Lambda}$ for the DJ $(\Lambda > 0)$ solution (40)—it is easy to see that the conditions (48) are satisfied and

$$A(u,v)|_{u=0} = 2a^2, \quad r^2_{,uv}|_{u=0} = -4a^2. \tag{50}$$

Then (49) reduces to

$$\frac{d^2 f}{d\phi'^2} + f = 4\pi \tilde{T}_{uu}. \tag{51}$$

It may immediately be observed that a solution with $f = 4\pi\rho$, where ρ is a constant, represents a uniform distribution of null matter (of density ρ) over the circular horizon. Since Eq. (51) is linear, this component can always be added to other components. However, we will ignore this possibility in the remainder of this section.

In those parts of the null surface on which $\tilde{T}_{uu} = 0$, Eq. (51) has the solution

$$f = c \sin(\phi' + \omega') = c \sin \alpha(\phi + \omega), \tag{52}$$

where c and $\omega' = \alpha\omega$ are arbitrary constants. This solution for f around the circular horizon can always be removed by a discontinuous coordinate transformation. However, solutions describing several discrete particles can be constructed by patching different sections of the sine wave, each with different amplitude and phase. Points at which f is C^0 but has a discontinuous first derivative can be interpreted as points at which null particles are located. The energy of each particle is then represented by the jump in the derivative of f, and the energy–momentum tensor $\tilde{T}_{uu}$ is given by a δ function. On considering (38), it may be observed that discontinuities in f may also be permitted. These represent point particles with spin and, in this case, the energy–momentum tensor $\tilde{T}_{uu}$ contains a derivative of a δ function.

For example, consider the case in which n particles each of energy p_i, $i = 1 \cdots n$, are located at points $\phi = \phi_i$ around the circular wave. The solution is then given by

$$f = c_i \sin \alpha(\phi + \omega_i) \quad \text{for} \quad \phi_{i-1} \leqslant \phi \leqslant \phi_i, \tag{53}$$

where $n+1 \to 1$. It is then possible to choose the $2n$ arbitrary constant c_i and ω_i such that

$$c_{i+1} \sin \alpha(\phi_i + \omega_{i+1}) - c_i \sin \alpha(\phi_i + \omega_i) = 0,$$

$$c_{i+1}\cos\alpha(\phi_i+\omega_{i+1})-c_i\cos\alpha(\phi_i+\omega_i)=\frac{4\pi p_i}{a}. \tag{54}$$

By choosing the constants appropriately, it is possible to construct solutions in which $n(\geqslant 2)$ null particles of arbitrary energy are distributed arbitrarily around the circular wave.

In particular, we can consider the two-particle solution in which the particles are located at opposite ends of a diameter of the circle. Since $0\leqslant\phi'<2\pi\alpha$ around the circle, we may consider the particles to be located at points given by $\phi'=0$ and $\phi'=\pi\alpha$. We may also restrict attention to the case in which the two particles have identical energy p. Such a solution can be constructed by the above method in which

$$c_1=c_2=\frac{2\pi p}{a}\operatorname{cosec}\frac{\pi\alpha}{2},\quad \omega_1=\frac{(1-\alpha)\pi}{2\alpha},\quad \omega_2=\frac{(1-3\alpha)\pi}{2\alpha}. \tag{55}$$

This solution represents two null particles propagating in the DJ $(\Lambda>0)$ background. In the case in which $\alpha=1$, the background is the de Sitter space and the solution can alternatively be written in the form

$$f=\frac{2\pi p}{a}|\sin\phi|. \tag{56}$$

This is clearly identical (after some rescaling) to the solution (19) that was obtained by boosting two static particles in the de Sitter background, and thus confirms this solution.

It may also be observed that, in the particular case in which $\alpha=1/2$, the deficit angle in ϕ' is π and a one-particle solution at $\phi=0$ can easily be constructed using

$$f=c\sin(\phi/2),$$

where

$$0\leqslant\phi\leqslant 2\pi. \tag{57}$$

It is also possible to obtain solutions for null particles propagating in the DJ background with $\Lambda<0$. However, the Dray–'t Hooft[11] method cannot be directly used in this case. Nevertheless, equivalent equations can be obtained and these will include, for $\alpha=1$, the special cases (28) of a null particle and (38) of a spinning null particle propagating in an anti-de Sitter space.

V. CONCLUSION AND DISCUSSION

We have investigated null particle solutions in the three-dimensional de Sitter and anti-de Sitter spaces by boosting the corresponding static point source solutions (DJ solutions)[4] in the (anti-) de Sitter backgrounds. For the de Sitter case, the resulting solution describes two null particles located at opposite points on the cosmological horizon which forms a circle of constant size. For the anti-de Sitter case, the solution describes a single null particle located at the point of symmetry of a propagating hyperbola. We have also boosted the BTZ black hole solution to the ultrarelativistic limit. Although the BTZ black hole is quite different from the DJ solution globally, we have found that these two ultrarelativistic limits are equivalent to each other when the angular momentum of the hole is zero. This means that the boost method may lose some memory of the original solution in the process of the boost. In addition, we believe that the angular momentum of the hole gives the spin effect of the corresponding null particle.

By using the coordinate shift method, we have also obtained null particle solutions in DJ background. When $\alpha=1$, the DJ $(\Lambda>0)$ solution reduces to the de Sitter space, and the results obtained include that derived using the boost method. It may be observed that the boost method indeed is very powerful in the derivation of null particle solutions, not only in flat space–time, but also in the (anti-) de Sitter space in three dimensions as well as four.

Due to the special properties of the geometry in three-dimensional space–time, the nature of Einstein gravity is rather different from that in four dimensions. The static point source solutions, given in Ref. 1 in flat space–time and in Ref. 4 in (anti-) de Sitter space, clearly demonstrate the differences in the local and global aspects from the four-dimensional Schwarzschild and Schwarzschild-(anti-)de Sitter solutions. By comparing the null particle solution given by Deser and Steif[2] in three-dimensional flat space–time and some results given in this paper, we may observe some similarities as well as some differences in the null particle solutions in three and four dimensions. The main difference in four-dimensional space–time is that the null particles generate impulsive gravitational waves which are forbidden in three-dimensional theories. It is of some interest to further compare spacelike source solutions in three- and four-dimensional space–times. Furthermore, it also might be interesting to discuss the geodesics and particle scattering in the null particle solutions in the (anti-) de Sitter space.

Canonical general relativity: Matter fields in a general linear frame

M. A. Clayton[a)]
9 Hurndale Ave., Toronto, Ontario M4K 1R6, Canada

(Received 18 November 1998; accepted for publication 29 January 1999)

Building on the results of previous work [M. A. Clayton, ''Canonical general relativity: Diffeomorphism constraints and spatial frame transformations,'' J. Math. Phys. **39**, 3805–3816 (1998)], we demonstrate how matter fields are incorporated into the general linear frame approach to general relativity. When considering the Maxwell one-form field, we find that the system that leads naturally to canonical vierbein general relativity has the extrinsic curvature of the Cauchy surface represented by gravitational as well as nongravitational degrees of freedom. Nevertheless the metric compatibility conditions are undisturbed, and this apparent derivative-coupling is seen to be an effect of working with (possibly orthonormal) linear frames. The formalism is adapted to consider a Dirac Fermion, where we find that a milder form of this apparent derivative-coupling appears. © *1999 American Institute of Physics.* [S0022-2488(99)03407-6]

I. INTRODUCTION

In Ref. 1 we gave a detailed description of the surface geometry and canonical structure of general relativity (GR) in a general linear frame, using two different choices of the diffeomorphism constraints; the ''unprimed'' constraints which are compatible with a coordinate frame gauge choice, and the ''primed'' constraints which are compatible with an orthonormal (or Lorentz) frame gauge choice. These arose from considering an action that allows one to treat the metric and vierbein fields independently. Specializing to a surface-normal frame, we were led to a Hamiltonian formalism that treats the spatial frame as initial data that is independent of the spatial metric degrees of freedom, and with atlas fields $(N,N^a,N^a{}_b)$ that enforce the Hamiltonian, momentum and frame constraints respectively. The unprimed: $\underline{\mathcal{H}}$ and $\underline{\mathcal{H}}_a$, and primed: $\underline{\mathcal{H}}'$ and $\underline{\mathcal{H}}'_a$, constraints are related by nontrivial factors involving the generators of infinitesimal frame transformations: $\underline{\mathcal{J}}^a{}_b$. This work is essentially an extension of this, showing that the Hamiltonian description of matter fields minimally coupled to general relativity is compatible with the general linear frame formalism. Note that, as in Ref. 2, we have specialized somewhat by choosing a surface-normal frame and assuming the existence of a spatial coordinate frame, thereby choosing a minimal representation of the evolution of the spatial hypersurface in spacetime. Operationally this should be seen as no particular limitation since any numerical scheme would certainly begin from such a point of view. (For alternative points of view, see Refs. 3 and 4.)

We shall see that, as expected, the addition of matter fields poses no great difficulty. The somewhat surprising feature that appears is the breakdown of DeWitt's ''Riemannian Structure,''[5] since matter fields enter into the definition of the momenta conjugate to the frame fields (also occurring for any tensor field that behaves nontrivially under frame transformations). This is operationally due to the presence of derivatives of the frame field in the matter action, entering through the nonvanishing structure ''constants'' $C_{AB}{}^C$. Despite this mixing of gravitational and matter sectors, we show that the evolution of the spatial metric is identical to that required by the compatibility equations (i.e., the definition of the extrinsic curvature is unaltered) and the field equations are equivalent to those derived in a coordinate frame. Thus this form of derivative-

a)Electronic mail: Michael.A.Clayton@cern.ch

coupling is benign in the sense that the light cone structure of the theory is undisturbed[5]—trivially because it is a coordinate frame theory that has been rewritten. Despite naive expectation, this works because the matter stress-energy tensor remains independent of second-derivatives of the gravitational variables.

The ''unprimed'' system of constraints is closely related to coordinate frame approaches; the evolution equations and Lie transport act solely on the components of tensors with the frame playing a passive role. To be specific, infinitesimal spatial diffeomorphisms are defined to leave the frame unaffected and change the tensor components in the usual manner,[6] $\xi: T_a \to \mathcal{L}_{\xi}[T]_a$. Writing Einstein's equations in terms of the components of the metric γ_{ab}, frame $E^i{}_a$, and extrinsic curvature K_{ab} of a spacelike hypersurface Σ, we have

$$d_\perp[\gamma]_{ab} = 2K_{ab}, \quad d_\perp[E^i{}_a] = 0, \tag{1a}$$

$$d_\perp[K]_{ab} = -R_{ab} + \nabla_a \nabla_b[N]/N - KK_{ab} + 2K_{ac}K^c{}_b + \tfrac{1}{2}\overline{T}^{\mathrm{M}}_{ab}, \tag{1b}$$

where $d_\perp$ is the moving frame generalization (see the discussion in Sec. III B of Ref. 1 for more details) of the surface-covariant normal derivative operator.[7] We have added a matter stress-energy contribution $\overline{T}_{AB} := T_{AB} - \frac{1}{2} g_{AB} T$ to (1) for later reference, and have chosen $16\pi G = c = 1$. Lowercase Greek and Latin letters represent spacetime and spatial coordinate components and upper and lower case Roman letters indicate spacetime and spatial frame components, respectively. Symmetric and antisymmetric projection on any pair of indices is indicated by, for example, $T_{(ab)} := \frac{1}{2}(T_{ab} + T_{ba})$ and $T_{[ab]} := \frac{1}{2}(T_{ab} - T_{ba})$. Densities with respect to the spatial metric are represented as boldfaced symbols, and densities with respect to the determinant of the spatial vierbein with an underline. We also use ${}^4\nabla_A$ for the space–time covariant derivative and ∇_a for the intrinsic surface covariant derivative.

In the Hamiltonian system the action of $\mathcal{L}$ is represented on phase space by the momentum constraint $\underline{\boldsymbol{\mathcal{H}}}_a$ as $\mathcal{L}_{\vec{\xi}}[\,\cdot\,] \to \{\,\cdot\,, \underline{\boldsymbol{\mathcal{H}}}_a[\xi^a]\}$. We make use of the notation, for example, $\underline{\boldsymbol{\mathcal{H}}}_a[\xi^a] := \int_\Sigma d^3x\, \xi^a \underline{\boldsymbol{\mathcal{H}}}_a$, and $\{\cdot,\cdot\}$ is the Poisson bracket given by (32) of Ref. 1. The Hamiltonian constraint $\underline{\boldsymbol{\mathcal{H}}}$ represents the operator $d_\perp$ on phase space, and reproduces (1) weakly,

$$\{\gamma_{ab}, \underline{\boldsymbol{\mathcal{H}}}^{GR}[f]\} = 2\, f k_{ab}, \quad \{E^i{}_a, \underline{\boldsymbol{\mathcal{H}}}^{GR}[f]\} = 0, \tag{2a}$$

$$\{k_{ab}, \underline{\boldsymbol{\mathcal{H}}}^{GR}[f]\} = -fR_{ab} + \nabla_a \nabla_b[f] - fkk_{ab} + 2\, fk_{ac}k^c{}_b - \tfrac{1}{4} f \gamma_{ab} \mathcal{H}^{GR}, \tag{2b}$$

$$\{k'_{ab}, \underline{\boldsymbol{\mathcal{H}}}^{GR}[f]\} = -fR_{ab} + \nabla_a \nabla_b[f] - fkk'_{ab} + 2\, fk_{(a}{}^c k'_{cb)} - \tfrac{1}{4} f \gamma_{ab} \mathcal{H}^{GR} + fk_{(a}{}^c \mathcal{J}^{GR}_{[cb)]}. \tag{2c}$$

The extrinsic curvature K_{ab} is equivalently represented on phase space by the two tensors ($\underline{\pi}_{ab}$ and $\mathbf{p}^a{}_i$ are the momenta conjugate to $\boldsymbol{\gamma}^{ab}$ and $\underline{E}^i{}_a$, respectively),

$$k_{ab} := -(\pi_{ab} - \tfrac{1}{4}\gamma_{ab}\pi), \quad k'_{ab} := -\tfrac{1}{2}\gamma_{(ac} p^c{}_i E^i{}_{b)}, \tag{3}$$

and the weak equivalence of (2b) and (2c) guarantee that the evolution equations reproduce Einstein's equations (1). The generators of frame transformations on Σ: $\underline{\boldsymbol{\mathcal{J}}}^a{}_b$, act, for example on a covector field, as $\{T_a, \underline{\boldsymbol{\mathcal{J}}}^b{}_c[\omega^c{}_b]\} = \Delta_{\tilde{\omega}}[T]_a = -\omega^b{}_a T_b$, and satisfy the Lie algebra of $\mathfrak{gl}(3,\mathbb{R})$,

$$\{\underline{\boldsymbol{\mathcal{J}}}^a{}_b, \underline{\boldsymbol{\mathcal{J}}}^c{}_d[\omega^d{}_c]\} = \Delta_{\tilde{\omega}}[\underline{\boldsymbol{\mathcal{J}}}]^a{}_b. \tag{4}$$

Note that $\mathcal{J}^{GR}_{(ab)} = -2(k_{ab} - \gamma_{ab}k) + 2(k'_{ab} - \gamma_{ab}k')$, so that its weak vanishing implies that $k_{ab} \approx k'_{ab}$. The constraint algebra consists of (4) combined with

$$\{\underline{\boldsymbol{\mathcal{H}}}[f], \underline{\boldsymbol{\mathcal{J}}}^a{}_b[\omega^b{}_a]\} = 0, \quad \{\underline{\boldsymbol{\mathcal{H}}}_a[f^a], \underline{\boldsymbol{\mathcal{J}}}^a{}_b[\omega^b{}_a]\} = \int_\Sigma d^3x\, f^a \Delta_{\tilde{\omega}}[\underline{\boldsymbol{\mathcal{H}}}]_a, \tag{5a}$$

$$\{\underline{\boldsymbol{\mathcal{H}}}[f], \underline{\boldsymbol{\mathcal{H}}}[g]\} = (f\nabla_a[g] - g\nabla_a[f])\gamma^{ab}\underline{\boldsymbol{\mathcal{H}}}_b, \tag{5b}$$

$$\{\underline{\mathcal{H}}[f],\underline{\mathcal{H}}_a[g^a]\}=\int_\Sigma dx f\mathcal{L}_{\vec{g}}[\underline{\mathcal{H}}],\quad \{\underline{\mathcal{H}}_a[f^a],\underline{\mathcal{H}}_b[g^b]\}=\int_\Sigma d^3x f^a\mathcal{L}_{\vec{g}}[\underline{\mathcal{H}}]_a. \tag{5c}$$

This result was also derived in Ref. 2 using the geometric arguments of Teitelboim,[8,9] and is a fairly straightforward generalization of that found elsewhere (see, for example, Ref. 7).

We then noted [from the form of (1a) or (2a)] that these generators are not very convenient if one wishes to consider the restriction to orthonormal frames on Σ, since the choice $\gamma_{ab}=\delta_{ab}$ is not left invariant by the actions of $d_\perp$ and $\mathcal{L}$ (and therefore $\underline{\mathcal{H}}$ and $\underline{\mathcal{H}}_a$). There are, however, alternative representations of these operators in which the spatial frame plays a more active role. In particular, we represent an infinitesimal diffeomorphism by $\mathcal{L}'$ which acts on a frame as $\mathcal{L}'_{\vec{\xi}}[E^i{}_a]=\Delta_{\tilde{\nabla}\xi}[E^i{}_a]$, and on the components of tensors as the covariant derivative, $\mathcal{L}'_{\vec{\xi}}[T]_a=\xi^b\nabla_b[T]_a$; the action on the tensor itself is identical to that of $\mathcal{L}$: $\mathcal{L}_{\vec{\xi}}[T_a\theta^a]=\mathcal{L}'_{\vec{\xi}}[T_a\theta^a]$. The action of $\mathcal{L}'$ on the components of the spatial metric vanishes due to metric compatibility, and is therefore consistent with the limit to orthonormal spatial frames—note though that it is no longer consistent with the limit to a coordinate frame. Similarly we define the operator $d'_\perp$ to act on the frame as: $d'_\perp[E^i{}_a]=\Delta_{\tilde{K}}[E^i{}_a]=-K^b{}_aE^i{}_b$, and on the components of tensors as $d'_\perp=d_\perp+\Delta_{\tilde{K}}$. Using these, Einstein's equations (1) appear as

$$d'_\perp[\gamma]_{ab}=0,\quad d'_\perp[E^i{}_a]=\Delta_{\tilde{K}}E^i{}_b=-K^b{}_aE^i{}_b, \tag{6a}$$

$$d'_\perp[K]_{ab}=-R_{ab}+\nabla_a\nabla_b[N]/N-KK_{ab}+\tfrac{1}{2}\overline{T}^{\mathrm{M}}_{ab}. \tag{6b}$$

The action of $d'_\perp$ and $\mathcal{L}'$ are represented on phase space by the primed Hamiltonian constraint $\underline{\mathcal{H}}'$ and the primed momentum constraint $\underline{\mathcal{H}}'_a$, respectively (which correspond to a particular choice of mixing of the unprimed constraints with the frame rotation generators),

$$\{\gamma_{ab},\underline{\mathcal{H}}'^{GR}[f]\}=0,\quad \{E^i{}_a,\underline{\mathcal{H}}'^{GR}[f]\}=\Delta_{\tilde{k}'}[E^i{}_a]=-k'^b{}_aE^i{}_b, \tag{7a}$$

$$\{k_{ab},\underline{\mathcal{H}}'^{GR}[f]\}=-fR_{ab}+\nabla_a\nabla_b[f]-fk'k_{ab}-\tfrac{1}{4}f\gamma_{ab}\mathcal{H}'^{GR}-k'_{(a}{}^c\mathcal{J}^{GR}_{[b)c]}, \tag{7b}$$

$$\{k'_{ab},\underline{\mathcal{H}}'^{GR}[f]\}=-fR_{ab}+\nabla_a\nabla_b[f]-fk'k'_{ab}-\tfrac{1}{4}f\gamma_{ab}\mathcal{H}'^{GR}-fk'_{(a}{}^c\mathcal{J}^{GR}_{[b)c]}, \tag{7c}$$

and the constraint algebra for this primed system consists of (4) combined with (also derived in Ref. 2),

$$\{\underline{\mathcal{H}}'[f],\underline{\mathcal{J}}^a{}_b[\omega^b{}_a]\}=0,\quad \{\underline{\mathcal{H}}'_a[N^a],\underline{\mathcal{J}}^a{}_b[\omega^b{}_a]\}=\int_\Sigma d^3xN^a\Delta_{\tilde{\omega}}[\underline{\mathcal{H}}']_a, \tag{8a}$$

$$\{\underline{\mathcal{H}}'[f],\underline{\mathcal{H}}'[g]\}=\int_\Sigma d^3x(f\nabla_a[g]-g\nabla_a[f])(\gamma^{ab}\underline{\mathcal{H}}'_b-E\nabla_b[\underline{\mathcal{J}}]^{[ab]}), \tag{8b}$$

$$\{\underline{\mathcal{H}}'[f],\underline{\mathcal{H}}'_a[g^a]\}=\int_\Sigma d^3x(f\mathcal{L}_{\vec{g}}[\underline{\mathcal{H}}']-fg^a\Delta_{\tilde{k}'}[\underline{\mathcal{H}}']_a+2g^a\nabla_c[fk'_{ab}]\underline{\mathcal{J}}^{[bc]}), \tag{8c}$$

$$\{\underline{\mathcal{H}}'_a[f^a],\underline{\mathcal{H}}'_b[g^b]\}=-\int_\Sigma d^3xf^ag^bR^c{}_{dab}\underline{\mathcal{J}}^d{}_c. \tag{8d}$$

As we shall see, including matter presents no great difficulties. In Sec. II, we consider a scalar field as a brief demonstration of how matter fields fit into the generalized structure. In Sec. III, a one-form (gauge) field is introduced, transforming nontrivially under spatial frame rotations, and an additional constraint generating U(1) transformations appears. We find nontrivial mixing of the Maxwell canonical pair with that of the spatial vierbein, mixing that, at least superficially, resembles derivative-coupling. We will see that this is a manifestation of the gauge choice and is not ''true'' derivative-coupling since the metric compatibility conditions are unaffected. Finally, in Sec. IV, the spatial frame is constrained to be orthogonal in order to introduce a Dirac field.

In all three cases the matter action is added to that of vacuum *GR*: $S^{GR}\rightarrow S^{GR}+S^{M}$, and since both sets of vacuum *GR* constraints: $(\mathcal{H}^{GR},\mathcal{H}_a^{GR})$ and $(\mathcal{H}'^{\,GR},\mathcal{H}_a'^{\,GR})$, are equivalent to the components of the Einstein tensor: $(-2G^{\perp}{}_{\perp},-2G^{\perp}{}_{a})$, we find that the additively combined vacuum *GR* and matter constraints are weakly equivalent to adding $(T^{\perp}{}_{\perp},T^{\perp}{}_{a})$ to these. The matter stress-energy tensor is derived from the matter action S^M via

$$T_{AB}=\frac{2}{E}\left(\frac{\delta S^M}{\delta \mathbf{g}^{AB}}-\frac{1}{2}g_{AB}g^{CD}\frac{\delta S^M}{\delta \mathbf{g}^{CD}}\right)=\frac{1}{\sqrt{-g}}\left(g_{AC}E^{\mu}{}_{B}\frac{\delta S^M}{\delta \underline{E}^{\mu}{}_{C}}-g_{AB}E^{\mu}{}_{C}\frac{\delta S^M}{\delta \underline{E}^{\mu}{}_{C}}\right); \tag{9}$$

the equivalence of these two forms is a basic consistency requirement for the generalized treatment considered herein. By an argument of Floreanini and Percacci,[10] we know that once the matter action has been properly written in a general linear frame these forms will be consistent. Note though that in (9) we consider the metric and vierbein degrees of freedom *independently*, which will *not* work with the E–D system—only the second form is applicable. We will show (briefly) that the matter field equations and the stress-energy tensor determined from both forms of (9) are properly generated via a variational principle. Also that the action of the constraints on phase space properly generates spatial diffeomorphisms once matter has been incorporated into the canonical formalism, and (2) and (7) are properly extended to reproduce (1) and (6), respectively, with the appropriate stress-energy tensor.

One of the unfortunate aspects and at the same time strengths of diffeomorphism invariant theories is the great arbitrariness in parameterizing configuration and momentum space fields; any ''all-encompassing'' formalism would have to include canonical transformations that relate different parameterizations. The content of the ''geometric'' derivations of the constraint algebras[8,9,2] is that the algebra is fixed by the reduction of the space–time equations to the evolution of spatial quantities, that is, the algebra is a reflection of the spacetime diffeomorphism invariance. The details of the algebra will change depending on the parameterization of phase space and the choice of constraints, but is always of a fixed form once these choices are made. The point of this work is *not* to advocate any particular parameterization, merely to make it clear that there is actually a wider range of possibilities than heretofore considered. Within this wider class one finds that the Einstein–Dirac system may be treated in a particular limit, and not as an awkward construction that seemingly must be invented solely to deal with Fermion fields. Thus we find that the Einstein–Dirac (E–D) system is operationally no different than the Einstein–Klein Gordon (E–KG) or Einstein–Maxwell (E–M) systems; there is no more derivative-coupling in the E–D system than in the E–M system. Indeed the mixing of canonical variables is necessary in order to retrieve the correct surface frame transformation generators, while retaining the metric compatibility conditions at the level of the field equations.

II. A SCALAR FIELD

This example is a trivial extension of the vacuum GR results, included as a straightforward example of how the extension of the results of Ref. 1 outlined in Sec. I proceeds. Its simplicity is due to the fact that we have chosen canonical coordinates for the scalar field that do not transform under changes of spatial frame. Note that this is *not* necessary; we could just as well chosen to parameterize the scalar field action in terms of a densitized scalar field, in which case some of the structure that we will encounter in Sec. III would have appeared.

The scalar field Lagrangian density with self-coupling potential $V[\phi]$ is

$$\begin{aligned}\underline{\mathcal{L}}^{\phi}&=\mathbf{E}\left(\tfrac{1}{2}\mathrm{g}^{AB}\,{}^{4}\nabla_A[\phi]\,{}^{4}\nabla_B[\phi]-V[\phi]\right)\\&=\frac{\mathbf{E}}{2N}(\partial_t[\phi]-N^a e_a[\phi])^2-\frac{1}{2}\underline{N}\boldsymbol{\gamma}^{ab}\nabla_a[\phi]\nabla_b[\phi]-\underline{N}V[\phi],\end{aligned} \tag{10}$$

from which we derive [from either form of Eq. (9)],

$$T^{\phi}_{AB}={}^4\nabla_A[\phi]{}^4\nabla_B[\phi]-\tfrac{1}{2}g_{AB}g^{CD}\,{}^4\nabla_C[\phi]{}^4\nabla_D[\phi]+g_{AB}V[\phi], \tag{11a}$$

$$\overline{T}^{\phi}_{AB}={}^4\nabla_A[\phi]{}^4\nabla_B[\phi]-g_{AB}V[\phi]. \tag{11b}$$

Using the field equations for ϕ,

$$\frac{\delta S^{\phi}}{\delta\phi}=E\mathbf{g}^{AB}\,{}^4\nabla_A[{}^4\nabla_B[\phi]]-\mathbf{E}\delta_{\phi}[V], \tag{12}$$

it is straightforward to demonstrate that the conservation law ${}^4\nabla_B[T^{\phi}]^B{}_A=0$ is satisfied.

From (10) we see that the phase space of the scalar field may be parameterized by the conjugate pair, $(\phi,\underline{\mathbf{P}})$, where

$$\underline{\mathbf{P}}:=\frac{\mathbf{E}}{N}(\partial_t[\phi]-N^a e_a[\phi])=\mathbf{E}e_{\perp}[\phi]. \tag{13}$$

As a result, the Poisson bracket for the extended system is $\{F,G\}=\{F,G\}_{GR}+\{F,G\}_{\phi}$, where $\{.,.\}_{GR}$ is the *GR* sector Poisson bracket given in Ref. 1 and

$$\{F,G\}_{\phi}:=\int_{\Sigma}d^3x\left(\frac{\delta F}{\delta\phi(x)}\,\frac{\delta G}{\delta\underline{\mathbf{P}}(x)}-\frac{\delta G}{\delta\phi(x)}\,\frac{\delta F}{\delta\underline{\mathbf{P}}(x)}\right). \tag{14}$$

Since neither the extrinsic curvature nor time derivatives of the spatial metric or frame appear in the Lagrangian density (10), we see that the definitions of k_{ab} and k'_{ab} in (3) are undisturbed, and the frame rotation generators are identical to those in vacuum *GR*, $\underline{\mathcal{J}}^a{}_b=\underline{\mathcal{J}}^{GR\,a}{}_b$. Thus we find that

$$\underline{\boldsymbol{\mathcal{H}}}^{\phi}=\underline{\boldsymbol{\mathcal{H}}}'^{\phi}=\tfrac{1}{2}\mathbf{E}(P_{\phi})^2+\tfrac{1}{2}E\boldsymbol{\gamma}^{ab}\nabla_a[\phi]\nabla_b[\phi]+\mathbf{E}V[\phi]=\underline{\mathbf{T}}^{\phi\perp}{}_{\perp}, \tag{15a}$$

$$\underline{\boldsymbol{\mathcal{H}}}^{\phi}_a=\underline{\boldsymbol{\mathcal{H}}}'^{\phi}_a=\underline{\mathbf{P}}_{\phi}\nabla_a[\phi]=\underline{\mathbf{T}}^{\phi\perp}{}_a, \tag{15b}$$

are added to the *GR* constraints.

Hamilton's equations for the scalar field,

$$\{\phi,H\}=NP_{\phi}+N^a\nabla_a[\phi],\quad \{\underline{\mathbf{P}}_{\phi},H\}=E\nabla_a[N\boldsymbol{\gamma}^{ab}\nabla_b[\phi]]-\underline{\mathbf{N}}\delta_{\phi}[V]+E\nabla_a[N^a\mathbf{P}_{\phi}], \tag{16}$$

are equivalent to (12), and noting that $\{\boldsymbol{\gamma}^{ab},\underline{\boldsymbol{\mathcal{H}}}^M[f]\}=\{\boldsymbol{\gamma}^{ab},\underline{\boldsymbol{\mathcal{H}}}^M_a[f^a]\}=0$ and $\{\underline{E}^i{}_a,\underline{\boldsymbol{\mathcal{H}}}^M[f]\}=\{\underline{E}^i{}_a,\underline{\boldsymbol{\mathcal{H}}}^M_a[f^a]\}=0$, we see that neither of (2a) nor (7a) are altered. Using (with similar definitions with primes for Poisson brackets of the primed constraints)

$$\{\mathbf{p}^a{}_i,\underline{\boldsymbol{\mathcal{H}}}^{\phi}[f]\}=\mathbf{Y}^a{}_b[f]E^b{}_i-\tfrac{1}{2}\mathbf{Y}[f]E^a{}_i,\quad \{\underline{\pi}_{ab},\underline{\boldsymbol{\mathcal{H}}}^{\phi}[f]\}=\underline{X}_{ab}[f]-\gamma_{ab}\underline{X}[f], \tag{17a}$$

$$\{\mathbf{p}^a{}_i,\underline{\boldsymbol{\mathcal{H}}}^{\phi}_b[f^b]\}=\mathbf{W}^a{}_b[\vec{f}]E^b{}_i-\tfrac{1}{2}\mathbf{W}[\vec{f}]E^a{}_i,\quad \{\underline{\pi}_{ab},\underline{\boldsymbol{\mathcal{H}}}^{\phi}_c[f^c]\}=\mathbf{Z}_{ab}[\vec{f}]-\gamma_{ab}\mathbf{Z}[\vec{f}], \tag{17b}$$

where

$$W^a{}_b[\vec{f}]=W'^a{}_b[\vec{f}]=-f^a\mathcal{H}^{\phi}_b,\quad Z_{ab}[\vec{f}]=Z'_{ab}[\vec{f}]=0, \tag{18a}$$

$$X_{ab}[f]=X'_{ab}[f]=-\tfrac{1}{2}fT^{\phi}_{ab}=-\tfrac{1}{2}f(\overline{T}_{ab}-\gamma_{ab}\overline{T})-\tfrac{1}{2}f\gamma_{ab}\mathcal{H}^{\phi}, \tag{18b}$$

$$Y_{ab}[f]=Y'_{ab}[f]=-fT^{\phi}_{ab}=-f(\overline{T}_{ab}-\gamma_{ab}\overline{T})-f\gamma_{ab}\mathcal{H}^{\phi}, \tag{18c}$$

it is straightforward to show that the evolution of the extrinsic curvature is correctly generated. That is, we find that $\mathcal{H}^{GR} \rightarrow \mathcal{H}^{GR} + \mathcal{H}^{\phi}$ and $\frac{1}{2} f \overline{T}^{\phi}_{ab}$ is appended to the right-hand sides of (2b), (2c), (7b), and (7c) in accordance with (1) and (6). The unprimed and primed constraint algebras are identical to (44) and (49), respectively, of Ref. 1 with $\mathcal{H} = \mathcal{H}^{GR} + \mathcal{H}^{\phi}$ and $\mathcal{H}_a = \mathcal{H}^{GR}_a + \mathcal{H}^{\phi}_a$, or, equivalently, (40) and (45) combined with $\mathcal{H}^{A}_{U(1)} = 0$.

III. MAXWELL FIELDS

Since the vector potential of the Einstein–Maxwell system is a one-form field, it is associated to $GL\mathbf{M}$ through a (co-)vector representation of $GL(4,\mathbb{R})$, and therefore results in a nontrivial contribution to $\mathcal{J}^a{}_b$. This means that the primed and unprimed cases may no longer be considered together; the unprimed system is considered in Sec. III A and the primed in Sec. III B. We shall see that although the details of the calculation are nontrivial, the results are a fairly straightforward extension of those of vacuum *GR*.

The components of the field strength tensor: $F := dA = \frac{1}{2} F_{AB} \theta^A \wedge \theta^B$, are derived from the one-form $A := A_A \theta^A$ by

$$F_{AB} = {}^4\nabla_A[A]_B - {}^4\nabla_B[A]_A = e_A[A_B] - e_B[A_A] - C_{AB}{}^C A_C, \tag{19}$$

and the standard Lagrangian density is

$$\underline{\mathcal{L}}^A = -\tfrac{1}{4} \mathbf{E} g^{AC} g^{BD} F_{AB} F_{CD} = \underline{\mathbf{N}} \left(\tfrac{1}{2} \gamma^{ab} F_{\perp a} F_{\perp b} - \tfrac{1}{4} F_{ab} F^{ab} \right), \tag{20}$$

where $F_{ab} = \nabla_a A_b - \nabla_b A_a$, and

$$F_{\perp a} = (\partial_t [A_a] - A_b E^b{}_i \partial_t [E^i{}_a] - \mathcal{L}_{\vec{N}}[A]_a)/N - \nabla_a [A_\perp] - A_\perp \nabla_a [\ln(N)]. \tag{21}$$

The Maxwell field equations derived from (20) are

$$\frac{\delta S^M}{\delta A_A} = \mathbf{E}\, {}^4\nabla_B [F]^{BA} = 0, \tag{22}$$

and making use of the variation of the field strength tensor with respect to the spatial frame

$$\delta_E F_{AB} = 2\, {}^4\nabla_C [A]_{[B} E^C{}_\mu \delta E^\mu{}_{A]} + 2 A_C\, {}^4\nabla_{[B} [E^C{}_\mu \delta E^\mu{}_{A]}], \tag{23}$$

we find that the stress-energy tensor as determined by either form of (9) is

$$T^A_{AB} = \overline{T}^A_{AB} = -g^{CD} F_{AC} F_{BD} + \tfrac{1}{4} g_{AB} F^{BC} F_{BC}. \tag{24}$$

From the field equations (22) and using the Bianchi identity, ${}^4\nabla_A [F]_{BC} + {}^4\nabla_C [F]_{AB} + {}^4\nabla_B [F]_{CA} = 0$, we find that the conservation laws, ${}^4\nabla_B [T^A]^B{}_A = 0$, are satisfied. Note that despite the presence of the structure constants $C_{AB}{}^C$ in the field strength tensor (19); the variation of the action (20) using (23) does *not* lead to any terms containing the second-derivative of the frame.

We see from (20) and (21) that the momenta conjugate to A_a are

$$\frac{\delta L^{\mathrm{A}}}{\delta \partial_t [A_a]} = \underline{\gamma}^{ab} F_{\perp b} =: \underline{\mathbf{P}}^a. \tag{25}$$

The phase space of the Maxwell field may be parameterized by the conjugate pair $(A_a, \underline{\mathbf{P}}^a)$, and the Poisson bracket is extended by (summation over a is assumed)

$$\{F,G\}_{\mathrm{A}} := \int_\Sigma d^3x \left(\frac{\delta F}{\delta A_a(x)} \frac{\delta G}{\delta \underline{\mathbf{P}}^a(x)} - \frac{\delta G}{\delta A_a(x)} \frac{\delta F}{\delta \underline{\mathbf{P}}^a(x)} \right). \tag{26}$$

However, we also find that the ''geometrodynamical momentum'' conjugate to $\underline{E}^i{}_a$ as given in (30) of Ref. 1 becomes

$$\mathbf{p}^a{}_i := -2\mathbf{K}^a{}_b E^b{}_i - \mathbf{P}^a A_b E^b{}_i + \tfrac{1}{2} A^b \mathbf{P}_b E^a{}_i , \tag{27}$$

the first term of which is the ''gravitational momentum.''[5] Thus we find that the gravitational and nongravitational fields are mixed, and DeWitt's supermetric is no longer block-diagonal. By defining

$$\kappa_{ab} := -\tfrac{1}{2}(P_{(a}A_{b)} - \tfrac{1}{2}\gamma_{ab}P^c A_c), \tag{28}$$

we now have [cf. the discussion following (33) of Ref. 1],

$$K_{ab} \approx \bar{a} k_{ab} + (1-\bar{a})(k'_{ab} + \kappa_{ab}), \tag{29}$$

where the unprimed case corresponds to $\bar{a}=1$ and the primed case to $\bar{a}=0$. In addition, the generators of frame transformations become

$$\underline{\mathcal{J}}^a{}_b = 2\gamma^{ac}\underline{\pi}_{bc} - \underline{\pi}\delta^a_b - \mathbf{p}^a{}_i \underline{E}^i{}_b + \underline{\mathbf{p}}\delta^a_b - \underline{\mathbf{P}}^a A_b , \tag{30}$$

which correctly generate frame transformations on the vector field sector,

$$\{A_a , \underline{\mathcal{J}}^b{}_c[\omega^c{}_b]\} = \Delta_{\tilde{\omega}}[A]_a , \quad \{\underline{\mathbf{P}}^a , \underline{\mathcal{J}}^b{}_c[\omega^c{}_b]\} = \Delta_{\tilde{\omega}}[\underline{\mathbf{P}}]^a , \tag{31}$$

and satisfy (4).

The Lagrange multiplier $A_\perp$ enforces the U(1) constraint,

$$\underline{\mathcal{H}}^A_{U(1)} = -\mathbf{E}\nabla_a[P]^a, \tag{32}$$

and we find

$$\{\underline{\mathcal{H}}^A_{U(1)}[\alpha], \underline{\mathcal{H}}^A_{U(1)}[\beta]\} = 0, \quad \{\underline{\mathcal{H}}^A_{U(1)}[\alpha], \underline{\mathcal{J}}^a{}_b[\omega^b{}_a]\} = 0, \tag{33}$$

and the nonvanishing brackets,

$$\{A_a , \underline{\mathcal{H}}^A_{U(1)}[\alpha]\} = \nabla_a[\alpha], \quad \{\underline{\mathbf{P}}^a , \underline{\mathcal{H}}^A_{U(1)}[\alpha]\} = 0, \tag{34a}$$

$$\{\mathbf{p}^a{}_i , \underline{\mathcal{H}}^A_{U(1)}[\alpha]\} = -(\mathbf{P}^a E^b{}_i - \tfrac{1}{2}\mathbf{P}^b E^a{}_i)\nabla_b[\alpha]. \tag{34b}$$

This additional constraint is appended to the standard forms of the Hamiltonian via an additional atlas field, $\alpha := NA_\perp$, as (and similarly for the primed system),

$$H^{\mathrm{A}} = \int_\Sigma d^3x (N\underline{\mathcal{H}} + N^a \underline{\mathcal{H}}_a + N^a{}_b \underline{\mathcal{J}}^b{}_a + \alpha \underline{\mathcal{H}}^A_{U(1)}). \tag{35}$$

To determine the form of the other constraints appearing in (35) we follow the development in Ref. 1; choosing $K_{ab} = k_{ab}$ $(\bar{a}=1)$ leads to the unprimed system that closely resembles the coordinate frame approach (Sec. III A), whereas choosing $K_{ab} = k'_{ab} + \kappa_{ab}$ $(\bar{a}=0)$ leads to the primed case (Sec. III B).

A. The unprimed system

Since for the unprimed system $K_{ab} = k_{ab}$, the results follow from identifying the Hamiltonian and momentum constraints from the Maxwell Hamiltonian, leading to the following additions to the unprimed constraints:

$$\underline{\mathcal{H}}^{\mathrm{A}} := \tfrac{1}{2}\mathbf{E}P^a P_a + \tfrac{1}{4}\mathbf{E}F^{ab}F_{ab} = \underline{\mathbf{T}}^{A^\perp}{}_\perp , \tag{36a}$$

$$\underline{\boldsymbol{\mathcal{H}}}_a^A := \underline{\mathbf{P}}^b F_{ab} - \underline{\mathbf{A}}_a \nabla_b [P]^b = \underline{\mathbf{T}}^{A\perp}{}_a + A_a \underline{\boldsymbol{\mathcal{H}}}_{U(1)}^A . \tag{36b}$$

From these it is straightforward to determine

$$\{A_a, \underline{\boldsymbol{\mathcal{H}}}^A[f]\} = f P_a , \quad \{\underline{\mathbf{P}}^a, \underline{\boldsymbol{\mathcal{H}}}^A[f]\} = -\mathbf{E}\nabla_b [f F^{ab}], \tag{37a}$$

$$\{A_a, \underline{\boldsymbol{\mathcal{H}}}_b[f^b]\} = \mathcal{L}_{\vec{f}}[A]_a , \quad \{\underline{\mathbf{P}}^a, \underline{\boldsymbol{\mathcal{H}}}_b[f^b]\} = E\mathcal{L}_{\vec{f}}[\mathbf{P}]^a, \tag{37b}$$

and, using (34), Hamilton's equations for the Maxwell field are found

$$\{A_a, H\} = N P_a + \mathcal{L}_{\vec{N}}[A]_a + \Delta_{\tilde{N}}[A]_a + \nabla_a [\alpha], \tag{38a}$$

$$\{\underline{\mathbf{P}}^a, H\} = -\mathbf{E}\nabla_b [N F^{ab}] + E\mathcal{L}_{\vec{N}}[\mathbf{P}]^a + \Delta_{\tilde{N}}[\underline{\mathbf{P}}]^a. \tag{38b}$$

The combination of these with the $U(1)$ constraint (32) is equivalent to (22).

Using the definitions in (17) we find

$$\mathbf{W}^a{}_b[\vec{f}] = -\mathcal{L}_{\vec{f}}[A_b \mathbf{P}^a] - f^a \underline{\boldsymbol{\mathcal{H}}}_b^A , \quad Z_{ab} = 0, \tag{39a}$$

$$Y^a{}_b[f] = -f\overline{T}^A_{ab} - f P_a P_b - A_b \nabla_c [f F^{ca}], \quad X_{ab}[f] = -\tfrac{1}{2} f \overline{T}^A_{ab} . \tag{39b}$$

Noting that $\overline{T} := \gamma^{ab}\overline{T}_{ab} = \mathcal{H}^A$, it is straightforward to show that $\{k_{ab}, \underline{\boldsymbol{\mathcal{H}}}\} = \tfrac{1}{2} f \overline{T}_{ab} - \tfrac{1}{4}\gamma_{ab}\mathcal{H}^A$, and therefore the correct extension of (2b) is generated. In order to check the extension of (2c), note that we now must compute $\{k'_{ab} + \kappa_{ab}, \underline{\boldsymbol{\mathcal{H}}}[f]\}$, which correctly results in the additional contributions, $\tfrac{1}{2} f \overline{T}_{ab} - \tfrac{1}{4} f \gamma_{ab}\mathcal{H}^A - f k \kappa_{ab} + 2\, f k_{(a}{}^c \kappa_{cb)} + f k_{(a}{}^c \mathcal{J}^A_{[cb)]}$.

It is now possible to compute the algebra of the unprimed constraints, finding (4), (33), (5a), (5b), and

$$\{\underline{\boldsymbol{\mathcal{H}}}_{U(1)}^A[\alpha], \underline{\boldsymbol{\mathcal{H}}}[f]\} = 0, \quad \{\underline{\boldsymbol{\mathcal{H}}}_{U(1)}^A[\alpha], \underline{\boldsymbol{\mathcal{H}}}_a[f^a]\} = -\int_\Sigma d^3x\, \alpha \mathcal{L}_{\vec{f}}[\underline{\boldsymbol{\mathcal{H}}}_{U(1)}^A], \tag{40a}$$

$$\{\underline{\boldsymbol{\mathcal{H}}}[f], \underline{\boldsymbol{\mathcal{H}}}[g]\} = (f\nabla_a[g] - g\nabla_a[f])\,\gamma^{ab}(\underline{\boldsymbol{\mathcal{H}}}_b - A_b \underline{\boldsymbol{\mathcal{H}}}_{U(1)}^A). \tag{40b}$$

B. The primed system

After some algebra, the primed constraints found to be

$$\underline{\boldsymbol{\mathcal{H}}}'^A = \tfrac{1}{2}\mathbf{E} P^a P_a + \tfrac{1}{4}\mathbf{E} F^{ab} F_{ab} + \mathbf{E}(\kappa^a{}_b \kappa^b{}_a - \kappa^2) + 2\mathbf{E}(\kappa^a{}_b k'^b{}_a - k'\kappa), \tag{41a}$$

$$\underline{\boldsymbol{\mathcal{H}}}'^A_a = \underline{\mathbf{P}}^b \nabla_a [A]_b , \tag{41b}$$

which are related to (36) via combinations of the frame rotation generators given in Eq. (45) of Ref. 1, and therefore the combined constraints are equivalent to the Einstein equations, $G^\perp{}_A = \tfrac{1}{2} T^\perp{}_A$. Their action on the Maxwell phase space is found to be

$$\{A_a, \underline{\boldsymbol{\mathcal{H}}}'^A[f]\} = f P_a + f\Delta_{\tilde{k}' + \tilde{\kappa}}[A]_a , \quad \{\underline{\mathbf{P}}^a, \underline{\boldsymbol{\mathcal{H}}}'^A[f]\} = -\mathbf{E}\nabla_b [f F^{ab}] + f\Delta_{\tilde{k}' + \tilde{\kappa}}[\underline{\mathbf{P}}]^a, \tag{42a}$$

$$\{A_a, \underline{\boldsymbol{\mathcal{H}}}'^A_a[f^a]\} = f^b \nabla_b [A]_a = \mathcal{L}'_{\vec{f}}[A]_a , \quad \{\underline{\mathbf{P}}^a, \underline{\boldsymbol{\mathcal{H}}}'^A_a[f^a]\} = \mathbf{E}\nabla_b [f^b P^a] = \mathcal{L}'_{\vec{f}}[\underline{\mathbf{P}}]^a. \tag{42b}$$

Note that the actions (37) and (42) are those of $d_\perp$ and $\mathcal{L}$ and $d'_\perp$ and $\mathcal{L}'$ respectively. Hamilton's equations for the Maxwell sector are straightforward to find, and, as in the case of vacuum *GR* (see (52) of Ref. 1), are weakly equivalent to (38) when one makes the replacements, $N = N'$, $N_a = N'_a$, and $N^a{}_b = N'^a{}_b + \nabla_b [N']^a + N' k^a{}_b$.

Since $\{\underline{E}^i{}_a, \underline{\boldsymbol{\mathcal{H}}}'^A[f]\} = \Delta_{\tilde{\kappa}}[\underline{E}^i{}_a]$, the action of the Hamiltonian constraint on the frame is

$$\{\underline{E}^i{}_a,\underline{\boldsymbol{\mathcal{H}}}'[f]\}=f\Delta_{\tilde{k}'+\tilde{\kappa}}[\underline{E}^i{}_a],\tag{43}$$

properly reproducing the evolution of the vierbein in accordance with (6a). Again making use of the definitions in (17), we find

$$W'_{ab}[\vec{f}]=-f_a\mathcal{H}'^A_b+\nabla_c[f^cP_{[b}A_{a]}]+\nabla_c[P^cA_{(b}f_{a)}]-\nabla_c[A^cf_{(b}P_{a)}],\tag{44a}$$

$$X'_{ab}[f]=-\tfrac{1}{2}f\overline{T}^A_{ab}+\tfrac{1}{2}f\gamma_{ab}(\kappa^a{}_b\kappa^b{}_a-\kappa^2)$$
$$+f\gamma_{ab}(k'^a{}_b\kappa^b{}_a-k'\kappa)+f\kappa_{(a}{}^c\mathcal{J}^{GR}_{[b)c]}+f(k'_{(a}{}^c+\kappa_{(a}{}^c)\mathcal{J}^A_{[b)c]},\tag{44b}$$

$$Y'_{ab}[f]=-f\overline{T}_{ab}-fP_aP_b+A_b\nabla_c[fF_a{}^c]-2f(\kappa_a{}^ck'_{bc}-\kappa k'_{ab})$$
$$-f\gamma_{ab}(\kappa^a{}_b\kappa^b{}_a-\kappa^2)+f(\kappa_a{}^c-\delta^c_a\kappa)\mathcal{J}^{GR}_{[bc]},\tag{44c}$$

$$Z'_{ab}[\vec{f}]=\tfrac{1}{2}(\nabla_c[P^cf_{(a}A_{b)}]+\nabla_c[f^cP_{(a}A_{b)}]-\nabla_c[A^cf_{(a}P_{b)}]),\tag{44d}$$

and, noting that $\kappa_{(a}{}^c\mathcal{J}^A_{[cb)]}=\frac{1}{8}P^cP_cA_aA_b-\frac{1}{8}A^cA_cP_aP_b$, it is straightforward to show that the appropriate additions to (7b) and (7c) are generated from these. The primed constraint algebra consists of (4), (33), (8a), (8d), and

$$\{\underline{\boldsymbol{\mathcal{H}}}^A_{U(1)}[\alpha],\underline{\boldsymbol{\mathcal{H}}}'[f]\}=0,\quad \{\underline{\boldsymbol{\mathcal{H}}}^A_{U(1)}[\alpha],\underline{\boldsymbol{\mathcal{H}}}'_a[f^a]\}=-\int_\Sigma d^3x\,\alpha\mathcal{L}'_{\vec{f}}[\underline{\boldsymbol{\mathcal{H}}}^A_{U(1)}],\tag{45a}$$

$$\{\underline{\boldsymbol{\mathcal{H}}}'[f],\underline{\boldsymbol{\mathcal{H}}}'[g]\}=\int_\Sigma d^3x(f\nabla_a[g]-g\nabla_a[f])(\gamma^{ab}\underline{\boldsymbol{\mathcal{H}}}'_b-E\nabla_b[\boldsymbol{\mathcal{J}}]^{[ab]}-A^a\underline{\boldsymbol{\mathcal{H}}}^A_{U(1)}),\tag{45b}$$

$$\{\underline{\boldsymbol{\mathcal{H}}}'[f],\underline{\boldsymbol{\mathcal{H}}}'_a[g^a]\}=\int_\Sigma d^3x(\vec{f}\mathcal{L}_{\vec{g}}[\underline{\boldsymbol{\mathcal{H}}}']-fg^a\Delta_{\tilde{k}'+\tilde{\kappa}}[\underline{\boldsymbol{\mathcal{H}}}']_a+2g^a\nabla_c[f(k'_{ab}+\kappa_{ab})]\underline{\boldsymbol{\mathcal{J}}}^{[bc]}).\tag{45c}$$

IV. DIRAC SPINORS

In order to consider the introduction of a self-gravitating Dirac spinor, we need to do some preparatory work. The conditions for the existence of a spin structure on a manifold are known,[11,12] however, since we are primarily interested in the initial-value formalism, the relevant result is that any globally hyperbolic spacetime or space–time that admits a Cauchy surface admits a spin structure.[13] The general theory of spinors in curved spacetime (see, for example, Ref. 6) requires the introduction of an SL(2,ℂ) principle bundle—a Dirac spinor is associated to it through the product of a vector and conjugate vector representations of SL(2,ℂ). One may introduce spin frames, and would then develop formalism to deal with the initial-value problem similar to Ref. 14.

Here we will pursue a more straightforward, operationally-oriented path. We note that a Dirac spinor is associated directly to the Lorentz group through a spinor representation,[15] and so we will reduce the general linear frame bundle $GL\mathbf{M}$ to the Lorentz frame bundle $L\mathbf{M}$, with structure group O(1,3). (In fact, for the initial value problem we will be considering time and space oriented frames, and so have in effect reduced this further to $L^+_\uparrow\mathbf{M}$ with structure group the proper Lorentz group, $\mathcal{L}^+_\uparrow(1,3)=\{\Lambda\in O(1,3)|\det(\Lambda)=+1,\Lambda^0{}_0>0\}$.) Elements of $GL(4,\mathbb{R})$ are specialized to $O(1,3)$ as $M^A_B\rightarrow\Lambda^A{}_B$ and $|M^{-1}|^A_B\rightarrow\Lambda_B{}^A=\eta^{AC}\eta_{BD}\Lambda^D{}_C$, where $\Lambda^A{}_C\Lambda_B{}^C=\delta^A_B=\Lambda^C{}_B\Lambda_C{}^A$.

Given a Lorentz transformation Λ, the spinor ψ transforms as $\psi\rightarrow S(\Lambda)\psi$, and the gamma matrices satisfy the Dirac relations (we make use of the definitions and identities in Appendix 2A of Ref. 16), $\{\gamma^A,\gamma^B\}=2\eta^{AB}$, and $\Lambda^A{}_B\gamma^B=S^{-1}(\Lambda)\gamma^AS(\Lambda)$. Writing an infinitesimal Lorentz transformation as $\Lambda^A{}_B \approx \delta^A_B + \omega^A{}_B$, where $\omega^A{}_B$ are the antisymmetric generators of $\mathfrak{so}(1,3)$, for the spinor representation we have $S(\Lambda) \approx 1 - \frac{1}{4} i \hat{\omega}$, where $\hat{\omega} := \omega^A{}_B \sigma^B{}_A$, and $\sigma^{AB} := i \frac{1}{2} [\gamma^A, \gamma^B]$ satisfy the commutation relations

$$[\sigma^{AB}, \sigma^{CD}] = -2i(\sigma^{AC}\eta^{BD} - \sigma^{AD}\eta^{BC} + \sigma^{BD}\eta^{AC} - \sigma^{BC}\eta^{AD}). \tag{46}$$

Therefore the action of the generator of frame rotations Δ on the spinor is

$$\Delta_{\tilde{\omega}}[\psi] = -\tfrac{1}{4} i \hat{\omega} \psi, \tag{47}$$

and, using (46), it is straightforward to show that these generators satisfy the algebra

$$[\Delta_{\tilde{\omega}_1}, \Delta_{\tilde{\omega}_2}]\psi = -\Delta_{\widetilde{[\omega_1, \omega_2]}}[\psi]. \tag{48}$$

The covariant derivative operates on these spinors as

$${}^4\nabla_A[\psi] = e_A[\psi] + \tfrac{1}{4} i \Gamma^B_{AC} \sigma^C{}_B \psi = e_A[\psi] + \tfrac{1}{4} i \, {}^4\tilde{\Gamma}_A \psi, \tag{49}$$

and, as usual, $[{}^4\nabla_A, \gamma^B] = 0$.

The curved space–time Dirac action is (see Sec. 7.10.2 of Ref. 15),

$$S^{\mathrm{D}} = \int d^4x \, \det(E^A{}_\mu) \, \overline{\psi} (i \tfrac{1}{2} \gamma^A \, {}^4\overleftrightarrow{\nabla}_A - m) \psi, \tag{50}$$

where we employ the standard notation $\overline{\psi} \, {}^4\overleftrightarrow{\nabla}_A \psi := \overline{\psi} \, {}^4\nabla_A[\psi] - {}^4\nabla_A[\overline{\psi}] \psi$. A variation of (50) with respect to $\overline{\psi}$ and ψ leads to the Dirac equation

$$i \gamma^A \, {}^4\nabla_A[\psi] - m\psi = 0, \tag{51}$$

and its adjoint, respectively. As a consequence, the vector $J^A := \overline{\psi} \gamma^A \psi$, constructed from a solution to the Dirac equation, is covariantly conserved, ${}^4\nabla_A[J]^A = 0$. In a surface-adapted frame this becomes $\partial_t[E \psi^\dagger \psi] - E \nabla_a[N^a \psi^\dagger \psi] + E \nabla_a[N \psi^\dagger \alpha^a \psi] = 0$, which has the usual quantum-mechanical probabilistic interpretation. Unlike the scalar and Maxwell field examples, the spinor is *not* dimensionless after one has chosen $16\pi G = c = 1$. Indeed, the remaining length scale may be interpreted as the Planck length L_P (or $\hbar$). Here either ψ has dimension $length^{-1/2}$, or we have taken $\hbar = 1$. Note in particular that we will introduce neither $\gamma^\mu := E^\mu{}_A \gamma^A$ nor the coordinate components of the spacetime metric.

Using the variation of the ''spin-connection'' with respect to the vierbein,

$$\delta \hat{\Gamma}_A = \delta E^\mu{}_A E^D{}_\mu \hat{\Gamma}_D + (\eta_{BD} \, {}^4\nabla_A[E^D{}_\mu \delta E^\mu{}_C] - \eta_{BD} \, {}^4\nabla_C[E^D{}_\mu \delta E^\mu{}_A] + \eta_{AD} \, {}^4\nabla_B[E^D{}_\mu \delta E^\mu{}_C]) \sigma^{CB}, \tag{52}$$

and the second form of (9), we find the stress-energy tensor,

$$T^D_{AB} = i \tfrac{1}{2} \overline{\psi} \gamma_{(A} \, {}^4\overleftrightarrow{\nabla}_{B)} \psi, \quad T^D = m \overline{\psi} \psi. \tag{53}$$

Once again we find that there are no terms containing second derivatives of either the spatial metric or frame, albeit trivially because the Dirac action (50) only contains terms that are at mostly linear in first-order derivatives of these fields. The conservation laws, ${}^4\nabla_B[T^D]^B{}_A = 0$, follow from the use of (51), the Bianchi identities of the Riemann tensor, and the wave equation satisfied by the Fermion field, $(\eta^{AB} \, {}^4\nabla_A \, {}^4\nabla_B + m^2 - \frac{1}{4} R) \psi = 0$, where we have used $[{}^4\nabla_A, {}^4\nabla_B]\psi = \frac{1}{4} i R^C{}_{DAB} \sigma^D{}_C \psi = \frac{1}{4} i \hat{R}_{AB} \psi$ and $\hat{R}_{AB} \sigma^{AB} = -2R$.

A. The initial value formalism

To specialize the primed system to orthonormal frames is a simple matter of replacing γ_{ab} by δ_{ab} in all results and ignoring anything related to the $(\boldsymbol{\gamma}^{ab},\underline{\pi}_{ab})$ part of phase space (ending up with a description of canonical tetrad *GR* similar to that discussed in Ref. 17). In addition, it will be useful to introduce (using the conventions of Sec. 1.1 of Ref. 16), $\beta=\gamma^0$ and $\alpha^a=\gamma^0\gamma^a$, in terms of which we have $\sigma^{0a}=i\alpha^a$, and the spin matrices: $\sigma^{ab}:=-i\frac{1}{2}[\alpha^a,\alpha^b]$, satisfying the reduced version of (46),

$$[\sigma^{ab},\sigma^{cd}]=2i(\delta^{bc}\sigma^{da}+\delta^{bd}\sigma^{ac}+\delta^{ca}\sigma^{bd}+\delta^{da}\sigma^{cb}). \tag{54}$$

We define the reduction of the operator (47) that generates infinitesimal O(3) frame rotations by

$$\Delta_{\tilde{\omega}}\psi=i\tfrac{1}{4}\hat{\omega}\psi, \quad \text{where} \quad \hat{\omega}=\omega_{ab}\sigma^{ab}, \tag{55}$$

and the surface-covariant derivative as

$$\nabla_a[\psi]=e_a[\psi]+i\tfrac{1}{4}\hat{\Gamma}_a\psi, \tag{56}$$

where $\hat{\Gamma}_a:=\delta_{bd}\Gamma^b_{ac}\sigma^{bc}$. The commutator of two surface-covariant derivatives acting on a spinor results in $[\nabla_a,\nabla_b]\psi=\frac{1}{4}i\hat{R}_{ab}\psi=\frac{1}{4}iR_{cdab}\sigma^{cd}\psi$.

Decomposing the four-dimensional spin connection results in $i\frac{1}{4}{}^4\hat{\Gamma}_a=i\frac{1}{4}\hat{\Gamma}_a+\frac{1}{2}K_{ab}\alpha^b$ and $i\frac{1}{4}{}^4\hat{\Gamma}_\perp=\frac{1}{2}a_a\alpha^a-i\frac{1}{4}\hat{C}_\perp$, and so we have

$${}^4\nabla_a[\psi]=\nabla_a[\psi]+\tfrac{1}{2}K_{ab}\alpha^b\psi, \tag{57a}$$

$${}^4\nabla_\perp[\psi]=\frac{1}{N}\partial_t[\psi]-\frac{1}{N}N^a\nabla_a[\psi]-\frac{i}{4N}\nabla_a[N]_b\sigma^{ab}\psi+\tfrac{1}{2}a_a\alpha^a\psi+\frac{i}{4N}E_{ai}\partial_t[E^i{}_b]\sigma^{ab}\psi. \tag{57b}$$

(The quantity $\hat{C}_\perp:=\delta_{bc}C_{\perp a}{}^b\sigma^{ac}$, where $C_{\perp a}{}^b$, is given in (18b) of Ref. 1, and its role in the surface covariant normal derivative is discussed in Sec. III B of the same reference.)

Using these and introducing the ''half-densitized'' spinor fields (since $\det(\gamma_{ab})=\det(\delta_{ab})\equiv1$, densities of this type will not appear, and there should be no confusion with the boldfaced quantities of earlier sections),

$$\boldsymbol{\psi}:=E^{1/2}\psi, \quad \boldsymbol{\psi}^\dagger:=E^{1/2}\psi^\dagger, \tag{58}$$

from (50) it is straightforward to deduce the curved spacetime Dirac Lagrangian,

$$L^{\mathrm{D}}=\int_\Sigma d^3x\big(i\tfrac{1}{2}\boldsymbol{\psi}^\dagger\overleftrightarrow{\partial}_t\boldsymbol{\psi}+i\tfrac{1}{2}NE\psi^\dagger\alpha^a\overleftrightarrow{\nabla}_a\psi-mN\boldsymbol{\psi}^\dagger\beta\boldsymbol{\psi}-i\tfrac{1}{2}EN^a\psi^\dagger\overleftrightarrow{\nabla}_a\psi+\tfrac{1}{4}\nabla_a[N]_b\boldsymbol{\psi}^\dagger\sigma^{ab}\boldsymbol{\psi}$$
$$-\tfrac{1}{4}E_{ai}\partial_t[E^i{}_b]\boldsymbol{\psi}^\dagger\sigma^{ab}\boldsymbol{\psi}\big). \tag{59}$$

In order to perform the Legendre transform to obtain the E–D Hamiltonian, we need to choose an appropriate set of canonical coordinates in the Fermionic sector. In a flat space–time this is straightforward; one finds that (discarding a total time derivative from the action) the real and imaginary parts of ψ are canonically conjugate, and one can introduce complex coordinates on phase space and use the quantum-mechanical symplectic form[18] for a four component vector. In a curved space–time one finds that it is the densitized imaginary part of ψ that is conjugate to the real part, however, introducing the half-densitized spinors (58) allows the flat spacetime construction to proceed. Using the inner product on Σ (written first in covariant form, and then specialized to a surface-normal frame),

$$(\psi,\phi)_\Sigma = \int_\Sigma d\Sigma(x) n_A \overline{\psi}\gamma^A \phi = \int_\Sigma dx \, \boldsymbol{\psi}^\dagger \boldsymbol{\phi}, \tag{60}$$

to define the $L^2(\Sigma)$ pairing and therefore the quantum-mechanical symplectic form, the introduction of $(\boldsymbol{\psi},\boldsymbol{\psi}^\dagger)$ as complex coordinates on the Dirac sector of phase space results in the Poisson bracket,

$$\{F,G\}_D = -i\int_\Sigma dx \left(\frac{\delta F}{\delta \boldsymbol{\psi}(x)} \frac{\delta G}{\delta \boldsymbol{\psi}^\dagger(x)} - \frac{\delta G}{\delta \boldsymbol{\psi}(x)} \frac{\delta F}{\delta \boldsymbol{\psi}^\dagger(x)} \right). \tag{61}$$

On a fixed gravitational background, the result of the Legendre transformation would be to drop the first term in (59) and the negative of what remains is H^D. For the E–D system, we find that the final term in (59) contributes to the conjugate momentum of the vierbein, leading to

$$p^a{}_i := -2K^a{}_b E^b{}_i + \tfrac{1}{4}\psi^\dagger \sigma^{ab}\psi E_{bi}, \tag{62}$$

and once again the ''geometrodynamical momentum'' is not equal to the ''gravitational momentum.'' However, unlike the Maxwell case, the definition of the extrinsic curvature on phase space is undisturbed [$K_{ab} = k'_{ab}$ and (7a) is unaltered]; we find only a contribution to the frame rotation generators,

$$\mathcal{J}_{[ab]} := -p_{[ai}E^i{}_{b]} + \tfrac{1}{4}\psi^\dagger \sigma_{ab}\psi. \tag{63}$$

[Note that it is possible, and indeed somewhat simpler, to represent these rotation operators using $\mathcal{S}^a = \frac{1}{2}\epsilon^{abc}\mathcal{J}^{[bc]}$, making use of the spin matrices $s^a := \frac{1}{2}\epsilon^{abc}\sigma^{bc} = \sigma^a \mathbf{1}$, where σ^a are the Pauli spin matrices. We do not do so here simply because we wish to present results that are as similar as possible to those of the GL(3,$\mathbb{R}$) case.] In addition to generating infinitesimal frame rotations on the *GR* sector of phase space, we find that

$$\underline{\mathcal{J}}[\tilde{\omega}] = \int_\Sigma dx\, \omega_{ba} \underline{\mathcal{J}}^{[ab]}, \tag{64}$$

generates frame rotations on the Dirac sector

$$\{\boldsymbol{\psi}, \underline{\mathcal{J}}[\tilde{\omega}]\} = i\tfrac{1}{4}\hat{\omega}\boldsymbol{\psi} = \Delta_{\tilde{\omega}}[\boldsymbol{\psi}], \tag{65}$$

and the $\mathfrak{gl}(3,\mathbb{R})$ algebra (4) is reduced to that of $\mathfrak{so}(3)$,

$$\{\underline{\mathcal{J}}[\tilde{N}], \underline{\mathcal{J}}[\tilde{M}]\} = \int_\Sigma d^3x N_{ba} \Delta_{\tilde{M}}[\underline{\mathcal{J}}]^{[ab]}. \tag{66}$$

The resulting E–D Hamiltonian is once again in standard form,

$$H = \int_\Sigma d^3x (N' \underline{\mathcal{H}}' + N'^a \underline{\mathcal{H}}'_a + N'_{ba}\underline{\mathcal{J}}^{[ab]}), \tag{67}$$

where $\underline{\mathcal{H}}' = \underline{\mathcal{H}}'^{GR} + \underline{\mathcal{H}}^D$ and $\underline{\mathcal{H}}'_a = \underline{\mathcal{H}}'^{GR}_a + \underline{\mathcal{H}}^D_a$ (using the primed *GR* constraints with γ_{ab} replaced by δ_{ab}), and

$$\underline{\mathcal{H}}^D = -\tfrac{1}{2}iE\psi^\dagger \alpha^a \overleftrightarrow{\nabla}_a \psi + m\boldsymbol{\psi}^\dagger \beta \boldsymbol{\psi} = \underline{T}^{D\perp}{}_\perp, \quad \underline{\mathcal{H}}^D_a = i\tfrac{1}{2}E\psi^\dagger \overleftrightarrow{\nabla}_a \psi = \underline{T}^{D\perp}{}_a - E\nabla_b[\mathcal{J}^{D[ab]}], \tag{68}$$

arise from the Legendre transformation of (59). Note that the equivalence of these with the E–D stress-energy tensor components (53) is achieved by making use of the Dirac equation (51) to remove time derivatives of the spinor. Also note that the presence of the derivative of the Dirac frame rotation generator in the momentum constraint is consistent with the relationship between the unprimed and primed constraints in (45b) of Ref. 1. From (68) we find

$$\{\boldsymbol{\psi},\underline{\mathcal{H}}^{D}[f]\}=-fE^{1/2}\alpha^{a}\nabla_{a}[\psi]-\tfrac{1}{2}\nabla_{a}[f]\alpha^{a}\boldsymbol{\psi}-imf\beta\boldsymbol{\psi},\quad \{\boldsymbol{\psi},\underline{\mathcal{H}}_{a}'^{D}[f^{a}]\}=\mathcal{L}_{\mathbf{f}}'[\boldsymbol{\psi}], \tag{69}$$

where $\mathcal{L}'$ acts as described in Ref. 1,

$$\mathcal{L}_{\mathbf{f}}'[\boldsymbol{\psi}]=E^{1/2}f^{a}\nabla_{a}[\psi]+\Delta_{\tilde{\nabla}f}[E^{1/2}]\psi=E^{1/2}f^{a}\nabla_{a}[\psi]+\tfrac{1}{2}\nabla_{a}[f]^{a}\boldsymbol{\psi}. \tag{70}$$

Note that infinitesimal spatial diffeomorphisms act on the frame as $\{E^{i}{}_{a},\underline{\mathcal{H}}_{c}'[f^{c}]\}=-\nabla_{a}[f]^{a}E^{i}{}_{b}$; if one mixes in a spatial frame rotation so that only the symmetric part $\nabla_{(a}[f]_{b)}$ appears, then the resulting generator acting on ψ reproduces the action that is used, for example, in Ref. 19.

From (69) one finds Hamilton's equations for ψ,

$$\{\boldsymbol{\psi},H\}=E^{1/2}(N^{a}-N\alpha^{a})\nabla_{a}[\psi]+\tfrac{1}{2}(\nabla_{a}[N]^{a}-\alpha^{a}\nabla_{a}[N])\boldsymbol{\psi}-imN\beta\boldsymbol{\psi}+\tfrac{1}{4}i\hat{\omega}\boldsymbol{\psi}, \tag{71}$$

which are equivalent to (51). Again making use of the definitions (17) we find (we have used, $\{\sigma^{ab},\alpha^{c}\}=-2\epsilon^{abc}\gamma_{5}$),

$$W^{a}{}_{b}[\vec{f}]=-f^{a}\mathcal{H}_{b}^{D}-\tfrac{1}{4}\nabla_{c}[f^{c}\psi^{\dagger}\sigma_{b}{}^{a}\psi]-\tfrac{1}{4}\nabla_{c}[f^{a}\psi^{\dagger}\sigma^{c}{}_{b}\psi]+\tfrac{1}{4}\nabla_{c}[f_{b}\psi^{\dagger}\sigma^{ac}\psi], \tag{72a}$$

$$Y^{a}{}_{b}[f]=\tfrac{1}{2}if\psi^{\dagger}\alpha^{a}\overleftrightarrow{\nabla}_{b}\psi+\tfrac{1}{8}\nabla_{c}[f\psi^{\dagger}\{\alpha^{c},\sigma_{b}^{a}\}\psi], \tag{72b}$$

and using (53) to find

$$\overline{T}_{ab}^{D}=-\tfrac{1}{2}i\,\delta_{(ac}\psi^{\dagger}\alpha^{c}\overleftrightarrow{\nabla}_{b)}\psi+\tfrac{1}{2}\delta_{(ac}K_{b)d}\psi^{\dagger}\sigma^{cd}\psi+\tfrac{1}{2}\delta_{ab}m\psi^{\dagger}\beta\psi, \tag{73}$$

we find that contributions to (7b) and (7c) are generated to properly reproduce the E–D field equations. The constraint algebra combines (66) with (8), replacing $\gamma_{ab}\rightarrow\delta_{ab}$ everywhere in the latter. [Note that the derivation of the constraint algebra in Ref. 2 could be generalized to the Einstein–Dirac system along the lines of Ref. 20 note however the different parameterization of the spinor part of phase space and the resulting difference in the form of (68).]

V. DISCUSSION

The intent of the preceding[1] and present paper is to describe the Hamiltonian dynamics of general relativistic (vacuum and matter coupled) systems with respect to moving frames. This extended system of dynamical spatial metric *and* frame fields encompasses the following two natural limits: If we choose the diffeomorphism constraints to act on the components of tensors with the usual Lie action and fix the spatial frame to be a coordinate frame, we recover the standard coordinate frame approach to canonical general relativity. If we choose the spatial metric to be equal to the unit matrix and mix the diffeomorphism generators with the frame transformation generators to be compatible with this choice, we recover the orthonormal frame approach to canonical general relativity. Clearly there are also a variety of intermediate choices available, however this enlarged arena provides a bridge over which one may pass from the standard coordinate frame approach to the Lorentz (or orthonormal) frame approach that is more natural for the description of the Einstein–Dirac system.

In this generalized structure, we find that matter fields naïvely appear to be derivative-coupled since the momenta conjugate to the spatial frame fields are not (in general) independent of the matter fields. This sort of derivative-coupling turns out to be benign since the field equations are equivalent to the coordinate frame approach to the model in question. Indeed this feature is a necessary part of the frame approach, and will appear whenever the matter fields behave nontrivially under frame transformations. In this way we understand that the derivative-coupling in the Einstein–Dirac system is a necessary feature, merely reflecting the need to work with local orthonormal frames in order to define the system. We also end up with a simpler description of the Einstein–Dirac system than that given in Ref. 21 (note, however, their use of anticommuting fermions), and a much more natural system than that found in Ref. 22, where primary importance is still given to the coordinate components of the metric tensor. A more detailed examination of the Einstein–Dirac system in adjoint form (in the spirit of Ref. 23) is underway, and by adopting harmonic coordinate conditions and choosing the frame to fix the Local Lorentz gauge, we are able to prove local existence and uniqueness results.

All of the homogeneous Lorentzian structures on the oscillator group equipped with a bi-invariant Lorentzian metric, and then the associated reductive pairs, are obtained. Some of them are solutions of the Einstein–Yang–Mills equations.
 [S0022-2488(99)00107-3]

I. INTRODUCTION

The oscillator group has interesting features from the viewpoints of both differential geometry and physics (see, for instance, Refs. 1–12). It was introduced by Streater,[1] who named it so because its Lie algebra can be identified to that generated by the differential operators associated with the harmonic oscillator problem, acting on functions of a variable. The oscillator group is the only simply connected four-dimensional non-Abelian solvable Lie group which admits a bi-invariant Lorentzian metric.[3,4] Moreover, it is[8] an example of homogeneous space–time, which as causal space satisfies the so-called causal continuity.

Levichev studied in Ref. 5 the oscillator group with the biinvariant Lorentzian metric also given in Refs. 6 and 8, proving that this group (which geometrically is a Lorentzian symmetric space and physically is related to an isotropic electromagnetic field) provides a solution of the sourceless Einstein–Yang–Mills equations.

On the other hand, generalizing the classical characterization by Cartan[13] of Riemannian symmetric spaces as the spaces of parallel curvature, Ambrose and Singer[14] gave a characterization of Riemannian homogeneous spaces in terms of a (1,2) tensor field S, called homogeneous Riemannian structure in Ref. 15, satisfying certain differential equations (see (1) below). In Refs. 16 and 17, we have extended this concept to the pseudo-Riemannian case.

In Ref. 12, all of the homogeneous Lorentzian structures corresponding to a family of left invariant metrics on the general oscillator groups have been obtained, and the reductive decompositions for the non-bi-invariant metrics in that family have been determined.

In this paper we consider the four-dimensional oscillator group equipped with its usual Lorentzian bi-invariant metric and we determine all the homogeneous Lorentzian structures on it and all the associated reductive pairs. There appear six types of such pairs, and we prove that four of them are solutions of the Einstein–Yang–Mills equations. They have sources except for a particular case, where the symmetric pair appears as a solution of the sourceless Einstein–Yang–Mills equations.

II. PRELIMINARIES

Ambrose and Singer[14] gave a characterization for a connected, simply connected and complete Riemannian manifold to be homogeneous, in terms of a (1,2) tensor field S, called in Ref. 15 a *homogeneous Riemannian structure*. In Ref. 16 it is defined a *homogeneous pseudo-Riemannian* *structure* on a pseudo-Riemannian manifold (M,g) as a tensor field S of type (1,2) such that being ∇ the Levi-Civita connection and R its curvature tensor, the connection $\tilde{\nabla}=\nabla-S$ satisfies the Ambrose–Singer equations

$$\tilde{\nabla}g=0, \quad \tilde{\nabla}R=0, \quad \tilde{\nabla}S=0. \tag{1}$$

In Ref. 16 it is proved that *if* (M,g) *is connected, simply connected and geodesically complete then it admits a homogeneous pseudo-Riemannian structure if and only if it is a reductive homogeneous pseudo-Riemannian manifold*, which means that $M=G/H$, where G is a connected Lie group acting transitively and effectively on M as a group of isometries, H is the isotropy group at a point $o\in M$, and the Lie algebra $\mathfrak{g}$ of G may be decomposed into a vector space direct sum of the Lie algebra $\mathfrak{h}$ of H and an Ad(H)-invariant subspace $\mathfrak{m}$, that is $\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{m}$, $\mathrm{Ad}(H)\mathfrak{m}\subset\mathfrak{m}$. (If G is connected and M is simply connected then H is connected, and the latter condition is equivalent to $[\mathfrak{h},\mathfrak{m}]\subset\mathfrak{m}$).

Let (M,g) be a connected, simply connected and geodesically complete pseudo-Riemannian manifold, and suppose that S is a homogeneous pseudo-Riemannian structure on (M,g). We fix a point $o\in M$ and put $\mathfrak{m}=T_o(M)$. If $\tilde{R}$ is the curvature tensor of the connection $\tilde{\nabla}=\nabla-S$, we can consider the holonomy algebra $\tilde{\mathfrak{h}}$ of $\tilde{\nabla}$ as the Lie subalgebra of antisymmetric endomorphisms of $(\mathfrak{m},g_o)$ generated by the operators $\tilde{R}_{ZW}$, where $Z,W\in\mathfrak{m}$. Then, according to the Ambrose–Singer construction,[14,15] a Lie bracket is defined in the vector space direct sum $\tilde{\mathfrak{g}}=\tilde{\mathfrak{h}}\oplus\mathfrak{m}$ by

$$\begin{aligned}
[U,V]&=UV-VU, \quad U,V\in\tilde{\mathfrak{h}},\\
[U,Z]&=U(Z), \quad U\in\tilde{\mathfrak{h}},\ Z\in\mathfrak{m}, \\
[Z,W]&=\tilde{R}_{ZW}+S_ZW-S_WZ, \quad Z,W\in\mathfrak{m},
\end{aligned}\tag{2}$$

and we say that $(\tilde{\mathfrak{g}},\tilde{\mathfrak{h}})$ is the *reductive pair* associated with the homogeneous pseudo-Riemannian structure S. The connected and simply connected Lie group $\tilde{G}$ whose Lie algebra is $\tilde{\mathfrak{g}}$ acts transitively on M as a group of isometries and $M\equiv\tilde{G}/\tilde{H}$, where $\tilde{H}$ is the connected Lie subgroup of $\tilde{G}$ whose Lie algebra is $\tilde{\mathfrak{h}}$. The set K of the elements of $\tilde{G}$ which act trivially on M is a discrete normal subgroup of $\tilde{G}$, and the Lie group $G=\tilde{G}/K$ acts transitively and effectively on M as a group of isometries, with isotropy group $H=\tilde{H}/K$. Then M is (diffeomorphic to) the reductive homogeneous pseudo-Riemannian manifold G/H.

On the other hand, we consider (see e.g., Ref. 18, p. 134) the Einstein–Yang–Mills equations on a Lorentzian manifold (M,g),

$$r-\tfrac{1}{2}sg+\Lambda g=\kappa T, \tag{3}$$

where g denotes the metric tensor, r the Ricci tensor, and s the scalar curvature of g, Λ and κ the cosmological and gravitational constants, respectively, and T the stress-energy tensor of the gauge field with field strength F, given by

$$T(X,Y)=g^{-1}(i_XF,i_YF)-\tfrac{1}{4}g(X,Y)\|F\|^2, \tag{4}$$

i denoting the interior product.

Let $\mathfrak{g}$ be the Lie algebra with generators P,X,Y,Q, and brackets

$$[X,Y]=P, \quad [Q,X]=Y, \quad [Q,Y]=-X.$$

The corresponding simply connected Lie group G is called the *oscillator group*.

III. LORENTZIAN HOMOGENEOUS STRUCTURES AND REDUCTIVE DECOMPOSITIONS

Consider the bi-invariant Lorentzian metric g on the oscillator group G given in the basis $\{P,X,Y,Q\}$, by

$$g=\begin{pmatrix} & & & 1\\ & 1 & & \\ & & 1 & \\ 1 & & & \end{pmatrix}. \tag{5}$$

Let $\{\eta,\alpha,\beta,\xi\}$ be the dual basis to $\{P,X,Y,Q\}$. The Levi-Civita connection ∇ of g is determined by $2g(\nabla_W U,V)=g([W,U],V)-g([U,V],W)+g([V,W],U)$ for all $U,V,W\in\mathfrak{g}$. So, we obtain that ∇ is given by

$$\nabla_W P=0,$$

$$\nabla_W X=-\tfrac{1}{2}\beta(W)P+\tfrac{1}{2}\xi(W)Y,$$

$$\nabla_W Y=\tfrac{1}{2}\alpha(W)P-\tfrac{1}{2}\xi(W)X,$$

$$\nabla_W Q=\tfrac{1}{2}\beta(W)X-\tfrac{1}{2}\alpha(W)Y,$$

for every $W\in\mathfrak{g}$. The nonvanishing components of the curvature tensor field, for which we adopt the convention $R_{WU}V=\nabla_{[W,U]}V-\nabla_W\nabla_U V+\nabla_U\nabla_W V$, are given by

$$R_{QX}X=-\tfrac{1}{4}P,\quad R_{QX}Q=\tfrac{1}{4}X,\quad R_{QY}Y=-\tfrac{1}{4}P,\quad R_{QY}Q=\tfrac{1}{4}Y.$$

Thus, the only nonvanishing component of the Ricci tensor is $r(Q,Q)=\tfrac{1}{2}$ and the scalar curvature is $s=0$.

In Ref. 12 all the homogeneous Lorentzian structures on the general oscillator group are determined by solving the Ambrose–Singer equations (1). As a consequence, we have all the homogeneous Lorentzian structures on the four-dimensional oscillator group.

Proposition: All the homogeneous Lorentzian structures on (G,g) *are given by*

$$S=\theta\otimes(\alpha\wedge\beta)+\rho\otimes(\alpha\wedge\xi)+\sigma\otimes(\beta\wedge\xi), \tag{6}$$

where ρ, σ, *and* θ *are left invariant 1-forms on G satisfying the conditions*

$$\begin{aligned}\tilde{\nabla}\theta&=0,\\ \tilde{\nabla}\rho&=\sigma\wedge\theta-\tfrac{1}{2}\alpha\otimes\theta+\tfrac{1}{2}\xi\otimes\sigma,\\ \tilde{\nabla}\sigma&=-\rho\wedge\theta-\tfrac{1}{2}\beta\otimes\theta-\tfrac{1}{2}\xi\otimes\rho,\end{aligned} \tag{7}$$

with $\tilde{\nabla}=\nabla-S$.

Proof: Expression (6) follows from the equations $\tilde{\nabla}g=0$ and $\tilde{\nabla}R=0$ in (1). Conditions (7) are equivalent to the equation $\tilde{\nabla}S=0$. (See Theorem 4.1 in Ref. 12.) □

By (6), we can write the following general expression for the homogeneous Lorentzian structures on (G,g):

$$\begin{aligned}S=&(a_1\eta+a_2\alpha+a_3\beta+a_4\xi)\otimes(a\wedge\beta)+(b_1\eta+b_2\alpha+b_3\beta+b_4\xi)\otimes(\alpha\wedge\xi)\\ &+(c_1\eta+c_2\alpha+c_3\beta+c_4\xi)\otimes(\beta\wedge\xi),\quad a_1,\dots,c_4\in\mathbb{R}.\end{aligned}$$

Equations (7) give us, after some long but straightforward calculations, the relations to be satisfied by the coefficients. If $a_1\neq 0$ (we denote this case as (i)), we get the expression of S in terms of a_1,a_2,a_3,a_4,

$$\begin{aligned}S=&(a_1\eta+a_2\alpha+a_3\beta+a_4\xi)\otimes(\alpha\wedge\beta)\\&+\left(-a_3\eta-\frac{a_2a_3}{a_1}\alpha-\left(\frac{a_3^2}{a_1}+\frac{1}{2}\right)\beta+\left(\frac{a_3}{2a_1}-\frac{a_3a_4}{a_1}\right)\xi\right)\otimes(\alpha\wedge\xi)\\&+\left(a_2\eta+\left(\frac{a_2^2}{a_1}+\frac{1}{2}\right)\alpha+\frac{a_2a_3}{a_1}\beta+\left(\frac{a_2a_4}{a_1}-\frac{a_2}{2a_1}\right)\xi\right)\otimes(\beta\wedge\xi).\end{aligned}$$

If $a_1=0$, some tedious computations lead to another five cases, and the coefficients in the six cases (i)–(vi) are as follows:

	(i)	(ii)	(iii)	(iv)	(v)	(vi)
a_1	$\neq 0$	0	0	0	0	0
a_2	$\in\mathbb{R}$	0	0	0	0	0
a_3	$\in\mathbb{R}$	0	0	0	0	0
a_4	$\in\mathbb{R}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$\neq\frac{1}{2}$	$\neq\frac{1}{2}$
b_1	$-a_3$	0	0	0	0	0
b_2	$-\frac{a_2a_3}{a_1}$	0	0	$\in\mathbb{R}$	0	0
b_3	$-\frac{a_3^2}{a_1}-\frac{1}{2}$	$-\frac{1}{2}$	$-\frac{1}{2}$	$\neq-\frac{1}{2}$	$-\frac{1}{2}$	$-a_4$
b_4	$\frac{a_3}{2a_1}-\frac{a_3a_4}{a_1}$	0	$\in\mathbb{R}$	$\in\mathbb{R}$	$\in\mathbb{R}$	0
c_1	a_2	0	0	0	0	0
c_2	$\frac{a_2^2}{a_1}+\frac{1}{2}$	$\neq\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}-\frac{2b_2^2}{2b_3+1}$	$\frac{1}{2}$	a_4
c_3	$\frac{a_2a_3}{a_1}$	0	0	$-b_2$	0	0
c_4	$-\frac{a_2}{2a_1}+\frac{a_2a_4}{a_1}$	$\in\mathbb{R}$	$\in\mathbb{R}$	$-\frac{2b_2b_4}{2b_3+1}$	$\in\mathbb{R}$	0

In case (i), making the change $x=a_1\neq 0$, $y=a_2/a_1$, $z=a_3/a_1$, $w=a_4-\frac{1}{2}$, we can write the family of homogeneous Lorentzian structures as

$$\begin{aligned}S_{(x,y,z,w)}=&(x\eta+xy\alpha+xz\beta+(w+\tfrac{1}{2})\xi)\otimes(\alpha\wedge\beta)\\&-(xz\eta+xyz\alpha+(xz^2+\tfrac{1}{2})\beta+zw\xi)\otimes(\alpha\wedge\xi)\\&+(xy\eta+(xy^2+\tfrac{1}{2})\alpha+xyz\beta+yw\xi)\otimes(\beta\wedge\xi),\\&x,y,z,w\in\mathbb{R},\quad x\neq 0.\end{aligned}$$

In cases (ii)–(vi) one arrives (after some changes of notations for the coefficients) to the following families:

(ii)

$$S_{(q,c)} = \tfrac{1}{2}\xi \otimes (\alpha \wedge \beta) - \tfrac{1}{2}\beta \otimes (\alpha \wedge \xi) + (q\alpha + c\xi) \otimes (\beta \wedge \xi), \quad q,c \in \mathbb{R}, \quad q \neq \tfrac{1}{2}.$$

(iii)

$$S_{(b,c)} = \tfrac{1}{2}\xi \otimes (\alpha \wedge \beta) + (-\tfrac{1}{2}\beta + b\xi) \otimes (\alpha \wedge \xi) + (\tfrac{1}{2}\alpha + c\xi) \otimes (\beta \wedge \xi), \quad b,c \in \mathbb{R}.$$

(iv)

$$S_{(k,t,b)} = \tfrac{1}{2}\xi \otimes (\alpha \wedge \beta) + (k\alpha + (t - \tfrac{1}{2})\beta + b\xi) \otimes (\alpha \wedge \xi)$$
$$+ ((\tfrac{1}{2} - (k^2/t))\alpha - k\beta - (kb/t)\xi) \otimes (\beta \wedge \xi), \quad k,t,b \in \mathbb{R}, \quad t \neq 0.$$

(v)

$$S_{(a,b,c)} = a\xi \otimes (\alpha \wedge \beta) + (-\tfrac{1}{2}\beta + b\xi) \otimes (\alpha \wedge \xi) + (\tfrac{1}{2}\alpha + c\xi) \otimes (\beta \wedge \xi),$$
$$a,b,c \in \mathbb{R}, \quad a \neq \tfrac{1}{2}.$$

(vi)

$$S_a = a(\xi \otimes (\alpha \wedge \beta) - \beta \otimes (\alpha \wedge \xi) + \alpha \otimes (\beta \wedge \xi)), \quad a \in \mathbb{R}, \quad a \neq \tfrac{1}{2}.$$

Next, we determine $\tilde{\nabla} = \nabla - S$. We however omit the expression of $\tilde{\nabla}$ for the sake of brevity. Then, in each case we calculate the curvature $\tilde{R}$, and so we obtain generators of the holonomy algebra $\tilde{\mathfrak{h}}$ of $\tilde{\nabla}$, which will be expressed in terms of the basis $\{P,X,Y,Q\}$ of $\mathfrak{g}$.

In case (i), we have that the only not always null curvature operators are $\tilde{R}_{XY} = wU$, $\tilde{R}_{QX} = xzU$ and $\tilde{R}_{QY} = -xyU$, where

$$U = \begin{pmatrix} 0 & z & -y & 0 \\ 0 & 0 & 1 & -z \\ 0 & -1 & 0 & y \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

If $y = z = w = 0$ then $\tilde{R} = 0$, but if either y, z, or w is not zero then the holonomy algebra $\tilde{\mathfrak{h}}$ is one-dimensional and generated by U.

In case (ii), the holonomy algebra $\tilde{\mathfrak{h}}$ is generated by the vector

$$V = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

and the only nonvanishing curvature operator is $\tilde{R}_{QY} = (q - \tfrac{1}{2})V$.

In case (iii) (and (v)) we deduce $\tilde{R} = 0$.

In case (iv), the holonomy algebra $\tilde{\mathfrak{h}}$ is generated by

$$U=\begin{pmatrix} 0 & -t & k & 0\\ 0 & 0 & 0 & t\\ 0 & 0 & 0 & -k\\ 0 & 0 & 0 & 0 \end{pmatrix},$$

and the curvature of $\tilde{\nabla}$ is determined by $\tilde{R}_{QX}=U$ and $\tilde{R}_{QY}=-(k/t)U$.

In case (vi), the holonomy algebra $\tilde{\mathfrak{h}}$ has two generators

$$U=\begin{pmatrix} 0 & 1 & 0 & 0\\ 0 & 0 & 0 & -1\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad V=\begin{pmatrix} 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & -1\\ 0 & 0 & 0 & 0 \end{pmatrix},$$

and the curvature is determined by the operators $\tilde{R}_{QX}=(a^2-\frac{1}{4})U$, $\tilde{R}_{QY}=(a^2-\frac{1}{4})V$. If $a=-\frac{1}{2}$ then $\tilde{R}=0$ and if $a\neq-\frac{1}{2}$, then $\tilde{\mathfrak{h}}$ is two-dimensional and Abelian.

Through the usual identification of $\mathfrak{g}$ with the tangent space at the identity of G, we consider $\mathfrak{m}=\mathfrak{g}$ and use (2) in order to obtain the Lie bracket of $\tilde{\mathfrak{g}}=\tilde{\mathfrak{h}}\oplus\mathfrak{g}$ in each case. In particular, we will have the reductive pair $(\tilde{\mathfrak{g}},\tilde{\mathfrak{h}})$ associated with each homogeneous structure.

We next explicitly give those brackets. Some cases are broken in two subcases according to whether the dimension of the holonomy algebra depends on the particular values of the coefficients in the corresponding homogeneous structure.

Case (i$_1$). $(x,y,z,w\in\mathbb{R};\ x\neq 0;\ y,z,w$ not all null). The reductive decomposition associated with $S_{(x,y,z,w)}$ is $\tilde{\mathfrak{g}}_{(x,y,z,w)}=\tilde{\mathfrak{h}}\oplus\mathfrak{g}=\langle\{U,P,X,Y,Q\}\rangle$, with not always null brackets

$$[U,X]=zP-Y,\quad [U,Y]=-yP+X,\quad [U,Q]=-zX+yY,$$

$$[P,X]=-xzP+xY,\quad [P,Y]=xyP-xX,\quad [P,Q]=xzX-xyY,$$

$$[X,Y]=wU+(x(y^2+z^2)+1)P-xyX-xzY,$$

$$[Q,X]=xzU-zwP-xyzX+(w+xy^2+1)Y,$$

$$[Q,Y]=-xyU+ywP-(w+xz^2+1)X+xyzY.$$

Case (i$_2$) $(x\neq 0;\ y=z=w=0)$. The reductive decomposition associated with $S_{(x,0,0,0)}$ is $\tilde{\mathfrak{g}}_x=0\oplus\mathfrak{g}=\langle\{P,X,Y,Q\}\rangle$, with nonvanishing brackets

$$[P,X]=xY,\quad [P,Y]=-xX,\quad [X,Y]=P,\quad [Q,X]=Y,\quad [Q,Y]=-X.$$

Case (ii) $(q,c\in\mathbb{R};\ q\neq\frac{1}{2})$. The reductive decomposition associated to $S_{(q,c)}$ is $\tilde{\mathfrak{g}}_{(q,c)}=\tilde{\mathfrak{h}}\oplus\mathfrak{g}=\langle\{V,P,X,Y,Q\}\rangle$, with nonvanishing brackets

$$[V,Y]=P,\quad [V,Q]=-Y,\quad [X,Y]=(q+\tfrac{1}{2})P,$$

$$[Q,X]=(q+\tfrac{1}{2})Y,\quad [Q,Y]=(q-\tfrac{1}{2})V+cP-X.$$

Case (iii) $(b,c,\in\mathbb{R})$. The reductive decomposition associated with $S_{(b,c)}$ is $\tilde{\mathfrak{g}}_{(b,c)}=0\oplus\mathfrak{g}=\langle\{P,X,Y,Q\}\rangle$, with nonvanishing brackets

$$[X,Y]=P,\quad [Q,X]=bP+Y,\quad [Q,Y]=cP-X.$$

In this case, one obtains the Lie algebra of the oscillator group. In fact, putting $\tilde{X}=X-cP$, $\tilde{Y}=Y+bP$, we have $[\tilde{X},\tilde{Y}]=P$, $[Q,\tilde{X}]=\tilde{Y}$, $[Q,\tilde{Y}]=-\tilde{X}$.

Case (iv) $(k,t,b\in\mathbb{R};\ t\neq 0)$. The reductive decomposition associated with $S_{(k,t,b)}$ is $\tilde{\mathfrak{g}}_{(k,t,b)}=\tilde{\mathfrak{h}}\oplus\mathfrak{g}=\langle\{U,P,X,Y,Q\}\rangle$, with Lie brackets given by

$$[U,X]=-tP,\quad [U,Y]=kP,\quad [U,Q]=tX-kY,\quad [X,Y]=(1-(k^2+t^2)/t)P,$$

$$[Q,X]=U+bP+kX+\left(1-\frac{k^2}{t}\right)Y,\quad [Q,Y]=-\frac{k}{t}U-\frac{kb}{t}P+(t-1)X-kY.$$

Case (v) $(a,b,c\in\mathbb{R};\ a\neq\frac{1}{2})$. The reductive decomposition associated to $S_{(a,b,c)}$ *is* $\tilde{\mathfrak{g}}_{(a,b,c)}=0\oplus\mathfrak{g}=\langle\{P,X,Y,Q\}\rangle$, with nonvanishing brackets

$$[X,Y]=P,\quad [Q,X]=bP+(a+\tfrac{1}{2})Y,\quad [Q,Y]=cP-(a+\tfrac{1}{2})X.$$

Case (vi_1) $(a\in\mathbb{R};\ a\neq\frac{1}{2},-\frac{1}{2})$. The reductive decomposition associated with S_a is $\tilde{\mathfrak{g}}_a=\tilde{\mathfrak{h}}\oplus\mathfrak{g}=\langle\{U,V,P,X,Y,Q\}\rangle$, with nonvanishing brackets

$$[U,X]=P,\quad [U,Q]=-X,\quad [V,Y]=P,\quad [V,Q]=-Y,\quad [X,Y]=2aP,$$

$$[Q,X]=(a^2-\tfrac{1}{4})U+2aY,\quad [Q,Y]=(a^2-\tfrac{1}{4})V-2aX.$$

In particular, if $a=0$, one has $S=0$, and the associated reductive pair $(\tilde{\mathfrak{g}},\tilde{\mathfrak{h}})$ is a symmetric pair, which defines the oscillator group as a symmetric Lorentzian space.

Case (vi_2) $(a=-\frac{1}{2})$. The reductive decomposition associated to $S_{-(1/2)}$ is $\tilde{\mathfrak{g}}_{-(1/2)}=0\oplus\mathfrak{g}=\langle\{P,X,Y,Q\}\rangle$, with nonvanishing brackets

$$[X,Y]=-P,\quad [Q,X]=-Y,\quad [Q,Y]=X,$$

which also gives the Lie algebra of the oscillator group.

IV. CURRENTS, AND EINSTEIN–YANG–MILLS EQUATIONS

We consider the connection form ω on $\tilde{\mathfrak{g}}$, which is the $\tilde{\mathfrak{h}}$-component of the canonical 1-form on $\tilde{\mathfrak{g}}$, and we obtain, in each case, the curvature form $F=d\omega$ and then $\star F$, where $\star$ denotes the Hodge operator with respect to the Lorentzian metric g. The following table provides the values of F and $\star F$ for the cases with nontrivial holonomy,

	$F=d\omega$	$\star F$
(i_1)	$(-w\alpha\wedge\beta+xz\alpha\wedge\xi-xy\beta\wedge\xi)\otimes U$	$-(w\eta\wedge\xi+xz\eta\wedge\beta+xy\eta\wedge\alpha)\otimes U$
(ii)	$(q-\frac{1}{2})(\beta\wedge\xi)\otimes V$	$(q-\frac{1}{2})(\eta\wedge\alpha)\otimes V$
(iv)	$(\alpha\wedge\xi-(k/t)\beta\wedge\xi)\otimes U$	$-(\eta\wedge\beta+(k/t)\eta\wedge\alpha)\otimes U$
(vi_1)	$(a^2-\frac{1}{4})((\alpha\wedge\xi)\otimes U+(\beta\wedge\xi)\otimes V)$	$(a^2-\frac{1}{4})(-(\eta\wedge\beta)\otimes U+(\eta\wedge\alpha)\otimes V)$

Moreover, as the second Yang-Mills equation is $D\star F=J$, where J denotes the current, applying the usual formula[19] one obtains for all the cases

$$J=D\star F=d\star F+\omega\wedge\star F-\star F\wedge\omega=d\star F. \tag{8}$$

Thus, the currents are given, respectively, by

	J
(i_1)	$(xz\eta\wedge\alpha\wedge\xi-xy\eta\wedge\beta\wedge\xi+w\alpha\wedge\beta\wedge\xi)\otimes U$
(ii)	$(q-\frac{1}{2})(\eta\wedge\beta\wedge\xi+c\alpha\wedge\beta\wedge\xi)\otimes V$
(iv)	$(\eta\wedge\alpha\wedge\xi-(k/t)\eta\wedge\beta\wedge\xi+b(1+(k/t)^2)\alpha\wedge\beta\wedge\xi)\otimes U$
(vi_1)	$2a(a^2-\frac{1}{4})((\eta\wedge\alpha\wedge\xi)\otimes U+(\eta\wedge\beta\wedge\xi)\otimes V)$

On the other hand, we consider the metric on $\tilde{\mathfrak{g}}$ which is the direct product of the metric g_0 on $\mathfrak{g}$ and the metric on $\tilde{\mathfrak{h}}$ for which the basic vectors (U and/or V) are unitary.

Now we have $\|F\|^2=2w^2$ in the case (i_1) and $\|F\|^2=0$ in the remaining cases. We next compute the stress-energy tensor T, given by (4), and we express it in terms of the basis $\{P,X,Y,Q\}$ of $\mathfrak{g}$. In case (i_1) we have

$$T=\begin{pmatrix} 0 & 0 & 0 & -\frac{1}{2}w^2 \\ 0 & \frac{1}{2}w^2 & 0 & -xyw \\ 0 & 0 & \frac{1}{2}w^2 & -xzw \\ -\frac{1}{2}w^2 & -xyw & -xzw & x^2(y^2+z^2) \end{pmatrix}.$$

In cases (ii), (iv), and (vi_1), the only nonvanishing component is $T(Q,Q)$, which is, respectively, $(q-\frac{1}{2})^2$, $1+(k/t)^2$, and $2(a^2-\frac{1}{4})^2$.

It is then a matter of calculation to see that the field equations (3) are satisfied in cases (ii), (iv), and (vi_1), and in the case (i_1) if $w=0$ and $y^2+z^2\neq 0$, and to obtain the corresponding cosmological and gravitational constants.

Theorem: *The Lorentzian reductive pairs* $(\tilde{\mathfrak{g}},\tilde{\mathfrak{h}})$ *determined by the homogeneous Lorentzian structures on the four-dimensional oscillator group, in cases* (i_1) *(with* $w=0$ *and* $y^2+z^2\neq 0$*), (ii), (iv) and (vi₁) above, are solutions of the Einstein–Yang–Mills equations for an electromagnetic gauge field with cosmological constant* $\Lambda=0$*, and gravitational constant* κ *given, respectively, by*

$$\frac{1}{2x^2(y^2+z^2)},\quad \frac{1}{2(q-\frac{1}{2})^2},\quad \frac{t^2}{2(k^2+t^2)},\quad \frac{1}{4(a^2-\frac{1}{4})^2}.$$

The gauge algebra $\tilde{\mathfrak{h}}$ *is Abelian and two-dimensional in the last case and one-dimensional in the other three cases. The currents are given in the table following (8). They are nonvanishing except in the case* (vi_1) *for* $a=0$.

If $a=0$ in case (vi_1), the associated symmetric pair $(\tilde{\mathfrak{g}},\tilde{\mathfrak{h}})$ appears as a solution of the Einstein–Yang–Mills equations for a sourceless gauge field with cosmological constant $\Lambda=0$ and gravitational constant $\kappa=4$ (see Levichev[5]).

Radial conformal motions in Minkowski space–time

Alicia Herrero[a] and Juan Antonio Morales[b]
Departament d'Astronomia i Astrofísica, Universitat de València, E-46100 Burjassot, València, Spain

(Received 11 January 1999; accepted for publication 5 March 1999)

A study of radial conformal Killing fields (RCKF) in Minkowski space–time is carried out, which leads to their classification into three disjointed classes. Their integral curves are straight or hyperbolic lines admitting orthogonal surfaces of constant curvature, whose sign is related to the causal character of the field. Otherwise, the kinematic properties of the timelike RCKF are given and their applications in kinematic cosmology is discussed. © *1999 American Institute of Physics.* [S0022-2488(99)00507-1]

I. INTRODUCTION

The study of vector (and tensor) fields in a Lorentzian metric is a key issue, both from the theoretical and practical points of view. Infinitesimal transformations, fluid flows, eigendirections of a given 2-tensor field, critical points, continuous symmetries, directions attached to coordinate systems, light propagation and polarization in a medium, geodesic and accelerated observers are some examples of basic concepts which are described using vector fields. This work is devoted to analyzing in the Minkowski space–time the main properties of a particular type of fields that we have called *radial* conformal motions.

There are several reasons for carrying out such a study: (i) homothetic and hyperbolic radial motions belong to this kind of fields, (ii) conserved quantities along null geodesics are obtained from conformal Killing vectors, with particular expressions for the radial case, (iii) isotropic distribution functions of photons verifying the Liouville equation can be built from these conserved quantities and, (iv) this study can be easily extended to any conformally flat space–time and used to obtain its conformal factor imposing a given kinematic property of the field (geodesic, homogeneous expansion, etc.); in fact, Infeld–Schild work on kinematic cosmology[1] tacitly involves the concept of timelike radial conformal Killing field (RCKF) in the geodesic case.

Firstly, in Sec. II, we introduce the concept of RCKF and obtain its general expression and the type of subalgebra generated by them; we also present a study of their causal character according to the different domains of the space–time. We continue with a classification of these fields related to the sign of a quantity invariant by internal conformal transformations of the Minkowski metric (Sec. III). The associated integral curves are plotted in Sec. IV and we show that the orthogonal hypersurfaces of the field have constant curvature whose sign is related to its causal character (Sec. V). In Sec. VI, we focus on timelike RCKF and discuss their kinematic properties pointing out their connection with the Milne's interpretation of the cosmological recession velocity in the Minkowski space–time.[2] Finally, in Sec. VII, we comment on several applications of the present study. Some of these results have been presented, without proof, in the E.R.E., annual Spanish relativity meeting.[3]

II. RADIAL CONFORMAL KILLING FIELDS

Let us consider a radial vector field

$$\xi=\alpha(t,r,\theta,\varphi)\frac{\partial}{\partial t}+\beta(t,r,\theta,\varphi)\frac{\partial}{\partial r}$$

[a]Electronic mail: alicia.herrero@uv.es
[b]Electronic mail: antonio.morales@uv.es

in the Minkowski space–time,

$$\eta = -dt\otimes dt + dr\otimes dr + r^2 h, \tag{1}$$

with $h = d\theta\otimes d\theta + \sin^2\theta\, d\varphi\otimes d\varphi$, the metric on the 2-sphere.

The equation $\mathcal{L}_\xi \eta \propto \eta$ expresses that ξ is a conformal Killing field (or conformal motion) of η, where $\mathcal{L}_\xi$ represents the Lie derivative with respect to ξ. This condition leads to that the functions α and β are independent of the angular coordinates θ and φ, resulting in

$$\alpha(t,r) = a(t^2+r^2) + bt + c, \quad \beta(t,r) = r(2at+b), \tag{2}$$

where a, b, and c are arbitrary constants.

Proposition 1: In the Minkowski space–time, the general form of a RCKF is

$$\xi = (a(t^2+r^2)+bt+c)\frac{\partial}{\partial t} + r(2at+b)\frac{\partial}{\partial r}, \tag{3}$$

with a, b, and c as arbitrary constants.

Consequently, ξ can be obtained as linear combination of (the generators of) the timelike translation $\xi_1 = (\partial/\partial t)$, the dilation $\xi_2 = t(\partial/\partial t) + r(\partial/\partial r)$, and the special nonlinear conformal transformation along the t-axis $\xi_3 = (t^2+r^2)(\partial/\partial t) + 2tr(\partial/\partial r)$, that is

$$\xi = a\xi_3 + b\xi_2 + c\xi_1 .$$

The Lie brackets of these generators,

$$[\xi_1,\xi_2] = \xi_1, \quad [\xi_1,\xi_3] = 2\xi_2, \quad [\xi_2,\xi_3] = \xi_3$$

give us the type of the Lie algebra generated by RCKF. In fact, if we consider the vector fields

$$e_1 = \xi_1 - \tfrac{1}{4}\xi_3, \quad e_2 = \xi_2, \quad e_3 = -\xi_1 - \tfrac{1}{4}\xi_3,$$

then, their commutation relations are

$$[e_1,e_2] = -e_3, \quad [e_2,e_3] = e_1, \quad [e_3,e_1] = e_2$$

showing that this Lie algebra is isomorphic to the pseudo-orthogonal algebra AO(1,2); then we have the following result:

Proposition 2: RCKF generate a three-dimensional Lie algebra of Bianchi type VIII.

Note that using null coordinates, $u = t+r$ and $v = t-r$, expression (3) is written in a completely symmetric form

$$\xi = (au^2+bu+c)\frac{\partial}{\partial u} + (av^2+bv+c)\frac{\partial}{\partial v}, \tag{4}$$

where each null coordinate appears separately and in the same way in the corresponding component of the field ξ.

From (3) and (4) we have

$$P \equiv -\eta(\xi,\xi) = [a(t^2+r^2)+bt+c]^2 - r^2(2at+b)^2 = (au^2+bu+c)(av^2+bv+c). \tag{5}$$

The discussion of the sign of P will give the causal character of ξ in the different regions of the space–time (domains of causality of ξ). It is convenient to introduce the quantity

$$\Delta \equiv b^2 - 4ac$$

that make this discussion easier. The results are shown in Table I and plotted in Fig. 1.

TABLE I. Causal character of the field ξ given by (3) or (4) for the different values of the constants a and $\Delta=b^2-4ac$.

		Causal character of a radial conformal Killing vector
$a=0$	$b=0$	timelike everywhere
	$b\neq 0$	null on the light cone at the point $(t=-(c/b),\ r=0)$, timelike inside of the light cone and spacelike outside of the light cone. See Fig. 1(i)
$a\neq 0$	$\Delta<0$	timelike everywhere
	$\Delta=0$	timelike everywhere except for the light cone on $(t=-(b/2a),\ r=0)$ where it is null. See Fig. 1(ii)
	$\Delta>0$	null on the light cones at the points $(t_\pm, r=0)$, $t_\pm=(-b\pm\sqrt{\Delta})/2a$, timelike inside or outside of the two light cones and spacelike in other domains. See Fig. 1(iii)

III. A CLASSIFICATION OF THE RADIAL CONFORMAL MOTIONS

In order to classify the RCKF in equivalence classes, it is convenient to take in account the degree of freedom of the null coordinates $\{u,v\}$. Then we consider the coordinates

$$\overline{u}=\overline{u}(u),\quad \overline{v}=\overline{v}(v),\quad \overline{\theta}=\theta,\quad \overline{\varphi}=\varphi$$

verifying the condition

$$\overline{u}_u\overline{v}_v=\left(\frac{\overline{u}-\overline{v}}{u-v}\right)^2 \tag{6}$$

to obtain a conformally flat form of the Minkowski metric (1),

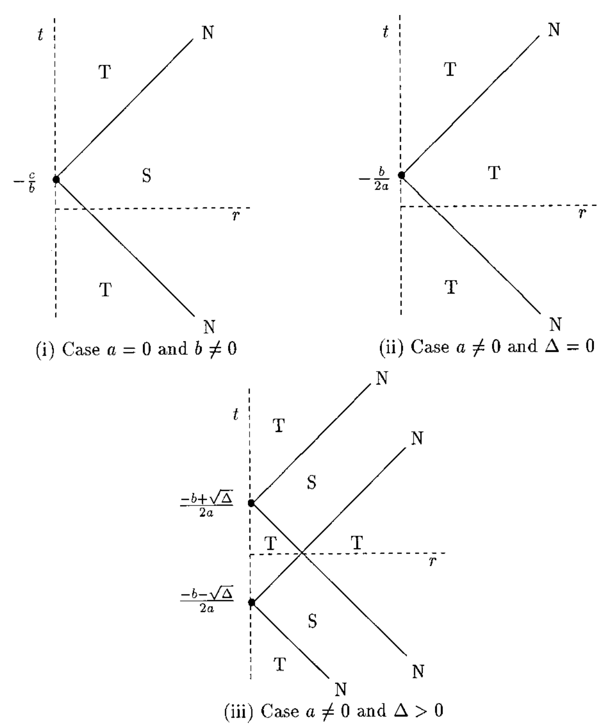

FIG. 1. Domains of causality of a RCKF ξ according to the values of the coefficient a and $\Delta=b^2-4ac$. The different possibilities for the causal character, Timelike, Spacelike or Null, in each domain, are abbreviated with the capital letters T, S, or N, respectively.

$$\eta = F(\bar{u},\bar{v})\left[-\frac{1}{2}(d\bar{u}\otimes d\bar{v}+d\bar{v}\otimes d\bar{u})+\left(\frac{\bar{u}-\bar{v}}{2}\right)^2 h\right],$$

where the *internal conformal factor, F,* is

$$F=\frac{1}{\bar{u}_u\bar{v}_v}=u_{\bar{u}}v_{\bar{v}} \tag{7}$$

with subindexes denoting derivation with respect to the coordinates.

The integration of Eq. (6) with respect to $\bar{u}(u)$, considering the v-coordinate as a parameter, gives

$$\bar{u}(u)=\frac{\bar{v}_v(u-v)}{1+(u-v)A}+\bar{v}, \tag{8}$$

where A is an arbitrary function of v. Now, taking into account that $\bar{u}$ does not depend on v, the derivative of (8) with respect to v gives the following system of equations for A and $\bar{v}$:

$$\begin{cases} A\bar{v}_{vv}-A_v\bar{v}_v+A^2\bar{v}_v=0\\ 2A\bar{v}_v+\bar{v}_{vv}=0. \end{cases} \tag{9}$$

If $A=0$ the solution of Eqs. (8) and (9) is linear, $\bar{u}(u)=pu+q$ and $\bar{v}(v)=pv+q$, where $p\neq 0$ and q are arbitrary constants. In the generic case, $A\neq 0$, the solution has the form

$$\bar{u}(u)=\frac{p}{u+q}+m,\quad \bar{v}(v)=\frac{p}{v+q}+m, \tag{10}$$

where $p\neq 0$, q and m are arbitrary constants; the internal conformal factor F results from Eq. (7),

$$F(\bar{u},\bar{v})=\frac{p^2}{(\bar{u}-m)^2(\bar{v}-m)^2}.$$

Therefore, taking $\bar{u}=\bar{t}+\bar{r}$ and $\bar{v}=\bar{t}-\bar{r}$, we obtain the following proposition:

Proposition 3: The nonlinear coordinate transformations $\bar{t}=\bar{t}(t,r)$, $\bar{r}=\bar{r}(t,r)$, *that maintain invariant the diagonal form of the Minkowski metric, except for an internal conformal factor F are given by*

$$\bar{t}=\frac{-p(t+q)}{r^2-(t+q)^2}+m,\quad \bar{r}=\frac{pr}{r^2-(t+q)^2}$$

with $p\neq 0$, q *and* m *as arbitrary constants. Then, this factor is*

$$F(\bar{t},\bar{r})=\frac{p^2}{(\bar{r}^2-(\bar{t}-m)^2)^2}.$$

Note that, these *internal conformal transformations* in the Minkowski space–time, given by (10), also maintain invariant the form (4) of the RCKF, that is

$$\xi=(\bar{a}\bar{u}^2+\bar{b}\bar{u}+\bar{c})\frac{\partial}{\partial\bar{u}}+(\bar{a}\bar{v}^2+\bar{b}\bar{v}+\bar{c})\frac{\partial}{\partial\bar{v}},$$

where the new constants $\bar{a}$, $\bar{b}$, and $\bar{c}$ are obtained from the following matricial relation:

$$\begin{pmatrix}\overline{a}\\ \overline{b}\\ \overline{c}\end{pmatrix}=\mathcal{M}\begin{pmatrix}a\\ b\\ c\end{pmatrix}\quad\text{with}\quad \mathcal{M}\equiv\frac{1}{p}\begin{pmatrix}-q^2 & q & -1\\ 2q(p+mq) & -(p+2mq) & 2m\\ -(p+mq)^2 & m(p+mq) & -m^2\end{pmatrix}. \tag{11}$$

Moreover $b^2-4ac=\overline{b}^2-4\overline{ac}$ and we have the following proposition:

Proposition 4: The form of a RCKF is invariant by the internal conformal transformations given in Proposition 3. Moreover, the quantity $\Delta=b^2-4ac$ *is also invariant by these transformations.*

Since $\det(\mathcal{M})=1$, the internal conformal transformations of the Minkowski metric are represented as orthogonal transformations on the algebra of the RCKF, considering its Killing form $\mathcal{K}$ as a metric. Hence, Δ is invariantly defined from the scalar product associated with $\mathcal{K}$, that is $\Delta=\mathcal{K}(\xi,\xi)$. The invariance of this quantity suggests us the possibility of a classification of the RCKF depending on the sign of Δ, which will be used to denote these classes. The classes $\Delta=0$, $\Delta>0$ and $\Delta<0$ can be represented by the fields ξ_1, ξ_2, and $\xi_3+\xi_1$, respectively.

Note that the fields ξ_1 and ξ_3 belong to the class $\Delta=0$ because the internal conformal transformation from Proposition 3 with $p=-1$, $q=0$ and m arbitrary lets us write the field ξ_3 as a timelike translation field in the new coordinates

$$\xi_3=(t^2+r^2)\frac{\partial}{\partial t}+2tr\frac{\partial}{\partial r}=\frac{\partial}{\partial \overline{t}}\equiv\overline{\xi_1}$$

as it follows from expression (11). The metric η in these coordinates has the form

$$\eta_{(\overline{t},\overline{r},\theta,\varphi)}=\frac{1}{[\overline{r}^2-(\overline{t}-m)^2]^2}\operatorname{diag}(-1,1,\overline{r}^2,\overline{r}^2\sin^2\theta). \tag{12}$$

Another interesting example is the equivalence between the fields ξ_2 and $\xi_3-\xi_1$ in the class $\Delta>0$. From Proposition 3 and Eq. (11), an internal conformal transformation with $p=-2m\neq 0$ and $q=1$ lets us write $\xi_3-\xi_1$ as the dilation field in the new coordinates $(\overline{t},\overline{r})$,

$$\xi_3-\xi_1=(t^2+r^2-1)\frac{\partial}{\partial t}+2tr\frac{\partial}{\partial r}=\overline{t}\frac{\partial}{\partial \overline{t}}+\overline{r}\frac{\partial}{\partial \overline{r}}\equiv\overline{\xi_2}$$

and now the metric η is written in the form,

$$\eta_{(\overline{t},\overline{r},\theta,\varphi)}=\frac{4m^2}{[\overline{r}^2-(\overline{t}-m)^2]^2}\operatorname{diag}(-1,1,\overline{r}^2,\overline{r}^2\sin^2\theta). \tag{13}$$

Then, as it is shown in last examples, we have the following result:

Proposition 5: The fields $\xi_3-k\xi_1$, *with* $k=0,+1,-1$, *may be taken as representatives of the equivalence classes* $\Delta=0$, $\Delta>0$, *and* $\Delta<0$, *respectively.*

Note that the representatives taken in the above proposition are obtained only from the fields ξ_1 and ξ_3, and then, they are not a basis of the radial conformal Killing algebra. But they generate by commutation the complete algebra, because ξ_2 is, up to a constant factor, the Lie bracket of any pair of these representatives.

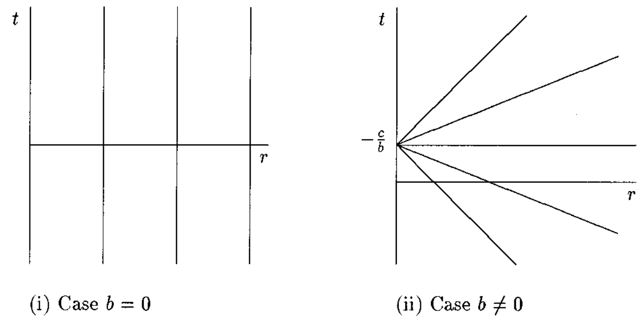

FIG. 2. Integral curves associated with a RCKF ξ given by expression (3) with $a=0$.

IV. INTEGRAL CURVES ASSOCIATED WITH A RADIAL CONFORMAL MOTION

The integral curves of a RCKF ξ given by (3) are the solution of the differential equation

$$\frac{dt}{a(t^2+r^2)+bt+c}=\frac{dr}{r(2at+b)}, \tag{14}$$

which has the following implicit form:

$$a(t^2-r^2)+bt-\omega r+c=0. \tag{15}$$

So, the integral curves are a one-parameter family of straight or hyperbolic lines, depending on the constants a, b, and c of the field and on the parameter ω. When $a=0$, Eq. (15) represents straight lines in the $\{t,r\}$-plane (Fig. 2). When $a\neq 0$, Eq. (15) can be written in the form

$$\left(t+\frac{b}{2a}\right)^2-\left(r+\frac{\omega}{2a}\right)^2=\frac{\Delta-\omega^2}{4a^2},$$

which represents a hyperbolic line for each value of the parameter ω except when $\omega^2=\Delta$ that corresponds to the light cone at the point $(t=-b/2a,\ r=-\omega/2a)$. The vertexes of each hyperbola are the points $[t=-(b/2a),\ r_{\pm}=(-\omega\pm\sqrt{\omega^2-\Delta})/2a]$ if $\Delta\leqslant 0$ or $\omega^2>\Delta>0$ and the points $[t_{\pm}=(-b\pm\sqrt{\Delta-\omega^2})/2a,\ r=-\omega/2a]$ if $\Delta>0$ and $\omega^2<\Delta$. We must consider only the part of the hyperbolic branches with $r>0$. Some of these integral curves are plotted in Fig. 3 for the different values of Δ. Note that in the case $\Delta>0$ there exist a double family of hyperbolic lines, Fig. 3(iii).

The vector field $\xi_2=t(\partial/\partial t)+r(\partial/\partial r)$ is called (the generator of) a dilation transformation since its integral curves are a radial congruence of straight lines [Figs. 1(i) and 2(ii)]. And the vector field $\xi_3=(t^2+r^2)(\partial/\partial t)+2tr(\partial/\partial r)$ is identified as (the generator of) an acceleration transformation along the t-axis, because each integral curve for $\omega\neq 0$ can be seen as a hyperbolic relativistic motion whose acceleration $\mathbf{a}$ has constant length, $|\mathbf{a}|=2|a/\omega|$ [Figs. 1(ii) and 3(ii)].

V. ORTHOGONAL SURFACES TO A RADIAL CONFORMAL KILLING FIELD

Let us consider the covector ξ_* associated by the metric to a RCKF ξ given by (3), that is

$$\xi_*=-(a(t^2+r^2)+bt+c)dt+r(2at+b)dr.$$

This 1-form is integrable, $\xi_*\wedge d\xi_*=0$, and admits as a potential the following function:

$$s(t,r)=\begin{cases} b(t^2-r^2)+2ct & \text{if } a=0\\ \dfrac{a(t^2-r^2)-c}{2at+b} & \text{if } a\neq 0\end{cases} \tag{16}$$

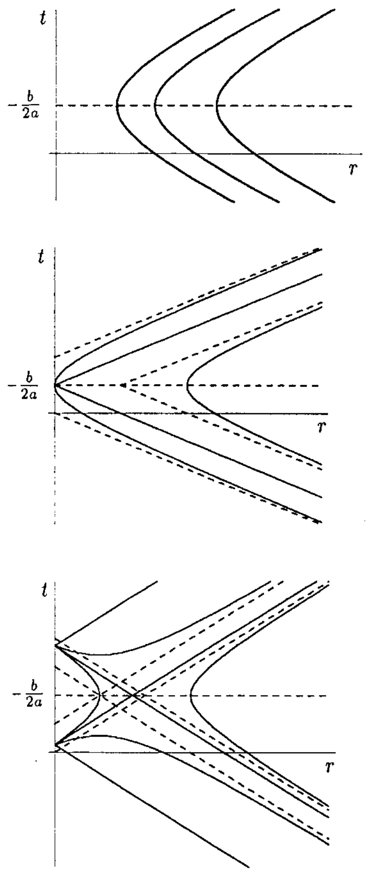

FIG. 3. Integral curves associated with a RCKF ξ given by expression (3) with $a\neq 0$, according to the sign of $\Delta = b^2 - 4ac$.

that is, $\xi_* \propto ds$ and the surfaces $\Sigma_s = \{(t,r,\theta,\varphi)/s = \text{constant}\}$ are orthogonal to the field ξ. Let us consider a domain where the field is not null on any point. The metric may be written using the coordinate s and another coordinate ω orthogonal to ξ, $\eta(d\omega,\xi)=0$. Such a coordinate has the expression

$$\omega(t,r) = \frac{a(t^2 - r^2) + bt + c}{r} \tag{17}$$

for any value of a, according to Eq. (15). In order to express the flat metric in these coordinates, we need the inverse transformation of Eqs. (16) and (17), which is

(i) For $a=0$,

$$t(s,\omega) = \begin{cases} \dfrac{s}{2c} & \text{if } b=0 \\ -\dfrac{c}{b} + \dfrac{\omega}{b}\sqrt{\dfrac{bs+c^2}{\omega^2 - b^2}} & \text{if } b\neq 0, \end{cases}$$

$$r(s,\omega) = \sqrt{\frac{bs+c^2}{\omega^2 - b^2}}. \tag{18}$$

(ii) For $a\neq 0$,

$$t(s,\omega)=\frac{1}{\sigma^2-\omega^2}\left[(\Delta-\omega^2)s-\frac{b}{2a}(\sigma^2-\Delta)\pm\frac{\omega}{2a}\sqrt{(\sigma^2-\Delta)(\omega^2-\Delta)}\right],$$

$$r(s,\omega)=\frac{\sqrt{\sigma^2-\Delta}}{2a(\sigma^2-\omega^2)}[-\sigma\sqrt{\omega^2-\Delta}\pm\omega\sqrt{\sigma^2-\Delta}], \tag{19}$$

where $\sigma\equiv 2as+b$ and the + (−) sign in the t coordinate corresponds to the + (−) sign in the r coordinate.

Then η, written in the coordinates $(s,\omega,\theta,\varphi)$, has the following diagonal form:

$$\eta_{(s,\omega,\theta,\varphi)}=\begin{cases} r^2(s,\omega)\mathrm{diag}\left(\frac{b^2-\omega^2}{4(bs+c^2)^2},\frac{1}{\omega^2-b^2},1,\sin^2\theta\right) & \text{if } a=0 \\ r^2(s,\omega)\mathrm{diag}\left(\frac{\Delta-\omega^2}{4(as^2+bs+c)^2},\frac{1}{\omega^2-\Delta},1,\sin^2\theta\right) & \text{if } a\neq 0. \end{cases} \tag{20}$$

Note that these coordinates $(s,\omega,\theta,\varphi)$ are not, in general, conformally flat coordinates. If we consider the coordinate transformations (18), (19) and Proposition 3, the resulting relation between (s,ω) and $(\bar{t},\bar{r})$ allows us to recover, from expression (20), the metric forms (12) and (13) presented in Sec. III.

From (20), the induced metric on the surfaces Σ_s by the Minkowski metric has the form

$$\gamma_{(\omega,\theta,\varphi)}=r^2(s,\omega)\mathrm{diag}\left(\frac{1}{\omega^2-\Delta},1,\sin^2\theta\right).$$

The Riemann double 2-form of curvature $\mathcal{R}$ of this induced metric can be expressed as $\mathcal{R}=[K(s)/2]\gamma\wedge\gamma$, where $\wedge$ denotes the exterior product of double 1-forms and $K(s)$ is given by

$$K(s)=\begin{cases} \frac{-b^2}{bs+c^2} & \text{for } a=0 \\ \frac{-a}{as^2+bs+c} & \text{for } a\neq 0. \end{cases} \tag{21}$$

Therefore each surface Σ_s (s=constant) has constant sectional curvature, $K(s)$. If we take into account expressions (5) and (16), we obtain

$$P=\begin{cases} bs+c^2 & \text{if } a=0 \\ \frac{as^2+bs+c}{a}(2at+b)^2 & \text{if } a\neq 0 \end{cases} \tag{22}$$

and the sectional curvature of Σ_s can be written in the form

$$K(s)=-\frac{1}{P}(2at+b)^2$$

whose sign depends on the causal character of the field ξ, and the following result follows.

Proposition 6: In the Minkowski space–time, the surfaces orthogonal to a RCKF are three-dimensional spaces with constant curvature, which will be negative or positive if the field is timelike or spacelike, respectively; except for the field $\xi=(\partial/\partial t)$ *(timelike everywhere), whose orthogonal 3-spaces are flat.*

VI. TIMELIKE RADIAL CONFORMAL MOTIONS

The case of timelike RCKF is specially interesting because they are associated with particular, but in general noninertial, observers in Minkowski space–time. We are going to study their kinematical properties. The shear and the vorticity of (the unit vector **u** associated with) a timelike RCKF are zero. The expansion is

$$\theta = \frac{3(2at+b)}{\sqrt{P}}$$

with P given by (5), and the acceleration has the form

$$\mathbf{a} = \frac{2ar}{P}(-r(2at+b)dt + (a(t^2+r^2)+bt+c)dr).$$

Note that $\eta(\mathbf{a},\mathbf{a}) = 4a^2/(\omega^2-\Delta)$ is constant along each integral curve, as we can see from (15). This agrees with the fact that the integral curves associated with a timelike RCKF describe hyperbolic or inertial motions. Then we have the following proposition in the Minkowski space–time:

Proposition 7: In the Minkowski space–time, the acceleration of a timelike RCKF has constant length on each integral curve, that is

$$|\mathbf{a}| = \frac{2|a|}{\sqrt{\omega^2-\Delta}},$$

where ω is given by (15).

Note that, in inertial coordinates, a timelike RCKF (3) is geodesic iff $a=0$. And it will have null expansion (that is, it will be a Killing vector field) iff the constants a and b are equal to zero.

Let us consider the 4-velocity of a timelike RCKF,

$$\mathbf{u} = \frac{\xi}{\sqrt{P}} = \frac{1}{\sqrt{1-\mathrm{v}^2}}\left(\frac{\partial}{\partial t} + \mathrm{v}\frac{\partial}{\partial r}\right),$$

the velocity v relative to the inertial observer $\partial/\partial t$ is given by the quotient between the components ξ^1 and ξ^0 of the field,

$$\mathrm{v} = \frac{r(2at+b)}{a(t^2+r^2)+bt+c}. \tag{23}$$

From Fig. 1, we can clearly see that when we are approaching (inside the timelike regions) to the light cones where the field ξ is null, the relative velocity $\mathrm{v}\to 1$. In particular, when $a=c=0$ we have $\mathrm{v}=r/t$. This corresponds to the geodesic field ξ_2 and adapting coordinates to it, the Minkowski metric is written

$$\eta = -d\tau^2 + \frac{\tau^2}{\left(1-\frac{\rho^2}{4}\right)^2}[d\rho^2 + \rho^2(d\theta^2 + \sin^2\theta d\varphi^2)], \tag{24}$$

which has the form of a Robertson–Walker metric with expansion factor $R(\tau)=\tau$. This is Milne's expression of the flat metric used to give a kinematic interpretation of the Hubble law.[2] The timelike coordinate τ represents the proper time of the geodesic radial congruence associated with the field $\xi_2 = \partial/\partial\tau$; and, according to Proposition 6, the surfaces $\tau=$constant are spaces of negative constant curvature.

Expression (24) can be obtained from (20) redefining the (s,ω) coordinates in the following way:

$$s=\tau^2, \quad \omega=\frac{\rho}{4}+\frac{1}{\rho}.$$

In this sense, Milne's interpretation of the recession velocity of galaxies can be understood adapting coordinates to a RCKF in Minkowski space–time.

VII. DISCUSSION AND COMMENTS

We have analyzed the main properties of the RCKF in Minkowski space–time. In a conformally flat space–time, whose metric can be locally written as $g=e^{2\lambda}\eta$, the form of the RCKF will be given by the same expression (3) or (4) as for the Minkowski space–time. But the acceleration and expansion of these fields will depend on the function λ and its first derivatives. So, additional conditions imposed on these kinematic properties lead to a differential equation for this function λ that can be used to determine it. For instance, imposing that a conformally flat space–time admits a geodesic RCKF, the corresponding differential equation allows one to obtain the conformal factor of the Robertson–Walker metric found by Infeld and Schild[1] in their work on kinematic cosmology.

Therefore, it is natural to wonder whether the existence of a RCKF with certain kinematic properties can characterize the Robertson–Walker metrics and other generalized nonhomogeneous conformally flat cosmological models. In fact, Robertson–Walker universes are those conformally flat space–times which admit a timelike geodesic RCKF.[3] Other kinematic properties over these RCKF (nongeodesic with homogeneous expansion or admitting homogeneous orthogonal 3-spaces) could be used to characterize generalized conformally flat cosmologies. We shall soon develop this idea further.[4]

(Received 9 July 1998; accepted for publication 4 March 1999)

The Lovelock gravity extends the theory of general relativity to higher dimensions in such a way that the field equations remain of second order. The theory has many constant coefficients with no *a priori* meaning. Nevertheless, it is possible to reduce them to two: the cosmological constant and Newton's constant. In this process one separates theories in even dimensions from theories in odd dimensions. In a previous work, gravitational collapse in even dimensions was analyzed. In this work attention is given to odd dimensions. It is found that black holes also emerge as the final state of gravitational collapse of a regular dust fluid. © *1999 American Institute of Physics.* [S0022-2488(99)03306-X]

I. INTRODUCTION

A generalization of Einstein gravity to other dimensions while keeping the same degrees of freedom (the field equations for the metric remain of second order) is given by the Lovelock action.[1] The theory can also be considered as an extension of Einstein–Hilbert action (see, e.g., Ref. 2), in which new terms make their appearance by taking into the action the Euler densities of the spaces with dimensions lower than the space in consideration.

In a previous work[3] we have studied gravitational collapse in Lovelock gravity for a spacetime with even dimensions, thus extending the Oppenheimer–Snyder collapsing model. Following the work of Refs. 2 and 4, the reason for separating even from odd dimensions in the Lovelock theory comes naturally in a $\mathcal{D}$-dimensional spacetime when one considers embedding the Lorentz group $SO(\mathcal{D}-1,1)$ into the anti-de Sitter group $SO(\mathcal{D}-1,2)$. The Lovelock theory then branches into two distinct classes, with Lagrangians for even dimensions and Lagrangians for odd dimensions. One also finds in this way that the number of constants, that proliferates when one goes to higher and higher dimensions, reduces drastically to two: the cosmological constant Λ and Newton's constant G.

In this work we study gravitational collapse in odd-dimensional spacetimes and show that black holes form from regular initial data consisting of a dust fluid. We follow closely the nomenclature and the division of sections made in Ref. 3. In Sec. II the Lovelock gravity for restricted coefficients in odd-dimensional spacetimes is presented. In Sec. III we display the static solutions in odd dimensions found in Ref. 4. In Sec. IV we find some cosmological or interior matter solutions for perfect fluids. In Sec. V we match the solutions found in Sec. IV to the solutions of Sec. III. In Sec. VI we show that black holes can form through gravitational collapse in Lovelock odd-dimensional gravity. In Sec. VI we comment on the formation of naked singularities and in Sec. VII we present some conclusions. In the paper we usually do $G=c=1$.

II. THE LOVELOCK THEORY

The most general action in $\mathcal{D}\geqslant 3$ spacetime dimensions that yields the same degrees of freedom of Einstein's theory is the so-called Lovelock action, given by[1,2]

$$S=\int \mathcal{L}_{\mathcal{D}}=\kappa \sum_{p=0}^{[(\mathcal{D}-1)/2]} \alpha_p \int_M \epsilon_{a_1\cdots a_{\mathcal{D}}} R^{a_1a_2}\wedge\cdots\wedge R^{a_{2p-1}a_{2p}}\wedge e^{a_{2p+1}}\wedge\cdots\wedge e^{a_{\mathcal{D}}}+S_m, \tag{2.1}$$

where $R^{ab}=d\omega^{ab}+\omega^a_c\wedge\omega^{cb}$ is the curvature two-form, e^a is the local frame one-form, and ω^{ab} is the spin connection, with $a_i=0,1,...,\mathcal{D}-1$. The symbol [ ] over the summation symbol means one should take the integer part of $(\mathcal{D}-1)/2$. S_m is a phenomenological action that describes the macroscopic matter sources.

In general, the constant coefficients α_p are arbitrary. However, it is shown in Ref. 4 that taking certain special choices one is able to get simple meaningful solutions. Following Ref. 4, one first considers embedding the Lorentz group SO$(\mathcal{D}-1,1)$ into the anti-de Sitter group SO$(\mathcal{D}-1,2)$, and then separates into two distinct classes of Lagrangians: Lagrangians for even dimensions and Lagrangians for odd dimensions.

For odd dimensions, $\mathcal{D}=2n-1$, one can find a construction similar to the Chern–Simons action construction in three dimensions. One starts with the Euler density in one dimension above $\mathcal{D}$,

$$E_{2n}=\kappa\epsilon_{A_1\cdots A_{2n}}\hat{R}^{A_1A_2}\wedge\cdots\wedge\hat{R}^{A_{2n-1}A_{2n}}, \tag{2.2}$$

with $A_1,A_2=0,1,...,2n-1$ being the anti-de Sitter indices. $\hat{R}^{AB}$ is the anti-de Sitter curvature two-form constructed with the SO$(\mathcal{D}-1,2)$ connection W^{AB}. Equation (2.2) is a local exact form, and can be written as an exterior derivative of a Lagrangian in $2n-1$ dimensions, i.e., $E_{2n}=d\mathcal{L}_{2n-1}$; see Ref. 4. Decomposing the connection W^{AB} into the connection under $\mathcal{D}$ rotations w^{ab} and inner translations e^a, one finds the anti-de Sitter curvature $\hat{R}$ in terms of the Lorentz curvature R:

$$\hat{R}^{ab}=R^{ab}+\frac{1}{l^2}e^a\wedge e^b, \tag{2.3}$$

where l is a scale factor that is to be related to the cosmological constant $l^2=-1/\Lambda$. Using Eq. (2.3), one finds that the Lagrangian in Eq. (2.2) can be put in the form

$$\mathcal{L}_{2n-1}=\kappa\sum_{p=0}^{n-1}\alpha_p\epsilon_{a_1\cdots a_{\mathcal{D}}}R^{a_1a_2}\wedge\cdots\wedge R^{a_{2p-1}a_{2p}}\wedge e^{a_{2p+1}}\wedge\cdots\wedge e^{a_{\mathcal{D}}}, \tag{2.4}$$

where the coefficients are given by

$$\alpha_p=\frac{1}{\mathcal{D}-2p}\binom{n-1}{p}l^{-\mathcal{D}+2p}, \tag{2.5}$$

and, for convenience, one can choose κ as

$$\kappa=\frac{\mathcal{D}-2}{16\pi Gn}l^{\mathcal{D}-2}. \tag{2.6}$$

Given the action (2.1), the field equations are obtained by the variation with respect to the one-forms e^a. Under the assumption of zero torsion, the variation with respect to the spin connection ω^{ab} vanishes identically. Although the equations have powers in the curvatures, they remain by construction second order in the metric. The field equations are given by

$$-\kappa\sum_{p=0}^{[(\mathcal{D}-1)/2]}\alpha_p(\mathcal{D}-2p)\epsilon_{a_1\cdots a_{\mathcal{D}}}R^{a_1a_2}\wedge\cdots\wedge R^{a_{2p-1}a_{2p}}\wedge e^{a_{2p+1}}\wedge\cdots\wedge e^{a_{\mathcal{D}-1}}=Q_{a_{\mathcal{D}}}, \tag{2.7}$$

where $Q_{a_{\mathcal{D}}}$ is a $(\mathcal{D}-1)$-form associated with the energy momentum tensor T^a_b through the following expression:

$$Q_i=\frac{1}{(\mathcal{D}-1)!}T_i^{a_1}\epsilon_{a_1\cdots a_{\mathcal{D}}}e^{a_2}\wedge\cdots\wedge e^{a_{\mathcal{D}}}. \tag{2.8}$$

III. EXTERIOR VACUUM SOLUTIONS

In the vacuum all components of the energy–momentum tensor vanish, so that the field equations (2.7) are given by

$$-\kappa\sum_{p=0}\alpha_p(\mathcal{D}-2p)\epsilon_{a_1\cdots a_{\mathcal{D}}}R^{a_1a_2}\wedge\cdots\wedge R^{a_{2p-1}a_{2p}}\wedge e^{a_{2p+1}}\wedge\cdots\wedge e^{a_{\mathcal{D}-1}}=0. \tag{3.1}$$

Inserting the coefficients α_p and the constant κ given in (2.5) and (2.6) in Eq. (3.1) one gets for odd dimensions $(\mathcal{D}=2n-1)$,

$$(R^{a_1a_2}+l^{-2}e^{a_1}\wedge e^{a_2})\wedge\cdots\wedge(R^{a_{2n-3}a_{2n-2}}+l^{-2}e^{a_{2n-3}}\wedge e^{a_{2n-2}})\epsilon_{a_1a_2\cdots a_{2n-1}}=0. \tag{3.2}$$

We consider now a static, spherical symmetric spacetime. One can write the metric in the following form:

$$ds_+^2=-g^2(r_+)dt_+^2+g^{-2}(r_+)dr_+^2+r_+^2d\Omega_{\mathcal{D}-2}^2, \tag{3.3}$$

where t and r are the time and radial coordinates and $d\Omega^2_{\mathcal{D}-2}$ is the arc element of a unit $(\mathcal{D}-2)$ sphere. The subscript + reminds that (3.3) is to be viewed as an exterior solution. With metric (3.3) and Eqs. (3.1) and (3.2), Bañados, Teitelboim, and Zanelli found the following exact solution for $\mathcal{D}=2n-1$:[4]

$$ds_+^2=-[1-(M+1)^{2/(\mathcal{D}-1)}+(r_+/l)^2]dt_+^2+\frac{dr_+^2}{1-(M+1)^{2/(\mathcal{D}-1)}+(r_+/l)^2}+r_+^2d\Omega_{\mathcal{D}-2}^2. \tag{3.4}$$

These solutions describe black holes. We will show that they also represent the exterior vacuum solution to a collapsing (or expanding) dust cloud in Lovelock's odd-dimensional theory, as in the even-dimensional case.[3]

IV. INTERIOR MATTER SOLUTIONS

The interior spacetime is modeled by a homogeneous collapsing (or expanding) dust cloud, whose metric is described by Friedmann–Robertson–Walker in $\mathcal{D}$ dimensions,

$$ds^2=-dt^2+a^2(t)\left[\frac{dr^2}{1-kr^2}+r^2d\Omega^2_{\mathcal{D}-2}\right]. \tag{4.1}$$

The coordinates t and r are comoving coordinates (we omit throughout the subscript − to indicate an interior solution). Note that that k has dimension of 1/[length]^2. The energy–momentum tensor for a perfect fluid is given by

$$T_{\alpha\beta}=(\rho+p)u_\alpha u_\beta+pg_{\alpha\beta}, \tag{4.2}$$

where ρ is the energy–density, p the pressure, and u^α is the $\mathcal{D}$ velocity of the fluid. From (4.1)–(4.2) and Lovelock equations (2.7), we obtain

$$-B\frac{d}{dt}\left(\frac{\dot{a}}{a}\right)+\frac{k}{a^2}=\rho+p, \tag{4.3}$$

$$(\mathcal{D}-1)B\left(\frac{\dot{a}}{a}\right)\left[-\frac{k}{a^2}+\frac{d}{dt}\left(\frac{\dot{a}}{a}\right)\right]=\dot{\rho}, \tag{4.4}$$

where

$$B\equiv(\mathcal{D}-2)!\sum_p \alpha_p 2p(\mathcal{D}-2p)\left(\frac{\dot{a}^2+k}{a^2}\right)^{p-1}, \tag{4.5}$$

where the coefficients α_p are given in (2.5), and κ is given in (2.6). Equations (4.3)–(4.4) have a first integral given by

$$\dot{a}^2=-k-\left(\frac{a}{l}\right)^2+\left(\frac{a_0}{l}\right)^2\left[\frac{8\pi l^2\rho_0}{(\mathcal{D}-2)!(\mathcal{D}-2)}\right]^{2/(\mathcal{D}-1)}, \tag{4.6}$$

where ρ_0 and a_0 are constants. Equations (4.3)–(4.4) also have a second integral, i.e., the solution of Eq. (4.6) is given by (see also Ref. 5)

$$a(t/l)=\frac{l}{r_\Sigma}\sqrt{\left\{\left(\frac{1}{l}\right)^{\mathcal{D}-3}\left[\frac{8\pi\rho_0(a_0r_\Sigma)^{\mathcal{D}-1}}{(\mathcal{D}-2)!(\mathcal{D}-2)}\right]\right\}^{2/(\mathcal{D}-1)}-kr_\Sigma^2}\,\sin(b+t/l), \tag{4.7}$$

where b is an arbitrary phase that will be neglected henceforward.

The Ricci quadratic scalar and the Kretschmann scalar are given by

$$R_{ab}R^{ab}=-(\mathcal{D}-1)^2\left(\frac{\ddot{a}}{a}\right)^2+(\mathcal{D}-1)\left[\frac{\ddot{a}}{a}+(\mathcal{D}-2)\frac{\dot{a}^2+k}{a^2}\right]^2, \tag{4.8}$$

$$R_{abcd}R^{abcd}=(\mathcal{D}-1)\left[\left(\frac{\ddot{a}}{a}\right)^2+\left(\frac{\dot{a}^2+k}{a^2}\right)^2\right], \tag{4.9}$$

respectively.

We now assume a dust fluid, $p=0$. For such an equation of state we have

$$\rho=\rho_0\left(\frac{a_0}{a}\right)^{\mathcal{D}-1}, \tag{4.10}$$

where ρ_0 and a_0 are the constants defined above.

Inserting Eq. (4.7) in Eq. (4.10), we obtain the evolution of the density in the dust model:

$$\rho(t/l)=\rho_0\left[\frac{a_0r_\Sigma/l}{\sqrt{\left\{\left(\frac{1}{l}\right)^{\mathcal{D}-3}\left[\frac{8\pi\rho_0(a_0r_\Sigma)^{\mathcal{D}-1}}{(\mathcal{D}-2)!(\mathcal{D}-2)}\right]\right\}^{2/(\mathcal{D}-1)}-kr_\Sigma^2}}\right]^{\mathcal{D}-1}\sin^{-(\mathcal{D}-1)}(t/l). \tag{4.11}$$

We see that the density (4.11) and the curvature scalars (4.8)–(4.9) diverge at $t/l=\pi$, which represents the formation of a singularity.

V. JUNCTION CONDITIONS

Now we match the exterior and interior spacetimes found in Secs. III and IV, respectively, across an interface of separation Σ. The junctions conditions are[6]

$$ds_+^2]_\Sigma = ds_-^2]_\Sigma , \tag{5.1}$$

$$K_{\alpha\beta}^+]_\Sigma = K_{\alpha\beta}^-]_\Sigma , \tag{5.2}$$

where $K_{\alpha\beta}$ is the extrinsic curvature,

$$K_{\alpha\beta}^\pm = -n_\epsilon^\pm \frac{\partial^2 x_\pm^\epsilon}{\partial \xi^\alpha \partial \xi^\beta} - n_\epsilon^\pm \Gamma^\epsilon_{\gamma\delta} \frac{\partial x_\pm^\gamma}{\partial \xi^\alpha} \frac{\partial x_\pm^\delta}{\partial \xi^\beta}, \tag{5.3}$$

and $n_\epsilon^\pm$ are the components of the unit normal vector to Σ in the coordinates $x_\pm$, and ξ represents the intrinsic coordinates in Σ. The subscripts $\pm$ represent the quantities taken in the exterior and interior spacetimes. Both the metrics and the extrinsic curvatures in (5.1)–(5.2) are evaluated at Σ. The metric intrinsic to Σ is written as

$$ds_\Sigma^2 = -d\tau^2 + R^2(\tau) d\Omega_{\mathcal{D}-2}^2, \tag{5.4}$$

where τ is the proper time on Σ and $d\Omega_{\mathcal{D}-2}^2$ denotes the line element on a $\mathcal{D}-2$-dimensional sphere.

Using the junction condition (5.1), metric (5.4), and the exterior metric (3.4), we obtain

$$r_+]_\Sigma = R(\tau), \tag{5.5}$$

and

$$[1-(M+1)^{2/(\mathcal{D}-1)} + (r_+/l)^2]\dot{t}_+^2 - [1-(M+1)^{2/(\mathcal{D}-1)} + (r_+/l)^2]^{-1}\dot{r}_+^2 = 1, \tag{5.6}$$

where $\cdot \equiv d/d\tau$, and both equations are evaluated at Σ. From now on, we will usually omit the subscript Σ to denote evaluation at the interface. Using (5.5) in (5.6), we find

$$\frac{dt_+}{d\tau} = \frac{\sqrt{[1-(M+1)^{2/(\mathcal{D}-1)} + (R/l)^2] + \dot{R}^2}}{[1-(M+1)^{2/(\mathcal{D}-1)} + (R/l)^2]}. \tag{5.7}$$

The unit normal to Σ in the exterior spacetime is

$$n_\epsilon^+ = \left(-\frac{dr_+}{d\tau}, \frac{dt_+}{d\tau}, 0,...,0 \right). \tag{5.8}$$

From (5.3) we then get

$$K_{\theta\theta}^+ = R \sqrt{\left[1-(M+1)^{2/(\mathcal{D}-1)} + \left(\frac{R}{l}\right)^2 \right] + \dot{R}^2}, \tag{5.9}$$

In what follows the other components of K_{ab}^+ are not needed.

The unit normal to Σ in the interior spacetime is

$$n_\epsilon^- = \left(0, \frac{a}{\sqrt{1-kr^2}}, 0,...,0 \right), \tag{5.10}$$

and from (5.3) we have

$$K_{\theta\theta}^- = R(\tau)\sqrt{1-kr_\Sigma^2}. \tag{5.11}$$

Using the junction condition (5.1) for the interior spacetime yields $ar_\Sigma = R(\tau)$. From the condition $K_{\theta\theta}^+ = K_{\theta\theta}^-$, (5.9) and (5.11), we obtain

$$\dot{R}^2+\left(\frac{R}{l}\right)^2+kr_\Sigma^2=(M+1)^{2(\mathcal{D}-1)}. \tag{5.12}$$

Multiplying Eq. (4.6) by r_Σ^2, we get

$$\dot{R}^2+\left(\frac{R}{l}\right)^2+kr_\Sigma^2=\left(\frac{R_0}{l}\right)^2\left[\frac{8\pi l^2\rho_0}{(\mathcal{D}-2)!(\mathcal{D}-2)}\right]^{2/(\mathcal{D}-1)}. \tag{5.13}$$

Comparing Eqs. (5.12) and (5.13), we have

$$M=\left(\frac{1}{l}\right)^{\mathcal{D}-3}\left[\frac{8\pi\rho_0(a_0r_\Sigma)^{\mathcal{D}-1}}{(\mathcal{D}-2)!(\mathcal{D}-2)}\right]-1, \tag{5.14}$$

which is the mass of the cloud expressed in terms of the constants given in the problem.

VI. BLACK HOLE FORMATION

In order to study black hole formation in this theory, we work with the solution found in (4.7). The interior and exterior metrics are given in (4.1) and in (3.4), respectively, and as we have shown in Sec. V, it is possible to make a smooth junction between both spacetimes. To be complete, we treat the cases $\mathcal{D}\geqslant 3$. The case $\mathcal{D}=3$ reduces to the collapse studied in Ref. 7.

For convenience, we rewrite Eqs. (4.6)–(4.9) and (4.11) in terms of the mass M. We thus have

$$a(t/l)=\frac{l}{r_\Sigma}\sqrt{(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2}\,\sin(t/l), \tag{6.1}$$

for the scale factor,

$$\rho(t/l)=\rho_0\left[\frac{a_0r_\Sigma/l}{\sqrt{(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2}}\right]^{\mathcal{D}-1}\sin^{-(\mathcal{D}-1)}(t/l), \tag{6.2}$$

for the density, and

$$R_{ab}R^{ab}=-\frac{(\mathcal{D}-1)^2}{l^4}+\frac{(\mathcal{D}-1)}{l^4}\left\{-1+(\mathcal{D}-2)\frac{[(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2]\cos^2(t/l)+kr_\Sigma^2}{[(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2]\sin^2(t/l)}\right\}^2, \tag{6.3}$$

and

$$R_{abcd}R^{abcd}=\frac{(\mathcal{D}-1)}{l^4}\left\{1+\left[\frac{[(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2]\cos^2(t/l)+kr_\Sigma^2}{[(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2]\sin^2(t/l)}\right]^2\right\}, \tag{6.4}$$

for the quadratic Ricci and Kretschmann scalars, respectively. In this work we restrict the values of the quantity kr_Σ^2, assuming $kr_\Sigma^2=0,\ \pm\frac{1}{2}$. These values have no special meaning, although for kr_Σ^2 positive and large enough there is no solution at all. Note also that the expression (5.14) for the mass is independent of the value chosen for kr_Σ^2.

Gravitational collapse occurs for $\pi/2\leqslant t/l\leqslant\pi$. The time $t/l=\pi/2$ marks the onset of collapse. At this moment there are no singularities in spacetime, as the curvature scalars (6.3)–(6.4) and the density (6.2) indicate. In fact, the singularity appears only at $t/l=\pi$, where all these quantities blow up.

To know whether a black hole has formed or not, one has to search for the appearance of an apparent horizon and an event horizon. The apparent horizon is defined to be the boundary of the region of trapped two-spheres in spacetime. To find this boundary on the interior spacetime, one looks for two spheres $Y \equiv a(t)r = \text{const}$ whose outward normals are null, i.e., $\boldsymbol{\nabla} Y \cdot \boldsymbol{\nabla} Y = 0$. Using metric (4.1), this yields

$$\frac{da(t)}{dt} = -\frac{\sqrt{1-kr^2}}{r}. \tag{6.5}$$

Using (6.1) in (6.5) gives the evolution of the apparent horizon in comoving coordinates,

$$\sqrt{\frac{(M+1)^{2/(\mathcal{D}-1)} - kr_\Sigma^2}{1-kr_\Sigma^2(r/r_\Sigma)^2}}\left(\frac{r}{r_\Sigma}\right) = -\frac{1}{\cos(t/l)}. \tag{6.6}$$

Now, the apparent horizon first forms at the surface r_Σ. Then, for $r = r_\Sigma$, Eq. (6.6) gives the time t/l at which the apparent horizon first forms. On the other hand, one should also be able to find the formation time of the apparent horizon on the surface Σ through an equation on Σ, Eq. (5.12). Indeed, at the junction one has $R = a(t)r_\Sigma$. Then, from junction condition (5.12) and Eq. (6.5) we have that the apparent horizon first forms when

$$\frac{R_{\mathrm{AH}}}{l} = \sqrt{(M+1)^{2/(\mathcal{D}-1)} - 1}. \tag{6.7}$$

Now, using (6.1), the time of formation of the apparent horizon can be found through the equation

$$\frac{R_{\mathrm{AH}}}{l} = a(t_{\mathrm{AH}})\frac{r_\Sigma}{l} = \sqrt{(M+1)^{2/(\mathcal{D}-1)} - kr_\Sigma^2}\,\sin\left(\frac{t_{\mathrm{AH}}}{l}\right). \tag{6.8}$$

Given a dimension $\mathcal{D}$ and an M, one can obtain R_{AH} through Eq. (6.7). Then Eq. (6.8) gives implicitly t_{AH}, the time of the formation of the apparent horizon on the surface Σ for a given k. For instance, for $\mathcal{D}=3$, $M=0.25$, and $kr_\Sigma^2=0$ we find $t_{\mathrm{AH}}/l = 2.68$. Putting this value back in Eq. (6.6) we verify that everything checks.

The event horizon, being a null spherical surface, is determined through the null outgoing lines of the metric (4.1), i.e.,

$$\frac{dt}{dr} = \frac{a(t)}{\sqrt{1-kr^2}}. \tag{6.9}$$

Equation (6.9) can be put in the following integral form:

$$\sqrt{(M+1)^{2/(\mathcal{D}-1)} - kr_\Sigma^2}\int_0^{r_1/r_\Sigma}\frac{d(r/r_\Sigma)}{\sqrt{1-kr_\Sigma^2(r/r_\Sigma)^2}} = \ln\left[\frac{\tan(x_1)}{\tan(x_0)}\right], \tag{6.10}$$

where $x \equiv (1/2)t/l$. Now, the time x_1 is to be precisely equal to the formation time of the apparent horizon, since one expects that in vacuum both horizons coincide.[8] One has then to integrate (6.10) to find the time x_0 at which the event horizon first forms, at $r=0$. For instance, $\mathcal{D}=3$, $M=0.25$, and $kr_\Sigma^2 = -\frac{1}{2}$ we obtain $t_0/l = 1.96$. A plot in comoving coordinates $(t/l, r/r_\Sigma)$ shows the evolution of the apparent and event horizons in Fig. 1. There we repeat the numerical calculations for the same value of $\mathcal{D}$ and M, but with $kr_\Sigma^2=0$ and $kr_\Sigma^2=\frac{1}{2}$, as is shown in lines (b) and (c). In Fig. 2 we show the formation of the apparent and event horizons for $\mathcal{D}=25$, and $M=0.25$ and $kr_\Sigma^2=0$. Intermediate $\mathcal{D}$ dimensions have a similar behavior. Making a matching to the vacuum exterior spacetime one finds the usual Penrose diagram for gravitational collapse and formation of a black hole in an anti-de Sitter background; see Fig. 3.

To study what happens to external observers we note that a light signal emitted from the surface $r_+]_\Sigma$ at the exterior time t_+ obeys the null condition

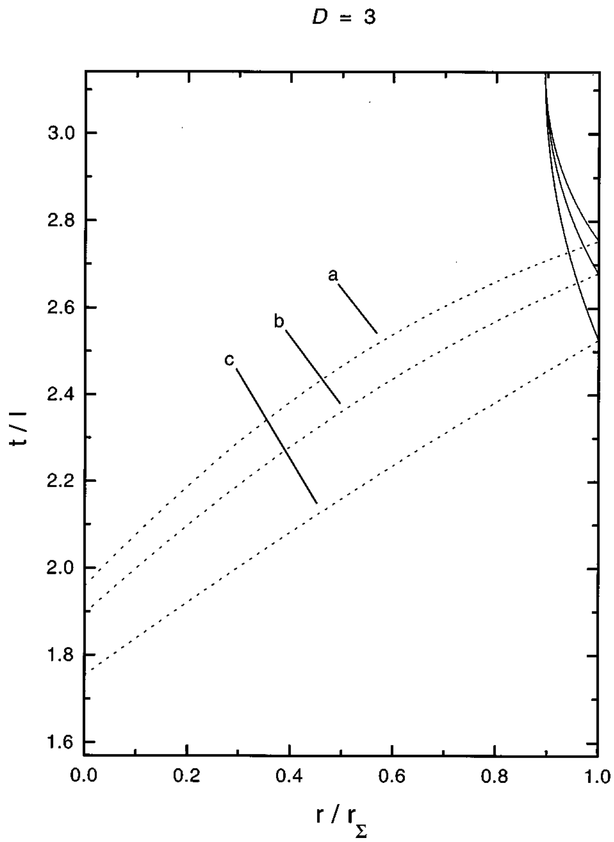

FIG. 1. Gravitational collapse in $\mathcal{D}=3$ dimensions in an asymptotically anti-de Sitter spacetime. The interior dust cloud in comoving coordinates $(t/l, r/r_\Sigma)$ fills the whole diagram. The left side represents the center of the cloud $r/r_\Sigma=0$; the right side the surface of the cloud $r/r_\Sigma=1$. The evolution of the event horizon (dashed line) and apparent horizon (full line) are drawn. The singularity occurs at $t/l=0$. $M=0.25$ was used. The three different cases are (a) $kr_\Sigma^2=-\frac{1}{2}$, (b) $kr_\Sigma^2=0$, and (c) $kr_\Sigma^2=\frac{1}{2}$.

$$\frac{dr_+}{dt_+}=1-(M+1)^{2/(\mathcal{D}-1)}+\left(\frac{r_+}{l}\right)^2 \tag{6.11}$$

[see Eq. (3.4)]. This light ray arrives at a point r_+ at time t_+ given by

$$\frac{t_+}{l}=\frac{t_+]_\Sigma}{l}+\frac{1}{2(M+1)^{2/(\mathcal{D}-1)}-2}\ln\left[\frac{(r_+/l)-[2(M+1)^{2/(\mathcal{D}-1)}-2]}{(r_+/l)+[2(M+1)^{2/(\mathcal{D}-1)}-2]}\right]_{r_+]_\Sigma/l}^{r_+/l}. \tag{6.12}$$

Thus, $t_+/l\to\infty$ when $r_+]_\Sigma/l\to\sqrt{(M+1)^{2/(\mathcal{D}-1)}-1}$, so the collapse to the event horizon appears to take an infinite amount of time to an exterior observer, and the collapse to $r_+=0$ is unobservable from the outside. Also, the redshift from the dust edge is given by

$$z=\frac{dt_+}{dt}-1=\frac{1}{\sqrt{1-kr_\Sigma^2}+\dot{R}}-1. \tag{6.13}$$

When the dust edge crosses the event horizon we have $\dot{R}=-\sqrt{1-kr_\Sigma^2}$, so $z\to\infty$. Thus the collapsing dust will fade from sight, as the redshift of the light from its surface diverges.

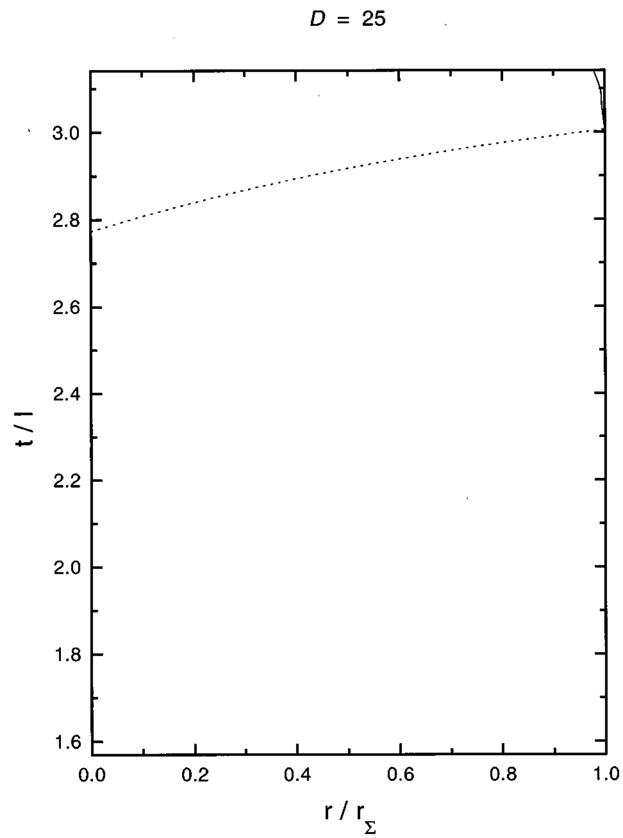

FIG. 2. The dimensionally continued Oppenheimer–Snyder collapse in $\mathcal{D}=25$ dimensions in an asymptotically anti-de Sitter spacetime. $M=0.25$ and $kr_{\Sigma}^{2}=0$ were used. See the subtitle of Fig. 1 for a more detailed explanation.

VII. NAKED SINGULARITIES

To study the presence of naked singularities, i.e., singularities not hidden by an event horizon, we analyze Eqs. (3.4), (6.1)–(6.4), and (5.14). Naked singularities appear only when $M<0$. Although solutions with negative mass are usually considered unphysical, they will be studied here because these generalize the three-dimensional solutions found in Refs. 9, 10, and 7. In the model adopted here, it is useful to separate two distinct classes.

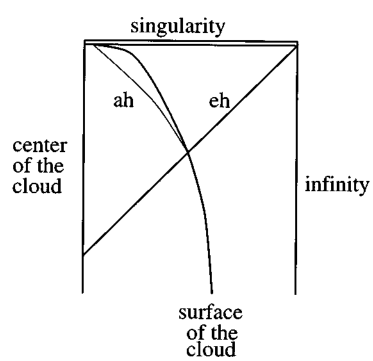

FIG. 3. Penrose diagram for the collapse of a dust cloud in an asymptotically anti-de Sitter spacetime. Each point in the diagram represents a $\mathcal{D}-2$ sphere (eh=event horizon, ah=apparent horizon).

(1) If l remains finite (in which case $\Lambda\neq 0$), for any $\mathcal{D}\geqslant 3$ the curvature scalars (6.3)–(6.4) will blow up when $t/l=\pi$, indicating the formation of a curvature naked singularity.

(2) If we take the limit $l\to\infty$ (in which case $\Lambda=0$), we see from the exterior metric (3.4) that the event horizon is no longer present, and the collapse will form a naked singularity. Taking the limit on Eqs. (6.3)–(6.4), we have

$$R_{ab}R^{ab}=\frac{(\mathcal{D}-1)(\mathcal{D}-2)}{t^4}\left[\frac{(M+1)^{2/(\mathcal{D}-1)}}{(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2}\right]^2, \tag{7.1}$$

$$R_{abcd}R^{abcd}=\frac{\mathcal{D}-1}{t^4}\,\frac{(M+1)^{2/(\mathcal{D}-1)}}{(M+1)^{2/(\mathcal{D}-1)}-kr_\Sigma^2}. \tag{7.2}$$

For any $\mathcal{D}>3$, both (7.1)–(7.2) will vanish because from Eq. (5.14), $M=-1+\mathcal{O}(l^{-\mathcal{D}+3})$, so in the limit we have $M=-1$. Also, from Eq. (6.1) we have in the limit, $a(t)=\sqrt{-k}t$, so that the only possible solution is when $kr_\Sigma^2<0$. Note also that $M=-1$ implies that the exterior metric (3.4) is a Minkowski one, although the interior density (6.2) is nonzero everywhere in the dust cloud. So at $t/l=\pi$ we will have $\rho\to\infty$ in a flat Mikowski spacetime. This is analogous to a Newtonian singularity.

For $\mathcal{D}=3$ we have $M=8\pi\rho_0(a_0r_\Sigma)^2-1$ and $a(t)=\sqrt{8\pi\rho_0a_0^2-k}t$, so that Eqs. (7.1)–(7.2) will be finite but nonzero and the collapse will form a naked conical singularity.[10,7]

VIII. CONCLUSIONS

We have analyzed gravitational collapse in Lovelock gravity for odd-dimensional spacetimes. We have showed that gravitational collapse of a regular initial nonrotating dust cloud proceeds, to form event and apparent horizons, and terminates at a spacelike curvature singularity.

Desingularization of Jacobi metrics and chaos in general relativity

Marek Szydłowski
Astronomical Observatory, Jagiellonian University, ul. Orla 171, 30-244 Cracow, Poland

(Received 29 June 1998; accepted for publication 4 February 1999)

It has been proposed by Wheeler and deWitt to look at the evolution of three-metrics as a geodesic flow on the superspace. Since then a lot of attention has been paid towards better understanding the geometric structure of the superspace. In particular it has been appreciated that the minisuperspace can in a natural way be equipped with the Jacobi metric. However the Jacobi metric is degenerate on certain codimension one hypersurfaces (boundary sets) leading to severe difficulties. The dynamics of minisuperspace models is a special case of dynamics of simple indefinite mechanical systems. It is proved that trajectories of an indefinite mechanical system (M,g,V), with the natural Lagrangian, are pregeodesics with respect to the Jacobi metric $g_E=2|E-V|g$, where M is the configuration space, g the metric defined by the kinetic energy form, V a potential function, and E the total energy of the system. In this paper we also propose to use Eisenhart's principle as an alternative geometrical construction on minisuperspace. Then the dynamics of general relativity is mapped onto a geodesic flow on a smooth manifold without boundary. Hence Eisenhart's proposal seems to be the right way to desingularization of motion in the Jacobi metric which is nontractable in the Jacobi picture. Different methods of desingularizing of the Jacobi metric through the isometric embedding into a more dimensional flat space with the Lorentzian signature is also presented. [S0022-2488(99)01007-5]

I. INTRODUCTION

Mechanical systems with natural Lagrange functions are described by the Lagrangian of the type $L=(1/2)g_{\alpha\beta}\dot{q}^\alpha\dot{q}^\beta-V(p)$, where $V:M\rightarrow\mathbf{R}$ is a potential function. The classical Maupertuis principle states that trajectories of a mechanical system with the total energy $E=(1/2)g_{\alpha\beta}\dot{q}^\alpha\dot{q}^\beta+V(p)$ are geodesics of the Jacobi metric $g_E^J=2(E-V)g$, where g is a Riemannian metric on a smooth manifold M being the configuration space of the system. Let g be given by the kinetic energy form $K(v)=(1/2)g(v,v)$, for every $v\in T_xM$, $x\in M$. The Jacobi metric g_E^J is determined on a submanifold $M_E=\{x\in M:V(x)<E\}$ which is called an *admissible configuration space* (see, for instance, Refs. 1 and 2).

In the previous work,[3] we have generalized the Maupertuis principle by admitting the case when g is a Lorentz metric on M; in such a case the Jacobi metric is of the form $g_E^J=2|E-V|g$, and consequently we have included into the admissible configuration space the regions for which $V(x)\geqslant E$, $x\in M$. According to our previous terminology, the above described mechanical system with the natural Lagrange function is called a *simple mechanical system* (SMS). If the kinetic energy form K is positive definite the system is said to be *classical*; if K is indefinite the system is said to be *relativistic*. In the present work we further study the trajectories of such systems (with respect to the Jacobi metric) and investigate their behavior when they pass through the singular boundary $(V(x)=E)$.

Relativistic systems appears in applications to general relativity and cosmology where the kinetic energy form is indefinite and the metric has the Lorentz signature. For instance, in the so-called ADM formulation of general relativity, the dynamics of space–time reduces to the study of a dynamical system with a suitable potential function which is determined by the geometry of spacelike sections of space–time.[4] In the case of homogeneous anisotropic cosmological models the potential function is determined by the Lie algebras of the corresponding isometry groups acting on spacelike sections of space–time.[5] In all these cases the admissible configuration space contains regions with $V(x)\geqslant E$, and the Jacobi metric g_E^J degenerates on the singular boundary $V(x)=E$.

The status of the Maupertuis principle in classical mechanics is rather ambiguous. (Some authors call this principle the Jacobi principle.[6]) Arnold in his beautiful book,[1] quoting Jacobi who said that ''in almost all textbooks, even in the best ones, this principle is presented in such a way that it is impossible to understand it,'' ironically admitted that also he himself did not want to damage this tradition, and restricted the usefulness of the Maupertuis principle to the cases when $E>V_{\max}(x)$. However, the investigation of classical dynamical systems with degenerate Jacobi metrics (for the cases in which $V(x)\leqslant E$)) began with the works of Wintner[7] and Seifert.[8] Interesting results in this domain were obtained by Kozlov.[9–11] In the present work, we give the proof of a theorem which can be regarded as a rigorous formulation of the generalized (to the case $E\leqslant V(x)$) Maupertuis principle for dynamical systems with the natural Lagrange functions.

It is worthwhile to mention that the Maupertuis principle, for the case with the indefinite kinetic energy form (i.e., for relativistic mechanical systems), was implicitly used by Misner in his minisuperspace construction[12] (and earlier by DeWitt in his concept of superspace).[13] Misner's idea was to define the space of spatially homogeneous and closed solutions of Einstein's equations. Analogously, the Maupertuis principle can be regarded as defining the space of solutions of the Euler–Lagrange equation (geodesics with respect to the Jacobi metric are ''points'' in this space). Other examples of relativistic (low-dimensional) mechanical systems are shown in Table I. In these systems we can find or suspect complex (chaotic) behavior of trajectories in the phase space. One should expect that this behavior has a counterpart in the behavior of geodesics in the space with the Jacobi metric.[14,15]

It was proposed by Wheeler and deWitt to look at the evolution of three-metrics as a geodesic flow on the superspace. Since then a lot of attention has been paid towards better understanding of the geometric structure of the superspace, which turned out to be nontrivial (a metrizable stratified union of manifolds which itself is not a manifold). In particular it has been appreciated that the minisuperspace can in a natural way be equipped with the Jacobi metric. [To see this one should replace, in Misner's formulas (47)–(49), the conformal factor $f^2(g^A)$ by our $2|E-V|$. In this case, Misner's supertime λ coincides with our parameter s.] However the Jacobi metric is degenerate on certain codimension one hypersurfaces (boundary sets) leading to severe difficulties.

It is worthwhile to mention that in the paper by Baierlein *et al.*[16] we can find that general relativity is governed by a Jacobi-type action. This fact was fully discussed in the paper by Barbour[17] in the context of construction of general relativity as a special case of timeless Machian geometrodynamics. Earlier Kuchar[18] showed that it is a possibility of general reduction of geometrodynamical phase space to a mini phase space by the group of motion.

The Hamiltonian function of simple mechanical systems has the form

$$\mathcal{H}(p,q)=\tfrac{1}{2}g^{ab}p_a p_b+V(q). \tag{1}$$

This function determines the first integral of motion, $\mathcal{H}=E=\text{const}$, where E is the total energy of the system. Trajectories of simple mechanical systems live in the phase space

$$\Omega=\{(q,\dot{q})\in R^{2n}:g_{ij}\dot{q}^i\dot{q}^j=2(E-V(q))\}. \tag{2}$$

Positive definiteness of kinetic energy confines the motion of classical systems to a certain domain D of configuration space with nonempty boundary ∂D,

$$D=\partial D\cup\{q\in R^n:E-V(q)>0\}, \tag{3}$$

where $\partial D=\{q\in R^n:E-V(q)=0\}$.

TABLE I. Examples of simple relativistic dynamical systems of two-dimensional configuration space. In these simple, low-dimensional systems we find or suspect complex (chaotic) behavior of trajectories in the phase space. Two identical trajectories of the system starting at slightly different positions (initial conditions) diverge in time. Such sensitive dependence on initial conditions is the main characteristic of chaotic systems and means that they are difficult to predict over long time scales, practically over the Lyapunov characteristic time.

Relativistic system	Hamilton function	Remarks
Friedman–Robertson–Walker cosmology coupled to real free massive scalar field	$\mathcal{H}=\frac{1}{2}(-p_1^2+p_2^2)+\frac{1}{2}(-q_1^2+q_2^2+m^2q_1^2q_2^2)=0$	$m=$ const[a]
Single scalar field evolving in the idealized de Sitter space	$\mathcal{L}=e^{3\nu t}[\frac{1}{2}\dot{\Phi}^2-\frac{1}{2}e^{-2\nu t}(\nabla\Phi)^2+\frac{1}{2}\mu^2\Phi^2-\frac{1}{4}\lambda\Phi^4-(\mu^2/4\lambda)]$	$\Phi(x,y,z,t)$-scalar field[b]
Charged particle in uniform magnetic field and linearly polarized gravitational wave	$\mathcal{H}=\frac{1}{2}(p_1^2-p_2^2)-\frac{1}{2}\frac{(x^1)^2}{1-\alpha\sin[\nu(x^1-x^0)]}\equiv\frac{1}{2}$	α, amplitude of a wave; ω, angular frequency of a wave; Ω, Larmor angular frequency of a charged particle; $\nu=\omega/\Omega$, relative frequency of wave.[c]
Friedmann–Robertson–Walker model with conformally coupled massive, real, self-interacting scalar field	$\mathcal{H}=\frac{1}{2}[-(p_1^2+kq_1^2)+(p_2^2+kq_2^2)+m^2q_1^2q_2^2+\frac{\lambda}{2}q_2^4+\frac{\Lambda}{2}q_1^4]\equiv 0$	$\Lambda,\lambda,m=$ const; $k=0, \pm 1$[d]

In the case of relativistic systems the whole R^n is accessible as a configuration space and ∂D plays the role of a boundary set, i.e., in any neighborhood of its elements one can find points belonging to D_+ or to D_-, where $D_+=\{q\in R^n:E-V(q)>0\}$, and $D_-=\{q\in R^n:E-V(q)<0\}$.

According to the classical Maupertuis principle the trajectories of SMS are mapped into broken geodesics of the Jacobi metric $g_E^J=2(E-V(q))g$.[3] The matching procedure at the boundary ∂D is provided by Kozlov's theorem.[9–11] These theorems describe the behavior of geodesics (images of physical trajectories) in a close vicinity of the boundary ∂D. Two properties are fundamental here: (1) trajectories reach the boundary transversally and (2) after the reflection from the boundary the motion takes place along the same trajectory (at the vicinity of the boundary).[3] This means, in particular, that not every piecewise geodesic curve in Jacobi geometry represents a physical trajectory of the system, e.g., curves composed with pieces of boundary on which $ds_J^2=0$. Therefore the direct approach from the Jacobi principle leads to unphysical orbits. As an alternative for this approach one can consider motion in the covering space (see Ref. 3) (in QT space, in the Synge terminology, Q is a normal configuration space, T is a space of absolute time).

In other words the mapping of trajectories via the Maupertuis–Jacobi principle does not provide a one-to-one correspondence. The demand of having an affinely parametrized geodesic introduces a new time-parameter s defined as $ds=2(E-V(q))dt$. By virtue of the energy conservation a tangent vector is normalized to unity in $\mathrm{int}\, D$ and is zero at the boundary ∂D. The Maupertuis principle has been formulated only for systems with empty boundary $\partial D=0$ and therefore is useless in realistic applications. In our previous papers[19] the problem of simple classical systems was reduced to the problem of broken geodesics on the manifolds with boundaries. However, the Jacobi metric is degenerate at the boundary. This circumstance is a source of many difficulties. It is convenient to treat the configuration space as a so-called differential space of constant dimension[3] on which geodesics are appropriately continued through the set of degeneracy of the metric. One should bear in mind, however, that behavior of geodesics on spaces with boundaries can be substantially different from that on smooth manifolds.

In the case of simple indefinite mechanical systems (SIMS) one is able to transfer Kozlov's results concerning behavior of geodesics in the neighborhood of ∂D. The Jacobi metric is now analogous to the case of SDMS but the conformal factor is taken with an absolute value $g_E^J = 2|E-V(q)|g$. In the regions D_+, ∂D, and D_- the tangent vector is normalized (i.e., $\|u\|^2 = g^J_{ab}u^a u^b$) to $+1$, 0, and -1, respectively. Now the problem of simple relativistic systems is reduced to the problem of matched geodesics on manifolds with a singular set. First we consider geodesics of the metrics $g_E^+ = 2(E-V(q))$ and $g_E^- = -2(E-V(q))$ separately but in whole R^n. Then we match them along ∂D so that the tangent vector at the boundary ∂D lies on a cone defined by a kinetic energy form.

Generally, if one wishes to see trajectories of simple classical (or relativistic) mechanical systems as geodesics in configuration space one obtains tractable although complicated geometrical structure having curvature singularities at the boundary ∂D.

In this paper we propose to use the so-called Eisenhart's principle as an alternative tool of reducing the dynamics to a geodesic flow. This principle maps the trajectories of Hamiltonian systems into geodesics on a certain (fictitious) extended configuration space. We present the details of this construction and apply it to minisuperspace.

The extended minisuperspace can be treated as a stationary ''space–time,'' where the additional fictitious dimension plays the role of ''time.'' This approach has several advantages:

(i) The dynamics is mapped onto a geodesic flow on a smooth manifold without the boundary, hence one can use standard theory of smooth manifolds;
(ii) The identification of trajectories of the system with geodesics on an extended configuration space is one-to-one (bijective), this property is not shared by the Jacobi metric picture where not every piecewise geodesic motion on the Jacobi space corresponds to the physical motion of the system;
(iii) Eisenhart's proposal seems to be the right way to desingularize motion in the Jacobi metric (e.g., the dynamics of homogeneous cosmological models near the initial singularity) which is nontractable in the Jacobi picture;
(iv) the interrelation between Jacobi's and Eisenhart's pictures is displayed; the latter produces a quotient structure $\mathcal{M}_{\mathrm{Eis}}/G_u$, where G_u is the translation group with respect to the fictitious ''time'' variable u.

As indicated by the line consequently developed in a series of the papers[3,19] our ultimate goal is to provide a geometrical model of the dynamics of mechanical systems which would be useful both for analytical and numerical analysis of complex motions. Special emphasis is put on the invariant indicators of sensitive dependence on initial conditions. Moreover, we find it attractive to see the dynamics of mechanical systems as geodesics in space–times. One can imagine the behavior of a simple mechanical system as a motion of a particle in a certain effective potential. This way of building up physical intuition permits most of the classical physics (including classical field theory). However, one can reproduce such motions in potential wells as the free (geodesic) motions in some fictitious spaces or space–times. This leads us to Eisenhart's geometry—the subject of this paper—in which the motion of a fictitious particle (representing state of the system) is governed by the Fermat principle of the shortest arrival time. The classical results concerning the formulation of dynamics in terms of Riemannian geometry can be found in Ref. 20.

Recently this principle has been extensively used by Pettini *et al.*[21,22] in their efforts to develop appropriate geometric tools for investigating the deterministic chaos and its connections with the foundations of statistical mechanics. Eisenhart's principle is very promising in the sense of being free from many of problems inherent to the standard (Maupertuis–Jacobi) approach. This principle states that the trajectories of SMS are geodesics in a certain $n+1$-dimensional space where the additional dimension is a fictitious one. In other words the motion of SMS can be represented as a free motion in a certain fictitious "space–time" in which the additional dimension is treated as "time."

In Sec. II, we show the existence and uniqueness of geodesics of the Jacobi metric passing through the singular boundary on which the conformal factor $|f|$ vanishes, and the metric $\overline{g}$ is degenerate. In Sec. III, we study trajectories of simple dynamical systems to formulate the generalized Maupertuis–Jacobi theorem. In Secs. IV–VII the advantages and obstacles of the formulation of dynamics in terms of the Eisenhart geometry are presented. It is pointed out that this approach is attractive in the context of the formulation of a local instability criterion. In Sec. VIII we find the one-to-one correspondence between the trajectories of simple mechanical systems and trajectories of particles or photons in the stationary space–times. In Sec. IX the interconnections between integrability of the original dynamics and integrability in its different models is given. In Sec. X we summarize our main results.

II. THE EXISTENCE AND UNIQUENESS OF GEODESICS OF THE JACOBI GEOMETRY THROUGH THE CONFORMAL SINGULARITY

Let us consider a pair (M,g), where M is a smooth manifold M and g a smooth semi-Riemannian metric on M. Let also $\overline{g}=fg$ be a conformal metric on M with $f:M\to\mathbf{R}$ being a smooth function on M. On the set Ξ of points in M at which the function f vanishes the metric $\overline{g}$ is degenerate; this set is called a *conformally singular set*.

Lemma 1: If $\dim M>1$, *and zero is a regular value of f (i.e., for every* $p\in M$ *such that* $f(p)=0$, *one has* $(df)_p\neq 0$*), the conformally singular set* $\Xi=f^{-1}(0)$ *is closed and is a boundary in M.*

Proof: The set Ξ is a $((\dim M)-1)$-dimensional submanifold of M. □

Let us consider a manifold M carrying the metric $\overline{g}=fg$, where $f=2(E-V)$. We assume that $d_p(f)\neq 0$, i.e., that the particle does not enter tangentially into the conformally singular set Ξ. (There are systems in which such a particle tangentially enters the set Ξ, for instance dynamical systems of the mixmaster type in relativistic cosmology.[19] This phenomenon is connected with the appearance of chaos, e.g., in the series of the Kasner epochs.) For simplicity, let us assume that $(df)(v)>0$ (this is not a general restriction since we can always change the direction of motion, multiplying by -1).

Let us notice that Lemma 1 (and in particular the assumption that zero is a regular value of f) is not required in proofs in Sec. III.

Definition 1: A C^0*-curve* $\gamma:(-\epsilon,\epsilon)\to M$ *is a pregeodesic through* $p\in\Xi$ *if* $\gamma(0)=p$, *and* $\gamma|(-\epsilon,0)$ *and* $\gamma|(0,+\epsilon)$ *are pregeodesics in* $M\backslash\Xi$. *If* γ *is a geodesic in* $M\backslash\Xi$ *we call it geodesic through* $p\in\Xi$.

Recall that a pregeodesic in $\mathcal{M}$ is a smooth curve $\gamma:I\to\mathcal{M}$, $I\subset R$ which can be reparametrized to a geodesic.

Now we shall prove the following theorem.

Theorem 1: *For any* $\alpha\in\mathbf{R}\backslash\{0\}$, $v\in T_p\underline{M}$, *such that* $g(v,v)=0$, *and* $v(E-V)>0$, *there exists the unique geodesic of the connection* $\nabla^{\overline{g}}$,

$$\gamma:(-\epsilon,\epsilon)\to M$$

satisfying the following conditions:

(a) $|f|\circ\gamma(s)\gamma'(s)\to v$, for $s\to 0$;
(b) $|f|g(\gamma',\gamma')\equiv\alpha$, for $s\neq 0$ or $g_E(\gamma',\gamma')\equiv\alpha$, for $s\neq 0$;
(c) $|f|\circ\gamma>0$, for $s\neq 0$,

where $\nabla^{\overline{g}}$ denotes a Levi–Civita connection with respect to metric $\overline{g}$; and $v(f)=v\cdot\operatorname{grad} f$ represents a directional derivative along vector v (f is a smooth function).

In the proof of this theorem we shall use Larsen's theorem 4.1 (Ref. 23) which describes the behavior of geodesics in the neighborhood of conformally singular set. However, the present situation is essentially different from that investigated by Larsen. First, we are considering the behavior of geodesics with respect to the Jacobi metric in their passing through the singularity. Geodesics in our sense are more general than those of Larsen, namely, as geodesics we mean continuous curves which, beyond the singular set, are geodesics in the usual sense. Second, we show that a geodesic (with respect to the Jacobi metric) can pass through the singular set with an *a priori* chosen velocity v (not necessarily $v=0$, as in the Larsen case). Let us notice that for g positive definite, if $\alpha=0$, the existence of γ is violated, but this case is excluded by the condition of $v=0$, the uniqueness of γ is violated (the freedom remains to make an affine reparametrization), but this is excluded by the condition $v(E-V)>0$.

Proof: We shall construct a geodesic passing through the singular set by joining together two geodesics in the usual sense. Let $\alpha\in\mathbf{R}$, $v\in T_pM$, $p\in\Xi$, $g(v,v)=0$. Let us also assume that $v(f)=v(2(E-V))>0$. Of course, $(-v)(-f)>0$. From Larsen's theorem it follows that there exists the unique geodesics (with respect to the metric $\overline{g}$) $\tilde{\gamma}_1:[0,\epsilon]\rightarrow M$ such that

$$(1a)\quad (-f)\circ\tilde{\gamma}_1(s)\tilde{\gamma}_1'(s)\rightarrow -v,\quad \text{for}\quad s\rightarrow 0;$$

$$(2a)\quad -\overline{g}(\tilde{\gamma}_1',\tilde{\gamma}_1')\equiv\alpha,$$

$$(3a)\quad -f\circ\tilde{\gamma}_1>0.$$

Let $\gamma_1:(\epsilon,0]\rightarrow M$ be given by $\gamma_1(s)=\tilde{\gamma}_1(-s)$. It can be easily seen that formulas (1a) and (3a) lead to $(-f)\circ\gamma_1(s)\gamma_1'(s)\rightarrow +v$, for $s\rightarrow 0$ and $-f\circ\gamma_1>0$, respectively.

Once more, by using Larsen's theorem, we easily see that there exists the curve $\gamma_2:[0,\epsilon]\rightarrow M$ such that

$$(1b)\quad f\circ\gamma_2(s)\gamma_2'(s)\rightarrow v,\quad \text{for}\quad s\rightarrow 0;$$

$$(2b)\quad \overline{g}(\gamma_2',\gamma_2')\equiv\alpha,$$

$$(3b)\quad f\circ\gamma_2>0.$$

Now, we define the curve $\gamma:(-\epsilon,\epsilon)\rightarrow M$, where $p=\gamma(0)\in\Xi(M)$, by

$$\gamma(s)=\begin{cases}\gamma_1(s) & \text{for}\quad s\in(-\epsilon,0)\\ \gamma_2(s) & \text{for}\quad s\in[0,\epsilon)\end{cases}.$$

Let us notice that γ is a geodesic satisfying conditions (a)–(c) of the theorem. The uniqueness of γ is the consequence of Larsen's theorem, and it should be understood in the following sense: if $\sigma:(-\overline{\epsilon},\overline{\epsilon})\rightarrow M$ is another geodesic satisfying the above conditions then $\sigma=\gamma$ on $(-\overline{\epsilon},\overline{\epsilon})\cap(-\epsilon,\epsilon)$. □

We can also see that from (2a) and (2b) it follows that the velocity vector $\gamma'(s)$ changes the sector of the cone, when passing through the singular set (at $s=0$), i.e., if before reaching the singular set, $\gamma'(s)$ is timelike with respect to the metric $\overline{g}$, then after passing through the singular set it becomes timelike with respect to the metric $-\overline{g}$, i.e., spacelike with respect to the metric $\overline{g}$.

Let the symbol Im( ) denote an image of the set with respect to some mapping, then geodesics γ_1 and γ_2, out of which γ is composed, are such that Im γ_1 is a subset of the subspace $M_-:=\{x\in M: f(x)\leqslant 0\}$, and Im γ_2 is a subset of the subspace $M_+:=\{x\in M: f(x)\geqslant 0\}$.

Let us consider the classical case when g is a Riemann metric and one has $E-V\geqslant 0$. In this case, $g(v,v)=0$ implies that $v=0$, and consequently theorem 1 describes the behavior of the zero velocity geodesics in a neighborhood of the singular set. The condition $E-V\geqslant 0$ means that the geodesic formed from joining together the geodesics γ_1 and γ_2 is such that both Im γ_1 and Im γ_2 are subsets of M_+. From the uniqueness of this geodesic it follows that Im γ_1=Im γ_2, and

$\gamma_1(s)=\gamma_2(-s)$, for $s\in(-\epsilon,0)$. Therefore, the mechanical system approaches the singular set Ξ, attaining at it the zero velocity, and then goes back along the same trajectory. Such a behavior has been demonstrated by Kozlov, for libration motions, with the help of topological methods.[11,24] Examples of classical simple mechanical systems can be found in Refs. 3, 11.

III. TRAJECTORIES IN THE GENERALIZED MAUPERTUIS–JACOBI METRIC

Let $\gamma:I\to M$, where $I=(a,b)$, be a trajectory of a simple mechanical system, i.e., γ satisfies the Euler–Lagrange equation

$$\nabla_{\gamma'(t)}\gamma'(t)=-(\mathrm{grad}\,V)\gamma(t), \quad '\equiv\frac{d}{dt}, \tag{4}$$

with $t\in I$. Equation (4) is defined on the configuration space M (which is a smooth manifold) carrying the metric $g=(1/2)K(v,v)$, $v\in T_xM$, $x\in M$ (which in general is semi-Riemannian). There exists a differentially continuous (this means continuous on M and smooth on $M\backslash\Xi$) reparametrization of $\gamma(t)$, $\gamma_1(s)=\gamma\circ t(s)$, such that $\gamma_1(s)$ is a geodesic with respect to the Jacobi metric $g_E^J=2|E-V|$ (see Ref. 3).

Let us consider the global reparametrization given by

$$\frac{ds}{dt}=2|E-V(\gamma(t))|, \tag{5}$$

i.e.,

$$s=2\int_0^t|E-V(\gamma(t))|d\tau. \tag{6}$$

Let us further consider the set $I_0\subset I$ of singular parameter values of the curve $\gamma:I\to M$,

$$I_0=\{t\in I:\gamma(t)\cap\Xi\neq\emptyset\}=\{t\in I:E-V(\gamma(t))=0\}.$$

A priori we can distinguish the following cases:

(i) I_0 is a set of isolated points;
(ii) I_0 contains intervals and eventually isolated points;
(iii) $I_0=I$.

In each of these cases, we must reparametrize the curve $\gamma(t)$ so as to obtain a geodesic with respect to the Jacobi metric.

(i) In this case, one can see from Eq. (5) that $(ds/dt)|_{I\backslash I_0}\geqslant 0$ and $(ds/dt)|_{I_0}=0$, and we can define the function $t=t(s)$ which is the inverse function of $s=s(t)$. It can be seen that $\gamma_1(s)=(\gamma\circ t)(s)$ is a geodesic with respect to the metric $\overline{g}$.

(ii) Let, for simplicity, I_0 consist of one interval (α,β). In this case, the function $s=s(t)$ is constant on the interval I_0 and strictly increasing elsewhere. We define the function

$$s^*(t)=\begin{cases} s(t) & \text{for } t\leqslant\alpha \\ s(t+\beta-\alpha) & \text{for } t>\alpha \end{cases}. \tag{7}$$

This function is strictly monotonic, therefore $\gamma^*(s^*)=\gamma(t(s^*))$, where $t(s^*)$ is the inverse function of $s^*(t)$, is a geodesic with respect to the metric $\overline{g}$. If I_0 consists of more than one interval we proceed analogously. [Of course, the function $s^*(t)$ can be interpreted as a function of a parameter on the quotient space if the appropriate equivalence relation identifies points of the interval (α,β).] With isolated points of I_0 we proceed as in (i).

(iii) This is a ''singular case'' in which Im γ is contained in the set Ξ and $s\equiv 0$ (and evidently, as the assumption of Lemma 2.1 that zero is the regular value of f is not satisfied). Let us notice that if $V\equiv E$ on an open subset $U\subset M$ then $\overline{g}=0$ on U and all curves on U can be formally regarded as geodesics with respect to the Jacobi metric $\overline{g}$. [Of course, in this case the Maupertuis principle is devoid of any practical meaning since the solutions of the Euler–Lagrange equation are, from the beginning, (nontrivial) geodesics with respect to the original metric g.]

There are reasons to believe that the condition $I_0\subset I$ means the existence of a period in which trajectories of the system behave in a chaotic unpredictable manner. For instance, the evolution of the Bianchi IX world model, according to the first and second Belinsky–Khalatnikov–Lifshitz approximations, consists in periods of evolving along the boundary $V=E$ and oscillating around it.[25] The reparametrization given by (7) is of purely formal character; it reduces the function $s(t)$ to the strictly monotonic function $s^*(t)$. In this way we remove from our analysis a certain, maybe interesting, part of the evolution. However, it is justified because this part is beyond the control of the Jacobi metric. Moreover, this strategy could be regarded as an approximation of a complex (chaotic) behavior by the regular behavior.

We can see that in all cases the trajectory of the original simple mechanical system can be reparametrized to a geodesic with respect to the Jacobi metric. Therefore, we can formulate our main result.

Theorem 2 (Generalized Maupertuis–Jacobi Theorem): *Every trajectory of any simple mechanical system* (M,g,V), *where* $\dim M>1$, *is a pregeodesic with respect to the Jacobi metric* $g_E=2|E-V|g$ *of type (i) or (ii). Every pregeodesic with respect to the Jacobi metric passing through a point of the boundary set* Ξ *is a trajectory of the system* (M,g,V).

Let us notice that the reparametrization of trajectories of a simple mechanical system leads to geodesics with respect to the Jacobi metrics described in the preceding section.

In our model of dynamics the time parameter s is distinguished. It seems to be against the spirit of relativity; however, in agreement with Synge's intuition,[26] the natural parameter s, for classical mechanical systems, has to be regarded as the proper time of the system, analogously to the proper time of the relativity theory (which in this theory is naturally distinguished).

The aim of our construction of geometry of cosmological dynamics is to show the effectiveness of representing trajectories in terms of geodesics for description of complexity in its dynamical behavior. It is very important because the standard dynamical criteria, like the Lyapunov exponents or the Kolmogorov–Sinai entropy, depend on time parametrization. From the other hand one would like to regard the phenomenon of chaos as an intrinsic property of the system (or as an intrinsic property of the orbit which could be recognized by investigating a fragment of this orbit). Such chaos would be by definition invariant with respect to the change of variables (time and phase variables). It was demonstrated by Cornish and Levin[27] that fractal basin boundaries provide an important means of characterizing chaotic systems in an observer independent manner. In our case laws of dynamics are geodesics principles in the configuration space and there is no need for time (for deeper discussion of the role of time in the Jacobi geometry, see Ref. 17).

IV. EISENHART'S GEOMETRY AS A MODEL OF DYNAMICS

The Eisenhart principle states that there is a one-to-one correspondence between trajectories $q^i(t)$ of the system (1) and geodesics of the metric,

$$ds^2=g_{ij}dq^idq^j+\frac{1}{2(V(q)+b))}du^2, \tag{8}$$

where b is constant. The demand that trajectories are mapped bijectively into geodesics of the metric (8) and conservation of energy produce together the following three relations:

(i) The relation between coordinate time t and the metric interval s

$$t=as, \quad a=\text{const}; \tag{9}$$

(ii) The relation between the fictitious ''time'' u and time coordinate t,

$$\frac{du}{dt}=2(V(q)+b); \tag{10}$$

(iii) Interrelation between the constants a and b [obtained by combining (i), (ii), and the Hamiltonian constraint $\mathcal{H}=E-$conservation of energy],

$$\frac{1}{a^2}=g_{ij}\dot{q}^i\dot{q}^j+2(V(q)+b)=2(E+b). \tag{11}$$

Sometimes one may wish to map the trajectories into null geodesics in an extended configuration space. This is, of course possible but then relation (i) loses its sense since the metric interval is null, (ii) and (iii) hold as above but formally $a=\infty$ and hence $b=-E$. In the case of non-null geodesics the relation (ii) rewritten as

$$u=-2\int T dt+2(E+b)t \tag{12}$$

reveals the connection with the Hamilton–Jacobi principle (for details see Ref. 28).

Let us note that $ds^2\geqslant 0$, i.e., Eisenhart's metric (8) is definite for classical as well as relativistic systems in contrast with the Maupertuis–Jacobi principle where the Jacobi metric is indefinite for relativistic systems. It means that the geodesics of Eisenhart's metric are either spacelike or null.

The determinant of Eisenhart's metric is equal to $g^{\mathrm{Eis}}=(2(V(q)+b))^{-1}g$, hence if g_{ij} is Euclidean, g_{ij}^{Eis} will change its signature to Lorentzian whenever $V(q)+b<0$. Eisenhart's metric is singular at $V(q)=-b$. If we reduce the dynamics to null geodesics then $b=-E$ and in this case singularity of Eisenhart's metric coincides with that of the Jacobi metric. If the potential is bounded as in the case of a harmonic oscillator, then we can choose b so that $V(q)+b\neq 0$ and singularity is avoided. If the potential is not bounded then metric singularity inevitably occurs along certain codimension two hypersurfaces. In Eisenhart's geometry with $g_{ij}=\delta_{ij}$ (an appropriate extension to a general case is straightforward) nonzero components of the Riemann tensor are

$$R_{0i0j}=[8(b+V(q))]^{-3}\left[-3\left(\frac{\partial V}{\partial x^i}\right)^2+2(V(q)+b)\frac{\partial^2 V}{\partial x^i\partial x^j}\right] \tag{13}$$

and the Ricci scalar reads

$$R=\frac{(b+V(q))^{-2}}{m}\left[-\frac{3}{2}(\nabla V)^2+(V(q)+b)\Delta V\right], \tag{14}$$

where ∇ and Δ are operators of gradient and Laplacian in $\mathbf{R}^n$, respectively. The last formula remains valid for the general form of the metric g_{ij} with appropriate understanding of gradient and Laplacian. Thus it can be seen that the singular set $D_{\mathrm{sing}}=\{V(q)=-b\}$ introduces a host of curvature singularities. It means that if we wish to have a simple geometric interpretation (geodesics) of physical systems (with often a complex dynamical behavior) the price we have to pay is the appearance of singular structures as was the case in Jacobi geometry. However, Eisenhart's approach has an advantage that the metric g^{Eis} is not singular on crossing D_{sing} in the same manner like the Jacobi metric g^J was along ∂D when the conformal factor was zero. Now, only one component (g_{00}^{Eis}) changes its sign across D_{sing} thus changing the signature of g^{Eis}. Such a behavior is more familiar and can become tractable, as it will be commented later on. Moreover by appropriate choice of the constant b one can move the singular set outside the domain of one's interests (in the Jacobi geometry ∂D was fixed by fixed E) and in the case when $V(q)$ is bounded the problem can be even desingularized.

Let us note that formulas (13) and (14) are explicitly independent of dimension of the space. One can also see that in the vicinity of critical points of the potential the sign of the Ricci scalar is determined by the Laplacian $\Delta V(q)$, i.e., it is negative in the neighborhood of the maximum and positive near the minimum. These properties are the same as for the Ricci scalar in the Jacobi geometry. In the particular case when the potential is a harmonic function the Ricci scalar takes a simple form

$$R=-\tfrac{3}{2}(\nabla \ln V(q))^2, \tag{15}$$

i.e., it is negative everywhere independently of the number of dimensions.

V. MINISUPERSPACE AS A SPACE OF GEODESICS IN EISENHART'S GEOMETRY

The notion of minisuperspace $\mathcal{MS}$ has been introduced about 20 years ago with the aim of providing an adequate state space for the construction of a wave function for gravity under the restriction to homogeneous degrees of freedom.[12] In particular homogeneous anisotropic cosmological models can be viewed as geodesics on this minisuperspace. The minisuperspace is also a natural setting for studying chaos because the evolution equations provided by the Einstein field equations reduce here to the ordinary differential equations. In the case of a full superspace, one could expect complex spatiotemporal behavior leading to the so-called metric turbulence.

The division between space and time in general relativity comes through foliating the space–time manifold M^4 into spacelike hypersurfaces Σ_t. The metric $g_{\mu\nu}$ on M^4 induces a metric γ_{ij} on Σ_t (the first fundamental form of Σ_t) and can be parametrized in the form

$$g_{\mu\nu}=\begin{pmatrix} N_iN^i-N^2 & N_j \\ N_i & \gamma_{ij}\end{pmatrix},$$

where N and N_i are called a lapse function and a shift vector, respectively. In the $3+1$ ADM formalism, dynamical evolution of geometries (three-metrics $g_A=\gamma_{ij}$) on spacelike hypersurfaces of constant time Σ is governed by the Hamilton equations derived from the Hamiltonian[12]

$$\mathcal{H}=\tfrac{1}{2}G_{ijkl}\pi^{ij}\pi^{kl}+V_G, \tag{16}$$

where $G_{AB}=G_{ijkl}=\frac{1}{2}(\gamma_{ik}\gamma_{jl}+\gamma_{il}\gamma_{jk}-\gamma_{ij}\gamma_{kl})$ is the ultralocal metric on $\mathcal{MS}$, the potential is equal $V_G=\frac{1}{2}\gamma^{(3)}R$, where ${}^{(3)}R$ is the Ricci scalar on Σ. The momenta π_{ij} are defined as equal to the second fundamental form on Σ_t: $\pi_{ij}=(1/2N)(N_{i|j}+N_{j|i}-(\partial\gamma_{ij}/\partial t))$ and '$|$' denotes covariant differentiation with respect to γ_{ij}.

Our idea is to transfer the classical construction of Eisenhart's geometry to the minisuperspace. Eisenhart's metric can be viewed as "static" with respect to an additional dimension u treated as a new "time" dimension (G_{00}^{Eis} component refers to this dimension). This extended minisuperspace $\mathcal{MS}^{\mathrm{Eis}}$ admits a Killing vector $\xi_u^\alpha=\delta_0^\alpha$ which is associated with cyclic nature of variable u. In other words $\mathcal{MS}^{\mathrm{Eis}}$ is invariant with respect to translation group $G_u: u\to u+\Delta u$. We can use this fact to build a quotient structure $\mathcal{MS}^{\mathrm{Eis}}/G_u$ with the property that homogeneous cosmological solutions are geodesics on this space. One can show that the metric on this quotient space is

$$d\hat{s}^2=\frac{1+a^{-2}G_{00}^{\mathrm{Eis}}}{-G_{00}^{\mathrm{Eis}}}dl^2, \tag{17}$$

where $dl^2=G_{AB}dg^Adg^B$. If we reduce the problem to null geodesics, i.e., formally $a=\infty$ the metric (17) takes the form of so called optical metric. (A similar construction but for a different purpose has been used by Abramowicz *et al.*[29]) It means that the reduction of $\mathcal{MS}^{\mathrm{Eis}}$ to lower dimensional space occurs according to Fermat's principle; null geodesics in a space $(\mathcal{MS}^{\mathrm{Eis}},G^{\mathrm{Eis}})$

with topology $\mathcal{MS}^{\mathrm{Eis}}=R\times\mathcal{MS}$ will be projected to $\mathcal{MS}$. The metric on $\mathcal{MS}$ is $(G_{AB}/-G_{00})$ and hence the affine parameter λ along the geodesics is exactly the same as coordinate u.

The quotient structure can be identified with the Jacobi geometry with the metric $G^J_{AB}=2V_G G_{AB}$. Closer look at Misner's discussion of minisuperspace[12] reveals that it is exactly the Jacobi geometry with $E=0$. However the occurrence of metric singularities on the set $\partial D=\{V_G=0\}$ is the major obstruction against this idea.

Let us consider a class of homogeneous cosmological models which admit the Hamiltonian formulation (i.e., Bianchi class A types, see also Ref. 30 for Hamiltonian formulation of class B models). In Bogoyavlenskii coordinates[31] we have

$$\mathcal{H}=T(p_i,q_j)+\tfrac{1}{4}V_G(q^i),$$

$$T(p_i,q_j)=2\sum_{i<j}^{3} p_i p_j q_i q_j-\sum_{i=1}^{3} p_i^2 q_i^2,$$

$$V_G(q_i)=2\sum_{i<j}^{3} n_i n_j q_i q_j-\sum_{i=1}^{3} n_i^2 q_i^2, \tag{18}$$

where $n_i\in\{-1,0,+1\}$ are constants which distinguish between various Bianchi types. An important group of models in class A systems is represented by so called Mixmaster models $[B(\mathrm{IX})\text{—}n_1=n_2=n_3=1$ and $B(\mathrm{VIII})\text{—}n_1=n_2=-n_3=1]$. As it has been noticed by Misner, trajectories of these models near the initial singularity concentrate around $V_G\approx 0$. In the Jacobi picture (which is a standard view on the minisuperspace) the trajectories are thus concentrated around singularities of the Jacobi metric. If we represent the dynamics in Eisenhart's picture the problem disappears. As discussed in Sec. IV Eisenhart's metric changes its signature upon crossing the singular set $D_{\mathrm{sing}}=\{V_G(q)=-b\}$. Let us rewrite Eisenhart's metric as

$$ds^2_{\mathrm{Eis}}=2(V_g(q)+b)du^2+G_{AB}dg^A dg^B. \tag{19}$$

In this notation $V_G(q)+b$ plays the role of a lapse function which is positive for some $u>u_0$, zero for $u=u_0$, and negative for $u<u_0$. Hence Eisenhart's space is a space with a variable signature. Such spaces have been contemplated by Ellis *et al.*[32]

VI. LOCAL INSTABILITY OF BIANCHI IX MODELS

Appropriate tools for describing the local instability constitute a necessary prerequisite for discussing the sensitive dependence on initial conditions (SIDC). It is well known that Poincaré and Lyapunov have introduced two different notions of stability. (The discussion of various notions of stability can be found in Szebehely.[33]) Lyapunov was interested in the behavior of the separation vector connecting the points on neighboring trajectories labeled with the same value of time (or arc-length parameter). Poincaré, on the other hand, introduced what is now called orbital stability as measured by the normal component of the separation vector. In our approach we are using the notion of stability in the sense of Poincaré rather than the Lyapunov conception.

The great advantage of the geometrical model lies in a possibility of formulating the criteria of local instability in terms of geometrical invariants. The simplest (but qualitative) invariant measure of separation of initially close geodesics averaged over all two-directions containing tangent and normal vectors is the Ricci scalar R. Since Eisenhart's metric is non-negatively defined, the (sufficient) criterion of local instability is very simple, $R<0$. Local instability implies the property of sensitive dependence on initial conditions.

Let us apply this criterion (in Eisenhart's picture) for dynamics of the Bianchi IX model near the initial singularity. Eisenhart's metric (8) has the following form:

$$ds^2 = G_{AB} dg^A dg^B + \frac{du^2}{2V(x,y,z) + a^{-2}}, \tag{20}$$

where $V(x,y,z) = \frac{1}{4}(2xy + 2xz + 2yz - x^2 - y^2 - z^2)$ is the potential in Bogoyavlenskii coordinates,[31] $g_A = \mathrm{diag}(x,y,z)$ and the minisuperspace metric G_{AB} is read off from the kinetic energy form

$$T = \frac{1}{4}\left(\frac{\dot{x}}{x}\frac{\dot{y}}{y} + \frac{\dot{x}}{x}\frac{\dot{z}}{z} + \frac{\dot{y}}{y}\frac{\dot{z}}{z}\right),$$

i.e.,

$$G_{AB} = \frac{1}{2xyz}\begin{bmatrix} 0 & z & y \\ z & 0 & x \\ y & x & 0 \end{bmatrix} \tag{21}$$

and if $V=0$, metric (20) is a Minkowski metric which is geodesically complete. Note that the b constant is determined by the Hamiltonian constraint to be $b = 1/2a^2$.

The Ricci scalar in Eisenhart's metric takes the form

$$R = -\frac{4a^2}{(1+2a^2V(x,y,z))^2}\{2(1+3a^2)V(x,y,z) + 3a^2[x^2V_{,x}^2 + y^2V_{,y}^2 + z^2V_{,z}^2]$$
$$+ 2V(x,y,z)(1+a^2V(x,y,z)) + 6a^2(xyV_{,x}V_{,y} + xzV_{,x}V_{,z} + yzV_{,y}V_{,z})\}.$$

It can be seen from the above formula that in the vicinity of $V(x,y,z) \approx 0$ states which correspond to a dynamical regime approximated by a series of the Kasner epochs, the Ricci scalar is negative and singularity-free. This allows us to hope that invariant description of the sensitive dependence on initial conditions in terms of curvature invariants of Eisenhart's metric is a right way to desingularize the standard Jacobi approach to minisuperspace.

VII. DESINGULARIZATION OF THE JACOBI METRIC THROUGH AN ADDITIONAL DIMENSION

As it was mentioned before the Jacobi metric is degenerate on the boundary $E - V(q) = 0$ of space admissible for motion which in turn leads to a metric singularity. The occurrence of the metric singularity is the major obstruction against the idea of using the sectional curvature in detecting local instability. Having the Jacobi metric $g_E^J = 2|E - V(q)|g$, one may perform an isometric embedding of the space with the Jacobi metric into the flat Euclidean space with the metric

$$ds^2 = g_{ij}dz^i dz^j + (z^{n+1})^2 - (z^{n+2})^2, \tag{22}$$

where

$$z^i = q^i\sqrt{2|E - V(q)|},$$

$$z^{n+1} = \tfrac{1}{2}(r^2 - 1)\sqrt{2|E - V(q)|},$$

$$z^{n+2} = \tfrac{1}{2}(r^2 + 1)\sqrt{2|E - V(q)|},$$

$$r^2 = g_{ij}q^i q^j.$$

The Jacobi geometry is now realized on the null cone

$$g_{ij}z^iz^j+(z^{n+1})^2-(z^{n+2})^2=0.$$

The vertex of the cone is the relic from the singular boundary set ∂D in the Jacobi metric.

On the other hand there is a consistent description of calculations of the geometrical quantities and invariant functionals of the metric on the conical defects. To elucidate this problem, let us recall that a cone is everywhere flat space except the tip where its curvature R is singular. Obviously, calculations by means of standard formulas of the Riemannian geometry cannot reveal this δ-like singularity, and the other methods must be used to obtain a correct result (for details see Ref. 34). Therefore initially dangerous singularities of the Jacobi metric takes the weak form for which there is some procedure of regularization in calculation of invariants of curvature.

Let us consider the space $\mathcal{M}$ with Eisenhart's metric g^{Eis} for a simple indefinite mechanical system and because metric g^{Eis} is stationary with respect to a given timelike Killing vector Y, and $\mathcal{M}$ admits a global space–time splitting $U\times\mathbf{R}$ adapted to Y. Roughly speaking, this means that $\mathcal{M}$ admits a global coordinate system $(q_1,\ldots,q_n,u)$ with $(q_1,\ldots,q_n)\in U$ open subset of $\mathbf{R}^n$, $t\in\mathbf{R}$ and $Y=\partial/\partial u$. The Killing property of Y is given by the fact that the coefficients of the metric $\mathcal{M}$ do not depend on the ''time'' variable u. The existence of the Killing vector in turn can be used to build a quotient space $\mathcal{M}^{\mathrm{Eis}}/G_u$, where G_u is a group of symmetry generated by the Killing vector. The metric on $\mathcal{M}^{\mathrm{Eis}}/G_u$ can be established on the base of the following theorem:

Theorem 3 (A timelike extension of Fermat's principle in GR): *Let* $(\mathcal{M},g)$ *be a stationary space–time with a Lorentzian signature* $(-,+,\ldots,+)$ *then the problem of geodesics on* $(n+1)$*-dimensional space–time*

$$\delta\left(\int ds^2_{n+1}\right)=0$$

can be reduced to the geodesics problem on n-dimensional fictitious conformally rescaled Riemannian space with the metric

$$d\overline{l^2}=\frac{1+hg_{00}}{-g_{00}}dl^2,\quad \delta\left(\int d\overline{l^2_n}\right)=0,$$

where $dl^2=g_{ij}dq^idq^j$, $g=g_{00}du^2+dl^2$*—metric of space–time,* $h=\mathrm{const}$; *h is positive for timelike geodesics, negative for spacelike geodesics, and* $h=0$ *for null geodesics.*

If we put $h=a^{-2}$ we obtain n-dimensional metric on $\mathcal{M}^{\mathrm{Eis}}/G_u$. It is natural to identify this metric $d\overline{l^2}$ as the Jacobi metric for a simple mechanical system $2(E-V)g_{ij}$. After this comparison we can obtain a theorem which establishes one-to-one correspondence between trajectories of simple definite systems and trajectories of fictitious particles in space–time with the Eisenhart geometry.

VIII. TRAJECTORIES OF SIMPLE MECHANICAL SYSTEMS FROM THE MOTION OF A FICTITIOUS PARTICLE IN A STATIONARY BACKGROUND

The results of the previous section show that the study of a simple mechanical system can be translated into the study of the test particle and photon motion in space–times of general relativity. There are several advantages of doing so. The majority of problems can be reduced to problems of geodesic motions, for which the notion of differential geometry on manifolds often gives more transparent and deeper insight into the underlying symmetry. Moreover, a geodesic motion can be also formulated as a Hamiltonian system, and all the techniques of searching for integrals developed for Hamiltonian dynamics can be used to obtain integrals which do not admit an obvious geometrical interpretation.

On the metric manifold, metric (8) (not necessarily Riemannian) is written in the condensed form, and then the geodesic motion is determined by the Hamiltonian

$$\mathcal{H}=\frac{1}{2m}g(P,P)=\frac{1}{2m}g^{\mu\nu}P_{\mu}P_{\nu} \tag{23}$$

which is equivalent to the geometrical equations of motion in terms of covariant derivatives.

Let us consider a particle trajectory with the momentum components P^{μ} in the space–time manifold with coordinates x^{ν} ($\mu,\nu=0,...,3$ and $x^0=u$, $x^i=q^i$). The corresponding mass parameter m is given by the condition

$$m^2=-g_{\mu\nu}P^{\mu}P^{\nu}, \tag{24}$$

where m represents the rest mass.

From hereafter we assume that space–time $\mathcal{M}$ with Eisenhart metric has the Lorentzian signature $(-+++)$ (the minus sign refers to the ''time'' u direction). The results for the Euclidean signature can be reinterpreted in a simple way. Any trajectory $x^{\mu}(\lambda)$ may be conveniently regarded as an integral curve of the following equations:

$$m\frac{dx^{\mu}}{d\lambda}=P^{\mu}=g^{\mu\nu}P_{\nu}, \tag{25}$$

where λ is an affine parameter along geodesics, and P^{μ} is determined from Eq. (24) as a function of x^{ν}.

Without any loss of generality we can consider only the case of a stationary (static) metric (8). This metric is characterized by the existence of a timelike Killing vector K^{μ}. Thus, it is possible to choose a frame of reference with a fictitious time coordinate

$$x^0=u, \tag{26}$$

with respect to which we have $K^{\mu}=\delta^{\mu}_0$. This means that the corresponding partial derivative of the metric is zero, i.e., $\partial g_{\mu\nu}/\partial x^0=0$. Thus, the vector field P^{μ} is stationary, i.e., $\partial P^{\mu}/\partial x^0=0$. This allows us to include directly a projected trajectory given by

$$m\frac{dx^i}{d\lambda}=P^i, \tag{27}$$

into the n-dimensional quotient manifold $\mathcal{M}/\mathcal{G}$, where $\mathcal{G}$ is a group of ''time'' transformations $u\to u+\Delta u$. The coordinate Killing vector $(\partial/\partial u)$—the generator of the infinitesimal group of isometry—is associated with the action of this group.

This quotient manifold has an induced positively-defined metric with components γ_{ij} which can be read out from the full $(n+1)$-dimensional metric by decomposing it to the form

$$ds^2=g_{00}du^2+2g_{0i}du\,dx^i+\gamma_{ij}dx^idx^j=g_{00}du^2+\gamma_{ij}dx^idx^j=g_{00}du^2+dl^2.$$

This is equivalent to setting

$$g_{00}=A,\quad g_{0i}=0,\quad g_{ij}=\gamma_{ij}.$$

Now, let us introduce a new conformally modified positive definite metric

$$d\hat{l}^2=\hat{g}_{ij}dx^idx^j, \tag{28}$$

on the quotient $\mathcal{M}/\mathcal{G}$ space by setting

$$d\hat{l}^2=\frac{1+hg_{00}}{-g_{00}}dl^2, \tag{29}$$

where $h=$const. For a null geodesic $h=0$, whereas for timelike geodesics $h>0$, and $h<0$ for a spacelike one.

Our aim is to find one-to-one correspondence between the motion of particles or photons in space–time background and trajectories of a simple mechanical system. Thus, it is natural to compare the above metric with the Jacobi metric; then we obtain

$$\frac{1+hg_{00}}{-g_{00}}=2(E-V). \tag{30}$$

Metric (29) is a positive definite metric on the quotient space $\mathcal{M}/\mathcal{G}$ of the dimension n. The constant h in (29) is related to the proper energy defined as the total energy of the particle per its mass $\bar{E}=\mathcal{E}/m$. Notice that u is a cyclic coordinate for the system with Lagrangian $\mathcal{L}=(m/2)\times(ds/d\lambda)^2$.

Thus, the corresponding momentum has to be conserved

$$P_0=\frac{\partial\mathcal{L}}{\partial\left(\frac{du}{d\lambda}\right)}=mg_{00}\frac{du}{d\lambda}=-m\bar{E}=-m\frac{1}{\sqrt{h}}. \tag{31}$$

This implies the relation between h and $\bar{E}$,

$$\mathcal{E}=m\bar{E}=m\frac{1}{\sqrt{h}}\rightarrow h=\bar{E}^{-2}. \tag{32}$$

From (29), (30), and (32) we obtain

$$h=-a^2=\bar{E}^{-2}. \tag{33}$$

Let us notice that in the Eisenhart geometry we study the spacelike geodesics and thus $h<0$ or $\bar{E}$ is pure imaginary.

If $a\rightarrow\infty$, i.e., for the case of null geodesics we have $b=-E$ and $h=0$. Relations (32) and (33) establish the one-to-one correspondence between the Jacobi geometry of simple classical dynamical systems and the geometry of fictitious particles moving in the space–time with the Eisenhart metric.

In the special case $h=0$, the metric (29) coincides with the so-called Fermat or optical metric. Abramowicz *et al.*[29] studied the role of this optical reference geometry for describing a test particle trajectory in the conformally projected three-space with metric (29) for $h=0$. With such a projection in the static space–time null lines of the four-dimensional manifold correspond to the three-dimensional space geodesics. One can easily see this fact considering Fermat's principle in its relativistic formulation.[35] This principle states that if $\mathcal{M}=R\times\Sigma$ is a static space–time with the metric $g=g_{00}dt^2+g_{ij}dx^i dx^j$, where Σ is a 3-manifold of constant time with Riemannian metric ${}^{(3)}g$, and $g_{00}<0$ is a smooth function. Neither function g_{00} nor metric ${}^{(3)}g$ depend on t. Thus, the null geodesics of $(\mathcal{M},g)$, when projected onto Σ, are precisely the Riemannian geodesics of the 3-geometry

$$\left(\Sigma\ ,\frac{{}^{(3)}g}{-g_{00}}\right), \tag{34}$$

and, furthermore, the affine parameter λ (i.e., the arc length) along the projected geodesics in g metric is precisely the static time coordinate t measured along the null geodesics in $(\mathcal{M},g)$. The above principle has a simple generalization to the case of non-null geodesics.[36]

On the other hand, we can regard the variational principle in the reduced space

$$\delta\int d\hat{l}^2=0 \Leftrightarrow \delta\int n^2(x^1,\ldots,x^n)dl^2=0, \tag{35}$$

as the variational principle in geometrical optics considering the problem of a light beam in an inhomogeneous medium characterized by the refraction factor $n(x^j)$ in space with metric dl^2. Therefore, instead of studying the problem of geodesics (null, spacelike or timelike) in the Eisenhart metric, one can equivalently investigate the problem of geodesics in a Riemannian or pseudo-Riemannian manifold with metric (29). The possibility of such a reduction appears as a consequence of ''the static form'' of the space–time metric. From the mathematical point of view, the reduced space corresponds to the conformally adjusted quotient space metric.

IX. INTEGRABILITY OF DYNAMICS IN DIFFERENT GEOMETRIES

There are several definitions of integrability. Generally, integrability means that the system under consideration possesses a sufficiently large number of first integrals. To be more precise, a Hamiltonian system with n degrees of freedom is integrable if it possesses n functionally independent first integrals which are in involution or which form a solvable Lie algebra. It is necessary to specify a class of functions which contains these first integrals as well as to define a domain of their definition.

The Maupertuis or Eisenhart geometry are only some geometrical models of given dynamical behavior. Of course, a given dynamics can admit many models, and different time parameters can be distinguished by different models. The only fact that matters is the existence of an isomorphism between the original dynamics and its model. Unfortunately, discovering a certain property in one of the models (e.g., existence of a first integral) we also find that this property cannot necessarily belong to any model. However if we want to prove nonintegrability in the original dynamics it is enough to find a single model of this dynamics in which the system is nonintegrable.

In this section interconnections between the property of existence of the first integral in different Eisenhart and Jacobi geometries are considered. To illustrate this let us consider a special case of a simple mechanical system given by the Hamiltonian

$$H=\tfrac{1}{2}g^{\alpha\beta}p_\alpha p_\beta+V, \tag{36}$$

where $g^{\alpha\beta}$ is a constant metric. Let,

$$H^J=\frac{1}{4(E-V)}g^{\alpha\beta}p_\alpha p_\beta=E^J=\frac{1}{2} \tag{37}$$

be the Hamiltonian for the Jacobi flow on $\mathcal{M}_E$. Then one can formulate the following theorem:

Theorem 4: *If $F(q^\alpha,p_\alpha)$ is a first integral of (36) then F is the first integral of (37) for H^J* $=1/2$.

Proof: Let $F(q^\alpha,p_\alpha)$ be a first integral of (36). Then,

$$g^{\alpha\beta}p_\beta\frac{\partial F}{\partial q^\alpha}-\frac{\partial V}{\partial q^\alpha}\frac{\partial F}{\partial p_\alpha}=0.$$

Thus,

$$\frac{1}{2(E-V)}g^{\alpha\beta}p_\beta\frac{\partial F}{\partial q^\alpha}-\frac{1}{2(E-V)}\frac{\partial V}{\partial q^\alpha}\frac{\partial F}{\partial p_\alpha}=0,$$

and we can write for points on $\mathcal{M}_E$,

$$\frac{\partial H^J}{\partial p_\alpha}\frac{\partial F}{\partial q^\alpha}-\frac{\partial H^J}{\partial q^\alpha}\frac{\partial F}{\partial p_\alpha}=0$$

for $H^J=1/2$.

From the other hand one can also prove the following:

Theorem 5: *If $F(q^\alpha,p_\alpha)$ is a first integral of (37) then $F(q^\alpha,p_\alpha)$ is a first integral of (36) on set $\mathcal{M}_E=\{(q,p):E-V>0\}$.*

Proof: Because F is a first integral of (37), then

$$\frac{1}{4(E-V)}g^{\alpha\beta}p_\beta\frac{\partial F}{\partial q^\alpha}-\frac{1}{E-V}H^J\frac{\partial V}{\partial q^\alpha}\frac{\partial F}{\partial p_\alpha}=0.$$

Taking points $(q,p)\in\{H^J=1/2\}$ we obtain that

$$g^{\alpha\beta}p_\beta\frac{\partial F}{\partial q^\alpha}-\frac{\partial V}{\partial q^\alpha}\frac{\partial F}{\partial p_\alpha}=0,$$

i.e., that F is a first integral of (36) on $\mathcal{M}_E$.

Finally one can formulate the following conclusions concerning the property of existence of a first integral in the original SMS and its geometrical model based on the Jacobi geometry.

(1) The existence of a first integral of SMS gives us the first integral in the Jacobi geometry but they are only partial first integrals on the energy level $H^J=1/2$.
(2) The first integrals of H^J determines the first integrals of H (i.e., SMS) but they are only partial first integrals on set $H^J=1/2$.
(3) If we find a first integral F for Hamiltonian H^J (i.e., in the Jacobi geometry) and for any value of total energy E, i.e., $\forall E\in R$ the commutator $\{H^J,F\}=0$ then F is also the first integral of H.

The analogous relations can be established in Eisenhart's geometry model of dynamics. Let us consider the Hamiltonian for the Eisenhart metric in the unified form

$$H_E=\frac{1}{2}g^{\alpha\beta}p_\alpha p_\beta,\quad \alpha,\beta=1,...,n+1, \tag{38}$$

where metric $g^{\alpha\beta}$ has the block diagonal form

$$g^{\alpha\beta}=\left[\begin{array}{c|c} g_{ij} & \\ \hline & \frac{1}{2(V+b)}\end{array}\right].$$

One can consider, without loss of the generality, a special form of this metric, namely $g_{ij}=\delta_{ij}$. Then equations of motion take the form

$$\frac{dq^i}{ds}=p_i,\quad \frac{dp_i}{ds}=-\frac{\partial V}{\partial q^i}p_u^2,$$

$$\frac{du}{ds}=2(V+b)p_u,\quad \frac{dp_u}{ds}=0, \tag{39}$$

and

$$ds^2=g_{ij}dq^idq^j+\frac{1}{2(V+b)}du^2.$$

It is easy to notice that our system has the first integral $p_u = g_{uu} dq^u/ds = du/ds/[2(V+b)] = \text{const}$, which gives us the relation between the natural Eisenhart parameter and additional variable $u:(du/ds) \approx 2(V+b)$.

If the original SMS has a first integral, say $F(q^i, \dot{q}^i)$, then

$$\dot{q}^i \frac{\partial F}{\partial q^i} - \frac{\partial V}{\partial q^i} \frac{\partial F}{\partial \dot{q}^i} = 0, \tag{40}$$

where the dot denotes differentiation with respect to mechanical time t.

From (39) we obtain that $\dot{q}^i = p_i/a$ and $\dot{q}^i = \sqrt{2(E+b)}(dq^i/ds)$ which from (40) implies

$$\frac{1}{a^2} p_i \frac{\partial F}{\partial q^i} - \frac{\partial V}{\partial q^i} \frac{\partial F}{\partial p_i} = 0.$$

Therefore if we choose $a=1$ then the first integral of SMS $F(q^i, \dot{q}^i)$ gives us the first integral for geodesic motion in the Eisenhart geometry $\tilde{F}(q^i, p_i)$.

The advantage of Eisenhart's picture of dynamics is that the first integral of geodesic motion determines (in contrast to the Jacobi geometry) all first integrals of the original system. Therefore from searching the first integral for the geodesic flow we simply obtain first integrals of the original system. This fact is a consequence of the following theorem:

Theorem 6: *If $F(q^i, \dot{q}^i)$ is a first integral of equations of motion for SMS, then $F(q^i, \dot{p}_i)$ is a first integral of the Hamiltonian equation with the Eisenhart Hamiltonian $H_E = \frac{1}{2}[\Sigma p_i^2 + 2(V+b)p_u^2]$ which corresponds to $p_u = a^2$.*

Moreover, if $G(q^i, p_i)$ is a first integral of equations of motion for Hamiltonian H_E which is independent on u and p_u, then $G(q^i, \dot{q}^i)$ is the first integral of the original equations of motion for SMS.

Proof: The fact that $G(q^i, p_i)$ is the first integral for Hamiltonian H_E implies the relation

$$p_i \frac{\partial G}{\partial q^i} - \frac{\partial V}{\partial q^i} p_u^2 \frac{\partial G}{\partial p_i} = 0.$$

After substitution of (39) into above formula we obtain

$$a\dot{q}^i \frac{\partial G}{\partial q^i} - \frac{\partial V}{\partial q^i} \frac{p_u^2}{a} \frac{\partial G}{\partial \dot{q}^i} = 0.$$

Now if we put $p_u^2/a^2 = 1$ we obtain the condition for existence of the first integral of SMS.

It seems that our results concerning integrability in the original dynamics and in its models can be generalized to the case of any g_{ij}.

X. CONCLUSIONS

There are reasons to believe that Szydłowski *et al.*'s paper[3] together with the present work provide a strong mathematical basis for the Maupertuis principle as applied to simple mechanical systems. Until now this principle could be only used for $(E-V)>0$ which strongly limited its physical relevance. Now, this limitation has been removed, and in this way the Maupertuis principle has obtained the universal character. Theorem 2 reduces the investigation of the trajectories of a simple mechanical system to the problem of geodesics with respect to the Jacobi metric. These geodesics are obtained by ''gluing together'' two corresponding geodesics (in the usual sense). Owing to this procedure singular points are treated on equal footing with other (regular) points. The Maupertuis principle understood in this way has a global character. Moreover, as it was pointed out by Barbour[17] the Maupertuis principle is more general than Newton's laws since it is, in the natural way, valid also for relativistic systems, which is not true as far as Newton's laws are concerned.

It would be interesting to elucidate interconnection between the topology of the configuration space and the behavior of trajectories of relativistic mechanical systems. Such interconnections, for the case $E>V$ were investigated by Kozlov.[11]

We have demonstrated the attractiveness of Eisenhart's principle from the point of view of constructing invariant criteria of local instability in general relativity (at least as limited to homogeneous degrees of freedom). The key idea is to map the evolution of homogeneous three-metrics under the action of Einstein's equations to a geodesic motion in extended minisuperspace equipped with Eisenhart's metric. The correspondence between the Eisenhart and more familiar Jacobi pictures was discussed. The latter approach is known (together with associated problems) since seminal works of Wheeler and DeWitt[37] and Misner.[12] The transition between $\mathcal{MS}^{\mathrm{Eis}}$ and $\mathcal{MS}^{J}$ is accomplished by constructing a quotient space $\mathcal{MS}^{\mathrm{Eis}}/G_u$, where G_u is the group of translations in u.

We have shown that Eisenhart's approach effectively desingularizes the Jacobi geometry of the minisuperspace in the vicinity of $V\approx 0$ states. This is of a fundamental importance for analysis of Mixmaster cosmological models near the initial singularity. The dynamics of these models can be approximated by a series of Kasner epochs, for which $V\approx 0$. This condition has been creating serious difficulties for the Jacobi approach—the appearance of infinities in the geodesic deviation equation.

Eisenhart's metric can prove useful also on the ground of classical mechanical systems. In particular we are able to restate classical mechanical problems in terms of geodesic motion in a ''static space–time.'' It can produce a feedback between the results obtained in classical mechanics and theory of relativity to build up a better physical intuition of various problems. Appropriate results will be presented in separate papers.

Geometrization according to the Eisenhart's principle should be perceived in a wider context. Namely, one is able to build geometrical models of dynamics in different spaces, e.g., Euclidean, Riemannian, Weyl spaces with affine connection, Einstein–Cartan spaces with torsion, Finsler spaces, etc.[38] The effectiveness of using the Finsler spaces for geometrizing the dynamical problems in rotating frames, where centrifugal forces do not allow us to use the Maupertuis principle directly, was demonstrated by Pettini.[21]

Our considerations were strongly focused on the invariant measures of local instability. The sensitive dependence on initial conditions is the one of the properties appearing in the definition of chaotic behavior.[14] It has been stated by Wiggins as a demand that any two arbitrarily close points evolved under the action of a dynamical system should eventually diverge. This property depends on the metric structure of the space (and also on its topology) in which we embed the trajectories of the system. The advantage of such a formulation of the SDIC is that one is not demanding that the separation be exponentially fast. In fact there are known examples of chaotic systems where the divergence of trajectories is slower than exponential. Moreover the rate of separation depends on the choice of time variable which can be arbitrary in general relativity.

If we construct a geometric model of the dynamics then we can capture this beautiful mathematical idea of the SDIC (see Ref. 14) in terms of geometric curvature invariants. The main problem is to make these quantities regular, i.e., to circumvent the divergencies appearing as the artifacts of the construction. In this respect Eisenhart's picture (although not the only one or by no means the best one) is promising since it allows us to make the singular sets movable and sometimes even regularize the problem completely.

Although it was not our key point here the results of our paper could be perceived in the context of invariant characterization of chaos. Therefore some remarks are in order. It is known that in the case of a manifold without boundary local instability criterion for a geodesic flow can be formulated in terms of sectional curvatures[39] $K_{u;n}g(u,u)<0$, where $K_{u;n}$ is a sectional curvature in two directions spanned on a tangent vector u and a normal n to geodesic. The above condition can be formulated in a more practical way by means of invariant polynomials (one of which is the Ricci scalar). This should hold for every two-direction in every point of the manifold. Whenever $g(u,u)>0$, i.e., positive definite metric (e.g., Eisenhart's metric) or spacelike tangent vector, a standard instability criterion for geodesics is recovered meaning that the system has

SDIC property. Of course, it is not sufficient for chaos to occur. Namely, one demands that the invariant submanifolds be compact (or closed). In our example of the harmonic oscillator there is no chaos despite the negative curvature Eisenhart's space. The reason is that the Eisenhart's space is not compact here. One should stress that although the approach sketched above has already been discussed in the context of the Jacobi geometry by many people (including ourselves) it has not been properly appreciated that the whole idea does not work for spaces with boundaries. In such cases the boundary effects can (and often are) dominant. Moreover very little is known about mathematical properties of the manifolds with boundaries, so it is dangerous to transfer here the intuition acquired by studying smooth (and often compact) manifolds. The Eisenhart's geometry depicted in this paper has an advantage of being boundary free and one may hope that it points toward a right way to proceed in quest for geometric indicators of SDIC.

ACKNOWLEDGMENTS

The author would like to thank Professor A. Staruszkiewicz for constructing remarks clarifying and improving the presentation of our results (especially the nomenclature of definite and indefinite systems). The author is grateful to Professor S. Bazanski and Dr. A. Krawiec for many inspiring discussions. We extend Witten's proof on positive mass conjecture to five-dimensional Lorentzian manifolds with a rigorous treatment in mathematics. © *1999 American Institute of Physics.* [S0022-2488(99)00707-0]

I. INTRODUCTION

Let N be an $(n+1)$-dimensional Lorentzian manifold with Lorentzian metric $\tilde{g}$ of signature $(-1,1,...,1)$, which satisfies the Einstein equations

$$\tilde{R}_{\alpha\beta}-\frac{\tilde{R}}{2}\tilde{g}_{\alpha\beta}=T_{\alpha\beta}, \tag{1.1}$$

where $\tilde{R}_{\alpha\beta}$, $\tilde{R}$ are the Ricci and scalar curvatures of $\tilde{g}$, respectively, $T_{\alpha\beta}$ is a symmetric tensor field which is interpreted physically as the energy-momentum tensor of matter. Choosing an orthonormal frame $\{e_\alpha\}$ with e_0 timelike. Then, physically, T_{00} is interpreted as the local mass density, and T_{0i} is interpreted as the local angular momentum.

Definition 1.1: A spacelike hypersurface M of N is called asymptotically flat of order τ if there is a compact set $K\subset M$ such that $M-K$ is the disjoint union of a finite number of subsets $M_1,\ldots,M_k$—called the ''ends'' of M—each diffeomorphic to the complement of a contractible compact set in R^n. Under the diffeomorphism the metric of $M_l\subset N$ is of the form

$$g_{ij}=\delta_{ij}+a_{ij} \tag{1.2}$$

in the standard coordinates $\{x^i\}$ on R^n, where

$$a_{ij}=O(r^{-\tau}),\quad \partial_k a_{ij}=O(r^{-\tau-1}),\quad \partial_l\partial_k a_{ij}=O(r^{-\tau-2}). \tag{1.3}$$

Furthermore, the second fundamental forms of M satisfy

$$h_{ij}=O(r^{-\tau-1}),\quad \partial_k h_{ij}=O(r^{-\tau-2}). \tag{1.4}$$

We will often identify the end $M_l\subset M$ with the corresponding set $M_l\subset R^n$.

For spacelike asymptotically flat hypersurface M, we can define the total energy and the total momentum. These quantities include contributions from both the matter and the gravitational field itself. They are defined in each asymptotic end M_l as limits over the sphere $S_{R,l}$ of radius R in $M_l\subset R^n$.

Definition 1.2: Total energy of end M_l is defined as

$$E_l=\lim_{R\to\infty} C_n^{-1}\int_{S_{R,l}}(\partial_j g_{ij}-\partial_i g_{jj})d\Omega^i, \tag{1.5}$$

total linear momentum of end M_l is defined as

[a)]Electronic mail: xzhang@math08.math.ac.cn

$$p_{lk}=\lim_{R\to\infty} C_n^{-1}\int_{S_{R,l}} 2(h_{ik}-\delta_{ik}h_{jj})d\Omega^i, \tag{1.6}$$

where $C_n=4(n-1)\omega_{n-1}$. When the asymptotic order $\tau>(n-2)/2$, these quantities are finite, also Bartnik proved that E_l is independent on the choice of asymptotic coordinates.[1]

Definition 1.3: M is satisfied the dominant energy condition if for each point $p\in M$ and for each timelike vector e_0 at p, $T(e_0,e_0)\geqslant 0$ and $T(e_0,\ )$ is a nonspacelike covector, see Ref. 2. This has the following consequences: if $\{e_\alpha|\alpha=0,1,...,n\}$ is an adapted orthonormal frame field at p $\in M$ with e_0 normal to M and $e_1,\ldots,e_n$ tangent to M, then

$$T^{00}\geqslant|T^{\alpha\beta}|, \quad T^{00}\geqslant(T_i^0T^{0i})^{1/2}. \tag{1.7}$$

(Here, and henceforth, repeated indices are summed with Latin indices running from 1 to n and Greek indices running from 0 to n.)

Now we give the statement of n-dimensional (generalized) positive mass conjecture.

Positive Mass Conjecture I: Let N be an $(n+1)$-dimensional Lorentzian manifold with Lorentzian metric $\tilde{g}$ of signature $(-1,1,...,1)$, $M\subset N$ be an n-dimensional spacelike asymptotically flat hypersurface of order $\tau>(n-2)/2$. If the dominant energy condition holds on M, then, on each end M_l,

$$E_l\geqslant|P_l|\equiv\left(\sum_{k=1}^{n} p_{lk}^2\right)^{1/2}.$$

If $E_{l_0}=0$ for some l_0, then M has only one end and N is flat along M.

When the spacelike hypersurface is maximal, i.e., $H=0$, the (generalized) positive mass conjecture states that

Positive Mass Conjecture II: Let M be an n-dimensional asymptotically flat manifold of order $\tau>(n-2)/2$. If the scalar curvature $R\geqslant 0$, then, on each end M_l, $E_l\geqslant 0$. If $E_{l_0}=0$ for some l_0, then M is isomorphic to R^n.

In general relativity, space–time is a four-dimensional Lorentzian manifold, i.e., $n=3$, the positive mass conjecture was originally conjectured more than 30 years ago by physicists.[3] Subsequently, a great many people worked on this problem and proved various special cases. In 1978, Schoen and Yau used a geometrical method to prove this conjecture for the case of maximal spacelike hypersurface (Conjecture II).[4] Using an auxiliary equation introduced by Jang,[5] they generalized their proof to the nonmaximal spacelike hypersurface case (Conjecture I),[6] and finally solving this long-standing problem. They have also applied their method to prove the positive action conjecture.[7] Two years later, Witten presented a simple new proof of the Conjecture I by using spinors although several points of his argument come from physical intuition and require justification.[8] Soon later, Parker and Taubes gave a complete, rigorous and self-contained proof of the Conjecture I, based on Witten's formulation.[9] The higher dimensional positive mass conjectures have been studied only in the maximal hypersurface case (Conjecture II); Schoen gave a detail n-dimensional proof of his work with Yau which proved the Conjecture II through the use of volume minimizing hypersurface.[10] The proof they gave works for $n\leqslant 7$ in which dimensions they have complete regularity of volume minimizing hypersurfaces. Bartnik proved Conjecture II for n-dimensional spin manifolds following Witten's approach.[1]

However, it has not appeared in the literature for the proof of higher dimensional Positive Mass Conjecture I (nonmaximal hypersurface case). Although, in principle, Witten's proof carries over to all dimensions, by assuming a spin structure, there still exists one technical difficulty: How to prove positivity of induced metric $\langle,\rangle=(e^0.,)$ (see Sec. II for details) on spinor bundle along a spacelike hypersurface? When $n=3$, Parker and Taubes prove it in terms of representation of spin group $SL(2,C)\cong \mathrm{Spin}^0(3,1)$. We shall prove it for $n=4$ in terms of representation of spin group $HU(1,1)\cong\mathrm{Spin}^0(4,1)$ where H denotes the field of quaternious. We expect this fact is true for all spin group $\mathrm{Spin}^0(n,1)$ by direct calculations in the Clifford algebra which do not need to invoke special representations, and we shall address it elsewhere.

The positive mass conjecture for the five-dimensional Lorentzian manifold is interested in the context of the Kaluza–Klein theory. In this paper, we shall prove

Theorem 1.1: *Let N be a five-dimensional Lorentzian manifold with Lorentzian metric $\tilde{g}$ of signature $(-1,1,1,1,1)$, $M\subset N$ be a spin spacelike asymptotically flat hypersurface of the order $\tau>1$. If the dominant energy condition holds on M, then, on each end M_l,*

$$E_l \geqslant |P_l| \equiv \left(\sum_{k=1}^{4} p_{lk}^2 \right)^{1/2}.$$

If $E_{l_0}=0$ for some l_0, then M has only one end and N is flat along M.

We refer to Ref. 11 for the positive mass theorem on a class of ''modified asymptotically flat manifolds'' which satisfy ''modified energy condition,'' and to Ref. 12 for nonspin spacelike hypersurface in five-dimensional Lorentzian manifolds.

II. HU(1,1) REPRESENTATION AND SPINORS

In this section, we assume *N* is a five-dimensional Lorentzian manifold with Lorentzian metric of signature $(-1,1,1,1,1)$, and *M* is a spin spacelike hypersurface in *N*. We shall show there is a globally defined HU(1,1) bundle *S* along *M*. With the help of HU(1,1) Hermitian structure on *S*, we construct a subbundle of End(S) which is exactly the cotangent bundle of *N*. This gives a natural definition of Clifford multiplication, and induce a positively define Spin(4) invariant Hermitian metric on *S*. We describe them first at the level of linear algebra and then globally on the manifold *M*.

Denote *H* as the field of quaternious. The hyperunitary group HU(1,1) is defined to be the subgroup of GL$(2,H)$ that fixes the standard *H*-Hermitian symmetric form

$$(p,q)=\overline{p_1}\cdot q_1-\overline{p_2}\cdot q_2,$$

where $p=(p_1,p_2)^t$, $q=(q_1,q_2)^t\in H^2$. The group $\mathrm{HU}(1,1)=\mathrm{Spin}^0(4,1)$ is the double covering group of connected Lorentz group $SO(4,1)$, see Ref. 13, p. 272. Let *V* be the fundamental representation of HU(1,1) on H^2. For any $X\in\mathrm{End}(V)$, denote X^* the adjoint of *X* under HU(1,1) Hermitian structure. We note that any $A\in\mathrm{HU}(1,1)$ if and only if $AA^*=I$, $A^*A=I$. On End(V), we define the operator

$$RT(X)=\mathrm{Re}\{\mathrm{Trace}(X)\}. \tag{2.1}$$

Proposition 2.1: RT is well-defined, i.e., RT is independent on the choice of basis. Moreover, for any $X,Y\in\mathrm{End}(V)$,

$$RT(X^*Y)=RT(YX^*)=RT(XY^*).$$

Proof: Choosing a basis, we can write

$$X=\begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix}, \quad Y=\begin{pmatrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{pmatrix}.$$

Then,

$$X^*=\begin{pmatrix} \overline{x_{11}} & -\overline{x_{21}} \\ -\overline{x_{12}} & \overline{x_{22}} \end{pmatrix},$$

and

$$Y^*=\begin{pmatrix} \overline{y_{11}} & -\overline{y_{21}} \\ -\overline{y_{12}} & \overline{y_{22}} \end{pmatrix},$$

where x_{11}, x_{12}, x_{21}, x_{22}, y_{11}, y_{12}, y_{21}, y_{22} are quaternious numbers. We have $RT(X)=\mathrm{Re}(x_{11}+x_{22})$. Changing basis, *X* changes to $A^{-1}XA$ for some $A\in\mathrm{HU}(1,1)$. So, for proving the first part of the proposition, we need only show that $RT(A^{-1}XA)=RT(X)$.

Let $A=\begin{pmatrix} a & b \\ c & d \end{pmatrix}$, then $A\in\mathrm{HU}(1,1)$ gives that

$$|a|^2-|b|^2=1, \quad |d|^2-|c|^2=1, \quad a\bar{c}-b\bar{d}=0.$$

We note that $\overline{xy}=\bar{y}\bar{x}$, $\mathrm{Re}(x)=\mathrm{Re}(\bar{x})$, $\mathrm{Re}(xy)=\mathrm{Re}(\overline{xy})$ for any quaternious numbers x, y. Therefore,

$$\begin{aligned}RT(A^{-1}XA)&=RT(A^*XA)\\&=\mathrm{Re}(\bar{a}x_{11}a-\bar{c}x_{21}a+\bar{a}x_{12}c-\bar{c}x_{22}c-\bar{b}x_{11}b+\bar{d}x_{21}b-\bar{b}x_{12}d+\bar{d}x_{22}d)\\&=\mathrm{Re}(|a|^2\overline{x_{11}}-|c|^2\overline{x_{22}}-|b|^2\overline{x_{11}}+|d|^2\overline{x_{22}}-c\overline{a x_{21}}+d\bar{b}\overline{x_{21}}+a\overline{c x_{12}}-b\bar{d}\overline{x_{12}})\\&=\mathrm{Re}(\overline{x_{11}}+\overline{x_{22}})=RT(X).\end{aligned}$$

For the proof of the second part, since

$$RT(X^*Y)=\mathrm{Re}(\overline{x_{11}}y_{11}-\overline{x_{12}}y_{12}-\overline{x_{21}}y_{21}+\overline{x_{22}}y_{22}),$$

$$RT(YX^*)=\mathrm{Re}(y_{11}\overline{x_{11}}-y_{12}\overline{x_{12}}-y_{21}\overline{x_{21}}+y_{22}\overline{y_{22}}),$$

$$RT(XY^*)=\mathrm{Re}(x_{11}\overline{y_{11}}-x_{12}\overline{y_{12}}-x_{21}\overline{y_{21}}+x_{22}\overline{y_{22}}).$$

Hence it follows. □

Corollary 2.1: On End(V), inner product

$$\langle X,Y\rangle=-\tfrac{1}{2}RT(X^*Y) \tag{2.2}$$

is independent on the choice of basis.

Set

$$\aleph=\{X\in \mathrm{End}(V):X=X^*\}. \tag{2.3}$$

It is independent on the choice of basis since $(A^*XA)^*=A^*X^*A=A^*XA$ for any $X\in\aleph$, $A\in \mathrm{HU}(1,1)$.

Proposition 2.2: On $\aleph$, $\mathrm{Trace}(X)$ *is independent on the choice of basis.*

Proof: Choosing a basis, let X be given by a matrix as above. Then, $X=X^*$ gives that $x_{11}=\overline{x_{11}}$, $x_{22}=\overline{x_{22}}$, $x_{12}=-\overline{x_{21}}$. Hence x_{11}, x_{22} are real numbers, and $RT(X)=x_{11}+x_{22}=\mathrm{Trace}(X)$. □

Proposition 2.3: Set

$$\aleph_0=\{X\in\aleph, \quad \mathrm{Trace}(X)=0\}, \tag{2.4}$$

then $(\aleph_0,\|\ \|)=(R^{4,1},\tilde{g})$, *where* $\tilde{g}$ *is the standard Lorentzian metric on* $R^{4,1}$.

Proof: Choosing a basis, and take $x_{11}=x_0$, $x_{22}=-x_0$, $x_{12}=x_1+x_2i+x_3j+x_4k\equiv x$, x_0, x_1, x_2, x_3, x_4 are all real numbers. It gives $X=X^*=\begin{pmatrix} x_0 & x\\ -\bar{x} & -x_0\end{pmatrix}$ for any $X\in\aleph_0$. Obviously, $\|X\|^2=\langle X,X\rangle=-x_0^2+x_1^2+x_2^2+x_3^2+x_4^2=\tilde{g}(X,X)$. Hence we can identify any $X=(x_0,x_1,x_2,x_3,x_4)\in R^{4,1}$ as an element in $\aleph_0$ with norm $\|X\|$, under a basis, which is given by the matrix

$$X=\begin{pmatrix} x_0 & x\\ -\bar{x} & -x_0\end{pmatrix}, \tag{2.5}$$

where $x=x_1+x_2i+x_3j+x_4k$. Moreover, this identification does not depend on the choice of basis. □

The spinors for $\mathrm{Spin}^0(4,1)=\mathrm{HU}(1,1)$ structure is defined by V. This space has a $\mathrm{HU}(1,1)$ invariant Hermitian inner product defined by

$$(\phi,\psi)=\overline{\xi_1}\cdot\eta_1-\overline{\xi_2}\cdot\eta_2 \tag{2.6}$$

for $\phi=(\xi_1,\xi_2)^t\in V,\ \psi=(\eta_1,\eta_2)^t\in V$. This inner product is not positive definite.

We define the Clifford multiplication map ‘‘.’’

$$.:R^{4,1}\otimes V\to V$$

$$X.\phi=X\phi,$$

where X is the correspondent element in $\aleph_0$ for point in $R^{4,1}$, choosing a basis, given by the matrix (2.5). Obviously, $X.Y.+Y.X.=-2\tilde{g}(X,Y)\cdot Id$. So by the universal property of Clifford algebra, the map ‘‘·’’ can be extended to a quaternious representation of Clifford algebra Cl(4,1), hence to the group HU(1,1).

Choosing an orthonormal basis $\{e_\alpha\}$ on $R^{4,1}$ with e_0 timelike, let $\{e^\alpha\}$ be its dual basis. The choice of a timelike covector e^0 yields a diagram

$$\begin{array}{ccc}\mathrm{Sp}(1)\times\mathrm{Sp}(1) & \overset{\hat\alpha}{\to} & \mathrm{HU}(1,1)\\ \rho_1\downarrow & & \downarrow\rho_2\\ \mathrm{SO}(4) & \overset{\alpha}{\to} & \mathrm{SO}(4,1),\end{array}$$

where the maps are defined as follows: write $x=x_1+x_2i+x_3j+x_4k\in H\cong R^4$, $X=\begin{pmatrix} x_0 & x\\ \bar{x} & -x_0\end{pmatrix}\in\aleph_0$ $\cong R^{4,1}$, for $p,q\in\mathrm{Sp}(1)$, $A\in\mathrm{HU}(1,1)$, $a\in\mathrm{SO}(4)$,

$$\rho_1((p,q))x=px\overline{q},\qquad \rho_2(A)X=AXA^*,$$

$$\hat\alpha((p,q))=\begin{pmatrix} p & 0\\ 0 & q\end{pmatrix},\qquad \alpha(a)X=\begin{pmatrix} x_0 & ax\\ -\overline{ax} & -x_0\end{pmatrix}.$$

The double-covering map ρ_1 is well-known. Now it is easy to check ρ_1 is also a double-covering map. Moreover, $d\rho_2:\mathrm{hu}(1,1)\cong\mathrm{so}(4,1)$ given by $d\rho_2(e^\alpha e^\beta)=2e^\alpha\wedge e^\beta$. Finally,

$$\rho_2\circ\hat\alpha((p,q))X=\begin{pmatrix} x_0 & px\overline{q}\\ -\overline{qxp} & -x_0\end{pmatrix}=\alpha\circ\rho_1((p,q))X.$$

The above diagram allows us to regard V as Spin(4)=Sp(1)×Sp(1) representation and gives V an another Hermitian structure. The Clifford multiplication $e^0=\begin{pmatrix}1 & \\ & -1\end{pmatrix}:V\to V$ gives an isomorphism $V\cong V$, the new Hermitian structure on V is given by this isomorphism together with the isomorphism $V\cong\overline{V}^*$ given by the HU(1,1) structure. In another word, there is another Hermitian inner product on V given by

$$\langle\phi,\psi\rangle=(e^0.\phi,\psi)=\overline{\xi_1}\cdot\eta_1+\overline{\xi_2}\cdot\eta_2 \tag{2.7}$$

for $\phi=(\xi_1,\xi_2)^t\in V,\ \psi=(\eta_1,\eta_2)^t\in V$. Hence this new inner product is positive definite and Sp(1)×Sp(1) invariant. Now it is easy to derive the following two propositions

Proposition 2.4: For any $X\in R^{4,1}$, spinors $\phi,\psi\in V$, we have $(X.\phi,\psi)=(\phi,X.\psi)$.

Proposition 2.5: For any $x=(x_1,x_2,x_3,x_4)\in R^4$ regarded as an embedding in $X=(0,x)\in R^{4,1}$, we have $\langle x.\phi,\psi\rangle=-\langle\phi,x.\psi\rangle$, and $\langle e^0.\phi,\psi\rangle=\langle\phi,e^0.\psi\rangle$.

If M is a spin spacelike hypersurface in N, the above algebra facts carry over to vector bundles once a spin structure is chosen. Let $F(N)$ denote the $SO(4,1)$ frame bundle of the cotangent bundle of N and let $i:M\to N$ be the inclusion. The required spin structure is a lift of the bundle $i^*F(N)$ to a HU(1,1) bundle over M. But

$$i^*F(N)=F(M)\times_\alpha SO(4,1),$$

so we need only lift the $SO(4)$ frame bundle of M to an Sp(1)×Sp(1) bundle $\widetilde{F(M)}$. The obstruction to such an $\widetilde{F(M)}$ is the Stiefel–Whitney class $\omega_2(M)$.

Since M is spin, $\omega_2(M)=0$, $\widetilde{F(M)}$ exists. The number of such lifts $\widetilde{F(M)}$ is then classified by $H^1(M,Z_2)$. Choosing one, we obtain the desired HU(1,1) bundle

$$i^*\widetilde{F(N)}=\widetilde{F(M)}\times_{\hat{\alpha}}\mathrm{HU}(1,1)$$

over M and the associated spin vector bundle

$$i^*\widetilde{F(N)}\times_\rho V=\widetilde{F(M)}\times_{\bar{\rho}}V,$$

where ρ is the representation V of HU(1,1), and $\bar{\rho}$ is its restriction to Sp(1)×Sp(1). This vector bundle—denoted S—carries the inner products (,) and ⟨,⟩. Sections of S are called hypersurface spinors along M. Proposition 2.3 implies $T^*N\cong\aleph_0(S)$, so the Clifford multiplication is globally-defined on M.

The metric connection $\tilde{\nabla}$ on $F(N)$ determines connections on $i^*\widetilde{F(N)}$ and its associated bundle. The resulting connection (also denoted) $\tilde{\nabla}$ on S is compatible with the metric (,) but not compatible with the metric ⟨,⟩. Let ∇ be the Riemannian connection on $F(M)$. It also induces a connection ∇ on $S=\widetilde{F(M)}\times_{\bar{\rho}}V$. We shall show that ∇ is compatible with ⟨,⟩.

Fix a point $p\in M$ and an orthonormal basis $\{e_\alpha\}$ of T_pN with e_0 normal and e_1, e_2, e_3, e_4 tangent to M. Extend e_1, e_2, e_3, e_4 to an orthonormal frame in a neighborhood of p in M such that $(\nabla_i e_j)_p=0$. Extend this to a local orthonormal $\{e_\alpha\}$ for N with $(\tilde{\nabla}_0 e_j)_p=0$. Let $\{e^\alpha\}$ be the dual coframe. Then

$$(\tilde{\nabla}_i e^j)_p=-h_{ij}e^0,\quad (\tilde{\nabla}_i e^0)_p=-h_{ij}e^j,$$

where $h_{ij}=\langle\tilde{\nabla}_i e_0,e_j\rangle$, $1\leqslant i,\ j\leqslant 4$, are the components of the second fundamental form at p. We have the following relations about two connections on S:

$$\tilde{\nabla}_i=\nabla_i+\tfrac{1}{2}h_{ji}e^0.e^j. \tag{2.8}$$

Proposition 2.6: The induced connection ∇ on S is compatible with the metric ⟨,⟩ and (,).

Proof: In the above frame we have,

$$\begin{aligned}d((\phi,\psi)*e_i)&=((\tilde{\nabla}_i\phi,\psi)+(\phi,\tilde{\nabla}_i\psi))*1\\&=((\nabla_i\phi,\psi)+(\phi,\nabla_i\psi)+(\tfrac{1}{2}h_{ij}e^0.e^j.\phi,\psi)+(\phi,\tfrac{1}{2}h_{ij}e^0.e^j.\psi))*1\\&=((\nabla_i\phi,\psi)+(\phi,\nabla_i\psi))*1.\end{aligned}$$

$$\begin{aligned}d(\langle\phi,\psi\rangle*e_i)&=d((e^0.\phi,\psi)*e_i)\\&=((-h_{ij}e^j.\phi,\psi)+(e^0.\tilde{\nabla}_i\phi,\psi)+(e^0.\phi,\tilde{\nabla}_i\psi))*1\\&=((-h_{ij}e^j.\phi,\psi)+(e^0.\nabla_i\phi,\psi)+(e^0.\phi,\nabla_i\psi)\\&\quad+(e^0.\tfrac{1}{2}h_{ij}e^0.e^j.\phi,\psi)+(e^0.\phi,\tfrac{1}{2}h_{ij}e^0.e^j.\psi))*1\\&=(\langle\nabla_i\phi,\psi\rangle+\langle\phi,\nabla_i\psi\rangle)*1.\end{aligned}$$

□

Finally, let $\Theta : R^4 - K_l \to M_l$ be the diffeomorphism which defines M_l. The pullback bundle $\Theta_l^* \widetilde{F(M)}$ is trivial over the end M_l and the bundle $\Theta_l^* S$ extends trivially over all of R^4. The Θ_l^{-1}—pullbacks of the constant sections of the bundle $R^4 \times S$ over R^4 then provide a set of ''constant spinors'' over the M_l.

III. THE WITTEN–DIRAC OPERATOR

In a local orthonormal coframe $\{e^i\}$ of M, Dirac operator D and the Witten–Dirac operator $\tilde{D}$ are defined by

$$D = e^i . \nabla_i , \quad \tilde{D} = e^i . \tilde{\nabla}_i ,$$

respectively, where ''.'' denotes Clifford multiplication. Obviously, D is self-adjoint under the metric $\langle , \rangle$. And we have the following Lichnerowicz formula:

$$D^* D = D^2 = \nabla^* \nabla + \frac{R}{4}, \tag{3.1}$$

where R is the scalar curvature of M.

Lemma 3.1: For any $\phi \in \Gamma(S)$, *we have*

$$\tilde{D} \phi = D \phi + \frac{H}{2} e^0 . \phi, \tag{3.2}$$

where $H = \Sigma h_{ii}$ *is the mean curvature of M.*

Proof: Since $h_{ij} = h_{ji}$, and $e^i . e^j . = - e^j . e^i .$, for $i \neq j$, then (2.8) gives

$$\tilde{D} \phi = e^i . \tilde{\nabla}_i \phi = e^i . \nabla_i \phi + \frac{1}{2} h_{ij} e^i . e^0 . e^j . \phi = D \phi + \frac{H}{2} e^0 . \phi.$$

In terms of (2.8), (3.2), we can prove

Lemma 3.2:

$$d(\langle e^i . \phi, \psi \rangle * e^i) = (\langle D \phi, \psi \rangle - \langle \phi, D \psi \rangle) * 1 = (\langle \tilde{D} \phi, \psi \rangle - \langle \phi, \tilde{D} \psi \rangle) * 1,$$

$$d(\langle \phi, \tilde{\nabla}_i \psi \rangle * e^i) = (\langle \tilde{\nabla}_i \phi, \tilde{\nabla}_i \psi \rangle - \langle \phi, (-\tilde{\nabla}_i + h_{ij} e^0 . e^j .) \tilde{\nabla}_i \psi \rangle) * 1.$$

Hence,

$$D^* = D, \quad \tilde{D}^* = \tilde{D}, \quad \tilde{\nabla}_i^* = -\tilde{\nabla}_i + h_{ij} e^0 . e^j .$$

Now we derive two Weitzenböck formulas, the second was given by Witten.[8,9]

Theorem 3.1: *For any* $\phi \in \Gamma(S)$,

$$\tilde{D}^2 \phi = \nabla^* \nabla \phi + \tfrac{1}{4}(R + H^2) \phi - \tfrac{1}{2} \nabla_i H e^0 . e^i . \phi \tag{3.3}$$

$$= \tilde{\nabla}^* \tilde{\nabla} \phi + \tfrac{1}{2}(T_{00} + T_{0i} e^0 . e^i .) \phi. \tag{3.4}$$

Proof: Since

$$\nabla_i(e^0.\phi)=(\tilde{\nabla}_i-\tfrac{1}{2}h_{ij}e^0.e^j.)(e^0.\phi)$$
$$=-h_{ij}e^j.\phi+e^0.\tilde{\nabla}_i\phi+\tfrac{1}{2}h_{ij}e^j.\phi$$
$$=e^0.(\tilde{\nabla}_i-\tfrac{1}{2}h_{ij}e^0.e^j.)\phi=e^0.\nabla_i\phi,$$

then Lemma 3.1 and the Lichnerowicz formula (3.1) show

$$\tilde{D}^2\phi=\left(D+\frac{H}{2}e^0.\right)\left(D\phi+\frac{H}{2}e^0.\phi\right)$$
$$=D^2\phi+\frac{H^2}{4}e^0.e^0.\phi+\frac{1}{2}e^i.\nabla_iHe^0.\phi$$
$$=\nabla^*\nabla\phi+\frac{R}{4}\phi+\frac{H^2}{4}\phi-\frac{1}{2}\nabla_iHe^0.e^i.\phi.$$

But

$$\tilde{\nabla}^*\tilde{\nabla}\phi=(-\tilde{\nabla}_i+h_{ij}e^0.e^j.)\tilde{\nabla}_i\phi$$
$$=(-\nabla_i+\tfrac{1}{2}h_{ij}e^0.e^j.)(\nabla_i\phi+\tfrac{1}{2}h_{ik}e^0.e^k.\phi)$$
$$=\nabla^*\nabla\phi-\tfrac{1}{4}h_{ij}h_{ik}e^j.e^k.\phi-\tfrac{1}{2}\nabla_i(h_{ij}e^0.e^j.\phi)+\tfrac{1}{2}h_{ij}e^0.e^j.\nabla_i\phi$$
$$=\nabla^*\nabla\phi+\frac{1}{4}\sum_{i,j}h_{ij}^2\phi-\frac{1}{2}\nabla_ih_{ij}e^0.e^j.\phi.$$

Therefore the second formula can be derived in terms of the following (Gauss and Codazzi) equations

$$T_{00}=\frac{1}{2}\left(R-\sum_{ij}h_{ij}^2+H^2\right),\quad T_{0i}=\sum_j\nabla_jh_{ij}-\nabla_iH.$$

□

The integral forms of Weitzenböck formula are

$$\int_M|\tilde{\nabla}\phi|^2+\langle\phi,\tilde{R}\phi\rangle-|\tilde{D}\phi|^2=\frac{1}{2}\int_{\partial M}\langle\phi,[e^i,e^j].\tilde{\nabla}_j\phi\rangle*e^i,\tag{3.5}$$

where $\tilde{R}=\tfrac{1}{2}(T_{00}+T_{0i}e^0.e_i.)$, and $[e^i,e^j]=e^i.e^j.-e^j.e^i.$

IV. BOUNDARY VALUE PROBLEM

In this section, we assume M is a spin spacelike asymptotically flat hypersurface of order $\tau>1$ in the five-dimensional Lorentzian manifold N. We shall study the infinity boundary value problem for the Witten–Dirac equation. We shall simplify the original arguments in Ref. 9.

First, we recall a lemma in Ref. 9, which can be easily extended to our case.

Lemma 4.1: Suppose M is asymptotically flat and ϕ, $\{\phi_i\}$ are C^1 hypersurface spinors along M which satisfy

$$\tilde{\nabla}\phi=0,\quad\tilde{\nabla}\phi_i=0\quad\textit{for each } i.$$

(i) *If $\lim_{x\to\infty}\phi(x)=0$, where the limit is taken along M in one asymptotic end, then $\phi=0$.*

(ii) *If $\{\phi_i\}$ are linearly independent in some end, then they are linearly independent everywhere on M.*

Proof: We sketch the proof in spirit of Ref. 9. (i) Since $\tilde{\nabla}\phi=0$, i.e., $\nabla_i\phi=-\frac{1}{2}h_{ij}e^0.e^j.\phi$, and $h=O(r^{-\tau-1})$, this gives $|d\ln|\phi||\leqslant Cr^{-\tau-1}$ on the complement of the zero set of ϕ. Integrating this along a path from $x_0\in M$ gives

$$|\phi(x)|\geqslant|\phi(x_0)|e^{C(|x_0|^{-\tau}-|x|^{-\tau})}.$$

Taking x to be the first zero of ϕ along the path of integration, or taking the limit as $|x|\to\infty$ if no such zero exists, shows that $\phi(x_0)=0$. Hence $\phi=0$ on the ends. On the compact set K, since h is bounded, we have

$$|\phi(x)|\geqslant|\phi(x_0)|e^{C(|x_0|-|x|)}.$$

Hence $\phi=0$ on K by taking the path to the ends. (ii) It follows from the first part. □

Now we define the weighted C^k space $C^k_\tau(S)$ as the set of C^k hypersurface spinors ϕ for which the norm

$$\|\phi\|_{C^k_\tau}=\sum_{i=0}^{k}\sup(r^{-\tau+i}|\nabla^i\phi|)$$

is finite. The weighted Hölder space $C^{k,\alpha}_\tau(S)$ is defined for $0<\alpha<1$ as the set of $\phi\in C^k_\tau(S)$ for which the norm

$$\|\phi\|_{C^{k,\alpha}_\tau}=\|\phi\|_{C^k_\tau}+\sup_{x,y}\left\{(\min\{r(x),r(y)\})^{-\tau+k+\alpha}\frac{|\nabla^k\phi(x)-\nabla^k\phi(y)|}{r(x,y)^\alpha}\right\}$$

is finite. Here, the supremum is over all $x\neq y$ such that y is contained in a normal coordinate neighborhood of x, and $\nabla^k\phi(y)$ is the spinor at x obtained by parallel transport along the radial geodesic from x to y. Note that the definitions of the weighted spaces depend on the "distance function" r, and thereby on a choice asymptotic coordinates. However, it is easy to see that r is uniformly equivalent to the geodesic distance from an arbitrary fixed point in M as $r\to\infty$, so all choices of r define equivalent norms.

If M is asymptotically flat of order $\tau>1$ with asymptotic coordinates $\{dx^i\}$ on the end. Orthonormalizing $\{dx^i\}$ yields an orthonormal coframe

$$e^i=dx^i+\tfrac{1}{2}a_{ik}dx^k+O(r^{-\tau-1}). \tag{4.1}$$

The connection coefficients of $\{dx^i\}$ are

$$\Gamma_{kjl}=\tfrac{1}{2}(\partial_j g_{kl}+\partial_l g_{kj}-\partial_k g_{jl})=O(r^{-\tau-1}),$$

thus we obtain

$$\nabla_j=\partial_j-\tfrac{1}{4}\Gamma_{kjl}dx^k.dx^l.+O(r^{-2\tau-1}). \tag{4.2}$$

Denote e^0 as dx^0, then

$$\tilde{D}=dx^j.\partial_j-\frac{1}{4}\Gamma_{kjl}dx^j.dx^k.dx^l.+\frac{H}{2}dx^0.+O(r^{-2\tau-1}). \tag{4.3}$$

Therefore $\tilde{D}$ gives the maps for the following weighted Hölder spaces:

$$C^{2,\alpha}_{-\tau}(S)\xrightarrow{\tilde{D}}C^{1,\alpha}_{-\tau-1}(S)\xrightarrow{\tilde{D}}C^{0,\alpha}_{-\tau-2}(S).$$

For constant spinor ϕ_0, $\partial_j\phi_0=0$, we have

$$\tilde{D}\phi_0=e^j.\nabla_j\phi_0+\frac{H}{2}e^0.\phi_0=-\frac{1}{4}\Gamma_{kjl}dx^j.dx^k.dx^l.\phi_0+\frac{H}{2}dx^0.\phi_0+O(r^{-2\tau-1}).$$

Hence $\tilde{D}\phi_0\in C^{1,\alpha}_{-\tau-1}(S)$, and $\tilde{D}^2\phi_0\in C^{0,\alpha}_{-\tau-2}(S)$.

Lemma 4.2: If M is asymptotically flat of order $\tau>1$ and the dominant energy condition holds on M, then the map

$$\tilde{D}^2:C^{2,\alpha}_{-\tau}(S)\rightarrow C^{0,\alpha}_{-\tau-2}(S) \tag{4.4}$$

is an isomorphism.

Proof: Note that $(\frac{1}{4}(R+H^2)-\frac{1}{2}\nabla_iHe^0.e^i.)\in C^{0,\alpha}_{-\tau-2}(S)$, thus we only need to show that the kernel of $\tilde{D}^2$ on $C^{2,\alpha}_{-\tau}(S)$ is trivial since, by (3.3) and Theorem 9.2(d),[14] the injectivity implies $\tilde{D}^2$ is an isomorphism. Let $\phi\in C^{2,\alpha}_{-\tau}(S)$ satisfy $\tilde{D}^2\phi=\tilde{\nabla}^*\tilde{\nabla}\phi+\tilde{R}\phi=0$. Then

$$\int_M|\tilde{\nabla}\phi|^2+\langle\tilde{R}\phi,\phi\rangle=\int_{\partial M}\langle\phi,\tilde{\nabla}_i\phi\rangle*e^i.$$

But $\langle\phi,\tilde{\nabla}_i\phi\rangle=\langle\phi,(\nabla_i\phi+\frac{1}{2}h_{ij}e^0.e^j.\phi)\rangle=O(r^{-2\tau-1})$, and $\mathrm{Vol}(\partial M)=O(r^{-3})$ by (1.2) and (1.3). Hence the right-hand side of the above integral vanishes. Therefore $\tilde{\nabla}\phi=0$ on *M*. Hence $\phi=0$ by Lemma 4.1 (i), and the proof of the lemma is complete. □

Theorem 4.1: *If M is asymptotically flat of order $\tau>1$ and the dominant energy condition holds on M, then for any constant spinor ϕ_0 on ends, the following boundary value problem has a unique solution $\phi\in C^{2,\alpha}(S)$:*

$$\begin{cases}\tilde{D}\phi=0\\ \lim_{r\rightarrow\infty}\phi=\phi_0.\end{cases} \tag{4.5}$$

Proof: Since $\tilde{D}^2\phi_0\in C^{0,\alpha}_{-\tau-2}(S)$. By Lemma 4.2, there is unique $\phi_1\in C^{2,\alpha}_{-\tau}(S)$ such that $\tilde{D}^2\phi_1=-\tilde{D}^2\phi_0$. Then $\phi=\phi_1+\phi_0$ satisfies $\tilde{D}^2\phi=0$. Let $\psi=\tilde{D}\phi\in C^{1,\alpha}_{-\tau-1}(S)$, then

$$\int_M|\tilde{\nabla}\psi|^2+\langle\tilde{R}\psi,\psi\rangle=\int_{\partial M}\langle\psi,\tilde{\nabla}_i\psi\rangle*e^i=\int_{\partial M}O(r^{-2\tau-3})=0.$$

Therefore $\tilde{\nabla}\psi=0$ on *M*. Hence $\psi=0$ by Lemma 4.1 (i). Thus ϕ is the unique solution of (4.5).□

V. POSITIVE MASS CONJECTURE

In this section, we shall prove the Positive Mass Conjecture.

Theorem 5.1: *Let N be a five-dimensional Lorentzian manifold with Lorentzian metric $\tilde{g}$ of signature (−1,1,1,1,1), $M\subset N$ be a spin spacelike asymptotically flat hypersurface of order $\tau>1$. If the dominant energy condition holds on M, then, on each end M_l,*

$$E_l\geqslant|P_l|\equiv\left(\sum_{k=1}^4 p_{lk}^2\right)^{1/2}.$$

If $E_{l_0}=0$ for some l_0, then M has only one end and N is flat along M.

Proof: For end M_l, let constant spinor $\phi_0 \neq 0$ on M_l, and $\phi_0 = 0$ on other ends. Denote $\phi = \phi_1 + \phi_0$, where $\phi_1 \in C^{2,\alpha}_{-\tau}(S)$, as the corresponding solution of (4.5) for this ϕ_0. Then (3.5) gives, under the coframe $\{e^i\}$ choosen in (4.1),

$$2\int_M |\tilde{\nabla}\phi|^2 + \langle \phi, \tilde{R}\phi\rangle = \int_{\partial M_\infty} \langle \phi, [e^i, e^j].\tilde{\nabla}_j \phi\rangle * e^i = \int_{\partial M_\infty} \langle \phi_0, [e^i, e^j].\tilde{\nabla}_j \phi_0\rangle * e^i + \sum ,$$

where

$$\begin{aligned}
\sum &= \int_{\partial M_\infty} (\langle \phi_1, [e^i, e^j].\tilde{\nabla}_j \phi_0\rangle + \langle \phi_0, [e^i, e^j].\tilde{\nabla}_j \phi_1\rangle + \langle \phi_1, [e^i, e^j].\tilde{\nabla}_j \phi_1\rangle) * e^i \\
&= \int_{\partial M_\infty} \langle \phi_1, [e^i, e^j].\nabla_j \phi_0\rangle * e^i + \int_{\partial M_\infty} \left\langle \phi_1, \frac{1}{2} h_{jk} [e^i, e^j].e^0.e^k.\phi_0 \right\rangle * e^i \\
&\quad + \int_{\partial M_\infty} \langle -\nabla_j \phi_0, [e^i, e^j].\phi_1\rangle * e^i + \int_{\partial M_\infty} d(\langle \phi_0, [e^i, e^j].\phi_1\rangle * (e^i \wedge e^j)) \\
&\quad + \int_{\partial M_\infty} \left\langle \phi_0, \frac{1}{2} h_{jk} [e^i, e^j].e^0.e^k.\phi_1 \right\rangle * e^i + \int_{\partial M_\infty} \langle \phi_1, [e^i, e^j].\tilde{\nabla}_j \phi_1\rangle * e^i \\
&= 2\,\mathrm{Re} \int_{\partial M_\infty} \langle \phi_1, [e^i, e^j].\nabla_j \phi_0\rangle * e^i + \int_{\partial M_\infty} \langle \phi_1, [e^i, e^j].\nabla_j \phi_1\rangle * e^i \\
&\quad + \mathrm{Re} \int_{\partial M_\infty} h_{jk} \langle \phi_1, [e^i, e^j].e^0.e^k.\phi_0\rangle * e^i + \frac{1}{2} \int_{\partial M_\infty} h_{jk} \langle \phi_1, [e^i, e^j].e^0.e^k.\phi_1\rangle * e^i.
\end{aligned}$$

Since $\phi_1 = O(r^{-\tau})$, $\nabla_j \phi_1 = O(r^{-\tau-1})$, $\nabla_j \phi_0 = O(r^{-\tau-1})$, and $h_{ij} = O(r^{-\tau-1})$, then $\Sigma = 0$. Now it is easy to see that $\langle \phi, e^i.e^j.\phi\rangle$ is pure imaginary for $i \neq j$. On the other hand, $|e^i - dx^i| = O(r^{-\tau})$, so we can replace the $\{e^i\}$ by $\{dx^i\}$ in the above integral without changing the value of the limit. And note $\Gamma_{kjl} = \Gamma_{klj}$, we obtain

$$\begin{aligned}
\int_M |\tilde{\nabla}\phi|^2 + \langle \phi, \tilde{R}\phi\rangle &= \frac{1}{2}\,\mathrm{Re} \int_{\partial M_\infty} (\langle \phi_0, [dx^i, dx^j].\tilde{\nabla}_j \phi_0\rangle + O(r^{-2\tau-1})) * dx^i \\
&= \mathrm{Re} \int_{\partial M_\infty} \left\langle \phi_0, -\frac{1}{4} \Gamma_{kjl} (\delta_{ij} + dx^i.dx^j.) dx^k.dx^l.\phi_0 \right\rangle * dx^i \\
&\quad + \mathrm{Re} \int_{\partial M_\infty} \left\langle \phi_0, \frac{1}{2} h_{jk} (\delta_{ij} + dx^i.dx^j.) dx^0.dx^k.\phi_0 \right\rangle * dx^i \\
&= \frac{1}{4}\,\mathrm{Re} \int_{\partial M_\infty} \langle \phi_0, (\Gamma_{jij} + \Gamma_{kjl} dx^i (2\delta_{jk} + dx^k.dx^j.) dx^l.)\phi_0\rangle * dx^i \\
&\quad + \frac{1}{2}\,\mathrm{Re} \int_{\partial M_\infty} \langle \phi_0, h_{jk} (\delta^{ij} + dx^i.dx^j.) dx^0.dx^k.\phi_0\rangle * dx^i \\
&= \frac{1}{4}\,\mathrm{Re} \int_{\partial M_\infty} \langle \phi_0, (\Gamma_{jij} + (2\Gamma_{jjl} dx^i.dx^l. - \Gamma_{kjj} dx^i.dx^k.))\phi_0\rangle * dx^i \\
&\quad + \frac{1}{2} \int_{\partial M_\infty} \langle \phi_0, (h_{ik} - \delta_{ik} h_{jj}) dx^0.dx^k.\phi_0\rangle * dx^i
\end{aligned}$$

$$=\frac{1}{4}\int_{\partial M_\infty}\langle\phi_0,(\gamma_{jij}-2\Gamma_{jji}+\Gamma_{ijj})\phi_0\rangle * dx^i$$

$$+\frac{1}{2}\int_{\partial M_\infty}\langle\phi_0,(h_{ik}-\delta_{ik}h_{jj})dx^0.dx^k.\phi_0\rangle * dx^i$$

$$=\frac{C_4}{4}(\langle\phi_0.E_l\phi_2\rangle+\langle\phi_0,p_{lk}dx^0.dx^k.\phi_0\rangle).$$

But $p_{lk}dx^0.dx^k.=(\begin{smallmatrix}0 & p_l\\ \bar{p}_l & 0\end{smallmatrix})$, where $p_l=p_{l1}+p_{l2}i+p_{l3}j+p_{l4}k$, has real eigenvalues $\lambda=\pm|P_l|$. Now we take ϕ_0 to be the eigenspinor of eigenvalue $-|P_l|$ with $|\phi_0|=1$. In terms of this constant spinor, we finally obtain

$$E_l-|P_l|=4C_4^{-1}\int_M|\tilde{\nabla}\phi|^2+\langle\phi,\tilde{R}\phi\rangle\geqslant 0.$$

Thus the proof of the first part is complete.

Now suppose $E_1=0$. Take constant spinors $\{\psi_{1c}|c=1,2\}$ which form a basis on M_1 and $\psi_{1c}=0$ on all other ends M_l. Let ψ_c be the solutions of $\tilde{D}\psi_c=0$ constructed from this data by Theorem 4.1. The vanishing of E_1 then implies $\tilde{\nabla}\psi_c=0$ and $\psi_c\to 0$ uniformly on each end except M_1. But this contradicts Lemma 4.1 (i) unless M_1 is the only end of M. By Lemma 4.1 (ii), $\{\psi_c\}$ are linearly independent everywhere on M, so in a local frame $\{e_i\}$ of M,

$$0=(\tilde{\nabla}_i\tilde{\nabla}_j-\tilde{\nabla}_j\tilde{\nabla}_i-\tilde{\nabla}_{[e_i,e_j]})\psi_c=-\tfrac{1}{4}\tilde{R}_{\alpha\beta ij}e^\alpha.e^\beta.\psi_c.$$

This implies

$$\tilde{R}_{\alpha\beta ij}=0,\quad 1\leqslant i,j\leqslant 4,\quad 0\leqslant\alpha,\beta\leqslant 4. \tag{5.1}$$

Then Einstein's equations give $T_{00}=\frac{1}{2}\Sigma\tilde{R}_{ijij}=0$. And the dominant energy condition shows $|T_{\alpha\beta}|\leqslant|T_{00}|=0$. Hence $\tilde{R}_{\alpha\beta}=0$. This together with (5.1) implies

$$\tilde{R}_{\alpha\beta\gamma\delta}=0,\quad 0\leqslant\alpha,\beta,\gamma,\delta\leqslant 4.$$

Therefore N is flat along M. And we complete the proof of Theorem. □

ACKNOWLEDGMENTS

(Received 11 July 1997; accepted for publication 10 March 1999)

We introduce a two-parameter deformation of 2×2 matrices without imposing any condition on the matrices and give the universal R-matrix of the nonstandard quantum group which satisfies the quantum Yang–Baxter relation. Although in the standard two-parameter deformation the quantum determinant is not central, in the nonstandard case it is central. We note that the quantum group thus obtained is related to the quantum supergroup $GL_{p,q}(1|1)$ by a transformation. © *1999 American Institute of Physics.* [S0022-2488(99)03806-2]

I. INTRODUCTION

Recently the matrix groups of all 2×2 nonsingular matrices like $GL(2)$, $GL(1|1)$, etc., were generalized in two ways as the standard deformation[1–3] and h-deformation.[4–7] Both are based on the deformation of the algebra of functions on the groups generated by coordinate functions that commute.

In standard deformation of matrix groups, these commutation relations are determined by a matrix R so that the functions do not commute but satisfy the equation

$$\hat{R}(T\otimes T)=(T\otimes T)\hat{R},$$

such that, they coincide with the matrix groups for particular values of the deformation parameter. In the h-deformation, this property is the same as the standard deformation. The structure of the matrix groups is important in both deformations since the classical (or super) matrix groups are obtained in some limit of the deformation parameters. In this work we shall construct a two-parameter deformation of 2×2 matrices without imposing any such condition on the matrices just as in Ref. 8 and obtain a two-parameter generalization of their results.

We briefly describe the content of this work. In Sec. II we introduce the group $G_{p,q}$ of the 2×2 matrices by using an R matrix. Section III is devoted to the corresponding Hopf algebra. In Sec. IV we give the universal enveloping algebra of this nonstandard quantum group.

II. $G_{p,q}$ MATRICES

Let

$$T=\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

be a 2×2 matrix with entries belonging to an algebra $\mathcal{A}$. We assume that the quantum group equation (no-grading)

$$\hat{R}(T\otimes T)=(T\otimes T)\hat{R} \tag{1}$$

holds, where

$$\hat{R}=\begin{pmatrix} -q & 0 & 0 & 0 \\ 0 & p^{-1}-q & 1 & 0 \\ 0 & qp^{-1} & 0 & 0 \\ 0 & 0 & 0 & p^{-1} \end{pmatrix}. \tag{2}$$

Equation (1) explicitly gives the following relations:

$$\begin{aligned} ab&=-qba, \quad db=qbd, \\ ac&=-pca, \quad dc=pcd, \\ bc&=pq^{-1}cb, \quad b^2=0=c^2, \\ ad&=da+(p^{-1}-q)bc, \end{aligned} \tag{3}$$

where p and q are nonzero complex numbers with $pq\pm 1\neq 0$.

It can be checked that the matrix $R=P\hat{R}$, where P is the usual permutation matrix, satisfies the quantum Yang–Baxter equation

$$R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12} \tag{4}$$

and the matrix $\hat{R}$ satisfies the braid group equation

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12}=\hat{R}_{23}\hat{R}_{12}\hat{R}_{23}. \tag{5}$$

We now assume that the matrix elements a and d of T are invertible. Then it is possible to define the inverse of T. To this end, we introduce

$$\Delta_1=ad-p^{-1}bc, \quad \Delta_2=da+q^{-1}cb. \tag{6}$$

Then one obtains

$$T_R^{-1}=\begin{pmatrix} \Delta_1^{-1}d & -q\Delta_1^{-1}b \\ p\Delta_2^{-1}c & \Delta_2^{-1}a \end{pmatrix}, \tag{7a}$$

as the right inverse of T. After some calculations we get

$$\Delta_1 d=d\Delta_1, \quad \Delta_2 a=a\Delta_2,$$

$$\Delta_k b=-q^2 b\Delta_k, \quad \Delta_k c=-p^2 c\Delta_k, \quad k=1,2.$$

Using these relations we obtain

$$T_L^{-1}=\begin{pmatrix} d\Delta_1^{-1} & q^{-1}b\Delta_2^{-1} \\ -p^{-1}c\Delta_1^{-1} & a\Delta_2^{-1} \end{pmatrix}=T_R^{-1}. \tag{7b}$$

Thus the proper left and right inverses of T are equal.

It is easily verified that $a^2\Delta_2^{-1}$ for all values of p and q, commutes with a,d, and anticommutes with b,c. Furthermore $a^2\Delta_2^{-1}$ is invertible. Therefore we obtain

$$S(T)=T^{-1}=\begin{pmatrix} d^{-1} & -a^{-1}ba^{-1} \\ -d^{-1}cd^{-1} & a^{-1} \end{pmatrix}\begin{pmatrix} d^2\Delta_1^{-1} & 0 \\ 0 & a^2\Delta_2^{-1} \end{pmatrix}. \tag{8}$$

We now consider the element

$$D(T)=ad^{-1}-bd^{-1}cd^{-1}=a^2\Delta_2^{-1}. \tag{9}$$

$D(T)$ cannot be regarded as a quantum determinant since it anticommutes with b and c. However, we may regard the element

$$\mathbf{D}(T)=a[D(T)-d^{-1}bd^{-1}c]d^{-1}=[D(T)]^2 \tag{10}$$

as the quantum determinant of T where $D(T)$ is given by (9).

In fact, it is easy to check that the matrix elements of the product matrix TT' satisfy relations (3) for any two commuting quantum matrices T and T' whose elements obey (3). As a consequence of this argument, we have the following relation:

$$D(TT')=D(T)D(T').$$

This result means that $\mathbf{D}(T)$ is central.

This case appears strange from the point of view of quantum group theory.[2] However, it becomes clear from the point of view of the corresponding two-parameter quantum supergroup.[9] We know, from the work of Ref. 9, that the quantum superdeterminant of any supermatrix in $GL_{p,q}(1|1)$ belongs to the center of the algebra generated by the matrix elements of the supermatrix. In the Appendix, we shall show that this nonstandard quantum group is related to the quantum supergroup $GL_{p,q}(1|1)$ by a transformation. So we may expect that the quantum superdeterminant in two-parameter nonstandard deformation must again be a central element.

Now let the nth power of T be

$$T^n=\begin{pmatrix} A_n & B_n \\ C_n & D_n \end{pmatrix}. \tag{11}$$

Then it is easy to check the following relations:

$$\begin{aligned} &A_nB_n=-q^nB_nA_n\,, \quad D_nB_n=q^nB_nD_n\,,\\ &A_nC_n=-p^nC_nA_n\,, \quad D_nC_n=p^nC_nD_n\,,\\ &B_n^2=0=C_n^2, \quad q^nB_nC_n=p^nC_nB_n\,, \end{aligned} \tag{12}$$

and

$$A_nD_n=D_nA_n+(p^{-n}-q^n)C_nB_n\,. \tag{13}$$

The proof of relation (13) is rather lengthy but straightforward.

Let us finally note the following. If the sum $T+T'$ of two $G_{p,q}$ matrices T and T' is required to be a $G_{p,q}$ matrix then the equation

$$\hat{R}'(T\otimes T')=(T'\otimes T)\hat{R}^{-1} \tag{14}$$

holds, where

$$\hat{R}'=\hat{R}^{-1}-(p-q^{-1})I. \tag{15}$$

Equation (14) explicitly reads

$$\begin{aligned} &a'a=pqaa', \quad dd'=pqd'd, \quad d'a=ad',\\ &b'a=-pab', \quad c'a=-qac', \quad bd'=pd'b,\\ &bb'=-b'b, \quad cc'=-c'c, \quad cd'=qd'c, \end{aligned}$$

$$a'b=-qba'+(p^{-1}-q)b'a, \quad a'c=-pca'+(pq-1)ac',$$
$$b'c=pq^{-1}cb'+(q^{-1}-p)ad', \quad bc'=pq^{-1}c'b+(p-q^{-1})d'a,$$
$$db'=qb'd+(q-p^{-1})bd', \quad dc'=pc'd+(pq-1)d'c,$$
$$a'd=da'+(p^{-1}-q)(bc'+b'c). \tag{16}$$

Note that the matrix $R'=P\hat{R}'$ again satisfies the quantum Yang–Baxter relation (4), where P is the usual permutation matrix.

III. THE HOPF ALGEBRA STRUCTURE OF $G_{p,q}$

Let $\mathcal{A}$ be an algebra generated by the elements a, b, c, and d satisfying the relations (3). Then $\mathcal{A}$ is the quoitent algebra

$$\mathcal{A}=\mathcal{C}[a,b,c,d]/J,$$

where $\mathcal{C}[a,b,c,d]$ is the free noncommutative algebra generated by a, b, c, and d and J is the ideal in $\mathcal{C}[a,b,c,d]$ generated by the relations (3).

The usual coproduct on the algebra $\mathcal{A}$ is defined by

$$\Delta:\mathcal{A}\rightarrow\mathcal{A}\otimes\mathcal{A}$$

such that

$$\Delta(t^i{}_j)=t^i{}_k\otimes t^k{}_j, \quad T=(T^i_j) \tag{17}$$

(sum over repeated indices) and the counit

$$\epsilon:\mathcal{A}\rightarrow\mathcal{C}$$

such that

$$\epsilon(t^i{}_j)=\delta^i{}_j. \tag{18}$$

The algebra $\mathcal{A}$ is now the matrix bialgebra generated by 1 and $T=(t^i_j)$, and it is a Hopf algebra with the antipode $S(T)$ which is given by (8). To give a proof of this, one has to verify the following:

$$(id\otimes\Delta)\circ\Delta=(\Delta\otimes id)\circ\Delta,$$
$$(id\otimes\epsilon)\circ\Delta=(\epsilon\otimes id)\circ\Delta, \tag{19}$$
$$m\circ[(id\otimes S)\circ\Delta]=m\circ[(S\otimes id)\circ\Delta],$$

where m denotes the multiplication mapping

$$m(a\otimes b)=ab$$

for any $a,b\in\mathcal{A}$. The proof follows directly.

IV. UNIVERSAL ENVELOPING ALGEBRA OF $G_{p,q}$

In this section we shall construct the quantum enveloping algebra in analogy with the FRT approach.[2]

We consider the matrices $L^{\pm}$ with the generators $U_{\pm}$, $V_{\pm}$, and $X_{\pm}$,

$$L^{+}=\begin{pmatrix} U_{+} & \lambda X_{+} \\ 0 & V_{+} \end{pmatrix}, \quad L^{-}=\begin{pmatrix} U_{-} & 0 \\ -\lambda X_{-} & V_{-} \end{pmatrix}, \tag{20}$$

where $\lambda = q - p^{-1}$. The matrices $L^{\pm}$ satisfy the following relations:

$$\hat{R} L_1^{\pm} L_2^{\pm} = L_2^{\pm} L_1^{\pm} \hat{R}, \tag{21}$$

$$\hat{R} L_1^{+} L_2^{-} = L_2^{-} L_1^{+} \hat{R}, \tag{22}$$

where $L_1 = L \otimes I$ and $L_2 = I \otimes L$. These relations give

$$\begin{aligned} &[U_+, U_-] = [V_+, V_-] = [U_\pm, V_\pm] = 0, \\ &U_+ X_\pm = -q^{\mp 1} X_\pm U_+, \quad V_+ X_\pm = q^{\mp 1} X_\pm V_+, \\ &U_- X_\pm = -p^{\pm 1} X_\pm U_-, \quad V_- X_\pm = p^{\pm 1} X_\pm V_-, \\ &X_+ X_- - q p^{-1} X_- X_+ = \frac{U_+ V_- - V_+ U_-}{q - p^{-1}}, \quad X_\pm^2 = 0. \end{aligned} \tag{23}$$

The coproduct of the generators is given by

$$\Delta(L^{\pm}) = L^{\pm} \dot{\otimes} L^{\pm}, \tag{24}$$

where $\dot{\otimes}$ denotes tensor product and matrix multiplication. Explicity, the action of the coproduct Δ on the generators is

$$\begin{aligned} \Delta(U_\pm) &= U_\pm \otimes U_\pm, \\ \Delta(V_\pm) &= V_\pm \otimes V_\pm, \\ \Delta(X_+) &= X_+ \otimes U_+ + V_+ \otimes X_+, \\ \Delta(X_-) &= X_- \otimes V_- + U_- \otimes X_-. \end{aligned} \tag{25}$$

The co-unit is given by

$$\epsilon(L^{\pm}) = I. \tag{26}$$

Explicitly,

$$\begin{aligned} \epsilon(U_\pm) &= \epsilon(V_\pm) = 1, \\ \epsilon(X_\pm) &= 0. \end{aligned} \tag{27}$$

The co-inverse is given by

$$\begin{aligned} &S(U_\pm) = U_\pm^{-1}, \quad S(V_\pm) = V_\pm^{-1}, \\ &S(X_+) = -U_+^{-1} X_+ V_+^{-1}, \\ &S(X_-) = V_-^{-1} X_- U_-^{-1}. \end{aligned} \tag{28}$$

Therefore one can easily verify that the algebra $\mathcal{U}_{p,q}(U_\pm, V_\pm, X_\pm)$ is a Hopf algebra generated by 1, $U_\pm$, $V_\pm$, $X_\pm$ satisfying the relations (23).

The coproduct of $U_\pm$ and $V_\pm$ together with the fact that they commute implies that they can be written as exponentials of commuting operators,

$$U_+=q^{-(H/2)}p^{(N/2)}, \quad U_-=p^{(H/2)}q^{-(N/2)},$$
$$V_+=q^{-(H/2)}p^{-(N/2)}, \quad V_-=p^{(H/2)}q^{(N/2)}, \tag{29}$$
$$[H,N]=0.$$

The commutation relations of $U_\pm$ and $V_\pm$ with $X_\pm$ in terms of new generators give the following:

$$[H,X_\pm]=\pm 2X_\pm, \quad [N,X_\pm]=0,$$
$$X_+X_- - qp^{-1}X_-X_+ = \left(\frac{p}{q}\right)^{(H+1)/2}[N]_{pq}, \tag{30}$$

where

$$[N]_{pq}=\frac{(pq)^{(N/2)}-(pq)^{(-N/2)}}{(pq)^{(1/2)}-(pq)^{(-1/2)}}. \tag{31}$$

Moreover, the coproduct is now

$$\Delta(H)=H\otimes \mathbf{1}+\mathbf{1}\otimes H,$$
$$\Delta(N)=N\otimes \mathbf{1}+\mathbf{1}\otimes N,$$
$$\Delta(X_+)=X_+\otimes q^{-(H/2)}p^{(N/2)}+q^{-(H/2)}p^{-(N/2)}\otimes X_+, \tag{32}$$
$$\Delta(X_-)=X_-\otimes p^{(H/2)}q^{(N/2)}+p^{(H/2)}q^{-(N/2)}\otimes X_-.$$

APPENDIX

A. Nonstandard quantum planes

In this section, we shall consider quantum planes which are similar to quantum superplanes introduced by Manin.[3]

(1) Quantum plane A_p: This plane, or, rather the polynomial function ring on it is generated by coordinates x and θ with the commutation rules

$$x\theta=-p\theta x, \quad \theta^2=0, \tag{A1}$$

where p is a complex number. The coordinates anticommute for $p=1$ and commute for $p=-1$.

(2) Quantum plane A_q^*: This plane is generated by coordinates φ and y with commutation rules

$$\varphi^2=0, \quad \varphi y=q^{-1}y\varphi, \tag{A2}$$

where q is a complex number. The quantum plane A_q^* is dual to the quantum plane A_p.

Note that the relations (A1) and (A2) are equivalent to the relations

$$\hat{R}(X\otimes X)=-q(X\otimes X),\quad \hat{R}(Y\otimes Y)=p^{-1}(Y\otimes Y).$$

B. Nonstandard quantum deformation of 2×2 matrices with nonstandard quantum planes

Let G be a matrix Lie group of rank 2 and T be any element of G, i.e.,

$$T=\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

with entries belonging to an algebra $\mathcal{A}$.

We consider linear transformations T with the following properties:

$$T:A_p\rightarrow A_p\,,\quad T:A_q^*\rightarrow A_q^*\,. \tag{A3}$$

The action of T on points of A_p and A_q^* is

$$\begin{pmatrix} \overline{x} \\ \overline{\theta} \end{pmatrix}=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} x \\ \theta \end{pmatrix},\quad \begin{pmatrix} \overline{\varphi} \\ \overline{y} \end{pmatrix}=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} \varphi \\ y \end{pmatrix}. \tag{A4}$$

We assume that the matrix elements of T commute with the coordinates of A_p and A_q^*. As a consequence of the linear transformations in (A3) the vectors $(\begin{smallmatrix} \overline{x} \\ \overline{\theta} \end{smallmatrix})$ and $(\begin{smallmatrix} \overline{\varphi} \\ \overline{y} \end{smallmatrix})$ should belong to A_p and A_q^*, respectively. This imposes (p,q) commutation relations among the entries of T in (3).

Note that it can be checked that the maps

$$\delta:A_p\rightarrow G\otimes A_p\,,\quad \delta^*:A_q^*\rightarrow G\otimes A_q^* \tag{A5}$$

such that

$$\delta(X)=T\otimes X,\quad \text{i.e.,}\quad \delta(x_i)=t_i^j\otimes x_j\,,\quad X=\begin{pmatrix} x \\ \theta \end{pmatrix},$$

$$\delta(Y)=T\otimes Y,\quad \text{i.e.,}\quad \delta(y_i)=t_i^j\otimes y_j\,,\quad Y=\begin{pmatrix} \varphi \\ y \end{pmatrix} \tag{A6}$$

define the co-action of the quantum group $G_{p,q}$ on the nonstandard quantum planes A_p and A_q^*, respectively.

Finally, one can show that the matrix quantum group (3) is isomorphic to the quantum supergroup $GL_{p,q}(1|1)$. Indeed, if we define the transformation

$$T'=TD, \tag{A7}$$

where T is a matrix whose the matrix elements satisfy (3) and

$$D=\begin{pmatrix} 1 & 0 \\ 0 & g \end{pmatrix},\quad D^2=I, \tag{A8}$$

and we assume that g commutes with a and d, and anticommutes with b and c, then $T'\in GL_{p,q}(1|1)$ as discussed in Ref. 9. In this case $\Delta(T')=T'\dot{\otimes}T'$, etc., are unchanged. One easily sees that when $p=q$, these relations go back to those of Ref. 8.

(Received 29 June 1998; accepted for publication 12 March 1999)

We present closed forms for the exponential of some infinitesimal generators of Lie groups which play an important role in physics and engineering applications. These explicit forms are based on the Putzer's method. We also compare this methodology and results with related work by other authors. © *1999 American Institute of Physics.* [S0022-2488(99)00607-6]

I. INTRODUCTION

Lie groups arise most often in engineering applications as the configuration space of mechanical systems and in physics as symmetry groups associated with conservation laws. We refer to Sattinger and Weaver,[1] for an introduction to the role of Lie groups in various fields of mathematics and physics. After Heisenberg in 1932, the neutron and the proton in nuclear physics started being treated as two states of an $su(2)$ doublet, the nucleon. In this sense, the proton and neutron are seen as families of particles that can be transformed into one another by the operations of the symmetry group SU(2). Later, the discovery of quarks from which other particles could be built, replaced the role of SU(2) by that of SU(3). The evolution of particle physics has led to the introduction of larger and more complex Lie groups. For instance, the 21-dimensional symplectic group $SP(3,\mathbb{R})$ is the dynamical group in the microscopic theory of nuclear collective motion (see, for instance, Rowe[2] for additional sources regarding the role of the symplectic group in physics). Many of these applications rely crucially on the use of the exponential mapping. Although the existence of an exponential mapping is guaranteed on any Lie group, finding a closed form for the exponential is a difficult issue. One way to circumvent this problem is by using approximation methods. We refer to the survey paper by Moler and Van Loan[3] for an account of several methods to compute the matrix exponential together with an analysis on the efficiency of the existing algorithms.

For some low-dimensional Lie groups however, there are explicit formulas for the exponential mapping, the most notable one being the Rodrigues' formula for the exponential on the rotation group $SO(3,\mathbb{R})$. The motion of a charged particle under the action of an electromagnetic field is given by a differential equation evolving on the Lorentz group $SO(1,3)$. For this Lie group, Zeni and Rodrigues presented in Ref. 4 an explicit formula for the exponential mapping. More recently we became aware of the work of Barut, Zeni, and Laufer,[5] generalizing the ideas in Ref. 4 to orthogonal groups and presenting a closed form for the exponential mapping for the conformal group O(2,4). As pointed out in their work, the Cayley–Hamilton theorem applied to the generators of orthogonal groups produces either even or odd powers, which amounts to a great simplification for the series defining the exponential. This remarkable characteristic of orthogonal groups is shared by other classical Lie groups as will be explained in Sec. II. Although in the present

paper the Cayley–Hamilton theorem also plays an important role, we take a different route from that of Barut, Zeni, and Laufer in Ref. 5 and use instead the Putzer's method.[6] This is key for finding closed forms for the exponential mapping on any matrix Lie group, without having to concern ourselves about the minimal polynomial of a matrix or its Jordan canonical form. One drawback in this method is that one assumes *a priori* that the eigenvalues of the matrix to be exponentiated are known. But this was also an assumption in the work of Barut, Zeni, and Laufer. In Sec. II we define a large class of Lie algebras having a symmetric spectrum. This class contains the Lie algebras that appeared in Refs. 4 and 5. The symmetric property of the spectrum considerably reduces the amount of work to be implemented. In Sec. III we briefly describe Putzer's algorithm and illustrate how to obtain closed forms for the exponential of infinitesimal generators for Lie groups playing a role in physics, including the 21-dimensional symplectic group.

II. PROPERTIES OF *P*-SKEW-SYMMETRIC MATRICES

Let $\mathcal{G}l(n,\mathbb{R})$ denote the set of all $n\times n$ matrices with real entries and P be any $n\times n$ orthogonal matrix, i.e., P satisfies $P^T=P^{-1}$. Define the following set:

$$G=\{X\in\mathcal{G}l(n,\mathbb{R}):X^TPX=P\}, \tag{1}$$

where X^T stands for the transpose X. G is an algebraic closed subgroup of the general linear Lie group $GL(n,\mathbb{R})$, consisting of the invertible matrices in $\mathcal{G}l(n,\mathbb{R})$, and so G is itself a Lie group (Helgason[7]). The infinitesimal generators of G are the matrices belonging to its Lie algebra. This Lie algebra can be identified with the tangent space of G at the identity I_n, that consists of all vectors that are tangent, at the identity, to curves $t\to X(t)$ in G, passing through the identity at time $t=0$. This geometric interpretation of the Lie algebra of a Lie group is enough to find the Lie algebra $\mathcal{L}$ of G. Indeed, differentiating both sides of $X^T(t)PX(t)=P$ with respect to t one gets

$$\frac{dX^T(t)}{dt}PX(t)+X^T(t)P\frac{dX(t)}{dt}=0.$$

Now evaluating at $t=0$ having into consideration that $X(0)=I$ and making $dX(t)/dt|_{t=0}=A$, it follows that the Lie algebra of G is defined by

$$\mathcal{L}=\{A\in\mathcal{G}l(n,\mathbb{R}):A^TP=-PA\}. \tag{2}$$

The Lie bracket on $\mathcal{L}$ is the commutator. It follows from the definition of $\mathcal{L}$ that, if $A\in\mathcal{L}$ then $A^T\in\mathcal{L}$. For the particular situation when $P=I$, $\mathcal{L}$ is the set of skew-symmetric matrices. From now on we will refer to the matrices in $\mathcal{L}$ as P-skew-symmetric.

Now consider the following set of matrices associated with $\mathcal{L}$:

$$\mathcal{J}=\{A\in\mathcal{G}l(n,\mathbb{R}):A^TP=PA\}. \tag{3}$$

It also happens that if $A\in\mathcal{J}$ then $A^T\in\mathcal{J}$. However, $\mathcal{J}$ is not closed under the commutator and so does not have the structure of a Lie algebra. Instead, $\mathcal{J}$ is closed under the product $\{A,B\}=AB+BA$ and possesses another interesting algebraic structure, namely the structure of a Jordan algebra. (For details concerning Jordan algebras see, for instance, Jacobson.[8]) When $P=I,\mathcal{J}$ is just the set of symmetric matrices. We will refer to the matrices in $\mathcal{J}$ as P-symmetric.

The matrices belonging to $\mathcal{L}$ and those belonging to $\mathcal{J}$ have remarkable properties. We start with a decomposition theorem that generalizes a very well known result in matrix theory, namely that every square real or complex matrix can be uniquely decomposed as the sum of a skew-symmetric matrix and a symmetric matrix.

Theorem 1: *If $P^2=\pm I$ and $\mathcal{L}$ and $\mathcal{J}$ are defined, respectively, by (2) and (3), then*

$$\mathcal{G}l(n,\mathbb{R})=\mathcal{L}\oplus\mathcal{J}. \tag{4}$$

Proof: Clearly $\mathcal{L}\cap\mathcal{J}=\{0\}$. Also any matrix $A\in\mathcal{G}l(n,\mathbb{R})$ may be written uniquely as

$$A=\tfrac{1}{2}(A-PA^TP)+\tfrac{1}{2}(A+PA^TP).$$

If we make $\frac{1}{2}(A-PA^TP)=A_1$ and $\frac{1}{2}(A+PA^TP)=A_2$, a trivial calculation shows that if $P^2=I$ then $A_1\in\mathcal{L}$ and $A_2\in\mathcal{J}$, while if $P^2=-I$ then $A_1\in\mathcal{J}$ and $A_2\in\mathcal{L}$. □

Lemma 2: If $A\in\mathcal{L}$ and $B\in\mathcal{J}$, then

(a) $A^{2j}\in\mathcal{J}$ and $A^{2j+1}\in\mathcal{L}$, $\forall j\in\mathbb{N}$;

(b) $B^j\in\mathcal{J}$, $\forall j\in\mathbb{N}$;

(c) $[\mathcal{L},\mathcal{L}]\subset\mathcal{L}$, $[\mathcal{L},\mathcal{J}]\subset\mathcal{J}$, $[\mathcal{J},\mathcal{J}]\subset\mathcal{L}$.

Proof: (a) May be easily proven by induction on *j*, (b) is a consequence of the fact that $\mathcal{J}$ is closed under $\{\cdot,\cdot\}$ and (c) follows easily from the definitions of $\mathcal{L}$ and $\mathcal{J}$. □

Theorem 3: *P*-skew symmetric matrices have a symmetric spectrum.

Proof: This is a consequence of the fact that if $A^TP=-PA$, then $\det(A-\lambda I)=(-1)^n\det(A+\lambda I)$. □

Corollary 4: If $A_{n\times n}$ is a P-skew-symmetric matrix, then

(a) trace $(A)=0$;

(b) If n is odd, $\det(A)=0$;

(c) The characteristic polynomial of A decomposes as

$$\det(A-\lambda I)=\lambda^r(\lambda^{2k}+C_2\lambda^{2k-2}+\cdots+C_{2k-2}\lambda^2+C_{2k}), \tag{5}$$

where r equals the number of zero eigenvalues of A and the coefficients $C_2,\ldots,C_{2k}$ may be written in terms of the nonzero eigenvalues of A, $\pm\lambda_1,\pm\lambda_2,\ldots,\pm\lambda_k$, in the following way:

$$C_{2l}=(-1)^l\sum_{1\leq i_1<i_2<\cdots<i_l\leq k}\lambda_{i_1}^2\lambda_{i_2}^2\cdots\lambda_{i_l}^2,\quad l=1,\ldots,\ k. \tag{6}$$

Proof: (a), (b) and first part of (c) are immediate consequences of theorem 3. Formula (6) can be proven by induction in the order of matrix *A* or, alternatively, we may use the fact that the spectrum of *A* is symmectic associated with the well known result, that the coefficients of the characteristic polynomial of a matrix *A* are the elementary symmetric functions of its eigenvalues. □

The coefficients of the characteristic polynomial of a general matrix may be written in terms of the traces of its powers, as shown in Barut, Zeni, and Laufer.[5] Unfortunately, that formula is very difficult to unravel, even though the traces of its powers may be easily computed if one knows the eigenvalues of the matrix. Equation (6) gives a more usable formula for the coefficients of the characteristic polynomial of a *P*-skew-symmetric matrix. Nevertheless, the following particular cases can be easily proven:

$$C_2=-\sum_{i=1}^{k}\lambda_i^2=-\frac{1}{2}\operatorname{trace}(A^2),$$

$$C_4=\sum_{1\leq i<j\leq k}\lambda_i^2\lambda_j^2=\frac{1}{8}(\operatorname{trace}(A^2))^2-\frac{1}{4}\operatorname{trace}(A^4),$$

$$C_6=\sum_{1\leq i<j<s\leq k}\lambda_i^2\lambda_j^2\lambda_s^2=\frac{1}{48}(\operatorname{trace}(A^2))^3-\frac{1}{8}\operatorname{trace}(A^4)\operatorname{trace}(A^2)+\frac{1}{6}\operatorname{trace}(A^6),$$

$$C_{2k}=(-1)^k\lambda_1^2\lambda_2^2\cdots\lambda_k^2. \tag{7}$$

Note that the formula for C_2 is a particular case of the well known formula $C_2 = \frac{1}{2}[(\mathrm{trace}(A))^2 - \mathrm{trace}(A^2)]$, when $\mathrm{trace}(A)=0$ (see, for instance, Ref. 7, p. 192 and Ref. 5) and $C_{2k}=(-1)^k \lambda_1^2 \lambda_2^2 \cdots \lambda_k^2$, coincides with $(-1)^k \det(A)$, whenever $\det(A)\neq 0$.

Particular cases of P-skew-symmetric matrices are the following:

(1) $P = I_{p,q} = \begin{bmatrix} I_p & 0 \\ 0 & -I_q \end{bmatrix}$, with $p+q=n$.

In this case, G is the orthogonal group $\mathrm{O}(p,q)$. This was the case treated in Barut, Zeni, and Laufer.[5]

The particular situation when $p=1$ and $q=3$, corresponds to the case when the Lie group G is the Lorentz group and has been analyzed by Zeni and Rodrigues in Ref. 4.

When $p=n$ and $q=0$, i.e., $P=I$, the Lie algebra of G consists of the skew-symmetric matrices in $so(n,\mathbb{R})$.

(2) $P = J_m = \begin{bmatrix} 0 & I_m \\ -I_m & 0 \end{bmatrix}$, with $2m=n$.

In this case G is the symplectic group $SP(2n,\mathbb{R})$. The Lie algebra of G consists of the set of Hamiltonian matrices.

(3) Although the Lie algebra of skew-Hermitian matrices $u(n)$ was not considered here, it may be embedded into $so(2n,\mathbb{R})$ through the mapping

$$A+iB \rightarrow \begin{bmatrix} A & B \\ -B & A \end{bmatrix},$$

and, consequently, the results in this section extend directly to the complex Lie groups $\mathrm{U}(n)$ and $\mathrm{SU}(n)$.

The last corollary has great impact in the structure of the exponential of P-skew-symmetric matrices. This was already pointed out by Barut, Zeni, and Laufer in Ref. 5, for the situation when the Lie group G is an orthogonal group. Indeed, if $A \in \mathcal{L}$, the power series defining its exponential may be split into even and odd powers as

$$e^{tA} = \sum_{j=0}^{+\infty} \frac{t^{2j} A^{2j}}{(2j)!} + \sum_{j=0}^{+\infty} \frac{t^{2j+1} A^{2j+1}}{(2j+1)!},$$

where the first sum belongs to $\mathcal{J}$ and the second belongs to $\mathcal{L}$.

Also, if $A \in \mathcal{L}$, we may apply corollary 4 and the Cayley–Hamilton theorem to write

$$A^r (A^{2k} + C_2 A^{2k-2} + \cdots + C_{2k-2} A^2 + C_{2k} I) = 0$$

or

$$A^n = -C_2 A^{n-2} - \cdots - C_{2k-2} A^{n-(2k-2)} - C_{2k} A^r.$$

As a consequence, if n is even (odd), r is also even (odd) and A^{n+2j} is a linear combination of the successive even (odd) powers of A, from $A^r (A^{r+1})$ up to $A^{n-2} (A^{n-1})$.

The coefficients in this linear combination may be obtained recursively from the coefficients appearing in the characteristic polynomial of A. To see these recurrence relations we index the coefficients so that if

$$A^n = -(C_2)_0 A^{n-2} - \cdots - (C_{2k-2})_0 A^{n-(2k-2)} - (C_{2k})_0 A^r,$$

then

$$A^{n+2j} = -(C_2)_j A^{n-2} - \cdots - (C_{2k-2})_j A^{n-(2k-2)} - (C_{2k})_j A^r,$$

$$A^{n+2j+1} = -(C_2)_j A^{n-1} - \cdots - (C_{2k-2})_j A^{n-(2k-3)} - (C_{2k})_j A^{r+1}.$$

A simple calculation shows that

$$(C_2)_j=(C_2)_0(C_2)_{j-1}+(C_4)_{j-1},$$

$$(C_4)_j=(C_4)_0(C_2)_{j-1}+(C_6)_{j-1},$$

$$\vdots$$

$$(C_{2k-2})_j=(C_{2k-2})_0(C_2)_{j-1}+(C_{2k})_{j-1},$$

$$(C_{2k})_j=(C_{2k})_0(C_2)_{j-1}.$$

This was the approach used by Zeni and Rodrigues in Ref. 4 and by Barut, Zeni, and Laufer in Ref. 5 to obtain closed forms for the exponential of $SO(1,3)$, the Lorentz group, and for $SO(p,q)$ when $p+q=6$. We point out that the closed forms presented in Barut, Zeni, and Laufer,[5] for the orthogonal group are only valid when a certain discriminant is nonzero, which corresponds to the case when one does not allow repeated eigenvalues for the matrix A. Using the Putzer's method, finding a closed form for the exponential of a matrix A is a simple and clear process, as long as there are methods to evaluate its eigenvalues. In the next section we illustrate Putzer's method for particular Lie algebras of P-skew-symmetric matrices.

III. APPLICATIONS OF PUTZER'S METHOD

In this section we revisit an old method to calculate the exponential of a square matrix A. The following theorem can be directly derived from the original work of Putzer,[6] later referred as the Putzer's method. Although this method has been around for more than three decades, it has not been fully incorporated into the literature. Among the few references we could find are Apostol[9] and, more recently, Horn and Johnson.[10]

Theorem 5 (Putzer's theorem): *If* $\lambda^n+C_1\lambda^{n-1}+\cdots+C_{n-1}\lambda+C_n=0$ *is the characteristic polynomial of a square matrix A, then*

$$e^{At}=f_1(t)I+f_2(t)A^2+\cdots+f_n(t)A^{n-1},$$

where the vector function $\xi=[f_1\ f_2\cdots f_n]^T$ *is the solution of the differential equation*

$$x^{(n)}+C_1x^{(n-1)}+\cdots+C_{n-1}\dot{x}+C_nx=0 \tag{8}$$

that satisfies

$$x(0)=e_1,\ \ \dot{x}(0)=e_2,\ldots,x^{(n-1)}(0)=e_n.$$

Remark 6: It is clear from Putzer's theorem that the coefficient functions f_i, $i=1,2,\ldots,n$, of the polynomial representation of the matrix exponential e^{tA}, are linearly independent solutions of the same nth order linear differential equation with constant coefficients. The roots of the associated characteristic polynomial are the eigenvalues of A. So, if one knows the eigenvalues of A, finding a closed form for e^{tA} reduces to differentiation of elementary functions and solving a system of n algebraic linear equations in n unknowns, having a coefficient matrix which is invertible. Although the eigenvalues of a general $n\times n$ matrix, with $n>4$, cannot be determined analytically, for matrices with additional structure it may be possible to compute directly the eigenvalues even when $n>4$. In particular, for matrices with a symmetric spectrum, like the ones presented in Sec. II, it is possible to compute directly the eigenvalues of matrices up to order 9, covering a range of very interesting cases.

To compute the polynomial representation of e^{tA}, when

$$\lambda^n+C_1\lambda^{n-1}+\cdots+C_{n-1}\lambda+C_n=0,$$

is the characteristic polynomial of A, it is an immediate consequence of Putzer's theorem that one simply has to follow the steps outlined in the following algorithm:

(1) Construct a fundamental set of solutions, $\{\varphi_1(t),\varphi_2(t),\ldots,\varphi_n(t)\}$ of the scalar differential equation

$$x^{(n)}+C_1x^{(n-1)}+\cdots+C_{n-1}\dot{x}+C_nx=0.$$

(This is a relatively straightforward matter if one knows the eigenvalues of A.)

(2) Construct the invertible matrix

$$M=\begin{bmatrix} \varphi_1(0) & \varphi_2(0) & \ldots & \varphi_n(0) \\ \dot{\varphi}_1(0) & \dot{\varphi}_2(0) & \ldots & \dot{\varphi}_n(0) \\ \vdots & \vdots & \ldots & \vdots \\ \varphi_1^{(n-1)}(0) & \varphi_2^{(n-1)}(0) & \ldots & \varphi_n^{(n-1)}(0) \end{bmatrix}.$$

(3) Compute the $1\times n$ matrix function

$$[\varphi_1(t)\ \varphi_2(t)\cdots\varphi_n(t)]M^{-1}.$$

(4) The coefficients $f_1(t),f_2(t),\ldots,f_n(t)$ for the polynomial representation of e^{tA} form the row of the matrix in step (3).

Next we illustrate the use of this algorithm for finding closed forms for the exponential of the infinitesimal generators of some matrix Lie groups, with emphasis in those important in physics. Our first example was chosen to complement the result presented in Barut, Zeni, and Laufer.[5] As already mentioned earlier, their results are only valid when the matrix to be exponentiated has distinct eigenvalues. Here we consider the repeated eigenvalues case. We also present one of the three nondegenerated cases for the exponential of infinitesimal generators of the 12-dimensional symplectic group $SP(3,\mathbb{R})$.

Any mathematical software package like Mathematica, Maple or Matlab may be used successfully to work out other examples. In some cases the formulas may be further simplified, simply by multiplying by det(M) or some factor in det(M). This seems to play the role of the discriminant in Zeni and Rodrigues[4] and Barut, Zeni, and Laufer.[5]

In the following we assume that a, b, and c are nonzero real numbers.

Example 1: Infinitesimal generators of the orthogonal group $SO(2,4)$. If $\sigma(A)=\{\pm ib,\pm ib,\pm c\}$, then

$$e^{tA}=f_1(t)I+f_2(t)A+f_3(t)A^2+f_4(t)A^3+f_5(t)A^4+f_6(t)A^5,$$

where

$$f_1(t)=\frac{c^2(2b^2+c^2)}{(b^2+c^2)^2}\cos bt+\frac{bc^2}{2(b^2+c^2)}t\sin bt+\frac{b^4}{(b^2+c^2)^2}\cosh ct,$$

$$f_2(t)=-\frac{c^2}{2(b^2+c^2)}t\cos bt+\frac{c^2(5b^2+3c^2)}{2b(b^2+c^2)^2}\sin bt+\frac{b^4}{c(b^2+c^2)^2}\sinh ct,$$

$$f_3(t)=-\frac{2b^2}{(b^2+c^2)^2}\cos bt-\frac{b^2-c^2}{2b(b^2+c^2)}t\sin bt+\frac{b^2}{(b^2+c^2)^2}\cosh ct,$$

$$f_4(t)=\frac{b^2-c^2}{2b^2(b^2+c^2)}t\cos bt-\frac{5b^4-c^4}{2b^3(b^2+c^2)^2}\sin bt+\frac{2b^2}{c(b^2+c^2)^2}\sinh ct,$$

$$f_5(t)=-\frac{1}{(b^2+c^2)^2}\cos bt-\frac{1}{2b(b^2+c^2)}t\sin bt+\frac{1}{(b^2+c^2)^2}\cosh ct,$$

$$f_6(t)=\frac{1}{2b^2(b^2+c^2)}\,t\cos bt-\frac{3b^2+c^2}{2b^3(b^2+c^2)^2}\sin bt+\frac{1}{c(b^2+c^2)^2}\sinh ct.$$

Example 2: Infinitesimal generators of the symplectic group $SP(3,\mathbb{R})$. If $\sigma(A)=\{a\pm ib, -a\pm ib, \pm ci\}$, then

$$e^{tA}=f_1(t)I+f_2(t)A+f_3(t)A^2+f_4(t)A^3+f_5(t)A^4+f_6(t)A^5,$$

where

$$\begin{aligned}f_1(t)=&\frac{c^2(-2a^2+2b^2+c^2)}{(b^2+(a-c)^2)(b^2+(a+c)^2)}\cosh at\cos bt\\&+\frac{c^2(a^4+b^2(b^2+c^2)-a^2(6b^2+c^2))}{2ab(b^2+(a-c)^2)(b^2+(a+c)^2)}\sinh at\sin bt\\&+\frac{(a^2+b^2)^2}{2(b^2+(a-c)^2)(b^2+(a+c)^2)}(\cos ct+\sin ct),\end{aligned}$$

$$\begin{aligned}f_2(t)=&\frac{-c^2(5a^4+b^2(b^2+c^2)-a^2(10b^2+3c^2))}{2a(a^2+b^2)(b^2+(a-c)^2)(b^2+(a+c)^2)}\sinh at\cos bt\\&+\frac{c^2(a^4+5b^4+3b^2c^2-a^2(10b^2+c^2))}{2b(a^2+b^2)(b^2+(a-c)^2)(b^2+(a+c)^2)}\cosh at\sin bt\\&+\frac{(a^2+b^2)^2}{2c(b^2+(a-c)^2)(b^2+(a+c)^2)}(\cos ct-\sin ct),\end{aligned}$$

$$\begin{aligned}f_3(t)=&\frac{2(a^2-b^2)}{(b^2+(a-c)^2)(b^2+(a+c)^2)}\cosh at\cos bt\\&+\frac{-a^4+6a^2b^2-b^4+c^4}{2ab(b^2+(a-c)^2)(b^2+(a+c)^2)}\sinh at\sin bt\\&+\frac{-2(a^2-b^2)}{(b^2+(a-c)^2)(b^2+(a+c)^2)}(\cos ct+\sin ct),\end{aligned}$$

$$\begin{aligned}f_4(t)=&\frac{5a^4-10a^2b^2+b^4-c^4}{2a(a^2+b^2)(b^2+(a-c)^2)(b^2+(a+c)^2)}\sinh at\cos bt\\&+\frac{-a^4+10a^2b^2-5b^4+c^4}{2b(a^2+b^2)(b^2+(a-c)^2)(b^2+(a+c)^2)}\cosh at\sin bt\\&+\frac{-2(a^2-b^2)}{c(b^2+(a-c)^2)(b^2+(a+c)^2)}(\cos ct-\sin ct),\end{aligned}$$

$$\begin{aligned}f_5(t)=&\frac{-1}{(b^2+(a-c)^2)(b^2+(a+c)^2)}\cosh at\cos bt\\&+\frac{a^2-b^2-c^2}{2ab(b^2+(a-c)^2)(b^2+(a+c)^2)}\sinh at\sin bt\\&+\frac{1}{2(b^2+(a-c)^2)(b^2+(a+c)^2)}(\cos ct+\sin ct),\end{aligned}$$

$$f_6(t)=\frac{-3a^2+b^2+c^2}{2a(a^2+b^2)(b^2+(a-c)^2)(b^2+(a+c)^2)}\sinh at\cos bt$$
$$+\frac{a^2-3b^2-c^2}{2b(a^2+b^2)(b^2+(a-c)^2)(b^2+(a+c)^2)}\cosh at\sin bt$$
$$+\frac{1}{2c(b^2+(a-c)^2)(b^2+(a+c)^2)}(\cos ct-\sin ct).$$

Second-order second-degree Painlevé equations related with Painlevé I–VI equations and Fuchsian-type transformations

U. Muğan[a)] and A. Sakka
Department of Mathematics, Bilkent University, 06533 Bilkent, Ankara, Turkey

(Received 3 February 1998; accepted for publication 2 April 1999)

One-to-one correspondence between the Painlevé I–VI equations and certain second-order second-degree equations of Painlevé type is investigated. The transformation between the Painlevé equations and second-order second-degree equations is the one involving the Fuchsian-type equation. © *1999 American Institute of Physics.* [S0022-2488(99)01507-8]

I. INTRODUCTION

Painlevé,[1] Gambier,[2] and Fuchs[3] addressed a question raised by E. Picard concerning the second-order first-degree ordinary differential equations of the form

$$v''=F(z,v,v'), \tag{1.1}$$

where F is rational in v', algebraic in v, and locally analytic in z, and have the property that all movable singularities of all solutions are poles. Movable means that the position of the singularities varies as a function of initial values. A differential equation is said to have the Painlevé property if all solutions are single valued around all movable singularities. Within the Möbius transformation, Painlevé and his school found 50 such equations. Among all these equations, 6 of them are irreducible and define classical Painlevé transcendents, PI, PII,...,PVI,[4] and the remaining 44 equations are either solvable in terms of known functions or can be transformed into one of the 6 equations. These equations maybe regarded as the nonlinear counterparts of some classical special equations. For example, PII has solution which has similar properties as Airy's functions.[5] Although the Painlevé equations were discovered from strictly mathematical considerations, they have appeared in many physical problems, and possess a rich internal structure. The properties and the solvability of the Painlevé equations have been extensively studied in the literature.[6–11]

The Riccati equation is the only example for the first-order first-degree equation which has the Painlevé property. Before the work of Painlevé and his school, Fuchs[3,4] considered the equation of the form

$$F(z,v,v')=0, \tag{1.2}$$

where F is polynomial in v and v' and locally analytic in z, such that the movable branch points are absent, that is, the generalization of the Riccati equation. Briot and Bouquet[4] considered the subcase of (1.2), that is, the first-order binomial equations of degree $m\in\mathbb{Z}_+$:

$$(v')^m+F(z,v)=0, \tag{1.3}$$

where $F(z,v)$ is a polynomial of degree at most $2m$ in v. It was found out that there are six types of equations of the form (1.3). But, all these equations are either reducible to a linear equation or solvable by means of elliptic functions.[4] Second-order binomial-type equations of degree $m\geqslant 3$,

[a)]Electronic mail: mugan@fen.bilkent.edu.tr

$$(v'')^m + F(z,v,v') = 0, \tag{1.4}$$

where F is polynomial in v and v' and locally analytic in z, were considered by Cosgrove,[12] who found out that there are nine classes. Only two of these classes can have an arbitrary degree m, and the others can have the degrees of three, four, and six. As in the case of first-order binomial-type equations, all nine classes are solvable in terms of the first, second, and fourth Painlevé transcendents, elliptic functions, or by quadratures. Chazy,[13] Garnier,[14] and Bureau[15] considered the third-order differential equations possessing the Painlevé property of the following form:

$$v''' = F(z,v,v',v''), \tag{1.5}$$

where F is assumed to be rational in v,v',v'' and locally analytic in z. But, in Ref. 15 the special form of $F(z,v,v',v'')$,

$$F(z,v,v',v'') = f_1(z,v)v'' + f_2(z,v)(v')^2 + f_3(z,v)v' + f_4(z,v), \tag{1.6}$$

where $f_k(z,v)$, $k=1,...,4$, are polynomials in v of degree k with analytic coefficients in z, was considered. In this class, no new Painlevé transcendent was discovered since, and all of them can be solved either in terms of known functions or one of the six Painlevé transcendents.

Second-order second-degree Painlevé type equations of the following form,

$$(v'')^2 = E(z,v,v')v'' + F(z,v,v'), \tag{1.7}$$

where E and F are assumed to be rational in v,v' and locally analytic in z, were subject the articles.[16,17] A special case of (1.7), given as

$$v'' = M(z,v,v') + \sqrt{N(z,v,v')}, \tag{1.8}$$

was considered in Ref. 16, where M and N are polynomials in v' of degree 2 and 4, respectively, rational in v, and locally analytic in z, and no new Painlevé transcendent was found. In Ref. 17, the special form of (1.7), $E=0$ and thus F polynomial in v and v', was considered and six distinct classes of equations denoted by SD-1,...,SD-VI, were obtained by using the α-method. Also, these classes can be solved in terms of classical Painlevé transcendents (PI,...,PVI), elliptic functions, or solutions of linear equations.

Let $v(z)$ be a solution of any of the 50 Painlevé equations, as listed by Ince,[4] each of which takes the form

$$v'' = P_2(v')^2 + P_1 v' + P_0, \tag{1.9}$$

where P_0, P_1, P_2 are functions of v, z, and a set of parameters α. The transformation, that is, Lie-point symmetry, which preserves the Painlevé property of (1.9), of the form $u(z;\hat{\alpha}) = f(v(z:\alpha),z)$ is the Möbius transformation:

$$u(z;\hat{\alpha}) = \frac{a_1(z)v + a_2(z)}{a_3(z)v + a_4(z)}, \tag{1.10}$$

where $v(z;\alpha)$ solves (1.9) with a set of parameters α and $u(z;\hat{\alpha})$ solves (1.9) with a set of parameters $\hat{\alpha}$. Lie-point symmetry can be generalized by involving $v'(z;\alpha)$, that is, the transformation of the form $u(z;\hat{\alpha}) = F(v'(z;\alpha), v(z;\alpha), z)$. The only transformation which contains v' linearly is the one involving the Riccati equation, that is,

$$u(z;\hat{\alpha}) = \frac{v' + av^2 + bv + c}{dv^2 + ev + f}, \tag{1.11}$$

where a,b,c,d,e,f are functions of z only.

In Ref. 6, the transformation of type (1.11) was used and the aim was to find a,b,c,d,e,f such that (1.11) defines a one-to-one invertible map between solutions v of (1.9) and solutions u of some second-order equations of the Painlevé type. An algorithmic method was developed to investigate the transformation properties of the Painlevé equations, and some new second-degree equations of Painlevé type related with PIII and PVI were also found. Therefore, second-degree equations are important in determining the transformation properties of the Painlevé equations.[18,6] Moreover, second-degree equations of Painlevé type appear in physics.[19–21] Furthermore, second-degree equations also appear as the first-integral of some of the third-order Painlevé-type equations.

Instead of considering the transformation of the form (1.11) one may consider the following transformation:

$$u(z;\hat{\alpha})=\frac{(v')^m+\Sigma_{j=1}^{m}P_j(z,v)(v')^{m-j}}{\Sigma_{j=1}^{m}Q_j(z,v)(v')^{m-j}}, \tag{1.12}$$

where P_j, Q_j are polynomials in v, whose coefficients are meromorphic functions of z and satisfy the Fuchs theorem[4,22] concerning the absence of the movable critical points. A second-order second-degree algebraic differential equation of the form

$$a_1(v'')^2+a_2v''v'+a_3v''v+a_4(v')^2+a_5v'v+a_6v^2=0, \tag{1.13}$$

where a_j, $j=1,2,...,6$, are meromorphic functions of z, was considered by P. Appell.[23] In Ref. 22, it was shown that Appell's condition for solvability of (1.13) is a necessary and sufficient condition for (1.13) to have its solutions free of movable branch points. Also, in Ref. 22, some analogous conditions were applied to irreducible first-order algebraic equations of the second degree, and necessary and sufficient conditions for the solutions of such equations to be free of movable branch points were obtained. A first-order algebraic differential equation of degree $n\geqslant 1$ is given as

$$a_1(z,v)(v')^n+a_2(z,v)(v')^{(n-1)}+\cdots+a_{n-1}(z,v)v'+a_n(z,v)=0, \tag{1.14}$$

where the functions $a_i(z,v)$, $i=1,...,n$, are assumed to be polynomials in v, whose coefficients are analytic functions of z. The necessary and sufficient conditions for the solutions of (1.14) to be free from movable branch points are given by the Fuchs theorem [Ref. 4 (Chap. XIII) and Ref. 22 (theorem 1.1)]. The Fuchs theorem shows that, apart from the other conditions, the irreducible form of the first-order algebraic differential equation of the second degree is

$$a_1(z)(v')^2+[a_2(z)v^2+a_3(z)v+a_4(z)]v'+[a_5(z)v^4+a_6(z)v^3+a_7(z)v^2+a_8(z)v+a_9(z)]=0, \tag{1.15}$$

where $a_i(z)$, $i=1,2,...,9$, are analytic functions of z and $a_1(z)\neq 0$. Let

$$F(v):=A_0v^4+A_1v^3+A_2v^2+A_3v+A_4, \tag{1.16}$$

where

$$A_0=4a_1a_5-a_2^2,\quad A_1=4a_1a_6-2a_2a_3,$$
$$A_2=4a_1a_7-2a_2a_4-a_3^2,\quad A_3=4a_1a_8-2a_3a_4, \tag{1.17}$$
$$A_4=4a_1a_9-a_4^2,$$

It is known that when $F(v)\neq 0$, there are unique monic polynomials $F_1(v),F_2(v)$ such that

$$F(v)\equiv A(z)F_1(v)[F_2(v)]^2, \tag{1.18}$$

where $A(z)$ is an analytic function and $F_1(z)$ has no multiple roots. In Ref. 22 it was shown (theorem 6.2) that the solutions of the equation (1.15) are free of movable branch points if and only if the following conditions hold:

$$\begin{aligned}
&(i)\ \ F_1(v) \quad \text{divides} \quad G_1(v) := (a_2v^2+a_3v+a_4)\frac{\partial F_1}{\partial v} - 2a_1\frac{\partial F_1}{\partial z},\\
&(ii)\ \ A_0=0 \quad \text{and } A_1\neq 0 \quad \text{imply } \ a_2=0,\\
&(iii)\ \ A_0=A_1=A_2=0 \quad \text{and } A_3\neq 0 \quad \text{imply } \ a_2=0.
\end{aligned} \tag{1.19}$$

The conditions of the Fuchs theorem are satisfied if and only if the conditions (1.19) are satisfied.

In this article, we investigate one-to-one correspondence between PI–PVI and some second-order second-degree Painlevé-type equations such that the transformation involving Eq. (1.15) is used and given by

$$u = \frac{(v')^2 + (a_2v^2+a_1v+a_0)v' + b_4v^4+b_3v^3+b_2v^2+b_1v+b_0}{(c_2v^2+c_1v+c_0)v' + d_4v^4+d_3v^3+d_2v^2+d_1v+d_0}, \tag{1.20}$$

where a_j, b_k, c_j, d_k, $j=0,1,2$, $k=0,1,2,3,4$, are functions of z and a set of parameters α. By using the transformations of the form (1.20), second-order second-degree Painlevé-type equations which are labeled as SD-I.a, SD-I.b, SD-I.c, SD-I.d, and SD-I.e in Ref. 17, can be obtained from PVI, PIII and PV, PIV, PII, PI, respectively. In the following sections, we first present the procedure to obtain these known equations, and for each Painlevé equation we provide an example of a second-order second-degree Painlevé-type equation that has not been considered in the literature.

The procedure used to obtain second-degree Painlevé-type equations and one-to-one correspondence with PI–PVI is as follows: Given Eq. (1.9), determine a_j, b_k, c_j, d_k, $j=0,1,2,3$, $k=0,1,2,3,4$, by requiring that (1.20) defines a one-to-one map between the solution v of (1.9) and solution u of some second-degree equation of the Painlevé type. Let $A_j := c_ju - a_j$, $B_k := d_ku - b_k$. Then the transformation (1.20) can be written as

$$(v')^2 = (A_2v^2+A_1v+A_0)v' + B_4v^4+B_3v^3+B_2v^2+B_1v+B_0. \tag{1.21}$$

It should be noted that if Eq. (1.21) is reducible, that is, if there exits a nontrivial factorization, then it can be reduced to a Riccati equation. If it is not reducible, then its solutions are free of movable branch points provided that the conditions given in (1.19) are satisfied. Differentiating Eq. (1.21) and using (1.9) to replace v'' and (1.21) to replace $(v')^2$, one gets

$$\Phi v' + \Psi = 0, \tag{1.22}$$

where

$$\begin{aligned}
\Phi &= (P_1 - 2A_2v - A_1)(A_2v^2+A_1v+A_0) + P_2(A_2v^2+A_1v+A_0)^2 + 2P_0 - 4B_4v^3 - (3B_3+A_2')v^2\\
&\quad - (2B_2+A_1')v - (B_1+A_0') + 2P_2(B_4v^4+B_3v^3+B_2v^2+B_1v+B_0),\\
\Psi &= (B_4v^4+B_3v^3+B_2v^2+B_1v+B_0)[P_2(A_2v^2+A_1v+A_0) + 2P_1 - 2A_2v - A_1]\\
&\quad - P_0(A_2v^2+A_1v+A_0) - (B_4'v^4+B_3'v^3+B_2'v^2+B_1'v+B_0').
\end{aligned} \tag{1.23}$$

There are two cases to be distinguished:

(I) $\Phi=0$: Equation (1.22) becomes

$$\Psi = 0. \tag{1.24}$$

If the solutions of the equation (1.21) are free of movable branch points, that is, the conditions given in (1.19) are satisfied, then one obtains the Painlevé-type equation of degree $n>1$ related with PI–PVI equations. To obtain the second-degree Painlevé-type equations, one should reduce the equation (1.24) to a linear equation in v. If (1.24) is reduced to an equation which is quadratic in v, then one obtains the second-order fourth-degree Painlevé-type equations related with PI–PVI, which are not considered in this article. Hence, one can find a_j, b_k, c_j, d_k such that (1.24) reduces to a linear equation in v,

$$A(u',u,z)v+B(u',u,z)=0, \tag{1.25}$$

then, substitute $v=-B/A$ into Eq. (1.21) to determine the second-order second-degree equation of the Painlevé type for u.

(II) $\Phi\neq 0$: If Φ divides Ψ, then (1.21) can be reduced to a Riccati equation and hence its solutions are free of movable branch points. Then, one can substitute $v'=-\Psi/\Phi$ in Eq. (1.21) and obtain the following equation for v:

$$\Psi^2+(A_2v^2+A_1v+A_0)\Phi\Psi-\Phi^2(B_4v^4+B_3v^3+B_2v^2+B_1v+B_0)=0. \tag{1.26}$$

Finding a_j, b_k, c_j, and d_k such that (1.26) reduces to a quadratic equation in v,

$$A(u',u,z)v^2+B(u',u,z)v+C(u',u,z)=0. \tag{1.27}$$

Solving the equation (1.27) for v and substituting into equation (1.22) yields a second-order second-degree Painlevé-type equation for u.

It turns out that PI admits transformations discussed in cases I and II, and PII–PVI admit only transformations of case II.

Second-order second-degree Painlevé-type equations were studied mainly by Bureau and Cosgrove.[16,17] But, as mentioned before, in both articles the special form of the second-degree Painlevé-type equations was considered, and no new Painlevé transcendent was found. In Refs. 24 and 25 the transformation (1.11) was used to obtain one-to-one correspondence between PI–PVI and certain second-degree Painlevé-type equations. Some of these second-degree equations had been obtained previously, but most of them had not been considered in the literature before. In this article, we investigate the transformation of type (1.20) to obtain the one-to-one correspondence between PI–VI and the second-order second-degree Painlevé-type equations. By using the transformation of type (1.11) and the procedure described above, it is possible to obtain all of the second-degree equations given in Ref. 17 except the ones which can be solvable in terms of elliptic functions or solutions of linear equations. In addition to known equations which are related with Painlevé equations through the transformation (1.20), it is possible to obtain some new second-degree equations of the Painlevé type. Since the calculations are extremely tedious, one new second-degree Painlevé-type equation for each Painlevé equation, PI–PVI, is given. Throughout this article $'$ denotes the derivative with respect to z and $\cdot$ denotes the derivative with respect to x.

II. PAINLEVÉ I

Let $v(z)$ be a solution of PI equation,

$$v''=6v^2+z. \tag{2.1}$$

Then, for PI the equation (1.22) takes the form of

$$(\phi_3v^3+\phi_2v^2+\phi_1v+\phi_0)v'+\psi_5v^5+\psi_4v^4+\psi_3v^3+\psi_2v^2+\psi_1v+\psi_0=0, \tag{2.2}$$

where

$$\phi_3=2(A_2^2+2B_4),\quad \phi_2=A_2'+3B_3+3A_1A_2-12,$$

$$\phi_1=A_1'+2B_2+A_1^2+2A_0A_2,\quad \phi_0=A_0'+B_1+A_0A_1-2z,$$

$$\psi_5=2A_2B_4,\quad \psi_4=B_4'+A_1B_4+2A_2B_3+6A_2, \tag{2.3}$$

$$\psi_3=B_3'+A_1B_3+2A_2B_2+6A_1,\quad \psi_2=B_2'+A_1B_2+2A_2B_1+6A_0+zA_2,$$

$$\psi_1=B_1'+A_1B_1+2A_2B_0+zA_1,\quad \psi_0=B_0'+A_1B_0+zA_0.$$

Case I: $\Phi=0$: One should choose $c_j=0$, $j=0,1,2$, $d_k=0$, $k=1,2,3,4$, $b_4=\frac{1}{2}a_2^2$, $b_3=-\frac{1}{3}a_2'+a_1a_2-4$, $b_2=-\frac{1}{2}a_1'+\frac{1}{2}a_1^2+a_0a_2$, $b_1=-a_0'+a_0a_1-2z$. One can always absorb b_0 and d_0 in u by a proper Möbius transformation. Hence, without loss of generality, one can set $b_0=0$ and $d_0=2$. The only possibility to reduce the equation $\Psi=0$ to a linear equation in v is to set $\psi_5=\psi_4=\psi_3=\psi_2=0$. Therefore, one obtains $a_2=a_1=a_0=b_4=b_2=0$, $b_3=-4$, and $b_1=-2z$. Then the equation (1.20) becomes

$$2u=(v')^2-4v^3-2zv, \tag{2.4}$$

and the linear equation for v reads

$$v+u'=0. \tag{2.5}$$

Equation (2.4) with the condition (2.5) satisfies corollary 6.3 in Ref. 22, and hence its solutions are free of movable branch points. By following the procedure discussed in the Introduction, one can get the following second-order second-degree equation for $u(z)$:

$$(u'')^2=-4(u')^3-2(zu'-u). \tag{2.6}$$

Equation (2.6) was first obtained by Cosgrove[17] and labeled as SD-I.e.

Case II: $\Phi\neq 0$: As an example, let $\phi_i=0$, $i=1,2,3$, $\phi_0\neq 0$, and $\psi_l=0$, $l=2,3,4,5$. These choices imply that $A_j=0$, $j=0,1,2$, $B_4=B_2=0$, and $B_3=4$. Then, Eq. (1.26) becomes

$$(B_1'v+B_0')^2-(B_1-2z)^2(4v^3+B_1v+B_0)=0. \tag{2.7}$$

To reduce the equation (2.7) to a quadratic equation for v, one has to take $d_1\neq 0$ and, hence, without loss of generality, $b_1=0$ and $d_1=1$. Moreover, d_0 and b_0 are the solutions of the following equations:

$$d_0'(b_0'-2zd_0')=0,\quad (d_0')^2+4d_0^3+b_0=0,\quad (b_0')^2-4z^2(d_0')^2=0. \tag{2.8}$$

Here, we only consider the case $d_0'=0$; then $d_0=\mu$ and $b_0=-4\mu^3$, where μ is a constant. Therefore, the equations (1.21) and (1.22) become

$$(v')^2=4v^3+uv+\mu(u+4\mu^2) \tag{2.9}$$

and

$$v'=\frac{-u'}{(u-2z)}(v+\mu), \tag{2.10}$$

respectively, and the quadratic equation for v takes the form of

$$4(u-2z)^2v^2-[(u')^2+4\mu(u-2z)^2]v-\mu(u')^2+(u+4\mu^2)(u-2z)^2=0. \tag{2.11}$$

Let $u(z)=-2(e^x/(y-1)+6\mu^2)$ and $z=e^x-6\mu^2$. Then the equations (2.9) and (2.11) give one-to-one correspondence between solutions $v(z)$ of PI and solutions $y(x)$ of the following second-order second-degree Painlevé-type equation

$$\{4y(y-1)(\ddot{y}-\dot{y})-(\dot{y}-y+1)[(7y-4)\dot{y}+5y(y-1)]+12\mu e^{2x}y^3(y-1)^2\}^2$$
$$=(y+2)^2\{[(\dot{y}-y+1)^2+12\mu e^{2x}y^2(y-1)^2]^2+32e^{5x}y^4(y-1)^3\}. \tag{2.12}$$

III. PAINLEVÉ II

Let $v(z)$ be a solution of PII equation

$$v''=2v^3+zv+\alpha. \tag{3.1}$$

Then, for PII, the equation (1.22) takes the following form:

$$(\phi_3v^3+\phi_2v^2+\phi_1v+\phi_0)v'+\psi_5v^5+\psi_4v^4+\psi_3v^3+\psi_2v^2+\psi_1v+\psi_0=0, \tag{3.2}$$

where

$$\phi_3=4(B_4+\tfrac{1}{2}A_2^2-1), \quad \phi_2=A_2'+3B_3+3A_1A_2,$$
$$\phi_1=A_1'+2B_2+2A_0A_2+A_1^2-2z, \quad \phi_0=A_0'+B_1+A_0A_1-2\alpha,$$
$$\psi_5=2A_2(B_4+1), \quad \psi_4=B_4'+A_1B_4+2A_2B_3+2A_1, \tag{3.3}$$
$$\psi_3=B_3'+A_1B_3+2A_2B_2+2A_0+zA_2, \quad \psi_2=B_2'+A_1B_2+2A_2B_1+zA_1+\alpha A_2,$$
$$\psi_1=B_1'+A_1B_1+2A_2B_0+zA_0+\alpha A_1, \quad \psi_0=B_0'+A_1B_0+\alpha A_0.$$

Here, we only consider the case $\phi_i=0$, $i=1,2,3$, $\phi_0\neq 0$, and $\psi_l=0$, $l=3,4,5$. $\psi_5=0$ implies that either $A_2=0$ or $B_4=-1$.

Case i: If $A_2=0$, then one obtains $A_1=A_0=0$, $B_4=1$, $B_3=0$, $B_2=z$ and $\phi_0=B_1-2\alpha$, $\psi_2=1$, $\psi_1=B_1'$, $\psi_0=B_0'$. With these choices, the equation (1.26) yields

$$(v^2+B_1'v+B_0')^2-(B_1-2\alpha)^2(v^4+zv^2+B_1v+B_0)=0. \tag{3.4}$$

To reduce the equation (3.4) to a quadratic equation in v, one possibility is to set the coefficients of v^4 and v^3 to zero. Then, one obtains $B_1=2\alpha+\epsilon$, where $\epsilon=\pm 1$, and by using the proper Möbius transformation, one may take $B_0=2u+\frac{1}{4}z^2$. Hence, the equations (1.21) and (1.22) become

$$(v')^2=v^4+zv^2+(2\alpha+\epsilon)v+2u+\frac{z^2}{4} \tag{3.5}$$

and

$$v'=\epsilon\left(v^2+2u'+\frac{z}{2}\right), \tag{3.6}$$

respectively. The quadratic equation in v is

$$4u'v^2-(2\alpha+\epsilon)v+4(u')^2+2(zu'-u)=0. \tag{3.7}$$

The equations (3.5) and (3.7) give one-to-one correspondence between solutions $v(z)$ of PII and solutions $u(z)$ of the equation

$$(u'')^2=-4(u')^3-2u'(zu'-u)+\tfrac{1}{16}(2\alpha+\epsilon)^2. \tag{3.8}$$

The equation (3.8) was first obtained by Cosgrove[17] and labeled as SD-I.d.

Case ii: If $B_4=-1$, then one obtains $A_2=2\epsilon$, $A_1=0$, $A_0=\epsilon z$, $B_3=0$, $B_2=-z$ and $\phi_0=B_1-2\alpha+\epsilon\neq 0$, $\psi_2=4\epsilon B_1+2\epsilon\alpha-1$, $\psi_1=B_1'+4\epsilon B_0+\epsilon z^2$, $\psi_0=B_0'+\epsilon\alpha z$, where $\epsilon=\pm 1$. Then the equation (1.26) becomes

$$(\psi_2 v^2+\psi_1 v+\psi_0)^2+2\epsilon\phi_0(v^2+\tfrac{1}{2}z)(\psi_2 v^2+\psi_1 v+\psi_0)+\phi_0^2(v^4+zv^2-B_1 v-B_0)=0. \tag{3.9}$$

To reduce the equation (3.9) to a quadratic equation in v one may set the coefficients of v^4 and v^3 to zero. Thus one obtains $B_1=0$, and without loss of generality one may take $B_0=\frac{1}{4}(u-z^2)$. Therefore, the equations (1.21) and (1.22) give

$$(v')^2=\epsilon(2v^2+z)v'-v^4-zv^2+\tfrac{1}{4}(u-z^2), \tag{3.10}$$

and

$$v'=\frac{\epsilon}{(2\alpha-\epsilon)}\left[(2\alpha-\epsilon)v^2+uv+\frac{\epsilon}{4}u'+\frac{1}{2}(2\alpha-\epsilon)z\right], \tag{3.11}$$

respectively, and the quadratic equation in v is

$$(4uv+\epsilon u')^2=4(2\alpha-\epsilon)^2 u. \tag{3.12}$$

The equations (3.10) and (3.12) give one-to-one correspondence between solutions $v(z)$ of PII and solutions $u(z)$ of the following second-order second-degree Painlevé-type equation:

$$[4uu''-3(u')^2+8zu^2+4(2\alpha-\epsilon)^2 u]^2=64u^5. \tag{3.13}$$

IV. PAINLEVÉ III

Let $v(z)$ be a solution of PIII equation

$$v''=\frac{1}{v}(v')^2-\frac{1}{z}v'+\gamma v^3+\frac{1}{z}(\alpha v^2+\beta)+\frac{\delta}{v}. \tag{4.1}$$

Then, for PIII, the equation (1.22) takes the following form:

$$(\phi_4 v^4+\phi_3 v^3+\phi_2 v^2+\phi_1 v+\phi_0)v'+\psi_6 v^6+\psi_5 v^5+\psi_4 v^4+\psi_3 v^3+\psi_2 v^2+\psi_1 v+\psi_0=0, \tag{4.2}$$

where

$$\phi_4=2\gamma-2B_4-A_2^2,\quad \phi_3=\frac{2\alpha}{z}-B_3-A_1A_2-A_2'-\frac{1}{z}A_2,\quad \phi_2=-\left(A_1'+\frac{1}{z}A_1\right),$$

$$\phi_1=\frac{2\beta}{z}+B_1+A_0A_1-A_0'-\frac{1}{z}A_0,\quad \phi_0=A_0^2+2B_0+2\delta,$$

$$\psi_6=-A_2(B_4+\gamma),\quad \psi_5=-\left(B_4'+\frac{2}{z}B_4+A_2B_3+\gamma A_1+\frac{\alpha}{z}A_2\right),$$

$$\psi_4=A_0B_4-B_3'-\frac{2}{z}B_3-A_2B_2-\gamma A_0-\frac{\alpha}{z}A_1, \tag{4.3}$$

$$\psi_3 = A_0 B_3 - B_2' - \frac{2}{z} B_2 - A_2 B_1 - \frac{\beta}{z} A_2 - \frac{\alpha}{z} A_0,$$

$$\psi_2 = A_0 B_2 - B_1' - \frac{2}{z} B_1 - A_2 B_0 - \frac{\beta}{z} A_1 - \delta A_2,$$

$$\psi_1 = A_0 B_1 - B_0' - \frac{2}{z} B_0 - \frac{\beta}{z} A_0 - \delta A_1, \quad \psi_0 = A_0 (B_0 - \delta).$$

As an example, let $A_0 = 0$, $A_1 = 2/z$, $B_1 = -2\beta/z$, and $B_0 = -\delta$. Then one gets $\phi_0 = \phi_1 = \phi_2 = 0$ and $\psi_0 = \psi_1 = \psi_2 = 0$. Moreover, if $\phi_4 = \psi_6 = 0$, then either $A_2 = 0$, $B_4 = \gamma$ or $A_2 = 2\sqrt{\gamma}$, $B_4 = -\gamma$, where γ can be taken with either sign.

Case i: If $A_2 = 0$, $B_4 = \gamma$, then equation (1.26) takes the following form:

$$(\psi_5 v^2 + \psi_4 v + \psi_3)^2 + \frac{2}{z} \phi_3 v (\psi_5 v^2 + \psi_4 v + \psi_3) - \phi_3^2 \left(\gamma v^4 + B_3 v^3 + B_2 v^2 - \frac{2\beta}{z} v - \delta \right) = 0. \tag{4.4}$$

To reduce the equation (4.4) to a quadratic equation in v one may set the coefficients of v^4 and v^3 to zero. Then, one obtains $B_3 = (2/z)(\alpha + 2\sqrt{\gamma})$, and without loss of generality, one may take $B_2 = u$. With these choices the quadratic equation in v takes the following form,

$$\begin{aligned} &8[\gamma z^3 u' + 2(\alpha + \sqrt{\gamma})(\alpha + 3\sqrt{\gamma})] v^2 + 8[(\alpha + 2\sqrt{\gamma})(zu' + u) + 4\gamma\beta] v \\ &\quad + z^2 (zu' + 2u)^2 + 16\gamma\delta z^2 = 0, \end{aligned} \tag{4.5}$$

and the transformations (1.21) and (1.22) become

$$(v')^2 = \frac{2}{z} v v' + \gamma v^4 + \frac{2}{z} (\alpha + 2\sqrt{\gamma}) v^3 + u v^2 - \frac{2\beta}{z} v - \delta \tag{4.6}$$

and

$$v' = \frac{-1}{4z\sqrt{\gamma}} [4\gamma z v^2 + 4(\alpha + \sqrt{\gamma}) v + z^2 u' + 2zu], \tag{4.7}$$

respectively. Then, the transformations (4.5) and (4.6) give one-to-one correspondence between solutions $v(z)$ of PIII and solutions $y(x)$ of the following second-order second-degree Painlevé-type equation

$$x^2 (\ddot{y})^2 = -4(\dot{y})^2 (x\dot{y} - y) - \frac{\gamma\delta}{16} (x\dot{y} - y) + \frac{\beta}{16} (\alpha + 2\sqrt{\gamma}) \dot{y} + \frac{1}{256} [\gamma\beta^2 - \delta(\alpha + 2\sqrt{\gamma})^2], \tag{4.8}$$

where $y(x) = \frac{1}{16}[z^2 u(z) + 1]$ and $x = z^2$. The equation (4.8) was first obtained by Cosgrove[17] and labeled as SD-I.b (with $A_1 = 0$).

Case ii: $A_2 = 2\sqrt{\gamma}$, $B_4 = -\gamma$: The equation (1.26) takes the form of

$$\begin{aligned} &(\psi_5 v^2 + \psi_4 v + \psi_3)^2 + \frac{2}{z} \phi_3 v (\sqrt{\gamma} z v + 1)(\psi_5 v^2 + \psi_4 v + \psi_3) \\ &\quad + \phi_3^2 \left(\gamma v^4 - B_3 v^3 - B_2 v^2 + \frac{2\beta}{z} v + \delta \right) = 0. \end{aligned} \tag{4.9}$$

One may set the coefficients of v^4 and v^3 to zero in order to reduce the equation (4.9) to a quadratic equation in v. Then, one obtains $B_3=-2\sqrt{\gamma}/z$, and without loss of generality one can take $B_2=u$. Then, the equation (1.21) becomes

$$(v')^2=\frac{2}{z}v(\sqrt{\gamma}zv+1)v'-\gamma v^4-\frac{2\sqrt{\gamma}}{z}v^3+uv^2-\frac{2\beta}{z}v-\delta. \tag{4.10}$$

By using the linear transformation $y(x)=z^2u(z)+1$, $2x=z^2$, and $\mu=\alpha-2\sqrt{\gamma}$, the equation (1.22) can be written as

$$v'=\sqrt{\gamma}v^2+\frac{1}{z}\left(\frac{\sqrt{\gamma}}{\mu}y+1\right)v+\frac{1}{2\mu}(\dot{y}-2\beta\sqrt{\gamma}), \tag{4.11}$$

and the quadratic equation for v is

$$4y(\gamma y-\mu^2)v^2+4z[\sqrt{\gamma}y(\dot{y}-2\beta\sqrt{\gamma})+2\beta\mu^2]v+z^2[(\dot{y}-2\beta\sqrt{\gamma})^2+4\delta\mu^2]=0. \tag{4.12}$$

The equations (4.10) and (4.12) give one-to-one correspondence between solutions $v(z)$ of PIII and solutions $y(x)$ of the following equation:

$$x^2[2y^2\ddot{y}-y\dot{y}^2-4(\delta\mu^2-\gamma\beta^2)y-8\beta^2\mu^2]^2=(y^2+4\beta\mu x)^2[y(\dot{y})^2-4(\gamma y-\mu^2)(\delta y+\beta^2)]. \tag{4.13}$$

V. PAINLEVÉ IV

Let $v(z)$ be a solution of PIV

$$v''=\frac{1}{2v}(v')^2+\frac{3}{2}v^3+4zv^2+2(z^2-\alpha)v+\frac{\beta}{v}. \tag{5.1}$$

Then, for PIV the equation (1.22) takes the following form,

$$(\phi_4v^4+\phi_3v^3+\phi_2v^2+\phi_1v+\phi_0)v'+\psi_6v^6+\psi_5v^5+\psi_4v^4+\psi_3v^3+\psi_2v^2+\psi_1v+\psi_0=0, \tag{5.2}$$

where

$$\begin{gathered}
\phi_4=3(1-B_4-\tfrac{1}{2}A_2^2),\quad \phi_3=8z-2B_3-2A_1A_2-A_2',\\
\phi_2=4(z^2-\alpha)-B_2-\tfrac{1}{2}A_1^2-A_0A_2-A_1',\quad \phi_1=-A_0',\quad \phi_0=\tfrac{1}{2}A_0^2+B_0+2\beta,\\
\psi_6=-\tfrac{3}{2}A_2(B_4+1),\quad \psi_5=-(B_4'+\tfrac{1}{2}A_1B_4+\tfrac{3}{2}A_2B_3+4zA_2+\tfrac{3}{2}A_1),\\
\psi_4=\tfrac{1}{2}A_0B_4-B_3'-\tfrac{1}{2}A_1B_3-\tfrac{3}{2}A_2B_2-2(z^2-\alpha)A_2-\tfrac{3}{2}A_0-4zA_1,\\
\psi_3=\tfrac{1}{2}A_0B_3-B_2'-\tfrac{1}{2}A_1B_2-\tfrac{3}{2}A_2B_1-2(z^2-\alpha)A_1-4zA_0,\\
\psi_2=\tfrac{1}{2}A_0B_2-B_1'-\tfrac{1}{2}A_1B_1-\tfrac{3}{2}A_2B_0-\beta A_2-2(z^2-\alpha)A_0,\\
\psi_1=\tfrac{1}{2}A_0B_1-B_0'-\tfrac{1}{2}A_1B_0-\beta A_1,\quad \psi_0=\tfrac{1}{2}A_0(B_0-2\beta).
\end{gathered} \tag{5.3}$$

As an example, let $A_0=0$ and $B_0=-2\beta$. Then one gets $\phi_0=\phi_1=\psi_0=\psi_1=0$. Moreover, setting $\phi_4=\phi_3=\psi_6=\psi_5=0$, one has the following two distinct cases: (i) $A_2=0$, $A_1=0$, $B_4=1$, $B_3=4z$ or (ii) $A_2=2\epsilon$, $A_1=4\epsilon z$, $B_4=-1$, $B_3=-4z$, where $\epsilon=\pm1$.

Case i: In this case Eq. (1.26) takes the form of

$$(\psi_4 v^2+\psi_3 v+\psi_2)^2-\phi_2^2(v^4+4zv^3+B_2v^2+B_1v-2\beta)=0. \tag{5.4}$$

To reduce the equation (5.4) to a quadratic equation in v, one may set the coefficients of v^4 and v^3 to zero. Then, one obtains $B_2=4(z^2-\alpha+\epsilon)$ and, hence, without loss of generality, one can choose $B_1=u$. Then the equations (1.21) and (1.22) become

$$(v')^2=v^4+4zv^3+4(z^2-\alpha+\epsilon)v^2+uv-2\beta \tag{5.5}$$

and

$$v'=\frac{-\epsilon}{4}(4v^2+8zv+u'), \tag{5.6}$$

respectively. The equations (5.5) and

$$8[u'+8(\alpha-\epsilon)]v^2+16(zu'-u)v+(u')^2+32\beta=0 \tag{5.7}$$

give one-to-one correspondence between solutions $v(z)$ of PIV and solutions $u(z)$ of the following equation:

$$(u'')^2=4(zu'-u)^2-\tfrac{1}{2}[(u')^2+32\beta](u'+8\alpha-8\epsilon). \tag{5.8}$$

The transformation $u=8(y-\mu z)$, where $\mu=\frac{1}{3}(\alpha-\epsilon)$, transforms the equation (5.8) to the following equation,

$$(y'')^2=-4(y')^3+4(zy'-y)^2+2(6\mu^2-\beta)y'-4\mu(2\mu^2+\beta), \tag{5.9}$$

which was first obtained by Cosgrove[17] and labeled as SD-I.c.

Case ii: In this case Eq. (1.26) can be written as follows:

$$[(\psi_4+\epsilon\phi_2)v^2+(\psi_3+2\epsilon z\phi_2)v+\psi_2]^2=\phi_2^2[(B_2+4z^2)v^2+B_1v-2\beta]. \tag{5.10}$$

It is clear that if one sets $\psi_4+\epsilon\phi_2=0$, then the equation (5.10) reduces to a quadratic equation in v. Thus, one should take $B_2=-4z^2$ and, without loss of generality, $B_1=u$. Then, the equations (1.21) and (1.22) become, respectively,

$$(v')^2=2\epsilon v(v+2z)v'-v^4-4zv^3-4z^2v^2+uv-2\beta \tag{5.11}$$

and

$$v'=\frac{\epsilon}{12\mu}[12\mu v^2-3(u-8\mu z)v-(\epsilon u'+2zu-4\beta)], \tag{5.12}$$

where $\mu=\frac{1}{3}(\alpha+\epsilon)$. The equations (5.11) and

$$9u^2v^2+2u(3\epsilon u'+6zu-12\beta-72\mu^2)v+(\epsilon u'+2zu-4\beta)^2+288\beta\mu^2=0 \tag{5.13}$$

give one-to-one correspondence between solutions $v(z)$ of PIV and solutions $u(z)$ of the following second-order second-degree Painlevé-type equation:

$$\begin{aligned}&[3uu''-2(u')^2-2\epsilon(zu-2\beta+12\mu^2)u'-2(4z^2-3\epsilon)u^2-8(6\mu^2-\beta)zu+16(6\mu^2-\beta)^2]^2\\&\quad=-27[u^2-16\mu(2\mu^2+\beta)]^2[\epsilon u'+2zu+2\beta-12\mu^2].\end{aligned} \tag{5.14}$$

VI. PAINLEVÉ V

Let $v(z)$ be a solution of PV:

$$v''=\frac{3v-1}{2v(v-1)}(v')^2-\frac{1}{z}v'+\frac{\alpha}{z^2}v(v-1)^2+\frac{\beta(v-1)^2}{z^2v}+\frac{\gamma}{z}v+\frac{\delta v(v+1)}{v-1}. \tag{6.1}$$

Then, for PV, Eq. (1.22) takes the form of

$$(\phi_5v^5+\phi_4v^4+\phi_3v^3+\phi_2v^2+\phi_1v+\phi_0)v'+\psi_7v^7+\psi_6v^6$$
$$+\psi_5v^5+\psi_4v^4+\psi_3v^3+\psi_2v^2+\psi_1v+\psi_0=0, \tag{6.2}$$

where

$$\phi_5=\frac{2\alpha}{z^2}-B_4-\frac{1}{2}A_2^2,\quad \phi_4=3B_4+\frac{3}{2}A_2^2-\frac{6\alpha}{z^2}-A_2'-\frac{1}{z}A_2,$$

$$\phi_3=2B_3+B_2+\frac{1}{2}A_1^2+2A_1A_2+A_0A_2+A_2'+\frac{1}{z}A_2-A_1'-\frac{1}{z}A_1+\frac{2}{z^2}[3\alpha+\beta+\gamma z+\delta z^2],$$

$$\phi_2=2B_1+B_2+\frac{1}{2}A_1^2+2A_0A_1+A_0A_2+A_1'+\frac{1}{z}A_1-A_0'-\frac{1}{z}A_0-\frac{2}{z^2}[\alpha+3\beta+\gamma z-\delta z^2],$$

$$\phi_1=3B_0+\frac{3}{2}A_0^2+\frac{6\beta}{z^2}+A_0'+\frac{1}{z}A_0,\quad \phi_0=-\left(\frac{2\beta}{z^2}+B_0+\frac{1}{2}A_0^2\right),$$

$$\psi_7=-\frac{1}{2}A_2\left(B_4+\frac{2\alpha}{z^2}\right),\quad \psi_6=B_4\left(\frac{3}{2}A_2+\frac{1}{2}A_1-\frac{2}{z}\right)-\frac{1}{2}A_2B_3+\frac{\alpha}{z^2}(3A_2-A_1)-B_4', \tag{6.3}$$

$$\psi_5=B_4\left(\frac{1}{2}A_1+\frac{3}{2}A_0+\frac{2}{z}\right)+B_3\left(\frac{3}{2}A_2+\frac{1}{2}A_1-\frac{2}{z}\right)-\frac{1}{2}A_2B_2$$
$$-\frac{A_2}{z^2}(3\alpha+\beta+\gamma z+\delta z^2)+\frac{\alpha}{z^2}(3A_1-A_0)+B_4'-B_3',$$

$$\psi_4=B_3\left(\frac{1}{2}A_1+\frac{3}{2}A_0+\frac{2}{z}\right)+B_2\left(\frac{3}{2}A_2+\frac{1}{2}A_1-\frac{2}{z}\right)-\frac{1}{2}A_2B_1-\frac{1}{2}A_0B_4$$
$$-\frac{A_1}{z^2}(3\alpha+\beta+\gamma z+\delta z^2)+\frac{A_2}{z^2}(\alpha+3\beta+\gamma z-\delta z^2)+\frac{3\alpha}{z^2}A_0+B_3'-B_2',$$

$$\psi_3=B_2\left(\frac{1}{2}A_1+\frac{3}{2}A_0+\frac{2}{z}\right)+B_1\left(\frac{3}{2}A_2+\frac{1}{2}A_1-\frac{2}{z}\right)-\frac{1}{2}A_2B_0-\frac{1}{2}A_0B_3$$
$$-\frac{A_0}{z^2}(3\alpha+\beta+\gamma z+\delta z^2)+\frac{A_1}{z^2}(\alpha+3\beta+\gamma z-\delta z^2)-\frac{3\beta}{z^2}A_2+B_2'-B_1',$$

$$\psi_2=B_1\left(\frac{1}{2}A_1+\frac{3}{2}A_0+\frac{2}{z}\right)+B_0\left(\frac{3}{2}A_2+\frac{1}{2}A_1-\frac{2}{z}\right)$$
$$+\frac{A_0}{z^2}(\alpha+3\beta+\gamma z-\delta z^2)+\frac{\beta}{z^2}(A_2-3A_1)+B_1'-B_0',$$

$$\psi_1 = B_0\left(\frac{3}{2}A_0 + \frac{1}{2}A_1 + \frac{2}{z}\right) - \frac{1}{2}A_0B_1 + \frac{\beta}{z^2}(A_1 - 3A_0) + B_0', \quad \psi_0 = \frac{-1}{2}A_0\left(B_0 - \frac{2\beta}{z^2}\right).$$

As an example, let

$$A_1 = \frac{-2}{z}(zA_0 + 1), \quad A_2 = \frac{1}{z}(zA_0 + 2),$$
$$B_3 = -\left(2B_2 + 3B_1 + 4B_0 - \frac{2\gamma}{z} + 4\delta\right), \quad B_4 = B_2 + 2B_1 + 3B_0 - \frac{2\gamma}{z} + 2\delta, \tag{6.4}$$

and let $\phi_0 = \phi_1 = \psi_0 = \psi_1 = 0$. Then, Eq. (7.2) can be written as

$$\phi_5 v' + \psi_7 v^2 + (\psi_6 + 3\psi_7)v - \psi_2 = 0, \tag{6.5}$$

and the equation (1.26) can be written as

$$\begin{aligned}[&\psi_7 v^2 + (\psi_6 + 3\psi_7 v - \psi_2 + \tfrac{1}{2}\phi_5(A_2 v^2 + A_1 v + A_0)]^2 \\ &= \phi_5^2[(B_4 + \tfrac{1}{4}A_2^2)v^4 + (B_3 + \tfrac{1}{2}A_1A_2)v^3 + (\tfrac{1}{4}B_2A_1^2 + \tfrac{1}{2}A_0A_2)v^2 \\ &\quad + (B_1 + \tfrac{1}{2}A_0A_1)v + (B_0 + \tfrac{1}{4}A_0^2)].\end{aligned} \tag{6.6}$$

Here $\psi_0 = 0$ implies that either $A_0 = 0$ or $B_0 = 2\beta/z^2$.

Case i: $A_0 = 0$: Equations (6.4) and $\phi_0 = \phi_1 = \psi_1 = 0$ imply that $A_1 = -2/z$, $A_2 = 2/z$, and $B_0 = -2\beta/z^2$. If $B_4 = (\mu^2 - 1)/z^2$, where $\mu = 1 - \sqrt{2\alpha}$ and $\sqrt{2\alpha}$ can take either sign, and without loss of generality $B_1 = (1/z^2)(4u + \gamma z - \mu^2 + 6\beta)$, then Eq. (6.6) reduces to the following quadratic equation for v:

$$Av^2 + Bv + C = 0, \tag{6.7}$$

where

$$\begin{aligned} A &= 8\mu^2[2(zu' + u) + \delta z^2 - \mu^2 + 2\beta] + (4u - \gamma z - 3\mu^2 + 2\beta)^2, \\ B &= 2(4u - \gamma z - 3\mu^2 + 2\beta)[4(zu' - u) + \mu^2 - 2\beta] - 4\mu^2(4u + \gamma z - \mu^2 + 6\beta), \\ C &= [4(zu' - u) + \mu^2 - 2\beta]^2 + 8\beta\mu^2. \end{aligned} \tag{6.8}$$

The equations (1.21) and (1.22) respectively become

$$\begin{aligned}(v')^2 = \frac{1}{z^2}[&2zv(v-1)v' + (\mu^2 - 1)v^4 + (4u - \gamma z - 3\mu^2 + 2\beta + 2)v^3 \\ &- (8u + 2\delta z^2 - 3\mu^2 + 6\beta + 1)v^2 + (4u + \gamma z - \mu^2 + 6\beta)v - 2\beta],\end{aligned} \tag{6.9}$$

and

$$v' = \frac{1}{2\mu z}[2\mu\sqrt{2\alpha}v^2 - (4u - \gamma z - 3\mu^2 + 2\beta + 2\mu)v - (4zu' - 4u + \mu^2 - 2\beta)]. \tag{6.10}$$

The equations (6.9) and (6.7) define one-to-one correspondence between solutions $v(z)$ of PV and solutions $u(z)$ of the following second-order second-degree Painlevé-type equation:

$$z^2(u'')^2=-4(u')^2(zu'-u)-2\delta(zu'-u)^2-[\delta(\mu^2-2\beta)-\tfrac{1}{4}\gamma^2](zu'-u)$$
$$+\tfrac{1}{2}\gamma(\mu^2+2\beta)u'+\tfrac{1}{8}[\gamma^2(\mu^2-2\beta)-\delta(\mu^2+2\beta)^2]. \tag{6.11}$$

The equation (6.11) was first obtained by Cosgrov[17] and labeled as SD-I.b.

Case ii: $B_0=2\beta/z^2$: Then $A_0=2(\mu-1)/z$, $B_1=-\frac{1}{2}A_0A_1$, where $(\mu-1)^2=-2\beta$. With out loss of generality, let $B_2=(1/z^2)[u-6(\mu-1)^2-6(\mu-1)-1+2\gamma z-2\delta z^2]$. Then Eq. (6.4) implies that $B_4=(1/z^2)(u-\mu^2)$, $B_3=(-2/z^2)[u+\gamma z-\mu(2\mu-1)]$. With these choices, the equation (6.6) becomes

$$Av^2+Bv+C=0, \tag{6.12}$$

where

$$A=u[u^2-2(\mu^2+2\alpha)u+(\mu^2-2\alpha)^2],$$
$$B=-4\mu zuu'-2(u+\gamma z)[u^2-2(\mu^2+2\alpha)u+(\mu^2-2\alpha)^2], \tag{6.13}$$
$$C=-[zu'-2\mu(u+\gamma z)]^2+(u-2\delta z^2+2\gamma z)(u+\mu^2-2\alpha)^2.$$

The equation (1.21) can be written as follows,

$$[zv'-(v-1)(\mu v-\mu-1)]^2=uv^4-2(u+\gamma z)v^3+(u-2\delta z^2+2\gamma z)v^2, \tag{6.14}$$

and the equation (1.22) becomes

$$v'=-\frac{1}{z(u+\mu^2-2\alpha)}\{\mu(u-\mu^2+2\alpha)v^2$$
$$+[zu'-u-2\gamma\mu z+(2\mu-1)(\mu^2-2\alpha)]v-(\mu-1)(u+\mu^2-2\alpha)\}. \tag{6.15}$$

Let $u(z)$ be a solution of the following second-order second-degree equation of Painlevé type:

$$[2uu''-(u')^2+2\delta u^2+2\gamma u-2\delta(\mu^2-2\alpha)^2-2\gamma^2(\mu^2+2\alpha)]^2$$
$$=8[u^2-\gamma z(\mu^2-2\alpha)^2]^2\{u(u')^2+(2\delta u+\gamma^2)$$
$$\times[u^2-2(\mu^2+2\alpha)u+(\mu^2-2\alpha)^2]\}. \tag{6.16}$$

Then Eqs. (6.12) and (6.14) give one-to-one correspondence between solutions $v(z)$ of PV and $u(z)$ of the equation (6.16).

VII. PAINLEVÉ VI

Let $v(z)$ be a solution of PVI

$$v''=\frac{1}{2}\left(\frac{1}{v}+\frac{1}{v-1}+\frac{1}{v-z}\right)(v')^2-\left(\frac{1}{z}+\frac{1}{z-1}+\frac{1}{v-z}\right)v'$$
$$+\frac{v(v-1)(v-z)}{z^2(z-1)^2}\left(\alpha+\frac{\beta z}{v^2}+\frac{\gamma(z-1)}{(v-1)^2}+\frac{\delta z(z-1)}{(v-z)^2}\right). \tag{7.1}$$

Then, for PVI, Eq. (1.22) takes the form of

$$(\phi_6v^6+\phi_5v^5+\phi_4v^4+\phi_3v^3+\phi_2v^2+\phi_1v+\phi_0)v'+\psi_8v^8$$
$$+\psi_7v^7+\psi_6v^6+\psi_5v^5+\psi_4v^4+\psi_3v^3+\psi_2v^2+\psi_1v+\psi_0=0, \tag{7.2}$$

where

$$\phi_6=\frac{2\alpha}{z^2(z-1)^2}-B_4-\frac{1}{2}A_2^2,\quad \phi_5=2(z+1)B_4+(z+1)A_2^2-\frac{4\alpha(z+1)}{z^2(z-1)^2}-A_2'-\frac{(2z-1)}{z(z-1)}A_2,$$

$$\phi_4=\frac{z}{(z-1)}A_2-\frac{(2z-1)}{z(z-1)}(A_1-A_2)+\frac{1}{2}A_1^2+A_0A_2+(z+1)A_1A_2-\frac{3}{2}zA_2^2+B_2+(z+1)B_3$$
$$-3zB_4+(z+1)A_2'-A_1'+\frac{2}{z^2(z-1)^2}[\alpha(z^2+4z+1)+\beta z+(\delta z+\gamma)(z-1)],$$

$$\phi_3=\frac{z}{(z-1)}(A_1-A_2)-\frac{(2z-1)}{z(z-1)}(A_0-A_1)+2A_0A_1-2zA_1A_2+2B_1-2zB_3$$
$$+(z+1)A_1'-A_0'-zA_2'-\frac{4}{z(z-1)^2}[(\alpha+\beta)(z+1)+(\gamma+\delta)(z-1)],$$

$$\phi_2=\frac{z}{(z-1)}(A_0-A_1)+\frac{(2z-1)}{z(z-1)}A_0+\frac{3}{2}A_0^2-(z+1)A_0A_1-zA_0A_2-\frac{1}{2}zA_1^2+3B_0-(z+1)B_1$$
$$-zB_2-zA_1'+(z+1)A_0'-\frac{2}{z(z-1)^2}[\alpha z+\beta(z^2+4z+1)+(\gamma z+\delta)(z-1)],$$

$$\phi_1=-\left[2(z+1)B_0+(z+1)A_0^2+\frac{4\beta(z+1)}{(z-1)^2}+zA_0'+\frac{z}{(z-1)}A_0\right],$$

$$\phi_0=z\left[B_0+\frac{1}{2}A_0^2+\frac{2\beta}{(z-1)^2}\right],$$

$$\psi_8=-\frac{1}{2}A_2\left[B_4+\frac{2\alpha}{z^2(z-1)^2}\right],$$

$$\psi_7=B_4\left[(z+1)A_2+\frac{1}{2}A_1-\frac{(2z-1)}{z(z-1)}\right]-\frac{1}{2}A_2B_3+\frac{\alpha}{z^2(z-1)^2}[2(z+1)A_2-A_1]-B_4',\quad (7.3)$$

$$\psi_6=B_4\left[\frac{3}{2}(A_0-zA_2)+\frac{2z}{(z-1)}+\frac{2(2z-1)}{z(z-1)}\right]+B_3\left[(z+1)A_2+\frac{1}{2}A_1-\frac{2(2z-1)}{z(z-1)}\right]$$
$$-\frac{1}{2}A_2B_2+(z+1)B_4'-B_3'+\frac{\alpha}{z^2(z-1)^2}[2(z+1)A_1-A_0]$$
$$-\frac{A_2}{z^2(z-1)^2}[\alpha(z^2+4z+1)+\beta z+(\delta z+\gamma)(z-1)],$$

$$\psi_5=B_3\left[\frac{3}{2}(A_0-zA_2)+\frac{2z}{(z-1)}+\frac{2(2z-1)}{z(z-1)}\right]+B_2\left[(z+1)A_2+\frac{1}{2}A_1-\frac{2(2z-1)}{z(z-1)}\right]-\frac{1}{2}A_2B_1$$
$$-B_4\left[\frac{1}{2}zA_1+(z+1)A_0+\frac{2z}{(z-1)}\right]+\frac{2\alpha(z+1)}{z^2(z-1)^2}A_0-\frac{A_1}{z^2(z-1)^2}[\alpha(z^2+4z+1)+\beta z$$
$$+(\delta z+\gamma)(z-1)]+\frac{2A_2}{z(z-1)^2}[(\alpha+\beta)(z+1)+(\gamma+\delta)(z-1)]+(z+1)B_3'-zB_4'-B_2',$$

$$\psi_4 = B_2\left[\frac{3}{2}(A_0 - zA_2) + \frac{2z}{(z-1)} + \frac{2(2z-1)}{z(z-1)}\right] + B_1\left[(z+1)A_2 + \frac{1}{2}A_1 - \frac{2(2z-1)}{z(z-1)}\right] - \frac{1}{2}A_2B_0$$
$$- B_3\left[\frac{1}{2}zA_1 + (z+1)A_0 + \frac{2z}{(z-1)}\right] + \frac{1}{2}zA_0B_4 - \frac{A_0}{z^2(z-1)^2}[\alpha(z^2+4z+1) + \beta z$$
$$+ (\delta z + \gamma)(z-1)] + \frac{2A_1}{z(z-1)^2}[(\alpha+\beta)(z+1) + (\gamma+\delta)(z-1)]$$
$$- \frac{A_2}{z(z-1)}[\alpha z + \beta(z^2+4z+1) + \gamma z(z-1) + \delta(z-1)] + (z+1)B_2' - zB_3' - B_1',$$

$$\psi_3 = B_1\left[\frac{3}{2}(A_0 - zA_2) + \frac{2z}{(z-1)} + \frac{2(2z-1)}{z(z-1)}\right] + B_0\left[(z+1)A_2 + \frac{1}{2}A_1 - \frac{2(2z-1)}{z(z-1)}\right] + \frac{1}{2}zA_0B_3$$
$$- B_2\left[\frac{1}{2}zA_1 + (z+1)A_0 + \frac{2z}{(z-1)}\right] + \frac{2\beta(z+1)}{(z-1)^2}A_2 + \frac{2A_0}{z(z-1)^2}[(\alpha+\beta)(z+1)$$
$$+ (\gamma+\delta)(z-1)] - \frac{A_1}{z(z-1)}[\alpha z + \beta(z^2+4z+1) + (\gamma z+\delta)(z-1)] + (z+1)B_1' - zB_2' - B_0',$$

$$\psi_2 = B_0\left[\frac{3}{2}(A_0 - zA_2) + \frac{2z}{(z-1)} + \frac{2(2z-1)}{z(z-1)}\right] - B_1\left[\frac{1}{2}zA_1 + (z+1)A_0 + \frac{2z}{(z-1)}\right]$$
$$+ \frac{1}{2}zA_0B_2 + (z+1)B_0' - zB_1' + \frac{\beta}{(z-1)^2}[2(z+1)A_1 - zA_2]$$
$$- \frac{A_0}{z(z-1)}[\alpha z + \beta(z^2+4z+1) + (\gamma z+\delta)(z-1)],$$

$$\psi_1 = \frac{\beta}{(z-1)^2}[2(z+1)A_0 - zA_1] + \frac{1}{2}zA_0B_1 - B_0\left[(z+1)A_0 + \frac{1}{2}zA_1 + \frac{2z}{(z-1)}\right] - zB_0',$$

$$\psi_0 = \frac{z}{2}A_0\left[B_0 - \frac{2\beta}{(z-1)^2}\right].$$

As an example, let

$$A_1 = \frac{-1}{z(z-1)}[(z^2-1)A_0 + 2], \quad A_2 = \frac{1}{z(z-1)}[(z-1)A_0 + 2],$$

$$B_3 = \frac{-1}{z^3(z-1)}[z^2(z^2-1)B_2 + z(z-1)(z^2+z+1)B_1 + (z-1)(z^3+z^2+z+1)B_0 - 2\gamma z^2 - 2\delta], \tag{7.4}$$

$$B_4 = \frac{1}{z^3(z-1)}[z^2(z-1)B_2 + z(z^2-1)B_1 + (z-1)(z^2+z+1)B_0 - 2\gamma z - 2\delta],$$

and $\phi_0 = \phi_1 = \psi_0 = \psi_1 = 0$. Then, the equation (7.2) takes the following form,

$$\phi_6 v' + \psi_8 v^2 + [\psi_7 + (z+1)\psi_8]v + \frac{1}{z^2}\psi_2 = 0, \tag{7.5}$$

and the equation (1.26) can be written as

$$\left(\psi_8 v^2+[\psi_7+(z+1)\psi_8]v+\frac{1}{z^2}\psi_2+\frac{1}{2}\phi_6(A_2v^2+A_1v+A_0)\right)^2$$
$$=\phi_6^2[(B_4+\tfrac{1}{4}A_2^2)v^4+(B_3+\tfrac{1}{2}A_1A_2)v^3+(B_2+\tfrac{1}{4}A_1^2+\tfrac{1}{2}A_0A_2)v^2$$
$$+(B_1+\tfrac{1}{2}A_0A_1)v+(B_0+\tfrac{1}{4}A_0^2)]. \tag{7.6}$$

The equation $\psi_0=0$ implies that either $A_0=0$ or $B_0=2\beta/(z-1)^2$.

Case i: $A_0=0$: Then, the equation $\phi_0=0$ implies that $B_0=-2\beta/(z-1)^2$ and then the equations $\phi_1=\psi_1=0$ are satisfied identically. Let $B_4=(\mu^2-1)/z^2(z-1)^2$, where $\mu=1-\sqrt{2\alpha}$ and $\sqrt{2\alpha}$ can take either sign, and without loss of generality, let $B_2=-[1/z^2(z-1)^2][4(z+1)u+(\beta-\alpha+\sqrt{\alpha})(3z+1)+(\gamma-\delta)(3z-1)]$. Then the equation (7.6) reduces to the following quadratic equation for v:

$$Av^2+Bv+C=0,$$
$$A=4\mu^2[4z(z-1)u'+4u+2\nu z-\kappa]+[4u-2\lambda(z-1)+\nu-\mu^2]^2, \tag{7.7}$$
$$B=2z[4u-2\lambda(z-1)+\nu-\mu^2][4(z-1)u'-4u-\nu]-4\mu^2z[4u+2(\gamma+\beta)(z-1)+\nu+4\beta],$$
$$C=z^2[4(z-1)u'-4u-\nu]^2+8\beta\mu^2z^2,$$

where $\kappa=\alpha-\beta+\gamma-\delta-\sqrt{2\alpha}+1$, $\lambda=\alpha+\delta-\sqrt{2\alpha}$, and $\nu=\beta+\gamma-\alpha-\delta+\sqrt{2\alpha}$. The equation (1.21) can be written as

$$[z(z-1)v'-v(v-1)]^2=\mu^2v^4+[4u-2\lambda(z-1)+\nu-\mu^2]v^3-[4(z+1)u+3\nu z-\kappa]v^2$$
$$+z[4u+2(\gamma+\beta)(z-1)+\nu+4\beta]v-2\beta z^2, \tag{7.8}$$

and the equation (1.22) becomes

$$v'=\frac{1}{2\mu z(z-1)}\{2\mu\sqrt{2\alpha}v^2-[4u-2\lambda(z-1)+\nu-\mu^2+2\mu]v-z[4(z-1)u'-4u-\nu]\}. \tag{7.9}$$

Equations (7.7) and (7.8) give one-to-one correspondence between solutions $v(z)$ of PVI and solutions $u(z)$ of the following second-order second degree equation of Painlevé type:

$$z^2(z-1)^2(u'')^2=-4u'(zu'-u)^2+4(u')^2(zu'-u)+\kappa(u')^2+\lambda(\gamma+\beta)(zu'-u)$$
$$+\tfrac{1}{4}[4(\gamma-\beta)(\mu^2-\lambda)+\nu^2]u'+\tfrac{1}{4}[\lambda^2(\gamma-\beta)+(\gamma+\beta)^2(\mu^2-\lambda)]. \tag{7.10}$$

The equation (7.10) was first obtained by Cosgrove[17] and labeled as SD-I.a.

Case ii: $B_0=2\beta/(z-1)^2$: Then $A_0=2(\mu-1)/(z-1)$, $B_0=\tfrac{1}{4}A_0^2$, and $B_1=-\tfrac{1}{2}A_0A_1$, where $(\mu-1)^2=-2\beta$. Without loss of generality, let

$$B_2=\frac{1}{z^2(z-1)^2}[zu-\mu^2(z^2+4z+1)+2\mu z(z+2)-(z^2+z-1)+2\gamma z(z-1)+2\delta(z-1)]. \tag{7.11}$$

Then one obtains $B_4=[1/z^2(z-1)^2](u-\mu^2)$ and $B_3=[-1/z^2(z-1)^2][(z+1)(u-2\mu^2)+2\mu z+\lambda(z-1)]$, where $\lambda=2\gamma+2\delta-1$. With these choices the equation (7.6) yields the following quadratic equation for v:

$$Av^2+Bv+C=0, \tag{7.12}$$

where

$$\begin{aligned} A&=u[u^2-2(\mu^2+2\alpha)u+(\mu^2-2\alpha)^2],\\ B&=-(4\mu z(z-1)uu'+[(z+1)u+\lambda(z-1)][u^2-2(\mu^2+2\alpha)u+(\mu^2-2\alpha)^2]),\\ C&=-(z(z-1)u'-\mu[(z+1)u+\lambda(z-1)])^2+[zu+2\gamma(z-1)^2+\lambda(z-1)](u+\mu^2-2\alpha)^2. \end{aligned} \tag{7.13}$$

The equations (1.21) and (1.22) become

$$\begin{aligned} &[z(z-1)v'-\mu v^2+(\mu z-z+\mu)v-(\mu-1)z]^2\\ &\quad =uv^4-[(z+1)u+\lambda(z-1)]v^3+[zu+2\gamma(z-1)^2+\lambda(z-1)]v^2, \end{aligned} \tag{7.14}$$

and

$$\begin{aligned} v'=\frac{-1}{z(z-1)(u+\mu^2-2\alpha)}&\{\mu(u-\mu^2+2\alpha)v^2+[z(z-1)u'-z(u+\mu^2-2\alpha)\\ &-\mu\lambda(z-1)+\mu(\mu^2-2\alpha)(z+1)]v-(\mu-1)z(u+\mu^2-2\alpha)\}, \end{aligned} \tag{7.15}$$

respectively. Let $u(z)$ be a solution of the following second-order second-degree equation of Painlevé type:

$$\begin{aligned} &[4z^2u^2u''-2z^2u(u')^2+4zu^2u'+P_4(u)]^2\\ &\quad=\left[\frac{(z+1)}{(z-1)}u^2-\lambda(\mu^2-2\alpha)\right]^2[4z^2u(u')^2+Q_4(u)],\\ &P_4(u):=u^4+(\lambda-4\gamma-\mu^2-2\alpha)u^3+[\lambda^2(\mu^2+2\alpha)+(\lambda-4\gamma)(\mu^2-2\alpha)^2]u-\lambda^2(\mu^2-2\alpha)^2,\\ &Q_4(u):=[u^2+2(\lambda-4\gamma)u+\lambda^2][u^2-2(\mu^2+2\alpha)u+(\mu^2-2\alpha)^2]. \end{aligned} \tag{7.16}$$

Then, the equations (7.12) and (7.14) gives one-to-one correspondence between solutions $v(z)$ of PVI and $u(z)$ of the equation (7.16).

Classification of differential calculi on $U_q(\mathfrak{b}_+)$, classical limits, and duality

Robert Oeckl
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge CB3 9EW, United Kingdom

(Received 27 July 1998; accepted for publication 5 March 1999)

We give a complete classification of bicovariant first order differential calculi on the quantum enveloping algebra $U_q(\mathfrak{b}_+)$ which we view as the quantum function algebra $C_q(B_+)$. Here, $\mathfrak{b}_+$ is the Borel subalgebra of $\mathfrak{sl}_2$. We do the same in the classical limit $q \to 1$ and obtain a one-to-one correspondence in the finite dimensional case. It turns out that the classification is essentially given by finite subsets of the positive integers. We proceed to investigate the classical limit from the dual point of view, i.e., with ''function algebra'' $U(\mathfrak{b}_+)$ and ''enveloping algebra'' $C(B_+)$. In this case there are many more differential calculi than coming from the q-deformed setting. As an application, we give the natural intrinsic four-dimensional calculus of κ-Minkowski space and the associated formal integral.
 [S0022-2488(99)00807-5]

I. INTRODUCTION

One of the fundamental ingredients in the theory of noncommutative or quantum geometry is the notion of a differential calculus. In the framework of quantum groups the natural notion is that of a bicovariant differential calculus as introduced by Woronowicz.[1] Due to the allowance of noncommutativity the uniqueness of a canonical calculus is lost. It is therefore desirable to classify the possible choices. The most important piece is the space of one-forms or ''first order differential calculus'' to which we will restrict our attention in the following. (From this point on we will use the term ''differential calculus'' to denote a bicovariant first order differential calculus.)

Much attention has been devoted to the investigation of differential calculi on quantum groups $C_q(G)$ of function algebra type for G a simple Lie group. Natural differential calculi on matrix quantum groups were obtained by Jurco[2] and Carow-Watamura *et al.*[3] A partial classification of calculi of the same dimension as the natural ones was obtained by Schmüdgen and Schüler.[4] More recently, a classification theorem for factorisable cosemisimple quantum groups was obtained by Majid,[5] covering the general $C_q(G)$ case. A similar result was obtained later by Baumann and Schmitt.[6] Also, Heckenberger and Schmüdgen[7] gave a complete classification on $C_q(SL(N))$ and $C_q(Sp(N))$.

In contrast, for G not simple or semisimple the differential calculi on $C_q(G)$ are largely unknown. A particularly basic case is the Lie group B_+ associated with the Lie algebra $\mathfrak{b}_+$ generated by two elements X,H with the relation $[H,X]=X$. The quantum enveloping algebra $U_q(\mathfrak{b}_+)$ is self-dual, i.e., is nondegenerately paired with itself.[8] This has an interesting consequence: $U_q(\mathfrak{b}_+)$ may be identified with (a certain algebraic model of) $C_q(B_+)$. The differential calculi on this quantum group and on its ''classical limits'' $C(B_+)$ and $U(\mathfrak{b}_+)$ will be the main concern of this paper. We pay hereby equal attention to the dual notion of ''quantum tangent space.''

In Sec. II we obtain the complete classification of differential calculi on $C_q(B_+)$. It turns out that (finite dimensional) differential calculi are characterized by finite subsets $I \subset \mathbb{N}$. These sets determine the decomposition into coirreducible (i.e., not admitting quotients) differential calculi characterized by single integers. For the coirreducible calculi the explicit formulas for the commutation relations and braided derivations are given.

In Sec. III we give the complete classification for the classical function algebra $C(B_+)$. It is essentially the same as in the q-deformed setting and we stress this by giving an almost one-to-one correspondence of differential calculi to those obtained in the previous section. In contrast, however, the decomposition and coirreducibility properties do not hold at all. (One may even say that they are maximally violated.) We give the explicit formulas for those calculi corresponding to coirreducible ones.

More interesting perhaps is the ''dual'' classical limit, i.e., we view $U(\mathfrak{b}_+)$ as a quantum function algebra with quantum enveloping algebra $C(B_+)$. This is investigated in Sec. IV. It turns out that in this setting we have considerably more freedom in choosing a differential calculus since the bicovariance condition becomes much weaker. This shows that this dual classical limit is in a sense ''unnatural'' as compared to the ordinary classical limit of Sec. III. However, we can still establish a correspondence of certain differential calculi to those of Sec. II. The decomposition properties are conserved while the coirreducibility properties are not. We give the formulas for the calculi corresponding to coirreducible ones.

Another interesting aspect of viewing $U(\mathfrak{b}_+)$ as a quantum function algebra is the connection to quantum deformed models of space–time and its symmetries. In particular, the κ-deformed Minkowski space coming from the κ-deformed Poincaré algebra[9,10] is just a simple generalization of $U(\mathfrak{b}_+)$. We use this in Sec. V to give a natural four-dimensional differential calculus. Then we show (in a formal context) that integration is given by the usual Lesbegue integral on $\mathbb{R}^n$ after normal ordering. This is obtained in an intrinsic context different from the standard κ-Poincaré approach.

A further important motivation for the investigation of differential calculi on $U(\mathfrak{b}_+)$ and $C(B_+)$ is the relation of those objects to the Planck-scale Hopf algebra.[11,12] This shall be developed elsewhere.

In the remaining parts of this introduction we will specify our conventions and provide preliminaries on the quantum group $U_q(\mathfrak{b}_+)$, its deformations, and differential calculi.

A. Conventions

Throughout, $\mathbb{k}$ denotes a field of characteristic 0 and $\mathbb{k}(q)$ denotes the field of rational functions in one parameter q over $\mathbb{k}$. $\mathbb{k}(q)$ is our ground field in the q-deformed setting, while $\mathbb{k}$ is the ground field in the ''classical'' settings. Within Sec. II one could equally well view $\mathbb{k}$ as the ground field with $q \in \mathbb{k}^*$ not a root of unity. This point of view is problematic, however, when obtaining ''classical limits'' as in Secs. III and IV.

The positive integers are denoted by $\mathbb{N}$ while the non-negative integers are denoted by $\mathbb{N}_0$. We define q-integers, q-factorials, and q-binomials as follows:

$$[n]_q = \sum_{i=0}^{n-1} q^i, \quad [n]_q! = [1]_q [2]_q \cdots [n]_q, \quad \begin{bmatrix} n \\ m \end{bmatrix}_q = \frac{[n]_q!}{[m]_q! [n-m]_q!}.$$

For a function of several variables (among them x) over $\mathbb{k}$ we define

$$(T_{a,x} f)(x) = f(x+a), \quad (\nabla_{a,x} f)(x) = \frac{f(x+a) - f(x)}{a},$$

with $a \in \mathbb{k}$ and similarly over $\mathbb{k}(q)$

$$(Q_{m,x} f)(x) = f(q^m x), \quad (\partial_{q,x} f)(x) = \frac{f(x) - f(qx)}{x(1-q)},$$

with $m \in \mathbb{Z}$.

We frequently use the notion of a polynomial in an extended sense. Namely, if we have an algebra with an element g and its inverse g^{-1} [as in $U_q(\mathfrak{b}_+)$] we will mean by a polynomial in g, g^{-1} a finite power series in g with exponents in $\mathbb{Z}$. The length of such a polynomial is the difference between highest and lowest degree.

If H is a Hopf algebra, then H^{op} will denote the Hopf algebra with the opposite product.

B. $U_q(\mathfrak{b}_+)$ and its classical limits

We recall that, in the framework of quantum groups, the duality between enveloping algebra $U(\mathfrak{g})$ of the Lie algebra and algebra of functions $C(G)$ on the Lie group carries over to q-deformations. In the case of $\mathfrak{b}_+$, the q-deformed enveloping algebra $U_q(\mathfrak{b}_+)$ defined over $\mathbb{k}(q)$ as

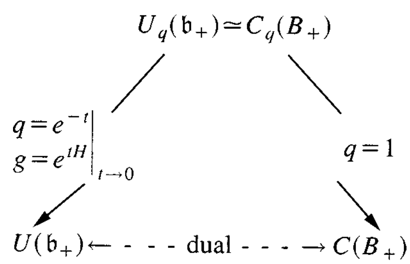
$$U_q(\mathfrak{b}_+)=\mathbb{k}(q)\langle X,g,g^{-1}\rangle \quad \text{with relations,}$$

$$gg^{-1}=1, \quad Xg=qgX,$$

$$\Delta X=X\otimes 1+g\otimes X, \quad \Delta g=g\otimes g,$$

$$\epsilon(X)=0, \quad \epsilon(g)=1, \quad \mathrm{S}X=-g^{-1}X, \quad \mathrm{S}g=g^{-1}$$

is self-dual. Consequently, it may alternatively be viewed as the quantum algebra $C_q(B_+)$ of functions on the Lie group B_+ associated with $\mathfrak{b}_+$. It has two classical limits, the enveloping algebra $U(\mathfrak{b}_+)$ and the function algebra $C(B_+)$. The transition to the classical enveloping algebra is achieved by replacing q by e^{-t} and g by e^{tH} in a formal power series setting in t, introducing a new generator H. Now, all expressions are written in the form $\Sigma_j a_j t^j$ and only the lowest order in t is kept. The transition to the classical function algebra on the other hand is achieved by setting $q=1$. This may be depicted as follows:



The self-duality of $U_q(\mathfrak{b}_+)$ is expressed as a pairing $U_q(\mathfrak{b}_+)\times U_q(\mathfrak{b}_+)\rightarrow\mathbb{k}$ with itself,

$$\langle X^n g^m, X^r g^s\rangle=\delta_{n,r}[n]_q!q^{-n(n-1)/2}q^{-ms} \quad \forall n,r\in\mathbb{N}_0 \; m,s\in\mathbb{Z}.$$

In the classical limit this becomes the pairing $U(\mathfrak{b}_+)\times C(B_+)\rightarrow\mathbb{k}$,

$$\langle X^n H^m, X^r g^s\rangle=\delta_{n,r}n!s^m \quad \forall n,m,r\in\mathbb{N}_0 \; s\in\mathbb{Z}. \tag{1}$$

C. Differential calculi and quantum tangent spaces

In this section we recall some facts about differential calculi along the lines of Majid's treatment in Ref. 5.

Following Woronowicz,[1] first order bicovariant differential calculi on a quantum group A (of function algebra type) are in one-to-one correspondence to submodules M of $\ker\epsilon\subset A$ in the category ${}^A_A\mathcal{M}$ of (say) left crossed modules of A via left multiplication and left adjoint coaction,

$$a\triangleright v=av, \quad \mathrm{Ad_L}(v)=v_{(1)}\mathrm{S}v_{(3)}\otimes v_{(2)} \quad \forall a\in A, v\in M.$$

More precisely, given a crossed submodule M, the corresponding calculus is given by $\Gamma=\ker\epsilon/M\otimes A$ with $\mathrm{d}a=\pi(\Delta a-1\otimes a)$ (π the canonical projection). The right action and coaction on Γ are given by the right multiplication and coproduct on A, the left action and coaction by the tensor product ones with $\ker\epsilon/M$ as a left crossed module. In all of what follows, ''differential calculus'' will mean ''bicovariant first order differential calculus.''

Alternatively,[5] given in addition a quantum group H dually paired with A (which we might think of as being of enveloping algebra type), we can express the coaction of A on itself as an action of H^{op} using the pairing

$$h \triangleright v = \langle h, v_{(1)} \mathrm{S} v_{(3)} \rangle v_{(2)} \quad \forall h \in H^{\mathrm{op}}, v \in A.$$

Thereby we change from the category of (left) crossed A-modules to the category of left modules of the quantum double $A \bowtie H^{\mathrm{op}}$.

In this picture the pairing between A and H descends to a pairing between $A/\mathbb{k}1$ (which we may identify with $\ker\epsilon \subset A$) and $\ker\epsilon \subset H$. Further quotienting $A/\mathbb{k}1$ by M (viewed in $A/\mathbb{k}1$) leads to a pairing with the subspace $L \subset \ker\epsilon c H$ that annihilates M. L is called a ''quantum tangent space'' and is dual to the differential calculus Γ generated by M in the sense that $\Gamma \cong \mathrm{Lin}(L,A)$ via

$$A/(\mathbb{k}1 + M) \otimes A \to \mathrm{Lin}(L,A) \quad v \otimes a \mapsto \langle \cdot , v \rangle a \tag{2}$$

if the pairing between $A/(\mathbb{k}1+M)$ and L is nondegenerate.

The quantum tangent spaces are obtained directly by dualising the (left) action of the quantum double on A to a (right) action on H. Explicitly, this is the adjoint action and the coregular action

$$h \triangleright x = h_{(1)} x \mathrm{S} h_{(2)}, \quad a \triangleright x = \langle x_{(1)}, a \rangle x_{(2)} \quad \forall a \in A^{\mathrm{op}}, h, x \in H,$$

where we have converted the right action to a left action by going from $A \bowtie H^{\mathrm{op}}$-modules to $H \bowtie A^{\mathrm{op}}$-modules. Quantum tangent spaces are subspaces of $\ker\epsilon \subset H$ invariant under the projection of this action to $\ker\epsilon$ via $x \mapsto x - \epsilon(x)1$. Alternatively, the left action of A^{op} can be converted to a left coaction of H being the comultiplication (with subsequent projection onto $H \otimes \ker\epsilon$).

We can use the evaluation map (2) to define a ''braided derivation'' on elements of the quantum tangent space via

$$\partial_x : A \to A \quad \partial_x(a) = \mathrm{d}a(x) = \langle x, a_{(1)} \rangle a_{(2)} \quad \forall x \in L, a \in A.$$

This obeys the braided derivation rule

$$\partial_x(ab) = (\partial_x a) b + a_{(2)} \partial_{a_{(1)} \triangleright x} b \quad \forall x \in L, a \in A.$$

Given a right invariant basis $\{\eta_i\}_{i \in I}$ of Γ with a dual basis $\{\phi_i\}_{i \in I}$ of L we have

$$\mathrm{d}a = \sum_{i \in I} \eta_i \cdot \partial_i(a) \quad \forall a \in A,$$

where we denote $\partial_i = \partial_{\phi_i}$. (This can be easily seen to hold by evaluation against $\phi_i \forall i$.)

II. CLASSIFICATION ON $C_q(B_+)$ AND $U_q(\mathfrak{b}_+)$

In this section we completely classify differential calculi on $C_q(B_+)$ and, dually, quantum tangent spaces on $U_q(\mathfrak{b}_+)$. We start by classifying the relevant crossed modules and then proceed to a detailed description of the calculi.

Lemma II.1: (a) Left crossed $C_q(B_+)$-submodules $M \subseteq C_q(B_+)$ by left multiplication and left adjoint coaction are in one-to-one correspondence to pairs (P,I), where $P \in \mathbb{k}(q)[g]$ is a polynomial with $P(0)=1$ and $I \subset \mathbb{N}$ is finite. $\mathrm{codim} M < \infty$ iff $P=1$. *In particular* $\mathrm{codim} M = \Sigma_{n \in I} n$ *if* $P=1$.

(b) The finite codimensional maximal M correspond to the pairs $(1,\{n\})$ with n the codimension. The infinite codimensional maximal M are characterized by $(P,\emptyset)$ with P irreducible and $P(g) \neq 1 - q^{-k} g$ for any $k \in \mathbb{N}_0$.

(c) Crossed submodules M of finite codimension are intersections of maximal ones. In particular $M = \cap_{n \in I} M^n$, with M^n corresponding to $(1,\{n\})$.

Proof: (a) Let $M \subseteq C_q(B_+)$ be a crossed $C_q(B_+)$-submodule by left multiplication and left adjoint coaction and let $\Sigma_n X^n P_n(g) \in M$, where P_n are polynomials in g, g^{-1} (every element of $C_q(B_+)$ can be expressed in this form). From the formula for the coaction ((A1), see Appendix) we observe that for all n and for all $t \leqslant n$ the element

$$X^t P_n(g) \prod_{s=1}^{n-t} (1-q^{s-n}g)$$

lies in *M*. In particular this is true for $t=n$, meaning that elements of constant degree in *X* lie separately in *M*. It is therefore enough to consider such elements.

Let now $X^n P(g) \in M$. By left multiplication $X^n P(g)$ generates any element of the form $X^k P(g) Q(g)$, where $k \geqslant n$ and Q is any polynomial in g, g^{-1}. (Note that $Q(q^k g) X^k = X^k Q(g)$.) We see that *M* contains the following elements:

$$\begin{array}{l}
\vdots \\
X^{n+2}P(g) \\
X^{n+1}P(g) \\
X^{n}P(g) \\
X^{n-1}P(g)(1-q^{1-n}g) \\
X^{n-2}P(g)(1-q^{1-n}g)(1-q^{2-n}g) \\
\vdots \\
XP(g)(1-q^{1-n}g)(1-q^{2-n}g)\ldots(1-q^{-1}g) \\
\quad P(g)(1-q^{1-n}g)(1-q^{2-n}g)\ldots(1-q^{-1}g)(1-g).
\end{array}$$

Moreover, if *M* is generated by $X^n P(g)$ as a module then these elements generate *M* as a vector space by left multiplication with polynomials in g, g^{-1}. (Observe that the application of the coaction to any of the elements shown does not generate elements of new type.)

Now, let *M* be a given crossed submodule. We pick, among the elements in *M* of the form $X^n P(g)$ with *P* of minimal length, one with lowest degree in *X*. Then certainly the elements listed above are in *M*. Furthermore for any element of the form $X^k Q(g)$, Q must contain *P* as a factor and for $k<n$, Q must contain $P(g)(1-q^{1-n}g)$ as a factor. We continue by picking the smallest n_2, so that $X^{n_2}P(g)(1-q^{1-n}g) \in M$. Certainly $n_2<n$. Again, for any element of $X^l Q(g)$ in *M* with $l<n_2$, we have that $P(g)(1-q^{1-n}g)(1-q^{1-n_2}g)$ divides $Q(g)$. We proceed by induction, until we arrive at degree zero in *X*.

We obtain the following elements generating *M* as a vector space by left multiplication with polynomials in g, g^{-1} (rename $n_1=n$):

$$\begin{array}{l}
\vdots \\
X^{n_1+1}P(g) \\
X^{n_1}P(g) \\
X^{n_1-1}P(g)(1-q^{1-n_1}g) \\
\vdots
\end{array}$$

$$X^{n_2}P(g)(1-q^{1-n_1}g)$$

$$X^{n_2-1}P(g)(1-q^{1-n_1}g)(1-q^{1-n_2}g)$$

$$\vdots$$

$$X^{n_3}P(g)(1-q^{1-n_1}g)(1-q^{1-n_2}g)$$

$$X^{n_3-1}P(g)(1-q^{1-n_1}g)(1-q^{1-n_2}g)(1-q^{1-n_3}g)$$

$$\vdots$$

$$P(g)(1-q^{1-n_1}g)(1-q^{1-n_2}g)(1-q^{1-n_3}g)\cdots(1-q^{1-n_m}g).$$

We see that the integers $n_1,\ldots,n_m$ uniquely determine the shape of this picture. The polynomial $P(g)$ on the other hand can be shifted (by g and g^{-1}) or renormalized. To determine M uniquely we shift and normalize P in such a way that it contains no negative powers and has unit constant coefficient. P can then be viewed as a polynomial $\in \Bbbk(q)[g]$.

We see that the codimension of M is the sum of the lengths of the polynomials in g over all degrees in X in the above picture. Finite codimension corresponds to $P=1$. In this case the codimension is the sum $n_1+\cdots+n_m$.

(b) We observe that polynomials of the form $1-q^j g$ have no common divisors for distinct j. Therefore, finite codimensional crossed submodules are maximal if and only if there is just one integer $(m=1)$. Thus, the maximal left crossed submodule of codimension k is generated by X^k and $1-q^{1-k}g$. For an infinite codimensional crossed submodule we certainly need $m=0$. Then, the maximality corresponds to irreducibility of P.

(c) This is again due to the distinctness of factors $1-q^j g$. □

Corollary II.2: (a) Left crossed $C_q(B_+)$-submodules $M\subseteq \ker\epsilon\subset C_q(B_+)$ are in one-to-one correspondence to pairs (P,I) as in Lemma II.1 with the additional constraint $(1-g)$ divides $P(g)$ or $1\in I$. $\operatorname{codim} M<\infty$ iff $P=1$. *In particular* $\operatorname{codim}M=(\Sigma_{n\in I}n)-1$ *if* $P=1$.

(b) The finite codimensional maximal M correspond to the pairs $(1,\{1,n\})$ with $n\geqslant 2$ the codimension. The infinite codimensional maximal M correspond to pairs $(P,\{1\})$ with P irreducible and $P(g)\neq 1-q^{-k}g$ for any $k\in\mathbb{N}_0$.

(c) Crossed submodules M of finite codimension are intersections of maximal ones. In particular $M=\cap_{n\in I}M^n$, with M^n corresponding to $(1,\{1,n\})$.

Proof: First observe that $\Sigma_n X^n P_n(g)\in\ker\epsilon$ if and only if $(1-g)$ divides $P_0(g)$. This is to say that that $\ker\epsilon$ is the crossed submodule corresponding to the pair $(1,\{1\})$ in Lemma II.1. We obtain the classification from the one of Lemma II.1 by intersecting everything with this crossed submodule. In particular, this reduces the codimension by one in the finite codimensional case. □

Lemma II.3: (a) Left crossed $U_q(\mathfrak{b}_+)$-submodules $L\subseteq U_q(\mathfrak{b}_+)$ via the left adjoint action and left regular coaction are in one-to-one correspondence to the set $\{\mathbb{N}_0\rightarrow\{1,2,3\}\}\times\{\mathbb{N}\rightarrow\{1,2\}\}$. Finite dimensional L are in one-to-one correspondence to finite sets $I\subset\mathbb{N}$ and $\dim L=\Sigma_{n\in I}n$.

(b) Finite dimensional irreducible L correspond to $\{n\}$ with n the dimension.

(c) Finite dimensional L are direct sums of irreducible ones. In particular $L=\oplus_{n\in I}L^n$ with L^n corresponding to $\{n\}$.

Proof: (a) The action takes the explicit form

$$g\triangleright X^n g^k=q^{-n}X^n g^k,\quad X\triangleright X^n g^k=X^{n+1}g^k(1-q^{-(n+k)}),$$

while the coproduct is

$$\Delta(X^n g^k)=\sum_{r=0}^{n}\begin{bmatrix} n\\ r\end{bmatrix}_q q^{-r(n-r)}X^{n-r}g^{k+r}\otimes X^r g^k,$$

which we view as a left coaction here. Let now $L \subseteq U_q(\mathfrak{b}_+)$ be a crossed $U_q(\mathfrak{b}_+)$-submodule via this action and coaction. For $\Sigma_n X^n P_n(g) \in L$ invariance under the action by g clearly means that $X^n P_n(g) \in L\ \forall n$. Then from invariance under the coaction we can conclude that if $X^n \Sigma_j a_j g^j \in L$ we must have $X^n g^j \in L\ \forall j$, i.e., elements of the form $X^n g^j$ lie separately in L and it is sufficient to consider such elements. From the coaction we learn that if $X^n g^j \in L$ we have $X^m g^j \in L\ \forall m \leqslant n$. The action by X leads to $X^n g^j \in L \Rightarrow X^{n+1} g^j \in L$ except if $n+j=0$. The classification is given by the possible choices we have for each power in g. For every positive integer j we can choose whether or not to include the span of $\{X^n g^j | \forall n\}$ in L and for every nonpositive integer we can choose to include either the span of $\{X^n g^j | \forall n\}$ or just $\{X^n g^j | \forall n \leqslant -j\}$ or neither, i.e., for positive integers ($\mathbb{N}$) we have two choices while for nonpositive (identified with $\mathbb{N}_0$) ones we have three choices.

Clearly, the finite dimensional L are those where we choose only to include finitely many powers of g and also only finitely many powers of X. The latter is only possible for the nonpositive powers of g. By identifying positive integers n with powers $1-n$ of g, we obtain a classification by finite subsets of $\mathbb{N}$.

(b) Irreducibility clearly corresponds to just including one power of g in the finite dimensional case.

(c) The decomposition property is obvious from the discussion. □

Corollary II.4: (a) Left crossed $U_q(\mathfrak{b}_+)$*-submodules* $L \subseteq \ker\epsilon \subset U_q(\mathfrak{b}_+)$ *via the left adjoint action and left regular coaction (with subsequent projection to* $\ker\epsilon$ *via* $x \mapsto x - \epsilon(x)1$*) are in one-to-one correspondence to the set* $\{\mathbb{N} \to \{1,2,3\}\} \times \{\mathbb{N}_0 \to \{1,2\}\}$. *Finite dimensional L are in one-to-one correspondence to finite sets* $I \subset \mathbb{N} \backslash \{1\}$ *and* $\dim L = \Sigma_{n \in I} n$.

(b) Finite dimensional irreducible L correspond to $\{n\}$ *with* $n \geqslant 2$ *the dimension.*

(c) Finite dimensional L are direct sums of irreducible ones. In particular $L = \oplus_{n \in I} L^n$ *with* L^n *corresponding to* $\{n\}$.

Proof: Only a small modification of Lemma II.3 is necessary. Elements of the form $P(g)$ are replaced by elements of the form $P(g)-P(1)$. Monomials with nonvanishing degree in X are unchanged. The choices for elements of degree 0 in g are reduced to either including the span of $\{X^k | \forall k>0\}$ in the crossed submodule or not. In particular, the crossed submodule characterized by $\{1\}$ in Lemma II.3 is projected out. □

Differential calculi in the original sense of Woronowicz are classified by Corollary II.2 while from the quantum tangent space point of view the classification is given by Corollary II.4. In the finite dimensional case the duality is strict in the sense of a one-to-one correspondence. The infinite dimensional case on the other hand depends strongly on the algebraic models we use for the function or enveloping algebras. It is therefore not surprising that in the present purely algebraic context the classifications are quite different in this case. We will restrict ourselves to the finite dimensional case in the following description of the differential calculi.

Theorem II.5: *(a) Finite dimensional differential calculi* Γ *on* $C_q(B_+)$ *and corresponding quantum tangent spaces L on* $U_q(\mathfrak{b}_+)$ *are in one-to-one correspondence to finite sets* $I \subset \mathbb{N} \backslash \{1\}$. *In particular* $\dim \Gamma = \dim L = \Sigma_{n \in I} n$.

(b) Coirreducible Γ *and irreducible L correspond to* $\{n\}$ *with* $n \geqslant 2$ *the dimension. Such a* Γ *has a right invariant basis* $\eta_0, \ldots, \eta_{n-1}$ *so that the relations*

$$\mathrm{d}X = \eta_1 + (q^{n-1}-1)\eta_0 X, \quad \mathrm{d}g = (q^{n-1}-1)\eta_0 g,$$

$$[a, \eta_0] = \mathrm{d}a \quad \forall a \in C_q(B_+),$$

$$[g, \eta_i]_{q^{n-1-i}} = 0 \quad \forall i, \quad [X, \eta_i]_{q^{n-1-i}} = \begin{cases} \eta_{i+1} & if \quad i < n-1 \\ 0 & if \quad i = n-1 \end{cases}$$

hold, where $[a,b]_p := ab - pba$. *By choosing the dual basis on the corresponding irreducible L we obtain the braided derivations*

$$\partial_i:f:=:Q_{n-1-i,g}Q_{n-1-i,X}\frac{1}{[i]_q!}(\partial_{q,X})^i f: \quad \forall i\geq 1,$$

$$\partial_0:f:=:Q_{n-1,g}Q_{n-1,X}f-f:$$

for $f\in \Bbbk(q)[X,g,g^{-1}]$ *with normal ordering* $\Bbbk(q)[X,g,g^{-1}]\to C_q(B_+)$ *given by* $g^nX^m\mapsto g^nX^m$.

(c) Finite dimensional Γ *and* L *decompose into direct sums of coirreducible, respectively, irreducible ones. In particular* $\Gamma=\oplus_{n\in I}\Gamma^n$ *and* $L=\oplus_{n\in I}L^n$ *with* Γ^n *and* L^n *corresponding to* $\{n\}$.

Proof: (a) We observe that the classifications of Lemma II.1 and Lemma II.3 or Corollary II.2 and Corollary II.4 are dual to each other in the finite (co)dimensional case. More precisely, for $I\subset\mathbb{N}$ finite the crossed submodule M corresponding to $(1,I)$ in Lemma II.1 is the annihilator of the crossed submodule L corresponding to I in Lemma II.3 and vice versa. $C_q(B_+)/M$ and L are dual spaces with the induced pairing. For $I\subset\mathbb{N}\setminus\{1\}$ finite this descends to M corresponding to $(1,I\cup\{1\})$ in Corollary II.2 and L corresponding to I in Corollary II.4. For the dimension of Γ observe $\dim\Gamma=\dim\ker\epsilon/M=\operatorname{codim} M$.

(b) Coirreducibility (having no proper quotient) of Γ clearly corresponds to maximality of M. The statement then follows from parts (b) of Corollaries II.2 and II.4. The formulas are obtained by choosing the basis $\eta_0,\ldots,\eta_{n-1}$ of $\ker\epsilon/M$ as the equivalence classes of

$$(g-1)/(q^{n-1}-1),X,\ldots,X^{n-1}.$$

The dual basis of L is then given by

$$g^{1-n}-1,Xg^{1-n},\ldots,q^{k(k-1)}\frac{1}{[k]_q!}X^kg^{1-n},\ldots,q^{(n-1)(n-2)}\frac{1}{[n-1]_q!}X^{n-1}g^{1-n}.$$

(c) The statement follows from Corollaries II.2 and II.4 parts (c) with the observation

$$\ker\epsilon/M=\ker\epsilon/\bigcap_{n\in I}M^n=\oplus_{n\in I}\ker\epsilon/M^n.$$

□

Corollary II.6: There is precisely one differential calculus on $C_q(B_+)$ *which is natural in the sense that it has dimension 2. It is coirreducible and obeys the relations*

$$[g,\mathrm{d}X]=0,\quad [g,\mathrm{d}g]_q=0,\quad [X,\mathrm{d}X]_q=0,\quad [X,\mathrm{d}g]_q=(q-1)(\mathrm{d}X)g,$$

with $[a,b]_q:=ab-qba$. In particular we have

$$\mathrm{d}:f:=\mathrm{d}g:\partial_{q,g}f:+\mathrm{d}X:\partial_{q,X}f:\quad \forall f\in\Bbbk(q)[X,g,g^{-1}].$$

Proof: This is a special case of Theorem II.5. The formulas follow from (b) with $n=2$. □

III. CLASSIFICATION IN THE CLASSICAL LIMIT

In this section we give the complete classification of differential calculi and quantum tangent spaces in the classical case of $C(B_+)$ along the lines of the previous section. We pay particular attention to the relation to the q-deformed setting.

The classical limit $C(B_+)$ of the quantum group $C_q(B_+)$ is simply obtained by substituting the parameter q with 1. The classification of left crossed submodules in part (a) of Lemma II.1 remains unchanged, as one may check by going through the proof. In particular, we get a correspondence of crossed modules in the q-deformed setting with crossed modules in the classical setting as a map of pairs $(P,I)\mapsto(P,I)$ that converts polynomials $\Bbbk(q)[g]$ to polynomials $\Bbbk[g]$ (if defined) and leaves sets I unchanged. This is one-to-one in the finite dimensional case. However, we did use the distinctness of powers of q in part (b) and (c) of Lemma II.1 and have to account for changing this. The only place where we used it, was in observing that factors $1-q^j g$ have no common divisors for distinct j. This was crucial to conclude the maximality (b) of certain finite codimensional crossed submodules and the intersection property (c). Now, all those factors become $1-g$.

Corollary III.1: (a) Left crossed $C(B_+)$-submodules $M\subseteq C(B_+)$ by left multiplication and left adjoint coaction are in one-to-one correspondence to pairs (P,I), where $P\in \Bbbk[g]$ is a polynomial with $P(0)=1$ and $I\subset\mathbb{N}$ is finite. $\operatorname{codim} M<\infty$ iff $P=1$. *In particular* $\operatorname{codim} M=\Sigma_{n\in I}n$ *if* $P=1$.

(b) The infinite codimensional maximal M are characterized by $(P,\emptyset)$ with P irreducible and $P(g)\neq 1-g$ for any $k\in\mathbb{N}_0$.

In the restriction to $\ker\epsilon\subset C(B_+)$ corresponding to Corollary II.2 we observe another difference to the q-deformed setting. Since the condition for a crossed submodule to lie in $\ker\epsilon$ is exactly to have factors $1-g$ in the X-free monomials this condition may now be satisfied more easily. If the characterizing polynomial does not contain this factor it is now sufficient to have just any nonempty characterizing integer set I and it need not contain 1. Consequently, the map $(P,I)\mapsto(P,I)$ does not reach all crossed submodules now.

Corollary III.2: (a) Left crossed $C(B_+)$-submodules $M\subseteq\ker\epsilon\subset C(B_+)$ are in one-to-one correspondence to pairs (P,I) as in Corollary III.1 with the additional constraint $(1-g)$ divides $P(g)$ or I nonempty. $\operatorname{codim} M<\infty$ iff $P=1$. *In particular* $\operatorname{codim} M=(\Sigma_{n\in I}n)-1$ *if* $P=1$.

(b) The infinite codimensional maximal M correspond to pairs $(P,\{1\})$ with P irreducible and $P(g)\neq 1-g$.

Let us now turn to quantum tangent spaces on $U(\mathfrak{b}_+)$. Here, the process to go from the q-deformed setting to the classical one is not quite so straightforward.

Lemma III.3: Proper left crossed $U(\mathfrak{b}_+)$-submodules $L\subset U(\mathfrak{b}_+)$ via the left adjoint action and left regular coaction are in one-to-one correspondence to pairs (l,I) with $l\in\mathbb{N}_0$ and $I\subset\mathbb{N}$ finite. $\dim L<\infty$ iff $l=0$. *In particular* $\dim L=\Sigma_{n\in I}n$ *if* $l=0$.

Proof: The left adjoint action takes the form

$$X\triangleright X^nH^m=X^{n+1}(H^m-(H+1)^m),\quad H\triangleright X^nH^m=nX^nH^m,$$

while the coaction is

$$\Delta(X^nH^m)=\sum_{i=1}^{n}\sum_{j=1}^{m}\binom{n}{i}\binom{m}{j}X^iH^j\otimes X^{n-1}H^{m-j}.$$

Let L be a crossed submodule invariant under the action and coaction. The (repeated) action of H separates elements by degree in X. It is therefore sufficient to consider elements of the form $X^nP(H)$, where P is a polynomial. By acting with X on an element $X^nP(H)$ we obtain $X^{n+1}(P(H)-P(H+1))$. Subsequently applying the coaction and projecting on the left-hand side of the tensor product onto X (in the basis X^iH^j of $U(\mathfrak{b}_+)$) leads to the element $X^n(P(H)-P(H+1))$. Now the degree of $P(H)-P(H+1)$ is exactly the degree of $P(H)$ minus 1. Thus we have polynomials $X^nP_i(H)$ of any degree $i=\deg(P_i)\leqslant\deg(P)$ in L by induction. In particular, $X^nH^m\in L$ for all $m\leqslant\deg(P)$. It is thus sufficient to consider elements of the form X^nH^m. Given such an element, the coaction generates all elements of the form X^iH^j with $i\leqslant n$, $j\leqslant m$.

For given n, the characterizing datum is the maximal m so that $X^nH^m\in L$. Due to the coaction this cannot decrease with decreasing n and due to the action of X this can decrease at most by 1 when increasing n by 1. This leads to the classification given. For $l\in\mathbb{N}_0$ and $I\subset\mathbb{N}$ finite, the corresponding crossed submodule is generated by

$$X^{n_m-1}H^{l+m-1},X^{n_m+n_{m-1}-1}H^{l+m-2},\ldots,X^{(\Sigma_i n_i)-1}H^l\quad\text{and}\quad X^{(\Sigma_i n_i)+k}H^{l-1}\quad\forall k\geqslant 0\quad\text{if}\quad l>0$$

as a crossed module. □

For the transition from the q-deformed (Lemma II.3) to the classical case we observe that the space spanned by $g^{s_1},\ldots,g^{s_m}$ with m different integers $s_i\in\mathbb{Z}$ maps to the space spanned by

$1,H,\ldots,H^{m-1}$ in the prescription of the classical limit (as described in Sec. I B, i.e., the classical crossed submodule characterized by an integer l and a finite set $I\subset\mathbb{N}$ comes from a crossed submodule characterized by this same I and additionally l other integers $j\in\mathbb{Z}$ for which $X^k g^{1-j}$ is included. In particular, we have a one-to-one correspondence in the finite dimensional case.

To formulate the analog of Corollary II.4 for the classical case is essentially straightforward now. However, as for $C(B_+)$, we obtain more crossed submodules than those from the q-deformed setting. This is due to the degeneracy introduced by forgetting the powers of g and just retaining the number of different powers.

Corollary III.4: (a) Proper left crossed $U(\mathfrak{b}_+)$*-submodules* $L\subset\ker\epsilon\subset U(\mathfrak{b}_+)$ *via the left adjoint action and left regular coaction (with subsequent projection to* $\ker\epsilon$ *via* $x\mapsto x-\epsilon(x)1$*) are in one-to-one correspondence to pairs (l,I) with* $l\in\mathbb{N}_0$ *and* $I\subset\mathbb{N}$ *finite where* $l\neq 0$ *or* $I\neq\emptyset$. $\dim L<\infty$ iff $l=0$. *In particular* $\dim L=(\Sigma_{n\in I}n)-1$ *if* $l=0$.

As in the q-deformed setting, we give a description of the finite dimensional differential calculi where we have a strict duality to quantum tangent spaces.

Proposition III.5: (a) Finite dimensional differential calculi Γ *on* $C(B_+)$ *and finite dimensional quantum tangent spaces L on* $U(\mathfrak{b}_+)$ *are in one-to-one correspondence to nonempty finite sets* $I\subset\mathbb{N}$. *In particular* $\dim\Gamma=\dim L=(\Sigma_{n\in I}n)-1$.

The Γ *with* $1\in\mathbb{N}$ *are in one-to-one correspondence to the finite dimensional calculi and quantum tangent spaces of the q-deformed setting (Theorem II.5(a)).*

(b) The differential calculus Γ *of dimension* $n\geq 2$ *corresponding to the coirreducible one of* $C_q(B_+)$ *(Theorem II.5(b)) has a right invariant basis* $\eta_0,\ldots,\eta_{n-1}$ *so that*

$$\mathrm{d}X=\eta_1+\eta_0 X,\quad \mathrm{d}g=\eta_0 g,$$

$$[g,\eta_i]=0\,\forall i,\quad [X,\eta_i]=\begin{cases}0 & \text{if } i=0 \text{ or } i=n-1\\ \eta_{i+1} & \text{if } 0<i<n-1\end{cases}$$

hold. The braided derivations obtained from the dual basis of the corresponding L are given by

$$\partial_i f=\frac{1}{i!}\left(\frac{\partial}{\partial X}\right)^i f\quad \forall i\geq 1,$$

$$\partial_0 f=\left(X\frac{\partial}{\partial X}+g\frac{\partial}{\partial g}\right)f$$

for $f\in C(B_+)$.

(c) The differential calculus of dimension $n-1$ *corresponding to the one in (b) with 1 removed from the characterizing set is the same as the one above, except that we set* $\eta_0=0$ *and* $\partial_0=0$.

Proof: (a) We observe that the classifications of Corollary III.1 and Lemma III.3 or Corollary III.2 and Corollary III.4 are dual to each other in the finite (co)dimensional case. More precisely, for $I\subset\mathbb{N}$ finite the crossed submodule M corresponding to $(1,I)$ in Corollary III.1 is the annihilator of the crossed submodule L corresponding to $(0,I)$ in Lemma III.3 and vice versa. $C(B_+)/M$ and L are dual spaces with the induced pairing. For nonempty I this descends to M corresponding to $(1,I)$ in Corollary III.2 and L corresponding to $(0,I)$ in Corollary III.4. For the dimension of Γ note $\dim\Gamma=\dim\ker\epsilon/M=\operatorname{codim}M$.

(b) For $I=\{1,n\}$ we choose in $\ker\epsilon\subset C(B_+)$ the basis $\eta_0,\ldots,\eta_{n-1}$ as the equivalence classes of $g-1,X,\ldots,X^{n-1}$. The dual basis in L is then $H,X,\ldots,(1/k!)X^k,\ldots,1/(n-1)!X^{n-1}$. This leads to the formulas given.

(c) For $I=\{n\}$ we get the same as in (b) except that η_0 and ∂_0 disappear. □

The classical commutative calculus is the special case of (b) with $n=2$. It is the only calculus of dimension 2 with $\mathrm{d}g\neq 0$. Note that it is not coirreducible.

IV. THE DUAL CLASSICAL LIMIT

We proceed in this section to the more interesting point of view where we consider the classical algebras, but with their roles interchanged, i.e., we view $U(\mathfrak{b}_+)$ as the "function algebra" and $C(B_+)$ as the "enveloping algebra." Due to the self-duality of $U_q(\mathfrak{b}_+)$, we can again view the differential calculi and quantum tangent spaces as classical limits of the q-deformed setting investigated in Sec. II.

In this dual setting the bicovariance constraint for differential calculi becomes much weaker. In particular, the adjoint action on a classical function algebra is trivial due to commutativity and the adjoint coaction on a classical enveloping algebra is trivial due to cocommutativity. In effect, the correspondence with the q-deformed setting is much weaker than in the ordinary case of Sec. III. There are much more differential calculi and quantum tangent spaces than in the q-deformed setting.

We will not attempt to classify all of them in the following but essentially contend ourselves with those objects coming from the q-deformed setting.

Lemma IV.1: Left $C(B_+)$-subcomodules $\subseteq C(B_+)$ via the left regular coaction are $\mathbb{Z}$-graded subspaces of $C(B_+)$ with $|X^n g^m| = n+m$, stable under formal derivation in X.

By choosing any ordering in $C_q(B_+)$, left crossed submodules via left regular action and adjoint coaction are in one-to-one correspondence to certain subcomodules of $C(B_+)$ by setting $q=1$. Direct sums correspond to direct sums.

This descends to $\ker\epsilon \subset C(B_+)$ *by the projection* $x \mapsto x - \epsilon(x)1$.

Proof: The coproduct on $C(B_+)$ is

$$\Delta(X^n g^k) = \sum_{r=0}^{n} \binom{n}{r} X^{n-r} g^{k+r} \otimes X^r g^k,$$

which we view as a left coaction. Projecting on the left-hand side of the tensor product onto g^l in a basis $X^n g^k$, we observe that coacting on an element $\Sigma_{n,k} a_{n,k} X^n g^k$ we obtain elements $\Sigma_n a_{n,l-n} X^n g^{l-n}$ for all l, i.e., elements of the form $\Sigma_n b_n X^n g^{l-n}$ lie separately in a subcomodule and it is sufficient to consider such elements. Writing the coaction on such an element as

$$\sum_t \frac{1}{t!} X^t g^{l-t} \otimes \sum_n b_n \frac{n!}{(n-t)!} X^{n-t} g^{l-n},$$

we see that the coaction generates all formal derivatives in X of this element. This gives us the classification, $C(B_+)$-subcomodules $\subseteq C(B_+)$ under the left regular coaction are $\mathbb{Z}$-graded subspaces with $|X^n g^m| = n+m$, stable under formal derivation in X given by $X^n g^m \mapsto n X^{n-1} g^m$.

The correspondence with the $C_q(B_+)$ case follows from the trivial observation that the coproduct of $C(B_+)$ is the same as that of $C_q(B_+)$ with $q=1$.

The restriction to $\ker\epsilon$ is straightforward. □

Lemma IV.2: The process of obtaining the classical limit $U(\mathfrak{b}_+)$ from $U_q(\mathfrak{b}_+)$ is well defined for subspaces and sends crossed $U_q(\mathfrak{b}_+)$-submodules $\subset U_q(\mathfrak{b}_+)$ by regular action and adjoint coaction to $U(\mathfrak{b}_+)$-submodules $\subset U(\mathfrak{b}_+)$ by regular action. This map is injective in the finite codimensional case. Intersections and codimensions are preserved in this case.

This descends to $\ker\epsilon$.

Proof: To obtain the classical limit of a left ideal it is enough to apply the limiting process (as described in Sec. I B) to the module generators. (We can forget the additional comodule structure.) On the one hand, any element generated by left multiplication with polynomials in g corresponds to some element generated by left multiplication with a polynomial in H, that is, there will be no more generators in the classical setting. On the other hand, left multiplication by a polynomial in H comes from left multiplication by the same polynomial in $g-1$, that is, there will be no fewer generators.

The maximal left crossed $U_q(\mathfrak{b}_+)$-submodule $\subseteq U_q(\mathfrak{b}_+)$ by left multiplication and adjoint coaction of codimension n $(n\geqslant 1)$ is generated as a left ideal by $\{1-q^{1-n}g,X^n\}$ (see Lemma II.1). Applying the limiting process to this leads to the left ideal of $U(\mathfrak{b}_+)$ (which is not maximal for $n\neq 1$) generated by $\{H+n-1,X^n\}$ having also codimension n.

More generally, the picture given for arbitrary finite codimensional left crossed modules of $U_q(\mathfrak{b}_+)$ in terms of generators with respect to polynomials in g,g^{-1} in Lemma II.1 carries over by replacing factors $1-q^{1-n}g$ with factors $H+n-1$ leading to generators with respect to polynomials in H. In particular, intersections go to intersections since the distinctness of the factors for different n is conserved.

The restriction to $\ker\epsilon$ is straightforward. □

We are now in a position to give a detailed description of the differential calculi induced from the q-deformed setting by the limiting process.

Proposition IV.3: (a) Certain finite dimensional differential calculi Γ *on* $U(\mathfrak{b}_+)$ *and quantum tangent spaces L on* $C(B_+)$ *are in one-to-one correspondence to finite dimensional differential calculi on* $U_q(\mathfrak{b}_+)$ *and quantum tangent spaces on* $C_q(B_+)$. *Intersections correspond to intersections.*

(b) In particular, Γ *and L corresponding to coirreducible differential calculi on* $U_q(\mathfrak{b}_+)$ *and irreducible quantum tangent spaces on* $C_q(B_+)$ *via the limiting process are given as follows:* Γ *has a right invariant basis* $\eta_0,\ldots,\eta_{n-1}$ *so that*

$$\mathrm{d}X=\eta_1,\quad \mathrm{d}H=(1-n)\eta_0,$$

$$[H,\eta_i]=(1-n+i)\eta_i\ \ \forall i,\quad [X,\eta_i]=\begin{cases}\eta_{i+1} & \text{if } i<n-1\\ 0 & \text{if } i=n-1\end{cases}$$

holds. The braided derivations corresponding to the dual basis of L are given by

$$\partial_i:f:=:T_{1-n+i,H}\frac{1}{i!}\left(\frac{\partial}{\partial X}\right)^i f:\quad \forall i\geqslant 1,$$

$$\partial_0:f:=:T_{1-n,H}f-f:$$

for $f\in \Bbbk[X,H]$ *with the normal ordering* $\Bbbk[X,H]\to U(\mathfrak{b}_+)$ *via* $H^nX^m\mapsto H^nX^m$.

Proof: (a) The strict duality between $C(B_+)$-subcomodules $L\subseteq\ker\epsilon$ given by Lemma IV.1 and Corollary II.4 and $U(\mathfrak{b}_+)$-modules $U(\mathfrak{b}_+)/(\Bbbk 1+M)$ with M given by Lemma IV.2 and Corollary II.2 can be checked explicitly. It is essentially due to mutual annihilation of factors $H+k$ in $U(\mathfrak{b}_+)$ with elements g^k in $C(B_+)$.

(b) L is generated by $\{g^{1-n}-1,Xg^{1-n},\ldots,X^{n-1}g^{1-n}\}$ and M is generated by $\{H(H+n-1),X(H+n-1),X^n\}$. The formulas are obtained by denoting with $\eta_0,\ldots,\eta_{n-1}$ the equivalence classes of $H/(1-n),X,\ldots,X^{n-1}$ in $U(\mathfrak{b}_+)/(\Bbbk 1+M)$. The dual basis of L is then

$$g^{1-n}-1,Xg^{1-n},\ldots,\frac{1}{(n-1)!}X^{n-1}g^{1-n}.$$

□

In contrast to the q-deformed setting and to the usual classical setting the many freedoms in choosing a calculus leave us with many two-dimensional calculi. It is not obvious which one we should consider to be the ''natural'' one. Let us first look at the two-dimensional calculus coming from the q-deformed setting as described in (b). The relations become

$$[\mathrm{d}H,a]=da,\quad [\mathrm{d}X,a]=0,\quad \forall a\in U(\mathfrak{b}_+),$$

$$\mathrm{d}:f:=\mathrm{d}H:\nabla_{1,H}f:+\mathrm{d}X:\frac{\partial}{\partial X}f:$$

for $f\in\mathbb{k}[X,H]$.

We might want to consider calculi which are closer to the classical theory in the sense that derivatives are not finite differences but usual derivatives. Let us therefore demand

$$\mathrm{d}P(H)=\mathrm{d}H\,\frac{\partial}{\partial H}P(H)\ \text{ and }\ \mathrm{d}P(X)=\mathrm{d}X\,\frac{\partial}{\partial X}P(X)$$

for polynomials P and $\mathrm{d}X\neq 0$ and $\mathrm{d}H\neq 0$.

Proposition IV.4: There is precisely one differential calculus of dimension 2 meeting these conditions. It obeys the relations

$$[a,\mathrm{d}H]=0,\quad [X,\mathrm{d}X]=0,\quad [H,\mathrm{d}X]=\mathrm{d}X,$$

$$\mathrm{d}{:}f{:}=\mathrm{d}H{:}\,\frac{\partial}{\partial H}f{:}+\mathrm{d}X{:}\,\frac{\partial}{\partial X}f{:}$$

where the normal ordering $\mathbb{k}[X,H]\to U(\mathfrak{b}_+)$ *is given by* $X^nH^m\mapsto X^nH^m$.

Proof: Let M be the left ideal corresponding to the calculus. It is easy to see that for a primitive element a the classical derivation condition corresponds to $a^2\in M$ and $a\notin M$. In our case $X^2,H^2\in M$. If we take the ideal generated from these two elements we obtain an ideal of $\ker\epsilon$ of codimension 3. Now, it is sufficient without loss of generality to add a generator of the form $\alpha H+\beta X+\gamma XH$. α and β must then be zero in order not to generate X or H in M, i.e., M is generated by H^2,XH,X^2. The relations stated follow. □

V. REMARKS ON κ-MINKOWSKI SPACE AND INTEGRATION

There is a straightforward generalization of $U(\mathfrak{b}_+)$. Let us define the Lie algebra $\mathfrak{b}_{n+}$ as generated by $x_0,\ldots,x_{n-1}$ with relations

$$[x_0,x_i]=x_i,\quad [x_i,x_j]=0\quad \forall i,j\geqslant 1.$$

Its enveloping algebra $U(\mathfrak{b}_{n+})$ is nothing but (rescaled) κ-Minkowski space as introduced in Ref. 10. In this section we make some remarks about its intrinsic geometry.

We have an injective Lie algebra homomorphism $b_{n+}\to b_+$ given by $x_0\mapsto H$ and $x_i\mapsto X$. This is an isomorphism for $n=2$. The injective Lie algebra homomorphism extends to an injective homomorphism of enveloping algebras $U(\mathfrak{b}_+)\to U(\mathfrak{b}_{n+})$ in the obvious way. This gives rise to an injective map from the set of submodules of $U(\mathfrak{b}_+)$ to the set of submodules of $U(\mathfrak{b}_{n+})$ by taking the preimage. In particular this induces an injective map from the set of differential calculi on $U(\mathfrak{b}_+)$ to the set of differential calculi on $U(\mathfrak{b}_{n+})$ which are invariant under permutations of the x_i $i\geqslant 1$.

Corollary V.1: There is a natural n-dimensional differential calculus on $U(\mathfrak{b}_{n+})$ *induced from the one considered in Proposition IV.4. It obeys the relations*

$$[a,\mathrm{d}x_0]=0\quad \forall a\in U(\mathfrak{b}_{n+}),\quad [x_i,\mathrm{d}x_j]=0,\quad [x_0,\mathrm{d}x_i]=\mathrm{d}x_i\quad \forall i,j\geqslant 1$$

$$\mathrm{d}{:}f{:}=\sum_{\mu=0}^{n-1}dx_\mu{:}\,\frac{\partial}{\partial x_\mu}f{:}$$

where the normal ordering is given by

$$\mathbb{k}[x_0,\ldots,x_{n-1}]\to U(\mathfrak{b}_{n+1})\ \text{ via }\ x_{n-1}^{m_{n-1}}\cdots x_0^{m_0}\mapsto x_{n-1}^{m_{n-1}}\cdots x_0^{m_0}.$$

Proof: The calculus is obtained from the ideal generated by

$$x_0^2,x_ix_j,x_ix_0\quad \forall i,j\geqslant 1$$

being the preimage of X^2, XH, X^2 in $U(\mathfrak{b}_+)$. □

Let us try to push the analogy with the commutative case further and take a look at the notion of integration. The natural way to encode the condition of translation invariance from the classical context in the quantum group context is given by the condition

$$\left(\int \otimes \mathrm{id}\right)\circ\Delta a = 1\int a \quad \forall a\in A$$

which defines a right integral on a Hopf algebra A.[13] (Correspondingly, we have the notion of a left integral.) Let us formulate a slightly weaker version of this equation in the context of a Hopf algebra H dually paired with A. We write

$$\int (h-\epsilon(h))\triangleright a = 0 \quad \forall h\in H, a\in A,$$

where the action of H on A is the coregular action $h\triangleright a = a_{(1)}\langle a_{(2)}, h\rangle$ given by the pairing.

In the present context we set $A=U(\mathfrak{b}_{n+})$ and $H=C(B_{n+})$. We define the latter as a generalization of $C(B_+)$ with commuting generators $g, p_1, \ldots, p_{n-1}$ and coproducts

$$\Delta p_i = p_i\otimes 1 + g\otimes p_i, \quad \Delta g = g\otimes g.$$

This can be identified (upon rescaling) as the momentum sector of the full κ-Poincaré algebra (with $g=e^{p_0}$). The pairing is the natural extension of (1),

$$\langle x_{n-1}^{m_{n-1}}\cdots x_1^{m_1}x_0^k, p_{n-1}^{r_{n-1}}\cdots p_1^{r_1}g^s\rangle = \delta_{m_{n-1},r_{n-1}}\cdots\delta_{m_1,r_1} m_{n-1}!\cdots m_1! s^k.$$

The resulting coregular action is conveniently expressed as (see also Ref. 10)

$$p_i\triangleright :f: = :\frac{\partial}{\partial x_i}f:, \quad g\triangleright :f: = :T_{1,x_0}f:$$

with $f\in\mathbb{k}[x_0,\ldots,x_{n-1}]$. Due to cocommutativity, the notions of left and right integral coincide. The invariance conditions for integration become

$$\int :\frac{\partial}{\partial x_i}f: = 0 \quad \forall i\in\{1,\ldots,n-1\} \text{ and } \int :\nabla_{1,x_0}f: = 0.$$

The condition on the left is familiar and states the invariance under infinitesimal translations in the x_i. The condition on the right states the invariance under integer translations in x_0. However, we should remember that we use a certain algebraic model of $C(B_{n+})$. We might add, for example, a generator p_0 to $C(B_{n+})$ that is dual to x_0 and behaves as the ''logarithm'' of g, i.e., acts as an infinitesimal translation in x_0. We then have the condition of infinitesimal translation invariance

$$\int :\frac{\partial}{\partial x_\mu}f: = 0$$

for all $\mu\in\{0,1,\ldots,n-1\}$.

In the present purely algebraic context these conditions do not make much sense. In fact they would force the integral to be zero on the whole algebra. This is not surprising, since we are dealing only with polynomial functions which would not be integrable in the classical case either. In contrast, if we had for example the algebra of smooth functions in two real variables, the conditions just characterize the usual Lesbegue integral (up to normalization). Let us assume $\mathbb{k}=\mathbb{R}$ and suppose that we have extended the normal ordering vector space isomorphism $\mathbb{R}[x_0,\ldots,x_{n-1}]\cong U(\mathfrak{b}_{n+})$ to a vector space isomorphism of some sufficiently large class of functions on $\mathbb{R}^n$ with a suitable completion $\hat{U}(\mathfrak{b}_{n+})$ in a functional analytic framework (embedding $U(\mathfrak{b}_{n+})$ in some operator algebra on a Hilbert space). It is then natural to define the integration on $\hat{U}(\mathfrak{b}_{n+})$ by

$$\int :f:=\int_{\mathbb{R}^n} f\, dx_0 \cdots dx_{n-1},$$

where the right-hand side is just the usual Lesbegue integral in n real variables $x_0,\ldots,x_{n-1}$. This integral is unique (up to normalization) in satisfying the covariance condition since, as we have seen, these correspond just to the usual translation invariance in the classical case via normal ordering, for which the Lesbegue integral is the unique solution. It is also the $q\to 1$ limit of the translation invariant integral on $U_q(\mathfrak{b}_+)$ obtained in Ref. 14.

We see that the natural differential calculus in Corollary V.1 is compatible with this integration in that the appearing braided derivations are exactly the actions of the translation generators p_μ. However, we should stress that this calculus is not covariant under the full κ-Poincaré algebra, since it was shown in Ref. 15 that in $n=4$ there is no such calculus of dimension 4. Our results therefore indicate a new intrinsic approach to κ-Minkowski space that allows a bicovariant differential calculus of dimension 4 and a unique translation invariant integral by normal ordering and Lesbegue integration.

ACKNOWLEDGMENTS

I would like to thank S. Majid for proposing this project, and for fruitful discussions during the preparation of this paper.

APPENDIX: THE ADJOINT COACTION ON $U_q(\mathfrak{b}_+)$

The coproduct on X^n is

$$\Delta(X^n)=\sum_{r=0}^{n}\begin{bmatrix} n \\ r \end{bmatrix}_q g^r X^{n-r}\otimes X^r,$$

$$(\mathrm{id}\otimes\Delta)\Delta(X^n)=\sum_{r=0}^{n}\sum_{i=0}^{r}\begin{bmatrix} n \\ r \end{bmatrix}_q \begin{bmatrix} r \\ i \end{bmatrix}_q g^r X^{n-r}\otimes g^i X^{r-i}\otimes X^i.$$

From this we get

$$\begin{aligned}
\mathrm{Ad_L}(X^n) &= \sum_{r=0}^{n}\sum_{s=0}^{r}\begin{bmatrix} n \\ r \end{bmatrix}_q \begin{bmatrix} r \\ s \end{bmatrix}_q g^r X^{n-r} \mathrm{S}X^s \otimes g^s X^{r-s} \\
&= \sum_{r=0}^{n}\sum_{s=0}^{r}\begin{bmatrix} n \\ r \end{bmatrix}_q \begin{bmatrix} r \\ s \end{bmatrix}_q g^r X^{n-r}(-g^{-1}X)^s \otimes g^s X^{r-s} \\
&= \sum_{t=0}^{n}\sum_{s=0}^{n-t}\begin{bmatrix} n \\ t+s \end{bmatrix}_q \begin{bmatrix} t+s \\ s \end{bmatrix}_q g^{t+s} X^{n-t-s}(-g^{-1}X)^s \otimes g^s X^{t} \\
&= \sum_{t=0}^{n}\sum_{s=0}^{n-t}\begin{bmatrix} n \\ t \end{bmatrix}_q \begin{bmatrix} n-t \\ s \end{bmatrix}_q g^{t+s} X^{n-t-s}(-g^{-1}X)^s \otimes g^s X^{t} \\
&= \sum_{t=0}^{n}\begin{bmatrix} n \\ t \end{bmatrix}_q g^t X^{n-t}\otimes X^t \sum_{s=0}^{n-t}\begin{bmatrix} n-t \\ s \end{bmatrix}_q q^{s(s+1)/2}(-q^{-n}g)^s \\
&= \sum_{t=0}^{n}\begin{bmatrix} n \\ t \end{bmatrix}_q g^t X^{n-t}\otimes X^t \prod_{u=1}^{n-t}(1-q^{u-n}g),
\end{aligned}$$

where we have used

$$\sum_{i=0}^{n} \begin{bmatrix} n \\ i \end{bmatrix}_q q^{i(i+1)/2} x^i = \prod_{j=1}^{n} (1+q^j x),$$

which can be easily checked by induction. Using the property

$$\mathrm{Ad_L}(ag^n) = \mathrm{Ad_L}(a)(1 \otimes g^n) \quad \forall n \in \mathbb{Z},$$

we obtain for any polynomial P in g, g^{-1},

$$\mathrm{Ad_L}(X^n P(g)) = \sum_{t=0}^{n} \begin{bmatrix} n \\ t \end{bmatrix}_q g^t X^{n-t} \otimes X^t P(g) \prod_{u=1}^{n-t} (1 - q^{u-n} g). \tag{A1}$$

(Received 30 September 1998; accepted for publication 11 November 1998)

Bases for SU(3) irreps are constructed on a space of three-particle tensor products of two-dimensional harmonic oscillator wave functions. The Weyl group is represented as the symmetric group of permutations of the particle coordinates of these spaces. Wigner functions for SU(3) are expressed as products of SU(2) Wigner functions and matrix elements of Weyl transformations. The constructions make explicit use of dual reductive pairs which are shown to be particularly relevant to problems in optics and quantum interferometry. © *1999 American Institute of Physics.* [S0022-2488(99)01506-6]

I. INTRODUCTION

Considerable progress has been made in the development of systematic algorithms for computing matrix elements of the infinitesimal generators of Lie groups in an arbitrary representation. Much less is known about the matrices of finite group elements other than those of SU(2), and the related groups E(2), HW(1), and SU(1,1).[1]

The matrix elements of finite SU(2) transformations are the well-known Wigner $\mathcal{D}$ functions. These functions are used in many areas of physics, notably in nuclear, atomic, and molecular spectroscopy. Recently, it has been shown that the Wigner functions of SU(2) (Ref. 2) and higher unitary groups[3] are needed in the analysis of quantum interferometers. Because of the Peter–Weyl theorem, Wigner functions also play a central role in the theory of harmonic analysis.

We consider here the Wigner functions for SU(3); such functions are needed, for example, in computing SU(3) Clebsch–Gordan coefficients in an SO(3) basis.[4] Expressions for SU(3) Wigner functions were first derived, to our knowledge, by Chacón and Moshinsky,[5] in terms of SU(2) Wigner functions and matrix elements of Weyl reflection operators. Matrix elements of some Weyl reflections were derived by Macfarlane *et al.*[6] and Mukunda and Pandit.[7] The latter gave the matrix elements as products of three SU(2) Clebsch–Gordan coefficients. Chacón and Moshinsky gave expressions for matrix elements of other Weyl reflections as SU(2) Racah coefficients. These results raise the question: what does the Weyl group have to do with SU(2)? The answer appears to be that basis states for SU(3) irreps (irreducible representations) are naturally expressed in an SU(2)-coupled basis, and elements of the Weyl group for SU(3), which is isomorphic to the permutation group S_3, act on such states as SU(2) recoupling operators. More explicitly, if one constructs basis states for SU(3) by SU(2) coupling the wave functions for three particles in two-dimensional harmonic oscillator states, then the Weyl reflection operators permute the coordinates of the particles. A similar interpretation of the Weyl reflections was given by Gal and Lipkin[8] as the permutations of a coupled system of three spin-$\frac{1}{2}$ quarks.

In deriving our results, we make use of two mutually commuting subgroups, U(3) and U(2), of U(6). When acting within the space of a fully symmetric representation of U(6), these subgroups are said to form a *dual reductive pair*.[9] Such dual pairs are particularly relevant for

describing the properties of three particles in a two-dimensional harmonic oscillator or three spin-half quarks. An overview of these and other dual pairs and their uses in optics and quantum interferometry is given in the Discussion section at the end of this paper.

II. PARAMETRIZATION OF SU(3)

Many parametrizations of SU(3) elements are possible. The most useful ones would appear to arise from factorization of SU(3) group elements into products of subgroup elements whose Wigner functions are known. Three obvious candidates for suitable subgroups are the groups $SU(2)_{12}$, $SU(2)_{13}$, and $SU(2)_{23}$, the three SU(2) subgroups whose root systems are subsystems of the SU(3) root system shown in Fig. 1. We denote an element of $SU(2)_{ij}$ by $R_{ij}(\alpha,\beta,\gamma)$, where (α,β,γ) are the standard Euler angles.

Murnaghan[10] has shown that a possible parametrization of an element $g\in SU(3)$ is given by

$$g(\alpha_1,\beta_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\delta_1,\delta_2)=e^{-i(h_1\delta_1+h_2\delta_2)}R_{23}(\alpha_1/2,\beta_1,-\alpha_1/2) \times R_{13}(\alpha_2/2,\beta_2,-\alpha_2/2)R_{12}(\alpha_3/2,\beta_3,-\alpha_3/2), \tag{1}$$

where h_1 and h_2 are elements of the Cartan subalgebra.

A similar parametrization, with a different ordering, was proposed by Reck *et al.*[3] These authors showed that one can factor a general $N\times N$ unitary matrix as a product of U(2) matrices and an overall phase, with the added insight that each U(2) transformation can be realized experimentally as an optical element.

In this paper, we choose a parametrization that takes advantage of the fact that, in a canonical basis, one constructs $U(N)$ irreps in a basis that reduces a particular $U(N-1)$ subgroup. Thus, an arbitrary $SU(N)$ matrix is factored

$$\left(\begin{array}{c|ccc} 1 & 0 & \cdots & 0 \\ \hline 0 & & & \\ \vdots & & X_{N-1} & \\ 0 & & & \end{array}\right)\left(\begin{array}{cc|c} e^{i\alpha}\cos(\beta/2) & -\sin(\beta/2) & 0 \\ \sin(\beta/2) & e^{-i\alpha}\cos(\beta/2) & \\ \hline & 0 & I_{N-2} \end{array}\right)\left(\begin{array}{c|ccc} 1 & 0 & \cdots & 0 \\ \hline 0 & & & \\ \vdots & & Y_{N-1} & \\ 0 & & & \end{array}\right) \tag{2}$$

where X_{N-1} and Y_{N-1} are $SU(N-1)$ matrices; I_{N-2} is the $(N-2)\times(N-2)$ identity matrix. For SU(2) [with the indices ordered (z,x,y)] this gives the usual factorization $R(\alpha,\beta,\gamma) =R_z(\alpha)R_y(\beta)R_z(\gamma)$. For $g\in SU(3)$, we obtain

$$g(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)=R_{23}(\alpha_1,\beta_1,\gamma_1)R_{12}(\alpha_2,\beta_2,\alpha_2)R_{23}(\alpha_3,\beta_3,\gamma_3). \tag{3}$$

The parameters in this expression are derived for an arbitrary $g\in SU(3)$ in the Appendix, by a method communicated to us by J. Repka.

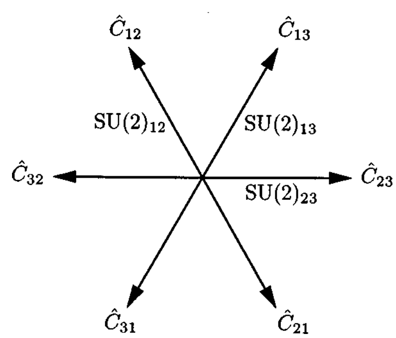

FIG. 1. Three SU(2) subsystems of the SU(3) root system.

All of the above factorizations enable one to express the SU(3) Wigner functions in terms of matrix elements of finite SU(2) transformations.

III. BASIS STATES

A. Highest weight states

An SU(3) irrep is characterized by a highest weight (λ,μ) and a corresponding highest weight state $|\phi(\lambda,\mu)\rangle$, defined as follows. The su(3) Lie algebra is spanned in the usual way by the subset of u(3) operators

$$\begin{aligned}&\hat{C}_{ij}, \quad i<j \ \text{ raising operators},\\ &\hat{C}_{ij}, \quad i>j \ \text{ lowering operators},\\ &\hat{h}_1=\hat{C}_{11}-\hat{C}_{22}, \quad \hat{h}_2=\hat{C}_{22}-\hat{C}_{33}, \quad \text{Cartan operators},\end{aligned} \tag{4}$$

where the $\{\hat{C}_{ij}\}$ operators satisfy the commutation relations

$$[\hat{C}_{ij},\hat{C}_{kl}]=\delta_{jk}\hat{C}_{il}-\delta_{il}\hat{C}_{kj}. \tag{5}$$

The highest weight state $|\phi(\lambda,\mu)\rangle$ then satisfies the equations

$$\begin{aligned}&\hat{C}_{ij}|\phi(\lambda,\mu)\rangle=0, \quad i<j,\\ &\hat{h}_1|\phi(\lambda,\mu)\rangle=\lambda|\phi(\lambda,\mu)\rangle, \quad \hat{h}_2|\phi(\lambda,\mu)\rangle=\mu|\phi(\lambda,\mu)\rangle.\end{aligned} \tag{6}$$

Without loss of generality, we suppose that $|\phi(\lambda,\mu)\rangle$ is also an eigenstate of the operator $\hat{C}_{33}$ with zero eigenvalue. It then satisfies the equations

$$\hat{C}_{11}|\phi(\lambda,\mu)\rangle=(\lambda+\mu)|\phi(\lambda,\mu)\rangle, \quad \hat{C}_{22}|\phi(\lambda,\mu)\rangle=\mu|\phi(\lambda,\mu)\rangle, \quad \hat{C}_{33}|\phi(\lambda,\mu)\rangle=0. \tag{7}$$

The Hilbert space, $\mathbb{H}^{(\lambda,\mu)}$, for the SU(3) irrep with highest weight (λ,μ) thereby becomes a Hilbert space for a U(3) irrep of highest weight $(\lambda+\mu,\mu,0)$.

B. The Gel'fand–Tsetlin basis

To use the factorization of Eq. (3) in computing Wigner functions, we need a basis for the Hilbert space $\mathbb{H}^{(\lambda,\mu)}$ that reduces the $\mathrm{SU}(3)\supset\mathrm{SU}(2)_{23}$ subgroup chain. Such a basis is the so-called canonical or Gel'fand–Tsetlin basis;[11]

$$\left\{\left|\begin{matrix}p & q\\ & r\end{matrix}\right\rangle \equiv \left|\begin{matrix}\lambda+\mu & \mu & 0\\ & p \quad q & \\ & r & \end{matrix}\right\rangle; \begin{matrix}\lambda+\mu\geqslant p\geqslant\mu\geqslant q\geqslant 0\\ p\geqslant r\geqslant q\end{matrix}\right\}, \tag{8}$$

which reduces the chain

$$\begin{matrix}\mathrm{U}(3)\\ (\lambda+\mu,\mu,0)\end{matrix} \supset \begin{matrix}\mathrm{U}(2)_{23}\\ (p,q)\end{matrix} \supset \begin{matrix}\mathrm{U}(1)_3\\ r\end{matrix}, \tag{9}$$

where $\mathrm{U}(1)_3\subset\mathrm{U}(2)_{23}$ is the subgroup whose Lie algebra is spanned by $\hat{C}_{33}$.

The Gel'fand states are eigenstates of the weight operators; i.e.,

$$\hat{C}_{ii}\left|\begin{matrix}p & q\\ & r\end{matrix}\right\rangle=\nu_i\left|\begin{matrix}p & q\\ & r\end{matrix}\right\rangle, \quad i=1,2,3, \tag{10}$$

with

$$\nu_1=\lambda+2\mu-p-q, \quad \nu_2=p+q-r, \quad \nu_3=r. \tag{11}$$

One sees that the components of a weight $\nu=(\nu_1,\nu_2,\nu_3)$ add up to $\lambda+2\mu$. They are linearly dependent and insufficient to define a state uniquely. However, the Gel'fand-Tsetlin states also reduce the subgroup chain

$$\begin{matrix} \mathrm{U}(3) \\ (\lambda+\mu,\mu,0) \end{matrix} \supset \begin{matrix} \mathrm{SU}(2)_{23} \\ I \end{matrix} \supset \begin{matrix} \mathrm{U}(1)_{23} \\ M \end{matrix}, \tag{12}$$

and have $\mathrm{SU}(2)_{23}$ quantum numbers, I and M, related to p, q, and r by

$$I=\tfrac{1}{2}(p-q), \quad M=\tfrac{1}{2}(\nu_2-\nu_3)=\tfrac{1}{2}(p+q)-r. \tag{13}$$

Thus, the weight ν and the $\mathrm{SU}(2)_{23}$ angular momentum I together uniquely define a basis state and, with the above relationships between ν, I and p, q, r, we can relabel a Gel'fand–Tsetlin state

$$|\nu I\rangle \equiv \left| \begin{matrix} p & & q \\ & r & \end{matrix} \right\rangle. \tag{14}$$

We shall refer to the basis $\{|\nu I\rangle\}$ either as a Gel'fand–Tsetlin basis or as a weight basis.

C. An SU(2)-coupled realization

The Gel'fand–Tsetlin states can be constructed explicitly as three-particle SU(2)-coupled products of two-dimensional harmonic-oscillator states.

The construction makes use of a well-known duality relationship (discussed by Moshinsky and Chacón[5]) between U(3) and $\mathcal{U}(2)$ as commuting subgroups of U(6). Let $\{a^\dagger_{im}, a_{im};\ i=1,...,3,\ m=1,2\}$ denote (two-dimensional) harmonic oscillator raising and lowering operators for three particles. The operators $\{a^\dagger_{im}a_{jn}\}$ then span a u(6) Lie algebra. This algebra has two mutually commuting subalgebras: u(3) spanned by the operators

$$\hat{C}_{ij}=\sum_{m=1}^{2} a^\dagger_{im}a_{jm}, \tag{15}$$

and $u(2)$ spanned by

$$\hat{B}_{mn}=\sum_{i=1}^{3} a^\dagger_{im}a_{in}. \tag{16}$$

The algebras u(3) and $u(2)$ are examples of a so-called *dual pair*.[9] The use of a dual pair $(\mathrm{u}(N),u(n))$ and the corresponding direct sum subalgebra $\mathrm{u}(N)+u(n)\subset \mathrm{u}(Nn)$ are well known, for example, in the classification of states of N particles in an n-dimensional harmonic oscillator; cf., for example, the paper by Hagen and MacFarlane[12] which presents a method for deriving the $\mathrm{SU}(m)\times\mathcal{SU}(n)$ content of $\mathrm{SU}(mn)$ and provides tables for the $\mathrm{SU}(6)\to\mathrm{SU}(3)\times\mathcal{SU}(2)$ branching rules.

Now observe that, if $|0\rangle$ is the state in which all particles are in their respective harmonic oscillator ground states, the state

$$|\phi(\lambda,\mu)\rangle=(a^\dagger_{11})^\lambda(a^\dagger_{11}a^\dagger_{22}-a^\dagger_{12}a^\dagger_{21})^\mu|0\rangle \tag{17}$$

satisfies all the conditions of Eq. (6). Thus, $|\phi(\lambda,\mu)\rangle$ is an (unnormalized) SU(3) highest weight state. But it also satisfies

$$\hat{B}_{12}|\phi(\lambda,\mu)\rangle=0,$$
$$\hat{B}_{11}|\phi(\lambda,\mu)\rangle=(\lambda+\mu)|\phi(\lambda,\mu)\rangle,\quad \hat{B}_{22}|\phi(\lambda,\mu)\rangle=\mu|\phi(\lambda,\mu)\rangle, \tag{18}$$

which means that $|\phi(\lambda,\mu)\rangle$ is simultaneously a highest weight state for $u(2)$ with highest weight $(\lambda+\mu,\mu)$ and a highest weight state for u(3) with highest weight $(\lambda+\mu,\mu,0)$, cf. Eq. (7). Moreover, since the u(3) and $u(2)$ operators commute with one another, we can identify all the desired SU(3) basis states with those of the subset of $\mathrm{U}(3)\times\mathcal{U}(2)$ states that are of $\mathcal{U}(2)$ highest weight. This result is a special case of a general result for dual pairs;[9] for any N and n, the commuting algebras u(N) and $u(n)$ have a complete set of highest weight states in common within the carrier space of a fully symmetric irrep of the Lie algebra u(Nn) [i.e., an irrep of highest weight $(\sigma,0,...)$, where σ, equal to $\lambda+2\mu$ in the present case, is the total number of harmonic oscillator quanta].

It is well known that basis states for an $su(2)$ irrep of spin s_i are given by

$$|s_i,m_i\rangle=\frac{(a_{i1}^\dagger)^{s_i+m_i}(a_{i2}^\dagger)^{s_i-m_i}}{\sqrt{(s_i+m_i)!(s_i-m_i)!}}|0\rangle. \tag{19}$$

These states are also a basis for a $u(2)$ irrep of highest weight $(2s_i,0)$. They are tensor products of pairs of $u(1)$ irreps of $u(1)$ spin (s_i+m_i) and $-(s_i-m_i)$, respectively. A Gel'fand basis for SU(3) can likewise be constructed from triple tensor products of $su(2)$ irreps.

Theorem: The weight basis, defined by Eqs. (8)–(14), can be expressed, to within arbitrary phase factors:

$$|\nu I\rangle=[|\tfrac{1}{2}\nu_1\rangle\otimes[|\tfrac{1}{2}\nu_2\rangle\otimes|\tfrac{1}{2}\nu_3\rangle]^I]^{\lambda/2}_{\lambda/2},$$

$$=\sum_{m_1m_2m_3(N)}(\tfrac{1}{2}\nu_3,m_3;\tfrac{1}{2}\nu_2,m_2|I,N)(I,N;\tfrac{1}{2}\nu_1,m_1|\tfrac{1}{2}\lambda,\tfrac{1}{2}\lambda)|\tfrac{1}{2}\nu_1,m_1\rangle|\tfrac{1}{2}\nu_2,m_2\rangle|\tfrac{1}{2}\nu_3,m_3\rangle, \tag{20}$$

with $\nu=(\nu_1,\nu_2,\nu_3)$.

Proof: It follows, from Eq. (15), that

$$\hat{C}_{ii}|\nu I\rangle=\nu_i|\nu I\rangle. \tag{21}$$

Thus, the states $|\nu I\rangle$ have the same weights as their Gel'fand–Tsetlin counterparts. It remains to show that a state $|\nu I\rangle$, defined by Eq. (20), has $\mathrm{SU}(2)_{23}$ angular momentum I.

Consider a set of states for particles 2 and 3 which span an irrep of $\mathrm{u}(2)\times u(2)\subset \mathrm{u}(3)\times u(2)$, where the $\mathrm{u}(2)\subset\mathrm{u}(3)$ subalgebra is spanned by the operators $\{\hat{C}_{23},\hat{C}_{32},\hat{C}_{22},\hat{C}_{33}\}$. If the two-particle states transform according to a u(2) irrep (p,q) then, by duality, they also belong to $u(2)$ irreps of the same highest weight, (p,q). Thus, if a state has su(2) angular momentum $I=(p-q)/2$, it also has $su(2)$ angular momentum I. It follows that the $su(2)$-coupled two-particle state,

$$[|\tfrac{1}{2}\nu_2\rangle\otimes\tfrac{1}{2}\nu_3]^I_N, \tag{22}$$

belongs to a $u(2)$ irrep (p,q) with

$$p+q=\nu_2+\nu_3,\quad p-q=2I, \tag{23}$$

and therefore to the u(2) irrep with the same labels (p,q) and to the irrep with angular momentum $I=\frac{1}{2}(p-q)$ of the subalgebra $\mathrm{su}(2)\subset\mathrm{u}(2)$. This completes the proof.

IV. MATRIX ELEMENTS OF WEYL OPERATORS

The Weyl group is generated by reflections of the roots in the hyperplanes perpendicular to each of the roots. Let α_{ij} denote the SU(3) root whose root vector is $\hat{C}_{ij}$ and let P_{ij} denote the reflection in the line perpendicular to α_{ij}. Then, for example,

$$P_{12}:\alpha_{12}\rightarrow\alpha_{21},\quad \alpha_{13}\rightarrow\alpha_{23},\quad \alpha_{32}\rightarrow\alpha_{31}, \tag{24}$$

and $P_{12}^2=1$. Thus, one obtains the known result that the Weyl group for SU(3) is isomorphic to the symmetric group S_3 of permutations of three objects and that the subset of reflections correspond to transpositions.

By writing Eq. (20) in the form

$$\Psi_{\nu I}(123)\equiv\langle 123|\nu I\rangle=[\psi_{\nu_1}(1)\otimes[\psi_{\nu_2}(2)\otimes\psi_{\nu_3}(3)]^I]^{\lambda/2}_{\lambda/2}, \tag{25}$$

we obtain representations of the Weyl group for SU(3) in which, for example,

$$[P_{12}\Psi_{\nu I}](123)=\langle 123|P_{12}|\nu I\rangle=\Psi_{\nu I}(213),$$

$$[P_{13}\Psi_{\nu I}](123)=\Psi_{\nu I}(321), \tag{26}$$

$$[P_{132}\Psi_{\nu I}](123)=[P_{12}P_{13}\Psi_{\nu I}](123)=\Psi_{\nu I}(312).$$

It follows that

$$\begin{aligned}[P_{12}\Psi_{\nu I}](123)&=[\psi_{\nu_1}(2)\otimes[\psi_{\nu_2}(1)\otimes\psi_{\nu_3}(3)]^I]^{\lambda/2}_{\lambda/2}\\ &=\sum_{I'}(-1)^{(\nu_3-2I-2I'+2\mu-\lambda)/2}\sqrt{(2I+1)(2I'+1)}\\ &\quad\times\begin{Bmatrix}\nu_1/2 & \nu_3/2 & I'\\ \nu_2/2 & \lambda/2 & I\end{Bmatrix}[\psi_{\nu_2}(1)\otimes[\psi_{\nu_1}(2)\otimes\psi_{\nu_3}(3)]^{I'}]^{\lambda/2}_{\lambda/2},\end{aligned} \tag{27}$$

where $\{{abc \atop def}\}$ is a Wigner $6\text{-}j$ symbol. Thus, we obtain the matrix elements

$$\langle\nu' I'|P_{12}|\nu I\rangle=\delta_{\nu_1',\nu_2}\delta_{\nu_2',\nu_1}\delta_{\nu_3',\nu_3}(-1)^{(\nu_3-2I-2I'+2\mu-\lambda)/2}\sqrt{(2I+1)(2I'+1)}\begin{Bmatrix}\nu_1/2 & \nu_3/2 & I'\\ \nu_2/2 & \lambda/2 & I\end{Bmatrix}. \tag{28}$$

In a similar way one determines that

$$\langle\nu' I'|P_{123}|\nu I\rangle=\delta_{\nu_1',\nu_3}\delta_{\nu_2',\nu_1}\delta_{\nu_3',\nu_2}(-1)^{(\nu_1+\nu_2-2I'+2\lambda)/2}\sqrt{(2I+1)(2I'+1)}\begin{Bmatrix}\nu_1/2 & \nu_2/2 & I'\\ \nu_3/2 & \lambda/2 & I\end{Bmatrix} \tag{29}$$

and

$$\langle\nu' I'|P_{132}|\nu I\rangle=\delta_{\nu_1',\nu_2}\delta_{\nu_2',\nu_3}\delta_{\nu_3',\nu_1}(-1)^{(\nu_1+2I+2\mu+\lambda)/2}\sqrt{(2I+1)(2I'+1)}\begin{Bmatrix}\nu_1/2 & \nu_3/2 & I'\\ \nu_2/2 & \lambda/2 & I\end{Bmatrix}. \tag{30}$$

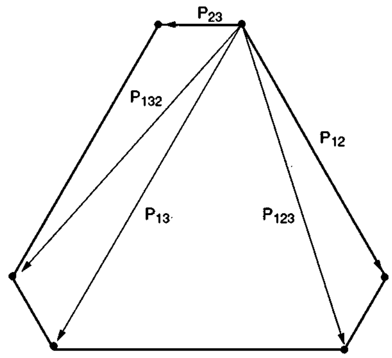

FIG. 2. The action of Weyl group elements on the highest weight of an SU(3) irrep.

To check these results, it is useful to apply them to the highest weight state. We find that

$$P_{12}\left|(\lambda+\mu,\mu,0)\,\frac{\mu}{2}\right\rangle=(-1)^{\mu}\left|(\mu,\lambda+\mu,0)\,\frac{\lambda+\mu}{2}\right\rangle,$$

$$P_{123}\left|(\lambda+\mu,\mu,0)\,\frac{\mu}{2}\right\rangle=\left|(0,\lambda+\mu,\mu)\,\frac{\lambda}{2}\right\rangle, \tag{31}$$

$$P_{132}\left|(\lambda+\mu,\mu,0)\,\frac{\mu}{2}\right\rangle=(-1)^{\mu}\left|(\mu,0,\lambda+\mu)\,\frac{\lambda+\mu}{2}\right\rangle,$$

consistent with the known action on the highest weight shown in Fig. 2. As expected, Weyl group elements map extremal states into other extremal states.

V. WIGNER FUNCTIONS

Matrix elements of $\mathrm{SU}(2)_{23}$ group elements are given immediately in the $\{|\nu I\rangle\}$ basis as SU(2) Wigner functions; viz.,

$$\langle \nu' I'|R_{23}(\alpha,\beta,\gamma)|\nu I\rangle=\delta_{\nu_1',\nu_1}\delta_{I'I}\mathcal{D}^{I}_{(\nu_2'-\nu_3')/2,(\nu_2-\nu_3)/2}(\alpha,\beta,\gamma), \tag{32}$$

where $\mathcal{D}^{I}_{M,N}$ is a standard SU(2) Wigner function.

To evaluate matrix elements of the other $\mathrm{SU}(2)_{ij}$ subgroups, we make use of the fact (noted by Chacón and Moshinsky[5]) that the different $\mathrm{SU}(2)_{ij}$ subgroups are Weyl transforms of one another. Thus, for example, the infinitesimal generators of $\mathrm{SU}(2)_{12}$

$$\hat{C}_{12},\quad \hat{C}_{21},\quad \tfrac{1}{2}(\hat{C}_{11}-\hat{C}_{22}), \tag{33}$$

are related to those of $\mathrm{SU}(2)_{23}$ by

$$\hat{C}_{12}=P_{132}\hat{C}_{23}P_{132}^{-1}=P_{132}\hat{C}_{23}P_{123}. \tag{34}$$

It follows that

$$R_{12}(\alpha,\beta,\gamma)=P_{132}R_{23}(\alpha,\beta,\gamma)P_{123}. \tag{35}$$

Similarly, one finds that

$$R_{13}(\alpha,\beta,\gamma)=P_{12}R_{23}(\alpha,\beta,\gamma)P_{12}. \tag{36}$$

Thus, with the parametrization given by Eq. (3), we obtain the SU(3) Wigner functions

$$D^{(\lambda\mu)}_{\nu' I',\nu I}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)$$

$$=\sum \mathcal{D}^{I'}_{(\nu_2'-\nu_3')/2,(\tau_2-\sigma_3)/2}(\alpha_1,\beta_1,\gamma_1)\langle(\nu_1',\tau_2,\sigma_3)I'|P_{132}|(\sigma_3,\nu_1',\tau_2)J\rangle$$

$$\times\mathcal{D}^{J}_{(\nu_1'-\tau_2)/2,(\nu_1-\sigma_2)/2}(\alpha_2,\beta_2,\alpha_2)\langle(\sigma_3,\nu_1,\sigma_2)J|P_{123}|(\nu_1,\sigma_2,\sigma_3)I\rangle$$

$$\times\mathcal{D}^{I}_{(\sigma_2-\sigma_3)/2,(\nu_2-\nu_3)/2}(\alpha_3,\beta_3,\gamma_3), \tag{37}$$

where the sum is over all σ, τ, and J values allowed by Eqs. (11), (13), and the betweenness conditions (8).

VI. MATRIX ELEMENTS OF SO(3)

If SO(3)⊂SU(3) is the subgroup whose infinitesimal generators are the angular momentum operators

$$\hat{L}_z=-i(\hat{C}_{23}-\hat{C}_{32}),\quad \hat{L}_x=-i(\hat{C}_{31}-\hat{C}_{13}),\quad \hat{L}_y=-i(\hat{C}_{12}-\hat{C}_{21}), \tag{38}$$

then we have the identities

$$\hat{L}_z=2\hat{I}_y,\quad \hat{L}_x=-2\hat{F}_y,\quad \hat{L}_y=2\hat{T}_y, \tag{39}$$

where $\hat{I}_y$, $\hat{T}_y$ and $\hat{F}_y$ belong to the Lie algebras of $\mathrm{SU}(2)_{23}$, $\mathrm{SU}(2)_{13}$, and $\mathrm{SU}(2)_{12}$, respectively. Thus, with the standard parametrization of an SO(3) element

$$\Omega(\alpha,\beta,\gamma)=e^{-i\alpha\hat{L}_z}e^{-i\beta\hat{L}_y}e^{-i\gamma\hat{L}_x}, \tag{40}$$

we have the identity

$$\Omega(\alpha,\beta,\gamma)=R_{23}(0,2\alpha,0)R_{12}(0,2\beta,0)R_{23}(0,2\gamma,0)=R_{23}(0,2\alpha,0)P_{132}R_{23}(0,2\beta,0)P_{123}R_{23}(0,2\gamma,0), \tag{41}$$

and the matrix elements

$$\langle\nu' I'|\Omega(\alpha,\beta,\gamma)|\nu I\rangle=\sum_{\sigma\tau J} d^{I'}_{(\nu_2'-\nu_3')/2,(\tau_3-\sigma_3)/2}(2\alpha)$$

$$\times\langle(\nu_1',\tau_3,\sigma_3)I'|P_{132}|(\sigma_3,\nu_1',\tau_3)J\rangle d^{J}_{(\nu_1'-\tau_3)/2,(\nu_1-\sigma_2)/2}(2\beta)$$

$$\times\langle(\sigma_3,\nu_1,\sigma_2)J|P_{123}|(\nu_1,\sigma_2,\sigma_3)I\rangle d^{L}_{(\sigma_2-\sigma_3)/2,(\nu_2-\nu_3)/2}(2\gamma), \tag{42}$$

where d^I_{MN} is a reduced SU(2) Wigner function.

VII. DISCUSSION

We have derived matrix elements of Weyl group elements and expressions for SU(3) Wigner functions by making use of the dual actions of U(3) and U(2) on the carrier spaces of symmetric representations of U(6).

The groups U(3) and U(2) are special cases of U(N) and U(n) groups that form dual pairs on the carrier spaces of fully symmetric irreps [i.e., irreps of highest weight (σ,0,...)] of U($N\times n$); they are also dual on a direct sum of such spaces.

The essential property of a dual pair[9,13] is that the constituent groups are the centralizers of each other's actions on a specified vector space. The classic example is the Schur–Weyl pair[14] of unitary, $U(n)$, and symmetric, $\mathbf{S}_N$, groups which have commuting actions on the N-fold tensor product, $\mathbb{C}^{N\times n}$, of a complex n-dimensional vector space, $\mathbb{C}^n$. The Schur–Weyl duality has been used effectively to relate the characters of unitary groups, which are infinite Lie groups, to those of the finite symmetric groups. It also underlies the famous Littlewood–Richardson rules[15] for tensor products and the methods of King, Wybourne, and others[16] for inferring branching rules.

Another famous dual pair comprises the orthogonal, $O(N)$, and symplectic, $Sp(n,\mathbb{R})$, groups acting on the N-fold tensor product $\mathbb{H}^{N\times n}$ of the n-dimensional harmonic oscillator Hilbert space $\mathbb{H}^n$.[17] Whereas the Schur–Weyl duality relates the properties of a finite-dimensional irrep of a Lie group to those of a discrete group, the symplectic-orthogonal duality relates the properties of an infinite-dimensional irrep of a noncompact Lie group to those of a compact Lie group. This duality was used, for example, to infer the $Sp(n,\mathbb{R})\to U(n)$ branching rules from known properties of $O(N)$.[18]

It is interesting to note that $U(n)\times U(N)$ and $Sp(n)\times O(N)$ are both direct products of dual pairs on a common harmonic oscillator Hilbert space $\mathbb{H}^{N\times n}$. Thus, one has the useful concept of dual subgroup chains

$$Sp(n,\mathbb{R})\supset U(n)\leftrightarrow O(N)\supset U(N), \tag{43}$$

involving the two dual pairs $Sp(n,\mathbb{R})\times O(N)$ and $U(n)\times U(N)$. These duality relations have been used[19] to relate the representations and tensor products of $U(N)$ in an $O(N)$ basis to those of $Sp(n,\mathbb{R})$ in a $U(n)$ basis. They also play an essential role in the microscopic theory of nuclear collective motion[20] with $\mathbb{H}^{N\times n}$ regarded as the Hilbert space for N-particles in an n-dimensional space.

It should be mentioned that dual subgroup chains were discovered long ago by Brauer[21] who extended the Schur–Weyl duality by observing that the centralizer of the orthogonal subgroup $O(n)\subset U(n)$ on $\mathbb{C}^{N\times n}$ is a group (also an algebra) that contains the symmetric group S_N as a subgroup [cf. Ref. 13 for a discussion of the $O(n)$–Brauer duality].

The physical significance of several of the above dual pairs is illustrated effectively by applications to optics and quantum interferometry, applications which motivated the present investigation.

It has long been known that geometrical optics is an application of Hamiltonian mechanics. Moreover, in the linear approximation, the transformation of a light beam by an optical element, such as a lens, is an $Sp(2,\mathbb{R})$ transformation. This observation is important because it means that the combined effects of many optical elements can be inferred by matrix multiplication. More importantly, one can go beyond the linear approximation to compute the aberrations of an optical system and how to correct them. The techniques for doing this have been developed into a fine art by Dragt and his students[22] and have revolutionized the design of charged-particle and optical beam systems; an introduction to the subject has been given by Guillemin and Sternberg.[23]

We note that there also exists a dual group action on optical systems. If a beam of light or charged particles is polarizable or has intrinsic spin degrees of freedom, then, in addition to the symplectic group action on its spatial phase-space coordinates, there is a dual orthogonal group action on its polarization state. Thus, for example, for light, with two linearly independent polarizations, or for spin-half particle beams, one has a dual $Sp(2,\mathbb{R})\times O(2)$ action on the combined space-spin degrees of freedom. [Note that we mean by $Sp(2,\mathbb{R})$ the rank-2 group of real canonical transformation of a four-dimensional phase space; some authors denote the same group by $Sp(4,\mathbb{R})$.] Thus, one can extend the dynamical group for an optical system from $Sp(2,\mathbb{R})$ to the direct product group $Sp(2,\mathbb{R})\times O(2)$ and thereby admit polarizing (spin rotation) as well as focusing elements. One can further extend the dynamical group to $Sp(4,\mathbb{R})\supset Sp(2,\mathbb{R})\times O(2)$ to include combinations of the two. [It is of interest to note that a general polarizing element is not restricted to $O(2)$ and may induce a $U(2)$ transformation that lies inside $Sp(4,\mathbb{R})$ but which does not commute with the group $Sp(2,\mathbb{R})$ of spatial transformations.]

Such extensions are relevant for describing the quantum interference of light or particle beams. In this case, one is interested in the detailed quantum states of many-photon (many-particle) system. Thus, one is interested in the unitary representations of the dynamical group and, as we have shown explicitly for $U(3)\times U(2)$ in Sec. III C, the irreps of a dynamical group are determined by those of its dual and vice versa.

It has recently been proposed that quantum interferometers should be analyzed in terms of unitary groups.[2,3] A typical quantum interferometer comprises a sequence of elements in which two input modes of the electromagnetic field (beams) are transformed linearly into two output modes. It has been shown that the transformation of the two modes by such an optical element is a $U(2)$ transformation [an $SU(2)$ transformation together with a phase shift].[2] It has also been shown[2] that a so-called *active* interferometer can similarly be represented by an $SU(1,1)$ transformation [note that $SU(1,1)$ is isomorphic to $Sp(1,\mathbb{R})$] and that a linear optical system, comprising n input modes, is represented by an $SU(n)$ transformation.[3]

The use of dual pairs provides a natural framework for the extension of these methods to include polarization and optical elements whose parameters depend on the polarization state of the input fields. To include polarization, one simply extends the $U(n)$ group to $U(n)\times U(2)$ and to include combinations of polarizers and beam splitters, for example, one extends to $U(2n)\supset U(n)\times U(2)$. This is particularly relevant in the quantal context because the input states available to σ photons, when there are n input modes and two linearly independent polarizations for each photon, span an irrep of highest weight $(\sigma,0,...)$ of the group $U(2n)$. The duality properties imply that the subrepresentations available to the subgroup $U(n)\times U(2)$, on restriction of the $U(2n)$ representation $(\sigma,0,...)$, are the so-called two-rowed irreps of type $(\lambda_1,\lambda_2,0,...)\times(\lambda_1,\lambda_2)$ (i.e., irreps whose highest weights have no more than two nonzero components). This follows simply because a $U(2)$ weight has only two components and the two subgroups, $U(n)$ and $U(2)$, being each other's duals, have highest weight states in common. This results in an enormous simplification in the analysis of a multi-mode interferometer. [Note that, as usual, the $SU(n)$ labels are obtained by taking differences of $U(n)$ labels, so that the $U(n)$ irrep $(\lambda_1,\lambda_2,0,...)$ restricts to the $SU(n)$ irrep $(\lambda_1-\lambda_2,\lambda_2,0,...)$.]

An important application of $SU(3)$ interferometry is the experimental test of Bell's theorem without inequalities, known as the GHZ test.[24] Standard tests of Bell's theorem, designed to test the hypotheses of local realism against quantum theory, involve spacelike-separated measurements of two polarization-correlated fields, and local realism establishes an upper bound on the possible degree of correlations between the two fields. The GHZ test, in its ideal form, yields one experimental result for local realism and an entirely different result for quantum theory. Thus, a particular observation determines which theory is correct, and an inequality is not necessary. In the context of $SU(3)$ Wigner functions, the important aspect of the GHZ test is that three polarization-correlated fields are used, and therefore $U(3)\times U(2)$, accounting for three fields and two polarizations, is appropriate here.

Consider, for example, the $SU(n)$ transformations of a one-rowed irrep, $(\lambda,0,...)$, by a system which ignores the polarization. For such an irrep, the highest weight state can be identified with the state

$$|\phi(\lambda,0,...)\rangle=(a_{11}^{\dagger})^{\lambda}|0\rangle. \tag{44}$$

of maximum polarization. Hence, all states of the $SU(n)$ irrep with this highest weight state have maximum polarization. Thus, the $SU(2)$ coupling becomes trivial and basis states for the irrep are labelled simply and uniquely by their weights. It follows that the basis states of the generalized version of the theorem of Sec. III C are simply the states

$$|\nu\rangle=\frac{(a_{11}^{\dagger})^{\nu_1}}{\sqrt{\nu_1!}}\frac{(a_{21}^{\dagger})^{\nu_2}}{\sqrt{\nu_2!}}\cdots\frac{(a_{n1}^{\dagger})^{\nu_n}}{\sqrt{\nu_n!}}|0\rangle. \tag{45}$$

The elements of the Weyl group are seen to act on such states by simply permuting the components $\{\nu_i\}$ of the weights.

For the general two-rowed irreps one must include explicit SU(2) coupling, as shown for SU(3) in Sec. III C. For example, basis states for a two-rowed irrep of U(4) are highest weight states of the dual algebra U(2) and have the general form

$$[|\tfrac{1}{2}\nu_1\rangle\otimes[|\tfrac{1}{2}\nu_2\rangle\otimes[|\tfrac{1}{2}\nu_3\rangle\otimes|\tfrac{1}{2}\nu_4\rangle]^I]^J]^{\lambda/2}_{\lambda/2}. \tag{46}$$

Thus, computing matrix elements of Weyl group elements for any two-rowed SU(n) irrep never involves more than SU(2) recoupling.

APPENDIX: FACTORIZATION OF AN SU(3) ELEMENT

Claim: Any element $g\in \mathrm{SU}(3)$ can be parametrized and expressed as a product

$$g(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)=R_{23}(\alpha_1,\beta_1,\gamma_1)R_{12}(\alpha_2,\beta_2,\alpha_2)R_{23}(\alpha_3,\beta_3,\gamma_3), \tag{A1}$$

where $R_{23}(\alpha,\beta,\gamma)\in \mathrm{SU}(2)_{23}$, $R_{12}(\alpha,\beta,\alpha)\in \mathrm{SU}(2)_{12}$, and the $\{\mathrm{SU}(2)_{ij}\}$ are the subgroups of SU(3) defined by the subsystems of roots shown in Fig. 1.

Proof: First observe that any SU(3) matrix can be brought to the form

$$\begin{pmatrix} * & * & * \\ * & * & * \\ 0 & * & * \end{pmatrix} \tag{A2}$$

by an $\mathrm{SU}(2)_{23}$ transformation; viz.

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & Y^* & Z^* \\ 0 & -Z & Y \end{pmatrix}\begin{pmatrix} x & * & * \\ y & * & * \\ z & * & * \end{pmatrix}=\begin{pmatrix} x & * & * \\ \sqrt{1-|x|^2|} & * & * \\ 0 & * & * \end{pmatrix}, \tag{A3}$$

where $Y=y(1-|x|^2)^{-\frac{1}{2}}$, and $Z=z(1-|x|^2)^{-\frac{1}{2}}$ and we have used the fact that $|x|^2+|y|^2+|z|^2=1$. A subsequent $\mathrm{SU}(2)_{12}$ transformation then brings the matrix to $\mathrm{SU}(2)_{23}$ form; i.e.,

$$\begin{pmatrix} x^* & \sqrt{1-|x|^2|} & 0 \\ -\sqrt{1-|x|^2|} & x & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} x & * & * \\ \sqrt{1-|x|^2|} & * & * \\ 0 & * & * \end{pmatrix}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & * & * \\ 0 & * & * \end{pmatrix}. \tag{A4}$$

Thus, we determine that

$$\begin{pmatrix} x^* & \sqrt{1-|x|^2|} & 0 \\ -\sqrt{1-|x|^2|} & x & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ 0 & Y^* & Z^* \\ 0 & -Z & Y \end{pmatrix}\begin{pmatrix} x & * & * \\ y & * & * \\ z & * & * \end{pmatrix}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & * & * \\ 0 & * & * \end{pmatrix}. \tag{A5}$$

Inversion of this equation gives

$$\begin{pmatrix} x & * & * \\ y & * & * \\ z & * & * \end{pmatrix}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & Y & -Z^* \\ 0 & Z & Y^* \end{pmatrix}\begin{pmatrix} x & -\sqrt{1-|x|^2} & 0 \\ \sqrt{1-|x|^2} & x^* & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ 0 & * & * \\ 0 & * & * \end{pmatrix}, \tag{A6}$$

which proves the claim with suitably chosen parameter values; e.g.,

$$x = e^{-i\alpha_2} \cos(\beta_2/2), \quad \sqrt{1-|x|^2} = \sin(\beta_2/2). \tag{A7}$$

A special irreducible matrix representation of the real Clifford algebra $C(3,1)$

K. Scharnhorst[a)]
Humboldt-Universität zu Berlin, Institut für Physik, Invalidenstrasse 110, D-10115 Berlin, Germany

(Received 1 May 1998; accepted for publication 29 October 1998)

4×4 Dirac (gamma) matrices [irreducible matrix representations of the Clifford algebras $C(3,1)$, $C(1,3)$, $C(4,0)$] are an essential part of many calculations in quantum physics. Although the final physical results do not depend on the applied representation of the Dirac matrices (e.g., due to the invariance of traces of products of Dirac matrices), the appropriate choice of the representation used may facilitate the analysis. The present paper introduces a particularly symmetric real representation of 4×4 Dirac matrices (Majorana representation) which may prove useful in the future. As a by-product, a compact formula for (transformed) Pauli matrices is found. The consideration is based on the role played by isoclinic 2-planes in the geometry of the real Clifford algebra $C(3,0)$ which provide an invariant geometric frame for it. It can be generalized to larger Clifford algebras.
 [S0022-2488(99)04606-X]

I. INTRODUCTION

Dirac (gamma) matrices used within many calculations in quantum physics can be understood as representations of Clifford algebras. In four-dimensional Minkowski or Euclidean space they are representations of the Clifford algebras $C(3,1)$, $C(1,3)$ or $C(4,0)$, respectively. While there is no problem to write down sets of complex 4×4 Dirac matrices which form irreducible representations of these Clifford algebras, a set of real 4×4 Dirac matrices (Majorana representation), which we will be interested in, can only be obtained for the Clifford algebra $C(3,1)$[1–4] (further material on real Clifford algebras can be found in Ref. 5, Chap. 13, Refs. 6–11). These matrices obey the standard relation

$$\gamma_\mu\gamma_\nu+\gamma_\nu\gamma_\mu=2\,\eta_{\mu\nu}\mathbf{1}, \tag{1}$$

where $\eta_{\mu\nu}$, $\mu,\nu=1,...,4$ are the elements of the diagonal matrix η with $\mathrm{diag}(\eta)=(1,1,1,-1)$ and $\mathbf{1}$ is the 4×4 unit matrix. An explicit representation of real gamma matrices is provided by the following expressions (adapted from Ref. 4):

$$\gamma_1=\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&1&0&0\\1&0&0&0\end{pmatrix}, \tag{2}$$

$$\gamma_2=\begin{pmatrix}0&0&1&0\\0&0&0&-1\\1&0&0&0\\0&-1&0&0\end{pmatrix}, \tag{3}$$

[a)]Electronic mail: scharnh@physik.hu-berlin.de

$$\gamma_3 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \tag{4}$$

$$\gamma_4 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}. \tag{5}$$

But, Eq. (1) is invariant under orthogonal transformations O of the gamma matrices

$$\gamma'_\mu = O\gamma_\mu O^T \tag{6}$$

and any other set of congruent [by virtue of (6)] gamma matrices γ'_μ will also be equally appropriate as representation of $C(3,1)$. (The general situation is described by Pauli's fundamental theorem.[12,13]) Now, let us denote the real linear vector space $\mathbf{R}_4$ in which the elements of the Clifford algebra $C(3,1)$ act as operators by V (spinor space). Then, the matrices γ_μ can be understood as representations of the generators of $C(3,1)$ with respect to a certain orthonormal basis in V which defines in it a rectangular coordinate system. Any transformation (6) of the gamma matrices corresponds to an orthogonal transformation in V and consequently to a change of the coordinate system in V. The concrete shape of the gamma matrices changes in performing these transformations. In explicit calculations in which gamma matrices occur the required effort may depend on the explicit shape of the gamma matrices. Therefore, in dependence on the physical problem under consideration one may ask whether it is possible to find a coordinate system in which the gamma matrices assume a particularly convenient shape for some calculational purpose. The detailed requirements certainly may depend on the purpose. From such a problem, recently we have been led to ask ourselves whether it is possible to find an irreducible representation of the real Clifford algebra $C(3,1)$ which is particularly symmetric with respect to the index μ of the gamma matrices γ'_μ. Indeed, it is possible to find an orthogonal transformation which transforms the gamma matrices (2)–(5) into the following expressions which are obviously particularly symmetric with respect to the index of the gamma matrices $k=1,2,3$ ($\mathbf{1}$ and $\mathbf{0}$ are the 2×2 unit and null matrices, respectively; φ_0 is some arbitrary real constant; cf. Sec. V),

$$\gamma'_k = \frac{1}{\sqrt{3}}\begin{pmatrix} \mathbf{1} & \mathbf{F}_k \\ \mathbf{F}_k & -\mathbf{1} \end{pmatrix}, \quad \mathbf{F}_k = \begin{pmatrix} f(-\varphi_k) & f(\varphi_k) \\ f(\varphi_k) & -f(-\varphi_k) \end{pmatrix}, \tag{7}$$

$$f(\varphi) = \cos\varphi + \sin\varphi = \sqrt{2}\cos\left(\varphi - \frac{\pi}{4}\right), \tag{8}$$

$$\varphi_k = \varphi(k) = \varphi_0 + \frac{2\pi}{3}k, \tag{9}$$

$$\gamma'_4 = \begin{pmatrix} \mathbf{0} & -\mathbf{1} \\ \mathbf{1} & \mathbf{0} \end{pmatrix}. \tag{10}$$

As a by-product, from the above expressions one obtains the following compact formula for transformed Pauli matrices [irreducible matrix representations of the complex Clifford algebra $C(3,0)$; cf. Appendix B].

$$\sigma'_k = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & \sqrt{2}e^{-i\varphi_k} \\ \sqrt{2}e^{i\varphi_k} & -1 \end{pmatrix}. \tag{11}$$

It is the purpose of the present article to systematically derive the above expressions relying on certain information not applied previously within the present context. The discussion is accompanied by references to the relevant but scattered literature.

Our considerations will be guided by the following idea. Related to the Clifford algebra $C(3,0)$, it should be possible to find an expression for the set of the gamma matrices γ'_k, $k=1,2,3$ which is particularly symmetric with respect to the index k. We approach the problem by noting that each gamma matrix γ_k has 2 two-dimensional eigenspaces related to the eigenvalues $\rho=1$ and $\rho=-1$ (which are orthogonal to each other). Any coordinate system in V stands in a certain geometric relation to all the eigenspaces of the gamma matrices whose mutual relation is an invariant under any transformation (6). Now, the idea consists in finding such a coordinate system in V with respect to which all the eigenspaces of the gamma matrices lie in a particularly symmetric way. Then, one may expect that the explicit expressions for the gamma matrices γ'_k reflect this symmetry. Therefore, in Sec. II we start with some observations concerning the eigenspaces of the generators of the Clifford algebra $C(3,0)$ (more precisely, in using this term we always mean the generators of its irreducible representations).

II. ISOCLINIC 2-PLANES IN $\mathbf{R}_4$

To begin with, let us discuss some aspects of the geometry of 2-planes in the affine space $\mathbf{R}_4$ which we also denote by V for simplicity. We restrict our consideration to 2-planes containing the point $\mathbf{x}=(0,0,0,0)$ [i.e., to the Grassmann manifold $G(2,4)$, for a related review see Ref. 14]. We will rely here on the general multidimensional matrix formalism presented in Ref. 15, Chap. 3, Sec. 3 (also see Ref. 16, Chap. III, Sec. 3.3) which we specialize to $\mathbf{R}_4$. In the following we will start with some material which provides the necessary information on those aspect of the formalism of Refs. 15 and 16 which is relevant for the present paper.

For our purposes, a point $\mathbf{x}$ of a given 2-plane A can be described in terms of the equation

$$\mathbf{x}=\mathbf{A}\mathbf{t}, \tag{12}$$

where $\mathbf{A}$ is a 4×2 matrix whose two columns are given by the coordinates of two linearly independent vectors spanning the 2-plane A while $\mathbf{t}$ is the two-component vector of the coordinates of the point $\mathbf{x}\in A$. Two 2-planes A and B can intersect in V in various ways. In order to study their relation, to each pair of lines $X\subset A$, $Y\subset B$ the angle they enclose can be calculated. Once a line $X\subset A$ is fixed, for any arbitrary line $Y\subset B$ the angle enclosed assumes values between some $\alpha_0\geqslant 0$ and $\pi/2$. In general, α_0 may lie between some minimal and some maximal value—the so-called *stationary angles (principal angles)* $\alpha_{\min}$, $\alpha_{\max}$—which are characteristic for the geometry of the pair of 2-planes A, B. Now, from an extremum principle a 2×2 matrix

$$\mathbf{W}=(\mathbf{A}^T\mathbf{A})^{-1}(\mathbf{A}^T\mathbf{B})(\mathbf{B}^T\mathbf{B})^{-1}(\mathbf{B}^T\mathbf{A}) \tag{13}$$

can be constructed[17] for whose eigenvalues w_1 and w_2 the equations

$$w_1=\cos^2\alpha_{\max}, \tag{14}$$

$$w_2=\cos^2\alpha_{\min} \tag{15}$$

apply. If the 2-planes A, B are given by means of Eq. (12) in terms of two orthonormal vectors each, Eq. (13) simplifies to the form[35]

$$\mathbf{W}=(\mathbf{A}^T\mathbf{B})(\mathbf{B}^T\mathbf{A}). \tag{16}$$

If the matrix $\mathbf{W}$ is proportional to the unit matrix (i.e., $w_1=w_2=w$)

$$\mathbf{W}=w\mathbf{1}, \tag{17}$$

the 2-planes A and B are said to be (mutually) *isoclinic*.[41] Then, to each vector $\mathbf{x}\in A$ a unique line in B exists (determined by the orthogonal projection of $\mathbf{x}$ onto B) which encloses with $\mathbf{x}$ the (stationary) angle $\alpha=\arccos\sqrt{w}$.[48] Finally, we would like to mention that under some natural bijection between $\mathbf{R}_4$ and $\mathbf{C}_2$ $((z_1,z_2)=(x_1+ix_2,x_3+ix_4)\in\mathbf{C}_2,\ (x_1,x_2,x_3,x_4)\in\mathbf{R}_4)$ two isoclinic 2-planes in $\mathbf{R}_4$ correspond to two lines through the origin in $\mathbf{C}_2$ (Ref. 23, Sec. 1-7, p. 51, theorem 1-7.4).

Now, the above formalism can be used to analyze the geometry of the set of 6 two-dimensional eigenspaces of the generators of the Clifford algebra $C(3,0)$ (i.e., more precisely, the generators of its irreducible representation). After some calculation using, e.g., the explicit representations of the gamma matrices (2)–(4) one finds that all their six eigenspaces are pairwise isoclinic 2-planes (some choice for the matrices $\mathbf{A}$ describing the eigenspaces is given in Appendix A). Of course, the two eigenspaces of a given gamma matrix γ_k are orthogonal to each other. But, any other two eigenspaces are pairwise isoclinic with an (stationary) angle $\alpha=\pi/4$. Consequently, we can find, at maximum, a set of three eigenspaces of the gamma matrices γ_k, $k=1,2,3$, whose elements are pairwise isoclinic with the angle $\pi/4$.[54] Such a set of 2-planes is called an *equiangular frame* (Ref. 22, Pt. I, Sec. 5, p. 40). With respect to the aim of the present paper, in the following we will just be interested in such sets.

III. THE CLIFFORD ALGEBRA $C(3,0)$ AND EQUIANGULAR FRAMES

We begin this section with some necessary information taken from Ref. 22[58] and specialized to the present needs (in the following the term ''adapted quote'' always means that the original text is quoted exactly except that any reference to the general multidimensional space $\mathbf{R}_{2n}$ has been specialized to $\mathbf{R}_4$). The following definition will be used: ''A *set of mutually isoclinic 2-planes* in $\mathbf{R}_4$ is characterized by the property that every two 2-planes of the set are isoclinic with each other. A set of mutually isoclinic 2-planes in $\mathbf{R}_4$ is called a *maximal* set if it is not subset of a larger set of mutually isoclinic 2-planes'' (this is an adapted quote from Ref. 22, Pt. I, Sec. 3, p. 19).[60]

In order to make contact with the formalism used in Ref. 22 which we will rely on in the further discussion we need to rewrite the defining equation (12) for a 2-plane A in one of the following two (alternative) ways:

$$\mathbf{x}_{(3,4)}=\tilde{\mathbf{A}}\mathbf{x}_{(1,2)}, \quad \tilde{\mathbf{A}}=\bar{\bar{\mathbf{A}}}(\overline{\mathbf{A}})^{-1}, \tag{18}$$

$$\mathbf{x}_{(1,2)}=\tilde{\tilde{\mathbf{A}}}\mathbf{x}_{(3,4)}, \quad \tilde{\tilde{\mathbf{A}}}=\overline{\mathbf{A}}(\bar{\bar{\mathbf{A}}})^{-1}. \tag{19}$$

Here, the notation $\mathbf{x}_{(1,2)}=(x_1,x_2)^T$, $\mathbf{x}_{(3,4)}=(x_3,x_4)^T$ is used and the 2×2 matrices $\overline{\mathbf{A}}$, $\bar{\bar{\mathbf{A}}}$ are related to the matrix $\mathbf{A}$ in the following way:

$$\mathbf{A}=\begin{pmatrix}\overline{\mathbf{A}}\\ \bar{\bar{\mathbf{A}}}\end{pmatrix}. \tag{20}$$

Equation (18) [(19)] is valid for any 2-plane which is isoclinic but not identical to the 2-plane $O_{(3,4)}$: $\mathbf{x}_{(1,2)}=0$ [$O_{(1,2)}$: $\mathbf{x}_{(3,4)}=0$] (this entails that the 2-plane A intersects the 2-plane $O_{(3,4)}$ [$O_{(1,2)}$] in the point $\mathbf{x}=(0,0,0,0)$ only and, therefore, ensures the invertibility of $\overline{\mathbf{A}}$ [$\bar{\bar{\mathbf{A}}}$]).

According to Wong (Ref. 22, Pt. I, Sec. 7, p. 54, theorem 7.2; also see Ref. 23, Sec. 1-7, p. 43), every maximal set of mutually isoclinic 2-planes in $\mathbf{R}_4$ is of dimension 2 and is congruent (i.e., related by an orthogonal transformation in $\mathbf{R}_4$) to the maximal set given by

$$\mathbf{x}_{(3,4)}=\tilde{\mathbf{B}}(\lambda_0,\lambda_1)\mathbf{x}_{(1,2)}=[\lambda_0\tilde{\mathbf{B}}_0+\lambda_1\tilde{\mathbf{B}}_1]\mathbf{x}_{(1,2)}, \tag{21}$$

$$\tilde{\mathbf{B}}_0=\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix},\quad \tilde{\mathbf{B}}_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \tag{22}$$

or

$$\mathbf{x}_{(1,2)}=\tilde{\tilde{\mathbf{B}}}(\lambda_0,\lambda_1)\mathbf{x}_{(3,4)}, \tag{23}$$

$$\tilde{\tilde{\mathbf{B}}}(\lambda_0,\lambda_1)=\tilde{\mathbf{B}}(\lambda_0,\lambda_1)^{-1}=\frac{1}{\lambda_0^2+\lambda_1^2}\tilde{\mathbf{B}}(\lambda_0,\lambda_1)=\tilde{\mathbf{B}}(\lambda_0',\lambda_1'),$$
$$\lambda_n'=\frac{\lambda_n}{\lambda_0^2+\lambda_1^2},\quad n=1,2, \tag{24}$$

where λ_0, λ_1 are two real parameters.[64]

Both of the 2-planes $O_{(1,2)}:\mathbf{x}_{(3,4)}=0$ and $O_{(3,4)}:\mathbf{x}_{(1,2)}=0$ belong to this maximal set (Ref. 22, Pt. I, Sec. 2, p. 16, lemma 2.2). Equations (21) and (23) entail that the matrix $\mathbf{B}$ to be inserted in the corresponding Eq. (12) reads, e.g. (we have chosen particularly simple expressions),

$$\mathbf{B}(\lambda_0,\lambda_1)=\frac{1}{\sqrt{1+\lambda_0^2+\lambda_1^2}}\begin{pmatrix}\mathbf{1}\\ \tilde{\mathbf{B}}(\lambda_0,\lambda_1)\end{pmatrix}, \tag{25}$$

or

$$\mathbf{B}(\lambda_0',\lambda_1')=\frac{1}{\sqrt{1+\lambda_0'^2+\lambda_1'^2}}\begin{pmatrix}\tilde{\mathbf{B}}(\lambda_0',\lambda_1')\\ \mathbf{1}\end{pmatrix}. \tag{26}$$

Furthermore, Wong finds that (adapted quote) ''in $\mathbf{R}_4$, any maximal set of mutually isoclinic 2-planes which contains the 2-plane $O_{(1,2)}$ corresponds to a linear subspace of the linear space of all 2×2 matrices'' (Ref. 22, Pt. I, Sec. 3, p. 20, lemma 3.2). Now, in this two-dimensional subspace a matrix basis can be chosen in such a way that the 2-planes described by the elements of the basis and the 2-plane $O_{(1,2)}$ (or $O_{(3,4)}$) form an equiangular frame (Ref. 22, Pt. I, Sec. 3, p. 24, lemma 3.3 and p. 40). As one may convince oneself easily by means of the explicit expressions given in Appendix A, each equiangular frame built from the eigenspaces of the gamma matrices contains a basis of one and the same maximal set of mutually isoclinic 2-planes.

For the purpose of the present paper it appears to be useful to consider two disjoint equiangular frames Ω connected with the gamma matrices (2)–(4)—one (Ω_1) related to the three eigenspaces to the eigenvalue $\rho=1$, and the other one (Ω_{-1}) related to the three eigenspaces to the eigenvalue $\rho=-1$. The following theorem by Wong will be helpful then (Φ is any maximal set of mutually isoclinic 2-planes in $\mathbf{R}_4$; the following is an adapted quote; the indices have also been changed to conform to the notation used in the present article): ''If the angles between any 2-plane of Φ and the three 2-planes of an equiangular frame are θ_k $(1\leq k\leq 3)$, then

$$\cos^2 2\theta_1+\cos^2 2\theta_2+\cos^2 2\theta_3=1. \tag{27}$$

Conversely, given any set of three angles θ_k $(1\leq k\leq 3)$ such that $0\leq\theta_k\leq\pi$ and $\Sigma\cos^2 2\theta_k=1$, then there exists a unique 2-plane isoclinic to each of the three 2-planes of a given equiangular frame, making angles θ_k with them, and this 2-plane belongs to Φ'' [Ref. 22, Pt. I, Sec. 5, p. 41, theorem 5.3 (b)]. From this insight we conclude that, obviously, to each equiangular frame Ω_1 [Ω_{-1}] two uniquely determined 2-planes $A_{1\pm}$ [$A_{-1\pm}$] exist which lie in a particularly symmetric way (isoclinic) relative to the elements of Ω_1 [Ω_{-1}]. For $A_{1\pm}$, $A_{-1\pm}$ it holds

$$\theta_1 = \theta_2 = \theta_3 = \theta_{\text{sym}}, \quad \cos 2\theta_{\text{sym}} = \pm \frac{1}{\sqrt{3}}. \tag{28}$$

For the corresponding eigenvalue of the matrix **W**, Eq. (17), one obtains

$$w = \cos^2 \theta_{\text{sym}} = \frac{1}{2}(1 + \cos 2\theta_{\text{sym}}) = \frac{1}{2}\left(1 \pm \frac{1}{\sqrt{3}}\right) = w_\pm . \tag{29}$$

The two different values of θ_{sym} (and w)) will not cause any major difference in the following considerations as both cases are related by a simple permutation of the indices of the gamma matrices.

IV. CHANGE OF THE COORDINATE SYSTEM

We may now set out to determine the position of the 2-planes $A_{1\pm}$, $A_{-1\pm}$ using the formulas given in Secs. II and III. For the 2-planes $A_{1\pm}$, $A_{-1\pm}$ we can apply a general ansatz according to Eqs. (21), (23), (25), (26) and calculate the eigenvalue of the matrix **W** for each of the three pairs given by one of the elements of the equiangular frame Ω_1 $[\Omega_{-1}]$ and $A_{1\pm}$ $[A_{-1\pm}]$. For each eigenvalue ρ of the gamma matrices (2)–(4), this leads to a set of three equations for the parameters λ_0, λ_1 which have to be solved simultaneously taking into account Eq. (29). These equations read for $\rho = 1$ (in sequence for the indices $k = 1$, $k = 2$ and $k = 3$ of the gamma matrices, respectively)

$$w_\pm = \frac{\lambda_0'^2 + (1 + \lambda_1')^2}{2(1 + \lambda_0'^2 + \lambda_1'^2)}, \tag{30}$$

$$w_\pm = \frac{(1 - \lambda_0')^2 + \lambda_1'^2}{2(1 + \lambda_0'^2 + \lambda_1'^2)}, \tag{31}$$

$$w_\pm = \frac{\lambda_0'^2 + \lambda_1'^2}{1 + \lambda_0'^2 + \lambda_1'^2}, \tag{32}$$

and for $\rho = -1$,

$$w_\pm = \frac{\lambda_0^2 + (1 - \lambda_1)^2}{2(1 + \lambda_0^2 + \lambda_1^2)}, \tag{33}$$

$$w_\pm = \frac{(1 + \lambda_0)^2 + \lambda_1^2}{2(1 + \lambda_0^2 + \lambda_1^2)}, \tag{34}$$

$$w_\pm = \frac{\lambda_0^2 + \lambda_1^2}{1 + \lambda_0^2 + \lambda_1^2}. \tag{35}$$

(Equations (30)–(32) [(33)–(35)] have been derived using the expressions given in Appendix A and Eq. (26) [(25)].) The solution of the above equations reads for $\rho = 1$,

$$\lambda_0' = -\lambda_1' = -\lambda_\pm , \tag{36}$$

and for $\rho = -1$,

$$\lambda_0 = -\lambda_1 = \lambda_\pm . \tag{37}$$

Here,

$$\lambda_{\pm}=\pm\sqrt{3}w_{\pm}, \tag{38}$$

which entails

$$2\lambda_{\pm}\lambda_{\mp}=-1. \tag{39}$$

Now, we may assume that the explicit representations for the gamma matrices (2)–(5) are related to the natural basis in V from which two pairs of basis vectors can be selected which define the orthogonal 2-planes $O_{(1,2)}$, $O_{(3,4)}$. In order to obtain a particularly symmetric representation for the gamma matrices it appears to be advantageous now to go over to an orthonormal basis from which two pairs of basis vectors can be chosen which define the orthogonal 2-planes $A_{1\pm}$, $A_{-1\pm}$. This change of the basis in V is associated with an orthogonal transformation O in V which transforms the gamma matrices in accordance with Eq. (6). We start by choosing an appropriate orthonormal basis in V from which the matrices $\mathbf{A}_{1\pm}$, $\mathbf{A}_{-1\pm}$ describing the 2-planes $A_{1\pm}$, $A_{-1\pm}$ can be built [we simply insert the solutions (36) and (37) into Eqs. (26) and (25), respectively],

$$\mathbf{A}_{1\pm}=\frac{1}{\sqrt{1+2\lambda_{\pm}^2}}\begin{pmatrix}\lambda_{\pm} & \lambda_{\pm}\\ \lambda_{\pm} & -\lambda_{\pm}\\ 1 & 0\\ 0 & 1\end{pmatrix}, \tag{40}$$

$$\mathbf{A}_{-1\pm}=\frac{1}{\sqrt{1+2\lambda_{\pm}^2}}\begin{pmatrix}1 & 0\\ 0 & 1\\ -\lambda_{\pm} & -\lambda_{\pm}\\ -\lambda_{\pm} & \lambda_{\pm}\end{pmatrix}. \tag{41}$$

One immediately recognizes that the 2-planes $A_{1\pm}$, $A_{-1\pm}$ are orthogonal to each other. Furthermore, by virtue of Eq. (39) it holds $A_{1\pm}=A_{-1\mp}$. Of course, the above choice for the matrices $\mathbf{A}_{1\pm}$, $\mathbf{A}_{-1\pm}$ is not unique and any orthonormal basis which is related to the basis used in the above equations by a rotation within the 2-planes $A_{1\pm}$, $A_{-1\pm}$ is equally well suited. In fact, further below we will use exactly this freedom to obtain our final result (7)–(10).

The transition from the natural basis in V which is related to the 2-planes $O_{(1,2)}$, $O_{(3,4)}$ to the basis which is given in terms of Eqs. (40) and (41) and which is related to the 2-planes $A_{1\pm}$, $A_{-1\pm}$ is described by the orthogonal transformation $O_{\pm}$,

$$O_{\pm}=\frac{1}{\sqrt{1+2\lambda_{\pm}^2}}\begin{pmatrix}\lambda_{\pm} & \lambda_{\pm} & 1 & 0\\ \lambda_{\pm} & -\lambda_{\pm} & 0 & 1\\ 1 & 0 & -\lambda_{\pm} & -\lambda_{\pm}\\ 0 & 1 & -\lambda_{\pm} & \lambda_{\pm}\end{pmatrix}, \tag{42}$$

which leads via $\gamma_{\mu}''=O_{\pm}\gamma_{\mu}O_{\pm}^T$ to the correspondingly transformed expressions for the gamma matrices γ_{μ} [of course, for our choice (42) it holds $O_{\pm}=O_{\pm}^T$]. After some algebra [taking into account Eq. (39)] one finds

$$\gamma_{1\pm}''=-\gamma_{2\mp}''=\pm\frac{1}{\sqrt{3}}\begin{pmatrix}1 & 0 & -\lambda_{\pm} & -\lambda_{\mp}\\ 0 & 1 & -\lambda_{\mp} & \lambda_{\pm}\\ -\lambda_{\pm} & -\lambda_{\mp} & -1 & 0\\ -\lambda_{\mp} & \lambda_{\pm} & 0 & -1\end{pmatrix}, \tag{43}$$

$$\gamma''_{3\pm}=\pm\frac{1}{\sqrt{3}}\begin{pmatrix}1&0&1&1\\0&1&1&-1\\1&1&-1&0\\1&-1&0&-1\end{pmatrix},\tag{44}$$

$$\gamma''_4=\begin{pmatrix}0&0&-1&0\\0&0&0&-1\\1&0&0&0\\0&1&0&0\end{pmatrix}.\tag{45}$$

From Eq. (43) one immediately recognizes that the two cases differing by the sign in Eq. (28) are related to each other by a permutation of the gamma matrices with the indices $k=1$ and $k=2$.

V. RESIDUAL ROTATIONS

Although in Sec. IV we have performed the transformation to a coordinate system which lies in a particularly symmetric way with respect to the equiangular frames Ω_1, Ω_{-1} built from the eigenspaces of the gamma matrices, at first glance the transformed expressions (43), (44) do not seem to exhibit any particular symmetry with respect to the index $k=1,2,3$ of the gamma matrices. However, the expected symmetry is there and we are going to reveal it now. Let us remind ourselves that the choice of the new basis (coordinate system) was not unique and we have disregarded for the moment the remaining freedom to perform rotations within the 2-planes $A_{1\pm}$, $A_{-1\pm}$. Any such rotation can be described by the orthogonal transformation

$$O(\beta_1,\beta_{-1})=\begin{pmatrix}\cos\beta_1&-\sin\beta_1&0&0\\ \sin\beta_1&\cos\beta_1&0&0\\0&0&\cos\beta_{-1}&-\sin\beta_{-1}\\0&0&\sin\beta_{-1}&\cos\beta_{-1}\end{pmatrix},\tag{46}$$

where β_1 and β_{-1} are the independent rotation angles within the orthogonal 2-planes $A_{1\pm}$ and $A_{-1\pm}$, respectively (for the sake of completeness we mention that in addition to the above rotations an inversion within one of the 2-planes $A_{1\pm}$, $A_{-1\pm}$ may be considered). Again, we can write down the further transformed gamma matrices $\gamma'_\mu=O(\beta_1,\beta_{-1})\gamma''_\mu O(\beta_1,\beta_{-1})^T$. For brevity, we give the relatively simple expressions for $\gamma'_{3\pm}$ and γ'_4 only,

$$\gamma'_{3\pm}(\varphi)=\pm\frac{1}{\sqrt{3}}\begin{pmatrix}1&0&f(-\varphi)&f(\varphi)\\0&1&f(\varphi)&-f(-\varphi)\\f(-\varphi)&f(\varphi)&-1&0\\f(\varphi)&-f(-\varphi)&0&-1\end{pmatrix},\tag{47}$$

$$\gamma'_4(\overline{\varphi})=\begin{pmatrix}0&0&-\cos\overline{\varphi}&\sin\overline{\varphi}\\0&0&-\sin\overline{\varphi}&-\cos\overline{\varphi}\\ \cos\overline{\varphi}&\sin\overline{\varphi}&0&0\\-\sin\overline{\varphi}&\cos\overline{\varphi}&0&0\end{pmatrix}.\tag{48}$$

Here, $\varphi=\beta_1+\beta_{-1}$ and $\overline{\varphi}=\beta_1-\beta_{-1}$. The gamma matrices $\gamma'_{k\pm}$, $k=1,2,3$, do not depend on $\overline{\varphi}$ while γ'_4 does not depend on φ. The function f is given by

$$f(\varphi)=\cos\varphi+\sin\varphi=\sqrt{2}\cos\left(\varphi-\frac{\pi}{4}\right). \tag{49}$$

Symmetry considerations now suggest that any set of (three) rotations $O(\beta_1,\beta_{-1})$ among whose elements $\varphi=\beta_1+\beta_{-1}$ changes by a multiple of $2\pi/3$ (mod 2π) will lead to a set of three gamma matrices with the indices $k=1,2,3$. Consequently, in order to describe this set we can write

$$\varphi(k)=\varphi_0+\frac{2\pi}{3}k=\varphi_k, \tag{50}$$

where φ_0 is some real constant. Any three gamma matrices given by Eqs. (47), (49), and (50) can be chosen to serve as an irreducible representation of the real Clifford algebra $C(3,0)$. If we choose $\varphi_0=0$, Eqs. (47), (49), and (50) exactly reproduce the set of gamma matrices (43), (44), i.e.,

$$\gamma'_{3\pm}\left(\frac{2\pi}{3}\right)=\gamma''_{1\pm}, \quad \gamma'_{3\pm}\left(\frac{4\pi}{3}\right)=\gamma''_{2\pm}. \tag{51}$$

Furthermore, for the sake of simplicity it seems to be convenient to set $\overline{\varphi}=0$ and to vary φ exclusively. [Such an orthogonal transformation is called a *Clifford translation* (Ref. 23, Sec. 2-6, p. 102) and has special properties. In this context, also note Ref. 66.] This way the final result [Eqs. (7)–(10), also see Appendix B for some related consideration] quoted in Sec. I is obtained [where we have omitted, for simplicity, the $\pm$ sign on the right-hand side of Eq. (47) which relates to the two inequivalent irreducible representations of $C(3,0)$ (Ref. 2, p. 1657)]. The generators of the real Clifford algebra $C(3,0)$ are found from one of them by means of a discrete $\mathbf{Z}_6\sim\mathbf{Z}_2\times\mathbf{Z}_3$ subgroup of the orthogonal group $O(4)$ (in other words, the $\mathbf{Z}_6$ subgroup realizes a permutation among the gamma matrices). The Clifford translation in the spinor space V with $\beta_1=\beta_{-1}=\pi/3$ corresponds to a rotation by $2\pi/3$ around the axis (1,1,1) in the vector space $\mathbf{R}_{3,0}$ associated with the Clifford algebra $C(3,0)$ (it is an element of the group Spin(3)).

We want to extend our discussion now to the real Clifford algebra $C(3,2)$, which is the largest Clifford algebra admitting an irreducible representation by means of 4×4 matrices. From Eqs. (47), (51) we can calculate the product

$$\gamma'_{3\pm}(\varphi_1)\,\gamma'_{3\pm}(\varphi_2)\,\gamma'_{3\pm}(\varphi_3)=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&-1\\0&0&1&0\end{pmatrix}, \tag{52}$$

which is found to be independent of the choice of φ_0. Allowing an arbitrary value for $\overline{\varphi}$, γ'_5 can then be calculated and reads

$$\begin{aligned}\gamma'_5=\gamma'_5(\overline{\varphi})&=\gamma'_{3\pm}(\varphi_1)\,\gamma'_{3\pm}(\varphi_2)\,\gamma'_{3\pm}(\varphi_3)\,\gamma'_4(\overline{\varphi})\\&=\gamma'_4\left(\overline{\varphi}-\frac{\pi}{2}\right)\\&=\begin{pmatrix}0&0&-\sin\overline{\varphi}&-\cos\overline{\varphi}\\0&0&\cos\overline{\varphi}&-\sin\overline{\varphi}\\\sin\overline{\varphi}&-\cos\overline{\varphi}&0&0\\\cos\overline{\varphi}&\sin\overline{\varphi}&0&0\end{pmatrix},\\{\gamma'_5}^2&=-\mathbf{1}.\end{aligned} \tag{53}$$

Finally, the charge conjugation operator C ($C^T=-C$, $C\gamma'_\mu C^{-1}=-\gamma'^T_\mu$) can be given by $C=\gamma'_4(\overline{\varphi})$. In difference to the $C(3,0)$ subalgebra of the Clifford algebra $C(3,2)$, which is generated by relying on Eq. (50) [a variation of φ by 2π leads to just one copy of the generators of $C(3,0)$], the $C(0,2)$ subalgebra can be represented by $\gamma'_4=\gamma'_4(\overline{\varphi})$, $\gamma'_5=\gamma'_4(\overline{\varphi}\pm\pi/2)$ [a variation of $\overline{\varphi}$ by 2π leads to two copies of the generators of $C(0,2)$].[67] In this context, note

$$\gamma'_4(\overline{\varphi})=-\gamma'_4(\overline{\varphi}+\pi). \tag{54}$$

For $\varphi=0$, the second generator of the real Clifford algebra $C(0,2)$ is obtained from the first by means of a discrete $\mathbf{Z}_8\sim(\mathbf{Z}_2)^3$ subgroup of the orthogonal group $O(4)$. A rotation (46) in the spinor space V with $\beta_1=-\beta_{-1}=\pi/4$ corresponds to a rotation by $\pi/2$ in the vector space $\mathbf{R}_{0,2}$ associated with the Clifford algebra $C(0,2)$ [it is an element of the group Spin(2)].

VI. DISCUSSION

According to Pauli's fundamental theorem[12,13] any set of (in general, complex) 4×4 gamma matrices γ_μ, which represent the Clifford algebra $C(3,1)$, is related to our expressions for γ'_μ [Eqs. (7)–(10)] by means of a nonsingular transformation S ($\gamma_\mu=S\gamma'_\mu S^{-1}$). Therefore, any such set can, in principle, be written in a form analogous to Eqs. (7)–(10) (of course, in general such a representation may look fairly cumbersome). It is clear, that this consideration of the (complex) Clifford algebra $C(3,1)$ immediately carries over with little change to the Clifford algebra $C(1,3)$ and does not require any further special investigation. Furthermore, it seems natural to expect that the discussion of the real Clifford algebra $C(3,1)$ performed in the present paper can appropriately be generalized also to other Clifford algebras. Of course, the simpler and rather trivial case of the real Clifford algebra $C(2,1)$ which is presented in Appendix C carries the traces of the structures found for $C(3,0)$. On the other hand, one should expect that these structures themselves are also traces of more general structures of Clifford algebras which contain $C(3,0)$ as a subalgebra. Let us emphasize at this point that the mathematical tools we have relied on in Secs. II and III are not specific to the present case (although, we have specialized them to the present case, for simplicity) and they can also be used in more general situations. As interesting as this may be, it goes far beyond the purpose of the present study and, therefore, will not be investigated here.

ACKNOWLEDGMENTS

I am grateful to B. A. Rosenfeld for kindly informing me of Ref. 16. The present work has been performed under the EC Training and Mobility of Researchers Program, return fellowship Contract No. ERBFMBICT961197.

APPENDIX A: DESCRIPTION OF THE EIGENSPACES OF γ_k

In this Appendix we give some explicit expressions for the matrices $\mathbf{A}_{k,\rho}$ which define via Eq. (12) the eigenspace (i.e., the 2-plane $A_{k,\rho}$) of the gamma matrix γ_k, $k=1,2,3$, to the eigenvalue $\rho=1,-1$. We rely on orthonormal basis vectors for each eigenspace.

$$\mathbf{A}_{1,1}=\frac{1}{\sqrt{2}}\begin{pmatrix}1&0\\0&1\\0&1\\1&0\end{pmatrix}, \tag{A1}$$

$$\mathbf{A}_{1,-1}=\frac{1}{\sqrt{2}}\begin{pmatrix}1&0\\0&1\\0&-1\\-1&0\end{pmatrix}, \tag{A2}$$

$$\mathbf{A}_{2,1}=\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 0\\ 0 & 1\\ 1 & 0\\ 0 & -1\end{pmatrix}, \tag{A3}$$

$$\mathbf{A}_{2,-1}=\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 0\\ 0 & 1\\ -1 & 0\\ 0 & 1\end{pmatrix}, \tag{A4}$$

$$\mathbf{A}_{3,1}=\begin{pmatrix}1 & 0\\ 0 & 1\\ 0 & 0\\ 0 & 0\end{pmatrix}, \tag{A5}$$

$$\mathbf{A}_{3,-1}=\begin{pmatrix}0 & 0\\ 0 & 0\\ 1 & 0\\ 0 & 1\end{pmatrix}. \tag{A6}$$

From Eqs. (12), (18)–(20) one easily recognizes that for the 2-planes $A_{3,1}$, $A_{3,-1}$ holds $A_{3,1}=O_{(1,2)}$, $A_{3,-1}=O_{(3,4)}$ ($O_{(1,2)}:\mathbf{x}_{(3,4)}=0$, $O_{(3,4)}:\mathbf{x}_{(1,2)}=0$).

APPENDIX B: TRANSFORMED PAULI MATRICES

As Pauli matrices [irreducible matrix representations of the complex Clifford algebra $C(3,0)$] play a significant role in theoretical physics, in this Appendix we wish to comment on the derivation of a particularly symmetric expression for these 2×2 matrices by means of the approach discussed in the main part of the paper. The standard expressions for the Pauli matrices read

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{B1}$$

In order to make contact with the main part of the paper it turns out to be useful to represent the complex numbers which are entries of the matrices (B1) by means of 2×2 matrices using the rule

$$z=a+ib\rightarrow\begin{pmatrix}a & -b\\ b & a\end{pmatrix}. \tag{B2}$$

This leads to a set of three real 4×4 matrices which are congruent to the gamma matrices given by Eq. (7). In order to obtain the desired final result we have to subject the latter gamma matrices to a further orthogonal transformation—an inversion [mentioned below Eq. (46)]. Then the rule (B2) can be reversed yielding the following transformed Pauli matrices ($k=1,2,3$):

$$\sigma'_k=\frac{1}{\sqrt{3}}\begin{pmatrix}1 & \sqrt{2}e^{-i\varphi_k}\\ \sqrt{2}e^{i\varphi_k} & -1\end{pmatrix}, \tag{B3}$$

$$\varphi_k=\varphi(k)=\varphi_0+\frac{2\pi}{3}k. \tag{B4}$$

Here, φ_0 is some arbitrary real constant which, however, has been shifted with respect to Eq. (9).

APPENDIX C: THE CASE OF THE REAL CLIFFORD ALGEBRA $C(2,1)$

In the present Appendix we want to illustrate the formalism used in the main part of the paper in the rather trivial case of the real Clifford algebra $C(2,1)$. We display the equations (including the notation) in close analogy to the discussion performed in the main part of the paper. We start with some explicit expressions for the gamma matrices [σ_k are the standard Pauli matrices (B1)],

$$\gamma_1=\sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \tag{C1}$$

$$\gamma_2=\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \tag{C2}$$

$$\gamma_3=i\sigma_2=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}. \tag{C3}$$

The eigenspaces of the gamma matrices γ_1, γ_2 are described by the following matrices:

$$\mathbf{A}_{1,1}=\frac{1}{\sqrt{2}}\begin{pmatrix}1\\ 1\end{pmatrix}, \tag{C4}$$

$$\mathbf{A}_{1,-1}=\frac{1}{\sqrt{2}}\begin{pmatrix}1\\ -1\end{pmatrix}, \tag{C5}$$

$$\mathbf{A}_{2,1}=\begin{pmatrix}1\\ 0\end{pmatrix}, \tag{C6}$$

$$\mathbf{A}_{2,-1}=\begin{pmatrix}0\\ 1\end{pmatrix}. \tag{C7}$$

It is clear that the angle between the eigenspaces (lines, 1-planes) which relate to different gamma matrices γ_1, γ_2 is $\pi/4$ (cf. Fig. 1).[68] Each line through the origin $\mathbf{x}=(0,0)$ is (trivially) isoclinic to each other such line. Therefore, the analogs of Eqs. (21), (23) are

$$x_2=\lambda x_1, \tag{C8}$$

$$x_1=\lambda' x_2, \quad \lambda'=\lambda^{-1}. \tag{C9}$$

Equations (25), (26) are mirrored by

$$\mathbf{B}(\lambda)=\frac{1}{\sqrt{1+\lambda^2}}\begin{pmatrix}1\\ \lambda\end{pmatrix}, \tag{C10}$$

and

$$\mathbf{B}(\lambda')=\frac{1}{\sqrt{1+\lambda'^2}}\begin{pmatrix}\lambda'\\ 1\end{pmatrix}. \tag{C11}$$

Of course, to each set of the eigenspaces $\{A_{1,1}, A_{2,1}\}$, $\{A_{1,-1}, A_{2,-1}\}$ two lines $A_{1\pm}$, $A_{-1\pm}$ exist, respectively, which lie symmetric with respect to the elements of the set (cf. Fig. 1). The analog of Eq. (27) reads (θ_k are the angles between the two eigenspaces to the eigenvalue $\rho=1$ [$\rho=-1$] and $A_{1\pm}$ [$A_{-1\pm}$])

$$\cos^2 2\theta_1 + \cos^2 2\theta_2 = 1. \tag{C12}$$

For $A_{1\pm}$, $A_{-1\pm}$ the relations [in analogy to Eqs. (28), (29)]

$$\theta_1 = \theta_2 = \theta_{\text{sym}}, \quad \cos 2\theta_{\text{sym}} = \pm\frac{1}{\sqrt{2}}, \tag{C13}$$

and

$$w = \cos^2\theta_{\text{sym}} = \frac{1}{2}(1+\cos 2\theta_{\text{sym}}) = \frac{1}{2}\left(1 \pm \frac{1}{\sqrt{2}}\right) = w_\pm \tag{C14}$$

are valid.

In analogy to Eqs. (30)–(35), in order to determine the lines $A_{1\pm}$, $A_{-1\pm}$ we have to solve the following equations for $\rho=1$ (in sequence for the indices $k=1$, $k=2$ of the gamma matrices, respectively)

$$w_\pm = \frac{(1+\lambda')^2}{2(1+\lambda'^2)}, \tag{C15}$$

$$w_\pm = \frac{\lambda'^2}{1+\lambda'^2}, \tag{C16}$$

and for $\rho=-1$,

$$w_\pm = \frac{(1-\lambda)^2}{2(1+\lambda^2)}, \tag{C17}$$

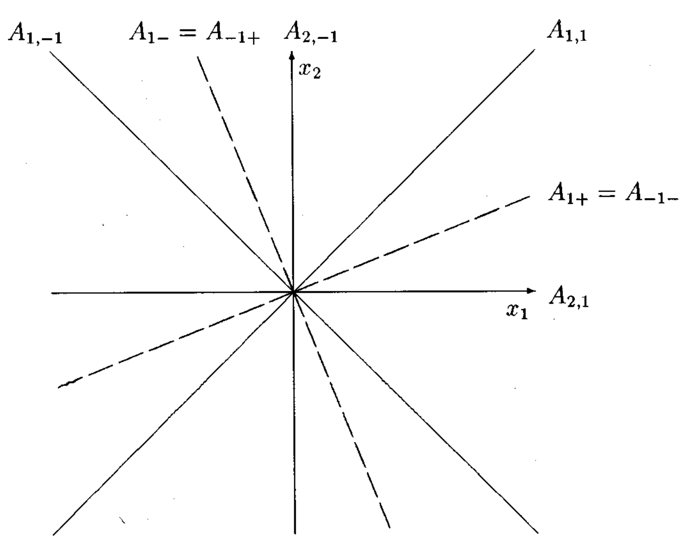

FIG. 1. Geometry of the eigenspaces of the gamma matrices γ_1, γ_2 [(C1), (C2)].

$$w_{\pm}=\frac{\lambda^2}{1+\lambda^2}. \tag{C18}$$

[Equations (C15), (C16) [(C17), (C18)] have been derived using Eq. (C11) [(C10)].] The solution of the above equations reads for $\rho=1$,

$$\lambda'=\lambda_{\pm}, \tag{C19}$$

and for $\rho=-1$,

$$\lambda=-\lambda_{\pm}. \tag{C20}$$

Here,

$$\lambda_{\pm}=\pm 2\sqrt{2}w_{\pm}, \tag{C21}$$

which entails

$$\lambda_{\pm}\lambda_{\mp}=-1. \tag{C22}$$

Inserting Eqs. (C20) and (C22) into Eqs. (C11) and (C10), respectively, one finds

$$\mathbf{A}_{1\pm}=\frac{1}{\sqrt{1+\lambda_{\pm}^2}}\begin{pmatrix}\lambda_{\pm}\\ 1\end{pmatrix}, \tag{C23}$$

$$\mathbf{A}_{-1\pm}=\frac{1}{\sqrt{1+\lambda_{\pm}^2}}\begin{pmatrix}1\\ -\lambda_{\pm}\end{pmatrix} \tag{C24}$$

(cf. Fig. 1; it holds $A_{1+}=A_{-1-}$, $A_{1-}=A_{-1+}$). The orthogonal transformation leading to the new coordinate system consequently reads

$$O_{\pm}=\frac{1}{\sqrt{1+\lambda_{\pm}^2}}\begin{pmatrix}\lambda_{\pm} & 1\\ 1 & -\lambda_{\pm}\end{pmatrix}. \tag{C25}$$

This way the following final result is obtained:

$$\gamma'_{1\pm}=\pm\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}, \tag{C26}$$

$$\gamma'_{2\pm}=\pm\frac{1}{\sqrt{2}}\begin{pmatrix}1 & -1\\ -1 & -1\end{pmatrix}, \tag{C27}$$

$$\gamma'_{3}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}. \tag{C28}$$

It is clear that in the present case there is no residual continuous symmetry which has been exploited in Sec. V of the main part of the paper which is dealing with the real Clifford algebra $C(3,1)$.

[60] In Ref. 61 the shorter term *isoclinic set of 2-planes* is used instead of the term ''maximal set of mutually isoclinic 2-planes.'' As we mainly rely on Ref. 22, in the present article we use the original term. Furthermore, every maximal set of mutually isoclinic 2-planes is also a *maximal normal set of 2-planes*—Refs. 61 and 62. The term *normal set* denotes a set of 2-planes which are pairwise either orthogonal or normally related to each other. Two 2-planes A, B are *normally related* if $A\cap B=A\cap B^{\perp}=\{0\}$. Finally, the relation of maximal sets of mutually isoclinic 2-planes to the Hopf map has been considered in Ref. 63.

[63] Y. C. Wong and K. P. Mok, Enseign. Math. **34**, 167 (1988).
[64] The corresponding expression of Wong—Ref. 22 is related to Eq. (21) by an orthogonal transformation (inversion) $(x_1,x_2,x_3,x_4)\rightarrow(-x_1,x_2,x_3,x_4)$. Equation (21) has been rederived in Ref. 65 by means of fairly elementary considerations. $\tilde{\mathbf{B}}(\lambda_0,\lambda_1)$ can be written as $\tan\theta\,\tilde{\mathbf{D}}$ ($\tan\theta=\sqrt{\lambda_0^2+\lambda_1^2}$), where θ is the angle between the 2-planes $O_{(1,2)}$, B, and $\tilde{\mathbf{D}}$ is an orthogonal matrix ($\tilde{\mathbf{D}}\in O(2)$)—Ref. 44.

Mebius, *Isocliny, Souillart matrices, quaternions and four-dimensional rotations*, Report No. 92-57 (Delft University of Technology, Faculty of Technical Mathematics and Informatics, Delft, 1992), available at the following URL: ftp://ftp.twi.tudelft.nl/pub/publications/tech-reports/1992/DUT-TWI-92-57.ps.gz.
[67] This difference between the Clifford subalgebras $C(3,0)$ and $C(0,2)$ is caused by the fact that during a full 2π turn around the axis (1,1,1) in the vector space $\mathbf{R}_{3,0}$ associated with $C(3,0)$ the rectangular coordinate system is mapped 3 times onto itself while during a full 2π turn in the vector space $\mathbf{R}_{0,2}$ associated with $C(0,2)$ the rectangular coordinate system is mapped 4 times onto itself (allowing reflections). Taking into account the different number of generators of $C(3,0)$ and $C(0,2)$, 3 and 2, respectively, this leads to a natural explanation for the difference.

(Received 30 November 1998; accepted for publication 5 March 1999)

It is shown that a $N\times N$ real symmetric [complex Hermitian] positive definite matrix V is congruent to a diagonal matrix modulo a pseudo-orthogonal [pseudo-unitary] matrix in $\mathrm{SO}(m,n)[\mathrm{SU}(m,n)]$, for any choice of partition $N=m+n$. It is further shown that the method of proof in this context can easily be adapted to obtain a rather simple proof of Williamson's theorem which states that if N is even then V is congruent also to a diagonal matrix modulo a symplectic matrix in $\mathrm{Sp}(N,\mathcal{R})[\mathrm{Sp}(N,\mathcal{C})]$. Applications of these results considered include a generalization of the Schweinler–Wigner method of ‘‘orthogonalization based on an extremum principle’’ to construct pseudo-orthogonal and symplectic bases from a given set of linearly independent vectors.
[S0022-2488(99)00307-2]

I. INTRODUCTION

It is well known that an N-dimensional real symmetric [complex Hermitian] matrix V is congruent to a diagonal matrix modulo an orthogonal [unitary] matrix.[1] That is, $V=S^\dagger DS$, where D is diagonal and $S\in\mathrm{SO}(N)[S\in\mathrm{SU}(N)]$. If, in addition, V is also positive definite, new possibilities arise for establishing its congruence to a diagonal matrix. For N even, it was shown by Williamson[2] some 60 years ago, and subsequently by several authors,[3,4] that such a V is also congruent to a diagonal matrix modulo a symplectic matrix in $\mathrm{Sp}(N,\mathcal{R})[\mathrm{Sp}(N,\mathcal{C})]$. That is, $V>0$ implies $V=S^\dagger D' S$, where D' is diagonal and $S\in\mathrm{Sp}(N,\mathcal{R})[S\in\mathrm{Sp}(N,\mathcal{C})]$. Williamson's theorem has recently been exploited in defining quadrature squeezing and symplectically covariant formulation of the uncertainty principle for multimode states.[5] In this work we establish yet another kind of congruence of a real symmetric [complex Hermitian] positive definite matrix to a diagonal matrix valid, for both odd and even dimensions. We show that an N-dimensional real symmetric [complex Hermitian] positive definite matrix V is congruent to a diagonal matrix modulo a pseudo-orthogonal [pseudo-unitary] matrix. That is, $V>0$ implies $V=S^\dagger D'' S$, where D'' is diagonal and $S\in\mathrm{SO}(m,n)[S\in\mathrm{SU}(m,n)]$, for any choice of partition $N=m+n$. A simple proof of this result is given. The strategy adopted in proving this result, with appropriate modification, works for the Williamson case as well, and affords a particularly simple proof of Williamson's theorem. Needless to add that the diagonal entries of neither D' nor D'' correspond to the eigenvalues of V.

The theorems established here play a crucial role in enabling one to construct pseudo-orthogonal and symplectic bases from a given set of linearly independent vectors via an extremum principle in the spirit of the work of Schweinler and Wigner.[6] In an important contribution to the age old ‘‘orthogonalization problem’’—the problem of constructing an orthonormal set of vectors

[a)]Electronic mail: simon@imsc.ernet.in
[b)]Electronic mail: scsp@uohyd.ernet.in
[c)]Electronic mail: vssp@uohyd.ernet.in

from a given set of linearly independent vectors—Schweinler and Wigner proposed an orthonormal basis which, unlike the familiar Gram–Schmidt basis (which depends on the particular initial order in which the given linearly independent vectors are listed), treats all the linearly independent vectors on an equal footing and has since found important application in wavelet analysis.[7] More significantly, they showed that this special basis follows from *an extremum principle*. In this work, we exploit our results on congruence to obtain generalizations of the Schweinler–Wigner extremum principle leading to pseudo-orthogonal and symplectic bases from a given set of linearly independent vectors. Conversely, the extremum principle, once formulated, can be interpreted as a procedure for finding the appropriate congruence transformation to effect the desired diagonalization.

II. CONGRUENCE OF A POSITIVE MATRIX UNDER PSEUDO-ORTHOGONAL (PSEUDO-UNITARY) TRANSFORMATIONS

The fact that a real symmetric [complex Hermitian] matrix is congruent to a diagonal matrix modulo an orthogonal [unitary] matrix is well known. While congruence coincides with conjugation in the real orthogonal and complex unitary cases, they become distinct when more general sets of transformations are involved. A question which naturally arises is whether congruence to a diagonal form can also be achieved through a pseudo-orthogonal [pseudo-unitary] transformation. The answer to this question turns out to be in the affirmative with the caveat that the matrix in question be positive definite, and can be formulated as the following theorem:

Theorem 1: Let V be a real symmetric positive definite matrix of dimension N. Then, for any choice of partition $N=m+n$, there exists an $S\in SO(m,n)$ such that

$$S^TVS=D^2=\text{diagonal} \ \ (\text{and} \ >0). \tag{1}$$

Proof: We begin by recalling that the group $\mathrm{SO}(m,n)$ consists of all real matrices which satisfy $S^TgS=g$, $\det S=1$, where

$$g=\mathrm{diag}(\underbrace{1,1,\ldots,1}_{m},\underbrace{-1,\ldots,-1}_{n}).$$

Consider the matrix $V^{-1/2}gV^{-1/2}$ constructed from the given matrix V. Since $V^{-1/2}gV^{-1/2}$ is real symmetric, there exists a rotation matrix $R\in\mathrm{SO}(N)$ which diagonalizes $V^{-1/2}gV^{-1/2}$,

$$R^TV^{-1/2}gV^{-1/2}R=\text{diagonal}\equiv\Lambda. \tag{2}$$

This may be viewed also as a congruence of g using $V^{-1/2}R$, and signatures are preserved under congruence. (Indeed, signatures are the only invariants if we allow congruence over the full linear group $GL(N,\mathcal{R})$.) As a consequence, the diagonal matrix Λ can be expressed as the product of a positive diagonal matrix and g,

$$R^TV^{-1/2}gV^{-1/2}R=D^{-2}g=D^{-1}gD^{-1}. \tag{3}$$

Here D is diagonal and positive definite.

Taking the inverse of the matrices on both sides of (3) we find that the diagonal entries of $gD^2=D^2g$ are the eigenvalues of $V^{1/2}gV^{1/2}$ and that the columns of R are the eigenvectors of $V^{1/2}gV^{1/2}$. Since $V^{1/2}gV^{1/2}$, gV, and Vg are conjugate to one another, we conclude that D^2 is determined by the eigenvalues of $gV\sim Vg$.

Define $S=V^{-1/2}RD$. It may be verified that S satisfies the following two equations:

$$S^TgS=g,$$

$$S^TVS=D^2=\text{diagonal}. \tag{4}$$

The first equation says that $S\in SO(m,n)$ and the second says that V is diagonalized through congruence by S. Hence the proof.

By replacing the superscript T by †, the group SO(m,n) by SU(m,n), and $R\in SO(N)$ by $U\in \mathrm{SU}(N)$ in the statement and proof of the above theorem, we have the following theorem which applies to the complex case.

Theorem 2: Let V be a Hermitian positive definite matrix of dimension N. Then, for any partition $N=m+n$, there exists an $S\in \mathrm{SU}(m,n)$ such that

$$S^{\dagger}VS=D^2=\text{diagonal (and } >0). \tag{5}$$

III. A SIMPLE PROOF OF WILLIAMSON'S THEOREM

It turns out that the above procedure when applied to the real symplectic group of linear canonical transformations leads a particularly simple proof of Williamson's theorem.

Theorem 3: Let V be a $2n$-dimensional real symmetric positive definite matrix. Then there exists an $S\in \mathrm{Sp}(2n,\mathcal{R})$ such that

$$S^TVS=D^2>0,$$

$$D^2=\mathrm{diag}(\kappa_1,\kappa_2,\ldots,\kappa_n,\kappa_1,\kappa_2,\ldots,\kappa_n). \tag{6}$$

Proof: Note that the $2n$-dimensional diagonal matrix D has only n independent entries. The group Sp$(2n,\mathcal{R})$ consists of all real matrices S which obey the condition

$$S^T\beta S=\beta,\quad \beta=\begin{pmatrix} 0 & 1\\ -1 & 0\end{pmatrix}, \tag{7}$$

with 1 and 0 denoting the $n\times n$ unit and zero matrices, respectively. Even though $S^T\beta S=\beta$ may appear to suggest that $\det S=\pm 1$, it turns out that $\det S=1$. In other words, Sp$(2n,\mathcal{R})$ consists of just one connected (though not simply connected) piece. Indeed, for every $n\geqslant 1$ the connectivity property of Sp$(2n,\mathcal{R})$ is the same as that of the circle.

The most general $S\in GL(2n,\mathcal{R})$ which solves $S^TVS=D^2$ is $S=V^{-1/2}RD$, where $R\in O(2n)$. Note that none of the factors D, R or $V^{-1/2}$ is an element of Sp$(2n,\mathcal{R})$. However, a V-dependent choice of D,R can be so made that the product $V^{-1/2}RD$ is an element of Sp$(2n,\mathcal{R})$ as we shall now show.

Since $\beta^T=-\beta$, it follows that $\mathcal{M}=V^{-1/2}\beta V^{-1/2}$ is antisymmetric. Hence there exists an $R\in SO(2n)$ such that[8]

$$R^TV^{-1/2}\beta V^{-1/2}R=\begin{pmatrix} 0 & \Omega\\ -\Omega & 0\end{pmatrix},\quad \Omega=\text{diagonal}>0. \tag{8}$$

Define a diagonal positive definite matrix

$$D=\begin{pmatrix} \Omega^{-1/2} & 0\\ 0 & \Omega^{-1/2}\end{pmatrix}. \tag{9}$$

Then we have

$$DR^TV^{-1/2}\beta V^{-1/2}RD=\beta. \tag{10}$$

Now define $S=V^{-1/2}RD$. It may be verified that S enjoys the following properties:

$$S^T\beta S=\beta,$$

$$S^TVS=D^2=\text{diagonal}. \tag{11}$$

The first equation says that $S \in \mathrm{Sp}(2n,\mathcal{R})$ and the second one says that V is diagonalized by congruence through S. This completes the proof of the Williamson theorem. To appreciate the simplicity of the present the reader may like to compare it with two recently published proofs of the Williamson theorem.[4]

We wish to explore the structure underlying the above proof a little further so that the relationship between D and S in (11) on the one hand and the eigenvalues and eigenvectors of βV^{-1} (or $V^{-1/2}\beta V^{-1/2}$) on the other becomes transparent. Again consider the matrix $\mathcal{M} = V^{-1/2}\beta V^{-1/2}$. It is a real, nonsingular, antisymmetric matrix and hence its eigenvalues $i\omega_\alpha$ and eigenvectors η_α have the following properties:

$$\mathcal{M}\eta_\alpha = i\omega_\alpha \eta_\alpha, \quad \alpha = 1,...,2n;$$
$$\omega_k > 0, \quad k=1,...,n; \quad \omega_{n+k} = -\omega_k;$$
$$\eta_{n+k} = \eta_k^*; \quad k=1,...,n. \tag{12}$$

The eigenvectors η_α can be chosen to be orthonormal even when the eigenvalues $i\omega_\alpha$ are degenerate. Arrange the eigenvectors η_α as columns of a matrix U. The matrix U thus obtained clearly belongs to the unitary group $U(2n)$, and satisfies

$$U^\dagger \mathcal{M} U = \Lambda, \quad \Lambda = \begin{pmatrix} i\Omega & 0 \\ 0 & -i\Omega \end{pmatrix}, \tag{13}$$

where $\Omega = \mathrm{diag}(\omega_1,...,\omega_n) > 0$. Now define the following $2n \times 2n$ unitary matrices:

$$\Sigma = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \Delta = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -i \\ 1 & i \end{pmatrix}. \tag{14}$$

These two matrices have the properties $\Sigma^2 = 1$, $U\Sigma = U^*$, and $\Sigma\Delta = \Delta^*$ ($*$ denotes the complex conjugate of a matrix). As a useful consequence of these properties we have

$$U^*\Delta^* = U^*\Sigma\Sigma\Delta^* = U\Delta. \tag{15}$$

We find that the unitary matrix $U\Delta$ is real; $U\Delta \in O(2n)$.

Now consider $S = V^{-1/2}U\Delta D$, where D is a diagonal matrix to be determined. It follows from the definition of S and the reality of $U\Delta \in O(2n)$ that

$$S^T V S = S^\dagger V S = D^2. \tag{16}$$

Further, recalling that $U^\dagger \mathcal{M} U = \Lambda$ we obtain

$$S^T \beta S = S^\dagger \beta S = D\Delta^\dagger U^\dagger \mathcal{M} U \Delta D = D\Delta^\dagger \Lambda \Delta D = D\begin{pmatrix} O & \Omega \\ -\Omega & O \end{pmatrix} D. \tag{17}$$

It is now evident that the following choice for D ensures that S is an element of $S \in \mathrm{Sp}(2n,\mathcal{R})$:

$$D = \begin{pmatrix} \Omega^{-1/2} & O \\ O & \Omega^{-1/2} \end{pmatrix}. \tag{18}$$

This completes our analysis of the manner in which S and D are related to the eigenvalues and eigenvectors of the matrix βV^{-1}.

As in the pseudo-orthogonal case, by replacing the superscript T by † in the statement and proof of Theorem 3, one obtains the following result:

Theorem 4: Let V be a $2n$-dimensional Hermitian positive definite matrix. Then there exists an $S\in \mathrm{Sp}(2n,\mathcal{C})$ such that

$$S^{\dagger}VS=D^2>0,$$
$$D^2=\mathrm{diag}(\kappa_1,\kappa_2,\ldots,\kappa_n,\kappa_1,\kappa_2,\ldots,\kappa_n). \tag{19}$$

An immediate consequence of the theorems stated above is that for a real symmetric [complex Hermitian] positive definite matrix we can not talk about *the* canonical form under congruence, for there are $m+n$ possible choices of $\mathrm{SO}(m,n)[\mathrm{SU}(m,n)]$, and in the case of even dimension one more choice coming from Williamson's theorem. Needless to add that for the same matrix V, the diagonal matrix D will be different for different choices.

IV. ORTHOGONALIZATION PROCEDURES

Assume that we are given a set of linearly independent N-dimensional vectors $v_1,\ldots,v_N$. Let G denote the associated Gram matrix of pairwise inner products, $G_{ij}=(v_i,v_j)$. The Gram matrix is Hermitian by construction, and positive definite by virtue of the linear independence of the given vectors. The orthogonalization problem, i.e., constructing a set of orthonormal vectors out of the given set of linearly independent vectors, amounts to finding a matrix S that solves

$$S^{\dagger}GS=1, \quad \text{i.e.,} \quad G^{-1}=SS^{\dagger}. \tag{20}$$

Each such S defines an orthogonalization procedure.

Let us arrange the set of N vectors as the entries of a row $\mathbf{v}=(v_1,v_2,\ldots,v_N)$, and let $\mathbf{z}=(z_1,z_2,\ldots,z_N)$ represent a generic orthonormal basis. The orthonormal set of vectors $\mathbf{z}$ corresponding to a chosen S are related to the given set of linearly independent vectors through $\mathbf{z}=\mathbf{v}S$. Clearly, there are infinitely many choices for S satisfying (20); given an S satisfying (20), any $S'=SU$, where U is an arbitrary unitary matrix also satisfies (20). Thus the freedom available for the solution of the orthonormalization problem is exactly as large as the unitary group $\mathrm{U}(N)$, and this was to be expected.

Schweinler and Wigner[6] posed and answered the following question: is there a way of discriminating between various choices of S that solves (20) and hence between various orthogonalization procedures? They argued that a particular choice of orthogonalization procedure should correspond ultimately to the extremization of a suitable scalar function over the manifold of all orthonormal bases, with the given linearly independent vectors appearing as parameters in the function. Different choices of onthonormal bases will then correspond to different functions to be extremized. They preferred the function to be symmetric under permutation of the given vectors. As an example they considered the following function which is quartic in the given vectors:

$$m(\mathbf{z})=\sum_k \left(\sum_l |(z_k,v_l)|^2\right)^2. \tag{21}$$

They showed that the extremum (maximum in this case) value of $m(\mathbf{z})$ is given by $\mathrm{tr}(G^2)$, and this value corresponds to the orthonormal basis $\mathbf{z}=\mathbf{v}U_0P^{-1/2}$, where U_0 is the unitary matrix which diagonalizes G: $U_0{}^{\dagger}GU_0=P$. We may refer to this as the Schweinler–Wigner basis, and the function $m(\mathbf{z})$ as the Schweinler–Wigner quartic form. It is clear that U_0 and hence the Schweinler–Wigner basis is essentially unique if the eigenvalues of the Gram matrix G are all distinct. We may note in passing that, unlike the Gram–Schmidt orthogonalization procedure, the Schweinler–Wigner procedure is democratic in that it treats all the linearly independent vectors $\mathbf{v}$ on an equal footing.

The content of the work of Schweinler and Wigner has recently been reformulated[9] in a manner that offers a clearer and more general picture of the Schweinler–Wigner quartic form

$m(\mathbf{z})$ and of the orthonormal basis which maximizes it. This perspective on the orthogonalization problem plays an important role in our generalizations of the Schweinler–Wigner extremum principle, and hence we summarize it briefly.

Since every orthonormal basis is the eigenbasis of a suitable Hermitian operator, it is of interest to characterize the Schweinler–Wigner basis in terms of such an operator. Given linearly independent N-dimensional vectors $\mathbf{v}=(v_1,v_2,\ldots,v_N)$, the operator $\hat{M}=\Sigma_j v_j v_j^\dagger$ is Hermitian positive definite. In a *generic orthonormal* basis $\mathbf{z}$, it is represented by a Hermitian positive definite matrix $M(\mathbf{z})$:$M(\mathbf{z})_{ij}=(z_i,\hat{M}z_j)$. Under a change of orthonormal basis $\mathbf{z}\rightarrow\mathbf{z}'=\mathbf{z}S$, $M(\mathbf{z})$ transforms as follows:

$$M(\mathbf{z})\rightarrow M(\mathbf{z}')=S^\dagger M(\mathbf{z})S,\quad S\in U(N). \tag{22}$$

Recall that $U(N)$ acts transitively on the set of all orthonormal bases and that $\mathrm{tr}(M(\mathbf{z})^2) = \sum_{j,k}|M(\mathbf{z})_{jk}|^2$ is invariant under such a change of basis, and hence is independent of $\mathbf{z}$. The Schweinler–Wigner quartic form $m(\mathbf{z})$ can easily be identified as $\sum_k(M(\mathbf{z})_{kk})^2$. In view of the above invariance, maximization of $\sum_k(M(\mathbf{z})_{kk})^2$ is the same as minimization of $\sum_{j\neq k}|M(\mathbf{z})_{jk}|^2$. The absolute minimum of $\sum_{j\neq k}|M(\mathbf{z})_{jk}|^2$ equals zero, and obtains when $M(\mathbf{z})$ is diagonal. Thus, the orthonormal basis which maximizes $\sum_k(M(\mathbf{z})_{kk})^2$ is the same as the one in which $\hat{M}$ is diagonal, and we arrive at the following important conclusion of Ref. 9:

Theorem 5: The distinquished orthonormal basis which extremizes the Schweinler–Wigner quartic form $m(\mathbf{z})$ over the manifold of all orthonormal bases is the same as the orthonormal basis in which the positive definite matrix $M(\mathbf{z})$ becomes diagonal.

Important for the above structure is the fact that the invariant $\mathrm{tr}(M(\mathbf{z})^2)$ is the sum of non-negative quantities, and therefore a part of it is necessarily bounded. It is precisely this property, which can be traced to the underlying unitary symmetry, that is not available when we try to generalize the Schweinler–Wigner procedure to construct pseudo-orthonormal and symplectic bases wherein the underlying symmetries are the noncompact groups $SO(m,n)$ and $\mathrm{Sp}(2n,\mathcal{R})$ respectively.

V. LORENTZ BASIS WITH AN EXTREMUM PROPERTY

In this section we show how the Schweinler–Wigner procedure can be generalized to construct pseudo-orthonormal basis based on an extremum principle. We begin with the case of real vectors.

We are given a set of linearly independent real N-dimensional vectors $\mathbf{v}=(v_1,\ldots,v_N)$ and we want to construct out of it a pseudo-orthonormal basis $[SO(m,n)$ Lorentz basis with $N=m+n]$, i.e., a set of vectors $\mathbf{z}=(z_1,\ldots,z_N)$ satisfying

$$(z_k,gz_l)=g_{kl},\quad g=\mathrm{diag}(\underbrace{1,1,\ldots,1}_{m},\underbrace{-1,\ldots,-1}_{n}).$$

Let $\hat{M}=\sum_j v_j v_j^T$ as before, and let the symmetric positive definite matrix $M(\mathbf{z})$:$M(\mathbf{z})_{ij} =(z_i,\hat{M}z_j)$ represent $\hat{M}$ in a *generic pseudo-orthonormal* basis $\mathbf{z}$. Under a pseudo-orthogonal change of basis $\mathbf{z}\rightarrow\mathbf{z}'=\mathbf{z}S$, the matrix $M(\mathbf{z})$ transforms as follows:

$$M(\mathbf{z})\rightarrow M(\mathbf{z}')=S^TM(\mathbf{z})S,\quad S\in SO(m,n). \tag{24}$$

Since $S^TgS=g$ (or $gS^T=S^{-1}g$) by definition, we have

$$S:\quad gM(\mathbf{z})\rightarrow gM(\mathbf{z}')=S^{-1}gM(\mathbf{z})S. \tag{25}$$

That is, as $M(\mathbf{z})$ undergoes congruence, $gM(\mathbf{z})$ undergoes conjugation. Thus, $\mathrm{tr}(gM(\mathbf{z}))^l$, $l=1,2,...$, are invariant. In what follows we shall often leave implicit the dependence of M on the generic pseudo-orthonormal basis $\mathbf{z}$.

Consider the invariant $\mathrm{tr}(gM(\mathbf{z})gM(\mathbf{z}))$ corresponding to $l=2$. Write $M=M^{\mathrm{even}}+M^{\mathrm{odd}}$, where

$$M^{\mathrm{even}}=\tfrac{1}{2}(M+gMg), \quad M^{\mathrm{odd}}=\tfrac{1}{2}(M-gMg). \tag{26}$$

In the above decomposition we have exploited the fact that g is, like parity, an *involution*.

With M expressed in the (m,n) block form

$$M=\begin{pmatrix} A & C \\ C^T & B \end{pmatrix}, \quad A^T=A, \quad B^T=B, \tag{27}$$

we have

$$M^{\mathrm{even}}=\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}, \quad M^{\mathrm{odd}}=\begin{pmatrix} 0 & C \\ C^T & 0 \end{pmatrix}. \tag{28}$$

Symmetry of M implies that M^{odd} and M^{even} are symmetric. Further, M^{odd} and M^{even} are trace orthogonal; $\mathrm{tr}(M^{\mathrm{odd}}M^{\mathrm{even}})=0$. Thus,

$$\mathrm{tr}(gMgM)=\mathrm{tr}(M^{\mathrm{even}})^2-\mathrm{tr}(M^{\mathrm{odd}})^2, \tag{29}$$

which can also be written as

$$\mathrm{tr}(MgMg)=\mathrm{tr}(M^2)-2\,\mathrm{tr}(M^{\mathrm{odd}})^2. \tag{30}$$

A few observations are in order:

(1) In contradistinction to the original unitary case, the invariant in the present case is no more a sum of squares. This can be traced to the noncompactness of the underlying $SO(m,n)$ symmetry. As one consequence, $\sum_k (M_{kk})^2$ is not bounded. As an example, consider the simplest case $m=1$, $n=1$ and let

$$M=\begin{pmatrix} a & 0 \\ 0 & b \end{pmatrix}, \quad a,b>0. \tag{31}$$

Under congruence by the $SO(1,1)$ element

$$S=\begin{pmatrix} \cosh\mu & \sinh\mu \\ \sinh\mu & \cosh\mu \end{pmatrix}, \tag{32}$$

the value of $\sum_k (M_{kk})^2$ changes from a^2+b^2 to $a^2+b^2+2ab\sinh^2\mu\cosh^2\mu$, which grows with μ without bounds, showing that $\sum_k (M_{kk})^2$ and hence $\mathrm{tr}(M^2)$ is not bounded. Thus, in contrast to the unitary case, extremization of the Schweinler–Wigner quartic form $\sum_k (M_{kk})^2$ will make no sense in the absence of further restrictions.

(2) The structure of the invariant $\mathrm{tr}(gMgM)$ in (30) suggests the further restriction needed to be imposed; within the submanifold of pseudo-orthogonal bases $\mathbf{z}$ which keep $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$ (and hence $\mathrm{tr}(M(\mathbf{z})^2)$) at a fixed value we can maximize $\sum_k M(\mathbf{z})_{kk}^2$. In particular we can do this within the submanifold which minimizes $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$, and hence $\mathrm{tr}(M(\mathbf{z})^2)$. Clearly, zero is

the absolute minimum of the nonnegative object $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$. But by Theorem 1 there exists a Lorentz basis $\mathbf{z}$ in which $M(\mathbf{z})$ is diagonal and hence $M(\mathbf{z})^{\mathrm{odd}}=0$. Thus the minimum $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2=0$, and hence the minimum of $\mathrm{tr}(M(\mathbf{z})^2)$, namely, $\mathrm{tr}(gM(\mathbf{z})gM(\mathbf{z}))$, is attainable.

The above observations suggest the following *two step analog of the Schweinler–Wigner extremum principle for Lorentz bases*. Choose the submanifold of Lorentz bases which minimize the quartic form $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$, and maximize the Schweinler–Wigner quartic form $m(\mathbf{z})=\sum_k (M(\mathbf{z})_{kk})^2$ within this submanifold. Clearly, the first step takes M to a block-diagonal form, and the second one diagonalizes it. Thus we have established the following generalization of Theorem 5 to the pseudo-orthonormal case:

Theorem 6: The distinquished pseudo-orthonormal basis which extremizes the ''Schweinler–Wigner'' quartic form $m(\mathbf{z})$ over the submanifold of pseudo-orthonormal bases which minimize the quartic form $\mathrm{tr}(M(\mathbf{z})^2)$ is the same as the pseudo-orthonormal basis in which the positive definite matrix $M(\mathbf{z})$ becomes diagonal.

The submanifold under reference consists of Lorentz bases which are related to one another through the maximal compact (connected) subgroup of $\mathrm{SO}(m,n)$, namely $\mathrm{SO}(m)\times SO(n)$. This subgroup consists of matrices of the block-diagonal form

$$\begin{pmatrix} R_1 & 0 \\ 0 & R_2 \end{pmatrix}, \quad R_1\in \mathrm{SO}(m), \quad R_2\in \mathrm{SO}(n), \tag{33}$$

and this is precisely the subgroup of $\mathrm{SO}(m,n)$ transformations that do not mix the even and odd parts of $M(\mathbf{z})$.

To conclude this section we may note that the above construction carries over to the complex case, with obvious changes like replacing T by † and $\mathrm{SO}(m,n)$ by $\mathrm{SU}(m,n)$.

VI. SYMPLETIC BASIS WITH AN EXTREMUM PROPERTY

Our construction in the pseudo-orthogonal case suggests a scheme by which the Schweinler–Wigner extremum principle can be generalized to construct a symplectic basis. Suppose that we are given a set of linearly independent vectors $\mathbf{v}=(v_1,v_2,\ldots,v_{2n})$ in $\mathcal{R}^{2n}$. The natural symplectic structure in R^{2n} is specified by the standard symplectic ''metric'' β defined in (7). Let $\mathbf{z}=(z_1,z_2,\ldots,z_{2n})$ denote a generic symplectic basis. That is, $(z_j,\beta z_k)=\beta_{jk}$, $j,k=1,2,...,2n$. The real symplectic group $\mathrm{Sp}(2n,R)$ acts transitively on the set of all symplectic bases.

To generalize the Schweinler–Wigner principle to the symplectic case, we begin be defining $\hat{M}=\sum_{j=1}^{2n} v_j v_j^T$. Let $M(\mathbf{z})$:$M(\mathbf{z})_{ij}=(z_i,\hat{M}z_j)$ be the symmetric positive definite matrix representing the operator $\hat{M}$ in a *generic symplectic* basis $\mathbf{z}$. Under a symplectic change of basis $\mathbf{z}\to\mathbf{z}'=\mathbf{z}S$, $S\in\mathrm{Sp}(2n,\mathcal{R})$, the matrix $M(\mathbf{z})$ undergoes the following transformation:

$$M(\mathbf{z})\to M(\mathbf{z}')=S^T M(\mathbf{z})S, \quad S\in \mathrm{Sp}(2n,R). \tag{34}$$

Since $S^T\beta S=\beta$ implies $\beta S^T=S^{-1}\beta$, we have

$$S: \quad \beta M(\mathbf{z})\to\beta M(\mathbf{z}')=S^{-1}\beta M(\mathbf{z})S. \tag{35}$$

That is, under a symplectic change of basis $M(\mathbf{z})$ undergoes congruence, but $\beta M(\mathbf{z})$ undergoes conjugation. Hence $\mathrm{tr}(\beta M(\mathbf{z}))^{2l}$, $l=1,2,...,n$ are invariant. (Note that $\mathrm{tr}(\beta M(\mathbf{z}))^{2l+1}=0$ in view of $\beta^T=-\beta$, $M(\mathbf{z})^T=M(\mathbf{z})$.)

Since $i\beta$ is an *involution* we can use it to separate $M(\mathbf{z})$ into even and odd parts,

$$M(\mathbf{z})=M(\mathbf{z})^{\mathrm{even}}+M(\mathbf{z})^{\mathrm{odd}},$$

$$M(\mathbf{z})^{\mathrm{even}}=\tfrac{1}{2}(M(\mathbf{z})+\beta M(\mathbf{z})\beta^T),$$
$$M(\mathbf{z})^{\mathrm{odd}}=\tfrac{1}{2}(M(\mathbf{z})-\beta M(\mathbf{z})\beta^T). \tag{36}$$

The even and odd parts of $M(\mathbf{z})$ satisfy the symmetry properties

$$\beta M(\mathbf{z})^{\mathrm{even}}\beta^T=M(\mathbf{z})^{\mathrm{even}},\quad \beta M(\mathbf{z})^{\mathrm{odd}}\beta^T=-M(\mathbf{z})^{\mathrm{odd}}. \tag{37}$$

Further. $M(\mathbf{z})^{\mathrm{odd}}$ and $M(\mathbf{z})^{\mathrm{even}}$ are trace orthogonal; $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}}M(\mathbf{z})^{\mathrm{even}})=0$.

The structure of the even and odd parts of $M(\mathbf{z})$ may be appreciated by writing $M(\mathbf{z})$ in the block form

$$M(\mathbf{z})=\begin{pmatrix} A & C \\ C^T & B \end{pmatrix},\quad A^T=A,\quad B^T=B. \tag{38}$$

We have

$$M(\mathbf{z})^{\mathrm{even}}=\begin{pmatrix} \tfrac{1}{2}(A+B) & \tfrac{1}{2}(C-C^T) \\ -\tfrac{1}{2}(C-C^T) & \tfrac{1}{2}(A+B) \end{pmatrix},$$
$$M(\mathbf{z})^{\mathrm{odd}}=\begin{pmatrix} \tfrac{1}{2}(A-B) & \tfrac{1}{2}(C+C^T) \\ \tfrac{1}{2}(C+C^T) & \tfrac{1}{2}(B-A) \end{pmatrix}. \tag{39}$$

Now consider the invariant $-\mathrm{tr}(\beta M(\mathbf{z})\beta M(\mathbf{z}))=\mathrm{tr}(\beta^T M(\mathbf{z})\beta M(\mathbf{z}))$. We have

$$\mathrm{tr}(\beta^T M(\mathbf{z})\beta M(\mathbf{z}))=\mathrm{tr}(M(\mathbf{z})^{\mathrm{even}})^2-\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2, \tag{40}$$

which can also be written as

$$\mathrm{tr}(\beta^T M(\mathbf{z})\beta M(\mathbf{z}))=\mathrm{tr}(M(\mathbf{z})^2)-2\,\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2. \tag{41}$$

The structural similarity of this invariant to that in the pseudo-orthogonal case should be appreciated.

Now, by an argument similar to the pseudo-orthogonal case one finds that, owing to the noncompactness of $\mathrm{Sp}(2n,\mathcal{R})$, the function $\mathrm{tr}(M(\mathbf{z})^2)$ and hence the Schweinler–Wigner quartic form $\sum_{k=1}^{2n}(M(\mathbf{z})_{kk})^2$ is unbounded if $\mathbf{z}$ is allowed to run over the entire manifold of all symplectic bases. For instance, in the lowest dimensional case $n=1$ with M chosen to be

$$M=\begin{pmatrix} a & u \\ d & b \end{pmatrix},\quad a,b>0,\quad ab-ud>0, \tag{42}$$

under congruence by the $\mathrm{Sp}(2,,\mathcal{R})$ matrix

$$S=\begin{pmatrix} \mu & 0 \\ 0 & 1/\mu \end{pmatrix}, \tag{43}$$

the value of $\sum_k(M_{kk})^2$ changes from a^2+b^2 to $\mu^2a^2+(1/\mu^2)b^2$ which, by an appropriate choice of μ, can be made as large as one wishes.

However, it follows from (41) that over the submanifold of symplectic bases which leave $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$ fixed, the function $\mathrm{tr}(M(\mathbf{z})^2)$ remains invariant and so the quartic form $\Sigma(M(\mathbf{z})_{kk})^2$ is bounded within this restricted class of symplectic bases and hence can be maximized. In particular the nonnegative $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$ can be chosen to take its minimum value. Williamson theorem implies that there are symplectic bases which realize the absolute minimum $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2=0$.

We can now formulate the *analog of the Schweinler–Wigner extremum principle for symplectic bases* in the following way: Take the subfamily of symplectic bases in which $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2$ and hence $\mathrm{tr}(M(\mathbf{z})^2)$ is minimum. [This minimum of $\mathrm{tr}(M(\mathbf{z})^2)$ equals the invariant $\mathrm{tr}(\beta^T M(\mathbf{z})\beta M(\mathbf{z}))$]. Then maximize the Schweinler–Wigner quartic form $m(\mathbf{z})=\sum_k (M(\mathbf{z})_{kk})^2$ within this submanifold of symplectic bases. This will lead, not just to a basis in which $M(\mathbf{z})$ is diagonal, but to one where $M(\mathbf{z})$ has the Williamson canonical form $M(\mathbf{z})=\mathrm{diag}(\kappa_1,...,\kappa_n;\kappa_1,...,\kappa_n)$. We have thus established the following generalization of the Schweinler–Wigner extremum principle to the symplectic case.

Theorem 7: The distinguished symplectic basis which extremizes the ''Schweinler–Wigner'' quartic form $m(\mathbf{z})$ over the submanifold of symplectic bases which minimize the quartic form $\mathrm{tr}(M(\mathbf{z})^2)$ is the same as the symplectic basis in which the positive definite matrix $M(\mathbf{z})$ assumes the Williamson canonical diagonal.

Note that once $M(\mathbf{z})^{\mathrm{odd}}=0$ is reached, as implied by $\mathrm{tr}(M(\mathbf{z})^{\mathrm{odd}})^2=0$, $M(\mathbf{z})$ has the special even form

$$\begin{pmatrix} A & C \\ -C & A \end{pmatrix}, \quad A^T=A, \quad C^T=-C, \tag{44}$$

so that $A+iC$ is Hermitian. The subgroup of symplectic transformations which do not mix $M(\mathbf{z})^{\mathrm{even}}$ with $M(\mathbf{z})^{\mathrm{odd}}$, and hence maintain the property $M(\mathbf{z})^{\mathrm{odd}}=0$ have the special form

$$S=\begin{pmatrix} X & Y \\ -Y & X \end{pmatrix}, \quad X+iY\in \mathrm{U}(n). \tag{45}$$

This subgroup, isomorphic to the unitary group $\mathrm{U}(n)$, is the maximal compact subgroup[10] of $\mathrm{Sp}(2n,\mathcal{R})$. Thus, diagonalizing $M(\mathbf{z})$ using symplectic change of basis, after it has reached the even form, is the same as diagonalizing an n-dimensional Hermitian matrix using unitary transformations.

VII. CONCLUDING REMARKS

To conclude, we have shown that an $N\times N$ real symmetric [complex Hermitian] positive definite matrix is congruent to a diagonal form modulo a pseudo-orthogonal [pseudo-unitary] matrix belonging to $\mathrm{SO}(m,n)[\mathrm{SU}(m,n)]$, for any choice of partition $N=m+n$. The method of proof of this result is adapted to provide a simple proof of Williamson's theorem. An important consequence of these theorems is that while a real-symmetric [complex-Hermitian] positive definite matrix has a unique diagonal form under conjugation, it has several different canonical diagonal forms under congruence. The theorems developed here are used to formulate an extremum principle a lá Schweinler and Wigner for constructing pseudo-orthonormal[pseudo-unitary] and symplectic bases from a given set of linearly independent vectors. Conversely, the extremum principle thus formulated can be used for finding the congruence transformation which brings about the desired diagonalization.

It is interesting that pseudo-orthonormal basis and symplectic basis could be constructed by extremizing *precisely the same Schweinler–Wigner quartic form* $m(\mathbf{z})=\sum_k (M(\mathbf{z})_{kk})^2$ that was originally used to construct orthonormal basis in the unitary case. However, it must be borne in mind that the similarity in the structure of the quartic form to be extremized in the three cases considered is only at a formal level. In reality, the three quartic forms are very different objects, for they are functions over topologically very different manifolds; $\mathbf{z}$ runs over the group manifold $\mathrm{U}(N)$ of orthogonal frames in the original Schweinler–Wigner case, the group manifold $\mathrm{SO}(m,n)$

of pseudo-orthogonal frames in the Lorentz case, and over the group manifold $Sp(2n,\mathcal{R})$ in the symplectic case. This has the consequence that, unlike the orthogonal case, this quartic form is unbounded in the noncompact $SO(m,n)[SU(m,n)]$ and $Sp(2n,\mathcal{R})$ cases. Insight into the structure of these groups was used to achieve constrained extremization within a natural maximal compact submanifold.

Invariant Painlevé analysis and coherent structures of two families of reaction-diffusion equations

Ugur Tanriver and S. Roy Choudhury[a)]
Department of Mathematics, University of Central Florida, Orlando, Florida 32816-1364

(Received 25 June 1998; accepted for publication 12 March 1999)

Exact closed-form coherent structures (pulses/fronts/domain walls) having the form of complicated traveling waves are constructed for two families of reaction–diffusion equations by the use of invariant Painlevé analysis. These analytical solutions, which are derived directly from the underlying PDE's, are investigated in the light of restrictions imposed by the ODE that any traveling wave reduction of the corresponding PDE must satisfy. In particular, it is shown that the coherent structures (a) asymptotically satisfy the ODE governing traveling wave reductions, and (b) are accessible to the PDE from compact support initial conditions. The solutions are compared with each other, and with previously known solutions of the equations. © *1999 American Institute of Physics.* [S0022-2488(99)01907-6]

I. INTRODUCTION

There has been considerable interest in coherent structure solutions of nonintegrable nonlinear partial differential equations (NLPDEs)[1–10] since these provide an organizing structure to the space of solutions. In a very rough sense, this is somewhat analogous to the way in which families of soliton solution act as basic building blocks for the solution space of integrable equations. Recent work, primarily in the context of generalized Ginzburg–Landau amplitude equations in pattern-forming systems, has included the existence of pulse (solitary wave), front (shock) and domain wall coherent structures using center manifold techniques,[11,12] as well as investigations of periodic and quasi-periodic solutions.[13–17] Another, more physics-oriented, approach was developed by van Saarloos[18,19] to investigate linear and nonlinear marginal stability of fronts. This approach has been comprehensively reviewed by van Saarloos and Hohenberg[20] in the context of generalized Ginzburg–Landau equations. Using the idea that spatio-temporal coherent structure solutions of NLPDEs, whether periodic, quasi-periodic, or chaotic, must obey the underlying singularity structure, Conte and co-workers[21,22] have used ideas related to the Painlevé test for integrability[23,24] and its modifications[25] to derive families of solutions of the complex cubic and quintic Ginzburg–Landau equation. Also, using phase-plane techniques on the ordinary differential equation (ODE) which must be satisfied by any traveling wave solution to the real Ginzburg–Landau equation, Powell *et al.*[26] have rederived and significantly elucidated several of van Saarloos' results[18,19] in a completely different manner. In addition, they use simple analytic solutions of the PDE obtained using truncated Painlevé expansions,[27] together with ideas from phase-plane analysis, as well as absolute versus convective instability of waves.[28] As a result, they show that front/pulse solution of the PDE must satisfy the traveling wave reduced ODE asymptotically. They also derive conditions for the accessibility of the solutions from compact support initial conditions.

In this paper, we consider coherent structures of the reaction-diffusion equation

$$u_t = u_{xx} + \frac{u}{b}(b+u)(1-u), \tag{1}$$

which has been considered in Refs. 4, 18 and 19. Note that other work on coherent structures of

[a)]Author for correspondence. Electronic mail: choudhur@longwood.cs.ucf.edu various reaction-diffusion equations is summarized in those papers, as well as in Section 1 of Ref. 26. For the purposes of comparison, we shall also consider coherent structures of the two families of reaction-diffusion equations

$$u_t=\beta u^2(1-u)+Du_{xx} \tag{2}$$

and

$$u_t=\beta u(1-u)+Du_{xx}\,. \tag{3}$$

Of these, (3) is the famous Fisher–Kolmogorov equation,[29,30] while (2) has second- and third-order nonlinearities, which is also true of (1). The primary difference between (1) and (2)/(3) is that the parameter b in the former adjusts the relative strength of the second- and third-order nonlinearities, while these strengths are fixed in (2) and (3).

To date, the approaches to the treatment of coherent structures may broadly be classified into three groups. First, there is the qualitative phase-plane/center manifold analysis of the traveling wave reduced ODEs to prove the existence of coherent structures. The second approach consists of actual construction of coherent structures via numerical simulation of the traveling wave reduced ODEs. The third approach comprises containment arguments wherein, starting from the correct boundary condition at one end of the interval, one shows that at the other end the solution asymptotes to a constant value. It thus corresponds to a coherent structure, rather than shooting off to infinity. Such containment arguments may often involve delicate analysis. The coherent structures derived in this paper are, in a sense, an attempt to connect the first two approaches by providing quantitative analytical expressions for nontrivial coherent structures. Clearly, these coherent structures are also of relevance in modeling the physics of the problems under consideration, although that is not the purpose of this paper. In fact, the next natural question to consider is their actual use in modeling applications. Some discussion regarding this follows the derivation of the coherent structures in Sec. IV.

In Sec. II we use invariant Painlevé expansions truncated at different orders to obtain nontrivial families of analytic solutions of the reaction-diffusion equations. Two points are worth noting in this context. First, the invariant Painlevé analysis[24] builds in invariance to the Möbius or homographic group ''*a priori*.'' In turn, this leads to simpler compatibility equations for the coefficients (the so-called Painlevé–Bäcklund equations) yielding more general solutions than obtained for (1) from the use of truncated noninvariant Painlevé expansions.[31] Second, although truncated invariant Painlevé expansions have been used fairly widely in recent years to derive analytic solutions (see Refs. 32–34, for instance), the Painlevé–Bäcklund equations which result from (1) and which are solved to obtain analytic solutions are quite complicated. Having obtained analytic solutions of the PDE in Sec. II, we next consider the properties of the ordinary differential equation governing traveling wave solutions in Sec. III. In Sec. IV, we discuss the compatibility of the PDE solutions and solutions derived earlier with those of the ODE, as well as accessibility from initial conditions. We also give numerical examples of various coherent structure solutions.

II. INVARIANT TRUNCATION PROCEDURE AND SPECIAL SOLUTIONS

A. Truncation procedure

For a NLPDE that is algebraic in u and its derivatives

$$E(u,x,t)=0 \tag{4a}$$

around a movable singular manifold

$$\Phi-\Phi_0=0, \tag{4b}$$

one looks, in the invariant Painlevé formulation,[24] for a solution as an expansion of the form

$$u=\chi^{-\alpha}\sum_{j=0}^{\infty} u_j\chi^j, \tag{5}$$

where the coefficients u_j are invariant under a group of homographic (Möbius) transformations on Φ. The expansion variable χ, which must vanish as $(\Phi-\Phi_0)$, is chosen to be

$$\chi\equiv\frac{\psi}{\psi_x}=\left(\frac{\Phi_x}{\Phi-\Phi_0}-\frac{\Phi_{xx}}{2\Phi_x}\right)^{-1}, \quad \psi=(\Phi-\Phi_0)\Phi_x^{-1/2}.$$

The variable χ satisfies the Riccati equations

$$\chi_x=1+\tfrac{1}{2}S\chi^2, \tag{6a}$$

$$\chi_t=-C+C_x\chi-\tfrac{1}{2}(CS+C_{xx})\chi^2, \tag{6b}$$

and the variable ψ satisfies the linear equations

$$\psi_{xx}=-\tfrac{1}{2}S\psi, \tag{7a}$$

$$\psi_t=\tfrac{1}{2}C_x\psi-C\psi_x. \tag{7b}$$

Note that the systems of equations (6) and (7) are equivalent to each other. In (6) and (7), the quantities S (Schwarzian derivative) and C (the ''dimension of velocity'' or celerity) are defined by

$$S=\frac{\Phi_{xxx}}{\Phi_x}-\frac{3}{2}\left(\frac{\Phi_{xx}}{\Phi_x}\right)^2, \tag{8a}$$

$$C=-\frac{\Phi_t}{\Phi_x}, \tag{8b}$$

and are invariant under the group of homographic (Möbius) or fractional linear transformations[18]

$$\Phi\to\frac{a\Phi+b}{c\Phi+d}, \quad ad-bc=1. \tag{9}$$

These homographic invariants are linked by the cross-derivative condition ($\Phi_{xxxt}=\Phi_{txxx}$)

$$S_t+C_{xxx}+2C_xS+CS_x=0. \tag{10}$$

B. Solutions via invariant Painlevé analysis

We apply the above formalism to (1). The leading-order dominant balance yields $\alpha=2$. Using (5), truncated at the constant term

$$u=u_0\chi^{-2}+u_1\chi^{-1}+u_2, \tag{11}$$

in (1), and eliminating the derivatives of χ using (6) yields a set of coupled nonlinear partial differential equations (the Painlevé–Bäcklund equations) order by order in powers of χ. These are given in Appendix A. The first four equations yield

$$u_0=0,$$

$$u_1=0 \text{ or } \pm\sqrt{2b}. \tag{12}$$

Inspection of (A5)–(A7) in Appendix A shows the need for further assumptions to allow their solutions. Making the further assumption[31–34] that C is a constant yields

$$\text{(a)}\quad 2+3b-3b^2-2b^3+(3\sqrt{2b}+3\sqrt{2}b^{5/2}+3\sqrt{2}b^{3/2})C-2\sqrt{2}b^{3/2}C^3=0,$$

$$\text{or}\ \ C=C_1\equiv\frac{-\sqrt{2}-2\sqrt{2}b}{2\sqrt{b}},\quad C=C_2\equiv\frac{-\sqrt{2}+\sqrt{2}b}{2\sqrt{b}}\tag{13a}$$

$$\text{or}\ \ C=C_3\equiv\frac{2\sqrt{2}+\sqrt{2}b}{2\sqrt{b}}\quad\text{for}\ \ u_1=\sqrt{2b},$$

with

$$S=\frac{C^2}{6}-\frac{b}{3}-\frac{1}{3b}-\frac{1}{3}=2Q^2,\tag{13b}$$

or

$$\text{(b)}\quad u_2=0,\ 1,\quad \text{or}\quad -b\quad \text{for}\ \ u_1=0\tag{14}$$

[this yields only trivial constant solutions using (11)]. The cross-derivative condition (10) is now satisfied identically. The Schrödinger equation (6a) yields

$$\psi(x,t)=A(t)\cos Qx+B(t)\sin Qx$$

and hence, using (6b),

$$\chi\equiv\frac{\psi}{\psi_x}=\frac{c_1\cos(Q\xi)-c_2\sin(Q\xi)}{-Q[c_2\cos(Q\xi)+c_1\sin(Q\xi)]}\tag{15a}$$

with

$$\xi=x-Ct.\tag{15b}$$

Hence, using (12) and (13) in (11), traveling wave special solutions of (1) (for $u_1=\sqrt{2b}$) are

$$u^{(1)}=\pm\frac{\sqrt{2b}}{\chi}+\frac{1}{6}(2-2b-C\sqrt{2b}),\tag{16}$$

where χ is given by (15a), and C has one of the values in (13a). A solution may be derived analogously for $u_1=-\sqrt{2b}$, and a similar, less interesting, solution may be obtained using (11), (12), and (14) (for $u_2=0$, 1 or $-b$). Note that C and Q are connected via (13b), and hence Q is (implicitly) a function of b.

A similar process applied to (2) yields a solution

$$u_1^{(2)}=\pm\frac{\sqrt{2D/\beta}}{\chi}+\left(\frac{2D\mp C\sqrt{2D/\beta}}{6D}\right),\tag{17a}$$

where χ is given by (15), with

$$S=\frac{C^2-2D\beta}{6D^2}\equiv 2Q^2,\tag{17b}$$

and C is a solution of the cubic

$$2\beta\left(\frac{1}{3}\mp\frac{C}{3\sqrt{2\beta D}}\right)^3-2\beta\left(\frac{1}{3}\mp\frac{C}{3\sqrt{2\beta D}}\right)^2\pm\sqrt{\frac{2D}{\beta}}C\left(\frac{C^2-2D\beta}{6D^2}\right)=0. \tag{17c}$$

For instance, with $D=1$, $\beta=2$, we obtain $C=-1$, or $C=2$.

By contrast, the same procedure applied to (3) yields simpler, relatively trivial, traveling wave solutions. For completeness, we include a solution of (2) obtained earlier[31] using noninvariant Painlevé analysis:

$$u_{\text{II}}^{(2)}=\gamma\sqrt{\frac{2D}{\beta}}\left[\frac{\alpha+\sqrt{2D/\beta}e^{\sqrt{\beta/2D}\,\xi_1}}{\alpha\gamma\xi_1+(2D\gamma/\beta)e^{\sqrt{\beta/2D}\,\xi_1}+\delta}\right], \tag{18a}$$

where

$$\xi_1\equiv x+\sqrt{\frac{\beta D}{2}}t, \tag{18b}$$

and α, γ, and δ are constants. Note that the discussion of this solution later in this paper is new, as is the framework of that discussion.

C. Preliminary discussion

We shall consider the behavior of the solutions (16)–(18) further in the next two sections. However, we first need to consider some results for the ODEs, derived from traveling wave reductions, of the underlying PDEs (1) and (2). This will be done in Sec. III. At this point, we make some preliminary observations regarding the solutions (16)–(18) which will be needed in Sec. III.

We note that we have aperiodic hyperbolic functions in (16) (corresponding to a coherent structure) for Q imaginary or, from (13a) and (13b),

$$\begin{gathered}0<b<\sqrt{\tfrac{3}{2}}\quad\text{or}\quad b<-\sqrt{\tfrac{3}{2}}\quad\text{for}\;\; C=C_1,\\ b>0\quad\text{or}\quad -3-\sqrt{6}<b<-3+\sqrt{6}\quad\text{for}\;\; C=C_2,\\ b>0\quad\text{for}\;\; C=C_3.\end{gathered} \tag{19}$$

For these cases, $\lim_{\xi\to\pm\infty}\chi=\pm 1/|Q|$ from (15), so that (16) yields

$$\lim_{\xi\to\pm\infty}u^{(1)}=\pm\sqrt{2b}|Q|+\tfrac{1}{6}(2-2b-C\sqrt{2b}). \tag{20}$$

For instance, for the first value of $C\equiv C_1$ given by (13a), this becomes

$$\lim_{\xi\to+\infty}u^{(1)}=1,\qquad \lim_{\xi\to-\infty}u^{(1)}=0. \tag{21}$$

Note that the solution $u^{(1)}$ tends to different values as $\xi\to\pm\infty$, and these values are independent of the constants c_1 and c_2 in (15a). Thus, the solutions (16) represent front solutions of (1).

Similarly, considering the solution $u_1^{(2)}$ of (2), if the roots of (17c) for C are C_4, C_5, and C_6 (say), then Q in (17b) may be imaginary for some ranges of β and D. For these cases, $Q\equiv i|Q|$, and $\lim_{\xi\to\pm\infty}\chi=\pm 1/|Q|$, so that (17) yields

$$\lim_{\xi\to\pm\infty}u_1^{(2)}=\pm\sqrt{\frac{2D}{\beta}}|Q|+\frac{1}{3}\pm\frac{C}{6D}\sqrt{\frac{2D}{\beta}}. \tag{22}$$

Note that $u_1^{(2)}$ tends to different values as $\xi \to \pm\infty$ and thus corresponds to a front solution of (2). For instance, with $D=1$, $\beta=2$, $C=\pm 1$ and the upper sign,

$$\lim_{\xi \to = -\infty} u_1^{(2)} = 0, \quad \lim_{\xi \to \infty} u_1^{(2)} = 1.$$

It may be shown in an analogous manner that the solutions $u_{\mathrm{II}}^{(2)}$ in (18) are also front solutions of (2). In the next section, we shall consider some properties of the ODE obtained by performing traveling wave reductions on the reaction-diffusion equations (1) and (2) before returning to discuss the solutions in this section further. We shall refer to (20)–(22) further during that discussion.

III. ANALYSIS OF TRAVELING WAVE REDUCED ODE

We shall look for traveling wave reductions of the PDE's (1) and (2). We present the results for (2) since the algebra is somewhat easier. The treatment for (1) is analogous.

Looking for traveling wave solutions of (2) of the form

$$u(x,t) = u(z) \equiv u(x - Ct) \tag{23a}$$

yields the ordinary differential equation

$$-Cu' = \beta u^2(1-u) + Du'', \tag{23b}$$

where the prime denotes d/dz. Note that we use z as an explicit traveling wave variable ''*a priori*,'' as distinct from the analogous variable ξ which emerged ''*a posteriori*'' in Sec. II from the Painlevé analysis.

Treating (23) as a dynamical system in the $(u,u') \equiv (u,v)$ plane in the standard way, we find the fixed (critical) points in the (u,v) plane:

$$(u_0,0) \equiv (0,0), \tag{24a}$$

$$(u_+,0) \equiv (1,0), \tag{24b}$$

whose linear stability is governed by the eigenvalues (which are also the spatial wave numbers in z space)

$$\lambda_0^{1,2} = 0,\ \frac{-C}{D}, \tag{25a}$$

$$\lambda_+^{1,2} = \frac{-C/D \pm \sqrt{C^2/D^2 + 4\beta/D}}{2}. \tag{25b}$$

Since β and D are positive, the fixed point $(u_+,0)$ is thus a saddle-point, while $(u_0,0)$ is a nonhyperbolic fixed point. The system (23) may thus have a heteroclinic orbit connecting $(u_0,0)$ and $(u_+,0)$. In the context of the underlying PDE (2), this corresponds to a front solution connecting $u_0(u_+)$ and $u_+(u_0)$ as z goes from $-\infty$ to $+\infty$. From (22), we see that the solutions (17) of the PDE (directly obtained from the PDE) are indeed heteroclinic orbits of (23). For instance, with $D=1$, $\beta=1$, $C=\pm 1$, and the lower sign in (22), $\lim_{\xi \to +\infty} u_1^{(2)} = 0$ and $\lim_{\xi \to -\infty} u_1^{(2)} = 1$, so that this front solution $u_{\mathrm{II}}^{(2)}$ is a heteroclinic orbit of (23) joining $(u_0,0)$ to $(u_+,0)$ as $z \to \pm\infty$. Note that for some PDEs (such as the long-wave equations[35]) this may not happen automatically—the integrated version of the traveling wave reduced ODE may contain unknown constants of integration which must be chosen to ensure this. An analogous treatment of (1) yields the traveling wave reduced ODE

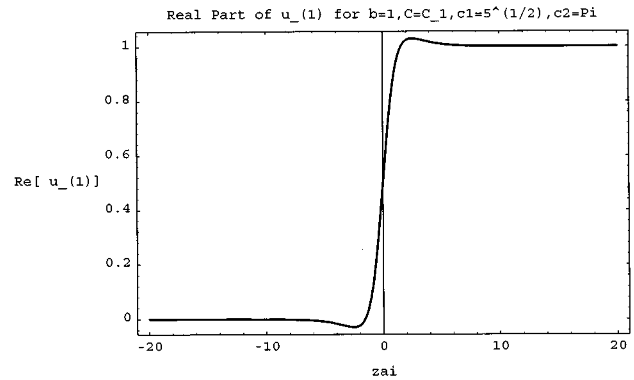

FIG. 1. Real part of $u\_(1)$ for $b=1$, $C=C\_1$, $c1=5\hat{}(1/2)$, $c2=Pi$.

$$-Cu'=u''+\frac{u}{b}(b+u)(1-u), \tag{26}$$

which, treated as a dynamical system in $(u,u')\equiv(u,v)$, has fixed points $(u_0,0)=(0,0)$, $(u_+,0)=(1,0)$ and $(u_-,0)=(-b,0)$. As for (2), it may be shown using (20) and (21) that the front solutions $u^{(1)}$ of (1) correspond to heteroclinic orbits of (26) joining two of the above fixed points. For instance, for $C\equiv C_1$, $\lim_{\xi\to-\infty}u^{(1)}=0$, $\lim_{\xi\to\infty}u^{(1)}=1$, so that the front solution $u^{(1)}$ of (1) is a heteroclinic orbit of (26) joining $(u_0,0)$ to $(u_+,0)$ as $z\to\pm\infty$. Once again, this need not happen automatically, as it does not for the long-wave equations,[35] for instance.

As extensively investigated and stressed by Powell *et al.*[26] the front solutions represented by the heteroclinic orbits of the traveling wave reduced ODEs (23) and (26) need not correspond to fronts obtained directly from the PDE (1). We shall now consider this further.

IV. DISCUSSION

In this section, we consider further features of the solutions $u^{(1)}$ and $u_1^{(2)}$ [in (16) and (17)] of (1) and (2) obtained by use of invariant Painlevé expansions. Powell *et al.*[26] have, among numerous other things, made the points that coherent structure solutions such as (16) and (17), which are directly obtained from a PDE, (a) must asymptotically satisfy the ODE governing traveling wave reductions, and (b) be accessible to the PDE from compact support initial conditions. Considering the traveling wave reduced ODE (23) obtained from (2), we have $z\equiv x-Ct\to-\infty$ as $t\to\infty$ (for $C>0$), and so u tends to the saddle-point $(u_+,0)$ in (24b) along its unstable manifold. From (25b), the eigenvalue along this direction is

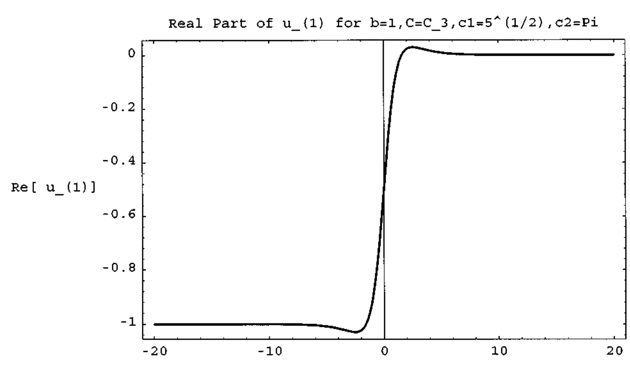

FIG. 2. Real part of $u\_(1)$ for $b=1$, $C=C\_3$, $c1=5\hat{}(1/2)$, $c2=Pi$.

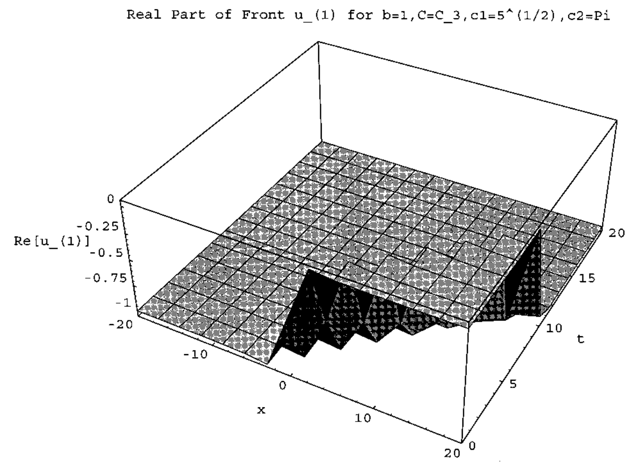

FIG. 3. Real part of Front $u\_(1)$ for $b=1$, $C=C\_3$, $c1=5\hat{}(1/2)$, $c2=Pi$.

$$\lambda_{\mathrm{ODE}}=\lambda_{+}^{1}=\frac{-C/D+\sqrt{C^2/D^2+4\beta/D}}{2}. \tag{27}$$

By the Unstable Manifold Theorem,[36] (27) gives the time asymptotic spatial wave number of the front solutions (2) [along the global unstable manifold of $(u_+,0)$] satisfying the ODE (23) and with solution values u_0 and u_+ for $t\rightarrow\mp\infty$. Inspection of the solutions $u_1^{(2)}$ in (17) reveals that the wave number ($\lambda_{\mathrm{PDE}}\equiv|Q|$) of these solutions obtained directly from the PDE are exactly the same as λ_{ODE} [this may be seen from (17b) and (27), using the fact that C satisfies (17c)]. In Sec. III, we verified that the values of (a) u_{PDE} for $\xi\rightarrow\pm\infty$, and (b) u_{ODE} for $z\rightarrow\pm\infty$ are matched; here we see that the resulting time asymptotic wavenumbers in the ODE and PDE solutions are also the same. Thus, as conjectured in Powell *et al.*, the solutions obtained via Painlevé analysis are indeed the so-called nonlinear solutions;[19] note that Powell *et al.* equivalently think of C as a function of λ, instead of λ as a function of C as done here. As pointed out by both Powell *et al.*[26] and Marcq *et al.*[22] for the GL equation, this is because the Painlevé analysis builds in ''*a priori*'' the singularity structure which must be satisfied by any coherent structure solution of the PDE.

Although the front solutions (16) and (17) satisfy the traveling wave reduced ODEs (26) and (23), we must also check the accessibility of these solutions to the PDEs (1) and (2) from compact support initial conditions as stressed in Ref. 26. Following the treatment of absolute versus convective instability in Ref. 28, we find the temporal growth rate at any fixed x spatial position

$$\sigma=|-C\lambda_{\mathrm{PDE}}|\equiv\left|-C|Q|=-C\left[\frac{2D\beta-C^2}{12D^2}\right]^{1/2}\right|. \tag{28}$$

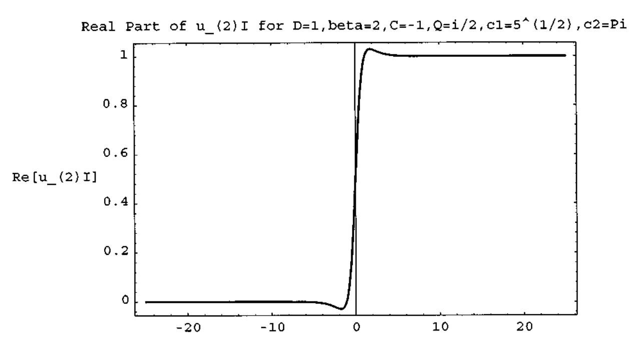

FIG. 4. Real part of $u\_(2)I$ for $D=1$, beta$=2$, $C=-1$, $Q=i/2$, $c1=5\hat{}(1/2)$, $c2=Pi$.

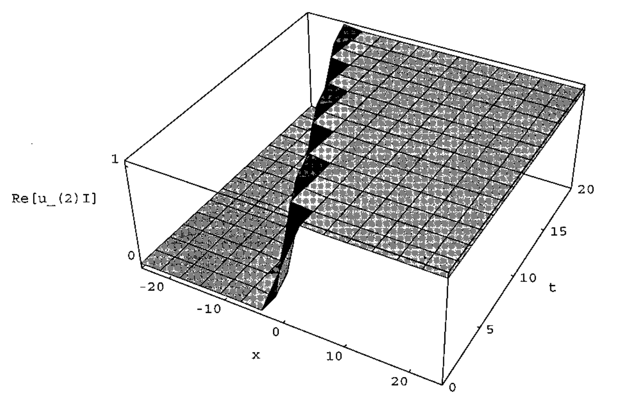

FIG. 5. Real part of $u\_(2)I$ for $D=1$, beta=2, $C=-1$, $Q=i/2$, $c1=5\hat{}(1/2)$, $c2=Pi$.

Thus, we expect that the front which emerges asymptotically in time from compact support initial conditions corresponds to the root of (17c) for which we have the maximum temporal growth rate. For instance, with $D=1$, $\beta=2$, we obtain $C=-1$ or 2 from (17c). From (17b), $|Q|=\frac{1}{2}$ for $C=-1$, and $|Q|=0$ for $C=2$. Thus the maximum σ occurs for $C=-1$.

Analogous results apply to the wave numbers and temporal growth rates of the solution (16) obtained directly from the PDE (1) and its traveling wave reduced ODE (26). The algebra is harder, but is tractable using a computer algebra system.

One should note that some of the results obtained by phase-plane analysis of the traveling wave reduced ODE are equivalent to those obtained by van Saarloos' linear and nonlinear marginal stability analysis and steepest envelope technique.[29] For completeness, this treatment is summarized in Appendix B for Eq. (2). An analogous treatment holds for (1).

Finally, let us consider plots of the solutions of (1) and (2) given by (16) and (17), and compare them further to predictions from the traveling wave reduced ODEs. For both (16) and (17), we choose representative parameter values corresponding to the front solutions discussed earlier. Note that we may choose the constants c_1 and c_2 to make (16) and (17) correspond to physically relevant real solutions. We pick arbitrary c_1 and c_2 values instead, and plot the real parts of the solutions.

Figures 1 and 2 show the real part of $u^{(1)}$ [given by (16)] for $b=1$, $c_1=\sqrt{5}$, $c_2=\pi$, and (a) $C=C_1$ for Fig. 1 and (b) $C=C_3$ for Fig. 2. Note that the primary difference between these plots is that the former, with $C=C_1$, corresponds to a front connecting the states 0 and 1 or u_0 and u_+ as $\xi\rightarrow\pm\infty$, while the latter front with $C=C_3$ connects the state -1 and 0 [note that the third fixed point $(u_-,0)=(-b,0)$ of (26) is $(-1,0)$ for $b=1$]. Figure 3 shows the same front as Fig. 2, but in (x,t) coordinates. Note the rightward propagation of the front (towards larger x) as t increases due to the phase speed $C=C_3=3/\sqrt{2}$ being positive.

Figures 4 and 5 show the solution (17) of the PDE (2) for $c_1=\sqrt{5}$, $c_2=\pi$, $D=1$, $\beta=2$, $Q=i/2$, and $C=-1$ [note that $Q=\pm i/2$, and $C=-1$ or 2 by (17b) and (17c)—we pick $Q=i/2$ and $C=-1$]. The solution corresponds to a front joining the states 0 and 1 [or the fixed points $(u_0,0)$ and $(u_+,0)$ of Eq. (23) given in (24)]. In Fig. 5, note the leftward propagation of the front due to the negative phase speed $C=-1$.

In conclusion, we have derived two nontrivial families of analytical solutions of (1) and (2), which may sometimes be coherent structures, and analyzed several of their properties. As mentioned in Sec. I, these analytical solutions act as a sort of bridge between two of the common approaches to the analysis of coherent structures. These two approaches are, first, proofs of the existence of coherent structure solutions of the traveling wave reduced ODEs, and, second, construction of coherent structures by numerical simulations of these ODEs. The analytical solutions may also be of relevance in modeling the physics of the problem under consideration. Although it is not the purpose of this article to consider detailed modeling issues, some of the approaches which may be relevant to modeling of reaction-diffusion equations include those in Ref. 29, Chap. 3 of Ref. 37, Chap. 6 of Ref. 38, as well as numerous research papers. Related modeling issues for other nonlinear PDEs are discussed, for instance, in Chap. 10 of Ref. 39 (this also discusses nonintegrable equations, not just integrable equations as the chapter title might seem to indicate), and the recent review article by Balmforth.[40]

ACKNOWLEDGMENT

The authors acknowledge the helpful comments of the referee regarding stylistic matters, inclusion of Appendix B, as well as a discussion of the relevance of the results in this paper. These improved the clarity and completeness of the paper greatly.

APPENDIX A

The equations obtained at different powers of χ are

$$O(\chi^{-6}): \quad u_0=0, \tag{A1}$$

$$O(\chi^{-5}): \quad u_0^2 u_1=0, \tag{A2}$$

$$O(\chi^{-4}): \quad 6u_0-u_0^2+\frac{u_0^2}{b}-\frac{3u_0u_1^2}{b}-\frac{3u_0^2u_2}{b}=0, \tag{A3}$$

$$O(\chi^{-3}): \quad -2Cu_0+2u_1-2u_0u_1+\frac{2u_0u_1}{b}-\frac{u_1^3}{b}-\frac{6u_0u_1u_2}{b}-4u_{0x}=0, \tag{A4}$$

$$O(\chi^{-2}): \quad u_0+4Su_0-Cu_1-u_1^2+\frac{u_1^2}{b}-2u_0u_2+\frac{2u_0u_2}{b}-\frac{3u_1^2u_2}{b}-\frac{3u_0u_2^2}{b}-u_{0t}+2u_0C_x-2u_{1x} + u_{0xx}=0, \tag{A5}$$

$$O(\chi^{-1}): \quad -CSu_0+u_1+Su_1-2u_1u_2+\frac{2u_1u_2}{b}-\frac{3u_1u_2^2}{b}-u_{1t}+u_1C_x-u_0S_x-2Su_{0x}-u_0C_{xx} + u_{1xx}=0, \tag{A6}$$

$$O(\chi^0): \quad \frac{1}{2}S^2u_0-\frac{1}{2}CSu_1+u_2-u_2^2+\frac{u_2^2}{b}-\frac{u_2^3}{b}-u_{2t}-\frac{1}{2}u_1S_x-Su_{1x}-\frac{1}{2}u_1C_{xx}+u_{2xx}=0. \tag{A7}$$

APPENDIX B: VAN SAARLOOS' TECHNIQUE

The tail of the coherent structure must obey the linear RD equation (2) as $x\rightarrow\infty$ (since $u\rightarrow 0$ or 1) so that

$$u_t=Du_{xx}\,. \tag{B1}$$

Consider the behavior of a linear mode

$$u=\exp[i(\omega-i\sigma)t+i(k-i\lambda)z],$$

where $z=x-Ct$ and C is the front speed. For this mode to be part of a persistent front, it must have zero temporal growth $\sigma=0$ in a frame moving at speed C. This gives the dispersion relation

$$i\omega-iC(k-i\lambda)=-D(k-i\lambda)^2. \tag{B2}$$

For a nonoscillatory mode with $\omega = 0$, separating the real and imaginary parts of (B2) yields either (a) $k = 0$, $\lambda = -C/D$, or (b) $\lambda = -C/(2D)$, $k^2 = -(C/2D)^2$. Case (b) with imaginary k implies no coherent structures, so we have

$$\lambda = -C/D,$$

which is equal to λ_{PDE}. Various other features discussed in the text may also be derived by this approach (see Refs. 18, 19, and 26).

(Received 21 August 1998; accepted for publication 14 February 1999)

Following the sine–cosine function, the sawtooth wave, square wave, triangular wave, trapezoidal wave, and so on become new easily generated periodic functions in modern electronics. Similar to Fourier's idea, a natural question is whether a signal can be considered as a superposition of easily generated functions with different frequencies. Therefore it is necessary to generalize Fourier analysis based on sine–cosine functions into frequency analysis based on general periodic functions. In this paper, we introduce the frequency series and frequency transformation based on general periodic functions. We discuss when a frequency system is a complete system or an unconditional basis in $L^2[-\pi,\pi]$, and when a frequency transformation can be carried out in $L^2(-\infty,+\infty)$. For practical convenience almost all easily generated functions in electronics are considered carefully as examples. As a new and practical generalization of classical Fourier analysis, these results will become a theoretical foundation for the technique of easily generated function analysis in signal processing. [S0022-2488(99)02706-1]

I. INTRODUCTION

In 1807 the French mathematician J. B. J. Fourier asserted that any function with period 2π can be expressed as a trigonometric series, and that any nonperiodic function can be expressed as a trigonometric integral. This great idea has had an important influence upon science and technology. In electronics, Fourier analysis has been playing an important role, and a signal is often considered as a superposition of many sine and cosine functions with different frequencies. However, with the development of electronic technique, the sawtooth wave, square wave, triangular wave, trapezoidal wave, and so on become new easily generated periodic functions. For example, it is quite convenient to get a system of square waves with different frequencies from a common high-frequency pulse by counters. A practical question arises naturally: *Can a signal be considered as a superposition of other periodic functions (such as square waves) with different frequencies*?

In order to answer this practical question, we need to introduce the frequency analysis based on general periodic functions in mathematics, which is a natural generalization of Fourier analysis based on the sine and cosine functions. Considering the fact that the theory for Fourier series in $L^2[-\pi,\pi]$ and the theory for Fourier transformation in $L^2(-\infty,+\infty)$ are both simple and important, we shall develop a theory for general frequency series in $L^2[-\pi,\pi]$ and a theory for general transformation in $L^2(-\infty,+\infty)$. In the following, we shall discuss when a frequency system is a complete system or an unconditional basis in $L^2[-\pi,\pi]$, and when a frequency transformation can be carried out in $L^2(-\infty,+\infty)$. For practical convenience, almost all easily generated functions in electronics are considered carefully as examples. The conclusions in this paper will provide a theoretical foundation for the technique of easily generated function analysis in electronics.

[a)]Electronic mail: weiyuch@bltda.com.bta.net.cn

The results show that frequency analysis based on general periodic functions has a close relation with the Dirichlet multiplication in number theory.

In this paper $L^2[-\pi,\pi]$ denotes the real Hilbert space of functions with the period 2π which are quadratically integrable on $[-\pi,\pi]$. It is well known that $L^2[-\pi,+\pi]$ can be decomposed into three mutually orthogonal subspaces:

$$L^2[-\pi,+\pi] = \text{constant function subspace} \oplus L^2_{\text{even}}[-\pi,+\pi] \oplus L^2_{\text{odd}}[-\pi,+\pi]$$

$$= \text{span}\{1\} \oplus \overline{\text{span}\{\cos nx\}_{n=1}^{\infty}} \oplus \overline{\text{span}\{\sin nx\}_{n=1}^{\infty}},$$

where $L^2_{\text{even}}[-\pi,+\pi]$ is the subspace of even functions with the mean-value 0, and $L^2_{\text{odd}}[-\pi,+\pi]$ is the subspace of odd functions.

II. A FREQUENCY SYSTEM IN $L^2[-\pi,\pi]$

In this section we suppose that the function

$$F(x) = \sum_{n=1}^{\infty} A(n)\cos(nx) + B(n)\sin(nx) \tag{1}$$

is a given nonzero element in $L^2[-\pi,\pi]$, where $A(n)$ and $B(n)$ denote its Fourier coefficients. We shall show that the frequency system based on the function $F(x)$,

$$F(x), F(2x), F(3x), \ldots, F(nx), \ldots, \tag{2}$$

is linearly independent, weakly convergent to zero, and incomplete in $L^2[-\pi,\pi]$.

Lemma: Suppose that f and g are two arithmetical functions and h is their Dirichlet product,[1] i.e.,

$$h = f*g. \tag{3}$$

Then we have

$$h=0 \Leftrightarrow f=0 \quad \text{or} \quad g=0. \tag{4}$$

In this paper, as an example, the notation $h=0$ means that

$$h(n)=0 \quad \text{for} \quad n=1,2,3,\ldots. \tag{5}$$

Proof: From the definition of Dirichlet multiplication, it follows obviously that

$$f=0 \quad \text{or} \quad g=0 \Rightarrow h=0. \tag{6}$$

Now let us consider

$$h=0 \Rightarrow f=0 \quad \text{or} \quad g=0. \tag{7}$$

There are three cases.

(1) If $f(1)\neq 0$, then $g=h*f^{-1}=0$. Here -1 denotes the inverse of an arithmetical function.[1] Similarly, if $g(1)\neq 0$, then $f=h*g^{-1}=0$.
Therefore relation (7) holds in this case.

(2) Suppose that

$$f(n)=g(n)=0 \quad \text{for} \quad n<k \tag{8}$$

and that $f(k)\neq 0$, where k is a positive integer greater than 1.
Then we have

$$h(k^2)=f(k)g(k)=0\Rightarrow g(k)=0,$$

$$h(k(k+1))=f(k)g(k+1)=0\Rightarrow g(k+1)=0,$$

$$\cdots\ \cdots\ \cdots,$$

$$h(k(k+i))=f(k)g(k+i)=0\Rightarrow g(k+i)=0,$$

$$\cdots\ \cdots\ \cdots,$$

where i is any non-negative integer. Therefore we have $g=0$.

Similarly, suppose that

$$f(n)=g(n)=0 \quad \text{for } n<k \tag{9}$$

and that $g(k)\neq 0$, where k is a positive integer greater than 1.
For the same reason, we have $f=0$. Therefore relation (7) holds in this case as well.

(3) Suppose that

$$f(n)=g(n)=0 \quad \text{for any positive integer } n. \tag{10}$$

In fact we already have $f=g=0$ and therefore relation (7) holds obviously in this case. In one word, relation (7) holds always.
This completes the proof of the lemma. □

Proposition 1: We have

$$\sum_{n=1}^{\infty} c(n)F(nx)=0\Leftrightarrow c=0, \tag{11}$$

where $c(n)$ is a real-valued arithmetical function.

Proof: If

$$c=0, \tag{12}$$

the conclusion is trivially true.

Let us consider the case

$$\sum_{n=1}^{\infty} c(n)F(nx)=0. \tag{13}$$

Putting (1) in (13), we have

$$\sum_{n=1}^{\infty} (a(n)\cos nx+b(n)\sin nx)=0, \tag{14}$$

where

$$a(n)=\sum_{d|n} A\left(\frac{n}{d}\right)c(d)=A*c(n),$$

$$b(n)=\sum_{d|n} B\left(\frac{n}{d}\right)c(d)=B*c(n),$$

Here $d|n$ means that d is a factor of n.

From (14), we obtain that

$$a=b=0.$$

Since $F(x)$ is a nonzero element, we have

$$A\neq 0 \quad \text{or} \quad B\neq 0. \tag{15}$$

By the lemma, we obtain that

$$c=0, \tag{16}$$

This completes the proof. □

Consequence: If a function $\psi(x)\in L^2[-\pi,\pi]$ can be expressed as a frequency series based on $F(x)$:

$$\psi(x)=c(1)F(x)+c(2)F(2x)+c(3)F(3x)+\cdots+c(n)F(nx)+\cdots, \tag{17}$$

then the coefficients $c(n)$ are unique.

Proposition 2: The frequency system $\{F(nx)\}_{n=1}^{\infty}$ converges weakly to 0.

Proof: Suppose that $\psi(x)\in L^2[-\pi,+\pi]$ is an arbitrary function, and its Fourier series is

$$\psi(x)=a_0+\sum_{l=1}^{\infty} a(l)\cos(lx)+b(l)\sin(lx). \tag{18}$$

We have

$$\begin{aligned}|\langle F(nx),\psi(x)\rangle| &= \pi\left|\sum_{l=1}^{\infty} A(l)a(nl)+\sum_{l=1}^{\infty} B(l)b(nl)\right| \\ &\leqslant \pi\sqrt{\sum_{l=1}^{\infty} A^2(l)}\sqrt{\sum_{l=1}^{\infty} a^2(nl)}+\pi\sqrt{\sum_{l=1}^{\infty} B^2(l)}\sqrt{\sum_{l=1}^{\infty} b^2(nl)} \\ &\leqslant \pi\sqrt{\sum_{l=1}^{\infty} A^2(l)}\sqrt{\sum_{l=n}^{\infty} a^2(l)}+\pi\sqrt{\sum_{l=1}^{\infty} B^2(l)}\sqrt{\sum_{l=n}^{\infty} b^2(l)}\rightarrow 0 (\text{as } n\rightarrow\infty).\end{aligned}$$

Therefore we have

$$\langle F(nx),\psi(x)\rangle\rightarrow 0 \quad (\text{as } n\rightarrow\infty). \tag{19}$$

This completes the proof. □

Proposition 3: The frequency system $\{F(nx)\}_{n=1}^{\infty}$ is incomplete in $L^2[-\pi,+\pi]$.

Proof: There are two cases.

(1) If $A(1)\neq 0$ or $B(1)\neq 0$, then there exists a nonzero element $\psi(x)=-B(1)\cos x+A(1)\sin x$ such that

$$\int_{-\pi}^{\pi} F(nx)\psi(x)dx=0 \quad \text{for } n=1,2,3,\ldots. \tag{20}$$

(2) If $A(1)=B(1)=0$, we have

$$\int_{-\pi}^{\pi} F(nx)\cos x\, dx=0 \quad \text{for } n=1,2,3,\ldots. \tag{21}$$

In one word, the frequency system $\{F(nx)\}_{n=1}^{\infty}$ is incomplete in $L^2[-\pi,+\pi]$. □

Now that the frequency system is incomplete in $L^2[-\pi,+\pi]$, we shall develop the problem in its odd function subspace $L^2_{\mathrm{odd}}[-\pi,+\pi]$ in the following section.

III. A FREQUENCY SYSTEM IN $L^2_{\mathrm{odd}}[-\pi,+\pi]$

In this section we suppose that the function

$$Y(x)=\sum_{n=1}^{\infty} B(n)\sin nx \tag{22}$$

is a given nonzero element in $L^2_{\mathrm{odd}}[-\pi,+\pi]$, where $B(n)$ denotes its Fourier coefficients.

We shall show that the frequency system $\{Y(nx)\}_{n=1}^{\infty}$ may be an orthogonal basis, an unconditional basis, a complete system, or an incomplete system in $L^2_{\mathrm{odd}}[-\pi,+\pi]$. Let us see a simple example.

Example: If $Y(x)=\sin x+k\sin 2x$, where k is a real number, then in $L^2_{\mathrm{odd}}[-\pi,+\pi]$ the frequency system $\{Y(nx)\}_{n=1}^{\infty}$ is:

(1) an orthogonal basis when $k=0$;
(2) an unconditional basis when $0<|k|<1$;
(3) a complete system, but not a basis, when $|k|=1$;
(4) an incomplete system when $|k|>1$.

Proof of the example:
(1) This is clear.
(2) This follows from Proposition 18, which we shall introduce.
(3) Let us consider the completeness first.
Suppose that $\psi(x)\in L^2_{\mathrm{odd}}[-\pi,+\pi]$ is a function such that

$$\int_{-\pi}^{\pi}\psi(x)Y(nx)dx=0 \quad \text{for } n=1,2,3,\ldots. \tag{23}$$

The Fourier series of $\psi(x)$ can be expressed as

$$\psi(x)=\sum_{n=1}^{\infty} b(n)\sin nx. \tag{24}$$

From relation (23), we obtain that

$$b(n)+kb(2n)=0, \tag{25}$$

or

$$b(n)=(-k)b(2n), \tag{26}$$

for all positive integer n.

Thus for an arbitrary positive integer l, we have

$$b(l)=(-k)b(2l)=(-k)^2b(2^2l)=\cdots=(-k)^m b(2^m l)=\cdots. \tag{27}$$

Since $b(n)\to 0$ as $n\to\infty$, we have

$$b(l)=0. \tag{28}$$

Since l is an arbitrary positive integer, we obtain $\psi(x)=0$. This completes the proof of the completeness.
However, the frequency system is not a basis of $L^2_{\mathrm{odd}}[-\pi,+\pi]$.

If it is a basis, the function $\sin x$ can be expressed as a frequency series:

$$\sin x=\sum_{n=1}^{\infty} D(n)Y(nx), \tag{29}$$

where $D(n)$ are coefficients.

Putting $Y(x)=\sin x+k\sin 2x$ in (29), we obtain that

$$\sin x=D(1)\sin x+(kD(1)+D(2))\sin 2x+D(3)\sin 3x+(kD(2)+D(4))\sin 4x+\cdots. \tag{30}$$

Considering the coefficients of the terms $\sin 2^m x$ $(m=0,1,2,...)$, we obtain that

$$D(1)=1, \tag{31}$$

and

$$D(2^m)+kD(2^{m-1})=0 \quad \text{for } m=1,2,3,... . \tag{32}$$

Thus we obtain that

$$D(2^m)=(-k)^m \quad \text{for } m=1,2,3,... . \tag{33}$$

Therefore $D(2^m)$ does not converge to 0 as m increases, and hence $D(n)$ does not converge to 0 either as n increases. This is a contradiction.

So the conclusion should be that the frequency system is not a basis of $L^2_{\text{odd}}[-\pi,+\pi]$.

(4) The frequency system is not complete in $L^2_{\text{odd}}[-\pi,+\pi]$, because there exists a function

$$\psi(x)=\sin x+\left(-\frac{1}{k}\right)\sin 2x+\left(-\frac{1}{k}\right)^2\sin 4x+\left(-\frac{1}{k}\right)^3\sin 8x+\cdots+\left(-\frac{1}{k}\right)^m\sin 2^m x+\cdots \tag{34}$$

such that

$$\int_{-\pi}^{\pi}\psi(x)Y(nx)dx=0 \quad \text{for } n=1,2,3,... . \tag{35}$$

This completes the proof of the example. □

Proposition 4: The frequency system $\{Y(nx)\}_{n=1}^{\infty}$ is an orthonormal basis of $L^2_{\text{odd}}[-\pi,+\pi]$ if and only if

$$Y(x)=\pm\frac{1}{\sqrt{\pi}}\sin x. \tag{36}$$

Proof: If part is clear.

Next let us consider the only-if part. If $\{Y(nx)\}_{n=1}^{\infty}$ is an orthonormal basis of $L^2_{\text{odd}}[-\pi,+\pi]$, then the function $\sin x$ has a frequency series based on $Y(x)$:

$$\sin x=\sum_{n=1}^{\infty} D(n)Y(nx), \tag{37}$$

where the coefficients $D(n)$ are determined by

$$D(n)=\int_{-\pi}^{\pi}\sin x\,Y(nx)dx. \tag{38}$$

It follows that

$$D(1)=\pi B(1), \tag{39}$$

$$D(n)=0 \quad \text{for } n=2,3,4,\dots . \tag{40}$$

Thus we have

$$\sin x=\pi B(1)Y(x) \tag{41}$$

$$=\pi B(1)\sum_{n=1}^{\infty} B(n)\sin nx. \tag{42}$$

From (42), we obtain that

$$B(1)=\pm\frac{1}{\sqrt{\pi}}, \tag{43}$$

$$B(n)=0 \quad \text{for } n=2,3,4,\dots, \tag{44}$$

i.e.,

$$Y(x)=\pm\frac{1}{\sqrt{\pi}}\sin x \qquad \square \tag{45}$$

Proposition 5: The frequency system $\{Y(nx)\}_{n=1}^{\infty}$ is incomplete in $L^2_{\text{odd}}[-\pi,+\pi]$ if $Y(x)$'s first Fourier coefficient $B(1)=0$.

Proof: It is because

$$\int_{-\pi}^{\pi} Y(nx)\sin x\, dx=0, \tag{46}$$

for $n=1,2,3,\dots$. □

Proposition 6: If $B(1)\neq 0$, then the frequency system

$$Y(x),Y(2x),Y(3x),\cdots,Y(nx),\dots \tag{47}$$

and the function system

$$g_1(x),g_2(x),g_3(x),\dots,g_n(x),\dots \tag{48}$$

are biorthogonal, where the functions $g_n(x)$ are defined by

$$g_n(x)=\frac{1}{\pi}\sum_{d|n} B^{-1}\left(\frac{n}{d}\right)\sin dx \tag{49}$$

for $n=1,2,3,\dots$. Here B^{-1} denotes the Dirichlet inverse of $B(n)$.

Proof: For any two positive integers m and n, we have

$$\langle Y(mx),g_n(x)\rangle=\left\langle \sum_{k=1}^{\infty} B(k)\sin(mkx), \frac{1}{\pi}\sum_{d|n} B^{-1}\left(\frac{n}{d}\right)\sin dx\right\rangle$$

$$=\sum_{m|d,d|n} B^{-1}\left(\frac{n}{d}\right)B\left(\frac{d}{m}\right)$$

$$=\begin{cases} 0 & m\dagger n \\ 0 & \dfrac{n}{m}=2,3,... \\ 1 & \dfrac{n}{m}=1 \end{cases}$$

$$=\begin{cases} 0 & m\neq n \\ 1 & m=n \end{cases}=\delta_{mn},$$

where $m\dagger n$ denotes that m is not a factor of n, and δ_{mn} is the Kronecher's delta symbol. This completes the proof. □

Proposition 7: If a function $\psi(x)\in L^2_{\text{odd}}[-\pi,+\pi]$ has a frequency series based on the function $Y(x)$ (with $B(1)\neq 0$):

$$\psi(x)=\sum_{n=1}^{\infty} D(n)Y(nx), \tag{50}$$

then the coefficients $D(n)$ can be determined uniquely by

$$D(n)=\int_{-\pi}^{\pi}\psi(x)g_n(x)dx, \tag{51}$$

where $g_n(x)$ are the biorthogonal functions defined by (49).

Proof: This proposition follows from Proposition 6 obviously. □

In the following sections, we shall discuss what properties the function $Y(x)$ need possess so that its frequency system is a complete system or an unconditional basis.

IV. A COMPLETE SYSTEM IN $L^2_{\text{odd}}[-\pi,+\pi]$

We shall discuss what properties the function $Y(x)$ need possess so that its frequency system is a complete system in $L^2_{\text{odd}}[-\pi,+\pi]$.

Definition: The subset W of $L^2_{\text{odd}}[-\pi,+\pi]$ is defined by

$$W=\left\{ Y(x)\in L^2_{\text{odd}}[-\pi,+\pi]:Y(x)=\sum_{n=1}^{\infty} B(n)\sin nx, \quad \text{with } \sum_{l=1}^{\infty}\left(\sum_{mn=1}|B^{-1}(n)B(m)|\right)^2<\infty.\right\}$$

Proposition 8: If $Y(x)\in W$, then

(1) the series

$$\sin x=\sum_{n=1}^{\infty} B^{-1}(n)Y(nx) \tag{52}$$

converges unconditionally in the sense of the norm of $L^2[-\pi,+\pi]$;
(2) the frequency system $\{Y(nx)\}_{n=1}^{\infty}$ is complete in $L^2_{\text{odd}}[-\pi,+\pi]$.

Proof:

(1) In fact we have

$$\sum_{n=1}^{\infty} B^{-1}(n)Y(nx) \tag{53}$$

$$=\sum_{n=1}^{\infty} B^{-1}(n)\sum_{m=1}^{\infty} B(m)\sin(mnx) \tag{54}$$

$$=\sum_{l=1}^{\infty} \sum_{mn=l} B^{-1}(n)B(m)\sin lx \tag{55}$$

$$=\sin x. \tag{56}$$

From (54) to (55), the summation order was changed. But this does not matter for the series encountered here are unconditionally convergent in the sense of the norm of $L^2[-\pi,\pi]$. The reason for unconditional convergence is that the series

$$\sum_{l=1}^{\infty} \sum_{mn=l} |B^{-1}(n)B(m)|\sin lx$$

is convergent, and its norm square

$$\pi\sum_{l=1}^{\infty} \left(\sum_{mn=l} |B^{-1}(n)B(m)|\right)^2<\infty. \tag{57}$$

(2) From (52), it follows that

$$\sin mx=\sum_{n=1}^{\infty} B^{-1}(n)Y(mnx) \tag{58}$$

for $m=1,2,3,\ldots$.

Since the sine function system $\{\sin nx\}_{n=1}^{\infty}$ is complete in $L^2_{\rm odd}[-\pi,+\pi]$, so is the frequency system $\{Y(nx)\}_{n=1}^{\infty}$. □

Definition: The subset Y of $L^2_{\rm odd}[-\pi,+\pi]$ is defined by

$$Y=\left\{Y(x):\ Y(x)=\sum_{n=1}^{\infty} B(n)\sin x,\right.$$

$$\left.\text{where } B(n) \text{ is quadratically summable and completely multiplicative.}\right\}$$

If $Y(x)\in Y$, one says that $Y(x)$ is an odd function with quadratically summable and completely multiplicative Fourier coefficients, or an odd WQSCMFC function. Here the term that $B(n)$ is quadratically summable means that

$$\sum_{n=1}^{\infty} B^2(n)<\infty.$$

The term that $B(n)$ is completely multiplicative means that $B(1)=1$ and $B(m)B(n)=B(mn)$ for any two positive integers.[1]

Proposition 9: Y is a subset of W, i.e., $Y\subset W$.

Proof: Since $B(n)$ is completely multiplicative, we have and $B^{-1}(n)=\mu(n)B(n)$.[1] It follows that

$$\sum_{l=1}^{\infty}\left(\sum_{mn=l}|B^{-1}(n)B(m)|\right)^2=\sum_{l=1}^{\infty}B^2(l)\left(\sum_{mn=l}|\mu(n)|\right)^2$$
$$\leqslant\sum_{l=1}^{\infty}B^2(l)d^2(l)$$
$$\leqslant\sum_{l=1}^{\infty}B^2(l)d*d(l)=\left(\sum_{l=1}^{\infty}B^2(l)\right)^4<\infty.$$

Here $d(n)$ denotes the number of positive divisors of a positive integer n, called the divisor function.[1] We have used the relation

$$d*d(n)=\sum_{m|n}d(m)d\left(\frac{n}{m}\right)\geqslant\sum_{m|n}d(n)=d^2(n). \tag{59}$$

Therefore we obtain that $Y\subset W$. □

Proposition 10: If $Y(x)\in Y$, and

$$\psi(x)=\sum_{n=1}^{\infty}b(n)\sin nx$$

is a function in $L^2_{\mathrm{odd}}[-\pi,+\pi]$ with

$$\sum_{n=1}^{\infty}b^2(n)d(n)<\infty, \tag{60}$$

then $\psi(x)$ can be expressed as a frequency system based on $Y(x)$:

$$\psi(x)=\sum_{n=1}^{\infty}D(n)Y(nx),$$

where

$$D(n)=\sum_{d|n}\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)b(d)=B^{-1}*b(n). \tag{61}$$

Proof: This proof is similar to that in Ref. 2. With the help of Ref. 2, readers should have no difficulties in constructing a complete proof except for the use of a new inequality

$$\sum_{j=1}^{\infty}B^2(j)d^3(j)\leqslant\left(\sum_{j=1}^{\infty}B^2(j)\right)^8<\infty. \tag{62}$$

It is because

$$d*d*d*d(n)\geqslant d^2*d^2(n)=\sum_{m|n}d^2(m)d^2\left(\frac{n}{m}\right)\geqslant\sum_{m|n}d^2(n)=d^3(n). \tag{63}$$

Proposition 11: If $Y(x)\in Y$, the orthonormalized functions of the frequency system $\{Y(nx)\}$ can be given explicitly by

$$e_n(x)=\frac{1}{\|Y(x)\|}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n}\mu\left(\frac{n}{d}\right)B\left(\frac{n}{d}\right)Y(dx), \tag{64}$$

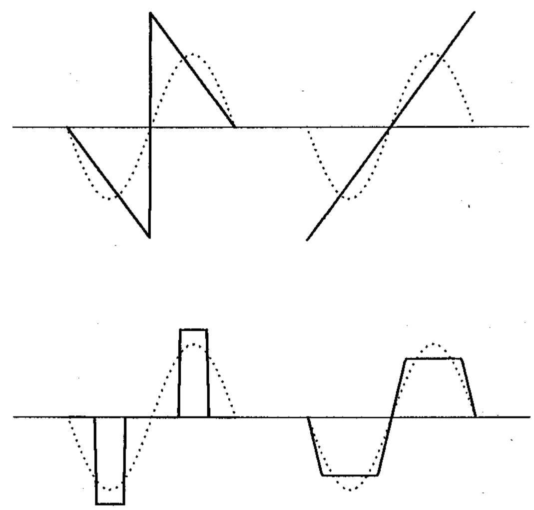

FIG. 1. The I-sawtooth wave, the II-sawtooth wave, the three-valued function, and the trapezoidal wave.

where the arithmatical function $\beta(n)$ is defined by

$$\beta(n)=\sum_{d|n}\mu(d)B^2(d). \tag{65}$$

Proof: Since this proof has little difference from that in Ref. 2, we omit it. Obviously the orthonormal system $\{e_n\}_{n=1}^{\infty}$ is an orthonormal basis of $L^2_{\text{odd}}[-\pi,+\pi]$. □

Proposition 12: If $Y_1(x)\in Y$, $Y_2(x)\in Y$, and that their Fourier coefficients are $B_1(n)$ and $B_2(n)$, respectively, then the two functions are related by

$$Y_1(x)=\sum_{n=1}^{\infty}D_{12}(n)Y_2(nx), \tag{66}$$

$$Y_2(x)=\sum_{n=1}^{\infty}D_{21}(n)Y_1(nx), \tag{67}$$

where

$$D12(n)=\sum_{d|n}\mu\left(\frac{n}{d}\right)B_2\left(\frac{n}{d}\right)B_1(d)=B_1*B_2^{-1}(n), \tag{68}$$

$$D21(n)=\sum_{d|n}\mu\left(\frac{n}{d}\right)B_1\left(\frac{n}{d}\right)B_2(d)=B_2*B_1^{-1}(n). \tag{69}$$

Proof: From Proposition 10, we can obtain this proposition easily. □

As examples, let us consider several basic wave forms, which are frequently used and easily generated in electronics.

Example 1: The I-sawtooth wave. The I-sawtooth wave $Y_{\text{Isa}}(x)$ is a function defined on $(-\infty,+\infty)$ with the period 2π, whose value in one period is given by

$$Y_{\text{Isa}}(x)=\begin{cases}(\pi-x)/2 & 0<x<2\pi\\ 0 & x=0\end{cases}. \tag{70}$$

See Fig. 1. By the way, in Fig. 1 the graphs of four functions are arranged in the following order:

$$\begin{pmatrix} Y_{\mathrm{Isa}}(x) & Y_{\mathrm{IIsa}}(x) \\ Y(\alpha,a;x) & Y_{\mathrm{tra}}(\alpha,a;x) \end{pmatrix}.$$

Its Fourier series is[3]

$$Y_{\mathrm{Isa}}(x)=\sin x+\tfrac{1}{2}\sin(2x)+\tfrac{1}{3}\sin(3x)+\cdots+\frac{1}{n}\sin(nx)+\cdots \tag{71}$$

$$=\sum_{n=1}^{\infty} B_{\mathrm{Isa}}(n)\sin(nx). \tag{72}$$

Its Fourier coefficient

$$B_{\mathrm{Isa}}(n)=1/n \tag{73}$$

is completely multiplicative, so the I-sawtooth wave $Y_{\mathrm{Isa}}(x)$ is an odd WQSCMFC function, i.e., $Y_{\mathrm{Isa}}(x)\in Y$.

Therefore the sine function can be considered as a superposition of I-sawtooth waves with different frequencies:

$$\sin x=Y_{\mathrm{Isa}}(x)-\tfrac{1}{2}Y_{\mathrm{Isa}}(2x)-\tfrac{1}{3}Y_{\mathrm{Isa}}(3x)+\cdots+\frac{\mu(n)}{n}Y_{\mathrm{Isa}}(nx)+\cdots. \tag{74}$$

The frequency system based on the I-sawtooth

$$Y_{\mathrm{Isa}}(x),\quad Y_{\mathrm{Isa}}(2x),\quad Y_{\mathrm{Isa}}(3x),\ldots,Y_{\mathrm{Isa}}(nx),\ldots \tag{75}$$

is complete in $L^2_{\mathrm{odd}}[-\pi,+\pi]$. (However whether it is a basis of $L^2_{\mathrm{odd}}[-\pi,+\pi]$ is still unknown.) Its biorthogonal system is

$$\frac{1}{\pi}\sin x,\ \frac{1}{\pi}(\sin 2x-\tfrac{1}{2}\sin x),\ \frac{1}{\pi}\left(\sin 3x-\frac{1}{3}\sin x\right),\ldots,\frac{1}{\pi}\sum_{d|n}\frac{d}{n}\mu\left(\frac{n}{d}\right)\sin dx,\ldots, \tag{76}$$

and its orthonormalized system is

$$\sqrt{\frac{6}{\pi^3}}Y_{\mathrm{Isa}}(x),\quad \sqrt{\frac{8}{\pi^3}}\left(Y_{\mathrm{Isa}}(2x)-\frac{1}{2}Y_{\mathrm{Isa}}(x)\right),\quad \sqrt{\frac{27}{4\pi^3}}\left(Y_{\mathrm{Isa}}(3x)-\frac{1}{3}Y_{\mathrm{Isa}}(x)\right),\ldots,$$

$$\sqrt{\frac{6}{\pi^3}}\frac{1}{\sqrt{\beta(n)}}\sum_{d|n}\frac{d}{n}\mu\left(\frac{n}{d}\right)Y_{\mathrm{Isa}}(dx),\ldots,$$

where

$$\beta(n)=\sum_{d|n}\frac{\mu(d)}{d^2}. \tag{77}$$

Example 2: The II-sawtooth wave. The II-sawtooth wave $Y_{\mathrm{IIsa}}(x)$ is a function defined on $(-\infty,+\infty)$ with the period 2π (Fig. 1), whose value in one period is given by

$$Y_{\mathrm{IIsa}}(x)=\begin{cases} x/2 & -\pi<x<\pi \\ 0 & x=-\pi,\pi. \end{cases} \tag{78}$$

Its Fourier series is[3]

$$Y_{\mathrm{IIsa}}(x)=\sin x-\frac{1}{2}\sin(2x)+\frac{1}{3}\sin(3x)+\cdots+\frac{(-1)^{n+1}}{n}\sin(nx)+\cdots \tag{79}$$

$$=\sum_{n=1}^{\infty} B_{\mathrm{IIsa}}(n)\sin(nx). \tag{80}$$

Its Fourier coefficient

$$B_{\mathrm{IIsa}}(n)=\frac{(-1)^{n+1}}{n}=\frac{\theta(n)}{n} \tag{81}$$

is not completely multiplicative, so the II-sawtooth wave $Y_{\mathrm{IIsa}}(x)$ is not a WQSCMFC function, i.e., $Y_{\mathrm{IIsa}}(x)$ is not in the set Y. Here θ is the arithmetical function defined by

$$\theta(n)=(-1)^{n+1}. \tag{82}$$

Furthermore, it is not difficult to prove that $Y_{\mathrm{IIsa}}(x)$ is not in the set W either [hint: see (94)]. Still, the frequency system based on the II-sawtooth

$$Y_{\mathrm{IIsa}}(x),\ \ Y_{\mathrm{IIsa}}(2x),\ \ Y_{\mathrm{IIsa}}(3x),\ldots,Y_{\mathrm{IIsa}}(nx),\ldots \tag{83}$$

is a complete system in $L^2_{\mathrm{odd}}[-\pi,+\pi]$ (see Proposition 13). Its biorthogonal system is

$$\frac{1}{\pi}\sin x,\ \ \frac{1}{\pi}\left(\sin 2x+\frac{1}{2}\sin x\right),\ \ \frac{1}{\pi}\left(\sin 3x-\frac{1}{3}\sin x\right),\ldots,\frac{1}{\pi}\sum_{d|n}\frac{d}{n}\,\theta^{-1}\left(\frac{n}{d}\right)\sin dx,\ldots, \tag{84}$$

and its orthonormalized system is

$$\sqrt{\frac{6}{\pi^3}}\,Y_{\mathrm{IIsa}}(x),\ \ 4\sqrt{\frac{2}{5\pi^3}}\left(Y_{\mathrm{IIsa}}(2x)+\frac{1}{4}Y_{\mathrm{IIsa}}(x)\right),\ \ \sqrt{\frac{27}{4\pi^3}}\left(Y_{\mathrm{IIsa}}(3x)-\frac{1}{3}Y_{\mathrm{IIsa}}(x)\right),$$

$$\sqrt{\frac{20}{3\pi^3}}\left(Y_{\mathrm{IIsa}}(4x)+\frac{3}{10}Y_{\mathrm{IIsa}}(2x)+\frac{1}{5}Y(x)\right),\ldots .$$

Here θ^{-1} is the Dirichlet inversion of θ, which is given explicitly by

$$\theta^{-1}(n)=\begin{cases}\mu(n) & l=0\\ 2^{l-1}\mu(2k+1) & l=1,2,3\ldots .\end{cases} \tag{85}$$

Here l and k are determined by

$$n=2^l(2k+1). \tag{86}$$

Proposition 13: The frequency system based on the II-sawtooth wave, i.e., $\{Y_{\mathrm{IIsa}}(nx)\}_{n=1}^{\infty}$, is a complete system in $L^2_{\mathrm{odd}}[-\pi,+\pi]$, but it is not a basis of $L^2_{\mathrm{odd}}[-\pi,+\pi]$.

Proof:

(1) It is complete in $L^2_{\mathrm{odd}}[-\pi,+\pi]$.

Suppose that there exists a function $\psi(x)\in L^2_{\mathrm{odd}}[-\pi,+\pi]$ such that

$$\langle Y_{\mathrm{IIsa}}(nx),\psi(x)\rangle=0 \quad \text{for } n=1,2,3,\ldots . \tag{87}$$

From the definitions of the two sawtooth waves, we have the relation

$$Y_{\rm IIsa}(x)=Y_{\rm Isa}(x)-Y_{\rm Isa}(2x). \tag{88}$$

Thus we obtain that

$$\langle Y_{\rm Isa}(nx),\psi(x)\rangle=\langle Y_{\rm Isa}(2nx),\psi(x)\rangle \quad \text{for} \;\; n=1,2,3,... . \tag{89}$$

Furthermore, for an arbitrary positive integer l we have

$$\langle Y_{\rm Isa}(lx),\psi(x)\rangle=\langle Y_{\rm Isa}(2lx),\psi(x)\rangle=\cdots=\langle Y_{\rm Isa}(2^m lx),\psi(x)\rangle=\cdots, \tag{90}$$

where $m=0,1,2,...$. Due to Proposition 2, $Y_{\rm Isa}(nx)$ converges weakly to zero, and we have

$$\langle Y_{\rm Isa}(lx),\psi(x)\rangle=0. \tag{91}$$

Since $\{Y_{\rm Isa}(nx)\}_{n=1}^{\infty}$ is complete, we have

$$\psi(x)=0. \tag{92}$$

This completes the proof about the completeness.

(2) It is not a basis of $L^2_{\rm odd}[-\pi,+\pi]$.

If it is a basis of $L^2_{\rm odd}[-\pi,+\pi]$, by Proposition 7, $\sin x$ can be expressed as a frequency series:

$$\sin x=Y_{\rm IIsa}(x)+\frac{1}{2}Y_{\rm IIsa}(2x)-\frac{1}{3}Y_{\rm IIsa}(3x)+\cdots+\frac{\theta^{-1}(n)}{n}Y_{\rm IIsa}(nx)+\cdots. \tag{93}$$

But this is impossible, because $\theta^{-1}(n)/n$ does not converge to zero. In fact, for $n=2^m$, $m=1,2,3,...$, we always have

$$\frac{\theta^{-1}(n)}{n}=\frac{1}{2}. \tag{94}$$

Therefore it is not a basis of $L^2_{\rm odd}[-\pi,+\pi]$.

Example 3: A periodic three-valued function. Suppose that $Y(\alpha,a;x)$ is a three-valued function of the period 2π (Fig. 1), the value in one period of which is given by

$$Y(\alpha,a;x)=\begin{cases} 0 & -\pi<x<-\pi+\alpha,-\alpha<x<\alpha,-\pi-\alpha<x<\pi \\ -a & -\pi+\alpha<x<-\alpha \\ a & \alpha<x<\pi-\alpha, \end{cases} \tag{95}$$

where $a>0$ and $0\leqslant\alpha<\pi/2$.

The Fourier series of $Y(\alpha,a;x)$ is[3]

$$Y(\alpha,a;x)=\frac{4a}{\pi}\left(\cos\alpha\sin x+\frac{1}{3}\cos 3\alpha\sin 3x+\frac{1}{5}\cos 5\alpha\sin 5x+\cdots\right) \tag{96}$$

$$=\sum_{n=1}^{\infty}B(n)\sin nx, \tag{97}$$

where the Fourier coefficients

$$B(n)=\begin{cases} \dfrac{4a}{\pi}\dfrac{\cos n\alpha}{n}, & n=1,3,5,... \\ 0, & n=2,4,6,... . \end{cases} \tag{98}$$

Proposition 14: $Y(\alpha,a;x)$ is an odd WQSCMFC function, i.e., $Y(\alpha,a;x)\in Y$ if and only if

$$(0)\quad \alpha=0,\quad a=\frac{\pi}{4}, \tag{99}$$

$$(1)\quad \alpha=\frac{\pi}{4},\quad a=\frac{\sqrt{2}\pi}{4}, \tag{100}$$

or

$$(2)\quad \alpha=\frac{\pi}{6},\quad a=\frac{\sqrt{3}\pi}{6}. \tag{101}$$

Proof: It is easy to verify that in the case (0), (1) or (2), the function $Y(\alpha,a;x)$ is an odd WQSCMFC function indeed.

Now let us prove that except for the three cases $Y(\alpha,a;x)$ is not an odd WQSCMFC function. If $Y(\alpha,a;x)$ is an odd WQSCMFC function, then its Fourier coefficients

$$B(n)=\begin{cases}\dfrac{4a}{\pi}\dfrac{\cos n\alpha}{n}, & n=1,3,5,\ldots\\ 0, \quad n=2,4,6,\ldots\end{cases} \tag{102}$$

are a completely multiplicative arithmetical function. From $B(1)=1$ it follows that

$$a=\frac{\pi}{4}\frac{1}{\cos\alpha}.$$

From $B^2(3)=B(9)$ it follows that

$$\left(\frac{\cos 3\alpha}{\cos\alpha}\right)^2=\frac{\cos 9\alpha}{\cos\alpha}. \tag{103}$$

Equation (103) has three solutions in $[0,\pi/2)$:

$$\alpha=0,\quad \alpha=\frac{\pi}{4},\quad \text{or}\quad \alpha=\frac{\pi}{6}.$$

The associated value of a is

$$a=\frac{\pi}{4},\quad a=\frac{\sqrt{2}\pi}{4},\quad \text{or}\quad a=\frac{\sqrt{3}\pi}{6}.$$

Thus there exist at most three WQSCMFC function among all $Y(\alpha,a;x)$ with $a>0$ and $0\leqslant\alpha<\pi/2$.
This completes the proof. □

For convenience, we call the three functions

$$Y\left(0,\frac{\pi}{4};x\right)=Y_{\mathrm{sq}}(x), \tag{104}$$

$$Y\left(\frac{\pi}{4},\frac{\sqrt{2}\pi}{4};x\right)=Y_{\pi/4}(x), \tag{105}$$

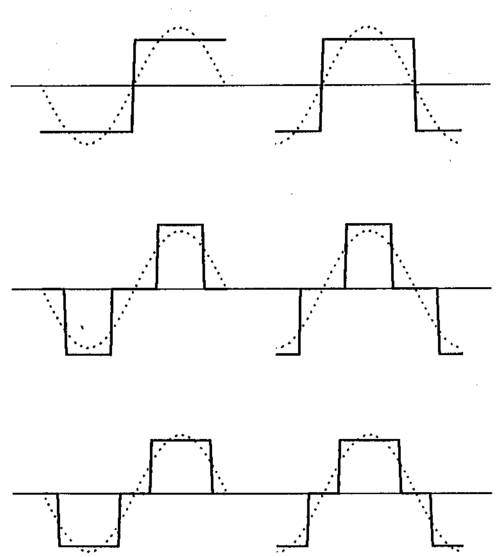

FIG. 2. The odd and even square waves, $\pi/4$ three-valued functions, and $\pi/6$ three-valued functions.

$$Y\left(\frac{\pi}{6},\frac{\sqrt{3}\pi}{6};x\right)=Y_{\pi/6}(x), \tag{106}$$

odd square wave, $\pi/4$ three-valued function, and $\pi/6$ three-valued function, respectively, which are common in electronics. See Fig. 2. By the way, in Fig. 2 the graphs of six functions are arranged in the following order:

$$\begin{pmatrix} Y_{\text{sq}}(x) & X_{\text{sq}}(x) \\ Y_{\pi/4}(x) & X_{\pi/4}(x) \\ Y_{\pi/6}(x) & X_{\pi/6}(x) \end{pmatrix}.$$

Regarding the three-valued functions the following questions are still open.

Questions:

(1) In the case (0), (1), or (2), is the frequency system $\{Y(\alpha,a;nx)\}$ a basis of $L^2_{\text{odd}}[-\pi,+\pi]$?

(2) Except for the case (0), (1), and (2), is the frequency system $\{Y(\alpha,a;nx)\}$ a complete system in $L^2_{\text{odd}}[-\pi,+\pi]$?

By Proposition 12, the sawtooth wave $Y_{\text{Isa}}(x)$ and the odd square waves $Y_{\text{sq}}(x)$ are related by

$$Y_{\text{Isa}}(x)=Y_{\text{sq}}(x)+\frac{1}{2}Y_{\text{sq}}(2x)+\frac{1}{4}Y_{\text{sq}}(4x)+\cdots+\frac{1}{2^m}Y_{\text{sq}}(2^m)+\ldots, \tag{107}$$

and

$$Y_{\text{sq}}(x)=Y_{\text{Isa}}(x)-\tfrac{1}{2}Y_{\text{Isa}}(2x). \tag{108}$$

V. AN UNCONDITIONAL BASIS IN $L^2_{\text{odd}}[-\pi,+\pi]$

We shall discuss what properties a function need possess so that its frequency system is an unconditional basis of $L^2_{\text{odd}}[-\pi,+\pi]$.

Definition: A function set B is defined by

$$B=\left\{Y(x):\ Y(x)=\sum_{n=1}^{\infty} B(n)\sin nx \text{ where } B(n) \text{ satisfies } \sum_{n=1}^{\infty}|B(n)|<\infty,\quad \sum_{n=1}^{\infty}|B^{-1}(n)|<\infty\right\}.$$

Obviously, B is a subset of W.

Proposition 15: If $Y(x)\in B$, then

(1) the series

$$\sin x=\sum_{n=1}^{\infty} B^{-1}(n)Y(nx) \tag{109}$$

converges absolutely and uniformly in $[-\pi,\pi]$;

(2) the frequency system $\{Y(nx)\}$ is an unconditional basis of $L^2_{\text{odd}}[-\pi,+\pi]$.

Proof:

(1) In fact we have

$$\sum_{n=1}^{\infty} B^{-1}(n)Y(nx) \tag{110}$$

$$=\sum_{n=1}^{\infty} B^{-1}(n)\sum_{m=1}^{\infty} B(m)\sin(mnx) \tag{111}$$

$$=\sum_{l=1}^{\infty}\sum_{mn=l} B^{-1}(n)B(m)\sin lx \tag{112}$$

$$=\sin x. \tag{113}$$

Since

$$\sum_{n=1}^{\infty}|B^{-1}(n)|\sum_{m=1}^{\infty}|B(m)\sin(mnx)|\le\sum_{n=1}^{\infty}|B^{-1}(n)|\sum_{m=1}^{\infty}|B(m)|<\infty,$$

by Weierstrass M-test, we obtain that the series (109) converges absolutely and uniformly in $[-\pi,\pi]$.

(2) Suppose that $\psi(x)\in L^2_{\text{odd}}[-\pi,+\pi]$ is an arbitrary function and that $b(n)$ denotes its Fourier coefficients. In fact, we have

$$\psi(x)=\sum_{n=1}^{\infty} b(n)\sin nx \tag{114}$$

$$=\sum_{n=1}^{\infty} b(n)\sum_{l=1}^{\infty} B^{-1}(l)Y(nlx) \tag{115}$$

$$=\sum_{n=1}^{\infty}\left(\sum_{d|n} b(d)B^{-1}\left(\frac{n}{d}\right)\right)Y(nx) \tag{116}$$

$$=\sum_{n=1}^{\infty} D(n)Y(nx), \tag{117}$$

where

$$D(n)=\sum_{d|n} b(d)B^{-1}\left(\frac{n}{d}\right)=B^{-1}*b(n). \tag{118}$$

From (115) to (116), the summation orders were changed. But this does not matter because all the following series

$$\sum_{n=1}^{\infty} b(n)\sum_{l=1}^{\infty} B^{-1}(l)Y(nlx)=\sum_{n=1}^{\infty} b(n)\sum_{l=1}^{\infty} B^{-1}(l)\sum_{m=1}^{\infty} B(m)\sin(nlmx)$$
$$=\sum_{k=1}^{\infty}\left(\sum_{nlm=k} b(n)B^{-1}(l)B(m)\right)\sin(kx)$$

are unconditionally convergent in $L^2[-\pi,\pi]$, or one can say, they have sums independent of order. The reason for the unconditional convergence is that the series

$$\sum_{k=1}^{\infty}\left(\sum_{nlm=k}|b(n)B^{-1}(l)B(m)|\right)\sin(kx) \tag{119}$$

is convergent, the norm of which is

$$\left\|\sum_{k=1}^{\infty}\left(\sum_{nlm=k}|b(n)B^{-1}(l)B(m)|\right)\sin(kx)\right\| \tag{120}$$

$$=\left\|\sum_{m=1}^{\infty}|B(m)|\sum_{l=1}^{\infty}|B^{-1}(l)|\sum_{n=1}^{\infty}|b(n)|\sin(nlmx)\right\| \tag{121}$$

$$\leqslant\sum_{m=1}^{\infty}|B(m)|\sum_{l=1}^{\infty}|B^{-1}(l)|\left\|\sum_{n=1}^{\infty}|b(n)|\sin(nlmx)\right\| \tag{122}$$

$$=\sum_{m=1}^{\infty}|B(m)|\sum_{l=1}^{\infty}|B^{-1}(l)|\sqrt{\pi\sum_{n=1}^{\infty}b^2(n)} \tag{123}$$

$$<\infty. \tag{124}$$

We can obtain the uniqueness of the series (117) by the consequence of Proposition 1.
Therefore $\{Y(nx)\}$ is an unconditional basis of $L^2[-\pi,\pi]$.
This completes the proof. □

Example: The function

$$Y(x)=\sin x-\frac{1}{2^2}\sin 2x+\frac{1}{3^2}\sin 3x+\cdots+\frac{(-1)^{n+1}}{n^2}\sin nx+\ldots, \tag{125}$$

is an element of *B*, since $B(n)$ satisfy that

$$B(1)=1,\quad \sum_{n=1}^{\infty}|B(n)|=\frac{\pi^2}{6},\quad \sum_{n=1}^{\infty}|B^{-1}(n)|=\frac{18}{\pi^2}. \tag{126}$$

Definition: The function set Y_a is defined by

$$Y_a=\left\{Y(x):Y(x)=\sum_{n=1}^{\infty}B(n)\sin nx,\right.$$

$$\left.\text{where } B(n) \text{ is absolutely summable and completely multiplicative}\right\}.$$

If $Y(x)\in Y_a$, one says that $Y(x)$ is an odd function with absolutely summable and completely multiplicative Fourier coefficients, or an odd WASCMFC function.

Here the term that $B(n)$ is absolutely summable means that

$$\sum_{n=1}^{\infty}|B(n)|<\infty.$$

Proposition 16: Y_a is a subset of *B*, i.e., $Y_a\subset B$.

Proof: If $B(n)$ is completely multiplicative, we have

$$\sum_{n=1}^{\infty}|B^{-1}(n)|=\sum_{n=1}^{\infty}|\mu(n)B(n)|\leqslant\sum_{n=1}^{\infty}|B(n)|<\infty. \tag{127}$$

Additionally, we have $Y_a\subset Y$.

Example: Trapezoidal wave. The trapezoidal wave $Y_{\text{tra}}(a,\alpha;x)$ is a function of the period 2π (Fig. 1), the value in one period of which is given by

$$Y_{\text{tra}}(\alpha,a;x)=\begin{cases}ax/\alpha & \text{for}-\alpha\leqslant x\leqslant\alpha\\ a & \text{for }\ \alpha\leqslant x\leqslant\pi-\alpha\\ -a & \text{for}-\pi+\alpha\leqslant x\leqslant-\alpha\\ a(\pi-x)/\alpha & \text{for }\ \pi-\alpha\leqslant x\leqslant\pi\\ -a(\pi+x)/\alpha & \text{for}-\pi\leqslant x\leqslant-\pi+\alpha,\end{cases} \tag{128}$$

where

$$0<\alpha\leqslant\pi/2, a>0. \tag{129}$$

Its Fourier series is[3]

$$Y_{\text{tra}}(\alpha,a;x)=\frac{4a}{\pi\alpha}\left(\sin\alpha\sin x+\frac{1}{3^2}\sin 3\alpha\sin 3x+\frac{1}{5^2}\sin 5\alpha\sin 5x+\cdots\right)=\sum_{n=1}^{\infty}B(n)\sin nx,$$

where

$$B(n)=\begin{cases}\dfrac{4a}{\pi\alpha}\dfrac{1}{n^2}\sin n\alpha, & n=1,3,5,\ldots\\ 0, & n=2,4,6,\ldots.\end{cases} \tag{130}$$

Proposition 17: The function $Y_{\text{tra}}(\alpha,a;x)$ is an odd WASCMFC function if and only if

$$(0)\quad \alpha=\frac{\pi}{2},\quad a=\frac{\pi^2}{8}, \tag{131}$$

$$(1)\quad \alpha=\frac{\pi}{4},\quad a=\frac{\sqrt{2}\pi^2}{16}, \tag{132}$$

or

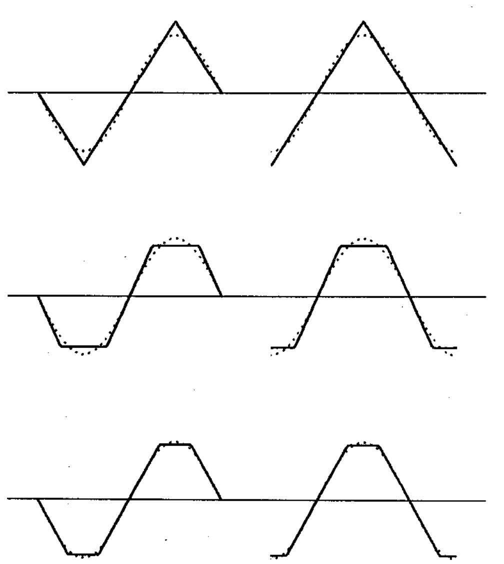

FIG. 3. The odd and even triangular waves, $\pi/4$ trapezoidal waves, and $\pi/3$ trapezoidal waves.

$$(2) \quad \alpha=\frac{\pi}{3}, \quad a=\frac{\sqrt{3}\pi^2}{18}. \tag{133}$$

Proof: This proof is similar to that of Proposition (14). □

For convenience, we call the three functions

$$Y_{\rm tra}\left(\frac{\pi}{2},\frac{\pi^2}{8};x\right)=Y_{\rm tri}(x), \tag{134}$$

$$Y_{\rm tra}\left(\frac{\pi}{4},\frac{\sqrt{2}\pi^2}{16};x\right)=Y_{\pi/4{\rm tra}}(x), \tag{135}$$

$$Y_{\rm tra}\left(\frac{\pi}{3},\frac{\sqrt{3}\pi^2}{18};x\right)=Y_{\pi/3{\rm tra}}(x), \tag{136}$$

odd triangular wave, $\pi/4$ trapezoidal wave, and $\pi/3$ trapezoidal wave, respectively, which are common in electronics. See Fig. 3. By the way, in Fig. 3 the graphs of six functions are arranged in the following order:

$$\begin{pmatrix} Y_{\rm tri}(x) & X_{\rm tri}(x) \\ Y_{\pi/4{\rm tra}}(x) & X_{\pi/4{\rm tra}}(x) \\ Y_{\pi/3{\rm tra}}(x) & X_{\pi/3{\rm tra}}(x) \end{pmatrix}.$$

Proposition 18: If the Fourier coefficients $B(n)$ of $Y(x)\in L^2_{\rm odd}[-\pi,+\pi]$ satisfy that

$$B(1)=1, \quad \sum_{n=2}^{\infty}|B(n)|<1, \tag{137}$$

then $Y(x)\in B$.

Proof: In fact we have

$$\left(\sum_{n=1}^{\infty} B(n)\right)^{-1} = \left(1+\sum_{n=2}^{\infty} B(n)\right)^{-1}$$
$$= 1+(-1)\sum_{n=2}^{\infty} B(n)+\cdots+(-1)^m\left(\sum_{n=2}^{\infty} B(n)\right)^m+\cdots = \sum_{n=1}^{\infty} B^{-1}(n).$$

Therefore we obtain that

$$\sum_{n=1}^{\infty} |B^{-1}(n)| \leqslant 1+\sum_{n=2}^{\infty} |B(n)|+\cdots+\left(\sum_{n=2}^{\infty} |B(n)|\right)^m+\cdots = \frac{1}{1-\Sigma_{n=2}^{\infty}|B(n)|} < \infty.$$

This completes the proof. □

Proposition 19: For $\pi/2 \geqslant \alpha > \arcsin(\pi^2/8-1)$, the frequency system $\{Y_{\mathrm{tra}}(\alpha,a;nx)\}$ is an unconditional basis of $L^2_{\mathrm{odd}}[-\pi,+\pi]$.

Proof: It does not matter taking

$$a = \frac{\pi}{4}\,\frac{\alpha}{\sin\alpha}. \tag{138}$$

The Fourier coefficients of $Y_{\mathrm{tra}}(\alpha,(\pi/4)\alpha/\sin\alpha;x)$ is

$$Y_{\mathrm{tra}}\left(\alpha,\frac{\pi}{4}\,\frac{\alpha}{\sin\alpha};x\right) = \sin x+\frac{1}{3^2}\,\frac{\sin 3\alpha}{\sin\alpha}\sin 3x+\frac{1}{5^2}\,\frac{\sin 5\alpha}{\sin\alpha}\sin 5x+\cdots. \tag{139}$$

$$= \sum_{n=1}^{\infty} B(n)\sin nx. \tag{140}$$

Obviously we have $B(1)=1$. Also we have

$$\sum_{n=2}^{\infty} |B(n)| = \frac{1}{\sin\alpha}\left(\frac{|\sin 3\alpha|}{3^2}+\left(\frac{|\sin 5\alpha|}{5^2}\right)+\cdots\right) \leqslant \frac{1}{\sin\alpha}\left(\frac{1}{3^2}+\frac{1}{5^2}+\cdots\right) = \frac{1}{\sin\alpha}\left(\frac{\pi^2}{8}-1\right) < 1.$$

By Proposition (18), we obtain this proposition. Here we have

$$\arcsin\left(\frac{\pi^2}{8}-1\right) \doteq \arcsin(0.233\,70) \doteq 13°31'. \tag{141}$$

VI. A COMBINATIVE FREQUENCY SYSTEM IN $L^2[-\pi,\pi]$

Since the case of the even function subspace $L^2_{\mathrm{even}}[-\pi,\pi]$ is similar to the case of the odd function subspace $L^2_{\mathrm{odd}}[-\pi,+\pi]$, let us return directly to the whole space $L^2[-\pi,\pi]$, and draw our general conclusions.

Suppose that

$$X(x) = \sum_{n=1}^{\infty} A(n)\cos nx \tag{142}$$

is a given function in $L^2_{\mathrm{even}}[-\pi,+\pi]$, and

$$Y(x) = \sum_{n=1}^{\infty} B(n)\sin nx \tag{143}$$

is a given function in $L^2_{\mathrm{odd}}[-\pi,+\pi]$.

Generally, if the frequency system

$$Y(x),Y(2x),Y(3x),\ldots,Y(nx),\ldots \tag{144}$$

is a complete system (an unconditional basis) in $L^2_{\mathrm{odd}}[-\pi,+\pi]$, and the frequency system

$$X(x),X(2x),X(3x),\ldots,X(nx),\ldots \tag{145}$$

is a complete system (an unconditional basis) in $L^2_{\mathrm{even}}[-\pi,+\pi]$ as well, then the combinative frequency system

$$1,X(x),Y(x),X(2x),Y(2x),\ldots,X(nx),Y(nx),\ldots \tag{146}$$

is a complete system (an unconditional basis) in the whole space $L^2[-\pi,\pi]$.

If the combinative frequency system (146) is a complete system in $L^2[-\pi,\pi]$, then its orthonormalized system is an orthonormal basis of $L^2[-\pi,\pi]$, and any function $f(x)\in L^2[-\pi,\pi]$ can be approximated by a linear combination of finite functions in (146) with an arbitrary mean-square error.

If the combinative frequency system (146) is an unconditional basis, then any function $f(x)\in L^2[-\pi,\pi]$ can be expressed as a combinative frequency series based on $X(x)$ and $Y(x)$:

$$f(x)=C_0+\sum_{n=1}^{\infty} C(n)X(nx)+D(n)Y(nx), \tag{147}$$

where the coefficients C_0, $C(n)$, and $D(n)$ can be determined by

$$C_0=\int_{-\pi}^{\pi} f(x)dx, \tag{148}$$

$$C(n)=\int_{-\pi}^{\pi} f(x)h_n(x)dx, \tag{149}$$

$$D(n)=\int_{-\pi}^{\pi} f(x)g_n(x)dx. \tag{150}$$

Here

$$h_n(x)=\sum_{d|n} A^{-1}\left(\frac{n}{d}\right)\cos dx, \tag{151}$$

$$g_n(x)=\sum_{d|n} B^{-1}\left(\frac{n}{d}\right)\sin dx \tag{152}$$

are the biorthogonal functions of $X(nx)$ and $Y(nx)$, respectively.

Speaking concretely, the complete combinative frequency systems of practical importance are (1) the square wave system[2]

$$1,X_{\mathrm{sq}}(x),Y_{\mathrm{sq}}(x),X_{\mathrm{sq}}(2x),Y_{\mathrm{sq}}(2x),\ldots,X_{\mathrm{sq}}(nx),Y_{\mathrm{sq}}(nx),\ldots, \tag{153}$$

(2) the $\pi/4$ three-valued function system

$$1,X_{\pi/4}(x),Y_{\pi/4}(x),X_{\pi/4}(2x),Y_{\pi/4}(2x),\ldots,X_{\pi/4}(nx),Y_{\pi/4}(nx),\ldots, \tag{154}$$

(3) the $\pi/6$ three-valued function system

$$1, X_{\pi/6}(x), Y_{\pi/6}(x), X_{\pi/6}(2x), Y_{\pi/6}(2x), \ldots, X_{\pi/6}(nx), Y_{\pi/6}(nx), \ldots, \tag{155}$$

and so on. Here the functions

$$X_{\mathrm{sq}}(x) = Y_{\mathrm{sq}}\left(x + \frac{\pi}{2}\right), \tag{156}$$

$$X_{\pi/4}(x) = Y_{\pi/4}\left(x + \frac{\pi}{2}\right), \tag{157}$$

$$X_{\pi/6}(x) = Y_{\pi/6}\left(x + \frac{\pi}{2}\right), \tag{158}$$

are called even square wave, $\pi/4$ three-valued function, $\pi/6$ three-valued function, respectively. See Fig. 2.

The unconditional bases of the practical importance are
(1) the triangular wave basis

$$1, X_{\mathrm{tri}}(x), Y_{\mathrm{tri}}(x), X_{\mathrm{tri}}(2x), Y_{\mathrm{tri}}(2x), \ldots, X_{\mathrm{tri}}(nx), Y_{\mathrm{tri}}(nx), \ldots, \tag{159}$$

(2) the $\pi/4$ trapezoidal wave basis

$$1, X_{\pi/4\mathrm{tra}}(x), Y_{\pi/4\mathrm{tra}}(x), X_{\pi/4\mathrm{tra}}(2x), Y_{\pi/4\mathrm{tra}}(2x), \ldots, X_{\pi/4\mathrm{tra}}(nx), Y_{\pi/4\mathrm{tra}}(nx), \ldots, \tag{160}$$

(3) the $\pi/3$ trapezoidal wave basis

$$1, X_{\pi/3\mathrm{tra}}(x), Y_{\pi/3\mathrm{tra}}(x), X_{\pi/3\mathrm{tra}}(2x), Y_{\pi/3\mathrm{tra}}(2x), \ldots, X_{\pi/3\mathrm{tra}}(nx), Y_{\pi/3\mathrm{tra}}(nx), \ldots, \tag{161}$$

and so on.

Here the functions

$$X_{\mathrm{tri}}(x) = Y_{\mathrm{tri}}\left(x + \frac{\pi}{2}\right), \tag{162}$$

$$X_{\pi/4\mathrm{tra}}(x) = Y_{\pi/4\mathrm{tra}}\left(x + \frac{\pi}{2}\right), \tag{163}$$

$$X_{\pi/3\mathrm{tra}}(x) = Y_{\pi/3\mathrm{tra}}\left(x + \frac{\pi}{2}\right), \tag{164}$$

are called even triangular wave, $\pi/4$ trapezoidal wave, and $\pi/3$ trapezoidal wave. See Fig. 3. In fact, for $\alpha > 13°31'$, a general trapezoidal wave system

$$1, X_{\mathrm{tra}}(\alpha, a; x), Y_{\mathrm{tra}}(\alpha, a; x), X_{\mathrm{tra}}(\alpha, a; 2x), Y_{\mathrm{tra}}(\alpha, a; 2x), \ldots X_{\mathrm{tra}}(\alpha, a; nx), Y_{\mathrm{tra}}(\alpha, a; nx), \ldots \tag{165}$$

is an unconditional basis of $L^2[-\pi, \pi]$, where the function

$$X_{\mathrm{tra}}(\alpha, a; x) = Y_{\mathrm{tra}}\left(\alpha, a; x + \frac{\pi}{2}\right) \tag{166}$$

is called even trapezoidal wave.

VII. A FREQUENCY TRANSFORMATION IN $L^2(R)$

In this section, we shall introduce in $L^2(R)$ the frequency transformation based on general periodic functions, which is a generalization of Fourier transformation based on sine–cosine functions.

$L^2(-\infty,+\infty)$ or $L^2(R)$ denotes the space of quadratically integrable functions on $R=(-\infty,+\infty)$. It is well known that $L^2(R)$ can be decomposed into an even function subspace $L^2_{\text{even}}(R)$ and an odd function subspace $L^2_{\text{odd}}(R)$:

$$L^2(R)=L^2_{\text{even}}(R)\oplus L^2_{\text{odd}}(R). \tag{167}$$

By Plancherel's theory,[4] Fourier transformation $\mathbf{F}$ and its inverse transformation $\mathbf{F}^{-1}$ are two bounded linear operators from $L^2(R)$ to itself, i.e., $\mathbf{F}\in B(L^2(R))$, $\mathbf{F}^{-1}\in B(L^2(R))$. $B(L^2(R))$ denotes the Banach space of all the bounded linear operators from $L^2(R)$ to itself.

That is to say, for any two functions $f(x)$, $\hat{f}(\omega)\in L^2(R)$, we have

$$\hat{f}(\omega)=(\mathbf{F}f)(\omega)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}f(x)e^{-i\omega x}\,dx \tag{168}$$

$$\Leftrightarrow$$

$$f(x)=(\mathbf{F}^{-1}\hat{f})(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}\hat{f}(\omega)e^{i\omega x}\,d\omega. \tag{169}$$

Strictly speaking, when the integrations in (168) and (169) do not exist, $\int_{-\infty}^{+\infty}$ should be considered to be $\lim_{N\to\infty}\int_{-N}^{N}$, where the limit is in the sence of the norm in $L^2(R)$, see Ref. 4.

In the even function subspace $L^2_{\text{even}}(R)$, Fourier transformation $\mathbf{F}$ and its inversion $\mathbf{F}^{-1}$ become Fourier cosine transformation $\mathbf{F}_{\cos}$ and its inversion $\mathbf{F}_{\cos}^{-1}$. That is to say, for any two functions $f_{\text{even}}(x)$, $a(\omega)\in L^2_{\text{even}}(R)$, we have

$$a(\omega)=(\mathbf{F}_{\cos}f_{\text{even}})(\omega)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}f_{\text{even}}(x)\cos(\omega x)dx \tag{170}$$

$$\Leftrightarrow$$

$$f_{\text{even}}(x)=(\mathbf{F}_{\cos}^{-1}a)(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}a(\omega)\cos(\omega x)d\omega. \tag{171}$$

In the odd function subspace $L^2_{\text{odd}}(R)$, there exist similar Fourier sine transformation and its inversion.

Next let us introduce the transformation based on general periodic functions step by step.

In this section we suppose that $X(x)\in L^2[-\pi,\pi]$ and $Y(x)\in L^2[-\pi,\pi]$ are a given even function and a given odd function with period 2π. Their Fourier series are

$$X(x)=\sum_{n=1}^{\infty}A(n)\cos nx,\qquad Y(x)=\sum_{n=1}^{\infty}B(n)\sin nx.$$

Their Fourier coefficients satisfy

$$\sum_{n=1}^{\infty} |A(n)| \frac{1}{\sqrt{n}} < \infty, \quad \sum_{n=1}^{\infty} |A^{-1}(n)| \frac{1}{\sqrt{n}} < \infty,$$

$$\sum_{n=1}^{\infty} |B(n)| \frac{1}{\sqrt{n}} < \infty, \quad \sum_{n=1}^{\infty} |B^{-1}(n)| \frac{1}{\sqrt{n}} < \infty.$$

Definition: The functions $\tilde{X}(x)$ and $\tilde{Y}(x)$ are called the dual functions of $X(x)$ and $Y(x)$, respectively, which are defined on $(-\infty,\infty)$ by

$$\tilde{X}(x) = \frac{1}{2\pi} \sum_{n=1}^{\infty} A^{-1}(n) \frac{1}{n} \cos\left(\frac{x}{n}\right), \tag{172}$$

$$\tilde{Y}(x) = \frac{1}{2\pi} \sum_{n=1}^{\infty} B^{-1}(n) \frac{1}{n} \sin\left(\frac{x}{n}\right). \tag{173}$$

Proposition 20: The functions $\tilde{X}(x)$ and $\tilde{Y}(x)$ are bounded and infinitely differentiable in $(-\infty,+\infty)$.

Proof: We have

$$|\tilde{X}(x)| \leqslant \frac{1}{2\pi} \sum_{n=1}^{\infty} \left| A^{-1}(n) \frac{1}{n} \cos\left(\frac{x}{n}\right) \right| \tag{174}$$

$$\leqslant \frac{1}{2\pi} \sum_{n=1}^{\infty} |A^{-1}(n)| \frac{1}{n}. \tag{175}$$

Therefore the function $\tilde{X}(x)$ is bounded. By Weierstrass M-test, the series (172) converges absolutely and uniformly in $(-\infty,\infty)$. By properties of a uniformly convergent series, the function $\tilde{X}(x)$ is infinitely differentiable.

The case of the function $\tilde{Y}(x)$ is similar.

Definition: The operator $\mathbf{T}(n): L^2(R) \to L^2(R)$ is defined by

$$\mathbf{T}(n) f(x) = f\left(\frac{x}{n}\right), \tag{176}$$

where $f(x) \in L^2(R)$ and n is any positive integer.

Proposition 21:

(1) The operator $\mathbf{T}(n)$ is a bounded linear operator, i.e., $\mathbf{T}(n) \in B(L^2(R))$, and its norm $\|\mathbf{T}(n)\| = \sqrt{n}$.

(2) For any two positive integers m and n, we have

$$\mathbf{T}(m)\mathbf{T}(n) = \mathbf{T}(mn), \tag{177}$$

that is to say $\mathbf{T}(n)$ is completely multiplicative.

Proof: This proposition is clear from the definition. □

Proposition 22: The operator series

$$\mathbf{S} = \sum_{n=1}^{\infty} A(n) \frac{1}{n} \mathbf{T}(n), \tag{178}$$

$$\mathbf{S}^{-1} = \sum_{n=1}^{\infty} A^{-1}(n) \frac{1}{n} \mathbf{T}(n) \tag{179}$$

converge absolutely in the sense of the norm in $B(L^2(R))$, and are mutually inverse.

Proof: Because

$$\sum_{n=1}^{\infty}\left\|A(n)\frac{1}{n}\mathbf{T}(n)\right\|\leqslant\sum_{n=1}^{\infty}|A(n)|\frac{1}{n}\|\mathbf{T}(n)\|=\sum_{n=1}^{\infty}|A(n)|\frac{1}{\sqrt{n}}<\infty, \tag{180}$$

$$\sum_{n=1}^{\infty}\left\|A^{-1}(n)\frac{1}{n}\mathbf{T}(n)\right\|\leqslant\sum_{n=1}^{\infty}|A^{-1}(n)|\frac{1}{n}\|\mathbf{T}(n)\|=\sum_{n=1}^{\infty}|A^{-1}(n)|\frac{1}{\sqrt{n}}<\infty, \tag{181}$$

the two operator series converge absolutely in the sense of the norm in $B(L^2(R)$. Thus $\mathbf{S}$ and $\mathbf{S}^{-1}$ are two bounded linear operators defined on $L^2(R)$, i.e., $\mathbf{S}\in B(L^2(R))$, $\mathbf{S}^{-1}\in B(L^2(R))$.

Furthermore, we have

$$\mathbf{S}\mathbf{S}^{-1}=\mathbf{S}^{-1}\mathbf{S} \tag{182}$$

$$=\sum_{n=1}^{\infty}A(n)\frac{1}{n}\mathbf{T}(n)\sum_{m=1}^{\infty}A^{-1}(m)\frac{1}{m}\mathbf{T}(m) \tag{183}$$

$$=\sum_{k=1}^{\infty}\frac{1}{k}\mathbf{T}(k)\sum_{n|k}A(n)A^{-1}\left(\frac{k}{n}\right) \tag{184}$$

$$=\mathbf{T}(1)=\mathbf{I}, \tag{185}$$

where $\mathbf{I}$ is the identical operator. In other words, the operators $\mathbf{S}$ and $\mathbf{S}^{-1}$ are mutually inverse. □

Proposition 23: For any two functions $f_{\mathrm{even}}(x)$, $C(\omega)\in L^2_{\mathrm{even}}(R)$, we have

$$C(\omega)=(\mathbf{W}_{\mathrm{even}}f_{\mathrm{even}})(\omega)=\int_{-\infty}^{+\infty}f_{\mathrm{even}}(x)\tilde{X}(\omega x)\,dx \tag{186}$$

$$\Leftrightarrow$$

$$f_{\mathrm{even}}(x)=(\mathbf{W}_{\mathrm{even}}^{-1}C)(x)=\int_{-\infty}^{+\infty}C(\omega)X(\omega x)\,d\omega. \tag{187}$$

Here $\mathbf{W}_{\mathrm{even}}:L^2_{\mathrm{even}}(R)\to L^2_{\mathrm{even}}(R)$ is called the transformation based on the even period function $X(x)$, and $\mathbf{W}_{\mathrm{even}}^{-1}:L^2_{\mathrm{even}}(R)\to L^2_{\mathrm{even}}(R)$ is its inverse.

Proof: Let us consider the case ⇒.

First we have

$$\begin{aligned}C(\omega)&=(\mathbf{W}_{\mathrm{even}}f_{\mathrm{even}})(\omega)\\&=\int_{-\infty}^{+\infty}f_{\mathrm{even}}(x)\tilde{X}(\omega x)\,dx\\&=\frac{1}{2\pi}\int_{-\infty}^{+\infty}f_{\mathrm{even}}(x)\sum_{n=1}^{\infty}A^{-1}(n)\frac{1}{n}\cos\left(\frac{x\omega}{n}\right)dx,\\&=\frac{1}{2\pi}\sum_{n=1}^{\infty}A^{-1}(n)\frac{1}{n}\int_{-\infty}^{+\infty}f_{\mathrm{even}}(x)\cos\left(\frac{x\omega}{n}\right)dx\\&=\frac{1}{2\pi}\sum_{n=1}^{\infty}A^{-1}(n)\frac{1}{n}\mathbf{T}_n\int_{-\infty}^{+\infty}f_{\mathrm{even}}(x)\cos(x\omega)\,dx\\&=\frac{1}{\sqrt{2\pi}}\sum_{n=1}^{\infty}A^{-1}(n)\frac{1}{n}\mathbf{T}_n\mathbf{F}_{\cos}f_{\mathrm{even}}(x)=\frac{1}{\sqrt{2\pi}}\mathbf{S}^{-1}\mathbf{F}_{\cos}f_{\mathrm{even}}(x).\end{aligned}$$

In one word, in $L^2_{\text{even}}(R)$ the operator $\mathbf{W}_{\text{even}}$ can be decomposed into two operators:

$$\mathbf{W}_{\text{even}}=\frac{1}{\sqrt{2\pi}}\mathbf{S}^{-1}\mathbf{F}_{\cos}.$$

Since both operators $\mathbf{S}^{-1}$ and $\mathbf{F}_{\cos}$ have inverse operators, the operator $\mathbf{W}_{\text{even}}$ has inverse operator as well:

$$\mathbf{W}^{-1}_{\text{even}}=\sqrt{2\pi}\mathbf{F}^{-1}_{\cos}\mathbf{S}. \tag{188}$$

Since all the operators $\mathbf{S}$, $\mathbf{S}^{-1}$, $\mathbf{F}_{\cos}$, and $\mathbf{F}^{-1}_{\cos}$ are bounded linear operators, so are $\mathbf{W}_{\text{even}}$ and $\mathbf{W}^{-1}_{\text{even}}$, i.e.,

$$\mathbf{W}_{\text{even}},\mathbf{W}^{-1}_{\text{even}}\in B(L^2_{\text{even}}(R)). \tag{189}$$

Therefore we have

$$\begin{aligned}
f_{\text{even}}(x)&=\mathbf{W}^{-1}_{\text{even}}C(\omega)\\
&=\sqrt{2\pi}\mathbf{F}^{-1}_{\cos}\mathbf{S}C(\omega)\\
&=\sqrt{2\pi}\mathbf{F}^{-1}_{\cos}\sum_{n=1}^{\infty}A(n)\frac{1}{n}\mathbf{T}(n)C(\omega)\\
&=\sqrt{2\pi}\mathbf{F}^{-1}_{\cos}\sum_{n=1}^{\infty}A(n)\frac{1}{n}C\left(\frac{\omega}{n}\right)\\
&=\int_{-\infty}^{\infty}\cos(\omega x)\sum_{n=1}^{\infty}A(n)\frac{1}{n}C\left(\frac{\omega}{n}\right)d\omega\\
&=\sum_{n=1}^{\infty}A(n)\frac{1}{n}\int_{-\infty}^{\infty}\cos(\omega x)C\left(\frac{\omega}{n}\right)d\omega\\
&=\sum_{n=1}^{\infty}A(n)\int_{-\infty}^{\infty}\cos(n\omega x)C(\omega)d\omega\\
&=\int_{-\infty}^{\infty}C(\omega)\sum_{n=1}^{\infty}A(n)\cos(n\omega x)d\omega\\
&=\int_{-\infty}^{\infty}C(\omega)X(\omega x)d\omega.
\end{aligned}$$

The case $\Leftarrow$ is similar. This completes the proof.

Similarly, we have the following two propositions.

Proposition 24: The operator series

$$\mathbf{R}=\sum_{n=1}^{\infty}B(n)\frac{1}{n}\mathbf{T}(n), \tag{190}$$

$$\mathbf{R}^{-1}=\sum_{n=1}^{\infty}B^{-1}(n)\frac{1}{n}\mathbf{T}(n) \tag{191}$$

converge absolutely in the sense of the norm in $B(L^2(R))$, and are mutually inverse.

Proposition 25: For any two functions $f_{\text{odd}}(x)$, $D(\omega)\in L^2_{\text{odd}}(R)$, we have

$$D(\omega)=(\mathbf{W}_{\text{odd}}f_{\text{odd}})(\omega)=\int_{-\infty}^{+\infty}f_{\text{odd}}(x)\tilde{Y}(\omega x)dx \tag{192}$$

$$\Leftrightarrow$$

$$f_{\text{odd}}(x)=(\mathbf{W}_{\text{odd}}^{-1}D)(x)=\int_{-\infty}^{+\infty}D(\omega)Y(\omega x)d\omega. \tag{193}$$

where $\mathbf{W}_{\text{odd}}:L^2_{\text{odd}}(R)\to L^2_{\text{odd}}(R)$ denotes the transformation based on odd periodic function $Y(x)$, and $\mathbf{W}_{\text{odd}}^{-1}:L^2_{\text{odd}}(R)\to L^2_{\text{odd}}(R)$ denotes its inverse.

Proposition 26: For any function $f(x)\in L^2(-\infty,+\infty)$, we have

$$f(x)=\int_{-\infty}^{\infty}C(\omega)X(\omega x)+D(\omega)Y(\omega x)d\omega, \tag{194}$$

where

$$C(\omega)=\int_{-\infty}^{\infty}f(x)\tilde{X}(\omega x)dx, \tag{195}$$

$$D(\omega)=\int_{-\infty}^{\infty}f(x)\tilde{Y}(\omega x)dx. \tag{196}$$

Proof: Combining Propositions 23 and 25, we obtain this one easily.

Definition: The two functions $W(x)$ and $\tilde{W}(x)$ are defined on $(-\infty,+\infty)$ by

$$W(x)=X(x)+Y(x), \tag{197}$$

$$\tilde{W}(x)=\tilde{X}(x)+\tilde{Y}(x), \tag{198}$$

Proposition 27: For any two functions $f(x)$, $f'(\omega)\in L^2(-\infty,+\infty)$, we have

$$f'(\omega)=\int_{-\infty}^{+\infty}f(x)\tilde{W}(\omega x)dx \tag{199}$$

$$\Leftrightarrow$$

$$f(x)=\int_{-\infty}^{+\infty}f'(\omega)W(\omega x)d\omega. \tag{200}$$

Proof: Combining Propositions 23 and 25, we obtain this one easily. By the way, this transformation is a generalization of Hartley transformation.[5]

Definition: The two complex-valued functions $Z(x)$ and $\tilde{Z}(x)$ are defined on $(-\infty,+\infty)$ by

$$Z(x)=X(x)+iY(x), \tag{201}$$

$$\tilde{Z}(x)=\tilde{X}-i\tilde{Y}. \tag{202}$$

Proposition 28: For any two functions $f(x)$, $\overline{f(\omega)}\in L^2(-\infty,+\infty)$, we have

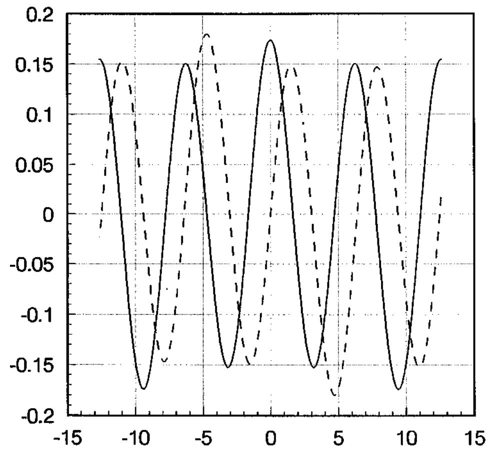

FIG. 4. The dual functions of square waves, $\tilde{X}_{sq}(x)$ and $\tilde{Y}_{sq}(x)$(---).

$$\overline{f(\omega)}=(\mathbf{W}f)(\omega)=\int_{-\infty}^{+\infty}f(x)\tilde{Z}(\omega x)dx \tag{203}$$

$\Leftrightarrow$

$$f(x)=(\mathbf{W}^{-1}\overline{f})(x)=\int_{-\infty}^{+\infty}\overline{f}(\omega)Z(\omega x)d\omega. \tag{204}$$

$\mathbf{W}:L^2(R)\rightarrow L^2(R)$ is called the transformation based on the periodic functions $X(x)$ and $Y(x)$, and $\mathbf{W}^{-1}:L^2(R)\rightarrow L^2(R)$ is its inversion.

Proof: Combining Propositions 23 and 25, we obtain this one easily.

The relation between the transform based on $X(x)$ and $Y(x)$ and Fourier transform of the same function $f(x)\in L^2(R)$ is

$$\overline{f}=C(\omega)-iD(\omega) \tag{205}$$

$$=\frac{1}{\sqrt{2\pi}}\mathbf{S}^{-1}a(\omega)-i\mathbf{R}^{-1}b(\omega) \tag{206}$$

$$=\frac{1}{\sqrt{2\pi}}\sum_{n=1}^{\infty}\left[A(n)^{-1}\frac{1}{n}a\left(\frac{\omega}{n}\right)-iB(n)^{-1}\frac{1}{n}b\left(\frac{\omega}{n}\right)\right], \tag{207}$$

where the even function $a(\omega)$ and the odd function $b(\omega)$ are defined by $f(x)$'s Fourier transform

$$\hat{f}(\omega)=a(\omega)-ib(\omega). \tag{208}$$

The dual functions of square waves, triangular waves, and $\pi/4$ trapezoidal waves are shown in Figs. 4, 5, 6, respectively.

VIII. CONCLUSIONS AND QUESTIONS

From the above discussion, under certain conditions we conclude that a function with period 2π may be expressed as a frequency series of general periodic functions, and that a nonperiodic

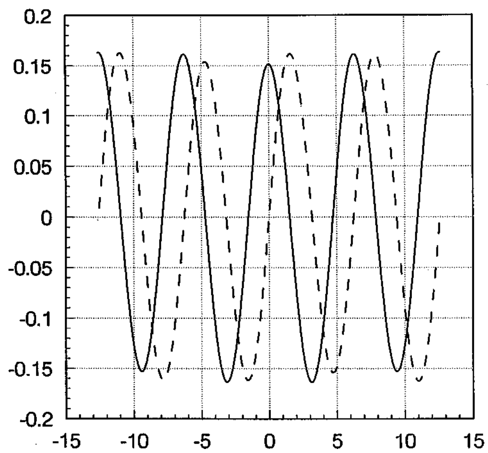

FIG. 5. The dual functions of triangular waves, $\tilde{X}_{\mathrm{tri}}(x)$ and $\tilde{Y}_{\mathrm{tri}}(x)$(---).

function can be expressed as a frequency integral of general periodic functions. This is a new and practical generalization of classical Fourier analysis based on sine–cosine functions.[6] In electronics, we can say in many cases that a signal can be considered as a superposition of easily generated functions with different frequencies. The results in this paper make it possible to represent a signal by use of square waves, triangular waves, and trapezoidal waves. This forms a theoretical foundation for the technique of easily generated function analysis in modern electronics.

However, regarding the frequency analysis based on general periodic functions, there is a lot of work to do.[7] The central questions are:

(1) What is the sufficient and necessary condition for a combinative frequency system $1,\{X(nx),Y(nx)\}_{n=1}^{\infty}$ to be

(1) a complete system;

(2) a basis;

(3) an unconditional basis;

in $L^2[-\pi,\pi]$?

(2) What is the sufficient and necessary condition for a function in $L^2(R)$ to be expressed as a frequency integral (see (194))?

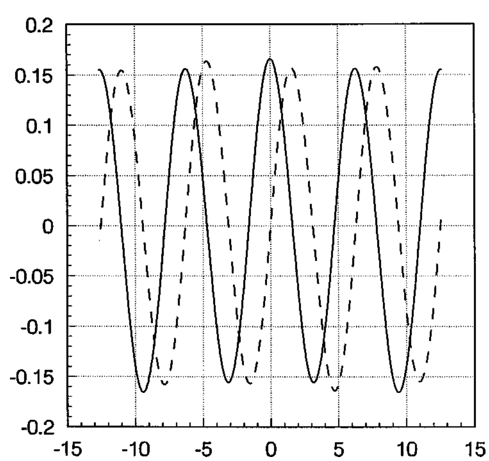

FIG. 6. The dual functions of $\pi/4$ trapezoidal waves, $\tilde{X}_{\pi/4\mathrm{tra}}(x)$ and $\tilde{Y}_{\pi/4\mathrm{tra}}(x)$(---).

Furthermore what about $L^p[-\pi,+\pi]$ and $L^p(R)$ (such as $p=1$) instead of $L^2[-\pi,+\pi]$ and $L^2(R)$?

Obviously these questions are quite challenging ones for mathematicians.

Comment on ''Generalized W_∞ symmetry algebra of the conditionally integrable nonlinear evolution equation'' [J. Math. Phys. 36, 3492 (1995)]

Wen-Xiu Ma[a)]
Department of Mathematics, City University of Hong Kong, Kowloon, Hong Kong, People's Republic of China

(Received 5 August 1997; accepted for publication 15 December 1998)

Two remarks on an inverse operator of a differential operator ∂_x and on symmetries of two kinds of differential equations $\Delta(u)=0$ and $\partial_x\Delta(u)=0$ are pointed out and then a few of remarks about the paper ''Generalized W_∞ symmetry algebra of the conditionally integrable nonlinear evolution equation'' [Y. Lou and J. P. Weng, J. Math. Phys. **36**, 3492 (1995)] are presented. It is in particular shown that if we consider ∂_x^{-1} to be a linear and right inverse operator of ∂_x, the vector fields $\sigma_n^u(f)$ proposed in the above paper are not certain to be symmetries of the Jimbo–Miwa–Kadomtsev–Petviashvili system under consideration. Moreover the commutators of a generalized W_∞ algebra established among these vector fields do not always hold. Therefore the vector fields $\sigma_n^u(f)$ do not provide an example of application of the formal series ansatz in the above paper. © *1999 American Institute of Physics.* [S0022-2488(99)03606-3]

I. INTRODUCTION

It is interesting to construct a kind of symmetries involving an arbitrary function of certain independent variable for nonlinear integrable equations. They often constitute a class of generalized W_∞ algebra

$$[\sigma_m^u(f_1),\sigma_n^u(f_2)]=\alpha\sigma_{m+n-l}^u((m+\beta)f_1f_{2t}-(n+\beta)f_{1t}f_2), \tag{1}$$

where l is a natural number, α, β are two arbitrary constants, and we assume that an involved specific independent variable is the time variable t. Some typical examples have been considered, including the Kadomtsev–Petviashvili equation,[1] the Davey–Stewartson equation,[2] the Hirota's bilinear equations,[3] and three-wave resonant interaction system,[4] etc.

Recently Lou and Weng considered the above-mentioned generalized W_∞ symmetry algebras for conditionally integrable nonlinear equations.[5] They took the Jimbo–Miwa–Kadomtsev–Petviashvili (JMKP) system of equations (see Ref. 6 for more information about the JMKP system) as an illustrative example. This system is a combination of the so-called Jimbo–Miwa equation and the Kadomtsev–Petviashvili equation:

$$\begin{aligned}K_0(u)&=u_{xxxy}+3(uu_y)_x+3u_{xx}\partial_x^{-1}u_y+3u_xu_y+2u_{yt}-3u_{xz}=0,\\ K_1(u)&=(u_{xxx}+6uu_x)_x+3u_{yy}-4u_{xt}=0.\end{aligned} \tag{2}$$

For the JMKP system (2), Lou and Weng[5] proposed a hierarchy of symmetries $\sigma_n^u(f)$ involving an arbitrary function $f=f(z)$ defined by:

$$\sigma_n^u(f)=\partial_x\sigma_n^w(f)|_{u=w_x},\quad n\geqslant 0, \tag{3}$$

[a)]Electronic mail: mawx@math.cityu.edu.hk

$$\sigma_n^w(f)=\frac{A_n}{n!}\sum_{k=0}^{n+1} f^{(n+1-k)}(z)\big(\tfrac{1}{3}\partial_x^2\partial_y+\partial_x^{-1}w_x\partial_x\partial_y+\partial_x^{-1}w_{xy}\partial_x+\partial_x^{-1}w_{xx}\partial_y$$
$$+\partial_x^{-1}w_y\partial_x^2+\tfrac{2}{3}\partial_x^{-1}\partial_y\partial_t-\partial_z\big)^k(yt^n)\big|_{H_0=0,H_1=0},\quad n\geqslant 0, \tag{4}$$

where A_n are constants and $f^{(i)}(z)=(\partial_z)^i f(z),\ i\geqslant 0$, and they pointed out that these symmetries constituted a generalized W_∞ algebra:

$$[\sigma_m^u(f_1),\sigma_n^u(f_2)]=\tfrac{1}{4}\sigma_{m+n-3}^u((m+1)f_1\dot{f}_2-(n+1)f_2\dot{f}_1), \tag{5}$$

where $\dot{f}_i=\partial_z f_i,\ i=1,2$. The vector fields $\sigma_n^w(f)$ defined by (4) are also regarded as symmetries of the following potential JMKP system

$$H_0=H_0(w)=w_{xz}-\tfrac{1}{3}w_{xxxy}-w_{xy}w_x-w_yw_{xx}-\tfrac{2}{3}w_{yt}=0,$$
$$H_1=H_1(w)=w_{xxxx}+6w_xw_{xx}+3w_{yy}-4w_{xt}=0, \tag{6}$$

which is a starting point to construct the symmetries $\sigma_n^u(f)$ of the JMKP system (2).

In this comment, we intend to provide two remarks on an inverse operator of a differential operator ∂_x and on relations between symmetries of two kinds of differential equations $\Delta(u)=0$ and $\partial_x\Delta(u)=0$, and then a couple of remarks about Lou and Weng's work in Ref. 5 It is shown that if we consider the inverse operator ∂_x^{-1} to be a linear operator and a right inverse operator of ∂_x, the vector fields $\sigma_n^u(f)$ and $\sigma_n^w(f)$ defined by (3) and (4) are not certain to be symmetries of the JMKP system (2) and the potential JMKP system (6), respectively, whatever boundary condition is imposed on the potential u. Moreover it is verified that the symmetry algebra defined by (5) does not always hold, and that a symmetry relation

$$\sigma^u(f)=\partial_x\sigma^w(f)\big|_{u=w_x} \tag{7}$$

is not always correct between the systems (2) and (6), although the system (6) may be generated from the system (2) after setting $u=w_x$. Only additional natural conditions $\partial_y\partial_x^{-1}=\partial_x^{-1}\partial_y$, $\partial_t\partial_x^{-1}=\partial_x^{-1}\partial_t$ and $\partial_z\partial_x^{-1}=\partial_x^{-1}\partial_z$ are needed in proving our above statements. Therefore the vector fields $\sigma_n^u(f)$ do not provide an example of application of the formal series ansatz in Ref. 5.

II. TWO OBSERVATIONS

Observation 1: Let us first make a remark on definitions of an inverse operator of ∂_x, where x is a coordinate of $\mathbb{R}^n$. Since we have a nonempty kernel of ∂_x, we cannot make any definition of an inverse operator ∂_x^{-1} such that the inverse operator ∂_x^{-1} maps $C^\infty(\mathbb{R}^n)$ into $C^\infty(\mathbb{R}^n)$ and satisfies the conditions of $\partial_x^{-1}\partial_x=\partial_x\partial_x^{-1}=1$, the most natural left and right inverse conditions on an inverse operator ∂_x^{-1}. However we can take a quotient space of the space $C^\infty(\mathbb{R}^n)$ under $\ker(\partial_x)$ as a new domain of definition of ∂_x. If we view the differential operator ∂_x as a mapping from the quotient space to the same quotient space, $\partial_x:[f]\mapsto[\partial_x f]$, where

$$[f]=\{g\in C^\infty(\mathbb{R}^n)\,|\,\partial_x g=\partial_x f\},$$

the operator ∂_x is still not injective and thus an inverse operator of ∂_x will not be well defined over the whole quotient space. In order to obtain one-to-one correspondence of ∂_x, we can make the following:

$$\partial_x:C^\infty(\mathbb{R}^n)/\ker(\partial_x)\to C^\infty(\mathbb{R}^n),\quad [f]\mapsto\partial_x f; \tag{8}$$

$$\partial_x^{-1}: C^\infty(\mathbb{R}^n) \to C^\infty(\mathbb{R}^n)/\ker(\partial_x), \quad f \mapsto \left[\int_0^x f(\cdots, x', \cdots) dx' \right]. \tag{9}$$

This definition satisfies the left and right inverse conditions: $\partial_x^{-1}\partial_x = \partial_x\partial_x^{-1} = 1$. But over the quotient space, we cannot keep the same differential operation ∂_x: $\partial_x(fg) = \partial_x(f)g + f\partial_x(g)$. This is to say, the equality

$$\partial_x([f][g]) = (\partial_x f)[g] + [f](\partial_x g) = \partial_x[h],$$

where $[f][g] = [h]$ is a multiplication on $C^\infty(\mathbb{R}^n)/\ker(\partial_x)$, will make no sense. There is an unavoidable problem: how to define $[f][g] = [h]$, $f[g]$ and $[f]g$ such that $(\partial_x f)[g] + [f](\partial_x g)$ is the same function as $\partial_x h (= \partial_x[h])$.

Nevertheless we can define a left and right inverse operator of ∂_x from some subspace of $C^\infty(\mathbb{R}^n)$ to the same subspace, or a right inverse operator of ∂_x from the whole space of smooth functions to the same whole space of smooth functions, and the differential operation ∂_x does not need to be changed over function spaces. In Sec. III, we use the latter definition to explain some problems because the former definition is not suitable for our discussion.

Observation 2: Let us secondly make a remark on symmetries of two kinds of systems of differential equations. Differentiating a given system of differential equations $\Delta(u, u_x, \ldots) = 0$ with respect to x leads to the system of differential equations $\partial_x\Delta(u, u_x, \ldots) = 0$. We call it a derivative system of the original system. For their symmetry algebras, we can have the following result.

Two symmetry algebras of the systems of differential equations $\Delta(u, u_x, \ldots) = 0$ *and* $\partial_x\Delta(u, u_x, \cdots) = 0$ *are not certain to be the same.*

Let us take a scalar equation $u_t = u_x$ as an illustrative example to show the above statement. This moment, the derivative equation reads as $u_{tx} = u_{xx}$. We choose a symmetry $\sigma(u) = u^2$ of the equation $u_t = u_x$. A direct computation gives rise to

$$\sigma_{tx} - \sigma_{xx} = (u^2)_{tx} - (u^2)_{xx} = 2u(u_{tx} - u_{xx}) + 2u_x(u_t - u_x).$$

This does not equal to zero if we choose a solution $u(x,t) = e^{x+t} + e^t$ to the derivative equation $u_{tx} = u_{xx}$. Therefore u^2 is not a symmetry of the derivative equation $u_{tx} = u_{xx}$.

On the other hand, we choose a symmetry $\sigma(u) = u_x + e^t$ of the derivative equation $u_{tx} = u_{xx}$. But the $\sigma(u) = u_x + e^t$ does not satisfy the linearized equation of the equation $u_t = u_x$ and thus it is not a symmetry of the equation $u_t = u_x$. Therefore it follows that the above statement is true.

III. COUNTEREXAMPLES

Let us now turn to discussion on the results in Lou and Weng's work of Ref. 5. We claim the conditions on ∂_x^{-1}:

$$\begin{gathered} \partial_x^{-1}: C^\infty(\mathbb{R}^4) \to C^\infty(\mathbb{R}^4) \ \text{being linear}, \ \partial_x\partial_x^{-1} = 1, \\ \partial_y\partial_x^{-1} = \partial_x^{-1}\partial_y, \partial_t\partial_x^{-1} = \partial_x^{-1}\partial_t, \ \partial_z\partial_x^{-1} = \partial_x^{-1}\partial_z, \end{gathered} \tag{10}$$

which may be achieved, for example, by defining

$$(\partial_x^{-1} f)(x,y,t,z) = \int_0^x f(x', y, t, z) dx'. \tag{11}$$

Note that we have $\partial_x^{-1} 0 = 0$, since ∂_x^{-1} is a linear mapping.

What we would like to show now is that under the definition of (10) for ∂_x^{-1}, both the vector fields given in Ref. 5,

$$\sigma_0^u(f)=fu_x \quad \text{with} \quad \dot{f}=\partial_z f\neq 0, \tag{12}$$

$$\sigma_u^4(1)=2u_{xxt}+4\partial_x^{-1}u_{tt}+3u_{xyy}+3\partial_x^{-1}u_{yz}+6u_x\partial_x^{-1}u_t+6uu_t \\ +12u_y\partial_x^{-1}u_y+3u_x\partial_x^{-2}u_{yy}+3u\partial_x^{-1}u_{yy}, \tag{13}$$

are not symmetries of the JMKP system (2). Actually from the JMKP system (2) itself, we easily find its linearized system:

$$K_0'(u)[\sigma]:=\sigma_{xxxy}+3(u\sigma_y+\sigma u_y)_x+3\sigma_{xx}\partial_x^{-1}u_y+3u_{xx}\partial_x^{-1}\sigma_y+3\sigma_x u_y+3u_x\sigma_y+2\sigma_{yt}-3\sigma_{xz}=0, \\ K_1'(u)[\sigma]:=(\sigma_{xxx}+6u\sigma_x+6\sigma u_x)_x+3\sigma_{yy}-4\sigma_{xt}=0. \tag{14}$$

The substitution of the vector field (12) into the expression of $K_0'(u)[\sigma]$ in the first equation of (14) leads to

$$K_0'(u)[\sigma_0^u(f)]=f\partial_x K_0(u)+3fu_{xx}\partial_x^{-1}u_{xy}-3fu_{xx}u_y-3\dot{f}u_{xx}. \tag{15}$$

Choose a solution $v(x,t)=2\ \mathrm{sech}^2(x+t)$ to the Korteweg–de Vries equation

$$v_t=\tfrac{1}{4}v_{xxx}+\tfrac{6}{4}vv_x. \tag{16}$$

This moment, $v_{xx}\neq 0$ and v_{xx} has and only has two zero points. The function $u(x,y,t,z)=v(x,t)$ is a solution to the JMKP system (2), and hence from (15) we have

$$(K_0'(u)[\sigma_0^u(f)])|_{u=v}=-3\dot{f}v_{xx}\neq 0, \tag{17}$$

noticing that $\partial_x^{-1}0=0$. This implies that $\sigma_0^u(f)$ is not a symmetry while $\dot{f}\neq 0$.

Let us now choose a solution $u(x,y,t,z)=g(t,z)$ where g is an arbitrary function satisfying $\dot{g}_{tt}=\partial_z g_{tt}\neq 0$. This moment, we have

$$\begin{aligned}(K_0'(u)[\sigma_4^u(1)])|_{u=g}&=(K_0'(u)[4\partial_x^{-1}g_{tt}+6gg_t])|_{u=g}\\&=(2\partial_y\partial_t-3\partial_x\partial_z)(4\partial_x^{-1}g_{tt}+6gg_t)\\&=8\partial_y\partial_t\partial_x^{-1}g_{tt}-12\dot{g}_{tt}\\&=8\partial_t\partial_x^{-1}\partial_y g_{tt}-12\dot{g}_{tt}=-12\dot{g}_{tt}\neq 0,\end{aligned} \tag{18}$$

which shows that $\sigma_4^u(1)$ is not a symmetry of the JMKP system (2), either.

Moreover, we can show that the vector field given in Ref. 5,

$$\sigma_4^w(1)=2w_{xxt}+4\partial_x^{-1}w_{tt}+3w_{xyy}+3\partial_x^{-1}w_{yz}+6w_xw_t+6w_y^2+3w_x\partial_x^{-1}w_{yy},$$

is itself not a symmetry of the potential JMKP system (6) at all. This is obvious by observing that

$$\sigma_4^w(1)|_{w=g(t,z)}=4\partial_x^{-1}g_{tt}, \quad (H_0'(w)[\sigma_4^w(1)])|_{w=g(t,z)}=4\dot{g}_{tt}, \tag{19}$$

where an arbitrary function $g=g(t,z)$ is always a solution to the potential JMKP system (6). It also implies that the formal series does not truncate in this case.

We point out that the explicit expressions for $\sigma_n^u(f)$ and $\sigma_n^w(f)$ for $0\leqslant n\leqslant 4$ in Ref. 5 may not be generated from the general formulas (3) and (4), if we view the involved inverse operator ∂_x^{-1} as a normal inverse operator, for example, as in (11). Nevertheless they satisfy the recursion relation [see (11) in Ref. 5] in the formal series ansatz, which is one of two conditions for a formal series to be a symmetry (the other is that the series must truncate). This implies that they can be generated from the formulas (3) and (4) but we have to choose a special integration constant for ∂_x^{-1} each time.

Next, we want to verify that the commutator relation (5) is not always correct for $m+n\geqslant 3$, besides its being incomplete due to making no sense for $m+n<3$. For example, we can work out

$$[\sigma_0^u(f),\sigma_4^u(1)]|_{u=g(t,z)}=0 \tag{20}$$

and can further find that

$$[\sigma_0^u(f),\sigma_4^u(1)]\neq \tfrac{1}{4}\sigma_1^u(-5\dot{f}), \tag{21}$$

in virtue of the quantities

$$\tfrac{1}{4}\sigma_1^u(-5\dot{f})=-\tfrac{5}{4}\dot{f}u_y-\tfrac{15}{16}\ddot{f}(tu_x+\tfrac{2}{3}),\quad \tfrac{1}{4}\sigma_1^u(-5\dot{f})|_{u=g(t,z)}=-\tfrac{5}{8}\ddot{f},$$

where $\ddot{f}=(\partial_z)^2 f$. Hence two sides of (21) cannot be balanced. This implies that our statement is true.

In addition, the vector field

$$\sigma_0^w(f)=fw_x+y\dot{f}$$

is always a symmetry of (6) for any f. Therefore we see that the relation (7), i.e., $\sigma^u(f)=\partial_x\sigma^w(f)|_{u=w_x}$, between symmetries of the JMKP system (2) and the potential JMKP system (6) is not appropriate. The reason is that the system (6) is generated from the system (2) through not only a Miura transformation $u=w_x$, but also an integration of x and an application of the left inverse condition $\partial_x^{-1}\partial_x=1$ (which actually could not be imposed). Let us now recall the second observation in Sec. II and the nonexistence of a left and right inverse linear operator ∂_x^{-1} on the whole space of smooth functions $C^\infty(\mathbb{R}^n)$. Therefore we cannot obtain the relation $\sigma^u(f)=\partial_x\sigma^w(f)|_{u=w_x}$ between symmetries of the JMKP system (2) and the potential JMKP system (6).

What we can get under $u=w_x$ is that if σ^w is a symmetry of the derivative potential JMKP system $\partial_x H_0(w)=0$ and $\partial_x H_1(w)=0$, where H_0 and H_1 are defined by (6), then $\sigma^u=\sigma^w|_{u=w_x}$ is a symmetry of the JMKP system (2). In the work of Ref. 5, the authors mix up two systems of the potential JMKP system and the derivative potential JMKP system above, which actually have different symmetry algebras in view of the second observation in Sec. II. The similar confusion appeared in the discussion of symmetries of the Kadomtsev–Petviashvili equation in Ref. 7.

IV. DISCUSSIONS

We remark that the JMKP system (2) is not a system of evolution equations with an evolution variable z, and so is not the potential JMKP system (6), either. For an evolution equation or a system of evolution equations: $u_t=K(x,u)$, which does not depend explicitly on the evolution variable t, a kind of more general symmetry algebras than Virasoro symmetry algebras has been considered in Ref. 8. However it has also been shown[9] that any Laurent polynomial time-dependent symmetry of $u_t=K(x,u)$ has to be of polynomial time-dependent form. Therefore for $u_t=K(x,u)$, there does not exist any symmetry of the following form:

$$\sigma(f)=\sum_{i=0}^{N}\frac{\partial^{N-i}f(t)}{\partial t^{N-i}}S_i(x,u),$$

where f is an arbitrary function of the time variable but $S_i(x,u)$, $0\leqslant i\leqslant N$, do not depend explicitly upon the time variable except the space variables. If we consider a t variable-coefficient system of evolution equations: $u_t=K(t,x,u)$, there appears a different situation.[10,11] For example, there exist Laurent polynomial time-dependent symmetries and much higher-degree polynomial time-dependent symmetries, even for a system of evolution equations in $1+1$ dimensions.[10,11]

One might ask whether or not the vector fields defined by (3) and (4) could become symmetries of the corresponding systems, under other conditions on ∂_x^{-1}. The answer is still no. Actually our conditions (10) on ∂_x^{-1} are the best possible set of conditions which gives a well-defined inverse operator of ∂_x. If we consider ∂_x^{-1} to be an indefinite integration operator as in Ref. 5, i.e., $\partial_x^{-1}: f \mapsto [\int_0^x f(\ldots,x',\ldots)dx']$ by using the notation in Sec. II, then we will meet some unsolvable difficulties in keeping reasonable differential operations as specified in Sec. II. But it is essential to keep differential operations when we make computation about, for example, Lie–Bäcklund symmetries. Therefore strictly speaking, there is no possibility which gives a definition of ∂_x^{-1} being an indefinite integration operation while discussing symmetries. Nevertheless one might disregard differential operations such as $\partial_x(fg)=\partial_x(f)g+f\partial_x(g)$ in order to view ∂_x^{-1} as an indefinite integration operation. But the vector fields defined by (3) and (4) are still not able to become symmetries of the corresponding systems, because our counterexamples can hold if the integration constants are chosen to be zero, one of all choices of integration constants. However one can even require some special integration constants to be introduced such that the symmetry conditions are satisfied. If so, there are at least two problems which cannot be solved. The first problem is that the vector fields involving ∂_x^{-1} are not already well defined, since the integration constants have not been chosen before checking symmetry conditions. The second problem is that the integration constants selected in this way will most likely depend on solutions of the original systems, because the symmetry conditions always contain solutions. Thus the symmetry vector fields themselves will sometimes be determined only after solutions of the original systems are given. This causes the symmetry vector fields not to be well defined. For the case of the JMKP and the potential JMKP systems, the vector fields defined by (3) and (4) are exactly such examples, if ∂_x^{-1} is viewed as an indefinite integration operator. There are some other similar situations, e.g., the situation of the modified KP equation, which is pointed out in Ref. 12.

In conclusion, what we have pointed out so far is that the vector fields defined by (3) and (4) cannot always become symmetries of the corresponding systems in any possible sense of ∂_x^{-1}. We are in doubt that such formal series as defined by (3) and (4) could become Lie–Bäcklund symmetries (except Lie-point symmetries) of differential equations. At least for evolution equations not explicitly depending on the evolution variable, there must be no such kind of symmetries, in Lie-point form or Lie–Bäcklund form, involving an arbitrary function of the evolution variable (see Ref. 9).

(Received 24 October 1998; accepted for publication 15 December 1998)

To verify the correctness of the high order symmetries for the Jimbo–Miwa–Kadomtsev–Petviashvilli system (JMKP) and the potential JMKP (PJMKP) system given in our paper [J. Math. Phys. **36**, 3492–3497 (1995)], Ma's definition of ∂_x^{-1} may be used only for the general *nonkernel* solutions of the models. For some types of special solutions which are the kernels of some differential operators, one has to use ∂_x^{-1} as the indefinite operator and selected the integral functions appropriately. [S0022-2488(99)01207-4]

In Ref. 1, the author tries to solve the ∂_x^{-1} problem and give some remarks on Lou and Weng's paper.[2] However, the main results of the paper are not correct or not self-consistent.

(i) On one hand, the author claims that it is sufficient to define a right inverse of ∂_x and

$$\begin{cases} \partial_x^{-1}: C^\infty(\|\mathbb{R}^4) \to C^\infty(\|\mathbb{R}^4) \ \text{ being linear, } \ \partial_x\partial_x^{-1} = -1, \\ \partial_y\partial_x^{-1} = \partial_x^{-1}\partial_y, \ \ \partial_y\partial_x^{-1} = \partial_x^{-1}\partial_y, \ \ \partial_y\partial_x^{-1} = \partial_x^{-1}\partial_y, \end{cases} \tag{1}$$

is the only condition on the operator ∂_x^{-1} and

$$\partial_x^{-1} 0 = 0. \tag{2}$$

On the other hand, all the results of the paper are illustrated by taking the solutions as some special forms which are the kernels of the differential operators (∂_x, ∂_y, ∂_z and ∂_ξ, $\xi = x + t$). It is impossible to obtain these solutions if one uses (2) and (1) only though they are really solutions.

(ii) $\sigma_4^w(1)$ and $\sigma_4^u(1)$ are really symmetries of the PJMKP and JMKP, respectively. If one uses Ma's definition of the operator to check the correctness of $\sigma_4^w(1)$ and $\sigma_4^u(1)$, one must take w and u being general *nonkernel* solutions of the PJMKP and JMKP systems. We do check the conclusion both by hand and by computer algebras. Because it is too long to write the detail verification procedures down here, I suggest the readers who are interested in this problem to check the conclusions by using some nontrivial (nonkernel) solutions, say, general multisoliton solutions. The single plane soliton solutions read

$$w = 2k_1 \tanh\left(k_1 x + k_2 y + \frac{1}{2}\,\frac{k_2(4k_1^4 + k_2^2)}{k_1^2} z + \frac{1}{4}\,\frac{4k_1^4 + 3a_2^2}{k_1} t \right) \tag{3}$$

[a)]Electronic mail: sylou@public.nbptt.zj.cn

for potential JMKP and

$$u=2k_1^2\ \mathrm{sech}^2\left(k_1x+k_2y+\frac{1}{2}\frac{k_2(4k_1^4+k_2^2)}{k_1^2}z+\frac{1}{4}\frac{4k_1^4+3a_2^2}{k_1}t\right) \tag{4}$$

for JMKP. The corresponding $\sigma_4^w(1)$ and $\sigma_4^u(1)$ read

$$\sigma_4^w(1)=\frac{3}{2}\frac{16k_1^8+40k_1^4k_2^2+5k_2^4}{k_1^2}\ \mathrm{sech}^2\left(k_1x+k_2y+\frac{1}{2}\frac{k_2(4k_1^4+k_2^2)}{k_1^2}z+\frac{1}{4}\frac{4k_1^4+3a_2^2}{k_1}t\right), \tag{5}$$

$$\sigma_4^u(1)=-3\frac{16k_1^8+40k_1^4k_2^2+5k_2^4}{k_1}\ \mathrm{sech}^2\left(k_1x+k_2y+\frac{1}{2}\frac{k_2(4k_1^4+k_2^2)}{k_1^2}z+\frac{1}{4}\frac{4k_1^4+3a_2^2}{k_1}t\right)$$
$$\times\tanh\left(k_1x+k_2y+\frac{1}{2}\frac{k_2(4k_1^4+k_2^2)}{k_1^2}z+\frac{1}{4}\frac{4k_1^4+3a_2^2}{k_1}t\right). \tag{6}$$

The general multisoliton solutions of the models can be found in literature, say, in Ref. 3.

(iii) The explanation of the observation 2 in Ref. 1 is not correct. It is known that if two equations $F(u)=0$ and $G(v)=0$ are related by a Bäcklund transformation $B(u,v)=0$, then the symmetries of two equations are related by $B_u'\sigma^u+B_v'\sigma^v=0$. The author uses $u_t=u_x$ and $v_{tx}=v_{xx}$ as a simple illustrative example (the author used the same notation for two equation). The solutions of these two equations may be related in two ways. (1) $v=u+f(t)$ for arbitrary $f(t)$ that means if σ^u is a symmetry of $u_t=u_x$ then it must also be a symmetry of $v_{tx}=v_{xx}$. The author's special example is $\sigma^u=u^2$. So u^2 (but not v^2!!) must also be a symmetry of $v_{tx}=v_{xx}$. (2) $u=v_x$ that means if σ^v is a symmetry of $v_{tx}=v_{xx}$, then $\sigma^u=\sigma_x^v$ must be a symmetry of the u equation. The author's confusion comes from his using the same notations of u and v.

(iv) If one uses the trivial (kernel) solutions as a special examples and the authors' definition of ∂_x, many important traditional conclusions related to symmetries and Bäcklund transformations will be destroyed. Say, in the proof procedures of the hereditary property of the recursion operators of (1+1)-dimensional integrable models, one has to use the condition, $u(x\to\infty,t)=0$, which is not valid for u is selected as a special kernel of differential operators.[4]

In summary, to verify the correctness of the high order symmetries for the JMKP and the PJMKP system Ma's definition of ∂_x^{-1} may be used only for the general *nonkernel* solutions of the models. For some types of special solutions which are the kernels of some differential operators, one has to use ∂_x^{-1} as an indefinite operator and selected the integral functions appropriately.

This note is a comment on the mathematical aspects of the paper by Mostafazadeh [J. Math. Phys. **37**, 1218 (1996)]. Its aim is to remove some of the ambiguities and mistakes of the paper by making more transparent the mathematics involved in the calculation of topological charges.
[S0022-2488(99)03406-4]

I. INTRODUCTION

In his paper,[1] Mostafazadeh discusses at length the relevance of the Borel–Weil–Bott theorem to Berry–Simon theory[2] and computations involving Chern classes as well as generators for the second de Rham cohomology of flag manifolds. However, there are some conceptual errors in the paper which may be a hindrance to a proper understanding. For example, on p. 1226 (line 2) of Ref. 1, one finds the statement that a flag manifold K/L of a compact Lie group K is a submanifold of K/T, T being a maximal torus of K, which is not true as both are homogeneous spaces of the same group K. At the infinitesimal level, i.e., the level of tangent spaces, the above statement holds. However, as a vector space has no topology, one must work directly with the manifold if one wants to compute Chern numbers. Also, the Chern number for the determinant bundle of $\mathbb{CP}^N$ is calculated to be 2 whereas it is $(N+1)$. In this note we rectify these mistakes. As the concepts relating to Chern numbers and their actual computations are important for physics, it is desirable to explain them in a clearer and more rigorous manner. We do this in Secs. II and III. We review two key examples in detail; later we give the precise statements in the most general form, omitting all proofs, and refer instead to the literature. All of this goes back essentially to Borel–Hirzebruch.[3]

II. TWO BASIC METHODS FOR OBTAINING GENERATORS OF COHOMOLOGY

The following examples illustrate two basic methods for obtaining cohomology generators:

(I) Let M be a complex manifold, $\{U_i\}_{i\in I}$ an open covering of M and $f_i: U_i \Rightarrow \mathbb{C}$ holomorphic functions such that on the intersection $U_{ij}=U_i\cap U_j$, $g_{ij}=f_i/f_j$ is nonzero. The system of functions defines a line bundle $\mathcal{L}$ on M,[4] namely, we identify $(p,z)\in U_i\times\mathbb{C}$ with $(q,w)\in U_j\times\mathbb{C}$ if and only if $p=q$ and $w=g_{ji}(p)z$. The functions $\{f_i\}$ represent a section σ, called the canonical section, of this bundle.[4] A norm on this bundle is given by a family of functions

$$\varphi_i : U_i \rightarrow \mathbb{R}^{>0}$$

such that on $U_i\cap U_j$, we have

$$\varphi_i/\varphi_j = |g_{ji}|.$$

The form

$$C(\mathcal{L})=\frac{i}{2\pi}\partial\overline{\partial}\log[N(\sigma)^{-2}]=\frac{i}{2\pi}\sum_{\alpha,\beta}\frac{\partial^2}{\partial z_\alpha\partial\overline{z}_\beta}[\log N(\sigma)]^{-2}dz_\alpha\wedge d\overline{z_\beta}$$

represents the Chern class of $\mathcal{L}$.

A standard way of obtaining line bundles is by using the functions which define a submanifold of codimension 1. For example, consider complex projective space $\mathbb{P}^1(\mathbb{C})$ with homogeneous coordinates $[z_0:z_1]$. Let $U_0=\{[z_0:z_1]:z_0\neq 0\}$, $U_1=\{[z_0:z_1]:z_1\neq 0\}$. Let $p=[0:1]$. To the point p there correspond the functions $f_0=1$ on U_0 and $f_1=z_0/z_1$ on U_1, so $g_{ij}=(z_j/z_i)$ $(i,j=0,1)$ and the norm of the canonical section σ represented by the functions $\{f_0,f_1\}$ is $\|\sigma\|=|z_0|/|z|$. So

$$C(\mathcal{L})=\frac{i}{2\pi}\partial\overline{\partial}\log\frac{|z|^2}{|z_0|^2}=\frac{i}{2\pi}\partial\overline{\partial}\log\left(1+\left|\frac{z_1}{z_0}\right|^2\right).$$

It represents a generator of $H^2(\mathbb{P}^1,\mathbb{Z})$. All generators of $H^2(M,\mathbb{Z})$, M a flag manifold—we define this term in Sec. III—are obtained in an analogous manner.

(II) Another way of obtaining generators of cohomology uses representation theory of groups. It is illustrated by the following example.

Consider the flag manifold

$$F_{1,2}=\{(\ell,\pi):\ell\subset\pi,\quad \ell \text{ and } \pi \text{ being lines and planes in } \mathbb{C}^3 \text{ passing through the origin}\}.$$

Let e_0,e_1,e_2 be the standard basis of $\mathbb{C}^3$, let $\ell_0=\mathbb{C}e_0$, $\pi_0=\mathbb{C}\langle e_0,e_1\rangle$, and $\xi_0=(\ell_0,\pi_0)$. So $F_{1,2}$ is the orbit of ξ_0 under the natural action of SL(3,$\mathbb{C}$). The stabilizer of ξ_0 in $G=\mathrm{SL}(3,\mathbb{C})$ is the group B of upper triangular matrices, so $G/B\cong G\cdot\xi_0=F_{1,2}$.

Now the basic representations of SL(3,$\mathbb{C}$) are $\mathbb{C}^3=V$ and $\wedge^2(V)$ and their highest weight vectors (i.e., those lines which are B invariant) are v_1 and $v_1\wedge v_2$, where $v_1=(1,0,0)^T$, $v_2=(0,1,0)^T$, T being the transpose. Consider the forms $\overline{\omega_\alpha}$ and $\overline{\omega_\beta}$ on G defined by

$$\overline{\omega_\alpha}=i\partial\overline{\partial}\log\|g\cdot v_1\|,$$

$$\overline{\omega_\beta}=i\partial\overline{\partial}\log\|g\cdot(v_1\wedge v_2)\|.$$

Let $\pi:G\to G/B=F_{1,2}$ be the natural map. The forms $\overline{\omega_\alpha},\overline{\omega_\beta}$ descend to forms ω_α and ω_β on $F_{1,2}$ in the sense that $\pi^*\omega_\alpha=\overline{\omega_\alpha}$, $\pi^*\omega_\beta=\overline{\omega_\beta}$. These forms generate $H^2(G/B,\mathbb{R})$ and the projective lines dual to these forms have the following explicit description.

Let

$$L_\alpha=\left\langle\begin{pmatrix}x & y & 0\\ z & t & 0\\ 0 & 0 & 1\end{pmatrix}:\begin{pmatrix}x & y\\ z & t\end{pmatrix}\in\mathrm{SL}(2,\mathbb{C})\right\rangle,$$

$$L_\beta=\left\langle\begin{pmatrix}1 & 0 & 0\\ 0 & x & y\\ 0 & z & t\end{pmatrix}:\begin{pmatrix}x & y\\ z & t\end{pmatrix}\in\mathrm{SL}(2,\mathbb{C})\right\rangle.$$

We have $\mathbb{P}_\alpha=L_\alpha$, $\xi_0\cong\mathbb{P}^1(\mathbb{C})$ and $\mathbb{P}_\beta=L_\beta\cdot\xi_0\cong\mathbb{P}^1(\mathbb{C})$ and moreover $\int_{\mathbb{P}_\beta}\omega_\alpha=\delta_{\alpha_\beta}$: see Ref. 5.

III. FLAG MANIFOLDS AND THEIR COHOMOLOGY: TOPOLOGICAL CHARGES

Let G be a complex semisimple Lie group and B a Borel subgroup of G; so B is a maximal connected solvable subgroup of G. A homogeneous space of the form G/P, where the group $P\supset B$, is a flag manifold. These are precisely those complex compact homogeneous spaces which are simply connected and are embeddable in some projective space.

In this section, we give a precise description of the second de Rham cohomology of flag manifolds and give a formula for the Chern class of line bundles on flag manifolds; this formula involves the so-called *topological charges* associated to line bundles. The results are due originally to Borel–Hirzebruch.[3] We will just state the results, as all the proofs are in Ref. 3; they are also given, from a different point of view, in Ref. 5. We assume familiarity with the theory of weights and roots as set forth in Refs. 6 and 7.

Let G be a complex reductive group, B a Borel subgroup of G,T a maximal torus of G contained in B,R the roots of T in G, R^+ the positive system of roots defined by the pair (B,T), and S the corresponding system of simple roots.

One knows that for each $\alpha\in\mathbb{R}^+$ there exist $X_\alpha, X_{-\alpha}\in \mathrm{Lie}(G)$ such that the map

$$\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}\mapsto X_\alpha, \quad \begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}\mapsto X_{-\alpha}$$

extends to an isomorphism of $\mathrm{SL}(2,\mathbb{C})$ onto the Lie algebra generated by $X_\alpha, X_{-\alpha}$. Hence there exists a homomorphism φ_α from $\mathrm{SL}(2,\mathbb{C})$ onto a subgroup L_α of G whose Lie algebra is generated by $X_\alpha, X_{-\alpha}$.

The group K generated by $\varphi_\alpha(\mathrm{SU}(2))$ (α simple) is a maximal compact subgroup of G. Let $\pi\subset S$ and $P_\pi = P$ be the corresponding parabolic subgroup. So P_π is generated by B and $L_\alpha(\alpha\in\pi)$. Let $\xi_0 = eP\in G/P$. For $\alpha\in S\setminus\pi$ we have $L_\alpha\cdot\xi_0\cong\mathbb{P}^1(\mathbb{C})\cong S^2$: denote this projective line by $\mathbb{P}_\alpha$. Let $\{\omega_\alpha:\alpha\in S\}$ be the fundamental dominant weights, ρ_α the irreducible representation with highest weight ω_α, and v a highest weight vector therein. Let $\overline{\omega_\alpha}$ be the form on G defined by

$$\overline{\omega_\alpha} = i\partial\bar\partial \log\|\rho_\alpha(g)\cdot v\|^2.$$

For $\alpha\in S\setminus\pi$, the form $\overline{\omega_\alpha}$ is the pull-back of a K-invariant form, which we also denote by ω_α, on G/P; namely, if s is a local cross section of the natural map $G\to G/P$, then $\omega_\alpha(\xi) = i\partial\bar\partial\log\|\rho_\alpha(s(\xi))\cdot v\|^2$. Using these forms, we have the following description of $H_2(G/P)$ and $H^2(G/P)$:

Theorem: *The projective lines* $\mathbb{P}_\alpha(\cong S^2)(\alpha\in S\setminus\pi)$ *form a basis of* $H_2(G/P)$ *and the forms* $\omega_\alpha(\alpha\in S\setminus\pi)$ *form a basis of* $H^2(G/P)$. Moreover,

$$\frac{1}{2\pi}\int_{\mathbb{P}_\beta}\omega_\alpha = \delta_{\alpha,\beta}.$$

For a proof, see Refs. 3 and 5.

Now consider a character χ of the parabolic group P of G. This character gives rise to a line bundle L_χ (over G/P) which is by definition $G\times\mathbb{C}/\sim$, where the equivalence relation $\sim$ is defined by

$$(g,z)\sim(g_1,z_1)\Leftrightarrow g_1 = gp, \quad z_1 = \chi(p)^{-1}z$$

for some $p\in P$.

Take a local nonvanishing section σ of the bundle L_χ. The Chern class $C(L_\chi)$ of L_χ is represented by

$$\frac{i}{2\pi}\,\partial\bar\partial\log\,[N(\sigma)]^{-2},$$

N being a norm on L_χ. So $C(L_\chi)=\Sigma_{\alpha\in S\setminus\pi} n_\alpha[\omega_\alpha]$.

Proposition: We have $n_\alpha=-\langle\chi,\check{\alpha}\rangle\in\mathbb{Z}$.

For a proof, see Ref. 5.

These integers are what are called topological charges in the physics literature and to which Mostafazadeh refers toward the end of Ref. 1.

Finally, let us determine the charge of the anticanonical bundle of $\mathbb{P}^n(\mathbb{C})$, i.e., the Chern class of the line bundle $\det T\mathbb{CP}^n$. Certainly this can be done using the above formula. However, it is more instructive to proceed directly. This is quite standard (see, e.g., Ref. 4). For the sake of completeness, we give a derivation in the present setup. For this, notice that if we are given local nonvanishing sections s_α of a line bundle L, defined on open sets U_α which cover the manifold M, then the map

$$(\xi,z)\mapsto(zs_\alpha(\xi))$$

is an isomorphism of $U_\alpha\times\mathbb{C}$ onto $\pi^{-1}(U_\alpha)$, $\pi:L\to M$ being the projection all of whose fibers are lines, so the transition functions of L are given by

$$g_{\beta\alpha}(\xi)=s_\alpha(\xi)/s_\beta(\xi).$$

For the computation of the Chern class $C(K(\mathbb{P}^n))$ of the canonical bundle $K(\mathbb{P}^n)$ of $\mathbb{P}^n$, we take the open sets

$$U_i=\{[z_0:\cdots:z_n]:z_i\neq 0\},\quad i=0,1,...,n$$

and on U_i the differential form ω_i defined by

$$\omega_i=d(z_0/z_i)\wedge\cdots\wedge d(z_{i-1}/z_i)\wedge d(z_{i+1}/z_i)\cdots\wedge d(z_n/z_i).$$

So $\omega_i=(z_i/z_0)^{-(n+1)}(-1)^i\omega_0$. Rescaling ω_i may assume that $\omega_i=(z_i/z_0)^{-(n+1)}\omega_0$. Therefore $\omega_i/\omega_0=(z_i/z_0)^{-(n+1)}$ and so $g_{0i}=(z_0/z_i)^{n+1}$. Hence

$$g_{ij}=g_{i0}g_{0j}=(z_i/z_j)^{n+1}.$$

On the other hand, the line bundle $[H]$ defined by the hyperplane $z_0=0$ is given on U_i by the functions z_0/z_i, so its transition functions $g_{\widetilde{ij}}$ are $g_{\widetilde{ij}}=(z_0/z_i)/(z_0/z_j)=(z_j/z_i)$. Therefore $g_{ij}=(g_{\widetilde{ij}})^{-(n+1)}$, so

$$K(\mathbb{P}^n)=-(n+1)[H]$$

and hence $\wedge^n T\mathbb{P}^n=(n+1)[H]$.

So the Chern number of the determinant bundle of $\mathbb{P}^n$ is $(n+1)$.

[S0022-2488(99)03506-9]

Azad *et al.*,[1] have informed me of a mistake in Eq. (64) of my paper, Ref. 2, which has led to another mistake in Eq. (61). These equations only hold for $N=1$. For arbitrary N, they must be changed to

$$c_1(T\mathbb{C}P^N)=\chi(\mathbb{C}P^N)=N+1, \tag{1}$$

$$\mathrm{Det}(T\mathbb{C}P^N)=\underbrace{E^*\otimes E^*\otimes\cdots\otimes E^*}_{N+1\ \text{times}}, \tag{2}$$

respectively. Equation (1) can be easily inferred from the computation of the total Chern class of $T\mathbb{C}P^N$ which can be found in Example 6.3 of Ref. 3. Equation (2) follows from Eq. (1) using the arguments given in Sec. IV of Ref. 2, below Eq. (61).

Note that the mistake that occurred in Eqs. (61) and (64) does not change any of the conclusions of Ref. 2.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 8 AUGUST 1999

Asymptotics of the scattering coefficients for a generalized Schrödinger equation

Tuncay Aktosun
Department of Mathematics, North Dakota State University, Fargo, North Dakota 58105

Martin Klaus
Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061

(Received 5 October 1998; accepted for publication 11 February 1999)

The generalized Schrödinger equation $d^2\psi/dx^2+F(k)\psi=[ikP(x)+Q(x)]\psi$ is considered, where P and Q are integrable potentials with finite first moments and F satisfies certain conditions. The behavior of the scattering coefficients near zeros of F is analyzed. It is shown that in the so-called exceptional case, the values of the scattering coefficients at a zero of F may be affected by $P(x)$. The location of the k-values in the complex plane where the exceptional case can occur is studied. Some examples are provided to illustrate the theory. © *1999 American Institute of Physics.* [S0022-2488(99)03007-8]

I. INTRODUCTION

In this paper we consider the generalized Schrödinger equation

$$\frac{d^2\psi(k,x)}{dx^2}+F(k)\psi(k,x)=[ikP(x)+Q(x)]\psi(k,x),\quad x\in\mathbf{R}, \tag{1.1}$$

where the properties of F will be detailed below. The functions P and Q satisfy

$$P\in L_1^1(\mathbf{R}),\quad Q\in L_1^1(\mathbf{R}), \tag{1.2}$$

where $L_1^1(\mathbf{R})$ is the class of measurable functions f such that $\int_{-\infty}^{\infty}dx\,|f(x)|(1+|x|)<+\infty$. For the majority of the paper, P and Q need not be real valued; if they are, this will be stated explicitly. In applications, k may correspond to a wave number while $F(k)$ may represent energy. The coefficient $P(x)$ may represent the absorptive properties of a medium, and $Q(x)$ may be a restoring force density or a potential for an external force. Some special cases of (1.1) are

(A) $F(k)=k^2$ with $P(x)\equiv 0$,
(B) $F(k)=k^2$ with $P(x)\not\equiv 0$,
(C) $F(k)=k^2+1/(4\beta^2)$ with $\beta>0$.

Case (A) corresponds to the well-known quantum-mechanical case of the Schrödinger equation on the line with potential $Q(x)$. Case (B) was studied by Jean and Jaulent,[1–4] and more recently by Sattinger and Szmigielski,[5] and by us[6] when P is real valued. Case (C) has been investigated by Kaup[7] in connection with the inverse scattering transform for an evolution equation (a long-wave water equation resembling the Boussinesq equation) by Tsutsumi[8] and, more recently, under the assumption that $\int_{-\infty}^{\infty}dx\,P(x)=0$, by Sattinger and Szmigielski.[9]

Our interest in (1.1) is motivated by various inverse problems associated with (1.1). In studying such problems, one needs to know the asymptotics of various quantities as the parameter k approaches certain special values, in particular as $F(k)\to\infty$ or as $k\to k_0$, where k_0 is a zero of F. In this paper we will only be concerned with the second situation. We will call $k_0\in\mathbf{C}$ a *critical* value of (1.1) if $F(k_0)=0$. Here, $\mathbf{C}$ denotes the complex plane. The quantities whose asymptotics we will study are the transmission and reflection coefficients associated with (1.1). Before we define these quantities we list the assumptions on F:

(H1) Supposing k_0 is a critical value of (1.1), there exists a set $\mathcal{S}\subset \mathbf{C}$ such that $F(k)$ is continuous on $\mathcal{S}$, $F(k)\neq 0$ on $\mathcal{S}\setminus\{k_0\}$, and the map $k\mapsto\mu(k)=\sqrt{F(k)}$ is one-to-one for $k\in S$. Here the branch of the square root is such that $0\leqslant\arg\mu<\pi$, where $\mu=\mu(k)$.

(H2) There is a path $\mathcal{P}(k_0)$ in $\mathcal{S}$ containing k_0 on which μ takes on real non-negative values.

Note that, by (H1), $\mathcal{D}=\mu(\mathcal{S})$ is a subset of the closed upper-half complex plane $\overline{\mathbf{C}^+}$. (H2) indicates that there is an $\epsilon>0$ so that $[0,\epsilon]\in\mathcal{D}$. In cases (A) and (B), $k_0=0$ is the only critical value. We may then choose $\mathcal{S}=\{k:0\leqslant\arg k<\pi\}\cup\{0\}$, so that $\mu(k)=k$ and $\mathcal{D}=\mathcal{S}$. For the path $\mathcal{P}(k_0)$ we may take the interval $[0,+\infty)$. In case (C) the critical values are $k_0=\pm i/(2\beta)$. The disk $\{k: |k-i/(2\beta)|\leqslant 1/(2\beta)\}$ can then be used as $\mathcal{S}$ near the critical point $+i/(2\beta)$ and we have $\mathcal{D}=\{\mu: |\mu|\leqslant 1/(2\beta),\ 0\leqslant\arg\mu<\pi\}\cup\{0\}$. As the path $\mathcal{P}(k_0)$ we can take the imaginary interval $i[0,1/(2\beta)]$. The modifications for the other critical point are obvious.

For $k\in\mathcal{S}$, (1.1) possesses the solutions $f_l(k,x)$ and $f_r(k,x)$, the so-called Jost solutions from the left and from the right, respectively, that are uniquely defined by their spatial asymptotics, namely,

$$f_l(k,x)=e^{i\mu x}[1+o(1)],\quad f_l'(k,x)=i\mu e^{i\mu x}[1+o(1)],\quad x\to+\infty, \tag{1.3}$$

$$f_r(k,x)=e^{-i\mu x}[1+o(1)],\quad f_r'(k,x)=-i\mu e^{-i\mu x}[1+o(1)],\quad x\to-\infty, \tag{1.4}$$

where the prime indicates the derivative with respect to the spatial variable x. For $k\in\mathcal{P}(k_0)\setminus\{k_0\}$ the Jost solutions obey

$$f_l(k,x)=\frac{1}{T(k)}e^{i\mu x}+\frac{L(k)}{T(k)}e^{-i\mu x}+o(1),\quad x\to-\infty, \tag{1.5}$$

$$f_r(k,x)=\frac{1}{T(k)}e^{-i\mu x}+\frac{R(k)}{T(k)}e^{i\mu x}+o(1),\quad x\to+\infty, \tag{1.6}$$

which define the transmission coefficient T and the reflection coefficients R from the right and L from the left, respectively. These quantities will collectively be referred to as scattering coefficients. It is also possible to define the scattering coefficients in terms of certain Wronskians of the Jost solutions. For example, letting $[f;g]=fg'-f'g$ denote the Wronskian, from (1.1) and (1.3)–(1.6) we get

$$\frac{2i\mu}{T(k)}=[f_r(k,\cdot);f_l(k,\cdot)]. \tag{1.7}$$

In analogy with the usual Schrödinger equation, given a critical value k_0 we will distinguish between two cases: We say that the generic (exceptional) case occurs at $k=k_0$ if and only if $f_l(k_0,x)$ and $f_r(k_0,x)$ are linearly independent (dependent). In the exceptional case, we let γ denote the nonzero constant defined as,

$$\gamma=\frac{f_l(k_0,x)}{f_r(k_0,x)}. \tag{1.8}$$

From (1.7) we see that k_0 corresponds to the exceptional case if and only if

$$F(k_0)=0,\quad \lim_{k\to k_0}\frac{\mu(k)}{T(k)}=0.$$

In short, we will say that k_0 is an exceptional value if it corresponds to the exceptional case for (1.1).

The behavior of the scattering coefficients of (1.1) at the critical values k_0 does not seem to have been studied in detail before, except in cases (A) and (B). In these two cases it is known[6,10–13] that there are two ways in which $T(k)$ can behave as $k\to 0$: either $T(k)=ick+o(k)$ for some nonzero c, or $T(k)=T(0)+o(1)$ with $T(0)\neq 0$. The former corresponds to the generic case and the latter corresponds to the exceptional case. In case (C) a detailed investigation of the behavior of the scattering coefficients near $k_0=\pm 1/(2\beta)$ does not seem to have been done before. This is one of our goals in this paper, and particular attention will be paid to the exceptional case. In connection with a statement made in Theorem 2.6 of Ref. 9 regarding case (C) with $\beta=\frac{1}{2}$, we would like to comment that while it is true that for reflectionless potentials only the exceptional case can occur at $k=\pm i$, there are also potentials $P(x)$ and $Q(x)$, in particular real ones, which are not reflectionless and for which the exceptional case occurs. This will be discussed in more detail in Sec. III.

This paper is organized as follows. In Sec. II we prove our main result concerning the behavior of the scattering coefficients at a critical value (Theorem 2.2) and apply it to cases (A)–(C) (Corollary 2.3). We also present some information about the location of the exceptional k-values in the complex plane. In Sec. III we consider case (C) in more detail, show that one must not identify the exceptional case with the reflectionless case, and provide four examples illustrating the location of the exceptional k-values and other aspects of the theory.

II. ASYMPTOTICS OF THE SCATTERING COEFFICIENTS

In this section we study the asymptotic behavior of the scattering coefficients as $k\to k_0$, where k_0 is a critical value of (1.1). In doing so we will only be concerned with the leading terms of the asymptotic expansions. Our main result is presented in Theorem 2.2. For its proof, we first need some results about the usual Schrödinger equation.

Consider the pair of Schrödinger equations

$$\frac{d^2\phi_j(\mu,x)}{dx^2}+\mu^2\phi_j(\mu,x)=V_j(x)\phi_j(\mu,x),\quad j=1,2, \tag{2.1}$$

where $V_j\in L^1(\mathbf{R})$. Here μ is allowed to range over all of $\overline{\mathbf{C}^+}$; it is not restricted to $\mathcal{D}$ defined earlier. Let t_j denote the transmission coefficient and r_j and l_j denote the reflection coefficients from the right and left, respectively, for the potential V_j. Let $g_{j;l}(\mu,x)$ and $g_{j;r}(\mu,x)$ denote the corresponding Jost solutions of (2.1) from the left and right, respectively. It is known[10,11,13] that

$$g_{j;l}(-\mu,x)=t_j(\mu)g_{j;r}(\mu,x)-r_j(\mu)g_{j;l}(\mu,x),\quad \mu\in\mathbf{R},$$

$$g_{j;r}(-\mu,x)=t_j(\mu)g_{j;l}(\mu,x)-l_j(\mu)g_{j;r}(\mu,x),\quad \mu\in\mathbf{R}. \tag{2.2}$$

Since μ appears as μ^2 in (2.1), $g_{j;l}(-\mu,x)$ and $g_{j;r}(-\mu,x)$ are also solutions of (2.1), and $g_{j;l}(-\mu,x)=e^{-i\mu x}[1+o(1)]$ as $x\to+\infty$ and $g_{j;r}(-\mu,x)=e^{i\mu x}[1+o(1)]$ as $x\to-\infty$.

Proposition 2.1: Suppose that $V_j\in L^1(\mathbf{R})$ for $j=1,2$. Then the scattering coefficients of (2.1) satisfy

$$\frac{1}{t_2(\mu)}=\frac{1}{t_1(\mu)}+\frac{i}{2\mu}\int_{-\infty}^{\infty}dx\,[V_2(x)-V_1(x)]g_{2;l}(\mu,x)g_{1;r}(\mu,x),\quad \mu\in\overline{\mathbf{C}^+}\setminus\{0\}, \tag{2.3}$$

$$\frac{l_2(\mu)}{t_2(\mu)}=\frac{l_1(\mu)}{t_1(\mu)}-\frac{i}{2\mu}\int_{-\infty}^{\infty}dx\,[V_2(x)-V_1(x)]g_{2;l}(\mu,x)g_{1;r}(-\mu,x),\quad \mu\in\mathbf{R}\setminus\{0\}, \tag{2.4}$$

$$\frac{1}{t_2(\mu)}=\frac{1}{t_1(\mu)}+\frac{i}{2\mu}\int_{-\infty}^{\infty}dx\,[V_2(x)-V_1(x)]g_{2;r}(\mu,x)g_{1;l}(\mu,x),\quad \mu\in\overline{\mathbf{C}^+}\setminus\{0\}, \tag{2.5}$$

$$\frac{r_2(\mu)}{t_2(\mu)}=\frac{r_1(\mu)}{t_1(\mu)}-\frac{i}{2\mu}\int_{-\infty}^{\infty}dx\,[V_2(x)-V_1(x)]g_{2;r}(\mu,x)g_{1;l}(-\mu,x),\quad \mu\in\mathbf{R}\setminus\{0\}. \tag{2.6}$$

Proof: First, let us note that (2.3) and (2.5) are given on p. 329 of Ref. 13, and some formulas related to (2.4) and (2.6) can be also found there. We will give a different proof which yields both (2.3) and (2.4) simultaneously. The proof of (2.5) and (2.6) is similar and hence will be omitted. By the variation of parameters formula, $g_{2;l}(\mu,x)$ obeys the integral equation

$$g_{2;l}(\mu,x)=g_{1;l}(\mu,x)+\int_x^\infty dy\,\mathcal{G}(\mu;x,y)[V_2(y)-V_1(y)]g_{2;l}(\mu,y), \tag{2.7}$$

where

$$\mathcal{G}(\mu;x,y)=\frac{g_{1;l}(\mu,x)g_{1;r}(\mu,y)-g_{1;r}(\mu,x)g_{1;l}(\mu,y)}{[g_{1;l}(\mu,\cdot);g_{1;r}(\mu,\cdot)]}. \tag{2.8}$$

Note that the Wronskian in (2.8) is related to the transmission coefficient as

$$t_j(\mu)=-\frac{2i\mu}{[g_{j;l}(\mu,\cdot);g_{j;r}(\mu,\cdot)]}. \tag{2.9}$$

Now (2.3) and (2.4) follow by letting $x\to-\infty$ in (2.7) and using (1.4), (1.5), (2.2), and (2.9). ■

In the next theorem, the behavior of the scattering coefficients of (1.1) is analyzed at critical k-values.

Theorem 2.2: Suppose $P,Q\in L_1^1(\mathbf{R})$ and $F(k)$ satisfies (H1) and (H2). If $k_0\in\mathbf{C}$ is a critical value of (1.1), then we have the following.

(i) In the generic case we have

$$T(k)=-\frac{2i\mu}{[f_l(k_0,\cdot);f_r(k_0,\cdot)]}+o(\mu),\quad k\to k_0\quad\text{in}\quad\mathcal{S}, \tag{2.10}$$

$$L(k)=-1+o(1),\quad R(k)=-1+o(1),\quad k\to k_0\quad\text{in}\quad\mathcal{P}(k_0).$$

(ii) In the exceptional case, using the constants α and ω defined by

$$\alpha=\lim_{k\to k_0}\frac{k-k_0}{\mu(k)},\qquad \omega=\gamma^2+1-\alpha\int_{-\infty}^\infty dx\,P(x)f_l(k_0,x)^2,$$

we distinguish two subcases: (a) If α exists and is finite and $\omega\neq0$, then

$$T(k)=\frac{2\gamma}{\omega}+o(1),\quad k\to k_0\quad\text{in}\quad\mathcal{S}, \tag{2.11}$$

$$L(k)=\frac{2\gamma^2-\omega}{\omega}+o(1),\quad k\to k_0\quad\text{in}\quad\mathcal{P}(k_0), \tag{2.12}$$

$$R(k)=\frac{2-\omega}{\omega}+o(1),\quad k\to k_0\quad\text{in}\quad\mathcal{P}(k_0). \tag{2.13}$$

(b) If $\lim_{k\to k_0}|(k-k_0)/\mu(k)|=+\infty$ and $\int_{-\infty}^\infty dx\,P(x)f_l(k_0,x)^2\neq0$, then

$$T(k_0)=0,\quad L(k_0)=-1,\quad R(k_0)=-1.$$

In the exceptional case, if α exists and $\omega=0$, then the scattering coefficients are not continuous at k_0; if α does not exist, then, in general, the scattering coefficients are not continuous at k_0.

Proof: In (2.3)–(2.6) we replace $V_1(x)$ by $ik_0P(x)+Q(x)$ and $V_2(x)$ by $ikP(x)+Q(x)$ and note that because of (1.2) we have $V_j\in L_1^1(\mathbf{R})$ for $j=1,2$ instead of just $V_j\in L^1(\mathbf{R})$. The stronger assumption allows us to take the limit $\mu\to 0$ in (2.3)–(2.6). Thanks to Proposition 2.1 we can make full use of the results[12] known in the case $P(x)\equiv 0$. For $g_{1;l}(\mu,x)$ and $g_{2;r}(\mu,x)$ in (2.3)–(2.6), we substitute $f_l^{[0]}(\mu,x)$ and $f_r^{[0]}(\mu,x)$, respectively, where the latter two are the Jost solutions of

$$\frac{d^2\varphi(\mu,x)}{dx^2}+\mu^2\varphi(\mu,x)=[ik_0P(x)+Q(x)]\varphi(\mu,x). \tag{2.14}$$

Let $T^{[0]}(\mu)$, $R^{[0]}(\mu)$, and $L^{[0]}(\mu)$ denote the scattering coefficients associated with (2.14). Then from (2.3) we get

$$\frac{1}{T(k)}=\frac{1}{T^{[0]}(\mu)}\left[1-\frac{k-k_0}{2\mu}T^{[0]}(\mu)\int_{-\infty}^{\infty}dx\,P(x)f_r^{[0]}(\mu,x)f_l(k,x)\right],\quad \mu\in\mathcal{D}\setminus\{0\}. \tag{2.15}$$

When $P,Q\in L_1^1(\mathbf{R})$, we have

$$|f_r^{[0]}(\mu,x)|\leqslant C(1+\max\{0,x\})e^{(\mathrm{Im}\,\mu)x},\quad \mu\in\overline{C^+}, \tag{2.16}$$

$$|f_l(k,x)|\leqslant C(1+\max\{0,-x\})e^{-(\mathrm{Im}\,\mu)x},\quad k\in\mathcal{S}, \tag{2.17}$$

where C is a constant independent of x and k. Hence, by the Lebesgue dominated convergence theorem, the integral on the right-hand side in (2.15) converges as $k\to k_0$. Now (2.10) follows from (2.9), (2.15), and the fact that in the generic case we have

$$[f_l(k_0,\cdot);f_r(k_0,\cdot)]=[f_l^{[0]}(k_0,\cdot);f_r^{[0]}(k_0,\cdot)]\neq 0.$$

In the exceptional case we obtain (2.11) by using (2.15)–(2.17) along with the fact that

$$f_r^{[0]}(0,x)=f_r(k_0,x)=\frac{1}{\gamma}f_l(k_0,x), \tag{2.18}$$

and (cf. Ref. 12)

$$T^{[0]}(0)=\frac{2\gamma}{\gamma^2+1},$$

where γ is the constant in (1.8). The statement $T(k_0)=0$ in part (b) follows directly from (2.15). Turning to $L(k)$, from (2.4) we get

$$\frac{L(k)}{T(k)}=\frac{L^{[0]}(\mu)}{T^{[0]}(\mu)}+\frac{k-k_0}{2\mu}\int_{-\infty}^{\infty}dx\,P(x)f_r^{[0]}(-\mu,x)f_l(k,x). \tag{2.19}$$

Using (2.16) and (2.17) one can show that the integral in (2.19) has a finite limit as $k\to k_0$. In the generic case, we have $L^{[0]}(0)=-1$ and

$$\lim_{k\to k_0}\frac{T(k)}{T^{[0]}(\mu)}=\frac{[f_l^{[0]}(0,\cdot);f_r^{[0]}(0,\cdot)]}{[f_l(k_0,\cdot);f_r(k_0,\cdot)]}=1,$$

$$\lim_{k\to k_0}\frac{T(k)}{\mu}=\frac{-2i}{[f_l(k_0,\cdot);f_r(k_0,\cdot)]}.$$

Thus (2.19) implies that $L(k_0)=-1$. To prove (2.12) we use (2.18), (2.19), and the fact that in the exceptional case we have

$$L^{[0]}(0)=\frac{\gamma^2-1}{\gamma^2+1}.$$

The arguments leading to (2.13) and in case (b) are similar. ■

The implications of Theorem 2.2 for the special cases (A)–(C) are as follows.

Corollary 2.3: Suppose $P,Q\in L_1^1(\mathbf{R})$ and $F(k)$ satisfies (H1) and (H2). If $k_0\in\mathbf{C}$ is an exceptional value, then we have the following.

(i) In case (A), we have $k_0=0$ and

$$T(k_0)=\frac{2\gamma}{\gamma^2+1},\quad L(k_0)=\frac{\gamma^2-1}{\gamma^2+1},\quad R(k_0)=\frac{1-\gamma^2}{\gamma^2+1}. \tag{2.20}$$

(ii) In case (B), we have $k_0=0$, $\mu(k)=k$, $\alpha=1$, and (2.11)–(2.13) hold.

(iii) In case (C), $k_0=\pm i/(2\beta)$ and $F(k)$ vanishes linearly at k_0; hence $\alpha=0$. In this case (2.20) holds.

Next we address the question of where in the complex plane the possible exceptional k-values can occur. Of course, in order for a k-value to correspond to the exceptional case, it must first be a critical value, and this depends on $F(k)$. In the next proposition, without referring to any specific form of $F(k)$, we present some sufficient conditions which ensure that the exceptional k-values cannot occur off the imaginary axis.

Proposition 2.4: Assume $P(x)\not\equiv 0$, $Q(x)$ and $P(x)$ are real valued, and $P,Q\in L_1^1(\mathbf{R})$. If k_0 is an exceptional value but not purely imaginary, then $\int_{-\infty}^{\infty}dx\,P(x)|f_1(k_0,x)|^2=0$. If $Q(x)\geqslant 0$, or $P(x)\leqslant 0$, or $P(x)\geqslant 0$, then the exceptional k-values for (1.1) can occur only on the imaginary axis.

Proof: Recall that in the exceptional case the Jost solutions of (1.1), $f_l(k_0,x)$ and $f_r(k_0,x)$, are linearly dependent and hence $f_l(k_0,x)$ remains bounded as $x\to\pm\infty$. Moreover, since $F(k_0)=0$, one can show [cf. (2.11) of Ref. 14] that $f_l'(k_0,x)=o(1/x)$ as $x\to\pm\infty$. Thus, from (1.1), after integrating by parts and using

$$\lim_{x\to\pm\infty} f_l'(k_0,x)f_l(k_0,x)^*=0,$$

where $*$ denotes complex conjugation, we obtain

$$\int_{-\infty}^{\infty}dx\,|f_l'(k_0,x)|^2+\int_{-\infty}^{\infty}dx\,Q(x)|f_l(k_0,x)|^2=-ik_0\int_{-\infty}^{\infty}dx\,P(x)|f_l(k_0,x)|^2.$$

Since the right-hand side has to be real, both assertions follow. ■

III. SPECIAL CASE (C) AND EXAMPLES

We first consider case (C) in some more detail and discuss the implications of our results for the work of Sattinger and Szmigielski.[9] To establish the connection between the notation used here and that used in Ref. 9, we note that in Ref. 9 the special case $F(k)=k^2+1$ was considered with the notation $E^2=k^2+1$ (i.e., E in Ref. 9 corresponds to μ here), and a complex uniformization parameter z was used to express E and k as

$$E=\frac{1}{2}\left(z+\frac{1}{z}\right),\quad k=\frac{1}{2}\left(z-\frac{1}{z}\right).$$

Then two sets of solutions of (1.1), $\psi_\pm(x,z)$ and $\phi_\pm(x,z)$, having specific asymptotic behaviors were defined. We state here only their connection with the Jost solutions of (1.1). We have

$$\psi_+(x,z)=f_l(k,x),\quad \psi_-(x,z)=T(k)f_r(k,x)-R(k)f_l(k,x),$$

$$\phi_+(x,z)=f_r(k,x),\quad \phi_-(x,z)=T(k)f_l(k,x)-L(k)f_r(k,x).$$

These definitions imply that

$$\phi_+(x,z)=a(z)\psi_-(x,z)+b(z)\psi_+(x,z),$$

$$\phi_-(x,z)=c(z)\psi_-(x,z)+d(z)\psi_+(x,z),$$

with

$$a(z)=\frac{1}{T(k)},\quad b(z)=\frac{R(k)}{T(k)},\quad c(z)=-\frac{L(k)}{T(k)},\quad d(z)=\frac{T(k)^2-L(k)R(k)}{T(k)}.$$

The quantities

$$r_+(z)=\frac{b(z)}{a(z)},\quad r_-(z)=\frac{c(z)}{d(z)},$$

were called generalized reflection coefficients in Ref. 9. In terms of our scattering coefficients we have

$$r_+(z)=R(k),\quad r_-(z)=\frac{L(k)}{L(k)R(k)-T(k)^2}.$$

Now let us apply Theorem 2.2 and Corollary 2.3 to the problem studied in Ref. 9. The critical points are $k=\pm i$, corresponding to $z=\pm i$. In the notation of Ref. 9, generically one has $r_\pm(i)=r_\pm(-i)=-1$; on the other hand, in the exceptional case, one has

$$r_+(\pm i)=\frac{1-\gamma_\pm^2}{\gamma_\pm^2+1},\quad r_-(\pm i)=\frac{1-\gamma_\pm^2}{\gamma_\pm^2+1}.$$

Here γ_+ and γ_- are the constants in (1.8) at the critical points i and $-i$, respectively. Thus, we see that potentials need not necessarily be reflectionless in order to violate $r_+(\pm i)=-1$ or $r_-(\pm i)=-1$. In fact, in the next example we show that even rather simple potentials may cause nontrivial reflection in the exceptional case. The following examples involve potentials of the form

$$P(x)=\begin{cases} b_+, & 0<x<1,\\ b_-, & -1<x<0,\\ 0, & \text{elsewhere,}\end{cases}\qquad Q(x)=\begin{cases} a_+, & 0<x<1,\\ a_-, & -1<x<0,\\ 0, & \text{elsewhere,}\end{cases}\tag{3.1}$$

where $a_\pm$ and $b_\pm$ are parameters.

Example 3.1: In (3.1) let us use $b_+=2$, $b_-=b$ with $b\geqslant 0$, $a_+=1$, $a_-=0$, and choose $F(k)=k^2+1$. We can solve (1.1) and evaluate the scattering coefficients explicitly. The critical points are $k=\pm i$. Letting $k=i(1-\epsilon)$, as $k\to i$ so that $\epsilon\to 0$ through positive values, we obtain

$$\frac{2i\mu}{T(k)}=\sqrt{b}\cos 1\sin\sqrt{b}+\sin 1\cos b+O(\sqrt{\epsilon}).\tag{3.2}$$

There are an infinite number of positive b-values that cause the leading term in (3.2) to vanish, and each such b-value causes $k=i$ to yield the exceptional case. The smallest is $b=6.77194$, the next two values are $b=36.3663$ and $b=85.7127$ (the overline means that the last digit may have been affected by round-off). For $b=6.77194$ we get $T(i)=-0.901744$ and $L(i)=-0.432166$; for $b=36.3663$ we get $T(i)=0.851046$ and $L(i)=-0.525091$; and for $b=85.7127$ we get $T(i)=-0.842793$ and $L(i)=-0.538224$.

Example 3.2: In (3.1) let $b_+=b_-=b$, $a_+=a_-=0$, and choose $F(k)=k^2$. Then we are in the exceptional case for every $b\geqslant 0$. The only critical value is $k_0=0$ and we have $f_l(k_0,x)=1$ and $\gamma=1$ [cf. (1.8)], and

$$\frac{1}{T(k)} = e^{2ik}\left[\cos(2\sigma) - \frac{2ik+b}{2\sigma}\sin(2\sigma)\right], \tag{3.3}$$

where $\sigma = \sqrt{k^2 - ikb}$. Hence

$$\frac{1}{T(0)} = 1 - b,$$

which is in agreement with (2.11). If $b=1$, then $\omega=0$ and $\alpha=1$ in Theorem 2.2, and (3.3) gives

$$T(k) = \frac{3i}{2k} + O(1), \quad k \to 0.$$

This shows that $T(k)$ can be discontinuous at a critical value.

We conclude with two examples illustrating the location of possible exceptional k-values; in these examples, unless otherwise indicated, $F(k)$ is not assumed to have any special form.

Example 3.3: In (3.1) let $b_+ = 1$ and $b_- = a_+ = a_- = -1$. Setting $k = k_0$ and $F(k_0) = 0$ we solve (1.1) to find the Jost solution $f_l(k_0, x)$ and then impose the condition that $f_l(k_0, x)$ be bounded as $x \to -\infty$; that is, we demand that $f_l'(k_0, -1) = 0$. This is a necessary condition for k_0 to be an exceptional value for any given function $F(k)$. A straightforward calculation shows that the (possibly) exceptional values are given by the solutions of the equation

$$\sqrt{-1+ik_0}\tanh\sqrt{-1+ik_0} + \sqrt{-1-ik_0}\tanh\sqrt{-1-ik_0} = 0.$$

This equation has infinitely many roots on the imaginary axis located symmetrically about the origin and, as can be seen numerically, one symmetric pair of roots on the real axis. The two real roots are $k_0 = \pm 1.355$, and the imaginary roots closest to zero are $k_0 = \pm 14.139i$. The corresponding Jost solution $f_l(k_0, x)$ is given by

$$f_l(k_0, x) = \begin{cases} \cosh(\sqrt{-1+ik_0}(1-x)), & 0 \leqslant x \leqslant 1, \\ \dfrac{\cosh\sqrt{-1+ik_0}}{\cosh\sqrt{-1-ik_0}}\cosh(\sqrt{-1-ik_0}(x+1)), & -1 \leqslant x \leqslant 0, \end{cases}$$

and on each of the intervals $(-\infty, -1)$ and $(1, +\infty)$, $f_l(k_0, x)$ is constant and obtained by continuity. This example shows the possibility of real as well as purely imaginary exceptional values. The two imaginary roots above would be critical values for case (C) if $\beta = 0.035$. The two real roots are not critical values for any of cases (A)–(C). In accordance with Proposition 2.4, one can verify that $\int_{-1}^{1} dx\, P(x) |f_l(k_0, x)|^2 = 0$.

Example 3.4: In (3.1) let $b_+ = b_- = 1$, $a_+ = 0$, and $a_- = -1$. Then the (possibly) exceptional values satisfy

$$\sqrt{ik_0}\tanh\sqrt{ik_0} + \sqrt{-1-ik_0}\tanh\sqrt{-1-ik_0} = 0.$$

There are again infinitely many purely imaginary roots; there are also complex roots, one pair of which is $k_0 = \pm 1.1008 + 0.5i$. The corresponding Jost solution $f_l(k_0, x)$ is given by

$$f_l(k_0, x) = \begin{cases} \cosh(\sqrt{ik_0}(1-x)), & 0 \leqslant x \leqslant 1, \\ \dfrac{\cosh\sqrt{ik_0}}{\cosh\sqrt{-1-ik_0}}\cosh(\sqrt{-1-ik_0}(x+1)), & -1 \leqslant x \leqslant 0, \end{cases}$$

and for $|x|>1$, $f_l(k_0,x)$ is constant and obtained by continuity. This example shows the possibility of exceptional values that are neither real nor purely imaginary. In case (C) only the purely imaginary roots could be critical values for suitable β.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 8 AUGUST 1999

On the dynamics of the Holstein model from the anticontinuous limit

Dario Bambusi[a)]
Dipartimento di Matematica dell'Università, Via Saldini 50, 20133 Milano, Italy

(Received 17 December 1998; accepted for publication 18 March 1999)

We consider the Holstein model describing an electron interacting with a lattice of identical oscillators. We remark that the on site system (i.e., the system in which the interaction between the different sites of the lattice vanishes) is integrable and anisocronous. This allows us to apply some recent Nekhoroshev-type results to show that corresponding to the majority of initial data in which the electron probability is concentrated on a finite number of sites, the electron probability distribution is approximatively constant for times growing exponentially with the inverse of the coupling parameter. Moreover, for the same times, the total energy of the oscillator system is approximatively constant. © *1999 American Institute of Physics.* [S0022-2488(99)00308-4]

I. INTRODUCTION

In this paper we consider the adiabatic Holstein model describing one electron in interaction with an infinite lattice of identical oscillators. It will be studied as a classical (infinite dimensional) nonlinear dynamical system. Scaling suitably time and the oscillator's variables, the equations of the system can be written in the form

$$\left.\begin{array}{c} -i\dot{\psi}_i=-q_i\psi_i-\epsilon[(\psi_i-\psi_{i-1})+(\psi_i-\psi_{i+1})] \\ \ddot{q}_i=-\omega^2 q_i+|\psi_i|^2 \end{array}\right., \quad i\in\mathbf{Z} \tag{1.1}$$

where q_i are the oscillator's variables, and $|\psi_i|^2$ is the probability of finding the electron at site i; ϵ is the coupling between the different sites, and ω the frequency of the oscillators.

The present work was stimulated by a paper by Hennig,[1] where the dynamics of the Holstein model in the case $\omega \gg 1$ was studied. Hennig applied the Nekhoroshev-type techniques of Ref. 2 to show that if ω is large enough, then there is no exchange of energy between the oscillator's system and the electron system for times growing exponentially with ω. He also presented some numerical simulations showing that if ϵ is small enough also each of the probability amplitudes $|\psi_i|^2$ remain constant. Finally he gave an heuristic explanation of such a phenomenon.

In the present paper we prove rigorously, at least in some quite general situation, and for long times, the constancy of the electron probability distribution, i.e., of the quantities $|\psi_i|^2$. More precisely, we will consider the class of initial data in which the electron probability distribution $|\psi_i|^2$ is essentially localized at a finite number of sites. We will prove that, provided ϵ is below some threshold (which could be explicitly computed), then corresponding to the majority of such initial data the quantities $|\psi_i|^2$ are approximately constant, and moreover the total harmonic energy of the oscillators is approximately constant for very long times, namely, for times of order $\exp(C\epsilon^{-a})$ with positive C and a.

The result is obtained in two steps. First, we consider the anticontinuous limit $\epsilon=0$ in which the system is decoupled into infinitely many identical systems with two degrees of freedom (on site system). Our starting point is the remark that the on site system is an integrable Hamiltonian

[a)]Electronic mail: BAMBUSI@MAT.UNIMI.IT

system. So, first of all we introduce its action angle variables. In this way it becomes clear that the on site system is anysocronous, i.e., the frequencies of its motion depend on the initial data. We come to the second step; to explain in a simple way the key idea consider initial data in which the electron probability is concentrated at one single site of the lattice, say the site $\bar{i}$. It turns out that, in the on site system, the phase of the electron's probability $\psi_{\bar{i}}$ rotates with a frequency which depends on the initial datum and therefore, in general, is nonresonant with ω. Moreover, the phases related to ψ_i $i\neq\bar{i}$ do not move at all. Then one can hope to use perturbation theory to show that also when $\epsilon\neq 0$ the total energy of the oscillator's system and the electron probabilities $|\psi_i|^2$ are essentially constant. The situation is similar when the electron probability is concentrated at a finite number of sites.

To show that this is actually what happens we use a Nekhoroshev-type result which was recently proved by the author[3] (for an improved version applicable to PDE's, see Ref. 4). In Ref. 3 a perturbation of an infinite dimensional system with $n<\infty$ frequencies was considered, and it was proven that there exists n functions which remain approximatively constant when the system is subjected to a smooth perturbation. In the present case such functions are $n-1$ electron probabilities and the total harmonic energy of the oscillator system. Exploiting also the conservation of the total probability of finding an electron in the lattice we are able to conclude that the whole probability distribution of the electron is approximatively constant for the considered times.

Finally we recall that Holstein model was already studied from the anticontinuous limit by Aubry[5] who proved that, provided ϵ is small enough, the Holstein model has quasiperiodic breathers, i.e., quasiperiodic localized solutions. Such solutions physically correspond to the situation in which one of the oscillators perform large amplitude oscillations while the other is approximatively at rest; the electron probability distribution is constant, but the phases rotate uniformly.

The paper is organized as follows: in Sec. II we discuss the on site dynamics; in Sec. III we recall the main abstract theorem of Ref. 3, state and prove the main result of the present paper (freezing of the electron's probabilities, and of the oscillator's energy). Finally in Sec. IV we discuss some possible extensions of these results.

II. THE ON SITE DYNAMICS

Consider the adiabatic Holstein model (1.1), define x_i, and y_i as the real and imaginary parts of ψ_i; then it is easy to verify that (1.1) are the Hamilton's equations of

$$H:=\sum_i H_{os}(p_i,q_i,x_i,y_i)+\frac{1}{2}\epsilon\sum_i [(x_i-x_{i-1})^2+(y_i-y_{i-1})^2], \tag{2.1}$$

where

$$H_{os}(p_i,q_i,x_i,y_i):=\frac{p_i^2+\omega^2 q_i^2}{2}+q_i\frac{x_i^2+y_i^2}{2}, \tag{2.2}$$

and $(p_k,q_k),(x_i,y_i)$ are canonically conjugated variables.

Remark 2.1: The quantity $\Sigma_i(x_i^2+y_i^2)/2$ *is a constant of motions for the dynamics of the Holstein model. It represents the probability of finding an electron in the lattice, so it should be subjected to the normalization condition*

$$\sum_i \frac{x_i^2+y_i^2}{2}=1.$$

For simplicity in the following we will drop this condition.

We begin by studying the on site dynamics described by the Hamiltonian (2.2). It is immediate to realize that the system (2.2) is integrable. Indeed the action $(x_i^2+y_i^2)/2$, is a constant of motion, and the Hamiltonian itself is the second constant.

Fix *i*, then one can explicitly construct action angle variables for H_{os} in two steps. First define the variables (J_i, ϕ_i) by

$$x_i = \sqrt{J_i}\cos\phi_i\,, \quad y_i = \sqrt{J_i}\sin\phi_i\,;$$

the Hamiltonian of the on site system takes the form

$$H_{os} = \frac{p_i^2 + \omega^2 q_i^2}{2} + q_i J_i\,. \tag{2.3}$$

Then the canonical transformation

$$Q_i = q_i + \frac{J_i}{\omega^2}, \quad P_i = p_i\,, \quad J_i' = J_i\,, \quad \phi_i' = \phi_i + \frac{P_i}{\omega^2}$$

(with generating function $P_i(q_i + (J_i'/\omega^2)) + J_i'\phi_i$) reduces the Hamiltonian (2.3) to the form

$$\frac{P_i^2 + \omega^2 Q_i^2}{2} - \frac{1}{2\omega^2} J_i^2, \tag{2.4}$$

where we omitted the prime from *J*. The main feature of this Hamiltonian is that it clearly shows that it is integrable and that the frequency of the electron's system is J_i/ω^2, which depends on the electron density at the considered site.

Remark 2.2: The quantity

$$J_i = \frac{x_i^2 + y_i^2}{2}$$

is the probability of finding an electron at the site i of the lattice.

The integration of this system is immediate and gives

$$P_i(t) = P_{i,0}\cos(\omega t) - \omega Q_{i,0}\sin(\omega t),$$

$$Q_i(t) = Q_{i,0}\cos(\omega t) + \frac{P_{i,0}}{\omega}\sin(\omega t),$$

$$J_i(t) = J_{i,0}, \qquad \phi_i'(t) = \frac{J_i}{\omega^2}t + \phi_{i,0}'.$$

So, along with the solutions the electron density J_i is a constant of motion, the corresponding phase ϕ' rotates uniformly, and the variables P_i, Q_i oscillate with frequency ω around zero. In terms of the original variables the solution appears as follows: the phase of the electron rotates and moreover performs an oscillation with frequency ω, while the oscillator still oscillates with frequency ω, but around the shifted equilibrium position $q_i = -J_i/\omega^2$.

III. THE COMPLETE SYSTEM

We use now perturbation theory to study the dynamics of the complete system. We will concentrate on the situation in which the electron's probability is concentrated at a finite number of sites of the lattice. Moreover, in order to avoid the singularity introduced by the action angle coordinates we prefer to give the main statement in terms of the original variables *p,q,x,y*. So, in the statement of the forthcoming theorem J_i must be interpreted as a short notation for $(x_i^2 + y_i^2)/2$; moreover we will denote by

$$h_0 := \sum_i \frac{1}{2}\left(p_i^2 + \omega^2\left(q_i + \frac{J_i}{\omega^2}\right)^2\right)$$

the total harmonic energy of the oscillators.

We fix a subset $\mathcal{L} \subset \mathbf{Z}$ with cardinality $n < \infty$ and an n-dimensional vector $\nu = \{\nu_i\}_{i \in \mathcal{L}}$ which fulfills the following diophantine condition

$$|\nu \cdot k + \omega l| \geq \frac{\gamma}{|(k,l)|^\tau}, \quad \forall (k,l) \in \mathbf{Z}^{n+1} \setminus \{0\}, \tag{3.1}$$

where $|(k,l)| := |l| + \Sigma |k_i|$, and γ and τ are strictly positive constants.

We will prove the following:

Theorem 3.1: *There exists a positive* ϵ_**, and positive constants* $C_1, \ldots, C_4$ *with the following properties: assume* $|\epsilon| < \epsilon_*$*, and consider an initial datum satisfying*

$$|J_i(0) - \nu_i \omega^2| \leq C_1 \epsilon, \quad \forall i \in \mathcal{L}; \quad \sum_{i \notin \mathcal{L}} J_i(0) \leq C_1 \epsilon, \quad h_0(0) < \infty; \tag{3.2}$$

then, along the corresponding solution one has

$$|J_i(t) - J_i(0)| \leq C_2 \epsilon^{1/2(\tau+1)} \epsilon, \quad \forall i \in \mathcal{L},$$

$$\sum_{i \notin \mathcal{L}} J_i(t) \leq C_2 \epsilon, \quad |h_0(t) - h_0(0)| \leq C_2 \epsilon^{1/2(\tau+1)} h_0(0), \tag{3.3}$$

for exponentially long times, namely, for the times t fulfilling

$$|t| \leq C_3 \exp\left(\frac{C_4}{\epsilon}\right)^{1/2(\tau+1)}. \tag{3.4}$$

The proof will be obtained by applying the normal form theorem of Ref. 3. Before going to the details we recall the result of Ref. 3 that will be applied here. We simplify slightly its statement since for the present application we need only to deal with a strongly symplectic space.

Consider a strongly symplectic Banach space $\mathcal{P}$, i.e., a Banach space endowed by a skew symmetric nondegenerate form Ω. Then one can define the application $\mathcal{P} \ni X \mapsto \Omega(X,.) \in \mathcal{P}^*$, which is injective. We recall that Ω is said to be strongly nondegenerate if such a map is also surjective. In this case the Poisson tensor J which is the inverse of this map is a linear *bounded* operator. It follows that the Hamiltonian vector field X_f of a C^∞ function f (which is defined by $X_f := J df$) is also of class C^∞. Consider the complexification $\mathcal{P}^{\mathbf{C}}$ of $\mathcal{P}$; we will denote by $B_R(z) \subset \mathcal{P}^{\mathbf{C}}$ the ball of radius R with center at z. Moreover, given a set $\mathcal{G} \subset \mathcal{P}$ we will denote

$$\mathcal{G}_R := \bigcup_{z \in \mathcal{G}} B_R(z).$$

On a set $\mathcal{G}$ consider a Hamiltonian function

$$H = h_\omega + f. \tag{3.5}$$

Fix a positive R; we will assume that both h_ω and f extend to complex analytic functions on $\mathcal{G}_R$. The main abstract result of Ref. 3 ensures that, if h_ω generates a quasiperiodic flow which leaves invariant $\mathcal{G}_R$, and f is small, the system has a certain number of approximate constants of motion, for times growing exponentially with a power of the inverse of the size of f.

To give a precise statement we write more explicitly the assumptions. We will denote by Φ_t the flow generated by the Hamiltonian vector field of h_ω. We assume

(1) $\Phi_t(\mathcal{G}_r)\subset\mathcal{G}_r$, for any $r\leq R$;

(2) Φ_t is quasiperiodic, namely, there exists a group action $\Psi:\mathbf{T}^n\times\mathcal{G}_R\to\mathcal{G}_R$ and an n dimensional real vector ω such that

$$\Phi_t(z)=\Psi_{\omega_1 t,\omega_2 t,\ldots,\omega_n t}(z),\ \ \forall z\in\mathcal{G}_R .$$

Moreover, there exists functions $I_1,\ldots,I_n$ analytic in $\mathcal{G}_R$ whose Hamiltonian vector fields generate the flows $\Psi_{\phi_1,0,0,\ldots,0}\cdots\Psi_{0,0,\ldots,0,\phi_n}$.

(3) The frequency vector is diophantine, namely there exist positive γ and τ such that

$$|\omega\cdot k|\geq\frac{\gamma}{|k|^\tau},\quad \forall k\in\mathbf{Z}^n\setminus\{0\}.$$

(4) Denote by $\mathbf{T}^n+i\sigma$ the set of the ϕ's belonging to the complexified torus such that $|\mathrm{Im}\,\phi_i|\leq\sigma$. There exist positive σ and $r_*>R/2$ such that Ψ extends to an analytic map $\Psi:\mathbf{T}^n+i\sigma\times\mathcal{G}_{r_*}\to\mathcal{G}_R$.

(5) Finally we assume that there exists a finite constant ϵ_f such that

$$\frac{1}{R}\sup_{z\in\mathcal{G}_R}\|X_f(z)\|\leq\epsilon_f . \tag{3.6}$$

Then Corollary 4.2 of Ref. 3 states that

Theorem 3.2: *Under the above assumptions there exists positive constants ϵ_*, C_5,C_6,C_7, independent of R, such that, provided $\epsilon_f\leq\epsilon_*$, then along the solutions of the Cauchy problem for (3.5), with initial data in $\mathcal{G}_{R/4}$, one has*

$$|I_i(z(t))-I_i(z(0))|\leq C_5\epsilon_f^{1/(\tau+1)}\sup_{z\in\mathcal{G}_R}|I_i(z)|,\quad i=1,\ldots,n$$

for all times $t\leq\min\{T_0,T_*\}$, where T_0 is the escape time of the solution from the domain $\mathcal{G}_{3R/8}$, and

$$T_*:=\frac{C_7}{\epsilon_f}\exp\left[\frac{C_6}{\epsilon_f}\right]^{1/(\tau+1)}.$$

Proof of theorem 3.1: We will apply the above theorem 3.2, and then we will show that the escape time T_0 is larger than T_*. We prepare the system by introducing ''action angle'' variables $(J_i,\phi_i),(P_i,Q_i)$ for the on site system at the sites $i\in\mathcal{L}$; making a translation of the action J_i, namely, introducing the variables

$$I_i:=J_i-\nu_i\omega^2,$$

the Holstein model assumes the form

$$H=h_\omega+f_1+f_2+f_3,$$

where

$$h_\omega:==h_0-\sum_i\ \nu_i I_i,$$

$$f_1:=\epsilon H_{\mathrm{int}},\quad f_2:=-\sum_{i\in\mathcal{L}}\frac{I_i^2}{2\omega^2},\ \ f_3:=-\sum_{i\notin\mathcal{L}}\frac{J_i^2}{2\omega^2},$$

where

$$H_{\rm int}=\frac{1}{2}\sum_i \,[(x_i-x_{i-1})^2+(y_i-y_{i-1})^2],$$

and, for $i\in\mathcal{L}$, x_i and y_i must be intended as functions of the action angle variables, while, for $i\notin\mathcal{L}$, the symbols P_i, Q_i, and J_i must be intended as short notations for their complete expression. We fix a parameter R and define the norm of a sequence

$$z=(\{P_i,Q_i,I_i,\phi_i\}_{i\in\mathcal{L}},\{p_i,q_i,x_i,y_i\}_{i\notin\mathcal{L}})$$

by

$$\|z\|^2:=\sum_{i\in\mathcal{L}}\frac{|P_i|^2+\omega^2|Q_i|^2}{2}+\sum_{i\notin\mathcal{L}}\frac{|p_i|^2+\omega^2|q_i|^2}{2}+\max_{i\in\mathcal{L}}|I_i|^2+\max_{i\in\mathcal{L}}R^2|\phi_i|^2+R\sum_{i\notin\mathcal{L}}\frac{|x_i|^2+|y_i|^2}{2}$$

and define $\mathcal{P}$ as the completion of set of sequences with compact support in this norm. We choose the domain $\mathcal{G}\subset\mathcal{P}$ to be the set

$$\left\{z\in\mathcal{P}:h_0(z)\leqslant 2E,\quad I_i=0,\quad \forall i\in\mathcal{L},\quad J_i=\frac{x_i^2+y_i^2}{2}=0,\quad \forall i\notin\mathcal{L}\right\}.$$

And we extend it to the complex using again the parameter R.

It is now easy to compute ϵ_f. To this end remark that $H_{\rm int}$ is a bounded polynomial of the variables x,y, so it is analytic as a function of these variables. Since the change of variables involving action angle variables is also analytic, $H_{\rm int}$ is analytic also as a function of these variables. Moreover $H_{\rm int}$ is independent of the p,q variables. It follows that there exists a constant independent of ϵ and R which bounds the norm of the Hamiltonian vector field of f_1. Concerning the vector field of f_2, it has only ϕ components. It is linear in J, and therefore it is bounded by a constant times R^2. Finally consider f_3; the corresponding vector field is a cubic polynomial in x,y and therefore the square of its norm is bounded by a constant times R times R^3. It follows that we have

$$\frac{1}{R}\|X_f\|\leqslant C\left(\frac{\epsilon}{R}+\epsilon+R\right)$$

with a suitable constant C. Choosing $R=\sqrt{\epsilon}$ we have

$$\epsilon_f=C'\sqrt{\epsilon}. \tag{3.7}$$

We define now the group action Ψ. We denote by ψ_1,ψ_2,ψ_{n+1} the angles on the torus. Then $(P,Q,J,\phi,p,q,x,y):=\Psi_{\psi_1,\psi_2,\psi_{n+1}}(P_0,Q_0,J_0,\phi_0,p_0,q_0,x_0,y_0)$ is defined by

$$I_i=I_{i,0},\quad i\in\mathcal{L},\quad \phi_i(\psi_{j_i})=\phi_{0,i}+\psi_{j_i},\quad i\in\mathcal{L},$$

$$P_i(\psi_1)=P_{0,i}\cos\psi_1-\omega Q_{0,i}\sin\psi_1,\quad i\in\mathcal{L},$$

$$Q_i(\psi_1)=Q_{0,i}\cos\psi_1+\frac{P_{0,i}}{\omega}\sin\psi_1,\quad i\in\mathcal{L},$$

$$q_i(\psi_1)=\left(q_{0,i}+\frac{J_i^2}{\omega^2}\right)\cos\psi_1+\frac{p_{0,i}}{\omega}\sin\psi_1-\frac{J_i}{\omega^2},\quad i\notin\mathcal{L},$$

$$p_i(\psi_1)=-\omega\left(q_{0,i}+\frac{J_i}{\omega^2}\right)\sin\psi_1+\frac{p_{0,i}}{\omega}\cos\psi_1,\quad i\notin\mathcal{L},$$

$$x_i(\psi_1)=x_{0,i}\cos\left(\frac{p_i(\psi_1)-p_{i,0}}{\omega^2}\right)+y_{0,i}\sin\left(\frac{p_i(\psi_1)-p_{i,0}}{\omega^2}\right),\quad i\notin\mathcal{L},$$

$$y_i(\psi_1)=x_{0,i}\sin\left(\frac{p_i(\psi_1)-p_{i,0}}{\omega^2}\right)+y_{0,i}\cos\left(\frac{p_i(\psi_1)-p_{i,0}}{\omega^2}\right),\quad i\notin\mathcal{L},$$

where j_i is defined by $j_i\in[2,...,n+1]$, $i<i'$ implies $j_i<j_{i'}$.

So it is possible to apply theorem 3.2 obtaining the estimates (3.3) for times which are the minimum between the escape time from $\mathcal{G}_{3R/8}$ and the times (3.4). To bound the escape time remark that the function h_0 can be used as a Lyapunov functions to show that the variables P,Q cannot leave their domains for the times we are interested in. The same is obviously true for the variables I_i. To bound also the escape time for the variables $\{x_i,y_i\}_{i\notin\mathcal{L}}$ just use the information that $\Sigma_i(x_i^2+y_i^2)/2$ is a constant of motion. This allows us to conclude that

$$\sum_{i\notin\mathcal{L}}\frac{x_i(t)^2+y_i(t)^2}{2}\leqslant\sum_{i\notin\mathcal{L}}\frac{x_i(0)^2+y_i(0)^2}{2}+\sum_{i\in\mathcal{L}}|I_i(t)-I_i(0)|$$

but the latter quantity is estimated by (3.3), and therefore also the variables x_i,y_i cannot escape from their domain. So the theorem is proven. ■

IV. DISCUSSION

So, we have proved that, provided ϵ is small enough, and corresponding to the majority of initially localized electron probability distributions, the electron probabilities $|\psi_i|^2$ and the total energy of the oscillators are essentially constant for very long times. One can ask what happens corresponding to the other initial data.

We expect that the electron probability distribution should be essentially constant corresponding to *any* initial datum with $|\psi_i|^2$ concentrated at a finite number of sites. Namely we expect that there is no need of the diophantine condition (3.1). The reason is that the Holstein model appears as a perturbation of the Hamiltonian

$$h_0-\sum_i\frac{J_i^2}{2\omega^2},$$

which is quasiconvex as a function of J_i and h_0. For quasiconvex systems with finitely many degrees of freedom Nekhoroshev theory ensures that the actions are approximatively constant under perturbation, and for exponentially long times. This of course requires the development of the geometric part of Nekhoroshev theorem. The Holstein model however is infinite dimensional; we recall that the extension of the geometric part of Nekhoroshev's theorem to some infinite dimensional systems has been carried out (following the finite dimensional proof by Lochak[6]) Refs. 2 and 7. We expect the techniques of Ref. 7 to be applicable to the present case. However, since there is not a general theorem which is directly applicable to Holstein model, one should repeat the whole argument of Ref. 7. For this reason we limited ourselves to deal with the much simpler nonresonant case.

For what concerns probability distributions which are not concentrated, we have not a precise idea, but we expect that (in general) there should not be an analog of theorem 3.1.

In the present paper we limited ourselves to the one electron Holstein model. However it is easy to see that also the on site dynamics of the M electron Holstein model is integrable, and that its Hamiltonian, in terms of action angle variables has exactly the form (2.4). So, one can expect theorem 3.1 (and its possible extensions) to hold also in the M electron case. However, its proof is much more difficult in the case of M electrons. This is due to the singularities that appear introducing action angle variables, which are much harder in the M electron case. We expect that it should be possible to overcome such difficulties using the techniques developed by Niedermann[8] which avoid completely the introduction of action angle variables (see also Ref. 9).

Finally we remark that the case where the linear restoring force for the oscillators is substituted by a nonlinear force (as Ref. 5), can also be dealt with by the same techniques developed here. Indeed also in this case the on site system is integrable. However, since the explicit introduction of action angle variables cannot (in general) be done, the proof of theorem 3.1 would turn out to be slightly more difficult. On the contrary the case of a nonlinear interaction between different sites can be treated without additional difficulties.

Phase-space representation of quantum state vectors: The relative-state approach and the displacement-operator approach

Masashi Ban
Advanced Research Laboratory, Hitachi, Ltd., Akanuma 2520, Hatoyama, Saitama 350-0395, Japan

(Received 17 August 1998; accepted for publication 7 April 1999)

Phase-space representation of quantum state vectors has been recently formulated by means of the relative-state method developed by the present author [J. Math. Phys. **39**, 1744 (1998)]. It is, however, pointed out by Møller that the displacement-operator method provides another basis of phase-space representation of quantum state vectors [J. Math. Phys. (to appear)]. Hence the relation between the relative-state approach and the displacement-operator approach is discussed, both of which yield equivalent phase-space representations. © *1999 American Institute of Physics.* [S0022-2488(99)02407-X]

I. INTRODUCTION

Phase-space functions that represent quantum state vectors are very useful for investigating physical and chemical properties of quantum mechanical systems.[1] Furthermore, measurement processes of quantum states of light can be described in terms of phase-space functions. Hence it is important to formulate a phase-space representation of quantum state vectors from the first principles of quantum mechanics without introducing additional assumptions. The present author has recently formulated the phase-space representation by means of the relative-state method.[2] It has been shown that under certain conditions, the results become equivalent to those obtained by Torres-Vega and Frederick[3] and Harriman.[4] The phase-space representation obtained by means of the relative-state method provides the mathematical and physical basis of their results. Møller has recently pointed out that besides the relative-state method, there is another method for obtaining a phase-space representation of quantum state vectors.[5] In fact, he has formulated the phase-space representation by means of the displacement-operator method and shown that under certain conditions, the relative-state method and the displacement-operator method yield the equivalent phase-space representations. This short note that discusses the relation between these two methods is a response to the comment by Møller.[5]

II. PHASE-SPACE REPRESENTATIONS

A. The relative-state approach

We first summarize the phase-space representation of quantum state vectors formulated by means of the relative-state method.[2] Let $\mathcal{S}$ be a relevant quantum system that we describe the physical properties, and let $\mathcal{S}_r$ be a reference system. In some cases, a reference system represents a measurement apparatus for the relevant quantum system. The sets of the position eigenstates of the relevant and reference quantum systems are denoted as $\{|x\rangle | x\in \mathbf{R}\}$ and $\{|x\rangle_r | x\in \mathbf{R}\}$, where $\mathbf{R}$ stands for the set of all real numbers.[6] Then we introduce a state vector $|\omega(r,k;s)\rangle\rangle$ of the compound quantum system $\mathcal{S}+\mathcal{S}_r$,[2]

$$|\omega(r,k;s)\rangle\rangle=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dx\,e^{ikx}\left|x+\frac{1}{2}(1+s)r\right\rangle\otimes\left|x-\frac{1}{2}(1-s)r\right\rangle_r$$

$$=\frac{1}{\sqrt{2\pi}}e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx\,e^{ikx}|x\rangle\otimes|x-r\rangle_r, \tag{1}$$

which is the simultaneous eigenstate of operators $\hat{x}\otimes\hat{1}_r-\hat{1}\otimes\hat{x}_r$ and $\hat{p}\otimes\hat{1}_r+\hat{1}\otimes\hat{p}_r$ with eigenvalues r and k. The state vector $|\omega(r,k;s)\rangle\rangle$ is called the relative-state vector.[2]

Since we investigate the properties of the relevant quantum system $\mathcal{S}$ and the reference quantum system $\mathcal{S}_r$ is irrelevant, we fix some state vector $|\phi\rangle_r$ of the reference quantum system that may be arbitrarily chosen. In this case, the relevant quantum system is described in terms of the reduced relative-state vectors,

$$|\omega(r,k;s)\rangle={}_r\langle\phi|\omega(r,k;s)\rangle\rangle=\frac{1}{\sqrt{2\pi}}e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx\,e^{ikx}\phi^*(x-r)|x\rangle, \tag{2}$$

where $\phi(x)={}_r\langle x|\phi\rangle_r$ is an arbitrary wave function normalized as $\int_{-\infty}^{\infty}dx\,|\phi(x)|^2=1$. It is easy to see that the set of the reduced relative-state vectors, $\{|\omega(r,k;s)\rangle|r,k\in\mathbf{R}\}$, becomes an overcomplete system.[2] Hence any quantum state vector $|\psi\rangle$ of the relevant system is represented by the phase-space function $\psi_s(r,k;s)=\langle\omega(r,k;s)|\psi\rangle$ which is normalized as $\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk|\psi_s(r,k)|^2=1$. The position and momentum operators, $\hat{x}$ and $\hat{p}$, are represented by

$$\langle\omega(r,k;s)|\hat{x}|\psi\rangle=\left[\frac{1}{2}(1+s)r+i\frac{\partial}{\partial k}\right]\psi_s(r;k), \tag{3}$$

$$\langle\omega(r,k;s)|\hat{p}|\psi\rangle=\left[\frac{1}{2}(1-s)r-i\frac{\partial}{\partial r}\right]\psi_s(r;k). \tag{4}$$

The average values and fluctuations of the phase-space variables, r and k, with respect to the probability density $|\psi_s(r,k)|^2$, are given by $\overline{r}=x_\psi-x_\phi$, $\overline{k}=p_\psi+p_\phi$, $(\Delta r)^2=(\Delta x_\psi)^2+(\Delta x_\phi)^2$ and $(\Delta k)^2=(\Delta p_\psi)^2+(\Delta p_\phi)^2$, where we set $x_\psi=\langle\psi|\hat{x}|\psi\rangle$, $p_\psi=\langle\psi|\hat{p}|\psi\rangle$, $(\Delta x_\psi)^2=\langle\psi|\hat{x}^2|\psi\rangle-(\langle\psi|\hat{x}|\psi\rangle)^2$, and so on.

The phase-space function $\psi_s(r;k)$ depends on the quantum state $|\phi\rangle_r$ of the reference system. Thus, besides the intrinsic fluctuation of the relevant system, the additional fluctuation is introduced in the phase-space representation. For example, the fluctuation of the phase-space variable r is given by $(\Delta x_\psi)^2+(\Delta x_\phi)^2$, but not $(\Delta x_\psi)^2$, where $(\Delta x_\psi)^2$ is the intrinsic fluctuation and $(\Delta x_\phi)^2$ is the additional one. Such an additional fluctuation can be attributed to the effect of the measurement apparatus which is used to obtain the information about the position and momentum of the relevant system. In the fuzzy-space formulation,[7,8] the quantum state $|\phi\rangle_r$ characterizes the finite accuracy of the position and momentum variables. Therefore, the phase-space representation is the operational description of the relevant quantum system rather than the intrinsic description.[9]

We can investigate the physical and chemical properties of the relevant quantum system in terms of the phase-space function $\psi_s(r,k)$ and the differential operators $\frac{1}{2}(1+s)+i\partial/\partial k$ and $\frac{1}{2}(1-s)-i\partial/\partial r$. It is shown that under certain conditions,[2] these results become equivalent to those obtained by Torres-Vega and Frederick[3] and Harriman.[4] The properties of the phase-space representation obtained by the relative-state method have been investigated in detail.[2]

B. The displacement-operator approach

We next introduce the phase-space representation of quantum state vectors obtained by the displacement-operator approach.[1,5] The displacement operator $\hat{D}_s(r,k)$ used in this approach is given by

$$\hat{D}_s(r,k)=\exp[i(k\hat{x}-r\hat{p}-\tfrac{1}{2}skr)], \tag{5}$$

where the parameter s determines the operator ordering; the standard ordering $\hat{D}_1(r,k) = e^{-ir\hat{p}}e^{ik\hat{x}}$ for $s=\mathbf{1}$, the antistandard ordering $\hat{D}_{-1}(r,k)=e^{ik\hat{x}}e^{-ir\hat{p}}$ for $s=-1$, and the symmetric ordering $\hat{D}_0(r,k)=e^{i(k\hat{x}-r\hat{p})}$ for $s=0$.[10] Using the displacement operator $\hat{D}_s(r,k)$, Mølller introduces a state vector $|\Omega(r,k;s)\rangle$ to formulate the phase-space representation of the relevant quantum system,

$$|\Omega(r,k;s)\rangle = \frac{1}{\sqrt{2\pi}}\hat{D}_s(r,k)|\chi\rangle = \hat{D}_s(r,k)|\Omega(0,0;s)\rangle, \tag{6}$$

where $|\chi\rangle$ is an arbitrary normalized state vector of the relevant quantum system $\mathcal{S}$. In particular, if $|\chi\rangle$ is a vacuum state, $|\Omega(r,k;s)\rangle$ becomes the Glauber coherent state, except for the phase factor and the normalization constant.[11] It is easy to see that the set $\{|\Omega(r,k;s)\rangle | r,k\in\mathbf{R}\}$ becomes an overcomplete system. Thus a quantum state vector $|\psi\rangle$ of the relevant system is represented by the phase-space function $\tilde{\psi}_s(r,k;s)=\langle\Omega(r,k;s)|\psi\rangle$ which is normalized as $\int_{-\infty}^{\infty}dr\int_{-\infty}^{\infty}dk|\tilde{\psi}_s(r,k)|^2=1$. We obtain the phase-space representation of the canonical position and momentum operators,

$$\langle\Omega(r,k;s)|\hat{x}|\psi\rangle = \left[\frac{1}{2}(1+s)r + i\frac{\partial}{\partial k}\right]\tilde{\psi}_s(r;k), \tag{7}$$

$$\langle\Omega(r,k;s)|\hat{p}|\psi\rangle = \left[\frac{1}{2}(1-s)r - i\frac{\partial}{\partial r}\right]\tilde{\psi}_s(r;k), \tag{8}$$

which are identical with those obtained by the relative-state approach [see Eqs. (3) and (4)]. This result indicates that the relative-state approach and the displacement-operator approach yield the equivalent phase-space representations of quantum state vectors of the relevant system. We finally remark that the phase-space representation by the displacement-operator approach depends on the quantum state $|\chi\rangle$. This arbitrariness is equivalent to that in the relative-state approach. Thus, the displacement-operator approach also yields the operational description of the relevant system.

III. RELATION BETWEEN THE RELATIVE-STATE APPROACH AND THE DISPLACEMENT-OPERATOR APPROACH

We have found that the phase-space representation obtained by the relative-state method is equivalent to that obtained by the displacement-operator method. The equivalence results from fact that the state vector $|\Omega(r,k;s)\rangle$ introduced by Mølller is identical with the reduced relative-state vector $|\omega(r,k;s)\rangle$. In fact, using the normalizability of the wave function $\phi(x)$, we obtain

$$\begin{aligned}
|\omega(r,k;s)\rangle &= \frac{1}{\sqrt{2\pi}}e^{-i(1+s)kr/2}\int_{-\infty}^{\infty}dx\, e^{ikx}\phi^*(x-r)|x\rangle \\
&= e^{-ir\hat{p}}\frac{1}{\sqrt{2\pi}}e^{i(1-s)kr/2}\int_{-\infty}^{\infty}dx\, e^{ikx}\phi^*(x)|x\rangle \\
&= e^{-ir\hat{p}}e^{-k\hat{x}}\frac{1}{\sqrt{2\pi}}e^{i(1-s)kr/2}\int_{-\infty}^{\infty}dx\, \phi^*(x)|x\rangle \\
&= e^{i(k\hat{x}-r\hat{p}-skr/2)}\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dx\, \phi^*(x)|x\rangle \\
&= \hat{D}_s(r,k)|\omega(0,0;s)\rangle = \frac{1}{\sqrt{2\pi}}\hat{D}_s(r,k)|\gamma\rangle,
\end{aligned} \tag{9}$$

where the normalized state vector $|\gamma\rangle$ of the relevant system is given by

$$|\gamma\rangle=\int_{-\infty}^{\infty}dx\,\phi^*(x)|x\rangle. \tag{10}$$

Hence, if we identify the state vector $|\gamma\rangle$ in the relative-state method with the state vector $|\chi\rangle$ in the displacement-operator method [or equivalently $\phi^*(x)=\chi(x)$ (Ref. 5)], we obtain the equality $|\omega(r,k;s)\rangle=|\Omega(r,k;s)\rangle$ and thus the equivalence is obvious.

We now consider the relation between the relative-state approach and the displacement-operator approach from the probabilistic point of view. Suppose that the relevant system is in a pure quantum state described by a statistical operator $\hat{\rho}=|\psi\rangle\langle\psi|$. Although we can consider a mixed quantum state, we confine ourselves to investigating a pure quantum state since we are interested in the phase-space representation of quantum state vectors. From the general theory of the operational quantum mechanics,[12,13] the probability $P(X,Y)$ that the phase-space variables r and k take values respectively in the subsets X and Y of the set $\mathbf{R}$ is given by

$$P(X,Y)=\mathrm{Tr}[\hat{\mathcal{M}}(X,Y)\hat{\rho}]=\langle\psi|\hat{\mathcal{M}}(X,Y)|\psi\rangle. \tag{11}$$

The operator $\hat{\mathcal{M}}(X,Y)$ defined on the Hilbert space $\mathcal{H}$ is a positive operator-valued measure (POVM), but not a projection-valued measure in general. In the phase-space representation obtained by the relative-state method or the displacement-operator method, the POVM is given by

$$\hat{\mathcal{M}}(X,Y)=\int_{r\in X}dr\int_{k\in Y}dk\,|\omega(r,k;s)\rangle\langle\omega(r,k;s)|=\int_{r\in X}dr\int_{k\in Y}dk\,|\Omega(r,k;s)\rangle\langle\Omega(r,k;s)|. \tag{12}$$

Then we obtain the phase-space probability

$$P(X,Y)=\int_{r\in X}dr\int_{k\in Y}dk\,|\psi_s(r,k)|^2=\int_{r\in X}dr\int_{k\in Y}dk\,|\tilde{\psi}_s(r,k)|^2, \tag{13}$$

which indicates that the probability amplitude in phase space is given by $\psi_s(r,k)$ or $\tilde{\psi}_s(r,k)$. It is important to note that the POVM $\hat{\mathcal{M}}(X,Y)$ given by Eq. (12) is not a projection-valued measure because of the nonorthogonality of the state vectors $|\omega(r,k;s)\rangle$ and $|\Omega(r,k;s)\rangle$.

It is well known that any POVM is made some projection-valued measure by extending a Hilbert space (the Naimark theorem).[13] The operators $\hat{x}\otimes\hat{1}_r-\hat{1}\otimes\hat{x}_r$ and $\hat{p}\otimes\hat{1}_r+\hat{1}\otimes\hat{p}_r$ of the compound system $\mathcal{S}+\mathcal{S}_r$ are commutable and thus represent simultaneously measurable quantities, the eigenstate of which is given by the relative-state vector $|\omega(r,k;s)\rangle\rangle$ [see Eq. (1)] in the sense of Ref. 6. The projection operator[14]

$$\hat{\mathcal{N}}(X,Y)=\int_{r\in X}dr\int_{k\in Y}dk\,|\omega(r,k;s)\rangle\rangle\langle\langle\omega(r,k;s)| \tag{14}$$

describes the simultaneous measurement, where the measurement outcomes of $\hat{x}\otimes\hat{1}_r-\hat{1}\otimes\hat{x}_r$ and $\hat{p}\otimes\hat{1}_r+\hat{1}\otimes\hat{p}_r$ belong to X and Y. Then it is easy to see that this operator satisfies the relation

$$P(X,Y)=\mathrm{Tr}[\hat{\mathcal{M}}(X,Y)\hat{\rho}]=\mathrm{Tr}\,\mathrm{Tr}_r[\hat{\mathcal{N}}(X,Y)\hat{\rho}\otimes\hat{\sigma}_r], \tag{15}$$

where we have used $|\omega(r,k;s)\rangle={}_r\langle\phi|\omega(r,k;s)\rangle\rangle$ and Tr_r is the trace operation over the reference system $\mathcal{S}_r$. This result indicates that the projection operator $\hat{\mathcal{N}}(X,Y)$ is the Naimark extension of the POVM $\hat{\mathcal{M}}(X,Y)$ in the sense of Ref. 6. In Eq. (15), $\hat{\sigma}_r=|\phi\rangle_{rr}\langle\phi|$ is called the Naimark state. In particular, when $|\phi\rangle_r$ is the vacuum state, the projection operator $\hat{\mathcal{N}}(X,Y)$ describes the balanced homodyne detection and the heterodyne detection.[15–17] Therefore, we have found that the relative-state approach corresponds to the Naimark extension of the displacement-operator approach.

In conclusion, it is shown that the quantum state vector $|\Omega(r,k;s)\rangle$ used in the displacement-operator approach is equivalent to the reduced relative-state vector $|\omega(r,k;s)\rangle$. Thus it is obvious that the relative-state approach and the displacement-operator approach yield equivalent phase-space representations of quantum state vectors. From the probabilistic point view, the relative-state approach corresponds to the Naimark extension of the displacement-operator approach.

A one-dimensional model for *n*-level atoms coupled to an electromagnetic field

Zorawar S. Bassi[a] and André LeClair
Newman Laboratory, Cornell University, Ithaca, New York 14853

(Received 1 February 1999; accepted for publication 4 May 1999)

A model for *n*-level atoms coupled to quantized electromagnetic fields in a fibrillar geometry is constructed. In the slowly varying envelope and rotating wave approximations, the equations of motion are shown to satisfy a zero curvature representation, implying integrability of the quantum system. © *1999 American Institute of Physics.* [S0022-2488(99)02808-X]

I. INTRODUCTION

The interaction of radiation with two-level atoms has been extensively studied under various approximations. In one spatial dimension, the reduced Maxwell–Bloch equations resulting from the slowly varying envelope and rotating wave approximations are known to be quantum integrable.[1] In this paper we generalize the one-dimensional case of two-level atoms to that of *n*-level atoms.

In the first of two main parts, we construct the fully quantum *n*-level model. The system consists of *n*-level atoms distributed in a fibrillar geometry, interacting with radiation through a minimally coupled Hamiltonian. In the remaining section we apply the approximations, and show that the Heisenberg equations of motion for the reduced system satisfy the so-called zero curvature representation. This implies that the system is integrable and can be solved by the quantum inverse scattering method.

II. MATHEMATICAL BACKGROUND

Let us first recall the sl_n Lie algebra. The n^2-1 generators, written as

$$\{E_{ij},H_m|1\leq i\neq j\leq n,\ 1\leq m\leq r\},\tag{2.1}$$

where $r=n-1$ is the rank, satisfy the following brackets (in the Chevalley basis):

$$[E_{ij},E_{kl}]=\begin{Bmatrix}\delta_{kj}E_{il}-\delta_{il}E_{kj} & \text{if}\quad \delta_{il}\delta_{kj}=0\\ \sum_{m=i}^{j-1}H_m(i<j) & \text{if}\quad \delta_{il}\delta_{kj}=1\end{Bmatrix},\tag{2.2a}$$

$$[E_{ij},H_m]=(\delta_{jm}-\delta_{im}-\delta_{jm+1}+\delta_{im+1})E_{ij},\tag{2.2b}$$

$$[H_a,H_b]=0.\tag{2.2c}$$

The set spanned by $\{H_m\}$ is the Cartan subalgebra. [Note that in the bracket (2.2a) a term of the form $\delta_{i\neq j}E_{kk}$ is formally equal to zero, even though E_{kk} has not been defined. The set $\{E_{ij}|1\leq i,j\leq n\}$ satisfying the first relation in (2.2a) is a basis for the algebra gl_n.] A representation ρ of sl_n will be denoted as

$$\{E^{\rho}_{ij}=\rho(E_{ij}),H^{\rho}_m=\rho(H_m)\}.\tag{2.3}$$

---
[a]Electronic mail: zorawar@mail.lns.cornell.edu

The $r\times r$ Cartan matrix A has the explicit form

$$A_{uv}=2\,\delta_{uv}-\delta_{uv-1}-\delta_{uv+1}\,. \tag{2.4}$$

It is a symmetric matrix with diagonal elements 2 and nearest off-diagonal elements -1. We now proceed to build our quantum system.

III. THE INTERACTING *n*-LEVEL HAMILTONIAN

We model a free n-level atom as having a single electron with eigenstates $|i\rangle$, $i=1,2,...,n$, and energies $\epsilon_1>\epsilon_2>\cdots>\epsilon_n$. The energy splitting between states $|i\rangle$ and $|i+1\rangle$ will be denoted by ω_i or ω_{ii+1},

$$\omega_i=\omega_{ii+1}=\epsilon_i-\epsilon_{i+1}\,,\quad 1\leqslant i<n. \tag{3.1}$$

The second notation can be generalized as follows:

$$\omega_{ij}=\epsilon_i-\epsilon_j\,,\quad 1\leqslant i<j\leqslant n. \tag{3.2}$$

The notation ω_i is only defined for the energy splitting between successive states.

To define various atomic operators, we first introduce fermion creation and destruction operators $\{b_i\,,b_i^\dagger\}$ for $1\leqslant i\leqslant n$. The operator $b_i^\dagger(b_i)$ creates (destroys) an electron in the ith level. These operators satisfy the algebra

$$\{b_i\,,b_j\}=\{b_i^\dagger\,,b_j^\dagger\}=0,\quad \{b_i\,,b_j^\dagger\}=\delta_{ij}\,. \tag{3.3}$$

The atomic operators can now be written as

$$\mathcal{O}_{ij}=b_i^\dagger b_j\,,\quad 1\leqslant i,\ j\leqslant n \tag{3.4}$$

or linear combinations of the $\mathcal{O}_{ij}$'s. The action of $\mathcal{O}_{ij}$ on an atomic state $|k\rangle$ is given by

$$\mathcal{O}_{ij}|k\rangle=b_i^\dagger b_j|k\rangle=\delta_{kj}|i\rangle. \tag{3.5}$$

From (3.3) the general commutator for the $\mathcal{O}$ operators is

$$[\mathcal{O}_{ij}\,,\mathcal{O}_{kl}]=\mathcal{O}_{il}\delta_{jk}-\mathcal{O}_{kj}\delta_{il}\,. \tag{3.6}$$

Operators of the form $\mathcal{O}_{i<j}$ are referred to as raising operators. These cause a transition from the lower energy state $|j\rangle$ to the higher energy state $|i\rangle$. Similarly the operators $\mathcal{O}_{j>i}$ are lowering operators. We also define a set of commuting operators, denoted $\mathcal{H}_m$, as follows:

$$\mathcal{H}_m=\mathcal{O}_{mm}-\mathcal{O}_{m+1m+1}\,,\quad 1\leqslant m\leqslant r. \tag{3.7}$$

The set $\{\mathcal{O}_{i\neq j}\,,\mathcal{H}_m\}$ satisfies (2.2), thus forming a representation of sl_n. (We shall often use the notation $X_{a<b}(X_{a>b})$ to mean X_{ab} with $a<b(a>b)$ for X any quantity, operator, c number, etc.)

The free atomic Hamiltonian can be written as

$$H_0^{\text{atom}}=\sum_{u=1}^{r}\left(\sum_{v=1}^{u}\epsilon_v\right)\mathcal{H}_u+\left(\sum_{v=1}^{n}\epsilon_v\right)b_n^\dagger b_n\,. \tag{3.8}$$

We will choose the arbitrary lowest state energy ϵ_n to be such that $\Sigma_{v=1}^{n}\epsilon_v=0$. In terms of the ω_i's and the inverse Cartan matrix A^{-1}, this means setting

$$\epsilon_n=-\sum_{v=1}^{r}A_{rv}^{-1}\omega_v\,, \tag{3.9}$$

which implies

$$\sum_{v=1}^{u} \epsilon_v = \sum_{v=1}^{r} A_{uv}^{-1} \omega_v . \tag{3.10}$$

The atomic Hamiltonian (3.8) thus takes the form

$$H_0^{\text{atom}} = \sum_{1 \leqslant u,v \leqslant r} A_{uv}^{-1} \omega_v \mathcal{H}_u . \tag{3.11}$$

To couple the atom to an electromagnetic field we make use of the minimal coupling prescription (see any standard text on quantum mechanics, e.g., Ref. 2). The standard Hamiltonian is

$$H = H_0^{\phi} + H_0^{\text{atom}} + H_{\text{int}} , \tag{3.12}$$

where

$$H_0^{\text{atom}} = \frac{1}{2m_e} \vec{p} \cdot \vec{p} + V(\vec{x}), \tag{3.13}$$

$$H_{\text{int}} = -\frac{e}{2m_e} (\vec{p} \cdot \vec{A}(\vec{x}) + \vec{A}(\vec{x}) \cdot \vec{p}) + \frac{e^2}{2m} \vec{A}(\vec{x}) \cdot \vec{A}(\vec{x}), \tag{3.14}$$

and H_0^{ϕ} is the free field Hamiltonian. The Hamiltonian (3.13) is identified with (3.11), i.e., the exact eigenstates and energies of (3.13) are taken to be $\{|i\rangle, \epsilon_i\}$, $i=1,...,n$. If the spatial variation of the vector potential $\vec{A}$ is small across the atom, we can take its value at a fixed point $\vec{x}_0$ inside the atom. Using

$$\vec{p} = -i m_e [\vec{x}, H_0^{\text{atom}}], \tag{3.15}$$

we get

$$-\frac{e}{2m_e} \langle a | \vec{p} \cdot \vec{A}(\vec{x}) + \vec{A}(\vec{x}) \cdot \vec{p} | b \rangle = i(\epsilon_b - \epsilon_a) \vec{A}(\vec{x}_0) \cdot \langle a | \vec{d} | b \rangle, \tag{3.16}$$

where $\vec{d} = e\vec{x}$ is the electric dipole operator. Since $\vec{d}$ is a vector operator and the atomic states are assumed to be parity eigenstates, we have $\langle i | \vec{d} | i \rangle = 0$. The nonzero matrix elements can be parametrized as follows $(i<j)$:

$$\langle i | \vec{d} | j \rangle = d_{ij} e^{i\alpha_{ij}} \hat{n}_{ij} , \quad \langle j | \vec{d} | i \rangle = d_{ij} e^{-i\alpha_{ij}} \hat{n}_{ij} , \tag{3.17}$$

where $d_{ij} \geqslant 0$ and the $\hat{n}_{ij}$'s are unit vectors. We will consider the situation where $\hat{n}_{ij}$ is independent of i,j due to some symmetry of the system and write $\hat{n} \equiv \hat{n}_{ij}$. The dipole operator can be expanded in terms of the raising and lowering operators as

$$\vec{d} = \hat{n} \sum_{i<j} (d_{ij} e^{i\alpha_{ij}} \mathcal{O}_{ij} + d_{ij} e^{-i\alpha_{ij}} \mathcal{O}_{ji}), \tag{3.18}$$

which gives for the interaction Hamiltonian

$$H_{\text{int}} = -i \vec{A}(\vec{x}_0) \cdot \hat{n} \sum_{i<j} \omega_{ij} d_{ij} (\mathcal{O}_{ij} e^{i\alpha_{ij}} - \mathcal{O}_{ji} e^{-i\alpha_{ij}}) + \frac{e^2}{2m_e} \vec{A}(\vec{x}_0) \cdot \vec{A}(\vec{x}_0). \tag{3.19}$$

To reduce this system to a one-dimensional model, we make use of the fibrillar geometry. The atom can be thought of as an impurity in an optical fiber of cross-sectional area $\mathcal{A}$ and length L, with $L \gg \sqrt{\mathcal{A}}$. Taking the fiber along the $\hat{x}$ direction, the reduced field action is found to be (see Ref. 3 for details)

$$S_{\text{Maxwell}} = \int dx\, dt \tfrac{1}{2}(\partial_t \phi \partial_t \phi - \partial_x \phi \partial_x \phi), \tag{3.20}$$

where ϕ is a dimensionless scalar field defined through

$$\vec{A} \cdot \hat{n} = \sqrt{\frac{4\pi}{\mathcal{A}_{\text{eff}}}}\, \phi. \tag{3.21}$$

Here $\vec{A}$ is the vector potential depending only on the x coordinate and $\mathcal{A}_{\text{eff}}$ is the effective fiber cross-sectional area. The field ϕ satisfies the commutation relation

$$[\phi(x,t), \partial_t \phi(x',t)] = i\,\delta(x-x'). \tag{3.22}$$

From the action the free field Hamiltonian is found to be

$$H_0^{\phi} = \int dx \frac{1}{2}[(\partial_t \phi)^2 + (\partial_x \phi)^2] + \frac{2\pi e^2}{m_e \mathcal{A}_{\text{eff}}} \phi^2(x_0), \tag{3.23}$$

where the last term is the quadratic potential term taken from H_{int}. Now the interaction Hamiltonian is

$$H_{\text{int}} = -\frac{i}{2} \phi(x_0) \sum_{i<j} \omega_{ij} \beta_{ij} (\mathcal{O}_{ij} e^{i\alpha_{ij}} - \mathcal{O}_{ji} e^{-i\alpha_{ij}}), \tag{3.24}$$

where (explicitly showing $\hbar$ and c)

$$\beta_{i<j} = \sqrt{\frac{16\pi}{\hbar c \mathcal{A}_{\text{eff}}}}\, d_{ij}. \tag{3.25a}$$

For $1 \leqslant m \leqslant r$ we define

$$\beta_m = \sqrt{\frac{16\pi}{\hbar c \mathcal{A}_{\text{eff}}}}\, d_{mm+1} = \beta_{mm+1}. \tag{3.25b}$$

The β parameters are the important dimensionless coupling constants of the model. The spontaneous decay rate $\Gamma_{ij}^s = 1/\tau_{ij}^s$ of a single excited atom from the state $|i\rangle$ to the state $|j\rangle$ is given by

$$\Gamma_{ij}^s = \frac{\beta_{ij}^2}{4} \omega_{ij}. \tag{3.26}$$

Next to make the transition to a continuous system. For N atoms positioned at $x = x_m$, $m = 1,...,N$, let $\vec{d}_m = e(\vec{x} - \vec{x}_m)$ and $\mathcal{O}_{ij}(x_m)$ be the dipole and transition operators for the atom at x_m. The matrix elements of $\vec{d}_m$ are independent of the position, however, the orientation $\hat{n}$ can vary from atom to atom. The operator $\vec{d}_m$ can be written in terms of the single atom matrix elements as

$$\vec{d}_m = \hat{n}_m \sum_{i<j} d_{ij} (\mathcal{O}_{ij}(x_m) e^{i\alpha_{ij}} + \mathcal{O}_{ji}(x_m) e^{-i\alpha_{ij}}). \tag{3.27}$$

For simplification, we suppose the situation where all atoms are aligned $\hat{n}_m = \hat{n}$ (e.g., by an external electric field), giving

$$H_{\rm int} = -\frac{i}{2}\int dx\, \phi(x)\sum_{i<j} \omega_{ij}\beta_{ij}(\mathcal{O}_{ij}(x,t)e^{i\alpha_{ij}} - \mathcal{O}_{ji}(x,t)e^{-i\alpha_{ij}}), \tag{3.28}$$

where we have introduced the space-dependent (continuous) transition operators

$$\mathcal{O}_{ij}(x,t) = \sum_{m=1}^{N} \mathcal{O}_{ij}(x_m,t)\,\delta(x-x_m). \tag{3.29}$$

The discrete operator $\mathcal{O}_{ij}(x_m,t)$ acts only on the atom at x_m to cause a transition from $|j\rangle$ to $|i\rangle$. [Note the abuse of notation, we are using the same symbol $\mathcal{O}_{ij}$ for both the continuous and discrete operators. Henceforth only the continuous version $\mathcal{O}_{ij}(x,t)$ will appear.] A time dependence in (3.29) signifies that the $\mathcal{O}_{ij}$ operators are to be treated as Heisenberg operators. The continuous $\mathcal{H}_m(x,t)$ operators are defined similarly. The general commutator for the space–time transition operators is

$$[\mathcal{O}_{ij}(x,t),\mathcal{O}_{kl}(x',t)] = (\mathcal{O}_{il}(x,t)\,\delta_{jk} - \mathcal{O}_{kj}(x,t)\,\delta_{il})\,\delta(x-x'), \tag{3.30}$$

from which it is easily seen that the algebra (or now more appropriately current algebra) satisfied by the set $\{\mathcal{O}_{i\neq j}(x,t),\mathcal{H}_m(x,t)\}$ is identical to the sl_n algebra (2.2). The free atomic Hamiltonian takes the form

$$H_0^{\rm atom} = \int dx \sum_{1\leq u,v\leq r} A_{uv}^{-1}\omega_v \mathcal{H}_u(x,t). \tag{3.31}$$

The complete Hamiltonian for the system is therefore $H_0^{\rm atom} + H_0^{\phi} + H_{\rm int}$, with $H_0^{\rm atom}$, H_0^{ϕ}, and $H_{\rm int}$ given by (3.31), (3.23), and (3.28), respectively.

IV. TWO APPROXIMATIONS AND INTEGRABILITY

We now make use of two approximations common in quantum optics to further simplify $H_{\rm int}$—these being the slowly varying envelope and rotating wave approximations.[4]

In the slowly varying envelope approximation, one assumes that near resonant photons with energies $\approx\omega_{ij}$ are most relevant. Then the scalar field ϕ can be expanded about the various resonances as

$$\phi(x,t) \approx \sum_{i<j} (e^{-i\omega_{ij}(t-x)}\psi_{ij}(x,t) + e^{i\omega_{ij}(t-x)}\psi_{ij}^{\dagger}(x,t)), \tag{4.1}$$

where $\psi_{ij}(x,t)$ and $\psi_{ij}^{\dagger}(x,t)$ are destruction and creation fields with mode expansions

$$\psi_{i<j}(x,0) = \frac{1}{\sqrt{2\omega_{ij}}}\int \frac{dk_e}{\sqrt{2\pi}}\hat{a}_{ij}(k_e)e^{ik_e x}, \tag{4.2a}$$

$$\psi_{i<j}^{\dagger}(x,0) = \frac{1}{\sqrt{2\omega_{ij}}}\int \frac{dk_e}{\sqrt{2\pi}}\hat{a}_{ij}^{\dagger}(k_e)e^{-ik_e x}, \tag{4.2b}$$

and

$$\hat{a}_{ij}(k_e) = a_{ij}(k_e+\omega_{ij}), \quad \hat{a}_{ij}^{\dagger}(k_e) = a_{ij}^{\dagger}(k_e+\omega_{ij}). \tag{4.3}$$

Here a_{ij} ($a^\dagger_{ij}$) is the usual photon destruction (creation) operator. (Note that we are only considering right-moving plane waves.) The operator $\hat{a}_{ij}(k_e)$ ($\hat{a}^\dagger_{ij}(k_e)$) destroys (creates) a photon with energy

$$|k|=|k_e+\omega_{ij}|\approx\omega_{ij}\,. \tag{4.4}$$

Thus k_e acts as an ''envelope'' vector about the ω_{ij} resonance. The photon operators satisfy standard commutation relations

$$[\hat{a}_{ij}(k),\hat{a}^\dagger_{kl}(k')]=[a_{ij}(k),a^\dagger_{kl}(k')]=\delta_{ik}\delta_{jl}\delta(k-k'). \tag{4.5}$$

In writing (4.1) and the above commutation relations, we have assumed that all resonances ω_{ij} $\{\frac{1}{2}(n^2-n)$ in total) are distinct (i.e., $\omega_{ij}=\omega_{kl}\Leftrightarrow i=k$ and $j=l$) and sharp. From (4.5) the component fields satisfy

$$[\psi_{ij}(x,t),\psi^\dagger_{kl}(x',t)]=\frac{1}{2\omega_{ij}}\,\delta_{ik}\delta_{jl}\delta(x-x'), \tag{4.6}$$

with all other commutators zero.

The rotating wave approximation reduces the number of interactions in H_{int}. Using (4.1) in H_{int} we obtain terms with both photon creation ($a^\dagger$) and atomic raising ($\mathcal{O}_{i<j}$) operators (or photon destruction and atomic lowering $\{a,\mathcal{O}_{j>i}\}$), or two photon creation (destruction) operator terms in H_0^ϕ. Such high frequency terms lead to vacuum fluctuations and higher order processes. The rotating wave approximation sets these processes to zero. We also set to zero terms of the form $\psi_{i<j}\mathcal{O}_{k<l}$ (or $\psi^\dagger_{i<j}\mathcal{O}_{l>k}$) for $(i,j)\neq(k,l)$ since they give no contribution to lowest order in perturbation theory. So we only retain those terms which pair creation/lowering or destruction/raising operators (and creation/destruction operators in H_0^ϕ) and connect states with approximately equal energy.

Combining these two approximations we get

$$H_{\text{int}}=-\frac{i}{2}\int dx\sum_{i<j}\beta_{ij}\omega_{ij}(\psi_{ij}e^{i\alpha_{ij}}\mathcal{O}_{ij}e^{-i\omega_{ij}(t-x)}-\psi^\dagger_{ij}e^{-i\alpha_{ij}}\mathcal{O}_{ji}e^{i\omega_{ij}(t-x)}), \tag{4.7}$$

$$H_0^\phi=-2i\int dx\sum_{i<j}\omega_{ij}\psi^\dagger_{ij}\partial_x\psi_{ij}\,. \tag{4.8}$$

The free field Hamiltonian follows from the field action, which using

$$|k_e|^2\ll\omega_{ij}^2\Rightarrow|\partial_x\psi_{ij}|\ll\omega_{ij}|\psi_{ij}|,\quad |\partial_t\psi_{ij}|\ll\omega_{ij}|\psi_{ij}|, \tag{4.9}$$

approximates to

$$\int dx\,dt\tfrac{1}{2}((\partial_t\phi)^2-(\partial_x\phi)^2)\approx 2i\int dx\,dt\sum_{i<j}\omega_{ij}\psi^\dagger_{ij}(\partial_x+\partial_t)\psi_{ij}\,. \tag{4.10}$$

[In (4.8) we have dropped the quadratic term that appears in (3.23). For electric fields small compared with e/a_0^2, this term is negligible in relation to H_{int}.] The phases $e^{\pm i\alpha_{ij}}$ and $e^{\pm i\omega_{ij}x}$ can be absorbed into $\{\psi_{ij},\psi^\dagger_{ij}\}$ and $\{\mathcal{O}_{ij},\mathcal{O}_{ji}\}_{i<j}$, respectively, without changing the commutation relations. The time-dependent phase $e^{-i\omega_{ij}t}$ ($e^{+i\omega_{ij}t}$) cancels the time dependence of $\mathcal{O}_{i<j}$ ($\mathcal{O}_{j>i}$) coming from the free atomic Hamiltonian. Thus we can set H_0^{atom} to zero and consider the model defined by the complete Hamiltonian

$$H=-2i\int dx\sum_{i<j}\omega_{ij}\psi^\dagger_{ij}\partial_x\psi_{ij}-\frac{i}{2}\int dx\sum_{i<j}\omega_{ij}\beta_{ij}(\psi_{ij}\mathcal{O}_{ij}-\psi^\dagger_{ij}\mathcal{O}_{ji}). \tag{4.11}$$

Finally we rescale ψ_{ij} and $\psi_{ij}^\dagger$ as

$$\psi_{ij}\rightarrow\frac{\psi_{ij}}{\sqrt{2\omega_{ij}}},\quad \psi_{ij}^\dagger\rightarrow\frac{\psi_{ij}^\dagger}{\sqrt{2\omega_{ij}}}, \tag{4.12}$$

which gives for the commutator (4.6),

$$[\psi_{ij}(x,t),\psi_{kl}^\dagger(x',t)]=\delta_{ik}\delta_{jl}\delta(x-x'), \tag{4.13}$$

and defining

$$\tilde{\omega}_{i<j}=\frac{1}{2\sqrt{2}}\beta_{ij}\sqrt{\omega_{ij}}=\sqrt{\frac{\Gamma_{ij}^s}{2}},\quad \tilde{\omega}_m=\tilde{\omega}_{mm+1}\quad (1\leqslant m\leqslant r), \tag{4.14}$$

the Hamiltonian (4.11) becomes

$$H=-i\int dx\sum_{i<j}\psi_{ij}^\dagger\partial_x\psi_{ij}-i\int dx\sum_{i<j}\tilde{\omega}_{ij}(\psi_{ij}\mathcal{O}_{ij}-\psi_{ij}^\dagger\mathcal{O}_{ji}). \tag{4.15}$$

The first interaction term, $\psi_{ij}\mathcal{O}_{ij}$, causes an atomic transition from a lower energy state $|j\rangle$ to a higher energy state $|i\rangle$, along with the absorption of a photon of energy $\approx\omega_{ij}$. The second term, $\psi_{ij}^\dagger\mathcal{O}_{ji}$, causes a transition from a higher energy state $|i\rangle$ to a lower energy state $|j\rangle$, along with the creation of a photon of energy $\approx\omega_{ij}$.

From H we can obtain the Heisenberg operator equations of motion. Explicitly we find

$$\partial_t\mathcal{O}_{k<l}=-\sum_{j>l}\tilde{\omega}_{lj}\psi_{lj}\mathcal{O}_{kj}+\sum_{i<k}\tilde{\omega}_{ik}\psi_{ik}\mathcal{O}_{il}+\sum_{\substack{i<l\\ i\neq k}}\tilde{\omega}_{il}\psi_{il}^\dagger\mathcal{O}_{ki}-\sum_{\substack{j>k\\ j\neq l}}\tilde{\omega}_{kj}\psi_{kj}^\dagger\mathcal{O}_{jl}+\tilde{\omega}_{kl}\psi_{kl}^\dagger\sum_{m=k}^{l-1}\mathcal{H}_m, \tag{4.16a}$$

$$\partial_t\mathcal{O}_{l>k}=\partial_t\mathcal{O}_{k<l}^\dagger=-\sum_{j>l}\tilde{\omega}_{lj}\psi_{lj}^\dagger\mathcal{O}_{jk}+\sum_{i<k}\tilde{\omega}_{ik}\psi_{ik}^\dagger\mathcal{O}_{li}+\sum_{\substack{i<l\\ i\neq k}}\tilde{\omega}_{il}\psi_{il}\mathcal{O}_{ik}$$
$$-\sum_{\substack{j>k\\ j\neq l}}\tilde{\omega}_{kj}\psi_{kj}\mathcal{O}_{lj}+\tilde{\omega}_{kl}\psi_{kl}\sum_{m=k}^{l-1}\mathcal{H}_m, \tag{4.16b}$$

$$\partial_t\mathcal{H}_m=-2\tilde{\omega}_{mm+1}(\psi_{mm+1}\mathcal{O}_{mm+1}+\psi_{mm+1}^\dagger\mathcal{O}_{m+1m})-\sum_{j>m+1}\tilde{\omega}_{mj}(\psi_{mj}\mathcal{O}_{mj}+\psi_{mj}^\dagger\mathcal{O}_{jm})$$
$$-\sum_{i<m}\tilde{\omega}_{im+1}(\psi_{im+1}\mathcal{O}_{im+1}+\psi_{im+1}^\dagger\mathcal{O}_{m+1i})+\sum_{i<m}\tilde{\omega}_{im}(\psi_{im}\mathcal{O}_{im}+\psi_{im}^\dagger\mathcal{O}_{mi})$$
$$+\sum_{j>m+1}\tilde{\omega}_{m+1j}(\psi_{m+1j}\mathcal{O}_{m+1j}+\psi_{m+1j}^\dagger\mathcal{O}_{jm+1}), \tag{4.16c}$$

$$(\partial_t+\partial_x)\psi_{k<l}=\tilde{\omega}_{kl}\mathcal{O}_{lk}, \tag{4.16d}$$

$$(\partial_t+\partial_x)\psi_{k<l}^\dagger=\tilde{\omega}_{kl}\mathcal{O}_{kl}. \tag{4.16e}$$

Each term in the equations of motion for the atomic operators has a simple physical interpretation. For example, consider the raising operator $\mathcal{O}_{k<l}$. The first summation in (4.16a) is a sum over all atomic and photon operator pairs, where the photon field destroys a photon of energy $\omega_{l<j}$, and

the atomic (raising) operator causes a transition from the lower state $|j\rangle$ to the higher state $|k\rangle$. The change in energy of the system corresponding to the atomic/field pair being ω_{kl} [as it is for every other term in (4.16a)]. If we think of a field destroying (creating) a photon of energy $\omega_{i<j}$ as ''connecting'' atomic states $|i\rangle$ to $|j\rangle$ ($|j\rangle$ to $|i\rangle$), along with $\mathcal{O}_{i<j}$ ($\mathcal{O}_{j>i}$) connecting $|j\rangle$ to $|i\rangle$ ($|i\rangle$ to $|j\rangle$) and $\mathcal{H}_m$ connecting $|m\rangle$ to $|m\rangle$ and $|m+1\rangle$ to $|m+1\rangle$, then (4.16a) is, aside from c-number factors, a sum over all atomic/field pairs connecting $|l\rangle$ to $|k\rangle$ through some intermediate state, i.e., $|l\rangle\rightarrow|j\rangle\rightarrow|k\rangle$. A similar interpretation follows for $\mathcal{O}_{l>k}$ and $\mathcal{H}_m$.

These equations of motion have a zero curvature representation (Refs. 5 and 6)

$$\partial_t A_x - \partial_x A_t = [A_x, A_t], \tag{4.17}$$

where A_x and A_t are matrices of quantum operators given by

$$A_x = \mu \sum_{1\leq m,n\leq r} A^{-1}_{mn}\mathcal{H}_n H^\rho_m + \mu \sum_{i<j} (\mathcal{O}_{ij}E^\rho_{ij} + \mathcal{O}_{ji}E^\rho_{ji}) + \sum_{i<j} \tilde{\omega}_{ij}(-\psi^\dagger_{ij}E^\rho_{ij} + \psi_{ij}E^\rho_{ji}) - \frac{1}{\mu}\sum_{1\leq m,n\leq r} A^{-1}_{mn}\tilde{\omega}^2_n H^\rho_m, \tag{4.18a}$$

$$A_t = \frac{1}{\mu}\sum_{1\leq m,n\leq r} A^{-1}_{mn}\tilde{\omega}^2_n H^\rho_m - \sum_{i<j} \tilde{\omega}_{ij}(-\psi^\dagger_{ij}E^\rho_{ij} + \psi_{ij}E^\rho_{ji}), \tag{4.18b}$$

provided that the $\tilde{\omega}_{i<j}$'s satisfy

$$\tilde{\omega}^2_{i<j} = \tilde{\omega}^2_{i<k} + \tilde{\omega}^2_{k<j}, \tag{4.19}$$

for any intermediate value of $k, i<k<j$. This is trivially satisfied by $\tilde{\omega}_{ii+1}$, in which case there is no such k. Here A^{-1}_{mn} is the inverse Cartan matrix, and $\{E^\rho_{i\neq j}, H^\rho_m\}$ are matrices in any representation ρ of sl_n satisfying (2.2). Requiring (4.17) to be valid for all values of the arbitrary spectral parameter μ, is equivalent to the equations of motion (4.16) [of course provided (4.19) is satisfied]. This equivalence can be shown by making use of the commutation relations (2.2). The equations of motion (4.16c) for the $\mathcal{H}_m$ operators can be rewritten in a more compact form

$$\partial_t \mathcal{H}_m = -\sum_{u=1}^{r} A_{mu} \sum_{u<l\leq n} \sum_{k=1}^{u} \tilde{\omega}_{kl}(\mathcal{O}_{kl}\psi_{kl} + \mathcal{O}_{lk}\psi^\dagger_{kl}). \tag{4.20}$$

The constraint (4.19) arises in forming a zero curvature representation for the field ($\{\psi_{ij}, \psi^\dagger_{ij}\}$) equations of motion, and reduces the number of free parameters to $r=n-1$, these being $\{\tilde{\omega}_m\}_{1\leq m\leq r}$. The definition (4.14) shows that the constraint is equivalent to the requirement that the spontaneous decay rate (for a single atom) from $|i\rangle$ to $|j\rangle$, Γ^s_{ij}, be equal to the sum of the decay rates Γ^s_{ik} and Γ^s_{kj} for any intermediate state $|k\rangle$,

$$\Gamma^s_{i<j} = \Gamma^s_{i<k} + \Gamma^s_{k<j}. \tag{4.21}$$

The equations of motion for the atomic operators have the zero curvature representation (4.17) independent of the constraint.

Having obtained a zero curvature representation, the system can now be solved using the quantum inverse scattering method (see Ref. 7 and references therein). In particular, from (4.17) and (4.18) one can construct a quantum monodromy matrix $T(\mu)$ depending on the spectral parameter μ, with the property that its trace, i.e., the transfer matrix $\tau(\mu) = \mathrm{Tr}\, T(\mu)$, commutes for arbitrary values of μ, $[\tau(\mu), \tau(\lambda)] = 0$. Furthermore, this commutation relation implies that $[H, \tau(\mu)] = 0$, which when expanded in μ leads to an infinite set of quantum conservation laws, hence integrability of the model. Eigenstates and eigenvalues of H can then be constructed with the algebraic Bethe ansatz.

(Received 25 February 1999; accepted for publication 21 April 1999)

In 1992, Dyson published Feynman's proof of the homogeneous Maxwell equations assuming only the Newton's law of motion and the commutation relations between position and velocity for a nonrelativistic particle. Recently Tanimura gave a generalization of this proof in a relativistic context. Using the Hodge duality we extend his approach in order to derive the two groups of Maxwell equations with a magnetic monopole in flat and curved spaces. [S0022-2488(99)00408-9]

I. INTRODUCTION

Various ways exist to present the Maxwell equations. The usual one is the historical approach in which the empirical basis for each equation is first given. Another remarkable way is exposed in an old unpublished work of Feynman, reported more recently in an elegant paper by Dyson.[1] His proof of Maxwell equations is shown assuming only the Newton's law of motion:

$$F^i = m\frac{d^2x^i}{dt^2}, \tag{1}$$

the commutation relations between position and velocity for a simple nonrelativistic particle, without reference to an action or variational principle:

$$[x^i, x^j] = 0, \tag{2}$$

and

$$m[x^i, \dot{x}^j] = i\hbar\,\delta^{ij}. \tag{3}$$

From this assumption he deduced that $\vec{F}$ has the form of the Lorentz force:

$$F^i(x^k, \dot{x}^k, t) = q\{E^i(x^k, t) + [\vec{\dot{x}} \wedge \vec{B}(x^k, t)]^i\}, \tag{4}$$

where the fields satisfy the first group of Maxwell equations:

$$\begin{gathered} \operatorname{div}\vec{B} = 0, \\ \frac{\partial\vec{B}}{\partial t} + \overrightarrow{\mathrm{rot}}\,\vec{E} = 0. \end{gathered} \tag{5}$$

The remaining two other equations are claimed to be a definition of charge density ϱ and current density $\vec{j}$. This is a nontrivial and very interesting result because first, the basic assumption appears to restrict the interaction of a nonrelativistic particle to the electromagnetic one and second, there is no need for the existence of Hamiltonian or Lagrangian formalism. Note however that Hojman and Shepley[2] showed how under certain conditions, an action could be associated to the Feynman's commutation relations using a Helmholtz variational inverse problem.[3]

Since then, several other authors have contributed to the success of this Feynman's presentation. In particular, Tanimura[4] has proposed a generalization in a Lorentz covariant form with a scalar evolution parameter τ and an extension to the case of non-Abelian gauge theories. In a recent letter[5] we have explained how, if a sO_3 Lie algebra structure is required, a Poincaré magnetic momentum and a Dirac magnetic monopole can be introduced in three dimensions.

In this letter, we extend Tanimura's work in the four-dimensional formalism to find the four Maxwell equations which appear as a consequence of the Jacobi identities. The main part is devoted to the demonstration of the generalized Maxwell equations with a magnetic monopole which requires the Hodge duality of the electromagnetic tensor $F^{\mu\nu}$. In this context the duality between the electric and magnetic fields is also due to the Jacobi identities. The case of a curved space is rapidly treated as a direct application of this formalism.

In this approach we can naturally introduce the fiber bundle formalism and particularly the tangent bundle structure (not the cotangent fiber bundle). This is, however, not essential for our purpose. The space where we work is the configuration space in the physicist's language.

II. MAXWELL EQUATIONS IN $D=4$

Assume a particle of mass m moving in the Minkowski space with position $x^\mu(\tau)$ ($\mu=1,2,3,4$) depending on the parameter τ. Contrary to Dyson, we do not postulate the Newton equation of motion. Instead we consider at the starting point a natural commutation relation:

$$[x^\mu,x^\nu]=0, \tag{6}$$

with the following property:

$$\frac{d}{d\tau}[x^\mu,x^\nu]=[\dot{x}^\mu,x^\nu]+[x^\mu,\dot{x}^\nu]. \tag{7}$$

Differentiating (6) with respect to time gives:

$$[\dot{x}^\mu,x^\nu]+[x^\mu,\dot{x}^\nu]=0, \tag{8}$$

which implies

$$[x^\mu,\dot{x}^\nu]=\frac{g^{\mu\nu}(x)}{m}, \tag{9}$$

where $g^{\mu\nu}(x)$ is a symmetric tensor. A symplectic structure is then defined on the tangent bundle like Souriau[6] in his symplectic classical mechanics.

Following Tanimura[4] we consider in Secs. I and II the case where $g^{\mu\nu}(x)$ is the metric tensor of the Minkowski space:

$$g^{\mu\nu}(x)=g^{\mu\nu}. \tag{10}$$

We also require that the brackets satisfy the relations:

$$\begin{gathered}[A,B]=-[B,A],\\ [A,BC]=[A,B]C+B[A,C]\quad\text{(Leibnitz rule)},\\ [A,[B,C]]+[B,[C,A]]+[C,[A,B]]=0\quad\text{(Jacobi identity)},\end{gathered} \tag{11}$$

where the quantities A, B, and C can be equal to x^μ or $\dot{x}^\mu$.

Combining Eqs. (9)–(11) we get:

$$[x^\mu, f(x^\rho)] = 0,$$
$$[x^\mu, f(x^\rho, \dot{x}^\rho)] = \frac{1}{m}\frac{\partial f(x^\rho, \dot{x}^\rho)}{\partial \dot{x}^\mu}, \tag{12}$$
$$[\dot{x}^\mu, f(x^\rho)] = -\frac{1}{m}\frac{\partial f(x^\rho)}{\partial x^\mu}.$$

On another hand, differentiating (9) gives:

$$[x^\mu, \ddot{x}^\nu] = -[\dot{x}^\mu, \dot{x}^\nu] = \frac{q}{m^2}F^{\mu\nu}, \tag{13}$$

where F is an antisymmetric tensor and q will be associated to the electric charge of the particle in the following.

Using the Jacobi identity (11) and the relations (12) we easily find that $F^{\mu\nu}$ is only position coordinates dependent and then deduce the first group of Maxwell equations:

$$\partial^\mu F^{\nu\rho} + \partial^\nu F^{\rho\mu} + \partial^\rho F^{\mu\nu} = 0. \tag{14}$$

Contracting two indices we find:

$$\partial^\nu F^\mu_\nu = -\partial^\nu F^\mu{}_\nu = -j^\mu, \tag{15}$$

which is the second group of Maxwell equations. Contrary to the three-dimensional case, the second group of Maxwell equations is not imposed as a definition of the matter as in Ref. 1. Here it is a direct consequence of the formalism.

Note that by integrating (13) we get also the equation of motion:

$$m\ddot{x}^\mu = qF^{\mu\nu}(x)\dot{x}_\nu + G^\mu(x), \tag{16}$$

where the field $G^\mu(x)$ satisfies

$$\partial^\mu G^\nu - \partial^\nu G^\mu = 0. \tag{17}$$

Taking the divergence of the "current density" we obtain the current density conservation law:

$$\partial_\mu j^\mu = [\dot{x}_\mu, j^\mu] = [\dot{x}_\mu, [\dot{x}^\nu [\dot{x}^\mu, \dot{x}_\nu]]] = 0. \tag{18}$$

We finally see that Tanimura's approach contains all the Maxwell equations in the presence of an electric source. In Sec. III we extend this formalism by introducing the Hodge duality of the electromagnetic tensor.

III. MAXWELL EQUATIONS WITH MAGNETIC MONOPOLE

Instead of (13) we choose for the definition of the gauge curvature:

$$[x^\mu, \ddot{x}^\nu] = -[\dot{x}^\mu, \dot{x}^\nu] = \frac{1}{m^2}(qF^{\mu\nu} + g{}^*F^{\mu\nu}), \tag{19}$$

where g will be interpreted as the magnetic charge of the Dirac monopole. The * operation is the Hodge duality.

As usually we deduce the equation of motion by integrating (19),

$$m\ddot{x}^{\mu}=(qF^{\mu\nu}(x)+g{}^{*}F^{\mu\nu}(x))\dot{x}_{\nu}+G^{\mu}(x)$$

and in the same manner as Sec. II we find:

$$\partial^{\mu}G^{\nu}-\partial^{\nu}G^{\mu}=0. \tag{20}$$

The Jacobi identity between the velocities (11) gives the following relation between the electromagnetic tensor and his dual:

$$q(\partial^{\mu}F^{\nu\rho}+\partial^{\nu}F^{\rho\mu}+\partial^{\rho}F^{\mu\nu})+g(\partial^{\mu}{}^{*}F^{\nu\rho}+\partial^{\nu}{}^{*}F^{\rho\mu}+\partial^{\rho}{}^{*}F^{\mu\nu})=0, \tag{21}$$

that is:

$$\begin{aligned}\partial^{\mu}F^{\nu\rho}+\partial^{\nu}F^{\rho\mu}+\partial^{\rho}F^{\mu\nu}&=gN^{\mu\nu\rho},\\ \partial^{\mu}{}^{*}F^{\nu\rho}+\partial^{\nu}{}^{*}F^{\rho\mu}+\partial^{\rho}{}^{*}F^{\mu\nu}&=-qN^{\mu\nu\rho},\end{aligned} \tag{22}$$

where $N^{\mu\nu\rho}$ is a tensor to be interpreted.

Using the differential forms language defined on the Minkowski space (M_4) we write the preceding equations in a compact form:

$$\begin{aligned}dF&=gN,\\ d{}^{*}F&=-qN,\end{aligned} \tag{23}$$

where F and ${}^{*}F\in\wedge^{2}(M_4)$ and $N\in\wedge^{3}(M_4)$.

If we put:

$$\begin{aligned}gN&=-{}^{*}k,\\ qN&={}^{*}j,\end{aligned} \tag{24}$$

where j and $k\in\wedge^{1}(M_4)$, we deduce:

$$\begin{aligned}\delta F&=j,\\ dF&=-{}^{*}k,\end{aligned} \tag{25}$$

δ being the usual codifferential,

$$\delta:\wedge^{k}(M_4)\rightarrow\wedge^{k-1}(M_4),$$

defined here as

$$\delta=(-)^{k(4-k+1)+1}({}^{*}d{}^{*}).$$

Interpreting the 1-forms j and k as the electric and magnetic four-dimensional current densities we obtained the two groups of Maxwell equations in the presence of a magnetic monopole. Note that the Jacobi identity imposes a proportionality relation between the two currents.

As in the absence of monopole we find the conservation of the two current densities:

$$\begin{aligned}\partial_{\mu}j^{\mu}&=[\dot{x}_{\mu},j^{\mu}]=\delta j=0,\\ \partial_{\mu}k^{\mu}&=[\dot{x}_{\mu},k^{\mu}]=\delta k=0,\end{aligned} \tag{26}$$

giving the following possible choice for the currents:

$$k^\mu=\rho_m\dot{x}^\mu,$$
$$j^\mu=\rho_e\dot{x}^\mu, \tag{27}$$

where ρ_m and ρ_e are evidently the magnetic and the electric charge densities.

Remark: The differential forms used in this part are of course singular differential forms which are naturally associated to the electric and magnetic current densities of point particles. These densities are then represented also by singular 1-forms defined throughout the whole Minkowski space.

IV. APPLICATION TO A CURVED SPACE

Like Tanimura[4] we now consider in (9) a general metric tensor,

$$[x^\mu,\dot{x}^\nu]=-\frac{g^{\mu\nu}(x)}{m}.$$

Differentiating this last equation we obtain

$$m[x^\mu,\ddot{x}^\nu]=-m[\dot{x}^\mu,\dot{x}^\nu]=-\partial_\rho g^{\mu\nu}\dot{x}^\rho.$$

Following the previous parts we define a new tensor $W^{\mu\nu}(x,\dot{x})$ and its dual, both position and velocity dependent, such that

$$[x^\mu,\ddot{x}^\nu]=-[\dot{x}^\mu,\dot{x}^\nu]=\frac{1}{m^2}(qW^{\mu\nu}(x,\dot{x})+g{}^*W^{\mu\nu}(x,\dot{x})), \tag{28}$$

which implies

$$q[x^\rho,W^{\mu\nu}]+g[x^\rho,{}^*W^{\mu\nu}]=m^2(\partial^\mu g^{\rho\nu}-\partial^\nu g^{\rho\mu}) \tag{29}$$

or

$$qW^{\mu\nu}+g{}^*W^{\mu\nu}=m(\partial^\mu g^{\rho\nu}-\partial^\nu g^{\rho\mu})\dot{x}_\rho+qF^{\mu\nu}(x)+g{}^*F^{\mu\nu}(x). \tag{30}$$

Integrating (28) and using (30) we recover the Lorentz force:

$$F^\mu(x,\dot{x},\tau)=m\frac{d\dot{x}^\mu}{d\tau}=-m\Gamma^{\nu\rho\mu}(x)\dot{x}_\nu\dot{x}_\rho-qF^{\nu\mu}\dot{x}_\nu-g{}^*F^{\nu\mu}\dot{x}_\nu+G^\mu(x,\tau). \tag{31}$$

The Christoffel symbols are defined by

$$\Gamma^{\nu\rho\mu}=\tfrac{1}{2}(\partial^\rho g^{\nu\mu}-\partial^\nu g^{\rho\mu}-\partial^\mu g^{\rho\nu}) \tag{32}$$

and the Hodge duality is

$${}^*F^{\mu\nu}=\frac{1}{2\sqrt{-g}}\epsilon^{\mu\nu\rho\sigma}F_{\rho\sigma}.$$

On another side, like Tanimura in the case without Hodge duality, we easily obtain

$$[\dot{x}_\mu,\dot{x}_\nu]=-\frac{1}{m^2}(qF_{\mu\nu}+g{}^*F_{\mu\nu}).$$

Requiring that the Jacobi identities (11) are also satisfied in this context, and introducing $x_\mu=g_{\mu\nu}x^\nu$, we can then demonstrate that

$$[\dot{x}_\mu,[\dot{x}_\nu,\dot{x}_\rho]]+[\dot{x}_\nu,[\dot{x}_\rho,\dot{x}_\mu]]+[\dot{x}_\rho,[\dot{x}_\mu,\dot{x}_\nu]]=0,$$
$$[x_\mu,[\dot{x}_\nu,\dot{x}_\rho]]+[\dot{x}_\nu,[\dot{x}_\rho,x_\mu]]+[\dot{x}_\rho,[x_\mu,\dot{x}_\nu]]=0, \tag{33}$$

and that the antisymmetric tensors $F^{\nu\mu}$ obeys the same equation as in the Minkowski case:

$$q(\partial_\mu F_{\nu\rho}+\partial_\nu F_{\rho\mu}+\partial_\rho F_{\mu\nu})+g(\partial_\mu^* F_{\nu\rho}+\partial_\nu^* F_{\rho\mu}+\partial_\rho^* F_{\mu\nu})=0.$$

Such an equation is not possible for the tensor $W^{\mu\nu}$, because it is also velocity dependent.

Repeating the same computation as in Sec. III we again arrive at

$$\delta F=j,$$
$$dF=-{}^*k. \tag{34}$$

V. CONCLUSION

The Tanimura covariant extension of Feynman's formalism is a good approach for the study of gauge theories with magnetic monopoles, the two groups of Maxwell equations being a direct consequence of the different Jacobi identities. We have presented two ways to find this result. The first one is an improvement of Tanimura's deduction. The second one is narrowly connected to the Hodge duality and to the presence of a magnetic monopole. The case without Hodge duality can be retrieved by setting the magnetic current density equal to zero. The generalization to a curved space is direct. The problem of the physical meaning of this τ parameter is still open.

(Received 27 October 1997; accepted for publication 1 April 1999)

We present in detail a class of solutions to the 4D SU(∞) Moyal–anti-self-dual Yang–Mills (ASDYM) equations (an effective 6D theory) that are related to *reductions* of the generalized Moyal–Nahm equations using the Ivanova–Popov ansatz. The former yields solutions to the ASDYM/SDYM equations for arbitrary gauge groups in four dimensions. A further dimensional reduction of the above effective 6D equations yields solutions to the Moyal–anti-self-dual gravitational equations in four dimensions. The self-dual Yang–Mills/self-dual gravity case requires a separate study. The SU(2) Toda lattice and SU(∞) (continuous) Moyal–Toda lattice equations are derived from the Moyal–Nahm equations. An explicit map taking the Moyal heavenly form (after a rotational Killing symmetry reduction of the Moyal heavenly equations) into the SU(2) Toda lattice field is found. Finally, the generalized Moyal–Nahm equations are conjectured that contain the (continuous) SU(∞) Moyal–Toda lattice equations, after a suitable reduction process. Embeddings of the different types of Moyal–Toda lattice equations into the Moyal–Nahm equations are described.

I. INTRODUCTION

The quantization program of the 3D continuous Toda theory (2D Toda molecule) is a challenging enterprise that we believe would enable us to understand many of the features of the quantum dynamics and spectra of the quantum self-dual membrane.[1] This is based on the observation that the light-cone-gauge (spherical) supermembrane moving in a D-dimensional flat space–time background has a correspondence with a $D-1$ SU(∞) super Yang–Mills (SYM) theory, dimensionally reduced to one temporal dimension; i.e., with an SU(∞) supersymmetric gauge quantum mechanical model (matrix model).[2,3]

It was shown in Ref. 1 that exact (particular) solutions of the $D=11$ light-cone (spherical) supermembrane, related to the $D=10$ SU(∞) SYM theory, could be constructed based on a particular class of reductions of the SYM equations from higher dimensions to four dimensions.[4] In particular, solutions of the $D=10$ YM equations given by the $D=10$ YM potentials, $\mathcal{A}_\mu$, can be obtained in terms of the 4D YM potentials, A_i, that obey the $D=4$ self-dual YM (SDYM) equations. Dimensional reductions of the latter SU(∞) SDYM equations to one temporal dimension are equivalent to the SU(∞) Nahm equations in the temporal gauge $A_0=0$.

Finally, the embedding of the continuous SU(∞) Toda equation into the SU(∞) Nahm equations was performed in Ref. 1 based on the connection between the $D=5$ self-dual membrane and the SU(2) Toda molecule/chain equations.[5] A continuous Toda theory in connection to self-dual

[a)]Electronic mail: castro@ctsps.cau.edu

gravity was also found by Chapline and Yamagishi[6] in the description of a three-dimensional version of anyon superconductivity. Based on the theory of gravitational instantons, a 3D model describing the condensation of quasi-particles (*chirons*) with properties related to fractional statistics was found.

The classical Toda theory can be obtained also from a rotational Killing symmetry reduction[7] of the 4D self-dual gravitational (SDG) equations expressed in terms of first heavenly form that furnish (complexified) self-dual metrics of the form: $ds^2=(\partial_{x^i}\partial_{\tilde{x}^j}\Omega)dx^i d\tilde{x}^j$ for $x^i=y,z$; $\tilde{x}^j=\tilde{y},\tilde{z}$ and Ω is the first heavenly form. The latter equations can, in turn, be obtained from a dimensional reduction of the 4D SU(∞) SDYM equations, an effective 6D theory (Refs. 8 and 9 and references therein). The Lie algebra su(∞) was shown to be isomorphic (in a basis-dependent limit) to the Lie algebra of area-preserving diffeomorphisms (diffs) of a 2D surface, $sdiff(\Sigma)$ by Hoppe.[2] It is for this reason that a Weyl–Wigner–Moyal (WWM) quantization of the reductions of the first heavenly equation will be used in this letter.

Using our results of Ref. 10 based on Ref. 11 we have shown that a Weyl–Wigner–Groenwold–Moyal (WWGM)[12] quantization approach yields a straightforward quantization scheme for the 3D continuous Toda theory (2D Toda molecule). Supersymmetric extensions can be carried out following Ref. 8 where we wrote down the supersymmetric analog of the heavenly equations for SD supergravity.

There are some differences between our results and those which in general have appeared in the literature. Among these are (i) one is *not* taking the limit of $\hbar\rightarrow 0$ while having $N=\infty$ in the classical SU(N). Recently, Fairlie[13] has written solutions to Moyal–Nahm equations, with $\hbar\neq 0$ for the eight transverse membrane coordinates in $D=11$ in terms of spinors using the WWM formulation. (ii) We are working with the generalized Moyal–Nahm equations involving a Moyal bracket wrt an *enlarged* phase space, q,p,q',p' and not with the standard SU(2) Moyal–Nahm equations involving a Moyal bracket wrt q,p only. We have $\hbar\neq 0$, $N=\infty$ simultaneously. (iii) The connection with the self-dual membrane and W_∞ algebras was proposed in Ref. 1. The results of Ref. 11 become very useful in the implementation of the WWM quantization program and in the embedding of the SU(2) Moyal–Nahm solutions into the generalized Moyal–Nahm equations studied in the present work.

In the next section we present in detail a class of solutions to the 4D SU(∞) Moyal anti-self-dual Yang–Mills equations that are related to *reductions* of the generalized Moyal–Nahm equations using the Ivanova–Popov ansatz. The former yields solutions to the anti-self-dual Yang–Mills (ASDYM)/SDYM equations for arbitrary gauge groups. A further dimensional reduction yields solutions to the Moyal anti-self-dual gravitational equations. The self-dual Yang–Mills/self-dual gravity case requires a separate study.

We write down the explicit Moyal quantization of all the equations involved in the Ivanova–Popov construction.[4] In particular, deformations of the ordinary Laplace equation in four dimensions are required. This is necessary in order to write down the equation governing the deformations of the scalar field involved in the construction of Ref. 4, and which is mapped into the Moyal deformed continuous Toda field via deformations of the twistor transform. Deformations of twistor surfaces have yet to be constructed. For comments in that direction we refer to the work of Strachan and Takasaki[14,15] in their study of higher-dimensional integrable models.

In Sec. III the SU(2) Toda lattice and (continuous) SU(∞) Moyal–Toda lattice-type equations are derived from Moyal–Nahm equations. By ''SU(∞) Moyal'' one means the Moyal deformations of the symplectic diffeomorphisms in four dimension instead of two. This will be explained in detail in the text. The Legendre-like transform between solutions to the rotational Killing symmetry reductions of the 4D Moyal heavenly equations and the SU(2) Toda lattice equations is studied, in particular, the explicit map taking the Moyal heavenly form into the SU(2). The Toda lattice field is found.

Finally, in Sec. IV, the generalized Moyal–Nahm equations are provided that *contain* the (continuous) SU(∞) Moyal–Toda lattice-type equations after a suitable reduction. Embeddings of the different types of Moyal–Toda lattice equations into the Moyal–Nahm equations are provided.

The most salient feature of the generalized Moyal–Nahm equation is that it involves an effective 8D theory associated with symplectic diffeomorphisms of a 4D manifold. This 8D effective theory may have an important role in understanding the quantum dynamics of the 11D supermembrane based on the the m(atrix) membrane models and their integrability properties.[3,13]

In the conclusion we discuss (among other things) briefly how deformation quantization techniques for higher-dimensional volume forms, the Zariski quantization,[16] may be used to quantize p branes. Other types of deformations are possible, like those which give up the *associative* character of the Moyal product, the so-called q deformations, and which can be used to construct deformations of the self-dual membrane (we refer to Ref. 17). We expect that a q-Moyal deformation program of the self-dual membrane might yield important information about how to quantize the full membrane theory beyond the self-dual exactly integrable sector and that the particle/soliton spectrum of the underlying conformal affine Toda models will shed some light onto the particle content of the more general theory.[1,10]

Note: Sometime after this work was completed we were informed[18] based on Strachan's work[14] that a map from the master equation involving the Moyal deformations of the SDYM equations to Strachan's SU(2) Toda lattice equation (a Toda lattice model whose discrete spacing is given by multiples of $\hbar$) could be obtained by a suitable dimensional reduction. However, the latter reduction is *not* a rotational Killing symmetry reduction studied in this work; i.e, the particular dimensional reduction of the effective 6D master equation is *not* a Moyal deformation of the heavenly equation (although the heavenly equation can be obtained from the master equation). The results of Ref. 18 are based on a *two*-step process where *after* performing the WWGM map, an explicit introduction of $\hbar$ is put in by hand. More on this shall be explained in the text.

Remark: In this paper we use the following abbreviations: ''Moyal–Nahm equation'' stands for ''the Moyal deformation of the Nahm equation;'' ''Moyal–Toda equation'' means ''the Moyal deformation of the Toda equations,'' etc.

II. THE SU(∞) MOYAL ASDYM/SDYM EQUATIONS

We will study in this section the Moyal 4D SU(∞) ASDYM/SDYM in connection to the ASDG/SDG equations and the continuous 2D Toda molecule. To begin with, the Moyal bracket of two YM potentials $A_y, A_{\tilde{y}}$, for example, can be expanded in powers of $\hbar$ as in Ref. 14:

$$\{A_y, A_{\tilde{y}}\}_{q,p} \equiv \sum_{s=0}^{\infty} \frac{(-1)^2 \hbar^{2s}}{(2s+1)!} \sum_{l=0}^{2s+1} (-1)^l (C_l^{2s+1}) [\partial_q^{2s+1-l} \partial_p^l A_y][\partial_p^{2s+1-l} \partial_q^l A_{\tilde{y}}], \tag{1}$$

where C_l^{2s+1} are the binomial coefficients.

The crucial difference between the solutions of the SU(2) Moyal–Nahm equations[11] and the generalized Moyal–Nahm case is that one *must* have an *extra* explicit dependence on another *set* of phase space variables, q', p'. In particular, those *reductions* of the generalized Moyal–Nahm equations that are linked to the Moyal–Toda equations must have an extra t dependence for the YM potentials. The continuous Toda molecule equation as well as the usual Toda system may be written in the double commutator form of the Brockett equation:[19]

$$\frac{\partial L(\tau,t)}{\partial \tau} = [L, [L, H]]. \tag{2}$$

Here L has the form

$$L \equiv A_+ + A_- = X_o(-iu) + X_{+1}(e^{(\rho/2)}) + X_{-1}(e^{(\rho/2)}), \tag{3}$$

with the connections $A_\pm$ taking values in the subspaces $\mathcal{G}_o \oplus \mathcal{G}_{\pm 1}$ of some $\mathbf{Z}$-graded continuum Lie algebra $\mathcal{G} = \oplus_m \mathcal{G}_m$ of a novel class. Here $H = X_o(\kappa)$ is a continuous limit of the Cartan element of the principal sl(2) subalgebra of $\mathcal{G}$. The functions $\kappa(\tau,t), u(\tau,t), \rho(\tau,t)$ satisfied certain equations given in Ref. 19.

Upon the elimination of u one obtains the Toda equation. A naive look at (2) might beg the question: Where is the t dependence? The t dependence is *encoded* in the continuum algebra commutation relations of the generators that are parametrized by a family of functions depending on both τ and t. It is in this fashion that the t dependence makes its presence in (2).

To implement the WWM prescription, one may consider the case when **G** is a group of unitary operators acting in the Hilbert space of square integrable functions on the line, $L^2(R^1)$. Then, $\mathcal{G}$ is now the associated (continuum) Lie algebra of self-adjoint operators acting in the Hilbert space, $L^2(R^1)$. The following operator-valued quantities depend on the two coordinates, τ and t, obey the operator version of the Brockett equation, and, after the WWM map, read

$$\frac{\partial \hat{L}(\tau,t)}{\partial \tau}=\frac{1}{i\hbar}[\hat{L},\frac{1}{i\hbar}[\hat{L},\hat{H}]]\leftrightarrow\frac{\partial\mathcal{L}}{\partial\tau}=\{\mathcal{L},\{\mathcal{L},\mathcal{H}\}\}, \tag{4}$$

where $\mathcal{L}(\tau,t,q,p;\hbar)$ and $\mathcal{H}(\tau,t,q,p;\hbar)$ are the corresponding elements in the phase space after performing the WWM map. The main problem with this approach is that we do *not* have representations of the continuum **Z**-graded Lie algebras in the Hilbert space, $L^2(R^1)$, and, consequently, we cannot evaluate the matrix elements $\langle q-(\xi/2)|\hat{L}(r,\tau)|q+(\xi/2)\rangle;\langle\hat{H}\rangle$. For this reason we have to return to another method to solve this problem.

The quantities $\mathcal{L}$ and $\mathcal{H}$ are defined as

$$\mathcal{L}(\tau,t,q,p;\hbar)\equiv\int_{-\infty}^{\infty}d\xi\left\langle q-\frac{\xi}{2}\right|\hat{L}(\tau,t)\left|q+\frac{\xi}{2}\right\rangle\exp\left[\frac{i\xi p}{\hbar}\right], \tag{5}$$

$$\mathcal{H}(\tau,t,q,p;\hbar)\equiv\int_{-\infty}^{\infty}d\xi\left\langle q-\frac{\xi}{2}\right|\hat{H}(\tau,t)\left|q+\frac{\xi}{2}\right\rangle\exp\left[\frac{i\xi p}{\hbar}\right]. \tag{6}$$

The latter matrix elements, if known, suffice to determine the quantities $\mathcal{L}$ and $\mathcal{H}$ associated with the 2D continuous Toda molecule equation.

Despite not knowing the explicit operator form of $\hat{L}(\tau,t)$ and $\hat{H}(\tau,t)$ acting in the Hilbert space, $L^2(R^1)$, one may still write down solutions for the continuous Moyal–Toda equation. This can be achieved starting from the original Moyal SDYM/ASDYM equations associated with the SU(∞) group in $D=4$ and looking for solutions. Ivanova and Popov,[4] in a summary of YM equations in $D\geqslant 4$, have discussed that solutions to the ASDYM/SDYM equations in $D=4$ for an arbitrary Lie group, G, which are *linked* to the Nahm equations, may be obtained from the ansatz:

$$A_\mu=-\eta^\alpha_{\mu\nu}T_\alpha(\phi(x^\mu))\partial_\nu\phi,\quad \eta^\alpha_{\mu\nu}=\epsilon^\alpha_{\beta\gamma},\quad \eta^\alpha_{\mu 0}=-\eta^\alpha_{0\mu}=\delta^\alpha_\mu. \tag{7}$$

The t'Hooft matrices obey the quaternionic algebra: $\eta^\alpha_{\mu\lambda}\eta^\beta_{\lambda\nu}=-\delta^{\alpha\beta}\delta_{\mu\nu}-\epsilon^{\alpha\beta\gamma}\eta^\gamma_{\mu\nu}$. The function ϕ obeys $\partial_\mu\partial^\mu\phi=0$ (ASDYM) and $\phi=x_\mu x^\mu$ (SDYM), and the three Lie algebra-valued *scalar* functions $T_\alpha(\phi)=T^A_\alpha(\phi)L_A$, for $\alpha=1,2,3$, satisfy the Nahm equations wrt the ϕ function:

$$\epsilon_{\alpha\beta\gamma}\frac{dT_\gamma}{d\phi}=\pm[T_\alpha,T_\beta], \tag{8}$$

where the $\pm$ corresponds to the SDYM/ASDYM case. Notice that the simple reflection $T_\alpha\to -T_\alpha$ converts the SDYM to the ASDYM solutions with the proviso that now ϕ obeys the 4D Laplace equation. It is very important to emphasize that Ivanova and Popov used a Euclidean space–time signature. This will become important later on when we discuss other results obtained in a $(++,--)$ signature.

The Ivanova–Popov ansatz, for Euclidean signatures, will yield solutions to the Moyal deformations of the anti-self-dual gravitational equations in four dimensions from dimensional reductions of the SU(∞) ASDYM equations. However, this will not be the case for the self-dual gravitational equations that can be obtained from reductions of the SU(∞) SDYM equations. The

Ivanova–Popov ansatz will not yield solutions to the Moyal deformations of the SDG equations. Another type of solutions will be required. For signatures $2+2$, the situation is reversed. More on this issue will be clarified in the next sections.

A WWM quantization requires writing down the symbol map of the *operators* acting in the Hilbert space, $L^2(R^1)$, associated with the three Lie-algebra-valued functions, $\hat{T}_\alpha$, so the Moyal–Nahm equations are

$$\epsilon_{\alpha\beta\gamma}\frac{\partial \mathcal{T}_\gamma}{\partial \phi}=\pm\{\mathcal{T}_\alpha,\mathcal{T}_\beta\}_{\text{Moyal}}, \tag{9a}$$

with $\mathcal{T}_\alpha(\phi(x^\mu;q,p,\hbar);q,p,\hbar)=\text{symbol}[\hat{T}_\alpha]$, where $\hat{T}_\alpha$ is a representation of the Lie-algebra-valued operators in $L^2(R^1)$. Shortly we will explain why ϕ acquires also a $q,p,\hbar$ dependence.

Rigorously speaking one should write $\mathcal{T}_\alpha[\mathcal{G}]$ to include the explicit dependence of $\mathcal{T}_\alpha$ on the Lie algebra $\mathcal{G}$ involved initially in the construction. In the case that $G=\text{SU}(\infty)$, one is required then to *extend* the symplectic diffeomorphisms in two to four dimensions. The Moyal bracket involves now a generalized phase space q_i,p_i for $i=1,2$. For $G=\text{SU}(2)$ the fact that the dual of the SU(2) Lie algebra is R^3 allows us to establish the *correspondence* among the three scalars $\mathcal{T}_\alpha$ with the three components X,Y,Z of a four-vector, after fixing the gauge $A_0=0$, replacing ϕ by τ and making the correspondence $A_x\leftrightarrow X$, $A_y\leftrightarrow Y$, $A_z\leftrightarrow Z$. In this way one retrieves the SU(2) Moyal–Nahm equations

$$\frac{\partial X}{\partial \tau}=\{Y,Z\},\ \ldots$$

for the three vector-valued functions $X_i=X_i(\tau;q,p,\hbar)$. Notice that, before, the Moyal–Nahm functions, $\mathcal{T}_\alpha$, are *scalar*-valued as well as ϕ.

Furthermore, if Moyal deformations of the Toda equations are related to the Moyal–Nahm equations via the Lax pair formalism, the scalar $\phi(x^\mu)$ will require, in general, a deformation of the type $\phi(x^\mu;q_i,p_i,\hbar)$ obeying a deformation of the Laplace equation. The latter equation is, in general, modified to include $\hbar$ corrections and derivatives acting on the phase space coordinates as well. A natural deformation of the Laplace equation is simply given by $\partial_\mu * \partial^\mu \phi(x^\mu;q,p,\hbar)=0$. Writing explicitly, the above equation yields

$$\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{i\hbar}{2}\right)^n \omega^{i_1j_1}\omega^{i_2j_2}\cdots\omega^{i_nj_n}(\partial_{i_1}\partial_{i_2}\cdots\partial_{i_n}\partial_\mu)(\partial_{j_1}\partial_{j_2}\cdots\partial_{j_n}\partial^\mu)\phi(x^\mu;q,p,\hbar)=0. \tag{9b}$$

Equations (9a) and (9b) are the *defining* Moyal deformations of the Ivanova–Popov equations. The deformed YM potential A_μ obtained from the ansatz (7) will then be equal to the Moyal star product:

$$A_\mu=-\eta^\alpha_{\mu\nu}T_\alpha[\phi(x^\mu,q,p,\hbar);q,p,\hbar]*\partial_\nu\phi(x^\mu,q,p,\hbar), \quad \eta^\alpha_{\mu\nu}=\epsilon^\alpha_{\beta\gamma}, \quad \eta^\alpha_{\mu 0}=-\eta^\alpha_{0\mu}=\delta^\alpha_\mu. \tag{9c}$$

Equations (9a)–(9c) are the Moyal deformations of the Ivanov–Popov construction. A particular solution to the deformed Laplace equation could be of the type $\phi=\Sigma\hbar^n\phi_n$. The $\hbar=0$ limit yields the ordinary Laplace equation for the function $\phi_0(x^\mu)$ and the others $\phi_n(x^\mu,q,p)$ contain an extra q,p dependence also.

This can be explicitly seen when one performs a direct Moyal quantization program of all the equations involved in the Ivanova–Popov construction. Operators are mapped into functions of phase space via the symbol map. Products of operators are mapped into the Moyal star product of their corresponding symbols and this involves derivatives of arbitrary order wrt q,p. Furthermore, a suitable ordering prescription must be specified *a priori*. Therefore, a Moyal quantization of the Ivanov–Popov construction induces a $q,p,\hbar$ dependence on the scalar ϕ and it deforms the original Laplace equation. We shall go back to this issue when we discuss the twistor transform mapping the nonlinear 3D Toda equation into the 3D Laplace equation for the scalar ϕ.

A particular class of solutions of the SU(2) Moyal–Nahm equations, Eq. (9a), in terms of the Jacobi elliptic functions wrt the *undeformed* ϕ has been given by[11]

$$\mathcal{T}_1 = sn[\phi]\left[\frac{i}{2}p(q^2-1) - \hbar\left(\beta+\frac{1}{2}\right)q\right], \quad \mathcal{T}_2 = dn[\phi]\left[-\frac{1}{2}p(q^2+1) - i\hbar\left(\beta+\frac{1}{2}\right)q\right],$$
$$\mathcal{T}_3 = cn[\phi]\left[-ipq - \hbar\left(\beta+\frac{1}{2}\right)\right], \quad \beta=\text{const}, \tag{10}$$

where the (undeformed) scalar function ϕ has a correspondence with *one*, and only one, temporal parameter, $\phi \to \tau$. When one replaces $\phi \to \tau$, the ansatz of (7) gives that $A_0=0$, $A_i \sim \mathcal{T}_i$, and, as expected, the SU(2) Moyal–Nahm equations involve the three components of a *four*-vector and the derivatives are taken wrt the temporal variable τ that does *not* transform as a scalar like ϕ.

It is important also to remark that if ϕ acquires a deformation $\phi(x^\mu;q,p,\hbar)$, the solutions to (9a) given by Eqs. (10) *no* longer hold. This is because the Moyal brackets affect also the q,p terms contained in $\phi=\phi(x^\mu,q,p,\hbar)$. To find solutions to the set of Eqs. (9a) and (9b) is a very difficult enterprise, mainly because the *deformed* scalar field ϕ obeys a very complicated differential equation. In the undeformed case, ϕ obeys the ordinary Laplace equation and the solutions of (9a) given by Eqs. (10) will be valid then. For the deformed $\phi=\phi(x^\mu,q,p,\hbar)$ case, the Moyal–Ivanov–Popov equations read after using the chain rule

$$\epsilon_{\alpha\beta\gamma}\frac{\partial \mathcal{T}_\gamma}{\partial \phi} = \pm\{\mathcal{T}_\alpha,\mathcal{T}_\beta\}_{\text{Moyal}} = \mathcal{T}_{\alpha\beta}[(\partial_q\phi)(\partial_\phi \mathcal{T}_\alpha);(\partial_p\phi)(\partial_\phi \mathcal{T}_\beta);\ldots;\partial_q \mathcal{T}_\alpha,\partial_p \mathcal{T}_\beta,\ldots], \tag{11a}$$

where $\mathcal{T}_{\alpha\beta}$ is a very complicated function of the derivatives of $\mathcal{T}_\alpha,\mathcal{T}_\beta$ wrt the ϕ function and the q,p variables. Also required is the knowledge of the derivatives of ϕ wrt the q,p variables. This involves first finding a solution to Eq. (9b) prior to writing (11). There is, however, a crucial condition needed to be imposed on the solutions to the deformed Laplace equation if Eq. (11a) is a meaningful set of differential equations involving *solely* functions of $\phi,q,p,\hbar$. The lhs of (11a) involves solely $\phi,q,p,\hbar$; therefore, the rhs of (11a) must also. This requires to set the derivatives $\partial_q\phi\partial_p\phi$ to be of the form (11c) such that the Moyal–Nahm equations have indeed the correct homogeneous form:

$$\epsilon_{\alpha\beta\gamma}\frac{\partial \mathcal{T}_\gamma}{\partial \phi} = \pm\{\mathcal{T}_\alpha,\mathcal{T}_\beta\}_{\text{Moyal}} = \mathcal{F}_{\alpha\beta}[\phi,q,p,\hbar]. \tag{11b}$$

For this last equation to hold one requires to fix the *first* derivatives of ϕ wrt the q,p variables to have the form

$$\partial_q\phi = F_q(\phi), \quad \partial_p\phi = F_p(\phi) \Rightarrow \partial_q^2\phi = F_q(\phi)\partial_\phi F_q(\phi), \quad \partial_p^2\phi = F_p(\phi)\partial_\phi F_p(\phi)\cdots,$$
$$\partial_p\partial_q\phi = \partial_q\partial_p\phi \Rightarrow F_p(\phi)\partial_\phi F_q(\phi) = F_q(\phi)\partial_\phi F_p(\phi). \tag{11c}$$

The mixed space–time derivatives are

$$\partial_\mu\partial_q\phi = (\partial_\mu\phi)(\partial_\phi F_q(\phi)), \quad \partial_\mu\partial_p\phi = (\partial_\mu\phi)(\partial_\phi F_p(\phi))\cdots. \tag{11d}$$

Hence, the equation $(\partial_\mu * \partial^\mu)\phi = 0$ will involve an infinite number of derivative terms of the form

$$\partial_\mu^2\phi, \quad (\partial_\mu\phi)^2, \quad \partial_\phi^n F_q(\phi), \quad \partial_\phi^n F_p(\phi), \quad \ldots. \tag{11e}$$

In other words, the meaningful set of solutions to the Moyal–Nahm equations (9a), (11a), and (11b) are parametrized by a family of solutions to the deformed Laplace equation and these, in turn, are given by a family (moduli) of functions $F_q(\phi), F_q(\phi)$ that restrict the *first* derivatives of ϕ wrt the q,p variables to be of the form (11c). Without these homogeneity conditions, Eq. (9a) could not have the desired form (11b).

Things simplify considerably in the undeformed scalar ϕ case because the rhs's of the Moyal–Nahm equations yield *ordinary* derivatives wrt the q,p variables so that Eq. (10), for example, will be a valid solution for any scalar ϕ obeying the 4D Laplace equation: one has *factorized* completely the ϕ dependence from the q,p one in the Moyal–Nahm functions $\mathcal{T}_\alpha$. No restrictions like (11c) will be needed.

By SU(2) Moyal–Nahm it is meant that the solutions (10) in Ref. 11 were obtained by performing the WWM map which takes su(2) Lie-algebra-valued operators belonging to the Hilbert space, $L^2(R^1)$, into functions of q,p. Before hand, the Wolf representation of the su(2) Lie-algebra-valued generators, in matrix form using the Pauli spin matrices, $A_i^a \tau_a$, needs to be used prior to evaluating the WWM map, i.e, it was essential to use a representation which takes the three Pauli spin SU(2) matrices into three known operators in $\hat{q},\hat{p}$. It is in this sense that one may speak of the solutions (10) to the SU(2) Moyal–Nahm equations.

Since representations of SU(∞) in terms of operators in the Hilbert space $L^2(R)$ are *not* known (as far as we know), one cannot evaluate explicitly the WWM map. In addition, SU(∞) requires use of the *extended* phase space which implies that the Moyal bracket to be used in (9) will be the one wrt the q_i, p_i phase space coordinates rather than to q,p. We have symplectic diffeomorphisms in four dimensions instead of two dimensions. Therefore, the generalized Moyal–Nahm equations require an *extra* set of variables q', p' that must be introduced to account for the area-preserving diffeomorphisms algebra associated with a 4D manifold instead of a two-dimensional surface (sphere, torus). So, now we have $\mathcal{T}_\alpha(\phi; q,p,\hbar; q',p')$. The Moyal brackets are then computed wrt the *enlarged* phase space involving the q,p and q',p'. We shall discuss this in detail in the last section.

Nevertheless, the generalized ''SU(∞)'' Moyal–Nahm equations admit *reductions* to the continuous Moyal–Toda equations and equations directly linked to the 4D SU(∞) Moyal ASDYM/SDYM equations. We refrain from using the term SU(∞) Moyal–Nahm because it is *not* really a WWM quantization of the classical SU(∞) Nahm equations but, instead, one has Moyal deformations of the algebra of symplectic diffeomorphisms in 4D. Such algebra is an infinite dimensional extension of the area-preserving diffeomorphisms of a two-dimensional surface.[20]

The ASDYM equations in 4D Euclidean space–time read $F_{y\tilde{y}} + F_{z\tilde{z}} = 0$ and $F_{yz} = 0$, $F_{\tilde{y}\tilde{z}} = 0$. For signature $(++,--)$ the situation is *reversed*; the SDYM equations are the ones of the form $F_{y\tilde{y}} + F_{z\tilde{z}} = 0$ instead. The Moyal deformed YM potentials are related to the Moyal heavenly form as follows:[9,10]

$$\partial_{\tilde{z}} A_{\tilde{y}} = \partial_{\tilde{w}} A_{\tilde{y}} = \partial_{\tilde{w}} \partial_w \Omega + \tfrac{1}{2}, \tag{12a}$$

$$\partial_{\tilde{y}} A_{\tilde{z}} = \partial_w A_{\tilde{z}} = \partial_{\tilde{w}} \partial_w \Omega - \tfrac{1}{2}, \tag{12b}$$

$$w = z + \tilde{y}, \quad \partial_w = \partial_z = \partial_{\tilde{y}}, \quad \tilde{w} = \tilde{z} - y, \quad \partial_{\tilde{w}} = \partial_{\tilde{z}} = -\partial_y, \tag{13}$$

where Ω is a solution of the Moyal heavenly equation:

$$\{\Omega_{,w}, \Omega_{,\tilde{w}}\}_{q,p} = \pm 1 \leftrightarrow \{\partial_{\tilde{z}} + A_{\tilde{z}}, \partial_{\tilde{y}} + A_{\tilde{y}}\} = 0. \tag{14}$$

The -1 is assigned to the ASDYM in four dimensions with signature $2+2$ related to anti-self-dual gravity. The $+1$ is assigned to the SDYM in four dimensions with signature $2+2$ related to self-dual gravity. For Euclidean signatures, the situation is *reversed*: The -1 is assigned to the SDYM in four dimensions with signature $4+0$ related to self-dual gravity. The $+1$ is assigned to the ASDYM in four dimensions with signature $4+0$ related to anti-self-dual gravity. The important thing to remember is that the scalar field obeying deformations of the Laplace equation is the solution connected to self-dual gravity in $2+2$ that corresponds precisely to the ASDYM equations in $4+0$ given by Ivanova and Popov.

The Moyal deformed YM potentials in terms of the Moyal–Nahm functions $\mathcal{T}_\alpha$ are obtained directly from the ansatz (9c) and, finally, the Moyal heavenly form, up to an integration ''constant'' $f(q,p)$ is

$$\Omega(w,\tilde{w},q,p,\hbar)=\int \left(A_{\tilde{y}}-\frac{1}{2}\tilde{w}\right) dw+\int \left(A_{\tilde{z}}+\frac{1}{2}w\right) d\tilde{w} \tag{15}$$

with

$$\tilde{y}=x^2-ix^3, \quad \tilde{z}=x^0+ix^1, \quad y=x^2+ix^3, \quad z=x^0-ix^1, \tag{16a}$$

and

$$A_{\tilde{y}}=A_2-iA_3, \quad A_{\tilde{z}}=A_0+iA_1. \tag{16b}$$

Equation (15) is the main equation of this section. It establishes the direct relation between solutions of the 4D Moyal heavenly equation in terms of the Moyal YM potentials via solutions of the Moyal–Nahm equations (9a). The relation between the YM potentials and the Moyal–Nahm functions is provided by Eqs. (9c) and (16b). We shall go back to Eq. (15) in Sec. III C when we discuss the Legendre-like transform relating rotationally Killing symmetry reductions of the 4D Moyal heavenly equations (from four to three dimensions), given by Ω, to solutions of the $2+1$ SU(2) Lattice equations. The latter are obtained from Moyal deformations of the SU(2) Nahm equations derived by Strachan.[14]

These reductions of the Moyal SU(2) SDYM/ASDYM equations in four dimensions, an *effective* 6D theory, to a final 4D equation, the Moyal heavenly equation given in Eq. (13), are also compatible with the fact that the Toda equations for SU(N) are obtained from particular reductions of Nahm equations which, in turn, can be represented in a Lax pair form:

$$L=T_1(\phi)+iT_2(\phi), \quad iT_3(\phi)=M, \quad \frac{dL}{d\phi}=[L,M]. \tag{17}$$

Consequently, in the $N=\infty$ limit, one can recast the continuous Moyal–Toda equations in the double commutator form after establishing the following *correspondence* (which are *not* identifications) [see (4)]:

$$\mathcal{L}(u,\rho)\leftrightarrow \mathcal{T}_1+i\mathcal{T}_2, \quad i\mathcal{T}_3=\mathcal{M}\leftrightarrow\{\mathcal{L},\mathcal{H}\}, \quad \frac{\partial\mathcal{L}}{\partial\tau}=\{\mathcal{L},\{\mathcal{L},\mathcal{H}\}\}, \tag{18}$$

where the $\mathcal{T}_\alpha$ obey (9).

The meaning of Eq. (18) is the following: The data $\{\mathcal{T}_1,\mathcal{T}_2,\mathcal{T}_3\}$, the Moyal–Nahm functions, can be mapped into the three functions $\{\mathcal{L},\mathcal{H},\mathcal{M}\}$ belonging to the Lax–Brockett formalism of continuum **Z**-graded Lie algebras.[19] Equation (18) establishes the correspondence among these data: a functional embedding of the data $\mathcal{T}_\alpha$, parametrized by one function ϕ, into the data $\{\mathcal{L},\mathcal{H},\mathcal{M}\}$ parametrized by the three functions: u,ρ,κ. With ρ being the (Moyal deformations of the) continuous Toda field. Finding the differential equations for the remaining two functions u,κ in the Moyal deformed case and eliminating them to arrive at the final equation involving solely the continuous Moyal–Toda field ρ is a highly nontrivial matter. This will involve Moyal deformations of continuum **Z**-graded Lie algebras. This subject has not been studied to our knowledge. In Sec. IV we shall go back to the Lax–Brockett formalism.

The reason that one can make the correspondences (which are *not* identifications) given by (18) is because there are continuum Lie algebras that are isomorphic to Poisson bracket algebras

$\sim$su(∞), which correspond to the Lie algebras of area-preserving diffeomorphisms of the sphere or torus.[19]. It is in this sense that the correspondence of Eq. (18) is implemented. There are two ways to retrieve Moyal–Toda equations: one way is to use the Lax–Brockett double commutator form, and another is to use the Lax representations for the SU(∞) Nahm equations. The correspondence between these two constructions of the Moyal equations originates from the fact that there is a Legendre-like transform that maps solutions of the $2+1$ continuous Toda equation to those of the 3D Laplace equation, i.e., $\rho \rightarrow \phi$.

The $2+1$ continuous Toda equation occurs in the theory of self-dual Einstein spaces and has a well-known Eguchi–Hanson solution.[21] Prasad[22] (and discussed by Chapline in Ref. 6) has shown that by a change of variables one can transform the Toda equation into a three-dimensional Laplace equation for a certain function $\phi=\phi(\rho)$ related to the two-center gravitational instanton of Gibbons and Hawking.[21] So the correspondence dictated by Eq. (18) is a reflection of the Legendre-like map which takes the Toda field ρ to ϕ obeying the Laplace equation after a dimensional reduction from $2+1$ to 2 dimensions. The Legendre-like transform determines the correspondence given in (18), once the suitable maps from the remaining u,κ functions to ϕ are found.

As stated earlier, a subtlety will now arise. Due to the Moyal deformations of the Toda equations, it is expected then that an accompanying *deformation* of the Laplace equation for the scalar field ϕ follows. The Prasad map taking $\phi \rightarrow \rho$ must be deformed as well. Therefore one should be forced to include $\hbar$ corrections to the scalar $\phi(x;\hbar)$. Similar considerations have been found in Ref. 18 *after* employing the WWGM map: an explicit introduction of $\hbar$ was made afterwards. Nevertheless, the correspondence given by Eq. (18) still holds once the deformed map from ϕ (obeying deformations of Laplace equation) to ρ (obeying deformations of the Toda equation) is found. Similar arguments apply to remaining functions u,κ; these also acquire $\hbar$ corrections. The Prasad[6,22] map will be studied in Sec. III A.

The sort of dimensional reductions of the 4D SU(∞) ASDYM/SDYM equations that we are studying in this section requires that one perform a series of coordinate redefinitions and dimensional reductions from the effective 6D theory to a 4D one:

$$\{x^0,x^1,x^2,x^3;q,p\} \rightarrow \{y,z,\tilde{y},\tilde{z};q,p\} \rightarrow \{w,\tilde{w};q,p\} \rightarrow \{\tau,t;q,p\}. \tag{19}$$

The Laplace equation fixes the family of (undeformed) functions ϕ. Due to the dimensional reduction, the 4D Laplace operator *degenerates* to zero. This can be verified by simple inspection:

$$w=x^0-ix^1+x^2-ix^3, \quad \tilde{w}=x^0+ix^1-x^2-ix^3, \quad w^* \neq \tilde{w},$$
$$\partial_0=\partial_w+\partial_{\tilde{w}}, \quad \partial_1=-i\partial_w+i\partial_{\tilde{w}}, \quad \partial_2=\partial_w-\partial_{\tilde{w}}, \quad \partial_3=-i\partial_w-i\partial_{\tilde{w}}. \tag{20}$$

One can verify the Laplace operator acting on (the undeformed) ϕ:

$$\partial_0^2+\partial_1^2+\partial_2^2+\partial_3^2=\partial_y\partial_{\tilde{y}}+\partial_z\partial_{\tilde{z}}=\partial_w\partial_{\tilde{w}}-\partial_w\partial_{\tilde{w}}\equiv 0, \tag{21}$$

hence, as a result of the dimensional reduction, $\phi(w,\tilde{w})$, the 4D Laplace operator acting on (the undeformed) ϕ degenerates to zero, i.e., *any* function of the form $\phi=\phi(w,\tilde{w})$ *obeys* automatically the 4D Laplace equation.

If one wishes, one may restrict the solutions of the 4D Laplace equation, $\partial_\mu\partial^\mu\phi(w,\tilde{w})=0$, for arbitrary functions ϕ to those obeying the 2D Laplace equation instead:

$$\partial_\tau^2\phi+\partial_t^2\phi=\partial_w\partial_{\tilde{w}}\phi=0 \Rightarrow \phi=f(w)+g(\tilde{w}), \quad w\equiv\tau+it, \quad \tilde{w}=\tau-it. \tag{22}$$

In this fashion one can remove the arbitrariness of the (undeformed) ϕ.

It is important to emphasize that $\tilde{w}\neq w^*$ and that τ,t are *complex* valued since the Moyal heavenly equations are defined in *complexified* 4D space–time. A real slice may be taken by choosing $\tilde{w}=w^*$, which implies that τ,t must be real and from (20) we learn in this case that

$(x^0)^* = x^0$; $(x^1)^* = x^1$ and $(x^2)^* = -x^2$; $(x^3)^* = -x^3$. The general solution to the 2D (complexified in general) (undeformed) Laplace equation for the (undeformed) ϕ is $\phi = f(\tau + it) + g(\tau - it)$ for f,g arbitrary.

The SDYM equations require a separate study since in this case (the undeformed) $\phi = y\tilde{y} + z\tilde{z}$ is fixed and does not obey the Laplace equation. A different kind of reduction other than the Ivanova–Popov ansatz, via the Moyal–Nahm equations, is necessary to obtain the Moyal SDG equations from the 4D SU(∞) SDYM equations.

To finalize this section we point out that the SU(2) Toda lattice equations can be derived from the SU(2) Moyal–Nahm equations involving a field $\Psi = \Psi(\tau, t, \hbar)$ with $\tau = z_+ + z_-$. This has been shown in Ref. 14 and discussed in Ref. 18 in the constructions of a master integrable equation that contains the Kadomtsev–Petviashvili (KP) and Korteweg–de Vries (KdV) hierarchies. The explict relation between rotational Killing symmetry reductions of Ω and the SU(2) lattice Toda field, Ψ, will be studied further in Sec. III C. We proceed now to study the Moyal–Toda equations in the next section.

III. THE MOYAL–TODA EQUATIONS

A. A continuous Moyal–Toda equation and the Legendre transform

In this section we shall display the different forms of the Moyal–Toda equations that are related to the quantities $\mathcal{L}(u,\rho)$ and $\mathcal{H}(\kappa)$ in Eqs. (5), (6), and (18) and the $\mathcal{T}_\alpha[\phi, q, p, \hbar]$. We return now to this discussion. After the WWM map is performed, u, ρ, κ *acquire* an additional dependence on $q, p, \hbar$. To illustrate this, let us look at the operator form of the original continuous Toda equation:

$$\frac{\partial^2 \hat{\rho}}{\partial \tau^2} = \frac{\partial^2 e^{\hat{\rho}}}{\partial t^2}. \tag{23}$$

Given an operator, $\hat{\rho}(\tau, t)$, acting in the Hilbert space of square integrable functions on the line, of the form

$$\hat{\rho} = \sum_{mn} \rho_{mn}(\tau, t)(\hat{q}^m \hat{p}^n + \hat{p}^m \hat{q}^n + \cdots), \tag{24a}$$

with a Weyl ordering prescription imposed on the monomials in $\hat{q}^m \hat{p}^n$,

$$\hat{q}\hat{p} \rightarrow \hat{q}\hat{p} + \hat{p}\hat{q}, \quad \hat{q}\hat{p}^2 \rightarrow \hat{q}\hat{p}^2 + \hat{p}^2\hat{q} + 2\hat{p}\hat{q}\hat{p} \cdots. \tag{24b}$$

More complicated operators are also possible that are not necessary sums of monomials. The WWM map converting operators, $\hat{\rho}(\tau, t)$, into functions in phase space (making use of the symbol map) yields

$$\text{symbol } [\hat{\rho}] = \rho(t, \tau, q, p, \hbar), \quad \text{symbol } [e^{\hat{\rho}}] = e^{*\rho} = 1 + \rho + \frac{\rho * \rho}{2!} + \frac{\rho * \rho * \rho}{3!} + \cdots. \tag{25}$$

Hence, the putative Moyal continuous Toda molecule equations reads

$$\frac{\partial^2 \rho}{\partial \tau^2} = \frac{\partial^2 e^{*\rho}}{\partial t^2}. \tag{26}$$

The Moyal star product of two functions of phase space of dimension $2n$ whose symplectic form has the inverse ω^{IJ} is defined

$$f * g = \sum_{n=0}^{\infty} \frac{1}{n!} \left(\frac{i\hbar}{2} \right)^n \omega^{i_1 j_1} \omega^{i_2 j_2} \cdots \omega^{i_n j_n} (\partial_{i_1} \partial_{i_2} \cdots \partial_{i_n} f)(\partial_{j_1} \partial_{j_2} \cdots \partial_{j_n} g). \tag{27}$$

When ω^{ij} is the inverse of the symplectic form in two dimensions, the derivatives are taken wrt the q,p variables only. To recover the $2+1$ continuous Toda requires replacing the lhs of (26) by $(\partial_\tau)^2$ by $\partial_{z_+}\partial_{z_-}$ and setting $\rho(z_+,z_-,t,q,p,\hbar)$:

$$\frac{\partial^2\rho}{\partial z_+\partial z_-}=\frac{\partial^2 e^{*\rho}}{\partial t^2}. \tag{28}$$

The Prasad transformation[6,22] maps the 3D Laplace equation (obtained from the solutions associated with the translational Killing symmetry reductions of a self-dual Euclidean Einstein space[7]) to the continuous Toda equation:

$$(\partial_z\partial_{\overline{z}}+\partial_U^2)S=0\leftrightarrow\frac{\partial^2\rho}{\partial z_+\partial z_-}=-\frac{\partial^2 e^{\rho}}{\partial t^2}. \tag{29}$$

[Notice the *sign* difference in Eq. (29) as compared with Eq. (28).] Here S is now a function of $z=x+iy$, $\overline{z}=x-iy$, and U. Chapline[6] has performed the Legendre transform between S and ρ for those solutions of the continuous Toda equation related with the Eguchi–Hanson instanton:

$$\rho(z,\overline{z},t)=\ln\frac{t^2-a^2}{(1+z\overline{z})^2},\quad e^{\rho}=(t^2-a^2)e^{-2\ln(1+z\overline{z})},\quad t>a. \tag{30a}$$

The reason we exponentiated the solution (30a) will become clear next when we discuss the embedding of the Liouville equation into the continuous Toda one. The Liouville field will be, in this case, $\phi_L=-\ln(1+z\overline{z})$.

The Prasad change of variables[22] allows us to transform the Toda equation into the 3D Laplace equation as Eq. (29) shows. The function $S=S(\rho)$ corresponding to the Eguchi–Hanson instanton solution (30a) written in terms of the new coordinates (after the Prasad transform) is

$$S=\frac{1}{2}\sum_{i=1}^{2}\ln\frac{R_i+U-U_i}{R_i-U+U_i},\quad -\infty<U<\infty;\quad R_i^2=(U-U_i)^2+4(z-z_i)(\overline{z}-\overline{z_i}). \tag{30b}$$

Here x_i,y_i,U_i are the locations of the two-quasiparticles (two-center instanton of Gibbons-Hawking[21]) for $i=1,2$.

The most general solution to the ordinary classical continuous Toda equations has been found by Saveliev.[19] The Eguchi–Hanson instanton solution is precisely the one related to the well-known *embedding* of the Liouville equation into the continuous Toda equations.[19] It is given that

$$\frac{\partial^2\psi_0}{\partial\tau^2}=\frac{\partial^2 e^{\psi_0}}{\partial t^2}. \tag{31}$$

One may plug in the ansatz which will automatically reproduce the Liouville equation:

$$e^{\psi_0}=(\tfrac{1}{2}t^2+bt+c)e^{\phi_L}\Rightarrow\partial_{z_+}\partial_{z_-}\phi_L(z_+,z_-)=e^{\phi_L}, \tag{32a}$$

after performing the dimensional reduction $\tau=z_++z_-$. So, in the $\hbar=0$ limit, Eqs. (26) and (28) reduce to the ordinary classical continuous Toda molecule (chain) equations. Equation (31) is the the relevant one to map Moyal deformations of ρ into the 3D deformed Laplace equation (29). The embedding relation between ρ and ϕ_L in the Moyal deformed case is

$$\frac{\partial^2\rho}{\partial z_+\partial z_-}=\frac{\partial^2 e^{*\rho}}{\partial t^2},\quad e^{*\rho}=\left(\frac{1}{2}t^2+bt+c\right)e^{*\phi_L}\Rightarrow\partial_{z_+}\partial_{z_-}\phi_L(z_+,z_-,q,p,\hbar)=e^{*\phi_L} \tag{32b}$$

with $\phi_L(z_+,z_-,q,p,\hbar)$ and $\rho(z_+,z_-,t,q,p,\hbar)$ obeying Eq. (28). The last expression of Eq. (32b) is the Moyal deformation of the Liouville equation.

The *star* logarithm operation allows us to express

$$\rho=\ln_*\left[\left(\frac{1}{2}t^2+bt+c\right)e^{*\phi_L}\right]=\ln_*\left[\left(\frac{1}{2}t^2+bt+c\right)\right]+\ln_*[e^{*\phi_L}]$$
$$=\ln_*\left[\left(\frac{1}{2}t^2+bt+c\right)\right]+\phi_L\Rightarrow\frac{\partial^2\rho}{\partial z_+\partial z_-}=\partial_{z_+}\partial_{z_-}\phi_L. \qquad (32c)$$

Equations (32) are the relevant ones to extend the results of Eqs. (29) and (30) to the Moyal case when we deform the 3D Laplace equation $(\partial_i*\partial^i)S=0$ for a Moyal deformed function $S=(z,\overline{z},U,q,p,\hbar)$. The Moyal–Prasad map yields the continuous Moyal–Toda equation (28) whose particular Eguchi–Hanson instanton-inspired solutions will be deformations of Eq. (30a) and (30b). The natural expansions $\phi_L=\Sigma\hbar^n\phi_n(z_+,z_-,q,p)$ and $\rho=\Sigma\hbar^n\rho_n(z_+,z_-,t,q,p)$ will generate solutions to (32b) and (28) to all orders in $\hbar$ by an infinite number of iterations. To each order in $\hbar^n$ one performs the Moyal–Prasad map (change of coordinates[22]) yielding the values of $S=\Sigma\hbar^n S_n(z,\overline{z},U,q,p)$ which solve the deformed 3D Laplace equation (to that given order in $\hbar^n$). It is a very difficult and challenging enterprise to achieve this in practice; i.e, to find the Moyal–Prasad transform to *all* orders in $\hbar$ in *closed* form!

The above equations (26), (28), and (32) were obtained from the operator form of the original continuous Toda equation. In general, at the quantum level, the forms of the operator equations of motion are *not* the same as those of the original classical field. A modification of (26) will be presented shortly where the rhs is modified; i.e., there will be derivatives of infinite order wrt the t variable that originate from deformations of the continuum graded Lie algebras as a result of replacing ordinary Poisson bracket by Moyal brackets.

The $\hbar=0$ limit of (26) yields on the rhs the ordinary exponential, e^ρ, because in the classical limit the Moyal star product becomes the ordinary pointwise product of functions. Since in the classical limit Eq. (26) involves a differential equation wrt the variables τ,t only, the classical limit of (26) does not determine the q,p dependence of $\rho(\tau,t,q,p,\hbar=0)$, which may be completely arbitrary. Assuming that ρ admits an expansion in powers of $\hbar$: $\rho=\Sigma\hbar^n\rho_n(\tau,t,q,p)$, one can impose the condition that the zeroth-order term does not depend on q,p: $\rho_0(\tau,t,q,p)\equiv\rho_{\text{class}}(\tau,t)$. In this fashion the $\hbar=0$ limit reproduces the classical continuous Toda equation for $\rho_{\text{class}}(\tau,t)$.

Another way to obtain the continuous Moyal–Toda equations directly should be to perform the master Legendre transform mapping, if indeed it exists, between $\Omega(y',\tilde{y}',z',\tilde{z}',\hbar)$ obeying the rotationally Killing symmetry reductions of the Moyal SDG equations[9,21] to $\rho(\tau\equiv z_++z_-,t,q,p,\hbar)$[1,9] obeying the continuous Moyal–Toda equations. The immediate problem with this is that the *number* of variables does not match. ρ has five whereas Ω has four. Nevertheless, an embedding of one into the other is possible as we shall see. Strachan[14] has shown that the SU(2) Moyal–Nahm equations admit a reduction to the SU(2) Toda lattice (which yields the *classical* continuous Toda equation in the $\hbar=0$ limit). Therefore, reductions of the SU(2) generalized Moyal–Nahm equations should yield the continuous Moyal–Toda lattice-type equations. This shall be studied in Sec. IV.

We shall continue shortly with the Strachan ansatz and write down a more general equation than (26) and (28) which contains derivatives of infinite order wrt the t variable; i.e., the operator equations of motion for the quantized Toda field *differ* from the classical counterpart. The Legendre-like transform will be discussed also. The study of the geometry associated with these Moyal deformations has been given in Ref. 23.

B. Strachan's reduction of the SU(2) Moyal–Nahm equations to the SU(2) lattice Toda equations

It is known that the ordinary continuous Toda equation may be obtained from axial-symmetry reductions of the SU(∞) classical Nahm equations. This fact permitted Strachan to construct SU(2) Toda lattice equations from Moyal deformations of the SU(2) Nahm equations by replacing the

Poisson bracket by the Moyal bracket.[14] If one writes the Moyal–Nahm equations of the type given (with the plus sign) by Eq. (8), replacing $\phi \rightarrow \tau$ and imposing the axial-symmetry reductions of the form

$$T_1 = X_1 = h(\tau, t = q, \hbar)\cos p, \quad T_2 = X_2 = h(\tau, t = q, \hbar)\sin p, \quad T_3 = X_3 = z(\tau, t, \hbar), \tag{33}$$

allows the *decoupling* of the $\cos p, \sin p$ terms after computing the Moyal bracket and after eliminating the function $z(\tau, t)$. Strachan arrived at

$$\frac{\partial^2 \psi}{\partial \tau^2} = \frac{1}{4}\left[\frac{\Delta - \Delta^{-1}}{\hbar}\right]^2 e^{\psi} = \frac{\partial^2}{\partial t^2} e^{\psi} + \frac{\hbar^2}{3}\frac{\partial^4}{\partial t^4} e^{\psi} + O(\hbar^{2n}) \cdots . \tag{34}$$

The shift operators Δ, Δ^{-1} and $\psi(\tau, t, \hbar)$ are defined:

$$\Delta \psi = \psi(t + \hbar), \quad \Delta^{-1} \psi = \psi(t - \hbar), \quad e^{\psi/2} \equiv h(\tau, t). \tag{35}$$

In general, the $2+1$ Toda lattice equation for the field $\psi(z_+, z_-, t, \hbar)$ reads

$$\frac{\partial^2 \psi}{\partial z_+ \partial z_-} = \frac{1}{4}\left[\frac{\Delta - \Delta^{-1}}{\hbar}\right]^2 e^{\psi}, \tag{36}$$

upon the reduction $2+1$ to 2 dimensions, $\tau = z_+ + z_-$, one recovers (34).

Equations (34) and (36) will be referred to from now on as the $D=2$ and $D=2+1$ SU(2) lattice Toda equations, respectively. They involve one field only, ψ, in the same way that the Liouville equation is tantamount to an sl(2) Toda field equation. In the classical limit, $\hbar = 0$ one recovers the *classical continuous* SU(∞) Toda molecule equation as expected. This can be seen by expanding $\psi(\tau, t, \hbar) = \psi_0 + \hbar^2 \psi_2 + \cdots$. The $\hbar = 0$ limit reproduces again the classical continuous Toda equation for the field $\psi_0(\tau, t)$, as Eq. (26) does for $\rho(\tau, t, q, p, \hbar = 0) = \rho_{\text{class}}(\tau, t)$.

It is an interesting question (although not the right question to ask) if one could find a representation of the su(2) Lie algebra in terms of $\hat{q}, \hat{p}$ operators that would yield Strachan's solutions after performing the WWM map of the operator equations associated with the su(2) Nahm equations. The solutions (33) clearly differ from those presented in Eq. (10), not only in the τ functional dependence implicit in the elliptic functions but also in the dependence of the phase space variables.

The reason that one should *not* view Strachan's construction as a direct WWGM quantization of the SU(2) Toda field, a Liouville theory, is because the discrete-differential equations (34) and (36) represent really a SU(2)/SL(2) Toda lattice theory which discrete-spatial spacings in multiples of $\hbar$: the field ψ is evaluated at discrete jumps $t, t \pm \hbar,$. However, there is continuous temporal dynamics represented by the ∂_τ derivatives. See the important work of Dimakis *et al.*[24] on this respect. The rhs of (34) and (36) is a forward/backward discrete difference operator in jumps of $\hbar$ (although the variable t is continuous) which can be expanded into an infinite number of derivatives, a nonlocal expression. The Moyal product is also nonlocal due to the infinite number of derivatives.

Therefore, rigorously speaking one must refer to the discrete-differential Strachan's equation as the SU(2) lattice Toda equation obtained from axial-symmetry reductions of the SU(2) Moyal–Nahm equations and *not* as a direct WWM quantization of the SU(2) Liouville equation. It has been speculated by Reuter[23] that the discrete operator arising from the Moyal brackets might be one source of nonlocalities in quantum mechanics.

From the form of (10) one should notice that a WWGM quantization program of Ref. 11 is *not* the same as the Strachan construction[14] and that of Ref. 18. In general, one may alter the operator form of the quantum field equations of motion from the original classical field equations. For example, the operator equations may be different from Eqs. (23) and read instead

$$\frac{\partial^2 \hat{\rho}}{\partial \tau^2} = \frac{1}{4}\left[\frac{\Delta - \Delta^{-1}}{\hbar}\right]^2 e^{\hat{\rho}} = \frac{\partial^2}{\partial t^2} e^{\hat{\rho}} + O(\hbar^{2n}) \cdots . \tag{37}$$

We may have again a discrete-differential operator equations of motion: the rhs involves derivatives of *infinite* order of the operator $\hat{\rho}(\tau,t)$ wrt the t variable. In general, upon quantization the structure of the Lie algebra could itself be modified as well. This occurs in the study of quantum groups and quantum Lie algebras where quantum integrability requires deformations of the classical Lie algebraic structures.

In view of this, a modification of the Moyal continuous Toda equation (a further deformation of the Strachan's Toda lattice equations by introducing the star exponential) is

$$\frac{\partial^2 \rho}{\partial \tau^2} = \frac{1}{4}\left[\frac{\Delta - \Delta^{-1}}{\hbar}\right]^2 e^{*\rho} = \frac{\partial^2}{\partial t^2} e^{*\rho} + O(\hbar^{2n}) \ldots , \tag{38}$$

and is obtained after performing the WWM map of Eq. (37). The Moyal star product is taken wrt the q,p variables only. The extra dependence on the two phase space variables, q,p, is due to the WWM symbol map taking operators into functions in phase space. The t parameter is the one that encodes the continuum Lie algebra generators and commutation relations.

An even further deformation of (38) is as well

$$(\partial_\tau * \partial_\tau)\rho(\tau,t,q,p,\hbar) = \frac{1}{4}\left[\frac{\Delta - \Delta^{-1}}{\hbar}\right]^2 e^{*\rho} = \frac{\partial^2}{\partial t^2} e^{*\rho} + O(\hbar^{2n}) \ldots , \tag{39}$$

where the operators on the lhs of (39) are deformed as well, similarly to the deformations of Laplace equation (9a) using Moyal star products of differentials. Equation (38) is an extension of Strachan's SU(2) lattice Toda equation for the field $\psi(\tau,t,\hbar)$; in particular, the latter SU(2) lattice Toda equation can be *embedded* into Eq. (38). This shall be studied in the next subsection. Equation (39) is an extension, on both sides of the equation, of the original Moyal–Toda equation given by Eq. (26). Both the rhs and the lhs of (26) have been extended in Eq. (39).

Once again, reinserting the z_+, z_- dependence on the ρ we have finally the following discrete-differential equation:

$$(\partial_{z_+} * \partial_{z_-})\rho(z_+, z_-, t, q, p, \hbar) = \frac{1}{4}\left[\frac{\Delta - \Delta^{-1}}{\hbar}\right]^2 e^{*\rho}. \tag{40}$$

This is the more general equation of all the equations presented in this subsection containing all others as special limiting cases.

Concluding this subsection, we shall refer to the three discrete-differential Equations (38)-(40) as equations of the continuous Moyal–Toda lattice type. Equation (26) is the continuous Moyal–Toda equation obtained directly from a WWM quantization of the classical continuous Toda equation. Equation (32b) is the Moyal–Liouville equation and, finally, Eqs. (34) and (36) are the SU(2) Toda lattice equations in 2 and $2+1$ dimensions obtained from axial symmetry reductions of the SU(2) Moyal–Nahm equations *a la* Strachan.[16] It is very important to *distinguish* among these families of equations. The continuous Moyal–Toda lattice equation given by (40) contains all others as special cases. In this sense Eq. (40) is a sort of master discrete-differential equation.

We have learned from Strachan that the SU(2) Toda lattice equation is *contained* in the SU(2) Moyal–Nahm equations and, similarly, one would expect that the SU(∞) (continuous) Moyal–Toda lattice equations should be *contained* in the *generalized* Moyal–Nahm equations. It is precisely for this reason that the generalized Moyal–Nahm equations must depend on an *extra* set of phase space variables as argued earlier. This will be studied in Sec. IV where, in particular, we shall provide a plausible embedding of the Moyal–Toda lattice equations into the generalized Moyal–Nahm equations.

In conclusion, after these steps are taken, the Strachan ansatz is a very special case of the most general Ivanova–Popov ansatz for the three functions, $\mathcal{T}_\alpha$. Solutions to (34) and (36) may be obtained through iterations after expanding in even powers of $\hbar$: $\psi_o+\hbar^2\psi_2+\cdots$. In this way an infinite, but known, number of differential equations yields iteratively the solutions for ψ_{2n}. To solve this system is another matter.

C. The Moyal heavenly equation and the SU(2) Toda lattice

Before we begin this section we must emphasize that the results of Refs. 14 and 18 are very different from the results of this section, mainly because the results of Ref. 18 do *not* involve a rotational Killing symmetry reduction of the Moyal heavenly equations; i.e., this involves a particular class of dimensional reductions of the Moyal SDYM master equations that does *not* lead to the Moyal heavenly equations (although the Moyal heavenly equation can be obtained by another reduction). The authors of Ref. 18 based their work on the results by Strachan[14] on the Toda/KP hierarchies and obtained the SU(2) Toda lattice equation from a *different* route than the one described here. The equations in Refs. 14 and 18 are the SU(2) Toda lattice equations whose discrete spacing is a multiple of $\hbar$. When $\hbar=0$ one recovers the continuous Toda equations, or the so-called Boyer–Finley equations obtained originally from Killing symmetry reductions of the heavenly equations.

As discussed earlier in Sec. II, we can conclude that Eqs. (15) and (33) already *contain* the required map from the Ω heavenly form obeying the Moyal heavenly equation, after a suitable rotational Killing symmetry reduction from four dimensions to three, to the $2+1$ SU(2) Toda lattice field equations for a field ψ obeying Strachan equation (36). This can also be achieved via the Lax pair formalism. This automatically solves the problem of finding the Legendre-like transform from (rotational Killing symmetry reductions of) Ω to the $2+1$ SU(2) Toda lattice field $\psi(z_+,z_-,t;\hbar)$.

Hence, Eq. (15) yields $\Omega=\Omega[A_i]$. The Strachan solution corresponds to the particular case when ϕ is replaced by τ, which implies that A_i is replaced by X_i and, finally, the remaining Eqs. (33) give the explicit relations $A_i=X_i$ in terms of $\psi(\tau\equiv z_++z_-,t,\hbar),z(\tau\equiv z_++z_-,t,\hbar)$ with $\exp\psi/2\equiv h(\tau\equiv z_++z_-,t,\hbar)$.

To relate Ω with ρ is not that straightforward. There is an obstruction if one wishes to study the map from Ω to the continuous Toda field $\rho(z_+,z_-,t,q,p,\hbar)$. The *number* of variables does *not* match. However, one can ''embed'' both Ω and ψ into $\rho(z_+,z_-,t,q,p,\hbar)$; i.e., embedding the solutions to the SU(2) Toda lattice equations into the continuous Moyal–Toda lattice ones. The embedding process is based on the following facts:

It has been known for some time that rotational Killing symmetry reductions of the self-dual gravitational or heavenly equations lead to the continuous Toda equations.[7] The relation between rotational Killing symmetry reductions of $\Omega(y',\tilde{y}',z',\tilde{z}',\hbar)$ obeying the 4D Moyal SDG equations and $\rho(z_+,z_,,t,q,p,\hbar)$ obeying the $2+1$ continuous Moyal–Toda lattice equation should be defined as the embedding map:[10,25]

$$\begin{aligned}\Omega(y',\tilde{y}',z',\tilde{z}',\hbar)&\equiv\sum_{n=0}^{\infty}\left[\frac{\hbar}{\tilde{y}'}\right]^n\Omega_n(r\equiv y'\tilde{y}';z',\tilde{z}')\\&\to\rho(z_+,z_-,t,q,p,\hbar)\\&=\sum_{n=0}^{n=\infty}\sum_{l=0}^{l=n}\sum_{m=-l}^{m=+l}\hbar^n\rho_n^{lm}(z_+,z_-,t)Y_{lm}(\theta,\varphi),\\ q=\cot(\theta/2)\cos\varphi,&\quad p=\cot(\theta/2)\sin\varphi.\end{aligned}\tag{41}$$

The clear problem with Eq. (41) is that the *numbers* of variables do *not* match: ρ requires *five* whereas Ω requires *four*. For this reason one should refer to Eq. (41) as an embedding relation between Ω and ρ. Let us proceed with the terms appearing in the expansion of the ρ field in spherical harmonics. The limits in l are defined with the proviso that in the limit $\hbar=0$ the zeroth-order terms will survive only giving

$$\rho_0^{00}(\tau,t)Y_{00}(\theta,\varphi)\equiv\rho_{\text{class}}(\tau,t),\quad \lim_{\hbar=0} e^{*\rho}=e^{\rho_{\text{class}}(\tau,t)},\quad \lim_{\hbar=0}\rho=\rho_{\text{class}}(\tau,t), \tag{42}$$

and, as expected, the zeroth-order terms do *not* depend on q,p. We have also performed the stereographic projection mapping the sphere into the complex plane (phase space of q,p). This implies that the embedding relation, up to the nth order, map must establish the correspondence:

$$\left[\frac{1}{\tilde{y}'}\right]^n \Omega_n(r\equiv y'\tilde{y}';z',\tilde{z}')\rightarrow\sum_{l=0}^{l=n}\sum_{m=-l}^{m=+l}\rho_n^{lm}(z_+,z_-,t)Y_{lm}(\theta,\varphi). \tag{43}$$

It is essential not to confuse the prime variables $y',z'\ldots$ with the variables $y,z,\ldots$. A detailed discussion of the maps between the primed and unprimed variables was given in Ref. 10 based on Ref. 25:

$$\{\Omega_{,z'},\Omega_{,y'}\}_{\tilde{z}'\tilde{y}'}=1\leftrightarrow\{\Omega_{,w},\Omega_{,\tilde{w}}\}_{q,p}=1. \tag{44}$$

The inverse symbol map takes functions of phase space into operators in $L^2(R)$ and Moyal brackets into commutators leading to the operator equations

$$\frac{1}{i\hbar}[\hat{\Omega}_{,z'},\hat{\Omega}_{,y'}]=\hat{1}\leftrightarrow\frac{1}{i\hbar}[\hat{\Omega}_{,w},\hat{\Omega}_{,\tilde{w}}]=\hat{1}, \tag{45a}$$

where

$$\Omega(w,\tilde{w},q,p,\hbar)=\sum(\hbar)^n\Omega_n(w,\tilde{w},q,p). \tag{45b}$$

Extreme care must be taken *not* to set Ω_n as a function of $u\equiv w\tilde{w}$ and q,p. If this is wrongly assumed, then the rhs of (45a) will be *zero* instead of 1. This corrects an erratum in Ref. 10. An example of the coordinate transformation (a field-dependent coordinate transformation up to zeroth order) between the primed and unprimed variables associated with the particular solution $\Omega=\Omega_0=z'\tilde{z}'+y'\tilde{y}'$ is[9]

$$\tilde{z}'=q,\quad \tilde{y}'=p,\quad z'=w+\frac{\lambda}{q},\quad y'=\tilde{w}-\frac{\lambda}{p}, \tag{46}$$

with λ a complex constant. As n runs the coordinate transformation varies and one speaks of a field-dependent transformation to the nth order. Notice in (46) that $r=\tilde{y}'y'=p\tilde{w}-\lambda$ which is not equal to $w\tilde{w}$.

The discrepancy, which at first sight might be troublesome, is that the number of variables of Ω and ρ does not match. It is only after the q,p dependence is factorized in (41) that one can match the variables in $\Omega_n(r,z',\tilde{z}')$ with those in $\rho_n^{lm}(t,z_+,z_-)$. However, the $\psi_n(z_+,z_-,t)$ belonging to the $2+1$ SU(2) Toda lattice equation admits a perfect match with the number of variables $\Omega_n(r,z',\tilde{z}')$. For this reason, when one speaks of the Legendre-like transform from the Ω, obeying the rotational Killing symmetry reductions of the Moyal heavenly equation, to the Moyal–Toda lattice-type equations, one must refer to Strachan's SU(2) Toda lattice equation (36) as discussed at the beginning of this subsection.

The embedding of the SU(2) Toda lattice equations (34) and (36) into the continuous Moyal–Toda lattice-type equations (38)–(40) requires us to find a particular subset of solutions to the ρ_n^{lm} such that the following factorization condition occurs:

$$\sum_{l=0}^{l=n}\sum_{m=-l}^{m=+l}\rho_n^{lm}Y_{lm}=\psi_n f_n(q,p)=\rho_n(z_+,z_-,t,q,p) \tag{47}$$

(no sum over n), where the functions ψ_n are precisely those solving Strachan equations (34) and (36) after expanding ψ in powers of $\hbar$; i.e., therefore, one has embedded the SU(2) Toda lattice equation into the continuous Moyal–Toda lattice ones. Solving for ρ_n^{lm} in (47) yields

$$\rho_n^{lm}(z_+,z_-,t)\sim\psi_n(z_+,z_-,t)\int d\varphi\, d(\cos\theta)Y_{lm}(\varphi,\theta)f_n(q,p). \tag{48}$$

Here q,p were given in terms of φ,θ in (41). The $f_n(q,p)$ functions in principle can be determined from the differential equations obtained after inserting Eq. (47) into (38) and after replacing ∂_τ^2 by $\partial_{z_+}\partial_{z_-}$ on the lhs of (38).

Concluding this subsection, by sorting out the signature subtleties used by different authors,[3,8] the transformation of rotational Killing symmetry reduction of the 4D Moyal heavenly equations into the $2+1$ SU(2) Toda lattice field equations is attained in a two-step process by using Eqs. (15) and (33). In this fashion one establishes the sought-after relation between (reductions of) Ω and $(\psi(\tau,t,\hbar),z(\tau,t,\hbar))$ after the three YM potentials A_i involved in (15) are replaced by the Moyal–Nahm functions X_i defined in (33). This is probably one of the most relevant results of this work. The embedding of ψ obeying the SU(2) lattice equations (34) and (36) into the ρ obeying the continuous Moyal–Toda lattice equation (38) was also provided through the factorization conditions (47) and (48).

IV. THE GENERALIZED MOYAL–NAHM EQUATIONS, MOYAL DEFORMATIONS OF LOOP ALGEBRAS, SYMPLECTIC DIFFEOMORPHISMS IN 4D AND CONTINUUM LIE ALGEBRAS

A. Reductions of Moyal–Nahm equations

We have been studying *reductions* of the generalized Moyal–Nahm equations related to the Moyal deformations of the SU(∞) ASDYM/SDYM equations in four dimensions, an effective 6D theory. The most general Moyal–Nahm equations require, at least, an extra set of q',p' coordinates and hence one has an effective 8D theory where the Moyal bracket is taken wrt the enlarged phase space, i.e., the Weyl–Wigner–Moyal formalism involves mapping operator-valued quantities living in a 4D space–time [belonging to a Hilbert space of $L^2(R^2)$, instead of $L^2(R^1)$] into functions of the enlarged phase space, q,p,q',p'. Instead of dealing with Moyal deformed symplectic diffeomorphisms of a two-dimensional surface, one is now dealing with Moyal deformed symplectic diffeomorphisms in four dimensions. Therefore the effective theory is now 8D instead of 6D!

We *define* the generalized Moyal–Nahm equations as

$$\epsilon_{\alpha\beta\gamma}\frac{\partial\mathcal{T}_\gamma}{\partial\phi}=\{\{\mathcal{T}_\alpha,\mathcal{T}_\beta\}\},\quad \mathcal{T}_\alpha[\phi(x^\mu;q,p,q',p',\hbar);q,p,q',p';\hbar], \tag{49}$$

where now the Moyal bracket must be taken wrt an enlarged phase space q,p,q',p'. There is an explict and implicit $q_i,p_i,\hbar$ dependence in the Moyal–Nahm functions. The Moyal bracket of f,g wrt the enlarged phase space is compactly written as

$$\{\{f,g\}\}\equiv\frac{1}{\hbar}f(\sin[\hbar(\overleftarrow{\partial}_q\vec{\partial}_p-q\leftrightarrow p+\overleftarrow{\partial}_{q'}\vec{\partial}_{p'}-q'\leftrightarrow p')])g. \tag{50}$$

Expanding the sine function in powers of $\hbar$ one retrieves the infinite derivative terms. The WWM map takes self-adjoint operator-valued quantities, living in the Hilbert space $L^2(R^2),\hat{A}(x^\mu)$, into real-valued functions in phase space $\mathcal{A}(x^\mu;q,p,q',p';\hbar)$:

$$\mathcal{A}(x^\mu;q,p,q',p';\hbar)\equiv\int_{-\infty}^{\infty}d^2\xi\left\langle \vec{q}-\frac{\vec{\xi}}{2}\right|\hat{A}(x^\mu)\left|\vec{q}+\frac{\vec{\xi}}{2}\right\rangle \exp\left[\frac{i\vec{\xi}.\vec{p}}{\hbar}\right],\quad \vec{q}=(q,q'),\quad \vec{p}=(p,p'), \tag{51}$$

$$\left|\vec{q}+\frac{\vec{\xi}}{2}\right\rangle=\left|q_1+\frac{\xi_1}{2}\right\rangle\otimes\left|q_2+\frac{\xi_2}{2}\right\rangle\cdots. \tag{52}$$

Imagine representing now the SU(2) Lie-algebra-valued YM potentials (matrices) in terms of operators in $\hat{q},\hat{p},\hat{q}',\hat{p}'$ and performing afterwards the WWM map.

The relevant algebra is now the Moyal deformations of symplectic diffeomorphisms in four dimensions instead of two. For this reason it is incorrect to say that one has ''SU(∞)'' Moyal–Nahm equations. For example, the generators are labeled as $V_m^{l,\vec{k}}$, where $\vec{k}=(k_1,k_2)$,[20] and obey the infinite-dimensional generalization of the w_∞ algebra (area-preserving diffeomorphisms of the plane):

$$[V_m^{l,\vec{k}},V_n^{j,\vec{l}}]=[(j+1)m-(l+1)n]V_{m+n}^{l+j,\vec{k}+\vec{l}}+\vec{k}\times\vec{l}\,V_{m+n}^{l+j+1,\vec{k}+\vec{l}}. \tag{53}$$

This algebra of symplectic diffeomorphisms in four dimensions has a realization in terms of ordinary Poisson brackets wrt the q,p,q',p' enlarged phase space variables. The Moyal deformations are obtained by replacing ordinary Poisson brackets by Moyal ones. If one had a presentation of the SU(2) algebra as linear operators in $L^2(R^2)$, instead of the known representations in $L^2(R^1)$,[11] one could then evaluate the WWM map (51) and obtain solutions to the generalized Moyal–Nahm equations as it was done in Ref. 11.

Another type of generalized Moyal–Nahm equation one could write is such where instead of having a Moyal bracket wrt the enlarged phase space, one has a *partial* Moyal bracket wrt one set of q,p variables:

$$\epsilon_{\alpha\beta\gamma}\frac{\partial\mathcal{T}_\gamma}{\partial\phi}=\{\mathcal{T}_\alpha,\mathcal{T}_\beta\}_{q,p},\quad \mathcal{T}_\alpha[\phi(x^\mu;q,p,q',p',\hbar);q,p,q',p';\hbar]. \tag{54}$$

The *problem* with Eq. (54) as such is that it does *not* determine the functional dependence on the q',p' variables since there is no differential operators which involve now the q',p' variables. For this reason we should *disregard* (54) as a valid equation.

We shall study the reductions of (49) with the goal of obtaining the continuous Moyal–Toda lattice-type equations (38)–(40). First, one replaces ϕ by τ and, as usual, $A_0=0$, $A_i\sim\mathcal{T}_i$. Second, one imposes the reduction condition $t=q'$ while recurring to an ansatz that allows one to decouple the $\cos p'$, $\sin p'$ terms, after computing the Moyal bracket in (49) and (50), giving, finally, an equation involving *only* the τ,t,q,p variables. If we set

$$\mathcal{T}_1=R(\tau,t=q',q,p,\hbar)\cos p',\quad \mathcal{T}_2=R(\tau,t=q',q,p,\hbar)\sin p',\quad \mathcal{T}_3=z(\tau,t=q',\hbar). \tag{55}$$

After plugging (55) into (49), the terms in $\cos p'$, $\sin p'$ decouple and, eliminating z, one obtains the following highly nontrivial equation for the function R, after computing the Moyal bracket wrt the enlarged phase space variables:

$$\frac{\partial^2\ln R}{\partial\tau^2}=\alpha\left(\frac{\Delta-\Delta^{-1}}{\hbar}\right)^2R^2+\beta\left(\frac{\Delta-\Delta^{-1}}{\hbar}\right)\sum_{n=1}^{\infty}(\hbar)^nC_{i_1\ldots i_n}(\partial_{i_1}\cdots\partial_{i_{n-1}}R)(\partial_{j_1}\cdots\partial_{j_n}R). \tag{56}$$

The second terms on the rhs of (56) contain mixed derivatives of infinite order wrt the t,q,p variables. Here α, β and $C_{i_1\ldots i_n}$ are constants. The Strachan SU(2) Toda lattice equation is recovered automatically by dropping the extra q,p dependence on R [so that the second term on the rhs of (56) becomes zero] and by equating $R^2=e^\rho$.

Due to the extra q,p dependence the situation changes drastically. In order to obtain an equation like (38) it is required to establish the *new* functional relation between the R and ρ functions. The previous relation $R^2=e^\rho$ does not work, for example, if one sets

$$R*R=e^{*\rho}\Rightarrow\frac{\rho}{2}\neq\ln R. \tag{57}$$

The lhs of Eq. (56) will no longer be $(1/2)\partial_\tau^2\rho$. Furthermore, if (57) was the correct relation between R and ρ, the rhs of (56) would *not* equal the rhs of (38) despite the fact that the rhs of (56) contains the same type of infinite derivative terms as Eq. (38) does. This is because [after using the relationship (57)] the *coefficients* on the rhs of Eqs. (56) and (38) *differ*. This could be fixed easily by adding terms on *both* sides of Eq. (56) with the appropriate coefficients so that the rhs of (56) equals precisely the corresponding term of Eq. (38):

$$\left(\frac{\Delta-\Delta^{-1}}{\hbar}\right)^2 R*R=\left(\frac{\Delta-\Delta^{-1}}{\hbar}\right)^2 e^{*\rho}.$$

However, there is still no assurance that the lhs of (56), after the addition of those terms which rendered the rhs of (56) in the required form given by Eq. (38), will have *also* the sought-after form,

$$\frac{\partial^2\ln_* R}{\partial\tau^2}=\frac{1}{2}\,\frac{\partial^2\rho}{\partial\tau^2}, \tag{58a}$$

where the *star* logarithm and *star* square root are defined as

$$\ln_*(e^{*\rho})\equiv\rho,\quad R*R=e^{*\rho}\Rightarrow R=[e^{*\rho}]_*^{1/2},\quad \ln_* R=\ln_*[e^{*\rho}]_*^{1/2}=\tfrac{1}{2}\rho. \tag{58b}$$

In other words, it is not clear that one can adjust *both* sides of Eq. (56), by adding terms on both sides simultaneously, to match the required form of the continuous Moyal–Toda lattice equation (38). It would have been very fortuitous that the simultaneous addition of terms on both sides of the equation (56) would lead exactly to the continuous Moyal–Toda lattice equation (38).

Therefore, by inspection, the ansatz proposed in (55) does not seem to work if one wishes to find a direct relation between R and ρ. This could be remedied by introducing two auxiliary functions as we shall see shortly. Although it is *undesirable* to introduce extraneous functions into this construction, the use of two auxiliary functions seems to work in principle. The source of the problem is to find to the new functional relationship between R and ρ that will render both sides of Eq. (56) correctly. Nevertheless, matters are not final. Equation (56) is *per se* satisfactory in the sense that it yields a well-defined differential equation for the R function with an infinite number of derivative terms. Imposing the condition

$$\frac{1}{2}\,\frac{\partial^2\rho}{\partial\tau^2}=\frac{\partial^2\ln R}{\partial\tau^2}\Rightarrow\frac{1}{2}\rho=\ln R+F(t,q,p,\hbar)\tau+G(t,q,p,\hbar) \tag{59}$$

fixes ρ in terms of R and two auxiliary functions, F,G. Solving for R yields

$$R=e^{\rho/2-F\tau-G}=e^{\rho/2}e^{-F(t,q,p,\hbar)\tau-G(t,q,p,\hbar)}. \tag{60}$$

Inserting this new value for R into the rhs of (56) and equating it to the rhs of (38) determines another differential equation for the F,G functions in conjunction with the original Moyal–Toda lattice equation. A coupled set of differential equations for ρ and F,G is obtained in this fashion: Eqs. (38), (56), and (59), three equations for three functions.

The main question now will be to see whether or not this system of coupled differential equations is self-consistent and has well-defined nontrivial and nonsingular solutions, in particular, whether, or not Eq. (59) is in fact *compatible* with the remaining two equations (38) and (56). This very difficult question remains to be answered.

B. Embeddings of the Moyal–Toda equations

It is also reasonable to look for other ways of embedding the continuous Moyal–Toda lattice equations into the Moyal–Nahm equations that do *not* require a direct decoupling of the $\cos p'$, $\sin p'$ functions, for example, integrating out the p' variable without the need to reduce the generalized Moyal–Nahm equations.

The use of the $\mathcal{T}_\alpha$ was successful earlier in obtaining the SU(2) Toda lattice equation from the Moyal–Nahm equations after one imposing the reduction $q=q'$, $p=p'$ conditions and replacing ϕ by τ and setting $t=q$. It is reasonable to ask if other embeddings/reductions are possible. The continuous Moyal–Toda equation (26) admits the following embedding into the Moyal–Nahm equations for those *special* solutions of ρ satisfying the *reduction* condition: $\rho(\tau,t,q,p,\hbar)=\rho(\tau \pm it,q,p,\hbar)$, where in addition one restricts the solutions of the deformed Laplace equation for the scalar ϕ to have the trivial values: $\tau\pm it$. For this very restricted case one has the following relations:

$$\frac{\partial \mathcal{T}_3}{\partial \phi}=\frac{\partial^2\rho}{\partial\phi^2}\Rightarrow\rho(\phi,q,p,\hbar)=\int \mathcal{T}_3\, d\phi+F(q,p,\hbar)\phi+G(q,p,\hbar), \tag{61a}$$

$$\{\mathcal{T}_+,\mathcal{T}_-\}=-\frac{\partial^2}{\partial\phi^2}e^{*\rho(\phi,q,p,\hbar)},\quad \rho=\rho(\phi,q,p,\hbar),\quad q=q',p=p', \tag{61b}$$

$$\frac{\partial^2\rho}{\partial\phi^2}=-\frac{\partial^2}{\partial\phi^2}e^{*\rho(\phi,q,p,\hbar)}. \tag{61c}$$

Following similar arguments as above yields a system of differential equations to solve for the three functions $\rho(\phi,q,p,\hbar),F,G$. One can infer directly from Eq. (61c)

$$\rho+e^{*\rho}=A(q,p,\hbar)\phi+B(q,p,\hbar). \tag{62}$$

In this simpler case we have an implicit equation for ρ. If one were able to invert this last equation, one will have then an expression of the form $\rho=\rho(\phi,q,p,\hbar)$ that would have been a particular solution to Eq. (61c) related to the embedding displayed by Eqs. (61a) and (61b). It is not an easy task to invert the latter equation. Furthermore, the full-fledged theory requires us to use more general solutions for the deformed scalar ϕ obeying the deformations of Laplace equation (9b). The choice $\tau\pm it$ was the trivial one.

Finally, a natural embedding of the continuous Moyal–Toda lattice-type equations (38)–(40) into the generalized Moyal–Nahm equations (49) is to set $q'=t$ and to replace as usual the function ϕ by τ so that the ansatz in (7) yields $A_0=0$ and $A_i(\tau,q'=t,p',q,p,\hbar)$ is replaced by $\mathcal{T}_i$ for $i=1,2,3$. Given a solution to the generalized SU(2) Moyal–Nahm equations (using Moyal brackets wrt the extended phase space variables) for the three potentials $\mathcal{A}_i$, one selects the particular equation

$$\frac{\partial\mathcal{A}_3}{\partial\tau}=\{\{\mathcal{A}_+,\mathcal{A}_-\}\},\quad \mathcal{A}_\pm=\frac{1}{\sqrt{2}}(\mathcal{A}_1\pm i\mathcal{A}_2). \tag{63}$$

A partial integration taken wrt the p' variable only yields the embedding relations

$$\int_{-\infty}^{+\infty}dp'\frac{\partial\mathcal{A}_3}{\partial\tau}=\frac{\partial^2\rho(\tau,t,q,p,\hbar)}{\partial\tau^2}, \tag{64}$$

$$\int_{-\infty}^{+\infty} dp' \{\{\mathcal{A}_+,\mathcal{A}_-\}\} = \frac{1}{4}\left(\frac{\Delta-\Delta^{-1}}{\hbar}\right)^2 e*^{\rho} = \partial_t^2 e*^{\rho(\tau,t,q,p,\hbar)} + \frac{1}{3}(\hbar)^2\partial_t^4 e*^{\rho} + \cdots. \tag{65}$$

There are some total derivative terms wrt p' which vanish after integration, but not all of the terms appearing on the lhs of (65) are total derivatives. From Eq. (64) one learns that

$$\rho = \int_{-\infty}^{+\infty} dp' \int_{\tau'=0}^{\tau'=\tau} \mathcal{A}_3\, d\tau' + \mathcal{F}(t,q,p,\hbar)\tau + \mathcal{G}(t,q,p,\hbar). \tag{66}$$

The functions $\mathcal{F}$, $\mathcal{G}$ are not arbitrary, but are part of the system of three coupled differential equations given by Eqs. (63)–(65). The embedding is characterized by integrating out the variable p' without imposing a reduction on the Moyal–Nahm equations (49) to decouple the p' variable directly. In all these embeddings, two auxiliary functions are required.

It is warranted to see whether or not is possible to find a Killing symmetry reduction of the generalized Moyal–Nahm equations (49) directly to the continuous Moyal–Toda lattice-type equations (38)–(40) *without* the need to recur to auxiliary functions and avoid the complicated set of coupled differential equations. The essence of the problem lies in the fact that the t variable plays two different roles. In one case, like in the rotational Killing symmetry reduction of the heavenly equation, it behaves like an ordinary space–time variable and, in another, it behaves like an *internal* phase space variable associated with the Lie algebra of the area-preserving diffeomorphisms of the sphere. It seems very difficult to reconcile both roles within the WWGM formalism without returning to the coupled system of differential equations. We believe that there maybe a reduction (other than the axial symmetry reduction proposed above) of the generalized Moyal–Nahm equations that successfully decouples the p' variable and that reproduces the continuous Moyal–Toda lattice equations *without* the introduction of auxiliary functions.

C. Continuum Lie algebras and the Lax–Brockett formalism

To finalize matters we recall again the Lax–Brockett formalism of **Z**-graded continuum Lie algebras[19] which is perhaps the most geometrical of all approaches.

The data $\{\mathcal{T}_\alpha\}$ for three Moyal–Nahm functions need to be related to the three functions $\{\mathcal{L},\mathcal{H},\mathcal{M}\}$ required in the Lax–Brockett formalism of continuum **Z**-graded Lie algebras.[19] Equation (18) establishes the correspondence among these data: a functional embedding of the data $\{\mathcal{T}_\alpha\}$ (parametrized by one function, ϕ) into the data $\{\mathcal{L},\mathcal{H},\mathcal{M}\}$ (parametrized by three functions, u,ρ,κ). However, this is only possible if one can construct the three twistorlike transformations which map the now-deformed scalar field $\phi(x^\mu;q_i,p_i,\hbar)$ into the now-deformed three functions appearing in Eqs. (2)–(4): ρ,u,κ depending on $\tau,t;q_i,p_i,\hbar$. One of them is the Moyal deformed continuous Toda field: ρ.

Presumably this should be related to the problem of deformations of twistor surfaces and Kodaira–Spencer deformation theory.[14] Unfortunately, we cannot say more on this matter. A start will be in constructing Moyal deformations of continuum Lie algebras. We are unaware if this has ever been done. A construction will provide the functional relations of $\{\mathcal{L},\mathcal{H},\mathcal{M}\}$ in terms of u,ρ,κ. The Lax–Brockett formalism of the Moyal–Nahm equations should yield the continuous Moyal–Toda equation for ρ (26) after the elimination of u,κ as it occurs in the undeformed case.[19]

For this reason, it is of tantamount importance to construct representations of continuum Lie algebras and for that matter representations of SU(∞) as well. A WWM quantization will then provide the functional relations of $\{\mathcal{L},\mathcal{H},\mathcal{M}\}$ in terms of u,ρ,κ.

The main solution to the problem of writing down Moyal–Toda equations from reductions of Moyal–Nahm equations requires the construction of Moyal deformations of the graded continuum Lie algebras. There are other Moyal deformations related to the infinite-dimensional loop algebras associated with w_∞ algebras. For example, the loop algebra of $sdiff(R^2)$, the algebra of maps of the circle into w_∞, in the basis of functions $x^{s+m}y^{s-m}$ is

$$[v_m^s(\sigma),v_n^t(\sigma')]=[(t-n)(s+m)-(s-m)(t+n)]v_{m+n}^{s+t-1}(\sigma)\frac{\partial}{\partial\sigma}\delta(\sigma-\sigma'). \tag{67}$$

These loop algebras may admit Moyal deformations as well since the Moyal deformation of the centerless w_∞ algebra *is* the centerless W_∞ algebra.[26–28] Central extensions can be added as well. Hence, the Moyal deformations of the algebra (67) will be just the infinite-dimensional loop algebra associated with W_∞.

Moyal deformations of the **Z**-graded continuum Lie algebras[19] ought to be very relevant in the Moyal quantization program of the continuous Toda theory. Especially in regards to determining the differential equations for the $u(\tau,t,q,p,\hbar)$ and $\kappa(\tau,t,q,p,\hbar)$ appearing directly in the Lax–Brockett double commutator formalism. More on this shall be said in a forthcoming publication.

V. CONCLUSION

We have explicitly presented in Sec. II a class of solutions to the Moyal SU(∞) ASDYM equations in four dimensions that are related to the *reductions* of the generalized Moyal–Nahm equations via the Ivanova–Popov ansatz. A dimensional reduction yields solutions to the Moyal deformations of the ASDG equations. The SDYM and SDG case requires a separate study.

Since the ASDYM equations studied by Ivanova and Popov[4] in Euclidean 4D correspond to the SDYM equations in $2+2$ dimensions studied in Ref. 9, one can write down the transformation that maps the rotational Killing symmetry reductions of the 4D Moyal heavenly equations given by Eq. (14) into the $2+1$ SU(2) Toda lattice equations given by Eq. (36). A two-step process is required to attain such a map and it is explicitly given by Eqs. (15) and (33). This is one of the most relevant results of this work.

Three *different* types of Toda equations have been studied. (i) The continuous Moyal–Toda equation (26) and the Moyal–Liouville equation (32b). Two types of discrete-differential equations, (ii) the SU(2) Toda lattice (34) and (36) and (iii) the continuous Moyal–Toda lattice equations, Eqs. (38)–(40). The generalization of the Prasad transformation[6,22] to the Moyal case mapping deformations of the 3D Laplace equation to the continuous Moyal–Toda equation (26) was discussed in Sec. III A.

Finally, the generalized Moyal–Nahm equations (49) have been provided that should *contain* the continuous Moyal–Toda lattice-type equations after a suitable reduction, similar to the one performed by Strachan[14] which yields the SU(2) Toda lattice from the SU(2) Moyal–Nahm equations. Unfortunately, this reduction requires the introduction of two auxiliary fields. Further details of the reduction *without* auxiliary fields is currently under investigation. Embeddings of the various forms of the Moyal–Toda equations into the Moyal–Nahm equation were also provided and, again, the introduction of two auxiliary fields was required.

The project for the future is to study the Lax–Brockett formalism of the generalized Moyal–Nahm equations. Unfortunately we lack an explicit knowledge of the form of the $\mathcal{L}$, $\mathcal{M}$ functions in terms of the deformed ρ,u,κ fields. If we did, then one could apply the Lax–Brockett formalism (18) to the Moyal–Nahm equations to obtain directly the Moyal–Toda equations for ρ upon eliminating the u,κ fields. Presumably, this could be a realization of deformations of twistor surfaces.[15] The connection to Kodaira–Spencer deformation theory[14] is unknown at the moment.

Other Moyal deformations applied to higher extended objects, p-branes, remain to be studied: the so-called Moyal–Nambu–Poisson algebras related to deformations of the volume forms. The natural deformation quantization technique is the Zariski product[16] which generalizes the Moyal product to p-branes. Octonionic[29] and quaternionic Moyal–Nahm equations can be constructed as well using the octonionic/quaternionic structure constants instead of the $\epsilon_{\alpha\beta\gamma}$ tensor density. The fact that the generalized Moyal–Nahm equations require eight dimensions may have an important role in understanding the quantum dynamics of the 11D membrane[13] and the role of W_∞ algebras.[25]

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 8 AUGUST 1999

Central charge and the Andrews–Bailey construction

Leung Chim
Department of Physics and Mathematical Physics, The University of Adelaide, Adelaide, SA, 5005, Australia

(Received 11 November 1998; accepted for publication 9 April 1999)

From the equivalence of the bosonic and fermionic representations of finitized characters in conformal field theory, one can extract mathematical objects known as Bailey pairs. Recently Berkovich, McCoy, and Schilling have constructed a ''generalized'' character formula depending on two parameters ρ_1 and ρ_2, using the Bailey pairs of the unitary model $M(p-1,p)$. By taking appropriate limits of these parameters, they were able to obtain the characters of model $M(p,p+1)$, $N=1$ model $SM(p,p+2)$, and the unitary $N=2$ model with central charge $c=3(1-2/p)$. In this letter we computed the effective central charge associated with this ''generalized'' character formula using a saddle point method. The result is a simple expression in dilogarithms which interpolates between the central charges of these unitary models. © *1999 American Institute of Physics.*

I. INTRODUCTION

More than a decade since its creation, two-dimensional conformal field theory (CFT)[1] and its integrable perturbations[2] still remain as one of the most active research topics in modern physics. A current focus is in the study of various bases of the Hilbert space in CFT. Different choices of the basis would lead to a different representation for the partition function of the CFT defined on a compact manifold such as a torus or a cylinder. This partition function is usually written in terms of characters of the Virasoro or some extended algebras. The ''bosonic'' form of these character formulas are well known for the minimal models of CFT (e.g., see Refs. 3–8, and references therein). Recently the Stony Brook group has constructed numerous new character formulas for minimal CFT based on fermionic quasiparticles.[9–12] For several CFTs, more than one ''fermionic'' expression exists for the same conformal character. In these cases, the different expressions are related to the different integrable perturbations of the same CFT. These developments all lend support to the idea of a massless scattering S-matrix description of CFT.[13–16] The construction of the quasiparticle basis of the Hilbert space is also apparently related to the problem of diagonalizing the infinite set of local integrals of motion in CFT.[17,18] For a description in terms of other bases see Refs. 19–21.

The equivalence of the bosonic and fermionic character formulas gives rise to beautiful q-series identities of the Rogers–Ramanujan type.[22–24] Such identities were proven by Schur[25] and Andrews[26] by establishing identities for families of polynomials whose limiting case yields the Rogers–Ramanujan identities. This method was applied to the character identities of the unitary minimal models by Melzer in Ref. 27, where he proposed a finitization of fermionic character formulas to match the bosonic polynomials of Ref. 28. In Ref. 29, several classes of q-series identities were proven using Andrews' generalization[30] of Bailey's lemma.[31] The key observations in Ref. 29 were that Bailey pairs can be extracted from finitized characters (which must be in the general bosonic form of Ref. 32)[33] and several series of CFT [including subsets of $M(p,p+1)$, $M(p,p+2)$, and $M(p,kp+1)$] are ''linked'' on a so-called Bailey's chain.[30] The equivalence proof for all members of a series is a straightforward application of Bailey's lemma, once a proof is established for a single member.[30]

In a remarkable paper,[34] the procedure of Ref. 29 was repeated using a more general form of the Andrews–Bailey construction which contains two parameters ρ_1 and ρ_2.[30,31] From the (dual)

Bailey pairs for the unitary minimal model $M(p-1,p)$, the more general construction gives a ''generalized'' character formula [Eq. (4.19) of Ref. 34] depending on the two parameters. Three specializations of these parameters lead to known results:

$$\begin{aligned}&(\mathrm{i}): \rho_1 \to \infty, \quad \rho_2 \to \infty;\\&(\mathrm{ii}): \rho_1 \to \infty, \quad \rho_2 = \text{finite};\\&(\mathrm{iii}): \rho_1 = \text{finite}, \quad \rho_2 = \text{finite}.\end{aligned} \tag{1.1}$$

In the first case, the ''generalized'' character formula becomes the character for the next model in the unitary series, i.e., $M(p,p+1)$ with central charge $1-6/p(p+1)$. Case (ii) leads to fermionic character formula for $N=1$ supersymmetric model $SM(p,p+2)$ with central charge $\frac{3}{2}-12/p(p+1)$, while case (iii) gives the fermionic character of unitary $N=2$ model with central charge $c=3(1-2/p)$. It is amazing that this ''generalized'' character formula connects the unitary models with their supersymmetric counterparts. In fact, this construction (and its generalizations) can also be applied to other minimal models $M(p,p')$.[29,11,35–37] A natural question (raised in Ref. 34) which needs addressing is whether this construction has any connection to massless renormalization group flows between these CFT.[13,38]

In this paper, we shall attempt to understand this ''generalized'' character formula for the unitary series by computing the associated ''generalized'' effective central charge. In Sec. II we give a brief review of the construction detailed in Ref. 34 and establish our notations. The generalized effective central charge is calculated in Sec. III via a saddle point approximation following Refs. 39, 40, 9, and special cases are treated. A discussion of our result is given in Sec. IV.

II. THE ANDREWS–BAILEY CONSTRUCTION OF THE UNITARY MODELS

The unitary CFT $M(p-1,p)$ is the continuum limit of the $(p-1)$-states RSOS lattice model[28] at its critical point between regimes III and IV.[41] The equivalence of the associated bosonic and fermionic finitized characters can be written as[27]

$$B_{r,s}^{(L,p)} = F_{r,s}^{(L,p)}. \tag{2.1}$$

The bosonic side has the form

$$B_{r,s}^{(L,p)}(q) = \sum_{j=-\infty}^{\infty} \left(q^{j(jp(p-1)+pr-(p-1)s)} \begin{bmatrix} L \\ [\frac{1}{2}(L+s-r)]-pj \end{bmatrix}_q - q^{(jp-s)(j(p-1)-r)} \times \begin{bmatrix} L \\ [\frac{1}{2}(L-s-r)]+pj \end{bmatrix}_q \right), \tag{2.2}$$

where $[n]$ denotes the integer part of n, and

$$\begin{bmatrix} n \\ m \end{bmatrix}_q = \begin{cases} \dfrac{(q)_n}{(q)_m (q)_{n-m}} & \text{for } 0 \leqslant m \leqslant n \\ 0 & \text{otherwise,} \end{cases} \tag{2.3}$$

is the usual q-binomial coefficient with

$$(a)_n = \frac{(a)_\infty}{(aq^n)_\infty}, \quad (a)_\infty = \prod_{l=0}^{\infty} (1-aq^l). \tag{2.4}$$

One should note that this finitized character is equal to the one-dimensional configuration sum of the underlying RSOS model in regime III, defined on a square lattice of size L,[28] and can be used to compute local height probabilities. In the limit $L\to\infty$, (2.2) becomes the character formula[3] for the irreducible representation generated by the primary field $\Phi_{(r,s)}$, with normalization $\chi_{r,s}(q)=1+\Sigma_{N\geqslant 1}a_N q^N$.

There are two forms for the fermionic character $F_{r,s}^{(L,p)}$, depending on the finite parameter L. Let C_{p-3} and I_{p-3} stand for, respectively, the Cartan and incidence matrices of the Lie algebra A_{p-3}. Furthermore denote the i unit vector in $\mathbb{R}^{p-3}$ as $\vec{e}_i$, and set $\vec{e}_i=\vec{0}$ for $i<1$ or $i>(p-3)$. Then

$$F_{r,s}^{(L,p)}(q) = q^{-(1/4)(s-r)(s-r-1)} \sum_{\vec{m}\in 2\mathbb{Z}^{p-3}+\vec{Q}_{r,s}} q^{(1/4)\vec{m}^T C_{p-3}\vec{m}-(1/2)\vec{A}_{r,s}\vec{m}} \prod_{i=1}^{p-3} \begin{bmatrix} \frac{1}{2}(I_{p-3}\vec{m}+\vec{u}_{r,s}+L\vec{e}_1)_i \\ m_i \end{bmatrix}_q , \tag{2.5}$$

where $\vec{m}^T=(m_1,\ldots,m_{p-3})$. When $L+r-s$ is even,

$$\vec{A}_{r,s}=\vec{e}_{s-1}, \quad \vec{u}_{r,s}=\vec{e}_{s-1}+\vec{e}_{p-r-1}, \tag{2.6}$$

$$\vec{Q}_{r,s}=(r-1)\sum_{i=1}^{p-3}\vec{e}_i+(\vec{e}_{s-2}+\vec{e}_{s-4}+\cdots)+(\vec{e}_{p-r}+\vec{e}_{p+2-r}+\cdots);$$

and when $L+r-s$ is odd,

$$\vec{A}_{r,s}=\vec{e}_{p-s-1}, \quad \vec{u}_{r,s}=\vec{e}_{p-s-1}+\vec{e}_r, \tag{2.7}$$

$$\vec{Q}_{r,s}=(s-1)\sum_{i=1}^{p-3}\vec{e}_i+(\vec{e}_{r-1}+\vec{e}_{r-3}+\cdots)+(\vec{e}_{p-s}+\vec{e}_{p+2-s}+\cdots).$$

These two forms yield the same q-series in the limit $L\to\infty$. Proofs of the fermionic sums are given in Refs. 42–46.

Two sequences $\{\alpha_n\}$ and $\{\beta_n\}$ form a (bilateral) Bailey pair relative to a if they satisfy the relation

$$\beta_n=\sum_{j=-\infty}^{n}\frac{\alpha_j}{(q)_{n-j}(aq)_{n+j}}. \tag{2.8}$$

If we set $L=2l+r-s+2x$, then from (2.1) we can read off a (bilateral) Bailey pair relative to $a=q^{r-s+2x}$ as

$$\alpha_n=\begin{cases} q^{j(jp(p-1)+pr-(p-1)s)} & \text{for } n=pj-x \\ -q^{(jp-s)(j(p-1)-r)} & \text{for } n=pj-r-x, \\ 0 \quad \text{for otherwise} & \end{cases} \tag{2.9a}$$

$$\beta_n=\begin{cases} \dfrac{1}{(aq)_{2n}}F_{r,s}^{(2n+r-s+2x,p)}(q) & \text{for } \geqslant 0 \\ 0 \quad \text{otherwise.} & \end{cases} \tag{2.9b}$$

An important step in the Andrews–Bailey construction of the unitary models is to define another Bailey pair relative to a,

$$A_n=\begin{cases} q^{j^2p-sj+x(s-r-x)} & \text{for } n=pj-x \\ -q^{j^2p-sj+x(s-r-x)} & \text{for } n=pj-r-x \\ 0 & \text{otherwise} \end{cases} \tag{2.10a}$$

$$B_n=\begin{cases} \frac{1}{(aq)_{2n}} q^{n^2}a^nF_{r,s}^{(2n+r-s+2x,p)}(q^{-1}) & \text{for } n\geqslant 0 \\ 0 & \text{otherwise,} \end{cases} \tag{2.10b}$$

which are dual to (2.9).[30,34] Here

$$F_{r,s}^{(L,p)}(q^{-1}) = q^{(1/4)(s-r)(s-r-1)} \sum_{\vec{m}\in 2\mathbb{Z}^{p-3}+\vec{Q}_{r,s}} q^{(1/4)\vec{m}^TC_{p-3}\vec{m}+(1/2)(\vec{A}_{r,s}-\vec{u}_{r,s}-L\vec{e}_1)\vec{m}} \times \prod_{i=1}^{p-3} \begin{bmatrix} \frac{1}{2}(I_{p-3}\vec{m}+\vec{u}_{r,s}+L\vec{e}_1)_i \\ m_i \end{bmatrix}_q . \tag{2.11}$$

This dual transformation ($q\to q^{-1}$) takes us from the $M(p-1,p)$ finitized characters to the $M(1,p)$ finitized characters.[10,44] The nonunitary minimal model $M(1,p)$ has actually zero operator content in the usual range of r and s, but admits nontrivial finitizations. In fact, up to some prefactors, (2.11) is the finitization[47] of the $\mathbb{Z}_{p-2}$ parafermions[48] which describe the critical point between regimes I and II of the RSOS model.[28]

The Andrews–Bailey construction tells us that if (2.10) is a (bilateral) Bailey pair, then

$$A_n'=\left(\frac{(\rho_1)_n(\rho_2)_n(aq/\rho_1\rho_2)^n}{(aq/\rho_1)_n(aq/\rho_2)_n}\right)A_n , \tag{2.12a}$$

$$B_n'=\sum_{m=-\infty}^{n}\left(\frac{(\rho_1)_m(\rho_2)_m(aq/\rho_1\rho_2)_{n-m}(aq/\rho_1\rho_2)^m}{(q)_{n-m}(aq/\rho_1)_n(aq/\rho_2)_n}\right)B_m \tag{2.12b}$$

also forms a (bilateral) Bailey pair with respect to a. Now using the defining relation (2.8) with this new Bailey pair and taking the limit $n\to\infty$, one easily obtains the formula

$$\frac{(aq/\rho_1)_\infty(aq/\rho_2)_\infty}{(aq)_\infty(aq/\rho_1\rho_2)_\infty}\sum_{j=-\infty}^{\infty} q^{j(jp-s)+x(s-r-x)}\left(\frac{(\rho_1)_{pj-x}(\rho_2)_{pj-x}(aq/\rho_1\rho_2)^{pj-x}}{(aq/\rho_1)_{pj-x}(aq/\rho_2)_{pj-x}} - \frac{(\rho_1)_{pj-r-x}(\rho_2)_{pj-r-x}(aq/\rho_1\rho_2)^{pj-r-x}}{(aq/\rho_1)_{pj-r-x}(aq/\rho_2)_{pj-r-x}}\right) = \sum_{n=0}^{\infty}(\rho_1)_n(\rho_2)_n(aq/\rho_1\rho_2)^n\frac{q^{n^2}a^n}{(aq)_{2n}}F_{r,s}^{(2n+r-s+2x,p)}(q^{-1}). \tag{2.13}$$

We shall refer to the expression in (2.13) as the ‘‘generalized’’ character formula, and we will compute the effective central charge associated with it in Sec. III. In the limiting case (i) (and setting $x=0$), (2.13) becomes the character formula for $\chi_{s,r}^{(p,p+1)}$, where $1\leqslant r\leqslant(p-2)$ and $1\leqslant s\leqslant(p-1)$. Similarly, the ‘‘generalized’’ character (2.13) yields characters for the $N=1$ supersymmetric model $SM(p,p+2)$ in the case (ii) (with $\rho_2=-q^{r-s+1/2}$), while case (iii) (for example with $\rho_1=-yq^{1/2}$ and $\rho_2=-y^{-1}q^{1/2}$ for $r=s=1$ in the Neveu–Schwarz sector) leads to characters of the $N=2$ model with central charge $c=3(1-2/p)$.[34] Repeating the Andrews–Bailey construction starting from (2.1) and taking $L=2l+r-s+2x+1$, another ‘‘generalized’’ character can be obtained. The latter becomes the character formula for $\chi_{s,r+2}^{(p,p+1)}$ in case (i), and gives more characters for the supersymmetric models in the cases of (ii) and (iii) (please see Ref. 34 for more details). Since this second ''generalized'' character leads to the same central charge as (2.13), it will not be considered further in this work.

III. EFFECTIVE CENTRAL CHARGE

In this section, we shall calculate the asymptotic behavior of (2.13) as $q \to 1^-$. This method of computing the effective central charge for CFT fermionic characters are by now standard.[39,40,9,43] Therefore we will be brief with the procedure, but detailing in places where our calculation differs from the norm. First we shall predict the asymptotic growth of the ''generalized'' character using a physical argument. Subsequently we will derive this asymptotic behavior directly from the character formula.

A. Asymptotic behavior of the ''generalized'' character

Characters in CFT admit an interpretation as the partition function of the model defined on a cylinder with conformal boundary conditions on its rims.[49] The modular invariance property of these character formulas give us precise information about their asymptotic behavior. The working assumption in this section will be that (2.13) also gives the cylindrical partition function for some quantum field theory with appropriate boundary conditions labeled a and b. Note that a and b depend on the values of r and s, as well as ρ_1 and ρ_2. Define the modular parameter

$$q = e^{2\pi i \tau}, \quad \tilde{q} = e^{-2\pi i/\tau},$$

with

$$\tau = \frac{iR}{2\pi L} \tag{3.1}$$

for a cylinder of length L and circumference R. If we take the (imaginary) time coordinate to be in the R direction and space in the L direction, the generalized character (2.13) can be written as

$$\chi_{s,r}^{(p)}(\rho_1,\rho_2;\tau) = \mathrm{Tr}_P e^{-R\mathcal{H}_{ab}(\rho_1,\rho_2|p)/L} = \mathrm{Tr}_P q^{\mathcal{H}_{ab}(\rho_1,\rho_2|p)}, \tag{3.2}$$

where $\mathcal{H}_{ab}$ is the (normalized) dimensionless Hamiltonian of the field theory with open boundary conditions a and b. The trace is taken over the sector of the Hilbert space with boundary condition P along the circumference of the cylinder. For the cases (1.1), $\mathcal{H}_{ab}$ becomes $L_0 - \Delta(s,r)$ where $\Delta(s,r)$ is the appropriate conformal dimension for each unitary model. If instead we take space to be compactified in the R direction and time to evolve in the L direction, then the partition function will be

$$\chi_{s,r}^{(p)}(\rho_1,\rho_2;\tau) = \langle a | e^{-L\mathcal{H}_P(\rho_1,\rho_2|p)/R} | b \rangle, \tag{3.3}$$

where $\mathcal{H}_P$ is the dimensionless Hamiltonian with closed boundary condition P. Here $\langle a|$ and $|b\rangle$ represent the boundary states at the ends of the cylinder. Note that extra prefactors (in powers of q) due to normalization have been dropped from the right-hand side of (3.3), as they are irrelevant in the following limit (where $q \to 1^{-1}$). In the limit $L \to \infty$, the inner product (3.3) is dominated by the ground state of $\mathcal{H}_P$ with energy E_0,

$$\lim_{L\to\infty} \chi_{s,r}^{(p)}(\rho_1,\rho_2;\tau) \sim g_a g_b \tilde{q}^{E_0/4\pi^2}, \tag{3.4}$$

where we denote the contributions from each boundary as g_a and g_b. (3.4) is our prediction of the asymptotic behavior of (2.13).

The fermionic form of the generalized character (2.13) is most suitable for taking the asymptotic limit $q \to 1^-$. The important thing to notice here is that for fixed p, E_0 depends only on the parameters ρ_1 and ρ_2, and is independent of r and s. Standard arguments[9] (related to the r and s independence of E_0) give us the freedom to remove the restriction $\vec{Q}_{r,s}$ and linear terms in the exponent of q from the fermionic sum in this limit. Thus to compute the asymptotic behavior of the generalized character, i.e., to obtain the leading exponent of $\tilde{q}$, we could just concentrate on the simplest case of the identity representation $\chi_{1,1}^{(p)}(\rho_1,\rho_2;\tau)$. To implement the special limits (1.1) in this case, let us parametrize ρ_1 and ρ_2 as

$$\rho_1 = -\frac{q^{1/2}}{A}, \quad \rho_2 = -\frac{q^{1/2}}{B}, \tag{3.5}$$

thus we have

$$\begin{aligned} &\text{(i)} \quad A=0, \quad B=0, \\ &\text{(ii)} \quad A=0, \quad B=1, \\ &\text{(iii)} \quad A=1, \quad B=1, \end{aligned} \tag{3.6a}$$

with $x=0$ and $a=1$ for all three cases. With our choice of parametrization, the limits (1.1) actually become (i) $\rho_1 \to -\infty$, $\rho_2 \to -\infty$ and (ii) $\rho_1 \to -\infty$, $\rho_2 =$ finite. However, we can still obtain the same conformal characters from (2.13). Here we specialized to the case of $y=1$ for the $N=2$ CFT. The limits (ii) and (iii) used here lead to the Neveu—Schwarz characters for the supersymmetric models. We will not consider the Ramond sector, although it can be treated by a straightforward generalization of the computation presented here. A convenient parametrization of the ground state energy E_0 is

$$E_0(A,B|p) = -\frac{\pi^2}{6}\tilde{c}(A,B|p). \tag{3.7}$$

From (3.4), we shall interpret $\tilde{c}$ as the ''generalized'' effective central charge, and expect that in the limits (3.6), it will take on the values of $1-6/p(p+1)$, $3/2-12/p(p+1)$, and $c=3(1-2/p)$, respectively.

B. Effective central charge

After all the simplifications mentioned above, the q-series we shall consider is

$$\begin{aligned} \tilde{\chi}_{1,1}^{(p)}(A,B;q) = \sum_{n=0}^{\infty} \sum_{m_1,\ldots,m_{p-3}=0}^{\infty} \left(-\frac{q^{1/2}}{A}\right)_n \\ \times \left(-\frac{q^{1/2}}{B}\right)_n (AB)^n \frac{q^{\vec{m}^T C_{p-3}\vec{m} - 2nm_1 + n^2}}{(q)_{2n}} \prod_{i=1}^{p-3} \begin{bmatrix} (I_{p-3}\vec{m} + n\vec{e}_1)_i \\ 2m_i \end{bmatrix}_q . \end{aligned} \tag{3.8}$$

If the coefficients in this series $\tilde{\chi}_{1,1}^{(p)} = \sum a_M q^M$ behave like $a_M \sim e^{2\pi\sqrt{M\tilde{c}/6}}$ for large M, then as $q \to 1^-$, $\tilde{\chi}_{1,1}^{(p)}$ diverges like $\tilde{q}^{-\tilde{c}/24}$. In other words one can obtain the ''generalized'' central charge $\tilde{c}$ from the asymptotic growth of the coefficient a_M. The latter is computed by applying the saddle point method to

$$a_{M-1} = \oint \frac{dq}{2\pi i} \tilde{\chi}_{1,1}^{(p)}(A,B;q) q^{-M} = \oint \frac{dq}{2\pi i} \sum_n \sum_{\vec{m}} f(n,\vec{m};q). \tag{3.9}$$

The saddle point occurs at the point where the derivatives of

$$\log f(n,\vec{m};q) \approx \int_0^n \log\left(1+\frac{q^k}{A}\right)dk + \int_0^n \log\left(1+\frac{q^k}{B}\right)dk + n\log(AB)$$
$$-\int_0^{2n}\log(1-q^k)\,dk + (n^2-2nm_1+\vec{m}^T C_{p-3}\vec{m}-M)\log q$$
$$+\sum_{i=1}^{p-3}\left(\int_0^{(I_{p-3}\vec{m}+n\vec{e}_1)_i} - \int_0^{(I_{p-3}\vec{m}+n\vec{e}_1-2\vec{m})_i} - \int_0^{2m_i}\right)\log(1-q^k)\,dk \tag{3.10}$$

with respect to n, $m_1,\ldots,m_{p-3}$ and q are all zero. In deriving the expression in (3.10), sums such as $\log\{(q)_n\}$ and $\log\{(-q^{1/2}/A)_n\}$ were approximated by integrals. There are several ways to make this approximation. Ultimately, the difference between the various approximation schemes is equivalent to a difference in the linear terms in the exponent of q, and do not influence the quadratic terms. Since the asymptotic growth is not expected to depend on the linear terms as explained above, we have the freedom to use the following two (different) approximations:

$$\log\{(q)_n\} \sim \int_0^n \log(1-q^k)\,dk, \tag{3.11a}$$

$$\log\left\{\left(-\frac{q^{1/2}}{A}\right)_n\right\} \sim \int_0^n \log\left(1+\frac{q^k}{A}\right)dk. \tag{3.11b}$$

This combination of approximations was chosen to simplify the algebra after differentiation.

Let us define

$$v_i = q^{-2m_i}, \quad w_i = q^{(I_{p-3}\vec{m}+n\vec{e}_1)_i}. \tag{3.12}$$

The differentiation with respect to m_i and n produced the following set of relations for their saddle point values $\overline{m_i}$ and $\overline{n}$:

$$(1-y_i)^2 = \prod_{j=1}^{p-3} y_j^{I_{ij}}, \tag{3.13a}$$

$$q^{2\overline{n}\delta_{1,i}}(1-x_i)^2 = \prod_{j=1}^{p-3} x_j^{I_{ij}}, \tag{3.13b}$$

$$(1-q^{2\overline{n}})^2 = (A+q^{\overline{n}})(B+q^{\overline{n}})q^{2\overline{n}}x_1, \tag{3.13c}$$

where

$$x_i = \frac{(1-\overline{w_i})\overline{v_i}}{1-\overline{v_i}\,\overline{w_i}}, \quad y_i = \frac{(1-\overline{w_i})}{1-\overline{v_i}\,\overline{w_i}}. \tag{3.14}$$

It is easy to show that in the special cases of (3.6), (3.13) reduces to a system of algebraic equations governed by the algebras A_{p-2}, A_{p-1}, and D_{p-1}, respectively. For these algebras, the corresponding systems of equations are solved in the literature, and are known to be related to the Thermodynamic Bethe Ansatz (TBA) approach (see, e.g., Refs. 50–54). Here we can easily write down the solution for y_i as

$$y_i = \frac{\sin^2 (1+i) \dfrac{\pi}{p}}{\sin^2 \dfrac{\pi}{p}}. \tag{3.15}$$

One can also show that

$$x_i = \frac{\sin^2 (p-1-i)\theta}{\sin^2 \theta} \tag{3.16}$$

satisfies (3.13) with the closure conditions

$$x_{p-2} = 1, \tag{3.17a}$$

$$x_0 = \frac{\sin^2 (p-1)\theta}{\sin^2 \theta} = q^{-2\bar{n}}, \tag{3.17b}$$

$$x_{-1} = \frac{\sin^2 p\theta}{\sin^2 \theta} = (1 + A q^{-\bar{n}})(1 + B q^{-\bar{n}}), \tag{3.17c}$$

(3.17d)

The parameter θ is related to A and B by the relation

$$(A+B)\sin\theta + AB \sin(p-1)\theta = \sin(p+1)\theta. \tag{3.18}$$

To compute $\log f(n,\vec{m};q)$ at the stationary point with respect to m_i and n, we first rewrite it using the relations

$$\int_0^{\bar{z}} \log(1-q^k)\,dk = \frac{1}{\log q}\left[L(1-q^{\bar{z}}) + \frac{1}{2}\log(1-q^{\bar{z}})\log q^{\bar{z}} \right], \tag{3.19a}$$

$$\int_0^{\bar{z}} \log\left(1+\frac{q^k}{A}\right) dk = \frac{1}{\log q}\left[L\left(\frac{q^{\bar{z}}}{q^{\bar{z}}+A}\right) - L\left(\frac{1}{1+A}\right) + \frac{1}{2}\log A \log\left(\frac{1+A}{q^{\bar{z}}+A}\right)\right] + \frac{\bar{z}}{2}\log\left(1+\frac{q^{\bar{z}}}{A}\right). \tag{3.19b}$$

The Rogers dilogarithm in (3.19) is defined by[55]

$$L(z) = Li_2(z) + \frac{1}{2}\log z \log(1-z), \quad Li_2(z) = -\int_0^z \frac{\log(1-w)}{w}\,dw \tag{3.20}$$

and $L(1) = \pi^2/6$. The five terms relation for the dilogarithm in our case can be written as

$$L(1-w_i) - L(1-v_i w_i) - L(1-v_i^{-1}) = L(1-y_i^{-1}) - L(1-x_i^{-1}). \tag{3.21}$$

Hence we have

$$\log f(n,\vec{m};q)\Big|_{\substack{\vec{m}=\bar{\vec{m}} \\ n=\bar{n}}} \approx -M \log q - \frac{\pi^2 \tilde{c}(A,B|p)}{6 \log q}, \tag{3.22}$$

where

$$\tilde{c}(A,B|p)=\frac{1}{L(1)}\left(L\left(\frac{1}{1+A}\right)+L\left(\frac{1}{1+B}\right)+L\left(1-\frac{1}{x_0}\right)-L\left(\frac{1}{1+\sqrt{x_0}A}\right)-L\left(\frac{1}{1+\sqrt{x_0}B}\right)\right.$$
$$\left.+\sum_{i=1}^{p-3}\left[L\left(1-\frac{1}{x_i}\right)-L\left(1-\frac{1}{y_i}\right)\right]+\frac{1}{2}\log A\log\left(\frac{1+\sqrt{x_0}A}{1+A}\right)+\frac{1}{2}\log B\log\left(\frac{1+\sqrt{x_0}B}{1+B}\right)\right). \tag{3.23}$$

By differentiating (3.22) with respect to q, we found the saddle point value of q to be

$$\overline{q}=e^{-\sqrt{\pi^2\tilde{c}/6M}}. \tag{3.24}$$

This leads to the expected asymptotic behavior of a_M for large M, and hence we can interpret $\tilde{c}(A,B|p)$ as a ''generalized'' effective central charge for (2.13). The sums in (3.23) can be further simplified using dilogarithm sum rules[55,56] to yield

$$\sum_{i=1}^{p-3}L\left(1-\frac{1}{y_i}\right)=\left(p-5+\frac{6}{p}\right)L(1), \tag{3.25}$$

$$L\left(1-\frac{1}{x_0}\right)+\sum_{i=1}^{p-3}\left[L\left(1-\frac{1}{x_i}\right)\right]=(p-1)L(1)-p(p-1)\theta^2+2Li_2\left(-\frac{\sin(p-1)\theta}{\sin\theta},p\theta\right)$$
$$+\log\left(\frac{\sin(p-1)\theta}{\sin\theta}\right)\log\left(\frac{\sin p\theta}{\sin\theta}\right), \tag{3.26}$$

where

$$Li_2(r,\theta)=\mathrm{Re}\{Li_2(re^{i\theta})\}=-\frac{1}{2}\int_0^r\frac{\log(1-2x\cos\theta+x^2)}{x}\,dx. \tag{3.27}$$

The resultant expression for the ''generalized'' central charge is

$$\tilde{c}(A,B|p)=\frac{1}{L(1)}\left[Li_2(-A)+Li_2(-B)-Li_2\left(-A\frac{\sin(p-1)\theta}{\sin\theta}\right)-Li_2\left(-B\frac{\sin(p-1)\theta}{\sin\theta}\right)\right.$$
$$\left.+\left(4-\frac{6}{p}\right)L(1)-p(p-1)\theta^2+2Li_2\left(-\frac{\sin(p-1)\theta}{\sin\theta},p\theta\right)\right]. \tag{3.28}$$

The simple expression in (3.28) is the main result of this letter. It gives the effective central charge associated with the ''generalized'' character formula (2.13) in terms of dilogarithm functions. The expressions in (3.23) and (3.28) are valid for $A\geqslant 0$ and $B\geqslant 0$.

C. Special cases

Consider the domain $A=0$, and $B=\sin(p+1)\theta/\sin\theta$ follows from (3.18). To implement the special case (i), we take the limit $B\to 0$, thus yielding $\theta=\pi/(p+1)$. Consequently by using the identity[55]

$$Li_2(2\cos\theta,\theta)=\left(\frac{\pi}{2}-\theta\right)^2,$$

we obtained $\tilde{c}(0,0|p)=1-6/p(p+1)$, which is the central charge of the unitary model $M(p,p+1)$. In the limit (ii), taking $B=1$ we found $\theta=\pi/(p+2)$. Using the limit

$$Li_2\left(-\frac{\sin(p-1)\theta}{\sin\theta}\right)+2Li_2\left(-\frac{\sin(p-1)\theta}{\sin\theta},p\theta\right)\bigg|_{\theta=\pi/(p+2)}=\frac{2}{3}\pi^2-2\frac{(2p+1)}{(p+2)^2}\pi^2,$$

we recover the central charge of the $N=1$ unitary model $\tilde{c}(0,1|p)=\frac{3}{2}-12/p(p+2)$.

It is interesting that $\tilde{c}(0,B|p)$ is a smooth monotonic function of B between the above two limits. In particular for the case of $p=3$, we have a function which connects the central charges of the Ising and tricritical Ising model, while the ''generalized'' character (2.13) takes us from the tricritical Ising character $\chi_{1,1}^{(4,5)}+\chi_{1,4}^{(4,5)}$ to the Ising character $\chi_{1,1}^{(3,4)}$. Hence it is desirable to compare $\tilde{c}(0,B|3)$ with the known ground state scaling function $\mathcal{C}(r)$ obtained from TBA.[13] Recall that the latter is a function of a scaling parameter r, with UV limit $(r\rightarrow 0)\frac{7}{10}$ and IR limit $(r\rightarrow\infty)\frac{1}{2}$, respectively. Therefore to compare the two expressions, we need to find a parametrization of the variable B in terms of r. This can always be done since one can in principle invert the function $\tilde{c}(0,B|3)$ to obtain the parametrization $B(r)=\tilde{c}^{-1}(\mathcal{C}(r))$. However we were unable to express $B(r)$ in a simple and closed form. This is perhaps not surprising since $\mathcal{C}(r)$ is written as an integral involving two pseudoenergies ϵ_1 and ϵ_2, which in turn are given by two coupled integral equations involving r. Only in the UV or IR limits do we get a simplification of the integral equations, which then allow us to write $\mathcal{C}$ in terms of dilogarithms.[13] Hence the parametrization $B(r)$, which yields an expression for $\mathcal{C}(r)$ in terms of dilogarithms for general r, is likely to be complicated. It is also unclear at this stage whether this parametrization admits any physical interpretations.

Now let us focus on the other domain $A=B$. The relation (3.18) tells us $A=[\cos(p+1)\theta/2]/[\cos(p-1)\theta/2]$. Of course in the limiting case (i), $A\rightarrow 0$, we found $\theta=\pi/(p+1)$ as before. Once again $\tilde{c}(A,A|p)$ is a smooth monotonic function of A. For the $N=2$ supersymmetric limit (iii), taking $A\rightarrow 1$, we get $\theta=0$ and $\tilde{c}(1,1|p)=3(1-2/p)$ as expected. Hence $\tilde{c}(A,B|p)$ indeed give us a function which interpolates between the central charges of an unitary model and its supersymmetric counterparts.

IV. DISCUSSION

In this work, we have studied the asymptotic behavior of the ''generalized'' character formula $\chi_{s,r}^{(p)}(\rho_1,\rho_2;q)$ (2.13) in the limit $q\rightarrow 1^-$. In this limit, we show that the q-series diverges like $\tilde{q}^{-\tilde{c}/24}$ and we found a simple expression (3.28) for the ''generalized'' effective central charge $\tilde{c}$ in terms of dilogarithms. In the limiting cases (i), (ii), and (iii), $\tilde{c}$ yields the central charges of the unitary models and their supersymmetric counterparts.

Having stated our conclusion, we shall take the liberty to indulge in some (pure) speculations. Of course it is not surprising that we can find a function which reproduces the correct central charges in the various limits. Indeed $\chi_{s,r}^{(p)}(\rho_1,\rho_2;q)$ also becomes the corresponding CFT characters in these limits. But what is *a priori* not expected from the Andrews–Bailey construction is that the ''generalized'' character (2.13) would exhibit the asymptotic behavior found in Sec. III. The prediction for this behavior was based on the assumption that (2.13) gives the partition function for some quantum field theory. This field theory must be invariant under interchanging roles of space and time. This suggests that $\chi_{s,r}^{(p)}(\rho_1,\rho_2;q)$, when multiplied by a suitable factor $q^{\mathcal{D}_{s,r}(\rho_1,\rho_2|p)}$, may be modular covariant. It would be very interesting to show directly from (2.13) that

$$q^{\mathcal{D}_{s,r}(\rho_1,\rho_2|p)}\chi_{s,r}^{(p)}(\rho_1,\rho_2;q)=\sum_{s',r'}S_{s,r}^{s',r'}(\rho_1,\rho_2|p)\tilde{q}^{\mathcal{D}_{s',r'}(\rho_1,\rho_2|p)}\chi_{s',r'}^{(p)}(\rho_1,\rho_2;\tilde{q})$$

for some ''generalized'' S-matrix. Presumably the elements of this S-matrix (if it exits) can be calculated from the nonperturbative corrections to the saddle point.[57,58] This computation would be much more involved than that in Sec. III since the elements of S depend on r and s

Another interesting puzzle is the nature of the quantum field theory with the Hamiltonian $\mathcal{H}_P$ discussed in Sec. III. From (3.7), the ground state energy of $\mathcal{H}_P(\rho_1,\rho_2|p)$ is proportional to

$\tilde{c}(A,B|p)$ which is written in terms of dilogarithms. This seems to indicate that $\mathcal{H}_P(\rho_1,\rho_2|p)$ is the Hamiltonian for a (maybe irrational) CFT which interpolates between the $N=0$, $N=1$ and $N=2$ unitary models. Last, it is worth investigating whether the approach taken here can be apply to the trinomial analog of Bailey's lemma.[37,12]

(Received 23 September 1998; accepted for publication 16 April 1999)

The implementation of modular invariance on the torus as a phase space at the quantum level is discussed in a group-theoretical framework. Unlike the classical case, at the quantum level some restrictions on the parameters of the theory should be imposed to ensure modular invariance. Two cases must be considered, depending on the cohomology class of the symplectic form on the torus. If it is of integer cohomology class n, then full modular invariance is achieved at the quantum level only for those wave functions on the torus which are periodic if n is even, or antiperiodic if n is odd. If the symplectic form is of rational cohomology class n/r, a similar result holds—the wave functions must be either periodic or antiperiodic on a torus r times larger in both directions, depending on the parity of nr. Application of these results to the Abelian Chern–Simons theory is discussed. [S0022-2488(99)04007-4]

I. INTRODUCTION

Since the pioneer work by Dirac[1] on the quantization of constrained systems, much work has been done on this subject, and plenty of methods have been developed to face this interesting and, many times, difficult problem. Roughly speaking, the different methods can be classified into two types, depending on whether the quantization of the corresponding unconstrained system is first performed and then the constraints imposed at the quantum level (the ''quantize-first'' method) or the constraints are first imposed and then the quantization of the resulting ''reduced'' system is performed (the ''constrain-first'' method). An example of the former is given by the above-mentioned paper by Dirac,[1] while the latter was originated by the work of Faddeev.[2] Many other procedures derive from these two, adapted to the properties of the particular system under consideration. Thus, for instance, the Becchi–Rouet–Stora–Tyutin (BRST) quantization is a ''quantize-first'' technique adapted to the covariant quantization of gauge invariant systems.[3] Also, the method proposed by Ashtekar[4] was designed to simplify the form of the quantum constraints in quantizing gravity. Alternatively, symplectic or Marsden–Weinstein reduction[5] is a specific technique developed to obtain a reduced classical phase space, which is the starting point for (some sort of) geometric quantization.[6]

The main drawback of the ''constrain-first'' method lies in the fact that the classical phase space could not be properly defined as a differential manifold or, even more, the classical equation of motion might have no general solution. In addition, all the problems that geometric quantization encounters in dealing with nontrivial phase spaces must be considered (anomalies, i.e., the lack of invariant polarizations, the search for operators compatible with the polarization, etc.).

The troubles with the ''quantize-first'' methods appear in the implementation of the quantum constraints; only quadratic constraints can be directly imposed due to normal-order ambiguities. Besides, finding the operators that preserve the quantum constraints is a nontrivial problem.

In Ref. 7 a method for studying quantum systems with constraints on a group-theoretical framework, Algebraic Quantization on a Group (AQG), was introduced. AQG is a ''quantize-first'' method in which both the unconstrained systems and the constraints are supposed to be dealt with in a group setting. This could seem, at first instance, a severe restriction but, in practice, most of the interesting cases can be treated with this formalism, and the advantages it provides are numerous. In particular, there are no ambiguities in the imposition of quantum constraints (even for nonpolynomical ones), and there is an operative characterization for the operators that preserves the quantum constraints.

Another advantage of AQG is the possibility of implementing the nontrivial topology of a phase space as a ''contraint subgroup'' that contains the first homotopy group of the phase space, made of discrete transformations, which can be easily addressed in this formalism.

In Ref. 8 the quantization of the Heisenberg–Weyl (HW) group with constraints was considered and the particular case of the HW group on the torus was studied. Now, we wish to implement modular invariance on the torus at the quantum level. In general, the modular invariance of a conformal theory formulated on a Riemannian surface of genus g,Σ_g, refers to the quotient group $\mathrm{Diff}(\Sigma_g)/\mathrm{Diff}_0(\Sigma_g)$, where $\mathrm{Diff}(\Sigma_g)$ is the group of diffeomorphisms of Σ_g and the subscript 0 designates the normal subgroup of diffeomorphisms connected to the identity (see, e.g., Refs. 9 and 10).

Clearly, modular transformations on the torus are the $SL(2,Z)$ subgroup of the group $SL(2,R)\approx Sp(2,R)$ of linear symplectic transformations of the plane that preserves the torus. Therefore we can implement them in the formalism of Algebraic Quantization on a Group by considering the Schrödinger group (or Weyl-Symplectic group, see Ref. 11) $WSp(2,R)$ as the symmetry group of the unconstrained system and imposing the appropriate constraints to obtain a torus as the (reduced) symplectic manifold, pretty much in the same manner as in Ref. 8. Then we expect to obtain modular transformations as good operators, i.e., those preserving the Hilbert space of wave functions satisfying the constraints. However, to obtain full modular invariance, we must impose some restrictions on the parameters of the theory. As in Ref. 8, three different cases should be considered, depending on the cohomology class of the symplectic form on the torus, which can be integer, fractional, or irrational. Only the integer and fractional cases will be considered here, since the irrational one requires techniques from noncommutative geometry[12] and lies beyond the scope of this paper.

These results are applied to $2+1$D Abelian Chern–Simons theory and compared with the ones obtained in the literature.

The present paper is organized as follows: In Sec. III we study the Schrödinger group without constraints and compute the metaplectic (or spinor) representation with the help of a higher-order polarization. Section IV is devoted to the determination of the constrained Hilbert space and good operators when the phase-space is constrained to be a torus. Two cases are considered, the one for which the symplectic form on the torus is of integer cohomology class n (Sec. IV A), where full modular invariance is obtained only when the wave functions are periodic for n even or antiperiodic for n odd, and the case of symplectic form of rational cohomology class n/r (Sec. IV B), where full modular invariance is obtained only when the wave functions are periodic for nr even or antiperiodic for nr odd. Here periodicity and antiperiodicity are understood in a torus which is r times larger in both directions. Finally, Sec. V is devoted to the application of our study to $2+1$D Abelian Chern–Simons theory.

In the Appendix, we study the representations of the subgroup T of constraints both for the integral and fractional case.

II. ALGEBRAIC QUANTIZATION ON A GROUP

Algebraic Quantization on a Group (AQG) (see Refs. 7 and 8) is a group-theoretical procedure developed for quantizing systems with constraints (both first and second class) in a first-quantize-then-constrain basis. The starting point is the group $\tilde{G}$ of quantum symmetries of the unconstrained system, which is a central extension by U(1) of the group G of classical symmetries of the unconstrained system. From $\tilde{G}$, a subgroup T, called the structure group, is selected for defining the constraints. For convenience, T is chosen to include the U(1) subgroup of the central extension, which accounts for the phase invariance of quantum mechanics [U(1) equivariance], in such a way that $\tilde{G}/T$ is the classical reduced phase space of the constrained system. (To be precise, $\tilde{G}$ contains in general symmetries without symplectic content, like time translations or rotations, so that $\tilde{G}/T$ is the reduced presymplectic manifold of the constrained system.)

The quantum Hilbert space $\mathcal{H}_T$ for the constrained system is defined by selecting, from the Hilbert space $\mathcal{H}$ associated with a unitary irreducible representation $U(\tilde{G})$ of $\tilde{G}$, those wave functions that transform irreducibly under a given unitary irreducible representation $D(T)$ of T. We shall say that these wave functions satisfy the T-function condition (or T-equivariance condition), which has the general form:

$$\Psi^{\alpha}(g_T * g) = D^{\alpha}(g_T)\Psi^{\alpha}(g), \quad \forall g_T \in T, \tag{1}$$

where the index α in D ranges over the set $\hat{T}$, the Pontryagin dual of T—that is, the set of all unitary irreducible representations of T. Precisely stated, α will be allowed to vary along the subset $\hat{T}_U \subset \hat{T}$ of those representations which are contained in the restriction of $U(\tilde{G})$ to T; otherwise the constraints would be inconsistent and the constrained Hilbert space $\mathcal{H}_T$ would be trivial. In particular, the representation D^{α}, when restricted to the subgroup $U(1) \subset T$, should be the natural (faithful) representation of U(1), $D^{\alpha}(\zeta) = \zeta, \ \forall \zeta \in U(1)$. That is, the T-equivariance condition must contain the U(1)-equivariance condition. Complex functions on the group satisfying the T-equivariance condition can be identified with sections of the vector bundle associated with the principal bundle $T \to \tilde{G} \to \tilde{G}/T$ through the representation D^{α} of T.[13]

Both the unitary irreducible representations $U(\tilde{G})$ and $D(T)$ can be obtained, for instance, by using the Group Approach to Quantization (GAQ) technique (see Ref. 7 and references therein), which uses the method of polarizations (see below) to reduce the left-regular representation of the group acting on U(1)-equivariant complex functions on the group $\tilde{G}$.

An important concept that we are forced to introduce is the notion of *good operators*, defined as those preserving the constrained Hilbert space $\mathcal{H}_T$. It is clear that, since $\mathcal{H}_T$ is in general smaller than $\mathcal{H}$, not all operators in $\tilde{G}$ will preserve it; otherwise the representation $U(\tilde{G})$ would be reducible. It is difficult to give a general characterization of these operators (for instance, there can be operators preserving $\mathcal{H}_T$ which belong neither to $\tilde{G}$ nor to its enveloping algebra, escaping to any algebraic or differential characterization), but we can find all good operators in $\tilde{G}$ simply by considering the *little group* of the representation $D^{\alpha}(T)$ of T—that is, the subgroup G_{good} of elements g_g that send the representation $D^{\alpha}(T)$ to an equivalent one under the adjoint action:

$$D^{\alpha}_{g_g}(g_T) \equiv D^{\alpha}(g_g * g_T * g_g^{-1}) \approx D^{\alpha}(g_T), \quad \forall g_T \in T, \quad \forall g_g \in G_{\text{good}}. \tag{2}$$

Note that this definition generalizes the (sufficient) ones given in Refs. 7 and 8. For instance, in the case in which the representation $D^{\alpha}(T)$ is one dimensional (in particular, if T is Abelian), the definition above gives $D^{\alpha}_{g_g}(T) = D^{\alpha}(T)$, and the sufficient condition given in Ref. 8,

$$[G_{\text{good}}, T] \subset \ker D^{\alpha}(T), \tag{3}$$

also proves to be necessary. This characterization reproduces the standard one for the case of first-class constraints, for which $T=C\times U(1)$, where C is the subgroup of constraints [U(1) only accounts for the phase-invariance of quantum mechanics]. If we choose for C the trivial representation [for U(1) the natural representation must always be chosen], then

$$[G_{\rm good},C]\subset C. \tag{4}$$

This condition gives $G_{\rm good}$ as the normalizer of the constraints, as is usually the case (see, e.g., Ref. 4). However, if a nontrivial representation of C is chosen, the subgroup of good operators can be smaller that the normalizer of the constraints, revealing a strong dependence of $G_{\rm good}$ on the representation $D^{\alpha}(T)$ of T and, therefore, we should use the more precise notation $G^{\alpha}_{\rm good}$ for the subgroup of operators preserving the reduced Hilbert space $\mathcal{H}^{\alpha}_{T}$. Note that, from the very definition of little group, $G^{\alpha}_{\rm good}\subset N_T$, $\forall\alpha\in\hat{T}_U$, where N_T is the normalizer of T in $\tilde{G}$, so that the appropriate place to look for good operators will be in N_T.

It is useful to examine the case in which C is an invariant subgroup of $\tilde{G}$ and we choose $D(T)$ to be the restriction of $U(\tilde{G})$ to T [or $U(\tilde{G})$ to be the induced representation by $D(T)$]. Then the constraints are trivial, i.e., they do not imply additional restrictions on the wave functions, and the constrained and unconstrained Hilbert spaces coincide. Moreover, the subgroup of good operators turns out to be the whole $\tilde{G}$. In this case, C is called a gauge group (see Ref. 14).

A separate study is warranted by the case when T cannot be written as $C\times U(1)$, for instance when T is a nontrivial central extension of C by U(1). In this case, C contains canonically conjugated variables, and the constraints are of *second class*. This case, also contemplated in Refs. 7 and 8, will be studied in Sec. IV B.

It should be noted that the same program can be carried out considering the Lie algebras $\tilde{\mathcal{G}}$ of $\tilde{G}$ and $\mathcal{T}$ of T, when these are simply connected groups. In this case, the treatment becomes simpler, since the representations $dU(\tilde{\mathcal{G}})$ and $dD(\mathcal{T})$ are easier to obtain. In general, however, the treatment is more involved, not only because the good operators can lie in the enveloping algebra, but also because the constraints themselves can be defined through higher-order differential equations.[15] But all these cases can be handled with a direct generalization of AQG.

Thus, AQG can be applied to constrained systems, irrespective of the type (first or second class) of constraints. Some examples of application of AQG can be found in Ref. 7, where parity in a two-particle system was introduced to obtain both bosonic and fermionic quantizations, and diffeomorphism constraints to obtain the bosonic string.

Other interesting examples for applying AQG are those systems in which the configuration or phase spaces are multiply connected and the group $\tilde{G}$ of quantum symmetries of the simply connected counterpart (universal covering) is known. If P is a multiply connected phase space which is homogeneous under a group G of symmetries, then P is locally diffeomorphic to a coadjoint orbit of G, or to a coadjoint orbit of a central extension of G by U(1) or R, $\tilde{G}$.[16] For the first case, if H is the isotropy group of P, G/H is locally diffeomorphic to P. If we choose G appropriately (taking coverings, if necessary) in such a way that G/H is simply connected, then P is the quotient of G/H by $\pi_1(P)$, the first homotopy group of P. For the cases in which P is locally diffeomorphic to a coadjoint orbit of a central extension $\tilde{G}$ of G, and if $\tilde{G}$ is chosen (taking coverings) in such a way that this orbit is simply connected, then P is the quotient of $\tilde{G}/H$ by $\pi_1(P)\times U(1)$ (or R). Then $C=\pi_1(P)$ and $T=C\times U(1)$.

However, if P is not the cotangent bundle of any configuration space (as, for instance, the sphere or the torus as symplectic manifolds), then it could well happen that $\pi_1(P)$, as a subset of $\tilde{G}$ (we should not forget that all operations of taking quotients are done in $\tilde{G}$, and therefore we must consider the embeding of $\pi_1(P)$ in $\tilde{G}$, and this could not be a group), contains canonically conjugated pairs. In this case, T is a central extension of C by U(1) and the constraints are of second class. However, if the representation D of T is finite dimensional (see the Appendix), even though T defines second-class constraints, the treatment follows as though they were first-class, yet non-Abelian.

III. THE SCHRÖDINGER GROUP

As mentioned in Sec. I, we shall replace the HW group used in Ref. 8 with the Schrödinger group, which coincides with the Weyl-Symplectic group W $Sp(2,R)$ in one dimension. It was first studied by Niederer[17] as the maximal kinematical invariance group of the Schrödinger equation with general quadratic potential. The complete classification of its unitary irreducible representations was given in Ref. 18. Mathematically it can be obtained from the Galilei (or from the Newton) group by replacing the time parameter with the three-parameter group $SL(2,R)$. The interest of the $SL(2,R)$ group in the present work lies in the fact that it constitutes the maximal finite subgroup of the diffeomorphisms (in fact symplectomorphisms) group of the phase space R^2 (see Ref. 19, where some physical meaning is given to the representations considered "unphysical" in Ref. 18).

To perform a global-coordinate treatment of the problem, we shall start by considering matrices $S \in GL(2,R)$ instead of $SL(2,R)$, and the condition for these matrices to belong to $SL(2,R)$ will appear naturally. A group law for the Schrödinger group can be written as:

$$
\begin{aligned}
\vec{x}'' &= \vec{x}' + \frac{S'}{|S'|^{1/2}}\vec{x}, \\
S'' &= S'S, \\
\zeta'' &= \zeta'\zeta \exp\frac{im\omega}{2\hbar}\left[\frac{-A'x_2'x_1 - B'x_2'x_2 + C'x_1'x_1 + D'x_1'x_2}{|S'|^{1/2}}\right],
\end{aligned} \tag{5}
$$

where

$$
\vec{x} = (x_1, x_2) \in R^2, \quad S = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in GL(2,R), \quad |S| \equiv AD - BC
$$

and $m\omega/\hbar$. is an adimensional constant parametrizing the central extensions of the HW group (we write it in this form for later convenience). The factor $|S'|^{-1/2}$ in the semidirect action of $GL(2,R)$ is needed in order to have a proper central extension.

Let us quantize this system using GAQ, whose principal ingredients will be introduced as needed (see Ref. 7 for details). From the group law, the left-invariant vector fields associated with the coordinates $x_1, x_2, A, B, C, D, \zeta$,

$$
\begin{aligned}
\tilde{X}^L_{x_1} &= |S|^{-1/2}\left[A\frac{\partial}{\partial x_1} + C\frac{\partial}{\partial x_2} + \frac{m\omega}{2\hbar}(-Ax_2 + Cx_1)\Xi\right], \\
\tilde{X}^L_{x_2} &= |S|^{-1/2}\left[D\frac{\partial}{\partial x_2} + B\frac{\partial}{\partial x_1} + \frac{m\omega}{2\hbar}(-Bx_2 + Dx_1)\Xi\right], \\
\tilde{X}^L_A &= A\frac{\partial}{\partial A} + C\frac{\partial}{\partial C}, \quad \tilde{X}^L_B = A\frac{\partial}{\partial B} + C\frac{\partial}{\partial D}, \quad \tilde{X}^L_C = B\frac{\partial}{\partial A} + D\frac{\partial}{\partial C}, \\
\tilde{X}^L_D &= B\frac{\partial}{\partial B} + D\frac{\partial}{\partial D}, \quad \tilde{X}^L_\zeta = i\zeta\frac{\partial}{\partial \zeta} \equiv \Xi,
\end{aligned} \tag{6}
$$

as well as the right-invariants ones,

$$
\begin{aligned}
&\tilde{X}^R_{x_1}=\frac{\partial}{\partial x_1}+\frac{m\omega}{2\hbar}x_2\Xi, \quad \tilde{X}^R_{x_2}=\frac{\partial}{\partial x_2}-\frac{m\omega}{2\hbar}x_1\Xi,\\
&\tilde{X}^R_A=A\frac{\partial}{\partial A}+B\frac{\partial}{\partial B}+\frac{1}{2}x_1\frac{\partial}{\partial x_1}-\frac{1}{2}x_2\frac{\partial}{\partial x_2},\\
&\tilde{X}^R_B=C\frac{\partial}{\partial A}+D\frac{\partial}{\partial B}+x_2\frac{\partial}{\partial x_1},\\
&\tilde{X}^R_C=A\frac{\partial}{\partial C}+B\frac{\partial}{\partial D}+x_1\frac{\partial}{\partial x_2},\\
&\tilde{X}^R_D=C\frac{\partial}{\partial C}+D\frac{\partial}{\partial D}-\frac{1}{2}x_1\frac{\partial}{\partial x_1}+\frac{1}{2}x_2\frac{\partial}{\partial x_2},\\
&\tilde{X}^R_\zeta=\Xi,
\end{aligned}
\tag{7}
$$

can be obtained. The commutation relations for the (left) Lie algebra are:

$$
\begin{aligned}
&[\tilde{X}^L_A,\tilde{X}^L_B]=\tilde{X}^L_B, && [\tilde{X}^L_A,\tilde{X}^L_{x_2}]=-\tfrac{1}{2}\tilde{X}^L_{x_2},\\
&[\tilde{X}^L_A,\tilde{X}^L_C]=-\tilde{X}^L_C, && [\tilde{X}^L_B,\tilde{X}^L_{x_1}]=0,\\
&[\tilde{X}^L_A,\tilde{X}^L_D]=0, && [\tilde{X}^L_B,\tilde{X}^L_{x_2}]=\tilde{X}^L_{x_1},\\
&[\tilde{X}^L_B,\tilde{X}^L_C]=\tilde{X}^L_A-\tilde{X}^L_D, && [\tilde{X}^L_C,\tilde{X}^L_{x_1}]=\tilde{X}^L_{x_1},\\
&[\tilde{X}^L_B,\tilde{X}^L_D]=\tilde{X}^L_B, && [\tilde{X}^L_C,\tilde{X}^L_{x_2}]=0,\\
&[\tilde{X}^L_C,\tilde{X}^L_D]=-\tilde{X}^L_C, && [\tilde{X}^L_D,\tilde{X}^L_{x_1}]=-\frac{1}{2}\tilde{X}^L_{x_1},\\
&[\tilde{X}^L_{x_1},\tilde{X}^L_{x_2}]=\frac{m\omega}{\hbar}\Xi, && [\tilde{X}^L_D,\tilde{X}^L_{x_2}]=\tfrac{1}{2}\tilde{X}^L_{x_2}.\\
&[\tilde{X}^L_A,\tilde{X}^L_{x_1}]=\tfrac{1}{2}\tilde{X}^L_{x_1}, &&
\end{aligned}
\tag{8}
$$

From these commutation relations we see that two linear combinations of vector fields can be introduced, $\tilde{X}^L_A-\tilde{X}^L_D$ and $\tilde{X}^L_A+\tilde{X}^L_D$ (the same for the right-invariant vector fields), in such a way that $\tilde{X}^L_A+\tilde{X}^L_D$ is a central generator, which is also horizontal (see below), and therefore is a gauge generator (see Ref. 14). In fact, it coincides with its right version, as is always the case for a central generator.

We define the Quantization 1-form Θ as the vertical component (dual to the vertical generator, Ξ, in this basis) of the canonical 1-form of the Lie algebra:

$$
\Theta=\frac{m\omega}{2\hbar}(x_2dx_1-x_1dx_2)+\frac{d\zeta}{i\zeta}. \tag{9}
$$

The 2-form $d\Theta$ defines a presymplectic form on $\tilde{G}$, and its value at the identity, $\Sigma = d\Theta|_e$, is a 2-co-cycle of the Lie-algebra, and it can be used to characterize the central extension (when the group $\tilde{G}$ is simply connected). A subalgebra is said to be *horizontal* if it lies in the kernel of Θ. The *characteristic subalgebra* is defined as $\mathcal{G}_\Theta = \mathrm{Ker}\,\Theta \cap \mathrm{Ker}\,d\Theta$, and in this case it has the form:

$$\mathcal{G}_\Theta = \langle \tilde{X}_A^L + \tilde{X}_D^L, \tilde{X}_A^L - \tilde{X}_D^L, \tilde{X}_B^L, \tilde{X}_C^L \rangle. \tag{10}$$

Note that $d\Theta/(\mathrm{Ker}\,d\Theta)$ defines a true symplectic form in R^2.

We define the representation $\mathrm{U}(\tilde{G})$ of $\tilde{G}$ to be given by the left regular representation on complex wave functions over $\tilde{G}$, satisfying the U(1)-function condition $\Xi\Psi = i\Psi$ (phase invariance of quantum mechanics). This representation is obviously reducible, and additional restrictions should be imposed on the wave functions in order to obtain an irreducible representation. These are accomplished by the polarization $\mathcal{P}$, defined as a maximal horizontal left subalgebra of $\tilde{\mathcal{G}}$. The condition $X^L\Psi = 0, \forall X^L \in \mathcal{P}$ leads, in most of the cases, to an irreducible representation $\mathrm{U}(\tilde{G})$ acting on the Hilbert space $\mathcal{H}$ of complex polarized functions on the group satisfying the U(1)-function condition.

However, there are groups, called anomalous (Ref. 11), for which this representation $\mathrm{U}(\tilde{G})$ so obtained is not irreducible, and a generalization of the concept of polarization is required for them. This task is acomplished by means of higher-order polarizations (see Refs. 11, 20, and 21), which admit elements of the left enveloping algebra to enter into them.

The system we are studying is an example of an anomalous system (see Refs. 11 and 21), and a higher-order polarization is required to obtain an irreducible representation. There are essentially two of them,[2] given by

$$\mathcal{P}^{\mathrm{HO}} = \Big\langle \tilde{X}_A^L + \tilde{X}_D^L, \tilde{X}_A^L - \tilde{X}_D^L - \frac{i\hbar}{2m\omega}(\tilde{X}_{x_1}^L \tilde{X}_{x_2}^L + \tilde{X}_{x_2}^L \tilde{X}_{x_1}^L), \tilde{X}_B^L + \frac{i\hbar}{2m\omega}(\tilde{X}_{x_1}^L)^2,$$
$$\tilde{X}_C^L - \frac{i\hbar}{2m\omega}(\tilde{X}_{x_2}^L)^2, \tilde{X}_{x_1}^L \quad \text{or} \quad \tilde{X}_{x_2}^L \Big\rangle. \tag{11}$$

(There are another two, if we allow for complex coordinates, but all of them lead to equivalent representations.) If we choose, for instance, $\tilde{X}_{x_1}^L$ to be in the polarization, the polarization equations are

$$(\tilde{X}_A^L + \tilde{X}_D^L)\Psi = 0, \quad \tilde{X}_B^L\Psi = 0,$$
$$(\tilde{X}_A^L - \tilde{X}_D^L)\Psi = -\tfrac{1}{2}\Psi, \tag{12}$$
$$\tilde{X}_{x_1}^L\Psi = 0, \quad \tilde{X}_C^L\Psi = \frac{i\hbar}{2m\omega}(\tilde{X}_{x_2}^L)^2\Psi.$$

The first of these equations has as solutions those complex wave functions on the group $\mathrm{GL}(2,R)$ which are defined on $\mathrm{SL}(2,R)$, as expected. Therefore, the solutions of this equation have the form:

$$\Psi = \Psi(a,b,c,d,x_1,x_2), \tag{13}$$

where

$$a \equiv \frac{A}{\sqrt{AD-BC}}, \quad b \equiv \frac{B}{\sqrt{AD-BC}}, \quad c \equiv \frac{C}{\sqrt{AD-BC}}, \quad \text{and } d \equiv \frac{D}{\sqrt{AD-BC}}, \text{ with } ad-bc=1.$$

To proceed further in solving the polarization equations, it is convenient to introduce local charts on SL(2,R). We choose them to be the ones defined by $a\neq 0$ and $c\neq 0$, respectively. (Certainly they really correspond to four contractible charts: $a>0$, $a<0$ and $c<0$, $c>0$, but the transition functions between each pair of these charts are trivial, so we shall consider them as only one chart.) The first chart contains the identity element I_2 of SL(2,R), and the second contains

$$J\equiv\begin{pmatrix} \mathbf{0} & 1 \\ -1 & 0 \end{pmatrix}.$$

The solutions to the polarization equations are given by:
For $a\neq 0$:

$$\Psi=\zeta a^{-1/2}\exp\left(\frac{im\omega}{2\hbar}xy\right)\chi(\tau,y), \tag{14}$$

where $x\equiv x_1$, $y\equiv x_2-\tau x_1$, and $\tau\equiv c/a$, with χ satisfying the Schrödinger-like equation

$$\frac{\partial\chi}{\partial\tau}=\frac{i\hbar}{2m\omega}\frac{\partial^2\chi}{\partial y^2}. \tag{15}$$

For $c\neq 0$:

$$\tilde{\Psi}=\zeta c^{-1/2}\exp\left(-\frac{im\omega}{2\hbar}\tilde{x}\tilde{y}\right)\tilde{\chi}(\tilde{\tau},\tilde{y}), \tag{16}$$

where $\tilde{x}\equiv x_2$, $\tilde{y}\equiv x_1-\tilde{\tau}x_2$, and $\tilde{\tau}\equiv a/c$, with $\tilde{\chi}$ satisfying the Schrödinger-like equation

$$\frac{\partial\tilde{\chi}}{\partial\tilde{\tau}}=-\frac{i\hbar}{2m\omega}\frac{\partial^2\tilde{\chi}}{\partial\tilde{y}^2}. \tag{17}$$

The element J represents a rotation of $\pi/2$ in the plane (x_1,x_2), and takes the wave function from one local chart to the other. (In fact, up to a factor, J represents the Fourier transform passing from the x_1 representation to the x_2 representation.) Obviously, $J^4=I_2$, but acting with J on the wave functions we obtain:

$$\Psi(J*g)=(-1)^{1/4}\tilde{\Psi}(g), \tag{18}$$

from which the result $\Psi(J^4*g)=-\Psi(g)$ follows, that is, the representation obtained for the subgroup SL(2,R) is two-valued. This representation is the well-known *metaplectic* or *spinor representation*. The metaplectic representation is for SL(2,R) as the $\frac{1}{2}$-spin representation is for SO(3) (see Ref. 22 and references therein, and also Ref. 16). We refer the reader to Ref. 19 for a detailed study of the Schrödinger group, including the nonanomalous representations and a physical interpretation for them.

IV. THE SCHRÖDINGER GROUP ON THE TORUS

Once we have obtained the polarized wave functions and therefore fixed the unitary and irreducible representation U($\tilde{G}$) of $\tilde{G}$ and the unconstrained Hilbert space $\mathcal{H}$, we have to impose the appropriate constraints to reduce the phase space to a torus. This task is achieved by the structure group T, which is a fiber bundle with base $\Gamma_{\vec{L}}\equiv\{e_{\vec{k}},\vec{k}\in Z\times Z\}$ and fiber U(1), where $e_{\vec{k}}$ are translations of $\vec{x}$ by an amount of $\vec{L}_{\vec{k}}\equiv(k_1L_1,k_2L_2)$, in such a way that $\tilde{G}/T$ is essentially the torus. [As was commented before, $\tilde{G}/T$ in this case is a presymplectic manifold, which, once the kernel of the (pre)symplectic form $d\Theta$ (containing the $SL(2,R)$ subalgebra) is removed, turns out to be a torus.] The fibration of T by U(1) depends on the values of m, ω, L_1, and L_2, and is, in general, nontrivial.

The following task is to obtain the irreducible representations of T. These are studied in detail in the Appendix, and here we shall report only the main results. The form of the representations of T depends strongly on its structure as U(1) bundle with base $\Gamma_{\vec{L}}$ (which plays the role of constraints C), and this is determined by the character of the adimensional parameter $m\omega L_1L_2/2\pi\hbar$, in such a way that:

(i) Integer Case: $m\omega L_1L_2/2\pi\hbar = n\in Z$. In this case T is Abelian, $T=\Gamma_{\vec{L}}\times U(1)$, and therefore all its representations are one dimensional.

(ii) Fractional Case: $m\omega L_1L_2/2\pi\hbar = n/r$, where n and r are relative prime integers (with $r>1$). In this case T is not Abelian, but its representations are of finite dimension.

(iii) Irrational Case: $m\omega L_1L_2/2\pi\hbar=\rho$, where ρ is an irrational number. In this case, T is not Abelian and possesses representations (the ones which are compatible with the U(1)-function condition) of infinite dimension.

The irrational case will not be considered here, since its study requires techniques from noncommutative geometry,[12] and therefore lies beyond the scope of the present work. The most interesting properties of this case, in particular, of the group C^*-algebra generated by the elements of T, denoted *irrational rotation algebra*, is that it is not a type I algebra[23] (in fact it is a type II_∞ algebra).

Although normally the integer and fractional cases are used in physical applications, like Abelian Chern–Simons theory (see Sec. V) or the quantum Hall effect (integer and fractional), there exists works[24] where the irrational case has been use to study the quantum Hall effect, using techniques of C^*-algebras and cyclic cohomology to explain the integrality of the conductance on the quantum Hall effect (see also Ref. 12).

A. The integer case

We shall consider first the integer case, for which $m\omega L_1L_2/2\pi\hbar = n\in Z$ and the structure group is $T=\Gamma_{\vec{L}}\times U(1)$, $\Gamma_{\vec{L}}$ being a subgroup isomorphic to $Z\times Z$. This case leads to a symplectic form on the torus of integer cohomology class n (and therefore the torus is quantizable according to Geometric Quantization), and n can be interpreted as the Chern number of a U(1)-bundle over the torus (see Ref. 8).

The representations of T [compatible with the U(1)-function condition] for the integer case are easily computed (see the Appendix), and have the form:

$$D^{\vec{\varphi}}(I_2,k_1L_1,k_2L_2,\zeta)=\zeta e^{i(\varphi_1k_1+\varphi_2k_2)}e^{-i\pi nk_1k_2}, \tag{19}$$

where $\varphi_1,\varphi_2\in[0,2\pi)$ parametrize the inequivalent representations of the subgroup $\Gamma_{\vec{L}}\approx Z\times Z$. They are the analog of vacuum angles in quantum chromodynamics (see, e.g., Ref. 25).

The T-function conditions are written as $\Psi^{\vec{\varphi}}(g_T*g)=D^{\vec{\varphi}}(g_T)\Psi^{\vec{\varphi}}(g)$, $\forall g_T\in T$. They can be interpreted as periodic boundary conditions, selecting those wave functions in $\mathcal{H}$ which are quasiperiodic, i.e., picking up a phase $e^{i\varphi_1}$ when translated by L_1 and $e^{i\varphi_2}$ when translated by L_2. This condition reduces to $\Psi^0(g_T*g)=\zeta\Psi^0(g)$ if the trivial representation for $\Gamma_{\vec{L}}$ is chosen (strictly periodic boundary conditions). As in Ref. 8, the rest of nonequivalent representations can be obtained by acting with those finite translations which are not good operators. We are not interested in their explicit form, so we refer the interested reader to Ref. 8 for the details of the computations.

The solutions to the T-function condition for the trivial representation are those functions Ψ of the form (14) for which $\chi(\tau,y)$ is of the form:

$$\chi^0(\tau,y)=\sum_{k=0}^{n-1} a_k\Delta_k^0(\tau,y), \tag{20}$$

with

$$\Delta_k^0(\tau,y)=\exp\left[i2\pi k\left(\frac{y}{L_2}-\frac{\delta}{2n}\tau k\right)\right]\sum_{q\in Z}\exp\left(i2\pi nq\left[\frac{y}{L_2}-\frac{\delta}{2n}\tau(k^2+nq)\right]\right), \tag{21}$$

$\delta\equiv L_1/L_2$ and a_k, $k=0,1,...,n-1$ being arbitrary coefficients. We can write these in a form which resembles the one obtained in Ref. 8, where we considered only the Heisenberg–Weyl subgroup:

$$\Delta_k^0(\tau,y)=\exp\left(i\frac{\delta L_2^2\tau}{4\pi n}\frac{d^2}{dy^2}\right)\Delta_k^0(y), \tag{22}$$

with $\Delta_k^0(y)=e^{i2\pi k(y/L_2)}\sum_{q\in Z}\delta(y-(q/n)L_2)$.

For the local chart at $J(c\neq 0)$, we could follow the same procedure or simply transform the wave function acting with J. The result obtained is completely analogous to the one obtained in the local chart at the identity. Therefore, the constrained Hilbert space $\mathcal{H}_T$ is finite dimensional, with a basis of n independent functions, $\{\Delta_k^0\}_{k=0}^{n-1}$.

Now we have to compute the *good operators*, those preserving the Hilbert space $\mathcal{H}_T$ of polarized wave functions verifying the T-function condition. We should look for good operators in the normalizer of T in $\tilde{G}$. In this case (this result is also valid for the fractional case), we have:

$$N_T=\left\{\left(\begin{pmatrix} a & b\\ c & d\end{pmatrix},x_1,x_2,\zeta\right)\in\tilde{G}\quad\text{such that } a,b\delta^{-1},c\delta,d\in Z,x_1,x_2\in R,\zeta\in \mathrm{U}(1)\right\}, \tag{23}$$

which implies that N_T is the semidirect product of SL(2,Z) by the HW group.

Since T is Abelian, the characterization (2) reduces to (3), and this leads to the condition:

$$(a-1)\frac{\varphi_1}{2\pi}+c\delta\frac{\varphi_2}{2\pi}+n\left(-a\frac{x_2}{L_2}+c\delta\frac{x_1}{L_1}-\frac{1}{2}ac\delta\right)=k\in Z,$$

$$(d-1)\frac{\varphi_2}{2\pi}+b\delta^{-1}\frac{\varphi_1}{2\pi}+n\left(-b\delta^{-1}\frac{x_2}{L_2}+d\frac{x_1}{L_1}-\frac{1}{2}db\delta^{-1}\right)=k'\in Z. \tag{24}$$

With regard to the HW subgroup (i.e., with $a=d=1$ and $b=c=0$), we get the same result as in Ref. 8: $x_1=k_1(L_1/n)$ and $x_2=k_2(L_2/n)$, with $k_1,k_2\in Z$. This implies that

$$W\equiv\{\zeta(\hat{\eta}_1)^{k_1/n}(\hat{\eta}_2)^{k_2/n},k_1,k_2\in Z,\zeta\in \mathrm{U}(1)\}\subset G_{\text{good}}^{\vec{\varphi}}, \tag{25}$$

with $\hat{\eta}_1\equiv e_{(1,0)}$ and $\hat{\eta}_2\equiv e_{(0,1)}$, for any values of the vacuum angles φ_1 and φ_2. These operators can be interpreted as the Wilson loops in a Chern–Simons theory on the torus (see Sec. V and Refs. 25 and 26).

When studying the SL(2,R) subgroup (i.e., with $x_1=x_2=0$), we can proceed in two ways. Either we can determine for which values of φ_1 and φ_2 we obtain the full modular group SL(2,Z) as good operators, or we can compute $G_{\text{good}}^{\vec{\varphi}}$ for given values of φ_1 and φ_2.

In the first case, from (24) we easily deduce that modular invariance is achieved for $\varphi_1=2\pi m_1$, $\varphi_2=2\pi m_2$ if n is even and for $\varphi_1=\pi(2m_1+1)$, $\varphi_2=\pi(2m_2+1)$ if n is odd, with $m_1,m_2\in Z$. Clearly, since the vacuum angles are defined modulo 2π these correspond to $\varphi_1=\varphi_2=0$, or periodic boundary conditions for n even and to $\varphi_1=\varphi_2=\pi$, or antiperiodic boundary conditions for n odd. This is an interesting result, since it reflects the fact that good operators really depend on the particular representation $D^{\vec{\varphi}}$ of T we are considering.

The group G_{good} of good operators for these cases would be obtained by taking the product of elements of SL(2,Z) with those of W given by (25). But from (24) we see that there are a few more good operators which cannot be obtained in this way. Altogether, we obtain the following group of good operators for $\varphi_1=\varphi_2=0$ with n even and for $\varphi_1=\varphi_2=\pi$ with n odd:

$$G_{\rm good}=\left\{\left(S,\frac{1}{n}SJ^m\vec{L}_{\vec{k}},\zeta\right)\ \text{such that}\ S\in \mathrm{SL}(2,Z),m=0,1,2,3,\vec{k}\in Z\times Z,\zeta\in \mathrm{U}(1)\right\}. \qquad (26)$$

The computation of $G_{\rm good}^{\vec{\varphi}}$ for arbitrary values of φ_1,φ_2 is a bit more involved. We have seen that the subgroup W given in (25) is always included in $G_{\rm good}^{\vec{\varphi}}$, so we have only to consider the SL(2,Z) subgroup. It is easy to see that if both $\varphi_1/2\pi$ and $\varphi_2/2\pi$ are irrational, then only the identity matrix in SL(2,Z) is a good operator, so there is no hint of modular invariance for this case. If $\varphi_1/2\pi$ is irrational and $\varphi_2/2\pi=p/q$ is rational (the case obtained by interchanging 1 and 2 is analogous), then only the subgroup of modular transformations of the form

$$\begin{pmatrix} 1 & \epsilon q\delta^{-1}k \\ 0 & 1 \end{pmatrix}$$

are good operators, with $k\in Z$ and with $\epsilon=1$ for n even and $\epsilon=2$ for n odd. If $\varphi_2/2\pi=p_1/q_1$ and $\varphi_2/2\pi=p_2/q_2$ are rational, then the good operators are given by the subgroup of modular transformations satisfying the following diophantine equations:

$$\begin{aligned}(a-1)\frac{p_1}{q_1}+c\delta\frac{p_2}{q_2}-n\frac{ac\delta}{2}&=k\in Z,\\ b\delta^{-1}\frac{p_1}{q_1}+(d-1)\frac{p_2}{q_2}-n\frac{db\delta^{-1}}{2}&=k'\in Z.\end{aligned} \qquad (27)$$

B. The fractional case

For the fractional case, we shall restrict ourselves to the determination of the subgroup of good operators. The computation of the explicit form of the constrained wave functions can be performed along the guidelines of Sec. IV A (they are essentially the ones given in Ref. 8 for the HW group), using the representations of T given in the Appendix. The dimension of the Hilbert space turns out to be nr, and it can be considered to be an n dimensional Hilbert space made of vector-valued wave functions, r being the dimension of the vector space.

To determine the subgroup $G_{\rm good}$ of good operators, we make use of the characterization (2) for the little group, where now, since the representations are of dimension r, the equivalence can be established through a nontrivial unitary matrix $V(g_g)$.

First, we compute, for

$$g_g=\left(\begin{pmatrix} a & b \\ c & d\end{pmatrix},x_1,x_2,\zeta'\right)\in N_T,$$

$$\begin{aligned}g_g*(I_2,k_1L_1,k_2L_2,\zeta)*g_g^{-1}=&(I_2,(ak_1+b\delta^{-1}k_2)L_1,(c\delta k_1+dk_2)\\ &\times L_2,\zeta e^{i2\pi(n/r)[(-a(x_2/L_2)+c\delta(x_1/L_1))k_1+(-b\delta^{-1}(x_2/L_2)+d(x_1/L_1))k_2]}),\end{aligned} \qquad (28)$$

and then we must find for which $g_g\in N_T$ we have

$$D^{\vec{\varphi}}(g_g*g_T*g_g^{-1})=V(g_g)D^{\vec{\varphi}}(g_T)V(g_g)^\dagger,\quad \forall g_T\in T, \qquad (29)$$

where the representations $D^{\vec{\varphi}}$ for the fractional case (obtained in the Appendix), are given by

$$D^{\vec{\varphi}}(I_2,k_1L_1,k_2L_2,\zeta)=\zeta e^{i(\varphi_1k_1+\varphi_2k_2)}e^{-i\pi(n/r)k_1k_2}A_r^{k_1}B_r^{k_2}. \qquad (30)$$

We proceed as in the integer case, computing first the good operators in the HW subgroup. Then the previous equation is written:

$$\exp\left[i2\pi\frac{n}{r}\left(-\frac{x_2}{L_2}k_1+\frac{x_1}{L_1}k_2\right)\right]A_r^{k_1}B_r^{k_2}=V(g_g)A_r^{k_1}B_r^{k_2}V(g_g)^{\dagger}. \tag{31}$$

This equation is the same one which states the equivalence of the representations $D^{(\mu_1,\mu_2)}$ and $D^{(0,0)}$ and, therefore, making use of the results given in the Appendix, we find that $x_1 = k(L_1/n)$ and $x_2=k'(L_2/n)$, with $k,k'\in Z$. This implies that the subgroup W given in (25) is included in $G_{\rm good}^{\vec{\varphi}}$ for all values of $\varphi_1,\varphi_2\in[0,2\pi/r)$.

As far as the SL$(2,Z)$ subgroup is concerned, we shall determine only the conditions under which full modular invariance is obtained as good operators, and for this purpose we shall make use of the fact that SL$(2,Z)$ is generated by two modular transformations:

$$g_1\equiv\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix},\quad g_2\equiv\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}. \tag{32}$$

Determining under which conditions these two transformations are good operators will tell us when the theory is fully modular invariant. For g_1 we obtain the condition:

$$\exp\left[i2\pi k_2\left(\frac{\varphi_1}{2\pi}-\frac{nk_2}{2r}\right)\right]A_r^{k_1+k_2}B_r^{k_2}=V(g_1)A_r^{k_1}B_r^{k_2}V(g_1)^{\dagger},\quad \forall k_1,k_2\in Z. \tag{33}$$

For this condition to hold, it is necessary that $\varphi_1=0$ if nr is even, or $\varphi_1=\pi/r$ if nr is odd. For the first case, the unitary matrix $V(g_1)$ has the form $V(g_1)_{ij}=\omega_r^{(i-1)^2/2}\delta_{ij}$, and, for the second, we have $V(g_1)_{ij}=\omega_r^{(i-1)/2n}\omega_r^{(i-1)^2/2}\delta_{ij}$.

For g_2 to be a good operator, we obtain the condition:

$$\exp\left[i2\pi k_1\left(\frac{\varphi_2}{2\pi}-\frac{nk_1}{2r}\right)\right]A_r^{k_1}B_r^{k_1+k_2}=V(g_2)A_r^{k_1}B_r^{k_2}V(g_2)^{\dagger},\quad \forall k_1,k_2\in Z. \tag{34}$$

Again, for this condition to hold it has to be $\varphi_2=0$ if nr is even or $\varphi_2=\pi/r$ if nr is odd. The unitary matrix $V(g_2)$ has the form:

$$V(g_2)=V=\frac{1}{\sqrt{r}}\begin{pmatrix}1 & \omega_r^{(r-1)(r-2)/2} & \cdots & \cdots & 1\\ 1 & 1 & \cdots & \cdots & \\ \omega_r & 1 & \cdots & \cdots & \\ \omega_r^3 & \omega_r & \cdots & \cdots & \vdots\\ \vdots & \vdots & \vdots & \vdots & \omega_r^{(r-1)(r-2)/2}\\ \omega_r^{(r-1)(r-2)/2} & \cdots & \cdots & 1 & 1\end{pmatrix}\quad \text{if } nr \text{ is even}$$

$$V(g_2)=A_r^{1/2n}V\quad \text{if } nr \text{ is odd},$$

where $(A_r^{1/2n})_{ij}=e^{i\pi[(i-1)/r]}\delta_{ij}$.

It should be stressed that the values of $\vec{\varphi}$ for which full modular invariance is obtained correspond to wave functions which are periodic if nr is even, or antiperiodic if nr is odd, where these boundary conditions should be understood with respect to translations by rL_1 and rL_2.

Note also that the matrix representation $V(g_1)$ and $V(g_2)$ obtained for g_1 and g_2 [and therefore for the whole SL$(2,Z)$ group] corresponds to their action on the r-dimensional vector space.

The complete action of any modular transformation on the wave functions (through $nr\times nr$ matrices) decomposes, thus, in a tensor product of an $n\times n$ matrix and an $r\times r$ matrix, each one acting on different indices of the wave functions.[26]

This structure of tensor product of the Hilbert space suggests a duality under the interchange of n and r. Indeed, the set of Wilson loops (25) for the theories characterized by n/r and r/n are isomorphic. Since all the information of the theory is contained in the Wilson loops, we could say that the two theories are equivalent. The case $n/r=1$ would, of course, be self-dual. Moreover, as pointed out in Ref. 27, if we denote by $\mathcal{A}_{n/r}$ the (group) algebra generated by A and B satisfying

$$AB=e^{i2\pi(n/r)}BA, \tag{35}$$

then we have $\mathcal{A}_{1/(nr)}=\mathcal{A}_{n/r}\times\mathcal{A}_{r/n}$. Therefore, the algebra of Wilson loops, besides being the same for a theory with $T=\mathcal{A}_{n/r}$ and $T=\mathcal{A}_{r/n}$, is given by the direct product of both (commuting) algebras. From the point of view of noncommutative C^*-algebras, the algebras $\mathcal{A}_{n/r}$ and $\mathcal{A}_{r/n}$ are strongly Morita equivalent, which means, in particular, that they possess the same representation theory[23] (see also Ref. 12).

V. 2+1D ABELIAN CHERN–SIMONS THEORY

As a first application of our results, let us consider a pure topological field theory on the torus.

Let M be a globally hyperbolic three-dimensional manifold, $M=\Sigma\times R$, where Σ is an orientable two-dimentional manifold.

The action for an Abelian Chern–Simons (ACS) theory is given by[28,25,26]

$$S_{\rm ACS}=\frac{k}{4\pi}\int_M (A\wedge dA), \tag{36}$$

where A is a one-form in M which takes values on the Lie algebra $\mathcal{K}$ of an Abelian Lie group K. It is straightforward to check that the action $S_{\rm ACS}$ is invariant under gauge transformations $A\rightarrow A+iU^{-1}dU$ for any (single-valued) $U:M\rightarrow K$.

The equations of motion are:

$$dA\equiv F=0, \tag{37}$$

the solution of which is the vector space $\mathcal{V}_{\rm ACS}$ of all flat connections on M. A generic element $A\in\mathcal{V}_{\rm ACS}$ can be written in the form $(A_0,iU^{-1}\nabla U+a(t))$, where a is a map from R to the fiber of $T^*(\Sigma)\otimes\mathcal{K}$.

This vector space of solutions can be endowed with a (pre-)symplectic structure by means of a (pre-)symplectic form

$$\Omega_{\rm ACS}(A',A)=\int_\Sigma J=\frac{k}{4\pi}\int_\Sigma A'\wedge A, \tag{38}$$

where $J^\mu\equiv(k/4\pi)\epsilon^{\mu\nu\sigma}A'_\nu A_\sigma$ is a divergenceless current which ensures the independence of $\Omega_{\rm ACS}(A',A)$ on the chosen Cauchy factorization of M, $M=\Sigma\times R$.

Since the exterior derivative d commutes with the pullback operator $*$, if f is a diffeomorphism of M, and A', $A\in\mathcal{V}_{\rm ACS}$, then $A'+f^*A$ is also a solution of (37).

With this information, we can propose a quantizing group $\tilde{G}_{\rm ACS}$ for this theory, the composition law of which is

$$f''=f'\circ f,\quad f,f',f''\in{\rm Diff}(M),$$
$$A''=f^{-1*}A'+A, \tag{39}$$

$$\zeta''=\zeta\zeta' \exp \Omega_{\mathrm{ACS}}(f^{-1*}A',A),$$

i.e., the extension by U(1) of the semidirect product $\mathcal{V}_{\mathrm{ACS}}\otimes_s \mathrm{Diff}(M)$. The characteristic subgroup (generated by the kernel of Ω_{ACS}, see Sec. III) of this group proves to be $G_\Omega=\{(f,A,1)/A=(A_0,iU^{-1}\nabla U)$ for some $U:M\rightarrow K\}\subset\tilde{G}_{\mathrm{ACS}}$, which contains the *gauge group* G_{gauge} of the theory, constituted by all (single-valued) $U:M\rightarrow K$. [To be precise, here, G_{gauge} is the orbit at the identity of Map(M,K) on $\mathcal{V}_{\mathrm{ACS}}$, under the action $A\rightarrow A+iU^{-1}dU$. Including the group Map(M,K) explicitly in $\tilde{G}_{\mathrm{ACS}}$ requires a slight modification of the notion of gauge transformation[29] (see also Ref. 14 for a discussion on the definition of *gauge group*).] Thus, the polarization conditions (which contain the characteristic subgroup) imply that wave functions depend only on topological and gauge invariant quantities. For this kind of theory, standard approaches claim that all gauge-invariant information of a connection can be extracted from the *Wilson loops* defined by

$$W(A,\gamma)=\exp\int_\gamma A, \tag{40}$$

for any loop γ in Σ. Since connections A are flat, the Wilson loops will depend only on the homotopy class $[\gamma]\in\pi_1(\Sigma)$ of the corresponding loop γ. For this reason the normal subgroup $\mathrm{Diff}_0(M)\subset\mathrm{Diff}(M)$ of diffeomorphism of M connected to the identity acts trivially on the Wilson loops. Therefore the diffeomorphisms that really matter in (39) are the quotient $\mathrm{Diff}(M)/\mathrm{Diff}_0(M)$ called the *modular group* (see Refs. 9 and 10) of the Riemann surface Σ (note that all diffeomorphisms of the R part of M are connected to the identity).

It should be stressed that if $\pi_1(\Sigma)=0$ [which implies that $H^1(\Sigma)=0$] then the ACS theory is trivial since all connections are of the form $A=iU^{-1}dU$ for some (always single-valued) $U:M\rightarrow K$. This implies that $G_\Omega=G_{\mathrm{ACS}}\equiv\mathcal{V}_{\mathrm{ACS}}\otimes_s\mathrm{Diff}(M)$ and $\tilde{G}_{\mathrm{ACS}}=G_{\mathrm{ACS}}\times \mathrm{U}(1)$, that is, the central extension is trivial (another way of seeing this is that since the homotopy group of M is trivial, all Wilson loops are trivial). Therefore we assume that Σ is a multiply connected oriented two-dimensional manifold. What makes the theory nontrivial in this case is the fact that the gauge group, G_{gauge}, is smaller than its simply connected counterpart $\overline{G}_{\mathrm{gauge}}$ in the universal covering space $\overline{M}$ of M, constituted by all $\overline{U}:\overline{M}\rightarrow K$, with $\overline{M}=\overline{\Sigma}\times R$, and $\overline{\Sigma}$ the universal covering space of Σ. In fact, the group $G_{\mathrm{gauge}}\subset\overline{G}_{\mathrm{gauge}}$ is made of those elements $\overline{U}\in\overline{G}_{\mathrm{gauge}}$ verifying $\overline{U}\circ[\gamma]=\overline{U}$, where here $[\gamma]$ represents the natural action (as diffeomorphism) of the homotopy class $[\gamma]\in\pi_1(M)$ on $\overline{M}$.

For the present case, $\Sigma=S^1\times S^1$ and $K=\mathrm{U}(1)$. The space $\mathcal{V}_{\mathrm{ACS}}$ is made of connections of the form $(A_0,ig^{-1}\nabla g+a(t))$, where U is single-valued on the torus. The solution manifold, that which remains once the quotient by the characteristic subgroup G_Ω is taken, is parametrized by the variables $a_1(t)$, $a_2(t)$ modulo an integer, defining a torus. The reason is that G_Ω also contains the *global (large) gauge transformations* (see for instance Ref. 26 and references therein),

$$a_j\rightarrow a_j+k_j,\quad k_j\in Z. \tag{41}$$

These large gauge transformations are clearly seen to come from transformations of the form $U=\exp(ik_jx^j)$, with $k_j\in Z$ and $\{x^j\}$ a set of local coordinates on the torus, in such a way that 0 and 2π are identified. The reason of the restriction of k_j to integers is the condition $\overline{U}\circ[\gamma]=\overline{U}$. This indicates that the gauge group G_{gauge} is a disconnected group, with $G_{\mathrm{gauge}}/G^0_{\mathrm{gauge}}=Z\times Z$, G^0_{gauge} being the connected component of the identity.

For this reason, in the quantum theory the operator associated with the variables A (more precisely, a) are not properly defined (they are *bad operators*, see Sec. II). We must resort to single-valued (*good*) operators of the form:

$$W(A)=\exp\left(2\pi i\sum_{j=1}^{2} n_j a_j\right), \tag{42}$$

where $n_j \in Z$ should be interpreted as the winding number of a path γ around the cycle j. Remember that for the torus, the homotopy classes $[\gamma]$ are generated by two elements, $[\gamma_j]$, $j=1,2$, representing loops (with winding number one) around each one of the two cycles of the torus. The modular group proves to be $\mathrm{Diff}(T^2)/\mathrm{Diff}_0(T^2)=\mathrm{SL}(2,Z)$.

At this point it should be stressed that the resulting theory corresponds to a quantum mechanical system with phase space a torus parametrized by $(q,p)\equiv(a_1 \bmod 1, a_2 \bmod 1)$.

According to this equivalence, we could have studied this system in the framework of AQG by starting with the group $\mathrm{HW}\otimes_s\mathrm{Diff}(R^2\times R)$ with structure group T a fiber bundle with base $Z\times Z$ and fiber U(1), where $Z\times Z$ is the subgroup of $\mathrm{Diff}(R^2\times R)$ of translations by (k_1L_1,k_2L_2), with $k_1,k_2\in Z$. Since the only relevant diffeomorphisms at the final theory on the torus will be the modular transformations $\mathrm{SL}(2,Z)\subset\mathrm{SL}(2,R)$, it is enough to start with $\mathrm{HW}\otimes_s\mathrm{SL}(2,R)$, which is the Schrödinger group. Thus, all the results of Sec. IV apply here. Of course, we could have started directly with $\mathrm{HW}\otimes_s\mathrm{SL}(2,Z)$, but this group, being disconnected, is more difficult to quantize than the Schrödinger group (in particular, finding a polarization for this group is a difficult task). In addition, we think that showing how SL(2,Z) emerges as good operators is a very illustrative way of studying the problem.

In summary

(1) The coupling constant k plays the same role as the quantity $\phi\equiv m\omega L_1L_2/2\pi\hbar$ in the Schrödinger group on the torus, determining the character of the resulting (finite-dimensional) Hilbert space.
(2) The set of Wilson loops (42) takes part of the set of good operators in our language. More precisely, they are the analog of the set W given in (25).
(3) The group of large gauge transformations is the analog of the structure group T. When the coupling constant k is fractional, this gauge group is called *anomalous*[26] because of its non-Abelian character due to the nontrivial fibration for this case, as oposed to the original Abelian gauge group K.
(4) The nonequivalent representations of T, parametrized by the indices φ_1,φ_2 (vacuum angles), characterize the nonequivalent quantizations of the theory.

The Chern–Simons theory constitutes a particular example of a drastic reduction of the number of original infinite (field) degrees of freedom to a finite number (which, in addition, contain a finite number of states, due to the compactness of the phase space when restricted to the torus), as a consequence of a huge gauge invariance which kills all of them except for the topologic ones.

A. Further comments

Comparing our results with those in the literature, we find full agreement with Ref. 25, in the context of U(1) Chern–Simon theory on the torus, as far as the integer case is concerned. For the fractional case, an apparent discrepance with the results in Ref. 25 appears: In our notation, modular invariance is obtained only for n even (and any value of r) and vacuum angles $\varphi_1=\varphi_2=0$. However, the agreement is achieved if we realize that the proper range of inequivalent vacuum angles in Ref. 25 should be $[0,2\pi/r)$.

This problem was also studied in Ref. 26 [also in the context of U(1) Chern–Simons theory and anyons on the torus], where full modular invariance was obtained for both the integer and fractional case, but they claimed that the vacuum angles always have to be $\frac{1}{2}$ disregarding the parity of the coupling constant (the equivalent of our n/r). A more detailed analysis of their results reveals that the vacuum angles they introduce are defined modulo $1/nr$, and $(\frac{1}{2} \bmod 1/nr)$ is 0 for even nr and $1/2nr$ for odd nr, corresponding to periodic and antiperiodic boundary conditions, respectively. Therefore, their results completely agree with ours.

In Ref. 27, a non-Abelian Chern–Simons theory is considered, with gauge group $SL(2,R)$. When restricted to the torus, they obtained essentially the same results as ours and those of Refs. 25 and 26 (with the above-mentioned remarks) with respect to the Hilbert space and the set of observables (good operators), because the reduced phase space of the theory is almost the space of flat connections of an Abelian gauge group.

APPENDIX: UNITARY AND IRREDUCIBLE REPRESENTATIONS OF *T*

The structure subgroup *T*, as defined in Sec. IV, is a U(1) bundle with base $\Gamma_L^{\vec{}}$, and can be written as

$$T=\{(I_2,k_1L_1,k_2L_2,\zeta)\in\tilde{G}/k_1,k_2\in Z,\zeta\in U(1)\}, \tag{A1}$$

with group law derived from the group law of the Schrödinger group:

$$(I_2,k_1'L_1,k_2'L_2,\zeta')*(I_2,k_1L_1,k_2L_2,\zeta)=\left(I_2,(k_1'+k_1)L_1,(k_2'+k_2)L_2,\zeta'\zeta \times\exp\left[i\frac{m\omega L_1L_2}{2\hbar}(k_1'k_2-k_2'k_1)\right]\right). \tag{A2}$$

To determine the structure of *T*, we compute the group commutator of two elements:

$$[(I_2,k_1'L_1,k_2'L_2,\zeta'),(I_2,k_1L_1,k_2L_2,\zeta)]=\left(I_2,0,0,\exp\left[i\frac{m\omega L_1L_2}{\hbar}(k_1'k_2-k_2'k_1)\right]\right), \tag{A3}$$

from which we see that its structure depends on the value of $m\omega L_1L_2/2\pi\hbar$, in such a way that there are three possibilities:

(i) Integer Case: $m\omega L_1L_2/2\pi\hbar=n\in Z$.
(ii) Fractional Case: $m\omega L_1L_2/2\pi\hbar=n/r$, $n,r\in Z$ and relative prime (with $r>1$).
(iii) Irrational Case: $m\omega L_1L_2/2\pi\hbar=\rho$, with ρ an irrational number.

Let us study the integer and fractional case separately. The irrational case will not be considered here (see Ref. 12 for a detailed study of this case).

1. Integer case

In this case, *T* is an Abelian group, and therefore $T=\Gamma_L^{\vec{}}\times U(1)$ and all its representations are of dimension 1. As stated above, we shall consider only those representations, which restricted to U(1), are the natural representations, and these have the form:

$$D^{\vec{\varphi}}(I_2,k_1L_1,k_2L_2,\zeta)=\zeta e^{i(\varphi_1k_1+\varphi_2k_2)}e^{-i\pi nk_1k_2},\quad \forall k_1,k_2\in Z,\quad \forall\zeta\in U(1), \tag{A4}$$

where the range of inequivalent representations, since they are one-dimensional, is given simply by $\varphi_1,\varphi_2\in[0,2\pi)$. Note that, except for the term $e^{-i\pi nk_1k_2}$ this is the product of the natural representation of U(1) times a representation of $\Gamma_L^{\vec{}}\approx Z\times Z$. This extra term is only a coboundary coming from the fact that we have used Bargmann's cocycle in the group law of the Schrödinger group, and Bargmann's cocycle does not satisfy the conditions given in Ref. 8 for the possible cocycles for the HW group on the torus. Note, thus, that this restriction can be relaxed by introducing this coboundary term in the representations of *T*.

2. Fractional case

In this case, T is not Abelian, and the commutator of two elements has the form:

$$[(I_2,k_1'L_1,k_2'L_2,\zeta'),(I_2,k_1L_1,k_2L_2,\zeta)]=(I_2,0,0,\omega_r^{k_1'k_2-k_2'k_1}), \tag{A5}$$

where $\omega_r\equiv e^{i2\pi(n/r)}$ is an rth root of unity. Note that if $|n|>r$, then $\omega_r=e^{i2\pi(n/r)}=e^{i2\pi(q/r)}$, where $q=n \bmod r$. Since n and r are relative prime, q and r turn out also to be relative prime and, therefore, we can use either of the two pairs to characterize T.

The group T admits a nontrivial characteristic subgroup (see Ref. 8), of the form:

$$G_C=\{(I_2,rk_1L_1,rk_2L_2,e^{i\pi nrk_1k_2})/k_1,k_2\in Z\}. \tag{A6}$$

The characteristic subgroup can be identified in this case with the Casimir elements of T which are not in U(1), i.e., those elements of T [not belonging to U(1)] which commute with all other elements in T. In fact, the center of T is given by $G_C\times \mathrm{U}(1)$.

If we quotient T by G_C, we obtain a group which is a *generalized Clifford group* G_2^r (see Ref. 30 for the definition and the study of representations of generalized Clifford groups) times U(1). Therefore, the representations of T can be obtained from those of G_C and G_2^r [and the natural representation of U(1)].

The representations of G_C, being isomorphic to $Z\times Z$, are characterized by two ''vacuum angles'' φ_1,φ_2, whose range of nonequivalence should be determined. The representations of G_2^r are studied in detail in Ref. 30, so that here we shall give only the results. It should be remarked, however, that in Ref. 30 ω_r is an arbitrary rth root of unity, and different choices for it give inequivalent representations of G_2^r, whereas here the value of ω_r is given *a priori* (it is determined by the fact that T is a subgroup of $\tilde{G}$), so that the representation of G_2^r is uniquely determined. In addition, since n and r are relative prime, ω_r is a primitive rth root of unity, implying that the representation of G_2^r associated with it is of dimension r, either for prime or nonprime r.

The r-dimensional unitary irreducible representation of G_2^r can be constructed with the aid of two $r\times r$ matrices, A_r and B_r:

$$(A_r)_{ij}=\omega_r^{i-1}\delta_{ij},\quad (B_r)_{ij}=\delta_{i,(j \bmod r)+1},\quad i,j=1,2,...,r, \tag{A7}$$

verifying $A_rB_r=\omega_rB_rA_r$, and $A_r^r=B_r^r=I_r$. Putting together this representation of G_2^r and that of $G_C\approx Z\times Z$, we can build a representation for the entire T, of the form:

$$D^{\vec{\varphi}}(I_2,k_1L_1,k_2L_2,\zeta)=\zeta e^{i(\varphi_1k_1+\varphi_2k_2)}e^{-i\pi(n/r)k_1k_2}A_r^{k_1}B_r^{k_2},\quad \forall k_1,k_2\in Z,\forall\zeta\in \mathrm{U}(1). \tag{A8}$$

One would naïvely expect that the range of nonequivalent representations would be $\varphi_1,\varphi_2 \in[0,2\pi)$, as in the integer case. However, since the representations are not one dimensional, there could be nontrivial unitary transformations relating representations in this interval and, therefore, reducing the range on nonequivalence.

Thus, we have to determine the minimum values of μ_1,μ_2 for which the representation $D^{(\mu_1,\mu_2)}$ is equivalent to the trivial representation $D^{(0,0)}$, i.e., there exists a unitary matrix V such that $D^{(\mu_1,\mu_2)}=VD^{(0,0)}V^\dagger$. Studying separately the cases $(\mu_1,0)$ and $(0,\mu_2)$, and after a few computations, we obtain:

(i) $D^{(\mu_1,0)}$ is equivalent to $D^{(0,0)}$ for $\mu_1=2\pi/r$, with $V=B_r^{m_0}$.
(ii) $D^{(0,\mu_2)}$ is equivalent to $D^{(0,0)}$ for $\mu_2=2\pi/r$, with $V=A_r^{1/n}$.

Here $(A_r^{1/n})_{ij}\equiv\omega_r^{(i-1)/n}\delta_{ij}=e^{i2\pi[(i-1)/r]}\delta_{ij}$, and $0<m_0<r$ is an integer solution of the diophantine equation:

$$1+nm_0=rk,\quad k\in Z, \tag{A9}$$

which has always two solutions in the range $\{-(r-1),\ldots,0,...,r-1\}$, provided n and r are relative prime (this is a particular case of the Bezout lemma, for $gcd(n,r)=1$, which in turn can be proven using Euclidean division of integers, see, for instance, Ref. 31). Note that $(A_r^{1/n})^n = A_r$ and $(B^{m_0})^n = B_r^{-1}$, so that these matrices can be considered as the nth roots of the matrices A_r and B_r^{-1}, respectively.

Therefore, the range of nonequivalent representations of T is reduced to $\varphi_1,\varphi_2\in[0,2\pi/r)$. This fact will be of extreme importance for the determination of the good operators in the fractional case.

We construct a free field realization of vertex operators of the dilute A_L models along with the Felder complex. For $L=3$, we also study an E_8 structure in terms of the deformed Virasoro currents.
[S0022-2488(99)01308-0]

I. INTRODUCTION

The dilute A_L model[1,2] is an integrable lattice model obtained by an RSOS restriction of the face model of type $A_2^{(2)}$.[3] It possesses several intriguing features. Among others, we are interested in the following points.

(i) At criticality, the dilute A_L model in regime 2^+ is described by conformal field theory (CFT), which belongs to the Virasoro minimal unitary series with the central charge $c=1-6/(L(L+1))$. The Andrews–Baxter–Forrester (ABF) model in regime III is known to be a different off-critical lattice model having the same critical behavior. While the ABF model corresponds to the (1,3)-perturbation of the minimal unitary CFT, the dilute A_L model corresponds to the (1,2)-perturbation of the same CFT.

(ii) In the particular case of $L=3$, the model falls within the same universality class as the two-dimensional Ising model in a magnetic field. The elliptic nome in the Boltzmann weights plays the role of a magnetic field, as opposed to the usual role as a temperaturelike variable. In the field theory limit, the scattering process of particles exhibits an E_8 structure.

In Ref. 4, bosonization of the ABF model in regime III was achieved. By ''bosonization'' we mean a free field realization of vertex operators (VOs) of the model as formulated in Ref. 5. It was also found that the deformed Virasoro algebra (DVA) proposed earlier in Ref. 6 arises naturally, in such a way that the VOs play the role of deformed chiral primary fields for DVA. (More specifically, the VOs of type I and type II correspond to the simplest primary fields ϕ_{21} and ϕ_{12}, respectively. Analogs of general ϕ_{mn} are obtained by a fusion procedure.[7] For an interpretation of the VOs as intertwiners for elliptic algebras, see Ref. 8.) The Becchi–Rouet–Stora–Tyutin

(BRST) resolution of Fock spaces, which singles out irreducible representations of the Virasoro algebra, carries over to the deformed version as well. Thus Ref. 4 presents an off-critical lattice version of the (1,3)-perturbation of the minimal unitary CFT in the free field picture. In this paper we study a similar problem for the (1,2)-perturbed CFT by bosonizing the dilute A_L model. For this purpose we adapt the construction of Refs. 5, 4, and 9 to the case of $A_2^{(2)}$.

In the trigonometric limit, bosonization of VOs has been given in Refs. 10 and 11 using representation theory of the quantum affine algebra $U_q(A_2^{(2)})$. In principle, we are to follow its elliptic analog on the basis of the face-type elliptic algebra.[12,8] Because of some technical difficulties in dealing with the latter, we take here a more pedestrian way and solve the exchange relations directly to obtain the bosonic realizations of VOs. In the course, we use the elliptic Drinfeld currents obtained by a ''dressing'' procedure.[8]

In view of points (i) and (ii) above, it is natural to expect that a different deformation of the Virasoro algebra arises from the dilute A_L models. Such a deformation was found in Ref. 13 through bosonization of the $A_2^{(2)}$ affine Toda field theory. (See Refs. 14 and 15 for more general deformed W algebras including the case $A_{2l}^{(2)}$.) To make a distinction from the original DVA of Ref. 6, we use the symbol $\mathcal{V}_{x,r}(A_2^{(2)})$ to denote the DVA of Ref. 13. In the original case, the generating function of DVA (hereafter referred to as the ''DVA current'') can also be obtained from ''fusion'' of the VOs.[16–18] In the same way, we reproduce the current of $\mathcal{V}_{x,r}(A_2^{(2)})$ by taking residues of products of the bosonized VOs in the present case.

For the dilute A_L models in regime 2^+, the space of states of the corner transfer matrix is an analog of the minimal unitary representation[2] for $\mathcal{V}_{x,r}(A_2^{(2)})$. In order to obtain them from the Fock spaces, we consider a Felder-type resolution using the elliptic currents of type $A_2^{(2)}$ as screening currents. Unlike the case of the ABF models, the BRST charges are not simply a power of screening operators. Such a complication seems to be common in the higher rank situations.[19] We prove the nilpotency of BRST charges with the help of the Feigin–Odesskii algebra.[19] Assuming a cohomological property of the resulting complex, we write down integral expressions for the two-point local height probabilities (LHPs) and traces of general product of the VOs.

In the case of the dilute A_3 model, it is of some interest to see how Zamolodchikov's E_8 structure of scattering process[20] looks like that in the free field picture. What plays the role of the Zamolodchikov–Faddeev operator for creation/annihilation of bound states is the DVA current.[16] Specializing to $L=3$, we introduce eight kinds of DVA currents by suitably fusing the elementary current of $\mathcal{V}_{x,r}(A_2^{(2)})$. We then find a curious similarity between the operator product expansions of these currents and the so-called T-system of E_8 type for the transfer matrix.[21,22] At present we do not understand its proper meaning.

This paper is organized as follows. In Sec. II, we review the definition of the dilute A_L model and give a brief description of the vertex operator approach. In Sec. III, we give bosonization of the VOs. We derive the current for $\mathcal{V}_{x,r}(A_2^{(2)})$ from them and state a conjecture for the Kac determinant formula for $\mathcal{V}_{x,r}(A_2^{(2)})$. We also present a Felder-type BRST complex of the Fock spaces. Section IV is devoted to an application of the bosonization to the calculation of the LHP. In Sec. V, regarding the $\mathcal{V}_{x,r}(A_2^{(2)})$ current as the ZF operator for the particles in the A_3 model, we discuss a similarity between the T-system and the ''bootstrap'' of the ZF operators. Appendix A is a summary of the operator product expansion formulas for the elliptic currents and VOs. In Appendix B, we prove the nilpotency of the BRST charges. Appendix C is devoted to an exposition of the fusion properties of the deformed W currents for $A_{N-1}^{(1)}$, which should be compared with those for the DVA currents associated with the dilute A_3 model in Sec. V.

II. THE DILUTE A_L MODELS

A. Boltzmann weights

Throughout this paper we fix a positive integer $L\geqslant 3$. In the dilute A_L model, the local fluctuation variables $a,b,\ldots,$ take one of the L states $1,2,\ldots,L$, and those on neighboring lattice sites are subject to the condition $a-b=0,\pm 1$. The Boltzmann weights can be found in Ref. 2, Eq.

(3.1). For our purpose it is convenient to use the parametrization given in Appendix A of Ref. 2, which is suitable in the ''low-temperature'' regime. With some change of notation we recall the formula below.

Let $x=e^{-2\pi\lambda/\epsilon}$, $r=\pi/(2\lambda)$, and $u=-u_{\mathrm{orig}}/(2\lambda)$, where λ,ϵ are the variables used in Ref. 2 and u_{orig} stands for ''u'' there. We shall restrict ourselves to the ''regime 2^+'' defined by

$$0<x<1, \quad r=2\frac{L+1}{L+2}, \quad -\frac{3}{2}<u<0. \tag{2.1}$$

Along with the variable u, we often use the multiplicative variable

$$z=x^{2u}.$$

Changing an overall scalar factor we put the Boltzmann weights in the form

$$W\left(\begin{matrix} a & b \\ c & d \end{matrix}\middle| u\right)=\rho(u)\overline{W}\left(\begin{matrix} a & b \\ c & d \end{matrix}\middle| u\right),$$

where $\rho(u)$ will be specified in (2.4) below. To give the formula for the $\overline{W}$ factors, let us set

$$[u]=x^{u^2/r-u}\Theta_{x^{2r}}(x^{2u}), \quad [u]_+=x^{u^2/r-u}\Theta_{x^{2r}}(-x^{2u}), \tag{2.2}$$

where

$$\Theta_p(z)=(z;p)_\infty(pz^{-1};p)_\infty(p;p)_\infty,$$

$$(z;p_1,\ldots,p_k)_\infty=\prod_{n_1,\ldots,n_k=0}^{\infty}(1-p_1^{n_1}\cdots p_k^{n_k}z).$$

Then we have

$$\overline{W}\left(\begin{matrix} a\pm1 & a \\ a & a\mp1 \end{matrix}\middle| u\right)=1,$$

$$\overline{W}\left(\begin{matrix} a & a\pm1 \\ a & a\pm1 \end{matrix}\middle| u\right)=\overline{W}\left(\begin{matrix} a\pm1 & a\pm1 \\ a & a \end{matrix}\middle| u\right)=-\left(\frac{[\pm a+3/2]_+[\pm a-1/2]_+}{[\pm a+1/2]_+^2}\right)^{1/2}\frac{[u]}{[1+u]},$$

$$\overline{W}\left(\begin{matrix} a\pm1 & a \\ a & a \end{matrix}\middle| u\right)=\overline{W}\left(\begin{matrix} a & a \\ a & a\pm1 \end{matrix}\middle| u\right)=\frac{[\pm a+1/2+u]_+}{[\pm a+1/2]_+}\frac{[1]}{[1+u]},$$

$$\overline{W}\left(\begin{matrix} a & a\mp1 \\ a\pm1 & a \end{matrix}\middle| u\right)=(G_a^+G_a^-)^{1/2}\frac{[1/2+u]}{[3/2+u]}\frac{[u]}{[1+u]},$$

$$\overline{W}\left(\begin{matrix} a & a \\ a\pm1 & a \end{matrix}\middle| u\right)=\overline{W}\left(\begin{matrix} a & a\pm1 \\ a & a \end{matrix}\middle| u\right)=-(G_a^\pm)^{1/2}\frac{[\pm a-1-u]_+}{[\pm a+1/2]_+}\frac{[1]}{[1+u]}\frac{[u]}{[3/2+u]},$$

$$\overline{W}\left(\begin{matrix} a & a\pm1 \\ a\pm1 & a \end{matrix}\middle| u\right)=\frac{[\pm 2a+1-u]}{[\pm 2a+1]}\frac{[1]}{[1+u]}-G_a^\pm\frac{[\pm 2a-1/2-u]}{[\pm 2a+1]}\frac{[u]}{[3/2+u]}\frac{[1]}{[1+u]},$$

$$\overline{W}\left(\begin{matrix} a & a \\ a & a \end{matrix}\middle| u\right)=\frac{[3+u]}{[3]}\frac{[1]}{[1+u]}\frac{[3/2-u]}{[3/2+u]}+H_a\frac{[1]}{[3]}\frac{[u]}{[1+u]}.$$

Here

$$G_a^{\pm}=\frac{S(a\pm 1)}{S(a)},\quad S(a)=(-1)^a\frac{[2a]}{[a]_+},\quad H_a=G_a^{+}\frac{[a-5/2]_+}{[a+1/2]_+}+G_a^{-}\frac{[a+5/2]_+}{[a-1/2]_+}. \tag{2.3}$$

We choose $\rho(u)$ so that the partition function per site of the model equals 1. Explicitly it is given by[2]

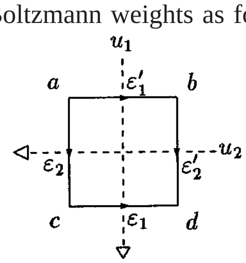
$$z^{(r-1)/r}\rho(u)=\frac{\rho_+(u)}{\rho_+(-u)},\quad \rho_+(u)=\frac{(x^2z,x^3z,x^{2r+3}z,x^{2r+4}z;x^6,x^{2r})_\infty}{(x^5z,x^6z,x^{2r}z,x^{2r+1}z;x^6,x^{2r})_\infty}, \tag{2.4}$$

where $z=x^{2u}$, and we have introduced the notation

$$(a_1,\ldots,a_n;p_1,\ldots,p_k)_\infty=\prod_{j=1}^{n}(a_j;p_1,\ldots,p_k)_\infty. \tag{2.5}$$

Graphically we represent the Boltzmann weights as follows:

$$W\begin{pmatrix}a & b\\ c & d\end{pmatrix}\!\!\left|u_1-u_2\right) =$$



$$b=a+\varepsilon_1',\quad c=a+\varepsilon_2,\quad d=b+\varepsilon_2'=c+\varepsilon_1.$$

For definiteness we list below the basic properties of the Boltzmann weights:
The Yang–Baxter equation

$$\sum_g W\left(\begin{matrix}a & b\\ g & c\end{matrix}\middle| u\right)W\left(\begin{matrix}a & g\\ f & e\end{matrix}\middle| v\right)W\left(\begin{matrix}g & c\\ e & d\end{matrix}\middle| u+v\right)=\sum_g W\left(\begin{matrix}a & b\\ f & g\end{matrix}\middle| u+v\right)W\left(\begin{matrix}b & c\\ g & d\end{matrix}\middle| v\right)W\left(\begin{matrix}f & g\\ e & d\end{matrix}\middle| u\right);$$

unitarity

$$\sum_g W\left(\begin{matrix}a & b\\ g & c\end{matrix}\middle| u\right)W\left(\begin{matrix}a & g\\ d & c\end{matrix}\middle| -u\right)=\delta_{bd};$$

crossing symmetry

$$W\left(\begin{matrix}b & d\\ a & c\end{matrix}\middle| -\frac{3}{2}-u\right)=\sqrt{\frac{S(a)S(d)}{S(b)S(c)}}\,W\left(\begin{matrix}a & b\\ c & d\end{matrix}\middle| u\right);$$

and initial condition

$$W\left(\begin{matrix}a & b\\ c & d\end{matrix}\middle| 0\right)=\delta_{bc}.$$

B. Vertex operators

Hereafter we assume that L is odd. The model has ground states labeled by odd integers $l=1,3,\ldots,L-2$.[2] They are characterized as configurations in which all heights take the same value b. If $L=4m\pm 1$, then the possible values are $b=l\,(1\leqslant l\leqslant 2m-1, l\text{: odd})$ or $b=l+1\,(2m+1\leqslant l\leqslant L-2, l\text{: odd})$.

Consider the corner transfer matrices $A(z),B(z),C(z),D(z)$ corresponding to the NW, SW, SE, and NE quadrants, respectively. In the infinite volume limit, we have

$$C(z)=A(z)=z^{-\mathcal{H}},\quad B(z)=D(z)=\sqrt{S(k)}x^{3\mathcal{H}}z^{\mathcal{H}},$$

with k denoting the value of the central height. The operator $\mathcal{H}$ (the corner Hamiltonian) is independent of z. We denote by $\mathcal{L}_{l,k}$ the space of eigenstates of $\mathcal{H}$ in the sector where the central height is fixed to k and the boundary heights are in the ground state l. It was found in Ref. 2 that the generating function of the spectrum of $\mathcal{H}$ coincides with the character of the Virasoro minimal unitary series. Namely,

$$\mathrm{tr}_{\mathcal{L}_{l,k}}(q^{\mathcal{H}})=\chi_{l,k}(q), \tag{2.6}$$

where

$$\chi_{l,k}(q)=\frac{q^{\Delta_{l,k}-c/24}}{(q;q)_\infty}\sum_{j\in\mathbb{Z}}(q^{L(L+1)j^2+((L+1)l-Lk)j}-q^{L(L+1)j^2+((L+1)l+Lk)j+lk}),$$

$$c=1-\frac{6}{L(L+1)},\quad \Delta_{l,k}=\frac{((L+1)l-Lk)^2-1}{4L(L+1)}.$$

Consider next the half-infinite transfer matrix extending to infinity in the north. We denote it by

$$\Phi^{(k,k+\epsilon)}(z):\mathcal{L}_{l,k+\epsilon}\to\mathcal{L}_{l,k}\quad(\epsilon=0,\pm1).$$

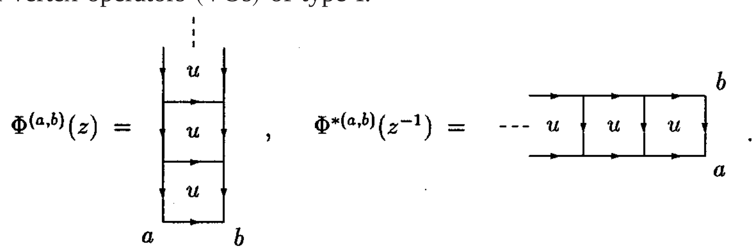
Likewise we denote by

$$\Phi^{*(k+\epsilon,k)}(z^{-1}):\mathcal{L}_{l,k}\to\mathcal{L}_{l,k+\epsilon}\quad(\epsilon=0,\pm1)$$

the half-infinite transfer matrix extending to infinity in the west. We shall also write

$$\Phi^{(k,k+\epsilon)}(z)=\Phi_\epsilon(z),\quad \Phi^{*(k+\epsilon,k)}(z)=\Phi^*_\epsilon(z),$$

and call them vertex operators (VOs) of type I.



Intuitive graphical arguments based on the properties of the Boltzmann weights lead to the following formulas. For details we refer the reader to Refs. 23 and 4,

$$\Phi^{(a,c)}(z_2)\Phi^{(c,d)}(z_1)=\sum_g W\left(\begin{matrix}a & g\\ c & d\end{matrix}\middle| u_1-u_2\right)\Phi^{(a,g)}(z_1)\Phi^{(g,d)}(z_2)\quad(z_j=x^{2u_j}),$$

$$w^{\mathcal{H}}\Phi^{(a,b)}(z)w^{-\mathcal{H}}=\Phi^{(a,b)}(wz),\quad \Phi^{*(b,a)}(z)=\sqrt{\frac{S(a)}{S(b)}}\Phi^{(b,a)}(x^{-3}z),$$

$$\sum_g \Phi^{*(a,g)}(z)\Phi^{(g,a)}(z)=1,\quad \Phi^{(a,b)}(z)\Phi^{*(b,c)}(z)=\delta_{ac}.$$

As explained in Ref. 5, multipoint local height probabilities are expressed as traces of VOs. Consider neighboring $n+1$ lattice sites in a row. Let $P_l(a_0,\ldots,a_n)$ denote the probability of finding these local variables to be $(a_0,\ldots,a_n)$. Then we have

$$P_l(a_0,\ldots,a_n)=Z_l^{-1}S(a_n)\mathrm{tr}_{\mathcal{L}_{l,a_n}}(x^{6\mathcal{H}}\Phi^{*(a_n,a_{n-1})}(z)\cdots\Phi^{*(a_1,a_0)}(z)\Phi^{(a_0,a_1)}(z)\cdots\Phi^{(a_{n-1},a_n)}(z)). \tag{2.7}$$

Here the nomalization factor Z_l is

$$Z_l=\sum_{k=1}^{L} S(k)\chi_{l,k}(x^6),$$

which can be expressed in product of theta functions with conjugate modulus.[2] In the simplest case $n=0$, the one-point function $P_l(k)$ is given by $P_l(k)=Z_l^{-1}S(k)\chi_{l,k}(x^6)$.

Remark: We follow mostly the notation of Ref. 9 but there are minor changes. The $\Phi(\zeta^{-1})$ in Ref. 9 corresponds to $\Phi(z)$ in the present notation. We have also reversed the orientation of edges of the Boltzmann weights.

III. BOSONIZATION OF VERTEX OPERATORS

A. Bosons

In this section we present a bosonic realization of vertex operators. The working closely follows Refs. 4 and 9. We set

$$[n]_x=\frac{x^n-x^{-n}}{x-x^{-1}},$$

and introduce the oscillators α_n $(n\neq 0)$ and P,Q satisfying the commutation relations

$$\begin{gathered}[\alpha_n,\alpha_m]=\frac{[n]_x([2n]_x-[n]_x)}{n}\frac{[rn]_x}{[(r-1)n]_x}\delta_{n+m,0},\\ [P,iQ]=1.\end{gathered} \tag{3.1}$$

Notice that $[2n]_x-[n]_x=[3n]_x[n/2]_x/[3n/2]_x$. We shall also use

$$\alpha_n'=(-1)^n\frac{[(r-1)n]_x}{[rn]_x}\alpha_n.$$

We denote by

$$\mathcal{F}_{l,k}=\mathbb{C}[\alpha_{-1},\alpha_{-2},\ldots]|l,k\rangle$$

the Fock space generated by

$$|l,k\rangle=e^{p_{l,k}iQ}|0,0\rangle,\quad P|l,k\rangle=p_{l,k}|l,k\rangle,$$

where $p_{l,k}$ is

$$p_{l,k}=-\frac{l}{2}\sqrt{\frac{r}{r-1}}+k\sqrt{\frac{r-1}{r}}=-l\sqrt{\frac{L+1}{2L}}+k\sqrt{\frac{L}{2(L+1)}}. \tag{3.2}$$

[Recall that $r=2(L+1)/(L+2)$.] These Fock spaces are graded by

$$d=\sum_{n=1}^{\infty}\frac{n^2}{[n]_x([2n]_x-[n]_x)}\frac{[(r-1)n]_x}{[rn]_x}\alpha_{-n}\alpha_n+\frac{1}{2}P^2-\frac{1}{24},$$

which satisfies $[d,\alpha_n]=-n\alpha_n$, $[d,iQ]=P$ and $d|l,k\rangle=(\Delta_{l,k}-c/24)|l,k\rangle$. For later use, we define the operators $\hat{l},\hat{k}:\mathcal{F}_{l,k}\to\mathcal{F}_{l,k}$ by

$$\hat{l}|_{\mathcal{F}_{l,k}}=l\times\mathrm{id}_{\mathcal{F}_{l,k}},\quad \hat{k}|_{\mathcal{F}_{l,k}}=k\times\mathrm{id}_{\mathcal{F}_{l,k}}.$$

B. Vertex operators

In Refs. 10 and 11, a bosonic realization of the level-one representation of the quantum affine algebra $U_q(A_2^{(2)})$ and associated vertex operators have been obtained. We shall consider their elliptic counterparts.

The elliptic version of the Drinfeld currents are constructed from the trigonometric ones by a ‘‘dressing’’ procedure described in Ref. 8. Applying it to the present case of $U_q(A_2^{(2)})$, we obtain

$$x_+(z):\mathcal{F}_{l,k}\to\mathcal{F}_{l-2,k},\quad x_-(z):\mathcal{F}_{l,k}\to\mathcal{F}_{l,k-1},$$

$$x_+(z)=:\exp\left(-\sum_{n\neq 0}\frac{\alpha_n}{[n]_x}z^{-n}\right):\times e^{\left(\sqrt{\frac{r}{r-1}}iQz^{\sqrt{\frac{r}{r-1}}P+\frac{r}{2(r-1)}}\right)},\tag{3.3}$$

$$x_-(z)=:\exp\left(\sum_{n\neq 0}\frac{\alpha'_n}{[n]_x}z^{-n}\right):\times e^{\left(-\sqrt{\frac{r-1}{r}}iQz^{-\sqrt{\frac{r-1}{r}}P+\frac{r-1}{2r}}\right)}.\tag{3.4}$$

The elliptic version of VOs (of type I and type II) are defined in terms of their trigonometric ones and a ‘‘twistor’’ given by an infinite product of the universal R matrix.[24] They satisfy the commutation relations of the type (3.11)–(3.13) in Sec. III C. As we do not know how to evaluate the twistor in the bosonic realization, we have solved relations (3.11)–(3.13) directly for $\Phi_\epsilon(z),\Psi^*_\epsilon(z)$. We obtain the following.

Type I:

$$\Phi_\epsilon(z):\mathcal{F}_{l,k}\to\mathcal{F}_{l,k-\epsilon},$$

$$\Phi_-(z)=:\exp\left(-\sum_{n\neq 0}\frac{\alpha'_n}{[2n]_x-[n]_x}z^{-n}\right):\times e^{\left(\sqrt{\frac{r-1}{r}}iQz^{\sqrt{\frac{r-1}{r}}P+\frac{r-1}{2r}}\right)},\tag{3.5}$$

$$\Phi_0(z)=x^{(1-r)/2r}\oint_{C_0}\underline{dz_1}\Phi_-(z)x_-(z_1)\frac{1}{\sqrt{[\hat{k}+1/2]_+[\hat{k}-1/2]_+}}\frac{[u-u_1+\hat{k}]_+}{[u-u_1+1/2]},\tag{3.6}$$

$$\Phi_+(z)=x^{(1-r)/r}\oint\oint_{C_+}\underline{dz_1}\underline{dz_2}\Phi_-(z)x_-(z_1)x_-(z_2)$$
$$\times\sqrt{\frac{S(\hat{k}-1)}{S(\hat{k})}}\frac{1}{[\hat{k}-1/2]_+[2\hat{k}-2]}\frac{[u-u_1+2\hat{k}-3/2]}{[u-u_1+1/2]}\frac{[u_1-u_2+\hat{k}]_+}{[u_1-u_2+1/2]}.\tag{3.7}$$

Type II:

$$\Psi^*_\epsilon(z):\mathcal{F}_{l,k}\to\mathcal{F}_{l-2\epsilon,k},$$

$$\Psi_-^*(z) = :\exp\left(\sum_{n\neq 0} \frac{\alpha_n}{[2n]_x - [n]_x} z^{-n}\right): \times e^{\left(-\sqrt{\frac{r}{r-1}} iQz - \sqrt{\frac{r}{r-1}} P + \frac{r}{2(r-1)}\right)}, \tag{3.8}$$

$$\Psi_0^*(z) = ix^{r/2(r-1)} \oint_{C_0^*} \underline{dz_1} \Psi_-^*(z) x_+(z_1) \frac{1}{\sqrt{[(\hat{l}+1)/2]_+^* [(\hat{l}-1)/2]_+^*}} \frac{[u-u_1-\hat{l}/2]_+^*}{[u-u_1-1/2]^*}, \tag{3.9}$$

$$\Psi_+^*(z) = x^{r/(r-1)} \oint \oint_{C_+^*} \underline{dz_1} \underline{dz_2} \Psi_-^*(z) x_+(z_1) x_+(z_2)$$
$$\times \sqrt{\frac{S^*(\hat{l}/2-1)}{S^*(\hat{l}/2)}} \frac{1}{[(\hat{l}-1)/2]_+^* [\hat{l}-2]^*} \frac{[u-u_1-\hat{l}+3/2]^*}{[u-u_1-1/2]^*} \frac{[u_1-u_2-\hat{l}/2]_+^*}{[u_1-u_2-1/2]^*}. \tag{3.10}$$

Here $z = x^{2u}$, $z_j = x^{2u_j}$, $\underline{dz_j} = dz_j/(2\pi i z_j)$ and

$$[u]^* = x^{u^2/(r-1)-u} \Theta_{x^{2r-2}}(x^{2u}), \quad [u]_+^* = x^{u^2/(r-1)-u} \Theta_{x^{2r-2}}(-x^{2u}), \quad S^*(a) = (-1)^a \frac{[2a]^*}{[a]_+^*}.$$

The poles of the integrand of (3.6)–(3.10) and the integration contours are listed in the following table ($n = 0,1,2,...$). For example, C_0 is a simple closed contour that encircles $x^{1+2rn}z$ $(n \geqslant 0)$ but not $x^{-1-2rn}z$ $(n \geqslant 0)$.

	Inside	Outside
C_0	$z_1 = x^{1+2rn}z$	$z_1 = x^{-1-2rn}z$
C_+	$z_1 = x^{1+2rn}z$	$z_1 = x^{-1-2rn}z$
	$z_2 = x^{1+2rn}z_1$	$z_2 = x^{-1-2rn}z, x^{-1-2rn}z_1, x^{2-2r(n+1)}z_1$
C_0^*	$z_1 = x^{-1+2(r-1)n}z$	$z_1 = x^{1-2(r-1)n}z$
C_+^*	$z_1 = x^{-1+2(r-1)n}z$	$z_1 = x^{1-2(r-1)n}z$
	$z_2 = x^{-1+2(r-1)n}z_1$	$z_2 = x^{1-2(r-1)n}z, x^{1-2(r-1)n}z_1, x^{-2-2(r-1)(n+1)}z_1$

C. Commutation relations and inversion identities

The VOs given above satisfy the following commutation relations:

$$\Phi_{\epsilon_2}(z_2)\Phi_{\epsilon_1}(z_1) = \sum_{\substack{\epsilon_1', \epsilon_2' \\ \epsilon_1'+\epsilon_2' = \epsilon_1+\epsilon_2}} W\left(\begin{matrix} \hat{k} & \hat{k}+\epsilon_1' \\ \hat{k}+\epsilon_2 & \hat{k}+\epsilon_1+\epsilon_2 \end{matrix} \middle| u_1 - u_2\right) \Phi_{\epsilon_1'}(z_1)\Phi_{\epsilon_2'}(z_2), \tag{3.11}$$

$$\Psi_{\epsilon_1}^*(z_1)\Psi_{\epsilon_2}^*(z_2) = \sum_{\substack{\epsilon_1', \epsilon_2' \\ \epsilon_1'+\epsilon_2' = \epsilon_1+\epsilon_2}} W^*\left(\begin{matrix} \hat{l}/2 & \hat{l}/2+\epsilon_1 \\ \hat{l}/2+\epsilon_2' & \hat{l}/2+\epsilon_1+\epsilon_2 \end{matrix} \middle| u_1 - u_2\right) \Psi_{\epsilon_2'}^*(z_2)\Psi_{\epsilon_1'}^*(z_1), \tag{3.12}$$

$$\Phi_{\epsilon_2}(z_2)\Psi_{\epsilon_1}^*(z_1) = \tau(u_1-u_2)\Psi_{\epsilon_1}^*(z_1)\Phi_{\epsilon_2}(z_2). \tag{3.13}$$

Here we have set (for $z = x^{2u}$)

$$W^*\left(\begin{matrix} a & b \\ c & d \end{matrix}\middle| u\right) = \overline{W}\left(\begin{matrix} a & b \\ c & d \end{matrix}\middle| u\right)\Bigg|_{r\to r-1} \times \rho^*(u), \tag{3.14}$$

$$z^{-r/(r-1)}\rho^*(u) = \frac{\rho_+^*(u)}{\rho_+^*(-u)}, \quad \rho_+^*(u) = \frac{(x^3z,x^4z,x^{2r}z,x^{2r+1}z;x^6,x^{2r-2})_\infty}{(z,xz,x^{2r+3}z,x^{2r+4}z;x^6,x^{2r-2})_\infty}, \tag{3.15}$$

$$\tau(u) = z\,\frac{\Theta_{x^6}(-xz^{-1})\Theta_{x^6}(-x^2z^{-1})}{\Theta_{x^6}(-xz)\Theta_{x^6}(-x^2z)}. \tag{3.16}$$

Note that

$$\rho^*(u) = -\rho(u)|_{r\to r-1} \times z\,\frac{\Theta_{x^6}(xz^{-1})\Theta_{x^6}(x^2z^{-1})}{\Theta_{x^6}(xz)\Theta_{x^6}(x^2z)}.$$

We do not present the tedious but straightforward verification of (3.11)–(3.13).

For the description of correlation functions we need also the ''dual'' VOs. Define

$$\Phi_\epsilon^*(z) = g\sqrt{S(\hat{k})}^{-1}\Phi_{-\epsilon}(x^{-3}z)\sqrt{S(\hat{k})}, \tag{3.17}$$

$$\Psi_\epsilon(z) = g^{*-1}\sqrt{S^*(\hat{l}/2)}\Psi_{-\epsilon}^*(x^{-3}z)\sqrt{S^*(\hat{l}/2)}^{-1}, \tag{3.18}$$

where

$$g^{-1} = \frac{(x;x^{2r})_\infty}{(x^2;x^{2r})_\infty^2(x^{2r-1};x^{2r})_\infty(x^{2r};x^{2r})_\infty^4}\,\frac{(x^5,x^6,x^{2r},x^{2r+1};x^6,x^{2r})_\infty}{(x^2,x^3,x^{2r+3},x^{2r+4};x^6,x^{2r})_\infty},$$

$$g^* = \frac{(x^{-1};x^{2r-2})_\infty}{(x^{-2};x^{2r-2})_\infty^2(x^{2r-1};x^{2r-2})_\infty(x^{2r-2};x^{2r-2})_\infty^5}\,\frac{(x^3,x^4,x^{2r},x^{2r+1};x^6,x^{2r-2})_\infty}{(x,x^6,x^{2r+3},x^{2r+4};x^6,x^{2r-2})_\infty}.$$

Then we have

$$\Phi_{\epsilon_2}(z)\Phi_{\epsilon_1}^*(z) = \delta_{\epsilon_1,\epsilon_2}\times \mathrm{id}, \quad \Psi_{\epsilon_1}(z_1)\Psi_{\epsilon_2}^*(z_2) = \frac{\delta_{\epsilon_1,\epsilon_2}}{1-z_1/z_2} + \cdots \quad (z_1\to z_2), \tag{3.19}$$

$$\sum_\epsilon \Phi_\epsilon^*(z)\Phi_\epsilon(z) = \mathrm{id}, \quad \sum_\epsilon \Psi_\epsilon^*(z_2)\Psi_\epsilon(z_1) = \frac{1}{1-z_1/z_2} + \cdots \quad (z_1\to z_2). \tag{3.20}$$

D. Deformed Virasoro algebra

Brazhnikov and Lukyanov[13] pointed out that one can associate to the algebra $A_2^{(2)}$ a deformed Virasoro algebra (DVA) which is different from the one found in Ref. 6. The original DVA of Ref. 6, associated with $A_1^{(1)}$, arises also as a ''fusion'' of VOs.[16] Let us discuss this point in the present case of $A_2^{(2)}$.

Let

$$\Lambda_\pm(z) = :\exp\left(\pm\sum_{n\neq 0}\lambda_n(x^{\pm 3/2}z)^{-n}\right):\times x^{\pm 2\sqrt{r(r-1)}P},$$

$$\Lambda_0(z) = -\frac{[r-1/2]_x}{[1/2]_x}:\exp\left(\sum_{n\neq 0}\lambda_n(x^{-n/2}-x^{n/2})z^{-n}\right):, \tag{3.21}$$

$$T(z) = \Lambda_+(z) + \Lambda_0(z) + \Lambda_-(z),$$

where

$$\lambda_n=(-1)^n(x-x^{-1})\frac{[(r-1)n]_x}{[2n]_x-[n]_x}\alpha_n=(x-x^{-1})\frac{[rn]_x}{[2n]_x-[n]_x}\alpha'_n,$$

$$[\lambda_n,\lambda_m]=(x-x^{-1})^2\frac{1}{n}\frac{[n]_x[rn]_x[(r-1)n]_x}{[2n]_x-[n]_x}\delta_{m+n,0}.$$

Then $T(z)$ is obtained from VOs by fusing them,

$$\Phi_{\epsilon_2}(x^{r+3/2}z')\Phi^*_{\epsilon_1}(x^{-r+3/2}z)=\left(1-\frac{z}{z'}\right)(-1)^{\epsilon_1+1}\delta_{\epsilon_1,\epsilon_2}T(z)\cdot x^{1-r}\frac{(x,x^6,x^{5-2r},x^{6-2r};x^6)_\infty}{(x^3,x^4,x^{2-2r},x^{3-2r};x^6)_\infty}+\cdots\quad(z'\to z). \tag{3.22}$$

The $T(z)$ satisfies the DVA of Ref. 13

$$\begin{aligned}&f\left(\frac{z_2}{z_1}\right)T(z_1)T(z_2)-f\left(\frac{z_1}{z_2}\right)T(z_2)T(z_1)\\&=(x-x^{-1})\frac{[r+1/2]_x[r]_x[r-1]_x[r-3/2]_x}{[1/2]_x[3/2]_x}\left(\delta\left(x^3\frac{z_2}{z_1}\right)-\delta\left(x^{-3}\frac{z_2}{z_1}\right)\right)\\&\quad+(x-x^{-1})\frac{[r]_x[r-1/2]_x[r-1]_x}{[1/2]_x}\left(\delta\left(x^2\frac{z_2}{z_1}\right)T(xz_2)-\delta\left(x^{-2}\frac{z_2}{z_1}\right)T(x^{-1}z_2)\right),\end{aligned} \tag{3.23}$$

where $f(z)$ is

$$\begin{aligned}f(z)&=\exp\left(-\sum_{n>0}(x-x^{-1})^2\frac{1}{n}\frac{[n]_x[rn]_x[(r-1)n]_x}{[2n]_x-[n]_x}z^n\right)\\&=\frac{1}{1-z}\frac{(x^{2-2r}z,x^{3-2r}z,x^4z,x^5z,x^{2r}z,x^{2r+1}z;x^6)_\infty}{(x^{5-2r}z,x^{6-2r}z,xz,x^2z,x^{2r+3}z,x^{2r+4}z;x^6)_\infty}.\end{aligned} \tag{3.24}$$

The notation of Ref. 13 is related to ours by $x_{\mathrm{BL}}=x^{3/2}$, $b/Q=r$, $1/(Qb)=1-r$, $g(z)=f(z)$, $\mathbf{V}(z)=T(z)$. In what follows we call this algebra $\mathcal{V}_{x,r}(A_2^{(2)})$. The relation (3.23) is invariant under

$$r\mapsto 1-r,\quad x\mapsto x,\quad T(z)\mapsto -T(z). \tag{3.25}$$

We remark that $\tilde{T}(z)=-\Lambda_+(z)+\Lambda_0(z)-\Lambda_-(z)$ also satisfies (3.23), which is obtained from type II VOs,

$$\Psi_{\epsilon_1}(x^{r-1+3/2}z')\Psi^*_{\epsilon_2}(x^{-(r-1)+3/2}z)=\frac{1}{1-z'/z}(-1)^{\epsilon_1+1}\delta_{\epsilon_1,\epsilon_2}\tilde{T}(-z)\times(-x^{-r})\frac{(x^2,x^3,x^{5-2r},x^{6-2r};x^6)_\infty}{(x^5,x^6,x^{2-2r},x^{3-2r};x^6)_\infty}+\cdots\quad(z'\to z).$$

Let us discuss some features of $\mathcal{V}_{x,r}(A_2^{(2)})$.

Conformal limit: In the conformal limit ($x=e^{\hbar}\to 1,r$: fixed), (3.23) admits two limits[13] related by (3.25),

$$T(z)=3-2r+\hbar^2(8r(r-1)z^2L(z)+\tfrac{1}{6}r(r-1)(1-2r)+(2-r)^2)+O(\hbar^4), \tag{3.26}$$

$$T(z)=-1-2r+\hbar^2(-8r(r-1)z^2\tilde{L}(z)+\tfrac{1}{6}r(r-1)(1-2r)-(1+r)^2)+O(\hbar^4), \tag{3.27}$$

where $L(z),\tilde{L}(z)$ are the Virasoro currents with the central charges $c,\tilde{c}$, respectively,

$$c=1-\frac{3(2-r)^2}{r(r-1)}=1-\frac{6}{L(L+1)},\quad \tilde{c}=1-\frac{3(1+r)^2}{r(r-1)}.$$

In the free boson realization (3.21), $T(z)$ and $\tilde{T}(z)$ have ''natural'' expansions (3.26) and (3.27), respectively, by the following identification:

$$\lambda_n=2\hbar\sqrt{r(r-1)}\sqrt{\frac{x^{rn}-x^{-rn}}{2\hbar rn}\frac{x^{(r-1)n}-x^{-(r-1)n}}{2\hbar(r-1)n}\frac{1}{x^n-1+x^{-n}}}a_n,$$

$$P=a_0-\frac{2-r}{2\sqrt{r(r-1)}}=\tilde{a}_0-\frac{r+1}{2\sqrt{r(r-1)}},$$

$$L(z)=:\frac{1}{2}(\partial\phi(z))^2:+\frac{2-r}{2\sqrt{r(r-1)}}\partial^2\phi(z),$$

$$\tilde{L}(z)=:\frac{1}{2}(\partial\tilde{\phi}(z))^2:+\frac{r+1}{2\sqrt{r(r-1)}}\partial^2\tilde{\phi}(z),$$

where $[a_n,a_m]=n\delta_{n+m,0}$, $\partial\phi(z)=\Sigma_{n\in\mathbb{Z}}a_nz^{-n-1}$ and $\partial\tilde{\phi}(z)=\partial\phi(z)|_{a_0\to\tilde{a}_0}$. On the other hand, $T(z)$ has an expansion of the form (3.27) with

$$P=\tilde{a}_0-\frac{r+1}{2\sqrt{r(r-1)}}+\frac{i\pi(2n+1)}{2\hbar\sqrt{r(r-1)}}\quad(n\in\mathbb{Z}).$$

Kac determinant: Let $T(z)=\Sigma_{n\in\mathbb{Z}}T_nz^{-n}$, and let $U_\pm$ be the algebra generated by $\{T_n\}_{\pm n>0}$. As usual, the Verma module of highest weight $\lambda\in\mathbb{C}$ is defined as the free left U_--module generated by a vector $|\lambda\rangle$ such that $T_n|\lambda\rangle=0$ $(n>0)$ and $T_0|\lambda\rangle=\lambda|\lambda\rangle$. Likewise the right Verma module is defined by $\langle\lambda|T_n=0$ $(n<0)$, $\langle\lambda|T_0=\lambda\langle\lambda|$, and $\langle\lambda|\lambda\rangle=1$. At level N there are $p(N)$ (the number of partition) independent states, $T_{-n_1}T_{-n_2}\cdots T_{-n_l}|\lambda\rangle$ $(n_1\geqslant n_2\geqslant\cdots\geqslant n_l>0,\ \Sigma_{i=1}^l n_i=N)$. Let us number these states by the reverse lexicographic ordering for $(n_1,n_2,\ldots,n_l)$, i.e., $|\lambda;N,1\rangle=T_{-N}|\lambda\rangle$, $|\lambda;N,2\rangle=T_{-N+1}T_{-1}|\lambda\rangle,\ldots,|\lambda;N,p(N)\rangle=T_{-1}^N|\lambda\rangle$. Similarly we define $\langle\lambda;N,1|=\langle\lambda|T_N$, $\langle\lambda;N,2|=\langle\lambda|T_1T_{N-1},\ldots,\langle\lambda;N,p(N)|=\langle\lambda|T_1^N$.

We conjecture that the Kac determinant at level N is given by

$$\det(\langle\lambda;N,i|\lambda;N,j\rangle)_{1\leqslant i,j\leqslant p(N)}=\prod_{\substack{l,k\geqslant1\\lk\leqslant N}}\left((\lambda-\lambda_{l,k})(\lambda-\tilde{\lambda}_{l,k})\times\frac{(x^{rl}-x^{-rl})(x^{(r-1)l}-x^{-(r-1)l})}{x^l-1+x^{-l}}\right)^{p(N-lk)},\tag{3.28}$$

where

$$\lambda_{l,k}=x^{-lr+2k(r-1)}+x^{lr-2k(r-1)}-\frac{[r-1/2]_x}{[1/2]_x},$$

$$\tilde{\lambda}_{l,k}=-x^{l(r-1)-2kr}-x^{-l(r-1)+2kr}-\frac{[r-1/2]_x}{[1/2]_x}.$$

We remark that in the free boson realization $T_0|l,k\rangle=\lambda_{l,k}|l,k\rangle$ and $T_0 e^{\alpha iQ}|2k,l/2\rangle =\tilde{\lambda}_{l,k}e^{\alpha iQ}|2k,l/2\rangle$, where

$$\alpha=\frac{i\pi(2n+1)}{2\hbar\sqrt{r(r-1)}}\quad (n\in\mathbb{Z}).$$

E. Felder complex

The Fock spaces $\mathcal{F}_{l,k}$ themselves do not give a bosonic realization of the space of states $\mathcal{L}_{l,k}$ of the corner Hamiltonian. For this we need a cohomological construction using an analog of the Felder complex:[25]

$$\cdots \xrightarrow{X_{-2}} \mathcal{F}_{2L-l,k} \xrightarrow{X_{-1}} \mathcal{F}_{l,k} \xrightarrow{X_0} \mathcal{F}_{-l,k} \xrightarrow{X_1} \mathcal{F}_{l-2L,k} \xrightarrow{X_2} \cdots, \tag{3.29}$$

$$X_j X_{j-1}=0.$$

In the case of the algebra $A_1^{(1)}$, Lukyanov and Pugai constructed the coboundary map X_j as a power of a single operator (Ref. 4, see also Ref. 26). In our case, the formula for X_j is a little more involved.

Set

$$Q_1=\oint_{|z|=1}\underline{dz}\, x_+(z)\frac{[u+\hat{l}/2]^*}{[u+1/2]^*},$$

$$Q_2^{(a)}=\oint\oint_{|z_1|=|z_2|=1}\underline{dz_1}\,\underline{dz_2}\, x_+(z_1)x_+(z_2)\frac{1}{[u_1+1/2]^*[u_2+1/2]^*}$$
$$\times\frac{[u_1-u_2]^*}{[u_1-u_2+1]^*[u_1-u_2-1/2]^*} f_2^{(a)}(u_1+\hat{l}/2,u_2+\hat{l}/2),$$

where

$$f_2^{(a)}(u_1,u_2)=[2a+1]^*[a-1/2]^*[u_1-a]^*[u_2+a-1]^*[u_1-u_2+a-1/2]^*$$
$$-[2a-1]^*[a+1/2]^*[u_1+a]^*[u_2-a-1]^*[u_1-u_2-a-1/2]^*.$$

These operators are mutually commutative (see Lemma B1). We define ''BRST charges'' Q_l $(1\le l\le L-1)$ as follows:

$$Q_l=\begin{cases} Q_1 Q_2^{(1)}\cdots Q_2^{(m)} & (l=2m+1)\\ Q_2^{((L+1)/2-m)}\cdots Q_2^{((L-3)/2)}Q_2^{((L-1)/2)} & (l=2m)\end{cases}.$$

Note that $Q_L=Q_l Q_{L-l}$.

We prove the following propositions in Appendix B (Propositions B2 and B3).

Proposition 3.1: Suppose l' is odd and $l'\equiv l \bmod L$ $(1\le l\le L-1)$. On the space $\mathcal{F}_{l',k}$, Q_l is expressed as

$$Q_l=\oint\cdots\oint_{|z_1|=\cdots=|z_l|=R}\underline{dz_1}\cdots\underline{dz_l}\, x_+(z_1)\cdots x_+(z_l)H_l(u_1,\ldots,u_l), \tag{3.30}$$

$$H_l(u_1,\ldots,u_l)=\pm\overline{h_l}(u_1,\ldots,u_l)\prod_{1\le i<j\le l}\frac{[u_i-u_j]^*}{[u_i-u_j+1]^*[u_i-u_j-1/2]^*}, \tag{3.31}$$

where $\overline{h_l}(u_1,\ldots,u_l)$ *is holomorphic, symmetric and satisfies* $\overline{h_l}(u_1+v,\ldots,u_l+v)=\overline{h_l}(u_1,\ldots,u_l)$. *We have*

$$H_l(u_1+r-1,...,u_l)=H_l(u_1,\ldots,u_l), \tag{3.32}$$

$$H_l(u_1+\tau,\ldots,u_l)=H_l(u_1,\ldots,u_l)e^{-\pi i(l-1)/(r-1)}, \tag{3.33}$$

where $\tau=\pi i/\log x$.

Hence (3.30) does not depend on $R>0$.

Proposition 3.2: Under the same condition as above, we have

$$Q_l Q_{L-l}=0 \quad (1\leqslant l\leqslant L-1).$$

Let us call $C_{l,k}$ the cochain complex (3.29) defined by

$$X_{2j}=Q_l: \quad \mathcal{F}_{l-2jL,k}\rightarrow\mathcal{F}_{-l-2jL,k},$$

$$X_{2j+1}=Q_{L-l}: \quad \mathcal{F}_{-l-2jL,k}\rightarrow\mathcal{F}_{l-2(j+1)L,k}.$$

In the conformal limit where $x\rightarrow 1$ and $z=x^{2u}$ are kept fixed, this complex formally tends to Felder's complex[25] for the minimal unitary series. In view of this, it is natural to expect that

$$H^j(C_{l,k})=\mathrm{Ker}\,X_j/\mathrm{Im}\,X_{j-1}=0 \quad (j\neq 0). \tag{3.34}$$

By the Euler–Poincaré principle, the 0th cohomology $H^0(C_{l,k})$ then has the same character as the space of states $\mathcal{L}_{l,k}$ [see (2.6)],

$$\mathrm{tr}_{H^0(C_{l,k})}(q^d)=\mathrm{tr}_{\mathcal{L}_{l,k}}(q^{\mathcal{H}}).$$

Henceforth we assume (3.34) and make an identification

$$H^0(C_{l,k})=\mathcal{L}_{l,k}, \quad d=\mathcal{H}.$$

Proposition 3.3: Under the same assumption as in Proposition 3.1, we have on $\mathcal{F}_{l',k}$

$$[\Phi_\epsilon(z),Q_l]=0 \quad (\epsilon=0,\pm), \tag{3.35}$$

$$[T(z),Q_l]=0. \tag{3.36}$$

Proof: (3.36) is a consequence of (3.35) and (3.22). Let us show

$$\Phi_-(z)Q_l=Q_l\Phi_-(z).$$

The left (respectively, right) hand side is well defined if we choose $R\ll 1$ (respectively, $R\gg 1$) in (3.30). As meromorphic functions we have $\Phi_-(z)x_+(z_j)=x_+(z_j)\Phi_-(z)$, and the product has no poles. Since Q_l does not depend on R, the conclusion follows.

Next let us prove (3.35) with $\epsilon=0$. The case $\epsilon=+$ can be shown similarly. Dropping irrelevant constants we consider

$$\Phi_0'(z)=\oint_{C_0}\underline{dz'}\,\Phi_-(z)x_-(z')\frac{[u-u'+\hat{k}]_+}{[u-u'+1/2]}.$$

As meromorphic functions we have

$$x_-(z)x_+(z')=x_+(z')x_-(z)=\frac{z+z'}{(z+xz')(z+x^{-1}z')}:x_-(z)x_+(z'):.$$

We use the expression (3.30) with $x^2|z|<R<x^{-2}|z|$. Taking into account the symmetry in the integration variables $z_1,\ldots,z_l$, we obtain

$$[\Phi_0'(z),Q_l]=l\oint\cdots\oint_{|z_1|=\cdots=|z_l|=R}\underline{dz_1}\cdots\underline{dz_l}H_l(u_1,\ldots,u_l)(\mathrm{res}_{z'=-xz_1}+\mathrm{res}_{z'=-x^{-1}z_1})\Phi_-(z)x_-(z')x_+(z_1)\cdots x_+(z_l)\frac{[u-u'+\hat{k}]_+}{[u-u'+1/2]}\underline{dz'}.$$

By noting the identity

$$:x_+(z)x_-(-x^{-1}z):=x^{-2r+1}:x_+(z^{2r-2}z)x_-(-x^{2r-1}z):,$$

we can rewrite the right-hand side as follows:

$$l\oint\cdots\oint_{|z_2|=\cdots=|z_l|=R}\underline{dz_2}\cdots\underline{dz_l}\left(\oint_{C_1}\underline{dz_1}A(z_1,z)x_+(z_2)\cdots x_+(z_l)H_l(u_1,\ldots,u_l)-\oint_{C_2}\underline{dz_1}A(x^{2r-2}z_1,z)x_+(z_2)\cdots x_+(z_l)H_l(u_1,\ldots,u_l)\right), \tag{3.37}$$

where

$$A(z_1,z)=\mathrm{res}_{z'=-xz_1}\Phi_-(z)x_-(z')x_+(z_1)\frac{[u-u'+\hat{k}]_+}{[u-u'+1/2]}\underline{dz'}$$
$$=\frac{\text{holomorphic function}}{(-x^2z_1/z,-x^{2r}z/z_1;x^{2r})_\infty}:\Phi_-(z)x_-(-xz_1)x_+(z_1):.$$

The contours for z_1 are $(n\geqslant 0)$

	Inside	Outside
C_1	$z_1=-x^{2r(n+1)}z$	$z_1=-x^{-2-2rn}z$
C_2	$z_1=-x^{2+2rn}z$	$z_1=-x^{-2r(n+1)}z$

Moreover the product $:x_-(-xz_1)x_+(z_1):x_+(z_j)$ is holomorphic in z_1 for $|x^{2r}z_j|<|z_1|$. In view of the periodicity (3.32), the two terms of (3.37) cancel out by shifting the contour $z_1\rightarrow x^{2r-2}z_1$. □

IV. LOCAL HEIGHT PROBABILITIES

We present here a calculation of the local height probabilities (LHPs) for the dilute A_L models in the regime 2^+.

A. Two-point LHP

We have already mentioned the result (2.6) about the one-point function. As the next simplest case, let us consider the probability $P_l(a-\epsilon,a)$ of finding two neighboring local height variables to be $a-\epsilon$, $a(\epsilon=0,\pm)$:

$$P_l(a-\epsilon,a)=\frac{1}{Z_l}S(a)\mathrm{tr}_{\mathcal{L}_{l,a}}(x^{6\mathcal{H}}\Phi_\epsilon^*(z)\Phi_\epsilon(z))$$
$$=\frac{1}{Z_l}g\sqrt{S(a)S(a-\epsilon)}\mathrm{tr}_{\mathcal{L}_{l,a}}(x^{6\mathcal{H}}\Phi_{-\epsilon}(x^{-3}z)\Phi_\epsilon(z)). \tag{4.1}$$

Note that $P_l(a-\epsilon,a)$ is independent of z. From (4.1) and the property of the type I VO (3.20), we have the following relations:

$$\sum_{\epsilon=\pm1,0} P_l(a-\epsilon,a)=\frac{S(a)\chi_{l,a}(x^6)}{Z_l},\quad P_l(a-\epsilon,a)=P_l(a,a-\epsilon),\quad P_l(0,1)=0.$$

The evaluation of the trace yields the following expressions:

$$P_l(a-1,a)=-\frac{S(a-1)x^{(1-r)/r}}{[a-\frac{1}{2}]_+[2a-2]}\oint\oint_{C_+(1)}\underline{dw_1}\,\underline{dw_2}\,\mathcal{I}(w_1,w_2)\times\frac{[v_1-\frac{1}{2}][v_1-2a+\frac{3}{2}][v_1-v_2+a]_+}{[v_1+\frac{1}{2}][v_1-\frac{1}{2}][v_1-v_2+\frac{1}{2}]},$$

$$P_l(a,a)=\frac{S(a)x^{(1-r)/r}}{[a+\frac{1}{2}]_+[a-\frac{1}{2}]_+}\oint_{C_0(x^{-3})}\underline{dw_1}\oint_{C_0(1)}\underline{dw_2}\,\mathcal{I}(w_1,w_2)\frac{[v_1-a+\frac{3}{2}]+[v_2-a]_+}{[v_1+1][v_2-\frac{1}{2}]},$$

$$P_l(a+1,a)=-\frac{S(a)x^{(1-r)/r}}{[a+\frac{1}{2}]_+[2a]}\oint\oint_{C_+(x^{-3})}\underline{dw_1}\,\underline{dw_2}\,\mathcal{I}(w_1,w_2)\times\frac{[v_1-2a+1][v_1-v_2+a+1]_+[v_2+\frac{1}{2}]}{[v_1+1][v_1-v_2+\frac{1}{2}][v_2-\frac{1}{2}]}.$$

Here $w_i=x^{2v_i}$ $(i=1,2)$ and

$$\begin{aligned}\mathcal{I}(w_1,w_2)&=\mathrm{tr}_{\mathcal{L}_{l,a}}(x^{6\mathcal{H}}\Phi_-(x^{-3})x_-(w_1)\Phi_-(1)x_-(w_2))\\&=\mathcal{O}_{l,a}(w_1,w_2)\frac{(x^5,x^6;x^6,x^{2r})^2_\infty}{(x^{2r+3},x^{2r+4};x^6,x^{2r})^2_\infty}\\&\quad\times\frac{(x^{2r+2}w_1,x^{2r+2}/w_1,x^{2r-1}w_2,x^{2r+2}/w_2;x^3,x^{2r})_\infty}{(x^4w_1,x^4/w_1,xw_2,x^4/w_2;x^3,x^{2r})_\infty}(x^6,w_2/w_1,x^6w_1/w_2;x^6)_\infty\\&\quad\times\frac{G_{x^6}(x^{2r-1},w_2/w_1)G_{x^6}(x^2,w_2/w_1)}{G_{x^6}(x^{2r-2},w_2/w_1)G_{x^6}(x,w_2/w_1)},\end{aligned}$$

where $\mathcal{O}_{l,a}(w_1,w_2)$ is the zero-mode contribution

$$\begin{aligned}\mathcal{O}_{l,a}(w_1,w_2)&=(x^6)^{\Delta_{l,a}-c/24}(x^3w_1w_2)^{(l(L+1)-aL)/(2(L+1))+L/(4(L+1))}\\&\quad\times\sum_{j\in\mathbb{Z}}(x^3w_1w_2)^{-Lj}((x^6)^{L(L+1)j^2-(l(L+1)-aL)j}\\&\quad-(x^6)^{L(L+1)j^2+(l(L+1)+aL)j+la}(x^3w_1w_2)^{-l}),\end{aligned}$$

and

$$G_{x^6}(A,z)=(x^6A;x^6,x^{2r})^2_\infty(Az;x^6,x^{2r})_\infty(x^6A/z;x^6,x^{2r})_\infty.$$

The contours $C_+(1),C_0(x^{-3})\cup C_0(1),C_+(x^{-3})$ are chosen as follows $(n,m\geqslant0)$: For all the contours, the poles $w_1=x^{4+3m+2rn}$, $w_2=x^{4+3m+2rn}$, $x^{4+6m+2r(n+1)}w_1$, $x^{1+6(m+1)+2rn}w_1$ are inside and the poles $w_1=x^{-4-3m-2rn}$, $w_2=x^{-1-3m-2rn}$, $x^{2-6m-2r(n+1)}w_1$, $x^{-1-6m-2rn}w_1$ are outside. In addition,

	Inside	Outside
$C_+(1)$	$w_1=x^{-1+2r(n+1)}$	$w_1=x^{-1-2rn}$
	$w_2=x^{1+2rn}w_1$	$w_2=x^{-1-2rn},x^{-1-2rn}w_1$, $x^{2-2r(n+1)}w_1$
$C_0(x^{-3})\cup C_0(1)$	$w_1=x^{-2+2rn}$	$w_1=x^{-4-2rn}$
	$w_2=x^{1+2rn}$	$w_2=x^{-1-2rn}$
$C_+(x^{-3})$	$w_1=x^{-2+2rn}$	$w_1=x^{-4-2rn}$
	$w_2=x^{1+2rn}$, $x^{1+2rn}w_1$	$w_2=x^{1-2r(n+1)}$, $x^{-1-2rn}w_1$, $x^{2-2r(n+1)}w_1$

B. General case

Integral representation of the N-point correlation functions can be derived in a similar manner. It is written in terms of the traces of the type I vertex operators as in (2.7):

$$Z_l^{-1}S(k)\mathrm{tr}_{\mathcal{L}_{l,k}}(\Phi^*_{\epsilon_1}(x^6z_1)\cdots\Phi^*_{\epsilon_N}(x^6z_N)\Phi_{\epsilon_N}(x^6z_N)\cdots\Phi_{\epsilon_1}(x^6z_1)x^{6\mathcal{H}}). \tag{4.2}$$

Here we give only the integral formula for the traces over the Fock module in a general situation

$$\mathrm{tr}_{\mathcal{F}_{l,k}}(\Phi_{\epsilon_1}(z_1)\cdots\Phi_{\epsilon_N}(z_N)x^{6\mathcal{H}}). \tag{4.3}$$

We assume $\Sigma_{t=1}^N \epsilon_t=0$. Otherwise (4.3) vanishes.

First we prepare several functions,

$$F(z)=\frac{(x^{5+2r}z;x^6,x^{2r})}{(x^7z;x^6,x^{2r})},\quad G(z)=\frac{F(z)}{F(xz)F(x^{-1}z)},$$

$$H(z)=\frac{(x^8z,x^9z,x^{9+2r}z,x^{10+2r}z;x^6,x^6,x^{2r})}{(x^{11}z,x^{12}z,x^{6+2r}z,x^{7+2r}z;x^6,x^6,x^{2r})}.$$

Define $h_{\epsilon_n}(z_n,\{w_{n,i}\},\hat{k})$ $(\epsilon_n=0,+)$ by normal-ordering the integrand of (3.6) and (3.7),

$$\Phi_{\epsilon_n}(z_n)=\oint\left(\prod_{i\in I(\epsilon)}\underline{dw_{n,i}}\right):\Phi_-(z_n)\prod_{i\in I(\epsilon)}x_-(w_{n,i}):h_{\epsilon_n}(z_n,\{w_{n,i}\},\hat{k}),$$

$$I(0)=\{1\},I(+)=\{1,2\}.$$

Explicitly we have

$$h_0(z,w,k)=\frac{x^{(2u-2v+k+1/2)(k-1/2)/r^2-k+1/2}(xz^2)^{(1-r)/2r}}{\sqrt{[k+1/2]_+[k-1/2]_+}}\,\frac{(-x^{2k}z/w,-x^{2r-2k}w/z;x^{2r})_\infty}{(xw/z,xz/w;x^{2r})_\infty},$$

$$h_+(z,w_1,w_2,k)$$

$$=\sqrt{\frac{S(k-1)}{S(k)}}\frac{x^{\{4(k-1)(u-v_1+k-1/2)+(k-1/2)(2v_1-2v_2+k+1/2)\}/r^2-3k+5/2}(xz^2/w_1)^{(1-r)/r}}{[k-1/2]_+[2k-2]}$$

$$\times\frac{(x^{2r-1}w_2/z,x^{4k-3}z/w_1,x^{2r-4k+3}w_1/z;x^{2r})_\infty}{(xw_2/z,xw_1/z,xz/w_1;x^{2r})_\infty}$$

$$\times\frac{(x^2w_2/w_1,-x^{2k}w_1/w_2,-x^{2r-2k}w_2/w_1;x^{2r})_\infty}{(xw_2/w_1,x^{2r-2}w_2/w_1,xw_1/w_2;x^{2r})_\infty}\left(1-\frac{w_1}{w_2}\right).$$

We use the symbol $\langle\langle A(z)B(w)\rangle\rangle$ to denote the normal ordering factors

$$A(z)B(w)=\langle\langle A(z)B(w)\rangle\rangle:A(z)B(w):.$$

(See the list in Appendix A.)

With this notation we have

$$\mathrm{tr}_{\mathcal{F}_{l,k}}(\Phi_{\epsilon_1}(z_1)\cdots\Phi_{\epsilon_N}(z_N)x^{6\mathcal{H}})$$

$$=\oint\cdots\oint\prod_{\substack{1\leq m\leq N\\ \epsilon_m\neq -}}\left(\prod_{j\in I(\epsilon_m)}\underline{dw_{m,j}}\right)h_{\epsilon_m}\left(z_m,\{w_{m,j}\},k+\sum_{t=1}^{m}\epsilon_t\right)$$

$$\times\prod_{1\leq m<n\leq N}\langle\langle\Phi_-(z_m)\Phi_-(z_n)\rangle\rangle\prod_{\substack{1\leq m<n\leq N\\ i\in I(\epsilon_n);j\in I(\epsilon_m)}}\langle\langle x_-(w_{m,j})x_-(w_{n,i})\rangle\rangle$$

$$\times\prod_{\substack{1\leq n<m\leq N\\ j\in I(\epsilon_m)}}\langle\langle\Phi_-(z_n)x_-(w_{m,j})\rangle\rangle\prod_{\substack{1\leq m<n\leq N\\ j\in I(\epsilon_m)}}\langle\langle x_-(w_{m,j})\Phi_-(z_n)\rangle\rangle$$

$$\times\mathrm{tr}_{\mathcal{F}_{l,k}}\left(:\Phi_-(z_1)\cdots\Phi_-(z_N)\prod_{\substack{1\leq m\leq N\\ j\in I(\epsilon_m)}}x_-(w_{m,j}):x^{6\mathcal{H}}\right),\tag{4.4}$$

where

$$\mathrm{tr}_{\mathcal{F}_{l,k}}\left(:\Phi_-(z_1)\cdots\Phi_-(z_N)\prod_{\substack{1\leq m\leq N\\ j\in I(\epsilon_m)}}x_-(w_{m,j}):x^{6\mathcal{H}}\right)$$

$$=\prod_{1\leq m,n\leq N}H(z_n/z_m)\prod_{\substack{1\leq m,n\leq N\\ i\in I(\epsilon_n),j\in I(\epsilon_m)}}G(w_{n,i}/w_{m,j})$$

$$\times\prod_{\substack{1\leq n,m\leq N\\ j\in I(\epsilon_m)}}F(z_n/w_{m,j})F(w_{m,j}/z_n)\times\frac{x^{6(p_{l,k}^2/4-1/24)}}{(x^6;x^6)_\infty}$$

$$\times\left(\left(\prod_{\substack{1\leq m\leq N\\ j\in I(\epsilon_m)}}w_{m,j}\right)\Bigg/\left(\prod_{1\leq n\leq N}z_n\right)\right)^{\sqrt{(r-2)/r}\,p_{l,k}}$$

$$\times\left(\prod_{\substack{1\leq m\leq N\\ j\in I(\epsilon_m)}}w_{m,j}\prod_{1\leq n\leq N}z_n\right)^{(r-1)/(2r)},\tag{4.5}$$

where $p_{l,k}$ is given in (3.2). The following are the list of poles of the integrand as functions of $w_{m,j}$. The contour for $\underline{dw}_{m,j}$ encircles only those denoted ''inside'' $(a,b\in\mathbb{Z}_{\geqslant 0})$:

	Inside	Outside
$h_0(z_m,w_{m,1},k)$	$w_{m,1}=x^{1+2rb}z_m$	$w_{m,1}=x^{-1-2rb}z_m$
$h_+(z_m,w_{m,1},w_{m,2},k)$	$w_{m,1}=x^{1+2rb}z_m$	$w_{m,1}=x^{-1-2rb}z_m$
	$w_{m,2}=x^{1+2rb}w_{m,1}$	$w_{m,2}=x^{-1-2rb}w_{m,1},x^{-1-2rb}z_m$
$\langle\langle x_-(w_{m,j})\Phi_-(z_n)\rangle\rangle$	$w_{m,j}=x^{1+2rb}z_n$	
$\langle\langle \Phi_-(z_n)x_-(w_{m,j})\rangle\rangle$		$w_{m,j}=x^{-1-2rb}z_n$
$\langle\langle x_-(w_{m,j})x_-(w_{n,i})\rangle\rangle$	$w_{m,j}=x^{1+2rb}w_{n,i}$	
	$w_{m,j}=x^{-2+2r(1+b)}w_{n,i}$	
$G(w_{n,i}/w_{m,j})$	$w_{m,j}=x^{7+2rb+6a}w_{n,i}$	
	$w_{m,j}=x^{2r(1+b)+6(1+a)}w_{n,i}$	
	$w_{m,j}=x^{4+2r(1+b)+6a}w_{n,i}$	
$F(z_n/w_{m,j})$	$w_{m,j}=x^{7+2rb+6a}z_n$	$w_{m,j}=x^{-7-2rb-6a}z_n$

The formula for the N-point correlation function (4.2) can be obtained through specializing (4.5) and noting

$$H(x^3z)H(z)=\frac{1}{F(x^2z)F(xz)}.$$

Since the result is lengthy we do not present it here.

V. DISCUSSION

As was discussed in the main text, the DVA for the dilute A_L model [which we have denoted by $\mathcal{V}_{x,r}(A_2^{(2)})$] exactly coincides with the one found by Brazhnikov and Lukyanov.[13] In Ref. 13, $\mathcal{V}_{x,r}(A_2^{(2)})$ with $|x|=1$ was treated as the Zamolodchikov–Faddeev (ZF) algebra for the Bullough–Dodd model ($A_2^{(2)}$ Toda field theory). We regard $\mathcal{V}_{x,r}(A_2^{(2)})$ with $0<x<1$, $r=2(L+1)/(L+2)$ as the ZF algebra for the dilute A_L model (restricted face model), and apply the idea of bootstrap method to study the fusion of the $\mathcal{V}_{x,r}(A_2^{(2)})$ current $T(z)$.

The two-dimensional Ising model at the critical temperature $T=T_c$ is described by the $c=1/2$ minimal CFT. Perturbing it by a magnetic field while keeping the same temperature ($T=T_c$), an off-critical integrable model is obtained.[20] A fascinating feature of this theory is that the Lie algebra E_8 appears as a hidden symmetry; one can check that the integrals of motion P_s appear at the exponents of E_8, $s=1,7,11,13,17,19,\ldots$, the bootstrap program closes within eight particles, the mass ratios are given by the Perron–Frobenius vector for the incidence matrix of E_8, and so on. Further discussions of the model as the $\phi_{1,2}$-perturbation of the $c=1/2$ CFT can be found in Ref. 27. It is argued that the dilute A_3 model is in the universality class of the magnetic-perturbed Ising model.[1] As in the case of the ABF model,[4] our free field realization for the dilute A_3 model properly reduces to that of the $c=1/2$ CFT, including the VOs, $\mathcal{V}_{x,r}(A_2^{(2)})$, and the Felder complex. Our description of the dilute A_3 model, therefore, provides a lattice analog of the $\phi_{1,2}$-perturbation of the $c=1/2$ CFT.

In this section, we study an E_8 structure arising from $\mathcal{V}_{x,r}(A_2^{(2)})$ for the dilute A_3 model ($r=8/5$). We construct eight fused DVA currents $T^{(a)}(u)$ $(a=1,2,\ldots,8)$ from the fundamental $\mathcal{V}_{x,r}(A_2^{(2)})$ current $T(z)$ using a bootstrap procedure. We show that these fused currents obey a set of relations which resembles the so-called level-two restricted T-system of type $E_8^{(1)}$.[21]

The T-system of type $E_8^{(1)}$[21] is written as

$$T_m^{(a)}(u-\tfrac{1}{20})T_m^{(a)}(u+\tfrac{1}{20})=T_{m-1}^{(a)}(u)T_{m+1}^{(a)}(u)+g_m^{(a)}(u)\prod_{b\sim a}T_m^{(b)}(u), \tag{5.1}$$

where $T_m^{(a)}(u)$ $(a=1,2,...,8)$ denotes the eigenvalues of the transfer matrix, the symbol $b\sim a$ means that b and a are adjacent nodes in the Dynkin diagram of E_8, and $g^{(a)}(u)$'s are some functions. (We have rescaled the u variable of Ref. 21 to fit the present notation.) If the face model is restricted, then we have the truncation $1\leqslant m\leqslant \ell$. The integer ℓ is called level. If $\ell=2$, $T_2^{(a)}(u)$ becomes proportional to the identity, and (5.1) reduces to

$$T_1^{(a)}(u-\tfrac{1}{20})T_1^{(a)}(u+\tfrac{1}{20})=\phi^{(a)}(u)+g_1^{(a)}(u)\prod_{b\sim a}T_1^{(b)}(u), \tag{5.2}$$

with some functions $\phi^{(a)}(u)$. This is called the level-two restricted T-system of type $E_8^{(1)}$. In Ref. 22, the T-system in (5.2) is realized in terms of the ''quantum'' transfer matrix for the dilute A_3 model.

Now we come back to the deformed Virasoro algebra $\mathcal{V}_{x,r}(A_2^{(2)})$ for the dilute A_3 model. Before going into the technical details, let us roughly state the type of formulas we find for $\mathcal{V}_{x,r}(A_2^{(2)})$ with $r=8/5$.

Definition 5.1: Define the eight DVA currents $T^{(a)}(u)$ $(a=1,2,...,8)$ corresponding to the simple roots of E_8 by

$$T^{(a)}(u)=T_{\bar{a}}(u),\quad a=1,2,3,4,5,$$

$$T^{(6)}(u)=f_{1\bar{3}}(u_2-u_1)T_1(u_1)T_{\bar{3}}(u_2)\Big|_{\substack{u_1=u+11/20\\ u_2=u-3/20}},$$

$$T^{(7)}(u)=T_2(u),$$

$$T^{(8)}(u)=f_{1\bar{2}}(u_2-u_1)T_1(u_1)T_{\bar{2}}(u_2)\Big|_{\substack{u_1=u+9/20\\ u_2=u-4/20}}.$$

Here the fused DVA currents $T_n(u)$, $T_{\bar{n}}(u)$ and the structure function $f_{m\bar{n}}(u)$ are defined in Definition 5.5 below.

Proposition 5.2: The following relations hold:

$$f^{(1)}(u_1,u_2)T^{(1)}(u_1)T^{(1)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=T^{(2)}(u), \tag{5.3}$$

$$f^{(2)}(u_1,u_2)T^{(2)}(u_1)T^{(2)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=g^{(2)}(u_1,u_2)T^{(1)}(u_1)T^{(3)}(u_2)\Big|_{\substack{u_1=u\\ u_2=u}}, \tag{5.4}$$

$$f^{(3)}(u_1,u_2)T^{(3)}(u_1)T^{(3)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=g^{(3)}(u_1,u_2)T^{(2)}(u_1)T^{(4)}(u_2)\Big|_{\substack{u_1=u\\ u_2=u}}, \tag{5.5}$$

$$f^{(4)}(u_1,u_2)T^{(4)}(u_1)T^{(4)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=g^{(4)}(u_1,u_2)T^{(3)}(u_1)T^{(5)}(u_2)\Big|_{\substack{u_1=u\\ u_2=u}}, \tag{5.6}$$

$$f^{(5)}(u_1,u_2)T^{(5)}(u_1)T^{(5)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=g^{(5)}(u_1,u_2,u_3)T^{(4)}(u_1)T^{(6)}(u_2)T^{(8)}(u_3)\Big|_{\substack{u_1=u\\ u_2=u\\ u_3=u}}, \tag{5.7}$$

$$f^{(6)}(u_1,u_2)T^{(6)}(u_1)T^{(6)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=g^{(6)}(u_1,u_2)T^{(5)}(u_1)T^{(7)}(u_2)\Big|_{\substack{u_1=u\\ u_2=u}}, \tag{5.8}$$

$$f^{(7)}(u_1,u_2)T^{(7)}(u_1)T^{(7)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=T^{(6)}(u), \tag{5.9}$$

$$f^{(8)}(u_1,u_2)T^{(8)}(u_1)T^{(8)}(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}=T^{(5)}(u), \tag{5.10}$$

with appropriate functions $f^{(a)}$, $g^{(a)}$ (*see Definition 5.15*). *Both sides are regarded as operators on the cohomology* $H^0(C_{l,k})$. *Likewise we have the relations*

$$[\![u_2-u_1-\tfrac{3}{2}]\!] f^{(a)}(u_1,u_2)T^{(a)}(u_1)T^{(a)}(u_2)\Big|_{\substack{u_1=u+1/20-r/2\\ u_2=u-1/20+r/2}} = c^{(a)}\mathrm{id}, \tag{5.11}$$

for $a=1,2,...,8$, *where* $c^{(a)}$*'s are some constants and the symbol* $[\![\;]\!]$ *is defined below in* (5.14).

We notice that (5.3)–(5.11) for the fused $\mathcal{V}_{x,r}(A_2^{(2)})$ currents look very similar to the *T*-system (5.2) arising from the analytic Bethe ansatz. There is, however, an obvious discrepancy between them; while the *T*-system (5.2) comprises two terms, (5.3)–(5.11) consists of only one term. More precisely, the right-hand side of (5.3)–(5.10) corresponds to the second term in (5.2), whereas that of (5.11) corresponds to the first term. In the left-hand side, the spectral parameters u_1-u_2 of (5.3)–(5.10) and (5.11) differ by *r*. Such a shift by *r* is irrelevant in the *T*-system (5.2), because the transfer matrix eigenvalues $T_m^{(a)}(u)$ (with appropriate normalization) are periodic, $T_m^{(a)}(u+r)=T_m^{(a)}(u)$. This is a reflection of the quasiperiodicity of the Boltzmann weights. On the other hand, the $\mathcal{V}_{x,r}(A_2^{(2)})$ currents $T^{(a)}(u)$ *are by no means* doubly quasiperiodic; we have $T^{(a)}(u+\pi i/\log x)=T^{(a)}(u)$ but $T^{(a)}(u+r)\neq T^{(a)}(u)$.

We have not understood yet the reason why we have such similarities between the *T*-system for the Bethe ansatz and the exchange relations for the DVA. For the purpose of comparison, we summarize in Appendix C the fusions of the DVA current and the ''*T*-system'' for the algebra $A_{N-1}^{(1)}$.

In the rest of this section, we briefly sketch the derivation of Proposition 5.2.

A. Operator product expansions

Let *r* be generic for a while. We set

$$r^*=r-1, \tag{5.12}$$

$$[u]_x=\frac{x^u-x^{-u}}{x-x^{-1}}, \tag{5.13}$$

$$[\![u]\!]=\frac{[u]_x}{[u+r^*+1]_x}=\frac{1}{[\![-u-r^*-1]\!]}. \tag{5.14}$$

In this section we prefer to use the additive notation and write $f(u)$ for the structure function $f(z)$ $(z=x^{2u})$ in (3.24). It satisfies the relations:

Lemma 5.3:

$$(i)\qquad \frac{f(u-\frac{1}{2})f(u+\frac{1}{2})}{f(u)}=\frac{[\![u-r^*-1/2]\!]}{[\![u-1/2]\!]},$$

$$(ii)\qquad f(u)f\left(u\pm\frac{3}{2}\right)=\frac{[\![\pm u-r^*]\!]}{[\![\pm u]\!]}\frac{[\![\pm u-r^*+1/2]\!]}{[\![\pm u+1/2]\!]},$$

$$(iii)\qquad f(u-1)f(u)f(u+1)=\frac{[\![u-r^*-1]\!]}{[\![u-1]\!]}\frac{[\![u-r^*-1/2]\!]}{[\![u-1/2]\!]}\frac{[\![u-r^*]\!]}{[\![u]\!]}.$$

The operators $\Lambda_\pm(z)$, $\Lambda_0(z)$ are defined by (3.21).

Lemma 5.4: The operator product expansions (OPEs) among $\Lambda_i(u)$ *are*

$$f(u_2-u_1)\Lambda_i(x^{2u_1})\Lambda_j(x^{2u_2})=:\Lambda_i(x^{2u_1})\Lambda_j(x^{2u_2}):\times\begin{cases}1 & (i,j)=(+,+)\\ \frac{[\![u_1-u_2-r^*]\!]}{[\![u_1-u_2]\!]} & (i,j)=(+,0)\\ \frac{[\![u_1-u_2-r^*]\!]}{[\![u_1-u_2]\!]}\frac{[\![u_1-u_2-r^*+1/2]\!]}{[\![u_1-u_2+1/2]\!]} & (i,j)=(+,-)\\ \frac{[\![u_1-u_2-r^*-1]\!]}{[\![u_1-u_2-1]\!]} & (i,j)=(0,+)\\ \frac{[\![u_1-u_2-r^*-1/2]\!]}{[\![u_1-u_2-1/2]\!]} & (i,j)=(0,0)\\ \frac{[\![u_1-u_2-r^*]\!]}{[\![u_1-u_2]\!]} & (i,j)=(0,-)\\ \frac{[\![u_1-u_2-r^*-1]\!]}{[\![u_1-u_2-1]\!]}\frac{[\![u_1-u_2-r^*-3/2]\!]}{[\![u_1-u_2-3/2]\!]} & (i,j)=(-,+)\\ \frac{[\![u_1-u_2-r^*-1]\!]}{[\![u_1-u_2-1]\!]} & (i,j)=(-,0)\\ 1 & (i,j)=(-,-)\end{cases}.$$

B. Fused $\mathcal{V}_{x,r}(A_2^{(2)})$ currents $T_n(u)$ and $T_{\bar{n}}(u)$

Suggested by the bootstrap program for general r, we introduce the following fused currents of $\mathcal{V}_{x,r}(A_2^{(2)})$.

Definition 5.5: Define the fused DVA currents $T_n(u)$ and $T_{\bar{n}}(u)$ by

$$T_0(u)=T_{\bar{0}}(u)=\mathrm{id},\quad T_1(u)=T_{\bar{1}}(u)=T(x^{2u}),$$

$$T_n(u)=\prod_{1\le i<j\le n} f(u_j-u_i)\cdot T_1(u_1)T_1(u_2)\cdots T_1(u_n)\Big|_{\substack{u_i=u+((n-1)/2)r^*-(i-1)r^*\\ 1\le i\le n}},$$

$$T_{\bar{n}}(u)=\prod_{1\le i<j\le n} f(u_j-u_i)\cdot T_1(u_1)T_1(u_2)\cdots T_1(u_n)\Big|_{\substack{u_i=u+((n-1)/2)(r^*-1/2)-(i-1)(r^*-1/2)\\ 1\le i\le n}}.$$

Define the structure functions for $T_n(u)$, $T_{\bar{n}}(u)$ by

$$f_{mn}(u)=\prod_{i=1}^{m}\prod_{j=1}^{n} f\left(u+\frac{n-m}{2}r^*-(j-i)r^*\right),$$

$$f_{\overline{mn}}(u)=\prod_{i=1}^{m}\prod_{j=1}^{n} f\left(u+\frac{n-m}{2}\left(r^*-\frac{1}{2}\right)-(j-i)\left(r^*-\frac{1}{2}\right)\right),$$

$$f_{\bar{m}n}(u)=f_{n\bar{m}}(u)=\prod_{i=1}^{m}\prod_{j=1}^{n} f\left(u+\frac{n+1}{2}r^*-\frac{m+1}{2}\left(r^*-\frac{1}{2}\right)-jr^*+i\left(r^*-\frac{1}{2}\right)\right).$$

These fused DVA currents enjoy the ZF exchange relations.

Lemma 5.6: As meromorphic functions, the following exchange relations hold:

$$f_{mn}(v-u)T_m(u)T_n(v)=f_{nm}(u-v)T_n(v)T_m(u),$$

$$f_{\overline{mn}}(v-u)T_{\overline{m}}(u)T_{\overline{n}}(v)=f_{\overline{nm}}(u-v)T_{\overline{n}}(v)T_{\overline{m}}(u),$$

$$f_{m\overline{n}}(v-u)T_{m}(u)T_{\overline{n}}(v)=f_{\overline{n}m}(u-v)T_{\overline{n}}(v)T_{m}(u).$$

Lemma 5.7:

$$(i)\quad [\![u-v\pm 1]\!]f(v-u)T_1(u)T_1(v)|_{u=v\mp 1}=\frac{\mp T_1(v\mp 1/2)}{[\![-1/2]\!][\![-1]\!]},$$

$$(ii)\quad [\![u-v\pm 3/2]\!]f(v-u)T_1(u)T_1(v)|_{u=v\mp 3/2}=\frac{\mp \mathrm{id}}{[\![1/2]\!][\![-1]\!][\![-3/2]\!]},$$

$$(iii)\quad [\![u_1-u_2-1]\!][\![u_2-u_3-1]\!]f(u_2-u_1)f(u_3-u_1)f(u_3-u_2)T_1(u_1)T_1(u_2)T_1(u_3)|_{\substack{u_2=u_1-1\\ u_3=u_2-1}}$$

$$=\frac{\mathrm{id}}{[\![1]\!]\left[\!\!\left[\frac{1}{2}\right]\!\!\right]\left[\!\!\left[-\frac{1}{2}\right]\!\!\right][\![-1]\!][\![-1]\!]\left[\!\!\left[-\frac{3}{2}\right]\!\!\right][\![-2]\!]}.$$

We need the analyticity properties of the operator products. (Some details of the derivation are given in Appendix C for the case of $A_{N-1}^{(1)}$.)

Lemma 5.8: The product $f_{mn}(v-u)T_m(u)T_n(v)$ has poles only at

$$u-v=\begin{cases}\left(\frac{m+n}{2}-k\right)r^*-1\\ \left(\frac{m+n}{2}-k\right)r^*-\frac{3}{2}\\ -\left(\frac{m+n}{2}-k\right)r^*+1\\ -\left(\frac{m+n}{2}-k\right)r^*+\frac{3}{2}\end{cases}\quad k=1,2,...,\min(m,n).$$

All the poles are simple.

Lemma 5.9: The product $f_{\overline{mn}}(v-u)T_{\overline{m}}(u)T_{\overline{n}}(v)$ has poles only at

simple pole:

$$u-v=\begin{cases}\left(\frac{m+n}{2}-k\right)\left(r^*-\frac{1}{2}\right)-\frac{3}{2}\\ -\left(\frac{m+n}{2}-k\right)\left(r^*-\frac{1}{2}\right)+\frac{3}{2}\end{cases}\quad k=1,2,...,\min(m,n),$$

and

poles with multiplicity min(min(m,n),min(l,$m+n-l$)):

$$u-v=\begin{cases}\left(\frac{m+n}{2}-l\right)\left(r^*-\frac{1}{2}\right)-1\\ -\left(\frac{m+n}{2}-l\right)\left(r^*-\frac{1}{2}\right)+1\end{cases}\quad l=1,2,...,m+n-1.$$

Lemma 5.10: The product $f_{\overline{m}n}(v-u)T_{\overline{m}}(u)T_n(v)$ has poles only at

$$u-v=\begin{cases} \frac{n-1}{2}r^*+\left(\frac{m+1}{2}-l\right)\left(r^*-\frac{1}{2}\right)-1 & \\ \frac{n-1}{2}r^*+\left(\frac{m+1}{2}-k\right)\left(r^*-\frac{1}{2}\right)-\frac{3}{2} & l=1,2,\dots m, \\ -\frac{n-1}{2}r^*-\left(\frac{m+1}{2}-l\right)\left(r^*-\frac{1}{2}\right)+1 & k=1,2\dots,\min(m,n). \\ -\frac{n-1}{2}r^*-\left(\frac{m+1}{2}-k\right)\left(r^*-\frac{1}{2}\right)+\frac{3}{2} & \end{cases}$$

All the poles are simple.

C. The case of the dilute A_3 model

The parameters for the dilute A_3 model are given by

$$L=3, \quad r=2\frac{L+1}{L+2}=\frac{8}{5}, \quad r^*=\frac{3}{5}.$$

For $L=3$, we expect to have the following extra symmetry for $T_n(u)$.

Conjecture 5.11: As operators acting on the BRST cohomology $H^0(C_{l,k})$ $(k=1,2,3,\ l=1,2)$, we have

$$(i) \quad T_3(u)=\frac{T_2(u)}{[\![\frac{2}{10}]\!][\![\frac{3}{10}]\!]},$$

$$(ii) \quad T_4(u)=\frac{-T_1(u)}{[\![-\frac{9}{10}]\!][\![-\frac{4}{10}]\!][\![-\frac{3}{10}]\!][\![\frac{3}{10}]\!][\![\frac{2}{10}]\!][\![\frac{8}{10}]\!]},$$

$$(iii) \quad T_5(u)=\frac{-\mathrm{id}}{[\![-\frac{15}{10}]\!][\![-\frac{10}{10}]\!][\![-\frac{9}{10}]\!][\![-\frac{4}{10}]\!][\![-\frac{3}{10}]\!][\![\frac{2}{10}]\!][\![\frac{3}{10}]\!][\![\frac{8}{10}]\!][\![\frac{9}{10}]\!][\![\frac{14}{10}]\!]}.$$

One of the grounds for this Conjecture 5.11 is the degeneration of the structure functions.

Lemma 5.12: For $r^*=3/5$, we have

$$(i) \quad f_{13}(u)=f_{12}(u)\frac{[\![u-\frac{7}{10}]\!][\![u-\frac{12}{10}]\!]}{[\![u-\frac{4}{10}]\!][\![u-\frac{9}{10}]\!]},$$

$$(ii) \quad f_{14}(u)=f_{11}(u)\frac{[\![u-\frac{10}{10}]\!][\![u-\frac{15}{10}]\!]}{[\![u-\frac{1}{10}]\!][\![u-\frac{6}{10}]\!]},$$

$$(iii) \quad f_{15}(u)=\frac{[\![u-\frac{13}{10}]\!][\![u-\frac{18}{10}]\!]}{[\![u+\frac{2}{10}]\!][\![u-\frac{3}{10}]\!]}.$$

Using Lemmas 5.12, 5.8, 5.9, and 5.10, we can check that the replacement $T_m(u)\leftrightarrow T_{5-m}(u)$ will not affect the analyticity in any of the OPEs acting on the BRST cohomology space.

To obtain the correct proportionality constants in Conjecture 5.11, we calculated $\langle l,k|T_m(u)|l,k\rangle$ for $k=1,2,3$, $l=1,2$.

D. Fusions of $T_2(u)$ at $r^*=3/5$

If we study the bootstrap for E_8-symmetric particles carefully,[20] we realize that it is helpful to consider the fusions of $T_2(u)$.

Lemma 5.13: For $r^*=3/5$, *the following equalities hold.*

$$(i)\quad f_{22}(u_2-u_1)T_2(u_1)T_2(u_2)\Big|_{\substack{u_1=u+1/20\\ u_2=u-1/20}}$$

$$=\frac{[\![-\frac{8}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{2}{10}]\!][\![\frac{3}{10}]\!]}{[\![-\frac{5}{10}]\!][\![-\frac{4}{10}]\!][\![-\frac{3}{10}]\!]} f_{1\bar{3}}(u_2-u_1)T_1(u_1)T_{\bar{3}}(u_2)\Big|_{\substack{u_1=u+11/20\\ u_2=u-3/20}}$$

$$=\frac{[\![-\frac{8}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{2}{10}]\!][\![\frac{3}{10}]\!]}{[\![-\frac{5}{10}]\!][\![-\frac{4}{10}]\!][\![-\frac{3}{10}]\!]} f_{\bar{3}1}(u_2-u_1)T_{\bar{3}}(u_1)T_1(u_2)\Big|_{\substack{u_1=u+3/20\\ u_2=u-11/20}},$$

$$(ii)\quad f_{22}(u_2-u_1)T_2(u_1)T_2(u_2)\Big|_{\substack{u_1=u+7/20\\ u_2=u-7/20}}$$

$$=\frac{[\![-\frac{8}{10}]\!]}{[\![-\frac{5}{10}]\!][\![-\frac{3}{10}]\!][\![-\frac{2}{10}]\!]} f_{1\bar{2}}(u_2-u_1)T_1(u_1)T_{\bar{2}}(u_2)\Big|_{\substack{u_1=u+9/20\\ u_2=u-4/20}}$$

$$=\frac{[\![-\frac{8}{10}]\!]}{[\![-\frac{5}{10}]\!][\![-\frac{3}{10}]\!][\![-\frac{2}{10}]\!]} f_{\bar{2}1}(u_2-u_1)T_{\bar{2}}(u_1)T_1(u_2)\Big|_{\substack{u_1=u+4/20\\ u_2=u-9/20}}.$$

To prove these, we use

$$\tfrac{5}{2}r^*-\tfrac{3}{2}=0,\quad T_2(u)=[\![\tfrac{2}{10}]\!][\![\tfrac{3}{10}]\!]T_3(u),$$

and Lemma 5.7.

E. $T_{\bar{5}}(u)$, $T_{\bar{6}}(u)$, $T_{\bar{7}}(u)$ at $r^*=3/5$

The fused DVA currents $T_{\bar{5}}(u)$, $T_{\bar{6}}(u)$, $T_{\bar{7}}(u)$ for $r^*=3/5$ can be rewritten as follows.

Lemma 5.14: For $r^*=3/5$, *we have*

$$T_{\bar{5}}(u)=\left[\!\!\left[-\frac{1}{2}\right]\!\!\right][\![-1]\!]\left(\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!]}\right)^2[\![u_2'-u_2-1]\!]f_{\bar{2}1}(u_2-u_1)f_{\bar{2}1}(u_2'-u_1)f_{\bar{2}\bar{2}}(u_3-u_1)$$

$$\times f_{11}(u_2'-u_2)f_{1\bar{2}}(u_3-u_2')f_{1\bar{2}}(u_3-u_2)T_{\bar{2}}(u_1)T_1(u_2)T_1(u_2')T_{\bar{2}}(u_3)\Big|_{\substack{u_1=u+3/20\\ u_2=u-1/2\\ u_2'=u+1/2\\ u_3=u-3/20}},$$

$$T_{\bar{6}}(u)=\left[\!\!\left[-\frac{1}{2}\right]\!\!\right][\![-1]\!]\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!]}\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{8}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!][\![-\frac{14}{10}]\!]}[\![u_2'-u_2-1]\!]f_{\bar{3}1}(u_2-u_1)$$

$$\times f_{\bar{3}1}(u_2'-u_1)f_{\bar{3}\bar{2}}(u_3-u_1)f_{11}(u_2'-u_2)f_{1\bar{2}}(u_3-u_2')$$

$$\times f_{1\bar{2}}(u_3-u_2)T_{\bar{3}}(u_1)T_1(u_2)T_1(u_2')T_{\bar{2}}(u_3)\Big|_{\substack{u_1=u+3/20\\ u_2=u-11/20\\ u_2'=u+9/20\\ u_3=u-4/20}},$$

$$T_{\bar{7}}(u)=f_{5\bar{2}}(u_2-u_1)T_{\bar{5}}(u_1)T_2(u_2)|_{u_1=u, u_2=u}=\left[\!\left[-\frac{1}{2}\right]\!\right][\![-1]\!]\left(\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{8}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!][\![-\frac{14}{10}]\!]}\right)^2$$

$$\times[\![u_2'-u_2-1]\!]f_{\bar{3}1}(u_2-u_1)f_{\bar{3}1}(u_2'-u_1)f_{\bar{3}\bar{3}}(u_3-u_1)f_{11}(u_2'-u_2)$$

$$\times f_{1\bar{3}}(u_3-u_2')f_{1\bar{3}}(u_3-u_2)T_{\bar{3}}(u_1)T_1(u_2)T_1(u_2')T_{\bar{3}}(u_3)|_{u_1=u+4/20, u_2=u-1/2, u_2'=u+1/2, u_3=u-4/20}.$$

F. Structure functions

In accordance with the currents $T^{(a)}(u)$, we introduce the following structure functions.
Definition 5.15: Define $f^{(a)}$ $(a=1,2,...,8)$, $g^{(a)}$ $(a=2,3,...,6)$ *by*

$$f^{(a)}(u_1,u_2)=f_{\bar{a}\bar{a}}(u_2-u_1) \quad (1\leqslant a\leqslant 5),$$

$$g^{(a)}(u_1,u_2)=f_{\overline{a-1}\,\overline{a+1}}(u_2-u_1) \quad (2\leqslant a\leqslant 4),$$

$$g^{(5)}(u_1,u_2,u_3)=\left[\!\left[-\frac{1}{2}\right]\!\right][\![-1]\!]\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!]}\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{8}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!][\![-\frac{14}{10}]\!]}\frac{[\![-\frac{4}{10}]\!][\![-\frac{5}{10}]\!][\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!]}{[\![-\frac{10}{10}]\!][\![-\frac{11}{10}]\!][\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!]}$$

$$\times f_{\bar{4}\bar{3}}\left(u_2-u_1+\frac{3}{20}\right)f_{\bar{4}1}\left(u_2-u_1-\frac{11}{20}\right)f_{\bar{4}1}\left(u_3-u_1+\frac{9}{20}\right)f_{\bar{4}\bar{2}}\left(u_3-u_1-\frac{4}{20}\right)$$

$$\times[\![u_3-u_2]\!]f_{\bar{3}1}\left(u_3-u_2+\frac{6}{20}\right)f_{\bar{3}\bar{2}}\left(u_3-u_2-\frac{7}{20}\right)f_{11}(u_3-u_2+1)$$

$$\times f_{1\bar{2}}\left(u_3-u_2+\frac{7}{20}\right),$$

$$f^{(6)}(u_1,u_2)=\left[\!\left[-\frac{1}{2}\right]\!\right][\![-1]\!]\left(\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{8}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!][\![-\frac{14}{10}]\!]}\right)^2\frac{[u_1-u_2-\frac{1}{10}]_x}{[\frac{16}{10}]_x}\left[\!\left[u_1-u_2-\frac{1}{10}\right]\!\right]$$

$$\times f_{1\bar{3}}\left(u_2-u_1+\frac{4}{10}\right)f_{\bar{3}\bar{3}}\left(u_2-u_1-\frac{3}{10}\right)f_{11}\left(u_2-u_1+\frac{11}{10}\right)f_{\bar{3}1}\left(u_2-u_1+\frac{4}{10}\right),$$

$$g^{(6)}(u_1,u_2)=f_{5\bar{2}}(u_2-u_1),$$

$$f^{(7)}(u_1,u_2)=\frac{[\![-\frac{5}{10}]\!][\![-\frac{4}{10}]\!][\![-\frac{3}{10}]\!]}{[\![-\frac{8}{10}]\!][\![-\frac{7}{10}]\!][\![-\frac{2}{10}]\!][\![\frac{3}{10}]\!]}\times f_{22}(u_2-u_1),$$

$$f^{(8)}(u_1,u_2)=\left[\!\left[-\frac{1}{2}\right]\!\right][\![-1]\!]\left(\frac{[\![-\frac{6}{10}]\!][\![-\frac{7}{10}]\!]}{[\![-\frac{12}{10}]\!][\![-\frac{13}{10}]\!]}\right)^2\left[\!\left[u_1-u_2-\frac{1}{10}\right]\!\right]f_{1\bar{2}}\left(u_2-u_1-\frac{5}{20}\right)$$

$$\times f_{\bar{2}\bar{2}}\left(u_2-u_1+\frac{8}{20}\right)f_{11}\left(u_2-u_1-\frac{18}{20}\right)f_{\bar{2}1}\left(u_2-u_1-\frac{5}{20}\right).$$

Collecting all the information together, we easily obtain the ‘‘T-system’’ with the E_8 symmetry stated in Proposition 5.2.

ACKNOWLEDGMENTS

We thank Atsuo Kuniba, Yaroslav Pugai, and Junji Suzuki for discussions and their interest in this work. M.J. is grateful to Olivier Babelon and Jean Avan for their kind invitation and hospitality during his stay in Paris VI, where part of this work was done.

APPENDIX A: OPERATOR PRODUCT EXPANSIONS

We list the normal ordering relations. For operators $A(z),B(w)$ that have the form :exp(linear in boson):, we use the notation

$$A(z)B(w)=\langle\langle A(z)B(w)\rangle\rangle:A(z)B(w):$$

and write down only the part $\langle\langle A(z)B(w)\rangle\rangle$,

$$\langle\langle x_+(z_1)x_+(z_2)\rangle\rangle=z_1^{r/(r-1)}(1-z_2/z_1)\,\frac{(x^{-2}z_2/z_1,x^{2r-1}z_2/z_1;x^{2r-2})_\infty}{(x^{-1}z_2/z_1,x^{2r}z_2/z_1;x^{2r-2})_\infty},$$

$$\langle\langle x_-(z_1)x_-(z_2)\rangle\rangle=z^{(r-1)/r}(1-z_2/z_1)\,\frac{(x^{2}z_2/z_1,x^{2r-1}z_2/z_1;x^{2r})_\infty}{(xz_2/z_1,x^{2r-2}z_2/z_1;x^{2r})_\infty},$$

$$\langle\langle x_\pm(z_1)x_\mp(z_2)\rangle\rangle=z_1^{-1}\frac{1+z_2/z_1}{(1+xz_2/z_1)(1+x^{-1}z_2/z_1)},$$

$$\langle\langle \Phi_-(z_1)x_-(z_2)\rangle\rangle=z_1^{-(r-1)/r}\frac{(x^{2r-1}z_2/z_1;x^{2r})_\infty}{(xz_2/z_1;x^{2r})_\infty},$$

$$\langle\langle x_-(z_2)\Phi_-(z_1)\rangle\rangle=z_2^{-(r-1)/r}\frac{(x^{2r-1}z_1/z_2;x^{2r})_\infty}{(xz_1/z_2;x^{2r})_\infty},$$

$$\langle\langle \Phi_-(z_1)x_+(z_2)\rangle\rangle=\langle\langle x_+(z_2)\Phi_-(z_1)\rangle\rangle=(z_1+z_2),$$

$$\langle\langle \Psi^*_-(z_1)x_+(z_2)\rangle\rangle=z_1^{-r/(r-1)}\frac{(x^{2r-1}z_2/z_1;x^{2r-2})_\infty}{(x^{-1}z_2/z_1;x^{2r-2})_\infty},$$

$$\langle\langle x_+(z_2)\Psi^*_-(z_1)\rangle\rangle=z_2^{-r/(r-1)}\frac{(x^{2r-1}z_1/z_2;x^{2r-2})_\infty}{(x^{-1}z_1/z_2;x^{2r-2})_\infty},$$

$$\langle\langle \Psi^*_-(z_1)x_-(z_2)\rangle\rangle=\langle\langle x_-(z_2)\Psi^*_-(z_1)\rangle\rangle=(z_1+z_2),$$

$$\langle\langle \Phi_-(z_1)\Phi_-(z_2)\rangle\rangle=z_1^{(r-1)/r}\frac{(x^2z_2/z_1,x^3z_2/z_1,x^{2r+3}z_2/z_1,x^{2r+4}z_2/z_1;x^6,x^{2r})_\infty}{(x^5z_2/z_1,x^6z_2/z_1,x^{2r}z_2/z_1,x^{2r+1}z_2/z_1;x^6,x^{2r})_\infty},$$

$$\langle\langle \Psi^*_-(z_1)\Psi^*_-(z_2)\rangle\rangle=z_1^{r/(r-1)}\frac{(z_2/z_1,xz_2/z_1,x^{2r+3}z_2/z_1,x^{2r+4}z_2/z_1;x^6,x^{2r-2})_\infty}{(x^3z_2/z_1,x^4z_2/z_1,x^{2r}z_2/z_1,x^{2r+1}z_2/z_1;x^6,x^{2r-2})_\infty},$$

$$\langle\langle \Phi_-(z_1)\Psi^*_-(z_2)\rangle\rangle=z_1^{-1}\frac{(-x^4z_2/z_1,-x^5z_2/z_1;x^6)_\infty}{(-xz_2/z_1,-x^2z_2/z_1;x^6)_\infty},$$

$$\langle\langle \Psi^*_-(z_2)\Phi_-(z_1)\rangle\rangle=z_2^{-1}\frac{(-x^4z_1/z_2,-x^5z_1/z_2;x^6)_\infty}{(-xz_1/z_2,-x^2z_1/z_2;x^6)_\infty}.$$

As meromorphic functions we have

$$x_+(z_1)x_+(z_2)=\frac{[u_1-u_2+1]^*}{[u_1-u_2-1]^*}\frac{[u_1-u_2-1/2]^*}{[-u_1+u_2-1/2]^*}x_+(z_2)x_+(z_1),$$

$$x_-(z_1)x_-(z_2)=\frac{[u_1-u_2-1]}{[u_1-u_2+1]}\frac{[u_1-u_2+1/2]}{[-u_1+u_2+1/2]}x_-(z_2)x_-(z_1),$$

$$x_\pm(z_1)x_\mp(z_2)=x_\mp(z_2)x_\pm(z_1),$$

$$\Phi_-(z_1)x_-(z_2)=\frac{[u_1-u_2+1/2]}{[-u_1+u_2+1/2]}x_-(z_2)\Phi_-(z_1),$$

$$\Phi_-(z_1)x_+(z_2)=x_+(z_2)\Phi_-(z_1),$$

$$\Psi_-^*(z_1)x_+(z_2)=\frac{[u_1-u_2-1/2]^*}{[-u_1+u_2-1/2]^*}x_+(z_2)\Psi_-^*(z_1),$$

$$\Psi_-^*(z_1)x_-(z_2)=x_-(z_2)\Psi_-^*(z_1),$$

$$\Phi_-(z_1)\Phi_-(z_2)=\rho(u_2-u_1)\Phi_-(z_2)\Phi_-(z_1),$$

$$\Psi_-^*(z_1)\Psi_-^*(z_2)=\rho^*(u_1-u_2)\Psi_-^*(z_2)\Psi_-^*(z_1),$$

$$\Phi_-(z_1)\Psi_-^*(z_2)=\tau(u_2-u_1)\Psi_-^*(z_2)\Phi_-(z_1).$$

Here $\rho(u)$, $\rho^*(u)$, and $\tau(u)$ are given respectively by (2.4), (3.15), and (3.16).

APPENDIX B: BRST CHARGES

We give here a proof of the properties of BRST charges stated in Sec. III E. The method is a proper adaptation of Ref. 19 to the present situation.

1. Feigin–Odesskii algebra

First let us prepare the notation. Let $\widetilde{A}_n$ be the set of all functions $F(u_1,\ldots,u_n)$ which is holomorphic on $\mathbb{C}^n$, symmetric in $u_1,\ldots,u_n$, and enjoys the quasiperiodicity properties ($r^*=r-1$),

$$F(u_1+r^*,u_2,\ldots,u_n)=(-1)^nF(u_1,u_2,\ldots,u_n), \tag{B1}$$

$$F(u_1+\tau,u_2\ldots,u_n)=(-1)^nF(u_1,u_2,\ldots,u_n)\exp\left(\frac{2\pi i}{r^*}\left(nu_1-\sum_{j=2}^n u_j-\frac{n-1}{2}+n\frac{\tau}{2}\right)\right), \tag{B2}$$

where $\tau=\pi i/\log x$. Clearly,

$$\widetilde{A}_1=\mathbb{C}f_1,\quad f_1(u)=[u]^*.$$

We have also $\dim\widetilde{A}_2=2$. If $F\in\widetilde{A}_n$ is not identically 0, then it has n zeroes $\{u_1^{(j)}\}_{j=1}^n \bmod \mathbb{Z}r^*\oplus\mathbb{Z}\tau$ satisfying

$$\sum_{j=1}^n u_1^{(j)}=\sum_{j=2}^n u_2+\frac{n-1}{2}.$$

Let $F\in\widetilde{A}_m$, $G\in\widetilde{A}_n$. Following the line of Ref. 19, we define the $*$-product $F*G\in\widetilde{A}_{m+n}$ by

$$(F*G)(u_1,\ldots,u_{m+n})$$
$$=\mathrm{Sym}\left(F(u_1-n,\ldots,u_m-n)G(u_{m+1},\ldots,u_{m+n})\prod_{\substack{1\le i\le m\\ m+1\le j\le m+n}}\frac{[u_i-u_j+1]^*[u_i-u_j-1/2]^*}{[u_i-u_j]^*}\right).$$

Here the symbol Sym stands for the symmetrization. $\widetilde{A}=\oplus_{n=0}^{\infty}\widetilde{A}_n$ equipped with the $*$-product is an associative graded algebra with unit. We denote by $A=\oplus_{n=0}^{\infty}A_n$ $(A_n=\widetilde{A}_n\cap A)$ the subalgebra of $\widetilde{A}$ generated by $\widetilde{A}_1$ and $\widetilde{A}_2$.

Let us say that a function $F(u_1,\ldots,u_n)$ has the property (P) if either $n=1,2$, or $n\geqslant 3$ and

$$F(u_1,\ldots,u_n)|_{u_j-u_i=u_k-u_j=1/2}\equiv 0 \quad \text{for any distinct } i,j,k.$$

Lemma B.1: (i) Elements of A have the property (P).

(ii) A is commutative.

Proof: From the definition of $*$ we can verify that, if $F\in\widetilde{A}_m$ and $G\in\widetilde{A}_n$ have the property (P), then so does $F*G$. Hence (i) follows.

Let $g\in A_2$ be an element linearly independent from $f_1*f_1\in A_2$. To see (ii), it suffices to show that $f_1*g=g*f_1$. Set $h=f_1*g-g*f_1$. A simple check shows that $h(u+1,u,u-1)=0$. By symmetry and the property (P), $h(u_1,u_2,u_2-1)$ viewed as a function of u_1 has zeroes at $u_2+1,u_2-1/2,u_2-2$. Since their sum is different from $2u_2 \bmod \mathbb{Z}r^*\oplus\mathbb{Z}\tau$, we have $h(u_1,u_2,u_2-1)\equiv 0$. By symmetry, this implies that $h(u_1,u_2,u_3)$ has four zeroes $u_1=u_2\pm 1,u_3\pm 1$. Hence $h\equiv 0$. □

2. BRST charges

For $F\in A_n$, we define

$$Q(F)=\oint\cdots\oint\prod_{j=1}^{n}\frac{dz_j}{[u_j+\frac{1}{2}]^*}x_+(z_1)\cdots x_+(z_n)$$
$$\times\left(\prod_{1\le i<j\le n}\frac{[u_i-u_j]^*}{[u_i-u_j+1]^*[u_i-u_j-1/2]^*}\right)F(u_1+\hat{l}/2,\ldots,u_n+\hat{l}/2),$$

where the contour is $|z_1|=\cdots=|z_n|=1$. Because of the quasiperiodicity (B2), the integrand is single valued. Using the exchange relation

$$x_+(z_1)x_+(z_2)=-\frac{[u_1-u_2+1]^*}{[u_2-u_1+1]^*}\frac{[u_1-u_2-1/2]^*}{[u_2-u_1-1/2]^*}x_+(z_2)x_+(z_1)$$

along with $\hat{l}x_+(z)=x_+(z)(\hat{l}-2)$, we find

$$Q(F)Q(G)=Q(F*G). \tag{B3}$$

Now set

$$f_1(u)=[u]^*,$$

$$f_2^{(a)}(u_1,u_2)=[2a+1]^*[a-1/2]^*[u_1-a]^*[u_2+a-1]^*[u_1-u_2+a-1/2]^*$$
$$-[2a-1]^*[a+1/2]^*[u_1+a]^*[u_2-a-1]^*[u_1-u_2-a-1/2]^*,$$

and introduce $h_l\in A_l$ $(1\leqslant l\leqslant L)$ by

$$h_{2m+1}=f_1*f_2^{(1)}*\cdots*f_2^{(m)}\quad\left(0\leqslant m\leqslant\frac{L-1}{2}\right),$$

$$h_{2m}=f_2^{((L+1)/2-m)}*\cdots*f_2^{((L-3)/2)}*f_2^{((L-1)/2)}\quad\left(1\leqslant m\leqslant\frac{L-3}{2}\right).$$

We have $h_L=h_l*h_{L-1}$ $(1\leqslant l\leqslant L-1)$. We define the BRST charges by

$$Q_l=Q(h_l).$$

Propositions 3.1 and 3.2 reduce to the following assertions.

Proposition B.2: $h_l(u_1,\ldots,u_l)$ can be written as

$$h_l(u_1,\ldots,u_l)=\overline{h_l}(u_1,\ldots,u_l)\times\begin{cases}\prod_{i=1}^{l}\left[u_i+\dfrac{-l+1}{2}\right]^* & (l:\ \text{odd})\\ \prod_{i=1}^{l}\left[u_i+\dfrac{L-l+1}{2}\right]^* & (l:\ \text{even})\end{cases},\tag{B4}$$

where $\overline{h_l}$ are holomorphic and satisfies

$$\overline{h_l}(u_1+r^*,\ldots,u_l)=(-1)^{l-1}\overline{h_l}(u_1,\ldots,u_l),$$

$$\overline{h_l}(u_1+\tau,\ldots,u_l)=\overline{h_l}(u_1,\ldots,u_l)\times\exp\left(\frac{2\pi i}{r^*}\sum_{j=2}^{l}\left(u_1-u_j+\frac{\tau}{2}\right)\right).$$

Moreover it is translationally invariant, i.e.,

$$\overline{h_l}(u_1+v,\ldots,u_l+v)=\overline{h_l}(u_1,\ldots,u_l).$$

Proposition B.3: We have $h_L\equiv 0$.

Proof of Proposition B.3: Let $0\leqslant m\leqslant(L-3)/2$. In the equality $h_L=h_{2m+1}*h_{L-2m-1}$ we set $u_1=-m-1$. Using Proposition B.2, we find that each summand in the symmetrization (B.3) vanishes. Similarly, if we set $u_1=m$, then each summand of $h_L=h_{L-2m-1}*h_{2m+1}$ vanishes. Therefore h_L has $L-1$ zeroes $u_1=0,1,\cdots,(L-3)/2,-1,-2,\ldots,-(L-1)/2$.

Suppose h_L did not vanish identically. From the quasiperiodicity, h_L has a zero at $u_1=\Sigma_{j=2}^{L}u_j+L-1$. By symmetry, $u_1=u_2-\Sigma_{j=3}^{L}u_j-(L-1)$ must also be a zero. This is a contradiction. □

In the next subsection we prove Proposition B.2.

3. Proof of proposition B.2

We prove Proposition B.2 for odd $l=2m+1$. The statement is obvious for $m=0$. Assuming $m\geqslant 1$ we proceed by induction on m.

Lemma B.4: For $m=1,\ldots,(L-1)/2$ we have

$$h_{2m+1}(m,m\pm 1,u_3,\ldots,u_{2m+1})\equiv 0.\tag{B5}$$

Proof: We use the property

$$f_2^{(a)}(\pm a,\pm a+1)=0.\tag{B6}$$

In the definition of $h_{2m+1}=h_{2m-1}*f_2^{(m)}$, set $u_1=m,u_2=m+1$. Using the induction hypothesis $h_{2m-1}(m-1,\ldots)\equiv 0$ and $f_2^{(m)}(m,m+1)=0$, we see that each summand vanishes. Similarly if we set $u_1=m,u_2=m-1$ in $h_{2m+1}=f_2^{(m)}*h_{2m-1}$ and use $f_2^{(m)}(-m,-m+1)=0$, the result is zero.□

Lemma B.5: For $t=2,3,\ldots$, we have

$$h_{2m+1}(m,u_2,\ldots,u_{2m+1})\Big|_{\substack{u_{2s+1}=u_{2s}+1/2\\ t\leqslant s\leqslant m}}\equiv 0. \tag{B7}$$

Taking $t=m+1$ we obtain the first assertion of Proposition B.2.

Proof: Denote the left-hand side of (B7) by g_t. We show $g_t\equiv 0$ by induction on t.

Let $t=2$, and consider first

$$h_{2m+1}(m,m\pm 1/2,u_3,\ldots,u_{2m+1})\Big|_{\substack{u_{2s+1}=u_{2s}+1/2\\ 2\leqslant s\leqslant m}}. \tag{B8}$$

As a function of u_3, (B8) has $2m+1$ zeroes at $m+1,m-1,m\mp 1/2$ and $u_{2s}+1,u_{2s}-1/2$ $(2\leqslant s \leqslant m)$. Comparing with the quasiperiodicity, we conclude that (B8) vanishes identically. This means that g_2 as a function of u_2 has $2m+2$ zeroes at $m\pm 1,m\pm 1/2$ and $u_{2s}+1,u_{2s}-1/2$ $(2 \leqslant s\leqslant m)$. Therefore $g_2\equiv 0$.

Suppose we have shown $g_t\equiv 0$, and consider

$$g_{t+1}=h_{2m+1}(m,u_2,\ldots,u_{2t},u_{2t+1},u_{2t+2},u_{2t+2}+1/2,\ldots,u_{2m},u_{2m}+1/2). \tag{B9}$$

From the induction hypothesis, it vanishes for $u_{2t+1}=u_{2t}+1/2$. By symmetry it vanishes for

$$u_2=u_3\pm 1/2,\ldots,u_{2t+1}\pm 1/2.$$

It also vanishes for $u_2=m\pm 1$ and $u_2=u_{2s}-1/2,u_{2s}+1$ $(t+1\leqslant s\leqslant m)$. Since the number of zeroes exceed $2m+1$, we conclude $g_{t+1}\equiv 0$. □

In the case of even l, we note that

$$f_2^{((L-1)/2)}(u_1,u_2)=[2]^*\left[\frac{L}{2}\right]^*\left[u_1+\frac{L-1}{2}\right]^*\left[u_2+\frac{L-1}{2}\right]^*\left[u_1-u_2-\frac{L}{2}\right]^*$$

has a zero at $u_1=(1-L)/2$. Using this the proof goes similarly.

Lemma B.6: The function $\overline{h_l}$ in (B4) is translationally invariant.

Proof: Consider

$$\overline{h_l}(u_1+v,\ldots,u_l+v).$$

It is holomorphic and doubly periodic in v, hence it is a constant. The conclusion follows by setting $v=0$. □

APPENDIX C: DEFORMED *W* ALGEBRA FOR $\mathfrak{sl}_N$

We discuss here the fusion of the deformed W algebra (DWA) associated with $\mathfrak{sl}_N$.[28,29]

1. Basic current

Fix complex numbers $x,r^*\in\mathbb{C}$, $0<|x|<1$. We keep the notation $[u]_x$ (5.13) and $[\![u]\!]$ (5.14). In this appendix we consider the case of "generic" r^* i.e., we assume that $m,n\in\mathbb{Z},[m+nr^*]_x=0$ implies $m=n=0$.

In the free field realization, the simplest current of DWA for the algebra $\mathfrak{sl}_N$ is presented in the form

$$W_{(1)}(u)=\sum_{i=1}^{N}\Lambda_i(u).$$

Each $\Lambda_i(u)$ is a normally ordered exponential of bosonic oscillators. Their explicit formula is irrelevant here [see, e.g., Ref. 28, Eq. (2), wherein $z=x^{2u}$, $q=x^{2r^*+2}$, $t=x^{2r^*}$ in the present notation]. We need only the following normal ordering rule for their products:

$$f(u,v)\Lambda_i(u)\Lambda_j(v)=:\Lambda_i(u)\Lambda_j(v):\times\begin{cases}\dfrac{[\![u-v-1-r^*]\!]}{[\![u-v-1]\!]} & (i<j)\\ 1 & (i=j)\\ \dfrac{[\![u-v-r^*]\!]}{[\![u-v]\!]} & (i>j),\end{cases} \tag{C1}$$

where the structure function $f(u,v)=f(v-u)$ is given by

$$f(u)=\frac{1}{(1-x^{2u})}\frac{(x^{2(u+N-1)},x^{2(u+1+r^*)},x^{2(u-r^*)};x^{2N})_\infty}{(x^{2(u+1)},x^{2(u+N+r^*)},x^{2(u+N-r^*-1)};x^{2N})_\infty}.$$

Lemma C.1: We have the exchange relation as meromorphic functions

$$f(u,v)W_{(1)}(u)W_{(1)}(v)=f(v,u)W_{(1)}(v)W_{(1)}(u). \tag{C2}$$

Both sides are regular except for simple poles at $u-v=\pm 1 \bmod \Gamma$, *where* $\Gamma=(\pi i/\log x)\mathbb{Z}$. Notice that the pole $u=v$ which appears in (C1) is canceled in (C2). In general, each matrix element of the product

$$\prod_{1\le s<t\le m} f(u_s,u_t)\times W_{(1)}(u_1)\cdots W_{(1)}(u_m)$$

is a rational function of x^{2u_i} with at most simple poles at $u_i-u_j=\pm 1$ $(i<j)$.

2. Fused currents

Let $\lambda=(\lambda_1,\ldots,\lambda_l)(\lambda_1\geqslant\cdots\geqslant\lambda_l>0)$ be a partition. We identify λ with a Young diagram. For $j,s=1,2,\ldots$, we attach a variable $u(j,s)$ to the box on the jth row and sth column of λ:

$\lambda =$  , $\quad u(j,s)=u-(j-1)-(s-1)r^*.$

For partitions $\lambda=(\lambda_1,\ldots,\lambda_l)$, $\mu=(\mu_1,\ldots,\mu_m)$, we set

$$f_{\lambda,\mu}(u,v)=\prod_{\substack{1\le j\le l\\ 1\le s\le\lambda_j}}\prod_{\substack{1\le k\le m\\ 1\le t\le\mu_k}} f(u(j,s),v(k,t)). \tag{C3}$$

We shall associate "fused" currents $W_\lambda(u)$ with each λ. First consider the case of a single row diagram $\lambda=(m)$.

Definition C.2:

$$W_{(m)}(u)=\left(\prod_{1\le s<t\le m} f(u_s,u_t)\times W_{(1)}(u_1)\cdots W_{(1)}(u_m)\right)\Bigg|_{\substack{u_s=u-(s-1)r^*\\ 1\le s\le m}}.$$

In view of the remark after Lemma C.1, the right-hand side is well-defined. Alternatively $W_{(m)}(u)$ can be defined inductively as

$$W_{(m)}(u)=f_{(m-1),(1)}(u,u')W_{(m-1)}(u)W_{(1)}(u')\Big|_{u'=u-(m-1)r^*} \tag{C4}$$

$$= f_{(1),(m-1)}(u,u')W_{(1)}(u)W_{(m-1)}(u')\Big|_{u'=u-r^*}. \tag{C5}$$

Lemma C.3: We have

$$f_{(1),(m)}(u,v)W_{(1)}(u)W_{(m)}(v) = f_{(m),(1)}(v,u)W_{(m)}(v)W_{(1)}(u). \tag{C6}$$

Both sides of (C6) are regular except for simple poles $(\mathrm{mod}\,\Gamma)$ at $u-v=-1,\ 1-(m-1)r^*$.

Proof: The exchange relation (C6) is obvious. Let us verify the statement about the position of poles by induction on *m*. The case $m=1,2$ can be verified by direct calculation. Suppose it is true for $m-1$. Using the expressions (C4) and (C5) and the induction hypothesis, we see that the possible poles in u are confined to

$$\{v-1, v+1-(m-2)r^*, v\pm 1-(m-1)r^*\}\cap\{v\pm 1, v-r^*-1, v+1-(m-1)r^*\}$$
$$=\{v-1, v+1-(m-1)r^*\}.$$

□

Arguing similarly, we have
Lemma C.4:

$$f_{(m),(n)}(u,v)W_{(m)}(u)W_{(n)}(v) = f_{(n),(m)}(v,u)W_{(n)}(v)W_{(m)}(u). \tag{C7}$$

Both sides of (C7) are regular except for simple poles $(\mathrm{mod}\,\Gamma)$ *at*

$$u-v = 1-jr^* \quad (\max(0,n-m)\leqslant j\leqslant n-1)$$
$$= -1+jr^* \quad (\max(0,m-n)\leqslant j\leqslant m-1).$$

For a general partition $\lambda=(\lambda_1,\ldots,\lambda_l)$, we define
Definition C.5:

$$W_\lambda(u) = \left(\prod_{i=1}^{l-1}[\![u_i-u_{i+1}-1]\!]\cdot\prod_{1\leqslant i<j\leqslant l} f_{(\lambda_i),(\lambda_j)}(u_i,u_j)\cdot W_{(\lambda_1)}(u_1)\cdots W_{(\lambda_l)}(u_l)\right)\Bigg|_{\substack{u_i=u-(i-1)\\ 1\leqslant i\leqslant l}}.$$

This definition makes sense by Lemma C.3. We have

$$f_{\lambda,\mu}(u,v)W_\lambda(u)W_\mu(v) = W_\mu(v)W_\lambda(u)f_{\mu,\lambda}(v,u). \tag{C8}$$

In the case of a single column diagram $\lambda=(1^a)$, $W_{(1^a)}(u)$ coincides with the fundamental DWA currents $W_a(z)$ in Refs. 28 and 29 up to a numerical factor and a shift of u [see (C10) below].

We remark that another fused current can be constructed similarly by replacing $u(j,s)=u-(j-1)-(s-1)r^*$ with $u-(j-1)+(s-1)r$ $(r=r^*+1)$.

3. Tableaux sum

Let λ be a partition. Denote by $\mathrm{SST}(\lambda)$ the set of semistandard tableaux of shape λ on the letters $\{1,2,\ldots,N\}$. For $T\in\mathrm{SST}(\lambda)$, we set

$$\Lambda_T(u) = :\prod_{\substack{1\leqslant j\leqslant l\\ 1\leqslant s\leqslant\lambda_j}}\Lambda_{T(j,s)}(u(j,s)):,$$

where $T(j,s)\in\{1,\ldots,N\}$ signifies the letter in the (j,s)th position of T.

The current $W_\lambda(u)$ is given explicitly as follows.

Proposition C.6: We have

$$W_\lambda(u)=d_\lambda \sum_{T\in \mathrm{SST}(\lambda)} c_T\cdot \Lambda_T(u).$$

The coefficients d_λ, c_T *are given by*

$$d_\lambda=\prod_{1+j<k}\frac{[\![k-j-1-\lambda_j r^*]\!]_{\lambda_k}}{[\![k-j-1]\!]_{\lambda_k}}\cdot\prod_{k=2}^{l}\frac{[\![-\lambda_{k-1}r^*]\!]_{\lambda_k}}{[\![r^*]\!]_{\lambda_k-1}},$$

$$c_T=\prod_{j=1}^{l}\frac{\Pi_{i=1}^{N}[\![-1]\!]_{w_{ji}}}{[\![-1]\!]_{\lambda_j}}\cdot\prod_{j<k}\frac{[\![k-j-\lambda_j r^*]\!]_{\lambda_k}}{[\![k-j-1-\lambda_j r^*]\!]_{\lambda_k}}\prod_{j<k}\prod_{i=1}^{N}\frac{[\![k-j-1+(s_{k,i-1}-s_{j,i-1})r^*]\!]_{w_{k,i}}}{[\![k-j+(s_{k,i-1}-s_{j,i})r^*]\!]_{w_{k,i}}},$$

where w_{ji} *is the number of the letter* i *in the* jth *row of* T $(1\leq j\leq l,\ 1\leq i\leq N)$, $s_{ji}=w_{j1}+\cdots+w_{ji}$, and

$$[\![u]\!]_n=[\![u]\!][\![u+r^*]\!]\cdots[\![u+(n-1)r^*]\!].$$

We omit the proof. Notice that $c_{T_0}=1$ for the tableau T_0 with $T_0(j,s)=j$ for all j,s.

Example.

$$W_{(m)}(u)=\sum_{\substack{w_1,\dots,w_N\geq 0\\ w_1+\cdots+w_N=m}}\frac{\Pi_{i=1}^{N}[\![-1]\!]_{w_i}}{[\![-1]\!]_m}\cdot\Lambda_T(u),\tag{C9}$$

where $T=(1^{w_1},2^{w_2},\dots,N^{w_N})$,

$$W_{(1^a)}(u)=d_{(1^a)}\sum_{1\leq i_1<\cdots<i_a\leq N}:\Lambda_{i_1}(u)\cdots\Lambda_{i_a}(u-a+1):.\tag{C10}$$

4. $W_\lambda(u)$ in terms of $W_{(1^a)}(u)$

$W_\lambda(u)$ can also be obtained from $W_{(1^a)}(u)$. First note the following fact which can be shown similarly as Lemma C.4.

Lemma C.7: *We have*

$$\tilde f_{(1^a),(1^b)}(u,v)W_{(1^a)}(u)W_{(1^b)}(v)=\tilde f_{(1^b),(1^a)}(v,u)W_{(1^b)}(v)W_{(1^a)}(u),\tag{C11}$$

where $\tilde f_{\lambda,\mu}(u,v)$ *is defined similarly as in (C3) with* $f(u,v)$ *replaced by*

$$\tilde f(u,v)=\frac{[\![u-v-1]\!]}{[\![u-v-r^*]\!]}f(u,v)=\frac{[\![v-u-1]\!]}{[\![v-u-r^*]\!]}f(u,v).$$

Both sides of (C11) are regular except for simple poles $(\mathrm{mod}\,\Gamma)$ *at*

$$\begin{aligned}u-v&=r^*-j\quad(\max(0,b-a)\leq j\leq b-1)\\&=-r^*+j\quad(\max(0,a-b)\leq j\leq a-1).\end{aligned}$$

We remark that the exchange relation (C8) holds true with $f_{\lambda,\mu}(u,v)$ replaced by $\tilde f_{\lambda,\mu}(u,v)$.

Returning to the general λ, denote by $\mu_1\geq\cdots\geq\mu_m$ its column lengths (hence the transposed diagram is $\lambda'=(\mu_1,\dots,\mu_m)$).

Lemma C.8:

$$W_\lambda(u)=\left(\prod_{i=2}^{m}[\![u_{i-1}-u_i-r^*]\!]^{-\mu_i+1}\right.$$
$$\left.\left.\times\prod_{1\leqslant i<j\leqslant l}f_{(1^{\mu_i}),(1^{\mu_j})}(u_i,u_j)\cdot W_{(1^{\mu_1})}(u_1)\cdots W_{(1^{\mu_m})}(u_m)\right)\right|_{\substack{u_i=u-(i-1)r^*\\1\leqslant i\leqslant m}}.$$

Proof: Let $\overline{\lambda}$ be the diagram obtained by removing the last column of λ so that $\lambda'=(\overline{\lambda}',\mu_m)$. We show

$$W_\lambda(u)=[\![u-v-(m-1)r^*]\!]^{-\mu_m+1}f_{\overline{\lambda},(1^{\mu_m})}(u,v)W_{\overline{\lambda}}(u)W_{(1^{\mu_m})}(v)|_{v=u-(m-1)r^*}\tag{C12}$$

by induction on μ_m. The lemma follows by repeated use of this equation.

If $\mu_m=1$, then (C12) is immediate from the definition. Assuming the statement is true for μ_m $(\mu_{m-1}\geqslant\mu_m+1\geqslant 2)$ we consider (C12) with $\lambda'=(\overline{\lambda}',\mu_m+1)$. We have

$$\begin{aligned}&[\![u-v-(m-1)r^*]\!]^{-\mu_m}f_{\overline{\lambda},(1^{\mu_m+1})}(u,v)W_{\overline{\lambda}}(u)W_{(1^{\mu_m+1})}(v)\\&\quad=[\![u-v-(m-1)r^*]\!]^{-\mu_m+1}[\![u-v'-\mu_m-(m-1)r^*]\!]^{-1}f_{\overline{\lambda},(1^{\mu_m})}(u,v)f_{\overline{\lambda},(1)}(u,v')\\&\quad\times[\![v-v'-\mu_m]\!]f_{(1^{\mu_m}),(1)}(v,v')W_{\overline{\lambda}}(u)W_{(1^{\mu_m})}(v)W_{(1)}(v')|_{v'=v-\mu_m}.\end{aligned}\tag{C13}$$

Let us verify that the right-hand side of (C13) (before specialization $v'=v-\mu_m$) is regular at $v=u-(m-1)r^*$, $v'=u-\mu_m-(m-1)r^*$. From the induction hypothesis,

$$[\![u-v-(m-1)r^*]\!]^{-\mu_m+1}f_{\overline{\lambda},(1^{\mu_m})}(u,v)W_{\overline{\lambda}}(u)W_{(1^{\mu_m})}(v)$$

is regular at $v=u-(m-1)r^*$, and

$$[\![v-v'-\mu_m]\!]f_{(1^{\mu_m}),(1)}(v,v')W_{(1^{\mu_m})}(v)W_{(1)}(v')$$

is regular at $v'=v-\mu_m$. Finally Lemma C.7 implies that

$$\tilde{f}_{\overline{\lambda},(1)}(u,v')W_{\overline{\lambda}}(u)W_{(1)}(v')$$

is regular at $v'=u-\mu_m-(m-1)r^*$, and

$$\begin{aligned}&[\![u-v'-\mu_m-(m-1)r^*]\!]^{-1}\frac{f_{\overline{\lambda},(1)}(u,v')}{\tilde{f}_{\overline{\lambda},(1)}(u,v')}\\&\quad=[\![u-v'-\mu_m-(m-1)r^*]\!]^{-1}\prod_{\substack{1\leqslant k\leqslant m-1\\1\leqslant j\leqslant\mu_k}}\frac{[\![u-v'-(j-1)-kr^*]\!]}{[\![u-v'-j-(k-1)r^*]\!]}\end{aligned}$$

is also regular (since $\mu_{m-1}\geqslant\mu_m+1$).

We let $v=u-(m-1)r^*$ in (C13) and change the order of specialization. Using the induction hypothesis for the diagram $\tilde{\lambda}'=(\overline{\lambda}',\mu_m)$, we obtain

$$\begin{aligned}&[\![u-v'-\mu_m-(m-1)r^*]\!]^{-1}[\![u-(m-1)r^*-v'-\mu_m]\!]\\&\quad\times f_{\overline{\lambda},(1)}(u,v')f_{(1^{\mu_m}),(1)}(u-(m-1)r^*,v')W_{\tilde{\lambda}}(u)W_{(1)}(v')|_{v'=u-\mu_m-(m-1)r^*}\\&\quad=f_{\tilde{\lambda},(1)}(u,v')W_{\tilde{\lambda}}(u)W_{(1)}(v')|_{v'=u-\mu_m-(m-1)r^*}=W_\lambda(u).\end{aligned}$$

□

5. Rectangular diagrams

For a rectangular Young diagram $\lambda=(m^a)$, we write $W_m^{(a)}(u)=W_{(m^a)}(u)$. The following relations may be viewed as an analog of the T-system for the transfer matrices discussed in Ref. 21.

Proposition C.9:

$$f_{(m^a),(m^a)}(u,v)W_m^{(a)}(u)W_m^{(a)}(v)|_{v=u-r*}$$
$$=(-1)^{a-1}f_{((m+1)^a),((m-1)^a)}(u,v)W_{m+1}^{(a)}(u)W_{m-1}^{(a)}(v)|_{v=u-r*}, \tag{C14}$$

$$\tilde{f}_{(m^a),(m^a)}(u,v)W_m^{(a)}(u)W_m^{(a)}(v)|_{v=u-1}$$
$$=(-1)^{m-1}C_m^{(a)}\tilde{f}_{(m^{a+1}),(m^{a-1})}(u,v)W_m^{(a+1)}(u)W_m^{(a-1)}(v)|_{v=u-1}, \tag{C15}$$

where

$$C_m^{(a)}=\prod_{1\leqslant s,t\leqslant m}\frac{[\![a-1-(s-t)r*]\!]}{[\![a-(1+s-t)r*]\!]}.$$

Both sides of (C14), (C15) are well defined.

We sketch below the proof of (C14). First we check the regularity of both sides at $v=u-r*$. For the right-hand side, this can be shown from Lemma C.4. For the left-hand side, we use Lemma C.7 to find that

$$\tilde{f}_{(m^a),(m^a)}(u,v)W_m^{(a)}(u)W_m^{(a)}(v)$$

has poles of order at most $2(m-1)$ at $u=v-r*$. Since

$$\frac{f_{(m^a),(m^a)}(u,v)}{\tilde{f}_{(m^a),(m^a)}(u,v)}=O([u-v+r*]_x^{2(m-1)}) \quad (u\to v-r*),$$

the desired regularity follows. In the same way (using Lemma C.4) we see that

$$f_{(m^a),((m-1)^a)}(u,v)W_m^{(a)}(u)W_{m-1}^{(a)}(v)$$

has poles of order at most $(a-1)$ at $u=v-r*$.

Consider the expression

$$A\equiv f_{(m^a),((m-1)^a)}(u,u')f_{(m^a),(1^a)}(u,v)f_{((m-1)^a),(1^a)}(u',v)W_m^{(a)}(u)W_{m-1}^{(a)}(u')W_1^{(a)}(v).$$

From the definition of $W_\lambda(u)$, we have

$$A=[\![u'-v-(m-1)r*]\!]^{a-1}f_{(m^a),(m^a)}(u,u')W_m^{(a)}(u)W_m^{(a)}(u')$$
$$+O([\![u'-v-(m-1)r*]\!]^a) \quad (v\to u'-(m-1)r*)$$

$$=[\![u-v-mr*]\!]^{a-1}f_{((m+1)^a),((m-1)^a)}(u,u')W_{m+1}^{(a)}(u)W_{m-1}^{(a)}(u')$$
$$+O([\![u-v-mr*]\!]^a) \quad (v\to u-mr*).$$

Writing $y=u-v-mr*$, $y'=u'-v-(m-1)r*$ and multiplying both sides by $[\![u-u'-r*]\!]^{a-1}$ we have the equality of the form

$$\varphi(y,y')=[\![y]\!]^{a-1}[\![y-y']\!]^{a-1}\psi(y-y')+O(y^a)\quad (y\to 0)$$
$$=[\![y']\!]^{a-1}[\![y-y']\!]^{a-1}\psi'(y-y')+O(y'^a)\quad (y'\to 0),$$

where $\varphi(y,y')$, $\psi(y-y')$, and $\psi'(y-y')$ are regular near $y=y'=0$. This implies that $(-1)^{a-1}\psi(0)=\psi'(0)$, and (C14) follows.

Exact solutions of the Dirac equation in a nonfactorizable metric

M. N. Hounkonnou[a)] and J. E. B. Mendy
Unité de Recherche en Physique Théorique (URPT), Institut de Mathématiques et de Sciences Physiques (IMSP), B.P. 613 Porto-Novo, Bénin

(Received 10 September 1998; accepted for publication 27 January 1999)

We present the covariant generalization of the Dirac equation in a nonfactorizable metric and give the corresponding exact solutions in terms of special functions as well as the explicit form of the spinor solution. Then we treat the particular case of the Weyl equation for the neutrinos.
[S0022-2488(99)02807-8]

I. INTRODUCTION

One of the most exciting challenges of the present day relativistic quantum theory remains, undoubtedly, the task of finding exact solutions of the Dirac equation in the presence of external fields. This can be explained by the intense research made in the subject.[1–13] The motivations for these activities are diverse and evident in view of the wide role of the Dirac equation in modern physics, for example, for investigating the spin $-\frac{1}{2}$ particle and for the necessity of analysis of synchrotronic radiation.[6]

To this purpose, many systems have been subjects of considerable interest and studies. The pioneering investigation could be the work by Brill and Wheeler in 1957,[1] who considered the Dirac equation in a central gravitational field associated with a diagonal metric. Using a normal diagonal tetrad, these authors constructed the generalized angular momentum operator separating the variables in the Dirac equation.

In a remarkable paper entitled ‘‘*Criteria of separability of the variables in the Dirac equation in gravitational fields*,’’ which appeared in 1987,[10] Shishkin and Andrushkevich provided the necessary and sufficient conditions, based on rigorous theorems, for separability of the variables for a diagonal tetrad gauge, and deduced the operators that determine the dependence of the wave function on the separated variables. In the same year, Barut and Duru[2] gave exact solutions of the Dirac equation in spatially flat Robertson–Walker space–times for models of expanding universes and discussed the current decomposition. In 1989, Shishkin and Villalba analyzed the possibilities of using the method of separation of variables in the Dirac equation in the presence of external vector fields.[6] Later, Villalba and Percoco[3] presented exact solutions and separation of variables in the Dirac and Weyl equations in a universe filled with radiation, an arbitrary expansion of the Robertson–Walker metric and in open flat and closed expanding cosmological Robertson–Walker universes. In Ref. 4, the author gave exact solutions of the Dirac equation in a static reducible Einstein space and analyzed the asymptotic behavior of the spinor solution. In Ref. 11, Shishkin and Cabos considered the separation of variables in the Dirac equation for the case of a general set of connections of the Dirac particle with the external fields, using Cartesian coordinates, whereas in Ref. 7 there are presented the possibilities of using the method of algebraic separation of variables in the Dirac equation in the presence of gravitational fields. The same technique was used[5] in the local rotating diagonal gauge in spherical coordinates and exact solutions are obtained, the energy spectrum computed and its dependence in the intensity of the Aharonov–Bohm and the magnetic monopole strengths analyzed. Let us also mention that exact solutions of the Dirac equation and the structure of metric functions were given[8] in the presence of gravitational

[a)]Electronic mail: hounkon@syfed.bj.refer.org

fields for massless neutrinos and in terms of special functions for electric neutral particles with anomalous electric and magnetic moments.[9]

Here, we provide exact solutions of the Dirac equation in a nonfactorizable metric, using the method of separation of variables adopted in Ref. 7. The general study of solutions to the Dirac equation in a curved space–time is clearly of physical interest. Indeed, such analysis is the prerequisite for the quantization of the corresponding quantum field theory. In turn, the quantized field theory enables the representation of associated quantum processes, such as particle creation through gravitational acceleration, or pair creation in the presence of strong gravitational fields, existent either close to black holes or during stellar gravitational collapse, or at the initial conditions of the Universe. Even though these issues have been well studied in specific curved space–times, such as the Schwarschild solution,[14] an analysis within a general class of space–time metrics could add new insight into the physics of such phenomena.

In Sec. III, the general class of metrics used in the present paper is introduced, for which the Dirac equation may explicitly be solved through separation of variables. These metrics are represented by

$$ds^2=-dt^2+a^2(t)(dx^2+b^2(x)[dy^2+c^2(y)dz^2]), \tag{1}$$

where $a(t)$, $b(x)$ and $c(y)$ are *a priori* arbitrary functions of the local coordinates t, x and y. This general class of metrics includes as particular cases well-established examples, which themselves could belong to other general classes of models. Thus, for example, the usual Friedman–Lemaître–Roberston–Walker homogeneous and isotropic metric of standard cosmology is of the above form (whether in Cartesian or spherical coordinates), and, more generally, the choice (1) also includes general classes of Kantowski–Sachs metrics[15] for anisotropic cosmologies. Moreover, some examples of metrics used in models for stellar gravitational collapse are[16] of the form (1). As a matter of fact, even when particularizing to specific functions $a(t)$, $b(x)$ and $c(y)$ later on, some of the considered examples correspond to these well-established curved space–times. Finally, it may also be worth pointing out that *a priori*, the above class of metrics solves Einstein's equations for specific distributions of energy-momentum of matter in space–time, in the presence of which the study of the quantized Dirac field may be of interest. Though no specific example will be provided, this avenue could be pursued in future work. The paper is organized as follows. In Sec. II, we present the covariant generalization of the Dirac equation in the nonfactorizable metric. In Sec. III, exact solutions of the Dirac equation and the explicit form of the spinor solution are obtained. Finally, in Sec. IV, we give an exact solution of the Weyl equation considering the same nonfactorizable metric.

II. DIRAC EQUATION IN A NONFACTORIZABLE METRIC

We consider the nonfactorizable metric[12]

$$ds^2=-dt^2+a^2(t)(dx^2+b^2(x)[dy^2+c^2(y)dz^2]), \tag{2}$$

and the covariant generalization of the Dirac equation

$$\{\overline{\gamma}^{\mu}(\partial_{\mu}-\Gamma_{\mu})+m\}\tilde{\Psi}=0. \tag{3}$$

The Γ_{μ} are the spinor connections satisfying the relation

$$\Gamma_{\mu}=-\tfrac{1}{4}(\partial_{\mu}h_a^{\rho}+\Gamma^{\rho}_{\sigma\mu}h_a^{\sigma})g_{\nu\rho}h_b^{\nu}\gamma^b\gamma^a. \tag{4}$$

The $\overline{\gamma}^{\mu}$ are the Dirac matrices associated with the line element (2) and are related to the γ^a-standard flat Dirac matrices as follows:

$$\overline{\gamma}^{\mu}=h_a^{\mu}\gamma^a, \quad \overline{\gamma}_{\mu}=h_{\mu}^a\gamma_a. \tag{5}$$

The tetrad components h_a^μ are defined as[7]

$$g^{\mu\nu}=h_a^\mu h_b^\nu \eta^{ab}, \quad g_{\mu\nu}=h_\mu^a h_\nu^b \eta_{ab}, \tag{6}$$

where $g_{\mu\nu}$ and η_{ab} are the metrics given by (2) and the Minkowski space–time, respectively. The following anticommutation relations hold:

$$[\overline{\gamma}^\mu,\overline{\gamma}^\nu]_+=2g^{\mu\nu}\mathbb{1}, \quad [\gamma^a,\gamma^b]_+=2g^{ab}\mathbb{1}. \tag{7}$$

We can write

$$h_\mu^a=\mathrm{diag}(1,a,ab,abc), \quad g_{\mu\nu}=\mathrm{diag}(1,a^2,a^2b^2,a^2b^2c^2). \tag{8}$$

So, Eq. (4) can be decompose as

$$\Gamma_0=0, \quad \Gamma_1=\tfrac{1}{2}a_{.t}\gamma^0\gamma^1, \quad \Gamma_2=\tfrac{1}{2}ba_{.t}\gamma^0\gamma^2+\tfrac{1}{2}b_{.x}\gamma^1\gamma^2, \tag{9}$$

$$\Gamma_3=\tfrac{1}{2}bca_{.t}\gamma^0\gamma^3+\tfrac{1}{2}cb_{.x}\gamma^1\gamma^3+\tfrac{1}{2}c_{.y}\gamma^2\gamma^3, \tag{10}$$

and the Dirac equation (3) rewrites as

$$\left\{\gamma^0\partial_t+\frac{1}{a}\gamma^1\partial_x+\frac{1}{ab}\gamma^2\partial_y+\frac{1}{abc}\gamma^3\partial_z+m\right\}\Psi=0, \tag{11}$$

where $\tilde{\Psi}$ is related to Ψ by

$$\tilde{\Psi}=a^{-3/2}b^{-1}c^{-1/2}\Psi. \tag{12}$$

Since the metric (2) is a function only of variables t, x and y, we can set

$$\Psi=\Psi(t,x,y)\exp(ik_z z). \tag{13}$$

Using the method of separation of variables,[7] we transform (11) as a sum of two first-order differential operators commuting as follows:

$$[\hat{K}_1,\hat{K}_2]_+=0, \quad \{\hat{K}_1+\hat{K}_2\}\Phi=0, \quad -\hat{K}_1\Phi=\hat{K}_2\Phi=k\Phi, \tag{14}$$

where k is a constant of separation, and

$$\hat{K}_1=-i(ab\gamma^0\partial_t+b\gamma^1\partial_x+abm)\gamma^1\gamma^0, \quad \hat{K}_2=-i\left(\gamma^2\partial_y+\frac{1}{c}\gamma^3\partial_z\right)\gamma^1\gamma^0, \tag{15}$$

$$\Psi=\gamma^1\gamma^0\Phi. \tag{16}$$

Let consider the suitable representation of Dirac matrices:[13]

$$\gamma^0=\begin{pmatrix}-i & 0\\ 0 & i\end{pmatrix}, \quad \gamma^k=\begin{pmatrix}0 & \sigma^k\\ \sigma^k & 0\end{pmatrix}, \quad k=1,2,3. \tag{17}$$

There exists a unitary transformation S that connects Dirac matrices and the spinor Φ in the diagonal gauge to Dirac matrices and the spinor Φ':

$$\gamma^\mu\to\gamma'^\mu=S^{-1}\gamma^\mu S, \quad \Phi\to\Phi'=S^{-1}\Phi, \tag{18}$$

such that the matrix S is given by

$$S=\tfrac{1}{2}(I+\gamma^1\gamma^2+\gamma^2\gamma^3+\gamma^3\gamma^1). \tag{19}$$

Substituting (18) into (14) and expressing γ'^{μ} in terms of γ^{μ}, we obtain

$$(ab\gamma^3\partial_t+b\gamma^0\partial_x+abm\gamma^3\gamma^0+ik)\Phi'=0, \tag{20}$$

$$\left(\gamma^1\gamma^3\gamma^0\partial_y+\frac{1}{c}\gamma^2\gamma^3\gamma^0\partial_z-ik\right)\Phi'=0. \tag{21}$$

Equation (21) splits into two first-order differential equations as

$$\left(\sigma^2\partial_y+\frac{ik_z}{c}\sigma^1-ik\right)\Phi_1'=0, \quad \left(-\sigma^2\partial_y-\frac{ik_z}{c}\sigma^1-ik\right)\Phi_2'=0, \tag{22}$$

where

$$\Phi'=\begin{pmatrix}\Phi_1'\\ \Phi_2'\end{pmatrix}. \tag{23}$$

Using the algebra of Pauli matrices and taking into account the form of (22), we obtain

$$\left(\partial_y+\frac{k_z}{c}\right)\chi_1-k\chi_2=0, \quad \left(\partial_y-\frac{k_z}{c}\right)\chi_2+k\chi_1=0. \tag{24}$$

It is easy from (22) to see that the spinor Φ' has the following structure:

$$\Phi'=\begin{pmatrix}U(t,x)\chi_1(y)\\ U(t,x)\chi_2(y)\\ V(t,x)\chi_1(y)\\ -V(t,x)\chi_2(y)\end{pmatrix}\exp(ik_z z). \tag{25}$$

Eliminating χ_1 and χ_2 from the system (24), respectively, we obtain

$$d_{yy}^2\chi_1+\left(-\frac{k_z}{c^2}d_y c-\frac{k_z^2}{c^2}+k^2\right)\chi_1=0, \quad d_{yy}^2\chi_2+\left(\frac{k_z}{c^2}d_y c-\frac{k_z^2}{c^2}+k^2\right)\chi_2=0. \tag{26}$$

To apply the method of the separation of variables, it is convenient to rewrite Eq. (20) as

$$\left[(a\gamma^0\partial_t+am)\gamma^3\gamma^0+\left(\gamma^0\partial_x+\frac{ik}{b}\right)\right]\Phi'=0. \tag{27}$$

The auxiliary function ξ defined by

$$\Phi'=\left[(a\gamma^0\partial_t+am)\gamma^3\gamma^0+\left(\gamma^0\partial_x-\frac{ik}{b}\right)\right]\xi, \tag{28}$$

and the substitution of Eq. (28) into Eq. (27) give

$$\left[(a\gamma^0\partial_t+am)(-a\gamma^0\partial_t+am)+\left(\gamma^0\partial_x+\frac{ik}{b}\right)\left(\gamma^0\partial_x-\frac{ik}{b}\right)\right]\xi=0. \tag{29}$$

Equation (29) reduces to

$$[\hat{K}_3,\hat{K}_4]_+=0, \quad \{\hat{K}_3+\hat{K}_4\}\xi=0, \tag{30}$$

with

$$\hat{K}_3=(a\gamma^0\partial_t+am)(-a\gamma^0\partial_t+am),\quad \hat{K}_4=\left(\gamma^0\partial_x+\frac{ik}{b}\right)\left(\gamma^0\partial_x-\frac{ik}{b}\right), \tag{31}$$

$$-\hat{K}_3\xi=\hat{K}_4\xi=\lambda^2\xi. \tag{32}$$

From Eq. (32), we can express ξ as follows

$$\xi=\begin{pmatrix}\Sigma_1(t)R_1(x)C_1(y,z)\\ \Sigma_1(t)R_1(x)C_2(y,z)\\ \Sigma_2(t)R_2(x)C_3(y,z)\\ \Sigma_2(t)R_2(x)C_4(y,z)\end{pmatrix}, \tag{33}$$

such that the spinor Φ' can be written as

$$\Phi'=A_0\begin{pmatrix}\Sigma_1(t)R_1(x)\chi_1(y)\\ \Sigma_1(t)R_1(x)\chi_2(y)\\ \Sigma_2(t)R_2(x)\chi_1(y)\\ -\Sigma_2(t)R_2(x)\chi_2(y)\end{pmatrix}\exp(ik_z z), \tag{34}$$

where $\Sigma_1(t)$, $\Sigma_2(t)$, $R_1(x)$ and $R_2(x)$ satisfy

$$\left(\partial_x+\frac{k}{b}\right)R_1=\lambda R_2,\quad \left(\partial_x+\frac{k}{b}\right)R_2=-\lambda R_1, \tag{35}$$

$$(a\partial_t+iam)\Sigma_2=-i\lambda\Sigma_1,\quad (a\partial_t-iam)\Sigma_1=-i\lambda\Sigma_2. \tag{36}$$

Eliminating R_1,R_2 from (35), and Σ_1,Σ_2 from (36), we have

$$\left(\partial_{xx}^2-\frac{k}{b^2}\partial_x b-\frac{k^2}{b^2}+\lambda^2\right)R_1=0,\quad \left(\partial_{xx}^2+\frac{k}{b^2}\partial_x b-\frac{k^2}{b^2}+\lambda^2\right)R_2=0, \tag{37}$$

$$\left(\partial_{tt}^2+m^2+\frac{\lambda^2}{a^2}\right)\Sigma_1=0,\quad \left(\partial_{tt}^2+m^2+\frac{\lambda^2}{a^2}\right)\Sigma_2=0. \tag{38}$$

III. EXACT SOLUTIONS OF DIRAC EQUATION

As already discussed in Sec. I, many works have been devoted to the problem of finding exact solutions to the Dirac equation in external fields and recently some exact solutions have been obtained using different techniques and methods.[2,4] One of the most effective and powerful tools in solving systems of partial differential equations is the method of separation of variables.[6] That is, of course, not just restricted to scalar equations such as the Hamilton–Jacobi, Helmholtz and Laplace–Beltrami equations of mathematical physics, but also applies to systems of partial differential equations such as the Dirac equation in flat or curved space–time. In the last case, this method allows us to reduce the problem to solving a system of ordinary differential equations.

The study of the behavior of relativistic particles obeying the Dirac equation in curved space, in particular in expanding universes, is of considerable importance in astrophysics and cosmology. Such investigations go back to Fock,[17] Tetrode,[18] Schrodinger,[19,20] and McVittie[21] and enable us to quantize the relativistic spin $-\frac{1}{2}$ electron field in curved background and study the effect of gravity in atomic spectra.[22] Thus, the Dirac equation in the zero-momentum limit has been solved by Isham and Nelson[23] who proposed a quantization and obtained a mass of the order of the Universe, so the equation has a different interpretation than the electron. Barut and Duru[2] have been interested in the behavior of the electrons and neutrino in curved spaces and obtained an exact solution for arbitrary momentum and mass, in spatially flat Robertson–Walker space–times. Parker[24] studied the pair creation of $-\frac{1}{2}$ particles (massive and massless) in Robertson–Walker universes. He showed that for massless neutrinos, as a result of conformal invariance, there was no pair creation. Here, we consider the four-dimensional nonfactorizable metric (2) and the final equations (37) and (38). To find exact solutions to these equations in terms of special functions is not always easy. It depends on the analytical expressions of the metric functions $a(t)$, $b(x)$ and $c(y)$. In this section, we restrict our analysis to some interesting particular cases corresponding to the most relevant situations in astrophysics and cosmology[2,17–21,24,25] such as the Robertson–Walker space–times or the Friedman–Robertson–Walker metric, which lead to exact solutions in terms of special functions.

(*i*) $c(y)=\beta y$, where β is arbitrary constant. Substituting this expression into (26), we obtain

$$d_{yy}^2\chi_1+\left(-\frac{k_z}{\beta y^2}-\frac{k_z^2}{\beta^2 y^2}+k^2\right)\chi_1=0,\quad d_{yy}^2\chi_2+\left(\frac{k_z}{\beta y^2}-\frac{k_z^2}{\beta^2 y^2}+k^2\right)\chi_2=0, \tag{39}$$

which have solutions

$$\chi_1=d_1 y^{1/2}\mathcal{C}_{k_z/\beta+1/2}(ky)\quad\text{and}\quad\chi_2=d_2 y^{1/2}\mathcal{C}_{k_z/\beta-1/2}(ky), \tag{40}$$

where $\mathcal{C}$ is the general solution of the cylindrical Bessel equation.[26] The relation between the constants d_1 and d_2 can be obtained in a straightforward way, by substituting (40) into (24).

(*ii*) $c(y)=\beta\exp(\alpha y)$, where α and β are arbitrary constants. The system (26) takes the form

$$d_{yy}^2\chi_1+\left(-\frac{k_z}{\beta\exp(\alpha y)}-\frac{k_z^2}{\beta^2\exp(2\alpha y)}+k^2\right)\chi_1=0, \tag{41}$$

$$d_{yy}^2\chi_2+\left(\frac{k_z}{\beta\exp(\alpha y)}-\frac{k_z^2}{\beta^2\exp(2\alpha y)}+k^2\right)\chi_2=0. \tag{42}$$

Making the change of variables

$$z=2\beta^{-1}k_z\alpha^{-1}\exp(-\alpha y),\quad \chi_{1,2}=z^{1/2}\tilde{\chi}_{1,2}, \tag{43}$$

Eqs. (41) and (42) take the form

$$d_{yy}^2\tilde{\chi}_1+\left(-\frac{1}{4}-\frac{1}{2z}+\frac{\frac{1}{4}+k^2/\alpha^2}{z^2}\right)\tilde{\chi}_1=0,\quad d_{yy}^2\tilde{\chi}_2+\left(-\frac{1}{4}+\frac{1}{2z}+\frac{\frac{1}{4}+k^2/\alpha^2}{z^2}\right)\tilde{\chi}_2=0. \tag{44}$$

Taking into account (43), we get the solutions[26]

$$\chi_1=d_1(\exp(-\alpha y))^{ik/\alpha}\exp(-pe^{-\alpha y})M\left(1+\frac{ik}{\alpha},1+\frac{2ik}{\alpha},2pe^{-\alpha y}\right), \tag{45}$$

$$\chi_2=d_2(\exp(-\alpha y))^{ik/\alpha}\exp(-pe^{-\alpha y})M\left(\frac{ik}{\alpha},1+\frac{2ik}{\alpha},2pe^{-\alpha y}\right), \tag{46}$$

$$p=k_z\beta^{-1}\alpha^{-1}, \tag{47}$$

where $M(a,b,z)$ is the confluent hypergeometric function.

(*iii*) $c(y)=\tan(\alpha y)$. In this case, we get

$$d_{yy}^2\chi_1+\left(-\frac{k_z\alpha+k_z^2}{\sin^2(\alpha y)}+k_z^2+k^2\right)\chi_1=0,\quad d_{yy}^2\chi_2+\left(\frac{k_z\alpha-k_z^2}{\sin^2(\alpha y)}+k_z^2+k^2\right)\chi_2=0. \tag{48}$$

Making the change of variables

$$u = \sin^2(\alpha y), \tag{49}$$

and putting

$$\chi_1 = \sin^{q_1}(\alpha y) f(y), \quad \chi_2 = \sin^{q_2}(\alpha y) g(y), \tag{50}$$

where

$$q_1 = \frac{1}{2} + \left(\frac{1}{4} + \frac{k_z}{\alpha} + \frac{k_z^2}{\alpha^2}\right)^{1/2}, \quad q_2 = \frac{1}{2} + \left(\frac{1}{4} - \frac{k_z}{\alpha} + \frac{k_z^2}{\alpha^2}\right)^{1/2}, \tag{51}$$

the system (48) becomes

$$u(1-u) d_{uu}^2 f + \left(\frac{1}{2} + q_1 - (1+q_1)u\right) d_u f - \left(\frac{q_1^2}{4} - \frac{k_z^2 + k^2}{4\alpha^2}\right) f = 0, \tag{52}$$

$$u(1-u) d_{uu}^2 g + \left(\frac{1}{2} + q_2 - (1+q_2)u\right) d_u g - \left(\frac{q_2^2}{4} - \frac{k_z^2 + k^2}{4\alpha^2}\right) g = 0. \tag{53}$$

The solutions of these equations can be expressed in terms of hypergeometric functions of Gauss $F(a,b,z)$.[26] So, taking into account Eq. (49), they are given by

$$\chi_1 = d_1 \sin^{q_1}(\alpha y) F\left(\frac{1}{2}q_1 + \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, \frac{1}{2}q_1 - \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, q_1 + \frac{1}{2}, \sin^2(\alpha y)\right), \tag{54}$$

$$\chi_2 = d_2 \sin^{q_2}(\alpha y) F\left(\frac{1}{2}q_2 + \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, \frac{1}{2}q_2 - \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, q_2 + \frac{1}{2}, \sin^2(\alpha y)\right). \tag{55}$$

(*iv*) $c(y) = \cot(\alpha y)$. The system (26) transforms to

$$d_{yy}^2 \chi_1 + \left(\frac{k_z \alpha - k_z^2}{\cos^2(\alpha y)} + k_z^2 + k^2\right)\chi_1 = 0, \quad d_{yy}^2 \chi_2 + \left(-\frac{k_z \alpha + k_z^2}{\cos^2(\alpha y)} + k_z^2 + k^2\right)\chi_2 = 0. \tag{56}$$

The solutions of (56) can be obtained from Eqs. (54) and (55) by making the identification

$$\alpha y \to \alpha y + \frac{\pi}{2}. \tag{57}$$

Thus, these solutions take the forms

$$\chi_1 = d_1 \cos^{q_1}(\alpha y) F\left(\frac{1}{2}q_1 + \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, \frac{1}{2}q_1 - \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, q_1 + \frac{1}{2}, \cos^2(\alpha y)\right), \tag{58}$$

$$\chi_2 = d_2 \cos^{q_2}(\alpha y) F\left(\frac{1}{2}q_2 + \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, \frac{1}{2}q_2 - \frac{(k_z^2+k^2)^{1/2}}{2\alpha}, q_2 + \frac{1}{2}, \cos^2(\alpha y)\right), \tag{59}$$

where

$$q_1 = \frac{1}{2} + \left(\frac{1}{4} - \frac{k_z}{\alpha} + \frac{k_z^2}{\alpha^2}\right)^{1/2}, \quad q_2 = \frac{1}{2} + \left(\frac{1}{4} + \frac{k_z}{\alpha} + \frac{k_z^2}{\alpha^2}\right)^{1/2}. \tag{60}$$

(*v*) $c(y) = \tanh(\alpha y)$. In this case, the system (26) rewrites as

$$d_{yy}^2\chi_1+\left(-\frac{k_z\alpha+k_z^2}{\sinh^2(\alpha y)}-k_z^2+k^2\right)\chi_1=0,\quad d_{yy}^2\chi_2+\left(\frac{k_z\alpha-k_z^2}{\sin^2(\alpha y)}-k_z^2+k^2\right)\chi_2=0. \tag{61}$$

Making the change of variables

$$v=-\sinh^2(\alpha y), \tag{62}$$

and following the analog way as in (*iii*), we transform (61) to get

$$v(1-v)d_{vv}^2f+\left(\frac{1}{2}+q_1-(1+q_1)v\right)d_vf-\left(\frac{q_1^2}{4}-\frac{k_z^2-k^2}{4\alpha^2}\right)f=0, \tag{63}$$

$$v(1-v)d_{vv}^2g+\left(\frac{1}{2}+q_2-(1+q_2)v\right)d_vg-\left(\frac{q_2^2}{4}-\frac{k_z^2-k^2}{4\alpha^2}\right)g=0. \tag{64}$$

The solutions of these equations can be also expressed in terms of hypergeometric functions of Gauss $F(a,b,z)$. Thus, taking into account Eq. (62), they are given as

$$\chi_1=d_1\sinh^{q_1}(\alpha y)F\left(\frac{1}{2}q_1+\frac{(k_z^2-k^2)^{1/2}}{2\alpha},\frac{1}{2}q_1-\frac{(k_z^2-k^2)^{1/2}}{2\alpha},q_1+\frac{1}{2},-\sinh^2(\alpha y)\right), \tag{65}$$

$$\chi_2=d_2\sinh^{q_2}(\alpha y)F\left(\frac{1}{2}q_2+\frac{(k_z^2-k^2)^{1/2}}{2\alpha},\frac{1}{2}q_2-\frac{(k_z^2-k^2)^{1/2}}{2\alpha},q_2+\frac{1}{2},-\sinh^2(\alpha y)\right). \tag{66}$$

(*vi*) $c(y)=\coth(\alpha y)$. The system (26) rewrites as

$$d_{yy}^2\chi_1+\left(\frac{k_z\alpha+k_z^2}{\cosh^2(\alpha y)}-k_z^2+k^2\right)\chi_1=0,\quad d_{yy}^2\chi_2+\left(\frac{-k_z\alpha+k_z^2}{\cosh^2(\alpha y)}-k_z^2+k^2\right)\chi_2=0. \tag{67}$$

We can obtain from Eqs. (65) and (66) the solutions of (67) by making the identification

$$\alpha y\rightarrow\alpha y+\frac{i\pi}{2}. \tag{68}$$

Thus, we get

$$\chi_1=d_1\cosh^{q_1}(\alpha y)F\left(\frac{1}{2}q_1+\frac{(k_z^2-k^2)^{1/2}}{2\alpha},\frac{1}{2}q_1-\frac{(k_z^2-k^2)^{1/2}}{2\alpha},q_1+\frac{1}{2},\cosh^2(\alpha y)\right), \tag{69}$$

$$\chi_2=d_2\cosh^{q_2}(\alpha y)F\left(\frac{1}{2}q_2+\frac{(k_z^2-k^2)^{1/2}}{2\alpha},\frac{1}{2}q_2-\frac{(k_z^2-k^2)^{1/2}}{2\alpha},q_2+\frac{1}{2},\cosh^2(\alpha y)\right), \tag{70}$$

where q_1 and q_2 are given by (51).

(*vii*) $c(y)=\sin(\alpha y)$. The system (24) becomes

$$\left(d_y+\frac{k_z}{\sin(\alpha y)}\right)\chi_1-k\chi_2=0\quad\text{and}\quad\left(d_y-\frac{k_z}{\sin(\alpha y)}\right)\chi_2+k\chi_1=0. \tag{71}$$

It is enough to consider the solutions of the system (71) when k and k_z are positive; the other three cases can be obtained by interchanging the roles of χ_1 and χ_2. Considering the ansatz

$$\chi_1=(\sin(\alpha y))^{k_z/\alpha}\sin\left(\frac{\alpha y}{2}\right)f(y)\quad\text{and}\quad\chi_2=(\sin(\alpha y))^{k_z/\alpha}\cos\left(\frac{\alpha y}{2}\right)g(y), \tag{72}$$

and making the change of variables

$$u=\cos(\alpha y), \tag{73}$$

we obtain the differential equations

$$(1-u^2)d_{uu}^2 f+\left(-1-2\left(1+\frac{k_z}{\alpha}\right)u\right)d_u f-\left(\left(\frac{k_z}{\alpha}+\frac{1}{2}\right)^2-\frac{k_z^2}{\alpha^2}\right)f=0, \tag{74}$$

$$(1-u^2)d_{uu}^2 g+\left(1-2\left(1+\frac{k_z}{\alpha}\right)u\right)d_u g-\left(\left(\frac{k_z}{\alpha}+\frac{1}{2}\right)^2-\frac{k_z^2}{\alpha^2}\right)g=0, \tag{75}$$

whose solutions are given in terms of Jacobi polynomials $P_n^{(\alpha,\beta)}$.[26] Thus, taking into account Eqs. (72) and (73), we get

$$\chi_1=d_1(\sin(\alpha y))^{k_z/\alpha}\sin\left(\frac{\alpha y}{2}\right)P_n^{(k_z/\alpha+1/2,k_z/\alpha-1/2)}(\cos(\alpha y)), \tag{76}$$

$$\chi_2=d_2(\sin(\alpha y))^{k_z/\alpha}\cos\left(\frac{\alpha y}{2}\right)P_n^{(k_z/\alpha-1/2,k_z/\alpha+1/2)}(\cos(\alpha y)), \tag{77}$$

where n reads as

$$n=\frac{k}{\alpha}-\frac{k_z}{\alpha}-\frac{1}{2}. \tag{78}$$

(*viii*) $c(y)=\cos(\alpha y)$. The system (37) becomes

$$\left(d_y+\frac{k_z}{\cos(\alpha y)}\right)\chi_1-k\chi_2=0 \quad \text{and} \quad \left(d_y-\frac{k_z}{\cos(\alpha y)}\right)\chi_2+k\chi_1=0. \tag{79}$$

Their solutions can be obtained by analogy with (76) and (77), making the identification

$$\alpha y\to\alpha y-\frac{\pi}{2}, \tag{80}$$

such that

$$\chi_1=d_1(-\cos(\alpha y))^{k_z/\alpha}\left[\sin\left(\frac{\alpha y}{2}\right)-\cos\left(\frac{\alpha y}{2}\right)\right]P_n^{(k_z/\alpha+1/2,k_z/\alpha-1/2)}(\sin(\alpha y)), \tag{81}$$

$$\chi_2=d_2(-\cos(\alpha y))^{k_z/\alpha}\left[\cos\left(\frac{\alpha y}{2}\right)+\sin\left(\frac{\alpha y}{2}\right)\right]P_n^{(k_z/\alpha-1/2,k_z/\alpha+1/2)}(\sin(\alpha y)), \tag{82}$$

where n is given by (78).

(*ix*) $c(y)=\sinh(\alpha y)$. Substituting it into (24), we obtain

$$\left(d_y+\frac{k_z}{\sinh(\alpha y)}\right)\chi_1-k\chi_2=0 \quad \text{and} \quad \left(d_y-\frac{k_z}{\sinh(\alpha y)}\right)\chi_2+k\chi_1=0. \tag{83}$$

Considering the ansatz

$$\chi_1=(\sinh(\alpha y))^{k_z/\alpha}\sinh\left(\frac{\alpha y}{2}\right)f(y), \quad \chi_2=(\sinh(\alpha y))^{k_z/\alpha}\cosh\left(\frac{\alpha y}{2}\right)g(y), \tag{84}$$

and making the change of variables

$$u=-\cosh(\alpha y), \tag{85}$$

we obtain the differential equations

$$(1-u^2)d_{uu}^2 f+\left(1-2\left(1+\frac{k_z}{\alpha}\right)u\right)d_u f-\left(\left(\frac{k_z}{\alpha}+\frac{1}{2}\right)^2+\frac{k_z^2}{\alpha^2}\right)f=0, \tag{86}$$

$$(1-u^2)d_{uu}^2 g+\left(-1-2\left(1+\frac{k_z}{\alpha}\right)u\right)d_u g-\left(\left(\frac{k_z}{\alpha}+\frac{1}{2}\right)^2+\frac{k_z^2}{\alpha^2}\right)g=0, \tag{87}$$

whose solutions are also given in terms of Jacobi polynomials $P_n^{(\alpha,\beta)}$, taking into account Eqs. (84) and (85), as

$$\chi_1=d_1(\sinh(\alpha y))^{k_z/\alpha}\sinh\left(\frac{\alpha y}{2}\right)P_n^{(k_z/\alpha-1/2,k_z/\alpha+1/2)}(-\cosh(\alpha y)), \tag{88}$$

$$\chi_2=d_2(\sinh(\alpha y))^{k_z/\alpha}\cosh\left(\frac{\alpha y}{2}\right)P_n^{(k_z/\alpha+1/2,k_z/\alpha-1/2)}(-\cosh(\alpha y)), \tag{89}$$

where n reads as

$$n=\frac{ik}{\alpha}-\frac{k_z}{\alpha}-\frac{1}{2}. \tag{90}$$

(*x*) $c(y)=\cosh(\alpha y)$. Here the system (24) becomes

$$\left(d_y+\frac{k_z}{\cosh(\alpha y)}\right)\chi_1-k\chi_2=0 \quad \text{and} \quad \left(d_y-\frac{k_z}{\cosh(\alpha y)}\right)\chi_2+k\chi_1=0. \tag{91}$$

As in the previous case, using Eqs. (88) and (89) and making the identifications

$$\alpha y\to\alpha y-\frac{i\pi}{2}, \quad k_z\to ik_z, \tag{92}$$

we get

$$\chi_1=d_1(-i\cosh(\alpha y))^{ik_z/\alpha}\left[\sinh\left(\frac{\alpha y}{2}\right)-i\cosh\left(\frac{\alpha y}{2}\right)\right]P_n^{(ik_z/\alpha-1/2,ik_z/\alpha+1/2)}(i\sinh(\alpha y)), \tag{93}$$

$$\chi_2=d_2(-i\cosh(\alpha y))^{ik_z/\alpha}\left[\cosh\left(\frac{\alpha y}{2}\right)-i\sinh\left(\frac{\alpha y}{2}\right)\right]P_n^{(ik_z/\alpha+1/2,ik_z/\alpha-1/2)}(i\sinh(\alpha y)), \tag{94}$$

where n is given by

$$n=\frac{ik}{\alpha}-\frac{ik_z}{\alpha}-\frac{1}{2}. \tag{95}$$

The metrics associated to cases (*vii*)–(*x*) can be identified as particular cases of Robertson–Walker spaces–times.[3]

When n is not an integer value, we have to express the Jacobi polynomials in terms of the Gauss hypergeometric functions, by means of the relation[26]

$$P_n^{(\alpha,\beta)}(x)=\frac{\Gamma(n+\alpha+1)}{\Gamma(n+1)\Gamma(\alpha+1)}F\left(-n,n+\alpha+\beta+1,\alpha+1,\frac{1-x}{2}\right). \tag{96}$$

Now we proceed to analyze the system of Eq. (35). These equations can be solved in terms of special functions for the following cases.

(*i*) $b(x)=\beta x$, where β is an arbitrary constant. Substituting this expression into (37), we arrive at

$$d_{xx}^2R_1+\left(-\frac{k}{\beta x^2}-\frac{k^2}{\beta^2x^2}+\lambda^2\right)R_1=0 \quad \text{and} \quad d_{xx}^2R_2+\left(\frac{k}{\beta x^2}-\frac{k^2}{\beta^2x^2}+\lambda^2\right)R_2=0, \tag{97}$$

which have solutions

$$R_1=c_0x^{1/2}\mathcal{C}_{k/\beta+1/2}(\lambda x) \quad \text{and} \quad R_2=c_0x^{1/2}\mathcal{C}_{k/\beta-1/2}(\lambda x), \tag{98}$$

where $\mathcal{C}$ is the general solution of the cylindrical Bessel equation.

(*ii*) $b(x)=\beta\exp(\alpha x)$, where α and β are arbitrary constants. The system (37) leads to

$$d_{xx}^2R_1+\left(-\frac{k}{\beta\exp(\alpha x)}-\frac{k^2}{\beta^2\exp(2\alpha x)}+\lambda^2\right)R_1=0, \tag{99}$$

$$d_{xx}^2R_2+\left(\frac{k}{\beta\exp(\alpha x)}-\frac{k^2}{\beta^2\exp(2\alpha x)}+\lambda^2\right)R_2=0. \tag{100}$$

Since Eqs. (99) and (100) have the same structure as the system (41) and (42), we obtain

$$R_1=c_1(\exp(-\alpha x))^{i\lambda/\alpha}\exp(-pe^{-\alpha x})M\left(1+\frac{i\lambda}{\alpha},1+\frac{2i\lambda}{\alpha},2pe^{-\alpha x}\right), \tag{101}$$

$$R_2=c_1(\exp(-\alpha x))^{i\lambda/\alpha}\exp(-pe^{-\alpha x})M\left(\frac{i\lambda}{\alpha},1+\frac{2i\lambda}{\alpha},2pe^{-\alpha x}\right), \tag{102}$$

where $M(a,b,z)$ is the confluent hypergeometric function, and p reads as

$$p=k\beta^{-1}\alpha^{-1}. \tag{103}$$

(*iii*) $b(x)=\sin(\alpha x)$. We have the new system

$$\left(d_x+\frac{k}{\sin(\alpha x)}\right)R_1-kR_2=0 \quad \text{and} \quad \left(d_x-\frac{k}{\sin(\alpha x)}\right)R_2+kR_1=0, \tag{104}$$

from which we deduce

$$R_1=c_2(\sin(\alpha x))^{k/\alpha}\sin\left(\frac{\alpha x}{2}\right)P_n^{(k/\alpha+1/2,k/\alpha-1/2)}(\cos(\alpha x)), \tag{105}$$

$$R_2=c_2(\sin(\alpha x))^{k/\alpha}\cos\left(\frac{\alpha x}{2}\right)P_n^{(k/\alpha-1/2,k/\alpha+1/2)}(\cos(\alpha x)), \tag{106}$$

where n reads as

$$n=\frac{\lambda}{\alpha}-\frac{k}{\alpha}-\frac{1}{2}. \tag{107}$$

(*iv*) $b(x)=\cos(\alpha x)$. Substituting this expression into (35), and making the identification with (105) and (106),

$$\alpha x \rightarrow \alpha x - \frac{\pi}{2}, \tag{108}$$

the solutions take the forms

$$R_1 = c_3(-\cos(\alpha x))^{k/\alpha}\left[\sin\left(\frac{\alpha x}{2}\right) - \cos\left(\frac{\alpha x}{2}\right)\right] P_n^{(k/\alpha+1/2, k/\alpha-1/2)}(\sin(\alpha x)), \tag{109}$$

$$R_2 = c_3(-\cos(\alpha x))^{k/\alpha}\left[\cos\left(\frac{\alpha x}{2}\right) + \sin\left(\frac{\alpha x}{2}\right)\right] P_n^{(k/\alpha-1/2, k/\alpha+1/2)}(\sin(\alpha x)), \tag{110}$$

where n is given by (107).

(*v*) $b(x)=\sinh(\alpha x)$. The system (35) gives

$$\left(d_x + \frac{k}{\sinh(\alpha x)}\right) R_1 - kR_2 = 0 \quad \text{and} \quad \left(d_x - \frac{k}{\sinh(\alpha x)}\right) R_2 + kR_1 = 0. \tag{111}$$

As from the system (83), we obtain

$$R_1 = c_4(\sinh(\alpha x))^{k/\alpha} \sinh\left(\frac{\alpha x}{2}\right) P_n^{(k/\alpha-1/2, k/\alpha+1/2)}(-\cosh(\alpha x)), \tag{112}$$

$$R_2 = c_4(\sinh(\alpha x))^{k/\alpha} \cosh\left(\frac{\alpha x}{2}\right) P_n^{(k/\alpha+1/2, k/\alpha-1/2)}(-\cosh(\alpha x)), \tag{113}$$

where n is given by

$$n = \frac{i\lambda}{\alpha} - \frac{k}{\alpha} - \frac{1}{2}. \tag{114}$$

(*vi*) $b(x)=\cosh(\alpha x)$. Substituting this expression into (35), and making the identification with (112) and (113),

$$\alpha x \rightarrow \alpha x - \frac{i\pi}{2}, \quad k \rightarrow ik, \tag{115}$$

the solutions take the form

$$R_1 = c_5(-i\cosh(\alpha x))^{ik/\alpha}\left[\sinh\left(\frac{\alpha x}{2}\right) - i\cosh\left(\frac{\alpha x}{2}\right)\right] P_n^{(ik/\alpha-1/2, ik/\alpha+1/2)}(i\sinh(\alpha x)), \tag{116}$$

$$R_2 = c_5(-i\cosh(\alpha x))^{ik/\alpha}\left[\cosh\left(\frac{\alpha x}{2}\right) - i\sinh\left(\frac{\alpha x}{2}\right)\right] P_n^{(ik/\alpha+1/2, ik/\alpha-1/2)}(i\sinh(\alpha x)), \tag{117}$$

where n is given by

$$n = \frac{i\lambda}{\alpha} - \frac{ik}{\alpha} - \frac{1}{2}. \tag{118}$$

For the cases (vii) $b(x)=\tan(\alpha x)$, $(viii)$ $b(x)=\cot(\alpha x)$, (ix) $b(x)=\tanh(\alpha x)$ and (x) $b(x)=\tan(\alpha x)$, we obtain the same solutions as in (iii) $c(y)=\tan(\alpha y)$, (iv) $c(y)=\cot(\alpha y)$, (v) $c(y)=\tanh(\alpha y)$ and (vi) $c(y)=\coth(\alpha y)$ by changing

$$k\rightarrow\lambda \quad \text{and} \quad k_z\rightarrow k. \tag{119}$$

Note that the different cases (iii) $b(x)=\sin(\alpha x)$, (v) $b(x)=\sinh(\alpha x)$, (vii) $c(y)=\sin(\alpha y)$ and (ix) $c(y)=\sinh(\alpha y)$ correspond to the Friedman–Robertson–Walker metric,[12] where we have introduced an arbitrary constant α.

Now we proceed to analyze the systems (38). We consider three special models for expansion.[2]

(i) $a(t)=\beta t$. This model also considered by Schrödinger[2] here leads to

$$\left(d_{tt}^2+m^2+\frac{\lambda^2}{\beta^2t^2}\right)\Sigma_1=0. \tag{120}$$

Changing the variable t to

$$z=2imt, \tag{121}$$

Eq. (120) becomes

$$\left(d_{zz}^2-\frac{1}{4}+\frac{\lambda^2}{\beta^2z^2}\right)\Sigma_1=0. \tag{122}$$

We recognize the Whittaker differential equation which gives the solution, by taking into account (121), as follows

$$\Sigma_1=b_1W_{k,\mu}(2imt), \quad \text{where} \quad k=0, \quad \mu=\sqrt{\frac{1}{4}-\frac{\lambda^2}{\beta^2}}. \tag{123}$$

Using the Whittaker function identities[26]

$$zW'_{k,\mu}(z)=\left(\frac{z}{2}-k\right)W_{k,\mu}(z)-W_{k+1,\mu}(z), \tag{124}$$

from (36), we get

$$\Sigma_2=-\frac{ib_1\beta}{\lambda}W_{1,\mu}(2imt). \tag{125}$$

(ii) $a(t)=e^{\alpha t}$, an inflationary universe. Substituting the above expression into (38), we arrive at

$$(d_{tt}^2+m^2+\lambda^2e^{-2\alpha t})\Sigma_1=0. \tag{126}$$

Introducing the new coordinates z by

$$z=\frac{\lambda}{\alpha}e^{-\alpha t}, \tag{127}$$

Eq. (126) becomes the Bessel equation

$$(z^2d_{zz}^2+zd_z+z^2+m^2)\Sigma_1=0. \tag{128}$$

Taking into account Eq. (127), we obtain

$$\Sigma_1 = b_2 J_{im}\left(\frac{\lambda}{\alpha} e^{-\alpha t}\right). \tag{129}$$

Using the Bessel function identities[26]

$$\frac{d}{dz} J_\nu(z) = -J_{\nu+1}(z) + \frac{\nu}{z} J_\nu(z), \tag{130}$$

and from (36) we get

$$\Sigma_2 = \frac{ib_2}{\lambda}\left(\lambda J_{im+1}\left(\frac{\lambda}{\alpha} e^{-\alpha t}\right) - im(\alpha+1) J_{im}\left(\frac{\lambda}{\alpha} e^{-\alpha t}\right)\right). \tag{131}$$

(*iii*) $a(t) = \beta\sqrt{t}$, a model of a radiation-dominated universe. Substituting the above expression into (38), we obtain

$$\left(d_{tt}^2 + m^2 + \frac{\lambda^2}{\beta^2 t}\right)\Sigma_1 = 0. \tag{132}$$

Making a change of variables

$$t = iz^2, \tag{133}$$

Eq. (132) takes the form

$$\left(d_{zz}^2 - \frac{1}{z} d_z - 4m^2 z^2 + \frac{4i\lambda^2}{\beta^2}\right)\Sigma_1 = 0. \tag{134}$$

Putting

$$\Sigma_1(z) = e^{-v/2} F(v) \quad \text{and} \quad v = 2mz^2, \tag{135}$$

we can write Eq. (134) as follows:

$$\left(v d_{vv}^2 - v d_v + \frac{i\lambda^2}{m\beta^2}\right) F = 0. \tag{136}$$

Taking into account (133) and (135), the solution of (136) is given by the confluent hypergeometric function ${}_1F_1(a,b,z)$:

$$\Sigma_1(t) = b_3 e^{imt}\, {}_1F_1\left(0, \frac{-i\lambda^2}{m\beta^2}, -2imt\right). \tag{137}$$

Using the confluent hypergeometric function identities[26]

$$b\ {}_1F_1'(a,b,z) = b\ {}_1F_1(a,b,z) - (b-a)\, {}_1F_1(a,b+1,z), \tag{138}$$

and from (36) we get

$$\Sigma_2 = \frac{\beta b_3}{\sqrt{4i\lambda^2}} e^{imt}(\sqrt{4it} - im - 1)\, {}_1F_1\left(0, \frac{-i\lambda^2}{m\beta^2}, -2imt\right) - \frac{\lambda b_3}{\beta m^2}\sqrt{\frac{t}{4i}}\, {}_1F_1\left(0, \frac{-i\lambda^2}{m\beta^2} + 1, -2imt\right). \tag{139}$$

The different cases (*i*), (*ii*) and (*iv*) are analyzed by Barut *et al.*,[2] considering $b = 1$ and $c = 1$.

IV. SOLUTION OF THE WEYL EQUATION

Neutrinos in the nonfactorizable metric (2) are described by the Weyl equation which corresponds to the massless limit of the Dirac equation. The chirality condition, in the representation (17), reads

$$(1-i\gamma_5)\tilde{\Psi}'=0, \quad \gamma_5=\gamma_0\gamma_1\gamma_2\gamma_3. \tag{140}$$

The Weyl spinor can be expressed in terms of the solution of the Dirac equation as follows:

$$(1+i\gamma_5)\tilde{\Psi}'=\Psi_w. \tag{141}$$

The matrix γ_5 commutes with the matrix transformation S. Therefore, we can write

$$(1+i\gamma_5)\tilde{\Psi}=\Psi_0. \tag{142}$$

Taking into account (12), (16) and (34), the relation (142) takes the form

$$\Psi_0=A_0 a^{-3/2}b^{-1}c^{-1/2}e^{ik_z z}\begin{pmatrix} h \\ ih \end{pmatrix}, \tag{143}$$

where

$$h=\begin{pmatrix} (i-1)(\Sigma_2 R_1+i\Sigma_1 R_2)\chi_1-(1+i)(\Sigma_2 R_1-i\Sigma_1 R_2)\chi_2 \\ (i-1)(\Sigma_2 R_1+i\Sigma_1 R_2)\chi_1+(1+i)(\Sigma_2 R_1-i\Sigma_1 R_2)\chi_2 \end{pmatrix}. \tag{144}$$

The solution in this gauge can be obtained applying the unitary transformation (18) to the spinor (143).

In this paper, we have used the algebraic method of separation of variables to show the possibility of separating Dirac equation in a nonfactorizable metric in terms of two commuting first-order differential operators. We have given analytical solutions in terms of special functions, setting conditions on the metric functions $a(t)$, $b(x)$ and $c(y)$. Some particular cases correspond to the Friedman–Robertson–Walker metric[12] and to the Robertson–Walker spaces–times.[3]

ACKNOWLEDGMENTS

The authors thank the referee for his positive comments on the manuscript, and are grateful for his suggestion to emphasize better the physics motivations for their study. They also thank Professor Jan Govaerts of Unité FYNU, Université Catholique de Louvain, Belgium, for useful discussions, and gratefully acknowledge the UNB/CUD-CIUF-IMSP*I* Belgian Cooperation for financial support.

One-loop stress-tensor renormalization in curved background: The relation between ζ-function and point-splitting approaches, and an improved point-splitting procedure

Valter Moretti[a)]
Department of Mathematics, Trento University, and Istituto Nazionale di Fisica Nucleare, Gruppo Collegato di Trento, I-38050 Povo (TN), Italy

(Received 12 February 1999; accepted for publication 22 March 1999)

We conclude the rigorous analysis of a previous paper [V. Moretti, Commun. Math. Phys. **201**, 327 (1999)] concerning the relation between the (Euclidean) point-splitting approach and the local ζ-function procedure to renormalize physical quantities at one-loop in (Euclidean) Quantum Field Theory in curved space–time. The case of the stress tensor is now considered in general D-dimensional closed manifolds for positive scalar operators $-\Delta+V(x)$. Results obtained formally in previous works [in the case $D=4$ and $V(x)=\xi R(x)+m^2$] are rigorously proven and generalized. It is also proven that, in static Euclidean manifolds, the method is compatible with Lorentzian-time analytic continuations. It is proven that the result of the ζ-function procedure is the same obtained from an improved version of the point-splitting method which uses a particular choice of the term $w_0(x,y)$ in the Hadamard expansion of the Green's function, given in terms of heat-kernel coefficients. This version of the point-splitting procedure works for any value of the field mass m. If D is even, the result is affected by an arbitrary one-parameter class of (conserved in absence of external source) symmetric tensors, dependent on the geometry locally, and it gives rise to the general correct trace expression containing the renormalized field fluctuations as well as the conformal anomaly term. Furthermore, it is proven that, in the case $D=4$ and $V(x)=\xi R(x)+m^2$, the given procedure reduces to the Euclidean version of Wald's improved point-splitting procedure provided the arbitrary mass scale present in the ζ-function is chosen opportunely. It is finally argued that the found point-splitting method should work generally, also dropping the hypothesis of a closed manifold, and not depending on the ζ-function procedure. This fact is indeed checked in the Euclidean section of Minkowski space–time for $A=-\Delta+m^2$ where the method gives rise to the correct Minkowski stress tensor for $m^2\geqslant 0$ automatically. [S0022-2488(99)01008-7]

I. INTRODUCTION

In a previous paper,[1] we have considered the relationship between the ζ-function and the point-splitting procedures in renormalizing some physical quantities: effective Lagrangian, effective action, and field fluctuations. The more interesting quantity, namely, the stress tensor, is the object of the present paper. The aim of this paper is hence twofold. First we want to give a rigorous mathematical foundation as well as a generalization of several propositions contained in Ref. 2 where they have been stated without rigorous proof. This is a quite untrivial task because it involves an extension of the heat kernel theory considering the derivatives of its usual ''asymptotic'' expansion. As we shall see shortly, this is the core of all the analyticity properties of the generalized tensorial ζ-functions involved in the stress-tensor renormalization procedure.

[a)]Electronic mail: moretti@science.unitn.it

Second, we want to study the relation between our technique and the more usual point-splitting procedure in depth. This is another open issue after the appearance of Ref. 2. We know, through practical examples, that these two approaches agree essentially in several concrete cases, but up to now, no general proof of this fact has been given. Anyhow, it was conjectured by Wald[3] that, in general, these two approaches should lead to the same results. The extension of the ζ-function approach to the stress tensor has been introduced in Ref. 2 formally. This paper contains a proof of mathematical consistence of the method in a generalized case as well as a general proof of the agreement between the two approaches under our hypotheses on the manifold and the field operator.

It is a well-known fact that the point-splitting procedure faces some difficulties in the case of a field which is massless. Indeed, in such a case, one cannot make use of the Schwinger–deWitt algorithm to fix w_0 in the Hadamard expansion[3,4] and, at least in the massless conformally coupled case, the point-splitting procedure has been improved in order to get both the conformal anomaly and the conservation of the renormalized stress tensor.[3] Recently, Wald has argued that such an improved procedure, which picks out $w_0 \equiv 0$, can be generalized in more general cases.[5] Differently from the point-splitting procedure, the local ζ-function approach seems to work without to distinguish between different values of mass and coupling with the curvature. This fact makes more intriguing the issue of the relation between the two procedures.

This paper is organized as follows. In the first part, we shall recall the main features of the classical theory of the stress tensor to the reader and we shall introduce the main ideas concerning the renormalization of the stress tensor via the ζ-function. In a second part, first we shall develop further the theory of the heat-kernel expansion in order to build up the theory of the ζ-function of the stress tensor. All the work is developed in a closed D-dimensional manifold for a quite general Euclidean motion operator of a real scalar field. Successively, we shall state and prove several theorems concerning generalizations of several mathematical conjecture employed in Ref. 2. The final part of this work is devoted to investigating the relation between the two considered techniques and to introduce a generalized point-splitting procedure. Indeed, within that part, we shall give a proof of the agreement of the two approaches, introducing an improved point-splitting procedure which is quite similar and generalizes that pointed out in Refs. 3 and 5. We shall see that our prescription gives all the expected results (it gives the trivial stress tensor in Minkowski space–time, the conformal anomaly, and a conserved stress tensor, in general, producing agreement with the result of the field fluctuations renormalization). A final summary ends the work. In the Appendix, the proofs of some theorems and lemmata are reported.

II. PRELIMINARIES

Within this section, we state the general mathematical hypotheses we shall deal with and, very quickly, we review the main physical ideas concerning the classical stress tensor and its one-loop renormalization via point-splitting[4–6] and via local ζ-function.[2]

We assume all the definitions and theorems given in Ref. 1 and we shall refer to those definitions and theorems throughout all parts of this work.

A. General hypotheses and notations

The hypotheses we shall deal with in this work are the same as in Ref. 1. Therefore, from now on, $\mathcal{M}$ is a Hausdorff, connected, oriented, C^∞ Riemannian D-dimensional manifold. We suppose also that $\mathcal{M}$ is compact without boundary (namely, is ''closed''). Concerning the operators, we shall consider real elliptic differential operators with the Schrödinger form ''Laplace–Beltrami operator plus potential''

$$A' = -\Delta + V : C^\infty(\mathcal{M}) \to L^2(\mathcal{M}, d\mu_g), \tag{1}$$

where, locally, $\Delta = \nabla_a \nabla^a$, and ∇ means the covariant derivative associated to the metric connection, $d\mu_g$ is the Borel measure induced by the metric, and V is a *real* function belonging to

$C^\infty(\mathcal{M})$. We assume that A' is bounded below by some $C \geq 0$ (namely A is positive). (See sufficient conditions in Ref. 1.) These are the **general hypotheses** which we shall refer to throughout the paper.

Moreover, in the most part of the theorems, we shall use also the fact that the *injectivity radius* of the manifold r is strictly positive in closed manifolds (see Ref. 1 for further comments on this point).

As general remarks, we remind the reader that, as in the previous work, ''holomorphic'' and ''analytic'' are synonyms throughout this paper, natural units $\hbar = c = 1$ are used, and the symbol A indicates the only self-adjoint extension of the essentially self-adjoint operator A'. In the practice, as seen in Ref. 1, A coincides with the Friedrichs self-adjoint extension of A'. Also, R indicates the scalar curvature. Moreover, the symbol $\sigma(x,y)$ means one-half the squared geodesical distance of x from y which is continuous everywhere and C^∞ in any convex normal neighborhood.

Concerning derivative operators, we shall employ the notations in a fixed local coordinate system,

$$D_x^\alpha := \left. \frac{\partial^{|\alpha|}}{\partial x^{1\alpha_1} \cdots \partial x^{D\alpha_D}} \right|_x , \tag{2}$$

where the *multindex* α is defined by $\alpha := (\alpha_1 \ldots, \alpha_D)$, $\alpha_i \geq 0$ is any natural number ($i = 1,...,D$), and $|\alpha| := \alpha_1 + \cdots + \alpha_D$. Moreover, n_k will indicate the multindex $(0,\cdots 0,n,0,\cdots 0)$ where the only nonvanishing number is $n \in \mathbb{N}$ which takes the kth position.

Concerning the definitions of the metric-connection symbols and curvature tensors, we shall follow the notations and conventions employed in Ref. 1 which are the same employed in Ref. 6, either for Riemannian or Lorentzian signature.

B. Physical background and classical definitions

All quantities related to A' we have considered in Ref. 1 and the averaged stress tensor we consider here, for $D = 4$, appears in (Euclidean) Quantum Field Theory (QFT) in curved background and concerns the theory of quasifree scalar fields. In several concrete cases of QFT, the form of $V(x)$ is $m^2 + \xi R(x)$, where m^2 is the square mass of the considered field, R is the scalar curvature of the manifold, and ξ is a real parameter. As usual the *conformal coupling* is defined by[4,6,7]

$$\xi_D := (D-2)/[4(D-1)]. \tag{3}$$

Similarly to the physical quantities considered in Ref. 1, also the stress tensor is formally obtained from the Euclidean functional integral

$$Z[A'] := \int \mathcal{D}\phi e^{-(1/2)\int_{\mathcal{M}} \phi A'[\mathbf{g}]\phi d\mu_g} =: e^{-S_{\text{eff}}[A']}. \tag{4}$$

Here S_{eff} is the (Euclidean) effective action of the field. (Here, we use the opposite sign conventions in defining the effective action and thus the stress tensor, with respect the conventions employed in Ref. 2. Our conventions are the same as used in Ref. 8.)

The integral above can be considered as a partition function of a field in a particular quantum state corresponding to a canonical ensemble.[8,9] The direct physical interpretation as a partition function should work provided the manifold has a static Lorentzian section obtained by analytically continuing some global temporal coordinate $x^0 = \tau$ of some global chart into imaginary values $\tau \to it$ and considering (assuming that they exist) the induced continuations of the metric and relevant quantities. It is required also that ∂_τ is a global Killing field of the Riemannian manifold generated by an isometry group S_1. Finally, it is required that ∂_τ can be continued into a (generally local) timelike Killing field ∂_t in the Lorentzian section (see Refs. 9 and 8). Then one assumes that $k_B \beta$ is the inverse of the temperature of the canonical ensemble quantum state, β

being the period of the coordinate τ. The limit case of vanishing temperature is also considered and, in that case, the manifold cannot be compact. Similar interpretations hold for the (analytic continuations of) the stress tensor.

Formally[4,8–11] we have $Z[A',\mathbf{g}]:=[\det(A'/\mu^2)]^{-1/2}$, where our definition of the determinant of the operator A' is given by the ζ-function approach[4,8–11] as pointed out in Ref. 1. The scale μ^2 present in the determinant is necessary for dimensional reasons[9] and plays a central role in the ζ-function interpretation of the determinant and in the consequent theory. Such a scale introduces an ambiguity which remains in the finite renormalization parts of the renormalized quantities and, dealing with the renormalization of the stress tensor within the semiclassical approach to the quantum gravity, it determines the presence of quadratic-curvature terms in effective Einstein equations.[2] Similar results are discussed in Refs. 3–6 employing other renormalization procedures (point-splitting).

Coming to the (Euclidean) *classical* stress tensor $T_{ab}(x)$, it is defined (e.g., see Ref. 7) as the locally quadratic form of the field obtained by the usual functional derivative once the field ϕ is fixed:

$$T_{ab}[\phi,\mathbf{g}](x):=\frac{2}{\sqrt{g}}\,\frac{\delta}{\delta g_{ab}(x)}\left(\frac{1}{2}\int_{\mathcal{I}}\sqrt{g(x)}\,\phi A'[\mathbf{g}]\phi\, d^Dx\right). \tag{5}$$

This functional derivative can be rigorously understood in terms of a Gâteaux derivative for functionals on real $C^\infty(\mathcal{I})$ *symmetric* tensor fields g_{ab} and the integration above is performed in the open set $\mathcal{I}$ containing x where the considered coordinate system is defined. Equation (5) means that, and this is the rigorous definition of the *symmetric* tensor field $T_{ab}[\phi,\mathbf{g}](x)$, for any C^∞ *symmetric* tensor field h_{ab} with compact support contained in $\mathcal{I}$

$$2\,\frac{d}{d\alpha}\bigg|_{\alpha=0} S_{\mathcal{I}}[\mathbf{g}+\alpha\mathbf{h}]=\frac{1}{2}\int_{\mathcal{I}}\sqrt{g(x)}\,T_{ab}[\phi,\mathbf{g}](x)h^{ab}(x)\,d^Dx, \tag{6}$$

where

$$S_{\mathcal{I}}[\phi,\mathbf{g}]:=\frac{1}{2}\int_{\mathcal{I}}\sqrt{g(x)}\,\phi A'[\mathbf{g}]\phi\, d^Dx. \tag{7}$$

In the case

$$A'=-\Delta+m^2+\xi R(x)+V'(x), \tag{8}$$

V' being a C^∞ function which does not depend on the metric, a direct computation of $T_{ab}(x)$ through this procedure gives

$$\begin{aligned}T_{ab}[\phi,\mathbf{g}](x)={}&\nabla_a\phi(x)\nabla_b\phi(x)-\tfrac{1}{2}g_{ab}(x)[\nabla_c\phi(x)\nabla^c\phi(x)+(m^2+V'(x))\,\phi^2(x)]\\&+\xi[(R_{ab}(x)-\tfrac{1}{2}g_{ab}(x)R(x))\phi^2(x)+g_{ab}(x)\nabla_c\nabla^c\phi^2-\nabla_a\nabla_b\phi^2(x)].\end{aligned} \tag{9}$$

As is well known, T_{ab} given in (9) and evaluated on ϕ is *conserved* ($\nabla_a T^{ab}\equiv 0$) provided ϕ is a sufficiently smooth (customary C^∞) solution of the Euclidean motion, namely, $A'\phi\equiv 0$, and $V'\equiv 0$. More generally for the solution of Euclidean motion, in local coordinates and for any point $x\in M$ one finds

$$\nabla_a T^{ab}[\phi,\mathbf{g}](x)=-\tfrac{1}{2}\phi^2(x)\nabla^b V'(x). \tag{10}$$

Another important classical property is the following one. Whenever the field ϕ is massless and conformally coupled [i.e., $V'(x)\equiv m^2=0$ and $\xi=\xi_D$], the Euclidean action $S_{\mathcal{M}}$ is invariant under local conformal transformations and it holds also

$$g_{ab}T^{ab}[\phi,\mathbf{g}](x)=0 \tag{11}$$

everywhere, for smooth fields ϕ which are solutions of the (Euclidean) motion equations. Equations (10) and (11) can be checked for the tensor in (9) directly, holding our general hypotheses.

Actually, the requirement of A' positive is completely unnecessary for all the definitions and results given above which hold true in any C^∞ Riemannian as well as *Lorentzian* manifold. In our approach, the Lorentzian stress tensor is obtained by analytic continuation of the Euclidean time as pointed out above.

Passing to the quantum-averaged quantities, following Schwinger,[12] the *one-loop stress tensor* averaged on the quantum state determined by the Feynman propagator obtained from the Green's function of A' can be *formally* defined by[4,5,8,9]

$$\langle T_{ab}(x|A')\rangle := \frac{2}{\sqrt{g}}\frac{\delta}{\delta g_{ab}(x)}S_{\rm eff} = Z[A',\mathbf{g}]^{-1}\int \mathcal{D}\phi e^{-(1/2)\int_{\mathcal{M}}\phi A'[\mathbf{g}]\phi d\mu_g}T_{ab}[\phi,\mathbf{g}](x). \tag{12}$$

It is well known that the right-hand sides of (12) and the corresponding quantity in the Lorentzian section are affected by divergences whenever one tries to compute them by trivial procedures.[4,6,8] For instance, proceeding as usual (e.g., see Ref. 5), interpreting the functional integral of $\phi(x)\phi(y)$ as a Green's function of A' (the analytic continuation of the Feynman propagator), $G(x,y)$, and then defining an off-diagonal quantum averaged stress tensor,

$$\langle T_{ab}(x,y)\rangle = Z[A',\mathbf{g}]^{-1}\int \mathcal{D}\phi e^{-(1/2)\int_{\mathcal{M}}\phi A'[\mathbf{g}]\phi d\mu_g}O_{ab}(x,y)\phi(x)\phi(y) = O_{ab}(x,y)G(x,y), \tag{13}$$

where $O_{ab}(x,y)$ is an opportune bivectorial differential operator (see Ref. 5), the limit of coincidence of arguments *x* and *y*, necessary to get $\langle T_{ab}(x)\rangle$, trivially diverges. One is therefore forced to remove these divergences *by hand* and this is nothing but the main idea of the *point-splitting procedure*. Within the point-splitting procedure (10) is requested also for the quantum-averaged stress tensor at least in the case $V'=0$. Conversely, the property (11) generally does not hold in the case of a conformally coupled massless field: a *conformal anomaly* appears.[3–6]

Another approach to interpret the left-hand side of (12) in terms of local ζ-function was introduced in Ref. 2 without rigorous mathematical discussion. Anyhow, this approach has produced correct results and agreement with point-splitting procedures in several concrete cases[2,13] and it has pointed out a strong self-consistence and a general agreement[2] with the general axiomatic theory of the stress tensor renormalization built up by Wald.[5] (It is anyway worth stressing that Wald's axiomatic approach concerns the Lorentzian theory and thus any comparison involves an analytical continuation of the Euclidean theory. In such a way all the issues related to the locality of the theory cannot be compared directly with the general ζ-function approach.) Moreover, differently from the known point-splitting techniques, no difficulty arises dealing with the case of a massless conformally coupled field.

Similarly to the cases treated in Ref. 1, the *definition* of the formal quantity on the left-hand side of (12)[2] given in terms of the ζ-function and heat kernel contains an implicit *infinite renormalization* procedure in the sense that the result is finally free from divergences.

C. The key idea of the ζ-function regularization of the stress tensor

The key idea of ζ-function regularization of the stress tensor concerns the extension of the use of the ζ-function from the effective action to the stress tensor employing some manipulations of the series involved in the ζ-function technique. We remind the reader that formally one has[9,8,1]

$$S_{\rm eff}[A]_{\mu^2} = \frac{1}{2}\frac{d}{ds}\bigg|_{s=0}\left\{-\sum_{j\in\mathbb{N}}{}'\left(\frac{\lambda_j}{\mu^2}\right)^{-s}\right\}. \tag{14}$$

Here μ is the usual arbitrary mass scale necessary for dimensional reasons. Actually, the identity above holds true in the sense of the analytic continuation. Then, one can try to give some meaning to the following formal passages:

$$\langle T_{ab}(x)\rangle_{\mu^2}=\frac{2}{\sqrt{g(x)}}\frac{\delta}{\delta g_{ab}(x)}\frac{1}{2}\frac{d}{ds}\bigg|_{s=0}\left\{-\sum_{j\in\mathbb{N}}{}'\left(\frac{\lambda_j}{\mu^2}\right)^{-s}\right\}$$
$$=\frac{1}{2}\frac{d}{ds}\bigg|_{s=0}\left\{-\sum_{j\in\mathbb{N}}{}'\frac{2}{\sqrt{g(x)}}\frac{\delta}{\delta g_{ab}(x)}\left(\frac{\lambda_j}{\mu^2}\right)^{-s}\right\}$$
$$=\frac{1}{2}\frac{d}{ds}\bigg|_{s=0}\left\{\frac{s}{\mu^2}\sum_{j\in\mathbb{N}}{}'\left(\frac{\lambda_j}{\mu^2}\right)^{-(s+1)}\frac{2}{\sqrt{g(x)}}\frac{\delta\lambda_j}{\delta g_{ab}(x)}\right\}. \tag{15}$$

The functional derivative of λ_j has been computed in Ref. 2, at least formally. The passages above are mathematically incorrect most likely; anyhow, in Ref. 2 it was conjectured that the series in the last line of (15) converges and it can be analytically continued into a regular function $Z_{ab}(s,x|A/\mu^2)$ in a neighborhood of $s=0$. Then, one can *define* the renormalized averaged one-loop stress tensor as

$$\langle T_{ab}(x)\rangle_{\mu^2}:=\frac{1}{2}\frac{d}{ds}\bigg|_{s=0}Z_{ab}(s,x|A/\mu^2). \tag{16}$$

The explicit form of Z_{ab} found in Ref. 2 following the route above was

$$Z_{ab}(s,x|A/\mu^2)=2\frac{s}{\mu^2}\zeta_{ab}(s+1,x|A/\mu^2)+sg_{ab}(x)\zeta(s,x|A/\mu^2), \tag{17}$$

where $\zeta_{ab}(s,x|A/\mu^2)$ is the analytic continuation of the series

$$\sum_{j\in\mathbb{N}}{}'\left(\frac{\lambda_j}{\mu^2}\right)^{-s}T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x), \tag{18}$$

and

$$T_{ab}[\phi,\phi^*,\mathbf{g}](x):=-\frac{2}{\sqrt{g(x)}}\frac{\delta}{\delta g_{ab}(x)}\frac{1}{2}\int_{\mathcal{I}}\phi A'[\mathbf{g}]\phi^*\,d\mu_g. \tag{19}$$

However, no proof of the convergence of the series above was given in Ref. 2 for the general case, but the method was checked in concrete cases, where it was found that the series above converges really as supposed. In Ref. 2, it was shown also that, assuming reasonable mathematical properties of the involved functions, this approach in four-dimensional operators $A'=-\Delta+\xi R(x)+m^2$ should produce a stress tensor which is conserved and gives rise to the conformal anomaly. In Ref. 2, it was also (not rigorously) proven that the ambiguity arising from the presence of the arbitrary scale μ^2 gives rise to conserved geometric terms added to the stress tensor, in agreement with Wald's axioms.

We expect that the not completely rigorous procedures employed in Ref. 2 make sense provided the usual heat-kernel ''asymptotic'' expansion at $t\to 0$ can be derived in the variables which range in the manifold producing a similar expansion (this result is not trivial at all) and provided the series (18) can be derived under the symbol of summation (also this fact is not so obvious). Therefore, in the next parts of this work, we shall investigate also similar issues before we prove and generalize results found in Ref. 2.

III. THE LOCAL ζ-FUNCTION AND THE ONE-LOOP STRESS TENSOR

In this part and within our general hypotheses, we develop a rigorous theory of the ζ-function of the stress tensor and give a rigorous proof of some properties of particular tensorial ζ-functions introduced in Ref. 2.

The first subsection is devoted to generalizing some properties of the heat-kernel concerning the smoothness of several heat-kernel expansions necessary in the second subsection.

A. The smoothness of the heat-kernel expansion and the ζ-function

A first very useful result, which we state in the form of a lemma, concerns the smoothness of the heat-kernel expansion for $t\to 0$ (Theorem 1.3 of Ref. 1) and the possibility of deriving term by term such an "asymptotic expansion."

Before stating the result it is worth stressing that, in the trivial case $|\alpha|=|\beta|=0$, the statement of the lemma below and the corresponding proof include the point $(a2)$ in Theorem 1.3 of Ref. 1 given without proof there.

Lemma 3.1: Let us assume our general hypotheses on $\mathcal{M}$ *and* A'. *For any* $u\in\mathcal{M}$ *there is an open neighborhood* I_u *centered on u such that, for any local coordinate system defined therein, for any couple of points* x, $y\in I_u$, *for any couple of multindices* α, β, *and for any integer* $N>D/2+2|\alpha|+2|\beta|$ $(D/2+2$ *if* $|\alpha|=|\beta|=0)$ *the heat-kernel expansion (a) of Theorem 1.3 in Ref. 1 can be derived term by term obtaining* $[\eta\in(0,1)$ *is fixed arbitrarily as usual*$]$

$$D_x^\alpha D_y^\beta K(t,x,y)=D_x^\alpha D_y^\beta\left\{\frac{e^{-\sigma(x,y)/2t}}{(4\pi t)^{D/2}}\sum_{j=0}^{N} a_j(x,y|A)t^j\right\}+\frac{e^{-\eta\sigma(x,y)/2t}}{(4\pi t)^{D/2}}t^{N-|\alpha|-|\beta|}O_{\eta,N}^{(\alpha,\beta)}(t;x,y), \tag{20}$$

where the derivatives are computed in the common coordinate system given above and the function $(t,x,y)\mapsto O_{\eta,N}^{(\alpha\beta)}(t;x,y)$ *belongs to* $C^0([0,+\infty)\times I_u\times I_u)$ *at least, and for any positive constant* $K_{\eta,N}^{(\alpha,\beta)}$ *and* $0\leq t<K_{\eta,N}^{(\alpha,\beta)}$, *one gets*

$$|O_{\eta,N}^{(\alpha,\beta)}(t;x,y)|<M_{K_{\eta,N}^{(\alpha,\beta)}}|t|, \tag{21}$$

$M_{K_{\eta,N}^{(\alpha,\beta)}}$ *being a corresponding positive constant not dependent on* $x,y\in I_u$ *and* t.

Proof: See the Appendix. □

The next lemma concerns the possibility of interchanging the operators D_x^α, D_y^β with the symbol of series in the eigenvector expansion for the heat-kernel given in (b) of Theorem 1.1 in Ref. 1.

Lemma 3.2: Within our hypotheses on M and A', *the eigenvector expansion of the heat kernel given in (b) of Theorem 1.1 in* Ref. 1,

$$K(t,x,y|A)=\sum_{j=0}^{\infty} e^{-\lambda_j t}\phi_j(x)\phi_j^*(y), \tag{22}$$

where $t\in(0,+\infty)$, $x,y\in\mathcal{M}$, *and the real numbers* $\lambda_j(0\leq\lambda_0\leq\lambda_1,\leq\lambda_2,\leq\cdots)$ *are the eigenvalues of A with corresponding orthogonal normalized eigenvector* ϕ_j, *can be derived in x and y passing the derivative operators under the symbol of series. Indeed, in a coordinate system defined in a sufficiently small neighborhood* I_u *of any point* $u\in\mathcal{M}$, *for* $x,y\in I_u$, *for* $t\in(0,+\infty)$ *and for any couple of multindices* α,β,

$$D_x^\alpha D_y^\beta K(t,x,y|A)=\sum_{j=0}^{\infty} e^{-\lambda_j t}D_x^\alpha\phi_j(x)D_y^\beta\phi_j^*(y). \tag{23}$$

Moreover, for any $T>0$ *the following upper bounds hold:*

$$|e^{-\lambda_j t} D_x^\alpha \phi_j(x) D_y^\beta \phi_j^*(y)| \leq P_T^{(\alpha,\beta)} e^{-\lambda_j(t-2T)}, \quad (24)$$

$$|D_x^\alpha D_y^\beta K(t,x,y|A) - D_x^\alpha D_y^\beta P_0(x,y|A)| \leq P_T^{(\alpha,\beta)} \sum_{j\in\mathbb{N}}{}' e^{-\lambda_j(t-2T)} \quad (25)$$

$$\leq Q_T^{(\alpha,\beta)} e^{-\lambda(t-2T)}, \quad (26)$$

where $x,y \in I_u$ *and* $t \in (2T,+\infty)$, $P_T^{(\alpha,\beta)}$ *and* $Q_T^{(\alpha,\beta)}$ *are positive constants which do not depend on t,x,y,* $P_0(x,y|A)$ *is the integral kernel of the projector onto the kernel of A,* λ *is the value of the first strictly positive eigenvalue, the prime on the summation symbol indicates that the summation on the vanishing eigenvalues is not considered, and, finally,*

$$P_T^{(\alpha,\beta)} = [\sup_{x\in \overline{I_u}} \|D_x^\alpha K(T,x,.|A)\|_{L^2(\mathcal{M},d\mu_g)}][\sup_{y\in \overline{I_u}} \|D_y^\beta K(T,.,y|A)\|_{L^2(\mathcal{M},d\mu_g)}]. \quad (27)$$

Therefore, the convergence of the series in (23) is absolute in a uniform sense for (t,x,y) belonging in any set $[\gamma,+\infty)\times I_u \times I_u$, $\gamma > 0$.

Proof: See the Appendix. □

Remark: The right-hand side of (25) can be also written down as

$$P_T^{(\alpha,\beta)} \int_{\mathcal{M}} d\mu_g(z) \{K(t-2T,z,z|A) - P_0(z,z|A)\} = P_T^{(\alpha,\beta)} \,\mathrm{Tr}\{K_{(t-2T)} - P_0\}. \quad (28)$$

The two lemmata above enable us to state and prove a theorem concerning the derivability of the ζ-function. First of all, let us give some definitions (in the following we shall refer to Definitions 2.1 and 2.2 in Ref. 1).

Definition 3.1: Let us assume our general hypotheses on $\mathcal{M}$ *and* A'. *Fixing a sufficiently small neighborhood* I_u *of any point* $u \in \mathcal{M}$, *considering a coordinate system defined in* I_u *and choosing a couple of multindices* α,β, *the* **off-diagonal derived local ζ-function** *of the operator A is defined for* $x,y \in I_u$, $\mathrm{Re}\, s > D/2 + |\alpha| + |\beta|$, *as*

$$\zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2) := D_x^\alpha D_y^\beta \zeta(s,x,y|A/\mu^2), \quad (29)$$

provided the right-hand side exists, where both derivatives are computed in the coordinate system defined above.

Definition 3.2: Let us assume our general hypotheses on $\mathcal{M}$ *and* A'. *Fixing a sufficiently small neighborhood* I_u *of any point* $u \in \mathcal{M}$, *considering a coordinate system defined in* I_u *and choosing a couple of multindices* α,β, *the* **derived local ζ-function** *of the operator A is defined for* $x \in I_u$, $\mathrm{Re}\, s > D/2 + |\alpha| + |\beta|$, *as*

$$\zeta^{(\alpha,\beta)}(s,x|A/\mu^2) := \{D_x^\alpha D_y^\beta \zeta(s,x,y|A/\mu^2)\}_{x=y}, \quad (30)$$

provided the right-hand side exists, where both derivatives are computed in the coordinate system defined above.

Remark: The use of a common coordinate system either for x and y is essential in these definitions.

The following theorem proves that the given definitions make sense.

Theorem 3.1: *Let us assume our general hypotheses on* $\mathcal{M}$ *and* A'. *The local off-diagonal* ζ*-function of the operator A defined for* $x,y \in \mathcal{M}$, $\mathrm{Re}\, s > D/2$, $\mu > 0$ (μ *being a constant with the dimension of a mass*),

$$\zeta(s,x,y|A/\mu^2) = \frac{1}{\Gamma(s)} \int_0^{+\infty} d(\mu^2 t)(\mu^2 t)^{s-1} \{K(t,x,y|A) - P_0(x,y|A)\}, \quad (31)$$

can be derived in x and y under the symbol of integration in a common coordinate system defined in a sufficiently small neighborhood I_u of any point $u \in \mathcal{M}$, provided $\mathrm{Re}\, s$ is sufficiently large. In particular, for any choice of multindices α,β and $x,y \in I_u$, it holds
(a) *for $\mathrm{Re}\, s > D/2 + |\alpha| + |\beta|$ the derived local ζ-functions are well defined holding*

$$D_x^\alpha D_y^\beta \zeta(s,x,y|A/\mu^2) = \frac{1}{\Gamma(s)} \int_0^{+\infty} d(\mu^2 t)(\mu^2 t)^{s-1} D_x^\alpha D_y^\beta \{K(t,x,y|A) - P_0(x,y|A)\}. \quad (32)$$

Moreover, the right-hand side of (32) defines an s-analytic function which belongs to $C^0(\{s \in \mathbb{C} | \mathrm{Re}\, s > D/2 + |\alpha| + |\beta|\} \times I_u \times I_u)$ together with all its s-derivatives.
(b) *Whenever $x \neq y$ are fixed in I_u,*

(1) *the right-hand side of (32) can be analytically continued in the variable s in the whole complex plane.*

(2) *Varying $s \in \mathbb{C}$ and $(x,y) \in (I_u \times I_u) - \mathcal{D}_{I_u}$, the s-continued function in (31) defines an everywhere s-analytic function which belongs to $C^\infty(\mathbb{C} \times \{(I_u \times I_u) - \mathcal{D}_{Iu}\})$ [where $\mathcal{D}_{I_u} := \{(x,y) \in I_u \times I_u | x = y\}$] and it holds in $\mathbb{C} \times \{(I_u \times I_u) - \mathcal{D}_{Iu}\}$*

$$D_x^\alpha D_y^\beta \zeta(s,x,y|A/\mu^2) = \zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2), \quad (33)$$

where the function ζ on the left-hand side and the function $\zeta^{(\alpha,\beta)}$ on the right-hand side are the respective s-analytic continuations of the initially defined ζ-function (31) and the right-hand side of (32).

(3) *Equation (32) holds also when the left-hand side is replaced by the s-continued function $\zeta^{(\alpha,\beta)}$ for $\mathrm{Re}\, s > 0$, or everywhere provided $D_x^\alpha D_y^\beta P_0(x,y|A) = 0$ in the considered point (x,y).*
(c) *Whenever $x = y$ is fixed in I_u,*

(1) *the right-hand side of (30) can be analytically continued in the variable s in the complex plane obtaining a meromorphic function with possible poles, which are simple poles only, situated in the points*

$$s_j^{(\alpha,\beta)} = D/2 + |\alpha| + |\beta| - j, \quad j = 0,1,2,..., \quad \text{if } D \text{ is odd};$$

$$s_j^{(\alpha,\beta)} = D/2 + |\alpha| + |\beta| - j, \quad j = 0,1,2,...,D/2 - 1 + |\alpha| + |\beta|, \quad \text{if } D \text{ even}.$$

These poles and the corresponding residues are the same as for the set of analytic functions, labeled by the integer $N > D/2 + 2|\alpha| + 2|\beta|$ ($N > D/2 + 2$ if $|\alpha| = |\beta| = 0$),

$$R_N(s,x)_{\mu_0^{-2}} := \frac{\mu^{2s}}{(4\pi)^{D/2}\Gamma(s)} \sum_{j=0}^{N} \int_0^{\mu_0^{-2}} dt \times \{D_x^\alpha D_y^\beta e^{-\sigma(x,y)/2t} a_j(x,y|A)\}_{x=y} t^{s-1-D/2+j}, \quad (34)$$

defined for $x \in I_u$ and $\mathrm{Re}\, s > D/2 + |\alpha| + |\beta|$ and then continued in the s-complex plane. μ_0 is an arbitrary strictly positive mass scale which does not appear in the residues.

(2) *Varying $x \in I_u$, the s-continued function belongs to $C^0((\mathbb{C} - \mathcal{P}^{(\alpha,\beta)}) \times \mathcal{M})$ together with all its s derivatives, $\mathcal{P}^{(\alpha,\beta)}$ being the set of the actual poles (each for some x) among the points listed above. Moreover, for any coordinate x^k and $(s,x) \in \{\mathbb{C} - (\mathcal{P}^{(\alpha,\beta)} \cup \mathcal{P}^{(\alpha+1_k,\beta)} \cup \mathcal{P}^{(\alpha,\beta+1_k)})\} \times I_u$, $(\partial/\partial x^k)\zeta^{(\alpha,\beta)}(s,x|A/\mu^2)$ exists, is continuous in (s,x) with all of its s derivatives, analytic in the variable s and*

$$\frac{\partial}{\partial x^k} \zeta^{(\alpha,\beta)}(s,x|A/\mu^2) = \zeta^{(\alpha+1_k,\beta)}(s,x|A/\mu^2) + \zeta^{(\alpha,\beta+1_k)}(s,x|A/\mu^2), \quad (35)$$

where $\zeta^{(\alpha,\beta)}$ is the analytic continuation of the initially defined function (30).

(d) *For* $x,y \in I_u$, *the analytic continuations of the right-hand sides of (29) and (30) are well defined in a neighborhood of* $s=0$ *and it holds, and the result does not depend on the values of* $\mu_0>0$ *and* $\mu>0$,

$$[D_x^\alpha D_y^\beta \zeta(s,x,y|A/\mu^2)]_{s=0} + D_x^\alpha D_y^\beta P(x,y) = \delta_D \delta_{x,y} \lim_{s\to 0} R_N(s,x)_{\mu_0^{-2}}, \tag{36}$$

where $|_{s=0}$ *means the analytic continuation from* $\mathrm{Re}\, s>D/2+|\alpha|+|\beta|$ *to* $s=0$ *of the considered function and N is any integer* $>D/2+2|\alpha|+2|\beta|$ ($D/2$ *whenever* $|\alpha|=|\beta|=0$). *Finally, we have defined* $\delta_D=0$ *if D is odd and 1 otherwise,* $\delta_{x,y}=0$ *if* $x\neq y$ *or 1 otherwise.*

Sketch of Proof: The proof of this theorem is a straightforward generalization of the proof of Theorem 2.2 in Ref. 1, so we just sketch this proof. As in the proof of Theorem 2.2 in Ref. 1, the main idea is to break off the integration in (31) for $\mathrm{Re}\, s>D/2$ as

$$\zeta(s,x,y|A/\mu^2) = \frac{\mu^{2s}}{\Gamma(s)} \int_0^{+\infty} dt\, t^{s-1}[K(t,x,y|A) - P_0(x,y|A)] \tag{37}$$

$$= \frac{\mu^{2s}}{\Gamma(s)} \int_0^{\mu_0^{-2}} \{\cdots\} + \frac{\mu^{2s}}{\Gamma(s)} \int_{\mu_0^{-2}}^{+\infty} \{\cdots\}, \tag{38}$$

where $\mu_0>0$ is an arbitrary mass cutoff. Then one studies the possibility of computing the derivative passing D_x^α and D_y^β under the symbol of integration in both integrals on the right-hand-side above. This is possible provided the absolute values of the derived integrand are *x*,*y* uniformly bounded by integrable functions dependent on α,β in general, for any choice of α and β. This assures also the continuity of the derivatives because the derivatives of the integrands are continuous functions. The analyticity in *s* can be proved by checking the Cauchy–Riemann conditions passing the derivative under the symbol of integration once again. The *s*-derivatives of the integrand at any order can still be proven to be bounded with the same procedure. Then the proof is similar to the proof of Theorem 2.2 of Ref. 1. One uses Lemma 3.2 and (26) (choosing $2T<\mu_0^{-2}$) in place of the corresponding formula (99) of Ref. 1, to prove that the latter integral on the right-hand side of (38) can be derived under the symbol of integration obtaining an *s*-analytic function continuous with all of its *s*-derivatives, for $s\in\mathbb{C}$ and $x,y\in I_u$. The former integral can be studied employing Lemma 3.1 and, in particular, (20). The requirement $N>D/2+2$ in the expansion in Ref. 1 has to be changed $N>D/2+2|\alpha|+2|\beta|$ in the present case. The requirement in the point (a) $\mathrm{Re}\, s>D/2+|\alpha|+|\beta|$ arises by the term with $j=0$ in the heat-kernel expansion when all the derivatives either in *x* and in *y* act on the exponential producing a factor $t^{-|\alpha|-|\beta|}$ and posing $x=y$ in the end. Equation (101) and the successive ones of Ref. 1 have to be changed employing $O_\eta^{(\alpha,\beta)}$ in place of O_η and $t^{s-1+N-D/2-|\alpha|-|\beta|}$ in place of $t^{s-1+N-D/2}$.

The requirement $D_x^\alpha D_y^\beta P_0(x,y|A)=0$ in (b3) is simply due to the divergence of the integral $\int_0^{\mu_0^{-2}} dt t^{s-1}$ for $s\leqslant 0$.

Equation (36) is essentially due to the presence of the factor $1/\Gamma(s)$ in all considered integrals, which vanishes with a simple zero as $s\to 0$. □

Comments:

(1) The right-hand side of (36), for $x=y$ and when *D* is even, has the form

$$\frac{D_x^\alpha D_y^\beta a_{D/2}(x,y|A)+\cdots}{(4\pi)^{D/2}}, \tag{39}$$

where the dots indicate a finite number of further terms consisting of derivatives of product of heat-kernel coefficients and powers of $\sigma(x,y)$, computed in the coincidence limit of the arguments. In the case $|\alpha|=|\beta|=0$, this agrees with the found result for the simple local ζ-function given in Ref. 1.

(2) It is worth noticing that the right-hand side of (36) proves that the procedures of s-continuing $D_x^\alpha D_y^\beta \zeta(s,x,y|A/\mu^2)$ and that of taking the coincidence limit of arguments x,y *generally do not commute*. This means that, understanding both sides in the sense of the analytic continuation, in general

$$\zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2)|_{x=y} \neq \zeta^{(\alpha,\beta)}(s,x|A/\mu^2). \tag{40}$$

Above the coincidence limit is taken *after* the analytic continuation. Obviously, whenever $\mathrm{Re}\, s > D/2+|\alpha|+|\beta|$,

$$\zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2)|_{x=y} = \zeta^{(\alpha,\beta)}(s,x|A/\mu^2). \tag{41}$$

(3) The point (b2) proves that, for $x\neq y$, the Green's function of any operator A^n, $n=0,1,2,...$, defined in Ref. 1 via local ζ-function, is C^∞ as one could have to expect.

A second and last theorem concerns the possibility of computing the derived local ζ-functions through a series instead of an integral.

Theorem 3.2: *Within our hypotheses on $\mathcal{M}$ and A' and $\mu>0$, the (off-diagonal and not) derived local ζ-function can be computed as the sum of a series. Indeed, choosing a couple of multindices α,β, in a common coordinate system defined in a sufficiently small neighborhood of any point $u\in\mathcal{M}$, one has, in the sense of the punctual convergence,*

$$\zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2) = \sum_{j\in\mathbb{N}}{}' \left(\frac{\lambda}{\mu^2}\right)^{-s} D_x^\alpha \phi_j(x) D_y^\beta \phi_j^*(y), \tag{42}$$

$$\zeta^{(\alpha,\beta)}(s,x|A/\mu^2) = \sum_{j\in\mathbb{N}}{}' \left(\frac{\lambda}{\mu^2}\right)^{-s} D_x^\alpha \phi_j(x) D_x^\beta \phi_j^*(x), \tag{43}$$

provided $\mathrm{Re}\, s>3D/2+|\alpha|+|\beta|$ *and* $(x,y)\in I_u\times I_u$.

Proof: First of all it is worth stressing that, in the considered domain for s, the functions are continuous in all variables and

$$\zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2)|_{x=y} = \zeta^{(\alpha,\beta)}(s,x|A/\mu^2). \tag{44}$$

So, we perform our proof in the general case $x\neq y$, and then consider the coincidence limit of arguments. Therefore, from Theorem 3.1., for $\mathrm{Re}\, s>D/2+|\alpha|+|\beta|$, one has

$$\zeta^{(\alpha,\beta)}(s,x,y|A/\mu^2) = \frac{\mu^{2s}}{\Gamma(s)}\int_0^{\mu_0^{-2}} dt\, t^{s-1} D_x^\alpha D_y^\beta \{K(t,x,y|A) - P_0(x,y|A)\}$$
$$+ \frac{\mu^{2s}}{\Gamma(s)}\int_{\mu_0^{-2}}^{+\infty} dt\, t^{s-1} D_x^\alpha D_y^\beta \{K(t,x,y|A) - P_0(x,y|A)\}. \tag{45}$$

Here $\mu_0>0$ arbitrarily. Let us focus attention on the second integral. It can be written also

$$\frac{\mu^{2s}}{\Gamma(s)}\int_{\mu_0^{-2}}^{+\infty} dt \sum_{j\in\mathbb{N}}{}' t^{s-1} D_x^\alpha \phi_j(x) D_y^\beta \phi_j^*(y) e^{-\lambda_j t}, \tag{46}$$

where we have used Lemma 3.2. We want to show that it is possible to interchange the symbol of series with that of integration. We shall prove a similar fact for the other integral in (45), then the well-known formula $(a>0)$

$$a^{-s} = \frac{1}{\Gamma(s)}\int_0^{+\infty} dt\, t^{s-1} e^{-at} \tag{47}$$

will complete the proof of the theorem.

To prove the possibility of interchanging the integration with the summation in the integral (46), it is sufficient to show that the absolute value of the function after the summation symbol is integrable in the measure $\int dt \times \Sigma_j$. Then Fubini's theorem allows one to interchange the integrations. From Lemma 3.2, we know that, for $t > 2T > 0$,

$$\sum_{j\in\mathbb{N}}{}' |t^{s-1} D_x^{\alpha}\phi_j(x) D_y^{\beta}\phi_j^*(y) e^{-\lambda_j t}| \leqslant P_T^{(\alpha,\beta)} \sum_{j\in\mathbb{N}}{}' t^{\mathrm{Re}\, s-1} e^{-\lambda_j(2t-2T)}$$
$$\leqslant Q_T^{(\alpha,\beta)} t^{\mathrm{Re}\, s-1} e^{-\lambda(t-2T)}, \tag{48}$$

where λ is the first strictly positive eigenvalue of A. We choose the constant $T < \mu_0^{-2}/2$. The t-integration in $[\mu_0^{-2}, +\infty)$ of the last line above is finite for any $s \in \mathbb{C}$. Thus, a part of Fubini's theorem proves that the function after the summation symbol in (46) is integrable in the product measure.

Let us perform a similar proof for the first integral on the right-hand side of (45). It can be written down

$$\frac{\mu^{2s}}{\Gamma(s)} \int_0^{\mu_0^{-2}} dt \sum_{j\in\mathbb{N}}{}' t^{s-1} D_x^{\alpha}\phi_j(x) D_y^{\beta}\phi_j^*(y) e^{-\lambda_j t}. \tag{49}$$

We want to show that it is possible to interchange the symbol of series with that of integration. Posing $T = t/4$ we have, for $t \in (0, \mu_0^{-2}]$,

$$\sum_{j\in\mathbb{N}}{}' |t^{s-1} D_x^{\alpha}\phi_j(x) D_y^{\beta}\phi_j^*(y) e^{-\lambda_j t}| \leqslant P_{t/4}^{(\alpha,\beta)} t^{\mathrm{Re}\, s-1}\, \mathrm{Tr}\{K_{t/2} - P_0\}, \tag{50}$$

where for (27)

$$P_T^{(\alpha,\beta)} := [\sup_{x\in \bar{I}_u} \|D_x^{\alpha} K(T,x,.|A)\|][\sup_{y\in \bar{I}_u} \|D_y^{\beta} K(T,.,y|A)\|].$$

Employing (20) of Lemma 3.1 and taking account of the finite volume of the manifold one finds that there is a positive constant A such that, for $t \in (0, \mu_0^{-2}]$,

$$P_T^{(\alpha,\beta)} \leqslant A T^{-D-|\alpha|-|\beta|}. \tag{51}$$

This is due to the leading order for $t \to 0$ of the heat-kernel expansion (20). This upper bound, inserted in (50) with $T = t/4$, together with the x-integral of the heat-kernel expansion (19) in Theorem 1.3 of Ref. 1, entails

$$\sum_{j\in\mathbb{N}}{}' |t^{s-1} D_x^{\alpha}\phi_j(x) D_y^{\beta}\phi_j^*(y) e^{-\lambda_j t}| \leqslant B t^{\mathrm{Re}\, s-1-3D/2-|\alpha|-|\beta|}, \tag{52}$$

where B is a positive constant.

As in the previously considered case, for $\mathrm{Re}\, s > 3D/2 + |\alpha| + |\beta|$, we can interchange the symbol of integral with that of series also in the second integral of (45). Then (47) entails the thesis. □

Notice that, in the case $|\alpha| = |\beta| = 0$, the convergence of the series (43) arises for $\mathrm{Re}\, s > D/2$, and it is uniform as is well known.[1] Actually, our theorem uses a quite rough hypothesis. Nevertheless, this is enough for the use we shall make of the theorem above.

Following the way traced out in Theorem 1.3, we can give a precise definition concerning the ζ-function of the stress tensor. We shall assume, more generally than in Ref. 2, $A' := -\Delta + V$ where $V(x) := m^2 + \xi R + V'(x)$ and V' is real belongs to $C^{\infty}(\mathcal{M})$ and does not depend on the metric. Moreover, in this paper we consider a general D-dimensional manifold rather than the more physical case $D=4$ studied in Ref. 2. Also, as required by our general hypotheses, A' must be positive. It is worth stressing that this does not entail necessarily $m^2+\xi R(x)>0$ everywhere also when $V'\equiv 0$, and neither $V(x)>0$ everywhere in the general case (see Ref. 1).

B. The ζ-regularized stress tensor and its properties

For future convenience, let us define the symmetric tensorial field in a local coordinate system,

$$T_{ab}[\phi,\phi^*,\mathbf{g}](x) := \frac{2}{\sqrt{g(x)}}\frac{\delta}{\delta g_{ab}(x)}\frac{1}{2}\int_{\mathcal{I}}\phi A'[\mathbf{g}]\phi^*\, d\mu_g, \tag{53}$$

where $\phi\in C^\infty(\mathcal{M})$ and the functional derivative has been defined in Theorem 1.2. The precise form of $T_{ab}[\phi,\phi^*,\mathbf{g}](x)$ reads, in our case,

$$\begin{aligned}T_{ab}[\phi,\phi^*,\mathbf{g}](x) = {}& \tfrac{1}{2}(\nabla_a\phi(x)\nabla_b\phi^*(x)+\nabla_a\phi^*(x)\nabla_b\phi(x))\\ &-\tfrac{1}{2}g_{ab}(x)[\nabla_c\phi(x)\nabla^c\phi^*(x)+(m^2+V'(x))|\phi|^2(x)]+\xi[(R_{ab}(x)\\ &-\tfrac{1}{2}g_{ab}(x)R(x))|\phi|^2(x)+g_{ab}(x)\nabla_c\nabla^c|\phi|^2(x)-\nabla_a\nabla_b|\phi|^2(x)].\end{aligned} \tag{54}$$

A few trivial manipulations which make use of $A'\phi_j=\lambda_j\phi_j$ lead us to a simpler form for $T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x)$, namely

$$\begin{aligned}T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x) = {}& \tfrac{1}{2}(\nabla_a\phi_j(x)\nabla_b\phi_j^*(x)+\nabla_a\phi_j^*(x)\nabla_b\phi_j(x))-\xi\nabla_a\nabla_b|\phi_j|^2\\ &+\left(\xi-\frac{1}{4}\right)g_{ab}(x)\Delta|\phi_j|^2(x)+\xi R_{ab}(x)|\phi_j|^2-\frac{g_{ab}(x)}{2}\lambda_j|\phi_j|^2(x).\end{aligned} \tag{55}$$

Following the insights given in Sec. II C of this work as well as Ref. 2, we can give the following definition.

Definition 3.3: Within our hypotheses on $\mathcal{M}$ and $A' := -\Delta+m^2+\xi R+V'(x)$ defined above $(m,\xi\in\mathbb{R})$, the **local ζ-function of the stress tensor** *is the symmetric tensorial field defined in local coordinates as*

$$Z_{ab}(s,x|A/\mu^2) := 2\frac{s}{\mu^2}\zeta_{ab}(s+1,x|A/\mu^2)+s g_{ab}(x)\zeta(s,x|A/\mu^2), \tag{56}$$

where $\zeta_{ab}(s,x|A/\mu^2)$ is defined as the sum of the series below, in a sufficiently small neighborhood I_u of any point $u\in\mathcal{M}$ for $\mathrm{Re}\, s>3D/2+2$,

$$\sum_{j\in\mathbb{N}}{}'\left(\frac{\lambda_j}{\mu^2}\right)^{-s}T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x), \tag{57}$$

and $T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x)$ is defined in (53) and (55) with respect to a base of smooth orthogonal normalized eigenvector of A.

Comments:

(1) The definition given above makes sense since the relevant series converges for $\mathrm{Re}\, s>3D/2+2$ because of Theorem 3.2. Notice that the given definition does not depend on the base of smooth orthogonal normalized eigenvectors of A (take account that each eigenspace has finite dimension as follows from Theorem 1.1 in Ref. 1).

(2) The fact that the coefficients $Z_{ab}(s,x|A/\mu^2)$ do define a tensor is a direct consequence of (55) and (57). This can be trivially proven for $\mathrm{Re}\, s>3D/2+2$, where one can make use of the

series (57) which trivially defines a tensor since all terms of the sum are separately components of a tensor. Then, the proven property remains unchanged after the analytic continuation for values of s where the series does not converge.

(3) It is worthwhile noticing that the final expression of T_{ab}, and thus Z_{ab} self, does not contain either m^2 or V' explicitly.

(4) A definition trivially equivalent to (56) (up to analytic continuations in the variable s) is given by posing directly, for $\mathrm{Re}\, s > 3D/2+2$,

$$Z_{ab}(s,x|A/\mu^2) = s \sum_{j\in\mathbb{N}}{}' \left\{ \frac{2}{\mu^2}\left(\frac{\lambda_j}{\mu^2}\right)^{-(s+1)} T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x) + g_{ab}(x)\left(\frac{\lambda_j}{\mu^2}\right)^{-s}\phi_j(x)\phi_j^*(x)\right\}. \tag{58}$$

(5) Due to the uniqueness theorem for analytic functions and Theorem 3.2, each component of Z_{ab} can be built up, within opportune regions, employing the heat-kernel in the fashion of Theorem 3.1. Following this route, by Theorem 3.1, one proves trivially that the symmetric tensorial field $Z_{ab}(s,x|A/\mu^2)$ is continuous together for all of its s derivatives as a function of (s,x). In particular, each component defines a meromorphic function of the variable s whenever x is fixed. Therefore, let us consider the *simple* poles which may appear in the s-continued components of $Z_{ab}(s,x|A/\mu^2)$. One has to rewrite each component of this tensorial field in terms of simple ζ-functions and derived ζ-functions via Theorems 1.1 and 1.2. Once this has been done, one sees that the only functions which really appear in Z_{ab} are $\zeta^{(1_a,1_b)}$, $\zeta^{(1_b,1_a)}$, and ζ, each function evaluated at $s+1$ [see (59)]. The simple local ζ-function evaluated in $s+1$ admits possible simple poles in the points s_j with $s_j = D/2-j-1$ where $j=0,1,\ldots$, whenever D is odd, otherwise $j=0,1,\ldots,D/2-1$ whenever D is even. Anyhow, the factor s in (56) cancels out the possible pole at $s=0$, which may appear in $\zeta(s+1)$ when D is even. The functions $\zeta^{(1_c,1_d)}(s+1,x|A/\mu^2)$ have been considered in Theorem 1.1 and their possible simple poles may arise in s_j with $s_j = D/2+|1_a|+|1_b|-1-j = D/2-j+1$ and $j=0,1,\ldots$ whenever D is odd, otherwise $j=0,1,\ldots,D/2+1$ whenever D is even. Once again, because of the factor s on the right-hand side of (56), any possible simple pole at $s=0$ is canceled out.

The last comment above can be stated as a theorem.

Theorem 3.3: *In our general hypotheses on* $\mathcal{M}$ *and* A', *(a) each component of* $Z_{ab}(s,x|A/\mu^2)$ *can be analytically continued into a mesomorphic function of s whenever x is fixed. In particular, in the sense of the analytic continuation, it holds, for x belonging to a sufficiently small neighborhood of any point* $u\in\mathcal{M}$,

$$\begin{aligned} Z_{ab}(s,x|A/\mu^2) &= \frac{s}{\mu^2}[\zeta^{(1_a,1_b)}(s+1,x|A/\mu^2) + \zeta^{(1_b,1_a)}(s+1,x|A/\mu^2)] \\ &\quad + \frac{2s}{\mu^2}\left[\left(\xi-\frac{1}{4}\right)g_{ab}(x)\Delta + \xi R_{ab}(x) - \xi\nabla_a\nabla_b\right]\zeta(s+1,x|A/\mu^2). \end{aligned} \tag{59}$$

(b) The possible poles of each component of $Z_{ab}(s,x|A/\mu^2)$, *which are simple poles only, are situated in the points*

$$s_j = D/2-j+1, \quad j=0,1,2,\ldots, \quad \text{if } D \text{ is odd};$$

$$s_j = D/2-j+1, \quad j=0,1,2,\ldots,D/2, \quad \text{if } D \text{ even}.$$

(c) Varying $x\in I_u$ *and* $s\in\mathbb{C}$ *the s-analytically continued symmetric tensorial field* $(s,x)\mapsto Z_{ab}(s,x|A/\mu^2)$ *defines an s-analytic tensorial field of* $C^0((\mathbb{C}-\mathcal{P})\times I_u)$ *together with all its s derivatives, where* $\mathcal{P}$ *is the set of the actual poles (each for some x) among the points listed above.*

Proof: Sketched above. □

Remark: Equation (59) could be used as an independent definition of the ζ-function of the stress tensor. The important point is that it does not refer to any series of eigenvectors. It could be considered as the starting point for the generalization of this theory in the case where the spectrum of the operator A is continuous provided the functions on the right-hand side of (59) are defined in terms of t integrations of derivatives of the heat kernel.

Definition 3.4: In our general hypotheses on $\mathcal{M}$ and A' and for $x \in I_u$ where I_u is a sufficiently small neighborhood of $u \in \mathcal{M}$, the **one-loop renormalized stress tensor** *is defined in a local coordinate system in I_u by the set of functions $(a,b=1,...,D)$,*

$$\langle T_{ab}(x|A)\rangle_{\mu^2} := \frac{1}{2}\frac{d}{ds}\bigg|_{s=0} Z_{ab}(s,x|A/\mu^2), \tag{60}$$

where the tensorial field Z_{ab} which appears on the right-hand side is the s-analytic continuation of that defined above and $\mu^2>0$ is any fixed constant with the dimensions of a squared mass.

We can state and prove the most important properties of $\langle T_{ab}(x|A)\rangle_{\mu^2}$ in the following theorem. These results generalize previously obtained results[2,13] for a more general operator A and for any dimension $D>0$.

Theorem 3.4: *In our general hypotheses on $\mathcal{M}$ and A', the functions $x \mapsto \langle T_{ab}(x|A)\rangle_{\mu^2}$ defined above satisfy the following properties.*

(a) The functions $x \mapsto \langle T_{ab}(x|A)\rangle_{\mu^2}$ $(a,b=1,2,...,D)$ define a C^∞ symmetric tensorial field on $\mathcal{M}$.

(b) This tensor is conserved *for $V' \equiv 0$, and, more generally,*

$$\nabla^a \langle T_{ab}(x|A)\rangle_{\mu^2} = -\tfrac{1}{2}\langle \phi^2(x|A)\rangle_{\mu^2}\nabla_b V'(x) \tag{61}$$

everywhere in $\mathcal{M}$.

(c) For any rescaling $\mu^2 \mapsto \alpha\mu^2$, where $\alpha>0$ is a pure number, one has

$$\langle T_{ab}(x|A)\rangle_{\mu^2} \to \langle T_{ab}(x|A)\rangle_{\alpha\mu^2} = \langle T_{ab}(x|A)\rangle_{\mu^2} + (\ln\alpha)t_{ab}(x|A), \tag{62}$$

where $t_{ab}(x|A)=Z_{ab}(0,x|A)/2$, which coincides also with the residue of the pole of $\zeta_{ab}(s+1,x|A)$ at $s=0$, is a, conserved for $V' \equiv 0$, symmetric tensor not dependent on μ built up by a linear combination of product of the metric, curvature tensors, $V'(x)$ and their covariant derivatives evaluated at the point x. In general, it satisfies

$$\nabla^a t_{ab}(x|A) = -\delta_D \frac{a_{D/2-1}(x,x|A)}{2(4\pi)^{D/2}}\nabla_b V'(x), \tag{63}$$

where $\delta_D=0$ when D is odd and $\delta_D=1$ otherwise. In terms of heat-kernel coefficients one has also

$$t_{ab}(x|A) = \frac{\delta_D}{(4\pi)^{D/2}}\left\{ a_{D/2-1,(ab)}(x,x|A) + \frac{g_{ab}(x)}{2}a_{D/2}(x,x|A) + \left[\left(\xi-\frac{1}{4}\right)g_{ab}(x)\Delta + \xi R_{ab}(x) - \xi\nabla_a\nabla_b\right]a_{D/2-1}(x,x|A)\right\}, \tag{64}$$

where we have employed the notations (using the same coordinate system both for x and y)

$$a_{j,(ab)}(x,x|A) := \tfrac{1}{2}[(\nabla_{(x)a}\nabla_{(y)b} + \nabla_{(y)a}\nabla_{(x)b})a_j(x,y|A)]|_{x=y}. \tag{65}$$

(d) *Concerning the trace of $\langle T_{ab}(x|A)\rangle_{\mu^2}$ one has*

$$g^{ab}(x)\langle T_{ab}(x|A)\rangle_{\mu^2}=\left(\frac{\xi_D-\xi}{4\xi_D-1}\Delta-m^2-V'(x)\right)\langle\phi^2(x|A)\rangle_{\mu^2}+\delta_D\frac{a_{D/2}(x,x|A)}{(4\pi)^{D/2}}-P_0(x,x|A). \tag{66}$$

Above, $\langle\phi^2(x|A)\rangle_{\mu^2}$ *is the value of the averaged quadratic fluctuations of the field computed by the* ζ*-function approach.*[1,13]

[The coefficient $(4\xi_D-1)^{-1}$ above is misprinted in Ref. 13 where $(2\xi_D)^{-1}$ appears in place of it.]

Sketch of Proof: Barring the issue concerning the smoothness, the property (a) is a trivial consequence of the corresponding fact for $Z_{ab}(s,x|A/\mu^2)$ discussed in Comment (2) after Definition 3.3. The tensorial field belongs to C^∞ because of the C^∞ smoothness of the functions $(s,x)\mapsto Z_{ab}(s,x|A/\mu^2)$ for $(s,x)\in J_0\times I_u$, where J_0 and I_u are respectively neighborhoods of $s=0$ in $\mathbb{C}$ and $u\in\mathcal{M}$. Indeed, first of all, no pole at $s=0$ arises in the functions $(s,x)\mapsto Z_{ab}(s,x|A/\mu^2)$ and in their x derivatives. This is because, considering (56) and (c2) of Theorem 3.1, one notices that if any pole appears in the various $\zeta^{(\alpha,\beta)}$ functions used building up Z_{ab}, it has to be a simple pole. Anyhow, the factor s makes the global functions Z_{ab} regular at $s=0$. Using recursively (c2) of Theorem 3.1 one has that each function $x\mapsto Z_{ab}(s,x|A/\mu^2)$ is C^∞ in a neighborhood of u for any fixed $u\in\mathcal{M}$ and $s=0$. More generally, this result holds for s fixed in a neighborhood of 0 because, by (c1) of Theorem 3.1, one has that no pole can arise in an open disk centered in $s=0$ with radius $\rho=\frac{1}{2}$. The functions Z_{ab} and all their x derivatives are also s-analytic for x fixed in a neighborhood of 0. Then, we can conclude that any function $(s,x)\mapsto Z_{ab}(s,x|A/\mu^2)$ is C^∞ in a neighborhood of $(0,u)$ for any fixed $u\in\mathcal{M}$. The C^∞ smoothness of the stress tensor then follows trivially from (60) directly.

The property (b) can be proved as follows. From the point (c2) of Theorem 3.1 and taking account of (a) of Theorem 3.3 and the definition (60), we have that (b) holds true if $\nabla^a Z_{ab}(s,x|A/\mu^2)=-Z(s,x|A/\mu^2)\nabla_b V'(x)$ for the considered point x and $s\in\mathbb{C}$ away from the poles, the function Z on the right-hand side of the field fluctuations (see Definition 2.7 in Ref. 1). By the theorem of the uniqueness of the analytic continuation, if one is able to prove such an identity for $\mathrm{Re}\, s$ sufficiently large, this assures also the validity of $\nabla^a Z_{ab}(s,x|A/\mu^2)=-Z(s,x|A/\mu^2)\nabla_b V'(x)$ everywhere in the variable s. Therefore, let us prove that there is an $M>0$ such that $\nabla^a Z_{ab}(s,x|A/\mu^2)=-Z(s,x|A/\mu^2)\nabla_b V'(x)$ for $\mathrm{Re}\, s>M$ and this will be enough to prove the point (b). To get this goal we represent $\nabla^a Z_{ab}(s,x|A/\mu^2)$, employing (59) for each function Z_{ab}. Then we make recursive use of (35) of Theorem 3.1 and obtain $\nabla^a Z_{ab}(s,x|A/\mu^2)$ written as a linear combination of functions $\zeta^{(\alpha,\beta)}(s+1,x|A/\mu^2)$. Finally we can expand all these functions in series of the form (43) of Theorem 3.2, provided $\mathrm{Re}\, s>M$ for an opportune $M>0$. Taking account of the comment (4) after Definition 3.3, the explicit expression of the final series of $\nabla^a Z_{ab}(s,x|A/\mu^2)$ reads, for $\mathrm{Re}\, s>M$,

$$\nabla^a Z_{ab}(s,x|A/\mu^2)=s\sum_{j\in\mathbb{N}}{}'\frac{2}{\lambda_j}\left(\frac{\lambda_j}{\mu^2}\right)^{-s}\nabla^a\left\{T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x)+\frac{\lambda_j g_{ab}(x)}{2}\phi_j(x)\phi_j^*(x)\right\}. \tag{67}$$

Finally, using the form of the ζ-function of the field fluctuations given in Ref. 1, one has to prove that for any $x\in\mathcal{M}$,

$$\nabla^a\left\{T_{ab}[\phi_j,\phi_j^*,\mathbf{g}](x)+\frac{\lambda_j g_{ab}(x)}{2}\phi_j(x)\phi_j^*(x)\right\}=-\frac{1}{2}\phi_j(x)\phi_j^*(x)\nabla_b V'(x). \tag{68}$$

This is nothing but the generalized ''conservation law'' of the stress tensor for the action

$$S_j[\phi,\phi^*]=\frac{1}{2}\int_{\mathcal{M}}[\phi A'[\mathbf{g}]\phi^*-\lambda_j\phi\phi^*]d\mu_g. \tag{69}$$

Indeed, (68) holds when the field ϕ satisfies the motion equations for the action above $A'\phi=\lambda_j\phi$. This is satisfied by the C^∞ eigenfunctions of $A\phi_j$ with eigenvalue λ_j. Therefore (68) holds true and (b) is proven.

Concerning the point (c), (62) with $t_{ab}(x|A)=Z_{ab}(0,x|A)/2$ arises as a direct consequence of the definition (60), noticing that, from Theorem 2.3, $Z(s,x|A/\mu^2)$ is analytic at $s=0$ and, from (56), (60) can be written down also:

$$\langle T_{ab}(x|A)\rangle_{\mu^2}=\frac{1}{2}\left.\frac{d}{ds}\right|_{s=0}Z_{ab}(s,x|A)+\frac{1}{2}Z_{ab}(0,x|A)\ln\mu^2, \tag{70}$$

Similarly, from Definition 3.3, one sees also that $Z(s,x|A/\mu^2)/2$ evaluated at $s=0$ takes contribution only from the possible pole at $s=1$ of the function $s\mapsto\zeta_{ab}(s,x|A/\mu^2)$ (the remaining simple ζ function is regular for $s=0$) and coincides with the value of residue of the pole of this function at $s=0$. When D is odd, no pole of $s\mapsto\zeta_{ab}(s,x|A/\mu^2)$ arises at $s=1$ because of (c) of Theorem 3.1. This is the reason for the δ_D on the right-hand side of (64). The form (64) of t_{ab} assures that it is built up as a linear combination of product of the metric, curvature tensors, $V'(x)$, and their covariant derivatives, everything evaluated at the same point x. The property (63) is consequence of $\nabla^a Z_{ab}(s,x|A/\mu^2)=-Z(s,x|A/\mu^2)\nabla_b V'(x)$ proven during the proof of (b), employing the pole structure of the function $Z(s,x)$ given in Ref. 1. Notice also that t_{ab} is symmetric by construction. Therefore, we have to prove (64) and this concludes the proof of (c). It is sufficient to show that

$$\lim_{s\to 0} s\zeta_{ab}(s+1,x|A)=\frac{\delta_D}{(4\pi)^{D/2}}\left\{a_{D/2-1,(ab)}(x,x|A)+\frac{g_{ab}(x)}{2}a_{D/2}(x,x|A)\right.$$
$$\left.+\left[\left(\xi-\frac{1}{4}\right)g_{ab}(x)\Delta+\xi R_{ab}(x)-\xi\nabla_a\nabla_b\right]a_{D/2-1}(x,x|A)\right\}.$$

From (a) of Theorem 3.3 this is equivalent to

$$\lim_{s\to 0} s\,\frac{1}{2}[\zeta^{(1_a,1_b)}(s+1,x|A)+\zeta^{(1_b,1_a)}(s+1,x|A)]$$
$$+\lim_{s\to 0} s\left[\left(\xi-\frac{1}{4}\right)g_{ab}(x)\Delta+\xi R_{ab}(x)-\xi\nabla_a\nabla_b\right]\zeta(s+1,x|A/\mu^2)$$
$$=\frac{\delta_D}{(4\pi)^{D/2}}\left\{a_{D/2-1,(ab)}(x,x|A)+\frac{g_{ab}(x)}{2}a_{D/2}(x,x|A)\right.$$
$$\left.+\left[\left(\xi-\frac{1}{4}\right)g_{ab}(x)\Delta+\xi R_{ab}(x)-\xi\nabla_a\nabla_b\right]a_{D/2-1}(x,x|A).\right. \tag{71}$$

The proof of this identity is very straightforward so we sketch its way only. Using Theorem 3.1, it is sufficient to consider the decomposition for large Re s (and a similar decomposition interchanging a with b):

$$s\zeta^{(1_a,1_b)}(s+1,x,y|A/\mu^2)|_{x=y}=\frac{s}{\Gamma(s+1)}\int_0^{+\infty}dt\,t^s D_x^{1_a}D_y^{1_b}[K(t,x,y|A)-P_0(x,y|A)]|_{x=y}$$
$$=\frac{s}{\Gamma(s+1)}\int_0^{\mu_0^{-2}}D_x^{1_a}D_y^{1_b}\{\cdots\}\Big|_{x=y}+\frac{s}{\Gamma(s+1)}\int_{\mu_0^{-2}}^{+\infty}D_x^{1_a}D_y^{1_b}\{\ldots\}\Big|_{x=y}. \tag{72}$$

Then, we can expand the integrand of the first integral in the second line of (72) using (20) of Lemma 3.1 and we can continue both integrals in the second line of (72) as far as $s=0$. A direct computation proves that, because of the presence of the factor s, only the first integral in (72), expanded as said above, gives a contribution. The contribution arises from the terms of the heat-kernel expansion which, once integrated in t (taking account of the factor t^s in the integrand), have a pole for $s=0$. This pole is canceled out by the factor s giving a finite result. The terms which have no pole at $s=0$ vanish due to the factor s, in the limit $s\to 0$. A similar procedure can be employed concerning the second limit in (71). In performing calculations, it is worth to remember that $\nabla_{(x)a}\sigma(x,y)$ and $\nabla_{(y)b}\sigma(x,y)$ *vanish* in the limit $x\to y$, and, furthermore, $\nabla_{(x)a}\nabla_{(y)b}\sigma(x,y)|_{x=y}=-g_{ab}(y)$. Summing all contributions, one obtains (64).

Concerning the point (d), the proof is dealt with as follows. Starting from (55) one finds

$$g^{ab}T_{ab}[\phi_j,\phi_j^*,\mathbf{g}]=\nabla_c\phi_j\nabla^c\phi_j^*+\left\{\xi R+\left[\xi(D-1)-\frac{D}{4}\right]\Delta\right\}|\phi_j|^2-\frac{D}{2}\lambda_j|\phi_j|.$$

Then, employing the identities $2\nabla_c\phi^*\nabla^c\phi=\Delta|\phi|^2-\phi\Delta\phi^*-\phi^*\Delta\phi$ and $(-\Delta+\xi R+m^2+V')\phi_j=\lambda_j\phi_j$, we have also

$$g^{ab}T_{ab}[\phi_j,\phi_j^*,\mathbf{g}]=\left[\xi(D-1)-\frac{D-2}{4}\right]\Delta|\phi_j|^2-(m^2+V')|\phi|^2+\frac{2-D}{2}\lambda_j|\phi_j|.$$

Since $\xi_D=(D-2)/[4(D-1)]$, we have finally

$$g^{ab}T_{ab}[\phi_j,\phi_j^*,\mathbf{g}]=\left[\frac{\xi_D-\xi}{4\xi_D-1}\Delta-m^2-V'\right]|\phi_j|^2+\frac{2-D}{2}\lambda_j|\phi_j|.$$

From Definition 3.3, this entails that, for $\mathrm{Re}\, s$ sufficiently large,

$$g^{ab}Z_{ab}(s,x|\mu^2)=\frac{2}{\mu^2}\left[\frac{\xi_D-\xi}{4\xi_D-1}\Delta-m^2-V'\right]s\zeta(s+1,x|A/\mu^2)+2s\zeta(s,x|A/\mu^2). \tag{73}$$

The function $(s,x)\mapsto s\zeta(s+1,x|A/\mu^2)$ is C^∞ in a neighborhood of $(0,u)$ for any $u\in\mathcal{M}$. The proof is similar to that given in (b) above for $(s,x)\mapsto Z_{ab}(s,x|\mu^2)$. Finally, employing Definition 3.4 also taking account of Definition 2.7 in Ref. 1 and (34) in Theorem 2.2 in Ref. 1 [i.e., (74) below], one finds (66). □

Comments:

(1) Concerning the point (b) which generalizes the classical law (10), we stress that this result is strongly untrivial. We have not put this result somewhere ''by hand'' in the definitions and hypotheses we have employed. Notice also that, in the case $V'\equiv 0$, the tensor $T_{ab}[\phi_j,\phi_j^*,\mathbf{g}]$ we have used in the definitions is not conserved. Nevertheless, the final stress tensor is conserved. This should mean that the local ζ-function approach is quite a deep approach.

(2) Concerning the point (c), we notice that this result is in agreement with Wald's axioms [5] and, on a purely mathematical ground, it reduces the ambiguity allowed by Wald's theorem. Indeed, Wald's theorem involves at least two arbitrary terms dependent on two free parameters. Recently it has been proven that in the case of massive fields which are not conformally coupled such an ambiguity should be much larger.[14] The point (d) proves that the corresponding ambiguity related to the field fluctuations is consistent with that which arises from the stress tensor. Assuming the ζ-function procedure, the only ambiguity remaining is just that related to the initial arbitrary mass scale μ. On the other hand, there is no physical evidence that the ζ-function procedure is the physically correct one and thus one cannot conclude that this method gets rid of the ambiguity pointed out by Wald *et al.*

(3) Concerning the point (d), we notice that, in the case $\xi=\xi_D$ and $V'\equiv m^2=0$, the usual conformal anomaly[8,9] arises provided D is even and the kernel of A is trivial. Anyhow, in the case

Ker A is untrivial, the trace anomaly takes a contribution from the null modes also when D is odd. In any cases, for the anomalous term, it holds [(34) in Theorem 2.2 in Ref. 1]

$$\delta_D \frac{a_{D/2}(x,x|A)}{(4\pi)^{D/2}} - P_0(x,x|A) = \zeta(0,x|A/\mu^2) \tag{74}$$

also for $\xi \neq \xi_D$.

Let us consider some issues related to the physical interpretations of the theory. Suppose S_1 acts as a globally one-parameter isometry group on the Riemannian manifold $\mathcal{M}$ giving rise to closed orbits with period $\beta > 0$. Suppose also that there exist a $D-1$ embedded submanifold Σ which, barring fixed points, intersects each orbit just once and is orthogonal to the Killing vector field of the isometry group K (notice that any submanifold Σ_τ, obtained by the action on Σ of the isometry group on the points of Σ, remains orthogonal to the Killing vector field). In this case the Riemannian metric is said to be *static*, the parameter of the group τ is said to be the *Euclidean time* of the manifold with period β, and the submanifold Σ is said to be the *Euclidean space* of the manifold.

As is well known, β is interpreted as the ''statistical mechanics'' inverse temperature of the quantum state; anyway, it has no direct physical meaning because it can be changed by rescaling the normalization of the Killing vector K everywhere by a constant factor. The physical temperature, which, in principle, may be measured by a thermometer, is the local rescaling-invariant Tolman temperature $T_{\mathrm{T}} := 1/[\sqrt{(K,K)}\beta]$.

Whenever $\mathcal{M}$ is static and Σ is endowed with a global coordinate system $(x^1,\ldots,x^{D-1}) \equiv \vec{x}$, $\mathcal{M}$ is endowed with a natural coordinate system $(\tau,\vec{x})$, $\tau \in (0,\beta)$, $\vec{x} \in \Sigma - \mathcal{F}$, where $\mathcal{F}$ is the set of the fix points of the group (which, anyhow, may be empty). This coordinate system is obtained by the evolution of the coordinates on Σ along the orbits of the isometry group and is almost global in the sense that is defined everywhere on $\mathcal{M}$ except for the set of the (coincident) endpoints of each orbit at $\vec{x}$ constant including the fix points of the group. This set has anyway negligible measure. Coordinates $(\tau,\vec{x})$ given above are said to be *static coordinates*. Notice that, in these coordinates, $\partial_\tau g_{ab} = 0$ and $g_{\tau\alpha} = 0$ for $\alpha = 1,...,D-1$ everywhere. Local static coordinates are defined similarly.

The important result is that, under our general hypotheses, supposing also that $\mathcal{M}$ is static and admits static coordinates $(\tau,\vec{x})$ and V' does not depend on τ, one has that the stress tensor *depends on* $\vec{x}$ *only* and satisfies everywhere

$$\langle T_{\tau\alpha}(\vec{x}|A)\rangle_{\mu^2} = \langle T_{\alpha\tau}(\vec{x}|A)\rangle_{\mu^2} = 0 \tag{75}$$

for $\alpha = 1,...,D-1$. The remarkable point as far as the physical ground is concerned is that this result allows one to look for analytic continuations towards Lorentzian metrics performing the analytical continuation $\tau \to it$ and without encountering imaginary components of the continued stress tensor. Notice that also $\langle \phi^2(x|A)\rangle_{\mu^2}$ and the effective Lagrangian $\mathcal{L}_{\mathrm{eff}}(x|A)_{\mu^2}$ (see Definition 2.5 in Ref. 1) do not depend on the temporal coordinate and, moreover, all results contained in Theorem 3.4 hold true in the Lorentzian section of the manifold, considering the trivial analitic continuations of all the terms which appear in the thesis. One has the following theorem.

Theorem 3.5: *Within our hypotheses on* $\mathcal{M}$ *and A, suppose* $\mathcal{M}$ *is static with Euclidean time* $\tau \in (0,\beta)$ $(\beta > 0)$ *and* V' *is invariant under Euclidean time displacements. In this case, for any* $\mu^2 > 0$ *and any point* $x \in \mathcal{M}$,

$$\langle T_{ab}(x|A)\rangle_{\mu^2} \mathrm{K}^a(x)\sigma^b(x) = 0, \tag{76}$$

where K *is the Killing vector field associated to the time* τ *and* $\sigma(x)$ *is any vector orthogonal to* K *at x. Furthermore, denoting the Lie derivative along* K *by* $\mathcal{L}(\mathrm{K})$, *it holds everywhere on* $\mathcal{M}$ *(away from fixed points concerning (77))*

$$\mathcal{L}(\mathrm{K})_c \langle T^{ab}(x|A)\rangle_{\mu^2} = 0, \tag{77}$$

$$\mathcal{L}(\mathrm{K}) \langle \phi^2(x|A)\rangle_{\mu^2} = 0, \tag{78}$$

$$\mathcal{L}(\mathrm{K})\mathcal{L}_{\mathrm{eff}}(x|A)_{\mu^2}=0. \tag{79}$$

Finally, all the results of Theorem 3.4 hold in the Lorentzian section provided one considers the Lorentzian-time-continued quantities in place of the corresponding Riemannian ones everywhere.

Sketch of Proof: In the given hypotheses and fixed $x\in\mathcal{M}$ [x different from any fixed point in such a case, the thesis being trivial since $\mathrm{K}(x)=0$], let us consider a generally local coordinate system $\vec{x}$ on the Euclidean space Σ around the intersection of the orbit passing from $x\in\mathcal{M}$. This induces a natural local coordinate system on $\mathcal{M}$, $(\tau,\vec{x})$ [where $\tau\in(0,\beta)$], which includes the same point x. In our hypotheses (76) is trivially equivalent to (75) in the considered coordinate system.

Concerning the form of the ζ-function of the stress tensor given in Definition 3.3, taking account of (54), since $g_{\tau\alpha}(x)=0$ and $\partial_\tau g_{ab}(x)=0$, only the first line of (54) and the last term in the last line may produce the considered components of the stress tensor. Actually, the dependence from τ of the eigenfunctions ϕ_j of the operator A can be taken of the form $e^{i\omega\tau}$ with $\omega\in\mathbb{R}$ just because $\partial_\tau=\mathrm{K}$ is a Killing field as we shall prove shortly. Then, the last term in the last line of (54) immediately vanishes concerning the considered components because the argument of the covariant derivatives (which commute on scalar fields) does not depend on τ; furthermore, taking account that A is real and thus ϕ_j and ϕ_j^* correspond to the same eigenvalue, one sees that the contribution coming from the first line of (54) computed for $b\neq a=\tau$ and $a\neq b=\tau$ vanishes when one sums over j to get the stress tensor ζ-function. The validity of (77)–(79) is also obvious working in local static coordinates where the Lie derivative reduces to the ordinary τ derivative and taking account of the imaginary exponential dependence form τ of the modes. In fact, this dependence is canceled out directly in the various ζ-functions due to the product of ϕ_j and ϕ_j^* (or corresponding derivatives) which appear in their definitions.

Let us finally prove that one can define the normalized orthogonal eigenvectors of A' (and thus A) in order to have the dependence from τ said above. Remembering that each eigenfunction of A is a $C^\infty(\mathcal{M})$ function, and working in the local coordinate system around the orbit of x considered above where g_{ab} does not depend on τ, one trivially has that

$$A'\partial_\tau\phi_{jk_j}=\partial_\tau A'\phi_{jk_j}=\lambda_j\partial_\tau\phi_{jk_j}, \tag{80}$$

where ϕ_{jk_j} is an eigenvector of A with eigenvalue λ_j. This holds in the considered coordinates and, therefore, choosing different local coordinate systems in Σ and reasoning similarly, the above identity can be proven to hold *almost* everywhere on $\mathcal{M}$ provided $\partial_\tau\phi_{jk_j}$ is interpreted as the $C^\infty(\mathcal{M})$ scalar field $(\mathrm{K},\nabla\phi_{jk_j})$. Remembering that the dimension of each eigenspace d_j is finite (Theorem 1.1. in Ref. 1), it must be

$$\partial_\tau\phi_{jk_j}(x)=\sum_{l_j=1}^{d_j}c_{k_jl_j}\phi_{jl_j}(x), \tag{81}$$

almost everywhere. Remembering that locally $\partial_\tau g_{ab}=0$ and, since $g_{\tau\alpha}=0$, $g=(\mathrm{K},\mathrm{K})h$ (where h is the determinant of the metric induced on Σ), one finds from (81)

$$\begin{aligned}c^*_{k_jh_j}+c_{h_jk_j}&=\int_{\mathcal{M}}\partial_\tau\{\phi^*_{jk_j}(x)\phi_{jh_j}(x)\}d\mu_g(x)\\&=\int_0^\beta d\tau\frac{d}{dt}\int_\Sigma\phi^*_{jk_j}(\tau,p)\phi_{jh_j}(\tau,p)(K(p),K(p))^{1/2}d\nu(p),\end{aligned}$$

where p is any point on the submanifold Σ and ν is its (finite) Riemannian measure induced there from the metric. We have passed the derivative through the symbol of integration employing Fubini's theorem and Lebesgue's dominate convergence theorem. The right-hand side of the identity above vanishes, taking account that, for any fixed p,

$$\lim_{\tau\to 0^+} \phi(\tau,p)_{jk_j} = \lim_{\tau\to\beta} \phi(\tau,p)_{jk_j} \tag{82}$$

because the orbits of the coordinate τ are closed and the functions are continuous in the whole manifold. Therefore, the matrix of the coefficients c_{pq} is anti-Hermitian. Finally, in the considered eigenspace, we can choose an orthogonal base of smooth normalized eigenfunctions where the matrix above is represented by a diagonal matrix, the eigenvalues being $i\omega_{jl_j}$, $\omega_{jl_j}\in\mathbb{R}$ and $l_j = 1,2,...,d_j$. In the new base one rewrites (81), in local coordinates,

$$\partial_\tau \phi_{jk_j}(x) = i\omega_{jk_j}\phi_{jk_j}(x), \tag{83}$$

and this entails trivially, with $\omega_{jk_j} = 2\pi n_{jk_j}/\beta$, $n_{jk_j}\in\mathbb{Z}$ by (82),

$$\phi_{jk_j}(x) = e^{i\omega_{jk_j}\tau}\varphi_{jk_j}(x^1,\ldots,x^{D-1}). \tag{84}$$

We leave to the reader the simple proof of the last statement of our theorem which can be carried out in local coordinates. □

As a final remark notice that changes in the period β of the manifold which correspond to actual increases of the proper length of the orbits (and not to a simple rescaling of the normalization of the Killing vector), in general produce *conical singularities* in the fixed points of the Lie group provided they exist. In such a case the manifold fails to be smooth and, in general, the theorems proven in this work and in Ref. 1 may not hold.

IV. THE RELATION BETWEEN THE ζ-FUNCTION AND THE POINT-SPLITTING TO RENORMALIZE THE STRESS TENSOR. AN IMPROVED FORMULA FOR THE POINT-SPLITTING PROCEDURE

Similarly to the previous work, we prove here that, in our general hypotheses, a particular (improved) form of the point-splitting procedure can be considered as a consequence of the ζ-function technique.

A. The point-splitting renormalization

Let us summarize the point-splitting approach to renormalize the one-loop stress tensor[4–6] in the Euclidean case. First of all, we want to rewrite (9) into a more convenient form. Employing the motion equations $A'\phi\equiv 0$ one can rewrite the right-hand side of (9) as

$$\begin{aligned}
T_{ab}[\phi,\mathbf{g}](x) = {} & (1-2\xi)[\nabla_a\phi(x)\nabla_b\phi(x) + \phi(x)\nabla_a\nabla_b\phi(x)] \\
& + \left(2\xi - \frac{1}{2}\right) g_{ab}(x)[\nabla_c\phi(x)\nabla^c\phi(x) + \phi(x)\Delta\phi(x)] \\
& + \left[\frac{g_{ab}(x)}{D}\phi(x)\Delta\phi(x) - \phi(x)\nabla_a\nabla_b\phi(x)\right] \\
& - \xi\left[R_{ab}(x) - \frac{g_{ab}(x)}{D}R(x)\right]\phi^2(x) - \frac{V'(x)+m^2}{D} g_{ab}(x)\phi^2(x).
\end{aligned} \tag{85}$$

Notice that the first two lines on the right-hand side of (85) produce a vanishing trace in the case of $\xi = \xi_D (:= (D-2)/[4(D-1)])$; the third and the fourth lines have separately a vanishing trace not depending on ξ. Finally, the trace of the last line is $-[V'(x)+m^2]\phi^2(x)$ trivially. It is obvious that, in the case of conformal coupling ($\xi=\xi_D$, $V'\equiv m^2 = 0$), the trace of the stress tensor vanishes. Conversely, for $\xi\neq\xi_D$ one also obtains

$$g^{ab}(x)T_{ab}(x) = \left(\frac{\xi_D-\xi}{4\xi_D - 1}\Delta - m^2 - V'(x)\right)\phi^2(x). \tag{86}$$

This is nothing but the *classical* version of (66). The most important difference is the lack of the trace anomaly term which is related to the last two terms on the right-hand side of (66).

The point-splitting procedure can be carried out employing the expression above for the stress tensor (actually one expects that the same final result should arise starting from different but equivalent expressions of the stress tensor). The basic idea is very simple.[4–6,15,16] One *defines* the a,b component of the one-loop renormalized stress tensor in the point y as the result of the following limit:

$$\langle T_{ab}(y)\rangle := \lim_{x\to y} \mathcal{D}_{ab}(x,y)\{\langle \phi(x)\phi(y)\rangle - \mathrm{H}(x,y)\}, \tag{87}$$

where the quantum average of the couple of fields is interpreted as the Green's function of the field equation corresponding to the quantum state one is considering, and $\mathrm{H}(x,y)$ is a Hadamard local fundamental solution[5,6,17] which has just the task of removing the argument-coincidence divergences from the Green's function *and from its derivatives* and does not depend on the quantum state. The operator $\mathcal{D}_{ab}(x,y)$ ''splits'' the point y and it is written down following (85), after an opportune symmetrization of the arguments (again, the final result should not depend on this symmetrization procedure),

$$\begin{aligned}\mathcal{D}_{ab}(x,y) = {} & \frac{1-2\xi}{2}[I_a^{a'}\nabla_{(x)a'}\nabla_{(y)b} + I_b^{b'}\nabla_{(x)b'}\nabla_{(y)a} + \nabla_{(y)a}\nabla_{(y)b} + I_a^{a'}I_b^{b'}\nabla_{(x)a'}\nabla_{(x)b'}] \\ & + \left(2\xi - \frac{1}{2}\right)\frac{g_{ab}(y)}{2}[2I_c^{c'}\nabla_{(x)c'}\nabla^{(y)c} + \Delta_x + \Delta_y] \\ & + \frac{1}{2}\left[\frac{g_{ab}(y)}{D}(\Delta_x + \Delta_y) - \nabla_{(y)a}\nabla_{(y)b} - I_a^{a'}I_b^{b'}\nabla_{(x)a'}\nabla_{(x)b'}\right] \\ & + \xi\left[R_{ab}(y) - \frac{g_{ab}(y)}{D}R(y)\right] - \frac{V'(y)+m^2}{D}g_{ab}(y).\end{aligned} \tag{88}$$

Above $I_a^{b'} = I_{(y)a}^{(x)b'}(y,x)$ is a generic component of the bitensor of parallel displacement from y to x, so the (co)tangent space at the point x is identified with the fixed (co)tangent space at the point y.

What one has to fix, in order to use (87) on a particular quantum state, is the Hadamard solution H. It is known that, in the case D is even, this solution is not unique[5,6] and is determined once one has fixed the term $w_0(x,y)$ [see Comment (2) of Theorem 2.6 in Ref. 1]. This term, differently from the case of the renormalization of the field fluctuations, is not completely arbitrary. Indeed, it is possible to show that there are terms w_0 producing a left-hand side of (87) which is *not* conserved.[5] Moreover, the massless conformally coupled case, and, more generally, the case $m=0$ and $V'\equiv 0$, involves some difficulties for the choice of w_0. For $m\neq 0$, it is possible to fix w_0 through the Schwinger–deWitt algorithm[4] obtaining a conserved renormalized stress tensor.[4,5] This is not possible for $m=0$ because Schwinger–deWitt's algorithm becomes singular in that case. Anyhow, there is a further prescription due to Adler, Lieberman, and Ng[18] (see also Refs. 3 and 5) which seems to overcome this drawback: this is the simplest choice $w_0(x,y)\equiv 0$. However, in the case of a massless conformally coupled field at least, as pointed out by Wald,[3] another drawback arises: the above prescription cannot produce a conserved stress tensor. Nevertheless, as proven in Ref. 3, in the case of (analytic in the cited reference) either a Lorentzian or Riemannian manifold, it is still possible to add a finite term on the right-hand side of (87) which takes account of the failure of the conservation law in order to have a conserved final left-hand side. This further term carries also a contribution to the trace of the final tensor which then fails to vanish and coincides with the well-known conformal anomaly. In Ref. 5, it has been argued that such an improved procedure can be generalized to any value of m and ξ getting

$$\langle T_{ab}(y)\rangle := g_{ab}(y)Q(y) + \lim_{x\to y} \mathcal{D}_{ab}(x,y)\{\langle \phi(x)\phi(y)\rangle - \mathrm{H}^{(0)}(x,y)\}, \tag{89}$$

where $\mathrm{H}^{(0)}$ is the Hadamard solution determined by the choice $w_0 \equiv 0$ and Q is a term fixed by imposing both the conservation of the left-hand side of (89) and the request that the renormalized stress tensor vanishes in the Minkowski vacuum. Employing the local ζ-function approach, we shall find out a point-splitting procedure which, in the case of a compact manifold, generalizes Wald's one for a general operator $-\Delta+V$ in $D>1$ dimensions in a Riemannian, not necessarily analytic, manifold and gives an explicit expression for Q automatically.

B. Local ζ-function and point-splitting procedure. An improved point-splitting prescription

In this part of the work we shall state a theorem concerning the relation between the two considered techniques proving their substantial equivalence within our general hypotheses.

Theorem 4.1: *Let us assume our general hypotheses on $\mathcal{M}$ and A' and suppose also $D>1$.*

(a) The renormalized strees tensor $\langle T_{ab}(y|A)\rangle_{\mu^2}$ defined in Definition 3.4 can be also computed as the result of a point-splitting procedure. Indeed one has, for any $\mu^2>0$,

$$\langle T_{ab}(y|A)\rangle_{\mu^2} = \lim_{x\to y} \mathcal{D}_{ab}(x,y)\{G(x,y|A) - \mathrm{H}_{\mu^2}(x,y)\} + \frac{g_{ab}(y)}{D}\left(\delta_D \frac{a_{D/2}(y,y|A)}{(4\pi)^{D/2}} - P_0(y,y|A)\right), \tag{90}$$

where $\mathcal{D}_{ab}$ is defined in (88), $G(x,y|A) := \mu^{-2}\zeta(1,x,y|A/\mu^2)$ is the μ^2-independent "Green's function" of A defined in Ref. 1, $P_0(y,y|A)$ is the C^∞ integral kernel of the projector on the kernel of A and $\mathrm{H}_{\mu^2}(x,y)$ is defined as (the summation appears for $D\geqslant 4$ only)

$$\mathrm{H}_{\mu^2}(x,y) = \sum_{j=0}^{D/2-2} (D/2-j-2)!\left(\frac{2}{\sigma}\right)^{D/2-j-1} \frac{a_j(x,y|A)}{(4\pi)^{D/2}} - \frac{a_{D/2-1}(x,y|A)}{(4\pi)^{D/2}}(2\gamma + \ln\mu^2)$$
$$- \frac{2a_{D/2-1}(x,y|A) - a_{D/2}(x,y|A)\sigma}{2(4\pi)^{D/2}} \ln\left(\frac{\sigma}{2}\right). \tag{91}$$

if D is even, and (the summation appears for $D\geqslant 5$ only)

$$\mathrm{H}_{\mu^2}(x,y) = \sum_{j=0}^{(D-5)/2} \frac{(D-2j-4)!!\sqrt{\pi}}{2^{(D-3)/2-j}}\left(\frac{2}{\sigma}\right)^{D/2-j-1} \frac{a_j(x,y|A)}{(4\pi)^{D/2}}$$
$$+ \frac{a_{(D-3)/2}(x,y|A)}{(4\pi)^{D/2}}\sqrt{\frac{2\pi}{\sigma}} - \frac{a_{(D-1)/2}(x,y|A)}{(4\pi)^{D/2}}\sqrt{2\pi\sigma} \tag{92}$$

if D is odd.

(b) H_{μ^2} is a particular Hadamard local solution of the operator A' truncated at the orders L,M,N. Indeed, one has

$$\mathrm{H}_{\mu^2}(x,y) = \frac{\Theta_D}{(4\pi)^{D/2}(\sigma/2)^{D/2-1}} \sum_{j=0}^{L} u_j(x,y)\sigma^j(x,y)$$
$$+ \delta_D\left(\sum_{j=0}^{M} v_j(x,y)\sigma^j\right)\ln\left(\frac{\sigma}{2}\right) + \delta_D \sum_{j=0}^{N} w_j(x,y)\sigma^j, \tag{93}$$

where $\delta_D=0$ if D is odd and $\delta_D=1$ if D is even; $\Theta_D=0$ for $D=2$ and $\Theta_D=1$ otherwise; and furthermore,

(1) *$L=D/2-2$, $M=1$, and $N=0$ for D even, and $L=(D-1)/2$ when D is odd.*

(2) *The coefficients u_j and v_j of the above Hadamard expansion are completely determined by fixing the value as $x\rightarrow y$ of the coefficient of the leading divergent term in order that this expansion for $L,M,N\rightarrow +\infty$ defines a Green's function formally. Using our conventions, this means*

$$u_0(y,y)=\frac{4\pi^{D/2}}{D(D-2)\omega_D}, \tag{94}$$

for $D\geqslant 3,\omega_D$ being the volume of the unitary D-dimensional disk, and

$$v_0(y,y)=\frac{1}{4\pi} \tag{95}$$

for $D=2$.

(3) *The coefficients w_j, when D is even, are completely determined by posing*

$$w_0(x,y):=-\frac{a_{D/2-1}(x,y|A)}{(4\pi)^{D/2}}[2\gamma+\ln\mu^2]. \tag{96}$$

Proof: See the Appendix. □

Comments:

(1) Whenever D is even, the logarithm in (93) contains a dimensional quantity. At first sight, this may look like a mistake. Actually, this apparent drawback means that the third summation in (93) has to contain terms proportional to $\ln\mu^2$ which can be reabsorbed in the second summation transforming the argument of the logarithm from $\sigma/2$ into the nondimensional one $\sigma\mu^2/2$. Indeed, the term on the right-hand side of (96) makes this job concerning the term v_0 in (93). Since (93) is computed up to $M=1$, one may expect the presence of a corresponding term w_1 in the last summation in (93). Actually, this term gives no contribution to the stress tensor employing (90) and (88) as one can check directly, taking into account that in any coordinate system around any $x\in\mathcal{M}$ (with an obvious meaning of the notations)

$$I_b^{a'}(x,y)|_{x=y}=\delta_b^{a'} \tag{97}$$

and

$$\begin{aligned}\nabla_{(x)a}\nabla_{(x)b}\sigma(x,y)|_{x=y}&=-\nabla_{(x)a}\nabla_{(y)b}\sigma(x,y)|_{x=y}\\&=\nabla_{(y)a}\nabla_{(y)b}\sigma(x,y)|_{x=y}=-\nabla_{(y)a}\nabla_{(x)b}\sigma(x,x')|_{x=y}=g_{ab}(y).\end{aligned} \tag{98}$$

In particular, one can check that each line on the right-hand side of (88) vanishes separately when it is evaluated for $x\rightarrow y$ on the considered terms of the Hadamard expansion. This is the reason we have put $N=0$ in (93) and we have omitted the corresponding term in (91). Notice that, conversely, in the usual version of point-splitting procedure,[4,3,5] the term $w_1(x,y)$ is necessary. Similarly, the terms of order $\sigma^n\ln\sigma$ with $n>1$ give no contribution to the stress tensor and thus we have omitted them in (93).

(2) In the case D is odd, the expansions (92) and (93) do not consider terms corresponding to $\sigma^{k+(1/2)}$ with $k=1,2,\ldots$. In fact, these terms give no contribution to the stress tensor via (90) and (88). Also in this case, each line on the right-hand side of (88) gives a contribution which vanishes separately for $x\rightarrow y$. Since (88) and (90) involve that the result does not depend on the coordinate system, one can check this fact working in Riemannian normal coordinates centered in y.

(3) The point-splitting procedure suggested in Ref. 5 for $D=4$, differently from our procedure, requires $w_0\equiv 0$ rather than (96). Actually, the function σ which appears in Ref. 5 is defined as two times our function σ. Therefore, taking into account that the argument of the logarithm in the second line of (91) is a quarter of Wald's one, Wald's prescription corresponds to taking

$w_0(x,y)-v_0(x,y)\ln 4=0$ in our case. Actually, as clarified in Ref. 3, the logarithm argument which appear in Wald's prescription has to be understood as $\ln(\sigma/u^2)$, where u is the unit of length employed. In our formalism, this corresponds, in particular, to performing the changes $\ln(\sigma/2)\rightarrow\ln[\sigma/(2u^2)]$ and $\ln\mu^2\rightarrow\ln(\mu^2 u^2)$ in (91). Equation (91) with the changes above entails that Wald's prescription, namely $w_0(x,y)-v_0(x,y)\ln 4=0$, is satisfied provided one fixes a μ^2 such that $2\gamma+\ln(\mu^2 u^2/4)=0$, namely $\mu=2e^{-\gamma}/u$.

This proves that, under our hypotheses, our prescription generalizes Wald's when the latter is understood in the Euclidean section of the manifold. Moreover, our prescription, different from Ref. 5, gives explicitly the form of the Hadamard local function to subtract to the Green's function in the general case as well as an explicit expression for the term Q in (89), in terms of heat-kernel coefficients and, trivially, for any choice of the value of μ^2.

(4) Rescaling the parameter μ^2, the expression of the final stress tensor changes by taking a term $(\ln\alpha)t_{ab}(y)$. We know the explicit form of such a term; indeed, it must be that given in the point (c) of Theorem 3.4. Notice also that the obtained point-splitting method, also concerning the rescaling of μ^2, agrees with the corresponding point-splitting procedure for computing the field fluctuations given in Ref. 1. For example, the point (d) of Theorem 3.4 holds, provided both sides are renormalized with the point-splitting procedures above and the same value of μ^2 is fixed.

(5) The point-splitting procedure we have found out uses the heat-kernel expansion in Theorem 1.3 of Ref. 1 and nothing further. This expansion can be built up also either in noncompact manifolds or manifolds containing boundary, essentially because it is based upon local considerations (see discussion in Ref. 3 concerning Schwinger–deWitt's expansion). Therefore, it is natural to expect that the obtained procedure, not depending on the ζ-function approach, may work in the general case (namely, it should produce a symmetric conserved stress tensor with the known properties of the trace also in noncompact or containing boundary manifolds), provided the Green's function of the considered quantum state has the Hadamard behavior.

(6) As a final comment, let us check on the found point-splitting method in the Euclidean section of Minkowski space–time which is out of our general hypotheses, without referring to the ζ-function approach. In this case, for $A=-\Delta+m^2$, one has that the heat-kernel referred to globally flat coordinates reads

$$\mathrm{K}(t,x,y|A)=\frac{e^{-\sigma/2t}}{(4\pi)^2t^2}e^{-m^2t}, \tag{99}$$

and thus, supposing $m^2>0$,

$$a_j(x,y|A)=\frac{(-1)^j m^{2j}}{j!}. \tag{100}$$

As is well known, the (Euclidean) Green's function of Minkowski vacuum can be computed directly:

$$G(x,y|A)=\int_0^{+\infty}\mathrm{K}(t,x,y)\,dt=\frac{2m}{(4\pi)^2\sqrt{\sigma/2}}\mathrm{K}_1\left(2\sqrt{\frac{\sigma m^2}{2}}\right). \tag{101}$$

Expanding K_1 in powers and logarithms of σ one gets

$$G(x,y|A)=\frac{2}{(4\pi)^2\sigma}+\frac{1}{(4\pi)^2}\left\{m^2+\frac{m^4}{4}\sigma+\sigma^2 f(\sigma)\right\}\ln\left(\frac{\sigma}{2}\right)+\frac{m^2}{(4\pi)^2}(2\gamma-1+\ln m^2)+\sigma g(\sigma), \tag{102}$$

where f and g are smooth bounded functions. Then, employing (90), (93), and (100), it is a trivial task to prove that, *provided* the choice $\mu=me^{-3/4}$ is taken in (96), one gets $\langle T_{ab}(y)\rangle\equiv 0$ as it is expected. In particular, one finds also $Q(y)\equiv m^4/(128\pi^2)$ for the coefficient of $g_{ab}(y)$ in (89) and in the last line of (90). For a general value of μ^2, the computation of the stress-tensor trace via the formula in (d) in Theorem 3.4 reproduces the correct Coleman–Weinberg results [19] for the field fluctuations still obtained by the local ζ function approach[13] as well as by using the point-splitting formula given in Theorem 2.6 in Ref. 1.

The case $m=0$ is much more trivial. In this case the heat kernel is given by (99) with $m=0$, and thus only $a_0(x,y)\equiv 1$ survives in the heat-kernel expansion. In this case, A is not positive defined but positive only, the manifold is not compact, and the Minkowski vacuum Green's function can still be computed integrating the heat-kernel despite that the local ζ-function does not exist. Moreover, the Green's function coincides with the Hadamard local solution $2/[(4\pi)^2\sigma]$. Furthermore, $Q(y)\equiv 0$, and thus our procedure gives a vanishing stress tensor as well.

V. SUMMARY AND OUTLOOKS

In this paper we have concluded the rigorous analysis started in Ref. 1 concerning the mathematical foundation of the theory of the local ζ-function renormalization of the one-loop stress tensor introduced in Ref. 2. The other important point developed herein has been the relation between the local ζ-function approach and the (Euclidean) point-splitting procedure.

Concerning the first point, we have proven that the ζ-function theory of the stress tensor can be rigorously defined, at least in closed manifold, giving results which agree with and generalize previous results concerning the ζ-function renormalization of the field fluctuations.[1] On the mathematical ground, we have also proven a few new theorems about the smoothness of the heat-kernel expansions.

Concerning the second proposed goal, we have found out that the two methods (ζ-function and point-splitting) agree essentially, provided a particular form of point-splitting procedure is employed. Within the hypotheses of a Riemannian compact C^∞ manifold, this point-splitting procedure is a natural generalization (in any $D>1$ and for a larger class of Euclidean motion operators) of Wald's improved procedure presented in Ref. 3 and also discussed in Ref. 5 defined in a Lorentzian manifold (but the same arguments employed can be trivially extended to Riemannian manifolds). Our procedure also gives explicitly the form of the various terms which are employed in the point-splitting procedure in terms of the heat-kernel expansion.

In our opinion, the found point-splitting procedure should work also without the employed hypotheses and independently from the ζ-function procedure. We have anyhow checked this conjecture in the Euclidean Minkowski space–time, proving that it holds true as expected either in the case $m=0$ or $m>0$. Moreover, the obtained results concerning the point splitting procedure should be trivially generalized for static Lorentzian manifolds at least.

I am very grateful to D. Luminati for useful discussions. This work has been financially supported by a Postdoctoral Research Fellowship of the Department of Mathematics of the University of Trento.

APPENDIX: PROOF OF SOME LEMMATA AND THEOREMS

Proof of Lemma 3.1: Let us consider the form of the heat-kernel as it was built up in Ref. 20, Sec. 4, Chap. VI. This construction holds also in the case of an operator $A' := -\Delta + V$ and not only $A' := -\Delta$ as pointed out in Ref. 1. In our notations, one has by (45) in Sec. 4 of Chap. VI of Ref. 20

$$F_N(t,x,y)=\frac{e^{-\sigma(x,y)/2t}}{(4\pi t)^{D/2}}\chi(\sigma(x,y))\sum_{j=0}^{N} a_j(x,y|A)t^j, \tag{A1}$$

$N>D/2+2$ is a fixed integer.

[Actually, equation (45) in Sec. 4 of Chap. VI of Ref. 20 is misprinted in Ref. 20 because of the unnecessary presence of the operator L_x on the right-hand side of the first line of (45) in Sec.

4 of Chap. VI of Ref. 20. Since the absence of this operator in the correct formula, we cannot get the second line of (45) in a direct way. In fact, in Ref. 1 we have used a different (but equivalent in practice) form of the remaining of the heat-kernel expansion with respect to that which appears in (45). Some other parts of Sec. 4 of Chap. VI in Ref. 20 contain several other misprints like the requirement $F \in C^0(M \times M \times [0+\infty))$ in Lemma 2 in Ref. 20, which has to be corrected into $F \in C^1(M \times M \times [0+\infty))$.] Also,

$$\mathrm{K}(t,x,y|A) = F_N(t,x,y) + (F_N * F)(t,x,y,), \tag{A2}$$

where F_N is the $C^\infty((0,+\infty)\times\mathcal{M}+\mathcal{M})$ parametrix defined in Ref. 1.

The remaining proportional to $O_{\eta,N}$ in (20) of Lemma 3.1 of Ref. 1 is therefore $(F_N * F) \times (t,x,y)$. We remind the reader that $\sigma(x,y)$ is one-half the squared geodesical distance $(d(x,y))$ from x to y and defines an everywhere continuous function on $\mathcal{M}\times\mathcal{M}$ which is also C^∞ in the set of the points x,y such that $d(x,y)<r$. Here $\chi(u)$ is a non-negative $C^\infty([0,+\infty))$ function which takes the constant value 1 for $|u|<r^2/16$ and vanishes for $|u|\geqslant r^2/4$, r being the injectivity radius of the manifold. The convolution $*$ has been defined in Sec. 4 of Chap. VI of Ref. 20,

$$(G*\mathrm{H})(t,x,y) := \int_0^t d\tau \int_{\mathcal{M}} d\mu_g(z) G(\tau,x,z)\mathrm{H}(t-\tau,z,y), \tag{A3}$$

whenever the right-hand side makes sense.

Finally, the function F which appears in (A2) is defined by a uniformly convergent series in $[0,T]\times\mathcal{M}\times\mathcal{M}$ for any $T>0$ [see (43) in Sec. 4 of Chap. VI of Ref. 20].

$$F(t,x,y) := \sum_{l=1}^{\infty} [(A'_x - \partial/\partial t)F_N]^{*l}(t,x,y) \tag{A4}$$

(B^{*l} means $B*B*\ldots*Bl$ times). This function belongs to $C^L([0,+\infty)\times\mathcal{M}\times\mathcal{M})$ provided $M > D/2+2L$ (see Ref. 20). Equation (A2) satisfies the heat-kernel equation provided F is C^1 in all variables, namely $N>D/2+2$.

Let us consider (A2). The remainder of the ''asymptotic'' expansion of the heat kernel computed up to the coefficient $a_N(x,y|A)(N>D/2+2)$ is just the second term on the right-hand side. It can be explicitly written down (see Ref. 20)

$$(F_N*F)(t,x,y) = \int_0^t d\tau\, \tau^{-D/2}(t-\tau)^{N-D/2} \int_{\mathcal{M}} d\mu_g(z) \mathcal{F}_N(\tau,x,z)\mathcal{F}(t-\tau,z,y) \times e^{-\sigma(x,z)/2\tau} e^{-\sigma(z,y)/2(t-\tau)}. \tag{A5}$$

Here $\mathcal{F}_N(t,x,z)$ defines a function which belongs to $C^\infty([0,+\infty)\times\mathcal{M}\times\mathcal{M})$ and vanishes smoothly whenever the geodesical distance between x and z is sufficiently large, i.e., $d(x,z) \geqslant r/2$, due to the presence of the function χ in the expression of the parametrics (A1). $\mathcal{F}$ defines an everywhere continuous function which belongs also to C^L provided $N>D/2+2L$ and the geodesical distance between y and z is sufficiently short, i.e., $d(y,z)<r$, and $t\in[0,+\infty)$.

Then let us pick out a point $u\in\mathcal{M}$. We can find a geodesically spherical open neighborhood of u,J_u, with a geodesic radius $r_0<r/8$. By the definition of the function χ, it holds $\chi(\sigma(x,y)) = 1$ whenever $x,y\in J_u$ and thus the coefficient χ can be omitted in the heat-kernel expansion working with any coordinate system defined in a neighborhood of J_u (e.g., normal Reimannian coordinates). From now on concerning the points x and y we shall work within such a coordinate system in the neighborhood J_u. Notice also that, by the triangular inequality $d(x,y) [=\sqrt{2\sigma(x,y)}]<r/4$ whenever $x,y\in J_u$.

Now, let us suppose $N>D/2+2|\alpha|+2|\beta|$. This entails $F\in C^{|\alpha|+|\beta|}$ and thus also $\mathcal{F} \in C^{|\alpha|+|\beta|}$ provided the distance of its arguments defined on the manifold is less than r and $t \in (0,+\infty)$. We can apply operators D_x^α and D_y^β to both sides of (A2). The action of the derivatives

(A2) produces the first term on the right-hand side of (20) at least (notice that $\chi\equiv 1$ in our hypotheses). Let us focus attention on the action of the derivatives on the remaining in (A2). Our question concerns the possibility of passing these under the integration symbol in (A5). The action of the derivatives can be carried under integration symbols (obtaining also an x,y-continuous final function if the derivatives of the integrand are continuous) provided, for any fixed choice of a couple of of multindices α,β, the derivatives of the integrand are locally x,y-uniformly bounded by an integrable function (dependent on the multindices in general). We shall see that this is the case after we have manipulated the integral opportunely. Notice that the derivatives (with respect to the manifold variables) of the function $\mathcal{F}$ do exist because the second integral on the right-hand side of (A5) takes contribution only from the points z such as both $d(y,z)<r$ and $d(x,z)<r$ are fulfilled as required above. Indeed, it must be $d(x,y)<r/2$, otherwise, $\mathcal{F}_N(\tau,x,z)$ smoothly vanishes as pointed out above, and, taking account of $d(x,y)<r/4$, the triangular inequality entails also $d(y,z)\leqslant d(x,z)+d(x,y)<r/2+r/4=3r/4$.

Now, let us fix a new open neighborhood of u, I_u, such that its closure is contained in J_u, and fix $T>0$. Barring $\tau\mapsto\tau^{-D/2}$, all functions of τ,x,y,z and all their (x,y,z-)derivatives we shall consider are bounded in the compact $[0,T]\times\overline{I_u}\times\overline{I_u}\times\mathcal{M}$ where we are working because these are continuous therein. We can rearrange the expression (A5) into

$$(F_N*F)(t,x,y)=\int_0^t d\tau\tau^{-D/2}(t-\tau)^{N-D/2}\int_{S^{D-1}}d\vec{v}\int_0^{+\infty}d\rho\rho^{D-1}J(x,\vec{v},\rho)$$
$$\times e^{-\rho^2/2\tau}\mathcal{F}_M(\tau,x,z(x,\rho,\vec{v}))\mathcal{F}(t-\tau,z(x,\rho,\vec{v}),y)\times e^{-\sigma(z(x,\rho,\vec{v}),y)/2(t-\tau)}. \tag{A6}$$

where, to determine the position of z, we have employed a spherical system of normal coordinates $\rho,\vec{v}$ centered in any x, ρ is the distance of z from x, its range is maximized in the integrals above because the integrand vanishes smoothly for $\rho>r/2$, and thus all the functions contained in the integrand are well-defined within $\{\rho\in[0,+\infty)\}$. $\vec{v}$ is a unitary $(D-1)$-dimensional vector and $d\mu_g(z)=d\rho d\vec{v}\rho^{D-1}J(x,\vec{v},\rho)$, $d\vec{v}$ is the natural measure on S^{D-1}. The function J is continuous and bounded in $\overline{I_u}\times S^{D-1}\times\{\rho\in[0,r/2]\}$ together with all derivatives.

Then, we can change variables $\rho\mapsto\rho/\sqrt{\tau}=:\rho'$ obtaining

$$(F_N*F)(t,x,y)=\int_0^t d\tau(t-\tau)^{N-D/2}\int_{S^{D-1}}d\vec{v}\int_0^{+\infty}d\rho'\rho'^{D-1}J(x,\vec{v},\tau^{1/2}\rho')$$
$$\times e^{-\rho'^2/2}\mathcal{F}_M(\tau,x,z(x,\tau^{1/2}\rho',\vec{v}))\mathcal{F}(t-\tau,z(x,\tau^{1/2}\rho',\vec{v}),y)$$
$$\times e^{-\sigma(z(x,\tau^{1/2}\rho',\vec{v}),y)/2(t-\tau)}. \tag{A7}$$

The formal action of the operators D_x^α and D_y^β under the integration produces a sum of continuous and bounded functions (now the function $\tau\mapsto\tau^{-D/2}$ has disappeared and the remaining functions and their x,y,z-derivatives are bounded since they are product of bounded functions). Also, it changes $(t-\tau)^{N-D/2}$ into several terms of the form $(t-\tau)^{N-D/2-L_i}$ (where each $L_i\leqslant|\alpha|+|\beta|$), because of the derivatives of the second exponential. These functions of τ are continuous and bounded being $N>D/2+|\alpha|+|\beta|\geqslant L_i$ in our hypotheses. We can bound the absolute value of these functions by $Ce^{-\rho'^2/2}$, where C is a sufficiently large constant. This function is trivially integrable in the measure we are considering. This x,y,t-uniform bound assures that, concerning the x,y-derivatives of F_N*F, one can interchange the symbols of derivatives with those of integrals and also that the derivative of $(t,x,y)\mapsto(F_N*F)(t,x,y)$ are continuous functions in $(0,+\infty)\times\mathcal{I}_u\times\mathcal{I}_u$.

In order to finish this proof, let us consider a finer estimate of $O_{\eta,N}^{(\alpha,\beta)}(x,y)$. We have the inequality[20] for $\tau\in[0,t]$

$$\frac{d^2(x,y)}{t} \leqslant \frac{d^2(x,z)}{\tau} + \frac{d^2(z,y)}{t-\tau}, \tag{A8}$$

and thus, picking out any $\eta \in (0,1)$ and posing $\delta := 1-\eta \in (0,1)$, we get (notice that $t-\tau \geqslant 0$)

$$e^{-\sigma(x,z)/2\tau} e^{-\sigma(z,y)/2(t-\tau)} \leqslant e^{-\eta\sigma(x,y)/2t} (e^{-\delta\sigma(x,z)/2\tau} e^{-\delta\sigma(z,y)/2(t-\tau)}) \leqslant e^{-\eta\sigma(x,y)/2t} e^{-\delta\sigma(x,z)/2\tau}. \tag{A9}$$

We can use this relation in the x,y-derivatives of (A7), obtaining

$$|D_x^\alpha D_y^\beta (F_N * F)(t,x,y)| \leqslant \sum_i e^{-\eta\sigma(x,y)/2t} \int_0^t d\tau (t-\tau)^{N-D/2-L_i} \int_{S^{D-1}} d\vec{v} \int_0^{+\infty} d\rho' \rho'^{D-1} e^{-\delta\rho'^2/2} C_i, \tag{A10}$$

where the coefficients C_i are upper bounds of the absolute values of the continuous functions missed in the integrand and $L_i \leqslant |\alpha|+|\beta|$. We can execute the integral in τ obtaining, for $0<t \leqslant T$ and $x,y \in I_u$ (remember that $N>D/2+|\alpha|+|\beta|$)

$$|D_x^\alpha D_y^\beta (F_N * F)(t,x,y)| \leqslant e^{-\eta\sigma(x,y)/2t} \sum_i C'_{i,\delta} t^{N+1-L_i-D/2} \leqslant \frac{C_\delta}{(4\pi)^{D/2}} e^{-\eta\sigma(x,y)/2t} t^{N+1-D/2-|\alpha|-|\beta|}, \tag{A11}$$

where C_δ is a positive constant sufficiently large which depends on T,α,β in general. This proves the remaining part of the thesis posing $\mathrm{K}_{\eta,N}^{(\alpha,\beta)} := T$ and $M_{\eta,N}^{(\alpha,\beta)} := C_\delta$. Indeed, the remaining $O_{\eta,N}^{(\alpha,\beta)}$ we wanted to compute coincides with $D_x^\alpha D_y^\beta (F_N * F)$ just up to the factor $(4\pi t)^{-D/2} t^{N-|\alpha|-|\beta|} \exp(-\eta\sigma/2t)$. $O_{\eta,N}^{(\alpha,\beta)}$ can be defined in $t=0$ as $O_{\eta,N}^{(\alpha,\beta)}(0;x,y)=0$, obtaining a continuous function in $[0,+\infty) \times I_u \times I_u$. □

Proof of Lemma 3.2: Let us consider an eigenvector ϕ_j and fix $T \in (0,+\infty)$ and consider a neighborhood of $u \in \mathcal{M}, J_u$ where a coordinate system is defined. In the following, x and y are points in a new neighborhood of u, I_u, such that its closure is contained in J_u. These points are represented by the coordinate system given above and the derivative operators are referred to these coordinates. From Theorem 1.3 of Ref. 1, it holds

$$e^{-T\lambda_j} \phi_j(x) = \int_{\mathcal{M}} d\mu_g(z) \mathrm{K}(T,x,z|A) \phi_j(z). \tag{A12}$$

We can derive both sides of the equation above employing operators D_x^α. Since, for a fixed T the derivatives of K are bounded $[(x,z) \mapsto \mathrm{K}(T,x,z|A)$ is C^∞ and $\overline{I_u} \times \mathcal{M}$ is compact in our hypotheses[1]], we can pass the derivative operator under the integral symbol obtaining

$$|D_x^\alpha \phi_j(x)| = |e^{\lambda_j T} \int_{\mathcal{M}} d\mu_g(z) D_x^\alpha \mathrm{K}(t,x,z|A) \phi_j(z)| \leqslant e^{\lambda l_j T} \|D_x^\alpha \mathrm{K}(T,x,.|A)\|_{L^2(\mathcal{M},d\mu_g)}, \tag{A13}$$

where we have made use of the Cauchy–Schwarz inequality and we have taken account of $\|\phi_j\|=1$ [from now on we omit the index $L^2(\mathcal{M},d\mu_g)$ in the norms because there is no ambiguity]. The function $x \mapsto \|D_x^\alpha \mathrm{K}(T,x,.|A)\|$, for $x \in \overline{I_u}$ is continuous from Lebesgue's dominate convergence theorem since $D_x^\alpha \mathrm{K}(T,x,y|A)$ defines a continuous function in x and y and there is a constant (dependent on T, in general) M_T such that $|D_x^\alpha \mathrm{K}(T,x,z|A)|^2 \leqslant M_T$ for (x,z) which belong in the compact $\overline{I_u} \times \mathcal{M}$ and the measure of the manifold is finite. The same results holds whenever one keeps fixed y in I_u and integrates over x. Therefore, let us define

$$P_T^{(\alpha,\beta)} := [\sup_{x \in \overline{I_u}} \|D_x^\alpha \mathrm{K}(T,x,.|A)\|][\sup_{y \in \overline{I_u}} \|D_y^\beta \mathrm{K}(T,.,y|A)\|] \tag{A14}$$

and we have, for any $x,y \in I_u$, the λ_j-uniform upper bound

$$|e^{-\lambda_j t} D_x^\alpha \phi_j(x) D_y^\beta \phi_j^*(y)| \leqslant P_T^{(\alpha,\beta)} e^{-\lambda_j(t-2T)}. \tag{A15}$$

The found inequality proves that the absolute values of the terms of the series

$$\sum_{j\in\mathbb{N}}{}' e^{-\lambda_j t} D_x^\alpha \phi_j(x) D_y^\beta \phi_j^*(y) \tag{A16}$$

are x,y-uniformly bounded, for $(x,y,t)\in I_u \times I_u \times (2T,+\infty)$, by terms of the convergent series (see (30) in Ref. 1)

$$\sum_{j\in\mathbb{N}}{}' e^{-\lambda_j(t-2T)} P_T^{(\alpha,\beta)} = P_T^{(\alpha,\beta)} \int_{\mathcal{M}} d\mu_g(z) \{ \mathrm{K}(t-2T,z,z|A) - P_0(z,z|A)\}$$
$$= P_T^{(\alpha,\beta)} \,\mathrm{Tr}\{\mathrm{K}_{(t-2T)} - P_0\}.$$

This holds for any choice of the multindices α,β and this entails (23), (25), and (26). The final upper bound (26) is a trivial consequence of (99) in Ref. 1 and the fact that the manifold has a finite measure. □

Sketch of Proof of Theorem 4.1: Let us fix a coordinate system in a neighborhood I_u of a point $u\in\mathcal{M}$. All the following considerations will refer to these coordinates, and in particular to a couple of points x,y within that neighborhood. Then, let us consider the expression (58) for the ζ-function of the stress tensor. Employing the eigenvalue equation $A\phi_j = \lambda_j \phi_j$ one can rearrange (58) into

$$Z_{ab}(s,y|A/\mu^2) = \sum_{j\in\mathbb{N}}{}' \frac{2s}{\mu^2}\left(\frac{\lambda_j}{\mu^2}\right)^{-(s+1)} T'_{ab}[\phi_j,\phi_j^*,\mathbf{g}](y), \tag{A17}$$

where (C.C. means the complex conjugation of the terms already written)

$$\begin{aligned} T'_{ab}[\phi_j,\phi_j^*,\mathbf{g}](y) = {}&(1-2\xi)\frac{1}{2}(\nabla_a\phi_j(y)\nabla_b\phi_j^*(y) + \phi_j(y)\nabla_a\nabla_b\phi_j^*(y) + \text{C.C.})\\ &+\left(2\xi - \frac{1}{2}\right)\frac{g_{ab}(x)}{2}(\nabla_c\phi_j(y)\nabla^c\phi_j^*(y) + \phi_j(y)\Delta\phi_j^*(y) + \text{C.C.})\\ &+\frac{1}{2}\left(\frac{g_{ab}(y)}{D}\phi_j(y)\Delta\phi_j^*(y) - \phi_j(y)\nabla_a\nabla_b\phi_j^*(y) + \text{C.C.}\right)\\ &+\xi\left(R_{ab}(y) - \frac{g_{ab}(y)}{D}R(y)\right)|\phi_j(y)|^2 - \frac{V'(y)+m^2}{D}g_{ab}(y)|\phi_j(y)|^2\\ &+\frac{\lambda_j}{D}g_{ab}(y)|\phi_j(y)|^2. \end{aligned} \tag{A18}$$

The stress tensor is then given by (60) in Definition 3.4 after the analytic continuation in the variable s of $Z_{ab}(s,y|A/\mu^2)$ given in (A17). Employing Theorem 3.2 and (A18) and (A17), we can write down the expression of $Z_{ab}(s,y|A/\mu^2)$, employing also functions $\zeta^{[\alpha,\beta]}(s,y|A/\mu^2)$ defined as in Definition 3.2 with the difference that covariant derivatives are employed instead of ordinary derivatives. We get, omitting the arguments y and A/μ^2 in the various ζ-functions for the sake of brevity,

$$
\begin{aligned}
Z_{ab}(s,y|A/\mu^2)=&(1-2\xi)\,\frac{s}{\mu^2}\,(\zeta^{(1_a,1_b)}(s+1)+\zeta^{(1_b,1_a)}(s+1)+\zeta^{[1_a+1_b,0]}(s+1)\\
&+\zeta^{[0,1_a+1_b]}(s+1))+\left(2\xi-\frac{1}{2}\right)\frac{s g_{ab}(y)g^{cd}(y)}{\mu^2}\,(2\zeta^{(1_c,1_d)}(s+1)\\
&+\zeta^{[0,1_c+1_d]}(s+1)+\zeta^{[1_c+1_d,0]}(s+1))+\frac{s}{\mu^2}\left[\frac{g_{ab}(y)g^{cd}(y)}{D}\,(\zeta^{[0,1_c+1_d]}(s+1)\right.\\
&\left.+\zeta^{[1_c+1_d,0]}(s+1))-\zeta^{[0,1_a+1_b]}(s+1)-\zeta^{[1_a+1_b,0]}(s+1)\right]\\
&+\frac{2s\xi}{\mu^2}\left(R_{ab}(y)-\frac{g_{ab}(y)}{D}R(y)\right)\zeta(s+1)-\frac{V'(y)+m^2}{D}\,\frac{2sg_{ab}(y)}{\mu^2}\,\zeta(s+1)\\
&+\frac{2sg_{ab}(y)}{D}\,\zeta(s). \qquad \text{(A19)}
\end{aligned}
$$

First of all, we notice that the term proportional to $g_{ab}(y)$ in (90) arises from the last term above via item (c) of Theorem 2.2 in Ref. 1.

Let us consider the contribution to the stress tensor due to the terms $\zeta^{(1_a,1_b)}(s+1,y|A/\mu^2)$. Similarly to (101) in Ref. 1, we can define, for any $\mu_0^2>0$ fixed and N integer $>D/2+4$, taking account of Lemma 3.1 above:

$$
\begin{aligned}
\zeta^{(1_a,1_b)}(N,s+1,x,y|A/\mu^2,\mu_0^{-2}):=&\frac{\mu^{2s}}{\Gamma(s+1)}\int_0^{\mu_0^{-2}}dt\,t^s\frac{e^{-\eta\sigma(x,y)/2t}}{(4\pi t)^{D/2}}\,t^{N-2}O^{(1_a,1_b)}_{\eta,N}(t;x,y)\\
&+\frac{\mu^{2s+2}}{\Gamma(s+1)}\int_{\mu_0^{-2}}^{+\infty}dt\,t^s\nabla_{(x)a}\nabla_{(y)b}[\mathrm{K}(t,x,y|A)-P_0(x,y|A)]. \qquad \text{(A20)}
\end{aligned}
$$

Similarly to Lemma 2.1 in Ref. 1, one can prove that the function of s,x,y defined above is continuous in a neighborhood $I\times I_u\times I_u$, where I is a complex neighborhood of $s=0$ with all of its s derivatives, in particular, it is s-analytic therein. Employing Lemma 3.1 and the item (a) of Theorem 3.1 one can write also, for $\mathrm{Re}\,s+1>D/2+4$,

$$
\begin{aligned}
\zeta^{(1_d,1_b)}(s+1,x,y|A/\mu^2)=&\zeta^{(1_a,1_b)}(N,s+1,x,y|A/\mu^2,\mu_0^{-2})-\left(\frac{\mu}{\mu_0}\right)^{2s+2}\frac{\nabla_{(x)a}\nabla_{(x)b}P_0(x,y|A)}{(s+1)\Gamma(s+1)}\\
&+\frac{\mu^{2s+2}}{(4\pi)^{D/2}\Gamma(s+1)}\sum_{j=0}^{N}\nabla_{(x)a}\nabla_{(y)b}\left(\int_0^{\mu_0^{-2}}dt\,t^{s-D/2+j}e^{-\sigma/2t}a_j(x,y|A)\right). \qquad \text{(A21)}
\end{aligned}
$$

In particular, for $\mathrm{Re}\,s+1>D/2+4$, the left-hand side above is continuous in x,y and thus we can take the coincidence limit for $x\to y$. Noticing that one can also pass the derivatives under the sign of integration on the right-hand side and that $\nabla_{(x)a}\nabla_{(y)b}\sigma(x,y)|_{x=y}=-g_{ab}(y)$ and $\nabla_c\sigma(x,y)|_{x=y}=0$, we get for the right-hand side of the expression above multiplied by $2s/\mu^2$ and evaluated for $x=y$

$$\frac{2s}{\mu^2}\zeta^{(1_a,1_b)}(N,s+1,y,y|A/\mu^2,\mu_0^{-2})-\frac{2s}{\mu^2}\left(\frac{\mu}{\mu_0}\right)^{2s+2}\frac{P_{0ab}(x,y|A)}{(s+1)\Gamma(s+1)}$$
$$+\frac{2s}{\mu^2}\frac{\mu^{2s+2}}{(4\pi)^{D/2}\Gamma(s+1)}\sum_{j=0}^{N}\left\{\frac{a_{jab}(y,y|A)\mu_0^{-2(s-D/2+j+1)}}{s-D/2+j+1}\right.$$
$$\left.+\frac{g_{ab}(y)}{2}\frac{a_j(y,y|A)\mu_0^{-2(s-D/2+j)}}{s-D/2+j}\right\},$$

where $a_{jab}(y,y|A):=\nabla_{(x)a}\nabla_{(y)b}a_j(x,y|A)|_{x=y}$, and $P_{jab}(y,y|A):=\nabla_{(x)a}\nabla_{(y)b}P_0(x,y|A)|_{x=y}$. The contribution to the stress tensor, namely, to $(d/ds)|_{s=0}Z_{ab}(s,y|A/\mu^2)/2$ of the considered term, is then obtained by continuing the result above as far as $s=0$, executing the s derivative and multiplying for $(1-2\xi)/2$ the final result. Taking account that $\zeta(N,s,x,y|A/\mu^2,\mu_0^{-2})$ is smooth in a neighborhood of $s=0$, this leads to, apart from the unessential factor $(1-2\xi)$,

$$\left.\frac{d}{ds}\right|_{s=0}\frac{2s}{\mu^2}\zeta^{(1_a,1_b)}(s+1,y|A/\mu^2)$$
$$=\frac{1}{\mu^2}\zeta^{(1_a,1_b)}(N,1,y,y|A/\mu^2,\mu_0^{-2})-\frac{P_{0ab}(y,y|A)}{\mu^2}$$
$$+\frac{1}{(4\pi)^{D/2}}\sum_{j=0,j\neq D/2-1}^{N}\frac{a_{jab}(y,y|A)}{\mu_0^{2j-D+2}(j-D/2+1)}+\delta_D\left(\gamma+2\ln\frac{\mu}{\mu_0}\right)\frac{a_{(D/2-1)ab}(y,y|A)}{(4\pi)^{D/2}}$$
$$+\frac{g_{ab}(y)}{(4\pi)^{D/2}}\sum_{j=0,j\neq D/2}^{N}\frac{a_j(y,y|A)}{\mu_0^{2j-D}(j-D/2)}+\delta_D g_{ab}(y)\left(\gamma+2\ln\frac{\mu}{\mu_0}\right)\frac{a_{D/2}(y,y|A)}{(4\pi)^{D/2}}. \tag{A22}$$

Let us consider the first line on the right-hand side of (A19) for a moment. The other terms different from $\zeta^{(1_a,1_b)}(s+1)$ can be undertaken to a procedure similar to that developed above. The important point is that, once one has performed such a procedure, all terms with a factor $g_{ab}(y)$ similar to the terms in the last line of (A22) cancel out each other, and thus, in the final expression of the first line on the right-hand side of (A18), no term with a factor $g_{ab}(y)$ survives. The same fact happens for the second and third lines of (A19). Since $\zeta^{(1_a,1_b)}$ $\times(N,1,y,y|A/\mu^2,\mu_0^{-2})$ and the derivatives of heat-kernel coefficients are continuous in x,y we can compute the right-hand side of (A22) as a limit of coincidence:

$$\left.\frac{d}{ds}\right|_{s=0}\frac{2s}{\mu^2}\zeta^{(1_a,1_b)}(s+1,y|A/\mu^2)$$
$$=\lim_{x\to y}\left\{\frac{1}{\mu^2}\zeta^{(1_a,1_b)}(N,1,x,y|A/\mu^2,\mu_0^{-2})-\frac{P_{0ab}(x,y|A)}{\mu^2}\right.$$
$$+\frac{1}{(4\pi)^{D/2}}\sum_{j=0,j\neq D/2-1}^{N}\frac{a_{jab}(x,y|A)}{\mu_0^{2j-D+2}(j-D/2+1)}+\delta_D\left(\gamma+2\ln\frac{\mu}{\mu_0}\right)\frac{a_{(D/2-1)ab}(x,y|A)}{(4\pi)^{D/2}}$$
$$+\frac{g_{ab}(y)}{(4\pi)^{D/2}}\sum_{j=0,j\neq D/2}^{N}\frac{a_j(x,y|A)}{\mu_0^{2j-D}(j-D/2)}+\delta_D g_{ab}(y)\left(\gamma+2\ln\frac{\mu}{\mu_0}\right)\frac{a_{D/2}(x,y|A)}{(4\pi)^{D/2}}. \tag{A23}$$

Moreover, since the function in the limit is continuous, the same limit can be computed by identifying the tangent space at x with the tangent space at y and thus introducing the bitensor $I_a^{a'}=I_{(y)a}^{(x)a'}(y,x)$ of parallel displacement from y to x as usual. Employing (A21) we finally get

$$(1-2\xi)\frac{d}{ds}\bigg|_{s=0}\frac{2s}{\mu^2}\zeta^{(1_a,1_b)}(s+1,y|A/\mu^2)$$
$$=\lim_{x\to y}(1-2\xi)I_a^{a'}\nabla_{(x)a'}\nabla_{(y)b}\left\{\frac{1}{\mu^2}\zeta(1,x,y|A/\mu^2)-\mathrm{H}_N(x,y)\right\}+(1-2\xi)g_{ab}(y)\mathrm{H}'(y), \tag{A24}$$

where, as we said above, the final term proportional to $g_{ab}(y)$ gives no contribution to the final stress tensor because it cancels against similar terms in the first line of (A18). The explicit form of H_N reads

$$\mathrm{H}_N(x,y)=\sum_{j=0}^{N}\frac{a_j(x,y|A)}{(4\pi)^{D/2}}\int_0^{\mu_0^{-2}}t^{j-D/2}e^{-\sigma(x,y)/2t}-\frac{1}{(4\pi)^{D/2}}\sum_{j=0,j\neq D/2-1}^{N}\frac{a_j(x,y|A)}{\mu_0^{2j-D+2}(j-D/2+1)}$$
$$-\delta_D\frac{a_{D/2-1}(x,y|A)}{(4\pi)^{D/2}}\left[\gamma+\ln\left(\frac{\mu}{\mu_0}\right)^2\right]. \tag{A25}$$

The same procedure has to be used for each term on the right-hand side of (A18) except for the last term which, as it stands, produces the last term on the right-hand side of (90). Summing all contributions, one gets (90) with H_N in place of H_{μ^2}. Anyhow, executing the integrations above using the results (52)–(58) in Ref. 1 $(D>1)$, expanding H_N in powers and logarithm of σ and taking account of Comments (1) and (2) after Theorem 4.1 above, we have that, in the expansion of H_N one can take account only of the terms pointed out in the item (a) of Theorem 4.1; these are the only terms which do not contain the arbitrary parameter μ_0^2 (which cannot remain in the final result). Therefore, the part of H_N which gives contributions to the final stress tensor coincides with H_{μ^2} given in (91) and (92).

This proves the point (a) of Theorem 4.1. The point (b) is trivially proven by a direct comparison between (23)–(25) in Ref. 1 and the equation for the coefficients of the Hadamard local solution given in Chap. 5 of Ref. 17 which determines completely the coefficients u_j and v_j of the local solution once the values of the coefficients of the leading divergences are fixed for $x\to y$, and the coefficients w_j once w_0 has been fixed. In performing this comparison, concerning the normalization conditions (94) and (95) in particular, notice that the measure used in the integrals employed in Ref. (17) is the Euclidean one $d^n x$ instead of our measure $\sqrt{g(x)}d^n x$. □

Inverse problem for an inhomogeneous Schrödinger equation

A. G. Ramm[a)]
Department of Mathematics, Kansas State University, Manhattan, Kansas 66506-2602

(Received 8 March 1999; accepted for publication 27 April 1999)

Let $(l-k^2)u=-u''+q(x)u-k^2u=\delta(x)$, $x\in\mathbb{R}$, $\partial u/\partial|x|-iku\to 0$, $|x|\to\infty$. Assume that the potential $q(x)$ is real valued and compactly supported: $q(x)=\overline{q(x)}$, $q(x)=0$ for $|x|\geqslant 1$, $\int_{-1}^{1}|q|dx<\infty$, and that $q(x)$ produces no bound states. Let $u(-1,k)$ and $u(1,k)$, $\forall k>0$ be the data. It is shown that under the above assumptions these data determine $q(x)$ uniquely. © *1999 American Institute of Physics.* [S0022-2488(99)02108-8]

I. INTRODUCTION

For several decades, the following inverse problems of practical interest are open. Let

$$\nabla^2 u+k^2u+k^2v(x)u=-\delta(x), \quad \text{in } \mathbb{R}^3, \tag{1.1}$$

u satisfies the radiation condition at infinity, and $v(x)$ is a compactly supported piecewise-smooth function, supp $v\subset\mathbb{R}^3_-:=\{x:x_3<0\}$.

The data are the values $u(x_1,x_2,0,k)$ for all $\hat{x}:=(x_1,x_2)\in\mathbb{R}^2$ and $k>0$.

(IP1) The inverse problem is the following.

Given the data, find $v(x)$.

Uniqueness of the solution to this problem is not proved. IP1 is not overdetermined: the data is a function of three variables, and $v(x)$ is also.

A similar inverse problem can be formulated: Let

$$\nabla^2 u+k^2u-q(x)u=0, \quad \text{in } \mathbb{R}^3, \tag{1.2}$$

$$u=e^{ik\alpha\cdot x}+A(\alpha',\alpha,k)\frac{e^{ikr}}{r}+o\left(\frac{1}{r}\right), \quad r:=|x|\to\infty, \quad \alpha'=\frac{x}{r}, \tag{1.3}$$

where $\alpha\in S^2$ is a given unit vector, $q(x)$ is a real-valued piecewise-smooth function, supp $q(x)\subset B_a:=\{x:|x|\leqslant a\}$, and S^2 is the unit sphere.

(IP2) *Given* $A(\alpha',\alpha_0,k)$ *for all* $\alpha'\in S^2$, *all* $k>0$ *and a fixed* $\alpha=\alpha_0\in S^2$, *find* $q(x)$.

The uniqueness of the solution to (IP2) is not proved.

The third problem is the following.

Let

$$\nabla^2 u+k^2u-q(x)u=-\delta(x), \quad \text{in } \mathbb{R}^3; \tag{1.4}$$

u satisfies the radiation condition, and $q(x)$ is the same as in (IP2).

The data are the values $u(x,k)|_{|x|=a}$.

(IP3) *Given the data* $u(x,k)|_{|x|=a}$ *for all* $k>0$ *and all* x *on the sphere* $S_a:=\{x:|x|=a\}$, *find* $q(x)$.

Uniqueness of the solution to (IP3) is not proved.

An overview of inverse problems and references one can find in Refs. 1–3.

[a)]Electronic mail: ramm@math.ksu.edu

Our purpose in this paper is to study the one-dimensional analog of (IP3) and to prove for this analog a uniqueness theorem. The one-dimensional analog of (IP3) corresponds to a plasma equation in a layer.

Let

$$lu-k^2u:=-u''+q(x)u-k^2u=\delta(x), \quad x\in\mathbb{R}^1, \tag{1.5}$$

$$\frac{\partial u}{\partial|x|}-iku\to 0, \quad |x|\to\infty. \tag{1.6}$$

Assume that $q(x)$ is a real-valued function,

$$q(x)=0, \quad \text{for } |x|>1, \quad q\in L^\infty[-1,1]. \tag{1.7}$$

Suppose that the data,

$$\{u(-1,k),u(1,k)\}, \quad \forall k>0, \tag{1.8}$$

are given.

The inverse problem analogous to (IP3) is the following.

(IP) Given the data (1.8), find $q(x)$.

This problem, as well as (IP1)–(IP3), is of practical interest. One can think about finding the properties of an inhomogeneous slab (the governing equation is a plasma equation) from the boundary measurements of the field, generated by a point source inside the slab.

In the literature there are many results concerning various inverse problems for the homogeneous version of Eq. (1.5), but it seems that no results concerning (IP) are known.

Assume that the self-adjoint operator $l=-d^2/dx^2+q(x)$ in $L^2(\mathbb{R})$ has no negative eigenvalues [this is the case when $q(x)\geqslant 0$, for example]. The operator l is the closure in $L^2(\mathbb{R})$ of the symmetric operator l_0 defined on $C_0^\infty(\mathbb{R}^1)$ by the formula $l_0u=-u''+q(x)u$. Our result is the following.

Theorem 1: *Under the above assumptions IP has, at most, one solution.*

II. PROOF OF THEOREM 1

The solution to (1.5)–(1.6) is

$$u=\begin{cases}\dfrac{g(k)}{[f,g]}f(x,k), & x>0,\\[2mm] \dfrac{f(k)}{[f,g]}g(x,k), & x<0.\end{cases} \tag{2.1}$$

Here $f(x,k)$ and $g(x,k)$ solve homogeneous version of Eq. (1.5) and have the following asymptotics:

$$f(x,k)\sim e^{ikx}, \quad x\to+\infty, \quad g(x,k)\sim e^{-ikx}, \quad x\to-\infty, \tag{2.2}$$

$$f(k):=f(0,k), \quad g(k):=g(0,k), \tag{2.3}$$

$$[f,g]:=fg'-f'g=-2ika(k), \tag{2.4}$$

where the prime denotes differentiation with respect to the x variable, and $a(k)$ is defined by the equation

$$f(x,k)=b(k)g(x,k)+a(k)g(x,-k). \tag{2.5}$$

It is known (see, for example, Ref. 4) that

$$g(x,k)=-b(-k)f(x,k)+a(k)f(x,-k), \tag{2.6}$$

$$a(-k)=\overline{a(k)}, \quad b(-k)=\overline{b(k)}, \quad |a(k)|^2=1+|b(k)|^2, \quad k\in\mathbb{R}, \tag{2.7}$$

$$a(k)=1+O\left(\frac{1}{k}\right), \quad k\to\infty, \quad k\in\mathbb{C}_+; \quad b(k)=O\left(\frac{1}{k}\right), \quad |k|\to\infty, \quad k\in\mathbb{R}, \tag{2.7$'$}$$

$$[f(x,k),g(x,-k)]=2ikb(k), \quad [f(x,k),g(x,k)]=-2ika(k), \tag{2.8}$$

$a(k)$ is analytic in $\mathbb{C}_+$, $b(k)$, in general, does not admit analytic continuation from $\mathbb{R}$, but if $q(x)$ is compactly supported, then $a(k)$ and $b(k)$ are analytic functions of $k\in\mathbb{C}\backslash 0$.

The functions

$$A_1(k):=\frac{g(k)f(1,k)}{-2ika(k)}, \quad A_2(k):=\frac{f(k)g(-1,k)}{-2ika(k)}, \tag{2.9}$$

are the data; they are known for all $k>0$. Therefore one can assume the functions

$$h_1(k):=\frac{g(k)}{a(k)}, \quad h_2(k):=\frac{f(k)}{a(k)}, \tag{2.10}$$

to be known for all $k>0$, because

$$f(1,k)=e^{ik}, \quad g(-1,k)=e^{ik}, \tag{2.11}$$

as follows from the assumption (1.7) and from (2.2).

From (2.10), (2.6), and (2.5), it follows that

$$a(k)h_1(k)=-b(-k)f(k)+a(k)f(-k)=-b(-k)h_2(k)a(k)+h_2(-k)a(-k)a(k), \tag{2.12}$$

$$a(k)h_2(k)=b(k)a(k)h_1(k)+a(k)h_1(-k)a(-k). \tag{2.13}$$

From (2.12) and (2.13), it follows that

$$-b(-k)h_2(k)+h_2(-k)a(-k)=h_1(k), \tag{2.14}$$

$$b(k)h_1(k)+a(-k)h_1(-k)=h_2(k). \tag{2.15}$$

Eliminating $b(-k)$ from (2.14) and (2.15), one gets

$$a(k)h_1(k)h_2(k)+a(-k)h_1(-k)h_2(-k)=h_1(k)h_1(-k)+h_2(-k)h_2(k), \tag{2.16}$$

or

$$a(k)=m(k)a(-k)+n(k), \quad k\in\mathbb{R}, \tag{2.17}$$

where

$$m(k):=-\frac{h_1(-k)h_2(-k)}{h_1(k)h_2(k)}, \quad n(k):=\frac{h_1(-k)}{h_2(k)}+\frac{h_2(-k)}{h_1(k)}. \tag{2.18}$$

Problem (2.17) is a Riemann problem (see Ref. 5 for the theory of this problem) for the pair $\{a(k),a(-k)\}$, the function $a(k)$ is analytic in $\mathbb{C}_+ := \{k : k\in\mathbb{C}, \operatorname{Im} k>0\}$ and $a(-k)$ is analytic in $\mathbb{C}_-$. The functions $a(k)$ and $a(-k)$ tend to one as k tends to infinity in $\mathbb{C}_+$ and, respectively, in $\mathbb{C}_-$; see Eq. (2.7′).

The function $a(k)$ has finitely many simple zeros at the points ik_j, $1\le j\le J$, $k_j>0$, where $-k_j^2$ are the negative eigenvalues of the operator l defined by the differential expression $lu = -u'' + q(x)u$ in $L^2(\mathbb{R})$.

The zeros ik_j are the only zeros of $a(k)$ in the upper half-plane k.

Define

$$\operatorname{ind} a(k) := \frac{1}{2\pi i}\int_{-\infty}^{\infty} d\ln a(k). \tag{2.19}$$

One has

$$\operatorname{ind} a = J, \tag{2.20}$$

where J is the number of negative eigenvalues of the operator l, and, using (2.10), (2.20) and (2.18), one gets

$$\operatorname{ind} m(k) = -2[\operatorname{ind} h_1(k) + \operatorname{ind} h_2(k)] = -2[\operatorname{ind} g(k) + \operatorname{ind} f(k) - 2J]. \tag{2.21}$$

Since l has no negative eigenvalues, it follows that $J=0$.

In this case $\operatorname{ind} f(k) = \operatorname{ind} g(k) = 0$ (see Lemma 1 below), so $\operatorname{ind} m(k)=0$, and $a(k)$ is uniquely recovered from the data as the solution of (2.17), which tends to one at infinity; see Eq. (2.7′). If $a(k)$ is found, then $b(k)$ is uniquely determined by Eq. (2.15), and so the reflection coefficient $r(k) := b(k)/a(k)$ is found. The reflection coefficient determines a compactly supported $q(x)$ uniquely (see Ref. 2).

To make this paper self-contained, let us outline a proof of the last claim using an argument different from the one given in Ref. 2.

If $q(x)$ is compactly supported, then the reflection coefficient $r(k) := b(k)/a(k)$ is meromorphic. Therefore, its values for all $k>0$ determine uniquely $r(k)$ in the whole complex k plane as a meromorphic function. The poles of this function in the upper half-plane are the numbers ik_j, $j=1,2,\ldots,J$. They determine uniquely the numbers k_j, $1\le j\le J$, which are a part of the standard scattering data $\{r(k),k_j,s_j,1\le j\le J\}$, where s_j are the norming constants.

Note that if $a(ik_j)=0$ then $b(ik_j)\neq 0$: otherwise Eq. (2.5) would imply $f(x,ik_j)\equiv 0$, in contradiction to the first relation (2.2).

If $r(k)$ is meromorphic, then the norming constants can be calculated by the formula $s_j = -i[b(ik_j)/\dot{a}(ik_j)] = -i\operatorname{Res}_{k=ik_j} r(k)$, where the dot denotes differentiation with respect to k, and Res denotes the residue. So, for compactly supported potential, the values of $r(k)$ for all $k>0$ determine uniquely the standard scattering data, that is, the reflection coefficient, the bound states $-k_j^2$, and the norming constants s_j, $1\le j\le J$. These data determine the potential uniquely.

Theorem 1 is proved. □

Lemma 1: If $J=0$ then $\operatorname{ind} f = \operatorname{ind} g = 0$.

Proof: We prove $\operatorname{ind} f=0$. The proof of the equation $\operatorname{ind} g=0$ is similar. Since $\operatorname{ind} f(k)$ equals the number of zeros of $f(k)$ in $\mathbb{C}_+$, we have to prove that $f(k)$ does not vanish in $\mathbb{C}_+$. If $f(z)=0$, $z\in\mathbb{C}_+$, then $z=ik$, $k>0$, and $-k^2$ is an eigenvalue of the operator l in $L^2(0,\infty)$, with the boundary condition $u(0)=0$.

From the variational principle one can find the negative eigenvalues of the operator l in $L^2(\mathbb{R}_+)$ with the Dirichlet condition at $x=0$ as consecutive minima of the quadratic functional. The minimal eigenvalue is

$$-k^2 = \inf\int_0^{\infty}[u'^2 + q(x)u^2]dx := \kappa_0, \quad u\in \mathring{H}^1(\mathbb{R}_+), \quad \|u\|_{L^2(\mathbb{R}_+)} = 1, \tag{2.22}$$

where $\mathring{H}^1(\mathbb{R}_+)$ is the Sobolev space of $H^1(\mathbb{R}_+)$ functions, satisfying the condition $u(0)=0$.

On the other hand, if $J=0$, then

$$0\leqslant \inf\int_{-\infty}^{\infty}[u'^2+q(x)u^2]dx := \kappa_1, \quad u\in H^1(\mathbb{R}), \quad \|u\|_{L^2(\mathbb{R})}=1. \tag{2.23}$$

Since any element u of $\mathring{H}^1(\mathbb{R}_+)$ can be considered as an element of $H^1(\mathbb{R})$ if one extends u to the whole axis by setting $u=0$ for $x<0$, it follows from the variational definitions (2.22) and (2.23) that $\kappa_1\leqslant\kappa_0$. Therefore, if $J=0$, then $\kappa_1\geqslant 0$, and therefore $\kappa_0\geqslant 0$. This means that operator l on $L^2(\mathbb{R}_+)$ with the Dirichlet condition at $x=0$ has no negative eigenvalues. This means that $f(k)$ does not have zeros in $\mathbb{C}_+$, if $J=0$. Thus $J=0$ implies $\operatorname{ind} f(k)=0$.

Lemma 1 is proved. □

Remark 2: The above argument shows that, in general,

$$\operatorname{ind} f\leqslant J \quad \text{and} \quad \operatorname{ind} g\leqslant J, \tag{2.24}$$

so that (2.21) implies

$$\operatorname{ind} m(k)\geqslant 0. \tag{2.25}$$

Therefore the Riemann problem (2.17) is always solvable.

(Received 24 August 1998; accepted for publication 11 March 1999)

The relativistic particles described by the Bhabha equation (Bhabha particles) can possess several values of masses ($M_\tau = n/2\tau$) and spins $s \leq n/2$. In order to find the spin-mass content of such particles corresponding to the general irrep $\langle n^1 n^2 \rangle$ of the group $Sp(4)\sim O(5)$ which is the symmetry group of the Bhabha equation, the noncanonical chain of groups $Sp(4)\supset SU_s(2)\times U_\tau(1)$ is considered. In this paper, we construct the basis of the irrep $\langle n^1 n^2 \rangle$ in a boson realization form using the method of elementary permissible diagrams. This is achieved by the introduction of special ''symplectic'' bosons. The maximum and minimum values of spin s are established for each value of τ. The multiplicity of degenerate pairs (s,t) can be easily calculated with the help of the generating function obtained in this paper.
 [S0022-2488(99)01908-8]

I. INTRODUCTION

The Lorentz-invariant Bhabha equation[1] describes a free relativistic particle of arbitrary spin in terms of a single equation linear in 4-momentum, with the orthogonal group $O(5)$ as its symmetry group. The equation and its properties were extensively studied in the 1970's by Krajcik and Nieto in a series of papers.[2] Interest in the Bhabha equation has been increased recently[3] by the fact that all relativistic equations for particles with spin $s>1/2$ (Duffin–Kemmer, Fierz–Pauli, Bargmann–Wigner equations), are particular cases of the Bhabha equation (sometimes with additional conditions). Recently, a simpler way was proposed[4] by a research group including the present authors, to ''derive'' the Bhabha equation in a Lorentz-covariant way, and to study its properties using the canonical chain of orthogonal groups $O(5)\supset O(4)\supset O(3)\supset O(2)$. The equation is written in terms of the generators $\Lambda_{\mu 5}$ ($\mu=1,2,3,4$) of the group $O(5)$ as[4]

$$(2ic\Lambda_{i5}p_i + 2c\Lambda_{45}p_0 + nmc^2)\psi = 0, \tag{1}$$

with the index i taking values $i=1,2,3$. The quantity n is related to the spin such that $n/2$ gives the maximum possible spin value the particle can possess though the general spin ranges from $n/2,\ n/2-1\cdots$ to 0 or $\frac{1}{2}$ depending on whether n is even or odd.

It is well known[1,2,4] that Eq. (1) is not a single mass equation but describes several states of the particle (Bhabha particle) with different masses associated with each spin s.[1,2,4] The masses were found to be inversely proportional to the eigenvalues τ of the operator Λ_{45} such that[4]

$$M_\tau = \frac{n}{2\tau}. \tag{2}$$

[a)]Electronic mail: smirnov@nuclecu.unam.mx
[b)]Electronic mail: anju@fenix.ifisicacu.unam.mx

The general algorithm to find out the values of spin s compatible with given mass M_τ, was suggested in Refs. 1, 2, 4. But to the best of our knowledge, a closed group theoretical solution of this problem does not exist in the literature.

The difficulty in finding such a general solution arises due to the fact that the generator Λ_{45} responsible for several mass states of the Bhabha particle, is nondiagonal in the canonical group chain $O(5)\supset O(4)\supset O(3)\supset O(2)$ used in Refs. 2, 4. In order to find the spin-mass content of the Bhabha particles, it is necessary to use a basis adapted to a chain of subgroups for which the spin operator S^2 and the generator Λ_{45} would simultaneously be diagonal. Therefore in this paper, we propose to use the noncanonical group chain,

$$Sp(4)\supset SU_s(2)\times U_\tau(1), \tag{3}$$

to find out the solution of the spin-mass content problem mentioned above.

In group reduction (3), $Sp(4)$ is a group isomorphic to $O(5)$, $SU_s(2)$ is the group of the usual spin and the group $U_\tau(1)$ is generated by the operator Λ_{45} which is identical to the operator T_0 corresponding to the sign-spin projection considered in Ref. 5 in the framework of the supermultiplet scheme $SU(4)\supset SU_s(2)\times SU_t(2)$.

To the best of our knowledge the group reduction (3) has so far not been used in relativistic problems, although it was used widely in the nuclear shell model to describe the effects of the isotopic invariant pairing interaction between nucleons of both kinds in the same nuclear shell.[6]

In order to construct the basis adapted to the chain (3), we use in contrast to the previous works,[6] the classical method of elementary permissible diagrams (epd's)[7–9] applied to the boson representation of the states corresponding to the group chain,

$$U(4)\supset Sp(4)\supset SU_s(2)\times U_\tau(1). \tag{4}$$

The paper is organized as follows: In Sec. II, we give a realization of the generators of groups belonging to chain (4) in terms of the boson creation and annihilation operators. In the process, the generators of the group complementary to $Sp(4)$ are also constructed. In Sec. III, we calculate the epd's using a ''trial and error'' method by considering some of the lowest irreps of $U(4)$.[5] In order to obtain the basis vectors with a definite $Sp(4)$ symmetry, the so called ''symplectic bosons'' are used which correspond to a modified form of the bosons introduced earlier in Refs. 10, 11 for systems with the orthogonal and symplectic symmetry. Section IV is concerned with the structure of the basis corresponding to the chain (4). The generating function for this basis is constructed, and the completeness of the latter is verified by the calculation of its dimension. In Sec. V we deal with the spin-mass content of the Bhabha particle, i.e., the maximum and minimum values of spin s for a given mass M_τ are established. The multiplicity of each s,τ combination can be easily found from the generating function. Some final remarks are given in the conclusion.

II. GROUP CHAIN $SU(4)\supset Sp(4)\supset SU_s(2)\times U_\tau(1)$

A. Boson realization

In order to construct the basis for the $Sp(4)$ irrep $\langle\omega^1,\omega^2\rangle$ $(\omega^1\geqslant\omega^2\geqslant 0)$ in an explicit form, it is convenient to embed the group $Sp(4)$ into the group $U(4)$ and to use the standard boson realization for the latter. To obtain the general $Sp(4)$ irrep $\langle\omega^1,\omega^2\rangle$, it is sufficient to consider its embedding into the $U(4)$ irrep $\{h\}=\{h_1h_2h_3h_4\}$ with the Young scheme containing only two rows of length ω^1 and ω^2, i.e.,

$$\{h\}\equiv\{\omega^1\omega^2\}=\{\omega^1\omega^2 00\}. \tag{5}$$

For the realization of such a $U(4)$ irrep it is enough to use two kinds of creation and annihilation boson operators $\eta^1_{\sigma\tau},\eta^2_{\sigma\tau}$ and $\xi^1_{\sigma\tau},\xi^2_{\sigma\tau}$, where the projections σ and τ of the usual spin s and the sign-spin t take the values $\pm 1/2$.

The boson operators satisfy the standard commutation relations

$$[\eta^{\kappa}_{\sigma\tau},\eta^{\kappa'}_{\sigma'\tau'}]=[\xi^{\kappa}_{\sigma\tau},\xi^{\kappa'}_{\sigma'\tau'}]=0,\quad [\xi^{\kappa}_{\sigma\tau},\eta^{\kappa'}_{\sigma'\tau'}]=\delta_{\kappa\kappa'}\delta_{\sigma\sigma'}\delta_{\tau\tau'}\,. \tag{6}$$

The generators of the $U(4)$ group are expressed in terms of boson operators as follows:

$$A_{\sigma\tau,\sigma'\tau'}=\sum_{k=1,2}\eta^k_{\sigma\tau}\xi^k_{\sigma'\tau'}\,. \tag{7}$$

It was shown in Ref. 12 that they can also be chosen in a tensor form,

$$S_\mu=\sum_{k=1}^{2}[\eta^\kappa\times\xi^\kappa]^{10}_{\mu 0},\quad T_\nu=\sum_{k=1}^{2}[\eta^\kappa\times\xi^\kappa]^{01}_{0\nu},$$

$$R_{\mu\nu}=\sum_{k=1}^{2}[\eta^\kappa\times\xi^\kappa]^{11}_{\mu\nu},\quad \mu,\nu=0,\pm 1, \tag{8}$$

$$N=2\sum_{k=1}^{2}[\eta^\kappa\times\xi^\kappa]^{00}_{00}\,.$$

Here S_μ and T_ν are the operators of the ordinary and sign spin, respectively. The creation operators $\eta_{\sigma\tau}$ are the components of a double tensor operator of rank 1/2 with respect to both $SU_s(2)$ and $SU_t(2)$ groups,

$$\eta_{\sigma\tau}=V^{(1/2)(1/2)}_{\sigma\tau}\,. \tag{9}$$

The annihilation operators are connected with another tensor of the same rank 1/2, 1/2,

$$\xi_{\sigma\tau}=(-1)^{1-\sigma-\tau}W^{(1/2)(1/2)}_{-\sigma-\tau}=\eta^\dagger_{\sigma\tau}\,. \tag{10}$$

The tensor product of two operators into a common double tensor of the ranks r_1 and r_2 with respect to the groups $SU_s(2)$ and $SU_t(2)$ is denoted as follows:

$$[\eta\times\xi]^{r_1r_2}_{\rho_1\rho_2}=\sum_{\sigma_1\sigma_2,\tau_1\tau_2}\left\langle\frac12\sigma_1\frac12\sigma_2\middle|r_1\rho_1\right\rangle\left\langle\frac12\tau_1\frac12\tau_2\middle|r_2\rho_2\right\rangle V^{(1/2)(1/2)}_{\sigma_1\tau_1}W^{(1/2)(1/2)}_{\sigma_2\tau_2}\,, \tag{11}$$

where $\langle j_1m_1j_2m_2|jm\rangle$ are the usual Clebsch–Gordan coefficients. The commutation relations of the operators (8) are of the form

$$\begin{aligned}
[S_\mu,R_{\mu'\nu}]&=\sqrt{2}\langle 1\mu' 1\mu|1\mu+\mu'\rangle R_{\mu+\mu'\nu}\,,\\
[T_\nu,R_{\mu\nu'}]&=\sqrt{2}\langle 1\nu' 1\nu|1\nu+\nu'\rangle R_{\mu,\nu+\nu'}\,,\\
[R_{\mu\nu},R_{\mu'\nu'}]&=\delta_{\nu,-\nu'}\frac{1}{4\sqrt{2}}(-1)^{1-\nu}S_{\mu+\mu'}\langle 1\mu 1\mu'|1\mu+\mu'\rangle\\
&\quad+\delta_{\mu,-\mu'}\frac{1}{4\sqrt{2}}(-1)^{1-\mu}T_{\nu+\nu'}(1\nu 1\nu'|1\nu+\nu').
\end{aligned} \tag{12}$$

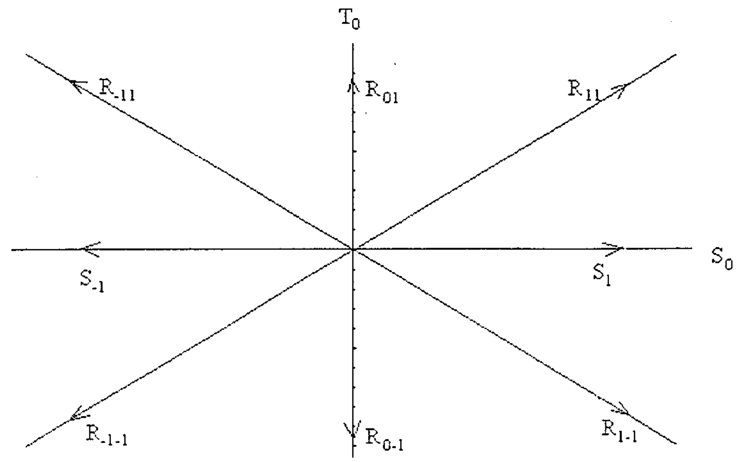

FIG. 1. Root diagram for the *Sp*(4) group.

The operator N in (8) commutes with the rest of the generators. If we remove from the set (8) the operators $N, T_1, T_{-1}, R_{10}, R_{00}$, and R_{-10}, the remaining 10 operators form a closed Lie algebra. It follows from (12) that

$$[S_0,[\eta\times\xi]^{r_1r_2}_{\mu\nu}]=\mu[\eta\times\xi]^{r_1r_2}_{\mu\nu},$$
$$[T_0,[\eta\times\xi]^{r_1r_2}_{\mu\nu}]=\nu[\eta\times\xi]^{r_1r_2}_{\mu\nu}. \tag{13}$$

Thus, if we take S_0,T_0 as the weight (Cartan) generators, the generator $[\eta\times\xi]^{r_1r_2}_{\mu\nu}$ corresponds to the root $(\mu\nu)$. As a result, we obtain the root diagram for these 10 generators given in Fig. 1. The two Cartan generators correspond to the center of this figure. It is known that such a diagram corresponds to the Lie algebra for the $Sp(4)\simeq SO(5)$ group.

Using the expression (12) we can verify that all commutation relations necessary to form the $Sp(4)$ group, are satisfied by the operators S_μ, T_0, $R_{\mu,\pm1}$, $\mu=0,\pm1$. Therefore these operators can be considered as the generators of the subgroup $Sp(4)$ of the group $U(4)$.

It should be noted that the antisymmetric bilinear combination,

$$I=[\eta^1\times\eta^2]^{01}_{00}=\tfrac{1}{2}(\eta^1_{++}\eta^2_{--}-\eta^1_{-+}\eta^2_{+-}+\eta^1_{+-}\eta^2_{-+}-\eta^1_{--}\eta^2_{++}), \tag{14}$$

commutes with all the $Sp(4)$ generators, i.e., it is an $Sp(4)$ invariant.

B. Group complementary to *Sp*(4)

In order to construct the polynomial basis in terms of epd's corresponding to the chain $Sp(4)\supset SU_s(2)\times U_\tau(1)$, it is necessary first to find out the form of the group G complementary to $Sp(4)$.[9,12] It should be noted in this connection that the group $U(4)$ is complementary to the group $U(2)$ defined by the generators

$$F^+=A^{12},\quad F^-=A^{21},\quad F^0=\tfrac{1}{2}(A^{11}-A^{22})=\tfrac{1}{2}(N^1-N^2),\quad N=A^{11}+A^{22}, \tag{15}$$

which satisfy the standard commutation relations for the $SU(2)$ group,

$$[F^0,F^\pm]=\pm F^\pm,\quad [F^+,F^-]=2F^0, \tag{16}$$

and commute with the number operator N,

$$N=N^1+N^2, \quad N^i=A^{ii}. \tag{17}$$

Here and below we use the notation

$$A^{\kappa\kappa'}=\sum_{\sigma\tau} \eta^{\kappa}_{\sigma\tau}\xi^{\kappa'}_{\sigma\tau}. \tag{18}$$

The irrep of the $U(2)$ group is characterized by the same partition $[n^1n^2]$ as the irreps of the $U(4)$ group[9,12] where (n^1n^2) is the highest weight of this irrep. Alternatively, this irrep can also be enumerated by the quantum numbers $N=n^1+n^2$ and

$$f=\tfrac{1}{2}(n^1-n^2), \tag{19}$$

giving the eigenvalue $f(f+1)$ for the $SU_F(2)$ Casimir operator,

$$F^2=F^-F^+ +F^0(F^0+1). \tag{20}$$

The basis vectors of the irrep are labeled by the quantum number ϕ which is the eigenvalue of the operator F^0. Since $Sp(4)$ is a subgroup of $U(4)$, it commutes with the generators of the $U(2)$ group mentioned above.

Thus the group G complementary to $Sp(4)$ must contain this group $U(2)$ [or $SU_F(2)$] as its subgroup. The additional operators commuting with the $Sp(4)$ generators are of the form

$$\begin{aligned} K_+ &= I=[\eta^1\times\eta^2]^{01}_{00}, \\ K_- &= (I)^\dagger=-[\xi^1\times\xi^2]^{01}_{00}, \\ K_0 &= \tfrac{1}{2}(N+4). \end{aligned} \tag{21}$$

They satisfy the commutation relations

$$[K_0,K_\pm]=K_\pm, \quad [K_-,K_+]=2K_0, \tag{22}$$

which are typical for the generators of the noncompact group $SU_K(1,1)$. The generators K commute with the generators F given in (15). Therefore we can consider the direct product of the groups $SU_F(2)$ and $SU_K(1,1)$ as a maximal group commuting with the group $Sp(4)$. It is known that this direct product is identical to the noncompact group $O^*(4)$. Thus we can say that the group G complementary to $Sp(4)$ is of the form

$$G=O^*(4)=SU_K(1,1)\times SU_F(2), \tag{23}$$

with κ and f giving the irreps of subgroups $SU_K(1,1)$ and $SU_F(2)$, respectively. Now it is necessary to prove that the characteristics of the irreps of G are connected unambiguously to the signature $\langle n^1n^2\rangle$ of the corresponding $Sp(4)$ irrep. It should be noted that the reduction of the $U(4)$ irrep $\{n^1n^2\}$ into the $Sp(4)$ irrep is of the form

$$\{n^1n^2\}=\langle n^1n^2\rangle+\langle n^1-1,n^2-1\rangle+\cdots+\langle n^1-n^2,0\rangle. \tag{24}$$

This means that the ket,

$$|\{n^1+r,n^2+r\}\langle n^1n^2\rangle\cdots\rangle\sim K_+^r|\{n^1n^2\}\langle n^1n^2\rangle\cdots\rangle, \tag{25}$$

with fixed values of n^1, n^2 and $r=0,1,2,\ldots,\infty$ (the remaining quantum numbers are substituted by dots), gives the basis of the infinite dimensional unitary irrep of the group $SU_K(1,1)$ belonging to the positive discrete series. By action of the $SU_K(1,1)$ Casimir operator,

$$K^2 = K_+ K_- - K_0(K_0-1), \tag{26}$$

on ket (25), and by taking into account that the lowest weight vector $|\{n^1n^2\}\langle n^1n^2\rangle\cdots\rangle$ is annihilated by the lowering generator K_-,

$$K_-|\{n^1n^2\}\langle n^1n^2\rangle\cdots\rangle = 0, \tag{27}$$

we obtain

$$K^2|\{n^1+r,n^2+r\}\langle n^1n^2\rangle\cdots\rangle = -k(k-1)|\{n^1+r,n^2+r\}\langle n^1n^2\rangle\cdots\rangle, \tag{28}$$

where

$$k = \tfrac{1}{2}(n^1+n^2+4). \tag{29}$$

Thus the ket (25) corresponding to the chain $U(4)\supset Sp(4)\supset SU_s(2)\times U_\tau(1)$, which is labeled by the symbols $\{n^1+r,n^2+r\}$ and $\langle n^1n^2\rangle$ for the irreps of these groups, can be characterized simultaneously by the quantum numbers

$$k = \tfrac{1}{2}(n^1+n^2+4), \quad f = \tfrac{1}{2}(n^1-n^2), \tag{30}$$

giving the irreps of the $SU_K(1,1)$ and $SU_F(2)$ groups (The value of r determines the ''projection'' K_0 of the non-compact moment K.)

According to (30) the symbols k and f of the $O^*(4)$ irreps can be expressed in a unique manner through the $Sp(4)$ irrep $\langle n^1n^2\rangle$, and thus the groups $Sp(4)$ and $O^*(4)$ are complementary. Our result agrees with that of Quesne[13] where she dealt with the general symplectic group $Sp(2n)$ and found $O^*(2n)$ as its complementary group.

Returning to our problem of the construction of the basis for the $Sp(4)$ irrep $\langle n^1n^2\rangle$, we want to construct at first the boson basis for the $U(4)$ irrep $\{n^1n^2\}$, and then to select in this basis the part corresponding to the first term $\langle n^1n^2\rangle$ in the expansion (24), i.e., to construct the vectors (25) with $r=0$ satisfying the relation (27).

C. The basis corresponding to the chain $SU(4)\supset Sp(4)\supset SU_s(2)\times U_\tau(1)$

In view of the previous section, the basis vectors of the $Sp(4)$ irrep $\langle n^1n^2\rangle$ corresponding to the chain $U(4)\supset Sp(4)\supset SU_s(2)\times U_\tau(1)$ can be written in the form of the following ket:

$$|\{n^1n^2\}\langle n^1n^2\rangle \Gamma s\sigma\tau; f\phi\rangle, \tag{31}$$

where the quantum numbers n^1 and n^2 label the irreps of the $U(4)$ and $Sp(4)$ group as well as the $O^*(4)$ group complementary to $Sp(4)$. The multiple irreps (s,τ) of the subgroups $SU_s(2)$ and $U_\tau(1)$ belonging to the given $Sp(4)$ irrep $\langle n^1n^2\rangle$ are distinguished by the symbol Γ. The quantum number f given in (30) represents the irrep of the $SU_F(2)$ group, ϕ is the weight of the vector (31) with respect to this group $(-f\leqslant\phi\leqslant f)$.

We shall construct the vectors (31) of the highest weight with respect to both $SU_S(2)$ and $SU_F(2)$ groups (i.e., $\sigma=s, \phi=f$). The vectors with smaller values of σ and ϕ can be obtained by applying the lowering operators S_{-1} and F_- to the highest weight vector $P^{s\tau}_{n^1n^2}(\eta^1,\eta^2)|0\rangle$.

The polynomial $P^{s\tau}_{n^1n^2}(\eta^1,\eta^2)$ which for brevity we denote by P, satisfies the following conditions:

$$N^1P|0\rangle = n^1P|0\rangle, \quad N^2P|0\rangle = n^2P|0\rangle,$$

$$S_+P|0\rangle = 0, \quad S_0P|0\rangle = sP|0\rangle,$$

$$F_+P|0\rangle = 0, \quad F_0P|0\rangle = fP|0\rangle,$$

$$K_0 P|0\rangle = \tfrac{1}{2}(n^1+n^2+4)P|0\rangle, \tag{32}$$

$$K_- P|0\rangle = 0. \tag{33}$$

By substituting $\xi \to \partial/\partial\eta$ in the expression for each generator, the set of above equations (32), (33) can be considered as differential equations on P-polynomials and then solved. In a way similar to Refs. 7–9, we shall seek the solution of the polynomial P as a product of the powers of the so called elementary permissible diagrams (epd's) W_i such that

$$P = \prod_i W_i^{k_i}(\eta^1, \eta^2), \tag{34}$$

where $W_i^{k_i}(\eta^1 \eta^2)$ are the polynomials of the lowest powers n_i^1, n_i^2 satisfying Eqs. (32) with definite values of spin s_i and the projection of the sign-spin τ_i, which cannot be reduced to a product of the powers of simpler solutions. Since all generators in (32) are first-order differential operators, it is clear that the monomial (34) satisfies Eqs. (32) if they are satisfied by the epd's $W_i(\eta^1, \eta^2)$.

Since $s = \Sigma_i k_i s_i$, $\tau = \Sigma_i k_i \tau_i$, it is obvious that the independent vectors (31) with the same values of s and τ are characterized by different sets of the epd powers $k_1, k_2 \dots$. A full set of epd's, their powers, spins and τ-values will be established below. In the next section, we consider only the solution of the equations (32). The problem of the construction of polynomials (monomials) P satisfying the condition (33) is postponed until Sec. IV.

III. ELEMENTARY PERMISSIBLE DIAGRAMS

In order to find out the epd's, we use the ''trial and error'' approach and start with few of the lowest irreps {1}, {2}, {11} of $U(4)$.

The irrep {1} is realized in a space of four boson operators $\eta^1_{\sigma\tau}(\sigma, \tau = \pm\frac{1}{2})$. As mentioned above, we are interested in the epd's with the maximum spin projection $\sigma_i = s_i$ and the maximum value of $\phi_i = f_i$. Therefore we select as the first two epd's the operators

$$a = \eta^1_{++} \quad \text{and} \quad b = \eta^1_{+-}, \tag{35}$$

corresponding to $s = \sigma = +1/2$, $f = \phi = +1/2$, $\tau = +1/2$ and $-1/2$, respectively. In (35) and below the values of σ and τ are substituted by the signs $+$ or $-$ of these projections. The operators $\eta^2_{\sigma\tau}$ can not be used as epd's because they correspond to $\phi = -1/2$.

For $n=2$, there exist two $U(4)$ irreps with partitions {2} and {11}. The symmetric irrep {2} is characterized by the values of the ordinary and sign spins $s=t=0$ and $s=t=1$.[5] Thus the list of the states with various τ and the maximal spin projections $\sigma = s$ is of the form

τ	$s=\sigma$	Expression in terms of epd's
1	1	a^2
0	1	ab
-1	1	b^2
0	0	c

. (36)

It is clear from this list that the first three vectors can be expressed in terms of the epd's a and b introduced in (35). However, the last vector with $s=t=0$ can not be reduced to the epd's (35). It should be considered as a new independent epd of the form

$$c=\sum_{\sigma\tau}\left\langle \frac{1}{2}\sigma\frac{1}{2}-\sigma\middle|00\right\rangle\left\langle\frac{1}{2}\tau\frac{1}{2}-\tau\middle|00\right\rangle \eta^1_{\sigma\tau}\eta^1_{-\sigma-\tau}=\eta^1_{++}\eta^1_{--}-\eta^1_{+-}\eta^1_{-+}. \tag{37}$$

The $U(4)$ irrep $\{2\}$ corresponds to the value $f=1$, and thus the vector (37) is characterized by $\phi=f=1$. The combinations $\eta^1\eta^2, \eta^2\eta^2$ correspond to $\phi=0$ and -1, respectively, and should thus be omitted.

For the realization of the antisymmetric $U(4)$ irrep $\{11\}$, both kinds of boson operators η^1 and η^2 are necessary. This irrep contains the states with $s=1, t=0$ and $s=0$, $t=1$.[5] They cannot be expressed in terms of epd's (35) and (37). Therefore all of them should be considered as new epd's. Their list with the corresponding $(\tau,s)-$ values is given below:

τ	$s=\sigma$	epd
1	0	d
0	0	I
-1	0	e
0	1	f

. (38)

The expressions for the epd's d, e and f in terms of the boson operators can be found in Table I.

As for the epd I, it coincides with the $Sp(4)$ invariant (14). It is clear that the inclusion of this epd in the monomial (34) does not change its $Sp(4)$ symmetry, but only increases its power. Therefore this epd can not be present in the construction of the vectors (31) we are interested in. It can be contained in the vectors $|\{h_1h_2\}\langle n^1n^2\rangle\cdots\rangle$ with $n^1+n^2<h_1+h_2$. Thus we do not consider the epd I further.

Using a procedure similar to what is done for the cases $n=1,2$, it can be easily shown that all $U(4)$ irreps corresponding to $n=3,4$ do not give rise to any new epd's but can be constructed using a, b, c, d, e and f. However, for the partition $\{31\}$ for $n=4$, we notice that there are two states occurring with the spin $s=1$ and $\tau=0$, which can be constructed using epd's in three possible ways: ea^2, db^2 and cf. This implies that out of these three possibilities only two are independent. In fact, it can be easily proved that

$$cf=Iab-ea^2-db^2. \tag{39}$$

TABLE I. Elementary permissible diagrams for the $U(4)$ group.

epd	n^1	n^2	s	τ	Relation with quantities in Ref. 14[a]
$a=\eta^1_{++}$	1	0	$\frac{1}{2}$	$\frac{1}{2}$	$AS^{1/2}T^{1/2}$
$b=\eta^1_{+-}$	1	0	$\frac{1}{2}$	$-\frac{1}{2}$	$AS^{1/2}T^{-1/2}$
$c=\eta^1_{++}\eta^1_{--}-\eta^1_{+-}\eta^1_{-+}$	2	0	0	0	A^2
$d=\eta^1_{++}\eta^2_{-+}-\eta^1_{-+}\eta^2_{++}$	1	1	0	1	BT
$e=\eta^1_{+-}\eta^2_{--}-\eta^1_{--}\eta^2_{+-}$	1	1	0	-1	BT^{-1}
$f=\eta^1_{++}\eta^2_{+-}-\eta^1_{+-}\eta^2_{++}$	1	1	1	0	BS

[a]For details see Secs. IV B and IV C of the text.

This suggests that out of 6 epd's given in Table I only five are independent. In other words, the relation (39) means that the monomials (34) can not contain epd's c and f simultaneously. Further analysis shows (see Sec. IV) that the set of epd's given in Table I, is complete. In this connection we can conclude that the basis of the $Sp(4)$ irrep $\langle n^1 n^2\rangle$ can be split into two parts. The first part consists of monomials (34) which do not contain the epd f; the second one includes monomials in which the epd c is absent.

Symplectic bosons

We now turn our attention to the problem of how the monomials of the form (34) satisfying the ''symplecticity'' condition (33) can be constructed.

Here we follow the concept of the modified or ''traceless'' bosons for the orthogonal and symplectic groups suggested and developed in Refs. 9–11. We introduce new creation operators which we call the ''symplectic bosons,'' viz.,

$$a^{1+}_{\sigma\tau}=\eta^1_{\sigma\tau}-(-1)^{1/2-\sigma}K_+\frac{1}{N+1}\xi^2_{-\sigma-\tau},$$
$$a^{2+}_{\sigma\tau}=\eta^2_{\sigma\tau}-(-1)^{1/2+\sigma}K_+\frac{1}{N+1}\xi^1_{-\sigma-\tau}, \tag{40}$$

where operators K_+ and N are given in Eqs. (21) and (17), respectively. They satisfy the commutation relations

$$[a^{k+}_{\sigma\tau},a^{k'+}_{\sigma'\tau'}]=0,\quad k,k'=1,2. \tag{41}$$

We then replace the ordinary boson operators $\eta^{1,2}$ by the symplectic ones $a^{1,2+}$ in the epd's given in Table I (and denote epd's with primes), and thus in the process we modify $P^{s\tau}_{n^1n^2}(\eta^1,\eta^2)$ to $P^{s\tau}_{n^1n^2}(a^{1+},a^{2+})$. Similarly, the raising $SU_K(1,1)$ generator K_+ gets modified into

$$K'_+=\sum_{\sigma\tau}(-1)^{1/2-\sigma}a^{1+}_{\sigma\tau}a^{2+}_{-\sigma-\tau}, \tag{42}$$

which can be simplified to

$$K'_+=\frac{1}{(N-1)(N-2)}K^2_+K_-. \tag{43}$$

Since K'_+ commutes with $P^{s\tau}_{n^1n^2}(a^{1+}a^{2+})$ both being constructed out of the commuting operators $a^{1,2+}$, we can write

$$K'_+P^{s\tau}_{n^1n^2}(a^{1+}a^{2+})|0\rangle=P^{s\tau}_{n^1n^2}(a^{1+}a^{2+})K'_+|0\rangle=0, \tag{44}$$

which is equated to zero because of (43). Therefore we obtain

$$\frac{1}{(N-1)(N-2)}K^2_+K_-P|0\rangle=0. \tag{45}$$

Since $[(N-1)(N-2)]^{-1}K^2_+=[(N-1)(N-2)]^{-1}I^2$ does not vanish identically, the states $P^{s\tau}_{n^1n^2}(a^{1+},a^{2+})|0\rangle$ satisfy the symplecticity condition (33).

Thus these states correspond to the irrep $\langle n^1n^2\rangle$ of $Sp(4)$ and $\{n^1n^200\}$ of $U(4)$, as we require a partition involving two numbers to characterize the general irreps of $Sp(4)$ and four numbers for irreps $U(4)$.[5,9] It can be easily verified that the other conditions (32) on polynomials

$P^{s\tau}_{n^1n^2}(a^{1+},a^{2+})$ remain unchanged by the introduction of symplectic bosons in the epd's of Table I. Our task now is to construct the basis vectors of the $Sp(4)$ irrep $\langle n^1n^2\rangle$ as polynomials (monomials) of these epd's.

IV. STRUCTURE OF THE BASIS, GENERATING FUNCTION AND THE DIMENSION OF THE $Sp(4)$ IRREP

A. Structure of the basis

As mentioned earlier in Sec. III, the epd's c' and f' can not occur simultaneously in a basis vector, i.e., if the power γ of c' is nonvanishing then the power φ of the epd f' is vanishing, and vice versa $\gamma=0$ if $\varphi\neq 0$. Thus the polynomial basis states can be distributed into two subsets:

$$I. \quad P_{n^1n^2}(a^{1+},a^{2+})|0\rangle = a'^{\alpha}b'^{\beta}c'^{\gamma}d'^{\delta}e'^{\epsilon}|0\rangle, \tag{46}$$

$$II. \quad P_{n^1n^2}(a^{1+},a^{2+})|0\rangle = a'^{\alpha}b'^{\beta}d'^{\delta}e'^{\epsilon}f'^{\phi}|0\rangle, \tag{47}$$

where $\alpha,\beta,\gamma,\delta,\epsilon,\varphi\geqslant 0$ are non-negative integers. Our aim now is to find out these exponents in terms of the fixed values of quantum numbers n^1, n^2, s and τ. We consider the cases (46) and (47) separately.

(i) Case I. From Table I and expression (46), we obtain the following relations:

$$\begin{gathered} n^1=\alpha+\beta+2\gamma+\delta+\epsilon, \quad n^2=\delta+\epsilon, \\ s=\tfrac{1}{2}(\alpha+\beta), \quad \tau=\tfrac{1}{2}(\alpha-\beta)+\delta-\epsilon. \end{gathered} \tag{48}$$

Solving them with respect to $\alpha,\gamma,\delta,\epsilon$ we obtain

$$\begin{gathered} \alpha=2s-\beta, \quad \gamma=\tfrac{1}{2}(n^1-n^2)-s, \\ \delta=\tfrac{1}{2}(n^2+\tau-s+\beta), \quad \epsilon=\tfrac{1}{2}(n^2-\tau+s-\beta), \end{gathered} \tag{49}$$

where the non-negative integer $\beta\geqslant 0$ is a free parameter here. Since $\gamma\geqslant 0$ is also a non-negative integer, the spin values s are restricted in this part of the basis by the condition

$$s\leqslant \tfrac{1}{2}(n^1-n^2). \tag{50}$$

(ii) Case II. Similar to (48) we have in this case the relations

$$\begin{gathered} n^1=\alpha+\beta+\delta+\epsilon+\varphi, \quad n^2=\delta+\epsilon+\varphi, \\ s=\tfrac{1}{2}(\alpha+\beta)+\varphi, \quad \tau=\tfrac{1}{2}(\alpha-\beta)+\delta-\epsilon. \end{gathered} \tag{51}$$

From here we obtain the following expressions for $\alpha,\delta,\epsilon,\varphi$:

$$\begin{gathered} \alpha=n^1-n^2-\beta, \quad \delta=\tfrac{1}{2}(n^2+\tau-s+\beta), \\ \epsilon=\tfrac{1}{2}(n^1-\tau-s-\beta), \quad \varphi=s-\tfrac{1}{2}(n^1-n^2), \end{gathered} \tag{52}$$

where the non-negative integer $\beta\geqslant 0$ is again a dummy variable here. Since φ is also a non-negative integer, we obtain for this part of the basis the condition

$$s\geqslant \tfrac{1}{2}(n^1-n^2). \tag{53}$$

Thus the two parts (46) and (47) of the basis of the $Sp(4)$ irrep $\langle n^2 n^2\rangle$ can be rewritten in the following form:

$$P_{n^1n^2}(a^{1+},a^{2+})|0\rangle = a'^{2s-\beta}b'^{\beta}c'^{(n^1-n^2)/2-s}d'^{(n^2+\tau-s+\beta)/2}e'^{(n^2-\tau+s-\beta)/2}|0\rangle,$$
$$\text{for}\ \ s\leqslant\frac{(n^1-n^2)}{2}, \tag{54}$$

$$= a'^{n^1-n^2-\beta}b'^{\beta}d'^{(n^2+\tau-s+\beta)/2}e'^{(n^1-\tau-s-\beta)/2}f'^{s-(n^1-n^2)/2}|0\rangle,$$
$$\text{for}\ \ s>\frac{(n^1-n^2)}{2}, \tag{55}$$

with the non-negative integer β being a dummy variable. It plays the role of an additional quantum number to distinguish independent polynomials $P_{n^1n^2}(a^{1+},a^{2+})$ corresponding to the same values of the quantum numbers s and τ. The possible values of β are determined by the requirement that all powers of the epd's in expressions (54), (55) are non-negative integers. We shall discuss this in more detail in Sec. V.

We now turn our attention to the generating function for the basis (54), (55).

B. The generating function

The generating function $F(AB;ST)$ for the group reduction $Sp(4)\supset SU_s(2)\times U_\tau(1)$ is defined in the following way:[14]

$$F(AB;ST)=\sum_{n^1n^2s\tau}\nu(n^1n^2s\tau)A^{n^1-n^2}B^{n^2}S^sT^\tau, \tag{56}$$

such that the coefficient $\nu(n^1n^2s\tau)$ in its power expansion gives the number of states with given values of s and τ in the $Sp(4)$ irrep $\langle n^1n^2\rangle$.

To construct the generating function (56) we start with the basis states (46), (47). The contribution of each epd into the generating function can be characterized by a definite combination of the quantities A,B,S,T which are given in the last column of Table I. As a result, the contributions of vectors (46) and (47) into a generating function can be represented by the expressions

$$A^{\alpha+\beta+2\gamma}B^{\delta+\epsilon}S^{(\alpha+\beta)/2}T^{(\alpha-\beta)/2+\delta-\epsilon} \tag{57}$$

and

$$A^{\alpha+\beta}B^{\delta+\epsilon+\varphi}S^{(\alpha+\beta)/2+\varphi}T^{(\alpha-\beta)/2+\delta-\epsilon}, \tag{58}$$

respectively. The independent summation of both of these expressions on α, β, γ, δ, ϵ and φ from 0 to infinity and unification of the two results, gives the following formula for the generating function:

$$F(AB;ST)=\frac{1}{(1-AS^{1/2}T^{1/2})(1-AS^{1/2}T^{-1/2})}\,\frac{1}{(1-BT)(1-BT^{-1})}\left\{\frac{1}{1-A^2}+\frac{1}{1-BS}-1\right\}. \tag{59}$$

The last term (-1) is included in the curly brackets in order to avoid the double counting of the states with $\gamma=\varphi=0$. The above formula is in agreement with the corresponding generating function (2.6) found in Ref. 14 using a different approach. This coincidence means that our basis (54), (55) is complete. However, it can also be verified by the calculation of the dimension of the $Sp(4)$ irrep $\langle n^1n^2\rangle$.

C. The dimension

It was demonstrated above that the structure of the basis (54), (55) is described by the generating function (59). We now calculate the dimension of the irrep $\langle n^1 n^2\rangle$. It is clear that this dimension can be found by the formula

$$\dim\langle n^1 n^2\rangle = \sum_{s\tau} \nu(n^1 n^2 s\tau)(2s+1). \tag{60}$$

In order to calculate it, we can do the power expansion of the function (59) in terms of the monomials (57), (58), and then select the terms with the fixed powers n^1-n^2 and n^2 of parameters A and B, respectively. As a result the number of summation indices decreases up to 3.

At last we add the factor $(2s+1)$ into the resulting sum in correspondence with (60), and substitute $A=B=S=T=1$. Such a procedure is first applied to (58) given the following restrictions: $\alpha+\beta=n^1-n^2$, $\delta+\epsilon+\varphi=n^2$. Using α, φ and $\xi=\epsilon+\varphi$ as summation indices and taking into account that $2s+1=n^1-n^2+2\varphi+1$, we obtain the following expression:

$$N_1=\sum_{\alpha=0}^{n^1-n^2}\sum_{\xi=0}^{n^2}\sum_{\varphi=0}^{\xi}(n^1-n^2+2\varphi+1)=\frac{1}{6}(n^1-n^2+1)(n^2+1)(n^2+2)(3n^1-n^2+3), \tag{61}$$

for the contribution of the vectors (47) into the dimension of the $Sp(4)$ irrep $\langle n^1 n^2\rangle$. To obtain (61), the well known identities were used,

$$\sum_{\kappa=1}^{n}\kappa=\frac{1}{2}n(n+1), \quad \sum_{\kappa=1}^{n}\kappa^2=\frac{1}{6}n(n+1)(2n+1). \tag{62}$$

In a similar manner, the contribution N_2 of the vectors (46) into $\dim\langle n^1 n^2\rangle$ can be found to give the following result:

$$N_2=\tfrac{1}{6}(n^1-n^2)(n^1-n^2+1)(n^1-n^2-1)(n^2+1). \tag{63}$$

We obtain the total dimension as

$$\dim\langle n^1 n^2\rangle = N_1+N_2=\tfrac{1}{6}(n^1-n^2+1)(n^2+1)(n^1+n^2+3)(n^1+2), \tag{64}$$

which coincides with the standard expression for the $Sp(4)$ irrep dimension.

V. SPIN-MASS CONTENT OF THE BHABHA PARTICLES

As mentioned in the Introduction, the Bhabha equation (1) describing a free particle of arbitrary spin,[1–4] with $Sp(4)$ as its symmetry group, represents several mass states occurring for each spin which can take values $\frac{1}{2}(n^1+n^2), \frac{1}{2}(n^1+n^2)-1,\ldots,0$ or $\frac{1}{2}$ depending on whether n^1+n^2 is even or odd. In this section, we find all possible values of spin s which a particle of mass M_τ can take. Since M_τ is proportional to $1/\tau$ [see Eq. (2)] we need to find the maximum and minimum values of s for a given τ in order to find spin-mass content of the Bhabha particles. This is facilitated by taking into account various limitations on the non-negative integer powers of each epd appearing in the polynomials (54), (55).

First of all, it should be noted that the root diagram shown in Fig. 1 is symmetric with respect to the substitution T_0 by $-T_0$ and T_0 by S_0 [these transformations are the elements of the group of Weyl reflections for $Sp(4)$]. It means that at $-\tau$ the same values of spin s are as admissible as for τ. Therefore we can restrict ourselves to the consideration of only the non-negative values of τ. Besides, the maximum possible value of τ is identical to the largest possible value of spin s in the $Sp(4)$ irrep $\langle n^1 n^2\rangle$. Both τ and s are simultaneously integer or half-integer.

The maximum possible value of spin, S_{max}, for a given τ can be calculated using the restrictions inherent to the part of the basis corresponding to $s \geqslant \frac{1}{2}(n^1 - n^2)$. By noting the fact that each of the powers in (55) are non-negative integers, we have

$$(1)\ \beta \geqslant 0, \quad (2)\ \beta \leqslant n^1 - \tau - s, \quad (3)\ \beta \geqslant -n^2 - \tau + s, \quad (4)\ \beta \leqslant n^1 - n^2. \tag{65}$$

It follows from (2) and (3) above that the largest possible value of s is equal to $(n^1+n^2)/2$. Therefore for τ we obtain

$$-\frac{1}{2}(n^1+n^2) \leqslant \tau \leqslant \frac{1}{2}(n^1+n^2). \tag{66}$$

In the interval $\frac{1}{2}(n^1-n^2) \leqslant \tau \leqslant \frac{1}{2}(n^1+n^2)$, the maximum value of spin S_{max} corresponds to the cross point of the boundaries determined by inequalities (1) and (2), i.e.,

$$S_{max} = n^1 - \tau. \tag{67}$$

For $0 \leqslant \tau \leqslant \frac{1}{2}(n^1-n^2)$ the value S_{max} corresponds to the cross-point of the boundaries determined by inequalities (2) and (3), i.e.,

$$S_{max} = \frac{1}{2}(n^1+n^2). \tag{68}$$

If $\tau < 0$ we obtain

$$S_{max} = n^1 - |\tau|, \quad \text{for } \frac{1}{2}(n^1-n^2) \leqslant |\tau| \leqslant \frac{1}{2}(n^1+n^2) \tag{69}$$

and

$$S_{max} = \frac{1}{2}(n^1+n^2), \quad \text{for } 0 \leqslant |\tau| \leqslant \frac{1}{2}(n^1-n^2), \tag{70}$$

because of symmetry with respect to the reflection $\tau \to -\tau$ mentioned before.

The minimum value of spin S_{min} at given τ is contained in the part of the basis (54) corresponding to $s \leqslant \frac{1}{2}(n^1-n^2)$. In this case, there exists the following limitations:

$$(1)\ \beta \geqslant 0, \quad (2)\ \beta \leqslant n^2 - \tau + s, \quad (3)\ \beta \geqslant -n^2 - \tau + s, \quad (4)\ \beta \leqslant 2s. \tag{71}$$

All possible (non-negative) values of τ can be distributed in two parts:

$$(i)\ \frac{1}{2}(n^1+n^2) \geqslant \tau \geqslant n^2, \quad (ii)\ n^2 \geqslant \tau \geqslant 0. \tag{72}$$

In the first case, the value S_{min} corresponds to the cross-point of the boundaries determined by the inequalities (1) and (2), i.e.,

$$S_{min} = \tau - n^2, \quad \text{for } \frac{1}{2}(n^1+n^2) \geqslant \tau \geqslant n^2. \tag{73}$$

In the second case the value S_{min} corresponds to an admissible point which is closest to the cross-point of boundaries determined by the inequalities (1) and (4), i.e., $S_{min} = 0, 1/2$ or 1 depending on the parity of n^1 and n^2. In order to establish the exact value of S_{min} it is necessary to take into account that in correspondence with (49) β can ''jump'' only by 2 units and has the same parity as $n^2 + \tau - s$. Therefore the value $S_{min} = 0$, i.e., $\beta_{min} = 0$, exists only if $n^2 + \tau$ is even. At $n^2 + \tau = \text{odd}$, we obtain $S_{min} = 1$. If $n^1 + n^2 = \text{odd}$, when all spins are half-integers, we have $S_{min} = 1/2$. We can summarize these results as follows:

$$S_{min} = |\tau| - n^2, \quad \text{for } |\tau| \geqslant \frac{1}{2}(n^1-n^2), \tag{74}$$

$$S_{min} = 0, \quad \text{if } n^1 + n^2 = \text{even}, \quad n^2 + |\tau| = \text{even}, \tag{75}$$

$$S_{\min}=1, \quad \text{if } n^1+n^2=\text{even}, \quad n^2+|\tau|=\text{odd}, \tag{76}$$

$$S_{\min}=\tfrac{1}{2}, \quad \text{if } n^1+n^2=\text{odd}. \tag{77}$$

Thus each mass state can take spin s whose value ranges from $S_{\max}, S_{\max}-1,\ldots,S_{\min}$, given by (69), (70), (74)–(77). The exclusion to these rules occurs for the irrep $\langle n^1 n^1\rangle$. In this case, the limitation (4) in (65) allows only one value $\beta=0$. It follows from (49) that the spin s jumps by 2 units in this case. Thus in correspondence with limitation (2) in (65) we obtain

$$s=n^1-|\tau|, n^1-|\tau|-2,\ldots,1 \quad \text{or} \quad 0, \tag{78}$$

for $n^1-|\tau|=$ odd or even, respectively.

In general, all the values of s except $S_{\min}$ and $S_{\max}$ are degenerate. The multiplicity of each pair (s,τ) is equal to the values of β at the given values of n^1, n^2, s and τ. It can also be found using the generating function described in Sec. IV. Because of the unique possible value $\beta=0$, all combinations of (s,τ) in the irrep $\langle n^1 n^1\rangle$ are not degenerate.

VI. CONCLUSION

In the present paper, the basis of the general $Sp(4)$ irrep $\langle n^1 n^2\rangle$ adapted to the noncanonical group chain $Sp(4)\supset SU_s(2)\times U_\tau(1)$ is constructed. Since the group $Sp(4)\simeq SO(5)$ is a symmetry group of the Bhabha equation,[1–4] the study of such a basis allows us to solve naturally the problem of finding the spin-mass content of the Bhabha particles, i.e., to determine what values of spin s are compatible with a definite mass value $M_\tau=n/2\tau$. The multiplicity of each pair (s,τ) can be easily calculated using the generating function for this basis found in Sec. IV. The noncanonical basis discussed in this paper is also useful to consider the nonrelativistic limit of the Bhabha equation in an interaction with the external fields and to obtain some intrinsic properties of the Bhabha particles (magnetic moment etc.).[15] After knowing the explicit form of the basis, it is possible to calculate the matrix elements of the $Sp(4)$ group generators in order to rewrite the Bhabha equation (1) in a matrix form. Because of the shortage of the space we do not discuss it in this paper.

We consider the Vlasov–Poisson–Ampère system of equations, and we seek solutions for the electric field $E(x,t)$ that are periodic in space and asymptotically almost periodic in time. Introducing the representation $E(x,t)=T(x,t)+A(x,t)$ (where T and A are, respectively, the transient and time-asymptotic parts of E) enables us to decompose the nonlinear Poisson equation into a *transient equation* and a *time-asymptotic equation*. We then study the latter in isolation as a bifurcation problem for A with the initial condition and T as parameters. We show that the Fréchet derivative at a generic bifurcation point has a nontrivial null space determined by the roots of a *Vlasov dispersion relation*. Hence, the bifurcation analysis leads to a general solution for A given (at leading order) by a discrete superposition of traveling-wave modes, whose frequencies and wave numbers satisfy the Vlasov dispersion relation, and whose amplitudes satisfy a system of nonlinear algebraic equations. In applications, there is usually a finite number of roots to the dispersion relation, and the equations for the time-asymptotic wave amplitudes reduce to a finite dimensional bifurcation problem in terms of the amplitude of the initial condition. © *1999 American Institute of Physics.* [S0022-2488(99)01208-6]

I. INTRODUCTION

The subject of this work is the well-known Vlasov–Poisson–Ampère (VPA) system of equations

$$\frac{\partial f_\alpha}{\partial t}+v\frac{\partial f_\alpha}{\partial x}+\frac{q_\alpha}{m_\alpha}E\frac{\partial f_\alpha}{\partial v}=0, \tag{1a}$$

$$\frac{\partial E}{\partial x}=4\pi\sum_\alpha q_\alpha\int dv\, f_\alpha, \tag{1b}$$

$$\frac{\partial E}{\partial t}=-4\pi\sum_\alpha q_\alpha\int dv\, v f_\alpha, \tag{1c}$$

for the propagation of longitudinal electric signals in a collisionless plasma. Here, $E(x,t)$ is the macroscopic longitudinal electric field, and $\alpha=1,\ldots,N_S$ are the indexes of the N_S different species of particles present in the plasma, each with charge q_α, mass m_α and single-particle distribution function $f_\alpha(x,v,t)$. A large body of recent mathematical literature[1–4] has produced extensive results on existence, uniqueness, and regularity of both classical and weak solutions to these equations. However, any concrete calculation of these solutions is made very difficult, especially in the long-time limit, by the strong nonlinearity of the problem.

[a)]Permanent address: University of Virginia, Charlottesville, Virginia 22903-2442.

Physically, the nonlinearity in the VPA system corresponds to the self-consistent feedback from the electric field on the distribution functions. Interestingly, in many wave-propagation problems we expect this feedback to become less and less important in the long-time limit, because the anharmonic mixing of the single-particle trajectories makes the plasma less and less able to exchange energy with the electric field in any coherent fashion. This fact was first pointed out in the physics literature by O'Neil.[5] In a classic paper, he argued that a sinusoidal perturbation to a thermal equilibrium will, in general, either Landau damp to a zero electric field[6] or lead to a nonzero time-asymptotic solution for the electric field, depending on the amplitude of the initial disturbance and on the magnitude of the Landau damping rate. O'Neil assumed the nonzero time-asymptotic solution for E to be given by a single traveling wave of constant amplitude, but in more realistic physical situations one can reasonably conjecture that the final state will be comprised of more than one wave mode. In fact, this scenario has been confirmed by a significant amount of experimental and numerical evidence.[7–9] Recent rigorous investigations[10–12] have shown that the nonlinear VPA system does indeed admit undamped traveling-wave solutions like those suggested in the physics literature. Particularly relevant to what will follow are the nonlinearly superimposed traveling-wave BGK-type[13] solutions obtained by Buchanan and Dorning.[12] However, it is not known whether any of these solutions can be reached as time-asymptotic limits of solutions to the initial value problem for the VPA system.

In this article we develop a new procedure for the analysis of the long-time behavior of the solutions to the VPA system for a certain class of initial conditions. Our method is based on the representation of the electric field as the sum of a transient term and a time-asymptotic term, and correspondingly, on the decomposition of the VPA problem into a transient part and a time-asymptotic part. This decomposition turns out to be fruitful in a number of ways, not all of which will be explored in this paper. For instance, we shall not analyze the transient problem, which seems amenable to a relatively straightforward perturbation analysis[14] since most of the well-known secularities in the VPA problem are associated with time-asymptotic evolution. We shall focus, instead, on the time-asymptotic part of the problem; the basic idea will be to show that this time-asymptotic part can be studied *in isolation* as a bifurcation problem for the time-asymptotic electric field with the initial condition and the transient field playing the role of parameters. Our main result shows that *if* the VPA system possesses a nonzero small-amplitude time-asymptotic solution (in a sense that will be defined below), then the corresponding electric field is given at leading order by a superposition of traveling-wave modes associated with the roots of a ''time-asymptotic'' Vlasov dispersion relation. This dispersion relation is completely determined by the initial condition and by the transient electric field, and the same is true for the amplitudes of these traveling-wave modes, which satisfy a nonlinear system of algebraic equations.

II. PRELIMINARIES

Throughout this study E and f_α will be assumed to be bounded $\mathcal{C}^1$ functions of their arguments, with $f_\alpha \geqslant 0$. In fact, it is enough to assume f_α to be bounded and non-negative at time zero, since then the Vlasov equation implies the *a priori* bounds

$$0 \leqslant f_\alpha(x,v,t) \leqslant \sup_{(x,v)} f_\alpha(x,v,0) \equiv M_\alpha . \tag{2}$$

We also shall assume f_α and $v f_\alpha$ to be integrable functions of v on $\mathbb{R}$ so that the charge and current densities are well defined. Both E and the f_α will be *spatially 2π-periodic*. In this case it is easy to show that replacing the Ampère equation by its spatially averaged form

$$\frac{dE_0}{dt} = -2 \sum_\alpha q_\alpha \int_{-\pi}^{+\pi} dx \int dv\, v f_\alpha \tag{1c$'$}$$

(where $E_0(t)$ is the $k=0$ spatial Fourier component of $E(x,t)$) yields a system of equations which is completely equivalent to Eqs. (1). Hence, we shall write the VPA system in the compact form

$$\frac{\partial f_\alpha}{\partial t}+v\frac{\partial f_\alpha}{\partial x}+\frac{q_\alpha}{m_\alpha}E\frac{\partial f_\alpha}{\partial v}=0, \tag{3a}$$

$$E=\Lambda(f_1,\ldots,f_{N_S}), \tag{3b}$$

where Λ is defined by its spatial Fourier components

$$\Lambda_k(f_1,\ldots,f_{N_S})\equiv\begin{cases}\dfrac{4\pi}{ik}\sum_\alpha q_\alpha\int dv f_{\alpha,k} & k\neq 0\\ E_0(0)-4\pi\sum_\alpha q_\alpha\int_0^t d\tau\int dv\, v f_{\alpha,0} & k=0\end{cases} \tag{4}$$

which have been obtained from Eq. (1b) and (1c′) for $k\neq 0$ and $k=0$, respectively. Here, the $f_{\alpha,k}$ are the spatial Fourier components of f_α, and $E_0(0)$ is an assigned initial condition for $E_0(t)$. The spatially uniform part of the Poisson equation, Eq. (1b), reduces to the zero-charge condition

$$\sum_\alpha q_\alpha\int_{-\pi}^{+\pi}dx\int dv f_\alpha=0. \tag{5}$$

From the Vlasov equation it follows immediately that this condition is satisfied as long as it holds at $t=0$.

The distribution functions satisfy initial conditions of the form

$$f_\alpha(x,v,0)=\mathcal{F}_\alpha(x,v)\equiv F_\alpha(v)+h_\alpha(x,v), \tag{6}$$

where the $F_\alpha(v)$ correspond to a Vlasov equilibrium and satisfy the conditions

$$q=\sum_\alpha q_\alpha\int F_\alpha(v)dv=0, \tag{7}$$

$$j=\sum_\alpha q_\alpha\int vF_\alpha(v)dv=0. \tag{8}$$

The function h_α in Eq. (6) will be taken to have no spatially uniform part, so that

$$\int_{-\pi}^{+\pi}dx h_\alpha(x,v)=0. \tag{9}$$

Equations (7) and (9) ensure that the $f_\alpha(x,v,0)$, and thus the $f_\alpha(x,v,t)$, satisfy Eq. (5). Clearly, once the $f_\alpha(x,v,0)$ are chosen, all the initial Fourier components for the field $E_k(0)$ with $k\neq 0$ are automatically assigned via the Poisson equation.

The characteristic system for the Vlasov equation, Eq. (3a), is given by Newton's equations $(dx/dt)=v$, $(dv/dt)=(q_\alpha/m_\alpha)E(x,t)$. All the electric fields E appearing in this paper will be such that these equations have global classical solutions that can be extended indefinitely in t according to classic theorems on ODEs.[15] Then, the general solution to the Vlasov equation can be written as

$$f_\alpha(x,v,t)=\mathcal{F}_\alpha(x_0^E(x,v,t),v_0^E(x,v,t))\equiv\mathbf{f}_\alpha(E,\mathcal{F}_\alpha), \tag{10}$$

where we have introduced the the ''inverse trajectories'' $x_0^E(x,v,t),v_0^E(x,v,t)$ determined by Newton's equations; these functions associate with each phase-point (x,v) the initial condition

(x_0^E, v_0^E) at time zero that leads to (x,v) at time t. We shall use the notation $f_\alpha(x,v,t) = \mathbf{f}_\alpha(E,\mathcal{F}_\alpha)$ whenever we want to emphasize the functional dependence of the distribution function on E and the initial condition. Similarly, we shall write

$$\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha) = \frac{\partial}{\partial v}[\mathcal{F}_\alpha(x_0^E(x,v,t), v_0^E(x,v,t))]. \tag{11}$$

Substituting Eq. (10) into Eq. (3b) reduces the problem to a single nonlinear equation for E

$$E = \mathcal{N}(E, F_\alpha, h_a), \tag{12}$$

where we have defined

$$\mathcal{N}(E,F_\alpha,h_\alpha) \equiv \Lambda(\mathbf{f}_1(E,\mathcal{F}_1),\ldots,\mathbf{f}_{N_S}(E,\mathcal{F}_{N_S})). \tag{13}$$

Equation (12) will be called the VPA equation; here, of course, the Vlasov equation has become part of the definition of $\mathcal{N}$ (through Eqs. (10) and (4)).

III. *A–T* DECOMPOSITION

As mentioned in our introductory discussion, we shall seek solutions for E that are the sum of a *transient* part and a *time-asymptotic* part, of the form

$$E(x,t) = T(x,t) + A(x,t). \tag{14}$$

Since our interest is in periodic traveling-wave solutions, all the functions involved will be assumed to be continuously differentiable and periodic in x. As far as the time variable is concerned, a very general class of functions that have the representation in Eq. (14) is given by the *asymptotically almost periodic continuous* (a.a.p.c.) functions of t.[16] Let $\mathcal{AP}$ be the set of all the *almost periodic continuous* (a.p.c.) functions of t uniformly with respect to x.[17] Let $\mathcal{T}$ be the set of all the continuous functions of t on $\mathbb{R}^+ g(x,t)$ such that $\lim_{t\to+\infty} g(x,t) = 0$ uniformly in x. The space of the a.a.p.c. functions of t on $\mathbb{R}^+$ (uniformly with respect to x, periodic and continuously differentiable in x) is given by the direct sum $\mathcal{AP}+\mathcal{T}$. Here, we shall focus on the subspace $\mathcal{W}\subset\mathcal{AP}+\mathcal{T}$ of the functions that are also continuously differentiable in t, i.e.,

$$\mathcal{W} \equiv \{W \in \mathcal{C}^1(\mathbb{R}\times\mathbb{R}^+) \;\; s.t. \;\; W = A + T, \quad A \in \mathcal{AP}, \quad T \in \mathcal{T}\}. \tag{15}$$

As shown by Fréchet,[16] a.a.p.c. functions enjoy many of the classic properties of almost periodic functions. In particular, if $W(x,t)$ is a.a.p.c. in t then it is bounded and uniformly continuous on $\mathbb{R}^+$; in fact, $\mathcal{AP}$, $\mathcal{T}$ and $\mathcal{W}$ can be made into Banach spaces with the supnorm

$$\|W\| = \sup_{I,\mathbb{R}^+} |W|, \tag{16}$$

where $I \equiv [-\pi, +\pi]$. Moreover, the *mean value* of W,

$$\mathbf{M}_t[W(x,t)] = \lim_{\sigma\to\infty} \frac{1}{\sigma} \int_0^\sigma W(x,t)\,dt \tag{17}$$

is always well defined and coincides with the mean value of the a.p.c. part of W, as follows from the fact that $\mathbf{M}_t[T(x,t)] = 0 \;\; \forall T \in \mathcal{T}$ (this will be referred to as "Fréchet's Lemma"[16] in what follows). The existence of the mean is very important because it makes it possible to associate with each a.a.p.c. W its *Fourier–Bohr coefficients*,

$$w(\lambda,x)=\mathbf{M}_t[W(x,t)e^{-i\lambda t}]=\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma W(x,t)e^{-i\lambda t}dt \tag{18}$$

which, of course, coincide with the Fourier–Bohr coefficients of the a.p.c. part of W. For this latter part we know that there exist at most a countably infinite set of real numbers λ_i such that $w(\lambda,x)\equiv 0\ \ \forall\lambda\neq\lambda_i$.[17] Hence, with each a.a.p.c. function W there is associated a unique Fourier–Bohr series

$$W(x,t)\sim\sum w_i(x)e^{i\lambda_i t} \tag{19}$$

(here $w_i(x)\equiv w(\lambda_i,x)$). The series in Eq. (19) coincides with the Fourier–Bohr series for the a.p.c. (time-asymptotic) part of W and determines it uniquely. Of course, it *does not* determine the *whole* function W, whose transient part has been averaged away in the computation of the coefficients w_i. In fact, the Fourier–Bohr series of an a.a.p.c. function gives an explicit representation of the fundamental projection operator $P_a:\mathcal{W}\to\mathcal{AP}$ such that

$$P_aE=A. \tag{20}$$

By associating with any $E\in\mathcal{W}$ its a.p.c. part A, P_a will play a major role in what follows, enabling us to ''sort out'' the essential features of long-time wave propagation from less interesting (and more complicated) transient phenomena.

Of course, the validity of the assumption that $E(x,t)\in\mathcal{W}$ is far from obvious, since there seems to be no easy way to prove rigorously *a priori* that the problem admits an asymptotic a.p.c. state. On the contrary, it could be argued that the intricacies of the nonlinear particle dynamics will always generate some ''noise,'' which cannot be reasonably expected to be a.a.p.c. in time. We are thinking here of the particles belonging to the thin stochastic layers generated by multiwave resonances in the phase plane, as described by Rechester and Stix[18] and by Buchanan and Dorning.[12] On the other hand, Buchanan and Dorning[12] obtained solutions that *are* a.p.c. to *leading order* in the field amplitude, and showed that the noise coming from the stochastic layers vanishes exponentially with that amplitude. Motivated by these results, we study the evolution of initial conditions that produce a *small* time-asymptotic state, and show that the *approximate* solution for $E(x,t)$ is a.a.p.c. in time, with an error that is negligible with respect to the time-asymptotic field amplitude.

Let us substitute the a.a.p.c. representation of E, Eq. (14), into the nonlinear VPA equation, Eq. (12); in order to ensure that this equation is well defined, we need to assume that the integral in dt in Eq. (4) is bounded (and thus a.a.p.c. (Ref. 17)) in time. This implies the necessary condition

$$4\pi\sum_\alpha q_\alpha \lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma d\tau\int dv\, v\, f_{\alpha,0}(v,\tau)=0 \tag{21}$$

which can also be obtained directly by taking the time-average of the Ampère equation, Eq. (1c). We now apply the projection operator P_a introduced above to both sides of Eq. (12) in order to decompose the problem into its transient and time-asymptotic components. This yields the following system of two coupled equations for the time-asymptotic field A and the transient field T:

$$A=P_\alpha\,\mathcal{N}(A+T,F_\alpha,h_\alpha), \tag{22a}$$

$$T=(I-P_a)\mathcal{N}(A+T,F_\alpha,h_\alpha). \tag{22b}$$

Our strategy will be to focus on the ''asymptotic equation,'' Eq. (22a). We shall show that it is possible to obtain important information about the structure of solutions to Eq. (22a) *independently* of the details of T. This will be done in the following steps:

(1) First, we shall show that the asymptotic equation can be studied as an infinite-dimensional bifurcation problem, because it possesses a manifold of vanishing solutions corresponding to different choices of the initial perturbation h_α and of the corresponding transient field T.

(2) Then, we shall show that there is a natural way to linearize Eq. (22a), which leads to a *time-asymptotic linear equation*, whose solutions are very different from those found in the traditional linear theory. In particular, the time-asymptotic linear theory will yield results that are perfectly consistent with the undamped nonlinear multiple traveling-wave solutions recently discovered by Buchanan and Dorning.[12]

(3) Finally, we shall exploit the properties of the time-asymptotic linear operator in order to reduce the original nonlinear problem to a lower-dimensional system of bifurcation equations for the amplitudes of the leading-order Fourier–Bohr coefficients of A.

IV. PURELY TRANSIENT ANALYSIS

We want to show that the time-asymptotic equation, Eq. (22a), is satisfied by the zero time-asymptotic field $A\equiv 0$ independently of the choice of the initial condition. Substituting $A\equiv 0$ into Eq. (22a) gives the equation

$$P_a \mathcal{N}(T,F_\alpha,h_\alpha)=0, \tag{23}$$

which in turn entails the analysis of the Vlasov equation for a purely transient field

$$\frac{\partial f_\alpha}{\partial t}+v\frac{\partial f_\alpha}{\partial x}+\frac{q_\alpha}{m_\alpha}T\frac{\partial f_\alpha}{\partial v}=0. \tag{24}$$

Of course, the general solution of this equation has the form $f_\alpha^T(x,v,t) =\mathcal{F}_\alpha(x_0^T(x,v,t),v_0^T(x,v,t))$, where the $[x_0^T(x,v,t),v_0^T(x,v,t)]$ give the ''inverse particle trajectory,'' i.e., the starting point at time zero for a particle that arrives at the point (x,v) at time t under the influence of the electric field T. The fundamental observation is that, as the *transient T* dies away, it acts on the particles more and more weakly, so that the trajectories tend asymptotically to straight lines as $t\to\infty$. This suggests that in the long-time limit the distribution function must approach some kind of Vlasov equilibrium, at least in a coarse-grained sense, so that Eq. (23) is satisfied.

To establish this, let us consider Newton's equations for the purely transient, spatially periodic field T: $\dot{x}=v$, $\dot{v}=T(x,t)$ (where we have set $q_\alpha/m_\alpha=1$ to avoid excessive notational detail). For the initial value problem with the initial conditions $x(0)=x_0$, $v(0)=v_0$, these equations can be written in the integral form

$$x(t)-x_0=v_0t+\int_0^t d\tau\int_0^\tau d\tau'\,T(x(\tau'),\tau'), \tag{25a}$$

$$v(t)-v_0=\int_0^t d\tau\;T(x,(\tau),\tau). \tag{25b}$$

We want the field $T(x,t)$ to decay fast enough, as $t\to\infty$, that both $\sup_x|T(x,t)|$ and $\int_t^\infty d\tau'\,\sup_x|T(x,\tau')|$ be integrable over the positive real axis. This will be ensured when $\sup_x|T(x,t)|$ tends to zero at least as fast as $t^{-\eta}$ as $t\to\infty$, with $\eta>2$. Under this condition, it follows immediately from Eq. (25b) that

$$\lim_{t\to\infty} v(t)=v_0+\int_0^\infty d\tau\;T(x(\tau),\tau), \tag{26}$$

where the integral on the right-hand side is a function only of the initial point (x_0,v_0) of the trajectory $x(t)$ in phase space. Hence, we shall write Eq. (26) in the form

$$\lim_{t\to\infty} v(t) = v_0 + H(x_0, v_0) \equiv v_\infty . \tag{27}$$

Then, Eq. (25a) can be rewritten immediately as

$$x(t) - x_0 = v_\infty t + \int_0^t d\tau \int_\tau^\infty d\tau' \, T(x(\tau'), \tau'). \tag{28}$$

Thus, under the above conditions on T,

$$\lim_{t\to\infty} [x(t) - v_\infty t] = x_0 + \int_0^\infty d\tau \int_\tau^\infty d\tau' \, T(x(\tau')\tau') \tag{29}$$

which will be written in the form

$$\lim_{t\to\infty} [x(t) - v_\infty t] = x_0 + G(x_0, v_0) \equiv x_\infty . \tag{30}$$

Equations (27) and (30) express the fact that, as t goes to infinity and $T(x,t)$ tends to zero, each trajectory tends asymptotically to the straight line trajectory starting at $t=0$ from the ''fictitious'' phase point (x_∞, v_∞). That is,

$$[x(t), v(t)] \xrightarrow[t\to\infty]{} [x_\infty + v_\infty t, v_\infty]. \tag{31}$$

Now, we want to obtain an analogous result for the ''inverse'' trajectories $[x^T(x,v,t), v^T(x,v,t)]$. This requires a slightly more sophisticated analysis, which leads to the following theorem:

Theorem 1: *If there is a number $\eta > 2$ such that both $\sup_x |T(x,t)|$ and $\sup_x |(dT/dx)(x,t)|$ go to zero as $t^{-\eta}$ as $t \to \infty$, then the corresponding inverse trajectories can be written in the form,*

$$x_0^T(x,v,t) = x - vt + \tilde{G}(x - vt, v) + \tau_1(x,v,t), \tag{32a}$$

$$v_0^T(x,v,t) = v + \tilde{H}(x - vt, v) + \tau_2(x,v,t), \tag{32b}$$

where $\tilde{G}, \tilde{H} \in \mathcal{C}(I \times \mathbb{R}^+)$ and $\lim_{t\to\infty} \tau_1(x,v,t) = \lim_{t\to\infty} \tau_2(x,v,t) = 0$, uniformly in x and v.

Proof: The proof of this result is based on the fact that, by definition, $x_0^T(x,v,t)$ and $v_0^T(x,v,t)$ must satisfy the Vlasov equations

$$\frac{\partial x_0^T}{\partial t} + v \frac{\partial x_0^T}{\partial x} + T \frac{\partial x_0^T}{\partial v} = 0, \tag{33}$$

$$\frac{\partial v_0^T}{\partial t} + v \frac{\partial v_0^T}{\partial x} + T \frac{\partial v_0^T}{\partial v} = 0, \tag{34}$$

which can be written in the integral form

$$x_0^T(x,v,t) = x - vt - \int_0^t d\tau \left[T \frac{\partial x_0^T}{\partial v} \right]_{(x - v(t-\tau), v)}, \tag{35}$$

$$v_0^T(x,v,t) = v - \int_0^t d\tau \left[T \frac{\partial v_0^T}{\partial v} \right]_{(x - v(t-\tau), v)}. \tag{36}$$

In this case, it is not immediately obvious that one can take $t \to \infty$ in the limits of integration, as was done for Eqs. (25). The core of the proof will be precisely the determination of appropriate bounds on the growth in time of $(\partial x_0^T/\partial v)$ and $(\partial v_0^T/\partial v)$, in order to show that the integrands on the right-hand sides of Eqs. (35) and (36) are, indeed, integrable at infinity. The superscript ''T'' will be dropped for the remainder of this proof.

Let us consider, first, the ''direct'' trajectories, written in the form $x(x_0,v_0,t),v(x_0,v_0,t)$. We shall exploit the decay properties of T in order to obtain bounds on the growth in time of the partial derivatives $\partial x/\partial x_0$, $\partial v/\partial x_0$, $\partial x/\partial v_0$, and $\partial v/\partial v_0$. To begin, we take the derivative with respect to x_0 of both sides of Eq. (25a),

$$\frac{\partial x}{\partial x_0}(x_0,v_0,t)=1+\int_0^t d\tau \int_0^\tau d\tau' \frac{\partial x}{\partial x_0}(x_0,v_0,\tau')T_x(x(x_0,v_0,\tau'),\tau'), \tag{37}$$

where $T_x(x,t)\equiv(\partial T/\partial x)(x,t)$. Now, let us multiply both sides of Eq. (37) by $T_x(x(x_0,v_0,t),t)$, rename the variable t as t' and integrate in dt' from 0 to t. We obtain

$$g(x_0,v_0,t)=h(x_0,v_0,t)+\int_0^t dt' T_x(x(x_0,v_0,t'),t')\int_0^{t'} d\tau\, g(x_0,v_0,\tau), \tag{38}$$

where we have defined

$$g(x_0,v_0,t)\equiv\int_0^t dt' \frac{\partial x}{\partial x_0}(x_0,v_0,t')T_x(x(x_0,v_0,t'),t') \tag{39}$$

and

$$h(x_0,v_0,t)\equiv\int_0^t dt' T_x(x(x_0,v_0,t'),t'). \tag{40}$$

The second term on the right-hand side of Eq. (38) is then integrated by parts, yielding

$$\begin{aligned}\int_0^t dt' T_x(x(x_0,v_0,t'),t')\int_0^{t'} d\tau\, g(x_0,v_0,\tau)&=h(x_0,v_0,t)\int_0^t dt' g(x_0,v_0,t')\\&\quad-\int_0^t dt' g(x_0,v_0,t')h(x_0,v_0,t')\\&=\int_0^t dt' g(x_0,v_0,t')\int_{t'}^t d\tau\, T_x(x(x_0,v_0,\tau),\tau).\end{aligned} \tag{41}$$

Thus, Eq. (38) can be written as a Volterra equation, i.e.,

$$g(x_0,v_0,t)=h(x_0,v_0,t)+\int_0^t dt' K(x_0,v_0,t,t')g(x_0,v_0,t'), \tag{42}$$

where the ''kernel'' $K(x_0,v_0,t,t')$ is given by

$$K(x_0,v_0,t,t')\equiv\int_{t'}^t d\tau\, T_x(x(x_0,v_0,\tau),\tau). \tag{43}$$

Due to the integrability of $|T_x|$,

$$|K(x_0,v_0,t,t')|\leqslant\int_{t'}^{t}d\tau|T_x(x(x_0,v_0,\tau),\tau)|\leqslant\int_{t'}^{\infty}d\tau\,|T_x(x(x_0,v_0,\tau),\tau)|\equiv H(x_0,v_0,t'). \tag{44}$$

Hence, Eq. (42) implies the inequality

$$|g(x_0,v_0,t)|\leqslant|h(x_0,v_0,t)|+\int_0^t dt'\,H(x_0,v_0,t')|g(x_0,v_0,t')|. \tag{45}$$

Then, from Gronwall's inequality it follows that

$$|g(x_0,v_0,t)|\leqslant C(x_0,v_0)e^{B(x_0,v_0)}\equiv M(x_0,v_0)<\infty, \tag{46}$$

where

$$C(x_0,v_0)\leqslant\int_0^{\infty}dt'\,|T_x(x(x_0,v_0,t'),t')| \tag{47}$$

and

$$B(x_0,v_0)\equiv\int_0^{\infty}dt'\,H(x_0,v_0,t'). \tag{48}$$

Now, let us go back to Eq. (37), and to the corresponding equation for $\partial v/\partial x_0$ which is obtained by taking the partial derivative of Eq. (25b) with respect to x_0. According to Eq. (39), these equations can be written in the form

$$\frac{\partial x}{\partial x_0}(x_0,v_0,t)=1+\int_0^t d\tau\; g(x_0,v_0,\tau), \tag{49a}$$

$$\frac{\partial v}{\partial x_0}(x_0,v_0,t)=g(x_0,v_0,t). \tag{49b}$$

From the bound on $|g(x_0,v_0,t)|$ in Eq. (46) it follows immediately that

$$\left|\frac{\partial x}{\partial x_0}(x_0,v_0,t)\right|\leqslant 1+Mt, \tag{50a}$$

$$\left|\frac{\partial v}{\partial x_0}(x_0,v_0,t)\right|\leqslant M. \tag{50b}$$

Here, M is defined as $\sup_{x_0,v_0}M(x_0,v_0)$ which exploits the fact that $M(x_0,v_0)$ is a uniformly bounded function of (x_0,v_0), as follows from Eqs. (46), (47), (48), and from the integrability properties of T_x. Equations (50) give the result sought: under the conditions on the time integrability of $T_x(x,t)$, we have found that $\partial x/\partial x_0$ and $\partial v/\partial x_0$ can grow at most linearly in time.

Using a completely analogous procedure to find similar bounds on the derivatives $\partial x/\partial v_0$ and $\partial v/\partial v_0$ we obtain

$$\left|\frac{\partial x}{\partial v_0}(x_0,v_0,t)\right|\leqslant Nt, \tag{51a}$$

$$\left|\frac{\partial v}{\partial v_0}(x_0,v_0,t)\right|\leqslant N. \tag{51b}$$

Here, $N \equiv \sup_{x_0,v_0} N(x_0,v_0)$, where

$$N(x_0,v_0) \equiv 1 + D(x_0,v_0) e^{B(x_0,v_0)}. \tag{52}$$

$B(x_0,v_0)$ is the same quantity that was defined in Eq. (48) and $D(x_0,v_0)$ satisfies

$$D(x_0,v_0) \leq \int_0^\infty dt' t' |T_x(x(x_0,v_0,t'),t')|. \tag{53}$$

From the inequalities in Eqs. (50) and (51), we easily obtain similar bounds on the time growth of the derivatives of the ''inverse'' functions x_0 and v_0. These bounds follow from the fact that the Jacobian matrix of $[x_0(x,v,t),v_0(x,v,t)]$ (viewed as a function from $\mathbb{R}^2$ onto $\mathbb{R}^2$) is the inverse of the Jacobian of the inverse function $[x(x_0,v_0,t),v(x_0,v_0,t)]$ for each given t, and that this latter has determinant equal to one. We find

$$\left|\frac{\partial x_0}{\partial x}(x,v,t)\right| \leq N, \tag{54a}$$

$$\left|\frac{\partial v_0}{\partial x}(x,v,t)\right| \leq M, \tag{54b}$$

$$\left|\frac{\partial x_0}{\partial v}(x,v,t)\right| \leq Nt, \tag{55a}$$

$$\left|\frac{\partial v_0}{\partial v}(x,v,t)\right| \leq 1 + Mt. \tag{55b}$$

By combining the decay properties of T with Eqs. (55), it is easy to see that the integrands $T(\partial x_0/\partial v)$ and $T(\partial v_0/\partial v)$ in the integrals in Eqs. (35) and (36) are integrable over $\mathbb{R}^+$. Hence, by adding and subtracting the corresponding integrals on $[t,\infty)$, we can write

$$x_0(x,v,t) \approx x - vt + \tilde{G}(x-vt,v), \tag{56a}$$

$$v_0(x,v,t) \approx v + \tilde{H}(x-vt,v), \tag{56b}$$

where the symbol $\approx$ is used to indicate that the two sides are equal up to certain transient functions of (x,v,t) that disappear in the time-asymptotic limit, uniformly with respect to x and v. The functions $\tilde{G}$ and $\tilde{H}$ are given by

$$\tilde{G}(x,v) \equiv \int_0^\infty d\tau \; T(x+v\tau,\tau) \frac{\partial x_0}{\partial v}(x+v\tau,v,\tau), \tag{57a}$$

$$\tilde{H}(x,v) \equiv \int_0^\infty d\tau \; T(x+v\tau,\tau) \frac{\partial v_0}{\partial v}(x+v\tau,v,\tau), \tag{57b}$$

and are clearly continuous (x_0 and v_0 being $\mathcal{C}^1$ according to standard theorems on ordinary differential equations). □

Equations (32) tell us that the inverse particle trajectories at long times tend asymptotically to the straight-line paths $(x-vt,v)$, but with one important qualification. Because of the effects of the transient, the phase point that is mapped backwards along the each straight-line trajectory *is not* (x,v) *itself*, but the ''surrogate'' point $x^T \equiv x + \tilde{G}(x,v)$, $v^T \equiv v + \tilde{H}(x,v)$. Of course, the two functions $\tilde{G}$ and $\tilde{H}$ are not known explicitly, since that would require the complete solution of the nonlinear Vlasov equations for x_0^T and v_0^T, Eqs. (33) and (34). The essential point, here, is that these functions exist and do not depend explicitly on t. It is worth noting that there is a relationship between the functions $\tilde{G},\tilde{H}$ and the functions G,H introduced in Eqs. (27) and (30). Equations (56) imply that

$$x_0 \approx x(x_0,v_0,t) - v(x_0,v_0,t)t + \tilde{G}(x(x_0,v_0,t) - v(x_0,v_0,t)t, v), \tag{58a}$$

$$v_0 \approx v(x_0,v_0,t) + \tilde{H}(x(x_0,v_0,t) - v(x_0,v_0,t)t, v). \tag{58b}$$

Taking the limit $t \to \infty$ and using Eq. (31) yields

$$x_0 = x_\infty + \tilde{G}(x_\infty, v_\infty), \tag{59a}$$

$$v_0 = v_\infty + \tilde{H}(x_\infty, v_\infty), \tag{59b}$$

where (x_∞, v_∞) are the quantities defined in Eqs. (27) and (30).

Substituting Eqs. (32) into the initial condition $\mathcal{F}_\alpha$ yields the solution f_α^T to Eq. (24) in the form

$$f_\alpha^T(x,v,t) = \mathcal{F}_\alpha^T(x - vt, v) + g_\alpha^T(x,v,t), \tag{60}$$

where

$$\mathcal{F}_\alpha^T(x,v) \equiv \mathcal{F}_\alpha(x + \tilde{G}(x,v), v + \tilde{H}(x,v)), \tag{61}$$

and

$$g_\alpha^T(x,v,t) = \mathcal{F}_\alpha(x_0^T, v_0^T) - \mathcal{F}_\alpha^T(x - vt, v). \tag{62}$$

Clearly, $g_\alpha^T(x,v,t) \to 0$ uniformly as $t \to \infty$, since according to Eqs. (32) the two terms on the right-hand side of Eq. (62) become identical in this limit. This means that, as t goes to infinity, f_α^T can be obtained by advection along straight-line trajectories, as long as we replace the initial condition $\mathcal{F}_\alpha$ by the modified function $\mathcal{F}_\alpha^T$ that contains the effects of the transient field T.

It follows from Eq. (60) that f_α^T can be replaced in Eq. (23) by a spatially uniform equilibrium that yields the same values for macroscopic quantities in the time-asymptotic limit. To be explicit, let us consider any integral of the form

$$\int_{\mathbb{R}} du\, \mathcal{G}(v,u) f_\alpha^T(x,u,t), \tag{63}$$

which can be either a charge or current density ($\mathcal{G}(v,u) = 1, u$), or any higher moment ($\mathcal{G}(v,u) = u^n$), or a filtered distribution function.[19] Substituting Eq. (60) into Eq. (63) and introducing the spatial Fourier series of $\mathcal{F}_\alpha^T$, it is easy to see that for all $k \neq 0$,

$$\lim_{t\to\infty} \int_{\mathbb{R}} du\, \mathcal{G}(v,u) f_{\alpha,k}^T(u,t) = \lim_{t\to\infty} \int_{\mathbb{R}} du\, \mathcal{G}(v,u) \mathcal{F}_{\alpha,k}^T(u) e^{-ikut} = 0 \tag{64}$$

by the Riemann–Lebesgue Lemma. Hence,

$$\lim_{t\to\infty} \int_{\mathbb{R}} du\, \mathcal{G}(v,u) f_\alpha^T(x,u,t) = \int_{\mathbb{R}} du\, \mathcal{G}(v,u) F_\alpha^T(u), \tag{65}$$

where

$$F_\alpha^T(v)=\mathcal{F}_{\alpha,0}^T(v)=\frac{1}{2\pi}\int_{-\pi}^{+\pi}dx\mathcal{F}_\alpha(x+\tilde{G}(x,v),v+\tilde{H}(x,v)). \tag{66}$$

The charge and current densities associated with F_α^T are

$$\rho_T=\frac{1}{2\pi}\sum_\alpha q_\alpha\int_{\mathbb{R}}dv\int_{-\pi}^{+\pi}dx\mathcal{F}_\alpha(x+\tilde{G}(x,v),v+\tilde{H}(x,v)), \tag{67}$$

$$j_T=\frac{1}{2\pi}\sum_\alpha q_\alpha\int_{\mathbb{R}}dv\int_{-\pi}^{+\pi}dx\ v\mathcal{F}_\alpha(x+\tilde{G}(x,v),v+\tilde{H}(x,v)). \tag{68}$$

Changing the integration variables to $(x_0,v_0)=[x+\tilde{G}(x,v),v+\tilde{H}(x,v)]$ and noting that this transformation preserves the area in phase space (since it is the time-limit of a Hamiltonian flow), we get

$$\rho_T=\frac{1}{2\pi}\sum_\alpha q_\alpha\int_{\mathbb{R}}dv_0\int_{-\pi}^{+\pi}dx_0\mathcal{F}_\alpha(x_0,v_0), \tag{69}$$

$$j_T=\frac{1}{2\pi}\sum_\alpha q_\alpha\int_{\mathbb{R}}dv_0\int_{-\pi}^{+\pi}dx_0[v_0+H(x_0,v_0)]\mathcal{F}_\alpha(x_0,v_0). \tag{70}$$

Since the spatially uniform part of the initial condition $\mathcal{F}_\alpha(x,v)$ has been taken to be a Vlasov equilibrium, it is easy to see that Eqs. (69) and (70) reduce to

$$\rho_T=0,\quad j_T=j_\infty^T, \tag{71}$$

where

$$j_\infty^T\equiv\frac{1}{2\pi}\sum_\alpha q_\alpha\int_{\mathbb{R}}dv_0\int_{-\pi}^{+\pi}dx_0H(x_0,v_0)\mathcal{F}_\alpha(x_0,v_0). \tag{72}$$

Whenever T is a solution of the self-consistent VPA equation, Eq. (12), $j_\infty^T=0$, as follows directly from the time-and-space averaged Ampère equation, Eq. (21). In general, let us define the subspace $\mathcal{T}_L\subset\mathcal{T}$ of the transient fields that satisfy the hypotheses of Theorem 1 and for which $j_\infty^T=0$. Then, Eq. (71) leads directly to the main result of this section:

Theorem 2: *For any choice of $\mathcal{F}_\alpha$ and $T\in\mathcal{T}_L$ the time-asymptotic equation, Eq. (22a), has the solution $A\equiv0$.*

V. VANISHING ASYMPTOTIC STATES

Theorem 2 can be given the following interpretation: the asymptotic equation, Eq. (22a), possesses an infinite dimensional manifold of vanishing solutions with respect to the initial condition $\mathcal{F}_\alpha(x,v)$, viewed as an infinite dimensional parameter in the Banach space $\mathcal{S}$ of all the $\mathcal{C}^1(\mathbb{R}\times\mathbb{R})$ functions such that

$$\|\mathcal{F}_\alpha\|_{\mathcal{S}}\equiv\sup_x\int_{\mathbb{R}}dv(1+|v|)|\mathcal{F}_\alpha(x,v)|<\infty. \tag{73}$$

In Eq. (6) $\mathcal{F}_\alpha(x,v)$ was written as the sum of a spatially uniform Vlasov equilibrium $F_\alpha(v)$ and another function $h_\alpha(x,v)$; in many situations it is convenient to consider $F_\alpha\in\mathcal{S}$ as fixed and study how the solutions to the VPA problem depend on h_α. Physically, this corresponds to assuming a given ''background equilibrium'' and varying a spatially dependent perturbation. Theorem 2 tells us that $A\equiv0$ is a solution to Eq. (22a) for all $h_\alpha\in\mathcal{S}$. Schematically, if we consider the h_α-A plane (where each axis represents an infinite dimensional space) this ''basic solution branch'' $A\equiv 0$ can be drawn as the horizontal line along the h_α axis. We shall call these solutions *vanishing asymptotic states*.

It is important to emphasize that these vanishing asymptotic states do not necessarily correspond to solutions of the complete system, Eqs. (22). In fact, it is not at all certain that if $A=0$ is substituted into Eq. (22b) the equation that results for T from Eq. (23),

$$T=\mathcal{N}(T,F_\alpha,h_\alpha) \tag{74}$$

will possess a solution in $\mathcal{T}$. Whenever it does possess such a solution for an initial perturbation h_α, we shall say that the corresponding point on the zero solution branch for the asymptotic equation, Eq. (22a), is *accessible* to the system. Clearly, at least one vanishing asymptotic state is always accessible, namely the ''origin'' $A\equiv h_\alpha\equiv 0$. Any other accessible vanishing asymptotic state (a.v.a.s. from now on) will correspond, physically, to strongly Landau damped evolution,[6] with the field damping completely to zero *before* trapping effects are able to sustain traveling-wave propagation.

Let us consider a generic a.v.a.s. $A\equiv 0$, $h_\alpha=h_\alpha^0$, associated with a transient field $T=T_0$ such that the nonlinear Ampère equation, Eq. (74) is satisfied. The corresponding distribution function $f_\alpha^{T_0}$ will be the solution of the Vlasov equation, Eq. (24), with the initial condition $f_\alpha^{T_0}(x,v,0)\equiv\mathcal{F}_\alpha^0(x,v)\equiv F_\alpha(v)+h_\alpha^0(x,v)$, where $F_\alpha(v)$ is a given Vlasov equilibrium. We now introduce the following definition:

Definition 1: An a.v.a.s. $(A,T,h_\alpha)=(0,T_0,h_\alpha^0)$ will be called *critical* if in every (arbitrarily small) neighborhood of $(0,T_0,h_\alpha^0)$ in $\mathcal{AP}\times\mathcal{T}\times\mathcal{S}$ there is a point $(A,T_0+\delta T,h_\alpha^0+\delta h_\alpha)$ such that the initial perturbation $h_\alpha^0+\delta h_\alpha$ generates a solution to the VPA problem in which the electric field has transient part $T_0+\delta T$ and *nonzero* time-asymptotic part A.

Obviously, this situation is physically very interesting, especially in the class of problems that fall under the label of ''nonlinear Landau damping;''[20] in these cases, we expect an a.v.a.s. of this kind to mark the transition between solutions that Landau damp completely and solutions that contain a nonzero small-amplitude asymptotic part. Another important example of a critical a.v.a.s. is found whenever the background equilibrium F_α allows undamped traveling wave solutions for perturbations of arbitrarily small amplitude. Examples are the recently discovered small-amplitude BGK and BGK-type solutions.[10,12] In these cases, of course, the critical a.v.a.s. is given by the ''origin'' $(A,T,h_\alpha)=(0,0,0)$.

Now, the fact that $A\equiv 0$ provides a solution to the asymptotic equation *in isolation* for any choice of h_α, suggests that the asymptotic equation itself may be amenable to a *bifurcation analysis* at the critical states. In fact, if we consider the asymptotic equation alone, in an arbitrarily small neighborhood of a critical a.v.a.s. the solution to the equation cannot be unique, since from Definition 1 both $A\equiv 0$ *and* the nonzero asymptotic solutions to the VPA system corresponding to $h_\alpha^0+\delta h_\alpha$ satisfy the equation. Thus, according to a rather general definition in nonlinear analysis (e.g., Ref. 21, p. 151), $A\equiv 0$, $h_\alpha=h_\alpha^0$ is a *bifurcation point* for the asymptotic equation. Of course, this is not true in general for the complete VPA system, for example, it is not true whenever the solution to the initial value problem is known to be unique. In summary, we have the following theorem:

Theorem 3: *Every critical a.v.a.s for the VPA initial value problem corresponds to a bifurcation point for the asymptotic Ampère equation, Eq. (22a).*

VI. TIME-ASYMPTOTIC LINEAR ANALYSIS

Let us now consider a given critical a.v.a.s. $\eta_0\equiv(0,T_0,h_\alpha)$. Instead of carrying out the bifurcation analysis of Eq. (22a) at η_0 directly, we shall study the equivalent problem comprised of the countable set of equations for the Fourier–Bohr coefficients of A,

$$a_{k,\omega_i}=\mathcal{N}_{k,\omega_i}(A+T,F_\alpha,h_\alpha). \tag{75}$$

These equations correspond to all the k and ω_i such that $a_{k,\omega_i}\neq 0$; by definition, the Fourier–Bohr coefficients $\mathcal{N}_{k,\omega_i}$ of the nonlinear operator $\mathcal{N}$ coincide with those of $P_a\mathcal{N}$. The double-indexed sequences $\mathbf{y}\equiv\{y_{m,\eta}\}$ of Fourier–Bohr coefficients of functions that are periodic in space and a.p.c. in time are characterized by the Riesz-type condition[22] $\Sigma_{m,\eta}|y_{m,\eta}|^2<\infty$, where it is understood that the index-set for η can be any countable subset of the real axis $\mathbb{R}$, and not just the integers. With the supnorm,

$$\|\mathbf{y}\|=\sup_{m,\eta}|y_{m,\eta}|, \tag{76}$$

the set of all the $\mathbf{y}$ is a Banach space, which we shall denote l_b. The sequence of nonlinear time-asymptotic equations, Eq. (75), can be reformulated as a single functional equation in l_b by writing $\mathbf{a}=\{a_{k,\omega_i}\}$ for the double sequence of the Fourier–Bohr coefficients of A and defining $N(\mathbf{a})\equiv\{\mathcal{N}_{k,\omega_i}(A+T,F_\alpha,h_\alpha)\}$. Then, Eq. (75) becomes

$$\mathbf{a}=N(\mathbf{a}). \tag{77}$$

Here, we are not explicitly writing the dependence of N on the transient field T, which is being treated as a free parameter along with F_α and h_α.

In a local analysis, the natural question is whether there is any appropriate *linear* approximation to the nonlinear problem under consideration. We answer this question by first establishing the following result:

Lemma 1: For $E\in\mathcal{W}$, $\mathcal{F}_\alpha\in\mathcal{S}$ and $k\neq 0$,

$$\begin{aligned}\mathcal{N}_{k,\omega_i}(E,F_\alpha,h_\alpha)&=\frac{2}{k}\sum_\alpha\frac{q_\alpha^2}{m_\alpha}\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma dt\int_{-\pi}^{+\pi}dx\; e^{-i\omega_i t-ikx}E(x,t)P\int_{\mathbb{R}}dv\,\frac{\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha)}{\omega_i+kv}\\&=\frac{2}{k}\sum_\alpha\frac{q_\alpha^2}{m_\alpha}\lim_{n\to\infty}\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma dt\int_{-\pi}^{+\pi}dx\; e^{-i\omega_i t-ikx}E(x,t)\int_{\Omega_{n,i}^c}dv\,\frac{\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha)}{\omega_i+kv},\end{aligned} \tag{78}$$

where $\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha)=\partial f_\alpha/\partial v(x,v,t)$ was defined in Eq. (11) and $\Omega_{n,i}^c$ represents the real axis $\mathbb{R}$ minus the one-dimensional sphere of radius $r_n<1/n$ centered at $-\omega_i/k$, $\Omega_{n,i}\equiv B[-(\omega_i/k),r_n]$.

Proof: The Fourier–Bohr coefficients $\mathcal{N}_{k,\omega_i}$ are given by

$$\mathcal{N}_{k,\omega_i}(E,F_\alpha,h_\alpha)=\frac{4\pi}{ik}\sum_\alpha q_\alpha\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma dt\; e^{-i\omega_i t}\int_{\mathbb{R}}dv\, f_{\alpha,k}(v,t), \tag{79}$$

The properties of f_α enable us to apply Fubini's theorem and rewrite this equation as

$$\mathcal{N}_{k,\omega_i}(E,F_\alpha,h_\alpha)=\frac{4\pi}{ik}\sum_\alpha q_\alpha\lim_{\sigma\to\infty}\lim_{n\to\infty}\int_{\Omega_{n,i}^c}dv\,\frac{1}{\sigma}\int_0^\sigma dt\; e^{-i\omega_i t}f_{\alpha,k}(v,t). \tag{80}$$

We substitute into the right-hand side of Eq. (80) the expression for f_α that is given by the Vlasov equation in integro-differential Fourier-transformed form

$$f_{\alpha,k}(v,t)=h_{\alpha,k}(v)e^{-ikvt}-\frac{q_\alpha}{m_\alpha}\int_0^t d\tau\frac{1}{2\pi}\int_{-\pi}^{+\pi}dx e^{-ik[x+v(t-\tau)]}E(x,\tau)\frac{\partial f_\alpha}{\partial v}(x,v,\tau). \tag{81}$$

The term proportional to $h_{\alpha,k}(v)$ does not contribute to Eq. (80) by the Riemann–Lebesgue Lemma. After an integration by parts, we are left with

$$-\frac{2}{k}\sum_{\alpha}\frac{q_{\alpha}^{2}}{m_{\alpha}}\lim_{\sigma\to\infty}\frac{1}{\sigma}P\int_{\mathbb{R}}dv\,\frac{e^{-i\omega_i\sigma}}{\omega_i+kv}\int_0^{\sigma}dte^{-ikv(\sigma-t)}\int_{-\pi}^{+\pi}dxe^{-ikx}E(x,t)\,\frac{\partial f_\alpha}{\partial v}(x,v,t)$$

$$+\frac{2}{k}\sum_{\alpha}\frac{q_{\alpha}^{2}}{m_{\alpha}}\lim_{\sigma\to\infty}\frac{1}{\sigma}\,P\int_{\mathbb{R}}dv\int_0^{\sigma}dt\,\frac{e^{-i\omega_i t}}{\omega_i+kv}\int_{-\pi}^{+\pi}dxe^{-ikx}E(x,t)\,\frac{\partial f_\alpha}{\partial v}(x,v,t). \tag{82}$$

Here, the two v-integrals, taken separately, would not be well-defined if the principal values had not been introduced via Eq. (80). The first term in Eq. (82) can be greatly simplified by noting that it contains the last term on the right-hand side of Eq. (81) evaluated at $t=\sigma$. Hence, that whole term vanishes in the limit $\sigma\to\infty$, since $1/\sigma$ multiplies functions that are bounded in σ. Finally, via another change in the order of integration (based on Fubini's theorem, and also on the Lebesgue dominated convergence theorem) in order to bring the limit $n\to\infty$ inside the integrals in dt and dx, we are left with the expression for the $\mathcal{N}_{k,\omega_i}$ on the first line in Eq. (78).

In order to obtain the second expression in Eq. (78), we need to change the order of the limits $\sigma\to\infty$ and $n\to\infty$. This can be done most conveniently in Eq. (79) in order to take advantage of the properties of f_α. Thus, we break the v integration in Eq. (79) into two parts, on $\Omega_{n,i}$ and $\Omega_{n,i}^c$, respectively. As $n\to\infty$, the part on $\Omega_{n,i}$ vanishes, since

$$\left|\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^{\sigma}dte^{-i\omega_i t}\int_{\Omega_{n,i}}dvf_{\alpha,k}(v,t)\right|\leqslant\frac{2M_\alpha}{n} \tag{83}$$

due to the *a priori* bound in Eq. (2). Taking the limit $n\to\infty$ we obtain the following expression for $\mathcal{N}_{k,\omega_i}(E,F_\alpha,h_\alpha)$:

$$\mathcal{N}_{k,\omega_i}(E,F_\alpha,h_\alpha)=\frac{4\pi}{ik}\sum_{\alpha}q_\alpha\lim_{n\to\infty}\lim_{\sigma\to\infty}\int_{\Omega_{n,i}^c}dv\,\frac{1}{\sigma}\int_0^{\sigma}dtf_{\alpha,k}(v,t). \tag{84}$$

Then, the same procedure that was applied to Eq. (80) (with minor adaptations) leads to the expression on the second line in Eq. (78). □

The fact that the order of the limits $n\to\infty$ and $\sigma\to\infty$ in Eq. (78) can be changed is crucial for the next Lemma, which shows that the explicit dependence on E in Eq. (78) actually involves only the asymptotic part A, while the term containing T vanishes. (Of course, the transient T still appears implicitly through the distribution function f_α, which is determined by *both* A and T via the Vlasov equation.)

Lemma 2: For any choice of $E\in\mathcal{W}$, $\mathcal{F}_\alpha\in\mathcal{S}$ *and* $k\neq 0$,

$$\frac{2}{k}\sum_{\alpha}\frac{q_{\alpha}^{2}}{m_{\alpha}}\lim_{n\to\infty}\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^{\sigma}dt\;e^{-i\omega_i t}\int_{-\pi}^{+\pi}dx\;e^{-ikx}T(x,t)\int_{\Omega_{n,i}^c}dv\,\frac{\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha)}{\omega_i+kv}=0. \tag{85}$$

Proof: Integrating by parts gives

$$\left|\int_{\Omega_{n,i}^c}dv\,\frac{\dfrac{\partial f_\alpha}{\partial v}(x,v,t)}{\omega_i+kv}\right|=\left|-\left[\frac{f_\alpha(x,v,t)}{\omega_i+kv}\right]_{-(\omega_i/k)-r_n}^{-(\omega_i/k)+r_n}+k\int_{\Omega_{n,i}^c}dv\,\frac{f_\alpha(x,v,t)}{(\omega_i+kv)^2}\right|$$

$$\leqslant\frac{4\pi M_\alpha}{r_n}+\frac{k}{r_n^2}\int_{\mathbb{R}}dv|f_\alpha|\leqslant\frac{4\pi M_\alpha}{r_n}+\frac{k\tilde{M}}{r_n^2}\equiv M_{\alpha,n}, \tag{86}$$

where we have exploited the *a priori* bound on $f_\alpha(x,v,t)$ and the fact that the total number of particles $\tilde{M}$ must be conserved (as follows from integrating the Vlasov equation over the whole phase plane). Hence, in the second line of Eq. (78),

$$\left| \lim_{\sigma\to\infty} \frac{1}{\sigma} \int_0^{\sigma} dt\ e^{-i\omega_i t} \int_{-\pi}^{+\pi} dx\ e^{-ikx} T(x,t) \int_{\Omega_{n,i}^c} dv\, \frac{\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha)}{\omega_i + kv} \right|$$

$$\leqslant \lim_{\sigma\to\infty} \frac{1}{\sigma} \int_0^{\sigma} dt |T(x,t)| 2\pi M_{\alpha,n} = 2\pi M_{\alpha,n} \mathbf{M}_t[|T(x,t)|] = 0, \tag{87}$$

where the mean value $\mathbf{M}_t$ was defined in Eq. (17) and $\mathbf{M}_t[|T(x,t)|]$ is zero since $T(x,t)$ is a transient. Thus Lemma 2 is proved. Clearly since $M_{\alpha,n}$ diverges in the limit $n\to\infty$, the order in which the two limits are taken in Eq. (85) is crucial. □

According to Eqs. (78) and (85), when $k\neq 0$ the Fourier–Bohr coefficients $\mathcal{N}_{k,\omega_i}$ can be rewritten as

$$\mathcal{N}_{k,\omega_i}(A+T,F_\alpha,h_\alpha) = \lim_{\sigma\to\infty} \frac{1}{\sigma} \int_0^{\sigma} dt \frac{1}{2\pi} \int_{-\pi}^{+\pi} dx e^{-i\omega_i t - ikx} A \mathcal{E}^{(k,\omega_i)}(A+T,F_\alpha,h_\alpha), \tag{88}$$

where we have introduced the notation

$$\mathcal{E}^{(k,\omega_i)}(E,F_\alpha,h_\alpha) \equiv \frac{4\pi}{k} \sum_\alpha \frac{q_\alpha^2}{m_\alpha} P \int_{\mathbb{R}} dv\, \frac{\mathbf{f}'_\alpha(E,\mathcal{F}_\alpha)}{\omega_i + kv}. \tag{89}$$

We next consider $k=0$ which we excluded from Lemmas 1 and 2. There are two possibilities, $\omega_i=0$ and $\omega_i\neq 0$. However, it is not necessary to study the former case since $a_{0,0}=0$ follows immediately from the fact that the VPA system conserves energy. Indeed, if $a_{0,0}$ were nonzero the corresponding time-asymptotic electric field, being uniform in both space and time, clearly would accelerate all the particles to infinite energies. Thus, we do not consider this case; for the same reason, we exclude the possibility of $\omega=0$ being an accumulation point for the ω_i. Then, for $k=0$ there must exist a $\lambda\in\mathbb{R}$ such that $k=0$, $\omega_i\leqslant\lambda \Rightarrow a_{k,\omega_i}=0$, which in fact is a well-known sufficient condition for the spatial average $A_0(t)$ to have an almost periodic primitive (Ref. 17, p. 74). Hence, we next consider the remaining case, $k=0$, $\omega_i\neq 0$, under this condition. The analogues of Lemmas 1 and 2 are developed immediately using the same arguments employed in these Lemmas, with Eq. (81) for the kth Fourier component replaced by

$$f_{\alpha,0}(v,t) = F_\alpha(v) - \frac{q_\alpha}{m_\alpha} \int_0^t d\tau \frac{1}{2\pi} \int_{-\pi}^{+\pi} dx\ E(x,\tau) \frac{\partial f_\alpha}{\partial v}(x,v,\tau), \tag{90}$$

which is obtained via the time integration of the $k=0$ component of the Vlasov equation. Substituting Eq. (90) into Eq. (4) and carrying out steps analogous to those implemented above for $k\neq 0$ leads to an expression identical to Eq. (88), with

$$\mathcal{E}^{(0,\omega_i)}(E,F_\alpha,h_\alpha) \equiv \frac{4\pi}{\omega_i^2} \sum_\alpha \frac{q_\alpha^2}{m_\alpha} \int_{\mathbb{R}} dv\, \mathbf{f}_\alpha(E,\mathcal{F}_\alpha). \tag{91}$$

Thus, Lemmas 1 and 2 have been extended to include the case $k=0$.

Equation (88) combined with Eq. (89) for $k\neq 0$ and Eq. (91) for $k=0$ leads directly to the following theorem;

Theorem 4: *Given a critical a.v.a.s.* $\eta_0\in\mathcal{AP}\times\mathcal{T}\times\mathcal{S}$, *let* $\mathcal{E}^{(k,\omega_i)}(E,F_\alpha,h_\alpha)$ *be continuous in* E *at* η_0. *Then,* $\mathcal{N}_{k,\omega_i}(A+T,F_\alpha,h_\alpha)$ *is Fréchet-differentiable with respect to* A *at* η_0, *the derivative being*

$$\mathcal{L}_{k,\omega_i}(T_0,F_\alpha,h_\alpha^0)A \equiv \lim_{\sigma\to\infty} \frac{1}{\sigma} \int_0^{\sigma} dt \frac{1}{2\pi} \int_{-\pi}^{+\pi} dx e^{-i\omega_i t - ikx} A \mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha^0). \tag{92}$$

Proof: Clearly $\mathcal{L}_{k,\omega_i}$ is a continuous linear operator, and due to Eq. (88) [Lemmas 1 and 2] and the continuity of $\mathcal{E}^{(k,\omega_i)}$ at η_0,

$$
\begin{aligned}
&|\mathcal{N}_{k,\omega_i}(T_0+A,F_\alpha,h_\alpha^0)-\mathcal{N}_{k,\omega_i}(T_0,F_\alpha,h_\alpha^0)-\mathcal{L}_{k,\omega_i}(T_0,F_\alpha,h_\alpha^0)A| \\
&\quad=\left|\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma dt\,\frac{1}{2\pi}\int_{-\pi}^{+\pi}dx e^{-i\omega_i t-ikx}A[\mathcal{E}^{(k,\omega_i)}(T_0+A,F_\alpha,h_\alpha^0)-\mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha^0)]\right| \\
&\quad\leqslant\|A\|\|\mathcal{E}^{(k,\omega_i)}(T_0+A,F_\alpha,h_\alpha^0)-\mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha^0)\|=o(\|A\|).
\end{aligned}
\tag{93}
$$

□

The sequence $\mathcal{L}_{k,\omega_i}A$ defines a linear operator $L\mathbf{a}\equiv\{\mathcal{L}_{k,\omega_i}(T_0,F_\alpha,h_\alpha^0)A\}$ on l_b. Introducing $M(\mathbf{a})\equiv N(\mathbf{a})-L\mathbf{a}$ enables us to write Eq. (77) in the form

$$(I-L)\mathbf{a}=M(\mathbf{a}). \tag{94}$$

The operator $(I-L)$ represents the linear approximation (at the given critical a.v.a.s.) to the original nonlinear equation, Eq. (77). Hence, the first step in the analysis of the nonlinear problem will be the study of the invertibility of this linear operator. Specifically, we must determine the null space of $(I-L)$; hence, we must study the *linearized time-asymptotic equation*

$$(I-L)\mathbf{a}=0. \tag{95}$$

Before proceeding with the general analysis of this equation, we consider a particularly simple case for which the analysis is straightforward. It is provided by the a.v.a.s. $h_\alpha\equiv 0$, i.e., the zero field solution

$$A(x,t)=T_0(x,t)\equiv 0,\quad f_\alpha^{T_0}(x,v,t)=\mathbf{f}_\alpha(0,F_\alpha)=F_\alpha(v) \tag{96}$$

for which $\mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha^0)$, which appears in Eq. (92), can be calculated immediately. From Eq. (89) and Eq. (91) it is

$$\mathcal{E}^{(k,\omega_i)}(0,F_\alpha,0)\equiv\frac{4\pi}{k}\sum_\alpha\frac{q_\alpha^2}{m_\alpha}P\int_{\mathbb{R}}dv\,\frac{F_\alpha'(v)}{\omega_i+kv} \tag{97}$$

for $k\neq 0$, and

$$\mathcal{E}^{(0,\omega_i)}(0,F_\alpha,0)\equiv\frac{4\pi}{\omega_i^2}\sum_\alpha\frac{q_\alpha^2}{m_\alpha}\int_{\mathbb{R}}dv F_\alpha(v)=\frac{\omega_p^2}{\omega_i^2} \tag{98}$$

for $k=0$, where ω_p is the *plasma frequency* that corresponds to the equilibrium $F_\alpha(v)$. The expressions given in Eqs. (97) and (98) are both constants and can be moved out of the integrals in Eq. (92). Thus, Eq. (95) takes the simple form

$$a_{k,\omega_i}\mathcal{D}_0(k,\omega_i)=0, \tag{99}$$

where

$$\mathcal{D}_0(k,\omega_i)\equiv 1-\frac{4\pi}{k}\sum_\alpha\frac{q_\alpha^2}{m_\alpha}P\int_{\mathbb{R}}dv\,\frac{F_\alpha'(v)}{\omega_i+kv} \tag{100}$$

for $k\neq 0$ and $\mathcal{D}_0(0,\omega_i)\equiv\omega_p^2/\omega_i^2$ (for $k=0$). $\mathcal{D}_0(k,\omega_i)$ is the well-known *Vlasov dielectric function*,[23] and Eq. (99) is trivial to solve; it implies that $a_{k,\omega_i}=0$ except for all the choices of k and ω_i that satisfy the *Vlasov dispersion relation*

$$\mathcal{D}_0(k,\omega_i)=0. \tag{101}$$

In general the linear operator in Eq. (95) is determined by $\mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha^0)$ through Eq. (92), and $\mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha^0)$ in turn is determined solely by the initial condition and the transient field T_0 via the distribution function $f_\alpha^{T_0}$ at the a.v.a.s. However, $f_\alpha^{T_0}$ generally will not be a simple Vlasov equilibrium because the transient T_0 is nonzero and affects the distribution function. Unfortunately, it is very difficult to solve exactly both the nonlinear Ampère equation for T_0, Eq. (74), and the Vlasov equation for $f_\alpha^{T_0}$, Eq. (24). However, it is possible, without doing this, to obtain important results on the asymptotic linear operator by exploiting the general properties of particle motion in a transient field. If we define a Vlasov equilibrium $F_\alpha^{T_0}$ according to Eq. (66), Eq. (65) shows that this $F_\alpha^{T_0}$ yields the same values for macroscopic quantities as the distribution functions $f_\alpha^{T_0}$ in the time asymptotic limit. We now raise the question of whether these Vlasov equilibria $F_\alpha^{T_0}$ yield the same values as $f_\alpha^{T_0}$ for the integrals in Eqs. (89) and (91) and therefore the same linearized operator $\mathcal{L}_{k,\omega_i}$. In fact, we have the following result:

Theorem 5: *At a given critical a.v.a.s. η_0,*

$$\mathcal{L}_{k,\omega_i}(T_0,F_\alpha,h_\alpha)A=[1-\mathcal{D}(k,\omega_i)]a_{k,\omega_i}, \tag{102}$$

where

$$\mathcal{D}(k,\omega_i)\equiv 1-\frac{4\pi}{k}\sum_\alpha \frac{q_\alpha^2}{m_\alpha}P\int_{\mathbb{R}}dv\,\frac{F_\alpha^{T_0\prime}(v)}{\omega_i+kv} \tag{103}$$

for $k\neq 0$ and $\mathcal{D}(0,\omega_i)\equiv 1-\omega_p^2(T_0)/\omega_i^2$ (for $k=0$). Here $F_\alpha^{T_0\prime}$ is the velocity derivative of the time-asymptotic Vlasov equilibrium defined in Eq. (66) and $\omega_p^2(T_0)$ is the corresponding plasma frequency.

Proof: We shall consider the case $k\neq 0$; the case $k=0$ is straightforward. After substituting Eq. (60) into Eq. (92) and explicitly writing out the expression for $\mathcal{E}^{(k,\omega_i)}$, Eq. (89), we can change the order of the limits $\sigma\to\infty$ and $n\to\infty$ according to Lemma 1. Then the term containing the functions $g_\alpha^{T_0}$ vanishes by Fréchet's Lemma[16] and we are left with

$$\frac{4\pi}{k}\sum_\alpha \frac{q_\alpha^2}{m_\alpha}\lim_{n\to\infty}\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma dt\,\frac{1}{2\pi}\int_{-\pi}^{+\pi}dx\; e^{-i\omega_i t-ikx}A(x,t)\int_{\Omega_{n,i}^c}dv\,\frac{\frac{\partial}{\partial v}[\mathcal{F}_\alpha^{T_0}(x-vt,v)]}{\omega_i+kv}. \tag{104}$$

By applying the convolution theorem to the integral in *dx* this becomes

$$\frac{4\pi}{k}\sum_\alpha \frac{q_\alpha^2}{m_\alpha}\lim_{n\to\infty}\lim_{\sigma\to\infty}\frac{1}{\sigma}\int_0^\sigma dt e^{-i\omega_i t}\sum_{k'}A_{k-k'}(t)\int_{\Omega_{n,i}^c}dv\,\frac{\frac{\partial}{\partial v}[\mathcal{F}_{\alpha,k'}^{T_0}(v)e^{-ik'vt}]}{\omega_i+kv}. \tag{105}$$

It can be easily seen that the term corresponding to $k'=0$ gives Eq. (102). Hence, it will be enough to show that all the terms with $k'\neq 0$ are equal to zero in order to establish the result. An integration by parts gives

$$\int_{\Omega_{n,i}^c} dv \frac{\frac{\partial}{\partial v}[\mathcal{F}_{\alpha,k'}^{T_0}(v)e^{-ik'vt}]}{\omega_i+kv} = k\int_{\Omega_{n,i}^c} dv \frac{\mathcal{F}_{\alpha,k'}^{T_0}(v)e^{-ik'vt}}{(\omega_i+kv)^2} - \frac{1}{r_n}\left[\mathcal{F}_{\alpha,k'}^{T_0}\left(-\frac{\omega_i}{k}-r_n\right)e^{i((k'/k)\omega_i+k'r_n)t} + \mathcal{F}_{\alpha,k'}^{T_0}\left(-\frac{\omega_i}{k}+r_n\right)e^{i((k'/k)\omega_i-k'r_n)t}\right]. \tag{106}$$

Now, the first term on the right-hand side vanishes in the time-asymptotic limit by the Riemann–Lebesgue Lemma. When the other terms are substituted into Eq. (105), they generate quantities proportional to the Fourier–Bohr coefficients $a_{k-k',\tilde{\omega}_i}$, where $\tilde{\omega}_i \equiv -(1-(k'/k))\omega_i \pm k'r_n$. Since A is almost periodic, all these coefficients will be equal to zero except those corresponding to some very special choices of the radii r_n such that $\tilde{\omega}_i$ belongs to the countable set of nonzero frequencies of A. However, since the set of these ''bad radii'' has zero measure in $\mathbb{R}$, we can always pick the sequence r_n (when introducing the family of spheres in Eq. (78)) in such a way that $a_{k-k',\tilde{\omega}_i}=0\,\forall n$; thus, the limit for $n\to\infty$ in Eq. (105) also will be zero, which proves the assertion. □

The conclusion of this analysis is that the operator $(I-L)$ can be written component-wise as

$$(I-L)\mathbf{a} \equiv \{a_{k,\omega_i}\mathcal{D}(k,\omega_i)\}. \tag{107}$$

Exploiting the regularity and integrability of $F_\alpha^{T_0}$, it is easy to see that the function $\mathcal{D}(k,\omega_i)$ is bounded, i.e., there is a constant $\hat{M}$ such that

$$|\mathcal{D}(k,\omega_i)| \leqslant \hat{M}. \tag{108}$$

This implies that $I-L$ maps l_b into l_b and is continuous, since

$$\sum_{k,\omega_i} |a_{k,\omega_i}\mathcal{D}(k,\omega_i)|^2 \leqslant \hat{M}^2 \sum_{k,\omega_i} |a_{k,\omega_i}|^2 < \infty \tag{109}$$

and

$$\|(I-L)\mathbf{a}\| = \sup_{k,\omega_i} |a_{k,\omega_i}\mathcal{D}(k,\omega_i)| \leqslant \hat{M}\|\mathbf{a}\|. \tag{110}$$

The null space of $I-L$ consists of those sequences whose only nonzero entries correspond to pairs of real indexes (k,ω_i) that satisfy the *time-asymptotic Vlasov dispersion relation*

$$\mathcal{D}(k,\omega_i)=0 \tag{111}$$

which is determined by the asymptotic Vlasov equilibria $F_\alpha^{T_0}$ corresponding to the transient field T_0 at the critical a.v.a.s. under consideration.

It is important to note that in most physically relevant situations there is only a *finite* number N of such pairs. In these cases the linear operator $I-L$ has a finite-dimensional null space $\mathcal{K} \equiv \mathrm{Ker}(I-L)$, with $\dim(\mathcal{K})=N$, and $I-L$ is a *Fredholm operator*. A good example is given by the Vlasov dispersion curve for the Maxwellian (Fig. 1), whose features are quite representative of what one encounters in most applications. There is a *cutoff wave number* k_d such that for $k>k_d$ Eq. (111) has no solution at all; hence, given any wave number $k \leqslant k_d$, Eq. (111) has a finite number N_k of simple real roots $\lambda_1(k)$, $\lambda_2(k)\cdots\lambda_{N_k}(k)$. Since the basic wave number is $k=1$, there will be $\varrho=[k_d]$ admissible wave numbers before cutoff, for a total of $N=\Sigma_{k=1}^{\varrho}N_k$ possible modes.

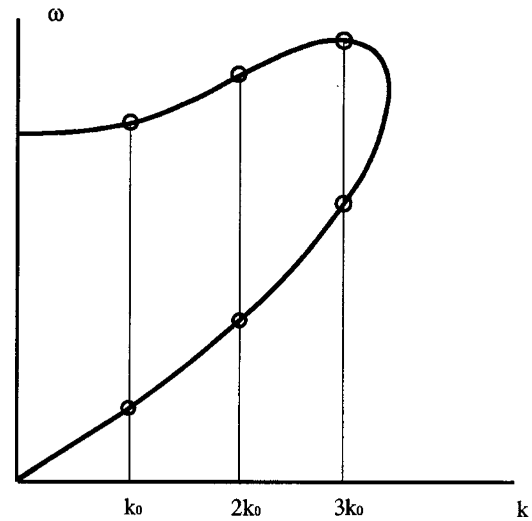

FIG. 1. The Vlasov dispersion curve for a Maxwellian $e-p$ plasma with $T_e = T_p$, and the roots $\omega(k)$ of the corresponding dispersion relation for a basic wave number k_0 and its harmonics; k is in units of the inverse Debye length $k_D \equiv 1/\lambda_D$ and ω is in units of the plasma frequency ω_p.

VII. TIME-ASYMPTOTIC FIELD SOLUTION

Now that we have carried out the analysis of the linearized time-asymptotic problem, we are ready for our final step, which is simply to show that the solution to the linearized problem provides (as should be expected) a leading order solution for A to the *nonlinear* time-asymptotic equation, Eq. (22a). Since the Fréchet derivative at the a.v.a.s. has a nontrivial null-space and is not invertible, the simplest thing to do is to apply the classical method of analysis known as the Alternative Method.[24] To do this, we decompose the space l_b into the direct sum of $\mathcal{K}$ and its complement $\mathcal{H}$. From Eq. (107) it follows immediately that $Rg(I-L) = [\text{Ker}(I-L)]^{\perp} = \mathcal{H}$. Let us consider the two projectors $Q_{\mathcal{K}}$ and $Q_{\mathcal{H}}$ associated, respectively, with $\mathcal{K}$ and $\mathcal{H}$. $Q_{\mathcal{K}}$ is the operator that starts from any element of l_b and annihilates all the entries except for those that have one of the N pairs of indexes that satisfy the Vlasov dispersion relation. Conversely, $Q_{\mathcal{H}}$ cancels only the entries that have such indexes. Let us define $\Psi \equiv Q_{\mathcal{K}} a$ and $\Phi \equiv Q_{\mathcal{H}} a$, so that $a = \Psi + \Phi$. Then, a standard procedure[24] leads from Eq. (94) to the two equations,

$$Q_{\mathcal{K}} M(\Psi + \Phi) = 0, \tag{112}$$

$$(I-L)\Phi = Q_{\mathcal{H}} M(\Psi + \Phi). \tag{113}$$

In the language of bifurcation theory, Eq. (112) is the *bifurcation equation*, while Eq. (113) is the *auxiliary equation*. It is easy to verify that when the operator $I-L$ is restricted to the subspace $\mathcal{H}$, it is invertible; from Eq. (107) it follows immediately that given $\mathbf{b} \in \mathcal{H}$,

$$(I-L)^{-1}\mathbf{b} = \left\{ \frac{b_{k,\omega_i}}{\mathcal{D}(k,\omega_i)} \right\}, \tag{114}$$

where $\mathcal{D}(k,\omega_i) \neq 0 \quad \forall b_{k,\omega_i}$ since $\mathbf{b} \in \mathcal{H}$. Then, the auxiliary equation, Eq. (113) can be written as a fixed point problem for Φ,

$$\Phi = (I-L)^{-1} Q_{\mathcal{H}} M(\Psi + \Phi). \tag{115}$$

Here, we are not interested in a detailed fixed point analysis of this equation, since we have been assuming from the beginning that an asymptotically almost periodic solution to the VPA problem does exist. In fact, the existence and uniqueness of the solution for A implies that the solutions for Φ and Ψ must also exist and be unique. What is important is that Eqs. (112) and (115) enable us to write the general form of the nonlinear solution for the time-asymptotic field A, as expressed in the following theorem:

Theorem 6: *Let $\eta \in \mathcal{AP}\times\mathcal{T}\times\mathcal{S}$ be a critical a.v.a.s., and let $\mathcal{E}^{(k,\omega_i)}(E,F_\alpha,h_\alpha)$ be continuous in E at η. Then, the general solution to the time-asymptotic equation, Eq. (22a), in a neighborhood of η in $\mathcal{AP}\times\mathcal{T}\times\mathcal{S}$ is given by*

$$A(x,t)=\sum_{k,\omega_i}\psi_{k,\omega_i}e^{ikx+i\omega_i t}+o(\|A\|), \tag{116}$$

where k and ω_i satisfy the time-asymptotic Vlasov dispersion relation, Eq. (111), and the amplitudes ψ_{k,ω_i} satisfy the bifurcation equation

$$Q_{\mathcal{K}}M(\Psi+\Phi(\Psi))=0, \tag{117}$$

where $\Phi(\Psi)=o(\|A\|)$ is determined by the auxiliary equation, Eq. (115).

Proof: In the light of the previous results, the proof reduces to establishing Eq. (116). For any pair (k,ω_i) such that $\mathcal{D}(k,\omega_i)\neq 0$, Eq. (115) gives

$$\phi_{k,\omega_i}=[\mathcal{D}(k,\omega_i)]^{-1}\mathcal{M}_{k,\omega_i}(A+T_0,F_\alpha,h_\alpha), \tag{118}$$

where

$$\mathcal{M}_{k,\omega_i}(A+T_0,F_\alpha,h_\alpha)=\mathcal{N}_{k,\omega_i}(A+T_0,F_\alpha,h_\alpha)-\mathcal{L}_{k,\omega_i}(T_0,F_\alpha,h_\alpha)A. \tag{119}$$

$\mathcal{M}_{k,\omega_i}(A+T_0,F_\alpha,h_\alpha)$ coincides with the expression on the first line in Eq. (93) (since $\mathcal{N}_{k,\omega_i}(T_0,F_\alpha,h_\alpha)=0$ at the a.v.a.s.) and

$$\begin{aligned}|\phi_{k,\omega_i}|&\leqslant|\mathcal{D}(k,\omega_i)^{-1}||\mathcal{M}_{k,\omega_i}(A+T_0,F_\alpha,h_\alpha)|\\&\leqslant|\mathcal{D}(k,\omega_i)^{-1}|\|A\|\|\mathcal{E}^{(k,\omega_i)}(T_0+A,F_\alpha,h_\alpha)-\mathcal{E}^{(k,\omega_i)}(T_0,F_\alpha,h_\alpha)\|=o(\|A\|).\end{aligned} \tag{120}$$

The decomposition $\mathbf{a}=\Psi+\Phi$ corresponds to the decomposition of the time-asymptotic field A in the form

$$A(x,t)=A_{\mathcal{K}}(x,t)+A_{\mathcal{H}}(x,t), \tag{121}$$

where

$$A_{\mathcal{K}}(x,t)\sim\sum_{k,\omega_i}\psi_{k,\omega_i}e^{ikx+i\omega_i t},\quad A_{\mathcal{H}}(x,t)\sim\sum_{k,\omega_i}\phi_{k,\omega_i}e^{ikx+i\omega_i t}. \tag{122}$$

Since these Fourier–Bohr series can be summed *uniformly* (e.g., via the Fejer–Bochner summation method) Eq. (120) implies that

$$\|A_{\mathcal{H}}\|=o(\|A\|) \tag{123}$$

and Eq. (116) follows immediately. □

As previously mentioned, in most cases of physical interest $\mathcal{K}$ is *finite-dimensional*, so that Eq. (117) reduces to a finite system of N nonlinear algebraic equations for the amplitudes ψ_{k,ω_i}.

VIII. CONCLUSION

The general solution for a small-amplitude time-asymptotic electric field near a critical a.v.a.s. is given by Eq. (116) as a superposition of undamped traveling-wave modes, whose frequencies and wave numbers satisfy the time-asymptotic Vlasov dispersion relation, Eq. (111). Remarkably, this result holds regardless of the details of the transient field T. Of course, T determines the time-asymptotic Vlasov equilibrium $F_\alpha^{T_0}$, and also the amplitudes a_{k,ω_i} via the nonlinear operator M in Eqs. (115) and (117). In this sense, the results reported here represent the first step in the study of the initial value problem for the VPA system near a critical a.v.a.s.; a complete quantitative analysis requires the study of the transient equation, Eq. (22b), and then of the bifurcation equation, Eq. (117). An example of how this can be done has recently been given by the authors in Ref. 20 (see also Ref. 14) where they derived an approximate solution for f_α from a ''transiently linearized'' Vlasov equation. That equation was solved analytically by applying Hamiltonian perturbation theory in order to determine the characteristics associated with a time-asymptotic field A of the form given by Eq. (116). Here, however, we have developed a much more general framework for the rigorous analysis of the long-time behavior of waves propagating in plasmas. This framework relies on two essential results of the analysis we have reported.

First, the fact that critical points for the VPA initial value problem are bifurcation points for the time-asymptotic equation opens an interesting new perspective on the study of nonlinear Landau damping, and in particular on the transition between initial conditions that Landau damp to a zero electric field and those that lead to a nonzero time-asymptotic field.[20]

Second, the determination of the time-asymptotic linearized operator $\mathcal{L}_{k,\omega_i}$ provides a new and more solid foundation for the nonlinear analysis of the VPA system. By computing the Fourier–Bohr coefficients $\mathcal{N}_{k,\omega_i}$ in the form of Eq. (88), we have been able, in effect, to take the limit $t \to \infty$ *before* linearizing the nonlinear Ampère equation. As a consequence, we have obtained a linear approximation to the time-asymptotic VPA problem which is very different from the traditional linear theory[6,25,26] and which is uniformly valid in the time-asymptotic limit. Indeed, the linearization is not about an initial unperturbed Vlasov equilibrium F_α, but about the *time-asymptotic* Vlasov equilibrium $F_\alpha^{T_0}$, that incorporates the cumulative effects of the transient field T_0. It is very significant that the corresponding *nonlinear* solution for the time-asymptotic electric field, Eq. (115), is formally so similar (especially in terms of the Vlasov dispersion relation) to the multiple-wave BGK-type nonlinear solutions[12] which have been traditionally regarded as the natural candidates to describe long-time plasma-wave propagation.

Conformal behavior of the Lorentz–Dirac equation and Machian particle dynamics

Sebastiano Sonego[a)]

and International School for Advanced Studies, Via Beirut 2-4, 34014 Trieste, Italy

(Received 25 November 1998; accepted for publication 5 March 1999)

It is shown that the self-interaction force on a pointlike electric charge in curved space-time has conformal weight -1. Motivated by this result, a conformally covariant version of the Lorentz–Dirac equation is presented, where the particle mass is treated as a position- and time-dependent quantity. This feature suggests that the underlying dynamics is Machian. © *1999 American Institute of Physics.* [S0022-2488(99)04607-1]

I. INTRODUCTION

Let us consider a point particle with electric charge e, tracing out a world line $x^\mu(\tau)$ in a four-dimensional space–time $(\mathcal{M},g_{ab})$, where τ is the particle proper time.[1] It is known, from the classic analysis of DeWitt–Brehme–Hobbs,[2,3] that the particle experiences an electromagnetic self-interaction force

$$F_a=\tfrac{2}{3}e^2d_a+\tfrac{1}{3}e^2k_a{}^bR_{bc}v^c+e^2v^b\int_{-\infty}^{\tau}\mathrm{d}\tau'\ f_{aba'}v^{a'}. \tag{1.1}$$

In this equation v^a is the four-velocity of the particle, the one-form d_a is defined as

$$d_a:=\ddot{v}_a-v_a\dot{v}_b\dot{v}^b, \tag{1.2}$$

where $(\cdots)^\bullet:=v^a\nabla_a(\cdots)$, $k_a{}^b=\delta_a{}^b+v_av^b$ is the projector onto the three-space orthogonal to v^a, R_{ab} is the Ricci tensor, and $f_{aba'}$ is a bi-tensor associated with the presence of ''tails'' in the electromagnetic field.[2,4] Thus, there are three contributions to F_a: One, the so-called von Laue force, is proportional to d_a and represents a simple covariant generalization of the usual force

$$\mathbf{F}=\tfrac{2}{3}e^2\ddot{\mathbf{v}} \tag{1.3}$$

due to the self-field of the charge.[5–7] The second term was discovered by Hobbs[3] and has no counterpart in special relativity, being proportional to the Ricci curvature of space–time. Remarkably, the Hobbs force is not associated with the acceleration $\dot{v}^a$ and vanishes in vacuum, if Einstein's field equation $G_{ab}=\kappa T_{ab}$ is assumed to hold. Finally, we have a third term that depends on the entire past history of the particle and on the property of waves of being backscattered by the space–time curvature,[2,4] summarized by the quantity $f_{aba'}$. This contribution is usually very small.[8]

The behavior of the von Laue term under a conformal transformation[9]

$$g_{ab}\rightarrow\tilde{g}_{ab}=\mathrm{e}^{-2\Phi}g_{ab} \tag{1.4}$$

has been investigated by Fulton, Rohrlich, and Witten.[10] They found that d_a changes in a rather messy way. This result seems to suggest that there is no simple conformally covariant generalization of the Lorentz–Dirac equation. In Sec. II of the present paper it is shown that, taking into

[a)]Electronic mail: sebastiano.sonego@dic.uniud.it account the Hobbs term, the ''bad behavior'' of d_a under a conformal transformation is neutralized by counterterms coming from the Ricci tensor, so that F_a transforms into $\tilde{F}_a = e^{\Phi} F_a$, i.e., F_a has conformal weight -1 (see Ref. 11, p. 447, for the definition of conformal weight). This conclusion makes the existence of a conformally covariant version of the Lorentz–Dirac equation much more plausible, because the self-interaction force no longer causes any problem, and the only obstruction is due to the presence of the particle mass in the equation of motion. This difficulty is circumvented in Sec. III by allowing the possibility that mass is position dependent. Finally, the implications of such an hypothesis on the formulation of a Machian dynamics, and the possibility that general relativity corresponds only to a particular gauge choice in a wider conformally covariant theory, are discussed in Sec. IV.

II. TRANSFORMATION OF THE SELF-INTERACTION FORCE

Let us treat separately the local contributions—the von Laue and Hobbs forces—and the nonlocal tail term.

A. Local terms

First of all, let us express the acceleration $a_a := v^b \nabla_b v_a$ in $(\mathcal{M}, g_{ab})$ in terms of the corresponding one $\tilde{a}_a = \tilde{v}^b \tilde{\nabla}_b \tilde{v}_a$ in $(\mathcal{M}, \tilde{g}_{ab})$. Requiring that $g_{ab} v^a v^b = \tilde{g}_{ab} \tilde{v}^a \tilde{v}^b = -1$, it must be $\tilde{v}^a = e^{\Phi} v^a$. Remembering that, for a generic X_a,

$$\tilde{\nabla}_b X_a = \nabla_b X_a - C^c{}_{ba} X_c, \tag{2.1}$$

where

$$C^c{}_{ba} = g_{ba} g^{cd} \nabla_d \Phi - \delta^c{}_b \nabla_a \Phi - \delta^c{}_a \nabla_b \Phi \tag{2.2}$$

(see Ref. 11, pp. 445–446), one obtains by straightforward calculations

$$\tilde{a}_a = a_a - k_a{}^b \nabla_b \Phi. \tag{2.3}$$

Next, let us compute $\ddot{v}_a$:

$$\ddot{v}_a = v^c \nabla_c a_a = v^c \nabla_c (k_a{}^b \nabla_b \Phi) + v^c \nabla_c \tilde{a}_a. \tag{2.4}$$

The two terms on the right-hand side of Eq. (2.4) are, separately,

$$\begin{aligned} v^c \nabla_c (k_a{}^b \nabla_b \Phi) &= k_a{}^b v^c \nabla_c \nabla_b \Phi + a_a v^b \nabla_b \Phi + v_a a^b \nabla_b \Phi \\ &= k_a{}^b v^c \nabla_c \nabla_b \Phi + k_a{}^c \nabla_c \Phi v^b \nabla_b \Phi \\ &\quad + v_a k^{bc} \nabla_b \Phi \nabla_c \Phi + \tilde{a}_a v^b \nabla_b \Phi + e^{-\Phi} \tilde{v}_a \tilde{a}^b \nabla_b \Phi \end{aligned} \tag{2.5}$$

and

$$v^c \nabla_c \tilde{a}_a = e^{-\Phi} \tilde{v}^b \tilde{\nabla}_b \tilde{a}_a + e^{-\Phi} \tilde{v}_a \tilde{a}^b \nabla_b \Phi - v^b \nabla_b \Phi \tilde{a}_a, \tag{2.6}$$

where Eqs. (2.1)–(2.3) have been used. Furthermore,

$$a_b a^b = k^{bc} \nabla_b \Phi \nabla_c \Phi + 2 k^{bc} \nabla_c \Phi \tilde{a}_b + k^{bc} \tilde{a}_b \tilde{a}_c, \tag{2.7}$$

where we have used the property $v^a \tilde{a}_a = \tilde{v}^a \tilde{a}_a = 0$. Placing Eqs. (2.4)–(2.7) into the definition of d_a, Eq. (1.2), we get

$$d_a = e^{-\Phi} \tilde{d}_a + v^c k_a{}^b \nabla_c \nabla_b \Phi + k_a{}^c \nabla_c \Phi v^b \nabla_b \Phi. \tag{2.8}$$

Thus, the von Laue force does not change by a simple rescaling under a conformal transformation. However, let us now consider the Hobbs term. We have

$$R_{bc}=\tilde{R}_{bc}-2\nabla_b\nabla_c\Phi-g_{bc}g^{de}\nabla_d\nabla_e\Phi-2\nabla_b\Phi\nabla_c\Phi+2g_{bc}g^{de}\nabla_d\Phi\nabla_e\Phi \tag{2.9}$$

(see Ref. 11, p. 446), and consequently

$$\tfrac{1}{2}k_a{}^bR_{bc}v^c=\tfrac{1}{2}k_a{}^b\tilde{R}_{bc}v^c-k_a{}^b\nabla_b\nabla_c\Phi v^c-k_a{}^b\nabla_b\Phi v^c\nabla_c\Phi. \tag{2.10}$$

Combining Eqs. (2.8) and (2.10) we obtain finally

$$d_a+\tfrac{1}{2}k_a{}^bR_{bc}v^c=\mathrm{e}^{-\Phi}(\tilde{d}_a+\tfrac{1}{2}\tilde{k}_a{}^b\tilde{R}_{bc}\tilde{v}^c). \tag{2.11}$$

Therefore, under a conformal transformation the local part of F_a, i.e., the *sum* of the von Laue and Hobbs forces, is just rescaled.

B. Nonlocal term

Let us first remember that $f_{aba'}=\nabla_b v_{aa'}-\nabla_a v_{ba'}$, where $v_{aa'}$ is a bi-tensor satisfying the wave equation[2]

$$g^{bc}\nabla_b\nabla_c v_{aa'}-R_a{}^b v_{ba'}=0, \tag{2.12}$$

together with the Lorentz gauge condition $\nabla^a v_{aa'}=0$. Equation (2.12) can be regarded as a particular case of the field equation for the vector potential A_a,

$$g^{bc}\nabla_b\nabla_c A_a-R_a{}^bA_b-\nabla_a\nabla^bA_b=-4\pi J_a, \tag{2.13}$$

when there are no sources (i.e., $J_a=0$) and $\nabla^aA_a=0$. By an easy but tedious calculation one can check that Eq. (2.13) is conformally invariant, i.e., it holds in $(\mathcal{M},g_{ab})$ iff the corresponding equation

$$\tilde{g}^{bc}\tilde{\nabla}_b\tilde{\nabla}_cA_a-\tilde{R}_a{}^bA_b-\tilde{\nabla}_a\tilde{\nabla}^bA_b=-4\pi\tilde{J}_a \tag{2.14}$$

holds in $(\mathcal{M},\tilde{g}_{ab})$, provided that one defines $\tilde{J}_a:=\mathrm{e}^{2\Phi}J_a$.[12] (This is, of course, related to the conformal invariance of the Maxwell equations for the electromagnetic field $F_{ab}=\nabla_aA_b-\nabla_bA_a$.[11,12]) For Eq. (2.12), then, one has that

$$\tilde{g}^{bc}\tilde{\nabla}_b\tilde{\nabla}_c v_{aa'}-\tilde{R}_a{}^b v_{ba'}-\tilde{\nabla}_a\tilde{\nabla}^b v_{ba'}=0 \tag{2.15}$$

and

$$\tilde{\nabla}^a v_{aa'}=-\tilde{g}^{bc}C^a{}_{bc}v_{aa'}=-2\tilde{\nabla}^a\Phi v_{aa'}. \tag{2.16}$$

Choosing $v_{aa'}=\tilde{v}_{aa'}+\nabla_a\Lambda_{a'}$, where $\Lambda_{a'}$ satisfies the condition

$$\tilde{g}^{ab}\tilde{\nabla}_a\tilde{\nabla}_b\Lambda_{a'}=-2\tilde{\nabla}^a\Phi v_{aa'}, \tag{2.17}$$

and replacing into Eq. (2.15), we find that

$$\tilde{g}^{bc}\tilde{\nabla}_b\tilde{\nabla}_c\tilde{v}_{aa'}-\tilde{R}_a{}^b\tilde{v}_{ba'}=0. \tag{2.18}$$

Since $\tilde{f}_{aba'}=\tilde{\nabla}_b\tilde{v}_{aa'}-\tilde{\nabla}_a\tilde{v}_{ba'}=f_{aba'}$, we have for the tail term,

$$e^2\tilde{v}^b\int_{-\infty}^{\tilde{\tau}}\mathrm{d}\tilde{\tau}'\,\tilde{f}_{aba'}\tilde{v}^{a'}=\mathrm{e}^{\Phi}e^2v^b\int_{-\infty}^{\tau}\mathrm{d}\tau'\,f_{aba'}v^{a'}, \tag{2.19}$$

where we have used the property $\mathrm{d}\tilde{\tau}=\mathrm{e}^{-\Phi}\,\mathrm{d}\tau$, which follows from (1.4).

III. CONFORMALLY COVARIANT LORENTZ–DIRAC EQUATION

Putting together Eqs. (2.11) and (2.19), one finds that $\tilde{F}_a=\mathrm{e}^{\Phi}F_a$. This result should not be surprising, because one can write $F_a=eF_{ab}^{(\mathrm{self})}v^b$, where $F_{ab}^{(\mathrm{self})}$ is the self-field of the particle evaluated at its position, after mass renormalization has been performed.[2] Since Maxwell equations are conformally covariant, one expects that $\tilde{F}_{ab}^{(\mathrm{self})}=F_{ab}^{(\mathrm{self})}$, so that $\tilde{F}_a=eF_{ab}^{(\mathrm{self})}\tilde{v}^b=\mathrm{e}^{\Phi}F_a$, as we have indeed just shown.

Far from representing a small general-relativistic effect, the Hobbs term is then conceptually very important, as it guarantees a ''good behavior'' of F_a under conformal transformations, which the von Laue term alone has not. In a conformally covariant perspective, it is improper to regard F_a as composed of three terms, because two of them mix under a conformal transformation. There are then just two contributions: The local one, given by the sum of the von Laue and the Hobbs forces, and the nonlocal integral.

In all the previous calculations it has been assumed that $\tilde{e}=e$. This hypothesis simultaneously guarantees the ''good behavior'' of the radiation reaction under conformal transformations, and the conformal covariance of the inhomogeneous Maxwell equation $\nabla^bF_{ba}=-4\pi J_a$. It seems to suggest a topological origin for charge (see, e.g., Ref. 13).

The properties of the Lorentz–Dirac equation[5,6]

$$ma_a=eF_{ab}v^b+F_a \tag{3.1}$$

under the conformal transformation (1.4) have been investigated in Ref. 10, where it was concluded that Eq. (3.1) is not conformally covariant, unless one rewrites it in terms of tensor densities. Our analysis suggests that such result, based on the exclusion of the Hobbs term, should be reconsidered. However, since

$$m\tilde{a}_a=-mk_a{}^b\nabla_b\Phi+\mathrm{e}^{-\Phi}(eF_{ab}\tilde{v}^b+\tilde{F}_a), \tag{3.2}$$

it seems that even taking into account the full expression of the radiation reaction, Eq. (3.1) still fails to be conformally covariant. This conclusion rests upon an implicit hypothesis, though—that the mass m do not change under a conformal transformation. If we drop this assumption,[10] and require instead that

$$\tilde{m}=\mathrm{e}^{\Phi}m, \tag{3.3}$$

then we must rewrite Eq. (3.2) in terms of the proper time derivative of momentum $\tilde{p}_a=\tilde{m}\tilde{v}_a$, namely,

$$\tilde{v}^b\tilde{\nabla}_b\tilde{p}_a=-\tilde{\nabla}_a\tilde{m}+eF_{ab}\tilde{v}^b+\tilde{F}_a, \tag{3.4}$$

where we have used the property $\tilde{k}_a{}^b=k_a{}^b$. Since, by Eq. (2.3),

$$\tilde{v}^b\tilde{\nabla}_b\tilde{p}_a+\tilde{\nabla}_a\tilde{m}=\mathrm{e}^{\Phi}(v^b\nabla_bp_a+\nabla_am), \tag{3.5}$$

we now have that the modified Lorentz–Dirac equation

$$v^b\nabla_bp_a=-\nabla_am+eF_{ab}v^b+F_a \tag{3.6}$$

is conformally covariant.

IV. DISCUSSION AND OUTLOOKS

The conformal covariance of Eq. (3.6) relies on the transformation law (3.3) for mass, that might seem odd at first sight. However, one may convincingly argue that Eq. (3.3) must be correct on heuristic grounds, assuming that at least part of the mass is of electromagnetic origin.[5–7] Of course, for a classical point charge the electromagnetic mass is actually divergent, but one can nevertheless express it formally as $m_{\rm em}=\lim_{\epsilon\to 0} e^2/2\epsilon$, where ϵ is the radius of a three-dimensional ball centered on the particle, measured in the comoving frame.[2] Then $\tilde{m}_{\rm em} =\lim_{\tilde{\epsilon}\to 0} e^2/2\tilde{\epsilon}={\rm e}^{\Phi} m_{\rm em}$, with Φ evaluated at the particle position. More generally, the energy density u of the electromagnetic field in any given reference frame transforms as $u\to\tilde{u}={\rm e}^{4\Phi}u$, as one can easily see from the expression $u=g^{ab}(E_aE_b+B_aB_b)/8\pi$, where E_a and B_a are the electric and magnetic fields, and recalling the transformation laws of E_a and B_a.[12] Since a three-dimensional volume element is rescaled by the factor ${\rm e}^{-3\Phi}$ under the conformal transformation (1.4), it follows that the mass–energy of the electromagnetic field contained into a small region changes according to Eq. (3.3). It is then natural to require that *any* mass, independent of its nature, transform in the same way. It should also be pointed out that the transformation law (3.3) guarantees that the Hamilton–Jacobi and Klein–Gordon equations for free massive particles are conformally covariant.[14]

The conformally covariant generalization (3.6) of the Lorentz–Dirac equation contains the force $-\nabla_a m$, which is however not observed in Nature. This problem is not as serious as it may look, because one can always ''gauge away'' such a term by a suitable choice of Φ. In order to have a better understanding of this point, let us consider a neutral particle (since the issue is clearly unrelated to the presence of a charge) with equation of motion

$$\tilde{v}^b\tilde{\nabla}_b\tilde{p}_a=-\tilde{\nabla}_a\tilde{m} \tag{4.1}$$

in the space–time $(\mathcal{M},\tilde{g}_{ab})$. If we choose Φ such that ${\rm e}^{-\Phi}\tilde{m}=$const we have, in a space–time $(\mathcal{M},g_{ab})$ with $g_{ab}={\rm e}^{2\Phi}\tilde{g}_{ab}$, that $g^{ab}p_ap_b=$const and $v^b\nabla_b p_a=0$, which is the usual description of a free neutral particle given by general relativity. The latter can thus be regarded as a particular gauge choice within a wider conformally covariant framework.

One can also take a different standpoint. Suppose that the geometry of space–time is $\tilde{g}_{ab}$ and that the particle mass $\tilde{m}$ is point dependent. A natural choice of units in which to express space and time measurements is then, e.g., $\tilde{L}=e^2/\tilde{m}c^2$ (the so-called classical radius of the particle) and $\tilde{T}=e^2/\tilde{m}c^3$, where c is the speed of light. Other choices will lead to the same dependence of $\tilde{L}$ and $\tilde{T}$ on $\tilde{m}$. But then, the *measured* space and time intervals will not agree with those computed on the basis of the metric $\tilde{g}_{ab}$, essentially because the units $\tilde{L}$ and $\tilde{T}$ are not constant with respect to $\tilde{g}_{ab}$, due to their dependence on $\tilde{m}$. However, one can introduce a *phenomenological* metric g_{ab}, which is so defined that the units $\tilde{L}$ and $\tilde{T}$ are constant with respect to it. Of course, such a metric is just $g_{ab}={\rm e}^{2\Phi}\tilde{g}_{ab}$, with en${}^{-\Phi}=$const$/\tilde{m}$. It is not hard to realize that this argument is completely general, in the sense that it can be extended to units based, e.g., on the atomic size and lifetimes, and can be used to argue that the metric adopted in general relativity might not have a fundamental status.[15]

The physical meaning of the force $-\tilde{\nabla}_a\tilde{m}$ in $(\mathcal{M},\tilde{g}_{ab})$ can be found by rewriting the equation of motion (4.1) in the equivalent form

$$\tilde{m}\tilde{a}_a=-k_a{}^b\tilde{\nabla}_b\tilde{m}. \tag{4.2}$$

In the Newtonian limit, Eq. (4.2) gives $\tilde{m}\tilde{\mathbf{a}}=-\tilde{\boldsymbol{\nabla}}(\tilde{m}c^2)$, which shows that one can identify $-\tilde{\nabla}_a\tilde{m}$ with a covariant generalization of the Newtonian gravitational force, and $\Phi=c^2\ln(\tilde{m}/{\rm const})$ with the corresponding gravitational potential. Remarkably, an equation like (3.3), with Φ the gravitational potential, was suggested by Nordström already in 1913, within the context of a conformally flat theory of gravity.[16] The present discussion highlights the fact that Einstein's choice of fully incorporating gravity into the metrical structure g_{ab} of space–time is only one among infinitely many possible ''gauges'' that are selected by fixing the conformal factor.

In the space–time $(\mathcal{M},\tilde{g}_{ab})$ gravity is identified with the effect of a position- and time-dependent inertia. Actually, one might well dispense with the notion of gravity, and think only in terms of a mass field. This point of view leads to some conceptual advantages. For example, it allows one to give a unified description of dynamics for massive and massless particles. Multiplying both sides of Eq. (4.1) by $\tilde{m}$ we obtain $\tilde{p}^b\tilde{\nabla}_b\tilde{p}_a=-\tilde{\nabla}_a(\tilde{m}^2/2)$. Thus, massive particles are affected by the force $-\tilde{\nabla}_a\tilde{m}$, while massless ones simply move on null geodesics. In the present context, gravity appears as just one manifestation of mass, therefore massless particles are not affected by it. Furthermore, since Φ depends on the distribution of matter (as we know from the Newtonian limit), so does $\tilde{m}$, because of Eq. (3.3). In other words, the inertia of a particle in $(\mathcal{M},\tilde{g}_{ab})$ depends on the arrangement of the other bodies; thus, particle dynamics in $(\mathcal{M},\tilde{g}_{ab})$ is Machian.[17] From the knowledge of the field equation for Φ and using Eq. (3.3), one could write down a field equation for $\tilde{m}$ (as, for example, in the Hoyle–Narlikar theory[18,19]), but this investigation is beyond the scope of the present article, so let us limit ourselves to a few qualitative remarks.

There are essentially two contributions to the mass $\tilde{m}$ of a particle. One is due to local matter, such as, e.g., a nearby planet or a star. This is usually very small—a fraction of the order of Φ/c^2 of the total mass—but, since matter is not distributed homogeneously, it leads to a position-dependent $\tilde{m}$ and is responsible for gravitational forces. The other comes from the large-scale distribution of matter in the universe, which gives a constant Φ (at least, constant over scales on which particle motion is usually analyzed) that has a much larger magnitude than the one due to local matter, because of the enormous number of sources. This accounts for a bulk, constant part of $\tilde{m}$—what is commonly meant by ''inertia'' of the particle. Thus, one would expect that the contribution to Φ/c^2 due to cosmological matter be of order 1, i.e., that $GM/Rc^2\sim 1$, where G, M, and R are Newton's gravitational constant, the mass, and the radius of the visible universe, the latter two quantities being defined as $M\sim\rho R^3$ and $R\sim c/H$, with ρ and H the values of the mean density and of the Hubble parameter, respectively. This relation, when rewritten as $G\rho/H^2\sim 1$, expresses essentially the so-called ''flatness problem,''[19] that seems therefore to find a natural explanation in a Machian framework.

ACKNOWLEDGMENTS

It is pleasure to thank Professor M. A. Abramowicz for hospitality at Chalmers University, Göteborg, where this work was completed, and an anonymous referee for suggesting some improvements in the presentation.

[1] Latin letters a, b,... are used as abstract indices (see, e.g., Ref. 11, pp. 24–25), which just indicate the tensorial nature of an object without requiring the specification of a coordinate system; greek letters μ, ν,... run from 0 to 3 and denote components in some chart. I choose +2 as signature of the metric and work in units in which $c=1$, except in the last section, where c will occasionally be reinserted for clarity. The conventions for the curvature tensors are those of Ref. 11; notice that R_{ab} then has the opposite sign than in Refs. 2 and 3.

We investigate the stability of the coupled soliton solutions of a two-component $Z(2)$ vector field model, in contraposition to similar solutions of a $Z(2)\times Z(2)$ model recently introduced. We demonstrate that the coupled soliton solutions of the $Z(2)$ model are classically unstable. © *1999 American Institute of Physics.* [S0022-2488(99)01107-X]

$Z(2)$ field theoretical models play a very important role in condensed matter physics. They have been used to describe a wide range of physical systems exhibiting phase transitions involving break of $Z(2)$ symmetry. Examples[1] of such systems are uniaxial antiferromagnets like Rb_2NiF_4 or K_2MnF_4, systems presenting order–disorder transitions on bipartite lattices like in β-brass, or liquid–gas transitions, etc. On the other hand, topological defects may be generated in phase transitions involving broken symmetry. They are low-energy, spatially localized, solutions of the field equations, which are topologically stable. They are of fundamental importance for a variety of physical phenomena in the systems where they appear. As an example of their importance, we mention the quasi-one-dimensional organic system *trans*-polyacetylene. The relevant topological defect here, the soliton, is responsible for a tremendous increase in the conductivity to almost metallic levels of this insulator when charged solitons are introduced by doping.[2]

In this work we are interested in double soliton solutions for coupled scalar fields in two-dimensional space–time. Such solutions have been recently investigated in a class of systems defined by a very specific potential.[3–5] These works have shown that there are solutions of the second order equations of motion that are also solutions of some first order differential equations. Also, the important issue of the stability of the soliton solutions has been addressed.[4] It was found that the soliton solutions of those systems, if they exist, are intrinsically stable when they also satisfy the first order equations. This is also important for condensed matter systems. For instance, there is evidence that solitons in coupled scalar field theories may be important to describe ferroelectric crystals[5] and hydrogen-bonded chains.[6] And it is known that stable solutions play relevant role at the quantum level.

Other issues concerning stability of the soliton solutions for coupled scalar fields have recently been considered in Ref. 7, for the class of systems introduced in Refs. 3–5. As we know, however, in the past a $Z(2)$ coupled scalar field model was shown to present very similar coupled soliton solutions.[8] Furthermore, the motivations presented in that work are closely related to the basic motivations introduced in more recent work.[3–5] For this reason, because that $Z(2)$ model and its soliton solutions are closely related to the models introduced in Refs. 3–5, it seems important to investigate the classical or linear stability of the soliton solutions found in Ref. 8 in order to identify possible distinctions in these two approaches. This is our main motivation, and here we present a detailed analysis of the stability of the coupled soliton solitons found in Ref. 8. Although the problem seems to be hard to handle, here we offer a simple and general way of investigating the issue of stability. Unfortunately, however, we conclude that the solutions found in Ref. 8 are always unstable.

We start with the Lagrangian density[8]

$$\mathcal{L}=\tfrac{1}{2}\partial_\alpha\phi\partial^\alpha\phi+\tfrac{1}{2}\partial_\alpha\chi\partial^\alpha\chi-U(\phi,\chi), \tag{1}$$

where the potential is

$$U(\phi,\chi)=\lambda\phi^4+\lambda\chi^4+2\lambda\phi^2\chi^2-(\mu+\nu)\phi^2-(\mu-\nu)\chi^2-\gamma. \tag{2}$$

The gradient of the potential with respect to the fields is given by

$$\nabla_{\phi,\chi}U=\begin{pmatrix}-2(\mu+\nu)\phi+4\lambda\phi\chi^2+4\lambda\phi^3\\ -2(\mu-\nu)\chi+4\lambda\phi^2\chi+4\lambda\chi^3\end{pmatrix}. \tag{3}$$

The potential has stationary points at $(\phi,\chi)=(\pm\sqrt{(\mu+\nu)/2\lambda},0)$. These points are (nondegenerate) minima when the Hessian of the potential is definite positive. The Hessian is given by

$$\text{Hess}\,U=\begin{pmatrix}12\lambda\phi^2+4\lambda\chi^2-2(\mu+\nu) & 8\lambda\phi\chi\\ 8\lambda\phi\chi & 12\lambda\chi^2+4\lambda\phi^2-2(\mu-\nu)\end{pmatrix}. \tag{4}$$

Substituting the value of the stationary points, we see that

$$\text{Hess}\,U=\begin{pmatrix}4(\mu+\nu) & 0\\ 0 & 4\nu\end{pmatrix}. \tag{5}$$

Thus, in order for the stationary points above to be minima of the potential, we require

$$\nu>0,\quad \mu>-\nu. \tag{6}$$

The equations of motion corresponding to the Lagrangian are obtained as the Euler–Lagrange equations of the functional $\int\mathcal{L}$. We are looking for static soliton solutions, and may thus neglect time. The functional becomes

$$E_c[\phi,\chi]=\int dx\left\{\frac{1}{2}\left(\frac{\partial\phi}{\partial x}\right)^2+\frac{1}{2}\left(\frac{\partial\chi}{\partial x}\right)^2+U(\phi,\chi)\right\}. \tag{7}$$

The Euler–Lagrange equations are [we write Δ_x for (d^2/dx^2)]

$$-\Delta_x\begin{pmatrix}\phi\\ \chi\end{pmatrix}-\nabla_{\phi,\chi}U=0. \tag{8}$$

The soliton solutions connect the two minima of the potential at $(\phi,\chi)=(\pm\sqrt{(\mu+\nu)/2\lambda},0)$. There are two sets of static soliton solutions,

$$\bar{\phi}=\pm\sqrt{\frac{\mu+\nu}{2\lambda}}\tanh\sqrt{\mu+\nu}\,x, \tag{9}$$

$$\bar{\chi}=0, \tag{10}$$

which together with Eq. (6) requires that

$$\nu>0,\quad \mu+\nu>0,\quad \lambda>0. \tag{11}$$

The second set of solutions is given by

$$\overline{\phi} = \pm \sqrt{\frac{\mu+\nu}{2\lambda}} \tanh \sqrt{4\nu} x, \tag{12}$$

$$\overline{\chi} = \pm \sqrt{\frac{\mu-3\nu}{2\lambda}} \operatorname{sech} \sqrt{4\nu} x, \tag{13}$$

implying in this case [with Eq. (6)]

$$\nu > 0, \quad \lambda > 0, \quad \mu - 3\nu > 0. \tag{14}$$

The first pair of solutions can be investigated easily. The calculations follow the same steps already introduced in Ref. 3 for the related pair of solutions. Therefore, here we will focus attention on the stability analysis of the coupled solitons of the second solution set.

Classical stability may be discussed in the following way: If we are to have stable solitons, the second variation of $E_c[\phi,\chi]$ evaluated at the solution should be a positive differential operator. We obtain thus

$$\mathrm{Hess}(E_c[\phi,\chi]) = \begin{pmatrix} -\Delta_x & 0 \\ 0 & -\Delta_x \end{pmatrix} + \mathrm{Hess}\, U, \tag{15}$$

as can be most easily seen from Eq. (8) and noting that Δ is linear. We will call this operator $\hat{S}$. Its lowest eigenvalue will be denoted by $E_0(\mu,\nu,\lambda)$. We will show that

$$E_0(\mu,\nu,\lambda) < 0. \tag{16}$$

This way we establish that the soliton solutions are always unstable.

For the second solution pair we get the Hessian,

$$\mathrm{Hess}(E_c[\phi,\chi]) = \begin{pmatrix} 12\lambda \overline{\phi}^2 + 4\lambda \overline{\chi}^2 - 2(\mu+\nu) & 8\lambda \overline{\phi}\,\overline{\chi} \\ 8\lambda \overline{\phi}\,\overline{\chi} & 12\lambda \overline{\chi}^2 + 4\lambda \overline{\phi}^2 - 2(\mu-\nu) \end{pmatrix}. \tag{17}$$

In order to decouple the corresponding eigenvalue equations we need to diagonalize the above matrix. After some algebra we find for its eigenvalues

$$\begin{aligned} V_{\pm} &= 2\mu - 12\nu + 16\nu f \pm 2\sqrt{16\nu^2 f^2 + 4\nu(\mu-5\nu) f + (\mu-2\nu)^2} \\ &= 2\nu\{\delta - 6 + 8f \pm \sqrt{16 f^2 + 4(\delta-5) f + (\delta-2)^2}\}, \end{aligned} \tag{18}$$

where $f = f(x)$ stands for $\tanh^2(\sqrt{4\nu x})$ and $\delta = \mu/\nu$. Notice that $f(x)$ varies in [0,1), and $\nu > 0$ and $\delta > 3$ are parameters [see Eq. (14)]. The operator $\hat{S}$ is now

$$\hat{S} = \begin{pmatrix} -\Delta_x + V_+ & 0 \\ 0 & -\Delta_x + V_- \end{pmatrix}. \tag{19}$$

Notice that $V_{\pm}$ now only depends on δ and ν. To eliminate the dependence on ν, write

$$V_{\pm}(x) = 4\nu U_{\pm}(\sqrt{4\nu} x),$$

and in the operator substitute $x = y/\sqrt{4\nu}$. It is easy to see that $\hat{S}$ now becomes

$$\hat{S} = 4\nu \begin{pmatrix} -\Delta_y + U_+(y) & 0 \\ 0 & -\Delta_y + U_-(y) \end{pmatrix}. \tag{20}$$

Now restrict attention to U_- and drop the subscript. We write

$$U_\delta = \tfrac{1}{2}\delta - 3 + 4f - \tfrac{1}{2}\sqrt{16f^2 + 4(\delta-5)f + (\delta-2)^2}, \tag{21}$$

where $f = \tanh^2(y)$ and $\delta > 3$.

We wish to derive an upper estimate for the lowest eigenvalue of the equation

$$(-\Delta_y + U_\delta(y))\psi(y) = \epsilon(\delta)\psi(y). \tag{22}$$

Notice that $U_\delta(-\infty) = U_\delta(\infty) = 1$ and that U_δ is well-shaped. It is known that in the one-dimensional case there is *always* at least a bound eigenstate.[9] That is, there is an eigenfunction ψ with associated eigenvalue less than 1, and with the property that $\int \psi^* \psi dy = 1$. Our estimate relies on the following observation. Let U_1 and U_2 be two potentials as above, but with the property that for all y: $U_1(y) \leqslant U_2(y)$. The associated eigenvalues, λ_1 and λ_2 then satisfy the same relation, $\lambda_1 \leqslant \lambda_2$.

For $\delta > 3$, the potential $U_\delta(y)$ is a (weakly) decreasing function of δ,

$$\frac{\partial U_\delta}{\partial \delta} \leqslant 0.$$

It then follows that if we denote by λ_δ the lowest eigenvalue associated with U_δ,

$$\lambda_\delta \leqslant \lambda_3, \tag{23}$$

where λ_3 stands for the case $\delta = 3$. It is an easy calculation to show that

$$U_3(y) = 1 - \frac{2}{\cosh^2(y)}. \tag{24}$$

The corresponding eigenvalue equation

$$(-\Delta_y + U_3(y))\psi(y) = \epsilon(3)\psi(y) \tag{25}$$

is easily solvable (see Refs. 3 and 10). The calculations lead to only one bound state at $\epsilon_0(3) = 0$ and a continuous spectrum $\epsilon_c(3) > 1$. Therefore $\lambda_3 = 0$ and by (23)

$$\lambda_\delta < 0. \tag{26}$$

In fact, we can show that we have here a strict inequality. Notice that $H_\delta = -\Delta_y + U_\delta$ implies that $H_\delta = H_3 + (U_\delta - U_3)$. Now take ψ_0 to be the groundstate eigenfunction of H_3. It follows that

$$\int_{-\infty}^{+\infty} \psi_0^*(y) H_\delta \psi_0(y) dy = \int_{-\infty}^{+\infty} \psi_0^*(y) H_3 \psi_0(y) dy + \int_{-\infty}^{+\infty} \psi_0^*(y)[U_\delta(y) - U_3(y)]\psi_0(y) dy.$$

Since $(U_\delta(y) - U_3(y)) \leqslant 0$ for $y \in (-\infty, +\infty)$, we have that $\int_{-\infty}^{+\infty} \psi_0^*(y)[U_\delta(y) - U_3(y)]\psi_0(y) dy < 0$. Also, since ψ_0 is not the ground state of H_δ for $\delta > 3$, then $\int_{-\infty}^{+\infty} \psi_0^*(y) H_\delta \psi_0(y) dy > \lambda_\delta$. With $\int_{-\infty}^{+\infty} \psi_0^*(y) H_3 \psi_0(y) dy = 0$ it follows that

$$\lambda_\delta < 0. \tag{27}$$

Alternatively, we see that the limit $\delta \to 3$ transforms the second pair of solutions (12) and (13) back to the first pair (9) and (10), for which we have $\lambda_3 = 0$. Thus, unicity of the ground state allows writing $\lambda_\delta \leqslant 0$ for $\delta \geqslant 3$, or better $\lambda_\delta < 0$ for $\delta > 3$, which is the region in parameter space where the second pair of solutions appears. This concludes our demonstration that $E_0(\mu, \nu, \lambda) < 0$ for all parameter values that respect Eq. (14), and thus that the soliton solutions discussed here are always unstable.

I. INTRODUCTION

During a long period of time the theory of disordered systems has been widely discussed in the physics literature. One of the first systems of this type which has been extensively investigated is spin glass. It is a disordered spin system with a zero average random interaction among spins. The mean field model of spin glass is analyzed and many interesting results are found in the physics literature.[1] The problem, as usual, is to study the thermodynamic behavior of the model, and this has been done, computing the limiting averaged free-energy. The most frequently applied method for solving such a problem is the replica calculation which until now has not found any rigorous support. For a long time there were only a few rigorous results (see Refs. 2 and 3) in this field, dealing only with the high-temperature region. Then in Refs. 4 and 5 we introduced an alternative rigorous method, the cavity method, which can work also in the low-temperature region. In this paper we solve some problems connected with the application of this approach to the Hopfield model.[6] The Hamiltonian of this model is

$$\mathrm{H}=-\frac{1}{2}\sum_{i,j=1}^{N} I_{ij}\sigma_i\sigma_j+\sum_{i=1}^{N} h_i\sigma_i\,, \tag{1}$$

where

$$I_{ij}=\frac{1}{N}\sum_{\mu=1}^{p} \xi_i^{\mu}\xi_j^{\mu}\,, \quad p=\alpha N \quad (\alpha>0) \tag{2}$$

with $\xi_i^{\mu}=\pm 1$ being independent random variables with zero mean.

One of the main points of the usual mean field theory (e.g., the Curie–Weiss model) was that the simple equality

$$\langle\sigma_1\rangle=\left\langle \tanh\left(\beta\sum_{i=2}^{N} I_{ij}\sigma_i+\beta h_1\right)\right\rangle \tag{3}$$

(valid for any interaction I_{ij}) can be rewritten as

$$\langle\sigma_1\rangle=\tanh\left(\beta\sum_{i=2}^{N} I_{ij}\langle\sigma_i\rangle+\beta h_1\right). \tag{4}$$

This relation follows from the factorization of the second correlation function in the thermodynamic limit

$$|\langle\sigma_i\sigma_j\rangle-\langle\sigma_i\rangle\langle\sigma_j\rangle|\to 0 \quad \text{as} \quad N\to\infty. \tag{5}$$

This property in the usual mean field theory is valid in the whole temperature region, if we add in the Hamiltonian some proper ''symmetry breaking field.''

It was rather natural to expect that in the mean-field-type model of spin glass (1) relations similar to (4) and (5) are also valid if we introduce some proper ''symmetry breaking field.''

In Ref. 4, using some special kind of infinitesimal field, it was shown that for the Sherrington–Kirkpatrick (SK) model[7] the relation (5) is equivalent to the self-averaging property of the Edwards–Anderson order parameter

$$E\{(q_N-E\{q_N\})^2\}\to 0 \quad \text{as} \quad N\to\infty, \tag{6}$$

where

$$q_N=\frac{1}{N}\sum_{i=1}^{N}\langle\sigma_i\rangle^2. \tag{7}$$

Deriving (5) from (6) and studying the moments of the random variable $\langle\sigma_1\rangle$, it was proved that if (6) is true, then in distribution

$$\langle\sigma_1\rangle=\tanh\left(\beta\sum_{i=2}^{N} I_{ij}\langle\sigma_j\rangle_0+\beta h_1\right). \tag{8}$$

Here and below the symbol $\langle\cdots\rangle_0$ means the average with respect to the Gibbs measure, corresponding to the Hamiltonian (1), if we set here $\sigma_1=0$.

This idea was developed in Ref. 8, where the infinitesimal field was replaced by an ordinary Gaussian one that, in particular, allows us to derive on the basis of Griffith's lemma an important relation, valid for almost all values of β and h_i,

$$\frac{1}{N}\sum_{i=1}^{N} h_i(\sigma_i-\langle\sigma_i\rangle)\to 0 \quad \text{as} \quad N\to\infty,$$

in the Gibbs measure and probability. This relation simplifies considerably the method of Ref. 4 and allows us to prove that (6) is equivalent to (8) in a more natural way. The further development of this method allows us to prove that (6) and (8) for the SK model are valid for a large region of parameters, including the low temperatures.[9]

The same method was used in Ref. 5, where we derived (8) from (6). Similar ideas were used later by M. Talagrand[10,11] to prove (8) for the SK model with a high temperature and for the Hopfield model with small α's. Analogous results were found in Ref. 12.

Now let us recall that in the case of the SK model

$$I_{ij}=\frac{1}{\sqrt{N}}J_{ij},$$

where $\{J_{ij}\}$ are independent (Gaussian) random variables with zero mean. Since $\langle\sigma_j\rangle_0$ does not depend on J_{1j} and the Lindeberg condition in the form

$$E\left\{N^{-2}\sum_{j=2}^{N}\langle\sigma_j\rangle_0^4\right\}\to 0 \quad \text{as} \quad N\to\infty \tag{9}$$

is trivial due to the bounded values of spins $\{\sigma_j\}$, the central limit theorem gives us immediately that the cavity field $\Sigma I_{1j}\langle\sigma_j\rangle_0$ converges in distribution to the Gaussian random variable. Thus, from (8) we obtain the relation

$$\overline{q_N}=E\{\langle\sigma_1\rangle_0^2\}=\int \tanh^2\beta(J\sqrt{\overline{q_N}}u+h_1)\frac{e^{-u^2/2}du}{\sqrt{2\pi}}d\mu(h_1)+o(1)\quad(\overline{q_N}=E\{q_N\}),$$

which gives us the so-called replica symmetric equation for $\overline{q}$.

However, in the case of the Hopfield interaction (2), the situation is more complicated. If we write in a natural way

$$\sum_{i=2}^{N} I_{1j}\langle\sigma_i\rangle_0=\sum_{\mu=2}^{p}\frac{\xi_1^\mu}{\sqrt{N}}\langle t_1^\mu\rangle_0$$

with

$$t_1^\mu=\frac{1}{\sqrt{N}}\sum_{i=2}^{N}\xi_i^\mu\sigma_i, \tag{10}$$

then $\langle t_1^\mu\rangle_0$, like in the SK case, are independent of $\{\xi_1^\mu\}$. However, to apply the central limit theorem now we have to check the condition of the type

$$E\left\{N^{-2}\sum_{\mu=2}^{p}\langle t_1^\mu\rangle_0^4\right\}\to 0\quad\text{as}\quad N\to\infty. \tag{11}$$

Since t_1^μ can be of the order $\sqrt{N}$, the property (11) is much less trivial then (9). The main aim of the present paper is to prove (11). In fact, we prove a stronger condition on $\langle t_1^\mu\rangle_0$ (see Lemma 1 below).

The paper is organized as follows. In Sec. II we describe exactly the model and the results, in Sec. III we prove the main results, and in the Appendix we prove some auxiliary results.

II. THE MODEL AND THE MAIN RESULTS

Define H as a sum of two Hamiltonians

$$\mathrm{H}=\mathrm{H}_0+\mathrm{H}_1, \tag{12}$$

where

$$\begin{aligned}\mathrm{H}_0&=-\frac{J}{2N}\sum_{\mu=s+1}^{p}\sum_{i,j=1}^{N}\xi_i^\mu\xi_j^\mu\sigma_i\sigma_j-\varepsilon_1\sum_{\mu=s+1}^{p}\gamma^\mu t^\mu+\varepsilon_2\sum_{i=1}^{N}h_i\sigma_i,\\ \mathrm{H}_1&=-\frac{J(1+d_N\zeta)}{2N}\sum_{\nu=1}^{s}\sum_{i,j=1}^{N}\xi_i^\nu\xi_j^\nu\sigma_i\sigma_j-h^1\sum_{i=1}^{N}\xi_i^1\sigma_i-\sum_{\nu=2}^{s}\gamma^\nu t^\nu,\end{aligned} \tag{13}$$

$s=[\log^{1/2}N]$ is the number of the patterns which are expected to be condensed, J, h^1, ε_1, and ε_2 are positive parameters, $d_N=s^{-2/3}$, ζ is an independent random variable uniformly distributed in the interval (1,2), and variables γ^μ,h_i are independent Gaussian random variables with zero mean and variance 1.

The Hamiltonian H_0 contains the contribution of the noncondensed patterns and the Hamiltonian H_1 includes terms due to the condensed patterns. The random variables γ^μ,h_i play the role of ''symmetry breaking fields'' (we need them for technical reasons) and after thermodynamic limit $N\to\infty$ we send $\varepsilon_1,\varepsilon_2\to 0$.

The variable t^μ is just a convenient notation for the following linear combination of spins:

$$t^\mu \equiv \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \xi_i^\mu \sigma_i, \quad \mu = 1,...,p. \tag{14}$$

We will use also notations

$$m^\mu \equiv \frac{1}{\sqrt{N}} t^\mu, \quad r_N = p^{-1} \sum_{\mu=s+1}^{p} \langle t^\mu \rangle^2, \quad U_N = N^{-1} \sum_{\mu=s+1}^{p} (t^\mu)^2,$$

$$q_N = N^{-1} \sum_{i=1}^{N} \langle \sigma_i \rangle^2, \quad \overline{r_N} = E\{r_N\} \quad \overline{q_N} = E\{q_N\}. \tag{15}$$

The main result of the paper is the lemma, which allows us to overcome one of the main technical difficulties, arising in the Hopfield model, if we try to generalize to it the methods proposed in Refs. 4 and 9 for the SK model. This difficulty is connected to the fact that the variables t^μ, which play here the role of ''spins'' of the SK model, are unbounded.

Lemma 1: Consider the set

$$\mathcal{M} \equiv \{\mathbf{m} = (m^1, \ldots, m^p) : \max_{\nu \geq s+1} |m^\nu| \geq 4\delta_N\},$$

where $\delta_N = s^{-1/3} = d_N^{1/3}$. *Let* $\chi_{\mathcal{M}}(m)$ *be the characteristic function of the set* $\mathcal{M}$:

$$\chi_{\mathcal{M}}(\mathbf{m}) = \begin{cases} 1, & \mathbf{m} \in \mathcal{M}, \\ 0, & \text{otherwise.} \end{cases}$$

Then for any $n > 0$ *there exists a constant* C_n *independent of N such that*

$$\text{Prob}\{\langle \chi_{\mathcal{M}}(\mathbf{m}) \rangle \leq e^{-\beta J N d_N^2/4}\} \geq 1 - C_n N^{-n}. \tag{16}$$

Moreover, if we add to the Hamiltonian H *any Hamiltonian* $\tilde{\text{H}}$ *which is symmetrical with respect to the variables* $\{\xi_1^\mu\}_{\mu>s}, \{\xi_2^\mu\}_{\mu>s}, \ldots, \{\xi_N^\mu\}_{\mu>s}$ *and the free energies of the sums* $\text{H}^a + \tilde{\text{H}}(\text{H} + \tilde{\text{H}})$ *satisfy the large deviation bounds of the type*

$$\text{Prob}\{|f(\text{H} + \tilde{\text{H}}) - E_{/\zeta} f(\text{H} + \tilde{\text{H}})\}| > \varepsilon\} \leq D_n N^{-n},$$

then the estimate of the probability (16) is valid for Gibbs averages with respect to $\text{H} + \tilde{\text{H}}$.

Here and below the symbol $E_{/\zeta}\{\cdots\}$ means the average with respect to all random variables of the problem except ζ.

Remarks:

(1) This lemma allows us to treat m^ν ($\nu > s$) like variables satisfying inequalities

$$|m^\nu| \leq 4 d_N^{1/2}, \tag{17}$$

because the measure of m^ν satisfying the opposite inequality decays exponentially with probability 1, starting from some large enough N, and so those m^ν can add only exponentially small contributions in our estimates. In particular,

$$E\left\{ \sum_{\nu=s+1}^{p} \langle (m^\nu)^4 \rangle \right\} \leq 16 d_N E\left\{ \sum_{\nu=s+1}^{p} \langle (m^\nu)^2 \rangle \right\} \leq 16 d_N E\{\|\mathcal{J}\|\} = \text{const}\, d_N. \tag{18}$$

(2) The other important corollary of Lemma 1 is the formula, analogous to the formula of integration by parts, which usually is used for Gaussian variables.

Proposition 1: Let t_1^μ *be defined by (10). Then for any* $\mu_1,\dots,\mu_k>s$, $\mu_i\neq\mu_j$, *and any bounded function* $F_1(\{\sigma\},\{\xi_i^\mu\}),\dots,F_l(\{\sigma\},\{\sigma_i^\mu\})$ *which do not depend on* ξ_1^μ,

$$N^{k/2}E\{\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\langle t_1^{\mu_1}\cdots t_1^{\mu_{k_1}}F_1(\{\sigma\},\{\xi_i^\mu\})\rangle\cdots\langle t_1^{\mu_{k_{l-1}+1}}\cdots t_r^{\mu_k}F_l(\{\sigma\},\{\xi_i^\mu\})\rangle\}$$

$$=N^{k/2}E\left\{\frac{\partial^k}{\partial\xi_1^{\mu_1}\cdots\partial\xi_1^{\mu_1}}\langle t_1^{\mu_1}\cdots t_1^{\mu_{k_1}}F_1(\{\sigma\},\{\xi_i^\mu\})\rangle\cdots\langle t_1^{\mu_{k_{l-1}+1}}\cdots t_1^{\mu_k}F_l(\{\sigma\},\{\xi_i^\mu\})\rangle\right\}+R, \tag{19}$$

with

$$|R|\leqslant d_N^{1/2}\cdot(2l)^{k+1}\max|F_1|\cdots\max|F_l|\cdot(2+\sqrt{\alpha})^k.$$

The same relations are valid for the Hamiltonian H^a *and any perturbed Hamiltonian* $\mathrm{H}^a+\tilde{\mathrm{H}}$ *with perturbation* $\tilde{\mathrm{H}}$, *if this perturbation is symmetrical with respect to* ξ_1^μ *in the sense of Lemma 1 and for any k, p,*

$$E^{1/p}\left\{\left\langle\left(\frac{\partial^k\tilde{\mathrm{H}}}{\partial\xi_1^{\mu_1}\cdots\partial\xi_1^{\mu_k}}\right)^{2p}\right\rangle\right\}\leqslant\frac{C_{k,p}}{N^k}. \tag{20}$$

with the constant $C_{k,p}$ *independent of N. Here and below the symbol* $\partial/\partial\xi_1^\mu$ *means the formal derivative, which can be obtained if we replace* ξ_1^μ *by a continuous variable.*

Lemma 1 and Proposition 1 allow us to prove a bit different variant of the main theorem of Ref. 5.

Theorem 1: *Consider the Hopfield model of the form (12) and (13). Set*

$$\Delta_N=E\left\{(Np)^{-1}\sum_{\mu>s,i\geqslant 1}\langle(t^\mu-\langle t^\mu\rangle)(\sigma_i-\langle\sigma_i\rangle)\rangle^2\right\}. \tag{21}$$

Then for almost all values of parameters J, h^1, ε_1, ε_2, α, *and* β, *parameters* $\overline{q}_N,\overline{r}_N$ *satisfy the system of equations*

$$\overline{r}_N=\frac{\{\overline{q}_N+\varepsilon_1^2J^2\beta^2(1-\overline{q}_N)^2\}}{(1-\beta J(1-\overline{q}_N))^2}+O(\Delta_N^{1/2})+o(1),$$

$$\overline{q}_N=E\left\{\int\frac{dv\,\exp(-v^2/2)}{\sqrt{2\pi}}\tanh^2\beta\left((\alpha\overline{r}_N(\varepsilon_1))^{1/2}v+h^1\xi_1^1+J\sum_{\nu=1}^{s}c^\nu\xi_1^\nu+\varepsilon_2h_1\right)\right\}$$
$$+O(\Delta_N^{1/2})+o(1), \tag{22}$$

where

$$\overline{r}_N(\varepsilon_1)=J^2\overline{r}_N+\frac{2J\beta\varepsilon_1^2}{1-\beta J(1-\overline{q}_N)}+\varepsilon_1^2$$

and parameters c^ν *satisfy the equations*

$$c^\nu=E\left\{\int\frac{dv\,\exp(-v^2/2)}{\sqrt{2\pi}}\xi_1^\mu\tanh\beta\left((\alpha\overline{r}_N(\varepsilon_1))^{1/2}v+h^1\xi_1^1+J\sum_{\nu=1}^{s}c^\nu\xi_1^\nu+\varepsilon_2h_1\right)\right\}$$
$$+O(\Delta_N^{1/2})+o(1).$$

To study the influence of the ‘‘condensed’’ patterns we use the following.

Lemma 2: Consider the ‘‘approximate’’ Hamiltonian of the form

$$\mathrm{H}^a(\mathbf{c})=\mathrm{H}_0-J(1+d_N\zeta)\sum_{\nu=1}^{s} c^\nu\sum_{i=1}^{N} \xi_i^\nu\sigma_i-\sum_{\nu=1}^{s} \gamma^\nu t^\nu-h^1\sum_{i=1}^{N} \xi_i^1\sigma_i+J(1+d_N\zeta)\frac{N}{2}\sum_{\nu=1}^{s} (c^\nu)^2, \tag{23}$$

where H_0 *is defined by formula (13) and* $\mathbf{c}\equiv(c^1,\ldots,c^s)$. *Then the free energies of the initial Hamiltonian* H *and the ‘‘approximate’’ Hamiltonian* H^a *satisfy the inequality*

$$0\leq\min_{\mathbf{c}} E_{/\zeta}\{f(\mathrm{H}^a(\mathbf{c}))\}-E_{/\zeta}\{f(\mathrm{H})\}\leq\frac{\mathrm{const}}{\log N}, \tag{24}$$

and for almost all J, h^1, ε_1, ε_2,

$$\overline{r_N^*}\equiv E\left\{p^{-1}\sum_{\mu=s+1}^{p} \langle t^\mu\rangle_*^2\right\}=\overline{r_N}+o(1),\quad \overline{q_N^*}\equiv E\left\{N^{-1}\sum_{i=1}^{N} \langle\sigma_i\rangle_*^2\right\}=\overline{q_N}+o(1). \tag{25}$$

Here and everywhere below we use notation

$$\mathrm{H}_*^a=\mathrm{H}^a(\mathbf{c}_*(\zeta))$$

for the Hamiltonian H^a computed at the point $\mathbf{c}_*(\zeta)\equiv(c_*^1(\zeta),\ldots,c_*^s(\zeta))$ which provides the minimum value of the mean free energy $E_{/\zeta}\{f(\mathrm{H}^a(c^1,\ldots,c^s))\}$, and the symbol $\langle\cdots\rangle_*$ for the respective Gibbs average. Thus the symbols $\overline{q_N^*}, \overline{r_N^*}$ are the values of order parameters computed by means of this Gibbs measure.

Remarks:

(1) Lemma 2 allows us to substitute the Hamiltonian H with H_*^a, which is linear with respect to the first s patterns.

(2) Since the Hamiltonian evidently has the form

$$\mathrm{H}_*^a=\mathrm{H}+\frac{J(1+\zeta d_N)N}{2}\sum_{\nu=1}^{s} (m^\nu-c_*^\nu)^2,$$

it is easy to see that it satisfies conditions of Lemma 1 and Proposition 1 for the perturbed Hamiltonians, and the estimates (19) are also valid for the $\langle\cdots\rangle_*$ averages.

Using Lemmas 1 and 2 and Proposition 1, one can prove Theorem 1 by the method proposed in Ref. 5. One of the main steps in the proof is given by the lemma about the properties of the cavity field, which needs some extra definitions for its statement.

Define the Hamiltonian $\Phi(\tau)$, interpolating between systems of $N-1$ and N spins,

$$\Phi(\tau)=\mathrm{H}_1^a-\frac{J\tau}{\sqrt{N}}\sum_{\mu=1}^{p} \xi_1^\mu t_1^\mu, \tag{26}$$

where

$$\mathrm{H}_1^a=\mathrm{H}_1^0-\frac{J}{2N}\sum_{\mu=s+1}^{p} (t_1^\mu)^2-J(1+\zeta d_N)\sum_{\nu=1}^{s} c_*^\nu\sum_{i=2}^{N} \xi_i^\nu\sigma_i-h^1\sum_{i=2}^{N} \xi_i^1\sigma_i$$
$$+\frac{JN(1+\zeta d_N)}{2}\sum_{\nu=1}^{s} (c_*^\nu)^2-\sum_{\nu=2}^{s} \gamma^\nu t_1^\nu. \tag{27}$$

It is easy to see that if $\tau=\sigma_1$, then $\Phi(\tau)$ coincides with H^a.

Consider also the corresponding partition function

$$Z(\tau)=\sum_{\sigma_2,\ldots,\sigma_N} e^{-\beta\Phi(\tau)}, \tag{28}$$

and define the relative free energy

$$u(\tau)=\ln\frac{Z(\tau)}{Z(0)}. \tag{29}$$

Lemma 3: The function $u(\tau)$ can be represented in the form

$$u(\tau)=\beta J\tau\sum_{\nu=s+1}^{p}\frac{\xi_1^\nu}{\sqrt{N}}\langle t_1^\nu\rangle_0+\beta J\tau\sum_{\mu=1}^{s}\xi_1^\mu c_*^\mu+(\langle U_N\rangle_0-\alpha\overline{r_N})\frac{\tau^2(\beta J)^2}{2}+R_N(\tau), \tag{30}$$

where $\langle\cdots\rangle_\tau$ is the Gibbs averaging, corresponding to the Hamiltonian $\Phi(\tau)$, U_N is defined by (15), and the remainder R_N can be estimated as

$$E\{R_N^2\}\leqslant\text{const}\,\Delta_N+o(1). \tag{31}$$

Remarks:

(1) Since $\langle t_1^\nu\rangle_0$ do not depend on ξ_1^ν, using Lemma 1, one can prove that the cavity field [the first sum on the rhs of (30)] converges in distribution to $\beta J_\tau\sqrt{\alpha r_N}\nu_1$, where ν_1 is a Gaussian random variable with zero mean and variance 1.

(2) At the present time there exists a proofs of Lemma 3 (see Refs. 5 and 10). Thus, in this paper we omit the proof of his lemma and the derivation of the equations (22).

III. PROOFS OF LEMMAS 1 AND 2 AND PROPOSITION 1

Proof of Lemma 1: For given $\mu\leqslant s$ and $\nu\geqslant s+1$ consider the set

$$\mathcal{A}^{\mu\nu}=\{\mathbf{m}=(m^1,\ldots,m^p):(1+d_N\zeta)|m^\mu|\leqslant|m^\nu|-3\delta_N\}. \tag{32}$$

Its Gibbs measure is

$$a^{\mu\nu}=\langle\theta(|m^\nu|-(1+d_N\zeta)|m^\mu|-3\delta_N)\rangle, \tag{33}$$

where $\theta(m)=\frac{1}{2}(1+\text{sign}\,m)$.

Let us assume that for any n we have proved the estimate

$$\text{Prob}\{a^{\mu\nu}\leqslant e^{-\beta JNd_N^2/5}\}\geqslant 1-C_n'N^{-n}. \tag{34}$$

Consider the set

$$\mathcal{A}\equiv\bigcup_{\mu=1}^{s}\bigcup_{\nu=s+1}^{p}\mathcal{A}^{\mu\nu}=\{\mathbf{m}=(m^1,\ldots,m^p):(1+d_N\zeta)\min_{\mu\leqslant s}|m^\mu|\leqslant\max_{\nu\geqslant s+1}|m^\nu|-3\delta_N\}. \tag{35}$$

Then it follows from (34) that the Gibbs measure $\langle\chi_{\mathcal{A}}(m)\rangle$ of the set $\mathcal{A}$ satisfies the estimate

$$\text{Prob}\{\langle\chi_{\mathcal{A}}(m)\rangle\leqslant s(p-s)e^{-\beta JNd_N^2/5}\leqslant e^{-\beta JNd_N^2/6}\}\geqslant 1-s(p-s)C_n'N^{-n}\geqslant 1-C_{n-2}N^{-(n-2)},$$

when N is large enough. Then we use the inequality

$$\langle\chi_{\mathcal{M}}(m)\rangle=\langle\chi_{\mathcal{M}\cap\mathcal{A}}(m)\rangle+\langle\chi_{\mathcal{M}\cap\overline{\mathcal{A}}}(m)\rangle\leqslant\langle\chi_{\mathcal{A}}(m)\rangle+\langle\chi_{\mathcal{M}\cap\overline{\mathcal{A}}}(m)\rangle. \tag{36}$$

However,

$$\mathcal{M}\cap\overline{\mathcal{A}}\equiv\{\mathbf{m}:(1+d_N\zeta)\min_{\mu\leqslant s}|m^\mu|\geqslant \max_{\nu\geqslant s+1}|m^\nu|-3\delta_N,\ \max_{\nu\geqslant s+1}|m^\nu|>4\delta_N\}$$

$$\subset\{\mathbf{m}:(1+d_N\zeta)\min_{\mu\leqslant s}|m^\mu|\geqslant\delta_N\}$$

$$\subset\left\{\mathbf{m}:(1+d_N\zeta)^2\sum_{\mu\leqslant s}(m^\mu)^2\geqslant s\,\delta_N^2\right\}. \tag{37}$$

By using the definition (15) of m^μ and then the result of Ref. 13, we get that for any $\tilde{d}>0$ [in our case $\tilde{d}=(\log N)^{1/6}/(1+d_N\zeta)-(1+\sqrt{\alpha})^2$] the probability of the event

$$\left\{\sum_{\mu\leqslant s}(m^\mu)^2\geqslant(1+\sqrt{\alpha})^2+\tilde{d}\right\}\subset\left\{\frac{1}{N}\sum_{i,j}J_{ij}\sigma_i\sigma_j\geqslant(1+\sqrt{\alpha})^2+\tilde{d}\right\}\subset\{\|\mathcal{J}\|\geqslant(1+\sqrt{\alpha})^2+\tilde{d}\}$$

is less than $e^{-N^{2/3}\tilde{d}^{4/3}\,\mathrm{const}}$. Therefore the probability to have the last set in (37) nonempty is also less then $e^{-N^{2/3}\,\mathrm{const}}$. Thus (36), (37), and (34) prove (16).

Now we are left to prove (34).

To this end we use the standard representation

$$\exp\left\{\beta JN\left((1+d_N\zeta)\frac{(m^\mu)^2}{2}+\frac{(m^\nu)^2}{2}\right)\right\}=\left((2\pi\beta JN)^{-1}(1+d_N\zeta)\right)^{1/2}\int dx\,dy$$
$$\times\exp\left\{\beta JN\left(xm^\mu+ym^\nu-\frac{x^2}{2(1+d_N\zeta)}-\frac{y^2}{2}\right)\right\} \tag{38}$$

and study

$$a_1^{\mu\nu}=\frac{\int\theta(|y|-|x|-2\delta_N)\exp\{\beta JNF_{N,\mu\nu}(x,y)\}dx\,dy}{\int\exp\{\beta JNF_{N,\mu\nu}(x,y)\}dx\,dy}, \tag{39}$$

where $F_{N,\mu\nu}(x,y)$ is a random function defined by the formulas

$$F_{N,\mu\nu}(x,y)\equiv f_{N,\mu\nu}(Jx,Jy)-\frac{x^2}{2(1+d_N\zeta)}-\frac{y^2}{2},$$

$$f_{N,\mu\nu}(x,y)\equiv\frac{1}{\beta JN}\log\sum_{\{\sigma\}}\exp\{-\beta\mathrm{H}_{\mu\nu}(\sigma;x,y),\} \tag{40}$$

with the Hamiltonian $\mathrm{H}_{\mu,\nu}(\sigma;x,y)$ of the form

$$\mathrm{H}_{\mu\nu}(\sigma;x,y)=-NJ\sum_{\mu'\neq\nu;\mu'>s}(m^{\mu'})^2-NJ(1+\zeta d_N)\sum_{\mu'\neq\mu;\mu'\leqslant s}(m^{\mu'})^2-\sum_{i=1}^N h_i\sigma_i$$
$$-\varepsilon_1\sqrt{N}\sum_{\nu'>s}\gamma^{\nu'}m^{\nu'}-\sqrt{N}\sum_{\mu'\leqslant s}\gamma^{\mu'}m^{\mu'}-Nxm^\mu-Nym^\nu.$$

Then we use the inequality which follows from the Laplace method:

$$\frac{\int \theta(|y|-|x|-2\delta_N)\exp\{\beta JN(m^\mu x+m^\nu y-x^2/2(1+d_N\zeta)-y^2/2)\}dxdy}{\int \exp\{\beta JN(m^\mu x+m^\nu y-x^2/2(1+d_N\zeta)-y^2/2)\}dxdy}$$
$$\geqslant(\theta(|m^\nu|-(1+d_N\zeta)|m^\mu|-3\delta_N)-e^{-N\beta J\delta_N^2/2(2+d_N\zeta)}). \qquad (41)$$

Indeed, if $|m^\nu|-(1+d_N\zeta)|m^\mu|-3\delta_N<0$, this inequality is trivial.

If $|m^\nu|-(1+d_N\zeta)|m^\mu|-3\delta_N\geqslant 0$, then the θ-function on the rhs of (41) is equal to 1 and the ratio on the lhs is equal to

$$1-\frac{\int_{\mathcal{D}}\exp\{\beta JN(-(x-x^*)^2/2(1+d_N\zeta)-(y-y^*)^2/2)\}dxdy}{\int \exp\{\beta JN(-(x-x^*)^2/2(1+d_N\zeta)-(y-y^*)^2/2)\}dxdy},$$

where $\mathcal{D}=\{(x,y):|y|-|x|-2\delta_N\leqslant 0\}$ and $x^*=(1+d_N\zeta)m^\mu$, $y^*=m^\nu$. In our case $(|m^\nu|-(1+d_N\zeta)|m^\mu|-3\delta_N\geqslant 0)$ and so $(x*,y^*)\notin\mathcal{D}$. According to the Laplace method, the last ratio in the above formula can be estimated from above:

$$\frac{\int_{\mathcal{D}}\exp\{\beta JN(-(x-x^*)^2/2(1+d_N\zeta)-(y-y^*)^2/2)\}dxdy}{\int \exp\{\beta JN(-(x-x^*)^2/2(1+d_N\zeta)-(y-y^*)^2/2)\}dxdy}$$
$$\leqslant\exp\left\{\beta JN\max_{\mathcal{D}}\left[-\frac{(x-x^*)^2}{2(1+d_N\zeta)}-\frac{(y-y^*)^2}{2}\right]\right\}\leqslant e^{-N\beta J\delta_N^2/2(+d_N\zeta)}.$$

Thus, we obtain that

$$a_1^{\mu\nu}=\frac{\int\theta(|y|-|x|-2\delta_N)\exp\{\beta JNF_{N,\mu\nu}(x,y)\}dxdy}{\int\exp\{\beta JNF_{N,\mu\nu}(x,y)\}dxdy}$$
$$=\frac{\Sigma_{\{\sigma\}}\exp\{-\beta H_{\mu\nu}(\sigma;0,0)\}\int\theta(|y|-|x|-2\delta_N)e^{\beta JN(m^\mu x+m^\nu y-x^2/2(1+d_N\zeta)-y^2/2)}\,dxdy}{2\pi\beta JN(1+\zeta d_N)^{-1/2}\Sigma_{\{\sigma\}}e^{-\beta H(\sigma)}}$$
$$\geqslant\frac{\Sigma_{\{\sigma\}}\exp\{-\beta H_{\mu\nu}(\sigma;0,0)\}\theta(|m^\nu|-(1+d_N\zeta)|m^\mu|-3\delta_N)\int e^{\beta JN(m^\mu x+m^\nu y-x^2/2(1+d_N\zeta)-y^2/2)}\,dxdy}{2\pi\beta JN(1+\zeta d_N)^{-1/2}\Sigma_{\{\sigma\}}e^{-\beta H(\sigma)}}$$
$$-e^{-N\beta J\delta_N^2/2(2+d_N\zeta)}$$
$$=a^{\mu,\nu}-e^{-N\beta J\delta_N^2/2(2+d_N\zeta)}.$$

So,

$$a^{\mu\nu}\leqslant a_1^{\mu\nu}+e^{-N\beta J\delta_N^2/2(2+d_N\zeta)}. \qquad (42)$$

Now we apply the Laplace method to the integral on the rhs of (39) [let us recall that evidently $|(\partial/\partial x)f_{N,\mu\nu}(x,y)|,|(\partial/\partial y)f_{N,\mu\nu}(x,y)|\leqslant 1$ and therefore $F_{N,\mu\nu}(x,y)$ has bounded derivatives in the field of interest]. We have

$$a_1^{\mu\nu}=\frac{\int_{|y|-|x|\geqslant 2\delta_N}\exp\{\beta JNF_{N,\mu\nu}(x,y)\}dxdy}{\int\exp\{\beta JNF_{N,\mu\nu}(x,y)\}dxdy}$$
$$\leqslant\exp\{\beta JN[\max_{|y|-|x|\geqslant 2\delta_N}F_{N,\mu\nu}(x,y)-\max_{x,y}F_{N,\mu\nu}(x,y)]\}. \qquad (43)$$

We will show below that

$$\max_{|y|-|x|\geq 2\delta_N} F_{N,\mu\nu}(x,y)-\max_{x,y} F_{N,\mu\nu}(x,y)\leq -\zeta\frac{d_N\delta_N^2}{2}. \tag{44}$$

From this inequality, using (43) and the fact that $1\leq\zeta\leq 2$, we get

$$a_1^{\mu\nu}\leq e^{-\beta JNd_N\delta_N^2/2}, \tag{45}$$

if N is large enough. This inequality together with (42) prove (34) and thus Lemma 1.

Now let us show (44). Denote by $E_{\mu\nu}\{\cdots\}$ the average with respect to all random parameters of the problem except γ^μ, γ^ν, and ζ and rewrite $F_{N,\mu\nu}(x,y)$ as

$$F_{N,\mu\nu}(x,y)=E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}+R_{N,\mu\nu}(x,y),\quad R_{N,\mu\nu}(x,y)\equiv F_{N,\mu\nu}(x,y)-E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}.$$

Then we have

$$\max_{|y|-|x|\geq 2\delta_N} F_{N,\mu\nu}(x,y)-\max_{x,y} F_{N,\mu\nu}(x,y)$$
$$\leq \max_{|y|-|x|\geq 2\delta_N} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}-\max_{x,y} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}+2\max_{x,y}|R_{N,\mu\nu}(x,y)|\}. \tag{46}$$

To proceed further, we use the following proposition.

Proposition 2: Let $f(x,y)$ be a smooth function, satisfying the symmetry conditions

$$f(x,y)=f(y,x),\quad f(x,y)=f(-x,y). \tag{47}$$

Consider the function $F(x,y)$ of the form

$$F(x,y)\equiv f(x,y)-\frac{x^2}{2(1+d)}-\frac{y^2}{2}\quad (d>0). \tag{48}$$

Then

$$\max F(x,y)-\max_{|x|\leq|y|-2\delta} F(x,y)\geq\frac{2d\delta^2}{(1+d)}. \tag{49}$$

We prove this proposition in the Appendix.

Let us remark that

$$\max_{|y|-|x|\geq 2\delta_N} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}-\max_{x,y} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}$$
$$\leq \max_{|y|-|x|\geq 2\delta_N} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}|_{\gamma^\mu=\gamma^\nu=0}$$
$$-\max_{x,y} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}|_{\gamma^\mu=\gamma^\nu=0}+2\left(\left|\frac{\gamma^\mu}{\sqrt{N}}\right|+\left|\frac{\varepsilon_1\gamma^\nu}{\sqrt{N}}\right|\right).$$

Now we apply Proposition 2 to the function $E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}|_{\gamma^\mu=\gamma^\nu=0}$ and use also the estimate

$$2\left(\left|\frac{\gamma^\mu}{\sqrt{N}}\right|+\left|\frac{\varepsilon_1\gamma^\nu}{\sqrt{N}}\right|\right)\leq\frac{1-d_N\zeta}{1+\zeta d_N}\zeta d_N\delta_N^2. \tag{50}$$

Since γ^μ and γ^ν are Gaussian random variables, this estimate is valid with probability larger than $1-e^{-N\,\text{const}\,d_N^2\delta_N^4}$. Thus,

$$\max_{|y|-|x|\geqslant 2\delta_N} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}-\max_{x,y} E_{\mu\nu}\{F_{N,\mu\nu}(x,y)\}$$

$$\leqslant -\frac{2d_N\zeta\delta_N^2}{1+\zeta d_N}+\frac{d_N\zeta\delta_N^2(1-\zeta d_N)}{1+\zeta d_N}$$

$$=-\zeta d_N\delta_N^2=-\zeta d_N^2 \tag{51}$$

with the same probability.

If also

$$2\max_{x,y}|R_{N,\mu\nu}(x,y)|\leqslant\zeta\frac{d_N^2}{2}, \tag{52}$$

then (46) and (51) imply (44). Thus, we obtain that the probability of (45) is bounded from above by the sum of probabilities of (50) and (52).

Now we are faced with the problem of estimating the probability of (52). To this aim let us remark, that since $|(\partial/\partial x)f_{N,\mu\nu}|,|(\partial/\partial x)f_{N,\mu\nu}|\leqslant 1$, all the extremal points of $F_{N,\mu,\nu}(x,y)$ are inside the square $\{(x,y):|x|,|y|\leqslant 1\}$. Besides, for any (x,y) from this square there exist i,j, $(|i|,|j|\leqslant M,\ M\equiv[4\sqrt{2}d_N^{-2}])$ such that

$$\begin{aligned}
f_{N,\mu\nu}(x,y)-E_{/\zeta}\{f_{N,\mu\nu}(x,y)\}&=f_{N,\mu\nu}\left(\frac{i}{M},\frac{j}{M}\right)-E_{/\zeta}\left\{f_{N,\mu\nu}\left(\frac{i}{M},\frac{j}{M}\right)\right\}+f_{N,\mu\nu}(x,y)\\
&\quad -f_{N,\mu\nu}\left(\frac{i}{M},\frac{j}{M}\right)+E_{/\zeta}\left\{f_{N,\mu\nu}\left(\frac{i}{M},\frac{j}{M}\right)\right\}-E_{/\zeta}\{f_{N,\mu\nu}(x,y)\}\\
&=f_{N,\mu\nu}\left(\frac{i}{M},\frac{j}{M}\right)-E_{/\zeta}\left\{f_{N,\mu\nu}\left(\frac{i}{M},\frac{j}{M}\right)\right\}+R_1+R_2,
\end{aligned} \tag{53}$$

where

$$|R_{1,2}|\leqslant\sqrt{\left(x-\frac{i}{M}\right)^2+\left(y-\frac{j}{M}\right)^2}\leqslant\frac{1}{\sqrt{2}M}\leqslant\frac{d_N^2}{8}.$$

Thus, for our goal it is enough to estimate the probability of the event

$$\left|f_{N,\mu,\nu}\left(\frac{i}{M},\frac{j}{M}\right)-E_{/\zeta}\left\{f_{N,\mu,\nu}\left(\frac{i}{M},\frac{j}{M}\right)\right\}\right|\leqslant\frac{d_N^2}{4}, \tag{54}$$

because this inequality and (53) imply (52).

Since, according to Ref. 14, the probability of the last event for fixed (i,j) can be estimated as

$$\text{Prob}\left\{|f_{N,\mu\nu}(x_k,y_k)-E_{/\zeta}\{f_{N,\mu\nu}(x_k,y_k)\}|\leqslant\frac{d_N^2}{4}\right\}\geqslant 1-D_nN^{-n},$$

and the number of the events of such a type is $4M^2$, the probability of the inequality (52) is more then $1-4M^2D_nN^{-n}\geqslant 1-C_n'N^{2-n}$. On the other hand, since γ^ν, γ^μ are Gaussian random variables, the probability of (50) is more then $1-e^{-N\,\text{const}\,d_N^2}$. Therefore the inequalities (42)–(54) and the last conclusions prove (34), that, as it was mentioned above, implies (16).

For the perturbed Hamiltonian the proof is the same.

Proof of Proposition 1: To simplify formulas we prove formula (19) in the case $l=1$. The general case for this formula and also its modification for the perturbed Hamiltonian can be proved similarly.

Let us introduce the vector $\overline{\theta}\in \mathbf{R^k}$, $\overline{\theta}\equiv(\theta_1,\dots,\theta_k)$, and define $\mathrm{H}(\overline{\theta})$ to be equal to the Hamiltonian H_*^a, if we substitute in the latter $\xi_1^{\mu_1},\dots,\xi_1^{\mu_k}$ by $\theta_1\xi_1^{\mu_1},\dots,\theta_k\xi_1^{\mu_k}$. Let

$$\phi(\theta_1,\dots,\theta_k)\equiv N^{k/2}\langle t_1^{\mu_1}\cdots t_1^{\mu_k}F_1(\{\sigma\},\{\xi_i^{\mu}\})\rangle_{\mathrm{H}(\overline{\theta})}.$$

Consider

$$E\left\{\int_0^1\cdots\int_0^1 d\theta_1\cdots d\theta_k\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\frac{\partial^k}{\partial\theta_1\cdots\partial\theta_k}\phi(\theta_1\cdots\theta_k)\right\}$$
$$=E\left\{\int_0^1\cdots\int_0^1\theta_2\cdots d\theta_k\,\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\frac{\partial^{(k-1)}}{\partial\theta_2\cdots\partial\theta_k}(\phi(1,\theta_2\cdots\theta_k)-\phi(0,\theta_2\cdots\theta_k))\right\}.$$

Since $\phi(0,\theta_2\dots\theta_k)$ does not depend on $\xi_1^{\mu_1}$, the second term on the rhs of the last relation after averaging with respect to $\xi_1^{\mu_1}$ becomes zero. Repeating this procedure $k-1$ times more, we get

$$E\left\{\int_0^1\cdots\int_0^1 d\theta_1\cdots d\theta_k\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\frac{\partial^k}{\partial\theta_1\cdots\partial\theta_k}\phi(\theta_1\cdots\theta_k)\right\}=E\{\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\phi(1,\dots,1)\}.$$

Therefore

$$E\{\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\phi(1,\dots,1)\}=E\left\{\xi_1^{\mu_1}\cdots\xi_1^{\mu_k}\frac{\partial^k}{\partial\theta_1\cdots\partial\theta_k}\phi(1\cdots1)\right\}+R_{\mu_1\cdots\mu_k}(\phi)$$
$$=N^{k/2}E\left\{\frac{\partial^k}{\partial\xi_1^{\mu_1}\cdots\partial\xi_1^{\mu_k}}\langle t_1^{\mu_1}\cdots t_1^{\mu_k}F_1(\{\sigma\},\{\xi_1^{\mu}\})\rangle_{\mathrm{H}(\overline{1})}\right\}+R_{\mu_1\cdots\mu_k}(\phi), \tag{55}$$

where

$$|R_{\mu_1\cdots\mu_k}(\phi)|\leqslant N^{k/2}E\left\{\max_{|\theta_1|,\dots,|\theta_k|\leqslant1}\frac{\partial^{k+1}}{\partial^2\theta_1\cdots\partial\theta_k}\phi(\theta_1\cdots\theta_k)\right\}+\cdots$$
$$+N^{k/2}E\left\{\max_{|\theta_1|,\dots|\theta_k|\leqslant1}\frac{\partial^{k+1}}{\partial\theta_1\cdots\partial^2\theta_k}\phi(\theta_1\cdots\theta_k)\right\}. \tag{56}$$

Now we should remark that since the Hamiltonian H_*^a contains ξ_1^{μ} only in the form $N^{-1/2}\xi_1^{\mu}\sigma_1(Jt_1^{\mu}+\varepsilon_1\gamma^{\mu})$, after differentiation with respect to ξ_1^{μ} this term will appear in a number of places. Thus, we obtain

$$R_{\mu_1,\dots,\mu_k}\leqslant\mathrm{const}\,E\{N^{-1/2}\langle|t_1^{\mu_1}|(|t_1^{\mu_1}|+\varepsilon_1|\gamma^{\mu_1}|)^2\cdot|t_1^{\mu_2}|(|(t_1^{\mu_2}|+\varepsilon_1|\gamma_{\mu_2}|)\cdots|t_1^{\mu_k}|(|(t_1^{\mu_k}|$$
$$+\varepsilon_1|\gamma_{\mu_k}|)|F_1(\{\sigma\},\{\xi_i^{\mu}\})|\rangle_{\mathrm{H}_*^a+S^1_{\mu_1,\dots,\mu_k}}\}\cdots+E\{N^{-1/2}\langle|t_1^{\mu_1}|(|(t_1^{\mu_1}|+\varepsilon_1|\gamma_{\mu_1}|)$$
$$\cdot|t_1^{\mu_2}|(|(t_1^{\mu_2}|+\varepsilon_1|\gamma_{\mu_2}|)\cdots|t_1^{\mu_k}|(|(t_1^{\mu_k}|+\varepsilon_1|\gamma_{\mu_k}|)^2|F_1(\{\sigma\},\{\xi_i^{\mu}\})|\rangle_{\mathrm{H}_*^a+S^k_{\mu_1,\dots,\mu_k}}\} \tag{57}$$

with $S^i_{\mu_1,\dots,\mu_k}$ of the form

$$S^i_{\mu_1,\ldots,\mu_k}=\frac{\theta_1(\mu_1,\ldots,\mu_k)}{\sqrt{N}}t_1^{\mu_1}\sigma_1+\cdots+\frac{\theta_k(\mu_1,\ldots,\mu_k)}{\sqrt{N}}t_1^{\mu_k}\sigma_1.$$

By using the inequalities $|S^i_{\mu_{1,\ldots,}\mu_k}|\leqslant k$ and then the bound (17), we obtain the estimate

$$\begin{aligned}|R_{\mu_1,\ldots,\mu_1}|&\leqslant \text{const}\, d_N E\{\langle((t_1^{\mu_1})^2+\varepsilon_1^2\gamma_{\mu_1}^2)((t_1^{\mu_2})^2+\varepsilon_1^2\gamma_{\mu_2}^2)\cdots((t_1^{\mu_k})^2\varepsilon_1^2\gamma_{\mu_k}^2)\rangle\}\\ &=\text{const}\, d_N^{1/2}E\left\{p^{-k}\sum_{\mu_1,\ldots,\mu_k=s+1}^{p}\langle((t_1^{\mu_1})^2+\varepsilon_1^2\gamma_{\mu_1}^2)((t_1^{\mu_2})^2+\varepsilon_1^2\gamma_{\mu_2}^2)\cdots((t_1^{\mu_2})^2\varepsilon_1^2\gamma_{\gamma_k}^2)\rangle\right\}\\ &\leqslant \text{const}\, d_N^{1/2}E\{(\alpha\|\mathcal{J}\|+\alpha\varepsilon_1^2)^k\}=O(d_N^{1/2}).\end{aligned}\tag{58}$$

Proposition 1 is proved.

Proof of Lemma 2: It is easy to see that for any **c**

$$\mathrm{H}^a(\mathbf{c})-\mathbf{H}=\frac{J(1+\zeta d_N)N}{2}\sum_{\nu=1}^{s}(m^\nu-c^\nu)^2.$$

Then, on the basis of the Bogolyubov inequality

$$\frac{1}{N}\langle \mathrm{H}_N^{(2)}-\mathrm{H}_N^{(1)}\rangle_{\mathrm{H}_2}\leqslant f_N(\mathrm{H}_2)-f_N(\mathrm{H}_1)\leqslant\frac{1}{N}\langle \mathrm{H}_N^{(2)}-\mathrm{H}_N^{(1)}\rangle_{\mathrm{H}_1},\tag{59}$$

we have for any c^ν

$$\frac{J(1+\zeta d_N)}{2}\sum_{\nu=1}^{s}\langle(m^\nu-c^\nu)^2\rangle_{\mathrm{H}^a(\mathbf{c})}\leqslant f_N(\mathrm{H}^a(\mathbf{c}))-f_N(\mathrm{H})\leqslant\frac{J(1+\zeta d_N)}{2}\sum_{\nu=1}^{s}\langle(m^\nu-c^\nu)^2\rangle.\tag{60}$$

Taking the minimum with respect to all **c** and averaging with respect to all random parameters of the problem, except ζ, we get

$$\begin{aligned}\frac{J(1+\zeta d_N)}{2}E_{/\zeta}\left\{\left\langle\sum_{\nu=1}^{s}(m^\nu-\tilde{c}^\nu)^2\right\rangle_{\mathrm{H}^a(\tilde{\mathbf{c}})}\right\}&\leqslant E_{/\zeta}\{\min_{c^\nu}f_N(\mathrm{H}^a(\mathbf{c}))\}-E_{/\zeta}\{f_N(\mathrm{H})\}\\ &\leqslant\frac{J(1+\zeta d_N)}{2}E_{/\zeta}\left\{\left\langle\sum_{\nu=1}^{s}(m^\nu-\langle m^\nu\rangle)^2\right\rangle\right\},\end{aligned}\tag{61}$$

where $\tilde{\mathbf{c}}$ is a random minimum point of the function $f_N(\mathrm{H}^a(\mathbf{c}))$. Integrating by parts with respect to the variables $\{\gamma^\nu\}_{\nu=1}^{s}$, it is easy to obtain

$$\begin{aligned}E_{/\zeta}\left\{\left\langle\frac{1}{2}\sum_{\nu=1}^{s}(m^\nu-\langle m^\nu\rangle)^2\right\rangle\right\}&=E_{/\zeta}\left\{\frac{1}{2\beta\sqrt{N}}\sum_{\nu=1}^{s}\gamma^\mu\langle m^\nu\rangle\right\}\\ &\leqslant E^{1/2}\left\{\frac{1}{4N}\sum_{\nu=1}^{s}(\gamma^\nu)^2\right\}E^{1/2}\left\{\frac{1}{N}\sum_{\nu=1}^{s}\langle t^\nu\rangle^2\right\}\\ &\leqslant\left(\frac{s}{p}\right)^{1/2}E^{1/2}\{\|\mathcal{J}\|\}.\end{aligned}$$

Substituting this estimate in (61), we get

$$\frac{J(1+\zeta d_N)}{2}E_{/\zeta}\left\{\left\langle \sum_{\nu=1}^{s}(m^\nu-\tilde{c}^\nu)^2\right\rangle_{\mathrm{H}^a(\tilde{\mathbf{c}})}\leqslant E_{/\zeta}\{\min_{c^\nu} f_N(\mathrm{H}^a(\mathbf{c}))\}-E_{/\zeta}\{f_N(\mathrm{H})\}\leqslant \mathrm{const}\left(\frac{s}{p}\right)^{1/2}.\tag{62}$$

Now to prove Lemma 2 we are left to prove that

$$|E_{/\zeta}\{\min_{c^\nu} f_N(\mathrm{H}^a(\mathbf{c}))\}-\min_{c^\nu} E_{/\zeta}\{f_N(\mathrm{H}^a(\mathbf{c}))\}|\leqslant o(1)\quad \text{as}\ \ N\to\infty.\tag{63}$$

Since evidently for fixed N $f_N(\mathrm{H}^a(\mathbf{c}))$ and $E_{/\zeta}\{f_N(\mathrm{H}^a(\mathbf{c}))\}$ tend to infinity, as $\mathbf{c}\to\infty$, these functions take their minimal values at the finite extremal points. But the extremal conditions for these functions have the form $c^\nu=\langle m^\nu\rangle_{\mathrm{H}^a(\mathbf{c})}$ and $c^\nu=E_{/\zeta}\{\langle m^\nu\rangle_{\mathrm{H}^a(\mathbf{c})}\}$ and since $|m^\nu|\leqslant 1$ to prove (63) it is enough to prove that

$$\mathrm{Prob}\{X\}\equiv\mathrm{Prob}\left\{\sup_{|c^\nu|\leqslant 1}|f_N(\mathrm{H}^a(\mathbf{c}))-E_{/\zeta}\{f_N(\mathrm{H}^a(\mathbf{c}))\}|\leqslant\frac{2J}{\log N}\right\}\leqslant o(1).\tag{64}$$

But, using once more the fact that the derivatives of the functions $f_N(\mathrm{H}^a(\mathbf{c}))$ and $E_{/\zeta}\{f_N(\mathrm{H}^a(\mathbf{c}))\}$ are bounded, we obtain that

$$|f_N(\mathrm{H}^a(\mathbf{c}_1))-f_N(\mathrm{H}^a(\mathbf{c}_2))|\leqslant J\sqrt{s}\left(\sum (c_1^\nu-c_2^\nu)^2\right)^{1/2}$$

and so, if $|c_1^\nu-c_2^\nu|\leqslant(2k)^{-1}(k\equiv[s\log N])$, then

$$|f_N(\mathrm{H}^a(\mathbf{c}_1))-f_N(\mathrm{H}^a(\mathbf{c}_2))|\leqslant\frac{Js}{2k}\leqslant\frac{J}{2\log N}.$$

Therefore

$$\sup_{|c^\nu|\leqslant 1}|f_N(\mathrm{H}^a(\mathbf{c}))-E_{/\zeta}\{f_N(\mathrm{H}^a(\mathbf{c}))\}|\leqslant\sup_{|j_1|,\dots,|j_s|\leqslant k}\left|f_N\left(\mathrm{H}^a\left(\frac{j_1}{k},\dots,\frac{j_s}{k}\right)\right)-E_{/\zeta}\left\{f_N\left(\mathrm{H}^a\left(\frac{j_1}{k},\dots,\frac{j_s}{k}\right)\right)\right\}\right|+\frac{J}{\log N}.$$

Thus,

$$\mathrm{Prob}\{X\}\leqslant\sum_{j_1,\dots,j_s}\mathrm{Prob}\{X_{j_1,\dots,j_s}\},\tag{65}$$

where $j_1,\dots.j_s$ are integer numbers from the interval $(-k,k)$ and $X_{j_1,\dots,j_s}$ is the notation of the event

$$\left|f_N\left(\mathrm{H}^a\left(\frac{j_\perp}{k},\dots,\frac{j_s}{k}\right)\right)-E_{/\zeta}\left\{f_N\left(\left(\frac{j_1}{k},\dots,\frac{j_s}{k}\right)\right)\right\}\right|\geqslant\frac{J}{\log N}.$$

According to the result of Ref. 14, the probability of the last event can be estimated by $D_1N^{-1}\log^2 N$. Thus, on the basis of (65),

$$\begin{aligned}\mathrm{Prob}\{X\}\leqslant D_1N^{-1}(2k+1)^s&\leqslant D_1\exp\{s\log(2k+1)+2\log\log N-\log N\}\\&=D_1\exp\{\mathrm{const}[\log N]^{1/2}(\log\log N)-\log N\}\\&\leqslant N^{-1/2},\end{aligned}$$

and we obtain (63) which joined with (62), proves (24).

Now let us prove relations (25). To this end we use

Lemma 4: Consider the sequence of convex random functions $\{f_n(t)\}_{n=1}^{\infty}(f_n''(t)\geqslant 0)$ *in the interval* (a,b). *If functions* f_n *are self-averaging, i.e., uniformly in t*

$$\lim_{n\to\infty} E\{(f_n(t)-E\{f_n(t)\})^2\}=0,$$

and bounded $(|E\{f_n(t)\}|\leqslant C$ *uniformly in* $n,t\in(a,b))$, *then for almost all t,*

$$\lim_{n\to\infty} E\{[f_n'(t)-E\{f_n'(t)\}]^2\}=0, \tag{66}$$

i.e., the derivatives $f_n'(t)$ *are also self-averaging ones for almost all t.*

In addition, if we consider another sequence of convex functions $\{g_n(t)\}_{n=1}^{\infty}(g_n''\geqslant 0)$ *which are also self-averaging uniformly in t,*

$$\lim_{n\to\infty} E\{(g_n(t)-E\{g_n(t)\})^2\}=0$$

and

$$\lim_{n\to\infty} |E\{f_n(t)\}-E\{g_n(t)\}|=0, \tag{67}$$

uniformly in t, then for all t which satisfy (66),

$$\lim_{n\to\infty} |E\{f_n'(t)\}-E\{g_n'(t)\}|=0, \quad \lim_{n\to\infty} E\{[g_n'(t)-E\{g'(t)\}]^2\}=0. \tag{68}$$

We prove Lemma 4 in the Appendix. Now let us note that, using this lemma and (24), we obtain

$$\beta E_{/\zeta}\{(1-q_N^*)\}=-E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H}^a)}{\partial\varepsilon_2}\right\}=-E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H})}{\partial\varepsilon_2}\right\}+o(1)=\beta E_{/\zeta}\{(1-q_N)\}+o(1),$$

$$\beta E_{/\zeta}\{(\langle U\rangle_*-\alpha r_N^*)\}=-E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H}^a)}{\partial\varepsilon_1}\right\}=-E\left\{\frac{\partial f_N(\mathrm{H})}{\partial\varepsilon_1}\right\}+o(1)=\beta E_{/\zeta}\{(\langle U\rangle-\alpha r_N)\}+o(1), \tag{69}$$

$$E_{/\zeta}\{\langle U_N\rangle_*\}+\sum_{\mu=1}^{s}\int_1^2 d\zeta(c_*^{\nu}(\zeta))^2$$
$$=-2E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H}^a)}{\partial J}\right\}=-2E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H})}{\partial J}\right\}+o(1)=E\left\{\langle U_N\rangle+\sum_{\mu=1}^{s}\langle(m^{\mu})^2\rangle\right\}+o(1),$$

Remark also that

$$\sum_{\mu=1}^{s}\int_1^2 d\zeta(_*^{\nu}(\zeta)^2)=-2\,\frac{1}{d_N}\int_1^2 d\zeta\, E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H}^a)}{\partial\zeta}\right\}$$
$$=-2\,\frac{1}{d_N}E_{/\zeta}\{(f_N(\mathrm{H}^a)|_{\zeta=2}-f_N(\mathrm{H}^a)|_{\zeta=1})\}$$
$$=-2\,\frac{1}{d_N}E_{/\zeta}\{(f_N(\mathrm{H})|_{\zeta=2}-f_N(\mathrm{H})|_{\zeta=1})\}+o(1)$$
$$=-2\,\frac{1}{d_N}\int_1^2 d\zeta\, E_{/\zeta}\left\{\frac{\partial f_N(\mathrm{H})}{\partial\zeta}\right\}+O\left(\frac{1}{\log Nd_N}\right)=E\left\{\sum_{\mu=1}^{s}\langle(m^{\mu})^2\rangle\right\}+o(1).$$

These relations, joined to (69), prove (25).

APPENDIX: PROOF OF PROPOSITION 2 AND LEMMA 4

Proof of Proposition 2: Due to the symmetry of the problem we can restrict ourselves to the case when x and y are positive.

If $x>0$ and $y>x+2\delta$, consider $x'=y$ and $y'=x$. Then

$$F(x',y')-F(x,y)=f(y,x)-\frac{y^2}{2(1+d)}-\frac{x^2}{2}-f(x,y)+\frac{x^2}{2(1+d)}+\frac{y^2}{2}$$
$$=\frac{d}{2(1+d)}(y^2-x^2)$$
$$\geqslant 4\delta^2\frac{d}{2(1+d)}. \tag{A1}$$

Proposition 2 is proved.

Proof of Lemma 4: Denote

$$d_n^{(1)}\equiv \max_{a\leqslant t\leqslant b} E\{[f_n(t)-E\{f_n(t)\}]^2\},\quad d_n^{(2)}\equiv \max_{a\leqslant t\leqslant b} E\{[g_n(t)-E\{g_n(t)\}]^2\},$$

$$d_n^{(3)}\equiv \max_{a\leqslant t\leqslant b} |E\{f_n(t)\}-E\{g_n(t)\}|,\quad \varepsilon_n=[\max\{d_n^{(1)},d_n^{(2)},d_n^{(3)}\}]^{1/3}.$$

Then, using the convexity of $f_n(t)$, we have

$$f_n'(t)-E\{f_n'(t)\}\leqslant\frac{f_n(t+\varepsilon_n)-f_n(t)}{\varepsilon_n}-E\{f_n'(t)\}$$
$$=-\frac{f_n(t)-E\{f_n(t)\}}{\varepsilon_n}+\frac{f_n(t+\varepsilon_n)-E\{f_n(t+\varepsilon_n)\}}{\varepsilon_n}$$
$$+\left[\frac{E\{f_n(t+\varepsilon_n)\}-E\{f_n(t)\}}{\varepsilon_n}-E\{f_n'(t)\}\right]. \tag{A2}$$

Denote also

$$R_n^+(t)\equiv\frac{E\{f_n(t+\varepsilon_n)\}-E\{f_n(t)\}}{\varepsilon_n}-E\{f_n'(t)\}$$

and prove that $R_n^+(t)\to 0$ for almost all t. To this end we study

$$\int_{a_1}^{b_1}R_n^+(t)dt=\left[\frac{F_n(b_1+\varepsilon_n)-F_n(b_1)}{\varepsilon_n}-F_n'(b_1)\right]-\left[\frac{F_n(a_1+\varepsilon_n)-F_n(a_1)}{\varepsilon_n}-F_n'(a_1)\right], \tag{A3}$$

where $F_n(t)\equiv\int_a^t E\{f_n(\tau)\}\,d\tau$ and (a_1,b_1) is some subinterval of (a,b). It is evident that

$$0\leqslant F_n''(t)=E\{f_n'(t)\}\leqslant 2(b-b_1)^{-1}\left[E\{f_n(b)\}-E\left\{f_n\left(\frac{b+b_1}{2}\right)\right\}\right].$$

Therefore if n is large enough to provide $\varepsilon_n\leqslant(b-b_1)/2$, then, according to the Taylor formula, the rhs of (A3) is of order $O(\varepsilon_n)$. Thus, since $R_n^+(t)\geqslant 0$, it follows from (A3) that $R_n^+(t)\to 0$ for almost all t.

On the other hand, similarly to (A2) we get that

$$f_n'(t)-E\{f_n'(t)\}\geqslant-\frac{f_n(t-\varepsilon_n)-E\{f_n(t-\varepsilon_n)\}}{\varepsilon_n}+\frac{f_n(t)-E\{f_n(t)\}}{\varepsilon_n}+R_n^-(t)$$

and $R_n^-(t)\equiv E\{f_n(t)\}-E\{f_n(t-\varepsilon_n)\}/\varepsilon_n-E\{f_n'(t)\}\to 0$ for almost all t. Then

$$\begin{aligned}E\{[f_n'(t)-E\{f'(t)\}]^2\}\leqslant 2E\left\{\left(\frac{f_n(t+\varepsilon_n)-E\{f_n(t+\varepsilon_n)\}}{\varepsilon_n}\right)^2\right\}\\+2E\left\{\left(\frac{f_n(t-\varepsilon_n)-E\{f_n(t-\varepsilon_n)\}}{\varepsilon_n}\right)^2\right\}+4E\left\{\left(\frac{f_n(t)-E\{f_n(t)\}}{\varepsilon_n}\right)^2\right\}\\+(R_n^-(t))^2+(R_n^+(t))^2\leqslant 8\varepsilon_n+(R_n^-(t))+(R_n^+(t))^2\to 0\end{aligned}$$

for almost all t.

By the same way,

$$\begin{aligned}E\{[g_n'(t)-E\{f_n'(t)\}]^2\}&\leqslant 2E\left\{\left(\frac{g_n(t+\varepsilon_n)-E\{f_n(t+\varepsilon_n)\}}{\varepsilon_n}\right)^2\right\}\\&\quad+2E\left\{\left(\frac{g_n(t-\varepsilon_n)-E\{f_n(t-\varepsilon_n)\}}{\varepsilon_n}\right)^2\right\}+4E\left\{\left(\frac{g_n(t)-E\{f_n(t)\}}{\varepsilon_n}\right)^2\right\}\\&\quad+(R_n^-(t))^2+(R_n^+(t))^2\\&=2E\left\{\left(\frac{g_n(t+\varepsilon_n)-E\{g_n(t+\varepsilon_n)\}}{\varepsilon_n}\right)^2\right\}\\&\quad+2E\left\{\left(\frac{g_n(t-\varepsilon_n)-E\{g_n(t-\varepsilon_n)\}}{\varepsilon_n}\right)^2\right\}+4E\left\{\left(\frac{g_n(t)-E\{g_n(t)\}}{\varepsilon_n}\right)^2\right\}\\&\quad+2\left(\frac{E\{g_n(t+\varepsilon_n)\}-E\{f_n(t+\varepsilon_n)\}}{\varepsilon_n}\right)^2\\&\quad+2\left(\frac{E\{g_n(t-\varepsilon_n)\}-E\{f_n(t-\varepsilon_n)\}}{\varepsilon_n}\right)^2+4\left(\frac{E\{g_n(t)\}-E\{f_n(t)\}}{\varepsilon_n}\right)^2\\&\quad+(R_n^-(t))^2+(R_n^+(t))^2\\&\leqslant 16\varepsilon_n+(R_n^-(t))^2+(R_n^+(t))^2.\end{aligned}\qquad\text{(A4)}$$

On the other hand,

$$E\{[g_n'(t)-E\{f_n'(t)\}]^2\}=E\{[g_n'(t)-E\{g_n'(t)\}]^2\}+[E\{g_n'(t)\}-E\{f_n'(t)\}]^2.$$

Therefore (A4) proves (67) and (68).

(Received 23 December 1998; accepted for publication 1 April 1999)

The special quasiperiodic solution of the $(2+1)$-dimensional Kadometsev–Petviashvili equation is separated into three systems of ordinary differential equations, which are the second, third, and fourth members in the well-known confocal involutive hierarchy associated with the nonlinearized Zakharov–Shabat eigenvalue problem. The explicit theta function solution of the Kadometsev–Petviashvili equation is obtained with the help of this separation technique. A generating function approach is introduced to prove the involutivity and the functional independence of the conserved integrals which are essential for the Liouville integrability.

I. INTRODUCTION

The confocal involutive system was first used systematically by J. Moser[1] in the investigation of soliton equations such as the Korteweg–de Vries (KdV) equation. Various new kinds of confocal involutive systems are obtained by the approach of nonlinearization of eigenvalue problems[2–4] or constrained flows,[5,6] which are useful tools in the study of $(1+1)$-dimensional soliton equations. The mechanism of the technique is that the finite-parametric solution (such as the finite-band solution) to a soliton equation could be separated into two systems of ordinary differential equations (ODEs), which are two members in the associated confocal involutive system. There are at least two useful applications. First, it provides an effective way in the numerical analysis and the graphic presentation of solutions, where only numerical solution of ODEs and algebraic calculations are concerned. As examples on the Dirac-Nonlinear Schrödinger (NS) system and the Toda lattice, see Refs. 7 and 8. Second, it provides another way to get the explicit expressions of quasiperiodic solutions by means of the Riemann theta functions resorting to the elliptic variables and the Abel–Jacobi coordinates, in contrast with that of the Baker function approach.[9,10]

In the present paper, we are going to extend the $(1+1)$ framework to the Kadometsev–Petviashvili (KP) equation, one of the typical $(2+1)$-dimensional soliton equations:

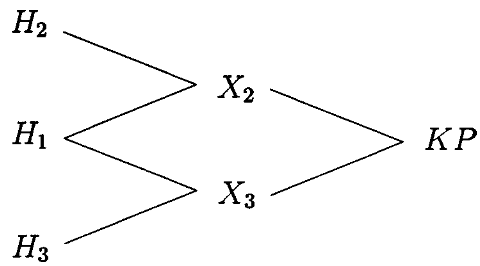
$$w_t=\tfrac{1}{4}(w_{xx}+3w^2)_x+\tfrac{3}{4}\partial_x^{-1}w_{yy}\,. \tag{1.1}$$

It is well-known that Eq. (1.1) is the compatible condition of two overdetermined linear equations, the Lax pair. Together with its conjugate version, the Lax pair is nonlinearized into the coupled nonlinear Schrödinger (NS) equation and the coupled modified Korteweg-de Vries (mKdV) equation, which are the second and the third members, respectively (the X_2 flow and the X_3 flow) in the Ablowitz–Kaup–Newell–Segur (AKNS) hierarchy.[11–13]

The AKNS hierarchy is the isospectral class of the Zhakharov–Shabat (ZS) eigenvalue problem. In order to separate the X_2 and X_3 flows, consider the nonlinearized ZS eigenvalue problem, which is completely integrable with a series of involutive integrals $\{F_k\}$[3]. According to the terminology suggested by Moser,[1] the integrals are called confocal since their generating function has the form:

$$\sum_{k=0}^{\infty} \frac{F_k}{\lambda^{k+1}} = \sum_{j=1}^{N} \frac{E_j}{\lambda - \alpha_j},$$

which gives confocal quadrics in $\mathbb{R}^N$. The coupled NS equation (the X_2 flow) has a Lax pair, which is nonlinearized into the H_1 flow and H_2 flow; while the Lax pair of the coupled mKdV equation (the X_3 flow) is nonlinearized into the H_1 flow and H_3 flow. It turns out that $\{H_k\}$ is essentially the confocal involutive system $\{F_k\}$ with some modifications (see Sec. V below). Thus the special solution of the KP equation is separated into three members in the confocal involutive system:



Specifically, let *x, y, t* be the variables of the H_1, H_2, and H_3 flow, and $(p(x,y,t),q(x,y,t))$ be a compatible solution of the flows. Then

$$w(x,y,t) = 2\langle p,p\rangle\langle q,q\rangle = 2\langle Ap,q\rangle + 4H_1 \tag{1.2}$$

solves the KP equation (1.1) (see Sec. VII below).

A deeper understanding of the nonlinearized ZS eigenvalue problem is necessary in realizing the above framework. The Liouville integrability plays a central role in the whole structure. We have introduced an effective way, the generating function flow method, to prove:

(i) the involutivity of $\{F_k\}$;
(ii) the functional independence of $F_0,\ldots,F_{N-1}$;

which are essential for the Liouville integrability. The functional independence means a sufficient number of integrals, which is important and usually difficult to verify. Some results are obtained by Ma *et al.*[14,15] It should be noted that the well-known three-body problem was proved nonintegrable by Bruns[16,17] since it has an insufficient number of integrals. The generating function flow method is also effective in calculating the evolution equations of the Abel–Jacobi coordinates, which give a clear dynamic picture of the KP flow, X_k flow, and H_k flow (see Sec. VIII below). The explicit expression of the finite-band potential and the solution to the KP equation by means of the Riemann theta function are obtained as a consequence (see Sec. X and XI).

II. PRELIMINARIES

The AKNS hierarchy of soliton equations is the isospectral class of the Zakharov–Shabat eigevalue problem:

$$\chi_x = U\chi, \quad U = \begin{pmatrix} \frac{\lambda}{2} & u \\ v & -\frac{\lambda}{2} \end{pmatrix}. \tag{2.1}$$

As the basis of investigating the zero-curvature form of the AKNS equation:

$$V_x-[U,V]=U_t\equiv U_*\begin{pmatrix}u_t\\ v_t\end{pmatrix},$$

we have the fundamental identity:

$$V_x-[U,V]=U_*\{P(K-\lambda J)\gamma\},\tag{2.2}$$

where U_* is the differential of the map $(u,v)^T\to U(u,v)$, P is the projective map $\gamma=(\gamma^1,\gamma^2,\gamma^3)^T\to(\gamma^1,\gamma^2)^T$, and $(\partial=\partial_x)$

$$V=\begin{pmatrix}\gamma_3 & \gamma_2\\ \gamma_1 & -\gamma_3\end{pmatrix},\quad K=\begin{pmatrix}0 & \partial & 2u\\ \partial & 0 & -2v\\ -u & v & \partial\end{pmatrix},\quad J=\begin{pmatrix}0 & 1 & 0\\ -1 & 0 & 0\\ 0 & 0 & 0\end{pmatrix}.\tag{2.3}$$

The Lenard gradients $\{g_j\}$ and the AKNS vector fields $\{X_j\}$ are defined recursively by

$$\begin{aligned}&Kg_j=Jg_{j+1},\quad Jg_{-1}=0,\\ &X_j=PJg_j=(g_j^2,-g_j^1)^T.\end{aligned}\tag{2.4}$$

The explicit recursive formulas for the first two components g_j^1, g_j^2 are evident. In order to eliminate the ambiguity in determining the third component g_j^3 since the existence of ∂^{-1}, consider

$$g_\lambda=\sum_{j=0}^{\infty}g_{j-1}\lambda^{-j},\quad g_{-1}=(0,0,\tfrac{1}{2})^T,\tag{2.5}$$

which satisfies $(K-\lambda J)g_\lambda=0$. By Eq. (2.2), $V=\sigma(g_\lambda)$ solves the stationary Lax equation $V_x-[U,V]=0$, thus $\det\sigma(g_\lambda)$ is a constant along the x flow. We adopt:
